***vs SED;#vs DM-EXE;&vs EXE P<0.05**.

Conclusions: Reductions in glycemia, fibrosis and MAP comparing DM-EXEvsDM-SED. The DM-EXE controlled weight loss(40%) compared to DM-SED, but did not prevent alteration in the CrCl/BW. However the effect of the EXE was strikingly observed in the reduction in both, mean uProt excretion(60%and25%) and in inflammatory factors comparing DM-SEDvsDM-EXE. Therefore preliminary data suggest that EXE can reduce proteinuria, renal fibrosis and inflammatory factors in diabetic animals and consequently diminish potential effects caused by diabetic and potentially could reduce the progression to renal failure.

TH-PO440

Enhanced Expression of Two Isoforms of Matrix Metalloproteinase-2 in Diabetic Nephropathy Sang Heon Song,[1] Eun Young Seong,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Ihm Soo Kwak,[1] David H. Lovett.[2] *[1]Internal Medicine, Pusan National Univ School of Medicine, Busan, Korea; [2]Internal Medicine, Univ of California San Francisco, San Francisco, CA.*

Background: We recently reported on the enhanced expression of two isoforms of matrix metalloproteinase-2 (MMP-2) in human renal transplantation delayed graft function. These consist of the conventional secreted full length MMP-2 isoform (FL-MMP-2) and a novel intracellular **N**-**T**erminal **T**runcated isoform (NTT-MMP-2) generated by oxidative stress-mediated activation of an alternate promoter in the MMP-2 first intron. This generates an intracellular, enzymatically active MMP-2 isoform that induces mitochondrial injury. Here, we evaluated the effect of hyperglycemia and diabetes mellitus on the in vitro and in vivo expression of the MMP-2 isoforms.

Methods: We quantified the abundance of the FL-MMP-2 and NTT-MMP-2 transcripts by qPCR in HK2 cells cultured with high glucose or 4-hydroxy-2-hexenal (HHE) and tested the NF-κB inhibitor pyrrolidine dithiocarbamate (PDTC). The streptozotocin (STZ) murine model and renal biopsies of human diabetic nephropathy were used in this study.

Results: Both isoforms of MMP-2 in HK2 cells were upregulated by high glucose and HHE stimulation. PDTC treatment did not suppress high glucose FL-MMP-2 expression, but potently inhibited NTT-MMP-2 expression. In STZ mice, renal cortical expression of the isoforms was increased (FL-MMP-2, 1.8-fold vs. NTT-MMP-2, over 7-fold). Isoform-specific immunohistochemical staining revealed low levels of the FL-MMP-2 isoform in controls, while NTT-MMP-2 was not detected. There was a modest increase in diffuse epithelial cell staining for FL-MMP-2 in STZ mice. In contrast, NTT-MMP-2 was intensely expressed in a basolateral pattern. FL-MMP-2 and NTT-MMP-2 transcript expression were both significantly elevated in renal biopsies of human diabetic nephropathy (12-fold and 3-fold, respectively). NTT-MMP-2 expression correlated with tubular atrophy.

Conclusions: The expression of FL-MMP-2 and NTT-MMP-2 is enhanced by hyperglycemia, oxidative stress and in experimental and human diabetes. Selective MMP-2 isoform inhibition could offer a novel approach for the treatment of diabetic renal disease.

TH-PO441

Treatment with a Novel Phosphodiesterase-4 Inhibitor Reduces Diabetic Kidney Disease in eNOS -/- db/db Mice Hongyu Zhang,[1] Jharna Saha,[1] Takanori Matsuo,[2] Masatoshi Hazama,[2] Frank C. Brosius.[1] *[1]Univ of Michigan; [2]Takeda Pharmaceutical Company.*

Background: Phosphodiesterase 4 (PDE4) isoforms are expressed in immune, other nonrenal cells and in tubular epithelia in the kidney. Inhibition of PDE4 can reduce inflammation in multiple conditions. However, little is known about PDE4 effects in the pathogenesis of diabetic kidney disease (DKD). Recent findings suggest that PDE4 inhibitors may ameliorate DKD both by lowering blood glucose levels and perhaps by other mechanisms. Therefore, we determined whether a novel specific PDE4 inhibitor (PDE4I) ameliorated the DKD phenotype and compared it to combined losartan/lisinopril treatment in a type 2 diabetic model, the C57BLKS eNOS -/- db/db mouse.

Methods: db/db and db/+ eNOS -/- mice were bred in our animal facility. Mice received either the PDE4 inhibitor (3 or 10mg/kg), losartan/lisinopril (30mg/kg and 20mg/kg, respectively) or equal volume of vehicle (0.5% methylcellulose) daily by gavage between 18 and 25 wks of age (n = 8/group). Urine, blood samples and kidney tissues were obtained from each animal at 26 wks.

Results: At 26 wks all groups of diabetic mice had elevated blood sugar and glycosylated hemoglobin values which were reduced by 10mg/kg PDE4I but not by 3mg/kg PDE4I when compared to vehicle-treated db/db eNOS -/- mice. Albuminuria, mesangial matrix and tubulointerstitial fibrosis were increased and podocyte density was reduced (all $p < 0.05$) in all groups of db/db mice. All these changes were improved significantly ($p < 0.05$) and to a similar extent by treatment with 3mg/kg PDE4I or losartan/lisinopril.

Conclusions: Seven week treatment with a PDE4I in a robust model of DKD, at a dose that did not reduce hyperglycemia, ameliorated the functional and pathologic features of DKD to an extent similar to that achieved with ACE inhibitor/ARB therapy. Therefore, PDE4I therapy could be a treatment for patients with DKD.

TH-PO442

Novel and Selective Phosphodiesterase Type 4 Inhibitor Ameliorates Albuminuria in Mouse Model of Diabetic Nephropathy Mitsugi Ookawara, Yasunori Nio, Midori Yamasaki, Kanako Kuniyeda, Guido Stefan Hanauer, Masatoshi Hazama, Takanori Matsuo. *Takeda Pharmaceutical Company Ltd, Fujisawa, Kanagawa, Japan.*

Background: Diabetic nephropathy (DN) is one of the major microvascular complications in patients with diabetes mellitus (DM), and leads to chronic kidney diseases and end-stage renal failure. Phosphodiesterase (PDE) 4 is an enzyme class that selectively hydrolyzes cAMP and activates various cellular events such as inflammatory and fibrotic response. A recent clinical study demonstrated that roflumilast, a PDE4 inhibitor (PDE4i), improved glycemic control in T2DM patients (Wouters et al. 2012). Based on these unique mechanisms of action, our novel and selective PDE4i is expected to show a protective effect in DN.

Methods: Male uninephrectomized *db/db* mice (UNx-*db/db*) and KKA^y mice were used as DN mice models. After 8-week repeated dose, glycosylated hemoglobin (GHb), plasma

glucose (PG) and urinary albumin/creatinine ratio (UACR) were measured. In vitro study, anti-fibrotic effect of the PDE4i on transforming growth factor (TGF)-β-induced mRNA expression was evaluated using NRK-52E, rat tubular epithelial cell line.

Results: In vitro studies, PDE4i increased intracellular cAMP level and suppressed TGF-β-induced mRNA expression of pro-fibrotic markers in a concentration dependent manner in NRK-52E. Before start of the treatment in in-vivo studies, UNx-*db/db* mice and KKA^{y} mice showed marked hyperglycemia and albuminuria. Treatment with PDE4i for 8 weeks improved glycemic control and increase of UACR in UNx-*db/db* mice. Significant suppressive effect on UACR was observed at lower dose than that of glucose-lowering activity, thus suggesting that inhibitory effect on UACR is, at least in part, achieved by direct effect on kidney cells. Treatment with the compound for 8 weeks also significantly inhibited the increase of UACR in KKA^{y} mice, which is another mouse model of DN with intact leptin axis.

Conclusions: Selective PDE4i can ameliorate albuminuria in vivo in addition to improving the glycemic control and inhibit fibrotic response in vitro. This indicates that PDE4i could be a novel therapeutic option with multiple mechanisms of action for the treatment of DN.

TH-PO443

Vasopressin Plays a Role in Fructose-Induced Metabolic Disease through the Vasopressin 1b Receptor Thomas Jensen,[1] Ana Andres-Hernando,[2] Miguel A. Lanaspa,[2] Carlos Alberto Roncal-Jimenez,[2] Richard J. Johnson.[2] *[1]Dept of Medicine, Div of Endocrinology, Univ of Colorado, Aurora, CO; [2]Dept of Medicine, Div of Nephrology, Univ of Colorado, Aurora, CO.*

Background: Elevated vasopressin (AVP), besides its role in urinary concentration has recently been implicated in metabolic syndrome and diabetes. We hypothesize that AVP plays a role in fructose induced metabolic disease through the AVP 1b (V1b) receptor.

Methods: We exposed V1b Receptor KO Mice, V1a Receptor KO Mice, and Wild Type Mice to 30 weeks of either water or 15% Fructose water on normal chow. We did hepatic H&E and oil red O staining, analyzed hepatic triglycerides, uric acid, and cholesterol, and serum cholesterol, triglycerides, uric acid, and glucose by Alera ACE. We did ELISA to analyze serum insulin, copeptin, glucagon, and leptin, and hepatic beat hydroxybutyrate. We did western blot to analyze hepatic KHK, GLut5, hypothalamic KHK, and adipose tissue pAkt and Akt. We did PCR for hypothalamic mRNA of AVP. We obtained serum copeptin from KHK A/C KO, KHK A KO and WT on similar 30 week diet as the first group.

Results: V1b Receptor KO mice on fructose had significant less weight gain, hepatic triglycerides, elevations in liver enzymes, elevations in insulin and insulin resistance as well as elevations in leptin and food consumption as compared to Wild Type on fructose. V1a Receptor KO mice had greater weight gain and with trends toward higher insulin, insulin resistance, and leptin while it had similar elevations in liver enzymes and hepatic triglycerides. KHK levels did not differ in V1bKO and WT on fructose nor Glut5 suggesting intact fructose metabolism. We show that V1bKO and WT on high fructose diet have elevated copeptin levels despite V1bKO being protected from weight gain, hepatic steatosis, insulin resistance, and hyperleptinemia. Meanwhile KHK A/C, but not KHK A were protected from elevations in copeptin in the setting of fructose, thus showing the role KHK C isoform has in the AVP system.

Conclusions: Fructose mediates AVP release, and AVP through the V1b plays a role in the development of fructose-induced weight gain, hepatic steatosis, insulin resistance, and hyperleptinemia.

TH-PO444

Inhibition of LPA Receptor 1 Protects against Development of DN Ming-Zhi Zhang,[1] Brian Murphy,[2] Robert Kaltenbach,[3] Peter T. Cheng,[3] Bradley Zinker,[2] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ, Nashville, TN; [2]Fibrosis Discovery Biology, Bristol-Myers Squibb, NJ; [3]Fibrosis Discovery Chemistry, Bristol-Myers Squibb, NJ.*

Background: Lysophosphatidic acid (LPA) acts through LPA receptors (LPARs). The role of LPA in development of diabetic nephropathy (DN) has not been previously studied. BMS002 is a novel, relatively selective LPAR1 antagonist. We examined whether BMS002 affected development of DN in a type II diabetes model of progressive nephropathy and GFR decline.

Methods: eNOS$^{-/-}$ *db/db* mice received vehicle or BMS002 (20 mg/kg/day) or as a positive control, losartan and enalapril, from 8 to 20 weeks of age. GFR was measured before and at the end of 12 weeks of treatment.

Results: At 20 weeks of age, LPAR1 inhibition with BMS002 led to a marked reduction in albuminuria (ACR: 771 ± 98 vs. 1799 ± 230 μg/mg, $P < 0.0005$, n = 10), similar to that seen with the positive control (586 ± 87 μg/mg). BMS002 protected against progression of DN, as indicated by reduced histological glomerular injury and decreased pro-fibrotic and fibrotic components including fibronectin, α-SMA, CTGF, collagen I, and TGF-β. BMS002 also inhibited renal macrophage infiltration and oxidative stress. Although GFR markedly decreased in the vehicle group from 8 to 20 weeks of age (0.223 ± 0.014 vs. 0.159 ± 0.019 ml/min/mouse, $P = 0.017$, n = 10), BMS002 prevented this reduction (0.243 ± 0.020 vs. 0.258 ± 0.022, $P = 0.636$, n = 10), and the change from week 8 baseline to week 20 was significantly different between vehicle and BMS002 ($P<0.05$).BMS002 also slowed podocyte loss (podocytes/glomerulus: 8 weeks: 18.11 ± 0.31, n = 4; 20 weeks: vehicle: 8.57 ± 0.256, n = 7; BMS002: 14.51 ± 0.30, $P < 0.0001$ vs. vehicle group, n = 8). Immunofluorescent staining determined that LPAR1 was expressed in podocytes and its expression in podocytes increased in diabetic mice.

Conclusions: These studies indicate that BMS002 protects against GFR decline and attenuates development of DN through multiple mechanisms, including protection against podocyte loss and inhibition of TGF-β-mediated fibrosis, macrophage infiltration, and oxidative stress, suggesting that LPAR1 is a potential therapeutic target for the treatment of DN.

TH-PO445

Incretin Effect Is Reduced in End-Stage Renal Disease Morten Buus Jørgensen,[1] Thomas Idorn,[1] Casper Rydahl,[2] Henrik Post Hansen,[2] Iain B. Bressendorff,[3] Lisbet Brandi,[3] Gerrit van Hall,[4] Jens Juul Holst,[5] Filip K. Knop,[5,6] Mads Hornum,[1] Bo Feldt-Rasmussen.[1] *[1]Dept of Nephrology, Rigshospitalet, Denmark; [2]Dept of Nephrology, Herlev Hospital, Denmark; [3]Dept of Cardiology, Nephrology and Endocrinology, North Zealand Hospital, Denmark; [4]CMCF, Rigshospitalet, Denmark; [5]The NNF Center for Basic Metabolic Research, Univ of Copenhagen, Denmark; [6]Center for Diabetes Research, Gentofte Hospital, Denmark.*

Background: Incretin hormone inactivity plays a pivotal role in the pathogenesis of postprandial hyperglycemia including impaired glucose tolerance (IGT) and diabetes. We hypothesized that uremia cause a (diabetes independent) reduced insulin secretion due to an impaired incretin effect which could contribute to the high incidence of IGT and diabetes observed in end-stage renal disease.

Methods: 12 chronic hemodialysis patients (ESRD) and 12 age, weight and height-matched healthy controls (CTRL), all with normal glucose tolerance, were included. On three separate days, a 2h euglycemic clamp followed by a 2h hyperglycemic (3 mM above fasting level) clamp was performed with concomitant (double-blinded) infusion of GLP-1 (1 pmol/kg/min), GIP (2 pmol/kg/min) or placebo. A 30% lower infusion rate was used in the ESRD group (derived from previous kinetic studies) to obtain comparable plasma concentrations.

Results: 22 patients and 14 controls were screened. Six patients had IGT and three diabetes, all diagnosed from postprandial (2h) plasma glucose levels. One withdrew consent. Two controls had elevated creatinine levels whereas one also had IGT. Glucose levels where comparable on all three examination days. The ratio of insulin during hyperglycemia and euglycemia on the placebo day was also comparable (ESRD: 3.1 [2.5 – 3.8] CTRL: 3.4 [2.9 – 3.9], NS). The relative effect of GLP-1 versus the placebo day tended to be lower during euglycemia in ESRD (26 [-18 – 53]%, NS) and was significantly reduced during hyperglycemia (50 [8 – 72]%, P=0.03). The relative effect of GIP during euglycemia tended to be lower in ESRD (23 [-5 - 43]%, NS) and was significantly reduced during hyperglycemia (34 [13 – 50]%, P=0.005).

Conclusions: The incretin effect is reduced in end-stage renal disease which could contribute to the high prevalence of postprandial hyperglycemia.

The DPP-4 Inhibitor Linagliptin Reduces Albuminuria Independently of Blood Glucose Levels Atsushi Uchida, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: In diabetes, both high glucose and albuminuria are becoming a theranostic factor of nephropathy. A previous study showed that a dipeptidyl peptidase (DPP)-4 inhibitor has an antioxidant effect in addition to its hypoglycemic effect. We assumed that endothelial damage due to oxidative stress was the cause of albuminuria. Thus, we tested whether a DPP-4 inhibitor, linagliptin, suppresses albuminuria via the antioxidant effect at an early stage of diabetes.

Methods: Male C57BL/6 control (wild-type; WT) mice and Akita mice were used. The mice were subdivided into 4 groups: (1) control, (2) WT+ linagliptin, (3) Akita, and (4) Akita+ linagliptin. Linagliptin was administered daily for 8 weeks. To visualize glomerular filtration, the two-photon laser microscopic in vivo imaging method was used. Glomerular morphological changes, glomerular oxidative stress, and urinary 8-hydroxy-2'-deoxyguanosine (8-OHdG) excretion were examined.

Results: The DPP-4 inhibitor did not cause any changes in body weight, urine volume, and blood pressure. With respect to renal function, there were no differences among all the groups. Blood glucose, HbA1c level, and albuminuria increased significantly in Akita mice. Administration of linagliptin did not reduce blood glucose and HbA1c level but reduced albuminuria significantly. In the Akita group, the size of glomeruli increased, the mesangial area was expanded, and the glomerular endothelial surface layer was lost compared with the control group. These changes were attenuated in the Akita+ linagliptin group. Excretion of urinary 8-OHdG, which is an oxidative-stress marker was suppressed by linagliptin. In the WT glomeruli, 70-kDa dextran did not leak from glomerular capillaries. However, the 70-kDa dextran leaked into the Bowman space in the Akita group. This leakage was attenuated by linagliptin.

Conclusions: We showed that a DPP-4 inhibitor has a protective effect on endothelial cells and reduces albuminuria by suppressing oxidative stress. These effects were independent of blood glucose. These data suggest that administration of a DPP-4 inhibitor starting at an early stage of diabetes can suppress the onset and progression of nephropathy.

TH-PO447

Renoprotective Effects of Dipeptidyl Peptidase Type 4 Inhibitor Linagliptin in Glucagon Like Peptide 1 Receptor Knockout Mice with 5/6 Nephrectomy

Berthold B. Hocher,[1,2,3] Ahmed A. Hasan,[1] Karoline von Websky,[1,4] Christoph Reichetzeder,[1,4] Jingli Guo,[1,4] Oleg Tsuprykov,[1,2,4] Thomas Klein.[5] *[1]Univ of Potsdam, Potsdam, Germany; [2]Inst für Laboriatorumsmedizin IFLb, Berlin, Germany; [3]Medical College of Hunan Normal Univ, Changsha, China; [4]Charité-Universitätsmedizin, Berlin, Germany; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany.*

Background: Dipeptidyl peptidase (DPP)-4 inhibitors were reported to have beneficial effects in experimental chronic kidney disease (CKD) models. The underlying mechanisms are not completely understood. Many studies suggested that these renoprotective effects are mediated via the glucagon like peptide-1 (GLP-1)/GLP-1 receptor pathway. To challenge this hypothesis we investigated the renal effects of the DPP-4 inhibitor linagliptin (LIN) in delaying CKD progression in GLP-1 receptor knockout (GLP-1r$^{-/-}$) mice with 5/6 nephrectomy (5/6 Nx).

Methods: The mice were allocated to the following groups: sham + placebo (PBO); 5/6 Nx + PBO; 5/6 Nx + LIN; sham + GLP-1r$^{-/-}$ + PBO; 5/6 Nx + GLP-1r$^{-/-}$ + PBO and 5/6 Nx + GLP-1r$^{-/-}$ + LIN and the treatment period was 12 weeks.

Results: LIN treatment led to a significant decrease in plasma DPP-4 activity and a significant substantial increase of plasma active GLP-1, which was more pronounced in GLP-1r$^{-/-}$ mice than wild-type mice. Moreover, 5/6 nephrectomy caused the development of renal interstitial fibrosis and glomerulosclerosis and increased plasma cystatin C levels in wild-type and GLP-1r$^{-/-}$ mice and these effects were counteracted by LIN treatment. In addition, proteins were separated from kidney tissues and subjected to liquid chromatography-matrix-assisted laser desorption ionization mass spectrometry (LC-MALDI-MS). After mass spectrometry-data acquisition, spectra were analyzed and 298 signals were differentially regulated among the groups, with 150 signals specific to LIN treatment. The identification of the amino acid sequences of the peptides corresponding to these signals, by means of tandem mass spectrometry, is currently going on.

Conclusions: The beneficial renal effects of LIN in mice with 5/6 nephrectomy cannot solely be attributed to the GLP-1/GLP-1 receptor pathway,highlighting the importance of other signaling pathways influenced by DPP-4 inhibition.

Insulin Inhibits Nuclear Factor Erythroid 2-Related Factor 2 Gene Expression and Prevents Hypertension and Kidney Injury in Type 1 Diabetes

Anindya Ghosh,[1] Shaaban Abdo,[1] Shuiling Zhao,[1] Yixuan Shi,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]CRCHUM, Univ of Montreal, Montreal, QC, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hospital, Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp, Boston, MA.*

Background: We hypothesized that insulin regulates nuclear factor erythroid 2-related factor 2 (*Nrf2*) gene expression via heterogeneous nuclear ribonucleoprotein F (hnRNP F) and hnRNP K, preventing Nrf2-stimulation of angiotensinogen (*Agt*) gene expression, hypertension and renal injury in Type 1 diabetic Akita mice.

Methods: Male Akita mice and non-Akita littermates (at week 12) were treated +/- insulin implants and euthanized at week 16. Hyperinsulinemic-euglycemic clamp was performed on adult wild-type mice. Effects of insulin on blood glucose, systolic blood pressure, renal proximal tubular cell (RPTC) gene expression and tubulointerstitial fibrosis were assessed. *In vitro* studies used rat immortalized PTCs (IRPTCs) stably transfected with *Nrf2*, *Agt*, *hnRNP F* or *hnRNP K* gene promoter.

Results: Insulin normalized hyperglycemia, inhibited renal *Nrf2* and *Agt* gene expression, up-regulated hnRNP F/K expression, and prevented hypertension and renal injury in Akita mice. *In vitro*, insulin inhibited *Nrf2* gene promoter activity via a specific DNA responsive element that binds hnRNP F/K, and averted Nrf2-stimulation of *Agt* gene expression via p44/42 mitogen-activated protein kinase signaling. Transient transfection of IRPTCs with *hnRNP F* and/or *hnRNP K* siRNA abolished insulin down-regulation of *Nrf2* gene expression. Furthermore, transient transfection of IRPTCs with *hnRNP F* and/or *hnRNP K* cDNA effectively blocked Nrf2 stimulation of *Agt* gene transcription. In hyperinsulinemic-euglycemic mice, renal *Nrf2* and *Agt* expression was lower, whereas *hnRNP F/K* expression was higher than in saline-infused mice.

Conclusions: We conclude that insulin prevented hypertension and nephropathy in diabetes, at least in part, via suppression of *Nrf2* transcription and consequently Nrf2-stimulation of renal *Agt* expression through enhancing hnRNP F/K expression.

Novel sGC Stimulator IW-1701 Prevents the Progression of Diabetic Nephropathy when Administered in Combination with Enalapril in the ZSF1 Rat Model

Jaime L. Masferrer,[1] Courtney Shea,[1] Elisabeth Lonie,[1] Guang Liu,[1] Albert Profy,[1] George Todd Milne,[1] Mark G. Currie.[1] *[1]Pharmacology, Ironwood, Cambridge, MA; [2]1; [3]1; [4]1; [5]1; [6]1; [7]1.*

Background: In diabetic nephropathy, elevated reactive oxygen species and reduced nitric oxide (NO) availability contribute to endothelial dysfunction and disease progression. Soluble guanylate cyclase (sGC) stimulators enhance NO signaling and increase the formation of cyclic guanosine monophosphate. Previous studies have shown the capacity of sGC stimulators to lower blood pressure and exert anti-inflammatory, antifibrotic and positive metabolic effects. This study assessed the effects of IW-1701, a novel sGC stimulator in clinical development, in the ZSF1 model of diabetic nephropathy.

Methods: Male ZSF1 rats were implanted with radiotelemetry transmitters (abdominal aorta) for continuous blood pressure recording. After recovery, rats received either plain or enalapril (3 mg/kg) in water for 10 days then 10 weeks of enalapril or enalapril + IW-1701 (10 or 30 mg/kg/d)in chow (n=8/group). Plasma and urine were collected during the study.

Results: After the initial 10 days, treatment with enalapril-only reduced mean arterial pressure (MAP) by 5+/-1 mmHg compared with untreated rats; this effect was sustained (8+/- 1 mmHg) through week 10 . Enalapril + IW-1701(10 and 30 mg/kg) reduced MAP by 13+/- 1 and 15 +/- 1 mmHg respectively ($p<0.05$ vs enalapril-only treatment). Kidney and liver hypertrophy were reduced in rats receiving enalapril + IW-1701 30 mg/kg/d. This dose combination also reduced fasted blood glucose, total cholesterol and triglycerides by ≥40% compared to untreated rats. Urinary protein creatinine ratio (UPCR) increased to 27.5+/- 3 by day 10 and to 51+/- 3 by week 10. Enalapril-only treatment reduced UPCR by 33% compared to untreated control. Enalapril + IW-1701 reduced UPCR by 54 and 90% at the 10 and 30 mg/kg/d doses, respectively.

Conclusions: IW-1701 in combination with enalapril demonstrated efficacy reducing blood pressure and proteinuria in the ZSF1 rats. This preclinical study suggests the sGC stimulator IW-1701 could be beneficial in preventing the progression of diabetic nephropathy when added to the standard of care.

Prolyl Hydroxylase Inhibitor Decreases Albuminuria and Improves Glucose and Lipid Metabolism in a Mouse Model of Type 2 Diabetes

Shinji Tanaka,[1] Tetsuhiro Tanaka,[1] Mai Sugahara,[1] Hisako Saito,[1] Kenji Fukui,[1,2] Yu Ishimoto,[1] Reiko Inagi,[1] Masaomi Nangaku.[1] *[1]Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Biological and Pharmacological Laboratories, Central Pharmaceutical Research Inst, Japan Tobacco Inc., Osaka, Japan.*

Background: Although prolyl hydroxylase (PHD) inhibition was reported to have beneficial effects in several kidney disease (especially acute kidney injury) models, the effect of long-term PHD inhibition on diabetic kidney disease remains unclear. We examined the effect of a specific PHD inhibitor, JTZ-951 (Japan Tobacco Inc., Japan), in a mouse model of type 2 diabetes.

Methods: Four-week-old male BTBR ob/ob mice were divided into the vehicle and JTZ-951 groups. JTZ-951 (0.005%; in feed) was administered from 4 weeks of age until euthanasia (at 22 weeks).

Results: During the study period, body weight and blood glucose level tended to be lower in the JTZ-951 group (HbA1c: 8.9±0.3 vs 8.2±0.2%) with comparable feed intake between the groups. JTZ-951 caused transient and mild polycythemia with an increase in plasma erythropoietin level (9.3±3.7 vs 21.0±2.4 mIU/mL) but did not affect plasma VEGF levels. PHD inhibition significantly decreased urinary albumin at 16 and 22 weeks (4.8±0.7 vs 1.9±0.4 and 5.9±1.3 vs 2.3±0.5 mg/mgCr, respectively). At euthanasia, GFR and kidney weight were comparable between the groups while PHD inhibition significantly decreased the epididymal white adipose tissue weight (1980±110 vs 1315±88 mg), total cholesterol (260±26 vs 164±19 mg/dL) and plasma insulin (6.0±1.0 vs 2.8±0.5 ng/mL) levels and increased plasma adiponectin levels (9.8±0.5 vs 15.8±1.4 ng/mL). Histological studies showed the glomerular tuft area, mesangial expansion, podocyte density, peritubular/glomerular capillary density, interstitial fibrosis, and macrophage infiltration were unaffected by PHD inhibition.

Conclusions: Long-term administration of JTZ-951 decreased urinary albumin levels and improved glucose/lipid metabolism without significant adverse effects in a mouse model of type 2 diabetes, indicating that PHD inhibition has potential as a novel therapeutic target in diabetic kidney disease.

Oral Treatment with PBI-4050, a Novel Anti-Diabetic and Anti-Fibrotic Compound, Reduces Renal and White Adipose Tissue Fibrosis in ob/ob Mice

Lyne Gagnon, Marie-Pier Cloutier, Alexandre Laverdure, Jonathan Richard, Liette Gervais, Alexandra Felton, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050 is a first-in-class novel orally active compound which displays anti-inflammatory/antifibrotic activities via a novel mechanism of action. PBI-4050 also displays metabolic properties by reducing blood glucose level. In healthy volunteers, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant adverse effects (SAEs). Similarly, PBI-4050 was well tolerated in chronic kidney disease (CKD) patients with no SAEs observed at 800 mg. PBI-4050 is presently in Clinical Phase II in diabetes (T2D) associated with metabolic syndrome. Preliminary data from this open-labeled phase showed that PBI-4050 significantly reduced glycated hemoglobin (HbA1c, -0.7), and biomarkers (IL-18, resistin, and pentraxin-3) from the first 12 enrolled patients. This study examined the effect of PBI-4050 in leptin-deficient ob/ob mice, a model of type 2 diabetes with renal fibrosis.

Methods: ob/ob mice (6 weeks old) were treated with vehicle or PBI-4050 (100 and 200 mg/kg, oral once a day) from day 1 through 105. Blood glucose, pro-inflammatory/fibrotic gene expression in kidney and white adipose tissue, as well as kidney histology were examined.

Results: In oral glucose tolerance test, PBI-4050 slightly improved glucose metabolism. Collagen type IV and VI gene expression was significantly reduced in white adipose tissue of PBI-4050 treated animals compared to control ob/ob mice. Further characterization of the activity of PBI-4050 in ob/ob mice by quantitative RT-PCR analysis of pro-fibrotic markers demonstrated that PBI-4050 reduced α-SMA, fibronectin, CTGF, MRC-1, MCP-1 and MMP-2 expression in kidney. Furthermore, histomorphometry analysis was performed on kidneys and PBI-4050 was shown to reduce collagen deposition in glomeruli as determined by Picro Sirius staining.

Conclusions: Taken together, these results suggest that PBI-4050 offers the potential as a novel therapy for diabetes, diabetic nephropathy, and pro-inflammatory /pro-fibrotic markers in kidney and white adipose tissue.

TH-PO452

PBI-4050 Protects against Renal Fibrosis and Improves Pancreatic Function in High Fat Diet db/db Mouse Model Lyne Gagnon, Martin Leduc, Mikaël Tremblay, Liette Gervais, François Sarra-Bournet, Alexandra Felton, Marie-Pier Cloutier, Kathy Hince, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050, a novel first-in-class orally active compound which is currently in a phase II clinical trial, significantly reduced glycated hemoglobin (HbA1c) after 12 weeks of treatment in patients with type 2 diabetes and metabolic syndrome with elevated HbA1c despite anti-hyperglycemic treatment. In the present study, we examined whether PBI-4050 affected high fat diet (HFD)-induced triglycerides, insulin and adiponectin levels and the development of renal fibrosis induced by HFD in db/db mice.

Methods: db/db mice were fed with a HFD and received vehicle (water) or PBI-4050 (200 mg/kg/day) by daily gastric gavage from 6 to 21 weeks of age.

Results: High fat diet induced an increase in triglycerides and a decrease in adiponectin levels in serum which were significantly improved by PBI-4050 treatment. PBI-4050 increased serum insulin which correlated with the improvement of β-cell function observed by immunohistochemistry analysis. Kidney function was also improved by PBI-4050 treatment as shown by a decrease in hyperfiltration measured by inulin clearance. Furthermore, expression of IL-6, Collagen I, CTGF, MCP-1, and iNOS in kidney were downregulated by PBI-4050 treatment.

Conclusions: These studies suggest that PBI-4050 improves insulin production and β-cell function and survival, and prevents renal fibrosis in association with regulation of pro-fibrotic biomarkers in HFD obese db/db mice.

TH-PO453

Oral Treatment with PBI-4547, a Novel Anti-Diabetic and Anti-Fibrotic Compound, Reduces Blood Glucose and Renal Fibrosis in ob/ob Mice Brigitte Grouix, Marie-Pier Cloutier, Alexandra Felton, Jonathan Richard, Alexandre Laverdure, Liette Gervais, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Type II diabetes is a major health problem worldwide. Adiponectin has been shown to play important roles in the regulation of energy homeostasis and insulin sensitivity, and its low level is predictive of future development of diabetes. PBI-4547 is an orally active compound that displays anti-fibrotic activities via a novel mechanism of action. This study examined the effect of PBI-4547 in leptin-deficient ob/ob mice, a model of type 2 diabetes with renal fibrosis.

Methods: ob/ob mice (6 weeks old) were treated with vehicle or PBI-4547 (10 and 50 mg/kg, oral once a day) from day 1 through 105. Blood glucose, white adipose tissue (WAT) histology, kidney pro-inflammatory/fibrotic gene expression, as well as serum adiponectin levels were examined.

Results: In oral glucose tolerance test, PBI-4547 increased glucose metabolism. Serum cholesterol and triglyceride levels were also reduced by PBI-4547. Serum level of adiponectin was reduced in ob/ob non-treated mice and strongly increased in PBI-4547-treated mice. Histomorphometry analysis performed on WAT indicated that PBI-4547 treatment reduced fibrosis, inflammatory cell infiltration and adipocyte size. Further characterization of the activity of PBI-4547 by quantitative RT-PCR analysis of pro-fibrotic markers in the kidney demonstrated that PBI-4547 reduced α-SMA, fibronectin, CTGF, MRC-1, MCP-1 and MMP-2 expression. Moreover, PBI-4547 reduced collagen deposition in glomeruli as determined by Picro Sirius staining.

Conclusions: Taken together, these results suggest that PBI-4547 offers the potential as a novel therapy for diabetes, diabetic nephropathy, and obesity by reducing blood glucose levels, reducing pro-inflammatory and pro-fibrotic markers in kidney, and by increasing serum adiponectin to regulate energy homeostasis.

TH-PO454

Effects of LCZ696 on Blood Pressure and Renal Injury in Type 2 Diabetic OLETF Rats with Overt Proteinuria Akira Nishiyama,[1] Yoshio Konishi,[2] Takashi Morikawa,[2] Daisuke Nakano,[1] Masahito Imanishi.[2] *[1]Dept of Pharamacology, Kagawa Univ Medical School, Japan; [2]Dept of Nephrology and Hypertension, Osaka City General Hospital, Japan.*

Background: In the present study, we aimed to examine the effect of LCZ696, an angiotensin receptor-neprilysin inhibitor, on blood pressure and renal injury in type 2 diabetic Otsuka-Long-Evans-Tokushima-Fatty (OLETF) rats with overt proteinuria.

Methods: In OLETF rats, vehicle (n=10), valsartan (30 mg/kg/day, n=10), LCZ606 (68 mg/kg/day, n=9) or valsartan plus hydralazine (3 mg/day, n=10) was treated from 56 to 80 weeks of age.

Results: At baseline (56-week-old), diabetic OLETF rats showed hypertension, overt proteinuria, glomerular injury (glomerular PAS positive area) and tubulointerstitial fibrosis (Sirius Red-positive area). At 80-week-old, vehicle-treated OLETF rats showed developed hypertension and proteinuria, severe glomerular injury and tubulointerstitial fibrosis, and increases in plasma BUN and creatine levels. Treatment with LCZ696 or valsartan plus hydralazine similarly caused greater blood pressure reduction than valsartan. On the other hand, LCZ696 caused greater attenuation of developments of proteinuria, glomerular injury and tubulointerstitial fibrosis than valsartan or valsartan plus hydralazine. LCZ696 also prevented the increases in plasma BUN and creatine levels.

Conclusions: These data suggest that LCZ696 elicits a reno-protective effect in type 2 diabetes with hypertension and nephrotic-range proteinuria.

Multi-Glycoside of *Tripterygium wilfordii* Hook. F. Alleviates Glomerulosclerosis in the Diabetic Nephropathy Model Rats via Inhibiting Microinflammation and IL-6/JAK2/STAT3 Signaling Activity Jingjing Yang,[1] Yigang Wan.[2] *[1]Dept of Graduate School, Nanjing Univ of Chinese Medicine, Nanjing, China; [2]Dept of Traditional Chinese Medicine, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School, Nanjing, China.*

Background: Multi-glycoside of *Tripterygium wilfordii* Hook. f. (GTW), an extractedphyto medicine has been proved clinically effective in improving microinflammation in early diabetic nephropathy (DN) patients in China.However, the therapeutic mechanisms involved in vivo remain unclear.In the process of early DN, microinflammation and the activation of IL-6/JAK2/STAT3are the important mechanisms by which hyperglycemia contributes to glomerulosclerosis (GS).Therefore, this study aimed toexamine the ameliorative effects of GTW on GS, then to clarify its anti-microinflammatory mechanisms by inhibiting IL-6/JAK2/STAT3 signaling activities in kidneys.

Methods: All rats were divided into 4 groups, the Sham group, the Sham+GTW group, the Vehicle group and the GTW group. The suitable dose of GTW and vehiclewere daily administrated for 8 weeks after the induction of DN by unilateral nephrectomy combined with streptozotocin (STZ)intraperitoneal injections.

Results: The results showed that, GTWimprovedthe DN model rats' general condition and biochemical parameters, but did not lower blood glucose; GTW attenuated GS and suppressed glomerular microinflammation including the infiltration of macrophage in glomeruli and the protein overexpressions of IL-6, TNF-α and TGF-β1 in kidneys; GTW inhibited the protein overexpressions of p-JAK2 and p-STAT3 in kidneys, as well as other classical inflammatory signaling molecules including p-p38MAPK and NF-κB.

Conclusions: In conclusion, using the modified DN model rats, we expounded that GTW, as a natural regulator in vivo, alleviates GS without lowering hyperglycemia in the DN model rats, by way of anti-microinflammation including reducing macrophage infiltration in glomeruli, suppressing TNF-α and TGF-β1 overexpressions in kidneys and inhibiting IL-6/JAK2/STAT3 signaling activity. This study may provide the first evidence in vivo that GTW directly contributes to the prevention of DN via an anti-microinflammatory action.

Treatment with Sodium Acetate Reduces Diabetic Kidney Injury in Mice Xiaochen Chen,[1] Steven J. Chadban,[1,2] Jin Ma,[1] Tony King-Tak Kwan,[1] Huiling Wu.[1,2] *[1]Kidney Node Laboratory, The Charles Perkins Centre, Univ of Sydney, Australia; [2]Renal Medicine, Royal Prince Alfred Hospital, Australia.*

Background: Short-chain fatty acids (SCFAs) are derived from the fermentation of dietary fibre by the intestinal microbiota and exert profound effects on immune responses and inflammation. SCFAs delivered by diet or intraperitoneal (ip) injection have been found to attenuate the development of autoimmune and inflammatory diseases. Here we test the hypothesis that the administration of SCFA will attenuate kidney injury in streptozotocin (STZ)-induced diabetic nephropathy (DN).

Methods: DN was induced in C57BL/6 mice by STZ. Two weeks after STZ injection, both diabetic and non-diabetic mice received daily intraperitoneal injections of either sodium acetate (SA), 200mg/kg i.p./animal or saline for 6 weeks and were then switched to oral sodium acetate 150mM in their drinking water for the duration of the study. Samples were collected at 12 weeks post-induction of diabetes.

Results: Diabetic mice that received SA or saline remained similarly hyperglycaemic. SA-treated diabetic mice exhibited reduced albuminuria compared to control diabetic mice (ACR 161±46 versus 333±248, $p<0.05$). SA-treated diabetic mice demonstrated improvement in histological parameters compared to control diabetic mice, including glomerular hypertrophy (glomerular volume: $15.8\pm1.1\times10^4$ versus $20.6\pm4.4\times10^4\mu m^3$, $p<0.01$), glomerular hypercellularity (25±2 versus 29±3 cells/glomerulus, $p<0.01$), podocyte injury (16±1 versus 13±1 $WT1^+$ podocytes/glomerulus, $p<0.01$) and interstitial macrophage accumulation (13±3 versus 18±6 $CD68^+$ cells/field, $p<0.01$). mRNA expression of cytokines(IL6&TGF-β),chemokine(CCL2) and pro-fibrotic(fibronectin) genes in the kidney were attenuated in diabetic mice treated with SA versus control diabetic mice ($p<0.05$).

Conclusions: Treatment with sodium acetate provided partial protection against the development of diabetic nephropathy in mice with STZ-induced diabetes. Dietary manipulation of the microbiome warrants further exploration in the prevention and management of diabetic nephropathy.

TH-PO457

Novel Immunomodulatory Cytokine Offers Multi-Pronged Protection from Type-2 Diabetic Nephropathy (T2DN) Rahul Sharma,[1] Marta Stremska,[1] Saleh Mohammad,[1] Poonam R. Sharma,[2] Mark D. Okusa.[1] *[1]Div of Nephrology, Dept of Medicine, Univ of Virginia, Charlottesville, VA; [2]Dept of Biomedical Engineering, Univ of Virginia, Charlottesville, VA.*

Background: While inflammation contributes to T2DN pathogenesis, regulatory T cells (Treg) are protective. We developed a novel cytokine (IL233) bearing IL-2 and IL-33 activities in a single molecule. IL233 promotes Treg and protects mice from acute kidney injury and lupus glomerulonephritis (Sharma R et al, Kidney week 2015). We investigated whether IL233 will enhance Treg, inhibit inflammation and protect from T2DN.

Methods: Male BTBR.Cg-*Lep*^{ob} (Ob) mice were treated with saline or IL233 (3pmoles/g/d) for 5 days at 4-5 weeks or 10-12 weeks of age. Body weight, fasting blood glucose, glucose tolerance, kidney function (urinary albumin creatinine ratio, ACR; mean±SEM) were analyzed. Spleen, kidneys and visceral fat were analyzed by flow cytometry and histology at necropsy.

Results: Compared to controls, treatment of 4-5wk old Ob mice with IL233 induced a 2x increase in Treg as measured in the blood, which persisted for > 4 months in lymphoid organs (1.5x) and adipose tissue (2.3x) upon necropsy. IL233 treated Ob mice had lower proteinuria (ACR: 29±4 mg/g at necropsy) than controls (ACR: 133±35 mg/g). IL233-treatment also inhibited diabetes (lower blood glucose and normalization of glucose tolerance) and obesity (lower body and adipose tissue weights) in the Ob mice. Kidney histology of control Ob mice showed leukocytic infiltration and mesangial expansion, which was inhibited in the IL233 treated mice. IL233 treatment of the 10-12 weeks old Ob mice also resulted in lower proteinuria (2.4x higher ACR in controls over IL233-treated). This was accompanied with lower blood glucose starting two weeks post treatment and persisting until the end of study, when the control mice had to be euthanized. Along with increasing Treg, IL233 also enhanced Treg's ability to produce IL-10.

Conclusions: The novel cytokine IL233 containing the activities of IL-2 and IL-33 bears therapeutic potential as it protects genetically obese mice from T2DN, by regulating multiple contributors of pathogenesis, namely inflammation, obesity and diabetes.

Identifying Novel Therapies in Diabetic Kidney Disease Mark Nguyen,[1] Minnie Sarwal.[2] *[1]Dept of Nephrology, Univ of California San Francisco, San Francisco, CA; [2]Dept of Surgery, Univ of California San Francisco, San Francisco, CA.*

Background: The development and progression of diabetic kidney disease (DKD) is thought to involve a combination of hemodynamic, metabolic, ischemic, and inflammatory factors; however, the exact mechanism remains to be elucidated. Given the pro-inflammatory component of DKD, gene expression of leukocytes is thought to provide additional insight into the disease. Here we describe microarray analysis of peripheral blood mononuclear cells (PBMCs) in diabetic patients with varying levels of albuminuria. The findings were compared against publicly available gene expression data from human diabetic kidney biopsies.

Methods: Microarray experiments were performed on PBMCs isolated from a cohort (Cohort I) of 33 healthy and diabetic patients (10 healthy controls, 11 normoalbuminuria, 7 microalbuminuria, and 5 macroalbuminuria). Gene expression across different levels of albuminuria were measured and ranked. From an independent cohort (Cohort II) of publicly available microarray experiments, a total of 67 microarray experiments (25 with DKD and 42 control) of kidney glomeruli were analyzed utilizing expression genome-wide association study. Immunohistochemistry (IHC) on tissue was done to validate protein expression.

Results: In Cohort I, there were 859 genes significant ($p < 0.05$) for increasing expression with higher levels of albuminuria. The meta-analysis of Cohort II, revealed 326 significant up regulated genes. There were 28 genes with increased expression in PBMCs and glomeruli with hypergeometric enrichment p value of 5E-04. From the list of candidate genes, we identified genes such as tumor necrosis factor and toll like receptor which have been previously described in the literature as playing a role in DKD progression thereby providing some validation to this methodology. Two targets, CCR1 and FcER1, were identified as potential mediators of disease progression. Protein expression was validated with IHC.

Conclusions: We described a novel study involving high throughput data to discover a number of candidate genes that may play a critical role in the development and progression of DKD in the hopes it will lead to novel therapies.

High-Fat Diet-Fed Medaka Model for Human Diabetic Nephropathy and Hyperglycemia Tomoko Obara. *Cell Biology, Univ of Oklahoma Health Sciences of Center, Oklahoma City, OK.*

Background: Chronic hyperglycemia promotes diabetic nephropathy, leading to chronic kidney diseases (CKD) associated with nephron loss. CKD requires dialysis or kidney transplantation for survival. There is a critical need for new therapeutic approaches to preserve kidney function using suitable animal models that mimic the human pathology of diabetic nephropathy and hyperglycemia. Due to the polygenic origin of diabetes, therapeutic approaches must target multiple signaling pathways. The membrane metallo-endopeptidase (MME) activates peptide hormones and generates bioactive peptides distributed throughout the body. *MME* knockout mice developed dyslipidemia and hyperglycemia, however its renal effects are poorly understood. Mechanisms of renal effects of MME in diabetic nephropathy and hyperglycemia remain unexplored.

Methods: We established a high-fat diet (HFD)-fed medaka model that mimics human diabetic nephropathy and hyperglycemia. By using this model, we performed shotgun proteomics, western blot, and subcellular immunohistochemical analysis and discovered MME down-regulation in the kidney. We applied genetics to confirm the MME involvement in diabetic nephropathy and hyperglycemia in medaka and mouse models. Furthermore, we confirmed the relevant role of MME in diabetic human kidney specimens. Finally, we evaluated whether this model can be used for drug screening.

Results: We demonstrated that 1) MME is down-regulated in HFD-fed medaka kidney by shotgun HPLC-ESI-MS/MS, western blot, and subcellular immunohistochemical analysis, 2) *MME* knockdown in medaka and mouse adults resulted in diabetic nephropathy and hyperglycemia, 3) MME protein subcellular downregulation is confirmed in the glomeruli specimens from human patients with diabetes, 4) treatment with Telmisartan, omega-3-PUFAs, and metformin prevented diabetic nephropathy and hyperglycemia induced by HFD-fed medaka.

Conclusions: These data implicate that our new animal models will highlight novel therapeutic targets suitable for preventing diabetic nephropathy and resulted in decreased kidney function in response to hyperglycemia. In summary, these discoveries will lead to identification of highly specific therapeutic targets against human CKD.

Lacking Fructokinase-A Exacerbates Renal Injury in Streptozotocin-Induced Diabetic Mice Tomohito Doke,[1] Takuji Ishimoto,[1] Takahiro Hayasaki,[1] Miguel A. Lanaspa,[2] Richard J. Johnson,[2] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]Dept of Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Renal Diseases and Hypertension, Univ of Colorado Denver, Aurora, CO.*

Background: Ketohexokinase (KHK), a primary enzyme for fructose, exists as two isoforms, KHK-C and KHK-A. We have reported that endogenous fructose and its metabolism produced by polyol pathway activation in diabetes may have a deleterious role in the pathogenesis of diabetic nephropathy using mice lacking both isoform KHK-A and KHK-C. KHK-C has higher affinity for fructose compared to KHK-A. Although both isoforms express in proximal tubule, the role of KHK-A is not yet elucidated. The aim of this study is to determine the role of KHK-A in the development of diabetic nephropathy in mice.

Methods: Male wild-type mice, KHK-A knockout mice, and KHK-A/C knockout mice (lacking both isoforms) were used. Diabetes was induced with intraperitoneal injections of streptozotocin (50 mg/kg/day, 5 days). Body weight, blood glucose were measured regularly. At 18 weeks, urine and blood samples and kidney tissues were collected. Kidney injuries were assessed for proteinuria, urinary NGAL, serum creatinine, and histology. Gene and protein expressions related to inflammation, hypoxia, oxidative stress, and polyol pathway enzymes were analyzed.

Results: The level of blood glucose was similar among three genotypes during study period. However, diabetic KHK-A knockout mice showed significant increase of urinary NGAL, renal dysfunction, glomerular hypertrophy, and tubular injuries accompanied by increased HIF1α expression, inflammatory cytokines and macrophage infiltration (F4/80 staining) compared to diabetic KHK-A/C knockout mice. While diabetic wild type mice also showed increase of urinary NGAL, the degree of renal injury, inflammation, hypoxia and oxidative stress was significantly less than diabetic KHK-A knockout mice.

Conclusions: Kidney injury in streptozotocin-induced diabetes was exacerbated in mice lacking KHK-A, but is prevented in mice lacking both isoforms, KHK-C and KHK-A. These results suggest that KHK-A has an important role in attenuation of endogenous fructose-related kidney injury in diabetic mice.

TH-PO461

Inhibition of YAP Activity Ameliorates Diabetic Nephropathy Jianchun Chen, Ming-Zhi Zhang, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Yes-associated protein (YAP) is a transcriptional regulator modulated by the Hippo signaling pathway. The Hippo/YAP signaling pathway controls the balance of cell proliferation, cell differentiation and cell death to define organ size, as well as to mediate fibrotic injury. Activation of YAP leads to nuclear translocation and interaction with the TEA domain (TEAD) family of transcription factors. The current studies investigated the effect of pharmacologic inactivation of YAP-TEAD interactions on development of diabetic nephropathy (DN).

Methods: We utilized a model of accelerated DN (STZ-eNOS-/-). Diabetic mice were treated for 20 weeks with vehicle or verteporfin (100 mg/kg, every other day), a porphyrin derivative that is used clinically as a photosensitizer for neovascular macular degeneration and that inhibits YAP-TEAD interactions.

Results: At 20 weeks of diabetes, verteporfin significantly decreased albuminuria (ACR: 232.7 ± 40.3 vs. 365.0 ± 31.8 μg/mg, $P < 0.05$, $n = 7$) and glomerulosclerosis index (0.74 ± 0.03 vs. 0.96 ± 0.06, $P< 0.01$, $n = 7$). It also decreased podocyte loss (15.83 ± 0.40 vs. 12.54 ± 0.60 podocytes/glomerulus, $P < 0.005$, $n = 7$) as well as decreasing kidney macrophage infiltration and increasing M2 markers including arginase 1 and YM-1. Immunoblotting showed that DN increased expression of the YAP-TEAD target genes CTGF and amphiregulin, which were inhibited by verteporfin. Immunostaining demonstrated higher CTGF expression in podocytes from vehicle-treated mice than in verteporfin-treated mice. Immunoblotting also indicated that verteporfin inhibited expression levels of markers of dedifferentiation and fibrosis, including TGF-ß, p-SMAD-2, a-SMA, snail-1, Kim-1, vimentin and collagen I.

Conclusions: Inhibition of YAP-TEAD activation ameliorates injury in a model of experimental diabetic nephropathy, suggesting an important role for this pathway in development of diabetic kidney injury and indicating that it may be a target for therapeutic intervention.

TH-PO462

p66Shc Knockout Prevents Development of Diabetic Nephropathy in Streptozotocin-Treated Dahl Salt-Sensitive Rats Bradley S. Miller, Shoshana R. Blumenthal, Kevin D. Wright, Andrey Sorokin. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: One of the main pathophysiological mechanisms, which are responsible for the kidney damage associated with diabetic nephropathy (DN), is the generation of reactive oxygen species (ROS) by mitochondrial electron transport system. The purpose of this study was to test whether adaptor protein p66Shc, a redox protein capable of promoting of mitochondrial ROS generation, is the cause of renal damage in streptozotocin-treated Dahl Salt-Sensitive (SS) rats.

Methods: p66Shc rat knockout and rats with a knock-in Ser36Ala substitution in p66Shc were generated using engineered Zinc Finger Nucleases (ZFN) and, in case of knock-in, also a template plasmid containing the desired mutation. Diabetes was induced in the SS control and mutant rats by an injection of streptozotocin (STZ). Hyperglycemia, excessive urination, body weight, albuminuria and display of renal pathologies, typical for patients with DN, was evaluated for the time period of twelve weeks after treatment.

Results: Following STZ injection SS rats develop hyperglycemia, excessive urination, albuminuria and other renal pathologies which accompany the progression of DN in patients. Both, p66Shc knockout and introduction of the mutation into p66Shc mutant, which incapacitated its translocation to mitochondria, prevented the development of DN in our rat model.

Conclusions: Adaptor protein p66Shc plays the principal role in the progression of DN in a STZ-triggered rat model of diabetes. The Ser36Ala substitution in p66Shc, which disables the phosphorylation-mediated mitochondrial translocation of p66Shc, is sufficient to prevent increase of albuminuria after treatment with STZ. Thus, the rat experimental model of DN provides novel opportunities for identification of new molecular targets and confirmation of previously identified molecules for therapeutic intervention in DN. The inhibiting of mitochondrial translocation of p66Shc could be considered as an efficient therapeutic strategy to combat DN.

TH-PO463

Role of P2Y2 Receptor in Adipogenesis and Metabolism Yue Zhang,[1] Carolyn M. Ecelbarger,[2] Christa E. Müller,[3] Anna U. Brandes,[1] Tao Liu,[1] Lisa Lesniewski,[1] Bellamkonda K. Kishore.[1] *[1]Univ of Utah & VA Medical Center, Salt Lake City, UT; [2]Georgetown Univ, Washington, DC; [3]Univ of Bonn, Bonn, Germany.*

Background: Previously we reported that genetic deletion of $P2Y_2$ receptor (R) confers significant resistance to the development of high-fat diet (HFD)-induced obesity, without reducing the food intake or causing steatorrhea. To understand the mechanisms involved in this protection, we investigated adipogenesis, lipid tolerance, energy metabolism and browning of white fat in $P2Y_2$-R knockout (KO) and wild type (WT) mice.

Methods: Preadipocytes from KO or WT mice were induced to mature in vitro in the absence or presence of AR-C 118925 to block $P2Y_2$-R. Intraperitoneal lipid tolerance test (LTT) was conducted in KO and WT mice. Metabolic Phenotype of KO and WT mice was determined in CLAMS Metabolic Cages. Browning of white fat was induced in vivo by injecting CL316,243 (β_3-adrenergic agonist) for 6 days or in vitro by adding rosiglitazone (PPARγ agonist) to the culture medium. UCP1 mRNA expression was used as an index of browning.

Results: When induced in vitro, preadipocytes derived from KO mice did not mature as robustly as those from WT mice, as assessed by the accumulation of lipid droplets (oil red staining). Blockade of $P2Y_2$-R in preadipocytes derived from WT mice prevented their maturation in a dose-dependent manner. Under basal conditions KO mice had significantly higher serum triglycerides and showed impaired lipid tolerance as compared to WT mice. Metabolic phenotyping revealed significantly increased VO_2 and energy production and decreased RER (respiratory exchange ratio) in KO mice vs. WT mice. When browning was induced, UCP1 expression was significantly higher in the inguinal fat of KO mice or adipocytes derived from KO mice vs. WT mice.

Conclusions: These results suggest that $P2Y_2$-R plays a significant role in the development of diet-induced obesity by promoting maturation of adipocytes, altering adipocyte lipid metabolism, and by negatively impacting browning of fat and thereby energy metabolism. Thus, targeting $P2Y_2$-R may be a viable strategy to prevent or treat diet-induced obesity.

Longitudinal Characterization of Glomerular Filtration Rate of the Naïve ZSF1 Rat Robin E. Haimbach, Li-Jun Ma, Maarten Hoek, Shirly Pinto, Xiaoyan Zhou. *Dept of Cardiometabolic Diseases, Merck & Co., Inc., Kenilworth, NJ.*

Background: The obese ZSF1 rat exhibits many features of metabolic syndrome in humans and is widely used as a translational model of diabetic nephropathy. However, the glomerular filtration rate (GFR) changes over time have not been fully characterized. Therefore, we evaluated FITC-sinistrin as a method to determine GFR and to characterize changes in GFR in ZSF1 rats with disease progression.

Methods: Male lean and obese ZSF1 rats were used for GFR measurements every 1-5 weeks from the age of 5 to 50 weeks old. GFR was measured using the plasma disappearance curve of the transcutaneous fluorescence of FITC-sinistrin excited and detected by a skin mounted detector (Mannheim Pharma & Diagnostics). In order to determine the robustness of FITC-sinistrin GFR measurement, additional groups of aged male ZSF1 rats (43-48 weeks old) were studied to compare the sensitivity and variability of FITC-sinistrin GFR with that of estimated GFR by creatinine clearance.

Results: Between 5 and 11 weeks of age, significant kidney hyperfiltration occurred ranging from a 22-45% increase compared to the lean ZSF1 control. After 15 weeks of age, we observed a progressive decrease in GFR until week 25 in both obese and lean rats. After week 25, the obese ZSF1 showed an increased rate of decline in kidney function compared to the lean ZSF1. Between 45-50 weeks, the ZSF1 obese rat displayed a sustained GFR decrease of ~50% compared to the lean. GFR values were replicated in three cohorts for the respective age groups of lean and obese rats. FITC-sinistrin GFR compared to creatinine clearance provides a 1.8-3.3x greater effect size that provides a more sensitive method to detect changes in GFR.

Conclusions: Data from these studies show that FITC-sinistrin GFR measurement is a more robust measurement of GFR than creatinine clearance in the ZSF1 rat. Consistent with the classical manifestation of early stage human diabetic nephropathy, the hyperfiltration phase of diabetic nephropathy in the male ZSF1 rat occurs at an early age (5-11 weeks old), with the obese ZSF1 GFR decline outpacing the lean ZSF1 GFR decline after 25 weeks of age.

TH-PO465

A New Model for Diabetic Nephropathy: A Hypoxia-Induced Antioxidant Metallothionein-3 BACTG Mice Yumi Takiyama,[1] Ryoichi Bessho,[1] Takahiko Nakagawa,[2] Masakazu Haneda.[1] *[1]Dept of Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan; [2]Industry-Academia-Goverment Collaboration Promotion Center, Nara Medical Univ, Nara, Japan.*

Background: Metallothionein (MT) is a cysteine-rich protein with low molecular weight, and an antioxidant against the toxicity of metals, ischemia, and ROS. MT3 is one of the four MTs, which is originally cloned as a neuronal growth inhibitory factor from brain and is decreased in Alzheimer's brain. We have recently found that MT3 is a target for Hypoxia Inducible Factor-1 and MT3 protein expression is increased in tubular cells in diabetic nephropathy (DN). In addition, we found four putative hypoxia response elements containing the consensus sequence (A/G) CGTG within the human MT3 gene, not in mouse. The purpose of this present study was to reveal the pathophysiologic potential of MT3 in DN.

Methods: In this study, we generated transgenic mice, harboring a 40-kb bacterial artificial chromosome (BAC) expressing human MT3 mRNA and protein to generate humanized BAC transgenic mice (MT3 BACTG). By inducing hypoxic condition in vivo, we used streptozotocin-induced diabetic or aged MT3 BACTG mice.

Results: Aged transgenic mice which overexpress MT3 in renal tubules showed the nodular glomerulosclerosis like Kimmelstiel-Wilson lesion, capsular drop and doughnut lesions without hyperglycemia. The glomerular nodule in transgenic mice was negative for phosphotungstic acid-hematoxilin stain. Electron microscopy showed no electron dense deposits in mesangial lesion with thickening of the glomerular basement membranes and podocyte process effacement.Intriguingly, endothelial cell marker CD31 staining showed peritubular capillary dilatation accompanied with the swelling endothelial cells which caused narrowing capillary lumen. Multiple low-dose streptozotocin injections induced moderate hyperglycemia, histological mesangial expansion and an accumulation of hyaline material in collapsing glomerular segments without glomerular hypertrophy.

Conclusions: Overexpressed MT3 in tubular cells in BACTG mice complicates peritubular capillary, which could retrogradely cause glomerular hypertension, leading to the glomerular lesion. Humanized MT3 BACTG mice propose a new model for the study of DN.

Myostatin, a New Mediator of Inflammation and Tissue Injury in Diabetic Nephropathy (DN) Giacomo Garibotto, Daniela Verzola, Samantha Milanesi, Francesca Ansaldo, Francesca Viazzi, Annalisa Carta, Daniela Picciotto, Francesca Costigliolo, Chiara Barisione. *DIMI, Genoa Univ and IRCCS AOU San Martino-IST, Genoa, Italy.*

Background: Myostatin (MSTN), a structurally-related member of the TGFβ superfamily, acts as negative regulator of tissue growth and promotes fibrosis/atrophy. Although initially described as a negative regulator of muscle growth, MSTN has been found in other tissues, including the kidney in pigs. In humans, MSTN participates to the

body response to hyperglycemia. However, there is no information regarding MSTN in the normal kidney and in patients with DN. The aim of this study was to evaluate the role of MSTN in the normal kidney and in DN.

Methods: MSTN and Activin Receptor 2B (rtPCR and immunohistochemistry) were evaluated in microdissected tubuli and glomeruli from normal kidneys (n=10) (C) and DN (n=15, proteinuria 2 g/d, eGFR 45+2 ml/min). Moreover, MSTN regulation in response to diabetic milieu was studied in proximal human tubule (HK-2) cells.

Results: In the normal kidney MSTN mRNA was faintly expressed both in the tubular and glomerular compartments. In DN, MSTN mRNA and protein were 5-6 folds overexpressed with respect to C ($p<0.05$-0.001) in the tubular compartment, and even more (~40 folds, $p<0.05$), in the glomeruli. Glomerular MSTN was localized in podocytes and mesangial cells. Tubular cells, interstitium and mainly CD45+ cells infiltrates were highly MSTN positive. Activin Receptor 2B protein expression was localized in glomeruli, tubuli and interstitial cells both in C and DN kidneys. However, Activin Receptor 2B was downregulated in all compartments in DN. In HK-2 cells, high glucose, glycated serum and glycated albumin upregulated both MSTN mRNA and protein (by ~6 and ~2 folds respectively $p<0.05$-0.01). When MSTN was added to HK-2 cultures (48 hours) cell division was slowed and MCP1 and RANTES mRNAs expression rose ($p<0.01$).

Conclusions: Our data indicate that MSTN is expressed in the human kidney and overexpressed in DN. Diabetic milieu induces MSTN in PTECs. In vitro, MSTN slows cell proliferation and induces inflammatory changes. The above reported data suggest that MSTN could be a new mediator of inflammation and injury in DN.

TH-PO467

High Intensity Interval Training (HIIT) Prevent Proteinuria on STZ Diabetic Rats Natália Lopes Reinecke, Rafael DaSilva Luiz, Rodolfo Rosseto Rampaso, Waldemar S. Almeida, Nestor Schor. *Medicine/Nephrology, UNIFESP, São Paulo, São Paulo, Brazil.*

Background: The benefits of physical exercise on Diabetes are already well known, however, the insertion of these patients on a regular physical training program is still a challenge, given that 'lack of time' remains one of the most commonly cited barriers to regular exercise participation. HIIT, which involves repeated bursts of vigorous exercise interspersed with periods of rest, has been demonstrate to have potential cardio metabolic benefits in Diabetic or pre-diabetic subjects, even requiring a lower commitment time than the current recommendation of exercise for this population. However, the effects of HIIT on renal function of diabetic rats have yet no been studied. The aim of this study was to examine the effects of low-volume HIIT on renal function and physical capacity in STZ Diabetic rats.

Methods: Wistar rats were submitted to HIIT following a protocol: 10 bursts of 1 minute(90% of maximal effort test) intersected with 10 periods of low intensity walking(50% of maximal effort test), 3days/wk, 8wk total. Diabetes was induced by a single injection(50mg/kg i.v.). Animals were divided into three groups 6 to 8 animals/group: Sedentary Control(SC), Sedentary Diabetic(SD) and Diabetic HIIT(DHIIT).

Results: HIIT improved the exercise capacity as shown by the higher maximal velocity reached in the exercise test (37±1.55vs25.2±2.7m/min, DHIITvsSD,$p<0.001$). HIIT also prevented the increased proteinuria caused by Diabetes in comparison to SD(9.9±6vs19.6±1.9mg/dL/24h, $p<0.05$,respectively) with no difference between DHIITvsSC(9.9±6vs9.0±2.3). The urinary volume(67.2±19.3vs95.4±13.8mL/24h,$p<0.05$), the water ingestion(93.4±24.5vs124.2±22.1mL/24h,$p<0.05$), and the loss on muscular weight(1.00±0.19vs0.73±0.22g Tibial muscle,$p<0.05$) were also attenuated by exercise in HIIT group when compared to SD group.

Conclusions: Results of this study demonstrate that HIIT can improve exercise capacity, prevent the lower glomerular function(showed by the proteinuria) and attenuate other diabetic symptoms as polyuria, polydipsia and sarcopenia. These data suggests that HIIT can be a time-efficient strategy to a non-pharmacological treatment to minimize Diabetes complications.

TH-PO468

Bias and Imprecision in Net Acid Excretion Predictions Lynda A. Frassetto,[1] Tanushree Banerjee.[1] *[1]UCSF; [2]Sunshine U.*

Background: Diets contribute to the body's net acid or base load. Several equations using diet cation, anion and protein content have been developed to help estimate whether specific foods would be acid or base containing and tested against the current gold standard, 24 hour net acid excretion(NAE), since measuring NAE requires a research lab. NAE has also been shown to correlate with urinary sulfate, organic acid and ion markers (UPRAL). How well equations or UPRAL predict any one individual's actual NAE has not been evaluated.

Methods: Retrospective analyses of studies where NAE and UPRAL were reported for same participant following both an acid and alkali dietary consumption were included. They also contained individual dietary data pertinent to estimating net endogenous acid production (NEAP). Estimate NEAP according to Frassetto (F), Remer/Manz (R), and Lemann (L) were computed in their usual manner. Bland-Altman technique was used to compute the accuracy and precision of the NEAP equations to NAE during the acid-forming and alkali consumption diets. All statistical analyses were completed using XLStat.

Results: The equations were too imprecise to NAE for any individual, although the accuracy of NEAP-R at a group level was reasonable for the acid-forming diets. Similar results for UPRAL vs NAE was noted, with agreement between the two techniques for the alkaline diets. See Table 1.

		Typical acid forming diets			Alkali supplementation		
	n	Bias	95% CI for the bias	Limits of agreement	Bias	95% CI for the bias	Limits of agreement
$NEAP_R$ vs NAE(mEq/d)	40	-0.7	-7.5, 5.9	-41.7, 40.2	-6.6	-13.1, -0.02	-46.8, 33.6
$NEAP_F$ vs NAE (mEq/d)	55	11.3	5.2, 17.4	-32.9, 55.5	35.1	25.7, 44.5	-32.8, 103.1
$NEAP_L$ vs NAE(mEq/d)	53	6.3	0.5, 12.2	-35.3, 47.9	19.4	11.1, 27.8	-39.8, 78.7
UPRAL vs NAE (mEq/d)	17	5.6	0.02, 11.1	-15.6, 26.7	0.93	-8.5, 10.4	-35.1, 37.0

Conclusions: Both dietary NEAP estimates and UPRAL are more precise for group as opposed to individual NAE estimates, and results differ depending on the diet acid or base load. Researchers may wish to collect both NEAP as well as UPRAL data when doing dietary acid experiments.

Genotype, Phenotype Correlations in Distal Renal Tubular Acidosis Benjamin A. Oliveira, Marilina Antonelou, Stephen B. Walsh, Detlef Bockenhauer, Robert Kleta, Robert J. Unwin. *Dept Renal Medicine, Univ College London, London, United Kingdom.*

Background: Distal renal tubular acidosis (dRTA) is characterized by an inability of α-intercalated cells in the distal nephron to secrete H^+ ions. Mutations leading to dRTA have been found in the anion-exchanger 1 (AE1), and vH^+ATPase subunits. AE1 mutations may be autosomal dominant or recessive, and dRTA has been described in compound heterozygotes who are also have the AE1 red cell disorder Southeast Asian Ovalocytosis (SAO). We sought to compare biochemical and hematological data among different genetic groups.

Methods: We compared patients with mutations in AE1 or vH^+ATPase subunits at our institution. Phenotypic data was collected including baseline electrolytes, hematological results, and urine tests.

Results: Tenty-six patients had a gene mutation known to cause dRTA; 5 were due to vH^+ATPase subunit mutations, 19 were due to AD AE1 mutations and 2 were AE1 compound heterozygotes for dRTA and SAO causing mutations ('dRTA/SAO group'). We found that serum bicarbonate was significantly lower in the dRTA/SAO group: 17 versus 23.5 and 22.4 mmol/L in the vH^+ATPase subunit and AD AE1 groups respectively ($P = 0.02$). There was a trend towards both AE1 groups having a lower citrate excretion than the vH^+ATPase subunit group; 0.12 versus 2.16 mmol/24h ($p=0.053$). The dRTA/SAO group had a hemoglobin of 111g/l which was significantly lower than the other two groups; 128 and 140 g/l ($p = 0.034$). The serum creatinine in the vH^+ATPase group was 73 µmol/L, which was significantly lower than the SAO and the AD AE1 groups; 124 and 112, respectively ($p =0.04$).

Conclusions: The lower hemoglobin seen in the dRTA/SAO group may reflect sub-clinical hemolysis known to occur in this group. Both the AE1 groups together had significantly worse GFR than the vH^+ATPase group; the trend towards lower serum bicarbonate and lower citrate excretion also suggests a more severe systemic acidosis. Acidosis may be both a factor contributing to deteriorating GFR, or a consequence. It has been suggested that vH^+ATPase subunit mutations cause a more severe phenotype than AE1 mutations; these data suggest that this might not always be the case and further work is required to elucidate this.

TH-PO470

Association of Serum Bicarbonate Levels with a Novel Marker of Serum Calcification Propensity Jessica B. Kendrick,[1,2] Emily Decker,[1] Andreas Pasch,[3] Zhiying You,[1] Michel Chonchol.[1] *[1]Univ of Colorado Denver; [2]Denver Health & Hospital; [3]Univ of Bern.*

Background: Acid retention in patients with chronic kidney disease (CKD) results in increased production of angiotensin II, aldosterone and endothelin-1, all of which can directly and indirectly induce vascular calcification. However, the relationship between serum bicarbonate levels and vascular calcification has not been examined. We evaluated the association between serum bicarbonate levels with a novel test that measures the overall calcification propensity of serum, T_{50}, in patients with CKD stage 3-4.

Methods: We measured serum bicarbonate levels and serum T_{50} levels in 128 patients with CKD stage 3-4. T_{50} measures the transformation time of amorphous calcium phosphate-containing primary calciprotein particles (CPP) to crystalline hydroxyapatite-containing secondary CPP. A higher T_{50} represents lower calcification propensity. Serum T_{50} was measured using a Nephelostart nephelometer (BMG Labtech, Offenburg, Germany). Multiple linear regression was used to examine the association between serum bicarbonate levels and T_{50}.

Results: The mean (SD) age and eGFR was 58.1 ± 12.4 years and 33.1 ± 10.2 ml/min/1.73m^2, respectively. Mean (SD) serum bicarbonate and T_{50} levels were 22.9 ± 2.9 mEq/L and 223.4 ± 46.8 min, respectively. Higher serum bicarbonate was associated with higher T_{50} (Table).

Serum Bicarbonate (mEq/L)	Serum T_{50} (minutes) β* (95% CI) *Adjusted for age, gender, race
< 21	-38.4 (-57.8 to -19.1)
21-23	-35.2 (-54.0 to -16.3)
>23	1.0 (REF)
per 1 mEq/L increase	5.18 (2.43 to 7.93)

Conclusions: Higher bicarbonate levels are associated with less overall serum calcification propensity in CKD stage 3-4, suggesting a beneficial role of alkali therapy on calcification in CKD.

Acute Regulated Expression of Pendrin in Human Urinary Exosomes (UEs)

Ganesh Pathare,[1,2] Nasser Dhayat,[1] Nilufar Mohebbi,[3] Carsten A. Wagner,[4] Daniel G. Fuster.[1,2] *[1]Div of Nephrology, Hypertension and Clinical Pharmacology, Inselspital, Univ Hospital of Bern, Switzerland; [2]Inst of Biochemistry and Molecular Medicine, Univ of Bern, Switzerland; [3]Div of Nephrology, Univ Hospital of Zurich, Switzerland; [4]Inst of Physiology, Univ of Zurich, Switzerland.*

Background: Regulation of pendrin upon chronic acid-base changes has been well studied in the rodent kidney. However, impact of acute acid-base changes on pendrin expression and subcellular localization is unknown. Furthermore, there is a paucity of data on the regulation of pendrin in the human kidney. Here we studied effect of acute acidosis, alkalosis or sodium chloride loading in humans on pendrin expression in urinary exosomes (UEs).

Methods: After acute acid NH_4Cl (100 mg/kg) or equimolar alkali NaHCO3 (157 mg/kg) or NaCl (110 mg/kg) loading in fasting individuals, urinary exosomes were isolated from hourly collected spot urine samples. Pendrin and the housekeeping UE protein alix were detected by immunoblotting. UE pendrin expression was normalized to alix expression.

Results: Acute NH_4Cl loading (n=8) elicited a systemic acidosis with a drop in urinary pH and an increase of urinary NH_4 excretion. Nadir urinary pH was achieved 5 hrs after NH_4Cl loading. UE pendrin expression was first significantly reduced after 3 hrs, lowest UE pendrin levels were observed after 4 hrs. In contrast, after acute equimolar $NaHCO_3$ loading (n=8), urinary and blood pH rose rapidly and urinary NH_4 excretion decreased. Densitometric analysis of immunoblots revealed rapid upregulation of UE pendrin expression already after 1 hr of $NaHCO_3$ loading. However, UE pendrin levels returned to baseline after 2 hrs. To analyze the effect of acute NaCl loading, we administered an oral equimolar amount of NaCl to healthy individuals (n=7). Urinary Na and Cl excretion increased significantly and rapidly after NaCl loading. Urinary pH, blood pH and urinary ammonia were unaltered throughout the experiment. Compared to baseline levels, UE pendrin abundance fell and was significantly lower at 3 hrs after NaCl loading.

Conclusions: Acute acid, alkali or chloride loading significantly alter UE pendrin expression in human UE within a few hours.

Urinary Exosomes Analysis of Renal Tubular Transporters in Patients with Acute and Chronic Hypokalemia

Chih-Chien Sung,[1,2] Chih-Jen Cheng,[1] Sung-Sen Yang,[1,2] Shih-Hua P. Lin.[1] *[1]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Graduate Inst of Medical Science, National Defense Medical Cente, Taipei, Taiwan.*

Background: Urinary exosomes contain membrane and cytosolic proteins from each renal epithelial cell type and has been used as an index of renal tubular transporter expression in primary aldosteronism or renal tubular disorders. Urinary exosome analysis of renal sodium (Na^+) and potassium (K^+) associated transporters in hypokalemia patients has not been studied.We aim to evaluate renal $Na^+$and K^+ transporters expression in patients with acute and chronic hypokalemia.

Methods: We have collected timely spot urine from 19 hypokalemia patients includingthyrotoxic periodic paralysis with acute hypokalemia (TPP, n=6), Gitelman syndrome with chronic hypokalemia (GS, n=13) and healthy control (n=6). Urinary exosomes were further isolated by ultracentrifugation method. Membrane transporters proteins abundance including NCC, pNCC, NHE3, NKCC2, *CLCNK*β,ENaCβ, ROMK, and Maxi-K were analyzed by immunoblotting and another urinary exosome maker CD9 used as internal control.

Results: Mean plasma K^+ concentration was 2.4±0.3 mmol/L in TPP patients with acute hypokalemia and 2.5±0.4 mmol/L in GS. In TPP patients, only NHE3 abundance (intensity 0.36±0.04 vs. 1.08±0.29,p<0.05) and ROMK (intensity 1.39±0.11 vs. 2.58±0.20, p<0.01) in parallel to urinary K^+ excretion (K^+/Creatinine ratio, 0.11±0.01 mmol/L/mg/dl) were significantly decreased in acute phase and increased in recovery phase. In GS patients, NCC and pNCC abundance significantly decreased corresponding to NCC mutation compared to healthy control. Na^+ associated transporters abundance of NHE3 and ENaCβ significantly increased while K^+ associated transporters abundance of ROMK and Maxi-K significantly increased.

Conclusions: Urine exosomics could evaluate the renal Na^+ and K^+ transporters expression in hypokalemia. Acute hypokalemia may not affect expression in distal Na^+ transporters but affect ROMK, not Maxi-K, in response to hypokalemia. Chronic hypokalemia with NCC defect could activate upstream NHE3 and downstream ENaCβ with concomitant increased ROMK and Maxi-K expression in response to flow.

