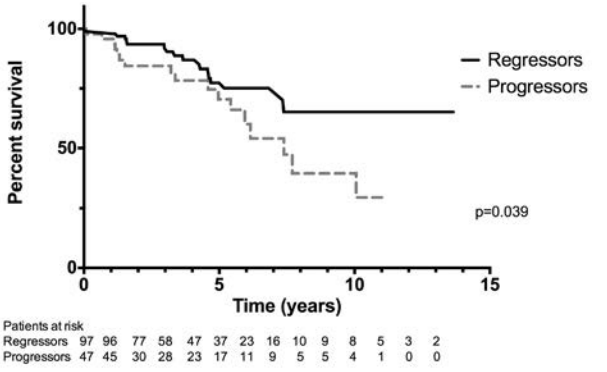
Results: We studied 144 intensive hemodialysis patients at a single center between 1999 to 2012 with a mean follow-up of 4.7 years. 97 patients (67.4%) had LVH regression or prevention and 47 patients (32.6%) had LVH progression. In a multivariate analysis, smoking history (OR 3.007, 95% CI 1.073-8.427, p=0.036) and presence of LVH at baseline (OR 3.654, 95% CI 1.506-8.868, p=0.004) were significant predictors for LVM progression. 18 patients (18.6%) in the regressors groups as compared to 17 patients (36.2%) in the progressors group developed the composite end-point. When adjusted for age and diabetes, LVH regression was significantly associated with a decreased risk (HR 0.422, 95% 0.214-0.835) for the composite end-point. On the basis of mortality alone, LVH regression was also significantly associated with a decreased risk of death in the adjusted analysis (HR 0.211, 95% CI 0.069-0.645).



Conclusions: Regression of LVH with intensive hemodialysis is associated with favorable clinical outcomes in patients with end-stage renal disease.

Left Ventricular Geometry in Peritoneal Dialysis Patients: Predictive Factors
Anabela M. Guedes, Teresa M. Jeronimo, Filipa B. Mendes, Ana Paula Silva, Idalecio Bernardo, Pedro Neves. *CHAlgarve, Portugal.*

Background: Left ventricular hypertrophy (LVH) is an independent risk factor of morbidity and mortality in chronic kidney disease (CKD). Concentric hypertrophy remains the main culprit. The aim of this study was to identify factors that could be associated with different geometric patterns of LVH on a PD population.

Methods: We evaluated 114 CKD patients who underwent both echocardiography and Peritoneal Dialysis (PD) for more than 2 months, since 1999 until 2015. LVH (LV mass >95 g/m(2) [women] and >115 g/m(2) [men]) and relative wall thickness (RWT) were used to define LV geometry: no LVH, LVH and RWT≤0.42 (eccentric), and LVH and RWT>0.42 (concentric). Descriptive statistics and multinomial logistic regression analysis were done.

Results: Baseline demographics included age (54.6±17.6 years), gender (56.1% males), diabetes prevalence (33.3%) and clinical parameters included systolic blood pressure (143±25mmHg), renal residual function (RRF - 6.0±5.6 ml/min), kt/V (2.7±1.0), normalized protein catabolic rate (nPCR - 0.99±0.32g/kg) hemoglobin (11.9±1.8g/dL), phosphorus (4.9±1.6mg/dL), PTH (656.0±641.8pg/mL), high sensitivity C-reactive protein (hs-CRP - 12.7±21.9mg/L), total cholesterol (208.6±58.1mg/dL). Vintage on PD was of 33.8±24.2 months and regarding LV geometry, 38 patients presented with concentric LVH and 11 with eccentric LVH.

In our population, higher phosphorus (p=0.043) and PTH (p=0.017) levels, higher systolic blood pressure (p=0.029) and lower nPCR (p=0.030) were predictive of concentric LVH, and hsCRP was predictive of eccentric LVH (p=0.048), when adjusting for gender, age, RRF, kt/V diabetes, cholesterol and hemoglobin levels and using the group without LVH as reference.

Conclusions: Modifiable factors, in this population, were conditioning concentric LVH, namely higher systolic blood pressure, worse mineral metabolism and nutrition parameters. Ameliorating these variables would we diminish cardiovascular mortality in CKD patients? Larger studies are needed, but worth attempting in daily practice.

FR-PO932

Relation between Different Blood Pressure Measurements and Left Ventricular Hypertrophy in Peritoneal Dialysis Patients
Yun Jung Oh,[1] Su Mi Lee,[2] Ji Yong Jung,[3] Sun Moon Kim,[4] Jiwon Ryu,[1] Chungsik Lee.[1] *[1]Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, Gacheon Univ Gil Hospital, Incheon, Republic of Korea; [4]Dept of Internal Medicine, Chungbuk National Univ Hospital, Cheongju, Republic of Korea.*

Background: Hypertension is prevalent in end stage renal disease (ESRD) and is associated with left ventricular hypertrophy (LVH), which is an independent predictor of cardiovascular mortality. Although hypertension is an important and modifiable risk factor for cardiovascular events, the optimal approach to monitor blood pressure (BP) in peritoneal dialysis (PD) patients for therapeutic guidance is unclear. In this study, we compared different methods of BP measurement and evaluated the relationship between different BP measurements and LVH in PD patients.

Methods: Fifty two prevalent PD patients were enrolled at a single dialysis center. We measured ambulatory BP, office BP, home BP, and central BP. The ambulatory BP was recorded for 24 hours, office BP was measured at least in two visits, and home BP was measured for one week. The central BP was estimated using radial artery tonometry. Left ventricular mass index (LVMI) was measured using echocardiography and the presence of LVH was ascertained.

Results: LVH was best predicted by ambulatory systolic BP (area under the curve (AUC), 0.811; 95% CI, 0.691-0.931) and home systolic BP (AUC, 0.786; 95% CI, 0.658-0.915). The office systolic BP (AUC, 0.643; 95% CI, 0.488-0.799) and central systolic BP (AUC, 0.662; 95% CI, 0.514-0.840) were inferior to ambulatory and home BP in predicting LVH. The adjusted odd ratio (OR) for home systolic BP (OR, 1.066; 95% CI 1.018-1.117) was higher than those for ambulatory (OR, 1.052; 95% CI 1.010-1.096) and central systolic BP (OR, 1.032; 95% CI 1.021-1.173) in LVH prediciton. The office systolic BP did not significantly predict LVH (OR, 1.026; 95% CI 0.986-1.068).

Conclusions: Home and ambulatory systolic BP were the strongest predictors of LVH suggesting that treatments targeting these BP measurements may prevent end organ damage in PD patients.

FR-PO933

Tallium-201 Washout Rate of Stress Myocardial Perfusion Imaging as a Predictor of Mortality in Diabetic Kidney Disease Patients Undergoing Hemodialysis: An Observational, Follow-Up Study

Toshihide Hayashi, Nobuhiko Joki, Ai Matsukane, Masaki Iwasaki, Yuri Tanaka, Hiroki Hase. *Div of Nephrology, Toho Univ Ohashi Medical Center, Tokyo, Japan.*

Background: Thallium-201 (^{201}Tl) washout rate of stress myocardial perfusion imaging (MPI) has been reported to correlate with coronary flow reserve which is a parameter of myocardial microcirculation and be useful to detect coronary artery disease and evaluate the severity. However, the evidence for its use in diabetic kidney disease (DKD) has been lacking, and the association between thallium-201 washout rate and adverse outcomes including death is unknown. Therefore, a hospital-based, prospective, cohort study was conducted to evaluate the predictive ability of thallium-201 washout rate for mortality in DKD patients undergoing hemodialysis.

Methods: A total of 96 DKD patients who had been started on maintenance hemodialysis undergoing pharmacologic or exercise stress MPI with thallium-201 within 1 year, 72 men and 24 women, with a median age of 67 years, were studied. The endpoint was defined as all-cause death. The Cox proportional hazards model was used to calculate hazard ratios (HR) and 95 % confidence intervals (CI).

Results: During the mean follow-up period of 3.1 ± 2.4 years, 18 (18.8 %) deaths occurred. Cumulative survival rates during the follow-up period, with thallium-201 washout rate levels in the lowest tertile (3.1 - 36.2 %), the middle tertile (36.5 - 46.3 %), and the highest tertile (46.4 - 66.2 %) were 47.7 %, 85.7 %, and 84.2 %, respectively (Figure).

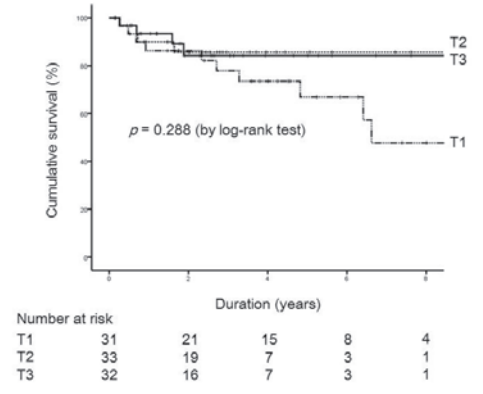

Figure. Cumulative survival in diabetic patients undergoing hemodialysis (n = 96) among three groups classified into tertiles by baseline tallium-201 washout rate levels.
Abbreviations: T1, lowest washout rate tertile (washout rate; 3.1 - 36.2 %); T2, middle washout rate tertile (washout rate; 36.5 - 46.3 %); T1, highest washout rate tertile (washout rate; 46.4 - 66.2 %).

Overall, the multivariate Cox regression analysis revealed that thallium-201 washout rate remained an independent predictor of death after adjusting by confounding variables (HR 0.92, 95 % CI 0.87 to 0.98).

Conclusions: Among DKD patients undergoing hemodialysis, thallium-201 washout rate seems to be useful for predicting death.

FR-PO934

Myocardial Perfusion Imaging in Renal Transplant Candidates

Ravi Jayanti. *Medicine, Interfaith Medical Center, Brooklyn, NY.*

Background: There is a high prevalence of coronary heart disease in patients with end stage renal disease (ESRD) with estimates ranging from 30-60% based on various screening modalities such as history, laboratory tests, myocardial imaging and cardiac catheterization. We studied the outcome of perfusion imaging as an indicator of coronary heart disease in African American patients with ESRD awaiting renal transplantation.

Methods: A retrospective analysis was done on patients with ESRD who were candidates for renal transplant and consecutively referred for a pre transplant cardiac evaluation. All patients had a thorough history and physical examination, standard laboratory tests,12 lead EKG, chest x-ray, echocardiogram and stress myocardial perfusion imaging. Patients with a positive perfusion test were considered to have ischemic heart disease and referred for cardiac catheterization.

Results: A total 289 patients were evaluated most of whom were African American; 62%(178) were male and 38%(111) females patients; mean age was 54.5 years; 75%(218) were on renal replacement therapy; mean duration of dialysis was 4.2years; Hypertension was present in 82%(238) and diabetes in 42%(121) of patients. Stress radionuclide myocardial perfusion imaging was suggestive of ischemic heart disease in 164(56.7%) patients and 125(53%) tested negative.

Conclusions: Although this subset of ESRD patients had less comorbidities, the prevalence of coronary heart disease was high at 57% in pre-transplant ESRD patients based on myocardial perfusion imaging. Further risk stratification is recommended to confirm coronary heart disease.

FR-PO935

Early Mortality and Late Outcomes for Coronary Revascularisation in End Stage Renal Disease - A Systematic Review and Meta-Analysis

Robin Ramphul, Debasish Banerjee. *Renal and Transplantation Unit, St. George's Univ Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: Despite the high prevalence of coronary artery disease in patients with end-stage renal disease (ESRD), the optimal method of coronary revascularisation remains unclear. We conducted a systematic review and meta-analysis of the available literature comparing outcomes after percutaneous coronary intervention (PCI) and coronary artery bypass graft (CABG) in ESRD patients.

Methods: We reviewed contemporary studies, conducted after the year 2000 as PCI therapy have improved, comparing PCI to CABG in ESRD patients, using Review Manager 5.1 for statistical analysis and PRISMA guidelines for reporting. Clinical end-points compared were early (in-hospital or 30-day) and late (> than 1 year) mortality; repeat revascularisation, occurrence of major adverse cardiovascular events (MACE) and myocardial infarction (MI) after revascularisation.

Results: In 12 studies investigating early mortality, the analysis demonstrated less early deaths for PCI compared to CABG (4% v 8%, p<0.001, Figure 1a). Late mortality was reported in 10 studies with late deaths similar for CABG and PCI (44% v 50%, p=0.32). Repeat revascularisation was reported in 9 studies. CABG was less likely to require revascularisation compared to PCI (12% v 41%, p<0.001, Figure 1b). The occurrence of MACE was reported in 3 studies. CABG was associated with less events compared to PCI (16% v 57%, p<0.001, Figure 1c). Similarly, MI alone occurred less often with CABG than PCI (5% v 11%, p=0.003, Figure 1d). There existed a selection bias with PCI preferred to CABG in single vessel disease and CABG for multivessel or left main disease.

Conclusions: The results demonstrate better early mortality in patients with ESRD undergoing PCI, however the results favoured CABG for repeat revascularisation, MACE and MI. CABG was only marginally beneficial for late mortality.

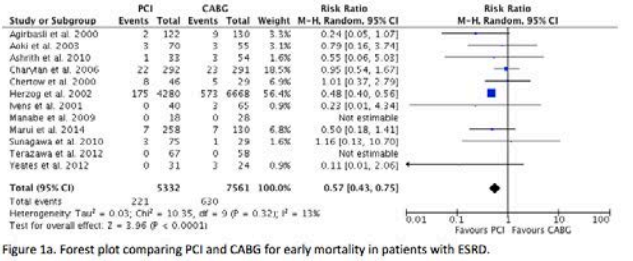

Figure 1a. Forest plot comparing PCI and CABG for early mortality in patients with ESRD.

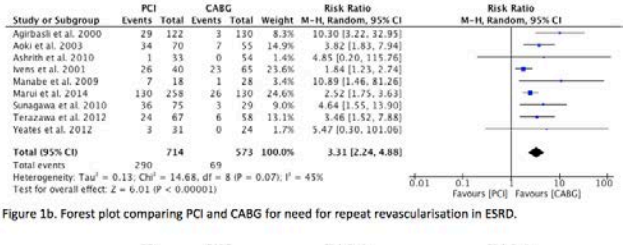

Figure 1b. Forest plot comparing PCI and CABG for need for repeat revascularisation in ESRD.

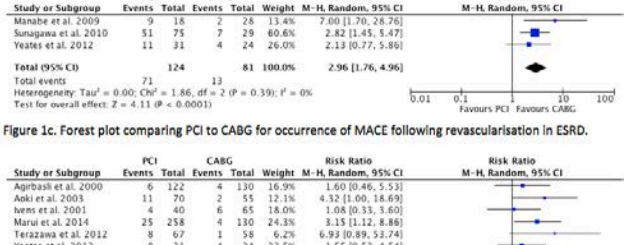

Figure 1c. Forest plot comparing PCI to CABG for occurrence of MACE following revascularisation in ESRD.

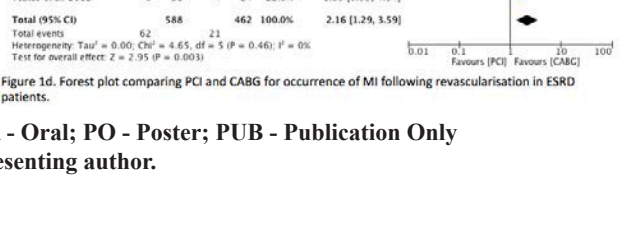

Figure 1d. Forest plot comparing PCI and CABG for occurrence of MI following revascularisation in ESRD patients.

FR-PO936

Use of Eliquis (Apixaban) in Atrial Fibrillation Patients Undergoing Hemodialysis Bobby Rajesh Malik, Anjali Om, Prabal K. Guha. *Cardiology, McLeod Regional Medical Center, Florence, SC.*

Background: Hemodialysis (HD) patients with multiple other cardiovascular (CV) risk factors are at high risk for development of atrial fibrillation (AFib). Most of these patients have high CHA2D2-VASc scores requiring anticoagulation treatment. For almost fifty years, warfarin has been the gold standard treatment, but with significant limitations, especially in its interaction with antibiotics that HD patients often require. In the last few years, non vitamin K oral anticoagulation (NOAC) has emerged as a new class of drug for reducing thromboembolic complications in these patients. However, out of 4 NOACs, only apixaban is approved for use in HD patients based solely on its pharmacokinetic data.

Methods: Medical records of 65 patients on HD with history of AFib treated with apixaban were retrospectively reviewed for any thromboembolic events and any bleeding. Average follow up was 150 days with minimum follow up being 30 days.

Results: There were 65 patients (47% male) age 43 to 85 with an average age of 68. There were no clinical thromboembolic events noted. Only one patient had epistaxis that was self-limiting, not requiring hospitalization or transfusion.

Conclusions: In this small retrospective study, apixaban was found to be well tolerated and effective with no significant bleeding complications. If supported in larger studies, apixaban could be an alternative in HD patients with a history of AFib.

FR-PO937

Utilization of Statin Medications in U.S. Veterans Receiving Maintenance Dialysis Arouna Senthilkumar, Talar Markossian, Nicholas Burge, Benjamin Ling, Kevin Stroupe, Vinod K. Bansal, David J. Leehey, Holly J. Kramer, Julia Schneider. *Hines VA Hospital, Hines, IL.*

Background: The Kidney Disease Improving Global Outcomes (KDIGO) guidelines do not recommend stopping statin medications when patients initiate dialysis. Guidelines state that statins should not be initiated for dialysis patients as large trials did not demonstrate mortality or cardiovascular benefits in dialysis population. The objective of this study was to examine current statin use and both initiation and discontinuation of statin medications in U.S. veterans receiving maintenance dialysis.

Methods: Retrospective analysis of U.S. Department of Veterans Affairs Healthcare System (VA) national databases to determine statin use in dialysis. Medications acquired with the VA system were obtained from the Managerial Cost Accounting National Data Extracts. Medications acquired outside the VA were obtained from the Corporate Data Warehouse (CDW). Statin medication use was ascertained from pharmacy dispensing records during years 2012 and 2013. The dialysis patients were identified using the CPT, ICD-9, and VA dialysis procedure codes at VA outpatient centers.

Results: A total of 17,883 veterans dialysis patients were evaluated. 97% were male, 55% aged ≥60-75 years and 18% aged ≥ 75 years; 38% were African-American. Diabetes and coronary artery disease were present in 59% and 32.3%, respectively. During fiscal year 2012, 63.3% of patients were using statins, and 57.7% were using statins in 2013. Of the 17,883 patients, 53.0% used statins continuously and 10.3% discontinued statin use during year 2013. Statin initiation was noted in 4.7% during 2013.

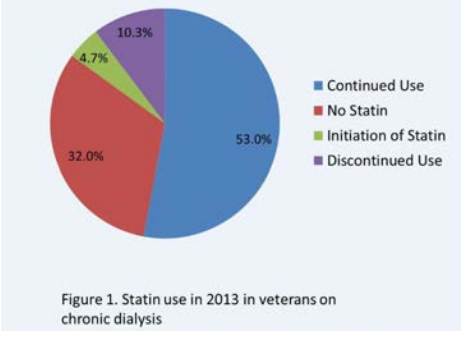

Figure 1. Statin use in 2013 in veterans on chronic dialysis

Conclusions: A large proportion of U.S. veterans on hemodialysis use statin medications. Very few discontinue statins and even fewer initiate them. Future studies should determine patient need for statin medication in dialysis patients considering large pill burden and financial costs.

Facility Use of Low Dialysate Temperature for Prevention of Intra-Dialytic Hypotension Is Associated with Lower Cardiovascular Mortality in the DOPPS Indranil Dasgupta,[1] G. Neil Thomas,[2] Joanne L. Clarke,[2] Alice Sitch,[2] Angelo Karaboyas,[3] Brian Bieber,[3] Manfred Hecking,[4] Bruce M. Robinson,[3] Hugh C. Rayner.[1] *[1]Heartlands Hospital, United Kingdom; [2]Univ of Birmingham, United Kingdom; [3]Arbor Research; [4]Medical Univ of Vienna, Austria.*

Background: Intra-dialytic hypotension (IDH) occurs during 20-30% of haemodialysis (HD) sessions and is associated with cardiovascular (CV) mortality and events. Aim was to investigate associations between HD facility practices related to the management of fluid volume and hypotension and adverse events.

Methods: Data on 8807 patients from 232 HD facilities across 12 countries in DOPPS phase 4 (2009-12) were analysed. Multi-level survival models assuming a Weibull distribution (allowing for clustering of data within facilities) were used to estimate associations between facility practices reported by MDs and patient all-cause and CV mortality, CV events and hospitalizations, adjusted for country**,** age, gender, vintage, pre-dialysis systolic BP, CV comorbidities, diabetes (model 1) plus BMI, smoking, residual renal function, Kt/V, vascular access (model 2). We tested 10 practices: (1) protocol for fluid volume management, (2) routine orthostatic BP measurement, (3) blood volume monitor (BVM), (4) bio-impedance device (BID), (5) BVM and BID, (6) limit to fluid removal, (7) isolated ultrafiltration and use of (8) a protocol, (9) routine sodium profiling and (10) low dialysate temperature for managing IDH.

Results: Among the 10 HD facility practices studied, routine use of low temperature dialysate for patients prone to intradialytic hypotension (47% of facilities vs. infrequent or no use) was associated with lower CV deaths in both models.

Low dialysate temperature for managing IDH	Model 1 Hazard ratio (99% CIs)	Model 2 Hazard ratio (99% CIs)
Hospitalization	1.02 (0.87-1.20)	1.02 (0.84-1.23)
All cause deaths	0.82 (0.65-1.02)	0.91 (0.67-1.22)
CV events	0.80 (0.64-0.99)	0.86 (0.67-1.10)
CV deaths	0.56 (0.39-0.79)	0.55 (0.35-0.85)

Conclusions: The HD facility practice of routinely using low dialysate temperature to limit or prevent IDH is associated with lower CV mortality. This merits further investigation in a randomised trial.

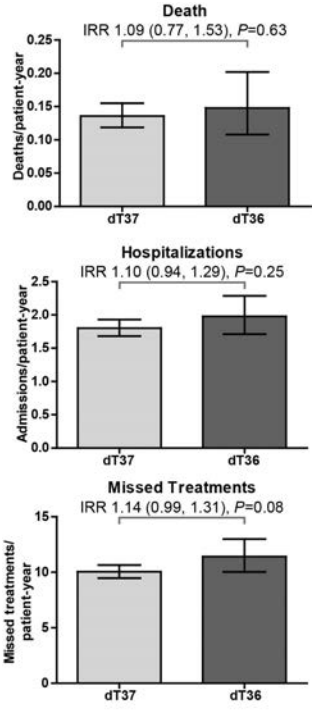
FR-PO939

Standardized Dialysate Temperature of 36 Degrees Celsius: Association with Clinical Outcomes Kathryn S. Gray, Dena E. Cohen, Steven M. Brunelli. *DaVita Clinical Research, Minneapolis, MN.*

Background: Hemodynamic insults may contribute to poor outcomes among hemodialysis (HD) patients. Individualized dialysate cooling based upon patient body temperature can improve intermediary outcomes but is difficult to operationalize. Here, we sought to test whether a standardized dialysate temperature of 36°C (dT36), which is easier to enact, might be a viable strategy to improve clinical outcomes.

Methods: Because patients with known hemodynamic instability may be selectively prescribed dT36, we minimized selection bias by considering incident adult in-center HD patients who (between Jan 2011-Dec 2013) received their first-ever HD treatment at a large dialysis organization and based exposure status on the order for this first-ever treatment (so that knowledge of intradialytic hemodynamics could not have factored into clinical decision-making). dT36 patients were propensity-score matched (1:5) to controls prescribed a temperature of 37°C (dT37). Outcomes (death, hospitalization, missed HD treatments) were considered from the date of first-ever HD treatment until death, loss to follow-up, crossover (month in which prescribed temperature was consistent with exposure group for <80% of treatments), or study end (Jun 2015).

Results: 313 dT36 patients were matched to 1565 dT37 controls; groups were balanced on all matched covariates at baseline. During follow-up, rates of death, hospitalization, and missed HD treatments were not significantly different between groups; nominal risk of each outcome was greater (IRR>1) for dT36 patients.



Conclusions: These data fail to demonstrate benefit of dT36 versus dT37; our results do not favor conversion to a default dialysate temperature of 36°C. These data do not pertain to other standardized or individualized cooled dialysate temperatures; further study of the latter should be advanced over study of standardized 36°C dialysate.

FR-PO940

Effect of Spironolactone on Heart Rate Variability in Hemodialysis - A Randomized Crossover Study

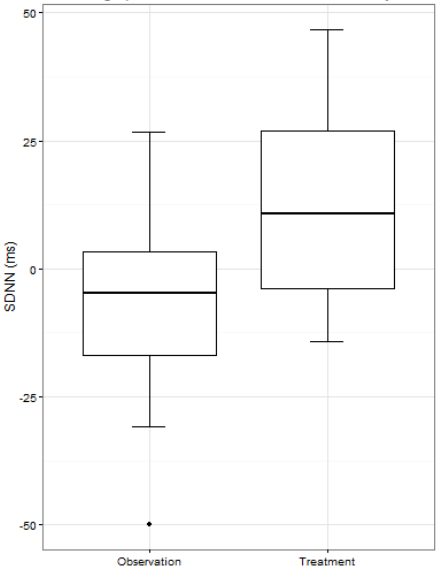
Hans Furuland,[1] Erik Nilsson,[2] Michael Eklund,[2] Olof Hellberg.[2] *[1]Renal Unit, Uppsala Univ Hospital, Sweden; [2]Renal Unit, Örebro Univ Hospital, Sweden.*

Background: Cardiac autonomic function is decreased and the risk of sudden cardiac death (SCD) is increased in hemodialysis (HD) patients. Spironolactone reduces the risk of SCD in congestive heart failure (CHF) and is associated with improvement of cardiac autonomic function as measured by heart rate variability (HRV). The effect of spironolactone on HRV in HD has rarely been studied and with varying results. This study measured HRV in HD patients treated with spironolactone.

Methods: This was a two center, open, randomized crossover study. Primary endpoint was the frequency of premature ventricular contractions (PVC) and this sub-study represents a secondary hypothesis. Subjects on HD (n = 30) were randomly allocated into two arms with either treatment with spironolactone 50 mg daily or observation for twelve weeks, then a six week wash-out period followed by cross-over for twelve weeks. HRV (time domain and frequency domain analysis) was measured by ambulatory 24-hour Holter electrocardiogram (LTECG). Differences in change of HRV parameters during the two periods were analyzed using confidence intervals (CI).

Results: Complete LTECG data could be analyzed for 16 participants, due to drop outs. The difference of differences (dod) for SDNN (the change during treatment with spironolactone minus the change during the observation period) was 20.98 ms (CI 3.21-38.74). The dod for SDANN was 19.14 (CI 0.78-37.49). Other HRV variables did not change significantly.

Fig 1: Change in heart rate variability during spironolactone treatment in hemodialysis



Conclusions: HRV was reduced and spironolactone treatment in HD patients increased time-domain HRV variables SDNN and SDANN, indicating a possible improvement in cardiac autonomic function. This may have an impact on SCD and mortality which needs to be studied in a larger randomized study.

FR-PO941

Utilization Pattern and Clinical Outcomes of Mineralocorticoid Receptor Blockers in U.S. Dialysis Patients: A National Registry Study

Xuerong Wen,[1] Rajesh Mohandas,[1,2] I. David Weiner.[1,2] *[1]Nephrology, Univ of Florida College of Medicine, Gainesville, FL; [2]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Background: Mineralocorticoid receptor blockers (MRB) are important therapies for resistant hypertension and for congestive heart failure (CHF). These are common problems in ESRD patients treated with hemo- or peritoneal dialysis (HD-PD), yet MRB use is limited in HD-PD patients. The current study sought to determine the utilization pattern and clinical outcomes of MRB use in HD-PD treated patients.

Methods: We conducted a retrospective cohort study with new user design using United States Renal Data System data and Medicare Part D claims data. The study cohort was adult patients initiating HD-PD between 7/1/2006-12/31/2011. MRB use was defined as filling more than one consecutive MRB prescription following HD-PD initiation. We compared outcomes to patients either with filled prescriptions for ACE-I/ARB alone or with both MRB and ACE-I/ARB. Subjects were followed until first occurrence of each endpoint: hyperkalemia (ICD-9 276.7), all-cause mortality, composite cardiovascular disease (CVD, ICD 410, 430, 431, 433.x1, 434.x1, and 436) mortality or CVD hospitalization.

Results: 516 patients used MRB alone, 183 used MRB+ACE-I/ARB, and 26,974 used ACE-I/ARB alone. Baseline differences included race (AA: 16%, 21%, 29%; P<.001), female sex (37%, 46%, 51%; P<.001), and history of CAD (65%, 70%, 57%; P<.001), CHF (45%, 41%, 36%; P<.001), diabetes mellitus (46%, 57%, 59%; P<.001), hypertension (83%, 93%, and 89%; P<.001), and hyperkalemia prior to dialysis (20%, 21%, 29%; P<.001). Multivariate Cox proportional hazard analyses showed MRB use alone was associated with reduced risk of hyperkalemia (aHR (adjusted hazard ratio): 0.68; 95%CI: 0.59-0.80; P<.0001), all-cause death (aHR: 0.79; CI: 0.70-0.90; P<.001), and composite CVD death and events (aHR: 0.72; CI: 0.65-0.80; P<0.001) as compared to ACE-I/ARB use.

Conclusions: MRB use alone was associated with decreased risk of hyperkalemia, CVD composite outcome, and all-cause mortality as compared to ACE-I/ARB use alone. These findings suggest MRB use may have substantial clinical benefits in ESRD HD-PD patients.

FR-PO942

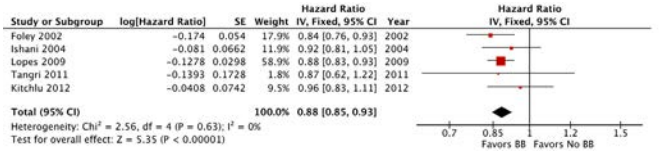
The Use of Beta-Blockers in Hemodialysis Patients: A Systematic Review and Meta-Analysis

Max Leither,[1] Areef Ishani.[2] *[1]Div of Renal Diseases and Hypetension, Univ of Minnesota, Minneapolis, MN; [2]Div of Nephrology, Minneapolis VA Medical Center, Minneapolis, MN.*

Background: Beta-blockers reduce mortality in patients with heart failure and after myocardial infarction. However, dialysis patients have been excluded from all large randomized trials of beta-blockers. Limited evidence of their efficacy and safety has led to inconsistent use in this population. We conducted a systematic review and meta-analysis on the use of beta-blockers in hemodialysis patients to analyze the existing evidence and inform and encourage future research.

Methods: A medical librarian designed a search strategy. We included studies of hemodialysis patients comparing those on beta-blockers vs. placebo or active control. Randomized controlled trials of any size, prospective cohort studies with at least 100 patients, and retrospective studies with at least 500 patients were included. All cause mortality was the primary outcome and a meta-analysis was pre-specified for this outcome.

Results: Of 465 articles screened, 16 met inclusion criteria and two were randomized trials, both small with intermediate outcomes and considerable opportunity for bias. One showed a significant mortality benefit in dialysis patients with ejection fraction <35% on carvedilol compared to placebo. Of the 14 observational trials, seven reported all cause mortality and five were included in the meta-analysis; hemodialysis patients on beta-blockers had lower mortality (HR 0.88, 95% CI 0.85-0.93, I^2=0%).



Conclusions: Evidence supporting the use of beta-blockers in hemodialysis patients is limited and randomized control trial data is particularly sparse. Existing evidence suggests a significant mortality benefit with carvedilol in those with reduced ejection fraction and possibly a modest benefit with beta-blockers in the general population of hemodialysis patients.

FR-PO943

Effect of Carvedilol on B-Type Natriuretic Peptide and High-Sensitivity Cardiac Troponin I in Dialysis Patients

Matthew A. Roberts,[1] Sunil V. Badve,[2] Robert Peter Carroll,[3] Darsy Darssan,[4] Carmel M. Hawley,[4] Nicole Isbel,[4] Magid Fahim,[4] Mark R. Marshall,[5] Elaine M. Pascoe,[4] Helen L. Pilmore,[6] Paul Snelling,[7] Ken-Soon Tan,[8] Andrew Maxwell Tonkin,[1] Liza A. Vergara,[4] Francesco L. Ierino.[9] *[1]Monash Univ, Melbourne, Australia; [2]St. George Hospital, Sydney, Australia; [3]Royal Adelaide Hospital, Adelaide, Australia; [4]Australasian Kidney Trials Network, Univ of Queensland, Brisbane, Australia; [5]Counties Manukau, Auckland, New Zealand; [6]Auckland City Hospital, Auckland, New Zealand; [7]Royal Prince Alfred Hospital, Sydney, Australia; [8]Logan Hospital, Brisbane, Australia; [9]Austin Health, Melbourne, Australia.*

Background: Beta-blocker therapy may modify left ventricular (LV) stress [measured by B-type natriuretic peptide (BNP)] and myocardial damage [measured by high-sensitivity cardiac troponin I (hs-TnI)]. We aimed to demonstrate the effects of the beta-blocker carvedilol on BNP and hs-TnI in adult dialysis patients.

Methods: Patients were randomized to carvedilol or placebo. BNP and hs-TnI (Abbott assays) were measured from samples collected at baseline (T0) and 12 months (T12). Change in biomarker levels was analyzed using ANCOVA adjusted for baseline values. Associations between T0 echo measures and biomarkers were assessed by Pearson's correlation coefficient.

Results: At T0, median (IQR) LV global strain was -14.27 (-11.93 to -22.07) and LV ejection fraction 61.0% (56.5 to 65.0). BNP was associated with LV global strain (r=0.30, p=0.04) and LV ejection fraction (r=-0.28, p=0.04). 16/26 and 18/23 participants randomized to carvedilol and placebo, respectively, had serum and plasma samples at T12. Change in BNP and hs-TnI was similar for the two groups (Table).

	Carvedilol	Placebo	P
BNP T0 (ng/L)	94 (50-154)	70 (25-208)	
BNP T12 (ng/L)	168 (101-314)	168 (86-275)	
BNP Change	+76 (+8 to +228)	+44 (-20 to +129)	0.64
hs-TnI T0 (ng/L)	11.2 (7.8-19.7)	20.1 (9.0-31.6)	
hs-TnI T12 (ng/L)	10.3 (6.3-13.6)	16.3 (7.8-36.8)	
hs-TnI Change	-0.5 (-2.7 to +1.9)	-0.6 (-6.8 to +7.9)	0.39

Conclusions: BNP was positively associated with global longitudinal strain and inversely associated with ejection fraction. Carvedilol therapy did not improve levels of biomarkers of LV stress or myocardial damage after 12 months of therapy. Sample size was a limitation.

Higher End-Stage Renal Disease (ESRD) Star Ratings Are Associated with Lower Mortality, Hospitalization, and Readmission Ratios

Andrea C. Besharat, Stephen A. Valderrama, Mahesh Krishnan, Allen R. Nissenson, Steven M. Brunelli. *DaVita Inc, Denver, CO.*

Background: The Centers for Medicare & Medicaid Services (CMS) Star rating system for ESRD was introduced in January 2015 to inform patient choice by creating transparency with respect to dialysis facility performance. Facilities are assigned a Star rating on a forced bell curve (1-5) based on 9 quality metrics that include standardized hospitalization and mortality ratios (SHR and SMR). We sought to assess whether facilities with higher Star ratings had lower SHR, SMR, and standardized readmission ratio (SRR; proposed for inclusion in future Star ratings), and whether change in current Star rating was associated with commensurate change in these metrics.

Methods: Data for calendar years 2013 and 2014 were derived from the CMS Dialysis Facility Compare website. Facilities with Star ratings and SHR (N=4896), SMR (N=4842), and SRR (N=4852) reported for both years were considered. Associations of Star rating in each year and change in rating from 2013 to 2014 with SHR, SMR, and SRR were assessed using generalized linear models.

Results: Mean SHR was 1.00 and SRR was 0.99 for both years, SMR was 1.031 and 1.026 (*P*-difference=0.02) for 2013 and 2014, respectively. In each year, higher Star rating was associated with lower SHR, SMR, and SRR (*P*-trend<0.001 for each; figure shows SHR). There were dose-dependent associations of change in Star rating from 2013 to 2014 with changes in SHR, SMR, and SRR (figure shows SHR).

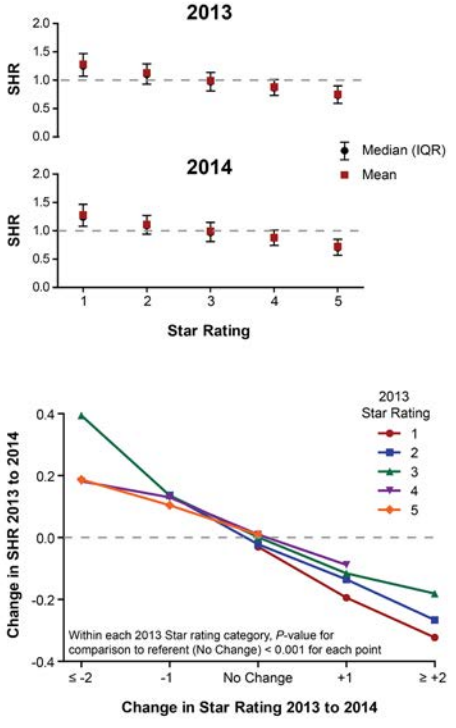

Figure. Association between Star Rating and SHR:
(top) 2013 and 2014 Star Rating each with contemporaneous SHR
(bottom) change in Star Rating from 2013 to 2014 with change in SHR from 2013-2014

Conclusions: Facilities with higher Star ratings perform better in key clinical outcomes SHR, SMR, and SRR than those with lower ratings. Moreover, year-over-year Star rating improvement is associated with like improvements in these metrics. Our study confirms that Star ratings reflect care quality and improvements in quality—as indicated by SHR, SMR, and SRR—and can be used by patients to inform dialysis care choices.

FR-PO945

Comparing Original and Updated Dialysis Facility Compare (DFC) Star Ratings

C. Harvey,[1] Yi Li,[1] C. Dahlerus,[1] J. M. Messana,[1] Ji Zhu,[1] R. Hirth,[1] C. Liao,[1] J. Affholter,[1] N. Scholz,[1] K. A. Wisniewski,[1] Z. Zhang,[1] Joel S. Andress.[2] *[1]Univ of Michigan Kidney Epidemiology and Cost Center; [2]Centers for Medicare and Medicaid Services.*

Background: Starting January 2015, CMS implemented star ratings for dialysis facilities using quality measures reported on DFC. CMS revised the methodology based on technical expert panel and stakeholder feedback. The changes focus on measure scoring techniques and use of a baseline year. This study compares star ratings given by the original and updated methodologies.

Methods: The original methodology calculates facility scores and assigns facilities 1-5 stars (10%, 20%, 40%, 20%, 10%). The updated methodology sets measure and rating category thresholds using a baseline year and applies these to a current year. The original methodology applied to year 2014 is compared to the updated methodology with 2013 as the baseline year and 2014 as the current year. Both methods use DFC measures currently included in the star rating.

Results: The updated methodology results in 5% more facilities in each 4 and 5 star category and a decrease in facilities with 1 and 2-stars as compared to the original methodology. The different measure scoring methods are consistent as indicated by the high correlation (.90) of the final scores.

Original Method	Updated Method					
Cell=Facility N	1	2	3	4	5	Total(%)
1	369	218	0	0	0	587 10%
2	6	677	491	0	0	1174 20%
3	0	12	1719	619	0	2350 40%
4	0	0	23	850	301	1174 20%
5	0	0	0	10	577	587 10%
Total	375 6%	907 15%	2233 38%	1479 25%	878 15%	5872 100%

Conclusions: Scoring against a baseline year lets consumers directly observe each facility's longitudinal improvement since scoring criteria remain fixed over a period of time, while the original method rates facilities relative to each other in the same year. There are tradeoffs with each method. The original method does not permit tracking improvement over time while the updated method using a baseline may allow more facilities to be rated 4 and 5 stars but could obscure meaningful differences between facilities. The new methodology is responsive to the TEP recommendations.

Evaluation of Missing Data Methods for Prevalent-Comorbidity-Adjusted Standardized Mortality Ratio

Bin Nan,[1] Jian Kang,[1,2] Yang Jiao,[2] Minling Zhang,[2] Tempie H. Shearon,[2] Kevin He,[1,2] John Wheeler,[2] J. M. Messana.[2,3] *[1]Dept of Biostatistics, Univ of Michigan, School of Public Health, Ann Arbor, MI; [2]Kidney Epidemiology and Cost Center, Univ of Michigan, Ann Arbor, MI; [3]Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: The standardized mortality ratio (SMR) for dialysis facilities is adjusted for prevalent comorbidities from prior year Medicare claims. In year 2013, 43% dialysis pts had <12 month of claims in 2012, 16% had 0, and 27% had 1-11 months, possibly yielding missing comorbidities. The current method includes all pts, but only adjusts for comorbidities for pts with ≥6 month of claims in prior year. The new method imputes comorbidities for pts with missing data.

Methods: We use the 57% pts in 2013 with 12 month of claims in 2012 as "full data", and randomly generate missing months to yield 100 analytic datasets mimicking the distribution of months with claims. We use logistic regression to impute the probability of comorbidity in pts with missing claims and no observed comorbidity in prior year. We calculated 3 versions of SMR using a facility-stratified Cox model adjusted for age, race, ethnicity, sex, DM, yrs of ESRD, nursing home status, BMI, and incident and prevalent comorbidities. 1)Gold standard uses "full data". 2)Current method applies 6-month cutoff to analytic datasets. 3)Imputation method uses analytic datasets with imputed comorbidities. SMR and facility classifications (better than, worse than or as expected based on DFC method) from methods 2 & 3 are compared to those from gold standard.

Results: Analyses of the 100 analytic datasets show that both methods are reasonably precise, but imputation is slightly better. The correlation of gold standard SMRs with imputation SMRs is improved from .957 (±.001) to .964 (±.001), and the MSE is improved from .017 (±.0004) to .014 (±.0004). Compared to the gold standard, 2.7% of facilities were classified differently in current method compared to 2.44% in imputation method, a 10% reduction.

Conclusions: The current method provides reasonably precise comorbidity-adjusted SMR. The precision can be improved slightly by imputation with a minimal increment of computing cost.

FR-PO947

Achievement of Quality Indicator Targets and Survival of Incident Hemodialysis Patients in Iceland Thordur P. Palsson,[1] Olafur S. Indridason,[2] Runolfur Palsson,[1,2] Helga K. Mogensen.[2] *[1]Univ of Iceland; [2]Landspitali - the National Univ Hospital of Iceland, Reykajvik, Iceland.*

Background: The use of clinical practice guidelines and treatment targets in the care of dialysis patients has been emphasized over the past decade. The aim of this study was to investigate the quality of hemodialysis (HD) care at the University Hospital in Reykjavik with respect to common quality indicators (QI) and to assess patient survival in relation to these QI.

Methods: This was a retrospective study of all incident HD patients in Iceland during 2003-2014, who received treatment for at least 3 months. Data was obtained from medical records. The QI included hemoglobin (target range, 100-120 g/L), iron saturation (>20%), URR (>65%), calcium (2.2-2.6 mmol/L), phosphate (0.85-1.78 mmol/L), PTH (130-585 pg/mL), CO_2 (>21 mmol/L) and albumin (>35 g/L), and the mean value of each QI for each patient was employed. Patients were assigned to 3 groups depending on how many QI targets they achieved; 1-3, 4-5 or 6-8. Kaplan-Meier plots were used to assess survival and groups were compared using the log-rank test. Cox regression was used to assess independent association of variables with survival.

Results: A total of 160 patients were included in the study, of whom 101 were males (63%). The median age at onset of HD was 68 (17-92) years. Sixteen patients (10.1%) achieved 1-3 QI targets, 56 (35.2%) achieved 4-5 targets and 87 (54.7%) achieved 6-8 targets. There was no significant difference in age or sex distribution between the three groups. Patient survival was significantly better when a greater number of QI targets was achieved ($p<0.001$) and this difference remained significant in multivariable analysis and if albumin was used as covariate rather than as a QI. One- and 3-year survival of patients achieving 1-3, 4-5 and 6-8 QI targets was 58.0% (95% CI, 35.2-95.7) and 34.8% (14.5-83.4), 84.3% (74.8-94.9) and 47.5% (34.0-66.3%), and 96.1% (91.8-100.0) and 78.5% (68.7-89.8), respectively.

Conclusions: A survival advantage is associated with a greater number of treatment goals achieved in HD patients. Thus, greater emphasis should be placed on achievement of treatment targets for established QI in HD care.

FR-PO948

Attaining the Standards Proposed in Guidelines - Results from EURODOPPS Sophie Liabeuf,[1] Karlijn J. Van Stralen,[2] Fergus J. Caskey,[3] Francesca Tentori,[4] Ronald L. Pisoni,[4] Ayesha Sajjad,[2] Kitty J. Jager,[2] Ziad Massy.[5] *[1]INSERM U1088, CRC, Amiens Hospital Univ, Amiens, France; [2]ERA EDTA Registry, Amsterdam Medical Center, Amsterdam, Netherlands; [3]UK Renal Registry, Southmead Hospital, Bristol, United Kingdom; [4]Arbor Research Collaborative for Health, Ann Arbor; [5]INSERM U 1018 and Div of Nephrology, Univ of Versailles Saint Quentin en Yvelines, Boulogne Billancourt, France.*

Background: In the field of chronic kidney disease (CKD), global clinical practice guidelines have been developed and implemented with a view to improving patient care and outcomes. We sought to measure and compare the extent to which various European countries have adopted and attained the targets set in international guidelines, with a focus on factors that can be modulated by pharmacological agents.

Methods: The EURODOPPS study is the European part of an international, prospective study of a cohort of adult, in-centre, haemodialyzed patients. For the current project, 6317 patients from seven European countries were included between 2009 and 2011. The mean follow-up period was 1.5 years. Data on laboratory test results and medication prescriptions were extracted from patient records, in order to determine the overall percentage of patients treated according to the international guidelines on anaemia, dyslipidaemia, metabolic acidosis and mineral bone disease (MBD).

Results: Attainment of the targets set in international guidelines was far from complete; only 34.1% of the patients attained their target blood pressure, and 31.2% attained their target haemoglobin level. Overall, only 3% of the patients attained all the relevant targets set in the guidelines. Levels of guideline uptake/application and the use of pharmacological agents varied from one European country to another.

Conclusions: The results of this first ever large-scale, European study of attainment of targets and drug prescription in haemodialyzed patients highlighted the low overall levels of target attainment and emphasized the marked disparities between European countries in this respect.

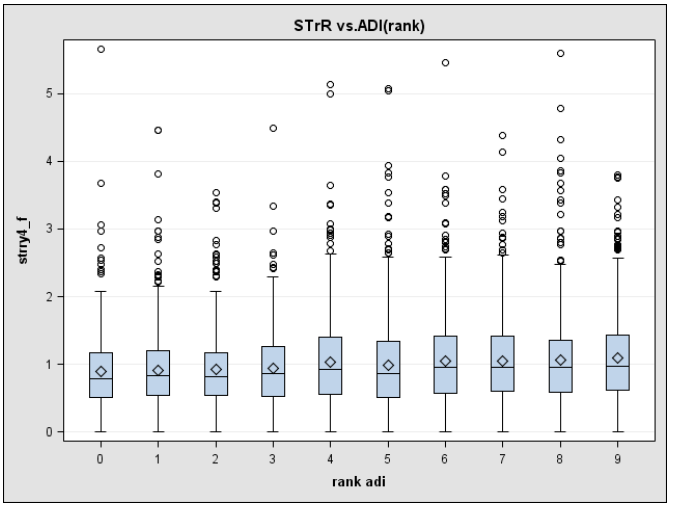
FR-PO949

Transfusion Practices by Area-Level Socioeconomic Deprivation C. Dahlerus, Shu Chen, Douglas E. Schaubel, Bin Nan, Jennifer Sardone, J. M. Messana. *Univ of Michigan Kidney Epidemiology and Cost Center.*

Background: The standardized transfusion ratio (STrR) is reported by CMS on Dialysis Facility Compare and will be implemented in the ESRD Quality Incentive Program. Stakeholders raised concerns that the STrR unfairly characterizes facility performance because of geographic variation, possibly related to area socioeconomic status (SES). This concern is buttressed by studies reporting geographic differences in SES influence many other health outcomes. In another abstract, we describe a revised, more conservative definition for defining transfusion events in STrR that results in reduced variation due to geographic-based differences. This abstract assesses the contribution of SES to the remaining geographic variation.

Methods: 2014 Medicare claims data are used to calculate STrR across SES deciles. SES is measured by deciles of mean zipcode-level Area Deprivation Index (ADI) scores with 2000 Census data from HIPxChange.org. We plotted mean STrR by deciles of ADI indicating least to most deprived areas.

Results: As reported in the companion abstract, mean STrR based on the new transfusion definition still shows some variation by geographic region. In contrast, differences in STrR across deciles of area deprivation vary in a non-monotonic pattern. Interquartile range values overlap substantially between deciles of lower vs higher deprivation scores (figure). Extreme values of STrR were observed in both the lowest and highest SES deciles.



Conclusions: We observed overall minimal differences in STrR by levels of area deprivation suggesting SES does not directly impact transfusions or drive regional differences in outcomes. Extreme values of transfusions in the lowest/highest categories of deprivation suggest SES works in concert with other characteristics that determine health care access along with provider practices that impact outcomes.

FR-PO950

Effects of Patient Sociodemographics (SDS) versus Comorbidities on Hospitalization and Mortality C. Dahlerus, John Wheeler, Tempie H. Shearon, Yang Jiao, John Stephen, Deanna Chyn, Minling Zhang, Yifan Wu, Jennifer Sardone, J. M. Messana. *Univ of Michigan Kidney Epidemiology and Cost Center.*

Background: Risk factor adjustment for hospitalization and mortality outcomes can increase measure validity. Public reporting of outcomes measures has raised interest in adjusting for SDS. Studies observe black and Hispanic ESRD patients typically have lower hospitalization and mortality while lower SDS is predictive of higher hospitalization and mortality. Prevalent comorbidities may attenuate the impact of SDS on outcomes. We examine the relationship of SDS to hospitalization and mortality w/ and w/o comorbidity adjustment.

Methods: 2014 Medicare claims data for readmission; 2011-14 for hospitalization and mortality. Analyses are limited to the Medicare population; prevalent comorbidities are claims based. We fit Cox models stratified by facilities. One set of models adjusts for patient clinical and demographic characteristics including age, sex, race, ethnicity and dual Medicare/Medicaid status. The second adds comorbidities. Analyses include main effects only for race and ethnicity. Hazard ratios (admission, mortality) and odds ratios (readmission) are calculated.

Results: Black patients had lower admissions, readmissions and mortality. The effect of black race decreased nominally when adjusting for comorbidities. Hispanic patients had lower likelihood of hospitalization, readmission, and mortality; all effects diminished w/ comorbidities. Dual status increased likelihood of all outcomes but the effects declined w/ comorbidities. Statistical significance and direction of covariates were consistent across models.

	Black	Hispanic	Dual
Admissions HR			
w/o comorb	0.92	0.87	1.13
w/comorb	0.94	0.93	1.08
Readmissions OR			
w/o comorb	0.94	0.88	1.11
w/comorb	1.00	0.94	1.04
Mortality HR			
w/o comorb	0.69	0.70	1.06
w/comorb	0.72	0.76	1.03

(all $p<0.01$).

Conclusions: The relationships among outcomes, SDS, and comorbidities are complex. Prevalent comorbidities may attenuate effects of SDS on outcomes. Caution is warranted in attributing outcomes directly to SDS when comorbidities may be a key driver.

Funding: Other U.S. Government Support

FR-PO951

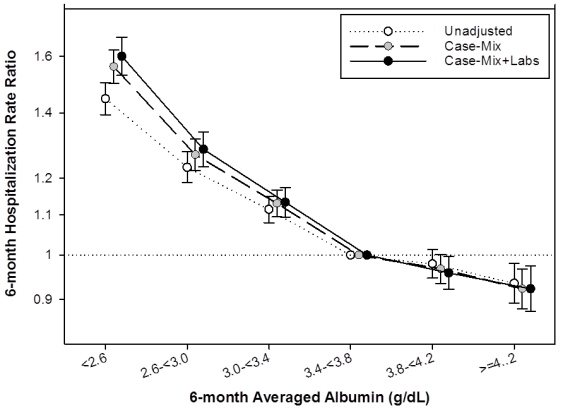
Low Albumin Levels prior to Transition to Dialysis and Early Dialysis Hospitalization among U.S. Veterans: A Transition of Care in CKD Study

Amanda R. Tortorici,[1] Elani Streja,[1] Melissa Soohoo,[1] Connie Rhee,[1] Rieko Eriguchi,[1] Yoshitsugu Obi,[1] Daniel L. Gillen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: Previous studies have shown the importance of albumin (Alb) as a predictor for a number of adverse outcomes including mortality and hospitalization in chronic kidney disease patients. However, the impact of Alb levels prior to end-stage renal disease (ESRD) on post-ESRD hospitalization is not known.

Methods: In 85,505 US veterans who transitioned to dialysis between 10/2007 and 3/2014, we identified 30,781 patients with available Alb measurements within the last 6-month prelude period (prior to ESRD transition). We examined the association of Alb (averaged over 6 months) as a categorical predictor of hospitalization within the first 6 months post transition, using Poisson models adjusted for demographics, comorbidities and 6-month prelude averaged laboratory covariates.

Results: The mean±SD age of the cohort was 68±11 years, among whom 30% were African-American, 8% were Hispanic, and 48% had diabetes listed as their primary cause of ESRD. The mean±SD Alb in the 6 months prior to transition was 3.4±0.6 g/dL. We observed a linear association between pre-ESRD Alb and 6-month post-ESRD hospitalization rate [Figure]. Patients with Alb levels < 3.4 g/dL demonstrated higher rate of post-ESRD hospitalization compared to the referent group (Alb 3.4-<3.8 g/dL), whereas patients with Alb levels ≥4.2 g/dL experienced a lower rate.



Conclusions: Among veterans transitioning to dialysis, higher Alb levels are associated with lower rate of early post-ESRD hospitalization. Additional studies are needed to examine if nutritional interventions in the predialysis period can lower post-ESRD hospitalization incidence.

Funding: NIDDK Support

FR-PO952

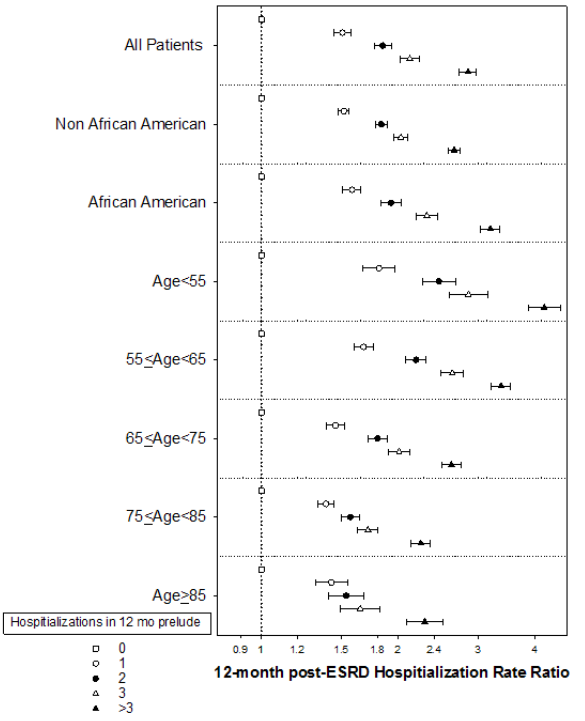
Disparities in Age and the Association of Number of Hospitalizations Pre-ESRD and after Dialysis Transition among U.S. Veterans: A Transition of Care in CKD Study

Melissa Soohoo,[1] Elani Streja,[1] Alpesh Amin,[1] Anna Mathew,[2] Danh V. Nguyen,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Northwell Health; [3]Univ of Tenn.*

Background: A previous study showed that younger African American(AfAm) dialysis patients are more frequently hospitalized during the first year of end-stage renal disease(ESRD), compared to older whites. It is unknown if more frequent hospitalizations within the last year pre-transition to ESRD is associated with hospitalization frequency within the first year post-transition. We seek to examine the impact of age and race on the relationship of pre and post ESRD hospitalization frequency.

Methods: In 85,505 US veterans who transitioned to ESRD between 10/2007 and 3/2014, we identified 41,241 patients who utilized VA or CMS resources during the last 12 months prior to ESRD and remained on dialysis for at least 1 year. We examined the association of the number of hospitalizations within the 12 month prelude period as a predictor of the number of hospitalizations in the first 12 months post transition, using Poisson models adjusted for demographics and comorbidities. Models were also stratified by incidence age and race.

Results: The cohort was 71±11(mean±SD) years and 23% were African American. Across all strata of age and race, we observed a direct relationship of hospitalization frequency pre and post-ESRD. However, the relationship between pre- and post-ESRD hospitalizations were stronger in AfAm patients (p-for-interaction<0.0001) and across in increasing age strata (p-for-trend<0.0001).



Conclusions: Patients who experience at least 1 hospitalization pre-ESRD have a higher risk of hospitalization post-transition. This association is more pronounced among younger patients who were hospitalized multiple times. Further studies are needed to understand the reasons why age and race exacerbate the impact of pre-ESRD hospitalizations on post-transition hospitalizations.

FR-PO953

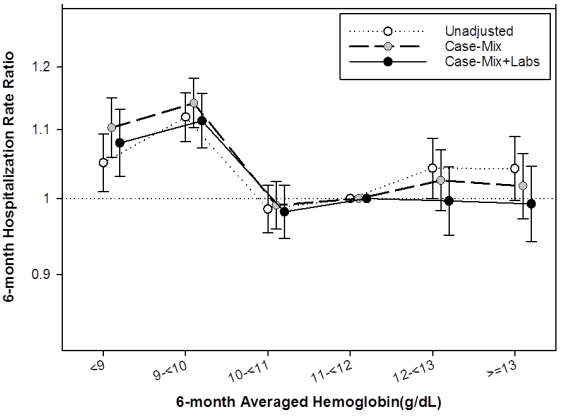
Hemoglobin Levels prior to Transition to Dialysis and Early Dialysis Hospitalization among U.S. Veterans: A Transition of Care in CKD Study

Melissa Soohoo,[1] Elani Streja,[1] John J. Sim,[2] Connie Rhee,[1] Danh V. Nguyen,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Kaiser Permanente SC; [3]Univ of Tenn.*

Background: Patients with advanced chronic kidney disease (CKD) are often afflicted with anemia. Previous studies have found that both lower and higher hemoglobin (Hgb) levels were associated with worse outcomes in dialysis and non-dialysis dependent CKD patients. However, the association between Hgb levels in the immediate period preceding dialysis (prelude) and early post-dialysis hospitalization remains unknown.

Methods: In 85,505 US veterans who transitioned to dialysis between 10/2007 and 3/2014, we identified 31,303 patients with available Hgb measurements within the last 6 month prelude period (prior to transition). We examined the association of Hgb (averaged over 6 months) as a categorical predictor of hospitalization within the first 6 months post transition, using Poisson models adjusted for demographics, comorbidities and laboratory covariates.

Results: The mean±SD age of the cohort was 68±11 years, among whom 30% were African-American, 8% were Hispanic, and 48% had diabetes listed as their primary cause of end-stage renal disease (ESRD). The mean±SD Hgb for the cohort was 10.7±1.6 g/dL. Across all levels of adjustment, patients with Hgb ≤10 g/dL demonstrated a higher rate of hospitalization post transition to ESRD compared to the referent group (Hgb 11-<12 g/dL).



Conclusions: Among patients transitioning to dialysis, lower pre-ESRD Hgb levels were associated with a higher rate of early post-transition to ESRD hospitalization. Clinical trials to examine the impact of anemia management during prelude on post-ESRD outcomes are indicated.

Funding: NIDDK Support

FR-PO954

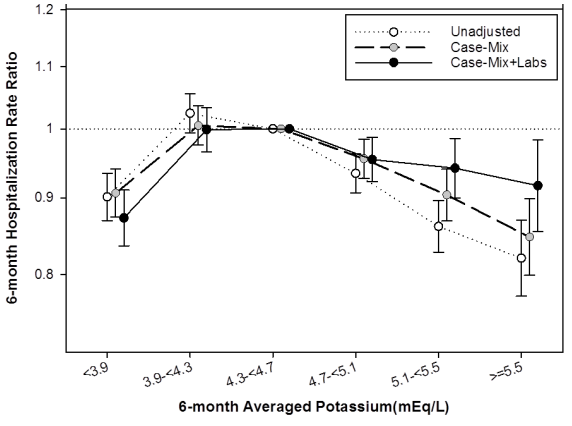
Association of 6-Month Pre-ESRD Potassium with Immediate Post-Dialysis Hospitalization among U.S. Veterans: A Transition of Care in CKD Study

Melissa Soohoo,[1] Elani Streja,[1] Connie Rhee,[1] Alpesh Amin,[1] Danh V. Nguyen,[1] Miklos Zsolt Molnar,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: Recent studies have shown that both high and low potassium (K) were associated with higher rates of hospitalization in non-dialysis dependent chronic kidney disease (CKD) patients. However, the impact of potassium measured in the immediate period prior to dialysis (prelude) and hospitalization post transition remains understudied.

Methods: Among 85,505 US veterans who transitioned to dialysis between 10/2007 and 3/2014, we identified 33,499 patients with available K measurements within the last 6-month prelude period (prior to transition). We examined the association of K (averaged over 6 months) as a categorical predictor of hospitalization within the first 6 months post transition to end-stage renal disease (ESRD), using Poisson models adjusted for demographics, comorbidities and laboratory covariates.

Results: The cohort was (mean±SD) 68±11 years old, and included 29% African-Americans, 7% Hispanics, and 48% had diabetes listed as their primary cause of ESRD. The mean±SD K of the cohort prior to transition was 4.5±0.6 mEq/L. Low serum K <3.9 mEq/L was associated with lower rate of hospitalization compared to the reference (K 4.3-<4.7 mEq/L). Furthermore, patients with higher K≥4.7 mEq/L were associated with a lower rate of hospitalization post transition to ESRD.



Conclusions: Among veterans transitioning to dialysis, both low (<3.9 mEq/L) and high (>4.7 mEq/L) K levels were associated with lower rate of early post-ESRD hospitalization. These results differ from the K-hospitalization association observed in patients with non-dialysis dependent CKD. Additional studies are needed to investigate the K-hospitalization relationship in this population.

FR-PO955

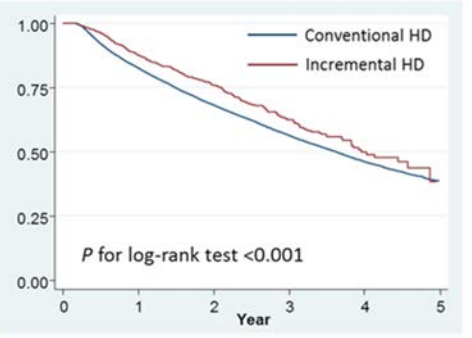
Twice Weekly Hemodialysis and Mortality in the United States

Anna Mathew,[1] Yoshitsugu Obi,[2] Connie Rhee,[2] Joline L.T. Chen,[3] Gaurang M. Shah,[2] Wei Ling Lau,[2] Csaba P. Kovesdy,[4] Rajnish Mehrotra,[5] Kamyar Kalantar-Zadeh.[2] *[1]Northwell Health; [2]UC Irvine; [3]VA Long Beach; [4]Univ of Tenn.; [5]Univ of Wash.*

Background: Most end stage renal disease patients in the United States are treated with a thrice-weekly hemodialysis(HD) regimen upon initiation of renal replacement therapy. Hemodialysis patients have the highest mortality during the first six months after HD initiation. Understanding the risk factors associated with the transition to HD is necessary to improve the outcomes of HD patients. We hypothesized that incremental transition to HD with a twice-weekly regimen does not compromise survival compared to a thrice-weekly schedule.

Methods: In a longitudinal national cohort of 1,124 incremental (twice-weekly) and 116,266 conventional (thrice-weekly) incident HD patients enrolled over five years (2007-2011), Cox regression analysis compared survival between these groups, with additional survival analyses after matching groups based on baseline and demographic parameters using coarsened exact matching methods.

Results: The matched cohort included 1,120 incremental and 54,633 conventional HD patients.In both the unmatched and cohort and matched cohorts, the incremental patients had a mean ± SD age of 70 ± 13 years, among whom 52% were male. The incremental group had lower mortality rates compared to the conventional group in both unmatched and matched cohorts, with case-mix adjusted HRs of 0.75 [95% CI, 0.66 to 0.86], and 0.76 [95% CI, 0.67 to 0.86], respectively. Data on residual kidney function was limited, and we were thus unable to incorporate this variable into our analysis.



Conclusions: Among incident HD patients, initiation with twice-weekly HD, non-inferior survival was observed with twice-weekly compared to thrice-weekly transition to HD. Randomized controlled trials are indicated to examine the effect of residual kidney function and dialysis treatment frequency on survival and other relevant outcomes.

FR-PO956

Gender Disparities in Hospitalization among Maintenance Hemodialysis Patients in the United States

Scott V. Adams,[1] Matthew B. Rivara,[1] Elani Streja,[2] Alfred K. Cheung,[3] Onyebuchi A. Arah,[4] Kamyar Kalantar-Zadeh,[2] Rajnish Mehrotra.[1] *[1]Kidney Research Inst, Univ of WA, Seattle, WA; [2]UC Irvine, Irvine, CA; [3]Univ of Utah, Salt Lake City, UT; [4]UCLA, Los Angeles, CA.*

Background: Hospitalization is a major burden among maintenance hemodialysis patients; reducing hospitalizations and readmissions is a target of healthcare policy in the US. We sought to detail subgroups of patients undergoing maintenance dialysis at highest risks of hospitalization and readmission.

Methods: We analyzed data from a cohort of 111,653 adult hemodialysis patients in the US (2007-2011). Rates of hospitalization and 30-day readmission were compared by gender, age, and race, adjusting for other case-mix and laboratory/clinical variables.

Results: There were 333,756 hospitalizations over 4 years of follow-up. The overall rate of hospitalization was 1.85 per person-year (1.68 among men and 2.08 among women). Hospitalization rates were higher for women than men of the same age and race; for example, women ages 35-44 y had a 49% (95% CI: 40% to 58%) higher hospitalization rate than men of the same age and race (Figure). The gender disparity in hospitalization risk decreased with older age, and was attenuated with adjustment for serum albumin. The probability of 30-day readmission followed similar patterns to hospitalization rate. The probability of readmission was strongly associated with previous admissions, rising from 27.0% (95% CI: 26.5% to 27.4%) following a patient's first hospitalization, to 38.6% (95% CI: 38.1% to 39.2%) following a patient's fifth hospitalization.

Conclusions: Women undergoing maintenance hemodialysis experience excess risk of hospitalization and 30-day readmission compared to men. Additionally, patients with multiple prior hospitalizations are at particularly high risk of readmission. Interventions focused on these groups may be of benefit in reducing hospitalization and readmissions among dialysis patients.

Figure:

FR-PO957

Geographic Variation in Hospital Readmissions Allan J. Collins,[1] Peer Kidney Care Initiative Investigators.[2] *[1]Chronic Disease Research Group, MMRF, Mpls, MN; [2]Peer Kidney Care Initiative.*

Background: Reducing 30-day hospital readmissions is a major CMS policy objective. Readmissions have fallen for both targeted and non-targeted diseases. USRDS reports show readmissions for the dialysis population almost twice those of the general Medicare population (35% versus 17%). We studied geographic trends over time in 30-day hospital readmissions, comparing the US census divisions.

Methods: The 2004-2013 prevalent dialysis population was assessed yearly from January 1 to November 30 to determine 30-day hospital readmission patterns. The index hospitalization, used to define a primary cause of hospitalization, was categorized by organ system and included causes targeted by CMS (MI/acute coronary syndrome, CHF/fluid overload, pneumonia), and causes not targeted (GI bleeding, hyperkalemia, vascular access complications, bacteremia/sepsis, Clostridium difficile infections). We assessed how readmission rates changed over time by US census division, a marker of geography.

Results: Overall, the relative decrease in readmission rates, 2011-2013, was 8%, greater than reported in the general Medicare population. The greatest decline was in the Mid-Atlantic division, 9.1%, and the least in the Pacific division, 7.2%. Overall, divisions with the greatest declines also had the highest admission rates. Index hospitalization causes leading to the highest percentage of 30-day readmissions were C. diff infections followed by MI/acute coronary syndrome, CHF/fluid overload, and bacteremia/sepsis.

Conclusions: The dialysis population, although not specifically targeted by CMS, has experienced a greater reduction in readmissions than the general Medicare population across broad geographic regions and index causes of hospitalization.

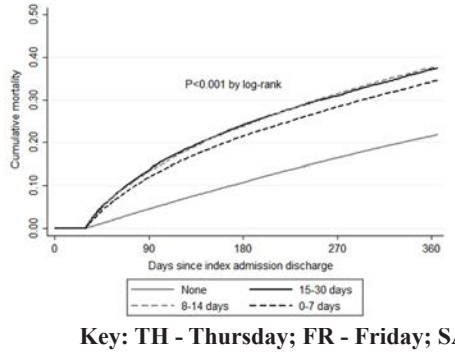
FR-PO958

Mortality by Hospital Readmission Window among U.S. Hemodialysis Patients Laura Plantinga,[1] Janice P. Lea,[1] Rachel E. Patzer,[1] Bernard G. Jaar.[2] *[1]Emory Univ, Atlanta, GA; [2]Johns Hopkins Univ, Baltimore, MA.*

Background: U.S. dialysis facilities will be accountable for hospital readmissions in 2017, but whether the 30-day window defined by pay-for-performance predicts poor outcomes as well as earlier windows is unknown. We examined the prevalence of hospital readmissions within 7 or 14 days of discharge and compared 1-year mortality by readmission window.

Methods: We identified 153,349 U.S. hemodialysis (HD) patients from a national registry (United States Renal Data System) who had at least one hospitalization in 2010 (first=index) and survived on HD for at least 30 days. Readmissions were defined by admissions within windows of 0-7, 8-14, or 15-30 days after discharge from the index admission. Kaplan-Meier analyses and multivariable Cox proportional hazards models were used to estimate the association between readmission window (referent=no readmission in 30 days) and time to mortality, censored at 1 year.

Results: Overall, 13.1%, 5.9%, and 9.6% of patients had readmissions within 0-7, 8-14, and 15-30 days of discharge from index admission; 45.8% of readmissions were within 7 days. Regardless of readmission window, patients with readmissions had about twice the risk of death within 1 year, compared to those with no readmissions; this effect was attenuated after 6 months.



Adjustment for age, sex, race/ethnicity, dialysis vintage and comorbid conditions made little difference: 15-30 days, HR=2.05 (95% CI, 1.98-2.12); 8-14 days, HR=2.06 (95% CI, 1.97-2.15); and 0-7 days, HR=1.80 (95% CI, 1.74-1.86).

Conclusions: Nearly half of 30-day readmissions occurred within the first 7 days after discharge, suggesting that opportunities for dialysis providers to prevent readmission may be limited. These results also suggest that readmission, regardless of timing, is associated with about 2-fold increased risk of mortality in the following year among U.S. HD patients.

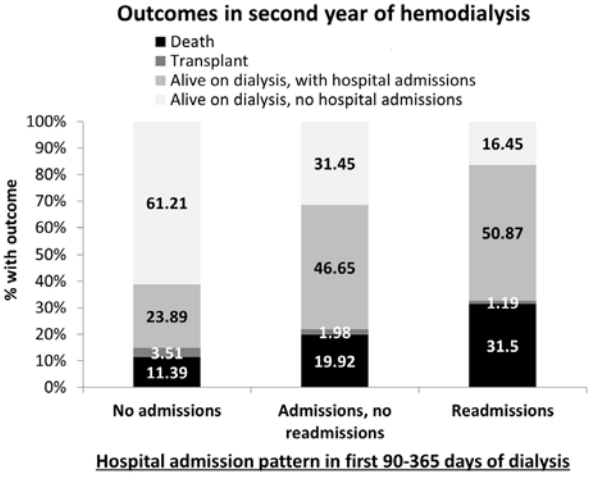
Long-Term Outcomes among Hemodialysis Patients Readmitted in the First Year of Dialysis Bernard G. Jaar,[1] Rachel E. Patzer,[2] Janice P. Lea,[2] Laura Plantinga.[2] *[1]Medicine - Nephrology, Johns Hopkins Univ, Baltimore, MD; [2]Medicine - Nephrology, Emory Univ, Atlanta, GA.*

Background: Readmissions are common among hemodialysis (HD) patients and may predict poor outcomes. We examined long-term outcomes among incident in-center HD patients readmitted in their first year of treatment.

Methods: We categorized 275,475 U.S. incident patients from a national registry (USRDS) who started HD between 9/2005 and 9/2009 and remained on HD alive for at least 1 year as having no admissions, admissions but no readmission (within 30 days), and 30-day readmissions in the 90-365 days after HD start. Outcomes (mortality, transplantation, and hospital admissions) were examined between 366 and 730 days. Multivariable Cox proportional hazards and Poisson models were used to estimate hazard ratios (HRs) and incidence rate ratios (IRRs).

Results: Overall, 15.8%, 25.0%, and 59.1% of patients had readmissions, hospital admissions but no readmission, and no admissions, respectively, in the first 90-365 days of HD. Patients with readmissions in year 1 were more likely to die and be hospitalized, and less likely to be transplanted in their year 2 of HD, compared to their counterparts with no readmission or no admission.



With adjustment for age, sex, race/ethnicity and comorbid conditions, those with readmissions and those with admissions but no readmission remained far more likely than those without admission in year 1, to have poor outcomes in their year 2: mortality, HR=2.84 (95% CI, 2.77-2.90) and 1.61 (95% CI, 1.51-1.65); and hospital admissions, IRR=5.02 (95% CI, 4.97-5.06) and 2.66 (95% CI, 2.64-2.68), respectively.

Conclusions: Having hospital readmissions (within 30 days) early in the course of HD, even beyond having hospital admissions alone, is highly predictive of poor long-term subsequent outcomes, including death, not being transplanted, and further hospital admissions.

FR-PO960

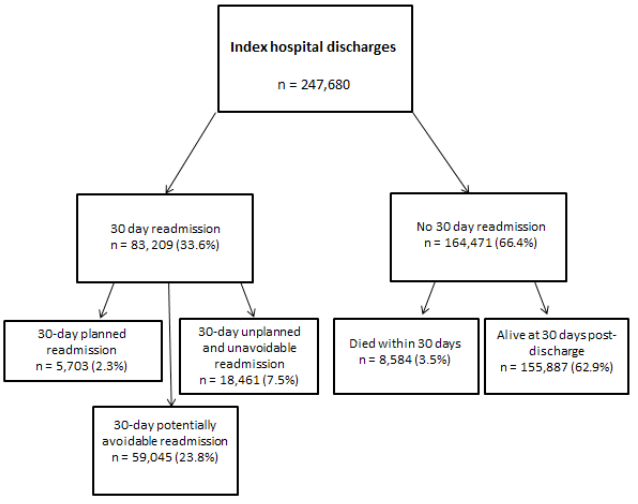
Potentially Avoidable Readmissions in United States Hemodialysis Patients Anna Mathew,[1] Lisa M. Rosen,[1] Renee Pekmezaris,[1] Andrzej Kozikowski,[1] Daniel W. Ross,[1] Thomas Mcginn,[1] Kamyar Kalantar-Zadeh,[2,3] Steven Fishbane.[1] *[1]Hofstra Northwell School of Medicine, Northwell Health, Great Neck, NY; [2]Harold Simmons Center for Kidney Disease Research, Div of Nephrology, Orange, CA; [3]Fielding School of Public Health, UCLA, Los Angeles, CA.*

Background: Patients with end stage kidney disease have a high risk of 30-day readmission after hospital discharge, associated with excessive financial cost and poor quality of life. Whereas all-cause readmissions have been described, potential avoidability of readmissions has not been previously analyzed. We aimed to analyze the frequency, causes and predictors associated with 30-day potentially avoidable readmission to hospital in maintenance hemodialysis patients.

Methods: In this historical cohort study using the United States Renal Data System, 107,940 prevalent HD patients with 248,680 index hospital discharges were assessed for the main outcome of 30-day potentially avoidable readmission after an index hospital discharge, as identified by a computerized algorithm.

Results: Of 83,209 thirty-day readmissions, 59,045 (70% of all readmissions and 24% of all hospital discharges) resulted in a 30-day potentially avoidable readmission.

Figure 1: Index hospital discharge outcomes and frequencies



Characteristics associated with 30-day potentially avoidable readmission included younger age, shorter time on dialysis, greater number of hospitalizations in preceding 12 months, black race, unemployed status, treatment at a for-profit facility, longer length of index hospital stay, and index hospitalizations which involved a surgical procedure.

Conclusions: Maintenance hemodialysis patients are at high risk for 30-day readmission to hospital, with over two-thirds (71%) of all 30-day readmissions potentially avoidable. Research is warranted to develop cost-effective and transferrable interventions to improve care transitions from hospital to outpatient dialysis facility and reduce readmission risk for this vulnerable population.

FR-PO961

Effect of a Medication Intervention on Acute Care Utilization after Hospitalization in Patients with ESRD Katherine R. Tuttle,[1,2] Radica Z. Alicic,[1,2] Robert Short,[1] Sterling McPherson,[1,3] Brad Dieter,[1] Joshua J. Neumiller,[3] Brian J. Gates,[3] Celestina Barbosa-Leiker,[3] Naomi Chaytor,[3] Cynthia F. Corbett.[1,3] *[1]Providence Health Care, Spokane, WA; [2]Univ of Washington, Spokane, WA; [3]Washington State Univ, Spokane, WA.*

Background: Hospital readmission rates in patients with end-stage renal disease (ESRD) exceed that of most chronic health conditions. Strategies to improve care are urgently needed.

Methods: The **E**nd **S**tage **R**enal **D**isease-**M**edication **I**ntervention **T**rial (ESRD-MIT) (www.clinicaltrials.gov NCT01459770) was a randomized, controlled clinical trial conducted between 2013 and 2015. Participants were patients with ESRD (treated by hemodialysis or peritoneal dialysis) acutely hospitalized at Providence Health Care. They were randomized to usual care or the intervention, a single home visit for medication management by a study pharmacist within 7 days of discharge. Acute care utilization (hospital readmission, emergency department or urgent care visits) for 90 days after hospital discharge was the primary outcome.

Results: Study participants (n=39) were 61±16, mean±SD, years of age and 41% (16/39) women. Hypertension and diabetes were present in 51% (20/39) and 59% (23/39), respectively. Duration of dialysis was 22 (3-71), median (IQ range), months. The most common primary diagnoses for index hospital admission included: infections 23% (9/39), cardiovascular diseases 15% (6/39), and vascular access procedures 18% (7/39). Length of stay was 3 (1.5-7) days. The primary outcome, analyzed as time-to-first event, occurred in 40% (8/20) of participants in the intervention group and in 47% (9/19) of those in usual care (p=0.64). Rates for each type of acute care event were similar between groups. For total hospital readmissions, the most common primary diagnoses included: infections 24% (5/21), respiratory diseases 19% (4/21), vascular access procedures 14% (3/21) and cardiovascular diseases 14% (3/21).

Conclusions: Acute care utilization after hospital discharge in patients with ESRD was not reduced by a medication management intervention. Comprehensive strategies to enhance care pre- and post-discharge may be needed to improve health outcomes.

FR-PO962

Hospitalization Rates before and after the Initiation of a Fluid Management Quality Improvement Project Using Crit-Line Monitors during In-center Hemodialysis Paul Balter,[1] Ludmila Anderson,[2] Alice Topping,[1] Claudy Mullon,[2] Robert J. Kossmann,[2] Linda H. Ficociello.[2] *[1]Renal Research Inst, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Patients on hemodialysis (HD) are at high risk for hospital admissions, especially fluid-related admissions. A fluid management quality improvement (QI) project utilizing Crit-Line monitors® (CLM) was conducted by the Renal Research Institute. CLM non-invasively assess intra-dialytic relative blood volume and provide real-time data that allow for ongoing fluid monitoring by clinical staff. The aim of this analysis was to determine whether fluid-related admission rates decreased during the year-long QI project. All-cause hospital admissions and mortality rates were also assessed.

Methods: Data were de-identified and extracted from routinely collected electronic data. Crude rates and rate ratios (RR) were calculated to compare baseline (BL; 12 months before the QI project) to follow-up (12 months during the QI project, after 1 month of CLM transition). To ensure complete outcome ascertainment, all outcomes occurring within 7 days of the last HD treatment were captured for each period. Patients treated in 2 or more centers during baseline and/or follow-up were excluded.

Results: Overall, 2,673 adult patients at 16 HD centers were eligible for analysis. Demographic characteristics varied minimally between study periods (p>0.05); although, a difference in reported congestive heart failure was noted (BL: 18.8% vs. 15.5%, p=0.02). Fluid-related hospitalization rate declined by 19% from 0.21 to 0.17 per patient-year (PY); RR: 0.81 (95% confidence interval: 0.67-0.97), and all-cause hospitalization rate declined by 10% from 1.88 to 1.70 per PY; RR: 0.90 (0.85-0.96). A non-significant decline in mortality rate was observed (16% decrease from 0.19 to 0.16 per PY; RR: 0.84 (0.69-1.01)).

Conclusions: Fluid-related and all-cause hospitalization rates decreased by 19% and 10%, respectively, during a year-long QI project utilizing CLM in 16 HD centers.

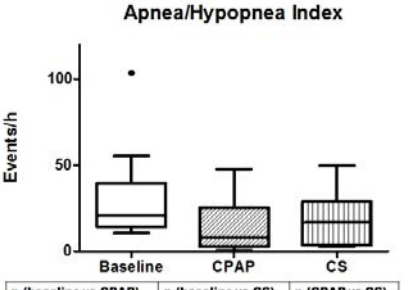
FR-PO963

Compression Stockings Improve Sleep Apnea in Hemodialysis Patients Bruno C. Silva,[1] Roberto S.S. Santos,[1] Luciano F. Drager,[1] Fernando Coelho,[2] Rosilene M. Elias.[1] *[1]Univ de São Paulo, Brazil; [2]UNIFESP, Brazil.*

Background: Sleep apnea (SA) is prevalent in edematous states, such as in hemodialysis (HD) patients. As nocturnal rostral fluid shift from the legs is implicated in its physiopathology, we hypothesized that avoiding fluid retention in the legs during the day, by wearing compression stockings (CS), would improve SA in HD patients.

Methods: We included 14 HD patients with SA (AHI)>5 events/hour) by polysomnography exam (PSG). Pts were submitted to another two PSGs: one for continuous positive airway pressure (CPAP) titration and another 1-week after daytime use of medium (20-30 mmHg) CS. Neck circumference (NC) and bioimpedance analysis (BIA) were performed before and after PSG.

Results: Mean age was 53±9 years (57% men), body mass index was 30±7 Kg/m², and dialysis vintage was 60±62 months. Dry weight and total week ultrafiltration volume were similar in the three exams. AHI decreased from 20.8 (14.2;39.6) at baseline to 16.7 (3.5;28.9) after CS use (p=0.017) and to 7.9 (2.8;25.4) events/hour with CPAP (p=0.004).



p (baseline vs CPAP)	p (baseline vs CS)	p (CPAP vs CS)
0,004	0,017	0,017

Overnight NC variation increased at baseline (0.7±0.4 cm), but decreased after CS use (-0.4±0.8 cm), p=0.001 and after CPAP (-1.0±0.4), p<0.0001. BIA revealed displacement of fluid from the legs to the intracellular compartment of trunk after wearing CS: comparing baseline, CPAP and CS, nocturnal lower limbs water content (relative to body water) was 34.1±2.1%, 34.3±2.3% and 33.5±2.3%, respectively (p=0.04), while nocturnal intracellular trunk water (relative to body water) as 61.8±1.5%, 61.6±1.5% and 62±1.6 %, respectively (p=0.03).

Conclusions: Wearing compression stockings in HD pts during the day avoided fluid retention in the legs, leading to lower nocturnal rostral fluid shift and, consequently, attenuated SA. Even though CPAP remains the mainstream treatment for SA, this study highlights an alternative treatment to such syndrome in HD patients.

FR-PO964

Asymptomatic Sleep Apnea Syndrome in End-Stage Renal Disease: Implications of Volume Overload for Obstructive Sleep Apnea Syndrome Toshiki Kano, Hitoshi Suzuki, Masao Kihara, Yusuke Suzuki, Satoshi Horikoshi. *Div of Nephrology, Dept of Internal Medicine, Juntendo Univ Faculty of Medicine, Bunkyo-ku, Tokyo, Japan.*

Background: Sleep apnea syndrome (SAS) has been reported in up to 50% to 70% of patients with end-stage renal disease (ESRD). It is hypothesized that SAS in patients with ESRD is caused by narrow upper airway due to volume overload. SAS is considered an independent risk factor for hypertension, congestive heart failure, acute coronary syndromes, pulmonary hypertension, arrhythmias, and cerebrovascular events. To improve the prognosis of patients with ESRD, management of appropriate body fluid in reference to degree of obstructive sleep apnea syndrome (OSAS) is essential. The aim of present study is to evaluate the association between severity of OSAS and volume overload in patients with ESRD.

Methods: The apnea-hypopnea index (AHI) and its severity were measured in fourteen patients with ESRD (CKD stage 5) using a portable sleep monitoring device. Body weight (BW), cardio thoracic ratio (CTR), serum levels of BNP, AHI were measured during the therapeutic course of hemodialysis. The association of AHI with age, gender, body mass index (BMI), history of smoking and complication of ESRD were analyzed.

Results: In fourteen patients with ESRD, 92.8 % were diagnosed as asymptomatic SAS. Those patients were divided according to AHI scores into mild (AHI 5-14.9, 21.4%), moderate (AHI 15-29.9, 21.4%), and severe OSAS (AHI≥30, 50.0%) groups. Age, gender, BMI, smoking and complication of ESRD were not associated with AHI. Improvement of AHI due to modification of volume overload was associated with decreased BW and BNP (P=0.032, P=0.026, respectively).

Conclusions: Present study suggested that the OSAS is a major complication in patients with ESRD. The OSAS is caused by narrow upper airway due to volume overload. Assessment of AHI using a portable sleep monitoring device is useful tool to evaluate the appropriate body fluid in patients with ESRD.

FR-PO965

Visual Changes in Response to Haemodialysis Huda Mahmoud,[1,2] Philip Wright,[1,3] Laurence Hodierne,[1] Andrew B. Newsham,[1] Simon E. De Sousa,[1] Patrick Richardson,[3] Nicholas M. Selby,[1,2] Oliver R. Smith.[1] *[1]Dept of Renal Medicine, Royal Derby Hospital, United Kingdom; [2]Centre for Kidney Research and Innovation, Univ of Nottingham, United Kingdom; [3]Dept of Opthamology, Royal Derby Hospital, United Kingdom.*

Background: Haemodialysis (HD) patients report visual disturbances associated with dialysis sessions although causes for these symptoms are poorly documented and understood. We performed an observational study to describe and assess the change in visual acuity (VA) in response to HD therapy.

Methods: All patients receiving chronic HD at our centre were invited to participate. VA of each eye was assessed before and after a single HD session. The Snellen result was converted to Logarithm for Minimal angle of resolution (LogMar) score for comparative analyses and categorized according to the World Health Organisation (WHO) classification of visual loss into normal, mild, moderate and severe. Patients' subjective perceptions of visual disturbances and HD treatment details were recorded.

Results: 148 (281 eyes) patients participated. The WHO classification of visual impairment based on best eye pre-dialysis results; 34% of patients had normal vision, 40% mild, 21% moderate and 5% severe visual impairment. This incidence of moderate and severe visual impairment was higher than would be expected from general population data. 44% of patients experienced a deterioration in VA in one or both eyes by the end of HD, equivalent to one row on Snellen chart. Looking at each eye separately, there was a significant deterioration in mean LogMar score comparing pre-dialysis (mean 0.4±0.2) and post-dialysis measurements (0.44±0.2,p=0.01). 17% of patients reported visual disturbances during HD, most commonly blurring of vision or difficulty reading. Of these 29% dropped a VA category across HD.

Conclusions: This study illustrates that HD patients have a high prevalence of visual impairment, and a subgroup experience significant decline in VA in response to dialysis treatment. This may pose a significant risk in this vulnerable population who often experience high levels of comorbidity and physiological frailty. Further work is required to understand the mechanisms, associated factors and impact of this problem.

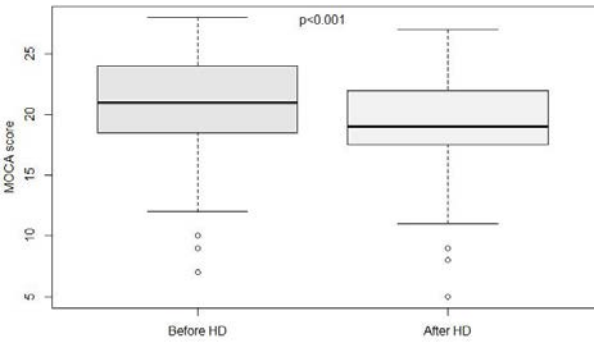
FR-PO966

Change in Cognitive Function over a Single Haemodialysis Session Indranil Dasgupta,[1] Nuredin Ibrahim Mohammed,[2] Mitesh Patel,[1] Jyoti B. Baharani,[1] Thejasvi Balaji Subramanian,[1] G. Neil Thomas,[2] George Tadros.[1] *[1]Birmingham Heartlands Hospital, United Kingdom; [2]Univ of Birmingham, United Kingdom.*

Background: Cognitive impairment (CI) is 3 times more common among haemodialysis (HD) patients compared with the general population, it declines progressively and is associated with increased mortality and reduced functional capacity. The effect of a single HD session on cognition is unclear. We aimed to assess change in cognitive function over a single HD session and risk factors associated with it.

Methods: All patients ≥50 years, on HD for ≥3 months, from 2 satellite HD units were selected. Patients with known CI and those unable to read and write English were excluded. Cognitive function was assessed before and after a single HD session using 2 parallel versions of the Montreal Cognitive Assessment (MOCA) tool and compared using a paired t-test. Linear regression was used to examine factors associated with CI including age, change in weight and BP, electrolytes, albumin, sedative drugs, depression score and comorbidity score.

Results: Of 176 patients, 100 met the inclusion criteria; 83 were able to complete both tests. Median age was 73 years (52 – 91), 59% male, dialysis vintage 41 months (3 – 388). 69 patients (83%) had mild CI at base line(MOCA score <26) with 13 (16%) severe CI (MOCA <17). Cognitive function declined significantly over a dialysis session (p<0.001, Figure1). All domains of cognitive function were affected except visuo-spatial and naming. No association was observed between change in MOCA score and putative risk factors.



Conclusions: Cognitive function declines significantly over a single HD session which has significant clinical implications including for self management advice given during HD and tasks requiring cognition following HD like driving. More research is needed to find the underlying cause of cognitive decline during HD and measures to prevent this.

FR-PO967

High Serum 25-Hydroxyvitamin D, Fibroblast Growth Factor 23, and Interleukin-6 Levels Are Associated with Self-Reported Sleep Quality in the HEMO Study Cohort Anna Jeanette Jovanovich,[1] Morgan E. Marcuccilli,[1] Jessica B. Kendrick,[1] Alfred K. Cheung,[2] Zhiying You,[1] Michel Chonchol,[1] Kristen L. Nowak.[1] *[1]Univ of Colorado; [2]Univ of Utah.*

Background: Although sleep problems are thought to be prevalent among patients who undergo chronic hemodialysis, there is limited information on the relationship between sleep quality with markers of mineral metabolism and inflammation.

Methods: This report uses data from the HEMO Study which was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Twelve-hundred two patients aged 18-80 years were randomized and completed the Kidney Disease Quality of Life Long Form (KDQOL-LF) at baseline. Sleep quality was assessed using the sleep subscale from the KDQOL-LF and a binary outcome of sleep disturbance was defined. Logistic regression models were used to investigate the association between presence and absence of sleep disturbances with markers of mineral metabolism and inflammation.

Results: Mean age (SD) was 58±14 years, 44% were male, 64% were Black, 37% had diabetes, and 32% had hypertension. The median (IQR) 25-hydroxyvitamin D (25(OH)D), fibroblast growth factor 23 (FGF23) and interleukin-6 (IL-6) levels were 19.1 (14.2-26.6) ng/mL, 3118 (726-12,928) pg/mL and 3.1 (1.6-5.7) pg/mL, respectively. After adjustment for potential confounders available in the database, the highest tertile of FGF23 (OR: 1.51, 95% CI 1.05-2.16; p=0.02) and IL-6 (OR: 1.54, 95% CI 1.10-2.16; p=0.01) were associated with an increased odds of sleep disturbance. In contrast, the highest tertile of 25(OH)D was associated with a decreased odds of sleep disturbance (OR: 0.65, 95% CI 0.47-0.90; p=0.04) when compared to the lowest tertile.

Conclusions: Decreased serum levels of vitamin D and increased circulating levels of FGF23 and IL-6 were associated with poor sleep quality in chronic hemodialysis patients. Future work should examine the link between sleep quality with abnormalities of mineral metabolism and inflammation.

Funding: NIDDK Support

FR-PO968

Parathyroid Hormone as a Novel Risk Factor of Hemodialyzer Clotting Kyohei Ogawa,[1] Keita Hirano,[1] Izumi Yamamoto,[2] Yukio Maruyama,[2] Ichiro Ohkido,[2] Nobuo Tsuboi,[2] Takashi Yokoo.[2] *[1]Nephrology, Ashikaga Red Cross Hospital, Ashikaga, Tochigi, Japan; [2]Kidney and Hypertension, Jikei Univ School of Medicine, Minato, Tokyo, Japan.*

Background: Hyperparathyroidism gives rise to low levels of HDL-cholesterol (HDL-C), and hence imposes a cardiovascular risk (Clin Endocrinol 2002;56:253). However, it is unknown whether parathyroid hormone (PTH) level also represents a risk factor for dialyzer clotting.

Methods: All outpatient dialysis sessions performed at Ashikaga Red Cross Hospital in 2015 were examined as a historical cohort. Blood remaining in more than 10 hollow fibers at the end of each session was taken as significant dialyzer clotting.

Results: Out of 4,207 dialysis sessions derived from 36 patients, significant dialyzer clotting was observed in 144 sessions (3.4%). Sessions were then stratified by the median of alkaline phosphatase (ALP) to 2,094 sessions as low ALP group and 2,113 sessions as high ALP group, because there was a significant interaction for the risk of clotting between PTH and ALP. On multivariate analysis adjusted with hemoglobin, albumin and APTT, PTH was associated with the risk of clotting especially in low ALP group (OR 2.10, 95%CI 1.43-3.06, per 100pg/ml of intact PTH), but the association was not observed in high ALP group (OR 1.17, 95%CI 0.87-1.58, P>0.2). Of note, although PTH was proportional to HDL-C in high ALP group (B 3.592, SE 0.279, P<0.001), it was inversely proportional to HDL-C in low ALP group (B -2.108, SE 0.441, P<0.001).

Conclusions: PTH is associated with dialyzer clotting especially in hemodialysis sessions with low ALP level. Consequently, it should deserve more attention when working towards more biocompatible dialysis with reduced dialyzer clotting.

FR-PO969

Polymorphisms of Vitamin D Signaling Pathway Genes and Calcium Sensing Receptor Gene in Respect to Survival of Hemodialysis Patients – A Prospective Observational Study (Part I) Alicja E. Grzegorzewska, Monika K. Swiderska, Adrianna Mostowska, Wojciech J. Warchol, Pawel P. Jagodzinski. *Poznan Univ of Medical Sciences, Poland.*

Background: Studies on associations of single nucleotide polymorphisms (SNPs) of vitamin D signaling pathway genes and calcium-sensing receptor gene (*CASR*) with survival of hemodialysis (HD) patients are scarce. We evaluated whether SNPs of abovementioned genes are determinants of mortality in HD patients.

Methods: Prevalence HD patients without history of renal transplantation (n = 532, men 56%, RRT vintage prior to the study 2.2, 0.0 - 24.7 years, age at the start of the study 61.2, 14.6 - 89.3 years, diabetic nephropathy 25.8%, dyslipidemia 41.0%) were enrolled in the 7-year prospective observational study at January 30, 2009. HRM analysis was used for *GC*rs2298849, *GC* rs1155563, *RXRA* rs10776909, *RXRA* rs10881578, and *CASR* rs7652589 genotyping. *GC* rs7041, *RXRA* rs749759, *VDR* rs2228570, and *VDR* rs1544410 were genotyped using PCR-RFLP analysis. Survival analyses were conducted using the Kaplan-Meier method and the Cox proportional hazard model.

Results: *GC* rs2298849 was associated with all-cause mortality in dominant model of inheritance (log rank test P = 0.02), and *VDR* rs2228570 - with cardiovascular mortality in additive model of inheritance (log rank test P = 0.04). Subjects bearing the minor allele in rs2298849 demonstrated the higher risk of death during 7 years on HD than the major allele homozygotes (OR 1.81, 95%CI 1.13 - 2.92, P = 0.02). Cardiovascular mortality was associated with major homozygosity (CC) in rs2228570 (HR 1.90, 95%CI 1.16 – 3.09, P = 0.01). The CC genotype patients were more often dyslipidemic compared to the TT genotype subjects (46 vs 31%, P = 0.03). Dyslipidemic HD patients showed higher frequency of the rs1544410_rs2228570 haplotype AC than non-dyslipidemic subjects (26 vs 18%, P_{corr} = 0.005), whereas the TT genotype patients were at lower risk of dyslipidemia compared to patients with CC/CT genotypes (HR 0.59, 95%CI 0.37 – 0.96, P = 0.04).

Conclusions: *GC*rs2298849 and *VDR* rs2228570 SNPs are associated with survival of HD patients. *VDR*-related cardiovascular mortality may occur due to connections of rs2228570 with dyslipidemia.

FR-PO970

Polymorphisms of T Helper Cell Cytokine-Associated Genes in Respect to Survival of Hemodialysis Patients – A Prospective Observational Study (Part II) Alicja E. Grzegorzewska, Monika K. Swiderska, Adrianna Mostowska, Wojciech J. Warchol, Pawel P. Jagodzinski. *Poznan Univ of Medical Sciences, Poland.*

Background: We evaluated in the 7-year prospective study whether variants in T helper cell cytokine-associated genes are determinants of mortality in hemodialysis (HD) patients (n=532).

Methods: HRM analysis was used for *IFNL3*, *IL12A*, *IL13*,and *IL4R* genotyping. *CCL2*, *IL12B*, and *IL18* were genotyped using PCR-RFLP analysis. Survival analyses were conducted using the Kaplan-Meier method and the Cox proportional hazard model.

Results: *IFNL3* rs8099917 was associated with all-cause mortality in recessive model of inheritance (log-rank test P = 0.044), *IL12A* rs568408 - in dominant model (log-rank test P=0.029). Minor homozygotes (GG) in rs8099917 showed shorter survival than major allele (T) bearers (3.6, 1.0–7.0 years vs 4.7, 0.1–7.0 years, P = 0.009), although their RRT vintage prior to the onset of the study was also shorter (1.4, 0.0-6.8 years vs 2.3, 0.0-22.2 years, P=0.010). The rs8099917 GG patients demonstrated higher risk of death than the remaining patients (GT+TT) (OR 1.94, 95%CI 1.11-3.40, P = 0.020). Major homozygosity (GG) in rs568408 was associated with higher mortality than that shown in bearers of the minor allele (AA+AG) (HR 1.31, 95%CI 1.02–1.69, P = 0.035). There were less responders to HBV vaccination in the genotype GG patients compared with the rs568408 minor allele bearers (84.6% vs 94.3%, P = 0.019). However, significant predictors of 7-year survival in multivariate analysis were only coronary artery disease (HR 1.685, 95% CI 1.297–2.191, P = 0.0001), age (HR 1.016, 95% CI 1.006–1.026 per each 1-year increase, P = 0.002), RRT vintage prior to the study onset (HR 1.053, 95% CI 1.013–1.093 per each 1-year increase, P=0.008), and serum PTH (HR 1.028, 95% CI 1.001–1.057 per each 100 pg/mL decrease, P=0.046). There were no associations of tested polymorphisms with cardiovascular, infection- or neoplasm-related mortalities, and no gene-gene interactions between tested polymorphisms in the 7-year survivors and non-survivors.

Conclusions: Polymorphisms of *IFNL3* rs8099917and *IL12A* rs568408 are associated with survival on HD, however, they are not significant predictors of all-cause mortality.

FR-PO971

Parathyroidectomy (PTX), KDOQI Targets and Mortality in a Cohort of Italian Dialysis (D) Patients: A Multicenter Observational Study Sandro Mazzaferro. *On Behalf of the Italian Study Group of Mineral Metabolism; Sapienza Univ of Rome, Dept of Cardiovascular, Respiratory, Nephrology, Anesthesiology and Geriatric Sciences, Rome, Italy.*

Background: Secondary hyperparathyroidism (SHP) plaques patients with ESRD on D negatively affecting survival. Achieving even once KDOQI target levels for Ca, P and PTH associates with lower risk of mortality. PTX, possibly by improving biochemical control, may improve survival. Aim of this study was to evaluate the impact of PTX on biochemical control and survival of Italian HD patients in the medium term.

Methods: Data were collected from 149 HD units spread throughout the Country, by means of a data sheet filled by a reference physician.

Results: We collected 524 living PTX cases (age: 57.90±12.52 y.o; D time: 14.57±8.37 y; sex: 231M/296F), out of a total 12515 receiving D (=4,2%). Time from surgery was 6,0 y (3,0-9,0; M, IQR). A control group was identified (432 cases, 58.9±16.5 y.o.; on D since 11.7±2.6 y; 192M/240F). Data were then collected on a yearly basis for 3 consecutive years. At enrollment, compared to the control group, PTX patients had lower Ca (8.76±0.87 vs 9.05±0.73 mg/dl; p <.05), P mg/dl (4.90±1.36 vs 5.10±1.34 mg/dl; p<.05) and PTH (181.9±292.5 vs 333.7±293.7 pg/ml; p<.01). At enrollment the percentage of patients at target was lower in the PTX group: P = 55,3% vs 58,8 (p<.05); Ca = 50,9% vs 57,6 (p<.001); PTH =17% vs 35% (p<.001). PTH, but not Ca and P, was confirmed to be more frequently at target in the control group (35% vs 21%, p<.05) during 1 and 2 years of follow-up. In multivariate adjusted analysis, sHR for all-cause mortality was 0,843 (CI 0,783-0,908; p<.0001) for PTX patients.

Conclusions: In conclusion, in D patients PTX associates with lower risk of mortality regardless of achievement of Ca,P or PTH targets.

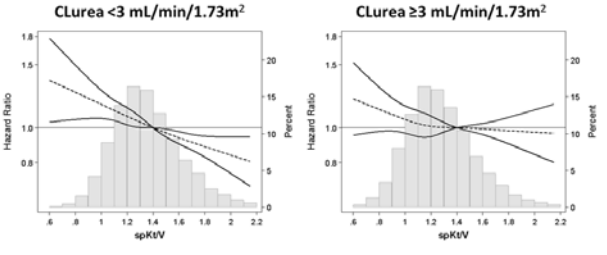
Residual Kidney Function Modifies the Association between Dialysis Dose and Mortality in Hemodialysis Patients Yoshitsugu Obi,[1] Mengjing Wang,[1] Connie Rhee,[1] Elani Streja,[1] Csaba P. Kovesdy,[2] Rajnish Mehrotra,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.; [3]Univ of Wash.*

Background: Recent studies have suggested that frequent hemodialysis is associated with faster decline in residual kidney function (RKF) and higher mortality among hemodialysis patients with substantial RKF. We hypothesized that dialysis dose is associated with better survival only in those with little or no RKF.

Methods: We identified 34,076 incident hemodialysis patients with measured residual renal urea clearance (CLurea) in a large dialysis organization in the U.S. between 2007 and 2011. The associations ofspKt/Vduring the first 91 days of dialysis with all-cause mortality were examined across two strata of baseline CLurea using Cox models with adjustment for case-mix characteristics and 9 laboratory variables associated with nutritional and inflammatory status.

Results: The mean age of the cohort was 63±15 years and included 43% females, 53% diabetics, and 29% African Americans. Median spKt/V andCLurea at baseline were 1.42 (IQR, 1.24–1.64) and 3.2 (IQR, 1.8–5.6) mL/min/1.73m^2, respectively. Lower spKt/V was associated with higher mortality among patients with low CLurea (i.e., <3 mL/min/1.73m^2, left panel); adjusted HRs (95%CIs) of mortality associated with spKT/V of 1.0 and 1.8(reference: 1.4) were 1.16 (1.06–1.27) and 0.89 (0.83–0.95), respectively. However,there was no significant association between spKt/V and all-cause death among patients with high CLurea (i.e., ≥3 mL/min/1.73m^2, right panel); adjusted HRs (95%CIs) of mortality associated with spKT/V of 1.0 and 1.8(reference: 1.4): 1.05 (0.97–1.15) and 0.98 (0.90–1.07), respectively.



Conclusions: Dialysis dose was not associated with mortality among patients with high CLurea. Further studies are needed to validate these findings and determine how they could be used to improve patient-centered outcomes without compromising survival if patients have substantial RKF.

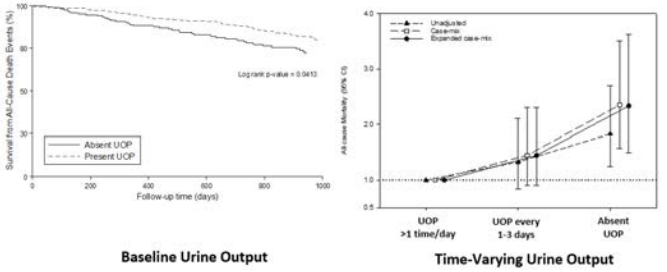
Residual Urine Output and Mortality in a Prospective Hemodialysis Cohort Amy Seung You, Kamyar Kalantar-Zadeh, Danh V. Nguyen, Alpesh Amin, Elani Streja, Yoshitsugu Obi, Tracy Nakata, Lidia Lou, Mary Veliz, Daniel L. Gillen, Csaba P. Kovesdy, Connie Rhee. *UC Irvine.*

Background: Assessment of residual urine output (UOP) is an important aspect of native kidney function evaluation in hemodialysis (HD) patients given its associations with better survival and quality of life. As frequent measurement by 24-hour urine collection may be cumbersome, self-reported UOP may be used as an adjunctive method of routine assessment in the clinical setting. We examined the association of patient-reported UOP with all-cause mortality in a prospective HD cohort.

Methods: Among 670 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Kidney Disease* study, we examined the association of patient-reported UOP with all-cause mortality. Patients underwent protocolized surveys querying about presence and frequency of UOP (absent, every 1-3 days, >1 time/day) every 6 months over 2011-16. We examined the association of baseline and time-varying UOP with all-cause mortality using unadjusted, case-mix, and expanded case-mix Cox models.

Results: In baseline and time-varying analyses, absence of UOP was associated with higher mortality risk in expanded case-mix models (ref: presence of UOP): HR (95%CI)

1.78 (1.16-2.72) and 2.01 (1.35-2.99), respectively. In baseline and time-varying analyses of UOP frequency, point estimates suggested a graded association between lower UOP frequency and higher mortality, although estimates for UOP every 1-3 days did not reach statistical significance: HR (95%CI) 1.29 (0.82-2.05) and 1.97 (1.24-3.12) for absence of UOP and UOP every 1-3 days, respectively (ref: UOP >1 time/day).



Conclusions: In HD patients there is a graded association between higher frequency of self-reported UOP and lower mortality. Further studies are needed to validate self-reported UOP as an alternative metric of residual kidney function, and to determine optimal approaches for preserving UOP.

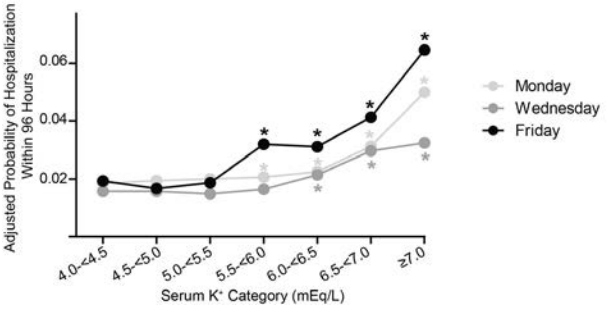
FR-PO974

Serum Potassium and Clinical Outcomes among Hemodialysis Patients: Impact of the Long Interdialytic Interval Steven M. Brunelli,[1] Charles Du Mond,[2] Nina Oestreicher,[2,3] Viatcheslav Rakov,[4] David M. Spiegel.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Relypsa Inc, Redwood City, CA; [3]Univ of California San Francisco, San Francisco, CA; [4]Vifor Pharma, Glattbrugg, Switzerland.*

Background: Hyperkalemia among hemodialysis (HD) patients is associated with morbidity and mortality. Among those who dialyze thrice-weekly, adverse outcomes peak after the 2-day interdialytic interval. Here, we estimated the independent association between serum potassium (K) concentration and outcomes among HD patients, and estimated how these associations were impacted by day of week.

Methods: This retrospective (2010-2011) study considered patient-interval data, defined as a routine K measurement made among adult Medicare Parts A & B enrollees receiving in-center HD on Monday/Wednesday/Friday (Mon/Wed/Fri) at a large US dialysis organization. Outcomes considered over the day of K measurement and the next 3 days were: hospital admissions, deaths, and emergency department (ED) visits.

Results: The association between high serum K and hospitalization risk was present on all days but most potently on Fri (*P*-interaction=0.008). Adjusted odds ratios (OR) for K5.5-<6, 6-<6.5, 6.5-<7, ≥7 (ref: 4-<4.5) were respectively: 1.68, 1.63, 2.19 and 3.51 on Fri; 1.04 (*P*=0.43), 1.37, 1.91 and 2.09 on Wed; and 1.12, 1.22, 1.70, 2.78 on Mon. Associations of high serum K with death and ED visit were significant but did not differ by day of week. Adjusted ORs for K 6-<6.5, 6.5-<7, ≥7 were 1.52, 2.42, 3.37 for death, and 1.19, 1.48, 2.62 for ED visit (for all, *P*<0.05 except as noted).



Conclusions: Higher serum K is associated with greater risk of hospitalization, death, and ED visit. The effect on hospitalization is modified by day of week, suggesting an enhanced burden of high K over the long interdialytic interval. Further work is needed to determine whether directed intervention ameliorates this risk.

FR-PO975

Oral Sodium Bicarbonate Reduces Inter-Dialytic Potassium Gain - The BicHD Trial Stella Kourtellidou, Damien Ashby, Lina Johansson. *Imperial College Healthcare NHS Trust, United Kingdom.*

Background: The intermittent nature of haemodialysis (HD) has adverse effects on clinical outcomes, with excess mortality associated with long intervals. High potassium contributes to this, but low levels post-HD can cause arrhythmias: a treatment reducing inter-HD potassium gain, would therefore be useful. Acidosis develops during each interval causing extracellular potassium shift - oral bicarbonate replacement may therefore limit potassium gains.

Methods: Prevalent in-centre HD patients with pre-HD bicarbonate <22mmol/l were randomly assigned to oral sodium bicarbonate or no treatment for 12 weeks. Starting dose was 2g/day with titration up to 4g/day. Electrolyte and blood pressure data are presented by paired testing in the intervention group. ECG and nutritional outcome analysis is in process.

Results: Forty-two patients were recruited, of which 16 (aged 27–74, 75% male) were randomised to and started the intervention. Average sodium bicarbonate dose after titration was 3.7g/day. On final doses, inter-HD bicarbonate loss was reduced from 6.42 to 3.72mmol/l (p<0.001), due mostly to an increase in pre-HD bicarbonate from 18.21 to 20.64mmol/l (p<0.001), although 75% of patients still fell below the target pre-HD bicarbonate. Inter-HD potassium gain was reduced from 1.89 to 1.70mmol/l (p=0.060), due mostly to a modestly significant reduction in pre-HD potassium by 0.15mmol/l (p=0.132). In the 11 responders whose pre-HD bicarbonate increased by at least 2.0mmol/l, pre-HD potassium was reduced by 0.29mmol/l (p=0.028). Pre-HD potassium was reduced by roughly 0.1mmol/l for every 1mmol/l increase in pre-HD bicarbonate, and the frequency of clinically relevant hyperkalaemia (>6.0mmol/l) was reduced from 12.1 to 4.9% of measurements (p=0.056). Systolic/diastolic blood pressures were increased by 6/4mmHg (p=0.021) without change in fluid gains.

Conclusions: Oral sodium bicarbonate is a well-tolerated treatment that reduces inter-HD potassium gain, hence lowering pre-HD levels. The effect size is modest, with achievable reductions in pre-HD potassium around 0.3mmol/l, but the impact on relevant hyperkalaemia and clinical events may be more substantial.

FR-PO976

Persistent and Episodic Hyponatremia Are Prevalent in Hemodialysis Patients and Associated with Increased Mortality Ryan A. Brenneis,[1,2] Darcy R. Visscher,[2] Branko Braam.[1] *[1]Univ of Alberta, Edmonton, AB; [2]The King's Univ, Edmonton, AB, Canada.*

Background: Hyponatremia is common in many patient populations and has been linked to increased mortality and undesirable outcomes. Limited information about hyponatremia in hemodialysis (HD) patients indicates a high prevalence, yet, information is lacking regarding outcome. The hypothesis of the current study was that both persistent and episodic hyponatremia in HD patients is prevalent and associated with increased mortality.

Methods: Hyponatremia (Na < 135 mmol/L) of 2473 patients on in-center HD was evaluated using monthly plasma Na over a median of 4.6 years. Prevalence of 10 patterns was studied: persistent hyponatremia, and combining episodic low (1-3 episodes), medium (4-7 episodes) or high (>=8 episodes) frequency with short (1-2 month), medium (>2-<=4 months) and long duration (>4 months). Mortality was assessed for persistent and episodic hyponatremia compared to normonatremia.

Results: Of the patients 34% had normal sodium (no hyponatremia), 1% had stable hyponatremia and 65% had an episodic sodium pattern. Frequencies of episodic hyponatremia and mortality are displayed in the table.

	Duration (Avg. months/episode)					
Frequency	Short 1 -2 months/episode		Average >2-<=4 months/episode		Long >4 months/episode	
	%	% mortality	%	% mortality	%	% mortality
High >8 episodes	9	20	4	14	1	9
Medium 3-7	13	26	3	42	2	40
Low <3	18	33	2	51	1	54

Both persistent hyponatremia and average and long duration, low and medium frequency were associated with decreased survival compared to patients without hyponatremia. High frequency hyponatremia episodes did not predict mortality compared to normonatremia.

Conclusions: In this HD cohort, episodic hyponatremia is highly prevalent implying that a cross-sectional analysis of hyponatremia underestimates prevalence. Moreover, average and long duration with low and medium frequency hyponatremia is associated with increased mortality. Factors that are associated to episodic hyponatremia need further study.

FR-PO977

Predicting Clinical Outcomes Using Phase Angle in Maintenance Hemodialysis Patients Chae Rim Kim, Jung-Ho Shin, Jin Ho Hwang, Su Hyun Kim. *Dept of Internal Medicine, Chung-Ang Univ Hospital, Seoul, Korea.*

Background: Protein-energy wasting is common in hemodialysis patients, and it is an independent risk factor for major adverse events. Recently, bioelectrical impedance analysis (BIA) has been widely used as a non-invasive method to estimate nutritional status. We retrospectively investigated whether nutritional markers measured by BIA can predict clinical outcomes in end-stage renal disease (ESRD) patients receiving hemodialysis.

Methods: ESRD patients who had been treated with outpatient hemodialysis were recruited. Using BIA, phase angle (PA), a nutritional marker, was obtained every 6 months, and patients were divided into two groups according to baseline PA: group A included those with PA ≥4.5°; and group B included those with PA <4.5°.

Results: A total of 142 patients (77 [54.2%] in group A and 65 [45.8%] in group B) were included and were followed for 29 (12, 42) months. The baseline PA was 4.6 ± 1.0°. We found that a decrease in the PA was associated with an increased risk for death, but it was disappeared after the adjustment for age, sex and comorbidity (HR 0.58, 95% CI 0.34–1.00; P = 0.051). Cardiovascular event was not associated with PA (P = 0.685). However, we found that PA predicted the occurrence of infection, independent of age, sex and comorbidity (HR 0.65, 95% CI 0.45–0.94; *P* = 0.20). Although the levels of hemoglobin did not differ between two groups during the study period, patients in group B received higher doses of erythropoiesis-stimulating agents and intravenous iron, compared with those in group

A (P = 0.004 and 0.044, respectively). In longitudinal analyses, patients who had mean Kt/V≥1.4, protein catabolic rate ≥1.2 g/kg/day, total carbon dioxide levels ≥22 mmol/L, or intact parathyroid hormone <300 pg/mL did not have the increases in PA over time.

Conclusions: Nutritional status can be simply assessed using BIA and those provide important information to predict clinical outcomes in ESRD patients with maintenance hemodialysis.

FR-PO978

Obestatin Predicts Clinical Outcomes in Hemodialysis Patients: A Prospective Cohort Study Ilia Beberashvili,[1] Inna Sinuani,[2] Ada Azar,[3] Leonid Feldman,[1] Shai Efrati.[1,4] *[1]Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Pathology, Assaf Harofeh Medical Ceneter, Zerifin, Israel; [3]Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel; [4]Research & Development, Assaf Harofeh Medical Center, Zerifin, Israel.*

Background: Obestatin, an anorexigenic gut peptide, has been reported as involved in appetite and energy homeostasis.It is not clear, however, if elevated levels of this hormone in maintenance hemodialysis (MHD) patients contribute to the protein-energy wasting and consequently adverse clinical outcomes.

Methods: A prospective cohort study on 261 MHD outpatients (39% women, mean age 68.6±13.6 years) with median follow-up - 28 months (interquartile range - 19-34 months). We measured obestatin, acyl-ghrelin (AG) levels, appetite, nutritional and inflammatory markers, prospective all-cause and cardiovascular (CV) mortality.

Results: Obestatin positively correlated with AG (r=0.25, p<0.001) and negatively correlated with BMI (r=-0.14, p=0.03) and lean body mass (r=-0.15, p=0.01). During follow-up, 109 patients died, 51 due to CV causes. For each 1.0 ng/ml increase in baseline obestatin levels, multivariable adjusted all-cause death HR was 0.85 (95% CI, 0.75 to 0.96, P=0.01) and CV death HR was 0.82 (95% CI, 0.69 to 0.97, P=0.02). Adjusted models included age, sex, vintage, diabetes, smoking, co-morbidity index, vascular access type, Kt/V, residual renal function, malnutrition-inflammation score and IL-6. Associations between obestatin and mortality risk continued to be significant in analyses that additionally accounted for AG levels. Cubic spline survival models confirmed linear trends.

Conclusions: Higher obestatin level is associated with lower death risk in MHD patients independent of nutritional status and inflammation.Future studies are needed to elucidate underlying mechanisms associated with improved outcomes in MHD population.

FR-PO979

Metabolically Abnormal Non-Obese Phenotype Is Significantly Associated with Increased Mortality in Incident Dialysis Patients Hae-Ryong Yun,[1] Youn Kyung Kee,[1] Changhwan Seo,[1] Seonghun Kim,[2] Tae-Hyun Yoo.[1,2] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Korea.*

Background: Metabolically abnormal obesity is associated with high all-cause mortality in general population. However, paradoxical inverse association between obesity and mortality was observed in dialysis population. Therefore, to investigate whether the concept of metabolic unhealthiness with obesity might be applicable in dialysis patients, we performed the post hoc analysis of a prospective cohort study.

Methods: During 2009 and 2015, Total 1,141 Patients who started dialysis were recruited from the Clinical Research Center for End Stage Renal Disease data set. Metabolic abnormality was determined by the presence of 2 or more of the following: 1) HbA1c ≥6.5% or history of diabetes, 2) Triglyceride ≥150 mg/dL, 3) HDL-C ≤40 mg/dL in men or ≤50 mg/dL in women, 4) hs-CRP ≥3 mg/L. Obesity was defined by BMI ≥25.0 kg/m². Patients were divided into four groups [metabolically healthy obesity (MHO), metabolically healthy non-obesity (MHNO), metabolically abnormal obesity (MAO), and metabolically abnormal non-obesity (MANO)].

Results: A 63 (5.5%), 316 (27.7%), 240 (21.0%), and 522 (45.7%) patients were classified into MHO, MHNO, MAO, and MANO group, respectively. All-cause mortality was observed with 5 (7.9%), 43 (13.6%), 35 (14.5%), and 148 (28.3%) patients in each groups, respectively. In Cox proportional hazard analysis, MANO group showed significantly higher all-cause mortality events (hazard ratio, 2.700; 95% confidence interval, 1.09-6.64; P=0.031) even after adjustment for age, sex, smoking status, systolic blood pressure, diastolic blood pressure, serum albumin, calcium, phosphate, uric acid, and total cholesterol and intact-PTH.

Conclusions: MANO group was significantly associated with higher mortality compared to other groups in dialysis patients. Obese phenotype stratified metabolic abnormality is substantially different from that in general population.

FR-PO980

Natural Course of Muscle Mass Change and Related Factors in Patients Undergoing Hemodialysis Hyoungnae Kim,[1] Su-Young Jung,[1] Changhwan Seo,[1] Boyoung Nam,[2] Dae-Suk Han.[1] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Korea.*

Background: Muscle wasting is a common feature found in patients undergoing dialysis. Although measurement of muscle mass has been noticed as a prognostic factor in hemodialysis (HD) patients, the natural course of muscle mass change over time and related factors are not fully elucidated in this patient group. Therefore, muscle mass alteration was evaluated and the relationship with demographic and clinical variables was investigated in patients undergoing HD.

Methods: Ninety-three prevalent HD patients were enrolled. The patients were followed-up from January 2011 to December 2015. Total skeletal muscle index (SMI) was evaluated by multifrequency bioimpedance using a four-paired electrode bioimpedance device (InBody 720; Biospace, Seoul, South Korea). Bioimpedance analysis was performed after dialysis on a mid-weak dialysis session every 3 months during the study duration, Biochemical and clinical data were also collected.

Results: The mean age of the enrolled patients was 62.2 ± 13.3 years, and 52 (55.9%) patients were male. Diabetes was accompanied in 34 (36.6%) patients. At baseline, the mean SMI was 9.2 ± 1.2 kg/m^2. During the mean follow-up duration of 49.2 ± 9.9 months, the rate of SMI change was –0.43 kg/m^2/year. SMI decrease was found in 62 (66.7%) patients, while SMI increased in 31 (33.3%) patients over time. Multiple linear regression analysis revealed that baseline CRP (β = 0.25, P < 0.001) and albumin (β = –0.60, P < 0.001) levels were significantly associated with the rate of SMI change after adjusting for confounding factors. However, no significant relationship was found with normalized protein catabolic rate (β = –0.20, P = 0.94), urea reduction ratio (β = –0.01, P = 0.06).

Conclusions: The rate of SMI change over time differs among patients. Chronic inflammation and nutritional status may affect SMI change while the amount of protein intake or dialysis adequacy may not.

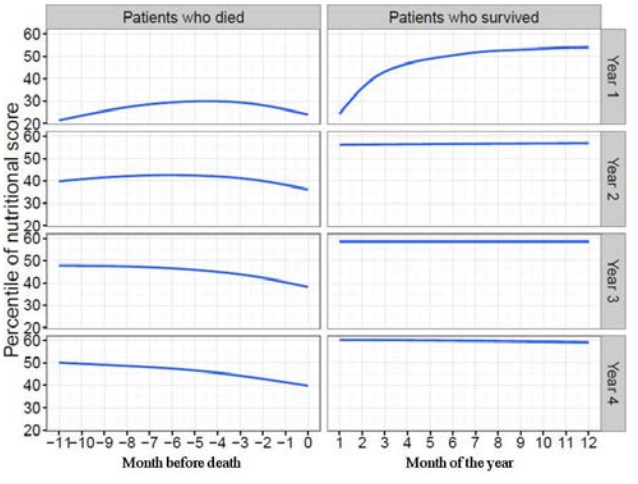
FR-PO981

Dynamics of Nutritional Status in Chronic Hemodialysis Patients before Death Xiaoling Ye,[1] Stephan Thijssen,[1] Jeroen Kooman,[2] Frank van der Sande,[2] Len A. Usvyat,[3] Peter Kotanko,[1,4] Franklin W. Maddux.[3] *[1]Renal Research Inst, New York, NY; [2]Maastricht Univ Medical Center, Maastricht, Netherlands; [3]Fresenius Medical Care North America, Waltham, MA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Previous studies in chronic hemodialysis (HD) patients(Pts) indicated a decline in nutritional competency up to a year(yr) before death (Thijssen et al., CJASN 2015), but the relationship with HD vintage has not been addressed.

Methods: The goal of this study was to assess nutritional competency in vintage-matched cohorts of HD Pts. We included all Pts who started HD in FMCNA clinics between 01/2006 and 12/2011. Nutritional competency was quantified monthly using a nutritional score that comprised of mean serum albumin, creatinine, phosphate, enPCR, and IDWG. In Pts who died (cases), the score was calculated in the 12 months(mo) before death. Vintage-matched survivors served as controls.

Results: We studied 67,752 HD pts, 26,057 cases (mean age 68; 58% males; 28% Blacks) and 41,695 controls (mean age 61; 56% males; 38% Blacks). Across vintage groups, the number of Pts were distributed as follows: yr1, 13,300 cases & 41,308 controls; yr2, 6,546 cases & 23,216 controls; yr3, 3,872 cases & 11,798 controls; yr4, 2,339 cases & 4,446 controls. In both cases and controls scores increased with longer vintage, we observed distinct differences between cases and controls.



First, across all groups, scores were lower in cases. Second, in controls, the scores either increased (yr 1) or remained stable (yr 2 to 4), whereas in cases scores declined in the final 12 mo. This terminal decline was more pronounced in yr 3 & 4, compared to yr 1 & 2.

Conclusions: Our study shows that nutritional competency is stable in survivors but declines in cases before death. This may indicate a deteriorating nutritional status and may alert health care workers.

FR-PO982

Low Body Mass Index and All-Cause Mortality in Patient with Hemodialysis
Ha Yeon Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: Malnutrition is common in patients with hemodialysis and is a major risk factor of mortality. The Korean Society of Nephrology (KSN) collected data of end-stage renal disease registry since 1985. We evaluated whether body mass index (BMI) can affect mortality in patient with hemodialysis.

Methods: From 2004 to 2015, a total of 32,163 patients starting hemodialysis were included. The patients were divided into four groups according to quartiles of BMI measurement.

Results: At baseline, mean age was 59.0 ± 14.3 years old, and 60.0% were men. The 5-year mortality of hemodialysis patients was 16.9 % (N=5,435) and ratio of unknown state was 24.9 % (N=7,996). The mean of BMI in each quartiles were 18.2 ± 1.2, 20.8 ± 0.5 22.8 ± 0.6, 26.4 ± 2.6 kg/m^2 respectively. The mean of BMI between survivor and non-survivor were different (22.3 ± 3.3 vs. 21.5 ± 3.2 kg/m^2). Cox-proportional regression multivariate analysis revealed that the 5-year all-cause mortality was associated with age (HR 1.04, CI 1.03-1.05), diabetes (HR 1.34, CI 1.07-1.7), coronary heart disease or heart failure (HR 1.3, CI 0.9-1.7), 2nd BMI quartile (HR 0.7, CI 0.5-0.9), 3rd BMI quartile (HR 0.6, CI 0.46-0.88), 4th BMI quartile (HR 0.59, CI 0.43-0.82), hypoalbuminemia (HR 2.9, CI 2.3-3.7) and anemia (HR 1.6, CI 1.2-2.0).

Conclusions: Higher quartiles of BMI was significantly associated with better survival rate in hemodialysis patients in Korea. Traditional risk factors of malnutrition, such as hypoalbuminemia, anemia were also independent risk factors for mortality. This result suggests that hemodialysis patients require nutritional support.

FR-PO983

Body Mass Index and Causes of Death in Incident Hemodialysis Patients in Korea
Sejoong Kim,[1] Shin-Young Ahn,[2] Jong Cheol Jeong,[3] Ki Young Na.[1] *[1]Seoul National Univ Bundang Hospital, Republic of Korea; [2]Korea Univ Medical Center Korea Univ Guro Hospital, Republic of Korea; [3]Ajou Univ School of Medicine, Republic of Korea; [4]The Catholic Univ of Korea, Republic of Korea.*

Background: In dialysis patients, higher body mass index (BMI) leads to better survival, so called "reverse epidemiology". However, distribution of BMI in Korea is different from western countries, and cause-specific death is still unknown. We examined 10,299 incident hemodialysis patients from Korean Society of Nephrology registry.

Methods: We evaluated whether various causes of death (cardiovascular disease, malignancy renal disease, diabetes, infection and others related deaths) may be associated with the BMI range using Cox proportional hazards analysis.

Results: During a median follow up of 9.1 years, 5,425 (52.7%) patients died. In multivariable model, a negative association was noted between BMI and all-cause mortality. Compared with the normal BMI group (18.5–24.9 kg/m^2), low BMI group (BMI < 18.5 kg/m^2) had higher mortality with hazard ratio 1.288 (95% C.I. 1.201 – 1.381, p<0.001) and obese group (BMI ≥ 30.0 kg/m^2) had lower mortality with hazard ratio 0.776 (95% C.I 0.588 – 1.023 , p=0.135). Low BMI group had higher kidney disease-specific mortality with hazard ratio 1.382 (95% C.I 1.243 – 1.537, p<0.001) and higher diabetes specific mortality with hazard ratio 1.310 (95% C.I 1.114 – 1.500, p<0.001).

Conclusions: This registry data showed that higher BMI group may be lower risk of all cause mortality, and that low BMI group may be at the higher risk of all-cause mortality, especially kidney specific and diabetes specific mortality.

FR-PO984

L-Carnitine Improves Gastrointestinal Disorders and Altered Intestinal Microbiota in Hemodialysis Patients
Yoshihiko Kanno,[1] Junichiro Irie,[2] Tadashi Yoshida,[3] Hiroshi Itoh,[2] Matsuhiko Hayashi.[3] *[1]Dept of Nephrology, Tokyo Medical Univ, Tokyo, Japan; [2]Div of Endocrinology, Metabolism and Nephrology Dept of Internal Medicine, Keio Univ, School of Medicine, Tokyo, Japan; [3]Apheresis and Dialysis Center, Keio Univ, School of Medicine, Tokyo, Japan.*

Background: Patients receiving hemodialysis also manifest gastrointestinal symptoms such as constipation, by restriction of water intake and the loss of body water balance. Because dietary carnitine deficiency is supposed to cause smooth muscle dysmotility of the gastrointestinal tract similarly to skeletal muscles, carnitine deficiency in hemodialysis patients may be one cause of gastrointestinal discomfort and dysfunctions.

Methods: We performed a multicenter nonrandomized single-arm prospective clinical trial. 15 Japanese patients receiving hemodialysis were administered L-carnitine tablets (900 mg) for 3 months, and clinical and biochemical analyses were performed before and after the treatment.

Results: Serum total carnitine level increased significantly by the supplementation of L-carnitine for 3 months (from 40.9 ± 2.6 μmol/L to 172.3 ± 19.0 μmol/L, P < 0.05). The myasthenia score decreased significantly by the supplementation (from 1.3 ± 0.3 to 0.8 ± 0.2, P < 0.05). The frequency of passing stool tended to increase with the treatment for 3 months (from 4.2 ± 0.5 times to 4.8 ± 0.5 times). The phyla-level analysis of microbiota showed that the composition of individual microbiota was not different between before and after the supplementation. The genus-level analysis, however, revealed that the genus Clostridium subcluster 4 significantly decreased in number by the supplementation (from 7.7 ± 1.9% to 4.7 ± 1.3%, P < 0.05).

Conclusions: Oral supplementation of L-carnitine to the patients receiving hemodialysis improved not only their muscle discomfort but also their gastrointestinal disorders and microbiota, although its effect on the prognosis of hemodialysis patients should be further investigated.

FR-PO985

Albumin Values with C-Reactive Protein Taken into Account Can Be a Good Predictor of Dialysis Patient Survival
Norio Hanafusa,[1] Hiroshi Kawaguchi,[2] Ken Tsuchiya,[1] Kosaku Nitta.[3] *[1]Dept of Blood Purification, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Jyoban Hospital, Iwaki, Fukushima, Japan; [3]Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Albumin is often used for the markers of wasting or malnutrition. However, albumin can also be affected by inflammation. We speculated that albumin values with the inflammatory status taken into account would be a better index in assessing albumin index, namely "C-reactive protein considered albumin". We investigated the association of this index with mortality, and compared the power of prediction of this index with other albumin indices.

Methods: In total, 397 patients were included into this study. Baseline data were obtained in July 2012. The survival until the end of August 2014 (follow up period of 25 months at most) was investigated. Firstly, the regression line was obtained from the entire population between albumin and CRP. Thereafter, the CRP-considered albumin levels were determined as a dichotomous variable; the patients with the albumin values above the regression line were considered high, vice versa. We investigated the association of three albumin indices (the actual values, the dichotomous index by median, and CRP-considered values) and mortality by Cox proportional hazard models.

Results: Among total population, albumin and CRP were correlated reciprocally and weakly significantly; albumin (g/dl) = 3.438 – 0.215 logCRP (log mg/dl), R2=0.126. During the observational period, 73 patients deceased. In univariate Cox analysis demonstrated that all three indices were associated with survival; HR 0.40 (95%CI 0.25 – 0.68), 0.41 (95%CI 0.25 – 0.68), and 0.46 (95%CI 0.28 – 0.74) for each increase of actual albumin, the higher dichotomous albumin by median, and the higher CRP-considered albumin, respectively. On the other hand, only the higher CRP-considered albumin related to the better survival (HR 0.51, 95%CI: 0.30 – 0.85). The degree to which the deviation of albumin was attributable to that of CRP was 12.9%.

Conclusions: CRP-considered albumin was shown to be a better predictor of mortality among dialysis population. In assessing albumin values, inflammatory status should be taken into account.

Individualized Prediction of Mortality Using Multiple Inflammatory Markers in Patients on Dialysis: A Prospective Multicenter Cohort Study
Sun-Hee Park, Hee-Yeon Jung, Kyu Yeun Kim, Min Jung Kim, Wonseok Do, Youngae Yang, Taehoon Yim, Inryang Hwang, Sukyung Lee, Ji-Young Choi, Jang-Hee Cho, Chan-Duck Kim, Yong-Lim Kim. *Internal Medicine, Kyungpook National Univ Hospital, Daegu, Republic of Korea.*

Background: This study was aimed to evaluate whether the incremental combination of inflammatory markers captured on routine clinical practice could improve predictive powers for mortalities in patients on dialysis and to develop a predictive model for mortality according to dialysis modality.

Methods: Inflammatory markers obtained at the time of enrollment from 3,309 patients on dialysis from a prospective multicenter cohort were used. Cox proportional hazards regression methods and time dependent ROC curves were constructed and net reclassification index and integrated discrimination improvement were calculated. Cox proportional hazards regression analysis was used to derive a prediction model of mortality.

Results: Addition of the three predictors (WBC, hsCPR, and albumin) one by one to the conventional risk factors had more predictive powers than conventional risk factors alone for all-cause and infection-related mortality in entire population. hsCRP and albumin had additional predictability for cardiovascular mortality in entire population and for infection-related mortality in HD patients. The incremental combination of WBC, hsCRP, and albumin improved predictive powers for all-cause mortality in entire population. hsCRP and albumin gradually increased predictive powers for all-cause and infection-related mortalities in HD patients. Cox multivariate analysis showed age, sex, presence of diabetes, history of coronary artery disease and dialysis vintage were statistically significant predictors of all-cause mortality. The prediction model using multiple inflammatory markers stratified mortality according to dialysis modality.

Conclusions: Multi-marker approaches using multiple inflammatory markers practically available in clinic provided higher predictive power for all-cause mortality in dialysis patients. The predictive model for mortality based on different combinations of inflammatory markers according to dialysis modality enables a stratified risk assessment in this population.

FR-PO987

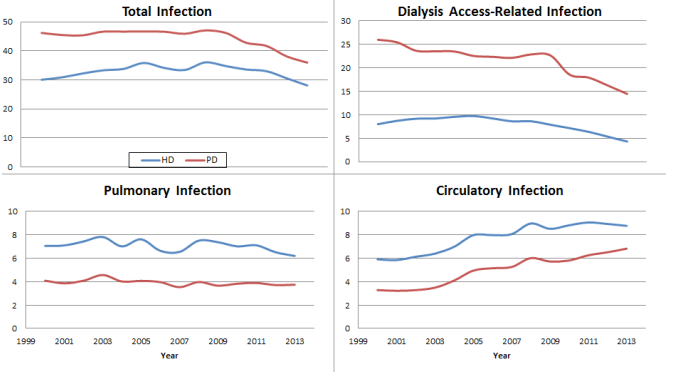
Infection Hospitalization Trend among Hemodialysis and Peritoneal Dialysis Patients

Jiannong Liu,[1] Peer Kidney Care Initiative Investigators.[2]
[1]CDRG, MMRF, Mpls, MN; [2]Peer Kidney Care Initiative.

Background: Infections are a major cause of morbidity and mortality in maintenance dialysis patients (pts). Previous work has shown that peritoneal dialysis (PD) pts are at higher risk for dialysis access (DA)-related infections and hemodialysis (HD) pts for most other infections. However, whether and how infectious hospitalization (IH) rates have changed over time, especially in recent years, is unknown.

Methods: Using the 2000-2013 CMS ESRD database, we identified pts and modalities on January 1 of each year. Pts were followed from January 1 to the earliest of death, transplant, loss of Medicare coverage, or year end. IHs were identified from medical claims and classified as circulatory, pulmonary, DA-related, or other based on the primary diagnosis code. A Poisson regression model was used to test the trend in IH rates and the trend differences between HD and PD pts, 2008-2013.

Results: Before 2008, the overall IH rate was stable among PD pts at approximately 46 per 100 patient-years, but increased among HD pts from 30.1 in 2000 to 36.0 in 2008. Rates then decreased by an average of 5.4% per year for PD and 4.6% per year for HD pts (P=0.001, PD-HD decrease rate comparison).



PD pts had much higher rates of DA-related IH than HD pts; rates decreased since 2008, on average 12.4% per year for HD and 9.1% per year for PD pts (P<0.001). Pulmonary, circulatory, and other IH rates were higher for HD pts. Since 2008, pulmonary IH rates decreased by 3.7% and 0.7% per year for HD and PD pts, respectively (P<0.001); circulatory IH rates increased by 0.2% and 3.3% per year for HD and PD pts, respectively (P<0.001); IH rates for other infections decreased 3.4% per year for HD and remained unchanged for PD pts (P<0.001).

Conclusions: Overall, IH rates decreased for both HD and PD pts in recent years, but more improvement is needed, especially for PD pts and for DA-related infections.

Associations between Apolipoproteins and Infection, Cardiovascular Events and Mortality in Patients Receiving Dialysis

George A. Kaysen,[1] Lorien S. Dalrymple,[1] Glenn Matthew Chertow,[2] Barbara A. Grimes,[3] Kirsten L. Johansen.[4,5] *[1]Nephrology, UC Davis, Sacramento, CA; [2]Nephrology, Stanford Univ, Palo Alto, CA; [3]Dept of Epidemiology and Biostatistics, UCSF, San Francisco, CA; [4]Nephrology, UCSF, San Francisco, CA; [5]Nephrology Section, SFVAMC, San Francisco, CA.*

Background: Lipid lowering therapy may not be beneficial in the dialysis population. Lipoproteins play a role in the innate immune system, providing a potential link to infection that may counterbalance cardiovascular (CV) effects.

Methods: We examined the associations between serum concentrations of apolipoproteins A1, B, C2, and C3 and all-cause mortality, CV- and infection-related hospitalization or death in 442 participants in the ACTIVE/ADIPOSE study of prevalent HD patients recruited 2009-2011, followed through March 2014. We examined associations between each lipoprotein and outcomes using Cox models with time-varying apolipoprotein concentrations (q 6 mos).

Results: In univariate models, higher levels of each of the apolipoproteins were associated with statistically significantly lower risk of infectious events and, except for apo A I, with lower all-cause mortality. Apolipoproteins were not associated with CV events. In multivariable models, higher Apo A1 concentration was associated with lower risk of infection and higher Apo B was associated with lower risk of all-cause mortality.

Analyte	Mortality		Infection		CV Outcome	
	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P
	Multivariable Analysis					
Apo A1 10 Units	0.96 (0.89-1.04)	0.35	0.94 (0.88-0.99)	0.030	0.94 (0.86-1.03)	0.18
Apo B 10 Units	0.91 (0.82-1.00)	0.047	0.95 (0.88-1.02)	0.17	0.93 (0.80-1.08)	0.34
Apo C2	0.95 (0.87-1.03)	0.23	0.95 (0.97-1.03)	0.19	0.99 (0.89-1.11)	0.88
Apo C3	0.96 (0.92-1.01)	0.13	0.97 (0.94-1.01)	0.18	1.01 (0.95-1.06)	0.82

Conclusions: Lipoproteins were associated with lower risk of infection-related outcomes and death but were not associated with CV outcomes. These results may help explain the unclear benefit of lipid lowering in the dialysis population.

Association between Plasma Macrophage Stimulating Protein Levels and Risk of All-Cause Mortality in Hemodialysis Patients

Tetsu Miyamoto,[1] Mika Matsumoto,[2] Yumi Furuno,[3] Kenichiro Bando,[1] Junichi Nakamata,[1] Yoko Fujimoto,[3] Ken Otsuji,[1] Ikutaro Furuno,[1] Yutaka Otsuji,[1] Masahito Tamura.[3] *[1]2nd Dept of Internal Medicine, Univ of Occupational and Environmental Health School of Medicine, Kitakyushu, Japan; [2]Yukuhashi Clinic, Yukuhashi, Japan; [3]Kidney Center, Univ of Occupational and Environmental Health School of Medicine, Kitakyushu, Japan.*

Background: Persistent low-grade inflammation, a condition observed in a majority of hemodialysis patients, is a major driving force of the uremic phenotype which leads to increased morbidity and mortality. Macrophage stimulating protein (MSP), also known as Hepatocyte Growth Factor-like protein (HGFL), has been demonstrated to play a key role in regulating inflammation in the peripheral tissues of multiple disease models.

Methods: In this multicenter prospective cohort study comprising 236 maintenance hemodialysis patients (37% female; median age, 66 years; age range, 21-92 years), we investigated the effect of MSP levels, measured by enzyme-linked immunosorbent assay, on all-cause mortality, with a particular focus on inflamed patients. We used Kaplan-Meier analyses and multivariate Cox regression analyses to estimate mortality risk.

Results: During the observation time (median observation time, 25 months), a total of 31 patients died during the observation period. Patients were categorized into two groups according to serum C-reactive protein (CRP) levels. In the inflamed patient group (CRP > 0.5 mg/dL, n=49), Kaplan-Meier analysis comparing the survival rate between lower and higher plasma MSP levels, showed that patients with lower MSP levels, defined as the lowest tertile of plasma MSP (<223 ng/mL), had an significantly higher mortality risk (Log rank X^2=8.0, P = 0.005). When adjusting for age, sex, dialysis vintage, diabetes mellitus and cardiovascular disease, lower MSP levels was independently related to increased mortality (Hazard ratio [HR]:3.8, 95%CI:1.3-11.1;P=0.01). Conversely, no association was observed in patients in the non-inflamed patient group (CRP < 0.5 mg/dL).

Conclusions: Plasma MSP levels may be a useful biomarker for assessing 2-year mortality risk in maintenance hemodialysis patients with high CRP levels.

FR-PO990

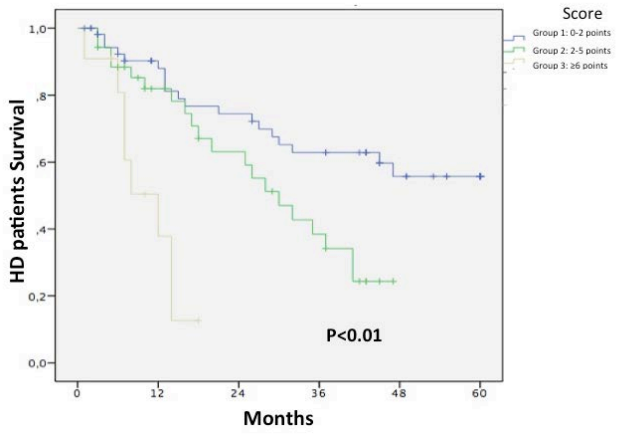
B-Lymphocytes Depletion, a New Mortality Risk Factor in Hemodialysis

Maria Molina, Enrique Morales, Luis Enrique Ramos, Manuel Praga. *Nephrology, Hospital 12 de Octubre, Madrid, Spain.*

Background: Acquired quantitative disturbances in immunity system are known in hemodialysis patients (HDP). It could explain the deaths for infection events, and a effect on the atherosclerosis process is discussed. The aim of this study was to analyze the effect of immune cell subsets (ICS) in the mortality of HDP.

Methods: Prospective observational single centre study in HDP from 2011-12. Total and ICS (CD3, CD4, CD8, CD56, CD19) were measured. We used a new score of mortalility with this variables: Charlson's index ≥7=2 points (p), Kt/V <1.2=3p, previous failed transplantation=-2p, low CD19 with normal serum albumin (SA)=3p, low SA with normal CD19 lymphocytes=6p and low SA with low CD19 lymphocytes=2p.

Results: We included 104 patients, 51% male, with mean age 64±15 years old. The mean Charlson's index was 6.5±2.7 and the mean time with renal replacement therapy was 57±76 months. The distribution of ICS was 45% low total lymphocytes (<1200cells/mm^3), 40% CD3 (<850cells/mm^3), 37% CD4 (<500cells/mm^3), and 58% CD19 (<100cells/mm^3) of the HDP. The mean of the follow-up was 23.8±17 months. Forty-eight (46%) patients died. The causes of death were 40% for cardiovascular disease, 31% infection disease and 13% oncology disease. The death risk factors showed in the univariable analysis were Charlson's index ≥7 (OR=2.5 (1.3-4.6), p<0.01), Kt/V <1.2 (OR=3.8 (1.6-9.4), p<0.01), previous failed renal transplantation (OR=0.4 (0.2-0.8), p<0.01), low CD19 (OR=2.2 (1.1-4.3), p=0.01) and SA <3.5 g/dL (OR=2.5 (1.3-4.8), p<0,01). We classified HDP according their punctuation in score: Group 1 with 0-2 points, Group 2 with 3-5 points and Group 3 with > 6 points. Survival is shown on the graphic.



Conclusions: Lower CD19 lymphocyte is a new independent mortality risk factor in HDP. Our score could be a new tool to predict the risk of death in HD patients. Our score needs to be validated in other populations for be generalized.

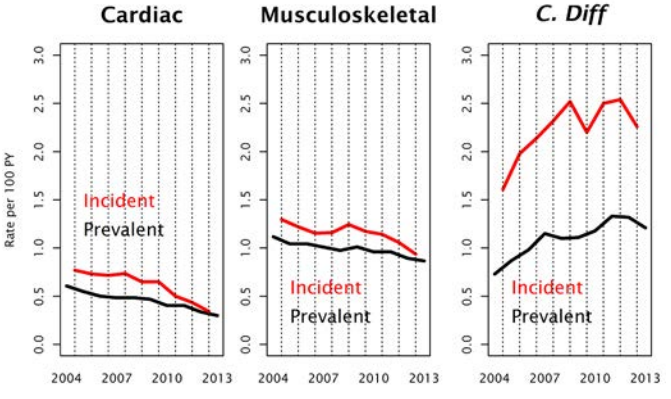
FR-PO991

Cardiac, Musculoskeletal, and *C. diff* Infections in Hemodialysis Patients David T. Gilbertson,[1] Peer Kidney Care Initiative Investigators.[2] [1]*Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN;* [2]*Peer Kidney Care Initiative.*

Background: Dialysis patients are at significantly increased risk of hospitalization due to infection. Trends in overall infection rates have been well described, but less is known about cause-specific infections. We assessed trends in cardiac (e.g., endocarditis), musculoskeletal (e.g., osteomyelitis, septic arthritis), and *C. diff* (e.g., colitis) infections in dialysis patients, 2004-2013.

Methods: We used the Centers for Medicare & Medicaid Services End-Stage Renal Disease database to examine rates of hospitalization with a primary cause of cardiac, musculoskeletal, or *C. diff* infection among dialysis patients. Analyses were performed separately for prevalent patients (> 1 year on dialysis) and incident patients (≤ 1 year on dialysis).

Results: For all three infection types, rates were higher in incident than in prevalent patients, particularly for *C. diff* infections. While rates of cardiac and musculoskeletal infections declined from 2004-2013, *C. diff* infections increased ~ 40% among incident and prevalent patients.



Conclusions: While overall hospitalized infection rates were relatively constant from 2004-2013 despite decreasing all-cause hospitalization rates, trends varied by infection type. These infections comprise only a modest percentage of all-cause infections, but the decrease in hospitalizations for cardiac and musculoskeletal infections is encouraging. However, dialysis patients with *C. diff* infections are at increased risk for morbidity and mortality, and interventions to reduce risk are needed.

Funding: Pharmaceutical Company Support - Financial support for the Peer Kidney Care Initiative is provided by the following participating provider organizations: American Renal Associates, Atlantic Dialysis Management Services, DaVita HealthCare Partners, Dialysis Clinic, Inc., Fresenius Medical Care, Independent Dialysis Foundation, Northwest Kidney Centers, Satellite Healthcare, The Rogosin Institute, U.S. Renal Care, and Wake Forest University

Infective Endocarditis in Dialysis-Dependent Chronic Kidney Disease: One Centre's Experience Andrew Nixon, Naeem Desai, Ajay Prabhakar Dhaygude. *Renal Medicine Dept, Royal Preston Hospital, Preston, Lancashire, United Kingdom.*

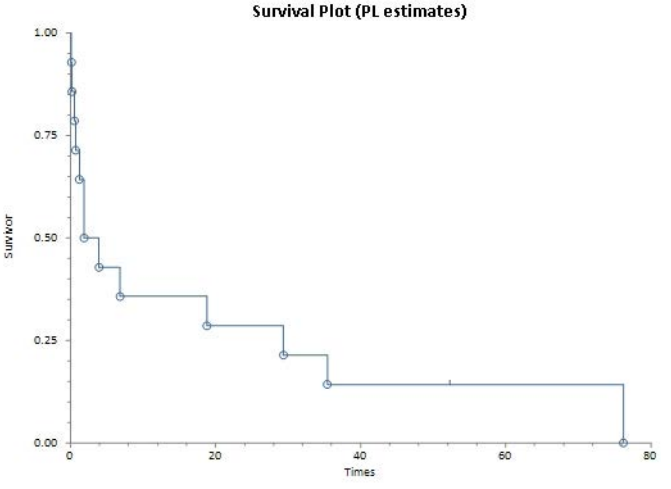
Background: Infective Endocarditis (IE) is a devastating complication of dialysis-dependent chronic kidney disease (CKD).[1,2] One-year survival rates were reported to be as low as 38.4% over a decade ago.[2] We wished to establish if there had been any improvement in outcomes in recent years.

Methods: The local echocardiogram database was reviewed to identify all reports suggesting a valve vegetation between August 2002 and March 2016. Clinical records were then reviewed to identify all those with dialysis-dependent CKD diagnosed with IE.

Results: Fourteen patients were identified (15 episodes). The median age was 65 years (range 32-84 years). The male:female was 1:1. The median dialysis vintage was 9 months (range 1-46 months). Table 1 demonstrates patient clinical characteristics.

Clinical Characteristics	Number of Episodes (%)
Haemodialysis	13 (87)
Central Venous Catheter	6 (40)
Pre-existing Valve Lesion	9 (60)
Previous Valve Surgery	2 (13)
Valve Affected -Mitral -Aortic -Tricuspid ->1 Valve	 10 (67) 4 (27) 4 (27) 3 (20)
Causative Organism(s) -*Staphylococcus Aureus* -*Enterococcus sp.* -*Other*	 8 (53) 5 (33) 3 (20)

Valve surgery was performed for 3 patients (21%). Survival rates were as follows: 30-day: 71% (n=10); 90-day: 50% (n=7); 1-year: 36% (n=5). Figure 1 demonstrates Kaplan-Meier survival analysis (months).



Conclusions: Dialysis-dependent CKD patients, irrespective of dialysis access and pre-existing valve disease, are at risk of IE. Survival rates remain low for patients with dialysis-dependent CKD diagnosed with IE. **References:** 1. Doulton T et al. Infective endocarditis in dialysis patients: new challenges and old. Kidney Int. 2003 Aug;64(2):720-7. 2. Shroff GR et al. Long-term survival of dialysis patients with bacterial endocarditis in the United States. Am J Kidney Dis. 2004 Dec;44(6):1077-82.

FR-PO993

Urinalysis in the Diagnostic Workup of Dialysis Patients with Possible Infection Katerina Oikonomou, Adib Alhaddad. *Internal Medicine, NYU Lutheran Medical Center, Brooklyn, NY.*

Background: Data on the role of urinalysis (UA) in the diagnostic workup of dialysis patients with possible infection are limited, and there is also variability in the coexistence of urinary tract infection (UTI).

Methods: A retrospective study was conducted to assess the sensitivity, specificity, and positive, and negative predictive values of urinalysis parameters in dialysis patients who were hospitalized between 9/2008 and 8/2015 with an admitting diagnosis of fever, sepsis or urinary tract infection. Characteristics of patients were recorded, and their associations with urinalysis parameters were assessed with Fisher's exact test. Receiver operating characteristic (ROC) analysis of urinalysis parameters was also performed.

Results: 275 dialysis patients (141 males, mean age 73±14.9 years) were assessed. Pyuria of different cut-offs (>10, >50 WBC/HPF) was associated with urine culture positivity (P< 0.001), and growth ≥10^5 CFU/ml (P=0.039), but not with presence of fever or sepsis. There was also association with urinary catheter use (P=0.001). Pyuria >10 WBC/

HPF had a sensitivity of 86%, and a specificity of 35% for identification of a positive urine culture with growth $\geq 10^5$ CFU/ml (P=0.025). Pyuria > 50 WBC/HPF had a sensitivity of 66% and a specificity of 58% (P=0.032). Bacteriuria, and leukocyte esterase (LE) positivity were associated with positive urine culture but not with growth $\geq 10^5$ CFU/ml. LE was also associated with presence of urinary catheter (P=0.031). No difference was found in patients with or without fever or sepsis in terms of bacteriuria, LE or nitrite positivity.

Conclusions: In the absence of adequate specificity and positive predictive value of urinalysis in dialysis patients with fever, sepsis or suspected UTI, a urine culture should be obtained to guide further treatment. Physicians should be vigilant for sources of infection other than the genitourinary tract.

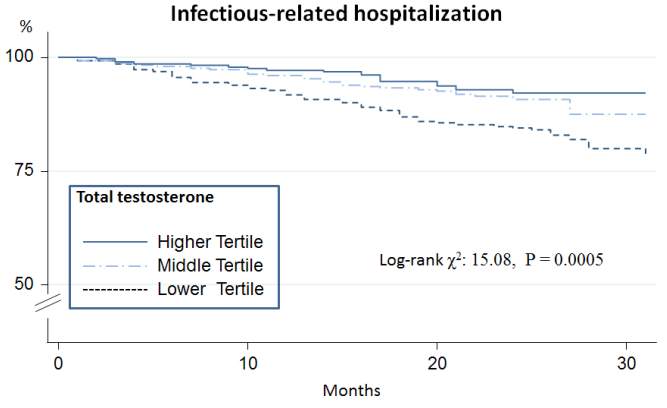
FR-PO994

Association between Low Serum Testosterone and All-Cause Mortality and Infection-Related Hospitalization in Male Hemodialysis Patients: Prospective Cohort Study Akio Nakashima, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Infectious diseases are the second-highest cause of death in patients on dialysis. In addition, testosterone deficiency is prevalent in dialysis. However, no studies have investigated the association between testosterone levels and infection-related hospitalization (IRH). We aimed to evaluate whether serum testosterone levels are associated with IRH and mortality in male hemodialysis patients.

Methods: We divided the study population into three groups based on serum testosterone levels. Associations between testosterone levels and the clinical outcomes of IRH, and all-cause mortality were analyzed using the Cox proportional hazard model after controlling for important clinical covariates.

Results: 902 male patients were enrolled and followed up for a median of 24.7 months. Their mean age (±SD) was 63.4 (± 11.8) years.123 participants died during follow-up. IRH occurred in 116 patients. IRHs were significantly more frequent in the lower than higher testosterone tertile (hazard ratio [HR], 2.12; 95% confidence interval [CI], 1.18-3.79) in adjusted models.



Moreover, all-cause mortality was significantly greater in the lower groups (HR, 2.26; 95%CI, 1.21-4.23).

Conclusions: These results suggest that low levels of testosterone are associated with higher rates of IRH and all-cause mortality in male hemodialysis patients.

FR-PO995

Nasal Methicillin-Resistant *Staphylococcus aureus* Carriage in Hemodialysis Patients: Hospital-Based versus Separate Dialysis Centers Georg Schlieper, Werner Kleophas. *MVZ DaVita Rhein Ruhr, Duesseldorf, Germany.*

Background: Methicillin-resistant Staphylococcus aureus (MRSA) colonization in hemodialysis patients is associated with higher risk for systemic infection. Recent hospitalization and temporary dialysis access are known risk factors for MRSA colonization. Whether MRSA colonization rates in hospital-based dialysis centers differ from separate dialysis centers is unknown.

Methods: Nasal swab cultures for MRSA were performed regularly according to the local health authority. MRSA-positive patients were decolonized according to a standardized protocol (intranasal mupirocin, tooth brush, oral and body octenidine). Results of positive swab cultures for MRSA were assessed in 358 hemodialysis patients of two separate dialysis centers (n=185) and four hospital-based dialysis centers (n=173) in February 2015 and February 2016.

Results: The rate of positive nasal swab cultures for MRSA of all centers were 4.8% in 2015 and with 1.4% significantly lower in 2016 (p=0.002). The MRSA rates of single centers ranged from 0% to 7.5%. The positive MRSA rate in hospital-based dialysis centers was higher than in separate dialysis centers (3.9% vs. 2.5%, p<0.001).

Conclusions: Despite significant differences of positive nasal swab cultures for MRSA in different years hospital-based dialysis centers had a higher positive MRSA rate compared to separate dialysis centers. Whether in-depth analysis of transmission ways may reduce MRSA rates in dialysis patients remains to be investigated in future studies.

FR-PO996

Efficacy and Safety of Sofosubuvir-Based Treatment in Patients with Chronic Hepatitis-C Infection and End Stage Renal Disease Haresh N. Savani. *Nephrology, Savanikidney Care, Surat, Gujarat, India.*

Background: treament for hepatitis-c infection for patients of end stage renal disease on regular haemodialysis is difficult, treatment option are limited.we have treated hepatitis-c infected patients on regular hemodialysis ,genotype-1 postive patients treated with fix dose combination of sofosbuvir and ledipasvir on alternate day,and genotype-3 positive patients with sofosbuvir and daclatasvir [alternate day].

Methods: in haemodialysis unit total 14 patients were infected with hepatitis-c, 11 patients of genotype-1, and 3 patients of genotype-3.genotype-1 infected patients were treated with fix dose combination tablet containg ledipasvir 90mg and sofosbuvir 400mg administered orally alternateday for 12 weeks.genotype-3 infected patients treated with tablet of sofosbuvir 400mg and tablet of daclatasvir 60 mg ,given orally alternate day for 12 weeks.routine clinical and laboratory data were collected at base line and during treatment.the primary out come was sustained virological response at week 12(SVR12).

Results: totlal 14 patients,10 male ane 4 female,of various age group between 34 to 71 years were included in this study.therapy was well tolereted. no patient discontinued treatment because of side effects.comparsion of lab at baseline and nadir level during treatment revealed no significant change in haemoglobin ,platletcount,ALT,and billirubin.all 14 patients had undetectable HCV RNA at the end of treatment.no cardiac or hepatobiliary toxicity observed during treatment.one patient had nausea,one patient had drop in haemoglobin by 1 gm/dl.other wise no side effects at all.

Conclusions: alternate day fix dose sofosbuvir and ledipasvir for HCV genotype-1 infection , and also alternate day sofosbuvir and daclatasvir for HCV genotype -3 infection ,was highly effective in previously untreated hepatitis-c infection in patients of end stage renal disease, on regular dialysis.treatment was safe,no significant adverse events were observed during the period of treatment.

FR-PO997

Sofosbuvir and Ribavirin Is Safe and Effective Therapy in Chronic Hepatitis C Patients with End-Stage Renal Disease and GFR (30 ml/min) Suman Nayak.[1] [1]*Nephrology, Inst of Liver and Biliary Sciences, New Delhi, Delhi, India;* [2]*hepatology, Inst of Liver and Biliary Sciences, New Delhi, Delhi, India.*

Background: Direct acting antiviral (DAAs) have been very effective in chronic hepatitis C. However, treatment of HCV in patients with advanced CKD on HD and low GFR (30ml) remains a major challenge due to the lack of reported efficacy and safety data of DAAs in this population. We investigated the efficacy and safety of Sofosbuvir (SOF) and Ribavirin (RBV) in chronic HCV infected CKD patients on HD and CKD stage 3 and 4 **Patients and methods:** Patients with CKD on HD and GFR (30 ml/min) having chronic HCV infection, were prospectively enrolled between September 2015 –June 2016 to receive SOF with RBV for 24 weeks. Patients were started on SOF 400 mg daily and RBV at 200 mg once to thrice weekly (as per tolerability of patients and serial Hb values). Safety and efficacy data were collected; including SVR12 and SVR24 data for all patients after completing therapy. **Results:**48 patients have been enrolled, with mean age of 44.99 ±11.99 yrs. 39(81.3%) patients were on dialysis and 7(14.6%) in stage 4, 2(4.1%) with stage 2 . 4 out of 48 patients were having Chronic liver disease and one patient was post liver transplant. The mean viral load at baseline was 5.78±1.4log (median =6 varies from 1.0-7.8 copies). HCV genotype 1 was present in 28(58.3%) and genotype 3 in 20 (41.7%) patients. 39 %(19) patients have completed 24 weeks of therapy. The virological cure was achieved in 19/19 (100%) of patients who have completed 24 weeks. Those who have reached 12 weeks & 24 weeks post-treatment had 100 % SVR at 12 & 24 Wk. 34% patients required adjustment in ribavirin dosage and increase in erythropoietin dose. **Conclusions**: Sofosbuvir plus ribavirin therapy, given for 24 weeksappears to be well tolerated in patients with advanced renal failure and carries good efficacy results with 100% SVR at 12 weeks.

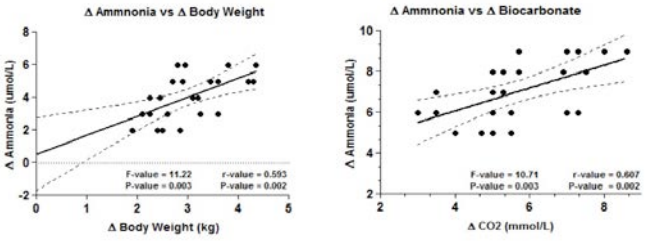
Effects of End-Stage Renal Disease (ESRD) and Dialysis Modalities on Blood Ammonia Level Madeleine V. Pahl, Mahyar Khazaeli, Ane C. Nunes, Kevin T. Harley, Hyder Said, Wei Ling Lau, Nosratola D. Vaziri. *Nephrology and Hypertension, Univ of California, Irvive, Orange, CA.*

Background: ESRD results in increased urea levels in gastrointestinal and glandular secretions. In the gut, bacterial hydrolysis of urea results in formation of ammonia and increased intestinal permeability. In the breath, nasopharyngeal bacterial hydrolysis and exhalation of circulating blood ammonia by the lungs contribute to ammonia levels. A direct correlation between breath ammonia and blood urea levels exits in ESRD, and hemodialysis (HD) treatments result in reduction of breath ammonia. The effects on blood ammonia are unknown and are explored here.

Methods: Blood from 23 HD (pre and post HD), 11 peritoneal dialysis (PD) and 6 controls (CNT) individuals were assayed for ammonia, urea, and bicarbonate.

Results: Baseline urea was significantly higher in HD (52.0 ± 21.1 mg/dL) and PD (44.8± 13.4 mg/dL) when compared with CNT groups (14.9 ± 4.5 mg/dL). No difference was found in baseline blood ammonia between HD (19.0 ± 1.4 umol/dL), PD (20.2 ±1.4 umol/dL) and CNT groups (25.3 ± 0.3 umol/dL). HD resulted in reduction in urea concentration (P<0.001) and a rise in blood ammonia level (28.8 ± 2.1 umol/dL; p<0.05). This was inversely related to the change in body weight and directly related with the change in bicarbonate concentration.



Conclusions: The post-HD fall in blood urea levels is paradoxically accompanied by a rise in breath ammonia. This rise is directly related to the extent of ultrafiltration and inversely related to the rise in bicarbonate concentration. Ultrafiltration may result in an acute reduction of hepatic perfusion limiting the liver's ability to convert gut-derived ammonia to urea. Additionally, the acute correction of mild acidosis in which ammonia is held as a nonvolatile ammonium, to a normal or alkalotic state can result in increased levels of volatile ammonia.

Quantification of Risk Factors for Progression of Medial Arterial Calcification W. Charles O'Neill,[1] Syed Mustafa Ahmed,[1] Shumila Manzoor,[1] Ioannis Sechopoulos,[2] Baowei Fei.[2] *[1]Renal Div, Dept of Medicine, Emory Univ, Atlanta, GA; [2]Dept of Radiology, Emory Univ, Atlanta, GA.*

Background: The relative effects of risk factors for medial arterial calcification are unknown because of the difficulty in quantifying it and distinguishing it from atherosclerotic calcification. Calcification of breast arteries is exclusively medial, readily apparent on mammograms (MGs), and correlates with peripheral arterial calcification and clinical outcomes. We hypothesized that progression and the effect of putative risk factors could be measured by routine mammography.

Methods: Women with breast arterial calcification (BAC) and the following single risk factors were identified: end-stage renal disease (ESRD) on hemo- or peritoneal dialysis, diabetes, warfarin therapy, or no risk factors (eGFR>90 ml/min/1.73 m2, no diabetes or warfarin). Lengths of calcified arterial segments were summed and compared between MGs in a blinded fashion, with BAC rate expressed as mm/yr per breast (+/- SE). Breast CT scanning was used to validate the measurements.

Results: Intra- and interobserver correlations were 0.99 (n=28) and 0.98 (n=31). Interstudy variability, determined by averaging residuals of the linear regression of 5 successive MGs, was 9.8 +/- 1.2%. The correlation between CT and MG was 0.92 (n=10 breasts). In subjects with no risk factors, BAC was rare before age 65 and the rate increased by 1.1 mm/yr each decade (mean 3.4 +/- 0.7 mm/yr; n=32; age: 78.8 +/- 1.2). BAC rate increased to 6.1 +/- 1.6 mm/yr in diabetics ($p<0.01$, n=15; age: 75.7 +/- 2.3) and 8.9 +/- 2.5 mm/yr in ESRD ($p<0.01$, n=18; age: 57.4 +/- 3.1) but the ESRD effect is greater considering the younger age. ESRD + diabetes resulted in very high rates (53.4 +/- 10.9 mm/yr; n=23; age: 61.1 +/- 1.4). In MGs before and during warfarin, progression increased 10-fold from 1.7 +/- 0.7 to 16.4 +/- 5.4 mm/yr (age: 78.7 +/- 3.6; n=11). BAC rate did not correlate with baseline BAC (r=0.08).

Conclusions: Mammography is a convenient and reliable method to measure progression of medial arterial calcification. Age, diabetes, ESRD, and warfarin are all risk factors for progression, with warfarin, ESRD, and ESRD + diabetes being the strongest.

Residual Renal Function Is Associated with Vascular Calcification and Valvular Calcification in Hemodialysis Patients Dong Ho Shin, Eunjung Kim, Jung-Woo Noh, Ja-Ryong Koo. *Hallym Univ College of Medicine.*

Background: Vascular calcification (VC) and cardiac valvular calcification (CVC) are common and may contribute to cardiovascular mortality in hemodialysis patients. Although there are multiple risk factors associated with VC and CVC in hemodialysis patients, little is known about the potential influence of RRF on VC and CVC in hemodialysis patients. Thus, we investigated VC and CVC according the degree of RRF in hemodialysis patients.

Methods: A total of 144 patients with RRF on maintenance hemodialysis for > 3 months were recruited between January 2014 and February 2016 at Kangdong Sacred Heart Hospital, Kangnam Sacred Heart Hospital, and Dontan Sacred Heart Hospital. Abdominal aortic calcification (AAC) score was measured on lateral lumbar radiographs and arterial stiffness was assessed by brachial-ankle pulse wave velocity (baPWV). Additionally, CVC was assessed using echocardiogram. Univariate and multivariate logistic regression were conducted to ascertain the potential influence of RRF on VC and CVC.

Results: Themean patient age and dialysis duration were 56.4 ± 10.8 years and 36.3 ± 11.2 months, respectively. The median RRF was 1.2 ml/min/1.73 m^2 (interquatile range 0.4 - 2.1 ml/min/1.73 m^2). AAC score [9 (3 - 22) vs. 5 (0 - 17), p = 0.04] and baPWV [1895.0 (1707.0 - 2155.5) cm/s vs. 1785.0 (1558.0 - 1983.0) cm/s, p = 0.003] were significantly higher in patients with RRF < 1.2 ml/min/1.73 m^2. CVC was common in patients with RRF < 1.2 ml/min/1.73 m^2 (45.1% vs. 23.1 %, p = 0.04). In multivariate analysis, RRF was identified as factors affecting AAC scoring (β = -0.210, P = 0.03) and baPWV (β = -0.146, P = 0.04), after adjusting for age, diabetes, smoking history, C-reactive protein, total cholesterol, and calcium-phosphate product.

Conclusions: This study showed that RRF in hemodialysis patients contributes significantly to the VC and CVC. Therefore, continuous monitoring of RRF may be useful to predict the risk of cardiovascular event in hemodialysis patients.

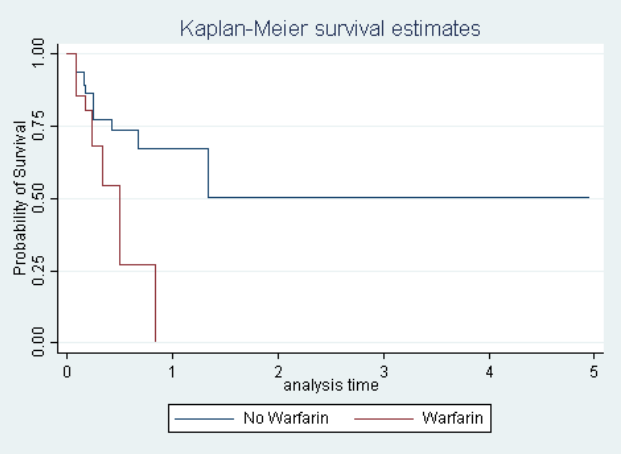
FR-PO1001

The KUMC Calciphylaxis Registry-Clinical Characteristics and Factors Associated with Mortality Peter W. Santos,[1] Jianghua He,[2] Ahmad M. Tuffaha,[2] James B. Wetmore.[3] *[1]AKDHC, Phoenix, AZ; [2]Univ of Kansas Medical Center, Kansas City, KS; [3]Hennepin County Medical Center, Minneapolis, MN.*

Background: We sought to describe clinical characteristics, methods of diagnosis, treatments prescribed, and mortality in CUA patients using cases reported in the University of Kansas Medical Center Calciphylaxis Registry (KUMC CR), a voluntary web-accessible registry.

Methods: Descriptive was reported as percents or means. Univariate analysis using the Cox survival model was conducted to estimate the hazard ratios (HRs) for factors associated with mortality. Kaplan-Meier survival curves of subgroups with different risk burdens were compared with log-rank tests.

Results: Of 117 patients, mean age was 58.5 years, females comprised 63.8%, and 63.8% were white. Mean BMI was 31.9 kg/m^2. DM was present in 66.7% and cardiovascular disease (CVD) in 62.2%. Warfarin was used in 40.2%. The mean iPTH level was 459 pg/ml, P was 6.3 mg/dl, uncorrected Ca was 9.0mg/dl, and Alb was 3.1 g/dl. Clinical suspicion (56.7%) was the most common diagnostic approach, while 32.5% had a histological diagnosis; only 9.4% underwent a bone scan. While nonspecific wound care was initiated in 70.9% of patients, debridement was undertaken in only 42.6% of cases. Sodium thiosulfate (STS) was initiated in 54.7% of patients, with the majority (74.1%) receiving ≥ 12.5 mg of STS, most often for <3 months (79.7%). In univariate analysis higher mortality was observed in patients with CVD (HR=10.47; 95% CI, 1.40 to 78.38), and those taking warfarin (HR=2.74; 95% CI, 1.16 to 6.51).



Conclusions: In real-world clinical practice, there is substantial heterogeneity in the diagnosis and treatment of CUA. Bone and mineral parameters were not often strikingly abnormal. The presence of CVD and use of warfarin appear to be mortality risk factors.

FR-PO1002

UK Calciphylaxis Study: Interim Analysis Abby Leah Huckle, Helen Alderson, Smeeta Sinha, Philip A. Kalra. *Vascular Research Group, Inst of Population Health, The Univ of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom.*

Background: Calcific uraemic arteriopathy (CUA or calciphylaxis) is a rare condition associated with a high mortality. It predominantly affects dialysis patients and is characterised by debilitating skin ulceration and calcification of cutaneous arterioles.

Methods: The UK calciphylaxis Study is a UK wide prospective observational internet-based study of CKD associated calciphylaxis. Data including demographics, laboratory results, medication use and therapeutic interventions are collected from enrolled patients on a 4 monthly basis.

Results: Data was available for 63 patients enrolled between 2012 and 2016. 76.2% were on renal replacement therapy (peritoneal or haemodialysis). 52.4% were female, median age was 57.5 years (IQR 52-66). 58.2% had a BMI >30 and 80.8% a BMI of >25. Prior to lesion development 66.7% (n=42) were prescribed a phosphate binder, 36.5% (n=23) a vitamin K antagonist. Baseline mean corrected calcium was 2.41 (SD±0.209) mmol/l, phosphate 1.68 mmol/l (SD±0.58) and iPTH median was 91.1 (IQR=29.6-189.8) mmol/l. The majority of lesions were on the lower extremities (57.1%), followed by the thighs (28.6%) and abdomen (15.9%). The treatment used varied considerably between patients.

Conclusions: 80.8% of patients in this study were overweight in comparison to the average dialysis population. Vitamin K antagonist use was highly prevalent in keeping with the literature; both may be important risk factors for the development of CUA. Therapeutic strategies varied greatly identifying a need for more research and consensus on the management of this condition.

FR-PO1003

Direct Links between Coronary Artery Calcification, Abnormal Cardiac Function, and Mortality in CKD-5D Paul Anaya,[1,2] Gustav A. Blomquist,[3] Daniel Davenport,[4] Marie-Claude M. Faugere,[5] Vincent L. Sorrell,[1,2] Hartmut H. Malluche.[5] *[1]Div of Cardiovascular Medicine; [2]Dept of Internal Medicine; [3]Dept of Radiology; [4]Dept of Surgery; [5]Div of Nephrology, Bone & Mineral Metabolism, Univ of Kentucky, Lexington, KY.*

Background: Coronary artery calcification (CAC) is common in patients with chronic kidney disease on hemodialysis (CKD-5D) and is an important predictor of mortality, but cardiac functional links between CAC and mortality have not been well-established. This study tested the hypothesis that CAC increases mortality by adversely affecting cardiac function.

Methods: Patients were recruited from 37 regional dialysis centers. 2-D and Doppler echocardiographic (Echo) analyses were performed and CAC was measured using 64-slice computed tomography. Relationships between CAC and Echo measures of left ventricular (LV) function were analyzed. Survival was assessed with median follow-up of 37 months.

Results: There were 157 patients: 59% men, 46% Caucasian, 48% diabetic. Median age was 55 years and median duration of CKD-5D was 45 months. Agatston CAC scores >100 were found in 69% of patients with 51% having a score >400. CAC was associated with measures of LV systolic and diastolic function (global longitudinal strain [GLS; rho=0.270, p=0.004]), mean LV systolic velocity (rho= -0.259, p=0.004), and estimate of LV filling pressure (E:E'; rho=0.286, p=0.001). Multivariate regression confirmed these relationships after adjustment for age, gender, ejection fraction and coronary artery disease. Valvular calcification varied linearly with CAC (p<0.05). Both LV diastolic and systolic functional measures were significant predictors of mortality; the strongest of which was LV diastolic dysfunction.

Conclusions: These findings show a link between CAC, cardiac function, and mortality in CKD-5D. LV diastolic function (E:E'), peak LV systolic velocity, and GLS are independent predictors of mortality. Valvular calcification may be an important marker of CAC in CKD-5D. These effects on cardiac function likely explain the high mortality with CKD-5D and describe a potentially valuable role for Echo in the routine management of these patients.

Clinical Significance of Vascular Calcification Volume Assessed by 3D Imaging Software Kaori Takaori,[1] Hirotsugu Iwatani,[1] Yuta Asahina,[1] Shintaro Koizumi,[1] Yoko Tomiyama,[1] Ikue Nagayama,[1] Takahito Ito,[2] Masafumi Yamato.[1] *[1]Nephrology, Osaka National Hospital, Osaka, Japan; [2]Nephrology, Kataguilli Medical Center, Shibata, Niigata, Japan.*

Background: Vascular calcification (VC) is closely associated with cardiovascular events and mortality. Quantification methods of VC vary among studies. We studied clinical significance of vascular calcification volume (VCV) assessed by 3D imaging software.

Methods: This is a retrospective cross-sectional observational study. Out of 69 patients undergoing thoracoabdominal computed tomography from May 2014 to December 2015 in our department of Osaka National Hospital, 65 patients were subjected to the analysis. The patient characteristics were as follows; 71 ± 11y.o., 36 males, eGFR 20.4 (8.94-40.0) ml/min/1.73m^2, P 3.8±1.1 mg/dl, hypertension 55 (85%), diabetes 27 (42%), macroangiopathy 19 (29%), use of ACE-I/ARB 28 (43%), use of phosphate-binder 6 (9.2%), and Brinkman Index (BI) 130 (0-750). Four patients were excluded because of the treatment history of aortic aneurysm. Using the Hounsfield Unit more than 130 as the cut-off level, VCV of the entire aorta was measured with 3D imaging software. Statistical analysis was performed by JMP and p-value less than 0.05 was considered significant.

Results: VCV was 6.6 (2.7-18.1) ml. Univariate analysis showed that log(VCV) was significantly associated with age, sex, log(eGFR), log(BI), use of phosphate-binder, use of ACE-I/ARB, hypertension, and macroangiopathy. Use of warfarin was marginally significant. Multivariate analysis for log(VCV) by these 9 parameters indicated that age (b 0.053, p 0.026), log(BI) (b 0.57, p 0.035) and use of ACE-I/ARB (b 0.53, p 0.0042) were independent positive predictors and log(eGFR) (b -0.69, p 0.015) was an independent negative predictor of high aortic VCV.

Conclusions: The quantification method of VC using 3D imaging software is visible and clinically useful. Our results are consistent with the already known risk factors of VC. Unexpectedly, ACE-I/ARBs seemed to promote VC. Our results are, however, compatible with a recent report that angiotensin II prevents phosphate-induced calcification in human aortic smooth muscle cells.

FR-PO1005

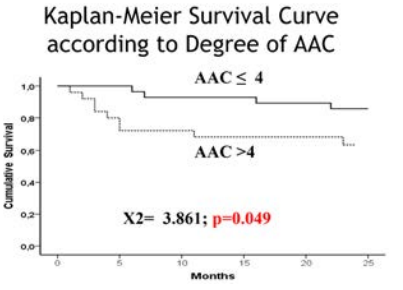
Abdominal Aortic Calicifications as a Prognostic Factor of All Cause Mortality in Hemodialysis Patients Kyriaki Stamatelou,[1] Dimitra Bacharaki,[2] Ioannis Griveas,[3] John Kyriazis,[4] Dimitrios V. Vlahakos.[2] *[1]Nephrology, Galinos Hospital, Athens, Greece; [2]Nephrology, Atticon Hospital, Chaidari, Greece; [3]Dialysis, NEFROIATRIKI, Athens, Greece; [4]Nephrology, General Hospital, Chios, Greece.*

Background: Vascular calcification has been associated with adverse clinical outcomes in hemodialysis patients. In this prospective study we examined the role of abdominal aortic calcification (AAC) in predicting all cause mortality in HD patients.

Methods: We studied 53 HD patients, 26 men, 27 women. After assessing the degree of AAC with Leena Kauppilla score (range 0-24) in lateral abdominal X-rays, patients were prospectively followed for two years, while recording fatal events. Kaplan-Meier survival analysis and univariate and multivariate Cox model were used.

Degree of AAC	≤4	>4	SS(p)
Age (y)	60±16	74±12	0.001
Dialysis Vintage (m)	26(16-58)	55(17-125)	0.011

Results: Median follow-up was 19.8 months, 13 deaths recorded, of which 11(27.3%) due to cardiovascular causes. Kaplan Meier survival analysis showed that patients with AAC score higher than the median score of 4, had worse survival compared to patients with AAC score ≤ 4 (17.6 versus 23.6 months; p <0.05).



Univariately, patients with advanced age, low diastolic blood pressure, history of coronary heart disease, high Ca X P product and high AAC score had an increased risk of death. In multivariate (stepwise) Cox regression analysis, only the degree of AAC emerged as an independent predictor of worse outcome. For each increment of the AAC by 1 degree, the risk of death increased by 10%(adjusted HR= 1.10, CI95%, 1.02-1.20). The area under the ROC curve for predicting mortality was 0.717(p=0.022) and at an optimal AAC score cutoff of 7.5, the sensitivity and specificity of AAC score in predicting all-cause mortality were 69% and 80% respectively.

Conclusions: The degree of AAC is a reliable indicator for estimating the risk of death in hemodialysis patients.

FR-PO1006

Aortic Calcification Area Index Predicts Increased Mortality in Peritoneal Dialysis Patients Fumiko Kuwahara, Saeko Miura, Kenji Harada, Hidetoshi Kanai. *Nephrology, Kokura Memorial Hospital, Kitakyushu, Japan.*

Background: Patients with end-stage renal disease have a high prevalence of vascular calcification, and cardiovascular diseases are an important cause of deaths. Here, we investigated the relationship of aortic calcification area index(ACAI) and mortality using the aortic calcification rate as an indicator of arteriosclerosis.

Methods: 76 patients (50 men and 26 women) who initially started peritoneal dialysis(PD) therapy and who took an abdominal computed tomography(CT) scan between Febuary 2010 and November 2013 were included. We calculated the calcification rate(%Area) for abdominal aortic vascular volume by using the abdominal CT. Patients were divided into two groups; low ACAI<11.7%(low ACAI group) ,n=43, and high ACAI≥11.7%(high ACAI group), n= 33. We analyzed the abdominal aortic calcification and mortality in PD patients using the Kaplan-Meier method.

Results: Median follow up period was 47.7±13.1 months. Median patient age was 63.6±11.7. Median value of ACAI was 11.7±10.5. High ACAI group were significantly older, higher ALP value and higher calcification rate of change than low ACAI group. Calcium, phosphorus, whole parathyroid hormone, uric acid, albumin, hemoglobin A1c, blood pressure, residual renal Kt/V and urine volume were not significantly differences in the two groups. In the Kaplan-meire method, high ACAI group was increased mortality (log-rank test; p= 0.0348). In the univariate Cox proportional hazards model, ACAI was a significant predictor of survival (hazard ratio 1.056 per 1.0% increment ACAI, 95% CI 1.007-1.108, P<0.05). However, in the multivariate Cox proportional hazards model, we could not show that ACAI was prognostic factor for survival.

Conclusions: In this study, we found that high ACAI group was associated with increased mortality by Kaplan-meire method. However, non cardiovascular death such as infection and cancer death is in the majority, therefore we could not show ACAI was prognostic factor for survival. We suggest that ACAI might be associated with mortality in PD patients.

FR-PO1007

Phosphorus and Panthotenic Acid Intake Are Related to Vascular Calcification in Class III and IV CKD: The PROGREDIR Study
Alisson Diego Machado,[1] Fernanda Silva Nogueira dos Anjos,[1] Maria Alice Muniz Domingos,[1] Maria del Carmen B. Molina,[2] Dirce Marchioni,[3] Rosa M.A. Moyses,[1] Paulo Lotufo,[4] Isabela M. Bensenor,[4] Silvia M. Titan.[1] *[1]Nephrology Div, School of Medicine, Sao Paulo Univ, Sao Paulo, Brazil; [2]Nutrition Dept, Federal Univ of Espirito Santo, Vitória, Espírito Santo, Brazil; [3]Nutrition Dept, School of Public Health, Sao Paulo Univ, Sao Paulo, Brazil; [4]Epidemiological and Clinical Research Center, Univ Hospital, Sao Paulo Univ, Sao Paulo, Brazil.*

Background: Vascular calcification (VC) is a widespread condition in CKD. Diet may be a determinant, but its role is not clear. We analysed the association between nutrient intake and VC in class III and IV CKD.

Methods: Data from 454 participants (Progredir Study) was used. A validated food frequency questionnaire was applied and nutrient intake was estimated using the USDA Database, adjusted for energy. Agatston Score (CAC) was obtained and those with coronary stent were excluded (artifact), leaving 372 people, which were classified by CAC (≥100).

Results: Median CAC was 165, with 50% of values >100. Age, male sex, race, diabetes, hypertension and smoking were related to CAC. While macronutrient intake was not different, a higher intake of phosphorus, calcium, vitD, vitB2, pantothenic acid (vitB5), potassium and magnesium was observed in the CAC>100 group. In logistic regression, all micronutrients except vitB2 remained related to CAC, even after adjustment for age, sex, diabetes, smoking, and protein intake. Lastly, we added micronutrient intake to the adjusted model and phosphorus intake remained significantly related to CAC [OR=1.002, 95%CI 1.000-1.003, p=0.01], whereas vitB5 showed a nearly significant relation [OR=1.286, 95%CI 0.98-1.70, p=0.07).

Conclusions: Our results show that (1) phosphorus intake is independently associated to VC in CKD, responsible for the major effect among nutrients related to CAC; (2) pantothenic acid intake may be related to CAC. This last finding raises questions about vitB5 in VC, considering its role in coenzyme A, fatty acids and cholesterol synthesis, metabolic pathways which have been related to the osteogenic differentiation of the vascular smooth muscle cell.

Funding: Government Support - Non-U.S.

Serum Bicarbonate Concentration and Arterial Stiffness: The Health ABC Study
Wei Chen,[1] Anne B. Newman,[2] Linda F. Fried,[2] Dena E. Rifkin,[3] Michael Shlipak,[4] Mark J. Sarnak,[5] Ronit Katz,[6] Magdalena Madero,[8] Kalani L. Raphael,[7] David A. Bushinsky,[1] Joachim H. Ix.[3] *[1]Univ of Rochester; [2]Univ of Pittsburg; [3]Univ of California, San Diego; [4]Univ of California, San Francisco; [5]Tufts Medical Center; [6]Univ of Washington; [7]Univ of Utah; [8]Inst Nacional de Cardiología Ignacio Chávez.*

Background: Arterial calcification contributes to arterial stiffness. Animal studies suggest that metabolic acidosis protects against arterial calcification. The relationship between serum bicarbonate and arterial stiffness in community-living older individuals is unknown.

Methods: We performed cross-sectional analyses in 1,698 participants aged 70-79. Serum bicarbonate was measured by arterialized venous blood gas at the point of care and categorized into <23 (low), 23-27.9 (ref) and ≥28mEq/L (high). Arterial stiffness was assessed by pulse wave velocity (PWV) and by high ankle-brachial index (ABI; >1.3/non-compressible vs. 0.91-1.3). We used linear and logistic regression to evaluate association of bicarbonate with PWV and high ABI respectively.

Results: The mean age was 76 years (52% women, 35% black). Mean bicarbonate was 25.2± 2.1mEq/L; 4.6% had low and 10.5% had high bicarbonate. Median PWV was 793 cm/s (IQR 632-1033), 5% had high ABI, 19% had diabetes and mean eGFR was 80±17mL/min/1.73m^2. High bicarbonate was not associated with high PWV or high ABI in either demographic or fully adjusted models. Results were similar among participants with and without CKD (p for interactions >0.05).

Association of bicarbonate categories with PWV and high ABI			
	<23	23-27.9	≥28
Log-PWV (n=1698) [β (95% CI)]			
M1	0.071 (0.012, 0.130)	ref	-0.015 (-0.074, 0.045)
M2	0.021 (-0.044, 0.085)	ref	-0.033 (-0.095, 0.030)
High ABI (n=1434) [OR (95% CI)]			
M1	1.81 (0.98, 3.35)	ref	0.95 (0.42, 2.15)
M2	1.34 (0.65, 2.77)	ref	0.88 (0.36, 2.17)
M1: adjusted for age, sex, race, clinical site M2: adjusted for covariates in M1 + eGFR, albuminuria, DM, systolic BP, diuretics, RAAS blocker, smoking status, heart rate			

Conclusions: These findings do not support an independent association between high bicarbonate and arterial stiffness in community-living elders.

Sodium Thiosulfate Intervenes Coronary Artery Calcification in Maintenance Hemodialysis Patients
Yi Yu. *Dept of Blood Purification, Dept of Medical Imaging, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: The purpose is to investigate the factors correlated to coronary artery calcification in maintenance hemodialysis (MHD) patients, further to observe the effect of sodium thiosulfate (STS) on the progression of vascular calcification and its safety.

Methods: All subjects underwent coronary artery CT scan using Philip's spiral CT and the calcification degree was evaluated by calcification scores. First, the MHD patients were divided into coronary artery calcification group(CAC scores <10)and non-coronary artery calcification group (CAC scores >10). The differences of age, duration of dialysis and other hematological indexes between the two groups were analyzed. Then, those with coronary artery calcification (CAC scores >50) received intravenous 0.18g/kg STS (dissolved in 100ml saline) in 30 minutes after each dialysis for 3 months (n=15) or received conventional treatment (n=10). The changes of vascular calcification imaging, CAC scores, biochemical and bone mineral density were compared between two groups before and after the treatment. Besides, adverse reactions were observed during the treatment of STS.

Results: 27 in 38 patients (71.05%) had coronary artery calcification, The patients with coronary artery calcification had significantly higher age, duration of dialysis, phosphate, the product of calcium and phosphate, PTH and hsCRP and lower serum albumin (P<0.05) than patients without coronary artery calcification. There was no significant difference in the baseline characteristics between STS treatment group and the conventional treatment group. CAC score was unchanged in the STS treatment group (P=0.053), but increased significantly in the conventional treatment group (P=0.021). Difference of calcification score parameters before and after treatment showed statistically significant difference between the two groups (P= 0.004). After STS treatment, hsCRP and $HCO3^-$ levels decreased, and serum calcium levels increased (P<0.05).

Conclusions: Coronary artery calcification is commonly present in MHD patients. STS treatment seems to be feasible, safe and may decrease the rate of progression of vascular calcification, reduce inflammation in MHD patients.

AKt/mTOR Signalling Is Involved in VSMC Calcification Induced by High Phosphate
Yi Yu. *Dept of Blood Purification, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: The aim is to characterize the possible role of AKt/mTOR signalling in the vascular smooth muscle cells (VSMC) calcification induced by high phosphate.

Methods: Passage 3 to 5 of VSMC were used for experiments. VSMC were divided into two groups: normal phosphate group (Pi 1.3 mmol/L) and high phosphate group (Pi 2.6 mmol/L). Cbfα1 and OPN mRNA levels were determined by Real-Time PCR. p-AKt (ser473), p-mTOR (S2448), Cbfα1 and OPN protein expressions were quantified by Western Blot. When p-Akt and p-mTOR expression of VSMC were enhanced by high phosphate, Akt/mTOR inhibitors were respectively added in high phosphate group. VSMC then were divided into seven groups: high phosphate group (Pi 2.6 mmol/L); high phosphate+ Wortmannin(10, 50, 100 nmol/L); high phosphate+rapamycin (1, 10,100ng/ml). After 24-48h, Cbfα1 and OPN mRNA levels were determined, and p-AKt, p-mTOR, Cbfα1 and OPN protein expressions were quantified. All experiments were repeated 3 times.Calcium deposition was visualized by Alizarin stain method at day 7-14.

Results: After 7 days, compared with normal phosphate group, calcium deposition was obvious in high phosphate group. Cbfα1 and OPN mRNA expressions were significantly increased and the expressions of p-Akt/p-mTOR, Cbfα1 and OPN protein were significantly increased in high phosphate group (P<0.05). Cultured for another 7 days, calcium deposition was significantly decreased in high phosphate+ Wortmannin(50, 100nmol/L) groups and high phosphate +rapamycin(100ng/ml)group, compared with high phosphate group. After 24 -48hours, Cbfα1 and OPN mRNA expressions were significantly decreased; p-AKt, p-mTOR, Cbfα1 and OPN protein expressions were significantly decreased in high phosphate+ Wortmannin(50, 100nmol/L) and high phosphate+rapamycin(10, 100ng/ml) groups(P<0.05) compared with high phosphate group.

Conclusions: AKt/mTOR inhibitors, may suppress VSMC calcification and expressions of p-AKt/p-mTOR, Cbfα1 and OPN. Akt/mTOR is involved in VSMC calcification induced by high phosphate.

SNF472 - A Potential Novel Calcification Inhibitor in CKD-MBD
Nadine Kaesler,[1] Ayshe Hyusein,[1] Miquel D. Ferrer,[2] Ana-Zeralda Canals,[2] Carolina Salcedo,[2] Joan Perelló,[2] Jürgen Floege,[1] Vincent Brandenburg.[3] *[1]Nephrology, Univ Hospital of the RWTH Aachen, Germany; [2]Laboratoris Sanifit SL, Palma, Spain; [3]Cardiology, Univ Hospital of the RWTH Aachen, Germany.*

Background: Chronic kidney disease (CKD) is associated with cardiovascular calcification (CVC) in response to mineral and bone disorder. SNF472 (an intravenous formulation of the hexasodium salt of myo-inositol hexaphosphate) directly inhibits calcification by binding to growth sites of the hydroxyapatite crystal. We investigated the effects of SNF472 upon vascular smooth muscle cell (VSMC)-mediated calcification triggered by high calcium (Ca) and phosphate.

Methods: The anti-calcific effects of SNF472 or sodium thiosulfate (STS) were analyzed on primary VSMC from rat aorta treated with 3 mM calcium phosphate (CaPO).

Ca content, apoptosis rate and gene expression were measured. Dose Finding: Calcifying VSMCs were treated with 1, 10, 30 and 100 µM of SNF472 and 25, 50, and 100 mM of STS for 5 days. Apoptosis was measured by TUNEL assay, gene expression by Taqman real-time PCR. Time dependency: Using the most efficient anti-calcification dosage, treatment with SNF472 was started 3, 5, and 7 days after the beginning of the calcification experiment until day 10.

Results: SNF472 significantly reduced Ca concentrations compared to untreated VSMCs (maximum inhibition of 97%). CaPO treatment increased apoptosis rate compared to the control group after 7 days (control group: 0.09% vs. CaPO group: 1.5%). SNF472 treated cells showed an apoptosis rate of 0.8% at 30 µM. STS was most effective at 100 mM in reducing calcification (96% inhibition) but increased apoptosis rate by 77%. SNF472 (30 µM) is also effective in lowering the Ca content in later calcification stages. SNF472 treatment prevented CaPO-induced downregulation of SMA and also prevented upregulation of Alk Phos and cbfa1.

Conclusions: SNF472 decreased the calcium deposition in the ECM of rodent VSMC in a high CaPO microenvironment without inducing apoptosis. Moreover, it prevented upregulation of genes indicating switch form contractile VSMC to osteoblast-like cells. SNF472 qualifies as a promising research target to inhibit cardiovascular calcification in CKD patients undergoing dialysis.

Safety, Pharmacokinetics and Pharmacodynamics of SNF472 in Hemodialysis Patients: New Data from a Phase 1b/2a Randomised Placebo-Controlled Clinical Trial

Carolina Salcedo,[1] Joan Perelló,[1,2] Raquel Ojeda,[3] Pieter H. Joubert,[1,4] Marta Arias,[3] Ana-Zeralda Canals,[1] Miquel D. Ferrer,[1] Maria del Mar Perez,[1] Jose-Vicente Torregrosa,[3] Francisco Maduell.[3] *[1]Laboratoris Sanifit, Palma, Spain; [2]Univ de les Illes Balears, Palma, Spain; [3]Dept Nephrology, Hospital Clínic, Barcelona, Spain; [4]Inst of Pharmaceutical Science, King's College, London, United Kingdom.*

Background: SNF472 (an intravenous formulation of inositol hexaphosphate) inhibits calcification by binding to the growing sites of hydroxyapatite (HAP). SNF472 is being developed for the prevention of vascular calcification in patients with end-stage renal failure on hemodialysis (HD). Non-clinical investigations and a single dose study in healthy volunteers and HD patients supported proceeding to a repeated dose trial in HD patients.

Methods: A double-blind, randomized, repeated dose study was performed in two cohorts of eight HD patients on three HD sessions per week. SNF472 was administered by a 4-hour infusion during the HD sessions. Doses of 1, 3, 5, 12.5, and 20 mg/kg were given during three consecutive HD sessions, with a 3-week washout period between doses. A second cohort received 10 mg/kg during 12 consecutive HD sessions. Standard safety parameters, serum bio element concentrations, pharmacokinetics, and calcification pharmacodynamics (PD) were determined.

Results: No adverse events, systemic side effects or local irritation related to SNF472 administration were reported. Dose linearity was observed in terms of C_{max} and AUC between 3 and 20 mg/kg. No SNF472 accumulation was observed after 1 month of administration at 10 mg/kg. Serum P, Mg^{2+}, and K^{+} were decreased as a consequence of HD, but SNF472 did not affect these changes. Ionized calcium was unaffected by SNF472 administration. The doses of 5, 12.5, and 20 mg/kg were on a PD plateau and reduced the HAP formation propensity by 80%. The EC_{50} using this assay was 2.18 mg/kg.

Conclusions: The findings support continuation of the clinical development program, namely a phase 2 three-month study in calciphylaxis assessing wound healing and a phase 2 one-year dose-finding study in HD patients evaluating coronary artery calcification progression. Supported by RETOS COLABORACIÓN: RTC-2014-2460-1 ISCIII grant.

Warfarin-Induced Vascular Calcifications: Underlying Cellular Mechanisms and Effects on Bone Mineralization

Annelies De Maré, Britt Opdebeeck, Ellen Neven, Patrick C. D'Haese, Anja Verhulst. *Pathophysiology, Univ of Antwerp, Belgium.*

Background: Vascular calcification (VC) is considered to be an important risk factor for cardiovascular morbidity and mortality in CKD patients. Loss of calcification inhibitors is one of the mechanisms responsible for the development of VC in the media of the vessel wall. Matrix gla protein (MGP) is a strong inhibitor of VC and its activity depends on vitK-mediated γ-carboxylation. As warfarin interferes with vitK recycling, active (carboxylated) MGP is depleted and VC consequently develop. Here, we investigated cellular mechanisms underlying warfarin-induced VC as well as its effects on the bone.

Methods: Calcifications were induced in rats by daily administration of a warfarin-supplemented diet (3mg warfarin/g diet + 1.5mg vitK1/g diet). Rats receiving a standard diet, served as controls (CTR). At sacrifice at 4, 6, 8 and 10 wk, VC, aortic mRNA expression and bone status were assessed by bulk calcium (Ca) analysis, q-rt PCR and bone histomorphometry.

Results: Aortic Ca concentration gradually increased and significantly differed from CTR in 4-wk treated rats (p=0.0286), reaching a 50-fold increase in 10-wk treated rats, (p=0.0061 vs CTR). mRNAs of osteochondrogenic transdifferentiation markers were upregulated, among which the transcription factor Sox9 and β-catenin, an important protein in the anabolic Wnt/β-catenin bone signaling pathway (p=0.0317 and 0.0159, resp.). Interestingly also the mRNAs of the Wnt/β-catenin pathway inhibitor sclerostin as well as the Wnt/β-catenin upstream protein activin receptorIIA were significantly up-regulated (p=0.0159 and 0.0317, resp.). A mild decrease in bone area, trabecular number and -thickness (p=0.0095 vs CTR for each) was observed in rats treated for 10 wk.

Conclusions: The current study allows to suggest that, Wnt/β-catenin signaling in concert with or in addition to transdifferentiation of vascular smooth muscle cells, also plays a crucial role in warfarin-induced VC. Findings may lead to identifying e.g. upstream proteins/inhibitors of the Wnt/β-catenin pathway as new targets for treating VC. Furthermore, it became clear that warfarin induces a mild reduction of mineralized bone volume by a currently unknown mechanism.

Characterization and Comparison of Vascular Calcification in Two Mouse Strains with Adenine-Induced CKD

Annelies De Maré, Britt Opdebeeck, Ellen Neven, Patrick C. D'Haese, Anja Verhulst. *Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: Medial vascular calcifications (VC) are frequently observed in patients with chronic kidney disease (CKD) and are associated with increased morbidity and mortality. Until now, our and other laboratories studied these CKD-induced VC in a rat model of adenine-induced CKD. However, because of the availability of knockout mice that lack expression of proteins potentially playing a role in the development of these VC, the development of a CKD-induced mouse model of VC is highly desirable.

Methods: Two mice strains, C57Bl6 (n=10) and DBA2 mice (n=10), received alternately a 0.30% and 0.15% adenine supplemented diet, containing 1% phosphate. Serum creatinine and phosphate levels were monitored in the animals in order to follow-up the development/progression of CKD. At sacrifice (C57Bl6 at 8 weeks, DBA2 at 12 weeks), VC were assessed by bulk calcium analysis and von Kossa staining and compared to control mice with normal renal function.

Results: The adenine-supplemented diet led to a clear induction of CKD in C57Bl6 and to a lesser extent in DBA2 mice, as reflected by increased serum creatinine and phosphate levels. Due to mortality (4/10 mice), C57Bl6 mice were sacrificed after 8 weeks of treatment. One animal of this group developed obvious VC in the aorta, confirmed by bulk calcium analysis (9.9 mg Ca/g wet tissue vs 0.16 mg Ca/g wet tissue in controls) and von Kossa staining (6.6% calcified tissue vs 0.008% in controls). Less mortality was observed in DBA2 mice (1/10). All DBA2 mice developed severe media calcifications in the aorta (average: 20.2mg Ca/g wet tissue, 12.4% calcified tissue). Furthermore because calcification of the heart was macroscopically visible at sacrifice, von Kossa staining was performed on cardiac tissue. All DBA2 animals seemed to have developed severe cardiac calcification of which quantification is ongoing.

Conclusions: In this study we managed to develop a mouse model of CKD-induced medial VC. DBA2 mice however, seemed to be more prone to the development of VC compared to C57Bl6 mice.

Inhibition of Nephritis and the CKD-MBD in Alports Syndrome by an ActRIIA Ligand Trap

Olga A. Agapova,[1] Toshifumi Sugatani,[1] Yifu Fang,[1] Keith A. Hruska.[1,2] *[1]Renal Div, Pediatrics, Washington Univ, Saint Louis, MO; [2]Renal Div, Medicine, Washington Univ, Saint Louis, MO.*

Background: To examine the role of ActRIIA signaling in interstitial nephritis and the CKD-MBD, we used the murine Alport's homolog (Col4α5 deficiency) with CKD and 70% reduction in GFR at 200 days of life, we found the CKD-MBD to be characterized by marked reductions in renal klotho, elevated FGF23 and PTH levels, normophosphatemia, cardiac hypertrophy and vascular calcification.

Results: Plasma activin levels and aortic p-smad 2/3 levels were increased in Alport's, $p<0.01$, and decreased by treatment with RAP-011, an ActRIIA ligand trap 10mg/kg SC twice weekly from day 75 to 200. Aortic Ca levels were 0.27mg/g in 200do wild type littermates, 0.59 in Alport's and 0.36 in Alport's mice treated RAP-011, $p<0.05$ versus Alport's. Aortic micro CT and histology showed the calcium apatite deposits to be advential abutting the muscularis. The vascular smooth muscle levels of sm22α and αSMA (transcriptional targets of p-smad 2/3) were actually increased in Alport's mice, and Runx2 (a marker of osteoblastic transition of VSMC) was not expressed. However, osterix, a second osteoblastic transcription factor was expressed in advential cells adjacent to the calcium deposits. Heart weight was 6.2mg/mm (weight/tibial length) in Alport's and corrected to normal (4.9mg/mm) by RAP-011 treatment. In the Alport's kidney, activin expression, elevated p-smad 2/3, Col1, fibronectin and interstitial fibrosis were inhibited by RAP-011 treatment. Glomerular sclerosis was diminished and GFR was increased by RAP-011 treatment, $p<0.01$.

Conclusions: In conclusion, the results are consistent with renal production of activin stimulating ActRIIA signaling and driving fibrosis and glomerular sclerosis, and contributing to the vascular and cardiac components of the CKD-MBD. ActRIIA signaling may be a therapeutic target in Alport's syndrome.

Reducing Dietary Phosphate in Experimental CKD Is Sufficient to Attenuate Vascular Stiffness and the Associated Left Ventricular Hypertrophy
Bruno Svajger,[1] Kimberly J. Laverty,[1] Cynthia M. Pruss,[1] Emilie C. Ward,[1] Paul S. Jeronimo,[1] Mandy E. Turner,[1] Martin P. Petkovich,[1] Rachel M. Holden,[2] Michael A. Adams.[1] *[1]Biomedical and Molecular Sciences, Queen's Univ, Kingston, ON, Canada; [2]Medicine, Queen's Univ, Kingston, ON, Canada.*

Background: Impaired renal function in CKD causes hyperphosphatemia and alters hormonal regulators (calcitriol, FGF-23). One hypothesis is that the increased phosphate (PO_4) pool combined with elevated FGF-23 and the generation of vascular calcification (VC) cause cardiovascular disease (CVD). Understanding this mechanism is important as CVD-related outcomes in CKD patients account for over half of all CKD mortality. To determine the importance of dietary PO_4 on CKD-based CVD we sought to determine the effects of low versus high dietary PO_4 in a rat model of CKD.

Methods: 16 wk male SD rats were fed a CKD-inducing diet (0.25% adenine, 0.5% PO_4, n=35) for 4 wks, were taken off adenine and separated into 3 diet grps: 0.5% PO_4 (n=14), 1% PO_4 (n=11), and 1.5% PO_4 (n=10). Non-CKD control groups on 0.5% PO_4 (n=8) or 1.5% PO_4 (n=5) were compared. After 4 wks, hemodynamic changes were measured and the rats sacrificed.

Results: Low PO_4 (0.5% diet) in CKD rats did not change serum PO_4 or aortic VC vs. controls; while high PO_4 (1% and 1.5% diets) led to increased serum PO_4 (6.2±2.1 vs 2.1±0.2mM, $p<0.05$) and VC compared to controls (413.0±525.6 vs 4.1±0.76 & 6.1±2.8 mmol/mg). PWV was elevated in high PO_4 compared to controls and low PO_4 (0.13±0.1 vs 0.06±0.02 m/s*mmHg, $p<0.05$). CKD induction increased serum FGF-23 ($p<0.05$) with significant elevations in high PO_4 groups compared to low PO_4 (30±28.4 vs 2±1.6 ng/mL, $p<0.05$). High PO_4 groups have significant LVH compared to control and low PO_4 groups ($p<0.05$).

Conclusions: Increasing dietary PO_4 in CKD leadsto greater propensity for VC and this appears to directly contribute to the development of CVD. Our findings show that maintaining low dietary PO_4 protects vessels against VC and vascular stiffening, ultimately reducing the extent of LVH in CKD. These findings support the value of dietary PO_4 regulation for CKD patients and the use of dietary PO_4 binders to help improve CVD complications in CKD patients.

In Vivo Effect of Indoxyl Sulfate (IS) and p-Cresyl Sulfate (PCS) on the Development of Vascular Calcification in Rats with Adenine-Induced Uremia
Britt Opdebeeck,[1] Annelies De Maré,[1] Bjorn Meijers,[2] Pieter Evenepoel,[2] Anja Verhulst,[1] Patrick C. D'Haese,[1] Ellen Neven.[1] *[1]Pathophysiology, Univ of Antwerp, Belgium; [2]Nephrology, Univ Hospitals Leuven, Belgium.*

Background: Vascular calcification (VC) is frequently seen in patients with chronic kidney disease (CKD). Recently uremic toxins, IS and PCS, have been postulated as novel promoters for VC development. To provide further evidence for this, a rat model with adenine-induced uremia was used to define whether IS and PCS are major contributors to VC development during CKD.

Methods: To induce CKD, rats were treated with adenine sulfate during 10-days via daily oral gavage (600 mg/kg/day). Simultaneously, rats were continuously exposed to either (i)IS or (ii)PCS via the drinking water until wk2 followed by oral gavage at a dose of 150 mg/kg/day until sacrifice at wk7. Control animals received vehicle. Calcium(Ca), phosphorus(P) and creatinine were determined in serum and urine samples. Serum IS and PCS levels were analyzed by LC MS/MS. As uremic toxins may interfere with glucose(Glu) metabolism serum Glu was measured at the start and end of the study. At sacrifice, VC was evaluated by bulk calcium(Ca) and Von Kossa staining.

Results: CKD was present in all groups as indicated by a significant reduction of the creatinine clearance and increasing serum P levels. CKD rats exposed to IS showed a significantly higher creatinine clearance and lower serum P levels as compared to vehicle treated CKD rats. Induction of CKD resulted in significantly increased serum IS and PCS levels which were comparable to levels in CKD patients. Glu levels were significantly elevated at the end of the study in both IS and PCS treated rats. No calcification had developed in the aorta, femoral or carotid arteries in CKD rats exposed to vehicle. Development of moderate to severe VC as indicated by a distinct Von Kossa positivity and significant increase in Ca content was observed in the aorta and peripheral vessels of CKD rats exposed to IS and PCS.

Conclusions: IS and PCS induced vascular calcification in the aorta and peripheral vessels of CKD rats and thus can be considered as vascular toxins. Further research will explore the mechanisms by which both toxins affect the vascular wall.

Indoxyl Sulfate Promotes Aortic Calcification through Notch Signaling Pathway Activation in Vascular Smooth Muscle Cells
Maimaiti Yisireyili,[1] Kyosuke Takeshita,[1] Toshimitsu Niwa.[2] *[1]Dept of Cardiology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Faculty of Health and Nutrition, Faculty of Health and Nutrition, Shubun Univ, Ichinomiya, Aichi, Japan.*

Background: Vascular calcification is common in chronic kidney disease (CKD), and recognized as surrogate marker for cardiovascular disease (CVD). Indoxyl sulfate (IS) is a protein bound uremic toxin to exacerbate vascular calcification in CKD patients, and its therapeutic target has been searched for. We hypothesized that Notch signal pathway alterations caused by IS is involved in vascular calcification because Notch signal activation increase cell survival of vascular cells in developmental and pathological status.

Methods: IS (200 mg/kg/day in drinking water) administered Dahl rat and vehicle rat were used to evaluate vascular calcification. Human arterial smooth muscle cells (HASMCs) was culture under various concentration of IS, and the expression of Notch 1 and 3, and apoptosis were assessed with RT-PCR, caspase activity assay, and TUNEL staining.

Results: Aortic calcification was observed solely in IS-administered rats. The expression of Notch1 and 3 was slightly increased in aortic SMCs from IS- administered rats compared to vehicle rat. Notably the expression of Notch1 and 3 was fainted in vascular calcification in IS-treated rats. In cultured HASMCs, the expression of Notch1 and 3 was peaked at 24h after administration of IS (1000μM), and fainted within 72h. Exposure to IS increased TUNEL positive cells and caspase3/7 activity in a dose- and time-dependent manner. IS and Notch signal inhibition accelerated inorganic phosphate-induced calcification in HASMCs, and the effect was canceled by pharmacological inhibition of apoptotic signaling.

Conclusions: IS transiently activates Notch signal in vascular smooth muscle cells, but the effect was fainted getting along with higher concentration and longer duration of exposure to IS. The decreased Notch activity induced formation of apoptotic body and calcified lesions. Thus Notch signal would be a novel therapeutic target for vascular calcification in CKD patients.

Metformin Prevents from Severe Kidney Failure, Vascular Calcification and High Bone Turnover Disease
Patrick C. D'Haese,[1] Benjamin Arthur Vervaet,[1] Kerstin Brand,[2] Ulrike Gottwald-Hostalek,[3] Geert Dams,[1] Anja Verhulst,[1] Jean-Daniel Lalau,[4] Said Kamel,[4] Marc E. De Broe,[1] Ellen Neven.[1] *[1]Laboratory of Pathophysiology, Univ of Antwerp, Wilrijk, Antwerp, Belgium; [2]Global Medical Affairs, Merck KGaA, 64293 Darmstadt, Germany; [3]Research and Development, Merck KGaA, 64293 Darmstadt, Germany; [4]Unité INSERM U-1088, Univ de Picardie Jules Verne, Amiens, France.*

Background: Chronic renal impairment causes systemic dysregulation of the mineral metabolism and coincides with vascular calcification and bone disorders which is called 'Chronic Kidney Disease-Mineral and Bone Disorder' (CKD-MBD). Metformin, an oral anti-hyperglycemic agent used for type II diabetes mellitus as a standard treatment, has been shown to have beneficial effects on kidney fibrosis and atherosclerosis. This study aims to investigate the effect of metformin on renal function and structure, arteries and the bone in CKD-MBD.

Methods: To induce CKD, rats received a 0.25% adenine/low vitamin K diet for 8 weeks. Animals were daily treated with 200 mg/kg metformin or vehicle by oral gavage from 1 week after CKD induction onwards until week 8. Renal function, histology, fibrosis and inflammation were assessed. The calcium content in the arteries was determined and static and dynamic bone parameters were measured.

Results: Severe, stable CKD along with serious hyperphosphatemia and hypocalcemia had developed in vehicle treated rats which led to calcification in the arteries and high bone turnover disease. Metformin treatment protected adenine dosed rats from the evolution towards severe CKD and serum phosphorus and calcium concentrations remained within the normal range. The kidney of the metformin group showed significant less cellular infiltration, fibrosis and inflammation. Metformin also prevented the development of vascular calcification and inhibited the progression towards high bone turnover disease.

Conclusions: In conclusion, metformin treatment protected against the development of severe renal failure and preserved the calcium phosphorus homeostasis which presumably prevented the onset of vascular calcification and development of high bone turnover disease.

Funding: Pharmaceutical Company Support - This work was supported by a research grant from Merck KGaA, Darmstadt, Germany

FR-PO1020

High Dose Vitamin D-Induced Vascular Calcification Is Attenuated in TLR4 Deficient Mice Jianheng Zhou,[1] Yuan Min Wang,[1] David C. Harris,[2] Heather J. Medbury,[3] Helen Williams,[3] Anne M. Durkan,[1] Grahame J. Elder,[2] Steven J. Chadban,[4] Huiling Wu,[4] Stephen I. Alexander,[1] Vincent W.S. Lee.[2] *[1]Centre for Kidney Research, Children's Hospital at Westmead, Westmead, NSW, Australia; [2]Centre for Transplantation and Renal Research, Westmead Inst of Medical Research, Westmead, NSW, Australia; [3]Vascular Biology Research Centre, Westmead Hospital, Westmead, NSW, Australia; [4]Renal Medicine, Royal Prince Alfred Hospital, Kidney Node Laboratory, Charles Perkins Centre, Univ of Sydney, NSW, Australia.*

Background: Vascular calcification is strongly associated with cardiovascular morbidity and mortality. Several studies have suggested that monocytes/macrophages are involved in arterial vascular calcification, while the involvement of the TLR4 pathway in vascular calcification has also been proposed.

Methods: WT C57BL/6 and TLR4-/- mice aged 8 weeks were injected with a high dose of vitamin D (500000IU/kg/day) subcutaneously at 0, 24 and 48 hours. All mice were sacrificed 4 days after the final injection. Kidneys were collected for examination of injury by histochemistry. Whole aortas were dissected. Macrophage infiltration, TLR4 expression and vascular calcification were examined by immunohistochemistry and histology.

Results: High dose vitamin D treated WT mice demonstrated significantly higher calcium deposition in their aortas (15.5% of vessel area) than did WT and TLR4-/- mice without injection (0.5% $p<0.001$, 0.2% $p<0.001$). Aortic calcium deposition was significantly attenuated in TLR4-/- mice with vitamin D injection (1% $p<0.001$) as compared to vitamin D treated WT mice. This was accompanied by a lower level of macrophage infiltration and TLR4 expression in aortas of high dose vitamin D treated TLR4 -/- mice compared to high dose vitamin D treated WT mice, whilst untreated mice had minimal aortic macrophage infiltration. High dose vitamin D treatment did not induce kidney fibrosis or tubular injury in WT and TLR4-/- mice, as assessed by GT fibrosis score and PAS tubular damage score.

Conclusions: Accelerated vascular calcification and macrophage infiltration with high dose vitamin D treatment was reduced in TLR4 -/- mice compared to WT mice. These data suggest a potential role for macrophages and the TLR4 pathway in vascular calcification.

FR-PO1021

Effect of Pioglitazon on Calcification of Rat Vascular Smooth Muscle Cells through the Down-Regulation of Wnt/β-Catenin Signaling Pathway Huijuan Mao. *Nephrology, First Affiliated Hospital of Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: To investigate the effect and possible mechanism of Pioglitazon(PIO) on calcification of rat vascular smooth muscle cells (VSMCs)in vitro.

Methods: β-glycerophosphate (10mmol/L) was used to induce calcification of VSMCs, with different concentrations(5,10,15,20μmol/L)of PIO to intervene for 12d.Calcium deposits were tested by Alizarin red staining. Extracellular calcium content was detected by Calcium Assay Kit. Western Blot was used to measure the expressions of α-smooth muscle actin (α-SMA), runt-related transcription factor 2 (Runx2),bone morphogenetic protein-2 (BMP2),β-catenin,GSK-3β,p-GSK-3β and cyclin-D1. On the basis of 10mmol/L β-glycerophosphate and 20 μmol/L PIO, 20 μmol/L PPARγ antagonist GW9662 was added to the cell culture media. The changes of the above indexes were observed.

Results: 1.The calcium content in calcification group increased significantly compared with the control's($P<0.05$),and all different concentrations of PIO reduced extracellular calcium content($P<0.05$).Alizarin red staining was strong positive in calcified VSMCs, and PIO(20μmol/L) intervention group was almost negative. 2.The expressions of Runx2,β-catenin,p-GSK-3β,BMP2 and cyclin-D1increased significantly in calcification group, and 20μmol/L PIO group obviously down-regulated the expressions of all the above proteins, while up-regulated the expression of α-SMA. 3. PPARγ antagonist GW9662 could partly block the effect of PIO on calcified VSMCs.

Conclusions: PPARγ agonist PIO can alleviate rat aortic VSMCs calcification induced by β-glycerophosphate via inhibiting the activity of Wnt/β-catenin signaling pathway.

FR-PO1022

Vascular Calcification Induced by High Extracellular Phosphate Imply Activation of Aldosterone Receptor and Transactivation of Epidermal Growth Factor Receptor Victor Manuel Barrientos,[1] Rodrigo Alzamora,[1] Luis F. Michea.[1,2] *[1]Facultad de Medicina, ICBM, Univ of Chile, Chile; [2]Millennium Inst on Immunology and Immutherapy, Univ of Chile, Chile.*

Background: Vascular calcification (VC) is a mayor mortality risk factor in CKD patients. During VC the vascular smooth muscle cells (VSMC) of the tunica media transdifferentiate into osteoblast-like cells. High extracellular phosphate (HP) promotes VC through the induction of the sodium-dependent phosphate cotransporter (Pit1) activity. Recent studies indicate that spironolactone (mineralocorticoid receptor antagonist) ameliorated VC in Klotho-deficient mice. However, the potential activation of mineralocorticoid receptor (MR) and the potential mechanisms that could mediate the activation of the MR are unknown. MR activation produces transactivation of epidermal growth factor receptor (EGFR), a mechanism that could participate in VC. We analyzed if HP, via sodium-dependent phosphate transport, activates MR leading to EGFR transactivation and VC.

Methods: A7r5 VSMC cells were switched from normal to HP medium. We analyzed the time course of receptor activity and the dependence on sodium-dependent phosphate cotransport by using buffers with/without sodium (sodium replaced by choline and potassium). We determined the role of MR and EGFR with pharmacological antagonists (spironolactone and AG1478 respectively) and the intracellular signaling pathways: ERK1/2 and MR genomic effect on an early response gene, the Neutrophil Gelatinase-Associated Lipocalin (NGAL).

Results: HP (2.5mM, sodium buffer) induced a time-dependent activation of ERK (2.7 times, 10 min *vs*. 0 min; $P<0.05$; n=4). The incubation of VSMC with no-sodium HP buffer did not cause ERK activation (n=4). Spironolactone (10uM) or AG1478 (10uM) in the culture medium suppressed HP-induced activation of ERK ($P<0.05$ vs. 0 min; n=4). Finally, HP induced NGAL mRNA expression (1.67 times *vs.* NP; $P<0.05$; n=4). Spironolactone prevented the induction of NGAL. In contrast, AG1478 did not prevent NGAL induction by HP (n=4).

Conclusions: We conclude that HP activates the MR via sodium-dependent phosphate transport, leading to EGFR transactivation in VSMC. Funding: FONDECYT 1130550-1151423, IMII P09-016-F.

Inhibiting Post-Translational Core Fucosylation Prevents Vascular Calcification in Chronic Kidney Disease Wen Xin Yu. *Nephrology, The First Affiliated Hospital of Dalian Medical Univ, Dalian, Liaoning, China.*

Background: Vascular calcification (VC) is an independent risk factor for cardiovascular disease and mortality in chronic kidney disease. Post-translational core fucosylation is implicated in a number of pathological processes.

Methods: We investigated the role of core fucosylation and key receptors of TGF-β1 pathway on calcified arteries *in vivo*. To determine whether blocking core fucosylation effectively inhibited vascular calcification and TGF-β/Smad signaling pathway, we established an *in vitro* model of phosphate-induced calcification in rat vascular smooth muscle cells (VSMCs) to assess the role of core fucosylation in VC.

Results: Core fucose could be detected at markedly higher levels in calcified VSMCs than control. *Fut8* (α-1,6 fucosyltransferase), the only enzyme responsible for core fucosylation in humans, was significantly upregulated by high phosphate. Exposed to high phosphate condition, blocking core fucosylation in VSMCs by knocking down *Fut8* using a siRNA markedly reduced calcium and phosphorus deposition and Cbfα1 expression (osteoblast-specific transcription factor), and increased α-SMA expression (smooth muscle cell marker). The TGFβ/Smad2/3 signaling pathway is involved in VC. *Fut8* siRNA significantly inhibited TGF-β/Smad2/3 signaling activation in VSMCs cultured in high phosphate media.

Conclusions: This study provides evidence to suggest core fucosylation plays a major role in the process of VSMCs calcification and appropriate blockade of core fucosylation may represent a potential therapeutic strategy for treating VC in end-stage renal disease.

The Anti-Calcific and Anti-Apoptotic Effects of GSK-3 Inhibitors in Cultured Human Aortic Smooth Muscle Cells Narihito Tatsumoto,[1,2] Masaki Arioka,[2] Shunsuke Yamada,[1] Masanori Tokumoto,[3] Kazuhiko Tsuruya,[1,4] Takanari Kitazono,[1] Toshiyuki Sasaguri.[2] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Clinical Pharmacology, Faculty of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [4]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Vascular calcification is an active, cell-mediated, and complex pathology that includes apoptosis of vascular smooth muscle cells (SMCs). Recent experimental studies showed that Wnt/β-catenin signaling pathway is involved in the pathogenesis of vascular calcification. However, it still remains unclear whether or not inhibition of glycogen synthase kinase (GSK)-3, a critical downstream component of Wnt/β-catenin signaling, affects the calcification process of vascular SMCs.

Methods: Human aortic SMCs were incubated in the calcification medium containing 3 mM phosphate and 10% fetal bovine serum. Calcification media were supplemented with either vehicle, lithium chloride (15 mM), or SB216763 (10 μM); the latter two are known as GSK-3 inhibitors. After 14 days of incubation, calcification of human aortic SMCs was assessed by von Kossa staining and calorimetric quantification of calcium (Ca) content after elution with 0.6N hydrochloride. The expressions of Wnt/β-catenin signaling pathway and apoptosis-related proteins were analyzed by western blotting.

Results: Calcification medium increased the Ca content in the human aortic SMCs in parallel with an increased expression of cleaved caspase-3. Both GSK-3 inhibitors decreased Ca deposition and reduced phosphorylated-β-catenin to total-β-catenin ratio, suggesting the activation of Wnt/β-catenin signaling pathway. The increased expression of cleaved caspase-3 was suppressed by the treatment with both GSK-3 inhibitors.

Conclusions: GSK-3 inhibitors attenuated Pi-induced calcification via suppression of apoptosis in human aortic SMCs.

High Phosphorus Leads to Aortic Calcification via β-Catenin in Chronic Kidney Disease Li Yao, Tianhua Xu, Chuang Ren, Xing Fan, Jiangmin Feng, Jianfei Ma, Lining Wang. *Nephrology, The First Hospital of China Medical Univ, ShenYang, LiaoNing, China.*

Background: Vascular calcification is a risk factor for cardiovascular events and has high prevalence with occurrence of chronic kidney disease (CKD). However, the molecular mechanism underlying this pathogenic process is still obscure.

Methods: Vascular smooth muscle cells (VSMCs) were induced by high concentration of phosphorus (Pi) at 2.5 mM and subjected to cell calcification analyzes. The effect of high Pi on Wnt/β-Catenin pathway was measured by TOP/FOP-Flash reporter assay. The transcriptional regulatory of β-Catenin on Pit-1 was confirmed by promoter reporter and ChIP assays. 5/6 nephrectomized (Nx) rat were used asin vivo model and divided into four different groups. Serum levels of phosphate, calcium, creatinine and blood urea nitrogen were measured. Abdominal aortic calcification was examined.

Results: High Pi induced VSMCs calcification, down-regulated expression levels of VSMC markers and up-regulated levels of osteogenic markers. High Pi activated Wnt/β-Catenin pathway and β-Catenin activity. And β-Catenin was involved in the process of high Pi induced VSMC calcification. Further investigation revealed that β-Catenin transcriptionally regulated Pit-1, a necessary player in VSMC osteogenic phenotype change and calcification. The in vivo study showed that β-Catenin was involved in rat abdominal aortic calcification induced by high Pi. When knocking down expression of β-Catenin in rat, the occurrence of aortic calcification was reduced.

Conclusions: These results suggest that β-Catenin is an important player in the process of high phosphorus induced aortic calcification in CKD.

FR-PO1026

Hydrogen Sulfide (H2S) Attenuates CPP-Induced Calcification of Vascular Smooth Muscle Cells via Activation of the KEAP1/NRF2/NQO1 Signaling Pathway Parisa Aghagolzadeh,[1] Ramin Radpour,[1] Matthias Bachtler,[1] Harry Van Goor,[2] Edward R. Smith,[3] Alex Odermatt,[4] Willi Jahnen-Dechent,[5] Andreas Pasch.[1] *[1]Univ Hospital Bern, Bern, Switzerland; [2]Univ Medical Center Groningen, Netherlands; [3]Royal Melbourne Hospital, Australia; [4]Univ of Basel, Switzerland; [5]RWTH Univ of Aachen, Germany.*

Background: Vascular calcification is associated with increased morbidity and mortality in chronic kidney disease (CKD). Secondary calciprotein particles (CPP) and oxidative stress induce calcification of Vascular Smooth Muscle Cells (VSMC) in vitro. Hydrogen sulfide (H_2S) is a signaling molecule with antioxidant properties. Here we investigated the anticalcific properties of H_2S in a CPP-induced *in vitro* model of VSMC mineralisation.

Methods: We used next-generation sequencing to investigate differential transcriptomic changes in NaHS- (H_2S-donor) treated versus non-treated calcifying VSMC. The potential role of regulatory pathways in calcification-prevention identified using this approach were investigated using RT-PCR, Western-blotting and silencing with small interfering RNA (siRNA).

Results: Secondary CPP induced calcification of VSMC. Transcriptomic analysis revealed the dysregulation of 423 genes in VSMC upon exposure to secondary CPP. H_2S-treatment prevented calcification and exerted anti-oxidant activity in VSMC. The specific anti-calcification activity of H_2S was mediated via NAD(P)H dehydrogenase [quinone] 1 (NQO1). Corroborating this finding, silencing of the Kelch-like ECH-associated protein 1 (KEAP1) (84% silencing) enhanced NQO1 expression, while silencing of Nuclear factor (erythroid-derived 2)-like 2 (NRF2) (85% silencing) reduced the expression of NQO1 and the calcification-suppressing activity of H_2S.

Conclusions: H_2S attenuates CPP-induced calcification of VSMCs *in vitro* via activation of the *NQO1* and KEAP1-NRF2 antioxidant defense system.

FR-PO1027

The Protective Effects of Caloric Restriction on P-Induced Calcification via the Up-Regulation of SIRT1 in Human Vascular Smooth Muscle Cells Masanori Tokumoto,[1] Shunsuke Yamada,[2] Kazuhiko Tsuruya,[3] Takanari Kitazono,[2] Hiroaki Ooboshi.[1] *[1]Dept of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: It is well-known that caloric restriction is effective for the prevention of premature aging via the up-regulation of sirtuin. However, the effect of caloric restriction on vascular calcification remains unknown. Thus, we examined how caloric restriction affects P-induced calcification in human vascular smooth muscle cells (VSMCs).

Methods: Human VSMCs were cultured in the culture media (DMEM) with low or high glucose (100 or 450 mg/dl) for a week, followed by either low or high glucose DMEM with the additional P load of 0, 1.0, 1.5, or 2.0mM for another week. The degree of calcification, the content of calciprotein particles (CPP) in the media, and the expression of SIRT1, intrinsic calcification inhibitors and osteogenic differentiation markers were examined at Day 8 and 14. The degree of calcification was expressed as the Ca content precipitated on the human VSMCs, and the CPP content was expressed as the Ca content in the precipitation centrifuged by 16,000g for 2 hours at room temperature.

Results: Regardless of P load amount, the degree of both calcification and CPP formation and the expression of bone morphogenetic protein 2 (BMP2), an osteoblastic differentiation marker, at Day 14 were the lowest in human VSMCs with the alternation of DMEM from high to low glucose (caloric restriction). At Day 8, the expression of SIRT1 and osteoprotegerin (OPG), a calcification inhibitor, was up-regulated by caloric restriction. The content of calcification at Day 14 correlated with CPP content and BMP2 expression at Day 14, and inversely with SIRT1 and OPG expression at Day 8. The OPG expression at Day 8 correlated with SIRT1 expression at Day 8, and inversely with BMP2 expression at Day 14.

Conclusions: In conclusion, caloric restriction maintained the phenotype of VSMCs and inhibited P-induced calcification via the up-regulation of SIRT1 expression in human VSMCs.

FR-PO1028

Heparin Induces Sclerostin Release in Humans Jacek Borawski, Justyna Zoltko, Barbara Labij-Reduta, Beata Naumnik. *Ist Dept of Nephrology, Medical Univ, Bialystok, Poland.*

Background: Sclerostin (Scl) - an inhibitor of bone formation is also involved in cardiovascular calcification that is highly prevalent in maintenance HD patients. Recently, intriguing heparin-binding features of Scl molecule were discovered. We conducted a pilot study to challenge for the first time the hypothesis that iv enoxaparin (ENX) releases Scl into the blood.

Methods: In 16 males (46.7±11.3 yrs, 85.5±8.62 kg, BMI 26.7±3.11 kg/m^2) fasted venous blood samples (T_0) were obtained and an iv bolus of ENX was injected (82.5±6.83 mg, 0.97±0.06 mg/kg, 3.12±0.32 mg *per* kg/m^2). The consecutive samples were drawn after 10 min (T_{10}), 2 h (T_{2h}), 6 h (T_{6h}) and 24 h (T_{24h}).

Results: Plasma immunoreactive Scl levels changed following iv ENX administration (χ^2 ANOVA=50.7, P<0.0001). They increased consistently by a mean of 184% (min 51% - max 461%): from 0.56±0.17 ng/mL at T_0 to a median of 1.36 (1.08–1.97) ng/mL at T_{10} (Wilcoxon P=0.0004). At T_{2h} Scl levels were 0.71±0.19 ng/mL, lower than those at T_{10} (P=0.004) and elevated by a median of 21% vs baseline (P=0.0005). At T_{6h} Scl levels were 0.61±0.16 ng/mL and still higher by a median of 8.7 % vs baseline (P=0.017). At T_{24h} they normalized (0.56±0.16 ng/mL).The percentage of increase in plasma Scl (ΔScl) at T_{10} tended to be directly associated with the dose of ENX *per* kg (Spearman *rho*=0.430, P=0.096) and was significantly and directly correlated with ENX dose *per* kg/m^2 of BMI (*rho*=0.587, P=0.017). Notably, the ΔScl at T_{10} strongly and inversely correlated with the baseline levels of Scl (*rho*= -0.747, P=0.0008). The above relation was also inverse but not significant for ΔScl at T_{2h} and T_{6h} (both P>0.138). A strong negative association between the ΔScl increment at T_{10} vs baseline and the ΔScl fall at T_{2h} vs T_{10} was also observed (*rho*= - 0.835, P<0.0001).

Conclusions: The rapid, extensive and dose-dependent increase in plasma Scl constitutes a novel pharmacological effect of iv ENX. Plausible hypotheses to prove and of importance to nephrologists are: 1) the rise in Scl results from its liberation from vascular stores; 2) the effect leads to depletion of the inhibitor; 3) the use of ENX for HD anticoagulation (~75.000 mg a year!) promotes/propagates vascular calcification in HD patients.

MicroRNA-34b/c Inhibits Uremia Related Vascular Smooth Muscle Cells Calcification via a SATB2/Runx2 Pathway Jianbing Hao, Lirong Hao. *The Second Nephropathy and Hemodialysis Center, The First Affiliated Hospital of Harbin Medical Univ, Hrbin, Heilongjiang, China.*

Background: Vascular (vascular smooth muscle cell, VSMC) calcification is a common complication of end stage renal disease (ESRD). Increasing evidence shows that aldosterone and specific microRNAs play an important role in VSMC calcification. In this study, we aimed to explore the mechanistic links between miR-34b/c and aldosterone in VSMC calcification *in vitro* and *in vivo*.

Methods: First, the levels of aldosterone, miR-34b/c, and special AT-rich sequence-binding protein 2 (SATB2) were measured. Then, miR-34b/c mimics or inhibitors were transfected into VSMCs to evaluate the function of miR-34b/c. Luciferase reporter assays were used to demonstrate whether SATB2 was a direct target of miR-34b/c.

Results: Aldosterone and SATB2 were found to be markedly upregulated during VSMC calcification, whereas miR-34b/c expression was downregulated. Treatment with the mineralocorticoid receptor (MR) antagonist eplerenone inhibited VSMC calcification. In aldosterone-induced VSMC calcification, miR-34b/c levels were downregulated and SATB2 protein was upregulated. Furthermore, miR-34b/c overexpression alleviated aldosterone-induced VSMC calcification as well as inhibiting the expression of SATB2 protein, whereas miR-34b/c inhibition markedly enhanced VSMC calcification and upregulated SATB2 protein. In addition, luciferase reporter assays showed that SATB2 is a direct target of miR-34b/c in VSMCs. Overexpression of SATB2 induced Runx2 overproduction and VSMC calcification.

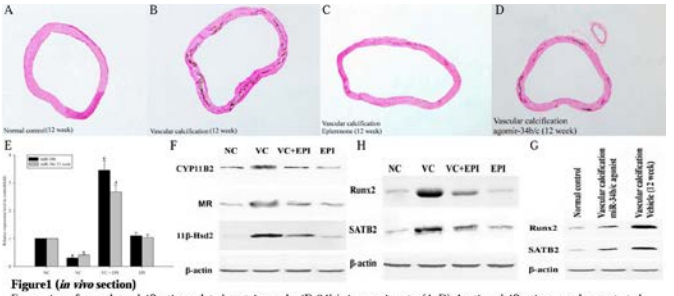

Figure1 (*in vivo* section)
Expression of vascular calcification-related proteins and miR-34b/c in uremia rats. (A-D) Aortic calcification was demonstrated by Von Kossa staining (10×4). (E) Expression of miR-34b/c in aortic tissue as detected by qPCR. (F) The levels of aldosterone and aldosterone function-related protein (MR, 11β-Hsd2, and CYP11B2) were increased in the calcified aortas of uremic rats. (G-H) Levels of SATB2 and Runx2 protein in aortic tissue as detected by western blot analysis (n = 8, mean ± SD, *P < 0.001 versus normal control group, #P < 0.001 versus vascular calcification).
NC: normal control; **VC:** vascular calcification; **VC+EPI:** vascular calcification+ eplerenone; **EPI:** eplerenone

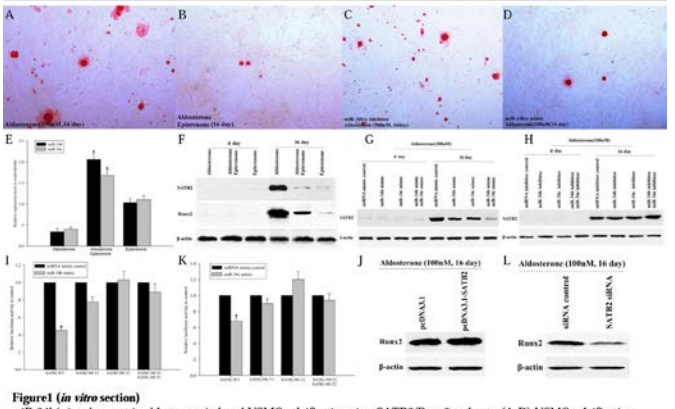

Figure1 (*in vitro* section)
miR-34b/c involvement in aldosterone-induced VSMC calcification via a SATB2/Runx2 pathway. (A-D) VSMC calcification was evaluated by Alizarin Red S staining (10×20). (E) Expression of miR-34b/c in calcified VSMCs as evaluated by qPCR. (F-H) The SATB2 and Runx2 levels in calcified VSMCs were detected by western blot analysis (n=3, mean ± SD, *P < 0.001 versus day 0). (I-K) miR-34b/c targets the 3'-UTR of the SATB2 gene in VSMCs. (n=3, mean ± SD, *P < 0.01 versus the miRNA mimic control). (J-L) SATB2 regulates VSMC calcification via a Runx2-dependent pathway. (n=3, mean ± SD, *P < 0.01 versus the siRNA control).

Conclusions: miR-34b/c participates in aldosterone-induced VSMCs calcification through a SATB2/Runx2 pathway in uremic rat. miR-34b/c might be a negative regulator and potential therapeutic target of VSMC calcification.

β-Glucans Counteract Phosphate-Induced Vascular Calcification by Reducing miR-145-Driven Osteogenic Differentiation of Vascular Smooth Muscle Cells

Sara Panizo,[1] Natalia Carrillo-Lopez,[1] M. Vittoria Arcidiacono,[2] Anabel Castro,[2] Petya Valcheva,[2] Laura Martinez-Arias,[1] Emerenziana Ottaviano,[1] Isabel Rodriguez,[1] Jorge B. Cannata-Andia,[1] Adriana S. Dusso.[1] *[1]Bone and Mineral Reseach Unit, HUCA. RedinRen del ISCIII. Univ de Oviedo, Oviedo, Asturias, Spain; [2]Experimental Nephrology, IRBLleida, Lleida, Cataluña, Spain.*

Background: In CKD, high phosphorus (P)-induced inflammatory signals and osteogenic vascular smooth muscle cell (VSMC) differentiation contribute to vascular calcification. Because anti-inflammatory dietary barley ß-glucans reduce aortic calcification in uremic rats fed high P, this study characterized ß-glucans anti-calcifying properties.

Methods: Aortic calcium, miR-145 content, mRNA levels of inflammatory (TNFa, ADAM17) and/or osteogenic differentiation (a-actin, Runx2, Osterix) markers were measured in: a) Aortas from 5/6 nephrectomized rats fed high P, with or without 40mg of barley ß-glucans daily, for 4 weeks; b) Aortic rings from normal rats or c) A7r5 cells (rat VSMC) exposed to calcifying media (2mM Ca; 3mM P), with or without synthetic barley ß-glucans (100 ug/ml) for 4 days.

Results: In uremic rats, dietary ß-glucans reduced aortic calcium content by 50%, which paralleled 80% decreases in TNFa and ADAM17 mRNA expression, an inflammatory loop that down-regulates miR-145, critical to maintain VSMC phenotype. Importantly, in these uremic rats, aortic miR-145 reductions correlated with increased calcification ($r=0.83$; $p<0.05$). Overexpression and silencing of miR-145 in A7r5 cells corroborated this novel role for miR-145 reductions in the osteogenic differentiation and calcium deposition induced by a calcifying medium. Significantly, in aortic rings and A7r5 cells exposed to calcifying media, ß-glucans reduced calcium deposition by 68% and attenuated both miR-145 reductions (35%) and osteoblastic VSMC differentiation (a-actin reductions (53%); Runx2 (54%) and osterix (57%) increments).

Conclusions: ß-glucans protect against high P-induced calcification, at least in part, by an unprecedented action: The maintenance of miR-145 levels and the phenotype of VSMC.

Matrix Vesicles Induce Cell-Cell Communication That Facilitates Vascular Calcification

Neal X. Chen,[1] Kalisha O'Neill,[1] Sharon M. Moe.[1,2] *[1]Medicine, Indiana Univ School of Medicine; [2]Roduebush VAMC, Indianapolis.*

Background: In patients with CKD and ESRD, the major risk factor for progression of arterial calcification is the presence of existing (baseline) calcification. We have shown that VSMC from CKD rats produce matrix vesicles (MV) that are similar to exosomes. We hypothesized that calcification of arteries is propagated/extended by MV induced cell-cell communication from calcifying VSMC to normal VSMC.

Methods: We isolated MV from VSMC from Cy/+ rats with advanced CKD incubated with high phosphorus media. MVs were co-cultured with VSMC from normal littermates and endocytosis examined by confocal microscopy. MV mediated alteration of intracellular calcium ($[Ca]_i$), MAP kinase signaling, and gene expression in recipient VSMC were assessed using calcium Rhod-3 Calcium Imagingt, Western blot, and qPCR, respectively.

Results: The addition of MV from VSMC from CKD rats enhanced the calcification of recipient VSMC. Confocal imaging confirmed that MV can be endocytosed by recipient VSMC. The addition of MV to normal VSMC increase $[Ca^{2+}]_i$. In contrast, the addition of MV similarly isolated from NIH-3T3 fibroblasts to VSMC had no effect on $[Ca^{2+}]_i$despite evidence that both MV can be endocytosed. MV-induced increased in $[Ca^{2+}]_i$ in recipient VSMC is partially mediated by 1,4,5-trisphosphate (IP3)-induced $[Ca^{2+}]_i$release as treatment with an IP3 inhibitor reduced MV-induced increase in $[Ca^{2+}]_i$ In contrast, blocking L-type calcium channel with verapamil had no effect. The addition of MV also increased the activity of phospho-p44/42 MAPK and phospho-MEK1 in recipient VSMC. The inhibitor of MAP kinase, U0126, also decreased MV-induced increase in $[Ca^{2+}]_i$ in VSMC. Finally, the addition of MV altered gene expression involved in VSMC phenotype (SM22α), osteoblastic differentiation (BMP-2) and oxidative stress [NOX1 and angiotensin II type I receptor (AT1R)] in recipient VSMC.

Conclusions: MV isolated from VSMC from rats with CKD are endocytosed by recipient VSMC from normal rats, increase $[Ca^{2+}]_i$ and MAPK cell signaling, modify gene expression and increase calcification of the normal recipient VSMC. This cell-cell communication may lead to propagation of arterial calcification in CKD.