TH-PO473

Identification of a CACNA1S-Specific Missense Mutation in a Three Generation Pedigree with Hypokalemic Periodic Paralysis

Martin Russwurm, Andreas Hofmeister, Joachim Hoyer, Ivica Grgic. *Nephrology, Philipps-Univ Marburg, Marburg, Germany.*

Background: Hypokalemia is an electrolyte imbalance that is not only common, but can also be debilitating and life-threatening to a patient if not addressed appropriately. Mechanisms that may lead to hypokalemia include decreased intake, increased losses via sweat, urine or the GI tract, and disproportionate translocation into cells. A rather rare cause (~1:100,000) of recurrent, modest to severe hypokalemia with accompanying muscle weakness is a neuromuscular disorder known as hypokalemic periodic paralysis (HypoPP). HypoPP is related to a skeletal muscle channelopathy of either the voltage-activated sodium channel $Na_v1.4$, encoded by SCN4A, or the L-type calcium channel $Ca_v1.1$, encoded by CACNA1S. We suspected the disease in an otherwise healthy 26-year-old male carpenter with no family history of hereditary disorders, who presented to the emergency room with flaccid quadriparesis and a serum potassium of 2.3 mmol/L.

Methods: We extracted the patient's genomic DNA and designed primers to specifically amplify and study the S4 voltage-sensor domains of $Na_v1.4$ and $Ca_v1.1$. DNA from HeLa cells was used as control template.

Results: Sequencing and alignment identified a heterozygous single nucleotide exchange (G to A) at position 1583 of the CACNA1S gene (chromosome 1q31-32), predicting an amino acid switch at position 528 from highly conserved arginine to histidine (R528H). To test the hypothesis of a de-novo mutation in this index case, we obtained and analyzed the DNA from the patient's first and second degree relatives. Interestingly, we found the same pathological single nucleotide polymorphism (SNP) in the patient's mother and maternal grandmother, although they have never had symptoms characteristic of HypoPP including sudden onset of profound muscle weakness or hypokalemia.

Conclusions: In conclusion, we have identified a new pedigree with autosomal-dominantly inherited HypoPP in central Germany. The possibility of missing or incomplete clinical manifestation of HypoPP has to be considered. The causal relationship between gender and HypoPP penetrance remains unclear and needs further investigation.

Funding: Government Support - Non-U.S.

TH-PO474

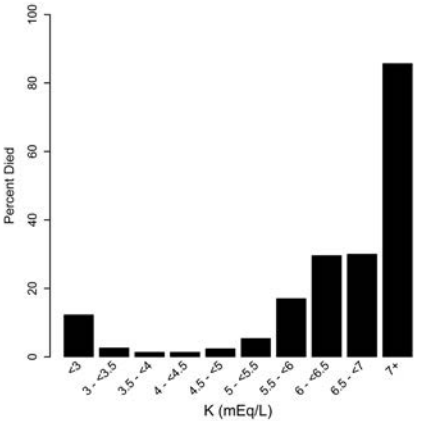
Association of Potassium Values with Mortality: Data from a Metropolitan Safety-Net Hospital

David T. Gilbertson,[1] James B. Wetmore,[1,2] Wendy L. St. Peter,[1,2] Charles A. Herzog.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Hennepin County Medical Center, Minneapolis, MN; [2]Univ of Minnesota, Minneapolis, MN.*

Background: Extremes of serum potassium (K) levels have been associated with adverse outcomes. We examined the association between K values with mortality in patients hospitalized at a metropolitan safety-net hospital.

Methods: We obtained K values for all patients hospitalized over a 1-yr period (July 2014-June 2015) and analyzed the association between K level, and variability, with in-hospital mortality. We also assessed the % of patients with K > 5.0 overall and by comorbidity: Diabetes Mellitus (DM), Chronic Kidney Disease (CKD), and Congestive Heart Failure (CHF).

Results: 17,317 hospitalizations with K values were included. The mean age was 50.2 yrs, 57.3% of patients were male, 47.7% white, 33.7% black; for comorbidities, 25.9% had DM, 14.1% CKD, and 6.2% CHF. The distribution of K <3.5, 3.5-<5, 5-<6, and 6+, was 7.9%, 88.7%, 3.1%, 0.3%, respectively. There was a U-shaped relationship between K and mortality, with the lowest risk between 3.5 and 5.0 mEg/L (see figure). The % of patients with K > 5.0 for patients with DM was 4.0%, CKD 6.4%, CHF 6.0%, compared to 0.9% among patients without any of the three comorbidities (all p < 0.001). For the association between K standard deviation (for each increase of 0.1) and in-hospital mortality, the odds ratio was 1.19 (p < 0.001).



Conclusions: Although both low and high K values were associated with an increased risk of mortality, risk of death increased once potassium exceeded 5.5 mEq/L and increased markedly thereafter. Increasing variability in K was also associated with mortality. The comorbid conditions of DM, CKD, and CHF are all associated with increased serum K levels. More intense efforts targeted to prevent severe hyperkalemia in pts with DM, CKD, and CHF may be warranted.

TH-PO475

Serum Potassium and the Risk of Adverse Outcomes: A CKD Prognosis Consortium Meta-Analysis Csaba P. Kovesdy, Kunihiro Matsushita, Yingying Sang, Juan Jesus Carrero, Gabriel Chodick, Takeshi Hasegawa, Atsushi Hirayama, Areef Ishani, Gijs W.D. Landman, Adeera Levin, Rupert Major, Dorothea Nitsch, David C. Wheeler, Josef Coresh, Stein I. Hallan, Varda Shalev, Morgan Grams. *CKD Prognosis Consortium.*

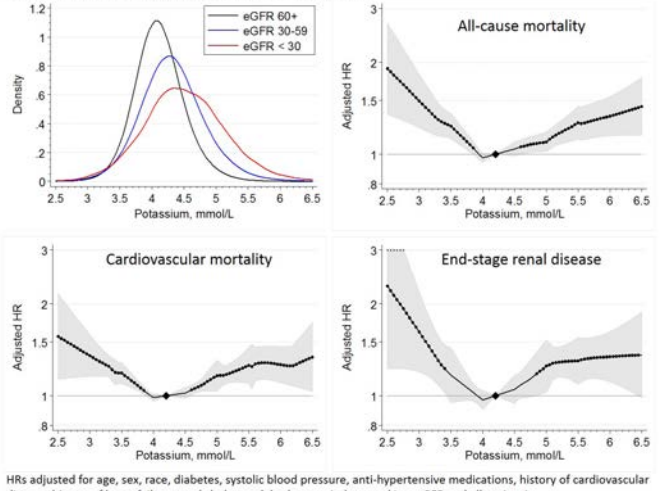
Background: Potassium levels outside the normal range may be dangerous. We evaluate the continuous relationship between potassium and all-cause mortality, cardiovascular mortality, and end-stage renal disease in 21 international cohorts.

Methods: We used Cox regression followed by random-effects meta-analysis to assess the relationship between baseline potassium (spline term with knots at 3.5, 4, 4.5, 5, and 5.5 mmol/L) and adverse outcomes, adjusted for age, sex, race, diabetes, systolic blood pressure, anti-hypertensive medications, cardiovascular disease, heart failure, total cholesterol, body-mass index, smoking, eGFR and albuminuria. We tested for effect modification by levels of eGFR (60+, 30-59, and <30 ml/min/1.73 m^2).

Results: There were 418,999 participants with both eGFR and albuminuria across 11 general population, 2 high cardiovascular risk, and 8 CKD cohorts followed for an average of 5 years. Mean baseline potassium was 4.2 mmol/L. Average age was 55 years, 54% were female, and 4% were black. Average eGFR was 83 ml/min/1.73 m^2, 19% had albuminuria, and 44% were on antihypertensive medications. The relationship between potassium and all-cause mortality demonstrated higher risk outside of the 3.5-5 mmol/L range (**Figure**). Compared to a reference of 4.2 mmol/L, the adjusted hazard ratio for all-cause mortality was 1.27 (95% CI: 1.12-1.45) at 5.5 mmol/L and 1.36 (95% CI: 1.17- 1.57) at 3.2 mmol/L. Risk relationships were similar for cardiovascular mortality and end-stage renal disease. Associations were similar but slightly attenuated in persons with lower eGFR.

Conclusions: Potassium levels both above and below the normal range are associated with adverse outcomes across a range of eGFR.

Distribution of potassium and adjusted hazard ratios (HRs) for all-cause mortality, cardiovascular mortality, and end-stage renal disease



HRs adjusted for age, sex, race, diabetes, systolic blood pressure, anti-hypertensive medications, history of cardiovascular disease, history of heart failure, total cholesterol, body-mass index, smoking, eGFR and albuminuria

TH-PO476

Hypothermia Induced Hypokalemia and Recovery during Rewarming: Risk for Hyperkalemia Khaled Boobes, Daniel Batlle, Tanya Tocharoen Tang, Robert M. Rosa. *Nephology, Northwestern Univ, Chicago, IL.*

Background: Induced hypothermia is a commonly recommended intervention to improve neurological outcome in patients who have survived prolonged cardiac resuscitation. Different degrees of hypothermia are currently used (91.4-96.8°F). Hypothermia, however, can produce hypokalemia and can be associated with rebound hyperkalemia during the rewarming phase.

Methods: We obtained retrospective data on 74 patients who underwent hypothermia after cardiac arrest of whom 64 developed hypokalemia (range 1.9-3.5 mEq/dl). We then excluded for this analysis who did not survive the rewarming phase.

Results: Hyperkalemia (defined as K >5.0 mEq/dL) developed in 47 out of the 74 patients. Of those, 18 had a K ≥ 6.0 mEq/dL and 5 had K > 7.0 mEq/dL.

A striking correlation was observed during the rewarming phase between the rising K and the rising temperature.

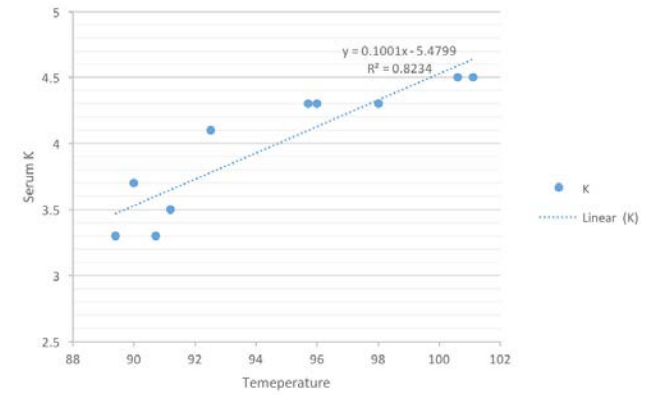

Figure 1 (representative patient)

In 5 patients we calculated the slope of K as a function of temperature, which revealed a linear relationship.

Table 1. Correlation coefficient calculated from the slope of K and Temperature during rewarming. Patients also received variable amounts of K supplementation.

Patients	R^2
1	0.894
2	0.823
3	0.846
4	0.564
5	0.569

Conclusions: Marked hypothermia produces hypokalemia due to a shift in the distribution of K between extracellular and intracellular compartments possibly by slowing down cellular K exit via K+ channels. The increase in K and the linear relationship between K and temperature during rewarming suggests the dominance of the K+ channels (exit pathway) over the Na,K-ATPase (entry pathway) by reactivation of temperature dependent K+ channels. The hyperkalemia encountered suggests that K+ supplementation should be minimized during rewarming.

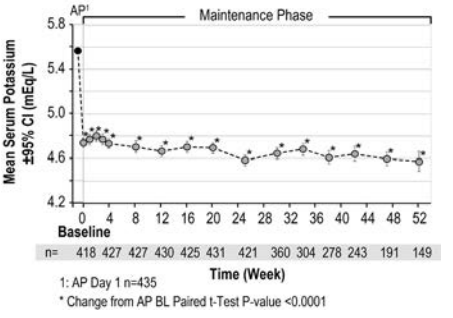
TH-PO477

Long-Term Sodium Zirconium Cyclosilicate Treatment in Patients with Hyperkalemia: Interim Analysis of an Open-Label Phase 3 Study Bruce S. Spinowitz,[1] James A. Tumlin,[2] Edgar V. Lerma,[3] Wajeh Y. Qunibi,[4] Bhupinder Singh,[5] Jose A. Menoyo,[5] Philip T. Lavin,[6] Henrik S. Rasmussen,[5] Steven Fishbane.[7] *[1]New York Presbyterian, Queens and Weill Medical College of Cornell Univ; [2]Univ of Tennessee College of Medicine; [3]Univ of Illinois at Chicago College of Medicine, Advocate Christ Medical Center; [4]Univ of Texas Health Science Center at San Antonio; [5]ZS Pharma; [6]Boston Biostatistics Research Foundation; [7]Hofstra Northwell Health School of Medicine.*

Background: Sodium zirconium cyclosilicate (ZS-9) is a non-absorbed, selective cation trap that binds potassium (K^+) throughout the GI tract.

Methods: This ongoing, open-label, single-arm Phase 3 trial enrolled adult patients (pts; N=751) with hyperkalemia (HK; K^+ ≥5.1 mEq/L). Pts received ZS-9 10g TID for 24–72 h (induction phase). Pts who achieved normokalemia (K^+ 3.5–5.0 mEq/L) received ZS-9 5g/d for ≤12 mo (maintenance phase).

Results: As of Dec 7, 2015, 751 pts were enrolled and 436 pts had completed 6 mo of treatment; 64.6% were on RAASi and 34.4% had heart failure. During the induction phase, 99.3% of pts achieved normokalemia and mean K^+ declined from 5.6 mEq/L at baseline to 4.7 mEq/L at maintenance phase start. Mean K^+ for all pts was 4.7 mEq/L during the maintenance phase. Among pts treated for ≥6 mo (n=436; figure), mean K^+ was 4.7 mEq/L and 89% of pts had mean K^+ ≤5.1 mEq/L over mo 3–12; results were similar for pts treated for ≥9 mo (n=287). The most common AEs across all treated pts were constipation (5.0%), peripheral edema (7.6%), and worsening hypertension (HTN; 8.2%); rates did not increase over time with increasing duration of exposure to ZS-9. No pts discontinued study drug due to edema or HTN. **Figure. Mean K^+ in Pts Treated ≥6 Mo (n=436)**.



Conclusions: These initial findings indicate that normokalemia was maintained with daily ZS-9 dosing in pts treated for ≥6 mo. Safety data is presented from all treated pts through Dec 7, 2015.

Funding: Pharmaceutical Company Support - ZS Pharma

TH-PO478

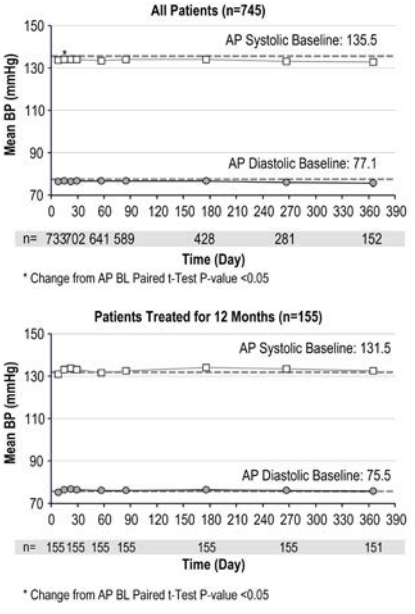
Effect of Sodium Zirconium Cyclosilicate Treatment for Hyperkalemia on Blood Pressure in a Long-Term Open-Label Phase 3 Study

Pablo E. Pergola,[1] Bruce S. Spinowitz,[2] Peter A. McCullough,[3] Bhupinder Singh,[4] Jose A. Menoyo,[4] Philip T. Lavin,[5] Henrik S. Rasmussen,[4] Steven Fishbane.[6] *[1]Renal Associates PA, San Antonio, TX; [2]New York Presbyterian, Queens and Weill Medical College of Cornell Univ, Flushing, NY; [3]Baylor Univ Medical Center, Dallas, TX; [4]ZS Pharma, San Mateo, CA; [5]Boston Biostatistics Research Foundation, Framingham, MA; [6]Hofstra Northwell Health School of Medicine, Great Neck, NY.*

Background: Sodium zirconium cyclosilicate (ZS-9) is a non-absorbed, selective cation trap that binds potassium (K^+) in exchange for H^+ and Na^+ throughout the GI tract. This interim analysis assessed the effects of ZS-9 on blood pressure (BP) in a 12-month study in patients (pts) with hyperkalemia (HK).

Methods: This ongoing, open-label, single-arm Phase 3 trial enrolled adult patients (pts; N=751) with HK (K^+ ≥5.1 mEq/L). Pts received ZS-9 10g TID for 24–72 h (induction phase). Pts who achieved normokalemia (K^+ 3.5–5.0 mEq/L) received ZS-9 5g daily for ≤12 mo (maintenance phase).

Results: As of Dec 7, 2015, 751 pts were enrolled; 82.6% with hypertension (HTN), 34.4% with heart failure and 64.6% on RAASi. During the induction phase, 99.3% of pts achieved normokalemia and mean K^+ declined from 5.6 mEq/L at baseline to 4.7 mEq/L at start of maintenance phase. There were no clinically meaningful changes in mean systolic and diastolic BP nor in related variables like body weight over time for all treated patients and those who completed 12 mo of treatment (n=155; figure). The most common AEs were constipation (5.0%), peripheral edema (7.6%), and worsening HTN (8.2%); rates did not increase over time with increasing duration of exposure to ZS-9. No pts discontinued study drug due to edema or HTN. **Figure. Mean BP Over Time**



Conclusions: These initial findings indicate no clinically meaningful changes in BP were observed with daily ZS-9 treatment of HK. Safety data is presented from all treated pts through Dec 7, 2015.

Aldosterone, Renin and Blood Pressure during Patiromer Treatment of Hyperkalemia in CKD

Matthew R. Weir,[1] David M. Spiegel,[2] Daniel J. Wilson,[2] Wade Benton,[2] Jinwei Yuan,[2] Coleman Gross.[2] *[1]Univ of Maryland School of Medicine; [2]Relypsa, Inc.*

Background: Patiromer, a non-absorbed K-binding polymer, reduced serum K (sK) in CKD patients (pts) with hyperkalemia (HK), all on renin-angiotensin-aldosterone system (RAAS) inhibitors at baseline (BL), in the Phase 3 OPAL-HK study. Blood pressure (BP) and aldosterone (ALD) reductions occurred during OPAL-HK. Patiromer may also bind sodium (Na) in the GI tract. We explored patiromer effects on BP in pts with low plasma renin activity (PRA) and low ALD.

Methods: This was a post-hoc analysis (N=243) from the 4-week (Wk) initial treatment phase of OPAL-HK (NCT01810939). Starting patiromer doses were 8.4 and 16.8 g/d based on BL sK (5.1-<5.5 and ≥5.5-<6.5 mEq/L, respectively [local lab]). We identified 2 levels of low PRA low ALD at BL depending on sK (≥5.1 or ≥5.5 mEq/L [central lab]), reflecting diminished RAAS activity: ALD<5 ng/dL, PRA<1 µg/L/h, sK≥5.1 mEq/L (LRA1) and ALD<10 ng/dL, PRA<2 µg/L/h, sK≥5.5 mEq/L (LRA2). Change in sK, ALD, PRA and BP at Wk 4 was analyzed for pts with and without LRA1 or LRA2. Data are mean±SD.

Results: Of 243 pts with BL sK≥5.1 mEq/L, 24 had LRA1; of 151 pts with BL sK≥5.5 mEq/L, 44 had LRA2. sK and BP decreased similarly in all groups (Table). ALD did not decrease in LRA1 and LRA2 but did decrease in other groups. Baseline SBP and DBP were higher in LRA1 (p= NS/p<0.01) and LRA2 (p=0.04/p<0.001) by unpaired t-test compared to pts without LRA1 or LRA2, respectively. PRA increased in LRA1 and LRA2 only.

Conclusions: Patiromer reduced sK in HK pts with CKD regardless of BL ALD level. ALD decreased in pts without diminished RAAS activity. LRA1 and LRA2 had higher BL BP and patiromer did not decrease ALD but modestly increased PRA. This may reflect mild volume expansion in LRA1 and LRA2 that improved with patiromer treatment. BP reduction was observed in all groups possibly due to both aldosterone reduction and decreased Na absorption.

Evaluation of Potential Pharmacodynamic Interactions with Antihypertensive Drugs Given Concomitantly with Patiromer: Pooled Analysis of Phase 2/3 Clinical Trials

Matthew R. Weir,[1] Martha Mayo,[2] Dahlia Garza,[2] Natalie Panov,[2] Lilla S. Simon,[2] Charles Du Mond,[2] Lance Berman,[2] George L. Bakris.[3] *[1]Univ of Maryland School of Medicine, Baltimore, MD; [2]Relypsa, Inc., Redwood City, CA; [3]Univ of Chicago Medicine, Chicago, IL.*

Background: Patiromer is a sodium-free, non-absorbed potassium binder approved for the treatment of hyperkalemia (HK). In *in vitro* studies, patiromer was shown to bind about half of the oral medications tested. Recent studies in healthy volunteers indicate that there may be a much lower potential for pharmacokinetic interactions with patiromer. We retrospectively evaluated the potential for adverse pharmacodynamic (PD) effects on 3 antihypertensive drugs that showed *in vitro* binding and were most frequently used in patiromer clinical trials.

Methods: Safety data were pooled from 4 patiromer trials, (2 HK treatment studies in CKD patients and 2 HK prevention studies in HF). Patiromer was initiated at total daily doses of 8.4-33.6 g (divided BID). In patients on stable doses of oral antihypertensive drugs (AHDs) of interest at baseline (amlodipine [AM], furosemide [FUR], and metoprolol [MP]), objective measures of PD effects, ie changes in systolic and diastolic blood pressure (SBP/DBP), and AHD dose increases, were evaluated during the first 4 weeks after patiromer initiation.

Results: Overall 666 patients were treated with patiromer in the clinical trials; hypertension was present in 97.3%. Of these, 512 were receiving oral AHDs of interest at baseline: AM (n=227), FUR (n=227) and MP (n=58). Mean ± SD SBP at baseline, at week 4 and change from baseline to week 4 are shown (Table). An oral AHD dose increase was required in 1 patient each in the AM and MP groups and in 5 patients in the FUR group.

Conclusions: No evidence of adverse systematic BP effects of oral AHDs were observed after the initiation of patiromer in clinical trials for the prevention or treatment of hyperkalemia.

Blood Pressure	Statistics/Parameter	Amlodipine	Furosemide	Metoprolol
	Baseline:			
	N	227	227	58

Profound Hypokalemia and Generalized Paralysis following the Chronic Ingestion of Large Amounts of Ibuprofen Opeyemi Oladele, Paul Zamudio, Nand K. Wadhwa, Edward P. Nord, Rajeev B. Patel, Wilfred Lieberthal. *Medicine, Stony Brook Medicine, Stony Brook, NY.*

Background: The effects of an acute overdose with the non-steroidal anti-inflammatory drug (NSAID) Ibuoprofen are well described, and include oliguric AKI, alterations in mental state, metabolic acidosis and gastrointestinal bleeding. However, the effects of the chronic ingestion of large amounts of Ibupfrofen are rarely documented.

Results: CASE REPORT: A 48 year old male complained of progressive muscle weakness for 10 days prior to presentation. He was taking 10-12 tablets (600mg/tablet) of Ibuprofen every 4-6 hours almost daily for about one year for back pain. He was fully oriented with normal vital signs. The only notable finding on exam was profound weakness and an inability to lift his extremities or sit up. Laboratory data on admission: Serum electrolytes: BUN 68mg/dL, creatinine 3.84 mg/dL, sodium 123 mmol/L, potassium < 1.5 mmol/L, chloride 78 mmol/L, bicarbonate 7 mmol/L (anion gap 38 mmol/L). Calcium 8.1 mg/dL, phosphorus 5.4 mg/dL, magnesium 2.7 mg/dL. Plasma beta-hydroxybutrate 0.6 mmol/L. L-lactate 2.4 mmol/L. D-lactic acid undetectable. Toxicology screen negative. Urine electrolytes: pH 5.5, sodium 80 mmol/L, potassium 118 mmol/L and chloride 56 mmol/L. The patient was given potassium intravenously (IV) and orally. When his potassium exceeded 2.0 mmol/L, an IV infusion of sodium bicarbonate was started. Two days after admission the BUN was 45 mg/dL and creatinine 3.1 mg/dL. The serum sodium was 141 mmol/L, the bicarbonate 20mmol/L and the anion gap 16 mmol/L. When the patient was seen in renal clinic 2 months later after discharge his BUN was 31 mg/dL, his creatinine 2.6 mg/dL and his electrolytes were normal.

Conclusions: There are sparse reports of Ibufrofen abuse causing profound hypokalemia with a non-anion gap acidosis and a urine pH >6.0, suggesting a form of renal tubular acidosis. By contrast, the severe life threatening hypokalemia and metabolic acidosis in this case, was associated with a large anion gap of undetermined cause and a urine pH of 5.5. To the best of our knowledge, no cases of Ibuprofen abuse with these electrolyte abnormalities have been described previously.

TH-PO482

Dietary Salt Induces Catabolism in Humans Kento Kitada,[1] Natalia Rakova,[2] Steffen Daub,[1] Tetyana Pedchenko,[1] Yahua Zhang,[1] Friedrich C. Luft,[1,2] Jens Titze.[1] *[1]Div of Clinical Pharmacology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Experimental and Clinical Research Center, Charité Medical Faculty and the Max- Delbrueck Center for Molecular Medicine, Berlin, Germany.*

Background: The concept that increasing salt intake elevates fluid intake and urine volume originates from short-term experiments in humans exposed to extremes in salt intake. In the first ultra-long term sodium and water balance study performed in man, we tested the hypothesis that increasing salt intake by only 6 g/day induces similar changes in water balance.

Methods: We performed two separate balance studies of 105 and 205 days in 10 healthy male subjects simulating a space flight to Mars. We exposed our subjects to 3 salt intake levels (12 g/day, 9 g/day and 6 g/day) and monitored their daily water intake and urine volume. We studied the effect of increasing salt intake on water balance, urine osmolyte elimination and free water excretion and their relation to glucocorticoid excretion.

Results: Elevated salt intake and sodium excretion increased urine volume, but surprisingly decreased water intake in all 10 subjects. High salt intake suppressed aldosterone levels, but increased glucocorticoid levels. This salt-driven increase in glucocorticoid excretion predisposed our subjects to increased urine volume with low urine osmolality despite reduced fluid intake, indicating a catabolic state with increased free water production and excretion. This salt-induced catabolic state was characterized by increased sodium concentration and reduced urea concentration in the urine.

Conclusions: The seemingly paradoxical decrease in fluid intake during high dietary salt consumption can be explained by a glucocorticoid-driven catabolic endogenous water production. Dietary salt is excreted by a urine concentration mechanism. Catabolic urea production and accumulation of urea osmolytes in the renal medulla may provide the necessary driving force for water reabsorption when sodium is concentrated into the urine.

TH-PO483

High Salt Intake Induces Muscle Wasting via Catabolic Urea Formation in Mice Kento Kitada,[1] Steffen Daub,[1] Yahua Zhang,[1] Janet D. Klein,[2] Daisuke Nakano,[3] Tetyana Pedchenko,[1] Akira Nishiyama,[3] Friedrich C. Luft,[1] Jeff M. Sands,[2] Jens Titze.[1] *[1]Div of Clinical Pharmacology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Renal Div, Dept of Medicine, and Dept of Physiology, Emory Univ, Atlanta, GA; [3]Dept of Pharmacology, Kagawa Univ, Kagawa, Japan.*

Background: In the first ultra-long term salt and water balance study performed in man, we found that high salt intake induced a catabolic state with increased metabolic water formation that accompanied the excretion of dietary salt by renal concentration. We hypothesized that salt induces energy-intense urea generation, which is accumulated in the renal medulla and provides with the osmotic driving force necessary to concentrate the urine and excrete dietary salt without osmotic diuresis.

Methods: We fed male mice (C57/B6) a low-salt diet (<0.1%NaCl) with tap water (LSD) or a high-salt diet (4%NaCl) with 0.9% saline to drink (HSD) for 4 consecutive weeks, followed by 2 weeks of pair-feeding to match energy intake in both groups. We studied the effects of high-salt intake on osmolyte and water balance and urea generation.

Results: HSD increased urea content and urea transporter expression in the renal medulla, resulting in reduced urea osmolyte excretion. Retaining urea osmolytes, HSD mice preserved their urine concentration ability despite excess Na and Cl osmolyte excretion, thereby preventing osmotic diuresis. HSD induced arginase-driven urea production in liver and skeletal muscle, but not in the kidney. Metabolomic analysis revealed corticosterone-driven free amino acid wasting in muscle to provide liver with nitrogen for urea generation. The energy-intense nature of urea osmolyte generation resulted in a catabolic state with exploitation of stored energy fuels and ketogenesis.

Conclusions: Na metabolism cannot be understood without investigation of urea metabolism. The biological pattern of dietary salt excretion includes urea osmolyte generation and accumulation in the kidney to concentrate the urine and prevent salt-driven water loss by osmotic diuresis. The resulting reprioritization of energy metabolism for energy-intensive urea production may explain muscle wasting in patients with Na overload.

The Relationship of Tissue Sodium Concentration to Cardiovascular Indices in Advanced Chronic Kidney Disease Nicos Mitsides,[1] Damien J. Mchugh,[2] Jane Alderdice,[1] Paul E. Brenchley,[1] Geoff J.M. Parker,[2] Sandip Mitra.[1] *[1]Manchester Academic Health Science Centre; [2]Centre for Imaging Sciences of the Univ of Manchester.*

Background: Body sodium (Na) balance is considered to be an important determinant of cardiovascular (CV) risk. Chronic kidney disease (CKD) is considered to be a salt sensitive state. However the role of Na tissue accumulation in influencing CV parameters in CKD has not been investigated.

Methods: The relationship of tissue Na concentration to CV indices was investigated using a 3T Magnetic Resonance (MR) scanner & a dual-tuned $^{1}H/^{23}Na$ coil. We acquired ^{23}NaMR images of the lower legs of 6 healthy volunteers (HV) and 7 CKD stage 5 patients (eGFR<15 ml/min, not yet on dialysis) and calculated Na concentration in the muscle and subcutaneous (SC) tissue using calibration saline phantoms placed under the leg. Participants underwent simultaneous assessment of their CV status using pulse wave velocity (PwV), 24hr ambulatory Blood Pressure monitoring (ABPM), skin auto-fluorescence & sublingual dark field capillaroscopy.

Results: The MR derived Na concentrations (mmol/l) for CKD participants were higher than HV. This difference was more pronounced in the SC tissue (CKD 26.3±9.4, HV 18.1±3.5, $p<0.05$) than in the muscle (CKD 24.3±4.0, HV 22.6±3.0, $p=0.19$). The mean ABPM measurements (mmHg) for the entire cohort was systolic (127±12.5), diastolic (79.9±8.6) and mean arterial pressure (MAP) (95.8±9.6). Muscle Na concentration showed a positive correlation with ABPM derived systolic ($p=0.02$), diastolic ($p=0.02$) and MAP ($p=0.02$). Both Na concentration for muscle and SC tissue correlated with capillaroscopy measured markers of endothelial glycocalyx damage with the former exhibiting a positive association with the thickness of the Perfused Boundary Region of large size capillaries ($p=0.02$) and the latter with Red Cell width ($p<0.01$).

Conclusions: Our results indicate that CKD leads to higher tissue accumulation of salt. Both SC and muscle Na concentrations are linked to microvascular injury and the muscle Na accumulation is closely linked to hypertension.

TH-PO485

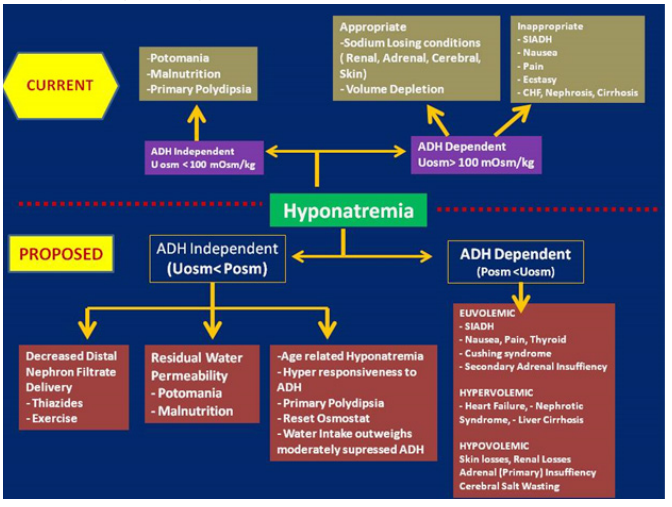
Syndrome of Inappropriate ADH versus Reset Osmostat: Blind Spots in Classification and Evaluation of Hyponatremia Hormaz Dara Dastoor,[1] Chandra Mauli Jha,[2] Ken J. Donaldson,[3] Thalakunte Muniraju,[3] Samra Abouchacra,[1] Hatem Mohyeldin Ebeid.[4] *[1]Div of Nephrology, Rahba Hospital- Johns Hopkins International, Abu Dhabi, United Arab Emirates; [2]Div of Nephrology, Burjeel Hospital, Abu Dhabi, United Arab Emirates; [3]Div of Nephrology, Dumfries and Galloway Royal Infirmary, Dumfries, United Kingdom; [4]Div of Nephrology, Al Noor Hospital, Abu Dhabi, United Arab Emirates.*

Background: We present a case diagnosed as SIADH on the basis of current classification of Hypotonic Hyponatremia. However, further evaluation including measurement of Vasopressin levels revealed the diagnosis as Reset Osmostat. A careful review reveals that present diagnostic algorithm of hypotonic hyponatremia has a tendency to over diagnose SIADH and it is long overdue to reclassify Hyponatremic Hyponatremia.

Methods: Case A 72-year-old lady presented with nausea and euvolemic hyponatremia with Plasma Sodium 121 mmol/l, urine osmolality 162 mOsm/kg. On the basis of prevalent diagnostic algorithm she was diagnosed to have SIADH and Fluid restriction raised her P_{Na+} to 130 mmol/l. However measured ADH levels at time of admission was found to be < 0.1 pg/ml (normal 0.7- 3.8 pg/ml) suggesting near absence of ADH. The patient had either Reset Osmostat or Age related inability to excrete Free Water with Primary Polydipsia.

Results: We find the current t diagnostic algorithm of hyponatremia leads to a false over diagnosis of SIADH.

Conclusions: Using a diagnostic approach of combining the pathophysiology of hyponatremia and measurement of Urine Osmolarity, we have been able to accurately diagnose pathologies which have been mistakenly labelled as SIADH. These include Residual Water Permeability, Reset Osmostat and Age related Hyponatremia. and Diagnosis of SIADH in euvolemic hyponatremic patients with urinary Na <100 mOsm/L appears to be faulty causing over diagnosis of SIADH.



TH-PO486

Is the Fall in Serum [Na] in Response to a Rise in Serum Glucose ([Glu]) Affected by Prevailing [Glu]? Philip Goldwasser,[1] Andrea Roche-Recinos,[2] Robert H. Barth.[1] *[1]Medicine, VA NY Harbor Heathcare System, Brooklyn, NY; [2]Medicine, SUNY Downstate, Brooklyn, NY.*

Background: [Na] falls (ΔNa) as [Glu] rises (ΔGlu), but the slope of this effect (ΔNa/ΔGlu) may vary. Theory predicts the slope should shallow as [Glu] increases (Robin '79; Moran '85), but one *post hoc* study found it to steepen when [Glu] exceeded 400 mg/dL (Hillier '99). Changes in total protein (TP), hemoglobin (Hb) and bicarbonate (tCO_2)—which often accompany ΔGlu—cause bias in [Na] measured by either the indirect (diluted) method (iNa), in chemistry (chem) panels, or the direct method (dNa), in gas panels. Prior estimates of ΔNa/ΔGlu didn't account for these biases. We recently derived linear corrections for them in 772 paired chem and gas panels, obtained up to 19 min. apart (median: 4 min.), retrospectively collected from our critical care units [NDT '15; ASN Nov '15].

Methods: To test whether [Glu] itself influences ΔNa/ΔGlu, we classified each pair, by the mean of its chem and gas [Glu], into one of 4 subgroups: [A] ≤100 mg/dL; [B] 101-200; [C] 201-300; [D] >300. Next, defining ΔGlu as chem [Glu] - gas [Glu] and ΔNa as iNa - dNa, we estimated the effect on ΔNa of ΔGlu by regression, adjusting for TP, Hb, and tCO_2, in the subgroups and the entire cohort. Data on changes in the balance of Na, K and water were unavailable.

Results: In the entire cohort, mean [Glu] ranged from 40 to 1043 mg/dL, and ΔGlu from -189 to 164; ΔNa was -2.4 ± 0.4 [SE] mEq/L per 100 mg/dL of ΔGlu ($p< 10^{-8}$). The subgroup slopes varied from -1.4 to -5.1, but pairwise comparison of the 4 slopes yielded only one difference of even borderline significance (C vs D: p=.05, unadjusted for multiple comparisons).

Group	N	[Glu] mean±SE	Slope [95%CI]	p
A	124	87±1	-5.1 [-9.0 to -1.2]	.01
B	504	136±1	-2.0 [-3.2 to -0.8]	.001
C	96	243±3	-1.4 [-2.9 to +0.05]	<.06
D	48	472±26	-3.6 [-5.0 to -2.3]	10^{-5}

Conclusions: Mean ΔNa/ΔGlu varied markedly, but not significantly, according to prevailing [Glu], in an analysis that accounted for assay bias, but not for water and salt balance. While the results don't exclude an effect of prevailing [Glu] on the slope, they are consistent with no interaction at all.

Hyponatremia in the Emergency Department, Role of Prescription Medications Gudrun Sigurdardottir,[1] Petur S. Gunnarsson,[1,2] Anna Ingibjörg Gunnarsdóttir,[1,2] Elin Ingibjorg Jacobsen,[1] Runolfur Palsson,[1,2] Olafur S. Indridason.[2] *[1]Univ of Iceland; [2]Landspitali - the National Univ Hospital of Iceland, Reykajvik, Iceland.*

Background: Commonly prescribed medications have been associated with development of hyponatremia. We examined the frequency of hyponatremia, defined as serum sodium (SNa) ≤135 mmol/L in patients visiting a University Hospital emergency department (ED) and its relationship to medication use.

Methods: This was a retrospective study of all patients >18 years, who visited the ED in 2014. SNa levels and other clinical data were obtained from the electronic medical records. Information on drug dispensing for subjects with hyponatremia and matched controls drawn from ED patients with normal SNa levels, was obtained from the National Pharmaceuticals Database of the Directorate of Health. Patients were matched on age, sex, creatinine and diagnoses of hypertension, diabetes, coronary artery disease, COPD, malignancy and psychiatric disorders. Kaplan-Meier method was used for survival analysis and the log-rank test to compare groups.

Results: In total, 40,365 individuals had 58,137 ED visits. SNa was measured at 26,474 visits of 19,159 patients, with hyponatremia present at 2,287 (3.9%) visits of 1,785 (4.4%) patients, of whom 62.5% were women. Frequency of hyponatremia increased with age and was 12.8% in patients >70 years. Compared with the control group, more patients with hyponatremia had filled a prescription for thiazides (25.6% vs 19.6%, p<0.001), amiloride (11,0% vs 7.4%, p<0.001), aldosterone antagonists (8.7% vs 5.5%, p<0.001), proton pump inhibitors (42.1% vs 36.9%, p<0.001), carboxamide anti-epileptics (2.7% vs 0.8%, p<0.001), ACE inhibitors (16.9% vs 14.0%, p=0.04) and tricyclic antidepressants (6.2% vs 4.8%, p=0.048). No difference was observed for SSRI (21.7% vs 21.3%, p=0.74) or SNRI (13.3 vs 13.8%, p=0.86). One-year survival was 78.3% (95% CI, 76.3-80.2%) in the hyponatremia patients compared with 84.6% (95% CI, 82.9-86.4%) in the control group (p<0.001).

Conclusions: Hyponatremia is common in the ED, especially among older individuals and is associated with increased mortality. Thiazides, aldosterone antagonists and proton pump inhibitors are likely causative agents in many patients.

TH-PO488

Severe Hyponatremia in the Hospital Setting: Incidence, Etiology and Outcome Arni H. Geirsson,[1] Runolfur Palsson,[1,2] Kristinn Sigvaldason,[1,2] Olafur S. Indridason.[1] *[1]Landspitali - The National Univ Hospital of Iceland; [2]Univ of Iceland, Reykjavik, Iceland.*

Background: Severe hyponatremia can be a devastating disorder and its management is frequently very challenging. The aim of this study was to investigate the incidence, etiology and outcome of severe hyponatremia, defined as serum sodium (SNa) <120 mmol/L, in a metropolitan area.

Methods: This was a retrospective study that included all patients >18 years of age with SNa <120 mmol/L at the University Hospital in Reykjavik, in 2005-2014. Patients were identified in the electronic database of the Department of Clinical Biochemistry and clinical data were extracted from medical records. Incidence was calculated per hospital admission and per 100,000 population of the greater Reykjavik area. Changes in incidence were evaluated by poisson regression.

Results: A total of 590 patients suffered 619 episodes of severe hyponatremia. Median age was 74 (range, 23-98) years and 76% were females. The average annual incidence was 2.49/1000 admissions, increasing from 1.69/1000 to 2.59/1000 over the study period (p=0.007). The average population incidence was 41.6/100,000/year, without a significant change during the study period (p=0.59). The etiology of severe hyponatremia was considered to be SIAD in 205 cases (33.1%), volume depletion in 153 (24.7%) and a thiazide diuretic in 141 patients (22.8%), 113 (80.1%) of whom were women. Intensive care was required in 102 cases (16.5%). Eighty patients (12.9%) had acute hyponatremia and 24 (3.9%) received emergency treatment with 3% saline. The in-hospital mortality was 9%. Five patients experienced neurologic complications following correction of SNa. Thirteen patients (2.1%) had SNa <105 mmol/L, of whom 2 died and 5 could not be dischargeddirectly to their home.

Conclusions: The frequency of severe hyponatremia is increasing in hospitalized patients and most commonly occurs in females and older individuals. Intensive care management is often needed and the mortality rate is substantial. Since thiazide diuretics are a common cause of severe hyponatremia, a more cautious use of these agents is warranted in patients at increased risk, such as elderly women.

TH-PO489

The Association between Serum Sodium Levels at Hospital Admission and Outcomes among 2.7 Million Hospitalized Patients Saleem M. Al Mawed,[1] Matthew Sandoval,[2] Maria-Eleni Roumelioti,[1] V. Shane Pankratz,[1] Mark L. Unruh.[1] *[1]Div of Nephrology, Univ of New Mexico Health Sciences Center, Albuquerque, NM; [2]CTSC, Univ of New Mexico, Albuquerque, NM.*

Background: Hyponatremia is the most common electrolyte disturbance in hospitalized patients. While studies have addressed its association with selected outcomes, few included a large cohort of hospitalized patients. In this study we examined the association of serum sodium at hospital admission with subsequent outcomes.

Methods: We extracted data from the Cerner Health Facts database. We included the index hospital admission defined by the first inpatient encounter of any patient between 2000 and 2014 that met the following inclusion criteria: age ≥ 18 years and serum sodium levels drawn during 24 hours before admission. ICD-9 codes were used to identify the comorbidities. Logistic regression models were used in the analysis.

Results: 2.7 million patients were included in this analysis. 14.7% of patients had serum sodium (Na) <135 mEq/L. The prevalence of Na <135 mEq/L increased with age. Adjusting for age, sex, and race, patients with diabetes mellitus, end stage renal disease, cirrhosis, lung cancer, adrenal insufficiency, and HIV were associated with a higher likelihood of Na <135 mEq/L. After adjusting for age, sex, race, and the Deyo Charlson Comorbidity Index, a serum Na across a range of 115 to <135 had a higher likelihood of in-hospital mortality compared to Na of 140 to <145 mEq/L (p<0.001). Similar trends were observed between Na and discharge to hospice while inverse relationship was observed between Na and discharge to home (figure1).

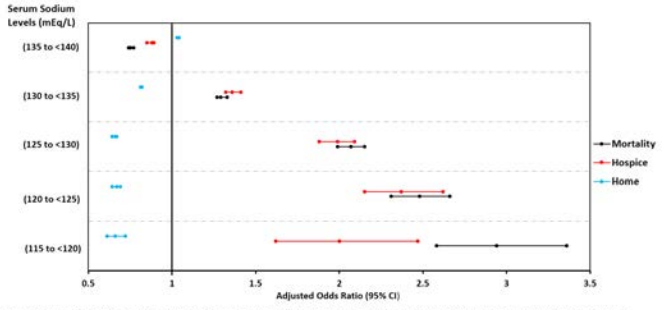

Figure 1: Forest plot of the odds ratios (95% confidence intervals (CI)) for in-hospital mortality, discharge to hospice, or discharge to home associated with different intervals of serum sodium levels (mEq/L) at hospital admission. Serum sodium levels of (140 to <145 mEq/L) served as referent. The odds ratios were derived from logistic regression models adjusted for age, sex, race, and Deyo Charlson Comorbidity Index.

Conclusions: Hyponatremia (Na <135 mEq/L) is common in patients who present to the hospital and is independently associated with outcomes such as in-hospital mortality and discharge to hospice. More research is needed to study other outcomes associated with hyponatremia.

Association of Hyponatremia with Impaired Cognition Kristen L. Nowak,[1] Eric Orwoll,[2] Joachim H. Ix,[3] Zhiying You,[1] Michel Chonchol.[1] *[1]Univ of Colorado Anschutz Medical Campus; [2]Oregon Health and Science Univ; [3]Univ of California San Diego.*

Background: Hyponatremia is a common finding in older adults and is linked to attention deficits, gait disturbances, and risk of falls. However, the association of hyponatremia with cognition in older adults is currently unknown. We hypothesized that hyponatremia would be associated with cognitive impairment and risk of cognitive decline in asymptomatic, community-dwelling older men.

Methods: 5,376 men aged > 65 years who were enrolled in the Osteoporotic Fractures in Men (MrOS) study were included in this analysis. Multivariable logistic regression was used to examine the association between baseline serum sodium levels and the odds of both prevalent cognitive impairment (cross-sectional analysis; modified mini-mental status [3MS] score <80 or Trail Making Test Part B score >1.5 S.D. above the mean [>223.4 sec]) and decline incident cognitive impairment (prospective analysis [n=3,667]: follow-up 3MS score of <80 or decline of >5 points, or change in Trails B time >1 S.D. above mean change in completion time [>45.1 sec]).

Results: Mean age was 74±6 years with a mean serum sodium level of 141±3 mmol/L. After adjustment demographics, education, co-morbid conditions, smoking, alcohol, body-mass index, estimated glomerular filtration rate, physical activity, and quality of life measures, serum sodium was associated with prevalent cognitive impairment (quartile 1 [126-140 mmol] vs. quartile 4 [143-153 mmol] OR: 1.49, 95% CI: 1.15-1.92). For incident cognitive impairment (median follow-up of 4.6 years), quartile 3 (142-143 mmol) was associated with lower odds of cognitive impairment vs. quartile 4 (143-153 mmol; adjusted OR: 0.77, 95% CI: 0.61-0.96), with no difference in quartile 1 (126-140 mmol) vs. quartile 4 (adjusted OR: 0.95, 95% CI: 0.77-1.18).

Conclusions: In asymptomatic, community-dwelling older men, hyponatremia was associated with prevalent but not incident cognitive impairment.

TH-PO491

Postoperative Hyponatremia in Urologic Surgery Is Associated with Poor Survival and Long-Term Renal Outcome Sehoon Park,[1] Jung Nam An,[2] Jung Pyo Lee,[2] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[1] Chun Soo Lim.[2] *[1]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea.*

Background: Although in-hospital hyponatremia is a well-known factor for adverse clinical outcomes, the impact of postoperative hyponatremia in urology remains unclear.

Methods: We examined the incidence, risk factors, and outcomes of postoperative hyponatremia in urologic surgery. Patients with events of postoperative sodium level lower than 135 mEq/L within 7 days after surgery were included in our study group, and the others in the control group. Primary outcomes were postoperative all-cause mortality and end-stage renal disease (ESRD) progression, defined by the start of dialysis or newly diagnosed stage 5 chronic kidney disease (eGFR < 15ml/min/1.73m^2). The secondary outcome was the worsening of the long-term renal outcome, including ESRD progression and serum creatinine doubling/eGFR halving from baseline, occurring 1 month or more after surgery.

Results: The medical records of 9,449 cases of bladder, prostate, ureter, and kidney surgery were collected. Incidence of postoperative hyponatremia was 16.5% (1,562/9,449). Postoperative hyponatremia mostly developed in patients with high-risk perioperative characteristics. Moreover, postoperative hyponatremia was related to both mortality (adjusted HR 1.46, 95% CI 1.02-2.11, $P = 0.04$) and ESRD progression (adjusted HR 1.31, 95% CI 1.07-1.62, $P = 0.008$). The secondary outcome was also related to the electrolyte imbalance in prostate (adjusted HR 1.78, 95% CI 1.21-2.62, $P = 0.003$), ureter (adjusted HR 1.83, 95% CI 1.07-3.13, $P = 0.03$), and kidney (adjusted HR 1.22, 95% CI 1.01-1.49, $P = 0.04$) surgery. However, this relationship was not observed in bladder surgery cases (adjusted HR 1.09, 95% CI 0.83-1.45, $P = 0.54$).

Conclusions: Postoperative hyponatremia was a common electrolyte imbalance after urologic surgery, especially in patients with high-risk perioperative status. Postoperative hyponatremia was an important predictor of both mortality and adverse renal outcome in major urologic operations.

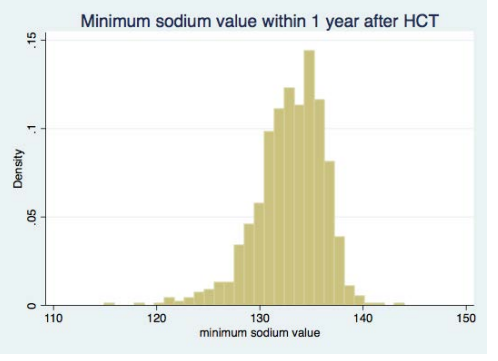
TH-PO492

Hyponatremia Is Common among Patients Receiving Stem Cell Transplant and Is an Independent Predictor of Mortality Jaya Kala, Amit Lahoti. *Nephrology, Univ of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Electrolyte disturbances are common among patients who undergo hematopoietic cell transplant (HCT). Hyponatremia is frequently diagnosed in this population. However, there have been few studies published to date examining the incidence and prognostic effect of hyponatremia in patients receiving HCT.

Methods: We retrospectively analyzed the records of 1041 patients who underwent hematopoietic cell transplant (HCT) at our institution from Jan 2004 through Dec 2006. A Cox Proportional Hazards Model was used to examine the effect of hyponatremia on mortality. Hyponatremia was defined as a level less than or equal to 135 meq/L. The minimum sodium level obtained within 1 year after transplant was included in the analysis. Other covariates included age, gender, race, HTN, diabetes, CMV status, prior HCT, transplant type, sepsis, acute kidney injury, acute GVHD, and maximum bilirubin.

Results: The majority of patients (76%) developed hyponatremia within 1 year of HCT. Minimum sodium values were 131-135, 126-130, and <=125 meq/L in 57%, 15.8%, and 2.8% of patients, respectively. The hazard ratios for mortality were 1.9, 2.9, and 3.1 (p<.001 for all categories), respectively. When analyzed as a continuous variable, we found a 9% decrease in mortality per 1 meq/L rise in sodium level. Other variables associated with mortality included acute kidney injury, acute GVHD, and allogeneic transplant (HR 1.9, 3, and 2.9, respectively).



Conclusions: We found that a majority of our patients developed some degree of hyponatremia after HCT, and even mild decreases in serum sodium (131-135 meq/L) are associated with a significantly increased risk of mortality in a multivariate model. Whether correction of hyponatremia after transplant improves survival is of interest.

TH-PO493

Hyponatremia in Cancer Patients Treated with Immune Checkpoints' Inhibitors: Is Adrenal Impairment the Cause? Laura Cosmai,[1] Wanda Liguigli,[2] Camillo Porta,[3] Maurizio Gallieni,[4] Marina Foramitti,[1] Fabio Malberti.[1] *[1]Nephrology, Istituti Ospitalieri, Cremona, Italy; [2]Oncology, Istituti Ospitalieri, Cremona, Italy; [3]Oncology, IRCCS San Matteo Univ Hospital Foundation, Pavia, Italy; [4]Nephrology, San Carlo Borromeo Hospital, Milan, Italy; [5]Nephrology, Istituti Ospitalieri, Cremona, Italy; [6]Nephrology, Istituti Ospitalieri, Cremona, Italy.*

Background: Immune checkpoints' inhibitors such as Ipilimumab and Nivolumab are more and more commonly used to treat patients (pts) with different solid cancers (e.g. melanoma, lung cancer and kidney cancer).

Methods: We have observed 7 pts who developed hyponatremia during treatment with Ipilimumab + Nivolumab (within a randomized phase III trial conducted in metastatic kidney cancer, n = 6) or Ipilimumab monotherapy (for melanoma, n = 1).

Results: Of the 7 pts observed, 1 had a grade 4, 3 a grade 2, and 2 a grade 1 hyponatremia. The patient with grade IV was hospitalized (seriuos adverse event was reported) and treated with 40 mEq sodium i.v. supplementation over 24 hours for 4 days, before complete resolution; of the other 3 pts with a grade 2 hyponatremia, 2 received 20 mEq sodium i.v. supplementation over 24 hours for 1 to 2 days, and 1 was treated with steroids (methylprednisolone 32 mg i.v.) for 2 days. All events resolved, but in 5 out of 7 cases, hyponatremia relapsed at the following administrations (never worst than grade 1); the only patients treated with steroids had a complete and long lasting resolution of his hyponatremia.

Conclusions: Hyponatremia is a relatively frequent event during treatment with immune checkpoints' inhibitors; its pathogenesis is unknown, but a drug-induced adrenal impairment/inflammation could be postulated and the efficacy of steroids in one of our cases do support this hypothesis.

TH-PO494

Predictors of Rapid Correction of Hyponatremia Caused by the Syndrome of Inappropriate Secretion of Antidiuretic Hormone during Treatment with Tolvaptan Jesse H. Morris,[1] Rachel E. Crawford,[2] Denise O. Kelley,[3] Nicole Bohm,[4] Bhavna Bhasin,[1] Paul Nietert,[5] Juan Carlos Q. Velez.[1] *[1]Div of Nephrology, Dept of Medicine, Medical Univ of South Carolina; [2]Dept of Pharmacy, Wake Forest Baptist Medical Center; [3]Dept of Pharmacy, UF Health Jacksonville; [4]Dept of Clinical Pharmacy and Outcomes Sciences, Medical Univ of South Carolina; [5]Dept of Public Health Sciences, Medical Univ of South Carolina.*

Background: Tolvaptan can correct hyponatremia caused by SIADH rapidly, thus carrying a risk for central pontine demyelination. We hypothesized that clinical and/or lab parameters predict the likelihood of rapid correction of SIADH-induced hyponatremia during treatment with tolvaptan.

Methods: Data were extracted from hyponatremic [serum sodium (sNa) ≤ 130 mmol/L] adults with SIADH treated with tolvaptan (1st dose 15 mg) at 3 university hospitals between 2010 and 2015. Those who also received po/i.v. sodium or demeclocycline were excluded. The ability of baseline parameters to predict the change in sNa was assessed by Spearman correlations and a multivariate linear mixed model.

Results: A total of 22 patients entered the analyses. Mean baseline sNa was 121.2 mmol/L and the mean rise in sNa over the first 24 hrs was 8.4 mmol/L. Correction of sNa > 12 or > 8 mmol/L/24 hrs occurred in 27% and 36% of the cases, respectively. Change in sNa over 24 hrs significantly correlated with baseline sNa (r=-0.75, p=0.0001), blood urea nitrogen (BUN) (r=-0.76, p=0.0001) and eGFR (r=0.58, p=0.01), but not with other parameters. A model incorporating time and baseline sNa (p<0.0001) explained 64% of the variation in 24 hr sNa. When baseline BUN was added to the model, it explained 75% of the variation in 24 hr sNa, although its effect did not reach significance (p=0.10). Four out of 4 patients with baseline sNa <120 mmol/L and BUN < 7 mg/dL corrected their sNa > 12 mmol/L/24 hrs (mean rise in sNa: 17.8 mmol/L/24 hrs).

Conclusions: Lower baseline sNa is significantly predictive of the magnitude of response to tolvaptan therapy for SIADH, and a lower baseline BUN may also be predictive. We advise caution when dosing tolvaptan in patients with particularly low sNa (< 120 mmol/L) and low BUN (< 7 mg/dL).

TH-PO495

Use of Salt Tablets in the Treatment of Mild-to-Moderate Hyponatremia due to Syndrome of Inappropriate Antidiuresis Ittikorn Spanuchart,[1] Thomas Aldan,[1] Hideaki Watanabe,[1] Dominic Chow,[1,2] Roland C.K. Ng.[1,2] *[1]Univ of Hawaii Internal Medicine Residency Program; [2]Univ of Hawaii John A. Burns School of Medicine.*

Background: Hyponatremia is the most common electrolyte disorder with significant morbidity and mortality. However, the effectiveness of salt tablets in treating this disorder has never been systematically examined. In this retrospective cohort study, we examined the effectiveness of salt tablet treatment in correcting mild-to-moderate hyponatremia.

Methods: Eighty-three patients with hyponatremia on fluid restriction, and laboratory values of urine osmolality >100 mosm/kg and urine sodium >30 mEq/L, who did not correct with normal saline infusion, were studied. Patients who had received salt tablets and fluid restriction were compared with those on fluid restriction alone. The primary outcome was the change in serum sodium at 48 hours.

Results: There were 41 patients in the non-salt treated group (NS) and 42 patients in the salt-treated group (S).The median serum sodium before treatment was (NS) 129 mEq/L (IQR: 125-131.5) and (S) 124 mEq/L (IQR121-129). The S patients tended to be older (p=0.019), female (p=0.049), lower weight (p=0.039), and have lower initial serum sodium (p=0.005). The serum sodium after 48 hours of treatment increased significantly more with salt tablets (S) than with fluid restriction (NS) alone (p=0.014). The change in serum sodium remained significant with S even after adjustment for age, gender, weight and initial serum sodium. The length of stay was longer in the S group (p=0.006). When the analysis was confined to more refractory patients (urine osmolality >500 mosm/kg), S (8 patients) and NS (5 patients), treatment with salt tablets resulted in a significant increase in serum sodium (p=0.004) compared with fluid restriction alone. Adverse effects such as congestive heart failure and severe hypertension were not different in the two groups.

Conclusions: Use of salt tablets in the treatment of mild-to-moderate hyponatremia due to syndrome of inappropriate antidiuresis is effective. Further studies of a prospective, randomized nature should be done to confirm these data.

TH-PO496

Salt Taste Thresholds and Salt Preference in Patients with Chronic Kidney Disease According to Stage: A Cross-Sectional Study Jae Wan Jeon, Hyosang Kim, Soon Bae Kim. *Internal Medicin, Nephrology, Asan Medical Center, Seoul, Republic of Korea.*

Background: Increased salt thresholds may affect the adequate control of oral salt intake and subsequent high blood pressure. This study was performed to evaluate the differences in salt taste thresholds among normal controls and non-dialysis chronic kidney disease (CKD) patients according to the stage and to evaluate the relationship between salt taste thresholds or salt preference and the mean spot urine sodium.

Methods: This cross-sectional study enrolled 436 patients with nondialysis CKD who visited Asan Medical Center (Seoul, Korea) more than three times and underwent spot urine sodium measurement at each clinic visit. We averaged the three most recent spot urine sodium concentrations and used this "mean spot urine sodium" value to estimate sodium intake. In addition, 74 normal controls were enrolled and their one-time spot urine sodium was measured. We evaluated the detection and recognition thresholds, salt preference, and salt usage behavior (via questionnaire) in CKD patients and normal controls.

Results: The detection thresholds of the stage 3a, 3b, 4 and 5 CKD patients and the recognition thresholds of the stage 3a and 3b CKD patients were higher than those of normal controls. The salt preference of the stage 5 patients and the salt usage behavior scores of the stage 4 and 5 patients were lower than those of normal controls. Estimated glomerular filtration rate (eGFR), salt usage behavior, and salt preference significantly correlated with the mean spot urine sodium in CKD patients. Age, sex, the detection and recognition thresholds, and serum zinc did not show a relationship with the mean spot urine sodium. Multiple regression analysis showed that eGFR, salt preference, and salt usage behavior score independently correlated with the mean spot urine sodium.

Conclusions: The detection and recognition thresholds are increased and salt preference and the salt usage behavior score are decreased in CKD patients. eGFR, salt preference, and the salt usage behavior score are independent predictors of the mean spot urine sodium in CKD patients. However, detection and recognition thresholds are not associated with the mean spot urine sodium in CKD patients.

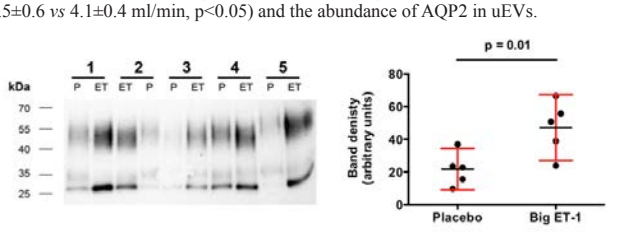
TH-PO497

Endothelin Induces Aquauresis in Man via an AQP2-Independent Mechanism Robert W. Hunter. *Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom.*

Background: Endothelin-1 (ET-1) receptor antagonists show promise in the treatment of diabetic nephropathy. Their use is complicated by salt / water retention. Whereas in animal models ET_B receptors cause natriuresis and aquauresis, with collecting duct ET_B inhibiting the activation of AQP2 channels, the pathogenesis of fluid retention with ET antagonists in man is not known. We aimed to determine the effect of ET-1 on water transport in the human collecting duct.

Methods: We conducted a 2-phase randomised, double-blind, placebo-controlled crossover study in 10 healthy volunteers. After sodium restriction, subjects received either intravenous placebo or the inactive ET-1 precursor, big ET-1, in an escalating dose (up to 300pmol/min). We prepared urinary extracellular vesicles (uEVs) by ultracentrifugation and analyzed them by immunoblot using antisera to AQP2 (Millipore).

Results: Big ET-1 infusion increased plasma concentration and urinary excretion of ET-1. Fractional excretion of ET-1 rose from 0.6 to 2.4% and urine ET-1/creat from 0.05 to 0.20pg/μmol. Big ET-1 caused a fall in heart rate (~8 beats/min) but no change in other measures of systemic hemodynamics or in GFR. Fractional excretion of sodium increased by ~0.5%. There was no change in urine flow rate. Big ET1 increased free water clearance (5.5±0.6 *vs* 4.1±0.4 ml/min, p<0.05) and the abundance of AQP2 in uEVs.



Conclusions: In man, ET-1 increased AQP2 excretion in uEVs (a proxy for AQP2 density in the collecting duct apical membrane). ET-1 stimulates pituitary AVP release, a

potential cause of increased AQP2 expression. However there was an apparent paradoxical increase in free water clearance. Thus the mechanism responsible for aquauresis was independent of any effect of ET-1 on AQP2. Further exploration of this mechanism will help manage the fluid retention associated with ET antagonists, a prerequisite for their use in the therapy of diabetic nephropathy.

TH-PO498

Tolvaptan Increases Renal Water and Sodium Excretion More Than Furosemide in Patients with Congestive Heart Failure Complicated by Advanced Chronic Kidney Disease Naoto Tominaga,[1] Keisuke Kida,[2] Takayuki Inomata,[3] Naoki Sato,[4] Tohru Izumi,[5] Yoshihiro J. Akashi,[2] Yugo Shibagaki.[1] *[1]Div of Nephrology and Hypertension, St. Marianna Univ, Japan; [2]Div of Cardiology, St. Marianna Univ; [3]Dept of Cardio-angiology, Kitasato Univ; [4]Cardiology and Intensive Care Unit, Nippon Medical School Musashi-Kosugi Hospital; [5]Div of Cardiology, Niigata Minami Hospital.*

Background: Tolvaptan (TLV) is known to increase electrolyte-free water clearance. However, TLV actions on renal electrolytes including urine sodium (uNa) excretion and its consequences are less well understood in congestive heart failure (CHF) patients with CKD. This subanalysis investigated the effect of add-on TLV compared to furosemide (FUR) on both free water and electrolyte clearance in patients with CHF complicated by advanced CKD.

Methods: The Kanagawa Aquaresis Investigators Trial of TLV on HF Patients with Renal Impairment was a multicenter, open-labeled, randomized, and controlled prospective clinical study. Eighty-one Japanese patients with congestive HF and residual signs of congestion despite oral FUR treatment (≥40 mg/day) were recruited. They were randomly assigned to a 7-day treatment with either add-on ≤40 mg/day FUR or ≤15 mg/day TLV. However, 31 patients dropped out during the study and 16 patients had missing data resulting in 17 patients in each group. Free water and electrolyte excretion were compared before and after therapy between the two groups.

Results: As expected, free water clearance was significantly higher in the add-on TLV group than in the add-on FUR group (0.25±0.07 vs. -0.01±0.04 mL/min, P=0.001). However, electrolyte clearance was also higher in the add-on TLV group than in the add-on FUR group (0.06±0.06 vs. -0.08±0.07 mL/min, P=0.185). This was mainly because ΔuNa excretion was significantly higher in the add-on TLV group than in the add-on FUR group (13.8±10.9 vs. -16.2±12.0 mEq/day, P=0.040), since ΔuK excretion was significantly lower in the add-on TLV group than in the add-on FUR group (-6.7±2.4 vs. 0.8±1.2 mEq/day, P=0.014).

Conclusions: Add-on TLV may have an effect to increase both renal water and Na excretion in CHF patients with advanced CKD to a greater degree than add-on FUR.

TH-PO499

Urea for SIADH: The First U.S. Long Term Results Gregory Lee Braden, Michael H. O'Shea, Daniel L. Landry. *Nephrology Div, Baystate Medical Center/Tufts Medical School, Springfield, MA.*

Background: Urea has been used in Europe for >35 years to treat SIADH but it is not available in the U.S. Also, the long term effects of Urea on uric acid(UA) handling in SIADH have not been defined. We obtained Urea USP from MEDISCA, a compounding company with U.S. distributors. The Urea is made by Merck in Germany and costs a patient(pt) $30/mo. We studied Urea in 6 female pts with only Medicare plan D for meds, ages 66-91 with SIADH (4 lung cancer, 1 idiopathic & 1 psych meds) who failed 1000 ml/d fluid restriction, demeclocycline(DMC) [3 nausea, 1 aki & 6 unaffordable at $600-900/mo] or tolvaptan(TOL) unaffordable at >$700/mo.

Methods: We measured serum(S) sodium (Na), BUN, creatinine, UA, plasma(P) Osm, Urine Osm, fractional excretion(FE)Na, & FE UA before Urea , & 7 d, 30 d & 180 d after starting Urea 10 -15 grams twice daily. Fluid was restricted to 1500 ml daily for 1 week then liberalized to ad lib.

Results: Results are expressed as X+SEM:

	Before Urea	7d	30d	180d	p
S Na (mEq/L)	126+1	132+1	135+1	136+1	.0007
P Osm (mOsm/kg)	266+3	278+1	289+3	287+3	.0044
S UA (mg/dL)	2.7+0.4	3.8+0.2	4.8+0.5	4.7+0.4	.0092
FE UA (%)	16.8+1	12.1+0.5	8.1+0.4	8.1+0.5	.0017

S Na was near normal after 7 d and thereafter remained normal for 180d. BUN increased from 13.8+2.6 mg/dl to 27.2+3.7 after 7d, to 39.3+6 after 30d & to 36.5+5 after 180 d confirming the pts took Urea (.0084). The S UA was normal after 7d & remained normal at 180 days(p=.0092). The FE uric acid was elevated,>12%, before Urea but was normal thereafter(p=.0017). No patient had polyuria or any reaction to Urea except for it being distasteful . Their were no differences in urine Osm ,urine Na, FE Na or serum creatinine.

Conclusions: Indeed, pharmaceutical grade Urea USP is available in the US & all Baystate Medical Center pharmacies stock it. Urea is a safe, effective, inexpensive alternative therapy for pts with SIADH intolerant to DMC or who can't afford DMC or TOL. Similar to successful fluid restriction in SIADH, Urea normalizes S UA & FE UA as the S Na reaches normal levels.

TH-PO500

A Gain of Function NKCC2 Mutation in a Patient with Chronic Cyclic Edema Minhtri K. Nguyen,[1] Alejandro Rodriguez-Gama,[2] Erika Moreno,[2] Theresa L. Nilson,[1] Gerardo Gamba,[2] Ira Kurtz.[1] *[1]David Geffen School of Medicine, UCLA, Los Angeles, CA; [2]Molecular Physiology Unit, INCMNSZ-IIB-UNAM, Mexico City, Mexico.*

Background: We report a 20 y.o. female with a complex medical history significant for chronic cyclic edema, who has a homozygous R116H substitution in the *SLC12A1* gene. The patient was normotensive without any electrolyte or metabolic acid-base abnormalities. Urine studies showed significantly reduced 24 hr excretion of Na^+, K^+, Cl^-, Ca^{2+}, and Mg^{2+} consistent with increased NKCC2 activity: Na^+ 63 meq, K^+ 24 meq, Cl^- 44 meq, Ca^{2+} 22 mg, Mg^{2+} undetectable, creatinine 710 mg (weight 50 kg). The patient's cyclic edema was completely prevented by treatment with 20 mg of Lasix.

Methods: Expression/phosphorylation of NKCC2 was assessed by Western blot in proteins extracted from transiently transfected HEK-293 cells with wild-type and mutant NKCC2-R116H that were exposed to control and different osmolar conditions.

Results: Basal phosphorylation was similar between wild-type and NKCC2-R116H. However, following exposure to low chloride stress for 10, 20 and 30 min (known to activate NKCC2), the mutant transporter was phosphorylated significantly more rapidly than the wild-type transporter. In separate experiments, the rate of dephosphorylation was monitored following cell swelling (known to inhibit NKCC2). The phosphorylation of NKCC2 at 10, 20 and 30 min decreased from 1.0 ± 0.01 (arbitrary units) at basal state to 0.74 ± 0.06, 0.6 ± 0.1, and 0.5 ± 0.07 respectively, while in mutant NKCC2-R116H at the same time points the decrease in phosphorylation was significantly less: 1.0 ± 0.01 to 0.95 ± 0.03, 0.83 ± 0.05, and 0.8 ± 0.09 respectively.

Conclusions: The NKCC2 dephosphorylation is precluded by the R116H mutation. Since phosphorylation of NKCC2 stimulates its transport activity, the R116H mutation in our patient appears to represent the first gain of function NKCC2 mutation ever reported.

Gender Difference in Thiazide Sensitive Na-Cl Cotransporter Activity and Expression in Wild Type and Angiotensin II Type 1a Receptor (AT1a) Deficient Mice Jing Li,[1] Ryo Hatano,[1] Lei Yang,[2] Shuhua Xu,[1] Alan Mark Weinstein,[2] Lawrence G. Palmer,[2] Tong Wang.[1] *[1]C. & M. Physiology, Yale Univ, School of Medicine, New Haven, CT; [2]Physiology and Biophysics, Weill Medical College of Cornell Univ, New York, NY.*

Background: Thiazide sensitive Na-Cl cotransporter (NCC) mediates the majority of NaCl absorption in the distal tubule. Alteration of NCC directly affects salt and water balance and blood pressure. We studied gender differences in NCC activity and expression in WT and AT_{1a} receptor knockout (KO) mice.

Methods: Renal clearance experiments were performed on both male and female WT and KO mice. Urine volume (UV), GFR, absolute (ENa) and fractional (FNa) Na excretion were measured and compared at peak changes after a bolus iv injection of hydrochlorothiazide (HCTZ; 30mg/kg). NCC mRNA expression was examined by Q-PCR; total NCC (tNCC) and phosphorylated NCC (pNCC) were examined by Western-blotting. In WT mice, HCTZ produced greater diuretic and natriuretic effects in females, compared to males.

Results: The fractional increases of UV, ENa and FENa by HCTZ were 8.3- vs. 5.3-fold; 13.3- vs. 6.7- fold and 9.4-vs. 4.9-fold in female, compared with male, respectively (n=6, $P<0.05$). In contrast, there was no gender difference in $AT_{1a}^{-/-}$ mice, since HCTZ produced stronger diuretic and natriuretic effects on male $AT_{1a}^{-/-}$ than the WT, and female WT and KO mice had the same effect. The fractional increases of UV, ENa and FENa by HCTZ were 8.9- vs. 6.3-fold; 10.5- vs. 15.1- fold, and 7.8- vs. 13.7-fold in female compared with male respectively ($P>0.05$). NCC mRNA expression was 39% and 48% higher in female, both WT and KO, mice compared to the male mice (n=4, $p<0.05$). Total NCC and pNCC expression was 36% and 34% higher in female WT compared to the male, consistent with the larger response to HCTZ. tNCC increased by 30% in both male and female KO, but pNCC was not significantly different from WT.

Conclusions: We conclude that in WT higher NCC expression in females correlates with activity; the gender-specific difference in activity is absent in $AT_{1a}^{-/-}$ mice. The findings are consistent with less reliance on the renin-angiotensin system for BP maintenance in females.

Impaired Renal Electrolyte Reabsorption in Moesin-Deficient Mice Kotoku Kawaguchi, Ryo Hatano, Shinji Asano. *College of Pharmaceutical Sciences, Ritsumeikan Univ, Kusatu, Shiga, Japan.*

Background: ERM (ezrin, radixin, and moesin) proteins have important roles in organizing membrane domains through their ability to cross-link transmembrane proteins and actin cytoskeleton. Previously, we have reported that ezrin plays important roles in the regulation of membrane localizations of Na^+ dependent phosphate transporter (NaPi2a) and scaffolding protein NHERF1 in the proximal tubules. However, physiological roles of radixin and moesin in the kidney still remain unclear. In the present study, we have investigated the physiological functions of radixin and moesin in the kidney using knockout mice.

Methods: To investigate the renal functions in male radixin (*Rdx*$^{-/-}$) and moesin (*Msn*$^{-/y}$) knockout mice, these mice were housed in metabolic cages. After acclimation for 7 days, daily urine volume and water intake were measured. Spot urine was collected

for the measurement of urinary excretion of electrolytes. These mice were sacrificed to obtain plasma and renal tissue after experiments. Glomerular filtration rate (GFR), absolute (ENa, EK), and fractional excretion (FENa, FEK) were measured. Brush border membrane vesicles (BBMVs) were prepared from renal cortex of these mice to compare the membrane localizations of transmembrane proteins in proximal tubules. Subcellular localization of associated proteins was examined by immunofluorescent analysis.

Results: *Msn*$^{-/y}$ mice showed significant increase in the absolute (ENa) and fractional (FENa) Na^+ excretion, although there was no apparent abnormality in the solute reabsorption in *Rdx*$^{-/-}$ mice. Expression levels of Na^+ transporters as NaPi2a and Na^+/H^+ exchanger 3 (NHE3) located in proximal tubules were unaltered in BBMVs from both Rdx$^{-/-}$ and Msn$^{-/y}$ mice compared to WT mice, suggesting that proximal tubular Na^+ reabsorption is not impaired. Immunofluorescent analysis exhibited the colocalization of moesin and NKCC2 in the apical membrane of thick ascending limb of Henle (TAL). Moesin is also co-immunoprecipitated with NKCC2 using renal medulla.

Conclusions: Our results suggest that moesin, but not radixin, plays an important role in the regulation of sodium reabsorption in the TAL, possibly due to the regulation of membrane localizations of NKCC2.

Urokinase-Type Plasminogen Activator Is Not Required for Edema Formation in Experimental Nephrotic Syndrome Ferruh Artunc, Bernhard Bohnert, Matthias Woern, Sophie Daiminger. *Internal Medicine, Div of Nephrology, Univ Hospital, Tuebingen, Germany.*

Background: Edema formation in nephrotic syndrome is thought to arise from activation of the epithelial sodium channel (ENaC) by the serine protease plasmin after conversion of aberrantly filtered plasminogen by tubular urokinase-type plasminogen activator (uPA). Inhibition of uPA might prevent plasmin generation and subsequent edema formation.

Methods: We investigated the effects of inhibiting of uPA in a model of experimental nephrotic syndrome using a pharmacological approach with amiloride in wild-type mice or in mice with genetic uPA deficiency (uPA$^{-/-}$ mice). Proteinuria was induced by a single injection of doxorubicin (14.5 µg/g). Urinary uPA and plasmin activity was measured using chromogenic substrates, conversion of plasminogen to plasmin was analyzed with western blot (WB).

Results: Amiloride inhibited urinary uPa activity of control mice with an IC50 of 6 µM (95%CI 4;9). In amiloride-treated wild-typ mice (10 µg/g i.p., once daily) weight gain was almost completely prevented after onset of proteinuria (+6±1% , n=6 vs. +20±2% in vehicle-treated mice, n=8; p=0.001). Urinary amiloride concentration reached up to 362 µM 4 h after injection and fell to zero after 24h. Urinary uPa and plasmin activity was significantly reduced by amiloride (p=0.04); WB showed absent plasminogen conversion in amilorid-treated mice. In uPA$^{-/-}$ - mice, there was no urinary uPA activity detectable under control conditions. After induction of proteinuria the increase in urinary plasmin activity was completely absent in uPA$^{-/-}$ - mice and WB showed only a single plasminogen band. However, uPA$^{-/-}$ - mice were not protected from weight gain (+21±1%, n=7 vs. +20±1%, n=7; p=0.85) and sodium retention (minimal urinary sodium concentration 8±3 vs. 11±9mM, p=0.72) compared to uPA$^{+/+}$ - mice.

Conclusions: uPA is responsible for conversion of aberrantly filtered plasminogen to plasmin in the tubulus lumen. This is however not essential for edema formation in experimental nephrotic syndrome.

TH-PO504

Extending the Use of Bioimpedance Spectroscopy and Body Composition Modelling for Assessment of Fluid Status to Children Indranil Dasgupta,[1] Elizabeth J. Lindley,[2] Peter Wabel.[3] *[1]Heartlands Hospital, United Kingdom; [2]Leeds Teaching Hospitals, United Kingdom; [3]Fresenius Medical Care, Germany.*

Background: Bioimpedance spectroscopy (BIS) together with a whole-body model to distinguish excess fluid from the hydration of major body tissues provides an objective assessment of fluid status. This technology is integrated into the Body Composition Monitor (BCM,Fresenius AG, Bad Homburg) and has been well validated in adults. The aims were (a) to assess the agreement between total body water (TBW) measured using BIS and a gold standard technique; (b) to compare the estimated hydration of lean tissue (LT) in children and adults; (c) to look for systematic deviation from zero in the measured excess fluid in healthy children.

Methods: TBW_D2O was determined from the decline in the concentration of deuterium in urine samples, collected for 5 days following a drink containing 7% D_2O. dilution. The hydration of LT was estimated by extrapolating a plot of TBW/weight vs. %fat measured with DEXA to 0% body fat. TBW_BCM and excess fluid was determined from a standard wrist-to-ankle BCM measurement. The agreement between TBW_D2O and TBW_BCM was analysed using Bland-Altman method.

Results: 61 healthy children between 6 and 14 years (32 male, median age 10.3) completed the study, 5 children aged 2 to 5 years were recruited for aim (c) only. 60 children provided sufficient urine samples for analysis. The BMI correction to fluid volumes determined from BIS was not appropriate for children, but there was good agreement between the uncorrected TBW_BCM and TBW_D2O with a bias of +0.6 L (95% limits of -2.0 to +3.2 L). The estimated water content of lean tissue of 70.4% (95% CL 68.0-72.7%) was consistent with the 70.3 ± 0.9% estimate for adults. The median absolute excess fluid volume was +100 mL (IQR -140 to +480 mL). The median excess fluid normalised to body weight was +0.48% (IQR -0.51% to + 1.45%). There was no correlation between age and either absolute or normalised excess fluid in this group of healthy children.

Conclusions: Although BCM data should be used with caution in patients that differ significantly from the population used to develop the models, these results suggest that the device can be used in children.

TH-PO505

Exploring the Effect of Tacrolimus on the Renal Kinome: Identification of Novel Phosphoproteins Felice K.Y. Leung,[1,2] Benedetta Lombardi,[1] Mark Desmond Crawford,[1] Anselm A. Zdebik,[1,2] Jasminka Godovac Zimmermann,[1] Joanne Marks,[1,2] Stephen B. Walsh.[1] *[1]Centre for Nephrology, UCL, London, United Kingdom; [2]Dept of Neuroscience, Physiology and Pharmacology, UCL, United Kingdom.*

Background: Tacrolimus is a calcineurin inhibitor (CNI), and the main immunosuppressant used in organ transplantation. However, it causes complications such as hypertension, acidosis, hyperkalaemia, diabetes mellitus and hypercalciuria, mimicking the metabolic syndrome, which may be mediated by altered renal tubular transport mechanisms.

Methods: Male C57BL/6J mice, 6-8 weeks of age, were administrated vehicle or tacrolimus (2mg/kg/day/ I.P) for two weeks. At the end of the treatment period they were euthanized by cervical dislocation, under Schedule 1, and the kidneys were removed. The cytoplasmic and membrane fraction of the renal cortices were separated by centrifugation. The proteins were reduced, alkylated and digested by trypsin. Peptides were then labelled with isobaric Tandem Mass Tags, followed by TiO_2 phosphopeptide enrichment. Vehicle and tacrolimus treated samples were combined and injected into the liquid chromatography-mass spectrometry (LC-MS/MS) for analysis.

Results: Several hypertension-related phosphopeptides were identified in this study. The thiazide-sensitive sodium-chloride cotransporter (NCC) had significantly increased phosphorylation at T122 (+13.32%) and S124 (+12.09%); a novel phosphosite- S127 was also identified with increased phosphorylation (+17.74%), and the coexpression of pS124 and pS127 showed enhanced phosphorylation (+20.71%) after tacrolimus treatment. Other phosphopeptides identified included regulatory factors involved in tacrolimus induced hypertension. Angiotensin-converting enzyme had increased phosphorylation at S1305 (+23.89%). Sodium-hydrogen exchanger regulatory factor 1 (12.18-25.61%) had increased phosphorylation at a number of phosphosites.

Conclusions: The data suggests that the effects of calcineurin inhibition on renal electrolyte transport and their potential regulators are complex, profound and may relate to adverse effects of CNIs. Further investigation of the role of these novel candidates in the effects of CNIs is warranted.

TH-PO506

The Effect of Tacrolimus on Distal Renal Calcium Transporter Expression Felice K.Y. Leung,[1,2] Joanne Marks,[1,2] Stephen B. Walsh.[1] *[1]Centre for Nephrology, UCL, United Kingdom; [2]Dept of Neuroscience, Physiology and Pharmacology, UCL, United Kingdom.*

Background: Tacrolimus (FK506) is an immunosuppressant widely used in transplant medicine to prevent rejection. Hypercalciuria, hypertension, hyperkalaemia, metabolic acidosis and diabetes mellitus are common side effects of tacrolimus; the effect of tacrolimus on calcium handling in the distal nephron is unclear.

Methods: This study investigated the effect of tacrolimus on the renal mRNA and protein expression of calcium-transport proteins: the apical transient receptor potential cation channel-V (TRPV5) and basolateral plasma membrane Ca^{2+} ATPase (PMCA) and basolateral sodium-calcium exchanger (NCX1). Regulatory proteins including: cytosolic Ca^{2+}-binding protein calbindin-D (D28k), calcineurin and calnexin were also investigated. Male C57BL/6J mice of 6-8 weeks age were treated with vehicle or tacrolimus (2mg/kg/day/I.P) for 2 weeks. Quantification of mRNA expression was determined by qPCR and protein levels were quantified by Western blotting. Values are presented as mean fold changes relative to controls ± S.E.M.; statistical significance was calculated using unpaired t-test.

Results: FK506 significantly increased renal mRNA expression of TRPV5 (1.48±0.11, $p<0.01$); mRNA expression of the other transport-proteins: PMCA1, PMCA4 and NCX1, was not significantly different. FK506 significantly decreased mRNA expression of D28k (0.60±0.10, $p<0.05$), but changes in calcineurin was not observed. Furthermore, FK506 caused no change in the protein abundance of TRPV5 but significantly increased the protein levels of PMCA (3.02±0.24, $p<0.0001$) and NCX1 (2.76±0.27, $p<0.001$). Although the protein abundance of the regulatory proteins: D28k and Canx, showed no significant difference after FK506 treatment, a decreasing trend post-FK506 treatment was observed in D28k.

Conclusions: These data are not compatible with FK506 induced hypercalciuria arising from altered calcium transporter levels in the distal convoluted tubule. The increase in the protein abundance of PMCA and NCX1 may be due to the removal of the inhibitory effect of calcineurin and dysregulated protein kinase C signalling.

TH-PO507

The Effect of Sodium Nitrite Infusion on Renal Variables, Brachial and Central Blood Pressure during Enzyme Inhibition by Allopurinol, Enalapril or Acetazolamide in Healthy Subjects: A Randomized, Double-Blinded, Placebo-Controlled, Cross-Over Study Jeppe B. Rosenbaek, Erling B. Pedersen, Jesper N. Bech. *Univ Clinic in Nephrology and Hypertension, Dept of Medical Research, Regional Hospital West Jutland and Aarhus Univ, Denmark.*

Background: Sodium nitrite ($NaNO_2$) causes vasodilation, presumably by enzymatic conversion to nitric oxide (NO). Several enzymes with nitrite reducing capabilities have been discovered in vitro, but their relative importance in vivo has not been investigated. We aimed to examine the effects of $NaNO_2$ on hemodynamics, fractional sodium excretion (FE_{Na}), free water clearance (C_{H2O}) and GFR, following pre-inhibition of xanthine oxidase, angiotensin-converting enzyme and carbonic anhydrase.

Methods: In a double-blinded, placebo-controlled, cross-over study, 16 healthy subjects were treated, in a randomized order, with placebo, allopurinol 150 mg twice daily (x 2), enalapril 5 mg x 2, or acetazolamide 250 mg x 2. After four days of treatment and standardized diet the subjects were examined at our lab. During administration of 240 mg $NaNO_2$/kg/hour for two hours, we measured brachial and central blood pressure (BP), plasma and urine osmolality, GFR by Cr-EDTA clearance, FE_{Na} and urinary excretion rate (UER) of cyclic guanosine monophosphate (cGMP) and nitrite and nitrate (NO_x). Subjects were supine and orally water-loaded throughout the examination day.

Results: After 90-120 min of $NaNO_2$ infusion we observed an increase in FE_{Na}, heart rate, UER of NO_x, and a decrease in C_{H2O}, UER of cGMP, and brachial systolic BP irrespective of pretreatment. We observed a consistent trend towards a reduction in central systolic BP, which was only significant after allopurinol. An increase in GFR was only observed after placebo.

Conclusions: This study shows a BP lowering and natriuretic effect of $NaNO_2$ regardless of preceding enzyme inhibition. GFR was increased by $NaNO_2$ infusion, when no enzymes where inhibited. The decrease in UER of cGMP indicates little or no conversion of nitrite to NO, thus the effect of $NaNO_2$ does not seem to be mediated by NO generation.

Generation of p62/SQSTM1 (p62) KO Cell Lines Using CRISPR/Cas9 -The Role of p62 on WNK1 Regulation by Changes of Extracellular Potassium Concentration- Yutaro Mori,[1,2] Shintaro Mandai,[1] Takayasu Mori,[1] Eisei Sohara,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Dept of Nephrology, Graduate Schools of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Div of Nephrology, Tsuchiura Kyodo General Hospital, Tsuchiura, Ibaraki, Japan.*

Background: We reported that KLHL3 binds to WNK4 and Cullin3 (CUL3) and ubiquitinate WNK4 and that the impaired WNK4 ubiquitination and degradation cause human hypertensive disease through the activation of WNK-OSR1/SPAK-NCC cascade. We also discovered that p62/SQSTM1 (p62), an autophagic adaptor protein, binds to WNK4-KLHL3 complex and is degraded together by selective autophagy. However, the physiological role of autophagic degradation of WNKs remained to be determined. Here, we generated p62 knockout (KO) cell lines by using CRISPR/Cas9 system and investigated the physiological role of selective autophagy in WNKs degradation.

Methods: We generated p62 KO HEK293T cell lines by using CRISPR/Cas9 system and analyzed them by western blotting. We exposed wild-type and p62 KO cells to different potassium concentration medium and examined WNK protein levels. We also performed siRNA knockdown (KD) experiments of p62 using COS7 cells and performed similar experiments.

Results: We designed the guide RNA targeting the exon 3 of p62 gene. We transfected HEK293T cells with the guide RNA expression vector and Cas9 vector. By single colony isolation after transfection, some hetero or homo KO cell lines were obtained. We confirmed that expressed WNK4 and KLHL3 protein level was dramatically increased in p62 KO cells. In wild-type HEK293T and COS7 cells, exposure to low potassium medium increased WNK1 expression, and high potassium medium decreased. However, in p62 KO and KD cells, WNK1 changes were partially canceled compared with wild-type.

Conclusions: We succeeded the generation of p62 KO cell lines. We confirmed that p62 degraded WNK4-KLHL3 complex by selective autophagy. Furthermore, this degradation system may regulate WNKs expression under changes of extracellular potassium concentration.

TH-PO509

Three-Layered Proteomic Analysis of MAGED2 Signaling Markus M. Rinschen,[1] Malte P. Bartram,[1] Thomas Benzing,[1] Robert A. Fenton,[2] Martin Kömhoff,[3] Bodo B. Beck.[4] *[1]Internal Medicine, Univ Hospital Cologne, Cologne, Germany; [2]Dept Biomedicine, Aarhus Univ, Aarhus, Denmark; [3]Univ Children's Hospital, Philipps Univ Marburg, Germany; [4]Human Genetics, Univ Hospital Cologne, Cologne, Germany.*

Background: Loss of function mutations in the X-chromosomal MAGED2 gene were recently discovered as a novel cause for X-linked antenatal Bartter's syndrome and polyhydramnios. The antenatal Bartter's syndrome was severe but completely resolved within a few weeks after birth. Staining of a fetal kidney from a patient with a truncating mutation in *MAGED2* revealed decreased total and apical abundance of NKCC2 and NCC. Cell culture studies demonstrated impaired maturation of the NKCC2 and NCC protein in the absence of MAGED2.

Methods: To investigate the function of MAGED2 in an unbiased manner, we performed a three-layered proteomic analysis. First, we analyzed the interactome of native MAGED2 in HEK293T cells. We also analyzed the interactome of wildtype (WT) and mutant (R446C)-MAGED2 when overexpressed in HEK 293T cells. Finally, we analyzed the effect of MAGED2 knockdown on the proteome and phosphoproteome.

Results: We performed an initial interactomic analysis of MAGED2 natively expressed in HEK293T cells using two different antibodies. We found that MAGED2 interacts with the nucleolar proteins NAP1L1, NAP1L2, and the stimulatory G-protein Gsalpha (gene symbol: GNAS). Next, we expressed tagged WT- and R446C-MAGED2 in HEK293T cells. The R446C mutant was less stable as compared to the WT MAGED2. In interactomic analysis, both WT- and R446C-MAGED2 were found to interact with NAP1L1 and NAP1L2. MAGED2 WT, but not R446C-MAGED2 interacted with GNAS and Hsp40. Cell culture studies confirmed the involvement of MAGED2 in controlling G-protein coupled receptor signaling. Proteomic and phosphoproteomic analyses of cells with MAGED2 knockdown demonstrated that several candidate proteins and substrates are controlled by MAGED2.

Conclusions: Our analyses suggest that MAGED2 could be a modulator of GNAS function. During renal development, sensitivity of adenylate cyclase increases. To understand the transient phenotype, the role of MAGED2 in controlling cAMP signaling in the distal nephron needs to be elucidated in greater detail.

TH-PO510

Free Vitamin D May Be Altered during Chronic Kidney Disease Anaïs Bouchara, Marie-Christine Carlier, Laetitia Koppe, Mathilde Nouvier, Maurice Laville, Bertille Pommier, Denis Fouque, Solenne Pelletier. *Univ de Lyon, Lyon, France.*

Background: Most chronic kidney disease (CKD) patients suffer from 25OH vitamin D (25OHvitD) deficiency, which might contribute to adverse health outcomes. Because vitamin D binding is altered during CKD, it has been proposed that serum free 25OHvitD better reflects vitamin D metabolism than total 25OHvitD. We aim to evaluate whether serum free 25OHvitD varies regarding the different stages of CKD, in comparison with total 25OHvitD.

Methods: We prospectively assessed 34 CKD patients during a glomerular filtration rate measurement (GFR) by inulin clearance. We measured serum free 25OHvitD by ELISA (DiaSource, Leuven, Belgium) and total 25OHvitD by immunoluminometry (DiaSorin, Italy).

Results: Patients were aged 54.7 ±13.6 yr, 44% were males. Mean GFR was 59 ±26 ml/min/1.73m^2, serum total 25OHvitD was 59.9 ±27.5 ng/ml and serum free 25OHvitD 5.45 ±1.96 pg/ml. We found a strong association between free 25OHvitD and total 25OHvitD ($r=0.88$, $p<0.001$). There was no correlation between free 25OHvitD and GFRwhereas total 25OHvitD significantly declined with GFR decrease($r=-0.34$, $p=0.048$). Of interest, the ratio free/total 25OHvitD strongly decreased with the decline of kidney function ($r=0.55$ $p<0.001$).We did not find any relationship between free 25OHvitD nor total 25OHvitD and measures of mineral metabolism.

Conclusions: This pilot study suggests that vitamin D bioavailability may be reduced in advanced CKD. The serum level of total 25OHvitD may indeed mask low free 25OHvitD and inadequate correction of vitamin D deficiency. Free 25OHvitD may represent a new target for treatment adaptation.

TH-PO511

Effect of Vitamin D Therapy on CKD-MBD Biomarkers in CKD: A Post Hoc Analysis of the PACE Study Stuart M. Sprague,[1] Ying Zhou,[1] Mark D. Faber,[2] Daniel W. Coyne.[3] *[1]NorthShore Univ HS-Univ of Chicago; [2]Henry Ford Hosp; [3]Washington Univ.*

Background: PACE, a 24 week randomized study comparing calcitriol (Calci) and paricalcitol (Pari) in CKD stage 3 & 4. Both Calci and Pari similarly decreased PTH, with minimal effects on Ca and Phos. Few studies have evaluated the effect of VDRA therapy on other mineral biomarkers in CKD. Therefore, a *post hoc* analysis of biomarkers was performed in a subgroup of subjects at baseline and week 24.

Methods: PACE, an open label, active comparator, multi-center, parallel group, phase 4 study of Pari vs Calci for suppression of PTH in CKD stages 3 & 4. Of the 110 original subjects, serum was available for 76 (38 in each group) for analysis of FGF23, sclerostin, bone specific alkaline phosphatase (BSAP), tartrate resistant acid phosphatase (TRAP), osteocalcin (OC), and 1,25 vitamin D (1,25D). The effect of therapy on their serum levels were analyzed.

Results:

	Calci		Pari		Calci vs Pari	
	Mean Change (SE)	p	Mean Change (SE)	p	Mean Diff (SE)	p
Ca (mg/dL)	0.34±0.07	<0.001	0.36±0.0.07	<0.001	-0.02±0.10	NS
PTH* (pg/mL)	-0.68±0.07	<0.001	-0.84±0.07	<0.001	0.16±0.10	NS
1,25D (pg/mL)	4.95±5.39	0.416	21.84±6.20	0.0014	-16.90±8.63	0.059
FGF23 (RU/mL)	184.4±45.2	0.001	190.8±44.4	<0.001	-6.4±63.4	NS
BSAP (µg/L)	-3.69±0.96	0.0007	-2.96±0.97	0.006	-0.74±1.36	NS
TRAP (ng/mL)	-1.08±0.20	<0.001	-0.73±0.20	0.0007	-0.35±0.29	NS
OC (ng/mL)	-16.40±8.95	0.078	-17.38±9.70	0.085	0.98±13.20	NS
Sclerostin (pg/mL)	88.2±31.5	0.008	152.38±33.15	<0.001	-64.20±45.77	NS

*Log transformed

Conclusions: Calci and Pari had comparable actions on biomarkers of bone activity, including significant increases in Ca, FGF23, and sclerostin, with significant suppression of bone turnover markers PTH, TRAP, BSAP, and a trend toward reducing OC. Pari, but not Calci, significantly increased 1,25D. Except for the difference between Calci and Pari on 1,25D, there was no differential effects on multiple biomarkers of these agents in a 6-month prospective clinical trial treating SHPT in patients with CKD.

Modified-Release Calcifediol Is Effective in African-American and Non-African-American Patients with Stage 3-4 CKD, Secondary Hyperparathyroidism and Vitamin D Insufficiency

Stuart M. Sprague,[1] Stephen A. Strugnell,[2] Joel Z. Melnick,[2] Martin P. Petkovich,[3] Charles W. Bishop.[2]
[1]NorthShore Univ HealthSystem, Evanston, IL; [2]OPKO Health, Miami, FL; [3]Queen's Univ, Kingston, ON, Canada.

Background: Current treatments for vitamin D insufficiency (VDI) and related secondary hyperparathyroidism (SHPT) in stage 3 or 4 CKD are ineffective, a particular concern with African-American (AA) CKD patients who have lower serum total 25-hydroxyvitamin D (25D) and higher PTH levels than non-AA patients. In the present studies, the effectiveness of oral modified-release calcifediol (MRC) for treating VDI and SHPT was evaluated in AA versus non-AA subjects.

Methods: Two identical, randomized, double-blind, placebo-controlled trials were conducted in 429 subjects (138 AA, 291 non-AA) with stage 3 or 4 CKD, SHPT (>85 pg/mL) and VDI (25D of 10-29 ng/mL) and the data were pooled. Subjects were randomized 2:1 to receive MRC or placebo for 26 weeks. MRC dosing started at 30 µg/d and was increased after 12 weeks to 60 µg/d, as needed, to lower plasma iPTH. Changes in plasma iPTH, serum total 25D, total 1,25-dihydroxyvitamin D (1,25D), calcium (Ca) and phosphorus (P) were compared within AA and non-AA subjects using the per-protocol population.

Results: MRC increased mean serum 25D from 18.7 to 66.3 ng/mL in AA subjects, and from 20.3 to 69.6 ng/mL in non-AA subjects ($p < 0.001$); levels in placebo-treated subjects declined slightly. MRC reduced mean plasma iPTH by 15.7% (from 153 to 129 pg/mL) in AA subjects, and by 25.2% (139 to 104 pg/mL) in non-AA subjects ($p < 0.05$ for both relative to placebo). Mean iPTH in placebo-treated AA and non-AA subjects increased 4% and 10%, respectively. MRC increased mean serum 1,25D levels by 16 pg/mL in AA subjects and 11 pg/mL in non-AA subjects versus 5 pg/mL with placebo. Adverse event rates were similar between treatment groups within AA and non-AA subjects. Changes in serum Ca and P with MRC were similar in AA and non-AA subjects, and were slightly greater (~0.1 mg/dL) than with placebo.

Conclusions: MRC was effective for correcting VDI and reducing iPTH in both AA and non-AA subjects with stage 3 or 4 CKD.

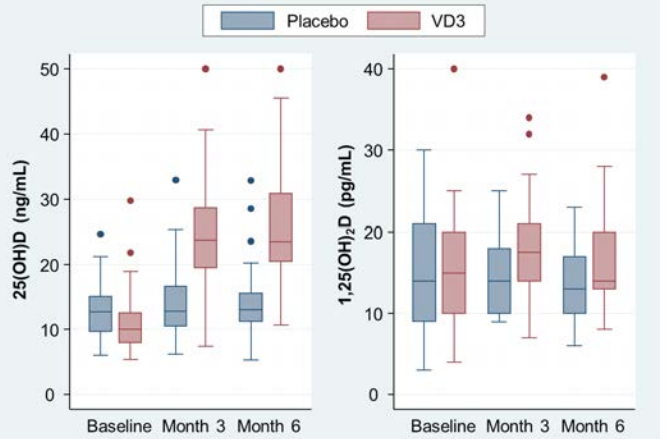
Cholecalciferol Supplementation and MBD-Related Parameters in Hemodialysis Patients - A Randomized Controlled Trial

Yoshitsugu Obi,[1,2] Takayuki Hamano,[1] Yusuke Sakaguchi,[1] Akihiro Shimomura,[1,2] Yoshitaka Isaka.[1]
[1]Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Univ of California Irvine, Orange, CA.

Background: A previous study demonstrated that ergocalciferol supplementation showed no effects on CKD-MBD related parameters in maintenance hemodialysis (MHD) patients. However, still scarce data exist regarding the effect of cholecalciferol (VD_3) and the impact of administration interval in this population.

Methods: This is a post-hoc analysis of a double-blind RCT of VD_3 supplementation in MHD patients. Patients were randomly assigned to either thrice-weekly (TW) 3,000 IU VD_3, once-monthly (OM) VD_3 (equivalent to 9,000 IU/week), TW placebo, or OM placebo. Based on the intention-to-treat principle, we compared VD_3 vs. placebo by using *a priori* defined generalized linear model with baseline adjustment ignoring the administration intervals. We also examined the differences between TW- vs. OM-VD_3.

Results: Out of 96 participants, 3 and 4 dropped out until Month 3 and between Month 3 and Month 6, respectively. Median (IQR) serum 25(OH)D levels at baseline and Month 6 were 13 (10–15) and 13 (11–16) ng/mL in the placebo, 10 (8–13) and 24 (21–31) ng/mL in the VD_3 group, respectively. After baseline adjustment, no significant differences were observed in serum levels of calcium, phosphorus, or intact PTH between the placebo vs. VD_3 groups. However, the VD_3 group showed 1.2 (95%CI, 1.1–1.4) times higher serum $1,25(OH)_2D$ levels at both Month 3 and 6. Their vitamin D receptor activator (VDRA) doses were more frequently reduced overtime than the placebo group (P=0.055 and 0.023 at Month 3 and 6, respectively). Any of those indices did not show differences between TW- and OM-VD_3.



Conclusions: Both TW- and OM-VD_3 supplementation are effective in increasing serum $1,25(OH)_2D$ levels and hence, reduces VDRA doses without affecting serum levels of calcium, phosphorus, and PTH in MHD patients.

TH-PO514

Impact of Genetic Variants in DBP, CYP2R1, CYP24A1, and VDR on Serum 25-Hydroxyvitamin D Levels and Cholecalciferol Supplementation in Hemodialysis Patients

Yoshitsugu Obi,[1,2] Takayuki Hamano,[1] Yusuke Sakaguchi,[1] Akihiro Shimomura,[1,2] Yoshitaka Isaka.[1]
[1]Osaka Univ Graduate School of Medicine; [2]Univ of California Irvine.

Background: Genetic variants in vitamin D-related genes have been linked to serum 25(OH)D levels and the effect of cholecalciferol (VD_3) supplementation. However, it still remains unclear whether these findings can be extrapolated to hemodialysis population where vitamin D deficiency is frequently observed.

Methods: This is a post-hoc analysis of a double-blind RCT of VD_3 supplementation in MHD patients. A total of 96 patients were randomly assigned to either thrice-weekly 3,000 IU VD_3, monthly VD_3 (equivalent to 9,000 IU/week), thrice-weekly placebo, or monthly placebo. Of those, 89 (93%) provided informed consent to this gene study. We put each genetic variant in DBP (*rs7041*, *rs12512631*, and *rs2282679*), CYP2R1 (*rs10741657* and *rs2060793*), CYP24A1 (*rs2209314*), and VDR (*rs11568820*) into multivariate linear regression model with adjustment for age, sex, and season of blood draw ignoring the administration intervals.

Results: Baseline serum 25(OH)D levels were median 11 (8–14) ng/mL. The T allele at *rs11568820* was associated with 1.12 (95%CI, 1.01–1.24) times higher serum 25(OH) D levels per allele while alleles in the other candidate variants did not show significant association. Median (IQR) change in serum 25(OH)D levels was 2.0 (-1.0–5.1) ng/mL in the placebo and 13.5 (8.4–18.8) ng/mL in the VD_3 group at Month 3, and none of genetic variants did not significantly modify the effect of VD_3 on serum 25(OH)D levels.

Conclusions: Patients with the T allele at *rs11568820* had slightly lower serum 25(OH)D levels but the effect of VD_3 supplementation was not modified by these genetic variants in MHD patients.

Baseline 25-Hydroxyvitamin D Level and the Anti-Albuminuric Response to Vitamin D Receptor Activation in Patients with Chronic Kidney Disease

Maarten A. de Jong,[1] Charlotte A. Keyzer,[1] Fenna van Breda,[2] Marc G. Vervloet,[2] Gozewijn Dirk Laverman,[3] Marc H. Hemmelder,[4] Wilbert M. Janssen,[5] Hiddo Jan Lambers Heerspink,[6] Stephan J.L. Bakker,[1] Gerjan Navis,[1] Martin H. De Borst.[1]
[1]Div of Nephrology, UMCG, Groningen, Netherlands; [2]Dept of Nephrology, VuMC, Amsterdam, Netherlands; [3]Dept of Internal Medicine, ZGT, Almelo, Netherlands; [4]Dept of Internal Medicine, MCL, Leeuwarden, Netherlands; [5]Dept of Internal Medicine, Martini Hospital, Groningen, Netherlands; [6]Dept of Pharmacology, UMCG, Groningen, Netherlands.

Background: Vitamin D receptor activators (VDRA) reduce albuminuria beyond RAAS-blockade; it is unclear whether this effect is similar among vitamin D sufficient and deficient individuals. We studied whether baseline 25(OH) vitamin D status determines the anti-albuminuric response to VDRA treatment.

Methods: We performed a posthoc analysis of the VIRTUE trial (NTR2898); a double-blind, randomized, cross-over trial including patients with stage 1-3 CKD (eGFR 67±22) and albuminuria >300 mg/day. Patients received ramipril (10 mg/d) plus four 8-wk study periods in a random order: regular (RS, 200 mmol/d Na^+) or low-sodium (LS, 50 mmol/d) diet combined with VDRA (paricalcitol, 2 µg/day, PARI) or placebo (PLAC). Plasma 25(OH)D levels were measured with LC-MS/MS. Analyses were limited to patients with >95% compliance to PARI (N=34). Albuminuria is shown as geometric mean [95% CI]; 25(OH)D as mean±SD.

Results: Plasma 25(OH)D was 21.2±9.1 ng/mL during RS+PLAC and did not change between study periods (P_{ANOVA}=0.29). 25(OH)D level was <20 ng/mL in 48% and 20-30 ng/mL in 39% of patients. Paricalcitol reduced residual albuminuria beyond the effect of sodium restriction (RS+PLAC: 1004 [716-1407]; LS+PLAC 804 [489-1,321], LS+PARI 690 [417-1,143] mg/24h; P=0.04 vs LS+PLAC, P<0.001 vs RS+PLAC). There was no association between baseline 25(OH)D and the anti-albuminuric effect of PARI during RS (*r -0.08,* P= 0.31) or LS (*r* -0.10, P=0.52). Findings were similar in regression models adjusted for baseline albuminuria and $eGFR_{CKD\text{-}Epi}$ (RS: st.b -0.22, P=0.25, LS: st b 0.11, P=0.63).

Conclusions: The anti-albuminuric response to VDRA is independent of baseline 25(OH)D levels, suggesting that VDRA therapy should not be restricted to vitamin D-deficient patients.

TH-PO516

Effect of Vitamin D Receptor Activation and Sodium Restriction on Calcification Propensity and Fibroblast Growth Factor 23: The Virtue-CKD Trial Maarten A. de Jong,[1] Charlotte A. Keyzer,[1] Fenna van Breda,[2] Marc G. Vervloet,[2] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Harry Van Goor,[3] Andreas Pasch,[4] Martin H. De Borst.[1] *[1]Div of Nephrology, UMCG, Groningen, Netherlands; [2]Dept of Nephrology, VuMC, Amsterdam, Netherlands; [3]Dept of Pathology, UMCG, Groningen, Netherlands; [4]Div of Nephrology, Inselspital, Bern, Switzerland.*

Background: Vitamin D receptor activators (VDRA) reduce albuminuria but also increase FGF23 levels and vascular calcification. To address whether these effects are linked, we studied the effect of VDRA on FGF23 and calcification propensity in relation to its efficacy (i.e. albuminuria reduction).

Methods: This is a posthoc analysis of a double-blind, randomized, cross-over trial (NTR2898) in patients with stage 1-3 CKD (eGFR 67±22) and albuminuria >300 mg/d, treated with ramipril (10 mg/d) throughout plus four 8-wk study periods: VDRA (paricalcitol, 2 µg/day, PARI) or placebo (PLAC) combined with a regular (RS, 200 mmol/d Na^+) or low-sodium (LS, 50 mmol/d) diet. Patients ≥95% VDRA compliant were analyzed (N=34). C-terminal FGF23 was measured by ELISA, calcification propensity by calciprotein particle maturation time (T_{50}). Effects were assessed with linear mixed models and Pearson's r. Data is shown as geometric mean[95%CI].

Results: During RS, PARI didn't reduce albuminuria (1082[666;1756]mg/d) vs. PLAC (1177[715;1939]mg/d), but increased FGF23 (113[79;137] to 140[104;185]RU/mL, P=0.001) and reduced T_{50} (388[355;420] to 332[300;366]min, P<0.01). During LS, PARI reduced albuminuria (804[489;1321] to 690[417;1143]mg/d, P=0.04), while FGF23 levels increased from 111[96;128] to 141[121;165]RU/mL (P=0.001) and T_{50} remained similar (354[321;387] vs. 354[323;385]min). Changes in FGF23 and T_{50} were not associated with albuminuria reduction during RS (r=-0.11, P=0.5 and r=0.08, P=0.6, respectively) or LS (r=-0.08, P=0.6 and r=0.16, P=0.4).

Conclusions: VDRA treatment increased plasma FGF23 levels and calcification propensity (i.e. reduced T_{50}). Notably, the changes in FGF23 and T_{50} weren't associated with albuminuria reduction. This intra-individual discordance suggests distinct mechanisms for the beneficial (anti-albuminuric) and adverse (FGF23/T_{50}) effects of VDRA treatment, and suggests potential for personalized medicine.

TH-PO517

FGF23 and Inflammatory Markers Blood Levels Decrease with Paricalcitol and Atorvastatin Combined Treatment in Hemodialysis Patients with Tunneled Central Vascular Catheters: The SENPARIC Study (NCT 1820767) Ricardo Mouzo,[1] Valter Ruggiero Lombardi,[2] Jose Carlos Diez Baylon,[3] Herless Rodrigo Avellaneda Campos,[1] Fernando Simal,[1] Jose Paniagua De la Riva,[1] Ana Tierra,[1] Jorge Estifan Kasabji,[4] Carmen Perez Nieto.[1] *[1]Nephrology, Hospital El Bierzo, Ponferrada, Leon, Spain; [2]Laboratory, CODEBI, A Coruña, Spain; [3]Hemodialysis Unit, PONFEDIAL, Ponferrada, Leon, Spain; [4]Nephrology, Hospital El Bierzo, Leon, Spain.*

Background: The aim of the current study was to evaluate the effect of different oral treatments, paricalcitol (P), paricalcitol plus atorvastatin (P+A), and atorvastatin (A) alone on FGF23 and pro-inflammatory cytokines/oxidative stress blood markers.

Methods: Thirty patients (age 71 ±16) in Hemodialysis (HD) treatment 3 times per week for 48 ± 64 months were randomized to a 12 weeks period study. Group 1 (n=10) was treated with P; Group 2 (n=11) was treated with P+A; Group 3 (n=9) received A alone. Blood samples were collected two weeks before treatment (T-2), at baseline (T0), 6 weeks (T6) and 12 weeks after treatment (T12) and 2 weeks post treatment (T14). FGF-23, COX-2, iNOS and PEG-2 serum levels were analyzed by ELISA. CD3, CD4, CD8, CD19, CD25, CD56, CD69 and CD95 lymphocytes markers and serum levels of IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12p70, IL-1β, TNF-α ,TNF-β and IFN-γ were analyzed by flow cytometry.

Results: Treatment with P+A significantly reduced FGF23 (T0 vs T12: p=0.044) and the expression of CD25, CD56, CD25/CD56 and CD69 compared with P and A alone. A diminution in IFN-γ, IL-1β, IL-2 and IL-5 was also noted, mainly in Groups 1 and 2, as well as in COX-2 p<0.012 (T0 vs T12).

Conclusions: It is well known that the administration of vitamin D analogues to HD patients is associated with improved survival despite an increase of FGF23 serum levels. This apparent paradox is not observed in our CT where the combined treatment with P+A to HD patients reduces FGF23 levels and elicits an early and significant decrease of inflammation and oxidative stress. These results could be of interest in the approach to atherosclerotic disease in HD patients.

Let-7 and microRNA-148 Regulate Parathyroid Hormone Levels in Secondary Hyperparathyroidism Iddo Z. Ben-Dov, Vitali Shilo, Irit Mor Yosef Levi, Gilad Wasserman, Tally Naveh-Many. *Nephrology, Hadassah Hebrew Univ Medical Center, Jerusalem, Israel.*

Background: Secondary hyperparathyroidism (SHP) commonly complicates chronic kidney disease (CKD) and associates with morbidity and mortality. MicroRNA (miRNA) are small RNAs that regulate gene expression. Parathyroid specific deletion of *Dicer* that mediates the final step of miRNA maturation showed that miRNA are essential for the increase in serum PTH during both acute and chronic hypocalcemia, uremia and the hyperplastic process in SHP.

Methods: We profiled miRNA in parathyroids from SHP models and CKD patients by miRNA deep-sequencing. We demonstrated the function of specific miRNA using antagonizing oligonucleotides *in vivo* in normal and CKD rats and *in vitro* in parathyroid organ cultures.

Results: miRNA deep-sequencing showed that human, rat and mouse parathyroids share similar profiles. Parathyroids from SHP and normal rats segregated based on their miRNA expression profiles, and a similar finding was observed in humans. We identified specific parathyroid miRNAs that were dysregulated in experimental SHP, including miR-29, miR-21, miR-148, miR-30 and miR-141 (up-regulated) and miR-10, miR-125 and miR-25 (down-regulated). Importantly, inhibition of the parathyroid abundant let-7 family increased PTH secretion in normal and CKD rats, as well as in parathyroid organ cultures. Conversely, inhibition of the up-regulated miR-148 family prevented the increase in serum PTH in CKD rats and decreased secreted PTH in parathyroid cultures.

Conclusions: The evolutionary conservation of abundant miRNA and their regulation in SHP indicates their importance for parathyroid function and the development of SHP. Specifically, let-7 and miR-148 antagonism modified PTH secretion *in vivo* and *in vitro*, implying roles for these miRNA in SHP. Our studies show that let-7 members restrict PTH secretion, while miR-148 members promote secretion. In CKD, the expression of parathyroid let-7 and the increase in miR-148 members would contribute to the development of SHP. Our findings suggest a role for miRNA in parathyroid physiology and disease. They may be utilized for therapeutic interventions aimed at altering PTH expression in diseases such as osteoporosis and SHP.

TH-PO519

The Down-Regulated Vitamin D Receptor Involves in the Parathyroid Glands Hyperplasia via Nuclear Factor-κB Pathway Activation Sen Kan, Qian Zhang, Minmin Zhang, Jing Chen. *Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

Background: Vitamin D receptor (VDR) plays a key role in the parathyroid gland (PG) hyperplasia of secondary hyperparathyroidism (SHPT). However, the mechanism is still unclear. The study aimed to explore the role of nuclear factor-kappa B (NF-κB) pathway in parathyroid hyperplasia, and the correlation between VDR and NF-κB pathway in growth of parathyroid.

Methods: Parathyroid gland samples obtained from hemodialysis patients who accepted the parathyroidectomy surgery were divided into diffuse hyperplasia and nodular hyperplasia according to the H.E staining.Sham-operated rats were fed with the normal diet. 5/6-nephrectomized rats were fed with a high phosphate diet and treated with NF-κB inhibitor PDTC or calcitriol. Rats were sacrificed to collect the blood and parathyroid samples after 3 months. The expressions of PCNA, VDR and activation of NF-κB pathway in PGs were determined by immunohistochemistry and Western Blot.

Results: The activation of NF-κB pathway was significantly increased in nodular hyperplasia PGs than diffuse PGs in SHPT patients (P<0.05), the activated NF-κB p65 positive cell were (32.2±5.9)% and (59.5±5.9)% respectively. 5/6-nephrectomy rats fed with a high-phosphate diet had markedly higher serum PTH levels and larger PGs than sham-operated rats. The PCNA level and activation of NF-κB pathway in PGs were higher compared with the control rats (P<0.05), the VDR level was decreased significantly (P<0.05). NF-κB inhibitor and calcitriol attenuated the enlargement of PGs in uremic rats (P<0.05). Besides, the notably reduced serum PTH, down-regulated expression of PCNA and activation of NF-κB pathway were detected in the rats treated with NF-κB inhibitor or calcitriol compared with the 5/6-nephrectomy rats fed with a high-phosphate diet (P<0.05). The expression of VDR was markedly up-regulated by calcitriol (P<0.05).

Conclusions: Our study demonstrated that NF-κB pathway is involved in the growth of parathyroid gland. VDR deficiency might play an important role in the parathyroid hyperplasia through the activation of NF-κB pathway.

TH-PO520

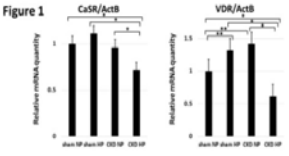
Hypermethylation of the CaSR and VDR Genes in the Parathyroid Glands in Chronic Kidney Disease Rats with High Phosphate Diet

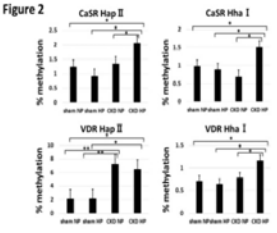
Taketo Uchiyama, Sahoko Kamejima, Ichiro Ohkido, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) disrupts mineral homeostasis and its representative pathosis is defined as secondary hyperparathyroidism (SHPT). SHPT occurs during the early course of progressive renal insufficiency, and is associated with mortality and cardiovascular events. SHPT causes reduction of calcium-sensing receptor (CaSR) and vitamin D receptor (VDR) in the parathyroid glands during CKD. However, the precise mechanism of *CaSR* and *VDR* reduction is largely unknown.

Methods: CKD was induced through two-step 5/6 nephrectomy, then CKD rats and sham-operated rats were maintained for 8 weeks on diets containing 0.7% phosphorus (normal phosphate) or 1.2% phosphorus (high phosphate). In gene expression analysis taqman probes were used for quantitative real-time polymerase chain reaction. CaSR and VDR protein expressions were analyzed using immunohistochemistry. DNA methylation analysis was performed using a restriction digestion and quantitative PCR.

Results: CaSR and VDR mRNA were reduced only in CKD rats fed the high phosphorus diets (CKD HP), then CaSR and VDR immunohistochemical expressions were compatible with gene expression assay. SHPT was observed only in CKD HP rats. Furthermore CKD HP rats showed the hypermethylation in *CaSR* and *VDR* genes; however, the percentage methylation of both genes was low.





Conclusions: Although *CaSR* and *VDR* hypermethylation was demonstrated in PTGs of CKD HP rats, the extent of hypermethylation was insufficient to support the relevance between hypermethylation and down-regulation of gene expression because of the low percentage of methylation. Consequently, our data suggest that mechanisms, other than DNA hypermethylation, were responsible for the reduction in mRNA and protein levels of *CaSR* and *VDR* in PTGs of CKD HP rats.

Intact Parathyroid Hormone Is Associated with Increased Risk of Death but Not Fragility Fracture in Patients with Chronic Kidney Disease

Alex R. Chang,[1] Amanda Young,[1] Ion D. Bucaloiu,[1] James E. Hartle,[1] Morgan Grams.[2] *[1]Geisinger Health System; [2]Johns Hopkins Univ.*

Background: Patients with chronic kidney disease (CKD) are at increased risk for secondary hyperparathyroidism and fragility fractures. Little is known about the relationship between intact parathyroid hormone (iPTH) and adverse outcomes in CKD patients.

Methods: We evaluated the association between iPTH with risk of incident fragility fracture (vertebral, hip, wrist, humerus) and death in 4737 patients in the Geisinger Health System who had estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^{2}and no history of end-stage renal disease. Analyses were adjusted for demographics, smoking status, eGFR, albuminuria, renal risk factors, and medications that affect bone.

Results: Median values (interquartile range) of eGFR and iPTH were 40.8 (30.0-50.2) ml/min/1.73m^2 and 59 (38-94) pg/ml, respectively. The prevalence of iPTH >= 130 pg/ml (twice the upper limit of normal range) was 4.3%, 7.8%, 28.8%, and 62.7% in patients with eGFR 45-59, 30-44, 15-29, and <15 ml/min/1.73m^2. Over a median of 5.6 (4.0-7.8) years of follow-up, 708 (15.0%) patients experienced an incident fragility fracture. Compared to iPTH in the normal range (15-65 pg/ml), elevated iPTH >= 130 pg/ml was not associated with increased risk of fragility fracture (aHR 1.10 (95% CI: 0.84-1.43; p=0.5), but was associated with a 35% increased risk of death (aHR 1.35, 95% CI: 1.15-1.58, p=<0.001). Low PTH <15 pg/ml was not significantly associated with incident fragility fracture (aHR 1.35, 95% CI: 0.90-2.02; p=0.1) or mortality (aHR 1.18, 95% CI: 0.86-1.62; p=0.3). Results for fragility fracture were similar in analyses accounting for competing risk of death.

Conclusions: Elevated iPTH levels are associated with increased risk of death but not fragility fracture in CKD patients. Additional strategies beyond controlling PTH levels are needed to improve bone health.

Table 1. Adjusted* Hazard Ratios of Fragility Fracture and Mortality by Intact PTH Category

Intact PTH Category	Fragility Fracture			Mortality		
	IR (per 1000 PY)	aHR (95% CI)	P Value	IR (per 1000 PY)	aHR (95% CI)	P Value
<15 pg/ml (n=124)	31.2	1.35 (0.90-2.02)	0.2	45.1	1.18 (0.86-1.62)	0.3
15-65 pg/ml (n=2502)	25.8	REF		36.0	REF	
65-130 pg/ml (n=1492)	24.9	0.98 (0.82-1.68)	0.8	55.3	1.11 (0.98-1.25)	0.1
≥ 130 pg/ml (n=619)	23.6	1.10 (0.84-1.43)	0.5	82.5	1.35 (1.15-1.58)	<0.001

Abbreviations: IR (incidence rate), PY (person-years), aHR (adjusted hazard ratio)
*Adjusted for age, sex, race, smoking status, eGFR, albuminuria, blood pressure, body mass index, cardiovascular disease, medications affecting the bone (corticosteroids, diuretics, anti-psychotics, estrogens, testosterone, calcium, vitamin D, and calcimimetics)

TH-PO522

Parathyroidectomy Effects on Bone Mineralization in Patients with Chronic Kidney Disease and Secondary Hyperparathyroidism

Geovanna Oliveira Pires,[1] André L. Teixeira,[1] Ivone Braga de Oliveira,[1] Melissa Fernanda Pinheiro Santos,[1] Luciene dos Reis,[1] Wagner Dominguez,[1] Aluizio B. Carvalho,[2] Rosa M.A. Moyses,[1,3] Vanda Jorgetti.[1] *[1]Nephrology Div, Univ of Sao Paulo, São Paulo, SP, Brazil; [2]Nephrology Div, Federal Univ of Sao Paulo, São Paulo, SP, Brazil; [3]Medicine Master Degree Program, Univ Nove de Julho (UNINOVE), São Paulo, SP, Brazil.*

Background: Secondary hyperparathyroidism (SHPT) is a complication of chronic kidney disease (CKD) which compromises skeletal integrity, since excessive parathyroid hormone (PTH) increases remodeling, especially resorption, and decreases bone mineral density, increasing the risk of fractures. Patients with SHPT undergoing parathyroidectomy (PTX) go from a very high PTH condition to another where hormone levels drop dramatically. The effects of PTX in bone tissue are poorly studied, especially in osteocyte-expressed proteins, such as fibroblast growth factor-23 (FGF23), dentin matrix protein 1 (DMP1), matrix extracellular phosphoglycoprotein (MEPE), sclerostin, receptor activator of nuclear factor-κB ligand (RANKL) and osteoprotegerin (OPG), which regulate remodeling and especially bone mineralization. Studies that evaluated bone biopsies (BB) after PTX showed low remodeling and impaired bone mineralization. The aim of this study is to characterize bone expression of FGF23, DMP1, MEPE, sclerostin, RANKL and OPG and analyze their correlations with histomorphometric analysis results of BBs of patients with SHPT pre and post PTX.

Methods: We studied 10 patients with SHPT undergoing pre bone biopsy and at 6 to 12 months after PTX. We assessed histomorphometry and osteocyte-expressed proteins by immunohistochemistry.

Results: After PTX, there was significant increase in sclerostin expression 3.91 ± 2.76 vs10.3 ± 1.34 % / p=0.013) and of OPG [0.88 (0.17-3.03) vs 1.91 (0.53-16.13) % / p=0.002]. Percentage change of MEPE was inversely correlated with the time interval for mineralization (MLT) (r= -0.62 / p=0.05) and directly with bone formation rate (BFR / BS) (r= 0.73 / p=0.02). After PTX, six patients showed worsen mineralization and significant increase in OPG expression [1.1 (0.8-3.0) vs 2.3 (1.2-10.7) % / p=0.03].

Conclusions: Significant changes in expression of bone proteins (sclerostin, OPG and MEPE) that can potentially compromise mineralization were observed after PTX.

TH-PO523

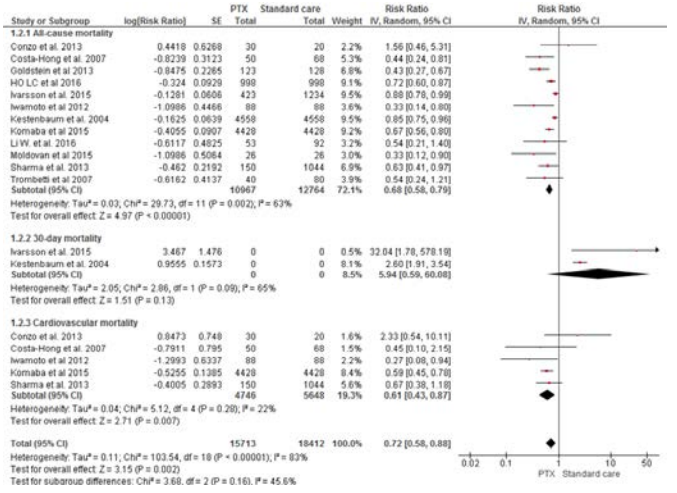
Surgical Parathyroidectomy Confers a Survival Advantage in Chronic Kidney Disease Patients - Results of the Largest Meta-Analysis

David Goldsmith,[1] Mugurel Apetrii,[2] Dimitrie Cristian Siriopol,[2] Ionut Nistor,[2] Dragos Scripcariu,[2] Adrian Covic.[2] *[1]Guy's and St. Thomas' Hospitals, London, United Kingdom; [2]Parhon Hospital, Iasi, Romania.*

Background: Secondary hyperparathyroidism (SHPT) leads to progressive enlargement of parathyroid glands, and increasingly "autonomous" parathormone (PTH) secretion. Vitamin-D therapy is the usual treatment, but if refractory, patients have traditionally then had surgical parathyroidectomy (SPTX). We aimed to assess the impact of PTX in SHPT patients.

Methods: A systematic review and meta-analysis was conducted on observational and randomized controlled trials (RCTs) in adults with CKD/ESRD that evaluated the role of PTX in determining clinical outcomes. We studied CKD/ESRD patients who had undergone parathyroid surgery. The surgery itself could be (1) total parathyroidectomy without auto transplantation, (2) total parathyroidectomy with auto transplantation, or, (3) subtotal parathyroidectomy.

Results: 12 cohort observational studies, comprising 23,731 participants were included in the final analysis. The follow-up period varied between 12 and 360 months. Compared with standard treatment, parathyroidectomy significantly decreased all-cause mortality (RR 0.68 [95% CI, 0.58 to 0.78], p<0.001) in ESRD patients with biochemical and / or clinical evidence of SHPT . PTX had also a positive effect on decreasing CV mortality (RR 0.61 [95% CI, 0.43 to 0.87], p<0.01) in 5 observational studies that included almost 10,000 patients.



Conclusions: This is the largest and most comprehensive meta-analysis of SPTX reported to date. We show that a there is clinically significant beneficial effect of PTX on all-cause and CV mortality in CKD patients with SHPT. The immediate need now is for a well-conducted,independent RCT comparing surgical PTX with cinacalcet therapy examining mortality, major morbidity, to mental and physical health, quality of life, and pharmaco-economics.

TH-PO524

Downregulation of ABCG2, a Urate Exporter, by Parathyroid Hormone Enhances Urate Accumulation in Secondary Hyperparathyroidism Hiroshi Watanabe,[1] Ryusei Sugimoto,[1] Motoko Tanaka,[2] Hirotaka Komaba,[3] Masafumi Fukagawa,[3] Toru Maruyama.[1] *[1]Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan; [2]Dept of Nephrology, Akebono Clinic, Kumamoto, Japan; [3]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Hyperuricemia occurs with increasing frequency among patients with hyperparathyroidism. However, the molecular mechanism by which serum parathyroid hormone (PTH) regulates serum urate levels remains unknown.

Methods: Secondary hyperparathyroidism (SHPT) model rats were created by feeding a high phosphorus diet (Ca 0.6%, P 1.2%) to the 5/6 renal nephrectomy rats. In vitro experiments were performed to investigate the effect of PTH on ABCG2 expression in Caco-2 cells. A total of 17 patients in stable medical condition with SHPT were enrolled in this study.

Results: We show that, in rats with SHPT, serum urate levels are increased and urate excretion in the intestine and kidney is decreased, presumably due to the downreguration of the intestinal and renal membrane expression of a urate exporter ABCG2. These effects were prevented by the administration of the calcimimetic PTH suppressor, cinacalcet, indicating that PTH downregulates ABCG2 expression. In Caco-2 cells, the plasma membrane expression of ABCG2 was directly downregulated by PTH (1-34) and its mRNA level remained unchanged, but an inactive PTH derivative (13-34) had no effect, suggesting a posttranscriptional regulatory system acting through the PTH receptor. Additional clinical studies showed, as observed in an animal study, that treatment with cinacalcet resulted in significant reductions in serum urate levels together with decreases in PTH levels in SHPT patients who were undergoing dialysis.

Conclusions: PTH downregulates ABCG2 expression on plasma membrane, and thereby suppresses intestinal and renal urate excretion, and that the effects of PTH can be prevented by a cinacalcet treatment.

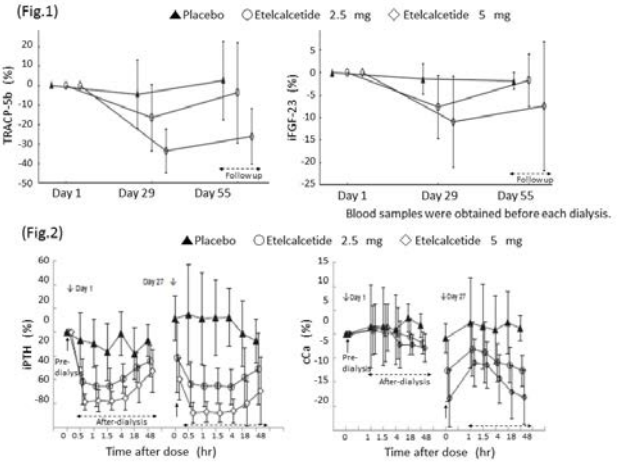
TH-PO525

Etelcalcetide (ONO-5163/AMG 416) Influences Bone Metabolism and Exhibits Stable Pharmacodynamics Keitaro Yokoyama,[1] Masafumi Fukagawa,[2] Takashi Shigematsu,[3] Takashi Akiba,[4] Akifumi Fujii,[5] Motoi Odani,[5] Tadao Akizawa.[6] *[1]The Jikei Univ; [2]Tokai Univ; [3]Wakayama Medical Univ; [4]Sekikawa Hospital; [5]Ono Pharmaceutical Co., Ltd.; [6]Showa Univ, Japan.*

Background: Etelcalcetide, a novel intravenous calcimimetic, lowers PTH and is expected to affect bone metabolism and lower Ca. It is important to clarify the pharmacodynamic parameters for a multiple-dose of etelcalcetide to appropriately assess its efficacy and safety. This study was conducted to investigate the time-course changes and daily fluctuations in pharmacodynamic parameters after multiple-dose administration of etelcalcetide three times/week for 4 weeks in Japanese patients with secondary hyperparathyroidism on hemodialysis.

Methods: This was a multicenter, randomized, double-blind, placebo-controlled, parallel-group study. In two cohorts (2.5 or 5 mg), 11 patients each were randomized to etelcalcetide or placebo at an 8:3 ratio.

Results: Etelcalcetide dose-dependently decreased the levels of TRACP-5b and intact FGF-23 after multiple dosing (Fig 1). However, the daily fluctuations of intact PTH and corrected Ca after the multiple dosing did not vary largely compared with the levels after the initial dose (Fig 2).



Conclusions: If unstable fluctuations of pharmacodynamic parameters are observed, the timing for assessment of efficacy and safety needs to be considered. Although etelcalcetide influenced bone metabolism, marked daily fluctuations of pharmacodynamic parameters did not occur. Therefore, it may not be necessary to consider the timing for its assessment.

TH-PO526

Etelcalcetide (ONO-5163, AMG 416), an Intravenously Available Agonist of the Calcium-Sensing Receptor, Effectively Controls Plasma Parathyroid Hormone Levels in a Rat Chronic Renal Insufficient Model with Secondary Hyperparathyroidism Masakazu Konno, Kazutsune Harada. *ONO Pharmaceutical Co., Ltd., Osaka, Japan.*

Background: Secondary hyperparathyroidism (SHPT) is a complication of chronic kidney disease and end stage renal disease that results in defective Ca and P homeostasis, thereby persistently elevated levels of parathyroid hormone (PTH) in blood caused by the ongoing release of excess amounts of PTH from enlarged parathyroid glands. Currently, we have developed the first intravenously available CaSR agonist etelcalcetide (ONO-5163 or AMG 416). The objectives of these studies were to elucidate *in vitro* pharmacological profile and *in vivo* PTH lowering activity of etelcalcetide in rat 5/6 nephrectomized (5/6 Nx) model of chronic renal insufficiency with SHPT.

Methods: To determine *in vitro* activity, cells stably expressing human CaSR and parent cells were treated with etelcalcetide, and the intracellular Ca concentration was measured using Fura-2-AM dye. Also, the primary cultured rat parathyroid cells were treated for 24 hours with etelcalcetide, and the PTH concentrations in culture supernatant were measured.To determine *in vivo* activity, nine-week-old male 5/6 Nx rats were fed a special diet (1.0% phosphate) to induce SHPT. Following 3 weeks on the special diet, 5/6 Nx rats were intravenously single injected with etelcalcetide (0.3, 1, 3 mg/kg). Blood were sampled predose and at 1, 6, 24, 48 hours after dosing and the plasma PTH and the serum Ca were measured.

Results: *In vitro*, etelcalcetide increased the intracellular Ca concentration in cells stably expressing human CaSR with EC_{50} of 0.53 µmol/L. No signaling activity was observed in parent cells. Etelcalcetide also suppressed PTH secretion from the primary cultured rat parathyroid cells with EC_{50} of 0.36 µmol/L. Furthermore, *in vivo*, etelcalcetide dose-dependently suppressed circulating levels of plasma PTH and subsequently serum Ca in rat 5/6 Nx with SHPT. Reductions of PTH and Ca were reversible.

Conclusions: We have identified etelcalcetide as a novel calcimimetics with a potent PTH lowering efficacy via CaSR-agonistic activity. Etelcalcetide will provide a new therapeutic option for the SHPT patients that may improve compliance and pill burden.

TH-PO527

Interim Analysis of a Multicenter Single-Arm Extension Study to Describe the Long-Term Safety of Etelcalcetide (AMG 416) in the Treatment of Secondary Hyperparathyroidism in Subjects with Chronic Kidney Disease on Hemodialysis Kevin J. Martin,[1] Geoffrey A. Block,[2] Sunfa Cheng,[3] Botond Csiky,[4] Hongjie Deng,[3] K. Adu Ntoso,[5] Rainer Oberbauer,[6] Mariano Rodriguez,[7] Dennis L. Ross,[8] Glenn Matthew Chertow.[9] *[1]St. Louis Univ SOM, St. Louis, MO; [2]Denver Neph, Denver, CO; [3]Amgen; [4]FMC Hungary, Budapest, Hungary; [5]Penn Neph Assoc, Philadelphia, PA; [6]Med Univ of Vienna, Vienna, Austria; [7]Univ of Cordoba, Cordoba, Spain; [8]KS Neph Physicians, Wichita, KS; [9]Stanford SOM, Palo Alto, CA.*

Background: Etelcalcetide is a novel IV calcimimetic shown to decrease parathyroid hormone (PTH) in 3 26-week (wk) phase 3 (P3) trials, with sustained efficacy in a 52-wk open label extension (OLE) trial. This follow-on OLE further characterizes the long-term safety of etelcalcetide.

Methods: Subjects (subj) enrolled from previous OLEs stayed on the same dose; subj from the P3 trial of etelcalcetide vs cinacalcet had a 4 wk washout. Etelcalcetide was titrated by 2.5mg or 5mg to a max of 15mg, at a frequency based on the site's standard of care to achieve PTH ≥2x to ≤9x the upper limit of normal (ULN). Primary endpoint was subj incidence of adverse events (AEs). Secondary endpoints were (1) PTH ≥2x to ≤9x the ULN and (2) phosphorus (P) ≤ULN at months (M) 6, 12, 18.

Results: 902 subj enrolled; mean time on drug was 391 days. Mean dose/session at M6, M12, M18 was 5.1, 5.3, and 5.0 mg. 82% and 41% had AEs and serious AEs (SAEs), respectively. 4% had AEs that led to stopping drug. Most common AE (>10%) was blood Ca decreased (decr) (25%); most common SAEs (≥2%) were pneumonia (4%) and sepsis (2%). Most common AEs leading to stopping drug were blood Ca decr, nausea, vomiting-4 subj each. The secondary endpoints and additional analyses results are:

	M6	M12	M18
PTH≥2x and ≤9x ULN	515/767 (67%)	434/591 (72%)	93/133 (70%)
P ≤ULN	288/739 (39%)	197/533 (37%)	43/122 (35%)
PTH ≥2x and ≤9x ULN AND P ≥3.5 and ≤5.5 mg/dL	211/716 (30%)	194/520 (37%)	34/110 (31%)
PTH ≥2x and ≤9x ULN, P ≥3.5 and ≤5.5 mg/dL, normal corrected Ca	151/701 (22%)	154/516 (30%)	26/109 (24%)

Conclusions: (1) No new safety findings with additional long-term treatment; (2) using real-world PTH targets achieved sustained reductions in PTH and P.

TH-PO528

The Evaluation of the Safety and Efficacy with Etelcalceide (ONO-5163/AMG 416: A Novel Intravenous Calcimimetic) on Secondary Hyperparathyroidism (SHPT) for 52 Weeks in Japanese Hemodialysis Patients Takashi Shigematsu,[1] Masafumi Fukagawa,[2] Keitaro Yokoyama,[3] Takashi Akiba,[4] Akifumi Fujii,[5] Hiroe Tani,[5] Motoi Odani,[6] Tadao Akizawa.[7] *[1]Div of Nephrology, Dept of Internal Medicine, Wakayama Medical Univ, Wakayama, Japan; [2]Dept of Nephrology, Endocrinology and Metabolism, Tokai Univ, School of Medicine, Isehara, Japan; [3]Dept of Nephrology and Hypertension, Jikei Univ, School of Medicine, Tokyo, Japan; [4]Dept of Nephrology, Sekikawa-kai, Sekikawa Hospital, Tokyo, Japan; [5]Clinical Development, Ono Pharmaceutical Co., Ltd., Osaka, Japan; [6]Data Science, Ono Pharmaceutical Co., Ltd., Osaka, Japan; [7]Dept of Nephrology, Showa Univ, School of Medicine, Tokyo, Japan.*

Background: Etelcalcetide had decreased serum intact PTH (iPTH) in Japanese HD patients with SHPT for a 12-week. We designed the 52-week, phase III, multicenter, open-label, single-arm study to evaluate the long-term safety and efficacy of etelcalcetide.

Methods: We prescribed etelcalcetide intravenously at 3 times/week for 52 weeks on all HD subjects with the both of serum iPTH >240 pg/mL and corrected calcium (cCa) level ≥8.4 mg/dL. The initial dose was 5 mg, followed by individual adjustment to dose of 2.5–15 mg to achieve Japanese serum iPTH target of 60–240 pg/mL.

Results: 191 subjects were enrolled, of whom 83.8% completed the 52-week treatment. The 96.8% and 14.7% of subjects experienced AEs and serious AEs, respectively. The 7.4% had AEs that led to stopping etelcalcetide. Vomiting, nausea, and symptomatic hypocalcaemia were observed in 9.5%, 4.7%, and 1.1%, respectively. The serum iPTH were achieved as 60–240 pg/mL in 87.5%. The 90.6% subjects can achieve the 30% or more reductions in iPTH. The serum cCa, phosphorus, and intact fibroblast growth factor-23 were also decreased rapidly and subsequently maintained.

Conclusions: Etelcalcetide is an effective intravenous therapy on SHPT with no new safety findings for the long-term 52-week treatment compared to the results in the previous shorter study.

TH-PO529

Treatment with Cinacalcet Reduces Oxidative Stress in Hemodialysis Patients with Secondary Hyperparathyroidism Marcin Adamczak,[1] Piotr Kuczera,[1] Grzegorz Machnik,[2] Boguslaw Okopien,[2] Andrzej Wiecek.[1] *[1]Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland; [2]Dept of Internal Medicine and Clinical Pharmacology, Medical Univ of Silesia, Katowice, Poland.*

Background: It is known well that oxidative stress is one of the factors contributing to the increased mortality in patients with chronic kidney disease (CKD). Cinacalcet is used in the treatment of secondary hyperparathyroidism (sHPT) in patients with CKD. The purpose of this prospective clinical study was to assess the influence of treatment with cinacalcet on the oxidative stress in patients on hemodialysis with sHPT.

Methods: In 58 hemodialysed patients with sHPT plasma Advanced Oxygenation Protein Products (AOPP) and total antioxidant capacity – ImAnOx (TAS/TAC) and serum PTH, calcium and phosphate concentrations were assessed before the first dose of cinacalcet and after 6 months of treatment. A log transformation was used to normalize the distribution of PTH, AOPP and ImAnOx concentrations, thus these results are presented as geometric means with 95% CI. Paired t-test was then used to assess the variables change over time. Correlation coefficients were calculated using Spearman's rank correlation.

Results: Serum PTH concentration decreased significantly from 895 (748-1070) pg/ml to 384 (289-510) pg/ml and plasma AOPP concentration decreased significantly from 152 (126-185) µmol/l to 49 (43-57) µmol/l after 6 months of treatment; p<0.0001. Plasma antioxidant capacity (ImAnOx) significantly increased from 260 (251-270) µmol/l to 272 (264-280) µmol/l; p=0.047. After 6 months of treatment a significant, positive correlation as found between ImAnOx and the dose of cinacalcet (r=0,30; p=0.02). Also the change of plasma ImAnOx during treatment with cinacalcet significantly correlated with the dose of cinacalcet r=0.35; p=0.01. No significant correlations were found between plasma AOPP concentration or ImAnOx and PTH, nor their changes in time.

Conclusions: 1. 6-month treatment with cinacalcet reduces oxidative stress in maintenance hemodialysis patients with sHPT 2. This beneficial effect seems to be related rather to the direct action of cinacalcet than to the decrease of serum PTH concentration.

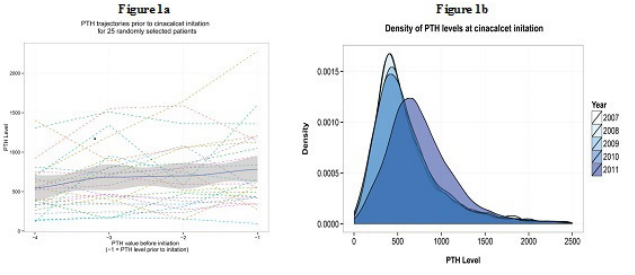
Cinacalcet Initiation at Varying Parathyroid Hormone (PTH) Levels Paul Dluzniewski,[1] M. Alan Brookhart,[2] Diane Reams,[2] Kerry Cooper,[1] Abhijit V. Kshirsagar,[2] Brian D. Bradbury.[1] *[1]Amgen Inc., Thousand Oaks, CA; [2]Univ of North Carolina, Chapel Hill, NC.*

Background: Despite evidence of the effectiveness of cinacalcet in managing secondary hyperparathyroidism (SHPT) related biochemistries, PTH levels are increasing over time, possibly due to delays in treatment initiation. We sought to describe real-world PTH levels and trajectories leading up to cinacalcet initiation.

Methods: Using patient-level data from a large dialysis provider merged with data from the USRDS, we identified adult new users of cinacalcet (2007-2011) from Part D prescription claims. We estimated the mean ± standard deviation of PTH levels (same assay throughout follow-up period) and the distribution across PTH categories: 150-300, 301-600, 601-900, and > 900 pg/mL. We also assessed PTH trajectories in the 12 months prior to cinacalcet initiation.

Results: We identified 21,786 patients who initiated cinacalcet during our study period. Overall, PTH levels increased steadily in the 12 months leading up to initiation of cinacalcet. We observed varying patterns of increasing versus decreasing PTH levels prior to the initiation of cinacalcet (Figure 1a). We also observed substantial variability in PTH levels at the time of cinacalcet initiation (Figure 1b).



Conclusions: In clinical practice, the PTH level motivating initiation of cinacalcet therapy is frequently higher than recommended targets, including levels above 1000 pg/mL. Future research is needed to understand the impact of delaying calcimimetic treatment.

Disparate Actions of Paricalcitol and Cinacalcet on Parathyroid Oxyphil Cell Content in Patients with Chronic Kidney Disease Cynthia S. Ritter, Brent W. Miller, Alex J. Brown, Eduardo Slatopolsky. *Div of Nephrology, Washington Univ School of Medicine, St. Louis, MO.*

Background: Parathyroid (PT) oxyphil cell content increases in patients with uremia. This increase is even more enhanced in patients receiving treatment with the calcimimetic cinacalcet and/or calcitriol for hyperparathyroidism (HPT). Previously, we reported that oxyphil cells have significantly more calcium-sensing receptor (CaSR) than chief cells, supporting the hypothesis that the CaSR and, likewise, calcimimetics are involved in the transdifferentiation of a chief-to-oxyphil cell type. Here, we compared the effect of the vitamin D analog paricalcitol (which is less calcemic than calcitriol) and cinacalcet on the oxyphil content in uremic patients to investigate further the genesis of oxyphil cells.

Methods: We analyzed archived H&E-stained sections of PT tissue from 28 CKD patients who underwent parathyroidectomy (PTX) for secondary HPT. Patients received the following treatment for HPT prior to PTX: no treatment (n=7), cinacalcet (n=8), paricalcitol (n=8), and cinacalcet+paricalcitol (n=5). Tissue from 4 "normal" subjects was examined. Each tissue section was digitally captured in its entirety using serial images (200x) and analyzed using Image-Pro Plus software. Oxyphilic areas were circumscribed, the area calculated and reported as % of the total area of tissue for each patient.

Results: The % PT oxyphil content was as follows (avg±sem): no treatment, 5.3 ± 1.25%; cinacalcet, 27.9 ± 4.79% (p≤0.001 vs no treatment); paricalcitol, 6.9 ± 1.81% (p≤0.001 vs cinacalcet); cinacalcet+paricalcitol, 12.7 ± 7.10%; normal subjects, 1.03 ± 1.03%.

Conclusions: Unlike cinacalcet, treatment of patients with paricalcitol does not stimulate genesis of oxyphil cells. Because the function of the oxyphil cell is not known, the question remains as to whether the genesis of oxyphil cells is favorable or unfavorable to the patient. Nevertheless, the finding that two conventional treatments for HPT have disparate effects on parathyroid composition, and perhaps function, is provocative and may be useful when evaluating future drugs for HPT.

Calcium Sensing Receptor Genotype and Response to Cinacalcet Sharon M. Moe,[1] Brian S. Decker,[1] Leah Wetherill,[1] Dongibng Lai,[1] Safa Abdalla,[2] Jin Long,[2] Matteo Vatta,[1] Tatiana Foroud,[1] Glenn Matthew Chertow.[2] [1]*Indiana Univ, Indpls, IN;* [2]*Stanford, Stanford, CA.*

Background: The calcimimetic cinacalcet is a calcium sensing receptor (CASR) allosteric activator, and thus polymorphisms in *CASR* may alter the drugs therapeutic response. Genetic mutations in *CASR* are known to lead to diseases of mineral metabolism. We tested the hypothesis that single nucleotide polymorphisms (SNPs) in *CASR* alters the biochemical response to cinacalcet.

Methods: We analyzed DNA samples in the EVOLVE trial (EValuation Of Cinacalcet Hydrochloride (HCl) Therapy to Lower CardioVascular Events (EVOLVE), a randomized trial comparing cinacalcet to placebo on a background of usual care (calcitriol or analogues and binders). 49% of subjects in EVOLVE consented to DNA collection, and 1,852 samples were of initial adequate quality to be genotyped for 18 known *CASR* polymorphisms. All SNPs were in Hardy-Weinberg equilibrium in the European American (EA, N=1,086) and African American (AA, N=413) samples; these groups were assessed separately. The association of SNPs with baseline and change from 0 to 20 weeks in calcium, phosphorus, PTH and FGF23 was determined using PLINK.

Results: There was modest association of baseline PTH and bone alkaline phosphatase levels with *CASR* SNPs in the EA population (all $p<0.04$), but not in the AA population. In contrast, there was a modest association of baseline calcium, and FGF23 levels with *CASR* SNPs (all $p<0.03$) in the AA, but not in the EA, sample. The only *CASR* SNP that showed association with percent reduction in PTH after adjustment for significant covariates was rs1393199 in the EA sample ($p = 0.042$). Among placebo-treated patients, those with genotype CC for rs1393199 had higher percent change in PTH relative to individuals with AA genotype. Cinacalcet-treated patients had approximately equal percent change in PTH, irrespective of genotype.

Conclusions: SNPs in *CASR* are only modestly associated with baseline CKD-MBD laboratory tests with different clinical phenotypes in EA and AA groups. Only one SNP was associated with change in PTH at 20 weeks in the EA population. This association was not seen in patients treated with cinacalcet.

TH-PO533

Oral Calcitriol and Outcomes in Hemodialysis Patients Lin Ma,[1] Ravi I. Thadhani,[2] Norma J. Ofsthun,[1] Amanda Stennett,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] [1]*Fresenius Medical Care North America, Waltham, MA;* [2]*Massachusetts General Hospital, Boston, MA.*

Background: A large clinical pilot began at Fresenius Medical Care North America (FMCNA) in December of 2013 to examine the feasibility of administering oral calcitriol (OC) rather than intravenous Vitamin D (IVD) for in-center hemodialysis (IHD) patients. We conducted a matched case-control study to compare the survival and hospitalization risks associated with OC and IVD treatments.

Methods: 6,613 cases (OC) and 13,226 matched controls (IVD) were selected from IHD patients who started OC or received only IVD between December 1, 2013 and June 30, 2014. Cases and controls were 1:2 matched on propensity score of index date, age, sex, white (Y/N), hispanic (Y/N), incident patient (Y/N), HD catheter (Y/N), diabetes (Y/N), the most recent albumin at baseline. The index date was set to the date of starting OC or a random date within the study period for those patients receiving IVD. Kaplan-Meier and multivariable Cox proportional hazards models were used to examine all-cause mortality and hospitalization risks in the first year.

Results: For cases, the mean age was 61.6 years; 57.1% were male; 42.5% were white; 38.4% were black; 19.1% were of other racial ancestry; 10.9% were incident patients; 25.6% had an HD catheter; 64.4% were diabetic. Cases and matched controls were not significantly different on these matching factors. Compared with IVD, crude mortality rate for OC was 23.9% lower (12.8% vs. 16.9%) and hospitalization risk was 5.2% lower (54.4% vs. 57.4%) at 1 year. Hazard ratios (HRs) of 1-year death: unadjusted was 0.73 (95%CI: 0.68, 0.79); case-mix adjusted was 0.73 (95%CI: 0.67, 0.79); case-mix and lab adjusted was 0.71 (95%CI: 0.66, 0.77). HRs of hospitalization: unadjusted was 0.90 (95%CI: 0.87, 0.94); case-mix adjusted was 0.92 (95%CI: 0.89, 0.96); case-mix and lab adjusted was 0.91 (95%CI: 0.87, 0.95), all $p<0.0001$. The mean serum calcium and median iPTH were in the normal range for 12 months before and after the index date.

Conclusions: Hospitalization and mortality outcomes were not worse in the oral calcitriol group at 1 year, and may have been slightly better. Follow-up laboratory results were comparable and remained within the KDIGO guidelines.

TH-PO534

IL-6 Acts on Bone to Increase FGF23 Expression in Acute and Chronic Kidney Failure and In Vitro Ronen Levi,[1] Karina Durlacher,[1] Alia Hassan,[1] Jonathan H. Axelrod,[2] Justin Silver,[1] Tally Naveh-Many.[1] [1]*Nephrology, Hadassah Hebrew Univ Medical Center, Jerusalem, Israel;* [2]*Gene Therapy, Hadassah Hebrew Univ Medical Center, Jerusalem, Israel.*

Background: Acute kidney injury (AKI) is a common complication in hospitalized patients. The development and pathogenesis of the high serum FGF23 levels in AKI patients and in experimental models is unclear. We show a central role of cytokines and specifically IL-6 in the high levels of FGF23 in acute and chronic kidney failure.

Methods: We induced AKI in mice by a single ip injection of folic acid. Dexamethasone (DEX) was injected 1 h prior to folic acid. Chronic uremia was induced in control and *IL-6* knock-out mice by an adenine high phosphorus diet given for 3 w. FGF23 mRNA levels were analyzed by qRT-PCR in calvarial tissue, UMR106 cells and neonatal calvarial organ cultures.

Results: In mice with folic acid induced AKI, serum FGF23 levels increased 5-fold at 6 h. Serum levels of several cytokines were increased at 3 h. Serum IL-6 levels rose from 64 ± 15 to 8608 ± 2250 pg/ml, $p= 0.01$. DEX, that decreased serum IL-6, prevented the increase in serum FGF23 at 6 h after folic acid. Calvarial FGF23 mRNA levels increased 11-fold in mice treated with folic acid compared to controls, but only 4-fold in mice treated with DEX before AKI induction. IL-6 receptor/IL-6 fusion protein (Hyper-IL-6) increased FGF23 mRNA levels in calvarial cultures (11 -fold at 6 h) and in osteoblast like UMR106 cells, demonstrating a direct effect of IL-6 to increase FGF23 expression. Uremic *IL-6* knock-out mice had an impaired increase in serum FGF23 and calvarial FGF23 mRNA levels in adenine high phosphorus induced chronic kidney failure, compared to the marked increases in uremic wild type mice, indicating that IL-6 is also necessary for the increased FGF23 of prolonged uremia.