Vitamin K2 Supplementation and Arterial Stiffness in the Renal Transplant Population – A Single-Arm, Single-Center Clinical Trial

Sola Aoun Bahous,[1,2] Essa Hariri,[1] Anthony G. Mansour,[1] Yazan Daaboul,[1] Serge Korjian,[1] Andrew El Alam,[1] Hala Kilany,[1,2] Albert Karam,[1,2] Antoine Stephan.[1,2] *[1]School of Medicine, Lebanese American Univ, Byblos-Jbeil, Lebanon; [2]Div of Nephrology, Lebanese American Univ Medical Center - Rizk Hospital, Ashrafieh, Lebanon.*

Background: Functional vitamin K2 deficiency is highly prevalent among renal transplant recipients and is associated with an increased risk of cardiovascular (CV) disease. The association between vitamin K2 supplementation and improvement in arterial stiffness, a surrogate of early CV disease, has not been investigated.

Methods: The KING trial is a single-arm pilot study that evaluated the association between the change in measures of functional vitamin K2 status and arterial stiffness following 8 weeks of vitamin K2 supplementation (360 µg qd) among 60 renal transplant recipients with stable graft function. Functional vitamin K2 deficiency was defined as serum dephosphorylated-uncarboxylated Matrix Gla Protein (dp-ucMGP) > 500 pmol/L. Arterial stiffness was evaluated by carotid-femoral pulse wave velocity (CFPWV).

Results: At baseline, the prevalence of functional vitamin K2 deficiency was 53.3%. After supplementation, mean dp-ucMGP concentration was significantly reduced by 55.1%, and the prevalence of functional vitamin K deficiency decreased to 13.3% ($p=0.001$). Vitamin K2 supplementation was associated with a 14.2% reduction in mean CFPWV at 8 weeks (mean pre-CFPWV=10.0±2.4 m/s vs. mean post-CFPWV=8.4±1.5 m/s; $p<0.001$). When controlled for age, duration of hemodialysis and transplant, and change in mean arterial pressure from baseline to 8 weeks, the improvement in arterial stiffness remained independently associated with the improvement in dp-ucMGP ($p=0.02$).

Conclusions: Among renal transplant recipients, vitamin K2 supplementation for 8 weeks is associated with improvement in functional vitamin K2 status and arterial stiffness.

Apabetalone Reduces Levels of Key Markers Involved in Vascular Calcification Ewelina Kulikowski,[1] Dean Gilham,[1] Laura Tsujikawa,[1] Sylwia Wasiak,[1] Kamyar Kalantar-Zadeh,[2] Christopher Halliday,[1] Jan O. Johansson,[1] Michael Sweeney,[1] Norman C.W. Wong.[1] *[1]Resverlogix, Calgary, AB, Canada; [2]Univ of California, Irvine, Orange, CA.*

Background: Apabetalone (RVX-208) treatment lowered alkaline phosphatase (ALP) in CVD patients in phase II studies. Apabetalone inhibits the interaction of BET (bromodomain extra terminal) proteins & acetyl-lysine marks on histone tails. BET proteins control recruitment of transcriptional machinery to coordinate gene transcription of sensitive genes, including factors that contribute to vascular calcification. Vascular calcification is an underlying process in CKD pathogenesis. We examined the effect of apabetalone on markers known to contribute to vascular calcification in vitro & in the clinic.

Methods: Microarrays of human whole blood (WB) & primary human hepatocytes (PHH) treated with apabetalone were analyzed. Expression of vascular calcification markers was evaluated using real-time PCR in PHH & U937 macrophages. Proteomic analysis of plasma samples (n=47 apabetalone; n=47 placebo) from phase II CVD trials was performed using SOMAscan™. SOMAscan™ uses aptamers which are highly specific for their cognate protein, to assess levels of ~1300 proteins.

Results: In WB treated with apabetalone, microarrays showed suppression of a variety of vascular inflammation & calcification factors. Expression of osteopontin (SPP1), a proinflammatory molecule, is reduced in LPS stimulated U937 macrophages (-94%) as well as in PHH (-82%). Expression of additional calcification related genes was also reduced in PHH including ALP, RANKL, CCL2, IL8, OPG & BMP2. In the 26 week ASSURE trial, circulating levels of OPG (associated with higher incidence of arterial calcification) & IBSP (major component of bone matrix) were reduced by 14% & 18% ($p<0.05$) versus placebo.

Conclusions: BET inhibition by apabetalone decreases expression & circulating levels of markers known to contribute to vascular calcification, which may decrease pathology & mortality in CKD. The potential of apabetalone to treat high-risk diabetes & CKD patients is being explored in the phase III BETonMACE trial. Further, a PK study in severe renal impaired patients is underway.

FR-PO1034

Hemodialysis versus Peritoneal Dialysis: A Five Years, Two International Centers, Retrospective, Observational Study Renhua Lu,[1,2,3] Leonardo Claudino Ribeiro,[3] Claudio Ronco.[3] *[1]Dept of Nephrology, Kashgar Prefecture Second People's Hospital, Kashgar, Sinkiang, China; [2]Dept of Nephrology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China; [3]Nephrology, Dialysis and Transplantation, San Bortolo Hospital, the International Renal Research Inst of Vicenza, Vicenza, Veneto, Italy.*

Background: It is well known that the incidence of ESRD become increasingly higher all over the world. Given that it is difficult to randomize ESRD patients to either HD or PD, differences between these two renal replacement therapy are of major interest and still controversial.

Methods: All data of maintenance dialysis patients including HD and PD during 2009 to 2013 in Ren Ji Hospital, china and San Bortolo Hospital, Italy were selected by Network. Patients who changed the therapy from HD to PD or PD to HD during this study were excluded.

Results: 919 maintenance dialysis patients were included in this study (HD=509,PD=410). Baseline laboratory test data were comparable. After five years follow-up, to compare with PD, MAP and weight were higher in HD patients. The level of HCO_3^- was significantly better in PD patients than that in HD patients. Regarding the infection markers such as WBC and CRP were significantly higher in PD patients than HD patients. Hemoglobin was significantly higher in PD patients than HD patients. Total albumin and phosphate were higher in HD patients than PD patients. The top three causes of death in HD patients ranged as cerebral vascular disease, infection and cardio vascular disease. In PD, infection was the main cause of death, followed as cerebral vascular disease and cardio vascular disease. The Kaplan-Meier patient survival was similar between HD and PD patients.

Conclusions: Based on 5 years data of two international dialysis centers, we demonstrated that lipid metabolism and nutrition were better in HD patients. However, BP control, acid-base balance, P control and the concentration of Hb and iron were better in PD patients. PD patients might have more chance of infection. The main cause of death in HD and PD is cerebral vascular disease and infection respectively. Considering to dialysis vintage, the 5-year survival rate for HD and PD patients is similar.

FR-PO1035

Outcomes of Pediatric Peritoneal Dialysis Patients: Experiences from a Single Center in Khartoum, Sudan Alice Topping,[1] Rasha Hassan Hussein,[2] Jochen G. Raimann,[1] Peter Kotanko,[1,3] Hasan Abu-Aisha.[4] *[1]Renal Research Inst, New York, NY; [2]Soba Univ Hospital, Khartoum, Sudan; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Sudan PD Program.*

Background: Peritoneal dialysis (PD) is the most common modality for pediatric patients (pts) with end stage renal disease (ESRD) (Warady, et al 2012) and is particularly advantageous in developing countries due to less resource requirements. The Soba University Hospital (SUH) in Khartoum, Sudan, began its PD program in 2005. It aims to encourage PD use, particularly in children, and train health professionals on PD. This descriptive analysis aims to characterize the population and their outcomes at the hospital.

Methods: Retrospective study of all pediatric PD pts treated at SUH from 06/2005 to 06/2015. Descriptive statistics of pt demographics, causes of ESRD and clinical outcomes including episodes of peritonitis. Factors associated with mortality are analyzed by development of a Cox Proportional Hazards (PH) model.

Results: One hundred twenty pts who received treatment during the study period were included in this analysis (44% male, median age 10 yrs [1-17 yrs], median length of PD 350 days). Forty pts traveled >200km to the center for treatment. The most common causes of ESRD were glomerulopathy (38%) and congenital urological malformation (24%). Fifty-two cases of peritonitis were recorded, 46 first episodes (eps) and 6 secondary eps. The rate of first peritonitis ep was one ep/2.85 years of follow-up. The rate of second peritonitis ep was one ep/6.39 years of follow up. During the study period, 24% of pts died, 32.5% switched to HD and 17.5% received transplants. The mortality rate was 16.6 deaths/100 patient years at risk. The Cox PH model shows 3 times higher hazard of death in winter compared to summer [HR 3.0 (95% CI 1.67-5.39)] and a 2.5 higher hazard in autumn (95% CI 1.43- 4.54). Age was also associated with risk of death (HR 1.07 [95% CI 1.01-1.13]).

Conclusions: PD is a common and appropriate method of renal replacement therapy for pediatric ESRD pts. These results provide a view into the potential of PD in pediatric pts in developing countries. Funding for PD programs such as at SUH can help provide essential services to children with ESRD.

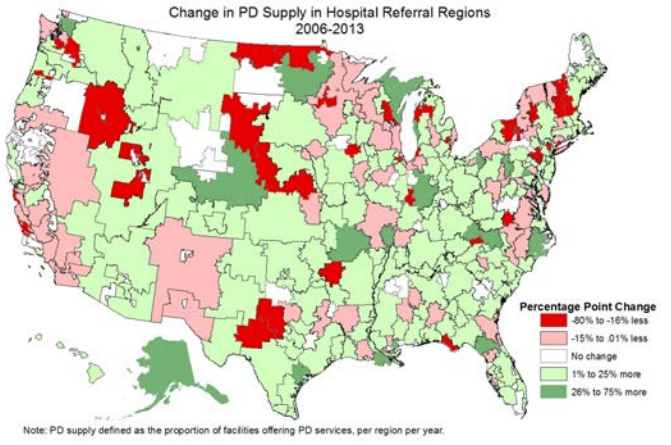
Changes in Regional Dialysis Facility Provision of Peritoneal Dialysis after Medicare Payment Reform Virginia Wang,[1,2] Cynthia Coffman,[1,2] Linda L. Sanders,[1] R. Hirth,[3] Shoou-Yih Daniel Lee,[4] Matthew L. Maciejewski.[1,2] *[1]Duke Univ, Durham, NC; [2]HSRD, Durham VA Med Ctr, Durham, NC; [3]Univ of Mich, Ann Arbor, MI; [4]UNC-CH, Chapel Hill, NC.*

Background: Much attention has been paid to patient use of peritoneal dialysis (PD), with little consideration of the supply-side PD provision by dialysis facilities. Medicare implemented an ESRD bundled payment that is expected to encourage greater PD provision among providers.

Methods: We used data from the USRDS on dialysis facilities in 2006-2013. Choropleth maps illustrated change in the regional distribution of facilities offering PD services before and after bundled payment in 2011. A random effects model examined the impact of payment reform on the change in the proportion of facilities offering PD in regions, adjusting for facility and patient demographics.

Results: Growth in the number of facilities offering PD outpaced growth in total US dialysis facilities, but there was significant regional variation in PD supply. Between 2006 and 2013, the unadjusted mean (± SD) percentage of regional US facilities offering PD increased from 41% (± 20%) to 43% (±20%). The majority of regions experienced growth in PD service offerings, most notably in rural portions of the South, Midwest, and West.



In adjusted analysis, the mean percentage of regional facilities offering PD increased 2.8% [95% CI 1.6%, 4.1%] before and after the bundled payment (2011-13). Regional PD prevalence, white ESRD patients, concentrated dialysis markets (versus more competitive markets), and per capita income were associated with increases PD supply; employed ESRD patients was associated with diminished PD supply (all $p< 0.0001$).

Conclusions: Results suggest the success of bundled payment to align patient preferences as demonstrated by increasing availability of PD. Future research should explore the extent to which modality choice is available and accessible to various subgroups of patients with ESRD.

FR-PO1037

Effect of Distance and Time to a Home Dialysis Unit on Home Dialysis Utilization Rajat Maheshwari,[1] Ninad S. Chaudhary,[2] Russell Griffin,[2] Eric L. Wallace.[1] *[1]Nephrology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Dept of Epidemiology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Distance to a home dialysis unit (HDU) may pose a barrier to home dialysis uptake and impact outcomes. Studies have shown that with increasing distance to an HDU, home dialysis utilization increases, however its impact on outcomes has received less attention.

Methods: This is a retrospective cohort analysis of incident dialysis patients in 2010 using USRDS data. Patients and dialysis units were geocoded to the population center of each zip code using from which the travel distance and time to their closest HDU was calculated. Driving distance was further categorized as: 0-10 miles, 10-30 miles, >30 miles, and the travel time was categorized as: 0-30, 30-60, >60 mins. We assessed the first dialysis modalities in-center hemodialysis (ICHD), and home dialysis which included PD and home hemodialysis (HHD). Bivariate associations were reported using one-way ANOVA and chi-square tests were deemed appropriate. Logistic regression analyses adjusted for demographics, and medical conditions were used to determine the effect of distance and time to the closest HDU on utilization of home dialysis compared to ICHD.

Results: We analysed 84202 incident dialysis patients. Overall, 91% utilized ICHD, 8.3% PD, and 0.7% HHD. Dialysis patients living >30 miles from a HDU were more likely to utilize PD (OR=1.40; 95%CI 1.28-1.53) but less likely to use HHD (OR=0.66; 95%CI 0.47-0.93) than those living <10 miles. Patients living >30 miles from their closest HDU on home dialysis trended towards higher technique failure rates than those <10 miles (OR=1.17 95%CI 0.77-1.77) but this did not reach statistical significance. Patients >30 miles from an HDU whose primary modality was ICHD trended towards an increased likelihood of switching to home dialysis (OR=1.13, 95%CI 0.96-1.32). Similar significant effects were observed when stratifying by time to a HDU.

Conclusions: Patients living remotely from their closest HDU are more likely to use PD but less likely to use HHD. Larger studies are needed to determine if the effect of distance from a HDU truly impacts outcomes such as technique failure rates.

Does Dialysis Modality Impact Employment? A Cross Sectional Study R. Ram,[1] Boju Sangeetha Lakshmi,[1] Anil Kumar Cheni Venkata,[1] Hari Krishna Reddy Mogili,[1] V. Siva Kumar,[1] Abhilash Koratala.[2] *[1]Sri Venkateswara Inst of Medical Sciences, India; [2]Univ of Florida.*

Background: Long-term dialysis therapy for End stage renal disease (ESRD) takes a heavy toll on quality of life the patient. Dialysis creates a whole range of obstacles to employment which includes, health related barriers, economic barriers and attitudinal barriers. This study was designed to gain insights into the employment rates in maintenance dialysis patients which no Indian study has reported so far to the best of our knowledge.

Methods: A cross-sectional study of employment of patients on hemodialysis (HD) and peritoneal dialysis (PD) in a state government run tertiary institute in South India was performed between June 2015 and December 2015. Only patients who completed 3 months of regular dialysis were included. The data was collected using a de-identified, self-administered patient survey after obtaining a formal written consent.

Results: The number of patients on HD was 157 and on PD was 69.The employment status before initiation of dialysis was 60% (93 out of 155) and 63.7% (44 out of 69) in HD and PD groups respectively. After initiation, loss of employment was observed in 44% (41 out of 93) in HD and 51.2% (26 out of 44) in PD group (p= 0.2604). Even though there was fall in absolute number of job holders in both the blue and white collar jobs, the proportion of job holders in the white collar jobs improved. On univariate analysis, the factors that are associated with the loss of employment were male sex, age between 50 and 60 years,number of comorbidities > 2, illiteracy and blue collar versus white collar job before the initiation of dialysis. The majority of patients had the scores above 80 on Karnofsky Performance Scale and the majority belonged upper and middle strata than lower strata on Modified Kuppuswamy's socioeconomic status scale.

Conclusions: Our study shows that there was no difference between HD and PD in the loss of employment of our patients which is in contrast to the impression that the PD offers freedom from treatment schedules and possibility for out-of-work-hours dialysis, making it a suitable option for employed patients.

FR-PO1039

Factors Associated with Eventual Renal Replacement Therapy Decisions after Evaluation of Patients Initially Planned for Peritoneal Dialysis Benjamin Zhi En Khoo,[1] Hankun Wang,[2] Adrian Liew.[1] *[1]Renal Medicine, Tan Tock Seng Hospital, Singapore; [2]National Univ of Singapore.*

Background: Ideal outcomes in patients on peritoneal dialysis (PD) are dependent on multiple medical and social factors. Patients with end-stage renal disease are often started on PD without in-depth assessment for these influences. Since 2011, our centre mandated that all patients being planned for PD are to be evaluated by a multidisciplinary PD team. This study aims to evaluate the factors that determined the eventual therapy outcome after pre-PD assessment (PDA).

Methods: We conducted a case-controlled study of 252 patients who were initially planned for PD, undergoing PDA from 2011-2015. Outcomes after the PDA included continuation with PD [n=171,67.8%], switch to hemodialysis (HD) [n=64,25.4%] or acceptance of palliative treatment (PALL) [n=17,6.8%]. Demographics, medical and social variables were obtained from medical records.

Results: 252 patients (mean age 63.2±14.1 years, 52% female, 75.8% Chinese and 75.2% diabetics) were evaluated during PDA. Older patients (PALL:79.5±7.6 vs PD:62.4±14.3 vs HD:61.1±12.0,p<0.0001) with a higher Charlson Comorbidity Index (PALL:9.35±1.80 vs PD:7.02±2.72 vs HD:7.07±2.46,p=0.0022), requiring ADL (PALL:47.1% vs PD&HD:11.5%,p=0.002) and mobility assistance (PALL:82.4% vs PD&HD:43.8%,p=0.006) were likely to accept PALL after PDA. For patients who eventually started dialysis, those who continued with the decision for PD were more likely not to have received interim HD (68.4% vs 42.2%,p<0.001), and had higher serum albumin (30.7±5.5 vs 28.6±6.0,p=0.0096). Factors which were traditionally thought to have a poorer impact on the choice of PD were not significantly different between the dialysis groups, including BMI, DM, HbA1c, prior abdominal surgery, ADPKD, respiratory diseases, small housing size or having pets.

Conclusions: Engagement on the option of palliative treatment could be considered for older patients with poorer functional status. Exposure to prior hemodialysis is likely to waive the initial decision for PD. With improved PD technology and effective mitigation of social factors, traditional issues that were previously unattractive are no longer obstacles to PD.

FR-PO1040

Routine Use of Decision Making Tools Increases Peritoneal Dialysis Choice and Take on in an International Setting Belen Marron,[1] Janusz Ostrowski,[2] Delia Timofte,[3] Marietta Török,[4] Michael Roesch,[5] Claudia Martin,[6] Pawel Kochman,[2] Orosz Attila,[7] Jose C. Divino-Filho,[8] Jorgen B.A. Hegbrant.[9] *[1]Diaverum Home Therapies. Medical Office, Munich, Germany; [2]Wloklawek Diaverum Clinic, Wloclawek, Poland; [3]Sema Diaverum Clinic, Bucharest, Romania; [4]Rokus Diaverum Clinic, Budapest, Hungary; [5]Schlankreye Diaverum Clinic, Hamburg, Germany; [6]Barracas Diaverum Clinic, Buenos Aires, Argentina; [7]Bajcsy Diaverum Clinic, Budapest, Hungary; [8]Karolinska Inst., Stockholm, Sweden; [9]Diaverum Medical Office, Lund, Sweden.*

Background: Lack of patient choice or inability to offer high quality modality information programs remain as causes for low PD use.

Objectives:To analyze the impact of a structured modality information program with the use of decision making tools (DMTs) on type of modality choice and start.

Methods: Observational, prospective and international registry. All patients under ESRD 4-5 and/or after an unplanned dialysis start (if non-informed before) were recruited to undergo a DMTs process for RRT choice. Process included: personal values evaluation, RRT information with different tools, deliberation support and patient´s modality election.

Results: 1141 patient-aimed modality information between Aug. 2014-Dec. 2015 in 45 clinics (Poland, Romania, Hungary, Germany and Argentina). Staff considered PD as contraindicated in 32%. 800 patients (mean 59,5 y.) were considered optimal for HD/PD (48% were prone for a home therapy). Written information was largely used for 69-95% of patients; DVD in 14-30% and in centre HD/PD touring visits in 10-76%. Relatives' participation in the process was 82%. PD choice (39%) varied among countries: 16% (RO, 12 clinics), 38% (PL, 19 cl.) 41% (HU, 10 cl.), 84% (GE, 3 cl.) and 93% (AR,1 cl.). For patients who started dialysis (n= 612), PD as chronic RRT reached 31% (10% with an unplanned HD start); 13% (RO), 30% (PL), 36% (HU), 75% (GE), 93% (AR).

Conclusions: Use of DMTs at the time of RRT modality choice complies with patient empowerment. A remarkable increase in PD take-on occurred in our clinic network after DMTs process introduction. Therefore, modality information should always be delivered through a structured information process based on decision sharing.

FR-PO1041

Peritoneal Dialysis Annual Dropout in a Large International Setting Belen Marron,[1] Gustavo Lorenzo Moretta,[2] Michael Roesch,[3] Janusz Ostrowski,[4] Marietta Török,[5] Daniel Eduardo Perez,[6] Delia Timofte,[7] Carlos Zuniga,[8] Paul Stroumza,[9] Elisabeth Fabricius,[10] Jorgen B.A. Hegbrant.[11] *[1]Diaverum Home Therapies. Medical Office, Munich, Germany; [2]Diaverum LA Medical Office, Buenos Aires, Argentina; [3]Schlankreye Clinic, Hamburg, Germany; [4]Wloklawek Clinic, Wloclawek, Poland; [5]Rokus Diaverum Clinic, Budapest, Hungary; [6]SEINE Clinic, Montevideo, Uruguay; [7]Sema Clinic, Bucharest, Romania; [8]Colina Clinic, Concepción, Chile; [9]Marseille Clinic, Marseille, France; [10]Visby Clinic, Visby, Sweden; [11]Diaverum Medical Office, Lund, Sweden.*

Background: Peritoneal dialysis (PD) growth is limited by a high annual drop out (DO) (40-75%) which is often not routinely measured.

Objectives: To analyze the introduction of a new tool based on the monitoring of accumulated annual PD DO and the underlying DO causes.

Methods: Observational, prospective registry in 6 European (EU) countries (FR, GE, HU, PL, RO, SWE) and 3 Latin American (LA) countries (AR, CH, UR). LA provided results as a one single region. During Jan 1-Dec 31 2015, all prevalent and incident PD patients were tracked on a monthly basis for DO due to: transplantation (TX), residual renal function (RRF) recovery, transfer to HD (due to peritonitis, exit site issues, catheter problems, ultrafiltration failure, low adequacy, burn out or others), transferred to other centers or death. Total DO, controllable DO (transfer to HD and to other centers) and underlying causes are provided as result/patients at risk.

Results: 1011 pt. (667 prevalent and 344 incident) in 61 clinics were tracked. PD withdrawal: 312 pt. Total DO and controllable DO varied among regions: 49% and 19% in EU vs. 42 and 18% in LA. TX accounted for 8% (higher in PL and lower in LA, GE and RO), RRF recovery 0.3%, transfer to other centers 4%, death 18% (lower in LA and PL). Half of deaths were attributed to cardiac events and 6% to peritonitis. Transfer to HD: 15% (peritonitis 6.5%, catheter issues 2%, low adequacy 1.3%, UF failure 0.4%, burn out 1.2%, others 3.5%).

Conclusions: Annual accumulated DO monitoring increase quality in PD. This tool allows homogeneous comparisons across countries and provides assessment of DO causes that if promptly and efficiently resolved may improve technique and patient survival.

FR-PO1042

Offering Patients Therapy Options in Unplanned Start (OPTiONS) Anna Machowska,[1] Mark Dominik Alscher,[2] Satyanarayana Reddy Vanga,[3] Michael Koch,[4] Michael Aarup,[5] Abdul Rashid Tony Qureshi,[1] Bengt Lindholm,[1] Peter Rutherford.[6] *[1]Renal Medicine & Baxter Novum and Renal Medicine, CLINTEC, Karolinska Inst, Huddinge, Sweden; [2]Robert-Bosch- Krankenhaus, Stuttgart, Germany; [3]Univ Hospital of North Staffs, Stoke, United Kingdom; [4]Nephrologisches Zentrum, Mettmann, Germany; [5]Odense Univ Hospital, Odense, Denmark; [6]Quintiles, Reading, United Kingdom.*

Background: Patients (pts) with unplanned dialysis start (UPS) have worse clinical outcomes than non-UPS pts, and receive peritoneal dialysis (PD) less frequently. In the OPTiONS study an educational programme (UPS-EP) aiming at improving care of UPS patients and enabling informed choice of dialysis modality was implemented. We report impact of UPS-EP on modality choice and clinical outcomes in UPS pts.

Methods: This non-interventional, prospective, multi-centre, observational study included 270 UPS pts from 26 centres in 6 European countries (Austria, Germany, Denmark, France, United Kingdom and Sweden) presented acutely, or followed by nephrologist but required urgent dialysis start. Effects of UPS-EP on choice and final decision of dialysis and outcomes in 12 months follow up were analyzed.

Results: Among 270 pts, 214 received and 203 completed UPS-EP while 56 pts - who were older ($p=0.01$) and had higher Charlson comorbidity index (CCI; $p<0.01$) - did not receive UPS-EP. Among 177 pts who chose dialysis modality, 103 (58%) chose PD (but only 81% of them received PD) and 74 (42%) chose HD (95% received HD). Logistic regression analysis showed that diabetes, OR=2.62 (CI, 1.38 – 4.97) and receiving UPS-EP, OR=3.80 (CI, 1.63 – 8.89) predicted receipt of PD. Patients choosing PD had higher CCI ($p=0.01$), higher prevalence of congestive heart failure ($p<0.01$) and myocardial infarction ($p=0.02$), and were more likely in-patients ($p=0.02$) or referred from primary care ($p=0.02$). One year survival did not differ significantly between PD and HD pts. Peritonitis and septicaemia rates were better than international guideline standards.

Conclusions: UPS-EP predicted patient use of PD but 19% of those choosing PD after UPS-EP did not receive the modality they preferred. Patient survival in patients choosing and/or receiving PD was similar to HD despite age and comorbidity disadvantages of the PD groups.

Funding: Pharmaceutical Company Support - Baxter Healthcare, Government Support - Non-U.S.

FR-PO1043

Practical Experience with Automated Peritoneal Dialysis (APD) for Urgent Start Peritoneal Dialysis Yang Li, Haiyun Wang, Ying Wang, Zijuan Zhou, Bingyan Liu, Wei Yang, Ying Cui, Xuemei Li, Limeng Chen. *Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Recently APD has become an option for urgent start PD in new end-stage renal disease (ESDR) patients. However, there were limited knowledge about urgent start APD in China. This study aims to analysis the survival outcomes of APD in urgent start PD compared to non-APD.

Methods: Retrospective data of 625 peritoneal dialysis (PD) patients in our center from 1996-03 to 2015-12 were analyzed. Urgent-start dialysis were defined as starting unplanned dialysis within 14 days after catheter insertion due to late referral or unexpected deterioration of residual renal function among known patients. Kaplan-Meier analysis were used to evaluate the survival and technique survival. The survival outcome was analyzed by the Cox's regression model.

Results: About 190 patients receiving urgent start PD (30.4%). The survival rate at 3 months, 1 year for urgent and non-urgent start PD group were 95.2%, 83.3% vs. 97.4% ,90.7% respectively ($P=0.025$). And there is no significant difference of the technical survival rate and peritonitis frequency between urgent and non-urgent start PD patients. For urgent start PD patients, 25 patients (13.2%) received APD (30.4% women, 62.1±19.1 years old), and 48.0% of them were diabetic nephropathy. Both APD group and non-APD group had no significant difference of age, gender, Kt/V, CCr and nPCR at baseline. The median survival time of APD and non-APD group was similar (42m vs 49m, $P=0.227$). The survival rate and the technical survival rate at 3 months and 1 year of were also similar. The peritonitis frequency of APD and non-APD was 1 episode/ 82.71 months and 1 episode/ 81.18 months. After adjusted by gender and PD modality, age (1 years, HR=1.051, 95%CI 1.029-1.074, $P=0.000$) and diabetic nephropathy ($P=0.002$) independently predicted the mortality in urgent start PD patients.

Conclusions: Urgent start PD has a lower 1-year survival rate than non urgent start PD patients. However, there is no difference of the 3-month and 1-year survival and technical survival rate between APD and non-APD in urgent start PD.

FR-PO1044

Designer Dialysis: Designing a Peritoneal Dialysis Prescription That Fits a Patient's Lifestyle Nicholas B. Helmstetter, Mihran V. Naljayan, Simone Fertel. *Internal Medicine, LSUHSC - New Orleans, New Orleans, LA.*

Background: Peritoneal dialysis (PD) is a renal replacement therapy for patients with end-stage renal disease, and is typically done daily via 4 manual exchanges, or a cycler overnight. Clearance is measured using Kt/V which accounts for PD and residual renal function (RFF). We hypothesize that patients with some RRF can perform less PD and still achieve adequate removal of toxins and volume. By maximizing use of RRF, we can reduce the numbers of daily exchanges, cycler time, or even the number of days of dialysis each week. We hypothesize that this will preserve RRF for a longer time, limit peritoneal membrane exposure to glucose leading to longer membrane life, and improve patient quality of life.

Methods: We recruited 10 patients with RRF Kt/V above 1 and total Kt/V above 1.7. Patients were counselled for reducing their PD regimen to a new prescription calculated to preserve adequacy levels. Adequacy checks were performed after one month and every three months following to ensure adequate levels of total Kt/V, and residual renal Kt/V are preserved. Monthly 24 hour urine collections were performed to assess for volume and creatinine clearance. All patients were maintained on Furosemide 160 mg twice daily.

Results: After six months of modified PD, all but one patient were above adequate levels for total Kt/V. A t-test of the 1st and 6th month data indicated a significant reduction in PD (0.775, $p=0.0105$) and total Kt/V (2.183, $p=0.0071$), but did not indicate a significant change in RRF Kt/V (1.411, $p=0.0892$). Six patients were enrolled in the study for 9 months, and this data shows a similar trend of lowered PD Kt/V and preserved RRF and total Kt/V. A t-test of the 9th and 6th month data indicated that Kt/V changes for PD (0.775, $p=0.3981$), RRF (1.318, $p=0.1130$), and total Kt/V (2.093, $p=0.0691$) were not significant.

Conclusions: Our study has shown that after reducing the PD prescription, RRF and total Kt/V can be preserved at or above adequate values. By reducing the frequency of exchanges, patient quality of life can be significantly improved in regards to reducing the likelihood of burnout, decreasing glucose exposure, and potentially reducing other complications.

FR-PO1045

A Mobile Medical App May Help Peritoneal Dialysis Patients to Share Relevant Clinical Information with Their Doctors Francesco Iannuzzella, Mattia Corradini, Sonia Pasquali. *Dept of Internal Medicine, Nephrology and Dialysis Unit, IRCCS Arcispedale Santa Maria Nuova, Reggio Emilia, Italy.*

Background: Using only free online resources, we developed an intuitive medical app to empower peritoneal dialysis (PD) patients to take an active role in their health. The app allows PD patients to record all the information needed for their monthly visits, including ultrafiltration, weight, blood pressure and the presence or absence of specific symptoms. This information is then automatically transmitted to the PD clinic in either a table format or graphs.

Methods: We screened all patients who attended our PD clinic between January 2015 and May 2016. From a total of 73 PD patients, 53 patients were excluded because they did not have access to the internet. Seven patients were excluded as they refused to give informed consent. Consequently, 13 (8 M/5 F) patients, aged between 24 and 74 years

(median 51 years) formed the final study cohort. This remote monitoring group answered daily symptom question and took daily weight, ultrafiltration, and blood pressure readings for a mean follow-up of 94+/- 13 days. The self-administered KDQOL-SF Instrument was used to assess quality of life. Continuous variables were reported as mean +/- SD, categorical data as frequencies per 100 patient-days or percentages. Student's t-test was used for normal distribution variables and Wilcoxon test for not normally distributed variables.

Results: Enrolled patients were significantly younger than other screened patients and showed a better socioeconomic status and a higher degree of instruction. Seven of 13 patients used a mobile phone, whereas the remainder used both mobile phones and other devices. Missing readings throughout the study showed a frequency of 0.6 per 100 patient-days. On a total of 851 recordings, data were reported erroneously in 2.3% of cases. There was no significant difference in QoL during the study period, but significant changes were reported for the items of emotional well-being and patient satisfaction.

Conclusions: A mobile app was successfully adopted as a telemonitoring system for a group of PD patients, showing an impressive compliance and an acceptable percentage of errors in data collection.

FR-PO1046

Shared Medical Appointment for Peritoneal Dialysis Patients Sana Waheed, Roy A. Jhagroo. *Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Improving access to care by allowing providers with demanding clinical schedules to see patients with the same chronic condition in a group setting is the main driving force behind shared medical appointments (SMAs). Despite potential advantages of improved efficiency and better patient satisfaction with this model, it has not been implemented for dialysis patients. In this abstract, we describe our single center experience of SMAs with our peritoneal dialysis (PD) patients.

Methods: Our SMA comprises of 4-5 patients, a dietitian, a social worker, patient's primary nurse and a nephrologist. We spend an hour discussing their laboratory data, dietary changes and social issues. We collected laboratory data on patients who take part in the SMAs (n=9) and compared the quality metrics of these patients to the ones who do not (n=32).

Results: Majority of patients in both groups were Caucasian males. There were no significant differences in terms of outcomes between the two groups.

	SMA [Mean(SD)]	Non-SMA [Mean (SD)]
White (%)	89	69
Male (%)	55.6	59
Albumin (g/dL)	3.6 (0.3)	3.5 (0.5)
Hemoglobin (mg/dL)	11.1 (1.4)	11 (1.5)
Calcium (mg/dL)	9.5 (0.5)	9.3 (0.5)
Phosphorus (mg/dL)	4.6 (0.9)	5.4 (1.2)
Magnesium (mg/dL)	2.0 (0.2)	2.3 (0.4)

Conclusions: Our results emphasize that despite requiring less provider time, patients attending SMAs have similar medical outcomes as patients who are seen individually. In our program, SMAs for PD patients were started in an effort to expand our home dialysis population despite provider time constraints. Since giving patients the option of attending SMAs, our home program census has increased from 35 to 50, which accounts for 19% of our total dialysis population-a number much higher than the national average. Moreover, these meetings provide a support system for home dialysis patients as the can discuss their struggles with others who are undergoing similar experiences. In conclusion, SMAs provide an efficient system for providing care to PD patients and are an attractive alternative to the conventional clinic visits for PD patients.

FR-PO1047

Patient-Centric User-Interface in Automated Peritoneal Dialysis: Impact on Training and Outcomes at a Single Center Shuchita Sharma,[1] Mary Grace Gonzales,[1] James A. Sloand,[2] Jaime Uribarri.[1] *[1]Nephrology/Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Renal Div, Baxter Healthcare Corporation.*

Background: Automated peritoneal dialysis (APD) is a preferred method to do peritoneal dialysis (PD) by many patients. It gives the patients the comfort of performing multiple overnight exchanges using a cycler. A new, recently approved APD cycler (AMIA 2.0) has additional features of animated graphics, voice guidance and a touchscreen control panel. These patient-centric features could hypothetically increase the efficiency of training and administration of therapy. The cycler also has a remote web-based connectivity platform which allows health care providers to have access to the patient's treatment data remotely. We sought to assess whether these new technologies had any benefits over using the legacy cycler (Home-choice, HC). We report our single-center experience comparing outcomes in our first 14 patients on AMIA with historic controls on HC.

Methods: We conducted a retrospective chart review of 28 patients (14 in each group, respectively). Data collection included age and demographics for the patients, their training and treatment characteristics, and relevant clinical outcomes and laboratory data, over 60 days after initiating treatment on the cycler.

Results: We found a significant difference in number of training days for the two cyclers (AMIA vs HC): 3.07 +/- 0.83 vs 4.36 +/- 1.6, p-value: 0.015. The age and demographics were similar in the two groups. There was no difference in drop-out rate (0/14 vs 1/14), rate of peritonitis (0/14 in each group), exit site infections (0/14 vs 1/14), or hospitalizations (1/14 vs 2/14) at 60 days. We also did not find any significant difference in dialysis adequacy, serum phosphate, calcium- phosphate product, and anemia parameters when compared at the initiation and again at 60 days of cycler therapy.

Conclusions: New patient-centric features for APD cycler were found to provide more efficient training for patients. No impact was seen on 60-day dropout or other clinical parameters with this limited number of patients; a longer term follow-up and a larger N will be required to confirm these outcomes.

FR-PO1048

Assisted Peritoneal Dialysis in British Columbia: Results of a 12 Month Pilot Project Micheli U. Bevilacqua,[1,2] Rajinder S. Singh,[1] Helen Chiu,[2] Adeera Levin,[1,2] Michael A. Copland,[1] Paul Andrew Taylor.[1] *[1]Nephrology, Univ of British Columbia, Vancouver, BC, Canada; [2]British Columbia Provincial Renal Agency, Vancouver, BC, Canada.*

Background: PD is challenging to patients with compromised strength, dexterity, vision and/or cognitive deficits who have high attrition from the therapy; assisted PD (PDA) has been used in other jurisdictions to maintain patients on PD instead of transferring to HD. A 12 month pilot spanning multiple health authorities in BC was conducted to examine the effect of PDA on PD technique survival, clinical outcomes and cost.

Methods: Eligible CCPD patients for PDA service were identified by standardized criteria at 4 pilot sites. Participating patients received daily assistance with cycler dismantle and setup provided by a contracted caregiver. Patients remained responsible for other aspects of PD including connections and choice of dialysate. Outcomes for the PDA cohort were compared against: the general CCPD cohort and patients who met criteria for PDA but did not utilize the service (PDA eligible) in BC.

Results: The 53 PDA patients had an 88% (95% CI: 78-97%) 1-year death and transplant censored technique survival on PD, which was similar to the general CCPD cohort (84% [95% CI: 81-87%]) and PDA eligible cohort (86% [95% CI: 77-96%]). PDA cohort had lower peritonitis rates (0.18 episodes per patient-year vs 0.22 and 0.36), but higher hospitalization (55% vs. 34% and 35%). Qualitative feedback from patients and PD clinicians was overwhelmingly positive for PDA. The cost of PDA was approx. $15,000/year in addition to existing PD costs. PD with PDA costs $29,000/year less than HD or $23,500 less than long term care.

Conclusions: PDA was an effective way to support independent CCPD patients who were identified as at risk of PD technique failure and yielded acceptable clinical outcomes for this at risk group. The annual PDA cost is less than transfer to HD or placement in long term care, which represents a cost-minimization for a failing self-care PD patient. The strengths of our study include recruiting multiple health authorities and using a very similar comparator (PD eligible) in addition to the general CCPD population comparator.

FR-PO1049

Pilot Use of Assisted Peritoneal Dialysis for Temporary Interruptions in Self-Care Peritoneal Dialysis Micheli U. Bevilacqua,[1,2] Rajinder S. Singh,[1] Helen Chiu,[2] Adeera Levin,[1,2] Michael A. Copland,[1] Paul Andrew Taylor.[1] *[1]Nephrology, Univ of British Columbia, Vancouver, BC, Canada; [2]British Columbia Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Acute illness, injury or caregiver absence can render PD patients temporarily unable to perform dialysis independently. These patients remain in hospitals, care facilities or are transferred to HD. We evaluated Respite PDA (assisted PD) for: reasons for use, duration of service, cost and impact on self-care PD retention.

Methods: This was one part of a 12-month pilot of PDA. Patients with acute interruptions in self-care CCPD were offered Respite PDA. Patients received daily assistance with cycler setup/dismantle provided by an contracted caregiver. Patients were responsible for other aspects of PD including connections and dialysate choice.

Results: 11 patients received Respite PDA. The most common reasons for use were primary caregiver absence and MSK injury. 8/11(73%) patients returned to self-care PD, 1 transferred to HD, 1 transferred to long term PDA and 1 deceased with PDA facilitating palliation. Median use of respite PDA was 29 days (range:1 to 213 days). Excluding existing PD costs, PDA cost $43/visit or approx. $1,250 for the median PDA respite usage. Estimated cost of hospital admission or transfer to HD is $7000-$10000 for the same duration.

Reason for Respite PD	Frequency	Duration of Respite PD (Days)	Disposition after Respite PDA
Primary caregiver away	2 pts*2 uses 2 pts*1 use	13, 16,2,2 3,32	All returned to self-care PD
Fall: wrist fracture	1 pt	40	Self-care PD
Hand injury	1 pt	14	Self-care PD
Fall: tibia fracture	1 pt	91	Self-care PD
Arm fracture	1 ptt	70	Self-care PD
Neurologic: allow assessment for long term care	1 pt	1	Transferred to HD
Palliative support prior to hospice placement	1 pt	12	Hospice
Surveillance for general weakness	1 pt	213	Convert to long term PDA, then long term care

Conclusions: Respite PDA is an effective way to support patients with temporary interruption in self-care PD. Majority of patients returned to independent PD. Respite PDA is cost-effective compared to hospital admission or transfer to HD.

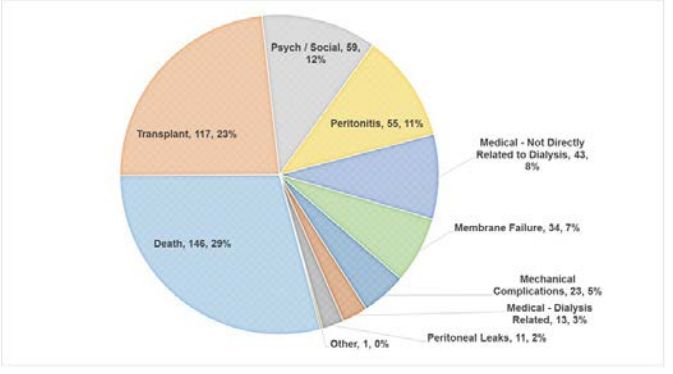
FR-PO1050

Peritoneal Dialysis Dropout - Experience from an Integrated Healthcare System with High PD Prevalence Leonid Pravoverov, Chitra R. Reddy, Neelam M. Bhalla, Joanna Mroz, Maribeth Ann Alcaraz, Sijie Zheng. *Nephrology, The Permanente Medical Group, CA.*

Background: Peritoneal Dialysis (PD) is an excellent option for renal replacement therapy (RRT). Kaiser Permanente Northern California (KPNC) is an integrated health care system with approximately 4 million members and 4700 patients on dialysis. KPNC has a higher PD prevalence (24%) compared with the national average (10%). We retrospectively analyzed the reasons patients discontinue PD.

Methods: Retrospective analysis of all patients on PD from 10/1/2013 to 12/21/2014 was conducted. Patients were followed through 3/31/2015. Patients who stopped PD for at least 60-days were identified and analyzed further. We excluded patients who lost KP membership while active on PD and included patients who stopped PD due to a kidney / SPK transplant.

Results: 502 PD patients were identified in the study period. Death (29%) and Transplantation (23%) were the two main reasons for discontinuing PD. Other reasons included: 1. Psychosocial (12%); 2. Peritonitis (11%); 3. Non-PD related medical issues (8%); 4. Peritoneal membrane failure (7%); 5. Mechanical complications (5%); 6. Medical – Dialysis related (3%); 7. Peritoneal Catheter Leaks (2%); 8. Other (<1%). The average time on PD was 2.01 years (Median was 1.36 years; with a range from 0.02 to 17.59 years).



Conclusions: Besides death and transplantation, psychosocial issues and peritonitis were the top potentially preventable reasons for patients to discontinue PD in our study. Further analysis is required to identify primary cause of death; strategies to prevent peritonitis, and steps to provide psychosocial support for patients to remain on PD.

FR-PO1051

Technique Survival and Rates of Short Term Dropout in Peritoneal Dialysis Miguel Goncalves,[1,2] Vanda Guardado,[2] Maria Joao Carvalho,[2] Jorge Malheiro,[2] Andreia Campos,[2] Ana Castro,[2] António Cabrita,[2] Anabela Rodrigues.[2] *[1]Nephrology, Hospital Central do Funchal, Funchal, Portugal; [2]Nephrology, Centro Hospitalar do Porto, Porto, Portugal.*

Background: Peritoneal dialysis (PD) and hemodialysis (HD) are equivalent modalities for CKD stage 5d treatment. PD is underused, and this may be due to the high drop-out. Objective: evaluate the specific causes of technical failure according to treatment time.

Methods: Analysis of longitudinal registry data of incidents patients admitted since 1985. Technique survival analysis considered competitive risks. Risk factors for drop-out were explored (age, sex, diabetes, type of technique and first modality for renal replacement therapy). Poison test used to compare drop-out rates according to tertile of time of follow-up.

Results: Studied population: 525 patients, 211 (40,2%) male, a mean age of 48±15,7yr, a median follow up of 23 months (IQR 9-41,5). The reasons for drop-out were: transfer to HD (n=186, 35,4%); kidney transplantation (27,6%) and death (21,7%). Transfer probability for HD was 19,2% at 2yr and 34.2% at 5yr. Transfer rates to HD by specific reasons in early and late follow-up are expressed in table.

Tertile at time of follow-up (Months)	No. patients	**Drop-out causes** (Episodes / 100 patient-months)			
		Infection related to access	Hypervolaemia/ inadequate UF/ sub-optimal dialysis	Nonadherence / inability to perform the technique	Surgical causes/ mechanical catheter complications
0,5-13	72	6.9	2.4	3.5	5.1
14-33	48	1.8	0.9	0.5	0.6
34-173	66	0.8	0.5	0.1	0.2
ρ		0.000003	0.019	0.0003	0.00002

No predictors for early failure were identified.

Conclusions: The spectrum of causes changed with time of follow-up. The critical period is the initial phase of PD threatened by complications in postoperative management of catheter (infections or mechanical/surgical), as well as non adherence/inability to technique. Early drop-out occurred unexpectedly due to hypervolaemia/inadequate UF, probably reflecting lack of compliance to fluid restrictions since baseline UFF is rare. Drop-out rates decrease with time. Investment in surgical team and infection prophylaxis, and better selection/coaching of incident patient can minimize premature failure.

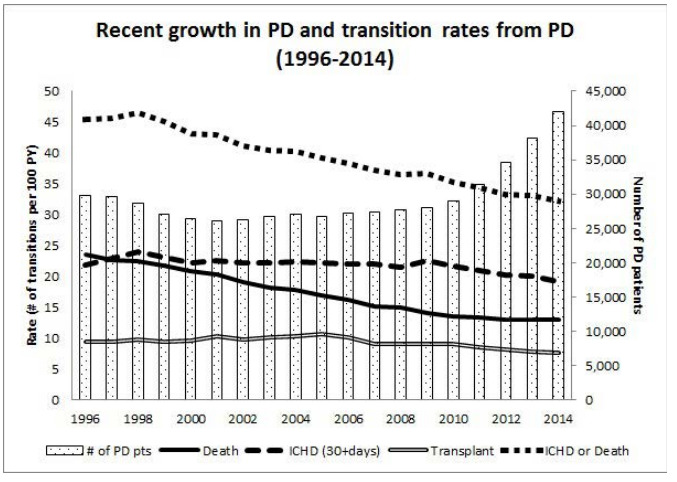
FR-PO1052

Transitions from Peritoneal Dialysis to Other Renal Replacement Therapies: Trends in the United States Renal Data System from 1996-2014 Nidhi Sukul,[1] Purna Mukhopadhyay,[2] Jeffrey Pearson,[2] Douglas E. Schaubel,[1] Marc Turenne,[2] Rajiv Saran,[1] Bruce M. Robinson,[2] Ronald L. Pisoni.[2] *[1]Univ of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Transitioning from peritoneal dialysis (PD) to in-center hemodialysis (ICHD) is highly disruptive to patients (pts) and has been associated with higher mortality and hospitalization rates. To understand how transitions from PD to other renal replacement therapies have changed over time, we examined trends in the United States Renal Data System.

Methods: Annual cohorts of pts on PD for at least 30 consecutive days as of Jan 1st were tracked over one year for transition to ICHD (defined as ICHD for 30+ days), transplant, or death. Time at risk (expressed per 100 patient-years [PY]) was calculated as days from Jan 1st until date of transplant, death, 30 days after switching to ICHD, recovery of renal function, loss to follow-up, discontinuation of dialysis, or year end.

Results: From 1996 to 2014, the size of the annual PD cohort increased by 41%, from 29,749 to 42,035 pts. Trends in transition rates per 100 PY from 1996 to 2014 were: 23.5 to 13.1 for death, 21.8 to 19.1 for ICHD, 45.4 to 32.2 for ICHD or death, and 9.5 to 7.6 for transplant. The percent of PD pts with no transition over one year increased from 58% to 67%.



Conclusions: From 1996 to 2014, mortality rates declined sharply among prevalent PD pts, and with recent increases in new PD starts, the prevalent counts of PD pts will likely continue to rise. In contrast, the rate of transition to ICHD declined only modestly, underscoring the need for further efforts to avoid or delay transition to ICHD. Future research is needed to better understand patient-level and center-level predictors of transition; the effects of transition on medical complications and the patient experience; and rates and determinants of transition among incident PD pts.

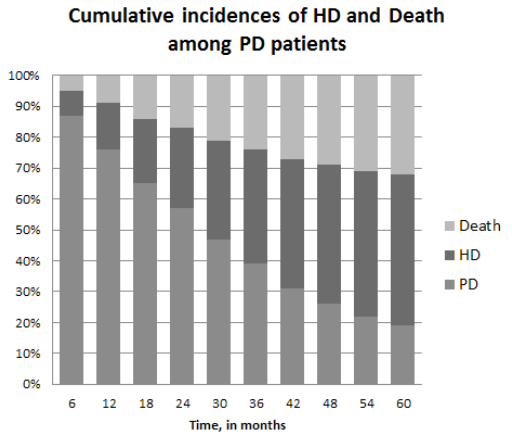
FR-PO1053

Hemodialysis Vascular Access Needs among Peritoneal Dialysis Patients Rita L. McGill, Eduardo K. Lacson, Robin Ruthazer, Klemens B. Meyer, D. Miskulin, Daniel E. Weiner. *Nephrology, Tufts Medical Center, Boston, MA.*

Background: When peritoneal dialysis (PD) patients transfer to hemodialysis (HD), >90% initiate with HD catheters. HD access is sought later in the natural history of kidney failure, reducing the likelihood of AV fistulas or grafts. Obtaining pre-emptive HD access in all PD patients may subject some patients to unnecessary surgery. Accordingly, we examined subsequent vascular access needs of patients who initiate therapy with PD.

Methods: A cohort of all incident adult PD patients in USRDS 2005-2007 were followed until a non-PD outcome occurred. Death was analyzed as a competing risk; successful kidney transplant, recovery, and loss to follow-up were censored. Cumulative incidence was calculated over five years. Competing risk regression (CRR) was used to model the impact of multiple clinical covariates on the cause-specific hazards of transfer to HD in a subset with 2 years of pre-PD Medicare.

Results: Among 16,506 incident PD patients followed over a mean of 2.3 (range 0-8.6) years, 42% transferred to HD, 28% died, and 20% received kidney transplants. HD was a more common outcome than death at all time points. Cumulative PD technique survival was less than 50% by 2½ years, by which time 32% of patients were receiving HD. Cumulative PD technique survival was < 20% at 5 years.



In the multivariable CRR model (subset n=4,687), Black race and BMI>25 were associated with more HD and less death; older age, arrythmia, and lower creatinine were associated with more death and less HD; diabetes as the cause of kidney failure was associated with increases in both HD and death (p<0.001 for all).

Conclusions: More than 40% of PD patients eventually transfer to HD, despite the competing risk of death. Vein protection and a vascular access plan are needed for any PD patients expected to survive more than 2-3 years without access to early kidney transplantation.

FR-PO1054

Dialysis Modality Change and Complications in PD Patients following CABG or Laparoscopic Surgery Lu Y. Huber,[1,2] Matt Day,[1] Sandra Tadros,[1] Jennifer L. Waller,[3] Mufaddal F. Kheda,[1] Jake Everett Turrentine,[4] Rhonda E. Colombo,[1] N. Stanley Nahman.[1,2] *[1]Medicine, Augusta Univ, Augusta, GA; [2]Medicine, Charlie Norwood VA Medical Center, Augusta, GA; [3]Biostatistics and Epidemiology, Augusta Univ, Augusta, GA; [4]Dermatology, Augusta Univ, Augusta, GA.*

Background: There is an increasing effort to avoid interruption of PD when PD patients undergo surgery. We queried the USRDS to investigate patterns of dialysis modality change and post-op complications in PD patients undergoing CABG and laparoscopic surgeries.

Methods: Incident PD patients in 2004-2011 who underwent CABG or laparoscopic surgeries were queried. Groups with no interruption of PD (group P), planned temporary (PHP) or permanent switch to HD (PHH), urgent temporary (UHP) or permanent switch (UHH) were identified. Demographics and comorbidities were assessed. The relative risk (RR) for complications within 3 months post-op was estimated.

Results: 8743 incident PD patients with CABG (1445), laparoscopic (7298) or both (332). 57% female, 19% black. Age 55±18yrs. Average time on PD 18±19mos. Post-op outcomes Table 1. Risk factors for complications in Table 2.

Variable	PHP	PHH	UHT	UHH	T
	2508 (28.7)	1600 (18)	322 (3.7)	304 (3.5)	4009 (46)
Hospitalizations	1.5 +/- 1.3	0.8 +/- 0.9	1.8 +/- 1.2	1.2 +/- 1.0	0.7 +/- 0.9
Peritonitis	84 +/- 3.4	15 +/- 0.9	29 (9.0)	11 (3.6)	79 (2.0)
Bacteremia	328 +/- 13.1	69 +/- 3.7	49 (15.2)	42 (10.5)	120 (3.0)
Wound Infection	76 +/- 3.0	20 +/- 1.3	2 (6.8)	15 (4.9)	40 (1.0)
Variable	Peritonitis	Bacteremia	Wound Infection		
PHD vs. P	1.66 (1.2-2.2)	4.38 (3.52-5.45)	2.31 (1.56-3.42)		
PHH vs. P	0.45 (0.26-0.78)				
UHP vs. P	4.95 (3.17-7.73)	5.30 (3.70-7.58)	5.94 (3.46-10.21)		
UHH vs. P	1.93 (1.01-3.68)	3.47 (2.29-5.26)	3.54 (1.91-6.55)		

Conclusions: Continuing PD during CABG or laparoscopic surgery appears safe. Need for urgent HD (UHP) is uncommon but associated with a higher risk of post-op complications. Future studies may focus on risk stratification to identify these patients prior to surgery.

FR-PO1055

Longer Peritoneal Dialysis Is Associated with Better Survival in Peritoneal Dialysis Patients Hironori Nakamura, Yasushi Makino, Anayama Mariko, Masaki Nagasawa. *Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: The Japanese Society for Dialysis Therapy reported 5- and 10-year survival rates of 60.5% and 36.2% for hemodialysis (HD) patients. However, the survival rate of peritoneal dialysis (PD) patients after the therapy is switched to HD remains unknown in Japan and worldwide.

Methods: One hundred and thirty-five patients who underwent PD were retrospectively analyzed. We investigated the long-term survival rate of patients, including those who switched from PD to HD, and evaluated the correlation between survival time and clinical features at PD initiation. Death was considered a final event, and patients who were transferred to another hospital, who underwent transplantation, or the end of the study period (April 2016) were censored. Age, gender, body mass index (BMI), diabetes, serum albumin (Alb), creatinine (Cr), PD duration, dialysate to plasma creatinine ratio (D/PCr), peritoneal protein excretion (PPE) amount, and urine volume were included and analyzed by the Cox proportional hazard model and Kaplan–Meier tests.

Results: 1) The following patient characteristics were observed: mean age, 63.8 ± 15.1 years; BMI, 23.8 ± 4.6 kg/m^2; diabetes, 35.2%; Alb, 3.3 ± 0.5 g/dL; Cr, 8.6 ± 4.1 mg/dL; D/PCr, 0.67 ± 0.16; urine volume, 716 ± 522 mL; and PPE, 5644 ± 2723 mg. Mean PD duration was 44.8 ± 35.8 months, and survival was 66.5 ± 57.8 months. 2) Univariate analysis revealed significant effects of age, PD duration, Alb, PPE, and urine volume on survival. Cox proportional hazard analysis revealed that survival was significantly affected by age [hazard ratio (HR), 1.07; 95% confidence interval (95% CI), 1.03–1.11; $p < 0.001$] and PD duration (HR, 0.96; 95% CI, 0.94–0.98; $p < 0.001$). 3) Survival analysis between the two groups revealed an estimated survival of 47.2 ± 7.0 months in the short-duration PD group and 141.7 ± 10.3 months in the long-duration PD group (log rank, $p < 0.001$). Cumulative patient survival rates were: 58.3% (5 years) and 39.3% (10 years).

Conclusions: Longer PD duration was significantly associated with better survival of PD patients. The long-term survival of PD patients was similar to that of HD patients, although these were non-comparable situations.

FR-PO1056

Incidence, Hospital Charges, Length of Stay, and Mortality for Peritonitis in Children Undergoing Chronic Peritoneal Dialysis in the U.S.A. Neha Dhingra, Brian Becknell, Rose M. Ayoob. *Pediatric Nephrology, Nationwide Childrens Hospital, Columbus, OH.*

Background: Peritoneal dialysis (PD) is the most common modality utilized for children with End Stage Renal Disease (ESRD) worldwide. Peritoneal dialysis catheter-related infections cause significant morbidity and mortality in children. The frequency of peritonitis in children is increased compared to adults. The Pediatric Health Information System (PHIS) is a comprehensive pediatric database which includes clinical, administrative, and financial details for more than six million patients in participating US children's hospitals.

Methods: Data was collected for patients hospitalized with the principal diagnosis of PD catheter-related infection and ESRD (ICD-9 codes 996.68 and 585.6) from 2007 to 2015 using the PHIS database.

Results: From 2007 to 2015, the total number of hospitalizations with the diagnosis of PD catheter-related infections was 944, of which 62% were male. The total number of patients age 0-18 years was 881, with 30% of patients in the 1-4 year age group. Individuals <1 year of age accounted for 10% of total hospitalizations, but had the longest mean length of stay (69.9 days), highest mean charges ($317,093), and the highest aggregate charges (over $28 million dollars). Furthermore, in the patients in the < 1 year of age group, there were more reported deaths. More than 50% of patient hospitalizations occurred in the south region of the United States.

Conclusions: PD catheter-related infections remain a significant cause of morbidity and mortality in children with ESRD. Patients <1 year of age account for only 10% of total discharges but have longer LOS, mean charges and aggregate charges as well as higher number of deaths. The PHIS database can be a useful tool to follow trends specifically related to mortality and hospital charges in pediatric-related disease, in which there are often smaller number of patients.

FR-PO1057

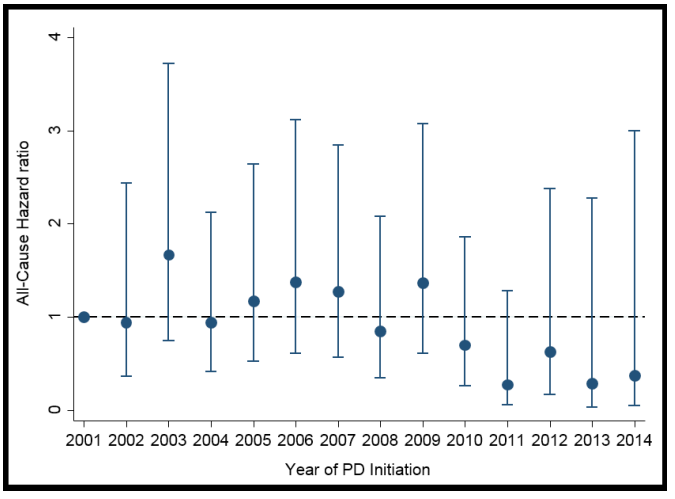
Death Risks over Time from 2001 to 2015 in Incident Peritoneal Dialysis Patients: A Retrospective Cohort Study with 15-Year Follow-Up Byeongwoo Kim,[1] Sunwoo Kang,[1] Yeong Hoon Kim,[1] Miyeon Kim,[2] Hyun Woo Kim,[2] Tae Hee Kim.[1] *[1]Internal Medicine, Inje Univ, Busan, Republic of Korea; [2]Internal Medicine, Jeju National Univ, Jeju, Republic of Korea.*

Background: Even though previous study has shown that there was no difference for survival between hemodialysis and peritoneal dialysis (PD) since 2002, the incident rate to initiate PD in patients with end-stage renal disease has decreased in developed countries. Hence, we investigated the change in trends and death risk in incident PD patients followed over up to 15 years.

Methods: In a 15-year (1/2001-12/2015) cohort of 592 incident peritoneal dialysis patients in our dialysis center, we examined death risk across the year of PD initiation from 2001 to 2014 using Cox proportional hazard models. To account for the competing

risk of transplantation across the year of PD initiation, we conducted the competing risk regression to estimate sub—hazard ratios of death risk. Models were adjusted for age, female, and diabetes.

Results: Patients were 50±13 years old, 45% female, and 50% diabetic. A total of 178 (30%) all-deaths were reported. 133 (23%) among 592 patients received kidney transplantation. Median follow up period was 2.8 years (IQR 1.4, 4.8 years) Compared with the patients who started PD in 2001, death risk tends to decrease with each subsequent year of PD initiation since 2010, but there was no significant difference across the year of PD initiation.



These trends were very similar in competing risk regression as well.

Conclusions: The survival rates in PD patients did not change until 2009 and then tended to improve since 2010. However, it has not shown significant association with the year of PD initiation over up to 15-year follow-up period. Further studies to understand the conditions influencing these death risks are needed.

FR-PO1058

Body Mass Index Trends in Patients Undergoing Peritoneal Dialysis for Decades and Their Effect on Patient Survival: Analysis of Data from an End-Stage Renal Disease Registry (1985_2014) in Korea Seon Deok Hwang,[1] Moon-Jae Kim,[2] Seoung Woo Lee.[3] *[1]Inha Univ College of Medicine; [2]Inha Univ College of Medicine; [3]Inha Univ College of Medicine.*

Background: Significant increases in the prevalence of obesity have been observed among patients with incident end-stage renal disease (ESRD). However, the changes in body mass index (BMI) status in prevalent Korean patients undergoing peritoneal dialysis (PD) over the recent decades and their impact on patient survival remain unknown.

Methods: Among 80,674 patients from the ESRD registry of the Korean Society of Nephrology since 1985, 6075 patients who were undergoing PD were included in the study. According to BMI, registered year, and serum albumin (SA) concentration the first-registered year, the patients were classified as follows: underweight (UW; <18 kg/m^2), normal weight (NL; 18–22.9), overweight (OW; 23–24.9), and obese (OB; ³25); low (<2.5 g/dL) and high (>2.5), respectively. The patients' BMIs were compared with those of 4986 subjects in the general population who participated in the sixth Korea National Health and Nutrition Examination Survey (KNHANES), 2014.

Results: The mortality risks of the OW and OB groups were respectively 1.149 and 1.188 times higher than that of the NL group after adjustments. When the patients in the NL and high SA groups were considered as reference groups, the mortality risks of the patients in the UW + low SA group and UW + high SA groups were respectively 2.73 and 1.72 times higher than that of the reference groups, even after adjustment for age, sex, diabetes, hemoglobin level, and blood pressure. We found that the mortality risk of the patients with OB and high albumin levels was 1.165 times higher than that of the reference patients. When the analysis was restricted to patients who were undergoing PD for 1 year, the mortality risks were similar to those of all the patient groups.

Conclusions: In the Korean PD patients, no significant increase in the number of UW patients was observed over the recent decades, but the proportion of OB patients tended to increase, similar to that of the general population. Both the UW and OB patients showed increased mortality risk.

FR-PO1059

Relationship between Future BMI and Baseline Nutritional Markers in Incident Peritoneal Dialysis Patients Emma H. Elphick, Mark Lambie, Simon J. Davies. *Keele Univ.*

Background: A higher body mass index (BMI) is known to relate to better survival in haemodialysis, but this remains uncertain in peritoneal dialysis (PD). BMI is frequently used as an epidemiological marker of nutritional status in the PD population however it is not known what biological determinants are involved in this assessment.

Methods: We used incident PD patients from the Global Fluid Study to test for associations between nutritional markers with baseline BMI and change in BMI after 2 years on PD. These included plasma and dialysate interleukin 6 (IL6), serum albumin, creatinine generation rate, urine volume, urine urea, ultrafiltration, dialysate glucose exposure, icodextrin use, age, gender, ethnicity and comorbidity score. A multivariate linear regression analysis was used.

Results: 297 patients had BMI measurements taken before 6 months and after 2 years on PD. Of these 214 were used. At baseline there was a significant positive association between BMI and creatinine generation rate (coeff 2.10 95% CI 0.6-3.6 p=0.006), glucose exposure (coeff 0.02 95% CI 0.007=0.030 p=0.001), urine urea (Wald 3.57 p=0.03) and urine volume (coeff 0.001 95% CI 0.0002-0.002 p=0.015). There was a negative association with male gender (coeff -1.2 95% CI -2.5 to -0.02 p=0.045) and Korean ethnicity (vs Caucasian) (coeff -2.5 95% CI -4.0 to -1.0 p=0.001). Change in BMI over 2 years had a significant positive association with age (coeff 0.03 95% CI 0.006 – 0.05 p=0.012), comorbidity score (Wald 2.49 p=0.044), Korean ethnicity (coeff 1.0 95% CI 0.3 – 1.8 p=0.009) and a negative association with creatinine generation rate (coeff -9.8 95% CI -17 to -2.4 p=0.009).

Conclusions: An increase in muscle mass is associated with an increase in BMI at baseline but a larger reduction in BMI over time. Korean centres had a lower initial BMI but less of a reduction in BMI over time. Fluid balance is positively associated with BMI at baseline but did not influence change in BMI. Albumin and inflammation did not have a significant effect.

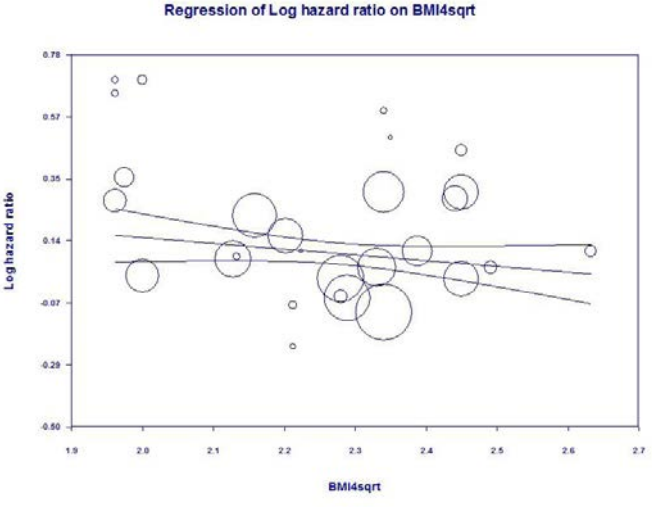
FR-PO1060

The Association between Body Mass Index and Mortality in Peritoneal Dialysis Patients Jin Ho Hwang,[1] Chae Rim Kim,[1] Geun Joo Choi,[2] Hyun Kang.[2] *[1]Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; [2]Anesthesiology and Pain Mecidine, Chung-Ang Univ Hospital, Seoul, Republic of Korea.*

Background: Unlike the general population, a higher body mass index (BMI) was consistently found to be a strong predictor of decreased mortality in patients with end-stage renal disease who receive maintenance hemodialysis (HD). This phenomenon has been referred to as the "Obesity paradox" or "reverse epidemiology". Similar tendency has been observed in several studies with peritoneal dialysis (PD) patients, but the studies have reported conflicting results. We conducted this study to evaluate the association between BMI and all-cause mortality in PD patients.

Methods: A systematic search was conducted for published studies in Medline, EMBASE, and the Cochrane library databases from 1970 to April 2015. We identified the studies evaluating the impact of BMI on mortality among PD patients. Data of hazard ratios and 95% confidence intervals (CIs) were obtained for respective BMI groups provided by each study. We performed meta-regression analysis using unrestricted maximum likelihood model.

Results: The Medline, EMBASE, and the Cochrane library search provided a total of 3,047 articles. After screening of all titles, 513 abstracts were selected. Finally, 9 cohort studies with 33,090 patients were included in the final analysis. Log hazard ratio for all-cause mortality showed a trend negatively associated with increasing four square root of BMI (slope coefficient: -0.1976, 95% CI -0.4110 to 0.0158, p= 0.0695).



Conclusions: In PD patients, BMI was inversely associated with mortality as in HD patients. Other outcomes such as cardiovascular death, peritonitis incidence, and technical failure will be additionally evaluated.

FR-PO1061

Impact of Metabolic Syndrome in Incipient Peritoneal Dialysis Patients Silvia Ros. *Nephrology, Regional Malaga Hospital, Malaga, Spain.*

Background: Metabolic syndrome (MS) is a clustering of risk factors among which are included diabetes mellitus (DM) and cardiovascular disease (CVD). It is associated with a high morbidity and mortality in general population. Its prognostic implication among patients undergoing peritoneal dialysis (PD) is not clearly defined. We studied MS and its individual components effect on both patient and technique survival.

Methods: Incident PD patients from the period of 1 January 1992 to 31 december 2014 were included. Demographic and biochemical variables were analyzed including blood, urine and peritoneal effluent. Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria was used to define MS. We used t-student and chi-square to compare the results and the survival was expressed by Kaplan- Meier curves. P < 0.005 was considered significant.

Results: Two hundred and sixty-two patients were included, among them 139 (53%) fulfilled the NCEP criteria with an average age of 60 ± 14,8 years (55% men). Sixty-six per cent patients were in automated peritoneal dialysis. The patient follow-up was 22,1 ± 13,4 months. Patients with MS showed higher incidence of DM (42% vs 2,6%, p=0.0001), CVD (34,5% vs 17%, p=0.005) and body mass index (30 ± 5,3 vs 25 ± 3,7, p=0.0001); lower normalized protein catabolic rate (1,04 ± 0,3 vs 1,13 ± 0,3 g/kg/day, p=0.012) and were older (63 ± 12,5 vs 58 ± 16,6 years, p=0.009) compared with patients without MS. Patient and technique survival did not differ between patients with and without SM irrespective of the diabetic status (log-rank test, p=0.937; log-rank test, p=0.941, respectively).

Conclusions: The presence of MS at the begining of PD was not associated with a lower patient and technique survival despite the higher morbidity. Further studies are needed to establish new prognostic factors for risk stratification of patients undergoing PD.

FR-PO1062

Increased Serum Lactate in Peritoneal Dialysis Patients Presenting with Intercurrent Illness Emilie Trinh, Nalinee Saiprasertkit, Joanne M. Bargman. *Univ Health Network, Toronto, ON, Canada.*

Background: Lactate is the most commonly used buffer in peritoneal dialysis (PD) solutions. It rapidly diffuses from the PD fluid to the blood and is metabolized via the Krebs cycle or gluconeogenesis. While prior studies have shown that lactate blood values are normal in stable PD patients, the purpose of our study was to evaluate if abnormal lactate values are more common in PD patients presenting to the emergency department (ED) and have the same significance as in the general population.

Methods: This observational cohort study assessed the prevalence of elevated lactate blood values among PD patients presenting to the emergency and evaluated clinical factors associated with an abnormal lactate value.

Results: We studied 172 patient visits in 89 PD patients to the ED at a major academic center between January 1, 2015 and December 31, 2015. An initial venous blood lactate value was performed in 91 visits (53%) and was found to be elevated (>2 mmol/L) in 26 cases (29%). While an abnormal lactate was associated with signs of hemodynamic compromise such as ICU admission (26.9% vs. 10.8%, p=0.05) and tachycardia (46.2% vs. 9.2%, p<0.01), in 46% of the cases with elevated lactate, there was no evidence of hemodynamic instability at initial presentation. Moreover, an abnormal lactate value was also associated with a greater likelihood of undergoing an abdominal CT scan (46.2% vs. 18.5%, p<0.01), but bowel ischemia was present in only one case.

Conclusions: An abnormal lactate value is often seen in PD patients presenting in the ED, even in the absence of signs of hemodynamic instability, and very rarely indicates bowel ischemia. We postulate that in the setting of an acute intercurrent illness, there is a transient disruption in the metabolism of the PD fluid lactate. This novel observation suggests that elevated serum lactate in the sick PD patient does not necessarily indicate tissue hypoperfusion or gut ischemia and may obviate unnecessary investigations.

FR-PO1063

Impact of Anemia on Loss of Residual Kidney Function in Patients on Peritoneal Dialysis Kazuhiko Tsuruya,[1] Hisako Yoshida,[1] Takanari Kitazono.[2] *[1]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Anemia control has been considered to be important for the reduction of mortality in end-stage kidney disease patients on peritoneal dialysis (PD) as well as those on hemodialysis. Recent studies have demonstrated the importance of RKF in the survival of chronic dialysis patients, and also stressed the importance of RKF in anemia management. However, it remains elucidated whether anemia impacts on RKF.

Methods: In the present study, we investigated the effect of anemia on loss of RKF in 106 PD patients treated at our hospital. The primary outcome was loss of RKF defined as urine output <100 mL. The subjects were divided into four groups based on their hemoglobin (Hb) levels; <9, 9.0–9.9, 10–10.9, and ≥11 g/dL. The time-dependent Cox hazard model was used to determine the impact of Hb levels on loss of RKF.

Results: During median (range) follow-up period of 42 (6–102) months, 31 subjects developed RKF loss. The univariable and multivariable-adjusted incidence rate of RKF loss increased significantly with lower Hb levels (*P* for trend = 0.03). Compared with those with Hb of ≥11.0 g/dL, the multivariable-adjusted hazard ratios for the development of RKF loss were 0.55 (95% confidence intervals, 0.15–2.04), 1.71 (0.53–5.55), and 4.65 (1.27–16.94) in subjects with Hb of 10–11 g/dL, 9–10 g/dL, and <9 g/dL, respectively, after adjustment for age, sex, origin of kidney disease (diabetic nephropathy or not), renal Kt/V, systolic blood pressure, serum albumin, logarithmic serum brain natriuretic peptide, PD modality (automated PD or not), and use of icodextrin solution, 2.5% glucose solution, diuretics, and renin-angiotensin receptor antagonists.

Conclusions: This result suggests that severe anemia as indicated by an Hb level <9 g/dL is a significant risk factor for loss of RRF, thus indicating the importance of anemia management. To the best of our knowledge, no reports have described the effect of anemia on RKF, which makes the findings of the present study particularly noteworthy.

FR-PO1064

Ferric Carboxymaltose Intravenous Administration to Control Anemia in Patients with Peritoneal Dialysis Jose Luis Merino, Vicente Paraiso, Sara Castrillo, Esther Garcia, Blanca Bueno, Patricia Dominguez, Beatriz Espejo, Alicia Gomez. *Nephrology, Hospital Univ del Henares, Coslada, Madrid, Spain.*

Background: A single dosage of ferric carboxymaltose(FCM) has proven effective to control iron-deficiency anemia in hemodialysis patients as well as in situations of end-stage renal disease. Its application in patients on peritoneal dialysis(PD) is less known. We show the observation of FCM administration in PD patients.

Methods: Patients on PD treatment were included in this study. The criteria for the administration of the iv iron therapy were: hemoglobin <12 g/dL, serum ferritin levels<200,TSI<30, oral iron therapy and/or the erythropoietic stimulating factors(ESF) treatment. Patients with a previous reaction to other iv iron formulations were excluded. The dosage was 1,000 mgivFCM, and not to exceed 15mg of iron per Kg. of body weight.

Results: Sixteen PD patients were administered the iv FCM. At the time of the study, two had received a kidney transplant only 6 months prior and three still have not followed up after the 6 month check-up. Finally eleven patients have completed at least 6 months of the treatment after the administration of FCM. The average age was 53±16 years. The etiology of kidney disease was glomerulonephritis in 6 cases, 5 diabetes cases, 2 interstitial nephritis, unknown in 2 cases and 1 patient, polycystosis. The results are reflected in the table. Five patients received oral iron therapy at the beginning, and all but one received ESF.

Conclusions: The FCM is an easy alternative to manage and has few side effects. It also maintains recommended levels of ferritin up to at least six months after administration. The requirements of ESF and oral dosage of iron could be reduced.

(1) P<0.001 (2) P<0.05	basal	2 meses	4 meses	6 meses

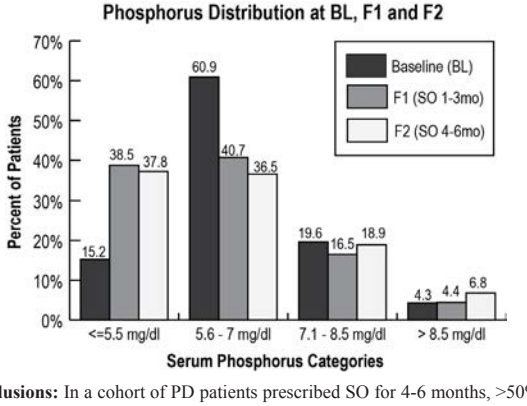
Serum Phosphorus and Phosphate Binder Pills per Day in Peritoneal Dialysis Patients Switched to Sucroferric Oxyhydroxide as Part of Routine Care Vidhya Parameswaran, Linda H. Ficociello, Carly R. Van Zandt, Norma J. Ofsthun, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America, Waltham, MA.*

Background: The majority of dialysis patients require phosphate binders (PB) to control serum phosphorus (sP) levels. However, poor adherence to PB prescription is common and may be related to high pill burden. This retrospective analysis assesses changes in sP control and PB pills/day in peritoneal dialysis (PD) patients who switched to sucroferric oxyhydroxide (SO) as part of routine clinical care.

Methods: PD patients (n=92) prescribed SO through a renal pharmacy service for 4-6 months were analyzed. Patients were required to be on PB monotherapy. Changes in percent of patients achieving sP ≤ 5.5 mg/dl and PB pills/day were compared during baseline (BL; 3 months prior to SO switch), F1 (1-3 months of SO) and F2 (4-6 months of SO).

Results: At BL, 84.8% of patients had hyperphosphatemia (sP > 5.5 mg/dl), and were being prescribed, on average, 9.9 PB pills/day. After SO prescription, a 58% and 54% reduction (p<0.0001) in pill burden was observed at F1 (4.2 pills/day) and F2 (4.6 pills/day), respectively. Significant improvement (all comparisons, p<0.001) in percent of patients achieving sP ≤ 5.5 mg/dl was observed comparing BL to F1 (153% increase) and BL to F2 (149% increase). Additionally, percent of patients with sP between 5.6 – 7 mg/dl decreased by 33% and 40% between BL and F1 (60.9% to 40.7%, p=0.002) and BL and F2 (60.9% to 36.5%, p<0.0001).



Conclusions: In a cohort of PD patients prescribed SO for 4-6 months, >50% fewer PB pills/day (mean decrease of >5 pills/day) were prescribed and patients with sP ≤ 5.5 mg/dl more than doubled.

FR-PO1066

Time of Therapy with Paricalcitol Is Related with Peritoneal Protein Loss in Peritoneal Dialysis - A Double-Center Study Teresa M. Jeronimo,[1] Gloria Del Peso,[2] Anabela M. Guedes,[1] Lucia Rodriguez-Gayo,[2] Ana Paula Silva,[1] Pedro Neves,[1] Rafael Selgas,[2] Maria A. Bajo.[2] *[1]CHAlgarve; [2]Hospital La Paz.*

Background: Peritoneal protein losses (PPL) are a good marker for endothelial dysfunction and an independent predictor for mortality in Peritoneal Dialysis (PD). Little is known about the effect of paricalcitol on PPL in PD, namely after the identification of Vitamin D Receptor on the peritoneal membrane.

Methods: In a cross-sectional study we included patients stable on PD for a minimum period of three months. The patients were divided into two groups: Group 1 (G1), treated with paricalcitol at least for three months, and group 2 (G2), without paricalcitol. Clinical and laboratory data were collected from all patients at the time of PPL analysis. In statistical analysis Student's t-test, Chi-square test and Linear Regression Model were used.

Results: Eighty-two patients (G1=41; G2=41) were included: 53 male, age 55±17 years, time on PD 23.5±20.1 months, Charlson Comorbidity Index 5±3, 22% with diabetes, 61% in automated PD (APD), 62.2% medicated with angiotensin-converting enzyme inhibitors (ACEIs)/angiotensin II receptor blockers (ARBs) during 9.5±11.1 months. The mean residual renal function (RRF) was 5.4±3.1 mL/min, reactive C protein (RCP) 8.3±14.5 mg/L, creatinine dialysate-to-plasma ratio (D/P creatinine) 0.67±0.11 and the majority of patients were high-average (52.4%) or low-average (22.0%) transporters, without differences between the two groups. The mean time of paricalcitol therapy was 5.1±8.5 months. We found higher PPL in G2 (6.34±2.07 vs. 5.01±1.87 g/24h, p=0.003). Patients in CAPD and with higher transport status (D/P creatinine>0.68) had higher PPL than patients in APD (6.35±2.28 vs. 5.30±1.85 g/24h, p=0.026) and lower transport status (6.43±2.11 g/24h vs. 4.97±1.80 g/24h, p=0.002). We found that time of therapy with paricalcitol (r=-0.283; p=0.021) was related with PPL, adjusted for diabetes, PD modality, RCP, D/P creatinine and time of therapy with ACEIs/ARBs.

Conclusions: In this study, time of therapy with paricalcitol was related with lower PPL. Prospective controlled studies, with greater number of patients comparing paricalcitol with placebo are needed to confirm the effect of paricalcitol on PPL.

FR-PO1067

Predictors of Outcome in Patients Commenced on Peritoneal Dialysis for Chronic Cardiorenal Syndrome Nalinee Saiprasertkit, Rory F. McQuillan, Emilie Trinh, Joanne M. Bargman. *Div of Nephrology, Univ of Toronto, Toronto, ON, Canada.*

Background: Studies have demonstrated that PD is a safe and efficient therapeutic modality in patients with cardiorenal syndrome (CRS), leading to decreased hospitalization rates, and improved functional status and quality of life. We have observed that some of these patients thrive on PD, while others continue to deteriorate. However, the predictors of outcome of PD in this group of patients have not yet been identified.

Methods: In this retrospective cohort study, we assessed the 6-month technique survival and hospitalization rates of all incident PD patients with CRS at a major academic center. Subsequently, clinical and laboratory parameters predicting 6-month PD (patient and technique) survival were examined.

Results: Of 185 patients who initiated PD between January 1, 2013 and February 29, 2016, 39 patients with CRS were identified. Median survival on PD was 252 days (4-1079 days).The 180-day PD survival rate was 62.2%, with a mortality rate of 35.1% and technique failure of just 2.7%. Hospitalization rates for congestive heart failure 6 months after initiation of PD were significantly lower compared to the 6 months prior to the start of dialysis (7.1% after vs. 85.7% before). Moreover, a baseline serum sodium less than 135 mEq/L was found to be a significant predictor of shorter PD survival (OR12.1[95%CI2.1-70.2], p= 0.005). Age, gender, etiology of heart failure, baseline ejection fraction, diabetic status, and hemoglobin levels were not predictive of survival on PD.

Conclusions: While patients with cardiorenal syndrome on PD have an overall poor prognosis, the initiation of PD in these patients significantly decreased hospitalization rates. Interestingly, as in the general population, hyponatremia is a major prognostic factor for reduced PD survival in this cohort.

FR-PO1068

Peritoneal Dialysis in Orthotopic Liver Transplantation Recipients: One Center's Experience Nalinee Saiprasertkit,[1] Camila Hitomi Nihei,[2] Joanne M. Bargman.[1] *[1]Div of Nephrology, Univ of Toronto, Toronto, ON, Canada; [2]Div of Nephrology, Univ de Sao Paulo, Sao Paulo, Brazil.*

Background: Despite the lack of evidence, many programs are reluctant to initiate Peritoneal Dialysis (PD) in liver transplant patients needing renal replacement therapy. This retrospective study reviews the outcome of PD in liver transplant patients at a major transplantation and dialysis center.

Methods: We performed a retrospective cohort study in patients who underwent liver transplant followed by chronic PD between the years of 1991 and 2016. Patient demographics, laboratory parameters and adverse events were collected from our electronic database.

Results: Between 1991-2016, 15 patients underwent liver transplant and subsequently received PD. Mean age was 58.7 ± 8.1 years; 40% women; mean time from transplant to peritoneal dialysis initiation was 9.0 ± 4.2 years; follow up in PD was 31.2 ± 25.6 months. Hepatitis C was the main cause of liver failure (7 patients). Calcineurin nephropathy was the lead cause of End Stage Kidney Disease (12 patients), biopsy-proven in four. Eight patients underwent liver biopsies during their time on PD without complication. The overall peritonitis rate was one episode every 43.8 months (0.27 episodes per year at risk). There was one case of relapsing peritonitis, and one patient had severe infection and died. Mean survival time was 58.9 ± 11.2 months, 5 patients died, 3 received a kidney transplant, one patient was transitioned to hemodialysis due to poor ultrafiltration, two patients were transferred to other programs, two remain on PD and two patients recovered renal function. Peritonitis and mortality rates were no different from other solid organ recipients, or even from our general PD population.

Conclusions: There appears to be no specific concern related to liver transplant patients undertaking PD. Peritonitis and mortality rates were no different from other solid organ recipients or even from the general PD population. The hepatic graft was never threatened, even during peritonitis. Therefore, these patients should not be denied the option for peritoneal dialysis.

FR-PO1069

Peritoneal Dialysis for Patients with Refractory Heart Failure and Chronic Kidney Disease Nageswara Pamidi,[3] Aruna Mangipudi,[1] Hari Krishna Reddy Mogili,[1] Anil Kumar Cheni Venkata,[1] Boju Sangeetha Lakshmi,[1] R. Ram,[1] V. Siva Kumar,[1] Abhilash Koratala.[2] *[1]Sri Venkateswara Inst of Medical Sciences, India; [2]Univ of Florida; [3]Care Hospitals, Hyderabad, India.*

Background: Heart failure (HF) is a major public health problem in India and the proportion of patients presenting with both HF and chronic kidney disease (CKD) is large and steadily increasing. Currently available therapies for decongestion mainly rely on diuretics which have their shortcomings. Peritoneal dialysis (PD) is a relatively simple choice for chronic, gentle fluid removal, and appears to be an useful option for the management of patients with HF with difficult to manage volume status. Our objective is to study the impact of PD on CKD patients with refractory HF for which, there is limited data in Indian patients.

Methods: In this 3-year prospective study conducted at a tertiary health center in South India, we initiated PD in patients with refractory HF (NYHA class IV) with varying degrees of CKD. We excluded patients with end stage renal disease. We recorded the pertinent data before and after initiation of PD.

Results: During the study period, we treated 7 patients with HF & CKD with PD. Mean age of the patients was 56.8 years and 6 out of 7 were males. The mean duration of follow up was 11.4 ± 9.8 months. Results are as follows:

Parameter (Mean ± SD)	Before PD	After PD
Serum Creatinine (mg/dL)	3.2± 0.6	1.8± 0.4
eGFR (ml/min)	36 ± 9.1	32 ± 3
Ejection fraction	28.2± 3.3	36.2 ± 3*
Urine output (cc)	950± 135	1450 ± 205*
No. of exchanges per day	-	1
Ultrafiltration per session (cc)	-	650± 80
No. of days of hospitalization per month	12 ± 3	1±1*
BNP (pg/mL)	1702± 1177	882.2 ± 757.2*

The asterisk (*) symbol indicates significant P value. 2 episodes of non-refractory peritonitis were observed.

Conclusions: We conclude that PD is a beneficial treatment strategy for optimizing fluid status in patients with refractory HF with CKD. It improves laboratory parameters including ejection fraction, diuretic resistance and decreases the hospital stay of these patients. Larger controlled trials are needed to explore the potential impact of PD on the mortality of patients with HF.

FR-PO1070

Peritoneal Dialysis in Adult Polycystic Kidney Disease Ying Ma, Haiyun Wang, Zijuan Zhou, Bingyan Liu, Xuemei Li, Limeng Chen. *Nephrology Dept, Peking Union Medical College Hospital, Beijing, China.*

Background: Adult Polycystic kidney disease (APKD) is the most common hereditary cause of renal failure. PKD renal failure has been traditionally considered a relative contraindication for peritoneal dialysis (PD) because of overexposing to technique failure and peritonitis. This study was to compare the outcomes and dialysis efficacy in PKD renal failure patients treated with PD, in comparison with hemodialysis (HD) and non-PKD subjects.

Methods: From1993 to 2015, total 47 ESRD patients with PKD in Peking Union Medical College Hospital were recruited. Dialysis adequacy, PD-related complications, PD-technique failure, clinical outcomes and survival rate were compared among patients with PKD-HD group (n=33), PKD-PD group (n=14) and non PKD-PD group (n=43, random sampling from 622 cases PD patients).

Results: The average age of PKD-PD patients was 56±14years old, of which 57.1% were women. One patients received APD treatment and others were CAPD. When compared with PKD-HD group and non PKD-PD group respectively, no significant difference of age, gender, comorbidities and biochemical index were observed in PKD-PD patients at baseline. The Kt/V, Ccr of PKD-PD patients were similar to non PKD-PD group at 3 months, 1 year, 3 years and 5years. The average time on dialysis of PKD-PD was 36.2±33.1months, which was similar to non PKD-PD group (33.6±28.9, *P*=0.551) and PKD-HD group (45.4±39.5, *P*=0.760). There were no significant difference of the peritonitis rate and technical survival rate between the PKD-PD group and non PKD-PD group. The survival rate at 1 year, 3 years, and 5 years for PKD-PD group was similar to non PKD-PD group and PKD-HD group respectively.Three PKD-PD patients convert to HD because of peritonitis and 3 received kidney transplantation. Multivariate Cox regression analysis showed that neither PKD nor PD independently predicted the mortality.

Conclusions: PD could be an option for ESRD patients with APKD.

FR-PO1071

A Multicenter, Randomized, Controlled Trial Comparing Cefepime Monotherapy versus Combination of Cefazolin plus Ceftazidime for Empirical Treatment of CAPD-Associated Peritonitis
Thidarat Kitrungphaiboon,[1] Piyatida Chuengsaman,[2] Guttiga Halue,[3] Monchai Siribamrungwong,[4] Saraporn Matayart,[5] Kamonrat Chongthanakorn,[6] Ussanee Poonvivatchaikarn,[7] Chanchana Boonyakrai,[8] Wanida Somboonsilp,[9] Pisut Katavetin,[1] Talerngsak Kanjanabuch.[1] *[1]Chulalongkorn Univ, Bangkok, Thailand; [2]Banphaeo Hospital, Bangkok, Thailand; [3]Phayao Hospital, Phayao, Thailand; [4]Lerdsin Hospital, Bangkok, Thailand; [5]Buddhasothorn Hospital, Chachoengsao, Thailand; [6]Charoenkrung Pracharak Hospital, Bangkok, Thailand; [7]Nakhonpathom Hospital, Nakhonpathom, Thailand; [8]Chaophraya Yommarat Hospital, Suphanburi, Thailand.*

Background: To avoid laboring and contamination risk of combination antibiotics for empirical treatment of continuous ambulatory peritoneal dialysis (CAPD)-associated peritonitis, single broad-spectrum antibiotic should be proposed instead.

Methods: In a multicenter, open-label, noninferiority trial, we randomly assigned patients who diagnosed CAPD-associated peritonitis to receive intraperitoneal cefepime 1 g loading then 250 mg all exchanges (dose increased by 25% in patients with residual renal function) or combination of cefazolin and ceftazidime with the same regimen for 14 to 21 days. Patients were followed for 28 days after treatment completion. A primary outcome was primary response (at day 10) rate, with a noninferiority limit of 10 percentage points.

Results: 146 patients were randomized (72 in the monotherapy group and 74 in combination group). Patient characteristics of both groups were comparable. Cefepime monotherapy was noninferior to cefazolin plus ceftazidime as the primary response rate was 81.9% in monotherapy group and 81.1% in combination group (difference points = 0.8, 95% confidence interval (CI) -9.7 – 21.4). Initial response (at day 5) and end treatment response rates were 66.67% and 87.5% in monotherapy group versus 60.81% and 89.2% in combination groups [(difference points = 5.86, 95% CI -9.7 – 21.4), (difference points = -1.7, 95% CI -12.1 – 8.7)], respectively. No serious adverse event of cefepime were reported.

Conclusions: Intraperitoneal administration of cefepime monotherapy is noninferior to combination of cefazolin and ceftazidime. Cefepime monotherapy should be considered as an alternative empirical antibiotic for CAPD-associated peritonitis.

Identifying Peritoneal Fluid Microbiome in Patients Receiving Maintenance Peritoneal Dialysis
Esho Georges, Holly J. Kramer, Vinod K. Bansal, Julia Schneider, Michael Zilliox, Kavitha Vellanki. *Dept of Nephrology and Hypertension, Loyola Univ Medical Center, Maywood, IL.*

Background: Peritoneal fluid is considered to be sterile in patients receiving peritoneal dialysis (PD) in the absence of peritonitis. No data exists on the microbiome of peritoneal fluid in stable PD patients. The aim of this single site pilot study is to identify peritoneal fluid microbiome characteristics in PD patients without clinical peritonitis.

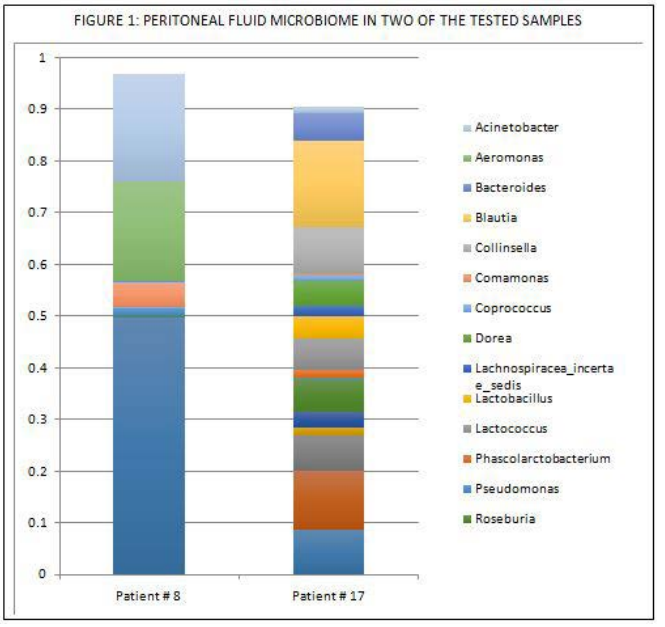
Methods: Patients who are 18 years and older, receiving maintenance PD with no symptoms of peritonitis were included. We collected 10 cc of PD output from each patient participant using routine sterile techniques and 16S rRNA gene sequencing was used to identify bacteria not routinely cultivated by clinical microbiology laboratories. The bacterial types for each specimen were identified.

Results: Of the 25 patients receiving PD at our site, 20 were included in the study. Baseline characteristics are shown in table 1.

Table 1: Baseline Characteristics of Study Population (n=20)

Mean age in years	57.5 years
Sex (M:F)	1:1.2 (9:11)
Race	AA: 35 % (7) Hispanic: 25 % (5) Others: 40 % (8)
Diabetes	45 % (9)
History of peritonitis (over last year)	15 % (3)
History of abdominal surgery	85 % (17)
Type of transporter	High Average: 55 % (11) Low Average: 20 % (4) High: 15 % (3) Low: 0 % (0) Undetermined: 10 % (2)
Native urine output	45 % (9)
Mean dialysis vintage time in years	2.65 years

Two patients tested positive for bacteria above the cut off threshold (> 2000 reads).



Both patients with positive reads are females with no history of peritonitis and are high average transporters.

Conclusions: Peritoneal microbiome may not be sterile in some PD patients without clinical peritonitis. Further research is needed to delineate its role in the success/failure of long term PD.

FR-PO1073

Impact of Hypokalemia on Peritonitis in Peritoneal Dialysis Patients: A Systematic Review
Kentaro Nakai,[1,2] Kei Saitoh,[1,2] Shinichi Nishi.[1,2] *[1]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan; [2]Dept of Nephrology and Kidney Center, Kakogawa East City Hospital, Kakogawa, Japan.*

Background: Hypokalemia is a common electrolyte disorders in peritoneal dialysis patients. Some studies showed the association of serum potassium levels with all-cause and cardiovascular mortality and infection, and hypokalemia can cause muscle weakness, paralytic ileus and peritonitis. This review aims to clarify the relationship of hypokalemia and peritonitis in peritoneal dialysis.

Methods: The MEDLINE and Cochrane Library databases were searched for articles published from 1990 to May 2016. The following search terms were used: hypokal(a)emia, potassium, peritoneal dialysis, peritonitis, infection. Additional studies were identified by hand searching through references and using the MEDLINE related articles option.

Results: A total of 159 abstracts were identified, and 6 trials were included in the systematic review (n=3613). One prospective study and three retrospective studies indicated that hypokalemia increases the risk of peritonitis, whether a prospective observational study and a case-control study indicated otherwise.

Conclusions: Convincing clinical trial data are unavailable to show the association of hypokalemia with peritonitis in peritoneal dialysis patients, and we need to clarify whether the therapeutic intervention to normalize serum potassium levels, such as KCl, spironolactone, adjustment of food or dialysate, decreases the risk of peritonitis and infection-related mortality in peritoneal dialysis patients.

FR-PO1074

Risk Factors and Outcomes of Vancomycin-Resistant Enterococcus Colonization in Patients on Peritoneal Dialysis
Jason Yeung, John Yiu Han Chan, Wai-Leung Chak. *Medicine, Queen Elizabeth Hospital, Hong Kong.*

Background: Vancomycin-resistant Enterococcus (VRE) colonization is common among patients with chronic renal diseases, including those undergoing peritoneal dialysis (PD). The aim of this study is to evaluate the risk factors and various clinical outcomes for VRE colonization among PD patients within a tertiary dialysis centre in Hong Kong.

Methods: This is a single-centered retrospective cohort study of 166 hospitalized patients who used PD as mode of renal replacement therapy from 1 st August 2013 to 31 st July 2014. All patients were screened for VRE colonization status via rectal swabs or stool specimen during hospitalization. They were categorized into two groups: VRE-positive group and VRE-negative group. Baseline characteristics and other potential risk factors were analyzed in both groups. Clinical outcomes including all-cause mortality, infection with VRE, peritonitis-free survival, length of hospitalization, VRE spontaneous clearance rate and VRE relapse rate were also analyzed.

Results: Among the 166 PD patients, 28 (16.9%) were VRE-positive. Multivariate analysis showed that previous contact history with VRE-positive patients (OR: 417.86; 95% CI: 17.21-10147.26, p<0.01), previous use of vancomycin in 3 months (OR: 130.32; 95% CI: 5.35-3176.30, p<0.01) and age (OR: 1.13; 95% CI: 1.02-1.24, p=0.02) were the

three independent risk factors for VRE colonization. Patients in VRE-positive group had significantly longer length of hospitalization stay but there was no significant difference in all-cause mortality and peritonitis-free survival.

Conclusions: VRE-colonization is an important issue among hospitalized PD patients. Cautious use of antibiotics and infectious control measures may be necessary to prevent spreading of VRE especially in those higher risk patients.

FR-PO1075

Electron Microscopy in the Evaluation of Renal Transplant Biopsies: Global Practices and Trends Indicate the Need for Standardization

Harsharan Kaur Singh,[1] Volker Nickeleit,[1] Candice A. Roufosse.[1] *[1]Dept of Pathology, The Univ of North Carolina, Chapel Hill, NC; [2]Dept of Cellular Pathology, Hammersmith Hospital, Imperial College, London, United Kingdom.*

Background: Electron microscopy (EM) is universally accepted in workup of native renal biopsies with established criteria in use worldwide. However, use of EM in the transplant setting outside of the workup for recurrent / de novo glomerular diseases is not well standardized. Glomerular basement membrane (GBM) duplications / remodeling, including changes seen by EM only, presence of peritubular capillary basement membrane [PTC] multi-laminations (PTCL) and endothelial cell activation are considered adjunct EM features of rejection induced injury. In 2015, a Banff-EM-Working Group was created to define and validate EM criteria for diagnosing rejection related changes. A survey was conducted to evaluate current EM practices and results are reported here.

Methods: Members of the European Society for Pathology- Nephropathology Working Group and The Banff Society were surveyed (SurveyMonkey).

Results: 135 members responded [79% United States-Europe; 10% Asia; 5% Latin America; 2% Middle East; 1% each-Russia, Africa, Australia]. 75% were specialized renal pathologists with >10 year experience, access to EM facilities, and evaluation of >100 transplant biopsies annually. EM was performed in only 38% of indication biopsies worldwide after 3 months post-transplantation. Presence of proteinuria (69%) or suspicion of recurrent disease (86%) were the most common triggers for EM evaluation. The approach to find and study lesions varied greatly [<50% agreement] including: #glomeruli/glomerular loops examined, scope magnification and #PTC optimal for PTCL assessment, criteria to record results and to approach diagnostic decision-making [geographic location showed no significant differences].

Conclusions: The current survey shows that ultrastructural changes in rejecting renal allografts are incompletely defined and diagnostic criteria lack standardization. The Banff-EM-Working Group will next develop criteria to standardize detection and recording of EM changes followed by evaluation of diagnostic cut-off levels for GBM and PTCL lesions.

FR-PO1076

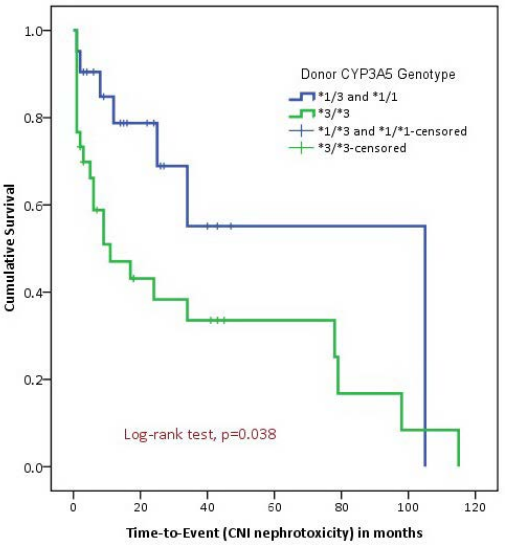
Association of Donor CYP3A5 Genotype and Tacrolimus Nephrotoxicity in Kidney Transplantation

Suwasin Udomkarnjananun,[1] Pajaree Chariyavilaskul,[2] Kroonpong Iampenkhae,[3] Yingyos Avihingsanon,[1] Kearkiat Praditpornsilpa,[1] Natavudh Townamchai.[1] *[1]Nephrology, Chulalongkorn Univ, Thailand; [2]Pharmacology, Chulalongkorn Univ; [3]Pathology, Chulalongkorn Univ.*

Background: The CYP3A5,which is mainly expressed in liver,is also expressed in kidney tissue and might contribute to local drug clearance.This study aim to evaluate the association between the kidney allograft CYP3A5 (donor genotype) and transplant outcomes in Asian population which has variety of CYP3A5 expression.

Methods: Genotyping for donor *CYP3A5* expression were carried out by RT-PCR of the available specimens,blood samples from living donor and extraction from kidney biopsy paraffin tissue in deceased donor.CNI nephrotoxicity was documented by renal pathologist from surveillance biopsy,blindly to CYP3A5 genotype.The primary outcome is time-to-CNI nephrotoxicity in the expressor genotype compare to the non-expressor genotype.

Results: The total of 51 patients were enrolled,21 donors were the expressor genotype (*1/*1 and *1/*3) and 30 donors were the non-expressor genotype (*3/*3).Baseline characteristic showed no difference in donor age, follow-up time, and tacrolimus dosage(C0/mg) between groups.The incidence of CNI nephrotoxicity was significantly higher in non-expressor compared to expressor(73% vs 33%, p<0.05).Median time to event was 11 months in non-expressor group and 105 months in expressor groups(p<0.05).



Cox regression analysis showed hazard ratio of 0.306 (p<0.05) for the donor expressor genotype compare to non-expressor genotype.

Covariates	Hazard ratio	p-value
Donor CYP3A5(expressor vs non-expressor)	0.306	0.028
Delayed graft function(Yes vs NO)	0.825	0.687
Donor age	1.005	0.821
Recipient age	1.037	0.069
TAC C0/mg	0.435	0.019

Conclusions: Donor CYP3A5 non-expressor genotype (*3/*3) is an independent risk for CNI nephrotoxicity, probably due to poor local allograft tissue drug clearance.

FR-PO1077

Impact of Tacrolimus Formulation Switching on Trough Variability

Edward Lee,[2] Ashley R. Perry,[1] David Facklam,[1] Jason J. Schwartz,[2] Billy Franks,[2] Gary Thal,[2] James R. Spalding,[2] Maria E. Vassilakis,[2] William Irish.[1] *[1]CTI Clinical Trial and Consulting, Cincinnati, OH; [2]Astellas Pharma Global Development, Inc., Northbrook, IL.*

Background: For a narrow therapeutic index drug like tacrolimus (TAC), variations in exposure could result in reduced immunosuppression or toxicity.

Methods: This retrospective cohort study examined differences in trough variability between fixed regimen (FR) and variable regimen (VR) patients (pts). US National Drug Codes (NDC) for TAC, 3–15 months (mos) post-transplant (tx), were used to allocate pts to FR or VR groups. VR was defined as a change in NDC within a specific strength or a dose adjustment that resulted in an NDC change for any continuing dose strength. Adult kidney tx pts, between 09/2009 through 12/2012, with stable renal function (SCr<1.5mg/dL), and no acute rejection at 3 mos post-tx, were eligible. A total sample size of 816 pts was expected.

Results: Data on 305 of the proposed 816 pts were collected from 4 sites: 261 pts (86%) in the FR group and 44 (14%) in the VR group. Thirty-five (80%) VR pts came from a single site. VR pts tended to be non-white (70% v 36%), on dialysis longer (57 vs 39 mos), had government insurance (84% vs 65%), and had received an ECD kidney (30% vs 4%). Key results were summarized:

Month 3–15 Post-Tx	Fixed (n=261)	Variable (n=44)	P-value
Mean no. of dose adjustments	2.40	2.77	0.237
Mean cumulative mg dose change	3.40	3.72	0.506
Mean trough to dose (T/D) ratio	2.02	2.22	<0.001
Mean no. of trough measurements	22.6	29.2	<0.001
TAC levels above 120% or below 80% of a pt's overall mean were examined. Excursions outside this range were significantly higher for the VR group 3–15 mos post-tx (13.8 vs 10.5, P<0.001).			

Conclusions: Preliminary findings show that VR pts in this study were more vulnerable and were associated with greater TAC trough level excursions and a difference in T/D ratio, and may explain why more TAC trough measurements were observed in VR pts. This may be relevant given recent evidence linking several outcome measures with increases in TAC variability. However, small sample size and potential for selection bias in VR pts needs to be considered when interpreting results.

FR-PO1078

Variation in Tacrolimus Level Is Associated with Pediatric De Novo DSA and Renal Allograft Rejection Hilda E. Fernandez,[1] Sandra Amaral,[1] Susan L. Furth.[1] *[1]Columbia Univ Medical Center; [2]Children's Hospital of Philadelphia.*

Background: De novo donor specific anti-HLA antibodies (dnDSA) following kidney transplant (txplt) have been demonstrated to increase risk of rejection (rjxn) in renal allografts. Variation in tacrolimus (CV TAC) immunosuppression has been associated with non-adherence to medical therapy and increased risk of rjxn. This study assessed CV TAC in relation to appearance of dnDSA and allograft rejection in pediatric (ped) kidney transplant.

Methods: Retrospective study of ped renal txplt patients (pts) at CHOP from 2008 to 2011 with routine monitoring of DSA post-txplt.

Results: From 9/2008 - 12/2011, 47 pts were transplanted and had serially monitored DSA post-transplant. Induction was primarily antithymocyte globulin (85%), 57% were male, 21% had living kidney txplt, 62% were Caucasian, with 43% having CAKUT as cause of ESRD. 25% had a prior allograft txplt, and 83% had >2 HLA mismatch. During a median follow-up time of 4.3 yrs, 23 pts developed dnDSA in a median 0.77 yrs following txplt. No sig diff in sex, ethnicity, living donor, HLA MM seen between pts w/and w/o dnDSA. Pts w/ dnDSA had higher allograft rejection (15 v 1) and allograft loss (7 v 1) than pts w/ out dnDSA ($p < 0.01$). Pts w/ dnDSA had significantly higher CV TAC following KT than pts w/out dnDSA up to 18 months post-txplt ($p = 0.04$). Also, pts w/ dnDSA had a faster rate of decline of creatinine over the period of follow-up than pts w/o dnDSA ($p = 0.03$).

Conclusions: Pts with dnDSA had higher CV TAC, more allograft rejection and loss, and greater decline in creatinine than pts without dnDSA. As CV TAC has been associated with allograft rejection, this suggests that higher variation in tacrolimus levels are reflected in the development of dnDSA.

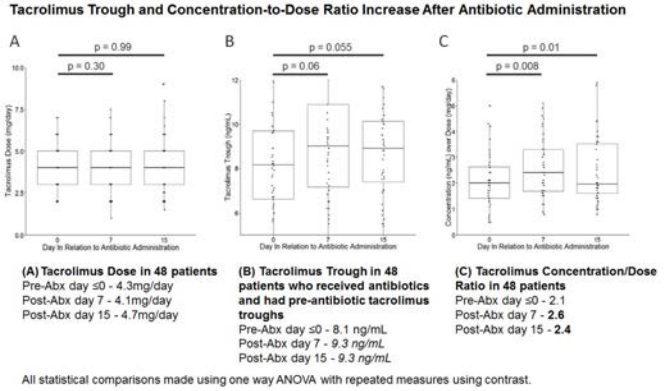
FR-PO1079

Antibiotics and Tacrolimus Trough Variability in Kidney Transplant Recipients Yuanpu Zheng, Anjali Masand, Michael P. Wagner, Thangamani Muthukumar, Darshana Dadhania, Manikkam Suthanthiran, John R. Lee. *Nephrology and Transplantation Medicine, Weill Cornell Medical Center, New York, NY.*

Background: Based on our recent finding suggesting that the gut microbial community structure is associated with tacrolimus dose requirements, we tested the hypothesis that antibiotics, documented to alter the gut microbiota, increase tacrolimus trough variability.

Methods: We conducted a retrospective study of 229 kidney recipients transplanted 2012 to 2013 at New York Presbyterian Hospital - Weill Cornell. Patients receiving antibiotic therapy during post-operative day (POD) 0-30 were assigned to the Antibiotic group (ABX, n= 60) and those who did not receive antibiotics were assigned to the No Antibiotic group (No ABX, n=169). We analyzed pre- and post-antibiotic tacrolimus trough and dose changes in the ABX group. We also compared tacrolimus trough variability using intra-patient Standard Deviation (SD) and Coefficient of Variation (CV) between both groups.

Results: In the ABX Group, the mean tacrolimus dose did not change from pre-antibiotic to post-antibiotic day 7 and 15 ($p=0.30$ and $p=0.99$, Panel A), but tacrolimus trough levels increased ($p=0.06$ and $p=0.055$, Panel B) and the ratio of tacrolimus trough to dose increased ($p=0.008$ and $p=0.01$, Panel C) from pre-antibiotic to post-antibiotic day 7 and 15. The ABX subgroup that received penicillin class antibiotics had an increased ratio of trough to dose ($p=0.03$) after antibiotics.



Intra-patient SD and CV of tacrolimus troughs taken during POD 31-45 were significantly higher in the ABX group than the No ABX group (SD: median 2.6 ng/mL vs. 1.4 ng/mL, p=0.008, Wilcoxon; CV: median 0.29 vs. 0.17, p=0.004, Wilcoxon).

Conclusions: We have identified that antibiotic use impacts tacrolimus trough level variability and recommend closer monitoring of tacrolimus trough concentrations after antibiotic treatment.

FR-PO1080

Pharmacokinetics of Once-Daily Envarsus XR in Diabetic versus Non-Diabetic Kidney Transplant Recipients: A Pooled Subgroup Analysis Daniel C. Brennan,[1] Patricia West-Thielke,[2] Daniel R. Stevens.[3] *[1]Washington Univ, St. Louis; [2]Univ of Illinois, Chicago; [3]Veloxis Pharmaceuticals.*

Background: Tacrolimus (tac) has a narrow therapeutic range. In transplant recipients, too low exposure risks graft rejection while too high risks toxicity. The pharmacokinetics (PK) of tac may be unfavorably affected by diabetes. In particular, gastroparesis is common in individuals with diabetes and may impact drug absorption and ultimately, drug exposure. In clinical studies, the MeltDose® formulation of once-daily extended release tac (Envarsus® XR; LCPT) showed improved bioavailability with quicker attainment of therapeutic trough levels, lower peak-to-trough fluctuation, and a lower dose requirement vs. twice-daily immediate release tac (Prograf®; IR-Tac). With LCPT the release of tac occurs over a larger portion of the GI tract and over an extended period of time vs. IR-Tac. We sought to assess LCPT PK in patients with diabetes, a high proportion of whom may have gastroparesis.

Methods: This pooled analysis of data from two phase III and one phase II randomized trials examined tac PK in 123 stable kidney transplant patients with (n=50; 72% male; mean age: 52.9±9.9) and without diabetes (n=73; 58% male; mean age: 45.5±11.3) who were converted from IR-Tac to LCPT at doses 67-80% of the pre-conversion total daily tac dose.

Results: The PK parameters associated with LCPT (lower C_{max} and lower peak-to-trough fluctuation while maintaining a therapeutic trough) were evident regardless of diabetes status [Table1]. All PK comparisons for LCPT were not statistically significant.

Conclusions: Results show that the improved PK previously documented with LCPT is maintained in kidney transplant patients with diabetes.

	LCPT		IR-Tac	
Day 7 PK Parameter	No Diabetes (N=73)	Diabetes (N=50)	No Diabetes (N=73)	Diabetes (N=50)
T_{max}[1]	5.9 (3.0-7.9)	5.9 (4.0-6.0)	1.5 (1.0-2.0)	1.5 (1.0-2.9)
AUC[2]	246.7 (97.6)	221.4 (74.0)	216.7 (66.9)	212.8 (74.5)
C_{max} (ng/mL)[2]	16.1 (7.0)	14.6 (6.1)	20.2 (8.4)	20.4 (11.4)
C_{min} (ng/mL)[2]	7.6 (3.1)	6.8 (2.4)	6.7 (1.9)	6.7 (2.1)
% fluctuation[1]	77.7 (47.6-104.9)	73.1 (51.9-109.7)	131.9 (106.7-179.7)	133.8 (87.7-193.9)

FR-PO1081

Evaluation of Flexible Tacrolimus Drug Level Monitoring Approach in Patients Receiving Extended-Release Envarsus XR® Benjamin Philosophe,[1] Nicolae Leca,[2] Patricia West-Thielke,[3] Timothy A. Horwedel,[4] Daniel R. Stevens.[5] *[1]Johns Hopkins Univ; [2]Univ of Washington Medical Center; [3]Univ of Illinois; [4]Barnes Jewish Hospital; [5]Veloxis Pharmaceuticals.*

Background: Tacrolimus is a drug with a narrow therapeutic range. To ensure adequate exposure in transplant patients, 12-hour post-dose monitoring is required for twice-daily tacrolimus capsules. Due to timing of every 12-hour administration of twice daily tacrolimus, most patients will need phlebotomies at similar times which creates clinic backlogs and logistical challenges. Once daily tacrolimus tablets (Envarsus XR®) are made with proprietary MeltDose technology which results in a tacrolimus formulation with 50% increased bioavailability vs. twice-daily immediate-release tacrolimus capsules (Prograf®) and similar efficacy and safety, at a 30% reduced dose.

Methods: This analysis examined whether the trough measurement window could be extended for Envarsus XR due to its flatter kinetic curve. Extending the window for trough level measurement would allow greater flexibility in timing of blood draws for tacrolimus levels, potentially reducing early morning patient overload in clinics. PK data from 30 Envarsus XR-treated kidney transplant patients participating in an open label cross-over study were used. Primary results were previously reported; here, the 21-27 slow-tail analysis is reported.

Results: Results for Envarsus XR showed that AUC_{0-24} and C_{21}, C_{24}, C_{27}, are highly correlated (Pearson's correlation coefficient >0.9168; $p<0.0001$) with corresponding levels of (mean ±SE) 7.204 ng/mL±0.538; 6.801±0.521; 6.296±0.506 respectively. The elimination rate was -1.90% per hour between C21 and C24 and -2.61% per hour between C24 and C27; The results show that therapeutic drug monitoring window of +/- 3 hours for LCPT tacrolimus levels in clinics can be performed with confidence and without any/minimal adjustment for the differences in time points. This offers an alternate solution with greater flexibility for clinicians and patients.

Conclusions: Extending "trough measurement window" provides the opportunity for potentially improving the provider and out-patient experience.

FR-PO1082

Long-Term Results of a Prospective Randomized Study of Efficacy and Safety of Early Tacrolimus Conversion to Sirolimus after Kidney Transplantation Amgad E. El Agroudy. *Medicine, Arabian Gulf Univ, Manama, Bahrain.*

Background: We report a prospective, open-label, randomized study to evaluate the safety and efficacy of converting patients with stable renal function from Tacrolimus (Tac)-based regimen to a Sirolimus (SRL)-based regimen after kidney transplantation.

Methods: Fifty eight low risk renal allograft recipients who were eligible to the study, 6 months posttransplant and receiving Tac, were randomly assigned to continue Tac (n=29) or convert to SRL (n=29). We evaluated the 3-year outcomes including patient and graft survival, graft function and safety profile.

Results: 3-year patient and graft survival in SRL and Tac groups was 93.1% vs. 100% (P=0.32), and 89.7% vs. 100% (P=0.11), respectively. However, the SRL group had significantly better renal function, from the second year post-transplant until the last follow-up. Four (13.8%) patients in the SRL group and 3 (10.3%) in the Tac group (P=0.5) developed biopsy proven acute rejection. Mean urinary protein excretion increased significantly after SRL conversion. Diastolic blood pressure was significantly lower at the end of the study in patients who eliminated tacrolimus (80.4 vs. 75.6 mmHg in Tac and SRL group, respectively) (P = 0.03). Mean hemoglobin concentrations decreased after SRL conversion and remained significantly lower from 12 months to 36 months (P=0.01). The mean serum cholesterol (6.1±0.5 mmol/l) and triglyceride (2±0.3 mmol/l) levels increased significantly in the SRL group, compared to TAC group (5.5±0.7 mmol/l) (P=0.03) and 1.6±0.3 mmol/l) (P= 0.04).

Conclusions: our experience demonstrates that conversion to sirolimus from calcinuerin inhibitors (CNI)-based therapy may result in better renal function and blood pressure control.

FR-PO1083

Inadequate Mycophenolic Mofetil Exposure Is Associated with More Ejection and Graft Loss in Kidney Transplant Patients Amgad E. El Agroudy. *Medicine, Arabian Gulf Univ, Manama, Bahrain.*

Background: Although MMF is generally well tolerated, optimal therapy may be limited by adverse effects, in particular gastrointestinal toxicity. MMF dose changes resulting from these adverse events may lead to sub-therapeutic dosing and impaired clinical outcomes. Aim of our study is to investigate the impact MMF dose reduction on the incidence of acute rejection and graft survival.

Methods: In this study, a cohort of 150 kidney transplant recipients who received immunosuppression using MMF in conjunction with cyclosporine and prednisone was evaluated. We classified patients into 3 groups according to MMF dose per day in gm; group I with 2 gm/day, group II 1.5 gm/day and group III 1 gm or less per day. Clinical outcomes were compared and contrasted between patients with and without MMF dose changes post-transplantation. The study followed the Declaration of Istanbul (DOI) ethics' statement. The study was undertaken in accordance with the Declaration of Helsinki, and all subsequent amendments, and was approved by the local ethics committees.

Results: The majority of patients (52.7%) had at least one dose change within the first post-transplant year. Compared with the 79 patients who did not have a dose change, these patients had a significantly higher incidence of acute rejection within the first post-transplant year (36% vs. 10%, p <0.01). This resulted in a significantly decreased 5-yr death-censored graft survival (77% vs. 68% and 57% in the groups I, II and III, respectively, p = 0.04). The incidence of acute rejection for patients who had a dose change was highest if the dose change occurred within the first post-transplant 6 months (38%). The duration to the first acute rejection was dose related (2.3±1.1 and 4.6±1.4 months in group II and III, respectively, p<0.05). Regarding other complications, there was no significant differences in terms of incidence of infections and malignancy within five year of follow-up.

Conclusion: Altering the dose of MMF within the first post-transplant year correlated with a significantly worse clinical outcome in renal transplant recipients. These data suggest that avoidance of MMF dose changes would result in improved graft survival.

FR-PO1084

Outcome of Conversion from Calcineurin Inhibitors or mTOR Inhibitors to Belatacept in Renal Transplant Patients Sahil Bawa,[1] Marat Abdullin,[2] Michael J. Germain.[2] *[1]Nephrology, RTANE, Springfield, MA; [2]Nephrology, Baystate Medical Center, Springfield, MA.*

Background: Calcineurin Inhibitors(CNI's) are used in over 90% of RTP in the United States.The efficacy of mTOR inhibitors for primary maintenance immunosuppressive therapy in RTP is well documented.The use of Belatacept(BELA) is a reasonable alternative.

Methods: Patients(Pt's) who were switched to belatacept from CNI or mTOR inhibitors were studied.Laboratory data including hemoglobin(Hb),serum creatinine(SCr),triglyceride s(Tg),serum glucose(SG),urinary protein/creatinine ratio(PCR) before and after conversion were compared. We used 3 measurements for SCR, Hb and BS, and 2 measurements for Tg and PCR before and after transition.

Results: 66 Pt's(14 male and 10 female) were switched from CNI group(11 Pt's) and mTOR group(13 Pt's) based regimens to BELA.Pt's average age was 45.3(17-74) years old. Average allograft age was 8(1.5-20) years. Average follow up on BELA therapy was 13.2(4-28) month.Indications for conversion were various side effects of conventional immunosuppression,including proteinuria,pulmonary toxicity,uncontrolled diabetes,CNI toxicity,etc.SCr decreased in Pt's converted from CNI and remained unchanged in mTOR group.There was insignificant increase in Hb in both groups.Tg and fasting hyperglycemia improved in both groups.PCR decreased in both groups.No significant side effects with BELA were reported.Blood Pressure is still being evaluated and be reported later.14 Pt's responded to questionnaire. On a three point Lickert scale 10 out 14 Pt's reported feeling better after conversion,none of them felt worse.10 out of 14 Pt's felt that side effects they had with conventional immunosuppression either resolved or improved. None of the Pt's we asked wanted to go back to the old immunosuppressive regimen.

Conclusions: Clinical experience of conversion to BELA from CNI and mTOR inhibitor demonstrated that this is a safe alternative which is well-tolerated by Pt's and associated with improved renal function in Pt's transitioned from CNI and stable renal function in Pt's transitioned from mTOR inhibitor. It was also associated with improved metabolic parameters and decrease proteinuria.

FR-PO1085

Effectiveness and Safety Profile Comparison of Sirolimus and Everolimus in Renal Transplantation Priscilla P. How,[1,4] Li Fang Goh,[2] Puay Hoon Lee,[2] Petrina Fan,[2] Terence Kee Yi Shern.[3] *[1]Dept of Pharmacy, National Univ of Singapore; [2]Dept of Pharmacy, Singapore General Hospital; [3]Dept of Renal Medicine, Singapore General Hospital; [4]Dept of Medicine (Nephrology), National Univ Hospital.*

Background: Mammalian target of rapamycin inhibitors (MTOR-I), such as sirolimus (SRL) and everolimus (ERL) are used as alternative immunosuppressive agents in renal transplant patients who develop calcineurin-inhibitor intolerance. However, no head-to-head trials comparing ERL and SRL have been reported. This study aimed to compare the effectiveness and safety outcomes between patients receiving ERL and SRL over a 12-month period.

Methods: A retrospective cohort study was conducted on kidney transplant patients in the Singapore General Hospital who were started on ERL or SRL as part of their immunosuppressive regimen, regardless of period of MTOR-I initiation post-transplant. The patients were followed for 12 months or until MTOR-I was discontinued. The primary endpoint was the incidence of biopsy-proven acute rejection (BPAR) and calculated creatinine clearance (CCT). Secondary endpoints included patient's urinary protein-to-creatinine ratio (UPCR), hemoglobin, as well as incidences of dyslipidemia, hypertriglyceridemia, diabetes, and hospitalization for infections and pneumonitis.

Results: Ninety-one patients were included (ERL n=47, SRL n=44). At 12 months, 8 and 12 patients in the ERL and SRL groups, respectively, developed BPAR (p=0.24). Mean CCT in the ERL and SRL groups were similar among patients who were initiated on MTOR-I early post-transplant (ERL vs SRL: 53.7 vs 40.1ml/min, p=0.12) and among late MTOR-I initiators (43.4 vs 36.3ml/min, p=0.07) at 12 months. Although no significant between-group differences in post-baseline secondary endpoints were observed, trends towards smaller increase in proteinuria and lesser impact on lipid profile were seen in patients on SRL.

Conclusions: No significant differences in the effectiveness and safety endpoints between ERL and SRL were noted. However, SRL may be preferred in patients with severe proteinuria and uncontrolled lipid profile at baseline.

FR-PO1086

Long-Term Outcomes with Everolimus (EVR) and Other Regimens in Kidney Transplantation in the United States Diane Cibrik,[1] William Irish,[2] Kevin M. Mccague,[3] Dharmesh Patel,[3] Helio Tedesco Silva.[4] *[1]Univ of Michigan, MI; [2]CTI Consulting, NC; [3]Novartis, NJ; [4]Hospital do Rim UNIFESP, Brazil.*

Background: Using the United Network for Organ Sharing database, we compared long-term clinical outcomes of regimens used in kidney transplant (KTx) recipients.

Methods: First time kidney only transplant recipients, ≥ 18 years old, transplanted between January 1, 1998 and December 31, 2014, and receiving EVR or sirolimus (SIR) or mycophenolic acid (MPA) + calcineurin inhibitor (CNI) ± steroids at time of discharge were included in the analysis. KTx recipients were excluded if their allograft failed prior to hospital discharge, they had received a donor organ with cold ischemia time >40 hours or transplantation occurred in 2001 or 2008-2009 (when EVR was not used). Treatment selection bias was addressed using risk-adjusted methods in the design and analysis. Cohorts were matched based on the propensity score for EVR using a greedy matching algorithm within donor type (living vs. deceased donor). Two mutually exclusive transplant periods were defined (ERA1: 1998-2007 and ERA2: 2010-2014; EVR was approved in the US in 2010). Kaplan-Meier and stratified Cox hazard models were used to estimate and compare outcomes between cohorts.

Results: Median follow-up was 8 years. Propensity score matching created clinically well-matched cohorts. Results (rate ± standard error) are below. Risk of graft failure was comparable between the EVR vs SIR and EVR vs MPA cohorts. The relative effect of EVR vs SIR and EVR vs MPA was comparable when the analysis was restricted to tacrolimus-based regimens.

Donor Type	Cohort comparison	Adjusted Graft survival at 5 years (%)
Living	EVR (n=369) vs SIR (n=1,173)[1]	85.8 ± 1.1 vs 84.4 ± 1.0
	EVR (n=432) vs MPA (n=2,034)[2]	87.3 ± 0.9 vs 86.3 ± 0.9
Deceased	EVR (n=352) vs SIR (n=1,203)[1]	74.3 ± 1.3 vs 72.0 ± 1.3
	EVR (n=403) vs MPA (n=1,936)[2]	75.1 ± 1.4 vs 73.3 ± 1.4

[1] Rates adjusted for ERA, antibody induction & donation after cardiac death [2] Rates adjusted for ERA and tacrolimus maintenance immunosuppression at time of discharge.

Conclusions: Long term graft survival outcomes were similar for EVR vs SIR and EVR vs MPA regimens in KTx regardless of donor status and CNI.

Everolimus-Facilitated Cyclosporine A Sparing Immunosuppression Might Improve Glycemic Control in Kidney Transplant Recipients – A Retrospective Analysis Florian Kälble,[1] Jörg Seckinger,[2] Matthias Schaier,[1] Christian Morath,[1] Martin G. Zeier,[1] Claudia Sommerer.[1] *[1]Nephrology, Medical Univ Hospital, Heidelberg, Germany; [2]Internal Medicin, Div Nephrology, Zug Cantonal Hospital, Baar, Switzerland.*

Background: Mammalian target of rapamycin inhibitors (mTORi) allow calcineurin inhibitor (CNI) sparing therapy in renal transplant recipients with possible beneficial effects on the long-term allograft function and cardiovascular risk profile. While the adverse effects of CNI on glucose metabolism have been documented, the influence of mTORi is still under discussion.

Methods: In a retrospective analysis, renal allograft recipients switched from a cyclosporine A (CsA) to an everolimus (EVR) based immunosuppression in the first year after transplantation were compared with patients on continued CsA treatment. Clinical and biochemical data were collected at 6-month intervals. The prevalence of impaired fasting glucose (IFG) and new onset of diabetes after transplantation (NODAT) was documented.

Results: A total of 146 renal transplant recipients were included in the present study. The cumulative prevalence of IFG and NODAT 30 months post transplantation was significantly lower in patients switched to a primary immunosuppression with EVR compared to patients on continued CsA treatment (10% versus 22%, p=0.049). Patients switched to EVR revealed a mean HOMA-IR (homeostasis model assessment insulin resistance) <2 while the index in patients on continued full-dose CsA was 4 (1.7±1.3 versus 3.9±1.1, p<0.05), suggestive of insulin resistance. Patients switched to a CsA-sparing regimen showed a higher incidence of acute cellular rejection episodes in the first 12 months (23% versus 12%, p=0.048).

Conclusions: The switch to an EVR-based immunosuppression was associated with an improvement in glycemic control. However, due to higher rates of acute cellular rejections, patients switched to EVR should be carefully selected and closely monitored.

FR-PO1088

Effect of Everolimus on the Cardiac Function in Kidney Transplant Recipients Kazuma Tsujimura. *Surgery, Tomishiro Central Hospital, Tomishiro-shi, Okinawa, Japan.*

Background: In this study, we evaluated the effect of everolimus (EVR), one of the mammalian targets of rapamycin on cardiac function in kidney transplant recipients.

Methods: We retrospectively studied 76 participants who underwent kidney transplantation (KTx) between March 2009 and May 2017. All participants received tacrolimus or cyclosporine, mycophenolate mofetil, and methylprednisolone for maintenance immunosuppression after KTx. To standardize EVR administration at our institution, the following criteria were used: (1) The recipient did not have donor-specific antigen before KTx. (2) The recipient did not have proteinuria and uncontrollable hyperlipidemia after KTx. (3) Acute rejection was not observed on protocol biopsy 3 months after KTx. According to these criteria, we included EVR administration for maintenance immunosuppression after KTx. We compared the cardiac function of the group receiving treatment with EVR (n=30) and the non-treatment group (n=46). All participants underwent echocardiography before KTx and every year after KTx.

Results:

Table 1 Patient Characteristics (Mean±SD)

	Treatment group (n=30)	Non-treatment groip (n=46)	p-value
Male, n (%)	22 (73.3%)	29 (63.0%)	0.351
Age (years)	48.7 ± 14.2	49.2 ± 12.9	0.867
Scr before KTx (mg/dL)	10.8 ± 3.5	11.5 ± 3.9	0.452
EF before KTx (%)	65.6 ± 8.1	65.4 ± 8.9	0.931
FS before KTx (%)	36.4 ± 5.8	36.3 ± 6.4	0.948
E/A ratio before KTx	1.00 ± 0.38	0.95 ± 0.33	0.494

Scr, serum creatinine; EF, ejection fraction; FS, fractional shortening; E/A ratio, E-wave/A-wave

The characteristics of the 2 groups did not differ significantly (Table 1.). The mean observation period of the treatment and non-treatment group was 41.3 ± 12.6 and 43.9 ± 19.8 months, respectively (p=0.573). The mean ejection fraction (EF), fractional shortening (FS), and E-wave/A-wave (E/A) ratio of the treatment and non-treatment groups after KTx was 66.5 ± 7.9 % vs. 69.6 ± 5.5 % (p=0.024), 37.1 ± 6.2 % vs. 39.3 ± 4.7 % (p=0.045), and 1.07 ± 0.44 % vs. 0.94 ± 0.31 % (p=0.494), respectively.

Conclusions: Supplementary administration of EVR after KTx may not affect cardiac diastolic function, but may reduce cardiac systolic function.

FR-PO1089

Utility of Cystatin C–Based Equation for GFR Estimation in a Living Kidney Donor Takayuki Adachi,[3] Kazuma Tsujimura.[1,2] *[1]Surgery, Tomishiro Central Hospital, Tomishiro-shi, Okinawa, Japan; [2]Urology, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan; [3]Nephrology, Tomishiro Central Hospital, Tomishiro-shi, Okinawa, Japan.*

Background: To evaluate the utility of the cystatin C–based equation for determining the estimated glomerular filtration rate (eGFR) in a live kidney donor.

Methods: Between March 2010 and March 2016, 83 donors were evaluated at our institution; they provided written informed consent. The study population included 27 men and 56 women, with a mean age of 52.9 ± 11.9 years (range, 24–76 years). Based on the guidelines of the Japanese Society of Nephrology, eGFR was estimated using the creatinine-based equation (eGFRcre) and the cystatin C–based equation (eGFRcys). The eGFRcre and eGFRcys values were calculated as:

$eGFRcre = 194 \times Scr^{-1.094} \times Age^{-0.287}$ (× 0.739 for females)

$eGFRcys\ (male) = (104 \times Cys\text{-}C^{-1.019} \times 0.996^{age}) - 8$

$eGFRcys\ (female) = (104 \times Cys\text{-}C^{-1.019} \times 0.996^{age} \times 0.929) - 8$

The creatinine clearance rate (CCr) was measured using a 24-hour urine collection test. We compared eGFRcre and eGFRcys values with the CCr in living kidney donor.

Results: The mean serum creatinine level was 0.67 ± 0.13 mg/dL (range, 0.45–1.02 mg/dL), and the mean serum cystatin C level was 0.82 ± 0.11 mg/dL (range, 0.60–1.09 mg/dL). The mean CCr, eGFRcre, eGFRcys were 108.4 ± 21.6 mL/min/1.73 m^2 (range, 63.7–168.7 mL/min/1.73 m^2), 81.5 ± 14.2 mL/min/1.73 m^2 (range, 55.4–117.5 mL/min/1.73 m^2), 91.4 ± 16.3 mL/min/1.73 m^2 (range, 59.9–128.9 mL/min/1.73 m^2), respectively. The eGFRcre was significantly lower than the Ccr ($p < 0.001$). The correlation coefficient for the relationship between the eGFRcre and Ccr values was 0.445, and the mean difference between the two values was -26.9 (24.8%), with a root mean square error of 19.5. The eGFRcys was significantly lower than the Ccr ($p < 0.001$). The correlation coefficient for the relationship between the eGFRcys and Ccr values was 0.466, and the mean difference between the two values was -17.0 (15.7%), with a root mean square error of 19.2. Bland-Altman plots showed that eGFRcre and eGFRcys underestimated GFR values compared with Ccr in 79 and 65 of 83 cases, respectively.

Conclusions: Although eGFRcys was more useful than eGFRcre, it still did not accurately estimate GFR in Japanese living kidney donors.

FR-PO1090

Late Conversion to Belatacept in Biopsy Proven Tacrolimus Toxicity Shruti Gupta, David Wojciechowski. *Nephrology, Massachusetts General Hospital.*

Background: The calcineurin inhibitor tacrolimus is excellent at preventing acute rejection in renal transplantation. However, it is associated with chronic nephrotoxicity, manifested as interstitial fibrosis/tubular atrophy (IF/TA) and arteriolar hyalinosis on biopsy. Once toxicity develops, a tacrolimus minimization strategy is often used but ongoing allograft injury can still occur even with reduced tacrolimus exposure. Conversion from tacrolimus to belatacept may be a potential strategy to preserve renal function.

Methods: We evaluated a cohort of 7 patients biopsied for a rising creatinine. These patients were found to have chronic tacrolimus toxicity with at least 1+ IF/TA and 1+ arteriolar hyalinosis by Banff, and were thereafter converted to belatacept. We conducted a retrospective analysis of these patients 1) comparing changes in eGFR at conversion to the eGFR at 6 and 12 months post conversion, and 2) assessing allograft and patient survival at 1 year post conversion. We also assessed the incidence of infection and rejection post-conversion.

Results: The mean age at conversion was 52.3. Four of 7 patients were male. Causes of ESRD were IgA nephropathy, lithium toxicity, obstructive uropathy, FSGS, dysplastic kidney disease, and nephrocalcinosis. Patients were converted to belatacept 7.7 to 18.3 years post-transplant. The eGFR (mL/min/1.73m^2) at conversion and post-conversion is listed in the table.

Patient	1	2	3	4	5	6	7
GFR at conversion	14	38	38	46	35	41	32
Month 3	15	40	46	43	37	37	31
Month 6	11	40	50	38	32	37	31
Month 12	11	50	50	34	31	34	34

Three of 7 patients had no infections post conversion, while 1 patient had a citrobacter urinary tract infection, 1 had gastroenteritis, and 2 patients had bacteremia. All grafts survived except for patient 1, whose graft dysfunction led to retransplantation 13 months after conversion.

Conclusions: In patients with late allograft dysfunction due to chronic tacrolimus toxicity, conversion to belatacept stabilized the eGFR in 4 out of 7 patients and resulted in an increased eGFR in 2 of 7 patients. This strategy should be evaluated in a larger cohort of patients to better assess the efficacy of this approach.

FR-PO1091

One Year Outcome of Preemptive Low Dose Rituximab in Flow Cytometery Crossmatch Positive Kidney Transplant Recipients Sagar Gupta, Thin Thin Maw, Daniel C. Brennan. *Nephrology, Washington Univ in Saint Louis, St. Louis, MO.*

Background: Significance of positive flow cytometry crossmatch(+ve FCC) in kidney transplantation remains unclear,though such patients tend to have poorer outcomes.The role of B cells in the pathogenesis of acute rejection and late allograft dysfunction continues to be increasingly recognized.Anti-B cell therapy can impair antigen-presenting function of B cells,suppress antibody production and other mechanisms of immune mediated injury.

Methods: Retrospective chart review for patients transplanted at our center between May2009 and October2014 with +ve T or B cell FCC was performed. 28 out of 155 transplant recipients received one dose of rituximab(200 mg) preemptively before discharge. Incidence of acute rejection, DSA development, renal function and graft survival over 12 months were recorded.

Results: Among 28 patients who received rituximab, 8 had pre-formed DSA and 10 developed de novo DSA. However, 50% (14/28) had a prior transplant in this group. They

tend to be younger with a mean age of 43 years. The mean serum creatinine (Sr Cr) trended to be lower in rituximab group at all points during the 12-month follow up period, though this was not statistically significant. Acute cellular rejection (ACR), antibody mediated rejection (AMR) and graft loss at 1 year were lower in rituximab group, not reaching statistical significance given low sample size and incidence numbers.

	Rituximab(n=28)	No Rituximab(n=127)	p-value
Mean age (yrs)	43	50	0.013
Prior transplant	14(50%)	32(25%)	0.090
T cell flow (MCS)	79	49	0.047
B cell flow (MCS)	125	127	0.900
Preformed DSA	8(28.6%)	2(1.6%)	<0.001
Denovo DSA	10(35.7%)	21(16.5%)	<0.026
Sr Cr mg/dl(mean)			
1 mo	1.4	1.55	0.36
3 mo	1.2	1.41	0.32
6 mo	1.29	1.34	0.53
9 mo	1.33	1.44	0.48
12 mo	1.3	1.47	0.30
ACR	1(3.6%)	7 (5.5%)	0.1
AMR	1(3.6%)	6 (4.7%)	1
ACR+AMR	1(3.6%)	12 (9.4%)	0.46
Graft loss 1 yr	0	5 (3.9%)	0.586

Conclusions: Although there is no statistically significant difference in Sr Cr, acute rejection rate and graft loss at 1 year between rituximab group and no rituximab group,there was a trend towards lower acute rejection rate and graft loss in rituximab group.

FR-PO1092

Effects of Basiliximab on Lymphocyte Subsets in Living-Related Kidney Transplantation

Xianping Yu, Jianghua Chen. *The Kindey Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang Province, China.*

Background: To observe the effects of basiliximab on peripheral lymphocyte subsets in early time of living-related kidney transplantation (LRKT).

Methods: 28 LRKT recipients were enrolled in the study. 12 accepted the induction therapy of basiliximab (induction group), and 16 were not given induction therapy (control group). The maintenance immunosuppressive regimen consisted of tacrolimus, mycophenolate mofetil and steroids. The peripheral lymphocyte subsets were monitored before and one week after the operation by using flow cytometry. The renal allograft function, infection and acute rejection were observed by month six after transplantation.

Results: One week after the operation, the percentages of Th lymphocyte, Ts lymphocyte and B lymphocyte in the induction group were 44.1%±6.4%, 28.1%±7.0% and 23.8%±5.6%, whereas the percentages in the control group were 39.9%±8.6%, 28.2%±8.0% and 21.9%±6.4% respectively. (p=0.1, p=1.0, p=0.4, respectively).

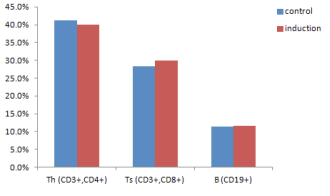

Fig 1: lymphocyte subsets before transplantation

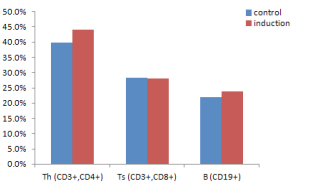

Fig 2: lymphocyte subsets after transplantation

The serum creatinine concentrations by month six in the induction and control group were 120.8±48.9μmol/L and 119.6±29.2μmol/L (p=0.9). The estimated glomerular filtration rate (eGFR-EPI) by month six after transplantation in the induction and control group were 66.9±16.5ml/min and 70.8±18.2ml/min (p=0.6). During the first six months, there was 1 case of infection (1/12, 8.3%) needed hospitalization in the induction group, and 3 cases (3/18, 18.8%) in the control group, the difference was not significant (p=0.4). In both groups, there was 1 case of acute rejection (1/12, 9.3% vs 1/18, 6.3%, p=0.7) by month six after transplantation.

Conclusions: Basiliximab would not influence the lymphocytes subsets of LRKT recipients in the early time after transplantation, and would not influence the renal allograft function, occurrence of infection and acute rejection either.

FR-PO1093

Safety of Percutaneous Pancreas Allograft Biopsy in Enteric Drained Pancreas Transplant: A Single Center Experience in the New Millennium

Yvonne El Kassis, Ziad S. Zaky. *Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Pancreas allograft biopsy (Bx) is the gold standard in diagnosing allograft rejection. The safety of this procedure has been controversial, thus limiting its widespread use. The largest safety data was published 15 years ago describing the rate of complications with ultrasound (US) guided percutaneous Bx in both enteric and bladder drained pancreas transplants (Tx). Since then, pancreas Tx surgical techniques have evolved, including mostly enteric rather than bladder drained Tx. We hereby review the safety of US and computed tomography (CT) guided percutaneous pancreas allograft Bx in 109 consecutive Bx of enteric drained pancreas allografts.

Methods: We reviewed 271 cases of pancreas Tx performed at our institution between 2001 and 2014. 68 patients (30 simultaneous pancreas kidney, 19 pancreas after kidney, and 19 pancreas Tx alone) underwent one or more percutaneous allograft Bx. Biopsies were performed with an 18-gauge needle, under direct US or CT guidance.

Results: A total of 109 Bx were performed. 30 Bx were in patients with enteric exocrine venous portal drainage (PD) and 79 in patients with systemic drainage (SD). 25 Bx were performed under CT guidance and 84 under US guidance. 84% of the Bx in the CT group and 86.6% of the Bx in the US group were adequate (p=0.74). There were a total of 4 Bx related complications (3.67%), all occurring in the US guided group. Those included 2 inadvertent small bowel punctures that were clinically silent and 2 intra abdominal bleeds that were managed conservatively. The small bowel punctures occurred in patients with PD as opposed to the bleeds that occurred in those with SD. No complications occurred in the CT guided group. There were no graft losses and no complications requiring surgical intervention.

Conclusions: Percutaneous pancreas allograft Bx has a low incidence of complications in the most recent era of enteric drained pancreas Tx, and appears to be as safe as renal allograft Bx. The more recent widespread use of CT guided Bx, rather than US guided Bx, seems to be promising in decreasing the incidence of Bx related complications, but larger studies are needed to corroborate this hypothesis.

FR-PO1094

Antiproteinuric Effect of Spironolactone in Kidney Transplant Recipients: Results of a Brazilian Reference Center

Marcos Vinicius Sousa,[1] Jose Paulo Siqueira Guida,[2] Marilda Mazzali.[1] *[1]Nephrology, State Univ of Campinas, Campinas, SP, Brazil; [2]Obstetrics, State Univ of Campinas, Campinas, SP, Brazil.*

Background: Proteinuria is a marker of kidney damage and increases cardiovascular risk. Onset of proteinuria in transplantation is associated with impaired allograft function and mortality. Aldosterone is involved in progression of chronic transplant dysfunction. Spironolactone appears to be protective in kidney allograft, reducing proteinuria.

Methods: Retrospective cohort in kidney transplant recipients with persistent proteinuria treated with spironolactone. Exclusion criteria: hyperkalemia, medication hypersensivity, graft dysfunction (serum creatinine >3 mg/dL) and hard-to-control hypertension (MAP>120 mmHg). Discontinuity criteria: refractory hyperkalemia, drug intolerance. Demographic, clinical and laboratorial data were obtained at beggining and at 1st, 3rd, 6th, 9th and 12th months. Data were analyzed using EpiInfo7; categorical data were compared with Bartletts test and numerical data with T-student test.

Results: 144 individuals, mean age: 49±13.2 years, 75% male. Average time post transplant: 90+136.5 months. Most cases (78%) were from deceased donor, 18.7% expanded donor, with cold ischaemia time of 20.4+6 hours. 96.1% of recipients were previosly hypertensive and 15.7% diabetic. None of the subjects were discontinued of the study due to hyperkalemia or drug intolerance. Individuals were divided into 3 groups according to initial proteinuria and results are shown in Table 1, * indicates p<0.05.

	A(<1g,n=31)	B(1-3g,n=82)	C (>3g,n=27
Time post transplantation*	58.4±60.5	85.6±96.3	74.5±59.5
Initial proteinuria	0.6±0.2	1.6±0.5	5.9±2.2
Initial GFR*	43.5±22	44.6±18.2	36.4±11.1
Proteinuria 6m	0.6±0.6	1.1±1	3.3±2.8
Proteinuria 12m	0.6±0.4	1±0.8	2.8±2.2

In B and C groups, a significant reduction in proteinuria was observed at 6th month and 1st year follow-up. Half of group B and a third of group C decreased their proteinuria to less than 1g after one year.

Conclusions: Spironolactone seems to be an alternative to control and reduce proteinuria in this population, particularly in proteinuria over 1g, and it is a safe drug for this population.

FR-PO1095

Double-Negative T Cells Are Reduced in Transplanted Patients Treated with mTOR-Inhibitor

Margherita Gigante,[1] Giuseppe Castellano,[1] Nada Choaul,[1] Rossana Franzin,[1] Marco Fiorentino,[1] Giuseppe Grandaliano,[2] G. Stallone,[2] Loreto Gesualdo,[1] Elena Ranieri.[2] *[1]D.E.T.O., Univ of Bari, Italy; [2]Medical and Surgical Sciences, Univ of Foggia, Italy.*

Background: CD4-CD8-double-negative T cells (DNTs) are CD3+ T lymphocytes which lack CD4, CD8 and CD56. They are specifically involved in immune regulation and tolerance and constitute about the 1-5% of lymphocytes in healthy human donors. DNTs express either aß or γΔT-cell receptors (TCR) and can act both as regulatory T cells (Tregs) or as cytotoxic T cells. The aim of this study was to assess the frequency and the phenotype of circulating DNTs in transplanted patients (pts) treated with mTOR-inhibitor compared with pts treated with CNI (without mTOR-inhibitor) and healthy donors as controls.

Methods: Peripheral blood (PB) samples of 15 transplanted pts (6/24 months from Tx) treated with mTOR inhibitors (Everolimus or Rapamycin) and 15 pts with CNI (Cyclosporine or Tacrolimus) were selected. As control PB samples of 10 healthy donors were collected. Circulating DNT subsets (TCRαβ+ and TCRγΔ+) were characterized for their ontogeny, tolerogenic or cytotoxic attitude by staining with the following antibodies:

CD3,CD4,CD8,CD56,CD45,TCRαβ,CD45Ra,CD45Ro,CCR7,CD27and CD28. Tregs were also characterized with CD3,CD4,CD25 and CD127. Isotype-matched MAbs were used as staining controls. Data were acquired using an 8-colour flow cytometer and analyzed using Kaluza software. Data were compared among the groups using the Mann-Whitney non-parametric test.

Results: As expected, mTOR inhibitors significantly increased Tregs compared with CNI population (p=0.005). Interestingly, the αβDNTs significantly decreased in mTOR inhibitor treated-pts as compared with CNI (p=0.04) and were comparable with healthy controls. Furthermore, αβDNTs showed a tolerogenic phenotype, associated with a decrease of terminally differentiated effector memory (DNT-EMRA; $CD45RA^+CCR7^-CD27^-CD28^-$) known to be DNT cells expressing high levels cytotoxic molecules.

Conclusions: DNTs are increased in kidney-transplanted pts with CNI treatment and significantly decreased by mTOR inhibitors treatment. Additional investigations will be necessary to determine their exact role and association with kidney graft dysfunction.

FR-PO1096

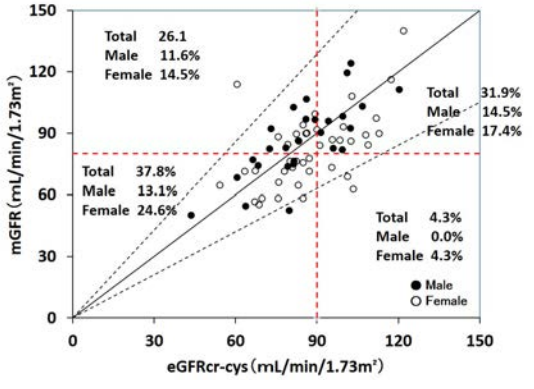
Inconsistency between KDIGO Draft and Japanese Living Kidney Donors Guidelines in Kidney Function Evaluation

Yoshinari Yasuda, Takayuki Katsuno, Shoichi Maruyama. *CKD Intiatives/Nephrology, Nagoya Univ, Nagoya, Japan.*

Background: KDIGO Living Kidney Donors draft guideline (GL) recommends that measured GFR (mGFR)≥90 mL/min/1.73m² as an acceptable level of kidney function, and that eGFR based on serum cystatin C (Cys) or the combination of serum creatinine (Cr) and Cys is acceptable if mGFR is not available. And Japanese GL recommends mGFR≥80 for kidney donation. Inconsistency between 2 GLs was analyzed in this study.

Methods: The study subjects were 69 (42 female) kidney transplant donor candidates whose GFR were measured by inulin clearance in Nagoya University Hospital. IDMS-traceable Cr values were measured by enzymatic method and standardized Cys values were measured by colloidal gold immunoassay. Estimated GFR was calculated by Japanese and CKD-Epi equations based on Cr, Cys and combination, and inconsistency rate was analyzed.

Results: Baseline characteristics (mean±SD) of study subjects in male and female were 58.4±6.9 and 61.1±8.0 years old, 168.5±4.1 and 154.0±4.9 cm, 68.5±6.2 and 54.2±9.0 kg, Cr: 0.79±0.15 and 0.56±0.09 mg/dL and Cys: 0.90±0.20 and 0.81±0.14 g/L. 30% accuracy and RMSE in eGFRcr, eGFRcys, eGFRcr-cys, EPIcr, EPIcys and EPIcr-cys were 0.855, 0.812, 0.928, 0.700, 0.797, 0.607 and 17.30, 16.35, 15.20, 21.02, 18.76, 21.32, respectively. Inconsistency between mGFR≥80 and eGFR≥90 was demonstrated in 31.9 (male: 17.4, female14.5), 20.3 (male: 7.2, female: 13.1) and 26.1 (male:11.6, female: 14.5)% underestimation and in 4.3 (male: 0.0, female: 4.3), 3.7 (male: 0.0, female: 8.7) and 4.3 (male: 0.0, female: 4.9) % overestimation by eGFRcr, eGFRcys and eGFRcr-cys, respectively.



Conclusions: Japanese GFR equations were superior to EPI equations, and eGFRcr-cys was the most accurate among Japanese kidney transplant donor candidates, however GFR should be measured because of considerable under- and overestimation rate, especially in female.

FR-PO1097

Consequences of Using Estimated GFR in Living Kidney Donors: The Nephrologist in the Mist

Ana González Rinne, Sergio Luis Lima, Natalia Negrín, Federico J. Gonzalez-Rinne, Ana Aldea Perona, Lourdes Pérez Tamajon, Armando Torres, Esteban Porrini. *Nefrología, Hospital Univ de Canarias, La Laguna, Santa Cruz de Tenerife, Spain.*

Background: An accurate assessment of GFR before donation is crucial to reduce the risk of renal impairment after donation and to provide acceptable renal mass to the donor. Formulas that estimate GFR (eGFR) have a wide error in reflecting real GFR. This may have consequences in the evaluation of living kidney donors.

Methods: 54 consecutive donors with eGFR >80 ml/min (cut-off level for donation) based on MDRD and/or two 24-h creatinine clearances (CCL) underwent the plasma clearance of iohexol to measure GFR (mGFR). Subjects with mGFR <80 ml/min who had eGFR >80 ml/min were analyzed. The agreement between mGFR and eGFR assessed by 52 creatinine and/or cystatin-based formulas was evaluated with the Concordance correlation coefficient (CCC), total deviation index (TDI) and coverage probability (cp).

Results: In 5 subjects of 54 (9%) mGFR was <80 ml/min (~70 ml/min) while MDRD and/or CCR were >90 ml/min. All were women, with reduced weight, height, BMI and Body Surface Area (BSA) compared with those in whom MDRD, CCR and mGFR were >80 ml/min.

	mGFR < 80 ml/min eGFR/CCL > 80 ml/min	mGFR >80 ml/min eGFR/CCL < 80 ml/min
N	5	49
Age (yr)	45 ± 11	46 ± 11
Gender (female)	5 (100%)	28 (57%)
Weight (kg)	57 ± 7	72 ± 11*
Height (cm)	156 ± 10	166 ± 7*
BSA (m^2)	156 ± 18	180 ± 11*
BMI (kg/m^2)	23.5 ± 4	26 ± 3*
24h CCL	90 ± 9	106 ± 29
aMDRD	87 [70-93]	82 [76-93]
S creatinine (mg/dL)	0.78 ± 0.18	0.86 ± 0.16
mGFR	72.1 ± 1.6	96.6 ± 15.2

These cases were excluded for donation. All formulas showed poor agreement with mGFR: CCC–0.50; TDI:from 47.3% to 26.1% (~37%), indicating that 90% of eGFR had an error of ±37%. No formula included 90% of the estimations within a cp of ±10%.*$p<0.05$.

Conclusions: Formulas and CCL are not appropriate to evaluate living donors since they may overestimate real renal function, particularly in women with reduced BSA. Measured GFR is an important tool in the evaluation of living donors.

Funding: Government Support - Non-U.S.

FR-PO1098

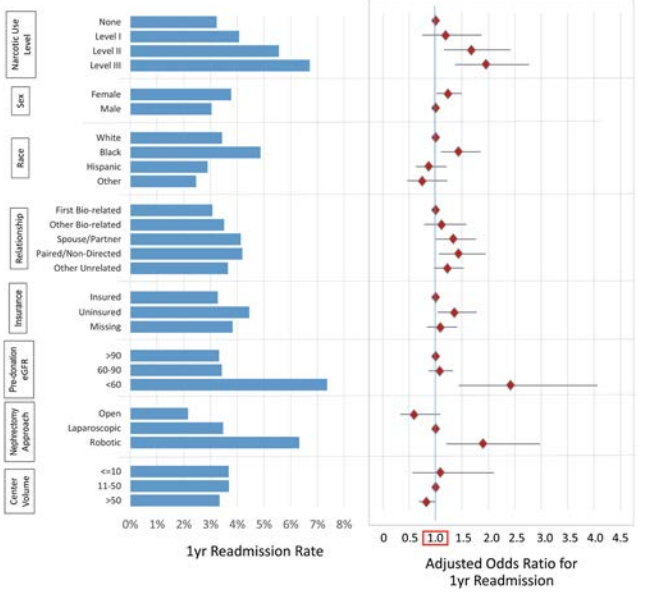
Pre-Donation Prescription Narcotic Use: A Novel Risk Factor for Readmission after Living Kidney Donation

Krista L. Lentine,[1] Ngan Lam,[2] Mark Schnitzler,[1] Gregory P. Hess,[3] Bertram L. Kasiske,[4] David A. Axelrod,[5] Amit X. Garg,[6] Jesse D. Schold,[7] Daniel C. Brennan,[8] Dorry L. Segev.[9] *[1]Saint Louis Univ; [2]Univ Alberta; [3]Symphony Health; [4]Hennepin County Med Center; [5]Brody School of Med; [6]Western Univ; [7]Cleveland Clinic; [8]Washington Univ; [9]Johns Hopkins.*

Background: Implications of narcotic use in living kidney donors for key outcomes, including readmission rates after nephrectomy, are unknown.

Methods: We integrated 1) national Scientific Registry of Transplant Recipients data with 2) pharmacy fill records from a nationwide pharmacy claims clearinghouse, and 3) administrative records from an academic hospital consortium (98 centers, 2008-2012). Narcotic fills in the yr before donation were assessed and normalized to morphine equivalents. Associations of predonation narcotic use (adjusted odds ratio, aOR) and other baseline clinical, procedural, and center factors with readmission within 1 yr postdonation were examined using multivariate logistic regression.

Results: Among 14,959 living donors, 11.3% filled ≥1 narcotic prescription in the year before donation. Pre-donation narcotic use level bore graded associations with 1-yr readmission; donors with the highest pre-donation narcotic use were twice as likely to be readmitted as non-users (6.7% vs. 3.2%; aOR 1.95, 95% CI 1.38-2.77). Adjusted readmission risk was also significantly (p<0.05) higher for women (aOR=1.23), African Americans (aOR=1.43), exchange participants (aOR=1.44), uninsured donors (aOR=1.36), donors with pre-donation estimated glomerular filtration rate <60 mL/min/1.73 m² (aOR=2.42), and after robotic nephrectomy (aOR=1.90). Donors at high-volume centers (>50 per yr) had lower readmission rates (aOR=0.83).



Conclusions: Pre-donation narcotic use is independently associated with readmission after donor nephrectomy. Future research should examine underlying mechanisms and approaches to reducing risks of post-donation complications.

Identifying Donors at Risk for Developing Chronic Kidney Disease Using Non-Invasive Ultrasound-Based Measurement of Glomerular Diameter

Ashraf El-Meanawy, Liliana Osadchuk. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: There is a non-insignificant risk for developing chronic kidney disease (CKD) or end stage renal disease (ESRD) in the donor. The lifelong risk of ESRD in living kidney donors is as high as 11 folds that of control group. One important risk factor which is neglected, mainly due to inability to access, is nephron endowment in the donor. Donors how have low nephron endowment are at risk for developing hyperfiltration injury. The persistent hyperfiltration injury leads to chronic kidney disease and ultimately ESRD.

Methods: Technique was validated using pig kidney. Cohort: Single center prospective study. All living donors at Froedtert kidney transplant program who are willing to participate were included in the study. **Clinical Data and Biochemical analysis:** Standard of care data. **Sonographic data collection:** Raw radiofrequency data were collected of kidneys before donation, 9 days post donation, 6 month, and 1 year after donation. **Data Analysis by blinded observer:** Glomeruli are delineated and measured using acoustic scatter and integrated backscatter.

Results: The technique is valid and provide accurate measurement of glomerular diameter. Moreover, we encountered donors with glomerular diameters which are significantly larger than the median. Donors with expected low nephron endowment (prematurity and/or low birth weight) have larger glomeruli predonation or have significant glomerular enlargement over time. Those donors failed to recover renal function 6 month after donation.

Conclusions: Pre-donation Glomerulomegally or significant increase in glomerular diameter after donation could indicate low nephron endowment. These subjects are at higher risk for post-donation CKD. Measuring glomerular diameter using ultrasound could prove to be very useful tool in assessing live kidney donor risk for CKD post donation. Failure to identify kidney donors who have reduced nephron endowment will put them at risk for developing CKD and possibly ESRD in their life time. The renal disease progression in these subjects is usually driven by hyperfiltration injury from surgical reduction in nephron number below a threshold that meets the metabolic demand.

FR-PO1100

Utilizing Renal Efficiency to Determine Graft Quality in Live Kidney Donors

Alejandro Diez, Garrett P. Diltz, Rima Kang. *Div of Nephrology, The Ohio State Univ, Columbus, OH.*

Background: Donor age and renal function along with mass and volume donated kidney graft are factors that have been associated with subsequent living donor kidney transplant outcomes. Measurements of renal volume (size) and function (measured or estimated GFR and Creatinine Clearances) are routinely performed prior to donation. Currently, there is no term which describes the quality of the donated tissue. We coined the term: "Renal Efficiency" (RE) to describe this concept. We defined RE as the creatinine clearance that is produced per milliliter (ml) kidney tissue.

Methods: Under IRB approval, we designed a single center retrospective study of all consecutive living kidney donors who donated between January 1, 2008 and December 31, 2013; abstracting demographic and clinical data. Renal function was determined using the CKD-EPI equation and 24hr timed creatinine clearance measurements (mCrCl). 24 hour urine collections were included when the observed urine creatinine excretion rate was within 25% of the expected production (derived from Cockcroft-Gault). All CT-V were calculated using semi-automated region of interest [ROI] volumetry.

Results: 312 cases were reviewed. The average total CT-V (combined right and left kidneys) was 349.91 ml (sd 65.96). The mean mCrCl was 123.21 ml/min (sd 27.34) whereas the mean GFR (CKD-EPI) was 98.87 ml/min sd (15.39). We found a strong correlation between mCrCl and total CT-V (Pearson Correlation: 0.65, $p<0.001$). This was not replicated when utilizing CKD-EPI (Pearson Correlation: 0.122, $p<0.05$). Utilizing mCrCl, we determined the average RE was 0.35 ml/min (clearance) per ml (renal tissue) [Std Error: 0.003, 95% CI: 0.343 – 0.357]. Both univariable (unadjusted) and multivariable (adjusted) linear regression modeling showed significant correlations with patient age and race; for every ten year increase in age we noted a renal efficiency decreases of 4% ($p < 0.001$). Whereas non-white as compared to white race increased efficiency by 10% ($p = 0.001$).

Conclusions: We hope to incorporate RE in further studies to show that combined measurements of renal efficiency and renal volume may be a surrogate for "renal dosing" to predict renal function in kidney transplant recipients.

FR-PO1101

Correlation between Renal Volume and Function in Living Kidney Donors

Alejandro Diez, Rima Kang, Garrett P. Diltz. *Div of Nephrology and Comprehensive Transplant Center, The Ohio State Univ, Columbus, OH.*

Background: CT imaging utilized in pre-donation testing allows for the evaluation of renal anatomy and vasculature. Recent data suggest that renal morphology (kidney volume) may correlate with renal function. Surprisingly, previous work has failed to show a statistically meaningful correlation between renal function as defined by 24 hr timed creatinine clearance measurements (mCrCl) and renal volume as determined by 3D reconstructions of CT angiograms (CT-V). We set forth to determine if a strong correlation exists in a large cohort utilizing strict data validation and enhanced imaging techniques.

Methods: Under IRB approval, we designed a single center retrospective study of all consecutive living kidney donors who donated between January 1, 2008 and December 31, 2013; abstracting demographic and clinical data, pre-donation mCrCl, and CT-V. 24 hour urine collections were included when the observed urine creatinine excretion rate was within 25% of the expected production (derived from Cockcroft-Gault). All CT-V were calculated using semi-automated region of interest [ROI] volumetry.

Results: 322 cases met inclusion criteria; (Male vs Female 102:220 (32%:68%); White vs Non-White = 284:38 (88%:12%); Ave Age: 43y/o (sd 11.64). The average total CT-V (combined right and left kidneys) was 349.91 ml (sd 65.96). The average mCrCl was 123.21 ml/min (sd 27.34) Univariable linear regression modeling showed male sex, weight, height, and BSA to be associated with both increasing renal volume and function (all $p<0.001$). Increased age was inversely associated with mCrCl ($p<0.001$). Multivariable linear regression modeling (adjusted) showed that BSA remained associated with both increasing renal volume and function ($p<0.001$). Increased age remained inversely associated with mCrCl ($p<0.001$). Pearson correlation between CT-V and mCrCl was 0.65 ($P < 0.001$).

Conclusions: Our analysis of a large cohort using strict data validation methodology and improved imaging reconstruction shows the strong linear relationship that exists between renal size and function.

FR-PO1102

Living Renal Donation – Gender Effects on Quality of Life

Claudia Sommerer, Sarah Estelmann, Matthias Schaier, Christian Morath, Martin G. Zeier. *Nephrology, Medical Univ Hospital, Heidelberg, Germany.*

Background: A careful donor selection is important as well as a consistent donor follow-up. Gender specific effects might be detected concerning quality of life.

Methods: Living renal donors at the Transplant Center Heidelberg, University Hospital, were evaluated using the standardized 36-item short form health survey [SF-36] questionnaire).

Results: Altogether 211 living renal donors were evaluated (131 female, 62.1%). The SF-36 physical component summary score was comparable in female and male donors (51.8±10.1 versus 53.9±7.9; ns). The SF-36 mental component summary score was significantly lower in female donors compared to male donors (47.6±13.0 vs. 51.7±11.0, $p=0.012$). In all sub-scale male donors presented higher scores compared to female donors. Male donors had the highest scores in social functioning, female donors in physical functioning. In most of the SF-36 scales, female donors showed comparable or even better results compared to a German general population. However, in the scales social functioning, emotional role functioning and mental health female donors had lower scores compared to an age- and gender-matched general population. Male donors presented higher scores in all SF-36 sub-scales compared to an age- and gender-matched general population (significant scales: vitality, physical component summary score).

Conclusions: Quality of life assessed by the SF-36 questionnaires shows several gender specific differences in living renal donors. Especially, female donors are on increased risk concerning mental and emotional health after donation. Careful evaluation of these female donors is mandatory.

FR-PO1103

5 Year Follow-Up Results of the HERAKLES Study: Superior Renal Function after Early Conversion to an Everolimus-Based Calcineurin Inhibitor Free Regimen

Claudia Sommerer,[1] Wolfgang Arns,[1] Ingeborg A. Hauser,[1] Volker Kliem,[1] Petra Reinke,[1] Rolf A. Stahl,[1] Bruno Vogt,[2] Martina Porstner,[3] Thomas Rath,[1] Frank Lehner,[1] Oliver Witzke,[1] Klemens Budde.[1] *[1]Herakles Study Group, Germany; [2]Herakles Study Group, Switzerland; [3]Novartis Pharma GmbH, Germany.*

Background: To follow up on renal function (GFR) 5 years after kidney transplantation (KTx) in patients (pts) on immunosuppressive regimen with different everolimus (EVR) and calcineurin inhibitor (CNI) exposures.

Methods: 1 year, prospective, open-label, randomized, controlled multi-center study with observational follow-up (FU) to Mo 60 post Tx. After induction therapy all pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 Mo post Tx, 499 pts were randomized 1:1:1 to either a) continue standard CsA (100-180ng/ml) + EC-MPS (n=166) (STD) or convert b) to a calcineurin inhibitor (CNI)-free regimen with EVR (5-10ng/ml) + EC-MPS (n=171) or c) to a CNI-reduced regimen with EVR (3-8ng/ml) + reduced CsA (50-75ng/ml; n=162). All pts continued on steroids according to centers practice. In total 81% of pts completed the FU period.

Results: GFR (Nankivell, ITT) was similar at randomization 3 Mo post Tx and had significantly improved at Mo12 by +5.6mL/min ($p<0.001$) and remained significantly improved by +6.7mL/min in favor of the CNI-free regimen after 5 years ($p<0.001$; Fig1). There was no significant difference between the CNI-reduced and STD groups (p=ns). Benefit on GFR was highest for non-switcher pts: CNI-free Mo60 GFR was 78.33mL/min vs. 64.33mL/min for CNI-reduced and 61.68mL/min for STD pts ($p<0.0001$). Mean CsA C0-levels at Mo60 were 80ng/mL in CNI-reduced and 109ng/mL in STD group (ITT).

eGFR (Nankivell) [mL/min/1.73m2] ITT FU pop. to Mo60	CNI-free	CNI-reduced	Standard CNI	Difference: CNI-free vs standard CNI (95% CI) P value*	Difference: CNI-reduced vs standard CNI (95% CI) P value*	Difference: CNI-free vs CNI-reduced (95% CI) P value*
Nankivell formula (ITT population)						
Unadjusted eGFR, mL/min/1.73m², mean(±SD)	68.94 (21.31)	58.27 (19.27)	59.20 (19.92)	-	-	-
Adjusted (ANCOVA) eGFR, mL/min/1.73m², LS mean (95%CI)*	66.98 (63.78-70.17)	58.74 (55.58-61.90)	60.24 (57.11-63.38)	6.73 (3.22-10.24) 0.0002	-1.50 (-5.01-2.01) 0.4008	8.23 (4.73-11.73) <0.0001
Nankivell formula (non-switcher)						
Unadjusted eGFR, mL/min/1.73m², mean(±SD)	78.33 (13.02)	64.33 (19.78)	61.68 (18.58)	-	-	-
Adjusted (ANCOVA) eGFR, mL/min/1.73m², LS mean (95%CI)*	74.69 (69.61-79.77)	64.61 (58.51-70.71)	60.32 (56.04-64.59)	14.37 (9.14-19.59) <0.0001	4.29 (-2.29-10.87) 0.1996	10.08 (3.04-17.12) 0.0053
(*) ANCOVA model with treatment, center, donor type as factors and GFR value at V4/M3/BL2 as covariate Replacement of missing values: LOCF = last observation (>Randomization) carried forward						

Conclusions: CNI-free EVR regimen was associated with significant higher eGFR maintained for 5 years after Tx. The results of this large trial confirm previous reports of improved GFR after CsA withdrawal with EVR-based regimen.

FR-PO1104

Living Renal Donation – Association between Gender and Mental Stress after Living Donation Claudia Sommerer, Sarah Estelmann, Matthias Schaier, Christian Morath, Martin G. Zeier. *Nephrology, Medical Univ Hospital, Heidelberg, Germany.*

Background: In living renal donation, careful donor selection is as important as consequent donor follow-up. This includes both, physical and mental health. There might be some gender specific differences. The question to be answered by this evaluation was: Are there any associations between gender and signs of mental stress or impairment?

Methods: Living renal donors at the Renal Transplant Center Heidelberg were evaluated using standardized questionnaires (Hamilton Anxiety Depression Scale, HADS-D; Perceived Stress Scale (PSS)).

Results: Altogether, 211 of 261 (80.8%) questionnaires could be analyzed. Mean age at time of donation was 51.7±9.9 years (131 female), and mean time after donation was 9.7±5.2 years. Results on the HADS-D depression scale (4.0±3.71 vs. 3.68±3.58) and as the anxiety scale (5.09±3.54 vs. 4.4±3.56) were comparable in female and male donors. Female and male living donors aged >60 years had better results compared to a German general population. Female and male living donors aged 40 to 59 years showed comparable results to a German general population. Mental stress was evaluated using the PSS. Female donors presented significantly increased mental stress compared to male donors (p=0.003).

Conclusions: Generally, there is no increased mental stress after living donation compared to a general population. However, there are distinct gender- and age-specific differences. Female donors should be evaluated carefully concerning mental health.

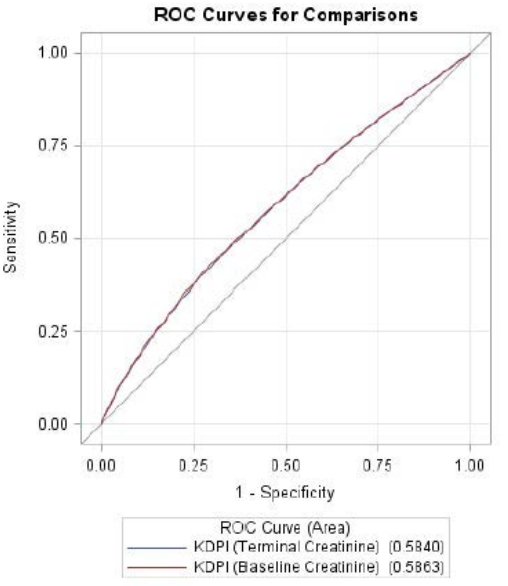
FR-PO1105

Using the Baseline Creatinine Instead of the Terminal Creatinine to Calculate the Kidney Donor Risk Index Mariana C. Chiles,[1] Dustin Carpenter,[1] Rachel E. Patzer,[3] Stephen O. Pastan,[3] Bekir Tanriover,[2] Jae Hyung Chang,[1] David J. Cohen,[1] Sumit Mohan.[1] *[1]Columbia Univ Medical Center, New York, NY; [2]Univ of Texas Southwestern Medical Center, Dallas, TX; [3]Emory Univ School of Medicine, Atlanta, GA.*

Background: The Kidney Donor Risk Index (KDRI) is a numerical expression of deceased donor organ quality and is currently used as part of the New Kidney Allocation System in the US. The KDRI includes the terminal creatinine (Cr_{ter}) even though the baseline creatinine (Cr_{base}) may be a more appropriate, particularly for kidneys with AKI that are already at increased risk of discard.

Methods: Our analysis included 112,809 deceased donor kidneys from 62,370 donors with data provided by the Organ Procurement Transplant Network (OPTN) procured for transplanted from 2002-2015 with $Cr_{base} < Cr_{ter}$ and excluded donors with $Cr_{base} < Cr_{ter} \geq 8$mg/dL. ROC curves were constructed to illustrate the diagnostic performance of the KDRI when calculated with baseline ($KDRI_{base}$) and terminal ($KDRI_{ter}$) creatinine on predicting death-censored graft failure.

Results: In the cohort, 50.4% of kidneys had evidence of AKI ($Cr_{ter} > 0.3$mg/dL above Cr_{base}) and were 1.96 times more likely to be discarded. Transplanted kidneys were obtained from donors who were 62% male, 17.2% black with a mean age of 38.7±15.9 years, the median Cr_{ter} was 2.5mg/dL (IQR = 3.6), the median Cr_{base} was 1.20mg/dL (IQR = 0.7), the median delta creatinine was 0.26mg/dL (IQR = 0.4) and the median delta KDRI was 0.05 (IQR =0.08) The ROC curve depicting the power of $KDRI_{ter}$ had an AUC of 0.5840 while the $KDRI_{base}$ had an AUC of 0.5863 (p<.0001).



Conclusions: Our results suggest that while the overall classification benefit of using Cr_{base} over Cr_{ter} is limited, using the lower $KDRI_{base}$ in individual instances is more reflective of the true quality of the kidney and may help to lower the discard of kidneys with AKI.

FR-PO1106

Comparison of Estimated and Measured Glomerular Filtration Rate in Longitudinal Follow-Up after Living Kidney Donation Marco van Londen, Jan-Stephan Sanders, Jannieta J. De Vries, Margriet Fleur Charlotte de Jong, Robert Pol, Stefan P. Berger, Gerjan Navis, Martin H. De Borst. *UMCG, Groningen, Netherlands.*

Background: Donor safety requires reliable long term follow-up of renal function after donation. We tested the longitudinal performance of estimated Glomerular Filtration Rate (eGFR) to detect renal function loss after donation.

Methods: We compared the slopes of MDRD, Cockcroft-Gault (CG) and CKD-EPI equations with mGFR (^{125}I-iothalamate) to assess renal function loss from 3 months after donation until 5 or 10 years after donation. We tested eGFR slopes for bias by tertiles of mGFR slopes.

Results: At donation, donors (age 51(10) years, 53% male) had a median [IQR] mGFR of 103 [92-115] mL/min. After donation, mGFR was 65 [59-72], 66 [57-75] and 69 [61-77] mL/min at 3 months, 5 and 10 years, respectively. In donors with decreasing mGFR, the slope was underestimated by all eGFR equations (table 1) (P<0.001).

	Tertiles of mGFR slopes		
	Low	Intermediate	High
5 years (N=146)			
mGFR slope	-0.5 [-1.3;0.0]**	1.1 [0.8;1.6)]**	3.5 [2.8;4.2]
CKD-EPI slope	1.6 [0.4;2.8]*	1.6 [0.7;2.7]	2.6 [1.2;4.2]
bias	-2.4 [-3.8;-1.1]**	-0.5 [-1.4;0.4]*	0.7 [-1.0;1.9]
MDRD slope	1.7 [0.5;2.9]	1.7 [0.9;2.7]	2.4 [1.4;3.9]
bias	-2.6 [-3.7;-1.2]**	-0.6 [-1.4;0.2]*	0.7 [-1.0;2.0]
CG/BSA slope	0.5 [-0.2;1.3]*	0.4 [-0.8;0.9]	1.6 [0.5;2.0]
bias	-0.6 [-2.2;-0.3]*	0.6 [-0.1;2.1]	1.6 [1.3;3.4]
10 years (N=59)			
mGFR slope	-0.2 [-0.9;0.0]**	0.5 [0.3;0.6]**	1.6 [1.1-2.0]
CKD-EPI slope	0.5 [-0.0;0.9]	1.0 [0.2;1.3]	1.0 [0.4;1.7]
bias	-0.7[-1.8;-0.3]**	-0.6 [-0.8;-0.1]*	0.6 [-0.1;1.2]
MDRD slope	0.6 [0.1;1.0]	1.1 [0.4;1.5]	1.1 [0.5;1.8]
bias	-0.8 [-1.9;-0.5]**	-0.6 [-0.9;-0.1]*	0.5 [-0.2;1.1]
CG/BSA slope	0.2[-0.2;0.3]*	0.6 [0.2;0.9]	0.5 [0.3;1.6]
bias	-0.3 [-1.1;-0.1]**	-0.2 [-0.4;0.2]*	0.8 [0.4;1.6]
* P<0.05, ** P<0.001 vs. highest mGFR slope tertile Slopes are in mL/min/1.73m²/yr			

In donors with an mGFR decline of >1 mL/min/yr, all equations underestimated the decline vs. donors with less or no decline (p<0.001).

Conclusions: eGFR equations underestimate the slope of renal function in living donors with pronounced mGFR loss, underlining the value of mGFR in long term follow-up.

FR-PO1107

Overweight Young Female Donors Have a Lower Post-Donation Reserve Capacity - Implications for Preeclampsia Marco van Londen,[1] Anouk Wma Schaeffers,[1] Gerjan Navis,[1] Martin H. De Borst,[1] Titia Lely.[2] *[1]Univ Medical Center Groningen, Groningen, Netherlands; [2]Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Young female kidney donors are at increased risk of gestational hypertension or preeclampsia. Absence of pregnancy-induced renal vasodilation is a hallmark of preeclampsia and might reflect low renal reserve capacity (RC). We previously observed that higher donor BMI is associated with a lower RC after donation. Therefore, we now studied the relationship between BMI and renal RC before and after donation in female donors of childbearing age.

Methods: RC, defined as rise in glomerular filtration rate (GFR, 125I-Iothalamate clearance) during dopamine, was measured in female donors of childbearing age (<45 years) at 4 months prior and 2 months after kidney donation. Difference between overweight (BMI>25) and non-overweight donors was tested by t-test; the association between BMI and renal hemodynamics was tested with linear regression analysis.

Results: We included 105 female donors who were 41 [36-43] (median[IQR]) years old at donation with a BMI of 25 [22-27] kg/m2. Pre-donation GFR was 118 (17) ml/min (mean(SD)) rising to 128 (19) ml/min during dopamine; mean RC was 10 (10) ml/min. BMI was positively associated with GFR (st. beta 0.31, p=0.001) but not with pre-donation RC (st. beta -0.04, p=0.70). Post-donation GFR was 76 (13) ml/min, rising to 80 (12) during stimulation; RC was 3 (6) ml/min (p<0.001 vs. predonation). Loss of RC was more prominent in overweight donors (-7 vs. -4 ml/min, p=0.05), and higher BMI was associated with lower RC after donation, independent of GFR, age, and use of antihypertensives or contraceptives (st. beta -0.37, p=0.02).

Conclusions: BMI is inversely associated with post-donation RC in female donors of childbearing age. Reduced renal RC might be involved in the increased risk of preeclampsia and gestational hypertension in overweight female kidney donors. Overweight female kidney donors with the desire to have children should be counselled to reach a normal BMI.

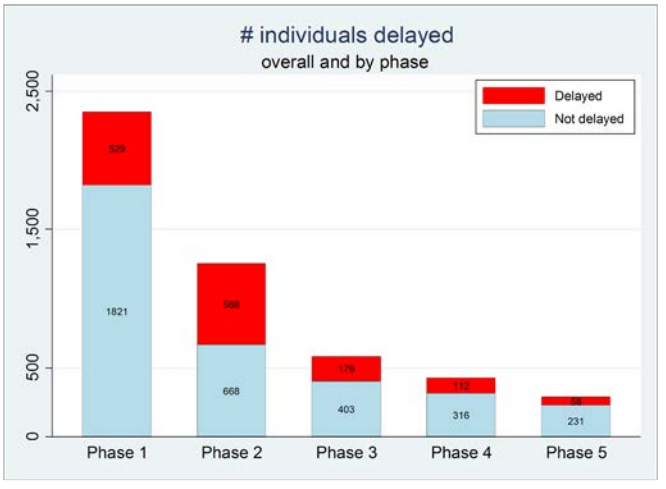
FR-PO1108

Clearance and Delays in the Live Kidney Donor Evaluation Process Joseph Leanza, Dorry L. Segev. *Surgery, Johns Hopkins Univ, Baltimore, MD.*

Background: The live kidney donor evaluation process is a poorly understood barrier to live donation. We quantified clearance time for each evaluation phase and identified factors associated with spending excessive time in each phase, i.e. getting "delayed."

Methods: Eligible potential donors (PDs), who initiated evaluation at Johns Hopkins between 1/1/2011 and 12/31/2014, were followed through five evaluation phases: 1, questionnaire; 2, blood and tissue typing; 3, routine screening and physical exam; 4, evaluation and clearance; 5, recipient clearance, scheduling and donation. Delay was defined for each phase as ≥ 90th percentile of time spent by PDs who cleared that phase (respectively 41, 159, 149, 106, and 328 days).

Results: Of 2,738 PDs, 90.3% completed phase 1, 27.4% phase 2, 18.8% phase 3, 13.0% phase 4, and 9.6% donated. There were 1,466 total delays.



On multivariate logistic regression, African American donors had lower odds of ultimately donating (p<0.01) and of clearing phases 1 (p<0.01), 3 (p=0.03), and 5 (p<0.001). African Americans had higher odds of delay in phase 3 (p=0.03) and phase 5 (p=0.03).

Conclusions: Nearly 50% of PDs were delayed at some point, particularly those of African American race. Efforts to improve LKD rates in this subgroup may benefit from nephrologist involvement at early phases or optimizing the evaluation process.

Funding: NIDDK Support, Private Foundation Support

FR-PO1109

Clinical Outcome of Elderly Living Kidney Donors Kohei Unagami, Masayoshi Okumi, Kazunari Tanabe, Hideki Ishida. *Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Previous studies and current guidelines have suggested that elderly persons can be living kidney donors; however, reports on elderly donors >70 years old are limited. In order to clarify the donor safety and feasibility, we investigate the clinical outcomes of living kidney donors > 70 years old after nephrectomy.

Methods: We conducted a case-series study of living kidney donations involving 48 donors aged >70 years at the time of transplantation. The kidney donations occurred between 2001 and 2014 at our institution. The primary outcomes were survival or end-stage renal disease (ESRD)-free rate and all crude event-free rates, including cardiovascular-, infection-, ESRD-, or death-free rate. The secondary outcome was serum creatinine level at the end of the follow-up period.

Results: The 48 cases were followed up for a median of 4 years. The survival rate among the donors was 100% until the fifth year, and only two donors died during follow-up. The ESRD-free rate was 100% during the follow-up period. The overall event-free rate was 100% at 1 year, 85.7% at 3 years, and 75.0% at 5 years. The mean serum creatinine level was 1.18 ± 0.24 mg/dL at the time of hospital discharge and did not increase (1.18 mg/dL) at the end of follow-up.

Conclusions: Living kidney donation from elderly donors >70 years old appears to be a safe and acceptable option for patients requiring renal-replacement therapy.

FR-PO1110

Opinions of the Medical Community at the University of Iowa Regarding Disincentives and Incentives in Living Kidney Donation Based on Age Maria T. Story,[1] Sarat C. Kuppachi.[1,2] *[1]Internal Medicine, Univ of Iowa Hospitals and Clinics, Iowa City, IA; [2]Organ Transplant Center, Univ of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: As the kidney transplant waiting list continues to increase annually, transplant societies have been debating options of incentives to increase organ donation. We surveyed healthcare employees at our institution regarding removal of disincentives and providing incentives to living kidney donors to determine if differences in opinions exist based on age.

Methods: The opinions of employees in Internal Medicine, General Surgery, Nursing, and medical students were collected via a web-based survey of 18 questions. IRB approval was obtained. Responses were analyzed using the chi-square test for independence.

Results: Out of 624 who completed the survey, 120 were <25 years old. 58.7% thought it acceptable to reimburse expenses, while 25.7% advocated for additional incentives. 38.3% believed it was unethical to offer financial incentives for exchange of an organ, while 22.8% believed it was ethical. 82.5 % were concerned about exploitation if financial incentives were offered. There were no differences in these opinions based on age < or >25. Respondents aged <25 were significantly more likely (p=0.0002) to accept money for a kidney than those >25.

Perspective on incentivizing living kidney donation P= 0.3514		
	Age<25 N=120	Age>25 N= 504
Donation is altruistic; no incentives	8	45
Acceptable to reimburse expenses (remove disincentives)	74	296
Acceptable to provide incentives	33	130
I don't have an opinion	2	25

Conclusions: Individuals < 25 were more likely to accept financial incentives for kidney donation than those >25. As transplant societies contemplate incentives in organ donation, we believe awareness of the increased interest from the younger community is important given that long-term outcomes of living kidney donation at a young age are not well understood. Further studies will be necessary to better understand factors for the differences in opinion.

Abstract Withdrawn

FR-PO1112

Nationwide Strategy for Kidney Transplantation with Controlled Cardiac Death Donor (cDCD) Has Improved Global Results. Spanish Multicentre SENTRA-GEODAS Group Jose M. Portoles,[1,2] Maria Jose Perez Saez,[1,2] Anna Manonelles,[1,2] María Marques Vidas,[1,2] Naroa Maruri,[1] Anton Fernandez Garcia,[1] Auxiliadora Mazuecos,[1] Rosalia Valero,[1] Alberto Rodriguez-Benot,[1] Julio Pascual,[1,2] Maria Jose Perez Saez. *[1]Nephrology, Hospital Puerta de Hierro SENTRA / GEODAS, Majadahonda, Spain; [2]Public Health Research Net RedinRen16/009/009 RETYC ISCIII.*

Background: Controlled donation after cardiac death (cDCD) programs are running in US for years and some European countries has recently started on it. National transplant organization (ONT) has developed a nationwide program in Spain from jan-2012 and 45 Centers had joined by Dec2015 (370 cDCD donors on 2012-15). Eighteen centres have entered our study group. We present here the main clinical outcomes.

Methods: Observational prospective multicentre study. Systematic inclusion of every kidney transplant-KTx from cDCD at joined units. Local center surgical procedures and IS protocols.

Results: We included 215 cDCD, donors aged 56,9 year who have died mainly due to CV events (74%). Effective harvest rate was 93% higher than reported for uncontrolled DCD by ONT (66%) 13 kidneys were discharged for several reasons; his pairs were successfully implanted. 28 transferred and implanted in centers out of our group. We include 389 ESRD recipients: 56.3y, 69.1% males, for 75,6%of them were the first KTx .Immunosuppression regimen included 98,8% induction (Thymoglobulin 67,3%/ Basiliximab 31,5%) plus prednisone-MMF-Tacrolimus (83,1%) or mTOR (6,9%). Median Cold ischemia time (CIT) was 12,5h and warm IT 24min. Median HLA-mismatch was 4 [0-5]. **Clinical outcomes:** Primary graft failure (PGF) rate was 3% mainly associated to vascular problems no single hyperacute rejection case. Delayed graft function (DGF) was defined as dialysis use on 1st week after KTx. In spite of DGF rate of 49,7% the death censored graft survival was 97,9% at 1 yr and92,2% at 2 yr.13 patient died with functional graft and patient survival was 95,3% (Kaplan-Meier).

Conclusions: Harvested graft rate for cDCD are higher than reported for uncontrolled DCD. KTx with cDCD present higher DGF than historic reference for brain death donor but similar PGF rate and patient or graft survival rates. Our results aim us to promote this cDCD all over the country.

FR-PO1113

Neighborhood Poverty and Gender Disparities in Live Donor Kidney Transplant Outcomes in the United States Tanjala S. Purnell, Xun Luo, Deidra C. Crews, Lisa A. Cooper, Dorry L. Segev. *Johns Hopkins Univ.*

Background: Little is known about the association of neighborhood poverty with gender differences in live donor kidney transplant (LDKT) outcomes in the United States.

Methods: Using data from the Scientific Registry of Transplant Recipients and the US Census, we tested whether neighborhood poverty modifies gender disparities in death-censored graft loss and patient death after LDKT. We performed Cox regression models to compare 5-year outcomes among 27,978 men and 17,263 women who received a first LDKT in 2005-2013. We adjusted all models for recipient, donor, and center factors, and we categorized neighborhoods as poor (≥20% poverty), middle-income (5-19% poverty), or wealthy (<5% poverty).

Results: Women living in poor (aHR: 1.34, 95% CI: 1.16-1.55) and middle-income (aHR: 1.26, 95% CI: 1.13-1.40) neighborhoods had higher risk of graft loss than men, but there were no gender differences in graft loss among recipients in wealthy neighborhoods (aHR: 0.98, 95% CI: 0.80-1.21) (p for gender/poverty interaction = 0.029). **(Figure 1A)** In subsequent models, women living in wealthy (aHR: 0.74, 95% CI: 0.61-0.92) and middle-income (aHR: 0.84, 95% CI: 0.76-0.94) neighborhoods had lower risk of mortality than men, but women living in poor areas did not experience a statistically significant survival advantage over men (aHR: 0.90, 95% CI: 0.75-1.07). **(Figure 1B)**

Figure 1A. Gender Differences in Graft Loss after LDKT by Neighborhood Poverty

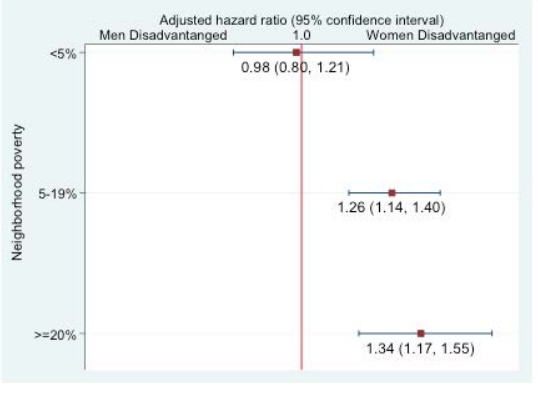

Figure 1B. Gender Differences in Patient Death after LDKT by Neighborhood Poverty

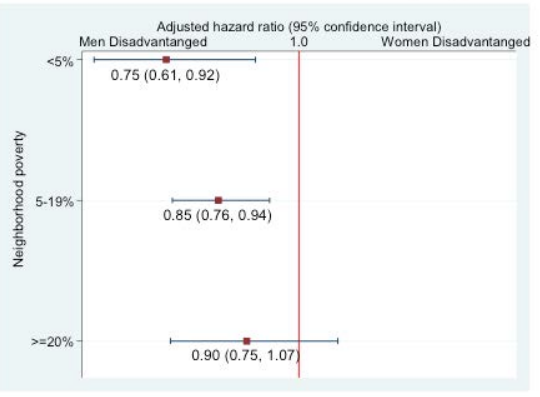

Conclusions: Women living in poor neighborhoods were at highest risk of graft loss after LDKT. Targeted efforts to address barriers among women living in poor areas may help to mitigate gender disparities in LDKT outcomes.

Diabetes Mellitus in Living Pancreas Donors: Use of Integrated National Registry and Pharmacy Claims Data to Characterize Donation-Related Health Outcomes Ngan Lam,[1] Mark Schnitzler,[2] Dorry L. Segev,[3] Gregory P. Hess,[4] Bertram L. Kasiske,[5] David A. Axelrod,[6] Amit X. Garg,[7] Daniel C. Brennan,[8] Krista L. Lentine.[2] *[1]Univ of Alberta, Edmonton, AB; [2]Saint Louis Univ, St. Louis, MO; [3]Johns Hopkins School of Medicine, Baltimore, MD; [4]Univ of Pennsylvania, Philadelphia, PA; [5]Univ of Minnesota, Minneapolis, MN; [6]Dartmouth Hitchcock Medical Center, Hanover, NH; [7]Western Univ, London, ON; [8]Washington Univ School of Medicine, St. Louis, MO.*

Background: Living donor pancreas transplant is a potential treatment for diabetic patients with end-organ complications. While early surgical risks of donation have been reported, long-term medical outcomes in living pancreas donors are not known.

Methods: We integrated national Scientific Registry of Transplant Recipients data (1987-2015) with records from a nationwide pharmacy claims warehouse (2005-2015) to examine prescriptions for diabetic medications and supplies as a measure of post-donation diabetes mellitus. To compare outcomes in controls with baseline good health, we matched living pancreas donors to living kidney donors (1:3) by demographic traits and year of donation.

Results: Among 73 pancreas donors in the study period, 45 were identified in the pharmacy database: 62% women, 84% white, and 80% relatives of the recipient. Over a mean post-donation follow-up period of 16.3 years, 26.7% of pancreas donors filled prescriptions for diabetes treatments, compared with 5.9% of kidney donors (odds ratio [OR] 4.13, 95% confidence interval [CI] 1.91-8.93; $P = 0.0003$). Use of insulin (11.1% vs. 0%) and oral agents (20.0% vs. 5.9%; OR 4.50, 95% CI 2.09-9.68; $P = 0.0001$) was also higher in pancreas donors.

Conclusions: Diabetes is more common after living pancreas donation than after living kidney donation, supporting clinical consequences from reduced endocrine reserve.

FR-PO1115

The Impact of Donor Cannabinoid Intoxication on Outcomes of Kidney Transplantation Blaithin A. McMahon, Khushleen Jaggi, Edward S. Kraus, Tessa Kimberly Novick, Steven Menez, Niraj Desai, Sami Alasfar. *Johns Hopkins Univ School of Medicine, Johns Hopkins Univ, Baltimore, MD.*

Background: Most transplant centers now accept kidney grafts from victims who have acute drug intoxications. Despite the widely acceptance of many of these donors the effect of the acute intoxication on graft outcome is poorly understood.

Methods: This is a single center retrospective cohort analysis of patients undergoing deceased donor kidney transplantation (DDKT). Donor and recipient characteristics and post transplantation outcomes were obtained from the institutional transplant database. Urine toxicology agents tested from donor urine was alcohol, heroin, cocaine, opioids/methadone, cannabinoids, benzodiazepines, ecstasy, methamphetamine and LSD. Delayed graft function (DGF) was defined as the need for dialysis within 1 week of kidney transplantation (KT). Graft failure was defined as the need to return to dialysis. Multiple logistical regression (MLR) analysis was used to assess the odds of DGF and graft failure and was adjusted for donor age, donor race, donor terminal creatinine, cold ischemic time and baseline urinary flow rate.

Results: Of 300 random KTs performed at our institution between January 2012 and October 2015, 200 were from deceased donors. 92 deceased donors (46%) were current drug users. The main toxins detectable in donor urine were alcohol (n=45, 23%), heroin (n=29, 15%), opioid/methadone (n=17, 9%), cocaine (n=16, 8%), cannabinoids (n=38, 19%), benzodiazepines (n=5, 3%), ecstasy (n=1, 0.5%), methamphetamine (n=6, 3%), LSD (n=1, 0.5%). Alcohol, heroin, cocaine, opioids/methadone, benzodiazepines, ecstasy, methamphetamine and LSD were drugs of abuse that had no significant effect on KT

outcomes (DGF and graft failure). However, cannabinoid use in donors had significantly higher odds of DGF (odd ratio 2.9 +/- 1.4, P< 0.05) but no effect on graft loss or death (median follow up of 1.69 years). 42 donors (n=18) who used cannabinoids had concomitant use of alcohol but there was no interaction seen.

Conclusions: Cannabinoid use is known to cause acute kidney injury. Our data suggest that cannabinoid use in kidney donors may increase the risk of DGF.

FR-PO1116

Why Kidney Transplants from Uncontrolled Donation after Cardiac Death Donors (UDCDD) Don't Reach a Good Renal Function? Maria Molina, Eduardo Gutierrez-Martinez, Enrique Morales, Manuel Praga, Amado Andres. *Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: Kidneys grafts from UDCDD have higher ischemia injury. It develops in higher primary non function, lower graft survival and worst renal function compared to ideal donors. The aim was to describe risk factors associated with poor renal function (PRF) in a group of renal transplants (RT) from UDCDD.

Methods: We review all RT from UDCDD performed in our center with functioning graft at 1 year. We classified grafts into two groups: Group I grafts with serum creatinine (SCr) ≥ 2 mg/dL at 1 year from kidney transplantation and Group II with SCr < 2 mg/dl. We compared characteristics in both groups.

Results: Our center have performed 207 RT from UDCDD. We excluded 14 (7%) primary non-function and 9 (4%) grafts lost in the first year. 184 (89%) grafts were functioning at 1 year of transplantation. 13 (7%) patients were into Group I and 171 (93%) patients were into Group II. Characteristic of two groups are showed in Table.

	Group I: SCr > 2 mg/dL (13 patients)	Group II: SCr < 2 mg/dL (171 patients)	p
Donor gender (male)	92% (12)	88% (150)	ns
Donor age (years)	51 (47-54)	41 (35-50)	< 0.01
Donor SCr (mg/dL)	1.4 (1.2-1.6)	1.3 (0.9-1.5)	ns
Cold ischemia time (hours)	14 (9-15)	11 (9-14)	ns
Recipient age (years)	48 (41-58)	47 (39-56)	ns
Recipient weigh (kg)	78 (74-91)	70 (60-82)	0.01
Delayed graft function	69% (9)	76% (130)	ns
Contralateral functioning kidney at one year	62% (8)	85% (146)	0.04
LDH serum	1776 (1160-2280)	1463 (822-2520)	ns
SCr at 6 month	2.3 (2.1-2.8)	1.4 (1.1-1.7)	0.01
Graft survival at the end of follow-up	69% (9)	99% (169)	<0.01

Conclusions: The prevalence of PRF at 1 year in RT from UDCDD is low in our center although confers a bad renal graft prognosis. PRF is associated to donor age, non-function of contralateral kidney graft, recipient weigh and gender and acute rejection. A better screening of potencial UDCDD, more adecuate allocation of these kidneys and a lower acute rejection rate could improve the outcome of renal transplantation from UDCDD.

FR-PO1117

Donation after Cardiac Death, Not Extended Criteria Donor Maria Molina, Enrique Morales, Eduardo Gutierrez-Martinez, Manuel Praga, Amado Andres. *Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: There are few experiences published about long term follow-up of renal transplant (RT) from Donation after Cardiac Death Donors (DCDD) from category II of Maastricht classification (Uncontroled DCDD) (people presenting a irreversible cardiac arrest at home or on the street and dead despite appropriate resuscitation maneuvers). Outcomes from grafts from Uncontrolled DCDD are classically lower than organs from the Donation after Brain Death Donors (DBDD) .

Methods: We reviewed all characteristics from RT from Uncontrolled DCDD performed between July 2005-December 2012 in our hospital. We compared with a paired RT from DBDD, no hyperimmunized, first renal transplants with similar donor age performed in our hospital during the same period of time.

Results: We included 207 RT in Uncontrolled DCDD group and 207 RT in DBDD group. Results are shown on the table.

	DCDD group N=207	DBDD group N=207	P
Donor age (years)	43±10	41±11	ns
Recipient age (years)	48±11	45±11	0.01
Donor serum creatinine (mg/dl)	1.2±0.4	0.8±0.3	0.01
Delayed onset of Tacrolimus with Thymoglobulin induction (%)	187 (90%)	0 (0%)	0.01
Primary non-function (%)	14 (7%)	7 (3%)	ns
Delayed graft function (%)	162 (78%)	110 (53%)	0.01
1-year incidence of biopsy-proven acute rejection (%)	22 (11%)	27 (14%)	0.01
Graft survival (%)* / **	178 (86%)* / 182 (88%)**	176 (85%)* / 184 (89%)**	ns*/**
Patient survival (%)*	202 (98%)	200 (97%)	ns
Final serum creatinine (mg/dl)	1.5±0.8	1.4±0.7	ns

*at the end of the follow-up, **death censored

The high incidence of delayed graft function in uncontroled DCDD group, probably due to the high ischemic strees suffering these donors, has no negative impact on graft outcome.

Conclusions: Uncontroled DCDD is an adequate kidney donors. The expansion of this kind of donors can significantly increase the number of organ recovered and improve results in kidney transplant programs, particularly for median age recipients.

FR-PO1118

Assessing Deceased Donor Quality Using the Kidney Donor Risk Index: Performance in a Canadian Setting Ann Young,[1] Eric McArthur,[2] Stephanie Dixon,[2] Greg A. Knoll,[2,3] Amit X. Garg,[2,4] Charmaine E. Lok,[1,2] Ngan Lam,[5] Joseph Kim.[1,2] *[1]Dept of Medicine, Univ of Toronto, ON, Canada; [2]Inst for Clinical Evaluative Sciences, ON, Canada; [3]Div of Nephrology, Univ of Ottawa, ON, Canada; [4]Div of Nephrology, Western Univ, ON, Canada; [5]Div of Nephrology, Univ of Alberta, Edmonton, AB, Canada.*

Background: Deceased donor kidney allocation in the United States is guided by the Kidney Donor Risk Index (KDRI). The applicability of this newer allocation system in a Canadian setting is unknown.

Methods: This population-based cohort study followed deceased donor kidney transplant recipients in Ontario, Canada from Jan 2005 to Mar 2011. Subjects were identified from Ontario's Trillium Gift of Life Network and linked to other provincial healthcare databases. Ten donor factors were used to calculate the KDRI. Multivariable Cox proportional hazards models were used to assess the association of KDRI with graft loss or death. The role of KDRI in predicting long-term recipient outcomes, when compared to only using donor age, was explored using the likelihood-ratio test.

Results: A total of 1,299 deceased donor kidney transplants were divided into KDRI quintiles. Median follow-up time was 5.5 years. Mean donor age increased across KDRI quintiles from 27 to 64 years. A log-linear association between KDRI and total graft loss (i.e., death, return to chronic dialysis, or preemptive re-transplant) was observed. Total graft loss increased across KDRI quintiles from 39.6 to 90.2 events per 1,000 patient years. The adjusted hazard ratios (95% CI) from Q2 to Q5 (referent = Q1) were 1.27 (0.89, 1.80), 1.58 (1.13, 2.22), 1.43 (1.01, 2.02), and 2.15 (1.54, 2.99), respectively. Increased hazard ratios across KDRI quintiles were also observed for death-censored graft loss, but not for death. In this cohort, the KDRI significantly improved the assessment of donor quality compared to models using donor age alone (p=0.009).

Conclusions: The KDRI can be used in Canadian patients to identify kidneys at increased risk for graft loss, and can potentially inform risk assessment beyond using donor age alone. Whether the KDRI can be further refined in this population, and effectively applied in other Canadian jurisdictions, requires further study.

FR-PO1119

Risk Stratification for Optimized Utilization of Deceased Donor Kidneys with Acute Kidney Injury by KDIGO criteria Mi-Yeon Yu, Yong Chul Kim, Jung Pyo Lee, Yon Su Kim, Hajeong Lee. *Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Deceased donor kidneys with acute kidney injury (AKI) raise fear of poor graft outcomes to clinicians and consequently are often discarded. However, the growing evidence has suggested that they may be a good solution to overcome organ shortage. Although previous studies have focused on fair outcome of donor AKI, there is a limited data regarding the factors affecting long-term graft and recipient outcomes in patients received deceased donor kidneys with AKI.

Methods: We included all patients who received decreased donor kidney transplant from 2005 to 2011. We defined AKI by KDIGO criteria. Primary outcome was graft survival beyond 10 years by donor AKI stage. Secondary outcomes were 6 month, 1, 3, 5 years graft function, and 5-year recipient survival.

Results: Among a total of 413 patients, 156 received kidneys from donors with AKI including 84 stage 1, 38 stage 2, and 34 stage 3. Other 257 were received kidneys from donors without AKI (no AKI group). AKI developed more in ECD and hypotensive donors. There was no significant difference in delayed graft function, overall graft and recipient survival among AKI and no AKI groups. Interestingly however, when we followed up annual graft function, patients who received stage 3 AKI donor kidneys showed significantly lower 5-year graft function (median eGFR 45 [23–67] mL/min/1.73m^2), compared with no AKI (median eGFR 65 [40–90]), stage I AKI (median eGFR 59 [39–79]), and stage 2 AKI (59 [34–84]), respectively (P=0.019). Risk factor analysis for graft survival demonstrated worsening renal function just before transplantation elevated risk of both graft failure (adjusted HR 7.65, 95% CI 1.63–35.89) and patient survival (adjusted HR 20.67, 95% CI 1.33–321.99).

Conclusions: Although deceased donor AKI was not associated with overall graft and recipient survival, stage 3 AKI had an influence on lower graft function. Moreover, worsening renal function just before transplantation was an independent risk factor for both graft and patient survival.

FR-PO1120

Differential Intragraft Gene Expression Profile of Kidney Transplant Patients on Angiotensin Converting Enzyme Inhibitor (ACEI) or Angiotenin Receptor Blocker (ARB) Christian Suarez-Fuentes, Yi Bao, Enver Akalin. *Montefiore Einstein Transplant Center, Bronx, NY.*

Background: Treatment with ACEI/ARB has been shown to have anti-inflammatory effects in animal models but this effect has not been investigated in kidney transplant recipients. We aimed to study the effect of ACEI/ARB treatment on intragraft gene expression profiles of transplant kidney biopsies using microarrays.

Methods: We identified near normal biopsies with chronic sum allograft injury score (ct+ci+cv) ≤ 3 for gene expression profiling. Biopsies with a diagnosis of acute or chronic rejection, glomerular disease, or polyoma nephropathy were excluded. The gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays. We compared 2 groups; Group 1 (n=16), patients with no exposure of ACEI/ARB treatment and Group 2 patients (n=13) with exposure to ACEI/ARB at least 6 months prior to kidney biopsy.

Results: Both groups had similar demographics characteristics in terms of age, race, sex, type of transplant, previous history of transplantation or acute rejection, panel reactive antibody levels and immunosuppressive treatment. There were no differences in acute and chronic Banff allograft injury scores between the 2 Groups. Intragraft gene expression profiles of ACEI/ARB treated Group 2 biopsies showed decreased gene transcripts of interferon-gamma and rejection-associated transcripts (GRIT) and constitutive macrophage-associated transcripts (CMAT) compared to Group 1 biopsies. There were no statistically significant differences in expression of cytotoxic T cell (CAT), regulatory T cell (TREG), B-cell (BAT), natural killer cell (NKAT), and endothelial cell-associated transcripts (ENDAT) between the 2 Groups.

Pathogenesis Based Transcripts	G2 VS G1 (DOWNREGULATED)
GRIT	0.048
CAT	0.18
TREG	0.07
BAT	0.42
NKAT	0.35
CMAT	0.048
ENDAT	0.52

Conclusions: We have shown that exposure to ACEI/ARB was associated with down-regulation of GRIT and CMAT. This anti-inflammatory effect could be an additional benefit in kidney transplant recipients.

Epitope Sharing Causing Crossmatch Positivity in a Kidney Transplant Candidate with Very Low Pre-Transplantion Anti-Human Leukocyte Antigen Antibody Titer: A Case Report Iris C. De Castro,[1] Paul Warner,[2] Christopher D. Blosser.[1] *[1]Nephrology, Univ of Washington, Seattle, WA; [2]Bloodworks Northwest, Seattle, WA.*

Introduction: Human leukocyte antigen (HLA) have multiple epitopes. An epitope or *antigenic determinant* is a part of an antigen that is capable of stimulating an immune response. Epitopes can be shared by different HLA's. HLA antibodies usually react to epitopes rather than antigens. We present a patient who, despite having very low titer HLA antibodies, repeatedly tested positive on B cell flow crossmatch (FXM) with 6 potential donors making her not suitable to receive the kidney offer.

Case Description: 62yo ABO A+, Caucasian female with 3 pregnancies, no blood transfusions and ESRD from chronic glomerulosclerosis on peritoneal dialysis. Despite cPRA 0% and single antigen bead (SAB) test showing HLA Class I and II under 1,000MFI (positive cutoff is >2500MFI), she tested FXM positive with 6 potential donors. On review, all HLA-DR beads except HLA-DR7 were clustered with MFI between 300 and 950. She was found to have an antibody to a shared epitope by all HLA-DR antigens except HLA-DR7. As it was a single antibody, it only showed low level MFI on SAB making each, individually, insignificant. But, when crossmatched against non-DR7 lymphocytes, this was sufficient to yield a positive result. This was confirmed by FXM against numerous surrogate donors with different HLA-DR antigens. She had positive FXM with cells carrying any DR antigen other than DR7 and negative FXM to all HLA-DR7 homozygous donors.

Discussion: HLA antibodies that recognize broadly expressed epitopes can produce seemingly normal, low-level MFI SAB results, but FXM positive when exposed to only one of the antigens carrying the target epitope. Previous literature have reported that pre-transplantation low-level donor specific antibodies can induce severe acute antibody mediated rejection early after transplantation as a result of shared epitopes. Since the patient had persistent positive FXM against non-DR7 cells, all other DR antigens were added as unacceptable, resulting in a cPRA 99%. This case illustrates the importance of recognizing epitope sharing and its implications on kidney transplant allocation.

SA-PO002

Hyperkalemia during Voriconazole Treatment in Three Kidney Transplant Patients Mohammed Nazmul, Scott G. Westphal, Clifford D. Miles. *Nephrology, Univ of Nebraska Medical Center, Omaha, NE.*

Introduction: Voriconazole (VOR) is a commonly used antifungal agent in renal transplant recipients who develop fungal infection. Here we present a previously unreported observation of moderate to severe hyperkalemia occurring in three patients started on VOR. In each case, the hyperkalemia developed despite adjustment in tacrolimus (TAC) dose to maintain therapeutic, low serum levels.

Case Description: We identified three kidney transplant recipients who were started on VOR for the treatment of histoplasmosis, and developed hyperkalemia following its initiation. Each patient was maintained on a TAC-based immunosuppression regimen. Hyperkalemia was not present in any of the three patients prior to starting VOR, and TAC dose was decreased to keep trough levels at 3-6 ng/ml. All patients were instructed to follow a low potassium diet and additional medications known to cause hyperkalemia were avoided. Patient #1 had several episodes of severe hyperkalemia with a peak potassium level 8.5 mmol/L occurring 40 days after starting voriconazole. At that time, his TAC level was 4.1 ng/ml and creatinine was 2.3 mg/dl. He ultimately was converted from TAC to everolimus, and the hyperkalemia resolved. Patient #2 had persistent hyperkalemia following initiation of VOR. His peak serum potassium reached 6.5 mmol/L occurring 75 days after starting VOR. His TAC level was 4.0 ng/dl and creatinine was 1.8 mg/dl at that time. Patient #3 had intermittent moderate hyperkalemia after starting VOR. His peak potassium level was 5.7 mmol/L which occurred 54 days after starting VOR. At the time of his peak potassium, his TAC level was 2.1 ng/ml and creatinine was 2.9 mg/dl.

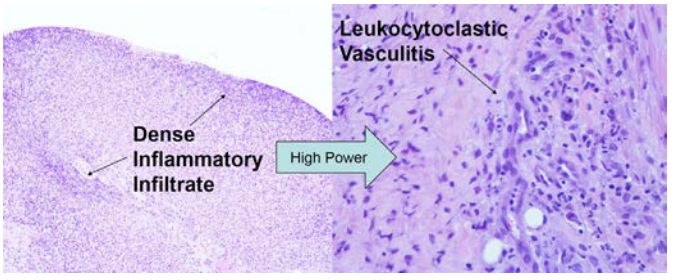
Discussion: While interactions between azoles and calcineurin inhibitors are widely recognized, this is the first report describing new onset hyperkalemia following initiation of VOR in kidney transplant patients receiving TAC. In each patient, the hyperkalemia developed despite maintaining low level, therapeutic TAC levels. The mechanism behind this observation remains unclear, but may warrant further investigation. Clinicians should be vigilant for hyperkalemia when TAC and VOR are used concurrently.

SA-PO003

Autoimmunity following Kidney Transplantation: A Case of De Novo Behcet's Disease Isabel Remedios,[1] Isa Ashoor.[2] *[1]Pediatrics, Louisiana State Univ Health Sciences Center, New Orleans, LA; [2]Nephrology, Children's Hospital, New Orleans, LA.*

Introduction: Autoimmune disease is a rare occurrence following kidney transplant (KT). Its development may be a marker of inadequate immunosuppression secondary to altered drug pharmacokinetics or non-adherence. We present a case of Behcet's disease (BD), a rare mucocutaneous ulcerative autoimmune condition in a non-adherent sexually active young adult KT recipient that was initially mistaken for Herpes Simplex Virus (HSV) infection.

Case Description: A 19 year-old African American female with a history of bilateral Wilms tumors, and prior failed KT due to chronic rejection presented 4 years following her second deceased donor KT with acute fever, non-bloody diarrhea, and ulcerations of the mouth, vulva, and perianal region. Her transplant course was notable for multiple rejection episodes and several sexually transmitted infections. The ulcers appeared herpetiform and aphthous in nature. Given her chronic immunosuppression with tacrolimus, mycophenolate, and prednisone, and and recent sexual encounter, disseminated HSV was suspected. She was empirically treated with IV acyclovir. After 1 week of therapy, fever and diarrhea resolved, but ulcers remained unchanged. All infectious studies returned negative. Lupus serologies and Crohn's disease screening tests were negative. Vulvar punch biopsy showed a neutrophilic/leukocytoclastic vasculitis consistent with BD.



Symptomatic treatment with analgesia, wound care, and sitz baths led to complete resolution within 3 weeks.

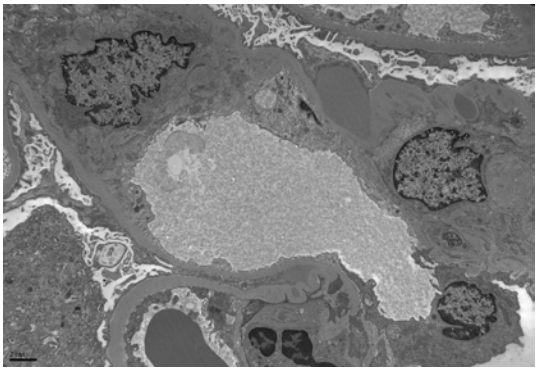
Discussion: Although rare, BD is an important cause of non-infectious orogenital ulcers. We describe the only KT patient in the literature with biopsy confirmed de novo BD independent of pre-existing glomerulonephritides. A high index of suspicion is required to diagnose BD in this population to limit prolonged exposure to nephrotoxic medications.

SA-PO004

De Novo Post-Streptococcal Glomerulonephritis as the Cause of Transplant Acute Kidney Injury Alexander Bullen, Mita M. Shah. *Div of Nephrology-Hypertension, Univ of California San Diego, San Diego, CA.*

Introduction: Acute kidney injury (AKI) is common in kidney transplant recipients (KTR) and is a risk factor for graft failure and death. We present a rare cause of AKI in a KTR, acute post-streptococcal glomerulonephritis (APSGN).

Case Description: A 45-year-old male with history of ESRD secondary to unknown etiology status post living donor kidney transplant two years prior, with baseline serum Cr of 1.5 mg/dL, presented to kidney transplant clinic. He was recovering from a "cold" the week prior. His immunosuppressive regimen consisted of tacrolimus 3 mg BID, mycophenolate mofetil 750 mg BID and prednisone 10 mg QD; he had inadvertently been taking 1 mg BID of tacrolimus for several weeks. On clinical exam he was normotensive and afebrile, without graft tenderness or bruit; 3-4 mm pitting edema was noted in the lower extremities. Laboratory data showed a Cr of 2.2 mg/dL increased from 1.6 mg/dL a month prior, tacrolimus trough of 4.9, UA moderate blood, > 50 RBCs, 3+ protein and urine protein/creatinine ratio of 8.2. UA a month prior did not reveal blood or proteinuria. Anti-streptolysin O antibody was elevated at 603 (0-330 IU/mL), C3 was low and C4 was normal. Biopsy revealed submembranous electron dense deposits in mainly paramesangial areas and large subepithelial electron dense deposits, consistent with APSGN and no evidence of cell or antibody mediated rejection.



A month later, Cr had decreased to 1.9 mg/dL. In three months, it had returned to baseline and proteinuria and hematuria had resolved.

Discussion: APSGN is caused by nephritogenic strains of group A beta-hemolytic streptococcus. The clinical spectrum ranges from asymptomatic disease to acute nephritic syndrome as in our patient. This case reveals the importance of a prompt and thorough evaluation of AKI in KTRs having a low threshold to perform a renal biopsy to assess for other entities such as APSGN.

SA-PO005

Haunted by Ghosts: An Unlikely Explanation of Hematuria in a Renal Transplant Patient Ruchita Jariwala,[1] Dia Rose Waguespack,[1] William F. Glass,[2] Angelina Edwards.[1] *[1]Div of Renal Diseases and Hypertension, The Univ of Texas Health Science Center at Houston, Houston, TX; [2]Div of Pathology and Laboratory Medicine, The Univ of Texas Health Science Center at Houston.*

Introduction: Anticoagulant use for the prevention and treatment of thrombosis is indicated in variety of clinical settings. Anticoagulant nephropathy is a clinical entity of great importance as more anticoagulants are developed and used in broader clinical settings. We report a case of anticoagulant nephropathy in a renal transplant recipient after the initiation of warfarin for lower extremity deep vein thrombosis.

Case Description: A 62-year-old man underwent a living related donor kidney transplant for end stage renal disease secondary to Hypertension and Diabetes. He had a complicated postoperative course requiring surgical correction of ureteral leak with stent placement, repair of the transplant renal artery and anticoagulation initiation with warfarin for lower extremity DVT. Despite his international normalized ratio (INR) remaining less than 3, he had persistent microscopic hematuria with intermittent episodes of gross hematuria. Upon completion of anticoagulation, a renal transplant biopsy was performed for evaluation of elevated creatinine and persistent microscopic hematuria. Biopsy was negative for rejection but showed acute tubuloepithelial injury with red blood cell (RBC) casts and RBC ghosts suggestive of prior glomerular hemorrhage and anticoagulant related nephropathy. His hematuria resolved at follow up and his creatinine gradually improved with cessation of anticoagulation.

Discussion: Anticoagulant related nephropathy is a cause of acute kidney injury (AKI) that is frequently underdiagnosed and underappreciated. Although most cases occur with supratherapeutic INR, anticoagulant related nephropathy can occur even with modest elevations. In this case, the pathologic findings of RBC ghost casts suggest lysis and degeneration of RBCs from prior bleeding episode. Thus, anticoagulant related nephropathy can be clinically relevant even after discontinuation of anticoagulation. Our case serves to broaden the differential of AKI and hematuria in a kidney transplant patient previously on anticoagulation.

SA-PO006

An Unusual Case of Acute Myeloid Leukemia Cell Infiltration of the Renal Allograft Sandhya Manohar,[1] Insara Jaffer Sathick,[1] Joseph P. Grande,[2] Ziad El-Zoghby,[1] Nelson Leung.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Pathology, Mayo Clinic, Rochester, MN.*

Introduction: Native kidney involvement of hematological malignancies is common and can often be the presenting feature. Renal involvement is seen in about 34% of patients by autopsy studies. To our knowledge, there has been no reported case of acute myeloid leukemia (AML) infiltration in the kidney allograft and here we present such a case in a kidney transplant patient.

Case Description: A 59-year-old male presented to us for management of his recently diagnosed AML. He had a history of end stage renal disease from diabetic nephropathy and underwent deceased donor kidney transplant at an outside facility. He was maintained on a prednisone and cyclosporine regimen with a unremarkable course for 14 years. A year prior to presentation, his platelet count was 50 X 10^9cells/L with a concurrent rise in creatinine. A bone marrow biopsy showed increased myeloid precursors with increased blasts (29%) consistent with the diagnosis of AML and he was sent to us for further management. Upon presentation to us, his creatinine was 2.7 mg/dl. His urinalysis revealed mild hematuria with 24 hour urine protein of 953 mg/g of creatinine. He underwent a kidney allograft biopsy which revealed multifocal myeloid infiltrates compatible with renal involvement of AML. He was started on chemotherapy but he progressively deteriorated and passed away.

Discussion: It is well known that transplant patients are at a higher risk of developing cancers with dermatological cancers and lymphomas being the bulk of these but AML is less common. The Cincinnati Transplant Tumor registry of 1991 noted 2.7% of the cancers to be due to leukemia, of which 43% were AML. A study of autopsy cases of patients with hematological cancers had shown renal involvement in 34% of the cases. It was most common in patients with acute lymphoid leukemia (83%) but interestingly patients with AML had the most dense infiltration with involvement of almost the entire kidney. But to our knowledge there are no reported cases of such malignancies involving the renal allograft and should be a consideration in transplant patients presenting with elevated creatinine.

SA-PO007

A Case Report - Phenytoin Overdose Treated with Hemodialysis Using a High Cutoff Filter Joelle Mardini,[1] Monique Cormier,[1] Simon Desmeules,[2] Marc Ghannoum.[1] *[1]Nephrology, Hopital de Verdun, Montreal, QC, Canada; [2]Nephrology, Centre Hospitalier Univ de Québec, Quebec, QC, Canada.*

Introduction: The role of hemodialysis (HD) to enhance phenytoin clearance in overdose cases is uncertain. Because of phenytoin's high protein binding (90%), it is hypothesized that dialysis using more porous filters may accentuate clearance of phenytoin. This report is the first description of phenytoin removal using a Theralite™ filter, a high cut-off filter that allows the removal of molecules with a molecular mass of up to 45 kDa.

Case Description: A 54-year-old man who ingested an unknown amount of phenytoin had a phenytoin level of 51.2 mg/L (therapeutic range 10-20mg/L) and coma, both of which remained relatively constant for 12 days. HD was prescribed to enhance elimination of phenytoin. Blood and dialysate flow were prescribed at 350 and 750 ml/min, respectively. Phenytoin and albumin sampling were simultaneously drawn from the arterial (entering) line of the dialyzer and the effluent line every 60 minutes from the start of HD. Phenytoin concentration decreased by 28.6% during the 8-hour HD treatment, and a total of 1.1 g of phenytoin was removed. During HD, measured apparent half-life was 18.5 hours, compared to 1109.8 hours before HD and 56.3 hours after HD [Figure 1]. Instantaneous phenytoin clearance remained constant during HD and averaged 80.1 mL/min, whereas a steady decline in albumin clearance was observed during the 8-hour session. Albumin removal from the Theralite filter was most important at the beginning of HD, which suggests adsorption (and saturation) of albumin on the filter.

Discussion: The high clearance of phenytoin obtained with this filter was due to its high surface area rather than its capacity to remove the albumin-phenytoin complex. This case confirms current data and recommendations that HD should be considered in phenytoin poisoning[1].

SA-PO008

Renal Auto-Transplantation: An Emerging Approach to Revascularization in Takayasu Arteritis-Induced Renal Artery Stenosis (TARAS) Joelle Mardini, Catherine L. Weber. *Nephrology, McGill Univ Health Center, Montreal, QC, Canada.*

Introduction: Takayasu arteritis (TA) can lead to stenosis, occlusion or aneurysmal transformation of the aorta and its primary branches. Renal artery involvement is common leading to renovascular hypertension and its complications. Renal revascularization in this setting has been shown to control blood pressure and enhance long-term renal and cardiac function as well as survival.We describe a case of successful renal revascularization via renal auto-transplantation (RAT).

Case Description: A 38 year-old hypertensive female was diagnosed with TA in 2014 when CT imaging revealed diffuse wall thickening of pulmonary arteries, abdominal aorta and bilateral renal artery stenosis: 100% on the right with an atrophic kidney and 80% on the left proximal to the first bifurcation with normal size kidney. Her immunosuppression included Prednisone and MMF as well as 4 anti-hypertensives to control her blood pressure. She experienced recurrent disease flares requiring high dose Prednisone as well as several episodes of acute kidney injury (worst Cr 6.4mg/dL). In April 2016, when disease activity was at its minimal, a RAT was performed to prevent loss of renal function in her remaining kidney. Her left kidney was removed and cold-perfused while the left saphenous vein was harvested and anastomosed to the renal artery above the first major bifurcation. The left kidney was then auto-transplanted onto the right external iliac vessels. Pre-op Cr was 1.0mg/dL; peaked post-op day 1 at 2.1mg/dL and returned to baseline on post op day 3. Today, she remains on 4 anti-hypertensive medications, Cr is 1.0mg/dL and renal function is stable.

Discussion: Optimal management of TARAS is not well established. While percutaneous angioplasty techniques are accessible and safe, their results seem less durable than bypass grafts. RAT has been described as the procedure of choice in patients for whom angioplasty and bypass graft are deemed too technically challenging due to advanced tissue inflammation. Although more studies are needed, it appears RAT should be favored in complex TARAS cases for blood pressure control and long-term renal function preservation.

SA-PO009

Preserved Renal Allograft Function While Using the PD-1 Pathway Inhibitor Nivolumab Valerie Suzanne Barta, Madhu C. Bhaskaran, Kenar D. Jhaveri, Nicole M. Ali, Viren G. Amin, Richard L. Barnett. *Nephrology, Northwell Hofstra School of Medicine, Great Neck, NY.*

Introduction: Treatment of malignancies in renal transplant (RT) recipients has largely consisted of targeting the cancer and reducing the immunosuppression. Newer therapies using programmed cell death protein 1 (PD-1) pathway inhibitors such as Nivolumab (N) have been associated with transplant rejection usually within 6-8 weeks of initiation. We report a living related donor (LRRT) where a pre-emptive steroid and sirolimus(S) regimen prevented the immune response of N on the kidney transplant.

Case Description: 70 year old Caucasian male, ESRD consequent to bilateral nephrectomy in 2000 and 2007 for renal cell cancer underwent LRRT in 2010. In early 2015 he developed adenocarcinoma of the duodenum metastatic to liver treated in the past year with intestinal stenting and with minimal response to multiple rounds of chemotherapy. Further disease progression led to initiation of N in 3/2016. 40mg/d prednisone was instituted and prograf was replaced by S. Serum Cr was 1.33mg/dl and dipstick protein negative. S was adjusted for trough levels 4-6 ng/ml. The following month upper intestinal obstruction was addressed with feeding J tube and venting G tube. In 5/2016 he was successfully treated for a port related Klebsiella bacteremia. Since N therapy his body weight has been maintained at 90kg, serum albumin 3.0g/dl, Cr DECLINED to 0.7 and urine protein/Cr was 0.3. 6/2016 donor specific antibodies were negative and CT scan revealed no disease progression.

Discussion: Checkpoint inhibitors of PD-1 class (N) and CTLA-4 antagonists have demonstrated benefit by restoring T cell mediated tumor suppression. Their use has been associated in the four prior RT case reports with rapid cell and antibody mediated rejection. In these patients lower dose steroids with calcineurin inhibitors were employed. We present a novel strategy to prevent rejection in the RT patients receiving PD-1 inhibitors using pre-emptive steroids and sirolimus.

SA-PO010

Babesiosis: An Unusual Cause of Sepsis in a Kidney Transplant Recipient
Negiin Pourafshar, Imtiaz M. Ather, Denise Schain, Asmita A. Gupte, Michael J. Casey. *Univ of Florida, Gainesville, FL.*

Introduction: Infections are a common cause of morbidity and mortality in solid organ transplant recipients due to the use of chronic immunosuppressive therapy necessary to prevent rejection. There is a dearth of literature regarding parasitic infections in organ transplant patients, with no randomized studies. We report a unique case of babesiosis presenting as sepsis in a renal transplant recipient.

Case Description: This case reports a 70-year-old female with a history of deceased-donor kidney transplant who presented with a recent history of severe fatigue and intermittent fevers. Vital signs and laboratory values met criteria for sepsis with 3 of 4 systemic inflammatory response syndrome (SIRS) criteria, along with a suspected source of infection. She was also noted to have acute kidney injury (AKI) and hemolytic anemia. A thorough workup did not reveal any specific hematologic etiology, and blood and urine cultures were negative for bacterial infection. Ultimately serology was positive for Babesia species, confirmed by PCR. The patient was successfully treated with a course of atovaquone and azithromycin and had a full recovery.

Discussion: Our case highlights the inherent difficulty in early recognition of babesiosis in the transplant patient population, in whom pancytopenia is a common finding with a broad differential diagnosis. Another interesting aspect of our case was the fact that our patient clinically presented with sepsis with a suspected source of infection. Parasites are usually an uncommon cause of sepsis, although it has been seen in severe malarial infections. In conclusion, our case represents the fifth reported case of babesiosis in a solid organ transplant recipient, as well as the first case of babesiosis presenting as sepsis which was successfully treated. As the solid organ transplant population has a high susceptibility to infection as well as numerous potential etiologies for the development of hemolytic anemia, it is essential for the clinician to be aware of babesiosis and consider it in the differential diagnosis in this setting.

A Rare Case of Severe Emphysematous Pyelonephritis of the Transplant Kidney Successfully Treated with Percutaneous Drainage and Antibiotics
Abdul Hameed Zaid, Anup Patel. *Internal Medicine, Saint Barnabas Medical Center, Livingston, NJ.*

Introduction: EPN is usually categorized into four prognostic classes based upon CT scan findings. Current evidence[1] suggests that most cases of EPN, especially those with extensive emphysematous changes (Class 3 and 4) in the presence of renal insufficiency, do not respond to percutaneous drainage (PCD) and antibiotics alone and require an allograft nephrectomy. We present a rare case of Class 3A emphysematous pyelonephritis of the transplant kidney in a diabetic successfully treated with PCD and antibiotics.

Case Description: A 41 year old lady with a history of ESRD from diabetes with a deceased donor renal transplant two years ago was transferred to our hospital after being treated for a urinary tract infection at an outside facility. She had sepsis and ongoing acute oliguric renal insufficiency and was started on intravenous antibiotics and fluids. Although her prednisone and tacrolimus were continued, mycophenolate was held due to the infection. An ultrasonogram revealed hyperechoic foci within renal transplant corresponding to regions of air with subcapsular and perinephric fluid collections with a CT scan confirming the same. A CT guided aspiration of the biggest fluid containing areas was performed the following day and purulent fluid drained. Over the next several days, her renal failure resolved and creatinine returned to baseline. She was discharged on oral antibiotics to complete a total of two weeks of antimicrobial therapy. A CT scan obtained 3 weeks later showed resolution of emphysematous changes with only trace perinephric stranding remaining.

Discussion: The case described above is a rare instance of severe EPN where an allograft nephrectomy was avoided and PCD with antibiotic therapy proved successful. Although available evidence[1] suggest that severe EPN has not been shown to respond to conservative management, early intravenous antimicrobial therapy and percutaneous drainage of identifiable pockets of gas and fluid may help salvage the allograft and give a new lease of life to it. 1. Emphysematous pyelonephritis. Clinicoradiological classification, management, prognosis and pathogenesis. Huang et al. *Arch Intern Med.* 2000;160(6):797-805.

SA-PO012

Furosemide Desensitization for Sulfonamide Hypersensitivity
Musab S. Hommos,[1] Jay Jin,[2] Gerald W. Volcheck,[2] Suzanne M. Norby.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Div of Allergic Diseases, Mayo Clinic, Rochester, MN.*

Introduction: Thiazide and loop diuretics with the exception of ethacrynic acid contain a sulfonamide moiety that can cause hypersensitivity reactions. While sulfonamide sensitive patients can take ethacrynic acid safely, volume management becomes challenging when ethacrynic acid is not tolerated.

Case Description: A 58-year-old male with systolic heart failure and chronic kidney disease stage IIIb developed a maculopapular skin rash and pruritus while taking furosemide. Skin biopsy showed subacute dermatitis with eosinophils compatible with drug reaction. A trial off his medications revealed furosemide as the probable cause of the rash. With two attempts at using ethacrynic acid, severe diarrhea occurred. Trials of sulfonamide-containing bumetanide, torsemide, hydrochlorothiazide and metolazone all resulted in rash. Ten days after stopping all diuretics, he was hospitalized for decompensated heart failure and underwent ultrafiltration. Repeat skin biopsy ruled out vasculitis, lichenoid tissue reaction and immunobullous disorders. During the next week, rash, pruritus and dyspnea resolved. Furosemide desensitization procedure was performed as outlined below without recurrence of skin rash. He was dismissed from hospital on furosemide 40 mg BID.

Discussion: Sulfonamide hypersensitivity is a clinical diagnosis with a variety of presentations, from limited skin reactions to life threatening anaphylaxis. Providers need to be aware of the possibility of cross reactivity due to the sulfonamide moiety present in many diuretics. Although desensitization is usually done for immediate type hypersensitivity, it is also reported to be successful in cases of delayed type hypersensitivity. Desensitization is a potential option when treating patients with diuretic intolerance due to sulfonamide hypersensitivity.

Oral Furosemide Desensitization (15 minutes between each dose)
Using furosemide 0.1 mg/ml:
Dose 1: 0.05 ml = 0.005 mg
Dose 2: 0.1 ml = 0.01 mg
Dose 3: 0.3 ml = 0.03 mg
Dose 4: 1 ml = 0.1 mg
Using furosemide 1 mg/ml:
Dose 5: 0.1 ml = 0.1 mg
Dose 6: 0.3 ml = 0.3 mg
Dose 7: 1 ml = 1 mg
Using furosemide 10 mg/ml:
Dose 8: 0.1 ml = 1 mg
Dose 9: 0.3 ml = 3 mg
Dose 10: 1 ml = 10 mg
Dose 11: 2 ml = 20 mg
Dose 12: 4 ml = 40 mg

SA-PO013

Infection in the Transplanted Kidney: TB or Not TB?
Megha Salani, Manish Anand, Mark Lusco, Beatrice P. Concepcion, Paul Persad. *Vanderbilt Univ Medical Center.*

Introduction: Solid organ recipients with latent tuberculosis infection (LTBI) are at increased risk for TB reactivation. These patients can have variable presentations, commonly with pulmonary, lymph node, and/or genitourinary tract involvement. We present a unique case of TB reactivation limited to the renal allograft.

Case Description: A 38 year old Indonesian female with ESRD due to IgA nephropathy underwent a deceased donor kidney transplant in 1/2015. Immediately post-transplant, she was found to have an LTBI and was treated with 9 months of isoniazid (INH). In 11/15, she presented with fever, allograft pain, and headaches. These symptoms persisted despite the use of broad-spectrum antibiotics. Initial blood and urine cultures were negative. Creatinine increased over the hospital course. The patient eventually underwent evaluation with a PET scan, which demonstrated hypermetabolic activity in the renal allograft. Kidney biopsy was performed and revealed diffuse multi-focal necrotizing granulomatous interstitial nephritis with a diffuse pleomorphic interstitial infiltrate. Bacterial, fungal, and mycobacterial stains, PCR, and cultures from the biopsy were negative. Adenovirus was detected but the pattern of granulomas was not consistent with adenovirus. Due to a high suspicion of TB based on histopathology, the patient was started on empiric INH, rifabutin, ethambutol, pyrazinamide, and moxifloxacin. After one week of therapy, her fevers resolved and her creatinine returned to baseline. She has completed 6 months of treatment and is currently without evidence of disease.

Discussion: Solid organ transplant recipients more commonly have extrapulmonary and disseminated TB than the general population. Our patient had a unique presentation limited to her renal allograft but was ultimately diagnosed with TB reactivation based on her history, histopathology on biopsy, and response to therapy. Given the low sensitivites of mycobacterial assays, a high index of suspicion for TB is warranted in patients with risk factors despite negative cultures or PCR. Particularly, the finding of necrotizing granulomas in a patient with prior TB exposure should prompt consideration of empiric TB treatment.

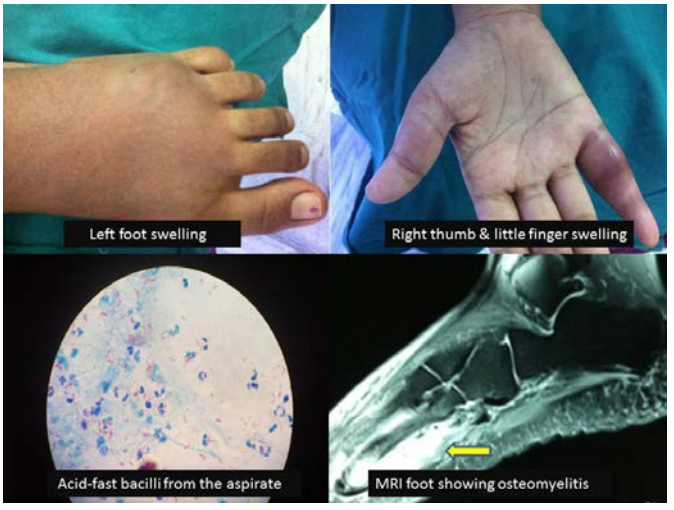
SA-PO014

Multi-Focal Tuberculous Osteomyelitis in a Renal Transplant Recipient
Hari Krishna Reddy Mogili,[1] Boju Sangeetha Lakshmi,[1] Anil Kumar Cheni Venkata,[1] R. Ram,[1] V. Siva Kumar,[1] Abhilash Koratala.[2] *[1]Sri Venkateswara Inst of Medical Sciences, India; [2]Univ of Florida.*

Introduction: Tubercular osteomyelitis, an uncommon form of extra-pulmonary tuberculosis (EPT), accounts for 1- 2% of all cases of tuberculosis (TB) and 10% cases of EPT. Spine is the most common location of skeletal TB accounting for ~50% cases. Multifocal tuberculous osteomyelitis with involvement of metatarsals and phalanges is extremely rare. Herein, we report a case of metatarsal and pharyngeal tubercular osteomyelitis in a kidney transplant recipient.

Case Description: A 26 year old Asian-Indian female presented to our institution for painful swelling in the left foot for ~10 days. She has history of End stage renal disease secondary to Lupus Nephritis and underwent deceased donor renal transplantation 3 months prior to presentation. At the time of transplant, she got Basiliximab induction and currently maintained on Tacrolimus 0.75mg bid, Mycophenolate mofetil 1000mg bid and Prednisone

17.5 mg/day. MRI of the foot showed osteomyelitis of second metatarsal with overlying abscess. Needle aspiration of the abscess revealed numerous acid-fast bacilli (AFB) with positive Mycobacterium TB polymerase chain reaction. 3 days later, she developed painful swelling of the right thumb and little finger and aspiration showed AFB. We started her on rifampicin-free anti-TB therapy and she responded well with clinical improvement over next two weeks.Pertinent findings are shown in the figure.



Discussion: Patients with skeletal TB usually present insidiously without systemic signs such as fever, night sweats, toxicity or extreme weakness. This condition may mimic malignancy, both clinically and radiographically. It's prudent for clinicians to consider this differential in immunocompromised patients presenting with long-term musculoskeletal pain especially those travelling from or transplanted in TB-Endemic countries.

SA-PO015

Emphysematous Cystitis in a Renal Transplant Recipient Don Henry Esprit, Abhilash Koratala, Michael Casey, Alfonso Santos, Shehzad Rehman, Karl L. Womer. *Nephrology, Hypertension and Renal Transplantation, Univ of Florida.*

Introduction: Emphysematous cystitis (EC) is a rare, but severe manifestation of urinary tract infection (UTI) characterized by spontaneous gas formation in the bladder lumen and bladder wall. Diabetes is the most common predisposing factor followed by neurogenic bladder and chronic bladder outlet obstruction. We report a case of EC in a kidney-pancreas transplant recipient on immunosuppressive therapy (IS) who is currently not a diabetic.

Case Description: 57 year old male with Diabetes mellitus type I, hypertension and ESRD status post combined Kidney-pancreas transplant 10 years ago presented with suprapubic pain, dysuria, and hematuria for 3 days. His maintenance IS included tacrolimus 6 mg bid, mycophenolate 750 mg bid and prednisone 10 mg daily. No fever. Labs showed hemoglobin 11.5 g/dL, WBC 9200 cells/cmm with 72.2% neutrophils. Serum creatinine was 1.2 mg/dl.Urinalysis showed hematuria and pyuria, urine culture revealed > 100,000 CFU/mL of Klebsiella pneumoniae. CT scan showed distended urinary bladder with abnormal urothelial enhancement and multiple foci of air in the bladder wall, suggestive of EC. Renal allograft was unremarkable and native kidneys were atrophic. Cystoscopy showed diffuse submucosal emphysematous lesions. He was treated with intravenous antibiotics and made a full recovery.

Discussion: EC is caused by gas-forming bacteria and fungi with the most common organism being E.coli. Patients usually present with symptoms of bladder irritation. Pneumaturia, if present, is highly suggestive of EC. CT scan is a better test to delineate the extent of the disease and patients usually respond to antibiotic therapy.EC should be considered in immunosuppressed patients and those with other predisposing conditions presenting with lower UTI symptoms to avoid delayed diagnosis which may put them at risk for life threatening infections and bladder rupture.

SA-PO016

Cerebral Lymphomatoid Granulomatosis (LYG) Treated Effectively with Rituximab in a Simultaneous Pancreas-Kidney (SPK) Transplant Patient Faisal Khaled Alhomayani, Muhammad A. Bukhari, David C. Holland, M. Khaled Shamseddin. *Nephrology Div, Queen's Univ, Kingston, ON, Canada.*

Introduction: Lymphomatoid granulomatosis (LYG) is a rare multisystem angiocentric B-lineage lymphoproliferative disease with significant malignant potential and mortality, affecting primarily immunocompromised patients . A 51 year-old female presented with a two-day history of headache, and vomiting. She had a history of type I diabetes, end stage renal disease, and SPK transplantation in 2004 (CMV: Donor negative/Recipient negative; EBV: Donor negative/Recipient positive), with normal function of both grafts. She had been induced with basiliximab then maintained on mycophenolate mofetil and tacrolimus. Post transplant course was uneventful, without any complication. Physical examination was unremarkable. investigations: CBC, electrolytes, creatinine, urea,LFT, INR, PTT were unremarkable. An enhanced MRI head showed seven ring-enhancing brain lesions. CT chest, abdomen and pelvis were unremarkable. The mycophenolate was tapered off, tacrolimus was reduced and prednisone introduced. The patient was diagnosed with LYG based on cerebral biopsy. With switching tacrolimus to sirolimus combined with 4 weekly doses of IV rituximab, complete resolution of 5/7 lesions occurred while the other lesions decreased significantly in size on MRI one-month post rituximab. She is clinically well with stable both graft functions. Her Epstein-Barr virus (EBV) viral load fell from 14,990 copies/ml to 0 at the cessation of rituximab. Post-transplant lymphoproliferative disease (PTLD) is the worst complication of solid organ transplantation occurring in 0.5-1.9% of patients . LYG is rarer than PTLD in transplant patients: both diseases may be triggered by EBV. Literature review identified seven cases of LYG in renal transplant patients. To our knowledge, this is the second report of successfully rituximab-treated cerebral LYG; the other being a renal transplant recipient with a durable (>4 years) complete remission of LYG.

Acute Posttransplant aHUS due to a Homozygous Deletion of CFHR1/CFHR3 with CFH-Autoantibodies Managed by a CNI-Free Regimen with Belatacept and Eculizumab Johannes Muench, Anette Bachmann, Christof Mayer, Tom H. Lindner, Jan Halbritter. *Internal Medicine, Div of Nephrology, Univ of Leipzig, Leipzig, Germany.*

Introduction: Acute renal graft failure may clinically present as atypical hemolytic uremic syndrome (aHUS), resulting from excessive activation of the complement cascade. Mutations of the complement coding genes predispose for development of aHUS. "Second hits" (e.g. drugs, pregnancy) commonly trigger the full-blown clinical picture. As calcineurin inhibitors (CNI) are considered as one of these potential triggers, CNI-free regimens would be favorable for avoidance of aHUS manifestation and long-term toxicity. However, there is little experience regarding management of posttransplant aHUS and adequate long-term immunosuppression in these patients.