Conclusions: Serum IL-6 levels increase in folic acid induced AKI and this precedes the increase in FGF23. DEX prevents the increase in FGF23 expression in AKI. Hyper-IL-6 acts directly on bone cells to increase FGF23. IL-6 is essential for the increased FGF23 serum and mRNA levels in chronic kidney failure. Therefore, IL-6 is an important mediator of the high levels of FGF23 in both acute and chronic uremia.

TH-PO535

WNK Pathway Regulates Osteoblastic FGF23 Secretion Olena Andrukhova,[1] Sibel Ada,[1] Yeliz Toluay,[1] Dario Alessi,[2] Reinhold Erben.[1] [1]*Dept of Biomedical Sciences, Univ of Veterinary Medicine Vienna, Vienna, Austria;* [2]*MRC Protein Phosphorylation & Ubiquitylation Unit, Univ of Dundee, Dundee, United Kingdom.*

Background: With-no-lysine kinases (WNK) are key regulators of intracellular trafficking of ion transporters such as the Na-Cl cotransporter (NCC) in the kidney. Chronic activation of the WNK signaling pathway by activation of the renin–angiotensin–aldosterone system (RAAS) or by genetic defects leads to increased renal sodium reabsorption, and hypertension. We previously reported that FGF23 signaling activates WNK4 and that FGF23 and aldosterone signaling interact in the kidney.

Methods: To better understand the mechanisms underlying this crosstalk,we used kelch-like 3 (KLHL3R528H/+) knock-in Mutant mice in which lack of the KLHL3-mediated degradation of WNKs results in a constantly activated WNK signaling pathway. In patients, this loss-of-function mutation in the RING ligase family member KLHL3 leads to pseudohypoaldosteronism type II (PHAII).

Results: As expected, KLHL3R528H/+ mutants exhibited a PHAII-like phenotype with hyperkalemia, hypernatremia and increased phosphorylation of NCC in the kidney. Surprisingly, KLHL3R528H/+ mutants also showed increased serum levels of Fgf23 and increased abundance of total and phosphorylated WNK1 and NCC protein in bone. Isolated primary osteoblasts from KLHL3R528H/+ mutants secreted increased amounts of Fgf23 in the medium as compared to wild-type (WT) cells, indicating that activation of WNK signaling in osteoblasts results in a cell autonomous increase in Fgf23 secretion. Treatment of mutant osteoblasts with the WNK pathway inhibitor closantel (0.3 μM) normalized the enhanced secretion and mRNA expression of Fgf23. To confirm the involvement of WNK in the physiological regulation of Fgf23 secretion, we treated WT osteoblasts with aldosterone (10 ng/ml) alone or in combination with closantel. Aldosterone increased WNK phosphorylation in WT osteoblasts, demonstrating that aldosterone activates WNK signaling in osteoblasts. However, the aldosterone-induced increase in Fgf23 mRNA and protein expression was abrogated by co-treatment with closantel.

Conclusions: Taken together, we identified WNK signaling as a novel regulator of Fgf23 secretion in osteoblasts.

TH-PO536

Klotho Does Not Have FGF23 Independent Functions in Mineral Homeostasis Olena Andrukhova, Jessica Bayer, Ute Zeitz, Reinhold Erben. *Dept of Biomedical Sciences, Univ of Veterinary Medicine Vienna, Vienna, Austria.*

Background: Fibroblast growth factor-23 (FGF23) is a bone-derived hormone regulating vitamin D production and mineral homeostasis by signaling through a FGF receptor/αKlotho (Klotho) complex. Whether Klotho has FGF23-independent effects on mineral homeostasis is a controversial issue.

Methods: Here, we aimed to shed more light on this controversy by comparing male and female triple knockout mice with simultaneous deficiency in *Fgf23* and *Klotho* and a nonfunctioning vitamin D receptor (VDR) (*Fgf23*/*Klotho*/VDR) with double (*Fgf23*/VDR and *Klotho*/VDR) and single *Fgf23*, *Klotho* and VDR mutants. Ablation of vitamin D signaling is known to rescue the severe phenotype of *Fgf23*and *Klotho* single mutants. To prevent hypocalcemia in VDR mutants, all mice were kept on a rescue diet enriched with calcium, phosphate and lactose.

Results: As expected, 4-wk-old *Fgf23* and *Klotho* knockout mice were hypercalcemic and hyperphosphatemic, whereas VDR, *Fgf23*/VDR and *Klotho*/VDR mice on rescue diet were normocalcemic and normophosphatemic. Mineral homeostasis did not differ between 4-wk-old triple *Fgf23*/*Klotho*/VDR and double *Fgf23*/VDR or *Klotho*/VDR knockout mice. Three-mo-old male and female *Fgf23*/VDR and *Klotho*/VDR compound mutants were characterized by hyperphosphatemia, hypocalcemia, increased serum PTH as well as renal Ca and sodium (Na) wasting. Notably, 3-mo-old *Fgf23*/*Klotho*/VDR triple knockouts were indistinguishable from double *Fgf23*/VDR and *Klotho*/VDR compound mutants in terms of body weight, serum Ca, serum Pi, serum Na, serum PTH as well as urinary Ca and Na excretion. Protein expression analysis revealed increased membrane abundance of

the Na-P-cotransporter NaPi-2a, and decreased expression of the Na- and Ca-transporting molecules NCC and TRPV5 in kidneys of *Fgf23/Klotho*/VDR, *Fgf23*/VDR, and *Klotho*/VDR mice, relative to WT and VDR mice, but no differences between triple and double knockouts. Similarly, bone mineral density remained unchanged in 4-wk-old and 3-mo-old *Fgf23/Klotho*/VDR mice compared with *Fgf23*/VDR and *Klotho*/VDR mice.

Conclusions: In conclusion, our data suggest that the main physiological function of Klotho for mineral homeostasis *in vivo* is its role as co-receptor for Fgf23 signaling.

TH-PO537

Excessive FGF23 Drives Progression of Chronic Kidney Disease in Mice via Partially Klotho-Independent Activation of WNK Signaling Olena Andrukhova,[1] Svetlana Slavic,[1] Jessica Bayer,[1] Reinhold Erben.[1] *[1]Dept of Biomedical Sciences, Univ of Veterinary Medicine Vienna, Vienna, Austria; [2]MRC Protein Phosphorylation & Ubiquitylation Unit, Univ of Dundee, Dundee, United Kingdom.*

Background: It is currently unclear whether elevated circulating fibroblast growth factor-23 (FGF23) causes maladaptive pathological effects in chronic kidney disease (CKD). Here, we analyzed the role of Fgf23 and its co-receptor Klotho in the pathogenesis of CKD in mice by a dual approach, using genetic loss-of-function together with pharmacological inhibition models.

Methods: CKD was induced by 5/6 nephrectomy in 3-month-old wild-type (WT) mice, vitamin D receptor (VDR) mutant mice, *Fgf23*$^{-/-}$/VDR$^{\Delta/\Delta}$ (Fgf23/VDR), and *Klotho*$^{-/-}$/VDR$^{\Delta/\Delta}$ (Klotho/VDR) compound mutant mice. All mice were kept lifelong on a rescue diet enriched with calcium, phosphorus, and lactose to prevent secondary hyperparathyroidism in VDR mutant mice. Sham-operated (SHAM) mice served as controls. In addition, SHAM and CKD WT, VDR, and Klotho/VDR mice were treated with low dose anti-FGF23 antibody (anti-FGF23Ab, 50 µg per mouse, two times per week) over 8 weeks.

Results: In our *in vivo* models, we found that high circulating concentrations of intact Fgf23 activate Klotho dependent and independent with-no-lysine kinase (WNK) signaling pathways in the kidney, contributing to volume overload, hypertension, hypercalcemia, cardiac dysfunction, and vascular calcification in CKD mice. Using Western blotting analysis as well as 2-photon microscopy of live 200-µm-thick renal slices prepared from WT and Klotho/VDR mice and treated with recombinant FGF23, we uncovered a novel Klotho-independent FGF23 action in the kidney, leading to FGF receptor 3/4- and WNK1/4-mediated stimulation of distal renal tubular Ca^{2+} and Na^{+} uptake.

Conclusions: In conclusion, our study identified excessive Fgf23 signaling as a major disease-modulating factor in CKD progression, promoting vascular calcification and volume overload.

TH-PO538

Oral Sodium Ferrous Citrate (Fe^{2}) Reduces the Serum Fibroblast Growth Factor 23 Levels of Maintenance Hemodialysis Patients to the Same Extent as Ferric Citrate Hydrate (Fe^{3}) Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Shigehiro Doi,[2] Takao Masaki,[2] Kenichiro Shigemoto.[1] *[1]Ichiyokai Harada Hospital; [2]Hiroshima Univ Hospital.*

Background: Iron deficiency stimulates FGF23 transcription. It was reported that ferric citrate hydrate (Fe^{3}) reduces the serum FGF23 levels of iron-deficient chronic kidney disease (CKD) and hemodialysis (HD) patients. However, ferric citrate hydrate is an iron-based phosphate binder and might reduce serum FGF23 levels via actions other than increasing iron stores. This study aimed to determine whether oral ferrous (Fe^{2}) iron reduces the serum FGF23 levels of iron-deficient maintenance HD (MHD) patients.

Methods: Thirty-one MHD patients with iron deficiency were enrolled in this study. The exclusion criteria included the use of intravenous or oral iron or iron-based phosphate binders within 8 weeks. The patients' iron stores and their serum FGF23, phosphate, calcium (Ca), intact parathyroid hormone (iPTH), albumin, and C-reactive protein (CRP) levels were examined at the baseline and after 3 months' treatment with sodium ferrous citrate.

Results: The patients' transferrin saturation values (13.8±0.8 vs. 38.8±4.4%, P<0.0001) and serum iron (37.4±2.3 vs. 94.6±11.3 µg/dl, P<0.0001) and ferritin levels (37.6±4.4 vs. 87.0±16.3 ng/ml, P<0.01) were significantly increased after 3 months' treatment, as were their serum albumin levels (P<0.05). Conversely, their serum intact FGF23 (iFGF23) (4157±1107 vs. 3045±736 pg/ml, P<0.05), C-terminal FGF23 (cFGF23) (643±127 vs. 506±129 pg/ml, P<0.05), and CRP (P<0.05) levels were significantly reduced after 3 months' treatment. No such changes in the patients' serum iFGF23:cFGF23 ratios or serum phosphate, Ca, or iPTH levels were detected. Multivariate analysis of variance showed that the changes in the subjects' serum iFGF23 and cFGF23 levels induced by sodium ferrous citrate supplementation were attributable to changes in their serum ferritin levels (p<0.05).

Conclusions: Short-term oral iron supplementation with sodium ferrous citrate (Fe^{2}) replenished the iron stores and reduced the serum iFGF23 and cFGF23 levels of iron-deficient MHD patients, and these changes occurred without variations in the patients' serum phosphate, Ca, or iPTH levels.

Iron Therapy and Fibroblast Growth Factor-23 in Hemodialysis: A Randomized Controlled Trial Matthew A. Roberts,[1] Louis L. Huang,[1] Darren H.K. Lee,[1] Robert J. Macginley,[1] Stefanie Troster,[1] Annette B. Kent,[1] Sukhvinder Singh Bansal,[2] Iain C. Macdougall,[3] Lawrence P. McMahon.[1] *[1]Eastern Health Clinical School, Monash Univ, Australia; [2]Inst of Pharmaceutical Science, King's College, United Kingdom; [3]Renal Medicine, King's College, United Kingdom.*

Background: Intravenous (IV) iron increases serum levels of intact fibroblast growth factor-23 (iFGF23) and decreases its c-terminal cleavage product (cFGF23) in iron-deficient people with normal renal function. We hypothesized that IV iron modulates levels of iFGF23 and cFGF23 in hemodialysis patients, with different effects according to formulation.

Methods: Prevalent hemodialysis patients requiring protocol IV iron were randomized to a single 200mg dose of IV ferric carboxymaltose (FCM) or iron sucrose (IS). The primary outcome, change in iFGF23 and cFGF23 from pre- (Day 0) to post-infusion (Day 2), used the Wilcoxon rank sum test. Serum hepcidin, ferritin and PO_4 were also measured. Linear mixed models with an interaction term for treatment and time evaluated between-group effects.

Results: In the FCM group (n=22), median (IQR) values of ferritin, hepcidin and cFGF23 increased but iFGF23 and PO_4 reduced; in the IS group (n=20), ferritin and hepcidin changed (Table). The between-group difference was only significant for serum hepcidin (p for interaction=0.03), with a greater increase in the FCM Group.

	IS (n=20)			FCM (n=22)		
	Day 0	Day 2	P	Day 0	Day 2	P
iFGF23, pg/mL	381 (245-1,526)	378 (235-1,584)	0.77	843 (313-1,922)	576 (356-1,296)	0.046
cFGF23, RU/mL	710 (448-1,548)	646 (307-1,576)	0.23	704 (475-1,204)	813 (267-1,156)	0.036
Ferritin, µg/L	191 (77-237)	370 (218-475)	<0.001	198 (129-276)	327 (281-472)	<0.001
Hepcidin, ng/mL	3.4 (2.7-8.8)	12.2 (7.3-19.2)	<0.001	7.8 (2.7-12.6)	21.4 (13.9-26.2)	<0.001
PO_4, mmol/L	1.29 (1.11-1.65)	1.34 (1.08-1.54)	0.089	1.53 (1.14-1.71)	1.37 (1.05-1.67)	0.030

Conclusions: Hemodialysis patients given protocol IV FCM demonstrated a fall in iFGF23 and rise in cFGF23, changes not evident with IS. This suggests a differential effect of IV iron according to formulation, and different effects to people with normal renal function.

Ferritin and Erythropoetin Are Main Determinants of Fibroblast Growth Factor 23 in Renal Transplant Recipients Michele F. Eisenga, Martin H. De Borst, Marco van Londen, Stephan J.L. Bakker, Carlo A. Gaillard. *Nephrology, UMC Groningen, Groningen, Netherlands.*

Background: Fibroblast growth factor 23 (FGF23) regulates phosphate and vitamin D homeostasis. In renal transplant recipients (RTR), an elevated level of FGF23 is an independent risk factor for mortality and allograft loss. To date, the interplay between FGF23, iron metabolism and red blood cell dynamics has not been fully evaluated.

Methods: Plasma C-terminal FGF23 was measured with enzyme-linked immunosorbent assay in stored plasma samples. Statistical analyses were performed using univariable linear regression followed by stepwise backward linear regression.

Results: We included 593 stable RTR (age 52±12 years; 53% males at 8.0±6.4 years after Tx). Median [IQR] FGF23 was 140 (95-219) RU/ml, ferritin was 160 (81-287) µg/l, EPO was 17.4 (12.0-24.5) U/L, and mean eGFR was 47±16 ml/min/1.73m2. In univariable and multivariable analysis, eGFR (ß=-0.39, p<0.001), phosphate (ß=0.23, p<0.001), EPO (ß=0.22, p=<0.001), ferritin (ß=-0.16, p<0.001), CRP (ß=0.13, p<0.001), and PTH (ß=0.12, p<0.001) (total model R^2=0.44) were identified as independent determinants of FGF23 (Table 1). Moreover, a significant interaction between EPO and hemoglobin on FGF-23 was noted (p=0.02).

Conclusions: We identified serum ferritin and EPO levels as major, potentially modifiable independent determinants of serum FGF23, alongside of the known association with phosphate homeostasis. EPO was positively associated with FGF23 independent of kidney function suggesting that anemia and/or EPO resistance may play a role in the association. Furthermore, since iron status and FGF23 are inversely associated, correction of iron deficiency may be a promising target to reduce FGF23 levels in an attempt to improve outcome.

Parameter	Univariable analysis		Multivariable analysis	
	std. ß	p-value	std. ß	p-value

Fibroblast Growth Factor 23 Associates with Resistance to Erythropoietin-Stimulating Agents in Maintenance Hemodialysis Patients Naoto Hamano,[1] Hirotaka Komaba,[1,2] Takehiko Wada,[1] Takatoshi Kakuta,[1] Masafumi Fukagawa.[1] *[1]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [2]The Inst of Medical Sciences, Tokai Univ, Isehara, Japan.*

Background: A recent experimental study has shown that fibroblast growth factor 23 (FGF23) inhibits erythropoiesis through suppression of erythropoietin production and downregulation of its receptor. However, it is unknown whether high levels of FGF23 affect renal anemia in hemodialysis patients.

Methods: To assess the relationship between resistance to erythropoiesis stimulating agents (ESA) and FGF23 levels, we used baseline data from the Tokai Dialysis Cohort Study, a prospective observational study of 654 hemodialysis patients. Erythropoietin resistance index (ERI), calculated as the weight-adjusted dose of ESA divided by the hemoglobin level, was used as an index of resistance to ESA. We defined top quartile of ERI as the ESA resistant group. Serum FGF23 levels were determined using a chemiluminescence immunoassay (Kyowa Medex Co., Ltd., Tokyo, Japan) that exclusively detects the full-length FGF23 peptide.

Results: A total of 458 patients were receiving ESA at baseline and were included in the analysis. The median ERI was 6.9 IU/kg/wk/g/dl (IQR 3.9-11.4 IU/kg/wk/g/dl) and the median FGF23 was 1,955 pg/ml (IQR 572-5,263 pg/ml). Multivariate logistic regression analysis identified body mass index, serum albumin, transferrin saturation, and FGF23 (OR 1.65, 95%CI 1.01-2.71 per 10-fold increase in FGF23) as independent risk factors for ESA resistance.

Conclusions: Our findings suggest that elevated FGF23 contributes to ESA resistance in patients undergoing hemodialysis. Future research should focus on whether FGF23-lowering treatment improves control of renal anemia in end-stage renal disease.

TH-PO542

Effect of Iron Deficient Diet on Fetuin A and FGF23 Regulation of Adriamycin-Induced CKD Model Mouse Masanori Takaiwa,[1] Kosei Hasegawa,[2] Takayuki Miyai.[2] *[1]Dept of Pediatrics, Matsuyama Red Cross Hospital, Matsuyama, Ehime, Japan; [2]Dept of Pediatrics, Okayama Univ Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: FGF23 is involved in the pathogenesis of CKD-MBD and cardiovascular disease in CKD. Deficiency of Fetuin A (Fet-A) is associated with increased arterial calcification and mortality in CKD. Fetuin-mineral complex, calciprotein particles (CPP), is increased in CKD and reflects extraosseous calcification stress. Previously, we produced an early CKD model mouse by adriamycin (ADR) treatment. Using this model, we observed that Fe deficiency enhanced the FGF23 elevation. In this study we examined the effect of Fe deprivation on FGF23, Fet-A and CPP of this model.

Methods: Upon making 6 groups (2% Fe and 2% Fe-CKD –fed a 2% Fe diet; 0.6% Fe and 0.6% Fe-CKD - fed a 0.6% Fe diet; 0.02% Fe and 0.02% Fe-CKD - fed a 0.02% Fe diet), 10-week-old male C57BL/6J mice were administered either ADR (2%-Fe-CKD, 0.6%-Fe-CKD and 0.02%-Fe-CKD) or serine every 7 days, and were sacrificed on day 28. Data were expressed as the mean±SEM. A value of $p<0.05$ was considered significant.

Results: The kidneys of ADR treated animals were smaller in size ($p<0.01$). There was no difference in Ca. Pi and PTH among all groups. In the 0.02% Fe-CKD, intact FGF23 (670.7±134.4 pg/ml) and a ratio between the intact FGF23 and C-terminal FGF23 (Int/C-FGF23 ratio) were higher than the other groups ($p<0.01$). Serum Fet-A is lower in the 0.02% Fe-CKD (55.0±2.0 ng/ml) than the 0.6% Fe (125.1±18.8 ng/ml) and all other groups ($p<0.05$). Fet-A mRNA of the 0.02% Fe-CKD was suppressed compared with the other ADR treated groups ($p<0.05$). The circulating CPP was elevated in the 0.02% Fe-CKD ($p<0.05$).

Conclusions: In this study, the increased intact FGF23 and Int/C-FGF23 ratio of the 0.02% Fe-CKD suggested that the FGF23 elevation was enhanced by the Fe deficiency. Significantly, the 0.02% Fe-CKD showed decreased Fet-A expression associated with increased CPP. Hence, it was suggested that Fe deprivation during the early CKD might accelerate CKD-MBD progression and strengthen the ectopic mineralization stress via inducing aberrant FGF23 proteolysis and Fet-A deficiency.

Elevations in FGF23 Precede Abrogation of Either Phosphate or Iron Homeostasis in a Mouse Model of Renal Insufficiency Jackie A. Fretz,[1] Tracy Nelson,[1] Xiuqi Li,[2] Karin Finberg.[2] *[1]Orthopaedics and Rehabilitation, Yale School of Medicine, New Haven, CT; [2]Pathology, Yale School of Medicine, New Haven, CT.*

Background: Phosphate and iron metabolism are linked intimately through the phosphatonin FGF23. Iron status is inversely correlated to the level of circulating FGF23, and improvement in iron status within individual patients correlates with a decrease in FGF23. Development of anemia during chronic kidney disease is a multifactoral process, but the exact mechanisms driving its development during the early stages of renal function decline are still not completely understood.

Methods: To better understand the events regulating the early dysfunction of iron bioavailability, phosphate balance and FGF23 we employed targeted deletion of the transcription factor Early B cell Factor 1 (Ebf1) from the kidney stromal progenitors (using Foxd1-cre). This results in a developmental abrogation of outer cortex development, and animals present with *glomerulosclerosis*, phosphate wasting, elevations in FGF23, and anemia. We profiled the sequential presentation of indicators of renal dysfunction (NGAL, albuminuria, hematuria, TGFβ), phosphate imbalance (PTH, $1,25(OH)_2D_3$, serum phosphate, phosphaturia), and regulators of iron bioavailability and transport (hepcidin, transferrin, erythrocyte counts, Epo, and splenic erythropoiesis) to understand the events that initiate and drive abrogation of the phosphate, iron, FGF23 regulatory axis.

Results: Elevated intact FGF23 coincides with the earliest indicators of renal dysfunction (elevated NGAL), and precede changes in urinary phosphate wasting or changes in iron homeostasis. Histological abnormalities are apparent at postnatal day 14, but proteinuria is not apparent until day 24, with splenomegaly at day 28. Serum Epo was normal until disease was well established, at 1 month, but was preceded by transferrin loss in the urine (day 20).

Conclusions: Elevated FGF23 has been shown to negatively regulate erythropoiesis. We conclude that it is primary elevations in FGF23 that drive the subsequent perturbations of phosphate and iron homeostasis in this model, and not a primary Epo-insufficiency generated by the actions of Ebf1 within the renal stroma.

Klotho Modulates FGF23-Mediated NO Synthesis and Oxidative Stress in Human Coronary Artery Endothelial Cells Maren Leifheit-Nestler, Beatrice Richter, Jacqueline Haller, Dieter Haffner. *Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany.*

Background: Endothelial dysfunction (ED) characterized by an imbalance of NO bioavailability and ROS formation is an early hallmark of CKD, a state of Klotho deficiency and excess of FGF23. Both dysregulations were shown to be associated with oxidative stress and ED. Klotho possesses antioxidative properties and increases resistance to oxidative stress but direct vascular effects of FGF23 remain largely elusive. We assess the effects of FGF23 in relation to Klotho on NO synthesis and ROS formation and detoxification in human coronary artery endothelial cells (HCAEC).

Methods: HCAEC were pre-treated with pan-FGF receptor (FGFR) or Akt inhibitor and anti-Klotho neutralizing antibody followed by stimulation with 10,000 pg/mL FGF23, resembling those found in moderate stages of CKD. Cells were investigated for FGFRs, membrane-bound and soluble Klotho, intracellular NO synthesis cascade, and ROS formation by qPCR, immunoblotting, and flow cytometry.

Results: Membrane-bound Klotho is expressed in HCAEC, and FGF23 increases the expression of the Klotho shedding protease ADAM17, and consequently the secretion of soluble Klotho. FGF23 stimulates NO release via FGFR/Akt-dependent activation of endothelial NO synthase (eNOS). Both FGFR-dependent ROS formation via NADPH oxidase 2 (Nox2) and ROS degradation via superoxide dismutase 2 (SOD2) and catalase (CAT) are stimulated by FGF23. Pre-incubation with Klotho inhibitor blunts the FGF23-stimulated Akt-eNOS activation and NO synthesis, decreases ROS degradation by blocking SOD2 and CAT enzymes, whereas FGF23-stimulated ROS synthesis via Nox2 is unaffected, resulting in low NO bioavailability and increased oxidative stress.

Conclusions: Our data indicate that in the presence of Klotho, FGF23 induces NO release in HCAEC and its stimulating effects on ROS production are counterbalanced by increased ROS degradation. In states of Klotho deficiency, e.g. CKD, FGF23-mediated NO synthesis is blunted and ROS formation overrules ROS degradation. Thus, FGF23 excess may primarily promote oxidative stress and consequently endothelial dysfunction.

TH-PO545

Soluble Klotho and Mortality in Maintenance Hemodialysis Patients Hisae Tanaka,[1] Hirotaka Komaba,[1,2] Takao Suga,[3] Takehiko Wada,[1] Takatoshi Kakuta,[1] Masafumi Fukagawa.[1] *[1]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [2]The Inst of Medical Sciences, Tokai Univ, Isehara, Japan; [3]Medical Corporation Showakai, Tokyo, Japan.*

Background: Klotho is a transmembrane protein that functions as a co-receptor for fibroblast growth factor 23 (FGF23). Klotho also exists as a soluble circulating protein, and recent experimental data demonstrated that soluble Klotho has multiple beneficial functions including renoprotection, prevention of vascular calcification, and inhibition of cardiac hypertrophy. However, it is unknown whether soluble Klotho levels are associated with risk of death in patients on hemodialysis.

Methods: We conducted a prospective cohort study of 654 maintenance hemodialysis patients (the Tokai Dialysis Cohort Study). The primary exposure variable was the baseline soluble Klotho level. The primary outcome was 3-year, all-cause mortality. Soluble Klotho levels and full-length FGF23 levels were measured using a sandwich ELISA kit (Immuno-Biological Laboratories, Co., Ltd, Gunma, Japan) and a chemiluminescence immunoassay (Kyowa Medex Co., Ltd., Tokyo, Japan), respectively.

Results: At study enrolment, the mean (±SD) soluble Klotho level was 377± 231 pg/ml and the median (IQR) FGF23 level was 1,878 (571-4,932) pg/ml. Higher levels of soluble Klothocorrelated with longer dialysis duration, higher hemoglobin, higher creatinine, and lower total cholesterol; there was no correlation with serum calcium, phosphorus, parathyroid hormone, or FGF23. In univariate analysis, soluble Klotho levels were not significantly associated with risk of mortality. This result was unchanged after multivariable adjustment.

Conclusions: Soluble Klotho levels were not related to parameters of bone mineral metabolism and did not predict mortality in patients undergoing hemodialysis. Further research is required to determine whether soluble Klotho plays a role in bone disease and vascular calcification in end-stage renal disease.

Funding: Government Support - Non-U.S.

Klotho and Inflammation in Early Stages of Chronic Kidney Disease

Ewelina Lukaszyk,[1] Mateusz Lukaszyk,[2] Ewa Koc-Zorawska,[1] Jolanta Malyszko.[1] *[1]2nd Dept of Nephrology and Hypertension with Dialysis Centre, Medical Univ of Bialystok, Bialystok, Poland; [2]Dept of Allergy and Internal Medicinie, Medical Univ of Bialystok, Bialystok, Poland.*

Background: One of the major functions of Klotho is its role as an obligatory co-receptor for FGF23 signaling. The effect of Klotho/FGF23 system is opposite to vitamin D. Reduced expression of Klotho may contribute to a number of complications of chronic kidney disease. Similarly inflammation is also well-known risk factor of progression and complications of CKD. The aim of the study was to asses Klotho status in patients in early stages of chronic kidney disease in correlation to inflammation.

Methods: 89 patients with CKD stage 2-3 according to KDIGO were enrolled to the study and divided into two groups – with and without subclinical inflammation according to hsCRP measurements. Serum creatinine was obtained using standard laboratory methods in certified local central laboratory. Commercially available kits were used to measure FGF23, Klotho, hsCRP, IL-6, GDF15, and vitamin D. Analyses of the correlation of each parameter were performed using Pearson or Spearman correlation coefficients.

Results: Klotho concentration was significantly lower in patients with inflammation defined as elevated hsCRP > 10 mg/dl (p=0.01). Klotho was significantly correlated with vitamin D in all patients, however in patients with inflammation this correlation was stronger ($r = 0.49$, $p<0.05$). Similarly we observed significant correlation between Klotho and GDF-15, especially marked in patients with inflammation($r = - 0.4$, $p<0.05$). No statistically significant correlations between Klotho and FGF23 as well as inflammatory parameters such as hsCRP and IL-6 have been observed. In multiple regression analysis vitamin D and GDF-15 were found to be predictors of Klotho.

Conclusions: Lower Klotho concentrations are connected with subclinical inflammation in patients with early stages of chronic kidney disease. As Klotho is linked to life expectancy, inflammation may also contribute to shortened survival in CKD.

TH-PO547

The Metabolic Bone Disease Associated with the Hyp Mutation Is Independent of Osteoblastic HIF1α Expression

Julia M. Hum,[1] Erica Clinkenbeard,[1] Pu Ni,[1] Matthew R. Allen,[2] Kenneth E. White.[1] *[1]Dept of Medical and Molecular Genetics, Indiana Univ School of Medicine, Indianapolis, IN; [2]Dept of Anatomy and Cell Biology, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: Fibroblast growth factor-23 (FGF23) is a hormone controlling key responses to systemic phosphate increases through its actions on the kidney. FGF23 also positively responds to iron deficiency anemia and hypoxia in rodents and humans and is responsible for late-onset ADHR. The disorder X-linked hypophosphatemia (XLH) is characterized by elevated FGF23 and an intrinsic bone mineralization defect. Further, the *Hyp* mouse model of XLH has disturbed osteoblast to osteocyte differentiation with altered expression of FGF23. Since Hypoxia inducible factor-1a (HIF1a) has been implicated in FGF23 production and is important for bone cell differentiation, the goals of this study were to determine whether HIF1a activation under normal iron conditions could influence FGF23, and to test the role of HIF1a on the *Hyp* endocrine and skeletal disease *in vivo*.

Methods: Treating primary cultures of osteoblasts/osteocytes and UMR-106 cells with HIF1a activator, AG490. Generation of *Hyp* mice bred onto the HIF1a/Osteocalcin-Cre background.

Results: Treatment of primary bone cultures and UMR-106 cells with the AG490 resulted in HIF1a stabilization and increased FGF23 mRNA (50-100 fold; $p<0.01$-0.001). Since FGF23 is elevated in the *Hyp* mouse, we sought to determine whether a bone-specific HIF1a deletion would correct FGF23 production and the *Hyp* disease phenotype. Although HIF1a effects on bone could be detected, the cross of *Hyp-HIF1a-OCN* had no effect on the metabolic bone disease associated with the *Hyp* mutation.

Conclusions: In summary, FGF23 can be driven by ectopic HIF1a activation under normal iron conditions *in vitro*, but factors independent of HIF1a activity after mature osteoblast formation are likely responsible for the elevated FGF23 in *Hyp* mice *in vivo*. Clinically, these findings suggest that although iron therapy holds promise for ADHR, patients with XLH would likely benefit from other treatment approaches.

TH-PO548

KRN23, a Fully Human Monoclonal Antibody to FGF23, Reverses Renal Phosphate Wasting and Improves Rickets in Children with X-Linked Hypophosphatemia

Anthony A. Portale,[1] Javier San Martin,[2] Thomas Carpenter.[3] *[1]Pediatrics, Univ of California San Francisco, San Francisco, CA; [2]Ultragenyx Pharmaceutical, Inc., Novato, CA; [3]Pediatrics, Yale Univ School of Medicine, New Haven, CT.*

Background: In patients with X-linked hypophosphatemia (XLH), high circulating FGF23 impairs renal phosphate (Pi) reabsorption and $1,25(OH)_2D$ production, resulting in hypophosphatemia, defective bone mineralization, and rickets. Conventional treatment with oral Pi and active vitamin D fails to restore Pi homeostasis and often leads to nephrocalcinosis and hyperparathyroidism.

Methods: In a phase 2 study, we administered KRN23, which binds and inhibits the renal actions of FGF23, to children (ages 5-12 years, ≤Tanner 2) with XLH, either biweekly (Q2W) or monthly (Q4W) by subcutaneous injection. KRN23 doses were titrated to achieve age-appropriate serum Pi concentrations, which were measured biweekly.

Results: At enrollment, 35 of the first 36 participants had received conventional treatment for a mean of 6.6 years. After 40 weeks of KRN23 treatment, renal TmP/GFR, serum Pi, and $1,25(OH)_2D$ increased significantly, and alkaline phosphatase decreased. Increases in serum Pi were more stable and sustained with Q2W dosing. In this interim analysis, increases in $1,25(OH)_2D$ did not impact serum or urinary calcium, PTH, or nephrocalcinosis. Radiographic findings of rickets improved substantially in most patients, with greater improvements in the subset with higher-severity rickets at baseline.

Mean (SD)		Baseline	Week 38	Week 40
Serum Pi (mg/dL)	Q2W	2.5 (0.4)	3.2 (0.4)*	3.2 (0.4)*
	Q4W	2.3 (0.3)	3.4 (0.4)*	2.8 (0.3)*
TmP/GFR (mg/dL)	Q2W	2.3 (0.5)	3.1 (0.6)*	3.2 (0.6)*
	Q4W	2.0 (0.4)	3.4 (0.4)*	2.6 (0.3)*
Serum $1,25(OH)_2D$ (pg/mL)	Q2W	40 (23)	69 (12)*	69 (16)*
	Q4W	41 (17)	83 (21)*	61 (17)*
Serum Calcium (mg/dL)	Q2W	9.8 (0.3)	9.8 (0.3)	9.6 (0.2)*
	Q4W	9.8 (0.5)	9.8 (0.4)	9.7 (0.4)
2-hr Urine Calcium/Creatinine Ratio (mg/mg)	Q2W	0.12 (0.08)	0.08 (0.04)	0.10 (0.09)
	Q4W	0.16 (0.10)	0.08 (0.05)*	0.13 (0.11)
Serum Alkaline Phosphatase (U/L)	Q2W	454 (109)		388 (95)*
	Q4W	443 (111)		415 (112)
		Baseline	**Week 36**	
Serum iPTH (pg/mL)	Q2W	48 (34)	48 (19)	
	Q4W	41 (24)	50 (23)	

* P<0.05 vs baseline values, by paired analysis. N=18 participants in each dosing schedule arm. In the Q4W dosing group, Week 38 is the midpoint of a dosing interval; Weeks 36 and 40 are the ends of the dosing intervals.

Conclusions: These data provide evidence that by binding and inhibiting excess FGF23, KRN23 improves the impairments in renal Pi reabsorption and $1,25(OH)_2D$ production in XLH and consequently, improves rickets, without adversely affecting calcium metabolism.

High Serum Levels of Fibroblast Growth Factor 23 Are Associated with Decreased Renal Blood Flow in Early Autosomal Dominant Polycystic Kidney Disease

Michel Chonchol,[1] Berenice Y. Gitomer,[1] Zhiying You,[1] Myles S. Wolf.[2] *[1]Medicine/Nephrology, Univ of Colorado, Aurora, CO; [2]Medicine/Nephrology, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Previous studies have reported a 4-fold elevation in circulating fibroblast growth factor 23 (FGF23) levels in early autosomal dominant polycystic kidney disease (ADPKD) when compared to other etiologies of chronic kidney disease (CKD). FGF23 levels have been associated with impaired vasoreactivity in CKD. We tested the hypothesis that higher serum FGF23 is a risk factor for a decrease in renal blood flow (RBF) in early ADPKD.

Methods: Intact FGF23 (iFGF23) serum levels (Kainos)were measured in 343 hypertensive ADPKD patients who participated in the HALT-PKD trial study A. Participants were randomized to standard or low blood pressure control and to either lisinopril plus telmisartan or lisinopril plus placebo, with evaluation of RBF by abdominal magnetic resonance imaging at baseline, 24, 48, and 60 months. The study population was divided into tertiles of iFGF23. We used mixed effect models to examine the associations between tertiles of iFGF23 with repeated measures of RBF during the course of the study.

Results: At baseline, participants mean age, CKD-EPI-eGFR and RBF were 37 ± 9 years, 88 ± 16 ml/min/1.73m^2, 606 ± 205 ml/min/1.73m^2, respectively. The median (IQR) iFGF23 was 40.5 (33-55) pg/mL. After adjustment for age, gender, race, randomization group, body mass index, systolic blood pressure, eGFR, urine albumin excretion, serum calcium, and phosphate, the highest iFGF23 tertile was associated with greater RBF decline (β: -42.76, [95% CI -2.38 to -83.14]; $p < 0.03$) compared with the lowest iFGF23 tertile. Similarly, when evaluated as a continuous variable, higher levels of iFGF23 were associated with a lower RBF (β: -35.88, [95% CI -2.23 to -69.53]; p=0.03 per natural log unit increase).

Conclusions: High serum iFGF23 levels are associated with a lower RBF over time in patients with early ADPKD. Further studies are required to determine the mechanisms underlying these relationships and to test whether interventions that reduce FGF23 levels might be renoprotective in early ADPKD.

FGF23 Can Predict the Worsening of Cognitive Impairment in Dialysis Patients? Valentina Corradi,[1,2] Fiorenza Ferrari,[2] Sara Samoni,[2] Roberto Zambianchi,[2] Ilaria Santolin,[3] Elisabetta Galloni,[3] Massimo de Cal,[1,2] Elisa Scalzotto,[2] Carlotta Caprara,[2] Ornella Gambero,[3] Lucia Meligrana,[3] Mariangela Mettifogo,[1,2] Alessandra Brendolan,[1,2] Federico Nalesso,[1,2] Carlo Crepaldi,[1,2] Francesco Perini,[3] Claudio Ronco.[1,2] *[1]Nephrology, San Bortolo Hospital; [2]IRRIV, San Bortolo Hospital; [3]Neurology, San Bortolo Hospital.*

Background: Cognitive impairment (CI) in patients with chronic kidney disease (CKD) patients on dialysis is common and shows a prevalence on the rise. Especially cognitive performance was significantly associated with eGFR in all domains except language. Several studies showed the uremia-related factors for cognitive impairment in CKD-stage V but its development remain unclear. Recently FGF23 was associated with worse performance on a composite memory score. FGF-23 levels in hemodialysis patients may contribute to cognitive impairment. The aim of our study was to determine if the FGF23 could predict the worsening of cognitive impairment.

Methods: We performed a prospectively study (baseline, T0 and after 1year, T1) in chronic dialysis (HD and PD). The assessment of cognitive status was performed through two psychometric tests: Mini-Mental State Exam (MMSE) and Montreal Cognitive Assessment (MoCA). The C-terminal FGF23 (cFGF23) levels were determined in plasma by ELISA (Immutopics, Inc.San Clemente, CA) as RU/ml. Statistical analysis was performed by R Core Team (2016).

Results: Baseline, we enrolled 133 pts, 58 HD and 75PD (mean age 64,09±13,65 yrs; 71% M; median dialysis time: 2,79 (1,38-6,03) years). The median cFGF-23 level baseline was 1493 (927-4035) RU/mL. The cognitive assessment of pts are shown in table 1.

variable	T0 (133)	T1 (104)	*p* value
MMSE	27.49 (24.40-28.48)	27.70 (26.30-28.48)	NS
MoCA (ES)	23,33 (20,63-25,71)	23,37 (20,07-26,11)	0.056

The linear regression model showed for all increase of 100 RU/ml of cFGF23 a decrease of MoCA ES of 0.003 unit from T0 to T1.

Conclusions: FGF-23 levels seems to be associated with worse performance of executive function of dialysis pts. High level of FGF-23 levels in dialysis patients could be contribute to cognitive impairment. Further studies are needed to confirm our data and to investigate the impact of different dialysis modalities on CI.

TH-PO551

Genetic Background Influences Cardiac Phenotype in Murine Chronic Kidney Disease Samantha Neuburg, Lixin Qi, Connor Francis, Xueyan Wang, Corey Dussold, Valentin David, Myles S. Wolf, Aline Martin. *Div of Nephrology and Hypertension, Northwestern Univ - Feinberg School of Medicine, Chicago, IL.*

Background: An increased levelof fibroblast growth factor (FGF)-23 is the earliest detectable sign of disordered mineral metabolism in chronic kidney disease (CKD), and a powerful risk factor for left ventricular hypertrophy (LVH), heart failure and death. Experimental models of CKD with elevated FGF23 and LVH are needed. We hypothesized that slower rates of CKD progression in the Col4a3^{KO} mouse model of CKD would increase exposure to elevated FGF23 and promote development of LVH.

Methods: We backcrossed 129X1/SvJ-Col4a3^{KO} with C57Bl6/J mice and generated Col4a3^{KO} and WT on a mixed background with either 25% C57Bl6/J (***129***) or 94% C57Bl6/J (***Bl6***) genomes. We compared overall survival and assessed renal function, FGF23 levels and cardiac morphology by echocardiography in WT controls and Col4a3^{KO} with advanced CKD: at 10 weeks in the ***129***, 20 weeks in the ***Bl6*** mice.

Results: ***Bl6-***Col4a3^{KO} lived significantly longer than ***129-***Col4a3^{KO} (22±1 vs. 11±1 weeks; p<0.05). 10 week-old ***129-***Col4a3^{KO} showed impaired renal function (BUN: 100±12 vs. 21±1 mg/dL), hyperphosphatemia (9.6±0.6 vs. 6.1±0.4 mg/dL) and a 10-fold increase in serum FGF23 levels (p<0.05 vs. WT for each). At 20 weeks, ***Bl6-***Col4a3^{KO} showed similarly impaired renal function (BUN: 78±17 vs. 25±2 mg/dL), hyperphosphatemia (7.9±0.4 vs. 6.2±0.3 mg/dL) and a 10-fold increase in FGF23 levels (p<0.05 vs. WT for each), indicating comparable severity of CKD to the 10-week ***129-***Col4a3^{KO}. Whereas ***129-***Col4a3^{KO} did not show significant cardiac alterations (LV Mass: 102±15 vs. 104±4 mg; NS vs. WT), ***Bl6-***Col4a3^{KO} demonstrated LVH (LV Mass: 132±3 vs. 96±5 mg; p<0.05 vs. WT).

Conclusions: The genetic background of the Col4a3^{KO} mouse influences its rate of CKD progression, cardiac phenotype and survival. Slower CKD progression and longer survival are associated with development of LVH in ***Bl6-***Col4a3^{KO}, which can serve as a novel model of cardiorenal disease. Whether LVH is mediated, in part, by longer exposure of ***Bl6-***Col4a3^{KO} mice to elevated FGF23 levels requires further study.

Increase in Cardiac Expression of Fibroblast Growth Factor 23 (FGF23) in Two Mouse Models of Chronic Kidney Disease Dorothy Daniel,[1] Emily M. Adamic,[2] Jason R. Stubbs,[3] Chad D. Touchberry,[2] Michael J. Wacker.[1] *[1]Univ of Missouri-Kansas City School of Medicine, Kansas City, MO; [2]Health and Sport Sciences, Univ of Memphis, Memphis, TN; [3]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: FGF23 is a hormone released from osteocytes in response to elevated serum phosphate and acts to decrease phosphate reabsorption. FGF23 serum levels rise with the progression of chronic kidney disease (CKD) and are associated with cardiovascular disease and mortality. While bone release of FGF23 is known to increase during CKD, it has not been fully elucidated if the heart directly contributes to FGF23 expression and if it is increased during CKD. To test this hypothesis, we utilized two mouse models of CKD: *Col4a3* null (Alport syndrome) and adenine diet (chronic tubulointerstitial nephritis). Both mouse models have progressive renal dysfunction as evidenced by elevated BUN, creatinine, phosphate, and FGF23 serum levels. Our aim was to measure changes in expression of FGF23 in the hearts of *Col4a3* null and adenine-fed mice and also determine if exercise would prevent these changes.

Methods: *Col4a3* null and wild-type (WT) mice were sacrificed at 10 weeks. For the adenine model, CD1 mice were fed 0.2% adenine daily for 12 weeks and a subset of these mice were exercised on a treadmill daily. Hearts were removed and real time RT-PCR was used to measure expression of FGF23. Analysis was performed using the 2^ddct method.

Results: Basal cardiac FGF23 expression was low in *Col4a3* WT and control diet mice, with an average delta CT of 16.9 in relation to β-actin expression. Cardiac FGF23 expression was increased 3.2 fold in *Col4a3* null mice (p<0.05; n=5) and increased 3.0 fold in adenine-fed mice (p<0.05; n=6) compared to control mice. Exercise did not improve kidney function in adenine-fed mice and FGF23 expression was elevated 3.2 fold (p<0.05; n=5).

Conclusions: FGF23 expression was increased in the hearts of CKD mice indicating that FGF23 may have paracrine effects on cardiac remodeling during CKD and could prove to be an important therapeutic target. This particular exercise regimen did not abate FGF23 expression and may be adverse for CKD disease.

TH-PO553

Correlation of Fibroblast Growth Factor Receptor and Fibroblast Growth Factor 23 Expression with Cardiac Structure and Function in Failing Human Hearts Morgan E. Marcuccilli,[1] Angela K. Peter,[1] Suneet Nitin Purohit,[1] Amrut V. Ambardekar,[1] Rahul Kakkar,[2] Leslie A. Leinwand,[1] Michel Chonchol.[1] *[1]Univ of Colorado; [2]Corvidia.*

Background: Experimental studies have demonstrated that fibroblast growth factor 23 (FGF23) promotes left ventricular hypertrophy by activating fibroblast growth factor receptors 4 (FGFR4). However, FGF23 can signal through multiple FGF receptors (FGFRs), and the relationship between FGF23 and FGFRs expression with echocardiographic measures of cardiac structure and function in humans with end stage heart failure is unknown.

Methods: We conducted a retrospective study in patients with normal kidney function and end-stage heart failure from either ischemic cardiomyopathy (n=10), ischemic cardiomyopathy treated with a left ventricle assisted device (n=10), hypertrophic cardiomyopathy (n=10) or non-ischemic or hyperthrophic cardiomyopathy with concentric left ventricular hypertrophy (LVH). Left ventricular tissue was collected and flash frozen at the time of heart transplant. FGFR 1-4 and FGF23 expression was evaluated using quantitative real-time PCR. Linear regression models were used to examine the association between FGFRs and FGF23 expression with echocardiographic parameters.

Results: Median (IQR) age was 53 (47-61) years, and 77% were male. The median (IQR) ejection fraction (EF), left ventricular internal diameter in systole (LVIDs) and diastole (LVIDd), systolic and diastolic volumes were 23 (15-30)%, 5.3 (4.3-6.3) cm, 5.8 (5.1-7.2) cm, 110 (70-187) ml and 155 (107-236) ml, respectively. After adjusting for age, gender, race and cardiac pathology, only FGFR3 and FGFR4 were associated with LVIDs [β(SE): - 0.70 ± 0.33; p=0.04 and β SE): -0.77±0.32; p=0.02, respectively] and systolic LV volume [β(SE): -46.25±19.47; p=0.02 and β SE): -51.49±17.64; p=0.0008, respectively]. FGF23 was strongly associated with fractional shortening (β(SE): 3.03±0.78; p=0.0005). Higher FGFR1, 3 and 4 expression were all associated with higher EF (P < 0.004 for all).

Conclusions: FGFR3, FGFR4 and FGF23 correlate with echocardiographic parameters of cardiac structure and function in end stage heart failure. Further studies should explore the possible mechanistic role of FGFR 3 and 4 in advanced cardiomyopathy.

TH-PO554

FGF23 Is Not Predictive of Functional Cardiovascular Reserve in Advanced CKD Kenneth Lim,[1] Stephen M.S. Ting,[2] Dihua Xu,[1] Sahir Kalim,[1] David H. Ellison,[3] Ravi I. Thadhani,[1] Daniel Zehnder,[4] Thomas F. Hiemstra.[5] *[1]Div of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Dept of Medicine, Heart of England NHS Foundation Trust, United Kingdom; [3]Div of Nephrology & Hypertension, Oregon Health and Science Univ, Portland, OR; [4]Div of Metabolic & Vascular Health, Warwick Medical School, United Kingdom; [5]School of Clinical Medicine, Univ of Cambridge, United Kingdom.*

Background: Chronic kidney disease (CKD) patients exhibit impaired functional cardiovascular reserve with reduced peak exercise oxygen consumption (VO_2max), a predictor of survival. In CKD, bone derived FGF23 is elevated and has been implicated in the development of cardiovascular disease. We sought to determine whether FGF23 is a predictor of VO_2max in CKD.

Methods: In this cross-sectional study, we enrolled 171 CKD stage V patients and 88 controls with essential hypertension: age 46.7±14.3 vs. 53.2±8.1years (p<0.001), male 60.2% vs. 48.9%, MAP of 98±13.4 vs 104.2±9.5mmHg (p<0.001). VO_2max was determined by cardio-pulmonary exercise test (CPET) and left ventricular mass index (LVMI) by 2D echocardiogram.

Results: CKD patients had higher FGF23 levels (2845.4 pg/ml, IQR 595.9-10947 vs 41.7pg/ml, IQR 35-51.7, p<0.001), higher LVMI (110±36.5 g/m^2 vs 87.6±16.9, p <0.001), and markedly reduced VO_2max (19.8±12.1 vs 24.8±23.4 ml/min/kg, p<0.001). Univariate regression showed that lnFGF23 was not associated with VO2max (p = 0.05), but was associated with LVMI (p < 0.05) in CKD; lnFGF23 were neither associated with VO2max or LVMI in controls. In a multivariate regression model for CKD: lnFGF23 was not associated with VO_2max (β=-.018, p=0.08), but positively associated with age (p<0.0001), HR (p<0.0001) and LVMI (p=0.002). In control: lnFGF23 was also not associated with VO_2max (β=-.07, p=0.4), but positively associated with HR (p<0.0001) and LVMI (p<0.0001) but not with age (p=0.6).

Conclusions: As previously observed, this study describes an association between FGF23 and LVMI in both CKD and essential hypertension. However, FGF23 did not predict cardiovascular reserve in the context of hypertension alone or CKD and hypertension.

TH-PO555

Fibroblast Growth Factor 23 Is Not Associated with Incident Acute Kidney Injury among HALT PKD Study B Participants Anna Jeanette Jovanovich,[1,2] Zhiying You,[2] Berenice Y. Gitomer,[2] Myles S. Wolf,[3] Michel Chonchol.[2] *[1]Denver VA Medical Center; [2]Univ of Colorado Denver; [3]Northwestern Univ.*

Background: Fibroblast growth factor 23 (FGF23) levels are elevated in acute kidney injury (AKI) independent of other bone mineral metabolism parameters. Furthermore, higher pre-operative FGF23 levels predict more severe AKI and greater need for renal replacement therapy among patients undergoing cardiopulmonary bypass surgery. To further evaluate the relationship between AKI and FGF23, we investigated the association of baseline serum FGF23 levels and AKI among patients with autosomal dominant polycystic kidney disease (ADPKD).

Methods: We measured intact FGF23 levels (Kainos) in stored baseline serum samples in the HALT PKD Study B, which evaluated the efficacy of renin-angiotensin-aldosterone system (RAAS) blockade on the progression renal disease among participants with ADPKD and GFR 25-60 mL/min/1.73 m^2. Participants were randomized to either single agent (lisinopril + placebo) or dual agent (lisinopril + telmisartan) RAAS blockade. Goal blood pressure was 110-130/80 mmHg. We used logistic regression analysis to evaluate the association of baseline FGF23 levels and incident AKI (increase in serum creatinine >0.3 mg/dL).

Results: A total of 437 participants were included in these analyses. Mean age was 49±8 years, 51% were female, mean CKD-EPI eGFR was 48±12 mL/min/1.73 m^2, and median serum intact FGF23 was 67 [49-90] pg/mL. Incident AKI occurred in 48 participants over 5-8 years of follow-up. In the unadjusted model, higher FGF23 was associated with 2-fold greater odds of incident AKI (odds ratio [OR] 2.1; 95% CI, 1.1-4.0). However, after full adjustment for demographic and clinical factors as well as treatment group, the magnitude of the association was somewhat attenuated and no longer significant (OR 1.8; 95% CI, 0.8-3.7).

Conclusions: Baseline serum FGF23 levels were not significantly associated with incident AKI among participants with ADPKD and stage III-IV chronic kidney disease. However, the number of incident AKI cases was small and the magnitude of the association was only slightly attenuated after full adjustment.

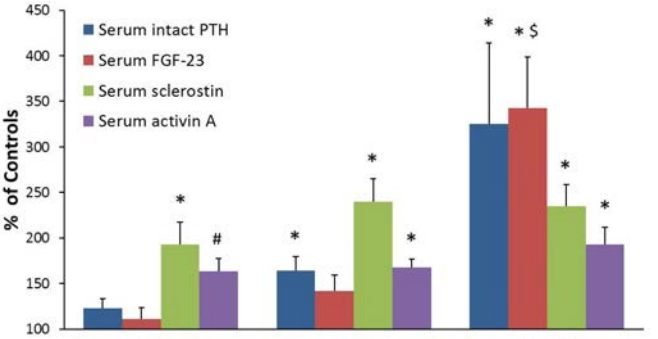
TH-PO556

Activin A and Sclerostin in Blood Increase before PTH and FGF-23 in CKD Stages 2 to 5 Florence Lima, Marie-Claude M. Faugere, Hanna W. Mawad, Amr El-Husseini Mohamed, Hartmut H. Malluche. *Div of Nephrology, Bone & Mineral Metabolism, Univ of Kentucky, Lexington, KY.*

Background: Renal osteodystrophy (ROD) develops in early stages of chronic kidney disease (CKD) and progresses during loss of kidney function. Serum levels of intact parathyroid hormone (iPTH) have been used as the primary indicator of bone abnormalities in ROD. There are other markers that may be useful for assessment of ROD in patients with various stages of CKD. This study evaluated changes in blood levels of iPTH, fibroblast growth factor 23 (FGF-23), bone-specific alkaline phosphatase (BSAP), tartrate resistant acid phosphatase 5b (TRAP-5b), sclerostin, activin A, Dickkopf-1 (DKK1), a-Klotho and cathepsin K in patients with CKD stages 2 to 5.

Methods: These biochemical parameters were measured in 71 subjects with CKD stages 2 to 5. There were 18 patients with CKD-2, 37 patients with CKD-3 and 16 patients with CKD-4 or 5 (not on dialysis). Serum levels of FGF-23, BSAP, TRAP-5b, sclerostin, activin A, DKK1, a-Klotho and cathepsin K were measured by ELISA and iPTH by chemiluminescent immunoassay (DiaSorin).

Results: In CKD-2, only serum activin A and sclerostin were significantly higher compared to normal controls. In CKD-3, activin A, sclerostin and iPTH were higher while in CKD-4/5, activin A, sclerostin, iPTH and FGF-23 were higher (Fig). DKK1 was not significantly higher compared to controls in CKD-2 and -3 but significantly lower in CKD-4/5 (P<0.05). BSAP, TRAP-5b, a-Klotho and cathepsin K were not different from normal controls at any stages of CKD.



# P < 0.05 versus controls. * P < 0.01 versus controls. $ P < 0.01 versus CKD-2 and CKD-3

Conclusions: The data show elevated blood levels of activin A and sclerostin as early as CKD-2 preceding elevated levels of iPTH and FGF-23. The pathogenic and diagnostic relevance of these findings awaits further studies. Activin A and sclerostin blood levels may be of interest as new biomarkers for ROD early in the course of loss of kidney function.

Changes in Markers of Mineral Metabolism following Living Kidney Donation Sven-Jean Tan,[1,2] Timothy D. Hewitson, Peter D. Hughes,[1,2] Stephen G. Holt,[1,2] Nigel David Toussaint.[1,2] *[1]Nephrology, The Royal Melbourne Hospital, Parkville, Victoria, Australia; [2]Medicine (RMH), The Univ of Melbourne, Parkville, Victoria, Australia; [3]The Royal Melbourne Hospital.*

Background: Aim: To evaluate the effect of nephrectomy on markers of mineral metabolism in living kidney donors (LKD) compared to healthy volunteers (HV) over 12 months. **Background:** LKDs experience reduction in kidney function however serum phosphate (sPi) levels are lower when compared to eGFR-matched CKD patients. Mineral metabolism adaptations that occur in LKDs have not been adequately investigated.

Methods: Twenty-one adult LKDs and twenty HVs were evaluated with respect to renal function and mineral metabolism parameters, including sPi, intact parathyroid hormone (PTH), fibroblast growth factor-23 (FGF23), soluble Klotho (sKl) and urinary phosphate, prior to donation (T_0), 1-month (T_1), 6-months (T_6) and 12-months (T_{12}) post kidney donation/baseline. Statistical analyses were conducted on normalised variables and changes were assessed using two-way ANOVA.

Results: Mean (±SD) age of LKDs and HVs were 54.1 ± 14.7 and 52.6 ± 8.0 years respectively. There were no baseline clinical or biochemical differences between LKDs and HVs. At T_1, mean (±SD) serum creatinine (sCr) increased from 75 ± 12 to 114 ± 22 umol/L, with FGF23 elevation (52 ± 15 to 70 ± 19 pg/mL) and sKl reduction (564 (469-662) to 424 (375-523) pg/mL), all p<0.001. Changes were sustained at T_{12}. Following donation, LKDs consistently demonstrated lower sPi compared with T_0 (1.08 ± 0.15 mmol/L) though maximal sPi change was detected at T_6 (0.89 ± 0.17 mmol/L), p<0.001. Other markers of mineral metabolism were unchanged in LKDs. There were no differences in parameters over 12 months in HVs.

Conclusions: Prospective evaluation of mineral metabolism parameters in LKDs provides valuable insight into compensatory mechanisms following reduction in kidney function. Further reduction of sPi at T_6 despite early alterations in FGF23 and sKl suggest adaptation of mineral metabolism continues long-term in LKDs.

TH-PO558

FGF23 Initially Plays a Important Role on Phosphate Homeostasis in Chronic Kidney Disease Takaaki Kimura,[1] Kazuhiro Shiizaki,[2] Makoto Kuro-o,[2] Takashi Yagisawa.[1] *[1]Div of Renal Surgery and Transplantation, Dept of Urology, Jichi Medical Univ, Shimotsuke-City, Tochigi, Japan; [2]Div of Anti-Aging Medicine, Center for Molecular Medicine, Jichi Medical Univ, Shimotsuke-City, Tochigi, Japan.*

Background: It has been well known that phosphate homeostasis is regulated by the increased level of fractional excretion of phosphorus (FEP), which is the ratio of clearance of phosphorus and creatinine, exerted by both fibroblast growth factor 23 (FGF23) and parathyroid hormone (PTH) as the phosphaturic hormones, so serum phosphate level is kept within the normal range until the end stage of chronic kidney disease (CKD). However, the precise mechanism and the induction point of such kind of compensatory mechanism for the phosphate homeostasis in CKD have not been recognized. We evaluated the phosphate homeostasis in the artificial CKD model, which is the patients undergone a nephrectomy (Nx) as the kidney donors.

Methods: Twenty-one kidney donors were included and the estimated glomerular filtration rate (eGFR), the amount of urine phosphorus excretion per day, FEP, serum FGF23, Vitamin D (1,25(OH)2D), and PTH levels were measured. These data were collected one month before and six months after Nx.

Results: The eGFR after Nx was significantly decreased from 74.0±15.4 mL/min/1.73m2 to 47.0±10.7 mL/min/1.73m2 ($p < 0.05$). The levels of FGF23 before and after Nx were 43.9pg/mL (IR: 35.7-48.0) and 62.0pg/mL (IR: 54.0-71.0), respectively ($p < 0.05$). FEP was significantly increased from 12.2% (IR: 9.7-15.1) to 20.6%(IR: 17.7-23.2) ($p < 0.05$) and 1,25(OH)2D was significantly decreased from 58.6pg/mL (IR: 50.1-66.9) to 52.7pg/mL (IR: 43.8-56.6) ($p < 0.05$). All of these changes were inducted at about 60.0 mL/min/1.73m2 of eGFR in the biphasic linear shape regression line fitted eGFR and FEP, FGF23 or 1,25(OH)2D levels. However, the amounts of urine excretion of phosphorus and serum PTH level did not change significantly (1.0g/day (IR:0.8-1.3) to 0.9g/day (IR:0.8-1.3) and 41pg/mL (IR: 33-53) to 47pg/mL (IR:34-61), respectively).

Conclusions: The compensatory mechanism for the phosphate homeostasis is induced at CKD stage 3 and the major contributing factor is FGF23 but not PTH.

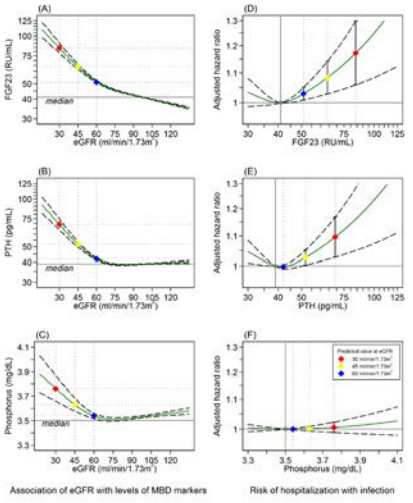
TH-PO559

Mineral and Bone Disease Markers and Risk for Hospitalization with Infection: Atherosclerosis Risk in Communities (ARIC) Study Junichi Ishigami,[1] Bernard G. Jaar,[1] Morgan Grams,[1] Csaba P. Kovesdy,[2] Josef Coresh,[1] Pamela L. Lutsey,[3] Kunihiro Matsushita.[1] *[1]Johns Hopkins Univ; [2]Univ of Tennessee; [3]Univ of Minnesota.*

Background: Elevated levels of mineral and bone disease (MBD) markers interfere with innate and adaptive immunity and thus may explain increased risk of infection in CKD patients.

Methods: Using 12,724 participants from the ARIC study (baseline during 1990-1992 and follow-up through 2013), we first assessed the cross-sectional association of serum fibroblast growth factor 23 (FGF23), parathyroid hormone (PTH), and phosphorus with eGFR; and then evaluated their longitudinal contributions to the risk for hospitalization with infection with restricted cubic spline terms.

Results: The mean age was 56.8 years, with 56% women and 25% black. At baseline, all the MBD markers were higher when eGFR was <60 ml/min/1.73m^2, and the slope for FGF23 was significantly positive across levels of eGFR (**Figure A-C**). During a median follow-up of 19.2 years, there were 5,753 hospitalizations with infection (IR, 28.2 per 1,000 person-years). Higher FGF23 and higher PTH, but not phosphorus, were associated with risk for hospitalization with infection in Cox analysis adjusting for potential confounders including eGFR (**Figure D-F**). Of note, while PTH started to be significantly associated with infection risk at around values corresponding to eGFR 45 ml/min/1.73m^2 (i.e., predicted value of PTH at eGFR 45 ml/min/1.73m^2) (yellow diamond in **Figure E**), FGF23 showed significant association even at a value corresponding to eGFR 60 ml/min/1.73m^2 (blue diamond in **Figure D**).



Conclusions: Higher levels of MBD markers were associated with low eGFR, and higher levels of FGF23 and PTH were associated with risk for hospitalization with infection beyond eGFR. FGF23 appeared to be a particularly important predictor of infection risk even at early stages of CKD.

TH-PO560

Fibroblast Growth Factor 23 and Risk of Incident Coronary Heart Disease Bhupesh Panwar,[1] Suzanne E. Judd,[1] Virginia J. Howard,[1] Virginia G. Wadley,[1] Nancy Jenny,[2] Monika M. Safford,[3] Orlando M. Gutierrez.[1] *[1]Univ of Alabama at Birmingham; [2]Univ of Vermont; [3]Weill Cornell Medicine.*

Background: Higher fibroblast growth factor 23 (FGF23) is associated with higher risk of heart failure and stroke. The associations of FGF23 with coronary heart disease (CHD) risk have been less consistent, perhaps due to the relatively few events in prior studies.

Methods: We examined the association of plasma FGF23 with incident CHD in the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study, a cohort of black and white adults ≥45 years of age. Using a case-cohort design, FGF23 was measured in 829 participants who developed incident CHD (cases) and in 812 participants randomly selected from the REGARDS cohort (comparison sub-cohort).

Results: In Cox regression models adjusted for demographic factors and established CHD risk factors FGF23 was associated with increased risk of CHD (Table 1). Sex modified the association of FGF23 with CHD (p-interaction 0.07) such that among men, higher FGF23 concentrations were associated with increased risk of incident CHD in the fully adjusted model, whereas no statistically significant association of FGF23 with risk of CHD was found among women. **Table 1.** HRs (95% CI) of incident CHD by quartiles of fibroblast growth factor 23 (FGF23) overall and stratified by sex.

	FGF23 Quartile 1 (< 53 RU/ml)	FGF23 Quartile 2 (53 - 70 RU/ml)	FGF23 Quartile 3 (70.5-100 RU/ml)	FGF23 Quartile 4 (> 100 RU/ml)
Overall				
Events	122	183	208	316
Model*	ref	1.69 (1.14,2.49)	1.47 (0.97,2.25)	2.29 (1.47,3.55)
Men				
Events	80	133	129	162
Model*	ref	2.11 (1.31,3.40)	1.75 (1.04,2.94)	2.87 (1.59,5.16)
Women				
Events	42	50	79	154
Model*	ref	0.96 (0.51,1.78)	0.95 (0.49,1.86)	1.41 (0.79,2.51)

* Fully adjusted model: adjusted for demographic, clinical, and laboratory variables including estimated glomerular filtration rate and natural log-transformed albumin to creatinine ratio.

Conclusions: The association of higher FGF23 with higher CHD risk differs by sex, with the magnitude and strength of this association being greater in men than women.

Fibroblast Growth Factor 23 Induced Left Ventricular Hypertrophy Is Reversible Alexander Grabner, Christopher Yanucil, Karla J. Schramm, Brian A. Czaya, Christian Faul. *Dept of Nephrology, Univ of Miami, Miami, FL.*

Background: Left ventricular hypertrophy (LVH) is a common feature of cardiovascular injury in chronic kidney disease (CKD). Serum levels of fibroblast growth factor (FGF) 23 continuously rise as patients progress to renal failure. We have previously shown that FGF23 can activate FGF receptor (FGFR) 4 and the PLCγ/calcineurin/NFAT pathway in cardiac myocytes and cause hypertrophy. Administration of a FGFR4 blocking antibody (anti-FGFR4) in the 5/6 nephrectomy model of CKD immediately after surgery protects rats from developing LVH. Furthermore, we could show that established LVH in rats 2 weeks after surgery is reversible and treatable with a pan-FGFR blocker. The aim of the current study is to investigate if FGF23 induced hypertrophy is reversible.

Methods: Isolated neonatal rat ventricular myocytes (NRVMs) were treated with FGF23 and anti-FGFR4. To study the reversibility of FGF23-mediated cardiac hypertrophy in vivo, we elevated serum FGF23 levels in wild type mice by administration of a high phosphate (2%) diet for 3 months, followed by 3 months of regular chow. Control animals remained on high phosphate diet, or were fed regular chow for 6 months.

Results: Cultured NRVM recovered within 24 hours from cellular hypertrophy upon removal of FGF23. In the presence of FGF23, co-treatment with anti-FGFR4 reversed established hypertrophy in NRVM. Serum levels of phosphate as well as FGF23 were elevated in mice on high phosphate diet when compared to control mice on normal chow. Animals on high phosphate developed LVH as evident by significantly increased LV wall thickness and myocyte cross sectional area. When wild type mice were switch from high phosphate to normal diet, the LVH phenotype resolved within 3 months and cardiac parameters were comparable to those of mice that constantly received regular chow.

Conclusions: These findings indicate that cardiac hypertrophy caused by FGF23 elevation is reversible when FGF23 levels are normalized. Hence, we propose that FGF23-induced LVH in CKD is treatable, and that the FGF23/FGFR4 signaling mechanism in the heart provides novel options for pharmacological interventions, including FGFR4 blockade.

Intravenous Calcium Loading Increases Fibroblast Growth Factor 23 in Normal and Uremic Rats Yasuto Shikida,[1] Masahide Mizobuchi,[1] Takashi Inoue,[1] Toma Hamada,[1] Hiroaki Ogata,[2] Fumihiko Koiwa,[3] Takanori Shibata.[1] *[1]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [2]Dept of Internal Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Kanagawa, Japan; [3]Div of Nephrology, Dept of Medicine, Showa Univ Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

Background: The mechanisms underlying the stimulation of FGF23 remain to be investigated. We studied the effect of intravenous calcium (Ca) loading on FGF23 levels in normal and 5/6 nephrectomized uremic rats.

Methods: Normal SD rats were fed a standard diet for 8 weeks and then divided into 2 groups: 1) with the standard diet (Normal-control), and 2) with intravenous calcium (20 µl/hr with 50% of $CaCl_2$ solution) infusion using a microinfusion pump (Normal-IV). Blood and urine were collected at day 1 and 7 and the kidneys were obtained at day 7 after the interventions. 5/6-nephrectomized uremic rats with the same protocol were also examined (Nx-control group and Nx-IV group).

Results: Serum creatinine and phosphorus levels were comparable throughout the period between Normal-control (Cre: 0.26±0.01 mg/dl, P: 6.1±0.2 mg/dl) and Normal-IV rats (Cre: 0.26±0.03 mg/dl, P: 6.0±0.2 mg/dl). Ionized Ca levels in blood and urinary Ca excretion at day 7 were significantly higher in Normal-IV (iCa: 1.6±0.02 mmol/l, urinary Ca: 11.0±3.5 mg/day) than those in Normal-control (iCa: 1.3±0.02 mmol/l, urinary Ca: 0.7±0.1 mg/day, $p<0.05$ respectively). FGF23 levels at day 7 in Normal-IV (1992±485 pg/ml) were significantly higher than those in Normal-control (431±22 pg/ml, $p<0.05$). Noteworthy finding was that urinary phosphate excretion at day 7 in Normal-IV (2.7±19.5 mg/day) was significantly suppressed compared with Normal-control (19.5±1.2 pg/ml) despite of FGF23 elevation. Renal Klotho mRNA expression in Normal-IV was prominently lower than that in Normal-control. These changes in the parameters were augmented in uremic rats.

Conclusions: These results suggest that intravenous Ca loading increases FGF23 in normal and uremic rats, however renal phosphate excretion was abolished suggesting that the bioactivity of FGF23 was inhibited. Decrease in renal Klotho expression might have some roles in this pathological process.

TH-PO563

Effects of Ferric Citrate Administration in a Murine Model of CKD Connor Francis, Samantha Neuburg, Lixin Qi, Xueyan Wang, Corey Dussold, Aline Martin, Myles S. Wolf, Valentin David. *Div of Nephrology and Hypertension, Dept of Medicine, and Center for Translational Metabolism and Health, Inst for Public Health and Medicine, Northwestern Univ-Feinberg School of Medicine, Chicago, IL.*

Background: Elevated levels of fibroblast growth factor 23 (FGF23) are strongly associated with cardiovascular disease, mortality and progression of chronic kidney disease (CKD). Hyperphosphatemia and iron deficiency are powerful stimuli of FGF23 production. This suggests that reducing dietary phosphate intake or absorption and increasing serum iron may lower FGF23 levels and improve clinical outcomes in CKD.

Methods: We investigated the effects of ferric citrate, which simultaneously corrects iron deficiency while also binding phosphate. We fed 4 week-old wild-type (WT) mice and Col4a3^{ko} mice (CKD), a mouse model of progressive CKD, a control diet or 5% ferric citrate-enriched diet (FC) for 6 weeks.

Results: At 10 weeks, CKD mice fed the control diet displayed a decline in renal function as shown by a 7-fold increase in BUN and a 9-fold increase in urinary albumin compared to WT in association with a marked increase in serum levels of FGF23 compared to WT (both total FGF23 [tFGF23], which detects intact and C-terminal: 11426 ± 2623 vs. 433 ± 32 pg/mL; and intact FGF23 [iFGF23]: 7312 ± 1749 vs. 207 ± 57 pg/mL; $p<0.05$ for each). Six weeks of FC significantly increased serum iron levels in both WT and CKD mice by 1.5-fold compared to mice of the same genotype fed the control diet. No other changes were observed in WT mice in response to FC. In CKD mice, 6 weeks of FC reduced serum phosphate and dramatically reduced tFGF23 by 6-fold and iFGF23 by 3-fold ($p<0.05$ for each vs. control diet). In addition, FC decreased BUN (33±8 vs. 158±24 mg/dL, $p<0.05$ vs. control diet) and 24h urine albumin (101±69 vs. 586±91 µg, $p<0.05$ vs. control diet).

Conclusions: FC administration to CKD mice reduced the magnitude of FGF23 elevation and slowed CKD progression. Further studies are needed to test whether FC might mitigate cardiac injury and improve clinical outcomes in CKD.

TH-PO564

Characteristics of Responders and Non-Responders to Phosphate Binder Therapy: A Post Hoc Analysis of a Phase 3 Study Jürgen Floege,[1] Stuart M. Sprague,[2] Anjay Rastogi,[3] Markus Ketteler,[4] Adrian Covic,[5] Sebastian Walpen,[6] Viatcheslav Rakov,[6] Sylvain Larroque,[6] Pablo E. Pergola.[7] *[1]RWTH Univ Hospital Aachen, Germany; [2]NorthShore Univ Health System, Chicago; [3]Univ of California; [4]Coburg Clinic and KfH-Dialysis Center, Germany; [5]'Gr. T. Popa' Univ of Medicine and Pharmacy, Romania; [6]Vifor Pharma, Switzerland; [7]Renal Associates PA, San Antonio, TX.*

Background: *Post hoc* analysis of a 52-wk Phase 3 study to evaluate predictors of treatment response to the iron-based phosphate binder sucroferric oxyhydroxide (SFOH) or sevelamer carbonate (SEV) in dialysis patients.

Methods: Overall, 1059 patients were randomized to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 wks' dose titration then 12 wks' maintenance. Eligible patients enrolled in a 28-wk extension study. Out of 497 patients who completed the 52-wk study, 302 responded to either SFOH or SEV (i.e. achieved serum phosphorus levels of ≤5.5 mg/dL at wk 52) and 195 patients did not respond. Differences in baseline characteristics and serum levels of CKD-MBD indices between these 2 subgroups were analyzed.

Results: Comparison of baseline characteristics showed that responders were older than non-responders ($p=0.005$). Baseline serum phosphorus levels were significantly lower in responders vs non-responders ($p<0.001$) (Table). Reductions in serum phosphorus levels during the study were greater in responders vs non-responders ($p<0.001$). Serum iPTH levels decreased in responders but increased in non-responders during the 52-wk study ($p<0.001$). FGF-23 decreased to a greater extent among responders vs non-responders after 24 and 52 wks ($p\leq0.017$).

Table: Baseline values and mean changes in serum phosphorus, iPTH and FGF23 in responders and non-responders

Parameter, Mean (SD)	Time point	Responders to SFOH or SEV (N=302)	Non-responders to SFOH or SEV (N=195)	P-value responder vs non-responder
Serum phosphorus, mg/dL	BL	7.30 (1.48)	7.85 (2.01)	<0.001
	ΔWeek 24	–2.44 (1.70)	–2.13 (2.28)	<0.001
	ΔWeek 52	–2.89 (1.62)	–0.99 (2.23)	<0.001
iPTH, pg/mL	BL	423.3 (282.5)	419.2 (287.1)	0.874
	ΔWeek 24	–51.0 (246.9)	–32.6 (237.1)	0.435
	ΔWeek 52	–28.6 (299.2)	102.7 (356.7)	<0.001
FGF23 (SD), µg/l	BL	98.4 (201.3)	110.4 (204.2)	0.532
	ΔWeek 24	–41.5 (187.9)	–20.0 (199.6)	0.017
	ΔWeek 52	–76.3 (185.2)	–51.5 (273.5)	0.011

Mean (standard deviation) serum levels. BL, baseline; iPTH, intact parathyroid hormone; FGF23, fibroblast growth factor receptor-23; SD, standard deviation; SEV, sevelamer carbonate; SFOH, sucroferric oxyhydroxide

Conclusions: Age and baseline serum phosphorus levels appeared to be predictive of treatment responses to SFOH or SEV. Greater reductions in serum phosphorus were associated with more pronounced decreases in serum iPTH and FGF-23, although the impact of concomitant medications should also be considered.

TH-PO565

Effect of Non-Calcium Phosphate Binders on CKD-MBD Indices in Dialysis Patients: A Post Hoc Analysis of a Phase 3 Study Markus Ketteler,[1] Stuart M. Sprague,[2] Adrian Covic,[3] Anjay Rastogi,[4] Bruce S. Spinowitz,[5] Sylvain Larroque,[6] Viatcheslav Rakov,[6] Sebastian Walpen,[6] Jürgen Floege.[7] *[1]Coburg Clinic and KfH-Dialysis Center, Germany; [2]NorthShore Univ Health System, Chicago; [3]'Gr. T. Popa' Univ of Medicine and Pharmacy, Romania; [4]Univ of California; [5]New York Hospital Queens; [6]Vifor Pharma, Switzerland; [7]RWTH Univ Hospital Aachen, Germany.*

Background: *Post hoc* analysis of a 52-wk Phase 3 study evaluated the impact of serum phosphorus control on CKD-MBD indices among dialysis patients treated with the iron-based phosphate binder sucroferric oxyhydroxide (SFOH) or sevelamer carbonate (SEV).

Methods: 1059 patients were randomized 2:1 to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 wks' dose titration plus 12 wks' maintenance. Eligible patients enrolled in a 28-wk extension. Since SFOH and SEV had a comparable phosphorus-lowering effect during the 52-wk study and a similar impact on CKD-MBD indices, treatment groups were pooled for this analysis.

Results: Table displays changes in CKD-MBD indices. Serum phosphorus control was maintained throughout the study. Significant decreases in serum FGF-23 were observed over 52 wks. Serum iPTH decreased after 24 wks, but returned to near baseline levels by wk 52. Only minimal changes in serum calcium were observed over 1 year. Of the bone resorption markers, TRAP5b decreased significantly over 1 year, whereas CTX levels initially increased, returning to baseline levels by wk 52. Serum levels of the bone formation markers BSAP and OST increased during the study.

Table: Mean (SD) change from baseline in levels of serum markers of CKD-MBD (Completers; N=549).

Marker	Baseline	Δ Week 24	Δ Week 52 endpoint§
Phosphorus (mg/dL)	7.5 (1.7)	–2.3 (1.9)*	–2.1 (2.1)*
FGF-23 (µg/L)	100.7 (198.6)	–29.7 (188.9)*	–65.6 (219.6)*
iPTH (pg/mL)	420.3 (280.4)	–43.6 (242.3)*	23.1 (330.4)
Ca^{2+} (mg/dL)	8.8 (0.7)	0.1 (0.7)*	0.2 (0.8)*
TRAP5b (U/L)†	5.0 (2.4)	–1.1 (2.6)*	–1.1 (2.9)*
CTX (ng/mL)†	3.1 (2.3)	3.1 (4.1)*	–0.2 (2.7)
BSAP (ng/mL)‡	15.5 (12.7)	3.7 (12.8)*	1.0 (13.6)
OST (ng/mL)‡	14.3 (16.0)	1.8 (17.0)*	10.3 (25.4)*

*Significant change from baseline ($p<0.05$); †markers of bone resorption; ‡markers of bone formation; §with last observation carried forward.

BSAP, bone-specific alkaline phosphatase; Ca^{2+}, calcium; CKD-MBD, chronic kidney disease-mineral bone disorder; CTX, carboxy-terminal collagen crosslinks; FGF-23, fibroblast growth factor 23; iPTH, intact parathyroid hormone; OST, osteocalcin; SD, standard deviation; TRAP5b, tartrate-resistant acid phosphatase 5b

Conclusions: One year of treatment with SFOH or SEV was associated with significant reductions in serum FGF-23; this may be of clinical benefit in CKD patients. The observed trend toward increased levels of bone formation markers indicates a beneficial effect of phosphate-binder therapy for the activation of bone metabolism; however, the potential impact of concomitant medications needs further evaluation.

TH-PO566

Phosphocalcic Markers and Calcification Propensity for Assessment of Interstitial Fibrosis and Vascular Lesions in Kidney Allograft Recipients

Lena Berchtold,[1] Belen Ponte,[1] Karine Hadaya,[1] Matthias Bachtler,[2] Pierre-Yves F. Martin,[1] Andreas Pasch,[2] Sophie M. De Seigneux.[1] *[1]Nephrology, Univ Hospital of Geneva, Geneva, Switzerland; [2]Cinical Research, Univ Hospital of Bern, Bern, Switzerland.*

Background: Renal interstitial fibrosis (IF) and arterial lesions predict loss of function in CKD. Currently, IF and arterial lesions are evaluated invasively through routine kidney biopsies but with many limitations. Noninvasive estimation of IF and vascular lesions are currently not available.

Methods: In this retrospective study, we analyzed the associations and predictive values of phosphocalcic markers and T_{50} with chronic histological changes in 129 Kidney allograft recipients. We hypothesized that phosphate, calcium, vitamin D (25D), PTH, T_{50}, Klotho and FGF23 level may be useful markers of IF and chronic vascular lesion.

Results: PTH, T_{50} and 25D levels were independently associated to IF. PTH elevation was associated with increasing IF severity (r=0.29, p=0.001) while T_{50} (r=-0.20, p=0.025) and 25D (r=-0.23, p=0.009) were protective. On the contrary, FGF23 (r=0.18, p=0.045) and Klotho (r=-0.18, p=0.045) correlated only modestly with IF whereas calcium and phosphate were not associated with IF. PTH, 25D and T_{50} were predictors of extensive fibrosis (>40%)(Figure 1B), whereas PTH and FGF23 were modestly predictive of low fibrosis (<20%)(Figure 1A). T_{50} was the only marker associated with chronic vascular lesions assessed by the Banff score. T_{50} decreased with increasing arterial lesions (r=-0.21, p=0.038). The discriminative performance of T_{50} in predicting significant vascular lesions was modest (Figure 1C).

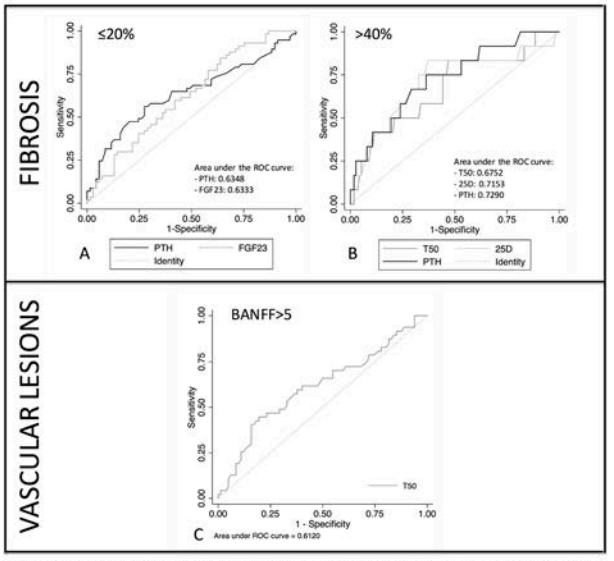

Figure 1: A: ROC curves of PTH and FGF23 in predicting fibrosis ≤20%; **B**: ROC curves of T50, 25D and PTH in predicting fibrosis >40%; **C**: Vascular lesions estimated by BANFF: ROC curve of T_{50} in predicting significant vascular lesions (BANFF cv+ah+aah >5).

As 25D and T_{50} are markers that are negatively associated with fibrosis we used the opposite values of those markers. FGF23 and PTH values were logarithmically transformed on a natural logarithm due to abnormal distribution. 25D: 25-hydroxyvitamin D; FGF23: Fibroblast growth factor 23; PTH: parathyroid hormone; ROC: Receiver Operating Characteristic; T_{50}: Calcification propensity.

Conclusions: In summary, we demonstrate that PTH, 25D and T_{50} may be useful in the noninvasive assessment of IF and vascular lesions in kidney allograft recipients. FGF23 and Klotho are in contrast of lower value in this context.

Funding: Government Support - Non-U.S.

Mineral Metabolites and Ambulatory Blood Pressure: Results from the African American Study of Kidney Disease and Hypertension (AASK)

Robert E. Olivo,[1] Tamara Isakova,[2] Brad C. Astor,[3] Huiman Barnhart,[1] Lawrence J. Appel,[4] Paul E. Drawz,[5] Myles S. Wolf,[2] Julia J. Scialla.[1] *[1]Duke Univ; [2]Northwestern Univ; [3]Univ of Wisconsin Madison; [4]Johns Hopkins Univ; [5]Univ of Minnesota.*

Background: Higher serum phosphorus (P_i) and P_i regulatory hormones [fibroblast growth factor 23 (FGF-23), parathyroid hormone (PTH)] associate with higher risk of cardiovascular disease (CVD) including left ventricular hypertrophy, stroke, and heart failure. While these outcomes are highly BP dependent, it is unknown if P_i, FGF-23, and PTH associate with adverse 24h ambulatory BP (ABP) profiles as a possible mechanism.

Methods: P_i, intact FGF-23, PTH, and ABP were measured at baseline in African Americans with CKD in the AASK Cohort Study. Participants were treated to contemporary BP goals with preference for an ACE inhibitor or ARB. We modeled the association of each mineral metabolite (MM) with mean 24h systolic BP (SBP) and diastolic BP (DBP), and with blunted nocturnal dipping (<10% drop in both SBP and DBP).

Results: In 396 participants with complete data, mean eGFR was 42.6 ± 19.4 mL/min/1.73m^2, mean P_i was 3.59 ± 0.77 mg/dL, median FGF-23 was 45.4 pg/mL (IQR 32.3-75.3 pg/mL), and median PTH was 41.9 pg/mL (IQR 27.5-67.5 pg/mL). Mean SBP and DBP were 136.5 ± 17.0 and 80.5 ± 10.5 mmHg respectively, and 79% had blunted nocturnal dipping. We saw no consistent association between any MM and mean SBP or DBP (p>0.05 for all). In unadjusted models, higher P_i associated with lower risk of blunted nocturnal dipping, but we saw no linear trend on full adjustment (p=0.08). CKD severity did not modify any relationships between MMs and ABP (p-interaction>0.05 for all).

Association Between Mineral Metabolites and 24h Ambulatory BP Patterns.

	Difference in Mean SBP (95% CI)		Difference in Mean DBP (95% CI)		Blunted Nocturnal Dipping OR (95% CI)	
	Unadjusted	Adjusted[1]	Unadjusted	Adjusted[1]	Unadjusted	Adjusted[1]
Per 1 mg/dL increase in P_i	-1.17 (-3.35, +1.01)	-1.93 (-4.34, +0.48)	-0.45 (-1.80, +0.90)	-0.22 (-1.73, +1.28)	0.71 (0.52, 0.96)	0.72 (0.49, 1.05)
Per FGF-23 doubling[2]	+0.78 (-0.53, +2.10)	+0.09 (-1.43, +1.62)	+0.48 (-0.33, +1.29)	+0.21 (-0.74, +1.16)	0.92 (0.76, 1.11)	0.83 (0.64, 1.05)
Per PTH doubling[2]	+0.68 (-0.83, +2.19)	-0.41 (-2.18, +1.36)	+0.48 (-0.45, +1.41)	+0.50 (-0.60, +1.60)	0.87 (0.70, 1.08)	0.77 (0.58, 1.03)

[1] Adjusted for age, gender, income, smoking, alcohol, eGFR, albuminuria, number of anti-hypertensive medications, and 24h urine sodium and urea nitrogen.
[2] Determined by use of FGF-23 and PTH values transformed to log base 2 values.

Conclusions: With CKD and well-treated BP, higher MM levels do not associate with adverse ABP profiles in African Americans. Whether previously documented MM associations with CVD are independent of ABP or mitigated by aggressive BP control remains to be determined.

TH-PO568

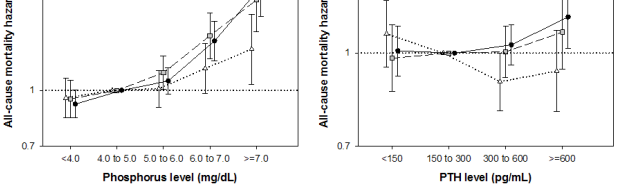
Impact of Residual Kidney Function on the Association between Parameters of Mineral Bone Disorder and Mortality in Hemodialysis Patients

Mengjing Wang,[1] Jing Chen,[2] Yoshitsugu Obi,[1] Elani Streja,[1] Csaba P. Kovesdy,[3] Rajnish Mehrotra,[4] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Fudan Univ, Shanghai, China; [3]Univ of Tenn.; [4]Univ of Wash.*

Background: The relationship between mineral and bone disorders (MBD) and survival has not yet been studied in hemodialysis patients according to their residual kidney function (RKF). We hypothesized that RKF modifies the association between MBD parameters and mortality.

Methods: The associations of serum phosphorus, uncorrected and albumin-corrected calcium, intact parathyroid hormone (PTH) and alkaline phosphatase (ALP) with all-cause mortality were examined across three strata of baseline residual renal urea clearance (CLurea) using Cox models with adjustment for clinical characteristics and laboratory measurements in 35,114 incident hemodialysis patients treated in a large dialysis organization in the U.S. between 2007 and 2011.

Results: There was an incremental mortality risk across higher serum phosphorus concentrations, which was pronounced among patients with higher CLurea (Pinteraction=0.001). Lower intact PTH were associated with higher mortality among patients with low CLurea (i.e., <1.5 mL/min/1.73m^2; Ptrend=0.02) while higher concentrations showed a trend toward higher mortality risk among patients with high CLurea (i.e., ≥3.0 mL/min/1.73m^2; Ptrend=0.09)(Pinteraction=0.002). CLurea did not modify the associations of uncorrected total calcium, corrected total calcium, and ALP with all-cause death (Pinteraction=0.8, 0.4, 0.14 respectively); higher concentrations of these markers were linearly associated with higher mortality risk across all CLurea strata.



Conclusions: RKF modified the association of serum phosphorus and intact PTH with mortality. RKF levels should be accounted for in better risk assessment of serum phosphorus and intact PTH. Additional studies are needed to better understand the mechanism behind these associations.

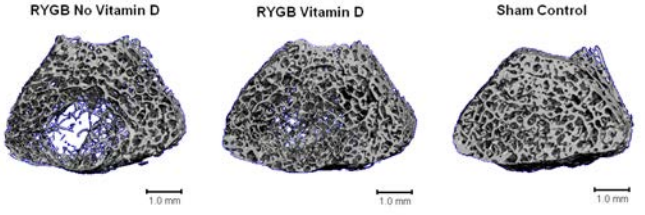
TH-PO569

Vitamin D Supplementation Does Not Improve Gastric Bypass-Related Bone Resorption Benjamin Canales,[1] Shahab Bozorgmehri,[1] Anne Schafer,[2] Thomas Carpenter.[3] *[1]Urology, Univ of Florida, Gainesville, FL; [2]Medicine, San Francisco Veterans Affairs Medical Center, San Francisco, CA; [3]Medicine, Yale Univ, New Haven, CT.*

Background: Roux-en-Y gastric bypass (RYGB)-associated bone resorption is believed to be driven by vitamin D deficiency (VDD) and secondary hyperparathyroidism. However, in humans, bone turnover markers (BTM) remain elevated despite adequate vitamin D supplementation (VDS) and PTH correction. We sought to determine additional drivers of bone resorption in a diet-induced obese (DIO) RYGB model.

Methods: Forty DIO female rats were randomized to sham or RYGB surgery. Post-operatively they were placed on 10% fat/1% calcium diet and assigned to RYGB VDD (n=10), RYGB VDS (n=10), sham pair-fed (n=10) or ad lib (n=10) groups. Calciotropic hormones, serum gut hormones, sex hormones, BTM, and urinary calcium/creatinine (UCC) were measured baseline and q4 weeks until week 12 euthanasia. Femurs were analyzed using micro-computed tomography (uCT) and 3 point bending test (BT).

Results: Compared to controls, RYGB animals had lower body weight, UCC, insulin, C-peptide, leptin, and progesterone levels along with higher GLP-1 and PYY hormones. RYGB VDS rats had higher 25-hydroxyvitamin D and lower parathyroid hormone levels than their VDD counterparts, reflecting vitamin D repletion. Despite VDS, both RYGB groups had elevated 1,25-dihydroxyvitamin, coupled increases in BTMs, more brittle bone by BT, and uCT skeletal findings of reduced trabecular bone volume and thickness (figure 1) and reduced cortical volume and thickness versus controls.



Conclusions: In our DIO model, RYGB-related bone resorption and calcium gut absorption occur independent of vitamin D status. Gut and sex hormones, particularly PYY and progesterone, may play a role in bone mass differences. Further mechanistic research to explore these differences may identify targets for RYGB bone loss prevention.

MEMO1 Deletion in Mice Causes a Mineral Disorder Resembling Hypophosphatasia Matthias B. Moor,[1] Suresh Krishna Ramakrishnan,[1] Barbara Haenzi,[2] Willy Hofstetter,[3] Olivier Bonny.[1,4] *[1]Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [2]Cambridge Centre for Brain Repair, Dept of Clinical Neuroscience, Univ of Cambridge, Cambridge, England, United Kingdom; [3]Dept of Clinical Research, Univ of Bern, Bern, Switzerland; [4]Service of Nephrology, Lausanne Univ Hospital, Lausanne, Switzerland.*

Background: Hypophosphatasia is a bone mineralization disorder generally caused by mutations in the gene coding for tissue-nonspecific alkaline phosphatase (ALPL). Mediator of ErbB2-driven Cell Motility 1 (Memo) is a redox protein and an intracellular signaling modulator of growth factors. We previously showed that renal FGF23-induced signaling requires Memo. Now, we report that Memo deficiency in mice causes a disease resembling hypophosphatasia.

Methods: Exon 2 of the *MEMO1* gene was deleted in Memo fl/fl mice using a tamoxifen-inducible Cre recombinase to obtain conditional knockout (cKO) mice. Littermates without Cre served as controls. Bones were studied by micro-computed tomography and histomorphometry. Serum, tissue and urinary chemistry were analyzed. Primary bone cell cultures were isolated and cultured for functional and metabolic studies.

Results: Memo cKO mice developed empty distal femoral metaphysis with severely disturbed trabecular structure and mineral apposition. The mice displayed higher serum calcium levels, hypercalciuria, and increased urinary inorganic pyrophosphate excretion. Serum and bone tissue ALP activities were decreased in cKO, and intracellular redox state in Memo null bone tissue was altered. Native PAGE and thiol conjugation studies revealed no differences in bone ALP protein between genotypes, but bone tissue from Memo cKO animals revealed a diminished ALP stability. Primary cultured osteoclasts and osteoblasts from Memo control and cKO animals were of comparable cellular function, but Memo null osteoblasts revealed an altered metabolic profile.

Conclusions: Memo deletion leads to a mineral disorder that may constitute a novel secondary form of hypophosphatasia associated with distinct metabolic changes in the bone.

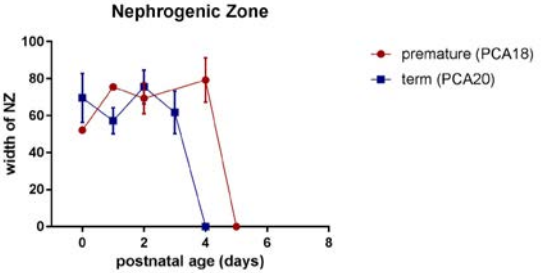
Early Cessation of Nephrogenesis in Mouse Model of Prematurity Jennifer R. Charlton, Valeria M. Pearl, Hiwot M. Abate, Jennifer M. Laws, Maria Luisa S. Sequeira Lopez. *Univ of Virginia.*

Background: Premature neonates are at risk of developing chronic kidney disease (CKD). Human nephrogenesis is completed by 36 weeks gestation, whereas in rodents nephrogenesis continues until a postnatal age (PNA) of 4 days. Completion of nephrogenesis is dependent on self-renewing cells in the nephrogenic zone (NZ), but their fate following premature birth is unknown. Using a mouse model of prematurity which develops CKD as an adult, we hypothesize that NZ depletion is determined by PNA not postconceptional age.

Methods: CD-1 dams underwent C-section at post-conception age (PCA) 18 days. The term group delivered at PCA20. All pups were fostered. Pups were euthanized in the first week of life or as adults. In the pups, NZ was measured on midsagittal kidney sections, apoptosis by TUNEL+ cells and proximal tubular (PT) fraction by lotus lectin. In the adults, glomerular area and PT fraction were measured.

Results: Both body (BW) and kidney weights (KW) were smaller in the premature group as compared in the term group on PNA 2 and 4 days (n=5/grp). The NZ of the premature mouse kidney persisted at PNA 4, but was depleted by PNA 5, truncating nephrogenesis by one day in prematurely born mice.



There was no difference in the PT fraction or apoptosis on the day prior to the end of nephrogenesis between the premature and term pup groups. The premature adult female kidneys weighed more than term female kidneys (diff: 43.3 mg, 95%CI (10.1 to 76.6), p=0.02) with a higher PT fraction in the adult premature group (diff: 6%, p=0.02). There was no difference in BW, glomerular area or serum creatinine between the premature and term adult groups (n=3/grp).

Conclusions: Prematurely born mice have a shorter duration of nephrogenesis which was associated with heavier kidneys and a larger PT contribution in the adults. This model of prematurity may provide insights into the connections between human prematurity and CKD.

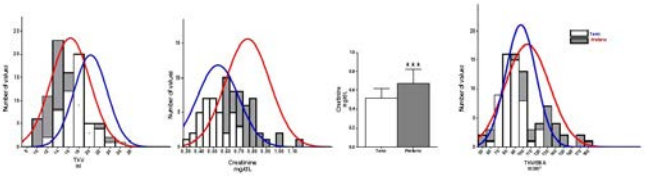
Assessment of Total Kidney Volume at Birth as a Surrogate of Nephron Mass Marissa J. Defreitas,[1] Wacharee Seeherunvong,[1] Chryso P. Katsoufis,[1] Teresa C. Cano,[1] Marta G. Galarza,[2] Salih Y. Yasin,[3] Gaston E. Zilleruelo,[1] Carolyn L. Abitbol.[1] *[1]Pediatric Nephrology, Univ of Miami/Holtz Children's Hospital, Miami, FL; [2]Neonatology, Univ of Miami/Holtz Children's Hospital, Miami, FL; [3]OB/GYN, Univ of Miami/Holtz Children's Hospital, Miami, FL.*

Background: An individual's "nephron endowment" has implications for lifelong renal health and is determined by the intrauterine environment and gestational age (GA). Hence, preterm birth or low birth weight may predispose to kidney disease in later life. Our objective was to determine if neonatal total kidney volume (TKV) indexed to body surface area (BSA) would reveal an advantage of nephron mass across GA groups and to provide baseline normative data to be followed prospectively relative to kidney function.

Methods: A cross-sectional cohort of 140 healthy newborns, 84 preterm (PT; ≤37 weeks GA) and 56 term (T; >37 weeks GA), was enrolled at birth for evaluation of kidney size and function. Infants with congenital anomalies, acute kidney injury by KDIGO modified criteria, ≤24 weeks GA, and ≤500 g were excluded. TKV was determined by renal ultrasound and reported in milliliters (ml) indexed to body size parameters. Kidney function was assessed by serum creatinine (Scr) and Cystatin C (CysC).

Results: TKV correlates closely with kidney function in the neonate. TKV/BSA (ml/m^2) is independent of GA. Average Scr ± SD for the entire cohort was 0.6±0.2, while T-Scr was 0.5±0.1 compared to PT-Scr of 0.7±0.2 mg/dl (p<0.001). Similarly, CysC distinguished T from PT infants (1.3±0.2 vs 1.5±0.2 mg/L; p<0.001).



Conclusions: TKV/BSA offers an assessment of nephron mass that is independent of gestational age providing a simple and non-invasive measure of renal adaptation potentially across a lifespan.

The Endocytic Role of OCRL and INPP5b in Mouse Proximal Tubulopathy

Kazunori Inoue,[1] Xuefei Tian,[1] Tong Wang,[2] Shuta Ishibe.[1] *[1]Internal Medicine, Yale Univ School of Medicine, New Haven, CT; [2]Cellular and Molecular Physiology, Yale Univ School of Medicine.*

Background: Human mutations in inositol polyphosphate 5-phosphatase, *Ocrl* (Occulocerebrorenal Syndrome of Lowe) has been demonstrated to cause proximal tubulopathy in Lowe Syndrome (LS) patients. In-vitro cell culture work suggests the role of Ocrl in the uncoating of clathrin coated pits and actin regulation. Yet, the in-vivo mechanisms on how the loss of function of OCRL results in Fanconi's Syndrome remains unclear.

Methods: Genetic ablation of *Ocrl* doesn't recapitulate the human phenotype in mice models suggesting that an OCRL paralog, *Inpp5b* may compensate for the lack of OCRL. Therefore doxycycline (Dox) induced renal tubule specific *Inpp5b* knockout mice on an underlying *Ocrl* KO background (*Ocrl*$^{-/-}$, *Pax8*^{rtTa}, *TetO-Cre Inpp5b*$^{fl/fl}$ (DKO)) were generated. To assess endocytosis in-vivo, fluorescently tagged lactoglobulin, dextran, or horseradish peroxidase (HRP) was injected in control, *Ocrl* KO, and DKO mice.

Results: DKO mice exhibited robust low molecular weight proteinuria, phosphaturia (control:6.70 (Urine phosphate/urine creatinine ratio)) vs DKO:16.30, 3 months after Dox induction), glucosuria, and acidemia which mimics what has been observed in LS patients. DKO mice displayed massive reduction in endocytic uptake of lactoglobulin, dextran, and HRP in the proximal tubules. To further elucidate how marked inhibition of endocytosis would impact NaPi2a function, we examined NaPi2a trafficking in-vivo. DKO mice showed a marked delay in NaPi2a internalization after PTH injection. DKO mice also displayed elevated plasma and urine PTH. Lastly, after 8 months following Dox induction, the mutant mice develop kidney failure and fibrosis.

Conclusions: We have generated a genetic mouse model of LS developing a proximal tubulopathy and have revealed that loss of Ocrl and Inpp5b function in-vivo results in significant defects in clathrin mediated endocytosis suggesting that this fundamental process likely contributes to the kidney manifestations observed in LS.

TH-PO574

AT2R Deficiency Induces Podocyte Apoptosis and Epithelial Mesenchymal Transformation via Ectopic Hedgehog Interacting Protein Gene Expression

Min-Chun Liao,[1] Xin-Ping Zhao,[1] Shiao-Ying Chang,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] John S.D. Chan,[1] Shao-Ling Zhang.[1] *[1]CRCHUM, Univ of Montreal, Montreal, QC, Canada; [2]Pediatr Nephrol Unit, Mass. Gen. Hosp., Boston, MA.*

Background: Angiotensin type 2 receptor (AT_2R) deficient mice (AT_2RKO) exhibit a spectrum of congenital abnormalities of the kidney and urinary tract (CAKUT); however, the mechanisms by which these abnormalities occur are poorly understood. We aimed to study whether AT_2R deficiency impairs glomerulogenesis via podocyte apoptosis and/or epithelial mesenchymal transformation (EMT) and also to elucidate the underlying mechanisms *in vivo* and *in vitro*.

Methods: Embryonic kidneys of nephrin-cyan fluorescent protein (CFP)-transgenic (Tg) (Nephrin-CFP-Tg) and Nephrin/AT_2RKO mice were used to assess glomerulogenesis; kidneys from neonate to 3 weeks old of suckling pups --both wild-type (WT) and AT_2RKO mice were used to evaluate mature podocyte morphology/function. Immortalized mouse podocytes (mPODs) were employed for *in vitro* studies.

Results: AT_2R deficiency resulted in diminished glomerulogenesis in E15 embryos, but had no impact on actual nephron numbers in neonates. Pups lacking AT_2R displayed features of renal dysplasia—e.g., lower glomerular tuft volume and podocyte number, and retarded podocyte maturation, as revealed by podocyte markers (Wilms tumor-1 (WT-1), p57, nephrin and synaptopodin). *In vivo* and *in vitro* studies, demonstrated that loss of AT_2R was associated with significantly elevated oxidative stress and increased ectopic hedgehog interacting protein (*Hhip*) gene expression in podocytes, which in turn, led to podocyte apoptosis. Concomitantly, the increased Hhip expression enabled interaction with TGFβ1 RI/II, targeting TGFβ1-Smad2/3 cascades to trigger epithelial-mesenchymal transition (EMT) in podocytes.

Conclusions: Loss of AT_2R is associated with podocyte apoptosis and EMT, and the underlying mechanism appears to be mediated, at least in part, via augmented ectopic Hhip expression.

TH-PO575

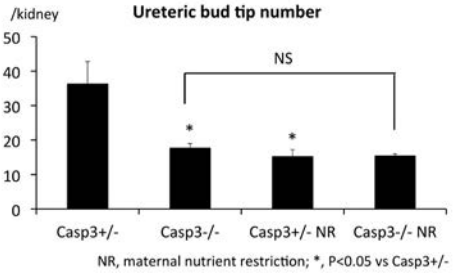
Caspase-3 Mediates Inhibition of Ureteric Branching and Nephrogenesis by Maternal Nutrient Restriction in Mice

Midori Awazu,[1] Yoshifumi Yamaguchi,[2] Masayuki Miura,[2] Mariko Hida.[1] *[1]Dept of Pediatrics, Keio Univ School of Medicine, Tokyo, Japan; [2]Dept of Genetics, Graduate School of Pharmaceutical Sciences, The Univ of Tokyo, Tokkyo, Japan.*

Background: We reported that maternal nutrient restriction (NR) inhibits ureteric branching, nephrogenesis, and caspase-3 (Casp3) activity in rats (Pediatr Res, 2015). Ureteric branching and nephron number are reduced in homozygous caspase-3-deficient mice (Casp3-/-) compared with heterozygous (Casp3+/-) and wild type mice (WT), probably due to Casp3's action to enhance migration of ureteric bud cells (ASN 2011, 2012). We now examined the role of Casp3 in reduced ureteric branching and nephrogenesis by NR in mice.

Methods: Pregnant C57BL/6J mice were subjected to 50% food restriction throughout pregnancy. Female Casp3 (+/-) or Casp3 (-/-) were mated with Casp3 (-/-) or Casp3 (+/-), respectively. Ureteric buds were visualized by pancytokeratin staining. Glomerular density was determined on HE sections. Glomerular number was counted by acid maceration.

Results: In WT, NR significantly reduced fetal body weight (156±4 vs 167±5 mg) and ureteric tip number (15.9±0.8 vs 36.9±2.4/kidney) at embryonic day 13 (E13). Glomerular number counted at 7 weeks was decreased in NR by 20% ($P<0.05$). At E13, body weight of Casp3-/- was not different vs Casp3+/- (131±10 vs 139±18 mg, n=5-6), but ureteric tip number was significantly reduced.



NR, maternal nutrient restriction; *, P<0.05 vs Casp3+/-

NR significantly decreased ureteric branching of Casp3+/- without affecting body weight (124±10 vs 139±18). In contrast, NR had no effect on body weight or ureteric tip number of Casp3-/-. Under NR conditions, there was no difference in glomerular density between Casp3+/- and Casp3-/- at E15 and E16.

Conclusions: NR reduces ureteric branching and nephrogenesis in WT and Casp3+/- mice. In contrast, NR had no effect in Casp3-/- suggesting that Casp3 mediates inhibition of ureteric branching and nephrogenesis by NR.

Aggravated Unilateral Ureteral Obstruction-Induced Renal Injury in Rat Offspring with Maternal Nutrient Restriction Is via Decreased Renal Nitric Oxide Production

Mariko Hida,[1] Tokiya Abe,[2] Akinori Hashiguchi,[2] Midori Awazu.[1] *[1]Dept of Pediatrics, Keio Univ School of Medicine, Tokyo, Japan; [2]Dept of Pathology, Keio Univ School of Medicine, Tokyo, Japan.*

Background: Maternal nutrient restriction (NR) not only reduces nephron number but may also affect tubules, interstitium, capillary density, and endothelial function. We reported that NR aggravates tubular necrosis and interstitial fibrosis after unilateral ureteral obstruction (UUO) without affecting peritubular capillary density (ASN 2015). Increased or decreased nitric oxide (NO) has been shown to alleviate or aggravate UUO-induced renal injury, respectively. We examined whether aggravated UUO-induced renal injury in NR is due to decreased renal NO production and if so investigated the mechanism.

Methods: Six-week-old offspring from rats given food ad libitum (CON, n=7) and those subjected to 50% food restriction throughout pregnancy (NR, n=11) were subjected to left UUO. Body weight, blood pressure (BP), blood urea nitrogen (BUN) were examined before and after UUO. Urine from the left kidney were collected at the time of sacrifice. Urine NO was measured by ELIZA. Kidneys were stained with HE and Masson trichrome for the quantification of collagen. Expression of eNOS was assessed by immunoblot.

Results: Before UUO, body weight was significantly lower (131±6 vs 163±8 g) and BP was significantly higher in NR than CON (104±3 vs 94±6 mmHg). After UUO, there was no difference in body weight between CON and NR (153±8 vs 177±15 g). Systolic BP increased significantly in NR (118±5) but not in CON (105±7 mmHg). BUN also did not change in CON (20.5±0.7 to 23.1±2.8) but increased significantly in NR (16.8±1.1 to 20.7±1.4 mg/dl) after UUO. Tubular necrosis was more extensive and the collagen area ratio of the obstructed kidney was significantly greater in NR compared with that in CON (5.4±2.3 vs 2.6±0.3%). Urine NO of the obstructed kidneys was significantly decreased in NR compared with that in CON (57±14 vs 586±238 nmol/mg Cr). eNOS expression of the obstructed kidney was increased vs contralateral kidneys in both CON and NR, but the extent was less in NR.

Conclusions: Decreased renal NO production in NR may explain more severe UUO-induced renal injury.

Uroplakins Play a Protective Role during Obstructive Nephropathy

Ashley R. Jackson,[1] Christina B. Ching,[1,2] Brian Becknell,[1,3] Kirk M. McHugh.[1,4] *[1]Center for Clinical and Translational Research, The Research Inst at Nationwide Children's Hospital; [2]Urology Div, Nationwide Children's Hospital; [3]Nephrology Section, Nationwide Children's Hospital; [4]Dept of Anatomy, Ohio State Univ.*

Background: Studies involving the *mgb*$^{-/-}$ mouse model of congenital obstructive nephropathy indicate an adaptive role for the renal urothelium during the development of progressive hydronephrosis. Specifically, uroplakin transcripts and protein expression were significantly increased, as well as the Krt14 progenitor cell marker. Recently, the tetraspanin uroplakin, *Upk1b*, has been implicated in urothelial plaque formation and stabilization of renal urothelium. We hypothesize that urothelial remodeling and increased urothelial plaque formation during congenital obstructive nephropathy is a protective measure against the development and progression of hydronephrosis.

Methods: To test our hypothesis, we destabilized the urothelial plaque through genetic ablation of *Upk1b* in *mgb*$^{-/-}$ mice and quantitated hydronephrosis using ultrasound. Biochemical and immunhistochemical techniques were used to characterize uroplakin, Krt14, Krt5, and Ki67 expression patterns in renal urothelium.

Results: Loss of *Upk1b* caused destabilization of the urothelial plaque in *mgb*$^{-/-}$ mice, increased proliferation, increased urothelial cell layers and expression of Krt14 and Krt5 basal urothelial cells. Electron microscopy and a FITC-dextran permeability assay identified defects in the urine permeability barrier in the absence of *Upk1b*. Compound homozygotes (*Mgb*$^{-/-}$;*Upk1b*$^{RFP/RFP}$) develop worse, bilateral hydronephrosis at an earlier age than either mouse strain alone (*Mgb*$^{-/-}$ - unilateral, moderate; *Upk1b*$^{RFP/RFP}$ - bilateral, moderate), and often die prematurely suggesting the loss of the urothelial plaque leads to earlier and faster disease progression.

Conclusions: To our knowledge, we provide the first evidence that remodeling of the renal urothelial plaque functions to protect the kidney in the context of congenital obstruction in a mouse model. The clinical significance of this finding remains to be fully evaluated in children with similar defects, such as ureteropelvic junction obstruction.

Funding: NIDDK Support

TH-PO578

Conditional Ablation of Urothelial Cells for Identification of Context Specific Roles during Renal Disease Ashley R. Jackson,[1] Christina B. Ching,[1,2] Birong Li,[1] Kirk M. McHugh,[1,4] Brian Becknell.[1,3] *[1]Center for Clinical and Translational Research, Nationwide Children's Hospital Research Inst; [2]Urology Div, Nationwide Children's Hospital; [3]Nephrology Section, Nationwide Children's Hospital; [4]Dept of Anatomy, Ohio State Univ.*

Background: Urothelium serves vitals roles in establishing a urine permeability barrier, in part through the elaboration of uroplakin (Upk) plaques. *Upk1b* deficiency leads to hydronephrosis, urothelial dysplasia, and altered infectious susceptibility. To better understand the role of Upk+ cells in renal disease, we adapted a technique to ablate Upk+ cells in an inducible manner. Here we provide the first report of genetic ablation of Upk2+ urothelial cells in the renal pelvis and urothelium.

Methods: The *Upk2-iCre* mouse was used to drive Cre/LoxP dependent expression of a tdTomato reporter (Ai14) or a floxed HBEGF (Diphtheria Toxin Receptor; DTR) in a tamoxifen (TM)-dependent manner. Five daily doses of 75 mg/kg body weight TM were IP injected into six week old *Upk2-iCre*$^{+}$*;Ai14*$^{+}$ and *Upk2-iCre*$^{-}$*;Ai14*$^{+}$ mice. Organs were harvested at 1 week. Adult *Upk2-iCre*$^{+}$*;ROSA*^{iDTR}and *Upk2-iCre*$^{-}$*;ROSA*^{iDTR} mice were Cre activated as above followed by a single IP dose of 0.25mg/kg or 0.5mg/kg body weight diphtheria toxin (DT). Mice were euthanized 24 hours after DT administration and cellular ablation was analyzed by routine histology and dual immunofluorescent labeling.

Results: Cre-recombinase specificity in Upk2(+) cells was confirmed in *Upk2-iCre*$^{+}$*;Ai14*$^{+}$ mice by anti-RFP detection. Multiple layers of bladder, ureter and renal pelvis urothelium were RFP+,whereas isolated RFP+ cells were identified in the renothelium. In *Upk2-iCre*$^{+}$*;ROSA*^{iDTR} but not *Upk2-iCre-;Rosa*^{iDTR}, Upk(+) cells were absent following DT treatment. While Krt14(+) and Krt5(+) basal urothelial cell populations remained in *Upk2-iCre*$^{+}$*;ROSA*^{iDTR}, bladder, ureter, renal pelvis and renothelium each revealed loss of Upk-expressing cells.

Conclusions: Temporally controlled, cell specific ablation of Upk+ cells can be achieved using the *Upk2-iCre* and *Rosa*^{iDTR} mice. This technique will be utilized to determine the impact of urothelial destabilization on renal injury in the settings of pyelonephritis and obstructive nephropathy.

Funding: NIDDK Support

TH-PO579

Morphologic Basis for Urothelial Remodeling during Obstructive Nephropathy Rachel Millner,[1] Ashley R. Jackson,[2] Kirk M. McHugh,[2,3] Christina B. Ching,[2,4] Brian Becknell.[1,2] *[1]Nephrology Section, Nationwide Children's Hospital; [2]Center for Clinical and Translational Research, Nationwide Children's Hospital; [3]Dept of Anatomy, Ohio State Univ; [4]Urology Div, Nationwide Children's Hospital.*

Background: Ureteropelvic junction obstruction (UPJO) is the most common cause of pediatric obstructive nephropathy. The urothelium establishes the urine permeability barrier and protects obstructed renal parenchyma. Here, we investigated the morphologic basis for pelvic urothelial remodeling during UPJO.

Methods: Resected tissues were obtained with informed consent from 15 patients undergoing pyeloplasty. Adult male FVB/N mice underwent unilateral ureteral obstruction or sham operation, followed by euthanasia at post-operative days 1, 3, 7, or 14. Sections from UPJ, proximal renal pelvis, and distal ureter were subject to histologic stains and immunofluorescence microscopy using urothelial markers (CK5, CK14, UPK3A) and proliferation antigens (Ki67, PCNA).

Results: In UPJO cases, urothelial thickening occurs in the proximal pelvis, with loss of structural integrity compared to distal ureter. Obstructed UPJ and renal pelvis exhibit absent or patchy UPK3A staining, whereas UPK3A is distributed uniformly at the apical surface of the urothelium in distal ureteral segments. CK5 and CK14, proteins typically expressed by basal progenitor cells, localize diffusely throughout the obstructed renal pelvis and UPJ, extending into the apical layer. Widespread urothelial expression of cell proliferation antigens Ki67 and PCNA occurs in CK5+ and CK14+ cells. In mice, UPJO leads to loss of mucosal integrity and expansion of CK5 and CK14 throughout the renal pelvis, with increased urothelial cell thickness and proliferative index.

Conclusions: This study provides a morphologic basis for urothelial remodeling during UPJO, characterized by exfoliation of UPK3A+ apical cells, disrupted urothelial barrier function, and proliferation of CK5+ and CK14+ progenitors. While urothelial remodeling may initially occur as a physiologic response to urine back-pressure, this may prove maladaptive and contribute directly to renal pathology in obstructive nephropathy. Further studies are warranted to test this hypothesis directly.

TH-PO580

Structural Variants Analysis in Patients with Posterior Urethral Valves Valentina Capone,[1] Miguel Verbitsky,[1] David Fasel,[1] Rik Westland,[2] Monica Bodria,[7] Friedhelm Hildebrandt,[3] Asaf Vivante,[3] Francesco SCOLARI,[4] Marijan Saraga,[5] Velibor Tasic,[6] Krzysztof Kiryluk,[1] Gian Marco Ghiggeri,[7] Simone Sanna-Cherchi.[1] *[1]Colmbia Univ, NY; [2]VU Univ Med Center, Amsterdam; [3]Harvard Medical School, Boston; [4]Div of Nephrology, Brescia; [5]Deptartment of Pediatrics, Univ of Split, Split; [6]Univ Children's Hospital, Skopje; [7]Gaslini Inst, Genoa.*

Background: PUV is among the most severe non-malignant urologic diseases, but its etiology is mostly unknown. Despite its rarity, PUV accounts for almost 20% of pediatric end-stage renal disease (ESRD). We hypothesize a genetic background of PUV based on its presence in genetically determined syndromes (i.e. Townes-Brocks and Down syndrome). No mutations associated to isolated PUV have been identified so far, providing a unique opportunity for gene discovery. Given the rarity of familial forms and its high mortality and morbidity, *de novo* dominant mutations are the most likely variant explaining PUV.

Methods: We performed genome-wide CNV analysis in 152 patients with PUV: 137 were genotyped using high-density SNP microarrays and 15 were subjected to WGS. QC of DNA microarrays data and CNV analysis were performed with PLINK and PennCNV software. Analysis of WGS data was performed using Genome STRiP and Delly v0.59. Structural variants were annotated with UCSC RefGene and RefExon, 1000 Genome data, an in-house list of 220 known genomic disorders and 21,575 controls.

Results: We identified structural variants diagnostic for 21 known genomic syndromes (7 deletions and 14 duplications) in 18/152 patients (12%), compared to 98/21,575 controls (0.45%; p-value<$2.2x10^{-16}$, OR=29.4). Duplications were found at loci usually deleted in patients with kidney malformations.

Conclusions: Our data indicate that PUV patients are enriched in genomic imbalances with a high burden of structural variants diagnostic for known genomic syndromes. The presence of heterozygous CNVs supports our model of dominant deleterious mutations with large effect size. Among the 5 patients with parental data, 3 CNVs were de novo and 2 inherited from the maternal side, which supports our hypothesis that PUV can be likely determined by de novo or by maternally inherited mutations, since the phenotype is not expressed in females.

TH-PO581

Novel Biomarkers of Obstructive Uropathy: Urinary Antimicrobial Peptides Brian Becknell,[1,2] Janae Preece,[3] Sudipti Gupta,[1] Rachel Millner,[2] Christina B. Ching.[1,3] *[1]Center for Clinical and Translational Research, Research Inst at Nationwide Children's Hospital; [2]Nephrology Section, Nationwide Children's Hospital; [3]Urology Div, Nationwide Children's Hospital.*

Background: Epithelial antimicrobial peptides (AMPs) are well defined in urinary tract infection due to their bactericidal and bacteriostatic activity. Their role in obstructive nephropathy, however, is less well known. We evaluated urinary AMP expression in anatomic and functional urinary tract obstruction.

Methods: With IRB approval, urine was collected from 3 pediatric populations: 1) Obstructed group: patients undergoing surgical intervention for ureteropelvic or ureterovesical junction obstruction; 2) Neurogenic group: patients with known spinal cord abnormality (i.e. myelomeningocele); 3) Control group: children in a general nephrology clinic without obstruction, neurologic lesion, or UTI. Patients with augmentation cystoplasty were excluded. ELISAs were run to detect beta defensin 1 (BD-1), human alpha defensin 5 (HD-5), HIP/PAP, LL-37, and NGAL, and normalized to urine creatinine. Results were analyzed with Mann-Whitney U test. A p-value of <0.05 was considered significant.

Results: 21 obstructed, 12 neurogenic, and 17 controls samples were obtained. The mean (median, range) age of obstructed, neurogenic, and control patients were: 5.4 years (4.3 years; 3.6 months-18.4 years), 5.7 years (4.6 years; 3.6 months-15.8 years), 12.9 years (13.3 years; 7-18 years). Males represented 76%, 58%, and 65% of the samples, respectively. All AMPs were significantly higher in obstructed and neurogenic patients as compared to controls: BD-1 (p<0.0001 and p=0.0006), HD-5 (p<0.0001 and p=0.0013), HIP/PAP (p<0.0001 and p=0.0004), NGAL (p=0.0046 and p=0.0416), and LL-37 (p<0.0001 and p=0.0005). BD-1 levels were significantly higher in neurogenic versus obstructed patients (p=0.0401).

Conclusions: AMPs may serve as biomarkers of obstructive uropathy, whether from anatomic obstruction or functional obstruction due to a neurologic lesion. Expression in non-infectious urinary tract conditions suggests alternative biological roles for AMPs as damage-associated molecular patterns and/or mediators of epithelial regeneration.

TH-PO582

Essential Roles for IL-6/Stat3 Signaling in Antimicrobial Gene Expression during Experimental Urinary Tract Infection Birong Li,[1] Sudipti Gupta,[1] Nicholas Ryan Mayne,[4] Christina B. Ching,[1,2] Brian Becknell.[1,3] *[1]Center for Clinical and Translational Research, The Research Inst at Nationwide Children's Hospital; [2]Urology Div, Nationwide Children's Hospital; [3]Nephrology Section, Nationwide Children's Hospital; [4]Nationwide Children's Hospital.*

Background: Host factors required for antimicrobial peptide (AMP) expression during urinary tract infection (UTI) are incompletely understood. Interleukin-6 (IL-6) levels increase during UTI, but the mechanisms whereby IL-6 promotes host immunity remain unclear. We hypothesized that IL-6 signals through the signal transducer and activator of transcription (Stat3), to drive AMP expression in infected urothelium.

Methods: We performed experimental UTI by transurethral inoculation of uropathogenic *Escherichia coli* (UPEC) in IL-6 knockout versus wild-type mice, as well as mice treated with IL-6 neutralizing antibody or isotype control. We determined the role of bacterial endotoxin signaling in Stat3 Tyr705 phosphorylation through *Tlr4* hypomorphic mice. We measured Stat3 activation based on Tyr705 phosphorylation in infected urinary tracts and primary human urothelial cells by immunoblotting. We localized pStat3 Tyr705 in experimentally infected urothelium by immunofluorescence. We measured mRNA expression of Stat3 target genes including AMPs by quantitative RT-PCR.

Results: UPEC inoculation leads to brisk Stat3 Tyr705 phosphorylation in bladder and renal urothelium in a Tlr4-dependent manner. IL-6 neutralization or gene ablation significantly reduces urothelial pStat3 Tyr705 levels. Conversely, administration of recombinant IL-6 leads to Stat3 Tyr705 phosphorylation in murine and human urothelium. We globally identify transcriptional targets of IL-6/pStat3 Tyr705 signaling in UPEC infected urothelium and demonstrate that IL-6 knockout mice exhibit significantly impaired expression of the AMPs *Reg3g* and *Reg3b* following experimental UTI.

Conclusions: IL-6/pStat3 Tyr705 signaling drives a conserved transcriptional program of AMP expression in UPEC infected urothelium. Deficiencies in IL-6/pStat3 Tyr705 activation may explain infection predisposition in certain patients with UTI. Conversely, local pharmacologic activation of pStat3 Tyr705 through IL-6 may promote mucosal immunity in individuals with recurrent UTI.

TH-PO583

Urinary YKL-40 as a Candidate Biomarker for Febrile Urinary Tract Infection in Young Children Jin-Soon Suh,[1] Byoung-Soo Cho.[2] *[1]Dept of Pediatrics, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea; [2]Director of MIRAE-iNG Kidney Center, MIRAE-iNG Kidney Center.*

Background: YKL-40 is regarded as a site-specific inflammatory marker. We sought to evaluate the association of YKL-40 with urinary tract infection (UTI) in febrile children.

Methods: We enrolled 44 children aged from 0 to 24 months with febrile UTI and 35 controls who were matched for age and sex, but had other causes of fever. An enzyme-linked immunosorbent assay was used to determine the level of YKL-40 in urine collected from each child.

Results: The ratio of urinary YKL-40/creatinine (Cr) was higher in the children with UTI than in the controls (P<0.001). The area under a receiver-operator characteristic curve for detecting UTI was 0.88 for urinary YKL-40/Cr, 0.86 for pyuria, and 0.71 for positive nitrite on urinalysis. We applied a cutoff value of 125.23 pg/mg to urinary YKL-40/Cr for detecting UTI. Eight of nine children in the control group with pyuria had urinary YKL-40/Cr levels lower than 125.23 pg/mg, and the one child in the UTI group without pyuria or positive nitrite had a urinary YKL-40/Cr level greater than 125.23 pg/mg.

Conclusions: Determining the levels of urinary YKL-40/Cr, may help identify true UTI in febrile young children, especially when they have pyuria, but not nitrite.

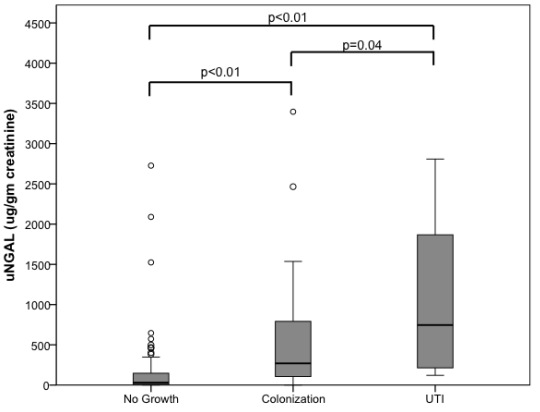
TH-PO584

Urine NGAL in Distinguishes Urinary Tract Infection from Colonization in Children on Clean Intermittent Catheterization Catherine Forster, Elizabeth C. Jackson, Stuart Goldstein. *Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Children with neurogenic bladders who require clean intermittent catheterization (CIC) frequently have bacteriuria, although distinguishing between urinary tract infection (UTI) and colonization (UTC) in this population can be difficult. Urinary neutrophil gelatinase-associated lipocalin concentrations [uNGAL] are increased in UTIs. We hypothesize that [uNGAL] will be higher in UTI compared to UTC and negative cultures.

Methods: Urine samples were obtained from children requiring CIC who had a urine culture sent for clinical care. Urine cultures were grouped as no growth, UTC, or UTI based on opinion of the managing clinician who did not know the [uNGAL]. Cultures with growth of mixed organisms or fungi, and from patients with concern for acute kidney injury were excluded. [uNGAL] was measured by ELISA, and [urine creatinine] by assay. Normally distributed continuous variables were compared by ANOVA and t-test; non-normally distributed variables were compared by Mann-Whitney U. Categorical variables were compared by chi-square.

Results: 171 cultures from 157 patients were included(no growth=80, UTC=77, UTI=14). Patients with no growth were younger than those with UTI (9.4±6.5 vs 14.7±6.7 years, p=0.02). There were more females in the UTC group compared to no growth (64.9% vs 38.8%, p<0.01). There was no difference in etiology of neurogenic bladder between groups. Median [uNGAL/Cr] was higher in the UTI group (746.1[205.7, 1914.3] µg/gm cr) compared to all groups (no growth, 30.3[8.9, 148.5](p=<0.01); UTC, 269.6 [105.7, 796.6](p=0.036)).



The AUC for NGAL for UTI was 0.79, 95% CI(0.69 -0.89).

Conclusions: [uNGAL] is elevated in children who require CIC who have UTI compared to negative cultures and UTC. uNGAL levels will provide actionable data to inform treatment decisions about UTIs in this unique population.

TH-PO585

Usefulness of Plasma NGAL as a Marker to Predict Renal Parenchymal Involvement in Infants with Febrile UTI Eun Mi Yang. *Dept of Pediatrics, Chonnam National Univ Hospital, Gwang-ju, Korea.*

Background: Accurate detection of renal parenchymal involvement in febrile urinary tract infections (UTI) is important, especially in infants. The aim of this study was to evaluate the predictive accuracy of plasma neutrophil gelatinase-associated lipocalin (NGAL) for biomarker of renal parenchymal involvement in infants with acute febrile UTI.

Methods: A total of 61 infants, who were admitted with febrile urinary tract infection, were enrolled in this study. Enrolled patients were divided into the cortical defect group (n = 40) and non-cortical defect group (n = 21), according to the result of renal scan.

Results: The patients' mean age was 4.4 ± 3.2 months. There were no significant differences between two groups in respect of age, gender, and fever duration. In cortical defect group, the white blood cell count and C-reactive protein levels were significantly higher than non-cortical defect group, respectively (11.7 ± 5.1 vs. 21.0 ± 19.5 10^3/mm^3, P < 0.001; 2,2 ± 1,3 vs. 5.5 ± 4.5 mg/dL, P = 0.001). Plasma NGAL also significantly increased in cortical defect group than non-cortical group (119 ± 135 vs. 677 ± 1951 ng/mL, P = 0.013). The most optimal cut-off value of plasma NGAL for predicting renal parenchymal involvement was defined as 230 ng/mL in the receiver operating characteristics curve analysis (sensitivity, 67.5%; specificity, 71.4%; AUC, 0.696; P = 0.006).

Conclusions: Plasma NGAL is significantly higher in cortical defect group. Although not a standalone test, plasma NGAL could be used for early detection renal parenchymal involvement in infants with acute febrile UTI.

TH-PO586

Use of Urine Sodium to Creatinine Ratio Multiplying by the Estimated Urine Creatinine for Prediction Urine Sodium in Pediatric Hypercalciuria Eun Mi Yang. *Dept of Pediatrics, Chonnam National Univ Hospital, Gwang-ju, Korea.*

Background: Elevated sodium excretion in urine resulting from excessive sodium intake can lead to hypercalciuria and contribute to the formation of urinary stones. The spot urine sodium to potassium ratio (Na/K) is a convenient method to estimate sodium excretion. The aim of this study was to evaluate the accuracy of predicting 24-hour urine sodium using spot urine sample in pediatric hypercalciuria.

Methods: This study included 58 children with hypercalciuria. The 24-hr urine creatinine level was estimated with the use of three existing equations: one equation for adult (Cockcroft-Gault formula) and two equations for children (Ghazali-Barratt and Hellerstein equation). The correlation was evaluated between spot urine samples, such as Na/K, urine sodium to creatinine ratio (Na/Cr), and corrected Na/Cr by 24-hour creatinine excretion, and 24-hour urine sodium.

Results: The patients' mean age was 8.5 years, 30 patients presented hypernatriuria (52%). There was a no significant correlation among Na/K, Na/Cr and 24-hour urinary sodium excretion. A moderate correlation was found between corrected Na/Cr by 24-hour creatinine excretion and 24-hour urine sodium (r = 0.387, P = 0.003). After estimating the 24-hr urine sodium levels by using the estimated urine creatinine, the correlation coefficients between the estimated and measured 24-hr urine sodium levels were 0.335, 0.372, and 0.351, respectively (All P < 0.05).

Conclusions: The corrected Na/Cr by 24-hour creatinine excretion improved the prediction of estimating 24-hour urine sodium. And spot Na/Cr multiplying by the estimated urine creatinine is not inferior to that of the corrected Na/Cr by measured 24-hour creatinine. The spot Na/Cr multiplying by the estimated urine creatinine can be used to predict 24-hour urine sodium in pediatric hypercalciuria.

TH-PO587

Inflammation Drives Renal Scarring in Experimental Reflux Nephropathy
Christina B. Ching,[1,2] Birong Li,[1] Ashley R. Jackson,[1] Brian Becknell.[1,3] *[1]Center for Clinical and Translational Research, The Research Inst at Nationwide Children's Hospital; [2]Urology Div, Nationwide Children's Hospital; [3]Nephrology Section, Nationwide Children's Hospital.*

Background: Children with vesicoureteral reflux can develop renal scars after pyelonephritis, and this reflux nephropathy is associated with hypertension, proteinuria, and renal insufficiency. Limited knowledge of histopathology, immune cell recruitment and gene expression changes during pyelonephritis restricts the development of therapies to prevent acquired renal scarring. Here, we address this knowledge gap using inbred, immunocompetent mice with vesicoureteral reflux.

Methods: Female C3H/HeOuJ mice with 100% vesicoureteral reflux were transurethrally inoculated with uropathogenic *Escherichia coli* (UPEC) strain CFT073. Kidneys were analyzed by histopathology and flow cytometry. Pyelonephritis transcriptomes were evaluated by RNAseq and pathway analysis.

Results: Transurethral inoculation of UPEC leads to renal mucosal injury, tubulointerstitial nephritis, and cortical fibrosis. Fibrosis correlates most significantly with inflammation 7 and 28 days post infection. Flow cytometry identifies recruitment of neutrophils and inflammatory macrophages to infected kidneys, in proportion to renal bacterial burden. Transcriptome analysis reveals molecular signatures associated with renal ischemia-reperfusion injury, immune cell chemotaxis, and antimicrobial peptide production.

Conclusions: This murine model recapitulates the cardinal histopathologic features observed in humans with acquired renal scarring following pyelonephritis. The integration of histopathology, flow cytometry, and transcriptome data begins, for the first time, to define potential mechanisms of tissue injury during pyelonephritis in the context of an intact immune response. The relationship between inflammatory cell recruitment and fibrosis supports the hypothesis that acquired renal scarring arises as a consequence of excessive host inflammation and suggests that immunomodulatory therapies should be investigated to reduce renal scarring in patients with pyelonephritis.

The Childhood Nephrotic Syndrome Observational Study: A Midwest Pediatric Nephrology Consortium Study
Michelle N. Rheault,[1] Lei Zhang,[1] Halima S. Janjua,[2] Donna J. Claes,[3] Tarak Srivastava,[4] Alejandro Quiroga,[5] Jason Misurac,[6] Takeshi Ninchoji,[7] Kazumoto Iijima,[7] Oleh M. Akchurin,[8] Larry A. Greenbaum,[9] John D. Mahan,[10] William E. Smoyer.[10] *[1]Univ of Minnesota Masonic Children's Hospital; [2]Cleveland Clinic; [3]Cincinnati Children's Hospital Medical Center; [4]Children's Mercy Hospital; [5]Helen DeVos Children's Hospital; [6]Univ of Iowa; [7]Kobe Univ Graduate School of Medicine; [8]Weill Cornell; [9]Emory Univ; [10]Nationwide Children's Hospital.*

Background: Childhood nephrotic syndrome (NS) is one of the most common pediatric glomerular disorders. Modern, large-scale natural history studies are lacking.

Methods: The Childhood NS Observational Study (CNOS) is a prospective, longitudinal study of children 1-18 yrs with incident NS. Children w/ secondary NS are excluded. Data are collected at presentation, 3 mo, and yearly. Two sample t-tests were used for continuous values and Fisher's exact tests for categorical values.

Results: 126 children from 10 sites had 3-month data. Prior to diagnosis, children had an avg (range) of 1.1 (0-6) primary care visits and 0.8 (0-3) ER visits with NS symptoms. 62.7% were hospitalized at dx. 84% of children were treated with a standard 12 week steroid course.

Demographic and clinical information at presentation (N)	Steroid-sensitive (N=96; 76%)	Steroid-resistant (N=30; 24%)	P-value
Age			0.003
≤ 6 years (72)	86%	14%	
> 6 years (54)	63%	37%	
Sex			0.67
Male (80)	78%	22%	
Female (46)	74%	26%	
Race/ethnicity			0.24
Caucasian, non-Hispanic (60)	78%	22%	
Black, non-Hispanic (37)	65%	35%	
Hispanic (14)	79%	21%	
Asian (8)	100%	0	
Mixed Race (2)	100%	0	
Gestational age			0.50
<37 weeks (13)	85%	15%	
≥37 weeks (80)	73%	27%	
Systolic HTN			0.18
yes (56)	71%	29%	
no (53)	83%	17%	
eGFR (ml/min/1.73m^2, mean, SD)	142.5 (81.6)	97.6 (26.8)	<0.001
Urine blood			0.43
Negative (46)	80%	20%	
Trace (14)	64%	36%	
Positive (60)	78%	22%	

Conclusions: Children w/ NS have high healthcare utilization around the time of dx. Children w/ steroid resistant NS are older and have lower eGFR at presentation. The CNOS registry will provide a framework for future observational and interventional studies in pediatric NS.

Race and Growth Velocity in Children with Nephrotic Syndrome: A Midwest Pediatric Nephrology Consortium Report
Oleh M. Akchurin,[1] Jason Misurac,[4] Hoda T. Hammad,[1] Paul Christos,[1] Tarak Srivastava,[2] Alejandro Quiroga,[3] John D. Mahan,[5] William E. Smoyer,[5] Larry A. Greenbaum,[6] Michelle N. Rheault.[7] *[1]Weill Cornell Medicine; [2]Children's Mercy Hospital; [3]Helen DeVos; [4]Univ of Iowa; [5]Nationwide Children's Hospital; [6]Emory Univ; [7]Univ of Minnesota.*

Background: Delayed linear growth occurs in a subset of children with nephrotic syndrome (NS), but the cause is incompletely understood. An association between race and growth has been reported in children with CKD, but it is unknown whether race affects growth in children with NS.

Methods: Growth velocity of children enrolled in the multicenter prospective Childhood Nephrotic Syndrome Observational Study was assessed as the difference between height z-scores at enrollment and 1 year follow-up. Children were enrolled at the time of initial diagnosis. Race and other variables were compared between children with growth velocity below vs. above the cohort median (S - "slow" growth group vs. F - "fast" growth group, respectively), using the two-sample t-test and chi-square test. The paired t-test was used to compare height z-scores between enrollment and 1 year follow-up.

Results: Growth data were available for 71 children (54% Caucasian, 26% Black, 11% Hispanic). Height z-score was 0.07±1.49 at enrollment and 0.11±1.17 at 1 year (p=0.90). Racial distribution was significantly different between the S vs. F groups (p=0.009): non-Hispanic Blacks were more prevalent in the S and Hispanics in the F groups; the prevalence of Caucasians was not different between the groups. Gender, birthweight, gestational age and type of health insurance were not different between the groups. There was a trend toward higher prevalence of steroid-responders in the F group (p=0.06).

Conclusions: Despite steroid exposure, height z-score did not change 1 year after diagnosis in this contemporary cohort of children with NS. However, growth rates were slower in Blacks and faster in Hispanics. Further analyses are ongoing to determine whether the effect of race on growth is mediated by steroid responsiveness and development of CKD.

TH-PO590

Vincristine Is Effective in Some Children with Challenging Nephrotic Syndrome
Vladimir Belostotsky, Steven Arora. *Pediatrics, McMaster Children's Hospital, Hamilton, ON, Canada.*

Background: Vincristine was proven to be effective in some children with Nephrotic Syndrome (NS) who had Frequently Relapsing (FRNS), Steroid Dependent (SDNS) or Steroid Resistant (SRNS) disease. Clinical trials were suggested in late 1990s to early 2000s, but never happened due to development of other therapeutic agents including Calcineurin Inhibitors (CNIs) such as tacrolimus (Tac), ciclosporin (CsA); MMF and rituximab (Rit). Aim: To review Vincristine use in our institution in complex cases of nephrotic syndrome where treatments with Steroids (S), CNIs, MMF were unsuccessful in inducing remission (Rem) (patients 1,3,4,5,6) or maintaining low frequency of relapses (patient 2).

Methods: Records of 6 children who received Vincristine for NS over last 5 years were reviewed.

Results: Vincristine was given at the dose of 1.5 mg/m^2 (max 2 mg) IV weekly for 4 doses. If successful in inducing remission then it was continued, otherwise it was stopped. Findings are summarized in table 1.

Diagnosis (D)	Biopsy	Age of D	Age now	Previous treatments and duration in months	Response to V	N of doses/ year	Current state
FRNS, SDNS then SRNS	FSGS, C1Q	2	12	S, pulsed S, CsA	yes	37/2012	Stable Rem on CsA
FRNS, SDNS	Minimal Change	2	12	S, cyclophosphamide, MMF, CsA	yes	38/2013	Stable Rem on CsA
FRNS, SDNS then SRNS	FSGS	4	11	S, pulsed S, CsA, MMF + Tac	no	4/2011	Rem after Rit+S
FRNS, SDNS then SRNS	FSGS	9	20	S, CsA, Tac, MMF	no	4/2012	Adult services
SRNS	FSGS	10	12	S, pulsed S, CsA, MMF + CsA, Plasma exchange	no	4/2015	Nephrotic on MMF
FRNS, SDNS then SRNS	Minimal Change	7	11	S, pulsed S, Tac	yes	6/2016	Rem, V ongoing

Conclusions: We found Vincristine to be effective in half of our small group of children with challenging course of NS which was resistant to CNIs and MMF. CsA seems to work better to maintain remission after treatment with Vincristine.

TH-PO591

COQ6 Mutations in Children with Steroid-Resistant Focal Segmental Glomerulosclerosis and Sensorineural Hearing Loss Eujin Park,[1] Yo Han Ahn,[2] Hee Gyung Kang,[1,3] Kee Hwan Yoo,[4] Young Seo Park,[5] IL-Soo Ha,[1] Hae Il Cheong.[1,3] *[1]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Republic of Korea; [2]Dept of Pediatrics, Hallym Univ Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [3]Research Coordination Center for Rare Diseases, Seoul National Univ Hospital, Seoul, Republic of Korea; [4]Dept of Pediatrics, Korea Univ Guro Hospital, Seoul, Republic of Korea; [5]Dept of Pediatrics, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: The phenotypic combination of steroid-resistant focal segmental glomerulosclerosis (SR-FSGS) and sensorineural hearing loss (SNHL) has been reported mainly in patients with mitochondrial cytopathies, including primary coenzyme Q10 (CoQ10) deficiency.

Methods: In this study of ten children with SR-FSGS and SNHL, we identified six patients with CoQ10 deficiency caused by biallelic COQ6mutations. We performed genotype and phenotype analyses of these six patients.

Results: The median age at the onset of nephrotic syndrome was 29 months (range 15–47 months). All patients progressed to end-stage renal disease within the median duration of 13 months (range 1–27 months) after onset. Kidney biopsies revealed FSGS with variable degrees of glomerular sclerosis, and abnormal mitochondrial proliferation in podocytes was a constant finding. None of the five patients who underwent kidney transplantation developed recurrence of FSGS.

Conclusions: Primary CoQ10 deficiency due to COQ6 mutations should be considered in children presenting with both SR-FSGS and SNHL. The condition is treatable when CoQ10 supplementation beginning in the early stage; therefore, early diagnosis of COQ6 mutations is essential. We recommend early kidney biopsy because detection of abnormal mitochondrial proliferation in podocytes might provide a means to earlier diagnosis.

TH-PO592

ADCK4-Associated Focal Segmental Glomerulosclerosis in Children Eujin Park,[1] Hee Gyung Kang,[1,2] Young Seo Park,[3] IL-Soo Ha,[1] Hae Il Cheong.[1,2] *[1]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Republic of Korea; [2]Research Coordination Center for Rare Diseases, Seoul National Univ Hospital, Seoul, Republic of Korea; [3]Dept of Pediatrics, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: ADCK4 is one of the novel genes causing autosomal-recessive steroid-resistant nephrotic syndrome (SRNS). ADCK4 interacts with components of the CoQ10 biosynthesis pathway. ADCK4 mutations usually manifest as isolated adolescent-onset focal segmental glomerulosclerosis (FSGS).

Methods: Here we tried to figure out the incidence of ADCK4 mutations in our Korean pediatric cohort of SRNS as well as phenotype analyses of the patients with ADCK4 mutations.

Results: The incidence of ADCK4-associated FSGS was 7.5% (4/53) of 5-year-old or older children with multidrug-resistant FSGS. Two additional patients were included for the phenotype analyses; one detected by family screening and the other with cyclosporine-responsive FSGS and medullary nephrocalcinosis. All six patients presented with incidentally found proteinuria. The median age at the onset was 110 months (range, 60–153 months), and five patients progressed to ESRD within a median duration of 46 months (range, 36–79 months) after the onset. Kidney biopsy revealed FSGS in all the patients (n=5), including a not-otherwise-specified (NOS) variant in three patients and a collapsing variant in two patients. Abnormal mitochondrial proliferation was detected in podocytes as well as in renal tubular epithelial cells. Interestingly, all patients accompanied bilateral medullary nephrocalcinosis of various degrees. None of the patients had neurologic or other extrarenal manifestation.

Conclusions: ADCK4 mutations should be considered in older children presenting with SR-FSGS. An early diagnosis of ADCK4mutations is essential because the condition is treatable when CoQ10 supplementation is started at the early stage. Abnormal mitochondrial proliferation in the kidney biopsy and accompanying medullary nephrocalcinosis may be useful diagnostic clues.

TH-PO593

Injuries of Glomerular Capillaries and Basement Membrane May Be Involved in Renal Dysfunction in Thin Basement Membrane Disease Yusuke Kajimoto, Takafumi Kanemitsu, Michiko Aoki, Yusuke Okabayashi, Shinya Nagasaka, Dedong Kang, Akira Shimizu, Kiyotaka Nagahama. *Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: Thin basement membrane disease (TBMD) is diagnosed by diffuse reduction of the thickness of glomerular basement membrane (GBM) in electron microscopy (EM), and characterized clinically by benign familial hematuria. However, some cases progress to end-stage renal disease. In the present study, we performed the clinico-pathological analyses of TBMD, especially focusing on glomerular capillary injuries, including morphological and qualitative alterations of GBM and glomerular capillaries, and correlated with clinical findings.

Methods: In our department, 27 renal biopsy cases of TBMD was identified in 1395 renal biopsy cases. We investigated clinical characteristics using clinical records. We also examined pathological characteristics using light microscopy and EM, immunostaining for CD34, which can detect glomerular capillaries, immunostaining for α5 (IV) chains of type IV collagen, which is one of the main component of GBM, and low-vacuum scanning electron microscopy (LV-SEM), which allows detailedthree-dimensional observation of GBM surface.

Results: In our cases, 26 cases (96.3%) had hematuria, 21 cases (77.8%) had proteinuria. In 6 cases, the eGFR declined in G3a to G4 in clinical CKD stage. In image analysis for CD34 immunostaining using a computer, narrowed glomerular capillaries significantly increased with accumulation of glomerular extracellular matrix (ECM) that may be associated with renal dysfunctions, compared with controls. In immunofluorescence, α5 (IV) expression was significantly reduced in the GBM with partial enhancement of α2 (IV). In LV-SEM observations, thinning and flattering of GBM was noted with multiple small holes and coarse manufactures in the surface of GBM.

Conclusions: In TBMD, narrowing glomerular capillaries with alterations of GBM developed with increased glomerular ECM, which may be associated with urinary abnormalities and renal dysfunctions. Injuries of glomerular capillaries and GBM may be developed in TBMD, and be associated with urinary abnormalities and renal dysfunction.

Kizilbash,[21] Erica Winnicki,[22] Tarak Srivastava,[3] Carla M. Nester.[4] *[1]Univ of North Carolina Kidney Center; [2]Univ of Nebraska Medical Center; [3]Children's Mercy Hospitals and Clinics; [4]Univ of Iowa Hospital; [5]Helen De Vos Children's Hospital; [6]Women and Children's Hospital of Buffalo; [7]Kentucky Children's Hospital; [8]Children's Hospital of Pittsburg of UPMC; [9]Dayton Children's Hospital; [10]Children's Hospital of Philadelphia; [11]Mayo Clinic; [12]Carolinas Medical Center; [13]Texas Children's Hospital; [14]SUNY Stony Brook; [15]Children's Hospital of Richmond; [16]Univ of Texas Southwestern; [17]Children's Hospital at Vanderbilt; [18]Emory; [19]Seattle Children's Hospital; [20]Utah; [21]Minnesota; [22]UC Davis.*

Background: Eculizumab is approved for treatment of atypical hemolytic uremic syndrome (aHUS) but is also being used "off-label" to treat disorders with presumed complement dysregulation. The aim of the study was to characterize the use and outcomes in children treated with Eculizumab according to diagnosis.

Methods: We performed a retrospective chart review of 152 patients ≤25 years of age, treated with eculizumab at 21 centers within the MWPNC.

Results: Eculizumab was used for "off-label" diagnoses in 44.1%. 31% received non-standard dosing. The reasons for alternative dosing included critical illness (15.2%), physician preference (15.2%) and other (47.8%). 46.5% of children remained on therapy at study end.

Primary Diagnosis		At Initiation	6 months*	12 months*	Most Recent Value**
aHUS	eGFR (n) # on RRT UPC (n)	42.1 (34) 43 9.2 (21)	108 (32) 5 0.5 (24)	101.8 (24) 3 2.2 (15)	110.6 (51) 8 2.0 (36)
ST-HUS	eGFR (n) # on RRT UPC (n)	21.6 (2) 15	98.1 (2) 1	115.2 (1) 0	89.1 (15) 3 0.5 (5)
Other Infectious HUS	eGFR (n) # on RRT UPC (n)	24 (3) 2 12 (2)			133.1 (4) 0 0.9 (4)
Other TMA	eGFR (n) # on RRT UPC (n)	67.5 (9) 3 6.9 (7)	53.5 (2) 2 1.5 (2)	1	100.9 (7) 4 2.7 (8)

DDD	eGFR (n) # on RRT UPC (n)	63.8 (2) 3 1.3 (1)	86.5 (5) 1 2.5 (3)	92.5 (2) 1 1.3 (2)	98.7 (3) 1 1.6 (3)
Antibody Mediated Rejection	eGFR (n) # on RRT UPC (n)	84.1 (6) 1	69 (3) 0	62.1 (2) 0	68.7 (6) 2

x̄ eGFR (n)=patients used to calculate x̄ eGFR
*Children excluded from eGFR calculations if they were off eculizumab therapy, on dialysis or following renal transplant
** Children excluded from eGFR calculations if they were on dialysis or following renal transplant

# on RRT = # of patients on RRT at each time point
UPC= x̄ urine protein to creatinine ratio in mg/mg (n)=patients used to calculate x̄ UPC

Conclusions: This large pediatric cohort shows 44% of current eculizumab use in children is for "off-label" indications. Renal outcomes for these "off-label" indications show no clear trend as compared to the aHUS patients.

TH-PO595

Efficacy of Cyclosporine A for Severe Henoch-Schönlein Purpura Nephritis in Children Takahisa Kimata, Jiro Kino, Sohsaku Yamanouchi, Chikushi Suruda, Shoji Tsuji, Kazunari Kaneko. *Pediatrics, Kansai Medical Univ, Hirakata-shi, Osaka, Japan.*

Background: Though the treatment for severe Henoch-Schönlein purpura nephritis (HSPN) is not established. While methylprednisolone and urokinase pulse therapy (MUPT) or intensive multiple-drug therapy including steroid (MDT) have been reported to be effective in some patients with HSPN of poor prognosis, others do not respond to these therapies. Recently, cyclosporin A (CsA) has been postulated to be effective for children with severe HSPN. Our aim was to assess the efficacy of CsA as the rescue therapy for steroid-resistant HSPN or the first line treatment for severe HSPN.

Methods: 9 children with severe HSPN (5 boys, median age 7.3: range 4-13 years) were enrolled. Severe HSPN was defined as both the histological severity of grade III-V and the clinical severity showing nephrotic range proteinuria. 4 patients allocated for the rescue therapy (G-I) received MUPT or MDT initially without success and were switched to CsA administration. Their median protein-to-creatinine (PC) ratios at the time of CsA initiation was 10.3 g/gCr. 5 patients allocated for the first line treatment (G-II) did not receive any steroid before the administration of CsA. Their median PC ratios at the time of CsA initiation was 16.1 g/gCr. CsA dosage ranged from 2.5 to 4 mg/kg per day. All patients in both groups received an angiotensin-converting enzyme inhibitor before CsA initiation. This study was approved by the ethical committee of Kansai Medical University.

Results: We excluded 1 patient in G-II from the study, as she developed hypertension after initiation of CsA. Except for this patient, other 8 patients responded well to CsA: proteinuria disappeared in all with the median period after CsA commencement of 4.7 months in G-I and 6.0 months in G-II: The total period of pharmacological treatment in G-II was shorter than that in G-I (10.6 vs 6.0 months, P=0.08). There were no significant differences in age, gender and the dose of CsA between the groups. Adverse events (anemia) were observed in two patients.

Conclusions: CsA is effective to reduce the amount of proteinuria not only as the rescue therapy for steroid-resistant HSPN but also as the first line treatment for severe HSPN.

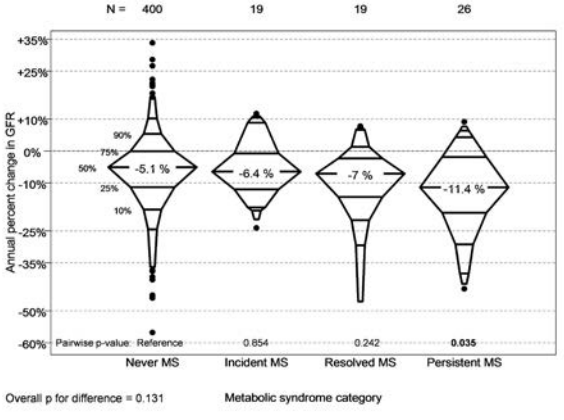
TH-PO596

Metabolic Syndrome and Associated Longitudinal Changes in Kidney Function in Children with CKD Shwetal P. Lalan,[1] Derek Ng,[2] Fernanda Kupferman,[1] Susan L. Furth,[5] Bradley Warady,[4] Mark Mitsnefes.[3] *[1]Brookdale Univ Hospital Center; [2]Johns Hopkins Bloomberg School of Public Health; [3]Cincinnati Children's Hospital; [4]Children's Mercy Hospital; [5]The Children's Hospital of Philadelphia.*

Background: While individual CV risk factors are frequent in children with CKD, incidence of metabolic syndrome (MS) and its effect on CKD progression are not well known. The goal of this study was to describe prevalence of MS and associated longitudinal changes in renal function in children in the CKiD study.