Case Description: A 58-year old Caucasian female (ESRD of unknown origin) developed acute renal graft failure within days after transplantation, which clinically presented as aHUS (hemolytic anemia, thrombocytopenia, glomerular thrombotic microangiopathy). While complement anaylsis revealed autoantibodies against complement factor H (CFH), genetic testing yielded a concomitant homozygous deletion of *CFH-related 1* (*CFHR1*) and *CFHR3*. Therapy consisted of plasmapheresis, eculizumab (C5-inhibitor), and belatacept (blocker of T-cell co-stimulation) instead of CNI. Subsequently, renal graft function partially recovered (eGFR of 32 ml/min) and hematologic remission (absence of hemolysis) was observed for 18-month of follow up under continued administration of belatacept, eculizumab, mycophenolate mofetil (MMF) and low dose prednisolone.

Discussion: This case describes successful management of posttransplant aHUS using an individualized CNI-free immunosuppressive regimen based on eculizumab and belatacept. Especially in patients with ESRD of unknown origin, (preemptive) recognition of predisposing risk factors, such as complement abnormalities, are crucial for initiation of tailored immunosuppressive regimens and better long-term renal graft survival.

SA-PO018

Fever in a Transplant Patient: Is It Always Infection? Abhilash Koratala, Volodymyr Chornyy, Alfonso Santos. *Univ of Florida.*

Introduction: Immune reconstitution inflammatory syndrome (IRIS), first recognized in HIV patients during HAART is an intense inflammatory response from recovery of the immune system leading to deterioration in clinical status. We report a unique case of IRIS in a non-HIV, immunocompromised renal transplant recipient due to interaction between rifampin and tacrolimus (FK).

Case Description: 74 year old Asian male with history of orthotopic liver transplant 4 years ago for Hep C cirrhosis, ESRD due to calcineurin inhibitor toxicity and status post deceased donor kidney transplant a year ago was transferred to our institution for management of disseminated TB. He was on RIPE (rifampin, isoniazid, pyrazinamide, ethambutol) therapy initiated at the originating hospital. Due to abdominal pain, his pyrazinamide was switched to levofloxacin with improvement of the symptom. Serum FK level at presentation was undetectable likely due to its accelerated metabolism from interaction with rifampin. He later developed fever (Tmax 104.4F), tachycardia, tachypnea and mild hypotension. There were no localizing findings or imaging evidence suggestive of infectious source. C reactive protein (CRP) was markedly elevated. He was started on broad spectrum antibiotics after obtaining cultures. Blood and urine cultures, serology for CMV, Histoplasma, Cryptococcus were negative. He was diagnosed with IRIS, antibiotics

were discontinued, treated with iv methylprednisolone and FK dose adjusted to achieve goal levels. He responded well and symptoms resolved. CRP trended down rapidly. His IRIS was probably due to immune system reactivation in the setting of improving infection and low FK levels.

Discussion: With the increasing use immunosuppressive and immunomodulatory agents with potent effects on the immune system in transplant patients, it is important for physicians of various specialties caring for these patients to be familiar with these drugs and their potential interactions. Rifampin is an inducer of CYP3A4 and P-glycoprotein in the liver and small bowel leading to increased metabolism of FK which may predispose to IRIS in patients with resolving TB. Timely recognition and appropriate treatment of IRIS is critical for prevention of severe complications including graft loss.

SA-PO019

A Novel Form of Retroviral Associated Proliferative Glomerulonephritis? Sumoyee Basu, Sanjana Gupta, Paul Bass, Ian Proctor, Sally Hamour, Alan D. Salama. *UCL Centre for Nephrology, Royal Free Campus, London, United Kingdom.*

Introduction: Numerous HIV-1 associated nephropathies have been described including HIVAN, HIVICK and diffuse infiltrative lymphocytosis syndrome (DILS) characterised by CD8+ interstitial deposits. Our case does not fall into any of these categories.

Case Description: A 41 year old Brazilian man presented with fever, diarrhoea, vomiting and visible haematuria. Past medical history included treated syphilis and schistosomiasis. He was newly diagnosed with HIV-1 with a viral load of $0.65x10^6$ copies/ml and CD4 count of $0.32x10^9$/L. Creatinine was 340 mcmol/l without a previous baseline rising rapidly to 852. He had proteinuria of 117 mg/mmol without leucocyturia. No other infectious agents were identified including Zika, Chikungunya, Nipah & BK viruses. Virology revealed successful hepatitis B immunisation, previous hepatitis A and hepatitis C negative. Renal biopsy showed a diffuse proliferative glomerulonephritis with neutrophils and sparse microthrombi. Alongside high anti-streptolysin titre, this prompted amoxicillin and prednisolone which had no effect on renal function.

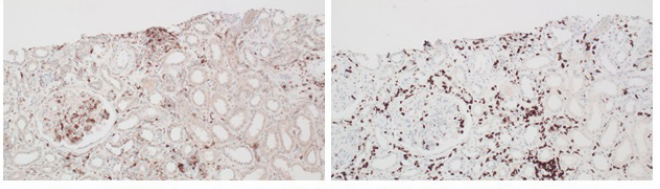

Figure 1: CD4+ glomerular and patchy tubular infiltrate (left) vs CD8+ stain (right)

Further review revealed hypercellular glomeruli with tuft inflammatory cells and no evidence of collapsing glomerulopathy. The glomerular and patchy tubular infiltrate was of predominantly CD3+ CD4+ but not CD8+ lymphocytes. There were no definite immune complexes on immunohistochemistry. Electron microscopy revealed tubuloreticular inclusions but no electron dense deposits. p24 antigen stain was negative. Commencement of high active retroviral therapy elicited viral load <40 copies/ml and a concomitant fall in creatinine and urine protein excretion.

Discussion: We believe this represents a novel form of HIV-1 associated nephropathy characterised by predominantly glomerular infiltration with CD4+ cells without immune complex deposition. We term this a 'diffuse glomerular lymphocytosis syndrome'.

SA-PO020

Rethinking Peritubular Capillary Basement Membrane Multilayering in Renal Transplant Histopathology: A Case Report Diana Maria Lopategui,[3] Elena N. Levtchenko,[1] Evelyne Lerut,[2] Noel Knops.[1] *[1]Pediatric Nephrology and Solid Organ Transplantation, UZ Leuven, Leuven, Belgium; [2]Morphology and Molecular Pathology, UZ Leuven, Leuven, Belgium; [3]Univ of Barcelona, Barcelona, Spain.*

Introduction: Severe multilayering of the peritubular capillary basement membranes (ML) in kidney allografts is considered an ultra-structural hallmark of chronic antibody mediated rejection (CAMR).We describe the findings in a young man with underlying focal segmental glomerulosclerosis who underwent a living-related donor transplant procedure, questioning the specificity of this phenomenon.

Case Description: The patient received a kidney from his mother, whose donor screening was unremarkable. He developed nephrotic-range proteinuria shortly after the procedure. The post-transplant biopsies performed within the first 6 months demonstrated ML (5-6 layers), suggestive for the onset of CAMR. Since there were no other criteria for CAMR, electron microscopy was performed on the baseline biopsy, and also demonstrated ML. Seven years later the donor still has no signs of kidney disease.

A review of the literature suggest this case to be the first description of ML in a person without apparent features of kidney disease. ML is believed to result from repeated endothelial injury and is also described in native kidney disease (lupus nephritis and thrombotic microangiopathy). The severity of ML is linked to the type and duration of endothelial distress. The presence of high-grade ML (≥7) in an allograft is considered highly suggestive for CAMR; the number of layers appears to increase with time after transplantation. In contrast, more than 5 layers are uncommon in native kidney disease. Additional clinical and genetic testing (including genes expressed in the glomerular and tubular basement membrane) could not reveal underlying kidney disease in the donor.

Discussion: We conclude that ML in the setting of renal transplantation is not specific for CAMR, can exist in several kidney diseases and even in asymptomatic donors. Further research is needed to determine the prevalence of ML in allograft biopsies at baseline and in non-allograft renal biopsies, which will enable us to better determine its value for renal histopathology.

SA-PO021

Prolonged Delayed Graft Function for Nine Months due to Renal Transplant Venous Hypertension Irfan Ahmed Moinuddin, Gaurav Gupta, Dhiren Kumar. *Nephrology, VCU Medical Center, Richmond, VA.*

Introduction: Delayed graft function (DGF) is defined as the need for dialysis within the first week of kidney transplantation (KTxp). The longest reported duration of DGF in literature is 4 months (Schulz et al, Am J Case Rep. 2016). Renal transplant venous hypertension has been reported in one case (McArthur et al, J Ultrasound Med. 2011) as the etiology of impaired allograft function although DGF has not been reported.

Case Description: We report the case of a highly sensitized (PRA=83%) thirty-nine year old female who was on anti-coagulation due to a history of access clots. She received a flow crossmatch positive second deceased donor KTxp in November 2013. She had a right thigh arterio-venous fistula (AVF) distal to the KTxp anastomosis. She had initial DGF for which a transplant biopsy was performed at 12 days post-txp. This biopsy showed antibody-mediated rejection. She was treated with plasmapheresis, rituximab, bortezomib and eculizumab. Her serologic and histologic evaluation six weeks later demonstrated absence of donor-specific antibodies and complete resolution of rejection. Despite this she remained hemodialysis dependent. Two additional biopsies over the next 2 months remained unrevealing. Molecular profile of her biopsy (MMDx, Alberta, Canada) demonstrated acute kidney injury but no rejection or fibrosis. Serial ultrasound imaging demonstrated increasing venous collaterization around the ktxp. A subsequent procedure to declot her thigh AVF revealed a thrombosed inferior vena cava. This was partially recanalized. Overtime her urine output started improving. It was felt that her DGF was related to renal venous hypertension due to IVC thrombosis as well as arterialization of the renal vein due to high venous return from her AVF. AVF ligation was considered but her renal function improved spontaneously and dialysis was discontinued at nine months post-transplant. Her most recent creatinine 30 months post-transplant is 1.7mg/dL.

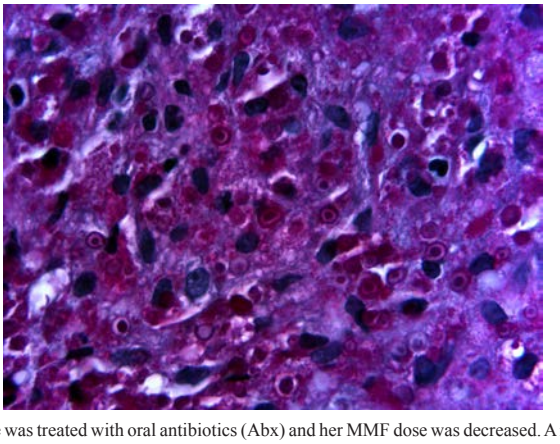
Discussion: Renal transplant venous hypertension should be considered in the rare case when other etiologies have been ruled out. The presence of a thigh graft on the side of kidney transplant or IVC thrombosis should particularly raise this concern.

SA-PO022

Renal Parenchymal Malacoplakia in an Asymptomatic Kidney Transplant Recipient Yvonne El Kassis,[1] Richard A. Fatica,[1] Leal C. Herlitz,[2] Andres G. Chiesa-Vottero,[2] Ziad S. Zaky.[1] *[1]Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH; [2]Anatomic Pathology, Cleveland Clinic Foundation.*

Introduction: Malacoplakia (MCP) is a rare granulomatous inflammation thought to be secondary to impaired phagocytic activity of macrophages, leading to incomplete bacterial elimination. We report a case of MCP found incidentally on the 6-month protocol biopsy (PBx) of an asymptomatic kidney transplant recipient (KTR).

Case Description: The patient is a 55 year-old female with bipolar disorder and ESRD secondary to lithium toxicity, who underwent a cadaveric kidney transplant. She received Thymoglobulin for induction and Tacrolimus, Mycophenolate Mofetil (MMF) and prednisone for maintenance immunosuppression (IS). Her post-transplant course was notable for recurrent asymptomatic E.coli urinary tract infections (UTIs). A 6-month PBx revealed focal granulomatous inflammation with foamy macrophages and abundant cytoplasmic inclusions consistent with Michaelis-Gutmann bodies, characteristic of MCP.



She was treated with oral antibiotics (Abx) and her MMF dose was decreased. A repeat 1-year PBx showed no evidence of ongoing MCP but did have inflammation consistent with BANFF borderline changes. Her urine cultures (UCx) remained positive, prompting a new prolonged course of intravenous Abx.

Discussion: MCP has been described in states of IS, including organ transplantation. It has been most commonly associated with E.coli UTIs and presents with obstructive uropathy or lower urinary tract masses mimicking malignancy. Untreated infections can lead to graft

loss and salt wasting nephropathy. Treatment focuses on reduction of IS and prolonged Abx therapy. To our knowledge, this is the first case of MCP incidentally discovered in PBx, highlighting a unique presentation of this rare disease. While her repeat Bx was negative for MCP this may represent failure to sample a patchy process, as her UCx remains positive.

SA-PO023

Cloud-Based Connectivity Platform Allows for Remote Management of Automated Peritoneal Dialysis and Early Recognition of Catheter Dysfunction: First Swiss Experience Valérie Jotterand Drepper,[1] Pierre-Yves F. Martin,[1] James A. Sloand.[2] *[1]Nephrology, Geneva Univ Hospital, Geneva, Switzerland; [2]Renal Div, Baxter Healthcare Corporation, Deerfield, IL.*

Introduction: Incident peritoneal dialysis (PD) patients tend to encounter more technical problems in weeks following training. Remote patient management (RPM) has the potential to detect early issues, allowing intervention prior to development of more significant problems that might lead to emergency visits, hospitalization or technique failure.

Case Description: A 23-year-old ESRD patient required hospitalization for urgent start of renal replacement therapy. Because of prior non-adherence, a newly available automated peritoneal dialysis (APD) RPM system (Sharesource) with cloud-based connectivity was implemented. Post-APD training and on return home, the patient's treatment was both remotely observed and altered regularly. Pre-defined RPM threshold parameters were set to identify clinically relevant issues, including PD catheter drain times.

On initial home discharge, the RPM system revealed no dashboard flag alerts and normal PD cycle volume profiles (Fig1a). However, in ensuing days, red flag dashboard alerts heralded prolonged drain times (Fig1b) leading to an early diagnosis of and surgical repositioning for catheter displacement.

Post-PD catheter repositioning, drain times were again normal as indicated by disappearance of flag alerts and cycle volume profiles. Non-adherence with clinic visits recurred, however, the RPM platform confirmed patient compliance with daily PD treatment.

Discussion: RPM of APD patients with a two-way cloud-based connectivity platform allows for monitoring and adjustment of therapy, as well as early recognition and timely management of adverse clinical issues. Larger scale observational studies will determine the impact of RPM in APD technique survival and resource utilization.

SA-PO024

Refusal of Dialysis in End Stage Renal Disease Patients Residing in Skilled Nursing Facilities Farida Migally, William Luke Whittier, Sheri Korbet. *Nephrology, Rush Univ Medical Center, Chicago, IL.*

Introduction: The number of ESRD pts in skilled nursing facilities (SNF) continues to grow. These pts have more co-morbidities and higher mortality when compared to those not living in SNFs. SNF ESRD pts on hemodialysis (HD) undergo either conventional three times weekly (CHD)(on site or in-center) or shorter more frequent HD (DHD). DHD is utilized to allow pts to adhere to rehabilitation which may translate to improvement in functional status. When pts on HD enter a SNF that performs DHD, they are often switching from CHD to DHD. Our hypothesis is that when ESRD pts who are naïve to DHD enter into a SNF that offers DHD, adherence to the more frequent sessions is low due to refusals. This may result in inadequate HD over time and could adversely affect outcomes.

Case Description: Data from nine SNFs with on-site HD programs were retrospectively compared from May-Dec 2015. Five programs delivered CHD, defined as conventional 3xs weekly HD using Fresenius equipment targeting a KT/V of 1.2. Four programs delivered DHD, defined as four or five times weekly HD using the NxStage System One, targeting a weekly KT/V of 2.0. Pts were excluded if they had been on DHD prior to entering the SNF. Missed treatments due to refusals were defined as a pt missing the entire HD session (without it being rescheduled) while residing in the SNF. Statistical analysis was performed using Fischer exact test for categorical data and Mann–Whitney for continuous data. Data was reported as mean±standard deviation.

There were a total of 335 pts who underwent 11,043 HD treatments. 171 underwent DHD with 6,398 treatments and 164 underwent CHD with 5,005 treatments (p=0.074). Both groups had similar ages (DHD 70±11 yrs vs. CHD 71±12 yrs, p=0.426). Missed treatments due to refusals were higher in DHD compared to CHD (DHD, 40.6±42% vs. CHD, 11.4±28%, p<0.0001).

Discussion: In our experience with HD in the SNF, there was a significant increase in percentage of missed treatments due to patient refusals in DHD. This lack of adherence to the dialysis prescription could adversely affect outcomes.

SA-PO025

Care of Kidney Transplant Recipients in Syrian War Zones Kamel Hatahet,[1] Nada Alachkar,[2] Crystal A. Gadegbeku,[1] Sami Alasfar.[2] *[1]Temple Univ Hospital, Philadelphia, PA; [2]The John Hopkins Univ, Baltimore, MD.*

Introduction: Care of kidney transplant recipients is complex and requires an organized infrastructure.The current Syrian conflict has led to deterioration in medical care for these patients. The information on management and outcome of such patients in Syrian war zones is lacking.

Case Description: prospective obervational study of 138 kidney transplant recipients in the Syrian northwestern providences, which are greatly affected by the war. Data on the patients are collected during the patients' clinic visits to two physicians involved in their care.

Mean follow up is 1.5 years. Patients are seen every month if their transplant is within 6 months and every 2 months if their transplant >6 months old. Routine labs checked includes CBC, BMP, UA, and drug levels.

Clinical parameters	N=138
Mean age at transplantation (yr)	40 +/- 10.9
Gender (M)	77%
Cause of original kidney disease Diabetes Hypertension Glomerulonephritis Other/Unknown	 7% 21% 24% 48%
Donor's type Living related Living unrelated	 60% 40%
Immunosuppression Tacrolimus Cyclosporine	 51% 49%
Mean most recent Creatinine	1.35 ± 0.67
Mean most recent CSA level	254 ± 215
Mean most recent FK level	5.8 ± 1.9
Mean distance from clinic (KM)	36 ± 21
Mean time from clinic (Min)	49 ± 28
Rejection (n)	4
Graft loss (n)	0

Complicated cases are referred to one nephrologist in the area or discussed through social media means with nephrologists in the US. Major Barriers to care identified as following: 1-availability of the immunosuppressions; 2-Cost of drug monitoring, 3- Lack of security during transportation. 4- Fear of targeting doctors. 5- Limited medical staff and ancillary studies. 6-Time needed to obtain results of lab and imaging studies.

Discussion: Despite many barriers and poor infrastructure, teamwork between physicians in Syrian war zones, Syrian American Nephrologists, and humanitarian organizations has translated into a life saving support to the Syrian renal transplant patients. More sustained effort and financial aid is needed for optimal management of these patients.

SA-PO026

Extracorporeal Treatments to Enhance Dapsone Elimination: A Case Report Amelie Bernier-Jean,[1] Marc Ghannoum,[2] Monique Cormier,[2] Dave Brindamour,[1] Clement Deziel,[1] Josee Bouchard.[1] *[1]Hôpital du Sacré-Coeur de Montréal, Canada; [2]Hôpital Verdun, Canada.*

Introduction: Intentional dapsone intoxication can be life-threatening. There is very limited data on the effect of extracorporeal treatments (ECTRs) on dapsone elimination. We describe a case of severe dapsone toxicity and report clearance, quantification and half-life of dapsone and its metabolites with different ECTRs.

Case Description: A 23 year-old woman was admitted 2.5 hours after ingesting 2.2 g of dapsone. On admission, the patient complained of headache, and the physical exam was remarkable for cyanosis. She developed severe methemoglobinemia (39.9%) and showed signs of toxicity (hemodynamic instability and slow processing) despite multiple-activated charcoal, methylene blue, vasopressors, and endotracheal intubation. Continuous venovenous hemofiltration (CVVH) was then initiated for 5 hours, followed by intermittent hemodialysis with hemoperfusion (IHD-HP) for 4 hours, and CVVH for another 48 hours. The platelet count dropped three hours after IHD-HP (nadir was 32 X 10^9/L). The elimination half-life of dapsone was 2.0 hours during IHD-HP, and 14.2 hours during CVVH. Mean dapsone clearance with IHD was 62 ml/min and with CVVH, 22 ml/min. Renal clearance was 6ml/min. IHD removed 95.3 mg, and CVVH removed 67.8 mg over 3.8 hours. The sieving coefficient of dapsone was 0.24-0.30. No rebound occurred following ECTR cessation. The toxicokinetics of dapsone metabolites were also accelerated during ECTR. The patient was extubated after 3.5 days and discharged without sequelae after 7 days.

Discussion: Contrary to previous reports and despite its high protein binding, dapsone appears to be dialyzable due to improvements in dialysis filters and catheters. In addition, ECTRs can accelerate dapsone elimination compared to multiple-dose activated charcoal alone. Although we obtained a shorter elimination half-life by combining IHD and HP, it remains unclear if this benefit is worth the costs and the risk of severe thrombocytopenia compared to IHD alone. We suggest that IHD with or without HP be considered following massive dapsone ingestion with life-threatening manifestations and high methemoglobinemia levels.

SA-PO027

Recurrent Acute Hypotension with Initiation of Dialysis and Ventricular Interdependence Sumeet Munjal,[2] Asma Mursleen,[2] Alberto Morales.[1] *[1]Div of Cardiology, Univ of South Florida; [2]Div of Nephrology, Univ at Buffalo, NY.*

Introduction: Ventricular interdependence is the mechanism whereby right heart failure (RHF) can cause left heart dysfunction. The primer bolus used before initiating dialysis can lead to an acute right ventricular volume overload. We report a case where primer bolus lead to acute RHF causing mobilization of interventricular septum towards the left, reducing cardiac output and lead to recurrent severe hypotension and syncope.

Case Description: 44 yo AAF with history of ESRD, DM, Non-ischemic cardiomyopathy (EF 15%) s/p AICD, presented after an episode of syncope while on dialysis. Patient had similar episode 2 weeks back and was started on midodrine before dialysis. Work up showed gram negative bacteremia due to infected catheter and was treated for septic shock with fluids, pressors and antibiotics. Patient recovered from sepsis but became volume overload requiring daily dialysis. However with each dialysis, she would become acutely unresponsive and apneic within 4-6 minutes after initiating dialysis causing early termination of sessions. Various interventions including albumin, lowering dialysate temperature and step sodium profiling was used to avoid hypotension, without any success. EEG negative for any seizure. Patient underwent TEE during dialysis which revealed worsening righ ventricular dilatation, severe hypokinesis and septal bouncing within minutes after starting dialysis. This was accompanied with drop in SBP from 128 to 78mm Hg. The septum shifted to the left consistent with right ventricle volume overload, ventricular interdependence accompanied with severe hypotensive. Hemodialysis was stopped and patient was given neosynephrine with improvement in BP. We concluded that primer bolus was sufficient to cause ventricular interdependence leading to severe hypotension. Dialysis was reinitiated but primer bolus was purged, patient successfully completed dialysis without any hypotension or syncope.

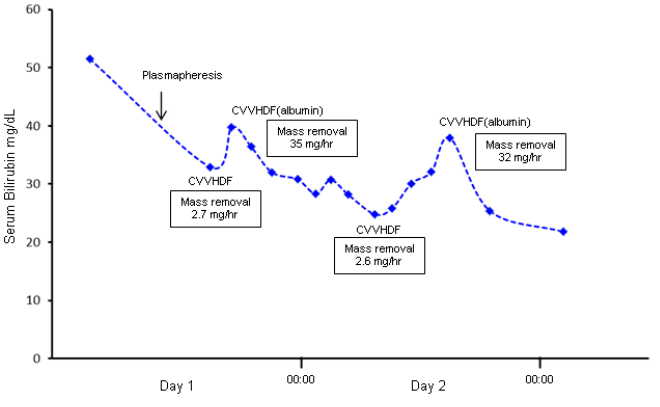
Discussion: Our case illustrates that 300cc of primer bolus is enough to cause acute RHF with subsequent LHF, causing recurrent severe hypotension and syncope. Simple purging of primer bolus allowed the patient to undergo dialysis repeatedly without any complications.

SA-PO028

Single-Pass Albumin Dialysis during Continuous Renal Replacement Therapy for Severe Hyperbilirubinemia Nathan T. Beins,[1] Marita Thompson,[2] Darcy K. Weidemann,[1] Rebecca M. Greene,[2] Uttam Garg,[3] Vimal Chadha.[1] *[1]Nephrology, Children's Mercy Hospital and Clinics, Kansas City, MO; [2]Critical Care Medicine, Children's Mercy Hospital and Clinics, Kansas City, MO; [3]Pathology and Laboratory Medicine, Children's Mercy Hospital and Clinics, Kansas City, MO.*

Introduction: Severe hyperbilirubinemia (SHB) is uncommon in critically ill children with multi-organ dysfunction syndrome (MODS). SHB can be a surrogate marker of hepatic failure and is associated with increased mortality. Furthermore, SHB can interfere with laboratory assays and near-infrared spectroscopic (NIRS) monitoring. While CRRT is commonly utilized for the management of acute kidney injury and fluid/electrolyte issues in children, it does not clear serum bilirubin. Molecular adsorbent recirculating system (MARS) has been successfully used for the management of hepatic failure, but is not FDA approved for SHB, and is unavailable in most centers. There are few case reports of single-pass albumin dialysis (SPAD) enhancing bilirubin clearance in children.

Case Description: A 7 month old male infant presented with MODS (underlying disease - autoimmune hemolytic anemia and hemophagocytic histiolymphocytosis) who developed SHB (peak total serum bilirubin 51.5 mg/dL). While he received CRRT and intermittent plasmapheresis, the serum bilirubin levels continued to remain significantly elevated. We performed SPAD (1.85% albumin in dialysate bag) for two consecutive days. Serum and dialysate bilirubin concentrations were monitored and are shown below:



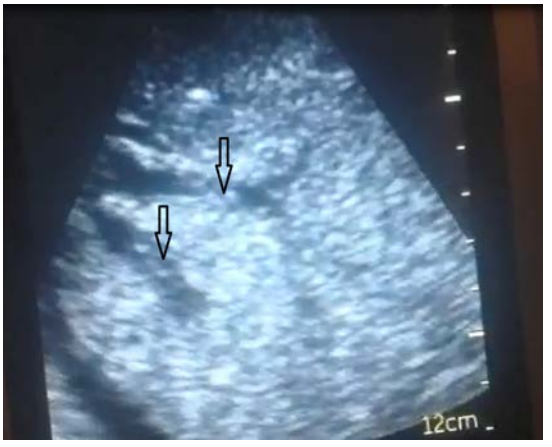
Discussion: Our experience shows >10-fold increase in bilirubin clearance with SPAD during CRRT. While SPAD is effective in decreasing serum bilirubin and possibly other protein-bound toxins, its impact on removal of nutrients and medications is unknown and needs to be carefully explored. Large scale studies are needed to see if SPAD can improve patient outcomes.

SA-PO029

Using Ultrasound to Detect Non-Occlusive Mesenteric Ischemia in a Hemodialysis Patient Sean Verma,[1] Alfredo M. Peguero,[2] Jorge A. Lamarche,[2] Craig S. Courville,[2] Marina Antar-Shultz,[2] Mohamed M. Taha.[2] *[1]Internal Medicine, Univ of South Florida; [2]Nephrology, James A. Haley Veterans' Hospital.*

Introduction: Non-occlusive mesenteric ischemia (NOMI) is a rare disorder seen in the hemodialysis (HD) population that carries a high mortality rate. The risk for NOMI in HD patients is estimated to be 44 times the risk of the average population. Ultrasound (US) is an adjunct diagnostic tool to diagnose NOMI in an HD patient.

Case Description: A 62-year-old woman with ESRD, malnourishment, and hypertension was admitted for failure to thrive. Vitals showed tachycardia and blood pressure 116/70 mmHg. Physical exam revealed cachexia and anasarca. Labs showed albumin 1.2 g/dL. She had prolonged intra and post dialytic hypotension associated with abdominal pain. A bedside US showed a collapsed inferior vena cava and gas (arrows) in the portal vein.



Also, extraluminal fluid accumulation, thinning of the bowel wall, and ileus were seen on US. Labs showed leukocytosis 10.99 10^9/L, lactic acid 3.5 mg/dL, and anion gap metabolic acidosis. CT scan showed portal venous gas and pneumatosis of the gastric fundus with patency of the mesenteric arteries suggestive of NOMI. She was not felt to be a surgical candidate due to her comorbidities. She was treated with albumin, fluids, and empiric antibiotics but expired 4 days later.

Discussion: Common NOMI findings include abdominal pain, fever, metabolic acidosis, and leukocytosis following intradialytic hypotension. Portal vein gas and/or mesenteric gas are ominous but late signs that are most consistent with mesenteric ischemia. US hasn't conventionally been used to detect NOMI and evaluate for portomesenteric gas, as CT scan has been the imaging of choice. However, bedside US is quicker and comparable in sensitivity. US with clinical suspicion for NOMI in ESRD patients may allow for a more prompt diagnosis via earlier CT scan ordering, and earlier initiation of treatment.

SA-PO030

An Extreme Case of Tumoral Calcinosis in End Stage Renal Disease Sean Verma,[1] Tambi Jarmi.[2] *[1]Internal Medicine, Univ of South Florida, Tampa, FL; [2]Nephrology, Univ of South Florida, Tampa, FL.*

Introduction: Tumoral Calcinosis is a rare and severe sequela of end stage renal disease (ESRD) patients on hemodialysis (HD) in which calcium salt deposits occur in periarticular soft tissue, typically around large joints such as the shoulder, elbow, and wrist.

Case Description: A 19-year-old woman with ESRD due to hemolytic uremic syndrome on HD presented for right shoulder and left elbow masses. She had a living related donor transplant at age fourteen with rejection two years later. Physical exam revealed right shoulder mass with overlying telangiectasias and left elbow mass with seropurulent, gritty drainage. Labs were notable for calcium 10.5 mg/dL, phosphorus 6.3 mg/dL, and intact parathyroid hormone 955 pg/mL. Right shoulder MRI revealed a periarticular heterogeneous mass with cystic and calcific components, consistent with tumoral calcinosis. Given the extent of her disease, the patient underwent parathyroidectomy for tumoral calcinosis due to tertiary hyperparathyroidism. In addition, she was treated with HD with low-calcium dialysate for five days per week. Upon two month follow up her calcium masses had decreased significantly in size.

Discussion: Tumoral calcinosis tends to occur more frequently in patients with high calcium-phosphate product, secondary/tertiary hyperparathyroidism, or hypervitaminosis D. Treatment involves intensification of HD with low-calcium dialysate, non-calcium containing phosphate binders, parathyroidectomy for secondary or tertiary hyperparathyroidism, and possible surgical removal of the calcium depositions. Surgical excision of the masses has often shown to be ineffective long term as they are prone to recur, unless biochemical correction of calcium-phosphate product can be achieved. Tumoral calcinosis is difficult to treat but has been shown to resolve after successful kidney transplantation.

SA-PO031

Apparent Picture of Dialysis Catheter in Chest CT Mariusz Kusztal, Tomasz Golebiowski, Krzysztof Letachowicz, Magdalena Krajewska, Marian Klinger. *Nephrology and Transplantation Medicine, Wroclaw Medical Univ, Wroclaw, Poland.*

Introduction: Unintentionally leaving dialysis catheter in the central vein is almost impossible. Here we present the case of a female patient with a history of dialysis catheter placement when chest CT scans strongly suggested migrated portion of central venous catheter (CVC).

Case Description: 44yo female with a 15 y history of SLE with poststeroidal osteoporosis who underwent plasmapheresis due to paresis. A week later the patient was admitted to the neurosurgery clinic for spinal fusion with vertebroplasty (polymethylmethacrylate cement injection) for osteoporotic fractures (L3). Subsequently, she became pyrexial and started cough. After admission to the pulmonology clinic, chest CT revealed a small lung abscess and a "portion of dialysis catheter".

After a failed endovascular attempt to retrieve the catheter, the patient was prepared for thoracotomy. Because the nephrologist was sure of the complete catheter removal initially, an alternative explanation of the findings was proposed. Thorough differentials and scrutiny in anamnesis (i.e. review of various chest CT scans from patients with implanted CVC) revealed that the catheter-like picture was in fact cement embolism in the right pulmonary artery – a complication of vertebroplasty occuring in 10-60% of such cases. Features distinguishing CVC from cement on CT scans are as follows: hollow and equal outline of CVC (usual diameter range of CVC 3.8-6mm). Based on measurements taken from 10 other patients with CVC in the chest, mean Hounsfield units were 1309 (range 1000-1585). Cement embolism in this case had an unequal outline (3.8-4.5 mm in diameter) and 1880 (1670-2020) Hounsfield units.

Discussion: This case is notable because two independent radiologist suggested catheter left in the chest as its implantation was reported in medical files, however cement embolism with high glare was the case.

SA-PO032

Encapsulating Peritoneal Sclerosis in Peritoneal Dialysis with Kidney Transplant Arun Kottarathara,[1] Matthew Abramson,[2] Yezina T. Nigatu,[1] Nand K. Wadhwa.[1] *[1]Dept of Nephrology, Stony Brook Univ Medical Center; [2]Dept of Medicine, Stony Brook Univ Medical Center.*

Introduction: Encapsulating peritoneal sclerosis (EPS) is a complication of long term chronic peritoneal dialysis (PD) following discontinuation of PD. We present two cases of EPS occurring following kidney allograft receiving steroid free immunosuppressive protocol.

Case Description: Case 1: A 41 year-old woman with End Stage Renal Disease (ESRD) secondary to hypertensive nephrosclerosis, on PD for 10 years, received a living related kidney allograft. 10 days post transplant (PT) S Cr was 1.3 mg/dl. PD catheter was removed 1 week PT. She developed nausea, vomiting and diffuse abdominal pain, and physical examination unremarkable. CT abdomen showed dilated small bowels and treated conservatively. S Cr was 0.8 mg/dl. 3 days later, she was readmitted with nausea, vomiting and abdominal pain. CT abdomen revealed dilated small bowels. GI follow through showed atonic small bowels. 23 days PT, she underwent exploratory laparotomy which revealed extensive brownish yellow peritoneum encapsulating entire bowel. She received IV prednisolone followed by oral prednisone in addition to tacrolimus and mycophenolic acid with complete resolution of symptoms in 4 weeks. She is prednisone 5 mg daily since and has been symptom free for 8 years. **Case 2:** A 48 year-old woman with ESRD of unknown etiology, on PD for 6 years received a deceased kidney allograft. 3 days PT, her S Cr was 3.0 mg/dl. 11 days PT, she had recurrent nausea, vomiting and diarrhea. CT abdomen revealed distended small bowels encased in fibrotic inflammatory membrane suggestive of abdominal cocoon**.** She needed nasogastric decompression and IV prednisolone, transitioned to oral prednisone. Prednisone 5 mg was continued with mycophenolic acid and tacrolimus. She has been symptom free for 13 months.

Discussion: Both patients had excellent outcomes with bowel rest and steroids. Our institution's transplant protocol involves alemtuzumab induction and steroid withdrawal within 3 days post-transplant. We suggest that PD patients undergoing renal transplant remain on immunosuppressive regimen including steroids to prevent EPS.

SA-PO033

Calciphylaxis after Acute Kidney Injury: A Mysterious Case of Painful Skin Necrosis Elizabeth Upton, Vimal K. Derebail. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

Introduction: We describe a case of calciphylaxis in an individual without end-stage renal disease (ESRD) who had recovered from an episode of acute kidney injury (AKI).

Case Description: A 43-year old female with history of prior Roux-en-Y gastric bypass surgery, non-alcoholic steatohepatitis, and former alcohol abuse presented with 8 weeks of skin necrosis on her abdomen, buttocks, and thighs. Three months prior to evaluation, she was admitted for sepsis complicated by liver and kidney failure not requiring dialysis. Admission labs included creatinine of 0.6 mg/dL, AST 15 U/L, ALT 25 U/L, PTH 44 pg/mL, and calcium phosphate product of 57. Skin biopsy demonstrated calcium deposition in the subcutaneous tissue and vessels, dermal and subcutaneous fat necrosis, and neutrophil and lymphocyte infiltration, consistent with calciphylaxis. Hypercoagulable, autoimmune, and infectious workups were negative. After therapy with intravenous sodium thiosulfate 25 g thrice weekly, oral sevelamer, and topical silver sulfadiazine, she had dramatic improvement over 6 months.

Figure 1: Necrotic skin lesion secondary to calciphylaxis.

Discussion: Calciphylaxis occurs rarely in patients without ESRD with other risk factors including female sex, obesity, primary hyperparathyroidism, malignancy, alcoholic liver disease, corticosteroid use, protein C/S deficiency, or a history of a Roux-en-Y surgery. Defects in vascular calcification pathways such as fetuin-A and matrix Gla protein and increased serum levels of matrix metalloproteinases contribute to calciphylaxis. Patients with underlying liver disease with AKI may be especially susceptible. Prognosis remains poor with mortality approaching 50%. Further studies are needed to elucidate the pathogenesis of all forms of calciphylaxis to develop specific treatments.

SA-PO034

Atypical Mycobacterial Peritoneal Dialysis Catheter Related Infections in Pediatric End-Stage Renal Disease Patients: A Case Series Jackson Londeree,[3] Donald K. Murphey,[2] David H. Simon,[1] Kartik Pillutla.[1] *[1]Pediatric Nephrology, Dell Children's Medical Center of Central Texas, Austin, TX; [2]Pediatric Infectious Diseases, Dell Children's Medical Center of Central Texas, Austin, TX; [3]Univ of Texas at Austin Dell Medical School, Austin, TX.*

Introduction: Atypical Mycobacterium peritoneal dialysis catheter related infections are rare and serious infectious complications. We report three cases of catheter related infections over eight months in our center.

Case Description: Case #1: A 10 month-old male with ESRD secondary to bilateral renal agenesis on peritoneal dialysis presented with an exit site and tunnel infection. His culture grew Mycobacterium fortuitum. **Case #2:** A 12 month-old with ESRD secondary to urethral agenesis on peritoneal dialysis presented with an exit site infection. His culture grew Mycobacterium fortuitum. **Case #3:** An 18 month-old with ESRD secondary to obstructive uropathy on peritoneal dialysis presented with peritonitis. His peritoneal culture grew Mycobacterium abscessus.

Discussion: All three patients were treated with antimicrobial therapy and catheter removal.

	Organism	Infection Type	Treatment	Exit site care	Outcome
Patient #1	M. fortuitum	Tunnel	Amikacin, TMP-SMX, Ciprofloxacin	Anti-bacterial soap and tap water	Catheter removal, conversion to hemodialysis
Patient #2	M. fortuitum	Exit site, Peritonitis	Amikacin, TMP-SMX, Ciprofloxacin	Anti-bacterial soap and tap water	Catheter removal, conversion to hemodialysis
Patient #3	M. abscessus	Peritonitis	Amikacin, Linezolid, Clarithromycin	Anti-bacterial soap and tap water	Catheter removal, conversion to hemodialysis

Infection control was consulted. Patients were non-ambulatory, began peritoneal dialysis in infancy and had gastrostomy tubes. Catheters were well healed and caregivers demonstrated appropriate technique. Exit site care consisted of washing site with soap and tap water followed by topical gentamicin daily. As atypical mycobacterium are found in the natural environment tap water contamination was suspected. Our policy was changed to clean the exit site with chlorhexidine gluconate in place of tap water for non-ambulatory patients.

SA-PO035

Longest Survival on Hemodialysis: 47 Continuous Years and Counting Laura Pilozzi-Edmonds, Murray L. Vasilevsky. *Nephrology, McGill Univ Health Centre, Montreal, QC, Canada.*

Introduction: We report a case of uninterrupted hemodialysis for 47 years and counting, which is the longest recorded in the published literature. This case illustrates the advances of hemodialysis over the years in technique, vascular access, treatment of bone disease and anemia. In the era of multi-modality renal replacement therapies, it also highlights a case of successful single modality hemodialysis for an exceptionally long period of time.

Case Description: The patient is a 57 year old man who developed end-stage renal disease at the age of 10 months secondary to congenital bladder neck obstruction. He was started on home hemodialysis in 1969 at age 11 and was the first pediatric patient to be dialyzed in Canada. His initial access was an ankle AV shunt. He had an AV fistula created in 1983 which lasted 23 years and undoubtedly contributed to his longevity on hemodialysis. He started dialysis with a Kiil dialyzer which required long treatments and sterilization. The introduction of hollow-fiber dialyzers improved dialysis efficiency and his quality of life by shortening his required dialysis time. Over time, he developed fractures due to osteitis fibrosa cystica and fluorosis from fluorinated city water. He was treated with subtotal parathyroidectomy and addition of a deionizer to his water treatment system. He was later found to have significant aluminum on bone biopsy from exposure to aluminum-based phosphate binders. He was transfusion dependent until the development of ESAs in 1989. The patient was never a candidate for renal transplantation or peritoneal dialysis and despite being on hemodialysis for most of his life he completed his education, studied architecture at a technical college and participated in the workforce for 28 years. He continues on center dialysis three times per week via a tunneled catheter.

Discussion: This case parallels the history of advances in hemodialysis from innovations in vascular access, dialyzers and water treatment to the development of non-aluminum phosphate binders and erythropoietin stimulating agents. It illustrates that single modality hemodialysis can be associated with excellent outcomes, including exceptional longevity and quality of life, in some patients.

SA-PO036

Hemodialysis Associated Thrombocytopenia Corrected with Changing Membrane Sterilization Method Sharica Brookins, Juan Pablo Arroyo, Ed Gould. *Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Hemodialysis (HD) associated thrombocytopenia (TCP) is a rare, but serious complication which needs to be identified quickly to prevent further morbidity and mortality in HD dependent patients. While a variety of membrane and sterilization techniques have been associated with the development of TCP, we present the first case of HD associated TCP which resolved after switching from electron beam sterilization to steam membrane sterilization.

Case Description: A 40 year-old Caucasian female with Polycystic Kidney Disease was admitted for initiation of dialysis in advance of bilateral nephrectomy to prepare for renal transplantation. Her platelet count was 226 $x10^3/\mu L$ one month prior to admission. Platelet count decreased to 114 $x10^3/\mu L$, 60 $x10^3/\mu L$, and then 14 $x10^3/\mu L$, after each consecutive dialysis session with the electron beam sterilized polysulfone HD membrane. A work-up for causes of TCP, including heparin induced thrombocytopenia, bleeding, and auto-immune disorders returned negative. Following platelet recovery, re-challenge with the same membrane once again led to decline in platelet count to 76 $x10^3/\mu L$. The HD membrane was changed to a steam sterilized dialysis membrane. With that change, pre (118 $x10^3/\mu L$) and post (110 $x10^3/\mu L$) HD platelet counts remained stable. Surgery was postponed, and her platelets recovered to 232 $x10^3/\mu L$ while receiving ongoing HD.

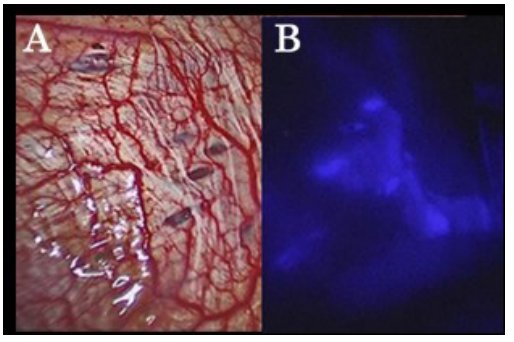
Discussion: Platelet half-life can be directly impacted by the dialysis membrane. HD membrane sterilization techniques, e.g., ethylene oxide, gamma-ray or electron-beam, and steam, are varied and may alter their biocompatibility. In our patient the switch from electron-beam sterilization to steam sterilization corrected the TCP. Previous case reports switched to either electron-beam or gamma-ray sterilization, we present the first reported case of platelet recovery after switching from electron beam to steam sterilization. This has only been previously reported to improve HD associated leukopenia and not TCP. It is important to note that although changes in biocompatibility are rare, early identification and management are essential to improving the care of the HD dependent patient.

SA-PO037

A Successful Case of Peritoneal Dialysis-Related Pleuroperitoneal Communication Diagnosed by Contrast-Enhanced Ultrasonography and Treated by Thoracoscopic Surgery Mimiko Matsumura, Takaaki Higashihara, Rie Uni, Hideki Takano. *Dept of Nephrology, Tokyo Teishin Hospital, Tokyo, Japan.*

Introduction: Pleuroperitoneal communication is a famous complication of peritoneal dialysis (PD). It is difficult to diagnose and treat because there may be no way to identify the pleural holes certainly. Here, we present a successful case of pleuroperitoneal communication.

Case Description: A 66-year-old woman with ESRD due to chronic glomerulonephritis was admitted to our hospital to start PD. After the PD catheter was inserted successfully, right-sided hydrothorax occurred caused by pleuroperitoneal communication. Immediately after injecting of Perflubutane into abdominal cavity through PD catheter, we could detect high echoic area around the pleural holes by contrast-enhanced ultrasonography. To prevent fluid reaccumulation, video-assisted thoracic surgery (VATS) was performed. Under an infrared light thoracoscope, the flow through holes in the diaphragm was clearly confirmed with the fluorescence color of indocyanine green (ICG) contained in the PD solution (figure 1). The holes in the diaphragm were removed with surgical stapling devices. She subsequently resumed automatic PD without recurrence for 6 months before undergoing kidney transplantation from a living donor.



A thoracoscopic view showing holes of the diaphragm (A), and an infrared light thoracoscopic view showing the inflow of indocyanine green (B).

Discussion: Contrast-enhanced ultrasonography using Perflubutane is a safe way for detection of the leakage and VATS is a feasible method for treating pleuroperitoneal communication.

SA-PO038

Case Report of Hypophosphatemia Occurring with the Use of Filgastrim in a Patient on Hemodialysis Sarath G. Nath, Vadim Abramov, Moro O. Salifu, Mary C. Mallappallil. *Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction: Hypophosphatemia is an electrolyte disturbance in which there is abnormally low level of phosphate in the blood. Hypophosphatemia most commonly seen in malnourished patients. Hypophosphatemia is rare in patients with end stage renal disease (ESRD) who are on hemodialysis (HD). Filgastrim is a granulocyte colony-stimulating factor analog used to stimulate the proliferation and differentiation of granulocytes that can result in hypophosphatemia. We report a rare case of severe hypophosphatemia 0.9 mg/dl after use of filgastrim in a HD patient being treated for neutropenia that was caused by use of carbamazepine.

Case Description: A 69 year old man with hypertension, seizure disorder, ESRD on HD, presented to the emergency room with a temperature of 101 Fahrenheit from his dialysis center. Admission laboratory were significant for white cell count (WBC) of of 0.81 10^9/l, phosphate 2.7 mg/dl. On the second day of admission he was started on filgastrim. He received 5 doses of filsgasrim before it was stopped as laboratory was noted for WBC count of 29.97 10^9/l, and phosphate of 0.9 mg/dl. Chemistry was repeated to show the value to be real. He was supplemented with phosphate while he continued to receive dialysis as scheduled. He had rapid resolution of his fever and quickly resumed his usual diet. He was not on phosphate binders and not on any medications which could cause hypophosphatemia. His serum calcium levels were 8.3mg/dL and his intact parathyroid hormone level was 208pg/mL.

Date	Serum Phosphate	WBC	Dialysis day
11/25/15	2.3	0.9	Yes
11/26/15	1.7	5.13	No
11/27/15	0.9 (pre dialysis early morning value)	29	Yes
11/28/15	2.4	33	No
11/29/15	1.4	52	No

He was never on Valproic acid (which has been noted to cause hypophosphatemia via Fanconi's syndrome).

Discussion: Hypophosphatemia is a possible outcome with figastrim use in a dialysis patient. Possible mechanism includes the combination of dialysis and consumption of phosphate in the process of rapid cell turnover of white cells. We report a case of severe hypophosphatemia that was cased with filstagtrim use in a patient on HD.

SA-PO039

Chyloperitoneum in a Neonate with ESRD on Peritoneal Dialysis: A Case Report Xiaoyan Wu, Molly R.W. Vega, Sarah J. Swartz, Mini Michael. *Pediatrics, Texas Children's Hospital.*

Introduction: Chyloperitoneum (CP) is a rare complication of peritoneal dialysis (PD). CP is diagnosed when triglyceride (TG) level (>110 mg/dL) in the PD effluent is elevated. Treatment is by changing to medium chain triglyceride (MCT) based diet as MCTs are absorbed by the intestine & transported by the portal system bypassing lymphatics, allowing the chylous fistula to heal naturally. We report a case of CP in an neonate on PD successfully managed with diet change alone.

Case Description: A 5 wk old male infant with ESRD due to bilateral cystic renal dysplasia initiated on manual PD at low exchange volume (EV) (10 ml/kg) at 12 days old, wt 3.5 kg & sCr 6.69 mg/dL. EV slowly increased by 10 ml every 5-7 days. Milky PD effluent (Fig1) developed without any other signs of infection 3 weeks after initiation of PD. PD effluent TG 184 mg/dL. Diet at diagnosis was expressed breast milk (EBM) supplemented with Similac PM 60/40, Duocal & Beneproteine. It was changed to skimmed EBM (sEBM) with MCT oil 1 ml/kg/day while waiting for MCT based formula. PD was continued. Within 12 hrs of formula change, milky appearance cleared & by 24 hrs, TG level of PD effluent returned to normal (< 10 mg/dL). Commerical formula with high % MCT (Enfaport) supplemented with Solcarb and Beneprotein added to sEBM & MCT oil once available. Regular EBM slowly reintroduced after 10 days. He tolerated transition to full feeds with EBM over 1 wk without recurrence of CP. PD EV advanced to full prescription (35 ml/kg) over the next 3 months without recurrence of CP. He was discharged home at 5 months on CCPD, on EBM + Similac PM 60/40 with Beneprotein without further problems.

Fig1: Milky PD effluent.

Discussion: CP is a rare complication of PD. Prompt diagnosis is important as it can be easily managed with change of diet to MCT based formula without cessation of PD. Regular formula can be slowly reintroduced after 1 wk.

SA-PO040

Successful Treatment of Severe Hyperkalemia and Hyponatremia Using Continuous Venovenous Hemodialysis Melissa L. Swee, Doreen Ventura. *Dept of Nephrology, Univ of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Renal replacement therapy has long been utilized as a potent means of correcting severe electrolyte disturbances, but does incur the risk of altering levels of other electrolytes, leading to unforeseen consequences. In particular, use of conventional fluids for RRT may treat hyperkalemia but also lead to unpredictable rises in [Na+], leading to osmotic demyelination. We present a case in which D5 and sodium bicarbonate in D5W were utilized to improve hyperkalemia while avoiding rapid shifts in serum sodium concentration.

Case Description: A 59-year old male with recently diagnosed CLL presented with acute respiratory failure due to H1N1 influenza. Vital signs were notable for tachycardia (114 bpm) and hypotension (96/52mmHg) on norepinephrine and vasopressin. Other vital signs were within normal limits (Temp 36.3*F, RR 16 bpm, SatO2: 98% on 40% FiO2). Laboratory data revealed serum creatinine 1.4 mg/dL, BUN 29 mg/dL, and [Na+] 118 mEq/L. Whole blood [K+] was persistently >14 mEq/L. He underwent leukopheresis and was started on CVVHD (dialysate rate: 5L/hr and blood flow rate: 250cc/min). The pre-filter replacement fluid was 150mEq of sodium bicarbonate/L D5, while the post-filter fluid was D5W. He was also started on an insulin infusion. [Na+] improved to 124mEq/L on day 2 and 130mEq/L on day 3. He continued to be hyperkalemic and both the pre- and post-filter were changed to normal saline (0.9%) for continued potassium clearance. [K+] normalized after day 4 (4.7mEq/L) while [Na+] remained between 136 and 140mEq/dL until day 14. The patient was discharged 2 weeks post induction of chemotherapy.

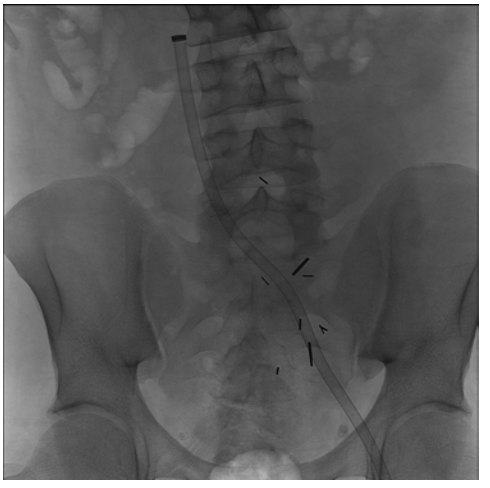
Discussion: Hyperkalemia is a life-threatening electrolyte disturbance that may be addressed promptly with RRT; at the time, rapid correction of concommitant hyponatremia, which may occur when using conventional forms of dialysate, may lead to other unforeseen consequences. This case illustrates that CVVHD using low [Na+] replacement fluids is a viable option for treating severe hyperkalemia without incurring osmotic demyelination. To our knowledge, this is the first instance of such a strategy being used to correct hyperkalemia while avoiding rapid shifts in [Na+].

SA-PO041

Thigh HeRO Catheter: The "Last Resort" Dialysis Vascular Access Alian Albalas,[1] Ahmed Kamel Abdel Aal,[2] Ammar Almehmi.[3] *[1]Nephrology, UAB, Birmingham, AL; [2]Radiology, UAB, Birmingham, AL; [3]Nephology and Radiology, UAB, Birmingham, AL.*

Introduction: Thigh vascular access is commonly employed in dialysis patients with upper extremity central venous system occlusive disease. On the other hand, Hemodialysis Reliable Outflow (HeRO) catheters have been used in tunneled catheter-dependent patients who have exhausted other access options. However, thigh HeRO catheter is rarely utilized as a possible vascular access option in those patients.

Case Description: This is a 34-year-old African American male with known history of end-stage renal disease due to hypertension, protein C deficiency who was started on hemodialysis via neck tunneled catheter 12 years ago. Multiple graft and fistula accesses on both upper extremities failed due to recurrent stenotic lesions and thromboses. In 2004, he underwent deceased kidney transplant that remained functional for 7 years. In 2011, he presented with acute kidney injury due to graft rejection (due to non-compliant with immunosuppressive medications), volume overload and respiratory failure that required renal replacement therapy via left femoral vein catheter. Due to the limited available vascular estate in this patient, the decision was to proceed with left thigh HeRO catheter placement.



He started using the HeRO catheter within 3 weeks after placement. Despite few thrombotic episodes, the HeRO catheter remains functional and provides a reasonable hemodialysis access in this patient for the last 5 years. It is worth mentioning that this patient is non-compliant with warfarin therapy used to treat protein C deficiency, which could explain the recurrent thromboses of the dialysis access.

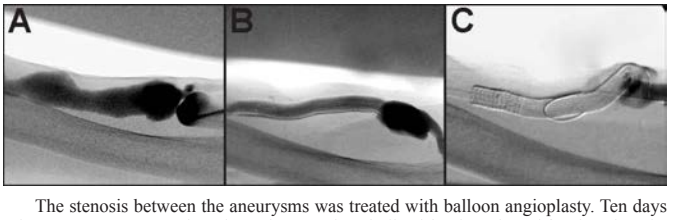
Discussion: The Hemodialysis Reliable Outflow (HeRO) catheter of lower extremities is a plausible "last resort" option and can be utilized in the subset of patients in whom the other vascular access options are exhausted.

SA-PO042

Using Stent Grafts for Fistula Aneurysms Exclusion: Case for Caution Alian Albalas,[1] Ahmed Kamel Abdel Aal,[2] Ammar Almehmi.[3] *[1]Nephrology, UAB; [2]Radiology, UAB; [3]Nephology and Radiology, UAB.*

Introduction: Dialysis fistula aneurysms are commonly encountered in clinical practice. Most of the fistula aneurysms do not require direct intervention other than making sure that the draining veins are adequate and the fistulae are not pressurized. Direct surgical interventions, are warranted only when there are associated clinical issues, such as active bleeding, skin defect/erosion, mural thrombosis, infection, and significant cosmetic issues.

Case Description: This is a 70-year-old hemodialysis patient with a left brachiocephalic arteriovenous fistula presented with low fistula flow and difficult cannulation. Six months prior to the current presentation, a fistulogram revealed multiple aneurysmal formations of the fistula vein



The stenosis between the aneurysms was treated with balloon angioplasty. Ten days prior to current presentation, the patient was hospitalized for thrombosed fistula, where he underwent thrombectomy as well as a stent graft placement in the fistula vein.

On current presentation, the physical examination disclosed diffuse infiltration over the fistula body and weak thrill. Additionally, large aneurysmal formations of the fistula body were noted. Angiographic exam revealed a long stent graft in the fistula vein. When viewed from a different angle, the distal end of the stent graft was kinked within the aneurysm and the lateral wall of the distal stent graft was blocking fistula blood flow.

Further endovascular intervention was unsuccessful due to the kinked stent graft and the fistula flow was not sufficient for dialysis. Consequently, the patient necessitated tunneled dialysis catheter insertion in order to continue his dialysis therapy.

Discussion: A high degree of caution is needed for the "off-label" use of stent grafts to manage fistula aneurysms and their associated complications, as stent grafts may create more problems than they are intended to solve.

SA-PO043

Development of Pancreatitis in an ESRD Patient with Preceding Sodium Thiosulfate Usage Sean Kumar. *Internal Medicine, Univ at Buffalo School of Medicine, Buffalo, NY.*

Introduction: Sodium thiosulfate is a drug with few known medical indications including cyanide poisoning, calciphylaxis and extravasation management in some chemotherapeutic regimens. Herein we present a case of acute pancreatitis in an ESRD patient with recent sodium thiosulfate usage with calciphylaxis. Sodium thiosulfate is a drug used frequently in calciphylaxis management in ESRD patients, but has not been previously documented to be associated with pancreatitis.

Case Description: A 58 year old Female with past history significant for ESRD on HD, presented to the hospital with 1 week history of nausea, vomiting, and epigastric pain. She was started on IV sodium thiosulfate with HD for calciphylaxis ten days prior to the admission. Full workup for typical etiologies of pancreatitis including alcohol use and cholelithiasis was negative. Labs were significant for a lipase of 1160 on admission. Triglyceride level was 152. Calcium level was 9.0. Abdominal CT study demonstrated changes consistent with acute pancreatitis. Patient underwent MRCP to evaluate pancreatic ducts with no pathology found. Patient was treated conservatively and Sodium thiosulfate was discontinued due to potential for drug-induced pancreatitis (no other medications of concern identified). No subsequent episodes of pancreatitis reported after discontinuation.

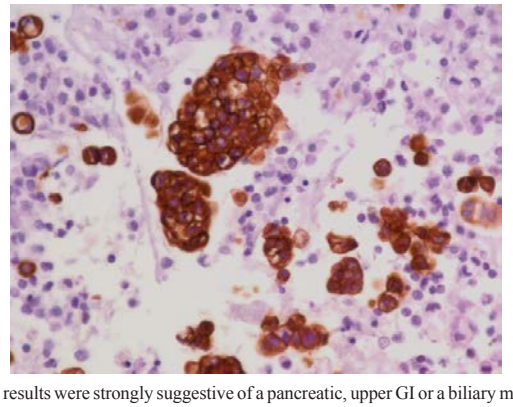
Discussion: Various etiologies have been identified in acute pancreatitis, with heavy alcohol consumption and gallstones being top culprits. Drug induced pancreatitis reflects a smaller portion of the total cases, estimated at 0.3 to 1.4%. The temporal relationship between initiation of a drug and development of pancreatitis is unclear, as some drugs demonstrate more immediate effects and others after weeks. There have not been any major studies involving sodium thiosulfate and its effects on the human pancreas to date. Based upon extensive review, sodium thiosulfate was believed to contribute to our patient's presentation. Withholding the suspected drug and conservative measures were all that was required for management. As the prevalence of ESRD continues to rise, consideration of sodium thiosulfate as a contributor to acute pancreatitis may become a prudent differential diagnosis.

SA-PO044

Use of Tenckoff Catheters in Diagnosing Abdominal Malignancies Sarthak Virmani,[1] Ari B. Geller.[2] *[1]Dept of Medicine, Univ of Connecticut School of Medicine, Farmington, CT; [2]Div of Nephrology, St. Francis Hospital, Hartford, CT.*

Introduction: Tenckoff catheters have been used for peritoneal dialysis since 1968. Peritonitis, traumatic chylous effusions, exit site infections, migration of the catheter and omental obstructions are common complications.

Case Description: We present a case of an 82-year-old male with a history of long standing uncontrolled hypertension leading to progressive chronic kidney disease (CKD). A clinical decision was made to initiate renal replacement therapy based on progressive fatigue and a reported 15 lbs weight loss. Despite his advanced age, the patient preferred peritoneal dialysis because of his active life style. A week after the insertion of the Tenckoff catheter, straw colored, hazy effluent was noted during his initial catheter drain. He did not complaint of pain and on physical exam, the abdomen was non-tender with no palpable masses. Peritoneal fluid analysis demonstrated a nucleated cell count of 247 and no bacteria. The total protein level was less than 3 gm/dl with albumin being 1200 mg/dl. Fluid triglycerides level was 69 mg/dl, glucose 661 mg/dl and LDH 70 U/L. Cytological analysis of the fluid revealed cells that were consistent with metastatic adenocarcinoma. Immunohistochemical staining showed positivity to BerEp4, CK7, EpiCAM, CEA and CA19.



These results were strongly suggestive of a pancreatic, upper GI or a biliary malignancy. Further diagnostic workup revealed elevated serum CA 19-9 levels (1393 U/ml). A subsequent PET-CT scan showing a hyper metabolic mass in the pancreatic body, confirming the diagnosis of pancreatic adenocarcinoma.

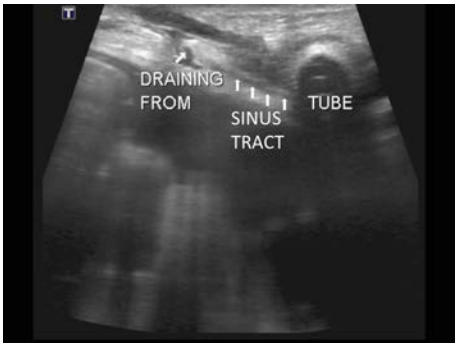
Discussion: This case demonstrates the diagnostic potential of cytologic analysis of peritoneal fluid. It also exemplifies the need for a broad differential when evaluating abnormal dialysis effluent in a newly placed peritoneal dialysis catheter.

SA-PO045

Two Tunnels for One Peritoneal Dialysis Catheter! A Rare Delayed Surgical Complication Volodymyr Chornyy, S. Irfan Qadri, Amir Kazory. *Nephrology, Hypertension and Renal Transplantation, Univ of Florida, Gainesville.*

Introduction: Catheter tunnel infection (CTI) is a known cause of adverse outcomes in peritoneal dialysis (PD)-related peritonitis. Extension of exit site infection is the most common reported reason for CTI. We report a case of PD-related peritonitis due to a delayed surgical complication.

Case Description: A 54 year old man with a history of end stage renal disease due to polycystic kidney disease (PCKD) was treated with continuous cycling PD for the past 5 years. He presented with fever, abdominal pain, and cloudy PD effluent. His abdomen was diffusely tender. Except for extruded external cuff, the PD catheter exit site was unremarkable. Serous drainage was noted one inch from the exit site where the trocar was inserted for laparoscopic PD catheter placement. The patient reported increasing drainage for 4 weeks prior to presentation. Laboratory studies were consistent with PD-related peritonitis. Broad spectrum antibiotics were initiated. Abdominal ultrasound confirmed a 1.5 inch sinus tract connecting the surgical trocar insertion site to the inner segment of the catheter tunnel.



The patient deteriorated rapidly but removal of the PD catheter resulted in progressive improvement in his clinical status.

Discussion: In addition to its rarity, this case is notable for a number of teaching points. Patients with PCKD are at risk for early PD fluid leak due to increased intra-abdominal pressure. Although uncommon, such complications can appear later and create a diagnostic dilemma. Moreover, this case shows importance of ultrasound imaging in evaluation of unexplained PD-related peritonitis even without overt symptoms of exit site infection. If technically feasible, it is prudent to insert the surgical trocar as far as possible from the exit site and the catheter tunnel. Finally, sinus formation should be considered when a previously healed scar develops abundant drainage.

SA-PO046

Diffuse Dermal Angiomatosis; an Unusual Cause for Painful Ulcerative Lesions in Patients with End Stage Renal Disease Hassan Alhalabi,[1] Meral K. El Ramahi,[1] Anna Marie Burgner,[1] Adriana Hung.[1,2] *[1]Vanderbilt Univ, TN; [2]TVHS, TN.*

Introduction: Diffuse Dermal Angiomatosis (DDA) is a benign vascular condition associated with peripheral vascular disease (PVD) and calciphylaxis in End Stage Renal Disease (ESRD) patients and presents as painful, ulcerative skin lesions. We describe two patients with ESRD who presented with painful ulcers and found to have DDA by skin biopsy. Given that DDA is hypothesized to be secondary to underlying hypoxia and ischemia, we treated each patient with topical Nitroglycerin and witnessed improvement in wound healing.

Case Description: Case 1: A 51 year old African American female with a history of end stage renal disease on hemodialysis and pulmonary embolism on Coumadin; was admitted with recurrent painful sacral and right breast wounds; which were previously felt to be due to calciphylaxis. Patient had a sub-total parathyroidectomy earlier with no improvement in her skin lesions. Later a skin biopsy showed Diffuse Dermal Angiomatosis. The patient was subsequently treated with topical Nitroglycerin with significant clinical improvement. Case 2: A 36 year old African American female with a history of poorly controlled diabetes mellitus, hypertension and end stage renal disease on peritoneal dialysis; who presented with gastroparesis related symptoms and a large very tender ulcerative abdominal wound, which developed from a small non healing laparoscopic surgical wound. Wound cultures showed a usual skin flora; diffuse dermal angiomatosis was shown on the skin biopsy. The patient was started on topical Nitroglycerin with significant clinical improvement.

Discussion: DDA is a rare, benign, acquired disease. It is characterized clinically by very painful erythematous to violaceous patches with central ulceration and histologically by diffuse vascular endothelial cell proliferation within the dermis. It has been thought to be caused by local hypoxia and described in association with PVD. Revascularization is very effective and treatment with steroids and isotretinoin had been successful occasionally. In our two patients; we used topical Nitroglycerin with good wound healing. The proposed mechanism of action for nitroglycerin is improvement of local perfusion.

SA-PO047

Shunt Nephritis and Pyogenic Spondylitis with a Positive PR3-ANCA Associated with Chronically Infected Ventriculo-Arterial Shunt Hiroyuki Ono, Seiji Kishi, Taizo Inagaki, Masanori Tamaki, Taichi Murakami, Kojiro Nagai, Hideharu Abe, Toshio Doi. *Nephrology, Tokushima Univ Hospital, Tokushima, Japan.*

Introduction: Shunt nephritis is a rare complication mostly described in the setting of chronic infection of venticulo-atrial (VA)-shunts. Although shunt nephritis is a well-recognized entity, diagnosis can be challenging and may be overlooked.

Case Description: A 56-year-old Japanese man presented with a persistent low grade fever for 4 months, hematuria and proteinuria and progressive kidney dysfunction. He had a history of secondary hydrocephalus associated with non-HIV cryptococcal meningitis at the age of 50, which was treated by ventriculo-peritoneal (VP) shunt, followed by replacement with VA shunt because of intraabdominal abscess. On admission, physical examination was unremarkable except for mild lower back tenderness. Laboratories revealed renal insufficiency (serum creatinine 2.35 mg/dl, baseline 0.86 mg/dl), hypocomplementemia (CH50 28 U/mL), elevated C-reactive protein(CRP) (4.33 mg/dl), positive PR3-ANCA (67.4U/ml), proteinuria (1.63 g/gCr) and hematuria (>100 erythrocytes/HPF). Blood culture and CSF culture were both returned positive for Staphylococcus captis. Transthoracic echo showed no vegetation. Lumbar-spine magnetic resonance imaging demonstrated findings consistent with pyogenic spondylitis. There was increased uptake in both kidneys on gallium scintigraphy. VA shunt was removed and antimicrobial therapy was immediately started. He had resolution of proteinuria and hematuria, improvement of renal function and hypocomplementemia, and normalization of CRP. He didn't show symptoms related to hydrocephalus again without a VA shunt and signs or symptoms of Wegener's granulomatosis. We didn't perform renal biopsy because urinalysis and renal function began to improve after treatment.

Discussion: We successfully treated a patient with shunt nephritis with antibiotic treatment and hematuria, proteinuria and progressive kidney dysfunction all improved. Physicians should be aware of the risks of infection-related GN in patients with VA shunts as early diagnosis and treatment initiation with antibiotics and shunt removal is a key to the successful management.

SA-PO048

Babesiosis Mimicking Hemolytic Uremic Syndrome as Cause of Hemolytic Anemia in an End Stage Renal Disease Patient Avantika Chenna, Pradeep Reddy Thodima, Mauricio Alexander Pedroza, Rasib Raja, Imara Dissanayake. *Nephrology, Albert Einstein, Philadelphia, PA.*

Introduction: Babesiosis is a tick borne disease and is seen in patients with recent history of travel to endemic areas. Since the advent of erythropoetic agents in ESRD patients, the number of cases of transfusion related babesiosis cases have diminished. We present a case of severe hemolytic anemia from babesiosis in ESRD patient from blood transfusion being misdiagnosed as HUS. There have been cases of babesiosis reported in HIV, splenectomy and renal transplant recipients. This is the first case described in ESRD patient to the best of our knowledge.

Case Description: 52 year old male with h/o ESRD recently started on hemodialysis, HTN , CHF with EF< 15% was admitted with low Hemoglobin (Hb) of 6.5gm/dl (baseline about 8-9g/dl).During previous admission for gastrointestinal bleeing,he received 1 unit of PRBC before discharge. During the current admission, physical exam was significant for - Jaundice, ejection systolic murmur, pedal edema and splenomegaly. Vital signs were normal. Labs showed – Hb-6.5 g/dL WBC-8.7 and Plt count of 52x10^3 /mcL. Na134,K 3.7, Cl 97, HCO3 22 mmol/L, BUN 78 and Cr 5.9 mg/dL. Coombs test was negative. LDH 724 IU/L with Haptoglobulin low at 8 mg/dL. Peripheral Blood smear was positive for occasional schistocytes . He was thus started on plasmapheresis and steroids for presumed HUS/TTP per hematology. ADAMTS 13 was pending. After receiving 3 sessions of plasmapheresis , due to persistent anemia and thrombocytopenia ,hematology repeated peripheral blood smear. It showed intra and extra erythrocytic ring forms concerning for parasitic infection. Plasmapheresis was thus discontinued. Patient was started on atovaquone and azithromycin per infectious disease . Babesia PCR was sent out. There was improvement in LDH, Hb and thrombocytopenia following the treatment.

Discussion: It is very rare to see hemolytic anemia from babesiosis in ESRD patients. Babesiosis and other arthropod born illnesses should be considered in ESRD patients even in the absence of localizing symptoms if patients are not improving with the standard treatment.

SA-PO049

Actinomyces Peritonitis: A Novel Therapy and Case Review Aaron P. Coulon, Rahul V. Kamat, Ashwin P. Jaikishen, Mihran V. Naljayan. *Dept of Medicine, Section of Nephrology and Hypertension, LSUHSC School of Medicine, New Orleans, LA.*

Introduction: Peritonitis is a leading complication of peritoneal dialysis (PD). Actinomyces is a very rare cause of PD peritonitis, and each of the previously reported cases employed a different management plan. We chose a unique, simplified approach using ceftriaxone without catheter removal.

Case Description: The patient is a 40-year-old female with end stage renal disease on PD for 2 months. She was on apixiban for a deep venous thrombosis and presented to the dialysis unit with a three-day history of pink effluent. Cell count, gram stain, and cultures were obtained, and she was empirically given vancomycin 1 gram intraperitoneal (IP). Initial cell count showed WBC 771 and RBC <10,000. She was admitted to the hospital and found to have leukopenia (4.1 x10^9/L) and anemia (hemoglobin 6.6 g/dL) with a normal abdominal exam. Repeat peritoneal fluid analysis showed WBC 266 and RBC 730, which decreased to 0 and 2, respectively, on hospital day three. A repeat culture grew gram positive rods (Diphtherioids), and the initial culture grew Actinomyces. We decreased apixiban and started ceftriaxone 1 gram IP daily for three weeks with a six-hour dwell and fluconazole 200 mg every other day. All follow up cultures were negative and effluent was clear.

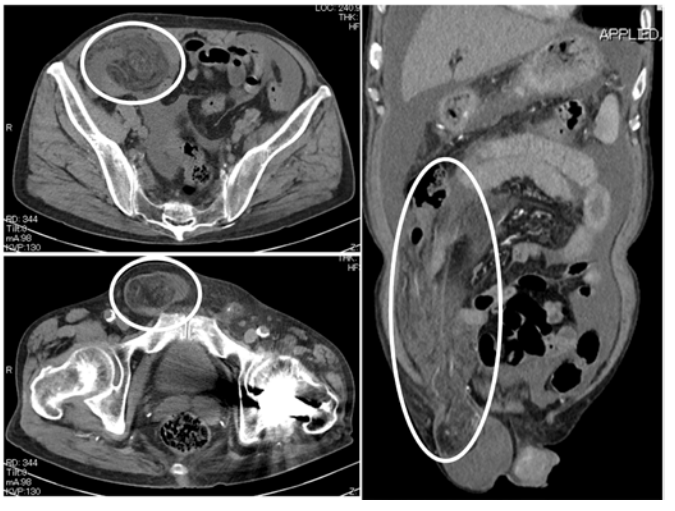
Discussion: Actinomyces can cause abdominal and pelvic infections, but peritonitis is rare. Infection classically follows mucosal compromise and causes fibrosis, abscesses, and fistulas. Penicillins are the cornerstone of therapy. The four previous PD peritonitis cases that used antibiotics chose penicillin, amoxicillin, or clindamycin either as primary treatment or to prevent relapse. Ceftriaxone has been successfully used in cases involving various organ systems, but no one had used IP ceftriaxone for peritonitis. We had success with three weeks of ceftriaxone IP and fluconazole for fungal prophylaxis. In this case, removal of the PD catheter and penicillin were not necessary. This case is one of a rare disease, actinomyces PD peritonitis, treated in a novel way. It is the first report of treatment with ceftriaxone alone, and it provides another example of successful treatment with catheter preservation.

SA-PO050

A Case of Tuberculous Peritonitis Diagnosed at the Onset of Omental Torsion after Six Years of the Cessation of Peritoneal Dialysis Daisuke Nakashima, Yukio Maruyama, Naoki Sugano, Ai Katsuma, Izumi Yamamoto, Nanae Matsuo, Yudo Tanno, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

Introduction: It is well-known that the incidence and prevalence of tuberculosis in patients with chronic kidney disease, especially dialyzed patients, is extremely higher than those of non-renal patients. Furthermore, dialyzed patients had a high percentage of extrapulmonary tuberculosis and it makes the diagnosis difficult for a nephrologist.

A 67-year-old man was admitted with complaints of pyrexia, abdominal pain, and acute inflammatory reaction. He initiated peritoneal dialysis for end-stage renal disease due to nephrosclerosis ten years ago, and transferred to hemodialysis because of underdialysis six years ago. He had no history of peritonitis as well as encapsulating peritoneal sclerosis. Subsequent abdominal computerized tomography (CT) showed right inguinal hernia, and it contained omentum majus.



We performed an emergency hernia operation. We diagnosed as omental torsion and remove damaged omentum. Then patient became asymptomatic. We suspected tuberculous peritonitis as the cause of omental torsion, because epithelioid granuloma was found in the specimen from resected omentum and ascites concentration of adenosin deaminase (ADA) was high. We initiated antituberculous agents without diagnostic confirmation from bacteriological examination. Tuberculosis bacterium was detected from the peritoneum six weeks later, and we confirmed the diagnosis.

Discussion: Dialyzed patients are susceptible to tuberculosis, especially extrapulmonary tuberculosis. Although tuberculous peritonitis is difficult to diagnose because of low detection rate of tuberculosis bacterium from ascites, this should be considered in the management of acute abdominal condition in dialized patients.

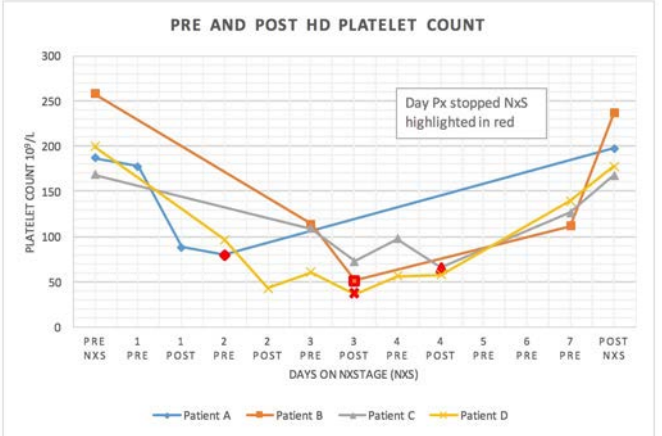
Thrombocytopenia during NxStage Home Hemodialysis (HHD) Orla Marie Dunne, Catherine Brumby, Yangmin Zeng, Rajinder S. Singh, Michael A. Copland. *British Columbia Provincial Renal Agency and Univ of British Columbia, Vancouver, BC, Canada.*

Introduction: The NxStage HHD machine was specifically designed for the home and offers simplified technology compared with traditional HHD machines. A key benefit of the streamlined NxStage setup is a drop-in cartridge which houses dialyzer tubing with a pre-attached dialyzer. The pre-attached dialyzer is composed of a gamma-ray sterilized polyethersulfone-PVP membrane. Our program has encountered four patients who have developed severe thrombocytopenia suspected to be directly related to the cartridge system.

Case Description: Four of twenty-six patients that have been exposed to NxStage dialysis in British Columbia developed platelet counts of <100 x10^9/L within the first week following transition from conventional HD as outlined in figure below. They did not experience any symptoms suggesting hypersensitivity or any clinical events related to thrombocytopenia. No changes, other than exposure to a new dialysis system, were made during these periods. HIT was unlikely as these patients were able to tolerate heparin during conventional HD treatments. Their platelets dropped incrementally with each NxStage dialysis session but rebounded back to baseline when switched back to conventional hemodialysis.

Discussion: The mechanism by which this dialysis-related thrombocytopenia developed is not understood, but the timing and pattern suggest that it is related either to the pre-attached dialyzer or dialysis tubing. Dialyzer-related thrombocytopenia has previously been linked to the composition of the dialyzer membrane and/or method of dialyzer sterilization. Although an alternate cartridge allows manual replacement of the dialyzer, this negates much of the advantage of the cartridge system. HHD programs using NxStage should monitor for thrombocytopenia and consider the platelet threshold at which patients require a dialyzer or machine change.



Platelet Count x10^9/L	Patient A	Patient B	Patient C	Patient D
Pre HD prior to NxS	187	258	169	200
Pre HD on NxS (nadir)	80	114	98	61
Post HD on NxS (nadir)	89	52	66	37
Pre HD after NxS (Day 7)		112	127	140
Pre HD on conventional HD	198	237	168	178

SA-PO052

Survival among Patients with End Stage Renal Disease in Low versus High Serum FLC Levels Yoonkyung Song, Jieun Kim, Gang Jee Ko, Young-Joo Kwon. *Div of Nephrology, Korea Univ, Seoul, Republic of Korea.*

Introduction: Approximately 500 mg/day polyclonal free light chain (FLC) is released into the blood in chronic inflammatory disease. Serum polyclonal FLC levels may reflect the activity of the adaptive immune system and is cleared by the kidney and reticular system. Moreover, some recent studies reported an association between polyclonal FLC level and mortality rate in CKD patients. This study was designed to determine whether polyclonal FLC level correlated with mortality rate in end-stage renal disease (ESRD) patients undergoing dialysis.

Case Description: Initially, 432 ESRD patients who started hemodialysis or peritoneal dialysis after 2005 were enrolled. The levels of serum total FLC, FLC kappa, FLC lambda were determined at the start of dialysis. Of the 432 patients, only 300 patients whose status, whether alive or dead, was available in the data from Korean Society of Nephrology were included in this study.

Of the 300 patients, 75 were dead and 225 were alive at the start of this study. Patient's survival status had no significant influence on the mean FLC levels. Furthermore, the levels of FLC as well as other serum parameters, including hemoglobin, phosphate, calcium, albumin, cholesterol, and PTH, showed no correlation with survival rate. For subgroup analysis, the patients were assigned to one of two groups based on age: ≤60 years and above 60 years. In the ≤60 years group, significant difference was observed in the mean FLC levels of surviving and non-surviving patients. In cox regression analysis, elevated total FLC levels were significantly correlated with overall mortality when stratified according to the five-fold upper limit of reference values (P = 0.015, exp(B) 3.7). FLC lambda showed significant positive correlation with mortality in the ≤60 years group when stratified according to the mean value, (P = 0.009, exp(B) 2.874). FLC kappa levels showed no significant association with adjustment of compounding factors.

Discussion: FLC levels were positively correlated with mortality in young patients (<60 years old). This finding highlights the importance of FLC level measurement for dialysis patients.

Gentamicin-Resistant Gram Negative Exit Site Infection in a Peritoneal Dialysis Patient Salma Elbehary,[1] Anupkumar Shetty.[2] *[1]Nephrology, Baylor Univ Medical Center, Dallas, TX; [2]Nephrology, Dallas Nephrology Associates, Dallas, TX.*

Introduction: Infection is the most common complication of peritoneal dialysis (PD). Prevention of exit site infection (ESI) is an important component of care of patients on PD. Bernardini *et al*. showed that topical prophylaxis at the exit site with gentamicin results in reduction of ESI with Gram-positive and Gram-negative organisms including *Pseudomonas*. Since publication of this paper, most dialysis centers have been using gentamicin 1% cream instead of mupirocin to prevent ESI.

Case Description: A 52 year old non diabetic African American male with end-stage renal disease was started on PD in November 2012 and he was using topical gentamicin cream to the exit site with each dressing change to prevent ESI. In April 2014, he was treated for gentamicin sensitive coagulase- negative *Staphylococcus* epidermidis exit-site infection with antibiotics. After completing treatment, we continued prophylactic gentamicin cream with dressing changes. He was doing well until April 2015, when he developed ESI. Culture grew pseudomonas aeruginosa resistant to gentamicin. He received oral Levaquin. Patient had unusually large amount of crust with underlying proud flesh that needed frequent cauterization with silver nitrate. More recently exit site swab in March 2016 grew gram positive bacilli. He continues to have large amount of crust and proud flesh. We switched to topical mupirocin cream along with topical sodium hypochlorite.

Discussion: There is a potential risk of developing gentamicin resistance which would limit antibiotic options for the treatment of ESI. Use of gentamicin cream alternating with mupirocin cream for prevention of PD related ESI needs to be investigated.

SA-PO054

Potential Role of Plasmapheresis in Severe CMV Infection with Ongoing Immune-Mediated Hemolysis and Low Complement Levels Yougandhar Akula,[1] Swetha Rani Kanduri,[1] Arnaldo F. Lopez-Ruiz,[1] Tibor Fulop.[2] *[1]Div of Nephrology, Univ of Mississippi Medical center, Jackson, MS; [2]Div of Transplantation, Univ of Debrecen, Jackson, MS.*

Introduction: Symptomatic CMV infection in patient with no previous history of immunosuppressive therapy is rare and it has only been reported after long hospitalization. We report the atypical case of young woman with ESRD who has developed a CMV infection resulting in liver damage and multiple systemic complications.

Case Description: A 33 year old woman with htn, type 2 diabetes chronic anemia and end-stage renal disease was admitted for acute diarrhea, elevated liver enzymes, and vaginal candidiasis. She was on hemodialysis for four months prior to admission. She had unexplained lower extremity weakness for same duration. C. diff testing by polymerase chain reaction was negative on three consecutive occasions. stool and blood cultures for bacteria, fungi and parasites were negative. Serology for HIV, acute hepatitis, autoimmune hepatitis or SLE were also negative. However, she was found to have low C3 and CH50 and low IgM and total IgG. Hemolytic work-up revealed ongoing hemolysis with low haptoglobin level and direct Coombs positivity. In the context of chronic unexplained wasting, persistently low albumin, chronic diarrhea and elevated liver enzymes, CMV serum PCR was obtained, revealing massive elevation at 9 million copies/mm^3. While CMV IgG titer was positive, IgM titer was negative repeatedly. CSF analysis was unremarkable including negative CMV PCR. Bone marrow biopsy was normal. Given Pt was unstable and has elevated viral load, pt had plasmapheresis for three sessions, CMV immune globulin and I.V. ganciclovir. After 2 weeks of therapy with ganciclovir, CMV decreased to 2600 viral copies/cm^3. But she developed unilateral blindness and right hemiparesis.

Discussion: This case was very unusual for the profound viremia without neutropenia and presence of CMV-mediated hemolysis with low complement level and negative IgM antibody during the illness and broadens our horizon of potential CMV-associated illnesses. Timely initiation of PLEX and CMV immune globulin infusion may contributed to recovery in our case.

SA-PO055

Basement Membrane Nephropathy Like Phenotype in a Family with an ARHGAP24 Mutation Known to Cause Familial FSGS Elizabeth Kotzen,[1] Gentzon Hall,[1] Megan Chryst-Ladd,[1] Guanghong Wu,[1] Brandon M. Lane,[1] Shashi K. Nagaraj,[1] John W. Foreman,[1] Michael J. Randles,[2] Rachel Lennon,[2] David Howell,[2] Rasheed A. Gbadegesin.[1] *[1]Pediatrics, Duke Univ Medical Center; [2]Pediatrics, Univ of Manchester, United Kingdom.*

Introduction: Alport Syndrome (AS), other glomerular basement membrane (GBM) disorders, and focal segmental glomerulosclerosis (FSGS) are major causes of glomerular disease worldwide. The pathogenesis and phenotypic spectrum of these conditions is not completely known, however recent genomic discoveries have demonstrated significant phenotypic overlap. In this study, we report a family with a mutation in the FSGS gene *ARHGAP24* and predominant GBM defects on renal biopsy.

Case Description: We identified a 3-year-old Hispanic female with persistent microscopic hematuria and proteinuria. Renal biopsy was performed. Light microscopy showed unremarkable glomeruli with no sclerosis or significant GBM thickening or duplication. Immunofluorescence staining showed patchy, discontinuous staining for alpha-3 and -5 chains of type IV collagen and electron microscopy revealed areas of thinning and thickening suggesting an AS phenotype. Audiologic and ophthalmologic evaluation were normal. Targeted sequencing of the *COL4A3, COL4A4, COL4A5, and MYH9* genes was

normal. Whole exome sequencing (WES) revealed the Q158R mutation in *ARHGAP24*. Q158R was previously reported as a cause of hereditary FSGS in a Hispanic kindred. We did not find a mutation in any of the known >50 FSGS genes, nor in *COL4A* genes. Direct sequencing of the family showed that the father, who had 1+ proteinuria, also carried the same mutation. *In-silico* analyses showed that *ARHGAP24* interacts with *TIAM1*, known to play a role in cell-matrix interactions.

Discussion: Rare variants in *ARHGAP24* may mimic GBM disorders such as AS. *In-silico* analysis of the *ARHGAP24* interactome suggests that the mutation may disrupt podocyte-matrix interactions at the GBM. Alternatively the disease in this family may represent a digenic inheritance of *ARHGAP24* and an unidentified functional deep intronic sequence variant in a *COL4A* gene. These findings emphasize the need for a multifaceted approach to glomerular disease classification that integrates clinical, morphologic, and genomic data.

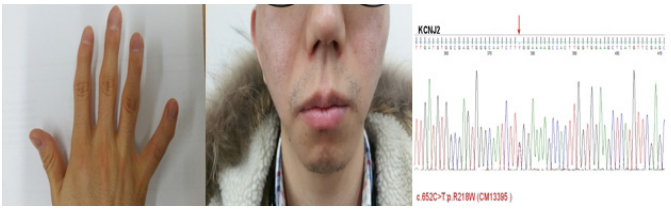
SA-PO056

Andersen Tawil Syndrome Presented with Hypokalemic Periodic Paralysis

Jong-Hwan Jung, Seon-Ho Ahn. *1 Div of Nephrology, Dept of Internal Medicine, Wonkwang Univ College of Medicine, Iksan, Jeonlabukdo, Korea.*

Introduction: Hypokalemic periodic paralysis is often developed in clinical settings, such as thyrotoxicosis, renal tubular dysfunction, and channelopathies related with potassium. The channelopathy of inward rectifier K^+ channel, I_{K1} is a disorder associated with mutations in an ion channel gene. Andersen Tawil syndrome associated with the channelopahty is characterized by dysmorphic features, ventricular arrhythmia, and hypokalemic periodic paralysis.

Case Description: A 25-year-old male visited our hospital due to lower legs paralysis. He took a medicine to control fever by acute pharyngotonsilitis for recent three days. He has no chronic disease. However, he has been on a bisoprolol daily for ventricular tachycardia during several years. His vital signs were stable on arrival. Electrocardiography showed normal sinus rhythm. His serum sodium and potassium were 145 mEq/L and 2.5 mEq/L. Arterial blood gas analysis showed normal. Hormonal assay also was within normal range. We were also not able to find out any evidence of renal potassium loss on urinalysis. But, he showed dysmorphic features, including clinodactyly and micrognathia [figure1]. We considered a genetic channelopathy such as Andersen Tawil syndrome. We did DNA sequencing for *KCNJ2* gene, encoding potassium channels.



We could confirm Andersen Tawil syndrome. His symptoms were completely improved after only supplement of potassium.

Discussion: Nephrologists will usually consider inherited renal tubular dysfunction related with hypokalemia or use of diuretics in situation of hypokalemic periodic paralysis without thyroid dysfunction. However, if the patients have distinctive features and arrhythmias, nephrologists also need to consider channelophathies. This effort can often reduce misdiagnosis in hypokalemic settings, especially.

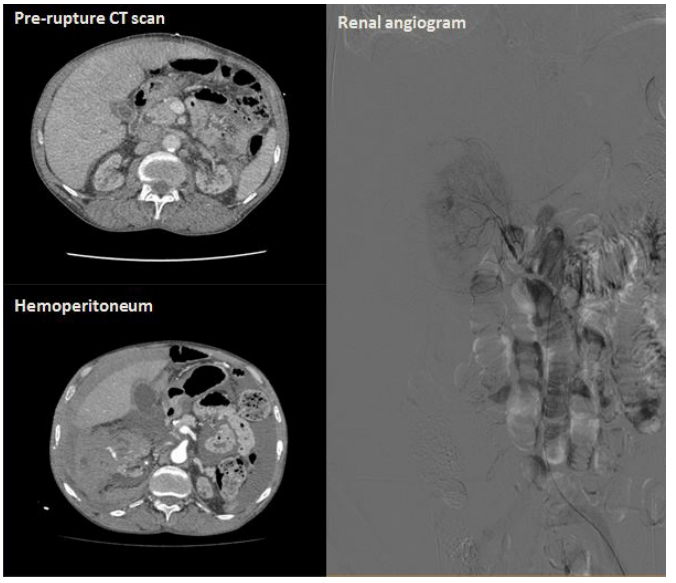
SA-PO057

A Fatal Complication (Hemoperitoneum) of Acquired Cystic Kidney Disease

Vikrampal Bhatti, Abhilash Koratala, Ashutosh M. Shukla. *Nephrology, Hypertension and Renal transplantation, Univ of Florida.*

Introduction: Acquired Cystic Kidney Disease (ACKD) in patients with advanced chronic kidney disease (CKD) and end stage renal disease (ESRD), unlike other forms of cystic renal diseases, is largely considered a benign pathology with no clear recommendations for follow up care.We present a unique complication due to ACKD resulting in death of a patient.

Case Description: A 48 year old man with ESRD on hemodialysis (HD) for 14 years developed acute abdominal pain during his outpatient HD session and was sent to the ER. He was found to be hypotensive requiring fluid resuscitation and vasopressors and acute anemia with hemoglobin of 8.5 g/dL. Abdominal CT revealed large Hemoperitoneum with a right perinephric sentinel clot, bilateral multiple renal cysts, and features suspicious of bleeding originating from the upper anterior pole of right kidney.Renal angiogram showed active ongoing extravasation from multiple branches of the right renal artery.



Selective right renal artery embolization was unsuccessful. An emergent laparotomy revealed a torn right renal capsule with subcapsular hemorrhage and a 1.4 cm ragged defect in the inferior portion of the kidney. He underwent right nephrectomy and pathology was negative for malignancy. Because of religious reasons, patient refused blood transfusion and unfortunately died of hemorrhagic shock after the surgery.

Discussion: Our case shows a fatal and potentially preventable complication due to ACKD. Without clear guidelines for follow up and majority of the studies on cystic renal diseases excluding patients with ACKD, the true incidence of complications in these patients is not known. We believe an observational cohort study on the lines of Bosniak classification, in patients with advanced CKD/ESRD should be considered such that natural history of this condition, including potential complications e.g. malignancy/bleeding can be better predicted.

SA-PO058

Improvement of Kidney Function by Everolimus in a Patient with Kidney Angiomyolipoma due to Tuberous Sclerosis Complex

Hideki Matsumura,[1] Akira Ashida,[1] Hyogo Nakakura,[1] Yuko Fujii,[1,2] Akihiko Shirasu,[1] Satoshi Yamazaki,[1] Motoshi Hattori,[3] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Osaka, Japan; [2]Internal Medicine, Kanzaki Municipal General Hospital, Hyogo, Japan; [3]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Introduction: Tuberous sclerosis complex (TSC) is a multisystem genetic disorder characterized by growth of hamartomas in various organs throughout the body, including the brain, kidney, and skin. In the kidney, angiomyolipomas occur in most patients with TSC and can lead to kidney failure. Recently, clinical trials with mTOR inhibitors have demonstrated promising results for several indications, such as renal angiomyolipoma, subependymal giant cell astrocytoma. Here we report for the first time a case of kidney angiomyolipoma due to TSC in which kidney function improved after administration of an mTOR inhibitor, everolimus.

Case Description: The patient was a 39-year-old man who had been diagnosed as having TSC associated with facial angiofibromas, brain subependymal nodules and angiomyolipoma in the kidney and liver. He also had neurological symptoms including intellectual disability and seizures. Both kidneys were fully filled with angiomyolipomas, and kidney function had decreased gradually to eGFR 13.7 mL/min/1.73 m^2. Because of his intellectual disability, it had been expected that initiation of dialysis would present many difficulties for him and his family. Therefore, we administered everolimus to preserve the patient's kidney function and to delay the initiation of renal replacement therapy. Although the rate of eGFR decline had been -4.6 mL/min per year before everolimus treatment, the eGFR recovered to 20.2 mL/min/1.73 m^2 (+4.7 mL/min per year) after four months of everolimus administration.

Discussion: Although everolimus has been approved as a new treatment option for TSC patients with kidney angiomyolipoma and is effective for reduction of tumor size, no previous report has indicated that it can improve kidney function. Although this is only a single case report based on short-term observation, everolimus therapy may be a promising new option for TSC patients with kidney insufficiency.

SA-PO059

Gastroparesis in a Patient with ADPKD

David M. Dewolfe,[1] Vinod Raman,[1] Andrew A. Wagner,[2] Theodore I. Steinman.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center; [2]Urology, Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: ADPKD is associated with cystic enlargement of the kidneys and has rarely been reported to cause mechanical bowel obstruction. Here, we document the first case of a kidney cyst causing gastroparesis in a patient with ADPKD.

Case Description: A 60 yo female with a history of ADPKD was referred with one year of intractable nausea and vomiting with oral intake, chronic right sided abdominal and flank pain, 25lb weight loss and malnutrition. The inability to tolerate any oral nutrition led to repeated hospitalizations for volume depletion. Exam revealed a chronically ill woman, enlarged kidneys, and tenderness to palpation in the right upper quadrant and right flank. Laboratory studies revealed a BUN 8mg/dL, Cr 0.7mg/dL, K 3.5mEq/L, Mg 1.4mg/dL, PO4 1.8mg/dL and albumin 2.9g/dL. CT scan revealed a 9.3cm x 6.5cm cyst in the upper pole of the right kidney directly abutting, but not obstructing, the gastric outlet. Upper endoscopy and endoscopic ultrasound were negative for anatomic lesion or luminal obstruction. A gastric emptying study was performed after withdrawal of anti-emetic, anxiolytic, and opioid medications which revealed a prolonged half-emptying time of 34.5 minutes (normal <19). TPN was initiated after GI consultation. Given the close proximity to the gastric outlet, the decision was made to pursue laparoscopic decortication of the large cyst. Within weeks after the procedure, she was tolerating oral nutrition, without symptoms. TPN was discontinued. Three months post-operatively, she was tolerating an unrestricted diet without need for anti-emetic or analgesic medication. Four months post-procedure a gastric emptying study and gastric motility were entirely normal.

Discussion: Large renal cysts have previously been reported to cause mechanical bowel obstruction, but this report is the first case of a cyst causing delayed gastric emptying without imaging or endoscopic evidence of luminal obstruction. We hypothesize the large renal cyst was an irritant to the nerve plexus responsible for gastric motility in the distal stomach. Decortication of the cyst has provided permanent relief of her abdominal pain, nausea, and vomiting.

SA-PO060

A Mutation of the Gene KLHL3 as a Cause of Gordon Syndrome Olufemi B. Aina, Nobuyuki (Bill) Miyawaki, Joseph Mattana, James Drakakis. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

Introduction: Hyperkalemic hypertension (Gordon Sydrome or pseudohypoaldosteronism type 2) can be defined as a disorder of abnormal regulation of the thiazide sensitive NaCl co-transporter (NCC). There have been several gene mutations implicated, including a gain of function in WNK1 (With No lysine 1) or a loss of function in WNK4. Other genes such as KLHL3 (kelch-like family member 3) and CUL3 (cullin 3) are also involved through interactions with WNK kinases, leading to increased sodium chloride reabsorption. Here, we report a case of adult hypertension and hyperkalemia, ultimately found to have a dominant mutation in the gene KLHL3.

Case Description: A 54 year old male with past medical history of uncontrolled hypertension and long standing hyperkalemia- thought to have caused two cardiac arrests, presented for evaluation. Serum K^+ was consistently 5.8-5.9 mmol/l. Medication list was without offending agent. Family history was significant for hypertension but without obvious inheritance pattern. Laboratory tests showed serum Na^+ 143 mmol/l, Cl^- 103 mmol/l, bicarbonate 21 mmol/l, BUN 18 mg/dl, creatinine 1.32 mg/dl. Plasma renin was suppressed at 0.24 ng/ml and aldosterone was 7.8. Transtubular potassium gradient was 2.3, consistent with failure to appropriately excrete potassium. Given this constellation, a presumptive diagnosis of Gordon syndrome was made and he was started on hydrochlorothiazide 12.5 mg 3x per week and sodium restriction. This led to improved blood pressure and serum K^+ values. During this course, results of genetic testing done several months prior revealed a dominant mutation in the KLHL3 gene.

Discussion: Gordon syndrome involves abnormalities in WNK kinases, proteins that affect the thiazide sensitive NCC. Mutations involving WNK1 and WNK4, or the proteins affecting their degradation can lead to unregulated chloride reabsorption in the distal tubule. Without luminal electronegativity, the driving force for aldosterone mediated potassium and hydrogen secretion is lost. Here, we report a case with high clinical suspicion of Gordon syndrome, confirmed with a discovered mutation in KLHL3, one such protein known to impair degradation of WNK kinases, leading to cellular accumulation.

SA-PO061

A Rare Genetic Cause of Profound Hypomagnesemia in a Patient with a History of an Eating Disorder Vinod Raman, Robert A. Cohen. *Div of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Determining the precise etiology of hypomagnesemia in a patient with an eating disorder history is challenging. We report a case of renal magnesium wasting in such a patient that remained unsolved for over a decade.

Case Description: A 39 year-old female is referred for chronic hypomagnesemia. Complaints: myalgias and palpitations. Past history: major depressive disorder; anorexia nervosa with laxative and diuretic abuse. No family history of renal disease, electrolyte disorders or diabetes. Medications: oral magnesium oxide (4800mg/day with variable compliance); twice weekly intravenous magnesium sulfate. She denies laxative or diuretic use, anorexia or bulimia in recent years. Hypomagnesemia has rarely been associated with hypokalemia. Exam: positive Chvostek sign. Labs: Mg 1.0mg/dL; Na 136mEq/L; K 4.3mEq/L; Cl 98mEq/L; HCO3 31mEq/L; BUN 11mg/dL; Cre 1.1mg/dL; Ca 9.1mg/dL; Phos 3.5mg/dL; Albumin 4.1g/dL, PTH 31pg/mL. Spot urine: Cre 109mg/dL, Na 45mEq/L, K 57mEq/L, Cl 66mEq/L, Mg 7.4mg/dL (serum Mg 1.2mg/dL). FEMg: 8.8%. Urine diuretic screens: negative three times. 24hr urine: 700ml; Cre 629mg; Mg 50mg; Ca 59mg; K 19.5mg. Renal ultrasonography: 8.3cm right kidney; 8.5cm left kidney, with1.2cm upper pole cyst. 24hr cardiac monitoring: frequent PVCs. Differential included occult diuretic use or Gitelman's. Genetic analysis: heterozygous whole gene deletion of the hepatocyte nuclear factor-1-beta (HNF1B) gene.

Discussion: HNF1B variants, which present with hypomagnesemia due to renal magnesium wasting, are most commonly associated with maturity-onset diabetes of the young with renal cysts (MODY5). Variants have also been associated with abnormal renal development or multiple simple renal cysts. Our case phenotypically resembles Gitelman's. It is a rare presentation of an HNF1B mutation given the absence of significant structural abnormalities or diabetes. Hypomagnesemia was previously mistakenly attributed to laxative or diuretic abuse. This case underscores the importance of maintaining a broad differential diagnosis and avoiding premature closure, particularly in a patient with a confounding history.

SA-PO062

2,8-Dihydroxyadenine Crystalline Nephropathy: A Forgotten Cause of Renal Allograft Dysfunction Mohammed Alzubaidi, Raghavesh Pullalarevu, Evelyn Bruner, Sally Self, Maria Aurora C. Posadas. *Medical Univ of South Carolina, Charleston, SC.*

Introduction: We describe a case of 2,8-dihydroxyadenine crystalline nephropathy (DHACN) in renal allograft leading to graft dysfunction. This disease is under-recognized and frequently missed. Complications in renal allograft can be prevented by prophylaxis with allopurinol prior to kidney transplant (txp).

Case Description: 39/F with ESRD due to presumed HTN received a deceased donor kidney. A month after transplant, pt developed AKI with Cr of 5 mg/dL. Renal txp US showed moderate hydronephrosis, not relieved by foley catheter. Kidney biopsy showed no evidence of acute rejection but brown, polarizable, crystalline material within tubular epithelium and lumina consistent with 2,8-DHA crystals. No crystals were identified on urine sediment. Urinary stone risk panel showed elevated oxalate and decreased citrate. Pt was started on allopurinol and sodium citrate. She required anterograde ureteral stent removal as stent broke during cystoscopy. Cr leveled off at 2.4 mg/dL at 4 months. Pt never had personal or familial history of kidney stones and was not on triamterene. Pt was found to have adenine phosphoribosyltransferase (APRT) deficiency by enzymatic activity testing.

Discussion: APRT deficiency is a rare AR disorder of purine metabolism. In the absence of APRT, adenine is oxidized by xanthine dehydrogenase to 2,8-DHA, which is poorly soluble and forms crystals at physiologic urine pH resulting in 2,8-DHA nephrolithiasis and crystalline nephropathy. APRT deficiency is frequently missed, owing to the absence of specific manifestations and lack of awareness of the disease among physicians. In kidney txp pts who are not on prophylactic treatment, 2,8-DHACN can recur in the kidney txp leading to allograft loss in more than 25% of cases. To date, only a few cases of recurrent 2,8-DHACN in kidney txp have been reported. In a series of 9 pts with 2,8-DHACN, diagnosis was missed in all cases prior to txp. 2,8-DHACN after kidney txp can manifest as delayed graft function or primary graft non-function. Management of APRT deficiency includes allopurinol which reduces the generation of 2,8-DHA, fluid intake, and avoidance of purine-rich diet.

SA-PO063

A COL3A1 Gene Mutation in a Young Male with Rupture of a Dissected Renal Artery Aneurysm: A Case Report Rio Noto,[1] Hideki Yokoi,[2] Tomoki Saito,[3] Hiroko Morisaki,[4] Akihiro Yoshimoto,[1] Motoko Yanagita.[2] *[1]Dept of Clinical Nephrology, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; [2]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Dept of Thoracic Surgery, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; [4]Dept of Medival Genetics, Sakakibara Heart Inst, Hucyu, Tokyo, Japan.*

Introduction: We presented the case at the ASN Kidney Week two years ago, however, we couldn't show the definite diagnosis of a rupture of renal artery aneurysm (RAA) with dissection in a young healthy male. The following genetic testing of specimen demonstrated the disease he actually suffered.

Case Description: A 26 year old male with a history of recurrent pneumothorax presented with progressive left flank pain. A computed tomography angiography (CTA) demonstrated a typical "string of beads" appearance with dissections of bilateral renal arteries and infarctions of bilateral kidneys. On day 8, he suddenly felt severe, left-sided abdominal pain. His hemoglobin decreased from 15.9 g/dl to 11.0 g/dl, and serum creatinine increased from 0.69 mg/dl to 1.52 mg/dl. He received blood transfusion and CTA, showing large retroperitoneal hemorrhage from ruptured left RAA. He was treated with a coil embolization of left renal artery, and then right RAA was embolized two days later with endovascular stent emplacement in right renal artery dissection. His renal function has luckily recovered. Two years later, he underwent video-assisted thoracoscopic bullectomy for recurrent pneumothorax. The DNA sequencing of the lung specimen and whole blood revealed a missense base mutation in the COL3A1 gene (c.3193G>A(p.Gly1065Arg)), which controls the production and assembly of type III collagen.

Discussion: Ehlers-Donlos syndrome (EDS) is a connective tissue disorder composed of several subtypes with distinct genetic and clinical features. The vascular type, EDS IV, represents the most severe form of the disease associated with the COL3A1 gene. Patients frequently experience rupture of arteries and intestine. He is fortunately spared from the next rupture but the same thing can happen anytime. Careful observation is necessary in order to avoid his sudden death.

SA-PO064

New Mutation Identified for Fabry Disease Fernanda Paula Feres Rios Da Costa, Alicia Imada, Luiz Fernando Christiani, Maria Izabel Neves de Holanda. *Nephology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

Introduction: Fabry disease affects about 1/40 000 live births X-linked, caused by partial or complete deficiency ofthe enzyme alpha-galactosidase A (alpha-GAL A). The absence of this enzyme leads to the progressive accumulation of neutral glycosphingolipids

with α-galactosyl terminal residue in the plasma and in the lysosomes of endothelial cells of several organs, mainly skin, kidney, cardiovascular system, eye, and brain, which results in functional loss. Clinical manifestations include angiokeratomas, acroparesthesia, anhidrosis, corneal/lens opacification, cardiovascular disease, cerebrovascular and kidney failure. Due to high morbidity and mortality of this disease it is important to recognize and treat it early.

Case Description: We report a case of a patient with a new mutation, never described before that presents severe manifestations.

M.M.C, male patient, 36 years old, presented acroparesthesiarelated to temperature changes since the age of 8y/o, fatigue,arthralgias, headache, tinnitus, extremity edema and reduced cognitive understanding. He was admitted in the emergency room and chronic renal failure was evident in the laboratory exams. He started hemodialysis and was evaluate for several diferential diagnoses. Fabry disease was thinking and the determination of alpha enzyme activity GAL A was collected. The result demonstrate avticity of 0.00 umol / L. The genotype of alpha gene GAL A showed pathological mutation in Exon 3 p.K168Q. This is a new mutation not described before in the literature, but potentially pathogenic. The treatment with enzyme replacement was started and he hadimprovement of symptoms, but didn't recovery renal function. The patient's brother was also screened, and the enzyme activity showed a very low activity and the same mutationwas identified He was diagnosed with Chronic kidney diseaseneeding hemodialysis.

Discussion: This mutation showed how aggressive this disease can be, since this patient had severe symptons and was underdiagnoses. We need to report this new mutations, so we can increase our knowledge about it. The diagnosis and its possible mutations enables early treatment and may prevents disease progression and complications.

SA-PO065

Rare Association of Autosomal Dominant Polycystic Kidney Disease (ADPKD) with Chromophobe Cell Carcinoma in a Young Patient Elena Beznea,[1] Andreea Andronesi,[1] Raluca Bobeica,[1] Bogdan Constantin Haineala,[2] Monica Gratiela Hortopan,[3] Emi Marinela Preda.[3] *[1]Nephrology, Fundeni Clinical Inst, Bucharest, Romania; [2]Urology, Fundeni Clinical Inst, Bucharest, Romania; [3]Pathology, Fundeni Clinical Inst, Bucharest, Romania.*

Introduction: ADPKD is one of the most common genetic disease caused by the mutation of PKD1 and PKD2 genes. There are very few cases described of ADPKD-chromophobe cell carcinoma association.

Case Description: A female patient, aged 32, without significant medical history, is admitted for pain in the lumbar left spine and pollakiuria. A CT-scan was done before in another medical facility which revealed ADPKD and a tumor 35 mm in diameter in the right kidney (RK), incompletely characterized by CT (angiomyolipoma? oncocytoma?). On admission the patient was afebrile, with normal blood pressure, positive Giordano sign on the left side, normal diuresis. The kidney ultrasound confirmed the diagnosis of ADPKD and the presence in the upper pole of the RK of a solid mass with a 38 mm diameter with significant deformation of the capsule, difficult to assess if it was an angiomyolipoma or a calcified cyst. Serum creatinine and urinalysis were normal. There were no inflammation, anemia, or changes in the clotting factors. Immunological assessment and tumor markers were negative kidney MRI was done confirming the polycystic kidneys with cortical cysts type Bosniak I, II and II F, and a RK medio-renal solid mass, possible an oncocytoma or a renal carcinoma with chromophobe cells. A total RK nephrectomy was done in the Urology department. The histiological exam established the positive diagnosis of chromophobe cell kidney carcinoma (the clear and eosinophilic variant).

Discussion: We present the case of a special association between a genetic kidney disease with a very rare histological type of kidney malignancy in the absence of hypertension, hematuria**,** or familly history of kidney cancer.

SA-PO066

Polycythemia and Peritubular Capillary Rarefaction in Two Adolescents Born Prematurely with Extremely Low Birth Weight Nariaki Asada,[1] Takanori Tsukahara,[3] Daisuke Matsuoka,[3] Megumi Furuhata,[6] Shunsuke Noda,[5] Kuniaki Naganuma,[4] Akinori Hashiguchi,[2] Midori Awazu.[1] *[1]Dept of Pediatrics, Keio Univ School of Medicine, Tokyo, Japan; [2]Dept of Pathology, Keio Univ School of Medicine, Tokyo, Japan; [3]Dept of Pediatrics, Shinshu Univ, Nagano, Japan; [4]Dept of Pediatrics, Iida Municipal Hospital, Nagano, Japan; [5]Dept of Pediatrics, Nagano Red Cross Hospital, Nagano, Japan; [6]Dept of Pediatrics, Saku Central Hospital, Nagano, Japan.*

Introduction: Low birth weight (LBW) infants have reduced number of nephrons and are at risk of chronic kidney disease (CKD). While CKD causes capillary rarefaction, LBW and/or prematurity may affect peritubular capillary development.

Case Description: Patient 1 and 2, born at 25 weeks of gestation with birth weight of 466 g and 728 g, showed mild proteinuria at age 6 and 8 years, respectively. In association with increasing proteinuria and blood pressure (BP), polycythemia developed at adolescence. Patient 1 and 2 underwent renal biopsy at age 15 and 18 years, when their BP was 143/59 and 137/82 mmHg, eGFR 90 and 114 ml/min/m^2, hemoglobin 18.7 and 19.0 g/dL, erythropoietin (EPO) 24.5 and 17.8 U/L, respectively. Polycythemia was considered to be due to increased EPO. Light microscopy showed glomerular hypertrophy, focal segmental glomerulosclerosis without severe interstitial fibrosis. Immunohistochemically, CD31- or CD34-positive endothelial cells were reduced showing peritubular capillary rarefaction, which probably resulted in renal hypoxia and elevated EPO. Since kidney function was almost normal and fibrosis was not severe, we considered that the capillary rarefaction was largely attributable to LBW and/or preterm birth. Varsartan was started after the biopsy, and hemoglobin, urinary protein, and BP normalized.

Discussion: Premature decrease of tubular VEGF causes peritubular capillary rarefaction leading to elevated EPO-induced polycythemia (Dimke, J Am Soc Nephrol 2015). VEGF expression becomes reduced with exposure to extrauterine relative hyperoxia after premature birth. Placental insufficiency also suppresses VEGF in the embryonic kidney. We therefore considered that the capillary rarefaction seen in our patients was caused by premature delivery and/or LBW.

SA-PO067

A Case of Epstein Syndrome with Slower Development of Kidney Impairment Miki Yarita, Naoki Sugano, Maiko Furuya, Nobuo Tsuboi, Yoichi Miyazaki, Makoto Ogura, Gorou Tokudome, Takashi Yokoo. *Nephrology and Hypertention, The Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan.*

Introduction: It is estimated that there are about 200 patients suffered from Epstein syndrome (ES) around the world. This is an autosomal dominant hereditary disease characterized by sensorineural hearing loss, macrothrombocytopenia, and nephritis. ES is also known as myosin heavy chain 9-related disorder. Generally, renal biopsy cannot be undergone because of severe thrombocytopenia, however in this case, he was received Eltrombopag, which raise platelet count, therefore he could be received renal biopsy.

Case Description: The patient is 29 years old male with progression of proteinuria. In X-24, thrombocytopenia was identified, and he was diagnosed as Idiopatic thrombocytopenic purpura . Although steroid therapy was administered, platelet count was about 10,000. In X-11, he visited the department of Hematology of our hospital, and was suspected to be ES, due to macrothrombocytopenia, bilateral sensorineural hearing loss and deterioration in renal function. In X-8, he was referred to our department of outpatient. Since the proteinuria increased, Lisinopril was administered under routine monitoring. Because of thrombocytepenia, renal biopsy was not possible to perform ever, however, since he was received Eltrombopag, the drug which raise platelet count, and in X-1, platelet count was increased to 80,000, therefore he was able to receive renal biopsy.His histological change is focal segmental glomerulosclerosis, typical finding of ES. However, usual clinical course of ES presents end stage of renal disease by age 20 in most cases, however his clinical course was not be similar to typical course. Genetic examination was conducted, and it was revealed that the gene variation of him is MYH9 R702 mutation. Consequently, he was duly diagnosed as ES and was confirmed to be administered Lisinopril continuously.

Discussion: Taking into account the slower development of kidney impairment, renal protective effect was foreseen by a long term administration of Lisinopril. Further investigation is expected to review the effectiveness of inhibition of RAS for the patients suffered from kidney impairment caused by gene variation in MYH9.

SA-PO068

Everolimus Can Induce Regression of Inferior Vena Cava and Renal Vein Tumour Thrombus in Invasive Renal Angiomyolipoma Emily J. See,[1] Simon T. Wood,[2] Nicole Isbel.[1] *[1]Dept of Nephrology, Princess Alexandra Hospital, Brisbane, Australia; [2]Dept of Urology, Princess Alexandra Hospital, Brisbane, Australia.*

Introduction: Tuberous sclerosis complex (TSC) is a genetic disorder characterised by multi-organ hamartomatous lesions, which frequently involve the kidney. The most common renal manifestation is angiomyolipoma (AML). Tumour thrombus invasion into the renal vein and inferior vena cava (IVC) is a rare complication and usually necessitates nephrectomy with tumour thrombectomy. Everolimus, an inhibitor of Mammalian target of rapamycin (mTORi), has been shown to have efficacy in reducing the size of uncomplicated renal AMLs, however its use in complicated disease has not been described.

Case Description: We report the case of a 19-year-old female with TSC manifesting as bilateral renal AMLs with normal biochemical function; cortical tubers with frequent seizures and neuropsychiatric deficits; myocardial involvement without outflow tract obstruction; and facial angiofibromas. She had previously experienced a life threatening retroperitoneal haemorrhage which required embolisation. On surveillance imaging, she was found to have extension of her right renal AML into the renal vein and IVC. There were no features to suggest renal cell carcinoma. To avoid the risks associated with extensive surgery, she was commenced on everolimus 10mg daily. Within 3 months, she experienced improvement in seizure frequency, neurocognitive function and cutaneous disease. The dose was increased to 15mg daily in split dosing to achieve trough levels of 5-10. At 6 months, partial regression of the IVC tumour was demonstrated on MRI. By 12 months, there was complete resolution of the IVC and renal vein tumour and reduction in the size of the intra-renal AMLs. Drug toxicity included mouth ulcers and intermittent mild neutropenia.

Discussion: This is the first reported case of tumour thrombus regression with everolimus in complicated renal AML. Traditionally, vascular invasion has been managed surgically due to the risk of cardiac or pulmonary tumour embolus, however operative intervention of this nature involves significant morbidity. Treatment with mTORi in patients with aggressive disease including tumour thrombus warrants consideration.

SA-PO069

Rothia Mucilaginosa Peritonitis Khurram Mehtabdin, Mala Sachdeva. *Div of Nephrology and Hypertension, Northwell Health, Great Neck, NY.*

Introduction: Peritonitis is a known complication in patients who are on peritoneal dialysis (PD) and is usually caused by *Staphylococcus* species, *Escherichia Coli*, and *Pseudomonas Aeruginosa.* Physicians should be aware of uncommon causes of bacterial peritonitis. We report a rare case of *R.mucilanginosa* peritonitis requiring catheter removal. To date, there have been only 5 reported cases of *Rothia mucilaginosa* peritonitis*, formerly known as Stomatococcus mucilaginosus* associated with PD.

Case Description: We report an 80 year old male on PD for eight years, with a history of *Bacillus* peritonitis four years prior who presented with nausea, vomiting, abdominal pain, and cloudy effluent. The patient had a history of poor dentition with numerous dental procedures in the years prior including tooth extractions and a jaw fracture with subsequent oral surgery. Initial cell count revealed 1856 total nucleated cells, and 97% polys. Final culture grew *Stomatococcus mucilaginosus*. The patient was started on intraperitoneal vancomycin. Day 5 cell counts showed 708 total nucleated cells and 90% polys, with the culture being negative. The patient continued to report malaise, weakness, and lack of appetite. Day 8 counts showed total nucleated cell count of 43, 85% polys; however the culture was again positive. Due to refractory peritonitis, his PD catheter was removed and he began hemodialysis.

Discussion: *R. mucilagnosa* is an encapsulated gram-positive, coagulase negative organism found in pairs, clusters and tetrads. It is considered to be part of the normal flora of the mouth or respiratory tract. Risk factors for this organism include dental work as this species has also been found in dental caries and plaques, indwelling catheters, leukemia, valvular disease, intravenous drug use, severe neutropenia or immunocompromised state. Prior cases have demonstrated this organism to be susceptible to penicillins. Despite treatment, the patient presented had refractory peritonitis, requiring removal of the PD catheter. Our case illustrates the importance of quick diagnosis and timely treatment in patients with rare organisms causing peritonitis.

SA-PO070

IVC Filter Migration Associated with Bilateral Renal Vein Thrombosis Treated with Thrombolytic therapy Arouna Senthilkumar, Benjamin Ling, Julia Schneider. *Nephrology and Hypertension, Hines VA Hospital, Hines, IL.*

Introduction: Little is known about the migration of IVC filters. Here we present a case of dislodged IVC filter, bilateral renal vein thrombosis with acute renal failure successfully treated with *tissue plasminogen activator (tPA).*

Case Description: 87 year old man with history of PE twice and a lower extremity DVT in 2014 treated with Warfarin but complicated by GI bleeding. VenaTech IVC filter was placed and Warfarin was stopped. He presented to the ED 10 days later with bilateral lower extremity edema, gross hematuria and acute oliguric renal failure. His baseline creatinine was 0.9mg/dl but on presentation was 3.4 mg/dl. Creatinine continued to rise by 1mg/dl per day. He was not volume depleted, not septic. There were no new medications. A non-contrast CT scan showed that the IVC filter migrated above the renal veins. There was also an ill-defined high density in the IVC suspicious for thrombus. A venogram demonstrated an IVC thrombus at the level of pre-existing filter, bilateral renal ostia and a suprarenal IVC. A venous duplex did not demonstrate new DVT in the lower extremities. The filter could not be retrieved. He underwent catheter guided thrombolysiswith 4 mg of *tPA* in each renal vein and 8mg in the inferior vena cava. Next, fogarty balloon was used for a pullback thrombectomy in the bilateral renal veins. Slow local tPA infusion (a total of 8mg overnight) was started. The next day, surveillance venogram showed significant improvement in clot burden. The renal function started to improve in 48 hours. Creatinine stabilized at 2mg/dl by discharge. He did not require dialysis during this admission.

Discussion: We report a second case of renal failure due to bilateral renal vein thrombosis associated with IVC filter migration. This was successfully treated with low dose tPA without having to retrieve IVC filter. At about two months after presentation creatinine had returned to normal. This report highlights that renal vein thrombosis is a rare but serious complication of IVC filter movement and that it could be treated non-surgically.

SA-PO071

A Case Report of Erdheim-Chester Disease Involving the Kidney and Retroperitoneum Vinay Srinivasa. *Medicine, Gold Coast Univ Hospital, Gold Coast, Queensland, Australia.*

Introduction: Erdheim-Chester Disease (ECD) is a rare non langerhans cell histiocytosis neoplasm, that has multi organ involvement The renal and retroperitoneum can be the primary sites of involvement and account for 30% of cases. We present an interesting case report of a gentleman who presented with multiple episodes of obstructive oliguric acute kidney injury with hydronephrosis who required repeat ureteric stenting. CT with non contrast revealed soft tissue thickening surrounding the left kidney. Open biopsy of this tissue showed features of ECD. Interestingly our case had a right nephrectomy for Renal cell Carcinoma in 2002. Retrospective review of biopsy showed features of ECD.

Case Description: Our patient initially presented to the nephrology outpatient clinic with deteriorating renal functions that were previously normal. He had multiple episodes of acute kidney injury with associated hydronephrosis on renal ultrasound. Ureteric stents were placed and his renal functions improved. CTKUB scan revealed a 15 mm soft tissue thickening around the left kidney which was not present in his initial CT scan. Open biopsy of the perinephric tissue showed features of ECD marked by histiocytes within the perinephric tissue. The biopsy was tested for the BRAF V600 mutation and was positive. He was commenced on Dabrafenib, an oral BRAF inhibitor.

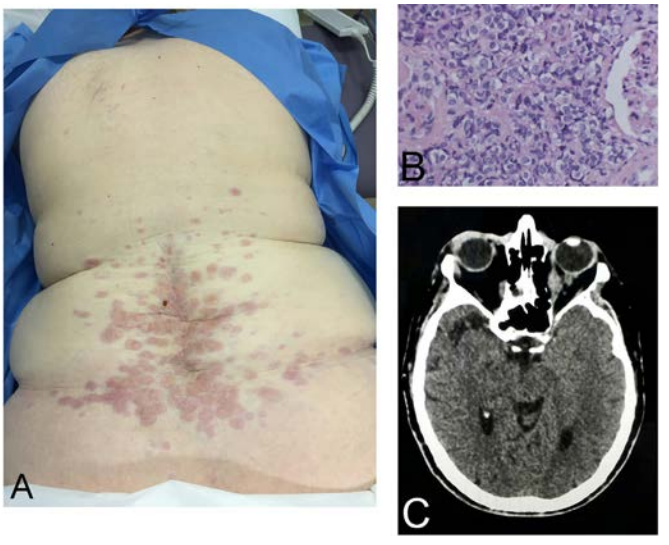
Discussion: Since its first description in 1930, over 500 cases of ECD have been reported. Common clinical manifestations include bone pain, diabetes insipidus and neurological complaints. Hydronephrosis, abdominal pain and dysuria are chief renal complaints. Retroperitoneal fibrosis illustrates retroperitoneal involvement. CTKUB reveals perinephric and peri-ureteric thickening giving the hairy kidney sign. Biopsy reveals xanthogranulomatous inflammation that may be BRAF mutation positive. BRAF mutation positive status has important implications; it is a tumour responsive mutation. Good response rates have been achieved using oral BRAF inhibitors. It is a potent therapeutic agent that can improve survival to a disease that was previously fatal.

SA-PO072

Breast Adenocarcinoma Infiltrates the Kidney and Skin Dearbhla Kelly,[1] Gasim Ahmed,[1] Anthony M. Dorman,[2] Liam F. Casserly.[1] *[1]Dept of Nephrology, Univ Hospital Limerick, Limerick, Ireland; [2]Dept of Pathology, Beaumont Hospital, Dublin, Ireland.*

Introduction: Kidney disease frequently complicates malignancy or its treatment. Renal failure in this setting is often multi-factorial. It includes pre-renal causes such as volume depletion, intrinsic renal disease such as membranous nephropathy or amyloidosis, and obstructive disease due to lymphadenopathy or retroperitoneal fibrosis.

Case Description: A 68-year-old woman presented with lower limb swelling and a nodular skin rash *(Figure 1A).* She had a non-oliguric acute kidney injury (AKI) (peak serum creatinine 360 µmol/L). Her urinalysis showed trace blood and 1+ protein. Renal ultrasound showed normal sized kidneys without hydronephrosis. Kidney biopsy *(Figure 1B)* showed diffuse parenchymal infiltration by malignant cells. The tumour cells were large with little cytoplasm, hyperchromatic nuclei and prominent nucleoli. They showed vacuolization with PAS-positive material. The features were most suggestive of high-grade breast adenocarcinoma. Breast examination revealed a hard mass in her left upper outer quadrant. The breast needle core biopsy confirmed invasive ductal carcinoma. Computerized tomography scans detected metastatic disease affecting her left orbit (*Figure 1C)*, peritoneum, vertebral bodies and pelvis. A punch skin biopsy from the left inframammary region was also consistent with infiltrative carcinoma.



Discussion: Although renal parenchymal invasion by solid and hematologic cancers is not uncommon, AKI in this context is unusual. Lymphomas and leukaemias are the most common culprits with metastatic extrarenal solid tumors causing AKI being especially rare. Those cases severe enough to cause acute renal failure are typically associated with widespread parenchymal replacement in both kidneys as in this case. Large kidneys in the absence of hydronephrosis are suggestive of tumor infiltration.

SA-PO073

Squamous Cell Carcinoma of the Renal Pelvis Associated with Nephrolithiasis Bryan Tucker, Anushree C. Shirali. *Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Introduction: Primary squamous cell carcinoma (SCC) is uncommon among kidney tumors, comprising less than 1% of renal cancers. We report a case of rapidly metastatic SCC of the renal pelvis associated with nephrolithiasis.

Case Description: A 55 y.o. female was admitted with bilateral hydronephrosis and acute kidney injury (AKI). Her history included stage 4 chronic kidney disease from bilateral staghorn calculi. CT imaging demonstrated cortical thinning on the right kidney and bilateral hydronephrosis (figure 1). To salvage residual renal function, she underwent a left percutaneous nephrolithotomy. This was complicated by a bleed requiring a left nephrostomy tube (NT). Her AKI progressed rapidly to ESRD requiring hemodialysis. At outpatient follow-up, she had pain around the NT site with a non-erythematous, tender bulge at her left flank, which CT scan reported as a 6.5cm soft tissue collection. She was re-admitted with a fever and growing flank mass. Repeat CT scan (Figure 2) revealed serial extension of the mass along the tract of the NT site. Differential diagnoses included abscess, hematoma or malignancy. Biopsy established the diagnosis of metastatic squamous cell carcinoma of the renal pelvis urothelium. The patient refused chemotherapy and one month later she died of malignancy related complications.

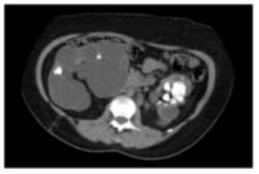


Figure 1. CT scan demonstrating severe hydronephrosis in both kidneys with staghorn calculi. Right kidney also shows cortical thinning.

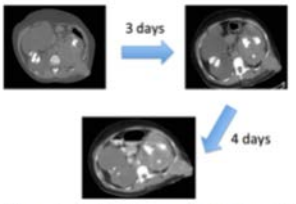

Figure 2. Serial CT scans displaying rapid extension of the left flank mass. Top arrow (from left to right) shows progression of the mass in 3 days, while the downward arrow shows progression over the next 4 days.

Discussion: Though rare, the incidence of kidney SCC is increased with nephrolithiasis, particularly with staghorn calculi. Other risk factors include horseshoe kidney, tobacco use, recurrent pyelonephritis, and use of phenacetin-containing analgesics. Early diagnosis is critical but kidney SCC is asymptomatic till later stages. As illustrated by our case, metastatic disease can be aggressive and has poor outcomes. At this stage, prognosis is poor even with radical nephroureterectomy with bladder cuff removal and chemotherapy, with overall 1-year survival at 52% and 5-year survival at 10%.

SA-PO074

Renal Manifestations of Leptospirosis Josef Bautista, Andrew Rogers, Jie Tang. *Section of Hypertension and Nephrology, Dept of Medicine, Rhode Island Hospital - Brown Univ, Providene, RI.*

Introduction: In the setting of infection, acute kidney injury is usually secondary to renal hypoperfusion and cytokine-induced inflammation, but not the infectious organism itself. Rarely, however, the infectious organism can directly injure the glomeruli and renal tubules. The net results are decreased glomerular filtration and electrolyte or acid-base disorders. In this case we present a patient with severe leptospirosis who developed acute kidney injury (AKI), hypokalemia, glucosuria, and non-anion gap acidosis. We also review the existing literature regarding the effects of leptospirosis on the renal tubules.

Case Description: A 55-year-old male with no significant past medical history presented with jaundice, myalgia and malaise. He had non-oliguric acute kidney injury with a creatinine of 10 md/dl, thrombocytopenia, transaminitis, hyperbilirubinemia and rhabdomyolysis. Physical examination revealed normotension, icterus, pulmonary crackles and no rash. Notable laboratory findings included serum potassium of 3.1 mg/dl, bicarbonate of 11 meq/L with anion gap of 10, and a urinalysis showing glucosuria with normal serum glucose. Urine microscopy showed muddy brown casts and renal tubular epithelial cells. He was treated with ceftriaxone for presumed leptospirosis, which was later confirmed by urine PCR. He became anuric within 24 hours, coincident with worsening pulmonary status. He was intubated and started on renal replacement therapy until his renal function recovered. On follow-up his hypokalemia and glucosuria resolved.

Discussion: This case highlights the several renal manifestations of leptospirosis, i.e. hypokalemia, proximal tubular dysfunction and acute tubular necrosis. While it is well established that Leptospira sp can directly injure the renal tubule and interstitium, more recent evidence also showed that Leptosiral infection could lead to altered expressions of sodium-hydrogen antiporter 3 and Na-KCl cotrasporter channels. Taken together, we can better appreciate the pathophysiologic mechanisms of the classic electrolyte and acid-base disorders associated with Leptospirosis infection.

SA-PO075

Atypical Presentation of Primary Renal Lymphoma Syed Rizwan A. Bokhari,[1] Abeera Mansur,[1] Maria Rizwan Bokhari.[2] *[1]Nephrology, Doctors Hospital and Medical Center, Lahore, Pakistan; [2]Radiology, Jinnah Hospital, Lahore, Pakistan.*

Introduction: Primary renal lymphoma (PRL) is a very rare disease, accounting for less than 1 % of extra nodal lymphomas. Usually renal tissue is devoid of lymphoid tissue, but it can be involved in cases of disseminated disease. We present a case of a young patient with bilaterally enlarged kidneys.

Case Description: 21-year-old male medical student presented with a 4-month history of left shoulder pain, continuous fever (100-101^0) and weight loss (13 lbs in 4 months) down to 53kg. He developed dull, generalized abdominal pain a week before presentation. There was no previous history of diabetes, hypertension, cardiovascular, hepatic, pulmonary or kidney disease. Patient received multiple courses of antipyretics, antibiotics, steroids and NSAIDS from local practitioners with no improvement. Personal and family history were insignificant. Examination no significant positive physical findings.

Laboratory data showed complete blood count within normal limits, chemistry panel indicated renal dysfunction with baseline creatinine of 1.3 that had increased to 2.1 over the last 2 months, no electrolyte or liver function tests abnormality was noted. Urine complete exam and culture sensitivity were unremarkable. Autoimmune profile, complement levels, thyroid function tests, lipid, coagulation and Infectious profile were all within normal limits. X rays of chest and left shoulder were normal. Ultrasound abdomen showed bilateral enlarged kidneys with grade I echogenicity, size had increased compared to a prior scan. Percutaneous renal biopsy revealed B cell CD 20, Ki-67, CD3 and Tdt positive lymphoblastic Non Hodgkin Lymphoma (NHL). CT scan of chest, abdomen and pelvis revealed bilateral diffuse enlargement of kidneys with heterogenous enhancement. No mediastinal or abdominopelvic lymphadenopathy was noted. Patient was referred to oncologist for NHL chemotherapeutic treatment. Patient is on regular follow up after chemotherapy with creatinine of 1.2.

Discussion: Although PRL is quite uncommon, it should be distinguished from other causes of renal enlargement, mainly renal cancer and infectious etiology apart from metastatic involvement. Prompt diagnosis and timely management can help as promising outcome.

SA-PO076

An Odd Thyroid Nodule Adel S. Haque,[1] Charles Thomas Tucker,[2] Matthew J. Diamond.[1] *[1]Div of Nephrology, Medical College of Georgia at Augusta Univ, Augusta, GA; [2]Coastal Nephrology Associates, Brunswick, GA.*

Introduction: The greatest risk of recurrence of Renal Cell Carcinoma (RCC) is within five years after nephrectomy. Current guidelines suggest active surveillance for recurrence of RCC for five years after removal. Rarely, RCC can recur ten years or more after nephrectomy, mostly in the contralateral kidney or a pulmonary lesion. We present a case of RCC recurrence solely as a solitary thyroid nodule twenty years after treatment of primary RCC with radiation and nephrectomy.

Case Description: A 76-year-old female was recently started on hemodialysis (HD) via a tunneled catheter in her right internal jugular vein. She has a history of RCC managed with a total right nephrectomy and radiation therapy twenty years before starting HD. Shortly after starting HD, she complained of dysphagia, as well as a new neck mass. Examination revealed a rapidly-enlarging thyroid nodule. All lab results, including thyroid function studies, were unremarkable. Ultrasound (US) guided fine needle aspiration of the nodule yielded non-discrete results leading to surgical excision. The patient underwent total thyroidectomy; subsequent pathology identified a 3.5x4.5x7.5cm hypervascular mass in the right lobe of the thyroid. Sectioning and staining of the mass confirms the recurrence of RCC, which was positive for CD10 and PAX-2, along with having a classic chicken-wire vascular appearance and clear cells on histologic analysis. US of the remaining kidney and whole-body PET/CT scan did not delineate further areas of malignancy, suggesting the recurrence of RCC was confined to the thyroid.

Discussion: While the bulk of RCC recur within five years of curative nephrectomy, long-term recurrence has been reported after a decade. Our patient is unique, as she presented with a thyroid nodule that was the discreet recurrence of her RCC excised two decades prior. Although RCC has been shown to metastasize to the thyroid, recurrence of RCC solely in the thyroid has not been reported in English literature. The findings of the case support the notion that any new mass in a patient treated for RCC should be considered a potential recurrence of the disease, even beyond the five-year active surveillance window.

SA-PO077

Bence Jones Cast Nephropathy in Two Patients with Lymphoma Amanda DeMauro Renaghan,[1] M. Lia Palomba,[2] Carol S. Portlock,[2] Steven Salvatore,[3] Surya V. Seshan,[3] Ilya Glezerman.[4] *[1]Nephrology, NY-Presbyterian Hospital/Cornell, NY; [2]Oncology, Memorial Sloan Kettering Cancer Center, NY; [3]Pathology, NY-Presbyterian Hospital/Cornell, NY; [4]Nephrology, Memorial Sloan Kettering Cancer Center, NY.*

Introduction: Monoclonal immunoglobulins may lead to renal damage through multiple pathogenetic mechanisms, so called monoclonal gammopathies of renal significance (MGRS). Most patients with cast nephropathy have multiple myeloma, while this pattern of injury is rarely seen in lymphoma. We present two cases of MGRS due to light chain (LC) cast nephropathy in patients with indolent lymphoma.

Case Description: 55 year old man with indolent marginal zone lymphoma (MZL) who was managed expectantly until he developed fever and night sweats. Exam: Notable for lymphadenopathy, splenomegaly. Labs: Cr 2.5 mg/dL, WBC 15.0 K/mcL, hemoglobin 10.0 g/dL, 2.91 g/dL M-spike (IgG lambda), free lambda LC 140 mg/dL. Urine studies: Trace protein, 2 RBCs and 2 WBCs per HPF, no casts on urinalysis (UA); 2.8 g protein on 24 hr urine collection; 33.9 mg/dL M-spike on UPEP. Kidney biopsy revealed abnormal tubular casts staining positive for monoclonal lambda LC consistent with cast nephropathy, as well as diffuse interstitial atypical lymphoid infiltrates consistent with extranodal MZL. Cr improved with steroids and hydration. Chemotherapy was administered several weeks later. 51 year old man with Stage IV lymphoplasmacytic lymphoma and normal baseline Cr who was monitored expectantly. Routine labs: Cr 6.4 mg/dL, WBC 5.7 K/mcL, hemoglobin 7.8 g/dL, 0.33 g/dL M-spike (IgM kappa), free kappa LC 236 mg/dL. Urine studies: 30 mg/dL protein, 2 RBCs and 2 WBCs per HPF on UA; spot urine protein/Cr 2; 87.0 mg/dL M-spike on UPEP. Kidney biopsy revealed extranodal low-grade B-cell neoplasm involving the renal tubulointerstitium and atypical tubular casts staining for kappa LC consistent with cast nephropathy. The patient was treated with chemotherapy. Most recent Cr was 2.8 mg/dL.

Discussion: We present two unique cases of MGRS presenting as cast nephropathy in patients with lymphoma. They highlight the relationship between the presence of LC and the development of renal damage, and underscore the role for therapies aimed at reducing the malignant clone and decreasing LC production.

SA-PO078

IgG4-Related Kidney Disease in a Patient with Plasma Cell Dyscrasia Chandrashekar Kashyap,[1] Anees Quyyumi,[1] Alton Brad Farris,[2] Kyle Bradley.[2] *[1]Dept of Nephrology, Emory Univ, Atlanta, GA; [2]Dept of Pathology, Emory Univ, Atlanta, GA.*

Introduction: IgG4-related disease (IgG4-RD) is an immune-mediated disease with manifestations in various organs. IgG4-RD has been increasingly recognized in nephrology for its role in causing acute or chronic renal failure. We report a case of a 80 year old male with plasma cell dyscrasia who presented with progressive renal failure. Kidney biopsy showed IgG4 related tubulointerstitial nephritis.

Case Description: An 80 year old Black male was referred to the Renal Clinic for evaluation of worsening renal function. Past medical history included plasma cell dyscrasia (diagnosed 2013) with stable plasma cells on bone marrow biopsy, hypothyroidism, hypertension, chronic pancreatitis and lymphadenopathy. He was asymptomatic with normal physical exam and blood pressure of 140/78. Lab Results: Baseline SCr was 0.89mg/dL in Aug 2014. SCr ranged from 3.1 to 3.7mg/dL from Oct 2015 to Jan 2016. SCr was 3.97 in Feb 2016. Complements were low; Autoimmune screen, hepatitis panel and HIV were negative; Serum IgG level was high at 4220mg/dL; Kappa/Lambda Ratio 1.86. Serum protein electrophoresis revealed IgG kappa paraprotein and urine electrophoresis spotted a faint IgG paraprotein band. Urine dipstick positive for 1+ protein. Proteinuria of 652mg/24hr was noted on 24 hr urine study. Kidneys showed normal size and echogenicity with no hydronephrosis on Renal ultrasound. A 3.5 x 3.4 x 3.2 cm cyst was seen in the interpolar right kidney. Kidney biopsy in Mar 2016 confirmed IgG4 related tubulointerstitial nephritis. Key biopsy findings were: Lymphoplasmacytic inflammation with dense IgG4+ plasma cell infiltrate, eosinophils and storiform fibrosis. Immunohistochemistry showed 50-100 IgG4+ plasma cells/high power field. IgG4/IgG ratio > 40%. Patient was started on prednisone at 40mg/day.

Discussion: IgG4-RD can masquerade many infectious, malignant and inflammatory conditions. This case illustrates the need to consider IgG4-related kidney disease as a potential differential in the workup of CKD and AKI. Thorough history and physical exam is vital as it can affect multiple organs. Early identification is necessary as it is a potentially treatable disorder.

SA-PO079

Diffuse Large B-Cell Lymphoma Localized in Peritubular Capillaries Diagnosed by Percutaneous Kidney Biopsy Kenji Harada,[1] Kosuke Masutani,[2] Kazuhiko Tsuruya,[2] Hidetoshi Kanai.[1] *[1]Div of Nephrology, Kokura Memorial Hospital, Kitakyusyu, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan.*

Introduction: Diffuse large B-cell lymphoma (DLBCL) is the most common histological subtype of non-Hodgkin's lymphoma, and gastrointestinal DLBCL is a frequent form of extranodal lymphoma. We hereby report a rare case of DLBCL showing various neurological symptoms and diagnosed by kidney and bone marrow biopsy.

Case Description: A 38-year-old Japanese male developed disturbance in gait, general fatigue, and nausea. He also developed urinary disturbance, and saw a neurologist. Physical examination revealed patellar tendon hyperreflexia, and paresthesia in both legs. Blood test showed increased alkaline phosphatase, lactate dehydrogenase, C reactive protein and soluble interlueukin-2 receptor levels. Thoracolumbar MRI revealed high intensity area in Th11, and brain MRI revealed multiple white matter lesions, suggesting malignant lymphoma (ML). The patient was transferred to our hospital for further examination. Random skin biopsy, and cytology of cerebrospinal fluid failed to diagnose ML. But we found abnormal uptake in bone marrow and bilateral kidneys on positron emission computerized-tomography (PET). Although urinary abnormalities and renal dysfunction were not evident, we performed percutaneous kidney biopsy as well as bone marrow biopsy. Kidney biopsy sample included six glomeruli in which one showed global sclerosis, and five non-sclerotic glomeruli did not show any abnormal findings. Moderate lymphoplasmacytic interstitial infiltration and minimal interstitial fibrosis/tubular atrophy were noted. The most striking finding on kidney biopsy was atypical cells localized in peritubular capillaries. We also found atypical cells in bone marrow, and the diagnosis of DLBCL was made. The patinet was treated with systemic chemotherapy and up-front auto peripheral blood stem cell transplantation (PBSCT), finally complete remission was achieved.

Discussion: This case serves as a reminder of the differential diagnosis of ML, and the usefulness of kidney biopsy to confirm diagnosis when a patient presents abnormal uptake in the kidney on PET.

SA-PO080

Post Transplant Mucormycosis: A Case Series of Four Patients with Pulmonary and Rhino-Orbital Involvement Louisette Soussan, Christopher Richard Kern, Gregory Malat, Dong Heun Lee, Alden Michael Doyle, Karthik M. Ranganna, Sandeep Aggarwal. *Transplant Nephrology, Drexel Univ College of Medicine.*

Introduction: Mucormycosis is a rare but fatal fungal infection that occurs in immunocompromised patients. Risk factors include DM, malignancies, radiation, cirrhosis, AKI, immunosuppression, neutropenia, burns/trauma, transplants and malnutrition. Here, we report 4 cases of Mucormycosis infection in kidney transplant recipients.

Case Description: All patients received Thymoglobulin (6mg/kg) as induction therapy. For maintenance immunosuppression, all received Tacrolimus (goal 6-8) and Prednisone 5 mg and either Mycophenolate mofetil (3 patients) or Azathioprine (1 patient). All patients were on standard immunoprophylaxis. Mean creatinine was 1.28±0.47 mg/dL. Mean HbA1C during the post-transplant period was 6.43±1.02. Median time from transplant to infection was 470 days (IQR 193, 853). All patients were treated with liposomal Amphotericin B; in addition, two received Isavuconazonium. Demographics/Individual patient data in table 1.

Age (years)	Sex	Ethnicity	Etiology of ESRD	Site of Infection	Specific Risk Factors	Comments
63	F	Black	DM	Rhino-orbital	Chronic mastoiditis /Cholesteatoma	ocular enucleation
65	M	Black	HTN	Disseminated Pulmonary	COPD/inhaled steroids	h/o RCC
74	F	Indian	DM	Rhino-orbital	Thyroid radiation/ epidural steroid injections	h/o BK viremia
65	M	White	DM	Localized Pulmonary	COPD/inhaled steroids	Had episode of AHR & received PLEX/ IVIG & Rituximab

Cell cycle inhibitors were stopped. Tacrolimus dose was reduced with levels maintained around 2-5 ng/mL. Both patients with pulmonary Mucormycosis died. One of the two patients with rhino-orbital disease survived requiring enucleation of the eye with resolution of infection and a functioning allograft.

Discussion: Mucormycosis, though a rare fungal infection, can result in a fatal outcome in kidney transplant recipients. In patients with risk factors, high clinical suspicion is essential for early diagnosis . Prompt use of adequate antifungal therapy along with surgical debridement/resection is critical for better outcomes.

SA-PO081

Development of a Functional Glomerulus at the Organ Level on a Chip to Mimic Hypertensive Nephropathy Mengying Zhou. *Dept of Nephrology, The First Affiliated Hospital of Dalian Medical Univ, Dalian, Liaoning, China.*

Introduction: To develop a microfluidic rapid evaluating of multi-inductors device to reproduce the structure and function of glomeruli. And studying the effect of glomerular hemodynamic on glometular filtration function under hypertension by microfluidic devise.

Case Description: This device consists of PDMS and polycarbonate membrane. Glomerular endothelial cell (MGEC) and podocyte (MPC-5) were co-cultured on the chip. MGEC cells and MPC-5 cells of each culiture unit were incubated under flow rate of 5μl/min, 10μl/min, 15μl/min medium. After 0h, 6h, 12h and 24h, the function of GFB were detected by liuorescence microplate, the expression of F-actin, CD-31, vWF of MGEC cells and F-actin, synaptopodin, nephrin, podocin of MPC-5 cells weredetected by immunofluorescent staining.The cell apoptosis was assessed by DAPI staining.

Compared with traditional cell-culture, MGEC cells and MPC-5 cells grew well and morphological features showed no significant change cell apoptosis.When MGEC cells and MPC-5 cells were treated with medium under 20μl/min, the function of GFB was promoted and the distribution of F-actin was changed. When MGEC cells and MPC-5 cells were treated with medium under flow rate of 10μl/min and 15μl/min.The function of GFB was impaired and the distribution of F-actin was changed obviously. CD-31 decreased and vWF increased progressively over flow rate increasing and time extend. Nephrin and podocin, markers of MPC-5 cells, deceased progressively over flow rate increasing and time($P<0.05$). The cell apoptosis increased under 15μl/min for 24h ($P<0.05$).

Discussion: This work provides an reappearance of the hypertransfusion, high filtration and high transmembrane pressure in glomerular capillary when hypertension leads to renal blood flow decompensation by adjusting the fluid infusion speed on glomerular microfluidic device which confirmed directly that the abnormal hemodynamic factors can degrade GFB function by injuring the skelemin of endothelial cells and podocytes and ligandin between cells.

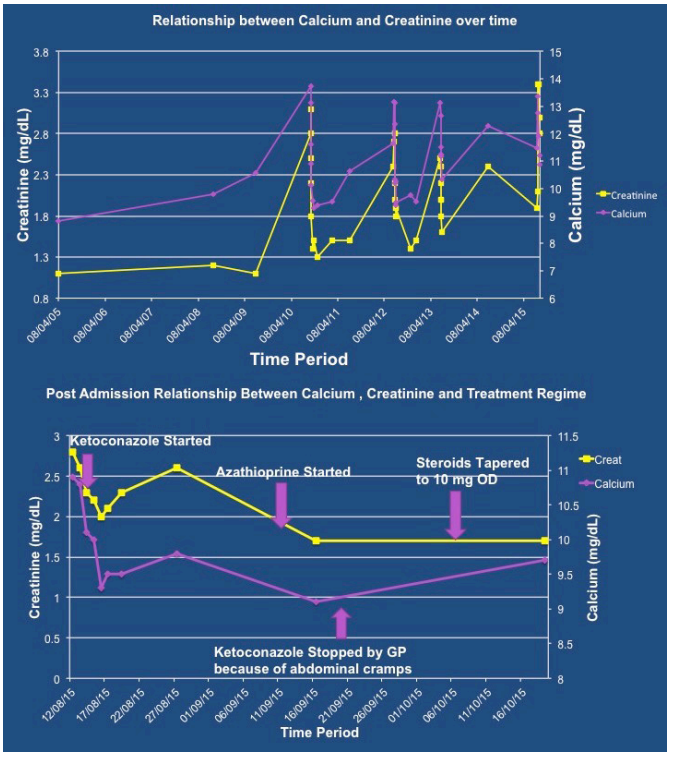
SA-PO082

Treatment in the Absence of Guidelines: Ketoconazole Sucessfully Resolves Hypercalcemia-Associated Acute Kidney Injury in Steroid-Resistant Sarcoidosis: A Case Report Muhammad Umair Sharif,[1,2] Mohamed Elsayed,[1,2] Ahmed Alghali,[1,2] Maurice O'Farrell,[2] Austin G. Stack.[1,2,3] *[1]Graduate Entry Medical School (GEMS), Univ of Limerick, Limerick, Ireland; [2]Dept of Nephrology, Univ Hospital Limerick, Limerick, Ireland; [3]Health Research Inst (HRI), Univ of Limerick, Limerick, Ireland.*

Introduction: Sarcoidosis is a multisystem granulomatous disease of unknown etiology characterized by the presence of non-caseating granulomas. Hypercalcaemia associated with sarcoidosis exhibits seasonal variability with peak incidence during summer months associated with elevated production of 1, 25 $(OH)_2$ Vitamin D. The impact of this on short-term and long-term kidney function and the extent to which it can be managed with corticosteroid treatment is poorly understood.

Case Description: Herein, we report on the case of a 64year male who presented to our unit with acute kidney injury (AKI) (peak creatinine 3.38 mg/dL) and moderate hypercalcemia (peak calcium 13.2 mg/dL) on a background of sarcoidosis, chronic kidney disease (CKD) and type II diabetes. Serum calcium levels failed to normalize despite two-weeks of high dose oral corticosteroid therapy and high volume normal saline infusion. Treatment with oral ketoconazole (200mg once daily) resulted in an immediate and sustained reduction in serum calcium levels with subsequent resolution of his AKI. A careful review of the patient's previous ten-year medical history revealed a seasonal pattern to his hypercalcemic episodes, corresponding with maximum daylight hours and triggering severe AKI.



Discussion: This report demonstrates the need for 1) vigilant monitoring of serum calcium levels among patients with sarcoidosis especially during summer months, 2) normalization of hypercalcaemia to prevent AKI, 3) the efficacy of ketoconazole in steroid-resistant hypercalcaemia, and the need for 4) frequent longitudinal surveillance of kidney function in sarcoidosis.

Phospholipase C γ 2 Is Required for the Renal Adaptation to Alkalosis
Nicolas Picard,[1] Igor E. Deyev,[2] Pascal Houillier,[1] Alexander Petrenko.[2] *[1]Centre de Recherche des Cordeliers, INSERM/CNRS, Paris, France; [2]Laboratory of Receptor Cell Biology, Inst of Bioorganic Chemistry, Moscow, Russian Federation.*

Background: Renal intercalated cells contribute to renal acid and base handling by modulating proton or bicarbonate secretion in the distal nephron. Bicarbonate loading stimulates bicarbonate secretion by β-intercalated cells (β-IC). To better understand the regulation of such processes, transcriptomic analysis of mouse connecting tubule (CNT) and collecting duct (CD) was performed to identify novel CNT/CD-enriched gene products. It identified the phospholipase C gamma 2 (PLCG2) as a protein expressed in the CNT/CCD. PLCG2 is part of the transduction pathways activated by membrane receptors such as tyrosine kinase receptors. PLCG2 is usually phosphorylated and its activity parallels its phosphorylation level. This study aims at understanding the role of this enzyme in the distal nephron.

Results: Colocalisation experiments with a specific β-IC marker (Pendrin) indicated that PLCG2 was expressed only in β-IC cells in human and mouse kidney. $NaHCO_3$ loading in the mouse increased renal PLCG2 phosphorylation whereas acid loading decreased it. To assess the role of PLCG2 in bicarbonate handling, PLCG2 null mice ($PLCG2^{-/-}$) were treated by NaHCO3 (0.28M in drinking water) for 14 days. After 3 days of the $NaHCO_3$ load, blood HCO_3^- was higher in $PLCG2^{-/-}$ mice than in $PLCG2^{+/+}$ ($PLCG2^{+/+}$ 27.6 ± 2.1 mM vs $PLCG2^{-/-}$ 33.6 ± 1.7 mM $p<0.05$). Blood HCO_3^- difference persisted after 14 days of $NaHCO_3$ treatment ($PLCG2^{+/+}$ 27.4 ± 0.8 mM vs $PLCG2^{-/-}$ 32.0 ± 1.5 mM $p<0.05$). Insulin receptor-related receptor (IRR) is a receptor tyrosine kinase activated by alkaline pH and is specifically expressed in β-IC where it increases distal bicarbonate secretion. Overexpression of both IRR and PLCG2 in HEK293 cells stimulated PLCG2 phosphorylation upon exposure to an alkaline medium. IRR inhibition by linsitinib blunted the effect of the alkaline medium on PLCG2 phosphorylation.

Conclusions: Overall, we propose that PLCG2 is important for the renal adaptation to alkaline load and may be part of the signaling pathway downstream to IRR in renal intercalated cells.

SA-PO084

Monophosphoryl Lipid A Prevents Inhibition of Bicarbonate Absorption by LPS in Medullary Thick Ascending Limb (MTAL) Through a TLR4-PI3K-Akt Pathway
Bruns A. Watts,[1] Thampi George,[1] Edward R. Sherwood,[2] David W. Good.[1] *[1]Univ TX Medical Branch; [2]Vanderbilt Univ Medical Center.*

Background: Monophosphoryl lipid A (MPLA) is a detoxified derivative of LPS that is used as a vaccine adjuvant in humans due to its immunomodulatory properties. MPLA functions as a TLR4 agonist to augment the innate host response to infection and pretreatment with MPLA reduces inflammation and increases survival in models of sepsis and endotoxemia. Whether MPLA may protect against sepsis- or LPS-induced kidney dysfunction is not known. Previously we demonstrated that LPS inhibits HCO_3^- absorption in the MTAL through a basolateral TLR4-ERK signaling pathway. Here we examined whether pretreatment of MTALs with MPLA would attenuate the effect of LPS to inhibit HCO_3^- absorption and the mechanisms involved.

Results: MTALs from rats were perfused in vitro with MPLA (1 µg/ml) in bath and lumen or bath alone for 2 hr, then LPS was added to (and MPLA removed from) the bath solution. Pretreatment with MPLA eliminated the effect of LPS to inhibit HCO_3^- absorption. In contrast, in MTALs pretreated with MPLA plus a phosphatidylinositol 3-kinase (PI3K) or Akt inhibitor, LPS decreased HCO_3^- absorption by 26%. Treatment with MPLA increased Akt phosphorylation 1.4-fold in dissected MTALs. The activation of Akt by MPLA was eliminated by a PI3K inhibitor and in MTALs from TLR4-deficient mice. Pretreatment of MTALs with MPLA prevented LPS-induced ERK activation; this effect of MPLA was eliminated by a PI3K inhibitor. Thus, blocking activation of PI3K or Akt by MPLA restored the ability of LPS to activate ERK and inhibit HCO_3^- absorption in MPLA-treated MTALs. MPLA alone had no effect on HCO_3^- absorption, indicating an ability of MPLA to convey resistance to LPS without inherent toxicity.

Conclusions: We conclude that pretreatment with MPLA prevents the effect of LPS to inhibit HCO_3^- absorption in the MTAL. This effect is mediated through MPLA stimulation of a TLR4-PI3K-Akt pathway, which prevents LPS-induced ERK activation. These studies show that MPLA induces protection against LPS in MTAL cells and identify TLR4-based immunomodulators as potential novel therapeutic agents to prevent or treat sepsis-induced renal tubule dysfunction.

SA-PO085

The NH3-H+ Transport Stoichiometry of Human SLC4A11
Xuesi Max Shao,[2] Liyo Kao,[1] Ira Kurtz.[1] *[1]David Geffen School of Medicine, UCLA, Los Angeles, CA; [2]Dept of Neurobiology, UCLA, Los Angeles, CA.*

Background: SLC4A11 was reported to be capable of functioning as a NH_3-H^+ co-transporter (Zhang et al. 2015) with a transport stoichiometry of 1 NH_3:2 H^+, and a suggested role in renal ammonia handling. The use of conventional reversal potential (E_{rev}) methods without a specific inhibitor to estimate the transport stoichiometry can be inaccurate due to currents mediated by other plasma membrane endogenous channels/electrogenic transporters.

Methods: HEK-293 cells expressing SLC4A11 were whole-cell voltage clamped, and steady state currents were measured at various voltages to obtain the I-V relationships. We first analyzed the I-V relationship using the delta current method (Shao et al. 2014). The NH_4Cl concentration in the patch pipette ($[NH_4Cl]_i$) was 1 mM, and the bath NH_4Cl concentration ($[NH_4Cl]_o$) was switched from 1 mM to 3 mM. The NH_3-H^+ transport stoichiometry was also estimated by recording the I-V relationship of HEK-293 cells expressing SLC4A11 and the I-V relationship of mock-transfected cells, with 1 mM $[NH_4Cl]_i$ and 3 mM $[NH_4Cl]_o$. The SLC4A11-specific IV curve was obtained by subtracting the mean I-V curve of mock-transfected cells from the mean I-V curve of SLC4A11-expressing cells.

Results: Using the delta current method, the NH_3-H^+ transport stoichiometry calculated according to: $2RT/(FV_2)\ln(\Delta I_{V2}/\Delta I_{V1=0})$, was 1 NH_3:2.94 H^+ (n = 14) or ~ 1:3, where ΔI_{V2} is the delta current at V2 = -10 mV, and $\Delta I_{V1=0}$ is the delta current at V1 = 0 mV. In the second series of experiments, the E_{rev} of the SLC4A11-specific I-V curve (SLC4A11-expressing cells, n = 14; mock-transfected cells, n= 8) was -8.6 mV which approximates the expected E_{rev} value of -9.3 mV for a 1 NH_3:3 H^+ stoichiometry calculated according to: $RT/(F(Z_p p+Z_q q))\ln(([NH_3]_i/[NH_3]_o)^p([H^+]_i/[H^+]_o)^q)$ when p = 1 and q = 3; where p is the stoichiometry of NH_3, q is the stoichiometry of H^+, Z_p is the valence of NH_3 (Z_p = 0), and Z_q is the valence of H^+ (Z_q = 1).

Conclusions: We used two independent methods to determine the NH_3-H^+ transport stoichiometry of SLC4A11 that correct for bias due to endogenous channel/transporter currents. Our results consistently demonstrate that the SLC4A11 transport stoichiometry is 1 NH_3:3 H^+.

SA-PO086

Normal Intrinsic Na/HCO3 Cotransport Activity but Altered Plasma Membrane Abundance of Phosphomimetic NBCe1-A Mutants
Evan J. Myers, Aniko Marshall, Mark Parker. *Physiology and Biophysics, SUNY at Buffalo, Buffalo, NY.*

Background: Renal phosphoproteomic studies by others have revealed two in-vivo phosphorylation sites (Ser982 and Ser985) on the cytosolic C-terminus of the renal Na/HCO_3 cotransport NBCe1-A that can exhibit a phosphorylated state either individually (pS982 or pS985) or in tandem (pS982/pS985). Others have suggested that dephosphorylation of Ser982 can change the Na:HCO_3 stoichiometry from 1:2 (as observed in most heterologous expression systems) to 1:3 (as predicted, but rarely observed, in kidney cells).

Methods: In order to probe the phosphorylation status of the NBCe1-A C-terminus in our experiments, we generatednovel phosphospecific antibodies designed to detect the singly phosphorylated state pS982/S985 or the doubly phosphorylated state pS982/pS985. We also created a series of EGFP-tagged phosphomimetic mutants D982/A985, D982/D985, A982/D985, and A982/A985. To investigate the consequence of phosphorylation, we performed western blotting on cell extracts, two-electrode voltage clamp on *Xenopus* oocytes heterologously expressing NBCe1-A, and immunofluorescence on MDCK-II cells.

Results: We detected both phosphorylation states of NBCe1-A in mouse kidney and *Xenopus* oocytes. Our electrophysiological studies reveal that all phosphomimetic mutants exhibit a similar per-molecule HCO_3-dependent cotransport activity and a reversal potential consistent with a 1:2 stoichiometry. However, biotinylation assays and fluorescence microscopy on oocytes reveal significant differences in plasma membrane abundance among the mutants, notably A982/D985 was least abundant (75% less abundant than D982/D985). In polarized MDCK-II cells all mutants except A982/D985 consistently localized to the basolateral membrane; 3 of 6 cells transfected with A982/D985 exhibited evidence of intracellular NBCe1-A retention.

Conclusions: Our data confirm that Ser982 and Ser985 are phosphorylated in vivo and suggests that the phosphorylation status of Ser982 influences plasma membrane abundance but not activity. Our antibodies will allow us to probe changes in the phosphorylation state of these two residues in response to physiological and pathological cues.

SA-PO087

Proximal Tubule Glutamine Synthetase Expression Is Necessary for the Normal Response to Dietary Protein Restriction Hyun-Wook Lee,[1] Gunars Osis,[1] Mary E. Handlogten,[1] Chao Chen,[1] Jill W. Verlander,[1] I. David Weiner.[1,2] *[1]Nephrology, Univ of Florida College of Medicine, Gainesville, FL; [2]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Background: Dietary protein restriction has multiple benefits in kidney disease. Because protein intake is a major determinant of endogenous acid production, it is important that net acid excretion decreases during protein restriction. Glutamine synthetase (GS) catalyzes the reaction of NH_4^+ and glutamate, which regenerates the essential amino acid, glutamine, and can decrease net ammoniagenesis. GS is highly expressed in the proximal tubule, and its expression increases during dietary protein restriction. This suggests ammonia recycling via GS during protein restriction could decrease net ammoniagenesis and decrease ammonia excretion. The current study's purpose was to determine proximal tubule GS's role in the renal response to protein restriction.

Methods: We generated mice with proximal tubule-specific GS deletion (PT-GS-KO) using Cre-loxP techniques. Cre-negative control (C) and PT-GS-KO mice in metabolic cages were fed 20% protein diet for 2 days and were then changed to low protein (6%) diet for the next 7 days. Additional PT-GS-KO mice were maintained on 20% protein diet.

Results: Dietary protein restriction caused a rapid decrease in urinary ammonia in both genotypes, but the decrease was significantly less in PT-GS-KO mice. There were no significant genotype-dependent differences in urinary pH or volume, or in ABG parameters. Immunoblot analyses of cortical and medullary homogenates from mice fed 6% protein showed no differences between C and PT-GS-KO mice in expression of other proteins involved in renal ammonia handling, including NHE3, PDG, PEPCK, NKCC2 and Rhbg. In PT-GS-KO mice fed either 20% or 6% protein diet, mice fed 6% protein had decreased discrete apical H-ATPase a4 subunit, apical Rhcg and basolateral Rhbg immunolabel in medullary collecting duct intercalated cells compared to 20% protein fed mice, consistent with decreased H^+ and NH_3 transport mediated ammonia secretion.

Conclusions: Proximal tubule glutamine synthetase is necessary for the expected decrease in ammonia excretion during dietary protein restriction.

Expression of Sodium-Dependent Dicarboxylate Transporter 1 (NaDC1/SLC13A2) in Normal and Neoplastic Human Kidney Hyun-Wook Lee,[1] Gunars Osis,[1] Mary E. Handlogten,[1] William L. Clapp,[2] Dara N. Wakefield,[2] Jill W. Verlander,[1] I. David Weiner.[1,3] *[1]Nephrology, Univ of Florida College of Medicine, Gainesville, FL; [2]Pathology, Univ of Florida College of Medicine, Gainesville, FL; [3]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Background: Regulated citrate excretion is critical to acid-base homeostasis and to prevention of calcium nephrolithiasis. Luminal citrate reabsorption via NaDC1 is believed to be the primary mechanism regulating renal citrate excretion. However, the cellular distribution of NaDC1 expression in human kidneys has not been reported previously. The purpose of the present study was to determine the expression of NaDC1 in normal and neoplastic human kidneys.

Methods: We used commercially available human kidney protein lysates for immunoblot analysis and used kidneys removed for routine clinical treatment that were no longer needed for diagnostic purposes for immunohistochemical analyses. We used previously described anti-NaDC1 antibodies validated for specificity using NaDC1 knockout mice.

Results: Immunoblot analysis of human whole kidney and cortical protein isolates demonstrated expression of a protein of ~58 kDa. Immunohistochemistry showed apical NaDC1 immunolabel in the proximal tubule of normal human kidney tissue; well-preserved proximal tubule brush border was clearly labeled. We confirmed proximal tubule localization by double-immunolabel with antibodies to NBCe1. No NaDC1 immunolabel was detected in other renal cells. NaDC1 immunolabel was not detected in renal tumors of presumed proximal tubule origin, clear cell and papillary renal cell carcinoma.

Conclusions: In summary: 1) this is the first study reporting the cellular expression of NaDC1 in the human kidney; 2) in human kidney, NaDC1 is present in the apical region of the proximal tubule including the brush border, which is identical to NaDC1 distribution in mouse and rat kidney; and, 3) detectable NaDC1 immunolabel is not present in renal cell carcinoma derived from proximal tubule cells, likely indicating cellular dedifferentiation. These studies support a similar role for NaDC1 in the human kidney as identified in experimental rodent studies.

In Silico and In Vitro Characterization of Low pH-Induced Genes in Intercalated Cells of the Collecting Ducts Yuichiro Izumi,[1] Koji Eguchi,[1] Naomi Matsuo,[1] Yushi Nakayama,[1] Hideki Inoue,[1] Hiroshi Nonoguchi,[2] Yutaka Kakizoe,[1] Takashige Kuwabara,[1] Masashi Mukoyama.[1] *[1]Dept of Nephrology, Kumamoto Univ, Kumamoto, Japan; [2]Dept of Internal Medicine, Kitasato Univ Medical Center, Saitama, Japan.*

Background: Recent studies have suggested that metabolic acidosis exacerbates chronic kidney disease. Dietary acid intake accumulates acids in interstitium of the kidney. The effect of low pH on renal tubular cells is unclear. We have presented transcriptional start site-sequencing (TSS-Seq) of low pH-induced gene transcripts in the intercalated cells of the collecting ducts at Kidney Week 2015. In the present study, we further performed comprehensive analyses to characterize the global effect of low pH on intercalated cells and molecular biology experiments to support the findings obtained from the analyses.

Methods: We performed Gene Ontology (GO) and motif analyses for low pH-induced gene transcripts obtained from TSS-Seq using a rat intercalated cell line (IN-IC cells) that are incubated either in pH 7.4 or 7.0 for 24h. To evaluate ubiquitin-proteasome pathway, cells were incubated either in pH 7.4 or 7.0 for 12h, then further incubated in the presence of MG132, a proteasome inhibitor, for 8h. Western blotting was examined using anti-ubiquitin antibody. Quantitative PCR was examined to measure the expressions of specific mRNAs after cells were incubated either in pH 7.4 or 7.0.

Results: GO analysis showed the enrichment of genes that are classified into "programmed cell death": Fgf2, Jak2, Tgm2, and Gclc. Those genes are known to be involved in renal fibrosis. We found many ubiquitin-proteasome system (UPS)-related genes up-regulated by low pH: six ubiquitin protein ligases, five ubiquitin conjugating enzymes, two deubiquitinating enzymes, and four other genes involved in UPS. Western blot showed that low pH induced global ubiquitination of protein. Motif analysis predicted motif sequences associated with low pH-induced transcription that possibly interact with specific transcription factors such as EGR1, SP1, and KLF5. We found that the expression of EGR1 mRNA was immediately increased by low pH in 2h.

Conclusions: The results implied various possible mechanisms that are involved in acidosis-induced renal injury.

Why Does SLC26A7 Not Compensate the Loss of kAE1 in Distal Renal Tubular Acidosis? A.K.M. Shahid Ullah,[1] Rawad Lashhab,[1] Jennifer C. King,[3] Valentina Peleh,[2] Johannes M. Herrmann,[2] R. Todd Alexander,[1] Emmanuelle Cordat.[1] *[1]Dept of Physiology, Univ of Alberta, Edmonton, AB, Canada; [2]Cellular Biology, Univ of Kaiserslautern, Kaiserslautern, Germany; [3]Univ of Calgary, Calgary, AB, Canada.*

Background: SLC26A7 and kidney anion exchanger 1 (kAE1) proteins are Cl^-/HCO_3^- exchangers that are both expressed at the basolateral membrane of the α-intercalated cells in the medullary collecting duct of the kidney. Mutations in the kAE1 gene or knockout of the SLC26A7 gene can cause distal renal tubular acidosis (dRTA) in humans and mice, respectively. This study aimed to clarify the role of the SLC26A7 protein in renal epithelial cells under physiological or pathological conditions. We hypothesized that the SLC26A7 activity is compromised in dRTA patients due to the loss of kAE1.

Methods: MDCK cells expressing SLC26A7 were grown in either normal, hypertonic or acidic growth conditions to mimic the medulla and dRTA environment, respectively, and the protein were examined by immunoblot. kAE1 or SLC26A7 functions were examined using the pH-sensitive fluorescent probe BCECF-AM.

Results: Comparison of SLC26A7 or kAE1 abundance when expressed in Madin-Darby Canine Kidney (MDCK) cells grown in normal or hypertonic conditions showed that, in contrast with kAE1, SLC26A7 is upregulated by hyperosmotic conditions. Functional assays showed an increase in the SLC26A7 anion exchange activity after incubation in hypertonic conditions. However, growing MDCK cells under acidic conditions, as occurs in dRTA patients, resulted in decreased abundance of SLC26A7 suggesting that in dRTA patients, SLC26A7 is downregulated and unable to compensate for the loss of kAE1 protein. Furthermore, total anion transport was reduced in cells co-expressing both SLC26A7 and kAE1 R901X dRTA mutant compared to cells expressing individual proteins, suggesting an inhibitory effect of one protein on the other when co-expressed.

Conclusions: This study provides insight into the physiological role of SLC26A7 in kidney epithelial cells under various hyperosmotic or low extracellular pH conditions and thus an explanation for the lack of a compensatory effect of SLC26A7 in dRTA patients.

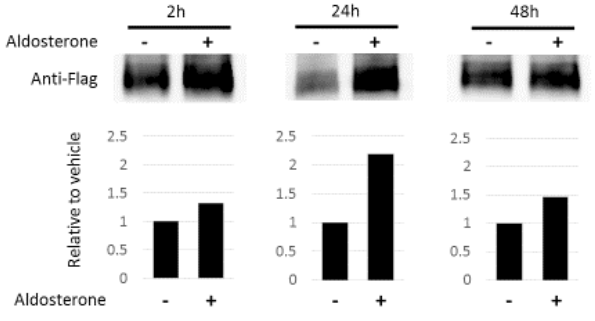
Involvement of Aldosterone and the Ubiquitin-Proteasome System in the Regulation of Expression of an Ammonia Transporter, Rhesus Blood Group C Glycoprotein, in the Intercalated Cells Koji Eguchi, Yuichiro Izumi, Yushi Nakayama, Hideki Inoue, Yutaka Kakizoe, Takashige Kuwabara, Naomi Matsuo, Terumasa Nakagawa, Masashi Mukoyama. *Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Acid-base balance is regulated by aldosterone which stimulates acid secretion in the intercalated cells of the collecting ducts of the kidney. Rhesus blood group C glycoprotein (Rhcg) is an ammonia transporter which cooperates with H^+-ATPase to secrete H^+ from the intercalated cells. We presented in Kidney Week 2015 that aldosterone induces the expression of Rhcg in membrane fraction *in vivo* and *in vitro*. In the present study, we further investigated the regulation mechanism of Rhcg.

Methods: We established a cell population of IN-IC cells (a rat intercalated cell line) stably expressing mouse Flag-tagged Rhcg (Rhcg-Flag). Cells were treated with aldosterone (10^{-6} M) for 2, 24, and 48 h, and then membrane fraction was extracted. To see whether the ubiquitin-proteasome system (UPS) is involved in the regulation of Rhcg, cells were treated with MG132, a proteasome inhibitor, and whole cell lysates were extracted. Immunoprecipitation using anti-Flag antibody was performed to examine coimmunoprecipitation with ubiquitin. Western blotting was applied with anti-Flag and anti-ubiquitin antibodies.

Results: Treatment with aldosterone increased the expression of Rhcg-Flag in membrane fraction by 30, 120, and 50 % at 2, 24, and 48 h, respectively.



Treatment with MG132 (5 to 50 uM) increased the expression of Rhcg-Flag protein in whole cell lysates in a dose dependent manner. Immunoprecipitation showed that Rhcg-Flag was coimmunoprecipitated with ubiquitin.

Conclusions: These results indicate that aldosterone and UPS should regulate the expression of Rhcg protein, suggesting a crosstalk between aldosterone and UPS in the intercalated cells.

SA-PO092

The Stimulation of Ammoniagenesis Plays an Important Role in the Development of Renal Hypertrophy in Diabetes Mellitus Hassane Amlal, Sihame Amlal, Sulaiman Sheriff. *Internal Medicine, Univ of Cincinnati, Cincinnati, OH.*

Background: Studies have shown that total ammonia ($NH_4^+ + NH_3$) causes renal cell hypertrophy *in vitro* and that diabetes mellitus (DM) is associated with an early increase in kidney mass. However, whether hyperglycemia-induced ammoniagenesis plays a role in the development of early renal hypertrophy in DM remains elusive.

Methods: Rats treated with streptozotocin (STZ) and Akita mice and their wild-type (Type I DM); *ob/ob* mice and their lean controls (Type II DM) and adenine-treated rats (model of renal failure) and their controls were housed in metabolic cages for food and water balance studies. Urinary NH_4^+ excretion was analyzed and correlated with changes in kidney mass (kidney weight/BW).

Results: STZ-treated rats exhibited a significant increase in Kidney mass, which correlated with a 4-fold increase in urinary NH_4^+ excretion as early as 6 days of hyperglycemia. The stimulation of ammoniagenesis is corrected by insulin treatment. Hyperglycemic Akita mice showed a 4-fold increase in NH_4^+ excretion at 4 weeks and kidney mass doubled at 9 weeks of age vs. wild-type mice. Similarly, *ob/ob* mice exhibited a sharp hyperglycemia which correlated with a 7-fold increase in NH_4^+ excretion with significant increase in kidney mass at 9 weeks of age vs. lean mice. Lastly, normoglycemic adenine-treated rats exhibited a sharp increase in ammoniagenesis with 32% increase in kidney mass after 1 week of treatment vs. controls.

Conclusions: The development of renal hypertrophy correlates with early hyperglycemia-induced ammoniagenesis in both type I and type II DM models. The stimulation of ammoniagenesis also correlated with early renal hypertrophy in the adenine fed rat model known to progress to renal failure. Hence, ammoniagenesis likely contributes to the development of early renal hypertrophy, which subsequent progresses to kidney disease in diabetes mellitus and in the adenine-fed animals.

Interaction of the Renal NH3/NH4+ Transporters Rh Glycoproteins with Cellular Proteins Involved in Acid-Base Homeostasis Nazih L. Nakhoul,[1,2] L. Lee Hamm,[1] Karen Brown,[1] Solange Abdulnour-Nakhoul.[1,2] *[1]Medicine, Tulane Medical School, New Orleans, LA; [2]SLVHCS.*

Background: Renal excretion of NH_4^+ accounts for at least two-thirds of net acid excretion and increases significantly during acid loads. In the collecting duct, two Rh glycoproteins, Rhbg and Rhcg, expressed in the intercalated cells are involved in trans-cellular NH_3 and NH_4^+ transport. Our earlier studies showed that Rhbg transported NH_4^+ and NH_3, whereas Rhcg predominantly transported NH_3. Little is known about regulation of these transporters. Recent data indicate that Rh proteins may interact with other cellular proteins. In this study, we examined whether Rhbg and Rhcg associate with specific membrane proteins known to affect acid-base transport.

Methods: We determined the association of Rhcg with pendrin (both at the apical membrane) and Rhbg and Rhcg with carbonic anhydrases (CA IV & CA II). We used immunohistochemistry to co-localize Rhbg, CA IV, CA II and pendrin in mouse kidney sections. We then used co-immunoprecipitation of kidney lysates from either medulla or cortex to investigate the association of the specific proteins with Rh transporters.

Results: We used Rhbg antibody (Rhbg-ab) bound to activated magnetic beads to pull down CA IV and Rhcg-ab to pull down pendrin. The reverse configuration and appropriate controls were also used. The eluates were examined by Western analysis. The blots showed positive staining for Rhbg in the eluates when Rhbg or CA IV antibodies were coupled to the beads, and positive staining for CA IV when CA IV or Rhbg antibodies were on the beads. Similar results were obtained with pendrin and Rhcg. Immuno-precipitating Rhcg with H-ATPase was negative. To confirm the co-IP results we demonstrated that pulled-down Rhbg band was glycosylated (at 50 KD) and that it can be de-glycosylated (to 37 KD) similar to the native Rhbg in kidney lysates. Lastly, using pH measurements by microelectrodes we showed that co-expressing Rhbg with CA IV in frog oocytes attenuated NH_3/NH_4^+ transport by Rhbg.

Conclusions: These data are consistent with association of Rhbg with CA IV and Rhcg with Pendrin. It is likely that this interaction may affect expression, trafficking or regulation of NH_3/NH_4^+ by the Rh proteins.

Insulin Stimulates Renal Proximal Tubule Sodium Transport via Akt2/mTORC2 Pathway Motonobu Nakamura,[1] Masashi Suzuki,[1] Nobuhiko Satoh,[1] George Seki,[2] Atsushi Suzuki,[1] Yusuke Sato,[3] Yukio Homma,[3] Shoko Horita,[1] Masaomi Nangaku.[1] *[1]Dept of Internal Medicine, The Univ of Tokyo Hospital; [2]Yaizu City Hospital; [3]Dept of Urology, The Univ of Tokyo Hospital.*

Background: We found that the IRS2/PI3K-dependent stimulation of renal proximal tubule (PT) sodium transport by insulin is preserved even in insulin resistance or overt diabetic nephropathy (JASN 16, 2005, Kidney Int 87, 2015, BBRC 461, 2015), indicating that hyperinsulinemia, by facilitating sodium retention, may contribute to hypertension associated with these pathological conditions. The roles of Akt isoforms or mammalian target of rapamycin complex (mTORC1/2) have been well established in insulin-stimulated glucose uptake into adipocytes. However, the roles of these protein kinases in insulin-mediated PT sodium transport regulation remain unknown.

Methods: By monitoring cell pH decrease in response to bath HCO_3 reduction with a pH-sensitive dye BCECF, we measured Na-HCO_3 cotransporter (NBCe1) activity in freshly-isolated rat PTs or human PTs obtained during surgery for renal cell carcinoma. For rat PTs, we also measured NBCe1 activity after 24-hr incubation with siRNA against Akt1, Akt2, Raptor (an mTORC1 component), or Rictor (an mTORC2 component).

Results: In freshly-isolated rat and human PTs 10^{-8} M insulin induced 50-80% increase in NBCe1 activity above baseline, and this stimulation was completely suppressed by Akt1/2 inhibitor VIII. Furthermore, incubation with siRNA against Akt2, but not Akt1, completely suppressed the stimulatory effect of insulin in rat PTs. While an mTORC1/2 inhibitor PP242 completely suppressed the insulin-mediated NBCe1 stimulation in rat and human PTs, an mTORC1-specific inhibitor rapamycin failed to affect the insulin effect. Moreover, siRNA against Rictor, but not Raptor, completely suppressed the insulin-mediated NBCe1 stimulation in rat PTs. Consistent with the essential roles of Akt2 and mTORC2, Akt1/2 inhibitor VIII and PP242, but not rapamycin, strongly suppressed the insulin-induced Akt Ser^{473} phosphorylation in renal cortex of rats and humans.

Conclusions: Stimulation of PT sodium transport by insulin is mediated via Akt2/mTORC2 pathway, which may be a therapeutic target for hypertension in metabolic syndrome.

Gprc5c - A Renal GPR Involved in Systemic pH Homeostasis Premraj Rajkumar,[1] Boyoung Cha,[2] Mark Donowitz,[2] Jennifer L. Pluznick.[1] *[1]Physiology, Johns Hopkins SOM, Baltimore; [2]Medicine & Physiology, Johns Hopkins SOM, Baltimore; [3]Molecular Membrane Neuroscience, RIKEN Brain Science Inst, Japan.*

Background: Recent studies have identified orphan G-protein coupled receptors (GPRs) as sensors of physiological metabolites. Our goal is to elucidate the functional role of an understudied renal GPR, Gprc5c, which we previously found to be highly expressed in the kidney (Rajkumar et al., 2014).

Methods: Immunofluorescence (IF) was performed on mouse kidney sections. Ligand-induced GPCR internalization assays were performed in HEK293T cells. Blood pH and electrolytes were measured using iSTAT (CG4+ & CHEM8+) and blood pressure by tail cuff. Ratiometric fluorescence was measured in BCECF-AM loaded HEK293T cells using a PTI spectrofluorometer.

Results: We find that Gprc5c localizes to the apical renal proximal tubules (PTs) in wild-type (WT) mice by IF, where it colocalizes with two PT markers - LTA & megalin. Staining was absent in Gprc5c knockout (KO) mice. In an *in vitro* assay, alkaline pH (but not other chemicals tested) triggered Gprc5c internalization (an index of activation), with maximal internalization seen above pH 7.4 (pH 8.0>pH 7.4>pH 6.5). Other GPCRs tested as controls showed no changes in internalization over the pH range tested. *In vivo*, Gprc5c KO were not different from WT with respect to blood pressure, kidney/body weight, blood levels of Na^+, Cl^- & glucose, and urine levels of creatinine & glucose. However, Gprc5c KO had higher urine pH (WT: 5.48±0.01, n=6; KO: 5.81±0.06, n=6; p<0.05). In addition, the blood pH of Gprc5c KO mice trends acidic compared to WT in unanaesthetized mice (WT: 7.44±0.04, n=4; KO: 7.34±0.02, n=4; p=0.07), or in mice under isofluorane (WT: 7.22±0.03, n=5; KO: 7.03±0.04, n=5; p<0.05). Furthermore, in an *in vitro* assay Gprc5c increases sodium proton exchange under alkaline conditions (pH8) by 1.6 fold compared to empty vector controls (p<0.05); this increase is Tenapanor-sensitive, implying that it is mediated via NHE3 (a transporter which localizes apically in the renal PT).

Conclusions: Gprc5c localizes to the renal PTs apically where it contributes to systemic pH homeostasis via modulation of NHE3 function.

Decreased Renal Threshold for Urinary Excretion of Ammonia Underlies Proximal Renal Tubular Acidosis in TASK2 K Channel-Deficient Mice

Yukiko Yasuoka,[1,2] Tomomi Oshima,[1] Yuichi Sato,[3] Masato Ohtsuka,[4] Minoru Kimura,[4] Hiroshi Nonoguchi,[5] Katsumasa Kawahara.[1,2] *[1]Physiol., Kitasato U. Sch. of Med, Sagamihara, Japan; [2]Cell & Mol. Physiol., Kitasato U. Grad. Sch. of Med. Sci., Sagamihara, Japan; [3]Mol. Diag., Kitasato U. Sch. of Allied Health Sci., Sagamihara, Japan; [4]Mol. Life Sci., Tokai U. Sch. of Med, Isehara, Japan; [5]Internal Med., Kitasato U. Medical Center, Kitamoto, Japan.*

Background: TASK2 (TWIK-related acid-sensitive K^+ channel)-deficient ($task2^{-/-}$) mice showed metabolic acidosis (Warth et al, 2004) and may be a good model for proximal renal tubular acidosis (pRTA). However, the pathophysiological mechanism by which this metabolic acidosis occurs has yet to be elucidated.

Methods: In $task2^{+/+}$ (WT) and $task2^{-/-}$ (KO) mice, we investigated the effects of acid/alkali-containing diet on blood and urine data to evaluate the maximum capacity of the renal acid/base transport system. We also investigated the acid/alkali-load-induced changes on immunostainings of carbonic anhydrase type II (CAII) and phosphoenolpyruvate carboxykinase (PEPCK) in the kidney.

Results: We confirmed that KO mice fed normal diets showed hyperchloremic metabolic acidosis (pH 7.24 (KO) vs. pH 7.37 (WT), n=6 each, $P < 0.005$) with negligible urinary excretion of both HCO_3^- (1.1 +/- 0.3 µmol/d) and NH_3/NH_4^+ (1.0 +/- 0.2 mg/mgCre). Interestingly, when WT and KO mice were treated with $NaHCO_3$ for 6 days, plasma pH returned to normal (7.43 +/- 0.01 (WT), 7.38 +/- 0.02 (KO), n=3 each) in association with increased urinary loss of HCO_3^- (60.1 +/- 32.7 (WT) and 136.4 +/- 24.9 µmol/d (KO), $P > 0.05$). On the other hand, when treated with HCl-containing diet for 6 days, the urinary NH_3/NH_4^+ excretion significantly ($P < 0.005$) increased to 15.0 +/- 1.1 (WT) and 15.8 +/- 1.9 mg/mgCre (KO) (n=5 each, vs. Day 0). Most importantly, the renal threshold for urinary NH_3/NH_4^+ excretion significantly decreased by ~0.1 pH unit (plasma) in the KO mice. Moreover, immunostaining of CAII (PT, CCD, OMCD) and PEPCK (PT), faint in normal diet, increased similarly and markedly upon acid-load (6 d).

Conclusions: We conclude that the decreased threshold is caused by inappropriately suppressed ammoniagenesis which is the result of putative intracellular alkalinization in the proximal tubule.

Targeted Deletion of the NCOA7 Gene Results in Incomplete Distal Renal Tubular Acidosis in Mice

Maria Merkulova,[1,2] Teodor G. Paunescu,[1,2] Anil V. Nair,[1,2] Chia-Yu Wang,[1,2] Sylvie Breton,[1,2] Dennis Brown.[1,2] *[1]Div of Nephrology, Mass. Gen. Hospital; [2]Harvard Medical School, Boston, MA.*

Background: Primary distal renal tubular acidosis (dRTA) is a rare disease with various levels of severity from growth retardation in its complete form to almost asymptomatic when it is incomplete. Three genes, SLC4A1, ATP6V1B1 and ATP6V0A4, are known to cause this disease in humans. However in some dRTA cases no mutations in any of them have been found, suggesting that other genes are involved. By generating a renal V-ATPase interactome, we recently discovered that several novel proteins (including NCOA7, nuclear receptor coactivator-7 of unknown function) interact with ATP6V1B1 and may regulate V-ATPase function.

Methods: To study if deletion of the NCOA7 gene can cause dRTA, blood pH and bicarbonate (HCO3) levels, and urine pH were compared in wild type (WT) mice and NCOA7 knockout (KO) mice fed a standard rodent diet and after acid loading with ammonium chloride (NH4Cl) for 3 days. Kidney intercalated cells were examined by immunofluorescence microscopy with anti-V-ATPase antibodies.

Results: On the standard diet, there was no significant difference between WT and KO mice in blood pH (7.26±0.07 vs 7.26±0.06) and HCO3 level (20.31±2.79 vs 20.43±2.79 mM), but urine pH was significantly higher in KO than in WT (6.98±0.56 vs 6.15±0.39). At the microscopic level, intercalated cells in the inner stripe of outer medulla were larger and formed continuous rows in NCOA7 KO compared to WT mice, a phenotype previously associated with acidosis. When WT and KO mice were challenged with NH4Cl, their blood pH was slightly reduced to a similar degree (7.23±0.08 and 7.22±0.10 respectively). HCO3 levels were reduced in WT but even more in KO mice (17.58±3.31 and 14.71±3.70 mM). pCO2 levels were also lower in NCOA7 KO (36.46±6.14 vs 43.43±6.04 mmHg). Urine pH was reduced after NH4Cl treatment in both WT and KO mice, but was still higher in KO mice (5.88±0.10 vs 5.60±0.15).

Conclusions: NCOA7 KO mice do not maximally acidify their urine and demonstrate incomplete dRTA. This suggests that the NCOA7 gene may play a role in regulating V-ATPase induced urinary acidification.

Maternal Acidosis Directs Intercalated Cell Subtype Distribution in Young Progeny

Jeffrey M. Purkerson, Alexandra N. Marasco, George J. Schwartz. *Pediatrics, Univ of Rochester Medical Center, Rochester, NY.*

Background: In the cortical collecting duct (CCD), modulations of acid-base balance are mediated by α and β intercalated cells; α-intercalated cells (IC) secrete protons via a basolateral AE1 and apical B1-VATPase, whereas β-IC secrete bicarbonate via apical pendrin and basolateral H^+-ATPase. A previous study in rats suggested that maternal acid-base status during pregnancy influences intercalated cell differentiation (Narbaitz et al. AJP 264:F415, 1993).

Methods: To confirm and extend this study maternal acidosis was induced in pregnant rabbit does via administration of ammonium chloride in water and food during the 3rd-4th week of gestation, and its effect on intercalated cell differentiation in rabbit progeny at one to three weeks was studied. The numbers of $AE1^+$(α-IC), PND^+(β-IC) and $B1^+$(total IC) per unit length (i.e.100 µm) of CCD were determined in images of immunofluorescent stained kidney sections.

Results: The normal IC subtype distribution in the adult rabbit CCD is α:β, 23%:77%, and this distribution is relatively stable during normal rabbit maturation (1 week old kits: 26%:74%; 3 week old kits: 22%:78%). In contrast, maternal acidosis (5 days) reduced the number of β-IC from 7.4±0.5 in normal control kits to 5.2±0.5/100µm at 1 week and from 9.0±1.0 to 5.9±0.2 in 3 week old kits (p<0.05 Normal®Maternal acidosis. In normal kits and adults there are 2.6±0.1 α-IC/100µm, whereas maternal acidosis increased this number to 3.0±0.3 and 3.1±0.1 in one and three old kits (p<0.05 Normal®Maternal acidosis) such that the IC subtype distribution was 37%:63% and 34%:66%, respectively.

Conclusions: The influence of maternal acidosis on IC subtype differentiation persists for at least several weeks. Whether postnatal acid-base status overrides developmental programming and promotes differentiation of β- over α-subtypes to compensate for the alkaline-rich diet is currently under investigation.

SA-PO099

The Pseudohypoaldosteronism Type II-Causing Mutant Cul3 Protein Forms Dimer with KLHL3 and Inhibits the Degradation of WNK4 with a Dominant-Negative Effect

Yuya Araki,[1] Tatemitsu Rai,[2] Eisei Sohara,[2] Takayasu Mori,[2] Yuichi Inoue,[2] Yutaro Mori,[2] Shinichi Uchida.[2] *[1]Dept of Nephrology, Ome Municipal General Hospital, Ome-City, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Medical and Dental Univ, Bunkyo-Ku, Tokyo, Japan.*

Background: Pseudohypoaldosteronism type II (PHAII) is a hereditary hypertensive disease caused by mutations in four different genes: WNK1 and 4, KLHL3, and cullin 3 (Cul3). Cul3 and KLHL3 form an E3 ligase complex that ubiquitinates and reduces WNK4 protein. PHAII causing mutation in cullin 3 gene results in the production of Cul3 protein with a 57-amino acid deletion ($Cul3^{\Delta 403\text{-}459}$). However, precise mechanism how $Cul3^{\Delta 403\text{-}459}$ causes PHAII is unclear. And it is controversial whether $Cul3^{\Delta 403\text{-}459}$ is a gain-of-function mutation or loss-of-function mutation.

Methods: We generated and studied the mice which express $Cul3^{\Delta 403\text{-}459}$ by the induction of Cre-loxP recombination. $Cul3^{WT}$ and $Cul3^{\Delta 403\text{-}459}$ constructs carrying the mutation K712R, in which Cul3 neddylation site was mutated, were expressed in HEK293T cell. Co-immunoprecipitation assays were used to assay interaction of $Cul3^{WT}$, $Cul3^{\Delta 403\text{-}459}$, and KLHL3.

Results: We successfully generated $Cul3^{WT/\Delta 403\text{-}459}$ mice. These mice had the phenotype similar to PHAII; hyperkalemia, metabolic acidosis and hypertension. $Cul3^{WT/\Delta 403\text{-}459}$ mice revealed that $Cul3^{\Delta 403\text{-}459}$ were highly neddylated and the expression level of $Cul3^{WT}$ was suppressed than wild type mice. Co-IP assays revealed that $Cul3^{\Delta 403\text{-}459}$ formed a dimer with $Cul3^{WT}$ and KLHL3. While neddylation is generally required for efficient ubiquitylation, $Cul3^{\Delta 403\text{-}459\ K712R}$ mutant also interfered the degradation of WNK4 by $Cul3^{WT}$-KLHL3 complex, though $Cul3^{WT\ K712R}$ did not.

Conclusions: Expression level of $Cul3^{WT}$ was reduced in mutant Cul3 PHAII model mice. Our studies showed that the inactive Cul3 mutant composed complex with $Cul3^{WT}$ and KLHL3 and interfered the degradation of WNK4 with a dominant-negative effect. This dominant-negative inhibition was not dependent on neddylation of Cul3. This may explain why $Cul3^{\Delta 403\text{-}459}$ causes a more severe phenotype than other mutations.

The Corticosteroid-Repressible Protein DCNL4 Promotes WNK Kinase Degradation via the KLHL3/CUL3 Complex Ankita Roy, Lubika J. Nkashama, Cary R. Boyd-Shiwarski, Michael Butterworth, Arohan R. Subramanya. *Univ of Pittsburgh.*

Background: WNK kinases regulate NaCl and K transport in the distal nephron. Abundance of these kinases is controlled by the KLHL3/CUL3 complex, a cullin-RING E3 ligase (CRL) that ubiquitylates the WNKs, marking them for degradation. Little is known about the mechanisms that physiologically regulate KLHL3/CUL3 activity. Mammalian DCN-like (DCNL) proteins are a family of 5 CRL co-activators that promote cullin activity through neddylation. Of these proteins, DCNL4 was identified as a candidate stimulator of KLHL3/CUL3 activity and WNK substrate turnover, as a kidney RNAseq database noted DCNL4 expression in the distal tubule, and 4 independent prediction algorithms identified DCNL4 as a target of miR-27, a corticosteroid-induced microRNA whose activity is linked to cardiovascular disease. Thus, we hypothesized that corticosteroid-mediated repression of DCNL4 might downregulate KLHL3/CUL3 activity, increasing WNK expression and activity in the distal nephron.

Methods: We evaluated DCNL4 expression in the mouse kidney by RT-PCR, IF, and Western. DCNL4 was transiently coexpressed with KLHL3/CUL3 and WNKs in 293 cells to assess CUL3 neddylation and WNK turnover by CHX chase. mCCD cells were treated with aldo (50nM) or a miR27 mimic and DCNL4 mRNA was quantified by qRT-PCR.

Results: Renal DCNL4 was detectable by RT-PCR & immunoblot. Under standard diet, DCNL4 antibodies recognized a strong proximal and distal tubule-specific signal. In 293 cells, DCNL4 enhanced CUL3 neddylation. Compared to KLHL3/CUL3, KLHL3/CUL3/DCNL4 coexpression decreased WNK4 abundance by 80%, via enhanced proteasomal degradation. Consistent with KLHL3/CUL3 dependency, DCNL4 did not reduce WNK4 abundance when it was coexpressed with FHHt-associated KLHL3 mutants that disconnect WNK4 from CUL3. In mCCD cells, aldo and miR27 mimics reduced DCNL4 mRNA by 50%.

Conclusions: These data support a model in which DCN-like proteins trigger the degradation of WNK kinases by potentiating KLHL3/CUL3 complex activity through neddylation. MicroRNA-mediated downregulation of active KLHL3/CUL3/DCNL4 complexes might represent a novel mechanism by which corticosteroid hormones can augment WNK signaling in the distal nephron.

RFxV Motif Analysis in WNK4: Mechanistic Insights into the WNK4-SPAK Pathway Alejandro Rodriguez-Gama, Adrian R. Murillo-de-Ozores, Silvana Bazua-Valenti, Gerardo Gamba, Maria Castañeda-Bueno. *Molecular Physiology Unit, INCMNSZ-IIB-UNAM, Mexico City, Mexico.*

Background: WNK kinases modulate activity of SPAK/OSR1 kinases which in turn regulate SLC12 Cation-Chloride Cotransporters (CCCs). PF2 domains in SPAK/OSR1 can mediate interactions with RFxV motifs present in WNKs and CCCs. WNK kinases present one RFxV motif within the kinase domain (KD) and one or more in the C-terminal region. Elimination of the KD motif of WNK1 or WNK3 impairs their ability to activate SPAK-NCC without affecting kinase activity. The functional consequence of the absence of C-terminal RFxV motifs in full-length WNK1 and WNK4 has not been tested. Here we addressed the role of each of the two RFxV motifs present in WNK4. We also investigated the role of the WNK4's PF2-like domains which may have the potential to interact with RFxV motifs.

Methods: HEK293 cells were used to express WNK4 and SPAK wild-type and mutant constructs. SPAK-S373 and WNK4-T-loop phosphorylation was measured by Western Blot. Protein-protein interactions were assessed by coimmunoprecipitation and colocalization assays.

Results: Both RFxV motifs in WNK4 were required for SPAK-S373 phosphorylation, but only motif #2 (in the C-terminus) was necessary for co-immunoprecipitation. The lack of SPAK activation by WNK4-RFxV motif #1 (KD) mutant was not due to loss of catalytic activity since the mutant displayed autophosphorylation. SPAK-independent WNK4-NKCC1 interaction was observed. WNK1, WNK2 and WNK3 present an RFxV motif in the KD in a different position to that observed in WNK4. Introduction of an RFxV motif in this position in WNK4 could not restore function of WNK4-motif #1 mutant. Confocal microscopy showed a vesicular localization for WNK4. This pattern was replicated by SPAK, but not in the presence of WNK4-motif #2 mutant. The PF2-like domains in WNK4 were required to fully activate SPAK, but were not essential for SPAK and NKCC1 interaction.

Conclusions: WNK4´s RFxV motif #1 is required for SPAK activation and motif #2 is critical for SPAK interaction. Integrity of PF2-like domains in WNK4 is crucial for full kinase activity.

A Novel Regulatory Mechanism of WNK4 Activity Involving Canonical Angiotensin II-PKC or PKA Mediated Phosphorylation Maria Castañeda-Bueno,[1,3] Juan Pablo Arroyo,[1] Junhui Zhang,[1] Jeremy Puthumana,[1] Shigeru Shibata,[1] Orlando Yarborough,[1] Lorena Leonor Rojas,[3] Gerardo Gamba,[3] Jesse Rinehart,[2] Richard P. Lifton.[1] *[1]Dept of Genetics, Yale Univ School of Medicine and Howard Hughes Medical Inst.; [2]Dept of Cell and Molec. Physiology and Systems Biol. Inst., Yale Univ School of Medicine, USA; [3]UNAM and INCMNSZ, Mexico City, Mexico.*

Background: The With-No-lysine kinase 4 (WNK4) regulates activity of the thiazide-sensitive Na^+:Cl^- cotransporter (NCC) by phosphorylating the kinases SPAK (Ste20-related Proline Alanine rich Kinase) and OSR1 (Oxidative Stress Responsive kinase), which in turn phosphorylate and activate NCC. WNK4 levels are regulated by binding in to KLHL3, which targets WNK4 for ubiquitylation and degradation. This activity is regulated by phosphorylation of KLHL3 via protein kinase C (PKC), downstream of Angiotensin II (AngII) or via PKA, likely downstream of vasopressin.

Methods: We tested whether these signaling pathways also have effects on phosphorylation and activity of WNK4 using mass spectrometry, pharmacological inhibitors, site-specific phosphoantibodies, *in vitro* kinase assays and mouse studies.

Results: By tandem mass spectrometry we identified several WNK4 phosphorylation sites, five of which are phosphorylated by PKC *in vitro* and in mammalian cells, downstream of AngII (S47, S64, S1169, S1180, S1196). They are also target for phosphorylation by PKA. Elimination of these phosphorylation sites prevents WNK4-mediated activation of SPAK in HEK293, which is attributable to loss of phosphorylation at S64 and S1196 in WNK4. Loss of phosphorylation at these sites markedly reduces activation of WNK4 kinase via phosphorylation of the kinase T-loop at S322. Thus, AngII signaling leads to phosphorylation of WNK4, which stimulates kinase's activation, inducing downstream signaling. We further show that phosphorylation occurs *in vivo* in mouse with AngII stimulation, primarily in the distal convoluted tubule, where phosphorylated WNK4 co-localizes with SPAK.

Conclusions: AngII activates WNK4 through direct phosphorylation of key sites in WNK4 C- and N-terminal domains. Activated WNK4 then orchestrates activation of SPAK/OSR1-NCC, resulting in increased Na^+ and Cl^- reabsorption.

SA-PO103

Distal Convoluted Tubule Aggrephagy Involving WNK Kinases Is a Response to Metabolic Stress Causing NCC Activation Tim Michael Bewarder,[1] Aljona Borschewski,[1] Katharina Ilse Blankenstein,[1] Alejandro Federico Cornejo Mueller,[1] Carsten Dittmayer,[1] Andrew Terker,[2] David H. Ellison,[2] Kerim Mutig,[1] Sebastian Bachmann.[1] *[1]Inst für Vegetative Anatomie, Charité, Berlin, Germany; [2]Div of Nephrology & Hypertension, Oregon Health & Science Univ, Portland, OR; [3]VA Portland Health Care System, Portland, OR.*

Background: Sodium chloride reabsorption by the distal convoluted tubule maintains K^+ homeostasis during periods of metabolic stress, through WNK kinases and enhanced thiazide-sensitive NaCl cotransporter (NCC). Early work, using cultured cells, suggested that osmotic stress leads to the accumulation of WNK kinases in vesicular structures representing the trans-Golgi network. in vivo, hypokalemia induced by OSR1 knockout or low K^+ diet, also leads to SPAK/WNK4 puncta. Here, we tested whether stress generates unique cellular structures.

Methods: Mice received high salt/low K^+ (HS/LK) or control diets for 10 days. Rats received furosemide or vehicle via osmotic minipump for 7 days. WNK1-transfected HEK293 cells were exposed to vehicle or hyperosmotic stress (0.2 M NaCl). Immunostaining for WNK1, WNK4, SPAK, S383-phospho-SPAK, and autophagy markers was performed.

Results: Both HS/LK and furosemide led to accumulation of WNKs and SPAK in perinuclear puncta within DCT cells. These puncta were undetectable in mice on high NaCl or control diets. The autophagy marker ATG5 colocalized in the puncta, whereas standard lysosomal markers did not. Electron microscopy revealed abundant aggresome-like structures adjacent to autophagosomes in kidneys from HS/LK or furosemide-treated animals, but not in controls. In transfected cells, hyperosmotic stress-induced formation of similar, WNK1/ATG5-positive puncta, with markers suggesting that they too are autophagosomes. In control cells, WNK1 and ATG5 did not co-localize and were, instead, diffusely expressed in the cytoplasm.

Conclusions: Activation of the DCT induces formation of perinuclear, autophagosome-like structures containing WNK pathway proteins involved in the phosphoregulation of renal distal transporters. Our data suggest that the autophagy pathway is permissively involved in the regulation of salt reabsorption along the distal nephron.

WNK4 Regulates Adipocyte Differentiation in 3T3-L1 Cells Daiei Takahashi, Takayasu Mori, Eisei Sohara, Motoko Chiga, Yuichi Inoue, Naohiro Nomura, Moko Zeniya, Tatemitsu Rai, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

Background: The with-no-lysine (WNK) 1 and WNK4 genes are responsible for pseudohypoaldosteronism type II (PHAII), a hereditary hypertensive disease. We previously demonstrated the importance of the WNK4–OSR1/SPAK–NCC signaling cascade in the kidney for blood pressure regulation. WNKs are widely expressed in the body, and recent studies have suggested that, other than this cascade, WNKs also regulate cell growth,

differentiation, and development. However, neither their metabolic functions nor their extrarenal roles are clear, especially in case of WNK4. In the present study, we report a novel role of WNK4 as a regulator of adipogenesis in 3T3-L1 cells.

Methods: We stimulated 3T3-L1 fibroblasts and induced adipogenesis with differentiation medium, containing insulin, dexamethasone, and 3-isobutyl-1-methylxantine. The potential function of WNK4 in the 3T3-L1 cells was examined by knockdown experiments using siRNA specific to WNK4 (si-WNK4). The effect of WNK4 inhibition on 3T3-L1 adipocytes was examined by Oil-red O staining, qRT-PCR, and immunoblotting.

Results: The expression level of WNK4 mRNA in the undifferentiated 3T3-L1 cells was low. However, when adipogenesis was induced, WNK4 expression was markedly increased to 44 fold in the very early phase of adipocyte differentiation, preceding the expression of key transcriptional factors PPARγ and C/EBPα. When the differentiated cells were transfected with siWNK4, they exhibited impaired lipid accumulation and PPARγ expression, and the results were supported by immunoblot analysis. It was also indicated that involvement of WNK4 with adipocyte differentiation was independent of WNK1 or the known downstream effector, OSR1/SPAK-NKCC1 signaling cascade.

Conclusions: We found a novel role of WNK4 as a regulator of adipocyte differentiation in 3T3-L1 cells and have offered novel insights into the relationship between WNKs and adipogenesis. Our results also indicate that WNK4 inhibition might be beneficial in the management of both hypertension and obesity.

Phosphorylation of KLHL3 at Serine 433 Impairs Its Interaction with the Acidic Motif of WNK4: A Molecular Dynamics Study Lingyun Wang, Ji-Bin Peng. *Div of Nephrology, Dept of Medicine, Nephrology Research and Training Center, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Interaction between the acidic motif (AM) of protein kinase WNK4 and the Kelch domain of KLHL3 are involved in the pathogenesis of pseudohypoaldosteronism type II, a hereditary form of hypertension. This interaction is disrupted by some disease-causing mutations in either WNK4 or KLHL3, or by angiotensin II- and insulin-induced phosphorylation of KLHL3 at serine 433, which is also a site frequently mutated in patients. However, the mechanism by which this phosphorylation disrupts the interaction is unclear.

Methods: In this study, we approached this problem using molecular dynamics simulation with structural, dynamical and energetic analyses.

Results: Results from independent simulations indicate that when S433 was phosphorylated, the electrostatic potential became more negative in the AM binding site of KLHL3 and therefore was unfavorable for binding with the negatively charged AM. In addition, the intermolecular hydrogen bond network that kept the AM stable in the binding site of KLHL3 was disrupted, and the forces for the hydrophobic interactions between the AM of WNK4 and KLHL3 were also reduced. As a result, the weakened interactions were no longer capable of holding the AM of WNK4 at its binding site in KLHL3.

Conclusions: In conclusion, phosphorylation of KLHL3 at S433 disrupts the hydrogen bonds, hydrophobic and electrostatic interactions between the Kelch domain of KLHL3 and the AM of WNK4. This study provides a key molecular understanding of the KLHL3-mediated regulation of WNK4, which is an integrative regulator of electrolyte homeostasis and blood pressure regulation in the kidney.

Molecular Dynamics Simulation Unveils Impaired Interactions between the Acidic Motif of WNK4 and KLHL3 Carrying Disease-Causing Mutations on the Surface of the Kelch Domain Lingyun Wang, Ji-Bin Peng. *Div of Nephrology, Dept of Medicine, Nephrology Research and Training Center, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Mutations in Kelch-like 3 (KLHL3) and with-no-lysine [K] kinase 4 (WNK4) are found in patients with pseudohypoaldosteronism type II, a hereditary form of hypertension. At least ten disease-causing mutations are localized in the Kelch domain of KLHL3, which is involved in the interaction with WNK4, an important step for WNK4 ubiquitination and degradation. However, the mechanisms by which these mutations disrupt the interaction between KLHL3 and WNK4 are not well understood.

Methods: To approach this problem, molecular dynamics simulations with structural, dynamical and energetic analyses were performed based on the crystal structure of the Kelch domain of KLHL3 in complex with the acidic motif of WNK4.

Results: Significant increases in the distance between the acidic motif and the Kelch domain were observed for mutations on the surface of the Kelch domain, including Q309R, S432N, S433N, R528H,and N529K. These mutations also altered the electrostatic potential in the binding site for the acidic motif and disrupted the hydrogen bonds and hydrophobic interactions between the Kelch domain and the acidic motif. In addition, S432, S433, and R528 of KLHL3 form hydrogen bonds with residues in the acid motif of WNK4; and these bonds were directly disrupted by the S432N, S433N and R528H mutations. For the mutations not on the surface of Kelch domain, including A340V, R384Q, L387P, S410L and A494T, no significant changes were observed in the distance, hydrogen bond and hydrophobic interaction between the Kelch domain and the acidic motif.

Conclusions: In conclusion, molecular dynamics simulation well detected the disruption of interaction between the acidic motif of WNK4 and the Kelch domain of KLHL3 by the mutations on the surface of the Kelch domain. Further studies are needed to determine the impairments caused by the mutations buried inside the Kelch domain.

Single-Cell RNA Sequencing Reveals Transcriptomes of Four Cell Types Isolated from the Mouse Renal Collecting Duct Lihe Chen, Chung-Lin Chou, Mark A. Knepper. *National Heart Lung and Blood Inst.*

Background: The renal collecting duct contains principal cells (PCs) and at least two types of intercalated cells (ICs). These cell types bear different molecular signatures and mediate different physiological functions. The development of next generation DNA sequencing techniques offers the ability to carry out RNA sequencing (RNA-Seq) in single cells. Here, we use this technology to profile transcriptomic profiles of all cell types in the renal collecting duct.

Methods: We isolated cells from mouse kidney cell suspensions using reagents that recognize two collecting duct cell surface markers to enrich collecting duct cells, viz. c-kit for ICs and *Dolichos biflorus* agglutinin (DBA) for PCs. The resulting cells were used for single cell RNA-Seq using a microfluidic single-cell isolation device (Fluidigm) followed by reverse transcription, initial amplification, and library preparation with bar coding, prior to sequencing on an Illumina HiSeq2500 platform.

Results: We profiled transcriptomes in 66 individual cells with an average of 10.9M reads, and 95% of mapped reads and 78% uniquely mapped reads per cell. The average transcriptome depth was 3386 genes (RPM>1). We classified each of the 66 cells, based on canonical markers for each cell type, as follows: 21 PCs, 13 β-ICs, 3 α-ICs, 14 "hybrid" ICs, 4 fibroblasts, one distal convoluted tubule cell, and 10 unclassified cells. The "hybrid" ICs are of particular interest. These cells expressed IC-specific H-ATPase subunits plus a combination of α and β IC markers. Interestingly, seven of the 30 cells classified as ICs also expressed aquaporin-2 at low, but readily detectable levels, suggesting that aquaporin-2 expression is not an exclusive characteristic of PCs or connecting tubule cells.

Conclusions: In conclusion, single cell RNA-Seq in mouse renal collecting duct cells showed the presence of intermediate cell types that are not clearly identifiable as PCs, α-ICs, or β-ICs based on standard markers. The single cell RNA-Seq method, more broadly applied, has the potential of identification of the mechanisms of cell-type specific gene expression and physiological regulation in the collecting duct.

Empagliflozin Lowers Blood Pressure and Inhibits NHE3 Activity in Hypertensive Rats Adriana C.C. Girardi,[1] Corina De Albuquerque Silva,[1] Regiane Cardoso Castelo Branco,[3] Renato Crajoinas,[1] Gerhard Malnic,[3] Weverton M. Luchi.[2] *[1]Heart Inst, Univ of Sao Paulo Medical School, Sao Paulo, Brazil; [2]Hospital Univ Cassiano Antonio de Moraes, Federal Univ of Espirito Santo, Sao Paulo, Brazil; [3]Physiology and Biophysics, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: SGLT2 inhibitors have clinically significant antihypertensive effects in patients with type 2 diabetes. In the proximal tubule, SGLT2 co-localizes with the major apical sodium transporter NHE3.The aim of this study was to test the hypothesis that inhibition of SGLT2 by empagliflozin reduces blood pressure and inhibits proximal tubule NHE3 activity in an experimental model of hypertension not associated with hyperglycemia.

Methods: Fourteen-week-old male spontaneously hypertensive rats (SHR) were treated with empagliflozin (10 mg/kg/day) or vehicle (control) for two weeks. Blood pressure and renal function were measured before (baseline) and after treatment (post-treatment). Post-treatment proximal tubule NHE3 activity and expression were determined by stationary in vivo microperfusion and immunoblotting, respectively.

Results: Blood pressure decreased in empagliflozin-treated SHRs (188 ± 4 vs. 177 ± 5 mm Hg, $p < 0.05$) and increased in vehicle-treated SHRs (187 ± 4 vs. 200 ± 6 mm Hg, $p < 0.05$, post-treatment vs. baseline). Urinary flow, sodium and glucose excretion were similar between the two groups of rats at baseline, increased significantly after treatment with empagliflozin and remained similar with baseline in vehicle-treated rats. Proximal tubule NHE3-mediated bicarbonate reabsorption was remarkably lower in empagliflozin-treated SHRs compared to control (0.67 ± 0.09 vs. 1.18 ± 0.09 nmol/cm^2.s, $p < 0.001$). No differences were observed on renal cortical NHE3 protein expression between the two groups of rats.

Conclusions: Collectively, these results indicate that inhibition of SGLT2 reduces blood pressure in euglycemic hypertensive rats. Inhibition of NHE3 activity by empagliflozin may contribute to the antihypertensive effect of empagliflozin in SHRs.

Claudins along the Cortico-Medullary Axis of the Thick Ascending Limb of Henle's Loop Nina Himmerkus,[1] Vera C. Wulfmeyer,[1] Hoora Drewell,[2] Kerim Mutig,[2] Tilman Breiderhoff,[3] Jianghui Hou,[4] Markus Bleich,[1] Dorothee Günzel,[3] Susanne Milatz.[1] *[1]Inst of Physiology, Christian-Albrechts-Univ, Kiel, Germany; [2]Dept of Anatomy, Charité – Universitätsmedizin, Berlin, Germany; [3]Inst of Clinical Physiology, Charité – Universitätsmedizin, Berlin, Germany; [4]Dept of Internal Medicine – Renal Div, Washington Univ School of Medicine, St. Louis, MO, Germany.*

Background: The thick ascending limb of the loop of Henle (TAL) fulfills distinct physiological tasks in the kidney: (a) Being water tight but actively transporting NaCl it is considered to be the motor which drives the counter current mechanism and the concentration ability of the kidney. (b) Providing a lumen-positive transepithelial potential

it is one of the main sites of divalent cation reabsorption through the tight junction (TJ). The TJ is composed of different claudins which interact within the same plasma membrane (*cis*-interaction) and between neighboring plasma membranes (*trans*-interaction) resulting in the formation of a complex TJ strand meshwork.

Methods: Electrophysiological measurements of transcellular and paracellular transport were performed on freshly isolated cortical and medullary TAL in combination with claudin expression analyses by subsequent immunostaining and confocal laser-scanning microscopy. *Cis*- and *trans*-interaction of the relevant TAL claudins was examined by means of live cell imaging and Förster/fluorescence resonance energy transfer (FRET) in an overexpression system.

Results: Cortical and medullary TAL differed regarding their paracellular permeability properties and their equipment with claudins 3, 10, 11, 16, and 19. A clear correlation between dominance of specific claudins within the TJ and ion selectivity was observed. Not all claudins were expressed in the same TJ in native TAL and some of them failed to interact with each other in *cis*- or in *trans*-configuration in the overexpression system.

Conclusions: We reveal a specific claudin expression pattern in the TAL which can be explained by the particular interaction capabilities of different claudins. On that basis, we suggest the existence of at least two spatially distinct types of paracellular pores with different preferences for Na^+, Ca^{2+} and Mg^{2+} in the TAL.

Technical Advance to Identify Novel Associated Proteins with CLC-5 Chloride Channel by Integrated Analysis of Immunoprecipitation Assays with a Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS) Hisato Sakamoto, Miyuki Ogawa, Makoto Itakura. *Nephrology, Graduate School of Medical Sciences, Univ of Kitasato, Sagamihara, Kanagawa, Japan.*

Background: CLC-5 plays an important physiological role in regulation of receptor-mediated endocytosis and trafficking of megalin and cubilin. However, little is known about the functional molecular regulation of this channel. Previous study only demonstrated the interaction between CLC-5 and kinesin family member 3B (KIF3B) using yeast two-hybrid strategy (*Am J Physiol* 298: F365–F380, 2010). In this work we aimed to identify novel associated proteins with CLC-5 more effectively rather than yeast two-hybrid screening.

Methods: We generated specific anti-peptide antibodies (Ab) against a synthetic peptide corresponding to the C- or N-terminal of ClC-5. Following to immunoisolation of ClC-5-bearing vesicles using the magnetic beads, we performed the analysis by LC-MS/MS and immunoprecipitation assays to identify specific binding partners. Furthermore CLC-5 and co-localization with associated proteins were imaged using confocal microscopy.

Results: In the direct analysis of highly complex protein mixtures with CLC-5 after proteolysis by LC-MS/MS, the 75-100-kDa band contained CLC-5 (H^+/Cl^- exchange transporter 5), H^+-ATPase accessory subunit a4, Kinesin-like protein KIF2**C**, meprin, and GABA receptor-associated proteins (GABARAP). Among these identified proteins, we focused on the GABARAP, which was thought to be important for the protein trafficking. Actually co-immunoprecipitation studies revealed that the CLC-5 interacted directly with GABARAP, and also immunocytochemistry showed significant co-labeling of ClC-5 and GABARAP in brush-border membrane and subapical intracellular vesicles of the proximal tubule.

Conclusions: The integration of immunoprecipitation assays with analysis by LC-MS/MS might be advanced approach to elucidate a novel regulation of channel trafficking. Enhanced understanding about the associated proteins that control CLC-5 expression may ultimately inform therapeutic strategies to correct or repair the disorder of tubular endocytosis of low molecular weight proteins.

Identification and Functional Characterization of CLCNKB Mutations in Patients with Classic Bartter's Syndrome Shih-Hua P. Lin, Jen-Chi Chen, Yi-Fen Lo, Chih-Jen Cheng. *Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Classic Bartter's syndrome (cBS) is caused by mutations in *CLCNKB* gene encoding voltage-gated chloride ClC-Kb channel. More than 50 *CLCNKB* mutations have been identified in patients with cBS, but less than half of these mutations have been functionally validated, partly due to poor ClC-Kb expression in mammalian cells.

Methods: In this study, we thoroughly investigated the functional consequences of 22 uncharacterized *CLCNKB* mutations including 2 novel missense mutations (L335P, G470E) in our patients.

Results: The wild type human *CLCNKB* construct was poorly expressed in HEK-293 cells. In-frame green fluorescent protein (GFP) insertion, either in N- or C-terminal cytoplasmic domain, greatly boosted the protein expression of ClC-Kb channel, probably by improving protein stability. Co-transfection of barttin further enhanced the protein level of ClC-Kb channel. Most cBS pathogenic mutations, especially those in transmembrane domains and linkers, significantly disrupted the protein expression of ClC-Kb channel and reduced ClC-Kb-barttin current by 30~100%. Besides the nonsense mutations in transmembrane domains, mutations in dimer interface (P216L, A242E) and in selectivity filter (G437C) resulted in most severe functional loss. Of note, mutations in C-terminal cytoplasmic domain, including three cystathionine-β-synthase (CBS) motif truncated mutations (Q513X, W610X and C667X), did not affect protein expression, membrane trafficking or current. Analysis of the potential correlation between patients' genotype and phenotype showed a significant association between the severity of current reduction by mutation and the patient's age at diagnosis ($p = 0.0125$).

Conclusions: In conclusion, in-frame GFP motif and co-expression of barttin enhances ClC-Kb protein expression. Most *CLCNKB* mutations reduced the protein expression to various degrees except the mutations in C-terminal cytoplasmic domain, indicating that two CBS motifs may modulate other intracellular regulations for ClC-Kb channel. With the extensive functional studies of nearly all *CLCNKB* mutations, we identified a significant genotype-phenotype association in cBS patients.

Phosphorylation of Na-Cl Cotransporter Regulates Its Interaction with AP3 Sung-Sen Yang, Chih-Jen Cheng, Chih-Chien Sung, Shih-Hua P. Lin. *Div of Nephrology, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Reduced σ subunit of adaptor protein 3 (AP3), a lysosomal sorting-related protein, was observed in hypertensive patients and Na-Cl cotransporter (NCC) was reported to interact with AP3.To uncover the physiological role of AP3 on the regulation of NCC *in vitro* and *in vivo*.

Methods: The interaction between AP3 and phosphor-mimic or phosphor- defective NCC was tested *in vitro*. We also generated and analyzed both the kidney tubule-specific cadherin gene promoter driven flag-tagged mouse AP3S1 (KSP-Flag-mAP3S1) transgenic (Tg) and AP3S1 heterozygous (He) knockout mice. The phenotype and expression of NCC and other interested targets were evaluated at age of 10-12 weeks fed with normal rodent chaw.

Results: In AP3S1 Tg mice, normal serum electrolytes but an enhanced urine K+ and Ca2+ excretion as well as an attenuation of total and phosphor-NCC expression were observed. While, hyperkalemia with lower urine K+ and Ca2+ excretion as well as an enhanced total and phosphor-NCC were found in AP3S1 He knockout mice. SPAK/OSR1 and WNK1/4 abundance was not significantly changed in both AP3S1 Tg and He knockout mice. We also observed that the phosphorylation status of NCC T60 residue, which locates in one of the putative canonical YXXθ ($YNT_{60}I$) binding motifs of the μ subunit of AP complexes, could affect its binding ability with AP3. Leupeptin (a lysosome inhibitor) could enhance the membrane expression of phosphor-defective T60M-NCC in MDCK cells and NCC T58M knock-in mice.

Conclusions: AP3 could regulate NCC abundance and phosphorylation of NCC T60 residue, the most important phosphor acceptor site of SPAK/OSR1 kinase, might play a role on affecting AP3-realted lysosomal degradation of NCC.

14-3-3 γ Modulates NCC Through ERK1/2-NEDD4-2 Signaling Pathway Independent of SPAK/OSR1 Signaling Xiuyan Feng,[1,2] Shan Chen,[1,3] Hui Cai.[1,2] *[1]Medicine/Renal Div, Emory Univ School of Medicine, Atlanta, GA; [2]Nephrology, Atlanta VA Medical Center, Decatur, GA; [3]Nephrology, Union Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: 14-3-3 γ belongs to a family of multifunction regulatory proteins that mainly bind to phosphorylated Ser/Thr residues in the target proteins. Our previous data also suggested that 1433 γ decreased NCC expression via increasing its ubiquitination. The purpose of this study is to investigate whether SPAK/ORS1, ERK1/2 or NEDD4-2 is involved in NCC ubiquitination induced by 1433 γ.

Methods: Cell culture, transfection, Western Blot analysis, Immunostaining and immunoprecipitation, WT C57/B6 mice aldosterone osmotic mini-pump manipulation were used in this study.

Results: We first did co-immunoprecipitation (Co-IP) which showed 14-3-3γ binding to NCC N-terminus. To investigate whether SPAK/OSR1 signaling involves the 14-3-3 γ-mediated NCC modulation, we mutated the SPSK/OSR1 phosphorylation sites on NCC (T46A, T50A, T55A, T60A, S73A and S91A). Co-IP showed that 14-3-3 γ binds to all of these hNCC mutants. We then knocked down the 14-3-3γ by siRNA in Cos-7 cells and transfected cells with same amount hNCC WT and all hNCC mutants. We found that NCC expressions were increased in hNCC WT and all mutants groups while the 14-3-3 γ was knocked down. We also analyzed the phosphorylation of SPAK, ERK1/2 and NEDD4-2 expression and found that SPAK/OSR1 did not change while the NCC expression increased in 14-3-3γ siRNA group compared to these in the control group, whereas both ERK1/2 phosphorylation and total NEDD4-2 expression increased in the 14-3-3γ siRNA group. To further test the effect of 14-3-3γ on ERK1/2 phosphorylation and NEDD4-2, we overexpressed 14-3-3 γ in Cos7 cells and found that ERK1/2 phosphorylation increased in a dose- dependent manner. While knocking down 14-3-3γ we found that NEDD4-2 expression decreased. Moreover, when we knocked down the ERK1/2 expression, the NEDD4-2 expression decrease as well, whereas the 14-3-3γ expression did not change.

Conclusions: 1433 γ modulates NCC through ERK1/2-NEDD4-2 signaling pathway independent of SPAK/OSR1 Signaling.

SA-PO114

Site Specific Ubiquitylation of the Thiazide Sensitive Sodium Chloride Cotransporter NCC Is Important for Plasma Membrane Abundance and Function Lena Lindtoft Rosenbæk,[1] Federica Rizzo,[3] Olivier Staub,[3] Robert A. Fenton.[2] *[1]Dept of Neuroscience and Pharmacology, Univ of Copenhagen, Denmark; [2]Dept of Biomedicine, Univ of Aarhus, Denmark; [3]Dept of Pharmacology and Toxicology, Univ of Lausanne, Switzerland.*

Background: A critical role for phosphorylation to modulate NCC function is well established, but recent findings indicate that NCC is ubiquitylated on at least 11 conserved lysine residues. Although the role of each of these sites is not established, we have recently demonstrated that an inverse relationship between NCC phosphorylation and ubiquitylation corresponds with the levels of NCC in the apical cell membrane. The aim of this study was to systematically assess the role of various ubiquitylated lysines in NCC for modulation of NCC function.

Methods: Novel tetracycline inducible MDCKI cell lines stably expressing human wt NCC and various K-R mutants were generated and characterized using immunoprecipitation coupled to biotin-based membrane abundance assays and phospho-specific antibodies. A Na^{22} uptake assay was developed to measure NCC activity in these polarized cell lines.

Results: Relative to wt NCC, 4 mutants (K706R, K828R, K885R, and K909R) had significantly higher abundance in the apical plasma membrane under basal conditions. Low chloride stimulation significantly increased membrane abundance of these and additional K128R and K706R mutants, to similar or greater levels than wt NCC. Under basal conditions K828R, K909R, and K948R mutants had detectably lower ubiquitylated NCC in the plasma membrane, and all mutants displayed reduced NCC ubiquitylation following low chloride stimulation. Thiazide-sensitive Na^{22} uptake assays verified elevated transport activity in the K706R, K828R, and K909R mutants.

Conclusions: Several specific ubiquitylation sites in NCC are important for modulation of NCC function.

SA-PO115

A New Ubiquitylation Site Plays a Role in the Regulation of the Sodium/Chloride Cotransporter NCC Federica Rizzo,[1] Lena Lindtoft Rosenbæk,[2] Robert A. Fenton,[3] Olivier Staub.[1] *[1]Univ of Lausanne, Switzerland; [2]Univ of Copenaghen, Denmark; [3]Univ of Aarhus, Denmark.*

Background: The Na-Cl Cotransporter (NCC) is expressed in cells of the Distal Convoluted Tubule (DCT), where it plays an important role in NaCl reabsorption and maintenance of blood pressure. NCC is intricately regulated by a variety of post-translational modifications such as glycosylation, phosphorylation and ubiquitylation. In this study we aimed to address the role of ubiquitylation in the modulation of NCC function.

Methods: A UbiScan assay on mouse kidney lysates and analysis of human/rat urinary exosomes identified several ubiquitylated lysines (K) in NCC. These individual sites in NCC were mutated to arginine (R), and the WT NCC and various mutants expressed in HEK293 and MDCK cells to examine NCC localization and activity.

Results: Biotinylation assays determined that four NCC K-R mutants were of greater abundance in the plasma membrane compared to WT NCC when transiently expressed in HEK293 cells. In particular K828R NCC was increased about 50% in the membrane compared to NCC WT. This result was confirmed in tetracycline-inducible NCC expressing MDCKI cell lines. In these cells the quantity of K828R NCC in the apical membrane in normal chloride conditions is comparable to the amount of NCC WT in the apical membrane after low chloride stimulation, which has been previously demonstrated to dramatically increase function and membrane expression of the cotransporter. Furthermore the increase of the mutant in the apical membrane is coupled with a reduction in the basolateral one suggesting an involvement of the ubiquitylation in lysine 828 in the trafficking of NCC. Na^{22} uptake demonstrated increased NCC activity in the K828R mutant relative to WT NCC, which correlates well with its increased membrane expression.

Conclusions: Our data indicate that at least one ubiquitylated lysine in NCC has an important role in the trafficking, membrane expression and activity of the cotransporter. To our knowledge, this is the first identification of an ubiquitylation site directly involved in the regulation of the cotransporter.

SA-PO116

Synergistic and Profound Diuretic Effect of Hydrochlorothiazide/Probenecid Combination Sharon L. Barone,[1,2] Jie Xu,[1] Marybeth Brooks,[1,2] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH.*

Background: Concomitant deficiency of Na-Cl co-transporter (NCC) and pendrin leads to significant salt wasting and diuresis. Probenecid is an inhibitor of the organic anion transporter, OAT3, in the kidney proximal tubule and a uricosuric agent. Probenecid is also an inhibitor of pendrin in mammary cells. The diuretic effect of HCTZ, which is a specific inhibitor of NCC, is significantly blunted due to compensatory salt absorption by pendrin. We hypothesized that pre-treatment with probenecid will downregulate pendrin, therefore enhancing the diuretic effect of HCTZ.

Methods: The effect of probenecid treatment on pendrin-transfected HEK-293 cells and male Sprague Dawley rats (200-225 g) was examined.

Results: Probenecid (0.5 mM) significantly inhibited pendrin-mediated Cl^-/HCO_3^-exchange in transfected HEK293 cells as measured by the pH sensitive dye, BCECF. Daily treatment of rats with probenecid (250mg/kg) for 6 days significantly reduced pendrin expression in B-intercalated cells without affecting diuresis; while treatment of rats with HCTZ (40mg/kg) alone caused a very mild diuresis (12.5 to 14 ml/24 hrs after 4 days of HCTZ, $p>0.05$). However, co-administration of HCTZ and probenecid to rats that were pre-treated with probencid for 6 days caused a significant increase in urine output (15.3 ml/day in rats treated with probenecid for 10 days vs 35 ml/day in rats treated with probenecid for 6 days and then with HCTZ plus probenecid for 4 additional days). Compared to either probenecid or HCTZ treatment animals, rats pre-treated with probenecid for 6 days and then given probenecid plus HCTZ for 4 days exhibited enhanced kidney renin expression and volume depletion. While probenecid partially interfered with HCTZ secretion into the urine, the higher HCTZ blood levels were unlikely to be responsible for the profound diuresis.

Conclusions: Despite being considered a mild agent, we propose that HCTZ could be a potent diuretic when administered in individuals pre-treated with probenecid.

Reverse Feeding with High Salt Impairs Diurnal Variation of Sodium Excretion Joshua S. Speed, Kaehler J. Roth, Dingguo Zhang, Chunhua Jin, Karen L. Gamble, David M. Pollock. *Medicine and Psychiatry, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Night shift work increases risk of cardiovascular disease associated with an altered time of day feeding behavior. Elevating this risk is the overall increase in salt intake observed in the typical Western diet. Our lab has shown that high salt intake alters renal circadian rhythms that has been shown to affect Na^+ handling. Normally, renal Na^+ excretion has a distinct diurnal pattern, independent of time of intake, yet the interaction between the time of intake and the amount of salt ingested has yet to be determined. The hypothesis of the current study is that reversed feeding (RF, food restricted to inactive period) in addition to high salt feeding will disrupt the diurnal rhythm of renal Na^+ excretion.

Methods: Male Sprague Dawley rats were placed on either normal (NS 0.49% NaCl) or high (HS, 4% NaCl) salt diet. Rats were housed in metabolic cages and allowed food ad libitum or subject to RF. Urine was collected every 12 hours. Data is expressed as mean ± SEM of the inactive to active ratio (I/A).

Results: As expected, rats fed NS and allowed food *ad libitum* had a diurnal rhythm in Na^+ excretion (0.37±0.08 I/A). Interestingly, the rhythm in Na^+ excretion was not significantly different after 5 days of RF compared to *ad libitum* rats (0.42±0.12 I/A). In response to HS, the diurnal rhythm in Na^+ excretion (0.26±0.07 I/A) was similar to NS fed rats, but was abolished after 5 days of reverse feeding (1.5±0.4 I/A). In addition, RF significantly reduced the diurnal variation in urinary aldosterone excretion in both NS (0.33±0.05 vs. 0.85±0.19, *ad libitum* vs. RF) and HS (0.36±0.06 vs. 1.21±0.30, *ad libitum* vs. RF) fed rats. There was no difference in 12 hour mean arterial pressure as measured by telemetry.

Conclusions: These data support the hypothesis that high salt intake impairs circadian mechanisms associated with renal Na^+ excretion. Finally, these data suggest that consuming food during one's typical inactive phase impairs diurnal variation in aldosterone production and provide a possible mechanism for increased cardiovascular risk in night shift workers.

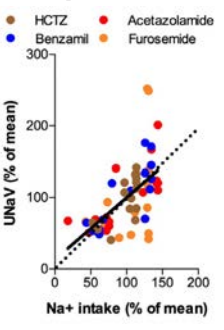
Sodium Intake Affects Excretion over Short Time Periods in Steady-State C57Bl/6J Mice Jonathan Nizar,[1] Lise Bankir,[2] Vivek Bhalla.[1] *[1]Nephrology, Stanford Univ, Palo Alto, CA; [2]Centre de Recherche des Cordeliers, INSERM, Paris, France.*

Background: Homeostatic balance of sodium is a criterion for the study of channel/transporter-specific tubular transport or any physiological process that regulates sodium excretion. Traditionally, animals are thought to balance sodium over 12 to 24 hours, with relatively little effect of sodium intake during shorter time periods. We tested the hypothesis that in mice with tight control of sodium intake over days, small amounts of sodium intake over 2 - 4 hours would not influence sodium excretion.

Methods: To accomplish this, adult C57BL/6J mice were fed a high sodium diet as gel food over two weeks. In metabolic cages, mice consumed 2.6 +/- 0.05 mmoles Na^+ / day for at least three days before undergoing intraperitoneal injection with saline or one of several diuretics and urine collection over 4 hours.

Results: After each diuretic and saline injection, sodium excretion varied predictably with the diuretic or vehicle treatment and significantly varied with the amount of ingested sodium during the collection period ($p<0.001$, linear regression compared to slope = 0), despite nearly identical intake over the prior 24 hours.



Solid line indicates linear regression of all drugs in aggregate.

Conclusions: These results highlight the technical challenges of balance experiments in mice and warrant the need to adjust excretion data for intake, even during short collection intervals.

Dietary Salt Impacts Active Sodium Transport and Metabolic Sensing along the Kidney Tubule Khalil Udwan,[1] Ahmed Abed,[1] Carla Bettoni,[2] Isabelle Roth,[1] Carsten A. Wagner,[2] Eric Feraille.[1] *[1]PHYME, Univ of Geneva, Geneva, Switzerland; [2]Inst of Physiology, Univ of Zurich, Zurich, Switzerland.*

Background: Variations of dietary sodium intake induce adaptive changes in renal sodium handling in order to maintain sodium balance. Both glomerular filtration rate and tubular reabsorption process are modulated in response to dietary sodium load. The physiological changes in active sodium reabsorption by tubular cells are associated with changes in ATP and oxygen consumption. These changes may modulate the activity of metabolic sensors such as HIF and AMPK promoting anaerobic glycolysis.

Methods: We used micro-dissected kidney tubules to identify segment-specific effect of salt intake on ion transport systems and metabolic sensor pathways such as HIF and AMPK. Control mice were placed on low (LSD 0.06%), normal (NSD 0.18%) or high (HSD 1.26%) sodium diet for 7 days.

Results: HSD increased the GFR but paradoxically decreased the total expression levels of most Na^+ transporters in both kidney cortex and medulla. However, analysis of the expression levels and activity of Na,K-ATPase as well as the activation levels of metabolic sensors such as HIF and AMPK, revealed that Na^+ transport is actually increased all along the kidney tubule except in distal convoluted tubule. On the other hand, LSD slightly decreased GFR and significantly increased the expression of apical Na^+ transporters NCC and ENaC in DCT and collecting duct, respectively. This effect was associated with increased Na,K-ATPase activity in CD but decreased HIF and AMPK activities. These results indicate that the driving force for Na^+ reabsorption in CD was increased but that actual Na^+ transport was decreased in relation with low Na^+ delivery.

Conclusions: From our experiments, we conclude that the actual Na^+ transport in different segments of the nephron is better reflected by the expression level of Na,K-ATPase and the activation level of metabolic sensors, rather than the expression levels of apical Na^+ transporters alone. Our results show that under physiological conditions, ATP and oxygen supplies are limited enough to trigger both HIF and AMPK signaling pathways.

SA-PO120

Role of β_1Pix in the Regulation of ENaC by AMPK Pei-Yin Ho,[1] Hui Li,[1] Tengis S. Pavlov,[2] Lei Cheng,[3] Robert A. Fenton,[3] Alexander Staruschenko,[2] Kenneth R. Hallows.[1] *[1]Medicine, USC Keck School of Medicine, Los Angeles, CA; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI; [3]Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: AMP-activated protein kinase (AMPK) inhibits the epithelial Na^+ channel (ENaC) by increasing binding of Nedd4-2 to ENaC. The Rho-GEF protein β_1Pix promotes Nedd4-2 targeting of ENaC by impairing the 14-3-3/Nedd4-2 association. We hypothesized that AMPK may enhance ENaC degradation by regulation of β_1Pix and the Nedd4-2/14-3-3 association.

Methods: Mass spectrometry (MS) and in vitro phosphorylation assays were used to detect AMPK phosphorylation sites in β_1Pix. Wild-type and mutant β_1Pix were overexpressed in lentivirally transduced collecting duct mpkCCD$_{c14}$ cells. Co-immunoprecipitation (co-IP) assays were used to examine modulation of β_1Pix/14-3-3/Nedd4-2 interactions by AMPK in renal epithelial cells. Patch-clamp and epithelial volt-ohmmeter (EVOM) studies were performed in CHO and mpkCCD$_{c14}$ cells co-expressing ENaC and various β_1Pix and AMPK constructs.

Results: AMPK directly phosphorylates β_1Pix in vitro, and at least two potential AMPK phosphorylation sites were detected by MS. AMPK stimulation by metformin inhibited the binding of Nedd4-2 to 14-3-3 proteins but did not modulate 14-3-3-β_1Pix interaction in MDCK cells. Whole-cell ENaC currents were decreased by the AMPK activator AICAR or by β_1Pix over-expression in CHO cells, but these effects were not additive. Co-expressing a β_1Pix mutant unable to bind 14-3-3 protein (Δ602-611) abolished the ENaC current inhibition by AICAR or overexpression of a constitutively active AMPK mutant. Finally, over-expression of β_1Pix Δ602-611 increased, whereas wild-type β_1Pix decreased ENaC short-circuit currents in mpkCCD$_{c14}$ cells, supporting the results found in CHO cells.

Conclusions: The regulation of ENaC by AMPK requires both functional Nedd4-2 and β_1Pix. AMPK reciprocally stimulates Nedd4-2-ENaC binding and inhibits Nedd4-2-14-3-3 binding, thereby promoting ENaC degradation. β_1Pix participates in this regulation, but the mechanisms involved are currently unclear. The potential role of AMPK phosphorylation of β_1Pix in the regulation of ENaC will be assessed through additional mutagenesis studies.

Regulation of the Epithelial Sodium Channel by Paraoxonase-2 Shujie Shi, Carol L. Kinlough, Allison L. Marciszyn, Rebecca P. Hughey, Thomas R. Kleyman. *Renal-Electrolyte Div, Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Paraoxonase-2 (PON-2) is a membrane-bound lactonase with unique anti-oxidative property. PON-2 shares key structural elements with *C. elegans* MEC-6, an endoplasmic reticulum-residingchaperone that is indispensable for the worm's gentle touch response. MEC-6 is required for proper folding and assembly of MEC-4, a pore-forming subunit of the mechanosensitive ion channel in *C. elegans* touch receptor neurons. MEC-4 belongs to the same family as the epithelial Na^+ channel (ENaC), a key mediator of Na^+ uptake in the aldosterone-sensitive distal nephron. As the overall structures are highly conserved between MEC-4 and ENaC subunits, we hypothesized that mechanisms by which these ion channels are regulated are also evolutionally conserved and that PON-2, like MEC-6 by analogy, regulates ENaC activity.

Methods: We therefore examined PON-2 expression in mouse kidney, and its interaction with ENaC subunits in HEK293 cells. The function of PON-2 on ENaC activity was assessed in *Xenopus* oocytes.

Results: We found tubular-specific expression of PON-2 in mouse kidney, including principle cells and intercalated cells of distal nephron segments. When co-expressed with ENaC in *Xenopus* oocytes, PON-2 reduced amiloride-sensitive whole cell Na^+ currents, but not K^+ currents mediated by ROMK, the renal outer medullar potassium channel. As ENaC activity is tightly regulated by a variety of endogenous or external factors that affect channel biogenesis or gating, the inhibitory effect of PON-2 could reflect a reduction in channel P_O or the number of channels on cell surface. We found that PON-2 did not alter ENaC gating in response to extracellular Na^+, flow-mediated shear stress, or α-chymotrypsin, suggesting that channel P_O was not altered by PON-2. In contrast, surface expression of ENaC was reduced by PON-2 co-expression Additionally, we found that PON-2 interacted with ENaC subunits in HEK293 cells and PON-2 inhibited ENaC activity in a dose-dependent manner.

Conclusions: In summary, our results suggest that PON-2 functions as a chaperone to regulates the surface expression of ENaC.

Effect of ENaC Inhibition on Na+ Reabsorption Is Partially Compensated by a Reduction in Paracellular Secretion: A Modeling Study Anita T. Layton,[1] Aurelie Edwards,[2] Volker Vallon.[3] *[1]Dept of Mathematics, Duke Univ, Durham, NC; [2]Centre National de la Recherche Scientifique, Centre de Recherche des Cordeliers, Paris, France; [3]Dept of Medicine and Pharmacology, Univ of California San Diego, San Diego, CA.*

Background: The amiloride-sensitive Na^+ channel (ENaC) is expressed on the apical membrane of the principal cells in the distal nephron. Together with the basolateral Na^+-K^+-ATPase, ENaC regulates Na^+ reabsorption and plays a major role in total body salt and water homeostasis and blood pressure control. We aimed to investigate the extent to which ENaC inhibition alters urinary solute excretion and Na^+ transport (T_{Na}) efficiency.

Methods: We developed a multi-nephron computational model that represents detailed transcellular and paracellular transport processes along the nephron of a rat kidney. Using that model, we simulated the inhibition of ENaC.

Results: Under baseline conditions, ENaC was predicted to mediate ~7% of renal T_{Na}, more than commonly thought. ENaC-mediated Na^+ reabsorption was accompanied by substantial paracellular Na^+ secretion. Consequently, ENaC-mediated T_{Na} exceeded total Na^+ reabsorption along the distal nephron segments. ENaC inhibition was predicted to significantly impact connecting tubule T_{Na}. However, the fractional reduction in active T_{Na} was substantially lower than the fractional inhibition of ENaC. That discrepancy can be attributed to the elevated luminal [Na^+], which increased the driving force for transmembrane Na^+ reabsorption and attenuated paracellular Na^+ secretion. Connecting tubule T_{Na} efficiency, given by the number of moles of Na^+ reabsorbed per moles of O_2 consumed, decreased from 4.5 (baseline) to -1.6 (full ENaC inhibition). Additionally, ENaC inhibition lowered K^+ secretion, most notably into the connecting tubules, since Na^+ reabsorption generates the transmembrane potential difference that drives K^+ secretion. When ENaC was fully inhibited, urinary Na^+ and K^+ excretion was predicted to increase by ~3.5 folds and to decrease by ~80%, respectively.

Conclusions: ENaC inhibition has a major impact on both transcellular and paracellular T_{Na} along the distal nephron, and on K^+ secretion and excretion.