Methods: MS was defined as presence of obesity (BMI >90th percentile) and at least 2 of the 4 comorbidities: high triglycerides (TG)(> 200 mg/dl), low HDL cholesterol (<40mg/dl), hypertension (HT)SBP/DBP >95th percentile, diagnosis or use of antiHT therapy) and hyperglycemia (>100mg/dl). Subjects were classified as never MS, incident MS, resolved MS and persistent MS with annual eGFR change. Wilcoxon rank sum tests compared the distributions of annual percent change in GFR by MS classification, overall and pairwise with never MS as the reference group.

Results: Of 706 children, 64 (9%) had MS at the baseline. The majority had high TG levels (83%) and HT (78%), hyperglycemia occurred in 31%. 71% of those with MS had 3 and 30% had 4 components of MS. Of those without MS at baseline, 43% had HT, 38% had high TG and 12% had hyperglycemia. Among those free of MS, 96% continued to be free (never MS) and 5% developed incident MS. Of the 64 with baseline MS, 42% did not have MS after 2 years (resolved MS) and 58% continued to have MS (persistent MS). Children with and without MS had similar eGFR at baseline. The decline in eGFR per year was faster in children with persistent MS, -11.4% compared to never MS, -5.1% (p=0.04).



Conclusions: Persistent MS was associated with accelerated eGFR decline, preventing or treating these comorbidities, particularly obesity, may slow the progression of CKD.

TH-PO597

The Excretory Activity of the Kidneys in Children Treated for Overweight or Obesity Tomasz Jerzy Irzyniec,[1,2] Anita Kocieba-Laciak,[3] Izabela Maciejewska-Paszek.[1] *[1]Dept of Health Promotion and Community Nursing, Faculty of Health Sciences, Medical Univ of Silesia, Katowice, Poland; [2]Dept Nephrology/ENDO, MSWiA Hospital, Katowice, Poland; [3]Medical Univ of Silesia, Katowice, Poland.*

Background: Children with excess weight usually exhibit enhanced kidney perfusion resulting in glomerular hyperfiltration. Unfortunately, there are no noninvasive methods to precisely evaluate GFR in children. A useful method of GFR estimation in obese children is the calculation of eGFR according to the Bouvet formula. The aim of the study was to evaluate the influence of excess weight and successful weight reduction on the excretory activity of the kidneys in overweight or obese children.

Methods: Creatinine (Cr) and cystatin C (cyC) concentrations were determined and eGFR was calculated using the Bouvet formula in a group of 95 children (9-13y.), of whom 62 were overweight and 33 obese.The results were compared to the values, which could be found in the population of Polish children (PC) with BMI at the 50th percentile (BMI 17.5±0,8kg/m^2, Cr 0.6±0.2mg/dL, cyC 0.54±0.1 mg/L, eGFR 53.1±4.3ml/min). The results obtained before and after a 6-month weight reduction period in 23 patients, who demonstrated BMI reduction of over 5% were also analyzed.

Results: Children with excess weight had higher cyC and eGFR compared to PC. Despite of the different BMI (30±4 vs 24.5±2kg/m2), CyC and eGFR were only slightly higher in obese compared to overweight children (1.21±0.5 vs 1.14±0.4 mg/L - ns and 100.7±29.7 vs 90.8±25 ml/min, p=0.08). In contrast to overweight, in obese children, after a 6-month weight reduction program, the decreases in cystatin C level (1.3±0.8 vs 0.8±0.4 mg/l, p<0.02) and eGFR (107.6±46.5 vs 79.3±29.2 ml/min, p<0.01) were significant. Further calculations revealed that the decrease in cystatin C level (p<0.04) and eGFR (p<0.04) was only significant in male obese patients.

Conclusions: 1. Excess weight in children causes glomerular hyperfiltration. 2. Due to reduced glomerular hyperfiltration, weight loss has a beneficial effect on the excretory activity of the kidneys, in obese children. 3. Following weight reduction, a significant decrease in cystatin C level and eGFR value occurs but only in obese boys.

TH-PO598

Identification and Staging of Blood Pressure Using the STOP Intervention in Pediatric Nephrology Ambulatory Care Hailey Woollen, Donald J. Weaver, Charles P. McKay, Susan F. Massengill. *Pediatric Nephrology, Levine Children's Hospital, Charlotte, NC.*

Background: Prior studies in pediatric patients with chronic kidney disease (CKD) have shown an association with declining kidney function and hypertension (HTN), yet uncontrolled HTN persists in children with CKD. The goal of the STOP (**S**urveillance, **T**arget, **O**utpatient, blood **P**ressure) study is to increase the recognition, diagnosis, and control of hypertension in pediatric CKD patients through a simple practice-based intervention.

Methods: In a pediatric nephrology CKD practice, ambulatory BPs were measured, classified and labeled as optimal (<75%, green), pre-hypertensive (76-89%, yellow) and hypertensive (>90%, red) according to age, height and sex specific percentiles. Color-coded cards were placed on encounter documents for provider use during the visit. Assessment of provider actions related to BP were collected by chart review and classified as repeated measure, further evaluation, medication change or none.

Results: 47 patients, mean age 11, range 2-19 years, were analyzed. 32 (68%) had glomerular CKD, 8 (17%) had HTN and 6 (13%) were on anti-HTN therapy prior to baseline. At baseline, initial BP class was 21 (45%) Green, 15 (32%) Yellow and 11 (23%) Red. Final BP class was 33 (70%) Green, 10 (21%) Yellow and 4 (9%) Red. 44 (94%) had repeat measures, 4 (9%) had re-evaluation and 2 (4%) had medication adjustment.

Conclusions: Repeat BP measurement was common regardless of initial BP classification. One third of patients were either pre-hypertensive or hypertensive at the final reading but only 13% had an intervention of additional evaluation or therapy change. The remaining 17% forms an at-risk group for practice improvement. The study is ongoing and will address the blood pressure control outcome in an expanding cohort of children with CKD.

TH-PO599

Ambulatory Blood Pressure Tracking in Pediatric Kidney Transplant Recipients Gilad Hamdani,[1] Edward Nehus,[1] Coral D. Hanevold,[2] Judith Sebestyen VanSickle,[3] Scott E. Wenderfer,[4] David K. Hooper,[1] Bradley Warady,[3] Mark Mitsnefes.[1] *[1]Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Pediatric Nephrology, Seattle Children's Hospital, Seattle, WA; [3]Pediatric Nephrology, Children's Mercy Hospital, Kansas City, MO; [4]Pediatric Renal Section, Texas Children's Hospital, Houston, TX.*

Background: Hypertension (HTN) is common after kidney transplantation, and is associated with adverse outcomes. We aimed to assess blood pressure (BP) control by using ambulatory BP monitoring (ABPM) in pediatric and young adult kidney transplant recipients.

Methods: A retrospective chart review of all kidney transplant recipients in 4 pediatric centers with at least two ABPMs during the follow up post transplantation. Casual HTN was defined as systolic/diastolic BP ≥95th%tile or ≥130/90. Abnormal ABPM was defined as 24H-BP load ≥25%.

Results: One hundred and twenty four patients (median age 17y, 40% young adults, 69% male) were included in the study. Median time between first and last ABPM was 2 years. More patients were taking BP medications at last follow up (79% vs. 71%, p=0.01); 47% had normal first ABPM and 62% had normal last ABPM (p=0.01). At initial ABPM, 36% and 17% of patients were classified as having masked and sustained HTN, respectively, compared with 31% and 7% at last ABPM. The proportion of controlled HTN (normal BP on hypertensives) increased from 27% to 42%, whereas uncontrolled HTN decreased from 41% to 32% (table). Proportion of patients with masked HTN not on hypertensives decreased from 11% to 4%.

BP Status according to initial and last ABPM (n=124)								
	Off BP medications				On BP medications			
	Normal BP	White Coat HTN	Masked HTN	Sustained HTN	Controlled HTN	White Coat HTN	Masked HTN	Sustained HTN
Initial ABPM	17 (14%)	4 (3%)	14 (11%)	1 (1%)	33 (27%)	4 (3%)	31 (25%)	20 (16%)
Last ABPM	19 (15%)	0	5 (4%)	3 (2%)	52 (42%)	6 (5%)	33 (27%)	6 (5%)

Conclusions: Using ABPM to monitor BP, we observed improvement in BP control in pediatric and young adult kidney transplant recipients during follow up.

TH-PO600

Left Ventricular Hypertrophy in Pediatric Hypertension and Obesity: A Systematic Review of Echocardiographic Studies Iwona Dziewa, Haseena Sahib, Katarina Supe-Markovina, Robert Woroniecki. *Pediatrics and Pediatric Nephrology, Stony Brook Children's Hospital, Stony Brook, NY.*

Background: Left ventricular hypertrophy (LVH) is an important end point of hypertension (HTN), and/or obesity-associated cardiovascular disease. However, there are multiple definitions of LVH in children, and it is unclear how those definitions affect LVH prevalence. Our objective was to perform a systematic review of literature to report LVH prevalence as determined by echocardiography (ECHO) in children with HTN and/or obesity, and to examine how various definitions affect LVH prevalence.

Methods: PubMed search was performed in accordance with the PRISMA statement. We used terms: left ventricular hypertrophy, LVH, LVMI, obesity, hypertension, echocardiogram, ECHO, cardiac hypertrophy, obesity, cardiomyopathy, and limited search to infants, children and adolescents. Full text articles published in English from 01/01/2000 to 05/31/2016 were included. Subjects with kidney transplantation or chronic kidney disease were excluded. We examined effect of 4 definitions on LVH, based on left ventricular mass index (LVMI): (A) LVMI> 51 g/m$^{2.7}$, (B) LVMI >38.6 g/m$^{2.7}$(Daniels *et al.*), (C) LVMI> the 95th-tile LMS reference (Foster *et al.*), and (D) LVMI >95th-tile for gender and chronological age (Khoury *et al)*.

Results: Our search yielded 111 articles, and 13 studies that met all inclusion/exclusion criteria were included in the final analysis. There were 1613 subjects, 13.9±1.9 years old, 56.1% males, with body mass index (BMI) 27.4±5.1, 44.9% were obese. 7/13 (53.8%) studies reported Caucasian race: 215/754 subjects (28%), and 4/13 (30.8%) studies, African-American race: 421/545 subjects (77.2%). LVMI was significantly and positively correlated with systolic blood pressure (SBP) parameters in 4/13, and with BMI in 3/13 studies. LVH data is presented in the Table:

Definition	LVH prevalence (%)	95%CI
A	25.3	22.2-28.4
B	37.5	34.6-40.4
C	14.8	7.9-21.7
D	25.0	15.0-35.0
Overall	25.6	23.7-27.5

Conclusions: LVH prevalence determined by ECHO is variable. LVMI/LVH are associated with SBP/BMI. More precise indexing of left ventricular mass is required in the management of childhood HTN/obesity.

Left-Ventricular Hypertrophy and Associated Factors in Children with Chronic Kidney Disease: Results from the KoreaN Cohort Study for Outcomes in Patients with Pediatric Chronic Kidney Disease (KNOW-Ped CKD) Heeyeon Cho,[1] Kyoung Hee Han,[7] Seong Heon Kim,[4] Hee Sun Baek,[2] Min Hyun Cho,[2] Jae Il Shin,[6] Joo Hoon Lee,[3] Young Seo Park,[3] Hyun-Jin Choi,[5] Hee Gyung Kang,[5] IL-Soo Ha,[5] Hae Il Cheong.[5] *[1]Pediatrics, Samsung Medical Center, Seoul, Korea; [2]Pediatrics, Kyungpook National Univ Children's Hospital, Daegu, Korea; [3]Pediatrics, Asan Medical Center, Seoul, Korea; [4]Pediatrics, Pusan National Univ Hospital, Pusan, Korea; [5]Pediatrics, Seoul National Univ Children's Hospital, Seoul, Korea; [6]Pediatrics, Severance Hospital, Seoul, Korea; [7]Pediatrics, Jeju National Univ Hospital, Jeju, Korea.*

Background: Children with chronic kidney disease (CKD) has been known to be a high risk group of cardiovascular disease, and left-ventricular hypertrophy (LVH) is an early marker of cardiovascular disease. We assessed the prevalence and contributing factors of LVH in pediatric CKD patients.

Methods: We conducted a cross-sectional study using baseline data from the KoreaN cohort study for Outcome in patients With Pediatric Chronic Kidney Disease (KNOW-Ped CKD), a nationwide, prospective, and observational cohort study of pediatric CKD. Univariate and multiple logistic regression analysis were performed to evaluate the association of variables with LVH. LVH in children has been widely defined as a left ventricular mass index (LVMI) > 95th percentile. However, LVMI increases with decreasing height in young children, and we used a novel method of expressing left ventricular mass relative to body size in children. The patients with left ventricular mass above the 95th percentile for height (z score>1.64) were classified as having LVH.

Results: Total 381 children with CKD were enrolled, and the mean age was 9.93±5.45 years. Thirty patients (9.1 %) were diagnosed with LVH. Univariate logistic regression revealed positive association between LVH and primary disease (glomerulonephritis), body mass index, and systolic hypertension. Primary disease of glomerulonephritis and systolic hypertension were independently associated with LVH in multivariate logistic regression (p=0.0055, p<0.001).

Conclusions: The results of this study suggest that the history of glomerulonephritis and systolic hypertension might predispose to increased LVMI in pediatric patients with CKD.

Carotid Intima Media Thickness in Children with Chronic Kidney Disease Abdullahi Mudi,[1,2] Zaiboonisa Holland,[3] Caroline Dickens,[4] Daynia Ballot,[1] Cecil S. Levy.[1] *[1]Dept of Paediatrics and Child Health, Univ of the Witwatersrand and Charlotte Maxeke Johannesburg Academic Hospital, Johannesburg, South Africa; [2]Dept of Paediatrics, Bayero Univ, Kano, Nigeria; [3]Dept of Radiology, Charlotte Maxeke Johannesburg Academic Hospital, Johannesburg, South Africa; [4]Dept of Medicine, Univ of the Witwatersrand, Johannesburg, South Africa.*

Background: Cardiovascular disease (CVD) is a common complication of chronic kidney disease (CKD). In children with CKD, CVD may manifest as early changes in arterial thickness and or stiffness. We aimed to determine the correlates of carotid intima media thickness (cIMT) in children with CKD.

Methods: Seventy-one children with CKD stage 1–5 had a physical examination, routine follow up blood tests and a Carotid Doppler ultrasound to determine the average cIMT.

Results: The mean age of the children was 11.1y ± 3.4, with 46/71 males and 25/71 females and a mean cIMT of 0.504mm ± 0.062. There were 43/71 pre-dialysis CKD patients and 28/71 on chronic dialysis. The mean cIMT and mean arterial pressure(MAP) were greater in patients on dialysis (0.530mm ± 0.067 and 92.00mmHg ± 2.67) when compared to the pre-dialysis CKD patients (0.488mm ± 0.054 and 80.44mmHg ± 2.54), and there was a significant difference between the means (p=0.005 and 0.004). There was a significant positive correlation of cIMT with MAP, blood urea, alkaline phosphatase and PTH levels (p<0.05). There was also a significant negative correlation of cIMT with haemoglobin levels (p<0.05). Duration on dialysis also showed a positive correlation with cIMT. After adjusting for the various correlates in a multivariate regression model, only MAP had a significant association with cIMT (p=0.023).

	cIMT r (p value)
Age (yr) n=71	0.069 (0.567)
Duration on dialysis (months) n=28	0.459 (0.014)
MAP (mmHg) n=71	0.261 (0.028)
Hb (g/dl) n=71	-0.405 (0.001)
Urea (mmol/l) n=71	0.242 (0.042)
Ca (mmol/l) n=71	-0.201 (0.093)
Alkaline Phosphatase (U/l) n=71	0.256 (0.031)
PTH (pmol/l) n=71	0.357 (0.002)
Ferritin (ug/l) n=71	0.220 (0.065)
Urine protein/creatinine (g/mmol) n=47	0.242 (0.101)

Conclusions: MAP is an independent correlate of cIMT in both pre dialysis and dialysis CKD children.

TH-PO603

Circulating Mid-Region Pro-Adrenomedullin Is Associated with Abnormal Aortic Pulse Wave Velocity in Pediatric Chronic Kidney Disease Isaac Liu,[1] Qiao-Zhi Chee,[1] Mya Than,[1] Lingli Gong,[2] Josephine Berboso Lunaria,[2] Teng Hiang Heng,[1] Chloe Chan,[1] Yew Weng Perry Lau,[1] Wee Song Yeo,[1] Lieng H. Ling,[2] Mark Richards,[2] Yiong Huak Chan,[3] Kar Hui Ng,[1] Hui Kim Yap.[1] *[1]Shaw-NKF-NUH Children's Kidney Center, KTP-Univ Children's Medical Inst, National Univ Health System, Singapore; [2]Cardiovascular Research Inst, National Univ Health System, Singapore; [3]Biostatistics Unit, Yong Loo Lin School of Medicine, National Univ of Singapore, Singapore.*

Background: Children with chronic kidney disease (CKD) are at risk of early arteriopathy and aortic pulse wave velocity (PWV) is a predictor of cardiovascular mortality. This study examined its association with circulating biomarkers such as mid-region pro-adrenomedullin (MR-proADM).

Methods: Cross-sectional analysis of baseline parameters was carried out in a cohort of 67 (39 male) consecutive patients (mean age 14.2±6.3 years) with CKD stage 2–5D (mean duration of disease 10.6±6.4 years). Aortic PWV was measured by B-mode ultrasound. MR-proADM, N-terminal pro-B-type natriuretic peptide (NT-proBNP), asymmetric dimethylarginine (ADMA), and high-sensitivity C-reactive protein were measured along with routine biochemical parameters including hemoglobin, uric acid, calcium, and phosphate. Univariate and multivariate logistic regression was performed to examine associations between abnormal PWV (>2 SD for height) and biomarkers with performance of ROC analysis.

Results: Thirteen (19.4%) patients had abnormally increased PWV. On univariate analysis, phosphate (OR 3.17; 95%CI 1.01–9.98; p=0.048) and MR-proADM (OR 2.50; 95%CI 1.30–4.82; p=0.006) were significantly associated with abnormal PWV. On multivariate logistic regression, MR-proADM remained independently associated with abnormal PWV (OR_{adj} 4.37; 95%CI 1.18–16.19; p=0.027). MR-proADM discriminated normal from elevated PWV by ROC analysis (AUC=0.75; 95% CI 0.60–0.90; p=0.005). MR-proADM >1.44 nmol/L, had 85% sensitivity and 67% specificity for detection of elevated PWV.

Conclusions: MR-proADM is an independent identifier of abnormally increased aortic PWV, and may be useful for predicting arteriopathy in children with CKD.

TH-PO604

Improving Blood Pressure Control in a Pediatric Chronic Kidney Disease Population

Donna J. Claes,[1] Masatoshi Ashiki,[2] Devesh S. Dahale,[2] David K. Hooper.[1] *[1]Div of Pediatric Nephrology, Cincinnati Children's Hospital, Cincinnati, OH; [2]James M Anderson Center of Healthcare Excellence, Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Intensive blood pressure (BP) control can slow pediatric chronic kidney disease (CKD) progression, yet many have untreated or uncontrolled BP. We wished to understand how system-level interventions would improve systolic BP (SBP) control.

Methods: We developed an EMR CKD registry, pre-visit planning, and patient care tools that displayed the 3 previous clinic SBP and achievement of CKD care goals. The registry was queried monthly for the last clinic SBP%. Using cross-sectional analysis or statistical process control (SPC), we assessed 1) 5 "perfect BP measurement" elements 2) anti-hypertensive therapy in pts with SBP > 75%, & 3) controlled clinic SBP to < 90%, 75%, or 50%. Results were limited to CKD stage 2-4 pts between 2-18 yrs of age.

Results: 494 visits occurred in 119 patients (57% male, avg 1.9 visits/pt/yr) during the study. CKD etiology was non-glomerular (57%), glomerular (11%), or unknown/undocumented (32%) in origin. The median creatinine (Schwartz)-based eGFR was 56 ml/min/1.73 m2; 85 (71%) had a cystatin C eGFR > 45 ml/min. 34 (29%) were overweight; 22 (19%) were obese (BMI > 85% vs 95% for age & gender, respectively). "Perfect BP measurement" was documented 81% of the time. There was no significant increase in anti-hypertensive med Rx in pts with SBP > 75% (from 61% to 71%; p=0.34). Pts prescribed BP medications (n=70) had similar CKD severity compared to untreated patients. Median cycle time between current & previous SBP reading was prolonged overall (9.3 m), with no difference between treated and untreated pts (8.9 vs 10.1 m; p=0.33). From 2/2014 to 4/2016, we observed improvement in SBP control to < 75% (56% to 72%; p=0.03); there was no change in SBP control to < 90% (80 vs 85%) or < 50% (33% vs 39%).

Conclusions: System-level interventions led to improved SBP control to < 75% in a pediatric CKD population. Further interventions to optimize medication dosing, reduce cycle time in those with elevated SBP, and recognize & mitigate barriers to adherence are all hypothesized to improve BP control in this population.

TH-PO605

Genomic Imbalances in Children with Chronic Kidney Disease

Beata S. Lipska-Zietkiewicz,[1] Magdalena Koczkowska,[1] Elke Wuehl,[2] Craig S. Wong,[3] Anette Melk,[4] Uwe Querfeld,[5] Franz S. Schaefer.[2] *[1]Medical Univ of Gdansk, Poland; [2]Univ of Heidelberg, Germany; [3]Univ of New Mexico; [4]Hannover Medical School, Germany; [5]Charite Berlin, Germany.*

Background: Chromosomal microarrays are routinely utilized for genetic testing of developmental delay/intellectual disability, autism spectrum disorders or multiple congenital anomalies. Here, we studied the prevalence of DNA copy number variations (CNVs) in a large cohort of European and Turkish children presenting with chronic kidney disease.

Methods: 998 consecutive patients enrolled in the ESCAPE and 4C studies were genotyped at ~2.4 millionsingle-nucleotide polymorphism (SNP) markers using the Illumina Infinium 2.5M microarray. Data was interpreted in accordance to ACMG Practice Guidelines using the Nexus Copy Number software. Filtering criteria included the size of imbalance, overlap with known benign CNVs, gene content, and verification against Decipher and ISCA databases.

Results: Three out of forty patients with clinically suspected syndromic disease were molecularly confirmed. Among 958 children without overt syndromic features, 39 (4.1%) were classified as having a definite pathogenic genomic aberration, and another 11 as having a likely pathogenic CNV. Definite diagnoses were made in 4.4% of individuals with CAKUT, 4.1% of patients with a glomerulopathy and 2.9% of those with a tubulointerstitial disorder. The most frequent imbalances were 17q12 deletions encompassing the *HNF1B locus* (n=9), 1q21.1 deletions including the *CHD1L* gene (n=7) and rearrangements at 22q11.2 (n=5). Small, including single gene, rearrangements were reported for *CTNS, EYA1, HNF1B, PKD1, TSC2, FAM58A, BMP2* and *TFAP2A loci*.

Conclusions: The detection of a genomic imbalance allowed for reverse phenotyping in most cases, resulting in clinical interventions such as evaluation for extra-renal involvement and multidisciplinary care. Genomic disorders account for a small but significant portion of children with CKD and their diagnosis has important implications for genetic counseling and clinical management.

TH-PO606

Office Blood Pressure Has Similar Associations with ESRD and Death as 24 Hour Ambulatory Blood Pressure in Hypertensive CKD

Elaine Ku,[1] Charles E. McCulloch,[1] Francis B. Gabbai,[2] Joachim H. Ix,[2] Chi-Yuan Hsu.[1] *[1]UCSF; [2]UCSD.*

Background: Although ambulatory blood pressure monitoring (ABPM) is considered the best method of assessing blood pressure, few studies have performed comparisons of the ability of ABPM vs. office blood pressures (BPs) to discriminate risk of adverse outcomes in patients with CKD.

Methods: In the African American Study of Kidney Disease Cohort (AASK) study (N=527), we compared office vs. ABPM BPs in their prediction and discrimination of risk for two outcomes: i) concurrent left ventricular hypertrophy (N=285) by echocardiography and ii) subsequent ESRD or death (N=267). Unadjusted models were used to compare the association between these outcomes and i) one office systolic (SBP) or diastolic (DBP) reading vs. ii) mean 24 hour SBP or DBP ABPM readings taken concurrently. C-statistics were determined for all models, and net reclassification indices (NRI) determined in models where ABPM was added to office BPs.

Results: For all outcomes, c-statistics were similar for models with office vs. ABPM BPs, and differences in the c-statistics did not achieve statistical significance for either SBP or DBP (all p>0.05). There was no improvement in NRIs when ABPM BPs were added to office BPs (all p>0.05).

	Odds ratio for LVH for every 10 mm Hg higher BP (95% CI)	**C-statistic for LVH** (95% CI)	**Hazard ratio for ESRD or death with every 10 mm Hg higher BP** (95% CI)	**C-statistic for ESRD or death** (95% CI)
Office SBP	1.10 (1.01-1.20)	0.56 (0.51-0.61)	1.12 (1.06-1.19)	0.57 (0.52-0.59)
Mean 24 hour SBP	1.14 (1.03-1.27)	0.56 (0.52-0.62)	1.19 (1.11-1.28)	0.57 (0.53-0.61)
Office DBP	1.03 (0.89-1.20)	0.52 (0.47-0.56)	1.17 (1.05-1.30)	0.54 (0.50-0.57)
Mean 24 hour DBP	1.06 (0.90-1.25)	0.52 (0.47-0.57)	1.20 (1.07-1.35)	0.55 (0.51-0.58)

Conclusions: A single office BP measurement taken in a standardized, protocol-driven setting in AASK is not inferior to ABPM in the discrimination of BP-related adverse outcomes. Overall, the discrimination of the risk for outcomes by office or ABPM BPs was poor. Future studies may need to consider the discriminatory performance of ABPM vs. office BPs when comparing their informative value.

TH-PO607

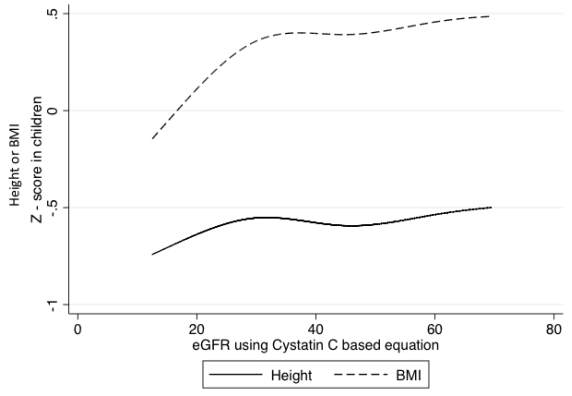
BMI and Height Trajectory with Declines in Kidney Function in Children with CKD

Elaine Ku,[1] Charles E. McCulloch,[1] Joel D. Kopple,[2] Mark Mitsnefes,[3] Kirsten L. Johansen.[1] *[1]UCSF; [2]Harbor-UCLA; [3]Univ of Cincinnati.*

Background: Protein-energy wasting and short stature are associated with poorer prognosis for children with CKD. However, few studies have rigorously described the relationship between CKD progression and longitudinal weight or height changes. We examined weight (assessed by changes in body mass index [BMI]) and height trajectory with declines in renal function over time in children in the Chronic Kidney Disease in Children (CKiD) cohort study.

Methods: We included 836 participants with CKD for longitudinal analysis. Weight, height, and serum cystatin C were measured annually. All BMI and height values were converted into age and sex standardized z-scores using Center for Disease Control normative standards. We used segmented, mixed effects regression for modeling the repeated measures of BMI z-score and linear mixed models for modeling height z-scores as a function of estimated GFR (using the 2012 Schwartz equation).

Results: Mean BMI z-score was 0.46, and mean height z-score was -0.55 at baseline. During mean follow-up of 3.1 years, BMI z-score was stable until eGFR of approximately 30 mL/min/1.73m^2. When eGFR dropped below 30 mL/min/1.73 m^2, a 0.3 (95% CI 0.2, 0.4) decline in BMI z-score was noted with each 10 mL/min/1.73 m^2 decline in eGFR. The associations between eGFR and BMI z-score trajectory before and after an eGFR of 30 mL/min/1.73 m^2 were statistically significantly different (p<0.001). In contrast, for height, there was a continuous and linear 0.01 decrease in height z-score with every 10 mL/min/1.73 m^2 decline in eGFR.



Conclusions: In children with CKD, steeper declines in BMI mostly occur when eGFR is ≤30 mL/min/1.73 m^2, whereas height exhibited a continuous and linear decline with advancing CKD. Further research is needed to determine whether earlier interventions to prevent weight loss and improve height accrual with advancing stages of CKD will improve outcomes.

Funding: Other NIH Support - NHLBI

Disparities in Transplant Access Partially Mediate Higher Risk of Mortality in Black versus White Children with ESRD Elaine Ku, Charles E. McCulloch, Barbara A. Grimes, Kirsten L. Johansen. *UCSF.*

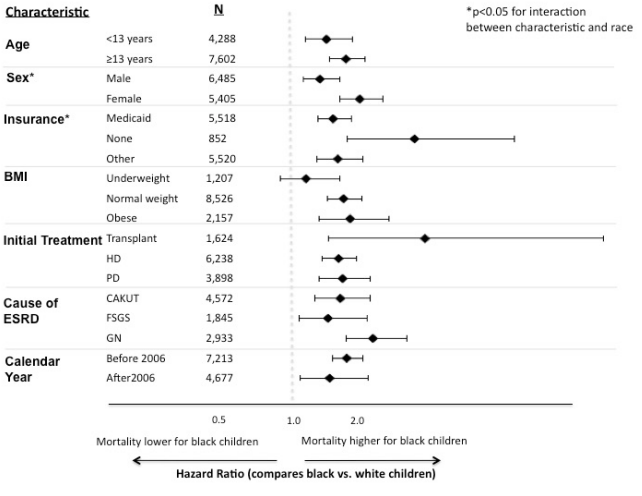
Background: Although black race is associated with worse health outcomes in the general population, observational studies have reported that black adults receiving dialysis have paradoxically better survival than their white counterparts. Whether this racial "survival paradox" exists in children with ESRD is unclear. Our objective was to compare the mortality risk among black versus white children treated with renal replacement therapy.

Methods: Retrospective analysis of mortality risk in black (N=8,782) or white (N=3,108) children who developed ESRD between 1995-2011 and were followed through 2012 in the national ESRD registry (US Renal Data System) using Cox models.

Results: During median follow-up of 7.1 years, 8,791 transplants and 1,579 deaths occurred. Risk of death was 1.58 times higher in black vs. white children (95% CI 1.42-1.76).

Overall cohort (N=11,890)	Hazard ratio (95% CI)	P-value
Unadjusted model	1.86 (1.68-2.05)	<0.001
Adjusted model*	1.58 (1.42-1.76)	<0.001
Adjusted model with transplant as time dependent covariate*	1.21 (1.08-1.34)	0.001
*Adjusted for co-variates listed in Figure		

The higher risk of death in black (vs. white) children did not differ significantly by age category, body mass index, initial treatment modality, cause of ESRD, or calendar period (all p>0.05 for interaction), but did differ by sex (p=0.003) and insurance status (p=0.04) such that the disparity was more pronounced among girls and children without insurance.



Adjustment for transplant as a time dependent covariate attenuated, but did not abolish, the higher risk of death in black children (HR 1.21 [95% CI 1.08-1.34]).

Conclusions: We did not find evidence of a racial survival paradox in children treated with dialysis. Instead black children had higher mortality than white children, which was explained, in part, by differences in access to transplantation.

Chronic Kidney Disease in Rural Indigenous Children: The FINISHED Screen/Triage/Treat Program Allison Dart,[1] Barry Ad Lavallee,[2] Caroline D. Chartrand,[2] Lorraine L. Mcleod,[2] Thomas W. Ferguson,[3] Navdeep Tangri,[3] Audrey Gordon,[3] Tom D. Blydt-Hansen,[4] Claudio Rigatto,[3] Paul Komenda.[3] *[1]Children's' Hospital Research Inst of Manitoba, Univ of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Diabetes Integration Project, Winnipeg, MB, Canada; [3]Internal Medicine, Univ of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [4]Pediatrics, Univ of British Columbia, Vancouver, BC, Canada.*

Background: Indigenous populations have high rates of chronic kidney disease (CKD), and progression to kidney failure on average 10 years prior to other ethnic groups. Burden of early disease in children is a key knowledge gap with important implications for prevention and treatment strategies. We sought to evaluate the prevalence of CKD and associated risk factors in youth from rural Indigenous communities.

Methods: The First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) project actively screened 11 rural First Nation communities in Manitoba, Canada. Body mass index (BMI), blood pressure, urine albumin-to-creatinine ratios (ACR), estimated GFR's (eGFR) and hemoglobin A1c's (A1c) were evaluated. CKD was defined by eGFR <90ml/min/1.73m2 and/or ACR >3mg/mmol.

Results: 353 Indigenous youth 10-17 years were recruited after community and school engagement. The median age was 12 years (IQR 10 – 13) and 55% were female. Fifteen percent of youth were identified with CKD. Fifty-five percent were overweight/obese, 5.4% had hypertension and 11.9% had pre-hypertension. Diabetes was identified in 1.4%, and 1.4% had pre-diabetes with A1c's between 6.1 and 6.49%. Although 31.8% of the overweight/obese group had hypertension or CKD, 54.7% of the group with CKD had no other risk factors.

Conclusions: CKD and associated risk factors are highly prevalent in rural Indigenous children. This study highlights the need to evaluate the efficacy of screening and intervention strategies in Indigenous children to slow the progression of kidney failure and address this critical population health issue.

TH-PO610

Systemic Anticoagulation with Enoxaparin in Children with End Stage Renal Disease Receiving Hemodialysis or Peritoneal Dialysis Sun-Young Ahn,[1] Asha Moudgil,[1] Kirtida Mistry,[1] Yaser A. Diab.[2] *[1]Nephrology, Children's National Health System, Washington, DC; [2]Hematology, Children's National Health System, Washington, DC.*

Background: Due to predictable pharmacokinetics (PK) and anticoagulation response, enoxaparin is the preferred anticoagulant in children. However, enoxaparin is renally cleared and bioaccumulation over time leading to over-anticoagulation and increased bleeding risk is a concern in End Stage Renal Disease (ESRD). The effect of Hemodialysis (HD)/Peritoneal Dialysis (PD) on enoxaparin PK is not clearly understood and there are no reports on the safety and efficacy of enoxaparin in pediatric dialysis patients. We report our center's experience with a recently implemented protocol for enoxaparin anticoagulation in children with ESRD receiving HD or PD.

Methods: Enoxaparin was initiated at an age- and weight-based dose administered at half the standard frequency (once daily) after HD or PD. Peak and trough anti-Factor Xa (anti-FXa) levels were monitored closely and dose and/or frequency were adjusted to achieve target peak anti-FXa levels and maintain trough anti-FXa ≤0.3 U/mL. We retrospectively reviewed the records of patients on dialysis who received enoxaparin for treatment or prevention of thromboembolism according to this protocol.

Results: 9 patients (3 males, median age 4 years) with ESRD on HD(5) or PD(4) received 10 enoxaparin courses (5 therapeutic, 5 prophylactic) per our protocol. 8 patients had at least 2 thrombophilic risk factors, with factor VIII elevation being the most common risk factor (63%). At the time of this study, the median duration of anticoagulation was 4.5 months (1-32) with 5 patients still receiving enoxaparin. Bioaccumulation was observed in 3 patients receiving daily therapeutic enoxaparin (2 PD, 1 HD) which resolved after adjusting the dose frequency to every other day. There were no anticoagulation failures or bleeding complications.

Conclusions: Enoxaparin is a feasible option for systemic anticoagulation in children on HD or PD but requires close laboratory monitoring to ensure safe and optimal anticoagulation. Larger studies are needed to clarify safety and efficacy of our protocol.

TH-PO611

Assessment of the Long-Term Safety and Efficacy of Multiple Doses of C.E.R.A. (Continuous Erythropoietin Receptor Activator – Methoxy Polyethylene Glycol-Epoetin β) for Maintenance Treatment of Anemia in Pediatric Patients with Chronic Kidney Disease (CKD) on Hemodialysis (HD) (NH19707, NCT00717366) Michel Fischbach,[1] Elke Wuehl,[2] Sylvie C. Meyer Reigner,[3] Zoe Morgan,[3] Franz S. Schaefer.[2] *[1]Univ Hospital Strasbourg, CHU HautePierre, Strasbourg, France; [2]Heidelberg Univ Hospital, Heidelberg, Germany; [3]F. Hoffman-La Roche Ltd, Basel, Switzerland.*

Background: The objective of this study was to document the long-term safety and efficacy of C.E.R.A. administration in pediatric patients with anemia associated with CKD.

Methods: This open-label multicenter study included a 2-week screening period, 16-week dose-titration period, and 4-week evaluation period. Stable patients (hemoglobin

[Hb] within ± 1 g/dL of baseline and between 10 and 12 g/dL) could enter a 1-year optional safety extension. Patients aged 6–17 years on HD with stable chronic renal anemia were given C.E.R.A. every 4 weeks at a starting dose determined by previous epoetin alfa/beta or darbepoetin dosing. Two conversion factors were tested sequentially. In the optimum dose group the starting dose was 4 µg for each weekly dose of 125 IU epoetin alfa/beta or 0.55 µg darbepoetin.

Results: 64 patients were enrolled, including 48 in the optimum dose group, and 47 finished the core phase. 37 entered the safety extension and 17 completed 73 weeks of treatment. Most withdrawals were due to renal transplantation. In the optimum dose group (mean age 13 years), median doses at the point the patient exited the study were 2.51 and 2.36 µg/kg/4 weeks for 6–11 and 12–17 year olds, respectively. Hb concentrations over time in response to adjusted doses of C.E.R.A. were stable. 70% of patients overall had an Hb value within 10–12 g/dL at the point they exited the study and 62% were within ± 1 g/dL of baseline. The overall pattern of reported adverse events was similar to that observed in studies in adult patients. No new safety signal was detected.

Conclusions: C.E.R.A. was efficacious in maintaining stable Hb levels in pediatric patients on HD with stable anemia of CKD when switched from maintenance treatment with epoetin alfa/beta or darbepoetin. Safety was consistent with the known safety profile for C.E.R.A. in adults.

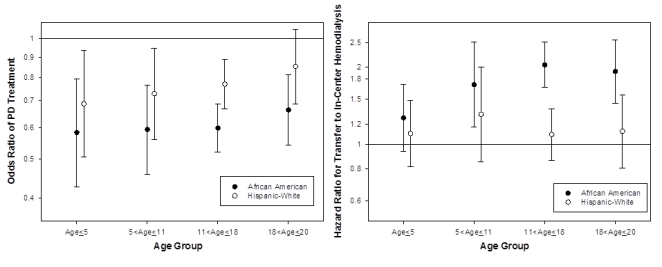
Racial/Ethnic Disparities in Use of Peritoneal Dialysis and Transfer to In-Center Hemodialysis among Pediatric Patients

Melissa Soohoo,[1] Elani Streja,[1] Matthew B. Rivara,[2] Scott V. Adams,[2] Connie Rhee,[1] Keith C. Norris,[3] Kamyar Kalantar-Zadeh,[1] Rajnish Mehrotra.[2] *[1]UC Irvine; [2]Univ of Wash.; [3]UCLA.*

Background: Racial/ethnic disparities exist in adult end-stage renal disease(ESRD) patients, showing that minorities are less likely to utilize peritoneal dialysis(PD) and African-Americans are more likely to transfer off of PD, compared to whites. PD is increasingly used for treating ESRD; however, racial/ethnic differences in utilization and outcomes among pediatric PD patients remain understudied.

Methods: We used logistic regression to examine the odds of PD use according to race/ethnicity among 14,109 pediatric(age<20 years) patients who initiated dialysis between 2000-2013 and treated for at least 60 days during follow-up, according to USRDS records. Among 6,551 pediatric PD patients, we used competing risk regression to examine the association of race/ethnicity with mortality, transplantation and transfer to in-center hemodialysis. Models were stratified by age at ESRD incidence and adjusted for cause of ESRD, demographics and socioeconomic factors.

Results: Among pediatric patients, African-Americans <20 years old and Hispanic whites ≤18 years old were less likely to use PD, compared to whites. The cohort treated with PD was comprised of 48% whites, 25% African-Americans and 27% Hispanic whites. We did not observe significant racial/ethnic survival differences while using PD. However, African-Americans and Hispanic whites had a lower risk of receiving a kidney transplant while on PD compared to whites. Finally across strata of age, African-American patients ≥5 years old had a higher risk of transferring to in-center hemodialysis(ref:whites).



Conclusions: Racial/ethnic and age disparities are present in the utilization of PD as well as transplantation and transfer to in-center hemodialysis among pediatric PD patients. Additional studies are needed to better understand the reasons for these differences.

Peritoneal Expression of Antimicrobial Ribonucleases in Pediatric Patients Undergoing Chronic Peritoneal Dialysis

Neha Dhingra,[1] Rose M. Ayoob,[1] Brian Becknell.[1,2] *[1]Nephrology Section, Nationwide Children's Hospital; [2]Center for Clinical and Translational Research, Nationwide Children's Hospital.*

Background: Peritoneal dialysis (PD) is the most common dialysis modality for children with End Stage Renal Disease (ESRD). PD catheter-related infections cause significant morbidity and mortality in children. Antimicrobial peptides serve critical roles in epithelial defense throughout the body, but their roles in the peritoneum are mostly unexplored. The Ribonuclease (RNase) A superfamily encodes multiple AMPs with potent microbicidal activity against pathogens implicated in peritonitis. We hypothesize that antimicrobial RNases are present in the peritoneum of children undergoing PD.

Methods: With institutional review board approval, we recruited 7 patients from our dialysis unit aged 3-21 years on chronic continuous cycling PD (CCPD). Up to 200 ml of PD effluent was collected from each patient, prior to starting nightly PD. Viable cells were isolated by centrifugation, and subject to protein extraction. Antimicrobial RNases and the Ribonuclease Inhibitor (RNH1) were detected by immunoblotting. RNase activity was measured by tRNA hydrolysis. Since these patients underwent omentectomy at the time of PD catheter placement, we localized RNases in omentum by immunostaining.

Results: RNase activity was detectable in PD effluents, which expressed RNase3, RNase6, and RNase7 proteins by immunoblotting. When effluents were subject to centrifugation, the RNase3, RNase6, and RNH1 proteins were detectable in the leukocyte-rich cellular sediment. Within omentum, RNase3 and RNase6 localized to neutrophils and mononuclear leukocytes, whereas RNase7 localized to mesothelium.

Conclusions: Leukocytes and mesothelial cells collaborate to release antimicrobial RNase3, RNase6, and RNase7 into human peritoneal fluid in the absence of peritonitis. This process is likely under tight regulation by RNH1, to prevent RNase cytotoxicity. These findings have important ramifications for our understanding of mechanisms governing sterility within the peritoneal space. Strategies aimed at enhancing antimicrobial RNase levels and activity may reduce the incidence and severity of infectious peritonitis in ESRD patients.

Hemodialysis in Neonates and Infants: A Systematic Review

Prashanth Vijayaraghavan,[1] Mohit Gupta,[2] Ramya Vajapey,[3] Jessica Darusz,[4] Siddharth Sethi,[5] Gaurav Kapur,[6] Rupesh Raina,[2] Vinod Krishnappa.[1] *[1]Akron Nephrology Associates, Akron, OH; [2]Internal Medicine, Akron General Medical Center, Akron, OH; [3]Northeast Ohio Medical Univ, Rootstown, OH; [4]Akron Nephrology Associates, Parma, OH; [5]Kidney and Urology Inst, Medanta, India; [6]Children's Hospital of Michigan.*

Background: Hemodialysis (HD) in neonates and infants is difficult to implement and maintain due to a lack of machines adapted to neonatal blood flow volumes. Subsequent issues include hemodynamic instability and difficult vascular access. Hence, peritoneal dialysis is preferred in neonates and infants. The purpose of this study was to systematically review HD and discuss innovations in HD for neonates and infants.

Methods: PubMed was searched for "hemodialysis", along with the Medical Subject Heading term, "infant". 1,310 potential matches were returned, of which 9 studies met inclusion and exclusion criteria. Pooled descriptive statistics were calculated, weighted according to the number of subjects in each study. Data regarding patient characteristics, hemodialysis indications, parameters, and patient outcomes was recorded.

Results: The total number of subjects across the nine selected studies was 104, with a mean age of 3.1 months (range: 2 days to 12 months). Among all subjects there was a 62% survival rate. Indications for HD included inborn errors of metabolism, acute kidney injury, and renal dysplasias. The most common complications were catheter dysfunction, hypotension, and anemia.

Total Patients	Average Age	Survival Rate	Transplant Rate	Common Causes for HD	Type of HD
104	3.1 months	62%	33%	Inborn errors of Metabolism (42%)	Acute (36.5%)
				Acute Kidney Injury (32%)	Chronic (63.5%)
				Renal Dysplasia (17%)	

Conclusions: Indications for hemodialysis included acute renal failure, primary intrinsic renovascular disorders, inborn errors of metabolism, and intoxications. Hemodialysis techniques used for neonates and infants included blood priming of extracorporeal circuits, minimizing extracorporeal circuit volumes and use of smaller catheters. This paper concludes with a discussion of techniques that are best suited for neonates and infants.

TH-PO615

Pediatric Intradialytic Hypotension: A Systematic Review

Prashanth Vijayaraghavan,[2] Mohit Gupta,[1] Vinod Krishnappa,[2] Gaurav Kapur,[3] Siddharth Sethi,[4] Rupesh Raina.[1] *[1]Internal Medicine, Akron General Medical Center, Akron, OH; [2]Akron Nephrology Associates, Akron, OH; [3]Children's Hospital of Michigan, Detroit, MI; [4]Medanta, Medicity Hospital, India.*

Background: Intradialytic hypotension (IDH) is commonly encountered in pediatric patients that receive hemodialysis (HD) sessions lasting 4 hours. The purpose of this study was to systematically review publications discussing IDH in pediatric patients and preventive measures taken in the particular patient population.

Methods: PubMed/MEDLINE was searched for the terms "hemodialysis" and "hypotension", with the word "peritoneal" excluded. The Medical Subject Heading (MeSH) terms included hypotension, infant, child, or adolescent, again with the word "peritoneum" excluded. 183 potential matches were returned, of which 11 met inclusion and exclusion criteria.

Results: The total number of subjects across the ten selected studies was 148 with ages ranging from 2 days – 18 years old, patient weight ranged from 3.2 kg to 61.4 kg. Non-invasive blood monitoring (NIVM) was implemented with HD in 65% of patients. Ultrafiltration (UF) strategies were not uniform across all studies. UF either remained constant throughout study duration or UF profiles were implemented based on changes observed in dry weight. Similar to UF, sodium levels were not synonymous across studies and either remained constant or sodium ramping in linear and/or stepwise fashion was observed. Although not reported in all studies, percent frequency of hypotensive events ranged from 19.6% - 75%, with lower percentages observed in patients who received NIVM during HD.

Conclusions: Among studies reviewed, use of NIVM was helpful in achieving appropriate dry weight as well as predicting and preventing intradialytic hypotension. Although such findings appear significant, studies reviewed had small patient populations and relatively short study durations. Hence, future studies involving larger study populations and NIVM utilization with the goal of reducing episodes of intradialytic hypotension will be necessary in determining the effectiveness of this approach in HD therapy in pediatric patients.

TH-PO616

Interinstitutional Cooperation Program in Pediatric Kidney Transplantation and the Impact on Transplantation Count Maria Goretti M.G. Penido, Marcelo S. Tavares, Carolina Moura Diniz Ferreira Leite, Mariana G. Penido de Paula, Felipe B.P. De Caux. *Pediatric Nephrology Unit, Santa Casa de Belo Horizonte, Belo Horizonte, MG, Brazil.*

Background: Kidney transplantation is the preferred treatment for the end stage of chronic renal disease in children and adolescents. The aim of this study was to evaluate an interinstitutional cooperation program between an experienced pediatric transplantation center and a developing center in other state, 600 km apart, and the count of kidney transplantation surgeries performed during the 3-year duration of the cooperation.

Methods: The cooperation consisted of short periods of fellowship (max 1 month) of pediatric nephrology residents, nurse and 2 physicians (one ped-nephrologist and 1 surgeon), along a 3-year period, as well as weekly teleconferences for case discussions once a week. The yearly count of pediatric kidney transplants (p-KT) in the developing center along the period was compared to the national mean as well to the state's mean.

Results: Since 2011, thirty pediatric patients were transplanted, 1 in 2011, 1 in 2012, 8 in 2013, 8 in 2014 and 12 in 2015. The interinstitutional program was held between 2012 and 2014. In comparison to the national count of p-KT, the developing center was responsible for 0.34% (2011), 0.26% (2012), 2.59% (2013), 2.29% (2014) and 3.79% (2015) of all p-KT. The analysis of the p-KT performed within the state showed that the developing center had a progressive participation on this procedure: 5% (2011), 3.2% (2012), 34.7% (2013), 36.3% (2014) and 46.15% (2015). However, there was a fall on the total count of p-KT during the period until 2014, but rose in 2015: 20 (2011), 31 (2012), 23 (2013), 22 (2014) and 26 (2015).

Conclusions: The results reflect a successful case of interinstitutional cooperation program that was valid for the development of a p-KT center, with progressive results. Investments in educational campaigns, targeting specifically the medical community as well the general public may allow an even higher increase of p-KT counts in the coming years. The model may be valid for localities with same goal of increasing the number of kidney transplantations.

TH-PO617

Latin America Pediatric Urolithiasis Register: Preliminary Report Maria Goretti M.G. Penido, Michelle M. Lopez, Nilzete Liberato Bresolin, Laura Alconcher, Mary Velasco, Stella M. Dieguez, Ana Paula Spizzirri, Jose Maria Ojeda, Judith Exantus, Morgana De Moro, Marcela Thiemi Korogi, María A. Colina. *Latin America Pediatric Urolithiasis Register - Multicentric Study.*

Background: Considering the socioeconomic and geographic variables, the objective of this study was to outline an epidemiological profile of primary pediatric urolithiasis in Latin America.

Methods: This is an observational, descriptive and retrospective study of pediatric patients with confirmed urolithiasis from Pediatric Nephrology Centers of Latin American from December of 1995 to December of 2015. Data were collected from medical records and placed at a database created online. The study was approved by each institutional review board.

Results: Of the 512 patients (58%M) all had normal serum creatinine, electrolytes and minerals. Urolithiasis was diagnosed by ultrasound in 80% of cases and by computerized tomography in 20%. Median age at diagnosis was 8,0 years (4,9-11,0). Microscopic or gross hematuria (36%), as well as flank or abdominal pain (58%) were the most common clinical presentations. Family history of kidney stones was positive in half of the cases (51%). The most common metabolic urinary abnormalities were idiopathic hypercalciuria (63%) and idiopathic hypocitraturia (52%), alone or in combination with other abnormalities. 22% of the patients had urine flow less than 1.0 ml/kg/hour, 30% had hyperuricosuria and 11% had mild idiopathic absorptive hyperoxaluria. Twenty-five patients had cystinuria (5%) and in 20% no metabolic abnormalities were found. The majority of kidney stones were unilateral (76%) and most of the patients had from 1 to 4 stones (80%).

Conclusions: Despite some differences between the populations, the leading causes of primary pediatric urolithiasis in Latin America were idiopathic hypercalciuria, followed by idiopathic hypocitraturia and "oliguria". The male-female ratio was almost equal, with a slight predominance of males. The diagnosis was done by ultrasound in the majority of the cases and hematúria associated to abdominal or flank pain was the most common clinical presentation. The finding of near similarity between the populations studied calls for combined efforts in addressing these challenging matters.

TH-PO618

Incidence and Clinical Impact of Cytomegalovirus in Pediatric Kidney Transplantation: Ten Years of Experience in a Single Center Liliana Rubio. *Pediatric Nephrology, Hospital Univ San Vicente Fundación, Medellin, Antioquia, Colombia.*

Background: Cytomegalovirus is opportunistic agent after transplantation, pediatric recipients are more likely to be CMV seronegative 62.7%. This study evaluated incidence CMV infection/disease and risk factors after transplantation and usefulness of prophylaxis with valganciclovir.

Methods: 56 pts. 1 to 15 yrs underwent transplantation, during 10 yrs. Pre transplantation test was done for CMV status using enzyme-linked assay for IgG antibodies. D+/R+,D+/R-,D-/R+ received prophylaxis, IV ganciclovir (5mg/Kg/BID) was given at 55% of the pts for two weeks, mean dose was 175,2 mg/day during 9,8 days followed by valganciclovir once a day at 100 % of pts. The dose was (mg)= 7 x surface area (m2) x creatinine clearance (mL/min per 1,73 m2). The mean daily dose of valganciclovir was 501mg/day for 125 days.

Results: CMV Serostatus: R+/D-n=4,R+/D+n=42,R-/D+n=10. Seven pts (12,5%) had CMV viremia, one patient had detectable CMV viremia before prophylaxis began, remaining 6 were positive after prophylaxis ended. The development of viremia was 54 days, the number of transplant with viremia positive was 5 in 100 days and 1 after 200 days. CMV disease occurred in 10,7% all received 100 days prophylaxis. The univariated analysis shows that the highest risk group of CMV viremia was D+/R- with 40 % of cases and that D+/R- increases 9.5 times the risk of CMV infection. (p= 0.01).

	Value p	OR	I.C. 95% EXP(B)	
			Low	High
Donor	0,010	9,556	1,705	53,550

Younger age of recipient was associated with higher incidence of infection, 7 yrs vs 10.5 yrs in the CMV-negative infection.

Conclusions: Kidney transplants recipients at highest risk for CMV viremia are those without preexistent CMV specific immunity. The main strategy against CMV in pediatric renal transplantation is universal prophylaxis with valganciclovir. Extending prophylaxis to 6 months in high-risk kidney transplantation is a recommendation that appears to provide a significant benefit.

PH1 Mutation p.Gly170Arg+ Urine Proteomics Ellen Brooks,[1,2] Dawn S. Milliner,[3] Bernd Hoppe,[4] Eduardo C. Salido,[5] Heather Price,[2] Craig B. Langman.[1,2] *[1]Feinberg School of Medicine, Pediatrics, Northwestern U, Chicago, IL; [2]Kidney Diseases, Ann & Robert H Lurie Children's Hosp of Chicago, Chicago, IL; [3]Nephrology, Mayo Clinic, Rochester, MN; [4]Pediatric Nephrology, U Hospital Cologne, Cologne, Germany; [5]Centre for Biomedical Research on Rare Diseases, U of La Laguna, Hosp U de Canarias, Tenerife, Canary Islands, Spain.*

Background: Primary hyperoxaluria type 1 (PH1) is a rare disorder with>100 mutations (m) in the liver peroxisomal alanine:glyoxylate aminotransferase (AGXT) gene that leads to hepatic oxalate (Ox) overproduction. Except for the homozygous (HOM) or heterozygous (HET) p.Gly170Arg AGXTm, limited genotype-phenotype correlation exists. Daily pyridoxine (Vit B_6) therapy may reduce or normalize urine (Ur) Ox in Gly170Arg$^+$patients.

Methods: Targeted multiplexed proteomic immunoassays of 24 hr. Ur (Myriad Rules Based Medicine, Austin TX) were used to compare HOM or HET Gly170Arg$^+$ patients (n=26) vs. Gly170Arg$^-$ (n=21). For this cross-sectional study, we hypothesized Vit B_6 treated Gly170Arg$^+$patients would exhibit uniformly protective proteomic patterns vs. Gly170Arg$^-$.

Results: Ur endothelin 1 (ET1) and IL17E were lower (p=0.04;0.03), while MMP9 and MIF1 were higher (p=0.002;0.03) in Gly170Arg$^+$. Trends were seen in Gly170Arg$^+$ for higher MIP1β, MCP4, and MMP7 (p=0.052-0.055). The table below includes other group differences

Group Differences (Md, IQR).			
Data	**Gly170Arg$^+$**	**GLy170Arg$^-$**	**p**
On Vit B_6 Rx (%)	96	62	-
Vit B_6 Dose (mg/day)	400 (300,475)	300 (250,525)	0.78
UrOx (mmol/L/1.73m^2)	0.82 (0.5,1.2)	1.3 (0.9,2.2)	0.008
Ur Calcium (mg/kg/d)	1.17 (0.6,2.5)	1.02 (0.7,1.6)	0.86
eGFR (ml/min/1.73m^2)	84.2 (57,104)	66.0 (54,93)	0.44

Conclusions: PH1 Gly170Arg$^+$ patients on Vit B_6 had lower UrOx and downregulated inflammatory and fibrotic factors, ET1 and IL17E but upregulated MIF1 and MMP9. No differences in oxidative stress and calcification inhibition or calcification promotion markers were seen between the groups. Vit B_6 therapy for Gly170Arg m$^+$ or $^-$ may not offer consistent suppression of extracellular matrix breakdown, macrophage accumulation and fibrosis despite lowering UrOx. B_6 compliance monitoring with targeted Ur proteomics should be considered.

Genetic Determinants of Uremic Toxins in Hispanic Children: The Viva La Familia Study V. Saroja Voruganti,[1] Geetha Chittoor,[1] Katie A. Meyer,[1] Karin Haack,[2] Sandra L. Laston,[3] Nitesh R. Mehta,[4] Shelley A. Cole,[2] Anthony Gean Comuzzie,[2] Nancy F. Butte.[4] *[1]Univ of North Carolina at Chapel Hill; [2]Texas Biomedical Research Inst; [3]Univ of Texas Rio Grande Valley; [4]Baylor College of Medicine.*

Background: Uremic toxins are organic compounds, which in excess concentrations negatively impact biologic functions. Uremic toxins have been linked to oxidative stress, endothelial dysfunction, increased risk for chronic kidney disease and acute kidney injury, and cardiovascular events and mortality. Adult studies showing environmental and genetic factors affecting uremic toxins cannot be extrapolated to children. Thus, our aim was to identify genetic determinants of 11 serum uremic toxins (low molecular weight molecules: creatine, creatinine, uric acid, xanthine, hypoxanthine, asymmetric dimethylarginine, uridine, and protein-bound molecules: p-cresol sulfate, indole acetate, kynurenine, kynurenate) in 686 Hispanic children.

Methods: Uremic toxins were measured by untargeted metabolomics profiling. A genome-wide association analysis was conducted using a measured genotype approach accounting for kinships.

Results: All uremic toxins were significantly heritable (h^2 = 0.2-0.9, $p < 0.005$). There was a strong association of serum uric acid with variants in uric acid transporter (*SLC2A9*), as previously reported. Of the 10 remaining uremic toxins, a strong association was observed between asymmetric dimethylarginine and rs13406433 of echinoderm microtubule associated protein like 6 (*EML6*)($p = 4.3 \times 10^{-8}$), and suggestive associations were observed between creatine and rs11711956 of calcium voltage-gated channel auxilliary subunit alpha2delta3 (*CACNA2D3*) and rs6593900 of ATPase plasma membrane Ca2+ transporting 4 (*ATP2B4*), indole acetate and rs17182135 of *LOC105378145*, uridine and rs11965452, rs28570682, rs3757328, rs9261261, rs6917477 of zinc ribbon domain containing 1 antisense, pseudogene (*ZNRD1-AS1*) and p-cresol sulfate and rs1078317 of *LOC105378909* ($p < 9 \times 10^{-7}$). The frequency of the minor allele and the effect sizes ranged from 1 - 47% and 2-5%, respectively.

Conclusions: In summary, we demonstrate significant genetic influence on uremic toxins in Hispanic children.

A CE-MS Pipeline for Long Term Comparable Assessment of the Urinary Metabolome Panagiotis Moulos,[1,2] Valerie Brunchault,[1] Benjamin Breuil,[1] Franck Boizard,[1] Julie Klein,[1] Stephane Decramer,[3] Jean-Loup Bascands,[1] Joost Schanstra,[1] Benedicte Buffin-Meyer.[1] *[1]INSERM U1048/I2MC, Toulouse, France; [2]HybridStat Predictive Analytics, Athens, Greece; [3]CHU Toulouse, Hôpital des Enfants, Toulouse, France.*

Background: 'Urinary omics' strategies are promising tools of high relevance in the clinical setting as they have already led to the design of multimarker protein-based models for the diagnosis of complex diseases. Compared to proteins, metabolites are in the closest biological proximity to the phenotype and can thereby provide functional signatures of pathological states. However, although the field of metabolomics has advanced significantly in the past years, there has been little progress in the discovery of clinically useful urinary metabolite biomarkers.

Methods: Most metabolomics studies use NMR spectroscopy and LC-MS. In contrast, capillary electrophoresis coupled to mass spectrometry (CE-MS) has been rarely used for metabolome analysis due to issues related to stable coupling of CE to MS instrument and limited loading capacity of CE columns. Here, we report an optimized CE-MS setup and data analysis pipeline that allows comparing the metabolite content in urine samples.

Results: A novel normalization procedure using endogenous stable urinary metabolites was developed based on the combined metabolome of 75 different urine samples from healthy and disease individuals. Using this normalization method, the CE-MS platform displayed high performance in terms of long-term stability as it allowed comparison of the same sample analyzed nearly 130 times over a range of 4 years. Next we evaluated the clinical utility of the CE-MS pipeline for the discovery of urinary biomarkers for diagnosis of obstructive nephropathy in infants. We compared the urine metabolome of 34 newborns with ureteropelvic junction (UPJ) obstruction and 15 healthy newborns. This led to the identification of 32 differentially excreted metabolites. Combination of the 32 compounds in a SVM classifier predicted with 88% sensitivity and 86% specificity (AUC 0.90) UPJ obstruction in a separate validation cohort of 24 individuals.

Conclusions: This proof-of-concept study demonstrates the feasibility to use CE-MS as a tool for identification of clinically relevant urinary metabolites.

TH-PO622

Newly-Identified Symptoms of Left Renal Vein Entrapment Syndrome Mimicking Orthostatic Disturbance Tomoki Miyazawa, Keisuke Sugimoto, Kohei Miyazaki, Hidehiko Yanagida, Mitsuru Okada, Tsukasa Takemura. *Pediatrics, Kindai Univ Faculty of Medicine, Osakasayama, Osaka, Japan.*

Background: In addition to the urinary abnormalities, symptoms of left renal vein entrapment between the aorta and superior mesenteric artery (left renal vein entrapment syndrome, LRVES) may include abdominal and flank pain as well as chronic fatigue. We investigated various LRVES symptoms in this study.

Methods: In 53 pediatric LRVES patients treated at our department, 22 had a score of 5 points or higher on orthostasis. Initial evaluation of LRVES by abdominal ultrasonography showed a stenotic-to-prestenotic vein diameter ratio of 0.2 or less. Definitive diagnosis was made by computed tomography and magnetic resonance angiography. Cortisol, catecholamine (CA), and brain natriuretic peptide (BNP) were also measured.

Results: The frequency of LRVES was 2.5 times higher in girls than in boys. Low or very low body mass indexes were seen in both sexes. The most common initial finding was urine abnormalities, followed by dizziness and malaise. In 6 patients, orthostasis precluded school attendance. 10 patients had orthostasis scores above 12. Patients unable to attend school had either low levels of plasma or urinary cortisol. Midodrine significantly decreased orthostasis scores. Some patients required treatment with fludrocortisone. Plasma CA, renin, and BNP levels were all normal.

Conclusions: Locally excessive venous pressure may cause reversible adrenal dysfunction with transitory Addisonian symptoms. Children with cryptogenic malaise or severe orthostasis should be evaluated for LRVES.

TH-PO623

The Relationship of Kidney Disease Knowledge with Self-Management and Healthcare Transition Readiness Maria E. Ferris,[1] Meaghan Nazareth,[1] Julie A. Wright Nunes,[2] Karina Javalkar,[1] Alex Phillips,[1] Sarah Elizabeth Cohen,[1] Jessica Cuttance,[1] Miranda A.l. van Tilburg,[1] Stephen R. Hooper,[1] Keisha L. Gibson,[1] Dorey A. Glenn,[1] Keia Sanderson,[1] Eniko Rak.[1] *[1]UNC Chapel Hill, Chapel Hill, NC; [2]Univ of Michigan, Ann Arbor, MI.*

Background: Successful transition from pediatric to adult-focused services requires knowledge and effective self-management of the chronic kidney disease (CKD).

Methods: English speaking adolescents and young adults (AYA) who attended the UNC Kidney Center clinic in 2015 completed the Kidney Knowledge Survey (KiKS) and the TRxANSITION Scale. Regression was used to explore this relationship while controlling for percentage of life with the disease, sex, race, and insurance.

Results: 155 AYA aged 10-20 years old completed the surveys (mean age 15.79 ± 2.34). Participants were 50.3% females, 36.8% white, 34.2% African American, 53.5% private insurance and 32.9% public insurance. All AYA had been diagnosed with CKD stages 1 to 5. The model as a whole predicted healthcare transition readiness ($F_{6,118}$=4.654, p=0.000). This significance was related to kidney disease knowledge (β=0.340, p=0.000) and percentage of life with the disease (β=-0.216, p=0.013). Race, sex, and insurance were not significant. Correlations of the 10 TRxANSITION Scale domains with the KiKS Score were performed, and Type of illness (r=0.366, p=0.000), $R_{x=\text{prescriptions}}$ (r=0.313, p=0.000), Issues of Reproduction (r=0.250, p=0.003), and Insurance (r=0.276, p=0.001) demonstrated significant, positive correlations.

Conclusions: Participants who had a great understanding of kidney disease knowledge were better prepared to transition to adult care. Increased kidney disease knowledge may also relate to increased knowledge in specific domains of transition readiness, although this relationship must be further explored. In turn, percentage of life with the disease was negatively related to transition readiness. Increase in percent of life with the disease is associated with a decrease in transition readiness.

TH-PO624

All You Need Is Love: A Low Literacy Curriculum for CKD Education and Self-Management Meaghan Nazareth, Jordan Richards, Jessica Cuttance, Karina Javalkar, Alex Phillips, Sarah Elizabeth Cohen, Eniko Rak, Miranda A.l. van Tilburg, Stephen R. Hooper, Brian H. Pitts, Maria E. Ferris. *UNC Chapel Hill, Chapel Hill, NC.*

Background: To successfully manage chronic kidney disease (CKD), patients need to be able to understand their condition. The efficacy of a low-literacy curriculum developed with interdisciplinary input needs to be assessed.

Methods: The ALL YOU NEED IS LOVE Curriculum provides CKD education, self-management tips, and mindfulness in 6 weeks. A graded intervention was deployed in two groups of adolescents and young adults (AYA). One group received CKD education and self-management and the second group received the same information enhanced with mindfulness activities. Mindfulness provides training in self-acceptance and coping, buffering stress resulting from having a chronic health condition as it integrates openness and present-moment awareness. English speaking AYAs (aged 12-29) with CKD stages

1-5 at pediatric and adult clinics of the UNC Kidney Center, received a booklet and a MP3 player. The outcome was change in the STARx Questionnaire (Ferris 2015), a self-management and transition readiness tool with a best score of 90. Paired t-tests were used to determine significance of changes in transition readiness.

Results: 20 AYA in pediatric and adult clinics have completed the study. Among the pediatric patients, 24% have an ADHD or ADD diagnosis, and 40% have an Individualized Education Plan or 504 plan at school. Mean STARx Questionnaire scores significantly improved, with a greater increase in those with the additional mindfulness intervention (Table 1).

Conclusions: Initial results suggest that this low-literacy curriculum is having a positive impact on knowledge and self-management of CKD among AYAs with this condition. Further exploration is ongoing.

	Mean Baseline STARx Score	Mean Follow-Up STARx Score	p-value
All Participants (n=20)	75.10±12.68	78.70±10.30	0.03
Pediatric Participants (n=16)	72.00±12.08	76.69±10.24	0.02
Adult Participants (n=4)	87.25±6.40	86.75±6.40	0.82
CKD Education + Self-Management (n=10)	75.50±16.43	78.70±13.33	0.20
CKD Education + Self-Management + Mindfulness	74.60±8.31	78.70±6.82	.09

Funding: Private Foundation Support

TH-PO625

Parent-Child Kidney Disease Knowledge Concordance Jordan Richards,[1] Meaghan Nazareth,[1] Julie A. Wright Nunes,[2] Karina Javalkar,[1] Alex Phillips,[1] Sarah Elizabeth Cohen,[1] Jessica Cuttance,[1] Miranda A.l. van Tilburg,[1] Eniko Rak,[1] Stephen R. Hooper,[1] Maggwa Dwayne Shaun Ndugga,[1] Maria E. Ferris.[1] *[1]UNC Chapel Hill, Chapel Hill, NC; [2]Univ of Michigan, Ann Arbor, MI.*

Background: Parents must help manage their children's chronic kidney disease (CKD). It is not clear how much disease-specific knowledge parents have and how concordant it is to their children's knowledge. It is also not clear how this knowledge relates to health care transition readiness.

Methods: English speaking adolescents and young adults (AYA) at the UNC Kidney Center and their parents completed an abridged form of the Kidney Knowledge Survey (KiKS) (max score 100%) as well as the TR$_x$ANSITION Scale (best score is 10). AYA and their parents reported demographic information including AYA age, age at diagnosis, sex, race, and insurance status. Linear regression was used examine the relationship between the parent kidney knowledge score and youth transition scale score total while controlling for percentage of life with the disease, sex, insurance, and race. Pearson's correlation was used to examine parent-AYA KiKS and TR$_x$ANSITION Scale concordance.

Results: 41 parent-AYA dyads completed the surveys. AYA's characteristics included females (68.3%); mean age 15.05 ± 1.89 (range 12-19); mean age at diagnosis 7.71 ± 6.26; private insurance (49%) and Caucasians (49%). The majority of parent participants were mothers (92.7%). The mean parent KiKS score was 70.2% ± 12.9% (range 40 – 100%). The mean AYA KiKS score was 60.7% ± 15.6% (range from 13.3 – 86.7%). Mean parental TR$_x$ANSITION Scale score was 8.1 ± 0.9, and mean AYA TR$_x$ANSITION Scale score was 6.6 ± 1.5. The model was not significant. Correlation between parent and AYA transition scales was significant (r=0.413, p=0.008), while correlation between parent and youth kidney knowledge was not significant.

Conclusions: Parents have lower than expected disease knowledge and transition preparation. Parents with more disease-specific knowledge are likely better prepared to educate AYA about their disease. We identified opportunity for parents to pass their knowledge on to children to further support future self-management and transition to adult care.

TH-PO626

The Prognostic Value of the Furosemide Stress Test in Predicting Delayed Graft Function following Deceased Donor Kidney Transplantation Blaithin A. McMahon,[1] Edward S. Kraus,[1] Tessa Kimberly Novick,[1] Steven Menez,[1] Sami Alasfar,[1] Niraj Desai,[1] Lakhmir S. Chawla,[3] Jay L. Koyner.[2] *[1]Johns Hopkins Univ School of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Medicine, Univ of Chicago, Chicago, IL; [3]Dept of Medicine, The George Washington Univ, San Diego, CA.*

Background: The Furosemide Stress Tess (FST) is a novel dynamic assessment of tubular function that has been shown in preliminary studies to predict patients who will progress to advanced stage Acute Kidney Injury, including those who receive dialysis.The aim of this study is to investigate if the urinary response to a single intraoperative dose of furosemide predicts delayed graft function (DGF) in patients undergoing deceased donor kidney transplant (DDKT).

Methods: This is a single center retrospective cohort analysis of 300 patients undergoing kidney transplantation (KT) at Johns Hopkins Hospital from January 2012 to October 2015. All patients undergoing KT received a single 100mg dose of intraoperative furosemide monitoring UO at 2 and 6 hr post furosemide administration.We utilized the 2 and 6 hour post FST urine output along with multiple logistical regression analysis and area under the receiver operator curves (AUC) to determine DGF (defined as receipt of RRT within 7 days of transplantation).

Results: In multivariate analysis, the FST predicted the need for dialysis after adjusting for donor age, donor race, recipient weight, cold ischemic time, pre-transplantation baseline urinary flow rates (classified as oliguria versus non oliguria),and donor serum creatinine. The AUC for prediction of DGF based on a UO of <150mls at 2 hours and 6 hours was 0.84 and 0.86, respectively.The median length of hospital stay among FST responders (>600mls at 6 hours) was 8 days compared to 12 days in non FST responders (<600mls at 6 hours). There was no significant difference in the prevalence of hypotension and hypokalemia (within 24 hours), as well as graft loss and death in those patients who were FST responders compared to those who were not (median follow up 1.69 years).

Conclusions: The FST is a predictor of DGF post DDKT and has the potential to identify patients requiring RRT early after KT.

TH-PO627

A Sensitive Urinary Furosemide HPLC Assay to Complement the Furosemide Stress Test Jonathan Street,[1] Erik H. Koritzinsky,[1] Lakhmir S. Chawla,[2] Peter S.T. Yuen,[1] Robert A. Star.[1] *[1]NIDDK, Bethesda, MD; [2]VA, Washington, DC.*

Background: The furosemide stress test has been reported as a functional biomarker with good performance in predicting adverse outcomes after AKI. Furosemide binds and inhibits NKCC2, causing a diuresis that can be easily measured. To reach the NKCC2 on the apical surface of the thick ascending limb furosemide must be actively secreted by the proximal tubule. We hypothesized that the excretion of furosemide may provide additional information beyond the urine volume. To investigate this we developed a sensitive assay for urinary furosemide.

Methods: We used a reverse phase HPLC separation with detection by absorbance at 335 nm to sensitively detect furosemide. A 5 µl sample of urine is mixed with 100 µl acetonitrile, centrifuged to pellet precipitated proteins, and the supernatant dried. The HPLC assay utilizes a 50 mm PRP-C18 column with a 10 min isocratic elution using 70% 20 mM potassium phosphate pH 4.5 / 30% acetonitrile as the mobile phase. The dried samples are resuspended in mobile phase prior to injection.

Results: The furosemide assay was linear from 0.5 to 500 ng/µl, with R^2=0.999. The protocol used had a coefficient of variation of 6%. Furosemide standard was spiked into urine and samples stored for 0, 4 and 24 hours at room temperature. There was no degradation with storage over this period (100% recovery). Furosemide was also stable over multiple freeze-thaw cycles with no change observed between 1 and 4 cycles. The assay was robust in the presence of albumin with no change in stability or variability.

Conclusions: Furosemide assay is sensitive, reproducible, and robust. Furosemide is stable in urine over both prolonged storage and multiple freeze-thaw cycles. The protocol is able to accurately measure furosemide concentration in 5 microliters of urine over ranges expected in both human and rodent studies.

TH-PO628

Furosemide Stress Test, Renal Angina Index, or Urinary Sediment: Which I Should Use to Predict Acute Kidney Injury? Rolando Claure-Del Granado, Daniela Torrico-Guillen, Ivan Chavez-Mostajo, Marcelo Coca-Villarroel, Alex J. Arauco-Meneses, Lety Castro-Cossio. *Hospital Obrero #2 - CNS, Cochabamba, Bolivia.*

Background: In recent years several approaches for identifying patients at risk of AKI were used; among them 2 have been of increasing interest: the furosemide stress test (FST) and the renal angina index (RAI). We recently used Perazella et al urinary sediment score (USS) to predict subsequent development of clinical AKI. All of these approaches aim to identify patients at risk for subsequent AKI. We assessed the performance of these 3 different approaches to identify patients at risk of AKI in an ongoing cohort of adult critically ill patients.

Methods: We analyzed data from 30 hospitalized patients admitted to a Medical ICU. We measured serum creatinine (sCr) every 24 h for 7 consecutive days following ICU admission, and urinary volume was assessed hourly each 24 h. At admission (day 0), **RAI** was calculated using the following formula: **Risk level** (presence of sepsis, use of vasopressors, use of invasive mechanical ventilation, and presence of DM) ***x*** **Injury level** (changes in eGFR); we evaluate **USS**; and we applied the **FST** at day 0 (as describe by Chawla et. al. Crit Care 2013; 17(5):R207). We assessed the performance of these 3 tests to predict the subsequent development of AKI using KDIGO sCr and urinary volume criteria.

Results: Of the 30 patients included in this study, 4 (13.3%) patients met the primary end point of AKI (sCr KDIGO criteria). The performance of **RAI**, **FST** and **USS** are shown on table 1.

Performance of the different tests and scores	Furosemide stress test	Renal angina index	Urinary sediment score
Sensitivity (%)	75	100	100
Specificity (%)	100	100	92
PPV (%)	100	100	67
NPV (%)	96	100	100
ROC-AUC (*p* value)	0.990 (0.002)	1.00 (0.002)	0.981 (0.002)

Of note, we consider a cut-off point of <600 cc of urine at 2 h for **FST** since none of the patients who developed AKI had <200 cc of urine as the original cut-off proposed value.

Conclusions: The RAI, FST and USS have robust predictive capacity to identify critically ill patients at high risk of developing AKI before a rise in sCr occurs. These preliminary data of our ongoing study warrants future studies to validate these findings.

TH-PO629

Subclinical Acute Kidney Injury Is an Early Stage of Acute Kidney Injury Rolando Claure-Del Granado,[1] Vania Cecilia Prudencio Ribera,[1] Ravindra L. Mehta.[2] *[1]Medicine, Hospital Obrero #2 - CNS, Cochabamba, Bolivia; [2]Medicine, Univ of California San Diego, CA.*

Background: A recent ADQI consensus on AKI biomarkers has suggested that novel biomarkers (NGAL, KIM-1, and IGFBP-7) can identify kidney damage prior serum creatinine (sCr) elevations. Combining damage and functional markers can thus permit recognition of an early stage of AKI termed **subclinical AKI** (S-AKI). We tested the hypothesis that a panel of damage biomarkers could detect ***S-AKI*** and would predict the subsequent development of **clinical AKI** (C-AKI).