SA-PO123

Exaggerated Urine Sodium Excretion by Mineralocorticoid Receptor (MR) Antagonists in Rats when Tested against Fludrocortisone Rather Than Aldosterone Krister Bamberg, Lena William-Olsson, Ulrika Johansson, Caroline Wingolf, Rasmus Jansson-Lofmark, Judith Hartleib-Geschwindner. *CVMD iMed, AstraZeneca R&D, Molndal, Sweden.*

Background: Electrolyte effects of MR antagonists in man are typically assessed by analysing urinary sodium secretion after single doses in presence of the orally administered mineralocorticoid fludrocortisone (fludro). In preclinical settings, effect of single dose MR antagonists on urinary sodium secretion is typically assessed in presence of subcutaneously administered aldosterone (aldo) or after a three day low salt diet to elevate endogenous aldo. AZD9977 is a novel MR modulator which in preclinical testing dissociates organ protective

effects from effects on urine electrolytes. To bridge preclinical data on electrolyte effects generated with aldo to clinical data generated with fludro, anti-mineralocorticoid effects of AZD9977 and eplerenone were compared using aldo or fludro as mineralocorticoid.

Methods: Aldo or fludro was administered repeatedly to healthy rats to achieve equivalent drug exposures. 2h after initiation a single dose AZD9977 or eplerenone was administered and amount sodium (mmol) secreted in urine over 6h was assessed.

Results: At AZD9977 and eplerenone doses yielding maximal effects, aldo mediated sodium retention (0.04±0.01 vs 0.22±0.05 for vehicle) was reversed by eplerenone (0.21±0.03), while AZD9977 had only a minimal effect (0.07±0.02). Fludro mediated sodium retention (0.06±0.01 vs 0.15±0.03 for vehicle) was reversed by AZD9977 (0.12±0.02), while eplerenone not only reversed sodium retention but also stimulated a natriuresis in excess of vehicle treated animals (0.43±0.11). At low doses that restore fludro induced sodium retention to vehicle levels, AZD9977 and eplerenone display similar effects on urine sodium, thus the differentiation between AZD9977 and eplerenone on urine electrolytes observed in presence of aldo is only apparent at saturating antagonist doses when tested against fludro.

Conclusions: The exaggerated effect on urine sodium excretion in rats seen by MR antagonists when tested against fludro rather than aldo indicates differences in the mode of action of fludro vs aldo. It remains to be established whether this is true also in man.

Electrolyte Homeostasis in AQP-2-Principal-Cell-Targeted Insulin Receptor (IR) and Mammalian-Target-of-Rapamycin (mTOR) Knockout (KO) Mice under Low- and Normal-Sodium Diets

Carolyn M. Ecelbarger,[1] Hwal Lee,[1] Swasti Tiwari,[2] Lijun Li.[1] *[1]Dept of Medicine, Georgetown Univ, Washington, DC; [2]Sanjay Gandhi Post-Graduate Inst of Medical Sciences, Lucknow, India.*

Background: Insulin has been shown to increase the reabsorption of sodium in the renal collecting duct (CD), but less is known about its effects on potassium or chloride handling at this site. Dysregulation of these key electrolytes can affect acid-base homeostasis and blood volume. Previous studies have demonstrated that mTOR may play a role in activation of ENaC by insulin in the collecting duct.

Methods: We assessed the impact of low-sodium (Na+) diet (0.05%, LSD) on blood chemistry and urine excretion in male AQP2-principal-cell-targeted insulin receptor and mTOR knockout (IRKO and mTORKO) mice, as compared to their respective WT littermates. Urine (24-hr) was collected on days 1-3 and 7 of LSD. Volume and electrolyte excretion was measured. In a separate experiment, mice were randomized to receive the LSD or control diet (0.5% Na+, n = 5-7/group) for one week, mice were euthanized, and blood was analyzed by iSTAT (EG8 cartridge) for chemistry profile.

Results: No obvious differences in urine Na+ excretion were found between genotypes; however, hematocrit was significantly ($p < 0.05$) higher (4-6%) in the IRKO and mTORKO versus their WT littermates under LSD. Plasma K+ levels tended to be lower in the KO (both types) on either control or LSD, while plasma Cl- was significantly reduced by LSD in the KO, but not WT. Furthermore, mTORKO had mild alkalosis as determined by significantly elevated blood pH, HCO_3, base excess, and reduced pCO_2, relative to WT, independent of diet. These differences were absent in the IRKO mice.

Conclusions: Overall, these results support a role for CD IR and mTOR in electrolyte homeostasis and blood volume control. Increased hematocrit in both KO lines suggested mild volume contraction under LSD, absent in WT mice. Similarities between the phenotypes with regard to plasma electrolyte profile suggests that IR may indeed be working through mTOR to regulate these electrolytes; however, differences in acid/base status suggest additional roles for CD mTOR independent of IR.

A Mathematical Model of the Rat Kidney: K-Induced Natriuresis

Alan Mark Weinstein. *Physiology and Biophysics, Weill Medical College of Cornell, New York, NY.*

Background: Increased K^+ intake is associated with natriuresis, but the renal locus of this effect is uncertain.

Methods: A model of the rat nephron (Am. J. Physiol. 308:F1098, 2015) has been extended with the addition of medullary vasculature. Within outer medulla (OM), the model specifies 20000 short descending vasa recta (DVR) and 4000 long DVR; within inner medulla (IM), long DVR coalesce, halving their number with each mm of medullary depth; cortical medullary rays (MR) are supplied by 7200 DVR. In all regions, ascending vasa recta (AVR) are twice the number of DVR, which provides for slower AVR flows, and secures equilibration of AVR and interstitial concentrations. Blood vessels contain all 15 solutes from the nephron model (Na^+, K^+, Cl^-, HCO_3^-, H_2CO_3, CO_2, urea, phosphate, ammonia, formate, and glucose), plus 14 additional species from the model of Atherton et al. (Am. J. Physiol. 247:F61, 1984), which represent hemoglobin buffering. For this kidney model, the global unknowns are initial proximal tubule pressures and flows (plus connecting tubule pressure) from the nephron model, plus medullary interstitial pressures and solute concentrations. With partitioning of OM into 2 sections, of IM into 5 sections, and a single MR section, there are 128 interstitial variables, yielding a total of 141 unknowns for the full kidney model.

Results: Solution of the model under antidiuretic conditions predicts OM interstitial gradients for Na^+, K^+, CO_2, and NH_4^+, such that at OM-IM junction, the respective concentrations relative to plasma are 1.2, 3.0, 2.9, and 8.0; within IM, there is high urea and low HCO_3^-, with concentration ratios of 11 and 0.5 near the papillary tip. When plasma K^+ is increased from 5.0 to 5.5 mM, Na^+ and K^+ excretion are predicted to increase 2.5- and 1.3-fold. The natriuresis derives from a 4% decrease in proximal Na^+ reabsorption, and occurs despite delivery-driven increases in Na^+ reabsorption in all distal segments; the kaliuresis derives from a 30% increase in connecting tubule Na^+ delivery.

Conclusions: Thus, in the absence of other regulation, this model favors the importance of proximal over distal events in K^+-induced diuresis.

The Distal Convoluted Tubule Requires Kir4.1 to Sense Plasma Potassium and Regulate Potassium Homeostasis Properly

Catherina A. Cuevas,[1] James A. McCormick,[1] Chao-Ling Yang,[1] WenHui Wang,[3] David H. Ellison.[1,2] *[1]Medicine, Oregon Health & Science Univ, Portland, OR; [2]Renal Section, Portland VA Medical Center, Portland, OR; [3]Pharmacology, New York Medical College, Valhalla, NY.*

Background: Urinary potassium excretion is mediated by secretion along the connecting tubule and collecting duct, but a key role for the upstream segment, the distal convoluted tubule has been recognized recently. The potassium channel, Kir4.1, which appears to be the dominant potassium conductive pathway in these cells, appears to play a key role. We recently developed a mouse model in which Kir4.1 can be deleted along the nephron in adult mice. The mice exhibit hypokalemia and decreased thiazide-sensitive NaCl cotransporter (NCC) abundance.

Methods: To test whether Kir4.1 is essential for the physiological response to a dietary K^+ challenge, kidney-specific Kir4.1 knockout (KS-Kir4.1 KO) mice were fed with diets deficient in K^+ (0% K^+,LK), rich in K^+ (5% K^+, HK) and with normal K^+ (0.8% K^+, NK) for 4 days each.

Results: On NK, KS-Kir4.1 KO mice were hypokalemic and alkalemic ([K+]: 2.5±0.1; [CO_2]: 25±2.4). When exposed to LK, the mice exhibited dramatic hypokalemia (1.0±0.1 mmol/l) along with even more marked metabolic alkalosis (35 ±0.8 CO_2 mmol/l), accompanied by continued urinary K^+ wasting. Even HK failed to normalize plasma [K+] in KS-Kir4.1 KO mice (3.2±0.1,mmol/L). The mechanism for K^+ wasting in the KS-Kir4.1 KO mice was revealed by analysis of NCC abundance. In contrast to wild type mice in which NCC abundance correlates inversely with dietary K^+ intake, NCC abundance was nearly undetectable in KS-Kir4.1 KO mice and unaffected by diet.

Conclusions: Together, these data show that Kir4.1 is required for the kidney to sense plasma [K^+] and that NCC activity is required to maintain K^+ balance, even under usual diet conditions.

Disturbed Renal K Handling in Carriers of the Gly40Ser Mutation of the Glucagon Receptor Suggests a Role for Glucagon in K Homeostasis

Lise Bankir,[1] Antonio Barbato,[2] Ornella Russo,[2] Gilles Crambert,[1] Roberto Iacone,[2] Nadine Bouby,[1] Pasquale Strazzullo.[2] *[1]INSERM Unit 1138-E2, Centre de Recherche des Cordeliers, Paris, France; [2]Clinical Medicine, Federico II Univ, Naples, Italy.*

Background: Clearance studies in rats showed that iv glucagon (Gluc) infusion increases urinary K excretion dose-dependently and reversibly [Ahloulay, *AJP* 269:F225,1995]. The present study investigates K handling in humans, taking advantage of the Gly40Ser mutation of the Gluc receptor that has been shown to induce a partial loss of function (lesser cAMP release by rat hepatocytes in vitro; lesser rise in plasma glucose after Gluc infusion in humans).

Methods: In the Olivetti cohort (male workers), 25 subjects who carried this mutation were matched 1:4 to 100 non-carriers for age (mean 57y) and weight (mean BMI 27-28 kg/m^2). Estimated osmolarity (Osm) of plasma and 24h urine was calculated as [(Na+K)*2+glucose+urea]. Transtubular K gradient (TTKG) reflecting the intensity of K secretion in distal nephron was calculated as [(urine K/serum K)/(urine Osm/serum Osm)].

Results: There was no significant difference in blood pressure, serum insulin, serum or urine urea and Na excretion. Urine volume was slightly higher and Osm slighly lower in carriers than non-carriers (but NS).

Means (interquartile range)	Non-Carriers (n=100)	Carriers (n=25)	p
Creat.Clear (ml/min/1.73m^2)	86 (82-90)	88 (81-95)	NS
Serum K (mmol/L)	4.5 (4.4-4.6)	4.5 (4.3-4.6)	NS
Urine K (mmol/L)	47 (43-51)	38 (34-43)	**p=0.030**
K excretion (mmol/d)	68 (64-73)	66 (57-74)	NS
TTKG	5.0 (4.7-5.2)	4.2 (3.9-4.6)	**p=0.015**

The difference in urine K and TTKG remained statistically significant after adjustments for serum insulin and 24h K and Na excretion.

Conclusions: These results in humans, along with previous observations in rats, strongly suggest that Gluc stimulates K secretion in the distal nephron. Infusion of K has been shown to stimulate both insulin and Gluc secretion in conscious dogs [Santeusanio, *JLabClinMed* 81:809, 1973]. Thus, besides insulin (that favors K entry into muscle cells), glucagon most likely also participates in K homeostasis by promoting renal K excretion, as hypothetized recently [Bankir, *AJP-Renal* Art.in press].

SA-PO128

Role of Cilia in Ca2+-Dependent Flow-Induced K Secretion (FIKS) in Rabbit Cortical Collecting Duct (CCD) Rolando Carrisoza-Gaytan,[1] Carlos Schreck,[1] Thomas R. Kleyman,[2] Lisa M. Satlin.[1] *[1]Pediatrics, Icahn SOM at Mount Sinai, New York, NY; [2]Medicine, Univ of Pittsburgh SOM, Pittsburgh, PA.*

Background: BK channels, present in both CCD principal (PC) and intercalated (IC) cells, mediate Ca^{2+}-dependent FIKS. PCs possess an apical cilium which responds to manipulation with an increase in cell Ca^{2+} concentration $[Ca^{2+}]i$, and are considered to mediate transepithelial Na absorption and K secretion. Immunoperfusion of rabbit CCDs with anti-BKα Ab revealed robust immunodetectable protein in PC cilia (MS in preparation).

Methods: (see Results)

Results: To test whether cilia BK channels mediate FIKS, net transepithelial transport (Jx) of Na and K was measured in microperfused control or deciliated (by luminal perfusion with 1 mM dibucaine, 30 min) CCDs isolated from NZW rabbits. Flow-stimulated JNa (70.4±4.5 and 53.2±7.8 pmol/min.mm; p=0.12) and FIKS (-21.2±1.6 and -19.0±3.6 pmol/min.mm; p=0.63) were similar in control and deciliated CCDs (n=4 and 5, respectively). The detection of FIKS in deciliated CCDs suggested that a flow-induced increase in $[Ca^{2+}]i$ must be preserved in absence of cilia. To test this, flow-induced $[Ca^{2+}]i$ transients, inferred from fluorescence intensity ratios (FIRs), were measured in control, deciliated or suramin (100 μM; nonspecific P2 receptor antagonist) pretreated CCDs loaded with fura-2. In control CCDs, a rapid increase in tubular fluid flow rate led to a typical high amplitude peak increase in FIR in both PC and IC, presumably reflecting release of Ca^{2+} from internal stores and influx of Ca^{2+} from the extracellular space, followed by gradual decay to a plateau value, considered to be mediated by luminal Ca^{2+} entry. Deciliation led to loss of the flow-induced Ca^{2+} peak, but the plateau elevation in FIR above baseline was retained during a period of sustained high flow. Suramin-treated CCDs subject to acute increase in flow exhibited a slow increase in $[Ca^{2+}]i$ to a sustained plateau, but no early peak response.

Conclusions: We conclude that cilia BK channels do not mediate FIKS in the CCD, and speculate that apical BK channels in CCDs that mediate FIKS are activated by elevations in $[Ca^{2+}]i$ elicited by mechanoactivated cilium- and P2 receptor-independent signaling.

14-3-3 γ Modulates BK Function Through Altering ERK1/2 Signaling Pathway Shan Chen,[1] Xiuyan Feng,[1,3] Douglas C. Eaton,[2] Hui Cai.[1,2,3] *[1]Renal/Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Physiology, Emory Univ School of Medicine, Atlanta, GA; [3]Nephrology, Atlanta VA Medical Center, Decatur, GA.*

Background: 14-3-3 γ belongs to a family of multifunction regulatory proteins that mainly bind to phosphorylated Ser/Thr residues in the target proteins. 14-3-3 has been shown to play an important role in the regulation of many potassium channels. Previous studies have shown that Big K (BK) channel has many associated proteins including 14-3-3. Sequence analysis of BK shows a 14-3-3 binding site (R*XX*S/T) between amino acid 1091-1164. Thus, we hypothesized that 14-3-3 modulates BK function.

Methods: Cell culture, transfection, electrophysiology study, western blot analysis and immunoprecipitation were used in this study.

Results: To determine whether 14-3-3 interacts with BK channel, we first did co-immunoprecipitation (Co-IP) experiments. We found that 14-3-3 β and γ interact with BK protein. To further investigate whether 14-3-3 γ affects BK activity, we did electrophysiology experiments in HEK 293 stably expressing BK cells transfected with or without 14-3-3 γ. We found that 14-3-3 γ significantly decreased the channel activity (NPo), channel numbers per patch and channel open probability (Po) of BK channel compared to the control group (n=11 for 14-3-3 γ group and n=9 for the control group, $p < 0.05$) in HEK 293 stably expressing BK cells using single channel recording. We further investigated whether 14-3-3 γ affects BK protein expression in Cos-7 cells transfected with both BK plasmid and an increasing doses of 14-3-3 γ. We found that 14-3-3 γ decreased BK protein expression in a dose-dependent manner while increasing ERK 1/2 phosphorylation.

Conclusions: These data suggested that 14-3-3 γ inhibits BK channel activity and its protein expression through altering ERK1/2 signaling pathway.

SA-PO130

Kidney CD4-CD8- Double Negative T Cell Development Is MHC Dependent Mohanraj Sadasivam, Sanjeev Noel, Sul A. Lee, Abdel Hamad, Hamid Rabb. *Dept of Medicine, Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Background: Prior studies have established important roles of $CD4^+$ T cells, natural killer T cells, and $CD4^+CD25^+FoxP3^+$ Tregs in acute kidney injury (AKI) pathogenesis. Recently, $CD4^-CD8^-$ (double-negative; DN) T cells have been found in mouse and human kidney, and directly influence the course of experimental AKI (*J Am Soc Neph* 2015). However, little is known about the immunobiology of these cells and mechanism of action in AKI. We hypothesized that MHC restricts the quantity and function of kidney DN T cells.

Methods: C57BL6-β2m MHC class-I , MHC class-II knockout (KO) and WT control mice were used to determine the MHC restriction kidney DN T cells (n=3-4). The lymphocytes from the kidneys, lymph node (LN) and thymus were analyzed by flow cytometry. Microarray analysis of kidney DN T cells compared to $CD4^+$ & $CD8^+$ was performed.

Results: Kidneys from both class I and class II MHC KO mice have reduced total numbers of DN T cells compared to WT controls (WT, 3,355±1,077 vs. MHC I KO, 1,016±471 vs. MHC II KO, 1,538±639; P<0.01). DN T cell numbers in LN were 16,546± 1,740 in WT, 9,383± 372 in MHC I KO and 21,988±7,157 in MHC II KO. (P<0.01) in thymus were 19,735±7,681 in WT, 7,610±3,215 in MHC I KO and 26,390±6150 in MHC II KO. (P<0.05) We also evaluated percentage of DN T percentage in comparison to $CD4^+$ & $CD8^+$ cells in kidney, LN and thymus (Table). Microarray analysis also revealed major differences between kidney cell types.

Table. Percentage of T cells

Mouse groups	DN T cells	$CD4^+$ T cells	$CD8^+$ T cells
Kidney			
WT	18.6 ± 3	54 ± 4	26± 4
MHC class-I KO	13 ± 3*	83 ± 4	2 ± 1*
MHC class-II KO	31 ± 1	14 ± 4*	50 ± 4
LN			
WT	4 ± 2	63 ± 6	33 ±3
MHC class-I KO	2 ± 1*	98 ± 1	1± 0.1*
MHC class-II KO	7 ± 2	4 ± 1*	85 ± 4
Thymus			
	2± 1	75 ± 2	15 ± 1
MHC class-I KO	1 ± 1*	90 ± 2	1 ± 1*
MHC class-II KO	5 ± 1	17 ± 2*	43 ± 1
* P value < 0.01			

Conclusions: These data demonstrate that DN T cells in the kidney have similarities but also unique MHC restriction compared to other lymphoid organs. Microarray analysis demonstrated further insightful differences. Further dissection of kidney DN T cell biology will help us understand the pathogenesis of AKI and other immune mediated kidney diseases.

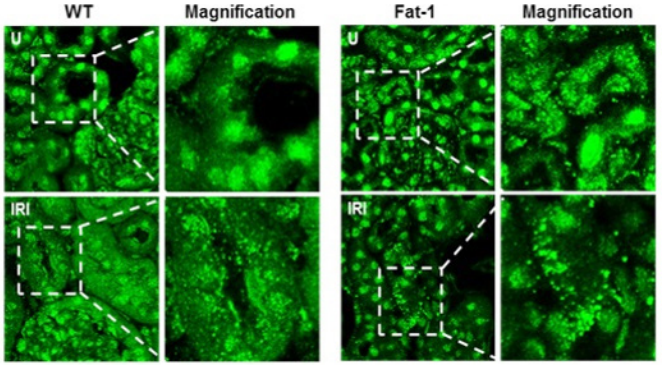
Transgenic Mice with High Endogenous Omega-3 Fatty Acids Are Protected from Ischemia-Reperfusion-Induced Acute Kidney Injury via Basal Autophagy Activation Won Min Hwang, Se-Hee Yoon, Sung-Ro Yun. *Dept of Nephrology, College of Medicine, Konyang Univ, Daejeon, Republic of Korea.*

Background: Several studies found that omega(ω)-3 fatty acid diet reduces kidney dysfunction followed by ischemic injury. However, oral appliance of ω-3 PUFA to experimental animals, in fact, can cause much variability arisen from diet procedure. fat-1 transgenic mouse produce abundant ω-3 PUFA, resulting in balanced ω-6 : ω-3 ratio than wild type mouse. We investigated to see whether ω-3 PUFA has advantages in ischemia/reperfusion(IR)-induced AKI using fat-1 transgenic mice. In addition, we investigated the involvement of autophagy process as a possible underlying mechanism of these protection.

Methods: Bilateral kidneys of experimental animals (fat-1 and C57BL/6 mice) were subjected to 30 min of warm ischemia. After 24hrs and 72hrs of reperfusion, animals were sacrificed. The effects of ω-3 PUFA on IR-induced AKI were evaluated in terms of serological marker for kidney function, kidney injury marker, morphology, and inflammatory cell infiltration. Finally, autophagy status in renal tubular cells with or without IR-induction was assessed by confocal microscopic observation.

Results: After I/R-induced AKI, fat-1 mice showed the reduced level of serum BUN and creatinine compared with control. Furthermore, Kim-1 levels and morphological damage of renal tubule were reduced. Neutrophil infiltration into renal cortex were minimized in fat-1 mice compared with control. Interestingly, immunohistochemical detection of autophagosomes revealed that autophagy were activated in fat-1 mice kidney at basal status. After IR-induced AKI challenges, autophagy levels were unchanged in fat-1 mice. Activated autophagy in basal status might contributed to tubular protection against AKI.



Conclusions: Long-term and high dose of omega-3 supplement may protect renal function and structures against AKI via basal autophagy activation.

SA-PO132

Interaction between miR-21 and Hypoxia Induced Factors (1α and 2α) in Ischemia /Reperfusion Induced Acute Kidney Injury

Nana Song,[1,2,3] Xialian Xu,[1,2,3] Ping Jia,[1,2,3] Yi Fang,[1,2,3] Xiaoqiang Ding.[1,2,3] *[1]Div of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Shanghai Key Laboratory of Kidney and Hemodialysis, Shanghai, China; [3]Shanghai of Inst Kidney and Dialysis, Shanghai, China.*

Background: Accumulating evidence suggests that miR-21 is importantly involved in pathophysiological processes of ischemia/reperfusion (I/R) injury. It was reported that overexpression of miR-21 and hypoxia-inducible factor (HIF) induced by hypoxia preconditioning protected against kidney I/R injury. However, it is little known whether miR-21 and HIF interact with each other in the progress of kidney I/R injury.

Methods: In this protocol, we applied in vitro [hypoxia ($1\%O_{2\ \text{for 6 hours}}$)/ reoxygenation($21\%O_{2\ \text{for 1 hour}}$), H/R] and in vivo [ischemia (bilateral renal pedicles were clamped for 35 min)/reperfusion (24hours), I/R] experimental models to investigate the feedback loop between miR-21 and HIF.

Results: The results revealed that expression of miR-21, HIF1α and HIF2α were increased by H/R in vitro and I/R in vivo . Interference expression of HIF1α and 2α by siRNA modulated elevated expression of miR-21 induced by hypoxia and inhibition of hydrolysis of HIF by L-mimosine (500μM) or $CoCl_2$ (200μM) increased expression of miR-21. Activation of AKT/mTOR pathway was stimulated by H/R, in vitro. Silence of miR-21 repressed phosphorylation of AKT and mTOR and reduced expression of HIF1α, HIF2α induced by H/R. Inhibiting AKT/mTOR pathway by LY294002 (20μM) and rapamycin (10nM) attenuated up-regulation of HIF1α and HIF2α induced by H/R. Additionally, Silence of miR-21, HIF1α and HIF2α increased necrosis of HK-2 cells caused by H/R. And Silence of miR-21 in vivo aggravated renal injury, however, administration of L-mimosine or $CoCl_2$ reduced kidney I/R injury.

Conclusions: In summary, our finding indicated that HIFα regulated expression of miR-21 and miR-21 interacted with HIFα by AKT/mTOR pathway in turn. The feedback loop between miR-21 and HIFα suppressed kidney I/R injury and may be a potential therapeutic target for I/R induced acute kidney injury. Additionally, the up-regulation of miR-21, HIFα during acute kidney injury may imply a self-protection mechanism of the kidney.

Transcriptional Profile in Kidneys Subjected to Ischemia Reperfusion Injury Modified by CHBP and Caspase-3 siRNA

Yuanyuan Wu,[1,2] Yufang Zhang,[2] Aifen Liu,[2] Bin Yang.[1,2,3] *[1]Infection, Immunity and Inflammation, Univ of Leicester, United Kingdom; [2]Basic Medical Research Centre, Nantong Univ, China; [3]Nephrology, Affiliated Hospital of Nantong Univ, China.*

Background: Ischemia reperfusion (IR) injury is a major cause of acute kidney injury (AKI) without effective treatment. Identifying the etiology and mechanism of AKI could facilitate individualised intervention timely. Here, transcriptional profiles were investigated in mouse IR injury kidneys, with or without erythropoietin derived cyclic helix B surface peptide (CHBP) or caspase-3 small interfering RNA (C3siRNA).

Methods: Genomic profiling along with other injury parameters was detected in mouse kidneys subjected to 30-min bilateral renal occlusion followed by 48-h reperfusion. Comparisons were performed in 4 groups: IR, IR+24 nmol/kg CHBP, IR+CHBP+0.03 mg/kg C3siRNA, and IR+CHBP+NCsiRNA.

Results: CHBP altered 97 genes expression in the IR kidneys, while differentially expressed genes between C3siRNA and NCsiRNA in the IR+CHBP kidneys increased to 228, with only 5 genes in common such as PDK4 (1.5-fold, $p<0.05$). These genes broadly involved in multi tissue injury and repair processes and 28 genes have been reported closely related to renal-related injury. 8 genes such as CALCA and CYP3A13 positively and MYO5A and FGF1 negatively associated with tubulointerstitial damage (TID), with CALCA also positively related to serum creatinine (SCr) and apoptosis; and additional 7 genes related to apoptosis and caspase-3 activation, which were all reduced by CHBP. On the other hand, due to additional C3siRNA, PDK4, GREM1 and TMEM100 negatively related to TID; additional 13 genes, APLN and TM7SF21 positively associated with SCr, rest 11 genes such as GREM1, TMEM100 and CFHR2 negatively related to SCr and apoptosis. Most interestingly, attributed to C3siRNA+CHBP treatment, TMEM100 and COL11A1 positively related to all SCr, apoptosis, TID and caspase-3 activation.

Conclusions: IR injury might be closely related to genes involving in vascular integrity and renal cell survival, which was improved by CHBP and further enhanced by C3siRNA. Candidate genes such as PDK4, CALCA, TMEM100 and COL11A1, as potential biomarkers and therapeutic targets, need to be further validated.

The Endothelial Hypoxia-Inducible Factor -1 and -2 Mediate Protection from Acute Kidney Injury in the Context of Endothelial Prolyl Hydroxylase Domain 2 Deficiency

Ganeshkumar Rajendran, Michael P. Schonfeld, Pinelopi P. Kapitsinou. *Nephrology Div, Univ of Kansas, Kansas City, KS.*

Background: Prolyl-hydroxylases (PHDs) have emerged as safeguards of cellular metabolism through their oxygen sensing function, which enables them to regulate the activity of hypoxia-inducible factors (HIF). We have previously reported that loss of endothelial PHD2 protected from renal ischemia reperfusion injury (IRI) but the molecular mechanisms remain undefined. Here, we investigated the contribution of HIF in renoprotection induced by endothelial PHD2 loss and examined the impact of HIF-activation in endothelial cell (EC) metabolism.

Methods: EC-specific HIF activation was achieved by crossing Vecadherin (Cdh5)-Cre transgenics to Phd2 floxed mice, while the contribution of each HIF isoform was assessed by generating double mutants lacking both PHD2 and HIF1 (PHD2HIF1) or PHD2 and HIF2 (PHD2HIF2). IRI was induced by unilateral renal artery clamping. Metabolic profiling was conducted by LC/MS and GC/MS while bioenergetic analysis was performed using a Seahorse Extracellular Flux Analyzer.

Results: Deletion of either endothelial HIF1 or HIF2 in endothelial PHD2 deficient background reversed the renoprotection conferred by endothelial PHD2 loss as indicated by histological injury scores and *Kim1* mRNA levels in kidney homogenates (Day 3 post IRI, n=8 mice/group). Metabolomic analysis of ECs exposed to PHD inhibitor revealed significant increase in glycolytic metabolites with simultaneous reduction in TCA cycle metabolites suggesting that HIF activation led to glycolytic shift and suppression of mitochondrial metabolism (n=5), also indicated by reduction in oxygen consumption rate on bioenergetic analysis. In contrast, preconditioning of ECs with PHD inhibitor abolished the significant defects in mitochondrial metabolism triggered by hypoxia-reoxygenation (H/R).

Conclusions: Our data establish that both HIF-1 and HIF-2 are required in endothelial PHD2 mediated renoprotection. Furthermore, we show that the PHD/HIF axis leads to alterations in EC metabolism with critical consequences in response to H/R. Therefore, endothelial HIF may promote resistance to kidney injury by reprogramming EC metabolism.

Similar Serum Creatinine, but Non-Overlapping Gene Expressions

Katherine Xu,[1] Paul Rosenstiel,[1] Neal A. Paragas,[1] Christian Hinze,[3] Kai M. Schmidt-Ott,[3] Paolo Guarnieri,[1] Jonathan M. Barasch.[1] *[1]Dept of Medicine/Nephrology, Columbia Univ Medical Center, New York, NY; [3]Nephrology, Charite, Berlin, Germany.*

Background: Acute kidney injury (AKI) is currently diagnosed by the rise in serum creatinine (sCr) or a decrease in urine output without emphasis on its potential etiologies or on its clinical heterogeneity. While any etiology of AKI worsens patient outcomes, it remains unknown how hemodynamic or volume-responsive (vAKI) is related to intrinsic AKI with tubular damage (iAKI).

Methods: To clarify their relationship, we performed renal transcriptional profiling in mouse models of vAKI and iAKI with matched sCr levels.

Results: We found thousands of genes responding specifically to vAKI or to iAKI with limited overlap. These gene sets activated different signaling pathways, were functionally unrelated, and were expressed in different regions of the kidney. Moreover some of these proteins encoded by these genes demonstrated distinctive patterns in human urine. A cytokeratin was expressed in human iAKI urine but not in vAKI urine, while a placental-associated protein that may play a role in salt-sensitive volume stress, was expressed in human vAKI urine, but was absent in iAKI due to its proteolysis, demonstrating the potential loss of a protective mechanism. This distinct patterning of vAKI and iAKI in human urine has a number of clinical applications including the possible utility of a new class of biomarkers responsive to reversible volume stresses.

Conclusions: Consequently, despite similar sCr levels, vAKI and iAKI in our models were biologically distinct, implying that tests for these genes could refine and enhance current definitions of acute injury of the kidney.

Regulation of IL-17 mRNA Expression by Elevated Sodium and Ang II in AKI Primed CD4+ T Cells Is Dependent on Cytosolic Ca+2 Signaling

Purvi Mehrotra, Seth D. Mckinney, Stacey L. Dineen, Michael Sturek, David P. Basile. *Cellular and Integrative Physiology, Indiana School of Medicine, Indianapolis, IN.*

Background: Th17 cells have been implicated in the pathogenesis of immune-mediated diseases and in acute kidney Injury (AKI). We have shown that during the AKI-chronic kidney diease (CKD) transition, the number of Th17 cells increased 2-4 fold. In addition, post ischemic rats on high salt diet when treated with angiotensin receptor (AT1) blocker, losartan significantly reduced IL-17+ cell infiltration as compared to vehicle control. To investigate IL-17 responses in post ischemic rats, CD4+T cells isolated from injured rats were treated with both Ang II (10^{-7}M) and elevated Na^+ (170 mM) in vitro. IL-17 mRNA expression significantly increased 5 fold when treated with both elevated Na^+ and Ang II as compared to either elevated Na^+ and Ang II alone. Interestingly, no IL-17 response was measured in CD4+ T cells isolated from sham-operated rats. The IL-17 response was significantly reduced by 2-aminoethoxydiphenyl borate (2-ABP) (93%; $p<0.05$) an inhibitor of store-operated Ca^{+2} channel and the L-type Ca^{+2} channel inhibitor, Nifedipine (1μM) (85%; $p<0.05$). In contrast there was no induction of IL-17 expression when osmolality was raised to the same degree by mannitol or choline chloride, suggesting the response was specific to extracellular Na^+. Multiple studies suggest that T cell receptor stimulation and Ang II independently increase intracellular free Ca^{+2} concentration, which induces proliferation and cytokine secretion. We hypothesize that elevated Na^+ and Ang II may enhances a Ca^{+2} influx in T cells leading increased IL-17 secretion.

Methods: Fura-2 was used to measure Ca^{2+} in renal CD4+T cells isolated from post-ischemic or sham operated rats 7 days post-surgery.

Results: Interestingly, elevated Na^+ and Ang II induced a sustained elevation of calcium influx, measured at the single cell level. The increase in Ca^{2+} response in post ischemic rats was present in 50% of the cells, whereas <1% of the sham-operated cells showed any effect.

Conclusions: Taken together, these data suggest that IL-17 gene regulation in AKI-primed T cells is dependent on on increased cytosolic Ca^{2+} via Ca^{2+} influx.

Protective Role of Endothelin B Receptor against the Development of Tunicamycin-Induced Renal Apoptosis Carmen De Miguel,[1] Janet Hobbs,[1] Pamela K. Carmines,[2] David M. Pollock,[1] Jennifer S. Pollock.[1] *[1]Medicine/ Nephrology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.*

Background: Renal injury is normally preceded by renal tubular apoptosis and loss of nephrons. The vasoactive peptide endothelin-1 (ET-1) is upregulated in cardiovascular and renal disease; however, the exact mechanisms by which ET-1 leads to renal injury are unclear. These studies were designed to determine the role of ET-1 receptors in the development of renal apoptosis in response to the acute kidney injury inducer tunicamycin (TM; 2 mg/g body weight i.p.).

Methods: ET_B deficient (ET_B def) or transgenic (TG) control rats were pre-treated with the ET_A antagonist ABT-627 (5mg/kg/day, drinking water) or vehicle for 1 week prior to TM injection. 24 hours after TM administration kidneys were collected and renal apoptosis assessed by TUNEL assay. TUNEL+ cells were evident in cortex and, to a greater extent, in medulla of TG control and ET_B def rats 24 hours after TM administration.

Results: Pre-treatment of TG control rats with ABT-627 almost completely obliterated TM-induced apoptosis in renal cortex (decreasing from 13.5±1.6 to 1.3±0.4 TUNEL+ cells/field; n=5-6/group; $p<0.05$) and medulla (decreasing from 30.2±2.7 to 1.6±0.4 TUNEL+ cells/field; n=5-6/group; $p<0.05$), indicating that ET_A receptor activation is critical for the development of renal apoptosis. In contrast, ABT-627 failed to prevent TM-induced cortical and medullary apoptosis in ET_B def rats (cortex: 17.6 ± 2.0 TUNEL+ cells/field; medulla: 39.0± 4.4 TUNEL+ cells/field), highlighting the important protective role of the ET_B receptor against development of renal apoptosis. Examination at high magnification revealed that the TUNEL+ cells in renal tissue are interstitial cells located between tubules and/or near vasa recta.

Conclusions: Taken together, these results underscore the involvement of the ET_A receptor in the development of TM-renal apoptosis and highlight the ET system as a possible therapeutic target against acute kidney injury. SA-PO138

Macrophages Regulate the Expression of Stromal Cell-Derived Factor 1 via Indoleamine 2,3-Dioxygenase after the Renal Acute Ischemia--Reperfusion Injury Xin Wan, Changchun Cao. *Dept of Nephrology, Nanjing First Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: To observe the expression of indoleamine 2,3-dioxygenase(IDO) and stromal cell-derived factor 1(SDF-1) in the kidney after ischemic reperfusion injury(IRI), and explore the relationship between IDO, SDF-1 and macrophage by depleting macrophages before the IRI.

Methods: A total of 32 healthy C57BL/6 male mice were used to establish renal IRI model by clamping unilateral renal pedicle for 60 minutes followed by reperfusion. Kidney tissue samples were collected at indicated time points. Renal histological changes were estimated. The expression of SDF-1 and IDO were determined by immunohistochemistry, ELISA and real-time PCR. In LC group, after the liposomal clodronate was injected intraperitoneally, the location of CD68 was observed by immunofluorescence. In 1-MT group, IDO was evaluated by immunofluorescence after injecting intraperitoneally with 1-methyl-tryptophan. Renalhistology and protein expression of SDF-1 and IDO were also detected.

Results: Compared with sham-operated group, classical tubular damage was found in IRI group, accompanied by a lot of inflammatory cells infiltrate. The expression of total renal SDF-1 and IDO peaked on day 1 and decreased to normal levels after two weeks. IDO doesn't express in healthy kidneys, while SDF-1 in healthy kidney was localized at cortex and expand to the other area of the kidney during IRI. Compared with IRI groups, elimination of macrophageby injection of liposomal clodronate alleviated renal IRI and down-regulated the expressions of CD68 while up-regulating SDF-1. In 1-MT group, which IDO was depleted by using 1-MT, the expression of CD68 was normal while SDF-1 was up-regulated.

Conclusions: SDF-1 expression is up-regulated in IRI kidney and is associated with macrophages express with IDO. SDF-1 may play a role in the early phase of acute kidney injury and IDO inhibiter can be a new medicine in therapy of AKI.

Inhibiting PERK Phosphorylation Prevents Expression of the Pro-Apoptotic Protein CHOP Rachel Carlisle,[1,2] Jeffrey G. Dickhout.[1,2] *[1]Medical Sciences, McMaster Univ, Hamilton, ON, Canada; [2]Nephrology, St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

Background: Acute kidney injury (AKI) is a major cause of morbidity and mortality in North America, and is regularly associated with endoplasmic reticulum (ER) stress. Tunicamycin, a nucleoside antibiotic, is often used as a mouse model of ER stress-induced AKI. Tunicamycin treatment results in vacuolization of the tubular epithelium, denudation and loss of cellular nuclei, apoptosis, and increased expression of ER stress markers, including GRP78 and CHOP. Interestingly, transgenic knock out of the pro-apoptotic protein CHOP prevented tunicamycin-mediated renal damage, implicating CHOP in the pathogenesis of AKI. GSK2606414 inhibits the phosphorylation of PERK, which is upstream of CHOP. We hypothesized that inhibiting PERK phosphorylation with GSK2606414 would prevent tunicamycin-induced CHOP expression and AKI.

Methods: Immortalized human proximal tubular cells were treated with vehicle, tunicamycin (1 μl/ml), tunicamycin and GSK2606414 (1 μM), or GSK2606414 alone, for 4 or 24 hrs. RT-PCR was performed for CHOP and Western blotting for CHOP and GRP78. Male wild type C57BL/6 mice were treated with a single dose of tunicamycin (0.5 mg/kg I.P.) or co-treated with tunicamycin and daily GSK2606414 (50 mg/kg) oral gavage. Mice were sacrificed after 3 days, and kidneys were subsequently stained for CHOP.

Results: Results demonstrate that tunicamcyin significantly increased CHOP mRNA and protein expression in proximal tubular cells; inhibiting PERK phosphorylation with GSK2606414 prevented this increase. Mice treated with tunicamycin exhibited an increase in nuclear CHOP staining. Mouse kidneys were protected from increased CHOP expression by co-treatment with GSK2606414.

Conclusions: These results suggest that CHOP plays a significant role in ER stress-induced renal damage, and attenuating its expression may provide new therapeutic strategies to protect against certain forms of AKI. Funding - Dr Dickhout is a Krescent New Investigator.

Niclosamide Relieves Renal Ischemia-Reperfusion Injury by Promoting Fatty Acid Oxidation in Tubular Epithelial Cells Jining Wu, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Acute kidney injury (AKI) induced by ischemia/reperfusion (I/R) injury is one of the major clinical challenges with increasing of morbidity and mortality. Defective fatty acid oxidation (FAO) is evident after I/R, which is fatal to tubular epithelial cells. It was recently reported that niclosamide, a mitochondrial uncoupling agent, could promote FAO in liver cells. However, whether niclosamide could reduce I/R injury via improving FAO is largely unknown.

Methods: Male C57BL/6J mice were subjected to renal I/R. Niclosamide was given orally from 1 day before the surgery till the end of the study. Renal function, kidney histological abnormalities and FAO disorders were examined.

Results: Compared to vehicle control, niclosamide treatment marked relieved renal dysfunction at day 1 after I/R as demonstrated by reduced the increase of blood urea nitrogen. Histological examination showed the relief of tubular injury in cortex and outer medulla by niclosamide. I/R-induced fatty acid deposition in tubular epithelium was almost diminished in niclosamide-treated mice. The reduced expressions of enzyme and transcription factor that mediates and regulates FAO (CPT1 and PPAR-α) after I/R were largely restored by niclosamide.

Conclusions: In this study, it was demonstrated that niclosamide protects IR-induced AKI by promoting FAO. Our results raised the possibility that correcting the defective FAO may be useful for preventing and treating acute kidney injury.

NAD+ Degradation in the Injured and PGC1α-Deficient Kidney Mei T. Tran, Samir M. Parikh. *Div of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: NAD+ is a key regulator of cellular energy metabolism. The kidney expends large amounts of energy in its main functions of reabsorption and secretion. Recent work showed that total NAD+ is markedly reduced in the kidney following ischemia reperfusion injury. Genetic induction of PGC1α activated de novo biosynthesis of NAD+, resulting in faster recovery from ischemic injury. Whether biosynthesis, reduced consumption from NAD-dependent enzymes, or a critical balance of both confers this NAD-related protection requires further investigation.

Methods: Genetic mice null (KO) or overexpressing PGC1α in the kidney (iNephPGC1α) underwent 20 min of bilateral renal ischemia, then 24h of reperfusion. Organs were harvested at 24h post-injury. Wildtype C57BL6 mice were injected with niacinamide (Nam, IP 400 mg/kg). Total NAD and Sirt1 activity were measured by colorimetric and fluorimetric assays. Gene expression was measured by qPCR.

Results: Enzymes involved in NAD+ biosynthesis were upregulated in iNephPGC1α mice at baseline, and remained elevated compared to control animals post-IRI. KO mice had lower basal expressions of these enzymes, which were further depleted in IRI. The rise and fall of these enzymes coincided with total NAD. To address if NAD+ fluctuations were due to increased NAD+ consumption, rather than reduced NAD+ biosynthesis, sirtuin expression and activity levels were measured in Nam-treated wildtype mice. Total NAD+ was elevated in Nam-treated mice, with no change in Sirt1 activity. Following IRI, NAD+ levels and Sirt1 activity decreased across all conditions. Relative to injured controls, total NAD+ was still greater in injured Nam-treated mice, and unexpectedly, Sirt1 activity was similarly elevated.

Conclusions: Results suggest that depletion of NAD+ in the injured or PGC1α-deficient kidney may not be due to greater NAD+ consumption, but as recent work proposes, inability to synthesize NAD+. Furthermore, though Nam is known to inhibit Sirt1, these studies show that basal Sirt1 activity was unchanged with systemic Nam administration. Even more surprising is that Sirt1 activity is higher in the injured Nam-treated mice, suggesting that sirtuin activity reflects overall kidney health.

Funding: NIDDK Support

Pannexin1 Deletion Protects Kidneys from Ischemia-Reperfusion Injury in Mice Jakub Jankowski,[1] Heather M. Perry,[1] Liping Huang,[1] Hong Ye,[1] Brant Isakson,[2] Kodi S. Ravichandran,[3] Mark D. Okusa.[1] *[1]Div of Nephrology; Center for Immunity, Inflammation and Regenerative Medicine, Univ of VA; [2]Dept of Molecular and Cellular Physiology, Univ of VA; [3]Dept of Microbiology, Immunology, and Cancer Biology, Univ of Virginia, Charlottesville, VA.*

Background: Extracellular ATP can contribute to inflammation following cell damage or death through its action as a danger molecule on P2X and P2Y receptors. The cellular mechanism of ATP release and its impact on kidney ischemia-reperfusion injury (IRI) are largely unknown. Pannexin1 (PANX1), a transmembrane channel, can be activated to release ATP yet its impact on kidney IRI is not known. We hypothesize that deletion of PANX1 and reduction of ATP release is protective in kidney IRI. We also predict this effect may be mediated by PANX1 in proximal tubules (PT), as they are a rich source of ATP and highly susceptible to IRI.

Methods: Global PANX1 (*Panx1*$^{-/-}$, n=10) and PT-specific PANX1 (*PepckCrePanx1*$^{f/f}$, n=4) KO mice and appropriate controls (n=9 and 3 respectively) were subjected to 26' bilateral kidney IRI or sham operation and 24h of reperfusion. Kidney function was assessed by plasma creatinine (PCr) and kidney injury by stereological quantification of acute tubular necrosis (% of outer medulla area) of H&E stained kidney sections. Proinflammatory markers were quantified by real-time PCR of whole kidney lysates. Apoptosis was assessed by detection of cleaved caspase3 by immunohistochemistry.

Results: Increased PCr (mg/dL) in WT mice after IRI was blunted in *Panx1*$^{-/-}$ mice (1.4 vs. 0.21; p<0.0001). Consistent with better kidney function, *Panx1*$^{-/-}$ kidneys had less necrosis (%) (19.65 vs 81.01, p<0.0001) and fewer cleaved-caspase 3 positive tubule cells. The increase in kidney mRNA of proinflammatory cytokines (*Tnfa, Il6, Csf1*), chemokines (*Cxcl1, Cxcl2*) and leukocyte adhesion molecules (*Icam1, Sele, Selp*) in WT mice after IRI was attenuated in *Panx1*$^{-/-}$ mice. Lastly, the increase in PCr in controls after IRI was markedly reduced in *PepckCrePanx1*$^{f/f}$ mice (1.84 vs 0.16 respectively).

Conclusions: These results show that both global and PT loss of PANX1 protect mouse kidneys from IRI and suggest that PANX1 may serve as a therapeutic target in AKI.

SA-PO143

Drp1-Dependent Mitophagy Protects against Cisplatin-Induced Apoptosis of Renal Tubular Epithelial Cells by Improving Mitochondrial Function Yanggang Yuan, Ningning Wang, Huijuan Mao, Chang Ying Xing. *Dept of Nephrology, The First Affiliated Hospital of Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Mitochondrial dysfunction plays an important role in cisplatin induced nephrotoxicity. Degradation of damaged mitochondria is carried out by mitophagy. Little is known of the precise role of mitophagy and its molecular mechanisms during cisplatin induced nephrotoxicity. Also, evidence that activation of mitophagy improved mitochondrial function is lacking. Furthermore, several evidences have shown that mitochondrial fission coordinates with mitophagy. The aim of this study was to investigate whether activation of mitophay protects against mitochondrial dysfunction and renal tubular cells injury during cisplatin treatment. The effect of mitochondrial fission on mitophagy was also investigated.

Methods: Autophagy was evaluated by autophagy markers and mRFP-GFP-LC3 adenovirus. Mitophagy was determined the co-localization of mitochondria with lysosomome. ROS levels were determined by DCFDA and MitoSOX. Mitochondrial membrane potential was assessed by JC-1. ATP concentration was quantitatively determined using an ATP determination kit. Cell viability and cell apoptosis were accessed by CCK-8 assay and AnnexinV-FITC–PI double staining assay respectively. Mitochondrial morphology was visualized by using MitoTracker Red. siRNAs were used to knock down mitochondrial fission main regulator dynamin-related protein-1 (Drp1) expression and subsequent changes were observed.

Results: In cultured human renal proximal tubular cells, we observed that 3-methyladenine, a pharmacological inhibitor of autophagy, blocked mitophagy and exacerbated cisplatin-induced mitochondrial dysfunction and cells injury. In contrast, autophagy activator rapamycin enhanced mitophagy and protected against the damage effects of cisplatin on mitochondrial function and cells viability. Knockdown of Drp1 decreased cisplatin-induced mitophagy. Meanwhile, Drp1 suppression protected against cisplatin-induced cells injury by inhibiting mitochondrial dysfunction.

Conclusions: Our results provide evidence that Drp1-depedent mitophagy has potential as renoprotective targets for the treatment of cisplatin-induced AKI.

SA-PO144

Thioredoxin-Interacting Protein (TXNIP) Regulates Mitochondrial Function of Renal Tubular Cells and Prognosis of Ischemia/Reperfusion-Induced Acute Kidney Injury Shigeru Nojima, Tatsuki Matsumoto, Koh Takahashi, Hirofumi Nishikawa, Yoshiko Shimamura, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Shimpei Fujimoto, Yoshio Terada. *Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan.*

Background: Thioredoxin-interacting protein (TXNIP) has been found to regulate the cellular reduction-oxidation (redox) state by binding to and inhibiting thioredoxin in a redox-dependent fashion. However, little is known about the role of TXNIP in mitochondrial function and acute kidney injury (AKI) pathogenesis.

Methods: We evaluated the role of TXNIP in renal function in bilateral renal ischemia (27 min)/reperfusion injury (IRI) model using TXNIP knock-out (KO) and wild type (WT) mice. We evaluated mitochondrial enzymes, morphology, ATP production, and membrane potentials of mitochondria from KO and WT mice. We also evaluate mitochondrial enzymes, inflammasomes by transfection of siRNA for TXNIP in cultured renal tubular cells (NRK-52E cells).

Results: TXNIP KO mice had significantly higher SCr (0.78+0.28 versus 0.45 + 0.17 mg/dl) and significantly higher BUN (152.5+32.5 versus 75.3+17.2 mg/dl) at 24h post ischemia compared to WT mice. Immunohistological examination showed severer tubular injury in cortex and outer medulla in TXNIP KO mice compared to WT mice. The number of TUNEL positive tubular cells was increased in TXNIP KO mice compared to WT mice. Dysmorphic mitochondria were observed in proximal tubules of TXNIP KO mice compared to WT mice. The protein expressions of mitochondrial enzymes (ATP5a, PGC1α and complex IV), ATP production, and membrane potentials were decreased in TXNIP KO mice at 24h post ischemia. In vitro experiments, protein levels of ATP5a, complex IV, PGC-1α were significantly decreased, and inflammasomes were activated by H_2O_2, and siRNA for TXNIP reduced changes of these enzymes in NRK-52E cells.

Conclusions: These data demonstrate that deficiency of TXNIP exaggerates IRI induced tubular injury. TXNIP changes mitochondrial function of renal tubular cells in oxidative conditions. These results indicate that TXNIP plays a key role in mitochondrial function and the pathophysiology of AKI.

SA-PO145

UCP2 Protects Tubular Epithelial Cells against Acute Ischemia/Reperfusion Injury by Regulating Fatty Acid Oxidation Yang Zhou, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Tubular epithelium reclaims more than 100l/d from glomerular filtrate. Reabsorption of so many sodium and solutes is an energy consumption process. Kidney is only second to heart in mitochondrial content—the energy producing plant. Tubular epithelial cells are especially rich in mitochondria. Moreover, tubular epithelial cells apply fatty acid oxidation (FAO) in mitochondria as its major energy resource, which is the most efficient way to generate ATP. Ischemia/reperfusion (I/R)-induced acute kidney injury (AKI) demonstrates both widespread mitochondrial injury and defective FAO. Uncoupling protein 2 (UCP2) is a mitochondrial anion carrier protein located in the inner membrane, which regulates the ratio of FAO vs. glucose metabolism during cell proliferation. Nevertheless, the role of UCP2 in FAO and AKI remains largely unknown.

Methods: Expression levels of UCP2 in kidneys were firstly examined after acute I/R injury. Proximal tubular cell specific UCP2 knockout mice were generated by cre-LoxP recombinant enzyme system. Mice were fed standard diets with conjugated linoleic acid (CLA) to upregulate UCP2. Both of them were applied to investigate the role of UCP2 in I/R-induced AKI.

Results: We examined the I/R injured kidneys and identified remarkable upregulation of UCP2 in the diseased kidneys. The proximal tubule specific UCP2 knockout mice were born and growth normal without kidney histological abnormalities or renal dysfunctions. As compared with littermates (wild-type), deletion of UCP2 exacerbated I/R-induced AKI as demonstrated by developing more severe renal dysfunction and worse morphologic abnormalities. In particular, we found that knockout mice had more significant declined expression of key enzymes and regulators of FAO and increased intracellular lipid deposition compared to wild-type mice. In contrast, upregulation of UCP2 by feeding CLA protected mice from I/R-induced AKI and mitigated FAO disorders. In vitro experiments indicated that UCP2 promoted FAO in primarily cultured tubular epithelial cells.

Conclusions: Our results raise the possibility that mitochondrial UCP2 may be useful for protecting tubular epithelium and treating AKI.

SA-PO146

Effect of Hypertonic Saline Solution and Pentoxifylline on Lipid Peroxidation and Apoptosis of Acute Kidney Injury Induced by Obstruction and Intestinal Ischemia in Rats Miguel A. Goes,[1,2] Roberto Rasslan,[3] Edna Frasson de Souza Montero,[3] Edivaldo Massazo Utiyama,[3] Samir Rasslan,[3] Gustavo Scapini.[2,3] *[1]Neprhology, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Nephrology, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil; [3]Surgery, Sao Paulo Univ, Sao Paulo, SP, Brazil.*

Background: Sepsis after intestinal obstruction and ischemia is associated to acute kidney injury (AKI). Apoptosis and oxidative stress are hallmarks of sepsis-induced AKI. Fluid resuscitation decrease sepsis-induced AKI. Objective: To evaluate the effects of hypertonic saline and pentoxifylline on oxidative stress and renal apoptosis in sepsis.

Methods: 48 male Wistar rats were underwent laparotomy to an obstruction and intestinal ischemia. They were treated randomly with different resuscitation solutions: Sham (n=8); Ringer Lactate (RL; n=16); Hypertonic Saline Solution 7.5% - (HSS; n=8); Pentoxifylline (PTX; n=8) and HSS associated with PTX (HSSPTX; n=8). They were infused over a 5 min period. The animals were sacrificed after 3 hours. Histopathological and immunohistochemical analyzes were performed with BcL-2 (ng/mg of protein), Bax (ng/mg) and TUNEL (ng/mg). Peroxynitrite (μM/mg of kidney tissue) by spectrophotometry and malondialdehyde (MDA- nmol/mg of protein) with the TBARS method dosages were performed.

Results: We observed a positive correlation between the levels of Bax and BcL-2 (r = 0.55; p <0.001), Bax and TUNEL (r = 0.48; p = 0.001), Bax and peroxynitrite (r = 0.32; p=0.03), Bax/BcL-2 and peroxynitrite (r=0.48; p=0.01). We found higher Bax

levels in PTX (5.75+0.71) than the RL (3.75+1.77; p<0.001). HSSPTX (1.38+0.74) had lower Bax levels than the RL (3.75+1.77) and PTX groups (5.75+0.71; p<0.001). BCL-2 immunohistochemical levels were higher in Sham group (5.50+1.69) than in the other groups (p<0.001). The Bax/BcL-2 ratio was higher in PTX (3.25+0.89) than HSSPTX group (2.38+0.92; p=0.009). TUNEL immunohistochemical levels were lower in HSS (18.5+6.93) and HSSPTX (10.7+2.77) groups than in the other groups (p<0.001). We did not observe difference in the concentration of MDA between the groups (p=0.62).

Conclusions: HSSPTX attenuated oxidative stress and decreased the immunohistochemical markers of apoptosis in sepsis-induced AKI.

Preconditioning with a Pharmacologic Activator of Adenine Monophosphate-Activated Kinase Reduces Apoptosis of Proximal Tubular Cells Exposed to Metabolic Stress: Role of Akt and Glycogen Synthase Kinase

Wilfred Lieberthal,[1] Jerrold S. Levine.[2] *[1]Medicine, Stony Brook Medicine, Stony Brook, NY; [2]Medicine, Univ of Chicago at Illinois, Chicago, IL.*

Background: We have reported that preconditioning proximal tubular cells (PTCs) with A-769662, an activator of adenine monophosphate-activated kinase (AMPK), ameliorates stress-induced apoptosis by preserving cell ATP stores (AJP: In Press). We now examine the role of Akt, a pro-survival kinase, and of glycogen synthase kinase-3b (GSK-3b) a pro-apoptotic kinase, in mediating the pro-survival effects of A-769662.

Methods: After preconditioning, PTCs were subjected to metabolic stress induced by antimycin without dextrose. Apoptosis was evaluated by FACS, the activity of Akt, GSK-3b, BAD and BAX by immunoblotting and cell survival using the MTT assay.

Results: Preconditioning with A-760662 reduced stress-induced apoptosis, increased the activation of Akt (by phosphorylating Thr-308 and Ser-437) and inhibited the activation of GSK-3b (by phosphorylating Ser-9). Preconditioning with A-760662 also inhibited the activation of BAD by phosphorylating Ser-136 (an effect mediated by Akt), and inhibited the allosteric activation of BAX, (an effect mediated by inhibition of GSK-3b). Knocking down AMPK activity reduced all these effects of A-769662 suggesting that they are mediated by AMPK activation. The increase in stress-induced cell survival induced by preconditioning with A-769662 alone, was reduced by preconditioning with A-769662 + MK-22-2 (an Akt inhibitor). Post-stress cell survival after preconditioning with MK-2202 alone, was lower than cell survival after preconditioning without A-769662 or MK-2202. The increased stress-induced survival of cells induced by preconditioning with A-769662 alone, or with A-769662 + TZDZ-8 (an inhibitor of GSK-3b) was comparable, while the post-stress cell survival after preconditioning with TZD alone was lower than after preconditioning with A-769662 + TZDZ-8, but higher than that after preconditioning without A-769662 or TZDZ-8.

Conclusions: The pro-survival effects of preconditioning PTCs with A-769662 before exposing them to stress is mediated, in part, by the activation of Akt and the inhibition of GSK-3b.

Vascular Adhesion Protein-1 Promotes Neutrophil Infiltration via Hydrogen Peroxide Generation in Renal Ischemia-Reperfusion Injury

Shinji Tanaka, Tetsuhiro Tanaka, Mai Sugahara, Hisako Saito, Reiko Inagi, Masaomi Nangaku. *Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Vascular adhesion protein-1 (VAP-1) acts as an adhesion molecule as well as an ectoenzyme catalyzing oxidative deamination of primary amines to generate hydrogen peroxide in extracellular space. While VAP-1 is implicated in leukocyte trafficking in various inflammatory diseases, its role in acute kidney injury is incompletely characterized. Thus, we examined the effect of VAP-1 inhibition in a rat model of renal ischemia-reperfusion (IR) injury.

Methods: Rats were subjected to left renal ischemia for 45 min after right nephrectomy, followed by reperfusion for 48 h. A specific VAP-1 inhibitor, Compound A (R-Tech Ueno, Tokyo, Japan; 40 mg/kg/day; in feed), or vehicle was administered to rats from 7 days before IR surgery.

Results: Immunofluorescence analysis suggested that VAP-1 was predominantly expressed in pericytes of rat kidneys. Primary mouse kidney pericytes expressed and released enzymatically active VAP-1. In vivo, Compound A administration significantly suppressed VAP-1 enzyme activity in the whole kidneys (7.0±1.3 vs 0.9±0.1 pmol/mg protein/min), which was accompanied by better renal function (BUN: 139±15 vs 69±6 mg/dL, Cr: 2.5±0.2 vs 1.4±0.1 mg/dL; p<0.01) and ameliorated histological tubular injury in the drug group. The number of neutrophils in the corticomedullary junction was significantly decreased in the drug group. There were no differences between groups in the numbers of macrophages/T lymphocytes or in the expression of other adhesion molecules. The protective effect of VAP-1 inhibition was absent in neutrophil-depleted rats. Moreover, in the under-agarose migration assay with purified human neutrophils, recombinant human VAP-1 significantly induced neutrophil migration, which was inhibited by Compound A or catalase.

Conclusions: These data suggest that VAP-1 plays an important role in the pathophysiology of renal IR injury by generating a local hydrogen peroxide gradient to enhance neutrophil infiltration, offering a promising view that VAP-1 inhibition can be a novel therapeutic target in ischemic acute kidney injury.

Methionine Sulfoxide Reductase A (MsrA)-Gene Deletion Aggravates Cisplatin-Induced Nephrotoxicity in Mice

Mi Ra Noh,[1] Jee In Kim,[2] Kwon Moo Park.[1] *[1]Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Korea; [2]Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Korea.*

Background: Methionine sulfoxide reductase A (MsrA) catalyzes stereospecifically the reduction of methionine-*S*-sulfoxide, and plays an antioxidant enzyme that scavenges reactive oxygen species (ROS). Cisplatin is the most widely used for the treatment of solid tumors. However, its side effects including nephrotoxicity limit use. In the present study, we investigated the role of MsrA in cisplatin-induced nephrotoxicity using MsrA gene-deleted ($MsrA^{-/-}$) and wild-type ($MsrA^{+/+}$) mice.

Methods: Mice were administrated with vehicle or cisplatin (10 mg/kg, i.p.) for 5 days.

Results: Cisplatin-induced renal functional and morphological impairments were greater in the $MsrA^{-/-}$ than in $MsrA^{+/+}$ kidneys. Cisplatin increased superoxide anion formation, hydrogen peroxide (H_2O_2) production, lipid peroxidation, and the ratio of oxidized glutathione (GSSG) to total glutathione (GSH) in the kidneys. These increases were much higher in $MsrA^{-/-}$ than in $MsrA^{+/+}$ kidneys. Cisplatin reduced the expression and activity of MsrA and MsrBs in the kidneys. Cisplatin reduced the expression of cystathionine-β-synthase (CBS) and cystathionine-γ-lyase (CSE), both of which are H_2S-producing enzymes, in the kidneys. Cisplatin exacerbated mitochondria dysfunction, reducing the levels of mitochondria fission 1 (Fis1), promoter of mitochondrial fission. Cisplatin also enhanced the pro-apoptotic response and increased the number of apoptotic cells. MsrA deficiency increased the cisplatin-induced mitochondrial dysfunction and apoptosis in the kidneys.

Conclusions: Taken together, these results demonstrate for the first time that cisplatin reduces MsrA activity and MsrA gene deletion exacerbates cisplatin-induced nephrotoxicity via increased oxidative stress, mitochondrial dysfunction, and apoptosis. It suggests that MsrA plays a crucial role in the pathogenesis of cisplatin-induced acute kidney injury (AKI) and may be a useful target protein to prevent cisplatin-induced nephrotoxicity.

SA-PO150

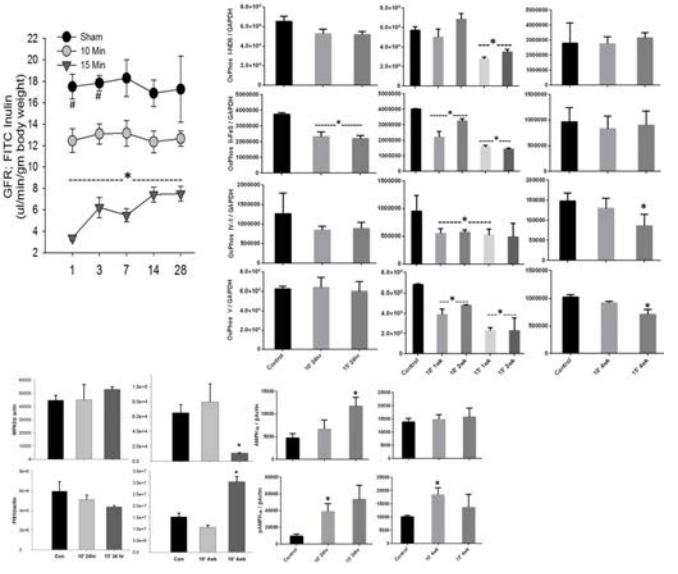
Mitochondrial Function during Injury and Recovery from AKI

Mark Hepokoski, Elanore Hall, Hai Pham, Ying Li, Prabhleen Singh. *Medicine, UC San Diego and VASDHS, San Diego, CA.*

Background: Renal tissue hypoxia is a common link between AKI and CKD. The kidney has high mitochondrial oxidative metabolism, and is exquisitely sensitive to hypoxic injury. Mitochondria play a central role in cell injury and their dysfunction has been implicated in various forms of AKI, but information on mitochondrial function during recovery from AKI is limited.

Methods: We performed 10-min and 15-min of bilateral renal artery clamping (IR) in mice and then serial GFR measurement by FITC inulin kinetics at days 1, 3, 7, 14 and 28 after ischemia and protein expression of mitochondrial oxidative phosphorylation complexes (Ox phos), fission, fusion and AMPK at the same time points.

Results:



Serial GFRs: In the 10-min group, GFR was significantly lower at days 1 and 3 but improved after that to levels similar in shams. In the 15-min group, GFR was dramatically reduced with partial recovery over 4 weeks. **Ox Phos expression:** Significant reduction in expression for both 10 and 15 min IR at 1-2 weeks for most complexes, with recovery in expression at 4 weeks for 10-min, but persistent reduction for 15-min IR. **Mitochondrial Proteins**-at 4weeks, 15-min IR showed significant reduction in Mfn2 and increase in Fis1 expression. Total **AMPK** expression was increased at day1, but no increase in pAMPK was seen in the 15-min IR kidney. In 10-min IR, pAMPK was increased at 24 hrs and persisted at 4 weeks.

Conclusions: Our findings show duration of IR corresponding with severity of injury and impaired recovery in GFR, and mitochondrial dysfunction with decreased Ox phos proteins and altered dynamics with impaired AMPK activation in IR kidneys, corresponding to severity of injury, but in some instances despite functional recovery. These may be important in transition of AKI to CKD. Additional studies to compare these two models when manipulated with maneuvers to worsen or improve recovery from IR are ongoing.

Antrum Mucosal Protein-18 Prevents Cisplatin-Induced Acute Kidney Injury in Mice Patrick Cunningham, Bradley K. Hack, Peili Chen, F. Gary Toback. *Section of Nephrology, Univ of Chicago, Chicago, IL.*

Background: Cisplatin induced nephrotoxicity is a frequent complication which limits the use of platinum based chemotherapy and increases morbidity in cancer patients. Antrum mucosal protein-18 (AMP-18) is a protein produced in the stomach which has mitogenic and protective effects on epithelium, mediated in part by strengthening intercellular tight junctions, previously demonstrated in cell culture and models of intestinal injury. We hypothesized that AMP-18 peptide would protect against cisplatin-induced nephrotoxicity in mice, which causes severe injury to the tubular epithelium (acute tubular necrosis, or ATN).

Methods: C57BL6 mice were given daily injections of AMP-18 peptide (25 mg/kg) starting two days before cisplatin administration. At day zero, mice were given cisplatin (30 mg/kg i.p.). AMP-18 injections were continued until sacrifice at 72 h after cisplatin (n = 6 per group). Serum was analyzed for BUN, and kidneys were collected for light microscopic staining and analysis of protein and mRNA.

Results: Mice in the cisplatin alone group had significant renal failure, but AMP-18 injected mice were profoundly protected (BUN 113.6 +/- 21.8 mg/dl in cisplatin + vehicle group, versus 39.8 +/- 5.2 mg/dl in cisplatin + AMP-18, $p < 0.01$). Mice injected with AMP-18 also had significantly less tubular necrosis on light microscopy (injury score 5.1 +/- 1.0 v. 1.0 +/- 0.2, $p = 0.003$), which correlated tightly with BUN readings. AMP-18 injected mice also had significantly less albuminuria after cisplatin (941 +/- 185 v. 444 +/- 105 mcg/mg creatinine, $p < 0.01$), as well as fewer apoptotic nuclei as seen by TUNEL staining. Immunofluorescence showed relatively preserved tight junctions in the tubular epithelium in AMP-18 treated mice.

Conclusions: In summary, AMP-18 peptide showed a strong protective effect in preventing cisplatin-induced nephrotoxicity. This finding may ultimately lead to therapies which could prevent cisplatin nephrotoxicity in patients.

Renoprotection of CHBP against Ischemia Reperfusion-Related Renal Injury Associated with Inhibiting Endoplasmic Reticulum Stress Qian Wang,[1] Yufang Zhang,[2] Aifen Liu,[2] Yuanyuan Wu,[4] Feng Liu,[1] Hui Wang,[1] Bin Yang.[1,2,5] *[1]Nephrology, Affiliated Hospital of Nantong Univ, China; [2]Basic Medical Research Centre, Nantong Univ, China; [3]Shanghai Key Laboratory of Organ Transplantation, Fudan Univ, China; [4]Pathology, Nantong Univ, China; [5]Infection, Immunity and Inflammation, Univ of Leicester, United Kingdom.*

Background: Ischemia reperfusion (IR) injury plays a key role in transplant and native kidneys alike. Our previous study revealed the renoprotection of cyclic helix-B surface peptide (CHBP) derived from erythropietin in IR injury, but its mechanism has not been fully defined. Endoplasmic reticulum stress (ERS) affects apoptosis and inflammation, involving in the pathogenesis of many diseases. This study aimed to explore the effects of CHBP on ERS in IR-related renal injury.

Methods: IR-related injury was established in mouse tubular epithelial cells via H_2O_2 stimulation and in mouse kidneys subjected to 30 min bilateral ischemia and followed by 2 & 8-wek reperfusion, with or without CHBP treatment. CHOP, an ERS hallmark, and its upstream regulatory PERK, and apoptosis and/or inflammation-related genes JNK and HMGB1 at mRNA and protein level were measured. In addition, apoptosis, cell viability and tubulointerstitial damage was also evaluated. Finally, the correlations between CHOP and assessed parameters were analyzed.

Results: The mRNA and protein of CHOP, PERK, JNK and HMGB1 were significantly increased in the TCMK1 cells stimulated by H_2O_2, while apoptosis was aggravated and cell viability was reduced. However, these effects were reversed by CHBP. In addition, CHOP protein was also significantly enhanced in the IR kidneys, but reduced by CHBP. Further more, CHOP mRNA was correlated with PERK mRNA and JNK protein ($r=0.955$ & 0.765, both $p<0.01$), while CHOP mRNA, PERK mRNA or JNK protein was respectively correlated with apoptosis positively ($r=0.647$ & 0.722, both $p<0.01$; $r=0.416$, $p<0.05$) and cell viability negatively ($r=-0.519$, -0.481 & -0.438, all $p<0.05$) *in vitro*. In addition, the level of CHOP protein was correlated with TID ($r=0.955$, $P < 0.01$) *in vivo*.

Conclusions: The renoprotection of CHBP in TCMK1 cells and kidneys subjected to IR-related injury might be associated with inhibiting ERS.

Renal Cold Storage plus Transplantation Alters Mitochondrial Dynamics: Involvement of Oxidants? Lee Ann MacMillan-Crow, Nirmala Parajuli, Stephen Shrum. *Pharmacology/Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: A major hurdle in the field of renal transplantation is the shortage of suitable donor kidneys. Renal transplantation using living-donor organs perform better when compared to deceased donor kidneys that were exposed to cold storage (CS) prior to transplantation (Tx). We recently reported that 4 hr CS compared to auto transplantation resulted in more severe mitochondrial and renal damage (J. Kidney, 2: 114, 2016). The purpose of the current study was to evaluate whether mitochondrial dynamics (fusion/fission pathways) were altered during CS/Tx and to dissect the molecular pathways involved.

Methods: Male rodent (Lewis) kidneys were isolated and cold stored for 0 or 18 hr and then transplanted in a naïve Lewis rat followed by right nephrectomy. Mitochondrial function was assessed via high resolution respirometry and ATP measurement. Mitochondrial dynamics were monitored using western blotting and electron microscopy (EM).

Results: EM data revealed marked mitochondrial fragmentation following CS+Tx Likewise, mitochondrial function was inhibited at complexes I, II, and III. Interestingly, CS alone led to impaired mitochondrial fusion (loss of long form of Opa1, which is critical for inner membrane fusion). CS+Tx also showed impaired Opa1 processing and decreased mitofusion expression (critical for outer membrane fusion). The mitochondrial protease, Oma1, has been shown to be activated by stress (and oxidants) which can lead to increased Opa1 processing and impaired mitochondrial fusion. Early studies show altered Oma1 activity during CS+Tx.

Conclusions: In summary, these studies suggest that renal CS initiates a defect in mitochondrial dynamics that likely involves increased oxidant-induced Oma1 protease function which then impairs mitochondrial fusion. Further studies designed to blunt Oma1 activity may protect donor kidneys from CS-mediated damage prior to transplantation.

Proximal Tubule-Specific Deletion of Cyclophilin D Prevents Cisplatin Nephrotoxicity Hee-Seong Jang,[1] Babu J. Padanilam.[1,2] *[1]Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; [2]Internal Medicine, Section of Nephrology, Univ of Nebraska Medical Center, Omaha, NE.*

Background: Damage of proximal tubule cell by chemotherapeutic agent cisplatin causes kidney injury and dysfunction. However, the underlying mechanism of cisplatin-induced tubular injury remains to be elucidated.

Methods: Since cyclophilin D (CypD) plays a critical role in necrotic cell death, we investigated whether proximal tubule-targeted deletion of CypD prevents cisplatin-induced kidney injury.

Results: Loss of proximal tubule CypD preserved mitochondrial morphology and function and prevented downregulation of mitochondrial biogenesis and expression of mitochondrial metabolism-related genes. Fatty acid metabolism was impaired in wild type mice, but was preserved in mice with proximal tubule deletion of CypD after cisplatin treatment. Consistent with mitochondrial damage, proximal tubule-targeted deletion of CypD suppressed cisplatin-induced tubular necrosis, apoptosis, inflammation, and kidney dysfunction. Pharmacological inhibition of CypD using Sanglifeherin A also prevented cisplatin-induced kidney injury. However, inhibition of ferroptosis by ferrostatin-1 did not protect, rather worsened, cisplatin-induced kidney injury, suggesting a dispensable role of ferroptosis in cisplatin nephrotoxicity.

Conclusions: Collectively, targeting CypD prevents cisplatin nephrotoxicity through preservation of mitochondrial metabolism, and may be developed asa potential therapeutic strategy for cisplatin nephrotoxicity.

Funding: NIDDK Support, Private Foundation Support

SA-PO155

Effect of Mitochondrial NADP+-Dependent Isocitrate Dehydrogenase (IDH2) on Cisplatin-Induced Nephrotoxicity Min Jung Kong,[1] Sang Jun Han,[1] Jee In Kim,[2] Kwon Moo Park.[1] *[1]Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Korea; [2]Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Korea.*

Background: Mitochondrial $NADP^+$-dependent isocitrate dehydrogenase (IDH2) is a major producer of NADPH producer which is critical for maintenance of glutathione (GSH) redox balance in the mitochondria. Cisplatin is one of the most common anticancer drugs. However, its nephrotoxicity due to a reduction of intracellular levels of glutathione by formation of cisplatin-GSH complex limits to use. Here, we investigated the role of IDH2 in cisplatin-induced nephrotoxicity using IDH2 gene-deleted ($IDH2^{-/-}$) and wild type ($IDH2^{+/+}$) mice.

Methods: Mice were administrated intraperitoneally cisplatin (20 mg/kg body weight). Some mice were treated Mito-Tempo, a mitochondria-specific antioxidant, before cisplatin injection.

Results: IDH2 deficiency aggravated cisplatin-induced renal functional and morphological impairments. MT reduced those cisplatin-induced renal functional and morphological impairments both $IDH2^{-/-}$ and $IDH2^{+/+}$ mouse kidneys. Cisplatin reduced NADPH levels in the kidney. This cisplatin-induced reduction of NADPH levels were greater in the $IDH2^{-/-}$ mouse kidneys than $IDH2^{+/+}$ mouse kidneys. Cisplatin increased hydrogen peroxide, lipid peroxidation and GSSG/total GSH ratio. These increases were

greater in the IDH2$^{-/-}$ mouse kidneys than IDH2$^{+/+}$ mouse kidneys. MT reduced those cisplatin-induced reduction of NADPH, and increases hydrogen peroxide, lipid peroxidation and GSSG/total GSH ratio both IDH2$^{-/-}$ and IDH2$^{+/+}$ mouse kidneys. Mitochondrial damage and renal cell death after cisplatin injection were greater in the IDH2$^{-/-}$ than IDH2$^{+/+}$ mouse kidneys. MT reduced those cisplatin-induced mitochondrial damage and cell death both IDH2$^{-/-}$ and IDH2$^{+/+}$ mouse kidneys. Above effects of MT were greater in IDH2$^{-/-}$ mouse kidneys when compared with IDH2$^{+/+}$ mouse kidneys.

Conclusions: These results indicate IDH2 deficiency aggravates cisplatin-induced nephrotoxicity by increasing mitochondrial oxidative damage, suggesting that IDH2 plays a crucial role in the pathogenesis of cisplatin-induced acute kidney injury (AKI).

SA-PO156

Deletion of Sirtuin 7 Ameliorates Cisplatin-Induced Acute Kidney Injury Through Regulation of Inflammatory Response Yoshikazu Miyasato,[1,2] Tatsuya Yoshizawa,[1] Terumasa Nakagawa,[2] Yutaka Kakizoe,[2] Yuichiro Izumi,[2] Takashige Kuwabara,[2] Masataka Adachi,[2] Eva Bober,[3] Masashi Mukoyama,[2] Kazuya Yamagata.[1] *[1]Medical Biochemistry, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [3]Cardiac Development and Remodeling, Max-Planck-Inst for Heart and Lung Research, Bad Nauheim, Germany.*

Background: Sirtuin 7 (SIRT7) is an NAD$^+$-dependent deacetylase. It is reported that SIRT7 has significant roles in disease conditions such as hepatic steatosis, cardiac dysfunction and cancer. However, very little is known about the functional roles of SIRT7 in kidney diseases. Therefore, we investigated the role of SIRT7 in acute kidney injury.

Methods: Acute kidney injury was induced by intra-peritoneal cisplatin administration (20mg/kg body weight) in SIRT7 deficient (SIRT7-/-) and wild-type (WT) mice. Mice were sacrificed at day 3 after cisplatin administration. Knockdown of SIRT7 in NRK52E, a rat renal proximal tubular cell line, was induced by short hairpin RNA (shRNA).

Results: SIRT7-/- mice showed significantly lower serum creatinine levels compared with WT mice (0.50±0.25 vs 0.85±0.38 mg/dL, $p<0.05$). Histological analysis revealed lower kidney injury score and macrophage accumulation in SIRT7-/- mice. The number of TUNEL positive cells was also significantly low. The survival rate of SIRT7-/- mice was significantly higher than WT mice at day 7 after cisplatin administration (Log-rank test, $p<0.01$). There were significant decreases in inflammation-related gene expression (TNF-α, IL-1β, IL-6, MCP-1) and oxidative stress-related gene expression (NOX2, p47 phox) in the kidney of SIRT7-/- mice compared with WT mice. In NRK52E, knockdown of SIRT7 ameliorated cell viability in WST-1 assay under cisplatin-exposed condition. In addition, the expression of inflammation-related genes also tended to lower in SIRT7 knockdown cells, but that of oxidative stress-related genes showed no change.

Conclusions: Our data demonstrated that the deletion of SIRT7 ameliorated cisplatin-induced acute kidney injury in mice, suggesting a possibility of novel pathogenic roles for SIRT7 in acute kidney injury through promoting inflammatory responses.

SA-PO157

Silencing Numb Exacerbates Cisplatin-Induced Acute Kidney Injury by Promoting Mitochondrial Fragmentation Ze Liu, Jing Nie. *The Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical Univ, Guangzhou, China.*

Background: Numb is a multifunctional protein involved in diverse cellular processes. We previous study showed that Numb is expressed in proximal tubules. Depletion Numb from proximal tubular cells attenuated interstitial fibrosis. The aim of the present study is to investigate the role of Numb in acute renal injury.

Methods: Scramble siRNA or Numb siRNA was injected into male BALB/C mice (18-20g) through tail vein. Cisplatin was administrated 24 h after siRNA injection and mice were sacrificed at day 3 after cisplatin injection. Renal function was evaluated by the level of serum creatinine. Renal morphology was examined by Hematoxylin and eosin staining. The apoptosis of tubules was tested by TUNEL assay, flow cytometry and western blotting. The mitochondrial morphology was assessed by electronic microscopy (EM) and immunofluorescence staining. The mitochondrial damage was evaluated by the release of cytochrome C.

Results: The expression of Numb was significantly upregulated after cisplatin administration both *in vivo* and *in vitro*. Silencing Numb exacerbated cisplatin-induced renal injury shown as increased Scr (2.0±0.4mg/dl vs 1.0±0.3mg/dl, $P<0.05$) and more severe morphological damage. TUNEL assay and flow cytometric analysis demonstrated that Numb deficiency dramatically increased cisplatin-induced apoptosis both *in vivo* and *in vitro*. EM showed that there was more mitochondrial fragmentation in Numb siRNA injected mice after cisplatin treatment. Similarly,compared with scramble siRNA transfected cells, mitochondrial fragmentation and cytochrome C release were more severe in Numb siRNA transfected NRK-52E cells after cisplatin treatment. Western blot analysis revealed that silencing Numb increased the protein level of Drp1, a key mitochondrial fission protein, after cisplatin stimulation both *in vitro* and *in vivo*. Pretreatment with mdivi-1, a pharmacological inhibitor of Drp1, attenuated cisplatin-induced mitochondrial fragmentation and apoptosis in Numb siRNA trasfected NRK-52E cells.

Conclusions: our data suggest that Numb plays a protective role in cisplatin-induced acute kidney injury by suppressing mitochondrial fragmentation, and the subsequent tubular cell apoptosis.

SA-PO158

Loss of Neutral Ceramidase in Mice Protects from Cisplatin-Induced Acute Kidney Injury Deanna L. Siow,[1] Tess Dupre,[1] Mark A. Doll,[1] Cierra Sharp,[1] Kumar Saurabh,[2] Judit Megyesi,[4] Ashley J. Snider,[5] Lina M. Obeid,[5] Yusuf A. Hannun,[6] Levi J. Beverly,[1,2,3] Leah J. Siskind.[1,3] *[1]Pharmacology and Toxicology, Univ of Louisville, Louisville, KY; [2]Medicine, Univ of Louisville, Louisville, KY; [3]JG Brown Cancer Ctr, Univ of Louisville, Louisville, KY; [4]Internal Medicine, Univ of Arkansas for Medical Sciences/Central Arkansas and Veterans Healthcare Sys, Little Rock, AR; [5]Medicine, Stony Brook Cancer Center, Stony Brook Univ, Northport Veterans Affairs Medical Center, Stony Brook, NY; [6]Medicine, Stony Brook Cancer Center, Stony Brook Univ, Stony Brook, NY.*

Background: Acute kidney injury (AKI) resulting from the use of the chemotherapeutic agent, cisplatin, remains a dose- and treatment-limiting obstacle for many patients. Sphingolipids, especially ceramide, play a central role in regulating the toxic effects of cisplatin on the kidney. Neutral ceramidase (nCDase) is a central enzyme in sphingolipid metabolism and loss of this enzyme has proven to be protective in traumatic injuries of both the brain and heart. We hypothesized that loss of nCDase would offer protection for cisplatin-induced AKI.

Methods: In this study we utilized a transgenic mouse whereby expression of nCDase has been depleted (nCDase$^{-/-}$) in combination with an established murine model of cisplatin-induced AKI. Nine week old nCDase$^{-/-}$ and wild-type (WT) C57BL/6 mice were used for this study.

Results: Our data indicate that loss of nCDase protects the kidney from cisplatin injury as evidenced by improved markers of kidney function (BUN, Serum Creatinine), reduced markers of kidney injury (NGAL), and improved kidney pathology. Expression levels of pro-inflammatory chemokines and cytokines (TNF-α, IL-1β, IL-6,MCP-1, and CXCL-1) and the numbers of inflammatory infiltrates were reduced in nCDase$^{-/-}$ mice as compared to that of the WT. Additionally, western blot analysis revealed that nCDase$^{-/-}$ mice exhibited reduced markers of ER stress (pERK, pJNK, IRE1α, CHOP, cleaved caspase 12).

Conclusions: Data presented indicate that loss of nCDase protects the kidney from the nephrotoxic effects of cisplatin treatment and thus inhibiting this enzyme is a potential renal protective strategy during cisplatin chemotherapy.

Renoprotective Effect of Prothymosin α-Derived Hexapeptide against Cisplatin-Induced Acute Kidney Injury Kenta Torigoe,[1] Yoko Obata,[1] Miki Sawa,[1] Satoru Oka,[1] Takehiko Koji,[2] Hiroshi Ueda,[3] Tomoya Nishino.[1] *[1]Dept of Nephrology, Nagasaki Univ Hospital, Nagasaki, Japan; [2]Dept of Histology and Cell Biology, Nagasaki Univ Graduate School of Biomedical Sciences, Nagasaki, Japan; [3]Dept of Pharmacology and Therapeutic Innovation, Nagasaki Univ Graduate School of Biomedical Sciences, Nagasaki, Japan.*

Background: Prothymosin alpha (ProTa) is reported to exert neuroprotective actions by inhibition of ischemia-induced necrosis and apoptosis in the brain and retina. Recently, the 6-amino acid peptide/P_6Q (NEVDQE), modified active core 6-amino acid peptide (a.a.51-56) in ProTa, also showed protective effect against retinal ischemia. Acute kidney injury (AKI) is caused by insults such as ischemia, hypoxia and nephrotoxicity, and is a common clinical event leading to high mortality and development of chronic kidney disease. However, to date, no effective treatment for AKI have been established. In this study we investigated the renoprotective effect of P_6Q against cisplatin-induced AKI.

Methods: 8 week old male Wistar rats were divided into 3 groups: vehicle-treated group, cisplatin (8mg/kg)-treated group, cisplatin-treated group with P_6Q (30mg/kg) injection. Cisplatin and P_6Q were administered intravenously, and P_6Q was injected 30 minutes before cisplatin treatment. Renal function was assessed at 1, 3, 5, 7, 9 days after cisplatin treatment by measuring serum creatinine. Renal histological change was assessed by PAS staining, and apoptosis of renal tubular cell was assessed by TUNEL staining.

Results: Serum creatinine level peaked at 5 days after cisplatin treatment. Histologic examination revealed extensive tubular damage such as tubular epithelial cell swelling, vacuolar degeneration, and desquamation in cisplatin-treated rats. Cisplatin treatment also increased the number of TUNEL-positive apoptotic cells at day 5. P_6Q injection significantly suppressed cisplatin-induced AKI and apoptosis of tubular cells.

Conclusions: We showed the renoprotective effect of ProTa-derived hexapeptide against cisplatin-induced AKI via suppression of apoptosis. Our results suggest that ProTa-derived hexapeptide may become a preventive drug for cisplatin-induced AKI.

Irf8 Regulated by DNA Methylation Contributes to Cisplatin-Induced Acute Kidney Injury Chunyuan Guo,[1,2] Xiao Xiao,[1] Qingqing Wei,[1,2] Huidong Shi,[3] Zheng Dong.[1,2] *[1]Dept of Cellular Biology and Anatomy, Augusta Univ, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA; [3]Dept of Biochemistry and Molecular Biology, Augusta Univ, Augusta, GA.*

Background: Acute kidney injury (AKI) is a major side effect of cisplatin chemotherapy in cancer patients. The pathogenesis of cisplatin-induced AKI remains largely unclear. This study was designed to determine the role of DNA methylation in cisplatin-induced AKI and identify the specific genes regulated by DNA methylation.

Methods: Reduced representation bisulfite sequencing (RRBS) was performed to determine the genome-wide DNA methylation changes in cisplatin-induced AKI. We also examined the effects of the DNA methylation inhibitor--5-aza-2'-deoxycytidine

(5-aza) on cisplatin-induced AKI in vitro. Furthermore, we determined the involvement of specific genes, such as Irf8, with methylation changes in cell culture model of kidney tubular cell injury.

Results: The genome-wide DNA methylation analysis showed aberrant DNA methylation alterations in cisplatin-induced AKI. DNA methylation inhibitor 5-aza sensitized RPTC cells to cisplatin-induced apoptosis. To identify the key genes regulated by DNA methylation which are involved in cisplatin-induced AKI, we analyzed the genome-wide DNA methylation data and found Irf8 showed hypomethylation at 5' UTR. This hypomethylation was associated with a marked increase of Irf8 expression in both mRNA and protein levels in cisplatin-induced AKI. Moreover, in RPTC cells, inhibition of DNA methylation by 5-aza upregulated Irf8 expression with or without cisplatin. And silencing Irf8 in RPTC cells inhibited cisplatin-induced apoptosis.

Conclusions: These results suggest that DNA methylation plays an important role in cisplatin-induced AKI by regulating specific genes, such as Irf8.

Mechanisms of Decreased Acute Kidney Injury (AKI) and Decreased Tumor Growth by Mitogen-Activated Extracellular Signal-Regulated Kinase (MEK) Inhibition

Kameswaran Ravichandran, Alkesh Jani, Raphael A. Nemenoff, Charles L. Edelstein. *Univ Colorado Denver.*

Background: The pathogenesis of cisplatin (Cis) AKI involves the MEK/ERK pathway. The MEK inhibitor U0126 blocks ERK activation. The effect of U0126 on AKI and tumor growth was determined in a 4 wk model of cisplatin AKI in tumor bearing mice.

Methods: Mice were injected with lung cancer cells. 10 days later, Cis (10 mg/kg/wk) and U0126 (5 mg/kg 2X/wk) were given for 4 wks. RIP3, a marker of necroptosis, cleaved caspase-3 (CC-3), a marker of apoptosis, PD-L1, an immune system suppressor, p-JNK and p-ERK (MAPK signaling) were measured by immunoblot. MAPK signaling RT² Profiler™ PCR Array was used to profile genes in the kidney.

Results: U0126 resulted in a significant decrease in BUN, SCr in mice with or without tumor. In kidney, U0126 protected against AKI despite increasing RIP3. ERK regulated cell cycle genes specifically cyclins, cyclin-dependent kinases (Cdk) and Cdk inhibitors were up to 78-fold increased by Cis and reduced by U0126. U0126 decreased tumor weight, potentiated the effect of cisplatin, increased CC-3, decreased p-ERK and p-JNK, had no effect on PDL1 in tumors.

	Vehicle	Veh+U0126	Cis	Cis+U0126
No cancer BUN	29	23	53 *	34 **
No cancer SCr	.14	.12	.25 *	.15 **
Cancer BUN	27	27	59 *	40 **
Cancer SCr	.1	.1	.3 *	.18 **
Kidney RIP3	+	++	+++	++
Tumor wt (g)	1.8	1.0	0.9 *	0.5 *
Tumor CC-3	+	+++	+	+++
Tumor PD-L1	+	+	+	+
Tumor p-JNK	+	+	+++	+
Tumor p-ERK	+	+	+++	+
Kidney gene	Fold increase by Cis	Fold decrease by U0126		
Cyclin A1	78	2.3		
Cyclin A2	58	11		
Cyclin B2	26	9		
Cyclin D1	22	2		
Cdk 4	9	.25		
Cdk inhibitor 1A (P21)	26	2.5		
Cdk inhibitor 1C (P57)	12	3		
Cdk inhibitor 2C	14	4		
	*P<0.05 vs. Vehicle, **P<0.05 vs. Cis			

Conclusions: The effect of U0126 to decrease AKI and tumor growth is independent of the presence of tumor. In kidney, U0126 increased RIP3 and the large increase in gene expression of cell cycle proteins regulated by ERK was decreased by U0126. Cell cycle proteins regulated by ERK signaling in AKI and cancer merits further study.

Doxycycline Ameliorates Cisplatin-Induced Nephrotoxicity in Mice Through Directly Acting on Proximal Tubular Cells and Promoting Cell Viability

Terumasa Nakagawa,[1] Yutaka Kakizoe,[1] Naoki Suenaga,[3] Yuki Narita,[3] Yoshikazu Miyasato,[1] Teruhiko Mizumoto,[1] Manabu Hayata,[1] Yuichiro Izumi,[1] Takashige Kuwabara,[1] Masataka Adachi,[1] Hirofumi Jono,[3] Hideyuki Saito,[3] Kenichiro Kitamura,[2] Masashi Mukoyama.[1] *[1]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Internal Medicine III, Univ of Yamanashi School of Medicine, Yamanashi, Japan; [3]Clinical Pharmaceutical Sciences, Kumamoto Univ Graduate School of Pharmaceutical Sciences, Kumamoto, Japan.*

Background: Cisplatin (CDDP) is a widely used anticancer agent but its use is sometimes limited by nephrotoxicity. We reported in Kidney Week 2015 that doxycycline (Dox) suppressed CDDP-induced acute kidney injury in mice through its anti-inflammatory, anti-oxidative and enzyme-inhibiting effects. In this study, in order to further explore the mechanism, we investigated the effect of Dox on the accumulation of CDDP in kidney tissue. Furthermore, we studied whether Dox attenuates cell injury caused by CDDP using cultured renal tubular cells.

Methods: C57BL/6J mice were divided into following three groups: 1) Control, 2) CDDP (20mg/kg, intraperitoneally) and 3) CDDP+Dox (2mg/ml in drinking water). After 7-day pretreatment of Dox, CDDP was administrated, and animals were sacrificed 24 hr later. The amount of platinum in the kidney tissue was measured by ICP-MS. Next, after cultured proximal tubular cells (NRK52E) were treated with CDDP and Dox, cell viability (WST-1) and mRNA expressions of cell injury markers were assessed.

Results: Renal accumulation of CDDP was not inhibited by treatment with Dox (CDDP 23.1±6.1 vs CDDP+Dox 21.5±8.2 pg/mg tissue), indicating that Dox may not affect pharmacokinetics of CDDP but exert protective effects by inhibiting detrimental reactions caused by CDDP within tubular cells. In NRK52E cells, CDDP reduced cell viability and induced mRNA expressions of IL-6, MCP-1, p67phox and Fas. These changes were mitigated significantly by treatment with Dox.

Conclusions: Dox suppressed CDDP-induced nephrotoxicity not through inhibiting CDDP accumulation but through directly attenuating detrimental reactions within tubular cells, suggesting that Dox could become a potential therapeutic strategy against CDDP-induced nephrotoxicity.

Exacerbated Cisplatin-Induced Renal Injury in NHERF1 KO Mice Is Associated with NF-E2 Regulation

Sanjana Rane, Shunying Jin, Caryl Conklin, Michelle T. Barati, Kenneth Gagnon, Eleanor D. Lederer, Madhavi J. Rane, Eleanor D. Lederer. *Medicine, Univ of Louisville.*

Background: Cisplatin, an effective chemotherapeutic drug, is highly nephrotoxic, limiting its use. Cisplatin toxicity is associated with acrolein accumulation in the cytosol of damaged renal tubules, yet the precise mechanisms underlying these events are unknown. Acrolein is known to modulate sodium-phosphate co-transport in renal cells, of which sodium-hydrogen exchange regulatory factor 1 (NHERF1) is a key mediator. Preliminary studies demonstrate renal regulation of Nuclear Factor Erythroid-derived 2 (NF-E2) by acrolein. Therefore, we hypothesized that mice treated with cisplatin induces kidney damage and fibrosis by modulating NF-E2 expression in a NHERF1-dependent manner.

Methods: Wild-type (WT) and NHERF1 knockout (NHERF1 KO) mice were treated with saline or cisplatin [20 mg/kg body weight] and sacrificed after 72 hours. Kidney homogenates and plasma samples were immunoblotted with appropriate antibodies. Kidney tissue sections were subjected to H&E staining and NF-E2 immunohistochemistry.

Results: Renal NF-E2 expression decreased in NHERF1 KO mice, compared to WT mice, which decreased further after cisplatin treatment, while cleaved-Cas-3 and Connective Tissue Growth Factor (CTGF) expression increased further. Cisplatin treatment resulted in loss of NF-E2 expression from the renal brush-border membrane in WT mice kidneys which was decreased further in cisplatin treated NHERF1 KO mice. Interestingly, NF-E2 was detected in the plasma of NHERF1 KO mice which was enhanced further after cisplatin treatment. Furthermore, NHERF1 KO mice were sensitized to more renal damage after cisplatin treatment compared to WT mice.

Conclusions: NHERF1 expression regulates intracellular and extracellular NF-E2 expression. Thus, NF-E2 could serve as a biomarker of AKI alleviating need for biopsies. NHERF1 could serve as a therapeutic target to modulate NF-E2 expression and treat AKI halting its progression to ESRD, in addition to potentially blocking cisplatin's nephrotoxic effects.

MAP3K14 Promotes Acute Kidney Injury Maria D. Sanchez-Niño,[1] Lara Valiño Rivas,[1] Laura Gonzalez-Lafuente,[1] Ana Belen Sanz,[1] Sergio A. Mezzano,[3] Harald Mischak,[4] Holger Husi,[2] Antonia Vlahou,[5] Alberto Ortiz.[1] *[1]Nephrology, IIS-Fundacion Jimenez Diaz, Madrid, Spain; [2]Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, United Kingdom; [3]Nephrology, Inst de Medicina, Univ Austral de Chile, Valdivia, Chile; [4]Mosaiques Diagnostics GmbH, Hannover, Germany; [5]Biomedical Research Foundation Academy of Athens, Greece.*

Background: The incidence of acute kidney injury (AKI) is increasing. There is currently no therapy that reliably prevents the progression to AKI or accelerates recovery of renal function. An improved understanding of pathogenic pathways may identify novel acute kidney injury therapeutic approaches.

Methods: Unbiased LC-MS/MS protein expression profiling combined with focused data mining identified MAP3K14 and non-canonical NFkB activation at the crossroads of the enriched pathways MAPK, chemokines, NFkB and apoptosis in the kidney cortex of experimental toxic AKI. Immunohistochemistry localized MAP3K14 expression to tubular cells. Validation of non-canonical NFkB pathway activation in experimental acute kidney injury (cisplatin, folic acid, bone marrow transplantation). siRNA targeting to study MAP3K14 in tubular cells.

Results: In AKI, the upstream kinase MAP3K14, the NFkB DNA binding heterodimer RelB/NFkB2, and proteins involved in NFkB2 p100 ubiquitination and proteasomal processing to p52, were up-regulated. Immunohistochemistry localized MAP3K14 expression to tubular cells in experimental and human AKI. In vivo evidence of MAP3K14 activation in experimental AKI consisted of NFkB2 p100 processing to p52, nuclear location and DNA binding of RelB and NFkB2. MAP3K14 activity-deficient aly/aly mice were protected from kidney dysfunction, inflammation and apoptosis in AKI. MAP3K14 siRNA targeting in cultured tubular cells decreased inflammation and cell death. Bone marrow transplantation experiments where consistent with a protective effect of renal cell MAP3K14 targeting. Cell culture and in vivo studies identified chemokines as MAP3K14 targets in tubular cells, thus identifying potential mediators of the deleterious effect of MAP3K14 in kidney injury.

Conclusions: In conclusion, MAP3K14 promotes kidney injury through promotion of inflammation and cell death and is a promising novel therapeutic target.

Apolipoprotein A-I Protects against Post-Myocardium Infarct Radiocontrast-Induced Acute Kidney Injury Roberto De Souza Moreira,[1,2] Jose Manuel Condor Capcha,[1] Talita R. Sanches,[1] Maria C. Irigoyen,[1] Lucia Andrade.[1] *[1]Univ of Sao Paulo School of Medicine, Sao Paulo; [2]Federal Univ of Goias, Goias, Brazil.*

Background: Radiocontrast (RC)-induced AKI develops in many patients after cineangiography and is associated with mortality and adverse outcomes. Hypercholesterolemia decreases nitric oxide availability, aggravating myocardial infarct (MI) and RC-induced AKI. ApoA-1 mimetic peptide 4F (4F) improves vascular function, reducing LDL oxidation.

Methods: Rats fed a high-cholesterol diet were sham-operated (n=6) or induced to MI by left anterior descending coronary artery ligation, treated or not 6h later: MI (n=15), MI+RC (intrafemoral iopamidol 2.9g/kgBW iodine, n=15), MI+4F (10 mg/kgBW i.p. 4F, n=8) and MI+RC+4F (n=8). At 24h, we analyzed echocardiograms; creatinine clearance (Ccr); serum total cholesterol, HDL and LDL; renal CD68 and TUNEL; and renal/cardiac eNOS. Data are mean±SEM.

Results:

	Sham	MI	MI+RC	MI+4F	MI+RC+4F
C_{cr} (ml/min/100gBW)	0.85±0.07	0.37±0.08[a,b,c]	0.17±0.04[a,b,c,d]	0.78±0.23	0.83±0.12

SA-PO166

Resveratrol Rescues Renal Function following Contrast-Induced Acute Kidney Injury in 5/6 Nephrectomy Rats Cassiane Dezoti da Fonseca, Daniel Malisani Martins, Mirian Watanabe, Sheila Marques Fernandes, Maria De Fatima Vattimo. *School of Nursing, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Contrast-Induced acute kidney injury (CI-AKI) is a common adverse effect in patients with chronic kidney disease. CI-AKI promotes renal vasoconstriction, hypoxia, activation of inflammatory cascade, oxidative cell damage and impaired renal function,This study evaluated the renoprotection of resveratrol (RSV), a polyphenol with vasodilating and anti-inflammatory properties in nephrectomized rats treated with iodinated contrast (IC).

Methods: Wistar, adult, male rats were randomized in four groups; Sham; Nx: 5/6 nefrectomy; Nx+IC: Nx rats that received iodinated contrast (6mg/kg); Nx+IC+resveratrol: Nx rats that received iodinated contrast (6 ml/kg, intraperitoneal, i.p.) and resveratrol (25 mg/Kg, i.p., 30 minutos before IC);. Renal function and hemodynamics were evaluated.

Results:

Groups (n)	Blood Pressure (mmHg)	Renal Blood Flow (mL/min)	Renal Vascular Resistance (mmHg/mL/min)	Inulin Clearance (mL/min)	NGAL (mg/dL)
SHAM (5)	87±6	9.5±1.6	9.4±2.4	0.66±0.10	47.9±19.1
Nx (5)	132±13*	8.7±2.3	16.1±4.8*	0.28±0.04*	76.7±31.3
Nx+IC (5)	122±6*	3.2±1.3*#	37.9±15.0*#	0.10±0.03*#	153.5±70,0*#
Nx+IC+RSV (5)	114±8*#	6.4±0.4°	18.0±2.2*°	0.24±0.04*°	57.5±22.1°

*p<0.05 vs SHAM; # p<0.05 vs Nx; ° p<0.05 vs Nx+IC Nx rats presented a decrease in inulin clearance and increase in NGAL levels. Renal hemodynamics showed an increase in renal vascular resistance, while IC enhanced this damage. Resveratrol maintained inulin clearance and NGAL levels and decreased renal vascular resistance in rats treated with IC.

Conclusions: Association between chronic kidney disease with CI-AKI predisposes to severe kidney injury. Resveratrol ameliorates renal function in CI-AKI by modulationg renal hemodynamics in Nx rats.

Funding: Government Support - Non-U.S.

Indole Analog MA-5 Protect against Contrast-Induced Renal Injury Takehiro Suzuki, Ryunosuke Numakura, Tetsuro Matsuhashi, Koichi Kikuchi, Hisato Shima, Eikan Mishima, Chitose Suzuki, Sadayoshi Ito, Takaaki Abe. *Tohoku Univ.*

Background: Contrast-induced nephropathy (CIN) is the most common cause of the iatrogenic and drug-induced kidney injury, but the therapeutic procedures have not been established. The renal hypoxia and the direct toxic effects of contrast media on renal tubular cells are postulated as the pathophysiologic mechanisms of CIN. Recently we reported mitochondria-targeted indole-derivative mitochonic acid-5 (MA-5) increased intracellular ATP, decreased mitochondrial ROS and improved cell survivals of fibroblasts form mitochondrial disease patients. MA-5 also improved the renal function and tubular cell injuries in murine renal ischemia reperfusion and cisplatin induced nephropathy models. The aim of this study is to examine the protective effects of MA-5 on CIN (Suzuki T. JASN 2015).

Methods: Immortalized human proximal tubular cell line HK-2 cells were cultured to 80% confluent and MA-5 at 10uM final concentration for 24hr without serum and then added radiocontrasts sodium ditrizoate, Iopamidol and iohexol at 75mg iodine /ml for another 1hr. Cell viability and cytotoxicity were accessed by WST-8 assay and LDH assay respectively. Male CD-1 mice, Body weight 30-35g were left-nephrectomized (Nx) and MA-5 was administrated, at 50mg/kg body weight by gavage, to mice 2hr before they injected with an inhibitor of prostaglandin synthesis (indomethacin, 10 mg/kg) intraperitoneally before iohexol (300 mg iodine/ml, 2 g iodine/kg) intravenously injection. 24hr after iohexol injection, mice were sacrificed, serum creatinine (Cr), urinary Neutrophil gelatinase-associated lipocalin (NGAL) and renal pathology were examined.

Results: MA-5 improved cell viabilities and reduced injured cell derived LDH activity in culture medium in Sodium ditrizoate, Iopamidol and iohexol treated HK2 cell culture. Serum Cr at 24hr after iohexol injection was not significantly different between MA-5 treated and control group. Urinary NGAl was significantly decreased in MA-5 treated animals compared to vehicle gavaged mice.

Conclusions: MA-5 exhibited improved viability in contrast medium treated HK-2 cells as well as decrease renal injury marker NGAL in CIN model mice. MA-5 might have the therapeutic potency on CIN.

SA-PO168

UII Receptor Knockout Prevents Mice from Acute Contrast-Induced Nephropathy Li Jie Zhang, Ai Hua Zhang. *Dept of Nephrology, Peking Univ Third Hospital, Beijing, China.*

Background: UII is a vasoactive, somatostatin-like cyclic peptide of 11 amino acids initially isolated from the urophysis of the goby fish. UII is generally agreed to be the most potent endogenous vasoconstrictor discovered to date. The present study explores whether UII can aggravate CIN and its pathogenesis in CIN by wild type C57Bl/6 mice with CIN and UIIreceptor gene knockout mice with CIN.

Methods: Plasma and urinary UII were measured by RIA, neutrophil gelatinase-associated lipocalin (NAGL) and retinol-binding protein 4 (RBP4) were measured by ELISA, immunohistochemistry and western blot were conducted on the kidney tissues of CIN with UII receptor gene knock-out mice (KO-CIN) , CIN with wild type mice (WT-CIN), and wild type control mice. Apoptosis of renal cells were detected by TUNE methods. Markers for autophagy (LC3-II and p62) were analyzed.

Results: Plasma creatinine was significantly increased in WT-CIN group and KO-CIN group in comparison to control group; however, plasma creatinine was significantly lower in KO-CIN group than in WT-CIN. Renal UII expression , urinary UII, NGAL and RBP4 significantly increased in WT-CIN group and KO-CIN group in comparison to normal control, whereas NGAL and RBP4 levels were significantly decreased in KO-CIN than those of WT-CIN. Apoptosis is increased in renal tubular epithelial cell in WT-CIN mice than that of normal control; however, apoptosis is inhibited in KO-CIN in comparison to WT-CIN mice. Expression of LC3-II is increased and P62 is reduced in comparison to that of the normal control, while expression LC3II is decreased and P62 is increased in KO-CIN mice in comparison to WT-CIN.

Conclusions: UII plays important roles in CIN and it can aggravate renal tubular epithelial cell injury. It can alleviate renal tubular epithelial cell injury in CIN if we interfere in UII action. The mechanisms involve inhibiting apoptosis and inhibiting overactive autophagy of renal tubular epithelial cells.

Thymoquinone Prevents Contrast-Induced Nephropathy
Murat H. Sipahioglu,[1] Serkan U. Topaloglu,[1] Cevat Yazici,[2] Cagri Sakalar,[3] Ismail Kocyigit,[1] Aydin Unal,[1] Sedat Sezen,[3] Bulent Tokgoz,[1] Oktay Oymak.[1] *[1]Nephrology, Erciyes Univ, Kayseri, Turkey; [2]Biochemistry, Erciyes Univ, Kayseri, Turkey; [3]Medical Biology, Erciyes Univ, Kayseri, Turkey.*

Background: Thymoquinone (TQ), the main constituent of the volatile oil from Nigella sativa seeds, is reported to possess strong anti-oxidant and anti-inflammatory properties. Pathophysiology of contrast induced nephropath (CIN) associates multipl factors including renal vasoconstruction, oxidative stress and increased inflammation. We hypothesized that TQ can attenuate renal injury in the rat experimental contrast induced nephropathy (CIN) model.

Methods: CIN was induced by injection of the radiocontrast medium diatrizoate in adddition to inhibition of prostoglandin and nitric oxide (NO) synthesis after 2 days of water deprivation.Rats were divided into 7 groups: control (C), L-NAME+INDO (NG-nitro-L-arginine+ indomethacin), contrast media (CM), TQ1 (TQ 1 mg/kg day), TQ 1.75 (TQ 1.75 mg/kg day), TQ1+CM, TQ 1.75+CM. TQ was given at two different doses (1 or 1.75 mg/kg day) for 4 days intraperitoneally before the contrast injection.

Results: Administration of 1 mg dose of TQ significantly attenuated the resulting renal dysfunction and inflammatory process **(table 1)** and histologic renal injury in the light microscopy.

	C	L-Name +Indo	CM	TQ1	TQ1.75	TQ1 +CM	TQ1.75 +CM	p
Creatinine (mg/dl)	0.3 ±0.03	0.56 ±0.27	2.03 ±1.28	0.29 ±0.01	0.28 ±0.02	0.41 ±0.06	2.23 ±0.8	CM vs TQ1+CM:0.004
BUN (mg/dL)	20.7 ±1.4	67.5 ±64.7	197.7 ±98	17.6 ±1.9	16.2 ±1.8	21.9 ±9.4	210 ±62	CM vs TQ1+CM:<0.001
NF-KB expression	%100	%79	%112	%102	%104	%72	%104	CM vs TQ1+CM:0.044
iNOS expression	%100	%109	%109	%93	%94	%45	%142	CM vs TQ1+CM:<0.001

Serum malondialdehyde and superoxide dismutase levels did not show any significant difference between the groups.

Conclusions: This study suggests that administration of thymoquinone may have potential as a new therapeutic approach to prevent CIN.

SA-PO170

Megalin Blockade with Cilastatin Suppresses Drug-Induced Nephrotoxicity
Shoji Kuwahara,[1] Michihiro Hosojima,[2] Ryohei Kaseda,[3] Sawako Goto,[3] Tomomichi Iida,[3] Akihiko Saito.[1] *[1]Applied Molecular Medicine, Niigata Univ, Niigata, Japan; [2]Clinical Nutrition Science, Niigata Univ, Niigata, Japan; [3]Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan.*

Background: Nephrotoxicity induced by anti-microorganism or anti-cancer drugs is a serious clinical problem. Megalin, an endocytic receptor expressed at the apical membranes of proximal tubules, mediates the nephrotoxicity of aminoglycosides (AGs) and colistin (CLT), which are key antimicrobials for multidrug-resistant organisms. The mechanisms underlying the nephrotoxicity induced by vancomycin (VCM), an antimicrobial for methicillin-resistant *Staphylococcus aureus*, and cisplatin (CDDP), an important anti-cancer drug, are unknown, but the nephrotoxicity of these drugs and of gentamicin (GM), an AG, is known to be suppressed experimentally with cilastatin (CS), which was developed originally as an inhibitor of renal dehydropeptidase-I. Here, we studied the mechanism underlying CS-mediated suppression of such drug-induced nephrotoxicity and the role of megalin.

Methods: Using quartz-crystal microbalance (QCM) analysis, we examined the binding of these drugs to megalin in the presence or absence of CS.Kidney-specific mosaic megalin knockout mice were used to investigate megalin-mediated nephrotoxicity with CLT, VCM, and CDDP. C57BL/6J mice were used to analyze the suppression of CLT-induced nephrotoxicity by CS. We performed agar disk diffusion analysis to assess whether CS affects the anti-bacterial activity of GM, CLT, and VCM.

Results: QCM analysis revealed that megalin is also bound by VCM and CDDP, and that the binding of GM, CLT, VCM, and CDDP to megalin is competed with CS. In addition, the nephrotoxicity induced by CLT, VCM, and CDDP was found to depend on megalin expression in the proximal tubules. CLT-induced nephrotoxicity in C57BL/6J mice was suppressed by concomitant CS administration. CS did not inhibit the anti-bacterial activity of GM, CLT, and VCM *in vitro*, just as CS was previously found not to affect the anti-cancer activity of CDDP.

Conclusions: Megalin blockade with CS efficiently suppressed the nephrotoxicity induced by GM, CLT, VCM, and CDDP.

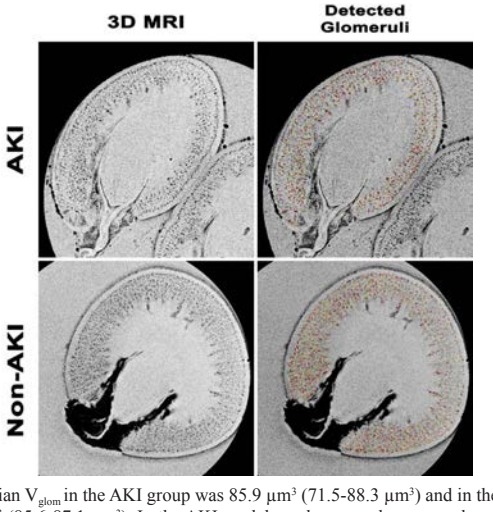
Reduced Glomerular Number in a Juvenile Rabbit Model of AKI Detected by MRI
Jennifer R. Charlton,[1] Edwin Baldelomar,[2] Valeria M. Pearl,[1] Kevin M. Bennett.[2] *[1]Univ of Virginia; [2]Univ of Hawaii.*

Background: There is a strong association between low nephron endowment and CKD. MRI techniques have made it possible to measure whole-kidney glomerular endowment (N_{glom}) and volume (V_{glom}) in the intact kidney, revealing pathology not detected by traditional biomarkers. Here we applied cationic ferritin enhanced-MRI (CFE-MRI) to investigate nephron loss from acute kidney injury (AKI) in a juvenile rabbit model.

Methods: New Zealand rabbits received 4 days of indomethacin (5 mg/kg) and gentamicin (100 mg/kg) during nephrogenesis at 1 wk of life. At 6 wks the AKI and controls received horse CF (1.92 mg/100 g BW, n=3/grp). Ninety minutes after the injection, the animals were euthanized. Images of intact kidneys were acquired with a 7T ClinScan (gradient echo: TE/TR: 80/20, 3 averages, resolution: 59x59x200 microns, slice thickness: 170 μm). N_{glom} and V_{glom} were determined using custom software.

Results: The AKI group weighed less than controls (diff: 655 g, p=0.004) and there was no difference the serum creatinine between the groups at 6 wks. Median N_{glom} by CFE-MRI in the AKI group was 100,932.5 (75,726-127,783) and in the controls median N_{glom} was 191,652 (138,417-251,180).



The median V_{glom} in the AKI group was 85.9 μm³ (71.5-88.3 μm³) and in the controls was 86.7 μm³ (85.6-87.1 μm³). In the AKI model, nephron number was reduced by 49% and histologic changes in AKI are consistent with a circumferential lesion of smaller, immature glomeruli.

Conclusions: CFE-MRI was used to detect glomerular morphology in the intact juvenile kidney. Induced AKI in neonatal rabbits causes a significant decrease in N_{glom} but no observed change in V_{glom} by 6 weeks of age, possibly due to the short duration from injury to evaluation. AKI in rabbits, induced by common medications and monitored through noninvasive MRI, provides an important model to study the impact of AKI on renal development later in life.

Ferroptosis, but Not Necroptosis, Plays an Important Role in Nephrotoxic Folic Acid Induced Acute Kidney Injury
Diego Martin-Sanchez,[1] Olga Ruiz Andrés,[1] Jonay Poveda,[1] Susana Carrasco,[1] Maria D. Sanchez-Niño,[1,2] Marta Ruiz-Ortega,[1,2] Jesus Egido,[1,2] Andreas Linkermann,[3] Alberto Ortiz,[1,2] Ana Belen Sanz.[1,2] *[1]Div of Nephrology, IIS- Fundación Jiménez Díaz, Madrid, Spain; [2]Nephrology, School of Medicine, Autonoma Univ, UAM, Madrid, Spain; [3]Clinic for Nephrology and Hypertension, Christian-Albrechts-Univ Kiel, Kiel, Germany.*

Background: Acute kidney injury is characterized by necrotic cell-death and inflammation. Diverse pathways of regulated necrosis have been reported to contribute to AKI but there is no agreement on the molecular regulators involved. We explored the contribution of ferroptosis and necroptosis to folic acid (FA) AKI in mice. FA-AKI in mice is associated with lipid peroxidation and downregulation of glutathione metabolism proteins, features that are typical of ferroptotic cell death.

Methods: We induced AKI with an overdose of folic acid in wild type, RIP3K-KO and MLKL-KO mice. Renal function was measured by plasma creatinine and BUN levels. Protein studies were assessed by western blot and immunohistochemistry, mRNA analyzing were tested by real-PCR. For cell death detection we use TUNEL.

Results: We demonstrate that ferrostatin-1 (Fer-1), an inhibitor of ferroptosis, preserved renal function and decreased histological injury, oxidative stress and tubular cell death in this model. With respect to the immunogenicity, we demonstrate that Fer-1 prevented the upregulation of IL-33, an alarmin that has been linked to necroptosis, and other chemokines and cytokines, as well as macrophage infiltration, suggesting that Fer-1 prevents renal inflammation by inhibition of ferroptosis. By contrast, the pan-caspase inhibitor zVAD-fmk was not protective. Additionally, although FA-AKI resulted in increased protein expression of the necroptosis mediators RIPK3 and MLKL, targeting necroptosis with the RIKP1 inhibitor necrostatin-1, or genetic deficiency of RIPK3 or MLKL did not preserve renal function. MLKL KO mice displayed more severe AKI. By contrast, inflammation was milder in RIPK3 KO mice.

Conclusions: These data suggest that ferroptosis is the primary cause of FA-AKI, and that immunogenicity secondary to ferroptosis may further worsen the damage, while necroptosis related proteins may play additional roles in AKI.

Vitamin D Deficiency Induces Acute Kidney Injury in Rats Treated with Lipid Formulation of Amphotericin B

Daniela Ferreira,[1] Daniele Canale,[1] Rildo A. Volpini,[1] Pedro H.F. Gois,[1] Maria H.M. Shimizu,[1] Adriana C.C. Girardi,[2] Antonio C. Seguro.[1] *[1]Nephrology - LIM12, School of Medicine, Univ of São Paulo, São Paulo, Brazil; [2]InCor, Univ of São Paulo, São Paulo, Brazil.*

Background: Lipid emulsion of Amphotericin B (AmB/LE) attenuates AmB-related nephrotoxicity and represents a lower cost alternative formulation with similar antifungal activity. In view of the high worldwide incidence of vitamin D deficiency (VDD), the aim of this study was to investigate whether VDD may induce AmB/LE-related nephrotoxicity.

Methods: Male Wistar rats were fed 25(OH)D-free or normal diets for 30 days. We studied four groups: control (C, n=8), VDD (n=6), AmB/LE (n=7, receiving 5mg/kg/day of AmB/LE intraperitoneally [IP] for 4 days) and VDD+AmB/LE IP for 4 days (n=9). We measured serum 25-hydroxyvitamin D (25(OH)D, ng/mL); inulin clearance (GFR, mL/min/100g); arterial blood pressure (BP, mmHg); urinary volume (UV, mL/24h) and osmolality (U_{Osm}, mOsm/kgH_2O); and urinary magnesium excretion ($U_{Mg}V$, mg/day). Immunoblotting for protein expression of aquaporin-2 (AQP2, %) was performed in kidney tissue. Morphological kidney damage was scored from 0 to 4. Data are expressed as mean ± SEM.

	C	VDD	AmB/LE	VDD+AmB/LE
25(OH)D	44.3±2.4	4.3±0.4[c]	45.4±5.2[f]	4.4±0.7[cg]
GFR	0.97±0.04	0.79±0.02[a]	0.99±0.06[d]	0.55±0.04[ce]
BP	130±3	129±4	131±5	148±5[a]
UV	20±1	26±1	21±1	32±2[cdg]
U_{Osm}	1028±89	656±64[c]	635±32[c]	367±21[cfg]
$U_{Mg}V$	1.91±0.16	1.81±0.10	2.03±0.15	3.21±0.31[cfg]
AQP2	100±3	75±15[a]	43±2[cd]	46±6[cd]
Kidney Damage	0.13±0.02	0.31±0.04	0.25±0.05	0.40±0.08[a]

[a]p<0.05,[b]p<0.01,[c]p<0.001 vs. C; [d]p<0.05,[e]p<0.01,[f]p<0.001 vs. VDD; [g]p<0.001 vs. AmB/LE

Results: Body weight was not different among the 4 groups. Association of AmB/LE and VDD resulted in reduced GFR, hypertension. These alterations were associated witn an increased urinary volume, lower U_{Osm} and more elevated $U_{Mg}V$.

Conclusions: VDD induces impaired renal function and tubular damage in AmB/LE treated rats. Therefore, the assessment of vitamin D in patients is essential independently of the modified formulations of AmB prescribed. Fapesp 2015/05513-1, CNPq 306148/2013-7.

Modeling Polymyxin B-Induced Renal Injury Using a Human Kidney Proximal Tubule Microphysiological System

Elijah Weber,[1] Jonathan Himmelfarb,[2,3] Edward J. Kelly.[1] *[1]Dept of Pharmaceutics, Univ of Washington, Seattle, WA; [2]Dept of Medicine, Univ of Washington, Seattle, WA; [3]Kidney Research Inst, Seattle, WA.*

Background: Our lab has developed a platform culturing proximal tubule epithelial cells (PTECs) in a microphysiological system (MPS) that recapitulates the physiology of the proximal tubule. A key application of our system is the response to nephrotoxicant exposure, as shown by induction of injury markers. We are using this MPS to determine the mechanism(s) of polymyxin-induced nephrotoxicity. Polymyxin antibiotics are one solution to the increasing frequency of drug-resistant microbes, despite clinical observations of severe renal injury. To mitigate these adverse effects, a polymyxin structural variant, which retains therapeutic efficacy, yet decreased *in vitro* toxicity, is currently being evaluated in our kidney MPS.

Methods: PTECs were cultured for 1 week (to reach confluency) and treated with 0 uM or 50 uM polymyxin B, or 50 uM polymyxin-analog, for 48 hours. Effluent was collected in 24 hour intervals and analyzed for kidney injury molecule-1 (KIM-1). Cell-associated injury was measured via induction of heme-oxygenase-1 (HO-1). Additionally, transcriptional response to drug will be analyzed via RNA-seq.

Results: In three separate donors, polymyxin B-induced toxicity was observed via induction of cell-associated HO-1 as well as a significant increase in KIM-1 biomarker in the effluent. Furthermore, the polymyxin-analog demonstrated a greater than 10-fold higher level of safety in comparison to polymyxin B when tested in standard 2D monolayer PTEC cultures.

Conclusions: We have demonstrated that our MPS can model polymyxin-induced injury and capable of screening novel analogs for an assessment of improved safety. Understanding the transcriptional response to polymyxin B and structural variants will allow identification of pathways involved in injury. Furthermore, we will define the transporter-mediated uptake mechanisms resulting in tubular accumulation and toxicity of this class of antibiotics using our MPS. This research was supported by an unrestricted gift from the Northwest Kidney Centers to the Kidney Research Institute.

Cilastatin Attenuates Vancomycin-Induced Nephrotoxicity via P-Glycoprotein

Hyo-Wook Gil,[1] Hye Jin Shin,[3] Hyeon Seok Hwang,[2] Dai Sig Im.[3,4] *[1]Dept of Internal Medicine, Soonchunhyang Univ Cheonan Hospital; [2]Dept of Internal Medicine, The Catholic Univ of Korea; [3]Dept of Chemistry, College of Life Sciences, Soonchunhyang Univ, Korea; [4]SH Company, 507 Venture B/D, SCH Univ.*

Background: Oxidative stress is one of the main pathogenic mechanisms in vancomycin-induced nephrotoxicity(VIN). In addition, animal studies suggest proximal renal tubular cell necrosis by vancomycin accumulation. Previous studies demonstrated that cilastatin has protective effects against drug-induced nephrotoxicity. P-glycoprotein (P-gp) is a strong membrane efflux pump extruding a variety of chemicals outside the cell. We investigated whether the P-gp regulation of cilastation prevent VIN in *in vitro* and *in vivo* models.

Methods: We tested in vitro study using immortalized proximal tubule epithelial cell line from HK-2, and in vivo study using Male C57BL/6J mice.

Results: Vancomycin showed toxicity at dose and time dependent pattern in HK2 and cilastatin attenuated VIN. Vancomycin provoked ROS at dose dependent pattern on DCF-DA. Caspase 3/7 activity increased in dose dependent pattern. Apoptosis was confirmed by Tunnel assay at 24 hr (Vancomcyin 2 mM). Cilastatin attenuated vancomycin indcued ROS production and apoptosis. Vancomycin suppressed p-gp function using Calcein AM test. Cilastatin attenuated vancomycin induced p-gp suppression. In vivo, vancomycin (400mg/kg, 600 mg/kg IP, 7day) induced acute kidney injury. Also histological examination indicated greater tubular damage in VIN.The number of TUNEL-positive cells was greater in mice kidney with VIN, and cilastatin attenuated these findings. Bax levels were significantly increased in VIN. The cilastatin treatment significantly ameliorated this pro-apoptotic marker in vancomycin injury Cilastatin treatment significantly decreased the vancomycin concentration of blood and kidney. When either cilastatin or vancomycin was administered, the P-gp expression on cellular membrane was increased in the regions of proximal tubular cells, and their cotreatment further enhanced the membrane expression of P-gp.

Conclusions: Our study showed that vancomycin induced nephrotoxicity might be involved suppression of P-gp function in kidney. Also cilastatin attenuated the VIN.

The Role of TLR4 Signaling in the Nephrotoxicity of Heme and Heme Proteins

Karl A. Nath,[1] John D. Belcher,[4] Anthony J. Croatt,[1] Joseph P. Grande,[2] Zvonimir S. Katusic,[3] Gregory M. Vercellotti.[4] *[1]Div of Nephrology and Hypertension, Mayo Clinic; [2]Dept of Pathology, Mayo Clinic; [3]Dept of Anesthesiology, Mayo Clinic, Rochester, MN; [4]Div of Hematology, Oncology and Transplantation, Univ of MN, Mpls., MN.*

Background: In experimental AKI, renal and plasma levels of heme are increased. In endothelial cells heme is known to be proinflammatory by activating the TLR4 receptor. This study examined the role of TLR4 signaling in renal responses to heme in vitro and in vivo.

Methods: Studies in vitro examined the proinflammatory effects of heme in tubular epithelial cells (TECs) and the effect of inhibiting TLR4 signaling with TAK-242. The role of TLR4 in mediating heme and heme protein-induced nephrotoxicity was assessed in vivo by the use of the TLR4 inhibitor, TAK-242, and $TLR4^{-/-}$ mice.

Results: TECs exposed to 5 μM heme exhibited NF-KB activation, upregulation of MCP-1 mRNA, and increased MCP-1 protein production; TAK-242 markedly reduced these proinflammatory effects. Acute administration of heme in vivo decreased renal blood flow (RBF), and pretreatment with TAK-242 led to greater preservation of RBF at 30 min: 0.24 ± 0.06 vs 0.71 ± 0.07 ml/min. As heme contributes to heme protein-mediated AKI in the glycerol model, we examined whether TAK-242 pretreatment is protective in this model. TAK-242 compared to vehicle did not significantly alter either BUN at day 1 (163 ± 4 vs 155 ± 8 mg/dl) and day 2 (219 ± 12 vs 212 ± 15 mg/dl), or serum creatinine at day 1 (1.7 ± 0.1 vs 1.7 ± 0.1 mg/dl) and day 2 (1.9 ± 0.3 vs 2.1 ± 0.4 mg/dl). We also tested the role of TLR4 in this model using $TLR4^{+/+}$ and $TLR4^{-/-}$ mice; there were no significant differences in filtration markers in $TLR4^{+/+}$ and $TLR4^{-/-}$ mice at day 1 and 2 after glycerol-induced AKI.

Conclusions: We conclude that: 1) "free" heme is proinflammatory and vasoconstrictive, and that these effects involve TLR4-dependent mechanisms; and 2) the in vivo nephrotoxicity of heme proteins does not involve TLR4-dependent pathways. We speculate that the contribution of heme to heme protein-induced AKI reflects the effects of intracellular heme, with little meaningful contribution by extracellular heme engaging membrane-based TLR4 receptors.

SA-PO177

The Renoprotective Effect of 5-Aminolevulinic Acid in Murine Rhabdomyolysis-Induced Acute Kidney Injury Is Independent of Heme Oxygenase-1 Activation Atsushi Uchida, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Rhabdomyolysis often occurs after severe skeletal muscle injury, and high morbidity and mortality have been reported for the acute kidney injury (AKI). 5-aminolevulinic acid (ALA) is the naturally occurring metabolic precursor of heme and serves as a protein material related to energy production. A previous study showed that ALA has the potential to prevent cisplatin-induced AKI via induction of heme oxygenase (HO)-1. To evaluate the renoprotective effect of ALA in another AKI model, we examined the efficacy of ALA and the role of HO-1 in a mouse model of rhabdomyolysis-induced AKI.

Methods: Male C57BL/6 mice were used. Mice were subdivided into 4 groups: (1) control group, (2) Rhabdomyolysis group, (3) Rhabdomyolysis+ ALA group, and (4) Rhabdomyolysis+ ALA+ ZnPPIX (HO-1 inhibitor) group. Rhabdomyolysis-induced AKI was caused by intramuscular injection of glycerol. ALA and ZnPPIX were administered each day at 48 h before glycerol administration. These mice were euthanized 72 h after glycerol injection, and the blood and renal tissues were collected.

Results: Serum creatinine, blood urea nitrogen, and urine neutrophil gelatinase-associated lipocalin excretion increased in the Rhabdomyolysis group compared to that in the control group. ALA significantly attenuated these changes. ALA also ameliorated glycerol-induced morphological tubular damage. Excretion of urinary 8-hydroxy-2'-deoxyguanosine, an oxidative stress marker, was suppressed by ALA. ALA significantly attenuated macrophagic infiltration and expression of proinflammatory cytokines. Notably, these changes did not disappear in the Rhabdomyolysis+ ALA+ ZnPPIX group.

Conclusions: ALA has a renoprotective effect and prevents tubular injury in rhabdomyolysis-induced AKI. It is already used for tumor diagnosis and fluorescence-guided resections in humans. Therefore, the safety of this drug has been proven in clinical practice. ALA treatment may be a new therapeutic target in rhabdomyolysis-induced AKI, but the mechanism is independent of HO-1. The renoprotective mechanisms of ALA in AKI should be elucidated.

SA-PO178

Quantitative Phosphoproteomic Analysis of Rat Renal Cortical Tubules in Response to Phospholipase A2 from Russell's Viper Venom Kavee Limbutara,[1,2] Poorichaya Somparn,[2] Narumol Pakmanee,[3] Lawan Chanhome,[3] Orawan Khow,[3] Narongsak Chaiyabutr,[3] Visith Sitprija,[3] Kearkiat Praditpornsilpa,[1] Trairak Pisitkun.[2] *[1]Div of Nephrology, Faculty of Medicine, Chulalongkorn Univ, Thailand; [2]Systems Biology Center, Faculty of Medicine, Chulalongkorn Univ, Thailand; [3]Queen Saovabha Memorial Inst, The Thai Red Cross Society, Thailand.*

Background: Russell's viper is a medically important snake causing multiple effects including impairment of renal sodium reabsorption. Phospholipase A2 (PLA2) is a major component in the Russell's viper venom (RVV) and possibly mediates the nephrotoxicity. This study was designed to uncover the direct effects of PLA2 and RVV to renal tubules.

Methods: PLA2 was purified from crude RVV by HPLC. Renal cortical tubules were isolated from Sprague Dawley rats by enzymatic digestion and centrifugation. Tubules were incubated with either 10 μg/mL of PLA2 or RVV for 10 minutes and vehicle as control. Samples were digested with trypsin and dimethyl-labelled. Phosphopeptide enrichment was performed using titanium dioxide columns and were analysed by LC-MS/MS. Data analysis was done using MaxQuant and Perseus.

Results: We identified a total of 1,957 phosphorylation sites from all samples combined. PLA2 treatment significantly induced up-regulation in 13 sites and down-regulation in 4 sites whereas RVV treatment significantly activated 10 up-regulated sites without down-regulated sites. Six phosphoproteins, including SMIM24, CANX, EEF1D, SGPP1, NHERF1, and OSTF1 were consistently up-regulated by both PLA2 and RVV. NHERF1 (Na+/H+ exchange regulatory cofactor 1) is predominantly expressed in renal proximal tubule where most of sodium reabsorption occurs. This regulatory protein has been shown to control expression and activity of sodium transporters. Conservation analysis of this site in NHERF1 (S287) also demonstrated perfect identity among mammalian species, indicating potentially functional importance.

Conclusions: PLA2 and RVV induced changes in phosphorylation of many proteins in rat renal cortical tubules. Phosphorylation of NHERF1 at S287 by the venom is potentially a key mediator of inhibitory effect on sodium reabsorption. This finding should be confirmed with functional study of sodium transport.

The Cat as a Model of Renal Interstitial Fibrosis: Characterisation of Primary Cultures of Feline Tubular Epithelial Cells Jack S. Lawson, Harriet M. Syme, Robert Purcell, Caroline Pd Wheeler-Jones, Jonathan Elliott. *Royal Veterinary College, London, United Kingdom.*

Background: Chronic kidney disease (CKD) is common in aged domestic cats, and the most prevalent pathology in these animals is chronic tubulointerstitial inflammation and fibrosis. These cases are a naturally occurring model for the study of tubulointerstitial fibrosis, offering some advantages over the murine unilateral ureteral obstruction model. Currently, little is known regarding the mechanisms involved in the progression of tubulointerstitial fibrosis in the cat. Epidemiological risk factors for progression include proteinuria, hyperphosphataemia and anaemia. The aim of this study was to isolate and characterise feline proximal tubular epithelial cells (fPTEC) and assess their response to TGF-β1 in comparison to the human proximal tubular cell line HK-2.

Methods: Cells were isolated from the kidneys of cats euthanized for welfare reasons with owner informed consent. Cells were characterised using immunofluorescence for intermediate filament proteins, enzyme histochemistry for gamma-glutamyl transamidase (GGT) and alkaline phosphatase (ALP), and RT-qPCR for gene expression analysis (normalised to GAPDH/RPS7). The fPTEC and HK-2 cells were exposed to 0-10ng/ml human recombinant TGF-β1 for 24-72hrs.

Results: Feline PTECs were successfully isolated from both normal and diseased feline kidneys. The fPTECs co-expressed the epithelial marker cytokeratin alongside vimentin, demonstrated ALP and GGT activity similar to HK-2 cells and expressed both N-Cadherin and E-Cadherin mRNA. Both fPTECs and HK-2 cells demonstrated a concentration-dependent induction of Col1a1, CTGF and TGF-β1 mRNA expression after TGF-β1 stimulation. Additionally, the fPTECs and HK-2 underwent morphological changes suggestive of epithelial-to-mesenchymal transition which was accompanied by a trend for decreased E-Cadherin and increased N-Cadherin mRNA expression.

Conclusions: In summary, it is feasible to obtain PTECs from feline kidneys. These are phenotypically similar to human proximal tubular cells and respond similarly to TGF-β1 stimulation. These data support the use of the cat as a model of tubulointerstitial fibrosis.

In Vivo Evidence of mTORC1-S6 Kinase Pathway Involvement in the Development of Glomerulosclerosis in Human IgA Nephropathy Kojiro Nagai, Tatsuya Tominaga, Taichi Murakami, Eriko Shibata, Seiji Kishi, Motokazu Matsuura, Hideharu Abe, Toshio Doi. *Nephrology, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.*

Background: Human IgA nephropathy is the most common glomerulonephritis. The disease results from abnormal IgA deposits in mesangial area. To clarify the mechanism of IgA nephropathy progression, mesangial function should be evaluated *in vivo,* but mice Cre-loxP system to knock out a target molecule in mesangial cells has not been established yet. Besides, mTOR complex 1 (mTORC1) -S6 kinase pathway plays an important role in cell proliferation and hypertrophy.

Methods: The aim of this study is to clarify mTORC1-S6 kinase pathway involvement in the development of glomerulosclerosis in human IgA nephropathy. First, 12 human IgA nephropathy cases derived from three men and nine women aged 15 to 63 years (mean ± SD, 32.8 ± 16.8years) were analyzed. Immunohistochemistry of phosphorylated ribosomal protein S6 (phospho-rpS6) (a surrogate marker of mTORC1-S6 kinase pathway) was performed. Next, mesangium-specific mTORC1 activation was induced by ablation of an upstream negative regulator, Tuberous sclerosis complex 1 (TSC1), using tammoxifen-induced Foxd1-Cre mice to clarify the role of mTORC1-S6 kinase pathway in the development of glomerulosclerosis.

Results: Phospho-rpS6 was detected in mesangial area of human IgA nephropathy. Mesangium-specific TSC1 ablation in mice (MsKOTSC1) caused rpS6 phosphorylation in mesangial area confirmed by immunohistochemistry and westernblot analysis. MsKOTSC1 showed IgA nephropathy features, including the increase of collagen IV accumulation at 12 weeks of age and collagen I and alpha smooth muscle actin upregulation at 1 year of age in glomeruli. However, MsKOTSC1 did not exhibit significant albuminuria. Furthermore, rapamycin treatment of MsKOTSC1 could suppress the increase of collagen IV expression.

Conclusions: Mesangium-specific mTORC1-S6 kinase pathway activation could develop glomerulosclerosis in mesangial area, which mimics human IgA nephropathy. However, the activation of mTORC1-S6 kinase pathway was not enough to cause albuminuria. Mesangium-specific Cre-loxP system is useful to clarify the mechanism of human IgA nephropathy.

Vitamin D Receptor Contributes to Disparate Effects during the Initiation and Progression of HIV-Associated Nephropathy (HIVAN) Xiqian Lan,[1] Waqaar Khawar,[1] Manoj K. Tembhre,[1] Judith Eng,[1] Seyedeh Shadafarin Marashi Shoshtari,[1] Hanan K. Tawadrous,[2] Anil K. Mongia,[2] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Pediatrics, Down State Medical Center, Brooklyn, NY.*

Background: Renin angiotensin system plays a role in the progression of HIV-associated nephropathy (HIVAN). Since angiotensinogen (Agt) is a substrate for renin, we hypothesized that mice with enhanced expression of Agt would display accelerated progression of HIVAN. We evaluated the effect of different copies of Agt in the initiation and progression of renal lesions in genetically engineered HIVAN mice (Tg26).

Methods: Control and Tg26 mice with 2 (Tg26/Agt-2) and 4 (Tg26/Agt-4) copies of Agt were evaluated for severity of renal lesions, arteriosclerosis and hypertension at 8 weeks and 16 weeks. Renal cortical sections were stained with sirus red and PAS. RNA was extracted from renal tissues and probed for AT1, AT2, PAI-1, VDR, and molecules involved in Tert and epithelial mesenchymal transition (EMT) pathways.

Results: Tg26/Agt-4/8wks showed lower blood pressure ($P<0.01$) vs. Tg26/Agt-2/8 wks. While Tg26/Agt-4/16wks displayed higher blood pressure vs. Tg26/Agt-2/16wks. Tg26/Agt-4/8wks displayed attenuated expression of PAI-1 vs. Tg26/Agt-2/8wks; however, Tg26/Agt-4/16wks showed 3-fold greater PAI-1 expression than to Tg26/Agt-2/16wks.

Tg26/Agt-2/8wks displayed attenuated expression VDR and enhanced production of Ang II vs. Tg26/Agt-4/8wks, however this pattern reversed at 16 wks. Tg26/Agt-4/8wks displayed attenuated expression of AT1 and AT2 and down regulation of Tert, TGF-β, Snail, and vimentin when compared to Tg26/Agt-2/8wks. However, all these markers were comparable between these groups at 16 wks of age. Tg26/Agt-2/8wks developed renal lesions which were more advanced than Tg26/Agt-4/8wks. Conversely, Tg26/Agt-4/16wks displayed more advanced renal lesions vs. Tg26/Agt-2/16wks.

Conclusions: VDR dynamics determined the initiation and acceleration of renal lesions in Tg26/Agt-4 and Tg26/Agt-2 mice both at early and later time periods.

VDR Agonist Preserves Podocyte Molecular Phenotype Through Reversal of Epigenetic Alterations in HIV Milieu Nirupama Chandel, Kamesh R. Ayasolla, Vinod Sharma, Abheepsa Mishra, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: Epigenetic alterations play a role in the development of HIV-associated Nephropathy. We recently reported that HIV stimulated podocyte SNAIL expression. We now hypothesize that HIV-induced podocyte SNAIL expression would compromise podocyte molecular phenotype (nephrin and p-cadherin) through epigenetic mechanisms and a vitamin D receptor (VDR) agonist (VDA) would be able to preserve it through reversal of epigenetic alterations.

Methods: Renal tissues of 6 week old control, HIVAN (Tg26), and VDR agonist (VDA) treated Tg26 (2 weeks) mice and vector (V/HP) or HIV (NL4-3)-transduced (HIV/HPs) human podocytes were evaluated for expression SNAIL, VDR, nephrin, and p-cadherin. ChIP assays were carried to confirm binding of SNAIL at nephrin promoter. Immunoprecipitation studies were carried out to analyze composition of SNAIL repressor complexes. Genomic DNA was isolated and CpG island methylation was measured in V/HPs and HIV/HPs.

Results: Protein blots of renal tissues from HIVAN mice and HIV/HPs displayed enhanced expression of SNAIL but down regulation of nephrin, p-cadherin, and VDR. VDA partially preserved expression of nephrin in renal tissues of Tg26 mice as well as in HIV/HPs. Genomic DNA methylation studies confirmed hypermethyalated CpG islands at *Nephrin* promoter in HIV/HPs.ChIP assay suggested that enhanced SNAIL expression by HIV/HPs was the consequence of histone 3 methylation at lysine (K) 4 residues (H3K4me3) on *SNAIL* promoter, whereas, down regulation of nephrin seems to be the consequence histone 3 methylation at lysine 27 residues (H3K27me3). Co-immunoprecipitation studies in lysates of HIV/HPs revealed the association of histone deacetylase (HDAC) 4, DNMT3b and DNMT1, mSin3A and EZH2 with SNAIL; conversely, VDA treatment of HIV/HPs decreased the expression of HDAC4, DNMT3B, DNMT1, mSin3A, and EZH2 (disruption of SNAIL complex).

Conclusions: VDA preserves podocyte nephrin expression through down regulation of SNAIL transcription, disruption of SNAIL repressor complex and attenuation of methylation at H3K27 residue at nephrin promoter.

Autophagy Activity and Expression Pattern of Autophagy-Related Markers in the Podocytes of Patients with Lupus Nephritis: Association with Pathological Classification Juan Jin, Yiqiao Li. *Dept of Nephrology, Zhejiang Provincial People's Hospital.*

Background: To identify the significance of autophagy in lupus nephritis (LN), we counted the number of autophagosomes in podocytes and evaluated the expression of multiple molecular markers associated with autophagy in LN specimens.

Methods: Autophagosomes in podocytes were counted using transmission electron microscopy. Beclin-1, microtubule-associated protein light chain 3 (LC3), autophagy-related gene 7 (Atg7), and UNC-51-like kinase 1 (ULK1) expression levels were measured using immunohistochemistry in renal biopsy specimens from 90 patients with LN and 15 healthy controls.

Results: The number of autophagosomes in patients with LN types III, IV, and combined V-IV type were significantly higher than in controls ($p<0.0001$; $p<0.0001$; $p=0.009$, respectively). However, autophagosomes numbers in patients with II and V types LN were significantly lower than controls (both $p<0.0001$). Various levels of marker expression were identified, and correlated significantly with LN pathology classifications. The percentage of marker expression in LN types III, IV and V-IV were significantly higher than controls ($p<0.05$), while marker expression in types II and V were lower than controls, although the differences for LC3 and ULK1 were not statistically significant.

Conclusions: Autophagy activity and expression pattern of autophagy-related markers in podocytes were significantly positively correlated with LN types III, IV and V-IV, but negatively correlated with II and V types. Autophagy could therefore be a useful predictor of LN pathology type, and could be informative for the development of treatment strategies in a clinical setting.

Ubiquitin C-Terminal Hydrolase L1 (UCH-L1) Is Required for Regulated Protein Degradation Through the Ubiquitin Proteasome System in Murine Kidneys in Health and Immune-Complex Nephritis Jan Hendrik Knop, Anna Reinicke, Ulrich O. Wenzel, Rolf A. Stahl, Catherine Meyer-Schwesinger. *Internal Medicine, Univ Medical Center Hamburg-Eppendorf.*

Background: UCH-L1 is a major deubiquitinating enzyme of the nervous system. In the human kidney, UCH-L1 is expressed in tubular and parietal epithelial cells and in the setting of glomerulonephritis UCH-L1 is upregulated in the tubular compartment and de novo expressed in podocytes. Biochemically, UCH-L1 is thought to regulate the intracellular pool of monoubiquitin, required for ubiquitination procedures. Nothing is known about the significance of UCH-L1 in the kidney in health and disease.

Methods: We generated constitutive UCH-L1-deficienct mice which were phenotypically characterized by histological and biochemical assays. Anti-podocyte-nephritis (APN), an immune-complex glomerulonephritis, was induced by injection of anti-podocyte antibodies and clinical and morphological disease development was monitored.

Results: Naïve UCH-L1-deficient mice developed systemic hypotension and urine retention in the bladder due to over-all neurodegeneration. The renal and glomerular pool of polyubiquitinated and of oxidative-modified proteins was increased. Simultaneously, proteasomal activity was decreased and the balance between the 26S and the i26S proteasomal content was altered in both whole kidney and in isolated glomeruli. Interestingly, UCH-L1-deficient mice developed proteinuria and podocytes showed signs of stress despite an inconspicuous overall glomerular morphology. Induction of APN in wild-type mice demonstrated that similarly to human glomerulonephritis, UCH-L1 is up-regulated in tubular cells and in glomerular cells such as podocytes and endothelial cells. UCH-L1-deficient mice exhibited an exacerbated course of disease with increased tubulointerstitial and glomerular damage and nephrotic syndrome. UCH-L1-deficient mice failed to upregulate the proteolytic effective i26S proteasome resulting in decreased proteasomal activity and accumulation of oxidative-modified and of K48-polyubiquitinated proteins in whole kidney and glomeruli.

Conclusions: UCH-L1 is required for regulated protein degradation in murine kidneys in health and disease.

Evaluation of DLK1 Absence in Unilateral Ureteral Obstruction Model Laura Marquez-Exposito,[1] Carolina Lavoz,[3] Eva Blanco,[2] Sandra Rayego-Mateos,[1] Raquel Rodrigues-Diez,[1] Sergio A. Mezzano,[3] Marta Fierro-Fernández,[2] Santiago Lamas,[2] Marta Ruiz-Ortega.[1] *[1]Univ Autónoma Madrid; [2]Centro de Biologia Molecular, Madrid, Spain; [3]Univ Austral, Chile.*

Background: The Notch signaling molecular pathway is involved in kidney embrionary development. Notch expression is virtually absent in adult human kidneys, whereas overexpression of ligands and receptors have been described in many human chronic renal diseases. There are several non-canonical Notch ligands that can activate or inhibit Notch signaling. The non-canonical ligand DLK1 (Delta-like homologue 1) has been suggested as a Notch inhibitor in Drosophila and mammal cells *in vitro*, regulating several processes, including adipogenesis, differentiation and angiogenesis. However, its role in renal injury is unknown.

Methods: The role of DLK1 in renal damage was evaluated using a Dlk1-null mice in the model of unilateral ureteral obstruction (UUO).

Results: In obstructed kidneys, activation of the canonical Notch/Jagged-1 pathway was found at 2 days, determined by nuclear translocation of active Notch-1, production of Jagged-1 and increased gene expression of the effector Hes-1, as previously described. Interestingly, upregulation of the non-canonical ligands Dlk1 and Dlk2 gene expression was observed after 5 days, later than Notch/Jagged-1 activation. In several tissues and pathological conditions, Dlk1 deletion was associated to over-activation of the Notch pathway. However, neither control nor obstructed kidneys of Dlk1-null mice presented further renal Notch/Jagged-1 activation than wild-type mice. Only hey-1 and Dlk2 gene levels were significantly elevated in Dlk1 null mice compared to wild-type. In obstructed kidneys of Dlk1-null mice a marked gene expression of renal injury biomarkers was found, but there were no significant differences compared to wild-type mice, at any time evaluated until 14 days. Moreover, there were no significant changes in inflammatory parameters or renal fibrosis between wild-type and Dlk1-null mice.

Conclusions: Our data suggest that DLK1 is not acting as an endogenous Notch inhibitor, at least in the experimental model of unilateral ureteral obstruction.

Rapamycin Attenuates Parietal Epithelial Cell Proliferation in a Model of Collapsing Focal Segmental Glomerulosclerosis Bart Smeets,[1] Shagun Sharma,[2] Jack F. Wetzels,[2] Brigith Willemsen,[1] Marinka Bakker-van Bebber,[2] Marcus J. Moeller,[3] Henry Dijkman,[2] Johan Van der Vlag.[2] *[1]Pathology, Radboud Univ Medical Center, Netherlands; [2]Nephrology, Radboud Univ Medical Center, Netherlands; [3]Nephrology and Clinical Immunology, RWTH Univ of Aachen, Germany.*

Background: Thy-1.1 transgenic mice develop glomerular lesions that mimic human collapsing FSGS. We questioned whether the mTOR inhibitor rapamycin (sirolimus) could prevent the development of these lesions and if protection is related to glomerular epithelial cell proliferation.

Methods: Anti-Thy-1.1 injected mice (day 0) were treated with sirolimus (oral gavage, 4mg/kg/day) during the development of the glomerular lesions (early treatments from day -3 to days 4, 7, and 21). In addition, we treated mice after development of the collapsing FSGS lesions (late treatment from day 11 to day 31). We compared kidney function, the development of glomerular lesions and kidney cell proliferation, between sirolimus- and vehicle-treated mice. In addition, the direct effects of rapamycin on cell activity (MTT assay) and growth of mouse primary parietal epithelial cells were examined.

Results: Early treatment with sirolimus from day -3 to days 4, 7 and 21 attenuated the development of glomerular lesions, whereas, late treatment from day 11 did not. The reduced number of glomerular lesions was associated with a significantly less activation (CD44 expression) and proliferation (Ki-67) of parietal epithelial cells, at day 4 and 7 after anti-Thy-1.1 injection. Interestingly, at these time points sirolimus treatment did not have an effect on albuminuria, blood urea nitrogen and podocyte injury reflected by the expression of desmin. In cell culture, we observed dose dependent reduction of the activity and growth of mouse primary parietal epithelial cells.

Conclusions: Inhibition of mTOR, attenuates the development of experimental collapsing FSGS. We propose that the effects are related to the ability of rapamycin to reduce parietal cell activation and proliferation.

Funding: Private Foundation Support, Government Support - Non-U.S.

Knocking Down Thymosin β4 in Endothelial Cells Impairs Recovery after Acute Tubular Injury, wth Decreased Peritubular Capillary Number and Function Jianyong Zhong,[1,2] Haichun Yang,[1,2] Agnes B. Fogo.[1,2] *[1]Pathology, Microbiology and Immunology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Pediatric Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Thymosin ß4 (Tß4) is a G-actin sequestering protein expressed ubiquitously, which affects cell proliferation, migration and angiogenesis. We previously found that exogenous Tß4 ameliorated matrix accumulation at day 14 after unilateral ureteral obstruction. In this study, we investigated the effect of Tß4 on endothelial cells and subsequent renal injury.

Methods: We generated inducible endothelial cell Tß4 knockdown mice (Tß4 KD) by mating Tß4 shRNA loxp mice with inducible SCL Cre mice, all on C57/BL6 background. SCL Cre negative mice were used as control (Cont). Folic acid (240ng/kg BW, i.p) was injected in male mice, age 12 weeks. Tamoxifen (5 times, i.p, qod) was administrated starting two weeks after folic acid to induce Tß4 knockdown. Mice were sacrificed at 6 weeks after folic acid injection.

Results: Tß4 expression in endothelial cells was significantly reduced in Tß4 KD compared to Cont. Peritubular capillary density, assessed by CD31 staining, was significantly decreased in Tß4 KD mice (Tß4 KD 1.00±0.12 *vs.* Cont 1.84±0.20%, P<0.01). Dextran was infused i.v., with more dextran leakage to interstitial areas in Tß4 KD than Cont mice. Tß4 KD mice had significantly higher collagen I (Tß4 KD 2.48±0.40 *vs.* Cont 1.09±0.12, P<0.05) and TGFß mRNA expression vs. Cont (Tß4 KD 1.11±0.12 *vs.* Cont 0.71±0.07, P<0.05), but Col I protein, assessed by IHC, was not different between the groups. Urinary NGAL, a marker of tubular injury, was also higher in Tß4 KD vs Cont (Tß4 KD 1872.47±373.52 *vs.* Cont 413.26±118.47 P<0.01).

Conclusions: We conclude that knockdown of thymosin ß4 in endothelial cells results in decreased endothelial cell number and impaired function, which decreases recovery of tubular injury.

Potassium Chloride in Hypoelectrolytic Isoosmotic Solution for Infusion Prevents an Artifact of Electron Microscopic Morphology for Fresh Renal Biopsy Specimen Takashi Takaki, Yasuhiro Nakamura, Naomi Sato, Kensuke Joh. *Tohoku Univ Graduate School of Medicine, Dept of Pathology, Sendai, Miyagi, Japan.*

Background: Wrapping fresh kidney biopsy specimens in saline-soaked gauze in order to avoid the drying of the specimens could be the major factor of artifacts.Hypoelectrolytic isoosmotic solution for infusion (SOLDEM 3A) instead of saline for soaking gauze prevents artifacts in electron micrograph(Pathol Int 2015 Nakamura et al).Concerning an underlying mechanism,high glucose concentration for maintaining osmolality or potassium chloride lacking in the saline were suspected as factors contributing a maintenance of morphology. Therefore,the purpose was to provide an evidence for finding a mechanism of preventing an artifact.

Methods: Before fixation with 2.5% GA in PB,fresh small cubes of the tissue from male SD rat were macerated either in group A(SOLDEM 1:Na^+90mEq/L,Cl^-70mEq/L,L-Lactate20mEq/L,Osmotic pressure ratio 1) or in group B(SOLDEM 3A:Na^+35 mEq/L,K^+20mEq/L,Cl^-35mEq/L,L-Lactate20mEq/L,Osmotic pressure ratio 1) for 10 min or 30 min.Thereafter,the samples were processed by 1% OsO_4 and embedded for observation. Each group was composed of five pieces of kidney tissue, respectively. In control group, the tissues were dropped directly into the fixative.

Results: In group A(SOLDEM 1 lacking potassium chloride),swollen endothelium and podocyte showing a dilatation of endoplasmic reticulum, mesangium showing a swollen capillary protuberance in the glomeruli as well as swollen mitochondria and swollen bush border of the tubules were seen after 10 min.maceration.These findings became prominent after 30 min.maceration.Foot processes were relatively preserved.In group B(SOLDEM 3A with potassium chloride),no abnormal findings,which were identical with those of control group,were seen after 10 min. and 30 min.maceration.

Conclusions: Since ATP driven sodium potassium pump links the export of sodium and import of potassium ions from the cell against their respective electrochemical chemical gradients,we suspect that a buffer containing potassium can help the maintenance of morphological architecture of the specimens,even after a cessation of the ion pump due to a removal of the tissue from the body.

Hyaluronidase Treatment Blocks the Glomerular Homing of Memory T Cells and Improves Proteinuria and Survival Rate in the NZM Mouse Model of Lupus Nephritis Hiroyuki Kadoya,[1] Chaim O. Jacob,[2] Janos Peti-Peterdi.[1] *[1]Physiology and Biophysics, Univ of Southern California, Los Angeles, CA; [2]Medicine/Rheumatology, Univ of Southern California, Los Angeles, CA.*

Background: Lupus Nephritis (LN) is a major cause of morbidity and mortality in patients with systemic lupus. The exact pathomechanism of LN has been elusive, and therefore current non-specific therapies are limited to general immunosuppression. The present study aimed to test the hypothesis that an interplay between cellular components of the immune system (activated memory T cells) and local kidney tissue factors (the CD44 ligand hyaluronic acid (HA) in the glomerular endothelial glycocalyx) is critically important in the glomerular homing of T cells, and therefore in the development and potential therapy of LN.

Methods: Intravital imaging with serial multiphoton microscopy (MPM) was used to track the fate of exogenous FACS sorted splenic activated memory T cells (1×10^6 cells) injected iv, or endogenous T cells labeled with anti-CD3 and anti-CD44 antibodies in vivo in New Zealand mixed (NZM) mice.

Results: Glomerular size, sclerosis and albuminuria were significantly increased at 4 weeks old NZM mice compared with control healthy mice. Activated memory T cells (the vast majority of all immune cells found in LN kidney) homed into affected glomeruli in LN mice and in a model of endothelial dysfunction (two weeks after L-NAME treatment and on high salt diet), but not into healthy kidneys. On average, we observed 30-40 $CD3^+CD44^+$ T cells per glomerulus sticking to endothelial cells within glomerular capillaries of LN mice, but not in control healthy mice. In a robust effect, a single iv injection of hyaluronidase (200 Unit) significantly reduced (by ~40%) the number of homed $CD44^+$ cells in glomeruli already within 1 hour after injection, and improved albuminuria and survival rate of NZM mice with high proteinuria.

Conclusions: Our results support the major importance of HA in the endothelial glycocalyx in the glomerular homing of memory T cells in the development and pathobiology of LN. Hyaluronidase treatment is a promising new therapeutic approach for LN.

SA-PO190

Transmembrane Protein 14A Is Differently Expressed in Human Proteinuric Renal Diseases Josephine Bonnemaijer, Ramzi Khalil, Jan A. Bruijn, Hans J. Baelde. *Pathology, Leiden Univ Medical Center.*

Background: Identifying individual components of the glomerular filtration barrier that are involved in the development of proteinuria can help to find new potential therapeutic targets for CKD. We previously showed that transmembrane protein 14A (TMEM14A) is involved in the development of proteinuria. In this study, we aim to assess its localization in the glomerulus and whether it is differentially expressed in human proteinuric renal diseases and in spontaneously proteinuric rats.

Methods: TMEM14A protein expression was assessed by immunohistochemistry in glomeruli of patients with IgA nephropathy, lupus nephritis, minimal change disease, and healthy controls. Renal tissue of spontaneously proteinuric Dahl rats and non-proteinuric SHR rats were also stained for TMEM14A protein. Furthermore, QPCR was performed to investigate TMEM14A mRNA expression in podocytes, HEK, and Huvec and compared to renal tissue.

Results: TMEM14A was primarily localized in podocytes, as shown by immunohistochemistry and *in vitro*. Expression was significantly higher ($p<0.05$, chi-square test) in glomeruli of proteinuric patients compared to controls. In Dahl rats, TMEM14A expression was significantly diminished ($p<0.05$, mann-whitney u-test) in Dahl rats aged 2 and 4 weeks of age compared to SHR rats, before onset of proteinuria.

Conclusions: Here, we show that TMEM14A is primarily expressed by podocytes and is differentially expressed under proteinuric circumstances. Interestingly, TMEM14A protein expression in Dahl rats is decreased before onset of proteinuria, similar to our previous findings in mRNA expression. In contrast with the findings in our rat model, we found that TMEM14A protein expression was significantly higher in glomeruli of patients with various proteinuric renal diseases. Based on the results of this study, we hypothesize that TMEM14A is part of a regulatory system that is involved in the development of proteinuria.

SA-PO191

Role of Non-Adrenergic α(2A)-Adrenoceptors in Renal Fibrosis
Johannes Stegbauer,[1] Steven D. Crowley,[2] Lars C. Rump,[1] Sebastian Alexander Potthoff,[1] Lydia Hering.[1] *[1]Nephrology, Medical Faculty, Heinrich-Heine-Univ Düsseldorf, Düsseldorf, Germany; [2]Nephrology, Duke Univ Medical Center, Durham, NC; [3]Nephrology, Medical Faculty, Heinrich-Heine-Univ Düsseldorf, Düsseldorf, Germany.*

Background: Increased sympathetic tone leads to progression of chronic kidney disease (CKD). α2A-adrenoceptors (α2A-AR) in adrenergic neurons are known for regulating sympathetic tone by a negative feedback mechanism. Not much is known about their function on non-adrenergic cells. Here, we investigate the impact of α2A-AR the development of renal fibrosis.

Methods: Unilateral ureteral obstruction (UUO) was performed in α2A-AR knockout (KO) and wild-type (WT) mice on a FVB background. Immunohistochemistry and gene expression analysis were performed 7 days after UUO.

Results: Despite increased renal sympathetic neurotransmission release, fibrosis, assessed by sirius red/fast green collagen staining ($p<0.05$) and collagen-1 expression ($p<0.001$), was attenuated in kidneys of KO compared to WT mice 7 days after UUO. Moreover, expression of the pro-inflammatory and pro-fibrotic cytokines and chemocines TNF-α, TGF-β, CCL2 and CCL5 ($p<0.05$) were reduced in KO compared to WT mice. In order to dissect between adrenergic and non-adrenergic effects, we also generate α2A-AR-KO mice in which α2A-ARs are restored in adrenergic cells under the control of the human dopamine beta-hydroxylase (DbH-KO). In DbH-KO, renal sympathetic neurotransmission was significantly reduced compared to KO but similar to WT mice suggesting functional presynaptic α2A-ARs in DbH-KO mice. Beside fibrosis, macrophage infiltration was significantly reduced in obstructed kidneys of DbH-KO compared to WT but similar to total KO suggesting a crucial role of non-adrenergic α2A-AR on immune cells in renal fibrosis. Indeed, stimulation of isolated macrophages from WT mice with the α2-AR-agonist UK14.304 (0.1μM) increased TNF-α expression of TNF-α ($p<0.05$).

Conclusions: Although adrenergic α2A-ARs are considered as a negative regulator of sympathetic tone, they also seem to promote inflammation and fibrosis in response to kidney injury. These effects seem to be mediated by non-adrenergic α2A-AR which might be a good candidate for reducing the progression of CKD.

SA-PO192

The Role of Resistance Training (Exe), before and after Nephrectomy (5/6Nx) Reduce Mortality and Prevent the Increase of Proteinuria in Rats with Chronic Kidney Desease
Alexandre Saud, Rafael DaSilva Luiz, Edson Andrade Pessoa, Nestor Schor. *Nephrology Div, Escola Paulista de Medicina/UNIFESP, São Paulo, Brazil.*

Background: The aim of this study was to evaluate the EXE effects on renal function and mortality rate in rats with 5/6Nx.

Methods: Adult Wistar rats were divided in two groups (n=8): Previous Exercise + Nx 5/6 + exercise (EXE-EXE), Previous exercise + Nx 5/6 (EXE-SED). The protocol was employed in 5/6Nx rats after 7 days from the surgical procedures, 6 to 12 climbs/day, 5 days/week, 40 a 60% of maximal loading, 8 weeks total (4 weeks before surgery Nx56 and 4 weeks after) for the group EXE-EXE and 4 weeks for EXE-SED (only 4 weeks after surgery). It was evaluated mean arterial pressure (MAP), creatinine clearance (CrCl), proteinuria (uProt), blood urea nitrogen (BUN) as well mortality rate.

Results: EXE did not modify the increment in MAP but prevent the increase in proteinuria rate (43,2±2,9 vs.82,1±2,5mg/24h, $p<0.0001$) and mean BUN in EXE+SED was higher compared with EXE+EXE, (114,2±8,4 vs 76,9±2,0mg/dl ,$p<0.0019$). A higher mortality rate was observed in EXE-SED (50%) vs EXE-EXE (0%).

	EXE-SED	EXE-EXE
MAP (mmHg)	215±7	213±8
Weight (g)	381±4	365±17
CrCL (ml/min/BW)	1,00±0,15	1,28±0,11
uProt (mg/24h)	82,1±2,5	43,2±2,9*
Mortality Rate (%)	50	0
BUN (mg/dl)	114,2±8,4	76,9±2,0*

* vs. EXE-SED.

Conclusions: Results suggested that the EXE minimize the impact of 5/6Nx, with much lower increase in BUN (28%), proteinuria (48%) and lower mortality in EXE+EXE vs EXE+SED. Minor impact of 5/6Nx on CrCl indicate that exercise could have a protective effect, especially under this experimental protocol. Thus, it is reasonable to suggest that EXE could be an additional strategy to be employed in CKD.

SA-PO193

Meprin Expression/Activity Impacts Metabolite Profiles in Kidney Tissue of Mice with STZ Induced Type 1 Diabetes
Elimelda Moige Ongeri,[1] Jean-Marie V. Niyitegeka,[1] Susan Mcritchie,[2] Susan Sumner,[2] Courtney Whitaker,[2] Jessica Gooding.[2] *[1]Biology, North Carolina A&T State Univ, Greensboro, NC; [2]NCTraCS Metabolomics Core, RTI International, Research Triangle Park, NC.*

Background: Meprin metalloproteinases are the most abundantly expressed proteins in the brush border membranes of proximal kidney tubules. Meprins have been shown to play a role in the pathophysiology of diabetic nephropathy (DN) in humans and mice. In vitro and in vivo studies have identified several meprin targets in the kidney which include cytoskeletal proteins, tight junction proteins, extracellular matrix proteins, and cell signaling molecules. It's not known how proteolytic processing of these and other targets by meprins impacts metabolic pathways in the kidney. This knowledge is important in delineating the mechanism(s) by which meprins modulate the progression of DN.

Methods: Low dose streptozotocin (STZ) was used to induce type 1 diabetes in 8 week old male wild-type (WT) and meprin ß knockout (ßKO) mice. The mice were sacrificed at 8 weeks post-STZ injection and kidney tissue harvested for metabolomics analysis. Biochemical assessment of kidney injury utilized ELISAs for creatinine, neutrophil gelatinase associated lipocalin (NGAL), and kidney injury molecule-1 (KIM-1). Lyophilized kidney proteins were reconstituted in 95:5 acetonitrile and loaded onto a UPLC-QTOF system for separation by HILIC chromatography and detection in MS^E mode.

Results: Metabolomics analysis found more than 200 compounds associated with diabetes in both WT and meprin βKO mice, including two annotated as the osmolytes glycerophosphocholine and betaine. One of the metabolites STZ only affected in WT mice, is N-Methyl-pyridone-carboxamide. It's isomers, 4-PY and 2-PY, are markers of peroxisome proliferation and inflammation and correlate with creatinine clearance as well as glucose concentrations in oral glucose tolerance tests. Importantly, the anti-diabetic drug, vildagliptin, lowers the concentrations of both isomers in urine.

Conclusions: The meprin ß-associated changed metabolites (e.g N-methyl-4-pyridone-3-carboxamide) have been implicated in kidney injury suggesting that meprins impact metabolic pathways that influence the progression of DN.

Changes in Malondialdehyde Levels with Age in the Nucleus, Cytosol and Mitochondria from Rat Kidney Cortex and Medulla
Marianna J. Zamlauski-Tucker, Cameron M. Behringer, Natalya Mezenina. *Dept of Biology, Ball State Univ, Muncie, IN.*

Background: Oxidative stress caused by free radicals generated in aerobic metabolism contributes to cell injury and dysfunction seen with age. Malondialdehyde (MDA) is a product of lipid peroxidation of cell and organelle membranes by free radicals, and is used as an indicator of oxidative stress. The present study was undertaken to investigate the effect of age on changes in MDA levels in the nucleus, cytosol and mitochondria from rat kidney cortex and medulla.

Methods: Young (3 months of age) and Old (22 months of age) female Lewis rats were used. The kidneys were harvested from anesthetized rats after being perfused with isotonic saline via a catheter in the abdominal aorta. The kidneys were separated into cortical and medullary sections and homogenized in isotonic saline. Differential centrifugation was used to isolate the nuclear, cytosolic and mitochondrial fractions. MDA levels were measured in the fractions using a spectrophotometric assay and expressed as nmol/g kidney wet weight. Differences were evaluated using a Student's t Test.

Results: There was a significant increase in MDA levels with age in the nucleus, cytosol and mitochondria from rat kidney cortex. There was not a significant increase in MDA levels with age in the nucleus, cytosol and mitochondria from rat kidney medulla. MDA levels of nuclei and mitochondria from kidney medulla were higher than MDA levels from kidney cortex in both Young and Old rats.

	Young (n = 6)	Young (n = 6)	Old (n = 6)	Old (n = 6)
	Cortex	**Medulla**	**Cortex**	**Medulla**
MDA - nmol/g kid wet wt				
Nucleus	5.56 ± 0.54	10.57 ± 0 .95[a]	7.38 ± 0.51*	9.20 ± 0.82[a]
Cytosol	14.81 ± 0.68	20.74 ± 1.30[a]	21.48 ± 2.50*	20.68 ± 3.70
Mitochondria	2.63 ± 0.24	7.04 ± 0.45[a]	4.06 ± 0.38*	6.65 ± 0.39[a]

All data expressed as X ± SEM; * significantly different from Young Cortex; [a] significantly different from age-matched Cortex.

Conclusions: The findings suggest that there is increased oxidative stress in the nucleus, cytosol and mitochondria from rat kidney cortex but not rat kidney medulla with age.

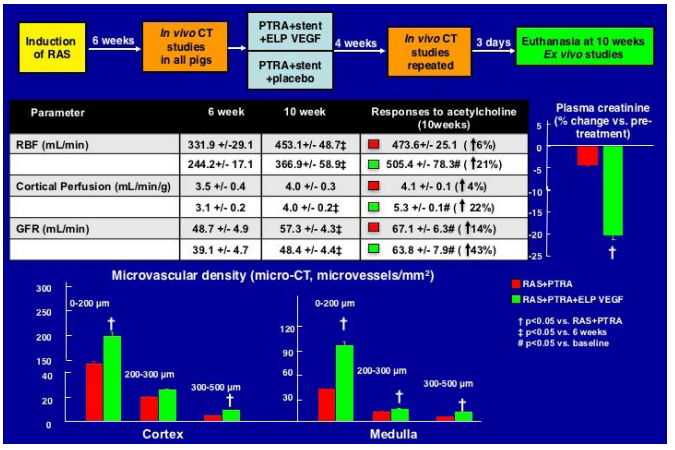
SA-PO195

Angioplasty Combined with Intra-Renal Administration of a Biopolymer-Delivered VEGF Construct to Improve Renal Recovery: A New Therapeutic Strategy
Alejandro R. Chade, Erika Guise, Luke J. Vincent, Gene L. Bidwell. *Univ of Mississippi Medical Center.*

Background: Renal angioplasty and stenting (PTRAS) can resolve renal artery stenosis (RAS) but not always improve renal function, possibly due to persistent parenchymal damage. We recently designed a novel bioengineered fusion of a drug delivery vector (elastin-like polypeptides, ELP) with VEGF, and showed that ELP-VEGF therapy improved stenotic-kidney function and damage. We aim to increase the therapeutic efficacy of PTRAS and hypothesize that co-adjuvant ELP-VEGF therapy following PTRAS will enhance renal recovery compared to PTRAS alone.

Methods: Unilateral RAS was induced in 10 pigs. Six weeks later, basal and stimulated stenotic-kidney blood flow (RBF), cortical perfusion, and filtration (GFR) were quantified *in vivo* using multi-detector CT, and then pigs were randomly divided in RAS+PTRAS or RAS+PTRAS followed by a single intra-renal infusion of ELP-VEGF (n=5 each). Pigs were observed for 4 additional weeks, *in vivo* CT studies repeated, and then euthanized for micro-CT quantification of the renal microvasculature and plasma creatinine.

Results: Pre-PTRA renal hemodynamics was reduced in all pigs. PTRAS similarly resolved RAS and improved basal GFR. However, RBF, cortical perfusion, responses to endothelium-dependent challenge (acetylcholine, intra-renal infusion), and creatinine showed greater improvements in RAS+PTRAS+ELP-VEGF compared to PTRAS alone, accompanied by marked recovery in renal microvascular density.



Conclusions: Our study determined the effectiveness of a novel co-adjuvant intervention for PTRAS. A single intra-renal administration of ELP-VEGF improved stenotic kidney outcomes after PTRAS by protecting the renal microvascular architecture and function, supporting the potential of a new strategy to enhance renal recovery in RAS.

Renal Tubular-Specific Jagged1 Deletion Ameliorates Kidney Fibrosis

Shizheng Huang, Chengxiang Qiu, Jihwan Park, Katalin Susztak. *Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

Background: Fibrosis is the histological manifestation of chronic kidney disease (CKD). Recent studies highlighted the reemergence of developmental pathways in fibrosis including Notch, Wnt, and Hedgehog. Notch is a basic cell-cell communication pathway where expression of the ligand, Jagged1,2 or Delta1,3,4 on signal-sending cells induces an intramembrane proteolysis of the receptor, Notch1-4 on the signal-receiving cell. Our group previously established that tubular epithelial cell (TEC) Notch signaling plays a key role in fibrosis by using models with global Notch deletion. However, the precise ligand and receptor pairs that contributes to kidney fibrosis still remains unknown. Here we performed a systematic analysis to define the specific ligand of Notch-induced fibrosis development.

Methods: Genome wide gene expression analysis of microdissected human kidney tubule samples (59 control and 36 CKD) was performed using Affymetrix microarrays. For *in vivo* study, Jagged1 flox/flox mice were crossed to transgenic mice expressing Cre recombinase under the cadherin 16 to generate animals with TEC deletion of Jagged1 (Ksp^{cre}/$Jagged1^{flox/flox}$). Kidney injury was induced by administering folic acid intraperitoneally. Histological and gene expression changes were analyzed in mouse kidneys. *In vitro* studies were performed using a co-culture system of rat fibroblasts and mouse stromal cells that expressed Jagged1.

Results: In human tissue samples, Jagged1 showed the best correlation with the degree of interstitial fibrosis (p=0.005). Ksp^{cre}/$Jagged1^{flox/flox}$ mice showed no kidney specific alterations. On the other hand, following folic acid injection kidney histology was markedly protected in the ksp^{cre}/$Jagged1^{flox/flox}$ mice. There was marked reduction in inflammatory and profibrotic gene expression in the Jagged1 knock-out mice when compared to littermate controls. *In vitro* co-culture studies indicated that Jagged1 expression induces proliferation and myofibroblastic transdifferentiation of resting fibroblasts.

Conclusions: Excessive Jagged1 activation in tubular epithelial cells stimulates myofibroblast proliferation and activation and leads to kidney fibrosis.

Pericyte C1q and Complement Activation in Tubulointerstitial Fibrosis

Sandhya Xavier,[1] Ranjit K. Sahu,[1] Susan G. Landes,[1] Jing Yu,[2] Srinivas Ayyadevara,[4] Judit Megyesi,[4] Jeremy Stuart Duffield,[5] Ronald P. Taylor,[3] Edimara S. Reis,[6] John Lambris,[6] Didier Portilla.[1,7] *[1]Dept of Medicine, Center for Immunity, Inflammation and Regenerative Medicine, Univ of Virginia; [2]Dept of Cell Biology, Child Health Research Center, Univ of Virginia; [3]Dept of Biochemistry, Univ of Virginia; [4]Nephrology Div, Univ of Arkansas for Medical Sciences; [5]Research and Development, Biogen Idec; [6]Dept of Pathology and Laboratory Medicine, Univ of Pennsylvania; [7]Salem Veterans Affair Medical Center.*

Background: Increased complement expression and activation occurs in kidney cells during acute kidney injury but little is known about its potential pathogenic role during progressive kidney disease.

Methods: We performed real time-PCR, immunoblots, immunohistochemistry, in situ hybridization and flow analysis in kidney tissue from WT, C1qA and C3 knockout mice subjected to unilateral ureteral obstruction and folic acid injury.

Results: We show that pericytes/myofibroblasts (PDGFβR+ cells) cultured from UUO or mice treated with folic acid secrete C1q without increased C1r/C1s, with increased cytokine and extracellular matrix production and Wnt signaling that are hallmarks of myofibroblast activation. Increased expression of C1q protein in tubulointerstitium space and mRNA expression of C1r/C1s in PDGFβR- cells were observed. Alternative pathway components C3b and C5 were also increased. Flow studies localized C1q to pericytes/myofibroblasts as well as CD11bhi F4/80hi cells and C3b to CD45+ cells in UUO mice. Global deletion of C1qa prevented C1qa secretion, but did not reduce fibrosis or prevent increased expression of C1r/C1s or C3b in whole kidney tissue. In contrast, global deletion of C3 reduced expression of C1r/C1s, resulting in reduced fibrosis. Clodronate-mediated depletion of CD11bhi F4/80hi macrophages in UUO mice resulted in reduced expression of C1r/C1s, C3, C5 and reduced fibrosis.

Conclusions: Our studies highlight the pathogenic role and complexity of complement activation in tubulointerstitial fibrosis. The undesirable activation of classical and alternative complement pathways in specific cell types represents novel therapeutic targets to ameliorate progression of chronic kidney disease.

Redirecting TGF-β Signaling via β-Catenin/Foxo to Prevent Kidney Fibrosis

Xi Qiao,[1,2] Padmashree Rao,[1] Min Hu,[1] Yuan Min Wang,[3] Geoff Yu Zhang,[3] Qi Cao,[1] Yiping Wang,[1] Vincent W.S. Lee,[1] Stephen I. Alexander,[3] Guoping Zheng,[1] David C. Harris.[1] *[1]Centre for Transplant and Renal Research, Westmead Inst for Medical Research, Sydney, NSW, Australia; [2]Dept of Nephrology, 2nd Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China; [3]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.*

Background: Conflicting effects of TGF-β (profibroticversus anti-inflammatory) have caused a challenge in treatment of kidney fibrosis. We propose that inhibition of β-catenin/TCF, the key of factor inTGF-β profibrotic pathways, will increase β-catenin/Foxo and thereby increase TGF-β's anti-inflammatoryeffects via regulatory T cells (iTreg).

Methods: iTregs were examined by flow cytometry analysis of Foxp3 expression, and by T cell fate mapping using Foxp3gfp Ly5.1 & Ly 5.2 mice.ICG-001 was used to inhibit β-catenin/TCF binding. The role of β-catenin/Foxo was investigated in vitro and in mouse unilateral ureteral obstruction (UUO).

Results: Inhibition of β-catenin/TCFincreasedβ-catenin/Foxo and Foxp3 expression, as shown by β-catenin/Foxo binding to Foxp3 promoter in EL-4 cells, and by cell fate mapping in rhTGF-β1-treated Foxp3gfpLy5.2 mice transfused with GFP(-)CD4(+)Ly5.1 T cells[16.92±2.13 *vs.* 13.36±2.56 GFP(+) cells %]. Co-administration of rhTGF-β1 with ICG-001 reduced UUO-induced kidney inflammation, with less infiltration (rhTGF-β1+ICG001 treated group vs. UUO group) of $CD45^+$ cells ($18.61\pm3.90\times10^4$ *vs.* $35.30\pm7.65\times10^4$), CD3 (18.32±4.79 *vs.* 48.96±8.36 cell/HPF) and F4/80 cells (4.20±1.02 *vs.* 14.69±3.65 area %), and in HE staining of infiltrating cells [29.07±6.98 *vs.* 104.89±24.21 cells/10 HP). Kidney fibrosis was also significantly reduced (Gomori trichrome:11.27±2.76 *vs.* 24.64±4.87 area %); Sirius red: (2.34±0.46 *vs.* 4.61±1.07 area %). Fibrosis caused by rhTGF-β1 in distant organs (Liver, Lung) was also prevented.

Conclusions: Targeting β-catenin/Foxo dissociates TGF-β's profibrotic effects from its anti-inflammatory effects, therebyallowing TGF-β to reduce both inflammation and fibrosis.

SA-PO199

The Proteasome Inhibitor Bortezomib Attenuates Renal Fibrosis in Mice

Moko Zeniya, Takayasu Mori, Naohiro Nomura, Naofumi Yui, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Renal fibrosis is a common pathologic consequence of various chronic kidney diseases (CKD) with uncertain mechanisms.Recently, a number of studies have shown that the proteasome inhibitor bortezomib attenuated renal impairment in patients with multiple myeloma (MM). We have already reported a case study of a MM patient with severe acute kidney injury, who received long-term bortezomib therapy resulting in a continuous recovery in renal function. This case indicated the possibility that bortezomib might be effective in directly preventing renal interstitial fibrosis. In this study, we investigated the effects of bortezomib to renal injury in a mouse model.

Methods: We investigated the renal effects of bortezomib in aristolochic acid nephropathy (AAN) mice as a renal fibrosis model. Mice were administered aristolochic acid-I with or without bortezomib twice a week for 10 weeks. After the treatment periods, we examined renal functions, expression of renal injury marker proteins, and pathological changes in the kidneys.

Results: In the AAN model, renal fibrosis accompanied with renal dysfunction occurred after the 10-week administration period. Treatment with bortezomib significantly attenuated AAN-induced renal dysfunction (sCre 0.428mg/dl to 0.275mg/dl), albuminurea, and reduced protein expression of renal fibrosis and kidney injury markers such as aSMA, Kim1 and Ngal. Furthermore, bortezomib prevented renal fibrosis pathologically assessed by Masson's trichrome stain. TGF-β1 mRNA expression in the kidney was also reduced in the bortezomib-treatment group.

Conclusions: Bortezomib may have great potential as a drug directly inhibiting renal fibrosis in CKD possibly via reducing TGF-β1 expression.

SA-PO200

Critical Role of Histone Deacetylase 3 in the Regulation of Inflammation and Renal Fibrosis Yuguo Wang,[1] Yanlin Wang.[1,2] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Center for Translational Research on Inflammation Diseases, Michael E. DeBakey VA Medical Center, Houston, TX.*

Background: Inflammation and fibrosis are common features of chronic kidney disease. However, the mechanisms underlying the development of inflammation and fibrosis are not fully understood. In this study, we examined the role of histone deacetylase 3 (HDAC3) in the regulation of inflammation and fibrosis.

Methods: To examine the role of HDAC3 in vivo, we generated mice with inducible deletion of HDAC3 using Cre-LoxP strategy, and we treated wild-type mice with RGFP966, a selective HDAC3 inhibitor. Unilateral ureteral obstruction (UUO) and ischemia-reperfusion injury (IRI) models were used to induce renal fibrosis. Cultured cells were used to examine the role of HDAC3 in the regulation of inflammation and fibroblast activation in vitro.

Results: HDAC3 expression was increased in the kidneys during the development of renal fibrosis. RGFP966 reduced the number of myofibroblasts and total collagen deposition in the kidney and inhibited production of extracellular matrix (ECM) proteins following UUO. Mice with tamoxifen-inducible deletion of HDAC3 (CAG-Cre, floxed HDAC3) were born normal and had no obvious morphological abnormality in the kidney. Compared with Cre negative, floxed HDAC3 mice, mice with tamoxifen-induced deletion of HDAC3 exhibited fewer myofibroblasts and expressed less α-SMA protein in the kidneys following UUO or IRI. Furthermore, inducible deletion of HDAC3 significantly reduced total collagen deposition and ECM protein production in the kidneys in response to UUO or IRI. Real-time RT-PCR showed that pro-inflammatory cytokines were significantly increased after UUO or IRI, which were significantly diminished in HDAC3 deficient mice. In cultured macrophages, HDAC3 deficiency reduced pro-inflammatory cytokine expression after stimulation with LPS or TNF-α. In cultured fibroblasts, deletion of HDAC3 or treatment with RGFP966 attenuated α-SMA and ECM protein expression in response to TGF-β1.

Conclusions: Our study identifies HDAC3 as a critical regulator ofinflammation and fibrosis. Therefore, HDAC3 may represent a novel therapeutic target for chronic kidney disease.

SA-PO201

Uromodulin Deficiency Modifies Tubular and Interstitial Cell Responses to Chronic Kidney Injury while Fibrosis Severity Is Not Altered Allison A. Eddy,[1] Olena Maydan,[1] Paul G. McDade,[1] Yan Liu,[2] Xue-Ru Wu.[2] *[1]Pediatrics, Univ of British Columbia; [2]Urology, New York Univ.*

Background: Human GWAS and Mendelian genetic studies have linked polymorphic variants and mutations in the human uromodulin gene (*UMOD*) with chronic kidney disease. The primary function of this unique kidney-specific and secreted protein remains elusive. This study investigated whether the response to unilateral ureteral obstruction (UUO)-induced kidney injury was altered by genetic UMOD deficiency.

Methods: Kidneys harvested from groups of 129SvEv male wild-type (WT) and knockout (KO)mice (n=7-10 each) were studied 7, 14 and 21 days after UUO.

Results: Compared to sham kidneys, UMOD kidney protein levels increased* 9-13x after UUO in the WT mice and were associated with increased urinary UMOD levels. TUBULAR RESPONSES:KIM-1 protein levels were higher* in the KO group at all time-points (4-13x), while NGAL protein levels were increased to similar levels on days 7 and 14, but were 66% lower* on day 21 in the KO group. Ksp-cadherin protein levels were 40-57% lower* in the KO groups. ROMK2, NKCC2 and AQ2 mRNA levels decreased* while TRPV5 mRNA levels were markedly increased* after UUO; only TRPV5 levels differed by UMOD genotype (1.5-7.0x higher* in the WT group). Levels of pro-apoptotic genes (TNFα, FasL) and the epithelial cell apoptotic protein marker M30 (cleaved cytokeratin 18) (day 14 only) were significantly lower in the KO groups. INFLAMMATION. MCP-1 and RANTES mRNA levels and macrophage F4/80 protein levels were all lower* in the KO groups. FIBROSIS. Kidney αSMA levels showed biphasic differences between the genotypes: higher* on day 7, similar on day 14 and lower* on day 21 in the KO groups. Total kidney collagen levels were similar on days 7 (1.4x and 1.6x sham kidney levels), 14 (3.0x and 2.6x) and 21 (3.4x and 3.8x); WT vs KO. * $P<0.05$.

Conclusions: UMOD protein accumulates in the kidney with marked intraluminal precipitation after UUO. In the absence of UMOD, tubular apoptosis and interstitial inflammation are attenuated, yet overall kidney fibrosis severity is unchanged. Elevated KIM-1 levels in the KO mice after UUO were remarkable nd merit further investigation.

Activation of Fibroblast β-Catenin Signaling Contributes to Kidney Fibrosis by Promoting Tubular EMT and Cell Cycle Arrest Dong Zhou, Haiyan Fu, Youhua Liu. *Dept of Pathology, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Activation of Wnt/β-catenin signaling plays a critical role in the pathogenesis and progression of a variety of chronic kidney diseases (CKD). As the principal mediator of canonical Wnt signaling, β-catenin controls the expression of a host of fibrosis-related genes. However, tubule-specific knockout of β-catenin does not affect kidney fibrosis after unilateral ureteral obstruction (UUO), suggesting β-catenin signaling in other cell types may play a predominant role. In this study, we examined the potential role of β-catenin signaling in interstitial fibroblasts in the pathogenesis of kidney fibrosis.

Methods: Mice with fibroblast-specific deletion of β-catenin were generated by mating Gli1-Cre transgenic mice and β-catenin-floxed mice. Mouse models of kidney fibrosis were established by UUO or ischemia/reperfusion injury (IRI). Kidneys were analyzed by Masson's trichrome staining, immunostaining, Western blotting.

Results: Fibroblast-specific ablation of β-catenin markedly reduced renal fibrosis, which was accompanied by reduced epithelial-mesenchymal transition (EMT), characterized by an increased E-cadherin and decreased vimentin, fibroblast specific protein 1 (FSP-1), Snail 1 and α-Smooth muscle actin. In addition, fibroblast-specific deletion of β-catenin in mice inhibited tubular epithelial cell cycle arrest at G2/M with reduced phospho-Histone H3, compared to the controls. Furthermore, less renal infiltration of inflammatory cells such as CD3 positive T cells and F4/80 positive macrophages was found in conditional knockout mice, comparing to controls. We found an increased hepatocyte growth factor (HGF) expression in mice with fibroblast-specific deletion of β-catenin. Similar results were observed in the kidney at 10 days after IRI. In vitro, Wnt ligands inhibited HGF expression in cultured normal rat kidney interstitial fibroblasts (NRK-49F).

Conclusions: These results demonstrate that loss of fibroblast β-catenin attenuates renal fibrosis by inhibiting partial EMT and tubular cell cycle arrest at G2/M, which is likely to be mediated by an increased HGF expression and secretion by interstitial fibroblasts.

NMDA Receptors-Mediated CaMKII/Erk Pathway Activation Contributes to Renal Fibrosis Jia Shen, Pengpeng Yan, Jingyi Zhou, Rending Wang, Xuelin He, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Renal fibrosis (RF) occurs virtually as a common end point in almost every type of chronic kidney disease. NMDARs, known as key ionotropic glutamate receptors, are widely expressed in the brain and peripheral tissues, and also in kidney. NMDARs are stimulated in acute injured and diabetic kidney, while it is unknown whether NMDARs expression change and participate in the development of the structural and functional degradation in RF.

Methods: Unilateral ureteral obstruction (UUO) model was used to induce RF in male C57BL/6 mice. Lentiviral vector-mediated shRNA interference the functional subunit NR1 expression via retrograde ureteral delivery, and KN93 were used to inhibit CAMKII activation. Fibrosis and the expressions of NMDAR subunit NR1, α-SMA, fibronectin, and S100A4 were evaluated in the obstructed kidneys.

Results: UUO caused up-regulated expressions of NR1, α-SMA, fibronectin, and S100A4. The fibrotic morphology and the expressions of α-SMA, fibronectin, S100A4, CaMKII, and Erk, as well as the activations of CaMKII and Erk were reduced by NR1 knockdown. KN93 significantly suppressed RF as well as the expression and activation of Erk, but not decreased the expression of NR1. KN93 only or combined with NR1 knockdown showed no significant difference on fibrosis severity and Erk activation.

Conclusions: NMDARs participate in the pathogenesis of RF at least partly through CaMKII activated Erk in UUO mice, which could be a potential therapeutic target for Renal fibrosis.

SA-PO204

Endoglin Expressed by Myofibroblasts in Patients with Diabetic Nephropathy Correlates with Interstitial Fibrosis and Reduced Renal Function Tessa Gerrits, Malu Zandbergen, Ingeborg M. Bajema, Jan A. Bruijn, Marion Scharpfenecker. *Pathology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease (ESRD). Thus far there is no treatment to stop the progression towards ESRD. A common histological change in DN is interstitial fibrosis, which contributes to the development of ESRD and the decline of kidney function. We observed an upregulation of endoglin in the interstitium of patients with DN suggesting that endoglin may be an important regulator of fibrosis. Upregulation of endoglin has also been described in other human fibrotic tissues such as liver, heart and intestine. Therefore, we correlated endoglin expression in the interstitium to other histologic and clinical parameters of diabetic patients. We also characterized the endoglin-expressing cell type in the interstitium.

Methods: Kidney autopsy material of 123 diabetic patients was collected. Sections were stained for endoglin and scored semi-quantitatively. A fibrotic index was determined on Sirius Red stained sections. Immunofluorescent double stainings for endoglin and a-SMA, vimentin, CD31 and CD68 were performed on biopsy material from a patient with and without DN.

Results: A significant correlation was found between the amount of interstitial endoglin expression and kidney fibrosis ($p<0.001$). In addition, endoglin expressed in the interstitium correlated with increased creatinine($p=0.004$), presence of proteinuria ($p=0.009$) and reduced GFR in diabetic patients ($p=0.001$). Immunofluorescence showed co-expression of endoglin with the myofibroblast marker a-SMA, whereas no co-localization with fibroblast (vimentin) or macrophage (CD68) markers was observed.

Conclusions: Endoglin plays a role in the development of fibrosis and progression towards ESRD in DN. Endoglin producing interstitial cells were identified as myofibroblasts. Ongoing studies aim at identifying the role of endoglin in differentiation and ECM production in these cells. Our research shows that Endoglin could be a future therapeutic target for patients with DN.

MAD2B Promotes Tubular Epithelial-to-Mesenchymal Transition and Renal Tubulointerstitial Fibrosis via Skp2 Chen Ye, Hui Tang, Hua Su, Chun Zhang. *Nephrology, Union Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: The mitotic arrest deficient protein MAD2B is a well-defined anaphase-promoting complex/cyclosome (APC/C) inhibitor and a small subunit of DNA polymerase zeta. It is critical for mitotic control and DNA repair. However, the pathological role of MAD2B in renal fibrosis has not been fully elucidated.

Methods: The objects of this study included patients with renal tubulointerstitial fibrosis (TIF) (secondary glomerulonephritis and interstitial nephritis were excluded), unilateral ureteral obstruction (UUO) mice and in vitro cultured rat proximal tubular epithelial cell line (NRK-52E). In vivo gene silence of MAD2B was carried out by intrarenal lentiviral gene delivery.

Results: By immunofluorescence and immunohistochemistry, we found an obvious MAD2B enhancement in tubular area of TIF patients and UUO mice. In vitro, transforming growth factor-β1 (TGF-β1) induced a time-dependent MAD2B accumulation prior to tubular epithelial-to-mesenchymal transition (EMT) in NRK-52E. Knocking down MAD2B with siRNA dramatically inhibited TGF-β1-induced tubular EMT process and subsequent extracellular matrix (ECM) production. We also found that the expression of Skp2, an APC/C-CDH1 substrate and E-cadherin destroyer, was increased in TGF-β1-treated NRK-52E, which could be suppressed by MAD2B depletion. Consistently, Skp2 expression was increased in renal tubular area of UUO mice. Locally knocking down MAD2B in renal cortex by using lentiviral transfection inhibited Skp2 expression, tubular EMT and subsequent ECM accumulation.

Conclusions: Our data suggests a pro-fibrotic role of MAD2B in the pathogenesis of tubular EMT and TIF by inducing Skp2 expression. MAD2B-Skp2 axis might be a promising target for renal TIF interventions.

The Role of Galectin-3 in the Renal Tubular Epithelial-Mesenchymal Transition Yuchen He, Linlin Qiu, Wenbin Tang, Hui Li, Ping Xiao, Qiaoling Zhou. *Dept of Nephrology, Kidney Inst, Changsha, Hunan, China.*

Background: Galectin-3 is a pleiotropic lectin that plays an important role in cell proliferation, apoptosis, adhesion and inflammatory responses. Recent evidence suggest that Galectin-3 may play a key role in the development of fibrosis, but the pathogenesis is still unclear. The Objective of this study is to observe the role of Galectin-3 in the renal tubular epithelial-mesenchymal transition and renal fibrosis.

Methods: In vivo, the model of renal fibrosis was induced by unilateral ureteral obstructive in Sprague Dawley rats. HE and Masson staining was used to evaluate the level of renal tissue fibrosis. The location and expression of Galectin-3, E-cadherin and α-SMA in renal tissue were tested by immunohistochemistry. In vitro, NRK-52E cells were treated with Ang-II or high glucose for different time. Furthermore, Galectin-3 was inhibited by modified citrus pectin(MCP) .The expressions of Galectin-3, E-cadherin, α-SMA were detected by Realtime-PCR and Western blot.

Results: In vivo, compared with the sham group rats, more severe tubular dilation, interstitial fibrosis and inflammatory cells infiltration were noted in UUO model rats. E-cadherin was downregulated and α-SMA was upregulated significantly especially in renal tubular cells. Meanwhile, the expression of Galectin-3 was upregulated in UUO model rats. In vitro, expressions of Galectin-3 and α-SMA increased remarkably in NRK-52E cells induced by angiotesin II or high glucose in a time-dependent manner compare with the control, however expression of E-cadherin reduced remarkably. The expression of Galectin-3 was negatively correlated with E-cadherin, but positively correlated with α-SMA. When Galectin-3 inhibitor MCP were used in NRK-52E cell stimulated by high glucose, α-SMA expression was significantly increased, E-cadherin expression was significantly reduced.

Conclusions: Galectin-3 was upregulated during the process of renal tubular EMT. Galectin-3 inhibitor MCP can promote EMT in renal tubular epithelial cells induced by high glucose. In view of these findings it is conceivable that Galectin-3 may serve as a potential novel target in pre-EMT states for the amelioration renal fibrosis seen in CKD.

Apoptosis Signal-Regulating Kinase 1 (ASK1) Inhibitor GS-4997 Decreases Tubulointerstitial Fibrosis in a Rat Model of Ureteral Obstruction John T. Liles, Saili Yi, Swetha Vandana Pendem, David G. Breckenridge. *Gilead Sciences, Inc., Foster City.*

Background: GS-4997 is a potent and selective ASK1 inhibitor that is currently in clinical development for the treatment of Diabetic Kidney Disease (DKD). ASK1 is a critical signaling node through which oxidative stress promotes inflammation, apoptosis, and fibrosis via downstream activation of the MAPK kinases p38 and c-Jun N terminal kinase (JNK). This study evaluated the pharmacodynamics and efficacy of GS-4997 in a rodent model of renal tubulointerstitial fibrosis, which is a final common pathway for progressive kidney diseases such as DKD.

Methods: Male Sprague-Dawley rats were subjected to unilateral ureteral obstruction (UUO) surgery(n=10/group) or sham surgery (n=6) and were orally administered GS-4997 (1, 3, 10 or30 mg/kg, BID) or vehicle for 7 days. Fibrosis was assessed by immunohistochemistry for collagen IV and alpha-smooth muscle actin (a-SMA) quantified using ImageScope software (Aperio).Collagen IV protein was also quantified in kidney cortex lysates by ELISA. ASK1 pathway activation was assessed by western blot and/or ELISA for phosphorylated ASK1 (p-ASK1), p-38 (p-p38) and JNK (p-JNK).

Results: ASK1 pathway activation was significantly increased in UUO kidneys compared to sham (15 ± 4 vs 1 ± 0.06, p-ASK1/IP90; 6 ± 2 vs 1 ± 0.01, p-p38/IP90; and 2 ± 0.2 vs 1 ± 0.02 p-JNK/IP90; $p<0.01$ for all groups), and was decreased by GS-4997 in a dose-dependent manner back to sham control levels. Increased immunostaining for interstitial collagen IV and αSMA positive myofibroblasts detected in UUO kidneys was reduced by GS-4997. In addition, collagen IV protein levels in kidney lysates was increased in UUO compared to sham (2.68 ± 0.2 vs 0.9 ± 0.1 mg/mg, $p<0.05$), and treatment with the ASK1 inhibitor GS-4997significantly decreased renal collagen IV protein levels (2 ± 0.3, 1.4 ± 0.07, and 1.6 ± 0.09 g/mg for the 3, 10, 30 mg/kg doses, respectively, $p<0.05$ for all groups).

Conclusions: GS-4997 inhibits ASK1 pathway activation and ameliorates renal fibrosis in the obstructed kidney. These data support the investigation of GS-4997 as a therapyto reduce renal fibrosis and halt progression in kidney diseases such as DKD.

Tight Junction Dysfunction in Proximal Tubular Cells Is Prohibited by Activation of the HSP72-Klotho Axis Jen Xu,[1] Frank Xu,[1] Li-Lun Ho,[1] Huixia Cao,[1] Kenneth Lim,[2] Tianqing Kong,[1] Tzongshi Lu.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Nephrology Div, Massachusetts General Hospital, Boston, MA.*

Background: Tight junctions (TJ) are specialized membrane domains that play multiple functions in kidney epithelial cells, including the maintenance of cellular polarity and work as a primary regulatory barrier. Studies indicate emerging links between TJ dysfunction and the development of kidney disease, particularly in autosomal dominant polycystic kidney disease (ADPKD) and ischemic acute renal failure. Klotho is a transmembrane protein that has been shown to exert anti-aging properties and its deficiency is involved in the development of renal failure. Heat shock proteins (HSPs) are universally expressed and their induction by a variety of stressors in organisms and cultured cells has been shown to be involved in the maintenance of cellular integrity and normal physiological functions. In this study, we describe a HSP72-Klotho axis and its role in preventing renal fibrosis and cystogenesis in ADPKD, through the regulation of TJs.

Methods: Madin-Darby canine kidney (MDCK) Tet-off inducible Gα12 and Gα12QL cell lines, HK2 cells were used to generate a ADPKD and fibrosis *in vitro* model, respectively. Sprague Dawley rats were used in an ischemia-reperfusion animal model. Heat shock proteins were induced by heat shock treatment (HST) at 43 °C for 30 minutes.

Results: Klotho expression was decreased in ADPKD and HK2 cells, however was preserved by HST. This was associated with the preservation of TJ proteins Occludin and Claudin-5. We also found that matrix metalloproteinase-2 (MMP2) and A Disintegrin and metalloproteinase domain-containing protein 10 (ADAM10) were significantly increased in ADPKD cells and fibrotic kidney tissues. This was associated with significantly decreased Klotho expression. However, HSP72 was induced by HST and this resulted in partial reversal of ADAM10 and MMP2 changes with an increase in Klotho expression and forms a HSP72-Klotho complex.

Conclusions: Our data describes a potential HSP72-Klotho axis in the stabilization of TJ proteins. Further investigation into the molecular mechanisms and clinical application are needed.

SA-PO209

Trimethylamine-N-Oxyde (TMAO) Plasma Accumulates in Uremic Mice and Promotes the Progression of Kidney Fibrosis Caroline C. Pelletier,[1,2] Maud Rabeyrin,[1] Mikael Croyal,[3] Michel Krempf,[3] Laurent Juillard,[1,2] Christophe O. Soulage.[2] *[1]Nephrology, Hospices Civils de Lyon, France; [2]Univ Lyon, INSA-Lyon, INSERM U1060, CarMeN Lab, France; [3]INRA, UMR 1280, CRNH, Mass Spectrometry Area, Nantes, France.*

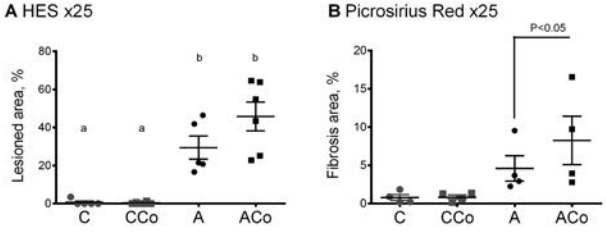
Background: TMAO was recently associated with poor cardiovascular outcomes in the general population and was described to accumulate in patients with chronic kidney disease (CKD). Some recent studies have suggested that the accumulation of TMAO could contribute to renal function.

Methods: TMAO was assayed in 18 control and 18 CKD mice, induced by 3 weeks of an adenin rich diet (0.25%w/w). In each group, half of the mice were then fed for 3 additional weeks with a 1% (w/w) choline-enriched diet to promote the production of TMAO.

Results: TMAO level is significantly increased in control mice after a choline supplementation, to the TMAO level of the CKD mice. TMAO concentration is 10-folds higher in CKD mice fed with choline-enriched diet.

Characteristics of control and CKD mice, with or without enriched choline food					
	Control		CKD		P-value
	Standard food	Enriched Choline food	Standard food	Enriched Choline food	
	C	CCo	A	ACo	
Kidneys, mg	298±28	300±42	150±11	125±10	****
24h-Diuresis, ml	0.74±0.18	0.11±0.06	2.84±1.91	2.48±0.39	****
Plasma urea, mg/dL	57.6±6.6	57.5±11.2	163.3±14.4	145.3±25.5	****
Proteinuria, mg/24h	-	0.08±0.03	1.71±1.45	0.79±0.48	**
TMAO µM	5.8±1.1	39.1±12.1	31.8±5.6	424.8±71.0	****
Means were compared with ANOVA test and sgnificant p was <0.05					

Supplementation decreased the survival of CKD mice (-33%, P<0.05) and promotes renal fibrosis assessed by 2 different histopathology techniques (HES and picro sirius red satinings).



Conclusions: Plasma TMAO accumulates in CKD mice. Higher plasma TMAO level in mices triggers an expansion of renal parenchyma fibrosis.

The Role of Flavin Monooxygenase 3 in Renal Fibrosis Jing Xu, Lei Jiang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Renal proximal tubular cells (PTCs) have been recognized as one of the important contributors to renal fibrosis. Prior studies reported that trimethylamine-N-oxide (TMAO) is elevated in subjects with impaired renal function, and it contributes to both development of renal insufficiency and mortality risk in chronic kidney disease. Since flavin monooxygenase (FMO) family members, especially FMO3 exhibit the highest activity in TMAO metabolism, deciphering the role and mechanisms for FMO3 in renal fibrosis are very necessary.

Methods: In this study, we employed mice with unilateral ureter obstruction (UUO) and TGFβ1-treated NRK-52E cells/primary PTCs as two model systems. FMO3 plasmid was injected one day before UUO surgery. Cells were transfected with FMO3 plasmid or siRNA to downregulate FMO3 expression and FMO3 activity was decreased by using methimazole.

Results: Here, western blot analysis and immunofluorescence staining confirmed that FMO3 expression was decreased in kidney from UUO and folic acid induced renal fibrosis mouse model. Then, we observed that both NRK-52E and primary proximal tubular cells transfected with plasmid or siRNA exhibit higher expression of fibronectin (FN), α-smooth muscle actin (α-SMA), Type1 collagen (COL I) compared with control. In line with this, cells treated with FMO3 activity inhibitor methimazole revealed similar results. Furthermore, 6-8 weeks old mice were injected with FMO3 plasmia via tail vein one day before UUO surgery. We found both gene and protein assay showed that the levels of FMO3 was downregulated in mouse kidneys with plasmia injection and mice that downregulated of FMO3 developed more serious kidney fibrosis in terms of higher expression of FN, α-SMA, COL I. Similar results were found in mice intragastric administration of methimazole. In addition, the mechanisms of FMO3 affect the development of renal fibrosis may through apoptotic pathway.

Conclusions: These results demonstrated that decreased activity or expression of FMO3 is critical for the development of renal fibrosis. Drugs that could specifically target FMO3 may attenuate renal fibrosis and need further research.

The MRTF/TAZ Pathway Is a Critical Inducer of the Profibrotic Epithelial Phenotype Andras Kapus,[1] Maria Zena Miranda,[1] Janne Folke Bialik,[1,2] Pamela Speight,[1] Qinghong Dan,[1] Stine Falsig Pedersen,[2] Katalin Szaszi.[1] *[1]Keenan Research Centre, St. Michael Hospital, Toronto, ON, Canada; [2]Cell Biology, Univ of Copengagen, Copenhagen, ON, Canada.*

Background: The Hippo effector TAZ and the Rho/actin-regulated myocardin-related transcription factor (MRTF) are TGFβ- and mechanosensitive transcriptional coactivators with key roles in the pathogenesis of organ fibrosis. We have shown that MRTF and TAZ exhibit crosstalk and both are critical for epithelial-myofibroblast (MF) transition (EMyT). Although *in vivo* the epithelium is a minor source of MFs, it is a key driver of fibrosis via a profibrotic epithelial phenotype (PEP) shift, hallmarked by the secretion of fibrogenic cytokines. We thus hypothesized that TAZ and MRTF mediate not only EMyT but also PEP and fibroblast-MF transition. Further, our recent data suggest that TAZ is regulated also at the level of its expression. Thus, we aimed to 1) characterize the effect of fibrogenic stimuli on TAZ expression and define the underlying mechanisms and 2) assess the role of MRTF and TAZ in PEP.

Methods: For in vitro studies 10T1/2 fibroblasts or LLC-PK1 proximal tubular cells were exposed to fibrogenic stimuli (TGFβ or cyclic stretch) with/without interfering with MRTF or TAZ. To detect PEP in vivo, renal fibrosis was induced in mice by unilateral ureteral obstruction (UUO), the tubular compartment was isolated by laser capture microdissection and analyzed.

Results: TGFβ induced a rapid and robust increase in TAZ mRNA and protein both in fibroblasts and tubular cells via a Smad3-indpendent, p38- and Akt-mediated process. These pathways converged on MRTF. Pharmacologic (CCG1423) or siRNA-mediated MRTF inhibition prevented the TGFβ-induced rise in TAZ, while MRTF overexpression induced TAZ expression and promoter activation. UUO concomitantly increased *tubular* TAZ mRNA and tubular TGFβ, PDGF, CTGF and Indian Hedgehog (IHH) mRNA levels. Stretch increased mRNAs for TGFβ, CTGF, IHH, and PDGF in LLC-PK1 cells, and these effects were suppressed by pharmacological (verteporfin for TAZ, CCG1423 for MRTF) or siRNA-mediated inhibition of TAZ or MRTF.

Conclusions: MRTF controls TAZ expression both in fibroblasts and epithelial cells, and both MRTF and TAZ are essential mediators of PEP.

PP242 Inhibits Fibroblast Activation and Kidney Fibrosis in Mice with Unilateral Ureter Obstructive Nephropathy Jianzhong Li, Chunsun Dai. *Nanjing Medical Univ.*

Background: PP242, an mTOR kinase inhibitor, caninhibit both mTORC1 and mTORC2 signaling pathways in many types of cell. Regarding the profibrotic role for mTORC1 and mTORC2 in kidney diseases, it is highly possible that blockade of mTOR signaling with PP242 may diminish fibroblast activation and kidney fibrosis.

Methods: In this study, NRK-49F cells, a rat kidney interstitial fibroblast cell line, were stimulated with TGFβ1. Unilateral ureter obstruction (UUO) was used to induce kidney fibrosis in mice.

Results: In cultured NRK-49F cells, TGFβ1 treatment could activate both mTORC1 and mTORC2 signaling in cultured NRK-49F cells at a time dependent manner, while administration of PP242 could dose dependently inhibit TGFβ1-induced mTORC1 and mTORC2 signaling activation. Additionally, PP242 could also dose dependently reduce TGFβ1-induced α-SMA and fibronectin expression in NRK-49F cells. In mice with UUO nephropathy, PP242 administration could markedly diminish total collagen deposition, fibronectin and α-SMA expression in the fibrotic kidneys with UUO nephropathy compared to those treated with vehicle.

Conclusions: In summary, these results suggest that PP242 may act as a new therapeutic reagent for fibrotic kidneys through inhibiting both mTORC1 and mTORC2 signaling pathways.

Wnts Promote Fibroblast Activation and Kidney Fibrosis Involving Smad Signaling Lei Jiang, Qi Sun. *Nanjing Medical Univ.*

Background: Wnts are divided into canonical and non-canonical subgroups relying on whether it can activate b-catenin or not.

Results: In this study, we found that several Wnt family members including Wnt3a, Wnt5a and Wnt5b but not Wnt4, Wnt9b or Wnt11 could markedly induce smad3 phosphorylation in many types of kidney cell including podocyte, NRK-49F cell and HKC. In addition, Wnt3a, Wnt5a and Wnt5b but not Wnt4, Wnt9b or Wnt11 could stimulate a-SMA and fibronectin expression in NRK-49F cells. Blockade of smad3 signaling with smad3 siRNA or SIS3 could largely abolish Wnt3a, Wnt5a and Wnt5b induced a-SMA expression, suggesting an indispensible role for smad3 signaling activation in such Wnts-induced fibroblast activation. Co-immunoprecipitation as well as co-immunostaining analysis demonstrated the co-localization of Wnt3a and type I receptor of TGFb1 in NRK-49F cells. Blockade of type I receptor of TGFb1 with siRNA or SB43152 could almost completely abolish Wnts-induced a-SMA and fibronectin expression. In mouse model with kidney fibrosis after UUO or IRI, Wnt5b expression was induced in kidney tissue and ectopic expression of exogenous Wnt5b could induce smad3 phosphorylation and mild kidney interstitial fibrosis in mice.

Conclusions: Together, this study indicates that smad3 phosphorylation mediates Wnt3a, Wnt5a and Wnt5b stimulated extracellular matrix production in kidney cells, which may be a novel mechanism for Wnts in promoting kidney fibrosis.

SA-PO214

Omega-3 Polyunsaturated Fatty Acids Ameliorate Fibroblast Activation and Kidney Fibrosis Involving Suppression of mTOR Signaling Pathway Zhifeng Zeng, Chunsun Dai. *Nanjing Medical Univ, Nanjing.*

Background: Epidemiologic studies have shown the correlation between the deficiency in omega-3 polyunsaturated fatty acids (PUFAs) and the progression of chronic kidney diseases (CKD), however, the role for omega-3 PUFAs in protecting against kidney fibrosis in CKD and the underlying mechanisms remains obscure.

Results: Here, NRK-49F cells, a rat kidney interstitial fibroblast cell line, were stimulated with TGFb1. DHA, one member of omega-3 PUFAs family, couldremarkably suppress TGFb1-induced fibroblast activation at a dose dependent manner. In addition, DHA could markedly reduce TGFb1 up-regulated p-Akt (Ser473), p-Akt (Thr308) but not p-S6 or p-smad3 abundance in NRK-49F cells. To further decipher the role for omega-3 PUFAs in protecting against kidney fibrosis, we deployed transgenic mouse model capable of endogenously producing omega-3 PUFAs while reducing omega-6 PUFAs owing to the expression of a Caenorhabditis elegans fat-1 gene encoding an omega-3 fatty acid desaturase. The mice were operated with unilateral ureter obstruction (UUO) to induce kidney fibrosis. Compared to the wild type mice, fat-1 transgenics developed much less kidney fibrosis and inflammatory cell accumulation accompanied by less p-Akt (Ser473), p-Akt (Thr308), p-S6 or p-smad3 in kidney tissue at day 7 after UUO.

Conclusions: Thus, omega-3 PUFAs strongly attenuate fibroblast activation and kidney fibrosis and may provide a therapeutic strategy for retarding the progression of chronic kidney diseases.

Dznep Ameliorates Tubulointerstitial Fibrosis via Reduction of TIMP2

Imari Mimura,[1] Yosuke Hirakawa,[1] Yasuharu Kanki,[2] Yutaka Suzuki,[3] Hiroyuki Aburatani,[4] Masaomi Nangaku.[1] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Isotope Science Center, The Univ of Tokyo, Tokyo, Japan; [3]Graduate School of Frontier Sciences, The Univ of Tokyo, Tokyo, Japan; [4]Div of GenomeScience, Research Center for Advanced Science and Technology, The Univ of Tokyo, Tokyo, Japan.*

Background: Tubulointerstitial fibrosis has been recently reported to be caused by the collapse of epigenetic regulations for kidney diseases. We examined whether one of inhibitors for histone modifications is effective against renal fibrosis. Dznep (3-deazaneplanocin A) is originally developed as an anti-cancer drug to delete repressive histone mark, H3K27me3. We found that Dznep contributes to the reduction of tubulointerstitial fibrosis. The aim of our study is clarifying the epigenetic mechanisms of ameliorating renal fibrosis using genome-wide analysis of mRNA and microRNA.

Methods: Although ischemia reperfusion injury model is well known to cause acute kidney injury, we have found that the unilateral ischemia reperfusion model also leads to chronic tubulointerstitial fibrosis after two months. We administered Dznep to these model mice for 8 weeks intravenously. Because epigenetic regulation is specific to the cell species, we need to focus only on the tubular cells. Therefore we picked up only tubular cells from *in vivo* samples using laser captured microdissection. We examined the level of mRNA and microRNA in tubular cells using high throughput sequencers (RNA-seq) to identify novel epigenetic factors associated with renal fibrosis. We also performed RNA-seq using *in vitro* samples of renal proximal tubular cell lines with the stimuli of hypoxia and Dznep.

Results: We analysed the results of RNA-seq and found that TIMP2 (tissue inhibitor of metalloproteinase 2) is suppressed with Dznep both *in vivo* and *in vitro* samples. TIMP2 is reported to be associated with promoting fibrosis. In addition, we identified the novel microRNAs which target TIMP2. The novel microRNAs have possibility of inhibiting the gene expression of TIMP2, leading to reducing renal fibrosis.

Conclusions: We found the novel epigenetic molecular mechanisms showing the inhibition of TIMP2 via microRNAs might contribute to reducing renal fibrosis.

Angiopoietin-1 Deficiency Increases Tubulointerstitial Fibrosis

Krishnapriya Loganathan,[1] Ebtisam Salem,[1] Susan E. Quaggin,[2,3] Marie Jeansson.[1] *[1]Immunology, Genetics and Pathology, Uppsala Univ, Uppsala, Sweden; [2]Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [3]Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in aSMA+ fibroblasts, myofibroblasts, that produce collagen. Identification of factors that regulate the fibrotic response are excellent candidate targets for treatment of kidney diseases. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to fibrosis in wound healing and diabetic nephropathy. Angpt1 acts through the Tie2 tyrosine-kinase receptor expressed on endothelial cells. Here, we test the hypothesis that loss of Angpt1-Tie2 signaling results in an increased fibrotic response in kidney fibrosis.

Methods: We first performed lineage tagging experiments using Tie2-Cre to better understand if cells using Angpt1-Tie2 signaling could contribute to the myofibroblast population in kidney fibrosis. FACS was used to isolate the tagged cells and to study gene regulation of myofibroblast markers. To study the role of Angpt1 in renal fibrosis we utilized Angpt1 conditional knockout mice in the unilateral ureter obstruction (UUO) model of kidney fibrosis.

Results: The Tie2-lineage contributed to almost 20% of myofibroblasts 10 days after UUO. I addition, there was a significant ($p<0.001$) upregulation of Tgfb and Fibronectin-1 gene expression in FACS sorted lineage tagged cells after UUO, suggesting that part of this population have become myofibroblasts. Angpt1 deficient mice showed a significant ($p<0.05$) increase in SMA+ area 3 days after UUO as well as an increase in the expression of Fibronectin-1 ($p<0.01$), Tgfb ($p=0.023$) and Kim-1 ($p=0.06$).

Conclusions: Our results suggest that loss of Angpt1-Tie2 signaling increases tubulointerstitial fibrosis as seen by the increased expression of fibrosis markers in Angpt1 deficient mice. Ongoing work is designed to use other models of fibrosis and to elucidate the mechanism(s).

MicroRNA Fine-Tuning of Endothelial Dysfunction and Prevention of Fibrosis by miR127-Complementary Locked Nucleic Acid Oligonucleotides

Sina Dadafarin, Jun Chen, Yujiro Kida, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

Background: Endothelial cells (EC), especially SIRT1-deficient, subjected to TGFβ develop premature senescence. It has been demonstrated previously that microRNAs (miR) are causally involved in induction of cell senescence and dysfunction, which in turn generates pro-fibrogenic secretome.

Methods: For this reason we performed profiling miRs in EC isolated from control and SIRT1-/- mice renal microvasculature. The samples were labeled using the miRCURY LNA™ microRNA Hi-Power Labeling Kit, Hy3™/Hy5™ and hybridized on the miRCURY LNA™ microRNA Array (7th Gen, Exiqon), following a dual-color experimental design. The microRNA profiling performed on the miRCURY™ LNA array identified microRNAs that have a log fold change > than 1. We have contrasted miR profile of wild-type and endothelial SIRT1-/- EC under basal and TGFβ-stimulated conditions.

Results: Notably, the known TGFβ-induced miRs -145a, -379 and -143 were present in both screens of EC, a proof of technical validity. Among differentially displayed (at least a log-difference) signatures of control and endothelial SIRT1-/- EC stimulated by TGFβ, miR-127 3p increased by 1.6 log FC. miR-410 3p, also identified as a downstream target of p16(INK4a) pathway (induced in cell senescence) and shown to reduce the expression of VEGF, was also upregulated. To gain insight into the in vivo role of elevated miR-127 and miR-410, complementary locked nucleic acid (LNA) oligonucleotides and respective scrambled controls were synthesized. Experiments were performed in 10-12 week-old α-SMA-GFP mice subjected to UUO. We treated UUO mice with LNA complementary to miR-127 3p and miR-410 3p. We observed no deleterious effects of LNA in FVBmice. The degree of fibrosis of UUO kidneys was significantly reduced in mice that received complementary LNA to miR-127 compared to scrambled LNA-treated mice. Mice receiving LNA to miR-410 showed a moderate reduction in fibrosis.

Conclusions: These studies demonstrate that complementary 127 3p LNA-induced amelioration of endothelial dysfunction leads to the concomitant reduction of renal fibrosis, thus establishing it as a valid therapeutic target.

Galunisertib Is a Promising Drug Candidate for the Treatment of Renal Fibrosis in Ex Vivo Tissue Slice Cultures

Emilia Bigaeva,[1] Emilia Gore,[1] Miriam Boersema,[1] Henricus A.M. Mutsaers,[1] Detlef Schuppan,[3] Peter Olinga.[1] *[1]Pharmaceutical Technology and Biopharmacy, Univ of Groningen, Groningen, Netherlands; [2]Boehringer Ingelheim, Biberah, Germany; [3]Inst of Translational Immunology and Research Center for Immunotherapy, Univ of Mainz Medical Center, Mainz, Germany.*

Background: Galunisertib (Galu) is an inhibitor of the TGFβR1 kinase and is currently tested in clinical trials as an anticancer drug. Galu could be a potential candidate for the treatment of fibrosis. Our objective was to investigate the effects of Galu on the early and end stages of fibrosis using precision-cut mouse and human kidney slices (PCKS).

Methods: PCKS were prepared from healthy and diseased mouse and human kidneys and incubated for 48 hours in the presence of 10 μM Galu, a non-toxic concentration. Unilateral ureteral obstruction (UUO) for 7 days was used to induce renal fibrosis in mice. Gene expression of key fibrosis markers, such as procollagen α1(I) (*Col1α1*), α-smooth muscle actin (*αSMA*), heat shock protein 47 (*Hsp47*) and fibronectin (*Fn*), was determined by qPCR.

Results: Incubation of healthy PCKS resulted in the early onset of fibrosis, as demonstrated by an up-regulation of the fibrosis markers in mouse (*Col1α1* 8.6 fold; *HSP47* 5.0 fold; *Fn* 176.7 fold) and human (*Col1α1* 2.8 fold). The fibrosis markers were even further increased in fibrotic PCTS prepared from UUO vs control mice (*Col1α1* 1.4 fold, *HSP47* 1.5 fold and *Fn* 4.7 fold). Galu inhibited gene expression of fibrosis markers in healthy mouse PCKS (*Col1α1* by 97%; *αSMA* by 89%; *HSP47* by 51%; *Fn* by 99%) and in PCKS prepared from UUO mice (*Col1α1* by 87%; *αSMA* by 63%; *HSP47* by 48%; *Fn* by 83%). In healthy human PCKS Galu inhibited gene expression of *Col1α1* (by 70%) and *Fn* (62%). The pilot experiment with fibrotic human PCKS indicated a similar trend (*Col1α1* was inhibited by 90%; *HSP47* by 58%; *Fn* by 76%).

Conclusions: Galu exhibits strong antifibrotic activity in the early and the end stage of fibrosis in mouse and human PCKS. The PCKS technique is a promising model to test antifibrotic agents both in rodent and human tissues, considering the latter as a bridge to clinical studies.

The DNA Damage Response Protein, Breast Cancer Factor 1 (BRCA1) Induces Interstitial Fibrosis Through Cell Cycle Arrest following Tubular Injury Akinwande A. Akinfolarin, Venkata Sabbisetti, Amrendra Kumar Ajay, Sarah J. Hill, Joseph V. Bonventre. *Nephrology, Brigham and Woman's Hospital, Boston, MA.*

Background: Repetitive tubular injury leads to chronic fibrotic kidney disease. Chemical, ischemic and obstructive kidney injuries lead to double strand DNA breaks (DSB), triggering the DNA damage response. *BRCA1* is a breast tumor suppressor gene with a role in homologous recombination (HR) and maintenance of genome integrity by DNA repair. Here we deplete BRCA1 in the adult mouse proximal tubule (PT) to examine its effect on development of interstitial fibrosis.

Methods: SLC34A1 Cre mice were crossed to mice with a floxed *BRCA1* allele yielding models of PT *BRCA1* gene deletion. After Tamoxifen-induced Cre induction, we subjected mice to bilateral ischemia/reperfusion (I/R), unilateral ureteric obstruction (UUO), or aristolochic acid (AA)-induced injury. Kidney extracts were evaluated by western blot, real time PCR and Masson's trichrome (MT) and Pico Sirius Red (PS) staining of kidney tissue for markers of interstitial fibrosis. Markers of DNA damage, cell cycle arrest and senescence were examined by immunofluorescence. PT cells were isolated from mice and treated with AA to explore the relationship between injury and cell cycle stage, apoptosis and senescence.

Results: Heterozygosity was associated with a reduction in PT *BRCA1* mRNA by in situ hybridization. There was reduced kidney interstitial fibrosis in mice heterozygous for PT *BRCA1* deletion compared to WT littermate controls by MT and PS staining after I/R and AA. PCR analysis of whole kidney cortex revealed reduction in fibrogenic factors such as CTGF, COL4A1, fibronectin and ACTA2. There was also a reduction in markers of G2 cell cycle arrest and senescence although markers of apoptosis were increased in heterozygous mice compared to WT. These murine data are supported by in vitro experiments with AA after depleting BRCA1 in PT cells which secreted fewer fibrogenic factors.

Conclusions: BRCA1 facilitates interstitial fibrosis following kidney tubular injury in mice through its role in DNA damage response.

SA-PO220

Metanephric Mesenchymal Cells Can Inhibit and Partially Reverse Epithelial to Mesenchymal Transition of Renal Tubular Epithelial Cells Yuansheng Xie,[1] Pengfei He,[1,2] Kai Wei,[1,2] Bo Fu,[1] Shaoyuan Cui,[1] Xiang-Mei Chen.[1] *[1]Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, China; [2]Medical College, NanKai Univ, Tianjin, China.*

Background: The epithelial-to-mesenchymal transition (EMT) of renal tubules is one of the main pathogenesis of renal interstitial fibrosis. In this study, we investigated the effects of metanephric mesenchymal cells (MMCs) on the EMT of renal tubular epithelial cells in order to provide new therapeutic strategies for renal interstitial fibrosis.

Methods: MMCs were extracted from the renal cortex of fetal pig 70 days after pregnancy. Transforming growth factor-β1 (TGF-β1) was used to induce EMT of a pig proximal tubular epithelial cell line (LLC-PK1). Transwell chambers were applied to co-culture MMCs with LLC-PK1. Light microscope,immunofluorescence confocal microscopy and western blotting were used to identify the MMCs and detect the phenotypic changes of LLC-PK1.

Results: The primary MMCs were spindle-shaped, positive for six2 and vimentin, and negative for cytokeratin-18 and e-cadherin. 10ng/ml TGF-β1 could induce the EMT of LLC-PK1 manifested as a change of pebble shaped epithelial cells into spindle-shaped fibroblast-like cells, down-regulation of e-cadherin and up-regulation of vimentin and α-SMA. Co-cultured MMCs with LLC-PK1 when administrated with TGF-β1 significantly inhibited EMT of LLC-PK1. Co-cultured MMCs with LLC-PK1 after incubation of TGF-β1 for 48h obviously ameliorated the extent of EMT, but this effect disappeared when the incubation time extended to 72h. Furthermore, MMCs could also inhibit TGF-β1 induced activation of β-catenin/ZEB1 signaling pathway, which indicated that this signaling pathway might involve in the inhibition and reverse of EMT.

Conclusions: Pig MMCs can inhibit and partially reverse TGF-β1 induced EMT of renal tubular epithelial cells, and β-catenin/ZEB1 signaling pathway may involve in the above processes. Our results may provide a new idea for the early intervention of renal interstitial fibrosis.

SA-PO221

Inhibition of BET Family Proteins as a Potential Epigenetics-Based Therapy for Renal Fibrosis Chongxiang Xiong, Monica V. Masucci, Xiaoxu Zhou, Shougang Zhuang. *Dept of Medicine, Rhode Island Hospital, Brown Univ, Providence, RI.*

Background: Bromodomain and extra-terminal (BET) protein inhibitors have been shown to effectively inhibit tumorgenesis by directly targeting bromodomain proteins that bind acetylated chromatin markers. However, its role in renal fibrogenesis remains to be explored.

Methods: In this study, we studied the role of BET in the activation of cultured renal interstitial fibroblasts and development of renal fibrosis in a murine model of unilateral ureteral obstruction as well as mechanisms involved.

Results: Our results show that in cultured renal interstitial fibroblasts, exposure of cells to I-BET151, or silencing of bromodomain-containing protein 4 (Brd4), a key BET protein isoform, significantly reduced their activation as indicated by decreased expression ofa-smooth muscle actin, collagen 1 and fibronectin. In a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), administration of I-BET151 suppressed renal fibroblast activation, fibrotic fibril deposition, and macrophage infiltration. Mechanistically, I-BET151 treatment abrogated UUO-induced phosphorylation of epidermal growth factor receptor and platelet derived growth factor receptor. It also inhibited the activation of Smad-3, STAT3 and NF-κB pathways, as well as the expression of c-Myc and P53 transcriptional factors in the kidney. Moreover, BET inhibition resulted in reduction of renal epithelial cells arrested at G2/M phase of cell cycle after UUO injury. Finally, injury to the kidney increased Brd4 expression and Brd4 was also highly expressed in human fibrotic kidneys.

Conclusions: These data indicate that BET proteins are implicated in the regulation of molecular and cellular machinery associated with renal fibrogenesis, and suggest that targeting BET proteins could be a potential epigenetics-based therapy for renal fibrosis.

SA-PO222

Nintedanib, a Triple Tyrosine Kinase Inhibitor, Inhibits Fibroblast Activation and Ameliorates Renal Fibrosis in Chronic Kidney Disease Feng Liu, Li Wang, Yi Wang, Shougang Zhuang. *Dept of Nephrology, Shanghai East Hospital Tongji Univ, Shanghai, China.*

Background: Nintedanib (BIBF1120) is a triple kinase inhibitor of platelet derived growth factor receptor (PDGFR), fibroblast growth factor receptor (FGFR) and vascular endothelial growth factor receptor (VEGFR) that has recently been approved by FDA to treat idiopathic pulmonary fibrosis. However, its efficacy in renal fibrosis remains unknown.

Methods: In this study, we evaluated the anti-fibrotic effect of nintedanib in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO).

Results: Administration of nintedanib immediately or 3 days after UUO injury attenuated renal fibrosis and inhibited activation of renal interstitial fibroblasts and expression of two extracellular matrix proteins, fibronectin and type I collagen. Delayed administration of nintedanib also partially reversed established renal fibrosis. Injury to the kidney induced phosphorylation of PDGFRb, FGFR1 and VEGFR2 as well as activation of several intracellular signaling molecules associated with renal fibrosis, including signal transducer and activator of transcription-3, nuclear factor-κB and Smad-3 in the kidney. Treatment with nintedanib blocked all these responses. In cultured renal interstitial fibroblasts, nintedanib abrogated transforming growth factor β1-induced activation of renal fibroblasts and phosphorylation of Smad3.

Conclusions: These data indicate that nintedanib is a potent anti-fibrotic agent in the kidney and may hold therapeutic potential as a treatment of chronic fibrotic kidney disease.

Funding: Other NIH Support - The National Nature Science Foundation of China

Jak-Stat Pathway Inhibition Attenuates UUO-Induced Renal Fibrosis in Rats Damian C. Matera, Glenn Gibson, Mark Mchugh, R. Paul Fracasso, James W. Tanner, Hu Sheng Qian, Glenn A. Reinhart, Steven M. Weldon. *CardioMetabolic Diseases Research, Boehringer Ingelheim, Ridgefield, CT.*

Background: The Janus kinase (Jak)-Signal transducer and activator of transcription (Stat) signaling pathway is implicated as an important regulator of inflammatory diseases and currently under clinical evaluation in rheumatoid arthritis. Understanding of Jak-Stat involvement in chronic kidney disease (CKD) is limited but attractive as a potential therapeutic target based on recent data demonstrating Stat3 involvement in the development of tubulointerstitial fibrosis (TIF) induced by unilateral ureteral obstruction (UUO). Our study was designed to understand the role of Jak-Stat activation and related inflammatory mediators in UUO-induced TIF in the rat.

Methods: Male rats were treated with EX76545 (Jak1/2 inhibitor; 1, 3, 10mg/kg, p.o.) or the anti-inflammatory agent EX76166 (10mg/kg, p.o.) that initiated concurrently with UUO surgery and continued daily for 7 days post-UUO. Blood was collected on days 4 and 7; kidneys collected on day 7 post-UUO. Kidneys were evaluated for TIF via Sirius Red morphometry (SRM) and pathway components (Jak1, Jak2, Stat3, and Socs3) via qPCR and ELISA.

Results: Following UUO, kidney mRNA transcripts for Jak1, 2 and Stat3 increased (2-2.5X) while Socs3 increased 25X compared to sham (RNAseq). UUO induced significant TIF in the vehicle group (SRM score=9.71±0.66*($p<0.05$), vs. sham (4.93±0.62). EX76545 reduced TIF by 52%* and 40%* for the 3 and 10 mg/kg doses, respectively, and was comparable to EX76166 (48%*). UUO-induced TIF was accompanied by increases in inflammatory (MCP-1, CSF-1, Txnip) and profibrotic (TGFβ, Fn, Acta2) genes that were attenuated by EX76545 demonstrating direct impact of Jak signaling on these pathways. EX76545 reduced protein expression of phos-Stat3 by 67%*, 99%*, and 112%* (1, 3, 10mg/kg, respectively) compared to vehicle control or EX76166 that were without effect, demonstrating target engagement and Jak-Stat pathway inhibition.

Conclusions: These results demonstrate for the first time that Jak1/2 inhibition reduces TIF and related pro-fibrotic and inflammatory genes generated by UUO highlighting inflammatory modulation as a potential therapeutic area for CKD.

SA-PO224

Post Translational Modifications to H3K9 during Renal Myofibroblast Differentiation Timothy D. Hewitson,[1] Chrishan S. Samuel,[2] Stephen G. Holt,[1] Edward R. Smith.[1] *[1]Nephrology, Royal Melbourne Hospital, Melbourne, VIC, Australia; [2]Pharmacology, Monash Univ, Melbourne, VIC, Australia.*

Background: Epigenetic regulation of fibroblasts is a key determinant of progression in renal disease. Although DNA methylation and miRNA regulation of fibroblasts are reported, the pattern of post-translational histone modifications (marks) and their significance are largely unknown. Lysine 9 on Histone 3 (H3K9) is of particular interest as it can be both methylated and acetylated. In this study we examined the distribution and acquisition of H3K9 modifications in fibrogenesis.

Methods: Confocal microscopy with histone mark specific antisera was used to examine global H3K9 acetylation (H3K9Ac) and tri-methylation (H3K9Me3) after 3 and 10 days of unilateral ureteric obstruction (UUO). Cell culture studies using confocal/ super-resolution microscopy and flow cytometry examined the effect of TGF-β1 on structural arrangement of these marks, and their relationship with kinetics and differentiation.

Results: Staining for H3K9Ac was diffuse and did not change after UUO, while H3K9Me3 was more intense in both proximal tubules (LTL lectin-positive cells) and myofibroblasts (α smooth muscle actin-positive cells). Sub-nuclear localisation in cultured primary rat renal fibroblasts and a proximal tubule cell line (NRK52e) showed that H3K9Ac was co-localised with phosphorylated-Ser2 RNA polymerase II (pRNAPol II), while H3K9Me3 was not, consistent with permissive and repressive effects on gene expression, respectively. H3K9Ac was diffusely distributed throughout the nucleus while H3K9Me3 was tethered to the nuclear membrane. Exogenous TGF-β1 had no effect on co-localisation with pRNAPol II, but resulted in a redistribution of H3K9Me3 within the fibroblast nucleus. This was unrelated to any change in mitogenesis. Flow cytometry showed that H3K9Me3 but not H3K9Ac was acquired in myofibroblast differentiation.

Conclusions: Myofibroblast differentiation is accompanied by changes in both histone mark arrangement and the acquisition of the repressive H3K9Me3 mark. Future studies will need to identify the genes involved and their ramifications.

Fibrosis and Altered Wnt10b Expression Occurs with Aging in the Kidney Priyantha Sumudhu Kulatilake, Helen Williams, Gavin Iain Welsh, Sarah J. George. *School of Clinical Sciences, Univ of Bristol, Bristol, England, United Kingdom.*

Background: Kidney fibrosis occurs with ageing, however little is known about the involvement of Wnt/β-catenin signalling in this process. Here we examined whether Wnt10b was altered with ageing and coincided with age-related renal fibrosis.

Methods: C57/Bl6 mice were aged to 18 months (old) and compared to mice aged 8 weeks (young). We excised the kidneys and processed them for RNA, protein and histological analysis.

Results: Initially, western blotting showed increased β-galactosidase protein in the old ($n=3$ $p<0.05$) mice and picrosirius staining of histology sections demonstrated increased fibrosis ($n=15$ $p<0.05$), confirming ageing and fibrosis, respectively. We observed a significant decrease in Wnt10b ($n=5$ $p<0.05$) protein with age and active β-catenin protein ($n=7$ $p<0.05$). Interestingly, the mRNA levels of Wnt10b however increased with age ($n=11$ $p<0.05$), suggesting suppressed mRNA translation of this protein. We scanned online databases for potential microRNAs (miRs) that could target Wnt10b mRNA. Predicted miRs that target Wnt10b included miR-22 and miR-29a, which we found to be increased with age, ($n=7$ $p<0.01$ and $n=7$ $p<0.05$, respectively). As miR-22 and miR-29a are not validated targets of Wnt10b our next step is to validate them as targets against Wnt10b with a luciferase assay.

Conclusions: These results suggest that decreased Wnt10b protein and resultant β-catenin activity may occur in the kidney due to an increase in interfering microRNA preventing Wnt10b translation into protein and this may be associated with kidney fibrosis.

SA-PO226

Shikonin and 2-Deoxyglucose Attenuate Renal Fibrosis via Inhibiting Aerobic Glycolysis in Renal Interstitial Fibroblast Hao Ding, Junwei Yang. *Center for Kidney Disease, Second Affiliatted Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Almost all chronic kidney diseases lead to renal fibrosis, however, the mechanism that governs renal fibrosis remains unclear. Recently energy metabolism became as particularly interesting topic in kidney disease research, the questions whether aerobic glycolysis is required for renal myofibroblast activation and whether modulation of renal fibroblast aerobic glycolysis can affect the occurrence and progression of renal fibrosis still remain to be addressed.

Methods: In this study, we employed mice with unilateral ureter obstruction (UUO) and TGFβ1-treated kidney interstitial fibroblast cells as two model systems. We profiled the gene expression involved in glucose metabolism by using RT2 Profiler PCR arrays. In addition, we examined pyruvate kinase type M2 (PKM2) levels in 20 renal biopsy samples from individuals with different degrees of renal fibrosis.

Results: Here we demonstrated that a switch of metabolism from oxidative phosphorylation to aerobic glycolysis in renal fibroblasts was the primary feature of fibroblast activation during renal fibrosis, and that suppressing renal fibroblast aerobic glycolysis could significantly reduce renal fibrosis. Both gene profiling and protein assay showed that the expression of glycolysis enzymes was upregulated in mouse kidneys with UUO surgery or TGFβ1-treated renal interstitial fibroblasts. Aerobic glycolysis flux, indicated by glucose uptake and lactate production, was increased in mouse kidney with UUO or TGFβ1-treated renal interstitial fibroblasts and positively correlated with fibrosis process. In line with this, aerobic glycolysis inhibitors shikonin and 2-deoxyglucose (2-DG) attenuate UUO-induced renal fibrosis and TGFβ1-stimulated myofibroblast activation. Furthermore, mechanistic study indicated that shikonin inhibits renal aerobic glycolysis via reducing phosphorylation of PKM2, a rate-limiting glycolytic enzyme associated with cell reliance on aerobic glycolysis.

Conclusions: In conclusion, our findings demonstrate the critical role of aerobic glycolysis in renal fibrosis and provide the treatment of aerobic glycolysis inhibitors shikonin and 2-DG as a potential anti-fibrotic strategy.

Evolutionary Conserved Transcriptional Changes in Kidney Fibrosis Jihwan Park, Chengxiang Qiu, Shizheng Huang, Szu-Yuan Li, Yi-An Ko, Katalin Susztak. *Renal Electrolyte and Hypertension Div, Univ of Pennsylvania, Philadelphia, PA.*

Background: Kidney fibrosis is the histological manifestation of chronic kidney disease (CKD) and observed in all forms of progressive kidney disease. In patients fibrosis is associated with global gene expression changes, some of them might be causally related to disease development, while others change as a consequence of disease. Mouse models can provide platform for understanding fibrosis and pathways that are recapitulated in a different species could have a higher likelihood to be causal, but individual mouse model do not fully recapitulate the complexity of the human disease.

Methods: We performed expression profiling for a large cohort (n=95) of human microdissected normal and CKD tubule samples. Using an adjusted linear regression model we identified genes those expression significantly associated with phenotypic changes including GFR and tubulointerstitial fibrosis. By using RNA sequencing we have examined gene expression changes in four mouse fibrosis models; folate induced fibrosis (FA), unilateral uretheral obstruction (UUO), tubule specific Notch transgenic and podocyte specific APOL1 transgenic mice.

Results: The expression of large number of genes correlated with fibrosis severity in human patient samples. To narrow target genes we identified 761 conserved expression changes between mouse and human and examined their correlation with fibrosis development. Genes differentially expressed in mouse models allowed proper clustering of control and diseased human kidney samples. Genes involved in immune response showed positive correlation with fibrosis development while genes with metabolism and oxidative reduction showed negative correlation both in mouse and human samples. Some of the known therapeutic target genes such as Il1a, Aoc3 and Itgb6 showed distinct patterns between mouse models. We are performing functional studies to identify key transcriptional regulators of fibrosis development.

Conclusions: Comparative analysis of human and mouse kidney fibrosis have identified conserved genes and pathways in kidney fibrosis. These genes can serve as potential new biomarkers or therapeutic targets for kidney disease development.

PBI-4425, a Novel Anti-Inflammatory/Fibrotic Compound, Improves Kidney Function in 5/6-Nephrectomized Rats Brigitte Grouix, Lilianne Geerts, Kathy Hince, François Sarra-Bournet, Liette Gervais, Alexandra Felton, Alexandre Laverdure, William Gagnon, Martin Leduc, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Chronic kidney disease (CKD) represents an important health problem worldwide, and affects approximately one-seventh of adults in the US. PBI-4425, a novel first-in-class treatment for fibrotic diseases, possesses a pleiotropic mechanism of action with anti-inflammatory, antioxidant and anti-fibrotic properties. The aim of this study was to investigate the protective effect of PBI-4425 on kidney function and structure in the 5/6-nephrectomized (NX) rat model of CKD.

Methods: Sprague-Dawley rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7 the right kidney was removed. Oral treatment with PBI-4425 (100 mg/kg, once a day) or vehicle was initiated at day 21, following randomization based on glomerular filtration rate (GFR) results. GFR was measured at day 21 and assessed every 3 weeks up to day 128 at which time the animals were sacrificed.

Results: Treatment with PBI-4425 resulted in a significant improvement in GFR as well as a significant reduction of urinary albumin to creatinine ratio (ACR). Histological kidney lesion scores were also significantly ($p<0.05$) decreased in PBI-4425-treated rats (2.51 ± 0.9) compared to control (4.47 ± 0.9), as determined by HPE, PAS and Masson's trichrome staining. PBI-4425 reduced the overexpression of inflammatory and fibrotic markers such as IL-6, MCP-1, TGF-β1, CTGF, collagen I, α-SMA, PAI-1, and MMP2 in kidney. Furthermore, a significant reduction of urinary MCP-1 and Beta-2 microglobulin levels was observed in PBI-4425-treated 5/6 nephrectomized rats.

Conclusions: Taken together, these results suggest that PBI-4425 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and can potentially improve residual kidney function in patients with end stage renal failure.

SA-PO229

Gremlin 1 Neutralization Does Not Attenuate Markers of Fibrosis in the Unilateral Ureteral Obstruction Model Philippe Costet,[1] Yanqing Kan,[1] Liyang Wang,[2] Sheena Mumick,[3] Kashmira Shah,[3] Tian-Quan Cai,[2] Michael Judo,[2] Brian E. Hawes,[3] Xiaoda Niu,[3] Kenny K. Wong,[2] Masahisa Handa,[4] Mohammad Tabrizifard,[5] Shirly Pinto.[1] *[1]Cardiometabolic Diseases, Merck, Kenilworth, NJ; [2]Discovery Bioanalytic, Merck, Palo Alto, CA; [3]Pharmacology, Merck, Kenilworth, NJ; [4]Pharmacology, Merck, Palo Alto, CA; [5]Discovery Operations, Merck, Palo Alto, CA.*

Background: Gremlin 1 (Grem1) is a secreted antagonist of the anti-proliferative bone morphogenic protein (BMP) signaling pathway, present in the extracellular space in rodents and in plasma in humans. Grem1 also promotes pro-fibrotic TGFb signaling. Grem1 expression is increased in fibrotic organs in patients with idiopathic pulmonary fibrosis, diabetic nephropathy. In mice, grem1 overexpression worsens kidney fibrosis in the unilateral ureteral obstruction (UUO) model. Grem1-/+ mice rendered diabetic with streptozotocin have improved kidney function compared with STZ WT mice. Our goal was to verify whether an antibody raised against gremlin 1 can attenuate fibrosis in the kidney.

Methods: We synthesized two antibodies raised against gremlin 1 and characterized their binding affinities for human and mouse gremlin using biacore, and their activity toward BMPs using functional assays.Next we evaluated their effect of in a preventive fashion in the unilateral ureteral obstruction model.

Results: We determined the EC50 for mAb1 and mAb2 to be 1 and 5 nM by measuring BMP4-stimulated psmad1/5/9 accumulation in mouse 3T3 cells. UUO mice exhibited increased expression of gremlin 1 mRNA, decreased BMP signaling and increased TGFb signaling compared to sham-operated mice. In an experiment with a total duration of 10 days post-surgery, Grem1 antibodies decreased TGFb activity marker psmad2 protein but there was only a trend in the increase of BMP target engagement marker psmad1/5/8. Some markers of fibrosis were improved, in particular col4A1 and PAI-1 mRNAs (-33% and -46% respectively, P<0.01)) and aSMA protein (-44%, P<0.05)). These findings were not reproduced in an experiment with an extended duration of 14 days despite similar level of exposure.

Conclusions: Gremlin 1 neutralization did not confer robust protection against kidney fibrosis in the UUO model.

Treatment Efficacy of PBI-4050, an Orally Active Anti-Fibrotic Agent, Can Be Monitored by Measuring Urinary Biomarkers in 5/6-Nephrectomized Rats Lyne Gagnon, François Sarra-Bournet, Martin Leduc, Alexandre Laverdure, Lilianne Geerts, Brigitte Grouix, Jean-Simon Duceppe, Boulos Zacharie, Pierre Laurin. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050, a novel first-in-class orally active compound which is currently in clinical phase Ib/II in chronic kidney disease (CKD) patients, displays anti-fibrotic activities via a novel mechanism of action. In the present study, we examined the anti-fibrotic effect of PBI-4050 by evaluating urine biomarkers in 5/6 nephrectomized (NX) rats.

Methods: Sprague-Dawley rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7 the right kidney was removed. Oral treatment with PBI-4050 (200 mg/kg, once a day) or vehicle was initiated at day 21, following randomization based on their glomerular filtration rate (GFR) results. GFR was measured at day 21 and assessed every 3 weeks up to day 190. Urinary protein biomarker levels were determined by Multiplex analysis.

Results: Treatment with PBI-4050 resulted in a significant improvement (up to three fold relative to control) in GFR and also significantly reduced proteinuria. Histological kidney lesion scores were also significantly (p<0.05) decreased in PBI-4050-treated rats (2.7 ± 1.5) compared to control (3.9 ± 1.4), as determined by HPE, PAS and Masson's trichrome staining. In correlation with improved kidney function, a significant reduction of urine protein biomarker (β-2 microglobulin, calbindin, cystatic C, NGAL, clusterin, Kim-1 and MCP-1) levels was observed in PBI-4050-treated 5/6-nephrectomized rats.

Conclusions: These results suggest that PBI-4050 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and treatment efficacy can be monitored with urinary biomarkers.

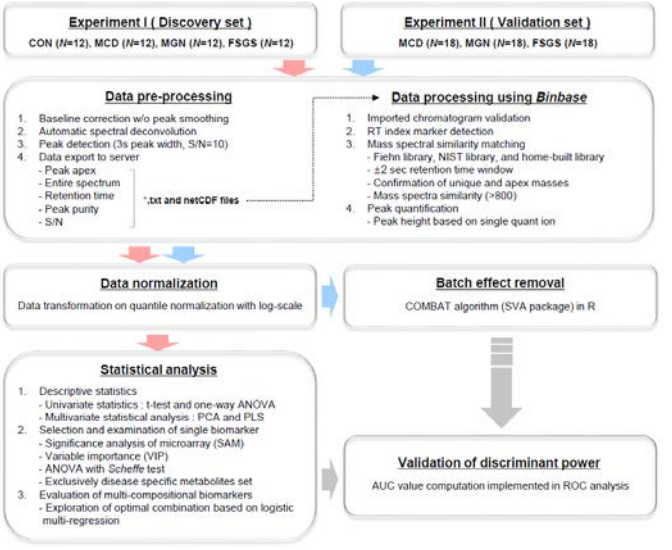
Systematic Biomarker Discovery and Coordinative Validation for Different Primary Nephrotic Syndromes Using Gas Chromatography-Mass Spectrometry Sang-Ho Lee,[1] Yu Ho Lee,[1] Jung-Eun Lee,[2] Yang Gyun Kim,[1] Kyung-Hwan Jeong,[1] Tae Won Lee,[1] Chun-Gyoo Ihm,[1] So-Young Lee,[3] Dong Ho Yang,[3] Do Yup Lee.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Kyung Hee Univ, Seoul, Korea; [2]The Dept of Bio and Fermentation Convergence Technology, Kookmin Univ, Seoul, Korea; [3]Div of Nephrology, Dept of Internal Medicine, Bundang CHA Univ Hospital, Seongnam, Korea.*

Background: Since urine metabolites may mirror disease-specific functional perturbations in kidney injury, we examined urine samples for distinctive metabolic changes to identify biomarkers for clinical applications. The goal of this study is to identifysystematic biomarker panelfor primary nephrotic syndromes from urine samples by applying a non-target metabolite profiling.

Methods: Measurements Urine samples from discovery sets (MCD, FSGS, MGN and control, respectively, n=12) were analyzed using mass spectrometry-based metabolite profiling. After multiple corrections, we created disease-specific panels based on the different metabolic alterations to discriminate three different causes of NS and applied these panels to validation sets (MCD, FSGS and MGN, respectively, n=18).



Results: Thirty-three urine metabolites were significantly altered compared with controls, particularly, branch-chained amino acids. We developed three models using the combination of altered metabolites: one of the model including citric acid, pyruvic acid, fructose, ethanolamine, and cysteine effectively discriminated FSGS from the others (area under the curve [AUC]: 0.812 against MCD and 0.802 against MGN), but not MCD from MGN. Thus, we developed an additional metabolite panel, including methionine, cysteine, citrulline, and pyruvic acid, which could discriminate between MCD and MGN (AUC 0.843).

Conclusions: We identified a disease-specific panel from common urine metabolites that mayhelp identify NS and guide therapeutic plans.

The Assessment of CD80 Expression and Urinary CD80 Excretion in Childhood Nephrotic Syndrome Rezan Topaloglu,[1] Fehime Kara Eroglu,[1] Mihriban Inozu,[1] Ali Duzova,[1] Fatih Ozaltin,[1] Diclehan Orhan.[2] *[1]Pediatric Nephrology, Hacettepe Univ Faculty of Medicine, Ankara, Turkey; [2]Pediatric Pathology, Hacettepe Univ Faculty of Medicine, Ankara, Turkey.*

Background: Minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) are the most common causes idiopathic nephrotic syndrome (INS) in children and pathogenesis is still unknown. Persistent CD80 expression was attributed in pathogenesis which may be caused by failure of regulatory T cells (Treg). But recent studies, which included mostly adult patients, questioned the reliability of immunohistochemistry (IHC) assays. Here we aimed to investigate CD80 podocyte expression and urinary CD80 excretion in a large cohort of pediatric patients and delineate the possible role of Tregs in pathogenesis.

Methods: IHC analyses of CD80, FOXP3 and CD4 were performed to 67 archival biopsies from 59 INS patients. CD80 expression was repeated with a different primary antibody by immunofluorescence (IF). Urine CD80 excretion was also measured by ELISA.

Results: All but four biopsies showed negative expression for CD80 with IHC staining. But 23 (%57) biopsies were stained positive for CD80 in IF staining. CD80 expression was significantly higher in steroid responsive patients (p=0,041) but did not differ significantly between MCD and FSGS (p=0,169) nor presence of proteinuria at the time of biopsy (p=0,153). Urine CD80 level was significantly higher in MCD patients with relapse compared to controls (p=0,001) and MCD patients in remission (p=0,014) but showed no significant difference with FSGS patients (p=0,402). FOXP3+ CD4 T cells were observed in 20 (%36) samples(18 FSGS, 2 MCD). FSGS had significantly high interstitial FOXP3+ cells/mm2 than MCD and controls (p <0,001 and 0,001). MCD had similar FOXP3+ cells compared to controls (p=0,843).

Conclusions: Although we cannot exclude that CD80 expression may vary in different stages of disease, it seems not a solid marker of disease activity in terms of proteinuria and for differentiating MCD and FSGS. FOXP3 positive Treg cells seem to play role in MCD not in a paracrine manner but increased infiltration seem to correlate with inflammation and chronicity in FSGS.

SA-PO233

Urinary Metabolomics in Clinical Hypertensive Nephrosclerosis – Is It a Real Disease or Normal Age-Related Kidney Function Decline with High Blood Pressure? Marius Altern Øvrehus,[1,2] Manjula Darshi,[3] Per Bruheim,[4] Kumar Sharma,[3] Stein I. Hallan.[1,2] *[1]Inst of Cancer Research and Molecular Medicine, Norwegian Univ of Science and Technology, Trondheim, Norway; [2]Dept of Nephrology, St. Olavs Hospital Trondheim Univ Hospital, Trondheim, Norway; [3]Inst of Metabolomic Medicine, Univ of California San Diego, San Diego, CA; [4]Dept of Biotechnology, Norwegian Univ of Science and Technology, Trondheim, Norway.*

Background: The clinical diagnosis of hypertensive nephrosclerosis (HN) is debated and not well studied. Some argue that these patients only reflect normal aging. We therefore compared metabolic characteristics in HN cases to age- and sex-matched relevant groups.

Methods: Urine samples from HN (n=126), diabetic nephropathy (DN, n=41), hypertension (HTN, n=60) and healthy controls (CTR, n=60) from the HUNT 3 study (2006-08, Norway) were analyzed. Nephrosclerosis was defined as eGFR <60mL/min/1.73m^2 with ≥10 years of hypertension, and no diabetes, hematuria or proteinuria. Samples were analyzed with gas chromatography coupled to tandem mass spectrometry (GC-MS/MS).

Results: Of 75 organic acids, 31 displayed significant differences between groups. Principal component analysis (PCA) components 1, 2 and 3 explained 68% of the total variance. PLS-DA analysis showed that HTN and CTR overlapped strongly. HN and DN had substantial overlap and a large proportion of these patients were outside the 95% CI of CTR. Random forest analysis selected phenyllactic, butyric, and methylcitric acids as most important for classification. The top-25 list also included several medium-chain fatty acids, TCA-cycle metabolites, and gut microbial end products.

Conclusions: Hypertensive nephrosclerosis patients have metabolic disturbances which make them cluster together with diabetes nephropathy rather than with hypertensive patients or healthy controls.

Figure 1. Discriminant analysis (PLS-DA) analysis showing separation of diagnoses based on measured metabolites.

SA-PO234

The Urinary Metabolomic Fingerprint of Hypertensive Nephropathy Marius Altern Øvrehus,[1,2] Manjula Darshi,[3] Per Bruheim,[4] Kumar Sharma,[3] Stein I. Hallan.[1,2] *[1]Inst of Cancer Research and Molecular Medicine, Norwegian Univ of Science and Technology, Trondheim, Norway; [2]Dept of Nephrology, St. Olavs Hospital Trondheim Univ Hospital, Trondheim, Norway; [3]Inst of Metabolomic Medicine, Univ of California San Diego, San Diego, CA; [4]Dept of Biotechnology, Norwegian Univ of Science and Technology, Trondheim, Norway.*

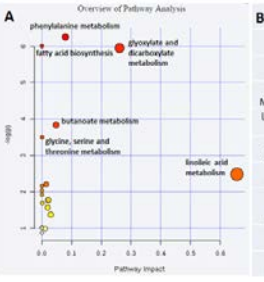
Background: Hypertensive nephropathy (HN) is a common cause of end-stage renal disease. In contrast to diabetic nephropathy, it has been the focus of only a few -omics based studies.

Methods: Urine samples from 126 HN patients and 60 age- and sex-matched healthy controls (mean age 71.8 vs 70.0 years, mean eGFR 50.5 vs 87.7 mL/min/1.73m^2) from the HUNT 3 Study (2006-08, Norway) were analyzed. Nephrosclerosis was defined as eGFR <60mL/min/1.73m^2 with at least 10 years of hypertension, and no diabetes, hematuria or proteinuria. Samples were derivatized and organic acids were quantified by targeted analysis with gas chromatography coupled to tandem mass spectrometry (GC-MS/MS).

Results: Out of 75 organic acids quantified 27 were significantly different between patients and controls, among which 17 remained significant after correction for multiple testing. Principal component analysis (PCA) components 1, 2 and 3 explained 63% of the variance. Cross validation showed acceptable model fit (R^2 0.6). The most significant metabolites were butyric acid, methylcitric, phenyllactic, octanoic, linoleic, glyceric, stearic and palmitic acids. Pathway analysis showed involvement of phenylalanine, glyoxylate/dicarboxylate, fatty acid, butanoate, and linoleic acid metabolism.

Conclusions: Urine metabolomic analysis identified global metabolite differences in hypertensive nephropathy patients compared with controls. Involved pathways covered phenylalanine, fatty acid, and glyoxylate/dicarboxylate acid metabolism.

Figure 1. A: Pathway plot. Impact on x-axis, -log(p) on y-axis. B: List of metabolite concentrations with largest difference between groups, with respective pathways.



B

Concentration

Compound	Controls	Cases	p	FDR	Pathway
Butyric acid	6.0	2.3	3.63E-10	2.6499E-8	Fatty acid metabolism
Methylcitric acid	0.02	6.0	9.3543E-9	3.4143E-7	Tricarboxylic acid metabolism
L-3-Phenyllactic acid	0.3	0.2	2.5164E-7	6.1232E-6	Phenylalanine metabolism
Octanoic acid	0.8	1.2	1.6059E-5	2.9308E-4	Fatty acid biosynthesis

Urine Epidermal Growth Factor, Monocyte Chemoattractant Protein-1 or Their Ratio as Biomarkers for Interstitial Fibrosis and Tubular Atrophy in Primary Glomerulonephritis Supanat Worawitchawong,[1] Chagriya Kitiyakara,[1] Suchin Worawichawong.[2] *[1]Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand; [2]Dept of Pathology, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.*

Background: The degree of tubular atrophy and interstitial fibrosis (IFTA) is an important prognostic factor in glomerulonephritis. Imbalance between pro-inflammatory cytokines such as monocyte chemoattractant protein-1 (MCP-1) and protective cytokines such as epidermal growth factor (EGF) likely determines IFTA severity. In separate studies, elevated MCP-1 and decreased EGF have been associated with IFTA severity, but the value of the combining of the two biomarkersin primary glomerulonephritis (GN) are unknown. In this study, we aim to evaluate the predictive value of urinary EGF/MCP-1 ratio compared to each biomarker individually for IFTA in primary GN.

Methods: Urine samples were collected from healthy controls (n=18) and primary GN (n=58) at biopsy. MCP-1 and EGF were analyzed by enzyme-linked immunosorbent assay.

Results: GN included IgA nephropathy, FSGS , minimal change disease, and membranous nephropathy. Compared to healthy controls, MCP-1 was higher (p<0.001), EGF levels were similar, and the EGF/MCP-1 ratio was lower in GN (p<0.001). In GN, MCP-1 correlated with GFR, and inversely with proteinuria. EGF correlated strongly with GFR (R=0.83), but not proteinuria. EGF/MCP-1 ratio correlated with eGFR and inversely with proteinuria. EGF, MCP-1 and EGF/MCP-1 ratio all correlated with IFTA. Univariate analysis showed that GFR, EGF, and EGF/MCP-1 ratio were associated with moderate to severe IFTA. By multivariate analysis, only EGF/MCP-1 ratio was independently associated with IFTA [OR: 0.92, p=0.008]. EGF/MCP-1 ratio of 17.7 ng/ng had a sensitivity of 88% and specificity of 74 % for IFTA. By ROC curve analysis, EGF/MCP-1 had good discrimination for moderate to severe IFTA (AUC=0.85), but the improvement over EGF alone was not significant.

Conclusions: EGF/MCP-1 ratio is independently associated IFTA severity in primary glomerulonephritis, but the ability of EGF/MCP-1 ratio to discriminate moderate to severe IFTA may not be much better than EGF alone.

Funding: Other NIH Support - Mahidol University

SA-PO236

Urinary Periostin Excretion Predicts Renal Outcome in IgA Nephropathy: A Prospective, Cohort Study Jin Ho Hwang,[1] Chae Rim Kim,[1] Jung Pyo Lee,[2] Seung Hee Yang,[3] Jung Nam An,[2] Hajeong Lee,[4] Yun Kyu Oh,[2] Kwon Wook Joo,[4] Dong Ki Kim,[4] Yon Su Kim,[4] Chun Soo Lim.[2] *[1]Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul; [3]Kidney Research Inst, Seoul National Univ Hospital, Seoul, Republic of Korea; [4]Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Periostin is a matricellular protein and plays a vital role tissue regeneration, fibrosis, and wound healing. However, data on its significance in nephrology are limited. We investigated the correlation between urinary periostin excretion and its clinical significance including renal histologic findings and prognosis in IgA nephropathy (IgAN).

Methods: Of 399 patients from a glomerulonephritis cohort recruited between Jan. 2009 and Dec. 2014, 314 were enrolled. Serum and urine POSTN were measured using ELISA. We divided the patients into 3 groups by urine periostin/creatinine (uPOSTN/Cr): group 1 (undetectable), group 2 (lower than the median), and group 3 (higher than the median). The occurrence of ESRD was the primary outcome of this study.

Results: The uPOSTN level was correlated with pathologic classifications and both initial and final IDMS-MDRD eGFRs (both *P*<0.001). Histologically, group 3 patients

were correlated with severe interstitial fibrosis/tubular atrophy (P=0.004), interstitial inflammation (P=0.007), hyaline arteriolosclerosis (P=0.001), and glomerular sclerosis (P<0.001). A higher initial uPOSTN/Cr level was associated with a greater decline in eGFR during follow-up (P=0.043 when initial eGFR≥60; P=0.025 when eGFR<60 mL/min/1.73 m^2), and the renal outcomes with ESRD (P=0.003), ESRD and/or eGFR decrease of >30% (P=0.033), and ESRD and/or eGFR decrease of >50% (P=0.046) occurred significantly more in group 3. In multivariate analysis, uPOSTN group 3 (HR, 2.839 vs. group 1+2; CI, 1.013-7.957; P=0.047) was independently associated with ESRD in IgAN patients.

Conclusions: Urine POSTN/Cr value at initial diagnosis correlated with renal fibrosis and predicted the renal outcomes in patients with IgAN. It could be a promising urinary biomarker for renal fibrosis.

SA-PO237

Urine Exosomal Ceruloplasmin - A Potential Early Marker of Kidney Damage That Precedes Proteinuria Krishnamurthy P. Gudehithlu,[1] Peter D. Hart,[1,2,3] Amit J. Joshi,[1,3] George Dunea,[1,2] Jose A.L. Arruda,[3,1,4] Ashok K. Singh.[1,2,4] *[1]Div of Nephrology, John H.Stroger, Jr. Hospital of Cook County, Chicago, IL; [2]The Hektoen Inst of Medicine, Chicago, IL; [3]Internal Medicine and Pathology, Rush Medical College, Chicago, IL; [4]Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL.*

Background: Pilot studies showed increased ceruloplasmin (CP) in urine exosomes of membranous nephropathy (n=9), lupus nephritis (n=8), FSGS (n=8), and IgA nephropathy (n=7) patients, suggesting that it could be a general marker of kidney damage. In this study we tested whether urine exosomal CP could serve as an early biomarker of kidney damage preceding proteinuria.

Methods: Experiments were performed in the rat model of passive Heymann nephritis (PHN), which mimics human membranous nephropathy. PHN induced by injecting rats with anti-gp600 antibodies. At times 0, week 1, 2 and 3, urine exosomes were isolated by differential centrifugation. Exosomal pellets were extracted for measurement of CP by ELISA and protein by Bio-Rad method. PHN was confirmed by histology (trichrome staining) and glomerular IgG deposits using immunofluorescence. Histochemical staining for CP was performed to validate the ELISA results. Control rats were injected with saline instead of antibody.

Results: Rats injected with antibody showed typical intramembranous IgG deposits by week 1, and loss of brush border suggestive of proteinuria by week 2. Accordingly, PHN rats were non-proteinuric (<20 mg/day) at week 1, but presented with proteinuria (>400 mg/day) at weeks 2 and 3 (n = 6). Urine exosomal CP levels (ng/mg of exosomal protein) at times 0 was 64.5±15, which increased by 3.5 fold at week 1 (228 ±39) and 6 fold by week 2 (409 ±17) and 3 (399 ±36) after the induction of PHN, suggesting that exosomal CP increased significantly even before proteinuria. These results were confirmed by enhanced immunofluorescent staining for CP observed in the interstitial area of proximal tubules of PHN rats compared to controls.

Conclusions: In conclusion, increase in urine exosomal CP could serve as a potential early biomarker of kidney damage that precedes the onset of proteinuria.

Dysmorphic Urinary Red Blood Cells: Clinical Utility in Glomerular Disease Abdurrahman M. Hamadah, Kamel A. Gharaibeh, Samar M. Said, Samih H. Nasr, Nelson Leung. *Mayo Clinic.*

Background: Dysmorphic red blood cells (dRBCs) assessment on urine microscopy has been used to differentiate glomerular vs. non-glomerular disease. However, large studies to establish its usefulness are lacking. In this study, we assess the prevalence of dRBCs in a large group of biopsy proven kidney disease, and evaluate dRBCs ability to differentiate glomerular from non-glomerular kidney disease.

Methods: This is a retrospective study of adult patients with biopsy-proven diagnoses and concurrent urine microscopy between 2012 and 2015 at our institution. The prevalence of dRBCs in glomerular vs. non-glomerular disease was assessed. dRBCs cutoff values of < 25% and ≥ 25% were compared using sensitivity, specificity, positive and negative predictive values (PPV and NPV). Variables potentially associated with glomerulonephritis (GN) (proteinuria, level of hematuria, dRBCs≥ 25%, creatinine, and serum albumin) were assessed using univariable and multivariable logistic regression.

Results: We identified 482 patients who had native kidney biopsy with concurrent urinalysis. Mean age was 55 years, 47.7 % were female, and 87.3% were white. Based on kidney biopsy findings, 372 (77.2 %) had glomerular disease (GD) (GN 46% and non-GN 54%), and 110 (22.8%) had non-glomerular disease. Significant dRBCs (≥ 25%) was seen in 28% of GN, in 12.4% of non-GN glomerular disease, and in 3.6% of non-GD. Dysmorphic RBCs level ≥ 25% showed a sensitivity of 28.5%, specificity 90.6%, PPV 63.5%, and NPV 68.7% for the diagnosis of GN. The logistic regression model showed that both dRBCs ≥ 25% (p<0.001) and urine RBC level (11-50 vs < 11 (p= 0.003) or > 50 vs < 11 (p=0.01) RBCs/hpf) were associated with presence of GN on univariable analysis, however, only urine RBC level (11-50 vs < 11 (OR 6.9, 95% CI (3.8-12.7), p= 0.003) or > 50 vs < 11 (OR 6.6, 95% CI (2.9-15.4), p= 0.03)) RBCs/hpf) was predictive of GN in multivariable analysis.

Conclusions: Based on a large group of biopsy-proven diverse renal disease entities, the finding of ≥ 25% dRBCs on urine microscopy, despite being specific for GN, did not add to the ability of hematuria (> 10 RBCs/hpf) to predict presence of GN on kidney biopsy, and may not have a significant diagnostic yield in this setting.

SA-PO239

The Association of Cardio-Metabolic Index with Microalbumiuria in General Population Joon-Sung Park,[1] Jong Wook Choi.[3] *[1]Internal Medicine, Hanyang Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, Hanyang Univ College of Medicine, Seoul, Korea; [3]Internal Medicine, Hanyang Univ College of Medicine, Seoul, Korea.*

Background: Cardio-metabolic index (CMI) is novel indicator of metabolic disturbance and it can discriminate diabetes and predict risk atherosclerosis progression. Here, we investigate whether CMI is related with development of microalbuminuria in general population.

Methods: We analyzed anthropometric and biochemical data from a nation-wide, population-based, case-control study (the Korean National Health and Nutritional Examination Surveys KNHANES VI). Eligibles as cases were all native Korean who were aged 20 years or more and had no any medical illness.

Results: A total of 5398 participants were divided into five CMI quintiles. Participants in highest CMI quintile were more hypertensive and had greater glycemic exposure, increased urine protein/creatinine ratio (UACR) and decreased kidney function as compared with other quintiles.Our Cochran-Armitage test showed that CMI had dose-response relationship with prehypertension, prediabetes, microalbuminuria, and early impaired kidney function.Adjusted multiple logistic regression analysis revealed that increased CMI was independently associated with prehypertension (adjusted OR = 1.161, 95% *CI* = 1.092-1.234), prediabetes (adjusted OR = 1.081, 95% *CI* = 1.021-1.142), and microalbuminuria (adjusted OR = 1.075, 95% *CI* = 1.001-1.154) although early impaired kidney function was not.

Conclusions: In this study, we demonstrated that mild increase of CMI is associated with slightly elevated blood pressure, mild hyperglycemia, and increased urinary excretion of albumin in the healthy population and may be a reliable predictor of with harmful effect of metabolic disturbance on kidney before appearance hypertension and diabetes mellitus. To confirm these findings, large population-based prospective clinical should be needed.

Tubular Subsegmental Omics and Quantitative 3D Imaging of Human Kidney Biopsies Reveal Signatures Underlying Progression of Renal Disease Tarek M. El-Achkar,[1,4] Michael T. Eadon,[1] Ken Dunn,[1] Seth Winfree,[1] Timothy A. Sutton,[1] Katherine J. Kelly,[1] Takashi Hato,[1] Bruce A. Molitoris,[1,4] Matthew D. Breyer,[3] Brad H. Rovin,[2] Samir Parikh,[2] Pierre C. Dagher.[1,4] *[1]Medicine, Indiana Univ, Indianapolis, IN; [2]Internal Medicine, The Ohio State Univ, columbus, OH; [3]Lilly Research Laboratories, Indianapolis, IN; [4]Medicine, Roudebush VA Medical Center, Indianapolis, IN.*

Background: Tubulointerstitial fibrosis is a determinant of outcome in all renal pathologies. Remarkably, patients with apparently identical biopsy readings exhibit variable rates of progression to terminal fibrosis. To date, investigation of the glomerular lesions and tubulointerstitium has failed to account for this unpredictable rate of progression. We now propose that the rate and extent of tubulointerstitial fibrosis, regardless of the initiating lesion, are determined by molecular signatures specific to individual tubular subsegments and the immune make-up of the interstitium.

Methods: We interrogated routine human kidney biopsies with broad "omics" readouts conducted on tubular subsegments obtained by laser microdissection. We also developed a novel 3D microscopy quantitative approach to quantify the immune cell make-up in the same biopsies.

Results: We show that tubular subsegmental transcriptomics and proteomics can be reliably obtained from a routine human kidney biopsy. The same biopsy can also be analyzed quantitatively with 3D fluorescence microscopy to reveal the type and distribution of immune cells in relation to renal tubular segments. Using this approach we examined biopsies from diabetic nephropathy patients who exhibited different rates of progression despite similar traditional biopsy readings. Our studies revealed unique signatures specific to each patient that correlated well with disease progression.

Conclusions: Our studies support the hypothesis that, at a subsegmental level, a unique molecular and cellular signature exists which determines the progression of most kidney diseases. This signature will guide our ability to determine best therapy and prognosis for individual patients, validate animal models and identify novel therapeutic targets.

Proteomics of Diabetic Nephropathy Glomerulus for Understanding Pathophysiology Tadashi Yamamoto,[1] Keiko Yamamoto,[1] Hidehiko Fujinaka,[2] Shigeru Miyazaki.[3] *[1]Biofluid Biomarker Center (BBC), Niigata Univ, Niigata, Japan; [2]Pediatrics, Niigata National Hospital, Kashiwazaki, Niigata, Japan; [3]Internal Medicine, Shinrakuen Hospital, Niigata, Japan.*

Background: Diabetic nephropathy (DN) is a crucial complication of diabetes mellitus, progressing to the end-stage of chronic kidney disease (CKD). However, molecular mechanisms of the progression or pathophysiology have not clarified yet. We aimed to understand the molecular mechanisms by analyzing glomerular proteomes of DN by mass spectrometric proteomics and bioinformatics since glomeruli are initially injured in DN.

Methods: Formalin-fixed paraffin-embedded kidneys from autopsy cases of DN patients were sectioned for laser microdissection of glomerular sections. Glomerular lesions of DN were classified into three categories, early (minor abnormalities or diffuse lesion), intermediate and advanced (marked increase of mesangial matrix or nodular lesion) (n=5

each) by histological examination. The glomerular sections were directly digested with trypsin and tryptic peptides were collected by using C18 column for liquid chromatography (LC)-MS. Proteins were identified by Mascot search engine and semi-quantified by the normalized spectrum index. The glomerular proteomes were compared between the three DN lesions and non-disease kidneys. The glomerular proteins, which increased or decreased more than 2-fold, were selected for IPA pathway analysis.

Results: Approximately more than one thousand proteins (by gene names) were identified in each glomerular sample semi-quantitatively by MS. Cellar localization was predicted for the proteins of more than 2-fold change in DN glomeruli at plasma membrane (10~15%) and cytoplasm (50~60%). Pathways related to Cell Death & Survival, Cell Mobility, Immunity & Inflammation and others were enhanced in the DN glomeruli and also upstream proteins, such as TGFb1 were depicted.

Conclusions: Proteomic analysis of DN glomeruli successfully demonstrated acceleration of several molecular pathways in the sites, providing knowledge of the pathophysiology and making possible to select crucial molecules for drug discovery.

KidneySeq™: A Comprehensive Inherited Kidney Disease Panel M. Adela Mansilla,[1] Ramakrishna Sompallae,[1] Sara Mason,[1] Carla Nishimura,[1] Anne E. Kwitek,[1] Colleen Ann Campbell,[1,2] Christie P. Thomas,[2] Richard J. Smith.[1,2] *[1]Inst of Human Genetics, Univ of Iowa, Iowa City, IA; [2]Internal Medicine, Univ of Iowa, Iowa City, IA.*

Background: KidneySeq™ is a comprehensive inherited kidney disease panel using next generation sequencing developed by the Iowa Institute of Human Genetics (IIHG) and the Division of Nephrology at the University of Iowa.

Methods: This clinical genetic test simultaneously interrogates 179 renal genes implicated in 75 renal diseases, facilitating the diagnosis of genetic renal diseases as well as aiding living kidney donor selection. Sequence data are processed through a custom bioinformatics workflow that includes detection of a wide range of genetic variation (single nucleotide polymorphisms, insertions, deletions and copy number variations). A parallel work flow for *PKD1* is included based on the complexity of unambiguous *PKD1* variant detection caused by pseudogene sequences. Each final variant list is reviewed by a multidisciplinary team of physicians, genetics counselors, bioinformaticians and researchers in the context of the patient's clinical data to determine whether a plausible genetic cause for the observed phenotype has been identified.

Results: Since launching KidneySeq™ 6 months ago, we have tested 21 clinical samples that include disorders of tubular ion transport, glomerulopathies, congenital anomalies of kidney and urinary tract (CAKUT) and ciliopathies. A genetic diagnosis was identified in 10 cases (48%). By disease type, the solve rate was: disorders of tubular ion transport, 33 % (3 of 9 cases); glomerulopathies, 50 % (3 of 6 cases); CAKUT, 67 % (2 of 3 cases); and ciliopathies, 67 % (2 of 3 cases).

Conclusions: In 7 cases, the genetic diagnosis differed from the clinically suspected diagnosis, emphasizing the overlapping phenotypic spectrum that characterizes several renal diseases and highlighting the value of comprehensive genetic testing. KidneySeq™ provides a rapid, cost-effective method to improve the care of patients with renal disease.

Assessment of the IRIDICA Technique for Rapid Detection of Acute Infection in Renal Patients Recently Treated with Antimicrobials Anamika Adwaney,[1] Sevda Hassan,[1] Arikana Massiah,[2] Mark Wilks,[2] Raj Thuraisingham.[1] *[1]Renal, Bartshealth Trust, London, United Kingdom; [2]Microbiology, Bartshealth Trust, London, United Kingdom.*

Background: The IRIDICA bacterial bloodstream (BAC BSI) assay is a semi-quantitative diagnostic test that uses polymerase chain reaction (PCR) and electrospray ionized-mass spectrometry (ESI-MS) to detect and identify bacterial, viral and fungal nucleic acids from a blood sample within 6 hours. Prompt management of sepsis is essential. Detection of pathogens with the current gold standard blood culture is challenging in the context of recent antimicrobial therapy. We compared the IRIDICA assay against blood culture technique in pyrexial renal patients.

Methods: We included renal patients who presented with a fever of >38ºC from January 2015 to April 2016. This included immunosuppressed transplant recipients and dialysis patients. A 5ml EDTA sample was taken with blood culture for retrospective IRIDICA analysis. The IRIDICA technician was blinded. We used our renal database to establish if patients had received antimicrobial therapy in the preceding 30 days. We excluded the patients who did not have a blood culture analysis at the time of fever.

Results: We analysed 182 samples from January 2015 – April 2016. Mean age of patients was 57.6 years. This included patients who had more than one presentation during this period. Compared to blood culture the IRIDICA assay demonstrated a sensitivity and specificity of 70%. The positive predictive value was 26% and the negative predictive value was 94%. 39 (21%) samples were positive for IRIDICA but negative for blood culture. Of these 72% had received antimicrobials in the preceding 30 days. 14 samples had both positive blood culture and IRIDICA samples. None of these patients had antimicrobial therapy in the preceding 30 days.

Conclusions: The IRIDICA assay is superior to blood cultures when detecting a pathogen in a renal patient who has been treated with antimicrobials in the preceding 30 days. IRIDICA is also effective in excluding infection. Without preceding antibiotic use, blood cultures are just as effective as the IRIDICA assay. However, the IRIDICA assay allows faster identification of pathogens compared blood culture, which can take 5 days.

SA-PO244

Decreased Expression of the Gut-Homing CCR9 Chemokine Receptor on Memory B-Cell Subsets in IgA Nephropathy Marten Segelmark,[1] Camilla Skoglund,[1] Daniel Söderberg,[1] Per Eriksson.[2] *[1]Medical and Health Sciences, Linköping Univ, Linköping, Östergötland, Sweden; [2]Clinical and Experimental Medicin, Linköping Univ, Linköping, Östergötland, Sweden.*

Background: IgA nephropathy and IgA vasculitis are characterized by the deposition of polymeric undergatactosylated IgA1 (GdIgA1) in the renal mesangium. GdIgA1 should normally be secreted into the respiratory and gastrointestinal tract, but is in IgAN often elevated in the systemic circulation. Defective homing of lymphocytes could contribute to ectopic production of GdIgA1.

Methods: The putative human counterparts to the three B-cells lineages defined in mice: B1-, B2- and MZ-B-cells were characterized by multi-channel flow cytometry and the percentage of each subset expressing IgA as wells as the chemokine receptor CCR9 was determined. 25 patients with IgAN/IgAV were compared with 20 healthy age matched controls.

Results: There were no differences between IgAN and IgAV patients. IgAN/V patients tended to have more lymphocytes and a larger percentage of B-lymphocytes, but differences were not significant. There were no differences in the proportion of naïve, B1-, MZ- and B2-like populations between patients and controls. Similarly the proportion of IgA+ cells was similar in all subsets. However, patients exhibited a significantly lower proportion of CCR9+ B1-like cells. When comparing the CCR9+ on IgA positive cells, the proportion was lower in patients for all types of memory B-cells, the most pronounced difference was found among the MZ-like cells.

	B1-like cells (CD43+,CD27+)		MZ-like cells (CD27+, IgM++,CD45RB++)		Memory B2- cells (CD27+, IgM-/int)	
	Pat/Con	p	Pat/Con	p	Pat/Con	p
I. % of B-cells	5.7/5.7	ns	12.6/10.7	ns	22.8/19.3	ns
II. % IgA+ of I	36.2/39.9	ns	11.8/9.5	ns	28.5/30.3	ns
III % CCR9+ of I	10.6/15.6	0.007	9.8/10.8	ns	9.6/11.5	ns
IV % CCR9+ of II	10.1/17.5	0.03	14.5/24.6	0.003	9.8/13.1	0.02

Conclusions: IgA bearing memory B-cells of three different subsets, but not naïve B-cells, from patients with IgAN and IgAV exhibit a lower percentage of CCR9 expressing cells. As CCR9 directs B-cells to the small intestine this could possible facilitate extra-mucosal production of GdIgA1.

SA-PO245

Identification of CD146 as a Novel Biomarker to Evaluate the Disease Progression and Prognosis in Early Diabetic Nephropathy Yang Fei,[1] Ying Fan,[1] Li Zheng,[2] Jiemin Wang,[2] Jiejun Wen,[1] Zhenzhen Jiang,[1] Li He,[1] John C. He,[3] Niansong Wang.[1] *[1]Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Project and Portfolio Management Team, Asia & Emerging Market iMED, AstraZeneca R&D, Shanghai, China; [3]Medicine, Icahn School of Medicine at Mount Sinai, New York.*

Background: Glomerular endothelial cell injury plays a crucial role in the development and progression of diabetic nephropathy (DN). CD146, an endothelial marker, was reported to increase in chronic renal failure reflecting endothelial dysfunction. However, the role of CD146 in DN remains largely unknown.

Methods: 159 non-dialysis type 2 DN patients from 2008 to 2015 were enrolled to measure the serum concentration of soluble CD146 (sCD146). 94 pure diabetes mellitus type 2 and 100 healthy participants were taken as controls. The subjects were categorized by their CKD stages and CKD1-3 was defined as early eGFR loss. Another independent cohort of 49 patients with definite diagnosis of DN by kidney biopsy were eligible for the immunohistochemistry study of CD146.

Results: Our data showed that serum concentration of sCD146 was upregulated in patients with DN (648.2±292.6 ng/mL) as compared to DM(434.68±150.01ng/ml) and healthy control (358.3±121.4 ng/ml,$P<0.01$) . Elevated serum sCD146 was inversely associated with renal function ($p<0.01$) and proved to be a more optimal marker(AUC=0.803) than urine albumin creatinine ratio (UACR) (AUC=0.574, $p<0.01$) to evaluate disease progression of DN at early GFR loss. In kidney tissues, CD146 was co-localized with endothelial marker CD31 and increased in DN when compared with MCD and normal controls. The intensity of CD146 in kidney was associated with disease progression and with severity of pathological findings in DN patients at early GFR loss. The univariate Cox regression suggested that both serum concentration of sCD146 and kidney *in situ* expression of CD146 were associated with the renal outcomes.

Conclusions: Our findings demonstrate that CD146 could be a practical biomarker to evaluate disease progression and predict renal outcomes in patients with early to moderate stages of DN. The aberrant expression of CD146 may reflect endothelial dysfunction and vascular angiogenesis in DN.

SA-PO246

Isolated Segmental Sclerosis (Without Significant Proteinuria) in the Early Post-Transplant Period Rarely Leads to Focal Segmental Glomerulosclerosis Vighnesh Walavalkar, Zoltan G. Laszik, Kuang-Yu Jen. *UCSF Medical Center, San Francisco, CA.*

Background: The aim is to study isolated segmental sclerosis (IS) seen in transplant (Tx) biopsies (Bx) from patients (pt) who do not have proteinuria.

Methods: TxBx from 01/2000-12/2015 were included. IS was defined as segmental sclerosis seen within 12 months of Tx from a pt without significant proteinuria (<750 mg/day) at time of Bx. Histology data, pt demographics and follow-up (FU) data ranging from 6-72 months were analyzed.

Results: IS was seen in 21/6366 (0.33%) of all Bx in the study period. 7/21 (33%) resulted in eventual graft loss, 1/21 (4.7%) of which progressed to focal segmental glomerulosclerosis (FSGS) with nephrotic range proteinuria (NRP). 14/21 (67%) had stable creatinine levels and no proteinuria in the 72 month FU period. 20/21 (95%) had FSGS-like histology. 5/21 (24%) had concurrent acute cellular rejection. Electron microscopy in 12 Bx showed: 5 with intact podocytes; 7 with focal effacement; and 0 with diffuse effacement.

Conclusions: IS in the early post-Tx period is rare. 1 case (4.7%) progressed to NRP, consistent with FSGS. Our study did not reveal sex, age or race predilection for IS. IS had no correlation with acute rejection. Histology could not predict which IS lesions would progress to FSGS. Awareness of IS and avoidance of usage of the term "FSGS" may help to prevent unnecessary treatment. Further studies are needed.

SA-PO247

Validation of Whole Slide Digital Imaging in the Renal Biopsy Service at a Large Academic Medical Center Vighnesh Walavalkar, Kuang-Yu Jen, Zoltan G. Laszik. *UCSF Medical Center, San Francisco, CA.*

Background: The aim of the study was to validate the use of whole slide digital imaging (WSDI) in the renal biopsy (RBx) service at our institution. Patient care, efficiency, education and quality control (QC) were emphasized.

Methods: From 11/1/2015 to 4/30/2016 three slides (2H&E and 1 PAS) from all consecutive 'rush' transplant and native RBx (n=160) were scanned in on Philips UFS scanners at 40x and the WSDI were prospectively interpreted for a preliminary diagnosis (pDx). Review of the glass slides served as the "gold standard" for interpretation. A prospectively designed workflow was used to validate the process. WSDI were evaluated for QC in three areas: histotechnological deficiencies (HD), scanning errors (SE), and interpretative errors (IE). IE (due to either HD or SE) were further subdivided into minor IE, defined as those which did not affect making a pDx; and major IE, defined as those which precluded making a pDx by WSDI and required review of glass slides.

Results: Using WSDI, an efficient workflow was established to convey a pDx to the nephrologist. An average turnaround time (TAT) from the time of biopsy to pDx was established at 5.5 hours which included IF stain interpretation. HD caused minor IE in 9 cases (6%) and a major IE in 1 case (0.6%). SE caused minor IE in 11 cases (7%) and no major IE (0%). Drawbacks reported were hand fatigue (among some trainees); difficulty in appreciating fibrin thrombi [2 cases (1.2%)] and difficulty in appreciating arteriolar hyalinosis [5 cases (3.1%)]. A virtual environment was developed and used for trainee teaching, daily clinical conferences and remote RBx review with nephrologists at other sites. Both trainees and nephrologists had a favorable outlook to using WSDI for future RBx review.

Conclusions: Standardized histology and scanning operational protocols were crucial for validating the use of WSDI for RBx interpretation. There were no major IE attributed to WSDI and the TAT decreased significantly for a pDx. WSDI also contributed to improved education and allowed for remote on-line RBx review with nephrologists at other sites. Overall use of WSDI was met with great enthusiasm by technologists, trainees and referring nephrologists.

SA-PO248

Glomerulonephritis Associated with Allogeneic Bone Marrow Transplantation Yu Tateishi,[1,2] Eiji Ishimura,[1] Mari Sakura,[1,2] Mitsuru Ichii,[1] Yoshiteru Ohno,[1] Shinya Nakatani,[1] Akihiro Tsuda,[1] Masayuki Hino,[1] Masaaki Inaba.[1] *[1]Osaka City Univ Graduate School of Medicine, Japan; [2]Ishikiri Seiki Hospital, Japan.*

Background: Clinicopathological characteristics of glomerulonephritis (GN) associated with allogeneic bone marrow transplantation (BMT) are still insufficient. Previous reports on these cases have mainly referred to glomerular immunological changes; while tubulointerstitial and vascular lesions are known to be major findings of graft rejection in cases with renal transplantation.

Methods: Out of 129 BMT cases in Osaka City University Hospital from 2008 to 2011, nephrotic syndrome (NS) was seen in 4 patients (50.8 ± 9.3 year-old, 3 males and 1 female) after BMT. Their primary hematologic diseases consisted of 2 cases with acute lymphocytic leukemia, 1 with adult T-cell leukemia, and 1 with aplastic anemia. We analyzed these 4 cases with BMT associated GN clinicopathologically.

Results: Mean duration (± SD) between BMT and the onset of NS was 29.5 (± 9.8) months. One case received immunesuppressive therapy (cyclosporine (CsA) 10mg/day) at the onset. Urinary protein level was 7.4 ± 4.2 g/day. Renal histological diagnosis of membranous GN (MGN) and proliferative GN (PGN) was made in 3 cases and in 1 case, respectively. Moderate to severe interstitial infiltration of mononuclear cells accompanied by tubulitis, approximately 20-50% of parenchyma, was observed in 2 cases with MGN. In a case with PGN, several glomerular segmental double contours with segmental endocapillary proliferations were seen in light microscopy. The lesions were not accompanied with epithelial cell increase nor mesangial proliferation, suggesting the presence of acute endothelial cell injury. Mild interstitial infiltration of mononuclear cells was also observed in this case. All 4 cases were treated with prednisolone 40-50 mg/day and/or CsA 40-100 mg/day. Complete or partial remission was achieved after the treatment (urinary protein levels: 1.1 ± 0.9 g/day) within 3 months.

Conclusions: This study indicates that MGN is main lesion and acute tubulointerstitial and vascular lesions accompany BMT-associated GN, which may not be so rare complication of BMT. Clinically, favorable response to immunosuppressive therapy can be expected.

SA-PO249

Improvement of Clinical Outcome in Kidney Diseases via Online Thai Glomerular Disease Registry: The First Year Report Ratana Chawanasuntorapoj. *Thai Glomerular Disease Collaborative Network, Bangkok.*

Background: End stage renal disease (ESRD) cause the high morbidity, mortality, and cost in health care system. The prevention of ESRD is the early recognition and appropriate treatment. Glomerulonephritis is the third most common cause of ESRD in Thailand comparable to the Western country. In 2013, Thailand Renal Replacement Therapy (TRT) reported Lupus nephritis (LN) was the most common cause of ESRD followed by IgA nephropathy (IgAN), and focal segmental glomerulosclerosis (FSGS). The quality registry and network can provide the prompt management in these patients.

Methods: Thai Glomerular Disease Collaborative Network (TGDCN) originally consists of 9 tertiary care centers, We developed the Web-based Online registry to collect the data from GN patients with aged>18 years. We recorded the demographic data including gender, age, education, native habitat, the laboratory tests, and the pathological findings.

Results: We recruited666 patients performed native kidney biopsy during Jul 1, 2014 to Jun 30, 2015. The female to male ratio was 2.16:1. The mean age, creatinine, albumin, and cholesterol were 42 (18-82) years, 1.4 (0.4-13) mg/dL, 2.9+0.8 g/dL, and 296+118 mg/dL in respectively. The median proteinuria was 3.2 (0-22) g/day. The patients presented with 34% of nephrotic syndrome, 22% of nephritis, 21.7% of nephrotic nephritis, 52% of renal impairment (creatinine>1.2 mg/dL), and 54.4% of new or aggravated hypertension. The renal pathological findings showed 38% of LN, 17.6% of IgAN, and 9% of FSGS. The mean age of LN, IgAN, and FSGS were 34, 38, and 46 years. The average creatinine at biopsy of LN, IgAN, and FSGS were 1.9, 2.4, and 2.4 mg/dL.

Conclusions: Our study described the first three common renal pathological findings including LN, IgAN, and FSGS with the initial renal impairment at kidney biopsy. This might be the severity of the disease or the delay in performing biopsy due to facility of kidney biopsy and referring system. All three diseases were the most common GN causing the ESRD in Thailand. The development of qualified registry and GN network may improve the health care service and support the further study in both clinical and translational research.

Serum Cholesterol in Predicting Nephrotic Syndrome Diseases
Wonngarm Kittanamongkolchai,[1] Samih H. Nasr.[2] *[1]Nephrology and Hypertesnion, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: Hypercholesterolemia is one of the criteria for nephrotic syndrome. However, the cut-off level of serum cholesterol for nephrotic syndrome has been not well defined.

Methods: The pathologic reports of native kidney biopsies of patients >18 years of age with proteinuria ≥3 g/day performed at Mayo Clinic, Rochester, MN between 1/2000 and 8/2014 were reviewed. Patients who had liver disease, malnutrition, urinary dysmorphic RBC or RBC cast, paraproteinuria with urine albumin < 3 g/day, inconclusive diagnosis, no electron microscopy report or received immunosuppression within 6 months prior to renal biopsy were excluded. Patients were divided into group 1: nephrotic syndrome diseases (MCD, primary FSGS, membranous nephropathy and amyloidosis) and group 2: other diseases presented with nephrotic range proteinuria (secondary FSGS, diabetic nephropathy, glomerulonephritis, TMA, advanced kidney disease and other diseases). Receiver operating characteristic (ROC) curve was used to determine sensitivity and specificity of serum cholesterol for prediction of nephrotic syndrome diseases.

Results: From total of 6,707 native renal biopsy reports, 251 patients fulfilled the above criteria and were included in the study. 137 patients were classified into group 1 and 114 were in group 2. The average serum cholesterol was significantly higher in group 1 (303±105 vs 206±68 mg/dL, P<0.0001). The ROC area under the curve for serum cholesterol to predict nephrotic syndrome diseases was 0.79 (P<0.001). Serum cholesterol 300 and 350 mg/dL were highly specific to nephrotic syndrome diseases (specificity 89% and 99%, respectively).

Serum Cholesterol (mg/dL)	Sensitivity	Specificity
≥200	85%	56%
≥250	65%	76%
≥300	55%	89%
≥350	29%	99%

Conclusions: Total cholesterol ≥ 300 mg/dL is highly specific to nephrotic syndrome diseases and may help differentiate with other diseases that also contribute to nephrotic-range proteinuria. Renal biopsy should be considered in patients with nephrotic-range proteinuria and serum cholesterol more than 300 mg/dL.

SA-PO251

Bedside Real-Time Ultrasound-Guided Kidney Biopsy Service Fully Run by Nephrology: Safety and Specimen Adequacy
Mohammed Alzubaidi, Jalal E. Hakmei, Na'Da Abouhassan, Juan Carlos Q. Velez. *Internal Medicine, Div of Nephrology, Medical Univ of South Carolina, Charleston, SC.*

Background: Percutaneous kidney biopsy (PKB) is routinely performed by a nephrologist with ultrasound (US) guidance from a radiologist, or solely by interventional radiology (IR). There is paucity of data regarding safety and feasibility of PKBs performed by a nephrology (NEPH) team without participation of a radiologist. We hypothesized that PKBs independently performed by a NEPH team are as safe and optimal in yield of kidney tissue as those performed by IR.

Methods: We established a NEPH clinical service to independently perform bedside real-time US-guided PKBs. Records were reviewed to compare complication rate [minor: hematoma, gross hematuria; major: blood transfusion (ordered at the discretion of the hospitalist) invasive procedure, intensive care or death] and biopsy adequacy (successful retrieval of glomeruli-containing tissue fully available for light, immunofluorescence and electron microscopy) of PKBs performed by the NEPH team vs. those performed by IR under computer tomography (CT) guidance.

Results: We identified 109 PKBs performed by NEPH (16g needle) and 103 by IR (68% 16g, 32% 18g) over the last 3 years. Groups were comparable regarding age (46.0 vs. 50.2 yrs) and baseline hemoglobin (10.6 vs. 10.2 g/dL) and platelet count (229 vs. 232 x10^3/mm^3), whereas mean body mass index (BMI) (28.5 vs. 31.8 kg/m^2; p=0.012) and estimated glomerular filtration rate (eGFR) (57.1 ± 47 vs. 32.3 ± 37 ml/min/1.73m^2; p<0.008) were different for NEPH and IR, respectively. Complication rates were similar between groups (major: 6.4% vs. 4.9%; minor: 2.7% vs. 6.8%, for NEPH and IR, respectively), even among those with BMI > 30 kg/m^2 or eGFR < 45 ml/min. Two IR cases but no NEPH cases required arterial embolization. One death occurred with IR, none with NEPH. Adequate tissue specimens were obtained in 104 cases (95.4%) of the NEPH cohort vs. 84 (81.6%) of the IR cohort (p=0.002).

Conclusions: Real-time US-guided PKBs performed by a NEPH service are as safe as CT-guided PKBs performed by IR in a high risk population at an academic medical center, and may provide superior tissue retrieval.

SA-PO252

The Characteristics of Class II MHC+ Mononuclear Cells within Native Kidney Are Distinct from Peripheral Blood and Transplant Kidney
Bairbre A. McNicholas,[1] Susan K. Anderson,[1] Matthew D. Griffin,[2] Kimberly A. Muczynski.[1] *[1]Div of Nephrology, Univ of Washington, Seattle, WA; [2]REMEDI, National Univ of Ireland, Galway, Ireland.*

Background: Mononuclear phagocytes (MPh) are a heterogeneous population of cells that resides in the kidney. Little is known of their phenotype in normal human kidney and of their contribution to injury compared to influx of circulating monocytes from blood.

Methods: Healthy kidney from 12 human nephrectomies and 3 transplant biopsy cores was enzymatically digested and compared to paired peripheral blood leukocytes using 7 color-flow cytometry. Nephrectomies were from subjects with normal renal function. Transplant biopsies were performed for worsening renal function. Lymphocytes, B and NK cells were excluding by negatively gating $CD3^+$, $CD56^+$ and $CD20^+$. The surface expression of $CD45^+$Class II MHC (HLA-DR), CD11b, CD11c, CD14 and, in a subset, CX3CR1, CD33, CD40 and CD86 was analyzed.

Results: The proportion of $CD45^+$ mononuclear cells positive for HLA-DR and their HLA-DR surface expression levels were higher for native kidneys compared to blood leukocytes and transplants. Three populations of HLA-DR^+ cells were identified in kidney. Their expression of the monocyte marker CD14 was compared among native kidney, transplant and matching blood leukocytes (table 1). Autofluorescent cells were increased in transplant and native kidneys experiencing ischemia during removal. CXC3R1, CD33, CD40, CD86 were found to be most highly expressed by $CD11b^{++}$/$CD11c^+$ MPh of native kidneys.

HLA-DR^+ Sub-population (%CD14)	Native Kidney	Blood (Native)	Transplant	Blood (Transplant)	P value
$CD11b^{++}$/$CD11c^+$	86.2 ±3.6*	83.9 ±4.9	46.4 ±26.9*	97.2 ±1.6	0.02*
$CD11b^+$/$CD11c^+$	33.6 ±8.8	18.2 ±4.8	88.8 ±11.1**	14.9 ±8.2**	0.005**
$CD11b^+$/$CD11c^-$	60.9 ±9.2^	10.8 ±8.2^	44.2 ±25.9	1.2 ±1.2	0.0006^
*Native Kidney vs. Transplant, **Transplant vs. Blood (Transplant), ^Native kidney vs. Blood (native)					

Conclusions: Class II MHC^+ MPh subpopulations from healthy human kidney, have higher HLA-DR expression than their counterparts in blood. Renal MPh subpopulations variably express the monocyte marker CD14. $CD14^+$ MPh were less frequent in transplant compared to native kidney.

The Clinicopathological Characteristics in Renal Insufficiency Patients with Different Renal Parenchymal Thicknesses
Yanna Dou,[1,2] Song Dong Yan,[1,2] Zhanzheng Zhao.[1,2] *[1]The Nephrology Center, The First Affiliated Hospital of Zhengzhou Univ; [2]Zhengzhou Univ Inst of Nephrology.*

Background: The normal value of renal parenchymal thickness (RPT) by ultrasound is about 1.5cm (1.28 to 2.08cm) in the adults, usually. The reduced renal parenchymal thickness is associated with renal impairment in patients with kidney disease. The aim of this study was to explore the pathological features in renal insufficiency patients with different renal parenchymal thickness.

Methods: The patients with kidney disease from our hospital from December 2014 through to December 2015 were screened. The inclusion criteria: 1) age ≥18 years old; 2) serum creatinine ≥115μmol/L (the reference value is 20~115μmol/L) or eGFR<60ml/mim/m^2 and 3) undergoing renal biopsy. The exclusion criteria:1) patients with renal biopsy specimen less than 10 glomerulus. 2) Patients with prerenal and postrenal kidney dysfunction. The clinical data, kidney dimensions at sonography and renal histopathologic data were collected. And the patients were divided into two groups according to the RPT value of 1.5cm, the normal RPT group and the reduced RPT group. SPSS 22.0 software was used for all analyses.

Results: 187 patients (aged 18-84 years) were enrolled. Compared to the normal RPT group (69 cases), the patients in the reduced RPT group (118 cases) showed less eGFR (28.0 (15.9, 40.9) vs. 36.8(17.4, 48.2) ml/(min*1.73 m^2) and lower total urine protein ((2.8 (1.2, 4.9) vs. 3.7(1.5, 8.1) g/day), higher albumin (33.7(27.6, 39.2) vs. 28.7(18.8, 36.0) g/L), respectively. And there is no significant difference in age, blood pressure, hemoglobin, serum creatinine and lipids. In the reduced RPT group, the ratio of total glomerular sclerosis >50% (40.7% vs. 15.9%, p<0.05),renal tubular atrophy (83.1% vs. 60.9%, p<0.05), interstitial inflammatory cell infiltration with fibrosis (80.5% vs. 60.9%, p<0.05), and small artery vitreous degeneration(53.4% vs. 36.2%, p<0.05), are higher than the normal RPT group, respectively.

Conclusions: The patients with the reduced RPT showed more glomerular sclerosis and interstitial fibrosis.

Endogenous Measures of Tubular Secretion in Spot versus Timed Urine Specimens
Pranav S. Garimella,[1] Kefeng Li,[2] Jane C. Naviaux,[2] Michael Shlipak,[3] Erick Orlando Castro,[2] Joseph A. Abdelmalek,[2] Robert K. Naviaux,[2] Edmund Capparelli,[2] Joachim H. Ix.[2] *[1]Tufts; [2]UCSD; [3]UCSF.*

Background: Tubular secretion is an important kidney function essential for drugs excretion. Recent studies using 24 hour urine samples have identified endogenous compounds that are highly secreted and are associated with mortality and progressive kidney disease. We aimed to evaluate the utility of spot urine specimens for assessing tubular secretion.

Methods: Three healthy adult male volunteers provided two spot serum samples and urine samples at 4 hourly intervals over 24 hours. Liquid chromatography tandem mass spectrometry was used to quantify serum and urine concentrations of solutes and the fractional excretion (FE, %) of each was calculated as (Metabolite urine × Creatinine serum)/(Metabolite serum × Creatinine urine)×100. We measured FE of 15 metabolites including 5 that in prior studies have shown to be secreted (FE > 100% relative to creatinine) and 10 others with unknown kidney handling. Among those metabolites found to be secreted, we evaluated the mean variability over 24 hours.

Results: The mean age was 38 years and the mean creatinine clearance using 24 hour urine collection was 138 ml/min. Overall 6 of 15 markers had FE > 100 (range 218 –1019%), 5 of which had been reported in prior studies using 24 hour urine samples. The FE of these 6 candidate secretion markers was relatively stable, with diurnal variation in secretion described as maximum to minimum FE ratios as high as 3.2:1 for cinnamoylglycine to a low of 1.9:1 for phenylacetylglutamine.

Fractional Excretion (%) of Candidate Secretion Markers over 24 hours

	4PM	8PM	12AM	4AM	8AM	12PM	4PM	Mean	SD	Maximum/ Minimum Ratio
Tigaglycine	766	737	1490	1313	1036	1162	627	1019	323	2.4
Isovalerylglycine	989	692	1012	857	1024	1444	608	947	273	2.4
Hippuric acid	826	682	1029	703	715	776	488	746	164	2.1
Phenylacetylglutamine	567	565	817	600	680	589	366	598	136	1.9
Suberic acid	194	204	337	214	186	235	171	220	55	2.0
Cinnamoylglycine	159	209	361	155	318	213	114	218	90	3.2

Abbreviations: SD- intra-individual standard deviation

Conclusions: Several endogenous markers of tubular secretion are relatively stable over the day, making spot urine specimens feasible for assessing tubular secretion. Studies evaluating these markers in older persons and across a wide range of eGFR are needed.

SA-PO255

Stretching and Exposure to Protein Synergistically Activate Innate Immunity and Inflammation in Proximal Tubular Cells Simone C.A. Arias,[1] Viviane D. Faustino,[1] Luciene dos Reis,[1] Flavia G. Machado,[2] Niels O.S. Camara,[1] Clarice K. Fujihara,[1] Roberto Zatz.[1] *[1]Univ of Sao Paulo; [2]Washington Univ.*

Background: Cell cyclic stretching (ST) stimulates inflammation in glomerular cells, but it is unclear whether tubular cells respond to ST in the same manner. Moreover, a conceivable effect of ST on innate immunity activity has not been examined. In addition, the effect of ST has been studied in the absence of protein, a condition not seen in vivo. We investigated whether: 1) ST alone activates innate immunity in proximal tubular cells (PTC); 2) Simultaneous PTC exposure to ST and protein results in more intense inflammation and innate immunity activation than ST alone.

Methods: Rat PTC (NRK52E) were cultured and subjected to ST (20% maximum elongation) (ST, N=4) or ST plus bovine serum albumin (BSA), 1 mg/mL (ST+BSA, N=4). Control cultures (C, N=4) were exposed to no ST or BSA. After 24 h, MCP-1 (pg/mL), IL-6 (pg/mg) and IL-1β (pg/mg) were evaluated by ELISA, while TGF-β, Collagen-1 (COLL-1), TLR4 and Caspase-1 contents were assessed by WB (x C).

Results:

	C	ST	ST+BSA
MCP-1	45±10	120±34	1112±204[ab]
TGF-β	1.0±0.2	1.8±0.1[a]	1.9±0.2[a]
COLL-1	1.0±0.2	2.0±0.5	3.4±0.9[a]
Caspase-1	1.0±0.1	2.3±0.4	4.2±1.1[ab]
TLR4	1.0±0.2	0.9±0.1	2.1±0.2[ab]
IL-1β	1.9±0.5	6.5±1.5	10.0±5.4
IL-6	1.2±0.4	1.0±2.8	11.1±6.8

Mean±EP, [a]p<0.05 vs C, [b]p<0.05 vs ST

Exposure of PTC to ST or ST+BSA resulted in no limitation of cell viability or proliferative capacity (not shown). ST alone significantly increased TGF-β. Exposure to both ST+BSA increased MCP1, IL-6 and COLL1 protein expression. In addition, ST+BSA activated innate immunity, as indicated by increased expression of TLR4, caspase-1 and IL-1β.

Conclusions: ST and BSA synergistically cooperate to activate innate immunity and enhance inflammation and COLL production. Since both abnormalities can be present in chronic kidney disease, this double insult can be an important factor leading to progressive tubulointerstitial fibrosis in this setting. FAPESP/CNPq.

The Low Albuminuria in the Face of Overt Proteinuria Reported in the African American Study of Kidney Disease and Hypertension (AASK) Patients Is an Artifact Caused by Acetic Acid Used as a Preservative Salem Almaani, Daniel J. Birmingham, Brad H. Rovin, Lee A. Hebert. *Div of Nephrology, Ohio State Univ, Columbus, OH.*

Background: The pathogenesis of AASK nephropathy (AASK-N) is unclear. As previously reported, progression occurred at low levels of proteinuria, most of which was non-album proteinuria (NAP). We attempted to determine whether the NAP of AASK-N consisted of low molecular weight proteins characteristic of a tubulopathy.

Methods: We obtained 298 AASK 24-hour urine samples from the NIDDK biorepository. From this, we selected 37 samples based on protein-to-creatinine ratios (PCR) of 0.2-1.0. Levels of albumin (Alb), cystatin C (Cys), beta-2 microglobulin (B2M), epithelial growth factor (EGF), neutrophil-gelatinase-associated lipocalin (NGAL), osteopontin (OPN), and uromodulin were measured. For comparison, levels were also obtained from 24-hour urine samples of 20 lupus nephritis (LN) patients with similar PCRs and storage conditions, and from 15 African American controls. Urine samples were also assessed by SDS-PAGE for overall protein quality.

Results: The AASK-N urines showed lower concentrations of Alb, B2M, Cys, EGF, and OPN compared to LN samples or to controls (all P < 0.01). In fact Alb, B2M, Cys, and OPN were undetectable in the majority of AASK-N samples. SDS-PAGE revealed near-absence of the intact 68kD albumin band in most AASK-N samples, but two prominent bands of <10 kD, documenting protein degradation. By comparison, the LN urines showed intact albumin and no bands <10 kD. A second NIDDK batch of the AASK-N urines as well as urines from these patients collected at different study visits revealed similar results. Attempts to replicate degradation in LN samples by storage up to 5 days at 37^0 C or after 8 freeze-thaw cycles were unsuccessful. However, treatment of these LN urine samples with acetic acid at the same concentration used for urine collections in the AASK protocol (0.5%) did replicate the protein degradation pattern seen in the AASK-N urines.

Conclusions: The low urine albumin and high NAP reported in AASK-N likely is an artifact related to the use of acetic acid as a preservative.

SA-PO257

Risk of Percutaneous Renal Biopsy of Native Kidneys in the Evaluation of Acute Renal Failure Stephen M. Korbet, William Luke Whittier. *Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: The purpose of this study is to assess the risk of bleeding complications in pts undergoing percutaneous renal biopsy (PRB) of native kidneys for the evaluation of acute renal failure (ARF).

Methods: PRB of native kidneys was performed in 958 adult pts from 1991 through 2015 at Rush Medical Center with real-time ultrasound and an automated biopsy needle. Baseline demographic, clinical and laboratory information was collected along with the indication for PRB and pts were followed prospectively for complications. PRB for evaluation of ARF was performed in 160 pts (17%). The remaining 798 pts were biopsied for hematuria, and/or proteinuria, and/or chronic kidney disease. Complication rates were compared between these 2 groups. A complication was defined by the need for an intervention (transfusion of packed red blood cells, an interventional radiologic (IR) or surgical procedure) or the need for re-admission or death. Statistical analysis was performed using Fischer exact test for categorical data and Mann-Whitney test for continuous data. Results are reported as means ± standard deviation and a p-value of <0.05 was considered significant.

Results: Pts biopsied for ARF were older (58±17 vs. 44±16 yrs, P <0.01), had a higher level of serum creatinine (SCr) (4.5±2.7 vs. 1.8±1.6 mg/dl, P <0.01 and >1.5 mg/dl in 94% vs. 37%,P <0.01), a lower hemoglobin (10.4±1.7 vs. 12.1±2.1, P <0.01 and <10.0 g/dl in 43% vs. 17%, P <0.01), and a greater proportion with an abnormal bleeding time (>9 min: 13% vs. 7% (P <0.05) and/or an abnormal PTT (>33 seconds: 15% vs. 5%, P <0.01), all risk factors for complications. The diagnostic adequacy of the biopsy was similar in both groups (ARF-98% vs. 99%). Complications post-PRB were significantly greater in pts biopsied for ARF (11.3% vs. 6.6%, P <0.05; OR 1.78) with pts biopsied for ARF requiring more transfusions (10% vs. 5.1%, P = 0.03) and twice as many IR procedures (1.9% vs. 1.0%, P = 0.4). There were no deaths in pts biopsied for ARF.

Conclusions: We conclude that pts biopsied for evaluation of ARF have increased risk factors for a complication and a greater rate of complication requiring intervention post-PRB compared to pts biopsied for other reasons.

SA-PO258

Proteomic Analysis of Micro-Dissected Nephron Segments and Urine Selected PLA2R1 and GGT5 as New Urinary Biomarker Candidates for Chronic Kidney Disease Hidehiko Fujinaka,[1,4] Shigeru Miyazaki,[2] Chizuko Kitabayashi,[3] Yoshio Konishi,[3] Tadashi Yamamoto.[4] *[1]Inst for Clinical Research, Niigata National Hospital, Kashiwzaki, Niigata, Japan; [2]Shinrakuen Hospital, Niigata, Japan; [3]Osaka City General Hospital, Osaka, Japan; [4]COI-s Biofluid Biomarker Center, Inst of Research Collaboration and Promotion, Niigata Univ, Niigata, Japan.*

Background: New biomarkers have been searched for the early diagnosis of chronic kidney disease (CKD), mostly in patients urine with overt proteinuria. The trials have not been so successful since most of the urinary proteins are derived from plasma in the patients.

Methods: We have changed the strategy for urinary biomarkers discovery: 2 proteome datasets of each nephron segment and of urine were analyzed. Each of the kidney nephron segment without apparent diseases was collected by laser micro-dissection and directly digested by trypsin. Urine proteins were purified from healthy volunteers and subjected to in-solution digestion with trypsin. Both of these obtained peptides were analyzed by mass spectrometry followed by semi-quantitative analysis. By comparing these proteome datasets, nephron-segment-unique urinary proteins were selected as urinary biomarker candidates. The site-uniqueness in the kidney was confirmed by IHC using specific antibodies. Amounts of the selected proteins in urine were measured by Surface Plasmon Resonance System in IgA nephropathy (IgAN) patients and healthy volunteers.

Results: Nephron-segment-unique urinary proteins were selected: glomerulus; 89, proximal tubule; 68, distal tubule; 8, collecting duct; 5, and others. Amongst them, PLA2R1 expression was confirmed in glomerular podocytes, and GGT5 in the interstitial matrix by IHC. PLA2R1 urinary excretion was significantly higher in IgAN rather than in normal (p<0.01), and the excretion in CKD stage 1 IgAN tended to be higher than that in normal (p=0.07). GGT5 urinary excretion was significantly higher in IgAN rather than in normal (p<0.01).

Conclusions: Proteomic analysis of the micro-dissected nephron segments and urine with antibody-based validation revealed that podocyte-derived PLA2R1 and interstitial-matrix derived GGT5 are proposed as new urinary biomarkers for glomerular injury and interstitial events.

SA-PO259

The Clinicopathological Characteristics of Central Fibrosis Nodule in Glomerular Vascular Pole Satoshi Hara,[1] Yutaka Yamaguchi,[2] Mitsuhiro Kawano.[1] *[1]Internal Medicine, Kanazawa Univ Graduate School of Medicine, Kanazawa, Ishikawa, Japan; [2]Yamaguchi's Pathology Laboratory, Chiba, Japan.*

Background: Central fibrous nodule in glomerular vascular pole (CFN) is histologically characterized by periodic acid Schiff-negative small nodular lesion located in glomerular vascular pole. Although this pathological finding is observed in various disease entity, the clinicopathological characteristic remains fully undetermined. The present study was conducted to clarify the epidemiology and clinicopathological characteristics of CFN.

Methods: 103 kidney needle biopsy specimens diagnosed in Kanazawa University Hospital during 2015 were used. First, the components of CFN were analyzed by immunostaining and electron microscopy. Second, patients were divided into 2 groups [CFN (+) or CFN (-) group], according to the presence of CFN. Clinical and histological features were compared between 2 groups.

Results: CFN was observed in 57 of 103 cases (55.3%). Immunostaining revealed that CFN consisted of fibrillar collagens (collagens I and III) in addition to collagen IV. Congo red staining was negative in all cases. Electron microscopy confirmed fibril-rich lesions of CFN. Clinically, CFN (+) group were older age (62.3±2.0 vs. 49.8±3.0 years; $p<0.01$) and had significant increase of hypertension (69.6 vs. 41.3%; $p<0.01$) and hyperlipidemia (58.9 vs. 34.9%; $p<0.05$) compared with CFN (-) group. Histologically, elastofibrosis of interlobular artery (72.5 vs. 44.2%; $p<0.01$) and arteriolar hyalinosis (66.7 vs. 41.3%; $p=0.01$) were significantly evident in CFN (+) group compared with CFN (-) group. There were no significance in regard to gender, body mass index, diabetes mellitus, hyperuricemia, proteinuria, hematuria, kidney dysfunction, and background kidney disease.

Conclusions: CFN is a fibril-rich nodule and the formation is associated with aging, hypertension and hyperlipidemia clinically. CFN is also associated with arteriolosclerosis and arteriolar hyalinosis histologically, suggesting that the pathophysiology of CFN resembles that of atherosclerosis in the kidney.

SA-PO260

A Novel Transgenic Mouse Model to Study Renal Tumorigenesis Anna Julie Peired,[1] Alessandro Sisti,[2] Giulia Antonelli,[1] Paola Romagnani.[1,2] *[1]Excellence Centre DENOTHE, Univ of Florence, Florence, Italy; [2]Nephrology Unit, Meyer Children's Univ Hospital, Florence, Italy.*

Background: Kidney cancer accounts for about 2% of all cancers, with about 190,000 new cases per year worldwide, with a higher incidence in developed countries. Recent studies suggest that chronic kidney disease (CKD) is a crucial risk factor for the development of kidney cancer. As other studies hint that the Notch pathway may be critical for CKD progression to end stage kidney disease, we created a transgenic mouse model that chronically express Notch1 in the tubular compartment, in order to study the mechanisms of kidney regeneration.

Methods: To this aim, we developed Pax8-rtTA/tetO-Cre/Rosa26-Confetti/Rosa26-Notch1 mice, in which the constitutive expression of cleaved Notch1 is limited to Pax8+ tubular cells, and is controlled by the inducible Tet-On system, allowing us to activate Notch1 expression only in adult animals. The Confetti reporter activated together with Notch1 led to the stochastic expression of one out of four fluorescent proteins, allowing us to verify the eventual presence of clonal cell proliferation.

Results: Analysis of kidneys showed numerous, multicentric and progressive pretumoral and tumoral lesions. Indeed, persistent Notch1 expression in tubular cells led to the formation of a broad spectrum of lesions of proliferative and non-proliferative nature. Monitoring over 9 months post induction allowed the determination of the evolutionary nature of the various types of lesions: glomerular cysts, simple tubular cysts, simple and atypical tubule hyperplasia. In addition, lineage tracing studies showed their evolution into papillary adenomas and even adenocarcinomas, characteristic of an increasingly aggressive phenotype. We could also observe the progressive loss of renal function. The Confetti reporter showed that most of the lesions were mono- or biclonal, demonstrating for the first time the clonal nature of pretumoral and tumoral renal lesions.

Conclusions: This mouse model represents a useful new tool for the study of tumor development mechanisms in the kidney and provides the first experimental demonstration of the link between CKD and the development of renal pre-neoplastic and neoplastic lesions up to cancer.

Influence of Physical Preconditioning in Renal Damage Induced by Adriamycin in Rats and Its Relationship with Endothelial Lesions and Angiogenesis in the Renal Cortex Camila M. Faleiros, Heloisa Della Coletta Francescato, Cleonice Silva, Terezila Machado Coimbra. *Univ of Sao Paulo, Ribeirao Preto, Sao Paulo, Brazil.*

Background: A single dose of adriamycin (ADR) in rats induces a progressive and irreversible proteinuria that progresses to focal segmental glomerulosclerosis and tubulointerstitial lesions. Regular physical activity can be a preventive and therapeutic intervention in clinical and experimental conditions. Physical training has beneficial effects on endothelial function. This study evaluated the influence of physical preconditioning in renal damage induced by ADR in rats and its relationship with endothelial lesions and angiogenesis.

Methods: Male Wistar rats were submitted or not to treadmill running for 4 weeks and injected (i.v.) with ADR (2.5 mg/kg) or saline. The animals were divided in: sedentary+saline (SED+SAL), physical training+saline (PhT+SAL), sedentary+adriamycin (SED+ADR), physical training+adriamycin (PhT+ADR) groups. Twenty-four-hour urine samples were collected 7, 30, and 60 days after injections to quantify albuminuria. The kidneys were removed 60 days after treatment for morphometric and immunohistochemical analysis.

Results: SED+ADR group presented progressive increase in albuminuria from the 7th to 60th days, which were less intense in PhT+ADR group. Those animals also presented higher desmin expression (marker of podocyte lesion) at the glomerular edge (1.31±0.15), enlargement of tubular interstitial area (33.7±2.12%), as well as higher macrophage numbers in the renal cortex (10.56±1.17) compared to control. These alterations were smaller in PhT+ADR group (0.65±0.09, 21.23±1.71, 6.37±0.58, respectively). The SED+ADR group also presented reduction in vascular endothelial growth factor (0.95±0.1), endothelial cells (0.74±0.15) and endothelial nitric oxide synthase (3.41±0.36) expressions in the renal cortex, which were attenuated in the PhT+ADR group (1.2±0.06, 1.07±0.08, 5.61±0.48, respectively).

Conclusions: Physical training prior to ADR injection reduced the renal damage induced by this drug. This effect was related to angiogenesis, reduction in the endothelial lesions and inflammatory process in the renal cortex of these animals. Grants: CAPES, FAPESP (12/50180-2).

Primary Endothelial Lesions in Mouse Kidneys Induce a Platelet Mediated Inflammatory Response Sophie Lengning, Jan Sradnick, Anika Luedemann, Bernd Hohenstein, Christian Hugo. *Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CGC, Dresden, Germany.*

Background: We have recently shown that platelets (PLT) directly mediate endothelial lesions in a murine model of site-selective endothelial cell (EC) injury. With respect to indirect, pro-inflammatory effects, PLT's status remains unclear. To further investigate their potential role for the inflammatory response we here induced EC lesions and depleted PLT 24 hours later.

Methods: The induction of EC injury was performed by renal-arterial perfusion of Concanavalin (ConA)/ anti-conA in 51 C57Bl/6 mice. On day 1, PLT were depleted using anti-GPIb alpha antibodies (n= 13), mice perfused with NaCl solution (n= 23) or polyclonal non-immune rat IgG (n= 15) served as controls (CTRL). Mice were sacrificed on days 2 and 5. FACS analysis was used to verify PLT depletion (morphological and $CD41^+$), and recruitment of neutrophils ($CD11b^+GR1^+$), macrophages ($F4/80^+CD11b^+CD11c^+GR1^-$), B-cells ($IgM^+B220^+CD19^+$) and T-cells ($CD4^+$ or $CD8^+$). Harvested kidneys were also partly fixed for immunohistochemical staining with MAC2, F4/80 and CD31 antibodies.

Results: Platelet depletion was successfully established (CD41+ CTRL: 92.99% vs. PLT depleted: 2.42%). FACS analysis detected a significant reduction of T-Cells, $CD4^+$ (day 2: 2.02% vs. 1.01% and day 5: 1.96% vs 1.14% in CTRL vs. PLT depleted mice), as well as $CD8^+$ (day 2: 2.64% vs. 1.08%, day 5: 3.77% vs. 1.87%). B-Cells were not different. Monocytes and their subpopulation of macrophages were reduced in PLT depleted mice (day 2: 0.29%, day 5: 0.48%) compared to CTRL (day 2: 0.53%, day 5: 0.84%). This finding was approved by periglomerular cell count of F4/80 positive cells and glomerular cell count of MAC2 positive cells. Systemic measurements did not reveal differences in cell counts.

Conclusions: The present study emphasizes the relevance of activated platelets after EC injury. It directly links the presence of platelets with the recruitment of various inflammatory cells in injured kidneys, representing an additional therapeutic aspect of platelet inhibition.

SA-PO263

Compound K Inhibits NF-κβ/NLRP3 Inflammasome Activation and Ameliorates Renal Inflammation in Unilateral Ureteral Obstruction Mice Shuk-Man Ka,[1] Ann Chen.[2] *[1]Graduate Inst of Aerospace and Undersea Medicine, National Defense Medical Center, Taipei, Taiwan; [2]Dept of Pathology, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Compound K (CK), a major absorbable intestinal bacterial metabolite of ginsenosides, has been shown to be anti-inflammatory, but its effect on renal inflammation and fibrosis remains largely unknown.

Methods: In the present study, we verified both the renoprotective and therapeutic effects on renal inflammation and fibrosis in a mouse unilateral ureteral obstruction (UUO) model and investigated the mechanisms of action, including the use of urine samples retained in the dilated pelvic cavity of the diseased kidney, renal draining lymph nodes, renal tubular epithelial cells (TECs) under mechanical-induced pressure, and macrophages.

Results: The results show that administration of CK decreased: [1] parenchymal loss, inflammation and fibrosis; [2] infiltration of macrophages and T cells; and [3] production of proinflammatory cytokines (renal tissues and in urine samples, the latter of which was collected from dilated pelvic cavity), in the kidney of the treated UUO mice. Notably, while given three days after the induction of UUO, CK clearly improved the tubulointerstitial lesions in the UUO mice. These beneficial effects from CK treatment correlated well with the inhibition of [1]NF-κB/NLRP3 inflammasome in the kidney; [2] NLRP3 inflammasome in cultured renal TECs under a mechanical-induced pressure; [3] NF-κB/NLRP3 inflammasome and mitochondrial damage in cultured macrophages; and [4] CD4 T cells activation in renal draining lymph nodes. These mechanistic investigations were also partly confirmed by a quantitative proteomics analysis.

Conclusions: We concluded that CK conferred its favorable effects on the renal tubulointerstitial lesions of UUO mice mainly by negatively regulating the NF-κB/NLRP3 inflammasome-mediated inflammatory pathway in the kidney.

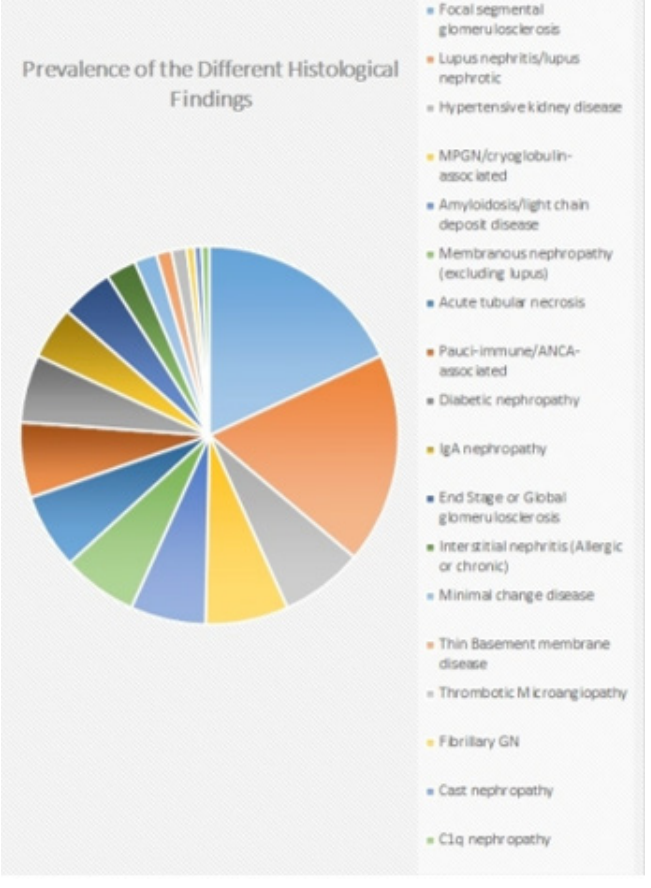
Retrospective Review of a Kidney Biopsy Series in an Urban Teaching Hospital among a Predominantly African-American Cohort Ravi K. Thimmisetty, Nashat Burhan Imran, Muhammad Omar Azam, Yahya M. Osman Malik. *Internal Medicine Dept/Nephrology Div, Wayne State Univ, Detroit, MI.*

Background: Kidney biopsy can aid in confirming a diagnosis, anticipating disease recurrence, and prognostication. It may alter the pre-biopsy proposed management. Indications include nephrotic/nephritic syndrome, and unexplained acute kidney injury.

Methods: Epidemiological retrospective analysis, single-center, urban hospital with a predominant demographic of African Americans. All kidney biopsies from February, 1st 2011 till June, 6th 2016. All biopsies were done using ultrasound guidance by either the nephrology service or interventional radiology.

Results: There were total of 561 biopsies in this time period. All pediatric, transplant, and surgical biopsies were excluded. The final 143 biopsies were analyzed with the following results: average age was 43.6 years (18-86), 49% male, 76.2% African Americans, average proteinuria 4.8 g/g, hypertension 76.2%. Unexplained acute kidney injury was the most common indication for biopsy (34%) followed by nephrotic syndrome (31%). Pre-biopsy clinical diagnosis was accurate in only 49% of the time. Focal segmental glomerulosclerosis (FSGS) and lupus nephritis classes were the two most common diagnoses (28% each).



Among African Americans, FSGS diagnosis was incorrectly presumed in 53% of the cases and was not suspected in 65% of patients with histological diagnosis of FSGS. There was a weak correlation between extent of fibrosis and creatinine values (Pearson coefficient r=0.358).

Conclusions: Percutaneous native kidney biopsy in an urban center showed FSGS and lupus nephritis as the most common diagnosis. Presumption that African American patient would have FSGS was incorrect in more than half of the time and was not suspected in 65% of the cases. There was a weak correlation between creatinine values and different extents of fibrosis.

SA-PO265

Plasma Soluble Coagulation Receptor Levels Are Not Associated with Venous Thromboembolism in Systemic Vasculitis Sarah Margaret Moran,[1] Alice M. Coughlan,[1] Eóin O'Brien,[1] Yvelynne P. Kelly,[1] Roger Preston,[2] Mark Alan Little.[1] *[1]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [2]Haemostasi Research Group, Trinity College Dublin, Dublin, Ireland.*

Background: ANCA associated vasculitis patients have a significantly elevated incidence of venous thromboembolism (VTE) compared to the general population, however, the molecular mechanisms underlying this increased risk remain elusive. We hypothesised that increased secretion of anticoagulant receptors from the vessel wall may predispose to VTE, or conversely, that increased soluble tissue factor may induce inappropriate clot formation.

Methods: Patients with vasculitis were identified within a longitudinal cohort. Clinical information was available for 346 patients. Soluble tissue factor (sTF), thrombomodulin (sTM) and endothelial protein C receptor (sEPCR) were measured by ELISA in a subset of 80-160 patients with available plasma samples.

Results: 9.5% of patients suffered a VTE, with an event rate of 6.95 per 100 patient years (64% PE, 18% DVT, 18% other VTE). sTF levels were moderately increased in active vasculitis (20.8 pg/ml, SD 31.3 pg/ml) compared to remission (14.0 pg/ml, SD 23.5 pg/ml, p value 0.019).There was no difference in sTF levels when stratified on VTE history (20.5 v 17.3pg/ml). sTM levels were unchanged between VTE history (mean level of 2952pg/ml in both VTE positive and negative), disease activity (active 2812pg/ml, remission 3044pg/ml) or disease severity (as defined by BVAS). sEPCR levels were below the level of detection of the assay.

Conclusions: sTF, sTM and sEPCR levels are not associated with increased VTE risk in our population.

Serum (pro)Renin Receptor Is Associated with the Index of Glomerular Lesion in Mesangioproliferative Glomerulonephritis Kaori Narumi, Emiko Sato, Takuo Hirose, Tae Yamamoto, Takashi Nakamichi, Mariko Miyazaki, Hiroshi Sato, Sadayoshi Ito. *Tohoku Univ Hospital, Sendai, Miyagi, Japan.*

Background: (Pro)renin receptor [(P)RR] is initially identified as a member of renin angiotensin system. (P)RR also functions as intracellular acidification as a part of V-ATPase, cell proliferation through Wnt signaling and inflammatory reaction via ERK1/2 pathway. We reported that (P)RR was present on infiltrating inflammatory cells around glomeruli with a crescent in anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN). Our finding suggests that (P)RR could contribute to the pathophysiology of GN. Soluble (P)RR [s(P)RR] is secreted into the extracellular space and is presented in plasma, implying that s(P)RR could become a biomarker for renal injury. Therefore, we examined association s(P)RR with various pathological indexes for renal injury in the patients with GN.

Methods: We measured serum s(P)RR and indoxyl sulfate (IS), one of a uremic toxin, in the mesangioproliferative GN patients diagnosed by renal biopsy at our hospital for past four years (n = 69). We evaluated the index of glomerular lesion (IGL), infiltration area of inflammatory cells and interstitial fibrosis area as pathological index. IGL is used for evaluation of chronic phase in mesangioproliferative GN and is converted into numerical values by the degree of mesangial proliferation or glomerulosclerosis. We investigated the association between serum s(P)RR and the pathological indexes or IS. Mouse mesangial cells, SV40 MES13, were used to evaluate the expression of (P)RR under IS stimulation.

Results: The serum s(P)RR was significantly associated with IGL after adjusted with confounding factors. Especially in IgA nephropathy patients, s(P)RR was significantly correlated with IGL and IS. In SV40 MES13, (P)RR expression was significantly increased depending on IS concentration and time.

Conclusions: The serum s(P)RR could reflect the degree of glomerulosclerosis. (P)RR could be involved in the mechanism of mesangial proliferation or glomerulosclerosis.

Vancomycin-Associated Nanospheres Cast Nephropathy Yosu Luque,[1,2] Kevin Louis,[1] Chantal Jouanneau,[2] Placier Sandrine,[2] Emmanuel Esteve,[2] Perrine Frere,[2] Eric Rondeau,[1,2,4] David Buob,[2,4,5] Emmanuel Letavernier,[2,4,6] Alice Mathilde Wolfromm,[7] Laurent Mesnard.[1,2,4] *[1]APHP, Hôpital Tenon, Urgences Néphrologiques et Transplantation Rénale, Paris, France; [2]Inserm UMR S 1155, Paris, France; [3]Laboratoire de Physique des Solides, Univ Paris Sud, France; [4]Sorbonne Univs, UPMC Univ Paris 06; [5]APHP, Hôpital Tenon, Anatomie et Cytologie Pathologiques, Paris, France; [6]APHP, Hôpital Tenon, Explorations Fonctionnelles Multidisciplinaires, Paris, France; [7]APHP, Hôpital Avicenne, Hématologie Clinique, Paris, France.*

Background: Vancomycin is a widely prescribed drug but some debate remains on its nephrotoxicity and the pathophysiological mechanism involved.

Methods: Here we initially described the case of a 56-year-old woman with normal renal function who developed unexplained very acute renal failure after administration of vancomycin.

Results: The renal biopsy, despite performed 2 weeks after vancomycin withdrawal, showed acute tubular necrosis with atypical granular tubular casts formation. These casts were surrounded by macrophagic infiltration and exhibited the infrared spectroscopy vancomycin signature. The location of vancomycin deposits was also confirmed by immunohistochemistry that we developed in-house. Scanning electron microscopy showed that the vancomycin-associated casts were made of non-crystal vancomycin nanospheres. To confirm these findings, we retrospectively analyzed from 1999 to 2016 seven additional cases of unexplained ATN associated with high vancomycin trough levels. We found similar tubular vancomycin deposits in these patients. Genuine control (that is ATN with concomitant vancomycin injection at time of the renal biopsy) did not express the staining of vancomycin. Finally, similar vancomycin nephrotoxicity mechanism was replicated experimentally in mice following vancomycin infusion. Intravital microscopy using fluorescent-tagged vancomycin dye showed vancomycin deposits formation in tubular lumens, starting 40 minutes after drug injection.

Conclusions: Taken together, these data confirm the yet unsuspected mechanism of acute tubular injury associated with vancomycin toxicity and the deleterious effect of nanospheric non-crystal vancomycin intra-tubular deposits.

SA-PO268

Autoantigen Determinants of Complement Activation by Goodpasture and Anti-PLA2R Autoantibodies Dorin-Bogdan Borza,[1] Tanu Rana,[1] Joshua M. Thurman,[2] Stephen Tomlinson,[3] Paul E. Brenchley,[4] Rachel Lennon.[5] *[1]Dept of Microbiology, Meharry Medical College, Nashville, TN; [2]Univ of Colorado School of Medicine, Denver, CO; [3]Medical Univ of South Carolina, Charleston, SC; [4]Manchester Royal Infirmary, Manchester, United Kingdom; [5]Univ of Manchester, Manchester, United Kingdom.*

Background: Complement activation is a prominent effector mechanisms of IgG autoantibodies (autoAbs) binding to glomerular autoantigens. Major epitopes targeted by Goodpasture (GP) autoAbs in anti-GBM disease and anti-PLA2R autoAbs in membranous nephropathy (MN) have been identified, but their role in complement activation is not known.

Methods: We assayed in vitro complement activation by GP autoAbs bound to a3(IV) collagen NC1 domain (a3NC1) or MN autoAbs bound to PLA2R. Recombinant autoantigen fragments containing select epitopes as well as competing mouse IgG mAbs were used to modulate the subsets of autoAbs forming immune complexes.

Results: GP sera containing predominantly IgG1 autoAbs activated complement, requiring a functional classical pathway, while the alternative pathway (AP) further amplifying C3 but not C4 deposition. GP autoAbs bind to two major epitopes (EA and EB) within a3NC1; inhibiting autoAb binding to either epitope significantly reduced deposition of C3 and C5b9, suggesting that both GP epitopes synergistically activate complement. Moreover, mAbs targeting these a3NC1 epitopes competitively inhibited complement activation by human GP autoAbs. For MN autoAbs, complement activation (C3 deposition) was inhibited by the PLA2R N-C3 domain or a peptide from the CysR domain, encompassing a major epitope, and also by mAbs raised against the N-C3 domain.

Conclusions: These results provide proof of concept that complement activation by autoAbs mediating glomerular disease can be inhibited in antigen-specific manner. Thus, detailed knowledge of the pathogenic epitopes may translate into disease-specific therapies.

SA-PO269

Proteomic Analysis of Complement Expression in Kidneys of Patients with Membranous Nephropathy Isabelle Ayoub,[1] Michael Merchant,[3] John P. Shapiro,[1] Daniel J. Birmingham,[1] Sergey V. Brodsky,[2] Jon B. Klein,[3] Tibor Nadasdy,[2] Brad H. Rovin.[1] *[1]Medicine, The Ohio State Univ, Columbus, OH; [2]Pathology, The Ohio State Univ, Columbus, OH; [3]Medicine, The Univ of Louisville, Louisville, KY.*

Background: Membranous nephropathy (MN) is a common cause of adult nephrotic syndrome. It is an autoimmune disease characterized by glomerular sub-epithelial deposits containing IgG. In experimental MN these deposits activate complement and cause kidney damage. The role of complement in human MN is less clearly defined. To further our understanding of this role, we performed a proteomic study of kidney biopsy tissue of MN, and focused the analysis on complement proteins.

Methods: Samples of normal kidney (n=5) were compared to 3 types of MN defined as: PLA2R+ (by glomerular staining or serum anti-PLA2R levels, n=3); PLA2R- (n=5), PLA2R- with electron dense spherules in the GBM (EDS, n=4). Glomeruli were isolated by laser capture microdissection, and analyzed by mass spectrometry. The levels of each complement protein among the four groups were analyzed by ANOVA or by Kuskal-Wallis for non-parametric data, and those showing significant differences were further analyzed by appropriate post-hoc tests. The alpha level for significance was set at 0.05.

Results: Seven complement activation proteins (C3, C4, C5, C6, C7, C8, C9) and two complement regulators (complement receptor type 1 (CR1), and FH-related protein 2 (FHR2)) were differentially present. Of the activation proteins, compared to normal controls, C3 and C4 levels were higher in all three MN groups, while C5, C6, C7, C8, and C9 were significantly higher only in MN with EDS. Of the regulators, compared to normal controls, CR1 levels were lower in EDS and PLA2R-, and FHR2 levels were greater in EDS.

Conclusions: Elevated levels of C3 and C4 in all MN groups, and decreased CR1 levels in at least two MN groups, support the involvement of complement activation in the pathogenesis of MN. Finding components of the membrane attack complex (C5-C9) only in EDS MN suggests complement's effect may be more severe, and direct, in this type of MN. These data raise the possibility that anti-complement therapies may be effective in some forms of MN.

SA-PO270

Synthesis of Complement Protein C3 in Podocytes Is an Important Mediator of Renal Injury in Glomerular Diseases Xuejuan Li, Jie Ding, Fangrui Ding. *Peking Univ First Hospital, Beijing, China.*

Background: We previously study demonstrated complement C3 was increased after podocyte injury by puromycin in vivo and in vitro. Podocytes are one of the major intrinsic glomerular cells, the foot processes of the neighboring podocytes form slit diaphragm, which is considered to be one of the most important structures for the glomerular filtration barrier, plays an important role in preventing the initiation and development of proteinuria. However, whether the increased podocyte-derived C3 is involved in glomerular podocyte injury are important questions that remain unclear. Therefore, the role of podocyte-derived C3 involving podocyte injury, as well as in proteinuric kidney diseases, further investigation is needed.

Methods: We generated transenic mice that overexpress C3 in podocytes using the podocin promoter. The genotyping of these transgenic mice were performed by conventional PCR. The gene and protein expression of C3 was detected by Real-time PCR and confocal in isolated transgenic mice glomerular. C3 transgenic mice were treated with PAN or saline solution. Excretion of albumin was expressed as the albumin-to-creatinine ratio. Transmission electron microscopy was used to evaluate the ultrastructural changes of glomerular. The confocal and western blot were used to detecte the podocyte injury marker proteins expression changes.

Results: We successfully constructed the podocyte specific overexpression C3 transgeninc mice. The albumin-to-creatinine ratio and podocytes damage in PAN induced wild type mice were aggravated in the Podocyte specific overexpression of C3 (Podo-C3) transgenic mice. Moreover, the expression of podocyte injury marker protein nephrin, synaptopodin, podocin decreased in PAN induced Podo-C3 transgenic mice. Moreover, the expression and distribution of the activated C3 cleavage fragment C3a and the C3aR were significantly increased in Podo-C3 PAN nephropathy model.

Conclusions: We demonstrated for first time that the podocyte-derived C3 aggravated podocyte damage in PAN nephropathy model. The possible mechanism might be through up-regulation of complement C3aR.

SA-PO271

Complement Activation in Diabetic Nephropathy Pascal Bus, Jamie S. Chua, Celine Klessens, Malu Zandbergen, Jan A. Bruijn, Ingeborg M. Bajema, Hans J. Baelde. *Pathology, LUMC, Leiden, Zuid-Holland, Netherlands.*

Background: Complement activation plays a role in various renal diseases. Experimental models suggest a role for complement activation in diabetic nephropathy. Therefore, the aim of this study was to investigate the prevalence and significance of complement deposits in a large cohort of renal tissue from patients with diabetes and diabetic nephropathy.

Methods: We investigated the presence of glomerular C4d, C1q, MBL, C5b-9 depositions on 163 renal autopsies with both type 1 and type 2 diabetes mellitus. Diabetic patients were divided into 2 groups: patients with and without histologically proven diabetic nephropathy; confirmed by light- and electron microscopy. Autopsies were re-evaluated histologically. Complement deposition patterns were scored blinded to the clinical and histological data.

Results: Diabetic nephropathy was present in 63% of patients. Complement activation marker C4d was significantly more prevalent in patients with DN (45%), compared to patients without DN (26%) ($p<0.05$). Glomerular C4d was associated with the presence of C1q ($p<0.01$) and C5b9 ($p<0.01$). MBL was infrequently observed (6% of all diabetic patients). C4d and C5b-9 deposits were significantly more prevalent in patients with interstitial fibrosis and tubular atrophy, than patients without these deposits ($p<0.05$). Patients with C4d also had more arteriosclerosis, and glomerular and arteriolar hyalinosis, than patients without C4d. No difference was seen between patients with type 1 DM and type 2 DM.

Conclusions: Complement activation is present in a selected number of patients with diabetic nephropathy, and seems to be associated with chronic lesions. Classic pathway complement activation was the route most frequently found. In our study, there were no differences between complement deposits in type 1 and type 2 diabetes.

SA-PO272

Clinically Available Janus Kinase (JAK) Inhibitors May Offer Treatment for Recurrent Focal Segmental Glomerulosclerosis (rFSGS) Virginia J. Savin,[1,2] Mukut Sharma,[1,2] Ellen T. McCarthy,[3] Tarak Srivastava,[5] Ram Sharma,[1] Jean-Francois Gauchat,[4] Jianping Zhou.[1] *[1]Nephrology, KC VA Medical Center, Kansas City, MO; [2]Research, MBRF, KC VA Medical Center, Kansas City, MO; [3]Kidney Inst, KU Medical Center, Kansas City, KS; [4]Pharmacology, Univ of Montreal, Montreal, QC, Canada; [5]Nephrology, Children's Mercy Hospital, Kansas City, MO.*

Background: Plasma of patients with rFSGS alters glomerular barrier function. We have identified CLCF1 in rFSGS plasma and proposed that its signaling via the JAK/STAT pathway is essential to injury induced by rFSGS plasma. Podocytes express primarily JAK2 and STAT3 and specific JAK2 or STAT3 inhibition prevents the effects of CLCF1 or of rFSGS plasma. We studied 3 clinically available JAK inhibitors Ruxolitinib, Incyte (Rux), Baricitinib, Lilly (Bari) and Tofacitinib, Pfizer (Tofa) to determine ability to block effects of CLCF1 on immortalized podocytes.

Methods: FDA approved JAK inhibitors Rux (1-15 nM) and Tofa (6-36nM), as well as Bari, (6-36nM), which is under FDA review, and BMS911543, a JAK2-specific inhibitor not used in clinical trials (1-5 nM), were studied at concentrations proximate to their respective IC_{50} for STAT3. CLCF1 (100nM) was included in some groups; this concentration increases both pSTAT3 and P_{alb}. pSTAT3 (Tyr^{705}) in immortalized mouse podocytes was analyzed using Western blotting at 5-60min.

Results: The JAK2-specific inhibitor BMS911543 prevented increases in pSTAT3 and glomerular P_{alb} caused by rFSGS serum or CLCF1 ($p<0.001$) (Transl Res 2015, 166:384-98). Rux, Tofa and Bari each decreased basal podocyte pSTAT3 in a dose- and time-dependent manner. At 60 min, Rux (3nM), Tofa (6nM) or Bari (5nM) prevented CLCF1-induced increase in pSTAT3 ($P<0.001$).

Conclusions: JAK2 inhibition is sufficient to prevent STAT3 and P_{alb} responses to CLCF1; JAK1 and JAK3 inhibition do not appear to be required. Repurposing available JAK inhibitor(s) may offer effective and specific treatment of rFSGS. Since Rux and Bari have relative specificity for JAK1 and JAK2 they may provide favorable toxicity profiles compared to Tofa. A clinical trial based on JAK2 inhibition in rFSGS may be warranted.

SA-PO273

An Endothelin Receptor Antagonist as a Promising Drug for Minimal Change Nephrotic Syndrome: Its Anti-Proteinuric Effect in Puromycin Aminonucleoside-Induced Nephrosis in Rats Jiro Kino, Shoji Tsuji, Sohsaku Yamanouchi, Chikushi Suruda, Takahisa Kimata, Kazunari Kaneko. *Pediatrics, Kanasai Medical Univ, 2-5-1 Shin-machi, Hirakata-shi, Osaka, Japan.*

Background: In recent years, the abnormal expression of podocyte-related molecules has been attracting attention with respect to the pathogenesis of minimal change nephrotic syndrome (MCNS). The endothelin (ET) receptor expressed on podocytes has been reported to be responsible for proteinuria and structural changes in podocytes. Therefore, we investigated, using a rat model, whether an endothelin A (ETA) antagonist could be used as a therapeutic agent for MCNS.

Methods: MCNS was induced by a single intravenous injection of puromycin aminonucleoside (PAN) in female Wistar rats. Two groups of 10 rats each were treated, either with the ETA antagonist ambrisentan or with 0.5% methylcellulose (control), orally. Treatment was administered once daily, starting 2 days before PAN injection lasting up to Day 9. Rats were euthanized at Day 12, and blood and tissue samples were collected for histological evaluation. Statistical significance between groups was evaluated by the Mann-Whitney U test. Significance was defined as $p < 0.05$.

Results: Proteinuria in the treatment group was significantly lower than in the control group (Day 9: antagonist group: 272.6 mg/kg/day, controls: 747.7 mg/kg/day, $p<0.05$). Same-day urine volume and serum creatinine values were not significantly different between the two groups (urine volume of Day 9: $p=0.82$, serum creatinine values of Day 9: $p=0.47$). Electron microscopy showed characteristic foot process fusion of podocytes in the control group, but not in the treatment group.

Conclusions: The results suggest that the ETA antagonist ambrisentan, an approved drug for pulmonary hypertension, acts directly on podocytes to exhibit an anti-proteinuric effect that is independent of renal vasoconstriction, and could potentially be used as a therapeutic agent for MCNS.

SA-PO274

B-Cell Signature in FSGS Rituximab Responders Chang-Yien Chan, Isaac Liu, Kar Hui Ng, Wee Song Yeo, Hui Kim Yap. *Paediatrics, National Univ of Singapore, Singapore.*

Background: We recently reported a subgroup of FSGS patients bearing an immunological signature of T-cell hyporesponsiveness who responded to rituximab treatment, suggesting a possible role of B-T cell interactions in modulating podocyte injury. This study aimed to investigate the cytokine-producing "regulatory" and "effector" B-cell subsets in FSGS patients in order to elucidate the role of B-cells in FSGS rituximab responders.

Methods: 22 FSGS patients (median age 14.4 years) were recruited prospectively to receive rituximab. Median duration of follow-up was 26.7 months. At baseline, B-cells were isolated using CD19 microbeads and cultured for 4 hours with and without lipopolysaccharide (LPS). Cytokine levels in culture supernatant were quantified using multiplex suspension bead array system, and compared with 16 healthy controls using Mann-Whitney U test.

Results: 12 patients (54.5%) responded to rituximab therapy, defined as complete resolution of proteinuria with cessation of prednisone and calcineurin inhibitors within 3 months. Baseline B-cell production of IL-4, IL-13, Eotaxin and MCP-1 in FSGS rituximab responders were significantly higher than non-responders and controls. Following stimulation, IL-4, IL-13, MCP-1 and IL-10 levels were also significantly higher in responders. No difference was seen in IFNγ, IL-12 and TNFα.

Cytokines	Unstimulated			LPS-stimulated		
	Responders	Non-responders	Control	Responders	Non-responders	Control
IL-4	2.8±0.4[a,b]	1.7±0.3	1.6±0.3	5.1±0.6[a,b]	2.9±0.3	2.9±0.3
IL-13	0.9±0.2[a,b]	0.3±0.1	0.3±0.1	1.4±0.2[a,b]	0.5±0.2	0.7±0.2
Eotaxin	19.5±2.0[a,b]	12.6±1.8	13.2±1.9	19.5±2.8[a,b]	20.3±2.1	20.1±1.6
MCP-1	12.1±3.5[a,b]	2.9±0.6	3.6±1.1	55.5±36.6[a,b]	3.7±0.7	3.2±0.9
IL-10	3.5±1.0	2.0±0.4	3.2±1.2	6.4±1.8[a,b]	2.3±0.3	3.7±1.2

[a]$P<0.05$, comparing responders and non-responders; [b]$P<0.05$, comparing responders and healthy controls

Conclusions: FSGS rituximab responders demonstrated higher baseline levels of IL-4, IL-13 and MCP-1 producing Be-2 cells and IL-10 producing regulatory B-cells, possibly explaining the T-cell hyporesponsiveness.

SA-PO275

Cytokine Profiling of Pediatric Minimal Change Nephrotic Patients Wee Song Yeo, Chang-Yien Chan, Isaac Liu, Kar Hui Ng, Hui Kim Yap. *Pediatrics, National Univ of Singapore, NUHS, Singapore.*

Background: Studies examining the etiology of minimal change nephrotic syndrome (MCNS) have suggested a role for cytokine(s) in its pathogenesis. The results of these studies have been mixed. This study aimed to reconcile the cytokine profile in MCNS patients using high throughput multiplexed Luminex® assay.

Methods: Forty MCNS patients (median age 12 years, range 3-25 years), of whom 12 had paired samples in relapse and remission, were analyzed. Paired blood samples were obtained from these patients when they were: i) Not on any treatment during blood sampling, or ii) On prednisolone only during relapse and remission for steroid-dependent patients. Forty aged-matched controls and seven pediatric focal segmental glomerulosclerotic (FSGS) patient controls were included in the analysis. Plasma cytokine profiling was performed using multiplexed Luminex® Cytokine Human 27-Plex assay. Statistical analysis was performed using Wilcoxon signed-rank test and Mann-Whitney U with a p-value of less than 0.05 considered as statistically significant.

Results: Of the 27 cytokines analyzed, there was no significant difference in each measured plasma cytokine level between controls and MCNS patients in remission. There were significantly higher plasma levels of IL-1b, IL-1RA, TNF-α, IL-6, IL-2, IL-5, IL-9, IL-13, IL-10, PDGF-BB, IL-8 and a significantly lower plasma level of RANTES in MCNS patients in relapse compared to controls ($p<0.05$). FSGS patients in relapse had significantly higher plasma levels of IL-1RA, IL-10 and PDGF-BB compared to controls ($p<0.05$). In the paired analysis, there were significantly higher plasma levels of IL-6, IL-15, IL-4, IL-5, IL-13, IL-17, IL-10, and VEGF in MCNS patients in relapse compared to remission ($p<0.05$). Common cytokines that were consistently significantly different between MCNS patients in relapse and remission/controls in both paired and unpaired analyses were IL-5, IL-6, IL-10, and IL-13, majority of which were Th2-related cytokines.

Conclusions: Cytokine profiling of pediatric MCNS patients in relapse demonstrated a Th2-cytokine bias, distinctly different from FSGS patients. Further mechanistic studies are required to ascertain the roles of these cytokines in the pathogenesis of MCNS.

Funding: Government Support - Non-U.S.

Altered B Cell Homeostasis in Nephrotic Syndrome Pediatric Patients Marina Vivarelli, Manuela Colucci, Giorgia Corpetti, Francesco Emma. *Nephrology, Bambino Gesù Pediatric Hospital - IRCCS, Rome, Italy.*

Background: A pathogenic role of B cells in non-genetic nephrotic syndrome (NS) has been suggested by the efficacy of rituximab, a B cell–depleting antibody, in inducing a prolonged remission. However, little or no information is available on B cell homeostasis in NS patients.

Methods: We retrospectively evaluated by flow cytometry levels of B cell subsets in 19 healthy age-matched children (HCs) and in 66 NS pediatric patients in different states of disease (37 in active disease and 29 in remission) and treated with differently combined immunosuppressive agents. 20 patients were at disease onset (active disease before any treatment), 17 were at relapse (12 treated with prednisone (PDN), 1 with cyclosporine (CSA), and 2 with PDN+CSA), and among the patients in remission, 7 were treated with PDN+mycophenolate mofetil (MMF), 13 with PDN+CSA/tacrolimus, and 9 with PDN+MMF+CSA/tacrolimus (triple immunosuppression).

Results: At onset, patients presented comparable levels of $CD19^+$, transitional, and total memory B cells respect to HCs, whereas mature B cells were reduced ($p<0.01$) and switched memory B cells were increased ($p<0.05$). Levels of B cell subsets did not significantly differ between patients at onset and in relapse, despite PDN and CSA treatment. Prednisone alone did not seem to have any effect on B cell subpopulations. $CD19^+$ levels were significantly reduced only in patients undergoing triple immunosuppression when

compared to HCs, patients at onset and patients in relapse ($p< 0.01$). Association of PDN with one or two IS drugs mainly affected transitional B cells ($p<0.001$ for all treatments compared with HCs and patients at onset), and mature B cells were mainly reduced in patients treated with PDN+MMF (with or without CSA/tacrolimus treatment; $p<0.02$ vs patients at onset). Immunosuppressive treatment excluding rituximab did not significantly modify memory B cell levels.

Conclusions: At onset, prior to all immunosuppressive treatment, patients with nephrotic syndrome seem to have reduced mature and increased switched memory B cells. Prednisone, non-steroidal and non–antiCD20 immunosuppressive treatment seems unable to modify these B cell subset alterations.

Enhanced Monocyte Responses to Toll-Like Receptor (TLR) and Inflammasome Stimuli in Chronic Kidney Disease Serika D. Naicker,[1] Susan Logue,[1] Grace A. O'Malley,[1] Matthew D. Griffin.[1,2] *[1]School of Medicine, Regenerative Medicine Inst (REMEDI), National Univ of Ireland, Galway, Ireland; [2]Nephrology Services, Galway Univ Hospital, Saolta Univ Health Group, Galway, Ireland.*

Background: CKD is associated with systemic inflammation but the stimuli and pathways responsible remain poorly understood. We compared the profiles and responses of blood monocytes to TLR ligands ± the inflammasome activator extracellular (e)ATP in healthy adults and subjects with CKD.

Methods: Peripheral blood mononuclear cells (PBMCs) from healthy adults (Ctrl, n=23) and adults with CKD stages 2-5 (n=90) were analyzed by 8-colour flow cytometry to quantify monocyte subsets and their expression of TLRs and the ATP-binding receptor P2X7R. PBMCs were stimulated with TLR4 (LPS, 0.5ng/ml) or TLR7/8 (R848, 50ng/ml) ligands for 2hrs followed by eATP(5mM) for 45mins ± P2X7R blocker. Additionally, healthy adult PBMCs were cultured with 5% Crtl or CKD serum during activation. Cytokines were quantified by ELISA. Assay results were correlated with clinical and laboratory indices. Statistical analyses were performed using GraphPad Prism© software.

Results: Surface P2X7R (but not TLR2,4,7,8) was increased on classical($CD14^{++}CD16^{-}$) monocytes of CKD compared to Ctrl and correlated with serum uric acid and total cholesterol. Monocyte release of IL-1β following TLR4 or TLR7/8 + eATP was greater for CKD3/4 compared to Ctrl and was partially suppressed by P2X7R blockade. LPS/eATP-triggered IL-1β release correlated with classical monocyte count and with eGFR. R848/eATP-triggered IL-1β release correlated with intermediate($CD14^{++}CD16^{+}$) and non-classical($CD14^{-}CD16^{++}$) monocyte count, serum creatinine and with eGFR. LPS and R848-triggered release of TNFα and IL-6 was greater for CKD3/4 compared to Ctrl irrespective of eATP presence. Culture of healthy PBMCs with serum from CKD compared to Ctrl resulted in greater TNFα (but not IL-1β or IL-6) release following LPS+eATP.

Conclusions: Our results indicate that CKD is associated with altered inflammatory response profiles of classical and intermediate monocytes involving multiple TLR pathways and the inflammasome. The mechanism underlying monocyte inflammatory profiles in CKD is likely to be multi-factorial.

Increased Neutrophil Extracellular Trap (NET) Formation Is Associated with Chronic Inflammation and Coronary Artery Disease in Uremic Patients Jwa-Kyung Kim,[1] Sun Ryoung Choi,[2] Jae-Won Lee,[3] Sung Gyun Kim.[1] *[1]Internal Medicine, Kidney Research Inst, Hallym Univ Sacred Heart Hospital, Anyang, Korea; [2]Internal Medicine, Sahmyook Medical Center, Seoul, Korea; [3]Internal Medicine, G sam Hospital, Anyang, Korea.*

Background: Neutrophils are involved in the pathogenesis of atherosclerosis by neutrophil extracellular traps (NETs) formation. End-stage renal disease (ESRD) patients have extremely higher mortality rate because of uremic toxins-associated inflammation and advanced ahterosclerosis, We hypothesized that the NETs formation of neutrophils might be changed in ESRD patients, leading to the higher prevalence of cardiovascular diseases.

Methods: A cross-sectional study was performed in 60 maintenance hemodialysis (MHD) patients, 30 age- and sex-matched healthy individuals (HV, negative control), and 30 patients with acute infection (positive control). Neutrophil activation and function was measured with reactive oxygen species (ROS) activity, degranulation, and NET formation. Also, changes of neutrophil phenotypes were assessed.

Results: Compared with HV patients, neutrophils extracted from MHD individuals displayed significantly higher levels of basal NET formation as well as ROS production, indicating that they were activated spontaneously. The median levels of NET fluorescence were 5187.3, 7767.6, and 9784.2 in the HV, MHD, and positive control groups, respectively. And neutrophils from HV patients were normal $CD16^{bright}/CD62L^{bright}$ cells; however, neutrophils from MHD patients were $CD16^{bright}/CD62L^{dim}$, similar to those from patients with acute infections. Baseline NET formation was positively correlated with the prevalent coronary artery disease (CAD), peripheral neutrophil count, and inflammatory markers such as neutrophil/lymphocyte ratio, and hs-CRP levels. Multivariate analyses identified the prevalent CAD and neutrophil counts as independent predictors of baseline NET formation ($\beta=0.323, p=0.016$ and $\beta=0.369, p=0.006$, respectively).

Conclusions: In ESRD, NET formation is significantly increased at basal state, and it has a close relationship with *in vivo* inflammatory conditions and prevalent CAD. Baseline neutrophil activation may be a sign of the presence of atherosclerotic vascular complications.

Increased Tubulointerstitial Recruitment of Human Natural Killer Cells in Renal Fibrosis and Chronic Kidney Disease Helen G. Healy,[1,2] Becker Meng-Po Lo,[1,2,3] Xiangju Wang,[1,2] Andrew J. Kassianos,[1,2,3,4] Ray Wilkinson.[1,2,3,4] *[1]Conjoint Kidney Laboratory, Pathology Queensland, Brisbane, Queensland, Australia; [2]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; [3]Faculty of Health, Queensland Univ of Technology, Brisbane, Queensland, Australia; [4]School of Medicine, Univ of Queensland, Brisbane, Queensland, Australia.*

Background: Natural killer (NK) cells are innate lymphoid cells that play a significant role in immune surveillance of stressed autologous cells. Mouse studies suggest a pathological role for NK cells in immune-mediated models of kidney disease. This study evaluates the NK cell profile in human fibrotic chronic kidney disease (CKD).

Methods: We extracted NK cells from healthy kidney tissue and diseased biopsies with and without fibrosis. NK cell subsets were identified, enumerated and phenotyped by twelve-colour flow cytometry. Localisation of NK cell subsets was examined by multi-colour immunofluorescent microscopy.

Results: We detected significantly elevated numbers of total NK cells ($CD3^{-}CD56^{+}$) in diseased biopsies with interstitial fibrosis compared with diseased biopsies without fibrosis and healthy kidney tissue. Numbers of both the $CD56^{dim}$ NK cell subset and, in particular, the $CD56^{bright}$ NK cell subset, were also significantly elevated in fibrotic kidney tissue. The increased numbers of $CD56^{bright}$ NK cells correlated significantly with loss of kidney function (eGFR). Furthermore, expression of the activation molecule CD69 on $CD56^{bright}$ NK cells was significantly increased in fibrotic biopsies compared with non-fibrotic kidney tissue, indicative of a pathogenic phenotype. Chemokine receptor analysis showed CXCR3 and CX3CR1 expression on $CD56^{bright}$ NK cells. Immunofluorescent staining of fibrotic kidney tissue localised the accumulation of NK cells within the tubulointerstitial compartment.

Conclusions: The correlation of activated $CD56^{bright}$ NK cells with functionally more severe CKD suggests a pathological role. Further functional dissection of this NK cell subset is necessary for the development of therapeutics capable of blocking this previously untargeted immune cell population.

Leukemia Inhibitory Factor Attenuates Tubulointerstitial Fibrosis by Suppression of Pro-Inflammatory Cytokines Sebastian Alexander Potthoff, Fabian Srugies, Lars C. Rump, Ivo Quack. *Nephrology, Medical Faculty - Heinrich-Heine Univ, Duesseldorf, Germany.*

Background: Tubulointerstitial fibrosis is common in chronic kidney disease which is often sustained by chronic inflammation. CD4+ T-cells play an important role in immune response in kidney disease. Leukemia inhibitory factor (LIF), a member of the Interleukin 6 family, and Interleukin 6 (IL-6) play a crucial role in regulating the balance between Th17- and regulatory T-cells (Treg): LIF augments expression of forkhead-box-P3 (Foxp3) leading to Treg, IL-6 induces RAR-related orphan receptor gamma (RORyt) driving Th17 lineage development. Dysregulation or overproduction of Th17 cells result in sustained inflammation. Here, we showed that LIF influences inflammatory response in a UUO model.

Methods: 6-week old male C57BL/6 mice were treated intraperitoneally daily either with LIF (10µg/kgBW; n=6 day 3;n=7 day 10) or PBS (control;n=8 day 3;n=8 day10). 3 and 10 days after UUO, kidneys, spleen and paraaortal lymphnodes were extracted.

Results: LIF treatment significantly reduced tubulointerstitial fibrosis in obstructed kidneys. qPCR from tissue lysates of obstructed kidneys day 3 (OB) revealed that IL-1b, MCP-1, RANTES, IL-6, TNF-α, Col1a1, TGFß and PAI-1 were upregulated in LIF treated mice. In contrast, qPCR from tissue lysates of obstructed kidneys day 10 (OB) revealed that NFκB and RANTES as well as collagen1 and TGF-β were significantly downregulated in LIF treated mice. There was no significant difference between IL17a, IL-1b, MCP1, IL-6, TNFα, PAI1 and PDGFR1. Accordingly, expression of MCP1, NFκB, RANTES and TNFα in paraaortal lymphnodes were reduced by LIF. IL-1b and IL-6 expression were reduced by LIF but failed to reach statistical significance. CD3+cells accumulated in obstructed kidneys. LIF significantly reduced CD3+cells at day 10 (OBvs.OB+LIF: 144±6vs.115±8; $p<0.01$) but not day 3. LIF treatment lead to a significant increase of the anti-inflammatory cytokine IL-10 ($p<0.001$) and downregulated pro-inflammatory IL-6, RANTES or G-CSF in plasma.

Conclusions: These data confirm the critical role of inflammation in UUO. LIF treatment suppresses a prolonged inflammatory response after UUO and therefore protects against tissue injury and fibrosis.

T-Cell Depletion Improves Diastolic Dysfunction in Mice with Uremic Cardiomyopathy Pamela D. Winterberg,[1] Mandy L. Ford.[2] *[1]Pediatric Nephrology, Emory Univ; [2]Dept of Surgery, Emory Univ, Atlanta, GA.*

Background: Uremic cardiomyopathy, characterized by left ventricular hypertrophy (LVH) and diastolic dysfunction, is a significant cause of morbidity and mortality among patients with chronic kidney disease (CKD), but the underlying mechanisms are incompletely understood. We aimed to determine whether T cells are involved in cardiac remodeling during CKD.

Methods: CKD was established in male 129X1/SvJ mice via two-stage partial nephrectomy with sham-operated mice serving as controls. CKD mice were further randomized to receive isotype antibody (Ab) or anti-CD3 Ab to deplete T cells. LVH

and diastolic dysfunction were assessed via echo at 6 weeks of CKD. Flow cytometry was performed to verify depletion of T cell populations in spleen, blood, and mediastinal lymph nodes and to characterize memory (CD44) and activation (PD-1) status of T cells. Blood pressures were measured using the tail-cuff method. Kidney function was assessed via measurement of plasma urea and cystatin C concentrations.

Results: Mice with CKD developed LVH and diastolic dysfunction as previously described, and displayed enlarged mediastinal lymph nodes (mLN) and accumulation of T cells bearing markers of activation (PD-1) and memory differentiation ($CD44^{hi}$) in spleen and mLN. Anti-CD3 Ab resulted in 100-fold reduction of T cell counts in blood and 50-75% reduction in splenic T cell counts compared to sham controls. Measures of diastolic function including isovolumic relaxation time (IVRT: isotype 22.3 ± 2.28 vs anti-CD3 16.9 ± 2.25 ms; $p<0.01$), myocardial performance index (0.63 ± 0.05 vs 0.48 ± 0.08; $p<0.001$) and trans-mitral flow index (E/A ratio: 0.9 ± 0.14 vs 1.2 ± 0.23; $p<0.01$) improved in CKD mice receiving T cell depletion, however, LVH, systolic blood pressure and measures of renal function were unaltered.

Conclusions: Mice with uremic cardiomyopathy have profound alterations in T cell differentiation and activation status including mediastinal lymphadenopathy. Depletion of T cells improved diastolic function in mice with CKD independent of blood pressure and kidney dysfunction. We are pursuing further work into the mechanisms by which T cells mediate diastolic dysfunction during uremic cardiomyopathy.

SA-PO282

Sulfatide-Selective NKT Cells Mediate M2 to M1 Polarization Resulting in Amelioration of Kidney Fibrosis Sunhwa Lee,[1] Seung Hee Yang,[1] Yong Chul Kim,[2] Mi-Yeon Yu,[2] Seung Seok Han,[1] Hajeong Lee,[2] Jung Pyo Lee,[3] Ran-Hui Cha,[4] Dong Ki Kim,[2] Yon Su Kim.[2] *[1]Biomedical Research Inst, Seoul National Univ; [2]Seoul National Univ Hospital; [3]Seoul National Univ Boramae Medical Center; [4]National Medical Center.*

Background: Kidney fibrosis is the major pathological features of chronic kidney disease, and currently efficient treatment for kidney fibrosis is absent. Macrophage subtype polarization has been suggested as a key player related to kidney fibrosis. However, the immunomodulatory role of natural killer T (NKT) cell in macrophage transdifferentiation has not been elucidated.

Methods: Sulfatide-selective NKT II cells from unilateral ureteral obstruction (UUO) B6.Jα281$^{-/-}$ mice lacking the invariant type I NKTs were used to elucidate its impact on phenotypic switch of bone marrow derived M1/M2 macrophages and interstitial fibrosis. A co-culture system, primary cultured proximal epithelial cells with sulfatide-selective type II NKT cells, was designed. In addition, macrophages stimulated by Sulfatide-selective NKT cells were adoptively transferred to the kidney capsule of WT and B6.Jα281$^{-/-}$ on the 7th day of UUO, followed by isolation of total cellular RNAs from minced kidney tissue for microarray.

Results: Severity of renal fibrosis of B6.Jα281$^{-/-}$ was attenuated comparing to WT. Subsequently added Sulfatide-selective NKT cells stimulated transdifferentiation from M2 to M1 accompanying by increased iNOS, STAT1, SOCS3 and decreased arginase, STAT3, followed by reducing fibrosis in proximal tubular epithelial cells. Profibrotic transcripts, fibronectin and TGFβ, decreased by adding sulfatide-selective NKT induced M1 of B6.Jα281$^{-/-}$ to macrophage-depleted B6.Jα281$^{-/-}$. Moreover, the expression level of NGAL and IL-1β, a marker of kidney damage and inflammation, was attenuated. At the same time, diminution of immunologic transcripts such as CD44, CCL5, CCL9, and macrophage mannose receptor 1 was also observed.

Conclusions: Sulfatide-selective NKT cell mediates transdifferentiation from M2 to M1 macrophage via switching on STAT1 resulting in ameliorating renal fibrosis. Inducing the polarization of macrophages by modulation of NKT cells can be suggested as therapeutic target for curbing fibrosis.

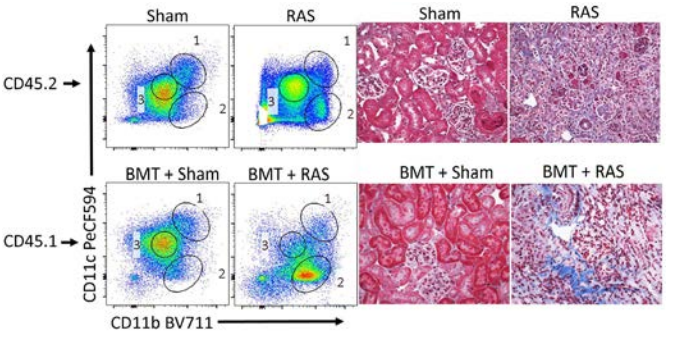
Reparative Renal Macrophages Contribute to Curtailing Fibrosis in the Stenotic Murine Kidney Amrutesh Puranik,[1] John R. Woollard,[1] Luke Barron,[3] Kyra L. Jordan,[1] Hui Tang,[1] Stephen C. Textor,[1] Jeremy Stuart Duffield,[3] Lilach O. Lerman.[1] *[1]Divs of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Biogen, Cambridge, MA.*

Background: We have previously demonstrated that chronic renal artery stenosis (RAS) induces increase in $CD64^{+}F4/80^{high}CD11b^{int}CD11c^{int}$ macrophages (MΦ3s) and that these protect against renal fibrosis in RAS. This study tested the hypothesis that renal MΦ3s are partly derived from bone marrow (BM), but the replenished MΦ3s might not abolish fibrosis effectively.

Methods: Wild type C57 CD45.2 mice underwent whole-body irradiation. Within 6 hours, BM cells obtained from donor CD45.1 mice were transplanted (BMT) retro-orbitally. After a reconstitution period of 60 days, unilateral RAS was induced and stenotic kidneys harvested 28 days later to study MΦ3s populations (polychromatic flow cytometry) and assess fibrosis (trichrome). Wild type mice 28 days after RAS or Sham served as controls. We also examined the ability of MΦ3s in vitro to inhibit TGFb-induced induction of pro-fibrotic genes (qPCR) and protein (FlowSight, Millipore) in murine embryonic fibroblast (MEF) obtained from Cola1-gfp mice.

Results: Flow cytometry data showed that in BMT+Sham MΦ3s repopulate from donor-derived (CD45.1) BM (Figure). However, upon induction of RAS in BMT mice, the donor-derived MΦ3s decreased significantly in RAS+BMT compared to untreated RAS and Sham kidneys, and mice with BM-derived MΦ3 experienced enhanced fibrosis.



In vitro, MΦ3s blunted expression of TGFb-induced profibrotic genes in MEF.

Conclusions: BM can regenerate MΦ3s in healthy kidneys following radioablation, but are incapable of sustaining their MΦ3 phenotype and anti-fibrotic properties in response to kidney injury. Hence, endogenous renal MΦ3s protect the stenotic kidney against injury more effectively than BM-derived MΦ.

SA-PO284

The Immunoglobulin Heavy Chain Locus Enhances Susceptibility to Renal Injury in Hypertensive Rats Isha Dhande,[1] Stacy M. Cranford,[1] Yaming Zhu,[1] Manuel Leonardo Gonzalez-Garay,[1] Scott E. Wenderfer,[2] Michael C. Braun,[2] Peter A. Doris.[1] *[1]Inst of Molecular Medicine, Univ of Texas Health Science Center at Houston, Houston, TX; [2]Dept of Pediatrics, Baylor College of Medicine, Houston, TX.*

Background: Hypertensive renal injury involves an immune component, though the specific molecular pathways are incompletely understood. We have demonstrated that high levels of genetic divergence exist in the immunoglobulin heavy chain (IgH) locus across the renal injury-prone spontaneously hypertensive rat SHR-A3 strain and the closely related SHR-B2 strain that resists renal injury. This divergence affects the complement of VDJ genes and creates functional variation in Fc encoding genes in the IgH locus. Additionally, serum IgG levels are genetically determined by sequence variation in the IgH locus across these two lines. We hypothesized that congenic substitution of the IgH locus from SHR-B2 into the SHR-A3 genetic background to create SHR-A3(chr6-IgH-SHR-B2) will reduce renal injury without affecting BP in this model.

Methods: We generated a congenic rat line in which the SHR-B2 IgH locus was transferred by backcrossing onto the SHR-A3 genetic background. The congenic status of the line was confirmed by genome-wide SNP genotyping and by examining serum IgG levels. BP was measured in conscious, unrestrained rats by telemetry for 7 weeks starting at age 18 weeks of age, when renal injury begins to emerge in SHR-A3 rats. Urine and kidneys were collected at 40 weeks of age to assess albuminuria and renal injury.

Results: Measurements of BP by telemetry indicated no difference between SHR-A3 and the congenic line both before and during the emergence of renal damage and proteinuria. Glomerular and tubulointerstitial injury, but not albuminuria, were significantly reduced in the congenic line compared to SHR-A3 rats at 40 weeks of age.

Conclusions: Our findings provide evidence that genetic variation in the IgH locus contributes to susceptibility to glomerular and tubular injury, independently of hypertension in SHR-A3 rats. However, factors distinct from the IgH variation possibly contribute to the complex phenotype of urinary albumin excretion.

SA-PO285

Hemoglobin Levels Increased by ESA Suppress the Progression of Renal Injury in Chronic Glomerulonephritis Rats Ryohei Kawasaki, Yoshihito Tashiro, Ken Aizawa, Yasushi Shimonaka, Michinori Hirata. *Product Research, Chugai Pharmaceutical Co., Ltd., Kamakura, Kanagawa, Japan.*

Background: It has been reported that erythropoiesis stimulating agents (ESAs) confer renoprotection in several kidney disease models. We previously reported that a single injection of epoetin beta pegol (continuous erythropoietin receptor activator; C.E.R.A.) conferred more effective renoprotection than a single injection of epoetin beta (EPO) in chronic glomerulonephritis (cGN) rats. At that time, hemoglobin levels were higher in the C.E.R.A-treated group than in the EPO-treated group in the early phase of the disease. Therefore, we evaluated whether hemoglobin levels increased by ESA affect the amelioration of renal injury in cGN rats.

Methods: To increase hemoglobin levels, EPO (1,000 IU/kg) was intravenously injected into rats (F344, 6 wks old, male) once on Days 0 (EPO first injection), 2 and 4. cGN was induced by injection of anti-Thy1.1-antibody (OX-7, 0.6 mg/kg, i.v.) to uninephrectomized rats (7 wks old) 5 days after the last EPO injection (Day 9) in order for EPO not to affect the amelioration of renal injury directly. To evaluate renal function, 24-hr urinary total protein (uTP) and 24-hr liver-fatty acid-binding protein (L-FABP) levels were measured at Day 67. Hemoglobin levels and EPO levels in blood were measured at cGN induction (Day 9).

Results: Hemoglobin levels were significantly higher in the EPO-treated group than in the vehicle-treated group (15.5 ± 0.1 vs. 12.9 ± 0.1 g/dL, mean ± SEM, n=15, $p<0.05$) at the cGN induction (Day 9). At that time, plasma EPO was not detected in either group. In the vehicle-treated cGN group, uTP levels (212.1 ± 16.6 mg/day, n=10) and L-FABP

levels (287.7 ± 28.6 ng/day, n=10) were high at Day 67. In the EPO-treated cGN group, uTP levels (93.8 ± 14.4 mg/day, n=10, p<0.05) and L-FABP levels (141.3 ± 18.1 ng/day, n=10, p<0.05) were significantly lower than those in the vehicle-treated cGN group at Day 67.

Conclusions: This study suggested that hemoglobin levels themselves increased by ESA could suppress the progression of renal injury in cGN rats.

SA-PO287

NaCl - Hypertonicity Inhibits the Cross-Priming Capacity of Dendritic Cells Zoran Popovic, Federica Chessa, Mahnaz Bonrouhi, Viola Nordström, Hermann-Josef Groene. *Dept of Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany.*

Background: Biophysical microenvironmental signals may modulate gene expression pattern and functional signature of infiltrating and resident mononuclear phagocytes. Tissue hyperosmolarity may be associated to physiologic and pathologic conditions, including both inflammation and neoplasia. Cross-priming is crucial for initiation of a specific cytotoxic immune response.

Methods: Here, we examined how a hyperosmotic microenvironment (340 mOsm – 450 mOsm) affects cross-priming capacity of dendritic cells. We applied ex vivo antigen uptake, processing, presentation and cross-priming assays involving murine bone marrow-derived dendritic cells; and stimulated emission depletion (STED) imaging as well as proximity ligation assay to analyze surface receptor cluster formation.

Results: Exposure of dendritic cells to hyperosmotic micromilieu inhibited the cross-priming in a NFAT5-independent manner. A significant inhibition of cross-priming has been achieved by application of nonionic osmolyte mannitol as well. We have observed TRIF as a key mediator of this phenomenon. Moreover, we have identified a hypertonicity-triggered, TRIF-dependent clustering of MHC class I – SIINFEKL complexes, but not of single MHCI molecules, associated with reduced dendritic cell – T cell contact. Our in vivo data using a renal allotransplantation approach has shown a similar distribution of T lymphocytes across kidney compartments of normotonic cortex and hyperosmolar medulla upon transplantation to TRIF-deficient recipients.

Conclusions: Collectively, this study provides evidence that high salt reduces cross-priming and suggests a novel mechanism of antigen-specific immune response inhibition in hyperosmolar microenvironments.

SA-PO288

Renal Sodium Gradient Orchestrates a Dynamic Antibacterial Defence Zone Miriam Berry, Rebeccah J. Mathews, Chenzhi Jing, Menna R. Clatworthy. *Dept of Medicine, Univ of Cambridge, United Kingdom.*

Background: Urinary tract infections are one of the commonest bacterial infections in humans yet infection of the renal parenchyma (pyelonephritis) is relatively rare. This protection is often attributed to the anterograde flow of urine which limits the ascent of bladder microbes. The medulla is the region of the kidney most vulnerable to infection, and also presents a novel environmental challenge to bacteria and resident immune cells due to the regional hypersalinity generated in order to concentrate urine. Little is known about mechanisms of innate immunity that protect the human kidney from infection, nor the modulating role played by the specialised micro-environment.

Methods: We characterised human kidney macrophages and DCs (mononuclear phagocytes, MNPs) using entire human kidneys, and evaluated the effect of the renal micro-environment on their role in defence against infection.

Results: We show that to counter the threat of bacterial infection, the mammalian immune system uses the renal sodium gradient to position functionally specialised MNPs in the region of the kidney most susceptible to infection. In human renal medulla, we identified an enrichment of MHC II+ CD11c+ CD14+ MNPs that avidly phagocytosed UPEC and promoted neutrophil recruitment and activation via the production of interleukin (IL)8, IL6, and tumour necrosis factor (TNF) αlpha. The high sodium environment in the medulla orchestrated CD14+ MNP position by stimulating TonEBP-dependent production of chemokines (MCP1 and CX3CL1) by renal tubular epithelial cells. Upon bacterial challenge, MNPs secrete the epidermal growth factor-like molecule amphiregulin to enhance epithelial survival and chemokine production, further amplifying local immunity. Increased extracellular sodium also optimised the antibacterial functions of MNPs, such that developmental, pharmacological or pathological disruption of the intrarenal sodium gradient in mice and humans resulted in aberrant MNP localisation and susceptibility to pyelonephritis and sepsis.

Conclusions: We show that urinary concentrating mechanisms essential for homeostasis in terrestrial mammals also act as a cue to optimise local immune defence in the kidney.

SA-PO289

Clinical Factors Associated with the Gene Expression of Angiotensin II Type 1 Receptor-Associated Protein on Human Leukocytes Kotaro Haruhara,[1,2] Kouichi Tamura,[1] Hiromichi Wakui,[1] Masato Ohsawa,[1] Kengo Azushima,[1] Kazushi Uneda,[1] Sona Haku,[1] Ryu Kobayashi,[1] Kohji Ohki,[1] Sho Kinguchi,[1] Nobuo Tsuboi,[2] Takashi Yokoo.[2] *[1]Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Previous studies have shown that the leukocyte gene expression of the renin-angiotensin system, particularly type1 angiotensin II receptor (AT1R), is involved in the pathogenesis of non-communicated diseases and target organ diseases. We found that AT1R-associated protein (ATRAP) is a novel molecule that specifically binds to AT1R and promotes internalization of AT1R along with the suppression of activated AT1R signal in animal models of non-communicated diseases. The aim of this study is to determine the factors that may regulate the gene expression of ATRAP on human leukocytes.

Methods: Blood samples were obtained from outpatients. The exclusion criteria were patients i) diagnosed with a hematological disease, ii) with a history of corticosteroid or immunosuppressive therapy within three months, and iii) undergoing renal replacement therapy. We examined the relationships between ATRAP mRNA on leukocytes and clinical variables.

Results: We obtained blood samples from 86 patients (mean age 63 years, hypertension in 95%, dyslipidemia in 76%, CKD in 63%). The ATRAP mRNA was positively correlated with the age, leukocyte count, neutrophil count, monocyte count, and serum CRP, and negatively correlated with the estimated urinary sodium chloride excretion and serum triglyceride levels. These associations remained significant after adjustment for age, sex, estimated glomerular filtration rate, and urinary albumin excretion. Furthermore, the ATRAP mRNA was positively correlated with the interleukin-1β and toll-like receptor 4 mRNA on leukocytes. In contrast, blood pressure, diabetes status, and the indices of arterial stiffness were not significantly associated with the ATRAP mRNA in these patients.

Conclusions: These results suggest that aging, inflammation, and dietary contents are involved in the regulation of the gene expression of ATRAP on human leukocytes.

SA-PO290

Knockdown of UGCG Induces Renal Tertiary Lymphoid Organ Formation Tess Dupre,[1] Kumar Saurabh,[2] Deanna L. Siow,[1] Cierra Sharp,[1] Levi J. Beverly,[2] Leah J. Siskind.[1] *[1]Pharmacology/Toxicology, Univ of Louisville; [2]Medicine, Univ of Louisville.*

Background: Glycosphingolipids (GSLs) are thought to play a role in a number of kidney pathologies including aging-related declines in kidney function, lupus nephritis, diabetic nephropathy, and transplant rejection.

Methods: To study the role of GSLs in kidney biology and pathology, we generated mice containing a doxycyline inducible shRNA that targets expression of UGCG (Tet-O-shUgCg); UGCG is the gene that encodes for glucosylceramide synthase, the enzyme that catalyzes synthesis of glucosylceramide from ceramide. Tet-O-shUgCg mice were bred with $CAG^{+/-}$rtTA3 mice (CAG-rtTA3/Tet-O-shUgCg) for universal expression of the shRNA.

Results: Following UGCG knockdown (KD), organized accumulations of CD19+ B cells and CD3e+ T cells associated with PNAd+ lymphatic vessels formed in the kidneys, which are defining features of tertiary lymphoid organs (TLOs). TLOs are are ectopic accumulations of lymphoid cells that can arise in areas of chronic inflammation via lymphoid neogenesis. In addition, cytokines and chemokines associated with both inflammation and TLO formation were increased following doxycycline administration to CAG-rtTA3/Tet-O-shUgCg mice but not control mice. To elucidate whether TLO formation in the kidneys was due to UGCG KD in the hematopoietic system or in the kidney (or both), bone marrow chimera experiments were performed. Data indicate that UGCG KD in either the bone marrow or the kidney was sufficient to induce TLO formation, as both control mice receiving CAG-rtTA3/Tet-O-shUgCg bone marrow and CAG-rtTA3/Tet-O-shUgCg mice receiving control bone marrow showed evidence of TLO formation. Data also indicate that TLO formation was not specific to the kidney as it was observed in the lungs and liver following UGCG KD.

Conclusions: Understanding the mechanism by which KD of UGCG expression leads to TLO formation and identifying the specific lipids responsible for this phenotype will improve our understanding of the role for GSLs in chronic inflammation and lymphoid neogenesis in a variety of disease states.

SA-PO291

Acute Interstitial Nephritis Secondary to Programmed Death-1 Blockade: Role for Loss of PD-L1 Inhibition of T-Cell:MHC Class II Interaction on Renal Microvascular Endothelium Bairbre A. McNicholas, Jonas M. Kwiatkowski, Mark Joseph Manalang Torres, Susan K. Anderson, Kimberly A. Muczynski. *Div of Nephrology, Univ of Washington, Seattle, WA.*

Background: Human renal microvascular endothelial cells (RMEC) normally express high levels of MHC class II. Role for the high level of MHC Class II on RMEC without associated inflammation remains unexplained but may be a mechanism for peripheral immune tolerance. We have previously shown that isolated RMEC activate T cells in a class II-peptide dependent manner leading to T cell proliferation and cytokine secretion. This

effect is blocked by antibodies to CD40, CD58 and HLA-DR and enhanced by antibodies to PD-L1 (B7-H1,CD274). We hypothesized that RMEC express PD-L1 in vivo to prevent or limit T cell activation to HLA class II presented peptides.

Methods: Normal human kidney from nephrectomies was reduced to single cell suspension for flow-cytometry. Surface expression of stimulatory and inhibitory second signaling components on RMEC ($CD34^{+,}$ $HLA\text{-}DR^{+}$, $CD45^{-}$) and renal-T cells ($CD45^{+}$, $CD3^{+}$) were assessed using 7 color-flow cytometry. Patients who developed AKI following PD-1 blockade with nivolumab were evaluated.

Results: RMEC express CD58, CD275 (ICOS L), CD274 (PD-L1), CD273 (PD-L2), B7-H3 and B7-H4. They lack CD80 and CD86. Renal T cells express CD2, CD28, CD274 (PD-L1) and CD279 (PD1), the receptor for CD274 and CD273. New PD-1 blocking monoclonal antibodies, such as nivolumab, are being used to treat advanced cancers by selectively blocking PD-1 interactions with ligands PD-L1 (CD274, B7H1) and PD-L2 (CD273, B7H2) present on tumor cells. We identified four cases of AKI in patients receiving PD-1 pathway blockade. Biopsies revealed an intense non-eosinophilic interstitial nephritis in the area of the class II expressing RMEC. No other causes of interstitial nephritis were identified from clinical history.

Conclusions: RMEC are poised to present peptide from circulating antigen to T-cells as an immune surveillance system, with the PD1 pathway functioning to restrain T cell activation. Acute interstitial nephritis following use of PD-1 monoclonal antibody may be due to loss of PD1 mediated immune checkpoint blockade.

Accumulation of Dysregulated Renal Mononuclear Phagocytes (rMoPh) and Th1 Cells in the Kidney of CD11c-Specific SHP-1 Knockout Mice

Mitsuharu Watanabe,[1] Keiju Hiromura,[1] Yoriaki Kaneko,[1] Yuko Ohishi,[1] Masato Kinoshita,[1] Toru Sakairi,[1] Hidekazu Ikeuchi,[1] Akito Maeshima,[1] Hiroshi Ohnishi,[2] Takashi Matozaki,[3] Yoshihisa Nojima.[1] *[1]Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Japan; [2]Dept of Laboratory Sciences, Gunma Univ Graduate School of Health Sciences, Japan; [3]Div of Molecular and Cellular Signaling, Dept of Biochemistry and Molecular Biology, Kobe Univ Graduate School of Medicine, Japan.*

Background: Renal mononuclear phagocytes (rMoPh) have attracted increasing attention because of their immunoregulatory roles in healthy and diseased kidneys (JASN 23:194, 2012). rMoPh simultaneously express traditional markers for either macrophages (such as F4/80) or dendritic cells (CD11c). We have previously reported that CD11c-specific ablation of protein tyrosine phosphatase, SHP-1, a negative regulator of hematopoietic cell signaling, spontaneously developed autoimmune nephritis in mice (J Immunol 2012, ASN 2015). To further explore mechanisms of renal injury of SHP-1 conditional knockout (SHP-1 CKO) mice, we characterized immune cells in the kidney.

Methods: Flow cytometry analysis were performed to characterize immune cells in the kidney of SHP-1 CKO and its control mice at 40 weeks.

Results: SHP-1 CKOdeveloped proliferative glomerulonephritis and tubulointerstitial nephritis. Immunohistochemical staining showed marked accumulation of $CD11c^{+}$ cells in both glomeruli and tubulointerstitial area and of $F4/80^{+}$ and $CD4^{+}$ cells in tubulointerstitial area of SHP-1 CKO. Flow cytometric analysis revealed that most $CD11c^{+}$ cells simultaneously expressed F4/80, suggesting that they are rMoPh. These cells showed lower expression of MHC class II, and higher expressions of CD11b, CX3CR1, and CCR5. In addition, rMoPh of SHP-1 CKO were more frequently positive for Ki67, a marker for proliferation, and produced more pro-inflammatory cytokines, TNFα and IL-6, than control mice. Flow cytometry also showed increased $CD4^{+}$ cells, predominantly producing IFNγ. The majority of $CD4^{+}$ cells had memory-phenotype ($CD62L^{low}CD44^{high}$), and the activated T cell marker, CD69.

Conclusions: CD11c-specific ablation of SHP-1 causes autoimmune nephritis characterized by the marked accumulation of dysregulated rMoph and Th1 cells.

IL-33-Mediated Expansion of Type 2 Innate Lymphoid Cells Ameliorates Progressive Glomerulosclerosis

Martina Becker,[1] Jan-Hendrik Riedel,[1] Mathis Duester,[1] Catherine Meyer-Schwesinger,[1] Rolf A. Stahl,[1] Ulf Panzer,[1] Jan-Eric Turner.[1] *[1]III.Medizinische Klinik, Univ Medical Center Hamburg, Hamburg, Germany; [2]Mill Hill Laboratory, T.*

Background: Over the last years, innate lymphoid cells (ILC) have been shown to play an important role in the immune systems response to different forms of infectious and non-infectious pathologies. Especially, IL-5- and IL-13-producing type 2 ILCs (ILC2s) have been implicated in repair mechanisms that are aimed at restoring tissue integrity after injury. Therefore, we characterized ILC populations in the human and murine kidney and addressed their role in a mouse model of CKD.

Methods: ILC populations in the human and murine kidney were analysed by flow cytometry. ILC2s were expanded in mice by treatment with recombinant IL-33. The effect of IL-33-mediated ILC2 expansion was tested in a mouse model of progressive glomerulosclerosis that is induced in BALB/c mice by injection of Adriamycin.

Results: In the present study, we show that ILC populations are present in in the human and murine kidney. A detailed characterization of kidney-residing ILC populations revealed that $IL\text{-}33R^{+}$ ILC2s are a major ILC subtype in the kidney of human and mice. Short-term IL-33 treatment in mice lead to sustained expansion of $IL\text{-}33R^{+}$ kidney ILC2s and ameliorated progressive chronic kidney disease induced by Adriamycin-injection in BALB/c mice. The IL-33 effect was independent of T and B cells but depended on the presence of ILCs for protection from progressive CKD. The tissue-protective mechanisms employed by IL-5- and IL-13-producing ILC2s included enhanced activation of alternatively activated macrophages, recruitment of eosinophils and limitation of neutrophil influx by downregulation of neutrophil-attracting chemokines.

Conclusions: In summary, we show that kidney-residing ILC2s can be effectively expanded by IL-33 in the mouse kidney and are central regulators of renal repair mechanisms. The presence of ILCs in the human kidney tissue, identifies ILCs as attractive therapeutic targets for chronic kidney disease in humans.

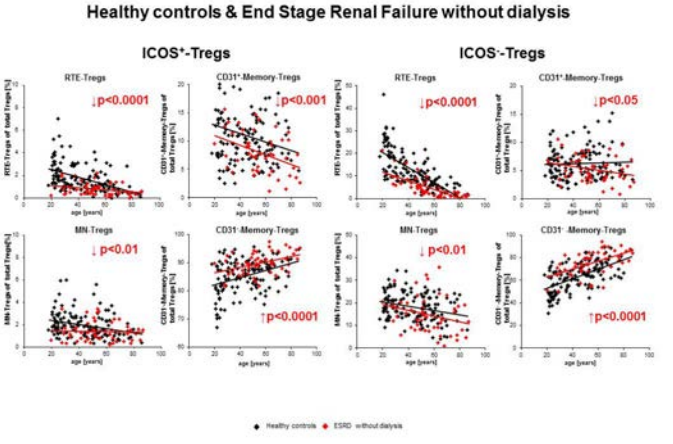
Renal Insufficiency and Impaired T-Cell Differentiation

Florian Kälble,[1] Angèle Leick,[1] Martin G. Zeier,[1] Andrea Steinborn,[2] Matthias Schaier.[1] *[1]Nierenzentrum Heidelberg, Univ of Heidelberg, Heidelberg, Deutschland, Germany; [2]Obstetrics and Gynaecology, Univ of Heidelberg, Heidelberg, Deutschland, Germany.*

Background: Regulatory T cells (Tregs) play a key role in maintaining immune homeostasis. The influence of renal insufficiency on Treg differentiation has not been elucidated. However patients with end-stage renal disease (ESRD) often present with an impairment of their immune system functions. The underlying mechanisms are not yet understood. Moreover the influence of a renal replacement therapy on a possible recovery of T-cell function needs further investigation.

Methods: Six-color flow cytometric analysis was used to determine the percentages of different subsets of naïve and memory T-cells within total $ICOS^{+}$- and $ICOS^{-}$-Tregs. Hence, the differentiation of both $ICOS^{+}$- and $ICOS^{-}$-RTE-Tregs in healthy patients (N=131), in patients with ESRD (N=49) and dialysis treatment (N=61) and in patients after kidney transplantation (N=190) could be analyzed.

Results: Patients with ESRD show significantly reduced amounts of naïve Tregs compared to healthy control patients, possibly induced by uremia toxins. Hence the share of highly differentiated CD31- memory Treg cells is increased reducing the adaptability of immune systems function.



However, after initiation of a hemodialysis treatment Treg cell function recovers as the percentage of naïve Tregs increased compared to ESRD patients without renal replacement therapy having started. This effect is even clearer after kidney transplantation.

Conclusions: Present data eludicate for the first time possible mechanisms underlying an impaired immune system of ESRD patients. The share of naïve Treg cells is significantly reduces compared to healthy control patients. Moreover evidence is given for a remarkable improvement after initiation of a renal replacement therapy.

SA-PO295

NET-Inducing Capacity Is a Potential Biomarker in MPA and GPA Independent of ANCA Antibodies

Tineke Kraaij,[1] Sylvia Kamerling,[1] Jaap A. Bakker,[1] Francesca Brunini,[2] Charles D. Pusey,[2] Rene Toes,[1] Hans Ulrich Scherer,[1] Ton J. Rabelink,[1] Cees van Kooten,[1] Yoe Kie Onno Teng.[1] *[1]Nephrology, Clinical Chemistry, Rheumatology, Leiden Univ Medical Center, Netherlands; [2]Imperial College, London, United Kingdom.*

Background: Neutrophil extracellular traps (NETs) play an important role in the pathogenesis of ANCA-associated vasculitis (AAV). Sera of MPO-ANCA or PR3-ANCA positive patients can induce NETs in vitro. This study investigates whether NET induction could serve as a biomarker in MPO- and PR3-positive AAV patients.

Methods: Healthy neutrophils were stimulated with 10% serum from 62 GPA patients, 37 MPA patients and 18 healthy subjects. NETs were imaged by automated 3D confocal microscopy. NET-inducing capacity was defined as fold increase of quantified NETs relative to healthy controls. To investigate NET induction by ANCA autoantibodies, IgG was isolated using protein G agarose beads. IgG depletion in the flow through was confirmed with ELISA.

Results: Both GPA and MPA samples showed significantly higher NET-inducing capacity (fold change mean±SEM for GPA 40±7.4, $p<0.0001$ and for MPA 153.2±44.9, $p<0.01$). MPA sera had a significantly higher NET-inducing capacity than GPA ($p<0.0001$).

In 14 AAV patients who had seroconverted, we observed that the NET-inducing capacity was similar to levels of healthy controls (1.40±0.42, p=0.37). However, we found no correlation of NET-inducing capacity with titers of MPO and PR3 antibodies (r=0.17, p=0.35 for MPO and r=-0.04, p=0.79 for PR3). To further determine whether NET release was mediated by ANCA autoantibodies, we isolated MPO-ANCA IgG and PR3-ANCA IgG from 5 sera. The purified IgG antibodies did not show NET-inducing capacity (1.40±0.33, p=0.45). In contrast, corresponding IgG-depleted sera had a similar NET-inducing capacity as whole sera (12.91±4.5 for IgG-depleted sera and 18.88±7.26 for whole sera, p=0.51).

Conclusions: These data show that NET release in AAV patients is independent of MPO- or PR3-ANCA. In addition, these data indicate that NET release might be a novel biomarker in AAV, independent of ANCA autoantibodies. Our data supports the hypothesis that NETs are a source of autoantigens for the production of ANCA.

SA-PO296

A Mouse Model of THSD7A-Associated Membranous Nephropathy

Nicola M. Tomas,[1] Catherine Meyer-Schwesinger,[1] Gunther Zahner,[1] Elion Hoxha,[1] Udo Helmchen,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Nierenregister, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Inst für Immunologie, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Thrombospondin type-1 domain-containing 7A (THSD7A) and phospholipase A2 receptor 1 (PLA2R1) are podocyte membrane proteins that have been identified as target antigens for autoimmunity in membranous nephropathy (MN). The investigation of the pathogenicity of the involved autoantibodies has been hampered by the fact that PLA2R1 is not expressed on rodent podocytes. On the other hand, THSD7A is expressed on mouse podocytes and shares over 90% of sequence homology with the human protein. We have recently demonstrated that anti-THSD7A antibodies isolated from a patient with THSD7A-associated MN can cause morphological and clinical MN in mice, allowing further investigations of disease pathogenesis. However, THSD7A-associated MN is a rare entity, incapacitating patient antibodies for larger experimental procedures.

Methods: Polyclonal rabbit antibodies against human and mouse THSD7A were generated using cDNA immunization. Purified IgG from these rabbits recognized, like patient autoantibodies, (a) conformation-dependent epitope(s) present in both native human and mouse THSD7A *in vitro*.

Results: Two hours after intravenous injection into mice, rabbit IgG was bound along the glomerular filtration barrier. Two days later, mice developed proteinuria that rapidly increased and reached around 10 g/g after 5 days and 200-300 g/g albumin-to-creatinine after 14 days with some mice developing a severe nephrotic syndrome with ascites and hyperlipidemia. In immunofluorescent analysis, granular rabbit IgG was found subepithelially along the glomerular filtration barrier after 14 days and immunohistochemistry for rabbit IgG showed the classic picture of human MN. Mice injected with purified IgG from rabbit serum that was taken before THSD7A-immunization failed to develop any of these changes.

Conclusions: Our study introduces a heterologous mouse model that allows further mechanistic investigations of the molecular events leading to membranous nephropathy.

SA-PO297

Glomerular and Tubulointerstitial Gene Expression Correlate with Anti-PLA2R Titer in Membranous Nephropathy

Laurence H. Beck,[1] Laura H. Mariani,[2] Sean Eddy,[2] Huateng Huang,[2] C. Avila-Casado,[3] Rivka Ayalon,[1] Peter X.K. Song,[4] David J. Salant,[1] Matthias Kretzler.[2] *[1]Boston Univ Medical Center; [2]Univ of Michigan School of Medicine; [3]Univ of Toronto; [4]Univ of Michigan School of Public Health.*

Background: NEPTUNE is a multicenter prospective cohort study of children and adults with proteinuric renal diseases enrolled at the time of renal biopsy. The NEPTUNE membranous nephropathy (MN) cohort provides a unique opportunity to examine glomerular and tubulointerstitial gene expression and assess correlation with novel parameters such as anti-PLA_2R titer.

Methods: Anti-PLA_2R was assayed by Western blot and ELISA using baseline sera. For those with a negative/equivocal anti-PLA_2R result, a corresponding kidney biopsy slide was immunostained for the presence of PLA_2R within immune deposits. On the basis of these assays, the cohort was grouped into PLA_2R-associated and non-PLA_2R-associated MN (Table). Gene expression was assessed using the Affymetrix 2.1 ST microarray from the glomerular and tubulointerstitial compartments of protocol renal biopsy cores. Genes significantly correlated with anti-PLA_2R titer (fdr <0.1) were analyzed for enrichment of canonical pathways and upstream regulators using the Ingenuity Pathway Analysis Software Suite.

Results:

	Entire MN cohort (n= 78)	PLA_2R assoc MN (n= 67)	Non-PLA_2R assoc MN (n= 11)
Age, yr (SD)	50 (15)	49 (14)	50 (15)
Female, n (%)	30 (38%)	25 (37%)	5 (45%)
Black Race, n (%)	16 (21%)	14 (21%)	2 (18%)
Baseline eGFR, mL/min/1.73m^2, mean (SD)	81 (28)	81 (28)	86 (31)
Baseline UPCR, mg/mg, median (IQR)	3.9 (2.4, 7.1)	3.6 (2.3, 6.5)	6.8 (4.8, 9.4)

The top predicted upstream regulators associated with the glomerular gene set (88 anti-PLA_2R correlated genes) implicate innate immunity pathways (e.g. LPS, IFNG, TNF). In contrast, there was a relative enrichment of adaptive immunity upstream regulators (e.g. TCR, BCR) in the tubulointerstitial gene set (109 correlated genes).

Conclusions: The titer of circulating anti-PLA_2R correlated with the expression level of a number of glomerular and tubulointerstitial genes. Such an approach offers a means by which to explore novel pathogenetic mechanisms in human MN.

Identification of Components of the Canonical Wnt Signalling Pathway in the Developing Kidney

Kyle Dickinson,[1] Thomas J. Carroll,[2] Paul R. Goodyer.[1,3] *[1]Dept of Experimental Medicine, McGill Univ, Montreal, QC, Canada; [2]Dept of Molecular Biology, UT Southwestern, Dallas, TX; [3]Dept of Human Genetics, McGill Univ, Montreal, QC, Canada.*

Background: The Wnt-signalling pathway has been shown to be essential for kidney development and exhibits a very specific and tightly regulated expression pattern, however, the specific signal transduction components have yet to be identified. Wnt specificity is determined by a co-receptor complex, consisting of one Frizzled (Fzd) and one Lipoprotein related receptor protein (Lrp). More recently, R-spondin1 (Rspo1), expressed in the developing kidney, has been shown to associate with this complex and also act as a Wnt agonist, increasing the signal transduction capacity of the signalling complex.

Methods: We investigated the role of a specific Wnt receptor complex responsible for potentiating response to Wnt9b exposure in M15 cells, a cell model representative of an early renal progenitor cell (RPC). To measure activation of the canonical Wnt pathway, we transfected our cells with reporter plasmid 8X TOPFlash and measured luciferase activity. RT-qPCR was also performed to determine mRNA expression levels.

Results: We took a systematic approach to test the effect of the addition of Fzds, Lrps and Rspo1 on Wnt response to determine the components involved in priming a RPC to complete a normal differentiation program. Exposure to exogenous Wnt9b resulted in no luciferase activity suggesting a signalling component is absent in our cell line. Signal activation was only observed in Wnt9b+Rspo1 conditions, indicating Rspo1 is a potent activator of Wnt signalling in our cells. Next, knockdown of Lrp6 using siRNA resulted in a 60% reduction in luciferase and mRNA levels. Lastly, we tested the effect of ectopic Fzds (Fzd1-10). A significant increase in luciferase activity was only observed in the Fzd5 condition in addition to Wnt9b and Rspo1 suggesting it is involved in potentiating a Wnt9b signal.

Conclusions: These data suggest that early RPCs require a specific receptor complex consisting of Fzd5, Lrp6 and Rspo1 to become responsive to a Wnt9b stimulus and to activate canonical Wnt-signalling during kidney development.

Development of Multipotent Adult Kidney Stem Cells

Hiroki Nomura,[1] Deborah P. Hyink,[2] Tomoko Obara.[1] *[1]Cell Biology, Univ of Oklahoma Health Sciences of Center, Oklahoma City, OK; [2]Medicine, Baylor College of Medicine, Houston, TX.*

Background: Nephrons are formed prenatally, and loss of nephrons leads to chronic kidney disease (CKD). In the past few years, it has been possible to use adult tissues to "reprogram" cells into adult stem cells that can be used to make variety of cell types, though the kidney remains a major challenge because of its complexity both in structure and function. To date, no one has been able to regenerate or model functional mammalian nephrons from normal or diseased kidneys. Recently, we identified a member of the ARID transcription factor family that regulates plasticity in renal cells. When knocked out, *ARID3a* allowed the generation of developmentally plastic cell lines from adult kidney that exhibited increased expression of multiple pluripotency-associated genes.

Methods: In this study, we explored the utility of an adult mouse *ARID3a*-knockout kidney cell line (KKPS5) for generating nephron structures in both *in vitro* and *in vivo* model systems. Furthermore, we determined the effect of ARID3a knockdown at the adult stage of kidneys using both mice and medaka.

Results: We showed that an adult mouse *ARID3a*-knockout kidney cell line (KKPS5) contains adult renal progenitors, and that these cells spontaneously developed into different kidney cell types in 3D matrigel cultures. Importantly, ARID3a elimination increased the number of renal adult stem cells in mice and in medaka kidneys. We are unaware of the existence of this unique multipotent property.

Conclusions: These data implicate KKPS5 cells provide a unique advantage for exploring kidney development. Moreover, we predict that further studies based on our findings will provide renal tissue available for transplantation for CKD treatment.

SA-PO300

Lineage Tracing Identifies c-Kit as a Marker of a Progenitor Cell Population with Regenerative Potential in Adult Kidney Erika B. Rangel,[1,2] Samirah A. Gomes,[1,3] Janaina Paulini Aguiar,[1] Matheus Van Schaik,[1] Garrett Goss,[4] Bradley J. Goldstein,[4] Barbara Seidler,[5] Dieter Saur,[5] Joshua M. Hare,[4] Erika B. Rangel.[1,2] *[1]Albert Einstein Hospital, Sao Paulo, SP, Brazil; [2]Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [3]Univ of Sao Paulo, Sao Paulo, São Paulo, Brazil; [4]Interdisciplinary Stem Cells Inst, Univ of Miami, Miami, FL; [5]Medizinische Klinik, Technische Univ München, Munich, Germany.*

Background: We recently reported that c-Kit cells isolated from developing kidneys exhibit progenitor cell properties. We hypothesize therefore that c-Kit cells represent a tissue-specific progenitor population that is involved in kidney development, is maintained during adult life, and contributes to kidney regeneration.

Methods: We crossed the inducible c-Kit Cre reporter mice with IRG, mT;mG, LacZ, and multicolored Confetti mice. By varying the timing of tamoxifen treatment, c-Kit+ cells and their descendants were specifically labelled with enhanced green fluorescent protein (EGFP), LacZ or multicolor fluorescence, and their spatiotemporal distribution was followed during kidney development and acute kidney injury (ischemia-reperfusion and rhabdomyolysis).

Results: c-Kit expression was more abundant in early postnatal (P) period (7.91 in P0.5-3.5; 10.6 in P7-14 vs 3.13 in embryonic [E]17.5-18.5, P<0.0001), and was maintained in adult life, although at lower levels (5.7 in P30 and 2.2 in P90-180). When tamoxifen was administered during E7.5-9.5, a few EGFP/LacZ+ cells were observed in tubular segments from cortex to medulla, and at E10.5-12.5, when metanephros development initiates, ribbons of c-KitEGFP/LacZ+ cells expanded to form tubular structures and were detected in structures resembling the S-shaped bodies. In postnatal period, the number of c-Kit-EGFP/LacZ/clonal multicolored cells increased in the cortex, medulla, and papilla. In adult mice, c-Kit-EGFP/LacZ/clonal multicolored cells were found in distinct renal segments (macula densa, distal tubules and collecting ducts). After acute kidney injury, the number of c-Kit clones increased from 10±3 to 36.5±8 (P<0.0001) in the outer medulla.

Conclusions: c-Kit marks a kidney progenitor population that is maintained in adult life and may have therapeutic application.

SA-PO301

A Novel Method to Differentiate Human ES Cells into Renal Tubule-Like Cells by a Combination of Transcription Factors Administration Ken Hiratsuka,[1] Toshiaki Monkawa,[1] Shintaro Yamaguchi,[1] Ryuji Morizane,[1] Shigeru B.H. Ko,[2] Hiroshi Itoh,[1] Minoru S.H. Ko.[2] *[1]Dept of Internal Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan; [2]Dept of Systems Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Background: Various protocols to differentiate human pluripotent stem cells (hPSCs) into kidney organoids have been developed recently. In a previous study, we have reported a method to differentiate human Embryonic Stem Cells (hESCs) to the cells which are positive for proximal tubule markers in kidney by an administration of single transcription factor (TF) with synthetic mRNAs. Here, we report successful differentiation of renal tubule-like cells of multi-segments from hESCs by a combinatorial administration of defined TF mRNAs.

Methods: To identify TFs which promote differentiation towards a renal lineage, we utilized the comprehensive date set, and represents correlation of gene expression response to the induction of human TFs (~350 genes) under doxycycline (Dox) control in hESCs with tissue-specific gene expression. Modified mRNAs for TFs were synthesized by in vitro transcription. hESCs were transfected with several combinations of synthetic mRNAs for TFs by lipofection and cultured for up to 9days. Morphological changes of these cells were microscopically observed. Marker gene expression were examined by qPCR analysis and protein expression by immunohistochemistry.

Results: By analyzing the data in silico, three candidate TFs which show highest correlation scores to the gene expression profiles of human kidney at 48 hours after Dox induction of each human TF were identified. Two days after the transfection of 3 TFs together into hESCs, intermediate mesoderm cell populations ($PAX2^+$, $LHX1^+$) were induced. On day 9, differentiated, epithelial cell-like morphological changes were clearly observed. mRNA expressions of proximal tubule cell markers such as AQP1, KSP or MEGALIN and distal tubule cell marker SLC12A3 were detected.

Conclusions: We have identified a set of specific TFs for the differentiation of hESCs toward renal lineage via intermediate mesoderm, and generated renal tubule-like cells from hESCs by a novel differentiation method using synthetic mRNAs.

SA-PO302

Functional Role of Epigenetic Memory Genes in Human Kidney Derived iPS Cells Osamu Takase, Taro Tsujimura, Masaomi Nangaku, Keiichi Hishikawa. *Dept of Advanced Nephrology and Regenerative Medicine, Graduate School of Medicine, the Univ of Tokyo, Tokyo, Japan.*

Background: Kidney specific differentiation induction method using iPS cells is not still established. Last year, we reported 73 epigenetic memory genes for advantage of kidney specific induction by genome-wide methylation analysis between fibroblast-derived iPS cells (F-iPS) and kidney epithelial-derived iPS cells (K-iPS).

Methods: We have analyzed the exhaustive 60,000 genes, OSR1 and T (brachyury) as the kidney development key gene by DNA microarray. As two kinds of induction methods using F-iPS and K-iPS cells, one is an intermediate mesoderm cell lines system (induction 1) (Nature Commu.), another is body axis stem cell lines system (induction 2) (Cell Stem Cells).

Results: In microarray cluster analysis, the whole gene expression of kidney induction using K-iPS cells was consistent with the renal epithelial cells, moreover was stronger expressed the kidney development gene than F-iPS cells. Also we confirmed the expression change (iPS cells/origin cells) in 73 epigenetic memory genes. In high methylation 56 genes, some gene expressions were downregulated in F-iPS cells as compared with K-iPS cells, such as GPR137B (F-iPS/K-iPS=0.39), HSPB1(0.49), and MAP3K5 (0.35). In low methylation 17 genes, some gene expressions were upregulated in F-iPS cells, such as GRB10 (2.27) and SOX8 (5.41). Further the expression of OSR1 (0.16) and T (0.45) was downregulation in F-iPS cells. Especially by kidney induction, the expression of OSR1 did not show strong expression, but T showed markedly strong expression by kidney induction 2 using K-IPS cells.

Conclusions: Interestingly, the expression of HSPB1 and SOX8 which regulates cell development and differentiation, showed high expression with kidney induction using K-IPS cells as compared with F-IPS cells. Transcription factor T which regulates mesoderm formation and notochord differentiation, may be newly involved in HSPB1 and SOX8. Our results demonstrate the functional role of epigenetic memory genes in human kidney derived iPS cells, and the mechanical role of these genes, including OSR1 and T, in kidney lineage specific induction will be discussed.

SA-PO303

Should I Stay or Should I Go? Influence of Cell Cycle on Self-Renewal and Differentiation in Human Nephrogenic Progenitors Stefano Da Sacco, Matthew Edward Thornton, Astgik Petrosyan, Ursula Kreuser, Sinem Kargin, Brendan Grubbs, Roger E. De Filippo, Laura Perin. *Children's Hospital Los Angeles.*

Background: Nephron progenitors (NP), co-expressing SIX2 and CITED1, control nephron endowment through proliferation and differentiation. The mechanisms involved in maintaining this balance are still poorly understood. Recent studies have linked lineage commitment and cell cycle progression; self-renewing cells present a short cell cycle and spend most of their time in replicative phase. In this work, we have investigated the relationship between cell cycle and renal differentiation in NP isolated from human fetal kidneys (hFK).

Methods: NP were isolated using RNA Smartflare probes. Nephrogenic characteristics were confirmed by RNA-seq and nephrogenic potential by in vitro differentiation and dissociation/reaggregation assays. Expression of cell cycle markers was confirmed by RNA-seq and by immunofluorescence on hFK. Cell cycle was studied using FUCCI (Fluorescent Ubiquitination-based Cell Cycle Indicator) in isolated NP under self-renewing or differentiating conditions.

Results: RNA-seq confirmed elevated expression of renal developmental genes including SIX2, SIX1, CITED1, WT1, EYA1 within NP and they differentiated into functional podocytes and tubules. RNA-seq analysis also revealed high levels of CDK1/cyclin B, CDK1/cyclin A, E2F2/E2F1 and low levels of retinoblastoma protein and cyclin E possibly suggesting that NP are in M or S phase. Immunofluorescence analysis on hFK confirmed expression of CDK4 and cyclin B in NP but lack of terminally differentiated cell markers like p21 or p27. We also found that increased G1 phase length leads to higher rates of NP differentiation, suggesting a key role of G1 in determining cell fate in NP.

Conclusions: We successfully isolated and characterized for the first time human NP based on SIX2 and CITED1 expression, confirming their nephrogenic identity. Our preliminary data indicate a strong link between cell cycle progression and induction. Since renal diseases correlate with nephron endowment deficit, identifying factors affecting nephron number like self-renewal/differentiation balance can potentially advance our understanding of renal disease initiation and progression.

Hemodialysis Patients-Derived Induced Pluripotent Stem Cells Can Be Powerful Tool for Kidney Regeneration Susumu Tajiri,[1,2] Toshinari Fujimoto,[1,2] Shuichiro Yamanaka,[1] Kei Matsumoto,[1] Makoto Ogura,[1] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Div of Regenerative Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: We could generate neokidnies using human-derived mesenchymal stem cells (hMSCs). However, we previously reported that hemodialysis (HD) patients derived- hMSC might not be appropriate for kidney regeneration due to their long-term uremic condition. Therefore, we hypothesized that induced pluripotent stem cells (iPSc) generated from HD patients could reset the uremic condition and could be useful cell source for kidney regeneration.

Methods: Three patients with end stage renal disease attending our institution for HD were enrolled. Of the three, one had diabetes mellitus and the other 2 had chronic glomerulonephritis. We generated and characterized iPSc from all patients and differentiated iPSc into nephron progenitor cells (NPC) following published protocol. Gene expression markers were compared between healthy control-derived NPC (HC-NPC) and HD patients-derived NPC (HD-NPC) using quantitative RT-PCR. To investigate whether NPC could undergo mesenchymal-to-epithelial transition (MET), we co-cultured them with spinal cords and conducted a histological analysis and gene expression of the structures.

Results: Established iPSc lines showed typical human embryonic stem cell -like morphology and expressed pluripotency markers. Moreover, they exhibited the ability to give rise to teratomas that contained derivatives of all three germ layers and a G-band analysis confirmed normal karyotype. We could differentiate them into HD-NPC that expressed several markers including WT1, PAX2 and SIX2 at the same level as HC-NPC. In addition, HD-NPC exhibited the ability to undergo MET and exhibited robust tubulogenesis. Moreover, clustered podocytes were formed and they expressed podocyte specific markers, such as nephrin and podocin.

Conclusions: To the best of our knowledge, this is the first instance of generating NPC, which were derived from HD patients and then differentiated them into renal tubules and podocyte. Our study demonstrated that HD patient-derived iPSc can be useful cell source for kidney regeneration.

SA-PO305

Identification of a microRNA Signature in Renal Cancer Stem Cells: A New Regulatory Mechanism Grazia Serino,[1,2] Fabio Sallustio,[2] Vanessa Galleggiante,[2] Monica Rutigliano,[2] Claudia Curci,[2] G. Lucarelli,[2] P. Ditonno,[2] M. Battaglia,[2] Francesco Paolo Schena.[2] *[1]IRCCS, Castellana Grotte, Ba, Italy; [2]Univ of Bari, Bari, Italy.*

Background: Clear cell renal cell carcinoma (ccRCC) is the most common form of kidney cancer in adults. Recent evidences show that in several human cancers a small subset of tumor cells called cancer stem cells (CSCs) is present. These cells can be responsible for tumor initiation, growth, metastasis, drug resistance and recurrence. CSCs have been found and characterized also in ccRCC tissue. To date, the role of microRNAs (miRNAs) in ccRCC have been extensively studied, but their function in renal CSCs has not yet been reported.

Methods: We isolated $CD133^{+}/CD24^{+}$ cells from healthy and tumor renal tissue of 28 patients who underwent nephrectomy for ccRCC. Cells were characterized for their mesenchymal phenotype and stemness proteomic profile. The global miRNA profile was identified using small RNA-Seq (llumina). Target gene prediction was performed using bioinformatic analysis. Results were confirmed by qRT-PCR.

Results: We identified 120 miRNAs differentially expressed in renal CSCs compared to healthy counterpart, of which 12 were downregulated and 108 were upregulated. Then, we studied the genomic distribution of the differentially expressed miRNAs. Interestingly, we found that 48 upregulated miRNAs were codified all together in a cluster on chr14:101341370-101533138, near the region 14q LOH that is associated with tumor progression of ccRCC. Moreover, some of these miRNAs putatively regulated the VHL gene that is involved in the ccRCC pathogenesis. Pathways analysis showed that all deregulated miRNAs were implicated in several pathways typical of cancer and renal cell carcinoma, as TGF-β signaling, PI3K-AKT signaling, WNT signaling. The real-time PCR on miR-205-5p, miR-543, miR-127-3p, miR-136-3p, miR-654-3p, miR-1246 and miR-889-3p confirmed results obtained from sequencing.

Conclusions: Our data support a new role of miRNAs in renal CSCs and these new molecules could provide a potential pharmacological target for new therapeutic approaches in ccRCC.

Obesity Modulates the miRNA Cargo Packed within Mesenchymal Stem/Stromal Cell-Derived Paracrine Extracellular Vesicles Alfonso Eirin, Xiang-Yang Zhu, Sreela Jonnada, Kyra L. Jordan, Amir Lerman, Andre J. Van Wijnen, Lilach O. Lerman. *Mayo Clinic.*

Background: Mesenchymal stem/stromal cells (MSC) are prevalent in many organs, and their kidney counterparts act as a reservoir of undifferentiated cells to address the repair needs of the kidney. MSC release extracellular vesicles (EV) that shuttle miRNA to damaged parenchymal cells, activating an endogenous repair program. Obesity is an important cardiovascular risk factor that may coexist with kidney disease. Our studies focus on the key question whether there are changes in the miRNA cargo of MSC-derived EV that could affect the endogenous repair system.

Methods: Autologous MSC were collected from abdominal fat of domestic pigs after 16 weeks of normal (Lean) or high cholesterol/carbohydrate (Obese) diet (n=5 each). EV were subsequently collected by ultracentrifugation. Next-generation sequencing (RNAseq) was performed to identify sequences differentially expressed between Lean- and Obese-EV. Functional annotation clustering analysis was used to identify cellular pathways regulated by miRNA altered in Obese-EV.

Results: RNAseq generated reads for over 400 miRNA, of which 10 were upregulated in Obese-EV compared to Lean-EV (fold change>2, $p<0.05$). These miRNA preferentially target mitogen-activated protein kinases (MAPK), a signaling pathway that acts as a defense mechanism via upregulation of pro-survival, anti-inflammatory, and anti-apoptotic factors. Notably, the expression of the MAPK member ERK1/2 was upregulated in vivo in renal tubular cells from obese pigs.

Conclusions: MSC-derived EV obtained from obese pigs have a distinct RNA content compared to their lean counterparts and are enriched for miRNA that selectively modulate renal expression of several members of the MAPK pathway. Modulation of MAPK signaling may be an important mechanism by which MSC exert their tissue effects and identifies this pathway as a novel therapeutic target.

Obesity-Induced Mitochondrial Dysfunction in Porcine Adipose Tissue-Derived Mesenchymal Stem Cells Yu Meng, Alfonso Eirin, Xiang-Yang Zhu, Hui Tang, Amir Lerman, Andre J. Van Wijnen, Lilach O. Lerman. *Mayo Clinic.*

Background: Transplantation of autologous mesenchymal stem cells (MSC) may be a viable option for treatment of chronic kidney disease (CKD). MSC efficacy depends on their mitochondrial function, which might be impaired in a noxious milieu. We hypothesized that obesity compromises mitochondrial structure and function, possibly via microRNA (miRNA)-based mechanisms.

Methods: MSCs were collected from swine abdominal adipose tissue after 16 weeks of Lean or Obese diet (n=6 each). Mitochondrial structure was assessed by electron microscopy, their respiration and ATP production by Seahorse Analyzer, oxidative stress by dihydroethidium, and apoptosis by caspase-3 staining. Next-generation sequencing (RNA-seq) of miRNAs was performed to identify miRNAs upregulated in Obese-MSCs, and predicted mitochondrial target genes were then identified (MitoCarta).

Results: Compared to Lean-MSCs, mitochondria from Obese-MSCs were swollen and showed cristae remodeling, fragmentation, and loss (Figure). Basal respiration and ATP production were decreased in Obese-MSCs, associated with increased oxidative stress and apoptosis. RNA-seq generated reads for 413 miRNAs, of which 5 miRNAs were upregulated in Obese-MSCs (fold change >2, $p<0.05$) and found to target 43 specific mitochondrial genes (Figure).

A. Transmission electron microscopy showing that Obesity impairs MSC mitochondrial structure. **B:** Basal respiration and ATP production were decreased in Obese-MSC. **C:** Dihydroethidium (pink) and Caspase-3 (red) were increased in Obese-MSC. **D:** miRNAs upregulated in Obese-MSCs compared to Lean-MSCs . **E:** List of mitochondrial genes targeted by miRNAs upregulated in Obese-MSCs. *p<0.05 vs. Lean-MSC.

Conclusions: Obesity impairs MSC mitochondrial structure and function, possibly mediated partly through miRNA-induced mitochondrial gene regulation, leading to increased MSC apoptosis and oxidative stress. Importantly, these alterations may limit the use of autologous MSCs in subjects with CKD and obesity.

Generation and Characterization of a Pkd1 Mutant Kidney MSC Line In Vitro Pamela Kairath Oliva,[1,2,3] Joan Li,[3] Melissa H. Little.[1,2,3] *[1]Murdoch Research Inst, Melbourne, Victoria, Australia; [2]Dept of Pediatrics, The Univ of Melbourne, Melbourne, Victoria, Australia; [3]Inst for Molecular Bioscience, Brisbane, Queensland, Australia.*

Background: The existence of an adult mesenchymal stem cell population resident within kidney (k-MSCs) was recently reported by our laboratory, providing the exciting prospect of a powerful treatment to repair acutely damaged organs. Microinjection of EGFP+ k-MSCs into the renal parenchyma of CD1 mice has shown that they home to and integrate into collecting duct structures, persisting for at least 15 days post-delivery.

Methods: Here we report the Long-term evaluation of kidney MSCs into the renal parenchyma of CD1 mice and the generation and evaluation of a new mutant kidney MSCs cell line isolated from a Pkd1 (flox/flox) mice.

Results: We found persistence of EGFP+ k-MSCs within the collecting duct even after 10 weeks post-delivery, with an average integration of 7.6 %. In order to test the true functional integration capacity of the k-MSC into the collecting duct, a Pkd1 mutant k-MSCs cell line was generated by isolation of bulk kidney k-MSC from a Pkd1 (flox/flox) mice. Derived k-MSCs then underwent *in vitro* CRE excision and clonal cell derivation to isolate a clone in which a homozygous recombination event had occurred. In order to prepare for further *in vivo* evaluation, a second Pkd1 mutant kMSC line was derived by crossing Pkd1 flox/flox mice with a tdTomato reporter line to enable to tracing of these cells post injection. Characterization of MSCs properties of the Pkd1 mutant k-MSC line compared to the previously described wildtype k-MSC line showed equivalent adherence to plastic and expression of key MSC surface markers CD44, CD81 and Sca1. In addition, genetic modification of the Pkd1 gene did not affect the migration capacity of these cells.

Conclusions: Taken together, we can conclude that Pkd1 gene inactivation did not alter the properties of kidney-derived mesenchymal stem cells, supporting the feasibility of microinjections of Pkd1 mutant k-MSCs into kidney compartments.

SA-PO309

Urine of Cystinosis Patients as Source of Undifferentiated Renal Cells for Disease Modelling and Therapy Fanny Oliveira Arcolino, Koenraad Veys, Mohamed A. Elmonem, Lambertus P.W.J. Van den Heuvel, Elena N. Levtchenko. *Dept of Development and Regeneration, KU Leuven, Leuven, Belgium.*

Background: Cystinosis is characterized by the pathological accumulation and crystallization of cystine in the lysosomes. If not treated, end stage renal disease invariably develops within the first decade of life. We have shown that cystinosis patients void excessive number of podocytes and proximal tubular cells in urine and here we hypothesized that in compensation for cell loss, ongoing regeneration might happen, and it could be reflected by the presence of undifferentiated cells in urine of patients.

Methods: We estimated the total number of cells and the number of kidney-undifferentiated cells in urine using pre-amplified cDNA from fresh urine samples of healthy donors (n = 10, range 4-12 years old) and cystinosis patients (n = 8, range 4-15 years old). None of cystinosis patients had kidney graft. The expression of vimentin was correlated to calibration curves derived from known numbers of adult kidney progenitor cells and normalized to volume of urine. We have cultured urinary cystinosis undifferentiated cells and characterized them at genetic and protein levels. Later we differentiated progenitor cells into functional podocytes or proximal tubular cells.

Results: We demonstrate a significant increased loss of kidney-undifferentiated cells in cystinosis patients' urine, while in controls these cells were not found. Cultured cells from patients expressed mesenchymal stromal cell proteins as CD73, CD44, CD105, CD29, did not express hematopoietic cell markers and were positive for the kidney proteins CD24 and CD133. The cells were positive for nephron progenitor genes, such as Vimentin, *PAX2* and *CITED1* and were able to differentiate into functional podocytes or proximal tubular cells.

Conclusions: Our data demonstrate the presence of kidney-undifferentiated cells in urine of cystinotic patients, which might indicate a fast turnover of cells and the attempt of tissue regeneration to compensate epithelial cell loss. Urinary undifferentiated cystinotic cells might have a therapeutic application in regenerative medicine once the correction of the genetic defect and consequent correction of the phenotype are successful.

Direct Reprogramming of Fibroblasts into Renal Tubular Epithelial Cells by Defined Factors Michael Kaminski,[1] Jelena Tosic,[2] Catena Kresbach,[1] Roman Pichler,[1] Florian Grahammer,[1] Tobias B. Huber,[1] Gerd Walz,[1] Sebastian Arnold,[2] Soeren S. Lienkamp.[1,3] *[1]Dept of Medicine, Renal Div, Univ of Freiburg Medical Center, Freiburg, Germany; [2]Dept of Clinical Pharmacology, Inst of Experimental and Clinical Pharmacology, Freiburg, Germany; [3]Center for Biological Signaling Studies (BIOSS), Univ of Freiburg, Freiburg, Germany.*

Background: Over-expression of transcription factors can convert one cell type into another. This process, referred to as direct reprogramming, is fast and bypasses pluripotency. However, conversion of fibroblasts towards renal cell types has not been achieved yet.

Methods: Based on in-silico analysis and whole-mount in-situ screens we identified candidate renal reprogramming factors. These transcription factors were tested for their potential to convert cells towards a renal fate using fibroblasts from tubule specific reporter mice. Induced cells were analyzed for their transcrpitomic profile, renal marker expression and function.

Results: We identified four transcription factors whose combined expression induced cells with high similarity to native renal tubular epithelial cells. They displayed typical epithelial characteristics, a global expression profile resembling their native counterparts, functional properties of renal tubular epithelial cells and sensitivity to nephrotoxic drugs. Further, they formed tubules along the extracellular matrix of decellularized kidneys and integrated into renal organoids.

Conclusions: Candidate reprogramming factors can be predicted based on their expression characteristics. Directly reprogrammed renal tubular epithelial cells could facilitate nephrotoxicity and drug testing, serve as a platform for disease modeling and may pave the way for regenerative approaches.

Differentiation of Human iPSC into Functional Renal Proximal Tubular Cells and Functional Podocytes with the Application for Drug Toxicity Screening Anja Wilmes, Caroline Rauch, Georg Kern, Elisabeth Feifel, Gerhard Gstraunthaler, Paul Jennings. *Medical Univ of Innsbruck, Dept Physiology and Medical Physics, Physiology, Innsbruck, Tirol, Austria.*

Background: Prevalence of chronic kidney disease (CKD) is estimated to be around 10% worldwide. While CKD is mainly a disease of age, it can be accelerated by certain risk factors including exposure to pharmaceuticals, chemicals and environmental pollutants. Furthermore, it is estimated that there is considerable individual variability in the sensitivity to toxins due to altered expression in xenobiotic uptake, extrusion and metabolizing proteins. Within the nephron, proximal tubular cells (PT) and podocytes are the most frequently affected cell types by drug induced kidney injury. The aim of our research is to develop methods to differentiate human induced pluripotent stem cells (iPSC) into monocultures of PTs or podocytes that can be used for drug toxicity testing and individual susceptibility.

Methods: Within the StemBANCC consortium, somatic cells from more than 300 patients have been reprogrammed with Sendai virus to generate iPSC. iPSC are cultured on Matrigel and then differentiated into either podocyte-like cells or proximal tubular-like cells with a combination of small molecules and growth factors.

Results: Toxicity studies require relatively pure cultures of single cell types. Both, podocyte-like cells and PT-like cells are derived in a relative pure culture after 10 and 16 days, respectively. Characterization of these cells show expression of specific podocyte marker, including synaptopodin and podocin, as well as specific PT markers including, claudin 2, AQP1, megalin and CD13. Functional analysis showed secretion of VEGF by podocytes-like cells and uptake of albumin and fluorescent labeled cations by PT-like cells. Preliminary toxicity experiments have been carried out with Doxorubin (aka Adriamycin), a gold standard compound for glomerular toxicity, and with Bardoxolone methyl (aka CDDO) an activator of the Nrf2 oxidative stress response pathway.

Conclusions: While we have made some gains in the development of renal target cells, more efforts need to be invested to increase the differentiation status, purity and stability of the derived cells.

Funding: Government Support - Non-U.S.

SA-PO312

Urinary Renal Progenitors as a Novel Predictor of Graft Outcome Anna Manonelles,[1] Roser Guiteras,[3] Oriol Bestard,[1,3] Paola Romagnani,[2] Josep M. Cruzado.[1,3] *[1]Nephrology and Transplant Unit, Hospital Univ de Bellvitge, Barcelona, Catalunya, Spain; [2]Nephrology, Meyer's Children Hospital, Florence, Italy; [3]Nephrology and Transplant Unit, IDIBELL, L'Hospitalet de Llobregat, Spain.*

Background: Long-term improvement of kidney allograft (KA) survival remains as unmet need. Most studies focus on environmental mechanisms of graft injury, whereas kidney reparative mechanisms were neglected. Isolation of Renal Progenitors from urine (uRP) may be a potential tool to evaluate the intrinsic regenerative capacity of the graft.

Methods: We include 66 recipients at the time of 6 month protocol biopsy. After cell culture, uRP were FACs cell-sorted (CD24/CD133). Cells were differentiated into podocytes and tubular cells. Clinical (demographic parameters, type of KA, treatment), analytical (GFR, proteinuria) and immunological data (donor specific antibodies, ELISPOT, urinary biomarkers) were assessed. Kidney biopsy was evaluated according to Banff classification and CD133/CD44 staining performed. We followed this cohort for 2 yrs.

Results: uRPs were isolated in 62.1% patients at the time of 6-m protocol biopsy. Therefore we divided patients in two groups: Group A having uRP and Group B without uRP. Study groups were comparable regarding baseline characteristic, immunosuppression, DGF, acute rejection, GFR and proteinuria. Protocol biopsy evaluation was similar between groups, without differences for particular Banff items. Glomerular CD44 staining was higher in patients without uRP. T-cell IFN-γ ELISPOT assay and donor specific antibody determination was comparable. We determined the variation of GFR between month 6 and months 12 and 24. Interestingly, patients with uRP at 6m showed a significant increase of GFR at 12m in comparison with stabilization of renal function in patients without uRP (+10±2 vs -3±1%; P=0.003), finding maintained at 2 years.

Conclusions: Despite showing similar effector mechanisms of damage, renal function and 6-month graft histology to patients without uRP, the presence of renal progenitors on urine of kidney recipients at 6 months identifies a subgroup of patients with significant improvement of GFR at 1 year. This finding raises new prospects as novel predictors of better graft outcomes.

SA-PO313

Dedifferentiation-Reprogrammed Mesenchymal Stem Cells with Improved Therapeutic Potential in Diabetic Nephropathy Yang Liu, Alice Zou, Wai Han Yiu, Dickson W.L. Wong, Kam Wa Chan, Loretta Y.Y. Chan, Joseph C.K. Leung, Kar Neng Lai, Sydney C.W. Tang. *Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong.*

Background: Podocyte loss is a hallmark of diabetic nephropathy (DN). Stem cell therapy has shown rescue effects on podocytes in animal models of DN, but low efficiency and poor survival of transplanted cells still are the major obstacles. We previously reported that dedifferentiation-reprogrammed mesenchymal stem cells (De-MSCs) derived from bone marrow mesenchymal stem cells (BM-MSCs) had therapeutic advantages compared to unmanipulated BM-MSCs in a brain hypoxic-ischemic animal model (Liu Y, et al. Stem Cells 2011). Here, we explored the therapeutic potential of renal lineage reprogrammed De-MSCs in DN.

Methods: De-MSCs were generated by inducing human BM-MSCs to go through renal differentiation, followed by dedifferentiation. De-MSCs were characterized by cell surface markers, multilineage differentiation, gene array profile and survival ability under H_2O_2 challenge. Immortalized human podocytes were exposed to glycated human serum albumin (AGEs) and co-cultured with De-MSCs or BM-MSCs. BTBR ob/ob mice, an animal model of type 2 DN, were transplanted with De-MSCs, BM-MSCs or PBS.

Results: Compared to BM-MSCs, De-MSCs retained stem cell properties with similar morphology but enhanced survival ability under normal condition or H_2O_2 stress. Co-culture with De-MSCs significantly prevented apoptosis in podocytes exposed to AGEs via rescuing expression of Bcl-2 and survivin, and cytoskeleton related genes synaptopodin, CD2AP and tight junction protein ZO-1. Compared with PBS- and BM-MSCs-treated groups, BTBR ob/ob mice injected with De-MSCs had significantly lower urinary albumin-to-creatinine ratio and BUN. Mechanistically, De-MSC treatment in animals remarkably restored podocin expression and reduced renal cortical HIF1 and p44/42 phosphorylation.

Conclusions: De-MSCs achieved improved therapeutic potential in DN both *in vitro* and *in vivo* over their BM-MSC counterpart, and deserve further investigation as a potentially important source of stem cell-based therapy for DN.

Pharmacological Proof-of-Concept of Extracorporeal Mesenchymal Stromal Cell Immunotherapy in Large Animals Biju Parekkadan. *Surgery (Bioengineering), Harvard Medical School, Boston, MA.*

Background: Human mesenchymal stromal cells (MSCs) metabolize and secrete molecular mediators that can globally shift a wound healing response. Controlled exposure to this cell therapy has been challenging with intravenous infusion of MSCs due to limits in tolerable cell dose and the rapid clearance of MSCs by the body. We have developed an extracorporeal MSC technology that maintains MSC viability and enables the continuous, controlled delivery of MSC molecules into the blood stream in a clinical setting. A human scale prototype of the technology will be presented showing sustained cell viability and function throughout cGMP manufacturing.

Methods: MSCs were integrated into hollow-fiber bioreactor devices whereby the cells, separated by a permeable membrane, can directly and dynamically provide systemic immunotherapy without entering the body. Pharmacological analysis of this bioreactor technology in a large animal toxicology and efficacy study in acute kidney injury (AKI) allowed for an unprecedented look at MSC therapy during product use.

Results: The study verified a pharmacokinetic and pharmacodynamic response to extracorporeal MSCs that is consistent with a potent immunomodulatory mechanism of action in large animals. The presentation will also report encouraging *in vivo* survival results of extracorporeal MSCs in a canine model of ischemic AKI.

Conclusions: We expect that a combined approach to optimize MSC therapy that employs pharmacology principles and cell delivery strategies will be essential to translating this stem cell product to AKI in humans and many other clinical applications of immunotherapy.

Late Stage Therapy of Chronic Kidney Disease with Multiple-Doses of Mesenchymal Stem Cells Improves Renal Function in a Rat Model Jon D. Ahlstrom,[1] Huihui Shi,[1] Jorge Isaac,[2] Anna Gooch,[1] Christof Westenfelder.[1,3] *[1]Dept of Medicine, Div of Nephrology, Univ of Utah and Salt Lake City VA Medical Center, Salt Lake City, UT; [2]Pathology, UPSI & Intermountain Healthcare, Murray, UT; [3]Dept of Physiology, Univ of Utah, Salt Lake City, UT.*

Background: Advanced stages of Chronic Kidney Disease (CKD) are difficult to treat and eventually require dialysis or a kidney transplant. We developed and clinically tested a Mesenchymal Stem Cell (MSC)-based therapy for cardiac surgery patients at high risk for post-operative AKI (NCT00733876). This intervention was shown to be safe and it prevented post-operative AKI, mortality and development of CKD long term. These observations prompted us to test in the present preclinical studies whether MSC therapy might also be of benefit to patients at later stages of CKD.

Methods: MSCs were derived from Sprague-Dawley (SD) rat bone marrow and used for therapy at passage 3 (~10 population doublings). After late-phase CKD was established in male SD rats as indicated by reduced renal function, elevated albuminuria and blood pressure (10-16 weeks post 5/6th nephrectomy), MSC therapy was given i.v. (2 million cells/kg b.wt.) 1 x per week for 4 weeks. MSC therapy was then halted and the progression of CKD was further monitored for 10 additional weeks.

Results: Our CKD model of 5/6th nephrectomy led to a progressive decline in renal function, elevated systolic blood pressures and albuminuria. MSC therapy given at this late-phase CKD significantly improved renal function (reduced SCr and BUN, increased GFR) and reduced albuminuria and blood pressures compared to vehicle controls. Improvements in albuminuria and hypertension from MSC therapy were sustained for 10 weeks after cessation of MSC therapy, while renal function again began to decline.

Conclusions: These data suggest that MSC therapy for CKD may be clinically feasible, even at later stages of CKD, a time when most pharmacological interventions become less or are no longer effective in the prevention of progression to end stage renal disease. Optimal long-term treatment protocols and investigation of the underlying mediator mechanisms of administered MSCs are in progress.

SGLT2 Inhibitor Attenuates Ischemia Reperfusion Renal Injury via HIF1 Activation Jin Young Jeong,[1,2] Hyunsu Choi,[3] Yoon-Kyung Chang,[4,5] Hong Jin Bae,[1] Young Rok Ham,[1] Dae Eun Choi,[1] Ki Ryang Na,[1] Kang Wook Lee.[1] *[1]Nephrology, Chungnam National Univ, Daejeon, Korea; [2]Medical Science, Chungnam National Univ, Daejeon, Korea; [3]Clinical Research Inst, Daejeon Saint Mary Hospital, Daejeon, Korea; [4]Nephrology, Catholic Univ, Seoul, Korea; [5]Nephrology, Daejeon Saint Mary Hospital, Daejeon, Korea.*

Background: SGLT2 inhibitor, dapagliflozin were developed for diabetes control. it wastes the glucose to urine. Some studies showed SGLT2 inhibition have renal protection(reduction of hyperfiltration and tubular oxidative stress) in Type1 DM. We evaluate whether SGLT2 inhibitor reduces the renal damage via ischemia reperfusion (IR). Also, we investigate the associating molecular pathway.

Methods: n vitro, hypoxia was simulated by mineral oil in HK-2 cells. Cell survival, apoptosis signal pathway, reactive oxygen species (ROS) generation, HIF1, ERK, and AMPK were evaluated in control and hypoxic HK-2 cell with or without SGLT2 inhibitor.

In vivo 10 weeks C57BL/6 mice were divided into 4 groups; vehicle (n=5) and dapagliflozin (10mg/kg) treated sham group (n=5), vehicle (n=7) and dapagliflozin (n=7) with ischemia reperfusion renal injury. Kidneys and blood were harvested 24hr after IR injury. We performed real time RT-PCR, western blot and immunohistochemistry for molecular study and H&E stain and PAS stain for histologic examination.

Results: Dapagliflozin treatment significantly increase survival of hypoxic HK-2 cells. Dapagliflozin treatment increase the level of HIF1 in hypoxic HK-2 cells. Also it decrease the Bax/Bcl2 ratio and 8-OH deoxyguanosine generation. in vivo, Dapagliflozin treatment significantly reduced the levels of BUN and serum creatinine in IR mice (p <0.05). In microscopy, dapagliflozin significantly reduced renal tubular epithelial cell necrosis and detachment in IR mice kidney. Dapagliflozin significantly increased the expression of HIF1 in IR kidney. Dapagliflozin significantly reduced the level of Bax/Bcl-2 ratio and cleaved caspase-E, 8-OH deoxyguanosine positive and TUNEL positive cells in IR kidney.

Conclusions: dapagliflozin significantly increases HIF1 in IR injured kidney. Also it attenuates ischemia reperfusion renal injury.

Extra Domain A Fibronectin Is an Acute Marker in AKI and a Novel Therapeutic Target in a Murine Model of Aristolochic Acid Nephropathy

Pritpal Singh Virdee,[1] Sujit Kumar Saha,[2] Subash Somalanka,[1] Claire C. Sharpe,[2] Mark E. Dockrell,[1] Mysore Keshavmurthy Phanish.[1] *[1]South West Thames Inst for Renal Research, Epsom and St. Heliers NHS Trust, Carshalton, Surrey, United Kingdom; [2]Div of Transplantation Immunology and Mucosal Biology, Kings College Foundation Trust, London, United Kingdom.*

Background: In models of tissue injury in animals and in vitro in human cells, production of Extra Domain A fibronectin (EDA + FN) is preferentially directed by alternative splicing. We explored the potential of EDA + FN as a target for RNAse H Independent antisense oligonucleotide(ASO) therapy with a view to attenuating fibrosis in a murine model of acute kidney injury induced by aristolochic acid (AA). We have previously shown effective knockdown of EDA + FN in human proximal tubule cells.

Methods: We compared expression of EDA + FN in 2 murine models. CD1 mice were injected with Intraperitoneal AA at 3.5mg/kg at D1 and 5, RNA from whole kidney lysate was extracted at D0, 12, 20 and 100 and qPCR performed using primers targeted to EDA + FN, EDA - FN and CTGF. Folic acid model (FA) model involved IV injection of Folic acid at D0 and D21 at 125mg/kg and whole kidney lysate retrieval at D0 and D84.

Results: In the AA model of kidney injury at D0 there was negligible detection of EDA + FN RNA by qPCR, at D12 there was a >2500 fold increase in its expression compared to its normal saline control (p<0.005), at D20 there was >900 fold (p<0.005) which was reduced to 13 fold (p<0.05) at D100 compared to control. EDA - FN RNA expression was also increased at D12, 20 and 100 (p<0.005) but to a lesser degree (40-70 fold increase) compared to normal saline control. CTGF expression followed a similar pattern with peak at D12 and subsequent fall. By comparison in FA model there was a 15 fold (p<0.005) increase in EDA + FN RNA expression at D84.

Conclusions: EDA+FN expression is significantly increased in the acute phase of kidney injury by AA. This isoform appears to be preferentially expressed by alternative splicing in response to insult. RNAse H independent ASOs can modulate splicing to prevent formation of EDA + FN and attenuate fibrosis and this will be the next step towards a therapeutic option for AKI and CKD following AKI.

SA-PO318

Ameliorating Effect of Gemigliptin on Renal Injury in Murine Adriamycin-Induced Nephropathy

Da Rae Kim,[1] Shin Yeong Lee,[2] Jin Sug Kim,[1] Tae Won Lee,[1] Chun-Gyoo Ihm,[1] Kyung-Hwan Jeong.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Kyung Hee Univ Hospital, Seoul, Republic of Korea; [2]Artificial Kidney Unit, Isu Clinic, Seoul, Republic of Korea.*

Background: Previous studies demonstrated anti-apoptotic and anti-inflammatory potential of DPP-IV in experimental models of renal injury. We assumed that renoprotective effect of gemigliptin in adriamycin-induced nephropathy might be mediated by suppression of apoptosis, inflammation and oxidative stress.

Methods: The mice were randomly separated into four groups and received a single tail-vein injection of normal saline(control), gemigliptin(GM), adriamycin(ADR) and adriamycin combined with gemigliptin(ADR+GM). Body weight change, urine albumin creatinine ratio(UACR) and serum glucose level between four groups were compared. Apoptosis, inflammation and oxidative stress-related molecules were analyzed by western blotting and real-time PCR. Glomerulosclerotic index(GSI) and tubulointerstitial index(TII) were examined using light microscope. WT-1 and nephrin were evaluated by immunofluorescence microscopy.

Results: In ADR+GM group, UACR significantly decreased compared with ADR group on day 15(ADR: 402.20±138.23 mg/g vs. ADR+GM: 133.70±60.57 mg/g, p=0.049). Serum DPP-IV activity was decreased and active GLP-1 level was increased in ADR+GM group compared with ADR group. GSI and TII in mice of adriamycin-induced nephropathy was decreased with treatment of gemigliptin([GSI] ADR: 62.79% vs. ADR+GM: 21.93%, p<0.01, [TII] ADR: 16.29% vs. ADR+GM: 3.74%, p=0.012). Mice of adriamycin-induced nephropathy expressed higher levels of apoptosis markers(Bax/Bcl-2 ratio, TGF-B1), oxidative stress-related molecules(Nitrotyrosin, iNOS, NOX4) and inflammatory cytokines(MCP-1, PAI-1, TNF-a) than control mice. Upregulation of these molecules was significantly reduced by treatment with gemigliptin. In ADR group nuclear WT-1 and nephrin were reduced but, these changes were inhibited in ADR+GM group([WT-1] ADR: 15.60 vs. ADR+GM: 8.27, p<0.01, [Nephrin score] ADR: 3.54 vs. ADR+GM: 2.09, p=0.04).

Conclusions: We demonstrated that gemigliptin ameliorated renal injury in adriamycin-induced nephropathy. These effect may be attributable to decreased inflammation, apoptosis and oxidative stress.

SA-PO319

Estrogen-Related Receptor (ERR)-γ Protects against Puromycin Aminonucleoside-Induced Podocyte Apoptosis by Targeting PI3K/Akt Signaling

Wei Gong,[2] Guixia Ding,[1] Jing Yu,[2] Shuzhen Li,[2] Zhanjun Jia,[2] Songming Huang,[1] Aihua Zhang.[1] *[1]Dept of Nephrology, Nanjing Children's Hospital affiliated to Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Lab of Pediatrics, Nanjing, China.*

Background: Accumulating evidence has shown that podocyte apoptosis is of vital importance for the development of glomerulosclerosis and progressive loss of renal function. However, the molecular mechanisms leading to podocyte apoptosis are still elusive. In this study, we investigated the role of estrogen-related receptor (ERR)-γ in modulating podocyte apoptosis, as well as the underlying mechanisms.

Methods: Puromycin Aminonucleoside (PAN) was administered to the cultured podocytes or rats to induce podocyte injury. ERRγ siRNA and PI3K inhibitor were used to determine their roles in this experimental setting.

Results: Application of PAN caused a dose- and time-dependent podocyte apoptosis in line with a significant reduction of ERRγ by about 50%. Interestingly, the occurrence of ERRγ downregulation appeared earlier than the onset of cell apoptosis, suggesting a potential that ERRγ reduction triggers apoptotic response in podocyte. To test this hypothesis, ERRγ siRNA was subjected to the podocytes. Strikingly, ERRγ silencing resulted in a significant cell apoptosis accompanied with increased injury markers of B7-1 and cathepsin L and decreased podocyte protein nephrin. In contrast, overexpression of ERRγ remarkably attenuated PAN-induced cell apoptosis. More importantly, ERRγ overexpression stimulated PI3K/Akt signaling pathway evidenced by increased expression of PI3K subunits p85α (+1.2 folds) and p110α (+88%) and phosphorylated Akt (+12.7 folds). Application of LY294002, a specific PI3K inhibitor, entirely reversed the anti-apoptotic effect of ERRγ following PAN treatment. Finally, we observed a remarkable reduction of ERRγ (66%) in PAN-treated rat kidneys in line with an apoptotic response, suggesting that this cell model could replicate the in vivo condition.

Conclusions: These data highly suggested that ERRγ played a novel role in regulating apoptotic process in podocytes by targeting PI3K/Akt signaling pathway.

SA-PO320

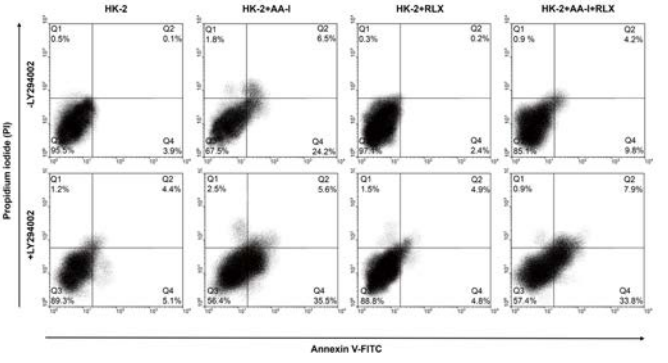
Relaxin Attenuates the Aristolochic Acid Induced Human Tubular Epithelial Cell Apoptosis In Vitro by Activation of PI3K/Akt Signaling Pathway

Xiangcheng Xie, Ming Wang, Xiao Fei. *Dept of Nephrology, Hangzhou First People's Hospital, Hangzhou, Zhejiang, China.*

Background: Aristolochic acid nephropathy (AAN) has long been known as a rapidly progressive renal fibrosis associated with the intake of Chinese herbs containing aristolochic acids (AAs). The treatment strategies remain limited. Emerging evidence has shown that H2 relaxin possesses powerful antifibrosis and anti-apoptotic properties, therefore, we aimed to investigate whether H2 relaxin can be employed to reduce AA-induced cell apoptosis.

Methods: Human proximal tubular epithelial (HK-2) cells exposed to AA-I were treated with or without H2 relaxin. Cell viability was examined using the WST-1 assay. Apoptotic morphologic alterations were observed using Hoechst 33342 stating method. Apoptosis was detected using flow cytometry. The expression of Caspase3, Bax, Bcl-2, and Akt proteins were determined by Western blot.

Results: Increased apoptosis was observed in AA-I treated group, which was reversed by relaxin co-treatment.



Immunoblotting showed the expression of phosphorylated Akt (p-Akt) decreased in AA-I treated cells, which was restored by relaxin. Increased Bax/Bcl-2 ratio and cleaved form of caspase-3 were found in AA-I treated cells, both of which were counteracted by relaxin co-treatment. Whereas, this anti-apoptotic effect of relaxin was attenuated by co-administration of Akt inhibitor LY294002, indicating the anti-apoptocic effect of H2 relaxin was mediated via PI3K/Akt dependent manner.

Conclusions: The present study demonstrated H2 relaxin can decrease AA-I induced increases of apoptosis through activation of PI3K/Akt signaling pathway, suggesting H2 relaxin might play a beneficial role in delaying the progression of AAN.

The Role of BMP4 Signal Pathway on the Podocyte Injury in Diabetic Early Stage Yui Fujita, Tatsuya Tominaga, Taichi Murakami, Seiji Kishi, Kojiro Nagai, Hideharu Abe, Toshio Doi. *Nephrology, Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.*

Background: The glomerulosclerosis induced by podocyte injury is most evident in the pathological change mechanisms. However, loss and apoptosis of podocyte in human renal biopsy is a rare case, podocyte injury mechanism has not been definitively elucidated. BMP4 is an important cytokine that cause mesangial expansion, we examined the mechanism of podocyte injury by BMP4-TAK1 pathway in this study.

Methods: We focused on the BMP4-TAK1 signaling and BMP4-Smad1 signaling in the development of podocyte injury. In cultured podocyte cells, apoptosis-related molecules (caspase3, p38) and tight junction molecule (nephrin, connexin 43) were analyzed under BMP4 stimulation. As inhibition experiments were analyzed using Smad1 suppression molecule (Dorsomorphin) and p38 suppression molecule (SB203580) for the analysis of apoptosis induction. The podocyte specificity induction Bmp4 transgenic mice were generated by CAG-CAT-Bmp4 (Bmp4 Tg) mice and Podocin Cre (PodCre) mice. These mice were induced diabetes by streptozotocin infusion. From these experiments, we clarified the detailed mechanism of the BMP4 signal, which induce podocyte apoptosis.

Results: The expression of pSmad1, pTAK1, pp38 and cleaved caspase3 was increased by BMP4 stimulation in the cultured podocyte cells. The expression of nephrin and connexin 43 was decreased by BMP4 treatment. The activated of pp38 and cleaved caspase3 was inhibited by SB203580 under BMP4 treatment. Dorsomorphin inhibited the phosphorylation of Smad1, but did not affect the activation of p38 and caspase 3. Bmp4 Tg x PodCre mice increased the expression of BMP4 in the kidney as age advances. Diabetic Bmp4 Tg x PodCre mice showed significantly expansion of mesangial matrix as compared to the control group in early stage.

Conclusions: We made clear that podocyte apoptosis was induced by BMP4-TAK1-p38 signal pathway. Bmp4 Tg x PodCre was shown to accelerate the development of glomerulosclerosis. These results suggested that BMP4 acted on the podocyte apoptosis in the early stage of diabetes and induces glomerulosclerosis.

Protective Effect of Epigallocatechin-3-Gallate (EGCG) against Oxalate-Induced Epithelial-Mesenchymal Transition (EMT) of Renal Tubular Cells Visith Thongboonkerd, Rattiyaporn Kanlaya. *Medical Proteomics Unit, Office for R&D, Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.*

Background: Oxalate can induce oxidative stress, cellular injury, calcium oxalate kidney stone formation, and chronic kidney disease (CKD). However, the underlying mechanisms of oxalate-induced CKD remained largely unknown. Our present study evaluated effects of oxalate on epithelial-mesenchymal transition (EMT), one of the priming phenomena preceding CKD. Moreover, epigallocatechin-3-gallate (EGCG), the most abundant polyphenol found in *Camellia Sinensis* (green tea), was also assessed for its potential anti-fibrotic property.

Methods: MDCK renal tubular cells were incubated with 0.5 mM sodium oxalate for 24-h with/without 1-h pretreatment with 25 μM EGCG. The cells were then subjected to morphological analysis, immunofluorescence staining and Western blot analyses of mesenchymal and epithelial markers, flow cytometric analysis of intracellular reactive oxygen species (ROS) production using dichlorofluoresceindiacetate (DCFH-DA) assay, immunofluorescence staining of Nrf2, and Western blot analysis of an anti-oxidant, catalase.

Results: Microscopic examination, immunoblotting and immunofluorescence staining revealed that oxalate-treated cells gained mesenchymal phenotypes by fibroblast-like morphological change and increasing expression of vimentin and fibronectin, while levels of epithelial markers (E-cadherin, occludin, cytokeratin and ZO-1) were decreased. EGCG pretreatment could prevent all these changes and molecular mechanisms underlying the prevention by EGCG were most likely due to reduced production of intracellular ROS through activation of Nrf2 signaling and increased catalase anti-oxidant enzyme.

Conclusions: Taken together, our data indicate that oxalate turned on EMT of renal tubular cells that could be prevented by EGCG. These findings also shed light onto development of novel therapeutics or preventive strategies of renal fibrosis in the future.

HIV Promotes SNAIL Expression and Proliferative Molecular Phenotype in Glomerular Epithelial Cells via Down Regulation of Micro-RNA193a Abheepsa Mishra, Vinod Sharma, Manoj K. Tembhre, Waqaar Khawar, Seyedeh Shadafarin Marashi Shoshtari, Judith Eng, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: Micro-RNA (miR) 193a has been considered to be a tumor suppressor and its down regulation has been reported to stimulate epithelial mesenchymal transition (EMT). EMT has been reported to play a role in proliferation of parietal epithelial cells (PECs)/podocytes (PDs) in HIV-associated nephropathy. We hypothesized that HIV might be stimulating PEC/PD proliferation via down regulation of miR193a and this effect of HIV could be abrogated by using rapamycin.

Methods: Renal tissues of 4 week old control and HIVAN (Tg26) mice (n=4) were assayed for microRNA profile. In another set of experiments, 4 week old Tg26 mice (n=4) were administered either normal saline or rapamycin (2.5 mg/kg, twice a week) for 4 weeks. Renal tissues were assayed for microRNA profile, severity of renal lesions and expression of epithelial mesenchymal transition markers such as SNAIL, α-SMA, PCNA, vimentin, and FSP-1 (immunoblotting of renal tissues and immunohistochemical studies of renal cortical sections). PECs and PDs were transduced with either vector or HIV (NL4-3) and evaluated for miR193a and SNAIL expression. Control and experimental cells were pretreated with rapamycin (100 ng/ml) for 24 hours followed by assay for miR193a and SNAIL expression.

Results: Renal tissues of Tg26 mice displayed a 4 fold decrease in miR193a expression; however, renal tissues of HIVAN mice receiving rapamycin displayed mir193a expression comparable to control mice. Renal tissue/renal cortical sections of Tg26 mice revealed enhanced expression of α-SMA, PCNA, and SNAIL; however, rapamycin attenuated this effect of HIV in Tg26 mice. In *in vitro* studies HIV down regulated miR193a expression but upregulated SNAIL expression both in PECs and PDs. Nonetheless, rapamycin inhibited down regulation of miR193a and prevented enhanced SNAIL expression in HIV-transduced PECs/PDs.

Conclusions: HIV-induced SNAIL expression and proliferative phenotype in glomerular epithelial cells may be mediated via down regulation of miR193a.

SA-PO324

IL-β Contributes to Parietal Epithelial Cell Proliferative Phenotype in HIV-Associated Nephropathy Vinod Sharma,[1] Nirupama Chandel,[1] Manoj K. Tembhre,[1] Abheepsa Mishra,[1] Catherine Meyer-Schwesinger,[2] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY; [2]Medicine, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Proliferating glomerular cells in HIVAN have been considered to be of parietal epithelial cell (PECs) lineage. However, the involved mechanism of PECs's proliferation is not clear. Since HIV promotes pyroptosis in podocytes (Am J Pathol, 2016), we hypothesize that IL-1 β production by HIV-infected podocytes leads to PEC proliferation in HIVAN.

Methods: Vector- transduced and HIV (NL4-3)-transduced podocytes were incubated in media for 48 hours. Incubation media (conditioned media, C. media) of vector –transduced podocytes (Control C. media) and HIV-transduced podocytes (HIV C. media) were collected (stored at -80°C). Equal numbers of PECs were plated in Petri dishes. PECs were serum starved for 24 hours, followed by incubation in serum-free media containing vector conditioned media (Control C. media , 10%), HIV conditioned media (HIV C. media, 10%), HIV conditioned media + IL-1β neutralizing antibody (HIV C. media + IL-1βab, 20 μg/ml), IL-1β antibody alone or human IgG (20 μg/ml) for 48 hours at 33°C (n=4). To determine the dose response effect of IL-1β, equal number of PECs were plated in Petri dishes and serum starved for 24 hours, followed by incubation in serum-free media containing variable concentrations of IL-1β (0, 100, 200, 400 ng/ml) for 48 hours at 33°C (n=4). At the end of experimental periods, the cells were counted. Renal tissue and serum levels of IL-1 β in control and HIVAN (Tg 26) mice were measured (n=6).

Results: HIV conditioned media enhanced proliferation of PECs ($P<0.05$) and this effect of HIV conditioned media was inhibited by IL-1β neutralizing antibodies. IL-1β enhanced PEC proliferation in a dose dependent manner (IL-1β 0 vs 100 ngml, $P<0.01$; IL-1β 200 and 400 ng/ml vs 100 ng/ml, $P<0.05$). Renal tissues as well as serum levels IL-1 β in HIVAN mice were several fold higher ($P<0.01$) than in control mice.

Conclusions: HIV infection of podocytes may be contributing to parietal cell proliferation in HIVAN via generation of IL-1β.

The Role of Chemerin/ChemR23 in the Regulation of Inflammation and Endothelial-Mesenchymal Transition of Glomerular Endothelial Cells in Diabetic Kidney Disease Luyao Wang,[1,2] Jia Guo,[1,2] Yanna Dou,[1,2] Zhanzheng Zhao.[1,2] *[1]The Nephrology Center, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China; [2]Inst of Nephrology, Zhengzhou Univ, Zhengzhou, Henan, China.*

Background: DKD has become the leading cause of end-stage kidney disease, there is no effective treatments so far. Chemerin, a novel adipocyte-derived factor, plays multiple roles by combining with its main ligand chemR23. Chemerin and its ligand chemR23 are closely associated with inflammation and Endothelial-to-mesenchymal transition (EndMT) of glomerular endothelial cells (GEnCs) which play important roles in the process of DKD. GEnCs injury could lead to an increased filtration of albumin in DKD . However, the role of Chemerin / ChemR23 in the pathogenesis of DKD is still not clear.

Methods: GEnCs were incubated with normal condition, 35mmol/L glucose (high glucose) or osmotic control for pre-set time course.And then GEnCs were incubated with normal condition, 10ng/ml Chemerin, 50ng/ml Chemerin, 100ng/ml Chemerin, 200ng/ml Chemerin respectively for 24 hours. Cell morphology was studied by light microscopy. The protein expressions of Chemerin, ChemR23, CD31, α-SMA, TGF-β1, AKT, phosphorylated AKT (p-AKT) were measured by Western Blot. The protein expressions of IL-6, TNF-α were measured by ELISA. The cells co-expression of α-SMA and CD31 were determined by immunofluorescence double labeling.

Results: 1.The expressions of Chemerin, IL-6, TNF-α, TGF-β1, α-SMA, AKT, p-AKT were significant increased and the expression of CD31 was decreased in GEnCs treated with high glucose for 48h($P<0.05$). Additionally, adjacent cells did not attach to each other as closely as control cells. The initially cobble-stone-like cells also adopted a spindle-like morphology. 2.The protein expressions of ChemR23, IL-6, TNF-α were significantly increased and the expression of CD31 was decreased after 200ng/ml Chemrin treatment

for 24hours($P<0.05$). Similarly, the protein expressions of α-SMA, TGF-β1, AKT, p-AKT were increased after 50ng/ml for 24hours with a Chemerin concentrations dependent manner($P<0.05$).

Conclusions: The inflammation and EndMT of GEnCs could be induced by high-glucose. Chemrerin played an important role in inflammation and EndMT of GEnCs.

The Phosphodiesterase 5 Inhibitor Can Alleviate the Epithelial Mescenchymal Transition in Kidney via Klotho Modulation Independent of Nitric Oxide System Jae Won Yang,[1] Jae Seok Kim,[1] Min Keun Kim,[1] Minseob Eom,[2] Byoung Geun Han,[1] Seung-Ok Choi.[1] *[1]Internal Medicine, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea; [2]Pathology, Yonsei Univ Wonju College of Medicine, Wonju, Republic of Korea.*

Background: The phosphodiesterase-5 inhibitor can vasodilate through blocking of cyclic GMP degradation. However, there are many controversies in whether it has another action in case of blocked nitric oxide system.The renal klotho level decreased in animals treated with L-NAME, suggesting that decreased NO result in down-regulation of klotho gene, but the inter-relationship between these two proteins is still obscure. We investigated PDE-5i can preserve epithelial mesenchymal transition and whether relationship existed between the NO pathway and the klotho expression in kidney.

Methods: The 10th weeks male SD rats were divided four groups. We supplied low salt diet to the control group (N=6), L-NAME 1 mg/mL in drinking water to the L-NAME group (N=6), udenafil 5mg/kg SQ to Udenafil group, and L-NAME and udenafil to the L-NAME and udenafil group (N=6) for 4 weeks. After the collection of blood and urine on day 28,serum creatinine was measured andurine nitrate/nitrite,NGAL, and cGMP were measured by ELISA, and kidney tissues were investigated by IHC stains or western blot of PCNA, α-SMA, E-cadherin, and klotho expression.

Results: The urine cGMP level showed 2.59±0.88, 1.79±0.99, 1.20±0.22, 0.69±0.59 nmol /μl ($p<0.05$, control vs Udenafil and L-NAME with udenafil). The klotho protein expression was increased in L-NAME with udenafil group compared with L-NAME group. The urine NGAL showed 279.8±126.8, 651.0±195.3, 473.7±114.9, 326.5±279.4 ng/ml ($p<0.05$ control vs LNAME and LNAME with udenafil), and PCNA expression showed 0.11±0.06, 0.31±0.14, 0.17±0.02, 0.19±0.08 cells ($p<0.05$, control vs L-NAME, and L-NAME vs L-NAME with udenafil). α-SMA showed increased density in L-NAME group compared with L-NAME with udenafil group ($p<0.05$) and E-cadherin protein density was decreased in L-NAME group compared with other groups ($p<0.05$).

Conclusions: The phosphodiesterase 5 inhibitor can alleviate the epithelial mescenchymal transition in kidney via klotho modulation independent of nitric oxide system.

SA-PO327

PGC1α Regulates NAD+ Biosynthesis, Mitochondrial Function, and Injury-Related Cellular Metabolism Kenneth M. Ralto, Vinod Raman, Samir M. Parikh. *Div of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: PPAR-γ coactivator 1 alpha (PGC1α) is transcriptional coactivator which regulates mitochondrial biogenesis. This protein has been shown to be protective against neurodegenerative diseases, ischemia-reperfusion injury, and toxicant exposure. NAD^+ is a coenzyme involved in cellular redox reactions and is a transporter of electrons for use in oxidative phosphorylation. Both PGC1α and NAD^+ play key roles in cells with high energy requirements, such as those found in the renal tubular epithelium.

Methods: A stable PGC1α-overexpressing mIMCD3 cell line was created with lentiviral transduction. A PGC1α knockout mIMCD3 cell line was developed using the CRISPR-Cas9 system. RNA isolation was performed, followed by quantitative PCR to measure expression of NAD^+ biosynthesis enzymes and electron transport chain (ETC) proteins in the transgenic cell lines. ATP and XTT cell proliferation assays were used to characterize metabolic response in the transgenic cell lines after exposure to cisplatin.

Results: PGC1α overexpressing mIMCD3 cells showed higher expression of NAD^+ biosynthetic enzymes (30-96% increase) and ETC proteins (41-66% increase). The PGC1α knockout cells showed reduction in most NAD^+ biosynthetic enzymes (48-70% reduction) and ETC proteins (38-60% reduction). PGC1α knockout cells showed 78.5% reduction in cell proliferation after cisplatin treatment ($p=0.001$) compared to only a 32.9% reduction in cell proliferation in PGC1α overexpressing cells ($p<0.0001$). Cisplatin exposure resulted in 30.6% higher ATP content in the PGC1α overexpressing cells compared to control ($p=0.0029$). In the PGC1α knockout cells, cisplatin exposure resulted in a 69.7% reduction in ATP content compared to control ($p<0.0001$).

Conclusions: PGC1α regulates the expression of several enzymes involved both in the biosynthesis of NAD^+ and in cell energy metabolism. PGC1α overexpressing and knockout transgenic cell lines will allow for research to further elucidate the role of PGC1α in mitochondrial function and energy metabolism.

High-Throughput Microfluidic Platform for Culture of 3D-Kidney Tissue Models Marianne K. Vormann, Remko Van Vught, Sebastiaan Trietsch, Jos Joore, Paul Vulto, Henriëtte Lanz. *Mimetas, Leiden, Zuid Holland, Netherlands.*

Background: Drug toxicity remains a major issue in drug discovery and stresses the need for better predictive models. Here, we describe the development of a perfused renal proximal tubule cell (RPTC) model in Mimetas' OrganoPlates®[1] to predict kidney toxicity. The OrganoPlate® is a microfluidic platform, which enables high-throughput culture of boundary tissues in miniaturized organ models. In OrganoPlates®, extracellular matrix (ECM) gels can be freely patterned in microchambers through the use of PhaseGuide technology. PhaseGuides (capillary pressure barriers) define channels within microchambers that can be used for ECM deposition or medium perfusion. The microfluidic channel dimensions not only allow solid tissue and barrier formation, but also perfused tubular epithelial vessel structures can be grown. The goal of developing a perfused RPTC model is to reconstruct viable and leak-tight boundaries for cytotoxicity, as well as transport and efficacy studies.

Methods: Human RPTC (SA7K clone, Sigma) were grown against an ECM in a 3channel OrganoPlate®, yielding access to both the apical and basal side.

Results: Confocal imaging revealed that the cells formed a tubular structure. Staining showed tight junction formation (ZO-1), cilia pointing into the lumen (acetylated tubulin) and correct polarization with microvilli on the apical side of the tubule (ezrin). Tightness of the boundary over several days was shown by diffusion of a dextran dye added to the lumen of the tubule. Addition of toxic compounds resulted in disruption of the barrier which could be monitored in time. The time point of loss of integrity corresponds with the concentration and the toxic effect of the compound. Furthermore, fluorescent transport assays showed functional transport activity of in- and efflux transporters.

Conclusions: The 3D proximal tubules cultured in the OrganoPlate® are suitable for high-throughput toxicity screening, trans-epithelial transport studies, and complex co-culture models to recreate an in vivo-like microenvironment. [1] Trietsch, S. J., Israëls, G. D., Joore, J., Hankemeier, T. & Vulto, P. Microfluidic titer plate for stratified 3D cell culture. Lab Chip 13, 3548–54 (2013).

A Podocyte High Throughput Screen Identifies a B-RAF Inhibitor as a Therapeutic Strategy for Kidney Disease Jonas Sieber,[1,2] Peter Mundel,[5] Andreas Werner Jehle,[4] Anna Greka.[1,2,3] *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Broad Inst of Harvard and MIT, Cambridge, MA; [4]Biomedicine, Univ Hospital Basel, Basel, Switzerland; [5]Medicine, Massachusetts General Hospital, Boston, MA.*

Background: Urgently needed therapies for kidney disease have been lacking for several decades. Recent discoveries revealed that damage and loss of podocytes contribute to progressive kidney diseases and ultimately kidney failure. Strategies protecting podocytes from cell death are now at the center of new efforts in kidney therapeutics. The objective of this study is to establish and validate a high throughput screen assay to identify small molecules preventing podocytes from ER stress –dependent and –independent death, which may lead to new potential therapeutic strategies.

Methods: Conditionally immortalized podocytes were differentiated for at least 11 days. Cell death was assessed by quantifying relative ATP-levels (high throughput screens) and annexin V positivity. shRNA-based gene silencing was performed by using a lentiviral system. mRNA and protein expression, and protein localization were analyzed by qPCR, Western blotting and IF staining, respectively.

Results: We developed and validated an ATP–based high throughput podocyte viability assay to screen small molecule libraries and to identify podocyte death–preventing compounds. A proof of concept screen of a library of clinically used and preclinical bioactive molecules identified the B-RAF inhibitor GDC-0879 and forskolin, an adenylate cyclase agonist, as inhibitors of podocyte death. We show that the effect of forskolin is mediated by cyclic AMP, but in a PKA– and Epac–independent fashion. Surprisingly, GDC-0879 and forskolin interfere at the level of cell death execution, which intriguingly points to a common and potentially druggable final pathway to podocyte death.

Conclusions: This study reports the development and successful implementation of a high throughput assay to identify podocyte protective compounds, and reveals downstream effects of the B-RAF inhibitor GDC-0879 and forskolin as podocyte-protective strategies.

Assessment of Telomere Length and Mitochondrial DNA Damage in Male Patients with Chronic Kidney Disease Prasanta Debnath,[1] Om Prakash Kalra,[1] Ashish Goel,[1] Rajarshi Kar,[2] Mohit Mehndiratta.[2] *[1]Internal Medicine, Univ College of Medical Sciences, New Delhi, Delhi, India; [2]Biochemistry, Univ College of Medical Sciences, New Delhi, Delhi, India.*

Background: Patients with CKD have accelerated aging process which may be reflected by reduced telomere length and increased mitochondrial DNA damage. The present study was intended to evaluate telomere length and mitochondrial DNA damage in male CKD patients and compare the same with age matched healthy controls and elderly healthy controls in the age group 61-70 years.

Methods: A case-control study which included 35 male patients with CKD between ages 31-40 years as the cases, an equal number of age matched healthy male controls and an equal number of elderly healthy male controls in age group 61-70 years, was conducted. Telomere length was measured by Real Time PCR (RT-PCR) for which telomere specific primer was used. Number of copies of mtDNA was estimated by RT-PCR using specific primers.

Results: The median (Inter-quartile range) values of relative telomere length in CKD patients was found to be 15 (6.25-27); whereas in elderly healthy controls it was 19 (10-35) and in age matched healthy controls it was 103 (70-202). On comparing CKD patients with age matched healthy controls, there was significant difference in telomere length ($p < 0.001$) while on comparing CKD patients with elderly healthy controls there was no significant difference. The median (Inter-quartile range) values of mitochondrial DNA copy number in CKD patients was found to be 123 (73.75-282.25), and that in elderly healthy controls to be 139 (76-185) and that in age matched healthy controls it was found to be 289 (214-541). There was significant difference in number of copies of mtDNA between CKD and age matched healthy controls but comparable results between CKD group and elderly healthy control group.

Conclusions: In our study it was found that telomere length and number of copies of mitochondrial DNA, a marker of mtDNA damage, were markedly reduced in CKD patients when compared with healthy controls of same age group but were comparable with that of elderly healthy controls.

Increased Cellular Senescence in the Murine Stenotic Kidney: Effect of Mesenchymal Stem Cells

Seo Rin Kim,[1] Xiangyu Zou,[1] Xiang-Yang Zhu,[1] Hui Tang,[1] Kyra L. Jordan,[1] LaTonya J. Hickson,[1] Tamara Tchkonia,[2] James L. Kirkland,[2] Lilach O. Lerman.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Robert and Arlene Kogod Center on Aging, Mayo Clinic, Rochester, MN.*

Background: Cellular senescence is a proliferation arrest evoked in response to stress and damage, and is irreversible without experimental intervention. Renal artery stenosis (RAS) may induce stenotic kidney (STK) ischemia and injury, but it is unclear whether these are associated with cellular senescence. Furthermore, while mesenchymal stem cells (MSC) decrease some forms of STK injury, it remains unknown if they can reverse cellular senescence in RAS. We hypothesized that murine RAS evokes STK cellular senescence, which would be ameliorated by MSC.

Methods: Three groups (n=6 each) of 129-mice were studied after 4 weeks of RAS, RAS treated with a tail-vein injection of MSC (5×10^5 cells) 2 weeks after induction, or sham. β-galactosidase activity (fluorometric) and H_2AX (western blot), P16, P21, P53, Activin-A and HIF-1α gene expression were used to assess senescence in STK, CLK, or sham homogenates.

Results: After 4 weeks of RAS, the STK was smaller than the sham and contralateral kidney (CLK) (both $P \leq 0.033$), and blood pressure was higher than sham ($P=0.049$). MSC had no effect on either kidney weight ($P=0.59$ vs. RAS) or blood pressure ($p=0.83$ vs. RAS). β-galactosidase activity was significantly increased in RAS ($P=0.009$ vs. sham) and normalized in MSC treated mice ($P=0.009$ vs. RAS). Renal P16, P21, P53, Activin-A and HIF-1α gene expression was markedly (up to 1,000-fold) elevated in the STK compared to sham and CLK (all $p \leq 0.007$), but showed no change after MSC delivery ($p \geq 0.4$ for all vs. RAS).

Conclusions: This study shows that murine RAS triggers cellular senescence, implicating this process in STK injury. MSC therapy only partly mitigates renal senescence activity, supporting exploration of a targeted senolytic therapy in RAS.

Oligomerization of Fn14-TRAIL by Endogenous TWEAK Leads to Robust, TRAIL-Mediated, Apoptosis of Renal Cell Carcinoma

Michal Dranitzki Elhalel,[1] Kobi Tzdaka,[1] Prigozhina Tatyana,[1] Ortal Avraham,[1] Fanny Shkedy,[2] Shira Amsili,[2] Efi Makdasi,[2] Noam Shani.[2] *[1]Nephrology and Hypertension, Hadassah-Hebrew Univ Medical Center, Jerusalem, Israel; [2]KAHE Medical LTD, Israel.*

Background: Renal Cell Carcinoma(RCC), the most abundant kidney tumor has no current treatments available for disseminated disease. TNF-Related Apoptosis-Inducing Ligand (TRAIL) was reported to induce selective apoptosis of malignant cells and spare normal ones. TNF-Related Weak Inducer of Apoptosis (TWEAK) with its receptor, Fn14, was shown to contribute to tumor growth and metastasis. Treatments designed to activate TRAIL signaling or block TWEAK were not effective enough in clinical trials and ways to potentiated TRAIL activity specifically at tumor microenvironment are needed. The novel dual signaling fusion protein Fn14-TRAIL (FT) is comprised of Fn14 domain that can bind and block endogenous TWEAK and of TRAIL domain that can direct apoptotic signals to TRAIL receptor bearing cells.

Methods: Potency of FT as apoptosis inducing agent of RCC was tested in-vitro (by flow-cytometry, MTS and WB), and in a xenograft model.

Results: 1) FT induces apoptosis in different RCC cell lines, while sparing non-malignant renal cells; 2) FT is more effective than sTRAIL, Fn14-Fc or their combination; 3) TRAIL decoy receptors expression was negatively correlated with sensitivity to FT 4) FT's activity can be blocked by anti-TRAIL or Fn14 Abs; 5) TWEAK KO cells lost sensitivity to FT effect and this could be reversed by TWEAK addition. 6) Interestingly, adding TWEAK to FT results in the formation of large Fn14-TRAIL-TWEAK complex with robust apoptotic activity specifically in RCC cells and not in non-malignant renal cells, and 7) FT effectively inhibits the growth of RCC tumors in a xenograft model.

Conclusions: These findings suggest that FT specifically in TWEAK's presence becomes super-active inducer of apoptosis of malignant cells, probably because of the larger complex presenting TRAIL to the target cells in a cluster form that is known to trigger the TRAIL receptors better than the trimer form. Taken together, these results propose Fn14-TRAIL as a potential treatment for TWEAK expressing RCC.

Interleukin-15-Receptor-α Contributes to Podocyte Anti-Apoptotic Signaling Through Activation of the PI-3K/AKT and JAK/STAT3 Pathways

Gentzon Hall,[1,3,4] Gina E. Kovalik,[1,4] Robert F. Spurney,[1,3,4] Guanghong Wu,[1,4] Brandon M. Lane,[2,4] Megan Chryst-Ladd,[4] Eugene C. Kovalik,[1,3] Rasheed A. Gbadegesin.[2,3,4] *[1]Dept of Medicine, Duke Univ Medical Center; [2]Dept of Pediatrics, Duke Univ Medical Center; [3]Div of Nephrology, Duke Univ Medical Center; [4]Duke Molecular Physiology Inst, Duke Univ Medical Center.*

Background: We recently identified a rare heterozygous missense variant (K47R) in the Interleukin-15 Receptor-α (IL-15Rα) as a contributor to autosomal dominant FSGS in an African American kindred. The K47R variant occurs within the high-affinity "sushi" ligand binding domain of IL-15Rα and exerts a loss-of-function effect on the receptor, which impairs podocyte anti-apoptotic signaling. To further characterize the role of IL-15Rα in podocyte anti-apoptotic signaling, we examined the effects of IL-15Rα overexpression and gene knockdown (KD) on its two known downstream effector pathways, PI-3K/AKT and JAK/STAT.

Methods: We used immunoblotting and immunofluorescence imaging to evaluate PI3K/AKT and JAK/STAT signaling in IL-15Rα knockdown, IL-15Rα*WT* -overexpressing, and IL-15$R\alpha_{K47R}$-overexpressing podocytes.

Results: In response to IL-15 stimulation, podocytes overexpressing IL-15$R\alpha_{K47R}$ exhibited reduced AKT and STAT3 activation relative to IL-15$R\alpha_{WT}$ -overexpressing podocytes. Nuclear localization of activated STAT3 was also reduced in IL-15$R\alpha_{K47R}$ -overexpressing podocytes stimulated with IL-15. In *IL-15Rα* KD podocytes, AKT and STAT3 activation were decreased with concomitant reductions in BAD phosphorylation at the AKT target site Ser136 and STAT3-mediated Bcl-2 and Bcl-xL expression. Cleaved Caspase 3 was also upregulated in *IL-15Rα* KD podocytes consistent with the initiation of apoptosis.

Conclusions: IL-15Rα is a key component of the podocyte anti-apoptotic signaling repertoire and the PI-3K/AKT and JAK/STAT3 pathways are important mediators of IL-15/IL-15Rα-induced anti-apoptotic signaling.

mTORC1 Regulates TCA Cycle in Renal Cyst Formation and Transformation

Luca Drusian,[1,2] Monika Pema,[1,2] Valeria Mannella,[1] Marco Chiaravalli,[1] Ana Sofia Henriques da Costa,[3] Christian Frezza,[3] Giovanna Musco,[1] Alessandra Boletta.[1] *[1]DGCB, San Raffaele Scientific Inst, Milano, Italy; [2]PhD Program in BBC, Univ San Raffaele, Milano, Italy; [3]MRC Cancer Unit, Cambridge Biomedical Campus, Cambridge, United Kingdom.*

Background: In many syndromes the kidney is affected by cyst formation, benign lesions of renal tubules. These lesions can evolve into cystadenomas and then renal cell carcinomas (RCC). Molecular causes of these manifestations are largely unknown.The mTOR pathway has been widely implicated in RCC.

Methods: To investigate the role of selective upregulation of mTORC1 in the kidney, we developed a mouse model carrying kidney-specific inactivation of the *Tsc1* gene. These mice develop renal cysts due to downregulation of PC-1, the product of the PKD1 gene mutated in Autosomal Dominant Polycystic Kidney Disease (*Pema et al, NatComm 2016*). In *Tsc1* mutants cortical lesions progressively transform with complete penetrance within a short window of time (3 months). Biochemical analysis performed on kidneys displaying cysts (P20), cystadenomas (P50) and carcinomas (P80) show the expected upregulation of mTORC1.

Results: We performed metabolomic profiling by NMR and LCMS on kidneys from *Tsc1* mutants and control mice. The analysis revealed unexpected increased levels of TCA cycle metabolites in the mutants. Fumarate was virtually exclusively detected in the mutant kidneys. qRT-PCR analysis revealed significantly reduced expression of the *Fh1* (*Fumarate Hydratase*) enzyme, deputed to convert fumarate into malate. Moreover, *Tsc1*$^{-/-}$, *Tsc2*$^{-/-}$ MEFs and mIMCD cells *knocked-down* for *Tsc1* show an accumulation of fumarate and a downregulation of *Fh1*, effects reverted by rapamycin treatment (72hrs). Finally, analysis of direct effectors of fumarate storage either by mass-spectrometry or by IHC showed a correlation between disease progression and fumarate increase in the *Tsc1* mutant kidneys.

Conclusions: To our knowledge this is the first animal model recapitulating a progressive RCC in kidney cortex. Our data suggest a previously unreported link between mTORC1 upregulation and TCA cycle alterations. Most importantly we show that mTORC1 can directly regulate the storage of fumarate in this mouse model, likely leading to progressive transformation.

SA-PO335

Intrinsic APOL1 Toxicity Requires Acidification along the Secretory Pathway Joseph Giovinazzo, Russell P. Thomson, Anibelky Almanzar, Simranjit Singh, Jayne Raper. *Biological Sciences, Hunter College, New York, NY.*

Background: Apolipoprotein L-1 (APOL1) is an innate immunity protein that forms pores in trypanosomes. Variants in APOL1 have been linked to kidney disease, yet the mechanism responsible remains controversial. Here we tested the hypothesis that APOL1 toxicity is cell intrinsic and dependent upon secretion via the Golgi, and thereby acidification followed by neutralization upon delivery to the plasma membrane, whereupon the cation selective pore initiates plasma membrane wound repair.

Methods: HEK293 cells were transfected with APOL1 and its variants, including deletion of the signal peptide. After 48h, cell cytotoxicity and viability were measured. Treatment with ammonium chloride was performed 2h prior to transfection to screen for prerequisite acidification. Recombinant APOL1 was purified from E. coli and reconstituted in planar lipid bilayers, where ion channel conductivity and selectivity were measured. 24 and 48h after transfection with APOL1, lysosomal enzyme activity of acid sphingomyelinase (ASM) and β-hexosaminidase were assayed in the supernatant, to probe for plasma membrane repair.

Results: Toxicity of APOL1 required the signal peptide, with complete ablation of toxicity across all variants. Pre-treatment of cells with ammonium chloride prior to transfection reduced the toxicity of all APOL1 variants. In planar lipid bilayers, rAPOL1 allowed the passage of Ca^{2+}. Influx of Ca^{2+} activates the cell wound repair pathway by causing lysosomal migration and fusion with the plasma membrane, releasing lysosome contents to initialize repair. Expression of APOL1 indeed activates the cell wound healing process, assayed by an increase in ASM and β-hexosaminidase activity in the supernatant. Continued delivery of pores to the membrane ultimately causes cell lysis.

Conclusions: These results support a model of APOL1 cell death, which mirrors that in trypanosomes. Herein, endogenous APOL1 inserts into membranes due to acidification along the secretory pathway, and forms pores upon neutralization at the plasma membrane. Prior to cell lysis, the lysosomal contents are released into the supernatant in an attempt to repair the APOL1-mediated damage at the cell surface.