Methods: We included 50 consecutive patients admitted to a Medical ICU. Daily sCr, urine albumin (uAlb) and urine β2–Microglobulin (uβ2-M) levels were measured each 24 h for 7 consecutive days; we evaluated urine sediment (USS) and assigned a score using Perazella et. al. criteria. We define ***S-AKI*** if any of the following criteria was reached in the absence of sCr elevations: new onset of uAlb ≥15 mg/L, or uβ2-M ≥3.2 mg/L, or USS ≥2. ***C-AKI*** was defined by KDIGO sCr criteria. We analyzed the predictive value of each of these biomarkers for the subsequent development of ***C-AKI*** as well to predict survival.

Results: Of the 50 patients, 11(22%) did not develop AKI while 39(78%) developed ***S-AKI***. Of the 39 patients with ***S-AKI,*** 26(67%) progressed to ***C-AKI*** while 13(33%) did not. The predictive value of uAlb, uβ2-M and USS at 24 and 48 h are show in table 1.

Predictive value of the different biomarkers	ROC-AUC (95% CI)	*p* value
Urinary Albumin (≥15 mg/L) 24 h 48 h	 0.753 (0.612-0.894) 0.707 (0.555-0.859)	 0.02 0.01
ß$_2$ Microglobulin (≥2.5 mg/L) 24 h 48 h	 0.770 (0.624-0.916) 0.703 (0.545-0.861)	 0.01 0.14
Urinary Sediment Score (≥ 2) 24 h 48 h	 0.818 (0.638-0.998) 0.773 (0.580-0.965)	 0.001 0.006

28-day mortality did not differ between patients with ***S-AKI*** who didn't developed ***C-AKI*** and patients with ***S-AKI*** who developed ***C-AKI***.

Conclusions: Our data shows high incidence of ***S-AKI*** that progressed to ***C-AKI***. These findings support the ADQI recommendations to consider ***S-AKI*** based on positive damage biomarkers alone as an early phase of AKI. Identification of ***S-AKI*** would potentially allow earlier intervention with preventive and treatment strategies to reverse kidney injury and improve recovery.

TH-PO630

Clinically Relevant Furosemide Stress Test Is Predictive for AKI Progression in ICU Patients with Elevated Plasma NGAL Level Ryo Matsuura,[1] Yohei Komaru,[1] Yoshihisa Miyamoto,[3] Teruhiko Yoshida,[1] Kohei Yoshimoto,[2] Rei Isshiki,[1] Kengo Mayumi,[1] Tetsushi Yamashita,[1] Yoshifumi Hamasaki,[3] Masaomi Nangaku,[1,3] Eisei Noiri,[1] Kent Doi.[2] *[1]Dept of Nephrology and Endocrinology, The Univ of Tokyo Hospital, Tokyo, Japan; [2]Dept of Emergency and Critical Care Medicine, The Univ of Tokyo Hospital, Tokyo, Japan; [3]Dept of Dialysis and Apheresis, The Univ of Tokyo Hospital, Tokyo, Japan.*

Background: Furosemide stress test (FST), which evaluates urine output after furosemide administration, has been suggested for predicting progression of severe AKI. Although the standardized dose (1 mg/kg) is required in FST, different doses are used to see urine output responsive to furosemide in the clinical. In addition, biomarker information is expected to improve prediction performance of FST.

Methods: We evaluated retrospectively plasma NGAL and furosemide response (FR), defined as urine output measured for 2 hours after injection, for stratifying the risk of AKI progression in our ICU. Furosemide dose was determined by clinical judgement based on the severity of illness including renal and cardiac function.

Results: 95 ICU patients were analyzed in this study. 18 patients developed AKI stage 3 within one week (19%). ROC analysis showed the AUC and cutoff values as follows; plasma NGAL 0.80 [0.67-0.88], 142 ng/ml and FR 0.87 [0.73-0.94], 3.9 ml/mg-furosemide. Only one patient with lower NGAL level (< 142 ng/ml) progressed to AKI stage 3. FR provides the AUC of 0.84 [0.67-0.94] for prediction of the development to AKI stage 3 even in the patients with higher NGAL (>142 ng/ml). With the cutoff value of 3.9 ml/furosemide dose (mg), 13 NGAL-high patients with FR negative developed AKI stage 3 (86.7%), while four FR positive patients developed to AKI stage 3 (11%) with the odds ratio of 52 (8.5-319.5) (p<0.01).

Conclusions: Although different doses of furosemide were administered, FR showed good performances for predicting AKI progression even in high plasma NGAL patients. This suggests combination of FR and biomarkers can stratify the risk in AKI progression in the clinical settings.

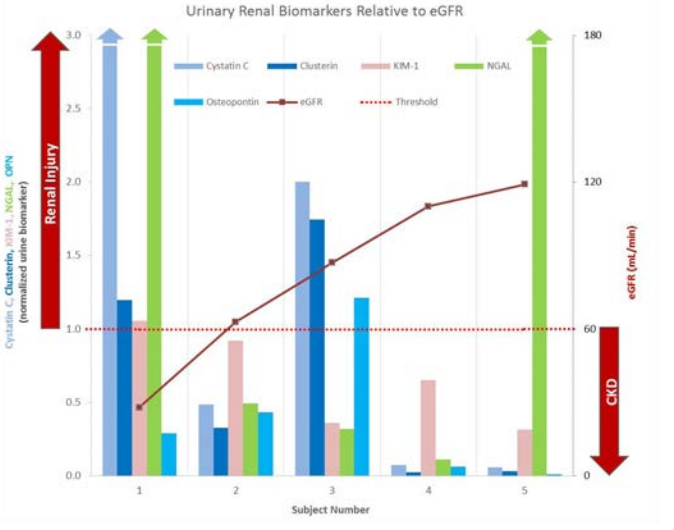
TH-PO631

Monitoring and Diagnosing Acute Kidney Injury Using Biochip Array Technology Candace M. Adamo,[1] Amar Sethi,[1] Eibhlin M. Mccole,[2] Marie Mcgarvey,[2] Ciaran Richardson,[2] Peter Fitzgerald,[3] John Lamont,[3] Timothy H. Carlson.[1] *[1]Pacific Biomarkers, Seattle, WA; [2]Randox Teoranta, Dungloe, Co. Donegal, Ireland; [3]Randox Laboratories, Crumlin, Co. Antrim, United Kingdom.*

Background: The risk of acute kidney injury (AKI) is currently assessed by serum creatinine and clinical representation using the KDIGO classification. Recent efforts have identified several novel biomarkers that are more specific and sensitive in the monitoring and diagnosis of AKI.

Methods: The collective response in 20 subjects of five urinary biomarkers (KIM-1, cystatin C, NGAL, osteopontin (OPN) and clusterin) were measured by ELISA and by a newly developed multiplexed biochip array (Randox Evidence Investigator™).

Results: Correlation coefficients (r^2) between the two methods were above ≥0.98 for all biomarkers except for clusterin (r^2=0.80), with a slope between 0.86 – 1.43, indicating excellent agreement. Preliminary comparison of sensitivity (NGAL=0.78 ng/mL; KIM-1=15.61 pg/mL) and dynamic range (data not shown) between the two methods showed equal or better performance. Multiplexing suggests improved AKI detection as subject 3 with normal eGFR had 3 of 5 biomarkers elevated, indicating renal injury; subject 1 with CKD and eGFR <60 mL/min had biomarker elevations in 4 of 5 tested. The biomarker profiles for the remaining subjects at risk for AKI differed, indicating reduced renal function may be better captured by several biomarkers, as each biomarker reflects different mechanisms that lead to the same injury outcomes (representative data shown below).



Conclusions: These results suggest the potential of this novel multiplex AKI panel to become a robust and cost-effective tool for monitoring renal injury, which is tested from a smaller sample volume with faster turn-around time and without compromising sensitivity or dynamic range.

TH-PO632

Evaluating Renal Injury and Function in Marathon Runners Using Injury and Repair Biomarkers Sherry Mansour,[1] Gagan Verma,[1] Rachel W. Pata,[2] Thomas Martin,[2] Chirag R. Parikh.[1] *[1]PATR, Yale Univ; [2]Quinnipiac Univ.*

Background: There is growing interest in the effects of strenuous activity on renal function, in light of the recent kidney disease epidemic among Mesoamerican sugarcane workers. Marathon running serves as a model of extreme activity and heat stress. This prospective study evaluated renal function of runners during the 2015 Hartford Marathon using conventional and novel renal biomarkers.

Methods: We enrolled 22 runners and collected samples 24 hours pre-marathon (Day 0), immediately after marathon (Day 1) and 24 hours post-marathon (Day 2). Six injury biomarkers: IL-6, IL-8, IL-18, kidney injury molecule-1, neutrophil gelatinase-associated lipocalin and tumor necrosis factor alpha, and two repair biomarkers: YKL-40 and monocyte chemoattractant protein-1 (MCP-1) were measured. Serum creatinine, creatine phosphokinase (CPK), urine microalbumin and urine microscopy were also evaluated. We assessed changes in biomarker levels, AKI (stage I or higher by AKIN criteria) and urine microscopy score ≥ 2 (strong predictor of ATN).

Results: The mean age of runners was 44 years old and 41% were males. 27% used NSAIDs pre-race. Serum creatinine was elevated on Day 1 versus Day 0 (1.33 mg/dL vs 0.85 mg/dL, p<0.01). Urine microalbumin was elevated on Day 1 versus Day 0 (6.46 mg/dL vs 0.57 mg/dL, p<0.01). On Day 2 creatinine and microalbumin levels started decreasing. 82% of runners developed AKI and 73% had a positive microscopy score. Serum CPK increased from Day 0 to Day 1 and continued to rise on Day 2 (110.32 U/l vs 299.86 U/l vs 769.19 U/l respectively, p <0.01). Urine biomarkers of injury were significantly elevated on Day 1 versus Day 0 and all biomarkers except IL-8 and TNF-α remained significantly elevated on Day 2 versus Day 0. Repair biomarkers were significantly elevated on Day 1 versus Day 0 but only MCP-1 remained significantly elevated on Day 2 versus Day 0.

Conclusions: Marathon runners developed AKI and urine sediments predictive of ATN. A rise in injury and repair biomarkers further indicated structural damage. These changes in renal function of runners may elucidate mechanisms of nephropathy in Mesoamerican sugarcane workers. Our results should be validated in larger cohorts.

TH-PO633

Back to Basics: Is Urinary Sediment Earlier Marker Than Urinary NGAL or KIM-1 for Diagnosis of AKI after Open Heart Surgery? Salah S. Naga. *Nephrology, Alexandria Faculty of Medicine, Alexandria, Egypt.*

Background: AKI is common after open heart surgery (CPB). Several biomarkers have been used including urinary NGAL and KIM-1 for the early diagnosis of AKI. This study was carried out to evaluate the role of urinary sediment scoring (USS) in comparison to NGAL and KIM-1 in the early detection of AKI after CPB.

Methods: This prospective cohort study was carried out on 45 adult patients of both sexes with a Cleveland score (CCS) (0-5) and scheduled for CPB surgery in Alexandria Main University Hospital. The renal function of the patients was assessed before and every day after surgery.Fresh urine samples were taken from every patient and centrifuged for microscopic examination of the urinary sediments and for measurement of NGAL and KIM-1 before, 2, 6, 12 and 24 hours after CPB.

Results: Eleven patients developed AKI. Patients with AKI had a higher CPB and cross clamp times (90+/-16.2 in comparison to 60.9+/-8.1 minutes in the non-AKI patients). Serum creatinine started to be significantly higher in the AKI group from the second postoperative day with a mean value of 1.56+/-0.28 mg/dl compared to a mean value of 0.85+/-0.14mg/dl in the non AKI group. Urine sediment score (USS) 1 and 2 were higher in the AKI group 2 hours after CPB and till the end of the first day with area under the curve (AUC) average of (0.865). Urinary NGAL significantly increased in the AKI group 2 and 6 hours after CPB with corresponding AUC of (0.710 and 0.700). Urinary KIM-1 was higher in the AKI group 12 and 24 after CPB with AUC of 0.725 and 0.703, respectively. Combination of USS, NGAL and KIM-1 gives an AUC of 0.906 in predicting AKI. Multivariable binary logistic regression analysis revealed that the most powerful independent predictors of AKI were USS 24 hours (RR 4.752) and urinary NGAL 6 hours (RR 1.020) after CPB.

Conclusions: Urinary microscopic examination to detect urinary sediments, which is often neglected, was found to have a higher sensitivity and specificity for early detection of AKI in comparison to the novel biomarkers NGAL and KIM-1. They can also be used in combination to improve their performance.

TH-PO634

Urinary Biomarkers at the Time of AKI Diagnosis as Predictors of Progression of AKI among Patients with Acute Cardiorenal Syndrome Xiaobing Yang, Fan Fan Hou. *Renal Div, Nanfang Hospital, Southern Medical Univ, Guangzhou, China.*

Background: A major challenge in early treatment of acute cardiorenal syndrome (CRS) is the lack of predictor for progressionof AKI. Weaim to investigate the utility of urinary angiotensinogen and other renal injury biomarkers in predicting AKI progression inCRS.

Methods: In this prospective, multicenter study, we screened 732 adults who admitted for acute decompensated heart failurefrom September 2011 to December 2014, and evaluated whether renal injury biomarkers measured attime of AKI diagnosis can predict worsening of AKI. In 213 patients who developed KDIGO stage 1 or 2 AKI,six renal injury biomarkers, including urinary angiotensinogen (uAGT), urinary and plasma neutrophil gelatinase-associated lipocalin (NGAL), urinary IL-18 (uIL-18), urinary kidney injury molecule-1 (uKIM-1), and urinary albumin to creatinine ratio (UACR), were measured at time of AKI diagnosis. The primary outcome was AKI progression defined by worsening of AKI stage (50 patients). The secondary outcome was AKI progression with subsequent death (18 patients).

Results: After multivariable adjustment, the highest tertile of three urinary biomarkers remained associated with AKI progression compared with the lowest tertile: uAGT (OR, 10.8; 95%CI, 3.4-34.7), uNGAL (OR, 4.7; 95%CI, 1.7-13.4) and uIL-18 (OR, 3.6; 95%CI, 1.4-9.5). Urinary AGT was the best predictor for both primary and secondary outcomes with AUC of 0.78 and 0.85. These three biomarkers improved risk reclassification compared with the clinical model alone, with uAGT performing the best(category-free net reclassification improvement for primary and secondary outcomes of 0.76 (95%CI, 0.46-1.06) and 0.93 (95%CI, 0.50-1.36), P<0.001). Excellent performance of uAGT was further confirmed with bootstrap internal validation.

Conclusions: Urinary AGT, uNGAL and uIL-18 measured at time of AKI diagnosis improved risk stratification and identified CRS patients at highest risk of adverse outcomes.

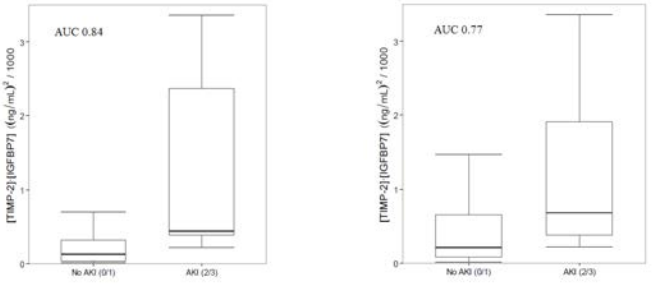
TH-PO635

Urinary [TIMP-2]·[IGFBP7] for Risk Prediction of Acute Kidney Injury in Decompensated Heart Failure Moritz Schanz,[1] Jing Shi,[2] Christoph Wasser,[1] Mark Dominik Alscher,[1] Martin Kimmel.[1] *[1]General Internal Medicine and Nephrology, Robert-Bosch Hospital, Stuttgart, Germany; [2]Walker Bioscience, Carlsbad, CA.*

Background: Acute decompensated heart failure (ADHF) is a common reason for hospitalization and the risk of acute kidney injury (AKI) is high. Early detection of patients at risk for cardiorenal syndrome is important. We tested urinary [TIMP-2]·[IGFBP7], a new FDA-cleared test to assess AKI risk, in a cohort of hospitalized ADHF patients.

Methods: 400 patients were enrolled in the ED at Robert-Bosch-Hospital, Stuttgart, Germany. Urinary [TIMP-2]·[IGFBP7] was analyzed in samples collected at enrollment, after 6 hours, and the following mornings over up to 7 days. We examined the predictive ability of urinary [TIMP-2]·[IGFBP7] for development of AKI stage 2 or 3 within 24 hours of sample collection in patients with ADHF. Operating characteristics were determined for the previously validated [TIMP-2]·[IGFBP7] cutoffs of 0.3 and 2.0. [TIMP-2]·[IGFBP7] results are reported in units of $(ng/mL)^2/1000$.

Results: Eleven (27.5%) of the 40 ADHF patients met the AKI stage 2-3 endpoint within 7 days. [TIMP-2]·[IGFBP7] discriminated for risk of AKI stage 2-3 with an AUC (95% confidence interval) of 0.84 (0.72-0.95) for initial presentation (within 24 hours) and 0.77 (0.65-0.88) for samples collected within 7 days.



At the 0.3 cutoff for [TIMP-2]·[IGFBP7], the sensitivity was 86% and the specificity was 71% for prediction of AKI stage 2-3 and at the 2.0 cutoff, the sensitivity was 43% and the specificity was 95% for samples collected within 24 hours of enrollment. Kaplan-Meier curves showed a trend (p=0.09) for decreased survival over one year in patients who reached AKI stage 2 or 3 within 7 days compared with those who did not.

Conclusions: In conclusion, urinary [TIMP-2]·[IGFBP7] predicts moderate-to-severe AKI in patients with ADHF.

TH-PO636

Urinary [TIMP-2]·[IGFBP7] in Platin-Induced Renal Injury Moritz Schanz, Martin Kimmel, Mark Dominik Alscher. *General Internal Medicine and Nephrology, Robert-Bosch Hospital, Stuttgart, Germany.*

Background: Platin-based chemotherapy is a potent antineoplastic agent, but cisplatin nephrotoxicity is a limiting side effect. Identifying those patients who are at risk for developing platin-induced renal injury is an important issue. We tested urinary [TIMP-2]·[IGFBP7], a new FDA-cleared test to assess AKI risk, in a cohort of patients with malignant disease receiving platin-based chemotherapy (PBC).

Methods: 58 patients were enrolled in this study. N=32 patients had available both, urinary [TIMP-2]·[IGFBP7] prior to PBC application and subsequent serum creatinine values for detecting AKI within 72 hours. Urinary [TIMP-2]·[IGFBP7] was collected on the same day prior to PBC application and the earliest available specimen after chemotherapy administration. We examined the predictive ability of [TIMP-2]·[IGFBP7] for development of KDIGO stage 1-3 within 72 hours after administration of chemotherapy in 32 patients with malignant disease. Operating characteristics were determined for the previously validated [TIMP-2]·[IGFBP7] cutoff of 0.3. [TIMP-2]·[IGFBP7] results are reported in units of $(ng/mL)^2/1000$.

Results: Four (12.5%) patients developed AKI stage 1-3 within 72 hours. Primary disease was in n=13 (40.6%) lymphoma and in n=19 (40.6%) solid tumors. Eight patients (25.0%) received carboplatin, n=24 (75.0%) cisplatin. [TIMP-2]·[IGFBP7] discriminated for risk of AKI stage 1-3 with an AUC (95% CI) of 0.86 (0.73-0.98). At the 0.3 cutoff for [TIMP-2]·[IGFBP7], the sensitivity was 75% and the specificity was 82% for prediction of AKI stage 1-3.

Sensitivity	Specificity	NPV	PPV	AUC
0.75 (0.19 – 0.99)	0.82 (0.63 - 0.94)	0.96 (0.79 – 1.00)	0.38 (0.09 - 0.76)	0.86 (0.73-0.98)

Comparing urinary [TIMP-2]·[IGFBP7] values prior to and after PBC application, a significant decrease of urinary [TIMP-2]·[IGFBP7] was remarkable (p=0.026).

Conclusions: Urinary [TIMP-2]·[IGFBP7] prior to PBC identifies patients who are at risk for developing platin-induced acute kidney injury. Because of a significant decrease of urinary [TIMP-2]·[IGFBP7] after PBC application (p=0.026), presumably due to prehydration, specimens gathered prior to chemotherapy seem to be more eligible for risk prediction of AKI.

TH-PO637

Cost-Effectiveness of NephroCheck® for Acute Kidney Injury in Critical Care Andrew J.P. Lewington,[1,2] Alison F. Smith,[2,3] David M. Meads,[3] Michelle Hutchinson,[3] Elizabeth D. Mitchell,[3] Judy M. Wright,[3] David Allan Cairns,[3] Michael P. Messenger,[1,2] Rebecca L. Kift,[1,2] Claire Louise Corps,[1,2] Patrick Hamilton,[4] Aleksandra Sobota,[3] Peter S. Hall.[2,5] *[1]Leeds Teaching Hospitals Trust, United Kingdom; [2]NIHR Diagnostic Evidence Cooperative Leeds, United Kingdom; [3]Univ of Leeds, United Kingdom; [4]Univ of Manchester, United Kingdom; [5]Univ of Edinburgh, United Kingdom.*

Background: Early diagnosis of acute kidney injury (AKI) in the Intensive Care Unit (ICU) may improve patient outcomes. The Nephrocheck® test (ASTUTE Medical, San Diego, CA) has gained FDA approval, but there is currently a lack of evidence on its cost-effectiveness. We therefore conducted a cost-utility analysis of NephroCheck® vs. standard care (daily serum creatinine and urine testing) from a UK NHS perspective.

Methods: All patients (AKI KDIGO stage≤1) were assumed to be tested on ICU admission. True Positive [TP], True Negative [TN], False Positive [FP] and False Negative [FN] cohorts were created using results from a systematic review and meta-analysis (sensitivity 0.91; specificity 0.49). A probabilistic lifetime Markov model was constructed and used daily cycles (day 0-90) to capture ICU KDIGO AKI stages, and annual cycles thereafter to capture long-term Chronic Kidney Disease (CKD) and mortality. TPs were assumed to have reduced risks (RR=0.78) of AKI progression due to early intervention; no harm was assumed for FP/FN results. In the absence of a published price for Nephrocheck® a range of values were tested.

Results: Nephrocheck® produced an average of 0.06 (95% CI:-0.21 to 0.37) extra QALYs at an additional cost of £154 (-1222 to 1554) to £332 (-1046 to 1731), assuming per-test costs of £10 [US$14] to £200 [$287] respectively. Incremental Cost-Effectiveness Ratios (ICERs) ranged from £2,420 [$3477] to £5,225 [$7507] per QALY. The test had a 65-68% and 68-69% probability of being cost-effective at willingness-to-pay per QALY thresholds of £20,000 [$28700] and £50,000 [$71800]. Results were sensitive to parameters including the AKI incidence and impact of early treatment.

Conclusions: These results can be considered sufficient justification for further research. The cost-effectiveness of Nephrocheck® compared to other market competitors should now be evaluated.

Funding: Government Support - Non-U.S.

TH-PO638

Comparison of NephroCheck(R) and Neutrophil Gelatinase-Associated Lipocalin for Risk Prediction in Combat Casualties Ian J. Stewart,[1] Jonathan Sosnov,[2] Kevin Chung,[3] Javance Tercero,[3] Elizabeth H. Babcock.[3] *[1]David Grant Medical Center, Travis AFB, CA; [2]San Antonio Military Medical Center, Fort Sam Houston, TX; [3]United States Army Inst of Surgical Research, Fort Sam Houston, Texas.*

Background: The NephroCheck®, which measures the product of tissue inhibitor of metalloproteinases-2 (TIMP-2) and insulin-like growth factor binding protein 7 (IGFBP7), has been shown to predict the subsequent development of AKI. We have previously shown that other novel urinary biomarkers for AKI, such as neutrophil gelatinase-associated lipocalin (NGAL), are associated with poor outcomes in a homogenous population of casualties from the war in Afghanistan. We hypothesized that the NephroCheck® would also predict poor outcomes in this patient population.

Methods: We conducted a prospective, observational study in a combat support hospital in Afghanistan. Patients that were US military members that suffered traumatic injury and were admitted to the intensive care unit (ICU) were included for analysis. Urine was collected at the time of admission to the ICU, frozen and shipped back to the US for later analysis. The combined outcome was defined by either death or the need for renal replacement therapy.

Results: Eighty seven patients were included in our study. Of these, 12 either died or required renal replacement therapy. Median admission product of TIMP-2 and IGFBP7 was higher in patients that subsequently developed the outcome (0.35, IQR 0.07-0.98) compared to those that did not (0.11, IQR 0.06-0.26), but this difference was not statistically significant (p=0.1). The area under the curve (AUC) for predicting the combined outcome was 0.65 and did not reach statistical significance (p=0.19). This stands in contrast to our prior our prior work examining urinary NGAL, which demonstrated an AUC of 0.82 (p<0.001).

Conclusions: In a group of young, critically injured military members, NephroCheck® did not significantly predict the combined endpoint of death or the need for renal replacement therapy. While the NephroCheck® has shown great promise for diagnosing AKI early, our work suggests that other urinary biomarkers, such as NGAL, may be superior at predicting other outcomes.

Urinary Biomarker TIMP-2 Predicts Adverse Outcomes in Patients with Acute Kidney Injury Sung Yoon Lim, Jihyun Yang, Young Ju Na, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Korea Univ Anam Hospital, Korea.*

Background: Several recent studies have shown that insulin-like growth factor-binding protein 7 (IGFBP7) and tissue inhibitor of metalloproteinases-2 (TIMP2) is a promising biomarker for the early detection of acute kidney injury (AKI), but the role of IGFBP7 and TIMP2 in predicting adverse clinical outcomes has not been well addressed. The purpose of this study was to evaluate the usefulness of urine IGFBP7 and TIMP2 as outcome predictor in patients with AKI.

Methods: This was a prospective cohort study enrolling established AKI patients. Urinary biomarkers, including IGFBP7, TIMP2 and NGAL were determined on admission and discharge from hospital. The primary clinical outcome variables were renal replacement therapy (RRT), renal recovery and in-hospital mortality.

Results: We prospectively enrolled 253 patients with AKI. Initial plasma creatinine concentrations and urinary biomarkers at AKI diagnosis were significantly higher in the RRT group than in the non-RRT group (Creatinine 5.17±3.59 vs 2.98±1.60 mg/dL; NGAL 2035.44±2431.73 vs 880.54±1413.68; IGFBP7 47.67±46.44 vs 33.23±44.55; TIMP2 24.27±45.60 vs 9.58±14.48 ng/mg creatinine, P<0.05). For predicting RRT requirement, increased plasma creatinine and TIMP2 was independently associated with greater odds of RRT in multiple logistic regression analysis. (odds ratio 1.77, P= 0.048; 48.30, P= 0.04, respectively) However, plasma creatinine and urinary biomarkers did not show statistically significant difference and could not predict recovery and the death in this study.

Conclusions: This prospective observational study could suggest that Urinary TIMP2 might be served as a strong predictor for the need for the renal replacement therapy early in the course of AKI.

TH-PO640

Value of Urinary Neutrophil Gelatinase Associated Lipocalin for Differential Diagnosis of Acute Kidney Injury in Decompensated Cirrhosis Sonia Rodriguez, Rossana O. Olmedo Ocampo, Barbara Vazquez-Cantu, Jose Antonio Nino-Cruz, Juan Antonio Ortega-Trejo, Rosalba Pérez-Villalva, Ricardo Correa-Rotter, Norma Bobadilla, Juan Carlos Ramirez-Sandoval. *Inst Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.*

Background: Early measurement of uNGAL could be useful for differential diagnosis of acute kidney injury (AKI) causes in patients with cirrhosis.

Methods: Observational cohort of patients with decompensated cirrhosis and AKI admitted to the Emergency Room. AKI was defined as an increase in SCr≥0.3 mg/dl from baseline; uNGAL was measured by ELISA in urine obtained at:(1) admission and diagnosis of AKI and (2) after 8-12 hours of volume expansion. We excluded patients with shock, massive bleeding, post-obstructive AKI, kidney transplant, and baseline sCr>2.5 mg/dL.

Results: We evaluated 65 patients (mean age: 59±14 years, female: 55% [n=33], sepsis: 57% [n=37]) of which we prospectively collected 130 urine specimens. All patients were initially treated with intravenous albumin and withdrawal of diuretics. A low initial uNGAL level predicted pre-renal AKI, with an area under the receiver operating characteristic curve (AUC-ROC) of 0.76 (95% confidence interval[CI]: 0.62-0.91, p:0.002). The 2nd uNGAL measurement, after 8-12 hours of treatment, had an AUC-ROC of 0.88 (95%CI: 0.77-0.99, p<0.001). At a cutoff concentration of 64 ng/mg uCr, the second measurement of uNGAL diagnosed pre-renal AKI with sensitivity of 93% and specificityof 81%. uNGAL was superior to predict full response to volume expansion (return to SCr baseline ±0.2mg/dL) compared with the initial Na fractional excretion or degree of AKI. We did not find differences in uNGAL levels between hepatorenal syndrome and intrinsic-AKI. uNGAL levels were positively associated with sepsis severityand MELD score (p<0.001).

Conclusions: Early uNGAL determination in patients with decompensated cirrhosis and AKI is useful to diagnose pre-renal AKI, even before diuretic withdrawal and plasma volume expansion with IV albumin for 2 days, and may avoid delay of effective treatment for other causes of non pre-renal AKI such as hepatorenal syndrome or intrinsic-AKI. uNGAL did not differentiate between hepatorrenal syndrome and intrinsic-AKI.

TH-PO641

The Clinical Value of Urinary Neutrophil Gelatinase-Associated Lipocalin (uNGAL) for the Diagnosis of Acute Kidney Injury during Hospitalization for Acute Heart Failure: Primary Findings of the Acute Kidney Injury N-gal Evaluation of Symptomatic Heart Failure Study (AKINESIS) Patrick T. Murray,[1] Alan S. Maisel.[3,4] *[1]School of Medicine, Univ College Dublin, Dublin, Ireland; [2]Dept of Cardiology, Univ Medical Center Groningen, Groningen, Netherlands; [3]Div of Cardiovascular Medicine, Veterans Affairs Medical Center, San DIego, CA; [4]Div of Cardiovascular Medicine, Univ of California San Diego, San Diego, CA.*

Background: Acute Kidney Injury (AKI) often occurs during acute heart failure (AHF) and can portend adverse outcomes; therefore, early identification may help mitigate risk. Urinary Neutrophil Gelatinase-Associated Lipocalin (uNGAL) is a novel renal biomarker that may predict AKI in certain disorders, but its value in AHF is unknown. Our objective was to determine whether uNGAL is superior to plasma creatinine (PCr) for prediction and/or prognosis of AKI in hospitalized patients with AHF.

Methods: A multicenter, prospective cohort study enrolling patients presenting with AHF requiring IV diuretics. The primary outcome was whether uNGAL could predict the development of AKI, defined as a sustained increase in PCr of ≥0.5 mg/dL or ≥50% above first value or initiation of acute renal replacement therapy (RRT), within the first five days of hospitalization. The main secondary outcome was in-hospital adverse events.

Results: 927 subjects (age 68.5 years, 62% men) were enrolled. The primary outcome occurred in 72 subjects (7.8%). First PCr was more predictive of the primary outcome than either the first or peak uNGAL values (AUCs 0.623, 0.593, and 0.567, respectively). First PCr was similarly more predictive of RRT within the first five days of hospitalization than

either first or peak uNGAL values (AUCs 0.88, 0.795, and 0.724, respectively). There were 235 in-hospital adverse events in 144 subjects. The first PCr was a better predictor of this composite outcome than either first or peak uNGAL (0.687, 0.648, and 0.604, respectively).

Conclusions: Urine NGAL was not superior to plasma creatinine for the prediction of AKI or adverse in-hospital outcomes in patients hospitalized with AHF. The use of uNGAL to diagnose AKI in AHF cannot be recommended at this time.

No Evidence of Chloride Nephrotoxicity Using Urinary Excretion of NGAL as Biomarker between 155 mmolar Chloride Infusion with 98 mmolar Chloride in Patients Undergoing Primary Uncemented Hip Replacement

Andreas Nygaard Jørgensen,[1] Jesper N. Bech,[1] Erling B. Pedersen,[1] Soren Bovling,[3] Niels Eterp Ekeloef.[2] *[1]Dept of Medical Research, Univ Clinic in Nephrology and Hypertension, Holstebro, Denmark; [2]Dept of Anesthesiology, Holstebro Hospital, Holstebro, Denmark; [3]Dept of Orthopedic Surgery, Holstebro Hospital, Holstebro, Denmark.*

Background: The use of fluids containing high amounts of chloride (Cl) reduced the need for renal-replacement-therapy. Animal studies showed that Cl reduced renal blood flow. Thus, Cl might cause acute ischemic kidney injury. The purpose of the study was to measure whether chloride induced kidney damage in a clinical study using urinary excretion rate of neutrophil gelatinase associated lipocalin (u-NGAL) as biomarker for nephrotoxicity.

Methods: In a randomized, double-blinded, placebo-controlled study of patients undergoing primary uncemented hip replacement, thirty eight-were randomized to receive either isotonic saline (155 mmolar chloride) or plasma-lyte (98 mmolar chloride) 15ml/kg during the first hour and 5ml/kg the following two hours after start of surgery. Urine was collected in four periods: Period 1: 24 hours before surgery, Period 2: 4 hours from the start of surgery, Period 3: from end of period 2 to 7.30 the next day and Period 4: 24 hours 10-12 days later. In addition, spot urine samples were collected before surgery and before discharge. Blood was collected before surgery and at the end of period 2 and period 3. We measured urinary u-NGAL and plasma concentrations of chloride (p-Cl) and creatinine (p-Crea).

Results: U-NGAL (median values) was the same in the saline group and the plasma-lyte group in all four periods. Period 1: 15.92 (plasma-lyte)/15.60 (saline) ng/min (p=0.54); Period 2: 22.51/9.88 ng/min (p=0.68); Period 3: 10.95/6.44 ng/min (p=0.05); Period 4: 4.05/2.04 ng/min (p=0.05). In the saline group p-Cl (mean value) 110.5 mmol/l was significantly higher than in the plasma-lyte group 107.9 mmol/l (p = 0.004). P-Crea was the same in both groups.

Conclusions: No evidence of nephrotoxicity was detected between infusions of high and low concentrations of chloride in a clinical trial using urinary excretion of NGAL as marker of kidney damage.

Funding: Private Foundation Support, Government Support - Non-U.S.

TH-PO643

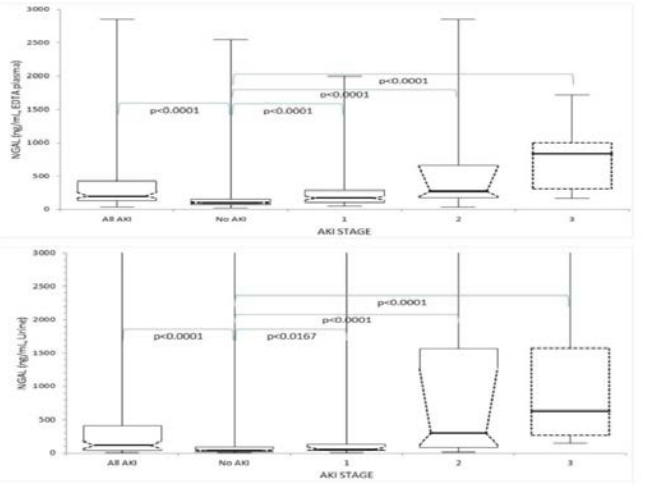
Neutrophil Gelatinase-Associated Lipocalin (NGAL) Correlates to AKI Stage in ICU Patients

Ladan Golestaneh,[1] A. Osama Gaber,[2] Sahir Kalim,[3] Peter A. McCullough,[5] Michael J. Germain.[4] *[1]Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Medicine, Houston Methodist Hospital, Houston, TX; [3]Medicine, Massachusetts General Hospital, Boston, MA; [4]Medicine, Baystate Medical Center, Springfield, MA; [5]Medicine, Baylor Univ Medical Center, Dallas, TX.*

Background: Acute kidney injury (AKI) is a commonly encountered complication in ICU patients and associated with poor outcomes. The diagnosis is based on serum creatinine (sCr) elevations compared to a poorly defined baseline. NGAL is a marker of AKI that has been shown to increase early in urine and plasma of different patient populations with AKI. We evaluated the ability of NGAL to detect AKI in a heterogenous ICU cohort.

Methods: Four sites participated in this study and recruited a total of 245 ICU patients. Blood and urine samples were taken daily and stored. Concentrations were determined with the NGAL Test (BioPorto) in batched samples by a central laboratory. Three clinicians adjudicated each patient case according to KDIGO guidelines and also determined the AKI stage once present. The clinical reviewers were blinded to the NGAL results.

Results: There was a statistically significant relationship between NGAL level and stage of AKI. For the subjects classified as not having AKI, median NGAL was 97 ng/mL, in EDTA plasma and 33 ng/mL in urine . For the subjects classified as having any stage of AKI, median plasma NGAL level was 197 ng/mL i and 116 ng/mL in urine. The median plasma NGAL levels for AKI- stage 1: 170 ng/mL and 53 ng/mL in urine: AKI-stage 2: plasma 274 ng/mL and urine300 ng/mL in U; AKI- stage 3: plasma 838 ng/mL and urine629 ng/mL in U.



Conclusions: NGAL is progressively increased in a graded fashion with ascending stages of AKI. These data suggest NGAL is a useful, objective tool, not only to identify patients with AKI but to also gauge the severity of their AKI.

TH-PO644

Impacts of Serial Plasma Neutrophil Gelatinase-Associated Lipocalin Measurement as Biomarker for Diagnosis and Prognosis in Acute Kidney Injury Patients of Emergency Room

Hyun Ho Ryu,[1] Hyun Lee Kim.[2] *[1]Emergency Medicine, Chonnam National Univ Hospital, Gwangju, Republic of Korea; [2]Internal Medicine, Chosun Univ Hospital, Gwangju, Republic of Korea.*

Background: Acute kidney injury (AKI) is a common and serious condition, the diagnosis of which currently depend on functional markers such as serum creatinine measurement. Neutrophil gelatinase-associated lipocalin (NGAL) appears to be a promising novel biomarker for the early diagnosis of AKI patients and a wide range in its predictive value has been reported. The aim of this study was to evaluate the predictive value of serum NGAL and serial measurement in patients with established AKI in emergency room.

Methods: Serum NGAL was measured in 701 patient at admission and 24hr later. Patients were divided four groups; group 1 includes patients with normal renal function, group 2 includes patients with AKIN stage 1, group 3 includes patients with AKIN stage 2, group 4 includes patients with AKIN stage 3. Serum NGAL was measured by ELISA at admission. We studied possible relationship between serum NGAL, estimated glomerular filtration rate (eGFR), and mortality in patient with AKI.

Results: Serum NGAL levels were significantly higher in AKI patient than in healthy control (452.19 ± 471.57 ng/mL vs. 183.12 ± 259.46 ng/mL, $p < 0.001$). The serum NGAL level showed a significant inversed correlation with GFR (r=0.164, p=0.018). The discriminatory ability of NGAL for AKI also increased with increasing AKIN stage. (AKIN1 56.0 (52.0-548.0), AKIN2 159.0 (77.5-425.5), AKIN3 503.5 (88.0-1300), $p < 0.001$).

Conclusions: From this results, we concluded that serum NGAL is a reliable marker of renal function in AKI patient. Serial NGAL measurement has impacts for diagnosis and prognosis, but monitoring protocols are needed for early detection and management of AKI patients.

TH-PO645

Urinary Angiogenin Reflects the Magnitude of Kidney Injury at the Infra-Histological Level

Nicolas Pallet,[1,2] Quentin Tavernier,[2] Alexandre Karras,[1] Eric Thervet,[1] Dany Anglicheau.[3] *[1]Hopital Européen Georges Pompidou; [2]Inst National de la Santé et la Recherche Médicale; [3]Hôpital Necker.*

Background: The ribonuclease angiogenin is secreted by renal epithelial cells upon activation of the IRE1a-sXBP1 axis, and is instrumental to the adaptation to acute kidney injury. It is unknown whether the amount of angiogenin in urines of individuals with a kidney injury reflects the magnitude of the lesions, and is predictive of the risk of organ failure.

Methods: To address this question, we explored individuals referred for a kidney injury and determined the biochemical characteristics of urinary angiogenin, as well as its diagnostic and prognostic values.

Results: In a cohort of 242 kidney transplant recipients with an acute allograft dysfunction, higher urinary angiogenin levels at the time of the biopsy were associated with a worse renal function and higher proteinuria, but did not correlate with histological lesions, as defined in the Banff classification. The risk of graft failure of kidney transplant recipients with urinary angiogenin amounts in the highest 50% was 3.59 times as high (95% confidence interval, 1.12-15.94) as that in the lowest 50%. We demonstrate that in the early post transplantation period, angiogenin is produced in large amounts in response to ischemia/reperfusion injury and acts as a paracrine mediator produced by renal epithelial cells under ER stress and primes non-stressed renal epithelial cells to activate the Integrated Stress Response pathway (PERK/eIF2a/ATF4), thereby promoting cell preconditioning. After 3 months, angiogenin is produced following the activation of sXBP1, as a consequence of smoldering immune infiltration (angiogenin levels are associated with interstitial inflammation scores, and sXBP1 is expressed by immune cells, including dendritic cells and B cells) and of non-immune insults associated with the activation of the IRE1a-sXBP1 axis.

Conclusions: The prognostic value of urinary angiogenin is related to the magnitude of renal injury, and angiogenin is not instrumental in the process of kidney allograft damage. Urinary angiogenin is a non-invasive indicator of the extent of tissue damage independent of the histological lesions, and a risk predictor of kidney allograft failure.

TH-PO646

The Role of Urine NGAL for Early Detection of Colistin-Induced AKI: A Randomized Controlled Trial Sadudee Peerapornratana, Nattachai Srisawat. *Div of Nephrology, Dept of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Colistin-induced acute kidney injury (AKI) are common cause of hospital acquired AKI. Neutrophil gelatinase-associated lipocalin (NGAL) is a promising biomarker for early detection of AKI which have been validated in various settings except in this specific setting. The aim of this study was to validate the role of serial urine NGAL measurement in improvement the detection of colistin-induced AKI.

Methods: We conducted a randomized controlled trial at King Chulalongkorn Memorial Hospital, Bangkok, Thailand during June 2015 and January 2016. Adult patients treated by colistin were randomized into two groups, using urinary NGAL or serum creatinine for AKI monitoring on day 1, 2, 3, 5, 7, 14 and 28. We also notified the primary physician when urinary NGAL >400 mcg/L in NGAL monitoring group or when achieving KDIGO stage I criteria in creatinine monitoring group. The primary outcomes was median time to AKI detection after colistin initiation.

Results: Thirty one patients were enrolled into the study. The mean age of patients were comparable in both group. Baseline glomerular filtration rate were 121.5±54.1 and 73.7±52.7 ml/min/1.73 m^2 in NGAL and creatinine monitoring group, respectively (P = 0.02). The overall incidence of colistin-induced AKI within 28 days was 70.9%. The median times to AKI detection were 1 and 5 days in NGAL monitoring and creatinine monitoring group, respectively (P = 0.001). There were no significant difference in renal replacement therapy and 28-day mortality.

Conclusions: Urinary NGAL monitoring could detect colistin-induced AKI more earlier than routine serum creatinine monitoring. The further study in larger population is still warrant.

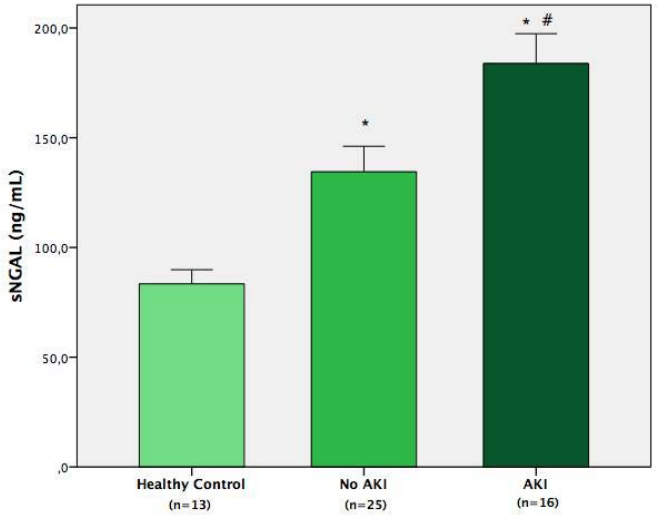
Serum Neutrophil Gelatinase-Associated Lipocalin Levels Predict Acute Kidney Injury in Visceral Leishmaniasis Gdayllon C. Meneses,[1] Elizabeth F. Daher,[1] Geraldo B. Silva Junior,[2] Gabriela F. Bezerra,[1] Alexandre B. Liborio,[2] Alice M.C. Martins.[1] *[1]Federal Univ of Ceara; [2]Univ of Fortaleza, Brazil.*

Background: Acute Kidney Injury (AKI) can be found in a significant proportion of patients with Visceral Leishmaniasis (VL). The aim of this study is to investigate the role of Neutrophil Gelatinase-Associated Lipocalin (NGAL) in the diagnosis of AKI in VL patients before specific treatment.

Methods: This is a prospective study with 41 patients with confirmed diagnosis of VL. This study was conducted in the Sao Jose hospital, a reference hospital of infectious disease in the state of Ceara, Brazil. At admission and before specific treatment for VL, blood and urine samples were collected. A control group was included with 13 healthy people. AKI was defined according to theKDIGO criteria. NGAL was measured in blood (sNGAL) and urine (uNGAL) through sandwich ELISA assay (R&D systems Inc). Urine biomarkers were expressed as ratios to urinary creatinine concentration (mg/g-Cr).

Results: Patients' average age was 45±19 years and 88% were male. In comparison with healthy controls, VL patients presented higher sNGAL and uNGAL levels than controls (sNGAL: 153±61 vs. 83±23ng/ml, p<0.001; uNGAL: 12±5.9 vs. 7.9±6.9ng/ml, p=0.03).



During hospital stay, 88% of VL patients received amphotericin B, and 16 (39%) developed AKI. sNGAL presented moderate to strong correlation with GFR, serum creatinine and urea in VL patients. Moreover, in logistic regression analysis, sNGAL was an independent risk factor for AKI. sNGAL was an important predictor of AKI in VL patients (AUC: 0.771; 95% CI 0.624-0.918, p=0.004).

Conclusions: VL patients presented high frequency of AKI during hospital stay. For the first time, serum NGAL levels on admission was evidenced to be a useful tool for assessing AKI risk among VL patients, even before specific treatment initiation.

TH-PO648

Copper-Zinc Superoxide Dismutase Is a Novel Prognostic Biomarker of Acute Kidney Injury following Cardiothoracic Surgery Joseph H. Holthoff,[1] Nithin Karakala,[1] Christian Herzog,[1] Joseph Alge,[2] John M. Arthur.[1] *[1]Internal Medicine - Div of Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Internal Medicine - Div of Nephrology, Medical Univ of South Carolina, Charleston, SC.*

Background: Acute kidney injury (AKI) remains a significant cause of morbidity and mortality, and approximately 20% of patients who undergo cardiothoracic surgery will develop AKI. The identification and prognosis of AKI, as well as the translation of preclinical therapeutic options has been impeded by the lack of a detectable biomarkers during AKI. Copper-Zinc superoxide dismutase (CuZn SOD) is an endogenous antioxidant protein which serves to neutralize superoxide radicals. Previous proteomics studies in our lab detected increased CuZn SOD in urine from patients who developed AKI after cardiothoracic surgery, as well as mice with ischemia-reperfusion injury and rat glycerol models of AKI. Thus, CuZn SOD offers a promising option as a novel biomarker for AKI.

Methods: Urine samples were obtained from 37 patients who developed stage 1 AKI within 48 hours of cardiothoracic surgery. Urine samples were diluted at 1:20 with phosphate-buffered saline (PBS), and urinary CuZn SOD was quantified by ELISA. Data were analyzed and a receiver operating characteristic curve (ROC) was constructed using Graphpad Prism 7.0.

Results: We found a significant increase in CuZn SOD concentration in the urine of patients that developed Stage 3 AKI, required renal replacement therapy (RRT), or died within 30 days when compared to patients who had a maximum increase in serum creatinine corresponding to stage 1-2 AKI. Urine CuZn SOD concentration was able to predict the combined outcome of stage 3 AKI, RRT, and mortality with an area under the ROC curve of 0.75 (95% C.I. = 0.59-0.91, p = 0.017).

Conclusions: This study demonstrates the potential for CuZn SOD to serve as a novel prognostic biomarker for AKI.

TH-PO649

Plasma Uric Acid and Development of Acute Kidney Injury in the Critically Ill Anand Srivastava, David E. Leaf, Venkata Sabbisetti, Sushrut S. Waikar. *Renal Div, Brigham & Women's Hospital, Boston, MA.*

Background: Elevations in plasma uric acid (PUA) may lead to acute kidney injury (AKI) through multiple mechanisms: tubular injury, mitochondrial dysfunction, endothelial dysfunction, oxidative stress, and intra-renal inflammation. The association between PUA levels and incident AKI in critically ill patients has not been rigorously evaluated.

Methods: We measured PUA levels in blood samples obtained within the first 24 hours of ICU admission in 117 critically ill patients without AKI. We fit multivariable logistic regression models to test the association between PUA levels and the primary end point of incident AKI, defined by the KDIGO criteria. Secondary end points were severe AKI (KDIGO stage 2 or 3) and the composite end point of renal replacement therapy (RRT) or in-hospital mortality.

Results: Mean age was 62.2 ± 14.4 years, 90.6% were white, 62.4% were female, and mean estimated glomerular filtration rate (eGFR) was 87.7 ± 21.4 ml/min/m^2. Mean ± SD PUA levels were 4.6 ± 2.0 mg/dl and were inversely correlated with eGFR (r = -0.30, p=0.0009). Patients who developed AKI had higher PUA levels and lower eGFR at enrollment than those who did not develop AKI (Table):

	Incident AKI	No Incident AKI	p-value
PUA, mg/dl	5.6±2.3	4.2±1.7	0.0008
Age, years	62.7±12.2	62.0±15.3	0.83
Female	40.6%	36.5%	0.68
Caucasian	87.5%	91.8%	0.48
eGFR, ml/min/m^2	75.1±23.5	92.4±18.7	<0.0001
APACHE II	14 [11-17]	14 [10-17]	0.61
*Data presented are Mean ± SD or Median [Interquartile range]			

After adjusting for age, sex, race, eGFR, and APACHE II score, PUA levels remained significantly associated with incident AKI (odds ratio 1.29, 95% confidence interval 1.02 to 1.64) and severe AKI (odds ratio 1.39, 95% confidence interval 1.01 to 1.90), but not the composite end point of RRT/mortality.

Conclusions: Higher PUA levels are associated with an increased risk for the development AKI in critically ill patients admitted to the ICU, independent of confounding factors including enrollment eGFR and severity of disease. These results are consistent with a pathogenic role for uric acid in the development of AKI.

Platelet Aggregability as a Predictor of Acute Kidney Injury and Cardiovascular Events in Vascular Surgeries Mauricio Teixeira,[1] Daniela Calderaro,[2] Etienne Macedo.[1,3] *[1]USP; [2]INCOR; [3]UCSD.*

Background: Platelet aggregation is one theory that can explain the AKI process after the reperfusion is obtained in the ischemic model. In the population with arterial illness, this process may play a role in acute ischemic events like AKI and Cardiovascular Events (CvEv). Evaluation of platelet aggregability is used to study perioperative cardiovascular risk. The purpose of this study is to evaluate if the platelet aggregation could be a marker to predict AKI and CvEv in patients submitted to vascular surgeries.

Methods: Analysis of a prospective cohort of patients submitted to a major vascular surgery from whom the platelet aggregation test was performed. The extent of aggregation assesses the amount of platelet aggregates after the exposure to some agonists. The arachidoniac acid (AA) is the most important agonist in the present study because every patient was under chronic use of aspirin. This medicine inhibits platelet aggregation by blocking cyclooxygenase. This is a validated tool for the measure of aspirin response. Severity of AKI was stratified by the KDIGO classification using the first creatinine before the surgery.

Results: A total of 185 patients were analyzed. The main vasculopathy was in the aorta, 36,2%. We had 70 (37,8%) patients with AKI and 42 (22,7%) CvEv. There was a significant association between higher platelet response to AA and AKI. The mean of resistance in the no AKI group was 5,06Ω (n=115) and in the AKI group was 6,92Ω, p = 0,037. We could demonstrate that the response to AA increases with the severity of AKI: 5,88Ω in the KDIGO 1 group (n = 45), 10,5Ω KDIGO 2 group (n = 9) and 7,8Ω in the KDIGO 3 group (n = 16), p = 0,022. There was also association between platelet aggregation and CvEv: 5,3 Ω no CvEv and 7,4 Ω in the CvEv group, p = 0,04. We also had an association between AKI and CvEv: 57% of the CvEv were in the AKI group, p=0,003.

Conclusions: Platelet aggregation may play a critical role in the pathophysiology of AKI and of CvEv. This can be one of the common pathways that predisposes some patients to develop ischemic events. In our cohort we showed that there was an association between platelet aggregation and AKI and also an association between AKI and CvEv.

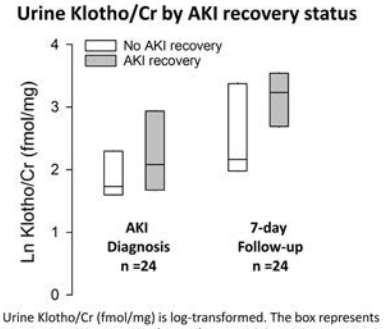
Urine Klotho Is a Potential Marker of AKI Recovery in the Intensive Care Unit Javier A. Neyra, Xilong Li, Federica Mescia, Victor E. Prado, Johanne Virginia Pastor, Beverley Adams-Huet, Ming Chang Hu, Robert D. Toto, Orson W. Moe. *UT Southwestern, Dallas, TX.*

Background: AKI carries increased risk for subsequent CKD. Klotho deficiency has been observed in AKI and low Klotho post-AKI is associated with progression to CKD in rodents. We aim to characterize post-AKI urine Klotho trajectories in ICU patients with and without 7-day AKI recovery.

Methods: We conducted a prospective study of 54 AKI patients and 52 controls without AKI in the ICU setting. We excluded patients with baseline eGFR<60 or kidney transplant. Urine samples were obtained within 24h of AKI diagnosis (KDIGO stage ≥2) and within 48h of ICU admission in frequency-matched controls (by baseline eGFR and age). Renal recovery was defined as the ratio of follow-up serum creatinine (SCr)/baseline SCr ≤1.5. Urine Klotho was measured by immunoprecipitation-immunoblot. Nonparametric tests were used for comparisons.

Results: Mean (SD) age was 57 (16) years, 57% were men and 70% white. Patients with AKI had higher critical illness scores than controls without AKI. Most AKI cases (76%) were attributed to ATN and/or sepsis. A total of 24 (44%) patients died and 18 (33%) required RRT in the AKI group. Urine Klotho adjusted by urine creatinine (uKlotho/Cr) was significantly lower in AKI cases than in controls, median 7 [IQR 5–10] vs 28 [11–59] fmol/mg, $p<0.001$. Furthermore, uKlotho/Cr significantly increased with time in patients that exhibited AKI recovery (n=8, Δ+266%, $p=0.02$) but not in those that did not (n=16,Δ+31%, $p=0.10$), between-group $p=0.03$, median follow-up 6 (3-7) days.



Urine Klotho/Cr (fmol/mg) is log-transformed. The box represents the interquartile range (25th to 75th percentile) and the horizontal line represents the median.

Conclusions: Urine klotho is significantly lower in patients with AKI when compared to ICU controls without AKI. Urine Klotho significantly recovered only in patients that exhibited 7-day AKI recovery. Urine Klotho may be a prognostic marker of AKI recovery in the ICU.

Proteomic Approaches to Identify Differentially Expressed Proteins in Cardiac Surgery Associated Acute Kidney Injury Ravi C. Dwivedi,[1] Mario Navarrete,[1] Nora Choi,[1,3,4] Vic Spicer,[1] Peyman Ezzati,[1] Claudio Rigatto,[2] Rakesh C. Arora,[4] Oleg Krokhin,[1] Julie Ho,[1,2,3] John A. Wilkins.[1,3] *[1]Manitoba Centre for Proteomics & Systems Biology, Health Sciences Centre, Univ of Manitoba; [2]Dept of Internal Medicine, Section of Nephrology, Univ of Manitoba; [3]Dept of Immunology, Univ of Manitoba; [4]Cardiac Sciences Program, St. Boniface Hospital, Winnipeg.*

Background: Acute kidney injury (AKI) after cardiopulmonary bypass (CPB) is an important cause of morbidity and mortality. Mass-spectrometry (MS)-based proteomics may allow us to improve our understanding of ischemia-reperfusion injury (IRI) and identify 'at-risk' individuals. The goal was to perform an in-depth proteomic analysis of patients undergoing CPB.

Methods: A nested case-control cohort (5 AKI & 5 non-AKI patients) from a prospective cohort of 306 adult CPB patients was evaluated at: baseline, start CPB, 1hr CPB, arrival to ICU, POD day 1 and 3-5. Pooled urines were processed using modified Filter Assisted Sample Preparation, separated and analyzed by 2D-LC-MS/MS for protein identification and to generate an ion library. A label-free approach was applied for protein quantitation. Protein identification accuracy was increased by analyzing the same samples with SWATH-MS (Sequential Window Acquisition of All Theoretical Fragment ion spectra Mass-Spectrometry). Protein relative abundance was compared in AKI vs non-AKI using both 2D-LC-MS/MS and SWATH.

Results: Using a high-content MS approach we confidently identified 2,061 proteins (≥2 peptides, log(e)≤-3) across all time-points. For more complete comparison we used SWATH-MS to provide quantitative data on 826 proteins, which demonstrated some overlap with the 2D-LC-MS/MS data. Differential analysis detected 10 decreased and 11 increased proteins in AKI vs non-AKI patients, based on normalized Z-scores >1 across all time-points. Urinary MMP9 was validated as decreased in AKI versus non-AKI pooled urines using ELISA.

Conclusions: This study provides high quality protein quantitation in AKI vs non-AKI patients throughout IRI. The differential proteomic changes identified may provide insight into the pathophysiology of IRI and potential novel biomarker identification.

TH-PO653

Low Regulatory T Cell Abundance before Cardiac Surgery Is Associated with Increased Risk of AKI: A Pilot Study Gilbert R. Kinsey,[1] Jennie Z. Ma,[2] John Kern,[3] Mark D. Okusa,[1] Charles H. Brooks,[1] Sandra Burks,[3] Ashley Craddock,[3] Adrienne Lynne Stimson,[3] Victoria L. Yu,[1] Brian K. Stevens.[1] *[1]Div of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, Univ of Virginia; [2]Public Health Sciences, Univ of Virginia; [3]Surgery, Univ of Virginia.*

Background: Patients who undergo cardiac surgery (CS) are at high risk of developing post-surgical acute kidney injury (AKI). The pathogenesis of AKI involves inflammation, nephrotoxins and ischemia-reperfusion injury (IRI). Preclinical studies have demonstrated regulatory T cells (Tregs) protect the kidney from inflammation and dysfunction induced by IRI and nephrotoxins. We hypothesized that patients with low circulating Treg numbers at the time of surgery would be at increased risk of developing AKI in the post-surgical period.

Methods: Circulating Treg number was determined by flow cytometry of blood from 45 adult CS patients on the morning of surgery, prior to initiating cardiopulmonary bypass, and again 24h after surgery. Occurrence of AKI was determined using KDIGO Stage II creatinine and urine output criteria over the first 48h after CS.

Results: The number of circulating Tregs ($CD4^{+}CD127^{low/-}CD25^{high}$) per ml of blood, prior to CS, was variable with a range of 7,100 to 84,000. Patients were split into low, medium and high tertiles based on Treg number and the rate of AKI compared between groups. Stage II AKI occurred in 60, 13, and 20% of patients in these groups, respectively. After adjusting for the effect of pre-existing CKD and advanced age in logistic regression, the odds ratio for developing AKI in the low Tregs group vs. high group was 7.0 (95% CI: 1.2-41.5), and there was no significant difference between middle and high groups. In 36/45 patients the circulating number of Tregs was decreased by an average of 30% after CS (P<0.01).

Conclusions: These results demonstrate that patients in this pilot study with low circulating Tregs, prior to CS, developed AKI at a higher rate than patients with middle or high levels of Tregs. Along with preclinical studies, this suggests strategies to boost Tregs prior to CS, in patients with low circulating Tregs, may reduce the risk of post-surgical AKI in these patients.

Urinary Excretion of Active Serine Hydrolases in Cardiac-Surgery Associated Acute Kidney Injury Mario Navarrete,[1] Julie Ho,[1,2,3] Ravi C. Dwivedi,[1] Nora Choi,[1,3] Peyman Ezzati,[1] Oleg Krokhin,[1] Vic Spicer,[1] Rakesh C. Arora,[4] Claudio Rigatto,[2] John A. Wilkins.[1] *[1]Manitoba Centre for Proteomics & Systems Biology, Health Science Centre, Univ of Manitoba, Winnipeg, MB, Canada; [2]Internal Medicine, Section of Nephrology, Univ of Manitoba, Winnipeg, MB, Canada; [3]Immunology, Univ of Manitoba, Winnipeg, MB, Canada; [4]Cardiac Science Program, St. Boniface Hospital, Winnipeg, MB, Canada.*

Background: Changes in enzyme activity are physiologically relevant and may be independent of enzyme quantity. Activity-based protein profiling (ABPP) is a proteomic approach to assess the functional status of enzymes. ABPP may offer insight into ischemia-reperfusion injury (IRI) and identify novel acute kidney injury (AKI) markers following cardiopulmonary bypass (CPB). The goal was to characterize urine serine hydrolase activity and composition throughout IRI.

Methods: A nested case-control cohort (8 AKI & 8 non-AKI patients) from a prospective cohort of 306 adult cardiac surgery patients was evaluated at: baseline, start CPB, 1hr CPB, arrival to ICU, POD 1 and 3-5. ABPP was visualized by SDS-PAGE and protein by Coomassie. Serine hydrolase composition was determined by MS/MS. Active serine hydrolases were affinity purified and identified on MS/MS.

Results: Serine hydrolase activity remained stable throughout IRI in non-AKI. AKI urines demonstrated early differential intraoperative serine hydrolase activity that was independent of protein quantity.

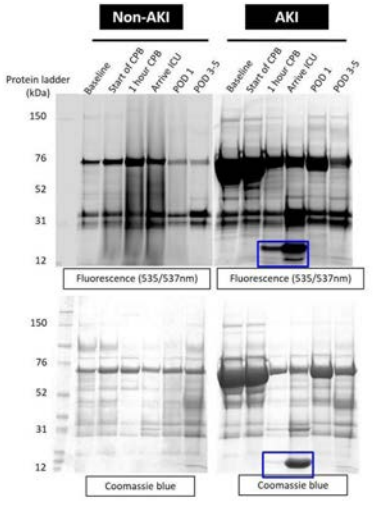

Figure 1. Serine hydrolase ABPP demonstrates early enzyme activity, independent of protein concentration, that differs between AKI versus non-AKI patients

AKI urines had 53 serine hydrolases on compositional analysis, whereas 31 were identified in their active state. Quantitative assays confirm differential enzyme activity between AKI and non-AKI.

Conclusions: We demonstrated novel serine hydrolase activity and confirmed differential enzyme activity in AKI vs. non-AKI patients. These findings have implications in understanding the serine hydrolase response to IRI and may be a potential early intraoperative marker of AKI.

Funding: Government Support - Non-U.S.

TH-PO655

Latent Class Analysis Identifies AKI Sub-Phenotypes with Differing Biomarker Profiles of Endothelial Dysfunction and Relation to Risk of Death and Need for Renal Replacement Therapy Pavan K. Bhatraju,[1] Cassianne Robinson-Cohen,[2] Jonathan Himmelfarb,[2] Mark M. Wurfel.[1] *[1]Pulmonary and Critical Care, Univ of Washington, Seattle, WA; [2]Kidney Research Inst, Univ of Washington, Seattle, WA.*

Background: The heterogeneity of acute kidney injury (AKI) may limit identification of patients at highest risk of poor outcomes. Latent class analysis (LCA) is a statistical modeling technique to identify unobserved sub-groups using observed clinical and biologic patient characteristics. We hypothesized that LCA would identify AKI sub-phenotypes with differing biomarker profiles and associations with outcomes.

Methods: We applied LCA to 806 ICU subjects with AKI (change in serum creatinine of 0.3 mg/dl, <72 hours of ICU admit) from a cohort of patients with systemic inflammatory response syndrome. Subjects were equally split into discovery and validation sets. In the discovery group the LCA included 25 biological and clinical variables measured on day 1 of study enrollment. We then tested the association of sub-phenotypes with 28 day mortality, incident RRT and identified sub-phenotype predictors using Akaike information criterion (AIC). Predictors were then tested in the validation set for associations with outcomes.

Results: A two-class model was the best fit in the derivation set ($p < .001$). Sub-phenotype 2 was characterized by higher biomarker levels of inflammation and endothelial dysfunction, higher use of vasopressors and higher levels of serum creatinine compared to sub-phenotype 1. There were higher rates of hospital mortality (25% vs 8% $p < .001$) and use of RRT (19% vs 4% $p < .001$) in sub-phenotype 2. Angiopoietin 2 (ang-2) had the lowest AIC. In the validation cohort ang-2 identified similar sub-phenotypes with sub-phenotype 2 having higher mortality (29% vs 8%) and RRT (18% vs 5%) compared to sub-phenotype 1, $p < .001$.

Conclusions: LCA identified two sub-phenotypes among critically ill patients with AKI, one of which is characterized by endothelial dysfunction and worse clinical outcomes. This AKI sub-phenotype may identify a more biologically homogeneous group at high-risk for poor outcomes.

TH-PO656

Soluble FAS and Soluble Tumor Necrosis Factor I, Biomarkers of Apoptosis and Inflammation, Are Differentially Associated with a Non-Resolving AKI Sub-Phentoype Pavan K. Bhatraju,[1] Cassianne Robinson-Cohen,[2] Jonathan Himmelfarb,[2] Mark M. Wurfel.[1] *[1]Pulmonary and Critical Care, Univ of Washington, Seattle, WA; [2]Kidney Research Inst, Univ of Washington, Seattle, WA.*

Background: Acute kidney injury (AKI) is a heterogeneous syndrome involving the interplay of apoptosis, inflammation and endothelial dysfunction. This heterogeneity limits the ability of biomarker analysis to identify potentially targetable pathways in disease development. We hypothesize that the trajectory of serum creatinine (resolving and non-resolving) in the first 72 hours of ICU admission will identify AKI sub-phenotypes with different levels of plasma biomarkers.

Methods: Among 1255 subjects with systemic inflammatory response syndrome and admitted to the ICU at Harborview Medical Center, we evaluated a panel of biomarkers of apoptosis, inflammation and endothelial dysfunction, from plasma obtained within 24 hours of admission: soluble tumor necrosis factor receptor 1 (sTNFR-I), soluble FAS (sFAS), interleukin 6, 8, 17, angiopoietin 1, angiopoietin 2 and soluble vascular cell adhesion molecule 1 (sVCAM-1). We examined associations of biomarkers with subsequent AKI sub-phenotypes using relative risk regression.

Results: During the first 72 hours of ICU admission, 816 (65%)subjects developed AKI. Of these 480 (59%) had a resolving sub-phenotype and 336 (41%) had a non-resolving sub-phenotype. The hospital mortality rate of subjects with no AKI was 4%, resolving sub-phenotype was 10% and a non-resolving sub-phenotype was 23%. Plasma sFAS, sTNFR-1 and sVCAM-1 concentrations were independently associated with a non-resolving sub-phenotype compared to resolving after adjustment for age, body mass index, diabetes and apache III scores ($p < .001$). Notably, after adjustment for endothelial dysfunction (sVCAM-1), a doubling of sFAS and sTNFR-1 remained strongly associated with a non-resolving sub-phenotype (RR 1.25 (95% CI 1.11, 1.42, $p<.001$)) and (RR 1.20 (95% CI 1.09, 1.33, $p<.001$)), respectively.

Conclusions: This work suggests research identifying modifiable targets in the sFAS and sTNFR-1 pathways may allow the prevention and treatment of a severe sub-phenotype of AKI.

TH-PO657

Serum Cystatin C Predicts Renal Recovery Earlier Than Serum Creatinine among Hospitalized Patients with Acute Kidney Injury Kamel A. Gharaibeh, Abdurrahman M. Hamadah, John C. Lieske, Ziad El-Zoghby, Nelson Leung. *Nephrology, Mayo Clinic, Rochester, MN.*

Background: Limited evidence suggests serum cystatin C (cysC) peaks earlier than serum creatinine (sCr) during the course of acute kidney injury (AKI). Earlier identification of AKI recovery could support less intensive resource utilization and earlier hospital discharge. We conducted an observational pilot study to determine the relative time course of sCr and cysC change in hospitalized patients with AKI in a tertiary medical center.

Methods: Hospitalized patients with AKI at our institution between May 2015 and May 2016 who had serial sCr and cysC levels measured during their hospitalizations were identified. AKI was defined based on the Acute Kidney Injury Network criteria. Demographic data, baseline creatinine, cause of AKI, and other significant comorbidities were collected by medical record review.

Results: Overall, 63 patients were identified. Mean age was 58.7 ± 13.9 years, 62% were men, 95% were white, and median BMI was 27.8 kg/m^2. Baseline median sCr was 1.05 (IQR 0.8-1.3), 13% had a kidney transplant and 37% had received corticosteroids. Co-morbidities included malignancy (38%), diabetes (33%), thyroid disorder (16%) and heart failure (19%). The majority of cases were AKI stage III (61%) with 22 patients (35%) requiring dialysis. The cause of AKI was ATN in 71% of patients. CysC peaked before sCr in 68% of patients (6% 3 days, 16% 2 days, 46% 1 day sooner), on the same day in 24%, and in 5 patients (8%) cysC peaked after SCr. Overall cysC peaked a mean of 0.92 days prior to sCr (95% CI 0.65-1.18; $p<0.001$). Exploratory analyses did not reveal effects of patient co-morbidities on the timing of peak cysC compared to sCr. Lower baseline eGFR predicted earlier recovery by cysC ($P=0.035$). Overall cysC performed equally well or better than sCr in 92% of patients in this study for monitoring recovery from AKI.

Conclusions: This study suggests cysC peaks earlier than sCr in the majority of hospitalized AKI patients. These findings have significant clinical implications for managing AKI with the potential for shortening hospital stay and reducing costs. A large prospective study is warranted to confirm these findings.

TH-PO658

Temporal Profiling Refines the Prognostic Value of Acute Kidney Injury Urinary Biomarkers Margaret Rachel Ninemire,[1] Shina Menon,[2] Erin K. Stenson,[3] Stuart Goldstein,[4] Rajit K. Basu.[3,4] *[1]Pediatrics, Cincinnati Children's Hospital; [2]Pediatric Nephrology, Seattle Children's Hospital; [3]Pediatric Critical Care, Cincinnati Children's Hospital; [4]Center for Acute Care Nephrology, Cincinnati Children's Hospital.*

Background: Acute kidney injury (AKI) is common in critically ill children with sepsis, and persistent AKI (pAKI) is associated with poor clinical outcomes. Novel urinary biomarkers used for AKI prediction have been studied in many populations. However, these studies generally only compare individual biomarkers measured at a single time point. Analysis of biomarker measurement trends over time to predict pAKI is not well described.

Methods: We conducted a single center, prospective study of children admitted to the intensive care unit (ICU) with multiple urinary biomarker levels (neutrophil gelatinase associated lipocalin (uNGAL) and kidney injury molecule-1 (uKIM-1)) in the first 36 hours to test the hypothesis that predictive performance of pAKI by changes in biomarkers was superior versus changes in serum creatinine (SCr). Stage 2-3 KDIGO SCr criteria 72 hours after admission defined pAKI.

Results: 173 pts (51% male, median age 6.7 yrs), including 42 with sepsis (24%) and 31 with pAKI (18%) were studied. Combination of a persistent elevation in uNGAL (>150 on days 1 and 2) and an increasing uKIM-1 (rising value from day 1 to 2) increased the likelihood of pAKI nearly 2-fold compared to doubling of SCr from baseline. When stratified by sepsis, the positive likelihood of pAKI predicted by the biomarker changes in combination remained statistically significant versus the changes in SCr.

Patients	↑ uNGAL	↑ uKIM-1	↑uNGAL ↑uKIM-1	↑2-3x SCr
All	2.6 (1.6-4.2)	1.4 (1.1-1.9)	4.6 (2.3-9.2)	2.8 (1.1-7.4)
No Sepsis	2.5 (1.3-4.9)	1.4 (0.9-2.0)	4.2 (1.6-10.7)	1.7 (0.2-15.8)
Sepsis	2.3 (1.3-4.0)	1.6 (1.0-2.7)	3.3 (1.4-7.7)	2.2 (0.8-5.6)

↑ = Multiple, Sequential Elevation

Conclusions: Together, how urinary biomarkers change over time may provide added insight for AKI prediction compared to single measurements and refine AKI stratification compared to current clinical standards. Further studies are needed to validate these findings.

TH-PO659

Biomarkers at Discontinuation of Renal Replacement Therapy Predict 90-Day Clinical Outcomes in Critically Ill Patients with Acute Kidney Injury Tingting Yang, Baihai Su. *Dept of Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: There is no consensus on the specific indications of weaning renal replacement therapy (RRT) in acute kidney injury (AKI).This study aimed to explore the prognostic value of several biomarkers at discontinuation of RRT for 90-day outcomes and find potential indicators for discontinuation of RRT.

Methods: We prospectively enrolled 102 patients with AKI who require RRT from intensive care unit (ICU). Serum osteopontin (sOPN), serum interleukin-6 (sIL-6), serum Cystatin C (sCysC), sIL-18, serum neutrophil gelatinase-associated lipocalin (sNGAL) and urinary NGAL (uNGAL) and uIL-18 were measured at discontinuation of RRT. Patients were followed-up till 90 days for survival and renal recovery. Multivariate logistic regression and ROC analysis were performed to assess the predictive value of each biomarker for prognosis.

Results: Patients who survived had lower levels of all serum and urinary biomarkers. Serum OPN was an independent predictor of 90d mortality (OR, 1.029; 95% CI, 1.013-1.047; p=0.001).Lower sOPN and sIL-6 were associated with greater odds of 90d survival (area under the ROC curve (AUC), 0.812 and 0.741). Lower sCysC was associated with greater odds of 90d renal recovery (AUC, 0.743). The AUC reached best when combining biomarkers with conventional indicators at discontinuation of RRT (0.881 for predicting survival and 0.923 for predicting renal recovery).

Conclusions: Serum and urinary biomarkers at discontinuation of RRT can be predictive for 90d survival and renal recovery in critically ill AKI patients. Serum OPN, IL6 and CysC are promising indicators for discontinuation of RRT.

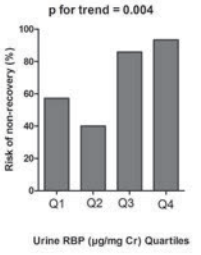
TH-PO660

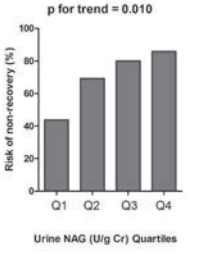
Urinary Retinol-Binding Protein as a Risk Factor of Poor Prognosis in Acute-on-Chronic Renal injury Yanhong Yuan, Shan Mou. *Dept of Nephrology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China.*

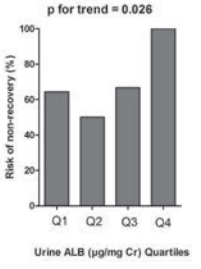
Background: Acute-on-chronic renal injury was commonly seen in clinical practice. This study tested whether urinary biomarkers could be used as a noninvasive prognostic marker in acute-on-chronic renal injury patients.

Methods: 108 adult patients with pre-existing chronic kidney disease presenting with acute-on-chronic renal injury were included. Urinary retinol-binding protein , N-Acetyl-b-D-Glucosaminidase and albumin was quantified.

Results: Reversibility of renal function was achieved in 43 patients of the included patients.The levels of urinary retinol-binding protein, N-Acetyl-b-D-Glucosaminidase and albumin for non-recovery acute-on-chronic renal injury patients were much higher than recovery patients. Quartiles of retinol-binding protein, urinary N-Acetyl-b-D-Glucosaminidase and albumin had a graded relationship with the risk for un-recovery AKI.







And the urinary retinol-binding protein was an independent risk factor for outcome of acute-on-chronic renal injury patients by multivariate logistic regression analysis

Characteristics	Univariate analysis			Multivariate analysis		
	HR	95% CI	P value	HR	95% CI	P value
Age (years)	1.026	1.001-1.051	0.038			0.172
baseline Scr (µmol/L)	1.007	1.001-1.013	0.016			0.068
Scr at AKI (µmol/L)	1.006	1.002-1.010	0.007			0.062
uRBP (µg/mg Cr)	1.175	1.046-1.320	0.007	1.162	1.036-1.303	0.010
uNAG (U/g Cr)	1.0112	0.999-1.026	0.06			0.377
uALB (µg/mg Cr)	1.000	1.000-1.001	0.046			0.29

Conclusions: In patients with acute-on-chronic renal injury, quantification of urinary retinol-binding protein may be developed as a non-invasive tool for predicting outcome of acute-on-chronic renal injury patients.