Comparison of Gene Expression Profiles in Podocyte Caused by APOL1 Wild Type and Risk Variants Guolan Xing,[1] Xiqian Lan,[1,2] Judith Eng,[2] Karl Leon Skorecki,[3] Ashwani Malhotra,[2] Pravin C. Singhal.[2] *[1]Dept of Nephrology, First Affiliated Hospital of Zhengzhou Univ, Zhengzhou Univ Inst of Nephrology, Henan, China; [2]Medicine, Feinstein Inst for Medical Research, Hofstra North Shore LIJ Medical School, Great Neck, NY; [3]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: Increasing evidences have demonstrated that African Americans develop chronic kidney diseases at higher ratios than European Americans, and this disparity has been attributed to two coding sequence variants (G1 and G2) in *APOL1* gene. However, the underlying mechanisms are poorly understood. Previous studies from our group as well as other groups showed that the variants G1 and G2 are more toxic than G0 to kidney cells. To further reveal the molecular mechanisms involved in APOL1-associated nephropathy, We have evaluated their gene expression profiles in podocytes expressing G0, G1, and G2.

Methods: We have generated human podocyte cell lines steadily expressing APOL1 wild type (G0), G1, or G2 proteins. To compare the expression profiles among these cells, podocytes expressing APOL1G0, G1 and G2 underwent RNA-seq, real time-PCR, and Western blot analysis.

Results: Podocytes APOL1 risk variants (G1 and G2) displayed multiples genes related to cellular endoplasmic reticulum (ER) stress, necrosis, and proliferation; RNA-seq results further revealed that the eIF2 signaling pathway was down regulated by G1 and G2.

Conclusions: Our study demonstrated the different gene expression profiles caused by APOL1 wild type and its variants, and will help to reveal the underlying molecular mechanisms of APOL1 variants caused kidney injury, which may highlight novel therapeutic targets for the prevention and treatment of APOL1-associated nephropathy.

Expression of APOL1 Risk Allele in Drosophila Nephrocytes Induces Hypertrophy and Leads to an Accelerated Cell Death Zhe Han, Yulong Fu, Jun-Yi Zhu, Adam Richman, Patricio E. Ray. *Children's National Health Systems, Washington, DC.*

Background: Apolipoprotein-1 (APOL1) risk alleles are strongly associated with an increased risk of developing renal diseases among persons of African ancestry. However, the mechanisms underlying APOL1 associated renal diseases are unknown. Because the *APOL1* gene is unique to humans and some primates, new experimental models are needed to understand the function of the *APOL1* risk alleles *in vivo*.

Methods: We generated transgenic *Drosophila* lines expressing the human *APOL1* wild type (G0) and the predominant *APOL1* risk allele (G1) in different tissues, including the nephrocytes, which share striking similarities to human podocytes. Various functional and structural assays were formed to access the role APOL1-RA effects in different tissues with focus on the nephrocytes.

Results: Ubiquitous expression of either G0 or G1 ApoL1 in *Drosophila* induced lethal phenotypes, with G1 being more toxic than G0. When G0 and G1 were expressed specifically in *Drosophila* nephrocytes, the structurally and functionally homologous of mammalian podocytes, these cells showed first an upregulated endocytic activity and increased accumulation of hemolymph proteins, dextran particles, and silver nitrate, leading to increase nephrocyte size and function. As these flies aged, the function of nephrocytes declined, and showed a reduced endocytic activity associated with progressive cell swelling, and cell death, mimicking the changes seen in cultured podocytes overexpressing APOL1. Furthermore, G0 and G1 impaired the acidification of organelles in nephrocytes.

Conclusions: We conclude that overexpression of APOL1 G0/G1 in fly nephrocytes, first increases the function of nephrocytes, causing hypertrophy rather than direct cell death. This new *Drosophila* model suggest a novel mechanism through which overexpression of APOL1 could precipitate renal diseases in humans, and may enable the identification of APOL1 interacting molecules that could serve as new targets for treatments against APOL1-associated renal diseases.

Scaffolding Protein JLP Modulates Kidney Fibrosis Induced by Unilateral Ureteral Obstruction via Mediation of Autophagy Activation Qi Yan, Huiming Wang, Ming Shi, Guohua Ding. *Dept of Nephrology, Renmin Hospital of Wuhan Univ.*

Background: Scaffolding protein JNK-associated leucine (JLP) plays a crucial role in signal transduction and molecular trafficking. Our previous study found that JLP deficiency deteriorated kidney fibrosis in mice model of unilateral ureteral obstruction (UUO), but the precise contribution of JLP in kidney fibrosis remains unknown. In the present study, we investigate the effect of JLP on the activation of autophagy in kidney fibrosis of UUO model.

Methods: *jlp* Wild type ($jlp^{+/+}$) and *jlp* deficient ($jlp^{-/-}$) mice were divided into six groups: $jlp^{+/+}$- and $jlp^{-/-}$-sham-operated groups, $jlp^{+/+}$- and $jlp^{-/-}$-unilateral ureteral obstruction (UUO)-operated groups ($jlp^{-/-}$- UUO group and $jlp^{+/+}$- UUO group), $jlp^{+/+}$- and $jlp^{-/-}$-unilateral ureteral obstruction (UUO)-operated plus Rapamycin groups ($jlp^{-/-}$- UUO + Rapa group and $jlp^{+/+}$- UUO + Rapa group). Mice were sacrificed at the days of 7 to evaluate the fibrosis by Masson and H&E staining. The expression of α-smooth muscle actin (α-SMA) were assayed by immunohistochemistry staining. The activity of autophagy was measured by expression of LC3 and p62.

Results: 1) One week after the surgery, more collagen deposition and expression of α-SMA was observed in the renal interstitial area in $jlp^{-/-}$- UUO group compared with $jlp^{+/+}$- UUO group. Moreover, the collagen deposition and α-SMA expression was also increased in $jlp^{-/-}$- UUO + Rapa group rather than in $jlp^{+/+}$- UUO + Rapa group. 2) Expression of LC3 were significantly increased in $jlp^{-/-}$- UUO-operated groups compared with $jlp^{+/+}$- UUO group, whereas expression of p62 show opposite trend. 3) Expression of LC3 was also significantly higher in $jlp^{-/-}$- UUO-operated + Rapa group than in $jlp^{+/+}$- UUO + Rapa group, whereas expression of p62 were decreased in $jlp^{-/-}$- UUO-operated + Rapa group compared with $jlp^{+/+}$- UUO + Rapa group.

Conclusions: Scaffolding protein JLP deficiency activates autophagy, which aggravates kidney fibrosis in UUO model.

Human Point Mutation in Umod Causes Progressive Interstitial Kidney Disease and Organ Failure in Mice Bryce Gordon Johnson, Lan Dang, Allie M. Roach, Jeremy Stuart Duffield. *R&D, Biogen, Cambridge, MA.*

Background: An estimated 10% of adults in the U.S. (~20 million individuals) are living with Chronic Kidney Disease (CKD), and kidney failure is a leading cause of death. UAKD accounts for <1% of CKD cases. The hallmarks of UAKD are hyperuricemia, polyuria, cortico-medullary cysts, and progressive tubulo-interstitial fibrosis leading to kidney failure by 30-70y. UAKD is caused by mutations in the *UMOD* gene that result in misfolding of the protein, and accumulation in the ER. This aggregation of misfolded protein sets off cascades of ER stress response.

Methods: We designed and generated the *Umod* $^{C147W/+}$ point mutation knock-in mouse model with Crispr/Cas9 technology. Whole kidney tissue preps and individual cell populations were isolated from mutant mice and analyzed compared to wild type littermates. Immortalized human UMOD+ cell lines were generated harboring both WT and C147W mutant alleles.

Results: Heterozygous mice develop spontaneous and progressive kidney disease with organ failure, highly similar to humans, over 24 wks.There is activation of the PERK/ATF4 and IRE1a/XBP1 ER stress pathways in the cells expressing misfolded protein. Surprisingly, autophagy is inhibited in this setting, potentially by putative inhibitors of ATF4/CHOP. The mTOR pathway, which antagonizes autophagy, is highly active in the kidneys of diseased animals. Diseased cells express increased amounts of pro-apoptotic factors, and are more susceptible to TNFa and Trail induced apoptosis in vitro.

Conclusions: We conclude that this new mouse model provides an excellent means for studying progressive human renal disease, as well as other human disease characterized by insult to proteostasis by mutant protein accumulation, leading to organ failure.

SA-PO340

D-Serine, a Novel Emerging Uremic Toxin Candidate, Induces Cell Cycle Arrest and Apoptosis Through Up-Regulation of ER Stress and Oxidative Stress in Proximal Tubular Cells Akira Okada,[1] Tzu-Ming Jao,[2] Hiroshi Maekawa,[1] Yu Ishimoto,[1] Masaomi Nangaku,[1] Reiko Inagi.[2] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Div of CKD Pathophysiology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Elevated D-serine concentration in plasma has been reported to be a poor prognosis marker of patients with chronic kidney disease (CKD), indicating the pathophysiological significance of D-serine in the kidney. However, the molecular mechanisms underlying D-serine induced toxicity in the kidney remain largely unknown. In the present study, we aimed to explore D-serine-mediated signaling pathways in the proximal tubular cells.

Methods: Human proximal tubular cell line, HK-2, was treated with D- or L-serine for 48 hr and evaluated the cell damages by cell proliferation (MTS assay and cell count), cell cycle status (PI staining, p53), apoptosis (Annexin V staining and caspase 3/7 activity). To find out the molecular mechanism of the cell damage by D-serine, we assessed the status of endoplasmic reticulum (ER) stress (real time RT-PCR and Western blotting for GRP78 and CHOP), oxidative stress (NADPH oxidase activity, mitochondrial ROS), pro-inflammatory cytokine expression (IL-1β, and IL-6) known as senescence-associated secretory phenotype (SASP). CHOP siRNA was also used.

Results: D-serine, but not L-serine, induced ER stress signal and oxidative stress associated with increased intracellular ROS, and thereby caused G2/M cell cycle arrest. Importantly, the cell arrest by D-serine was associated with the upregulation of p53 and SASP-related pro-inflammatory cytokines in HK-2. D-serine also induced apoptosis mediated by CHOP, namely apoptotic ER stress axis. It was supported by the results showing that CHOP siRNA ameliorated the apoptosis.

Conclusions: D-serine causes tubular cell damage via both premature senescence and apoptotic signals, both of which are mediated by ER stress or oxidative stress, suggesting a novel renal pathogenesis of D-serine as a potential uremic toxin in CKD patients. Our study sheds a new light on CKD pathophysiology from the point of view of vicious cycle of tubular damage by uremic toxins including D-serine.

SA-PO341

Effect of Cyanate on the p-AMP Kinase, Isocitrate Dehydrogenase, and Apoptosis in Huh7 Cells Yaerim Kim,[1,2] Sang Mok Yeo,[1,2] Seong Sik Kang,[1,2] Woo Yeong Park,[1,2] Kyubok Jin,[1,2] Sung Bae Park,[1,2] Kyo Chul Mun,[2,3] Seungyeup Han.[1,2] *[1]Dept of Internal Medicine, Keimyung Univ School of Medicine, Daegu, Republic of Korea; [2]Keimyung Univ Kidney Inst, Daegu, Republic of Korea; [3]Dept of Biochemistry, Keimyung Univ School of Medicine, Daegu, Republic of Korea.*

Background: Urea is a major factor of uremic syndrome which is accumulated by decreased kidney function. It can be degraded by ammonia and cyanate. We studied alteration of major enzyme for energy metabolism and effectiveness of apoptosis to confirm the impact of cyanate on energy metabolism in a patient of chronic kidney disease.

Methods: We checked pAMP kinase and isocitrate dehydrogenase which are major enzymes of energy metabolism. It was performed by using Huh7, liver cell carcinoma cell strain which is key cell in creation of energy. After cyanate processing to Huh7, we analyzed a viability of cell, performed western blot analysis about pAMP kinase and apoptotic factors like PARP, p53, cytochrome C, cIAP, and xIAP. And we checked activity of isocitrate dehydrogenase and took reverse transcriptional polymerase chain reaction.

Results: The viability of Huh7 cell was decreased in proportion to the concentration and exposure time to cyanate. According to the western blot analysis about cell apoptotic factors, protein of PARP was cleaved in accordance with the exposure time, and p53 was strongly expressed after cyanate processing. Free cytochrome C and xIAP was decreased in proportion to time of cyanate processing, cIAP was increased after cyanate processing. After cyanate processing to Huh7 cell, p-AMP kinase which mainly works in energy metabolism was decreased as time passes in Western blot analysis. Although isocitrate dehydrogenase activity was increased compared with control, expression of mRNA of isocitrate dehydrogenase was decreased after cyanate processing.

Conclusions: In our study,cyanate as uremic toxin induced apoptosis in Huh7 cells, activated TCA cycle, and inhibited energy metabolism. As a result, it leads to decline of energy generation, which makes CKD patients meet with fatigue, musculoskeletal problem and hypothermia.

SA-PO342

a-Lipoic Acid Attenuates p-Cresol Sulfate-Induced Renal Tubular Injury Through Suppression of Apoptosis and Autophagy in Human Proximal Tubular HK-2 Cells Jung Sun Park, Hoon In Choi, Eun Hui Bae, Seong Kwon Ma, Jong Un Lee, Soo Wan Kim. *Internal Medicine and Physiology, Chonnam National Univ Medical School, Kwang Ju, Korea.*

Background: The protein bound solute p-cresol sulfate accumulates in chronic kidney disease, and may play significant roles in the progression of renal injury. a-lipoic acid (ALA) is known to acts as antioxidants in cell injury protection. Here, we investigated the effects of a-lipoic acid treatment on p-cresol sulfate-induced renal tubular injury.

Methods: The effects ofa-lipoic acid by p-cresol sulfate-induced cell death were determined using human proximal tubular (HK-2) cells. A apoptosis was determined by flowcytometry using annexin-V-FITC/PI assay and levels of lactate dehydrogenase (LDH). The protein expression of apoptosis- and autophagy-related proteins (Bax, Bcl-2, cytochrome C, and LC3B, Beclin-1) was determined by semiquantitative immunoblotting. Mitochondria membrane potential (MMP/DY_m) was evaluated using fluorescence microscopy and flow cytometry analysis with Rho123 as the fluorescent probe.

Results: p-Cresol sulfate treatment significantly increased levels of lactate dehydrogenase (LDH) and induced time-, dose-dependent cell death in HK-2 cells. p-Cresol sulfate increased the expression of apoptosis-related protein Bax/Bcl-2, cytochrome C, as well as autophagy-related protein Beclin-1 and LC3B in HK-2 cells. In contrast, a-lipoic acid significantly reduced p-cresol sulfate-induced the expression of Bax/Bcl-2, cytochrome C, and loss of mitochondria membrane potential. Apoptosis of p-cresol sulfate-induced HK-2 cells was significantly reduced by specific autophagy inhibitor 3-methyladenine. Additionally, in the presence of the specific apoptosis inhibitor Z-VAD-FMK, p-cresol sulfate-induced autophagy was significantly reduced.

Conclusions: a-lipoic acid attenuated p-cresol sulfate-induced cell death through suppression of apoptosis and autophagy in HK-2 cells.

Funding: Government Support - Non-U.S.

SA-PO343

R428 as a Novel Therapeutic Agent for the Treatment of Experimental Immune-Mediated Nephritis Wenhai Shao. *Medicine, Temple Univ, Lewis Katz School of Medicine, Philadelphia, PA.*

Background: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease. Glomerulonephritis is a major cause of morbidity in SLE. Nephrotoxic serum-mediated anti-glomerular basement membrane (anti-GBM) disease is a well-studied mouse model of immune-mediated glomerulonephritis. Glomerular proliferation is essential for the pathogenesis and progression of glomerular diseases. Axl receptor tyrosine kinase mediates glomerular cell survival signaling, resulting in proliferative responses. R428 is a recently described selective small molecule inhibitor of Axl.

Methods: R428 was administered through oral gavage two day before nephrotoxic serum injection and continued for 12 days. Control mice were administered with the vehicle buffer. Blood samples were collected. Kidney samples were prepared for RNA and Western analysis.

Results: Our results show R428 effectively prevents disease progression and exacerbation with significantly reduced blood urea nitrogen levels and enhance survival rates as compared to the vehicle-treated nephritic mice. Mechanistic studies revealed that R428 suppresses the expression of pro-inflammatory cytokines and reduces Akt phosphorylation in the kidney.

Conclusions: In summary, these results indicate that R428, currently under clinical trial in cancer patients, may have clinical therapeutic application in lupus nephritis patients.

Nicotine Induces Podocyte Apoptosis Through Increasing Oxidative Stress Xiqian Lan, Judith Eng, Seyedeh Shadafarin Marashi Shoshtari, Ashwani Malhotra, Pravin C. Singhal. *Medicine and Immunology, Feinstein Inst for Medical Research and Hofstra North Well Medical School, Great Neck, NY.*

Background: Cigarette smoking plays an important roles in the progression of chronic kidney disease (CKD). Nicotine, one of the major components of cigarette smoking, has been demonstrated to increase proliferation of renal proximal tubular and mesangial cells. In this study, we examined the effect of nicotine on podocyte injury.

Methods: To determine the expression of nicotine receptors (nAChR subunits) in both cultured human podocytes and mouse kidney, protein blots and cDNAs of renal tissues and cellular lysates were probed for nAChR. We studied the effect of nicotine on podocyte ROS generation (DCFDA loading followed by fluorometric analysis), cell proliferation, and cell apoptosis (morphologic assays). We evaluated the effect of nicotine on podocyte downstream signaling (phosphorylation of AKT, ERK1/2, JNK, and p38) and established causal relationships by using specific inhibitors.

Results: Human podocytes displayed robust mRNA and protein expression of nAChR. Immunofluorescence studies in renal cortical sections of mice revealed co-localization of nAChR along with synaptopodin. Nicotine stimulated podocyte ROS generation; however, antioxidants such as N-acetyl cysteine and TEMPOL (superoxide dismutase mimetic agent) inhibited this effect of nicotine. Nicotine did not modulate proliferation but promoted apoptosis in podocytes. Nicotine enhanced podocyte phosphorylation of AKT, ERK1/2, JNK, and p38 and their respective inhibitors attenuated nicotine-induced apoptosis.

Conclusions: Nicotine induces podocyte apoptosis through ROS generation and associated downstream signaling. The present study provides insight into molecular mechanisms involved in smoking associated progression of chronic kidney disease.

SA-PO345

Podocyte Damage Is Mitigated by Normal High Density Lipoprotein (HDL) Yohei Tsuchida,[1] Jianyong Zhong,[1] Talat Alp Ikizler,[3] Agnes B. Fogo,[2] Haichun Yang,[2] Valentina Kon.[1] *[1]Pediatrics, Vanderbilt Univ Medical Center, Nashville, TN; [2]Pathology, Vanderbilt Univ Medical Center, Nashville, TN; [3]Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: HDL is beneficial to many different cells types. We showed that CKD makes HDL dysfunctiona. Although the glomerular filtration barrier limits direct contact and influence of HDL on podocytes, disruption in the filtration barrier permits greater interaction. We investigated the effects of normal HDL and its major apolipoprotein, ApoA1, on injured podocytes and compared these effects to HDL isolated from subjects with CKD.

Methods: Primary mouse podocytes were exposed to puromycin and injury compared to that seen with added HDL isolated from controls with normal kidney function, individuals with CKD or ESRD, or normal ApoA1 (EMD Millipore Company). We assessed podocyte viability by XTT Cell Viability, proliferation by Cell Titer96® Aqueous One Solution Cell Proliferation Assay, and cellular production of superoxide by HPLC. The membrane lipid raft component, phosphorylated caveolin-1 (Cav-1), was measured by western blot.

Results: PAN significantly reduced cell viability, proliferation, and increased ROS production.

	Cell viability	Cell proliferation	ROS production (pmol/mg)
PAN (-)	0.47±0.02	0.48±0.05	0.98±0.05
PAN (+)	0.37±0.03*	0.34±0.02*	1.84±0.05*
PAN (+)/ApoAI	0.41±0.02†	0.44±0.04†	1.30±0.03†
PAN (+)/HDL^{Cont}	0.41±0.03†	0.43±0.07†	1.29±0.05†
PAN (+)/HDL^{CKD}	0.40±0.06	0.41±0.06	1.48±0.04†#

Each of these effects was significantly quelled by exposing podocytes to ApoA1 or HDL^{Cont} and more variable nonsignificant results with HDL^{CKD}. Significant increase in PAN-induced Cav-1 phosphorylation was returned to baseline level by HDL^{Cont} 0.65±0.04vs 0.81±0.05 vs 0.70±0.09, respectively).

Conclusions: We conclude that podocyte damage can be mitigated by normal HDL or its main lipoprotein ApoA1, findings that parallel beneficial biological function of HDL/ApoA1 in other cell types. Restoration of normal HDL or exposure to normal HDL may mitigate podocyte injury and promote podocyte resilience.

COX-2/mPGES-1/PGE2 Cascade Mediates Uric Acid-Induced Mesangial Cell Proliferation Shuzhen Li,[2] Wei Gong,[2] Jing Yu,[2] Yue Zhang,[1] Guixia Ding,[1] Songming Huang,[1] Aihua Zhang,[1] Zhanjun Jia.[2] *[1]Dept of Nephrology, Nanjing Children's Hospital affiliated to Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Lab of Pediatrics, Nanjing, China.*

Background: Hyperuricemia is not only the main feature of gout but also a cause of gout -related organ-injuries including glomerular hypertrophy and sclerosis. Uric acid (UA) has been proven to directly cause mesangial cell (MC) proliferation, however, the mechanism is still elusive. Here we examined the role of inflammatory cascade of COX-2/mPGES-1/PGE_2 in UA-induced MC proliferation.

Methods: UA was administered to the mesangial cells to induce cell proliferation. Specific COX-2 inhibitor and mPGES-1 siRNA were used to determine their roles in this pathological process.

Results: By performing dose- and time-dependent experiments in MCs, UA increased cell proliferation as shown by increased number of cells in S and G2 phases by about 2 folds in parallel with the upregulation of cyclin A2 and cyclin D1 at both mRNA (1.5 and 2 folds, respectively) and protein levels (0.5 and 2.5 folds, respectively). Interestingly, UA-induced cell proliferation was accompanied by selectively induced COX-2 (not COX-1) and mPGES-1(not mPGES-2 and cPGES) protein and mRNA expressions by around 2 to 3 folds. Similarly, PGE2 production in medium was also elevated by 7 folds. Importantly, inhibition of COX-2 via specific COX-2 inhibitor NS398 markedly blocked UA-induced MC proliferation in parallel with an abolished PGE2 production. Furthermore, inhibiting specific PGE2 synthase mPGES-1 by a siRNA approach in MCs also ameliorated UA-induced MC proliferation by detecting the number of cells in the S and G2 phases and expressions of cyclin A2 and cyclin D1.

Conclusions: Our findings indicated that COX-2/mPGES-1/PGE_2 cascade mediated UA-induced MC proliferation. The study offered potential targets for the treatment and prevention of hyperuricemia-related glomerular hypertrophy and sclerosis.

Proliferation and Migration Ability of Renal Carcinoma Cells Is Enhanced by Autocrine MCP-1/CCR2 Signaling Christoph Kueper,[1] Franz Xaver Beck,[1] Wolfgang Neuhofer.[2] *[1]Cellular Physiology, Univ of Munich, Munich, Germany; [2]Nephrology, Clinic Traunstein, Traunstein, Germany.*

Background: The chemokine MCP-1 is an important mediator of monocyte recruitment during inflammatory processes via binding to CCR2. High expression levels of MCP-1 have been observed in various cancers, among them renal cell carcinoma (RCC), and are often associated with infiltration of proinflammatory monocytes, which promote tumor progression and metastasis. Besides paracrine effects, also autocrine MCP-1/CCR2 signaling has been described in cancer cells. The aim of the present study was to evaluate the function and the regulation of MCP-1 in RCC.

Methods: RCC cell lines and peripheral blood monocytes (PBM) were grown under standard conditions. MCP-1 and NFAT5 expression was determined by qRT-PCR, ELISA, and immunoblot. Migration and proliferation of RCC and PBM was determined by Boyden chamber, scratch assay and MTT assay in the presence or absensce of CCR2 inhibitor, MCP-1 neutralizing antibody, or recombinant MCP-1. NFAT-5 knockdown in RCC was achieved by specific siRNA.

Results: Experiments were performed in the RCC cell lines CaKi-1 (VHL-positive) and 786-O (VHL-negative). In both cell lines, expression of MCP-1 was significantly enhanced compared with non-cancerous control cells. As expected, secretion of MCP-1 facilitated the recruitment of PBM via the CCR2 receptor. Administration of an MCP-1 neutralizing antibody or of a CCR2 antagonist significantly decreased proliferation and migration ability of RCC cells; additionally, recombinant human MCP-1 stimulated cell migration, compared with untreated control cells. In CaKi-1 cells, expression of MCP-1 is largely mediated by the transcription factor NFAT5, while in 786-O cells deletion of the tumor suppressor gene VHL is probably responsible for MCP-1 upregulation.

Conclusions: Taken together, our results indicate that expression of MCP-1 in RCC cells promotes tumor progression and metastasis not only by paracrine, but also by autocrine MCP-1/CCR2 signaling events, which enhances cell proliferation and migration ability. These findings therefore suggest the MCP-1/CCR2 axis as a potential target for future therapeutic strategies in the treatment of metastatic RCC.

Up-Regulation of MARCKS in Kidney Cancer and Its Potential as Therapeutic Target Ching-Hsien Chen,[1] Eric Yu,[1] Muhammad S. Arif,[1] Robert H. Weiss.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Univ of California, Davis, Davis, CA; [2]Cancer Center, Univ of California, Davis, Sacramento, CA.*

Background: Targeted therapeutics such as targeting hypoxia inducible factor (HIF)/VEGF signaling are initially effective against kidney cancer (or renal cell carcinoma, RCC); unfortunately, drug resistance occurs by activation of bypass pathways. Through genome-scale integrated analysis of the HIF-α network, we identified the major protein kinase C substrate MARCKS as a potential target molecule in kidney cancer. In this study, we aimed to determine if MARCKS can serve as a therapeutic target.

Methods: The clinical relevance of MARCKS and its phosphorylation was first confirmed. Next, we used genetic and pharmacologic approaches to verify the functionality and molecular mechanisms of MARCKS in RCC.

Results: In a screen of 56 patients with RCC, we found that MARCKS expression and its phosphorylation are increased in RCC specimens and positively correlated with tumor grade. Genetic and pharmacologic suppression of MARCKS in high grade RCC cells led to a decrease in cell proliferation and migration. We further demonstrated that higher MARCKS expression promotes xenograft tumor growth and angiogenesis. Mechanistically, MARCKS acted upstream of the AKT/mTOR pathway and thereby activated HIF-target genes, especially VEGF-A. Following knockdown of MARCKS, the inhibitory concentration 50% of a multi-kinase inhibitor regorafenib was reduced in RCC cells. Consistently, MARCKS inhibition using the MPS peptide synergistically interacted with regorafenib treatment and decreased survival of kidney cancer cells through inactivating AKT and mTOR.

Conclusions: Our data suggest the major contribution of MARCKS to kidney cancer growth and also provide an alternative therapeutic strategy by improving the efficacy of multi-kinase inhibitors.

Genetic Variation at the 8q24.21 Renal Cancer Susceptibility Locus Affects HIF-Binding to an Enhancer of Oncogenic MYC and PVT1 Expression Steffen Grampp,[1] James L. Platt,[2] Victoria Lauer,[1] Rafik Salama,[2] Kai-Uwe Eckardt,[1] Peter J. Ratcliffe,[2] David Robert Mole,[2] Johannes Schödel.[1] *[1]Dept of Medicine 4 Nephrology and Hypertension, Univ Erlangen-Nürnberg, Erlangen, Germany; [2]Henry Wellcome Building for Molecular Physiology, Univ Oxford, Oxford, United Kingdom.*

Background: Clear cell renal cell carcinoma (ccRCC) origin from tubular cells. ccRCC is characterized by loss of von Hippel-Lindau protein (VHL) and uncontrolled expression of hypoxia inducible transcription factors (HIF). A genome-wide association study (GWAS) identified single nucleotide polymorphisms (SNP) on chromosome 8q24.21 interposed between *MYC* and *PVT1*. The SNPs are associated with increased susceptibility for ccRCC. MYC is upregulated in ccRCC, but compared to other tumors amplification of the MYC locus is rare. Hence, dysregulation of MYC in ccRCC must be caused by other mechanisms.

Methods: Using RNA analysis, chromatin immunoprecipitation (ChIP), analysis of open Chromatin, allele specific assays and genome editing (CRISPR/Cas9) we have investigated the 8q24.21 locus in primary human tubular cells and RCC cell lines.

Results: Hypoxia led to induction of MYC and PVT1 in primary tubular cells and VHL re-expressing ccRCC cell lines in a HIF-dependent manner. Strikingly, HIF-ChIP-seq experiments identified HIF-binding events in a distal regulatory DNA element which encompasses the ccRCC associated SNPs identified in GWAS. Hypoxic regulation of MYC and PVT1 RNA, HIF-binding and open chromatin at the 8q24.21 locus are highly cell type specific and restricted to cells of renal tubular origin. Physical and functional interaction of the distal enhancer with the MYC promotor was verified by capture-c-assay and genome editing. In cell lines heterozygous for the SNP, allele specific assays showed an increased activity of chromatin and HIF-binding for the risk haplotype.

Conclusions: In cells of tubular origin HIF are capable of regulating MYC and PVT1 expression through binding to a distal enhancer. Therefore, in VHL-defective ccRCC unrestrained expression of HIF leads to overexpression of the oncogenes MYC and PVT1. We conclude that the ccRCC associated SNP on 8q24.21 promotes these effects by modifying accessibility and activity of this site.

SA-PO350

Erythrocyte Sodium Sensitivity: Distribution in Hemodialysis Patients and Correlation with Eryptosis Anna Meyring-Wosten,[1] Viktoriya Kuntsevich,[2] Israel Campos,[1] Jie Ma,[1] Samir D. Patel,[1] Schantel Williams,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Inst, New York, NY; [2]Mount Sinai Beth Israel, New York, NY.*

Background: The glycocalyx of the vascular endothelium and erythrocytes selectively buffers sodium. Hence, damage of the glycocalyx leads to increased erythrocyte sodium sensitivity (ESS), which can be quantified by the 'salt blood test' (SBT) [Oberleithner and Wilhelmi, Pflugers Arch 2013].Eryptosis, suicidal death of red blood cells (RBCs), is accelerated in hemodialysis (HD) patients and is characterized by phosphatidylserine (PS) exposure on the RBC surface. While both ESS and eryptosis relate to RBC surface properties, their relationship has not yet been explored. Also, the acute impact of HD on eryptosis and ESS warrants investigation.

Methods: We enrolled 20 chronic HD patients. Blood samples were collected pre- and post-dialysis. SBT was performed in triplicates. PS exposure, a measure of eryptosis, was determined in duplicates from Annexin-V-FLUOS (ROCHE, Germany) binding by BD FACSCalibur™ System.

Results: The age of the subjects ranged from 28 to 75 years, 55% were white, 45% male, and 50% diabetic. ESS ranged from 2.4 to 8.0 with median at 3.4 before HD and from 1.9 to 7.7 with median at 3.5 after HD. The ESS dropped on average by 0.2 (95% confidence interval,-0.5 to 0.1; p=0.64). PS exposure decreased from 0.60±0.42% to 0.34±0.13% (p=0.02) during HD. There was no correlation between ESS and % eryptotic RBCs (R^2=0.005).

Conclusions: Glycocalyx integrity estimated by ESS did not correlate with suicidal death of erythrocytes. Kliche et al. [Cell Physiol Biochem 2015] observed a decrease of the ESS after dialysis in patients with high ESS. This could not be confirmed in our population, possibly due to a different dialysis modality (hemodialysis vs. postdilutional hemodiafiltration). The decrease of eryptosis after the hemodialysis treatment is contrary to findings by Abed et al. [J Mol Med, 2014] which might be the result of using ultrapure dialysate, a different type of erythropoiesis-stimulating agent used or uremic toxin removal.

Lipophagy Maintains Energy Homeostasis during Prolonged Starvation in the Kidney Proximal Tubule Satoshi Minami,[1] Takeshi Yamamoto,[1] Yoshitsugu Takabatake,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Jun Matsuda,[1] Taiji Matsusaka,[2] Fumio Niimura,[3] Yoshitaka Isaka.[1] *[1]Dept of Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Inst of Medical Science and Dept of Molecular Life Science, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [3]Dept of Pediatrics, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Background: Autophagy is a self-degradation process and combats starvation. Lipids are main energy source in the kidney proximal tubular cells (PTCs). Under starvation, PTCs increase fatty acids (FAs) uptake, form intracellular lipid droplets (LDs), and hydrolyze them for use. The involvement of autophagy in lipid metabolism in the kidney remains largely unknown.

Methods: We investigated the autophagy-mediated regulation of renal lipid metabolism under prolonged starvation using PTC-specific Atg5-deficient (*Atg5$^{F/F}$*;KAP) mice and *in vitro* serum starvation model.

Results: Twenty-four hours of starvation comparably induced LDs formation in the PTCs of control and *Atg5$^{F/F}$*;KAP mice; however, additional 24 hours of starvation lead to the reduction of the number of LDs in control mice, whereas they rather increased in *Atg5$^{F/F}$*;KAP mice. Autophagic degradation of LDs (lipophagy) in the PTCs was demonstrated by electron microscopic observation and biochemical analysis. *In vitro* pulse-chase assay elucidated that lipophagy mobilizes FAs from LDs to mitochondria during starvation, whereas impaired LDs degradation in autophagy-deficient PTCs lead to decreased ATP production and subsequent cell death. In contrast to the *in vitro* assay, despite impairment of LDs degradation, ATP content was preserved in 48 hour starved *Atg5$^{F/F}$*;KAP mice probably due to increased utilization of ketone bodies. This compensatory mechanism was accompanied by higher plasma fibroblast growth factor (FGF) 21 level and its expression in the PTCs; however, which is not essential for production of ketone bodies in the liver under prolonged starvation.

Conclusions: Autophagy combats prolonged starvation by promoting lipophagy in the PTCs to avoid cellular energy depletion.

Endothelial Autophagy Is Essential for the Integrity of Glomerular Capillaries Jun Matsuda,[1] Tomoko Namba,[1] Yoshitsugu Takabatake,[1] Atsushi Takahashi,[1] Takeshi Yamamoto,[1] Satoshi Minami,[1] Tomonori Kimura,[1] Jun-Ya Kaimori,[2] Isao Matsui,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Advanced Technology for Transplantation, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Autophagy is a lysosomal degradation system by which cytosolic materials and damaged organelles are broken down into basic components. Although some previous studies have suggested endothelial autophagy contributes to maintaining vascular homeostasis, the physiological role of glomerular endothelial autophagy remains poorly understood.

Methods: We generated endothelial cell-specific Atg5-deficient mice (Tie2-Cre *Atg5* flox/flox mice: KO mice). As Tie2 is expressed in some hematopoietic lineages as well as the endothelial cells, KO mice are dead by 3 months of age due to pancytopenia. Therefore, we subjected 1-month-old KO mice and controls to irradiation followed by bone marrow transplantation from Tie2-Cre negative littermates (WT®Δ*Atg5* and WT®WT mice, respectively).

Results: Although 1-month-old KO mice had no obvious changes except for splenomegaly, their glomeruli exhibited slightly distended capillary loops. Furthermore, electron microscopic analysis revealed segmental loss of glomerular endothelial fenestra accompanied with foot process effacement of podocytes adjacent to the transformed endothelial cells. The accumulation of reactive oxygen species and the number of apoptotic endothelial cells were increased in the glomerular capillaries of KO mice. Glomeruli of 2-month-old KO mice demonstrated lobular pattern with thickening of capillary loops and mesangial matrix expansion. WT®Δ*Atg5* mice exhibited similar glomerular phenotypes of KO mice, while no obvious histological changes were detected in other organs. In addition, mesangiolysis and glomerulosclerosis were observed in 12-month-old WT®Δ*Atg5* mice, and they developed significant increase in serum urea nitrogen and albuminuria compared with WT®WT mice.

Conclusions: These data suggest that endothelial autophagy protects glomeruli from oxidative stress and maintains the integrity of glomerular capillaries. Enhancing endothelial autophagy may provide a novel therapeutic approach to minimize glomerular diseases.

SA-PO353

Autophagy in Primary Renal Tubular Epithelial Cells Mediates Cellular Senescence Arpita Baisantry,[1,2] Sagar Bhayana,[2] Christoph Wrede,[3] Jan Hegermann,[3] Hermann G. Haller,[2] Anette Melk,[1] Roland Schmitt.[2] *[1]Kidney, Liver and Metabolic Diseases, Children's Hospital, Hannover Medical School (MHH), Hannover, Germany; [2]Nephrology, MHH, Hannover, Germany; [3]Functional and Applied Anatomy, MHH, Hannover, Germany.*

Background: Autophagy and senescence are two discrete pathways triggered during acute kidney injury and during renal repair especially in tubular epithelial cells. Although autophagy is considered renoprotective, it's a proven mediator of oncogene induced senescence and its specific role in promoting or exacerbating senescence is still debatable.

We have shown that genetic ablation of autophagy in a subset of kidney tubular cells abrogates *in vivo* senescence. Hence, to further investigate the potential link between autophagy and renal senescence we isolated primary tubular epithelial cells (PTEC) and tested the impact of autophagy modulation on senescence development.

Methods: PTEC isolated from C57BL/6J mice were driven towards accelerated senescence using γ-irradiation and retroviral overexpression of constitutively active mutant H-Ras oncogene (H-RasV12). Additionally, PTEC were allowed to undergo replicative senescence in culture by passaging. Autophagy induction by rapamycin and inhibition by chloroquine and Atg5 siRNA was validated by established autophagy markers and electron microscopy. Cellular senescence was evaluated by BrdU uptake, $p16^{INK4a}$ expression and quantification of $\gamma\text{-H2AX}^{+}/\text{Ki67}^{-}$ cells.

Results: Our results indicate that ex vivo PTEC culturing is associated with development of senescence and is preceded by a strong induction of baseline autophagy. Specific inhibition of this autophagic activity by Atg5 silencing counteracted senescence development under baseline and stress conditions and preserved the epithelial phenotype. Interestingly, while autophagy inhibition by chloroquine mildly enhanced senescence induction, rapamycin treatment bypassed senescence in PTEC.

Conclusions: Our results highlight a complex interaction between cell culture induced stress, autophagy and renal senescence. While chemical modifiers of autophagy such as chloroquine and rapamycin might have off-target effects, specifically silencing Atg5 attenuates the pro-senescent pathway of stress induced autophagy in vitro.

SA-PO354

Autophagy in Kidney Allografts of Rapamycin Treated Patients Arpita Baisantry,[1,2] Sagar Bhayana,[2] Thomas D. Kraemer,[2] Christoph Wrede,[3] Clemens L. Bockmeyer,[4] Jan U. Becker,[5] Jan Hegermann,[3] Wilfried Gwinner,[2] Hermann G. Haller,[2] Anette Melk,[1] Roland Schmitt.[2] *[1]Kidney, Liver and Metabolic Diseases, Children's Hospital, Hannover Medical School (MHH), Hannover, Germany; [2]Nephrology, MHH, Hannover, Germany; [3]Functional and Applied Anatomy, MHH, Hannover, Germany; [4]Pathology, Uniklink Erlangen, Erlangen, Germany; [5]Pathology, Unikinik Köln, Köln, Germany.*

Background: Autophagy is a cellular mechanism critical to many biological processes and diseases. Mammalian target of rapamycin (mTOR) inhibitors are used as autophagy inducers in experimental studies, but despite their growing use as immunosuppressants for solid organ transplantation, autophagy induction in renal allografts has never been investigated and constituted the aim of this proof-of-principle study.

Methods: Transplant biopsies of 15 patients receiving rapamycin along with calcineurin inhibitors and MMF were compared to biopsies of 20 patients treated with cyclosporine and MMF alone. An additional control group included 6 patients treated with belatacept and MMF. Autophagosomal volume fractions (AVF) were stereologically quantified using electron microscopy (EM). To prevent cell type bias and allow intersample comparability, the analysis was restricted to podocytes. Expression of autophagy related genes was evaluated in laser microdissected glomeruli using qPCR and by semiquantitative analysis in immunohistochemistry.

Results: EM quantification showed a significant >50% increase in AVF in Rapamycin treated patients. Transcriptional profiling of autophagy genes in laser microdissected glomeruli from the same patients showed no differences. Immunohistochemically, a significant increase in podocytic LC3 was observed, but autophagy degradation product p62 remained unchanged. No differences were found between biopsies of patients treated with CNI or belatacept.

Conclusions: Our results indicate an association of rapamycin treatment and autophagosome formation in renal transplants. Our biochemical findings indicate an autophagosomal buildup rather than increased autophagic flux. Hence, further investigation is needed to determine the functional consequences of the complex interaction between mTOR inhibitors and autophagy and its effect on short- and long-term outcome in transplant patients.

SA-PO355

JAK2 Regulates Transcription Factor EB Expression and Autophagy Completion in Podocytes Tamadher A. Alghamdi,[1] Syamantak Majumder,[1] Sri Nagarjun Batchu,[1] Kathryn E. White,[2] Youan Liu,[1] Angela S. Brijmohan,[1] Suzanne L. Advani,[1] Minna Woo,[3] Andrew Advani.[1] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Newcastle Univ, Newcastle upon Tyne, United Kingdom; [3]Univ Health Network, Toronto, ON, Canada.*

Background: The cytosolic kinase JAK2 has garnered attention as a promising therapeutic target for the treatment of chronic kidney disease. However, being ubiquitously expressed in the adult it is likely also to be important for normal organ function. Here, we examined the consequences of JAK2 depletion from glomerular podocytes.

Methods: Experiments were performed in conditional knockout mice and in cultured podocytes.

Results: Mice in which JAK2 had been conditionally deleted from podocytes exhibited an elevation in urine albumin excretion that was accompanied by increased podocyte autophagosome and lysosome fractional volume and p62 aggregation indicative of impaired completion of autophagy. In cultured podocytes, knockdown of JAK2 similarly impaired autophagy, which was accompanied by downregulation of the expression of a number of lysosomal genes and a reduction in cathepsin D activity, suggesting that the impairment in autophagy completion was due to lysosomal dysfunction. Because transcription factor EB (TFEB) has recently emerged as a master regulator of autophagosome-lysosome function, controlling the expression of several of the genes downregulated by JAK2 knockdown, we questioned whether the transcription factor itself is regulated by JAK2. We found that the downstream mediator of JAK2 signaling, STAT1 binds to the TFEB promoter and that JAK2 knockdown decreases TFEB promoter activity and gene expression. Finally, overexpression of TFEB was able to reverse lysosomal dysfunction in JAK2 deficient podocytes and to restore albumin permselectivity.

Conclusions: Collectively, these observations highlight the homeostatic actions of JAK2 in podocytes and the importance of TFEB to autophagosome-lysosome function in these cells. They also raise the possibility that therapeutically modulating TFEB activity may improve podocyte health in glomerular disease.

Role of TGF-β1 in the Aberrant Autophagy of Podocyte Induced by Mesangial Cell Proliferation Xing Mao,[1] Xialian Xu,[2,3] Zhigang Zhang,[1,2] Huijuan Wu.[1,2] *[1]Dept of Pathology, Fudan Uni., Shanghai, China; [2]Shanghai Inst for Kidneys and Dialysis, Shanghai, China; [3]Dept of Nephrology, Zhongshan Hospital, Fudan Uni., Shanghai, China.*

Background: Proteinuria is a common clinical manifestation of IgAN and an indicator of a damaged filtration membrane of which podocyte is an indispensable component. Under physiological condition, autophagy plays a pivotal role in podocyte homeostasis. During mesangial cells (MCs) proliferation, the activated MCs release various cytokines which influence other glomerular cells. Among those cytokines, it remains unknown whether and how TGF-β1 excreted by MCs interfered the autophagy of podocytes and what role decorin (DCN), a natural inhibitor of TGF-β1, acted.

Methods: In IgAN and rat anti-Thy1.1 nephritis, proteinuria was examined by gel electrophoresis, and podocyte autophagy was observed by electron microscope and LC3 staining;serum TGF-β1 and DCN were quantified by ELISA and TGF-β1/Smad/mTORC1 signaling was examined by western blot. Then *in vitro*, we firstly examined autophagy and TGF-β1/Smad/mTORC1 signaling in the cultured podocytes treated by TGF-β1 with/without Chloroquine. We next quantified TGF-β1 in the supernatant of MCs treated by TNF-α or PDGF-BB using ELISA and western blot. Furthermore, in the podocytes treated by TGF-β1 with/without SB431542 and TGF-β1 with/without soluble DCN, autophagy and TGF-β1/Smad/mTOR signaling were detected by western blot and IF.

Results: In IgAN and anti-Thy1.1 nephritis, we observed a presence of proteinuria, accompanied by aberrant autophagosome and decreased LC3; serum TGF-β1 was eminently elevated and DCN declined. In the glomeruli of anti-Thy1.1 nephritis and the cultured podocytes treated by TGF-β1, TGF-β1/Smad/mTORC1 signaling was activated with LC3II/LC3I ratio declined. When activated, the cultured MCs excreted a bulk of TGF-β1. Inhibition of autophagy by TGF-β1 could be reversed by SB431542 or DCN.

Conclusions: Activated MC excreted excessive TGF-β1 which mediated the abortion of macroautophagy in podocyte by activating mTORC1 in a TGF-β/smad2-dependent way. The deficiency of DCN in serum failed to neutralize TGF-β1 activity, making DCN and TGF-β1 potential clinical indicators of IgAN.

High Fat Diet-Induced Lysosomal Dysfunction and Impaired Autophagic Flux Contribute to the Lipotoxicity in the Kidney Takeshi Yamamoto,[1] Yoshitsugu Takabatake,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Jun Matsuda,[1] Satoshi Minami,[1] Tomonori Kimura,[1] Taiji Matsusaka,[2] Fumio Niimura,[3] Yoshitaka Isaka.[1] *[1]Dept of Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Inst of Medical Science and Dept of Molecular Life Science, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [3]Dept of Pediatrics, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Background: Excessive fat intake contributes to the progression of metabolic diseases via cellular injury and inflammation (termed lipotoxicity).

Methods: We investigated 1) the pathophysiology of lipotoxicity in the kidney proximal tubular cells (PTCs) with a focus on lysosomes and mitochondria, 2) lipid overload-mediated alterations in autophagic activity *in vivo* and *in vitro*, and 3) the effects of autophagy-deficiency on kidney morphology and function during lipid overload.

Results: High fat diet (HFD) first induced autophagy in the PTCs, which in itself mobilized phospholipids from cellular membranes to lysosomes, resulting in an accumulation of phospholipids in the enlarged lysosomes. Autophagic degradation activity progressively stagnated due to the impaired lysosomal acidification and consequent excessive lipid accumulation. Autophagy also suppressed HFD-induced mitochondrial dysfunction and inflammasome activation. However, HFD-fed mice had no capacity to further augment autophagic activity upon another pathological stress; this HFD-mediated autophagic numbness resulted in severer injury on ischemia-reperfusion. Pharmacological correction of phospholipid accumulation by eicosapentaenoic acid successfully restored autophagic flux. Finally, phospholipid accumulation in the enlarged lysosomes and impaired autophagic flux were recapitulated in the kidneys of obese patients.

Conclusions: Lysosomal dysfunction and impaired autophagic flux play the key role in the pathogenesis of lipotoxicity in the kidney. The findings provide key insights on the pathophysiology of lipotoxicity and clues to a novel treatment for obesity-related diseases.

Fatty Acids Suppress Autophagy in Renal Proximal Tubule Epithelial Cells Aala Jaberi, Ryan M. Mulhern, Angela Nolin, Steven C. Borkan, John H. Schwartz, Andrea Havasi. *Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Fatty acids are an important source of energy in renal tubular cells and have a key role in cellular signaling. However, under pathological conditions excess fatty acids promote lipotoxicity. In proteinuric states, large amounts of fatty acids carried by albumin enter proximal tubular epithelial cells by crossing both the basolateral and apical membranes. We hypothesize that fatty acid endocytosis with albumin results in tubular cell damage and suppresses macroautophagy including mitophagy, a process that maintains healthy organelles.

Methods: Autophagosomes, lysosomes, albumin and fatty acids were visualized in live cells using specific fluorescent markers. The effect of fatty acids on primary tubular cell autophagy was assessed by measuring autophagic flux, LC3-II and p62 levels. Mitochondrial morphology was visualized using confocal microscopy. Mitochondrial fusion and fission proteins were assessed by Western blot. Mitophagy was assessed by confocal imaging of mCherry-GFP-LC3 transfected tubular cells.

Results: Exposure of primary proximal tubular epithelial cells to albumin-bound fatty acids caused rapid endocytosis of these compounds and transport to both lysosomes and autophagosomes as well as decreased autophagic flux and mitophagy. Fatty acid treatment also altered mitochondrial morphology evidenced by increased mitochondrial fission and greater phosphorylation of dynamin-1 like protein (DRP-1), a mitochondrial fission protein.

Conclusions: Albumin-bound fatty acid endocytosis suppresses mitophagy in proximal tubular cells leading to decreased clearance and accumulation of fizzed, potentially toxic mitochondria. Mitochondrial dysfunction might contribute to tubular damage in proteinuric states.

SA-PO359

Synchronized Regulation of mTOR and Autophagy in Podocytes Tillmann Bork,[1] Wei Liang,[1] Kosuke Yamahara,[1] Pierre-Louis Tharaux,[2] Tobias B. Huber.[1] *[1]Dept of Nephrology, Univ Hospital Freiburg, Freiburg, Germany; [2]PARCC Paris Cardiovascular Centre, INSERM, Paris, France.*

Background: Autophagy emerged as a key mechanism to eliminate unwanted cytoplasmic materials, thereby preventing cellular damage and stress to safeguard long-lived podocytes. The atypical serine/threonine kinase mTOR (mammalian target of rapamycin) is a central regulator of cell growth and metabolism. Active mTOR signaling is a strong suppressor of autophagy in many tissues and cell lines. Podocytes however show highly activated mTOR-signaling in parallel with active autophagy. Aim of our experiments was to further elucidate the interplay of mTOR signaling and autophagy in podocytes.

Methods: Autophagy levels were monitored *in vivo* by crossing GPF-LC3 reporter mice to models of mTOR hyperactivation (Tsc1 PcKO) and mTOR loss of function (Raptor PcKO). In addition, podocyte-specific Raptor and Tsc1 KO mice were crossed to a Tomato/eGFP reporter line to efficiently isolate podocytes for primary cell culture studies. Treatment studies were performed to assess autophagic flux and dynamic changes in autophagy regulation *in vivo* and *in vitro*.

Results: Strikingly, podocytes did exhibit high basal autophagy rates independently of the mTOR activation status. There was no difference in LC3 conversion *in vivo* and no difference of the GFP-LC3 signal between Raptor and Tsc1 PcKO mice. Pharmacologic mTOR inhibition with Rapamycin increased autophagy, whereas long-term treatment showed no effect. *In vitro* and *in vivo* experiments revealed AMPK as an alternative regulator of autophagy bypassing the mTOR signaling cascade.

Conclusions: mTOR and autophagy are key regulators of podocyte function and maintenance. Our data highlight now a podocyte-specific AMPK-autophagy regulatory cascade, which allows to operate mTOR activity and high basal autophagy rates simultaneously in podocytes.

Murine Double Minute-2 Prevents Tubular Atrophy by Inhibiting p53 Overactivation-Dependent Cell Death (Podoptosis) in Tubular Cells Dana Thomasova,[1] Martrez Ebrahim,[1] Kristina Fleckinger,[1] Moying Li,[1] Helen Liapis,[2] Hans J. Anders.[1] *[1]Renal Div, Medizinische Klinik und Poliklinik IV, Klinikum der Univ München, Munich, Germany; [2]Dept of Pathology & Immunology, Washington Univ School of Medicine, St. Louis, MO.*

Background: The E3-ubiquitin ligase MDM2 is a non-redundant element of NF-κB signaling and the master negative regulator of tumor suppressor gene p53. We recently showed that MDM2 blockade can suppress renal damage in the early post-ischemic injury phase via NFkB modulation but MDM2 inhibition impairs subsequent tubular regeneration by p53-mediated cell cycle arrest. However, the role of the robust constitutive MDM2 expression in non-damaged tubular cells is unknown.

Methods: We generated and characterized doxycycline-inducible tubular-specific MDM2-knockout mice (Pax8-rtTACre/MDM2flox). In vitro we knocked-down MDM2 and p53 by siRNA.

Results: MDM2 depletion in a tubular cell line or in primary tubular cells caused tubular cell death, which could be rescued by co-deletion of p53. The analysis of Pax8-rtTACre/MDM2flox mice showed significant MDM2 decrease and p53 increase compared to controls by day 8 of doxy treatment. The tubular damage markers such as NGAL, TIMP2 or KIM-1 were also highly up-regulated. The histological analysis of tubular-MDM2 KO mice revealed progressive tubular cells swelling, their loss, tubular atrophy and granular casts. The proximal tubules were affected the most. Ultrastructural tubular changes such as vacuolation and cytoplasmic and mitochondrial swelling were prominent. The immunostaining showed massive upregulation of p53 in the tubular compartment. The tubular damage was associated with oliguria and increase of BUN and plasma creatinine from day 6 on. The tubular cell loss in this model was not sensitive to the pan-caspase inhibitor ZVAD-FMK treatment, excluding apoptosis and pyroptosis as modes of the tubular cell death due to the p53-overactivation (podoptosis). The pathology was rescued by co-deletion of MDM2 and p53 genes, confirming the p53-dependency.

Conclusions: In contrast to the pathogenic role of MDM2 in early phase of tubular injury in postischemic kidney, tubular cells need MDM2 during homeostasis to prevent podoptosis.

SA-PO361

Heme Oxygenase-1 Protects Proximal Tubule Epithelial Cells from Ferroptosis Oreoluwa O. Adedoyin,[1] Ravindra Boddu,[1] Amie Traylor,[1] Jeremie M. Lever,[1] James George,[2] Anupam Agarwal.[1,3] *[1]Div of Nephrology, Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [2]Div of Cardiothoracic Surgery, Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [3]Birmingham VA Medical Center, Birmingham, AL.*

Background: Ferroptosis is an iron-dependent form of programmed cell death that occurs in models of acute kidney injury (AKI) in vitro and in vivo. A potential source of iron for this process is HO-1, a cytoprotective enzyme that is robustly induced in renal proximal tubules in AKI where it generates CO, biliverdin, and iron. Therefore, we tested the hypothesis that HO-1 plays a role in regulation of ferroptotic cell death in renal proximal tubular epithelial cells (PTECs).

Methods: Immortalized PTECs obtained from HO-1$^{+/+}$ and HO-1$^{-/-}$ mice were treated with erastin (ferroptosis inducer), and analyzed for morphological changes and cellular metabolic activity. Induction of HO-1 in response to erastin treatment, and following co-treatment with anti-oxidants, iron, or an iron chelator were determined using qPCR and western blotting.

Results: Treatment of HO-1$^{+/+}$ PTECs with erastin resulted in a dose-dependent increase in HO-1 expression, as well as significant inhibition of cellular metabolic activity compared to vehicle-treated controls (mean ± SEM, control: 100±1.8; erastin 0.1μM: 91.6±2.5; erastin 1μM: 58.3±0.9, and erastin 10μM: 62.5±1.8%, $p<0.0001$, n=3/group). Iron supplementation using ferric ammonium citrate in cells treated with 1μM erastin further reduced cell viability from 54.7±1.5% to 38.4±1.5% ($p=0.0012$). Interestingly, co-treatment with 1μM hemin (HO-1 inducer), 0.1mM deferoxamine (iron chelator), or 0.1M N-acetyl-L-cysteine (glutathione replenisher) significantly increased cell viability. To test if ferroptosis is dependent on HO-1, HO-1$^{-/-}$ PTECs were treated with erastin. This resulted in increased sensitivity to ferroptosis (mean ± SEM, control: 100±3.1; erastin 0.1μM: 68.7±2.2; 1μM: 44.0±0.7, and 10μM: 53.8±1.9 %, $p<0.0001$, n=3/group).

Conclusions: HO-1 induction appears to attenuate erastin-induced ferroptotic cell death in renal epithelial cells; therefore, it may serve as a viable therapeutic target for intervention in AKI.

Wnt9a Accelerates Renal Fibrosis Through Induction of Tubular Senescence Lili Zhou, Congwei Luo. *Dept of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China.*

Background: As a key factor, Wnt is involved in pathogenesis of kidney diseases. However, the underlying mechanism is unknown. In this study, we detected the potential role of Wnt9a in tubular cell senescence and renal fibrosis.

Methods: Wnt9a was tested in mouse models of ADR nephropathy, UUO, and ischemia-reperfusion. The co-localization of Wnt9a and a biomarker for senescence, p16, was checked in sequential sections. In unilateral ischemic/reperfusion injury, ectopic overexpression or knockdown of Wnt9a was respectively induced.Fibrosis and tubular senescence were detected. To further confirm the effect of Wnt9a in senescence, 2 and 24-month-old mice were performed the surgery of UIRI, and a vector encoding the secreted form of Klotho was administrated to inhibit Wnt9a. In cultured tubular epithelial cells (HK-2), cell cycle and senescence-related gene were determined by overexpression of Wnt9a. In some cells, siRNA to Wnt9a was used in aristolochic acid (AA)-induced senescence. The cell-cell communication between fibroblasts and tubular cells was also examined.

Results: Wnt9a was upregulated in UUO and ADR nephropathy, and mainly located in tubules. Wnt9a overexpression was correlated with tubular senescence and renal fibrosis, as detecting by $p16^{Ink4A}$, Kim-1, Klotho and fibronectin. The exogenous expression of Wnt9a dramatically promoted renal fibrosis, deteriorated renal function, and induced tubular senescence. To the contrary, knockdown of Wnt9a protected renal fibrosis and tubular senescence. Compared to young mice, Wnt9a was remarkably upregulated in aging mice. Using cultured cell line HK-2, we found Wnt9a induced cell cycle arrest and upregulation of senescence-related gene $p16^{Ink4A}$, ARF and p21. However, siRNA to Wnt9a significantly inhibited AA-induced S-phase arrest and senescence-related gene expression. Wnt9a also directly induced fibroblasts proliferation, or indirectly induced secretion of matrix protein through conditioned-medium from cultured tubular cells. On the other hand, Wnt9a conditioned-medium from fibroblasts promoted senescence in tubular cells.

Conclusions: These results suggest that Wnt9a accelerates renal fibrosis through induction of tubular senescence.

The Effects of Periostin on the Aging Process Sehoon Park,[1] Jung Nam An,[2,3] Eun Nim Kim,[4] Sunhwa Lee,[1] Jinhyuk Kim,[2] Seung Hee Yang,[1] Dong Ki Kim,[1] Yun Kyu Oh,[2] Chun Soo Lim,[2] Yon Su Kim,[1] Jung Pyo Lee.[2] *[1]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [3]Dept of Critical Care Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [4]Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Periostin, a matricellular protein, has been reported in diverse processes and pathologies in tissue remodeling through the promotion of adhesion, cell survival, cellular dedifferentiation, and fibrogenesis. However, its role in aging process is unknown.

Methods: We investigated expressions of periostin in normal human kidney tissues classified by age (20, 40, and 60 years) and in mice kidney tissues of wild type (WT) C57BL/6 mice or *Postn null* (*Postn*$^{-/-}$) mice aged 24 months. In addition, chemistry data including serum creatinine and histopathology findings of WT mice or *Postn null* mice classified by age (young vs. aged; 2-months old vs. 24-months old) were examined.

Results: Periostin expressions in normal human kidney tissues were significantly different according to the age. Intrarenal periostin expressions were prominent in the patients aged 60 years compared to those aged 20 years. *In vivo*, the gross appearance and the kidneys of aged WT mice were bigger and heavier than young WT mice. Serum creatinine levels were also higher in the aged WT mice compared to those in the young WT mice. However, all these changes were diminished in the aged *Postn null* mice; serum creatinine levels were considerably lower in aged *Postn null* mice than in aged WT mice. Apparent tubular atrophic changes, interstitial fibrosis, and collagen fiber deposition which were prominent in the aged WT mice than in the young WT mice, were remarkably alleviated in aged *Postn null* mice. Furthermore, the expressions of periostin were also attenuated in aged *Postn null* mice compared to in aged WT mice.

Conclusions: Aging resulted in morphologic/physiologic changes and increased expressions of periostin. Periostin ablation could have protective effects in aging process.

SA-PO364

Cost-Effectiveness of Eculizumab Treatment after Kidney Transplantation in Atypical Hemolytic Uremic Syndrome Jan A.J.G. van den Brand, Jacobien Verhave, Eddy M. Adang, Jack F. Wetzels. *Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Kidney transplantation in patients with atypical hemolytic uremic syndrome (aHUS) is frequently complicated by recurrence of aHUS, often resulting in graft loss. Eculizumab prophylaxis prevents recurrence, improving graft survival. An alternative treatment strategy has been proposed where eculizumab is administered upon recurrence. We combined available evidence and performed a cost-effectiveness analysis of these competing strategies.

Methods: We created a decision tree with treatment strategies for aHUS patients with end stage renal disease (ESRD): *dialysis treatment*; *kidney transplantation*; kidney transplantation with *eculizumab upon recurrence* of aHUS; and kidney transplantation with *lifelong eculizumab* prophylaxis. We assumed that transplantation was performed with a kidney from a living donor. We performed a Markov analysis to compare cost-effectiveness of the strategies.

Results: The predicted probability of recurrence in the *kidney transplantation* and *eculizumab upon recurrence* strategies was 23% and 37% after 3 and 12 months. *Kidney transplantation* was the least costly alternative. By comparison, *dialysis* was more costly and resulted in fewer Quality Adjusted Life Years (QALYs) gained, and was therefore considered inferior to *kidney transplantation*. *Eculizumab upon recurrence* was more costly than *kidney transplantation* without eculizumab, but resulted in more QALYs gained. The incremental cost effectiveness ratio (ICER) was $42,961 per QALY. *Lifelong eculizumab* was even more costly, and gave an ICER of $63.1 million compared to *eculizumab upon recurrence*.

Strategy	Costs ($)	QALYs gained	ICER (Δ$/ΔQALY)
Kidney transplantation	425,032	6.52	
Dialysis	447,296	2.57	dominated
Eculizumab upon recurrence	559,499	9.65	42,961
Lifelong eculizumab	6,126,944	9.74	63,107,200

Conclusions: *Kidney transplantation* was more cost-effective than *dialysis* to treat ESRD due to aHUS. However, *Eculizumab upon recurrence* was more cost-effective than *kidney transplantation*. Gain in QALYs in the *lifelong eculizumab* strategy was offset by extremely high costs. Therefore, *eculizumab upon recurrence* of aHUS was more acceptable.

SA-PO365

Kidney Transpalnt in Atypical HUS: A Single Center Experience Gianluigi Ardissino,[1] Donata Cresseri,[1] Antenore Giussani,[1] Stefania Salardi,[1] Francesca Tel,[1] Sara Testa,[1] Michela Perrone,[1] Fabio Paglialonga,[1] Mirco Belingheri,[1] Martina Sgarbanti,[1] Lucrezia Furian,[2] Angela Nocco,[1] Silvana Tedeschi,[1] Piergiorgio Messa.[1] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; [2]Univ Hospital, Padova , Italy.*

Background: For decades, atypical hemolityc uremic syndrome (aHUS) has been considered a controindication to kidney transplant (KTx) for the very high risk of disease recurrence. The availability of Eculizumab (ECU) has made it possible to safely address patients (pts) with aHUS to KTx but the best approach to treatment (Rx) as to timing of 1st dosing, schedule, possibility of Rx discontinuation and pts' monitoring, is not well established.

Methods: During the past decade, a total 20 pts (6 children) with aHUS were followed for KTx at our Center (in 3 KTx had been performed elsewhere). Five pts had a previous KTx. The median time on RRT prior to KTx was 8.5 years. One pt has received the graft from a living-related donor. CFH-related disease (n:13) was the most common etiology followed by mutations on CFI (n:4), C3 (n:1), MCP (n:1) and Idiopathic (n:1). Based on the strategy used to prevent disease relapse before and after KTx, 3 groups can be identified (some pts were exposed to multiple preventive strategies): A: no prophylaxis (n:7); B: plasmaexchange/plasmainfusion (n:5); C: ECU (n:14).

Results:

	Group A	Group B	Group C
Etiology (CFH-related/other)	3/4	5/0	12/2
Cumulative observation period on KTx (yrs)	47	7	44
Relapse rate (event/patient/10 yrs)	0.4	1.4	0
Graft loss due to relapse	1	0	0
Graft loss for other causes	1	1	1

Pts in group B were switched to ECU once available. One pt discontinued ECU as soon as AntiCFHAb were no longer detectable. Based on complement activity targeted to <30%, out of the 12 pts currently on ECU, 4 are regularly receiving the infusion every 3 weeks and 8 every 4 weeks.

Conclusions: Our experience favours the prophylactic use of ECU in pts undergoing KTx with a history of aHUS. We recommend complete characterization (as to disease etiology) pre-KTx and that maintenance Rx is continued lifelong.

SA-PO366

Kidney Transplant Discussion Timing and Subsequent Wait Listing in a National Cohort Nancy G. Kutner,[1] Yijian Huang,[2] Rebecca H. Zhang.[2] *[1]Rehabilitation Medicine, Emory Univ, Atlanta, GA; [2]Biostatistics, Emory Univ, Atlanta, GA.*

Background: Patient awareness and understanding of kidney transplantation (KT) are widely shared goals, but variables associated with timing and outcomes of KT discussion merit ongoing study.

Methods: The USRDS CDS survey of 1634 incident dialysis patients (18+, median vintage 4 mos) from 296 randomly selected clinics asked "Was kidney transplantation discussed with you before you started your regular treatment for kidney failure?" and, later in the interview, "Has kidney transplantation been discussed with you since your started dialysis?" Patient characteristics, early nephrology care, whether "informed of KT options," and wait-listing (WL) events were identified in USRDS files. Excluding 60 patients with pre-dialysis WL, the adjusted association of KT discussion timing with WL (333 events, median 21.7 mos follow-up) was examined in Cox models.

Results: KT discussion was reported (a) Pre- and post-dialysis by 37.3% (b) Post-dialysis only by 25.4% (c) Pre-dialysis only by 12.5% (d) Not at all by 24.8%. Compared with no discussion, discussion post-dialysis only was associated with greater likelihood of WL (HR 3.78 [95% CI 2.28-6.25]), but patients with both pre- and post-dialysis discussion had even greater WL likelihood (HR 4.20 [95% CI 2.58-6.84]). Pre-ESRD nephrology care was highest (82.2%) in the duel exposure group. Patients with only pre-dialysis discussion had no increased likelihood of WL. Overall, 75% of patients reported exposure to KT discussion *at one or both* time points, similar to the proportion reported by providers on CMS Form-2728 as informed of KT options (72%).

Conclusions: Consistent with other research, perceived KT discussion after dialysis start was associated with greater likelihood of subsequent WL, but pre-dialysis plus post-dialysis exposure was associated with even greater likelihood. Patient/provider discrepancy in reported KT information exposure was minimal when patient-reported exposure included pre- and post-dialysis experience. The content as well as timing of reported "KT discussion" and "informed of KT options" are important variables in ongoing efforts to advance the understanding of effective KT education.

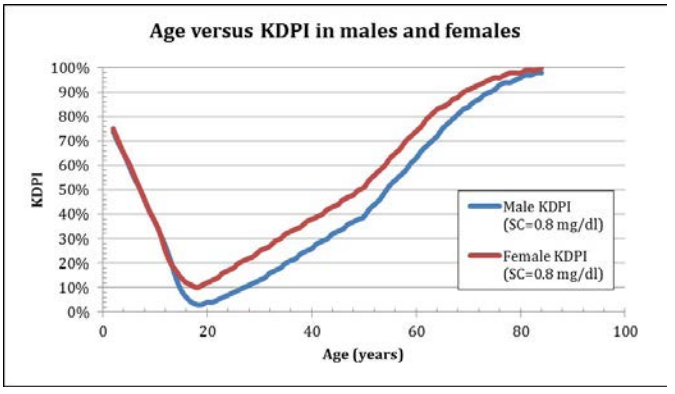
New KAS May Inappropriately Limit Access of Pediatric Donor Kidneys to Pediatric Recipients Based on KDPI Allison Peng,[1] Daniel Elchediak,[1] Meera Gupta,[1] Sandra Amaral,[2] Susanna Matsen Nazarian,[1] Matthew H. Levine.[1] *[1]Surgery, Univ of Pennsylvania/Children's Hospital of Philadelphia, Philadelphia, PA; [2]Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: The 2014 OPTN Kidney Allocation System (KAS) prioritizes allografts with Kidney Donor Profile Index (KDPI) ≤ 35 to pediatric recipients. Most donors < age 12 have KDPI over 35 even with ideal function. We sought to determine if transplants using such grafts differed in outcomes compared to ideal KDPI ≤ 35 grafts.

Methods: UNOS data from first deceased donor renal transplants 2000-2010 with follow-up to 3/31/2014 were used to compare graft survival among donors and recipients across age groups, using Kaplan Meier. Public Health Service (PHS) high risk comparisons used Pearson's chi-square. Donor height and weight median from US growth charts for age with no additional risk parameters were used to calculate KDPI.

Results: Pediatric recipients (listed age 0-17) had equivalent 1,3, 5, and 10 year graft survival when transplanted with grafts from donors with donors age 3-11 years with KDPI > 35 compared to older KDPI ≤ 35 donors (p=0.97). Young adult recipients (age 18-40) also had no different graft survival with these age 3-11 grafts vs. ideal grafts with KDPI ≤ 35 (p=0.51). Grafts from donors aged > 46 years with KDPI > 35 had diminished 5 and 10 year graft survival in both pediatric and young adult recipients vs. other donor groups. Donors age 12-46 years with KDPI ≤ 35 were more likely to be PHS high risk than donors age 3-11 (11% vs 1.5%, p < 0.001).



Conclusions: There is no evidence of excess graft loss for donors age 3-11 compared to those with KDPI ≤ 35 and these donors convey less PHS high risk exposure. These kidneys are not prioritized for allocation to children based on KDPI in the new KAS, thereby potentially limiting high quality kidney graft access for children with ESRD.

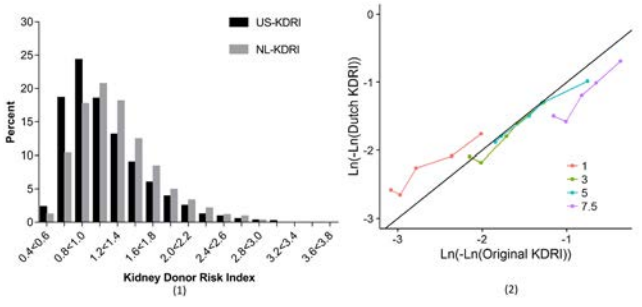
SA-PO368

Validation, Calibration and Model Revision of the Kidney Donor Risk Index Scoring System of a Deceased Donor Kidney for Transplantation in the Netherlands Hessel Peters-Sengers,[1] Martin B.A. Heemskerk,[2] Jaap Homan Van Der Heide,[1] Stefan P. Berger,[3] Frederike J. Bemelman.[1] *[1]AMC, Amsterdam, Netherlands; [2]Dutch Transplant Foundation, Leiden, Netherlands; [3]UMCG, Groningen, Netherlands.*

Background: The prognostic Kidney Donor Risk Index (KDRI)—developed and validated (c-statistic 0.62) in the US—is a widely used tool to predict transplant outcome of a deceased donor kidney at time of organ offer.

Methods: We aimed to externally validate the KDRI as proposed by Rao et al. (2009), containing 10 donor and 4 transplant factors. We used the Dutch Organ Transplantation Registry to include recipients (≥18y), transplanted from 2002 to 2012 with a first brain-death or circulatory-death donor kidney (≥18y). Outcome of graft survival was defined as time from transplantation to graft failure or death.

Results: Among 2554 transplanted kidneys, the median of the KDRI was higher compared with the US (1.05 *vs*. 1.21, see figure 1). Kidneys in the highest KDRI quintile (1.45+) had an adjusted 5-year graft survival of 68.9%, whereas the lowest KDRI quintile (<0.79) showed 84.7% survival. At year 1, the time-dependent (t) ROC of the KDRI showed 0.65 discriminative ability. At year 3, year 5, and year 7.5, the tROC was maintained (0.63;0.65;0.67, respectively). There was need to recalibrate the baseline hazard (see figure 2): graft failure in the first year was higher in the Dutch cohort, but lower after 7.5 years compared with the US. The calibration slope was 1.24 and higher than 1 (p=.012), indicating improved discrimination in the Dutch cohort. The revised tROC was improved at year 1 (0.67), and year 3 (0.67).



Conclusions: The NL-KDRI distinguished donors with low and high KDRI scores (<1 *vs.* >1.45) better than middle-ranged scores. We corrected the baseline risk and re-calibrated donor factors from the KDRI into the NL-KDRI. The discriminative ability of the NL-KDRI performs at least as well as in the US, and is useful for decision-making regarding the acceptance of a kidney organ offer.

SA-PO369

Impact of the New Kidney Allocation System on the Transplant Rate of HLA Sensitized Patients. A Single Center Experience Maria Ajaimy, Adriana Colovai, Enver Akalin. *Montefiore Transplant Center, Albert-Einstein College of Medicine.*

Background: Increasing access to transplantation of difficult-to-match patients was a key goal of the new kidney allocation system (KAS) implemented on Dec 4, 2014. In this study, we evaluated the impact of the new KAS on the transplantation rate of HLA sensitized candidates at our center.

Methods: During Jan 1 - Dec 4, 2014 (pre-KAS interval) and Jan 1 - Dec 4, 2015 (post-KAS interval), immunologic risk was assessed prior to transplantation using the same approach. Unacceptable HLA antigens were defined using the following cutoffs: 5000 MFI for HLA-A, -B and -DR, and 10,000 MFI for HLA-C and -DQ antigens. Deceased donor cross-matches (XMs) were performed by flow cytometry and complement dependent cytotoxicity (CDC). Patients were transplanted based on a negative flow and/or negative CDC XM.

Results: A 65% increase in total number of deceased donor cross matches performed during post-KAS (1188) and pre-KAS (715) intervals was observed, respectively. The percentage of XMs performed for sensitized patients (cPRA>0%) increased from 19% pre-KAS to 26% post-KAS (p<0.0001). A significant increase in the rate of transplantation of sensitized patients was observed. Out of 115 patients who received deceased donor kidney transplantation pre-KAS, only 16 (14%) patients had cPRA>0%. Post-KAS, out of 129 transplanted patients, there were 34 (25%) with cPRA>0% (p<0.0001). The percent of sensitized patients who received transplantation increased from 5% to 8% in the cPRA 50-79% subgroup, from 4% to 5% in the 80-98% subgroup, and, remarkably, from 0% to 8% for patients with cPRA>98%. This increase was balanced by a decrease in the percent of non-sensitized recipients (from 86% to 75%, pre- and post-KAS, respectively) and recipients with cPRA 0-49% (from 4% to 3%, respectively). At a median 8 months follow-up, the patient (94% vs. 94%) and graft (91% vs. 91%) survival and acute rejection rate (4% vs. 6%) were similar in patients with 0% cPRA compared to patients with cPRA>0%, respectively, in the post-KAS era.

Conclusions: The new KAS facilitated a marked increase in the transplant rate of sensitized candidates at our center.

SA-PO370

Employment and Transplant Status among End-Stage Renal Disease Patients Receiving Dialysis Deborah S. Evans,[1] Duane V. Dunn,[1] Shelley Murphy,[1] Kristine Robinson,[1] Rich Mutell,[2] Paul J. Broughton,[2] Deborah A. Benner.[1] *[1]DaVita Inc, Denver, CO; [2]Apex Health Innovations, Simi Valley, CA.*

Background: For patients with end-stage renal disease receiving dialysis, receipt of a transplant offers the best possible long-term treatment option. However, qualification for placement on the active transplant list requires a high level of patient motivation and engagement. Here, we sought to characterize transplant status among employed versus unemployed patients of a large dialysis organization (LDO).

Methods: Data on patient employment and transplant status were derived from LDO electronic health records. Employment and transplant status information is collected by LDO social workers during the course of routine care. Employment status categories considered were: employed (regular full-time, regular part-time, or per diem), unemployed, retired, and other. Transplant status categories considered were: active, delisted, denied, in work-up, inactive, no longer interested, on hold, and pending patient follow-up.

Results: As of May 2016, there were 91,231 active patients with available transplant and employment status information in the LDO database. Of these, 17,816 (19.5%) were employed, 28,185 (30.9%) were unemployed, and 24,352 (26.7%) were retired. Compared to unemployed patients, employed patients were more likely to have transplant status listed as active (34% vs 19%) and less likely to have transplant status listed as denied or pending patient follow-up (11% vs 20% and 20% vs 25%, respectively). Stratification of patients on the basis of age revealed that trends were conserved across age groups.

Conclusions: Among LDO patients who had expressed interest in transplant, those who were employed were more likely to progress through the qualification steps to active transplant status than those who were unemployed. Many of the factors identified by dialysis patients as barriers to working (eg, transportation issues, depression/lack of motivation), may also impede a patient's ability to successfully navigate the transplant qualification process. Conversely, positive outcomes of employment, such as improved financial status, may facilitate process completion.

SA-PO371

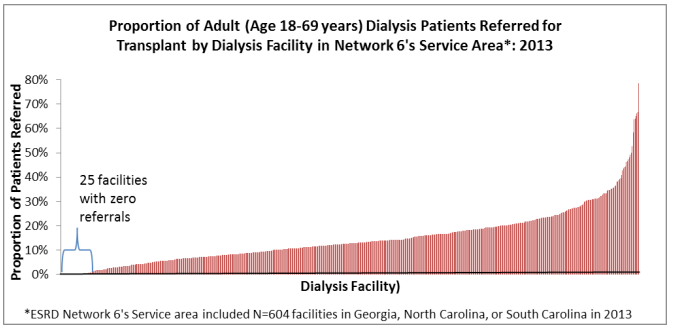
Variation in Dialysis Facility Referral for Kidney Transplantation in the Southeastern United States Rachel E. Patzer,[1] Jennifer C. Gander,[1] Laura Plantinga,[1] Amber M. Reeves-Daniel,[2] Matthew Jay Ellis,[3] Stephen O. Pastan.[1] *[1]Emory Transplant Center, Atlanta, GA; [2]Wake Forest Baptist Medical Center, Winston-Salem, NC; [3]Duke Univ, Durham, NC.*

Background: While variability in dialysis facility kidney transplant (KTx) referral between dialysis units has been studied in one state (Georgia), regional, facility-level data for KTx referral has not been examined.

Methods: We analyzed ESRD Network 6 data on KTx referrals from dialysis facilities in 2013, collected from 8 transplant centers in Georgia, North Carolina, and South Carolina. We linked with the 2012 Dialysis Facility Report data to obtain dialysis facility

characteristics. Multivariable-adjusted linear regression models were used to identify characteristics associated with low KTx referral (=% of prevalent dialysis patients aged 18-69 years referred in 2013).

Results: Among 604 dialysis facilities, the median facility-level percentage of adult prevalent dialysis patients referred for transplant in 2013 was 12.7% (IQR: 7.2%-19.6%; range: 0% to 78.6%); 25 facilities (4.1%) referred no dialysis patients.



In multivariable models, factors associated with lower facility referral included higher facility-level percentage of patients not being informed of transplant as a treatment option and higher percentages of patients who were smokers, had congestive heart failure, and had longer times on dialysis (all $p<0.05$). Facility profit status, number of staff, and the percentages of patients who were black or had employer insurance were not associated with facility–level referral.

Conclusions: The observed facility variability in transplant referral suggests the need to use transplant referral as a quality measure for dialysis facilities that could be tracked nationally.

SA-PO372

Willingness of Canadian ESRD Patients to Consider Transplant Tourism

Gurleen Gill, Caren L. Rose, John S. Gill, Adeera Levin, Jagbir Gill. *Medicine-Nephrology, Univ of British Columbia, Vancouver.*

Background: Transplant tourism refers to travel for transplantation that involves organ trafficking and/or transplant commercialism, and is associated with poor outcomes after transplantation. While characteristics of transplant tourists have been described, there are no data on end-stage renal disease (ESRD) patients who may be at high risk for engaging in this practice.

Methods: We surveyed Stage V chronic kidney disease (CKD) and dialysis patients in British Columbia, Canada to determine their willingness to travel outside of Canada and purchase a kidney.

Results: Of 592 patients surveyed, 342 (58%) were willing to travel for transplantation, with 149 (25%) strongly willing to travel. Figure 1 shows the willingness of patients to travel for transplantation under different circumstances. N=354 (60%) were willing to travel if they had a related living donor in another country or could be placed on an official transplant list in another country, while 143 (24%) were willing to pay for the kidney on top of paying the medical costs of the transplant. Thirty-three percent were willing to travel even if they knew the donor was an executed prisoner, but only 4% admitted that they were willing to break the law to obtain the transplant.

Patients that were willing to travel and purchase a kidney included a higher proportion of patients that were younger, male, of Asian ethnicity, had higher median household income, had initiated dialysis within the last year, and were less knowledgeable about the risks and legality of transplant tourism.

Conclusions: Nearly one quarter of ESRD patients surveyed were willing to purchase a kidney outside of Canada, and may be at high risk to engage in transplant tourism. Educating at- risk patients (particularly those who recently started dialysis) about the legal and medical risks of transplant tourism may help to deter this practice.

Histo-Molecular Assessment of Pre-Implantation Biopsies Demonstrates That Many Discarded Kidneys Are Similar to Successfully Transplanted Kidneys in Other Center

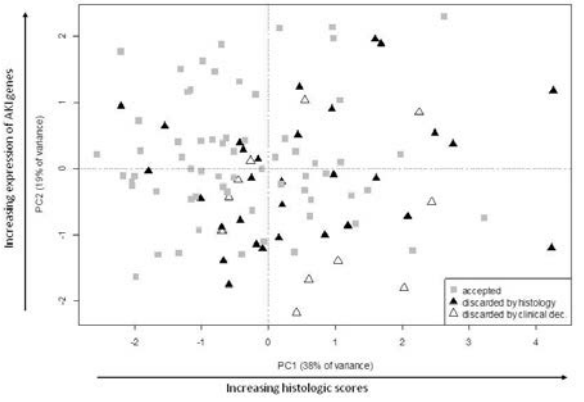
Konrad S. Famulski,[1] Jeff Reeve,[1] Silke V. Niederhaus,[2] Jonathan Bromberg,[2] Philip F. Halloran.[1] *[1]Univ of Alberta, Edmonton, Canada; [2]Univ of Maryland, Baltimore.*

Background: Increasing numbers of kidneys from older brain dead donors (DBD) are considered for transplantation. Many of these kidneys are discarded based on conventional (clinical or histologic) features. We previously observed that 50% of DBD kidneys discarded by conventional features had similarly low expression of Acute Kidney Injury (AKI) associated genes as those that were transplanted. Here, we are asking whether the combined histology and expression of AKI genes, that also are associated with transplant fibrosis, can demonstrate that kidneys discarded by conventional features are indeed similar to kidneys accepted for transplantation, using discarded and accepted kidneys from different centers.

Methods: We compared 43 discarded kidneys in one USA center to 64 accepted kidneys transplanted in one European center, all from older DBD, using Principal Component Analysis. All 64 functioned and 63 were surviving at 3 months post transplant. Following variables were used: summarized expression of AKI genes and histologic lesion scores: glomerulosclerosis, fibrous intimal thickening, fibrosis/atrophy and arterial hyalinosis.

Results: The Principal Component 1 (PC1) was associated with histologic lesions, while PC2 component (PC2) represented the summarized expression of AKI genes. Both PC1 and PC2 component scores did not show clear separation of discarded kidneys from the accepted kidneys (figure 1), also confirmed by the density plot analysis of PC1 and 2 scores.

Figure 1. Principal Component Analysis of discarded and accepted kidneys using histo-molecular assessment.



Conclusions: Combined histo-molecular features were not able to separate discarded kidneys in one center from the kidneys accepted and functioning in another center. We conclude that the current criteria for discarding kidneys based on conventional features, particularly histology, need to be reassessed.

SA-PO374

Requiring Demonstration of Persistently Low Renal Function Meaningfully Changes Timing of Kidney Transplant Waitlist Qualification

Benjamin J. Lee,[1] Charles E. McCulloch,[2] Barbara A. Grimes,[2] Sindhu Chandran,[1] Cynthia Delgado,[1] Chi-Yuan Hsu.[1] *[1]Medicine, Div of Nephrology, UCSF, San Francisco, CA; [2]Epidemiology and Biostatistics, UCSF, San Francisco, CA.*

Background: According to U.S. Organ Procurement and Transplantation Network policies, "measured ... creatinine clearance level or calculated glomerular filtration rate (Cockcroft-Gault or other reliable formula) less than or equal to 20 mL/min" triggers start of time-accrual on the kidney transplant waitlist. Since only a single CrCl or eGFR ≤20 is needed, the policy implicitly assumes that decline in renal function is monotonic (Mitch et al, Lancet 1976), but recent studies demonstrate that this is often not the case (Li et al, AJKD 2012).

Methods: To assess whether requiring patients to demonstrate renal function "persistently ≤20" would change waitlist qualification, we compared time to qualification as defined by 2 different rules: 1) at first eGFR ≤20, regardless of subsequent measurements (current paradigm) and 2) at second eGFR ≤20 given a prior eGFR ≤20 at least 3 months before (akin to the definition of CKD). We applied the CKD-EPI equation to serial creatinine measurements from 3 patient cohorts: 1 of waitlisted patients at a major U.S. academic center and 2 national, multicenter cohorts of CKD patients (the NIH-sponsored AASK and MDRD studies). Kaplan-Meier curves for the two rules were constructed for each cohort and used to estimate median times to qualification.

Results: Requiring patients to demonstrate eGFR ≤20 on two occurrences at least 3 months apart delays median time to qualification on the order of 0.5 to 2 years.

		Median Times to Waitlist Qualification (Days)	Difference between Rule 1 and Rule 2 (Years)
UCSF Cohort	1st eGFR ≤20	379	2.1
	2nd eGFR ≤20	1149	
AASK Cohort	1st eGFR ≤20	449	1.5
	2nd eGFR ≤20	988	
MDRD Cohort	1st eGFR ≤20	122	0.6
	2nd eGFR ≤20	356	

Conclusions: Requiring a single CrCl or eGFR ≤20 for waitlist qualification among non-dialysis-dependent patients may be insufficient. Demonstration of persistently low renal function may more appropriately identify when patients should qualify for the waitlist and meaningfully change time to waitlist qualification.

Health Disparities Impact Transplant Referral Antonia Harford,[1] S. Paine,[2] R. Schrader,[2] D. Miskulin,[3] Ambreen Gul,[2] Philip Zager.[1,2] *[1]Nephrology, UNM, Albuquerque, NM; [2]DCI, Albuquerque, NM; [3]Tufts, Boston, MA.*

Background: Kidney transplantation (TXP) offers longer life expectancy and better quality of life than any dialysis modality and is the treatment of choice for ESRD patients. We postulated that racial/ethnic and demographic factors may be associated with transplant related health disparities, which significantly impact referral, refusal, wait-listing and ultimately TXP rates.

Methods: To explore this hypothesis we studied 11,950 dialysis patients under age 70, treated in 230 facilities in 2015 operated by DCI, a large not-for-profit provider. We used DCI's MIS to abstract demographic data and TXP status. We constructed a random intercept, multinomial logistic regression model using Proc Glimmix in SAS with adjustment for clustering within facilities.

Results: Overall, 34.5% were referred but not yet listed, 19.3% refused referral, 23.8% were not referred, 18.7% were waitlisted (WL) and 3.7% received a transplant. The odds ratios for each step in the process leading to TXP by patient characteristics are shown. Females were more likely than males to refuse evaluation but if referred they were just as likely to progress to being WL or TXP. African Americans were more likely than whites to be referred but were less likely to progress to WL/TXP. Asians were less likely than whites to refuse. Extremes of BMI (<22 or ≥37), in-center dialysis, and age ≥63 years were associated with less likely to be referred and more likely to refuse referral.

Effect	Not Referred	Refused	Waitlisted/TXP
Females vs. Males	1.11	1.22*	1.05
African Americans vs. Whites	0.84*	0.89	0.86*
Asians vs. Whites	0.61*	0.47*	1.54*
Native Americans vs. Whites	0.98	0.88	0.61*
Age ≥ 63 vs. 50-62	1.41*	1.61*	0.89
BMI < 22 vs. 22-36	1.31*	1.20*	0.68*
BMI ≥ 37 vs. 22-36	1.56*	1.17*	0.48*
Place In-center vs. Home	2.02*	1.54*	0.57*
* P < 0.05			

Conclusions: Racial/ethnic and demographic factors are associated with significant TXP related health disparities leading to decreased referral. Dialysis facilities should have increasing roles in educating patients about TXP, referring patients and facilitating completion of evaluation and listing.

SA-PO376

Risk Factors for Preterm Birth in Kidney Transplant Recipients Swati Rao,[1] Fengzheng Zhu,[2] Dawn Armenti,[3] Lisa Coscia,[3] Mythili Ghanta,[1] Iris J. Lee,[1] Avrum Gillespie,[1] Serban Constantinescu,[1,3] Michael J. Moritz.[3,4] *[1]Nephrology, Temple Univ; [2]Fox School of Business, Temple Univ; [3]Gift of Life Inst; [4]Lehigh Valley Health Network.*

Background: The rate of preterm birth (<37 wks) in kidney transplant (KT) recipients is 5 times higher than general population (10%), but the risk factors have not been well quantified.

Methods: We analyzed 1374 pregnancies which resulted in live birth in 948 KT recipients from the National Transplantation Pregnancy Registry using logistic regression.

Results: The mean conception age was 29.7 yrs, gestational age was 36 wks, and birth weight was 2567g. The preterm birth rate was 49%. Recipients with HTN, DM, pre-eclampsia, acute rejection during pregnancy, higher serum creatinine pre-conception and during pregnancy had significantly increased risk of prematurity. Longer interval from transplant to conception was associated with higher odds for full term birth.

	Preterm Birth (< 37 weeks)				
	No n=701	Yes n=673	P value	Odds Ratio	P value
Pre-conception characteristics					
Age at conception, yrs, median	29.9	29.6	NS		
HTN, %	38.0	51.4	<0.001	1.72	<0.001
DM, %	2.8	6.5	0.001	2.41	0.002
Interval from transplant to conception, yrs %			<0.001		
<2	19.6	24.1		1	
2-5	32.8	38.5		0.95	0.751
5-10	32.2	24.9		0.62	0.003
>10	15.4	12.5		0.65	0.025
Pre-conception serum creatinine, mg/dl, median (range)	1.17 (0.50-4.00)	1.34 (0.58-4.40)	<0.001	2.99	<0.001
Deceased donor, %	35.74	43.75	0.002	1.39	0.003
Pregnancy characteristics					
HTN, %	41.8	60.4	<0.001	2.12	<0.001
DM, %	5.2	11.5	<0.001	2.37	<0.001
Preeclampsia, %	19.6	40.5	<0.001	2.80	<0.001
Serum creatinine, mg/dl, median (range)	1.17 (0.50-4.90)	1.56 (0.60-10.90)	<0.001	3.10	<0.001
Acute rejection, %	0.3	1.8	0.007	6.16	0.018

Conclusions: Graft function and co-morbid conditions significantly influence the risk of preterm birth, and should guide management of female KT recipients contemplating pregnancy.

SA-PO377

Association of Body Composition with Changes in Frailty after Kidney Transplantation Natalia Cortez, Daniel Velez, Eugenia Xiao, Sumit Mohan, Tom Nickolas. *Dept of Medicine, Columbia Univ, NY, NY.*

Background: Frailty is emerging as a risk factor for poor clinical outcomes in kidney transplantation (KT). Preoperative frailty is associated with increased risk for early hospital readmission, delayed graft function and mortality after KT independent of age. Weight loss is a component of frailty that can occur after KT, but changes in weight and body mass index (BMI) do not fully account for changes in lean and fat mass, which have opposing associations with frailty. We hypothesized that lower lean and higher fat mass at KT would be associated with greater degree of frailty 1-month after KT.

Methods: Whole body composition was obtained by dual-energy X-ray absorptiometry (DXA) within 3-weeks of KT. The Fried Frailty Assessment was completed both pre- and 1-month after KT. Each frailty component was scored 0 or 1 (absent or present) and the aggregate frailty score was calculated. Increases in frailty after KT were defined as an increase of ≥1 in the frailty score. Associations between percent lean and fat mass with frailty and change in frailty were determined by logistic regression and expressed as the odds ratio (95% CI).

Results: Forty-seven participants were enrolled (64% men) with a mean age of 51±14 years and BMI of 28.7±5.7; mean percent lean mass was 67.6±8.6% and fat mass was 32.4±8.6%. At baseline 56% were frail and at 1-month after KT 47% had an increase in frailty. Higher degree of frailty after KT was associated with older age (OR 1.10; 1.03-1.17), higher BMI (OR 1.13; 1.01-1.28) and fat mass (OR 1.12; 1.02-1.22), and lower lean mass (OR 0.90; 0.82-0.98) at baseline. An increase in frailty at 1-month after KT was associated with lower frailty (OR 0.09;0.02-0.43) before KT and decreases in BMI (OR 0.89; 0.79-0.99) after KT.

Conclusions: Frailty early after KT is associated with higher fat and lower lean mass at the time of KT, while increases in frailty after KT are associated with lesser frailty pre-KT and decreases in BMI after KT. Assessment of body composition before KT may predict frailty status early after KT. Future work will investigate how changes in body composition 12-months after KT affect frailty status and clinical outcomes.

Calcium Scores in Pre-Transplant Myocardial Perfusion Scans Are Increased by Beta-Blockers Rosa M. Montero, Fiyyaz Ahmed-Jushuf, Azhar Ali, Roshni Patel, Mona Wahba. *Epsom & St. Helier Univ Hospitals, Renal & Transplantation, United Kingdom.*

Background: End stage kidney disease(ESKD) is a risk factor for cardiovascular mortality. The prognostic value of myocardial perfusion scan(MPS) is reported to be 90% in renal transplants.Previous reports show a person with high calcium scores reflect coronary artery calcification and increased narrowing of the coronary arteries compared with a low calcium score. It is unclear if traditional cardiac risk factors or medications in particular beta-blockers affect the calcium score in patients with ESKD.

Methods: All pre-renal transplant patients in a single centre were identified. Clinical data, including;medications, cardiology investigations results were recorded in patients who underwent MPS as part of their transplant workup between 2011-2014. Cardiac risk factors including; hypertension, previous cardiovascular incident, cardiac family history, hypercholesterolaemia, diabetes mellitus(DM), body mass index(BMI) and smoking were recorded. Calcium scores of >100 reflected moderate atherosclerotic disease with high risk of coronary artery disease and significant vessel narrowing. Logistic regression was used for statistical analysis.

Results: 172 patients had a MPS with analysis performed on 154 who had no coronary stents. 62%M:56%F. 56% had DM. 95 patients on RRT. Median age was 60yrs(20-83). There was strong evidence that the odds of having Calcium scores >100 were 5.5x higher in patients on beta-blockers than those without(OR 6.07, 95%CI 2.62-14.1, p<0.001) and increased with 9.3% for each year of age(OR 1.093, 95%CI 1.04-1.14, p<0.001), independent of other factors. Weaker evidence that patients from black ethnicity had 83% lower odds(OR 0.17, 95%CI 0.042-0.69, p=0.013), while patients withT2DM had 3.2 fold higher odds of having calcium score>100(OR 3.17, 95%CI 1.25-8.03, p=0.015), adjusted for beta-blocker intake and age. Calcium scores were unaffected by calcium antagonists, ACE inhibitors/angiotensin receptor blockers, vitamin D, other traditional cardiac risk factors or dialysis.

Conclusions: We show beta-blockers are associated with a raised calcium score that is independent of age. The beta-blocker effect on calcium scores requires further investigation.

SA-PO379

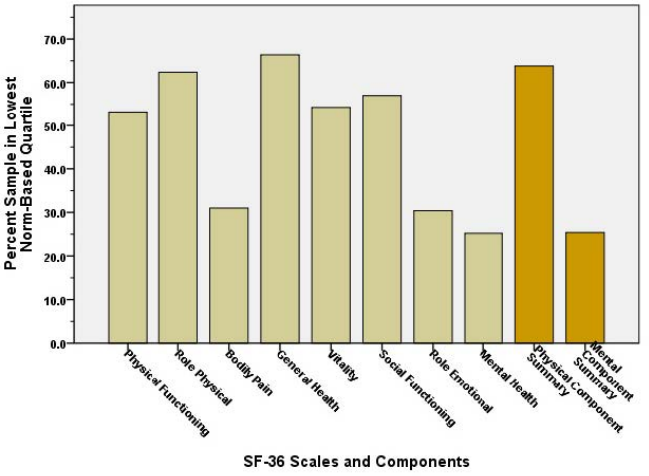
Pre-Transplant Health Related Quality of Life Is Not Associated with Short-Term Outcomes after Kidney Transplantation Beatrice P. Concepcion, Hassan Alhalabi, Rachel C. Forbes, Irene D. Feurer. *Vanderbilt Univ Medical Center.*

Background: Novel measures, such as frailty and physical functioning, which forecast post transplant outcomes are increasingly being recognized as potentially useful tools in risk stratifying kidney transplant candidates. We investigated whether pre-transplant patient-reported health-related quality of life (HRQOL) is associated with short-term adverse events after kidney transplantation.

Methods: Pre-transplant HRQOL was measured using the 8 scales and physical and mental component summary scores of the Short Form 36 Health Survey. Continuous scores were stratified based on scale- and component-specific general population norm quartiles. Binary outcomes (present/absent) were: delayed graft function (DGF), readmission within 90 and 365 days of transplant, any acute rejection episode(s). Data were analyzed using multivariable logistic regression models that adjusted for age, donor type and cardiovascular disease.

Results: The sample included 230 adults who were referred to our center for kidney transplantation and were subsequently transplanted. Patients were 59% male, 50% had a living donor, 49±14 years of age, 24% with CV comorbidity. Time pre-transplant at HRQOL was 13±9 months and follow-up time 52±35 months. Figure 1 shows the proportion of patients that were in the lowest norm-based quartile for each pre-transplant measure.

Figure 1



Post-transplant, 6% had DGF, 30% and 48% were readmitted within 90 and 365 days, respectively, and 12% had acute rejection. Multivariable models demonstrated that compared to patients in the upper quartiles, patients at the lowest quartile for each HRQOL measure did not have an increased risk for DGF, readmission within 90 or 365 days, or acute rejection (all p>0.5).

Conclusions: Pre-transplant HRQOL is not a useful metric for risk stratification of kidney transplant candidates for short-term adverse events after transplantation.

SA-PO380

Effect of Pre-Transplant Dialysis Modality and Duration on Recipient's Outcome: A National Population-Based Cohort Study between 2005 and 2008 in Korea Hyunjeong Cho,[3] Jung Nam An,[1,2] Yunmi Kim,[3] Eunjeong Kang,[3] Dong-Ryeol Ryu,[4] Kyoung Hoon Kim,[5] Yun Kyu Oh,[2] Chun Soo Lim,[2] Yon Su Kim,[3] Jung Pyo Lee.[2] *[1]Critical Care Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [2]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul; [3]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [4]Internal Medicine, Ewha Womans Univ, Seoul, Korea; [5]Public Health, Graduate School, Korea Univ, Seoul, Korea.*

Background: So far the effects of pre-transplant dialysis modality or duration on clinical outcomes after kidney transplantation (KT) have not been investigated.

Methods: We analyzed the clinical outcomes of 1,563 KT recipients among the 35,422 adult patients who were started hemodialysis and peritoneal dialysis from 2005 to 2008, using the Korean Health Insurance Review & Assessment Service database.

Results: During the median 6.9 years follow-up after KT, 106 (6.8%) patients were died and 28 (1.8%) patients had experienced major adverse cardiovascular events (MACE). In the multivariable-adjusted Cox proportional hazard model, pre-transplant dialysis modality was not associated with an increased risk of mortality and the development of MACE. Pre-transplant dialysis duration was not associated with the occurrence of MACE; however, the HR for mortality (comparing the group greater than 10.8 months with the group lower than 10.6 months regarding the duration of dialysis before KT) was 1.66 (95% CI 1.11-2.47) in total populations. In each group of hemodialysis and peritoneal dialysis, the duration of pre-transplant dialysis was also an independent risk factor for mortality.

Conclusions: The duration of dialysis before KT was independently associated with mortality, regardless of the dialysis modality in this national population-based cohort study. Pre-transplant dialysis duration could be useful marker in predicting mortality in KT recipients.

SA-PO381

Perception of Kidney Transplant Candidates of Deceased Donor Waiting List Outcomes Allyson Hart,[1,2] Marilyn J. Bruin,[3] Ajay K. Israni.[1,2] *[1]Nephrology, Hennepin County Medical Center, Minneapolis, MN; [2]Medicine, Univ of Minnesota, Minneapolis, MN; [3]College of Design, Univ of Minnesota, Minneapolis, MN; [4]Medicine, Minneapolis Veterans Affairs Medical Center, Minneapolis, MN.*

Background: Despite steady growth of the waitlist, living donor kidney transplant rates have fallen over the past decade. We sought to understand what transplant candidates understand about likely waitlist outcomes.

Methods: Adult (aged ≥ 18 years) kidney transplant candidates were recruited for in-depth interviews from 2 centers in Minnesota between March and June 2016 during their transplant evaluation. Systematic inductive and deductive analyses of the interviews were performed. Text was axial coded for expected answers, then open coded for new concepts within and across questions.

Results: 8 in-depth interviews were conducted. Mean age of the participants was 49.9 ± 12.6 yrs; 6 (75.0%) participants were male, 4 (50.0%) Caucasian and 4 (50.0%) African American. All had at least some college education; household income ranged from < $15,000 to > $75,000. Analyses revealed several themes, including a limited understanding of likely outcomes on the waiting list, the importance of friends and family in medical decision-making, and fear of the unknown. Several participants expressed dissatisfaction with generalizations and a desire to be given individualized descriptions of the outcomes. A conceptual model of how these factors may impact clinical decision making is shown in figure 1.

Conclusions: Kidney transplant candidates have a limited understanding of likely outcomes on the waiting list even after undergoing pre-transplant education and despite a high level of education. These findings suggest a need to provide candidate-specific, comprehensible information, and suggest a role for including friends and family in the education process.

SA-PO382

Internet Use Impact on Health-Related Quality of Life (HRQOL) in Renal Transplant Recipient (RTR) in France Yosra Mouelhi,[1] Valerie Moal,[2] Bertrand Dussol,[2] Stephanie Gentile.[1] *[1]Sante Publique et Evaluation Medicale, CHU Marseille, Marseille, France; [2]nephrology Unit, CHU Marseille, Marseille, France.*

Background: The Internet may provide new opportunities for communication that can help RTR to improve their quality of life (QOL). The aim of this study is to evaluate the impact of Internet access and social networks connections on HRQOL of RTR during long term renal transplantation.

Methods: This study analyzed psychosocial data (Internet access and social networks connections) and HRQOL measures by the generic scale (SF36) and a disease specific questionnaire validated in French language: the ReTransQol (RTQ). Self-administered questionnaires were completed by patients in a 2-year longitudinal and multicenter study of 1,424 RTR. We performed univariate analysis in order to determine the relationships between internet access and social networks connection and HRQOL scores.

Results: Nearly 80% of RTR had access to the internet. Among them, 80% regularly connected to a social network. Internet access was significantly associated with a better HRQOL for all dimensions of SF-36, and only for physical and for mental health of RTQ. Social networks connections played a significant role in the improvement of HRQOL for physical dimensions for both questionnaires.

Conclusions: This study showed significant association between internet access and a better HRQOL in our population. Providing internet access and encouraging social networks connections may be feasible to improve consistency of information to RTR ant their physical and psychosocial well-being.

SA-PO383

Factors Associated with Health-Related Quality of Life (HRQOL) in Renal Transplant Recipient (RTR) in France Yosra Mouelhi,[1] Valerie Moal,[2] Bertrand Dussol,[2] Stephanie Gentile.[1] *[1]Sante Publique et Evaluation Medicale, CHU Marseille, Marseille, France; [2]Nephrology Unit, CHU Marseille, Marseille, France.*

Background: The factors associated with HRQOL are not well defined in renal transplantation studies using extensive observations in large cohorts. A cohort of RTR was conducted in 5 university hospitals in France in order (a) to improve a disease specific questionnaire, the ReTransQol (RTQ) validated in french language for RTR (b) to identify factors associated with HRQOL in this population.

Methods: A 2-year longitudinal study was conducted in a representative sample of RTR. Measures included a patient questionnaire (socio-demographic characteristics), a medical questionnaire including kidney disease, health status, comorbidities, treatments and their side effects, and biological data. The RTQ and the generic scale (SF36) were used. Multiple linear regressions analysis were performed for RTQ and SF36.

Results: A total of 1,424 adults RTR were included. Patient's mean age was 56 ± 13 years and 61.4% were male. 38% had college education level, 39% had full time job, 35% were recipients of disability, and 68% lived with a partner. Clinical data were : 13% had a preemtive transplantation, 15% suffered from at least one rejection episode, 31% had a chronic transplant dysfunction (serum creatinine > 16mg/l). 18% had diabetes mellitus, 82% hypertension, and 15% obesity. In both questionnaires, we identified that older age, female gender, diasibility, to receive any social support, a chronic transplant dysfunction, and a high Charlson Comorbidity index were associated with a low HRQOL scores. HRQOL increased with higher monthly incomes, employment status and high Karnofsky performance scale (≥70%). Home internet connection increased significantly HRQOL for mental health dimensions.

Conclusions: We evidenced several variables related to HRQOL in RTR. A better understanding of the psychosocial factors' roles is essential for the development of psychosocial interventions to improve HRQOL in the context of long-term transplantation.

SA-PO384

Utility of Pre-Implanatation Deceased Donor Kidney Biopsy and Scoring System in Predicting Early Graft Outcome Based on Kidney Donor Profile Index and Estimated Post-Transplant Surival Shirley Shwu-Shiow Chang, Mareena Susan Zachariah. *Internal Medicine, Univ of Buffalo, Buffalo, NY.*

Background: Demand for kidney (K) grafts excces supply of avilable organs. There is increasing interests in evaluating the intrinsic donor organ quality by performing pre-transplant (tx) k biopsies (bx), especially in the older donors, is improtant for post-tx histologic evolution & long-term graft survival. Kidney Donor Profile Index (KDPI) characterizes deceased donors based on 10 factors, ranges from 1% to 100%. Estimated Post Transplant Survival (EPTS), assigned to tx candidates on the waiting list, is based on 4 factors (age, time on diaysis, diabetes status, and prior solid organ tx). We are interested in assessing pre-tx donor k bx, KDPI, EPTS affecting early graft outcome.

Methods: This is a single center retrospecitve study from University of Buffalo Transplant Center from January 2012 to Sept 2015. 183 deceased kidney tx recipients who had time zero donor kidney biopsies were inclueded. Induction immunosuppression was with Thymoglobulin 3 mg/kg, maintenance therapy was with prednisone, tacrolimus, MMF. All pre-implantation bx performed were scored based on modifed chronic Banff criteria (interstital fibrosis, tubular atrophy, glomerular mesangial matrix, vascular narriowing, and hyalinosis). glomerulosclerosis, inflammation, ATN. Each of above histologic features were graded from scales from 0 to 3, except for ATN (present or absent). Clinical data such as serum Cr, estimated GFR, was collected at 1 week, 1 month, 3 months, 6 months, 1 year, 2 years post-tx. The follow-up period was up to 4 years. Mutivariate mixed modeling was used.

Results: Increasing KDPI, modified Banff chronic score, cold ischemic time (CIT) were found highly signifcant for decreasing eGFR at baseline (all p values <0.001). Overtime, chronic Banff, EPTS, CIT had significant effects on eGFR ($p<0.03$, $p<0.04$, $P<0.02$, respectively).

Conclusions: While KDPI was meant to rank order the quality of donor k as defined by an aggregate population relative risk, a well graded time zero donor k bx could add to the ability along with composite clinical parameters as predictore of k allograft outcome.

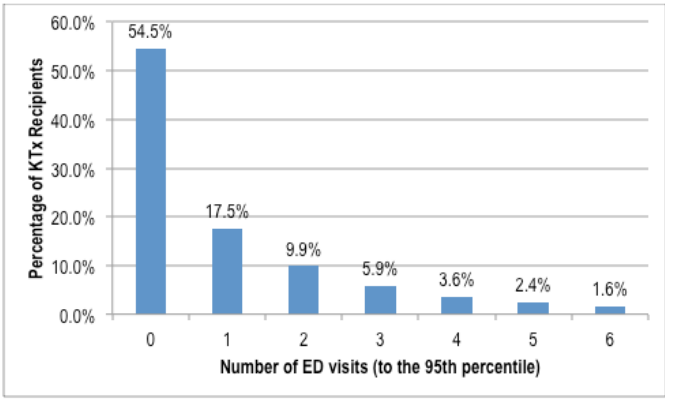
SA-PO385

Emergency Department Utilization among Kidney Transplant Recipients in the United States Brendan P. Lovasik, Rebecca H. Zhang, Justin D. Schrager, Stephen O. Pastan, Rachel E. Patzer. *Emory Univ, Atlanta, GA.*

Background: Single center studies suggest that kidney transplant recipients have a high rate of emergency department (ED) utilization, with 1.48 ED visits/patient-year, and ED visits are associated with graft failure and patient mortality. However, ED utilization among national renal transplant recipients has not been examined.

Methods: We examined a cohort of 103,155 incident adult kidney transplant patients in the United States Renal Data System from 2005-2011. ED utilization, hospital admission, and diagnoses were obtained from the USRDS and Medicare Physician/Supplier and Inpatient databases for Medicare Part A/B claims. Multivariable Poisson regression was conducted to assess the association of patient variables with ED utilization.

Results: In the first post-transplant year, nearly half (45.5%) of all kidney transplant recipients utilized the ED, with an average of 1.63 ED visits/patient-year; 22% visited the ED in the first 30 days. The national range was 0 to 216 ED visits, with 95th percentile 6 visits. Nearly 40% of ED visits resulted in hospital admission; graft complications, sepsis, and urinary tract infections were the most common diagnoses. Both patient death and graft failure were highly correlated with ED visits ($p<0.001$). Older age and male sex were associated with higher ED utilization; private insurance, preemptive transplant, and living donor transplant were associated with lower ED utilization (all $p<0.0001$).



Conclusions: This study is the first to our knowledge to describe ED utilization in a national sample of kidney transplant patients. Compared to the national average, transplant patients have higher ED utilization (1.63 vs. 0.4) and hospital admission rates (40% vs. 12%). A comprehensive understanding of factors associated with ED utilization can improve population health management by targeting interventions to high-risk patients.

SA-PO386

Early Renal Hemodynamic Changes with Doppler Ultrasound after Renal Transplantation Amir Shabaka, Estefania Yerovi, Victor Burguera, Maite Rivera, Fernando Liano. *Nephrology, Hospital Univ Ramón y Cajal, Madrid, Spain.*

Background: Doppler Ultrasound facilitates the global evaluation of intrarenal vasculature, making it a valuable noninvasive tool for early diagnosis of complications in renal transplants. The aim of this study was to explore the evolution of renal graft hemodynamics in the immediate postoperative and early periods.

Methods: A retrospective study in which all Doppler Ultrasound studies done within the first month of transplantation were reviewed in patients who received a renal graft at our centre from January 2013 to May 2015. We excluded patients with primary graft failure, delayed graft function, acute rejection, surgical complications (severe hemorrhage or urinary fistulae), significant hydronephrosis, or hemodinamically significant arteriovenous fistulae. We recorded receptor/donor characteristics, renal morphology, a subjective classification of renal vasculature by Color Doppler and hemodynamic measurements by Pulsed Doppler (intrarenal resistive index (RI), Systolic Acceleration Index (AI), Intrarenal Acceleration Time (AT), Peak systolic velocity at the arterial anastomosis (PSV), and wave morphology in the intraparenchymatous, renal and iliac arteries.

Results: Out of the 179 patients with renal transplantation, 71 patients met the inclusion/exclusion criteria; 74.6% males, mean age 53.6±13.6 years, 85.9% received their first graft, 39.4% were preemptive renal transplants, 32.4% were previously on hemodialysis and 28.2% on peritoneal dialysis, 91.5% received grafts from donors after brain death and 8.5% from live donors. Immunosuppression induction was done with basiliximab in 73.2%, ATG in 7.5% and 18.3% went without induction. 37.3% presented an AI <300 cm/s^2 in the first two days post-transplantation, decreasing to 16.7% between the third and tenth day($p=0.008$) and 0% in the last ten days of the first month($p<0.001$). There were no statistically significant differences in the evolution of RI, AT, PSV or wave morphology.

Conclusions: In uncomplicated renal transplants, the Systolic Acceleration Index by Doppler Ultrasound may be abnormal in the first two postoperative days, with gradual normalization within the first month of transplantation.

SA-PO387

Predictors of Survival in Deceased Kidney Transplant Using Data Mining Methods Ammar Almehmi,[1] Kazim Topuz,[3] Ferhat Zengul,[2] Mehmet Yildirim.[3] *[1]Nephrology and Radiology, Univ of Alabama in Birmingham, Birmingham, AL; [2]UAB-Dept of Health Administration, Birmingham, AL; [3]Wichita State Univ, Wichita, KS.*

Background: Prediction of graft survival after kidney transplantation is the most important factor in the donor-patient matching process. Several conventional statistical methods are employed to assess the effect of certain candidate variables on graft survival. However, the role of data mining using a large pool of variables in predicting survival is unknown. The objective of this study was to define predictors of renal graft survival by analyzing a large set of variables using data analytical approaches.

Methods: In this study, we used UNOS database of deceased kidney transplantation between. A comprehensive variable selection methodology was employed using medical literature search, conventional statistics and data analytic approaches. The analytical approaches included Elastic Net regression and structured data analytic based information fusion technique. The selected variables obtained from the medical literature and analytical methods were incorporated in the Bayesian Belief Network (BBN) to create a multi-class prediction survival model and to identify the interactions between these variables.

Results: A total of 31,207 deceased kidney transplants were included in this study between July 1, 2004 and March 31, 2015. We found that UNOS database contained more than 450 variables. Further, a total of 56 variables were found in the medical literature as predictors of kidney transplant survival. Another 28 variables were selected using data analytic methods. The interactions and relationships among the different selected variables were calculated using multi-class Bayesian risk level prediction as depicted in Figure 1. We found that the recipient's functional status (RFS) at listing was the most interacted variable in this model. Moreover, this variable was the strongest predictor of renal graft survival.

Conclusions: In this large cohort of deceased kidney transplant, we found that the RFS was the most prominent predictor of renal graft survival. Further, data mining approach was a powerful tool in exploring the complex relationships between multiple variables.

SA-PO388

Time Varying Proteinuria Is a Strong Predictor of Mortality and Graft Loss in Patients after Kidney Transplantation Benaya Rozen-Zvi,[1,2] Shelly Lichtenberg,[1,2] Hefziba Green,[1,2] Ruth Rahamimov.[1,2] *[1]Nephrology and Hypertension, Rabin Medical Center, Petach-Tikva, Israel; [2]Sackler School of Medicine, Tel Aviv Univ, Tel Aviv, Israel.*

Background: proteinuria is known to be associated with decreased graft and patient survival after kidney transplantation. Nevertheless, most of the data comes from cross sectional and cohort studies and the effect time varying proteinuria was not adequately evaluated.

Methods: we used the routine dipstick urine protein evaluation performed every three to six month for all patients at our post transplantation follow-up clinic. Urine protein concentration was allocated into ordinal scale (no proteinuria, trace, 25 ng/dl, 75 mg/dl, 150 mg/dl and 500mg/dl). The follow-up time was divided into 6 months intervals and proteinuria was evaluated by using all available protein measurements during each interval. The primary outcome was graft loss defined as the combination of death from any cause and graft dysfunction requiring chronic dialysis or retransplantation. Time dependent Cox proportional hazard model was used using univariate and multivariate adjusted analysis.

Results: One thousand two hundred and twenty patients transplanted between 1/1/2000 and 31/12/2013 had 153 events (91 graft loss and 62 death events) during median follow-up of 4 years (range 0.5 to 12.9 years). Time varying proteinuria was strongly associated with increased graft loss Hazard Ratio (HR) 1.78 per stage, 95% Confidence Interval (CI) 1.62-1.95,p<0.001), the association was not changed after adjusting for age, gender, time on dialysis, recipient heart disease, diabetes, donor type (living or deceased), donor age, HLA mismatch, panel reactive antibodies, delayed graft function, duration of hospital stay following transplantation ,creatinine at six month and urine protein level at 6 months (HR 1.78, 95% CI 1.61-1.96,p<0.001). Death censored graft survival was also associated with time varying proteinuria at univariate and multivariate analysis (HR 2.1, 95% CI 1.86-2.36,p<0.001) and (HR 2.16, 95% CI 1.87-2.49,p<0.001) respectively.

Conclusions: Time varying proteinuria is strongly associated with poor graft survival even after adjustment for baseline proteinuria and renal function.

SA-PO389

Do Phosphate-Binders Affect the Calcium Score in Pre-Renal Transplant Myocardial Perfusion Scans? Fiyyaz Ahmed-Jushuf, Roshni Patel, Azhar Ali, Rosa M. Montero, Mona Wahba. *Epsom & St. Helier Univ Hospitals, Renal & Transplantation, London, United Kingdom.*

Background: Myocardial perfusion scans(MPS) is used in pre-transplant workup as a minimally invasive tool to determine coronary artery disease in the potential recipient. The prognostic value of using this test has been reported with sensitivity 90%, specificity 85%. Vascular calcification is common with many renal patients taking calcium-based phosphate binders/vitamin D analogues to help regulate bone metabolism and reduce renal bone disease. It is unclear whether using calcium-based phosphate binders(CBPB) adds to vascular calcification. This retrospective study looked at whether calcium-based phosphate binders caused a high Calcium score predicting underlying coronary artery disease and high cardiovascular risk.

Methods: All patients undergoing a MPS as part of their pre-renal transplantation work-up were identified in a single centre from 2011-14. Clinical data, cardiac work-up investigations and serum calcium, phosphate and parathyroid hormone(PTH) levels were collected from notes of these patients. Logistic regression was used for analysis.

Results: 172 patients underwent MPS as part of their renal transplantation workup. 147 had no previous coronary artery stents. 14 went onto renal transplantation. 10 died from non-cardiac events; 61%M; 79 White, 24 Black, 44 Asian. 67 patients were on CBPB and 85 had PTH available for analysis. The mean corrected calcium levels were 2.33nmol/l(1.38-2.86), phosphate levels of 1.49nmol/l(0.7-3.11) and median PTH of 35pmol/l(3.3-209).52 patients(35%) had Calcium score >100. There was no association between Calcium score and serum calcium levels or Calcium score and CBPB. No effect was seen of phosphate binders on MPS outcome or cardiac investigations.

Conclusions: In this small cohort, phosphate binders did not affect Calcium scores in patients pre-renal transplant workup, irrespective of:age, gender, serum calcium or PTH levels. There were no coronary complications in those who went onto to have renal transplants. Further larger studies are required to confirm these findings and elucidate the mechanisms behind coronary artery vascular calcification in renal patients thereby providing novel therapeutic targets.

SA-PO390

A Single Center Experience of Kidney Transplant Recipients due to Scleroderma Kidney Disease Nishkarsh Saxena, Arjang Djamali, Brad C. Astor, Didier A. Mandelbrot, Maha A. Mohamed, Sandesh Parajuli. *Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: There is limited information on renal transplant recipients with end stage renal disease (ESRD) due to scleroderma.

Methods: This was an observational study that included patients with ESRD due to scleroderma kidney disease who received renal transplant between 01/1994 and 06/2013.

Results: There were ten kidney transplant recipients during the study period. They were all caucasian females. Mean post-transplant follow up was 76.75 ± 56.18 months. Mean age at time of transplant was 56.6 ± 11.99 years. Seven of them were living kidney transplant recipients. Mean dialysis vintage was 46.4 ± 80.35 months, ranging from 8 to 272 months. Mean serum creatinine (SCr) at 3, 6 and 12 months were 1.31 ± 0.47 mg/dL, 1.35 ± 0.51 mg/dL and 1.34 ± 0.49 mg/dL respectively. There were five graft failures with median graft survival of 101 months.Causes of graft failure were chronic transplant glomerulopathy in three patients, thrombotic microangiopathy and antibody mediated rejection in the other two patients. In those without graft failure, mean SCr at last follow up was 0.96 ± 0.39 mg/dL. Six patients were on angiotensin converting enzyme inhibitors (ACE-I) after transplant. One patient had developed new onset diabetes after transplant. In univariate analysis, none of the factors including, age at time of transplant (HR 1.10, 95% CI 0.89 to 1.36, p= 0.35), dialysis vintage (HR 1.01, 95% CI 0.99 to 1.02, p= 0.16), use of ACE-I (HR 0.57, 95% CI 0.09 to 3.54, p= 0.55), living transplant (HR 3.8, 95% CI 0.38 to 38.38, p= 0.25), CMV infection (HR 1.89, 95% CI 0.31 to 11.43, p= 0.49) and SCr at 1 year (HR 1.49, 95% CI 0.26 to 8.64, p= 0.66), were predictive of graft survival.

Conclusions: In this observational study we found a wide variation in outcomes after kidney transplantation in patients with scleroderma kidney disease. More studies are needed to assess the factors that may influence graft survival in this rare disease.

SA-PO391

Pre-Transplant Cardiovascular Risk Factors Affect Kidney Allograft Survival: A Multi-Center Study in Korea Jung Nam An,[1] Eunjin Bae,[4] Eunjeong Kang,[2] Yun Kyu Oh,[1] Chun Soo Lim,[1] Yon Su Kim,[2] Young Hoon Kim,[3] Jung Pyo Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [3]Dept of Surgery, Asan Medical Center, Seoul, Korea; [4]Dept of Internal Medicine, Gyeongsang National Univ Changwon Hospital, Korea.*

Background: Pre-transplant cardiovascular (CV) risk factors affect the development of CV events even after successful kidney transplantation (KT). However, the impact of pre-transplant CV risk factors on allograft failure (GF) has not been reported.

Methods: We analyzed the graft outcomes of 2,902 KT recipients who were enrolled in a multi-center cohort from 1997 to 2012. We calculated the pre-transplant CV risk scores based on the Framingham risk model using age, gender, total cholesterol level, smoking status, and history of hypertension.

Results: Vascular disease (a composite of ischemic heart disease, peripheral vascular disease, and cerebrovascular disease) was noted in 6.5% of the patients. During the median 6.4 years follow-up, 286 (9.9%) patients had developed GF. In the multivariable-adjusted Cox proportional hazard model, pre-transplant vascular disease was associated with an increased risk of GF (HR 2.51; 95% CI 1.66-3.80). The HR for GF (comparing the highest with the lowest tertile regarding the pre-transplant CV risk scores) was 1.65 (95% CI 1.22-2.23). In the competing risk model, both pre-transplant vascular disease and CV risk score were independent risk factors for GF. Moreover, the addition of the CV risk score, the pretransplant vascular disease, or both had a better predictability for GF compared to the traditional GF risk factors.

Conclusions: In conclusion, both vascular disease and pre-transplant CV risk score were independently associated with GF in this multi-center study. Pre-transplant CV risk assessments could be useful in predicting GF in KT recipients.

SA-PO392

Sustained Improvement in Depression after Renal Transplantation Aditi Gupta, David K. Johnson, Jeffrey M. Burns. *Univ of Kansas Medical Center.*

Background: Depression is a common problem in patients with end stage renal disease (ESRD). Whether renal transplantation improves depression is unexplored.

Methods: We followed patients with ESRD prospectively till one year after their renal transplantation. We assessed depressive symptoms by administering Beck Depression Inventory (BDI) at baseline (pre-transplant), 12 weeks and one year post-transplant. We used paired t tests for analyzing the change in depression scale from baseline to 12 weeks after transplant, baseline to one year after transplant and 12 weeks after transplant to one year after transplant.

Results: The participants were 56.5 ± 10.7 years old, 11 men and 2 women, 10 Caucasian and one African American. All 11 patients had successful transplantation with a mean serum creatinine of 1.6 ± 0.6 mg/dl with an estimated glomerular filtration rate (eGFR) of 45.2 ± 11.2 ml/min at 12 weeks after transplantation. The mean BDI score of depressive symptoms at baseline was 11.09 ± 8.14, at 12 weeks after transplant was 4.55 ± 2.98 and at one year after transplant was 5.73 ± 6.28. Compared to baseline scores there

was a significant improvement in depression score 12 weeks after transplantation (p = 0.02), which persisted at one year after transplantation (p=0.003). There was no significant difference in score at 12 weeks and at one year after transplantation (p=0.48). After 12 weeks of transplantation, only one patient had mild depression with a BDI score of >11 compared to five patients (45%) who had a BDI score of >11. There was no association of these scores with the eGFR.

Conclusions: Renal transplantation is associated with a significant improvement in depressive symptoms, which is sustained at one year after transplantation.

SA-PO393

Machine Learning Approach for Prediction of Graft Survival in Kidney Transplant Using a Multicenter Cohort Kyung Don Yoo,[1] Junhyug Noh,[2] Hajeong Lee,[3] Dong Ki Kim,[3] Chun Soo Lim,[3] Young Hoon Kim,[4] Yon Su Kim,[3] Gunhee Kim,[2] Jung Pyo Lee.[3] *[1]Dongguk Univ Medical Center, Gyeongju; [2]College of Engineering, Seoul National Univ; [3]Seoul National Univ College of Medicine; [4]General Surgery, Asan Medical Center.*

Background: Accurate prediction of graft survival has important implications for clarifying the benefits of kidney transplantation(KT). However, the complexity and heterogeneity of risk factors on allograft survival were remained.

Methods: This multicenter cohort study included adult KT recipients admitted to two experienced tertiary hospitals in Korea between 1997 and 2014. A total of 3,117 recipients were enrolled. Graft survival of these recipients was investigated by the individual learning algorithms such as survival decision tree, survival ridge/lasso/Cox regression, and ensemble learning algorithms such as survival bagging and random forest.

Results: We analyzed 3,117 recipients' records. Among them, we chose 33 independent attributes which could affect graft survival for building our models. Among various conventional decision tree (DT) models, serum creatinine at 3month from KT was found to be a first decision node and the most important risk factor for graft failure (Concordance index 0.711, predicted 10 year GF rate 77.1%). Survival tree algorithm had presented the most accurate prediction model, and it outperforms a conventional DT (Concordance index 0.808 vs. 0.711, respectively). In the survival decision tree model using graft survival duration, acute rejection episode within first year was found to be the most important prognostic factor. In the case of having rejection episode in the first year, risk of graft failure was predicted in 4.27 times compared to overall recipients. Serum creatinine at three months after KT, and also recipients' age showed significant association with graft survival. In recipients without rejection episode, creatinine cut-off value over 1.65 mg/dl showed high probability of graft failure (HR 3.001).

Conclusions: In this study, reducing acute rejection episode at the first year following the transplant might had been the most important factor for allograft survival. Machine learning modeling could present an accurate and versatile tool for forecasting graft survival.

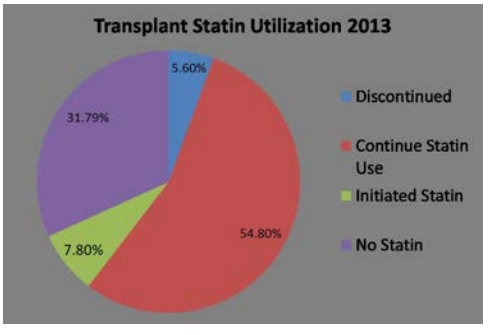
SA-PO394

Utilization of Statin Medications in U.S. Veterans with Post-Transplant Chronic Kidney Disease Arouna Senthilkumar, Talar Markossian, Kevin Stroupe, Nicholas Burge, Vinod K. Bansal, David J. Leehey, Julia Schneider, Holly J. Kramer, Benjamin Ling. *Hines VA Hospital, Hines, IL.*

Background: KDIGO and KDOQI guidelines recommend statin medications for kidney transplant recipients due to demonstrated cardiovascular benefits of statins with graded evidence of 2A. Results from few empirical studies suggest that statins are underutilized in transplant patients.

Methods: Retrospective analysis of U.S. Department of Veterans Affairs Healthcare System (VA) national databases to determine statin use in post-transplant patients with CKD. Medications acquired within the VA system were obtained from the Managerial Cost Accounting National Data Extracts. Medications acquired outside the VA were obtained from the Corporate Data Warehouse (CDW). Statin medication utilization was ascertained from pharmacy dispensing records in 2012 and 2013.

Results: A total of 626 veterans with CKD and history of kidney transplantation were identified. The majority of patients (97.3%) were male, 74.4% were aged ≥50 years and <2% were aged ≥75 years; 52.4% were white and 37.4% were African-American. Coronary artery disease, peripheral vascular disease and diabetes were present in 26.8%, 6.4% and 54.4% respectively. In 2012, 60.4% were using statins but only 54.8% were using statins during years 2012 and 2013 with 5.6% discontinued statins in 2013 while 7.8% initiated statins in 2013.



Conclusions: Despite KDIGO and KDOQI guidelines recommending statin use in transplant recipients, statin use is suboptimal in patients with post-transplant CKD receiving care in the VA health system. Interventions are needed to increase knowledge among treating physicians regarding the clinical importance of statin use in adults with post-transplant.CKD

Outcomes after Open Heart Surgery in Kidney Transplant Recipients and Matched Controls Bartlomiej J. Witczak,[1] Jan L. Svennevig,[3] Anders Hartmann,[2] Anders Aasberg.[2] *[1]Dept of Nephrology, Akershus Univ Hospital, Norway; [2]Dept of Transplant Medicine, OUS, Rikshospitalet, Norway; [3]Dept of Thoracic and Cardiovascular Surgery, OUS, Rikshospitalet, Norway.*

Background: Cardiovascular disease is common in kidney transplant recipients. We evaluated results of open heart surgery in these recipients at our center 1989-2015.

Methods: Ninety-five kidney transplant recipients underwent open heart surgery (48 coronary artery bypass operations, 27 valve replacements and 20 combined procedures) in the period. Controls (n=95) were matched for age, sex, diabetes and type and year of surgery. Mean follow-up time was 5.6 (4.9) years. Cox regression analyses were performed in the transplant group.

Results: Included were 76 men and 19 women with mean age 60.3 (11.1) years. Demographic and comorbidity data were similar, except a lower eGFR, more hypertension and less pulmonary hypertension in transplant recipients (p<0.001). Intraoperative data did not differ between groups, except that transplant recipients had higher hemorrhage volume (p=0.009). Postoperative data were also similar, although, transplant recipients received more red cell transfusions (p=0.04). Thirty-day mortality was similar in transplant patients and controls, but long-term survival was significantly lower in the former (p<0.001). Median survival in transplants was 6.3 years and in controls 13.3 years. Univariate Cox-regression analyses revealed only age, pulmonary hypertension and dialysis as risk factors for long term mortality. In a multivariate Cox-regression model, the same risk factors were significant: age (HR 1.07 per year, p<0.001), chronic dialysis (HR 4.29, p<0.001) and pulmonary hypertension (HR 2.53, p=0.02). Excluding transplant patients on chronic dialysis at time of surgery (n=13) showed similar results.

Conclusions: Kidney transplant recipients experienced more bleeding postoperatively. Intraoperative data and other postoperative complications, including short-term survival, were similar in kidney transplant patients compared with controls. Long-term survival was significantly lower in transplant recipients. Independent preoperative risk factors for long-term mortality were age, pulmonary hypertension and chronic dialysis.

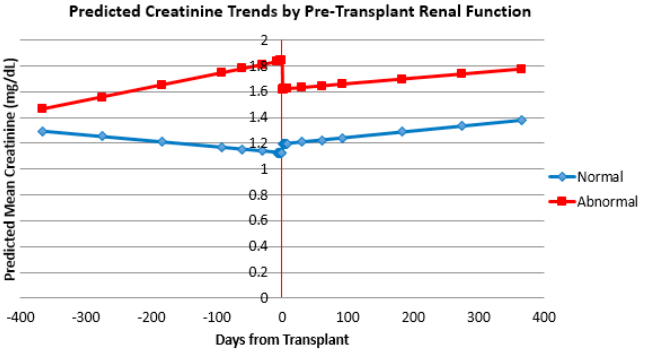
SA-PO396

Trajectory of Renal Function following Heart Transplant: Single Center, Retrospective Cohort Study Adetokunbo A. Taiwo, Margaret R. Stedman, Kiran K. Khush, Jane C. Tan. *Nephrology, Stanford Univ, Palo Alto, CA.*

Background: Heart transplant recipients with pre-transplant renal impairment have higher rates of mortality in the years following transplantation. Identifying appropriate candidates for combined heart-kidney transplantation relies on our ability to estimate the trajectory of renal function following heart transplantation. This study assessed longitudinal creatinine trends in heart transplant recipients stratified by pre-transplant renal function.

Methods: Using the Stanford Translational Research Integrated Database Environment, we identified all adult heart transplant recipients between May 1, 2008 and December 31, 2014. A mixed model analysis was used to assess pre- and post-transplant creatinine trends in those with normal versus abnormal pre-transplant renal function (defined as creatinine ≥ 1.5 mg/dL in the week prior to transplant).

Results: Twenty-two of the 115 identified heart transplant recipients had abnormal pre-transplant renal function. Baseline demographics and co-morbidities were similar in both groups. Renal function declined in both groups over time, but the group with abnormal pre-transplant renal function demonstrated initial improvement in renal function immediately following transplant (see figure 1). For patients with normal pre-transplant renal function, creatinine values continued to climb after transplant, however, on average, these values did not exceed 1.5 mg/dL 1-year post transplant. The likelihood of having a creatinine below 1.5mg/dL at 1-year post-transplant was 74% and 21% in the normal and abnormal renal function groups respectively.



Conclusions: Many patients with pre-transplant renal dysfunction experience initial improvement in renal function following heart transplantation, however, renal function in this group gradually worsens with time at a rate that is similar to those with normal pre-transplant renal function.

Funding: Other NIH Support - T32 Grant, Diversity Supplement

SA-PO397

Can Be Relied on Estimated GFR Decline in Renal Transplantation? The Nephrologist in the Mist Sergio Luis Lima,[1] Domingo Marrero,[1] Ana González Rinne,[1] Armando Torres,[1] Natalia Negrín,[1] Federico J. Gonzalez-Rinne,[1] Esteban Porrini.[2] *[1]Hospital Univ de Canarias, Spain; [2]Univ de La Laguna, Spain.*

Background: Renal transplant patients have a high rate of graft loss (4% per year). Thus, a reliable evaluation of graft function is crucial. Estimated GFR (eGFR) is neither accurate nor precise in the prediction of real GFR. Whether this error masks renal function loss in this population is not clear.

Methods: We measured GFR in 67 patients with the clearance of iohexol annually during 3 years. eGFR was evaluated by 52 creatinine and/or cystatin-c formulas. The agreement between mGFR- and eGFR-based decline was analyzed with the Concordance Correlation Coefficient (CCC).

Results:

	Accuracy	Precision	CCC
Creatinine-based			
aMDRD	0.94 (0.82)	0.44 (0.26)	0.42 (0.24)
CKD_EPI	0.91 (0.79)	0.43 (0.25)	0.39 (0.22)
Effersoe	0.95 (0.83)	0.45 (0.28)	0.43 (0.26)
Rule-MC	0.87 (0.74)	0.39 (0.20)	0.33 (0.17)
Cystatin-c-based			
Hoek	0.85 (0.71)	0.32 (0.12)	0.27 (0.10)
RuleCisc	0.84 (0.70)	0.31 (0.11)	0.26 (0.09)
CKD_EPI_ciscc	0.84 (0.70)	0.29 (0.09)	0.24 (0.07)
Creatinine + cystatin-c			
Stevens	0.96 (0.87)	0.49 (0.32)	0.47 (0.31)
Mac	0.98 (0.87)	0.48 (0.31)	0.47 (0.31)
CKD_EPI_creciscc	0.97 (0.86)	0.41 (0.2)	0.39 (0.22)

Table 1 shows the results of mGFR and eGFR decline for a representative group of 10 formulas (similar results were observed for the remaining equations). Mean GFR decline (mGFR) was 0.89±5.89 ml/min/year; 21 (31%) patients showed fast (< -3 ml/min/y), 28 (42%) slow or stable renal decline (-3 ml/min/y to 3 ml/min/y) and 18 (27%) increased mGFR decline (>3ml/min/yr). The agreement analysis showed poor accuracy and precision combined, which lead to a low concordance: CCC ranged from 26.08 to 47.84 (average~37.3%) between real and estimated GFR decline. Accordingly, formulas showed either over or underestimation of real GFR decline.

Conclusions: Renal function decline cannot be evaluated by estimation formulas in renal transplant patients. This can have important consequences in clinical trials and in day-to-day clinical practise.

Funding: Government Support - Non-U.S.

SA-PO398

Cystatin C-Based Equation for the Prediction of Glomerular Filtration Rate in Kidney Transplant Recipients Inryang Hwang, Youngae Yang, Kyu Yeun Kim, Min Jung Kim, Wonseok Do, Taehoon Yim, Sukyung Lee, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Yong-Lim Kim, Chan-Duck Kim, Jang-Hee Cho. *Dept of Internal Medicine, Kyungpook National Univ Hospital, Daegu, Korea.*

Background: Precise monitoring of glomerular filtration rate (GFR) is necessary for an optimal estimation of allograft function in kidney transplant recipients (KTRs). GFR is widely estimated by the formula based on serum cystatin C (SCys) as well as serum creatinine (SCr). We aimed to compare the efficacy of SCys-based equation with SCr-based equation to predict allograft function in KTRs.

Methods: We calculated the Modification of Diet in Renal Disease (eGFRMDRD), Chronic Kidney Disease Epidemiology Collaboration (eGFRCKD-EPI), CKD-EPI creatinine-cystatin C ($eGFR_{CKD\text{-}EPI\ Cr/Cys}$), and CKD-EPI cystatin C (eGFRCKD-EPI-Cys) equations in 66 KTRs. The measured GFR (mGFR) was defined as the GFR estimated by technetium-diethylen-etriaminepentaacetic acid (^{99m}Tc-DTPA) clearance. The accuracy and precision of the equations were compared to mGFR. The performance characteristics of a SCr and SCys were analyzed using receiver operating characteristic curves to ascertain the sensitivity and specificity at the cut off value lower than 45 ml/min/1.73m^2 DTPA.

Results: In overall patients, eGFRMDRD and eGFRCKD-EPI-Cys did not show significant differences from mGFR (P=0.760 and P =0.093 respectively) whereas eGFRCKD-EPI and $eGFR_{CKD\text{-}EPI\ Cr/Cys}$ significantly underestimated mGFR (P<0.001 and P= 0.008 respectively). In subgroup of mGFR lower than 45 ml/min/1.73m^2, eGFRCKD-EPI-Cys showed little bias (P=0.111), however, eGFRMDRD significantly underestimated mGFR (P=0.025). The area under curve for predicting mGFR less than <45 ml/min/1.73m^2 was 0.784 for SCys which was better than that for SCr of 0.745.

Conclusions: Cystatin C-based equations showed a better predictive performance of allograft function than creatinine-based equations especially for the KTRs with lower GFR. Cystatin C might be a good alternative method to monitor allograft function after kidney transplantation.

SA-PO399

Association of Gender and Age with Delayed Graft Function after Deceased Donor Kidney Transplantation Xun Luo, Allan Massie, Dorry L. Segev. *Johns Hopkins.*

Background: Previous studies demonstrated that better tolerance of ischemia-reperfusion injury, and hence lower delayed graft function (DGF) rate among females were mediated by higher estrogen level. Given the decreased estrogen level among older females, we hypothesized that the protective association between female sex and DGF might be attenuated among older recipients.

Methods: We identified adult kidney-only deceased donor recipients between 2000-2013 from SRTR data. DGF was defined as dialysis needed within the first week post-transplant. Recipients with primary non-functioning graft were excluded. We modeled DGF using logistic regression, adjusting for recipient, donor and transplant characteristics, and incorporating an interaction term of age (categorized as <40y, 40-59y, and 60+y) and female sex.

Results: Out Of 120,533 recipients, 47,603 (39.5%) were female. The rate of DGF was 19.4% among females and 26.1% among males. After adjustment, female sex was associated with 32% lower odds of DGF ($aOR=_{0.66}0.68_{0.71}$, p<0.001). The aOR was attenuated with greater age. Among recipient age <40, 40-59, and 60+, female sex was associated with 39% ($aOR=_{0.57}0.61_{0.65}$, p<0.001), 32% ($aOR=_{0.65}0.68_{0.71}$, p<0.001), and 26% ($aOR=_{0.71}0.74_{0.78}$, p<0.001) lower risk of DGF, respectively. Older age was associated with higher DGF rate only among female recipients (Table 1).

Table 1. The association of recipient age and DGF by recipient gender

	Adjusted odds ratio of DGF			
Age	Female	p value	Male	p value
<40	$_{0.82}\mathbf{0.88}_{0.94}$	**<0.001**	$_{0.93}0.98_{1.03}$	0.4
40-59	Reference	Reference	Reference	Reference
60+	$_{1.01}\mathbf{1.06}_{1.12}$	**0.03**	$_{0.93}0.97_{1.01}$	0.2

Conclusions: Female recipients had lower risk of DGF than male recipients. This association was attenuated among older recipients. Older age conferred higher DGF among female recipients but not male recipients. Clinical caution is warranted for older female recipients.

SA-PO400

30 Years of Kidney Transplantation in Infants (Age < 2 Years): A Single Center Experience Blanche M. Chavers,[1] Michelle N. Rheault,[1] Scott Jackson,[2] Arthur J. Matas,[3] Marie E. Cook,[3] Srinath Chinnakotla.[3] *[1]Pediatrics, Univ of Minnesota, Minneapolis, MN; [2]Transplant Information Services, Univ of Minnesota, Minneapolis, MN; [3]Surgery, Univ of Minnesota, Minneapolis, MN.*

Background: Infants (age < 2 years) with end stage renal disease (ESRD) have increased morbidity and mortality on dialysis compared to older age groups. Yet, because of technical and management issues, there are still concerns about transplanting infants. We evaluated our long-term experience with kidney transplants (KTx) in infants.

Methods: Between 1984-2014, 136 infants (mean age 1.3 ± 0.4 years) underwent KTx (116 living donor) with cyclosporine, prednisone, azathioprine maintenance immunosuppression. We examined trends in survival rates and complications by era (1984-1993 [era 1, n=59], 1994-2003 [era 2, n=42], 2004-2014 [era 3, n=35]).

Results: Patients were 92.6% Caucasian, 70.6% male, and 61.8% with ESRD due to congenital renal anomalies. Mean follow up was 15.7 ± 7.9 years. PostTx initial length of hospital stay declined 37% over the 30-year period (24 d era 1 vs 15 d era 3, p <0.01). Five-year patient survival improved from 95% in eras 1 and 2 to 100% era 3 (not statistically significant). Ten-year death censored graft survival improved from 60% era 1 to 80% era 2 (p=0.04). The incidence of acute rejection, renal artery thrombosis, cytomegalovirus, and urine leaks did not significantly change across eras. Epstein Barr virus (EBV) infection (era 2 vs 3, p < 0.01) frequency increased. PostTx lymphoproliferative disorder (PTLD) incidence was increased in era 2 versus eras 1 and 3 (p=0.03). Hypertension, post Tx diabetes mellitus, and avascular necrosis frequency did not significantly change across eras. Urine leaks (p=0.01) and EBV infection (p=0.02) but not PTLD were higher in infants compared to Tx patients > 2 years of age.

Conclusions: This is the largest series on complications of KTx in infants. Length of initial hospital stay, patient and graft survival rates after KTx have improved in infants since 1984. Urine leaks and EBV infection remain significant postTx complications in infants.

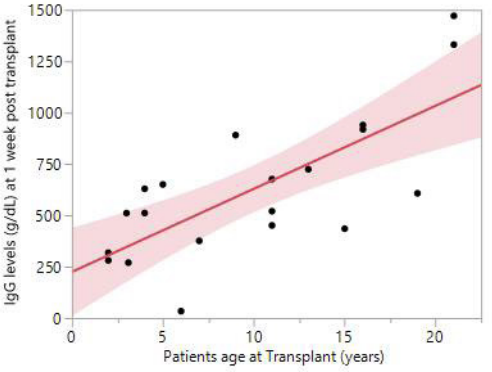
Immunological Profiling after Pediatric Kidney Transplantation Mariselis Rosa-Sanchez,[1] Marissa J. Defreitas,[1] Chryso P. Katsoufis,[1] Carolyn L. Abitbol,[1] Wacharee Seeherunvong,[1] Yonique P. Petgrave,[1] George William Burke,[2] Aura Jeannette Arenas Morales,[1] Jayanthi Chandar.[1] *[1]Pediatric Nephrology, Jackson Memorial/Holtz Children's Hospital, Miami, FL; [2]Miami Transplant Inst, Univ of Miami, Miami, FL.*

Background: Induction immunosuppressive therapy with anti-thymocyte globulin (rATG) is used by 22% of centers in the US after pediatric kidney transplantation (KT). We assessed the evolution of lymphocyte subsets and Immunoglobulin G (IgG) in the first year after KT in children with our center protocol.

Methods: Data was collected by retrospective analysis of pediatric KT recipients from January 2012 to June 2015 and included demographics, lymphocyte subsets and IgG in children <21 years of age at baseline, 1 week, 1, 6 and 12 months. Induction therapy consisted of rATG (cumulative dose of 3 to 5mg/kg), 2 doses of basiliximab and high dose methylprednisolone for 5-7 days with maintenance therapy of tacrolimus and mycophenolic acid.

Results: Among 52 patients, racial distribution was predominantly Hispanic and African American and 63% were male. Mean age was 10 ±6years. There was a significant drop from baseline in CD4 (55%), CD8 (63.5%), CD25 (13.4%) and NK cells (55%) at week one and a rise at 1 month with a gradual increase to baseline levels between 6 months to 1 year and a significant decline in IgG in younger children at 1 week (see figure; $p<0.0002$;$R^2$0.55) post transplant which improved with time. One child developed bacteremia following treatment of rejection and another had BK virus nephropathy. 1 year graft and patient survival were 98% and 100% respectively.



Conclusions: Triple induction therapy facilitated a steroid sparing protocol with good 1 year graft survival. However, younger patients were prone to hypogammaglobulinemia. Therefore, it is important to exercise vigilance and avoid excessive immunosuppression in the vulnerable younger patients.

SA-PO402

Donor Specific Antibodies and Graft Function in Pediatric Kidney Transplant Recipients Gilad Hamdani,[1] Jens W. Goebel,[2] Paul Brailey,[3] Elizabeth Portwood,[3] David K. Hooper,[1] Alin L. Girnita.[3,4] *[1]Div of Nephrology & Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Nephrology Div, Children's Hospital Colorado, Aurora, CO; [3]Hoxworth Blood Center, Univ of Cincinnati Academic Health Center, Cincinnati, OH; [4]Dept of Surgery, Univ of Cincinnati Medical Center, Cincinnati, OH.*

Background: Anti-HLA donor specific antibodies (DSAs) are associated with antibody mediated rejection (AMR) and graft loss in kidney transplant recipients. We aimed to find an association between specific DSA IgG subclasses and graft outcomes in pediatric and young adult kidney transplant recipients (KTRs).

Methods: We performed a single center retrospective chart review of pediatric KTRs with positive anti-HLA DSAs. Data regarding number, HLA classes, MFI, and IgG subclasses of the first positive DSAs was collected. Outcomes studied included AMR (based on the 2013 Banff criteria), clinical AMR (AMR with 15% eGFR reduction), and significant graft dysfunction (graft loss/50% decrease in eGFR).

Results: 35 patients (median age 15.6y, 66% white, 68% male) with DSAs detected 8 days-14 years post transplantation were included and were followed for a median time of 2.8y. Rates of IgG subclass detection were 89%, 31%, 57%, and 26% for IgG1, IgG2, IgG3, and IgG4, respectively. 76% of patients had AMR following DSA detection, 58% had clinical AMR, and 29% experienced significant graft dysfunction during follow up. No association between any IgG subclass and AMR was found. However, 91% of patients with significant graft dysfunction during follow up, all with clinical AMR, had positive IgG3 DSAs compared with 42% with more stable graft function (p=0.01). This association remained significant in a multivariable analysis (table).

Logistic Regression Analysis of Factors Associated with Significant Graft Dysfunction			
Parameter	**Estimate**	**95% CI**	***P* value**
IgG3 DSA	72.91	2.50->1,000	0.013
Time Post Transplantation (y)	1.34	1.03-1.74	0.029

Conclusions: Presence of IgG3 donor specific antibodies is independently associated with significant graft dysfunction in pediatric and young adult kidney transplant recipients.

SA-PO403

Longitudinal Renal Function after Liver Transplantation in Pediatric Patients Mai Sato,[1] Koichi Kamei,[1] Mureo Kasahara,[2] Kenji Ishikura.[1] *[1]Div of Nephrology and Rheumatology, National Center for Child Health and Development, Tokyo, Japan; [2]Transplantation Center, National Center for Child Health and Development, Tokyo, Japan.*

Background: Adult liver transplant (LT) recipients commonly develop advanced kidney disease; however, the burden of chronic kidney disease (CKD) in children is not well described. The objective of this study was to determine the incidence of CKD after pediatric LT.

Methods: We retrospectively analyzed the data of patients aged < 20 years who underwent LT between November 2005 and March 2015 in our institute. The following potential risk factors for renal dysfunction were analyzed: sex, age, primary liver disease, pre-existing kidney disease, rejection, and immunosuppressive agents.

Results: The cohort included 314 pediatric LT recipients (135 males). The median age at LT was 3.3 years (IQR 4.5) and the median follow-up duration was 3.9 years (IQR 4.5). Thirty-one patients died after LT. We divided the patients to three groups according to the primary disease: BA (biliary atresia), non-BA (other liver disease without primary renal complication), and KD (patients with pre-existing kidney disease). There were 143 patients (47 males) in the BA group, 139 (70 males) in the non-BA group, and 32 (18 males) in the KD group. The KD group comprised autosomal recessive polycystic disease (13 cases), methylmalonic acidemia (13 cases), primary hyper-oxaluria (5 cases) and nephronophthisis (1 case). Five-year renal survival, which endpoint was CKD stage 3, was 0.97 in BA group, 0.91 in non-BA group and 0.61 in KD group. We performed Cox regression survival analysis to adjust renal survival for confounding risk factors. There was no independent predictor by multivariate analyses, sex, age, rejection, but male and adolescent patients were likely to develop CKD.

Conclusions: In non-pre-existing kidney disease patients, 1.9% of patients developed over CKD 3 and 0.35% developed ESKD. These rates were lower than those in previous reports. Immunosuppressant strategy, additional mycophanolate mofetil and lower calcineurin inhibitor level may be effective to prevent progressive kidney damage.

SA-PO404

Sex and Age Differences in Medication Adherence in Adolescent and Young Adult Kidney Transplant Recipients Julie Boucquemont,[1,2] Bethany J. Foster,[1,2] The TAKE-IT Investigators.[3] *[1]Research Inst. of the McGill Univ Health Centre, Montreal, QC, Canada; [2]Dept of Epidemiology, Biostatistics and Occupational Health, McGill Univ, Montreal, QC, Canada; [3]The TAKE-IT Investigators.*

Background: Immunosuppressive medication adherence is poorer in adolescents than younger children, but it is unknown whether adherence differs between males and females, or by age, among adolescent and young adult kidney transplant recipients. We aimed to determine whether adherence differs by sex and age in this population.

Methods: We examined data from the 3-month run-in period (no intervention) of the randomized TAKE-IT trial. Adherence was monitored using a multidose electronic pillbox in 124 patients (11-24 y, ≥3 mo. post-transplant, followed in 8 transplant centers in Canada and USA), and classified as perfect (all doses taken; all doses on time) or not for each day of observation for each patient. We used logistic regression, with a random effect to account for correlation between adherence measurements within patients, to estimate the association between sex and adherence. We adjusted for race and time since transplant, and included an age by sex interaction.

Results: Among 124 patients, 61% were male; 65% were white. Median age at baseline was 16.2y [IQR 13.6-17.5]; median time since transplant was 2.7y [IQR 0.8-7.0]. There was a significant interaction between age and sex (p=0.009). Males ≥17y had a significantly lower likelihood of perfect adherence than younger males (OR=0.26, 95% CI [0.14-0.48]). There was no significant difference by age for females. Adherence did not differ by sex among patients <17y. Among those ≥17y, females had a significantly higher likelihood of perfect adherence than males (OR=3.82, 95% CI [1.09-13.40]).

Conclusions: Male kidney transplant recipients ≥17y have poorer adherence than younger adolescent males, whereas adherence does not differ by age among females. Adherence does not differ by sex in those <17 y, but among those ≥17y, adherence may be poorer in males than females.

SA-PO405

Risk Factors for Decline in eGFR Below 60 mL/min/1.73 m² after Kidney Transplantation in Japanese Children Kiyonobu Ishizuka, Ken-Ichiro Miura, Keiichi Takizawa, Yuji Tomii, Yohei Sasada, Naoto Kaneko, Tomoo Yabuuchi, Yasuyuki Sato, Hiroko Chikamoto, Yuko Akioka, Motoshi Hattori. *Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Maintenance of eGFR above 60 ml/min/1.73m² is necessary for optimal growth in children after kidney transplantation (KTx). The objective of this study was to investigate serial change in eGFR after KTx in children and identify risk factors for decline in eGFR below 60 ml/min/1.73m².

Methods: This study was approved by the Institutional Review Board at Tokyo Women's Medical University. Fifty-eight children aged < 20 years with congenital anomalies of kidney and urinary tract who underwent living donor KTx from 2003 to 2013 and were followed up for at least 1 year were included in this analysis. Immunosuppressive agents used were calcineurin inhibitors (CNI), mycophenolate mofetil, methylprednisolone, and basiliximab. eGFR values were calculated using formula developed for Japanese children (Clin Exp Nephrol 2013). Cox proportional hazard models were used to determine risk factors affecting the decline in eGFR below 60 ml/min/1.73m^2. The covariates included donor's age, recipient's age, body weight and height at KTx, graft weight, CNI (tacrolimus or cyclosporine), CNI toxicity, T cell-mediated rejection, antibody-mediated rejection, CMV infection, EB virus infection, BK virus infection. The median follow-up duration was 5.0 years (interquartile range, 3.0 to 5.0 years).

Results: The median eGFR values after RTx were 78.6 [68.5 to 88.3], 67.4[56.0 to 74.9], 65.2 [54.7 to 73.2], and 60.1 [54.2 to 67.2] ml/min/1.73m^2 at 1 month, 6 months, 1 year, and 5 years, respectively. The proportion of patients with eGFR above 60 ml/min/1.73m^2 was 65.9% and 52.1% at 1 year and 5 years, respectively. On multivariate analysis, independent risk factors for decline in eGFR below 60 ml/min/1.73m^2 were donor's age (hazard ratio [HR] 1.1, 95% confidential interval [CI] 1.0 to 1.1) and antibody-mediated rejection (HR 4.2, 95%CI 1.4 to 12.5).

Conclusions: Our study demonstrated that posttransplant eGFR values were unsatisfactory in a substantial proportion of children. Donor's age and antibody-mediated rejection were independent risk factors for decline in eGFR after KTx.

SA-PO406

Outcomes of Kidney Transplantation in Children and Young Adults with Cystinosis in the United States Sarah J. Kizilbash,[1] Jon J. Snyder,[2] Hassan N. Ibrahim,[3] Blanche M. Chavers.[1] *[1]Pediatric Nephrology, Univ of Minnesota, Minneapolis, MN; [2]Minneapolis Medical Research Foundation, Minneapolis, MN; [3]Nephrology, Univ of Minnesota, Minneapolis, MN.*

Background: Cystinosis is the cause of end-stage renal disease in 2% of kidney transplant recipients in the United States (US). Cysteamine has improved the prognosis of cystinosis; however, its impact on long-term kidney transplant outcomes is unknown.

Methods: All kidney transplant recipients (≤ 21 years of age) with data in the Scientific Registry of Transplant Recipients, transplanted before 12/31/2015, were included. We arbitrarily divided the study period into 3 eras: era1 (< 1995), era2 (1/1/1995-12/31/2005) and era3 (1/1/2006-12/31/2015). Survival rates were estimated using Kaplan-Meier methods. Hazard ratios were adjusted for era, age at transplant, race, gender, donor type and pre-transplant dialysis using cox proportional hazard models.

Results: We identified 317 patients with cystinosis and 26,554 without cystinosis who met our inclusion criteria. The median age at transplant for cystinosis did not change significantly over time (era1=12.5, era2=13.7, era3=13.6; p 0.4). The patient and graft survival are given in table 1. Delayed graft function was significantly lower in patients with cystinosis after adjusting for covariates (adjusted hazard ratio (aHR): 0.40 (0.19 – 0.85); p 0.018). The 5-year graft survival rates for cystinosis were 71.3%, 84.3% and 71.7% for era1, era2 and era3, respectively. After adjusting for covariates, patients transplanted in era2 had a 75% lower hazard of graft loss at 5 years compared to era1 (aHR: 0.25 (0.08 – 0.77); p 0.02), however, the 5-year graft survival was not significantly different between era1 and era3 (p 0.23).

Conclusions: The median age at transplant for cystinosis in the US has not changed from 1995-2015. Patients with cystinosis have superior 1 and 5-year graft survival compared to non-cystinosis patients. Alarmingly, the 5-year graft survival for US cystinosis patients has deteriorated over the last decade.

	Cystinosis (n = 317)	Non-cystinosis (n = 26,554)	P value
Patient survival (%)			
1-year	98.9	98.2	0.29
5-year	94.9	95.24	0.88
10-year	89.5	91.7	0.73
Graft survival (%)			
1-year	95.4	90.9	0.007
5-year	77.5	71.3	0.012
10-year	53.1	51.4	0.15

SA-PO407

Infectious Complications in Pediatric Kidney Transplant Recipients Treated with Rituximab: A Single-Center Study Naoto Kaneko, Ken-Ichiro Miura, Yuji Tomii, Keiichi Takizawa, Yohei Sasada, Tomoo Yabuuchi, Yasuyuki Sato, Kiyonobu Ishizuka, Yuko Akioka, Motoshi Hattori. *Pediatric Nephrology, Tokyo Women's Medical Univ.*

Background: To date, few reports have assessed safety of rituximab (RIT) use in pediatric kidney transplantation. The aim of this study was to evaluate infectious complications of RIT which occurred during the first year after transplantation.

Methods: This study was approved by the Institutional Review Board at Tokyo Women's Medical University. A total of 90 patients aged < 20 years underwent living donor kidney transplantation at our center between January 2005 and March 2016 and were divided into two groups; RIT group (21 patients) and non-RIT group (69 patients). Medical records were reviewed for clinical information. Immunosuppressive regimen consisted of calcineurin inhibitors, mycophenolate mofetil, methylprednisolone, and basiliximab in all patients. Indication of preoperative RIT use included primary focal segmental glomerulosclerosis, ABO incompatible transplantation, and HLA sensitized transplant. RIT group received a single dose of RIT (145 mg/m^2 [124 to 166 mg/m^2]) before transplantation. Antimicrobial prophylaxis was administered to all patients. We compared incidence of serious infections and late-onset neutropenia during one year after transplantation in two groups. Serious infection was defined by any bacterial, viral, and fungal infection requiring admission or prolongation of hospitalization. Late-onset neutropenia was defined by neutrophil count < 1000 /μL which occurred after 4 weeks of transplantation.

Results: The overall incidence of serious infection in two groups was comparable (23.8% in RIT group and 36.2% in non-RIT group, respectively, P=0.30). There were no significant differences in the occurrence of bacterial infection (9.5% versus 14.5%, P=0.72), viral infection (14.3% versus 13.0%, P=1.0), and late-onset neutropenia (9.5% versus 2.9%, P=0.23) between RIT and non-RIT groups. There were no fungal infections. CMV disease occurred only in non-RIT group (5.8%, P=0.57).

Conclusions: Our preliminary study indicates that RIT use does not increase infection risk during one year after kidney transplantation in pediatric population.

SA-PO408

Extremely High Risk of Cancer after Solid Organ Transplant in Childhood Abhijat Kitchlu,[1] Stephanie Dixon,[2] Jade S. Hayward,[3] Rahul Chanchlani,[1] Jovanka Vasilevska-Ristovska,[3] Karlota Borges,[3] Paul Nathan,[3] Vicky Ng,[3] Diane Hebert,[1,3] Joseph Kim,[1] Rulan S. Parekh.[1,3] *[1]Div of Nephrology, U of Toronto; [2]Inst for Clinical Evaluative Sciences; [3]Hosp for Sick Children.*

Background: Long-term immunosuppression after solid organ transplantation has been shown to increase the risk for subsequent neoplasm in adults. There is a paucity of data regarding cancer outcomes in pediatric solid organ transplant recipients.

Methods: We conducted a population-based retrospective cohort study in Ontario, Canada. We assessed recipients of pediatric solid organ transplants at the Hospital for Sick Children in Toronto between 1991-2014. We compared cancer outcomes to a non-transplanted population of Ontario residents (<18 years old) using provincial administrative data. The primary outcome was overall incidence of cancer. Secondary outcomes included survival and incidence of solid/non-solid cancers.

Results: A total of 951 childhood transplant recipients (kidney n=400, liver n=283, heart n=218, lung n=36, multiorgan n=14) were compared to over 5 million children from the general population of similar ages. Median age was 8 years old; 50% were male. Over a median follow-up of 10 years (range 0 - 24), the cumulative incidence of cancer was 20% in transplant recipients and 1.2% in the general population. Incidence of cancer, cancer-free and all-cause mortality are shown in Table 1. The incidence rate ratio of cancer in transplanted vs. non-transplanted was 33.

Conclusions: Recipients of solid organ transplants in childhood have a 30 times higher incidence of cancer compared to the general population up to 24 years after transplantation. Our data suggest that early surveillance may be warranted in this high-risk population.

Table 1: Incidence of Cancer and Mortality

	Event rate/1000 patient-years(95%CI)		Incidence rate ratio
	Non-transplant	Transplant	
	N=5,276,621	N=951	
All Cancers	0.32 (0.31-0.33)	10.6 (8.53-13.1)	32.9
Non-solid Cancers (incl PTLD)	0.08 (0.07-0.08)	6.28 (4.77-8.28)	81.3
Solid Cancers	0.24 (0.24-0.25)	4.27 (3.06-5.98)	17.6
Cancer-free Mortality	0.26 (0.26-0.27)	18.5 (15.7-21.7)	70.0
All-cause Mortality	0.29 (0.29-0.30)	21.2 (18.3-24.6)	73.1

SA-PO409

Impact of Obesity and Metabolic Syndrome on Myocardial Function and Strain in Children after Kidney Transplant Kl Sgambat, S. Clauss, M. Lasota, Asha Moudgil. *Children's National.*

Background: In light of the major impact of cardiovascular (CV) morbidity on outcomes in children with End Stage Renal Disease (ESRD), a prospective controlled longitudinal study was conducted to investigate myocardial function and strain in children before and after kidney transplant (Tx). Impact of obesity and metabolic syndrome (MS) on CV morbidity was investigated.

Methods: Kidney Tx recipients (3-20 yrs) had standard echo and myocardial strain by speckle tracking measured at 12 months pre-Tx, and 1, 18, and 30 months post-Tx. More negative strain signifies better cardiac contractility. Tx with MS met ≥3 criteria: glucose intolerance (HbA1c>5.6%or glucose>100), BP>95th%ile,central obesity(WC>95th%),HDL<5th%ile, TG>95th%ile. Controls were healthy, non-obese children. Statistical analysis by Student's t-test used for comparison between groups(pre-,post-Tx, and controls) and multivariate longitudinal GEE regression for association of variables.

Results: 39 Tx recipients(23 lean, 16 obese) were compared to 24 healthy children (age 12.7±0.3 vs. 11±0.1 yrs, p=0.2). LVM/Ht$^{2.7}$ was worse pre-Tx compared with controls (39.1±3.5 vs. 29.1±3.7),p=0.04, and did not improve within the first 30 months post-Tx (35.8±1.4). Ejection Fraction(EF) pre-Tx (61.4±0.9)was worse vs. controls (64.1±0.4%,p=0.01) but improved to 64.6±0.3% post-Tx, p=0.0003. There were no differences in LVM/Ht$^{2.7}$ or EF between lean and obese children, pre or post-Tx. Speckle tracking analysis revealed worse myocardial strain in obese vs. lean children post-Tx(-18.6±0.4 vs.-20.1±0.4, p=0.03). Overall strain improved from -17.8±0.7 pre-Tx to

-19.5±0.3 post-Tx (p=0.02), but remained worse vs controls (-23.1±0.4), p=0.02. GEE regression showed only obesity was significantly associated with impaired strain (β=1.32, p=0.006); MS and its individual components were non-significant.

Conclusions: Children with ESRD demonstrate improved EF after Tx, but continue to exhibit impaired myocardial strain, indicating ongoing subtle LV dysfunction detected by speckle tracking echo. Myocardial function after Tx is negatively impacted by obesity, which was also detectable only by speckle tracking echo. Efforts to prevent obesity may help to improve CV outcomes in this high risk population.

SA-PO410

Acute Rejection Is the Primary Determinant of Worse Kidney Allograft Outcomes in Patients with De Novo Donor-Specific Antibodies Scott Davis,[1] Jane Gralla,[2] Alexander C. Wiseman,[1] James E. Cooper.[1] *[1]Medicine, Univ of Colorado, Aurora, CO; [2]Pediatrics, Univ of Colorado, Aurora, CO.*

Background: Although many patients develop de novo donor-specific antibodies (dnDSA), only a portion will experience associated graft impairment or loss. Clinical acute rejection (cAR) may lead to or result from the development of dnDSA and may be the primary determinant of worse graft survival among these patients. The purpose of this study was to delineate the impact of cAR and dnDSA on graft outcomes.

Methods: From 2007 to 2013, 593 consecutive kidney recipients without pre-existing DSA were screened for dnDSA at months 1, 6, 12, yearly and when indicated. Acute rejection was diagnosed by clinical suspicion and was biopsy-proven in 89% of cases. Graft survival was assessed by KM analysis and time-dependent Cox modeling with median (IQR) follow-up time of 49 (31-69) months.

Results: 204 (34.4%) patients developed dnDSA (median onset 8.3 months). 5-year death-censored graft survival was lower in patients with dnDSA (Figure 1). cAR was more common in dnDSA(+) vs. dnDSA(-) patients (27% vs. 5%, p<0.001) and its timing relative to dnDSA detection did not effect graft outcomes. When stratifying patients by cAR and dnDSA status, patients had worse eGFR (p<0.001), more proteinuria (p<0.001), and lower 5-year graft survival (p<0.001) only when combined with cAR, regardless of dnDSA status (Figure 2). In a multivariable analysis accounting for both cAR and dnDSA, cAR had a stronger association with graft loss (HR 9.1, 95% CI 4.3-19.0, p<0.001) compared to dnDSA alone (HR 2.2, 95% CI 1.1-4.5, p=0.026).

Figure 1:
Death Censored Graft Survival by dnDSA(+) vs. dnDSA(-)

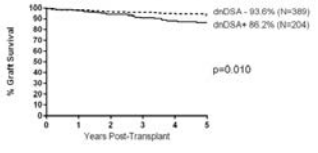

Figure 2:
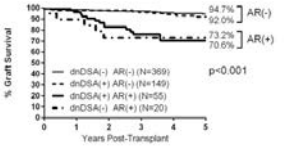
Death Censored Graft Survival by dnDSA and Acute Rejection



Conclusions: In this large retrospective analysis of a prospective dnDSA screening protocol, both dnDSA and cAR were associated with inferior intermediate term graft outcomes. Importantly, the deleterious impact of dnDSA on eGFR, proteinuria, and graft loss was only seen when combined with cAR.

SA-PO411

Indoleamine 2,3-Dioxygenase Is a Biomarker of Rejection in Experimental Kidney Transplantation Youli Wang,[2] Randi Lassiter,[1] Chak-Sum Ho,[4] Daniel Kleven,[3] Ryan P. Jajosky,[3] Eslam Mohamed,[2] Matthew Winn,[1] N. Stanley Nahman,[2] Todd D. Merchen.[1] *[1]Surgery, Medical College of Georgia at Augusta Univ, Augusta, GA; [2]Medicine, Medical College of Georgia at Augusta Univ, Augusta, GA; [3]Pathology, Medical College of Georgia at Augusta Univ, Augusta, GA; [4]Gift of LIfe Michigan, Ann Arbor, MI.*

Background: Indoleamine 2,3-dioxygenase (IDO) degradation of tryptophan promotes the induction of regulatory T cells (Treg), implying a role for IDO in mitigating allograft rejection. However, the effects of renal ischemia (RI) and allo transplantation on kidney IDO expression remain undefined. To address this question, we conducted auto and allo kidney transplants (Tx) in pigs.

Methods: Pigs underwent orthotopic allogeneic kidney Tx (Allo) (n=9) or autoTx (Auto) (n=10). For Allo, pairs of mismatched Yorkshire piglets were operated simultaneously with left kidneys exchanged. Allo and Auto had ~30 minutes of RI. All pigs had right nephrectomy (Nx) prior to closure and left Nx at sacrifice at 72hrs. No immunosuppression was used. IDO activity in kidney homogenates was assessed using HPLC. IDO mRNA was quantitated by PCR. Tissue IDO expression was assessed using IHC with IDO antibody. Activation of Tregs, dendritic cells (DC) and macrophages (MP) were identified using IHC with specific antibodies.

Results: All pigs experienced increased postop creatinine with significantly higher levels in Allo vs Auto (8.12±1.50 vs 2.83±0.60 mg/dL respectively, P=0.006). Auto had mild tubular injury without significant changes in IDO mRNA nor IDO activity when compared to right Nx controls (n=16). In contrast, Allo demonstrated acute rejection, increased IDO mRNA, and a 19.5 fold increase in IDO activity vs Auto. IDO expression (IHC) came from infiltrated cells and sloughed tubular cells. Both Auto and Allo had a notable infiltration of MP. There was a substantial accumulation of Tregs and DC observed in Allo kidneys vs Autos.

Conclusions: IDO does not increase as a consequence of RI. A dramatic increase of IDO mRNA, protein, and activity occurs in rejecting renal allografts. These data suggest that IDO may act as a biomarker of rejection in experimental renal transplantation.

SA-PO412

The Clinical Significance of Severe Ischemia-Reperfusion Injury (IRI) in Triggering Rejection Ibrahim Batal,[1] Glen S. Markowitz,[1] Vivette D. D'Agati,[1] Demetra Tsapepas,[1] Russell J. Crew,[1] Vanesa Bijol,[2] Mark A. Hardy,[1] Sumit Mohan,[1] Anil K. Chandraker.[2] *[1]Columbia Univ, New York, NY; [2]Brigham & Women's Hospital/Harvard Medical School, Boston, MA.*

Background: In non-immunosuppressed animals, IRI enhances allograft immunity and triggers rejection. In the era of potent immunosuppression, the effects of severe IRI on allograft function and alloimmunity in kidney transplant recipients need to be systematically assessed.

Methods: Acute tubular injury in post-reperfusion biopsies is a morphologic reflection of the severity of IRI. All post-reperfusion biopsies from patients who underwent deceased donor kidney transplantation at Columbia University Medical Center from 2006 through 2009 (n=382) were assessed for the presence of diffuse acute tubular injury (ATN) as a reflection of severe IRI. The samples were classified as "ATN" (n=134) and "no ATN" (n=248).

Results: Compared to patients without ATN, patients with ATN had a trend toward worse allograft survival (P=0.08) and a higher incidence of primary non-function [10/134 (8%) vs. 7/248 (3%), P=0.07]. However, even when primary non-function were excluded, patients with ATN had a mean lower eGFR at 1-year (P=0.04), 2-years (P=0.003), and 3-years (P=0.001) post-transplantation and showed increased number of rejection episodes during 1st year after transplantation [44/124 (35%) vs. 61/241 (25%), P=0.05], and higher frequency of rejection episodes/year [0.46 +/-0.99 vs. 0.30 +/-0.85, P=0.03] compared with patients without ATN. To provide a better understanding of the potential role of graft dendritic cells (DCs) in triggering rejection, DCs were assessed in a pilot cohort of post-reperfusion biopsies with (n=15) or without (n=12) subsequent rejection using the BDCA-1 marker. Patients who developed subsequent rejection had lower DC density compared to these without rejection (0.4 +/- 0.5 vs. 0.8 +/- 0.6 cells/high power field, P=0.007).

Conclusions: ATN in post-reperfusion biopsies is associated with subsequent inferior allograft function and increased rejection episodes in later biopsies. Low DC density in post-reperfusion biopsies may be associated with increased allograft immunogenicity.

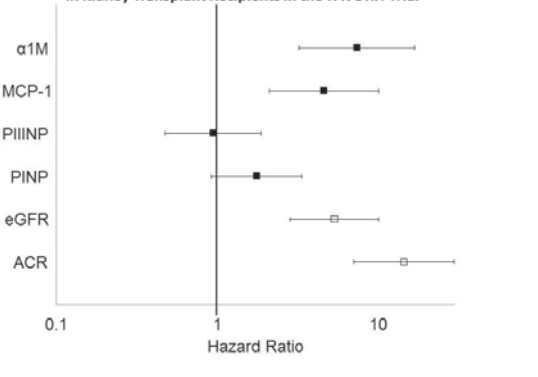
Urine Fibrosis Markers and Risk of Kidney Allograft Failure: The FAVORIT Trial Joachim H. Ix,[1] Ronit Katz,[2] Nisha Bansal,[2] Meredith C. Foster,[3] Daniel E. Weiner,[3] Vasantha Jotwani,[4] Jan M. Hughes-Austin,[1] Dianne B. McKay,[1] Francis B. Gabbai,[1] Chi-Yuan Hsu,[4] Andrew Bostom,[5] Andrew S. Levey,[3] Michael Shlipak.[4] *[1]UCSD; [2]UW; [3]Tufts; [4]UCSF; [5]Rhode Island.*

Background: Tubulo-interstitial fibrosis marks risk of allograft failure in kidney transplant recipients (KTRs) but is poorly captured by eGFR or urine ACR. Urine alpha 1 macroglobulin (α1M), monocyte chemoattractant protein-a (MCP1), procollagen type III (PIIINP) and type 1 (PINP) N-terminal propeptide are correlated with tubulo-interstitial fibrosis on biopsy. Whether these markers can noninvasively identify risk of allograft failure independent of eGFR and ACR is unknown.

Methods: In this case-cohort study in KTRs participating in the FAVORIT trial, we measured urine α1M, MCP1, PIIINP, and PINP in random sub-cohort of 491 participants and 257 allograft failure cases. We used weighted Cox models adjusted for demographics, CKD risk factors, eGFR, ACR, and urine creatinine (to account for tonicity). Each biomarker was evaluated on the log2 scale ("per doubling") and by quartiles.

Results: In the random sub-cohort, mean age was 51± 9 years, median graft vintage was 3.7 years, 42% had live donors, and mean baseline eGFR was 46±18 ml/min/1.73m^2. During 3.5 years mean follow-up, there were 257 kidney allograft failure events. Higher α1M (HR per doubling 1.73 [1.43, 2.08]) and MCP1 (HR 1.60 [0.32, 1.93]) were associated with allograft failure, independent of eGFR, ACR and other risk factors. Evaluating high vs. low quartiles, associations were similar in strength to extreme eGFR and ACR quartiles, despite adjusting for eGFR and ACR. Urine PIIINP and PINP were not independently associated with allograft failure.

Adjusted Association of High Quartile of Each Marker with Risk of Allograft Failure in Kidney Transplant Recipients in the FAVORIT Trial



Adjusted for urine creatinine, age, sex, race, country, FAVORIT randomization group, diabetes, SBP, CVD, smoking, graft vintage, living donor status, eGFR, and urine ACR.

Conclusions: Measurement of α1M and MCP1 in urine of KTRs may serve as a non-invasive marker of tubulo-interstitial fibrosis severity and risk of allograft failure independent of eGFR and ACR.

SA-PO414

Outcomes of Severe Tubulitis Are as Poor as Vascular Rejections Shefali Patel, Hilda E. Fernandez, Ibrahim Batal, Russell J. Crew. *Columbia Univ, NY.*

Background: The continuum of renal transplant acute cellular rejection(ACR) progresses in severity from borderline changes to tubulitis to vasculitis. Optimal treatment of severe tubulitis (grade 1B) is poorly defined w/ some centers given steroids and others immediately using lymphocyte depletion.

Methods: We identified transplant rejections and collected the following: demographics, induction therapy, rejection grade, other pathology findings, treatment, therapy response and infectious complications. Rejectors were compared to a control group without rejection.

Results: From 1/2012-12/2014, we transplanted 681 pts using lymphocyte depletion (antithymocyte globulin[ATG] or campath 1H), tacrolimus, mycophenolate, and rapid steroid withdrawal. 169 patients had ACR: 91 Borderline, 42 ACR1A, 39 ACR1B, 14 ACR2A and 1 ACR2B. There were no differences in age, sex, race, induction, or donor type between pts w/ ACR1B or ACR2. Creat at time of rejection was similar (2.83 vs 2.77, p-NS) as was time to rejection. ATG was used in 64.1% of ACR1B and 78.5% of ACR2. Creat remained higher in the ACR1B group during follow up (2.55 vs 1.73, approaching statistical significance ($p = 0.064$)), despite no initial difference in the distribution of chronic pathologic findings. Persistent (59%) and recurrent (7.9%) rejections were common in ACR1B group, but similar to ACR2 group (33% and 20%). Allograft failure occurred in 5 ACR1B vs 1 ACR2. There were no differences in creat, persistent or recurrent rejections among ACR1B pts who received ATG vs steroids alone. Viremic complications after treatment were similar between groups (1B rejectors= 3 BK, 5 CMV, 1 EBV; grade 2= 3BK). IFTA > 25% on initial ACR1B biopsy was associated with a higher creat at last follow-up 2.8 mg/dL vs 1.69 mg/dL ($p = 0.019$) but not failure or recurrent rejections. A control group of 40 pts w/out rejection had a median serum Cr 1.38 mg/dl at last follow-up ($p < 0.0001$) w/ 100% graft survival ($p = 0.029$).

Conclusions: Even in an era with more potent immunosuppression, ACR continues to impact allograft survival. In particular, pts w/ more severe tubulitis and vasculitis tend to have repeated rejections episodes despite antibody depleting therapy with increased infectious complications.

SA-PO415

The Effect of Histological CD20 Positive B Cell Infiltration in Acute Cellular Rejection on Kidney Transplant Allograft Survival Rending Wang, Jingyi Zhou, Jia Shen, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital of Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Acute rejection, especially the irreversible episodes, has definite impact on renal allograft. However, it is controversial whether lymphocytes infiltration exhibited in biopsy specimens is important for transplant outcomes. This study focused on the effect of CD20+ B cell infiltration in the biopsy specimens from the allografts with acute cellular rejection in Chinese population.

Methods: Totally 217 cases of biopsy-proved acute cellular rejection were documented in our renal transplantation system from Sep. 2001 to Dec. 2014. There was only 1 case lost-to-follow. According to the presence of CD20+ B cell infiltration and its degree, all 216 cases included were divided into CD20-group (n=83), mild CD20+ group (n=76), moderate CD20+ group (n=36), and severe CD20+ group (n=21). Baseline information, serum creatine and GFR before and after treatment, steroid resistance, reversal rate, graft loss and survival were analyzed.

Results: There was no significant difference between groups in baseline information. Steroid and antibodies combination treatment in CD20+ group (39.1%, 52/133) and CD20- group (59.0%, 49/83) didn't show significant difference (p=0.004). CD20+ group showed better serum creatine and GFR before treatment. After treatment, however, groups showed similar graft function. CD20+group had fewer graft loss (18.8% vs. 32.5%, p=0.022) and better survival rate. Further exploration in infiltration degree suggested that it was positively related with graft survival with no statistical significance.

Conclusions: Acute cellular rejection with CD20+ B cell infiltration showed better outcomes after treatment. The presence of CD20+ B cells is protective for renal allografts.

SA-PO416

The Effect of Histological Isolated Endarteritis Combined with CD20 Positive B Infiltration in Acute Cellular Rejection on Kidney Allograft Survival Rending Wang, Jingyi Zhou, Jia Shen, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital of Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Endarteritis post renal transplantation is regarded as T-cell mediated acute rejection (AR) by Banff classification. Results from DNA microarrays suggested that endovasculitis did not represent T-cell mediated AR exactly and its effect on allograft outcomes was unclear.

Methods: Totally 217 cases of biopsy-proved AR rejection were documented in our renal transplantation system from Sep 2001 to Dec 2014. There was only 1 case lost- to-follow. After 24 cases excluded because of tubulointerstitial rejection, 192 cases were included with 95 Class IA,16 Class IB, 79 Class IIA,and 2 Class IIB. According to the presence of endarteritis and CD20+B cell infiltration, all 192 cases were divided into CD20-endarteritis-group (n=33), CD20+endarteritis-group (n=78),CD20-endarteritis+ group (n=46), and CD20+endarteritis+group (n=35). Baseline information, serum creatine and GFR before and after treatment, steroid resistance, reversal rate, graft loss and survival were analyzed.

Results: There was no significant difference between groups in baseline information. Average time to rejection was separately 182 days, 374 days, 493 days and 729 days. The percentage of steroid and antibodies combination treatment was separately 42.8%, 63.0%, 54.5% and 35.9% (p=0.022). Graft loss was separately 8.6% (3/35), 23.9% (11/46), 42.4% (14/33) and 23.1% (18/78) (p=0.013). Endarteritis + group showed earlier rejection (291 days vs. 659 days) but higher reversal rate (77.5% (86/111) vs. 90.1% (73/81), p=0.022). GFR in endarteritis - group was significantly higher before and at rejection but signigicantly lower 3-60 months after biopsy. Endarteritis + group had a much lower graft loss rate (17.3% (14/81) vs. 28.8% (32/111), p=0.064). Although general survivals were similar, survival rate after rejection in endarteritis + group was higher. The best survival was observed in CD20+ endarteritis + group.

Conclusions: Acute cellular rejection with endarteritis showed better outcomes after treatment. Endarteritis with CD20+B cell infiltration implies lower graft loss and better graft survival.

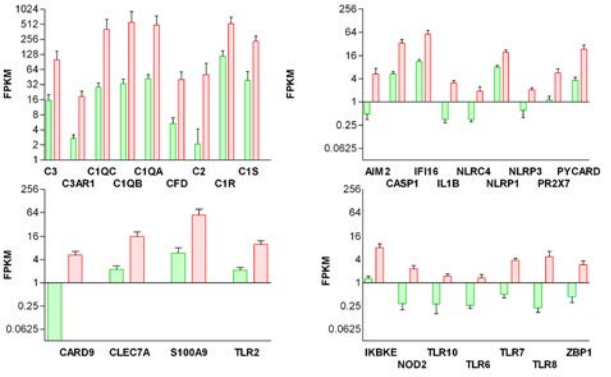
SA-PO417

Innate Immunity Is a Strong Feature of Acute Cellular Rejection in Human Kidney Allografts Franco B. Mueller, Hua Yang, Carol Y. Li, Karan Jatwani, Catherine Snopkowski, Liana S. Perry, Matthew Magruder, John R. Lee, Steven Salvatore, Darshana Dadhania, Surya V. Seshan, Manikkam Suthanthiran, Thangamani Muthukumar. *Weill Cornell Medicine.*

Background: Immunity is traditionally dichotomized as innate immunity and adaptive immunity. We and others have reported intragraft expression of mRNA encoding T and B cell proteins, cytokines and chemokines central to adaptive immunity. We now report that innate immunity is a strong feature of human allograft rejection following RNA-sequencing (RNA-Seq) of human kidney allograft biopsies.

Methods: We did RNA-Seq of of 5 clinically indicated acute cellular rejection (ACR) biopsies from 5 patients and 5 surveillance normal biopsies from 5 patients. Total RNA isolated from the biopsies were sequenced using the Illumina HiSeq platform. Differential gene expression analysis was done using edgeR. We used KEGG and NCBI databases for molecular gene grouping, gene family or gene pathway.

Results: As predicted, there was overexpression of adaptive immunity related transcripts in ACR biopsies. In addition, innate immunity related transcripts were overexpressed in ACR biopsies. In the ACR biopsies, 9 complement genes, 9 inflammasome-related genes, 5 damage associated molecular pattern (DAMP) genes and 11 pathogen associated molecular pattern (PAMP) genes were significantly differentially expressed. In the figure, genes belonging to overlapping categories are shown once only.



Kidney intragraft expression of **Complement genes** (top left), **Inflammasome genes** (top right), **DAMP genes** (bottom left) and **PAMP genes** (bottom right)
Bar graph depicts mean±SE
Red: For-cause biopsies showing acute cellular rejection (N=5); Green: Surveillancebiopsies reported as normal
FPKM- Fragments Per Kilobase of transcript per Million mapped reads

Conclusions: RNA-Seq of human kidney allograft biopsies provides a panoramic view of participants in acute cellular rejection in human kidney allografts. Very surprisingly, genes integral to innate immunity were a striking feature of acute cellular rejection, a process long considered to be the exclusive province adaptive immunity. Our novel findings invite consideration of other anti-inflammatory drugs such as IL-1 receptor antagonist, TNF-antagonist or alpha-1-antitrypsin as anti-rejection agents.

SA-PO418

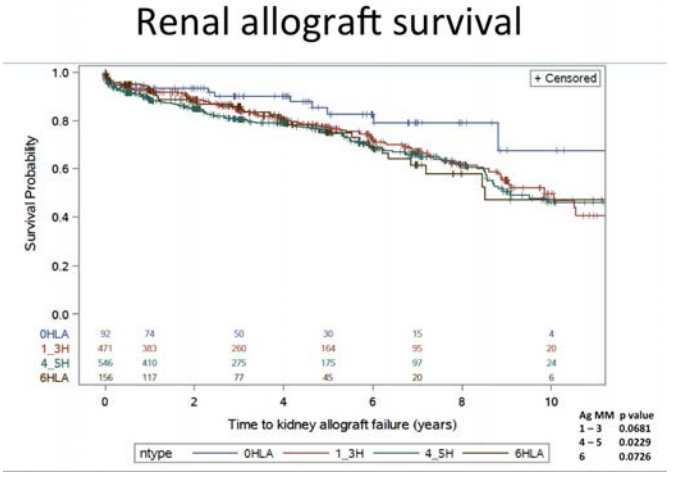
Impact of HLA Mismatch on the Renal Allograft Survival among ABO Incompatible Renal Transplant Karthikeyan Venkatachalam, Tarek Alhamad, Bilal A. Kanawati, Daniel C. Brennan. *Div of Nephrology, Washington Univ in Saint Louis, Saint Louis, MO.*

Background: Given the advances in immunosuppressive regimens and medical care, ABO incompatible kidney transplantation has become an acceptable option for highly sensitized patients. Data on the influence of HLA matching among ABO incompatible renal transplant outcomes are sparse.

Methods: We performed a retrospective analysis of ABO incompatible transplant recipients over 18 years of age at the time of transplantation from the Organ Procurement and Transplantation Network (OPTN) Database between 2000 and 2013. Patients were categorized into 4 groups according to the level of HLA mismatch; 0, 1-3, 4-5 and 6 HLA mismatches (HLA MM). Associations between HLA MM and post-transplant graft failure and patient death were examined by Cox regression.

Results: There were 1266 ABO incompatible living transplant recipients. Out of these, 7.3% had 0 HLA MM, 37.2% had 1-3 HLA MM, 43.2% had 4-5 HLA MM, and 12.32% had 6 HLA MM.

0 Antigen MM as control	Hazard ratio
1 - 3 Ag MM	1.705
4 - 5 Ag MM	1.932
6 Ag MM	1.792



Conclusions: 0 antigen mismatched ABO incompatible transplants had a better kidney allograft survival compared to other HLA mismatches. No significant differences existed between 1-6 antigens mismatched ABO incompatible recipients.

SA-PO419

The Effect of Regulatory T Cells on the Interaction of T Follicular Helper Cells and Memory B Cells during Plasmablast Formation Paul Fadakar, Kevin Hadi, Camila Macedo, Diana Metes. *Starzl Transplantation Inst, UPMC, Pittsburgh, PA.*

Background: Donor-specific antibodies (DSA) are an important biomarker for acute rejection, transplant glomerulopathy and late allograft failure in kidney transplantation. However, few studies have looked at the immunologic events that occur prior to DSA formation. T follicular helper (Tfh) cells provide B cells with critical cognate help necessary for differentiation into plasmablasts that secrete antibodies in response to antigen stimulation. Our previous results obtained in a cohort of KTx recipients receiving Thymoglobulin induction showed an imbalance between circulating Tfh cells and regulatory T cells (Tregs), which correlated with development of DSA. Here, we inquired whether Tregs can temper Tfh cell function to interfere with B cell responses, or if they directly modulate B cells' ability to differentiate into plasmablasts (PBs).

Methods: We isolated peripheral blood mononuclear cells from 5 healthy controls and FACS-sorted Tfh cells (CD4+CD45RO+CXCR5+), memory B (mB) cells (CD19+CD27+) and Tregs (CD4+CD25+CD127-). We co-cultured Tfh cells with mB cells at a 1:1 ratio for 6 days in the presence or absence of SEB to mimic antigen-specific interactions, with or without Tregs. In parallel, CD3/CD28-stimulated CFSE-labeled Tfh cells or mB cells exposed to a cytokine cocktail mimicking T cell help were incubated with or without Tregs at decreasing ratios for 6 days *in vitro*. Inhibition of Tfh cell proliferation measured by CFSE dilution and PB formation (CD19+CD27+CD38+) were measured to assess Treg function.

Results: Co-culture of mB cells with Tfh cells induced 30-80% of mB cells to differentiate into PBs. Addition of Tregs suppressed PB formation in a dose-dependent manner with 50-70% suppression at 1:1 ratio. Tregs inhibited proliferation of Tfh cells with 50% inhibition at 1:1 ratio, 30% at 1:2, 12% at 1:4 and 2% at 1:8.

Conclusions: Tregs suppress PB formation via direct effect on mB cells and indirectly by tempering Tfh cell function. These results provide valuable mechanistic understanding of the role of Tfh cells and Tregs during antibody responses with implications for monitoring for early detection of patients at risk for DSA generation.

Protective Effect of 1α,25-Dihydroxyvitamin D3 on Effector CD4+ T Cell Induced Injury in Human Renal Proximal Tubular Epithelial Cells Ji-Yeun Chang,[1,2] Kyoung Chan Doh,[2] Byung Ha Chung,[1,2] Chul Woo Yang.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea; [2]Transplant Research Center, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: The aim of this study was to investigate the effects of Vitamin D pretreatment on inflammatory response in human proximal renal tubular epithelial cells (HRPTEpiCs) induced by effector T cells or inflammatory cytokines.

Methods: First, we investigated the effect of 1α,25-dihydroxyvitamin D3 [1,25$(OH)_2$D3] on CD4+ T cell proliferation by FACs analysis and ELISA. Second, we investigated the effect of 1,25$(OH)_2$D3 on IL-6, IL-8, KIM-1 and fibronectin 1 expression in HRPTEpiCs, co-cultured with/without activated CD4+T cells using ELISA and real-time PCR and we analyzed mTOR/STAT3 signaling. Lastly, we divided 90 kidney transplant recipients (KTR) according to serum 25-hydroxyvitamin D [25(OH)D] level (<20 ng/mL or not) and compared the level of urine IL-6, IL-8, and KIM-1 between the groups.

Results: Pre-incubation with 1,25$(OH)_2$D3 significantly reduced the percentage of Th1 and Th17 cells compared to Th0 condition ($P<0.05$ for each). In contrast, 1,25$(OH)_2$D3 increased the proportion of Th2 and Treg cells in a dose dependent manner ($P<0.05$ for each). To evaluate the direct protective effect of vitamin D on the target organ, we investigated whether vitamin D protects HRPTEpiCs against inflammatory cytokine or effector T cell-induced inflammation. Our results showed that inflammatory cytokines (TNF-a, IL-17 and TGF-β) induced IL-6, IL-8 or KIM-1 production from HRPTEpiCs in a dose-dependent manner.Treatment with 1,25$(OH)_2$D3 significantly reduced the level of these cytokines ($P<0.05$ for all). In western blot analysis, mTOR/STAT3 pathway was down-regulated by 1,25$(OH)_2$D3 in HRPTEpiCs. Lastly,the concentration of urine IL-6/creatinine(Cr) ($p < 0.05$) and Kim-1/Cr ($p < 0.05$) was higher in low 25(OH)D group (n=41)) than in normal 25(OH)D group (n=49) in KTRs.

Conclusions: In conclusion, we suggest that treatment with 1 α, 25-dihydroxyvitamin D3 could be a new therapeutic strategy to reduce allograft tubule cell injury by effector T cells in kidney transplantation.

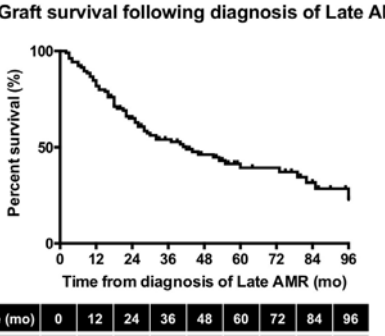
Late Antibody Mediated Rejection in Renal Transplant: Retrospective Review of Outcomes and Prognostic Indicators Irene Ruderman,[1] Matthew Sypek,[1] Moira J. Finlay,[2] Rosemary Masterson,[1] Peter D. Hughes.[1] *[1]Dept of Nephrology, Royal Melbourne Hospital, Melbourne, Victoria, Australia; [2]Dept of Anatomical Pathology, Royal Melbourne Hospital, Melbourne, Victoria, Australia.*

Background: Late antibody mediated rejection (AMR) is recognised as a major contributing cause to late allograft failure. Our aim was to identify predictors of renal allograft outcomes in late AMR in the context of a previously normal three-month protocol biopsy in a single centre transplant population.

Methods: We conducted a retrospective review and identified 106 transplant patients with late AMR. We went on to analyse the impact of histological, antibody and clinical factors on graft survival and compared the characteristics of this cohort with 968 patients without late AMR transplanted during the same period.

Results: Median time to diagnosis of rejection was 58 months post-transplant (range 26-97months). Thirty three percent of the cohort with late AMR was ABO incompatible (ABOi). Compared with the control group the late AMR group were younger ($p<0.001$) and had higher rates of ABOi. Late AMR was associated with a 2.8 times increased risk of graft loss compared to non-AMR controls. In the late AMR group, high chronicity scores on diagnostic biopsy and high serum creatinine at the time of diagnosis but not the degree of micro-vascular inflammation, C4d positivity or dsDNA were associated with worse graft outcomes. Graft survival was poor in the late AMR group with 50% graft loss 29 months post late AMR diagnosis.



Time (mo)	0	12	24	36	48	60	72	84	96
Total	106	85	56	40	21	18	15	4	1

Conclusions: Late AMR is associated with high rates of graft loss despite current treatments. Chronicity score on biopsy and lower kidney function are markers of poor graft survival.

SA-PO422

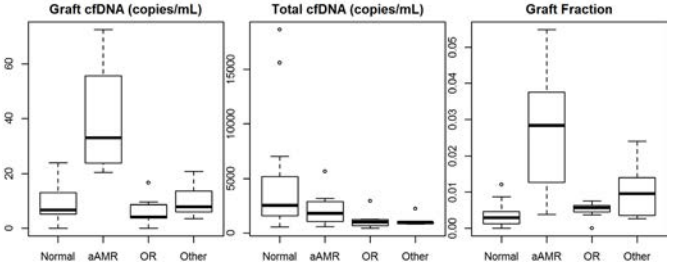
Absolute Measurements of Plasma Graft-Derived Cell-Free DNA Are Higher in Kidney Transplant Antibody Mediated Rejection

John B. Whitlam,[1] Ling Ling,[2] Francesco L. Ierino,[1] Damien Luis Bruno,[2] Howard Slater,[2] David A. Power.[1] *[1]Nephrology Dept, Austin Health, Heidelberg, Australia; [2]Murdoch Childrens Research Inst, Royal Children's Hospital, Parkville, Australia.*

Background: Cell-free DNA is an emerging biomarker of graft injury. We have developed a novel strategic approach that exploits ubiquitous copy number variation (specifically deletion), to create a "negative background" against which multiple independent informative markers can be used to measure absolute graft-derived cfDNA (gdcfDNA) using digital droplet PCR without prior donor or recipient genotyping.

Methods: A panel of 31 copy number variation assays was run on cfDNA extracted from plasma of 38 adult kidney transplant recipients undergoing biopsy for acute graft dysfunction. GdcfDNA and total cfDNA (tcfDNA) concentrations were measured and graft fraction (GF) calculated. The results were correlated with diagnostic biopsy histopathology.

Results: Biopsy results included 18 normal, 8 acute antibody mediated rejection (aAMR), 7 other rejection (OR) and 5 other non-rejection pathologies ("Other"). GdcfDNA was significantly elevated in aAMR compared with all other groups ($p<0.01$)(Figure 1, left panel). GF was higher in aAMR ($p<=0.01$) compared to all groups except "Other" ($p=0.1$)(Figure 1, right panel). For aAMR diagnosis, there is an indication that gdcfDNA is a better measure than GF.



Conclusions: Unlike other methods which rely upon GF, this novel approach permits absolute quantification of both gdcfDNA and tcfDNA. Both gdcfDNA and GF appear to be higher primarily in aAMR. Further study is warranted to confirm this pattern and establish whether dependence on GF by other approaches is subject to confounding by coincident rises in tcfDNA.

Funding: Private Foundation Support

SA-PO423

Urinary 1-Methylhistidine and 3-Methylhistidine Excretion as Biomarkers for Meat Intake and Long-Term Outcomes in Renal Transplant Recipients

Mohammad Yusof Said,[1] Joëlle Catharina Schutten,[1,2] Lyanne M. Kieneker,[1,2] Else van den Berg,[1] Gerjan Navis,[1,2] M. Rebecca Heiner-Fokkema,[1] Stephan J.L. Bakker.[1,2] *[1]Univ Medical Center Groningen; [2]Kidney Center, Groningen, Netherlands.*

Background: Mild protein restriction is recommended for chronic kidney disease (CKD) patients. It is unknown whether this also holds true for renal transplant recipients (RTR). Studies in CKD subjects did not take variation in nutritional value into account. Questionnaire-derived information may be biased, while information derived from biomarkers is more objective. We therefore aimed to study the associations of 24h urinary 1-methylhistidine and 3-methylhistidine excretion (U1ME and U3ME respectively) with meat intake and with the risk of mortality and graft failure (retransplantation or return to dialysis) in RTR.

Methods: We used food frequency questionnaires to assess total and specific protein intake, such as fish and processed meat intake. We measured 24h urinary amino acid excretion by the colorimetric ninhydrin method. Linear and Cox regression analyses were applied to analyse associations with outcome.

Results: We included 342 RTR, with mean age 53±13 years, 188(55%) males and mean eGFR 45±19 ml/min. Median U1ME and U3ME were 343 µmol/24h [IQR: 162-716] and 199 µmol/24h [IQR: 151-264], respectively. U1ME was associated with intake of white meat (R^2=0.072, St. β=0.181, P0.002) and U3ME with intake of processed red meat (R^2=0.137, St. β=0.131, P=0.02), both independent of adjustment for age, sex, and eGFR. During median follow-up of 3.9 years [IQR: 3.5-4.1], 52 RTR died and 24 developed graft failure. U1ME was neither associated with mortality nor graft failure. U3ME was associated with decreased risk of mortality, independent of adjustment for age, sex, eGFR, and urinary albumin excretion (HR 0.38, 95%CI 0.20-0.70). In a similar model, U3ME was independently associated with increased risk for graft failure (HR 3.68, 95%CI 1.29-10.49).

Conclusions: Our data suggest that high intake of red meat protein, as represented by U3ME, protects against premature mortality, while it increases the risk of graft failure. Optimal protein intake from the perspective of mortality may therefore be offset with increased risk of graft failure and vice versa.

SA-PO424

Evaluation of Soluble Urokinase Receptor as a Biomarker in Plasmapheresis Managed Focal Segmental Glomerulosclerosis

David Changli Wei,[1] Jing Li,[1] Jochen Reiser,[1] Nada Alachkar.[2] *[1]Dept of Medicine, Rush Univ Medical Center, Chicago, IL; [2]Dept of Medicine, Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Background: Plasmapheresis is the standard therapy in the management of recurrent focal segmental glomerulosclerosis (FSGS) post kidney transplantation. However, an effective biomarker justifying its application is still lacking. Elevated soluble urokinase receptor (suPAR) level was found independently associated with chronic kidney disease incidence and could contribute to the development of FSGS. In this study, we evaluated the applicability of suPAR as a biomarker in plasmapheresis managed post-transplant FSGS.

Methods: A retrospective cohort of post-transplant FSGS (n=19) managed at Johns Hopkins Hospital was analyzed for serum suPAR levels pre and post-transplantation, post-transplant FSGS diagnosis, before and after plasmapheresis. suPAR was then correlated with the clinical course. A prospective cohort of recurrent FSGS (n=14) was used for validation. suPAR downstream effector β3 integrin activity was indicated by podocyte AP5 immunofluorescence intensity.

Results: In the retrospective cohort, post-transplant suPAR was significantly lower than that at pre-transplant, but not distinct from that at the diagnosis of post-transplant FSGS. Plasmapheresis therapy alone or with Rituximab effectively reduced serum uPAR. The decrease in suPAR after treatment was correlated with the decrease in proteinuria ($r=0.59$, $p<0.05$). In the prospective cohort of recurrent FSGS, single course of plasmapheresis lowered serum suPAR by (37.0 ± 2.8)%. The combined treatment significantly decreased serum suPAR and proteinuria in 7 out of 11 patients. For the patients resistant to therapy, a high podocyte AP5 activity was persisted after treatment; 2 of 3 had increased in serum suPAR as well. When the two cohorts analyzed together, the results remained unchanged in that the combined therapy lowered suPAR and proteinuria significantly in 16 out of 26 patients, and that the changes of the both were significantly correlated.

Conclusions: In this study of post-transplant FSGS, our data suggests that serum suPAR is an effective biomarker in the monitoring of plamsapheresis therapy.

SA-PO425

Diffuse Extent of Peritubular Capillaritis in Late Antibody Mediated Rejection - Association with Transplant Glomerulopathy and More Severe Chronic Allograft Damage

Zeljko Kikic,[1] Farsad Alexander Eskandary,[1] Harald Herkner,[2] Georg Bohmig,[1] Nicolas Kozakowski.[3] *[1]Nephrology and Dialysis, Medical Univ Vienna; [2]Emergency Medicine, Medical Univ Vienna; [3]Inst of Clinical Pathology, Medical Univ Vienna.*

Background: Peritubular capillaritis (ptc) is a diagnostic criterion of antibody-mediated rejection (ABMR). Recently diffuse ptc extent (> 50% of the cortical renal tissue) has been identified as an independent risk factor for inferior outcomes.

Methods: This study assesses the clinical relevance of ptc subcharacterization (ptc score, extent and leukocytic subpopulation) in recipients with donor-specific antibody (DSA) and is a secondary analysis of a large prospective trial (BORTEJECT,-NCT01873157). It included 85 out of 741 stable transplant recipients subjected to cross-sectional antibody screening (≥6 months post transplantation). Based on DSA detection [mean fluorescence intensity (MFI) threshold >1,000], patients underwent protocol biopsy (scoring according Banff 2013 scheme). Outcomes were the presence of transplant glomerulopathy (TG) and the chronic lesion score (CLS), scoring was performed by one pathologist blinded for the outcome.

Results: Ptc (n=42) scores 1, 2, and 3 were present in 36%, 55% and 9 % while focal and diffuse ptc were found in 36% vs. 64%. Monocytes were the most prevalent leukocytic subpopulation (76%). Recipients with diffuse ptc were more frequently pre-sensitized, and presented with significantly higher post transplant DSA MFI sum (5172 (IQR: 3007-13783) vs. 2444 (IQR: 1355-7873), p=0.019). TG and CLS scores were significantly higher in recipients with diffuse ptc extent (1.1±1.1, p=0.002 and 6.8±2.2, p=0.01, respectively) vs. no ptc (0.3±0.6 and 5.2±3.3). Ptc score 2 was only associated to TG (1.2±1.0, $p<0.001$) but not to CLS. In cox regression analysis diffuse ptc remained an independent risk factor for TG (OR: 4.22 (95%CI: 1.47-12.14,p=0.007). and higher CLS (regression coefficient: 1.63 (95%CI 0.19-3.07) p=0.03) while ptc score 2 lost its significant association.

Conclusions: Our results suggest diagnostic and prognostic relevance of reporting diffuse ptc extent and further emphasize its role as a risk factor for chronic damage in kidney allografts.

SA-PO426

Circulating and Renal Expression of HLA-G Prevented Renal Allograft Dysfunction in Japanese Recipients

Yuki Okushi, Kazuaki Okino, Kiyotaka Mukai, Yuki Matsui, Norifumi Hayashi, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama. *Nephrology, Kanazawa Medical Univ, Uchinada, Ishikawa, Japan.*

Background: Although the risk for morbidity and mortality is studied in subjects with renal transplantation, there are limited data to access the long-term renal survival effects of non-classical HLA class I (HLA-G) in Japanese.

Methods: We investigated the alteration of estimated glomerular filtration rate (eGFR) based on the 3-variable GFR-estimating equation for Japanese (194 x serum creatinine $(SCr)^{-1.094}$ x $age^{-0.287}$ x 0.739, if female), and factors affecting the eGFR in 156 adult

Japanese subjects (97 males, 59 females; 125 living donors, 31 cadaveric donors) with at least 3 years of allograft survival in our hospital. Clinical backgrounds, gender, HLA matching, ischemic times, ABO incompatibility, immunosuppressive therapy, and serum soluble (s) HLA-G5 levels were examined. In addition, 22 renal biopsied specimens (9 males, 13 females; 19 living donors, 3 cadaveric donors) at before, 2-4 weeks and one year after transplantation were also evaluated for HLA-G1 expression using monoclonal anti-HLA-G antibody (clone 87G).

Results: During follow-up period, the rates of change per year of eGFR (ΔeGFR) and sHLA-G5 were -1.65 ml/min/1.73 m^2 and 11.6 ng/ml in median levels, respectively. ΔeGFR and sHLA-G5 showed positive correlation (r = 0.18, p=0.02). On multiple regression analysis, sHLA-G5, HLA matching and immunosuppressive therapy and were significant improving factors on ΔeGFR (beta 0.36535, p= 0.0210; beta -1.4956, p=0.0134; beta 0.56654, p= 0.0034 respectively). On histological examinations for HLA-G1 expression, 10 specimens showed perinuclear positive pattern on renal tubular epithelial cells after renal transplantation 2-4 weeks later. On the other hand, 12 specimens were negative for HLA-G1 staining except for interstitial infiltrating cells.

Conclusions: sHLA-G5 levels, HLA matching and immunosuppressive therapy were independent improving factors for renal allograft function judged by ΔeGFR in Japanese allograft recipients. HLA-G1 was also expressed on renal tubular epithelial cells 2-4 weeks after renal transplantation in some allograft recipients.

SA-PO427

A Paired Analysis of the Outcome after Kidney Transplantation in Peritoneal and Hemodialysis Patients Alicja Debska-Slizien,[1] Agnieszka Bobkowska-Macuk,[1] Beata Bzoma,[1] Grazyna Moszkowska,[2] Anna Milecka,[3] Dariusz Zadrozny,[3] Wojciech Wolyniec,[4] Andrzej Chamienia,[5,6] Monika Lichodziejewska,[1] Ewa Krol,[1] Zbigniew Sledzinski,[3] Boleslaw Rutkowski.[1] *[1]Nephrology, Transplantology and Internal Medicine, Medical Univ, Gdansk, Poland; [2]Dept of Clinical Immunology and Transplantology, Medical Univ, Gdansk, Poland; [3]Dept of General, Endocrine, and Transplant Surgery, Medical Univ, Gdansk, Poland; [4]Dept of Occupational, Metabolic and Internal Medicine, Medical Univ, Gdynia, Poland; [5]Kidney Transplant Regional Waiting List, Medical Univ, Gdansk, Poland; [6]Dept of General Nursing, Faculty of Medical Sciences, Medical Univ, Gdansk, Poland.*

Background: The impact of dialysis modality before transplantation on outcomes is not clear.

Methods: We analyzed the influence of dialysis modality on transplantation outcome. To minimize the donor bias, a paired kidney analysis was applied. 132 pairs of peritoneal dialysis PD and hemodialysis HD patients transplanted in our center between 1994 and 2015 who received kidneys from the same donor were included. There were no difference in the age of patients (44.9 vs 48.1 years), also Charlson Comorbidity Index was similar (3,13 vs 3,27) in both groups. The groups did not differ with respect to immunosuppressive protocols and number of mismatches.

Results: One-year patient (97 vs 98%) and graft (92 vs 95%) survival was similar, the Kaplan-Meier curves of patients and graft survival did not differ significantly. DGF and AR occurred more often in HD recipients (p>0.05). Graft vessel thrombosis resulting in graft loss occurred in 9 PD (7%) and in 4 HD (3%) patients (p>0.05). Creatinine serum and eGFR (MDRD) one-year and at last visit did not differ. On univariable analysis factors associated with graft lost were: age, DGF, eGFR and tacrolimus usage, the independent predictors upon multivariate analysis were age and eGFR. On univariable analysis the age and NOTAD were associated with death, but only age was the independent predictor.

Conclusions: Long-term outcome of renal transplantation is similar in PD or HD patients. PD patients experience significantly less DGF and AR. In both groups age was an independent predictor of the death of the patient and graft lost.

SA-PO428

The Closure of Arteriovenous Fistula Is Associated with a Significant Acceleration of eGFR Decline in Kidney Transplant Recipients Francois Jouret,[1] Pierre Delanaye,[1] Pauline Vanderweckene,[1] Hans Pottel,[2] Laurent E. Weekers.[1] *[1]Univ of Liège; [2]Kulak.*

Background: The creation of arteriovenous fistula (AVF) may retard CKD progression in the general population. Conversely, there is limited literature regarding the impact of AVF closure on renal function in kidney transplant recipients (KTR).

Methods: All KTR were retrospectively identified from 01/2007 to 12/2013, and grouped into: (0) no AVF; (1) closed AVF; and (2) left open AVF. GFR was estimated (eGFR) upon MDRD equations. Linear mixed models calculated the slope and intercept of eGFR decline *versus* time, starting at 3 months post transplantation (Tx).

	(0) No AVF	(1) Closed AVF	(2) Open AVF	p	
				ANOVA	(1) vs (2)
n	90	114	81		
Recipient					
Age (year)	48.5 ± 16.0	48.8 ±13.0	54.2 ± 13.7	<0.05	<0.05
Gender (F/M)	50/40	40/74	28/53	NS	
Donor					
Age (year)	42.5 ± 14.6	42.5 ± 14.8	48.1 ± 14.0	<0.05	<0.05
Gender (%M)	55	57	56	NS	
Transplant					
CIT (min)	653 ± 332	705 ±340	743 ± 325	NS	
DGF (%)	13	16	26	NS	
eGFR at 3 months post Tx (ml/min)	69 ± 29	64 ± 20	55 ± 21	<0.05	<0.05
eGFR slope (ml/min/month)	-0.204 ± 0.039	-0.102 ± 0.035	-0.186 ± 0.042	NS	

Comparative analyses of eGFR slopes were performed among groups, as well as before *vs* after AVF closure in group 1. For the latter, time was balanced before *vs* after AVF closure, with at least 10 observations per patient.

Results: The cohort included 285 KTR, with a median follow-up of 1750 days. Focusing on group 1, AVF closure occurred after a mean time of 653 ± 441 days post Tx. Balanced study periods before *vs* after AVF closure lasted 15.7 and 14.9 months, respectively. No difference was found between corresponding intercepts (p, 0.11) but eGFR slopes were significantly different before (0.043 ml/min/month) *versus* after (-0.176 ml/min/month) AVF closure (*p, 0.0115, n=95*).

Conclusions: A significant acceleration of eGFR decline is observed over the 15 months following the closure of functioning AVF in KTR.

SA-PO429

Machine Learning Approach for Prediction of Patient Survival in Deceased Donor Kidney Transplant Using a Nationwide Cohort from the Korean Network for Organ Sharing Database Kyung Don Yoo,[1] Junhyug Noh,[2] Hajeong Lee,[3] Dong Ki Kim,[3] Chun Soo Lim,[3] Young Hoon Kim,[4] Yon Su Kim,[3] Gunhee Kim,[2] Jung Pyo Lee.[3] *[1]Dongguk Univ Medical Center; [2]College of Engineering, Seoul National Univ; [3]Seoul National Univ College of Medicine; [4]Asan Medical Center.*

Background: The Korean Network for Organ Sharing was founded in 2000 for organ allocation in Korea. We propose a novel prediction approach of recipient survival based on machine learning techniques using KONOS data.

Methods: Our dataset is collected from 2000 to 2014 by the KONOS. Patients' survival of these recipients was investigated by the individual learners such as survival decision tree, survival ridge/lasso regression, and ensemble learners such as bagging and random forest.

Results: We analyze records of 5,430 deceased donor kidney transplants (DDKT) with more than 31 attributes, among which we choose 15 independent attributes to learn our models. Survival lasso algorithm had created the most accurate prediction model, and it outperforms a conventional method such as Cox regression (Concordance index 0.709 vs. 0.660, respectively). Among various survival decision tree models, the tree using patient's survival duration and age was found to be the best performed model for test dataset (Concordance index 0.690). In recipients under 51.5 years, survival hazard ratio (HR) was predicted as 0.58 compared to overall recipients. Duration from KT date showed significant association with mortality. If more than 51.5-years-old patient with longer duration from KT(>8.5years), predicted survival HR was 3.14. Even above the 51.5 years of recipients' age, if the age is not more than 61.5 years of age at the time of KT and shorter duration from KT(<8.5years), survival HR is only 0.97. Consequently, patients with over 61.5 years and longer duration from KT(>8.5years) were depend on donor's body weight for survival HR. In heavy donor (over 75kg) for old recipients, survival HR was increased up to 4.20.

Conclusions: We propose machine learning based models with estimated-death risks for presenting more accurate than conventional models. In our final model, recipient's age, duration from KT and body weight of donor were chosen as notable risk factors for mortality in KT recipients.

SA-PO430

Characterizing Glomerular Injury of Pediatric Kidneys Transplanted to Adult Recipients Steven Salvatore, Surya V. Seshan, Meredith J. Aull, Thangamani Muthukumar. *Weill Cornell Medical College.*

Background: Pediatric deceased donor kidneys are used effectively in transplantation to standard weight adult recipients. Due to postulated hyperfiltration-induced glomerular injury, the recipients may manifest proteinuria in the post-transplant period with pathology revealing "pediatric donor glomerulopathy" (PDG). We aim to characterize the spectrum of podocyte and glomerular injury.

Methods: From 2006-2016, 54 kidney transplant biopsies from 33 patients (of 86 total pediatric kidney recipients) were evaluated. Immunohistochemical (IHC) stains for podocin, WT1, CK AE1/AE3, and Ki67 were performed on 29 biopsies. Clinicopathologic parameters and follow-up were analyzed.

Results: 33 patients were studied, mean 373 days from transplant (range 11-1820d) for elevated creatinine, 0.7-21 mg/dL (M 4.0). 68% had proteinuria, 0-10g/24hr (M 2g).

The donor ages were 2 mo- 6 yrs with weights 6.5-20kg. Donor:recipient weight ratio was 8.3-37%, 3 patients had en bloc transplants. Biopsies showed PDG in 15/33, alone in 12 or with superimposed disease, 3. Other transplant related diagnoses included rejection in 10 (4 ACR, 5 AMR, 1 mixed), acute tubular injury 4, CNI toxicity 3, BKV 1, TMA 1, recurrent MGN 1, and 1 protocol. Among PDG cases, 53% had fetal glomeruli, 4 with collapsing glomerulopathy. Variable podocyte injury was seen by IHC in 45% and by EM in 68%. Ten (37%) had GBM lamellation, 13 (48%) endothelial injury. Follow-up was available on all cases for a mean 3.07 years (212 d to 7.9 yrs). Nine of 33 (27%) failed within mean 659 days (0-1193 d) , 23 had functioning grafts with Cr 0.95-5.2 and proteinuria 0-1.35 g at last follow-up, and 1 patient died with a functioning graft. Graft failures were from rejection (4/9), BKV (1), TMA (1), and only 3 had PDG. Overall, 13/23 pts had proteinuria and 12/23 had hematuria at last follow-up, 89% of patients had improvement in proteinuria.

Conclusions: Deceased donor pediatric kidneys are a viable option for increasing transplant demands. While PDG associated podocyte and glomerular basement membrane injury may lead to proteinuria and hematuria in the post-transplant setting, long term graft survival is preserved. Recognition of this form of glomerular injury may be amendable for therapy.

SA-PO431

Are Repeat Mismatches Associated with Decreased Kidney Graft Survival in Kidney Transplant Recipients Who Have Previously Been Transplanted with a Non-Renal Solid Organ? Jean Maxime Cote,[1] Mourad Dahhou,[2] Xun Zhang,[2] Edith A. Renoult,[1] Bethany J. Foster,[2] Heloise Cardinal.[1] *[1]Medicine, Univ de Montreal, Montreal, QC, Canada; [2]Medicine, McGill Univ, Montreal, QC, Canada.*

Background: Previous exposure to mismatched HLA antigens through a first transplant can lead to sensitization and increase the immunological risk of kidney transplantations (KT) performed after non-renal solid organ transplantation (SOT). We asked whether repeated mismatches were associated with lower kidney graft survival in patients who received a KT after a non-renal SOT.

Methods: Using the Scientific Registry of Transplant Recipients, we conducted a retrospective cohort study of patients who received a KT after one or more previous non-renal SOT between January 1st 1990 and August 15th, 2014. A repeated mismatch was coded if at least one HLA mismatch between the donor and the recipient at the time of KT had also occurred with a previous non-renal organ donor. We used a Cox regression model to assess the association between repeated HLA mismatches, overall and death-censored kidney graft survival.

Results: The full cohort comprised 4924 KT, of which 830 failed on follow-up. We observed no relationship between repeated mismatches and overall graft survival (hazard ratio (HR): 1.02, 95% confidence interval (CI) 0.87-1.19 for class 1 and HR: 0.88, 95%CI 0.72-1.08 for class 2). Donor age (HR: 1.23 per 10-year increase, 95%CI 1.17-1.29), African American donor (HR: 1.58, 95%CI 1.26-1.99), recipient race (HR: 1.32, 95%CI 1.05-1.67) and number of mismatches with the kidney donor (HR: 1.35 for 2-3, 95%CI 1.06-1.71 and HR: 1.52 for 4-6 versus 0-1, 95%CI 1.22-1.91) were associated with an increased risk of graft failure. Living donation (HR: 0.64, 95%CI 0.54-0.76) and older recipient age at transplantation (HR: 0.94 per 10-year increase, 95%CI 0.89-0.99) were associated with a decreased risk of graft failure. Similar results were observed for death-censored graft failure.

Conclusions: Repeated HLA mismatches with previous donors had no negative impact on overall or death-censored graft survival in KT performed after previous non-renal SOT. Hence, repeated mismatches should not be used as a criterion to refuse a kidney donor.

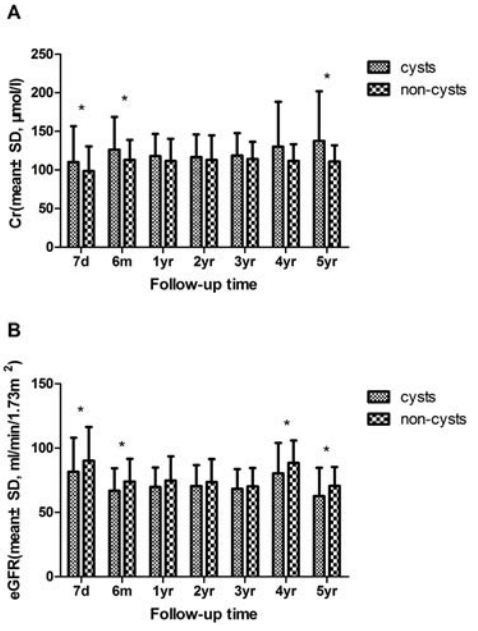
SA-PO432

Graft Bearing Cysts Contribute to Accelerated Decline of Kidney Allograft Function Wenxian Qiu, Wenhan Peng, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Simple renal cysts are the most common structural abnormality observed in adult kidneys. We investigated whether graft bearing sporadic cysts is associated with the accelerated decline of kidney allograft function in living donor kidney transplantation.

Methods: We retrospectively reviewed donors and recipients records of 716 living donor kidney transplants performed between April 2007 and April 2015 in our hospital. 64 recipients of grafts with cysts were noted. We compared this cohort to 128 non-cysts controls matched for the donors and recipients' gender, donor age, donor/recipient body surface area ratio, recipient age and donor baseline serum creatinine in turn.

Results: The mean serum creatinine of recipients in the two groups were 110.3±46.52 vs 98.86±31.88, 126.28±42.32 vs 113.24±25.65, 137.64±64.29 vs 111.16±20.99μmol/l on postoperative day 7, month 6, year 5 respectively($P<0.05$). Estimating glomerular filtration rate levels were 81.74±26.30 vs 90.19±26.36, 66.97±17.47 vs 74.02±17.68, 80.38±23.74 vs 88.45±17.55, 62.85±21.94 vs 70.63±14.64ml/(min·1.73m^2) on day 7, month 6, year 4, year 5 after surgery separately($P<0.05$).



However, the two groups did not significantly differ in terms of the other characteristics.

Conclusions: The donating kidney with cysts can influence the early and long-term allograft function. In living donor kidney transplantation, kidney presenting cystic diseases should be considered to be the next choice for transplantation.

SA-PO433

Interleukin-6 Production by Monocytes Is Associated with Graft Function Decline in Patients with Borderline Changes Suspicious for Acute T Cell-Mediated Rejection Sacha A. De Serres,[1] Olivier Desy,[1] Stephanie Beland,[1] Patrice Vallin,[1] Julie Riopel,[2] Eva Latulippe,[2] Anil K. Chandraker,[4] Ibrahim Batal.[3] *[1]Renal Div, Univ Health Center of Quebec, Laval Univ, Québec, QC, Canada; [2]Dept of Pathology, Univ Health Center of Quebec, Laval Univ, Québec, QC, Canada; [3]Dept of Pathology, Brigham and Woman's Hospital, Boston, MA; [4]Renal Div, Brigham and Woman's Hospital, Boston, MA.*

Background: The borderline changes suspicious for acute T-cell-mediated rejection (BL) is a diagnostic category questioned for its relevance. The undetermined clinical significance of this diagnosis leads to heterogeneous therapeutic management. Based on previous observations, we hypothesized that measuring IL-6 secretion by peripheral blood mononuclear cells (PBMCs) in patients with BL identifies those with ongoing graft damage.

Methods: From a cohort of 105 patients with concurrent biopsy and PBMC collection, we studied 28 patients with BL, in the absence of ABMR. The primary outcome was the change in eGFR at 6 months. We measured IL-6 levels secretion in PBMC culture supernatants. We characterized patients IL-6 secreting cells by flow cytometry, followed by characterization of mouse dendritic cells (DCs).

Results: The primary outcome was strongly associated with IL-6 levels (5.0±1.5 mL/min for each increase in log10 IL-6; $p=0.004$). These results were consistent after adjustment for baseline eGFR and antirejection treatment ($p=0.003$). 3mo samples were available in 19 patients and demonstrated that the secretion of IL-6 was stable over time. The main source of IL-6 was $CD14^+CD16^-CCR2^+HLADR^+CD86^+CD11c^+$ monocytes. In an independent cohort, we found a significant correlation between IL-6 secretion and interstitial DC density in the biopsy. In mice, we observed that kidney DCs share features with macrophages and function as effector cells secreting IL-6. Kidney DCs showed a lower capacity for proliferation of CFSE-labeled T cells and a lower production of IL-2 in MLR supernatants, compared with splenic DCs.

Conclusions: These data suggest that IL-6 is a potential marker of active rejection in patients with BL, is produced by monocytes in the blood, and correlates with DCs in the allograft.

SA-PO434

Urinary Tissue Inhibitor Metalloproteinase-2(TIMP-2) X IGF-Binding Protein-7(IGFBP7) Predict Delayed Graft Function after Kidney Transplantation Jihyun Yang, Sung Yoon Lim, Young Ju Na, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Dept of Internal Medicine, Div of Nephrology, Korea Univ Medical College, Seoul, Republic of Korea.*

Background: Recently, urinary TIMP-2 and IGFBP-7, markers for G1 cell cycle arrest, have been identified and validated in predicting the development of AKI in critically ill patients. It is unknown, however, whether these two biomarkers could predict the development of delayed graft function (DGF) after kidney transplantation.

Methods: This is a single center, prospective observational study. We enrolled 56 patients who underwent KT (living donor: 8, deceased donor: 48) between August 2013

and December 2015. Urine sample were collected right after the operation. The primary outcome was development of DGF as defined by need for dialysis of more than 1 session within 7 days of KT.

Results: Sixtenn patients (28%) were diagnosed as DGF. In univariate analysis, kidneys from expanded criteria donors, donor serum creatinine, donor estimated glomerular filtration rate (eGFR), urinary IGFBP-7 and TIMP-2 were significantly different between early graft function (EGF) and DGF. However, in multivariate analysis adjusting for effects of donor eGFR only IGFBP7 x TIMP-2 at 0 hour post transplantation could predict the development of DGF. The receiver operating characteristic curve for prediction of DGF showed an area under the curve of 0.77 (sensitivity 0.77, specificity 0.81) for a cut off value of 1.76.

Conclusions: Our results indicate that urine IGFBP7 x TIMP-2 immediately after transplantation could be an early, predictive biomarker of DGF in kidney transplantation.

HLA-DR Expression in Tubular Epithelial Cells and the Subsequent Development of Antibody-Meditated Rejection in Transplant Kidneys

Haruki Katsumata,[1] Yasuyuki Nakada,[1] Izumi Yamamoto,[1] Akimitsu Kobayashi,[1] Ai Katsuma,[1] Takafumi Yamakawa,[1] Mayuko Kawabe,[1] Yudo Tanno,[1] Ichiro Ohkido,[1] Hiroyasu Yamamoto,[1] Masayoshi Okumi,[2] Hideki Ishida,[2] Takashi Yokoo,[1] Kazunari Tanabe.[2] *[1]Div of Nephrology and hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Dept of Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: The mechanism of antibody-mediated rejection (ABMR), a prominent cause of kidney allograft loss, is associated with donor-specific antibody (DSA). It has been speculated that T-cell mediated rejection (TCMR) enhances *de novo* DSA and ABMR. High HLA-DR expression in tubular epithelial cells is correlated with TCMR. However, the clinical significance of HLA-DR expression in tubular epithelial cells and TCMR as a cause of ABMR is not clear. This study evaluated whether the early expression of HLA-DR in tubular epithelial cells is associated with ABMR of kidney allografts.

Methods: This retrospective cohort study enrolled consecutive renal allograft recipients transplanted at the Department of Urology, Tokyo Women's Medical University, from January 2005 to December 2009. We assessed biopsy samples obtained from 212 kidney allograft recipients at early phase. The HLA-DR expression in tubular epithelial cells was evaluated using immunofluorescence. The cases were classified into four groups according to HLA-DR expression and the progression of TCMR: the DR+TCMR+ (n=28), DR+TCMR– (n=70), DR–TCMR+ (n=15), and DR–TCMR– (n=99) groups. The incidence of ABMR and graft survival were analyzed using the Kaplan–Meier method and log-rank test.

Results: Overall, the kidney allograft survival was worse in the DR+TCMR+ group than in the DR–TCMR– group (p=0.0081). ABMR was more frequent in the DR+TCMR+ group than in the DR–TCMR– group (p=0.0284). Of note, in the DR+TCMR+ group, 21 of 28 (75%) cases simultaneously expressed HLA-DR and showed TCMR, and another 25% (7 of 28) of cases developed TCMR within 1 year. Of these, 15 recipients (7.1%) developed ABMR a median of 35 (range 0–116) months after HLA-DR expression.

Conclusions: These results suggest that HLA-DR expression in tubular epithelial cells and the subsequent development of TCMR are associated with ABMR and allograft survival.

SA-PO436

Short Term Modulation of Glomerular Filtration Rate and Funcional Renal Reserve by Protein Restriction in Healthy Living Kidney Donors

Carlos Schreck, Carlos Guido Musso, Nora Cristina Imperiali, Cesar Andrés Mombelli, Maria Cora Giordani, Silvia Rosana Groppa, Guillermo Javier Rosa Diez. *Servicio de Nefrología, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.*

Background: Dietary protein is an important modulator of glomerular filtration rate (GFR). Renal Reserve (RR) (> 20% increase in GFR after a protein load) is used to assess kidney function in living kidney donors. In some donors, RR is negative, particularly in those whose GFR is high. Because dietary protein content is usually high in Argentina, we decided to further standardize RR through protein restriction 48-hours prior as to avoid the effect of variation in dietary protein content on RR.

Methods: A 24-hour creatinine clearance (CrCl) without protein restriction was used to measure GFR prior (7-60 days) to RR. Two days before RR, patients received 1600 mg/d of cimetidine to inhibit Cr secretion and dietary protein was restricted by avoiding meat, eggs and dairy products. RR was then assessed as described previously: a baseline GFR was obtained by averaging 3 consecutive 30-40 min urine and collections and 1 blood sample for urinary and serum Cr. Immediately after, patients consumed a 1.5 g/kg dairy protein meal, and 4 more blood/urine collections were obtained. The RR was calculated as the percentage increase in GFR after the protein meal (highest post-protein meal GFR – pre-protein GFR/pre-protein GFR * 100%).

The 24-hour CrCl (no dietary restrictions) was compared to the RR baseline GFR (protein restricted). Results are expressed as mean ± SE. GFR differences were compared by a paired T-test.

Results: 61 patients were included (36 females, 25 males, age range: 24-73 years-old)). GFR after protein restriction + cimetidine was lower than the unrestricted 24-hour CrCl (102.2 ± 3.1 ml/min/1.73m² vs 130.3 ± 4.4 ml/min/1.73m², p < 0.00001). The increase in GFR after the dairy protein meal was 54.2 ± 4.8 ml/min/1.73m² (102.2 ± 3.1 ml/min/1.73m² pre-meal vs 156.4 ± 5.7 ml/min/1.73m² post-meal, p < 0.00001) and RR was 55.8 ± 4.8 %.

Conclusions: Protein restriction before RR is a useful method to standardize conditions for the test. It also allows to assess the ability to negatively modulate GFR.

SA-PO437

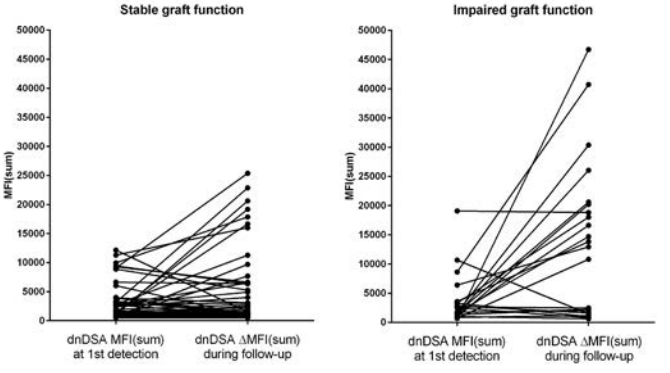
Change in De Novo Donor-Specific Antibody Intensity Predicts Allograft Dysfunction

Scott Davis,[1] Jane Gralla,[2] Alexander C. Wiseman,[1] James E. Cooper.[1] *[1]Medicine, Univ of Colorado, Aurora, CO; [2]Pediatrics, Univ of Colorado, Aurora, CO.*

Background: Although de novo donor-specific antibodies (dnDSA) are associated with decreased graft survival in multiple studies, it is not clear which patients with dnDSA will ultimately experience graft dysfunction or loss. Monitoring change in antibody mean fluorescence intensity (MFI) over time may identify patients at risk for antibody-mediated graft complications yet studies are lacking. The purpose of this analysis was to determine whether an increase in antibody intensity was associated with worse graft function in what represents the largest study of its kind.

Methods: Seventy-four kidney and kidney-pancreas recipients with stable renal function (eGFR ≥ 40 ml/min/1.73 m²) at the time of first detection of dnDSA were prospectively followed for 2 years with serial antibody testing. The sum MFI (MFIsum) of all dnDSA detected at a given time point was calculated and change in MFIsum (ΔMFIsum ≥50% and ΔMFIsum ≥100%) was compared between patients with stable graft function after dnDSA detection (ΔeGFR ≤25%) and patients who had evolving graft impairment (ΔeGFR >25%).

Results: Fifty-two patients had stable graft function and 22 patients had graft impairment after dnDSA detection. The graft impairment group experienced more acute rejection (50% vs. 13%) and death-censored graft loss (41% vs. 4%, p<0.001). A change in MFIsum greater than 50% (n=29) and greater than 100% (n=25) was significantly associated with graft impairment (p=0.036 and p=0.018, respectively). Actual change in MFI is shown in Figure 1.



Conclusions: An increase in dnDSA intensity over time is associated with allograft dysfunction. Serial monitoring of dnDSA intensity after detection to identify patients at risk for complications may be warranted.

SA-PO438

Prompt Follow-Up Biopsies Define Outcomes after Treatment of Antibody Mediated Rejections

Sandesh Parajuli, Maha A. Mohamed, Brenda L. Muth, Brad C. Astor, Robert R. Redfield, Weixiong Zhong, Didier A. Mandelbrot, Arjang Djamali. *Univ of Wisconsin- Madison.*

Background: There is limited information on the role of follow-up biopsies after the treatment of antibody medicated rejection(AMR) in kidney transplantation (KTx).

Methods: This observational study included patients diagnosed with AMR based on Banff 2013 between 03/2013 and 12/2015. Additional inclusion criteria were (a) follow-up biopsy within 3-12 weeks and (b) AMR treatment with steroids/IVIG ± rituximab (ritux). In cases with multiple episodes of AMR, only the first episode was included.

Results: Forty-eight of the 221 patients with AMR satisfied our selection criteria. Mean time from KTx to AMR was 76.8±72.05 months. Mean time between the two biopsies was 45±15.32 days. Mean follow-up after the diagnosis of AMR was 10.1±8.01 months. 26 patients received ritux (R+ group) and 22 did not (R- group). Aside from a younger age at KTx (37.3±16.37 vs. 49.9±16.37 years, p=0.01) there were no significant clinical, pathological or immunological differences between R+ and R- groups prior to the treatment. Immunopathological changes at the time of the follow-up biopsy demonstrated a significant decline in DSA class I (MFI_{sum} 7,418 ± 9,328 to 4,110 ± 5,147; p=0.002), DSA class II (MFI_{sum} 18,498± 15,853to 14,608±14,490; p<0.001), ptc+g score (2.56± 1.01to 1.56±1.23; p<0.001), and c4d score (1.5±1.32 to 0.95±1.24; p=0.001) after treatment. In the absence of ritux, the decline in ptc+g score and DSA class II reached statistical significance, but the decline in C4d score and DSA class I did not. Ritux was associated with a statistically significant decline in all four parameters. There were no significant differences in graft loss, last serum creatinine (Scr), or proteinuria between the R+ and R- groups. The immunopathological changes observed on follow up biopsies were not predictive of short term graft loss or poor kidney function (Scr > 2.5 mg/dl) using univariate or multivariate regression analyses.

Conclusions: In this short-term follow-up study, treatment of AMR with ritux was associated with improved class I and II DSA, microcirculation inflammation and C4d.Long-term studies are needed to determine whether follow-up biopsies after AMR are helpful.

SA-PO439

Molecular Crosstalk in Chronic Dysfunction of Renal Allografts: An Integrative Approach Sai Vineela Bontha, Daniel Maluf, Valeria Mas. *Surgery, Univ of Virginia.*

Background: Chronic renal allograft dysfunction (CRAD) with interstitial fibrosis and tubular atrophy (IFTA) in kidney transplant recipients (KTRs) is a major cause of graft loss. Considering the complexity associated with CRAD, its underlying molecular interactions need to be explored through an integrative approach to gain mechanistic insights. Thereby, the current study was done to get a holistic view of the molecular changes & interactions at epigenetic (miRNA, DNA methylation (DNAm)) and gene expression levels.

Methods: A total of 70 graft biopsies were evaluated. DNAm, gene expression and miRNA arrays were done from each of the kidney biopsies from KTRs with IFTA (n=10) and normal functioning allograft (n=11). Additional methylation arrays (n = 40) were performed in donor pre-implantation biopsies to evaluate if the methylation changes were IFTA specific and *denovo*.*Minfi*, *oligo & limma* Bioconductor packages in R were used for analysis of the arrays and the data was integrated. Differentially expressed miRNA and their gene targets thus obtained were further validated by qPCR in training (n=10) and independent sets (n=10).

Results: Integration analysis resulted in 3 miRNA that were hypomethylated in promoter regions and upregulated in IFTA biopsies. The gene targets of these 3 miRNA were further integrated using gene expression arrays from the same biopsies. Biological analysis of the integrated gene expression data showed that the genes repressed by these miRNA had kidney tissue specific metabolic functions, especially in the tubular epithelial cells (*BHMT2, CLCN5, G6PC, NTRK2, CLCNKB, PPM1H, AHCYL1*). Also, among them were inhibitors of TGF beta signaling pathway (*PPM1H, TGFB3*). Top disease functions associated with these genes in IPA analysis show dysgenesis, cell death, growth failure and hypoplasia (z-score > 2.621).

Conclusions: The results suggest that DNAm changes in graft biopsies are *denovo*. DNAm could be a consistent upstream regulatory mechanism through which the miRNA and thereby their gene targets are dysregulated and contribute to renal tubule dysfunction and may be partly responsible for tubular atrophy and tubulo-interstitial fibrosis.

Surveillance Renal Transplant Biopsies: Useful or Irrelevant? William M. Bennett, Erica Simonich, Alison M. Garre, Shaban Demirel, Margaret E. Marksthaler, Thomas D. Batiuk. *Legacy Transplant Services, Legacy Transplant Services, Portland, OR.*

Background: Performance of surveillance biopsies in kidney transplantation remains somewhat controversial. There are many centers that biopsy patients based only on rises in serum creatinine or symptoms.

Methods: Since 2011 we have performed surveillance biopsies at 2 months and 6 months post-transplant with follow up at 1 year for any abnormal results. Immunosuppression was Thymoglobulin induction (3 mg/kg) followed by Tacrolimus, mycophenolate and Prednisone.

Results: In 422 surveillance biopsies 54 (12.7%) had subclinical acute cellular rejection or borderline changes, 0.6% showed other abnormalities. In 241 biopsies "for cause" 35.7% were normal while 54.7% had acute cellular rejection or borderline changes. There were additional 5.4% of samples with abnormalities. Six (3.6%) patients had acute antibody mediated rejection. In 624 cases where C4d was available 78 (12.5%) were positive with 31 occurring in the surveillance biopsies. Thus there were many C4d positive patients without concurrent histologic evidence of antibody mediated rejection. There were no bleeding complications requiring transfusion or loss of function of the transplanted kidney.

Conclusions: Surveillance biopsies are safe and provide information valuable to patient management. C4d positivity was common in surveillance biopsy samples. Long term outcomes will ultimately determine the utility of our surveillance protocol.

SA-PO441

Early Loss of Peritubular Capillaries after Kidney Transplantation Is Associated with Later Renal Function Decline: A Validation Study in 121 Patients Anke Keijbeck,[1] Floortje Steegh,[1] Marielle Gelens,[2] Ernest Van Heurn,[3] Maarten H.L. Christiaans,[2] Carine Peutz-Kootstra.[1] *[1]Pathology, MUMC, Maastricht, Netherlands; [2]Internal Medicine, MUMC, Maastricht, Netherlands; [3]Surgery, AMC, Amsterdam, Netherlands.*

Background: Chronic transplant dysfunction is a major cause of renal graft loss and is preceded by interstitial fibrosis/tubular atrophy (IF/TA) in protocol biopsies. Previously we showed in a pilot study of 48 patients that IF/TA development is preceded by peritubular capillary (PTC) loss in the first 3 months after transplantation (Steegh *et al.* JASN 2011). The aim of this study is to validate these findings in a separate cohort.

Methods: The validation cohort consisted of 121 new patients, who received a kidney transplantation between August 2003 and December 2009 at the Maastricht University Medical Centre and of whom representative protocol biopsies were taken at transplantation, and 3 and 12 months posttransplant. IF/TA, PTC number and eGFR (MDRD) were studied as described in the pilot study.

Results: A significant loss of PTCs in the first three months after transplantation was found in post-mortal donor kidneys only (P<0.01). In univariate analyses, this PTC loss was associated with longer first warm and cold ischemia time, delayed graft function (DGF), (sub)clinical rejection, and with higher PTC density and IF/TA in the pre-implantation biopsy. This early PTC loss is associated with higher IF/TA score (ρ-0.372, P<0.01) after 1 year. Additionally, early PTC loss is correlated with lower eGFR at year 1 (ρ0.219, P=0.021) and 2 (ρ0.202, P=0.037) posttransplant. Although demographic and pre-transplant clinical variables were similar, PTC loss was less severe in the validation than in the pilot cohort, which may be related to lower incidence of DGF and shorter first warm ischemia time in deceased after cardiac death (DCD) donors.

Conclusions: This study confirms that PTC loss occurs mainly in postmortal donor kidneys, in the first three months after transplantation and is associated with higher IF/TA scores and a decreased eGFR at year 1 and 2. Preserving microvascular integrity may aid in prevention of chronic transplant dysfunction.

SA-PO442

Intratubular Calcification of Renal Allografts Detected by Protocol Biopsies: A New Classification - The Purple Study Ana Coloma,[1] Noa Diaz,[1] Manel Sole,[2] Jose-Vicente Torregrosa.[1] *[1]Nephrology, Hospital Clinic, Barcelona, Spain; [2]Pathology, Hospital Clinic, Barcelona, Spain.*

Background: Intratubular calcification has been described in renal allograft though its clinical relevance remains to be established. The aim of this observational study was to investigate mineral bone metabolism and graft function association to calcification of serial protocol biopsies done at 3 and 12 months after kidney transplantation.

Methods: We studied 515 biopsies from 271 kidney recipients in our center. Histological grouping was established according to intraluminal calcification findings: grade 0 had none or one (P0), grade 1 had two (P1) and grade 2 had more than two (P2). Demographic and transplant data was collected and laboratory data was evaluated at the moment of transplantation, 3, 6, 12, 24 and 36 months after.

Results: We observed more than one calcification in 112 recipients (41.3%). Calcification was not related neither to patient age and gender, dialysis mode, nor immunosuppressive drugs. Non-hearth-beating donor calcification grade (71.8%) was higher than both brain-dead (35.1%) and living ABO-compatible donor (30.5%) p<0.001. ABO-incompatible grafts revealed higher calcification grade when compared to ABO-compatible (65% and 30.5%; p<0.001). Patients on P1 and P2 groups had significantly delayed renal graft function (DGF) (66.2%; p<0.001). Histology of grafts at 3 months with moderate interstitial fibrosis and tubular atrophy had more calcifications than mild grade (Banff) p<0.05. In the first year of transplantation, patients with more calcifications had significantly higher serum parathormone (p<0.05) and alkaline phosphate, remaining the later higher during the 3 years of follow-up. Renal graft function was not related to calcification grade during the entire study period.

Conclusions: Non-hearth-beating donor, living ABO-incompatible donor and recipients with DGF had higher intratubular calcification grade in protocol biopsies. Mineral bone metabolism data and biopsy calcifications association could help to consider an earlier treatment. We propose to include calcification grade in protocol biopsies since it could provide information about type of donor and initial renal graft function.

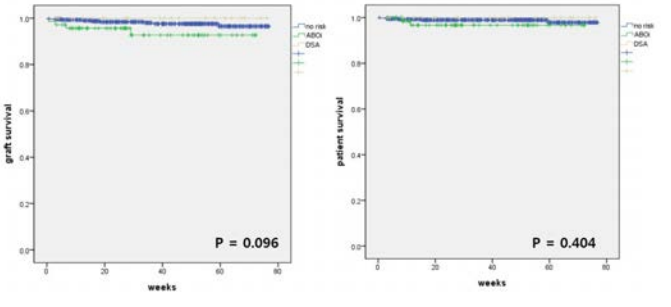
SA-PO443

Long Term Outcome in Donor Specific Antibody Positive and ABO-Incompatible Living Donor Kidney Transplant Patients after Desensitization: A Single Center Experience Yong Chul Kim, Mi-Yeon Yu, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Internal Medicine, Seoul National Univ Hospital, Republic of Korea.*

Background: The kidney organ shortage and increasing number of waiting kidney transplantation (KT) is a global issue. One of the solution is KT in ABO incompatible (ABOi) and Donor specific antibody (DSA) positive patients after desensitization.

Methods: We retrospectively analyzed 510 living donor KT patients from January 2010 to February 2016 at Seoul National University Hospital including 71 ABOi KT and 21 DSA positive KT patients who underwent desensitization with anti-CD20 Ab, plasmapheresis and intravenous immunoglobulin. Four hundred seventeen patients without anti-HLA antibodies (no risk) served as control group.

Results: Mean follow-up duration was 38.8 ± 21.5 weeks and mean age was 40.5 ± 16.5 years. There were no difference in 1-year and 3-year graft survival rate in these three groups (no risk vs ABOi vs DSA positive group) respectively (graft survival 1yr: 99.3% vs 95.7%, 100.0%, 3yr: 98.0% vs 92.7% vs 100.0%). One-year and 3-year patient survival were also similar (patient survival 1yr: 99.3% vs 96.7% vs 100.0%, 3yr: 99.0% vs 96.7% vs 100.0%).



There were more acute antibody-mediated rejection in ABOi KT and DSA positive KT than No risk group (ABOi : 17 (23.7%) vs DSA : 6 (28.5%) vs no risk : 23 (5.5%), p<0.001).

Conclusions: Despite there seems to be more acute antibody-mediated rejection, ABO-incompatible and DSA positive kidney transplantation after desensitization has a favorable graft and patient outcome.

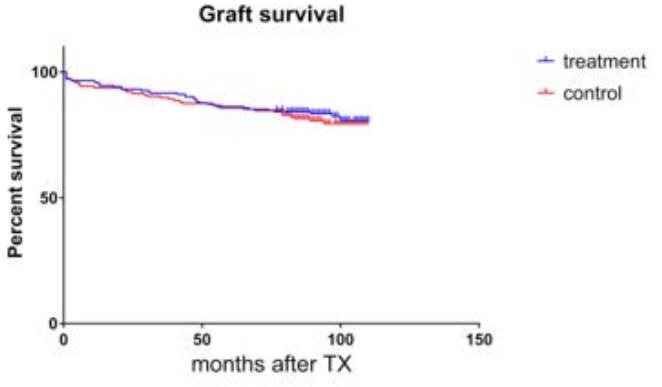
SA-PO444

Long Term Outcome of Steroid Pretreatment of Organ Donors – A Randomized, Controlled Trial Roman Reindl-Schwaighofer, Rainer Oberbauer, Alexander Kainz, Julia Wilflingseder. *Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria.*

Background: Organs from deceased donors show a reduced graft survival compared to organs from living donors. A major difference between the two groups is the rate of delayed graft function (DGF) that occurs in roughly 25% of recipients of organs from a deceased donor compared to below 5% following kidney transplantation from a living donor. Gene expression analysis in donor kidney biopsies revealed that organs with DGF showed an up-regulation of genes associated with inflammation, complement activation and apoptosis induction.

Methods: To determine whether systemic anti-inflammatory treatment of kidney donors following brain death reduces the incidence of DGF and improves long-term graft survival we performed a randomized placebo-controlled trial and enrolled 306 donors and 455 renal transplant recipients between February 2006 and November 2008. Donors either received 1000 mg of methylprednisolone or placebo.

Results: Incidence and duration of DGF at 1-week post translpant could not be reduced by corticosteroid treatment of the donors (Kainz et al. 2010). At the 5-year follow-up death censored graft survival as well as patient survival did not differ between the two groups. This is visualized by a KM plot (Figure 1). To assess influence on graft function we calculated the slope of eGFR. Again, no statistically significant difference between the two groups was observed.



Conclusions: Steroid treatment of donors prior to organ harvesting did not improve long term graft survival and function.

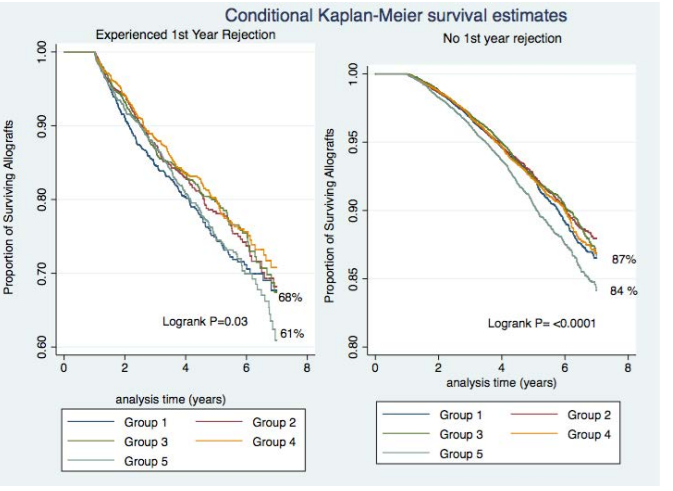
SA-PO445

Impact of Inadequate Donor Nephron Mass on First Year Rejection Risk Abhijit S. Naik, Roger C. Wiggins, Diane Cibrik. *Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Inadequate donor nephron mass is associated with hyper-filtration injury and reduced graft survival. Injury and the accompanying inflammation could stimulate an alloimmune response.However, whether inadequate nephron mass is associated with an increased risk of acute rejection remains unclear.

Methods: Study data were drawn from national transplant registry (OPTN data as of December 2015)) data for adult kidney-only recipients in 2008 to 2013. Inadequate donor nephron mass was defined as the recipient and donor body surface area mismatch (RDM) ratio, and categorized according to RDM quintiles as: Group 1, <0.87; Group 2, >0.87 to <=0.97; Group 3, > 0.97 to <= 1.07; Group 4, >1.07 to <=1.20; and Group 5, >1.20. A multivariate logistic regression model was used to determine associations between RDM and first-year acute rejection, adjusted for transplant, recipient and donor factors. Kaplan Meier Survival curves (conditional to allografts surviving first year) were constructed to assess long term (7 year) allograft outcomes.

Results: Among 73,624 recipients, the overall rejection rate was 9.15 % and ranged from 10.5 % in Group 5 to 8.4 % in Group 1. After covariate adjustment, compared to Group 3, Group 1 (OR=0.80 95% CI: 0.72-0.89) and Group 2 (OR= 0.85, 95% CI: 0.78-0.93) were associated with a lower rejection risk, while Group 4 (OR=1.10, 95 % CI 1.01-1.19) and Group 5 (OR=1.31, 95% CI: 1.19-1.44) were associated with increased risk. Recipient body mass index (BMI)> 30 (OR=1.12, p<0.05) and donor BMI (OR=1.01 per kg/m2, p<0.0001) were also independently associated with rejection. Long-term allograft outcomes across RDM groups were notable for worse outcomes in Group 5 (vs Group 1) both with and without rejection (P<0.05 for both).



Conclusions: Inadequate donor nephron mass is independently associated with increased risk of first year rejection and this effect is independent of both recipient and donor BMI. Efforts to minimize RDM may help mitigate this risk.

SA-PO446

Predicting Post-Transplant Mortality: A Single Center Comparison of Comorbidity Indices Ronald Brian Vigo, Wadi N. Suki, Duc T.M. Nguyen, Edward Graviss, Ahmed Osama Gaber. *Nephrology, Houston Methodist Hospital, Houston, TX.*

Background: Patients listed for renal transplantation can have multiple comorbidities leading to early mortality post-transplant. Multiple models have been developed to objectively measure the burden of these comorbid illnesses and some have been used successfully to predict mortality post-transplant. Our goal was to evaluate the utility of three of these tools as objective measures to predict negative outcomes in renal transplant recipients at our center.

Methods: We evaluated medical records from kidney recipients transplanted at our institution between 5/30/2008 and 5/31/2015. Patients who died within the first year post-transplant were included. Patients who survived beyond the first year were matched by age, sex and race in a 2:1 ratio and selected as controls. Data was analyzed using a Cox regression model. A base model which included outcome variables was developed with the intent of adding statistical power to the results. Variable selection for the multivariate model was based on Hosmer and Lemeshow's methodology. Bayesian information criterion (BIC) and likelihood ratio testing were used to assess the performance of the full and simplified predictive models.

Results: 23 patients with 46 matched controls were included in our study. Increased comorbidity was associated with reduced patient survival. Of the models examined, the Charlson Comorbidity Index(CCI) and its different versions yielded statistically significant results in patients aged <65.A CCI model adjusted for age and albumin offered the best results (p=0.001). None of the models yielded significant results for recipients ≥65. The CCI adjusted for base model yielded significant results in all patients and patients <65, but not in patients ≥65.

Conclusions: The CCI is a suitable tool for the objective measurement of comorbidity in renal transplant recipients aged <65. CCI adjusted for age and serum albumin increases the effectiveness of the CCI in predicting post-transplant mortality. CCI and age-adjusted CCI models when adjusted for with the base model significantly predicted post-transplant mortality in all patients.

SA-PO447

Predictors of Mortality in Renal Transplantation Recipients Marcos A. Meniconi,[1] Krissia K.S. Wallbach,[1,3] Luiza Pego Silva,[1] Jose Medina-Pestana,[1,3] Miguel A. Goes.[1,2,3] *[1]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Nephrology, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil; [3]Nephrology, Hospital do Rim e Hipertensão, Sao Paulo, SP, Brazil.*

Background: Graft and patient survival after kidney transplantation have improved over the past decade. In that context, death with a functioning graft has increased during this time. Our objective is to assess the mortality predictors after renal transplantation.

Methods: 688 patients were prospectively analyzed for 72 months post-renal transplantation. Follow-up started 90 days after renal transplantation and mortality was the primary outcome. Demographic data, pre-transplantation time on dialysis, delayed graft function (DGF), EPI-CKD, Hb concentration at baseline, type of kidney donor and medication used during follow-up were reported. We used t test to compare differences between groups (mortality versus non-mortality groups) and X^2 to analyze categorical variables. Binary logistic regression was used to determine independent predictors of mortality when p<0.1.

Results: Mean time on dialysis was 46+21 months. The main causes of ESRD were diabetes (35%) and hypertension (18%), followed by chronic glomerulonephritis (10%);

Kidney donation was 43% from deceased donors, 48% related living donors and 9% unrelated living donors; 67% used FK-506, 24% cyclosporine and 8% rapamycin as immunosuppressive drugs; EPI-CKD 69+27 mL/min and Hb 11.7+2.5g/dL at baseline. 68 patients died during follow-up (Mortality group). We observed that this group was older (49+12, 39+15 yo;p<0.001), had a longer time on dialysis (4+3,2+1 yr;p<0.001), higher cold ischemia time (20+12h,14+5h;p<0.001), used higher rHuEPO doses (5389+3560,3824+1616 IU;p=0.006), had lower Hb (10.6+3.1,12.7+2.5) and CKD-EPI (45+23,55+27; p=0.007) at baseline and also higher DGF (p<0.001). After binary logistic regression, age (b=1.063 95%CI 1.034-1.091;p<0.001), Hb (b=0.715 95%CI 0.634-0.808;p<0.001) and cold ischemia time (b=1.001 95% CI 1.000-1.001;p=0.009) were determined independent predictors of mortality.

Conclusions: This study shows that patient age, Hb concentration and cold ischemia time were independent predictors of mortality in renal transplant recipients.

SA-PO448

Long-Term Changes in Cardiovascular Structure and Function after Kidney Transplantation Nikita P. Punjabi, Azhar Ali, Sabiha Gati, Kristel E. Medina-Rodríguez, Juan Carlos Kaski, Debasish Banerjee. *Renal Dept, St. George's, Univ of London, London, United Kingdom.*

Background: Cardiovascular events rates are high in chronic kidney disease patients, which improve with kidney transplantation. However, the long-term cardiovascular structural and functional changes with kidney transplantation are poorly understood. This study prospectively investigates these changes in live-donor kidney transplant recipients.

Methods: 24 non-diabetic, live-donor kidney transplant patients (20 dialysis and 4 pre-dialysis, mean age 45±13 years, 75% male, 75% Caucasian) completed baseline (1-7 days before transplant) measurements. Patients underwent a detailed echocardiogram and a vascular endothelial function investigation using brachial artery flow-mediated dilatation (FMD). These were conducted together with routine blood and clinical examinations. Patients were followed up with the same investigations in the short term (9 patients, 8±0.5 months) and long-term (17 patients, 28±6 months).

Results: Left ventricular mass (LVM) regressed (208±82g to 178±63g) and ejection fraction (EF) improved (59±9% to 69.5±9%) over time, significantly in the long-term after transplantation. No significant changes were observed in FMD; however, a significant improvement was observed in nitroglycerin-mediated dilatation (NMD) (10±6% to 15±5.5%, p=0.022). Higher NMD values at baseline were correlated with greater improvement in LVM Index at follow up (p=0.009).

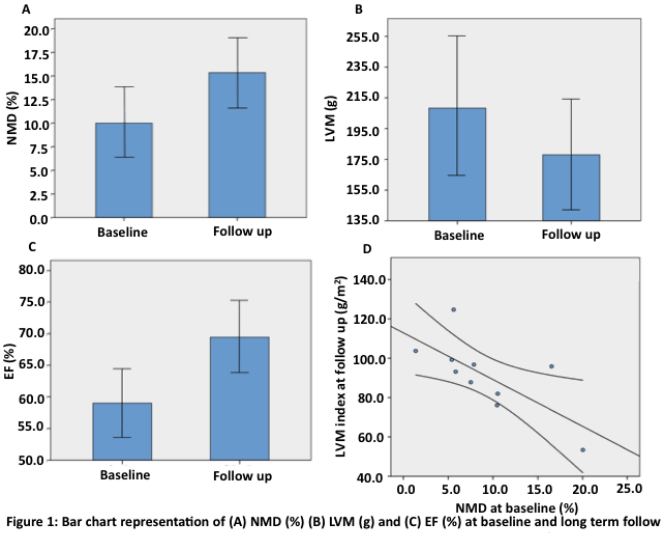


Figure 1: Bar chart representation of (A) NMD (%) (B) LVM (g) and (C) EF (%) at baseline and long term follow up. (D) Correlation between NMD at baseline (%) and LVM index at long term follow up (g/m2)

Conclusions: Cardiac structure and function significantly improved in the long term after kidney transplantation. The regression in LV hypertrophy, may be related to improvement in vascular distensibility.

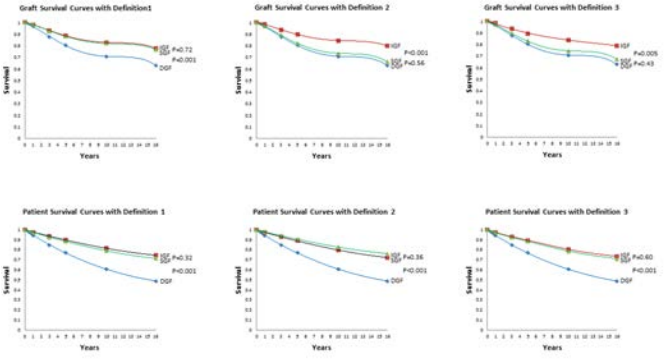
SA-PO449

Three Competing Definitions of Graft Function: Associations with Outcomes in Kidney Transplantation Ahmad M. Tuffaha,[1] Milind A. Phadnis,[3] Jonathan D. Mahnken,[3] James B. Wetmore,[2] Connie J. Wang.[2] *[1]Div of Nephrology, Univ of Kansas, Kansas City, KS; [2]Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; [3]Dept of Biostatistics, Univ of Kansas, Kansas City, KS.*

Background: We investigated how three competing definitions of post-kidney transplant (KT) graft function were associated with graft and patient survival.

Methods: A total of 1221 KT recipients were studied. In all three definitions (Def), delayed graft function (DGF) was defined as need for dialysis by postoperative (POD) 7. In Def 1, immediate graft function (IGF) was defined as a creatinine (Cr) reduction ratio between POD 1 and 2 ($CrRR_{1\text{-}2}$) of ≥30%, while slow graft function (SGF) was defined as $CrRR_{1\text{-}2}$ <30%. In Def 2, IGF was defined as Cr <3mg/dL by POD 5, and SGF as Cr ≥3mg/dL by POD 5. In Def 3, IGF was defined as Cr ≥1.5 or $CrRR_{1\text{-}3}$≥20% by POD 3, while SGF was Cr >1.5 and $CrRR_{1\text{-}3}$<20%. Association of each definition with time to graft failure and, separately, time to death was examined using a multi-regression model.

Results: For graft survival, there was a distinct difference between DGF and both IGF (p<0.001) and SGF (p=0.001), but no difference between IGF and SGF (p=0.72) for Def 1.



However, for both Def 2 and Def 3, there was no difference between DGF and SGF, while IGF was distinct from SGF and DGF (p<0.001 and p=0.005, respectively). In contrast, for patient survival, there was a distinct difference between DGF and both IGF (p<0.001 for all three definitions) and SGF (p<0.001 for all definitions), but no difference between IGF and SGF (p≥0.33 for all definitions).

Conclusions: Def 1 offers no value beyond the traditional dichotomy of requiring dialysis by POD 7. However, Def 2 and Def 3 utilize a useful construct, namely SGF, which categorizes patients as at risk for graft failure (like those with DGF) but not mortality (like those with IGF).

SA-PO450

Multi-Stakeholder Perspectives on the Relative Importance of Outcomes for Trials in Kidney Transplantation: An International Best Worse Scaling Survey Martin Howell,[1,2] Germaine Wong,[1,2,3] Benedicte Sautenet,[1] Nicole Evangelidis,[1,2] Jonathan C. Craig,[1,2] Allison Tong,[1,2] Kirsten Howard.[2] *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [2]School of Public Health, Univ of Sydney, Sydney, NSW, Australia; [3]Centre for Transplant and Renal Research, Westmead Hospital, Westmead, NSW, Australia.*

Background: To optimize the benefits of kidney transplantation, recipients and clinicians should have an agreed, shared management plan. This relies on prioritizing the same outcomes but patient experiences of transplantation and dialysis are likely to result in quite different preferences. As a sub study of the SONG-Transplant core outcome for clinical trials initiative, the aim was to evaluate the relative importance of outcomes in kidney transplantation.

Methods: Participants completed a best-worst scaling survey to elicit preferences for 16 critical outcomes identified by stakeholder consensus. Each participant was randomly assigned to five lists, each containing six of the outcomes and identified the most and the least important outcome from each list. Relative importance scores were calculated for each outcome and normalized to the range 0 (least important) to 1 (most important).

Results: In total, 334 (175 patients/caregivers, 149 health professionals) from 46 countries participated. Death was most important for health professionals (importance score 1.0 95% confidence intervals 0.92 to 1.07) compared to patients/caregivers where death (0.71:0.63 to 0.79) was ranked below graft function (0.94:0.87 to 1.00) and graft loss (0.82:0.75 to 0.88). In addition patients/caregivers placed greater importance on chronic and acute graft rejection, skin cancer, surgical complications and blood pressure, and less importance on hospitalization.

Conclusions: Patients consider graft function, graft loss, and chronic and acute rejection to be as important as death, or more important, compared to health professionals. This focus on graft-centric outcomes may reflect a strong aversion to returning to dialysis and equating graft dysfunction with graft loss.

Funding: Government Support - Non-U.S.

SA-PO451

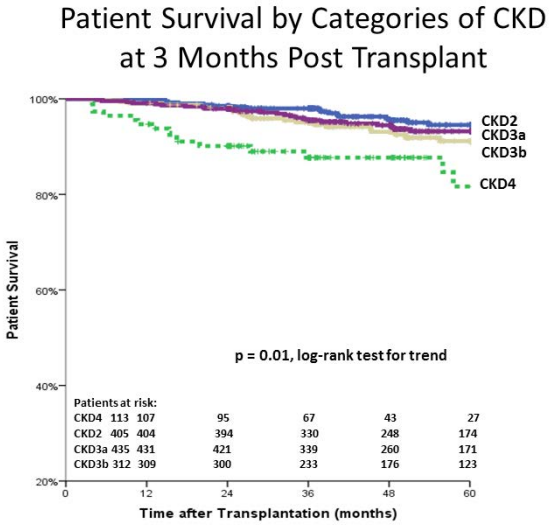
Impact of Early Graft Function on Patient Survival Post Kidney Transplantation Muna Alnimri, Angelo M. De Mattos. *Internal Medicine Section of Transplant Nephrology, UC Davis Medical Center, Sacramento, CA.*

Background: Early kidney allograft function affects pts survival post transplant.

Methods: single center historic cohort study. Adult recipients of kidney transplants between 1/2005 and 6/2013 were included. Pts with failed graft within 3 months or not followed for at least 2 years were excluded. MDRD formula was used to estimate GFR at 3 months. Categories of CKD were created according the NKF guidelines.

Results: 1,265 pts included.386(31%) had living and 879(69%)deceased donor(DD). 113 pts (8.9%) had CKD4, 312(25%) CKD3b, 435(34%) CKD3a, 405(32%) CKD2,at 3 months. Pts with CKD4 (57±12.3y) and 3b (55±12.9 y) were older than pts with CKD3a (52±13.6y) and 2 (50±14.1y)and received older kidneys (47±13.9 and 46±14y vs. 41±15.2 and 35±15y)p<0.001. CKD4 and 3b pts had higher proportion of DD(88% and 73%)vs CKD3a and 2 pts (61%,70%) p<.001. Years on dialysis, gender, diabetes, CAD were not

different among gps. At 2 years 32 pts (2.5%)expired (sepsis 11, cardiac/cva 11, cancers 6,other 4). CKD4 pts had higher mortality than pts with CKD3 or higher at 3 months (9.7% vs.1.8%; p<.001). Recipients of DD (2.8%, p=.001), and age (HR 1.085, 1.046-1.125, per year) were associated with higher mortality. Gender,DM,duration on dialysis, malignancy or CAD were not statistically significant. By multivariable (logistic regression) analysis: CKD4 (adjHR 3.9;1.75 – 8.92; p=.001)and age of recipient (adjHR 1.07; 1.025 – 1.117, p=.002) were the only factors associated with death within the first 2 years post transplant (model included DM, DD, donor age, CAD, years on dialysis).



Conclusions: Pts survival after kidney transplant seems related to early graft function ,older pts with CKD stage 4 post transplant have higher risk of death than other pts with better GFR 3 months post transplant , no specific cause of death was prevalent , this group of pts should be closely monitored.

SA-PO452

Economic Analysis of Survival for Patients Undergoing Kidney Transplant in Brazil Lucio Roberto Requiao-Moura,[1] Daniel Tavares Malheiro,[2] Silvia Regina Morgado,[3] Ana Carvalho Matos,[1] Alvaro Pacheco-Silva.[1] *[1]Renal Transplant Unit, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [2]Health Economy Dept, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [3]Management Dept, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: Brazil has one of the most important public programs of transplant in the world. However, there are few studies related to cost analysis in transplant in Brazil to support the maintenance of transplant as a therapy cost-effective. Aim: to perform an economic analysis of survival for kidney transplant patients in a philanthropic hospital.

Methods: We included in this study all admissions which resulted in cost related to kidney transplants, in all phases of transplant treatment (pre, transplant and post-transplant) of the year of 2014. Unit costs were associated to each health resource obtained from the hospital costing system. The unit costs of materials and medicines corresponded to the average direct costs of acquisition. For daily rates, tests and procedures unit costs corresponded to the fixed and variable costs associated with providing each service. Cost were collected in Brazilian Reais (R$) and converted to USD, considering the exchange rate from November 30th, 2014 (1USD=R$3.9). A survival analysis was done using the Cox model, using all kidney transplants performed since 2002 in our institution.

Results: The total cost used for kidney transplant program was U$ 6,015,160.77 in 2014. Considering the period of 2014, the cost was: in pre, transplant and post-transplant phases were $686,696.92, $1,283,362.56 and $4,045,201.28, respectively. The mean survival time was 4,497 days and the life expectancy calculated was 17 years in 922 patients included. Cost per patient per year of life-saved was $4,114.33.

Economic analysis	
Life expectation post transplant	17
Renal transplants performed in 2014	86
Life-saved years	1,462
Total cost of kidney transplant program in 2014	U$ 6,015,160.77
Cost per patient per year of life-saved	U$ 4,144.33

Conclusions: Kidney transplant was considered a cost-effective therapy since its value is lower than $50,000.00/year of life-saved, consumed in dialysis therapy.

SA-PO453

Evaluation of Baseline Allograft Biopsy and Long-Term Outcomes in Patients with Living-Donor Kidney Transplantation Takafumi Yamakawa,[1] Akimitsu Kobayashi,[2] Izumi Yamamoto,[2] Yasuyuki Nakada,[2] Takehiko Kawaguchi,[1] Toshiyuki Imasawa,[1] Takashi Yokoo,[2] Hiroshi Kitamura.[1] *[1]Nephrology, Chiba East Hospital, Chiba, Japan; [2]Nephrology, Jikei Univ, Minato-ku, Tokyo, Japan.*

Background: Donor shortage is a serious problem in kidney transplantation; consequently, increasing numbers of kidneys are from marginal donors or the elderly. Recent studies have shown that an evaluation of the baseline allograft biopsy may predict transplant outcomes in deceased-donor kidney transplantation. However, the pathology of the baseline allograft biopsy in living-donor kidney transplantation, including older donors, has not been fully validated.This study assessed the histological parameters of baseline allograft biopsy that affected the long-term graft survival in living-donor kidney transplantation.

Methods: Clinical data were examined in 192 patients who underwent living-donor kidney transplantation at Chiba East Hospital from April 2004 to April 2013. Patients experiencing rejection, BK virus nephropathy, and recurrent glomerular disease were excluded. All baseline biopsies were 1-hour biopsies and scored according to the Banff classification, and the relationship between the individual histological lesions and death-censored graft survival was assessed. Survival analysis was performed using Cox proportional hazards analysis and log-rank testing. We also evaluated the pathological findings in aging donor kidneys by stratification using donor age (under 50, 50 to 59, 60 to 69, over 70 years).

Results: The mean follow-up time after transplantation was 6.0 years. Arteriolar hyalinosis (HR, 2.16; 95% CI, 1.20–3.89; *P*=0.010) and glomerulosclerosis (HR, 3.64; 95% CI, 1.17–11.25; *P*=0.025) were significantly associated with death-censored graft survival, whereas interstitial fibrosis/tubular atrophy (IF/TA), and vascular intimal thickening were not. Although the prevalence of glomerulosclerosis, arteriolar hyalinosis, IF/TA, and intimal thickening were higher in the over-60 donor group, we could not predict graft survival using only donor age.

Conclusions: Arteriolar hyalinosis and glomerulosclerosis may be important pathological findings affecting long-term graft survival in living-donor kidney transplantation.

SA-PO454

Digital Quantification of Macrophage Abundance in a Cross Sectional Study of Native and Transplanted Kidneys Jessica Schmitz,[1] Abedalrazag Ahmad Khalifa,[1] Hermann G. Haller,[2] Hans Heinrich Kreipe,[1] Wilfried Gwinner,[2] Friedrich Feuerhake,[1] Jan H. Braesen.[1] *[1]Inst of Pathology, Hannover Medical School, Hannover, Germany; [2]Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Standardized markers based on quantitative and qualitative evaluation and localization of immune cell density in kidney biopsies may improve diagnostic accuracy.

Methods: Kidney biopsies were stained for macrophages using a monoclonal CD68 antibody, scanned (Leica) and whole slide images were analyzed for immunopositively stained area using a digital approach (Definiens Tissue Studio). Results were obtained separately for cortex, medulla and extrarenal tissue. Kidney biopsies were clinically indicated biopsies (native: 100%, KTx 64%). KTx biopsies partly came from the Hannover Protocol Biopsy Program (36%).

Results: CD68-positively immunostained area (% of the respective cortex, medulla, extrarenal area) was higher in KTx (n=368) vs. native kidney (n=134) biopsies (cortex: 2.9 vs. 1.0, medulla: 2.8 vs. 0.8, extrarenal tissue: 2.2 vs. 0.8; p<0.001). 38% of the studied KTx biopsies revealed rejection (borderline 15%, cellular 8%, humoral 7%, combined cellular and humoral 9%). Humoral and combined rejection were correlated with significantly increased macrophage infiltration (no rejection: cortex 2.6%, medulla 2.4%; borderline: cortex 1.9%, medulla 1.5%; cellular: cortex 2.5%, medulla 2.6%; humoral rejection: cortex 4.4%, medulla 5.9%; combined rejection: cortex 6.2%, medulla 6.9%). The density of macrophages correlated significantly with the time between transplantation and biopsy: Highest mean values were measured when post-transplant time exceeded 1 year (cortex: 5.8% compared to <1year >90 days (4.1%), <90 days >8 days (1.3%), <8 days (1.5%)) Evaluation of IF/TA according to Banff 2013 consensus showed a significant increase of infiltrating macrophages with fibrosis progression both in native and transplanted kidneys.

Conclusions: The findings suggest that macrophages have an essential in active rejection, chronic allograft injury and fibrosis. Digital morphological approaches may facilitate the characterization of immune cell-mediated kidney injury in native kidneys and after KTx.

SA-PO455

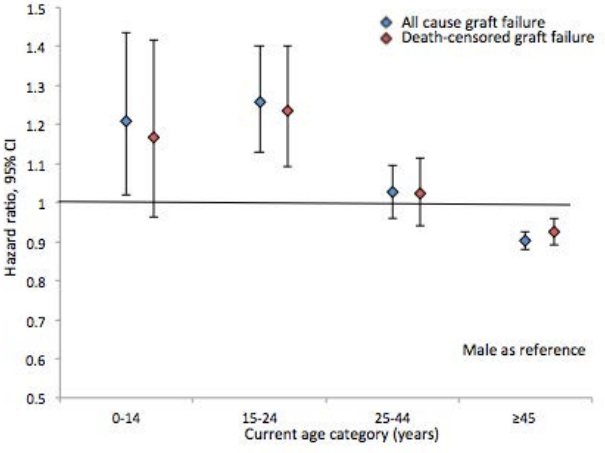
Sex Differences in Kidney Graft Outcomes Differ by Age Fanny Lepeytre,[1] Mourad Dahhou,[2] Xun Zhang,[2] Bethany J. Foster.[2] *[1]Hôpital du Sacré-Coeur de Montréal, Montréal, QC, Canada; [2]McGill Univ Health Centre, Montréal, QC, Canada.*

Background: Whereas studies of sex differences in graft survival among adult kidney transplant recipients showed conflicting results, several pediatric studies suggested poorer outcomes in females than males. We hypothesized that the impact of recipient sex on kidney graft survival differs by age.

Methods: We evaluated 159,417 patients recorded in the SRTR database who received a first deceased donor kidney transplant (1995-2013). We used time-dependent Cox models

to estimate the association between recipient sex and each of death-censored (DCGF) and all cause (ACGF) graft failure for patients of different ages. Models included a sex by current age (0 to 14, 15 to 24, 25 to 44, or ≥ 45 years) interaction term and the following covariates: race, primary disease, donor:recipient height ratio, donor age, donor sex, panel reactive antibody, and duration of dialysis pre-transplant.

Results: There were 66,562 graft failures and 37,564 deaths over a median of 4.9 years (IQR 2.0, 9.1). In multivariable models, females <25y had significantly higher risks of ACGF than males the same age (0-14y: HR 1.21 [95% CI 1.02, 1.43]; 15-24y: HR 1.26 [95% CI 1.40, 1.13]), and females ≥45y had significantly lower risks of ACGF than males the same age (HR 0.90 [95% CI 0.88, 0.93]). Compared with males of the same age, the risk of DCGF was significantly higher for females 15-24y (HR 1.24 [95% CI 1.09-1.40]) and lower for females ≥45y (HR 0.92 [95% CI 0.89-0.96]).



Conclusions: Female kidney transplant recipients <25y have a higher risk of poor outcomes than males of same age, whereas among those ≥45y, the risk of poor outcomes is higher for males than females. Differences in immune activation by sex, influenced by sex hormones, may play a role in these risk differences.

Opioid Use, Morbidity and Mortality in U.S. Kidney Transplant Patients

Paul L. Kimmel,[1] Kevin C. Abbott,[1] Chyng-Wen Fwu,[2] Paul W. Eggers.[1] *[1]DKUH, NIDDK, NIH, Bethesda, MD; [2]Social & Scientific Systems, Silver Spring, MD.*

Background: Pain is an important symptom for ESRD patients, linked to depression and diminished quality of life. Over the last 10 years, aggressive ESRD patient pain treatment has been advocated. The Medicare prescription drug benefit allows tracking ESRD prescriptions and linkage to outcomes. Few data exist on outcomes associated with pain and opioid medication prescription (OMP) in ESRD. The high prevalence of OMP and associated adverse events are increasingly evident. New Centers for Disease Control guidelines recommend caution in OMP. We assessed prevalence of OMP in kidney transplant patients, and associations between OMP and mortality and hospitalizations, with 2006–2010 USRDS data.

Methods: We limited our study sample to kidney transplant patients (≥365 d) with full Medicare Part A, B, and D coverage in each study year to ensure complete claim data. OMP was confirmed from Part D prescription claims. Cox proportional hazards regression models, controlled for demographic, ethnic, comorbidity and residence data examined associations of OMP in 2010 with subsequent all-cause death and hospitalization (2010 prevalent cohort; N=36,486).

Results: Approximately 14% of patients were prescribed 90 d opioids yearly. The most common OMPs in 2010 contained hydrocodone (6.4%) and oxycodone (3.8%). Patients with OMP for ≥90 d had increased death risk compared with those without (adjusted HR: 1.54 [95% CI, 1.38-1.71]). Short-term (1-89 d supply) and chronic OMP (≥90 d) also had increased hospitalization risk (1.20 [1.16-1.24] and 1.50 [1.44-1.57], respectively), compared with non-users. Rural transplant patients with OMP had higher mortality risk than their urban counterparts. Among individual opioids, hydrocodone, oxycodone, morphine, and hydromorphone were significantly associated with increased death risk.

Conclusions: Opioid drug prescription is associated with increased risk of death and hospitalization of ESRD transplant patients. While a causal relationship cannot be inferred, and opioid prescription may be an illness marker, efforts to treat pain effectively in ESRD transplant patients with less toxic interventions deserve consideration.

Everolimus with Low-Dose Tacrolimus versus Standard Immunosuppressive Regimen: Subgroup Analysis of Renal Function at 12 Months in De Novo Renal Transplant Patients

Fuad S. Shihab,[1] Yasir Qazi,[2] Shamkant P. Mulgaonkar,[3] Kevin M. Mccague,[4] Dharmesh Patel,[4] V. Ram Peddi,[5] David Shaffer.[6] *[1]Univ of Utah, Salt Lake City, UT; [2]Univ of Southern California, Los Angeles, CA; [3]Barnabas Health, West Orange, NJ; [4]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [5]California Pacific Medical Center, San Francisco, CA; [6]Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Reduction of tacrolimus (Tac) levels after kidney transplantation has a beneficial impact on renal function. The US92 study determined if everolimus (EVR) with low-dose Tac (LTac) is non-inferior to mycophenolate mofetil (MMF) with standard-dose tacrolimus (STac) on measures of allograft function and safety in de novo renal transplant patients. This post-hoc analysis of US92 assessed renal function of subjects with/without treated biopsy-proven acute rejection (tBPAR) or delayed graft function (DGF), and by induction therapy.

Methods: Subjects were randomized 1:1 to receive EVR (0.75 mg BID, adjusted to maintain trough level 3–8 ng/mL) + LTac (C0h 0–2 Months [M]: 4–7 ng/mL, 2–6M: 3–6 ng/mL, 6–12M: 2–5 ng/mL) or MMF (2 g/day) + STac (C0h 0–2M: 8–12 ng/mL, 2–6M: 7–10 ng/mL, 6–12M: 5–8 ng/mL).

Results: Despite some differences at M1, mean eGFR (MDRD) at M12 was similar between treatments irrespective of tBPAR, DGF or induction therapy (Table). In both treatment groups, subjects with tBPAR had lower eGFR at M12 vs. those without tBPAR. Improved eGFR from baseline was numerically greater in subjects with DGF vs. those without.

Conclusions: Renal function as assessed by eGFR was generally consistent between the US92 EVR+LTac and MMF+STac groups, regardless of tBPAR, DGF or induction therapy.

Follow-Up Results of HERAKLES Trial on Three Different Treatment Regimen and Switching off Effects in De Novo Renal Transplant Patients after 5 Years

Klemens Budde,[1] Oliver Witzke,[1] Bruno Vogt,[2] Petra Reinke,[1] Ingeborg A. Hauser,[1] Rolf A. Stahl,[1] Thomas Rath,[1] Martina Porstner,[3] Frank Lehner,[1] Volker Kliem,[1] Claudia Sommerer,[1] Wolfgang Arns.[1] *[1]Herakles Study Group, Germany; [2]Herakles Study Group, Switzerland; [3]Novartis Pharma, Germany.*

Background: To compare switching off effects from 3 different immunosuppressive (IS) regimen 5 years after renal transplantation (Tx).

Methods: 802 patients (pts) were included in this prospective, open-label, randomized, controlled multi-center study with observational follow-up (FU) to month (Mo) 60 post Tx. All pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids; at 3 Mo post Tx 499 pts were randomized 1:1:1 to either a) continue standard CsA (100-180ng/ml) +EC-MPS(n=166) (STD) or convert b) to an everolimus (EVR)-based calcineurin inhibitor (CNI)-free regimen (EVR 5-10ng/ml) +EC-MPS(n=171) or c) to an EVR (3-8ng/ml) regimen with reduced CsA (50-75ng/ml;n=162). All pts continued on steroids.

Results: After 5 years post Tx from initial ITT population there were 29% in CNI-free and 50% in STD group still on their initial assigned treatment and available for Mo 60 analysis. Switch as reported due to AEs occurred in 6% of STD, 5% CNI-free and 2% CNI-reduced pts during FU. Switch was performed at investigator discretion and for STD group mostly towards mTORi (EVR 21%, SRL 13%), in CNI-free group mostly towards Tac(48%) or CsA(50%). In the CNI-reduced group EVR was given in 47%, CsA in 56%, Tac in 29 % pts [drug combinations, sum can be >100%]. eGFR (Nankivell) at Mo 60 was significantly improved by +14.4 mL/min in CNI-free non-switcher population (74.7mL/min) over STD group ($p<0.001$), in switcher population (switched from CNI-free) eGFR was still 64mL/min. BPAR rate was similar in all 3 groups during FU (7.9% STD, 7.6% CNI-free, 7.5% CNI-reduced).

Conclusions: Mo 60 HERAKLES data show that EVR with reduced-dose or without CNI-exposure reflect an efficacious, safe therapeutic approach offering the opportunity for an individualized IS to minimize CNI-exposure. Pts who never switched off the assigned EVR-based CNI-free regimen showed a strong and significant improved renal function, pts that were switched back to a CNI-regimen still showed improved GFR.

SA-PO459

Development of a Bioartificial Kidney Device Dimitrios Stamatialis,[1] Natalia V. Chevtchik,[1] Michele Fedecostante,[2] Jitske Jansen,[2] Milos Mihajlovic,[2] Martijn J. Wilmer,[3] Marieke Rueth,[4] Rosalinde Masereeuw.[2] *[1]Biomaterials Science and Technology - MIRA Inst, Univ of Twente, Enschede, Netherlands; [2]Pharmaceutical Sciences, Utrecht Inst for Pharmaceutical Sciences, Utrecht, Netherlands; [3]Pharmacology and Toxicology, Radboud Inst for Molecular Life Sciences, Radboud Univ Medical Center, Nijmegen, Netherlands; [4]excorlab GmbH, Obernburg, Germany.*

Background: A key component of a bioartificial kidney device (BAK) is a "living membrane" consisting of a tight renal cell monolayer on an artificial porous membrane. Recently, we showed the creation of such a membrane using conditionally immortalized human renal proximal tubular epithelial cells (ciPTECs) on a polyethersulfone (PES)-based flat and hollow fiber membrane (HFM). Here, we present the development of an upscaled BAK system with "living" HFMs bringing the BAK closer to clinical implementation.

Methods: HFMs were mounted in modules and coated with L-Dopa and Collagen IV (CIV). The culture of ciPTECs with organic cationic (OCT) transporters was performed under static conditions. The ciPTEC morphology and monolayer quality was investigated via expression of tight junction protein Zonula Occludens-1 (ZO-1), permeation of inulin-FITC, fluorescent OCT substrate 4-(4-(dimethylamino)styryl)-N-methylpyridinium iodide (ASP^+) and of organic cationic solutes.

Results: The upscaling of the L-Dopa/CIV coating and seeding of the ciPTECs on the membranes was successful. After one week of culture, reproducible cell monolayers were formed within modules containing 3 HFMs and surface area of 4 cm^2. Tight monolayer ciPTECs culture was achieved with limited inulin leakage when compared to modules without cells (301 ± 103 and 812 ± 2 $pmol \cdot min^{-1} \cdot cm^{-2}$ respectively, $p < 0.001$, unpaired t-test). The ASP^+ uptake by the cells was reduced by 60% in presence of uremic toxin mix or cimetidine, confirming the functional cell monolayer.

Conclusions: Upscaled HFM modules supporting a functional monolayer of renal cells were successfully developed. Future work will include detailed characterization of protein-bound uremic toxin transport.

SA-PO460

Mixed Matrix Membranes for Removal of Protein-Bound Toxins from Human Plasma Dimitrios Stamatialis,[1] Denys Pavlenko,[1] Karin G. Gerritsen,[2] Esmée Van Geffen.[1,2] *[1]Dept of Biomaterials Science and Technology/MIRA Inst, Univ of Twente, Enschede, Netherlands; [2]Dept of Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Protein-bound toxins (PBT) accumulate in uremic patients due to their poor removal by conventional hemodialysis. Their removal can be improved by a mixed matrix membrane (MMM), which combines adsorption and diffusion. In this work, we developed a low flux MMM and compared its performance to a conventional low-flux dialyzer used in the clinic.

Methods: The inner and outer layers of hollow fiber MMM were produced using a polymer blend of polyethersulfone/ polyvinyl-pyrrolidone. Activated carbon was loaded in the outer polymer matrix layer for adsorption of PBTs. The membranes were characterized by scanning electron microscopy (SEM), clean water flux experiments and dialysis/adsorption experiments with plasma spiked with uremic concentrations of the PBTs indoxyl sulfate (IS) and p-cresyl sulfate (pCS). Low flux dialyzer F8HPS (Fresenius) was used for comparison.

Results: By optimizing spinning conditions, we produced new MMM fibers with inner diameter of 450µm (inner diameter of F8HPS 200 µm) and inner membrane layer thickness of 21 µm. The MMM have a lower ultrafiltration coefficient (UC) in comparison to F8HPS (3.4±0.8 versus 10 $ml/h/m^2/mmHg$, respectively) and molecular weight cut-off of around 12 kDa. Despite this lower UC, the MMM showed improved removal of PBTs in comparison to F8HPS, due to the additional adsorption of toxins by the activated carbon (maximum removal of 367±14 versus 187±12 mg/m^2 for IS and 380±54 versus 225±3 mg/m^2 for pCS.

Conclusions: We developed MMMs with optimal characteristics offering superior ability in removing PBTs in comparison to a commercial dialyzer. Acknowledgment.This work is funded by the EU Marie Curie ITN Project BIOART (grant no.316690, EU-FP7-PEOPLE-ITN-2012).

Perfused Glomerular Microvascular Unit: A Glomerular Pathophysiology Model Claire Rigothier,[1,2] Killian Flegeau,[1] Sebastien Rubin,[1,2] Simon Mucha,[1,2] Raphael Devillard,[1] Jerome Kalisky,[1] Christian Combe.[1,2] *[1]BIOTIS, INSERM U1026, Univ de Bordeaux, Bordeaux, France; [2]Service de Néphrologie, Transplantation et Dialyse, CHU de Bordeaux, Bordeaux, France.*

Background: The development of an artificial glomerular unit may be pivotal for renal pathophysiology studies at a microscopic scale. Using a tissue engineering approach, the project will reproduce the glomerular architecture by performing a glomerular perfused microfiber.

Methods: Human immortalized glomerular cell lines: podocytes and endothelial cells (EC) were used. Cells and 3-dimensional (3D) matrix have been characterized by immunofluorescence (IF) with confocal analysis and Western blot (WB). Optical microscopy was performed to study microfiber compaction and contraction. We also analyzed cell viability and cell metabolism within the 3D construct. Femtosecond laser was used to create the central lumen of microfibers.

Results: Using the microfiber method developed in the unit, we repeatedly obtained a cellularized microfiber sorting human glomerular cells in 3D. Around a central structure made of collagen I, we successively found the internal layer composed by EC, the neoformed glomerular basement membrane rich in collagen IV and the external layer of podocytes. Cell concentration, optimal seeding time and role of physical stresses were appreciated and modulated to obtain the microfiber. Cell viability and cell phenotype were confirmed by IF and WB analysis: expression of specific proteins, vWF, PECAM and VEGFR2 for EC and nephrin, synaptopodin and podocin for podocytes. Cell characteristics were maintained after central lumen formation by femtosecond laser for planned microfiber perfusion.

Conclusions: In summary, with this microfiber technique, endothelial cells and podocytes were better differentiated than in culture dishes, and produced a differentiated GBM. Glomerular fluid stresses and glomerular pathophysiological conditions will be shortly simulated in the glomerular microfibers using the microperfusion method. A glomerular microvascular network will allow us to study cell interactions in a 3D system and increase our knowledge on the glomerular pathophysiology.

SA-PO462

An Upscaled Bioartificial Kidney Device with an Apically Oriented Inflammatory Response upon LPS Exposure Michele Fedecostante,[1] Natalia V. Chevtchik,[2] Milos Mihajlovic,[1] Dimitrios Stamatialis,[2] Rosalinde Masereeuw.[1] *[1]Pharmacology, Utrecht Inst for Pharmaceutical Sciences, Netherlands; [2]Biomaterials Science and Technology, MIRA Inst for Biomedical Technology and Technical Medicine, UTwente, Netherlands.*

Background: The development of a bioartificial kidney (BAK) device for removal of protein-bound uremic toxins in plasma is needed to improve current therapy for end stage renal disease patients. Here, we investigated monolayer formation and immune response of human conditionally immortalized proximal tubule epithelial cell (ciPTEC) when cultured in an upscaled BAK device.

Methods: CiPTEC were cultured for 10 days on the outer surface of 3 assembled double-coated (L-DOPA (2 $mg \cdot ml^{-1}$) and collagen IV (25 $\mu g \cdot ml^{-1}$)) Polyethersulfone hollow fiber membranes (HFM, 4 cm^2 surface). Cell barrier integrity was investigated by immunostaining and inulin-FITC leakage. Immune response was assessed by ELISA measurements of IL-6 and IL-8 upon 24h lipopolysaccharide (LPS, 10 $\mu g \cdot ml^{-1}$) exposure.

Results: Tight monolayer of ciPTECs was achieved on HFM-BAK devices as shown by immunostaining and low inulin leakage compared to double-coated cell-free devices (244 ± 68 vs 1575 ± 128 $pmol \cdot min^{-1} \cdot cm^{-2}$, $p<0.001$, seeded vs. unseeded devices, resp.). Exposure of BAK devicesto LPS at the apical side resulted in pro-inflammatory cytokines release, which was more pronounced in the apical compartment (IL-6: 992 ± 53 *vs.* untreated: 17 ± 14; IL-8: 74 ± 10 *vs.* untreated: 5.8 ± 2.5; $ng \cdot cm^{-2}$) compared to the basolateral compartment (IL-6: 1.7 ± 1.4 *vs.* untreated: 2.0 ± 1.2; IL-8: 1.0 ± 0.5 *vs.* untreated: 0.4 ± 0.2 $ng \cdot cm^{-2}$). When BAK devices were exposed to LPS from the basolateral side, the cytokine response was 10.4±2.4- and 1.9±0.1-fold lower for IL-6 ($p<0.05$) and IL-8 as compared to apically exposed devices, respectively. This was also confirmed by immunostaining of Toll-like receptor 4 at the apical surface.

Conclusions: This study demonstrates an upscaled BAK device of renal epithelial cells on HFM with tight monolayer formation, good barrier function and polarized cytokine release upon LPS exposure. *Funding.* EU Marie Curie ITN Project BIOART (grant no.316690, EU-FP7-PEOPLE-ITN-2012).

Genome Engineering of Renal Epithelial Cells with the Goal of Improved Function in an Implantable Artificial Kidney Matthew H. Wilson,[1,2] Wentian Luo,[1] Rick C. Welch,[1] Shuvo Roy,[3] William Henry Fissell.[1] *[1]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [2]Nephrology, VA Medical Center, Nashville, TN; [3]Bioengineering and Therapeutic Sciences, Univ of California San Francisco, San Francisco, CA.*

Background: Development of an implantable artificial kidney (IAK) will require renal epithelial cells capable of reabsorption of salt and water. We are using genome engineering to bioengineer cells for improved Na+/H+ exchange and H20 reabsorption. The *piggyBac* transposon system offers a simple but highly efficient non-viral strategy for genome engineering cells to stably overexpress one or more transgenes simultaneously. The *piggyBac* transposase enzyme integrates transposon DNA containing one or more transgenes into the genomic DNA of cells via a cut-and-paste mechanism.

Methods: Standard molecular biology techniques were used to subclone the human sodium hydrogen exchanger 3 (NHE3) and aquaporin-1 (AQP1) cDNAs into *piggyBac* transposon vectors. The NHE3 transgene was engineered with a C-terminal hemagglutinin (HA) epitope tag. The AQP1 transgene contained flag and myc epitope tags. The *piggyBac* transposase was then co-delivered with these transposons to stably integrate and overexpress NHE3 or AQP1 in cultured renal epithelial cells.

Results: We generated MDCK cells stably expressing a cumate inducible NHE3 and confirmed cumate-induced overexpression via Western blot and immunofluorescence analysis of the HA tag. Confocal microscopy confirmed apical expression of NHE3 in polarized MDCK cells. We also generated MDCK cells stably overexpressing AQP1. Overexpression of AQP1 was confirmed using Western blot and immunofluorescence assays of the flag and myc tags.

Conclusions: We are currently also overexpressing NHE3 and AQP1 in cultured human renal proximal tubule cells (RPTECc). Cellular transport assays are ongoing to evaluate for increased capability in moving salt and water across a genome engineered cellular monolayer. These studies will allow us to determine the optimally genome engineered renal epithelial cell type for maximal function in the IAK.

Transport by Renal Tubule Cell Bioreactor Is Dependent on Extracellualr Matrix Choice Harold D. Love,[1] Nicholas J. Ferrell,[1] Jin Cheng,[1] Shuvo Roy,[2] William Henry Fissell.[1] *[1]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [2]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA.*

Background: Renal tubule cell bioreactors are of interest for in vitro disease models, high-throughput drug and toxicity testing, and renal replacement therapy. The parameter space to be exploited in optimizing in vitro cell phenotype is extensive. There are several commercially available extracellular matrix preparations available to facilitate cell-scaffold attachment, leading to the question of whether any one matrix was associated with particular phenotypic features.

Methods: Primary human renal tubule cells (HRTC) were grown to confluence on Transwell inserts preincubated with Collagen IV, Collagen I, Laminin, Matrigel, or fibronectin, with and without 50 uM ascorbic acid. TEER and inulin leak rates were measured to verify confluence. Apicobasal volume transport was measured in the presence and absence of ouabain, an inhibitor of basolateral sodium-potassium ATPase.

Results: HRTC grew to confluence on all substrates. Inulin leak rates were not different from a control well bearing an impermeable substrate. Transport rates were different in the presence and absence of ouabain ($p = 5.6 \times 10^{-10}$ by ttest). Transport rates differed between matrices (p=0.006 by one-way ANOVA). Fibronectin and laminin displayed highest volume transport. When cells were cultured in the presence of ascorbic acid, transport was not significantly different between substrates ($p > 0.08$ by one-way ANOVA).

Conclusions: Choice of extracellular matrix substrates influences apicobasal transport in bioreactors, but adding cofactors for basement membrane synthesis to the culture medium abolishes differences arising from initial matrix choice.

Respiratory Capacities and Differentiation of Novel Gluconeogenic Renal Cell Lines Harold D. Love,[1] Jin Cheng,[1] Shuvo Roy,[2] William Henry Fissell.[1] *[1]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [2]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA.*

Background: The renal proximal tubule relies on oxidative phosphorylation to carry out metabolically intensive transport. Cultured primary cells rapidly switch to a less differentiated glycolytic phenotype characteristic of most immortalized renal cell lines. Glucose starvation of non-gluconeogenic cell lines can induce and select for cells that have switched on gluconeogenesis as a survival mechanism, as glucose is essential for the production of ribose-5-phosphate, a precursor for nucleic acid biosynthesis. The selective pressure of glucose starvation not only induces gluconeogenesis, but the cells also exhibit other unique features that are characteristic of renal proximal tubular epithelial cells.

Methods: LLC-PK1 cells were adapted to serum-free media and starved of glucose after the method of Gstraunthaler and Handler. Gluconeogenic colonies were isolated and expanded in glucose-free medium. Initial characterization of the mitochondrial oxidative capacity and glycolysis was carried out using a 96-well high throughput Seahorse Bioscience assay.

Results: Numerous colonies of cells growing in glucose-free medium appeared after 3-4 weeks, and were sub-cloned and expanded. The phenotypic appearance of the colonies was quite variable, with many showing a pronounced differentiation compared to the parental cells. Cells typically formed compact, very dense monolayers, with extensive dome formation, even in very small colonies. Cell proliferation was observed primarily in peripheral cells, while contact inhibited cells rapidly differentiated. Initial characterization of cell lines found significant differences in oxygen consumption rates and glycolysis, compared to parental control cells, with and without glucose.

Conclusions: Gluconeogenic cell lines were induced from LLC-PK1 cells by culturing in glucose-free media. Several cell lines had a more differentiated appearance and enhanced oxygen consumption with reduced glycolysis, compared to parental cells. Preliminary results suggest that cell lines with enhanced renal function *in vitro* can be obtained via forced gluconeogenesis.

Sugars Alter the Mechanical Properties of Renal Tubular Basement Membrane Nicholas J. Ferrell. *Div of Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Diabetic nephropathy is characterized by loss of extracellular matrix (ECM) homeostasis in the kidney that results in thickening of the tubular basement membrane (TBM). In addition, hyperglycemia alters the biochemical structure of the ECM through formation of advanced glycation end-products that can crosslink the ECM and may alter the mechanical properties of the TBM. The mechanical properties of ECM play an important role in maintaining tissue function, and altered biophysical properties may affect disease progression. The goal of this work was to determine if incubation of renal tubules in sugars ex vivo alters the mechanical properties of TBM.

Methods: Tubules were manually dissected from the outer cortex of normal mouse kidneys. Tubules were incubated ex vivo in 100 mM glucose, 100 mM ribose, or PBS for four weeks. Stress-strain response of individual tubules was evaluated using a microcantilever-based tensile testing method. The stiffness (elastic modulus) of the tubular basement membrane was evaluated at strain ranges of 0-10%, 10-20%, and 20-30% strain by determining the slope of the linear regression of the strain-strain curves over those strain ranges.

Results: Glucose and ribose incubation resulted in a statistically significant ($p<0.05$) increase in the TBM stiffness over all strain ranges that were tested. Glucose incubated tubules had stiffness of 767±96 kPa, 1244±135 kPa, and 1944±200 kPa at strain ranges of 0-10%, 10-20%, and 20-30%, respectively. Ribose incubated tubules had stiffness of 1116±175 kPa, 2773±375 kPa, and 4342±413 kPa over the same strain ranges. This is a 2.2-2.6 fold increase in stiffness for glucose incubated tubules and a 3.8-5.2 fold increase in ribose incubated tubules compared to controls.

Conclusions: These data show that incubation of tubules with sugars is alone sufficient to alter TBM stiffness over a relatively short period of time. Both glucose and ribose increased TBM stiffness. Due to its higher reactivity, ribose had a more pronounced impact on TBM stiffness. These data suggest sugars may alter the biophysical properties of kidney extracellular matrix. These changes may play a role in disease progression in diabetic nephropathy.

Evaluation of Renal Cells for In Vitro Modeling of Proximal Tubule Drug Transport Aishwarya Jayagopal, Shuvo Roy, Deanna L. Kroetz. *Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA.*

Background: Active transport by renal proximal tubules plays a significant role in human drug disposition and is therefore important to model when developing drugs. Although several proximal tubule cell lines exist, limited data are available regarding their ability to act as acceptable models of the tubule. Here, several cell lines are compared with respect to monolayer formation, drug transporter expression and function, and cilia function.

Methods: hOCT2/hMATE1 double transfected (DT) MDCK cells, SV40 immortalized Human Proximal Convoluted Tubule (HPCT) cells, and hTERT immortalized Renal Proximal Tubule Epithelial Cells (RPTEC) were cultured on transwell inserts. Tight junctions and cilia were confirmed by immunofluorescence, monolayer tightness was measured by quantifying inulin leak through cells and RNA expression was measured by qRT-PCR. Transporter function was measured by quantifying cellular uptake and transport of substrates (+/- inhibitor). Cells were deciliated with 30 mM ammonium sulfate.

Results: All cells formed tight junctions as demonstrated by ZO-1 expression, but showed varying levels of monolayer tightness with MDCKs at ~1%, HPCTs at ~7%, and RPTECs at ~10% inulin leak. Both human cell types tested had comparable RNA expression levels of OCT2, MATE1, OAT3 and MRP4 (~ΔCT of: 14-15, 12-13, 15 and 5-9 respectively), while double transfected MDCK cells had high expression levels of OCT2 and MATE1 (~ΔCT of -2 and -4 respectively). Both DT-MDCK cells and HPCT cells showed inhibitable uptake and transport of ASP+ and Metformin. Lastly, both MDCK and HPCT cells grew cilia that could be removed without effects on tight junction formation, RNA expression of transporters and transporter function.

Conclusions: While overexpressing MDCK cells exhibit the best performance, both human proximal tubule cell lines show promise as potential models of human tubular function. Studies are ongoing to incorporate these cells into an engineered device to mimic renal drug elimination.

Kidney-Specific Gene Transfer by Hydrodynamic Renal Pelvis Injection Lauren Elizabeth Woodard,[1] Jizhong Cheng,[2] Rick C. Welch,[1] Felisha M. Williams,[1] Wentian Luo,[1] Matthew H. Wilson.[1] *[1]Dept of Medicine, Div of Nephrology, Vanderbilt Univ Medical Center/Veterans Affairs, Nashville, TN; [2]Dept of Medicine, Div of Nephrology, Baylor College of Medicine, Houston, TX.*

Background: New breakthroughs in the treatment of kidney disease are desperately needed to address the increasing shortage of organs available for transplantation and high mortality associated with dialysis. The first commercial gene therapy products have recently become available. Gene transfer to the mouse kidney is desirable both in terms of providing proof-of-concept for gene transfer to address genetic diseases and for the creation of new disease models.

Methods: We found that a fast injection into the renal pelvis with a DNA solution of sufficient volume was effective for delivery of plasmid DNA to the adult mouse kidney, with no other organs expressing the transgene by live animal imaging for luciferase. We used the *piggyBac* transposon system to permanently integrate the luciferase transgene and found that the EF1alpha promoter provided superior long-term gene expression.

Results: Staining for TdTomato revealed expression in a variety of cell types, including proximal tubules, located in punctate areas of expression along the injection path as traced by fluorescent beads. In order to assess the degree of damage caused by the injection, we performed renal pelvis hydrodynamic injections on mice that had undergone a unilateral nephrectomy. We found mice receiving injections had a significantly increased B.U.N. as compared to sham controls at two days following surgery that resolved completely within

two weeks. To test the effect of the immune response on long-term gene expression, we treated mice with cyclophosphamide and observed increased levels of luciferase expression compared to sham controls.

Conclusions: Hydrodynamic renal pelvis injection of naked DNA produced transgene expression in many cell types. Higher levels of long-term expression were achieved with transposons for permanent integration and cyclophosphamide for immunosuppression. We are currently testing hydrodynamic renal pelvis injection of biologically relevant transgenes for treatment of cystinuria, acute kidney injury, and anemia.

Targeting Kidney Pericytes with Adeno-Associated Virus: A Novel Method for Gene Therapy Yoichiro Ikeda,[1] Xiao Ru,[2] Luk Vandenberghe,[2] Benjamin D. Humphreys.[1] *[1]Div of Nephrology, Washington Univ in St. Louis, St. Louis, MO; [2]Schepens Eye Research Inst, Boston, MA.*

Background: Kidney perciytes are the major myofibroblast progenitor population and an important therapeutic target. There is no method to deliver genetic material to kidney pericytes, however. Recombinant adeno-associated virus (AAV) is non-integrating and infects both dividing and quiescent human cells and has emerged as a powerful viral vector for human gene therapy. Here we systematically evaluated the ability of AAV serotypes to transduce kidney pericytes.

Methods: We tested six different AAV capsid serotypes (2/2, 2/5, 2/6, 2/8, 2/9, 2/Anc80) with either the CMV or the synthetic 'CASI' promoter driving GFP or Cre recombinase. These were injected either into WT or R26TdTomato reporter mice and expression patterns evaluated in healthy and fibrotic kidneys.

Results: Among the 6 serotypes, AAV-2/8 and -2/Anc80 had the highest GFP expression in kidney. The CASI promoter drove higher per-cell expression than CMV, but the distribution was equivalent. Dose dependent expression was observed between the doses of 10^{10} - 10^{12} genome copies/mouse without toxicity. Expression was maximal 2-3 weeks after injection. Expression was limited to interstitial pericytes, mesangial cells and to SLC12A1+ macula densa epithelial cells. Since GFP expression was low in some cells, we used injected Cre recombinase AAV into R26TdTomato reporter mice to increase signal. At 10^{11} genome copies/mouse, we measured transduction of 17.6±12.4% of pericytes and 88.6±10.0% of mesangial cells. However at 10^{12} GC/mouse, 96.6±3.5% of PDGFRb+ pericytes were infected as well as 97.2±2.7% of mesangial cells. At the medium dose, AAV2/8-labeled pericytes differentiated into aSMA+ myofibroblasts after UUO, and 41.4±15.4% of aSMA+ interstitial area was TdTomato positive. Additional data validating this technique for knockout of floxed pericyte genes will be presented.

Conclusions: We demonstrate a novel AAV approach to deliver genetic material to nearly all kidney pericytes and mesangial cells. These results suggest the possibility of AAV-based gene therapies for kidney fibrosis.

SA-PO470

Immunoprotection of Renal Epithelial Cells by Silicon Nanopore Membranes Shuvo Roy,[1] William Henry Fissell.[2] *[1]UCSF, San Francisco, CA; [2]Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Immunoisolation of macroencapsulated renal cells is a fundamental requirement for an implantable bioartificial kidney that will circumvent the need for immunosuppressants. Silicon nanopore membranes (SNM) with precisely engineered pore dimensions have exhibited superior mass transfer and molecular selectivity characteristics for implanted hemofiltration. In this study, we investigated SNM competence for the protection of renal epithelial cells from an inflammatory cytokine known to induce necrosis and apoptosis.

Methods: Four different types of renal epithelial cells (MDCK, HK2, LLC-PK1, and HPTCs) were grown to confluence on SNM with 7-nm wide slit pores. Transwell chambers were used as the control membranes. The cells were exposed to 500 ng/ml human tumor necrosis factor-α (TNFα) for 6 hours and the subsequent monolayer integrity was assessed via transepithelial electrical resistance (TEER), cell viability assay, and immunohistochemistry (IHC) techniques.

Results: Without TNFα, cells on both Transwell and SNM maintained their monolayer integrity by expressing zona occludens (ZO1) protein at the intercellular junctions. TEER values were 100-150 ohm-cm2 and 580-620 ohm-cm2 on Transwell and SNM, respectively. For Transwells, TNFα disrupted epithelial tight junctions resulting in a decrease in TEER and 10 fold increase of cell apoptosis. In contrast, with SNM, cells maintained monolayer integrity with minimal changes in TEER and cell viability.

Conclusions: SNM perform an immunoisolation function that can be adapted for the development of an implantable bioartificial kidney.

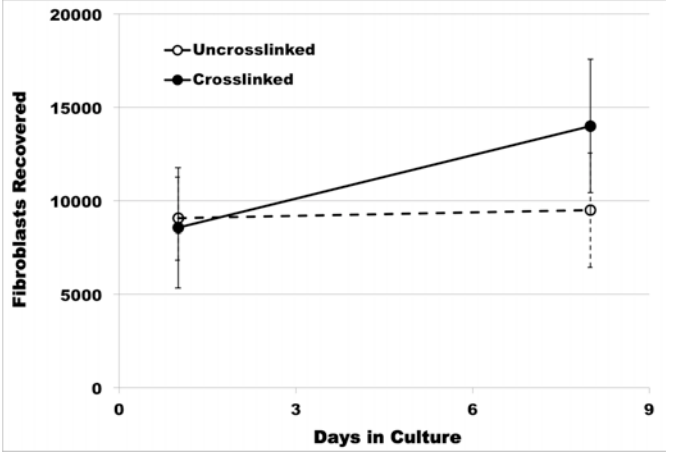
Cell Proliferation on Crosslinked Perfusion-Decellularized Kidney Organ Scaffolds Edward A. Ross,[1] Alexey Goloubev,[1] Andres Rubiano,[2] Alicia R. Brown,[1] Chelsey Simmons,[2] Bradley J. Willenberg.[1] *[1]Univ of Central Florida, Orlando, FL; [2]Univ of Florida, Gainesville, FL.*

Background: The repopulation of decellularized whole kidneys is a tissue engineering approach to solve the shortage of donor organs for transplantation. A major challenge has been consistent adhesion and growth of seeded cells. We hypothesize that the problem is methodologic in that decellularization and sterilization protocols (e.g. chemical, radiation) can reduce tissue rigidity, making it a suboptimal substrate for cell attachment and proliferation; repopulation would be restored by stiffening the matrix by chemical crosslinking. Therefore, we prepared uncrosslinked and crosslinked sections of decellularized porcine kidneys and studied the growth of cells on the biomaterials.

Methods: Perfusion-decellularized kidney scaffolds were prepared as previously described. Cortex was sectioned to ~0.25cm^2 and crosslinked using *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbodiimide hydrochloride (EDC, 0.007M) and *N*-hydroxysulfo-succinimide (0.007M) at 4°C for 21h. A custom milli-indention system quantified stiffness. Human lung fibroblasts (1×10^5) were seeded and cultured on uncrosslinked and crosslinked sections. After days 1 and 8 cells were isolated using collagenase and mechanical dissociation, and then counted using a hemocytometer.

Results: Crosslinking with EDC increased tissue stiffness as we previously described, with increased steady-state elastic modulus of decellularized kidney scaffold sections ~4× compared to uncrosslinked sections. We now report day 1 to 8 culture results, showing fibroblast proliferation was greater on crosslinked scaffolds.



Conclusions: Growth of human lung fibroblasts is enhanced by EDC crosslinking, supporting our hypothesis that stiffer perfusion-decellularized organ scaffolds enhance the proliferation of anchorage-dependent cells.

SA-PO472

Visualizing and Quantifying the Luminescent Kidney in 3D Neal A. Paragas,[1] Alexander Klose.[2] *[1]Medicine, Univ of Washington, Seattle, WA; [2]In Vivo Analytics, Inc, New York, NY.*

Background: We have developed a platform system to monitor and quantify luminescence with the multispectral bioluminescence tomography (BLT) co-registered to a novel digital mouse atlas. Permitting for the first time quantification of a luminescent signal in a cell specific manner. This will allow us to non-invasively uncover the changes occurring temporally and spatially to tubular epithelial cells of the kidney.

Methods: We modeled different compartments of the kidney by creating a Podocin, Slc34a1, and HoxB7 luciferase reporter animals. First, we acquired bioluminescence images with a bioluminescent optical imager at six different spectral windows centered at 580, 600, 620, 640, 660, and 680 nm and with bandwidth of 20 nm. The multi-orientation images were acquired using a mirror gantry for simultaneous imaging of the dorsal, ventral and side views. The animal was placed in a fixed position into a novel body shape conforming animal mold, placed onto the mirror gantry and spectral images were acquired. The light intensity imaging data became input to a novel BLT reconstruction algorithm based on an expectationmaximization (EM) method and the simplified spherical harmonics (SP3) equations for modeling in vivo light propagation. Post reconstruction, we calculated the total photon emission density of a volume of interest (VOI).We then calculated cell specific luciferase expression co-registering it to a novel digital mouse atlas.

Results: Our new system using the EM method reconstructed the 3D photon emission of Podocin, SLC34a1 and Hb7-luciferase expressing animals and mapped the signal to a novel organ probability map. For the first time, we could demonstrate the feasibility of quantifying cell number non-invasively in the kidneys.

Conclusions: The ability to do non-invasive tomographic reconstruction of the kidney using bioluminescence will be a powerful tool to monitor segmental changes after renal injury.

Isolation and Transcriptomic Analysis of Distinct Cell Populations from Mouse Renal Collecting Duct Lihe Chen,[1] Jae Wook Lee,[2] Chung-Lin Chou,[1] Susan M. Wall,[3] Dennis Brown,[4] Mark A. Knepper.[1] *[1]National Heart Lung and Blood Inst; [2]National Cancer Center, Korea; [3]Emory Univ School of Medicine; [4]Massachusetts General Hospital; [5]National Heart Lung and Blood Inst.*

Background: The renal collecting duct contains both principal cells (PCs) and intercalated cells (ICs). To better understand these cells, a reliable, high-yield isolation technique and systematic transcriptomic profiling are needed. To identify cell surface markers for ICs, we previously used transgenic mice that express GFP-driven by the

Atp6v1b1 promoter to enrich ICs. Transcriptomic analysis of these cells identified c-kit expression in these cells (confirmed by immunofluorescence microscopy). Previous studies have shown that *Dolichos biflorus* agglutinin (DBA) preferentially binds to mouse collecting duct principal cells.

Methods: We used DBA and an antibody to c-kit to isolate two populations of cells from mouse renal cell suspensions using FACS. The cell populations were characterized by RNA sequencing (RNA-Seq) using an Illumina HiSeq2500 platform.

Results: The average transcriptome depth was 11500 genes for DBA^+ cells (FPKM>1, n=2) and 11200 genes for c-kit^+ cells (FPKM>1, n=2). Based on mean c-kit/DBA FPKM ratio, the 10 top transcripts included several known IC markers, viz. Slc4a1, Oxgr1, Aqp6, Kit, Avpr1a, and Atp6v1g3, plus Tmem61, Dmrt2, Asb15 and Igkc, which have less well defined roles in ICs. Based on mean DBA/c-kit FPKM ratio, the 10 top transcripts included several known PC markers, viz Aqp4, Aqp2, and Fxyd4, plus Ptgds, C3, Ighj1, Epor, Ccl12 and Npnt, which have less well defined roles in PCs.

Conclusions: The profiling results confirmed that this flow-sorting method can isolate distinct cell populations that are enriched in PCs and ICs. The identification of additional IC and PC specific genes points to additional molecular functions of the two cell types.

SA-PO474

Identification of Biomarkers Associated with Progressive Fibrosis in Renal Transplant Patients Using High-Definition Fourier-Transform Infrared Imaging

Vishal K. Varma,[1] Sanjeev Akkina,[2] Suman Setty,[1] Michael J. Walsh.[1] *[1]Dept of Pathology, Univ of Illinois at Chicago, Chicago, IL; [2]Dept of Nephrology, Loyola Univ Chicago Health Sciences, Chicago, IL.*

Background: Renal allografts are often lost due to progressive accumulation of chronic changes as a consequence of rejection and infection. Close monitoring of grafts by surveillance biopsies to detect subclinical complications and apply corrective measure may prolong the life of the graft. Here we identify biochemical markers associated with progression of interstitial fibrosis in renal transplant biopsies using label free chemical imaging technique, Fourier-transform infrared (FT-IR) imaging.

Methods: A pilot study focused on identifying 5 patients with no progression of interstitial fibrosis (non-progressors) and 5 patients with an increase in interstitial fibrosis over time (rapid progressors). Serial sections were acquired and stained with Masson trichrome stain and imaged using chemical imaging. An early (3-4 months) and a late (6-24 months) time point protocol biopsy for each patient was analyzed and the difference between the rapid progressors and non-progressors groups were analyzed using the chemical information extracted from areas of fibrosis. Clinical data and other relevant information was used to further increase our understanding of the biochemical signature obtained from FT-IR imaging.

Results: Multivariable analysis of the collected chemical data allows us to use early biopsies to segregate between rapid progressors vs non-progressors. The biochemical signatures between the early biopsies from the rapid progressors and non progressors cohorts were distinct suggesting different underlying biochemical reactions in the two groups. In addition, these changes were noted in late biopsies as well.

Conclusions: The data shows promise as we have identified a number of biochemical markers that are associated with the advancement of interstitial fibrosis. In addition, we have highlighted a 'biochemical-signature' that may be predictive of the later interstitial fibrosis, using baseline biopsies. Additional cases should allow us to validate these preliminary findings.

Differential Urinary Proteome Analysis of IgA Nephropathy Using 2D-LC-MS/MS and iTRAQ Quantification

Ying Sun, Li Siqian, Xuemei Li, Mingxi Li. *Nephrology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China.*

Background: IgA nephropathy is a common primary glomerulonephritis, more accurate and non-invasive tests for its diagnosis and evaluation are urgently needed. Urinary proteome analysis has been applied to discovering biomarkers for kidney diseases. The aim of this study is to investigate the differential urinary proteome in various stages of IgA nephropathy.

Methods: Eighteen IgA nephropathy patients diagnosed by renal biopsy were recruited and were divided into three groups according to estimated glomerular filtration rate, IgA I (eGFR 90~120ml/min, n=6), IgA II (eGFR 60~89ml/min, n=6) and IgA III (eGFR 30~59, n=6).Six patients with membranous nephropathy were included as control (eGFR 90~120ml/min, n=6). Proteins from each group were digested by trypsin and then labeled with 4-plexiTRAQ regents. The pooled mixture of iTRAQ labeled samples were fractured and analyzed by LC-MS/MS. All MS/MS samples were analyzed using Mascot. Scaffold was used to validate MS/MS based peptide and protein identifications. Protein classification was performed based on functional annotations using Gene Ontology analysis.

Results: A total of 622 proteins were identified, 108 were found to be up or down regulated in a consistent trend from IgA I to IgA III. 13 of these108 proteins were highly up-regulated in IgA groups but down-regulated in control. Some inflammation-related, complement-activating and extracellular matrix proteins were found to be up-regulated in IgA groups, including tumor necrosis factor-binding protein-1, WNT1-inducible-signaling pathway protein 2 and Alpha-2-HS-glycoprotein chain A. Alpha-N-acetylglucosaminidase and other proteins turned out to be down-regulated in IgA groups. Selected differential proteins were validated by Western Blot.

Conclusions: This study established differential urinary proteome in various stages of IgA nephropathy. Some inflammation-related, complement-activating and extracellular matrix proteins, as well as proteins related to O-glycosylation defects may involve in the development and progression of IgA nephropathy, and could be potential biomarkers of IgA nephropathy.

SA-PO476

Bioinformatic Analysis of Differential Urinary Glycoproteome of Type 2 Diabetic Nephropathy

Zixuan Zhu, Ying Sun, Xuemei Li, Mingxi Li. *Dept of Nephrology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China.*

Background: Diabetic nephropathy(DN) is the leading cause of end-stage renal disease. The early detection and intervention may delay renal replacement therapy. The aim of this study is to identify the urinary glycoproteins during different stages of DN and find the potential biomarkers for early diagnosis of DN.

Methods: In our previous study, 72, 107 and 123 differential urinary glycoproteins were found from normoalbuminuria(n=7), microalbuminuria(n=8), and macroalbuminuria(n=8) patients. The differential proteins were classified into distinct clusters by hierarchical clustering, and Ingenuity Pathway Analysis (IPA) was performed to analysis the clusters altering most significantly during the disease progression.

Results: A total of 302 differential glycoproteins were hierarchically clustered into 9 clusters. In Cluster 2, 38 proteins were overrepresented in both microalbuminuria and macroalbuminuria, and increased progressively during disease progression. When IPA was performed, there was no difference between normal controls and normoalbuminuria. However, proteins involved in LXR/RXR activation pathway, FXR/RXR activation pathway and Acute Phase Response Signaling (APRS) pathway were significantly enriched. In cluster 4, 36 proteins presented a high level only in microalbuminuria, but down-regulated in other groups. IPA showed that the complementary pathway, APRS pathway, LXR/RXR activation pathway and Notch signaling pathway were enriched in this cluster.

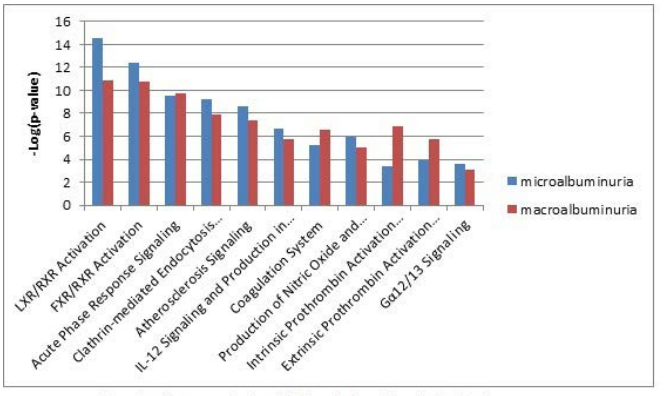

Figure1 pathway analysis of differential proteins in Cluster 2

Conclusions: The proteins involved in lipid metabolism, APRS, and complement activation significantly increased in the urine of DN patients along the disease progression, some of these proteins may become the candidate biomarkers for early diagnosis of DN.

SA-PO477

Immunomodulatory Therapy (Rx) Demonstrates Sustained Improvement in Myocardial Contractility in a Canine Model of Chronic Heart Failure (CHF)

H. David Humes,[1] D. Buffington,[2] A. Westover.[2] *[1]Internal Medicine, Univ of Michigan Medical School, Ann Arbor, MI; [2]Innovative BioTherapies, Ann Arbor, MI.*

Background: Cardiorenal syndrome (CRS), the most severe subset of CHF patients, is characterized by diuretic resistance in a volume overload. Current therapy is limited and new innovative approaches are needed. CHF is characterized by a proinflammatory state. Monocytes and tissue macrophages are sources of systemic inflammation in CHF and cause a decrease in cardiac contractility. Systemic MO levels correlate with poor outcome. A novel leukocyte (LE) immunomodulating device (SCD), when placed in an extracorporeal circuit with regional citrate anticoagulation has been shown to be effective in acute multiorgan failure. The biomimetic membrane device (BMD) is based on the same LE processing premise as the SCD.

Methods: Impact of BMD_{Rx} was evaluated in a CHF dog model; 2 groups were evaluated: BMD treated (BT) and untreated control (UC), n=4-5 per group. Dogs were administered either 1-3 BMD_{Rx} or no Rx sessions over a week period, with study termination immediately (Ti) postBMD_{Rx} session (n=2-3) or 4 weeks (T4) postRx session (n=2).

Results: Data demonstrated left ventricle (LV) ejection fraction (EF) increased substantially in the BT group from 33.6±1.3 (n=5) to 43.3±2.5 (n=5; 6-48hrs postRx) and 37.0±0% (n=2; 4wks postRx) reflective of 28.9 and 10.2% increase, respectively. The UC group (n=4) EF% did not change. This effect was not due to a decline in systemic vascular resistance which was similar in both groups. Ventriculograms demonstrated BMD_{Rx} to convert viable but non-contracting myocardium to contracting myocardium. The renal effects were also substantive. In the Ti dogs, fractional excretion (FE) Na nearly doubled in the BT group vs. UC group, increasing from 2.2±0.8 to 5.3±0.8%. FE_{urea} went from 59±3.1 to 81±11.3%. T4 dog FE results are pending. No adverse events of arrhythmia or hypotension were observed during BMD_{Rx}.

Conclusions: Immunomodulation with the BMD improves myocardial contractility and natriuresis. Removal of the cardiodepressant effects of the chronic inflammatory state of CHF may be an innovative approach to CRS.

SA-PO478

Lack of Allostimulatory Potential of Conditionally Immortalized Proximal Tubule Epithelial Cells for Bioartificial Kidney Application Milos Mihajlovic,[1] Annemarie J.F. Westheim,[1] Joost Hoenderop,[2] Lambertus P.W.J. Van den Heuvel,[3] Wil Allebes,[4] Luuk Hilbrands,[5] Rosalinde Masereeuw.[1] *[1]Pharmacology, UIPS, Utrecht, Netherlands; [2]Physiology, Radboudumc, Netherlands; [3]Pediatrics, Radboudumc, Netherlands; [4]Laboratory Medicine, Radboudumc, Netherlands; [5]Nephrology, Radboudumc, Netherlands.*

Background: Novel renal replacement treatments, such as a bioartificial kidney (BAK), are needed to improve current hemodialysis. When developing a BAK, availability of functional cells and their safety are frequently encountered problems. Here, we evaluated the alloimmunization of readily available conditionally immortalized human proximal tubule epithelial cells (ciPTEC) for use in BAK.

Methods: Two ciPTEC lines (urine derived ciPTEC-U, tissue derived ciPTEC-T1) were characterized by flow cytometry for HLA-class I, HLA-DR, CD40, CD80 and CD86 expression, as well as pro-inflammatory cytokines and soluble HLA-class I production by ELISA, in various stimulatory conditions (n≥3). ciPTEC immunogenicity was assessed in direct co-culture experiments with peripheral blood mononuclear cells (PBMC) by measuring their proliferation using CFSE staining.

Results: IFN-γ (300 ng/ml; 48h) and LPS (10 µg/ml; 48h) exposure resulted in an increase of HLA-class I expression by 37±12%, $p<0.01$ and 29±9%, $p<0.05$ respectively. CD40 expression was increased by conditioned medium from aCD3/aCD28 activated PBMC (48h) 87±9%, $p<0.01$. Cells were negative for HLA-DR, CD80 and CD86 in all conditions. Cytokine production was induced by LPS (IL-6: 3.2±0.2, IL-8: 3.5±0.7 fold, $p<0.001$) and indoxyl sulfate (IL-6: 1.7±0.2 fold; IL-8: 1.3±0.4 fold, $p< 0.05$). Finally, ciPTEC were not able to induce PBMC proliferation after 5 days of co-culture, compared to positive controls (aCD3/aCD28 dynabeads; 77±8% dividing cells, $p<0.001$, n=4) and allogeneic PBMC (25.7%)). The results shown here refer to ciPTEC-T1, and are comparable to those obtained for ciPTEC-U.

Conclusions: Although ciPTEC might have an accessory role in inflammatory responses as shown by cytokine production, the cells are not immunogenic and, therefore, represent a safe choice for BAK application. **Acknowledgement:**This work is funded by the EU Marie Curie ITN Project BIOART (grant no.31669 EU-FP7-PEOPLE-ITN-2012).

Neointima Formation in Hemodialysis Grafts: A Role for Abnormal Vein Wall Dynamics? Yan-Ting E. Shiu,[1] Daniel Pike,[1] Yong He,[2] Timmy C. Lee,[3] Edgar A. Jaimes,[4] Scott A. Berceli,[2,5] Alfred K. Cheung.[1,6] *[1]U of Utah; [2]U of Florida at Gainesville; [3]U of Alabama at Birmingham; [4]MSKCC; [5]Malcom Randall VAMC; [6]VASLCHCS.*

Background: Hemodialysis arteriovenous grafts (AVGs) often fail due to neointimal hyperplasia (NH) at the graft-venous anastomosis (VA). Abnormal regional mechanical factors may play a role in the focal nature of NH formation, but previous work has largely focused on the role of wall shear stress (WSS), ignoring other mechanical factors including the dynamic motion and compression of the vein wall. This study used fluid structure interaction (FSI) modeling in a patient specific AVG to analyze and compare both WSS and wall dynamics at the NH-prone and resistant regions.

Methods: MRI scans were performed on one hemodialysis patient's AVG and used to reconstruct AVG's lumen geometry and obtain blood flow in the up- and down-stream artery and vein. Simulations of blood flow in the AVG lumen as well as the wall motion and compression were performed in ANSYS Workbench using arterial BP (120/80 mmHg) and MRI-measured blood flow as boundary conditions, as well as published values of the elastic properties of the artery and vein.

Results: While disturbed flow patterns (e.g., spiral and recirculating flow) occurred at both the NH-prone VA and NH-resistant proximal vein (PV) (**Fig. 1A**), peak WSS was about 3-fold higher at the VA than at the PV (**Fig. 1B**). The motion of the inner wall (i.e., the intimal layer) and the compression of the entire wall during a cardiac cycle were also greater at the VA than at the PV (**Fig. 1C-D**). At the VA, the maximum wall changes occurred at the maximum WSS. Wall motion and compression were very small at the PA.

Conclusions: Our finding that the NH-prone region of a human AVG has increased wall dynamics is novel. Future analyses in a large study will elucidate the relative contributions of WSS and wall dynamics to NH development, with the objective of improving AVG durability.

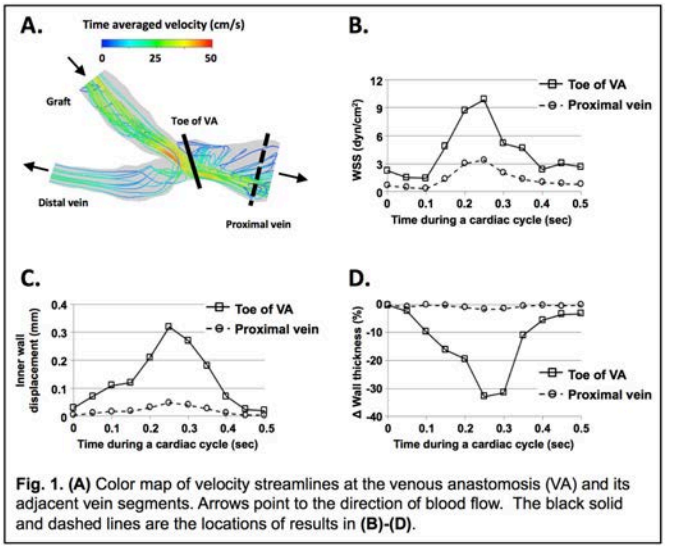

Fig. 1. (A) Color map of velocity streamlines at the venous anastomosis (VA) and its adjacent vein segments. Arrows point to the direction of blood flow. The black solid and dashed lines are the locations of results in **(B)-(D)**.

AFE System Provides Improved Hemodynamic Conditions for Vein Maturation Compared to Conventional AVF Howard M. Loree,[1] Daniel Pike,[2] John S. Richardson,[1] Yan-Ting E. Shiu,[2] Larry W. Kraiss,[2] Nicholas Franano.[3] *[1]R&D, Flow Forward Medical, Inc., Lowell, MA; [2]U of Utah, Salt Lake City, UT; [3]Flow Forward Medical, Inc., Olathe, KS.*

Background: Cyclic stretching of the AVF outflow vein and suboptimal vein wall shear stress (WSS) may contribute to AVF failure. The Arteriovenous Fistula Eligibility (AFE) System™ from Flow Forward Medical is a small, temporary, external blood pump system designed to deliver non-pulsatile blood flow from the right atrium to a peripheral vein for 10–14 days. Flow rate is set to provide a mean WSS dose of 4 Pa in the vein, previously shown to promote dilation, with the goal of increasing AVF eligibility and AVF maturation rates. This computational study investigated WSS and cyclic wall stretching in the outflow vein during AFE System treatment and after conventional AVF creation.

Methods: Using fluid-structure interaction (FSI)-computational fluid dynamics (CFD), we studied blood flow and cyclic wall stretching in an idealized model of an AFE System outflow conduit anastomosed to a cephalic vein (**Fig. 1A**). FSI-CFD was also performed for a radiocephalic AVF at typical flow rates (**Fig. 1B**). Lumen diameter was 4 mm for all vessels and boundary conditions were set using flow or pressure values measured in mock flow loop studies.

Results: With the AFE System, when pump speed was set to provide a mean WSS of 4 Pa in the outflow vein, max WSS was about 20 Pa (**Fig. 1A**) and there was no cyclic wall motion. With a conventional AVF at peak systole, mean WSS was about 6.5 Pa in the vein and max WSS was about 300 Pa (**Fig. 1B**) with a 10-12% cyclic increase in lumen diameter.

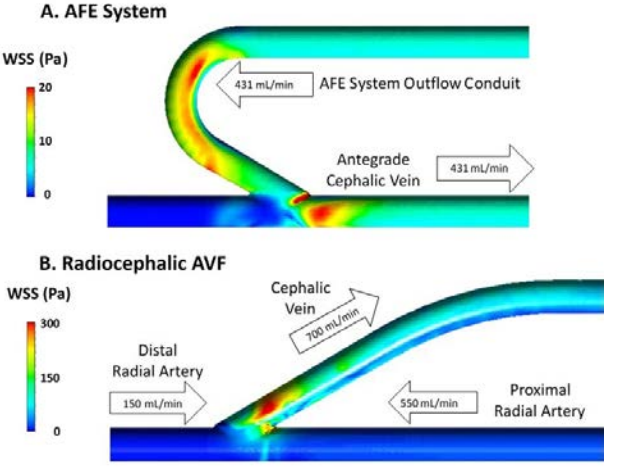

Fig. 1 Wall shear stress by FSI CFD in (A) AFE system outflow conduit & cephalic vein and (B) conventional radiocephalic AVF at peak systole. Arrows point to direction of blood flow at indicated mean flow rate.

Conclusions: The AFE System can provide a controlled dose of mean WSS to a peripheral vein without cyclic wall motion. A conventional AVF has cyclic stretching of the outflow vein, may not have ideal mean WSS, and may have very high peak WSS, all of which may contribute to failure.

Loop Mediated Amplification Assay versus Culture for Detection of *Escherichia coli* in Urine: A Single Center Pilot Study Vinai Kumar Katragadda,[1] Aravindhan Arumugarajah,[1] Jennifer Sheyman,[1] Christopher J. Webster,[1] Kalathil K. Sureshkumar,[1] Richard J. Marcus,[1] Abhay N. Vats,[2] Michelangelo Di Giuseppe,[3] Swati Arora.[1] *[1]Dept of Medicine- Nephrology, Allegheny General Hospital, Pittsburgh, PA; [2]Univ of Pittsburgh, Pittsburgh, PA; [3]Atharva LLC Molecular Diagnostics, Cranberry, PA.*

Background: Urinary tract infection (UTI) is a common cause of morbidity in the adult population. Urine cultures could take up to 5 days, thereby, exposing patients to unnecessary broad spectrum antibiotics. Over 80% of outpatient UTIs and 50% of inpatient UTIs are caused by *Escherichia coli*. Newer assays, such as, loop-mediated amplification (LAMP) assay for detection of E.coli can provide results within 60 minutes. This can potentially be used for point of care (POC) testing in the ambulatory and hospital settings.

Methods: A prospective study was done comparing E.coli LAMP assay and urine culture to detect UTI. LAMP assay was conducted on urine samples using a thermal cycler with incubation for 60 minutes with E.coli DNA primers. E.coli LAMP products were detected using Sybr green dye under UV illumination.

Results: Mean age was 58 years and 73% were females. About 50% of the samples were from outpatient setting, 27% from inpatient and source was not recorded in the remainder. Out of 393 samples, 43 urine cultures were positive for E.coli. Comparison with LAMP assay is shown in table.

Comparison standard	Sensitivity	Specificity	Positive predictive value	Negative predictive value	p-value
LAMP vs. E.coli culture	91	24	0.73	0.54	< 0.001
LAMP vs. E.coli culture >100,000 cfu/ml	93	21	0.73	0.58	< 0.001
LAMP vs. E.coli culture < 100,000 cfu/ml	97	3	0.70	0.36	0.66

Conclusions: LAMP assay displayed good sensitivity and could be used as a screening tool to rule out UTI as a POC test. It is not specific and does not provide quantitative information or antibiotic sensitivities to guide management. LAMP assay would pick up even less than 10 copies of E.coli as a "positive" test which is clinically insignificant. Lastly, LAMP assay is designed for one specific organism only. More prospective studies are needed to evaluate utility of LAMP in clinical practice.

SA-PO482

Contribution of Vibrational Spectroscopy in Nephrology Vincent Vuiblet,[1,2,3] Philippe Birembaut,[2] Olivier Piot,[1,4] Philippe Rieu.[1,3] *[1]UMR CNRS 7369 MEDyC, URCA, Reims, France; [2]Nephropathology Dept of Biopathology Laboratory, CHU de Reims, Reims, France; [3]Nephrology Dept, CHU de Reims, Reims, France; [4]PICT, URCA, Reims, France.*

Background: Despite that renal histopathology is essential for diagnosis and prognosis in nephrology, it presents some limiting features. So, the development of more reliable techniques is open. Vibrational spectroscopy (VS) including Raman spectroscopy (RS) and Fourier-transformed infrared spectroscopy (FTIR) brings out some molecular and structural data from tissue analysis in a label-free manner. Our objective was to demonstrate VS is able to provide histologic data actually unattainable by conventional techniques.

Methods: Our investigations focused on 1) the detection of exogenous molecules, by considering more precisely Hydroxyethyl starch (HES) because of its renal toxicity and its high difficulty to be detected in renal biopsies; 2) the detection of endogenous molecules: we were particularly interested in the mapping of Advanced glycation end-product (AGEs). Indeed, there are many kinds of AGEs which are undetectable simultaneously on the same biopsy slide 3) the reproducible quantification of interstitial fibrosis and inflammation in renal grafts which is a valuable information due to its impact on the therapeutic and the prognosis.

Results: 1) We reported an accumulation of HES by RS in renal biopsies from patients exposed HES. Moreover, accumulation of HES in kidney exposed to HES was dependent on the good quality of graft defined by kidney donor risk index and renal function at 3 months. 2) 4 AGEs were mapped and quantified by RS in diabetic and normal glomeruli. Levels of each AGE were higher in diabetic glomeruli *vs* controls. In diabetic glomeruli, some AGEs were collocated with collagen that was not found in normal glomeruli. 3) Interstitial fibrosis (IF) and inflammation were quantified in 166 renal graft biopsies by an automated FTIR-based imaging technique. We assessed the robustness of this technique for discrimination of fibrosis and inflammation. We proved the clinical relevance of this technique by showing a good correlation of IF with renal graft function.

Conclusions: VS is a promising technique for nephrology both in basic research and in clinical practice.

SA-PO483

Remote Monitoring of Patients on Automated Peritoneal Dialysis Saves Healthcare Resources in a Simulation Study Suzanne Laplante,[1] Kimberly Mcleod,[2] Judy A. Danek,[1] Timothy L. Kudelka,[1] James A. Sloand,[1] Mary Gellens,[1] Leslie P. Wong.[3] *[1]Baxter Healthcare Corporation, Deerfield, IL; [2]XCenda, Palm Harbour, FL; [3]Cleveland Clinic, Cleveland, OH.*

Background: Remote monitoring is useful in chronic diseases, but evidence is scarce in home dialysis. A two-way data exchange platform with remote monitoring capabilities may enable earlier intervention and healthcare savings. This study estimates the nature and importance of the savings in USA.

Methods: Twelve (12) automated peritoneal dialysis (APD) patient profiles (therapy non-adherence, fluid overload, low drain/unidentified alarms, missing/factitious data entry) were used to simulate healthcare resource use with remote monitoring information (treatment data, blood pressure, weight) and without. Four US nephrologists (expert in managing APD patients) validated the "without remote monitoring" resources. The "with remote monitoring" resources were estimated by 7 APD teams (1 nephrologist, 1 nurse). A Monte-Carlo simulation (1,000 iterations) was run on resources avoided (resources "without remote monitoring" minus those with). US public reimbursement rates or medical literature were used for costing (3 perspectives: public healthcare payer, direct provider costs, provider opportunity costs).

Results: The Monte-Carlo simulation estimated that in these 12 patient profiles (average follow-up: 25 days; range: 7-60 days), remote monitoring could avoid 5.0±0.5 emergency room visits; 2.0±0.2 hospitalizations; 2.2±0.3 changes to hemodialysis for potential savings of $22,862±$1,384 to the public healthcare payer. Providers could avoid 0.8±0.3 repeat adequacy tests resulting in $19±$6 direct savings while their opportunity costs resulting mainly from avoidance of 6.7±2.5 unplanned clinic visits and 64±15 unplanned clinic calls would total $1,249±$237. The 12 profiles were estimated to be representative of 17.3-37% of the US APD patient population.

Conclusions: In a simulation, remote monitoring saved healthcare resources in APD patients with treatment non-adherence, fluid overload, volume depletion, low drain/unidentified alarms, or missing/factitious data entry by enabling earlier medical intervention, avoiding complications and treatment drop-out.

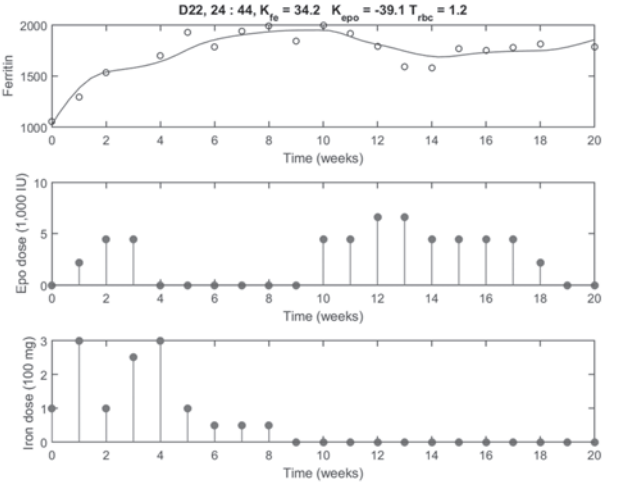
SA-PO484

Mathematical Modeling Approach to IV Iron Dosing in Hemodialysis Patients Adam E. Gaweda,[1] Yelena Z. Ginzburg,[3] Yossi Chait,[2] John Paul Middleton,[4] Michael J. Germain,[5] Michael E. Brier.[1] *[1]Univ of Louisville; [2]UMass Amherst; [3]New York Blood Center; [4]Duke Univ; [5]Renal and Transplant Associates of New England.*

Background: Coordinated dosing of Erythropoiesis Stimulating Agents (ESA) and Intravenous (IV) Iron is essential in anemia management of End Stage Renal Disease (ESRD). To aid physicians in this task we are developing a systems biology approach to modeling erythro- and ferrokinetic marker behavior. Here, we present a mathematical model of Ferritin (ferr) response to IV Iron and ESA.

Methods: A cohort of 23 hemodialysis patients was prospectively followed for 12 months at three dialysis centers in the United States. Data collected included weekly ferr concentration, ESA (Epogen), and IV Iron (Venofer) dose. We developed patient-specific models of comprising three parameters: 1) ferr sensitivity to iron dose, 2) ferr sensitivity to ESA dose, and 3) time constant, representing the time to reach 64% of steady state ferr response. We used a nonlinear least squares estimation to maximize the fit between model prediction and data.

Results: IV Iron doses greater than 100 mg/week result in a rapid increase of ferr . ESA dose increases in absence of IV Iron dose result in a decrease of ferr. We obtained the following model parameters: 1) ferr sensitivity to IV iron (median [min,max]): 42.6 [6.6, 135.2] ng/mL per 100 mg/week, 2) ferr sensitivity to ESA: -36.9 [-166.7, -3.2] ng/mL per 1,000 IU/week, 3) time constant: 5.4 [1.2, 16] weeks. The figure below shows an example of model prediction for a selected study subject.



Conclusions: Presented model reliably captures ferr response to IV Iron and ESA. The estimated model parameters are consistent with the physiology of erythropoiesis. Next steps involve addition of other ferrokinetic markers such as hepcidin and soluble transferrin receptor 1, and a validation of the model in a larger cohort of subjects.

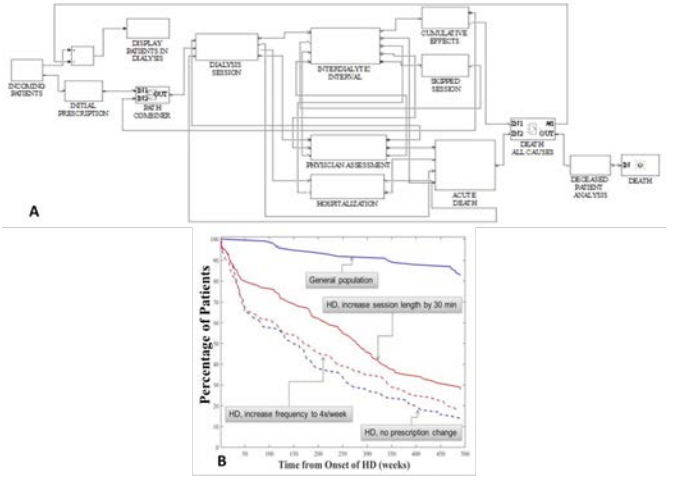
Discrete Event Model of Fluid Overload Complications in Hemodialysis

Victor Andreev,[1] Anca I. Stefan,[1] Michelle M.Y. Wong,[1] Jarcy Zee,[1] Robert Merion,[1] John Hartman,[2] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Visonex Data Management, LLC, Green Bay, WI.*

Background: Fluid overload is one of the most common complications of hemodialysis (HD) and is associated with adverse clinical outcomes. We developed a discrete event simulation (DES) model of HD that simulates survival of a cohort of incident dialysis patients by incorporating the cumulative effects of fluid overload and intradialytic hypotension (IDH) in the context of excessive fluid removal.

Methods: The DES model was developed with the SimEvents tool (Mathworks), and consisted of a set of interconnected modules corresponding to various events and outcomes in the course of a patient's HD experience: initial HD prescription, the dialysis session, interdialytic interval, physician evaluation, acute complications, cumulative effects of fluid overload and IDH, skipped or shortened sessions, hospitalizations, and death (Figure A). The model uses patient-level and HD session-level (e.g. blood pressure and ultrafiltration rate) data for a cohort of 194 HD patients from multiple US facilities from 2010 to 2015.

Results: Figure B shows simulated survival curves for 4 scenarios: (1) HD, with an average session duration of 3.5 hours, (2) HD with 30 min added to each session upon detection of fluid overload, (3) HD with increased frequency to four times a week, and (4) natural aging in a control group.



Conclusions: Our novel DES model of the HD process simulates patient survival. Further validation of the model and incorporation of more modules (e.g., infections, protein-energy wasting) is in progress. Applying this methodology to model the mechanisms of HD complications and their management strategies at the patient level can be used to identify algorithms for prevention and treatment of fluid overload in HD patients.

SA-PO486

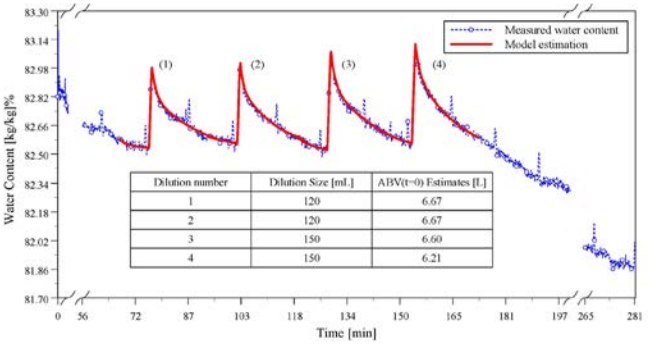
Estimating Absolute Blood Volume in Hemodialysis Patients

Hamed Samandari,[1] Joseph Horowitz,[1] Christopher V. Hollot,[1] Rammah M. Abohtyra,[1] Michael J. Germain,[2] Ravi I. Thadhani,[3] Daniel Schneditz,[4] Yossi Chait.[1] *[1]UMass; [2]WNERTA; [3]MGH; [4]Medical Univ of Graz.*

Background: Long- and short-term adverse outcomes have been associated with intradialytic hypotension, a common hemodialysis (HD) complication and significant cause of morbidity. It has been suggested that absolute blood volume (ABV) data is likely to significantly improve such outcomes.

Methods: Automatic on-line dialysate dilution and blood water concentration (BWC) measurement by blood volume monitor (BVM) were used to compare ABV estimation between classical single-pool (SP) back-extrapolation method and a new, physiological, intravascular BWC model (NM). The study included 3 arterio-venous (AV) and 3 central venous (CV) access patients, and multiple dilution tests (3-5) within each of several (2-6) HD treatments. Nested one-way ANOVA was used to compute intratreatment variability of estimates and Bland-Altman (BA) analysis was used to analyze agreement between the methods.

Results: A total of 84 bolus injections (60 to 210 mL) were performed over 21 HD treatments in 6 patients. Figure 1 shows measured BWC in a single treatment with 4 injections and the corresponding 4 distinct ABV estimations prior and post dilutions using NM. Intratreatment standard deviation (SD) of SP ABV estimates were 0.51L and 0.45L for CV and AV patients, respectively; the corresponding NM SD were 0.24L and 0.29L for CV and AV patients, indicating significant reductions in variability by 53% and 36%, respectively. BA agreement between the two methods was 0.12±1.14 and 0.09±0.84 L (bias±2SD) for AV and CV patients, respectively.



Conclusions: Our new model can successfully describe BWC dynamics during an on-line dialysate dilution protocol. The variability of ABV estimates using the new model is substantially smaller than that from SP estimates. The dilution protocol and the new ABV estimation method can be implemented within current HD technology.

SA-PO487

Characterization of Hemodialysis Patients Based on Systolic Blood Pressure Profiles

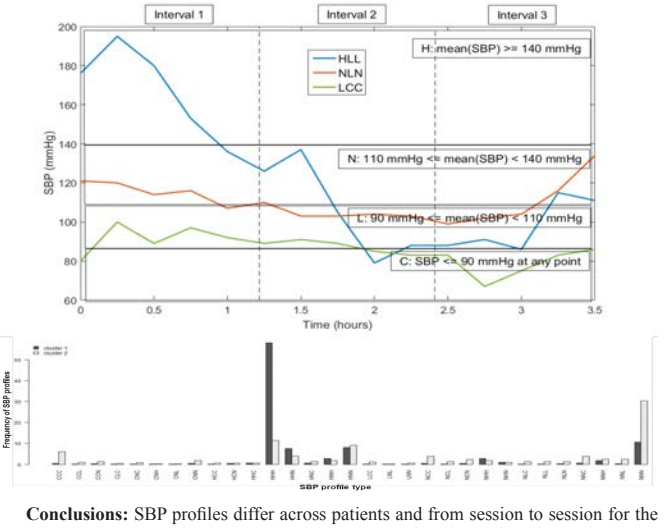
Anca I. Stefan,[1] Victor Andreev,[1] Michelle M.Y. Wong,[1] Gang Liu,[1] John Hartman,[2] Ronald L. Pisoni,[1] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Visonex Data Management, LLC, Green Bay, WI.*

Background: Observational studies have revealed a complex relationship between systolic blood pressure (SBP) and mortality in end-stage renal disease (ESRD) patients. We present a classification of hemodialysis (HD) patients based on their intradialytic SBP profiles.

Methods: We analyzed intradialytic SBP data recorded every 15 minutes during HD sessions for a cohort of 194 HD patients from multiple US facilities from 2010 to 2015. To describe each patient's SBP profile, a vector was constructed by dividing each session into three equal time intervals and classifying each interval based on the corresponding SBP values. Thus, each session was assigned a three letter code. A "patient vector" was created by counting the number of sessions of each type. The table shows an example of a patient vector with high SBP during 316 sessions.

HHH	HHN	HNC	HNH	HNN	NHH	HNH	NNN
316	90	6	12	18	14	9	18

Results: Two major clusters of SBP profiles emerged. In Cluster 1, the predominant profiles of the average patient consisted of sessions in which SBP exceeded 140 mmHg during one or more intervals, with HHH being the most common profile (58% of sessions). In Cluster 2, the most common SBP profile was NNN (30% of sessions), along with 28% of sessions where hypotension occurred.



Conclusions: SBP profiles differ across patients and from session to session for the same patient. However, there are predominant SBP profiles for each patient, which may have prognostic implications. Future analyses will assess associations of the predominant SBP profiles with hospitalizations and cardiovascular complications which will be applied in discrete event simulation models of complications in HD.

SA-PO488

Accuracy of Contrast-Enhanced Ultrasound for Characterizing Kidney Lesions in Patients with and without CKD Emily H. Chang,[1] Sandeep Kasoji,[3] Paul Dayton,[3] Wui K. Chong,[2] W. Kimryn K. Rathmell.[4] *[1]UNC Kidney Center, UNC, Chapel Hill, NC; [2]Radiology, UNC, Chapel Hill, NC; [3]Biomedical Engineering, UNC, Chapel Hill, NC; [4]Lineberger Cancer Center, UNC, Chapel Hill, NC.*

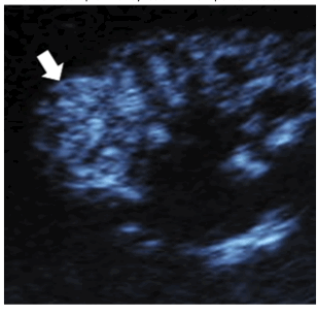
Background: Complex kidney lesions are often detected incidentally. Generally, lesions are further characterized by contrast-enhanced CT or MRI. However, these studies are often contraindicated in patients with chronic kidney disease (CKD). Contrast-enhanced ultrasound (CEUS; panel A), a new, non-nephrotoxic imaging technique, is a potential alternative for lesion surveillance among patients with CKD. We investigated the diagnostic accuracy of CEUS for malignancy or lesion progression prediction in patients with incidental kidney lesions.

Methods: CEUS was performed on 46 patients with known indeterminate or suspicious kidney lesions. Patients with and without CKD were evaluated to compare sensitivity in patients with vs without CKD. Results were independently interpreted by 2 blinded readers and risk-stratified by the Bosniak classification system. Using histologic diagnosis as the reference standard, CEUS sensitivity and specificity with 95% confidence intervals were calculated. As histology was available for resected lesions only, we performed secondary analyses considering histologic diagnosis *or* one-year follow-up imaging as the reference standard. The mean follow-up period was 18 months.

Results: In primary analyses, CEUS sensitivities ranged 95-100% for all patients and 100% for CKD patients (panel B). Specificities were low across all patients, in both primary and secondary analyses, ranging 0-68%.

Conclusions: CEUS has comparable sensitivity to CT and MRI and thus excellent potential as an alternative diagnostic tool for characterization of kidney lesions in patients with CT/MRI contraindications. The observed low specificity suggests that CEUS technique improvement is needed.

A. CEUS of complex kidney lesion. Arrow points out lesion.



B. Sensitivity and specificity with confidence intervals (CI) for reader 1 (R1) and reader 2 (R2) compared to tissue diagnosis and tissue diagnosis or follow-up imaging in all patients and those with CKD.

	All patients (N=46)				CKD (N=27)			
	Tissue Primary analysis (n=20)		Follow-up/Tissue Secondary analysis (n=46)		Tissue Primary analysis (n=5)		Follow-up/Tissue Secondary analysis (n=27)	
	R1	R2	R1	R2	R1	R2	R1	R2
Sensitivity (C.I.)	95% (85-100)	100%	88% (75-100)	100%	100%	100%	75% (45-100)	100%
Specificity (C.I.)	0%	0%	62% (41-83)	48% (26-69)	N/A	N/A	68% (48-89)	53% (30-75)

SA-PO489

A Pilot Study of Nuclear Magnetic Resonance to Detect Volume Changes during Hemodialysis Kristin M. Corapi,[1] Lina Avancini Colucci,[2] Matthew Li,[2] Dihua Xu,[1] Andrew S. Allegretti,[1] Jimy Hanna,[1] Xavier F. Parada,[1] Dennis A. Ausiello,[1] Michael J. Cima,[2] Herbert Y. Lin.[1] *[1]Nephrology, Massachusetts General Hospital, Boston, MA; [2]Dept of Materials Science and Engineering, Massachusetts Inst of Technology, Cambridge, MA.*

Background: Patients treated with hemodialysis (HD) are prone to volume overload. Physicians rely on clinical examination and an assessment of interdialytic weight gain to assess volume status, but a more reliable and precise method is needed. We conducted a pilot study to explore the potential of nuclear magnetic resonance (NMR) to detect changes in volume status in HD patients.

Methods: Adult HD patients who were admitted to our hospital between April and Dec 2015 were recruited. Patients were excluded if they were initiating HD, had a limb amputation, or were being treated in the intensive care unit. The first NMR device was a single sided sensor designed to take measurements at the upper calf and the second was a bore-configured sensor designed to take measurements at the finger. The first measurements were obtained at initiation of dialysis. NMR measurements were repeated at hourly intervals and at the completion of dialysis. Pearson correlation was used to look for an association between change in NMR measurements and ultra-filtration volume.

Results: The demographics of the 22 participants are below.

Age (years)	66.6 (12.5)
% Male	72.7
% White	81.8
BMI (kg/m^2)	27.6 (5.6)
% with diabetes	59.1
% with hypertension	90.9
Ultrafiltration volume (L)	1.7 (1.2)

NMR measurements at the finger, but not the leg, were found to have a significant correlation with UF volume (r= 0.47, p=0.028 and r=0.07, p=0.77 respectively).

Conclusions: NMR may be a reliable and objective way to monitor volume status in ESRD patients. The finger sensor may be superior to the leg sensor because of differences in signal to noise or because of the differences in tissue compartments in the volumes sampled within the finger and leg. Further study and correlations with other measures of volume status are needed to determine the clinical role of portable NMR sensors.

Automation Optimizes Risk Stratification for Acute Kidney Injury: Pilot Study of Electronic Health Record Based Patient Screening Rajit K. Basu, Patricia A. Holshouser, Tara C. Terrell, Theresa A. Mottes, Ryan Knox, Hilary E. Pitner, Catherine Johnson, Bill Young, Stuart Goldstein. *Center for Acute Care Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Earlier identification of patients at risk for AKI is hypothesized to improve outcomes. We previously validated a stratification methodology for AKI risk, termed the Renal Angina Index (RAI), in critically ill children for prediction of severe AKI. Screening for RAI elements requires extraction and calculation of objective data. We hypothesized that an automated electronic health record (EHR) screening algorithm would optimize the value of RAI screening compared to manual extraction and tabulation.

Methods: We integrated the RAI into our EHR to compare automated versus manual patient screening for AKI risk in two separate, single-center retrospective and prospective observational studies. The EHR-system and five practitioners with varying medical expertise (manual) screened 97 patients admitted to the pediatric intensive care unit (PICU) for RAI criteria 12 hours after ICU admission (time of eligibility). The primary outcome was "value", a composite of screening accuracy, time, and cost.

Results: Accuracy improved using automation in both the retrospective and prospective studies (auto: 91.1% and 92.2% vs. 75% and 77%, respectively). Median time required for screening individual patients was 00:07:25 (hr:min:sec) (range 00:04:18 – 00:14:27) and median time lag between patient eligibility and screening was 13:20:00 for the manual process (range 09:21:52 – 17:54:42). The automated process was instantaneous for both screening studies with no lag between first eligibility time and time of RAI reporting. Using average number of patients per day, required time for screening, and average hourly salary of researcher, the extrapolated daily cost for manual RAI screening alone would be $9,338.24/year/researcher or ~ $46,691.20 total.

Conclusions: Our data show that automation increases accuracy and decreases screening time, screening delay, and cost for using identifying patients at risk for AKI. Taken together, we suggest the EHR can be used to optimize the value of AKI risk screening for both research and clinical purposes.

SA-PO491

A Three-Dimensional Bioprinted Model of the Renal Proximal Tubule for Evaluation of Drug-Induced Nephrotoxicity Shelby King, Timothy Smith, James William Higgins, Celina Nino, Abigail Docuyanan, Alice Chen, Sharon Presnell, Deborah Nguyen. *Organovo, Inc., San Diego, CA.*

Background: Due to its exposure to high concentrations of xenobiotics, the proximal tubule (PT) is a primary site of nephrotoxicity and resulting drug attrition in drug development. Current pre-clinical methods using 2D cell cultures and animal models cannot fully recapitulate the *in vivo* human response to drugs.

Methods: Using Organovo's proprietary bioprinting platform, we have developed a human *in vitro* 3D tissue model of the PT to enable more accurate prediction of clinical outcomes.The tissue is composed of a thin interstitium supporting a basement membrane and polarized monolayer of primary human PT epithelial cells.

Results: The epithelial cells of the 3D tissues demonstrated formation of tight junctions, stable gamma glutamyl-transferase activity, and expression of renal transporters for at least 4 weeks in culture. The tissues also exhibited functional glucose transport via SGLT2, inhibited by the SGLT2 inhibitor canagliflozin, as well as P-gp mediated efflux of rhodamine 123 which was effectively blocked by the P-gp inhibitor zosuquidar. To validate the model for drug-induced toxicity assessment, the tissues were exposed to the nephrotoxin Cisplatin. Cisplatin induced a dose-dependent decrease in tissue metabolism and GGT activity and an increase in LDH release. Histologically, cisplatin induced a loss of epithelial nuclear and cellular morphology. The OCT2 inhibitor cimetidine almost completely reversed this damage, confirming the role of OCT2-mediated drug uptake and cytoplasmic drug accumulation as a mechanism for nephrotoxicity.

Conclusions: Together, these results support the use of this novel 3D tissue model of the PT for assessment of human renal toxicity over extended time in culture.

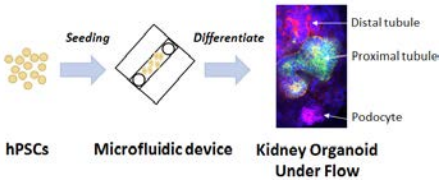
Organoid Differentiation under Flow: Bioengineering a Functional Kidney-on-a-Chip from Human Pluripotent Stem Cells Ramila E. Gulieva, Benjamin S. Freedman. *Div of Nephrology, Kidney Research Inst, and Inst for Stem Cell and Regenerative Medicine, Dept of Medicine, Univ of Washington, Seattle, WA.*

Background: Human pluripotent stem cells (hPSCs) have recently been differentiated into nephron-like kidney organoids, with important potential for kidney function. Microfluidic flow is an essential component of the kidney nephron, but is absent from existing kidney organoid cultures. We tested the ability of hPSCs to differentiate into kidney organoids under constant flow and perform kidney functions.



Methods: hPSCs were seeded in a multichannel microfluidic chamber and treated with specific growth factors to direct differentiation into kidney organoids under constant flow. Organoids were fixed and analyzed for kidney marker expression by immunofluorescence. Absorption of glucose and dextran probes was monitored live in kidney organoids under perfusion conditions.

Results: Over a two week period under constant flow, hPSCs seeded in microfluidic chambers differentiated efficiently into tubular kidney organoids (~15 organoids/cm^2). Each organoid contain segmented proximal tubules, distal tubules, and podocytes, which remained stable under flow. Organoid tubules exhibited functional ability to uptake glucose and dextran from the perfusate under flow.

Conclusions: Kidney organoid differentiation can be performed entirely under constant flow conditions, yielding a kidney-on-a-chip device capable of perfusion. Organoids arise intact in the chamber without disruption, preserving their complexity, and can perform functions of proximal tubules under flow. Bioengineering of this micro-physiological device, the first of its kind, represents an important step towards more functional organoid culture models for drug discovery and kidney regeneration. (Supported by an unrestricted gift from Northwest Kidney Centers to Kidney Research Institute).

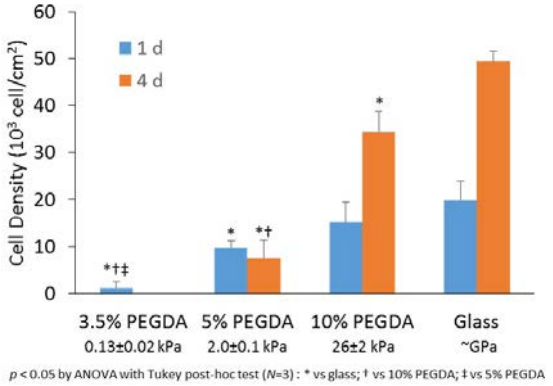
Extracellular Matrix Mechanics Influence Proliferation and Cytoskeletal Organization of Cultured Renal Proximal Tubular Epithelium Jeffrey A. Beamish, Evan Chen, Andrew J. Putnam. *Univ of Michigan.*

Background: Chronic kidney disease (CKD) is associated with poor prognosis after acute kidney injury (AKI) and also is associated with changes in the mechanical properties of the kidney parenchyma. Recovery from AKI often requires proliferation of renal proximal tubular epithelial cells (RPTECs). In this study, we utilized a synthetic extracellular matrix (ECM) engineered with well-defined mechanical properties to investigate the influence of substrate mechanics on proliferation of human RPTECs.

Methods: Synthetic ECMs were prepared by photopolymerizing poly(ethylene glycol) diacrylate (PEGDA) hydrogel films with various compositions engineered to obtain a range of shear storage moduli. Human collagen IV was tethered to the gel surfaces using sulfo-SANPAH. Human primary cultured RPTECs were seeded on these matrices, cultured in expansion medium, and fixed 1 d and 4 d post-seeding. Cell density was measured by counting DAPI stained nuclei. The actin cytoskeleton was visualized with phalloidin. Focal adhesions were visualized by immunofluorescence staining for vinculin.

Results: RPTEC attachment to the synthetic ECMs increased as the modulus increased (Figure). At 1 d, a qualitative tendency toward more robust networks of basolateral stress fibers was observed on more rigid substrates. Well-developed focal adhesions formed on glass but were less prominent in cells seeded on the synthetic matrices. Proliferation over 4 d was enhanced on the firmer gels (Figure).



$p < 0.05$ by ANOVA with Tukey post-hoc test (N=3) : * vs glass; † vs 10% PEGDA; ‡ vs 5% PEGDA

Conclusions: Increased synthetic matrix rigidity enhanced attachment and proliferation of RPTECs. This effect was correlated with the qualitative enhancement of basolateral stress fibers and focal adhesions. These results suggest ECM mechanics modulate RPTEC proliferation and may influence the recovery of tubular cells from AKI.

Stable Filtration by Silicon Nanopore Membranes under Pulsatile Flow Joseph J. Groszek,[1] Shuvo Roy,[2] William Henry Fissell.[1] *[1]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [2]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA.*

Background: Silicon Nanopore Membranes (SNM) optimize permeability-selectivity factors in ultrafiltration membrane design. The efficiency of the membranes reduces package size and pressure requirements for filtration, enabling implanted renal replacement therapy. The failure characteristics of SNM are described by statistical likelihood of fracture due to the crystalline nature of the material, rather than gradual failure. Hydraulic permeability and macromolecular sieving by SNM were characterized using pulsatile flow of a blood surrogate.

Methods: SNM were manufactured by bulk and surface micromachining as previously described. Sample membranes were mounted in custom-made ultrafiltration cells and perfused with a 37% (v/v) glycerol-saline mixture spiked with a polydisperse fluorescently-tagged polysaccharide, Ficoll) with similar viscosity to blood. Pressure and flow waveforms simulating arterial flow were produced by a computerized pump control system. Filtration rates were monitored by mass accumulation on an analytical balance Serial aliquots of feed and filtrate were analyzed by size-exclusion chromatography and szie-dependent sieving coefficients calculated as the ratio of ultrafiltrate concentration to feed concentration.

Results: Hydraulic permeability was unchanged over 12 (n=2) and 16 (n=2) days. Sieving coefficients were unchanged over the same period. No membranes were fractured or leaked after 1.3 million pulsatile cycles.

Conclusions: Ultrathin crystalline silicon membranes are mechanically stable for over 10^6 pressure cycles in vitro. Permeability/selectivity performance does not significantly degrade over two weeks.

Transcriptome Analysis of Three Progressive Models of Chronic Kidney Disease Identifies Pathways Implicated in Disease Progression Shannon Marie Harlan, Tao Wei, Zhonghua Qi, Martin S. Cramer, Dianna L. Jaqua, Matthew D. Breyer, Josef G. Heuer. *Lilly Research Labs, Eli Lilly and Company, Indianapolis, IN.*

Background: Publically available renal transcriptome data from patients with diabetic kidney disease (DKD) has served as a valuable resource for identification of genes and pathways upregulated in human DKD. Precisely how close animal models of DKD mimic many of the genetic features of human DKD remains unclear. The present studies explored gene expression profiles in three preclinical mouse models of renal disease, the remnant kidney, the *db/db*$^{-/-}$/*eNos*$^{-/-}$, and the ReninAAV *db/db* uNx model and compared them to published human DKD data sets.

Methods: Mice aged 20-26 weeks were used to isolate kidney RNA for microarray analysis (Asuragen, MOE-430 2.0 array). Differentially expressed genes (DEG) were defined as those with fold change >1.5, P value<0.05 and FDR <0.05. Results were compared to the published data set GSE30529 of human DKD.

Results: Clustering and pathway analysis of DEGs identified common pathways both up and down-regulated in the three mouse models with human DKD. Inflammation/immune and apoptosis/cell survival responses were both highly upregulated in all three models and in human DKD. Common pathways down-regulated in all three models and human DKD included amino acid metabolism and transporter activity. Comparing DEGs from the three models identified the highest concordance (84%) of DEGs to human DKD in the ReninAAV *db/db* uNx model consistent with this model most closely mimicking the pathophysiological characteristics of human DKD. KEGG analysis identified cytokine-cytokine receptor interaction as the top ranked pathway in this model, a pathway highly upregulated in human DKD.

Conclusions: Transcriptome data from the three mouse models of DKD supports the similarity of the models to human DKD, with the ReninAAV *db/db* uNx model having a molecular signature most closely resembling human DKD patients. In addition, inflammation which has been shown to be prominent feature of human DKD was highly upregulated in all models, suggesting a potential role of inflammation in the pathogenesis of DKD.

Genomic and Proteomic Profiling Reveal Insights of Mesangial Cell Function in Patients with IgA Nephropathy Emelie Lassén,[1] Peidi Liu,[1] Wenjun Ju,[2] Matthias Kretzler,[2] Kerstin Ebefors,[1] Jenny C. Nystrom.[1] *[1]Neuroscience and Physiology, Univ of Gothenburg, Gothenburg, Sweden; [2]Computational Medicine and Bioinformatics, Univ of Michigan, Ann Arbor, MI.*

Background: To understand disease onset and to discover new drug targets for IgA nephropathy (IgAN) we need to more closely determine the role of the mesangial cells in disease development and progression. Using a systems biology approach involving *in silico* nanodissection (Ju W et al, Genome Res. 2013) we investigated the role of the mesangium in patients with IgAN and the effect of galactose deficient IgA (gd-IgA) on mesangial cells *in vitro*.

Methods: Transcriptomic profiles of glomeruli from patients diagnosed with IgAN (n=20) and healthy kidney donors (n=22) were obtained using the Affymetrix platform. Expression of mesangial and podocyte standard genes obtained by *in silico* nanodissection were compared between the groups and correlated to clinical parameters. Additionally, primary human mesangial cells were treated with gd-IgA to mimic IgAN in vitro and the proteome analysed using LC-MS/MS. This enabled identification of shared pathways between the patient glomerular transcriptome and the proteome in the *in vitro* model.

Results: By transcriptome analysis we found 736 significantly regulated genes. Mesangial cell standard gene expression separated IgAN patients from healthy donors, while no separation was seen for podocyte standard genes. Activation z-scores based on mesangial cell standard gene expression yielded a significant correlation with creatinine and eGFR, while no correlation was found based on podocyte standard genes. 22 significantly regulated pathways, mainly inflammatory, were shared between the glomerular transcriptome and the proteome of mesangial cells treated with gd-IgA.

Conclusions: Expression of mesangial cell standard genes determined by in silico nanodissection clusters IgAN patient samples separately from healthy controls. Correlation with eGFR and creatinine indicate their usefulness as predictive biomarkers. Shared regulated inflammatory pathways between the glomerular transcriptome and gd-IgA treated mesangial proteome give rise to new and exciting data useful for target exploration in IgAN.

SA-PO497

Quantitative Magnetization Transfer Imaging to Evaluate Renal Fibrosis in Mouse Diabetic Nephropathy Daisuke Katagiri,[1] Feng Wang,[1] Shinya Nagasaka,[1,2] Hua Li,[1] Suwan Wang,[1] Keiko Takahashi,[1] Ming-Zhi Zhang,[1] Akira Shimizu,[2] Raymond C. Harris,[1] Takamune Takahashi.[1] *[1]Vanderbilt Univ, Nashville; [2]NIppon Medical School, Tokyo, Japan.*

Background: Currently few non-invasive methods are available to evaluate fibrosis according with progressed kidney disease. MRI-based quantitative magnetization transfer (qMT), which provides indices describing the interactions between free water protons and immobile macromolecular protons, is applicable to evaluate tissue fibrosis. However, this technique has not been applied to kidney disease. This study was conducted to evaluate the utility of qMT in assessing fibrosis in advanced diabetic nephropathy (DN) by comparison with histological analysis.

Methods: 8, 24 weeks old db/db eNOS -/- (DN; 8wDN and 24wDN) and C57BL/6 (Wild type; WT) mice were imaged with a 7T MRI. Henkelman-Ramani's model was applied to derive qMT. Cortical and outer medulla regions with significant higher pool size ratio (PSR) values were detected and fibrosis level was evaluated by threshold PSR. Mice were sacrificed and median 50 % of each kidney was evaluated fibrosis determined by Picrosirius red and collagen IV (14 sections per mouse, and 3 - 4 mice per group).

Results: Localized changes of PSR were observed in cortex and outer medulla. 24wDN mice developed significant higher fibrosis in cortex than WT mice on histology (3.0 vs 0.5 %; Sirius red, 12.3 vs 4.4 %; collagen IV) and these fibrosis areas corresponded to high PSR region. Mean PSR values in cortex were increased with DN progression (0.09; WT, 0.10; 8wDN, 0.12; 24wDN). The observed longitudinal relaxation rate (R_{1obs}) and transverse relaxation rate of the free water pool (R_{2a}) correlated highly with the regional distribution of PSR. % Areas with higher than +2SD of PSR were significantly dominant in 24wDN mice than WT mice (14.4 vs 4.5 %; PSR>Mean+2SD, 7.7 vs 0.7 %; >+3SD, and 3.9 vs 0.0 %; >+4SD, $p<0.01$). The cortical fibrosis levels estimated using threshold PSR showed a significant correlation with the fibrosis indices determined with Sirius red and collagen IV ($p<0.05$).

Conclusions: The present study provides the first demonstration that renal fibrosis in DN can be non-invasively assessed with qMT-MRI technique and threshold PSR analysis.

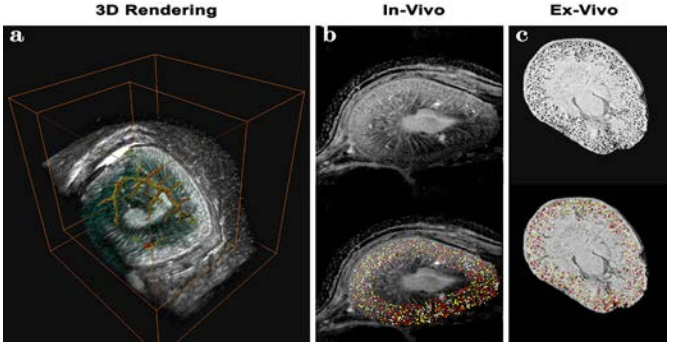
In Vivo Detection of Glomerulus Number and Size in the Whole Kidney Using MRI Edwin Baldelomar,[1] Jennifer R. Charlton,[2] Kevin M. Bennett.[1] *[1]Univ of Hawaii at Manoa; [2]Univ of Virginia.*

Background: Nephron endowment is an important factor in susceptibility to renal insufficiency with development of acute or chronic kidney disease. Here we report a novel, non-invasive, approach to measure nephron endowment *in vivo* using MRI with use of the biocompatible contrast agent cationized ferritin (CF). We report glomerular number (N_{glom}) and individual glomerulus volume (IGV) in live animals.

Methods: Sprague-Dawley (SD) rats were given a total dose of 5.75mg/100g of CF through a tail vein catheter in 3 separate injections at 90-minute intervals. Animals were then imaged with *in-vivo* MRI on a Bruker 7T MRI using a T2* weighted 3D gradient recalled echo (GRE) sequence. Individual 3D MR images were acquired in less than one hour. Motion artifacts were readily mitigated by gating. After imaging, animals were transcardially perfused and kidneys resected for ex-vivo imaging using a T2* weighted 3D-GRE sequence for comparison. N_{glom} and IGV were measured using custom software.

Results: Whole kidneys were imaged *in-vivo* with MRI and images rendered in 3D to visualize gross anatomy, glomeruli, and vasculature. CF accumulation in glomeruli was visible as dark spots in the cortex in both in-vivo and ex-vivo images.



N_{glom} and IGV distributions measured in vivo compared well with measurements in ex vivo MRI; N_{glom} = 35446±2832(in-vivo), 39163±3604(ex-vivo); Mean-IGV = 5.49±1.48(in-vivo),4.90±0.70(ex-vivo) $*10^{-4}$ mm^3. Under the current protocol, a total scan time of ~50 minutes in length allows 3D detection of N_{glom} and V_{glom} in the rat. Further technical improvements should reduce this time significantly.

Conclusions: CF-enhanced MRI can be used to measure nephron endowment *in vivo* in small animals. Given its apparent lack of toxicity at these doses and ease of translation, this approach may be important for preclinical and clinical diagnostics in the future.

SA-PO499

Beta Blocker Pharmacokinetics and Dialyzability in Chronic Hemodialysis Patients Alvin Tieu,[1] Thomas Velenosi,[1] Andrew S. Kucey,[1] Matthew A. Weir,[1,2] Brad Urquhart.[1,2] *[1]Dept of Physiology and Pharmacology, Western Univ; [2]Dept of Medicine, Div of Nephrology, Western Univ, London, ON, Canada.*

Background: There is a paucity of data available to describe drug dialyzability. Of the available information, most were obtained prior to implementation of modern hemodialysis (HD) membranes. This study aims to characterize the dialyzability of the four most commonly prescribed beta blockers in patients undergoing high-flux HD. Based on physicochemical properties, we hypothesize atenolol and metoprolol to be extensively removed by HD, while bisoprolol and carvedilol to be poorly dialyzed.

Methods: Chronic HD patients were recruited for a pharmacokinetic, 4-way crossover study. Atenolol, bisoprolol, carvedilol and metoprolol were administered separately to each patient over 4 HD sessions. Arterial and venous blood samples and total spent dialysate were collected. Beta blocker concentrations were measured by mass spectrometry and dialytic clearance was determined by the dialyzer and recovery clearance methods.

Results: After HD, 6.07, 1.11, 0.03 and 1.28 mg of atenolol, bisoprolol, carvedilol and metoprolol were recovered in spent dialysate. As a result, dialytic clearance rates for atenolol, bisoprolol and metoprolol were 117.1, 110.1 and 148.4 mL/min. These 3 beta blockers are significantly dialyzed as compared to carvedilol (17.8 mL/min). Other pharmacokinetic parameters that were calculated include non-dialytic clearance and post-dialysis doses required to maintain patients within a therapeutic window. For atenolol, bisoprolol and metoprolol, the fraction of elimination due to dialysis was 25, 19 and 13 % while the supplemental doses were 22.7, 2.88 and 1.39 mg. Only 4% of carvedilol was removed by dialysis.

Conclusions: Beta blocker efficacy can be hindered if substantial dialytic clearance occurs. Accordingly, atenolol and metoprolol are extensively cleared by HD, while carvedilol displays low dialyzability. Contrary to literature, our data indicates that bisoprolol is substantially eliminated by HD. With recent studies suggesting heightened mortality risk in HD patients prescribed highly dialyzed beta blockers, dialyzability data is critically important to optimize drug therapy in patients.

Apixaban Pharmacokinetics at Steady State in Hemodialysis Patients Thomas Mavrakanas,[1,2] Caroline Samer,[3] Mark L. Lipman.[1] *[1]Div of Nephrology, Sir Mortimer Davis Jewish General Hospital, McGill Univ, Montreal, QC, Canada; [2]Div of General Internal Medicine, Geneva Univ Hospitals, Geneva, GE, Switzerland; [3]Div of Clinical Pharmacology & Toxicology, Geneva Univ Hospitals, Geneva, GE, Switzerland.*

Background: Atrial fibrillation increases the risk of ischemic stroke in patients with end-stage renal disease. Warfarin may not protect these patients against ischemic stroke. Apixaban is only 27% renally excreted and could be an option in dialysis patients. However, there are no data on apixaban pharmacokinetics at steady state in hemodialysis patients.

Methods: Five patients with atrial fibrillation, on hemodialysis (thrice weekly for >6 months) without any residual renal function, received apixaban 2.5 mg bid for 9 consecutive

days. Venous blood samples were collected immediately before (0) and 0.5, 1, 1.5, 2, 2.5, 3, 4, 6, 9, 12, 24 h after apixaban administration on days 1 and 8 (non dialysis days). On day 9, the dose was increased at 5 mg bid and administered for 7 more days. Pharmacokinetic sampling was repeated as above on day 15. Apixaban levels were measured in the plasma using the chromogenic anti-Xa method and apixaban-specific calibrators and controls.

Results: Apixaban exposure at steady state (day 7 for the 2.5 mg bid dose) was 3.7 fold higher as compared to day 1 (mean AUC 1783.6 vs 487.6 ng.h/mL). The 2.5 mg bid dose in hemodialysis patients achieved reasonable drug exposure and trough levels, comparable to the 5 mg bid dose levels in the general population. In hemodialysis patients, the 5 mg bid dose was associated with significantly higher exposure (mean AUC 6112 ng.h/mL) exceeding the expected 90th percentile in the general population and supratherapeutic peak levels (1.5 fold) in some patients.

Conclusions: In conclusion, apixaban 2.5 mg bid was associated with therapeutic drug levels in hemodialysis patients while the 5 mg bid dose led to supratherapeutic levels. Apixaban dose should therefore be halved in hemodialysis patients and a 2.5 mg bid dose considered for stroke prevention in atrial fibrillation patients.

SA-PO501

Paricalcitol Pharmacokinetics in Children Is Not Affected by Chronic Kidney Disease Stage Matthew B. Dufek,[1] Sven Stodtmann,[1] Nicholas J. Webb,[2] Denise Beck,[1] Peter Noertersheuser,[1] Ann Katherine Eldred,[1] Peter G. Linde,[1] Cheri E. Klein.[1] *[1]Abbvie Inc, North Chicago, IL; [2]Univ of Manchester, Manchester, United Kingdom.*

Background: Two studies were completed to evaluate the pharmacokinetics, efficacy, and safety of paricalcitol (Zemplar) in the reduction of intact parathyroid hormone (iPTH) in children 10-16 years with stage 3-5 CKD. Results from these studies were used to determine covariates that impact the exposure of paricalcitol in children with stage 3-5 CKD.

Methods: The first study evaluated the pharmacokinetics of paricalcitol following administration of 3 μg paricalcitol capsules to children (n=12) with stage 3/4 CKD. The safety and efficacy portion of the study (n=36) included a 12-week blinded and a 12-week open-period where all children received paricalcitol. In the second study, safety and efficacy of open-label paricalcitol capsules was evaluated in children (n=13) with stage 5 CKD (on dialysis) for 12 weeks. A population pharmacokinetic model was used to evaluate subject-specific covariates that explained the observed variability.

Results: In the stage 3/4 CKD study, the paricalcitol treatment group had 5 (27.8%) children with 2 consecutive reductions ≥30% in iPTH from baseline compared with none (0%) in the placebo group. No new safety signals were identified. With a single 3 μg paricalcitol dose mean C_{max} was 0.13 ng/mL and mean AUC_{∞} was 2.87 ng•h/mL. In the stage 5 CKD study, 8 (61.5%) children had 2 consecutive iPTH reductions ≥30% from baseline and 5 (38.5%) had 2 consecutive iPTH values between 150-300 pg/mL. Population pharmacokinetic analysis showed sex and body weight were significant covariates while CKD stage was not. Sex was not considered clinically relevant since dosing is individualized for iPTH response. The estimated apparent volume of distribution (22.9 L for males) and apparent clearance (19.1 L/day) increased 15.9% and 21.7% for every 10 kg increase in body weight over 46 kg, respectively.

Conclusions: Oral paricalcitol dosing in children 10–16 years with stage 3–5 CKD reduced iPTH levels and no new safety signals were identified. Population pharmacokinetic analysis showed that CKD stage does not influence the pharmacokinetics of paricalcitol in children.

SA-PO502

Population Pharmacokinetics Using Scavenged Samples II: Biostatistics and Modeling Matthew S. Shotwell,[1] Joseph J. Groszek,[2] William Henry Fissell,[2] Alexandra F. Chancellor.[3] *[1]Biostatistics, Vanderbilt Univ, Nashville, TN; [2]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [3]Clinical Pathology, Vanderbilt Univ, Nashville, TN.*

Background: Antibiotic dosing in critical illness complicated by AKI is incompletely understood. Traditional pharmacokinetic studies require large number of patients and repeated sampling that is impractical in postmarketing studies. We implemented a population pharmacokinetic analysis using blood left over from clinical samples.

Methods: Plasma concentration of target drug was modeled using a one-compartment linear differential equation model. Separate solutions to the homogeneous (between infusions) and nonhomogeneous equations (during infusions) were combined to describe the time course of drug concentration across multiple doses. Concentrations were modeled as the cumulative effect of all prior doses. Nonlinear mixed-effects (NLME) regression was used to fit the one-compartment model to measured drug concentrations. Both the volume of distribution and elimination rate parameters were modeled using fixed and random effects to account for between-subject heterogeneity, where the latter were assumed to be normally distributed with mean zero and unstructured covariance.

Results: 171 piperacillin plasma concentration measurements were collected from scavenged blood samples from 92 patient encounters. The number of scavenged samples per encounter varied from 1 (54%) to 8. The number of piperacillin doses per encounter varied from 1 to 49, with a median of 11. The figure below illustrates the fitted one-compartment model for a typical patient encounter. In these data, the estimated population average volume of distribution and elimination rate were 30.9 L (95% CI: 21.9, 43.5) and 0.15 h^{-1} (95% CI: 0.11, 0.22), respectively. However, there was substantial population heterogeneity in both parameters.

Conclusions: Pharmacokinetic (PK)models estimated from antibiotic concentrations measured in scavenged blood samples yield parameter estimates similar to estimates from PK.

Funding: Clinical Revenue Support

SA-PO503

Population Pharmacokinetic/Pharmacodynamic (PK/PD) Analyses of C.E.R.A. (Continuous Erythropoietin Receptor Activator - Methoxy Polyethylene Glycol-Epoetin Beta) in Both Adults and Pediatric Patients with Chronic Kidney Disease (CKD) Pascal Chanu,[1] Nicolas Frey.[2] *[1]Certara Strategic Consulting, France; [2]F Hoffmann-La Roche Ltd, Basel, Switzerland.*

Background: Objectives were to determine the PK/PD characteristics of C.E.R.A. in pediatric patients (pts) with anemia of CKD on hemodialysis (HD) and whether they differ from those in adults.

Methods: Serum C.E.R.A. concentrations and hemoglobin (Hb) levels in a 20-week open-label Phase II study of intravenous (IV) C.E.R.A. in pts aged 6–17 years on HD with stable chronic renal anemia were pooled with data collected during the clinical development of C.E.R.A. (IV and subcutaneous [SC]) in adult patients with CKD. Adult PK/PD structural models previously developed were used for the analyses. A non-linear mixed effect modeling approach was applied using NONMEM version 7.3.0.

Results: The pediatric PK/PD dataset consisted of 63 pts with 676 C.E.R.A. serum values and 1580 Hb levels. The adult PK/PD dataset (2 phase II, 3 phase III) consisted of 524 pts with 5883 C.E.R.A. serum values and 12786 Hb levels. The same structural PK model as the adult one (1-compartment model with first order absorption and elimination) adequately described the pediatric data. As already determined in adults, C.E.R.A. clearance increased with body weight and the volume of distribution increased with body weight and age. Once those covariate influences were taken into account, there was no difference in PK between adult and pediatric pts. The PK/PD model developed on adult phase 2/3 data could be applied successfully to pediatric data. The drug dependent parameters (S_{max} and SC50) were comparable in pediatric and adult pts indicating that the C.E.R.A. exposure–response relationship is similar in both populations. The predicted baseline Hb value in absence of any erythropoietin-stimulating agent therapy was found to increase with body weight. This effect is driven by the pediatric population and is in accordance with generally higher Hb levels observed in adults. No difference in PK/PD parameters was found between IV and SC formulation and between dialysis types (including pts not on dialysis).

Conclusions: The PK/PD characteristics of C.E.R.A. are similar between adult and pediatric populations.

SA-PO504

Pharmacokinetics and Safety of KBP-5074 in Phase 1 Single and Multiple Ascending Dose Studies Bin Zhang, Xiaojuan Tan, Shumao Ni. *KBP Biosciences USA Inc.*

Background: KBP-5074 is a new investigational mineralocorticoid receptor antagonist being developed for chronic kidney disease. The primary objective of these studies was to determine the safety, tolerability, and pharmacokinetic (PK) profileof KBP-5074 following single (SAD) and multiple (MAD) ascending oral doses in healthy subjects.

Methods: The SAD study was comprised of 5 sequential cohorts (0.5, 1.0, 2.5, 10, 30mg) and 1 food effect cohort (10mg). The MAD study was comprised of 2 cohorts (2.5, 5.0 mg) dosed for 14 days. PK parameters included C_{max}, T_{max}, $AUC_{0\text{-}24h}$, AUC_{last}, and $T_{1/2}$. Safety parameters included adverse events, vital signs, clinical laboratory results, ECG, and physical examination.

Results: 46 and 12 healthy adults were enrolled in the SAD and the MAD study, respectively. KBP-5074 was generally safe and well-tolerated at single doses up to 30.0 mg and multiple doses up to 5.0 mg. Adverse events were mostly mild and unrelated to study drug. No hyperkalemia (serum potassium >5.5 mmol/L) was reported in the SAD study and the 2.5 mg cohort in the MAD study (3 occurred in the 5.0 mg cohort in the MAD study). Dose proportional increases in plasma levels were observed within the tested dose range after single and multiple ascending doses of KBP-5074 and subsequently declined mono-exponentially. The half-life of KBP-5074 ranged from 59.70 to 72.42 hr in the SAD study, and 55.57 to 60.45 in the MAD study. Food appeared to delay T_{max} from 6 hr to 9 hr.

PHARMACOKINETIC RESULTS			
PK Parameter	SAD Study (Day 1)	SAD Study Food Effect (Day 1)	MAD Study (Day 14)
†C_{max}	9.370 (1.618) - 259.4 (151.4)	177.8 (18.31)	140.4 (38.97) – 321.8 (66.13)
†$AUC_{0\text{-}24h}$	162.5 (31.64) - 5016 (2754)	3154 (261.3)	2865 (821.2) – 6376 (1028)
†AUC_{last}	542.1 (80.85) - 26674 (11755)	15128 (3579)	12481 (4900) – 27686 (6131)
‡T_{max}	4.02 (4.0, 5.0) - 7.00 (4.0, 24.0)	9.00 (5.0, 12.0)	6.00 (2.0, 8.0) – 4.00 (2.0, 10.0)
‡$T_{1/2}$	59.70 (8.926) - 72.42 (17.36)	64.35 (13.75)	55.57 (15.08) – 60.45 (5.475)

† Mean (SD) ‡ Median (min, max).

Conclusions: KBP-5074 was generally safe and well-tolerated by healthy adults in these studies.The maximum repeated dose level in clinical practice may be less than 5.0 mg.

SA-PO505

Pharmacokinetics and Pharmacodynamics of Eculizumab in Individualized Treatment of Atypical Hemolytic Uremic Syndrome Elena Volokhina,[1] Kioa L. Wijnsma,[1] Jack F. Wetzels,[1] Nicole Van De Kar,[1] Lambertus P.W.J. Van den Heuvel.[1,2] *[1]Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Univ Hospitals Leuven, Leuven, Belgium.*

Background: The atypical hemolytic uremic syndrome (aHUS) is a devastating renal disease, caused by complement dysregulation. Approval of monoclonal complement inhibitor eculizumab/Soliris started a new era in the treatment for this disease. However, data on pharmacokinetics and pharmacodynamics of this drug remain limited.

Methods: Eculizumab was measured by in-house ELISA method. Complement activity was analyzed using Wieslab® complement screen assay. In total, 209 samples were taken from 11 patients before the eculizumab infusion in the induction (weekly), maintenance (2-weekly) and tapering (every 3, 4 and 5 weeks) phases of therapy.

Results: Our newly-developed eculizumab assay had variation coefficients of 2.9 % (intra-assay, 352 µg/mL) and 5.2 % (inter-assay, 328 µg/mL) and detection limit of 8 µg/mL. The samples with >50 µg/mL demonstrated <6 % of complement activity in classical and alternative complement pathways. The eculizumab levels had ranges of 36-459 µg/mL and 40-772 µg/mL during induction and maintenance phases, respectively, with 3 samples from 2 patients <50 µg/mL, required for efficient complement inhibition. During tapering, ranges of 61-367 µg/mL, 11-256 µg/mL and 13-161 µg/mL were measured at 3, 4 and 5 week infusion intervals, respectively.

Conclusions: Our data demonstrate large differences in attained eculizumab concentrations among patients at all treatment stages. In induction and maintenance, the detected concentrations were up to 9-15 fold higher than required for efficient complement inhibition (50 µg/mL), although 3 samples did not reach this target value. Thus, eculizumab therapy should be adjusted to meet the needs of individual patients and monitoring of eculizumab concentration is useful to guide the treatment schemes. We have shown that target eculizumab values (> 50 µg/mL) may be reached with infusion intervals extended beyond 2 weeks; extension of intervals for these patients may improve cost-effectiveness of therapy.

Pharmacokinetics (PK), Pharmacodynamics (PD), and Safety of Single and Multiple Oral Doses of Vadadustat in Healthy Japanese and Caucasian Subjects Gurudatt A. Chandorkar,[1] Stan Jhee,[2] David S. Han,[3] Jason Chan,[1] Karishma Manzur,[1] Ramin Farzaneh-Far.[1] *[1]Akebia Therapeutics, Inc., Cambridge, MA; [2]PAREXEL International Early Phase, Glendale, CA; [3]California Clinical Trials Medical Group in Affiliation with PAREXEL Early Phase, Glendale, CA.*

Background: Vadadustat is a novel, once-daily, oral, hypoxia-inducible factor prolyl-hydroxylase inhibitor and has been shown to increase and maintain hemoglobin (Hb) levels for the treatment of renal anemia in patients with chronic kidney disease. Vadadustat is currently being evaluated in global Phase 3 studies. This study evaluated PK, PD, safety, and tolerability of vadadustat in healthy Japanese and Caucasian subjects.

Methods: Healthy Japanese (n=24) and Caucasian (n=24) subjects were randomized to receive double-blind vadadustat (150, 300, or 600 mg/day) or placebo for 10 days (3:1 ratio). 24-hour serial blood samples (from Days 1 and 10) were analyzed for PK (vadadustat and metabolite concentrations) using validated LC/MS/MS methods. PD markers (EPO, reticulocytes, and iron indices) were also measured. Standard PK parameters (area-under-the-curve $AUC_{0\text{-}t}$, peak plasma concentration C_{max}, and clearance CL/F) were estimated. Data analysis included 95% confidence intervals of $AUC_{0\text{-}t}$ and C_{max}. Safety and tolerability were based on vital signs, clinical laboratory tests, electrocardiography, and adverse events (AEs).

Results: Vadadustat exposure was similar between the ethnicities following single and multiple doses, and overall exposure increased in an approximate dose-proportional manner. Change in EPO and reticulocytes as a function of vadadustat exposure were similar between the ethnicities. Mean Hb remained stable over time following multiple doses in both ethnicities. No dose-related or ethnicity-related trends were observed for the iron indices. No safety concerns were identified: Only 2 mild AEs were reported in vadadustat-treated subjects and both events resolved.

Conclusions: PK, PD, safety, and tolerability of vadadustat were similar between the healthy Japanese and Caucasian subjects. These results demonstrate that the vadadustat clinical data meets ICH E5 criteria for bridging in support of the global Phase 3 studies.

Pharmacokinetics of Sparsentan in Healthy Subjects: In Vitro Metabolism and Effects of Food, Gender, Age, and Multiple-Dose Escalation Xin-Ru Pan-Zhou, Kevin Leach, Maria Beconi. *Retrophin, Inc., Cambridge, MA.*

Background: Sparsentan (RE-021) is a first-in-class, dual endothelin A and angiotensin 1 receptor antagonist that is being evaluated in a clinical trial (DUET) to treat focal segmental glomerulosclerosis (FSGS). Here we report on in vitro hepatic metabolism and in vivo pharmacokinetic (PK) studies in healthy subjects.

Methods: In vitro metabolism was assessed by incubating sparsentan in human liver microsomes and hepatocytes. PK studies in healthy subjects included evaluation of the effects of food, gender, age, and multiple ascending dose administration (50-1000 mg/d for 14 days).

Results: Sparsentan was primarily metabolized by CYP3A4. Up to 29 metabolites, mostly products of oxidation, were detected in HLM and hepatocytes after incubation with ^{14}C-sparsentan**.** Sparsentan exhibited rapid absorption and dose-related increases in systemic exposure after once-daily ascending dosing. The half-life of ~15 hours supported adequate coverage for once-daily dosing. No accumulation of sparsentan was observed after 14-day oral dosing (accumulation ratio ≤ 1.3 for all doses). Similar exposures were observed in men and women (%mean ratio [90% CI] = 92.80 [75.95, 113.38] for C_{max} and 89.69 [72.24, 111.36] for AUC). There was an increase in exposure driven by food (20% in AUC and 50% in C_{max}), but this was not considered clinically relevant. An age effect was observed, with the AUC 65%-67% higher in subjects ≥ 65 years vs those aged 22 to 39 years.

Conclusions: Hepatic metabolism of sparsentan was mainly mediated by CYP3A4. In healthy subjects, sparsentan exhibited linear PK and no accumulation after multiple days of dosing. Sparsentan can be dosed without regard to food due to only a modest change in AUC. While plasma exposure of sparsentan was higher in elderly subjects, there was no gender effect on the PK of the drug. These PK results support further clinical development of a once-daily dosing regimen of sparsentan in patients with FSGS.

Funding: Pharmaceutical Company Support - Pharmacopeia, Inc. funded the human pharmacokinetic studies. Retrophin, Inc. acquired sparsentan from Ligand Pharmaceuticals, Inc. (formerly Pharmacopeia) and funded the in vitro metabolism studies. Retrophin participated in the study design, data collection and interpretation, writing, reviewing, and approving this abstract for submission

SA-PO508

Safety and Pharmacokinetics in Healthy Human Volunteers of RG-012: An Inhibitor of MicroRNA-21 Being Investigated for Treatment of Alport Syndrome John Stewart Grundy, Kai Liu, Jacqueline Blem, Paul C. Grint, Michael Huang. *Regulus Therapeutics, San Diego, CA.*

Background: RG-012 is a single-stranded chemically modified oligonucleotide being developed to treat patients with Alport syndrome (AS), which is characterized by loss of renal function associated with defects in specific collagen genes expressed in the kidney glomerular basement membrane. RG-012 inhibits miR-21, a microRNA target associated with renal dysfunction and increased expression during kidney stress.

Methods: Safety and clinical pharmacokinetics (PK) of RG-012 (parent drug), RG0005 (active metabolite), and SUM (RG-012+RG0005) were evaluated in a placebo-controlled single ascending subcutaneous dose study (0.5, 1, 2, 4, and 8 mg/kg of RG-012; n=8/cohort including 6 active and 2 placebo) in healthy volunteers, with urine and plasma PK sampling performed up to 24 and 672 hours post dose, respectively. Concentrations of RG-012, RG0005, and SUM up to 24–48hrs post dose were determined using HPLC-MS/MS (LLOQ=10 and 50 ng/mL in plasma and urine, respectively). Very low plasma concentrations of SUM seen at ≥72hrs post dose were determined using HPLC-FL (LLOQ=0.623 ng/mL) which cannot resolve RG-012 and RG0005.

Results: Subcutaneous administration of RG-012 up to 8 mg/kg appeared to be generally safe and well tolerated in this study (no SAEs, severe AEs, or subject discontinuations). RG-012 was the main analyte observed in plasma and urine, with RG0005 being the sole major metabolite detected (achieving up to 47% of parent drug exposure). The plasma profiles of the evaluated analytes were characterized by relatively rapid absorption/appearance (median T_{max} range: 4–8 hours), dose-dependent exposure, and rapid clearance ($MRT_{0\text{-}24h}$ range: 6.9–9.2 hours) presumably reflecting extensive distribution to tissues. The mean terminal elimination half-life values of SUM ranged from 4–13 days, likely reflecting long tissue half-lives. Combined urinary excretion of RG-012 and RG0005 over the first 24 hours post dose was less than 1% of the total administered dose.

Conclusions: In conclusion, favorable safety and clinical PK results in this study appear generally consistent with reported results from other similar compounds in this oligonucleotide class.

Quantification of Cefepime, Meropenem, and Vancomycin Removal by Sustained Low-Efficiency Dialysis Joanna Q. Hudson,[1,2] Jagannath H. Saikumar,[2] Benjamin Duhart,[1] G. Morgan Jones,[3] Elvira Gosmanova.[4,5] *[1]UT Colleges of Pharmacy and; [2]Medicine, UT Health Science Center, Memphis, TN; [3]Methodist Univ Hospital, Memphis, TN; [4]Div of Nephrology, Albany Medical College; [5]Nephrology Section, Stratton VAMC, Albany, NY.*

Background: Adequate dosing of antibiotics is paramount for treating infections in critically ill patients undergoing renal replacement therapy. Little is known about antibiotic removal by sustained low efficiency dialysis (SLED). To address this knowledge gap, we quantified removal of cefepime (C), meropenem (M), and vancomycin (V) in intensive care unit (ICU) patients undergoing SLED.

Methods: Adult patients aged ≥18 years with acute kidney injury (AKI) or end-stage renal disease (ESRD) admitted to the ICU and receiving C, M and/or V while undergoing SLED were eligible for inclusion. Blood and dialysate flow rates were maintained at 250 and 100 mL/min, respectively. Simultaneous arterial and venous blood samples for analysis of C, M, and V concentrations were collected at time 0 and hourly for up to 8 hours during SLED (on-SLED). Arterial samples were collected every 2 hours for up to 6 hours while not receiving SLED (off-SLED) for calculation of SLED clearance (CL), half-life ($t_{1/2}$) on-SLED and off-SLED, and the fraction of removal by SLED (f_D). Antibiotic concentrations were measured by liquid chromatography/mass spectrometry.

Results: Sixteen patients completed the study: 56% male, mean age (±SD) 52±14 years, and mean weight 96±28 kg. Eighty-eight percent had AKI and 10 patients were receiving V, 9 M, and 4 C. A polysulfone dialyzer (F50 or F160) was used for all SLED sessions and the mean ultrafiltration rate was 96±49 mL/hr. Pharmacokinetic data for each drug are shown in the table (data shown as mean ±SD).

Drug	SLED CL, mL/min	On-SLED $t_{1/2}$, hr	Off-SLED $t_{1/2}$, hr	f_D, %
Cefepime	70±21	4.3±0.9	15.4±8.5	67±15
Meropenem	72±12	4.0±1.1	7.2±3.1	42±18
Vancomycin	33±12	12.3±6.6	N/A*	49±15

*No significant drop in concentration over sampling interval.

Conclusions: An 8-hour SLED session led to significant elimination of C, M, and V. If SLED is performed, additional doses of these antibiotics are warranted to avoid subtherapeutic concentrations.

SA-PO510

Displacer-Enhanced Hemodialysis for Treatment of Intoxications with Highly Protein-Bound Drugs: A Model-Based Analysis Xia Tao, Vaibhav Maheshwari, Doris H. Fuertinger, Peter Kotanko, Stephan Thijssen. *Renal Research Inst, NY, NY.*

Background: Over 9 million intoxication cases involving drugs were reported in the US in 2014. Hemodialysis (HD) is an appropriate treatment in life-threatening situations. However, the inefficiency of HD to remove highly protein-bound drugs limits its use to treat intoxications with such substances. We previously showed that infusing binding competitors (displacers) into the dialyzer blood inlet enhances the dialytic removal of protein-bound uremic toxins in a HD model. Here we report simulations using a novel mathematical model to predict the efficacy of displacer-enhanced HD for treating intoxications with highly protein-bound drugs.

Methods: The model comprises a multi-compartmental representation of the patient and spatiotemporal representation of the dialyzer, accounting for dynamic equilibrium of drug, albumin and albumin-drug complex. Carbamazepine and phenytoin were chosen as model substances to evaluate the efficacy of displacer-enhanced HD. Ibuprofen (800 mg over 2.5h; optimized infusion profile) and aspirin (1000 mg over 2.7h; optimized infusion profile) were used as displacers for carbamazepine and phenytoin, respectively. Q_b and Q_d were 250 and 500 mL/min, respectively. Distribution volume was 44 L in 70 kg male.

Results: Compared to conventional HD, non-toxic drug levels were achieved in a substantial shorter time with displacer-enhanced HD.

Table 1. Time required to lower plasma levels to therapeutic range.

Drug	Carbamazepine	Phenytoin
Mean peak overdose level (mg/l)	46	70
Protein binding	75%	90%
Primary albumin binding site	II	I
Native elimination	~60h	~58h
HD	5.5h	9.3h
Displacer-enhanced HD	2.5h	2.7h

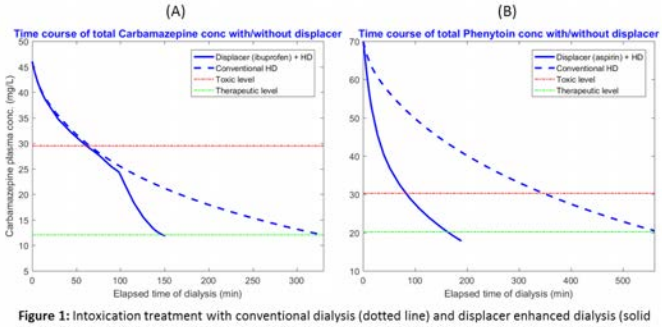

Figure 1: Intoxication treatment with conventional dialysis (dotted line) and displacer enhanced dialysis (solid line): (A) Carbamazepine removal with ibuprofen as displacer reduced HD duration by 180 min, (B) Phenytoin removal with aspirin as displacer reduced HD duration by 400 min. Time required by HD or Displacer enhanced HD denotes time to bring drug toxic concentration to therapeutic level.

Conclusions: Displacer-enhanced HD significantly improves the removal of highly protein-bound drugs. This efficacy gain may translate into resource savings and improved patient outcomes.

SA-PO511

Prediction and Validation of Hemodialysis Duration in Ethylene Glycol Poisoning Ioan-Andrei Iliuta,[1] Philippe Lachance,[2] Yannick Begin,[2] Fabrice Mac-Way,[2] Simon Desmeules,[2] Sacha A. De Serres,[2] Mohsen Agharazii.[2] *[1]Nephrology, Toronto General Hospital, Univ Health Network, Toronto, ON, Canada; [2]Nephrology, Hôtel-Dieu de Québec, Quebec City, QC, Canada.*

Background: Ethylene glycol (EG) poisoning is a fatal alcohol poisoning. Along with alcohol dehydrogenase (ADH) inhibition and supportive care, hemodialysis (HD) is required until correction of acidosis and serum EG level of < 3mmol/l. But, EG levels are not readily available, which could lead to under-dialysis or undue extension of HD. The aim of the present study is to define EG elimination half-life ($T_{1/2}$) during HD, use a training set to propose a $T_{1/2}$-based model for determining HD duration, and validate the model in a validation.

Methods: In a retrospective cohort study, we identified 26 episodes of EG in 24 subjects that met HD criteria. HD was performed using high-efficiency filters with a surface area > 2.0 m^2 , a blood flow of >350 ml/min and a dialysate flow of 750 ml/min. Using EG levels during HD, we calculated EG $T_{1/2}$ by one phase decay exponential regression analysis. Kinetic modelling was available for 21 cases, 2 of which were repeated poisoning. To predict HD duration, a training set used the 50th, 75th and 90th percentile of $T_{1/2}$ and target post-HD EG levels of 3, 2, 1 and 0.5 mmol/l. The optimal model was then validated in a validation set, and cross-validation was performed using leave-one-out approach.

Results: The overall elimination $T_{1/2}$ during HD, under ADH inhibition, was 158 min (95% CI 146-169). In the training set (n=12), the 50th percentile (165 min, 95% CI: 149-176 min) and a post-HD target level of 1 mmol/l provided the least difference in delivered versus predicted HD duration (13 min, 95% CI: -138 – 132 minutes), and assured a post-HD EG level of < 3mmol/l in all patients. In the validation set (n=7), all patients achieved a post-HD EG level of < 3 mmol/l and a difference between delivered versus predicted HD duration was -21 min (95%CI: -117 – 86). A cross-validation confirmed these findings.

Conclusions: Using an EG T1/2 of 158 min with high-efficiency HD, and a post-HD target EG level of 1 mmol/l, HD duration can be predicted accurately while assuring a safe post-HD EG level.

Cystatin C-Guided Vancomycin Dosing Improves Target Trough Achievement in the Critically Ill Compared to Standard Care with Creatinine Clearance Erin N. Frazee, Andrew D. Rule, John C. Lieske, Kianoush Banaei-Kashani, Jason N. Barreto, Abinash Virk, Philip Kuper, Ross Dierkhising, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Background: A cystatin-C inclusive vancomycin dosing algorithm may improve target trough achievement compared to serum creatinine-guided therapy in critically ill patients.

Methods: Patients initiated on intravenous vancomycin in three intensive care units at a single tertiary medical center were studied. Dosing regimens were selected and implemented after an individualized target vancomycin trough (10-15mg/L or 15-20mg/L) was established. Between 01/2012-10/2013 vancomycin was dosed according to serum creatinine (historical controls). From 12/2013-05/2015 a novel vancomycin algorithm was implemented which used the $CKDEPI_{creatinine\text{-}cystatin\ C}$ eGFR to guide dosing (prospective intervention arm). Steady state target trough achievement was compared between the two study arms with and without adjustment for potential confounders.

Results: Patients in the intervention arm (N = 135) experienced significantly greater target trough achievement than historical controls (N = 264) [(50% vs. 28%; OR 2.53 (95% CI 1.65, 3.90); P < 0.001)]. Group differences persisted after adjustment for age, sex, APACHE III score, fluid balance, baseline creatinine clearance, operative admission diagnosis, presence of sepsis, and goal trough range [adjusted OR 2.79 (95% CI 1.76, 4.44); P < 0.001]. There was no difference in treatment failure, acute kidney injury, renal replacement therapy or death between treatment arms.

Conclusions: Use of a combined serum creatinine and cystatin C-based vancomycin dosing nomogram significantly improved target trough achievement among critically ill patients with stable renal function. Further studies are warranted to characterize the relationship between use of cystatin C-guided dosing and clinical outcomes.

SA-PO513

Nephrotoxicity Associated with Concomitant Vancomycin and Standard Infusion versus Extended Infusion Piperacillin-Tazobactam in Obese Patients Justin G. Horowitz, Roberto L. Collazo-Maldonado. *Nephrology, Methodist Health System, Dallas, TX.*

Background: Researchers have alluded to improved pharmacodynamic activity and clinical outcomes by extending the infusion time of piperacillin-tazobactam (PT) from 30 minutes to 4 hours. Over the past 2 years there has been discussion in the literature of a potential synergistic nephrotoxicity using PT with vancomycin (VANC). Therefore, it is prudent to identify if the infusion rate of PT may mitigate this synergistic effect.

Methods: This was a single-center, retrospective chart review. Patients were identified if they received VANC concomitantly with PT from September 2013 through August 2015. Patients were included if they received this antibiotic combination for >48 hours, a BMI ≥30 kg/m^2. Any patient with history of CKD or admitted to an ICU were excluded. Comparator arms both include VANC, however the standard infusion group received PT administered over 30 minutes as compared to the extended infusion receiving a 4 hour infusion. The primary outcome is incidence rate of acute kidney injury (AKI) defined as an increase in SCr by 0.5 mg/dL or 50% from baseline. Secondary outcomes include time to AKI, and identification of contributing risk factors.

Results: A total of 158 patients were included in total. Patients were predominately female (58%), and had a mean body mass index of 39.0 kg/m^2. The average daily dose of PT was 14.2 and 11.6 grams for standard versus extended infusion, respectively. For the primary outcome, 29% patients in the standard PT infusion arm and 32% of patients in the extended infusion arm experienced an AKI (p=0.68). Time to AKI was between 3-4 days in both cohorts (p=0.88). Univariate analysis shows that higher doses of PT may independently implicated in causing nephrotoxicity with vancomycin (OR 1.2, 95% CI 1.06-1.38; p<0.05).

Conclusions: Although there was no statistically significant difference in the incidence of AKI in patients receiving concomitant VANC and standard versus extended infusion PT, patients receiving higher doses of PT may be at greater risk of developing AKI. This is a concern when using standard infusion PT as it is dosed more frequently and therefore associated with higher daily doses.

SA-PO514

Chemotherapy Dosing prior to Hemodialysis in Cancer Patients with Kidney Failure Frieder Keller. *Innere 1, Univ Hospital, Ulm, Germany.*

Background: In cancer patients, the incidence of acute kidney injury is 15 – 45 % per year. Due to growing age, chronic kidney disease is prevalent with 20 – 50 % in this population. On the other side, the pharmacokinetics depend on kidney function in 31 of 68 essential anti-cancer drugs (46 %). To adjust for kidney function, the dose frequently is reduce. Independent from kidney function, chemo-therapy was underdosed in 30 % of cancer patients with a negative impact on survival [Br J Cancer 2002].

Methods: Only few case reports or small case series are published on dosing of chemotherapy in cancer patients with kidney failure. Most experts plead for chemotherapy administration after dialysis [Semin Dial 2015]. We have reviewed the literature and extracted the concept to administer the dialyzable anticancer drugs prior to hemodialysis. According to our own experience [Eur J Haematol 2005], the chemotherapy administration before hemodialysis might allow for a higher, near normal dose without inacceptable toxicity.

Results: We have found 28 PubMed cited papers where the concept to administer high and near normal standard dose chemotherapy prior to hemodialysis is proposed for 17 drugs. At least 30 % of these drugs is eliminatied by dialysis. To simulate normal kidney function, however, hemodialysis should start 2 hours after cessation of the chemotherapy infusion and hemodialysis should be repeated on a daily basis for 4 to 6 days.

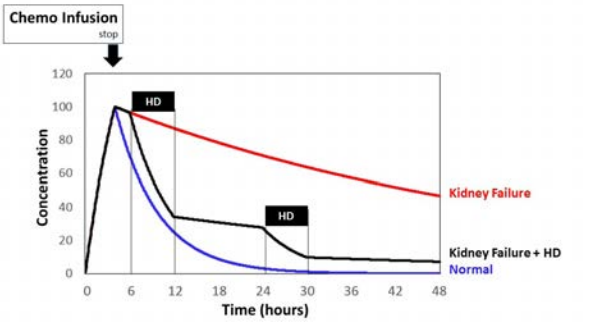

Figure 1: Concept of standard dose chemotherapy prior to hemodialysis (HD) in patients with kidney failure.

This concept has been reported for bleomycin, capecitabine (FBAL), carboplatin, cisplatin, cyclophosphamide, cytosine-arabinoside, fludarabine (2F-Ara-A), gemcitabine (dFdU), ifosfamide, iodine 131, irinotecan (SN-38), lenalidomide, methotrexate, oxaliplatin, pemetrexed, S-1 (tegafur), and topotecan.

Conclusions: Efficacy and safety of 17 essential chemotherapeutic agents could be improved by immediate post-infusion hemodialysis in patients with kidney failure.

SA-PO515

Cetuximab Prevents Methotrexate-Induced Nephrotoxicity Through Epidermal Growth Factor-Dependent Signaling Rosalinde Masereeuw,[1] Pedro Caetano Pinto,[1] Amer A. Jamalpoor,[2] Janneke Ham,[3] Carla Van Herpen,[3] Martijn J. Wilmer.[2] *[1]Pharmacology, Utrecht Inst for Pharmaceutical Sciences, Utrecht, Netherlands; [2]Pharmacology and Toxicology, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Medical Oncology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: A novel phase I/IIb study investigates the efficacy of combining methotrexate (MTX) with the epidermal growth factor receptor (EGFR) recombinant antibody cetuximab (CTX) in treatment of locally advanced head and neck squamous cell carcinoma. Here, we studied the effect of CTX on renal MTX handling by organic anion transporter 1 (OAT1), breast cancer resistance protein (BCRP) and multidrug resistance protein 4 (MRP4) in a renal cell model.

Methods: Conditionally immortalized proximal tubular epithelial cells over-expressing OAT1 (ciPTEC-OAT1) were used to examine activity and expression of OAT1, BCRP and MRP4 upon treatment with EGF (10 ng/ml), CTX (500 µg/ml) or the mitogen-activated protein kinase (MEK) inhibitor, U-0126 (2 µM). Nephrotoxic effects of MTX were determined using dimethylthiazol bromide (MTT) assay.

Results: MTX inhibited fluorescein uptake to 56±6% ($p<0.05$),decreased Hoechst33342 efflux to 71±5% ($p<0.05$) and chloromethylfluorescein-diacetate (CMFDA) to 58±5% ($p<0.05$), confirming the role of OAT1 in uptake and BCRP and MRP4 in renal efflux, resp. CTX reversed the EGF-increased expression of OAT1 to 32.2±1.3% ($p<0.05$) and BCRP to 32.0±9.7% ($p<0.05$), as well as their membrane expressions, while MRP4 was increased by 182±57% ($p<0.05$). This was supported by a decreased fluorescein uptake (to 68±1%; $P<0.01$) together with a decrease in Hoechst efflux (to 71±2%; $p<0.05$) and enhanced CMFDA efflux (by 133±6%; $p<0.05$). Furthermore, U-0126 decreased the functional expression of OAT1 (64±7%; $p<0.01$) and BCRP (67±7%, $p<0.05$) in EGF-stimulated cells, confirming EGFR-MEK signaling. Exposure of ciPTEC-OAT1 to MTX (100 µM) for 24h reduced viability to 40±3% ($p<0.05$), which was reversed by CTX or U-0126.

Conclusions: CTX downregulates OAT1 and BCRP while upregulating MRP4 via EGFR signaling. Further, CTX could prevent MTX-induced nephrotoxicity, which may open possibilities for nephroprotective co-medication therapies.

SA-PO516

Peak Platinum Excretion Correlates with Novel Urinary Biomarkers in Cancer Patients Receiving Cisplatin-Containing Therapy Melanie S. Joy,[1] Blessy George,[1] Marie Madeleine Gomez,[1] Nickie Lee Mercke,[1] Xia Wen,[2] Brian Buckley,[2] Daniel Bowles,[1] Cindy L. O'Bryant,[1] Lauren Aleksunes.[1] *[1]Skaggs School of Pharmacy, Cancer Center, and Renal Diseases and Hypertension, Univ of Colorado, Aurora, CO; [2]Ernest Mario School of Pharmacy, Rutgers Univ, Piscataway, NJ.*

Background: Novel biomarkers are under investigation for detecting kidney injury. Given the limitation of measuring cisplatin in patient kidneys, urinary Pt may be a quasi-marker of exposures and toxicity. The current study determined Pt PK and urinary biomarkers.

Methods: Blood (0-6h) and urine (0-6h) were obtained from cancer patients (n=11) receiving cisplatin. Pt was quantified using ICP/MS. PK analysis was conducted using Phoenix®. Urinary biomarkers were measured using a multiplex assay at baseline, 3 and 10 days post-cisplatin.

Results: Patient characteristics were age 58±10 y, 11 Caucasian/2 other, 8 male/5 females, BSA 1.9 m^2, dose (53.5±19 mg/m^2). Pt PK parameters were C_{max} 2.8±1.0µg/mL, $AUC^{0-\infty}$ 28.6±19.5mg h/L, volume 55.3±15.7L, clearance 5.4±3.6L/h. No significant correlations between C_{max} (as the driving force for urinary excretion) and peak urinary biomarkers were observed. Peak Pt excretion (20.9±12.2 µg/mL) occurred in the 0-2 h urine collection. Significant relationships (R^2) were found between peak Pt excretion and urinary biomarkers.

Table 1. Correlations Represent R^2 Values	Urine Pt	P-value
KIM-1	0.6406	0.0048
TFF3	0.8106	0.0005
Osteopontin	0.7849	0.0007
NGAL	0.7974	0.0006
Cystatin C	0.7424	0.0014
B2M	0.8584	0.0002
Albumin	0.7968	0.0006
MCP-1	0.0268	0.3368
GST pi-1	0.5268	0.0134
Clusterin	0.5822	0.0084
Calbindin	0.7773	0.0008
IL-18	0.7424	0.0014

Conclusions: The results from this comprehensive study corroborate a high degree of agreement between peak Pt and biomarkers in urine. Given the high degree of exposure of proximal tubule cells to Pt through transporter pathways in the kidney, the results suggest a direct mechanism between kidney exposures and toxicity. Future studies will employ physiologically-based PK to fully understand the relationships between kidney exposures and toxicity.

Effect of Experimental Kidney Disease on the Formation of TMAO by Flavin-Containing Monooxygenases Alexander J. Prokopienko,[1] Daniel P. Schrum,[1] Adam Fitch,[1] Alison Morris,[1] François A. Leblond,[2] Vincent Pichette,[2] Thomas D. Nolin.[1] *[1]Schools of Pharmacy and Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Service de Néphrologie et Centre de Recherche, Hôpital Maisonneuve-Rosemont, Montréal, QC, Canada.*

Background: Cardiovascular disease (CVD) is the leading cause of death in kidney disease (KD) despite aggressive management of traditional risk factors. As such, non-traditional risk factors have received attention as potential therapeutic targets. Systemic exposure of the microbiota-derived metabolite trimethylamine-*N*-oxide (TMAO), which is associated with poor CVD outcomes, increases in KD disproportionately to reductions in renal clearance. Flavin-containing monooxygenases (FMO) oxidize trimethylamine (TMA) to form TMAO and are an important class of drug metabolizing enzymes. We hypothesize that FMO activity is increased in the setting of KD, leading to increased TMAO formation. Therefore, we aimed to assess the effect of experimental KD on FMO activity using TMA as a substrate.

Methods: Microsomes were isolated from liver tissue of KD (5/6thnephrectomized) and control rats (n=7 and 6, respectively). Microsomal incubation conditions were optimized, then enzyme kinetics were determined and compared between groups. TMAO was measured via LC-MS, and formation rate of TMAO was used as an indicator of hepatic FMO activity. Also, in a subset of rats (n=3 KD, n=4 control), serum TMAO concentrations were determined at sacrifice, and exploratory 16S DNA sequencing of intestinal scrapings was performed to compare TMAO exposure and microbiomes.

Results: Metabolic formation of TMAO was significantly increased by 25.6% in KD compared to control rats (Vmax 67.09 ± 1.87 vs. 53.41 ± 2.25 µM/mg protein/hr, $p<0.0001$). No significant differences in Km were observed. No differences in Alpha and Beta diversity metrics were observed in the 16S DNA sequencing between KD and control intestinal scrapings. The median TMAO concentration was increased 16-fold in KD compared to control (64.35 vs. 3.78 µM, $p<0.0385$).

Conclusions: These results suggest that FMO activity increases in kidney disease and may contribute to dramatically increased systemic exposure of TMAO.

First-in-Human Study of TP0463518, a Novel Oral Hypoxia Inducible Factor Prolyl Hydroxylase (HIF-PH) Inhibitor with Liver-Specific Erythropoietin Secretion Hidekazu Ochiai, Fumihiko Sato, Shota Tokuyama, Kunika Kikumori, Fuki Kurimoto, Noriko Takayama, Saeko Uchida, Tomohiro Sugimoto, Hiroyuki Tamaoki. *Taisho Pharmaceutical Co., Ltd., Tokyo, Japan.*

Background: TP0463518 is a novel potent HIF-PH inhibitor being developed for renal anemia treatment and induces endogenous erythropoietin (EPO) secretion. It is well-known that kidney is the dominant organ of EPO production. However, TP0463518 had a unique feature to induce liver-specific EPO secretion in bilaterally nephrectomized rats. The purpose of this human study is to evaluate the safety, pharmacokinetics (PK), and pharmacodynamics (PD: EPO) of TP0463518, a liver-specific EPO inducer after single oral administration.

Methods: In this first-in-human, double-blind, placebo controlled and single administration study, 40 Japanese healthy male subjects were randomized to TP0463518 (3, 6, 11, 20, and 36 mg) or placebo.

Results: C_{max} and $AUC_{0\text{-}72h}$ of plasma TP0463518 concentration increased in a dose-dependent manner after single oral administration of 3 to 36 mg of TP0463518. T_{max} and $T_{1/2}$ were 1.2 to 2.0 and 5.9 to 7.4 hours, respectively. Throughout the study, TP0463518 was well-tolerated and no remarkable adverse events occurred. Baseline EPO levels in serum were similar among all treatment groups (9.6±2.8 and 8.1±3.8 mIU/mL, respectively, N=6), which were all within reference range. TP0463518 increased serum levels of EPO in a dose-dependent manner. Serum levels of EPO after TP0463518 oral administration were 33.5±18.3 mIU/mL at 6 mg and 278.2±155.3 mIU/mL at 36 mg (respectively, N=6). The EPO levels returned to baseline level within 24 to 48 hours at all doses tested. Changes in levels of serum EPO after TP0463518 administration was correlated with C_{max} of plasma TP0463518 concentration (r=0.85). Moreover, a correlation between $AUC_{0\text{-}72h}$ of serum EPO and that of plasma TP0463518 was observed (r=0.82).

Conclusions: TP0463518 was well-tolerated, showed favorable PK profiles, and dose-dependently increased EPO levels in serum, possibly derived from the liver. These results indicate that TP0463518 will be a unique drug for the treatment of renal anemia.

HTS Assay Based Discovery of Novel CD11b Agonists as Potential Therapeutics for Lupus Nephritis Xiaobo Li, Samia Khan, Vineet Gupta. *Rush Univ.*

Background: Systemic lupus erythematosus (SLE, lupus) nephritis is characterized by renal interstitial leukocytic recruitment that leads to chronic renal insufficiency in up to 30% of affected patients. Integrin CD11b/CD18 is critical for leukocyte adhesion and migration during inflammation and tissue injury. We previously used a cell-based, high-throughput screening (HTS) assay to identify small molecule CD11b agonists termed leukadherins that reduce leukocyte recruitment and inflammation in several disease models. Here we use this HTS assay to identify more novel CD11b agonists as potential therapeutics for lupus nephritis.

Methods: We used a cell-based HTS assay to screen a chemical library of >90,000 molecules for compounds that affected the adhesion of K562 cells that expressed CD11b/CD18 at the cell surface to the fibrinogen ligand. CD11b/CD18 K562 cells were exposed to titrating concentrations of molecules and the candidates with the lowest effective dose 50 (EC_{50}) were selected to investigate further.

Results: Using the HTS-adhesion assay, we screened a total of 90,000 molecules in a chemical library and determined 33 potential candidate molecules that bound to CD11b/CD18 K562 cells at $EC_{50} < 6\ \mu M$.

Conclusions: We will further investigate the anti-inflammatory properties of these newly selected candidates in vitro and in vivo. We will compare the efficacy of the new candidates, M1/70 a CD11b antagonist antibody, and CD11b agonist leukadherins in an anti-glomerular basement membrane nephritis model. We suggest that we can utilize this HTS assay to identify integrin-specific, small-molecule agonists that can provide effective therapeutics for lupus nephritis.

Development of a Novel Drug Formulation to Enhance Mesangial Deposition in Glomerulonephritis Uma R. Fogueri,[1] Gavriel Roda,[1] Georgia Charkoftaki,[1] Michael F. Wempe,[1] Joshua M. Thurman,[2] Melanie S. Joy.[1,2] *[1]Skaggs School of Pharmacy and Pharmaceutical Sciences, Univ of Colorado, Aurora, CO; [2]Div of Renal Diseases and Hypertension, Univ of Colorado, Aurora, CO.*

Background: Optimal kidney mesangial deposition for drug delivery vehicles are size 10-100 nm and neutral to negative charge. The overall goals of this project were to develop a novel nanoemulsion of the tyrosine-kinase inhibitor, Imatinib Mesylate (ImM NE), and evaluate pharmacokinetics (PK) when dosing naked vs. NE formulations to MRL/lpr (lupus) and MRL/MpJ (control) mice.

Methods: ImM was dispersed in fish oil droplets via a protocol and filter extrusion was performed to achieve a desired particle size of 80 nm. The ImM NE physical characteristics were evaluated. A 200 µL volume (28 µg) of ImM NE or naked ImM was injected (tail vein) into MRL/lpr (n=11) and MRL/MpJ (n=12) mice. Serial blood samples (25 µL) were obtained and applied to dried blood spot (DBS) cards. An LC-MS/MS assay was developed to measure ImM from DBS. ImM PK analysis was performed using Phoenix®. Differences in PK between ImM naked and NE were evaluated by Instat®.

Results: The ImM NE exhibited optimal characteristics for enhanced mesangial deposition; particle size 60-80 nm and zeta potential -4.226 ± 0.496 mV. The ImM NE was stable at pH 7.4 for up to 72 h. ImM PK showed significantly higher Vd and plasma clearance with the NE, while the naked formulation showed higher plasma Cmax and $AUC^{0\text{-}\infty}$.

Table 1	ImM NE	Naked ImM	p-value
Cmax (ng/mL)	957±414	1622±455	0.0015
$AUC^{0\text{-}\infty}$ (µg min/mL)	77.3±33.2	106±24.1	0.0320
Vd (mL)	33.6±18.7	17.6±4.8	0.0121
Clearance (mL/min)	27.0±14.0	16.7±4.2	0.0367
Lambda (min^{-1})	0.014±0.002	0.016±0.001	0.0041

Conclusions: The formulation demonstrated optimal characteristics for enhanced mesangial deposition and stability. The ImM PK was significantly different between formulations and suggested higher tissue disposition with the NE. Tissue ImM data are pending to confirm enhanced deposition to kidney mesangium. Future studies will evaluate biodistribution of the NE via imaging and relationships to lupus outcomes (kidney biomarkers and ds-DNA).

Mouse Models Treated with Therapeutic Recombinant ACE2 with Long Plasma Half-Life Showed Potent Blood Pressure-Control Effects Pan Liu, Jan A. Wysocki, Minghao Ye, Daniel Batlle, Jing Jin. *Dept of Medicine-Nephrology/Hypertension, Feinberg School of Medicine, Chicago, IL.*

Background: Angiotensin-converting enzyme 2 (ACE2) is a plasma membrane anchored monocarboxypeptidase that potently degrades angiotensin II (Ang II) to form angiotensin-(1-7). Recombinant ACE2 enzymatic ectodomain (termed sACE2) has been shown to have protective effects in several mouse disease models caused by activation of renin-angiotensin system. However, due to the very short plasma half-life of sACE2, the therapeutic potential of such treatment is limited. To circumvent this problem, we made a recombinant fusion of sACE2 with the constant region (Fc) of human immunoglobulin IgG1 to increase its plasma stability.

Methods: We constructed a plasmid to express a fusion protein of ACE2 (amino acid 1-740) and Fc. We transfected HEK293 cells with the plasmid and established a stable cell line that produces this sACE2-Fc protein into the culture medium. The recombinant enzyme was purified from serum-free culture medium by chromatography and the enzyme activity was verified. Following a single i.v. injection of 50ug enzyme to mice, the pharmacokinetics of ACE2 activity in the plasma and the ability of this enzyme to prevent angiotensin II–induced hypertension was monitored. The untagged sACE2 was used as control.

Results: The recombinant sACE2-Fc has its enzymatic activity comparable to that of untagged sACE2 as measured by their catalysis rates of Ang II. Notably, the Fc fusion significantly extended the plasma half-life of sACE2 from less than 10 min to 9 days, representing an increase of over 1000 times in blood residence time. The single i.v. injection of sACE2-Fc showed long-lasting effect on preventing bolus angiotensin II-induced high blood pressure for up to 2 weeks. By contrast, as short as 4 hours after injection of the untagged sACE2 control, its effects on blood pressure no longer exist.

Conclusions: Our results suggest that fusion of Fc greatly increases recombinant sACE2 plasma stability. This feature could make sACE2 a more effective therapeutic agent for blood pressure control.

SA-PO522

In Vivo siRNA Knockdown of LRP2 (Megalin) in Mice Michael T. Eadon, Yinghua Cheng, Kelly J. Mason, Pierre C. Dagher. *Nephrology, Indiana Univ, Indianapolis, IN.*

Background: siRNA stabilized with 2'O-methylation is filtered and reabsorbed in the renal proximal tubule (PT) following IV administration, reducing gene expression temporarily in the PT. Prior siRNA efforts have focused on preventing up-regulation of candidate genes in response to injury or disease. We instead proposed to reduce gene and protein expression of *LRP2* (megalin), which is constitutively expressed, in order to better understand the molecular regulation of this protein.

Methods: 2'O-methylated siRNA targeting mouse *LRP2* (si*LRP2*) was commercially obtained. Using si*LRP2*, reduction of *LRP2* gene expression was confirmed as compared to scrambled siRNA (siSCR) in mouse S1 PT cells with RT-PCR. For *in vivo* use, C57bl/6 mice were obtained and tunneled intra-jugular catheters were placed. si*LRP2* administration was optimized for: dose, site of administration, carrier solution, frequency of administration, and duration of administration. Kidney cortex, liver, lung, and blood were collected upon animal sacrifice. Pharmacodynamic measures of gene and protein expression were compared by RT-PCR, western blot, and immunohistochemistry (IHC).

Results: Compared to siSCR, si*LRP2* reduced gene expression in S1 PT cells to 16.6% (SD 0.6%). Gene expression reduction *in vivo* varied considerably depending on conditions. Under optimized conditions measured 3 h after administration, si*LRP2* reduced gene expression in mouse kidney cortex to 22.8% (SD 25%) as compared to siSCR mouse kidney cortex expression. Time course studies indicate that gene expression remains reduced at 6 h post-si*LRP2*, but increased at 24 h (170%, SD 26%). No discernible decrement in megalin renal protein expression was observed by either western blot or IHC under any condition, even with a maximized twice daily dose for 4 days. si*LRP2* reduced liver *LRP2* expression; however, lung and whole blood expression did not change significantly due to the low expression of *LRP2* in these tissues at baseline.

Conclusions: Megalin is a protein with constitutive expression and a long half-life. Although *LRP2* renal gene expression reduction can be achieved with siRNA, siRNA as an intervention to reduce *in vivo* megalin protein expression is difficult and not cost effective at present.

A Predictive Modeling of Tacrolimus Pharmacokinetic Parameters Based on a High-Throughput Genetic Screening Approach Nicolas Pallet,[1] Margaux Luck,[2] Eric Thervet,[1] Cecilia Damon.[2] *[1]Hôpital Européen Georges Pompidou; [2]Inst Hypercube.*

Background: *CYP3A4* and *CYP3A5* variants explain only a part of the variation in Tacrolimus (Tac) metabolism suggesting the involvement of a wider network of candidate genes. Therefore, other candidates are likely to explain the genetic basis for interindividual variability in dose adjusted Tac concentrations (Tac C_0). Given the high level of inter-dependence between individual genes, we can assume that any biochemical reactions underlying drug responses could not depend on individual gene-drug correlations but rather on a group of genes.

Methods: Based on a high-throughput genetic screening approach, we aimed to identify a set of covariant germline polymorphisms predictive of the interpatients Tac pharmacokinetics variability in kidney transplantation. Tac C_0 of 229 kidney transplant recipients were monitored at each follow-up time after transplantation during three months. We developed a predictive multivariate approach integrating an ensemble features selection scheme based on Fisher's test and Mutual Information, and a temporal multivariate predictive modeling with Partial Least Squares regression.

Results: At days 60 and 90 and over all days, the predictive models explained 70.2%, 62.9% and 22.9% of total log(Tac C0/Dose) variability with 44, 33 and 16 genes, respectively (p-value<0.003 with a permutation test). As expected, these models included the *CYP3A4* and *CYP3A5* variants, and highlight molecular networks of drug metabolism and oxydoreductase activities. In addition, we have identified a variant of the gene encoding SLC28A3, a nucleoside transporter, as a potential candidate gene. Carriers of the SLC28A3 rs10868152, which is an intronic variant without linkage disequilibrium, have consistently lower Tac C_0/Dose, both in the discovery cohort, and in an independent validation cohort of 189 kidney transplant recipients.

Conclusions: Genes variants networks explain 30 to 70% of the inter-patient variability of Tac metabolism; genes interaction networks related to oxydoreduction functions and mono-oxygenase activity have a major impact on Tac metabolism; unexpectedly, purine transporters appear to be involved in Tac metabolism and biodisponibility.

SA-PO524

A Functional SNP at MiR-582-5p Binding Site in Calcineurin Subunit PPP3R1 Leads to Tacrolimus Resistance in Idiopathic Membranous Nephropathy Patients Ying Zhu, Jun Xue, Chuanming Hao. *Nephrology, Huashan Hospital.*

Background: Pharmacokinetic information alone appears to be insufficient to explain the variable drug response. The study explored the contribution of polymorphisms in the genes encoding tacrolimus drug target (calcineurin) on the interpatient variability of its efficacy in idiopathic membranous nephropathy (IMN) patients.

Methods: We searched for variants in the genes encoding calcineurin (PPP3CA, PPP3CB, PPP3CC, PPP3R1 and PPP3R2) by whole-exome sequencing in 8 IMN patients who received tacrolimus, including 4 with complete (CR) or partial remission (PR), 4 with no response (NR). The variants found were genotyped in another 12 patients (5 with CR or PR, 7 with NR). All patients had tacrolimus trough blood concentrations in the target range. The associations of these variants with the response to tacrolimus were analyzed. The functions of the meaningful variants were further investigated in human peripheral blood mononuclear cells (PBMCs) and other cell lines.

Results: A total of 19 variants were observed. Logistic regression analysis showed that the C allele of rs875 (a T-to-C nucleotide change in the 3'UTR of PPP3R1) was significantly associated with an increased risk of tacrolimus resistance (P=0.0205, OR=12.5, 95% CI: 1.089–143.421). As compared with the TT genotype in rs875 (n=25), the TC/CC genotype (n=58) had a higher PPP3R1 protein expression level in human PBMCs as assessed by immunoblot (P=0.0163). Bioinformatics analysis predicted that the C allele of rs875 disrupted a binding site for miR-582-5p. Co-transfection of miR-582-5p and PPP3R1 3'UTR luciferase reporter vector demonstrated that a significantly higher luciferase activity was observed in the rs875 CC construct when compared with the rs875 TT construct (P<0.05). MicroRNA mimics transfection showed that miR-582-5p suppressed PPP3R1 expression in cultured human podocytes with TT genotype, but not in cells with TC genotype (P<0.05).

Conclusions: Our findings suggest that rs875 may contribute to the risk of tacrolimus resistance in IMN patients through disrupting the regulatory role of miR-582-5p on PPP3R1 expression. Besides pharmacokinetics, pharmacodynamics should also be taken into account in improving tacrolimus therapy.

SA-PO525

CYP 3A5 Genotype and Race Association to Tacrolimus Pharmacokinetics Kathleen M. Tornatore,[1,4] Daniel Brazeau,[2] Gregory E. Wilding,[3] Louise M. Cooper,[1] Rocco C. Venuto.[4] *[1]School of Pharmacy; [2]School of Pharmacy; Univ of New England; [3]School of Public Health; [4]School of Medicine; Univ at Buffalo.*

Background: Variability in tacrolimus(TAC) dosing and pharmacokinetics(PK) between African American(AA) and Caucasian(C) renal transplant recipients(RTR) is attributed to cytochrome P450-3A5(CYP3A5) isoenzymes. The Clinical Pharmacogenetics Implementation Consortium(CPIC) TAC guidelines indicates CYP3A5*1*1 [Wild-type(W/T)] are Extensive Metabolizers(EM) and *3*3 [major variant] are Poor Metabolizers(PM) yielding racial differences in dose-normalized troughs and dosing. This study evaluated CYP3A5 genotype associations to TAC PK in AA and C RTR.

Methods: A 12-hr PK study determined trough(C12), C12/Dose(C12+), Area Under the Concentration Curve0-12(AUC12), AUC12/Dose(AUC*) and clearance(CL) in 32 C and 33 AA and C > 6 months post-transplant on steady-state TAC and mycophenolic acid. TAC dosages were adjusted to troughs of 4-9 ng/ml. CYP3A5 polymorphisms *1 and *3 *[rs776746]* were determined. CPIC defined phenotypes grouped by race were: **1*1(W/T)* [EM]; *1*3 [Intermediate Metabolizer (IM)] and *3*3[PM].

Results: EM-AA required twice the dosage compared to PM with comparable C12. EM-AA had 50% of the AUC* with rapid CL compared to PM. IM in AA and C had similar AUC* and CL while C had no EM.

TAC PK	Gr 1:EM-AA [n=12]	Gr 2:IM-AA [n=17]	Gr3:PM-AA [n=4]	Gr 4:IM-C [n=3]	Gr 5:PM-C [n=29]	P value	Pair wise comparison
Dose (mg)	5.4 (1.9)	3.9 (1.2)	2.8 (1.5)	3.3 (0.6)	2.3 (1.0)	<0.001	**Gr1 vs Gr2; Gr1 vs Gr3; Gr1 vs Gr5**
C12 (ng/ml)	7.0 (1.4)	8.3 (2.0)	7.9 (0.9)	6.2 (0.5)	6.7 (1.8)	0.045	None
C12+ (ng/ml/mg)	1.5 (0.7)	2.4 (0.8)	4.2 (3.4)	1.9 (0.2)	3.3 (1.4)	<0.001	None
AUC12 (ng.hr/ml)	125.6 (30.0)	146.6 (34.3)	130.5 (7.4)	106.0 (6.8)	115.5 (29.3)	0.016	**Gr1 vsGr3; Gr1 vs Gr5**
AUC* (ng.hr/ml/mg)	26.5 (11.2)	41.1 (12.6)	66.5 (48.7)	32.6 (6.80)	55.3 (21.4)	<0.001	**Gr1 vs Gr3; Gr1 vs Gr5**
CL (L/hr)	43.9 (16.5)	27.2 (10.6)	23.6 (15.2)	31.8 (7.4)	20.7 (7.2)	<0.001	**Gr1 vs Gr2; Gr1 vs Gr5**

Conclusions: Differences in TAC PK exist between race-CYP3A5 genotypes and support race-adjusted dosing requirements to individualize TAC regimens.

SA-PO526

Influence of Age and Race on Mycophenolic Acid Pharmacokinetics Post-Transplant Kathleen M. Tornatore,[1] Kris Attwood,[2] Louise M. Cooper,[1] Rocco C. Venuto.[3] *[1]Pharmacy, School of Pharmacy and Pharmaceutical Sciences; [2]Biostatistics, School of Public Health; [3]Nephrology/Medicine, School of Medicine and Biomedical Sciences; Univ at Buffalo.*

Background: Minimal data is available describing the influence of age on mycophenolic acid(MPA) pharmacokinetics (PK) in African American (AA) and Caucasian (C) renal transplant recipients (RTR) in spite of increased renal transplantation in the elderly. Our sub-study investigated the impact of age on MPA PK in stable AA and C RTR.

Methods: The 12-hour PK study of MPA were investigated in 35 AA and 32 C RTR receiving enteric coated MPA and tacrolimus. Validated gastrointestinal(GI) adverse effects(AE) ratings were assessed including diarrhea, dyspepsia and vomiting. Patients were categorized by age as follows: Young: >21 & ≤ 40 years; Middle Age: >40 &≤ 60 years and Elderly>60 years. Apparent clearance (CL), area under the concentration-time curve 0-12h(AUC12), dose-normalized AUC12 (AUC*), AUC 6-12 hours (AUC6-12), AUC6-12/AUC12 with GI AE were determined and analyzed with univariate ANOVA.

Results: Table summarizes the results. All groups were above the therapeutic MPA AUC12 guide of 60 mg.hr/L. The elderly exhibited the lowest C0, reduced enterohepatic recirculation(AUC6-12/AUC12) and greater GI AE.

Endpoints	Young (n=16)	Middle Age (n=38)	Elderly (n=13)	P Value*
e-GFR	57.06 (16.04)	52.97(14.26)	59.40 (19.26)	0.390
Dose (mg)	641.3 (185.5)	630.0(176.3)	595.4(135.2)	0.757
C0 (mg/L)	5.8(3.6)	4.8(5.2)	3.3(3.6)	0.019
AUC12 (mg.hr/L)	75.05(34.18)	66.84(30.68)	67.43 (28.54)	0.023
AUC*	0.12(0.06)	0.11 (0.05)	0.11(0.04)	0.076
CL (L/hr)	9.90 (4.32)	11.04(5.18)	10.21(3.83)	0.076
AUC6-12 (mg.hr/L)	30.96(16.81)	25.80 (21.03)	21.55 (12.96)	0.061
AUC6-12 / AUC12	0.40(0.12)	0.37(0.13)	0.30(0.11)	0.066
GI AE Score	2.31(1.62)	2.53(1.86)	2.62 (1.80)	0.054
* Race Adjusted Statistical Analysis				

Conclusions: These findings suggest that MPA dosing regimens need be individualized based upon age and race. Further evaluation of age-related changes in MPA exposure and relation to clinical responses(i.e. adverse effects) are important.

Funding: NIDDK Support, Pharmaceutical Company Support - Novartis Pharmaceuticals

Micophenolic Acid Treatment in Long-Term Kidney Transplant Recipients

Antonino Previti, Gianni Cappelli. *Dept of Surgery, Medical and Dentistry, Univ Hospital of Modena, Modena, Italy.*

Background: Therapeutic Drug Monitoring (TDM) of Micophenolic acid (MPA) has been clearly defined for the early post-transplant period while it has been less explored in the long-term follow-up. We evaluated TDM of MPA in long-term kidney transplant (KTx) recipients with immunosuppressive regimens combined with cyclosporine (Cya) or tacrolimus (FK).

Methods: We selected recipients with at least 2 years from KTx, on a stable dose of Myfortic (dMyf) and stable clinical conditions in the previous 6 months, not previously tested for MPA exposure. In these patients, for a maximum of 6 control visits, we collected: pro-drug MPA doses, MPA trough level concentrations (TLC) and exposure with limited sample strategy (AUC-LSS), hemoglobin (Hb), eGFR, albumin, TLC of metabolite 7-O-MPA-glucuronide (MPAG).

Results: We obtained a total of 180 samples (111 from patients on CyA and 69 from patients on FK). The CyA group had lower Hb (12,39±1,53 vs 14,17±1,16 g/dl), eGFR (44,8±15,9 vs 61,5±17,1 ml/min) and higher MPAG-TLC (94,28±38,68 vs 44,38±21,33 µg/ml) than FK group ($p<0,001$), and no significant difference in dMyf and MPA-TLC. In 15 volunteers (10 on CyA, 5 on FK) we performed AUC-LSS and 12 on 15 patients were in range 30-60 mg*h/L.

Conclusions: Despite CyA group was prone to increased clearance of MPA (e.g. type of calcineurin inhibitor, worst eGFR etc.), they presented the same dMyf and not different MPA-TLC than the FK group. This finding suggest that, in long-term KTx with decreased dose of CyA (C0 86,1±22,5 ng/ml), there may be a similar enterohepathic circulation for MPA with both CyA and FK immunosuppressive regimens. AUC-LSS of our study had a high percentage of patients in a proper MPA exposure, but this finding could be limited by estimation with LSS based on formulas for early KTx. Some patients in 30-60 mg*h/L range received very low dMyf (e.g. 360 mg/day in the CyA group). We speculate that there isn't a low limit dose, but only a proper or inadequate exposure to MPA.

SA-PO528

The Gut Microbiota and Drug Metabolism over Chronic Kidney Disease Progression

Emily D. Hartjes,[1] Thomas Velenosi,[1] Andrew S. Kucey,[1] Kait Al,[2] Gregory B. Gloor,[3] Jeremy P. Burton,[2,4] Gregor Reid,[2] Brad Urquhart.[1] *[1]Physiology & Pharmacology, Schulich School of Medicine and Dentistry, London, ON, Canada; [2]Microbiology & Immunology, Univ of Western Ontario, London, ON, Canada; [3]Biochemistry, Univ of Western Ontario, London, ON, Canada; [4]Surgery, Div of Urology, Schulich School of Medicine and Dentistry, London, ON, Canada.*

Background: The hepatic drug metabolizing enzyme, cytochrome P450 3A (CYP3A), is downregulated in chronic kidney disease (CKD). The suspected cause is loss of renal clearance and subsequent retention of uremic toxins including indoxyl sulfate and p-cresyl sulfate. Differences in the gut microbiota between CKD and healthy patients further suggest that an increase in uremic toxin producing bacteria downregulates CYP3A. We aim to characterize the progression of CKD in terms of gut microbiota, uremic toxins and CYP3A expression to elucidate the mechanism of CYP3A regulation and potential targets for recovery.

Methods: Wistar rats were randomized into six groups defined by time of sacrifice (day 0, 3, 7, 14, 28 and 42). Each group (n=6) was pair-fed either control or CKD-inducing diet. mRNA expression of CYP3A and associated nuclear receptors (PXR/HNF4α) were determined by qPCR. CYP3A protein expression was determined by western blotting and the 16S rRNA gene from caecum swabs was amplified by Illumina sequencing. Metabolomics will be used to identify uremic toxins in plasma, tissues and feces.

Results: CKD significantly depleted CYP3A mRNA by day 14 (-83%, $P<0.001$) and persisted to day 42 (-83%, $P<0.001$). CYP3A protein expression followed a similar trend. PXR and HNF4α were decreased on days 14 and 28. Unsupervised principle component analysis of the cecum microbiota clearly separated CKD and control groups on day 14, 28 and day 42. Individual sequence analysis revealed an increase in bacterial genus *Turicibacter*, a novel finding in CKD.

Conclusions: Our model successfully indicated differences in bacterial composition across CKD progression. CYP3A expression is reduced in cohort with overt renal failure and occurs simultaneously as the observed bacterial changes, further supporting the hypothesised role of gut bacteria in CYP3A downregulation.

AZD9977 Is a Novel Mineralocorticoid Receptor (MR) Modulator with a Differentiated Mode of Action

Krister Bamberg, Ulrika Johansson, Lena William-Olsson, Majlis Hermansson, Susanna Myhre, Kenneth Granberg, Rasmus Jansson-Lofmark, Judith Hartleib-Geschwindner. *CVMD iMed, AstraZeneca R&D, Molndal, Sweden.*

Background: Excess MR activation promotes target organ dysfunction, vascular injury and fibrosis. MR antagonists (eplerenone, spironolactone) improve outcomes in patients with heart failure, but their use in diabetic populations and in chronic kidney disease is limited by the target associated risk for hyperkalemia. Novel, potent and selective MR antagonists should ideally increase the therapeutic window by separation of organ protection from effects on electrolyte balance to avoid hyperkalemia. AZD9977 is a first in class, selective non-steroidal MR modulator that has been compared to eplerenone in preclinical studies.

Methods: Organ protection was studied in uni-nephrectomised (UNX) rats administered aldosterone via osmotic minipumps and fed a high-salt diet with compounds admixed for 4w. Acute effects of AZD9977 and eplerenone on aldosterone driven Na+ retention was tested in male rats on a low salt diet by administering a single dose and subsequent urine collection for 8h.

Results: In vitro, AZD9977 and eplerenone show similar potencies in competition binding experiments and in reporter gene assays. AZD9977 promotes nuclear translocation of MR in EA.hy926 cells expressing endogenous MR while eplerenone antagonises aldosterone mediated nuclear translocation. In UNX rats, 10, 30, 100 mg/kg AZD9977 or 10, 30 mg/kg eplerenone dose dependently reduced urine albumine to creatinine ratio in 24h urine after 4w and improved histopathology scoring of kidney and heart to similar extent. In acute testing, AZD9977 up to 100 mg/kg caused a minimal increase in urine Na+ while 3 to 100 mg/kg eplerenone led to a dose dependent substantially increased Na+ secretion. Co-administration of 100 mg/kg AZD9977 with 10 or 30 mg/kg eplerenone reduced eplerenone mediated Na+ secretion, suggesting a differentiated action for the two compounds in the same pathway.

Conclusions: AZD9977 is a novel differentiated MR modulator which in preclinical testing dissociates organ protective effects from effects on urine electrolytes, predicting a reduced risk for hyperkalemia compared to regular MR antagonists in the clinical setting.

IgG/Creatinine Ratio in Spot Urine as a Prognostic Marker for Rituximab Therapy Outcome in Patients with Nephrotic Syndrome

Michelle Duong,[1] Klaus Stahl,[1] Roland Jacobs,[2] Mario Schiffer.[1] *[1]Dept of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Dept of Immunology and Rheumatology, Hannover Medical School, Hannover, Germany.*

Background: Rituximab is a chimeric monoclonal antibody targeting CD20+ expressing B-cells and is used for a wide range of neoplastic and immune-mediated diseases. The nephrotic syndrome summarizes a group of syndromes such as proteinuria, edema, hyperlipidemia and hypoalbuminemia. As a second line option in therapy refractory patients, Rituximab is often successfully used to treat the nephrotic syndrome with dosages ranging from 375 mg/m² BSA to 1000 mg absolute. However, there are therapy resistant patients and we suspect the failure of therapy is caused by a urinary loss of Rituximab. Therefore we aim to find an association between proteinuria and the loss of Rituximab and therapy outcome.

Methods: Nephelometric analysis and flow cytometry was used to detect IgG and Rituximab concentration in urine probes of 11 nephrotic patients who were resistant to first line therapy and received either 375 mg/m² BSA or 1000 mg Rituximab. Therefore spot urine before and 24-hour urine collection samples within the first day of the therapy were examined. Daudi cells as a CD20 expressing B-cell line was used to determine the Rituximab concentration.

Results: The analysis of the urine samples revealed a loss of IgG before treatment and excretion of Rituximab within the first 24 hours of Rituximab infusion in all included patients, which was not observed in control patients, who also received Rituximab but displayed no proteinuria. The data indicates a correlation between IgG excretion before treatment and the level of reduction of proteinuria afterwards.

Conclusions: The preliminary results show that the determined IgG/creatinine ratio of spot urine before therapy may be a feasible and quick predictor of a Rituximab therapy success and might help for dosage adjustment.

SA-PO531

The Burden of Hepatorenal Syndrome (HRS)

Khurram Jamil,[2] J. Bradford Rice,[1] Alan G. White,[1] Philip J. Galebach,[1] Aneesha Wagh,[1] Belinda Lovelace,[2] George J. Wan.[2] *[1]Analysis Group, Inc.; [2]Mallinckrodt Pharmaceuticals.*

Background: This study evaluated the characteristics, medical visits, rates and days on dialysis, rates of liver and kidney transplants, and costs from the payer perspective of HRS patients covered by commercial and Medicare insurance in the United States.

Methods: Patients were identified from claims databases of commercially-insured (OptumHealth Reporting and Insights) and Medicare beneficiaries (5% Standard Analytic Files). At the time of their first inpatient admission with an HRS diagnosis ("index date") (ICD-9 code 572.4), commercially-insured patients were required to be age 18-64 and Medicare patients were required to be age 65+. Outcomes were assessed during the 30 days prior, and the 30, 60, and 90 days following index.

Results: 784 commercially-insured and 1,061 Medicare HRS patients met the sample selection criteria. Patients were primarily male (~60%) with a mean age of 54.1 among

commercially-insured and 74.1 among Medicare patients. After admission, median survival was short (commercial: 95 days; Medicare: 33 days). Within the first 30 days, the average stay was 11-12 days in both groups. Based on Kaplan-Meier analyses, 36% of commercially-insured and 26% of Medicare patients were readmitted within the next 30 days. Within the first 30 days, a substantial number of patients received dialysis (commercial: 30.5%; Medicare: 20.6%). Commercially-insured patients spent an average of 7.2 days on dialysis (not available in Medicare data). During follow-up, 10.7% of commercially-insured and 1.6% of Medicare patients received liver transplants while 1.4% and 0.2% received renal transplants, respectively. Average costs within the 90 day follow-up period were $157,665 for commercially-insured and $48,322 for Medicare patients, with most costs occurring within the first 30 days. The primary cost driver was inpatient visits (commercial: 90.3% of costs; Medicare: 83.1% of costs), with differences between the populations associated with lower mortality, higher transplant rates, and higher dialysis rates among the commercially-insured.

Conclusions: HRS is associated with high mortality and rates of nephrology-related healthcare resource utilization and imposes a significant economic burden.

SA-PO532

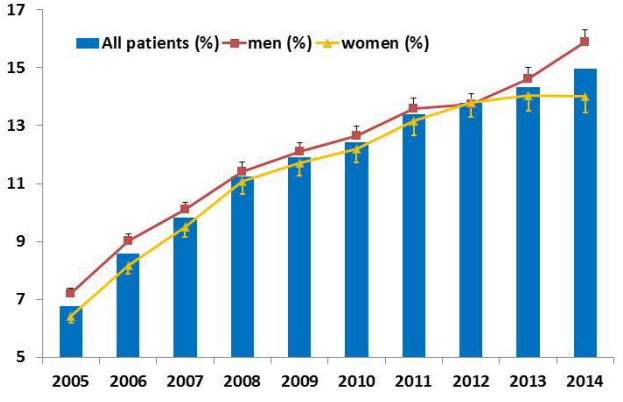
Temporal Trends in the Rates of Acute Kidney Injury across Healthcare Settings in the Irish Health System

Austin G. Stack,[1,2,4] Mohammed A. Kaballo,[1,2] Patrick T. Murray,[3] Xia Li.[4] *[1]Nephrology, Univ Hospital Limerick, Ireland; [2]Health Research Inst, Univ of Limerick, Ireland; [3]Medicine, UCD School of Medicine and Medical Sciences, Dublin, Ireland; [4]Graduate Entry Medical School, Univ of Limerick, Limerick, Ireland.*

Background: Complete ascertainment of the true rates of acute kidney injury (AKI) and emerging trends are essential for the deployment of robust management within health systems. We determined the incident rates of first AKI and annual trends from 2005-2014 in the Irish Health System.

Methods: Health data from regional information systems were linked with mortality data from 2005 to 2014 (n=587,087). AKI events were identified as per KDIGO guidelines. Incidence rates (per 1000 patients) were calculated for each year, by county, geographic region, location of medical supervision [Emergency room (ER), General practice (GP), Inpatient (IP), Outpatient (OP) Outside facility (OF)]. Analysis were conducted using general linear modeling and logistic regression.

Results: Average age was 47.3 ±19 years and 47% were men. AKI incidence rates increased significantly from 6.78 (6.60, 6.96) in 2005 to 14.96 (14.55, 15.37) in 2014 per 1000 patients. Rates were higher in men than in women, increased with advancing age, varied by county of residence, by region and by location of medical supervision, P<0.001 for all. From 2005 to 2014, the rates of AKI increased in IP (35.76 to 52.25/1000), in ER (from 8.41 to 20.44/1000), in OP (7.23 to 22.16/1000), in OF (3.0 to 9.21/1000, P< 0.001), and in GP (1.01 to 4.13/1000), P <0.001 for all trends. The likelihood of AKI was substantially higher in 2014 (OR=4.74, 95% CI: 4.12, 5.45) vs 2005 (OR= 1.00, referent).



Conclusions: AKI rates have increased substantially in the Irish health system over time and in all healthcare settings. Given the scale of the problem, a national strategic plan is necessary to reduce AKI events and avoid adverse consequences.

SA-PO533

Acute Kidney Injury Exerts Greater Impact on Mortality in Younger Men and Women Than among Older Patients within the Health System

Austin G. Stack,[1,2,3] Mohamed Elsayed,[1,2] Muhammad Umair Sharif,[1,2] Patrick T. Murray,[4] Ahmed Alghali,[1,2] Xia Li.[2,3] *[1]Nephrology, Univ Hospital Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick; [3]Health Research Inst, Univ of Limerick, Ireland; [4]UCD School of Medicine and Medical Sciences, Univ College Dublin, Ireland.*

Background: Recent studies have shown that acute kidney injury (AKI) independently predicts mortality. However it is unclear whether the risks are equal for both men and women and across age groups. We investigated whether the impact of AKI on mortality differs by age and sex within the Irish Health System.

Methods: Health data from 2 regional information systems were linked with mortality data from 1999 to 2011 (n=533, 773). AKI events were identified per KDIGO guidelines. Transient AKI events were identified as acute elevations in creatinine which fell to below 1.1 times baseline within 48 hours of initial event. Multivariate Cox regression modelled the associations (Hazard ratios and 95% CI) with death and interaction terms tested for differences between gender and age groups (≤ 59, 60-80, and >80 years). Patients were censored at death, lost-to-follow-up, or end of study. Analyses were adjusted for demographic, facility characteristics, and laboratory variables.

Results: In the full multivariable Cox model, the interaction term for age* gender*AKI stage was very significant (P<0.001). The stratum-specific hazard ratios for each age and gender subgroup are shown.

Variable	No AKI	Transient AKI	Stage 1	Stage 2	Stage 3
Men					
< 59	1.00	2.90 (2.31-3.64)	4.74 (3.84-5.85)	5.63 (4.03-7.85)	5.00 (3.33-7.50)
60-80	1.00	1.93 (1.70-2.19)	2.78 (2.47-3.12)	3.46 (2.88-4.15)	3.15 (2.51-3.95)
> 80	1.00	1.69 (1.43-2.00)	2.29 (1.95-2.67)	2.75 (2.15-3.51)	3.65 (2.75-4.85)
Women					
< 59	1.00	5.12 (3.84-6.85)	7.70 (6.13-9.66)	11.73 (8.21-16.74)	12.08 (7.51-19.43)
60-80	1.00	2.16 (1.86-2.5)	2.85 (2.51-3.23)	3.37 (2.75-4.11)	4.83 (3.75-6.22)
>80	1.00	1.55 (1.35-1.77)	1.77 (1.57-2.00)	2.25 (1.85-2.72)	1.9 (1.37-2.64)

Conclusions: AKI events are more deleterious for younger than for older patients, with younger women having the greatest risk.

SA-PO534

Acute Kidney Injury in Primary and Secondary Care in England: Lessons and Initial Results from a National Registry

Fergus J. Caskey,[1,2] Rebecca N. Evans,[1] Denny M. Abbott,[3] Nicholas M. Selby,[4] Daniel S. Lasserson,[5] Nitin V. Kolhe,[4] Richard J. Fluck.[4] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Univ of Bristol, United Kingdom; [3]National Kidney Federation, United Kingdom; [4]Royal Derby Hospital, United Kingdom; [5]Univ of Oxford, United Kingdom.*

Background: Acute Kidney Injury (AKI) is common and associated with considerable morbidity and mortality. This study aims to report progress and initial results from setting up a national AKI registry in England.

Methods: Since March 2015, NHS England has required all labs to 1) use a nationally agreed electronic detection algorithm to identify cases of potential AKI and 2) submit data on all cases, whether in primary or secondary care, to the UK Renal Registry. The algorithm looks back at local baseline creatinine results 1-7 and 8-365 days prior to the index result to produce a test result (AKI warning stage) 1, 2 or 3 based on an index to baseline ratio of 1.5-2.0, 2.0-3.0 or 3.0+ (or index >354 umol/L), respectively. For each AKI warning stage, patient identifiers, demographics and AKI stage are transmitted each month securely to the Registry and linked with the NHS spine for 30-day mortality tracing. Area-level social deprivation is assessed using the postcode-derived Index of Multiple Deprivation (IMD). This work is permitted without individual patient consent under the Registry's Section 251 support.

Results: In March 2015, 27 (21%) of an estimated 131 labs in England submitted data, increasing to 73 (56%) by March 2016. In that period, 569,375 AKI warning stage results were reported to the Registry in 184,354 individuals, 170,401 (92.4%) of whom had age, gender and IMD data and could be traced to the NHS Spine. The highest recorded AKI level for each individual was 1 in 65.2%, 2 in 18.5% and in 16.3%, with associated 30-day crude mortality rates of 14.3%, 29.7% and 31.5%, respectively. Compared to the least deprived decile, 30-day age- and sex-adjusted mortality was higher in people from the most deprived areas: 24.6%, 11.7% and 10.9% higher for AKI 1, 2 and 3, respectively.

Conclusions: Establishing a national registry of AKI in primary and secondary care is possible in England and has the potential to be a powerful quality improvement, public health and research tool.

SA-PO535

Comparing Community and Hospital Acquired Acute Kidney Injury in a Population Based Study

Hilda Hounkpatin,[1] Simon D.S. Fraser,[1] Matt Johnson,[2] David Culliford,[2] Paul J. Roderick.[1] *[1]I Academic Unit of Primary Care & Population Sciences, Univ of Southampton, United Kingdom; [2]Health Sciences, Faculty of Medicine, Univ of Southampton, United Kingdom.*

Background: Early recognition and management of acute kidney injury (AKI) is necessary to minimise preventable harm and high healthcare costs. The epidemiology of hospitalised AKI has been well described, but less is known about factors associated with community-acquired AKI (CA-AKI). Identifying those at risk of CA-AKI would be valuable

because approximately two-thirds of AKI originates in the community and some patients are not admitted to hospital. We aimed to describe the characteristics and associations of CA-AKI using a large, anonymised routine linked dataset.

Methods: Using data from the Hampshire Health Record (HHRA) UK, a data resource linking primary and secondary care (including laboratory) data, we applied KDIGO-based AKI criteria to identify AKI patients during 2014. Descriptive statistics and multivariate logistic regression models were used to compare characteristics of CA-AKI and hospital acquired AKI (HA-AKI) patients, adjusting for age, gender, socioeconomic status, co-morbidities and prescribed medication.

Results: 5,724 out of 643,039 eligible population generated at least one AKI alert: 61% (3469/5724) with CA-AKI and 39% (2255/5724) with HA-AKI. Being older, living in a deprived area, having hypertension, diabetes, chronic kidney disease, heart failure and being prescribed diuretics were risk factors for both CA-AKI and HA-AKI. Female gender and non-steroidal anti-inflammatory drugs (NSAIDS) were associated with CA-AKI but not HA-AKI. Renin angiotensin system inhibitors (RAASi) was associated with HA-AKI but not CA-AKI.

Conclusions: Incidence of CA-AKI was common (61% of all AKI) in our cohort. The study identified the characteristics of people at risk of CA-AKI in primary care who may benefit from targeted prevention, and indicates important differences in medication risk factors for CA-AKI and HA-AKI.

SA-PO536

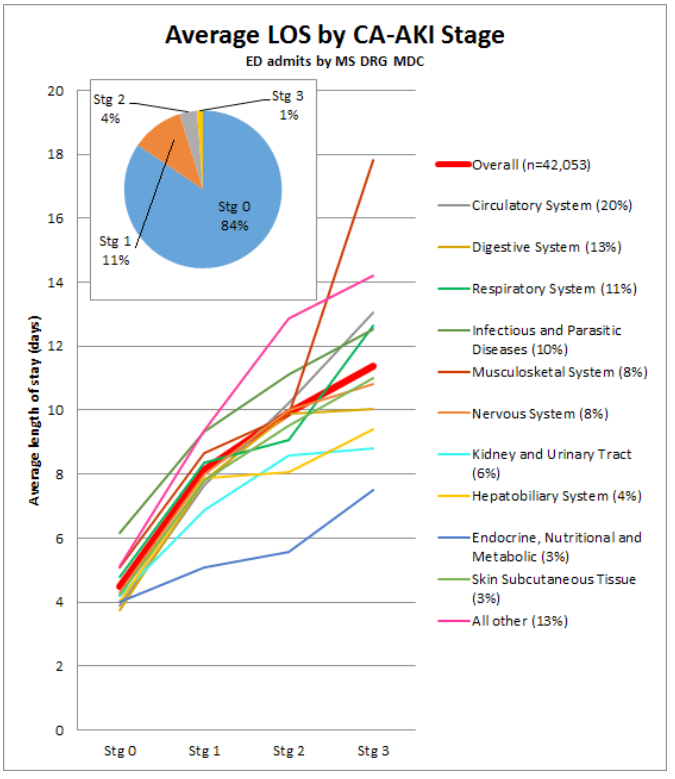
Community-Acquired Acute Kidney Injury (CA-AKI) Is Common and Correlates with Extended LOS across the 10 Most Common Diagnostic Categories in Emergency Department Admissions (ED) in a Large U.S. Integrated Delivery Network (IDN)

Liya Lomsadze, Jamie S. Hirsch, Tylis Chang. *Northwell Health.*

Background: In spite of increased global attention on AKI, including the 0by25 initiative, CA-AKI is not well understood in developed countries. CA-AKI, its associated diagnoses and impact on LOS were studied among patients admitted through EDs across a large IDN.

Methods: We identified all inpatient admissions over a 6 month period (10/15-3/16) that originated in the ED across 9 hospitals in urban and suburban settings in the Northeast US. Transfers from other acute care settings were excluded. CA-AKI was identified using KDIGO criteria from presenting creatinine values, using minimum values as the baseline. CA-AKI stage was correlated to diagnosis codes and LOS.

Results: 42,053 admissions met inclusion criteria. Mean patient age was 65.2y, and patients were 47.0% male. CA-AKI was identified in 6,494 admissions (15.4%), with stages 1, 2, and 3 present in 10.7%, 3.6% and 1.2%, respectively. The rate of CA-AKI varied from 12.5-18.3% across hospitals. The rate and distribution by stage were consistent across time. The MS-DRG Major Diagnostic Categories (MDCs) with the top 3 CA-AKI rates were infectious (34%), kidney & urinary tract (29%) and endocrine (28%) diseases. Average LOS (ALOS) was 4.5, 8.1, 9.9, and 11.4 days for stages 0-3 respectively, and demonstrated positive correlation for the top 10 most common MDC's (see fig). Sepsis was the most common DRG group with an ALOS by stage of 5.9, 8.5, 10.1 and 11.9 days, respectively. Regression demonstrated a 2.1 day increase in LOS for every 100% increase in creatinine.



Conclusions: Similar to low middle income countries, patients commonly present with CA-AKI in the developed world. Presentation with CA-AKI correlates with extended LOS across almost all MDCs, including circulatory, digestive, respiratory, infectious, as well as kidney disease.

SA-PO537

Epidemiology and Outcomes of Severe Septic Acute Kidney Injury Needing Renal Replacement Therapy – A Nationwide Population Based Study

Taomin Huang,[1] Vincent Wu.[1] *[1]Dept of Internal Medicine and College of Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [2]Dept of Internal Medicine, Mackay Memorial Hospital, Tapei, Taiwan.*

Background: Sepsis is the leading cause of hospital acquired acute kidney injury (AKI). Severe sepsis and septic AKI needing dialysis (AKI-D) are among the most lethal complications of sepsis. Population based epidemiology data are lacking, especially in the Asian ethnicity. Renal replacement therapy (RRT) is a potentially life-saving procedure for septic AKI. However, its roles in patients' outcomes are not clear, especially after adjustments for baseline comorbidities and illness. We use the Taiwan National Health Insurance Research Database (NHRID) to answer the questions.

Methods: From 1999 to 2007, a total of 2,619,534 patients was identifed. We defined severe sepsis using the diagnosis code with AKI, along with organ dysfunction. The cases undergoing RRT were identified using procedure codes. We calculated yearly incidence rates of AKI-D, along with mortality rates. A propensity matched cohort (1:4) was constructed with balanced profiles, to identify differences of 30 days' all-cause mortality rates after hospital discharge.

Results: A total of 312,686 (11.9%) patients was identified to have severe sepsis, while septic AKI-D developed in 4,977 (1.59%) patients, with the 30 days' mortality rate of 51.12%. The patients without AKI-D had a 30 days' mortality rate of 11.38% ($p<0.001$). Over the period, the yearly incidence of AKI-D in Taiwan increased from 1.45% to 1.75% (p for trend < 0.05). Yearly 30 days' mortality rates decreased from 53.0% to 48.1% (p for trend < 0.05). The incidence of respiratory tract (RTI) sepsis increased, while genitourinary tract infection (GUTI) sepsis decreased. The mortality rates of AKI-D decreased in both GUTI and RTI groups. Propensity matched cohort identified RRT to be an independent risk factor for 30 days' mortality (RRT: 2297 [52.30%] versus non-RRT: 6114 [34.8%)], $p <0.001$).

Conclusions: In the nationwide analysis, AKI-D incidence increased with time, but the associated mortality decreased. RRT has negative impacts on patients' outcome, but unidentified residual risks may account for the excessive risks.

SA-PO538

Redefining Neonatal Acute Kidney Injury: Insights from the Assessment of Worldwide Acute Kidney Injury Epidemiology in Neonates (AWAKEN) Cohort

Maroun J. Mhanna, Marissa J. Defreitas, Erin Rademacher, Louis J. Boohaker, Joshua Ross Dower, Thomas K. Davis, Namasivayam Ambalavanan, Russell Griffin, Rupesh Raina, Francis Sessions Cole, Sofia I. Perazzo, Patricio E. Ray, Michael Zappitelli, David J. Askenazi, Carolyn L. Abitbol. *Pediatrics, Neonatology and Nephrology, Neonatal Kidney Collaborative, Birmingham, AL.*

Background: Definitions of neonatal acute kidney injury (AKI) based on serum creatinine (sCr) derived from adult standards fail to incorporate confounders of gestational age (GA) and postnatal changes in sCr. Consequently, the incidence of neonatal AKI varies from 12-70% and its risks and long term morbidity have not been determined. The Neonatal Kidney Collaborative (NKC) represents 24 institutions from 4 countries and is dedicated to the study of neonatal AKI. Our objective was to refine the modified KDIGO definition of AKI by examining the effects of GA and rapid changes in sCr unique to the neonate.

Methods: Of 4273 NICU admissions screened retrospectively during the first 3 months of 2014, **2162** infants met inclusion/exclusion criteria of needing intravenous fluids ≥48 hours, no cardiac surgery and no severe kidney disease. Of these 1461(67%) had at least 2 sCr values and were included in the analysis. Receiver operating curve analyses were performed with area under the curve (AUC) for multiple parameters including maximum (Max) sCr, absolute and percent(%) rise in sCr for mortality (MORT) and length of stay (LOS).

Results: SCr parameters are summarized in the Table. AUC >0.7 is significant ($p<0.001$). Only Max sCr for LOS was not significant (AUC=0.59). SCr measures are in milligrams/deciliter (mg/dl).

Parameter		Overall Cohort	AUC	GA (<29 weeks)	GA (>29<36 weeks)	GA >36 weeks)
Max sCr	MORT	0.9	0.74	1.1	0.9	0.9
	LOS	0.8	0.59	0.9	0.8	0.8
Max sCr Rise	MORT	0.1	0.76	0.2	0.1	0.1
	LOS	0.1	0.74	0.2	0.0	0.0
Max %Rise sCr	MORT	35%	0.74	50%	25%	21%
	LOS	20%	0.73	50%	12%	10%

Conclusions: Diagnosis of neonatal AKI requires a definition based on GA and sCr rise in neonatal life. Future analyses will refine the sCr-based definition and provide a platform for prospective follow-up of this large neonatal cohort.

SA-PO539

A Phenome-Wide Association Study of Hospital-Acquired Acute Kidney Injury Nicolas Pallet, Eric Thervet, Anne Sophie Jannot. *Hôpital Européen Georges Pompidou.*

Background: Hospitalization Associated Acute Kidney Injury (HA-AKI) has been described in retrospective case-control studies but none has performed an exhaustive exploration of the dataset. Exhaustive methods hold a high explicative power, are easily understandable, and can generate a hierarchical classification of the risks factors associated with the outcome variable.

Methods: We extracted data from a French urban tertiary academic hospital (Georges Pompidou European Hospital, HEGP) I2B2 Clinical Data Ware House containing more than 700,000 single patients and more than 200,000,000 items and performed a Phenome-wide association study (PheWAS) to identify all of the ICD-10 diagnostic codes associated with HA-AKI (AKIN scores calculated during the first week after admission).

Results: We generated a database of 222,975 entries over a period of time of 10 years matched with 480 ICD-10 diagnostic codes. AKIN prevalence was 7.2%. The PheWas analysis generated 268 ICD-10 codes associated with AKI ($p<5.10^{-5}$), and the most important risk factor was post procedural disorders of the genitourinary system (N99) with an Odds Ratio (OR) of 17. The majority of the codes associated with an OR>5 were related to sepsis and infections, and also reflecting hemodynamic instability (shock, cardiac arrest, coma). Chronic kidney disease (N18) was positively associated with AKI with an OR of 4.5. Most of the codes negatively associated with AKI were related to follow-up examination (Z09, OR 0.06), screening (Z13, OR 0.08) and imaging (R93, OR 0.13). The most negatively associated code was Z56 (problems related to employment and non employment, OR 0.01). Interestingly, the ICD-10 code corresponding to AKI (N17) was found in less than 60% of the cases in which AKI was identified with the AKIN classification; conversely, AKIN "negative" patients received the N17 code in 30% of the cases, which might reflect misidentification of AKI by physicians.

Conclusions: The PheWas approach is a valuable mean to discover novel associations and to perform hierarchical classification of all the factors associated with HA-AKI. Our analysis delivers insights into how physicians identify AKI and its known risk factors, and might help to revise the current standard of care.

SA-PO540

Development and Validation of Acute Kidney Injury Risk Index in Patients with Abnormal Kidney Function Undergoing Non-Cardiovascular Surgery Lynette Espino Ilano, Shu-Yi Liao, Earl Ilano, Ali Motabar. *Univ of California, Riverside, Riverside Univ Health System Medical Center.*

Background: The authors sought to identify risk factors of Acute Kidney Injury (AKI) in patients with abnormal kidney function undergoing non-cardiovascular surgery and provide a risk index using a large representative national clinical data set.

Methods: The data from 2013-2014 American College of Surgeons–National Surgical Quality Improvement Program Participant Use Data File (ACS-NSQIP PUF) was used for analysis. AKI is defined as either ACS-NSQIP renal morbidity outcome of progressive renal insufficiency or acute renal failure necessitating dialysis. Patient's comorbidities and pre-operatives characteristics were evaluated as potential predictors in the model. A logistic regression model was used to build the scoring system to predict the risk of an event. The weighted risk score was constructed through the training set (75% of the whole data) and was evaluated by the area under curve (AUC). The final model was validated using the validation set (25% of the whole data).

Results: 1,195,825 operations between 2013 and 2014 were reviewed and 290,876 operations were included based on the inclusion/exclusion criteria. 2,450 subjects had AKI. Mechanical ventilation, hypertension requiring medications, ascites, sepsis, diabetes and abnormal kidney function stages were identified as potential predictors and were included in the final model. Each weight was assigned based on the estimate of coefficients. The full risk score ranged from 0 to 22 points. The AUC in the training set was 0.77 and was 0.79 using the validation set. People with a score of ≥ to 17 points had a 51.8 % risk of having AKI. People with a full score of 22 points had a 86.1% risk of having AKI compared to people with a score of 0 points who had a 0.3% risk of having AKI.

Conclusions: Our 22 points scoring systems with 6 variables were able to predict the risk of AKI in patient with abnormal kidney function stage 2-5. This tool is promising and may be used in the clinical setting for patients with abnormal kidney function undergoing non-cardiovascular surgery. External cohort that includes confirmed CKD patients is needed for further validation.

SA-PO541

Mild Postoperative Acute Kidney Injury: Incidence and Outcome Thorir E. Long,[1,2] Dadi Helgason,[1,2] Sólveig Helgadóttir,[2] Runolfur Palsson,[1,2] Tomas Gudbjartsson,[1,2] Gisli H. Sigurdsson,[1,2] Martin I. Sigurdsson,[3] Olafur S. Indridason.[2] *[1]Univ of Iceland; [2]Landspitali - the National Univ Hospital of Iceland, Reykjavik, Iceland; [3]Brigham and Woman's Hospital, Boston, MA.*

Background: A small rise in serum creatinine of 0.3 mg/dL over 48 hrs is currently included in the definition of acute kidney injury (AKI), yielding many mild cases of unknown significance. The aim of this study was to examine the incidence and outcome of individuals with mild AKI following surgical procedures.

Methods: This was a retrospective study of all adult patients who underwent abdominal, cardiothoracic, vascular or orthopedic surgeries at the National University Hospital in 2007-2015. Clinical data was extracted from electronic medical records. AKI was diagnosed according to the SCr component of the KDIGO criteria. The baseline characteristics and survival of patients with a mild AKI (only a rise in SCr of 0.3 mg/dL over 48 hrs, without 1.5 x baseline increase in 7 days) was compared with a propensity score matched control group (PSM,1:1) without AKI. This was performed for groups with and without preoperative reduction in kidney function (eGFR<60 mL/min//1.73 m^2).

Results: A total of 28,879 patients underwent 40,738 surgical operations during the study period. Both pre- and post-operative SCr was available for 19,072 operations. Median age at surgery was 68 yrs (IQR, 58-78) and 50% were female. AKI occurred following 1,557 operations (8%), 559 (3%) had mild AKI and 998 (5%) had more severe AKI. Patients with mild AKI were more likely to be male (66% vs. 54%, P<0.001), had a lower baseline eGFR, 48 (28-65) vs. 65 (47-83) mL/min/1.73 m^2 (p<0.001), and a higher comorbidity burden compared with patients with more severe AKI. Mild AKI patients with preoperative reduction in kidney function had worse 1-year survival than their PSM matched controls 76% vs 81%, (p<0.01). However, individuals with normal preoperative kidney function and mild AKI had similar 1-year survival as the PSM controls 89% vs 89% (p=0.5).

Conclusions: Our study suggests that mild AKI has a detrimental effect on outcome in patients with reduced kidney function, while those with preserved kidney function may tolerate mild AKI without adverse outcomes.

National Trends and Outcomes in Dialysis-Requiring Acute Kidney Injury in Patients with Septicemia Mihir Dave,[2] Harshil Shah,[1] Tushar Mishra,[2] Arpita Hazra,[2] Suman Khicher,[2] Abhishek Mishra,[4] Siddharth Mehta,[5] Kinsuk Chauhan,[1] Achint Patel.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Detroit Medical Center, Detroit, MI; [3]Univ Of Arkansas For Medical Sciences, Little Rock, AR; [4]Univ of Iowa and Clinics; [5]Mount Sinai Beth Isreal.*

Background: National Trends and Outcomes in Dialysis-Requiring Acute Kidney Injury in patients with Septicemia.

Methods: We used the nationwide inpatient sample (NIS) database 2002-2013 to identify adults hospitalized with septicemia using Clinical Classification Software (CCS) developed by AHRQ. We defined AKI-D based on previously validated ICD-9-CM codes including 584.xx for AKI, v45.11, v56.0 and v56.1 for dialysis and procedure code 39.95 for the dialysis procedure. We excluded hospitalizations that had codes for dialysis but not for AKI, as these were likely for ESRD patients on dialysis. We used the multivariate regression to analyze changes in trends and outcomes and explore potential reasons explaining these changes.

Results: From 2002-2013, of the 8,10,8048 patients who were hospitalized with septicemia, 214185 (2.64%) developed AKI-D. Proportion of AKI-D increased from 1.4% hospitalizations in 2002 to 2.65% hospitalizations in 2013 (p<0.001) (Figure 1). This trend increased annually by 4.2% (OR 1.035; 95% CI 1.03-1.04;p<0.001). This rise was completely explained by changes in demographics and increase in co-morbidities. Percentage of in-hospital morality (40% v/s 15%) and discharge to specialized care (63% v/s 37%) were higher among the AKI-D patients. Odds of in-hospital mortality (OR 2.08; CI 2.02-2.14; p<0.001) and discharge to specialized care (OR 1.78; CI 1.72-1.84; p<0.001) remains high. Although the percent in-hospital mortality after AKI-D was decreased, the adjusted odds increased (OR 1.63 to 2.14). And also, the adjusted odds of requiring specialized care in a facility increased during study period (OR 1.42 to 1.91).

Conclusions: The incidence of AKI-D in patients admitted with Septicemia has increased over the period of time. Our results emphasize the need for better risk stratification and early recognition of kidney dysfunction in patients with septicemia.

SA-PO543

Epidemiological Study on the AKI-CKD Communication: A Single-Center Retrospective Database Analysis Taro Horino,[1] Yutaka Hatakeyama,[2] Hiromi Kataoka,[2] Tatsuki Matsumoto,[1] Yoshiko Shimamura,[1] Kosuke Inoue,[1] Yoshio Terada,[1] Yoshiyasu Okuhara.[2] *[1]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Japan; [2]Center of Medical Information Science, Kochi Medical School, Kochi Univ, Nankoku, Japan.*

Background: Acute kidney injury (AKI) is a serious complication among hospitalized individuals and is closely associated with chronic kidney disease (CKD).This study investigated the extent of renal dysfunction progression after AKI events in both CKD and non-CKD patient groups.

Methods: This retrospective cohort study registered 131,358 individuals who visited Kochi Medical School hospital between October 19, 1981 and December 31, 2014. AKI and CKD was defined and staged according to the Kidney Disease Improving Global Outcomes (KDIGO) criteria, using measured serum creatinine levels. This study evaluated 10,189 AKI patients meet KDIGO criteria.

Results: The incidence of AKI in this cohort was 7.8% (95% confidence interval: 7.7–8.0%). AKI stage 1, 2 and 3 were 7,803, 1,703, and 683, respectively. We finally analyzed data from 1,846 AKI patients, excluding patients who had proven post-renal AKI or whose baseline SCr was not defined. Final cohort included 1,051 (56.9%) men. Patients without CKD (group A), patients with CKD after AKI event (group B), and patients with patients with CKD on baseline (group C) were 820, 543, and 483, respectively. The mean eGFRs on baseline, on AKI, and after AKI event in group A were 90.8, 53.1, and 77.4 mL/min/1.73m^2, respectively. Those in group B were 72.9, 42.5, and 55.0 mL/min/1.73m^2, respectively. Those in group C were 38.8, 24.7, and 36.0 mL/min/1.73m^2, respectively. Interestingly, mean eGFRs after AKI event in all three groups were significantly reduced compared to those on baseline. Furthermore, this eGFR reduction tended to progress on AKI frequency-dependent manner.

Conclusions: We found that AKI was a risk factor for CKD progression. We showed that lower eGFR levels before AKI are and more frequently AKI events occur, more the incidence of CKD increase. We propose that physicians should pay attention to AKI-CKD communication.

SA-PO544

Acute Kidney Injury in the Tertiary Care Setting in Rwanda Marla D. McKnight,[3,4] Fredric O. Finkelstein,[2] Grace Igiraneza.[1] *[1]Dept of Medicine, Univ of Rwanda, Butare, Rwanda; [2]Yale Univ, New Haven, CT; [3]Renal Div, Dept of Medicine, Brigham & Women's Hospital, Harvard Medical School, Boston, MA; [4]Rwanda Human Resources for Health Program, Ministry of Health, Kigali, Rwanda.*

Background: Acute kidney injury (AKI) is a global health concern impacting both developed and developing countries. There is limited data from low-income settings on the epidemiology and outcomes of AKI.

Methods: In this observational, multi-centre study conducted in Rwanda between September 1, 2014 and January 31, 2015, patients ≥ age 16 admitted to a tertiary care hospital were screened for elevation of serum creatinine in both hospital and external labs. Patients meeting KDIGO definition of AKI, based on change in serum creatinine, had demographic and clinical information collected and were followed until discharge or in-hospital death. Length of stay (LOS) and in-hospital mortality in patients with AKI were compared to that of all inpatients and regression models performed to determine predictors of mortality.

Results: Of the 14,918 patients admitted, 427 patients met KDIGO criteria for AKI—8.2% stage 1, 41.9% stage 2, 49.9% stage 3. Mean age of patients with AKI was 47.2 ± 19.9; 50.8% were male. Infections (68.9%), cardiovascular disease (35.5%), pregnancy related conditions (12.4%), diabetes (11.5%) and cirrhosis (8%) were frequently associated with AKI. 10.3% of patients had a nephrology consult and 9.4% received renal replacement therapy. Mean LOS in patients with AKI was 17.4 ± 18.7 compared to 7.1 for all admitted patients (p<0.001). All-cause mortality among patients with AKI was 31.9% compared to an overall hospital mortality rate of 4.4% (p<0.001). Patients with cirrhosis (OR=5.59, p< 0.001), sepsis (OR=3.03, p<0.001) and cancer (OR=3.3, p=0.007) were at significantly higher risk of in-hospital mortality.

Conclusions: AKI in the tertiary care setting in Rwanda is associated with significantly increased mortality and length of hospital stay compared to patients without AKI. Further research is needed to understand the etiologies of AKI in Rwanda and other low income settings in order to guide strategies to prevent and/or reduce AKI related morbidity and mortality.