TH-PO661

Five-Year Kidney Injury Biomarkers after Pediatric Acute Kidney Injury Jason Henry Greenberg,[1] Prasad Devarajan,[2] Heather Thiessen Philbrook,[1] Catherine Krawczeski,[3] Simon Li,[4] Amit X. Garg,[5] Steven G. Coca,[6] Chirag R. Parikh,[1] Michael Zappitelli.[7] *[1]Program of Applied Translational Research, Yale Univ, CT; [2]Pediatrics, Cincinnati Childrens, OH; [3]Pediatrics, Stanford Univ, CA; [4]Pediatrics, Maria Fareri Childrens, NY; [5]Medicine, Western Univ, London; [6]Medicine, Mount Sinai, NY; [7]Pediatrics, McGill Univ, Montreal.*

Background: We recently determined that pediatric AKI after cardiac surgery (CS) is not associated with an increased risk of CKD at 5 years of follow-up. We evaluated if at 5 years after CS, there was evidence of subclinical kidney injury, measured by renal injury biomarkers, in patients with *vs.* without AKI.

Methods: The Translational Research Investigating Biomarker Endpoints in AKI (TRIBE-AKI) long-term study is a 3 center prospective cohort study of children 1 month to

18 years old who underwent cardiopulmonary bypass for CS and survived hospitalization. At 5 years post-CS, we measured urine interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), monocyte chemoattractant protein-1 (MCP-1), and YKL-40 to evaluate for subclinical chronic renal injury. Biomarker levels were compared between patients with AKI (≥50% or ≥0.3 mg/dL serum creatinine rise) *vs.* without.

Results: 305 study subjects survived hospitalization: 4 (1.3%) died after discharge; 110 (42%) participated in the 5 year follow-up (median 5.4 years follow-up). Mean age at follow-up was 8.7 years; 52% were male. 49/110 (45%) had AKI. At 5 years, there was no significant difference in any of the biomarker concentrations between AKI groups (see Table).

Conclusions: Post-operative pediatric AKI is not associated with elevation of kidney injury biomarkers 5 years after CS. This may either represent a lack of chronic renal injury after pediatric AKI, that longer follow-up is needed to determine long-term AKI renal damage, or that our studied biomarkers are inadequate for evaluating subclinical chronic renal injury.

Table. Five-year biomarker results by AKI status

	AKI N=49	No AKI N=61	P value
Urine IL-18 (pg/mL)	16.57 [9.53, 24.25]	13.94 [7.92, 21.79]	0.26
Urine KIM-1 (pg/mL)	366.07 [157.56, 656.82]	336.34 [175.81, 525.38]	0.40
Urine MCP-1 (pg/mL)	103.44 [45.27,169.38]	116.4 [47.43,167.25]	0.83
Urine YKL-40 (pg/mL)	344.54 [184.23, 645.88]	330.11 [149.55, 614.82]	0.58
Values are expressed as median [interquartile range].

TH-PO662

Proteinuria Is an Independent Predictor for Acute Kidney Injury following Coronary Artery Bypass Grafting Kevin D. Hageman,[1] Alice M. Lee,[1] Joseph A. Forgione,[1] Injoon Lee,[1] Roja Chimakurthi,[2] Rodrigo Aguilar Campos,[1] Wen Shen,[2] Jaeil Ahn.[3] *[1]Dept of Medicine, Georgetown Univ Hospital, Washington, DC; [2]Dept of Nephrology and Hypertension, Georgetown Univ Hospital, Washington, DC; [3]Dept of Biostatistics, Georgetown Univ, Washington, DC.*

Background: Acute kidney injury (AKI), a common postoperative complication of CABG, is associated with increased morbidity and mortality. Proteinuria is a promising biomarker of early AKI. Understanding if preoperative proteinuria predicts AKI post-CABG may help us optimize treatment and minimize the risk of AKI.

Methods: A retrospective cohort study was conducted on patients undergoing first-time CABG between 2004-2014 with a preoperative urine study. Patients with age <18, eGFR of <30, history of RRT and combined cardiac surgery were excluded. A total of 557 patients were included. AKI diagnosis was based on SCr 48 hours after CABG, and was defined by AKIN criteria. Logistic regression was used to analyze the associations between proteinuria and AKI, AKI requiring RRT, and in-hospital mortality. The association models were further adjusted for confounding variables (age, race, gender, HTN, DM, CVA/TIA, CHF, anemia, CVA/TIA, PVD, smoking) known to correlate with AKI.

Results: The incidence of AKI in patients with preoperative proteinuria is higher than that without proteinuria [39.9% vs 18.9%, OR 2.85, 95% CI (1.95- 4.20), p < 0.001). Compared with no proteinuria, mild proteinuria increased the risk of AKI 2.13 times [95% CI (1.95, 4.20)], moderate proteinuria 3.58 times [95% CI (1.70, 7.49)] and severe proteinuria was associated with a 5.97 fold higher risk of AKI [95% CI (3.09, 11.75)]. After adjusting for covariates, proteinuria was still strongly associated with higher AKI incidence (OR 2.44, 95% CI (1.58- 3.79)). The incidence of AKI requiring RRT was higher in patients with proteinuria compared to patients without proteinuria, however, the difference is not statistically significant due to rare cases of AKI requiring RRT (2.8% vs 2.5%).

Conclusions: Preoperative proteinuria was strongly associated with post-CABG AKI before and after adjustment of covariates. The incidence of AKI increased along with the severity of proteinuria.

Prognosis Prediction by Biomarkers on Dialysis-Requiring Severe Acute Kidney Injury Tetsushi Yamashita, Eisei Noiri, Kengo Mayumi, Ryo Matsuura, Masaomi Nangaku, Kent Doi. *The Univ of Tokyo, Tokyo, Japan.*

Background: Many biomarkers have been developed mainly for early detection of AKI. Another challenge is prediction of mortality and renal recovery. It is clinically important to predict these outcomes of severe AKI patients requiring renal replacement therapy. This study was conducted to evaluate the performance of biomarkers measured at CRRT initiation for severe AKI.

Methods: This study enrolled 98 AKI patients who needed CRRT in the adult mixed ICU of The University of Tokyo Hospital from October 2013 to March 2015 by consecutive sampling. Blood biomarkers of NGAL, NT-proBNP, Cystatin C, and HMGB-1 and urine biomarkers of L-FABP, NAG, α1- microglobulin and TIMP-2 were measured at CRRT initiation. We evaluated whether these biomarkers could predict mortality and renal recovery by receiver operating characteristic (ROC) analysis. We also evaluated whether the addition of biomarkers to a clinical model, which consisted of age and SOFA score, is helpful to predict mortality and renal recovery using category-free net reclassification improvement (cfNRI) and integrated discrimination improvement (IDI).

Results: In-hospital mortality was 46% in this cohort and only urine L-FABP was significantly higher in the non-survivors than the survivors. ROC analysis showed the AUC-ROC of 0.64 [0.52-0.75]. The cfNRI demonstrated addition of L-FABP to the clinical model improved mortality prediction. Thirty-nine patients (40%) showed renal recovery, which was defined as being alive and independent from dialysis on discharge with a less than 50% decrease in eGFR. Only plasma NGAL was significantly lower in these patients than the others. The AUC-ROC of plasma NGAL for renal recovery prediction was 0.71 [0.60 - 0.81]. The cfNRI and IDI demonstrated addition of NGAL to the clinical model showed significant improvement of renal recovery prediction.

Conclusions: Urine L-FABP and plasma NGAL measured at CRRT initiation could predict mortality and renal recovery, respectively. Even in the most severe AKI, which requires RRT, L-FABP and NGAL have potential to predict hard outcomes.

Urinary Hepcidin-25 Is Elevated after Cardiac Surgery in Non-AKI versus AKI Patients Nora Choi,[1,2] Claudio Rigatto,[3] Brett M. Hiebert,[4] Ang Gao,[2] Simon Christie,[4] Michael Zappitelli,[5] Rakesh C. Arora,[4] Julie Ho.[1,2,3] *[1]Immunology, Univ of Manitoba, Winnipeg, MB, Canada; [2]Manitoba Centre for Proteomics & Systems Biology, Univ of Manitoba, Winnipeg, MB, Canada; [3]Internal Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [4]Cardiac Sciences Program, St. Boniface Hospital, Winnipeg, MB, Canada; [5]Pediatric Nephrology, McGill Univ, Montréal, QC, Canada.*

Background: Acute kidney injury (AKI) following cardiac surgery results in increased morbidity and mortality. Using proteomic techniques, we previously identified urine hepcidin-25 as a predictor for AKI avoidance. The goal of this study was to independently validate urine hepcidin-25 as an early AKI marker in a prospective observational cohort of cardiopulmonary bypass (CPB).

Methods: Serial urines were collected at baseline, start CPB, 1hr CPB, arrival to ICU, post-operative day (POD) 1 and 3-5. Urine hepcidin-25 was evaluated with ELISA in a nested case-controlled cohort of AKI vs. non-AKI (n=42) across 6 time points and at POD1 in the full cohort (n=306). AKI was defined using KDIGO (creatinine >50% or 26.5μmol/L/48hrs). Stepwise logistic regression was performed using significant univariate predictors of AKI.

Results: Peak hepcidin-25 levels were confirmed at POD1 in AKI and non-AKI patients. Univariate predictors of AKI were hepdicin-25, age, baseline eGFR & creatinine, diabetes (DM), congestive heart failure and THAKAR & EUROscore II. Urine hepcidin-25 was an independent predictor for AKI avoidance on multivariate analysis. The combined model with eGFR, DM and hepcidin-25 had an AUC 0.815.

Table 1.Urine hepcidin-25 is an independent predictor for avoidance of AKI after cardiac surgery

Variable	Odds Ratio	95% CI	p-value
eGFR (mL/min/1.72 m^2) – Per Unit	0.96	0.95 – 0.98	<0.01
Diabetes mellitus	3.08	1.47 – 6.45	<0.01
Average Hepcidin-25 Concentration (ng/ml) – Per 1000 Units	**0.67**	**0.50 – 0.95**	**0.02**

Final multivariable logistic regression model developed using stepwise selection method. Missing covariate values estimated via multiple imputation. **Area Under the ROC Curve = 0.815 (0.746 – 0.884)** Hosmer-Lemeshow P-Value = 0.90

Conclusions: We validated urine hepcidin-25 as an AKI avoidance marker in an independent cardiac surgery cohort. Urine hepcidin-25 may be renoprotective by sequestering iron in renal tubular epithelial cells.

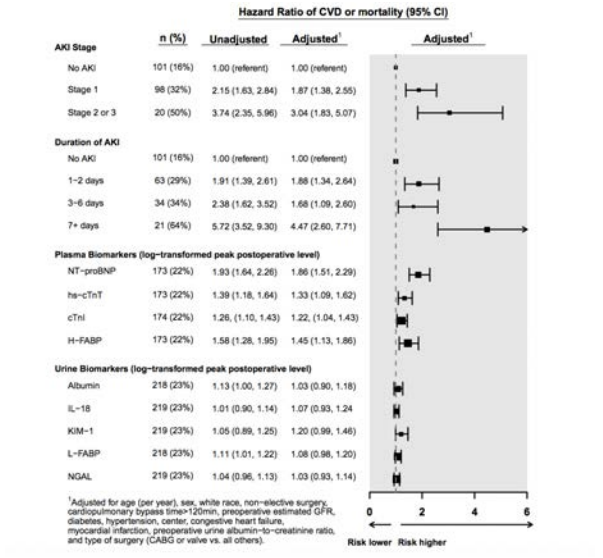
Association between Different Measures of Kidney Injury and Long-Term Risk of Cardiovascular Events and Mortality after Cardiac Surgery Chirag R. Parikh, Jeremy Puthumana, Amit X. Garg, Heather Thiessen Philbrook, Eric McArthur, Jay L. Koyner, Michael Shlipak, Steven G. Coca. *TRIBE-AKI Consortium.*

Background: Acute kidney injury (AKI) has been associated with cardiovascular disease (CVD) in observational studies. However, it remains unclear whether kidney injury is causally linked to CVD or whether the observed association between AKI and CVD is simply reflective of changes in renal perfusion due to underlying cardiac and hemodynamic dysfunction.

Methods: In a prospective multicenter study, we examined 968 adults who underwent cardiac surgery in the TRIBE-AKI cohort. On postoperative days 1-3, we measured the following urine biomarkers of renal injury: IL-18, NGAL, KIM-1, L-FABP, and albumin. In addition, we measured the following plasma biomarkers of cardiac injury: NT-proBNP, hs-cTnT, cTnI, and H-FABP. AKI was defined as a ≥50% or 0.3 mg/dL increase in serum creatinine, within 7 days of surgery. CVD and death were ascertained using administrative linkages with national datasets during a median follow-up of 3.8 (3.1-4.6) years.

Results: During follow-up, 136 (14.1%) patients experienced CV events and 83 (8.6%) patients died. We found that the magnitude and duration of postoperative creatinine-based AKI were strongly associated with CVD and mortality **(Figure)**. However, peak postoperative elevations in urinary kidney injury biomarkers were not significantly associated with risk for future CV events and mortality **(Figure)**. Instead, elevations in four cardiac injury biomarkers, independent of kidney injury, strongly associated with future CV events and mortality **(Figure)**.

Conclusions: These results suggest that creatinine-based AKI may be a surrogate for an inability of the kidneys of some patients to compensate to cardiovascular stress or injury, rather than an independent pathway for adverse cardiovascular outcomes.



Funding: Other NIH Support - R01-HL085757

TH-PO666

Serum and Urinary Hepcidin, but Not Free Iron as Protective and Inverse Biomarkers of CI-AKI in Patients Undergoing Percutaneous Coronary Interventions-PCI Jacek S. Malyszko,[1] Hanna Gajewska,[2] Ewa Koc-Zorawska,[3] Jolanta Malyszko,[2] Slawomir Dobrzycki.[2] *[1]1st Dept Nephrol, Medical Univ, Bialystok, Poland; [2]Dept Invasive Cardiology, Medical Univ, Bialystok; [3]2nd Dept Nephrol, Medical Univ, Bialystok.*

Background: Contrast-induced acute kidney injury (CI-AKI) is a common and potentially serious complication of percutaneous coronary interventions-PCI. Hepcidin, a peptide hormone that regulates iron homeostasis.Iron is supposed to be crucial in cell regeneration. We tested the hypothesis whether serum hepcidin could represent an early protective biomarker of CI-AKI in 80 patients with normal serum creatinine undergoing PCI. We also assessed serum and urinary NGAL, cystatin C, in these patients as well as LPI (labile plasma iron) and e eLPI(NTBI-non transferrin bound iron).

Methods: Serum and urinary hepcidin as well as NGAL, cystatin C, were evaluated before, and after 2, 4, 8, 24 and 48 hours after PCI using commercially available kits. LPI and e eLPI were assessed by Aferrix, Israel. Serum creatinine was assessed before, 24 and 48 hours after PCI.

Results: We found a significant rise in serum hepcidin as early as after 4 hours when compared to the baseline values. It was also significantly higher 8 and 24 hours after PCI. Serum NGAL increased after 2, 4 and 8 hours, and in urinary NGAL after 4,8 and 24 hours after PCI. We found a significant rise in serum NGAL after 2, 4 and 8 hours, and in urinary NGAL and IL-18 after 4, 8&24 hours after PCI. Serum cystatin C increased significantly 8 hours, reaching peak 24 hours after PCI and then decreased after 48 hours. In all the patients both LPI and eLPI When contrast nephropathy was defined as an increase in serum creatinine by >25% of the baseline level 48 hours after PCI, the prevalence of CI-AKI was 4/26. Urine hepcidin were significantly lower 8 and 24 hours after PCI in patients with CI-AKI, while serum and urine NGAL were significantly higher in patients with CI-AKI. Hepcidin correlated negatively with NGAL ($r=-0.42$, $p<0.05$).

Conclusions: Our findings suggest that serum hepcidin might be an early predictive biomarker of ruling out CI-AKI after PCI, thereby contributing to early patient risk stratification. Free iron does not appear to be involved in CI-AKI.

TH-PO667

Multi Center ICU Study Finds NGAL Increases Rate of AKI Detection Sahir Kalim,[1] A. Osama Gaber,[2] Ladan Golestaneh,[3] Michael J. Germain,[4] Peter A. McCullough.[5] *[1]Massachusetts General Hospital, Boston, MA; [2]Houston Methodist Hospital, Houston, TX; [3]Montefiore Medical Center, Bronx, NY; [4]Baystate Medical Center, Springfield, MA; [5]Baylor Univ Medical Center, Dallas, TX.*

Background: Acute kidney injury (AKI) is a severe and frequently encountered complication in ICU patients. AKI is often under diagnosed and detected late in the ICU because the diagnosis is based on elevations in serum creatinine (sCr), a relatively late marker of AKI. Neutrophil gelatinase-associated lipocalin (NGAL) is a biomarker indicating tubular damage that has been shown to rise early and dramatically in both urine and plasma during AKI. We examined the sensitivity of NGAL as a test for AKI, as compared to a clinical diagnosis using creatinine and the KDIGO guideline recommended criteria.

Methods: A total of 245 patients admitted to the ICU from four sites were enrolled. Blood and urine samples were taken daily and stored. NGAL concentrations were determined using the NGAL Test (BioPorto) in batch samples at a central laboratory with a cutoff value of 250 ng/mL. Retrospectively, a team of three clinicians, blinded to the NGAL results, adjudicated each patient case as having or not having AKI according to KDIGO guidelines.

Results: In this study, only 17 patients were chart diagnosed as having AKI. In contrast, NGAL identified AKI in a total of 56 patients, which represents an increase of 329% using a single cutoff of 250 ng/mL. Of those above this cutoff, there was 70% rate of confirmation of the diagnosis of AKI by the adjudicators.

Conclusions: The incorporation of serial NGAL measurements is a simple approach for increasing the rate and speed of AKI detection in an ICU population. Use of a structural kidney biomarker (NGAL) enhances the detection of AKI in combination with a functional biomarker (sCr).

Funding: Pharmaceutical Company Support - BioPorto

TH-PO668

Urinary UDP-Glucose as a Biomarker of Acute Kidney Injury in ICU Patients Rachel Nager Liberman,[1] Andrew S. Allegretti,[1] Juliana Sesma,[2] Leileata M. Russo,[1] Eduardo R. Lazarowski,[2] Sahir Kalim,[1] Dennis Brown,[1] Sushrut S. Waikar,[3] Ravi I. Thadhani,[1] Sylvie Breton.[1] *[1]Massachussetts General Hospital, Boston, MA; [2]UNC Chapel HIll, Chapel Hill, NC; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Acute Kidney Injury (AKI) in Intensive Care Unit (ICU) patients is common and complicates up to two thirds of cases. A rise in serum creatinine is the current diagnostic standard for AKI, but serum creatinine is a relatively late marker. We have recently identified UDP-glucose (UDP-G) to be a mediator of sterile inflammation in the kidney, through its action on the P2Y14 receptor. Injured cells release UDP-G that activates P2Y14 receptors oriented on the luminal side of intercalated cells (ICs). ICs subsequently secrete inflammatory chemokines, which results in pathological inflammatory cell recruitment into the renal medulla. Because AKI is often associated with uncontrolled inflammation, we investigated whether urinary UDP-G is an early biomarker of AKI in patients admitted into the ICU.

Methods: A prospective, longitudinal cohort study was performed using urine collected from 41 patients with 108 urine samples. Urine was collected daily from patients admitted through the ICU for up to 8 days. UDP-G concentration was measured by a radiometric assay. The association between urinary UDP-G and AKI status - as defined by AKIN criteria or ICU team clinical diagnosis - was measured by ROC-AUC analysis.

Results: UDP-G concentrations increased with AKIN stage of AKI ($P < 0.0001$). At a cutoff value of 40 nM urinary UDP-G to predict AKI, the ROC-AUC was 0.94 (sens. = 0.88, spec. = 0.86) when AKI was defined by the ICU team, and 0.80 (sens. = 0.59, spec. = 0.80) when AKI was defined by AKIN criteria. UDP-G levels were elevated up to 48 hours before an AKI-related change in serum creatinine occurred.

Conclusions: UDP-G is a promising biomarker of AKI due to its high sensitivity and specificity as a predictor of subsequent AKI. Furthermore, as UDP-G plays a functional role in the development of renal inflammation, pharmacological inhibition of the P2Y14 receptor may be a potential therapeutic target to prevent/mitigate AKI.

TH-PO669

Microparticles and Kidney Injury in Stroke Begoña Campos, Charuhas V. Thakar, Anthony C. Leonard. *IM Div of Kidney CARE, Univ of Cincinnati, Cincinnati, OH.*

Background: Acute kidney injury (AKI) affects 1-in-3 hospitalizations, and is more common in setting of other vital organ injury. Recent evidence demonstrates that in response to stress or injury cells release phenotypically distinct micro particles (MP's), which can be both markers or mediators of disease. The *objective* of this study was to evaluate type and quantity of MP's in setting of kidney injury (KI) and stroke.

Methods: In a prospectively collected biological repository of 38 eligible stroke subjects (14 ischemic and 24 hemorrhagic) and 37 controls. Demographic, comorbid and laboratory variables were collected at the time of admission. Kidney injury (KI) was defined as either admission creatinine > 1.2 mg/dl or development of AKI. Comparisons were made across Group I (Stroke) (Ia = no KI; Ib = KI) and Group II (no Stroke) (IIa = no KI; IIb = KI) Flow Cytometric analysis measured MPs in plasma for CD146 (endothelial cells), CD10 and CD13 (renal proximal tubular epithelial/RPTE markers). FlowJo software evaluated MP's, and levels were expressed as 10^7 and compared by Wilcoxon test (two-sided p-values).

Results: For Group I and II, CD146 MP's were 48.8 vs 39.3 ($p = 0.0026$); where as CD 10 MP's were 8.4 vs 15.4 ($p = 0.001$); and CD13 MP's were 19.4 vs 20.6 ($p = 0.21$) For Group II, RPTE MP's were higher in IIb vs IIa: CD 10 levels were 22.5 vs 14.0 ($p = 0.048$), and CD 13 were 23.4 vs 19.9 ($p = 0.023$). Within Group I, RTPE MP's and endothelial MP's were not different by KI status. When KI status was compared across Groups I and II (Ib vs IIb), CD146 levels were 50.0 vs 36.9 ($p = 0.002$); CD 10 were 8.9 vs 22.5 ($p = 0.0274$); CD 13 were 19.3 vs 23.4 ($p = 0.013$).

Conclusions: We confirm that endothelial MP's are increased in Stroke. In non Stroke patients, RPTE MP's are higher associated with KI; however this difference is not significant in Stroke subjects. Interestingly, when KI status was compared across Stroke vs Controls, RPTE MP's were significantly decreased in Stroke patients. This suggests an interplay between up-regulation of endothelial MP's and down regulation of RPTE MP's in the setting of dual organ injury. This is one of the first study to detect RPTE MP's in plasma of patients with vital organ dysfunction.

Extracellular Histones in Relation to Organ Dysfunction and Inflammation during Kidney-Lung Crosstalk Xin Wan, Yasser M.Z. Gendoo, Changchun Cao. *Dept of Nephrology, Nanjing First Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Mortality rates due to kidney-lung crosstalk have remained high despite advances in the management of AKI and ARDS. The inflammatory mediators believed to be responsible for this are yet unidentified. Extracellular histones are known to exacerbate inflammation and tissue injury. Here we investigate whether there is a clinical correlation between blood histone concentrations, kidney function, and lung function during AKI and ARDS.

Methods: In a prospective cohort, blood samples were collected from 54 patients upon admission to our hospital who were diagnosed with AKI, ARDS, community acquired pneumonia, or a combination of these. Serum histone concentrations were measured by ELISA and plotted against PaO_2/FiO_2, eGFR, neutrophils, and CRP. Pearson correlation test was performed and $p < 0.05$ was considered significant.

Results: The scatter-graphs show histone concentrations against the four parameters. In the overall sample population, histone concentrations were significantly correlated with PaO_2/FiO_2 ($P=0.0017, R^2=0.1652$); change of eGFR from baseline ($P<0.0001, R^2=0.3107$); neutrophil counts ($P=0.0174, R^2=0.1021$) and CRP ($P=0.0004, R^2=0.2207$). However, when patients were divided according to diagnosis, there was no significant correlation between these same parameters.

Conclusions: When viewed in light of the adverse effects of extracellular histones, the correlations reported in this study strongly suggest that extracellular histones may be potential mediators of kidney-lung crosstalk. Additional research is necessary to reveal the mechanisms of their involvement and whether they participate in or are merely a consequence of injury. Further endeavours to understand the pathophysiology of crosstalk will likely lead to improved treatment strategies and outcomes.

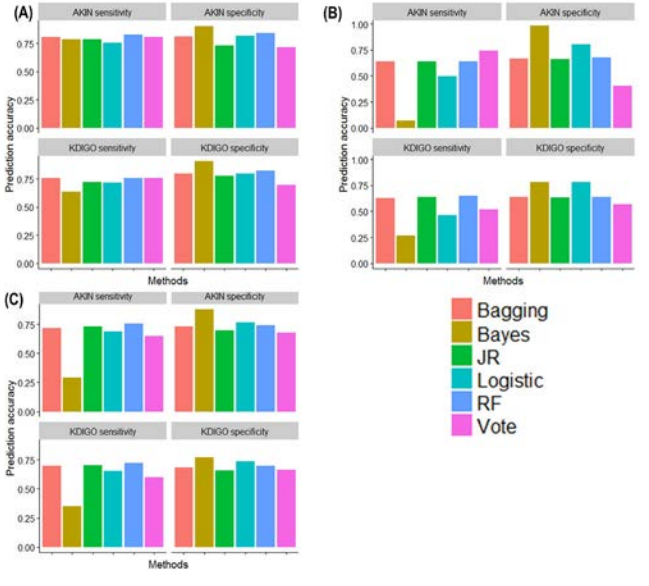
Prediction Model for Postoperative Acute Kidney Injury after Noncardiac Major Surgery Using Machine Learning Seokwoo Park, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Internal Medicine, Seoul National Univ of College of Medicine, Seoul, Korea.*

Background: Prediction for postoperative AKI can be helpful to identify high risk patients and elicit early intervention. In this study, we incorporated several pre- and intraoperative factors to build a prediction model for postoperative AKI using various machine learning methods.

Methods: We included adult (age ≥ 18 years) patients who received noncardiac major (duration>1 hour) surgery in Seoul National University Hospital from 2004 to 2013. Patients with baseline creatinine (Cr) over 4 mg/dl or maintenance renal replacement therapy (RRT) were excluded. AKI was diagnosed according to both KDIGO and AKIN criteria based on Cr measurements and initiation of RRT within 14 days after surgery. Variables used include age, sex, department, BMI, BP, comorbidities, medication, ASA class, anesthesia type, emergency, laboratory measurements, surgery duration and intraoperative BP measurements. We developed prediction models using Bagging, Naïve Bayes (Bayes), JRip (JR), logistic regression (Logistic), random forest (RF), and voted perception (VP) method, and calculated sensitivities and specificities of each method using 10-fold cross-validation.

Results: Among a total of 58,919 cases, 4,092 (6.95%) and 3,347 (5.68%) AKI were identified by KDIGO and AKIN, respectively. Prediction accuracy using preoperative (A), intraoperative (B), pre- and intraoperative variables (C) were demonstrated in Figure1.



RF method using all variables among the classifiers showed the highest sensitivity for AKI

	All	GS	OS	OG	UR	NS
AKIN	74.3	79.2	71.7	82.7	67.2	56.8
KDIGO	71.3	75.4	69.1	75.5	72.7	60.4

Conclusions: AKI prediction using pre- and intraoperative variables by machine learning algorithms showed fairly acceptable sensitivity and specificity. Further efforts are needed until clinical implication of machine learning algorithms.

TH-PO672

More Accurate AKI Diagnosis by Incorporating Urinary Biomarkers with No Reference Serum Creatinine Value Rei Isshiki,[1] Maki Sumida,[1] Yoshifumi Hamasaki,[1] Masaomi Nangaku,[1] Eisei Noiri,[1] Kent Doi.[2] *[1]Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.*

Background: The KDIGO guideline defines AKI based on relative changes in serum creatinine from baseline values, which is sometimes unavailable. This study was aimed to evaluate whether urinary biomarkers is useful to reduce misclassification rates of AKI compared with employing estimated serum creatinine value calculated by MDRD formula assuming a GFR of 75 ml/min/1.73m^2 (e-sCr).

Methods: We conducted a prospective observational study that included adult ICU patients with known baseline serum creatinine values. Misclassification rate of AKI was calculated when using e-sCr instead of available baseline values. A predictive model incorporating urinary biomarkers (NGAL and L-FABP) using decision tree analysis was developed for reducing AKI misclassification.

Results: Of 135 patients, 44 patients (32.6%) had developed AKI at ICU admission. When using e-sCr, 28 patients were misclassified as AKI (false positive rate 30.8%) and 4 patients were misclassified as non-AKI (false negative rate 9.1%) The total number of misclassification was 32 in all the enrolled patients (23.7%). Levels of urinary NGAL were significantly higher in the true AKI patients compared with the patients who were misclassified as AKI (839.8 vs 161.6 ng/ml; p=0.0047), however urinary L-FABP level showed no significant difference. Urinary NGAL alone showed a similar misclassification rate (22.9%) with the Youden-index cut-off value of 430 ng/ml. Decision tree analysis incorporating absolute serum creatinine values and urinary NGAL at ICU admission revealed that the misclassification rate was decreased to 17.7%. The area under the curve (AUC) for this developed decision tree analysis model was 0.87 (95%CI, 0.80-0.92), whereas the model using e-sCr alone showed a significantly lower AUC value (0.80 [0.73-0.86]; p=0.0002).

Conclusions: Even when no baseline serum creatinine value is available, urinary NGAL in addition to the absolute serum creatinine value at ICU admission can show more accurate AKI diagnosis compared with back calculation of baseline serum creatinine by MDRD formula.

TH-PO673

Severe Acute Kidney Injury in Hospitalized Patients Can Be Predicted from the Emergency Department: A Feasibility Study Holly R. Hanson, Michael Adam Carlisle, Rachel S. Bensman, Terri Byczkowski, Stuart Goldstein, Rajit K. Basu. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Early recognition of patients at risk of acute kidney injury (AKI) may expedite supportive and preventive care. We previously derived and validated an AKI risk stratification methodology, renal angina, for prediction of severe AKI in patients three days after admission to the intensive care unit (ICU). Use of renal angina applies context to patients, optimizing the predictive performance of biomarkers for subsequent AKI. AKI risk stratification in the emergency department (ED) has not been well described.

Methods: We conducted a prospective, single-center observational study in a tertiary pediatric ED to derive and validate a modified "acute" RAI (aRAI) for the prediction of severe AKI (SCr KDIGO Stage 2 or 3) at 48-72 after hospitalization. The aRAI was determined at the time of disposition from the ED.

Risk Strata Score		
Characteristic	**Risk**	**Score**
ED Concern for Sepsis or Shock	Moderate	1
History of Transplant and/or active Oncologic Disease	High	3
>40 mL/kg intravenous fluid and/or ED Intubation	Very High	5
Injury Score		
Change from Baseline Creatinine		**Score**
< 1.5x		1
≥ 1.5x to <2x		2
≥ 2x to <3x		4
≥ 3x		8
aRAI = Risk Strata Score x Injury Score **aRAI ≥ 8 fulfills renal angina**		

Results: 118 children were enrolled (48% male, mean age 7.8 ± 6.4 years). 11% were RAI positive for renal angina in the ED, 16% were admitted to the ICU, and 66% remained hospitalized after 48 hours (ICU or ward). The rates of severe AKI at 48 and 72 hours were 8.0% and 7.7%. The aRAI demonstrated a positive predictive value of 0.29 (0.05, 0.70) and negative predictive value of 0.97 (0.82, 0.99) with an AUC of 0.76 (0.43, 1.00) for severe AKI.

Conclusions: Our pilot study demonstrates a sensitive screening tool for stratification of patients by risk for AKI from presentation in the ED, the earliest time possible for intervention. Biomarker incorporation into the aRAI model is anticipated to augment the post-test probability of AKI and creates a model useful for testing of strategies targeted at mitigating further renal insult.

TH-PO674

Secretory Function in Acute Kidney Injury Frank J. O Brien, Scott M. Sutherland, Natalie Plummer, Timothy W. Meyer, Tammy L. Sirich. *VA Palo Alto HCS and Stanford Univ.*

Background: Impairment of renal function in acute kidney injury (AKI) is routinely evaluated by measurement of ureaN (UN) and creatinine (Cr) which are markers largely of tubular reabsorption and glomerular filtration. Tubular secretory function in AKI has much less often been assessed.

Methods: Plasma levels for the normally secreted solutes indoxyl sulfate (IS) and phenylacetylglutamine (PAG) were measured along with levels of UN and Cr in 6 AKI and 25 maintenance hemodialysis (HD) subjects. Solute clearances were also measured in the AKI subjects and 9 normal (NL) subjects.

Results: (mean±stdev; *p<0.05 AKI vs NL; **p<0.05 AKI vs HD):

	Fractional clearance (k_{solute}/k_{Cr})		Plasma levels (mg/dl)		Concentration ratio HD/AKI
	AKI	NL	AKI	HD	
IS	0.8 ± 0.7	0.4 ± 0.1	0.19 ± 0.18	2.9 ± 1.1	16**
PAG	2.9 ± 0.7	2.7 ± 0.5	0.22 ± 0.17	5.2 ± 2.5	23**
UN	0.3 ± 0.1	0.5 ± 0.1*	81 ± 14	65 ± 25	0.8
Cr	-	-	2.3 ± 0.5	10.8 ± 3.3	4.8**

Clearances relative to the Cr clearance (fractional clearance; k_{solute}/k_{Cr}) were well preserved for the secreted solutes in AKI. In contrast, the fractional clearance of UN was significantly reduced. As a result, the UN level in AKI was elevated to a similar degree as in HD. In contrast, the levels for the secreted solutes were significantly higher in HD than AKI subjects because hemodialysis does not replicate secretory function.

Conclusions: Secretory function is well preserved in AKI. Further studies of secreted solutes may enhance our ability to assess renal function in AKI and to determine the timing of dialysis initiation.

TH-PO675

Predictive Value of Cystatin C-Based eGFR for Successful Weaning from Continuous Renal Replacement Therapy: A Prospective Observational Study Chang Seong Kim,[1] Tae Ryom Oh,[1] Ha Yeon Kim,[1] Yong Un Kang,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Jong Un Lee,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Hospital, Gwangju, Republic of Korea; [2]Dept of Physiology, Chonnam National Univ Medical School, Gwangju, Republic of Korea.*

Background: Continuous renal replacement therapy (CRRT) is the mainstay of treatment for critically ill patients with acute kidney injury. The aim of our study is to identify whether biomarkers or factors of renal function can predict successful weaning from CRRT.

Methods: We conducted a prospective observational study of 110 patients who had received CRRT and were weaned from it after renal recovery. Successful weaning from CRRT was defined as elimination of the requirement for RRT for at least 14 days after cessation of CRRT, whereas redialysis within 14 days was defined as restart-RRT. Serum levels of cystatin C (CysC), neutrophil gelatinase-associated lipocalin (NGAL), and conventional biomarkers of renal function were checked at the time of cessation of CRRT.

Results: Of the 110 patients we evaluated, 89 patients (80.9%) were successfully weaned from CRRT while 21 (19.1%) patients were not. Setting of CRRT and simplified acute physiology score III did not differ significantly between both groups. Serum CysC levels were lower and urine output was higher in the success group compared with the restart-RRT group at the time of cessation of CRRT (CysC: 1.70 ± 0.68 mg/L vs. 2.47 ± 0.93 mg/L, $P < 0.001$; urine output: 2.03 ± 2.10 mL/h/kg vs. 1.02 ± 0.93 mL/h/kg, $P = 0.016$). Multivariable logistic regression showed that CysC-based estimated glomerular filtration rate (eGFR) was an independent predictor for successful weaning from CRRT (OR, 1.25; 95% CI, 1.04-1.51; $P = 0.016$) while NGAL and urine output were not associated with successful weaning from CRRT. The area under the receiver operating characteristic curve of CysC-based eGFR, which predicts successful weaning from CRRT, was 0.75 (95% CI, 0.63–0.86); sensitivity and specificity were 65.2% and 76.2%, respectively, at a cutoff of 32.9 mL/min/1.73 m^2.

Conclusions: Cystatin C-based eGFR at the time of cessation of CRRT is a good predictor of successful weaning from CRRT in critically ill patients with actue kidney injury.

TH-PO676

Pregnancy Related Acute Kidney Injury: A Single Center Experience Umesha Lingaraj. *Nephrology, Inst of Nephrourology, Bangalore, Karnataka, India.*

Background: Pregnancy Related Acute Kidney Injury (PRAKI) may comprise up to 25% of the referrals to dialysis centers in developing countries and is associated with substantial maternal and fetal mortality.

Methods: We conducted a prospective cross sectional observational study to evaluate the etiological factors and final outcome of AKI with special reference to pregnancy related acute kidney injury. AKI was diagnosed as per AKIN (Acute Kidney Injury Network) criteria.

Results: In this prospective study between February 2012 to February 2016, total of 624 patients were studied among them 460 were admitted with medical causes (73.7%), 124 with obstetrical causes (19.8%) and 40 (6.4%) with surgical causes. The mean age among PRAKI was 21±4 (17-36) years and duration of hospital stay was 9.41±7.3 days. Etiological factors include puerperal sepsis in 65(52.41%), pregnancy induced hypertension in 30(24.1%), 12(9.67%) patients had postpartum hemorrhage, 7(5.64%) antepartum hemorrhage, postpartum hemolytic uremic syndrome in 3 patients (2.41%) and miscellaneous causes was seen 7(5.6%). Renal biopsy was performed if a patient was oliguric or dialysis dependent at the end of 3 weeks. Biopsy was done on 22 patients and 6 of them had patchy cortical necrosis, 11 patients showed acute tubular necrosis, two with features of acute interstitial nephritis and three patients had thrombotic microangiopathy. Out of 124 patients 101(81.45%) patients recovered from acute kidney injury, 4(3.22%) patient remained on dialysis and 2(1.61%) patient had partial recovery from renal failure. Seventeen patients died with mortality rate of 13.70%. Out of these 9 patients died within 48 hours of admission. Sepsis, multiorgan dysfunction, coagulation abnormalities and retained products of conception were factors associated with mortality.

Conclusions: Pregnancy related acute kidney injury was comprising about 19.8% of the patients. Puerperal sepsis is the most frequent etiological factor and accounted for a majority of maternal mortality.

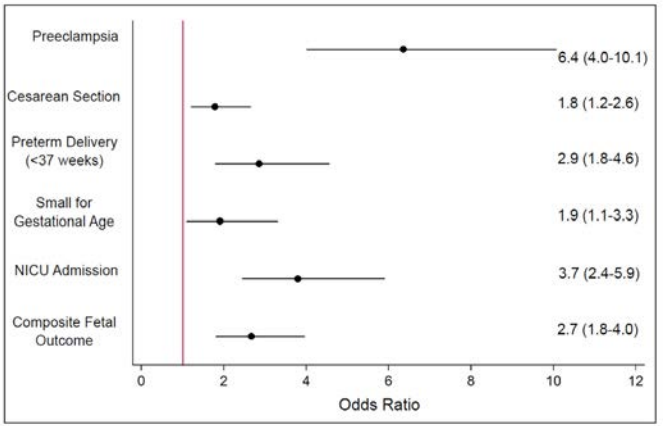
TH-PO677

Pregnancy Outcomes following Clinical Recovery from Acute Kidney Injury in Young Women Jessica Sheehan Tangren,[1] Camille Elise Powe,[1] Elizabeth D. Ankers,[1] Jeffrey Ecker,[1] Kate Bramham,[2] Michelle A. Hladunewich,[3] S. Ananth Karumanchi,[4] Ravi I. Thadhani.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]King's College London, London, United Kingdom; [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [4]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Acute kidney injury (AKI) is a risk factor for future morbidity and mortality but the effect of clinically recovered AKI on future pregnancy outcomes is unknown. Our objective was to assess if a previous episode of AKI with subsequent recovery of renal function is associated with adverse pregnancy outcomes, including preeclampsia.

Methods: We conducted a retrospective cohort study of women who delivered infants between 1998 to 2008 at the Massachusetts General Hospital. Pregnancy outcomes in women with recovered AKI (r-AKI) without a history of chronic kidney disease (n=105) were compared to outcomes in women without kidney disease (n=24,640). AKI was defined as a rise in serum creatinine to 1.5 fold above baseline with subsequent clinical recovery (eGFR > 90) prior to conception.

Results: Pre-pregnancy serum creatinine measurements in women with r-AKI were 0.70±0.20 mg/dl vs 0.69±0.10 mg/dl in controls. Women with r-AKI had an increased rate of preeclampsia (23% vs 4%, p<0.001). Infants of women with r-AKI were born earlier (37.6±3.6 vs 39.2±2.2 weeks, p<0.001), with increased rates of small for gestational age births (15% vs 8%, p=0.03). After multivariate adjustment including age, race, parity, obesity, hypertension and diabetes, r-AKI remained associated with increased odds of adverse maternal-fetal outcomes.



Conclusions: An episode of AKI, despite return to normal renal function prior to pregnancy, is associated with adverse pregnancy outcomes. This describes a new group of women at high risk for preeclampsia and preterm delivery. This finding may help explain disparate rates of preeclampsia across the globe.

TH-PO678

Outpatient Acute Kidney Injury Increases Risk of Chronic Kidney Disease and Mortality Regardless of Recovery Daniel P. Murphy,[1] Max Leither,[1] Scott Reule,[1] Areef Ishani,[2] Robert N. Foley,[1] Paul E. Drawz.[1] *[1]Div of Renal Diseases and Hypetension, Univ of Minnesota, Minneapolis, MN; [2]Div of Nephrology, Minneapolis VA Medical Center, Minneapolis, MN.*

Background: Hospital acquired acute kidney injury (AKI) is common and is a risk factor for all-cause mortality and chronic kidney disease. The epidemiology and outcomes of patients with outpatient AKI are poorly characterized, particularly those whose creatinine returns to baseline.

Methods: Patients with at least two primary care visits within the Fairview Health Service's electronic health record were included in this retrospective study. During an 18 month exposure period beginning with the second primary care visit, patients were categorized into five groups (no creatinine measurement, no AKI, AKI with recovery, AKI without recovery, and AKI without a repeat creatinine). AKI was defined by a 50% increase in creatinine compared to the average of the last three outpatient creatinine values between 30 and 365 days prior. Recovery was defined by any subsequent creatinine less than or equal to 110% of baseline creatinine. Mortality, obtained by Minnesota death certificate records, and a creatinine value >3 mg/dL at last follow-up were co-primary outcomes.

Results: There were 1.77 million patients in the electronic health record and 464,474 that visited primary care at least twice. Of these, 55.3% had no creatinine measured, 43.2% had no AKI, 0.4% had AKI without recovery, 0.8% had AKI with recovery, and 0.3% had AKI without a repeat creatinine. Patients with AKI were more likely to have a final creatinine >3 mg/dL and were more likely to die during follow-up.

	No Cr	No AKI	AKI with recovery	AKI without recovery	AKI with no repeat Cr
Count	256,908	200,674	3,653	1,929	1,279
Age (std dev)	35.9 (15.3)	51.4 (17.6)	62.8 (17.5)	62.9 (17.1)	57.5 (19.2)
Female	58.6%	54.5%	58.3%	57.3%	59.3%
Last Cr >3 mg/dL	0.2%	0.7%	6.4%	12.6%	5.3%
Mortality	0.7%	4.1%	20.6%	20.2%	15.6%

Conclusions: Outpatient AKI is associated with a significantly increased risk of development of chronic kidney disease and mortality regardless of whether creatinine returns to baseline.

TH-PO679

Hospital Readmissions after an Acute Kidney Injury Hospitalization Samuel A. Silver,[1] Ziv Harel,[1,2] Eric McArthur,[2] Danielle Marie Nash,[2] Rey R. Acedillo,[3] Abhijat Kitchlu,[1] Amit X. Garg,[2,3] Glenn Matthew Chertow,[4] Chaim Bell,[2,5] Ron Wald.[1,2] *[1]Nephrology, Univ of Toronto, Toronto, ON, Canada; [2]Inst for Clinical Evaluative Sciences, Toronto, ON, Canada; [3]Nephrology, London Health Sciences Centre, London, ON, Canada; [4]Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [5]Medicine, Mount Sinai Hospital, Toronto, ON, Canada.*

Background: The risk of hospital readmission in acute kidney injury (AKI) survivors is not well understood. We sought to estimate the rate of hospital use and identify the determinants of 30-day readmission after a hospitalization complicated by AKI.

Methods: We conducted a retrospective population-based study of all patients who survived a hospitalization complicated by AKI from 2003-2013 in Ontario, Canada. The primary outcome was 30-day hospital readmission. We used a propensity score model to match patients with and without AKI during the index hospitalization. We derived subdistribution hazard ratios and 95% confidence intervals from Cox proportional hazards models stratified on the matched sets with death as a competing risk. We used similar models to identify predictors of 30-day readmission in the entire cohort.

Results: We identified 156,690 patients who were discharged from hospital after an episode of AKI, of whom 27,457 (18%) were readmitted to hospital, 15,988 (10%) visited the emergency department (ED), and 7480 (5%) died without incurring a hospitalization or ED visit. We successfully matched 111,778 patients with AKI 1:1 to patients without AKI. The risk of 30-day readmission was higher in AKI survivors than patients without AKI (adjusted hazard ratio [aHR] 1.53 [95% CI 1.50-1.57]). The factors most strongly associated with 30-day rehospitalization were the number of hospitalizations in the preceding year (aHR 1.63 per 5 visits, 95% CI 1.51-1.76) and inpatient chemotherapy (aHR 1.49, 95% CI 1.36-1.63).

Conclusions: Patients who survive a hospitalization complicated by AKI are at high risk for readmission in the subsequent 30 days. Better strategies are needed to identify and care for AKI survivors in the community.

Funding: Government Support - Non-U.S.

TH-PO680

Acute Kidney Injury Recovery at 90 Days and Subsequent CKD in Critically Ill Sepsis Survivors Javier A. Neyra,[1] Xilong Li,[1] Beverley Adams-Huet,[1] Jerry Yee,[2] Orson W. Moe,[1] Robert D. Toto.[1] *[1]UT Southwestern, Dallas, TX; [2]Henry Ford Hospital, Detroit, MI.*

Background: AKI is a frequent complication of sepsis and is associated with increased risk for subsequent CKD. The purpose of this study was to investigate whether incomplete AKI recovery at 90 days post-discharge increases the risk of CKD in sepsis survivors.

Methods: Single-center, retrospective cohort study of adults admitted to the ICU with a diagnosis of severe sepsis/septic shock. Subjects with pre-admission eGFR <15 or receiving chronic RRT were excluded. AKI during ICU stay was diagnosed based on KDIGO serum creatinine (SCr)-criteria in reference to a baseline SCr within 3 months before admission. AKI recovery was determined by the ratio of 90-day SCr/baseline SCr in RRT-free survivors: <1.1 indicated complete recovery, ≥1.1 to <1.5 incomplete (mild) recovery and ≥1.5 incomplete (severe) recovery. Incident or progressive CKD post-AKI was adjudicated based on relative and/or absolute eGFR changes during the follow-up period.

Results: Of 6290 patients included in the study, 3642 (58%) suffered from AKI and 741 (12%) required acute RRT. The 90-day mortality rate was 26%. Among survivors, we identified 1249 patients who suffered from AKI, were RRT-free, and had available follow-up data. CKD occurred in 319 of the 1249 patients: 54% of those with incomplete (severe) recovery, 29% of those with incomplete (mild) recovery and 13% of those with complete recovery; median follow-up 2.5 years. 90-day AKI recovery status was an independent predictor of CKD: adjusted HR 4.7, 95% CI 3.5–6.3 for incomplete (severe) vs. complete recovery; 2.3, 1.7–3.1 for incomplete (mild) vs complete recovery; and 2.1, 1.6–2.8 for incomplete (severe) vs incomplete (mild) recovery. Other predictors of post-AKI CKD were older age, black race, anemia, and higher admission SOFA score.

Conclusions: Incomplete AKI recovery within 90 days following hospital discharge is a strong and independent predictor of CKD in sepsis survivors. The timely evaluation of AKI recovery may serve to risk-stratify sepsis survivors and implement more vigilant surveillance for CKD in this susceptible population.

TH-PO681

Impact of CKD on Adverse Outcomes in Critically Ill Septic Patients with and without AKI Federica Mescia, Xilong Li, Beverley Adams-Huet, Robert D. Toto, Orson W. Moe, Javier A. Neyra. *UT Southwestern, Dallas, TX.*

Background: AKI is a common condition in the ICU associated with substantial morbidity and mortality, including CKD post-AKI. Similarly, CKD increases the risk of AKI, severe infections and death. The coexistence of CKD and AKI is frequently encountered in critically ill septic patients, but how their interplay affects clinical outcomes is not well elucidated.

Methods: Single-center, retrospective cohort study of adults admitted to the ICU with a diagnosis of severe sepsis or septic shock. Subjects were classified into 6 subgroups (2x3 matrix) according to pre-admission eGFR and AKI status during ICU stay: MDRD-eGFR <60 (CKD) vs ≥60 (no-CKD) and KDIGO serum creatinine (SCr)-criteria (no-AKI, AKI stage 1, AKI stage ≥2), respectively. Outcomes were 90-day mortality and a composite of CKD (incident CKD =eGFR <60 and ≥25% reduction from baseline; progressive CKD =eGFR <15 or ≥50% reduction from baseline), dialysis and death.

Results: 2632 patients were included and classified as no-CKD/no-AKI (22.7%); no-CKD/AKI1 (13.8%); no-CKD/AKI≥2 (17.5%); CKD/no-AKI (20.4%); CKD/AKI1 (13.8%) or CKD/AKI≥2 (11.8%). Overall 90-day mortality rate was 26.7% and CKD/dialysis/death occurred in 19.1% over a median follow-up of 18 months. Multivariable Cox regression hazard models included relevant demographic and clinical parameters.

Subgroup	Adjusted HR (95% CI) 90-day mortality	Adjusted HR (95% CI) CKD/dialysis/death
no-CKD/no-AKI	Reference	Reference
no-CKD/AKI1	1.50 (1.13 – 1.98)	1.91 (1.26 – 2.91)
no-CKD/AKI≥2	2.44 (1.92 – 3.11)	2.56 (1.72 – 3.83)
CKD/no-AKI	1.07 (0.82 – 1.41)	1.23 (0.80 – 1.90)
CKD/AKI1	1.19 (0.89 – 1.60)	1.14 (0.71 – 1.84)
CKD/AKI≥2	2.22 (1.70 – 2.89)	2.63 (1.73 – 4.00)

Conclusions: Stage 1 AKI on CKD was not independently associated with an increased risk of adverse outcomes in critically ill septic patients. However, AKI stage ≥2 on CKD and any level of AKI in no-CKD patients were strongly and independently associated with adverse outcomes. Stage 1 AKI on CKD may represent a distinct AKI phenotype with more pre-renal cases or less severe *de novo* intrinsic damage.

Funding: Other NIH Support - UL1 TR001105; P30 DK079328-06

TH-PO682

Inhibition of IRAK4-Mediated Innate Immune Responses Is Protective in Acute Kidney Injury Irina Alexandra Leaf, Bryce Gordon Johnson, Ivan G. Gomez, Jeremy Stuart Duffield. *Duffield Lab, Biogen, Cambridge, MA.*

Background: Fibrotic diseases can affect all tissues and organs and lead to over 40% of natural deaths. We analyzed pathways enriched in human kidney biopsies and found that innate immune signaling is strongly associated with disease progression. Cell-specific profiling of injured kidneys show that pericytes are the major contributors of pro-inflammatory cytokines and chemokines. While in a healthy state these cells support

homeostasis, in injury, they become activated and differentiate into myofibroblasts depositing pathogenic extracellular matrix, a hallmark of fibrosis. Previous work had highlighted the role of innate immune signaling in kidney injury and MyD88 knockout mice were protected. Surprisingly, neither macrophage- nor epithelial cell-specific deletion of MyD88 contributed to this protective phenotype. Here we show that pericyte-specific ablation of MyD88 significantly attenuates tissue injury and fibrosis.

Further mechanistic studies show that in culture, pericytes respond to the TLR ligands and endogenous injured kidney DAMPs by secreting pro-inflammatory cytokines and chemokines in a TLR2/4-, MyD88- and IRAK4-dependent manner. Injury DAMPs are sufficient to prime and activate NLRP3 inflammasome leading to secretion of IL-1b. Additionally, pericytes respond to IL-1b in a MyD88- and IRAK4-dependent manner and provide an autocrine loop amplifying inflammation. Unexpectedly, TLR2/4, MyD88 and IRAK4 also control TGFb- or injury DAMPs-induced pericyte migration and myofibroblast differentiation. This mechanism is conserved, and human pericytes also activate inflammatory and fibrotic responses that require MYD88 and IRAK4.

Inhibition of IRAK4, a downstream kinase in TLR/MyD88 signaling, by a novel potent, highly selective small molecule BIIB-IRAK4i is highly protective in ischemia reperfusion injury and significantly reducing.

TH-PO683

Prediction of Death and Renal Replacement Therapy in Hospitalised Patients with Acute Kidney Injury Vishal Nangalia,[1] Alistair Connell,[1] Simon T. Brown,[1] Anne B. Dawnay,[2] Zudin Puthucheary,[1] David Barber,[1] Chris Laing,[1] Geraint Rees,[1] Hugh E. Montgomery.[1] *[1]UCL, London, United Kingdom; [2]UCLH NHS Trust, London, United Kingdom.*

Background: Acute kidney injury (AKI) is reported to be common and associated with poor outcomes including death and need for renal replacement therapy (D-RRT). In 2015, The English National Health Service (NHSE) mandated that all hospitals implement an Kidney Disease: Improving Global Outcomes (KDIGO)-based algorithm (NHSE-algorithm) to detect and stage (for severity/risk) AKI. In the largest AKI study ever, we characterised AKI prevalence and progression, explored weaknesses in the NHSE-algorithm, and determined whether machine learning (ML) methodologies might better determine risk.

Methods: Demographics, blood results, diagnoses, and procedure codes from 14 NHSE Hospital Trusts (2005-2015) were collated. Admissions were grouped by co-morbidities/ NHSE-algorithm-trigger-route, and D-RRT rates related to first (AKI_{first}) and maximum (AKI_{max}) AKI stage. A 'gradient-boosting-machine' ML model used data up to AKI_{first} to predict D-RRT using positive predictive value thresholds 1:2(ML50), 1:3(ML33) and 1:4(ML25).

Results: Of 1•9 million admissions, 170,596 (8•7%) developed AKI. Stage advanced from AKI_{first} in 23,226(13•6%). D-RRT affected 64,296 (3•3%, death 56,076 (2•8%) without AKI, but 21% of AKI cases, incidence rising with stage for both AKI_{max} (stage 1: 13•2%, 2: 27•3%, 3: 42•4%) and AKI_{first} (18•7%, 25•5%, 32•8% for AKI1-2 respectively). D-RRT rate also varied with the NHSE-algorithm-trigger-route by which an AKI stage was reached- from 12•7-16•6% in stage 1 and 3:38•6-45•9% (stage 3). Plotted against maximum Creatinine and ratio of Creatinine:Baseline Creatinine, D-RRT rates vary from 5-50% and 0•5-70% for AKI_{max} stages 1 and 3 respectively. The ML-model's AUROC was 85•3%, with ML50 (D-RRT=50%) and ML33 (D-RRT=33•3%) achieving sensitivities of 71•6 and 94•6% respectively.

Conclusions: AKI is prevalent and associated with increased morbidity and mortality. AKI stage poorly predicts individual risk, and machine learning models perform better.

Recognition and Management of Acute Kidney Injury in Children Around the World: The ISN 0by25 Global Snapshot Study Etienne Macedo,[1] Jorge Cerda,[2] Michael V. Rocco,[3] Ravindra L. Mehta.[1,4] *[1]Univ California San Diego; [2]Albany Medical College; [3]Wake Forest Univ; [4]On Behalf of the ISN 0by25 AKI investigators.*

Background: In low and middle-income countries, there is a lack of reliable data on the epidemiology of childhood acute kidney injury (AKI). The recently completed Global Snapshot, a study carried out by the International Society of Nephrology "*0 by 25*" AKI initiative, was an observational, cross-sectional analysis designed to evaluate AKI around the world.

Methods: A web based survey tool was used to prospectively obtain data from individual clinicians about pts who had AKI based on KDIGO criteria. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC). Need for dialysis, mortality, and renal recovery were assessed at 7 days after AKI diagnosis or at hospital discharge, whichever came first.

Results: 92 physicians from 41 countries collected data on 354 pediatric pts with AKI. The median (interquartile) age in years was 0.4 (0.03, 6.0) in HIC, 8 (2,16.5) in UMIC and 4 (0.3),13.5) in LLMIC. HIC children were much younger and developed post surgical AKI more commonly. Factors associated with AKI were dehydration (32.5%), hypotension (32%), infection (29%), and nephrotoxin exposure (20%). The percentage of pts dialyzed were 10.5% in HIC; 40.3% in UMIC; and 26.5% in LLMIC. Initiation of dialysis was much later in LLMIC than in other country categories. Dialysis was indicated but not used in 7 (9.2%) of LLMIC, 6 (14.0%) of UMIC and 2 (1.3%) of HIC patients ($P < 0.0001$). Overall mortality was lower in HIC countries (1.2%) compared to UMIC (12.5%) and LLMIC countries (19.6%) ($p < 0.0001$) . Community-acquired AKI-associated mortality was 7 times higher in LLMIC than HIC. Complete recovery from AKI at 7 days of observation was seen in 37%, partial recovery in 34% and none in 17%; status was unknown in 12%. AKI recovery was more often complete in LLMIC (44, 40.7%) than in HIC (63, 36.2%) or UMIC (21, 29.2%).

Conclusions: In resource-limited countries, pediatric AKI is associated with higher morbidity and mortality than in higher income countries, possibly related to late referral and limited resources.

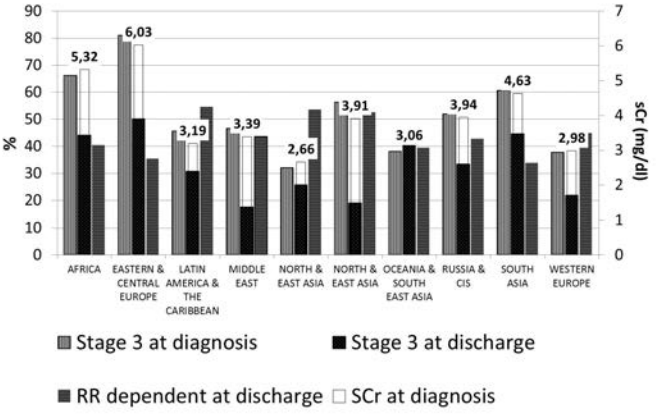
International Society of Nephrology 0by25 AKI Global Snapshot: Regional Analysis of Adult Patients Etienne Macedo,[1] Michael V. Rocco,[2] Ravindra L. Mehta.[1,3] *[1]Univ California San Diego; [2]Wake Forest; [3]On Behalf of the ISN 0by25 Investigators.*

Background: The ISN 0by25 AKI Global Snapshot Project (GSP) was designed to determine the spectrum of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians about pts with AKI based on KDIGO criteria. Countries were grouped into three categories based on gross national income per capita (GNI): High income with GNI > US$12476, low and lower middle income with GNI < US$4035, and upper middle income with GNI between levels 1 & 3.

Results: Of the 3664 adults AKI pts included in the analysis 305 (1091) were from North and East Asia, followed by Latin America and Caribbean (516, 14%) and Africa (507, 14%). Almost all centers from North and East Asia were located in cities with more than 1.5 million people and were from HIC and UMIC. African and Caribbean centers were more often located at smaller cities. While most pts in North and East Asia developed AKI in the hospital (689, 63%), about half the pts from Latin America and Caribbean (284, 55%) and the majority from Africa (430, 85%) developed AKI in the community. The creatinine level at both diagnosis and discharge, the severity of AKI at diagnosis and the need for renal replacement therapy varied by region.



In Eastern & Central Europe (68, 81%) and Africa (306, 66%), most pts were at AKI stage 3 at diagnosis, while in North & East Asia about half the pts (521, 51%) were at AKI stage 1 at diagnosis. The frequency of chronic kidney disease (CKD) was low, ranging from 1.6% in LLMIC countries of Latin American and the Caribbean to 10% in North America. The exception was Russia & Commenwealth Independent States, with 20% of pts with CKD.

Conclusions: There is wide variability in the incidence and severity of AKI by geographic region.

Characteristics and Outcomes of Adults Discharged Home from the Emergency Department with Acute Kidney Injury Rey R. Acedillo,[1,2] Ron Wald,[3,6] Eric McArthur,[4] Danielle Marie Nash,[4] Samuel A. Silver,[3] Matthew T. James,[5] Michael J. Schull,[6] Edward D. Siew,[7] Michael Edwin Matheny,[8] Andrew A. House,[1] Neil S. Klar,[2] Amit X. Garg.[1,2,4] *[1]Nephrology, London Health Sciences Centre, London, ON, Canada; [2]Epidemiology and Biostatistics, Western Univ, London, ON, Canada; [3]Nephology, St. Michael's Hospital, Toronto, ON, Canada; [4]Inst for Clinical Evaluative Sciences, London, ON, Canada; [5]Nephology, Foothills Hospital, Calgary, AB, Canada; [6]Inst for Clinical Evaluative Sciences, Toronto, ON, Canada; [7]Nephrology, Vanderbilt School of Medicine, Nashville, TN; [8]Veteran Affairs, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Adults discharged home from an emergency department (ED) with acute kidney injury (AKI) are not well described and may have poor outcomes.

Methods: We conducted a population-based retrospective cohort study in Ontario, Canada from 2003 to 2012 of 6,346 adults discharged from the ED with AKI. We used serum creatinine-based KDIGO criteria to define AKI. We assessed the 30-day risk of all-cause mortality and receipt of acute dialysis after ED discharge. To compare outcomes, we used propensity score methods to match 4,379 of these adults to 4,379 adults hospitalized with similar AKI stage (subpopulation 1). We assessed whether the association between

ED discharge versus hospitalization and mortality was modified by AKI stage. We also matched 6,188 of these adults to 6,188 adults discharged home from the ED without AKI (subpopulation 2).

Results: The mean age was 69 years, 4.6% had stage 2 AKI, and 0.7% had stage 3 AKI. Within 30 days of ED discharge, 2.3% (stage 2 AKI: 5.3%, stage 3 AKI: 15.9%) died, and 0.3% received acute dialysis. In subpopulation 1, an ED discharge versus hospitalization was associated with lower mortality (3.0% vs. 11.9%, RR: 0.25, 95% CI: 0.21-0.30). The difference in mortality was attenuated in adults with stage 3 AKI (15.9% vs. 15.9%, RR: 1.00, 95% CI: 0.38-2.64). In subpopulation 2, an ED discharge with AKI versus without AKI was associated with higher mortality (2.2% vs. 1.4%, RR: 1.56, 95% CI: 1.20-2.04).

Conclusions: Adults discharged from the ED with stage 2 and 3 AKI are at risk of poor 30-day outcomes. A better understanding of AKI care among this population is warranted.

TH-PO687

Acute Kidney Injury Related to Renal Colic: A Neglected Condition? Gabriela Ottati, Carolina Gelber, Andres Urrestarazu, Ricardo Silvariño, Alejandro Ferreiro, Oscar A. Noboa. *Centro de Nefrologia, Hospital de Clinicas, Facultad de Medicina, Univ de la Republica, Montevideo, Uruguay.*

Background: Kidney stone formation is highly prevalent with rates of up to 14.8%. Acute kidney injury during episodes of renal colic are frequently overlooked. The aim of this study is to determine the frequency of acute kidney injury (AKI) during acute episodes of renal colic (RC) of kidney stone etiology at the Emergency Department (ED) and its contributing factors.

Methods: This was a prospective, observational, single-center study. All patients assisted at the ED with a diagnosis of RC of renal stone etiology were prospective included. Clinical and analytical data were recorded. All patients were evaluated with abdominal echography at admission. AKI was defined according to AKIN criteria. Informed consent was collected and the Hospital Ethics Committee approved the study protocol. Exclusion criteria: patients with lumbar-abdominal pain of etiologies other than kidney stones. Cases with incomplete data at admission or evolution were also excluded.

Results: Data were obtained from 34 patients, 25 (73.5 %) male. Median age was 38.5 years (age range between 18-80). Previous history of RC was present in 21/34 (61.8 %). Hematuria in urinalysis was present in 19/34 (55.8 %). AKI was diagnosed in 11/34 (32.3 %) patients. In 10/11 (91 %) AKI was stage 1. Mean creatinine at recovery was 0.87 ± 0.28 mg% vs creatinine at diagnosis 1.18± 0.43 ($p<0.05$) The mean estimated glomerular filtration rate decrease was 42 ± 23, 44 ml/min, and 1 case was stage 3 AKI. The average time to complete glomerular filtration recovery was 15 days. Significant association was observed between the use of nonsteroidal antinflammatory (NSAIDs) drugs and development of AKI during the episode. AKI was associated to unilateral obstructive stones in 10/11 patients. None required renal replacement therapy.

Conclusions: AKI was frequent among those patients who consulted for RC in the ED (32.3%). NSAIDs consumption was significantly related with AKI development. Kidney stone obstruction was unilateral except for one patient that presented bilateral involvement.

TH-PO688

Long-Term Outcomes and Associated Risk Factors of Post-Hospitalization Dialysis-Dependent AKI (PHD-AKI) Ajay Singh Rathore,[1] Jennie Z. Ma,[2] Wenjun Xin,[2] Emaad M. Abdel-Rahman.[1] *[1]Nephrology, Univ of Virginia, Charlottesville, VA; [2]Public Health Sciences, Univ of Virginia, Charlottesville, VA.*

Background: CMS has reversed its clarification allowing AKI patients to be dialyzed at outpatient ESRD facilities starting 2017.Data assessing long-term outcomes and predictors of PHD-AKI are needed to adopt guidelines ensuring adequate management of these patients in the outpatient settings. We aimed to assess long-term outcomes and associated risk factors in patients with PHD-AKI.

Methods: Patients discharged from UVA between 4/13/2012 and 12/25/2013 with PHD-AKI, and who were alive 90 post hospital discharge (PHD) were prospectively followed for outcomes. The effects of baseline demographics and co-morbidities on the outcomes were assessed in a logistic regression.

Results: From 91 patients followed, 52 were declared ESRD (group 1) and 39 were dialysis-independent (group 2) at 90 days PHD. Outcome and follow up period is shown in table. At the end of the study 32/91 (35.2%) were dialysis-independent (3 from group 1 and 29 from group 2).Mortality was much higher in group 1 than group 2. After adjusting for demographics and co-morbidities, the odds ratio (OR) for mortality for both groups was 4.2 and 3.4 for being declared ESRD and requiring CRRT, respectively. Group 1 patients OR for mortality were 3.99 for CRRT and 3.55 for hypotension. Group 2 patients OR for composite outcome (ESRD and death) was 11.5 for GFR<45 ml/min. Other demographics or co-morbidities were not significant to predict long-term outcomes.

Outcome Status	Group 1 (n=52) N(%)	Group 1 (n=52) Follow up Time (Days)	Group 2 (n=39) N(%)	Group 2 (n=39) Follow up Time (Days)
ESRD	24 (46.1%)	1151.1 (538-1391)	7 (17.9%)	445 (35-900)
Recovered	3 (5.7%)	28.7 (13-53)	29 (74.4%)	1220 (916-1394)
Death	25 (48.1%)	431.7 (7-1219)	3 (7.7%)	402.7 (84-580)

Conclusions: Sustaining long-term dialysis-independence in patients with PHD-AKI is significant. Recovery, though minimal, is still possible in patients who remained dialysis dependent 90 days PHD. Baseline renal function and hemodynamic changes during hospitalization are predictors of long-term outcomes. Meticulous follow up of PHD-AKI patients in the outpatient dialysis facilities is crucial.

TH-PO689

Preoperative Echocardiography Predicts Acute Kidney Injury and Long-Term Mortality in Coronary Artery Bypass Grafting Seung Seok Han,[1] Seokwoo Park,[1] Dong Ki Kim,[1] Sejoong Kim,[1,2] Ho Jun Chin,[1,2] Ki Young Na.[1,2] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National Univ Bundang Hospital, Gyeonggi-do, Korea.*

Background: Acute kidney injury (AKI) is a common complication in patients undergoing coronary artery bypass grafting (CABG), which is associated with significant morbidity and mortality. This study identified echocardiographic predictors of AKI and determined whether these predictors were related to long-term mortality in CABG.

Methods: This retrospective cohort study included 1,300 patients who underwent echocardiography before CABG at two tertiary referral centers from 2004 to 2010. The best echocardiographic predictor of AKI was determined using multivariate and stepwise selection methods. Subsequently, patients were followed for 72 ± 28.8 months (maximum 11 years) for tracing all-cause mortality. Based on these information, we measured the adjusted odds ratio (OR) and hazard ratio (HR) for AKI and all-cause mortality, respectively, according to the chosen echocardiographic parameter.

Results: E/e' was the best predictor of AKI among echocardiographic parameters [figure 1]. The high E/e' group (>15) exhibited a higher OR for AKI [2.2 (1.51–3.27)] than the low E/e' group (<8). The high E/e' group required a longer hospital stay [16 days (12–23 days)] than the low E/e' group [14 days (11–17 days)]. There were 272 deaths (20.9%) during the following period. The high E/e' group exhibited a higher HR for mortality [1.9 (1.34–2.76)] than the low E/e' group, and this difference remained significant, regardless of the occurrence of AKI and the size of the ejection fraction volume.

Conclusions: E/e' in preoperative echocardiography is the best predictor of AKI and long-term mortality in patients undergoing CABG.

TH-PO690

Preoperative C-Reactive Protein Predicts Acute Kidney Injury and Long-Term Mortality after Coronary Artery Bypass Grafting Seung Seok Han,[1] Dong Ki Kim,[1] Sejoong Kim,[1,2] Ho Jun Chin,[1,2] Ki Young Na.[1,2] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National Univ Bundang Hospital, Gyeonggi-do, Korea.*

Background: Precise prediction of post-surgical acute kidney injury (AKI) is an important concern in patients with coronary artery bypass grafting (CABG) regarding high morbidity and mortality of AKI. The present study addressed whether preoperative C-reactive protein (CRP) is predictive of AKI and long-term mortality in CABG.

Methods: This retrospective cohort study included 1,700 patients whose high-sensitivity CRPs were measured before CABG at two tertiary referral centers from 2004 to 2010. The odds ratios (ORs) and hazard ratios (HRs) for AKI and all-cause mortality were estimated according to the tertiles of CRP levels after adjustment of multiple covariates. Net reclassification improvement (NRI) and integrated discrimination improvement (IDI) were calculated to determine whether the addition of CRP to risk model for AKI improves prediction.

Results: The prevalence of AKI was higher in the 3rd tertile group (42.4%) than in the 1st tertile group (25.7%). The corresponding OR of AKI and *P* values were 1.90 (1.44–2.52) and <0.001, respectively. Compared with the reference risk model, the addition of CRP improved the predictability with 0.107 of NRI (*P*=0.037) and 0.005 of IDI (*P*=0.007). During the median duration of 89 months (maximum 12 years), 491 deaths (28.9%) were observed. The 3rd tertile group exhibited a higher HR for mortality [1.64 (1.29–2.08)] than the 1st tertile group. This predictability for mortality remained consistent irrespective of the presence of sepsis or AKI.

Conclusions: Preoperative CRP may be needed to predict post-surgical AKI and mortality in patients undergoing CABG.

TH-PO691

Cardiovascular Mortality after Major Surgery in Elderly Negiin Pourafshar, Tezcan Ozrazgat-Baslanti, Anis Davoudi, Parisa Rashidi, Mark S. Segal, Azra Bihorac. *Univ of Florida, Gainesville, FL.*

Background: In the developed world, the increase in life expectancy with the resultant increase in the age of the population has led to a rise in multiple age-associated disorders. Among all the diseases in elderly, acute kidney injury (AKI) appears to have among the highest incidences and is a major risk factor for end stage renal disease (ESRD). The aim of this study is to determine the long-term cardiovascular-specific mortality in elderly patients with AKI or chronic kidney disease (CKD) after major surgery.

Methods: In a single-center cohort of 16,655 elderly (≥65 years-old) surgical patients undergoing major inpatient surgery, long-term cardiovascular-specific mortality was modeled using a multivariable subdistributional hazards model while treating any other cause of death as a competing risk. Preexisting CKD, ESRD and postoperative AKI were the main independent predictors and each model was adjusted for preoperative demographic and clinical variables.

Results: Prior to the admission, 3% and 12% of the cohort had preexisting ESRD and CKD not requiring renal replacement therapy, respectively. During hospitalization, 47% developed AKI. Among the 7768 deaths reported, the main causes of death were cardiovascular disease (32%) and cancer (31%). Adjusted cardiovascular mortality estimates for patients with no kidney disease, AKI without CKD, CKD without AKI, AKI with CKD, and ESRD at 10 years were 12.2%, 19.4%, 18.4%, 29.7%, and 45.8%, respectively. Adjusted hazard ratios (95% CIs) for cardiovascular mortality were significantly elevated among

patients with AKI without CKD (1.69 95% CI 1.52-1.87), CKD without AKI (1.59 95% CI 1.25-2.01), AKI with CKD (2.83 95% CI 2.47-3.24) and ESRD (5.21 95% CI 4.32-6.27), compared to patients with no kidney disease.

Conclusions: Perioperative AKI is common in elderly patients undergoing major surgery and is associated with a high risk for future cardiovascular-specific mortality. These findings emphasize the importance of preoperative and postoperative risk stratification for kidney disease and the application of strategies to prevent perioperative AKI.

TH-PO692

Development of Hypertension after Acute Kidney Injury in the Pediatric Intensive Care Unit

Erin Hessey, Ana Palijan, Michael Pizzi, Radu Alexandru Paun, Michael Zappitelli. *McGill U, QC, Canada.*

Background: Acute kidney injury (AKI) in the pediatric intensive care unit (PICU) is common and associated with poor hospital outcomes. Long-term renal effects of PICU-AKI, like microalbuminuria (MA) and hypertension (HTN), are not well understood. We will determine the prevalence of MA and HTN in children admitted to the PICU 5-10 years ago.

Methods: Design & population: Ongoing longitudinal follow-up study of children (<18 years old) admitted to the Montreal Children's Hospital PICU between 2005-2010. Patients in the neonatal ICU or with pre-PICU renal disease excluded. Study visit: Occur 5-10 years after PICU admission. We collect medical histories, anthropometric measures, 3 office BP measures, first morning urine for MA determination and 24-hour ambulatory BP monitoring (ABPM) for HTN determination. Exposure: KDIGO serum creatinine (SCr) AKI staging. Outcomes: MA defined by KDIGO (albumin/creatinine>30 mg/g). HTN defined by the 2014 American Heart Association guidelines (figure 1). Analysis: The prevalence of HTN and MA was calculated, ABPM HTN phenotypes were detailed. Univariate AKI *vs.* non-AKI comparisons were made using χ^2 tests.

Classification	Casual BP	Mean Ambulatory SBP and/or DBP (day, night, or 24hr)	SBP and/or DBP load (%) (day, night, or 24hr)
Normal BP	<90th %tile	<95th %tile	<25
White coat HTN	≥95th %tile	<95th %tile	<25
Prehypertension	≥90th %tile or >120/80mmHg	<95th %tile	≥25
Masked hypertension	<95th %tile	>95th %tile	≥25
Ambulatory HTN	>95th %tile	>95th %tile	≥25-50
Severe ambulatory HTN	>95th %tile	>95th %tile	>50
Other:			
Non-BP dipping	([mean daytime BP] – [mean nighttime BP])/mean daytime BP x 100 <10%		

Figure 1: American Heart Association staging of Ambulatory BP in children. The casual BP, mean ambulatory BP, and BP load must meet the criteria to be classified as hypertensive.
Casual BP values based on National High BP Education Program Task Force normative data.
ABP and BP load values based on the American Heart Associations normative data.
%tile = percentile; *BP* = blood pressure; *SBP* = systolic blood pressure; *DBP* = diastolic blood pressure; *HTN* = hypertension; *Load* = percentage of readings over the 95th percentile

Results: Study visits have been performed on 101 patients (male 51%, mean age±SD=11.0±4.8 years), 32/75 (42.7%) had past PICU-AKI (n=26 no SCr in PICU). 93 patients attempted the 24-hour ABPM, and 89 (96%) were successful. Of these, 11 (12.4%) had HTN (10 masked HTN, 1 ambulatory HTN), 4 (4.5%) had prehypertension, 1 (1.1%) had white coat HTN, and 34/68 (50%) had non-BP dipping. 5/29 (17%) of AKI patients had HTN *vs*. 5/38 (15%) non-AKI patients (p=0.6). MA was present in 9/100 (9%) patients with urine samples analyzed (AKI: 3.1% vs. no AKI: 11.6%, p=0.2).

Conclusions: HTN and non-BP dipping prevalence are high in children with past PICU admission. Future work must elucidate the risk factors for HTN to provide an evidence base for post-PICU follow-up guidelines.

TH-PO693

Acute Kidney Injury