SA-PO545

Acute Kidney Injury in Intensive Care Unit Patients: A Prospective Population-Based Study in Brazilian Amazon Fernando de Assis Ferreira Melo,[1] Etienne Macedo,[2] Ana Caroline Fonseca Bezerra,[3] Bruna Vitória Souza,[3] Bruna Cristina Meira Bruno,[3] Ravindra L. Mehta,[2] Emmanuel A. Burdmann,[1] Dirce M.T. Zanetta.[1] *[1]Univ of São Paulo, São Paulo, Brazil; [2]Medicine, Univ of California, San Diego, CA; [3]Medicine, Acre Federal Univ, Rio Branco, Acre, Brazil.*

Background: The Brazilian Amazon region is a resource constrained, impoverished area with limited health care facilities. The epidemiology of Acute Kidney Injury (AKI) in this region has not been described.

Methods: We performed a prospective study of the risk factors and incidence of AKI in patients admitted to all Intensive Care Units (ICU's) in Rio Branco (Acre), an Amazon region, from Feb 2014 to Feb 2016. Patients were screened at ICU admission and diagnosed with AKI based on modified KDIGO criteria and their course recorded through hospital discharge. AKI was characterized as community acquired (CAAKI) if AKI developed prior to hospital admission and hospital acquired (HAAKI) if developed during the hospital stay.

Results: Of 1494 patients admitted,1046 fulfilled selection criteria. A third of the patients developed AKI before ICU admission, only 6% were CAAKI. AKI incidence was 43.8%, with 61.9%, 19.5% and 18.6% Stage 1, 2 and 3 respectively and 5.4% received dialysis. Associated etiological factors for AKI included surgery (30.3%), hemodynamic instability (24%), and respiratory failure (19.2%). Only 1.7% had tropical diseases. Risk factors for AKI included use of nephrotoxic antibiotics (OR 8.6, p<0.001), anti-inflammatory drugs (OR 1.7, p=0.002), anemia (OR 3.8, p=0.001) and fluid balance over 1500 ml/24h (OR 1.6, p=0.003). AKI was associated with a higher ICU mortality (AKI 55.9% vs non AKI 13.9%, *p*<0.001). In a logistic regression model AKI mortality was associated with mechanical ventilation (OR 3.6, p<0.001), use of vasoactive drugs (OR 2.4, p=0.03) shock (OR 2.2, p<0.001), and use of antibiotics (OR 2.5, p<0.001).

Conclusions: AKI is common in ICU patients in the western Brazilian Amazon with few hospitalizations for tropical diseases and similar etiologies, risk factors and outcomes as developed countries; however with higher mortality rates that may represent the economic conditions and poor access to health care.

Funding: Government Support - Non-U.S.

Delay on Acute Kidney Injury Diagnosis in Critically Ill Patient: A Snapshot on Brazilian Amazon Fernando de Assis Ferreira Melo,[1] Etienne Macedo,[2] Ana Caroline Fonseca Bezerra,[3] Magela Teodorio Melo Fernandes Magela,[3] Bruna Cristina Meira Bruno,[3] Bruna Vitória Souza,[3] Ravindra L. Mehta,[2] Emmanuel A. Burdmann,[1] Dirce M.T. Zanetta.[1] *[1]Univ of São Paulo, Sao Paulo, Brazil; [2]Univ of California-San Diego, San Diego, CA; [3]Acre Federal Univ, Rio Branco, Acre, Brazil.*

Background: There are deficiencies in the recognition and management of patients who developed Acute Kidney Injury (AKI) in Intensive Care Unit (ICU) that can result delay in treatment and inappropriate referral to nephrologist, leading to worse outcomes as need for dialysis, recovery and mortality rates.

Methods: We performed a prospective study of AKI incidence in patients admitted to all ICU's in Rio Branco, state capital of Acre, from Feb 2014 to Feb 2016. We used medical records to compare the performance of the clinician to make the diagnosis of AKI with the diagnosis made by KDIGO criteria.

Results: We studied 1046 patients. Among 43.8% of patients who developed AKI in ICU, there were agreement of the diagnosis day in only 14.5%, in 65% the clinician did not make the diagnosis and in 8.2% it was delayed. Thirty seven percent of the delayed diagnosis patients presented AKI grade III. Dialysis was offered to only 0.3% of non-diagnosed patients in contrast with 31.3% in those who had timely diagnosis (p <0.001). The APACHE II score was lower in those non-diagnosed compared with those who had timely diagnosis (17.5 vs. 27, p <0.001). ICU and hospital stay were higher when diagnosis was delayed compared with timely diagnosis patients (10 vs. 8, p <0.001 and 21 vs 16, p <0.001, respectively). Mortality was also higher in those non-diagnosed and delayed diagnosed patients, compared with those who had timely diagnosis (61.8% vs 68.3% vs 40%, p <0.001).

Conclusions: In the vast majority of our patients, the clinic diagnosis of AKI was not done or occurred later. This fact may have contributed to delay on completion of dialysis, increased length of ICU and hospital stay and higher mortality rates. It is necessary to increase awareness of AKI in ICU and disseminate knowledge about acute kidney injury stressing that small changes in renal function often contribute to serious adverse outcomes.

SA-PO547

Epidemiology of Acute Kidney Injury in the Intensive Care Unit: A Systematic Review Fernando de Assis Ferreira Melo,[1] Etienne Macedo,[2] Ana Caroline Fonseca Bezerra,[3] Bruna Cristina Meira Bruno,[3] Bruna Vitória Souza,[3] Ravindra L. Mehta,[2] Emmanuel A. Burdmann,[1] Dirce M.T. Zanetta.[1] *[1]Univ of São Paulo, Sao Paulo, Brazil; [2]Univ of California-San Diego, San Diego, CA; [3]Acre Federal Univ, Rio Branco, Acre, Brazil.*

Background: AKI is commonly encountered in Intensive Care Unit (ICU) patients across the world; however, the epidemiology of Acute Kidney Injury (AKI) in the developed and developing world has not been systematically examined.

Methods: We conducted a systematic review of published studies (2005–2015) identified in PUBMED, CENTRAL, LILACS, and IBECs databases using the search terms "acute kidney injury" and "intensive care unit". We examined the differences in AKI incidence, severity (based on KDIGO criteria) and associated mortality and describe geographic variations based on the gross national income.

Results: We identified 94 studies: 60 from developed countries and 34 from developing countries. Of these, 75.5% used KDIGO-equivalent criteria; however, we found 10 different definitions for oliguria and 19 different definitions for baseline creatinine. The frequency of AKI was higher in studies using KDIGO-equivalent criteria (34.3% vs 24.3%), with lower mortality rates (median 29% vs median 42.5%). There were no differences in incidence of AKI between developed and developing countries. However, the need for RRT, ICU length of stay and mortality rates were higher in developing countries.

Conclusions: Despite the attempt to standardize the criteria for defining AKI, there is still no uniformity in the settings for "baseline creatinine" or "oliguria". Differences in ICU length of stay, need for RRT and mortality rates may reflect differences in the entry criteria and the social conditions, access to health care and hospital infrastructure.

Etiology and Outcome of Acute Kidney Injury – Study from Two Teaching Hospital from Nepal Sanjib Kumar Sharma.[1] *[1]Dept of Internal Medicine, B P Koirala Inst of Health Sciences, Dharan, Nepal; [2]Dept of Nephrology, College of Medical Sciences, Bharatpur, Nepal.*

Background: Most of the AKI occurs in developing nations. The etiologies and outcome is believed to be different in developed versus underdeveloped nations.

We conducted prospective observational study in two teaching hospital in Nepal to study the etiologies and the outcomes of acute kidney injury.

Methods: Consecutive patients attending out patient clinic or admitted in two teaching hospital in Nepal fulfilling AKIN criteria were enrolled and followed up for one year . The data were recorded in predefined validated case record form.

Results: The age distribution ranged from 15 years to 90 years. The most common etiology (31.38%, n=123) of the AKI was sepsis followed by community acquired pneumonia (71/392). However, significant number AKI patients had preventable causes of AKI like acute gastroenteritis (18.11%, n=46), obstructive uropathy (3.57%, n=14), malaria

(3.57%, n=14), and septic abortion (1.02%, n=4). The other etiologies were complicated UTI (19.13%, n= 75) and drug and toxins including herbal medicine (2.75%, n=19). Sixteen patients were of various etiologies and etiology of AKI could not be ascertain in 10 patients.

Sixty patients (15.3%) expired and 45 patients left against medical advised (LAMA). Among rest of the patients 84.69% patients recovered from AKI. Eight patients progressed to chronic kidney disease (0.98%+3.1%). Patients who were discharged from the hospital 12.5% were lost to follow up. The outcome of the AKI was significantly different in two centers (death and LAMA 44.44% Vs11.27%).

Conclusions: Though major etiology of teaching hospital setup remains similar to western world, there are still significant number of patients with AKI of preventable etiology. The mortality of even two teaching hospital set up differ significantly.

SA-PO549

Epidemiology of Acute Kidney Injury in an Intensive Care Unit of a Third Level Hospital in Mexico City Juan Reyna,[1] Sonia Hernandez,[3] Rodolfo Rincon-Pedrero.[2] *[1]Medicina Interna, Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, INCMNSZ; [2]Nefrología y Metabolismo Mineral, INCMNSZ; [3]Nutriología, INCMNSZ.*

Background: Acute kidney injury (AKI) is one of the most common complications in critically ill patients and is associated with a high risk of death, length of stay and costs. We aimed to determine incidence, associated risk factors and outcomes of AKI in a general ICU from a medical center in Mexico City.

Methods: We retrospectively studied a cohort of 463 patients admitted to an ICU during 1 year. Exclusion criteria were chronic kidney disease with CKD-EPI <60mL/kg/1.73m^2 and kidney transplantation. We measured AKI by Kidney Disease: Improving Global Outcomes (KDIGO) criteria.

Results: The overall incidence of AKI was 57%, distributed among the 3 stages: 22.7% stage 1, 33.7% stage 2 and 43.6% stage 3. Only 7.1% of AKI patients needed renal replacement therapy. Regarding the cause of AKI, septic shock, non surgical-associated hypovolemia, surgical-associated hypovolemia and nephrotoxic drugs contributed with 65.9, 27.3, 25 and 9%, respectively. Patients who developed AKI were more common men, had more diabetes, ischemic heart disease, hematological malignancies, septic shock and hypovolemia, stayed longer in the ICU, presented higher SAPS 2 score and more often needed mechanical ventilation (MV) and use of norepinephrine. The ICU mortality was 9% in patients without AKI, 15% in stage 1, 21.3% in stage 2 and 56.5% in stage 3. When adjusted for other variables; odds ratio of stage 1=1.12 (95% IC 0.40-3.09; p=0.8), stage 2=1.53 (95% IC 0.65-3.60; p=0.3) and stage 3=8.6 (95% IC 3.2-22.8; p=<0.001). Other independent risk factors for mortality included oligo-anuria, need for IMV, vasoactive therapy and SAPS 2 score, whereas a higher serum creatinine and body mass index (BMI) were associated with lower mortality risk.

Conclusions: There was a high incidence of AKI in this study. Only KDIGO stage 3 among other stages was considerably associated with mortality when adjusted for other variables. The strongest predictor of death was oliguria and we noted that lower serum creatinine levels were associated with an increased risk of death that could be related to volume overload or loss of muscle mass.

SA-PO550

The Effect of ICU System on Outcome of Critically Ill Patients with Acute Kidney Injury: Result from SEA-AKI Study Group Nattachai Srisawat, Warangkana Tantipornsinchai, Nobphathorn Mahamitra, Sadudee Peerapornratana, Kearkiat Praditpornsilpa, Somchai Eiam-Ong, Kriang Tungsanga. *Div of Nephrology, Dept of Medicine, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Variation of ICU system may affect to the AKI outcome. To our best knowledge, there is no study which demonstrates the effect of ICU organization and AKI outcome. Our study aimed to explore the effect of Closed versus Open ICU to AKI outcome across adult ICUs.

Methods: The prospective multicenter observational study was conducted in 15 ICUs from 5 regions across Thailand from April 2014 to April 2015. We collected the data by registration in electronic web-based format. The Closed ICU model was defined as an ICU service led and managed by an intensivist. The Open model was an ICU service where critically ill patients were managed by primary physician; they may or may not choose to consult an intensivist. The main outcome was hospital mortality.

Results: Of fifteen ICUs, 12 ICUs and 3 ICUs were defined as Open ICU and Closed ICU, respectively. We have totally enrolled 5,381 patients and did the first half analysis in 2,480 patients (Closed ICU n=640 and Open ICU n=1,840 cases). AKI occurred in 1,271 patients (51.3%). Twenty eight percent of AKI patients were cared in Closed ICUs. The Closed ICU had significant higher percentage of nephrologists, intensivists, and certified critical care nurses than Open ICU (all p<0.001). There were comparable hospital mortality rate between Closed and Open ICU, 42.2% vs 42.7%, p=0.86. However, in multivariable linear regression adjusted for APACHE II, sepsis, ICU structure and process of care factors, we found hospital mortality of AKI patients was significantly lower in Closed ICU than Open ICU (p=0.001, OR=0.38, 95%CI 0.22-0.68). When using propensity score matching, we still found the same result. AKI patients in Closed ICU had significantly lower length of ICU stay than in Open ICU (p<0.001, OR=0.30, 95%CI 0.18-0.49).

Conclusions: In this large multicenter study, we demonstrated Closed ICUs had more favorable AKI outcome than Open ICU. Further study to explore the contributing factors in process of care is still warrant for improvement AKI outcome.

SA-PO551

National Trends and Outcomes in Dialysis-Requiring Acute Kidney Injury in Patients with Pneumonia: 2002-2013 Harshil Shah,[2] Achint Patel,[1] Mihir Dave,[3] Tushar Mishra,[3] Suman Khicher,[3] Kinsuk Chauhan,[2] Siddharth Mehta,[4] Chandra Kumar Mallick Kodavanti,[3] Abhishek Mishra.[5] *[1]Univ of Arkansas For Medical Sciences; [2]Icahn School Of Medicine at Mount Sinai; [3]Detroit Medical Center; [4]Mount Sinai Beth Isreal; [5]Univ of Iowa and Clinics.*

Background: Acute kidney injury requiring dialysis (AKI-D) is a serious and preventable complication in patients admitted with pneumonia. However, data on national trends in AKI-D after pneumonia are lacking after 2002.

Methods: We used the nationwide inpatient sample (NIS) database 2002-2013 to identify adults hospitalized with pneumonia using Clinical Classification Software (CCS) developed by AHRQ.We defined AKI-D based on previously validated ICD-9-CM codes including 584.xx for AKI, v45.11, v56.0 and v56.1 for dialysis and procedure code 39.95 for the dialysis procedure. We excluded hospitalizations that had codes for dialysis but not for AKI, as these were likely for ESRD patients on dialysis. We used the multivariate regression to analyze changes in trends and outcomes and explore potential reasons explaining these changes.

Results: From 2002-2013, of the 11,46,3481 patients who were hospitalized with pneumonia, 36975 (0.32%) developed AKI-D. Proportion of AKI-D increased from 0.27% hospitalizations in 2002 to 0.43% hospitalizations in 2013 (p<0.001). This trend increased annually by 6.1% (OR 1.06; 95% CI 1.05-1.07;p<0.001). Percentage of in-hospital morality (33% v/s 4%) and discharge to specialized care (49% v/s 26%) were higher among the AKI-D patients. Odds of in-hospital mortality (OR 2.08; CI 2.02-2.14; p<0.001) and discharge to specialized care (OR 1.78; CI 1.42-1.91; p<0.001) remains high even after adjusting the various confounding factors. Although the percent in-hospital mortality after AKI-D was decreased, the adjusted odds increased (OR 2.53 to 2.94). And also, the adjusted odds of requiring specialized care in a facility increased during the study period (OR 1.32 to 2.76).

Conclusions: The incidence of AKI-D in patients admitted with pneumonia has increased over the period of time. Our results emphasize the need for better risk stratification and early recognition of kidney dysfunction in patients with pneumonia.

SA-PO552

Rhabdomyolysis in Young Adults Asif Khan,[1] Lily Xu,[1] Saleha Riaz,[1] Jay Patel,[1] Doreen Chen,[1] Marianne Smith,[1] Elie El-Charabaty,[2] Suzanne E. El Sayegh.[2] *[1]Internal Medicine, Staten Island Univ Hospital, Staten Island, NY; [2]Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Background: Rhabdomyolysis (RB) is characterized by marked elevation of creatine phosphokinase (CK), myoglobinuria and aldolase in blood as the result of rapid skeletal muscle breakdown. The median age of RB is 47 years; however, there is a scarcity of the risk factors for RB in younger population. The current diagnostic criteria for RB include plasma markers that are non-specific and only detect muscle injury after it has already occurred. Researchers have been investigating neutrophil-Lymphocyte ratio (NLR) as an indicator of systemic inflammation; however to date its association with RB is limited.

Methods: This retrospective cohort study identified subjects aged between 18–49 years who were diagnosed with RB with a CK level of >1500 IU/L within the first 48 hours of admission. Frequency distribution or descriptive statistics for demographic and baseline disease characteristics were presented for all patients.

Results: A total of 331 subjects were included. 87.2% of the subjects were male and 12.8% were female. The median length of stay was 4 days with an overall mortality was 2.8%. The etiologies of 34.83% of the RB cases were due to illicit drugs; 16.47% of the cases were exercise induced, of which 94.7% were male and 72.7% related to severe intensity workouts, with a median CK of 8,840 IU/L. Illicit drug use was the major etiology in 28.1% of subjects with CK levels between 1,500-50,000 IU/L. Exercise was the major etiology (40%) in subjects with CK levels above 50,000 IU/L. There was a significant positive correlation between the NLR and the length of stay (p <0.0001).

Conclusions: The major etiologies of RB in adults <50 years old were illicit drug use (34.83%) and exercise (16.47%). S. CK was not an accurate prognostic indicator of RB in adults <50. Subjects with exercise induced RB had a much higher median serum CK, but their length of stay was less than the median. The NLR was shown to be positively correlated to the levels of serum CK and the total length of stay. This data suggests that the use of NLR can be an important prognostic indicator in RB.

SA-PO553

Acute Kidney Injury in Intensive Care Unit Patients: An International Registry Josee Bouchard,[1] Anjali Acharya,[2] Jorge Cerda,[3] Elizabeth R. Maccariello,[4] Rajasekara Chakravarthi Madarasu,[5] Ashita J. Tolwani,[6] Rolando Claure-Del Granado,[7] Andrew J.P. Lewington,[8] Enrico Fiaccadori,[9] Ravindra L. Mehta.[10] *[1]U de Montreal; [2]Jacobi Medical Center; [3]Albany Medical Coll; [4]Hosp Quinta d'Or; [5]CARE Hosp; [6]UAB; [7]U Mayor de San Simon; [8]Leeds Teaching Hosp; [9]U of Parma; [10]UCSD.*

Background: Acute kidney injury (AKI) is common and associated with increased morbidity and mortality.

Methods: We are conducting a prospective observational study to better characterize AKI in patients from 13 countries using AKIN criteria. We aim to highlight differences in AKI patients characteristics and outcomes over time, dividing our cohort by the median time of enrollment (Aug 2008-March 2011/April 2011-Nov 2015).

Results: Between 2008 and 2015, 2027 of 9780 patients (21%) had AKI during their 1st week of ICU, and we enrolled 1091 of them (54%). Over time, we observed several differences in patients characteristics, a decrease in the use of starches and diuretics, an increase in the number of kidney biopsies performed, and an earlier timing of initiation of dialysis. However, we did not observe significant changes in outcomes.

Duration dialysis (days)	5 (2-14)	6 (3-17)	0.63
Lengths of stay (days)	13 (6-27)	14 (6-28)	0.25
Mortality	21.4	18.2	0.28
Dialysis-dependence at discharge	11.9	12.1	0.77

Conclusions: Over the last 8 years, although we observed differences in patients characteristics and management, overall outcomes associated with AKI remained unchanged.

A Nationwide Survey of Acute Kidney Injury in Patients with Malignancies in China

Juan Jin. *Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: Patients with cancer are at a high risk of acute kidney injury (AKI), but the overall incidence of AKI in such patients and its severity remain largely unknown. The present study aimed to capture the current situation of AKI in patients with cancer in China and provide extensive information for prevention and management of AKI in such patients.

Methods: This nationwide multicenter retrospective cross-sectional study covered 82% of the population. In 2013, 2,223,230 adult patients from 22 academic and local hospitals each were screened for AKI via the Laboratory Information System using two screening criteria. To make the scope more manageable, we only examined the medical records of 26,086 patients with suspected AKI who were hospitalized in January or July. We recorded hospitalization data, all-cause in-hospital mortality, etc., and compared these data between patients with malignant tumor-related AKI (MR-AKI) and non-MR-AKI.

Results: We enrolled 1418 patients with MR-AKI and 6186 with non-MR-AKI. The detection rate of MR-AKI was significantly higher in academic hospitals versus local ones, mid-China versus south and north China, and affluent areas versus poor ones. However, the rate of MR-AKI non-recognition by the physicians in charge was very high in both academic and local hospitals. The all-cause in-hospital mortality rate among patients with MR-AKI was high at 19.2%, and another 18.6% with severe AKI withdrew from treatment. The rates of non-recognition and delayed recognition of AKI, all-cause in-hospital mortality, and treatment withdrawal and in-hospital costs were higher among patients with MR-AKI than those with non-MR-AKI.

Conclusions: To our knowledge, this study has the widest coverage of its kind thus far and accurately reveals the present situation of MR-AKI in China. Our findings could have clinical implications for patients with cancer in other developing countries as well.

Phenotype of Vancomycin Associated Drug Induced Kidney Disease (DIKD): Results from the DIRECT Study

Linda Awdishu,[1] Rajasekara Chakravarthi Madarasu,[2] Stuart Goldstein,[3] Ashita J. Tolwani,[4] Melanie S. Joy,[5] Etienne Macedo,[1] Dinna Cruz,[1] Jorge Cerda,[6] David T. Selewski,[7] Andrew J.P. Lewington,[8] Michael Zappitelli,[9] Maria Ostermann,[10] Vivekanand Jha,[11] Ravindra L. Mehta.[1,12] *[1]Univ of California, San Diego; [2]Star Kidney Centers, India; [3]Cincinnati Children's Medical Center; [4]Univ of Alabama at Birmingham; [5]Univ of Colorado, Denver; [6]Albany Medical College; [7]Univ of Michigan; [8]Leeds Teaching Hospital, United Kingdom; [9]McGill Univ Health Center, Canada; [10]Guy's and St. Thomas' Hospital, United Kingdom; [11]Post Graduate Inst of Medical Education & Research, India; [12]On Behalf of DIRECT Investigators.*

Background: Vancomycin (VAN) is a frequently prescribed antibiotic in critically ill patients with conflicting published data on nephrotoxicity due to lack of phenotype standardization.

Methods: DIRECT is an international multi-center study which enrolled 634 patients with DIKD to identify drug-related polymorphisms by GWAS studies that were associated with standard phenotypes. Each case was adjudicated by 2 nephrologists.

Results: VAN associated AKI cases (N=171) were confirmed by adjudication (126 adult and 45 pediatric patients). Patients were 50% male with mean age of 47.7±18.2 years in adults and 12.3±4 years in pediatrics. Patients were 57% white, 24% hispanic, 13% black and 2% asian. Comorbidities included hypertension and diabetes in adults and asthma and cancer in pediatrics. AKI risk factors at baseline included diabetes 22%, hyperglycemia 28%, sepsis 21% and anemia 21%. The mean Scr increased from 0.78±0.34 to 4.42±2.46 mg/dL in adults and 0.46±0.19 to 2.5±1.95 mg/dL in pediatrics. Time to injury was 4(2-7) days. Biopsies were performed in 8% and dialysis was required for 17.5% cases. The initial VAN dose and serum concentration was 1991±899 mg/day and 26±18.4 mcg/mL in adults and 2191±1178 mg/day and 26.7±25.5 mcg/mL in pediatrics. Mortality was 5.4%, 9.4%, 19% at hospital discharge, 28 and 90 days and 27% of cases had elevations in Scr at 90 days.

Conclusions: VAN associated DIKD is a significant problem occurring in hospitalized patients receiving conventional dosing. Genome studies will further elucidate the mechanism of this injury.

Phenotype of NSAID Associated Drug Induced Kidney Disease (DIKD): Results from the DIRECT Study

Linda Awdishu,[1] Rajasekara Chakravarthi Madarasu,[2] Stuart Goldstein,[3] Ashita J. Tolwani,[4] Melanie S. Joy,[5] Etienne Macedo,[1] Dinna Cruz,[1] Jorge Cerda,[6] David T. Selewski,[7] Michael Zappitelli,[8] Andrew J.P. Lewington,[9] Maria Ostermann,[10] Vivekanand Jha,[11] Ravindra L. Mehta.[1,12] *[1]Univ of California, San Diego; [2]Star Kidney Centers; [3]Cincinnati Children's Medical Center; [4]Univ of Alabama at Birmingham; [5]Univ of Colorado, Denver; [6]Albany Medical College; [7]Univ of Michigan; [8]McGill Univ Health Centre; [9]Leeds Teaching Hospital; [10]Guy's and St. Thomas' Hospital; [11]Postgraduate Inst of Medical Education and Research; [12]On Behalf of the DIRECT Investigators.*

Background: Non-steroidal anti-inflammatory drugs can cause kidney injury by different mechanisms. Risk factors have been identified and include volume depletion and concurrent nephrotoxins.

Methods: DIRECT is an international multi-center study which enrolled 634 patients with DIKD to identify drug-related polymorphisms by GWAS studies that were associated with standard phenotypes. Each case was adjudicated by 2 nephrologists.

Results: NSAID associated AKI (N=64) and glomerular injury (N=2) were confirmed by adjudication (46 adult and 20 pediatric patients). Implicated NSAIDs were ibuprofen (N=39), indomethacin (N=2), ketorolac (N=16), ketoprofen (N=1) and naproxen (N=8). Patients were 44% male with mean age of 47.8±18.1 years in adults and 12.2±3.4 years in pediatrics. Patients were 45% white, 14% black, 14% hispanic and 27% asian. Co-morbidities included hypertension, diabetes and smoking in adults and asthma in pediatrics. The mean Scr increased from 0.91±0.31 to 4.48±2.84 mg/dL in adults and 0.49±0.18 to 3.04±2.76 mg/dL in pediatrics. Median (IQR) time to onset of injury was 4(2-7.5) days. Common risk factors were hyperglycemia, surgery and additional nephrotoxic exposures. Biopsies were performed in 17% with findings of interstitial nephritis in 64% of cases. Dialysis was required for 21.2% cases. Daily doses were ibuprofen 1131±654mg, ketorolac 58±36 mg and naproxen 974±402 mg. Mortality was 3.3%, 5.6% and 12.5% at hospital discharge, 28 and 90 days.

Conclusions: NSAIDs demonstrated significant increases in Scr across a range of risk factors, with infrequent definitive biopsies. Genome studies will further elucidate patient susceptibility to NSAID associated DIKD.

Vancomycin Induced Nephrotoxicity - Are We Over-Diagnosing

Abhisekh Sinha Ray,[1] Ammar Haikal,[2] Kassem Hammoud,[3] Alan S.L. Yu.[1] *[1]Nephrology and Hypertension, Kansas Univ Medical Center, Kansas City, KS; [2]Internal Medicine, Kansas Univ Medical Center, Kansas City, KS; [3]Infectious Disease, Kansas Univ Medical Center, Kansas City, KS.*

Background: Vancomycin has been in use for more than half a century, but its extent of nephrotoxicity is still controversial. Most studies pertaining to vancomycin nephrotoxicity are observational and confounded by comorbidities, other nephrotoxins and, in studies considering achieved vancomycin concentrations as a risk factor, reverse causation. Purpose of this systematic review was to determine risk of acute kidney injury (AKI) attributable to intravenous (IV) vancomycin.

Methods: Pubmed, Cochrane Library were searched from 1990 through 2015 for randomized controlled trials (RCT) and cohort studies comparing IV vancomycin to a control group with a comparator antibiotic, in which kidney function or kideny injury outcomes were reported.Two reviewers extracted data and assessed risk of bias, one reviewer adjudicated assessments. We screened 1328 titles and abstracts, reviewed 115 articles and 7 RCT and 6 cohort studies were included in final analysis.

Results: All cohort studies were judged to have moderate or high risk of bias, so only qualitative synthesis was performed and did not provide strong evidence for vancomycin nephrotoxicity. Meta-analysis of 7 RCT suggested vancomycin was associated with increased risk of AKI (pooled RR 2.45, 95% CI 1.69-3.55). There was minimal heterogeneity between the studies (chi-square 3.67, $p = 0.72$, and $I^2 = 0\%$). Inspection of funnel plot showed no strong evidence of publication bias.However, evidence of vancomycin nephrotoxicity was judged to be indirect and of moderate strength as 12 of 13 studies compared vancomycin only to linezolid.

Conclusions: Vancomycin modestly increases risk of AKI; although substantial but still much lower compared to well-recognized nephrotoxins e.g. aminoglycosides (RR: 8-10) or amphotericin B (RR: 4-10). Nevertheless, in patients being treated with IV vancomycin that develop AKI, more than half of cases can be attributed to vancomycin (attributable fraction 0.59). A RCT of vancomycin designed to study renal outcome is needed to draw unequivocal conclusions.

SA-PO558

Comparative Incidence of Acute Kidney Injury between Vancomycin/ Cefepime and Vancomycin/Piperacillin-Tazobactam Combination Therapy

Anthony Ndichu Muiru,[1] Andrew L. Lundquist,[2] Andrew S. Allegretti.[2] *[1]Medicine, Massachusetts General Hospital, Boston, MA; [2]Nephrology, Massachusetts General Hospital.*

Background: Acute kidney injury (AKI) is common during infections and may be potentiated by the use of nephrotoxic antibiotics. Combination of Vancomycin/ Piperacillin-Tazobactam (Vanc/Pip) has been associated with more AKI compared to Vancomycin/ Cefepime (Vanc/Cefe), though the mechanisms are unknown. We aim to compare rates of AKI after exposure to Vanc/Pip, Vanc/Cef, or Vanc/Pip/Cefe.

Methods: Multicenter retrospective cohort of adults exposed to >48 hours of (1) Vanc/Pip, (2) Vanc/Cefe or (3) Vanc/Pip/Cefe between January 2012 and January 2015. Participants in the Vanc/Pip/Cefe group were exposed to Cefepime either concurrently with Vanc/Pip, or within 90dys prior to admission. AKI was defined by AKIN criteria. Rates of AKI were analyzed using Chi-square tests and multivariable logistic regression.

Results: 5370 participants were included: 4,090 (76%) received Vanc/Cef, 997 (19%) received Vanc/Pip, and 283 (5%) received Vanc/Pip/Cefe.

Variable	Antibiotic Exposure			*P*
	Vanc/Cefe	Vanc/Pip	Vanc/Pip/Cefe	
Age, yrs, median (IQR)	65 (54, 75)	63 (51, 72)	63 (52, 73)	0.001
Male sex (%)	2283 (56)	576 (58)	163(58)	0.4
White race, (%)	3209 (78)	784 (79)	214 (76)	0.5
Hypertension (%)	2075 (51)	457 (45)	127 (45)	0.01
Diabetes (%)	1042 (26)	261 (26)	70 (24)	0.8
CKD (%)	1198 (29)	183 (18)	73 (26)	<0.001
LOS, days, median (IQR)	9 (5, 17)	9 (5, 15)	11 (6, 19)	0.001
Died during admission (%)	680 (17)	73 (7)	53 (18)	<0.001

Overall incidence of AKI was 24%. AKI was similar between Vanc/Pip and Vanc/Cef (24% vs. 23%; $P = 0.8$) but more common in the Vanc/Pip/Cefe group (31%; P=0.009). In multivariable analysis, compared to Vanc/Cefe, Vanc/Cefe/Pip use was associated with higher odds of AKI (OR 1.59 [95% CI 1.21, 2.10]), while Vanc/Pip use had similar odds of AKI (1.15 [95% CI 0.97, 1.40]).

Conclusions: Use of Vancomycin/Piperacillin-Tazobactam and Vancomycin/Cefepime resulted in similar rates of AKI. Use of all 3 antibiotics was associated with more AKI compared to either dual-regimen alone.

SA-PO559

Prescribing Patterns at the Time of Acute Kidney Injury: Opportunities to Improve Care

Sue Shaw,[1] Dominic Moore,[1] Aleli Akani,[1] Rebecca A. Packington,[1] Kerry L. Horne,[1] Maarten W. Taal,[1,2] Nicholas M. Selby.[1,2] *[1]Derby Teaching Hospitals NHS Foundation Trust; [2]Centre for Kidney Research and Innovation, Univ of Nottingham.*

Background: Currently, there is limited information about medication prescribing at the time of AKI and how this impacts on patient outcomes. We present a description of prescribing patterns at the time of AKI in the context of a prospective case-control study.

Methods: Participants were prospectively identified from a hospital-wide electronic AKI reporting system. Cases (hospitalised patients who sustained AKI) were matched 1:1 with controls (hospitalised patients without AKI) for age, baseline eGFR stage and diabetes. Electronic medical record was interrogated for complete prescribing details at sequential time points.

Results: 878 patients were successfully matched. Pharmacy confirmation of medication history occurred in 757 (87%) during admission.

At baseline, more cases than controls were prescribed ACE inhibitors/ARBs (206 (48%) vs 178 (41%), p=0.04) and NSAIDs (56 (13%) vs 30 (7%), p=0.003). There was no difference in prescription of statins, metformin or diuretics. At the time of AKI, 144 (33%) patients were administered ACEi/ARB and 37 (9%) cases received NSAIDs, suggesting suspension of medications in some cases.Within 24hrs of AKI onset, ACEi were stopped in 126 (88%) and NSAIDs in 34 (92%) of these. 188 cases were prescribed an antibiotic at the time of AKI; dosing was inappropriate in 61 (32%).

AKI diagnosis was communicated to primary care in 206 (47%) of cases at hospital discharge, and information regarding medication changes in only 123 cases (29%). At hospital discharge there was reduction in prescribing ACEi/ARB in both groups, but to a greater extent in AKI; 110 (26%) cases were prescribed ACEi/ARB at discharge, compared with 164 (37%) controls, p<0.001.

Conclusions: Whilst prescriber awareness of the importance of suspending nephrotoxic medications at time of AKI is evident, there are additional opportunities to reduce risk of AKI onset and to improve dose adjustment of common medications during AKI. Improving post-AKI care with consideration of restarting cardiovascular medications is another area in which benefits seem likely.

Carbapenem Antibiotics Are Associated with Significant Increases in Serum Creatinine after Contrast Administration

Parker Lehmann,[1] Cheri Lehmann,[2] Asish Thakkar,[2] Udayan Y. Bhatt.[2] *[1]New Albany High School, New Albany, OH; [2]The Ohio State Univ Wexner Medical Center, Columbus, OH.*

Background: Carbapenem antibiotic use has been growing with the increase in resistant organisms. Imipenem, the initial drug in this class, was combined with cilastatin to reduce nephrotoxicity. Newer agents in this class are felt to be less nephrotoxic. Complete adverse effects of newer agents have not been fully defined. On this basis, the purpose of this study is to explore changes in serum creatinine (SCr) after contrast administration in patients on carbapenem antibiotics.

Methods: Patients receiving IV contrast with CT imaging over a 6 month period were identified. Dialysis subjects were excluded. Demographic data were obtained. All laboratory studies done on the day of imaging and SCr at 48hours were extracted. Vital signs and all medications administered on the day of the CT scan were noted. Change in creatinine from the day prior to CT imaging to 2 days after was calculated (Delta_SCr).

Results: Records for 2530 subjects were obtained. Delta_Scr for the cohort was -0.015+0.34mg/dl (-0.039+0.028mg/dl in those not receiving antibiotics). Delta_Scr for different antibiotic classes are shown below

Antibiotic administered on day of contrast	**Delta creatinine (mg/dl) at 48 hours (mean +/- SD)**	**p-value**
TMP/SMX	0.00 +/- 0.04	NS
Aztreonam	-0.05 +/- 0.06	NS
Linezolid	-0.03 +/- 0.05	NS
Aminoglycosides	0.07 +/- 0.05	NS
Vancomycin	0.04 +/- 0.02	0.013
Carbapenems	0.06 +/- 0.03	0.016

In univariate analysis, Delta_Scr was 0.064+0.027mg/dl (p=0.016) in patients receiving carbapenem antibiotics and IV contrast with 10% of subjects having SCr increase by >0.3mg/dl. Multivariate analysis showed the change in SCr was 0.059+0.027mg/dl (p=0.03).

Conclusions: Concomitant administration of carbapenem antibiotics and IV contrast was associated with a significant worsening of SCr in both univariate and multivariate analysis adjusting for demographic, hemodynamic, and other potential nephrotoxic variables. This study identifies a potentially novel risk factor for contrast induced nephropathy.

SA-PO561

Serum Vancomycin Levels Correlate with Significant Increases in Serum Creatinine after Contrast Administration Parker Lehmann,[1] Cheri Lehmann,[2] Udayan Y. Bhatt.[2] *[1]New Albany High School, New Albany, OH; [2]The Ohio State Univ Wexner Medical Center, Columbus, OH.*

Background: Vancomycin is commonly used in the treatment of drug resistant organisms. Rare nephrotoxicity has been reported with its use. However, vancomycin nephrotoxicity has not been fully characterized. On this basis, the purpose of this study is to characterize change in serum creatinine (SCr) in patients after IV CT contrast who are also receiving vancomycin.

Methods: After institutional approval, patients receiving intravenous contrast with CT imaging over a 6 month period were identified. Dialysis patients were excluded. Demographic data were obtained. All laboratory studies done on the day of imaging and SCr 48 hours after imaging were extracted. Vital signs and all medications administered on the day of the CT scan were obtained. Change in creatinine from the day prior to CT imaging to 2 days after was then calculated (delta_cr).

Results: Complete records for 2530 subjects were obtained. In univariate analysis, a significant linear relationship between serum vancomycin level and delta_cr was noted (slope = 0.015, p=0.001). Variables evaluated for multivariate model inclusion included demographic data, vital signs, and concomitant medications including vasopressor use, aminoglycoside use, and other potential nephrotoxins. A significant linear relationship between vancomycin level and delta_cr remained (slope=0.016, p=0.000). Multivariate quartile analysis was then performed.

Vancomycin Quartile Range	Increase in SCr (mg/dL)	p-value
0 to 10.45mcg/mL	Reference	Reference
10.45 to 14.4mcg/mL	0.075	0.321
14.4 to 19.85mcg/mL	0.121	0.116
Above 19.85mcg/mL	0.243	0.002

Conclusions: A significant linear relationship between vancomycin level and worsening SCr after IV contrast was noted. For every 10mcg/mL increase in vancomycin level, Scr would be expected to rise by 0.16mg/dl. Multivariate analysis found that vancomycin levels > 19.85mcg/mL were associated with a significant rise in SCr of 0.24mg/dl. This study demonstrates the additive nephrotoxicity of vancomycin and IV contrast. It also supports the clinical use of monitoring serum vancomycin levels.

SA-PO562

Incidence and Predictors of Acute Kidney Injury following the First Course of Cisplatin Shveta S. Motwani,[1,2] Sushrut S. Waikar,[1] Benjamin D. Humphreys,[3] Gary C. Curhan.[1] *[1]Brigham and Women's Hospital; [2]Dana-Farber Cancer Inst; [3]Washington Univ at St. Louis.*

Background: Cisplatin (Cis) associated acute kidney injury (C-AKI) has been reported in 25-30% patients after multiple courses. Knowledge regarding the risk factors comes from small studies with one type of cancer. We investigated the incidence and predictors of C-AKI, regardless of cause, following the first course of Cis across all cancer types.

Methods: Patients ≥18 yrs of age who received Cis from 2006-2014 at Massachusetts General Hospital and from 2001-2014 at Dana-Farber Cancer Institute/ Brigham and Women's Hospital were included in the study. Those with missing baseline (BL) or follow-up creatinine (Cr) or BL Cr >1.5mg/dl were excluded. C-AKI was defined as ≥0.3mg/dl rise in Cr over BL within 14 days of receiving the first dose. Demographic, clinical and laboratory data were extracted. Incidence rates were calculated. Exposures of interest were analyzed using multivariable logistic regression analysis with C-AKI as the primary binary outcome.

Results: Of the 5942 patients in the combined cohort, the mean ± SD of age was 56 ± 13 yrs, Cis dose 109 ± 54mg, bl Cr 0.9 ± 0.2mg/dl, serum albumin 4±0.5 g/dl, height 169±10 cm, weight 171±42 lbs, body mass index (BMI) 27±6 kg/m^2, with 56% being male, 88% white, 15% diabetic and 51% hypertensive. C-AKI occurred in 617 patients (10.4%). The results of regression analyses are presented in the table, with final model adjusted for BL Cr.

Variable	Univariate			Multivariable		
	OR	95% CI	P value	OR	95%CI	P value
Age,per 10 yrs	1.4	1.3,1.5	<0.0001	1.4	1.3,1.5	<0.0001
Male	1.6	1.3,1.9	<0.0001			
White	1.2	0.9,1.6	0.18			
Diabetes	1.5	1.2,1.9	<0.0001			
Hypertension	2.3	1.9,2.8	<0.0001	1.6	1.3,2.0	<0.0001
BLCr,per 0.3mg/dl	1.4	1.2,1.5	<0.0001	1.1	0.9,1.3	0.1
Albumin,g/dl	0.6	0.5,0.8	<0.0001	0.6	0.5,0.7	<0.0001
Dose,per 25mg	1.3	1.2,1.3	<0.0001	1.3	1.2,1.4	<0.0001
Ht,per 10cm	1.1	1.0,1.3	0.0002			
Wt,per 10 lbs	1.0	1.0,1.1	<0.0001			
BMI,kg/m^2	1.0	1.0,1.1	<0.0001			

Conclusions: C-AKI is frequent even after a single course. Hypertension and hypoalbuminemia are novel risk factors for C-AKI. These data may help identify those at high risk for kidney injury.

SA-PO563

Acute Kidney Injury Biomarkers to Predict 3-Month Cisplatin Nephrotoxicity in Children Kelly McMahon,[1] Tom D. Blydt-Hansen,[2] Maury N. Pinsk,[3] Cherry Mammen,[2] Shahrad Rod Rassekh,[2] Ross T. Tsuyuki,[4] Prasad Devarajan,[5] Michael Zappitelli.[1] *[1]McGill U, Montreal; [2]U British Columbia, Vancouver; [3]U Manitoba, Winnipeg; [4]U Alberta, Edmonton, Canada; [5]Cincinnati Children's Hospital, Cincinnati.*

Background: Children often develop acute kidney injury (AKI) with cisplatin treatment. Late renal effects are common. Renal tubule injury markers neutrophil gelatinase-associated lipocalin (NGAL) and kidney injury molecule-1 (KIM-1) may help risk stratify for late cisplatin nephrotoxicity. Hypothesis: NGAL and KIM-1 predict chronic kidney disease (CKD) and hypertension (HTN).

Methods: Ongoing, 12-site, 3 year prospective study of cisplatin-treated children. Excluded: GFR<30 ml/min/1.73m^2. Protocol includes: Urine NGAL and KIM-1 measured at discharge of last (or second to last) cisplatin infusion; 3-month post-cisplatin visit outcomes: CKD: eGFR<90 by a)serum creatinine (SCr), b)cystatin C (CysC) equations ***or*** albumin-to-creatinine ratio>30mg/g; HTN: blood pressure≥95th percentile for age, gender, height. We compared cisplatin discharge NGAL&KIM-1 levels between subjects with/without 3-month CKD and HTN (Mann-Whitney) and calculated area under curve (AUC)[95%CI] for NGAL&KIM-1 to predict CKD, HTN.

Results: N=48 with complete 3-month data: median[IQR] age 6[3-12] years; 58% male. Table: Cisplatin discharge NGAL and KIM-1 were 2 to 8-fold higher in subjects with renal toxicity at 3 months. Table shows that cisplatin discharge NGAL predicted 3-month CKD or HTN more strongly (AUC 0.70-0.83) than KIM-1 did (AUC 0.60-0.70). AUCs for biomarkers to predict 3-month CKD were ~17% higher when CysC eGFR was used (Table).

Conclusions: Biomarkers measured near end of cisplatin therapy are associated with 3-month post-cisplatin CKD and HTN and may be useful to risk stratify for late renal effects screening and early cardiovascular risk reduction. CysC may be better at estimating GFR compared to SCr to define CKD in children.

Table: Urine NGAL and KIM-1 excretion and diagnostic characteristics for long-term renal outcomes 3 months post-cisplatin therapy completion. Comparison of patients with and without each late renal outcome. **Cisplatin Discharge**: last or before last cisplatin cycle of treatment plan (≥3rd infusion), biomarker measured at discharge.

Biomarkers of Cisplatin-Induced Kidney Injury in Children Kelly McMahon,[1] Tom D. Blydt-Hansen,[2] Maury N. Pinsk,[3] Cherry Mammen,[2] Shahrad Rod Rassekh,[2] Ross T. Tsuyuki,[4] Prasad Devarajan,[5] Michael Zappitelli.[1] *[1]McGill U, Montreal; [2]U British Columbia, Vancouver; [3]U Manitoba, Winnipeg; [4]U Alberta, Edmonton, Canada; [5]Cincinnati Children's Hosp, Cincinnati.*

Background: Acute kidney injury (AKI) and electrolyte abnormalities are common in children treated with cisplatin. Urine AKI biomarkers, neutrophil gelatinase-associated lipocalin (NGAL) and kidney injury molecule-1 (KIM-1), may allow early AKI diagnosis and treatment. Hypothesis: urine NGAL and KIM-1 are diagnostic of cisplatin AKI.

Methods: 12-site, ongoing prospective study of cisplatin-treated children. Exclusion: GFR<30ml/min/1.73m^2. Study visits: Early Acute Visit ([AVE]: 1st or 2nd cisplatin infusion); Later Acute Visit ([AVL]:≥3rd infusion). Blood and urine sampling: pre-infusion, morning post infusion and discharge. Measures: serum creatinine (SCr), NGAL, KIM-1. Outcomes: a)Kidney Disease Improving Global Outcomes (KDIGO) AKI:≥50% SCr rise; b)Electrolyte-AKI:≥National Cancer Institute Grade 1 electrolyte abnormality (low serum potassium, phosphate or magnesium). We calculated % with AKI, compared AKI *vs.* non-AKI biomarkers at each timepoint (Mann-Whitney), characterized biomarker changes on treatment (Wilcoxon signed-rank), calculated area under curve (AUC)[95%CI] for NGAL and KIM-1 to diagnose AKI.

Results: N=95 with data: AVE median[IQR] age 5[2-13] years; hospital stay 5[3-15] days; %SCr rise of 73[60-125]; 54% male. KDIGO AKI: 21% AVE, 13% AVL. Electrolyte-AKI: 53% AVE, 75% AVL. Both: 13% AVE, 8% AVL. Especially for KIM-1, levels drop

immediately post cisplatin, then rise at discharge (Table). Table shows AKI biomarkers tend to be higher in AKI group(†). Biomarker AUCs for AKI diagnosis are higher at AVL (later cisplatin infusion) than AVE (Table, AVL AUCs range from 0.65-0.83).

Conclusions: Our novel data show that NGAL and KIM-1 are diagnostic of cisplatin-AKI, more so with later cisplatin infusions during cancer treatment.

Table: NGAL & KIM-1 excretion during cisplatin. At each timepoint, AKI *vs.* non-AKI biomarkers are compared for Early Acute Visit (AVE) and later AVL. Area under the curve (AUC) with 95%CI: In boxes, biomarker to diagnose AKI. LEFT: AKI defined by SCr KDIGO definition. RIGHT: AKI defined by KDIGO & Electrolyte NCI definition. Timepoints: pre-infusion, post-infusion and discharge. Median [interquartile range] biomarker levels shown.

SA-PO565

Association of Proton Pump Inhibitors with Acute Kidney Injury in Geriatric Population Zara Nisar. *Nephrology, Khyber Teaching Hospital, Peshawar, KPK, Pakistan.*

Background: Acute Kidney Injury in elderly patients presents with a wide range of clinical manifestations from an elevation in serum creatinine to anuric renal failure, arises from multiple causes, and occurs in a variety of clinical settings. The main objective of this study is to establish the relationship of use of Proton Pump Inhibitors as a risk factor for AKI in geriatric population.

Methods: A retrospective descriptive analysis was done from 31st December 2012-31st December 2015. Data was analyzed using SPSS (version 21). A total number of 18,668 outpatient prescriptions for PPIs were written.

Results: A total number of 18,668 outpatient prescriptions for PPIs were written. Among them were 9978 (53.44%) cases of Acute Kidney injury reported within 120 days of receiving the prescription. 5577 (55.89%) patients presented with decrease in urine output. 3678 (36.86%) cases reported with additional shortness of breath, swelling in the ankles/legs. 723 (7.24%) cases were presented with confusion and dizziness. Serum creatinine level was greater to or equal to 1.5mg/dl in 7892 (79.09%). In 2086 (20.90%) cases it was greater than or equal to 2.5mg/dl.

Conclusions: PPIs use is associated with an increased risk of Acute Kidney Injury in elderly patients. The study was limited by its retrospective nature, which hindered the its ability to draw conclusions regarding the connection between PPIs exposure and AKI onset. However, PPIs are perhaps the most common avoidable AKI risk to which elderly patients are regularly exposed. Doctors should continue to provide careful PPI education to the patients, and they should be regularly monitored for signs of Acute Kidney Injury.

SA-PO566

Renal Toxicities of Anti-Myeloma Agents Rimda Wanchoo, Valerie Suzanne Barta, Vipulbhai Sakhiya, Kenar D. Jhaveri. *Nephrology, Hofstra Northwell School of Medicine, Great Neck, NY.*

Background: Survival for patients with multiple myeloma(MM) has significantly increased in the last decade in large part due to development of proteasome inhibitors and immunomodulatory drugs. Drugs with novel mechanisms of action and targeted therapies are being explored both in the pre-clinical and clinical settings in myeloma. A possible limiting feature for these agents is their potential for nephrotoxicity.

Methods: We reviewed the FDA adverse event reporting system (FAERS) quarterly legacy data file 3rd quarter of 2011 to 2nd quarter of 2016 for all novel MM agents. Well established chemotherapy agents such as cyclophosphamide, melphalan and anthracyclines were excluded. The adverse event terms queried were: "hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia, hypocalcemia, hypercalcemia, hyperkalemia, hypernatremia, hyperphosphatemia, proteinuria, renal failure acute, acute kidney injury, elevated creatinine, hypercreatinemia, hypertension and nephritis". We also reviewed the literature for case reports, case series and the primary studies of these agents for any known nephrotoxicities.

Results:

DRUG NAME	RENAL IMPAIRMENT*	HYPO-KALEMIA	HYPO-NATREMIA	HYPO-MAGNESEMIA	HYPER-KALEMIA	HYPOPHOSPHATEMIA	HYPER-NATREMIA	GRAND TOTAL
LENALIDOMIDE	881	136	61	33	25	28	8	1172
EVEROLIMUS	586	52	35	23	24	19	4	743
BORTEZOMIB	325	65	51	10	25	24	9	509
SIROLIMUS	249	8	13	2	9	7	0	288
VEMURAFENIB	176	11	18	2	4	0	0	228
POMALIDOMIDE	113	4	10	2	3	0	1	133
CARFILZOMIB	85	12	8	2	8	9	0	130
VORINOSTAT	44	26	26	0	10	16	2	124
DABRAFENIB	32	2	13	2	0	1	0	50
TRAMETINIB	28	1	11	3	0	1	0	44
NIVOLUMAB	20	5	14	2	4	1	0	44
PEMBROLIZUMAB	16	3	19	0	1	0	0	39
PANOBINOSTAT	11	2	3	1	2	2	0	22

Figure above summarizes the drugs studied and results found. Lenolidomide, everolimus and bortezomib were the top three offenders with AKI as the most common finding reported. Newer agents such as carfilzomib, BRAF inhibitors and PD-1 antagonists do have rare renal side effects. The review of literature found toxicities associated with lenolidomide, bortezomib and carfilzomib as top offenders. Importantly, the toxicities reported here are not just when these agents are used in MM but for other cancer treatments as well.

Conclusions: Novel targeted therapies being used in MM can be nephrotoxic. Knowledge of novel agents used in MM and their renal toxicities is important for the nephrologist and the hematologist.

SA-PO567

High-Dose Leucovorin as Sole Therapy for High-Dose Methotrexate Toxicity Carlos D. Flombaum,[1,2] Dazhi Liu,[1] Shirley Qiong Yan,[1] Amelia Chan,[1] Sherry Mathew,[1] Paul A. Meyers,[1,2] Ilya Glezerman,[1,2] Thangamani Muthukumar.[2,1] [1]*Memorial Sloan Kettering Cancer Center, New York, NY;* [2]*Weill Medical College of Cornell Univ, New York, NY.*

Background: High-dose MTX (HDMTX) therapy complicated by acute kidney injury is a medical emergency. Prolonged exposure to elevated MTX levels creates a high risk for severe mucositis, myelosuppression and death. High-dose leucovorin (HDLV) and alkalinization of the urine are the basis of support for these patients. More recently, glucarpidase (**G**) has been introduced to circumvent MTX toxicity. We aimed to investigate whether or not HDLCV and supportive therapy alone, without **G**, can prevent systemic toxicity from HDMTX.

Methods: To identify patients at high risk for severe MTX toxicity, we performed a retrospective review of all patients treated between 2000 and 2011 who had MTX levels 10 ≥ times of what are considered toxic levels at 48 and/or 72 hours after HDMTX (≥ 10 µmol/L at 48 hours and/or ≥ 1 µmol/L at 72 hours).

Results: 103 patients who received 113 courses of HDMTX were identified. Serum creatinine increased by a median of 2-fold from baseline (range 1–10 fold) but all patients recovered renal function. Median (range) MTX levels at 24, 48 and 72 hours post MTX administration were 69 (2. 2–410), 7.2 (1. 3–85) and 2.2 (0.0 5–26) µmol/L. MTX levels remained ≥0.1 µmol/L for a median of 9 days (range 0–19 days). There was a high correlation between MTX levels at 48, 72, 96 and 120 hours but not between 24 hours and subsequent time points. 83% of the patients received IV HDLCV, given within the first 48 hours in 84%. Myelosuppression was present in 39% of patients: grade≥III neutropenia in 27.4% and thrombocytopenia in 22%. Infectious complications, oral mucositis and diarrhea occurred in 19.5, 15 and 5.3 % of patients. There were 5 deaths, none directly attributed to complications from HDMTX.

Conclusions: We treated 113 episodes of HDMTX–associated renal dysfunction with a strategy that only included usual supportive measures and HDLV . We observed no HDMTX–associated mortality and the incidence of systemic complications was comparable to other studies where **G** was used. Glucarpidase is an extremely expensive drug and probably unnecessary in a significant number of patients.

SA-PO568

Renal Adverse Events of Immune Check Point Inhibitors Nupur N. Uppal, Valerie Suzanne Barta, Kenar D. Jhaveri, Rimda Wanchoo. *Nephrology, Hofstra Northwell School of Medicine, Great Neck, NY.*

Background: Enhancing anti-tumor T cell immunity with checkpoint inhibitor antibodies [anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) and anti-program death 1 (PD-1)] has shown significant clinical benefits in tumor regression and prolonged stabilization melanoma and other cancers. These agents are termed immune check point inhibitors(ICI).

Methods: To better understand recent published contributions related to ipilimumab, pembrolizumab and nivolumab induced renal toxicities, a Medline search of indexed manuscripts was conducted. The search terms 'renal failure' and 'acute kidney injury' with subheadings 'ipilimumab', 'pembrolizumab' , 'nivolumab' and 'nephrotoxicities' were employed. We also searched for 'hypokalemia, hypocalcemia, hyponatremia and hypophosphatemia'.Primary data from the initial studies of these agents and the FDA adverse reporting system(FAERS) database were also reviewed.

Results: A total of 18 citations were found. Acute interstitial nephritis, podocytopathy and hyponatremia are the three most common adverse renal findings related to the ICI. This figure compares the two reported classes of targeted therapies.The FAERS database had significant more reported renal toxicities with ipilimumab compared to the anti PD-1 agents.

Agents	CTLA-4 Antagonists(Ipilimumab)	PD-1 Inhibitors(Nivolumab and Pembrolizumab)
Onset of AIN	AIN appears 6-12 weeks	AIN appears 3 months – 12 months
Glomerular findings	Podocytopathy reported	No cases of podocytopathy reported
Gender	6/7 cases reported above were males	No gender preferences
Electrolyte disorders	Hyponatremia cases related to hypophysitis	Hyponatremia is rare
Transplant	In renal transplant patients, 2 cases reported no rejection when given as a solo agent.	When given lead to transplant rejection especially following use with CTLA-4 inhibitors(3 cases reported)

Conclusions: Renal injury appears to be part of the spectrum of immune-related adverse events. All agents are known to cause AIN. The renal insult related with ipilimumab appear to happen earlier in the course of the drug therapy (6-12 weeks following treatment) compared to events associated with PD-1 inhibitors appear around 6-10 months following initiation of treatment. Early recognition of immune mediated renal toxicities is important as treating with steroids promptly improves renal function. In kidney transplant patients, a preventive strategy might be needed to alleviate the chances of rejection.

SA-PO569

Incidence of AKI with Immune Checkpoint Inhibitors at a Single Center Jamie S. Hirsch,[1] Rimda Wanchoo,[1] Valerie Suzanne Barta,[1] Kenar D. Jhaveri,[1] Craig Devoe.[2] *[1]Nephrology, Hofstra Northwell School of Medicine; [2]Hematology/Oncology, Hofstra Northwell School of Medicine.*

Background: Immune checkpoint inhibitors (ICI) target the immune system and are increasingly being used to treat various cancers. Based on few published case reports, both anti-cytotoxic T lymphocyte protein-4 and anti-program death(PD-1) can lead to immune related adverse renal effects. We wanted to evaluate the incidence of AKI with these agents at a single center.

Methods: Data were obtained from Northwell Health's EHR, and included all patients receiving ipilimumab, nivolumab, or pembrolizumab at infusion centers between May 2011 & May 2016. Patients were included if they had at least one creatinine (Scr) measurement available prior to the first treatment and at least one Scr measurement following the first treatment. AKI was defined by KDIGO criteria. We compared data of the patients who developed AKI to those that didn't. Chi-squared testing was used to compare categorical variables and Student's t-test to compare continuous variables.

Results: Of 211 patients receiving ipilimumab (CTLA-4), nivolumab, or pembrolizumab at our center, 99 had Scr available for analysis. AKI Stage I developed in 29% (11/38) of CTLA-4 and 24.5% (15/61) of PD-1 patients, while AKI Stage II developed in 5% (2/38) and 10% (6/61), respectively. Table below summarizes the breakdown of patients that developed AKI vs no AKI, and no statistically significant differences were noted between the groups.

Ipilimumab	AKI	No AKI
Male (%)	82	70
Race (White) (%)	45	78
Mean SCr(mg/dl)	1.04	0.91
Melanoma diagnosis(%)	91	92.5
Median age(years)	66	64
Nivolumab/Pembrolizumab	**AKI**	**No AKI**
Male (%)	60	59
Race (White) (%)	47	61
Mean SCr (mg/dl)	0.96	0.98
Melanoma diagnosis(%)	13	21
Median age (years)	68	64

PD-1 were being used in cancers other than melanoma compared to CTLA-4 which was used primarily in melanoma.

Conclusions: In a single center study, the incidence of AKI in both CTLA- and PD-1 was high at 29% and 24.5%, respectively. No specific gender,age, or CKD differences were noted. Given the high incidence of AKI with ICIs,nephrologists & oncologists need to be aware of the nephrotoxicities.

SA-PO570

Gadolinium-Contrast Nephrotoxicity in Patients with Chronic Kidney Disease Stage 1 Shokichi Naito, Kouju Kamata, Kazuhiro Takeuchi, Tetsuya Abe, Haruka Takahashi, Yasuo Takeuchi. *Nephrology, Kitasato Univ School of Medicine, Sagamihara, Kanagawa, Japan.*

Background: Gadolinium (Gd)-contrast mediums (GCM) used in magnetic resonance imaging (MRI) have been traditionally considered non-nephrotoxic contrast materials. On the other hand, we have shown that an ionic contrast medium, Omniscan affected renal function transiently in patients with less than 1.6 mg/dl of serum creatinine (S-Cr) in ERA-EDTA 2012. However, there are no reports on the nephrotoxicity of GCM in early stages of chronic kidney disease (CKD). We investigated the effect of Gd-contrast medium on renal function in CKD stage 1 after MRI.

Methods: Patients aged 20–80 years, weighing 45–70 kg, and with CKD stage 1 in the 3 months prior to undergoing an MRI were enrolled. They were randomly divided into an ionic contrast medium (Omniscan) administration group (group O) and a nonionic contrast medium (Magnevist) administration group (group M). GCM (0.01 mmol/kg) was administered to all patients. We measured levels of S-Cr and serum cystatin C (S-Cys), as well as estimated glomerular filtration rate (eGFR) and estimated creatinine clearance rate (eCCr) using MDRD and the Cockcroft-Gault formula, respectively, just before and 24–72 h after the MRI. Mann-Whitney U-test and Wilcoxon signed-ranks test were employed for statistical analysis.

Results: There were no significant differences in the clinical background characteristics such as age, sex, and serum concentrations of albumin, S-Cr, S-Cys, eGFR, and eCCr between group O (n=21) and group M (n=32). There were no significant differences in S-Cr, eGFR, or eCCr before MRI and 24–72-h after MRI measurements of both groups. S-Cys levels increased significantly 24–72 h after MRI only in group O (0.69 ± 0.14 vs. 0.72 ± 0.11, P=0.047), whereas, there were no significant differences in S-Cys levels in group M (0.70 ± 0.18 vs. 0.69 ± 0.19, P=0.698).

Conclusions: The nonionic contrast medium, Magnevist, had no effect on renal function during MRI, while the ionic contrast medium, Omniscan, affected renal function transiently in the patients with CKD stage 1.

Outcome of Patients with Acute Kidney Injury Secondary to p-Phenylenediamine (Kala-Pathar) Poisoning Syed A. Khalid,[1] Sidra Saleem,[1] Syed Rizwan A. Bokhari,[1] Hafiz I. Ahmad,[1] Arif Asif.[2] *[1]Nephrology, Allama Iqbal Medical College/ Jinnah Hospital Lahore, Pakistan; [2]Internal Medicine, Jersey Shore Univ Medical Center, NJ.*

Background: In the developing countries, household hair dye ingestion is emerging as a cheap and readily available compound to commit suicide. This Hair dye (known as "kala-pathar" in local language) contains p-Phenylenediamine having a molecular weight of 108.14112 g/mol and a host of other chemicals which lead to multi-organ dysfunction. Renal manifestations include metabolic acidosis and severe acute kidney injury. Previous studies have revealed high morbidity and mortality with PPD poisoning. No specific antidote or medicine for p-Phenylenediamine poisoning is available so far. We aimed to explore the clinical course and outcome of patients who developed AKI in this poisoning.

Methods: In this case series we observed patients with AKI secondary to p-Phenylenediamine poisoning admitted under nephrology service between 12-2015 to 05-2016. Patient demographic characteristics, clinical features and their outcomes were recorded. AKI was defined as per Acute Kidney Injury Network Group.

Results: Six patients, with AKI secondary to p-Phenylenediamine poisoning, were included in this study. Four (66%) were females with mean age 20.8 (range 14-25). Five (83%) were admitted to the medical floor and one (17%) patient was admitted in the ICU for ventilatory support. All of these patients ingested Kala-Pathar with suicidal intention. Oliguria, cervicofacial edema and dysphagia were the commonest presentations. All 6 patients had oliguria at presentation, whereas 4(66.7%) developed anuria during the first few

days of hospital admission. Four patients (66.7%) had rhabdomyolysis. All patients required hemodialysis with an average of 7 sessions (range 5-8). Five patients on medical floor made a full recovery from AKI in 7-8 weeks, while one patient admitted to the ICU expired.

Conclusions: Our study is the first to demonstrate promising results in majority of patients recovering from AKI due to p-Phenylenediamine poisoning, with timely hemodialysis and supportive care.

SA-PO572

Save the Kidneys: Using a Scoring System to Reduce Contrast Induced Nephropathy following Coronary Angiography Kelly M. Tierney,[1] Aaron Ho,[1] Mingxi Dennis Yu,[1] Laura J. Maursetter,[1] Todd L. Goldman,[1] Brad C. Astor,[1] Carol F. Otterson,[2] Mary K. Lease,[2] Mohun Ramratnam.[1] *[1]Univ of Wisconsin, Madison, WI; [2]William S. Middleton VA, Madison, WI.*

Background: Contrast-induced nephropathy (CIN) is a leading cause of hospital-acquired acute kidney injury. Though pre-hydration is commonly used to prevent CIN, there is significant variability in its use. The goal of this study was to evaluate the utilization and outcomes associated with a pre-hydration protocol for cardiac angiography based on the Mehran risk score (MRS) to achieve a lower rate of CIN compared to published incidence (5-15%).

Methods: All patients undergoing a coronary angiogram at the William S. Middleton VA Hospital between Feb 2014 and Dec 2015 were enrolled, excluding those on dialysis or vasoactive agents. Risk for CIN was assessed with the MRS and pre-hydration was ordered for those with a score ≥6 if they were not hypervolemic. CIN was defined as an increase in creatinine (Cr) of >50% or 0.3 mg/dL 48-72 hrs post-procedure.

Results: A total of 412 patients enrolled and had follow-up Cr values. Of these, 42.5% had diabetes, 25.7% had CHF, and 23.1% underwent PCI. The average pre-procedural Cr was 1.18 mg/dL. Patients with higher MRS were more likely to receive pre-hydration ($p<0.001$). A total of 14 (3.4%) patients developed CIN. Those with CIN had higher pre-procedural Cr ($p<0.01$) and higher MRS ($p<0.001$) than those without. The MRS components most strongly associated with CIN were anemia (IR=1.5;95%CI 1.1-2.1) and GFR <60 ml/min/1.73m^2 (IR=2.1;95%CI 1.1-3.8). Pre-hydration was associated ($p=0.05$) with a lower incidence of CIN after adjustment for MRS (OR=0.95;95%CI 0.90-0.99). All patients with CIN were followed by inpatient providers or referred to nephrology and 12/14 (86%) had complete resolution of their CIN.

Conclusions: Protocol-driven pre-hydration, based on the MRS, was associated with a lower incidence of CIN compared to published rates. Pre-hydration was associated with lower risk of CIN after adjusting for risk score. This supports the use of pre-hydration prior to coronary angiography. Further studies are needed to define the most effective protocol and assess the impact this interdisciplinary approach has on outcomes.

SA-PO573

Incidence and Risk Factors for Acute Kidney Injury following Coronary Angiography in the Era of Isosmolar Contrast Agents Dadi Helgason,[1,2] Thorir E. Long,[1,2] Sólveig Helgadóttir,[2] Runolfur Palsson,[1,2] Gisli H. Sigurdsson,[1,2] Tomas Gudbjartsson,[2] Martin I. Sigurdsson,[3] Ingibjorg J. Gudmundsdottir,[2] Olafur S. Indridason.[2] *[1]Univ of Iceland; [2]Landspitali - the National Univ Hospital of Iceland, Reykajvik, Iceland; [3]Brigham and Woman's Hospital, Boston, MA.*

Background: Acute kidney injury (AKI) remains a serious complication of coronary angiography (CA), despite less toxic contrast media and advances in imaging.We studied recent trends in incidence and risk factors of AKI following CA.

Methods: This was a retrospective study of all patients undergoing CA, with or without coronary intervention, in Iceland in 2008-2015. All procedures were performed using iodixanol, an iso-osmolar contrast agent. AKI was defined according to the serum creatinine (SCr) part of the KDIGO criteria. Data was collected from the Swedeheart/SCAAR database and hospital electronic records. Poisson regression was used to evaluate incidence changes and multivariate logistic regression to identify predictors of AKI.

Results: A total of 10,891 patients underwent 13,983 CAs and baseline SCr was available for 97.3% of the cases. AKI occurred in 281 cases (2.1%); 218 (1.6%), 33 (0.2%) and 30 (0.2%) classified as stage 1, 2 and 3, respectively. Annual incidence of AKI was 20.6/1000 CA/year and did not change significantly over the study period ($p=0.31$). AKI patients received higher doses of contrast media compared to non-AKI patients (163.9 mL vs. 128.7 mL, $p<0.0001$). In multivariate analysis, age (per year, OR=1.04, 95% CI=1.03-1.05), eGFR <60 mL/min/1.73 m^2 (OR=5.91, 95% CI=4.30-8.07), emergency CA (OR 6.37, 95% CI=4.82-8.43), disease found requiring CABG evaluation (OR=2.74, 95% CI=1.83-4.06), femoral access (OR=1.38, 95% CI=1.06-1.81), contrast dose (per 10 mL; OR=1.03, 95% CI=1.004-1.046), fluoroscopic time (per 10 min; OR=1.17, 95% CI=1.03-1.31), and procedural complications (OR=4.15, 95% CI=1.97-8.10) were associated with increased risk of AKI.

Conclusions: In this nationwide study, the incidence of AKI following CA was 2%; with similar rates during the 8-year period. In spite of use of iso-osmolar contrast agent its dose still associates with AKI along with emergency CA, procedural duration and complications and femoral access.

Preinterventional Kynurenine Predicts Long-Term Outcome after Contrast Media Exposure due to Coronary Angiography Christoph Reichetzeder,[1,2] Fabian Heunisch,[2] Gina Von Einem,[2] Markus Lukas Alter,[3,2] Karl-Heinz Kellner,[4] Thomas Bernd Dschietzig,[5,9] Axel Kretschmer,[6] Berthold B. Hocher.[1,7,8] *[1]Inst for Nutritional Science, Univ of Potsdam; [2]Center for Cardiovascular Research, Charité - Universitaetsmedizin Berlin; [3]Dept of Nephrology - CBF, Charité - Universitätsmedizin Berlin; [4]Neuroimmun GmbH, Karlsruhe, Germany; [5]Dept of Cardiology and Angiology - CCM, Charité - Universitätsmedizin Berlin; [6]Bayer Pharma AG, Wuppertal, Germany; [7]Inst for Laboratory Medicine, Berlin, Germany; [8]Dept of Basic Medicine, Medical College of Hunan Normal Univ; [9]Immundiagnostik AG, Bensheim, Germany.*

Background: Contrast media (CM) induced nephropathy (CIN) remains a serious complication of CM enhanced procedures. There is still a lack of established biomarkers that help to identify patients at high risk for long term complications. The current study aimed to evaluate plasma kynurenine as a predictive biomarker for long term complications of CM exposure due to coronary angiography.

Methods: 245 patients undergoing coronary angiography were analyzed in this prospective cohort study. Blood and urine samples were obtained at baseline/24h/48h after CM application to diagnose CIN. Patients were followed for 120 days for adverse clinical events. Long term outcome was measured by the combined endpoint "Major adverse kidney events" (MAKE) including death, the need for dialysis, doubling of plasma creatinine and rehospitalization.

Results: Preinterventional plasma kynurenine (PKYN) was not associated with CIN. Patients who later developed MAKE displayed significantly increased PKYN levels ($p<0.0001$). ROC analysis revealed that PKYN is highly predictive for MAKE (AUC=0.838; $p<0.0001$;). The optimal cutoff was found at ≥3.5 µmol/L. Using this cutoff, the Kaplan-Meier estimator demonstrated that concentrations of PKYN ≥3.5 µmol/L were significantly associated with a higher prevalence for MAKE until follow up (Chisquare=31.59; $p<0.0001$;) This association remained significant in multivariate Cox regression models adjusted for relevant factors of long term renal outcome.

Conclusions: Results of this study showed that preinterventional kynurenine might serve as a highly predictive biomarker for MAKE up to 120 days after coronary angiography.

SA-PO575

Incidence and Risk Factors for Contrast Induced Nephropathy (CIN) Among Cancer Patients Sheron Latcha,[1] Junting Zheng,[2] Andrew Plodkowski.[3] *[1]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY; [3]Radiology, Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Recent publications question the existence of AKI from intravenous contrast administration. Understanding the incidence and risk factors for CIN in cancer patients is important since these patients rely on CT imaging to establish cancer stage and response to chemotherapy.

Methods: Retrospective data was collected on all adult inpatients at Memorial Sloan Kettering Cancer who had a contrast (CON) or non contrast (NC) CT of the head, neck and chest from 1/1/2012-12/30/2014 with a creatinine (Cr) within 3D pre and post CT. Patients were excluded if a CON CT was done within 3D before a NC CT. Acute kidney injury (AKI) was defined as an increase in Cr > 0.3mg/dl or 1.5X baseline. ICD 9 codes were used to identify diagnoses and medications previously identified as risk factors for CIN (multiple myeloma (MM), diabetes, congestive heart failure (CHF), hypotension, liver metastases, chronic kidney disease (CKD), AKI, nonsteroidal anti inflammatory medications (NSAIDs), ACE inhibitors, ANGII receptor blockers, bisphosphonates, VEGF and immune checkpoint inhibitors, EGFR therapy, tyrosine kinase inhibitors, gemcitabine and cisplatin). Rao-Scott Chi-square test was used to examine AKI rate differences.

Results: 5178 NC CT and 2654 CON CT were included. The incidence of AKI was significantly greater in the NC group (11.5% vs 7.2% in CON group) and in those with GFRs <59ml/min, CHF, no liver metastases, CKD, AKI, chemotherapy within 60D of CT, EGFR therapy, leukemia, lymphoma, MM ($p<0.001$ for all above), male genital system tumors ($p=0.014$) and NSAIDs ($p=0.007$).

Conclusions: In this large cohort of cancer patients, IV contrast administration was not associated with increased AKI from CIN. Indeed, a significantly higher incidence of AKI was found in the NC group. The incidence was also higher in those with GFR <59ml/min, AKI, recent chemotherapy, EGFR therapy, NSAIDs, leukemia, lymphoma, male genital tumor and MM.

SA-PO576

Impact of Serum Uric Acid on Renal Outcome after Contrast Enhanced Computerized Tomography Ming-Ju Wu. *Div of Nephrology, Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: The association between serum level of uric acid (sUA) and risk of acute kidney injury (AKI) after contrast-enhanced computerized tomography (CCT) is limited. The aim of this study was to determine whether elevated sUA could predict renal outcome after CCT.

Methods: We used a history cohort of 58106 non-dialysis adult patients who received non-ionic iso-osmolar CCT from June 1, 2008 to March 31, 2015 to evaluate the association of sUA and renal outcome. The exclusion criteria were patients with pre-existing AKI, multiple exposure, non-standard volume of contrast, and missing data for analysis.

Results: A total of 1440 patients were enrolled. Post-contrast-AKI (PC-AKI) occurred in 190 (12.5%) patients (18%) and the need of hemodialysis developed in 90 (6.3%) patients, both incidences were increased in patients with higher sUA. After adjusting for potential confounders, sUA was associated with an increased risk of PC-AKI [odds ratio (OR) of 2.62; 95% confidence interval (CI), 1.27~5.38, p=0.009] and the need of hemodialysis (OR, 5.40; 95% CI, 1.39~21.04, p=0.015). Comparing with sUA <8.0 mg/dL, patients with sUA ³8.0 mg/dL had higher incidence of PC-AKI (16.7% vs. 11.1%, p=0.012) and higher incidence of hemodialysis (12.1% vs. 4.3%, p<0.001). Additionally, 53.8% of patients with AKI had eGFR decreased ³20% after 3 months of CCT, compared to only 25.9% in patients without AKI (p<0.001).

Conclusions: Elevated sUA is associated with worse renal outcome after CCT. We suggest that elevated sUA may have potential as an independent risk factor for PC-AKI in patients scheduled to receive contrast-enhanced image study.

SA-PO577

Biomarkers for Diagnosis and Predicting Outcomes in Contrast Induced Nephropathy Justor Banda, Caroline Dickens, Saraladevi Naicker. *Internal Medicine, Univ of the Witwatersrand, Johannesburg, Gauteng, South Africa.*

Background: Serum creatinine is sub-optimal as a biomarker in the early diagnosis of contrast induced nephropathy (CIN). This study investigated a panel of novel biomarkers in the early diagnosis of CIN and in assessing patient outcomes.

Methods: This single centre, nested, prospective case-controlled study included 30 patients with CIN and 60 matched controls. Sera were collected pre-contrast; 24 hours (24h); 48h; and ≥5 days post contrast administration. Concentrations of NGAL, cystatin C, β_2M, IL18, IL10, and TNFα were determined using luminex and ELISA assays. Outcomes were biomarker diagnostic discrimination performance for CIN and mortality after generation of area under receiver operating characteristic curves (AUROC).

Results: Median 24h cystatin C and 48h β_2M levels were higher in CIN patients compared to controls (856.60ng/ml (IQR 620.75-1003.0) vs. 617.43ng/ml (533.11-805.21); p<0.001 and 5.3µg/ml (IQR 3.8-6.9) vs. 3.3µg/ml (2.7-4.5); p<0.001] with AUROCs of 0.75 and 0.78 respectively for early diagnosis of CIN. β_2M levels were higher at all time points. Baseline IL18 (p<0.001), β_2M (p=0.04) and TNFα (p<0.001) levels were higher in the non-surviving group and their AUROCs were all >0.80 for CIN+ mortality respectively. Baseline NGAL was superior for excluding patients at risk for CIN, with positive and negative predictive values of 0.50 and 0.81 respectively. Cystatin C (p=0.003) and β_2M (p=0.03) at 24h independently predicted CIN risk. β_2M predicted increased mortality of 40% at baseline and 50% at 24 hours.

Conclusions: Serum cystatin C was the best biomarker for CIN diagnosis, while IL18, β_2M and TNFα were best for predicting prognosis.

SA-PO578

Rapidly Reversible Contrast-Induced Acute Kidney Injury Does Not Increase the Risk for Worse Long-Term Renal Outcomes Darpan Gandhi,[1] Bhavna Bhasin,[1] Jorge Luis Castaneda,[2] Christopher D. Nielsen,[3] Juan Carlos Q. Velez.[1] *[1]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Div of Nephrology, Univ of Mississippi; [3]Div of Cardiology, Medical Univ of South Carolina.*

Background: Growing evidence indicates that contrast-induced acute kidney injury (CI-AKI) may increase the long-term risk for progression of chronic kidney disease (CKD) to end-stage kidney disease (ESKD). However, the duration of CI-AKI is highly variable and the impact of a sustained vs. a transient rise in serum creatinine (sCr) on long-term renal outcomes is not known. We hypothesized that recovery of CI-AKI within 7 days reduces the risk for worsening of long-term renal outcomes.

Methods: We reviewed records from non-ESKD patients with estimated glomerular filtration rate (eGFR) ≤ 45 ml/min who underwent coronary angiography (Cath) between 2008 and 2011 at MUSC. CI-AKI was defined as ≥ 25% rise in within 1-5 days post-Cath. CKD progression was defined as ≥ 30% fall in eGFR. Rapid recovery of CI-AKI was defined as improvement of sCr to a value < 25% above baseline within 7 days of Cath. Outcomes were assessed at 1 year.

Results: Of 2,098 subjects identified, 168 fulfilled the eGFR inclusion criteria, but 72 of them were excluded because of missing a sCr value after 24 hrs. The mean eGFR was 30.65 ± 9.9 ml/min, 58% were diabetics and the mean volume of dye was 107.2 ml. The incidence of CI-AKI was 29.2% (28/96). The composite endpoint of CKD progression, ESKD or death was reached by 50% (14/28) of those who developed CI-AKI compared to 17.6% (12/68) of those who did not develop CI-AKI [OR: 4.7 (95%CI: 1.7 – 12.3); p=0.002]. Eleven (39%) patients had a rapid recovery of CI-AKI, whereas the remaining 17 (61%) did not. Rapid recovery of CI-AKI was associated with a lower risk for the composite endpoint of CKD progression, ESKD or death [OR: 0.12 (95%CI: 0.02 - 0.75); p=0.023].

Conclusions: Although CI-AKI increases the long-term risk for worsening of renal outcomes, recovery within 7 days of the Cath is associated with a reduction in that risk, suggesting that severity of CI-AKI may impact its effect on long-term prognosis.

SA-PO579

Incidence and Risk Factors for Contrast-Induced Acute Kidney Injury in Patients Taking Trimethoprim-Sulfamethoxazole Hyun Seop Cho,[1,3] Tae Won Lee,[1] Eunjin Bae,[2] Hyun-Jung Kim,[1,3] Se-Ho Chang.[1,3] *[1]Internal Medicine, Gyeongsang National Univ Hospital, Jinju, Republic of Korea; [2]Internal Medicine, Gyeongsang National Univ Changwon Hospital, Changwon, Republic of Korea; [3]3 Inst of Health Sciences, Gyeongsang National Univ, Jinju, Republic of Korea.*

Background: Trimethoprim-sulfamethoxazole (TMP-SMX) is commonly used to prevent pneumocystis pneumonia and for wide range of infections in the outpatient setting. Previous studies have shown a relationship between TMP-SMX and acute kidney injury. The attributable risk for renal dysfunction from contrast medium in patients taking TMP-SMX not been well established.

Methods: We reviewed medical record database for all patients who received ≥3 days of treatment with TMP-SMX between from January 2009 to December 2015. Among these, we included patients underwent contrast-enhanced computed tomography (ECT) scan and for whom a baseline and follow-up determination of serum creatinine were available. CI-AKI was defined as an increase in serum creatinine (sCr) more than 25% of baseline value or 0.3 mg/dL at between 48 hours and 96 hours after ECT. We excluded patients who already had been receiving dialysis.

Results: Of 213 patients who met inclusion criteria, 18 (8.5%) had increases in sCr that met predetermined criteria for CI-AKI: The mean age was 58.81 ± 17.59 years. 45 patients (21.2%) had diabetes mellitus. Variables independently associated with CI-AKI included high potassium level (p=0.041), high potassium/sodium ratio (p=0.030), high Blood urea nitrogen level (p=0.027), high C-reactive protein(CRP) level (P=0.032), high HbA1c level (p=0.019), high CKD stage (p=0.023), concominant use of nephrotoxic drug (p=0.037). Multiple linear regression analysis shows hypoalbuminemia, hyperkalemia and concominant use of nephrotoxic drug to be significantly associated with CI-AKI (p=0.019, p=0.043 and p=0.013, respectively).

Conclusions: As it is well-known, the incidence of CI-AKI was higher in patients with high CRP level, advanced CKD satge and concominant use of nephrotoxic drug. Moreover, in high risk patients with hyperkalemia and hypoalbuminemia, TMP-SMX interruption should be considered to prevent the development of CI-AKI.

SA-PO580

Expression of Polycystins in LLC-PK1 Cells Does Not Increase Flow-Activated Calcium Fluxes Lindsey K. Stavola,[1] Helle A. Praetorius,[2] Michael J. Caplan.[1] *[1]Cellular and Molecular Physiology, Yale Univ, New Haven, CT; [2]Biomedicine, Aarhus Univ, Aarhus C, Denmark.*

Background: The primary cilium is thought to detect fluid flow in the kidney. The molecular basis of this mechanosensitivity is not fully elucidated. The polycystin 1 (PC1) and polycystin 2 (PC2) proteins, encoded by the genes that are mutated in Autosomal Dominant Polycystic Kidney Disease, localize in part to the primary cilium. PC1 is a ~450 kDa membrane protein with 11 membrane spans. PC2 belongs to the TRP family of Ca^{2+}-permeable channels. PC1 and PC2 form a complex, which is required for their trafficking to the primary cilium. It has been suggested that the ciliary pool of polycystins functions as a mechanosensitive ion channel that plays an obligate role in producing cilium-dependent flow-activated cytosolic Ca^{2+} transients.

Methods: We generated LLC-PK_1 renal epithelial cells stably expressing PC1 and PC2. Both proteins were abundantly present in the primary cilium. We conducted live cell imaging of the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) using these cells loaded with the Ca^{2+}-sensitive fluorescent dye Fluo4-AM.

Results: Overexpression of ciliary PC1 and PC2 did not increase the magnitude or duration of $[Ca^{2+}]_i$ transients elicited in response to increase in physiological fluid flow (10 µl/s corresponding to a linear velocity above the membrane of 70 µm/s). Thus, when expressed in this cell type, exogenous polycystins do not further add to the flow-activated $[Ca^{2+}]_i$ increase. Previous data suggested that TRPV4 forms a complex with the polycystins that confers mechanosensitivity on the cilium. To test this possibility, we co-expressed TRPV4 with PC1 and PC2 in LLC-PK_1 cells. Little or no TRPV4 protein was detectable in the primary cilium, but was found instead at the basolateral plasma membrane. Interestingly, expression of TRPV4 in LLC-PK_1 cells caused much larger flow-induced and ATP-induced $[Ca^{2+}]_i$ transients than was detected in cells expressing PC1 and PC2 alone.

Conclusions: These results demonstrate that exogenously expressed polycystins are not sufficient to further enhance ciliary mechanosensation and suggest that TRPV4 may play an indirect role in this process and in supporting cellular Ca^{2+} signaling.

SA-PO581

Loss of Fluid Shear Stress as a Pathogenic Mechanism in Polycystic Kidney Disease Robin L. Maser. *Clinical Laboratory Sciences and The Kidney Inst, Univ of Kansas Med Ctr, KC, KS.*

Background: Formation and expansion of renal cysts compresses neighboring tubules leading to obstruction of urine flow in these tubules and in segments up- and downstream of isolated cysts. Tubular obstruction is evident in kidneys from rodent PKD models and in human ADPKD. Fluid shear stress (FSS) increases antioxidant gene expression in mouse M-1 cortical collecting duct cells, providing protection from oxidant-mediated damage.

Methods: To elucidate consequences of acute loss of urinary FSS, gene expression was analyzed in M-1 cells at an early timepoint after cessation of FSS. Cells subjected to physiological levels of laminar FSS for 4 hrs were either harvested (FSS; control), or placed

in static condition for an additional 4 hrs prior to harvest (FSS-stasis). Gene expression was examined via qRT-PCR using the PrimePCR Oxidative Stress panel (BioRad). Oxidative DNA damage (8-OH deoxyguanosine; 8OHdG) was assessed in sections of normal and cystic kidneys from the cpk mouse and the Cy rat models of PKD by immunostaining. Mitochondrial (mt) DNA damage was analyzed on denaturing agarose gels with mtDNA isolated from liver and kidney of cpk mice.

Results: Relative to FSS, FSS-stasis led to >2-fold change in expression level of 67 of the 88 genes assayed, and to *de novo* induction of 9 additional genes. Genes with increased expression were associated with renal injury, apoptosis, inflammation, and DNA damage. A gene whose expression was increased by acute loss of FSS in 3 independent experiments is Ogg1, which encodes 8-oxoguanine DNA glycosylase, an enzyme involved in response to and repair of oxidized DNA. 8OHdG staining was evident in nuclear and cytoplasmic compartments of cyst-lining cells and adjacent non-cystic tubules in cystic kidneys. mtDNA degradation was increased in cystic compared to normal kidneys of 2- and 3-week old mice, while liver mtDNA was unaffected.

Conclusions: Our studies demonstrate that acute loss of FSS initiates changes in renal tubular epithelial gene expression associated with oxidant stress/damage and may lead to an alteration in renal cell metabolism. Altogether, these results support a mechanism by which cyst-mediated tubule obstruction could contribute to PKD pathogenesis.

SA-PO582

Modeling Polycystic Kidney Disease in Human Kidney Organoids from Genome-Modified and Induced Pluripotent Stem Cells Nelly M. Cruz, Benjamin S. Freedman. *Div of Nephrology, Kidney Research Inst, and Inst for Stem Cell and Regenerative Medicine, Dept of Medicine, Univ of Washington, Seattle, WA.*

Background: Human pluripotent stem cells (hPSCs) can differentiate into nephron-like kidney organoids for disease modeling and regenerative medicine. Organoids derived from genome-modified *PKD1*$^{-/-}$ or *PKD2*$^{-/-}$ hPSCs form cysts from kidney tubules, but the penetrance of this phenotype is low. Using a variety of PKD hPSCs, we investigated the potential of differentiation protocol, culture conditions, and genetic background to modulate PKD organoid cystogenesis.

Methods: Induced hPSCs from four ADPKD and ARPKD patients or genome-modified *PKD1*$^{-/-}$ and *PKD2*$^{-/-}$ hPSCs were differentiated into kidney organoids using two different published protocols. Organoids were cultured under 2D or 3D conditions with or without forskolin, an agonist of adenylyl cyclase. PKD organoids and cysts were counted, measured, and analyzed for kidney tubule marker immunofluorescence, compared to non-PKD controls.

Results: Under novel conditions, *PKD1*$^{-/-}$ and *PKD2*$^{-/-}$ organoids formed translucent cysts with diameters approaching 1 cm over several months in culture. Penetrance of the cystogenesis phenotype was increased to ~ 80 % in *PKD1*$^{-/-}$ and *PKD2*$^{-/-}$ organoids, compared to < 10 % in isogenic control organoids. Cysts derived primarily from proximal tubular cells and expanded rapidly upon forskolin treatment. Differentiation efficiency was highly variable between induced hPSCs from different patients, independent of PKD mutations. By comparison, genome-modified hPSCs exhibited much greater uniformity.

Conclusions: *PKD1*$^{-/-}$ and *PKD2*$^{-/-}$ kidney organoids establish a high-penetrance system for human PKD cystogenesis *in vitro*. Genetic background is a confounding factor in organoid differentiation, necessitating the use of genome modification. Cyclic AMP signaling enhances human PKD cystogenesis, similar to mouse models. The modularity of kidney organoid cultures makes them a powerful new pre-clinical model in which to investigate PKD pathophysiology and evaluate candidate therapeutics. Bioactive Lipid Alterations in the jck and pcy Mouse Models of Nephronophthisis Tamio Yamaguchi,[1] Nikhil Sidhu,[2] Jessay Gopuran Devassy,[2] Melissa Gabbs,[2] Amir Ravandi,[3] Masanori Kugita,[4] Shizuko Nagao,[4] Harold M. Aukema.[2] *[1]Dept of Clinical Nutrition, Suzuka Univ of Medical Science, Suzuka, Mie, Japan; [2]Dept of Human Nutritional Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [3]Inst of Cardiovascular Sciences, St. Boniface Hospital Research Centre, Winnipeg, MB, Canada; [4]Education and Research Center of Animal Models for Human Diseases, Fujita Health Univ, Fujita Health Univ, Toyoake, Aichi, Japan.*

Background: Oxylipins are bioactive lipids formed via oxidative metabolism of polyunsaturated fatty acids by the cyclooxygenase (COX), lipoxygenase (LOX) and cytochrome P450 (CYP) pathways. We have previously shown that the renal oxylipin profile is altered in three orthologous models of polycystic kidney disease (PKD). To determine whether the changes in these bioactive lipids also occur in nephronophthisis (NPHP), we examined the oxylipin profile in the *jck* and *pcy* mouse models of NPHP, which have mutations in *Nphp9* and *Nphp3*, respectively.

Methods: Kidneys from 12 week-old C57BL/6-*jck/jck* (diseased) and C57BL/6-*jck/+* or +/+ (normal) mice, and from 20 week-old diseased (CD1-*pcy/pcy*) and normal (CD1-+/+) mice with established NPHP were studied. Oxylipin levels were quantified by HPLC/MS/MS using stable isotope dilution.

Results: Over 40 oxylipins were quantified in both models of NPHP. In both models, the levels of COX derived oxylipins (e.g. prostaglandins) were elevated by as much as 20 times, while the LOX derived (e.g. hydroxy fatty acids) and CYP derived (e.g. epoxy fatty acids) were present at levels as low as 10-20% of normal.

Conclusions: Oxylipins derived from COX were elevated, while those derived via the LOX and CYP pathways were markedly reduced in both models of NPHP. These lower levels of LOX and CYP metabolites contrasts with orthologous models of PKD that primarily display alterations in the COX metabolites. Inhibition of oxylipin biosynthetic pathways therefore may offer potential treatment strategies for NPHP. (Supported by the Natural Sciences and Engineering Research Council of Canada and the Children's Hospital Research Foundation of Manitoba, Japan Society for the Promotion of Science Grants-in-Aid for Scientific Research).

Inihibition of Bromodomain Protein BRD4 Ameliorates Renal Fiborsis in ADPKD Xia Zhou,[1] Xiaoyan Li,[1] Dorien J.M. Peters,[2] Xiaogang Li.[1] *[1]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; [2]Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Bromodomain protein BRD4 recognizes and binds acetylated histones to regulate gene transcription. We found that therapeutic targeting of BRD4 with its inhibitor JQ1 delayed cyst growth in different ADPKD mouse models through inhibition of c-Myc transcription. Tubulointerstitial fibrosis is associated with the renal function decline during renal cyst progression. However, whether BRD4 regulates renal fibrosis in ADPKD remains unknown.

Methods: To understand the role of BRD4 in regulating renal fibrosis *in vivo*, we investigated renal fibrosis of *Pkd1*$^{nl/nl}$mice treated with JQ1.To explore the pathways underlying BRD4 mediated renal fibrosis, we treated renal fibroblasts with JQ1.

Results: We found that inhibition of BRD4 with JQ1 not only delayed cyst growth but also decreased renal interstitial fibrosis as examinedby Trichrome Masson and Picrosirus red staining. JQ1 treatment decreased the mRNA expression of fibrotic markers, Col1A1, Col3A1, α-SMA and Fibronectin as analyzed by qRT-PCR, and the protein expression of α-SMA as analyzed by immunohistochemistry staining in the kidneys from postnatal day 28 *Pkd1*$^{nl/nl}$ mice. TGF-β, the crucial cytokine in regulating fibrosis, and TGF-β/Smad signaling were elevated in cystic kidneys compared with the wild type kidneys. We further found that TGF-β1 treatment not only induced the expression of fibrotic markers (Col1A1, Col3A1, α-SMA and Fibronectin), but also increased the expression of BRD4 in rat kidney interstitial fibroblasts (NRK-49F). However, treatment with JQ1 plus TGF-β1 blocked the upregulation of fibrotic markers induced by TGF-β1 alone as analyzed by qRT-PCR and Western blot. BRD4 interacted with Smad3 but not Smad2 in NRF-49F cells as analyzed by co-IP. Inhibition of BRD4 with JQ1 decreased the cell proliferation of NRF-49F cells.

Conclusions: BRD4 promotes renal interstitial fibrosis in ADPKD. BRD4 plays an important role in TGF-β induced fibroblast activation through regulating the transcription of fibrotic markers, which may be mediated by its interaction with Smad3. BRD4 is a novel therapeutic target for renal fibrosis in ADPKD.

SA-PO585

Fibrosis Markers in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Wei Wang, Michel Chonchol, Berenice Y. Gitomer. *Univ of Colorado Denver.*

Background: In ADPKD patients the degree of renal fibrosis has been identified as the most significant and variable factor associated with progression to renal failure. However, there are no methods for direct assessment of fibrosis in ADPKD. Several tissue factors, including the matricellular proteins SPARC and periostin mediate fibrosis in pre-clinical models of ADPKD, but require renal tissue for measurement. However, changes in circulating micro RNA (miRNA) levels have been associated with fibrosis in liver, heart and kidneys. Thus we hypothesized that detection of fibrosis associated miRNAs in human serum from ADPKD patients might indicate fibrosis and serve as non-invasive biomarkers of disease progression.

Methods: Total RNAs were extracted from human ADPKD, chronic kidney disease (CKD) and normal control kidneys and mRNA levels of SPARC and periostin measured by RT-PCR. A total of 372 miRNAs were analyzed by microarray in the serum of 5 ADPKD patients with eGFR ≥60 ml/min/1.73m^2 and 3 age matched normal healthy controls at baseline. ADPKD patients were classified as fast (eGFR decrement> 3.4ml/min/1.73m^2/year) or slow (eGFR decrement ≤3.4ml/min/1.73m^2/year) progressors based on annualized eGFR change.

Results: Renal periostin mRNA expression was much higher in ADPKD patients compared to both in normal controls (0.093±0.047, n=5 vs 0.040±0.023, n=4, p=0.07) and in CKD patients (0.093±0.047, n=5 vs 0.023±0.027, n=4, p=0.02). Renal SPARC mRNA expression was also significantly higher in the kidneys from ADPKD patients than in normal controls (7.8±5.0, n=6 vs 2.2±1.1, n=5, p=0.049). Several serum miRNAs were differentially expressed in the fast disease progressors compared to slow progressors including the fibrosis related members of the miR-29 family (miR-29a, miR-29b, miR-29c) and miR-30.

Conclusions: Fibrosis in ADPKD kidney is indicated by increasedexpression of mRNAs for the matricellular proteins periostin and SPARC. The differential expression of several fibrosis related miRNAs measured at baseline in sera from patients with fast progressing disease indicates that a signature of fibrosis related circulating miRNAs might serve as a sensitive and non-invasive prognostic biomarker for more rapid disease progression.

Disruption of Subcellular Sorting Regulators in a New 3D Cystogenesis Model for ADPKD Eryn E. Dixon, Owen M. Woodward. *Physiology, Univ of Maryland School of Medicine, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common monogenic diseases worldwide. Loss of function mutations in *PKD1* or *PKD2* lead to deficiency of the polycystin-1 and -2 proteins, resulting in cystogenesis. However, many questions still remain about the mechanism of cyst formation, including effects of aberrant proliferation, mislocalization of growth signals, and alterations in fluid secretion machinery. Currently, cyst models are unable to demonstrate isolated, focal cysts, characteristic of ADPKD, with inactivation of *PKD1* or *PKD2*.

Methods: By employing a novel combination of culture techniques with an inducible cre model for *PKD1/2* inactivation, we have been able to demonstrate an increase in cystogenesis following heterogeneous inactivation of *PKD1* and *PKD2*. We have optimized the culturing of three dimensional organoids from primary postnatal mouse nephrons using a "sandwich" technique, where primary cells are seeded between two layers of polymerized Matrigel. This plating technique has promoted differentiation of organoids into more complex secondary structures. Finally, we have found a pulse of glial derived neurotrophic factor (GDNF) stimulates the mesenchymal to epithelial transition, activating tubulogenesis.

Results: This GDNF-induced epithelial switch, confirmed by expression of E Cadherin, is maintained after inactivation of *PKD1/2*, suggesting presence of epithelial organization in cystic structures. However, cystic fluid accumulation and expansion point to an altered localization of secretory machinery. To investigate, we looked closely at Ezrin and the phospho-Ezrin/Radixin/Moesin (p-ERM) complex, proteins important in organization of the membrane and cell structure. Here, we find that *PKD1/2* inactivation and cystogenesis disrupts Ezrin/p-ERM localization and activation, highlighting a potential mechanism of altered apical and basolateral sorting.

Conclusions: Our three dimensional cystogenesis model for ADPKD demonstrates persistence of epithelial characteristics with important defects in the membrane protein sorting mechanisms. **NIDDK 5P30DK090868 Baltimore PKD Center Pilot & Feasibility Grant**.

Functional Expression of CaSR in Conditionally Immortalized Proximal Tubular Epithelial Cells (ciPTEC) Deficient for Polycystin 1 or Derived from ADPKD1 Patients: CaSR as Possible Therapeutic Target Annarita Di Mise,[3] Grazia Tamma,[1] Marianna Ranieri,[1] Mariangela Centrone,[1] Giovanna Cinzia Baldelli,[1] Djalila Mekahli,[2] Elena N. Levtchenko,[2] Giovanna Valenti.[1] *[1]Univ of Bari Aldo Moro; [2]Univ of Cincinnati; [3]Albany Medical College.*

Background: Clinical and fundamental-research data suggest that altered Ca^{2+} and cAMP signaling might be two of the most proximal events in the pathogenesis of ADPKD. Cells from ADPKD cysts were reported to have a reduced resting cytosolic Ca^{2+} concentration and increased level of cAMP. CaSR is a G protein coupled receptor, which plays an essential role in regulating Ca^{2+} homeostasis whose activation is associated with an increase in intracellular calcium and decrease in cAMP making CaSR a possible candidate as therapeutic target.

Methods: Control human ciPTEC cells with stably down-regulated PKD1 (ciPTEC-$PC1_{KO}$) and ciPTEC generated from ADPKD1 patients (ciPTEC-$PC1_{Pt}$) were used as experimental tools.

Results: The expression of the endogenous CaSR in either ciPTEC-$PC1_{KO}$ and ciPTEC-$PC1_{Pt}$ was confirmed by Western blotting and by confocal analysis showing a clear apical localization of CaSR in the cells. CaSR functional expression was confirmed by studies with Fura2-AM showing that the calcimimetic NPS-R568, induced a significant increase in cytosolic calcium either in ciPTEC-$PC1_{KO}$ and in ciPTEC-$PC1_{Pt}$. Calibration of intracellular calcium demonstrated that resting cytosolic Ca^{2+} levels were significantly lower in ciPTEC-$PC1_{KO}$ with respect to ciPTECwt (93.4 nM vs 113.4 nM, P=0.0004) confirming calcium dysregulation in ciPTEC-$PC1_{KO}$. Conversely, as in native cells from cysts, significantly higher cAMP levels were found in ciPTEC$_{KO}$ with respect to ciPTEC-PC1wt. Of note, exposure of ciPTEC$_{KO}$ to the calcimimetic NPS-R568 significantly reduced intracellular cAMP levels.

Conclusions: We conclude that *i*. PKD1 mutation in humans preserves CaSR functionality *ii*. selective CaSR activation of human ciPTEC carrying PKD1 mutation increases intracellular calcium and reduces intracellular cAMP, improving the dysregulation of the two signaling molecules considered the most proximal events in the pathogenesis of ADPKD.

Phosphodiesterase Modulation of Renal Cystogenesis, and Effects of PKD2 on Development of Lateral Line Hair Cells Caroline R. Sussman, Raad B. Chowdhury, Madeline Rose Martell, Peter C. Harris, Vicente E. Torres. *Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

Background: cAMP is an important signaling molecule in Polycystic Kidney Disease (PKD), and PKD severity in animal models is affected by Phosphodiesterases (PDEs), which hydrolyze cAMP. We have shown using zebrafish that PDE1A modulates renal cystogenesis downstream of *Pkd2* and its product PC2. We explore here roles of zebrafish PDE3A in renal cystogenesis and effects of *Pkd2* mutation on development of lateral line hair cells (which express PC2), as a potential model for further studies of PDEs in PKD.

Methods: PDE3A levels were altered using morpholinos and RNA. PC2 effects were examined in *Pkd2* mutants.Phenotypes were examined using stereo-microscopy and immunofluorescence. Phenotypes were evaluated in at least 3 unique batches and significance tested using chi-square or t-test.

Results: Two splice-blocking *pde3a* morpholinos caused pronephric cysts and body curvature with dose dependence. The splice donor morpholino also caused hydrocephalus, otolith defects, and fin blistering with dose dependence. Co-injection of 125pg of mouse p*de3a* RNA with donor morpholino (5ng) rescued cysts (8% vs 33%; $p \leq 0.001$) and hydrocephalus (0% vs. 58%; $p \leq 0.001$). To examine the relevance of lateral line hair cells for further studies of PDEs and PKD, we assessed hair cell development in *Pkd2* mutant zebrafish (hi4166) by immunofluorescence of acetylated α-tubulin. Neuromasts were identified using DAPI and each was scored based on cilia appearance (normal (2), stunted (1), or missing (0)). Cumulative scores were calculated for lateral neuromasts. The average score for mutants was 30% lower than that of wild-type (1.1±0.15 vs. 1.5±0.18, $p < 0.01$). Additionally, *in situ* hybridization showed expression of *pde1a* in hair cells.

Conclusions: Morpholino and RNA studies further support involvement of PDE3A in renal cystogenesis and associated phenotypes, similar to PDE1A. Impaired development of lateral line cilia in *Pkd2* mutants suggest PC2 is involved in normal hair cell development. Expression of *pde1a* further suggests that lateral line hair cells may be an accessible model for studies of PDEs in PKD.

Hypermethylation of the MUPCDH Promoter as a Prognostic Biomarker for Cyst Growth in ADPKD Yu Bin Shin, Eun Ji Lee, Do Yeon Kim, Je Yeong Ko, Jong Hoon Park. *Biological Science, Sookmyung Women's Univ, Seoul, Korea.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disease, which shows the formation of multiple fluid-filled cysts, and it finally results in renal failure. Still, early diagnosis and treatment of ADPKD have yet to be defined. In this study, we suggest a specific epigenetic condition as a prognostic biomarker.

Methods: 1. Renal tissue samples from subjects with ADPKD. Renal cyst tissue was obtained from patients with ADPKD undergoing nephrectomy. As controls, non-ADPKD renal tissue specimens were obtained from patients undergoing surgery for clear cell renal cell carcinoma; malignant cell infiltration was excluded by histology. 2. DNA methylation analysis. DNA methylation patterns were validated in two steps, using MS-HRM and EpiTYPER® analyses. For MS-HRM analysis, primers covered the region extending for 2 kb from the translation start ATG upstream to intron 1. Bisulfite-treated genomic DNA was amplified by PCR 3. ChIP-qPCR. ChIP was performed as previously described40, using antibodies specific for RNA polymerase II (ab817; Abcam, Cambridge, UK), AP-2α (sc-184; Santa Cruz Biotechnology), H3K4 me3 (17-614; EMD Millipore, Billerica, MA, USA), H3K9 me3 (ab8898; Abcam), and H3Ac (06–599; EMD Millipore).

Results: The promoter region of the gene encoding mucin-like protocadherin (MUPCDH) was hypermethylated in renal tissue of ADPKD patients compared to non-ADPKD controls. As the promoter region is hypermethylated, the expression of MUPCDH was significantly repressed in cyst-lining cells of ADPKD patients. So our results indicate that aberrant methylation of MUPCDH promoter CpG islands can be negatively correlated with reduced expression level of MUPCDH. Furthermore, this epigenetic silencing contributes to abnormal cell proliferation in ADPKD.

Conclusions: In this study, we suggested that hypermethylation of MUPCDH promoter induces the transcriptional repression and increased cell proliferation in ADPKD. Also, methylation level of MUPCDH promoter region in genomic DNA from urine can be used as the novel epigenetic biomarker for prognosis of ADPKD.

SA-PO590

Repurposing of Targeted Cancer Therapies for Autosomal Dominant Polycystic Kidney Disease (ADPKD) Anna Nikonova, Vladislav Korobeynikov, Erica A. Golemis. *Molecular Therapeutics, Fox Chase Cancer Center, Philadelphia, PA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is an inherited disease that affects ~1 in 500 people. In ADPKD, mutations in *PKD1* and *PKD2* abnormally activate signaling pathways regulating cell proliferation, migration, and response to environmental cues. Some studies have suggested maintenance of cilia is critical for cyst development. Intriguingly, studies of the signaling defects associated with ADPKD have also identified defects paralleling many of those seen in cancer, in spite of the very different presentation of ADPKD and solid tumors.

Methods: We have been evaluating targeted signaling inhibitors in ADPKD models to probe biological similarities and differences between ADPKD and cancer, and to determine if cancer drugs are effective in ADPKD. We have explored the signaling interactions between PKD1 mutations, control of ciliary dynamics, and clinical agents with potential efficacy in ADPKD, with a goal of optimizing therapeutic options for patients with ADPKD.

Results: In initial studies, we found that HSP90 inhibition in conditional *Pkd1*$^{-/-}$ mice with the preclinical compound STA-2842 reduced initial renal cyst formation and slowed the progression of these phenotypes in mice with pre-existing cysts in animals up to 6 months of age. In ongoing work, we found treatment of *Pkd1*$^{-/-}$ mice with the clinical HSP90 inhibitor ganetespib controlled cyst growth for up to 50 weeks of treatment, extending survival in reference to vehicle treated mice. Suggestively, ciliation is reduced in the cysts of mice responding to ganetespib treatment relative to cysts found in control mice. Treatment of kidney epithelial cells with HSP90 inhibitors lead to the rapid resorption of primary cilia in the absence of serum.

Conclusions: These results support the idea that HSP90 inhibition and induced loss of cilia represent potentially useful therapeutic concepts for ADPKD. Extending the latter idea, we have now performed a screen of a library of targeted clinical candidates and agents to identify those regulating ciliary dynamics; assessment of additional candidates that cause ciliary resorption is in progress for in vivo control of Pkd1-dependent cyst formation.

High-Throughput, Comparative Variant Profiling Aids Molecular Diagnostics of ADPKD Vladimir Gainullin,[1] Christina M. Heyer,[1] Emilie Cornec-Le Gall,[1] Sarah L.R. Klein,[2] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Macalester College, St. Paul, MN.*

Background: A high level of allelic heterogeneity at the two genes, *PKD1* and *PKD2*, characterizes ADPKD, with the pathogenicity and penetrance of many inframe variants often uncertain after *in silico* and family/population analysis. The PKD1 and PKD2 proteins, PC1 and PC2, interact while folding in the ER and PC1 maturation and surface localization requires the ER chaperone function of PC2. Hence, quantitatively assaying the surface localization of PC1 represents an unbiased approach to determine the significance of both PC1 and PC2 variants.

Methods: We developed a high-throughput, quantitative flow-cytometry-based assay utilizing exogenously coexpressed PC1 and PC2 to determine the level of surface localized PC1. Assays were performed on 45 PC1 and 45 PC2 missense variants (predicted to range from fully penetrant pathogenic to neutral) and compared to wildtype and truncation mutation controls.

Results: We found for 20% of PC1 and 50% of PC2 variants that no PC1 was surface localized (fully penetrant allele), while 10% of PC1 and 40% of PC2 variants behaved like wild type with full surface localization. A group of 70% of PC1 and 10% of PC2 variants showed reduced surface delivery, consistent with being incompletely penetrant (hypomorphic) alleles. For six PC1 variants this designation was consistent with early onset disease when co-inherited in trans with a fully inactivating allele, while in two cases combinations of two or more hypomorphic variants in cis generated a fully penetrant haplotype. A high level (70%, PC1; 50%, PC2) of fully or incompletely penetrant folding mutants were temperature-sensitive: completely or to some extent rescued by incubation at 30°C.

Conclusions: Our data indicates that the majority of ADPKD missense variants are folding mutations and that the pathogenicity and penetrance of each variant and a combination of variants can be precisely quantified. In addition, the temperature-sensitive nature of many missense mutations suggests the potential to treat some patients with molecular chaperone therapy.

Determinants of Disease Variability in ADPKD: Insights from a Cohort of 1634 PKD1 Patients Emilie Cornec-Le Gall,[1] Berenice Y. Gitomer,[2] Arlene B. Chapman,[3] Alan S.L. Yu,[4] Dorien J.M. Peters,[5] Jon D. Blumenfeld,[6] York P. Pei,[7] Kyongtae Ty Bae,[9] Doris Rubio,[9] Christina M. Heyer,[1] Sarah R. Mauritz,[1] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Mayo Clinic; [2]U of Colorado; [3]U of Chicago; [4]U of Kansas; [5]Leiden; [6]The Rogosin Inst; [7]U of Toronto; [8]U of Maryland; [9]U of Pittsburgh.*

Background: ADPKD has marked clinical variability and extra-genic determinants remain poorly understood. ADPKD Modifier is a cross-sectional study designed to identify genetic, clinical, and environmental factors influencing renal disease severity and consists of mutation proven PKD1 caucasian patients.

Methods: The effect of possible modifying factors on renal survival was studied using Kaplan-Meier methods and Cox model, and their influence on square-root normalized eGFR and log-transformed height-adjusted total kidney volume (HtTKV) was analyzed using univariate and multivariate regression analyses.

Results: A total of 708 different *PKD1* mutations were identified in 1634 patients (727 males, 983 pedigrees). Median age at ESRD was 59.4y, but significantly earlier in males than females (55.8y vs. 62.3y, P<0.001), and in truncating vs. non truncating patients (58.1y vs. 61.3y, P=0.009). In addition, multivariate regression analysis showed that male gender, truncating mutations, diagnosis of hypertension before 35y and BMI or body weight were independently associated with lower eGFR and higher HtTKV (all P-values <0.005). As previously shown in the wider CKD population, alcohol consumption was associated with higher eGFR (P<0.001), however it had no influence on HtTKV. There was no apparent influence of smoking status, birth weight or caffeine intakes on HtTKV or eGFR. Intrafamilial correlation analysis estimated that heritability explained 12.2% and 30.9% of the variability of eGFR and HtTKV. Among the 40 patients with age and gender adjusted eGFR below the 2.5 percentile, 9 (22.5%) had severe associated conditions or nephropathies likely to account for the early progression to ESRD.

Conclusions: Beyond the effect of gender and mutation type, disease variability in ADPKD results from the combined effect of environmental factors and modifier genes. Early eGFR decline should prompt nephrologist to check for concomitant nephropathies.

SA-PO593

Using the PROPKD Score Can Enrich ADPKD Clinical Trials for Rapidly Progressive Patients Emilie Cornec-Le Gall,[1] Jaime Blais,[2] Christina M. Heyer,[1] Sarah R. Mauritz,[1] Frank S. Czerwiec,[2] John Ouyang,[2] Yannick Le Meur,[3] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Mayo Clinic; [2]Otsuka PDC; [3]CHU Brest, France.*

Background: The PROPKD score has been recently proposed to stratify the risk of progression to ESRD in ADPKD patients. We aimed to assess the prognostic value of this score in a subgroup of subjects from the TEMPO 3:4 trial.

Methods: The PROPKD score was calculated in 749 patients with an available DNA sample as the sum of the following factors: male: 1 pt; hypertension <35y: 2 pts; first urologic event <35y: 2 pts; *PKD2* mutation: 0 pt; nontruncating *PKD1* mutation: 2 pts; and truncating *PKD1* mutation: 4pts. Patients were classified into low risk (LR, 0-3 pts), intermediate risk (IR, 4-6 pts) and high-risk (HR, 7-9 pts) groups.

Results: HR patients (n=284, 36y) were significantly younger than IR (n=335, 40y) and LR (n=130, 45y) patients (p<0.001). While baseline renal function was similar across all 3 risk groups, baseline HtTKV significantly increased from the LR to the HR group (median values: 785 vs. 934 mL/m, P<0.001). In the placebo group, annual growth in TKV was highest in the HR group, and the rate of renal function decline was slowest in LR patients. Tolvaptan significantly slowed the rate of TKV growth in all 3 risk categories (LR: T=2.8 *vs.* P=5.0%, IR: T=2.2 *vs.* P=4.6 and HR: T=4.1 *vs.* P=6.6%, all P-values <0.005) and the rate of renal function decline in the IR and HR groups (IR: T=-2.4 *vs.* P=-3.5, P=0.01; HR: T=-2.7 *vs.* P=-3.8 ml/min/1.73m^2/y, P=0.01), but not in the LR group. In all subjects, tolvaptan reduced the rate of eGFR decline from -3.40 to -2.5ml/min/1.73m^2/y (p=0.0001) with a relative treatment effect (TE) of 27%. Excluding subjects in the LR group improved this difference (-3.6 to -2.5ml/min/1.73m^2/y, (p<0.0001), TE 33%). Similarly, while time to first renal event favored tolvaptan over placebo in the HR+IR (HR=0.39, P<0.0002), there was no difference in the LR group.

Conclusions: This study confirms the prognostic value of the PROPKD score and suggests that it will allow cost reduction of future trials and to maximize positive results by enriching the study population for rapidly progressing ADPKD subjects.

SA-PO594

Targeting Ciliogenesis by Modulating Tubulin Polymerization as a Therapeutic Approach for Polycystic Kidney Disease Sarah E. Moreno,[1] Herve Husson,[1] Laurie A. Smith,[1] Mandy M. Smith,[1] Ryan J. Russo,[1] Rose A. Pitstick,[2] Mikhail Sergeev,[3] Steven R. Ledbetter,[1] Nikolay Bukanov,[1] Monica Lane,[1] Kate Zhang,[1] George A. Carlson,[2] Jagesh V. Shah,[3] Laurent Meijer,[4] David Beier,[5] Oxana Beskrovnaya.[1] *[1]Sanofi-Genzyme, Framingham, MA; [2]McLaughlin Research Inst, Great Falls, MT; [3]Brigham and Women's Hospital, Boston, MA; [4]ManRos Therapeutics, Roscoff, France; [5]Seattle Children's Research Inst, Seattle, WA.*

Background: Polycystic kidney diseases (PKDs) are a class of genetic diseases that arise from abnormalities in the primary cilium and characterized by the continuous growth of renal fluid-filled cysts that leads to end-stage renal disease. Advancements in understanding the molecular mechanisms that drive cyst growth are crucial for the development of new therapeutic modalities.

Methods: Modulation of CDK5 was achieved through pharmacological inhibition or genetic inactivation in *jck* mice. Efficacy was measured by kidney to body weight ratio, blood urea nitrogen, and cystic volume. Effects of CRMP2 modulation on ciliary length and tubulin polymerization were assessed *in vitro*. Knockdown of CRMP2 *in vivo* was done using peptide-linked phosphorodiamidate morpholino antisense oligonucleotides (PPMO).

Results: We showed previously that inhibition of CDK5 *in vivo* leads to a reduction in ciliary length and attenuates progression of PKD. Mechanistic studies suggested that CDK5 may function through the regulation of tubulin dynamics by modulation of collapsing response mediator protein 2. Here we further expanded the role of CRMP2 on ciliogenesis. *In vitro* CRMP2 localizes to the primary cilium and *Crmp2* siRNA knockdown reduces tubulin polymerization leading to shortened cilia. *In vivo* we demonstrate that *jck* mice have increased microtubule stability and CRMP2 localizes to the primary cilium. *In vitro* modulation of CRMP2 with S-lacosamide results in decreased tubulin polymerization and reduces cilia length. *In vivo* knock down of CRMP2 in *jck* mice attenuated disease progression.

Conclusions: Taken together, our data supports targeting ciliogenesis as viable therapeutic approaches for the treatment of renal cystic diseases.

A Personalised Therapy for CEP290 Ciliopathy Syndrome John Andrew Sayer, Shalabh Srivastava, Simon Ramsbottom, Elisa Molinari, Colin Miles. *Inst of Genetic Medicine, Newcastle Univ, Newcastle, United Kingdom.*

Background: Mutations in CEP290 cause ciliopathy syndromes with a variety of clinical phenotypes. CEP290 is expressed in ciliary centrosomes; mutations are thought to affect the structure and function of the cilia. Over 130 different mutations have been described within CEP290. We present data concerning an affected boy aged 13 years, from consanguineous parents, with a cerebello-retinal-renal / Joubert syndrome phenotype.

Methods: Clinical features included ataxia, congenital amaurosis and progressive chronic kidney disease with renal cortical cyst formation. Mutation analysis (using a panel gene approach) revealed a homozygous nonsense mutation in exon 41 c.5668G>T (p.Gly1890X). This is a commonly reported mutation in CEP290.

Results: Using human urine derived renal epithelial cells (HuREC) from the patient we demonstrate loss of CEP290 protein and abnormalities in ciliary structure. Specifically we see elongated cilia (6.98 um vs 4.70 um in wild type controls) under scanning electron microscopy (SEM) and elongated cilia under immunofluorescence with a loss of acetylation of the axoneme at the distal end of the cilium. This ciliary abnormality could be rescued by treatment with the Hedgehog (Hh) agonist purmorphamine (2 micromolar) for 24 hours. As an alternative means of rescue we used a targeted morpholino oligonucleotide towards the intron-exon splice junction of exon 41. Using this approach we show, using RT-PCR, exon skipping and a rescue of expression of a near full-length CEP290 protein. Phenotypic rescue of elongated cilia was also confirmed.

Conclusions: In a patient with a homozygous truncating *CEP290* mutation, we have modelled the ciliary defect using HuRECs. The abnormal ciliary phenotype which included elongated cilia with abnormal axonemal acetylation was rescued by both Hh agonist treatment and targeted exon-skipping. This individualised approach offers new therapeutic options for the treatment of ciliopathies.

SA-PO596

Mutations in MAPKBP1 Cause Late Onset Cilia-Independent Nephronophthisis Maxence Macia,[1] Jan Halbritter,[2] Marion H. Delous,[1] Cecilie Bredrup,[3,4] Flora Silbermann,[1] Anne Elisabeth Christensen Mellgren,[3,4] Daniela A. Braun,[2] Heon Yung Gee,[2] Andreas W. Sailer,[5] Pierre Saint-Mezard,[5] Stephan Johansson,[4] Eyvind Rødahl,[3,4] Sophie Saunier,[1] Friedhelm Hildebrandt,[2] Alexandre Benmerah.[1] *[1]INSERM UMR1163, Imagine Inst, Paris Descartes Univ, Paris, France; [2]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [3]Dept of Ophthalmology, Haukeland Univ Hospital, Bergen, Norway; [4]Center for Medical Genetics and Molecular Medicine, Haukeland Univ Hospital, Bergen, Norway; [5]Novartis Insts for Biomedical Research, Basel, Switzerland.*

Background: Nephronophthisis (NPH), an autosomal recessive tubulointerstitial nephritis, is the most common cause of hereditary end-stage renal disease in the first three decades of life. Since most NPH gene products (NPHP) function at the primary cilium, NPH is classified as ciliopathy.

Results: We identified mutations in a novel candidate gene in 10 individuals from 6 families presenting late onset NPH with massive renal fibrosis. This gene encodes MAPKBP1, a poorly characterized scaffolding protein for JNK signaling. Immunofluorescence analyses showed that MAPKBP1 is not present at the primary cilium and that fibroblasts from affected individuals did not display ciliogenesis defects indicating that MAPKBP1 may represent a new family of NPHP not involved in cilia-associated functions. Instead, MAPKBP1 is recruited to mitotic spindle poles (MSPs) during the early phases of mitosis where it colocalizes with its paralog WDR62, which plays a key role at MSP. Detected mutations compromise recruitment of MAPKBP1 to the MSP and/or its interaction with JNK2 or WDR62. Additionally, we show increased DNA damage response signaling in fibroblasts from affected individuals and upon knockdown of *Mapkbp1* in murine cell lines, a phenotype previously associated with NPH.

Conclusions: In conclusion, we identified mutations in *MAPKBP1* as a genetic cause of late onset and cilia-independent NPH and propose "*NPHP21*" as an alias for *MAPKBP1*.

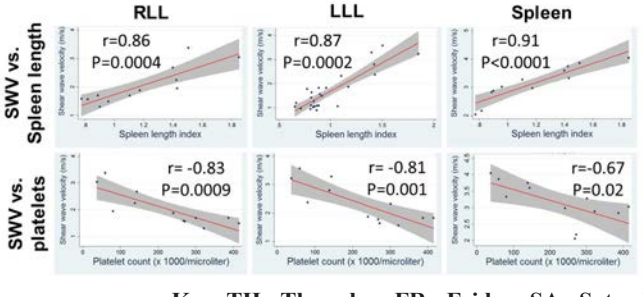
Quantification of Liver Disease Severity in Autosomal Recessive Polycystic Kidney Disease (ARPKD) Using Ultrasound Elastography with Acoustic Radiation Force Impulse (ARFI) Erum A. Hartung,[1,2] Kassa Darge.[1,2] *[1]Children's Hospital of Philadelphia; [2]Univ of Pennsylvania, Philadelphia, PA.*

Background: We previously showed liver and spleen stiffness by ARFI is higher in ARPKD vs. controls, and in ARPKD pts with vs. without portal HTN. Aims of this study are 1) determine if ARFI liver and spleen stiffness can quantify severity of portal HTN; 2) explore cut-offs to detect presence of portal HTN.

Methods: Stiffness of right and left liver lobes (RLL, LLL) and spleen evaluated in 12 ARPKD pts ≤21y using Siemens Acuson S3000 to measure shear wave velocity (SWV, m/s). Splenomegaly defined as spleen length >90th%ile. Spleen length index calculated as actual/90th%ile. Low platelets (PLTs) defined as <150K. Linear fit plots and Pearson correlation performed between liver and spleen SWV, spleen length index, and PLTs. Receiver operating characteristic analysis used to explore cut-offs for liver and spleen SWV to distinguish pts with vs. without portal HTN (splenomegaly and/or low PLTs).

Results: Liver and spleen SWV positively correlated with spleen length (RLL: r=0.86, p=0.0004; LLL: r=0.87, p=0.0002; spleen: r=0.91, p<0.0001) and negatively correlated with PLTs (RLL: r= -0.83, p=0.0009; LLL: r= -0.81, p=0.001; spleen: r= -0.67, p=0.02).



Proposed cut-offs (% sensitivity, sensitivity) for RLL, LLL, and spleen SWV to differentiate pts with vs. without splenomegaly: 1.69 m/s (88% sens, 95% spec), 1.87 m/s (88% sens, 100% spec), and 3.27 m/s (75% sens, 100% spec) respectively; to differentiate pts with vs. without low PLTs: 1.95 m/s, 2.37 m/s, and 3.32 m/s respectively (100% sens, spec at all sites).

Conclusions: ARFI liver and spleen stiffness correlate with severity of portal HTN in ARPKD. The proposed cut-offs have high sensitivity and specificity to distinguish pts with vs. without portal HTN. ARFI appears useful to measure severity and progression of ARPKD liver disease.

Screening of UMOD/REN/HNF1B Gene Variations in a Chinese Cohort with Autosomal Dominant Tubulointerstitial Kidney Disease Kunjing Gong, Yaqin Wang, Min Xia, Ying Liu, Yuqing Chen. *Nephrology, Peking Univ First Hospital, Beijing, China.*

Background: Autosomal dominant tubulointerstitial kidney disease (ADTKD) is characterized by tubulointerstitial damage and progressive chronic kidney disease. Four genes, including UMOD, REN, HNF1B and MUC1 have been identified contributing to ADTKD. In the present study, we screened genetic variations of UMOD, REN and HNF1B in a Chinese ADTKD cohort.

Methods: 44 probands from 44 different families were recruited for this study. The mean age of the cohort was 30±11years, numbers of males and females were almost equal. ADTKD was diagnosed according to the KDIGO report. We first sequenced all of the three genes and confirmed the gross deletion of HNF1B by multiple ligation-dependent probe amplification (MLPA) assays.

Results: 61.4% of patients showed positive family history of renal disease. We detected 11 point mutations (10 in UMOD, 1 in HNF1B) in this cohort, and three of them (p.Cys35Tyr, p.Asn38Ile and p.Cys287Phe) were novel mutations of UMOD. Point mutation of REN and gross deletion of the HNF1B were not found. All the patients with mutation suffered hyperuricemia, and the patient with HNF1B mutation also presented hypohepatia and hypokalemia.

Conclusions: Almost 25% of patients in our ADTKD cohort were confirmed to have UMOD gene mutations. And three of them were novel mutation of UMOD. The result indicated that gene sequencing is one of the reasonable methods to diagnose ADTKD.

Rapamycin Treatment Improves the Cystic Kidney in the ADPKD Mouse Model via the Mtorc1 and Cell-Cycle-Associated CDK1/Cyclin Axis Ao Li,[1,2] Song Fan,[1] Yangyang Zhang,[1] Jialin Meng,[1] Xufeng Shen,[1] Jun Mao,[1] Yuchen Xu,[1] Li Zhang,[1] Xiansheng Zhang,[1] Chao Zhao Liang,[1] Guanqing Wu.[1,2] *[1]PKD Center, Dept of Urology, the First Affiliated Hospital of Anhui Medical Univ and Inst of Urology, Anhui Medical Univ, Hefei, Anhui, China; [2]State Key Laboratory of Molecular Oncology, Cancer Hospital and Inst, Chinese Academy of Medical Sciences, Beijing, China.*

Background: Recent studies showed that rapamycin treatment can improve the cystic phenotypes in mouse models of ADPKD, but direct link between polycystin dysfunction and mTOR signaling changes or ADPKD cystogenesis has not been clearly identified.

Methods: We employed our recently developed ADPKD animal model (*Vil*-Cre;*Pkd2*$^{f3/f3}$ mice) in which full spectrum of cystic phenotypes similar to human ADPKD patients are closely displayed in adulthood. Rapamycin treatment did predominately inhibit proliferation, but not affect apoptosis, in the cyst-lining epithelia of the disease kidney. To explore the molecular mechanism by which rapamycin suppresses epithelial proliferation, we have searched our previously established cDNA microarrays data between our E8 cell line (*Pkd2*-null) and its maternally derived D3 cell line (*Pkd2*$^{+/-}$) (Kim et al. AJSN 2009;20:2556). Of the signature genes, *Ccnd1* mRNA level encoding cyclin D1 showed 4-fold higher elevated in E8 than in D3 cells. We also used qPCR from mRNAs of E8/D3 cells and renal tissues from *Vil*-Cre;*Pkd2*$^{f3/f3}$ and its normal control *Pkd2*$^{f3/f3}$ mice.

Results: We found that downregulating PC2 not only significantly increased *Ccnd1* expression, but also elevated all cell-cycle-associated cyclins (namely cyclin A, B, D1, and E), and cyclin-dependent kinase 1 (CDK1). In addition, we also found that rapamycin treatment arrested aberrant epithelial-cell proliferation in the ADPKD kidney by downregulating these cell-cycle-associated cyclins and CDK1, but not other CDKs.

Conclusions: Our newly defined molecular mechanism, by which rapamycin suppresses proliferation via inhibiting abnormally elevated CDK1 and cycle-associated cyclins, revealed the involvement of the mTORC1–CDK1/cyclin axis in ADPKD, which will lead to new molecular targets for treating this disease.

Effects of Metformin on the AMPK Pathway and Metabolism in ADPKD Kidney Epithelial Cells Hui Li, Kirt Gill, Daniel Rivera, Kenneth R. Hallows. *Medicine, USC Keck School of Medicine, Los Angeles, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in polycystin-1 (PKD1) and polycystin-2 (PKD2) and presents with progressive development of renal cysts. In PKD1 mutant cells increased activity of cell proliferation pathways (e.g., mTOR and ERK) and decreased AMP-activated kinase (AMPK) activity

occur, along with dysregulated cellular metabolism. However, these factors are not well characterized for PKD2 mutants. Our goals were to examine and correlate effects on these pathways and cellular bioenergetics in normal and PKD2-deficient cells treated with and without cAMP agonists and the AMPK activator metformin. We hypothesized that metformin would dampen cAMP agonist-induced stimulation of cell growth pathways and correct the perturbed energy metabolism in PKD.

Methods: Immortalized kidney epithelial cells with inducible PKD2 knockout were used. AMPK, mTOR and ERK pathway markers and levels of key glycolytic enzymes were checked by immunoblotting and correlated with time- and dose-dependent effects of metformin treatment. 3-D Matrigel cultures were used to assess cyst growth after treatment with metformin and cAMP agonists (forskolin and IBMX). Seahorse XF Analyzer assays were used to evaluate the metabolic phenotype of cells under different conditions.

Results: Metformin (300 μM) effectively activated AMPK in polarized PKD2-deficient cells over 3 d. Unlike in PKD1-deficient cells, however, these cells displayed neither excessive activation of the mTOR pathway, inhibition of the AMPK pathway nor apparent metabolic dysregulation under baseline conditions. Nevertheless, metformin significantly inhibited cyst growth in 3-D cultures of these cells, both in the presence and absence of cAMP agonists. Metformin also inhibited oxidative metabolism in both PKD2-null and wild-type cells without significantly affecting glycolytic flux.

Conclusions: Cystogenesis may occur through differing signaling pathways depending on PKD mutation. Metformin may exert beneficial effects in PKD2 mutant cells by mechanisms distinct from those proposed in PKD1 mutant cells and may be in part AMPK-independent.

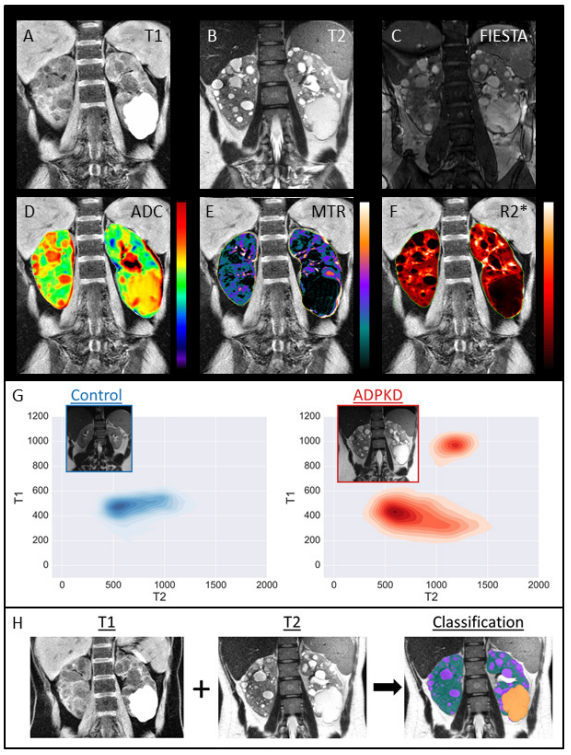
Advanced Magnetic Resonance Imaging and Image Analytics to Assess the Polycystic Kidney

Timothy L. Kline, Sudhakar K. Venkatesh, Maria V. Irazabal, Marie E. Edwards, Panagiotis Korfiatis, Peter C. Harris, Vicente E. Torres. *Mayo Clinic, Rochester, MN.*

Background: Advanced MR imaging and image analytics offer an opportunity to improve clinical monitoring and outcome prediction for PKD patients. These methods illuminate traditionally hidden features, such as: fibrotic tissue, restricted diffusion, increased stiffness, cyst heterogeneity, and changes in regional perfusion.

Methods: We performed a comprehensive MR imaging protocol (T1, T2, FIESTA, RBF, DWI, MT, BOLD, MRE) in 10 ADPKD patients (18-30 years old) and age and sex-matched control volunteers - all with normal renal function. Two exams were performed (on different days) on each volunteer to characterize repeatability of the measurements.

Results: The Figure shows examples of traditional MR imaging (A, B, C), and quantitative maps: apparent diffusion coefficient 'ADC' derived from DWI (D), 'MTR' derived from MT (E), and 'R2*' derived from BOLD (F). Quantitative MR imaging sequences were found to be repeatable. For the absolute difference between quantitative parameters measured at two different times, whole kidney MTR was 0.97 ± 0.76%, and whole kidney diffusivity was 0.086 ± 0.061. In addition, advanced multiparametric MR analysis techniques showed different pathologies, as well as the ability to perform tissue classification. Shown in 'G' is an example comparing T1/T2 values between an ADPKD patient vs an age and sex-matched control volunteer. Then, in 'H', an unsupervised clustering algorithm was used to perform cyst segmentation and classification of the PKD kidneys.



Conclusions: Quantitative and multiparametric MR imaging have strong potential for comprehensive characterization of the PKD kidney. It is likely that combining these techniques with other patient data will improve clinical decision making by providing new structural and functional information.

Using T2- versus T1-Weighted MR Images to Assess Total Kidney Volume in Patients with ADPKD

Maatje D.A. van Gastel,[1] A. Lianne Messchendorp,[1] Merel Anouk Kaatee,[1] Marissa De Jong,[1] Shekar Mahesh,[2] Ron T. Gansevoort.[1] *[1]Nephrology, UMCG, Groningen, Netherlands; [2]Radiology, UMCG, Groningen, Netherlands.*

Background: In ADPKD patients, measurement of total kidney volume (TKV) by MR imaging is performed to select patients for treatment with disease modifying drugs and to evaluate efficacy of novel treatments. Historically T1-weighted images were used, but the methodology of T2-weighted imaging has evolved, making T2-weighted imaging also suitable for TKV measurement. We studied the performance of T2- versus T1-weighted images to assess TKV and growth rate in TKV.

Methods: 30 patients with ADPKD were randomly selected. Patients underwent a standardized abdominal MRI-protocol on a 1.5-Tesla or 3.0-Tesla MRI-scanner at baseline and follow-up. TKV was measured by manual tracing with Analyze Direct 9.0 and 11.0 software (Inc. Overland Park, KS, USA). Three readers measured 12 scans to establish intra- and interreader coefficients of variation (CV). Correlations between T1 and T2 measured TKV and growth rates in TKV were tested with ICC and Bland-Altman analyses.

Results: Average age of the participants was 49.5±7.0 years, 46.7% were female, and estimated GFR was 48.4±10.8 mL/min/1.73m^2. Intra- and interreader CVs were low and comparable for T2- and T1-weighted images (intra: 0.83 (7.03) versus 1.15 (5.03)%, p=0.9, and inter: 2.18 (4.05) versus 1.69 (7.27)% , p=0.9, respectively). TKV was significantly higher for T2 images compared to T1 images, but numerically similar: 1938.6 [1257.1-2960.7] versus 1957.1 [1255.8-2788.5] mL, resp. (p=0.001) with a mean difference of only 1.6% and excellent agreement (ICC 0.996). Growth in TKV during a follow-up of 2.2±0.4 years was similar for T2- and T1-weighted images (9.2±10.5 versus 7.7±8.9%, p=0.1, respectively), with high agreement (ICC 0.849). Bland-Altman analysis showed no systematic under- or overestimation of TKV growth rate when using T2 instead of T1 weighted images.

Conclusions: In patients with ADPKD measurement and growth rate of TKV using T2-weighted images perform similarly compared to using T1-weighted images. Both methods can therefore be used in clinical practice.

SA-PO603

Imaging Techniques for Estimating Total Kidney Volume in Children with Autosomal Dominant Polycystic Kidney Disease: 3D-US versus MRI

Stephanie Le De Rechter,[1] Luc Breysem,[2] Marleen Smet,[2] Frederik De Keyzer,[2] Raymond H. Oyen,[2] Elena N. Levtchenko,[1] Djalila Mekahli.[1] *[1]Pediatric Nephrology, Univ Hospitals Leuven, Leuven, Belgium; [2]Radiology, Univ Hospitals Leuven, Leuven, Belgium.*

Background: Total kidney volume (TKV) has been shown in adult Autosomal Dominant Polycystic Kidney Disease (ADPKD) to be an independent and strong predictor for disease progression. In the current interventional clinical trials, TKV measurement by magnetic resonance (MR) imaging has been shown to be more accurate, reproducible and able to detect small changes over a short period of time than ultrasound (US). Since future therapies in ADPKD could be extended to include children, we aimed to examine whether the high-resolution 3D-US TKV measurements might be used as an alternative method to MR measurements in ADPKD children.

Methods: Prospective evaluations of renal MR, 2D- and 3D-US were performed, whereby TKV was calculated by means of manual delineations (MR, 3D-US) or by the ellipsoid method (2D-US). Correlations and differences between parameters were evaluated using Pearson r and Wilcoxon signed rank tests. After correction using the optimal linear regression, the variability of the measurements was examined using in Bland-Altman plots.

Results: We included 29 patients (17 male, 12 female) with a median age (SD) of 14.0 (3.4) years and eGFR 111 (17) ml/min/1.71m² leading to 58 evaluated kidneys. Although both US methods showed significantly lower TKV compared to MR (In ml, 3D-US: 181 (111); 2D-US 158 (101); MR 205 (132); all p<0.001), both showed a strong correlation to the MR TKV (2D-US: r=0.963; 3D-US: r=0.941). After correcting for the lower values in US, Bland-Altman plots showed slightly lower variability and error in 3D-US measurements compared to 2D-US in kidneys with a TKV below 200 ml (on average 15.5 ml error on 2D-US compared to 12.9 ml on 3D-US), although not reaching significance (p=0.23).

Conclusions: In children, 3D-US represents a good alternative for MR to measure TKV in ADPKD.Compared with MR, US TKV was prone to underestimation. After correcting for these, 3D-US tended to be slightly more comparable to MR in small TKV (<200 ml) than 2D-US.

SA-PO604

In Vivo Functional Genomics Screen to Identify Genetic Disease Modifier Driving Autosomal Dominant Polycystic Kidney Disease Phenotypic Heterogeneity Raphael A. Nemenoff, Kenneth H. Marsh, Emily K. Kleczko, Michel Chonchol, Katharina Hopp. *Univ of Colorado Denver, Anschutz Medical Campus.*

Background: ADPKD is characterized by significant phenotypic heterogeneity even within families, suggesting that factors other than the specific *PKD1/PKD2* mutation influence ADPKD severity. One explanation for this is the existence of additional mutations to other loci that modify ADPKD pathomechanisms and hence alter disease progression. Identification of such modifier genes, however, has been proven difficult in the past.

Methods: Here, we utilized the conditional Sleeping Beauty (SB) transposon mutagenesis mouse (SB11;T2/Onc3) driven by *Cdh16* cre-recombinase to identify PKD modifiers in a *Pkd1* haploinsufficient mouse model. Generally, $Pkd1^{+/-}$ mice do not develop cysts; however, since a small change of *Pkd1* gene product function beyond 50% is enough to drive cystogenesis, genes disrupted or overexpressed by T2/Onc3 integration that directly or indirectly function in *Pkd1* pathways will trigger a cystic phenotype.

Results: We generated experimental mice ($Pkd1^{del2/+}$;Ksp-$cre^{Tg/+}$;Rosa-26-$SB11^{Tg/+}$;T2/$Onc3^{Tg/+}$) and confirmed kidney specific cre-recombinase and SB11 expression. Additionally, we found SB11 to primarily be localized to the collecting duct and Loop-of-Henle, nephron segments thought to be key to ADPKD pathogenesis. Importantly, by MRI, US, and histology we show that our experimental mice develop several cysts as early as one month of age, while none were found in genetic littermate controls (negative for *Cdh16* or SB11). These cysts stained positive for SB11 by immunofluorescence, demonstrating proof-of-concept. Experiments to capture cystic lesions by laser micro-dissection, identify T2/Onc3 integration sites through next-generation sequencing, and pathway map common insertion sites are ongoing.

Conclusions: In summary, we developed a model that can in an unbiased fashion functionally identify genetic modifiers of ADPKD. Our preliminary findings indicate that mutations to additional genomic loci can trigger cystogenesis in a non-cystic background. These modifier loci will provide insight into ADPKD pathomechanisms, highlight novel therapeutic targets, and aid in patient management.

Serum Bicarbonate Levels and Total Kidney Volume in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease Kristen L. Nowak, Zhiying You, Berenice Y. Gitomer, Michel Chonchol, Melissa A. Cadnapaphornchai. *Univ of Colorado Anschutz Medical Campus.*

Background: Enhanced renal production of ammonia has been linked to cyst formation, and alkali administration has been found to reduce cystic tubular dilatation in animal models of autosomal dominant polycystic kidney disease (ADPKD). Whether lower serum bicarbonate concentrations are associated with an increased rate of total kidney volume (TKV) growth is unknown.

Methods: Participants were 85 children and young adults (8-22 years) participants with ADPKD and normal kidney function receiving lisinopril who were randomized to treatment with pravastatin or placebo for a 3-year period with evaluation of height-corrected TKV (HtTKV) at baseline, 18 and 36 months. The study population was divided into tertiles based on serum bicarbonate levels. We used Generalized Estimating Equations (GEE) models to examine the association between serum bicarbonate levels with repeat measures of HtTKV categorized as below and above the median level.

Results: Participants had a mean age of 15 ± 4 years. Mean serum bicarbonate level and estimated glomerular filtration rate were 24.4 ± 2.1 mEq/L and 115 ± 20 mL/min/1.73m^2, respectively. The median (IQR) HtTKV was 288 (221-394) ml/m. Compared to the first (lowest) tertile, the OR (95% CI) for a HtTKV above the median value during the course of the study were as follows: second tertile, 1.004 (0.73-1.38) and third tertile, 0.84 (0.72-0.97) after adjustment for age, gender, randomization group, body-mass index, systolic blood pressure, estimated glomerular filtration rate, and urine albumin excretion.

Conclusions: In a cohort of children and young adults with ADPKD with normal kidney function, higher serum bicarbonate concentrations were associated with a lower risk of increase in HtTKV.

SA-PO606

Design of a Phase I Clinical Trial with 2-Deoxy-D-Glucose in Autosomal Dominant Polycystic Kidney Disease Francesca Testa,[2] Marco Busutti,[2] Marco Chiaravalli,[1] Marco Leonelli,[2] Mariano Capistrano,[3] Francesco SCOLARI,[3] Donatella Spotti,[4] Alessandra Boletta,[1] Riccardo Magistroni.[1,2,4] *[1]Div of Genetics and Cell Biology, Molecular Basis of Polycystic Kidney Disease Unit, San Raffaele Scientific Inst, Milan, Italy; [2]Div of Nephrology, Univ of Modena and Reggio Emilia, Modena, Italy; [3]Second Div of Nephrology, Azienda Spedali Civili di Brescia, Brescia, Italy; [4]Div of Nephrology, San Raffaele Scientific Inst, Milan, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a life-threatening Mendelian disease. The epidemiology is controversial and an accurate estimation in a small region of the North of Italy is ongoing. The hallmark of ADPKD is bilateral renal cysts formation. Several deregulated pathways have been described and in recent studies we have shown that defective glucose metabolism is a feature of ADPKD. Others and we showed that the glucose analogue 2-deoxy-D-Glucose (2DG) slowed down disease progression in animal models. Few previous clinical trials describing the use of 2DG as antineoplastic agent suggest low side effects. We are now about to initiate a Phase I Clinical Trial in ADPKD.

Methods: The aim is to perform a Phase I Clinical Trial to assess 2-DG tolerability. With a combined effort involving preparation of the active compound ready for human administration and selection of a small number of patients, an exploratory study will be initiated.

Results: This is a single center, open label, one arm trial in adult subjects. The study will follow a modified accelerated titration model. After determining eligibility and recording baseline parameters, 2DG will be titrated from lowest (2mg/die) to highest tolerated levels. Preliminary data suggest a prevalence comprised between 4.2 and 4.6 : 10000 inhabitants. Based on this we defined a recruiting population supplied by three Nephrology Centers. A limited number of ADPKD patients, with large kidneys but not severely reduced function will be exposed to 2DG and clinically monitored.

Conclusions: This first exploratory study will provide information to design a long-term evaluation in a relatively small patient population to measure markers of potential efficacy of 2DG.

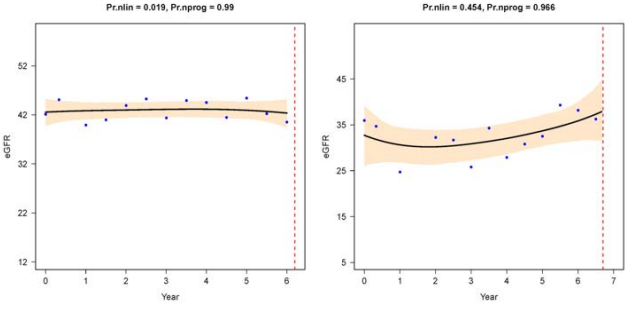
SA-PO607

Patterns of Renal Function Decline in the HALT PKD Trials Godela M. Brosnahan,[1] Kaleab Z. Abebe,[2] Frederic F. Rahbari-Oskoui,[3] Charity G. Moore,[2] Kyongtae Ty Bae,[2] Jared J. Grantham,[4] Robert W. Schrier,[1] Arlene B. Chapman,[5] Ronald D. Perrone,[6] Vicente E. Torres.[7] *[1]Univ Colorado; [2]Univ Pittsburgh; [3]Emory Univ; [4]Univ Kansas; [5]Univ Chicago; [6]Tufts Medical Center; [7]Mayo Clinic.*

Background: Renal function loss in autosomal dominant polycystic kidney disease (ADPKD) is generally believed to be steady and rapid once the limit of compensatory hyperfiltration has been reached. However, a detailed examination of individual patterns of renal function decline has not been performed.

Methods: Using data from the HALT trials we calculated the probabilities of linear or nonlinear trajectories of estimated glomerular filtration rate (eGFR) decline, as well as the probability of nonprogression for each participant using a previously validated Bayesian model. Twenty-six subjects with early disease and persistently high eGFR were excluded.

Results: The majority of participants (88% in Study A; 94% in Study B) experienced a progressive decline in eGFR during up to 8 years of follow-up, including those with well preserved renal function at baseline.A proportion (25% in Study A and 14% in Study B) of subjects with progressive decline had a nonlinear pattern. Interestingly, 12% of participants in Study A and 6% in Study B experienced a prolonged period of stable eGFR.



These individuals (Study A) had significantly smaller total kidney volumes, higher renal blood flow, lower urinary albumin excretion and lower body mass index than the majority; in Study B subjects with reduced but stable eGFR were older than the progressors but otherwise similar. Nontruncating weak *PKD1* mutations were enriched among participants with stable eGFR in both Study A and B.

Conclusions: Although the course of renal function loss is progressive in most individuals with ADPKD, 6 to 12% experience prolonged intervals during which GFR decline is no faster than expected of ageing alone. Maintaining a healthy body weight may help to preserve GFR in ADPKD.

SA-PO608

Serum Uric Acid, Total Kidney Volume and Disease Progression in Autosomal Dominant Polycystic Kidney Disease (ADPKD): Results from the HALT PKD Trial Godela M. Brosnahan, Berenice Y. Gitomer, Wei Wang, Zhiying You, Kristen L. Nowak, Diana I. Jalal, Michel Chonchol. *Univ Colorado, Aurora, CO.*

Background: Hyperuricemia has been implicated in the progression of chronic kidney disease (CKD) in clinical studies. We tested the hypothesis that higher serum uric acid levels may be associated with greater total kidney volume (TKV) and progression to end-stage renal disease (ESRD) in ADPKD.

Methods: We measured uric acid levels in stored serum samples in 766 patients who participated in the HALT-PKD randomized controlled trial of two different blood pressure

control strategies. Participants in HALT-Study A had abdominal MRI for total kidney volume measurement. We used mixed effect models (HALT- Study A; N=410) and Cox proportional-hazards models (HALT-Study B; N=356) to examine the associations between uric acid modeled as a continuous variable with repeated measures of height-corrected total kidney volume (HtTKV) during the course of the study and time to a 50% reduction in eGFR or ESRD, respectively.

Results: The mean age, serum uric acid level and eGFR in HALT-A were 37±8 years, 6±2 mg/dL and 90±17 ml/min/1.73m^2. The median (IQR) for HtTKV was 593 (409, 896) ml/m. In HALT-B the mean age, uric acid level and eGFR were 49±8 years, 7±2 mg/dL and 48±11 ml/min/1.73m^2. The b estimates (TKV) and hazard ratio (50% reduction in eGFR or ESRD) are summarized in table 1.

	Unadjusted	Adjusted
	HALT Study A	HALT Study A
ß estimate; 95% CI (per mg/dL increase)	-3.9 (-20.66 to 12.86; p=0.65)	-11.26 (-31.43 to 8.92; p=0.27)
	HALT Study B	HALT Study B
Hazard ratio; 95% CI (per mg/dL increase)	1.21 (1.11 to 1.29; p<0.0001)	1.10 (1.01 to 1.19; p=0.02)

Adjusted for age, gender, race, randomization group, body mass index, systolic blood pressure, eGFR, urine albumin excretion and genotype.

Conclusions: Higher serum uric acid levels are associated with increased hazard for kidney function decline and ESRD but not with larger kidney volume. Randomized interventional studies will be necessary to examine whether treating hyperuricemia has a protective role in ADPKD.

Funding: NIDDK Support, Pharmaceutical Company Support - Merck donated Lisinopril and Boehringer Ingelheim Pharmaceuticals donated Telmisartan and matched placebo, Private Foundation Support

Variability of PKD1-PKD2 in Autosomal Dominant Polycystic Kidney Disease (ADPKD): A 643 Patients Italian Experience

Paola Carrera,[1,2] Silvia Calzavara,[2] Riccardo Magistroni,[3,7] Johan T. Den Dunnen,[11] Francesca Rigo,[1] Stefania Stenirri,[1] Francesca Testa,[7] Piergiorgio Messa,[5] Roberta Cerutti,[5] Francesco SCOLARI,[8] Claudia Izzi,[8] Alberto Edefonti,[5] Susanna Negrisolo,[9] Elisa Benetti,[10] Maria Teresa Sciarrone Alibrandi,[4] Paolo Manunta,[4] Alessandra Boletta,[3] Maurizio Ferrari.[1,2,6] *[1]Genomics for Human Disease Diagnosis, IRCCS S.Raffaele S.I. Milano; [2]Clinical Molecular Biol, S.Raffaele S.I.; [3]Molecular Basis of Polycystic Kidney Disease, S.Raffaele S.I.; [4]Genomics of Renal Disease and Hypertension, S.Raffaele S.I.; [5]IRCCS Cà Granda Policlinico, Milano; [6]Vita-Salute S.Raffaele UnivMilano; [7]Univ of Modena; [8]AO Spedali Civili Brescia; [9]SDB Dept Padova; [10]Women's Children's Health D. Padova, Italy; [11]Leiden Univ Medical C. Netherlands.*

Background: ADPKD is the most common hereditary kidney disease.

Methods: We analysed PKD1 and PKD2, in a large cohort of 440 unrelated Italian patients with ADPKD and 203 relatives by direct sequencing and MLPA. Molecular and detailed phenotypic data have been collected and submitted to the PKD1/PKD2 LOVD database.

Results: We describe 701 variants, 249 (35.5%) already associated with ADPKD and 452 (64.5%) novel. According to the criteria adopted, the overall detection rate was 80% (352/440). Novel variants with uncertain significance were found in 14% of patients. Among patients with pathogenic variants, in 301 (85.5%) the disease was associated with PKD1, 196 (55.7%) truncating, 81 (23%) non truncating, 24 (6.8%) IF indels, and in 51 (14.5%) with PKD2. Enrichment of the cohort in subjects with an uncertain clinical diagnosis (21.8%) may explain the lower detection rate.

Conclusions: This is the first large retrospective study in Italian patients: our results outline the high allelic heterogeneity of variants, complicated by the presence of variants of uncertain significance and of multiple variants in the same subject. To this point, databasing (www.LOVD.nl/PKD1-PKD2) of both clinical and molecular data is crucial to improve the assessment of variant pathogenicity. Molecular analysis helped us to offer genetic counselling in at risk families: in relatives of probands with a pathogenic variant, we were able to prove 97 individuals to be free of the disease and 91 diagnosed with ADPKD.

Bone Mineral Density Is Reduced in Patients with Autosomal Dominant Polycystic Kidney Disease

Berenice Y. Gitomer,[1] Jason W. Stoneback,[1] Renata C. Pereira,[2] Isidro B. Salusky,[2] Diana George,[1] Wei Wang,[1] Myles S. Wolf,[3] Michel Chonchol.[1] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]Pediatrics, UCLA, Los Angeles, CA; [3]Medicine, Northwestern, Chicago, IL.*

Background: We previously identified low bone turnover in young patients with ADPKD and normal kidney function. Histomorphometric measurements are characterized by decreased indices of bone formation and resorption in trabecular bone and increased thickness of cortical bone. While fracture rates have not been reported in patients with ADPKD, we hypothesized that the abnormalities in bone turnover are associated with low bone mineral density (BMD) determined by dual energy x-ray absorptiometry (DEXA).

Methods: All patients provided informed consent and the protocol that was approved by the Colorado Multiple Institution Review Board. BMD was assessed, by DEXA scan in 15 patients with ADPKD and normal kidney function at 3 sites: lumbar spine L1-L4, neck of the femur and distal ⅓ of the radius. Z scores were calculated as standard deviations above or below normal age and sex matched participants from the National Health and Nutrition Examination Study.

Results: : BMD was assessed in 8 women and 7 men with ADPKD. Mean age of the patients was 33 ± 12 years; mean estimated glomerular filtration rate (eGFR) 93.1 ± 30.7 ml/min/1.73m^2. Bone density was lowest at the lumbar spine as shown in the table of Z scores.

Region (Z Score)	Spine L1-L4	Left Femoral Neck	Right Femoral Neck	Distal Third Radius
Mean	-0.55	-0.07	-0.08	0.16
Standard deviation	1.19	0.79	0.79	0.7

Thirty six percent of patients had a lumbar bone density ≤1 S.D. below normal age- and sex-matched healthy subjects.

Conclusions: We describe for the first time lower BMD in patients with ADPKD and normal kidney function. Lowest bone density was detected in the lumbar spine consistent with the higher proportion of trabecular/cortical bone in this region. Further studies are need to better understand clinical implications of these findings.

SA-PO611

Introduction of Tolvaptan for ADPKD: Implications for Renal Services

Kara Porch, Colin C. Geddes, Bruce Mackinnon, Jamie P. Traynor, Peter C. Thomson, Jonathan Fox. *Glasgow Renal and Transplant Unit, UK.*

Background: ADPKD is the most common hereditary renal disease. Following the TEMPO 3:4 trial, tolvaptan was approved by EMA in May 2015 for adults with ADPKD, eGFR >30 ml/min and 'rapidly progressing disease' (not defined further). In the USA, the FDA did not approve tolvaptan in this indication but requested further evidence – another randomised controlled trial will be completed in 2017. Glasgow Renal and Transplant Unit serves a population of 1.5 million. The aim of this study was to establish the number of patients who may be eligible for treatment and the implications for our service.

Methods: Adults with ADPKD attending Glasgow Renal and Transplant Unit were identified. Most recent, 1 year and 5 year values for eGFR using the CKD-EPI equation were collected. Rapid disease progression was defined as decline in eGFR ≥5ml/min in 1 year or ≥12.5ml/min over 5 years. Patients without evidence of rapid disease progression by eGFR were further evaluated by family history and imaging criteria. Numbers qualifying for treatment or requiring further imaging according to UK Renal Association guidelines (which include criteria for rapid progression by eGFR decline or kidney size increase) were calculated.

Results: 645 patients with ADPKD and attending Glasgow Renal and Transplant Unit were identified. Point prevalence of ADPKD was 430 per million population. 353 met age and renal function criteria and 185 also met criteria for rapid disease progression by declining eGFR. 168 did not have rapid disease progression by eGFR decline. 73 had no recent measurement of kidney length and require US. 12 had mean kidney length >16.5cm on US and require MRI to establish kidney volume. 64 had mean kidney length <16.5cm, requiring follow-up US every 2-3 years.

Conclusions: The introduction of Tolvaptan therapy for ADPKD will have significant implications for renal services. Many patients will require imaging by US and/or baseline and follow-up MRI. Treated patients require monthly blood tests for the first 18 months of therapy. Our data, derived from a population of defined size, will help renal units estimate the implications for their services.

SA-PO612

Implications of Transporter Studies on Development of Tesevatinib for Polycystic Kidney Disease: Multidrug and Toxin Extrusion (MATE)1/2-K Inhibition

James R. Tonra,[1] Caleb Isringhausen,[2] Kenta Hashizume,[3] Jeegar P. Patel,[1] John L. Ryan,[1] Olivier Schueller,[1] David A. Eiznhamer,[1] Mark S. Berger,[1] Anjay Rastogi.[4] *[1]Kadmon Corporation, New York, NY; [2]Sekisui XenoTech, Kansas City, KS; [3]Sekisui Medical, Ibaraki, Japan; [4]UCLA Medical Center, Los Angeles, CA.*

Background: Tesevatinib is a tyrosine kinase inhibitor in clinical development for the treatment of autosomal dominant PKD (ADPKD) based on its demonstrated ability to target EGFR, Src and HER2. Testing for inhibition of membrane transporters is required to determine drug-drug interaction potential.

Methods: P-gp, BCRP, BSEP, OATP1B1, OATP1B3, OCT1, OCT2, OAT1, OAT3, MATE1 and MATE2-K were screened for inhibition by tesevatinib *in vitro*. Tesevatinib concentration in EDTA-plasma from treated ADPKD subjects was determined by LC/MS/MS.

Results: Mean steady state plasma C_{min} and C_{max} was 111 and 136 nM in ADPKD patients treated QD with 50 mg tesevatinib. Total plasma tesevatinib C_{max}/IC50 for transporter inhibition was only >0.1 for MATE1 and MATE2-K (IC_{50} = 80nM and 68nM). MATE1/2-K inhibitors such as cimetidine may increase serum creatinine due to the reduced tubular creatinine secretion into ultrafiltrate, without clinically meaningful alteration in renal function. Consistent with this, ADPKD subjects receiving tesevatinib experienced non-progressive elevations of serum creatinine, without corresponding elevations in cystatin C that would indicate an impact on renal function. The median increase in creatinine from screening for 24 subjects receiving tesevatinib were 11.1, 14.3 and 10.0% on Days 3, 7 and 28 of treatment, while that for cystatin C was 0, 1.9, and -1.7%. Seven subjects with elevated serum creatinine during tesevatinib treatment had interruptions in drug administration

ranging in duration from 11 days to 32 days. All seven subjects exhibited a reduction in serum creatinine following the interruption in drug treatment ranging from 0.03 mg/dL to 0.20 mg/dL (mean reduction 0.13 mg/dL).

Conclusions: MATE inhibition by tesevatinib may explain serum creatinine increases associated with treatment, indicating the need for innovative approaches to eGFR assessment when conducting ADPKD clinical trials.

Haematologic Phenotype of Hereditary Polycystic Kidney Disease

Steven Van Laecke,[1] Tessa C.C. Kerre,[2] Evi V. Nagler,[3] Bart D. Maes,[4] Rogier Caluwé,[5] Wim Van Biesen,[6] Francis Verbeke.[7] *[1]Ghent Univ Hospital, Renal Div, Belgium; [2]Ghent Univ Hospital, Dept of Clinical Chemistry, Microbiology and Immunology, Belgium; [3]Ghent Univ Hospital, Renal Div, Belgium; [4]Dept of Nephrology, AZ Delta, Roeselare, Belgium; [5]Div of Nephrology, OLVZ, Aalst, Belgium; [6]Ghent Univ Hospital, Renal Div, Belgium; [7]Ghent Univ Hospital, Renal Div, Belgium.*

Background: Hereditary polycystic kidney disease (PKD) has a complex phenotype including not only renal cyst formation leading to end-stage kidney disease (ESKD) but also vascular abnormalities and endothelial dysfunction. Patients with PKD tend to have a higher susceptibility for urinary and respiratory infections and develop more skin cancer after transplantation.

Methods: We compared lymphocyte counts in patients with and without PKD at the time of transplantation in a cohort with follow-up until December 31, 2014. We analyzed flow cytometric immuno-phenotyping data if available. We also conducted a multicenter age-matched case-control study in a cohort including 202 patients with and 202 without PKD across comparable CKD strata with follow-up until February 1, 2016. We used multiple linear regression analysis to adjust for potential confounders in both models. We also recorded and analyzed other hematological characteristics.

Results: In a population of 700 patients with ESKD, total lymphocyte counts (and particularly $CD8^+$ T and B lymphocytes) were significantly lower in the 126 patients (18%) with versus without PKD ($p<0.001$ for both). After adjustment for age, sex, lnCRP and eGFR (in the CKD cohort only), PKD was associated with a lower lymphocyte count of 264/µL (95%CI 164 to 384; p<0.001) and 345/µL (95%CI 245 to 445; p<0.001) in the ESKD and CKD cohort respectively. Also, thrombocyte and monocyte counts were independently lower in patients with versus without PKD in both cohorts (p<0.001 for both cell types within each of the cohorts).

Conclusions: PKD is characterized by distinct haematological abnormalities and more particularly lymphopenia, independent of kidney function. A genetic basis for increased apoptosis of lymphoid cells and their precursors in PKD is conceivable.

SA-PO614

Smoking Worsens the Renal Phenotype of Pkd1-Deficient Cystic Mice

Marciana Veloso Sousa, Andressa Godoy Amaral, Bruno E. Balbo, Fernanda Souza Messias, Isac de Castro, Luiz F. Onuchic. *Divs of Nephrology and Molecular Medicine, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Smoking is a risk factor for progression to stage 5 chronic kidney disease in males, including the autosomal dominant polycystic kidney disease (ADPKD) scenario. To elucidate this matter, we analyzed the effects of smoking on the renal phenotype of a mouse model orthologous to ADPKD.

Methods: *Pkd1*-deficient cystic mice ($Pkd1^{cond/cond}$:$Nestin^{cre}$) and noncystic animals ($Pkd1^{cond/cond}$) were exposed to cigarette smoking from conception to 18 weeks of age, 2 times a day, 30-min cycles (CYS and NCS, respectively). Additional controls included cystic and noncystic mice not exposed to smoking (CY and NC, respectively). Serum urea nitrogen (SUN), renal cystic index by ultrasonography, cell proliferation, area of renal fibrosis and body weight (BW) were evaluated at 16-18 weeks in all groups.

Results: CYS mice had higher SUN than CY (57.2±32.4 *vs* 35.7±6.0 mg/dL, p<0.05) and NC animals (*vs* 32.0±3.1 mg/dL, p<0.001). NCS mice also showed higher SUN than NC animals (48.6±19.1 *vs* 32.0±3.1 mg/dL, p<0.01). No difference in SUN was detected, however, between CYS and NCS mice and between CY and NC animals. The cystic index was increased in CYS kidneys compared to CY [17.4% (6.0-31.7) *vs* 4.6% (2.7-8.4), p<0.05] while BW was lower in CYS than CY mice [24.2 (23.4-25.0) *vs* 28.3 g (27.1-29.4), p<0.0001]. Cell proliferation rate was increased in NCS kidneys compared to NC [0.9% (0.7-1.0) *vs* 0.2% (0.1-0.2), p<0.0001] and higher in CYS than CY cystic epithelia [2.1% (0.9-4.3) *vs* 1.1% (0.5-1.6), p<0.05]. Renal fibrosis was also higher in CYS mice than CY [1.1% (0.8-2.0) *vs* 0.3% (0.2-0.8), p<0.0001], NCS [*vs* 0.1% (0.09-0.2), p=0.01] and NC animals [*vs* 0.05 % (0.03-0.09), p<0.0001]. Increased fibrosis was also detected in CY kidneys compared to NCS and NC (p<0.0001) and in NCS kidneys compared to NC (p<0.05).

Conclusions: Our data revealed that smoking aggravated the renal phenotype of cystic mice, increasing the cystic burden, cell proliferation and fibrosis, and reducing kidney function. Deleterious effects were also observed in noncystic kidneys. Our findings support an accelerating effect of smoking on the progression of ADPKD.

Effect of Dietary Salt of the Progression of ADPKD in the HALT PKD Clinical Trials

Vicente E. Torres,[1] Kaleab Z. Abebe,[2] Robert W. Schrier,[3] Ronald D. Perrone,[4] Arlene B. Chapman,[5] Alan S.L. Yu,[6] William E. Braun,[7] Theodore I. Steinman,[8] Godela M. Brosnahan,[4] Marie C. Hogan,[1] Frederic F. Rahbari-Oskoui,[11] Jared J. Grantham,[6] Kyongtae Ty Bae,[2] Charity G. Moore,[9] Michael F. Flessner.[10] *[1]Mayo Clinic, Rochester, MN; [2]U of Pittsburgh, Pittsburgh, PA; [3]U of Colorado, Denver, CO; [4]Tufts U, Boston, MA; [5]U of Chicago, Chicago, IL; [6]Kansas U, Kansas City, KS; [7]Cleveland Clinic, Cleveland, OH; [8]Beth Israel Deaconess Medical Center, Boston, MA; [9]Carolinas Healthcare System, Charlotte, NC; [10]National Insts of Health, Bethesda, MD; [11]Emory Univ, Atlanta, GA.*

Background: The Consortium for Renal Imaging Studies in PKD (CRISP) found that 24 hours urinary sodium excretion (UNaE) associates with the rate of total kidney volume (TKV) increase. Whether sodium restriction can slow the progression of ADPKD is not known.

Methods: This post-hoc analysis of the HALT-PKD randomized clinical trials of renin-angiotensin blockade in ADPKD used linear mixed models to examine whether dietary sodium (reflected by UNaE) affected rates of TKV or eGFR change in patients with eGFR >60 ml/min/1.73 m^2 (Study A) or the risk for a composite endpoint of 50% reduction in eGFR, ESRD or death, or the rate of eGFR decline in patients with eGFR 25-60 ml/min/1.73 m^2 (Study B). Patients were instructed to follow a <100 mEq sodium diet.

Results: During the trial UNaE declined by 0.25 ± 0.04 and 0.41 ± 0.04 mEq/24 hr per month of follow-up in studies A and B (both P<0.001). In Study A, averaged and time varying UNaE were associated with kidney growth (2.4%/yr and 0.48%/yr for each 100 mEq UNaE, P<0.001 and P=0.005, respectively) and averaged UNaE was marginally associated with faster eGFR decline (-0.37 ml/min/1.73m^2/yr for each 100 mEq UNaE, P=0.09). In Study B, averaged but not time varying UNaE associated with increased risk for 50% reduction in eGFR, ESRD or death (HR 1.56 for each 100 mEq UNaE, P=0.01) and faster eGFR decline (-0.48 ml/min/1.73m^2/yr for each mEq 100 mEq UNaE, P<0.001).

Conclusions: These results reinforce the important role of moderate sodium restriction in the management of patients with ADPKD.

Prediction of GFR Slopes in Autosomal Dominant Polycystic Kidney Disease Patients with Normal Renal Function

Michal Mrug,[1,2] Sylvie Mrug,[1] Doug Landsittel,[3] Vicente E. Torres,[4] Kyongtae Ty Bae,[3] Peter C. Harris,[4] Lisa M. Guay-Woodford,[5] Michael F. Flessner,[6] William M. Bennett,[7] Alan S.L. Yu,[8] Jared J. Grantham,[8] Arlene B. Chapman.[9] *[1]U Alabama Birmingham; [2]Dept Veterans Affairs Medical Ctr, Birmingham AL; [3]U Pittsburgh; [4]Mayo Clinic; [5]Childrens Natl Health System; [6]NIDDK; [7]Legacy Good Samaritan Medical Ctr; [8]U Kansas; [9]U Chicago.*

Background: The Irazabal classification represents a major advance in prediction of renal function decline among patients with autosomal dominant polycystic kidney disease (ADPKD). Since this classification includes a limited number of predictors, we sought to improve the prediction of GFR decline by using a sequence of predictive models and taking the advantage of both the longitudinal HALT-A and CRISP data.

Methods: To improve prediction of GFR in ADPKD with normal renal function, we analyzed data from the HALT-A and CRISP cohorts; 558 and 241 ADPKD adults followed for 8 and 12 yrs respectively in these prospective, multicenter studies. We have developed statistical models of GFR linear trajectories over the duration of the HALT study and replicated the utility of this approach to predict GFR decline over time in the CRISP study.

Results: We built multilevel linear models of GFR trajectories by progressive addition of physical findings, laboratory data, PKD mutation type/severity and imaging studies (height-adjusted total kidney volume; htTKV). In the HALT-A cohort the final model explained 50% of variability of initial GFR and 31% of variability in GFR change over time (vs 41% and 22% explained by htTKV by age interaction only as used in the Irazabal classification). The best model includes variables and indices based on age, blood pressure, body surface area, hemoglobin, serum potassium, BUN, alkaline phosphatase, urine sodium, potassium and albumin, PKD mutation strength and htTKV. Most of these variables were replicated as significant predictors and explained 54% of variability of the initial GFR and 50% of the GFR slope in the CRISP cohort (vs 47% and 35% explained by the htTKV by age interaction).

Conclusions: HtTKV and age are important predictors of GFR decline in ADPKD patients with normal GFR. However, addition of selected physical findings and laboratory data further improves the model.

Development of a Customized Diagnostic Panel for Targeted Exome Sequencing of Polycystic Kidney Diseases Takuya Fujimaru, Takayasu Mori, Shintaro Mandai, Motoko Chiga, Hiroaki Kikuchi, Fumiaki Ando, Yutaro Mori, Naohiro Nomura, Shotaro Naito, Tomokazu Okado, Tatemitsu Rai, Shinichi Uchida, Eisei Sohara. *Nephrology, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

Background: Polycystic kidney disease (PKD) is an inherited kidney disorder. Genetic diagnosis is crucial for genetic counseling and the clinical management of patients and their families. However, especially among the child population, it is often difficult to make a precise diagnosis based on clinical features and imaging findings. Additionally, the increasing number of causative genes makes it difficult to perform DNA sequencing using conventional Sanger sequencing. Therefore targeted multiple genome resequencing using next-generation sequencing enables rapid and precise DNA diagnosis at a large scale.

Methods: With reference to Human Gene Mutation Database (HGMD^R), articles, opinion of experts, we created a custom capture RNA probe library (SureSelect Custom, Agilent Technologies) for 66 genes that cause nine types of hereditary PKD, such as autosomal dominant polycystic kidney disease (ADPKD), autosomal recessive polycystic kidney disease (ARPKD) and nephronophthisis. MiSeq sequencing was performed with 150 bp SE reads and each downstream analyses were conducted by using BWA, SAMtools, GATK, VEP, and GEMINI software. Copy number variations (CNVs) were evaluated with CONTRA.

Results: Provisional sequencing for four human subjects who were clinically diagnosed with PKD using this newly created panel secured 96.5% enough coverages (depth>10) for all the targeted genes with mean depth of 457.1. Of these, likely-pathogenic heterozygous variants in PKD1 are detected in a patient diagnosed with ADPKD. In another patient diagnosed with ARPKD, disease- causing compound heterozygous variants in PKHD1 are found with trio-based analysis.

Conclusions: We succeeded in developing a custom diagnostic panel specialized in PKD. In the situation that many responsible genes for PKD have been reported increasingly, comprehensive approach for genetic diagnosis will enable fast and efficient diagnosis of PKD in future.

SA-PO618

Epithelial Morphogenesis of Urine-Derived Renal Epithelial Cells from Children with Autosomal Recessive Polycystic Kidney Disease: An Ex Vivo Study Wolfgang H. Ziegler, Margarita E. Georgiadis, Kathrin Swolana, Birga Soetje, Dieter Haffner. *Dept of Pediatric Kidney, Liver, and Metabolic Diseases, Hannover Medical School, Hannover, Germany.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is caused by mutation of the *Pkhd1* gene, which encodes fibrocystin (FPC), a type I membrane protein of largely unknown function. Among other functions, FPC affects adhesion signaling of cells and their ability to orientate correctly towards one another. Recently, we established a link between loss of FPC function and defective epithelial morphogenesis in 3D cell culture using a canine cell line. Data in humans are lacking. Therefore, we set up assays for analyzing epithelial cells from ARPKD patients and healthy controls.

Methods: We take urine-derived renal epithelial cells (URECs) of ARPKD patients and respective controls in culture. The patients must have their original kidney(s) and still secrete urine. Populations of primary cells obtained within 14 days of culture are being characterized by different criteria and also tested in 3D cell culture conditions, which induce formation of epithelial spheroids with defined polarity, lumen and cilia.

Results: Using 2D and 3D-culture conditions, we observe URECs of three different phenotypes, spindle, patch, and cobblestone-like epithelial cells. While all different cell morphologies stain positively for the collecting duct marker aquaporin 2, only cobblestone-like cells give rise to a strong epithelial barrier as verified by impedance measurements and form spheroids in 3D culture conditions. Thus, cells of this phenotype are being studied preferentially to establish characteristic cell parameters with respect to growth rates, adhesion to micropatterned surfaces and spheroid formation. Cell of the suitable phenotype can be collected from all ARPKD patients, whereas it is restricted in samples from controls (10-20%) requiring a larger control cohort to distinguish cell properties from patients and controls.

Conclusions: By establishing methods allowing us to characterize the URECs of ARPKD patients, we aim to provide specific read-outs for future *ex vivo* analysis of the illness and for testing options of personalized pharmaceutical intervention.

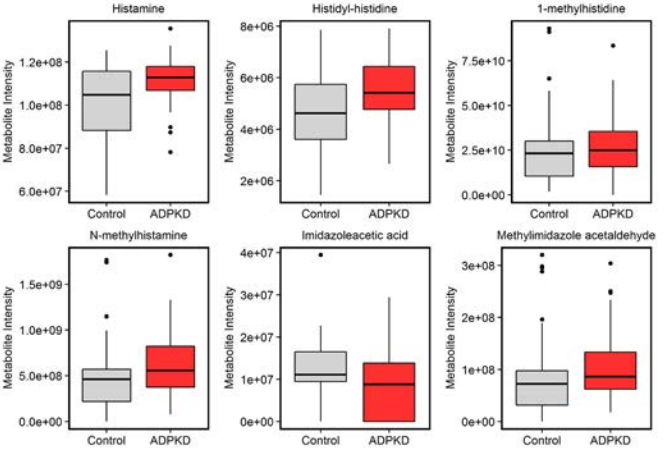
SA-PO619

Early Changes in Histidine Metabolism in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Sophia A. Banton,[1] Ken H. Liu,[1] Shuzhao Li,[1] Dean P. Jones,[1] Peili Chen,[2] F. Gary Toback,[2] Arlene B. Chapman.[2] *[1]Emory Univ; [2]Univ of Chicago.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), the most common inherited kidney disease, is characterized by expansive cyst growth, leading to increased total kidney volume (TKV), a decline in kidney function and ultimately end-stage renal disease. Evidence suggests that common cellular and molecular mechanisms are responsible for cystogenesis in ADPKD regardless of the genes mutated.

Methods: To further understand the pathophysiology and unique metabolomic features of early ADPKD, we used untargeted high-resolution metabolomics to analyze paired urine and plasma samples in a case-control framework comparing ADPKD patients (n=42, mean TKV 1,253.07±1,053.32 mL, mean eGFR 88.95± 31.08) to age and gender-matched healthy controls (n=18, eGFR 107.89±15.48).

Results: Among metabolic pathways that were different between ADPKD patients and controls, the most highly represented were histidine and purine metabolism. Complementary analyses that explored the relationships between renal function (eGFR) and disease severity (TKV) also showed differences in histidine metabolism. Plasma histamine (p=0.01) and histidyl-histidine (p=0.02) and urinary 1-methylhistidine (p=0.01), N-methylhistamine (p=0.02), and methylimidazole acetaldehyde (p<0.001) were elevated in ADPKD. Urinary imidazoleacetic acid (p=0.02) levels were lower in ADPKD patients. Histamine, histidyl-histidine, 1-methylhistidine and N-methylhistamine are associated with increased odds of ADPKD, and metabolome-wide association studies of these metabolites revealed that additional histidine metabolites are highly enriched in the urine and plasma of ADPKD patients.



Conclusions: ADPKD promotes dysregulation of the histidine pathway in PKD patients, which results in a metabolic profile that resembles clinical histidinemia.

SA-PO620

Next Generation Sequencing of an Extensive Kidney-Disease Gene Panel for a Comprehensive Genetic Diagnosis of Cystic and Glomerular Inherited Kidney Diseases Elisabet Ars,[1] Gemma Bullich,[1] Iván Vargas,[2] Patricia Ruiz,[1] Laura Lorente,[1] Gema Ariceta,[3] Jose Ballarin,[1] Roser Torra.[1] *[1]Molecular Biology Laboratory and Nephrology Dept, Fundacio Puigvert, Barcelona, Spain; [2]Informatics Dept, Inst de Diagnostic per la Imatge (IDI), Barcelona, Spain; [3]Pediatric Nephrology Dept, Hospital Vall d'Hebron, Barcelona, Spain.*

Background: The advent of next generation sequencing (NGS) has enabled the creation of comprehensive multi-gene panels, and served to broaden the phenotypic spectrum of inherited kidney diseases (IKD). Genetic diagnosis of cystic and glomerular IKD is complicated by their high genetic heterogeneity and phenotypic variability, with clinical manifestations that can be mimicked by mutations in several genes. We aimed to develop a comprehensive approach for genetic diagnosis of cystic and glomerular IKD.

Methods: NGS of 132 genes causative or associated with cystic or glomerular IKD was performed in 232 patients, a pilot study of 116 patients and a diagnostic cohort of 116 patients, consisting of 87 cystic and 29 glomerular IKD patients.

Results: In the pilot study, 134 out of 135 previously known mutations (99%) were identified, demonstrating similar sensitivity than Sanger sequencing. In the diagnostic cohort, disease-causing mutations were found in 86 out of 116 patients (74%), including 64 out of 87 cystic IKD patients (74%) and 22 out of 29 glomerular IKD patients (76%). Mosaic mutations were detected in 3 in the tuberous sclerosis patients and 2 ADPKD patients. Structural variants in *HNF1B*, *COL4A5* and *COL4A3* were found in 7 patients. Complex inheritance patterns were identified in a total of 5 patients, 3 ADPKD patients and 2 Alport syndrome patients. Mutations in low-frequency mutated genes such as *NPHP3*, *CUBN*, or *OFD1* were also identified.

Conclusions: Targeted sequencing of our kidney-disease gene panel is a comprehensive, efficient and cost-effective tool for genetic diagnosis of cystic and glomerular IKD.

Funding: Government Support - Non-U.S.

SA-PO621

Developmental Switch for Polycystic Hepatic and Kidney Disease (PKD) Treatment: Unmasking the Signaling Pathways That Temporally and Spatially Drive Cyst Initiation and Cyst Progression Olaya Lamas-Gonzalez,[1] Adrian Cordido,[1] Susana Bravo,[3] Ana Belen Sanz,[2] Alberto Ortiz,[2] Candido Diaz-Rodriguez,[1] Miguel A. Garcia-Gonzalez.[1] *[1]Group of Genetics and Developmental Biology of Renal Diseases, Health Research Inst of Santiago de Compostela (IDIS), Spain; [2]Fundación Jiménez Díaz, Spain; [3]Proteomic Unit, (IDIS), Spain.*

Background: Different mechanisms have been related to the pathogenesis of Polycystic Kidney Disease (PKD). This make hard to understand the principal mechanism underlying cystogenesis as well as the identification of therapeutic approach for complete and specific inhibition of cystogenesis.Although, strong evidences in cystic volume reduction and cystic progression have been described.

Methods: We have previously shown the identification of the differential proteome related to the developmental window identified for PKD progression, as well as the proteome related to cystic progression under inflammatory respond.

Results: In this study, we further explore the effect of therapeutic targeting our list of candidates (n=16) identified for ADPKD prevention and control. We previously described several proteins underlying altered cell morphogenesis, ECM-cell interactions and cell metabolism during cystogenesis. By drug targeting of several of those pathways, we blocked cystogenesis from distal nephron segment, reduced/delayed global cystic progression, as well as inhibited polycystic liver phenotypecompletely recovering kidney and liver function. These effects were potentiated in combination with Tolvaptan, although unexpected phenotypical effects were identified.

Conclusions: In conclusion, we have first described the ADPKD related proteome that help us to puzzle out the different signaling cascades that temporally and spatially play a role in cyst initiation and progression. Moreover, we also identified an effective treatment for both PKD and PLD controlling both cystic origin and progression, although more studies are need for the understanding of phenotypic side effects. Finally, our work unmasks the necessity of a multidrug cocktail strategy for the treatment of PKD, by the target of specific nephron segment cystic origin as well as blockage of the mechanisms underlying cystic progression and expansion.

Funding: Government Support - Non-U.S.

SA-PO622

Autosomal Dominant Tubulointerstitial Kidney Disease: The Spanish Cohort Nadia Ayasreh,[1] Gemma Bullich,[1] Monica Furlano,[1] Rosa Miquel,[2] Xavier Fulladosa,[3] Miguel A. Garcia-Gonzalez,[4] Jose Ballarin,[1] Elisabet Ars,[1] Roser Torra.[1] *[1]F. Puigvert; [2]H.U. Canarias; [3]H.U.Bellvitge; [4]C.H. Santiago de Compostela; [5]H. Reina Sofia, Spain.*

Background: Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) is a rare cause of end stage renal disease. It is caused by mutations in at least four different genes: *MUC1*, *UMOD*, *HNF1B* and *REN*. In this study we describe the clinical features of patients with *MUC1* and *UMOD* mutations.

Methods: Inclusion criteria were: autosomal dominant inheritance, renal failure without haematuria, and absent or minimal proteinuria, and exclusion of other causes of nephropathy. We have analyzed 59 families from different Spanish hospitals. We have collected clinical, laboratory, radiological and anatomopathological data, and performed the genetic study. Genetic analysis of *MUC1* insC mutation was optimized by SNaPshot.

Results: 24 of 59 families (40.6%) had genetic diagnosed: 9 families with *UMOD* mutations, 15 families with *MUC1* mutations and 1 family with *HNF1b* mutation. 124 individuals diagnosed, 39 *UMOD* (31.4%), 85 *MUC1* (68.5%) and 1 HNF1b (0.8%) Of the 60 individuals who developed ESRD, the median age of onset was 45.21 years (SD 11.52) for those with *MUC1* mutation vs 54.17 years (SD 13.46) for those with *UMOD* mutation ($p<0.05$). The prevalence of hyperuricemia was higher in patients with *UMOD* mutation (80.8% vs 56.6%, $p<0.05$) with a mean age at onset hyperuricemia similar in both groups. There were no statistical differences in proteinuria or imaging (cysts were present in 15% of patients with available data). Renal biopsies showed tubular atrophy and interstitial fibrosis.

Conclusions: The *MUC1* gene is responsible for the greatest percentage of ADTKD (21%), followed by *UMOD* gene (10%) and *HNF1B* (3%) With the data analyzed in the present study, the clinical difference between *MUC1* and *UMOD*, lies in the age of onset ESRD, which is almost 9 years before in patients with *MUC1*. Another interesting difference is the higher prevalence of hyperuricemia among *UMOD* patients. There is a great variability among and within families on the age of ESRD The analysis of the insC *MUC1* mutation is difficult which hampers routine implementation. We have optimized its analysis by SNaPshot.

SA-PO623

Effect of Renal Transcatheter Arterial Embolization on Quality of Life in Patients with Autosomal Dominant Polycystic Kidney Disease Tatsuya Suwabe, Yoshifumi Ubara, Akinari Sekine, Masayuki Yamanouchi, Junichi Hoshino, Masahiro Kawada, Kenmei Takaichi. *Toranomon Hospital, Dept of Nephrology, Minato-ku, Tokyo, Japan.*

Background: Patients with autosomal dominant polycystic kidney disease (ADPKD) and massive kidneys have various symptoms related to abdominal distension and renal dysfunction, which impair quality of life (QOL). However, current strategies for improving the QOL of ADPKD patients are very limited. Renal transcatheter arterial embolization (TAE) is effective for reducing kidney volume, but its impact on the QOL of ADPKD patients is unknown. This study aimed to clarify the influence of renal TAE on the QOL of ADPKD patients with enlarged kidneys.

Methods: All patients with ADPKD who undergo renal TAE at our hospital between 2010 and 2014 were enrolled. The short form-36 (SF-36) questionnaire and our original 15-item questionnaire about specific symptoms of patients with ADPKD were used to evaluate QOL. To estimate the mean values of the SF-36 physical component summary (PCS), mental component summary (MCS) and role/social component summary (RCS) and the answers to our 15-item questionnaire at each time point, the least squares mean (95% CI) were calculated using linear mixed model.

Results: A total of 188 patients on hemodialysis (92 men and 96 women, mean age: 56.7 ± 9.1 years, median total kidney volume: 4497 cm^3) were enrolled. The least squares mean of PCS, MCS and RCS before renal TAE were 38.21 (95%CI; 36.50 to 39.91), 48.45 (47.05 to 49.86), and 43.04 (40.70 to 45.37), respectively. These values improved to 42.0 (40.22 to 43.77: $p<0.001$ vs. before renal TAE), 51.25 (49.78 to 52.71: $p=0.001$), and 49.67 (47.22 to 52.12: $p<0.001$) at one year after renal TAE, respectively. Abdominal fullness, poor appetite, and heartburn showed marked improvement. Scores for fever, bodily pain, gross hematuria, and sleep disorder also improved slightly, but significantly. Scores for snoring, constipation, and use of analgesics/hypnotics/purgatives did not improved significantly after renal TAE.

Conclusions: Renal TAE was effective for improving abdominal fullness, appetite, heartburn, and SF-36 MCS and RCS scores, but not enough for improving sleep disturbance, constipation, and physical strength (PCS score).

Funding: Private Foundation Support, Government Support - Non-U.S.

SA-PO624

Development of Cost/Effective Strategies for Genetic Diagnosis of Polycystic Kidney Disease Based on the Population Mutagenesis Rate or Specific Needs M. Lara Besada-Cerecedo,[1] Lisbeth Silva,[1] Beatriz Sobrino,[2] Jorge Amigo,[2] Patricia Regueiro Casuso,[1] Ana Barcia de la Iglesia,[1] Manuel Fidalgo,[1] Carmen Vazquez,[1] Angel Carracedo,[2] Candido Diaz-Rodriguez,[1] Miguel A. Garcia-Gonzalez.[1] *[1]Group of Genetics and Developmental Biology of Renal Diseases, Health Research Inst of Santiago de Compostela (IDIS), Spain; [2]Galician Public Foundation of Genomic Medicine, Galician Public Foundation of Genomic Medicine, Spain.*

Background: Genetic tests have the benefit of ensuring an accurate diagnosis, is done one time in life and it can anticipate the disease, band the limitation of a high cost to be used in diagnostic routine. With the incorporation of the new generation sequencing (NGS), genetic tests have reduced dramatically the costs getting closer to the diagnosis by magnetic resonance imagen, and the advantage that it costs 100 times cheaper for the rest of family members.

Methods: We developed three strategies: T1)NGS panel for the genetic region responsible of the most polycystic kidney disease in the population (the replicated region of *PKD1,* exons 1-34), T2) NGS Panel for common polycystic disease (8 genes), and T3) NGS Panel for common, rare and ultra-rare polycystic kidney disease (all 72 known cystic genes).

Results: By analyzing a total of 252 PKD families (2150 patients), we identify the associated mutation in 90 families by using the T1, 128 by using T2 and 34 by using T3. In addition we reanalyzed all genetic variants identified to the moment, that help us to establish a PKD database of a total number of 3260 reclassified variants in four categories: 1174 class-I/definitely pathogenic (832 *PKD1*, 155 *PKD2* and 187 *PKHD1;* "stop codon", "frameshift insertions/deletions" and "canonical splice site alterations"); 141 class-II/probably pathogenic (107 *PKD1*, 12 *PKD2* and 22 *PKHD1;* "inframe deletion/insertions", "non canonical splice site mutations" and "amino acid substitutions"); 1594 class-III/uncertain significance (1119 *PKD1*, 85 *PKD2* and 390 *PKHD1)* and 351 SNPs (199 *PKD1*, 21 *PKD2* and 131 *PKHD1).* A total of 29 *PKD1* variants, 8 *PKD2* and 15 *PKHD1* were novel PKD mutations.

Conclusions: Here we describe the first cost/effective strategy applied for the diagnosis of all patients belonging to Local Health System for ADPKD.

Periostin Overexpression in Collecting Ducts Accelerates Polycystic Kidney Disease Archana Raman, Stephen C. Parnell, Aditi Khanna, Yuqiao Dai, Gail Reif, Darren P. Wallace. *Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Aberrant expression of extracellular matrix molecules and secreted factors contributes to cyst growth and fibrosis in polycystic kidney disease (PKD). Periostin, a matricellular protein involved in tissue development and repair, is overexpressed by cyst-lining epithelial cells and accumulates within the matrix adjacent to renal cysts. We found that periostin increased the activity of integrin-linked kinase (ILK) downstream signaling pathways, including the Akt-mTOR pathway and induced proliferation of human PKD cells. Cilengitide, an αVβ3- and αVβ5-integrin antagonist, blocked periostin-induced cell proliferation. Genetic knockout of periostin in pcy/pcy (pcy) mice, a slowly progressive model of cystic disease, reduced renal cell proliferation, cystic index and interstitial fibrosis, and improved the survival of the mice.

Methods: We generated periostin transgenic mice (Postntg) using a floxed STOP cassette in front of the periostin gene under the control of the ROSA26 promoter. Postntg mice were bred to Pkhd1-Cre mice to selectively overexpress periostin in collecting ducts (CD), a predominant site for cyst formation. To determine if periostin accelerates cystic disease, Postntg: Pkhd1-Cre mice were bred with pcy mice to generate pcy: Postntg: Pkhd1-

Cre mice. In addition, we determined if ILK knockdown in CD slowed PKD progression by generating pcy: ILK(floxed/+): Pkhd1-Cre mice. Both groups of mice were sacrificed at 10 weeks of age for tissue analysis.

Results: We found that overexpression of periostin increased CD staining for phosphorylated S6, a downstream target of mTOR, and significantly increased renal cell proliferation, cystic area and interstitial fibrosis. In contrast, heterozygous loss of ILK in the CDs of pcy mice significantly reduced renal cell proliferation, cystic area and interstitial fibrosis, and reduced levels of blood urea nitrogen consistent with improved renal function.

Conclusions: These results indicate that aberrant expression of ECM molecules, including periostin, contributes to elevated mTOR activity and cell proliferation, suggesting that the integrin-ILK signaling pathway may be a potential therapeutic target for PKD.

Collecting Duct-Specific Inactivation of HNF-1β Leads to Fibrocystic Disease and Impaired Urinary Concentration

Lama A. Noureddine,[1,3] Karam S. Aboudehen,[1,2] Patricia Cobo-Stark,[1] Svetlana Avdulov,[2] Shayan A. Farahani,[2] Daniel G. Bichet,[4] Marco Pontoglio,[5] Vishal Patel,[1] Peter Igarashi.[1,2] *[1]Internal Medicine, Univ of Texas Southwestern Medical Center, Dallas, TX; [2]Medicine, Univ of Minnesota, Minneapolis, MN; [3]Internal Medicine, Univ of Iowa, Iowa City, IA; [4]Medicine and Molecular and Integrative Physiology, Univ de Montréal, Montreal, Canada; [5]Development, Reproduction and Cancer, Inst Cochin, Univ Paris-Descartes, Paris, France.*

Background: Hepatocyte nuclear factor-1β (HNF-1β) is an essential transcription factor that regulates tissue-specific gene expression in the kidney. In humans, mutations of *HNF-1β* cause renal cysts and diabetes (RCAD) and congenital anomalies of the kidney and urinary tract (CAKUT).

Methods: We used Pkhd1/Cre mice to delete *Hnf-1β* specifically in renal collecting ducts. Water and solute excretion were measured using metabolic cages. HNF-1β targets were identified using ChIP-seq and gene expression profiling.

Results: *Hnf-1β* mutant mice survived long-term and developed slowly progressive cystic kidney disease, renal fibrosis, and hydronephrosis. *Hnf-1β* mutants had higher urine volume and lower urine osmolality than wild-type littermates. These abnormalities were present prior to the development of kidney cysts and hydronephrosis, suggesting a primary defect in urinary concentration. Circulating ADH levels were similar in wild-type and mutant mice. NR1H4 (FXR), a transcription factor known to regulate water homeostasis, was identified as a novel HNF-1β target. HNF-1β was bound to the FXR promoter *in vivo*,and FXR mRNA was downregulated in mutant mice. FXR protein localized to collecting ducts in wild-type mice and was diminished in the cysts of mutant mice. mIMCD3 cells exposed to hypertonic medium robustly upregulated FXR mRNA levels. This upregulation was lost in *Hnf-1β* mutant cells.

Conclusions: These findings reveal a new role for *Hnf-1β* in urinary concentration by regulating the transcription of FXR in the renal collecting duct.

Kcnn4 Dysregulation in Pkd1 Dosage-Dependent Mouse Models of ADPKD

Almira Kurbegovic,[1] Aïssatou Aïcha Sow,[1] Martin Couillard,[1] Boris Shmukler,[2] Seth L. Alper,[2] Marie Trudel.[1] *[1]Inst de Recherches Cliniques de Montréal, Montreal, QC, Canada; [2]Beth Israel Deaconess Med Ctr, Harvard Med School, Boston, MA.*

Background: The relentless increase of renal cyst number and size in ADPKD kidneys is governed in part by *PKD1*/PC1 gene dosage-dependent mechanisms.Cyst enlargement is regulated by epithelial cell secretion and proliferation, associated with tissue remodeling. Cyst fluid secretion is mediated by apical Cl^- channels requiring sustained basolateral Cl^- loading accompanied by basolateral K^+ recycling. The Ca^{2+}-activated K^+ channel, Kcnn4, provides a major pathway for K^+ recycling, consistent with PC1's role in epithelial Ca^{2+} homeostasis. We investigated Kcnn4's role in disease progression in both dosage-reduced $Pkd1^{F/F}$;*Ksp-Cre* and dosage-increased $SBPkd1_{TAG}$ mouse models of ADPKD.

Methods: Therenal-specific, *Pkd1* dosage-increased $SBPkd1_{TAG}$ mouse model develops severe renal cystic disease by age 5-6 months, whereas severe disease is evident by P10-18 in *Pkd1* dosage-reduced $Pkd1^{flox/flox}$;*Ksp-cre* mice. Epithelial cell proliferation, apoptosis, fibrosis and cilia length were respectively assessed by Ki67, TUNEL, Sirius red staining and acetylated tubulin; cAMP by ELISA, mRNA levels by qPCR and protein levels by immunoblot.

Results: Renal Kcnn4 mRNA was upregulated ~5-fold in $SBPkd1_{TAG}$ mice (n=12) and ~2-fold in $Pkd1^{flox/flox}$;*Ksp-cre* mice (n=7) vs age-matched controls (n=11 and 5). Levels of kidney cAMP were increased 4-fold in $SBPkd1_{TAG}$ mice (n=4) and 13-fold in $Pkd1^{flox/flox}$;*Ksp-Cre* mice (n=5) relative to age-matched controls (n=6 and 5). pERK1/2 was dramatically increased in $SBPkd1_{TAG}$ mouse kidney, suggesting MAPK pathway activation. $SBPkd1_{TAG}$ mice also showed 2-fold increased proliferative index in non-ectatic, "normal appearing" tubules, and 5-fold increased proliferative index in ectatic tubules and cysts. Consistent with increased cAMP, cilia were elongated in both $SBPkd1_{TAG}$ mice (n=5) and $Pkd1^{flox/flox}$;*Ksp-cre* mice (n=11).

Conclusions: Our study identified Kcnn4 as a pro-secretory and probably pro-cystogenic risk modifier in both *Pkd1* dosage-increase and dosage-decrease mechanisms, supporting Kcnn4 as a therapeutic target to retard cyst enlargement and disease progression in ADPKD.

SA-PO628

Low Dose Rituximab Therapy in Resistant Idiopathic Membranous Nephropathy: Single Center Experience

Soumita Bagchi,[1] Arun Kumar Subbiah,[1] Dipankar M. Bhowmik,[1] Sandeep Mahajan,[1] Raj Kanwar Yadav,[1] Geetika Singh,[2] Amit K. Dinda,[2] Sanjay K. Agarwal.[1] *[1]Nephrology, All India Inst of Medical Sciences, New Delhi, India; [2]Pathology, All India Inst of Medical Sciences, New Delhi, India.*

Background: 10-30% patients with idiopathic membranous nephropathy(IMN) progress to End Stage Kidney Disease in 10 years. The modified Ponticelli regimen(MPR) and Calcineurin inhibitors achieve remission in 60% patients. Most studies have used standard dose Rituximab in IMN: 375m/m2 weekly(4 doses) or 1g on day 1 and 15.Using this dose is expensive with high risk of infections. Few studies have used lower doses. Our study aims to do a preliminary assessment of the efficacy and safety of low dose Rituximab (LDR) in Indian patients with resistant IMN.

Methods: 17 patients with immunosuppression(IS) resistant IMN treated with LDR therapy from April 2015 to January 2016 were included.Treatment resistance was defined as no decrease in proteinuria after treatment with Modified Ponticelli regimen(MPR) and/or Tacrolimus(Tac) with Steroids for atleast 6 months.They received 2 doses of Rituximab(500mg each),7-10 days apart. A 3rd dose(500mg) was repeated if B cells were not depleted at 4 weeks after LDR or if no reduction in proteinuria by 12 weeks.

Results: 64.7% were males and their mean age was 35.1±13.9 years. Prior IS received by these patients were: 6-MPR, 2-Tac, 4- MPR then Tac, 2-Tac then Mycophenolate Mofetil(MMF)+Steroids and 3- MPR, Tac and then MMF. Proteinuria before therapy was 6.4±3.1g/day and serum creatinine was 0.9±0.4mg/dl. Four patients received a third dose:three for persistent proteinuria and one for inadequate B cell depletion. 12(70.6%) patients achieved remission(10-partial remission, 2- complete remission). Pre treatment serum Phospolipase A2 Receptor(PLA2R) levels were available in 11 patients-5 were negative. 2/5 PLA2R negative and 5/6 PLA2R positive patients achieved remission. Median time to remission was 2.1(0.7-6.1)months. Serum creatinine at follow up after 6.8(4.1-12.4) months was 1.0±0.5mg/dl. There were no adverse effects in any patient.

Conclusions: LDR therapy is effective and safe in IS resistant IMN.Further follow up is needed to determine relapse rates and long term outcome.

SA-PO629

Immunosuppressive Treatment for Elderly Membranous Nephropahty Patients

Eunjin Bae,[1] Tae Won Lee,[1] Jung Pyo Lee.[2] *[1]Dept of Internal Medicine, Gyeongsang National Univ Hospital, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Republic of Korea.*

Background: Primary membranous nephropathy (MN) is one of the most common nephrotic syndrome (NS) in elderly (age≥65yrs) patients. The number of people aged 65 or older is increasing annually. The aim of this study is to evaluate the use of immunosuppressant (IS) in elderly primary MN patients.

Methods: We retrospectively recruited 311 biopsy proven primary MN patients from 6 centers between 1990 and 2015. The endpoints were all-cause mortality, infection, doubling of the baseline serum creatinine or renal replacement treatment (RRT) and remission.

Results: To compare the baseline characteristics according to age, we divided into two groups of age ≥65 years (elderly, n=130) and <65 years (young, n=181). Of the 130 elderly patients, 104 (79.4%) presented with NS and of these, 25 (24%) had conservative treatment, 17 (16.3%) had steroid only therapy and 62 (59.6%) had steroid combination with other IS treatment. Yong group received higher rate (n=85, 66.9%) of steroid combination with other IS treatment than elderly group. The infection, death and renal outcome rate was higher with elderly group than young group, while remission rate was lower in elderly group. In elderly group, 73 (70.2%) patients achieved remission, 11 (10.3%) patients had RRT or doubling of serum creatinine, 9 (8.7%) patients were death and 17 (16.3%) patients were hospitalized because of infection. Treatment options of NS were not significantly associated with outcomes except infection. In elderly group, multivariate cox hazard models identified steroid only (HR 16.4, 95% CI 1.94-138.90, P=0.010), steroid combination with other IS treatment (HR 5.17, 95% CI 0.65-40.94) were significantly associated with infection. However, treatment options of NS in <65 years group were not significantly associated with composite outcomes.

Conclusions: Conservative therapy or steroid combination with other IS therapy are preferred than steroid only therapy in elderly patients at risk of infection. Prospective study is warranted to compare the efficacy and complications of treatment in elderly MN patients.

SA-PO630

Differences between Anti-PLA2R ELISA and IFT Assays in Idiopathic Membranous Nephropathy (iMN) during Therapy Anne-Els van de Logt,[1] Julia M. Hofstra,[2] Renate G. Van der Molen,[3] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Interne Geneeskunde, Gelderse Vallei, Ede, Netherlands; [3]Laboratory Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: In our center patients with iMN are treated with cyclophosphamide and steroids until disappearance of anti-PLA2R antibodies (aPLA2R) measured by indirect immunofluorescence (IFT). We previously showed excellent concordance (94 % agreement, kappa 0.85) between aPLA2R measured by IFT and ELISA in patients with iMN at diagnosis. We have assessed agreement in samples obtained during treatment.

Methods: We selected 31 aPLA2R positive patients. In all available serum samples aPLA2R were measured using IFT and ELISA, both obtained from Euroimmun®.

Results: Twenty patients were male, mean age was 56 ± 13 years, median serum creatinine level was 1.3 g/dl (1.1-1.6) and median protein creatinine ratio 7.3 g/g (5.0-11.2). We observed a more rapid disappearance of aPLA2R measured by ELISA compared to IFT.

	Baseline	8 weeks	8 weeks	16 weeks	16 weeks	24 weeks	24 weeks
IFT	pos	pos	neg	pos	neg	pos	neg
Elisa titer RU/ml (range)	94 (15-776)	13 (4-47)	2 (2-6)	14 (6-61)	2 (2-5)	12 (5-46)	-
pos	29	3	2	2	0	1	0
borderline	2	0	**1**	**1**	0	**1**	0
neg	0	**5**	**3**	**3**	5	**3**	0

After 8 weeks of therapy discordance was 24 %. There were no clear differences in laboratory parameters between patients with concordant and disconcordant results.

Conclusions: Our study demonstrates that the time course of disappearance of aPLA2R during therapy is dependent on the assay that is used. We speculate that the introduction of an ELISA assay might lead to a shorter duration of therapy. Additional studies are needed to evaluate if the ELISA assay allows more accurate prediction of clinical outcome. Of note, two of three patients with positive aPLA2R by IFT and negative aPLA2R by ELISA after 24 weeks were in partial remission at this time point.

SA-PO631

Anti-PLA2R Antibody (aPLA2R) Levels at Baseline Do Not Predict Response to Immunosuppressive Therapy in Patients with Idiopathic Membranous Nephropathy (iMN) Anne-Els van de Logt,[1] Julia M. Hofstra,[2] Renate G. Van der Molen,[3] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Internal Medicine, Gelderse Vallei, Ede, Netherlands; [3]Laboratory Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: In our center patients with iMN are treated with cyclophosphamide and steroids until disappearance of aPLA2R measured by indirect immunofluorescence (IFT). Recently ELISA assay was introduced, which allows quantitative measurements. It has been shown that patients with iMN and high aPLA2R levels did not respond to treatment with rituximab. We have evaluated the relationship between baseline aPLA2R levels and clinical response of patients treated with our antibody guided treatment regimen.

Methods: We included 30 anti-PLA2R positive (IFT) patients. In stored baseline samples aPLA2R were measured with ElISA (Euroimmun®).

Results: Nineteen patients were male, mean age was 56 ± 13 years, median serum creatinine level was 1.3 g/dl (1.1-1.6) and median protein creatinine ratio 7.7 g/g (5.5-11.3) . All patients tested positive with ELISA. When grouped in tertiles of aPLA2R, there were no differences in baseline characteristics.

aPLA2R titer	Lowest tertile	Middle Tertile	Highest Tertile	P value
Male/Female	7/3	5/5	7/3	ns
Elisa titer RU/ml (range)	15-67	86-134	136-776	0.000
Follow-up from start of therapy (IQR)	11.8 (2.8-25.9)	11.0 (5.4-29.8)	14.1 (3.4-20.4)	ns
IFT neg after 8 weeks	8	8	2	0.024
Remission	6	10	7	ns
Relapse	3	5	0	ns

In patients in the highest tertile the disappearance of aPLA2R was slower and as a consequence more prolonged immunosuppression was given. At the end of follow-up there were no differences in remission rate. Relapse rate was numerically lower in this group, however this might be related to the longer duration of therapy.

Conclusions: Patients with higher levels of aPLA2R often need more prolonged immunosuppressive therapy. However, with the use of antibody guided therapy clinical outcome is comparable.

SA-PO632

Low-Dose of Rituximab for Membranous Nephropathy Dario Roccatello, Roberta Fenoglio, Savino Sciascia. *Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), San Giovanni Hospital and Univ of Turin, Turin, Italy.*

Background: The key role of B cells in the pathogenesis of idiopathic membranous nephropathy (IMN represents the rationale of the B-cells depletion therapy with Rituximab (RTX). Traditional protocols proved to be effective in several open studies. A single-dose of RTX (sdRTX) has been reported to be as effective as the lymphoma protocol in some cases of immune-mediated diseases. Data on IMN patients (pts) treated with sdRTX as a front-line treatment are limited. In this study, the efficacy of the sdRTX in IMN was compared with a standardized therapy (Ponticelli protocol, PP).

Methods: 9 pts (mean age 64.7, 35-81 yrs) with nephrotic syndrome(NS) and major risk factors precluding conventional immunosuppressive therapy were perspectively treated with a single dose of 500 mg RTX. Pts were matched with those of the last 10 pts (mean age 59.9; 38–80 yrs) treated with PP in our Unit .

Results: In sdRTX-treated pts, proteinuria (uP) decreased from 11.0(IQ 6.5-24) to 2.4(IQ 2.3-21.2) g/24 hrs after 6 months ($p<0.05$). Among these sdRTX-treated pts, 1 became uP-free (< 0.5 g/24 hrs) within 6 months, 2 pts, who had a partial response (> 50% uP decrease) at 6 months, became uP-free in 12 months. 2 pts were unresponsive. The remaining 4 pts had a partial response, but 1 of these received an additional single dose of RTX for uP relapse. Creatinine (Cr) remained stable: 1.1 (range 0.7-1.7) mg/dl at 6 months vs 1.1(range 0.8-1.7) mg/dl at baseline. In PP-treated pts, uP decreased from 7.4(IQ 5.7-20.0) to 3.0(IQ 0.9-28) g/24 in 6 months ($p<0.05$). 6 pts had either complete (# 2) or partial (# 5) response. 3 pts were unresponsive. Cr remained stable: 1.1 (0.5-2.5) mg/dl at 6 months vs 1.2(0.7-3.5) mg/dl at baseline. There were no differences as regard to uP values and uP decrease in 6-month, between sdRTX and PP.

Conclusions: Current protocols of RTX treatment in immune-mediated diseases, were mainly derived from hematologic experience. Our data suggest that low doses of RTX are as effective as a standardized immunosuppressive treatment in the management of IMN pts. This sdRTX scheme could be especially indicated in pts with co-morbidities.

SA-PO633

Childhood and Adolescent Phospholipase A2 Receptor Related Primary Membranous Nephropathy: A Prospective Study on Prevalence and Treatment Outcome Harbir Singh Kohli,[1] Raja Ramachandran,[1] Ritambhra Nada,[2] Vivekanand Jha,[1] Krishan Lal L. Gupta.[1] *[1]Nephrology, PGIMER; [2]Histopathology, PGIMER, Chandigarh, India.*

Background: Primary membranous nephropathy (PMN) accounts for <5 and 10% of nephrotic syndrome in children and adolescents respectively. Autoantibodies to M-type phospholipase A2 receptor (aPLA2R) are seen in 70% of adult PMN . There are no prospective studies evaluating the prevalence of aPLA2R, its association with treatment outcome in PMN in this age group , hence the study was undertaken.

Methods: Children and adolescents (up to 19 yrs) with biopsy proven MN were included. Patients with positive viral makers, antinuclear factor or dsDNA antibodies were excluded. Blood for aPLA2R was drawn prior to immunosuppressive therapy. Patients were followed on monthly basis with proteinuria, serum albumin and creatinine. Serum $aPLA_2R$ (ELISA, EUROMMUN, value ≥ 20RU/ml considered positive) was done at baseline,6 and 12 months of treatment. Staining for PLA2R in the glomeruli was done. PLA2R related PMN was defined as presence of either enhanced glomerular staining or aPLA2R.

Results: A total of 20 patients were enrolled. Mean age was 15.25±3.90 (5-19) years. The mean proteinuria and serum albumin was 4.39±1.89 (2.4-9.2) g/day and 2.02±0.65 g/dL. Sixteen (80%) patients had PLA2R related PMN. Enhanced staining for PLA2R and aPLAR positivity was seen in 14 (70%)patients each. The median aPLA2R level in seropositive cases was 232.49 RU/mL. Twelve (75%) of 16 had both enhanced staining and serological positivity, with good association between the two ($p=0.03$). Patients were initiated on cyclical therapy of oral prednisolone (GC) and cyclophoshamide or tacrolimus (TAC) and GC. Of these two did not complete therapy. Remission was achieved in 11 (55%) patients at 1 year. Seven (35%) had complete and 4 (20%) partial remission. Those in remission had lower baseline aPLA2R (65.5RU/ml) as compared to resistant patients (358.53RU/ml). There was a parallel reduction in decrease in aPLA2R titre and proteinuria.

Conclusions: Childhood and adolescent onset PMN is PLA2R related in 80%. The response to therapy is seen in one half of patients. aPLA2R monitoring is clinically relevant and should be incorporated in the management of PMN.

SA-PO634

CD19 Targeted Rituximab Therapy in Adult Calcineurin Inhibitor Resistant,Dependent or Intolerant Nephrotic Syndrome due to Idiopathic Minimal Change Disease and Focal Segmental Glomerulosclerosis Harbir Singh Kohli,[1] Raja Ramachandran,[1] Indu R. Rao,[1] Ritambhra Nada,[2] Krishan Lal L. Gupta.[1] *[1]Nephrology, PGIMER; [2]Histopathology, PGIMER, Chandigarh, India.*

Background: Calcineurin inhibitors (CNIs) are first line agents in the management of steroid dependent (SD) and resistant (SR) nephrotic syndrome (NS) due to minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS). CNI use is limited by relapses and nephrotoxicity. Rituximab is a potential alternative, this prospective study was done to evaluate the efficacy and safety of targeted rituximab therapy in CNI intolerant/ dependent/resistant SD or SR MCD/FSGS.

Methods: A total of 24 adult patients of SDNS or SRNS (MCD/FSGS), who were CNI resistant/dependent/ intolerant were enrolled. All patients received rituximab 375mg/m^2 to target CD19 levels < 1% (48 hrs post infusion). CD 19 counts were monitored monthly and those with CD-19>1% received additional dose of rituximab. Patients were followed up monthly for at least 6 months. Study outcomes were remission rates and side effects. Definitions: CNI resistant: no response with 24 weeks, CNI dependent: relapse during or after CNI taper, CNI intolerant: irreversible nephrotoxicity or uncontrolled diabetes.

Results: Mean age was 23.2.±7.9 (16-46) years. The study included 17 (71%) and 7 (29%) cases of FSGS and MCD respectively. SR and SD was seen in 11 (46%) and 13 (54%) respectively. CNI dependence, intolerance and resistant were in 13 (54%), 4 (17%) and 7 (29%) patients respectively. All achieved CD19 depletion with 1 dose of Rituximab. Of 24, 10 (42%) needed 1 dose while 14 (58%) 2 doses during 6 months. By 12 months 3 or 4 doses were required in majority. At 6 months, 21 (87.5%) were in remission (13 complete, 8 partial). Three subjects had relapse despite CD 19 depletion and required additional threapy, CNIs in 2, low dose prednisolone in 1. Remission in SRNS was 73% vs 100% in SDNS. Remission in CNI dependent, intolerant and resistant was 100, 75 and 71% respectively. Rituximab was well-tolerated, with mild infusion reactions in 5 and pneumonia in 1.

Conclusions: CD-19 targeted rituximab therapy is a safe and effective in the management of adults with CNI resistant/dependent/intolerant MCD/FSGS.

SA-PO635

Clinicopatholgical Manifestation in Patients of Idiopathic Membranous Nephropathy with Nephrotic Syndrome Shinji Kitajima,[1] Akihiro Sagara,[1] Tadashi Toyama,[1] Akinori Hara,[1] Yasunori Iwata,[1] Norihiko Sakai,[1] Miho Shimizu,[1] Kengo Furuichi,[1] Hitoshi Yokoyama,[2] Takashi Wada,[1] Yasutaka Kamikawa.[1] *[1]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan; [2]Div of Nephrology, Kanazawa Medical Univ Hospital, Kanazawa, Japan.*

Background: The 20-year renal survival of Idiopathic membranous nephropathy (IMN) in Japanese adults with nephrotic syndrome was reported around 60%. In this study, we evaluated the predisposing clinicopathological factors for IMN patients with nephrotic syndrome.

Methods: One hundred five patients of nephrotic syndrome (62 males and 43 females; mean age 47.4 years) with biopsy proven IMN from 1965 to 2012 in Kanazawa Universitiy Hospital were evaluated in this study. The patients were followed for more than three years, or until renal or patient death. Clinicopathological factors, which might affect renal death and patient death were evaluated.

Results: Seventy out of 105 patients (67%) achieved complete remission(CR) or incomplete remission I(ICRI) (proteinuria < 1 g/day and plasma albumin concentration > 3.0g/dl) after initial treatments. Renal death was observed 14 out of 105 patients (13,3%). The group of renal death showed lower remission rate (CR or ICRI;renal death group; 21.4%, renal survive group; 73.6%). Based on the electron microscopic findings, the patients were assigned to two distinct types, homogeneous type and heterogeneous type (synchronous electron dense deposits or various phases of dense deposits in basement membrane, respectively) as we previously published in Kidney International in 2004. The rate of heterogeneous type was higher in renal death group (renal death group; 92.3%, renal survive group; 36.5%). Patients death was observed 23 four out of 105 patients (21.9%). The rate of death due to infection was higher in non-remission group (non-remission group; 33%, remission group; 21%).

Conclusions: These findings suggest that electron microscopic findings demonstrating heterogeneous type and no-remission of nephrotic syndrome was susceptible to renal death in patients with nephrotic IMN.

SA-PO636

Rituximab versus the Modified Ponticelli Regime in the Treatment of Primary Membranous Nephropathy: A Health Economic Model Patrick Hamilton,[1] Durga A.K. Kanigicherla,[1] Michael Venning,[2] Paul E. Brenchley,[1] David M. Meads.[3] *[1]Central Manchester Univ Hospitals, United Kingdom; [2]Univ of Manchester, United Kingdom; [3]Univ of Leeds, United Kingdom.*

Background: Membranous Nephropathy (MN) is among the most common causes of nephrotic syndrome worldwide with a high healthcare burden. Treatment using the modified Ponticelli regime (mPR) has remained the standard of care for decades, but newer therapies such as Rituximab are offering promising results with a reduced side effect profile. The cost of this treatment however can be a barrier to widespread use especially in resource limited healthcare systems.

Methods: We developed a decision-analytic model using a stochastic Markov model to estimate the cost-effectiveness of Rituximab versus the mPR over a one year horizon and from the perspective of the NHS. The primary outcome was cost of treatment at one year. Secondary outcomes were cost per treatment and incremental quality adjusted life years (QALY) over 5 years and a lifetime. The median age of patients at diagnosis is 53 years old; we therefore extended the lifetime over 47 years. Transition probabilities, costs and utility values to inform the model were obtained from published data following a systematic review.

Results: At one-year Rituximab is cheaper than mPr with an incremental cost of -£47.53, and with a better quality of life as shown by an incremental QALY of 0.02. At one-year Rituximab therapy is both cheaper and more effective (ie dominates) than mPR and is therefore the preferred option. The probability of Rituximab dominating at one year is 63%. Over five years, Rituximab remains the preferred option with an incremental cost of -£428.28 and an incremental QALY of 0.026. Over a lifetime the cost of Rituximab remains the cheaper option with an incremental cost of -£915.44.

Conclusions: This work indicates that the high single dose cost of Rituximab should not be a barrier to its use in the treatment of primary MN and highlights the need for a high quality clinical trial investigating the efficacy of Rituximab versus the current standard of care.

Comparative Effectiveness and Tolerance of Treatments for Idiopathic Membranous Nephropathy: A Network Meta-Analysis Daqing Hong, Li Wang, Guisen Li. *Renal Div and Inst of Nephrology, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Immunosuppressive treatment in general was shown to prevent renal progression and all-cause mortality in idiopathic membranous nephropathy (IMN) patients with nephrotic syndrome, however, the efficacy and safety of different immunosuppressive treatments have not been systematic assessed. A network meta-analysis was performed to compare different immunosuppressive treatment in IMN.

Methods: Cochrane library, MEDLINE, EMBASE and trial register system were searched for randomised controlled trials reporting the treatments for IMN to May, 2016. Composite endpoint of End-stage renal disease (ESRD) or mortality, complete or partial proteinuria remission and withdrawal because of treatment adverse events were compared combing direct and indirect comparison using network meta-analysis., Ranking different immunosuppressive treatment in the outcomes were analyzed by using SUCRA and MDS-ranking method.

Results: 36 randomised controlled trials were included. Compared with non-immunosuppressive treatment, only cyclophosphamide (CTX) and chlorambucil significantly reduced the risk of composite outcome of ESRD or mortality when combining the direct and indirect comparison (RR=0.31, 95%CI: 0.12-0.81 and RR=0.33, 95%CI: 0.12- 0.92). CTX increased the composite outcome of CR or PR (RR=4.29, 95%CI: 2.30-8.0) while chlorambucil did not (RR=1.58, 95%CI: 0.80-3.12) as compared with non-immunosupppressive treatment, chlorambucil also significantly increased withdrawal risk (RR=3.34, 95%CI: 1.37- 8.17) as compared to CTX. Both tacrolimus (RR=3.10, 95%CI: 1.36-7.09) and cyclosporine (RR=2.81, 95%CI: 1.08-7.32) also significantly increased the rate of CR or PR as compared with non-immunosuppressive treatment (without significant difference as compared with CTX), while ranking results showed that cyclosporine or tacrolimus was with less possibility of drug withdrawal as compared to CTX or chlorambucil.

Conclusions: Only alkylating agents can reduce risk of ESRD or mortality, however, they both had higher risk of drug withdrawal. Tacrolimus and cyclosporine can increase increase the possibility of proteinuria remission with less drug withdrawal.

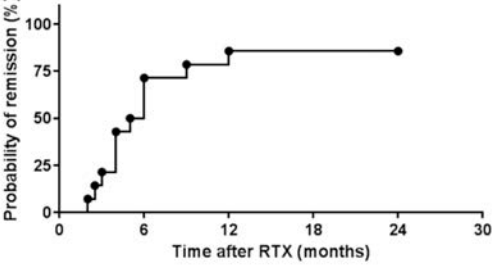
SA-PO638

Rituximab as Monotherapy for Pure Membranous Lupus Nephritis Nathalie Chavarot,[1,9] David Verhelst,[2,9] Agathe Pardon,[3,9] Valérie Caudwell,[3,9] Lucile Mercadal,[4,9] Antoinette Sacchi,[5] Jean-Marc Roger Dueymes-Laporte,[8] Veronique Le Guern,[6] Alexandre Karras,[7,9] Eric Daugas.[1,9] *[1]Nephrology, APHP, Bichat Hospital, Paris, France; [2]Nephrology, CH, Avignon, France; [3]Nephrology, CHSF, Corbeil-Essonnes, France; [4]Nephrology, APHP, Pitié Salpêtrière Hospital, Paris, France; [5]Internal Medicine, CH, Mantes la Jolie, France; [6]Internal Medicine, APHP, Cochin Hospital, Paris, France; [7]Nephrology, APHP, HEGP, Paris, France; [8]CH, Cayenne, French Guiana; [9]French Cooperative Group on Lupus Nephritis.*

Background: Optimal treatment for pure membranous lupus nephritis (MLN) remains undetermined. Rituximab constitutes a treatment option in lupus nephritis and is currently evaluated for idiopathic membranous nephropathy.

Methods: We retrospectively investigated patients with biopsy-proven pure class V lupus nephritis and protein-to-creatinine ratio (PCR) ≥ 2g/g and treated with Rituximab as monotherapy (1g infusion at day 1 and day 15, or 4 weekly infusions of 375mg/m^2) +/- low dose of steroids (≤20mg/day) +/- hydroxychrloroquine. Complete remission was defined as PCR <0.5 g/g with normal eGFR, and partial remission as ≥50% reduction in PCR to subnephrotic levels and normal eGFR. Treatment failure was considered when an additional immunosuppressive therapy or steroids > 20 mg/day were prescribed during the first 12 months.

Results: In 14 patients (13 women) median PCR ratio was 4.4g/g, median serum albumin 25.5g/L, and median eGFR (CKD-Epi) 121.5 mL/min/1.73m^2. The median follow-up was 29 months. Two patients experienced treatment failure. Remission was recorded in the remaining 12 (86%, complete remission in 8) within a median time of 5 months.



PCR decreased to 0.16g/g at month 12 and to 0.11g/g at month 24. All had serum albumin over 30g/L at month 12. eGFR remained stable in all. Three patients had relapse of proteinuria (at 12, 29 and 34 months). No patients experienced serious adverse event.

Conclusions: Rituximab as monotherapy might be an effective treatment for pure MLN.

SA-PO639

PLA2R Positive Membranous Nephropathy Associated with Viral Infection

Aikaterini K. Nikolopoulou, Megan Griffith, H. Terence Cook, Charles D. Pusey. *Imperial College London, United Kingdom.*

Background: Membranous Nephropathy (MN) can be associated with hepatitis infection and less commonly with HIV infection. The significance of anti-phospholipase A2 receptor (PLA2R) antibodies in this setting is not known.

Methods: A retrospective study of biopsy proven MN from January 2006 to January 2015 was undertaken. A total of 11 patients with MN and Hepatitis B (HBV), C (HCV) or HIV infection were identified. The biopsies were stained for PLA2R antigen and results were correlated to viral activity and clinical outcomes.

Results: The cohort consisted of 11 patients, 4 women and 7 men, mean age 39.9 years. HIV was detected in 5 patients, HBV in 4 and HCV in 3 (one patient HIV/HBV coinfection).

PLA2R staining was positive in 6 biopsies: 1 with HIV, 2 HBV, 3 HCV. Circulating anti-PLA2R antibodies were detected in 3 patients at time of biopsy. Viral load was undetectable at the time of biopsy in all but one patient with HBV. In the PLA2R negative group 3 patients had HIV, 1 HBV and 1 HIV/HBV coinfection. Viral load was detectable in 1 patient with HBV and 1 with HIV.

Mean proteinuria was higher in the PLA2R positive compared to the PLA2R negative group (mean uPCR= 801.6 vs 374.4mg/mmol) although this was not statistically significant. Electron microscopy in both groups showed predominantly subepithelial electron dense deposits (EDD). EDDs of all stages were present but stage II were the more frequent. Tubuloreticular inclusion bodies (TRI) were seen in 2 patients with interferon treated HCV in the PLA2R positive group; no TRIS were seen in the PLA2R negative group.

Follow up was available for 10 patients. At 24 months 9 had preserved renal function. One PLA2R and HCV positive progressed to ESRD. One patient with PLA2R positive MN and HIV went into spontaneous partial remission, others received tacrolimus (n=7), rituximab (n=2) or cyclophosphamide with high dose steroids (n=1).

Conclusions: PLA2R positivity can be found in MN associated with hepatitis infection and we describe a rare case of PLA2R positive MN and HIV. It is possible that the viral infection triggers immunological activity leading to the anti-PLA2R antibody response. MN can present even when infection is controlled and viral load undetectable.

SA-PO640

Membranous Glomerulonephritis with Crescents

Aikaterini K. Nikolopoulou, Isabel Huang-Doran, Stephen Paul McAdoo, Megan Griffith, H. Terence Cook, Charles D. Pusey. *Imperial College London, United Kingdom.*

Background: The coexistence of membranous glomerulonephritis (MGN) with necrotising and crescentic glomerulonephritis (NCGN) is rare. We examined the incidence and outcomes of patients with MGN and NCGN treated at our centre and the association with anti-neutrophil cytoplasm antibodies (ANCA) or anti-glomerular basement (anti-GBM) antibodies.

Methods: We report the clinical and pathological findings of 10 patients with MGN and NCGN, identified from our renal biopsy database from January 2004 to January 2015.

Results: The cohort consisted of 3 women and 7 men with a mean age of 58.8 years. ANCA and anti-GBM positivity was tested by ELISA. ELISA was positive in 9 patients (4 MPO-ANCA, 1 PR3-ANCA, 4 anti-GBM); one patient was negative and the biopsy showed IgA deposition. Clinical presentation included heavy proteinuria (mean urinary protein:creatinine ratio 1,731mg/mmol), microscopic haematuria and acute kidney injury (mean creatinine 390μmol/L (4.4mg/dL). Pathologic evaluation revealed MGN and NCGN with crescents involving a mean of 25% of glomeruli. Immunohistology available in 8 cases showed granular IgG deposits with linear IgG in anti-GBM cases. Electron microscopy showed stage I or II MGN changes in the majority of cases. PLA2R staining was negative in 8 available biopsies and no causes of secondary MGN were identified. One patient had a biopsy that showed MGN alone 6 months prior to anti-GBM disease. One patient had pre-existing p-ANCA vasculitis 2 years prior to MGN. Follow up was available for all 10 patients, and all were treated with steroids, together with cyclophosphamide (n=6), plasma exchange (n=1),rituximab (n=3) and MMF (n=2), alone or in combination. At a mean follow up of 48.1 months, 4 patients progressed to ESRD and 6 had stabilisation or improvement of renal function. One patient with ESRD died during the follow up period. The only independent predictor of progression to ESRD was serum creatinine at presentation.

Conclusions: MGN combined with NCGN is a rare dual glomerulopathy in which anti-PLA2R antibodies are not generally detected. Presentation is with proteinuria, haematuria and acute kidney injury. Prognosis is variable and seems to be related to renal function at presentation.

SA-PO641

The Concentration of Cyclosporine in the Treatment of Idiopathic Membranous Nephropathy (IMN) in Chinese Patients

Rui Zhang, Jiafan Zhou, Mengjun Liang, Yajuan Huang, Qianhui Zhang, Jiang Zongpei. *Nephrology, The Sixth Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guangdong, China.*

Background: CNI-based regimen is recommended in K-DIGO in IMN but causes severe pneumonia. There is no definitely safe and effective cyclosporine concentration that K-DIGO recommended. The concentration usually regarded nontoxic is 125~175ng/ml in many reports. We observed curative effect of cyclosporine in IMN patients in our department.

Methods: There were 53 patients with IMN in our department in 2012.10~2015.12. 30 patients were given cyclosporine plus prednisone, 16 males and 14 females. The age range was 28 to 69(mean age 47.5). Prednisone was given 0.25~0.5mg/kg.d, cyclosporine was 3.0~4.5mg/kg.d and adjusted to the concentration. We defined 6 months as the longest time to induce remissions.

Results: The remission rate was 70.0% (21/30) in 6 months, included complete remission rate 28.6%(6/21) and partial remission rate 53.6%(15/21). In the remission group, there were significant differences before and post treatment in plasma albumin(25.81±5.17g/L vs 33.19±3.47g/L, $p<0.01$), proteinuria(5.58±3.02g/d vs 1.68±0.81g/d, $p<0.01$). The average time of remissions was 125.75±95.67d. The eGFR(81.59±16.86ml/min/1.73m^{2}vs 84.18± 23.27ml/min/1.73m^2, p=0.539) was no significant change. We recorded 5 cases of severe pneumonia. The average concentration of cyclosporine of these patients was 134±53.7ng/ml. The cyclosporine concentration in the patients free of severe pneumonia was 77.04±26.65ng/ml, $p<0.01$ compared with patients with severe pneumonia. The average cyclosporine concentration was 78.51±25.02ng/ml and the average cyclosporine dose was 3.04±0.46mg/kg.d that induced remission in our department.

Conclusions: Cyclosporine plus prednisone is an effective regimen in IMN in our department. High concentration of cyclosporine is one of the reasons for severe pneumonia. We recommend 80±20ng/ml concentration of cyclosporine plus prednisone may be safty and effectively in treatment for Chinese patients with IMN.

SA-PO642

Prevalence of Circulating Anti-THSD7A Autoantibody in Patients with Membranous Nephropathy in Japan

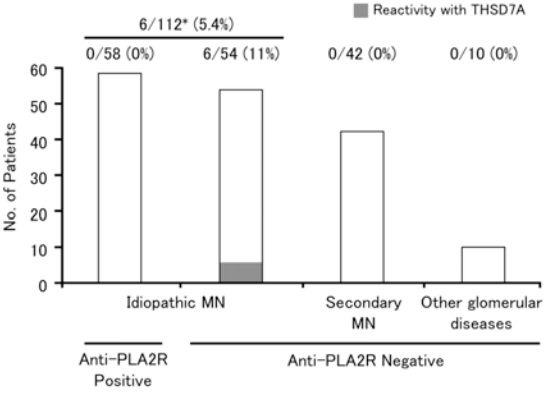
Shin'ichi Akiyama, Shoichi Maruyama. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan.*

Background: Circulating autoantibody against phospholipase A2 receptor (PLA2R) and thrombospondin type 1 domain containing 7 A (THSD7A) were well known as valuable biomarkers for idiopathic membranous nephropathy (iMN), and they were found in approximately 70% and 5%, respectively, of patients with iMN in Caucasian cohort. We previously reported the anti-PLA2R IgG was found in approximately 50% of patients with iMN in Japan; however the prevalence of anti-THSD7A IgG in Japanese patients is unclear.

Methods: We studied serum samples from biopsy-proven 112 patients with iMN, who consisted of 58 anti-PLA2R IgG positive patients and 54 anti-PLA2R negative patients, and 42 patients with secondary MN (sMN), and as controls, 5 each of patients with IgA-N, MCNS. All serum samples were collected before treatments. The anti-THSD7A IgG was analyzed by Western blot and indirect immuno fluorescence test cell-based assay (IIFT-CBA, EUROIMMUN). Western blot was performed under non-reducing condition with recombinant full-length THSD7A protein.

Results: As shown in Fig.1, the anti-THSD7A IgG was only detected in 6 out of 54 patients with anti-PLA2R IgG negative iMN, and was not detected in any of patients with anti-PLA2R positive iMN, sMN or other glomerular diseases. The major subclass of anti-THSD7A IgG was IgG4. Moreover, hyper-expressed THSD7A on podocytes were observed by immunofluorescent antibody technique using biopsy samples from patients with anti-THSD7A IgG positive iMN.

Conclusions: In Japanese cohort, the circulating anti-THSD7A was found in 6 (5.4%) out of 112 patients with iMN. No patients had both anti-THSD7A IgG and anti-PLA2R IgG. The prevalence and predominant IgG subclass of anti-THSD7A IgG and an expression manner of THSD7A on podocytes in Japanese patients with iMN are similar to those in Caucasian patients with iMN.



*No. of anti-THSD7A positive patents / No. of total patients.

SA-PO643

Serum Fibrinogen as a Predictive Biomarker of Response to Treatment in Patients with Membranous Nephropathy Hua Zhou, Ya Li, Congcong Jiao, Hairong Tang, Lizhi Li, Kong Weiwei, Lining Wang. *Dept of Nephrology, The First Hospital of China Medical Univ, China.*

Background: Membranous Nephropathy (MN) typically needs long time of treatment with steroid and immunosuppressants. A biomarker that predicts the response to treatment will likely help clinicians better manage MN. We aim to investigate whether serum fibrinogen (Fg) can predict response to steroid and immunosupressants.

Methods: 137 patients with MN proven by renal biopsy were treated with steroid and cyclophosphamide (CTX) at China Medical University from 2013 to 2014 (male: female is 89:48). The serum Fg, albumin (sAlb), low-density lipid cholesterol (LDL-C), and 24hour urinary protein excretion (uTP) were observed up to 9 months. The correlations between Fg before treatment and severity of nephrotic syndrome (uTp, sAlb, and LDL-C) before treatment, 3, 6, 9 months after treatment were analyzed.

Results: After 9 months' treatment of steroid and CTX, uTP excretion decreased (7.08±0.29 vs 2.50±0.42 g/24hr, p<0.01), sAlb increased (22.25±0.44 vs 34.35±0.78 g/L, p<0.01), and LDL-C reduced (6.08±0.22 vs 4.15±0.20 mmol/L, p<0.01). Fg was corrected to normal level (5.76±0.17 vs 3.80±0.36 g/L, p<0.01). The level of Fg before treatment positively correlated with uTp and LDL-C before and after treatment (uTP at 9 months and LDL-C at 6 months). Fg negatively correlated with sAlb pretreatment and 9 months post-treatment (see table).

Fg (g/L)	uTP (g/24hr)	sAlb (g/L)	LDL-C(mmol/L)
pretreat vs.pretreat	r=0.26(p<0.01) n=135	r=−0.41(p<0.01) n=135	r=0.55(p<0.01) n=133
pretreat vs.3m post-treat	r=0.27(p<0.01) n=106	r=−0.24(p<0.01) n=119	r=0.31(p<0.01) n=102
pretreat vs.6m post-treat	r=0.27(p<0.01) n=90	r=−0.21(p<0.05) n=93	r=0.31(p<0.01) n=88
pretreat vs.9m post-treat	r=0.36(p<0.01) n=74	r=−0.23(p<0.05) n=76	r=0.15(p=ns) n=68

Conclusions: The degree of hypercoagulation at the onset of MN correlates with the changing severity of nephrotic syndrome. Our data suggest that the level of serum fibrinogen before treatment might be a useful biomarker to predict the response to steroid and CTX. Thus, early correction of hypercoagulation might improve the outcome of membranous nephropathy.

Funding: Government Support - Non-U.S.

SA-PO644

Effects of Immunoadsorption and Immunoadsorption plus Rituximab on Circulating Phospholipase A2-Receptor Antibodies in Idiopathic Membranous Nephropathy Ammon Handisurya,[1] Renate Kain,[2] Elion Hoxha,[3] Thomas Perkmann,[4] Kurt Derfler,[1] Alice Schmidt.[1] *[1]Dept of Medicine III, Medical Univ of Vienna, Austria; [2]Dept of Pathology, Medical Univ of Vienna, Austria; [3]III. Dept of Internal Medicine, Univ Medical Center Hamburg-Eppendorf, Germany; [4]Dept of Laboratory Medicine, Medical Univ of Vienna, Austria.*

Background: 70% of all subjects with idiopathic membranous nephropathy (iMN) feature serum phospholipase A2-receptor-antibodies (PLA2R-Ab) which are linked to pathogenicity and course of the disease.

Methods: To evaluate whether immunoadsorption (IAS) effectively removes circulating PLA2R-Ab and results in a reduction of proteinuria, 4 subjects with biopsy-proven iMN, positive serum PLA2R-Ab and nephrotic range-proteinuria were treated with IAS (22-42 sessions within 68-366 days, 8000 ml total plasma volume per IAS) followed by 6 cycles of IAS combined with rituximab (Rtx; 2xIAS + 1xRtx 375 mg/m² body surface within 3 consecutive days; 4 weeks between each cycle) and a follow-up period of up to 500 days. Patients (pat.) 1-3 had iMN in their native kidneys, pat.4 a recurrence of iMN after renal transplantation. Pat.3 and 4 had received Rtx before, however without marked effect on disease activity.

Results: All pat. achieved partial remission (PR) according to the KDIGO-definition at the end of the study with reductions of serum PLA2R-Ab between -69.0 and -99.2% and urinary protein-creatinine-ratio (uPCR) between -49.3 and -82.6%. IAS-treatment alone removed serum PLA2R-Ab (-30.1 to -91.4%) only in pat.2-4, resulting in an attenuated uPCR (-25.7 to -82.9%) but PR only in pat.2. In pat.1, uPCR decreased by 24.9% but serum PLA2R-Ab interestingly increased by 2047.3%. PLA2R-Ab were detected in the eluate of pat.1-3 (not measured in pat.4). The combination of IAS with Rtx effectively reduced serum PLA2R-Ab by >90% in all but pat.4 (+13.6%) and resulted in PR of pat.1-3. During follow-up, PR was maintained in pat.1-3 and also pat.4 achieved PR 2 months after the final Rtx-administration.

Conclusions: Our data show that IAS removes PLA2R-Ab from circulation and sustains antibody removal in combination with Rituximab suggesting that IAS may improve rituximab-effects in known rituximab non-responders with iMN.

SA-PO645

Factor H Autoantibodies and Membranous Nephropathy Claudia Seikrit, Pierre M. Ronco, Hanna Debiec. *INSERM UMR-S1155, Tenon Hospital, Paris, France.*

Background: About 80% of patients with primary MN have autoantibodies against phospholipase A2 receptor (PLA2R), predominantly of IgG4 subclass. C3 and C5b-9 occur in glomerular immune deposits, implicating complement activation as a putative effector mechanism. Why 30% of patients will reach end-stage renal disease remains elusive. Here we report the case of a patient with PLA2R-related MN who later developed anti FH autoantibodies and degraded renal function.

Methods: Serum samples from patient were tested in parallel for the presence of PLA2R and FH autoantibodies using ELISA assays. To localize the binding domain of the FH autoantibodies, reactivity with recombinant FH fragments was measured.

Results: In 2009, histologically confirmed MN with circulating anti-PLA2R antibodies and normal renal function was diagnosed in a 64-year old male patient. A few months later and during the follow-up until 2016, he developed progressive renal insufficiency (serum creat: 103µmol/l (2009)- 296µmol/l (2015). He was not treated with immunosupressors. Circulating PLA2R antibodies were no longer detected after 2009. Instead a high titer of IgG3 isotype antibody reactive with FH was found in the serum between 2010 and 2015. This autoantibody recognized FH on Western blot only in non reduced conditions. IgG binding on immobilized FH was inhibited by pre-incubation with purified FH or rFH fragments containing a region that comprised the C terminal domains SCR15-20 but not the N-terminal domains SCR1-4. Plasma FH antigenic level was normal and genetic analysis revealed no abnormality in FH and FHRP1-5. Analysis of 84 sera from a retrospective cohort of patients with MN revealed that 3 additional patients had anti-FH antibodies, albeit at a lower titer than the index patient.

Conclusions: This is a first case of MN where autoantibodies targeting the C-terminal domains of FH were detected. Because FH is a major regulator of the alternative complement pathway, inhibition of FH activity by autoantibodies at podocyte cell surface might contribute to the overshooting of this pathway and accelerate disease progression. Patients with MN should be screened for anti-FH autoantibodies.

SA-PO646

Initial Anti-Phospholipase A2 Receptor Antibody Levels Predict Clinical Outcome in Patients with Idiopathic Membranous Nephropathy Jennie Lonnbro-Widgren,[1] Kerstin Ebefors,[3] Christine Payre,[4] Gerard J. Lambeau,[4] Johan C. Molne,[2] Borje Haraldsson,[1] Jenny C. Nystrom.[3] *[1]Univ of Gothenburg, Medicine, Gothenburg, Sweden; [2]Univ of Gothenburg, Biomedicine, Gothenburg, Sweden; [3]Univ of Gothenburg, Neuroscience and Physiology, Gothenburg, Sweden; [4]CNRS and Univ of Nice, Molecular and Cellular Pharmacology, Nice, France.*

Background: The clinical outcome in patients with idiopathic membranous nephropathy (iMN) is difficult to predict. PLA_2R antibodies are associated with persistence of nephrotic range proteinuria, and recent studies have provided evidence for epitope-spreading in the PLA_2R in patients with a less favorable clinical outcome.

Methods: In 25 patients with iMN and a mean follow-up of 63 months, levels of serum PLA_2R antibodies were measured at the time of renal biopsy, and correlated with the clinical outcomes. Additional glomerular staining for PLA_2R and THSD7A was performed, as well as measurement of serum epitope-specific titers and THSD7A antibodies at the time of renal biopsy.

Results: A statistically significant correlation (r=0.6, p<0.01) between a high serum PLA_2R antibody level at diagnosis and a less favorable clinical outcome was found. Patients with high autoantibody levels were more frequently exposed to immunosuppressive therapy, compared to patients with low autoantibody levels, and epitope spreading was seen among patients with higher PLA_2R antibody levels. In this study, 19 of 25 (76%) patients had a PLA_2R-associated iMN. One of the six PLA_2R-negative patients had detectable serum THSD7A autoantibodies and a positive glomerular staining for THSD7A. Moreover, THSD7A antibodies were not detected in any patient with PLA_2R-associated disease.

Conclusions: A high serum PLA_2R antibody level at presentation indicates a less favorable clinical outcome, and a higher risk of renal deterioration during follow-up. We therefore propose that these autoantibodies may be used as a prognostic marker for treatment decisions. In addition, the reactivity against three domains of PLA_2R, where the severity of the disease seems to be coupled to epitope spreading, may also be a tool to predict outcome of iMN.

SA-PO647

A Retrospective Analysis of Patients with Idiopathic Membranous Nephropathy Treated with Steroids and Intravenous Cyclophosphamide. A Single Centre Experience Hannah E. Wilkinson, Robin Ramphul, David Makanjuola, Hugh Gallagher, Bhrigu Raj Sood, Rebecca Suckling, Marie B. Condon. *Renal Unit, St. Helier Hospital, Surrey, United Kingdom.*

Background: The use of steroids and oral Cyclophosphamide is a well recognised treatment for patients with idiopathic membranous nephropathy (IMN). However, long term effects of high dose cytotoxic agents have been well established. Taking this into account we adopted a less toxic regimen with lower dose intravenous pulsed Cyclophosphamide as an alternative to higher dose oral Cyclophosphamide.

Methods: 20 patients were treated with oral Prednisolone and IV Cyclophosphamide between 2003 and 2015. All patients had biopsy proven IMN. Decision to treat was based

on persistent nephrotic syndrome +/- deterioration in renal function despite ACEI+/-ARB and maximal BP control. Treatment consisted of Prednisolone 40 mg/day for 30 days on month 1, 3 and 5. Cyclophosphamide was dosed according to bodyweight and renal function on day 1 of month 2, 4 and 6. 4 patients received IV Methylprednisolone pulses.

Results: All patients were male, mean age 61 yrs. 19 patients completed the treatment protocol. 11 patients (57.9%) achieved remission (either partial or complete). Average time to remission was 6.6 months. 6 went on to achieve CR (31.6%), average time to CR was 13.8 months. The treatment regimen significantly reduced uPCR (p=0.0025), increased serum albumin (p= 0.00287) and stabilised creatinine (p=0.0402) in the 48 months following treatment compared to the 6 months preceding therapy when censored for second line therapy. 2 (18%) patients relapsed, both treated with Tacroliums and achieved PR. 3 patients received Tacrolimus due to failure to achieve CR, all patients achieved PR or CR with Tacrolimus. 4 patients progressed to ESRF, 4 patients died during follow up with mean age 71 years, average time to death was 64.12 months after starting treatment. The mean cumulative dose of Cyclophosphamide in our study was 3284mg (range 2160-4500mg).

Conclusions: In our low toxicity protocol we have achieved remission rates approaching 60%. Furthermore this protocol has low relapse rate with less than 25% cumulative dose of Cyclophosphamide than would be received with the modified Ponticelli regimen.

SA-PO648
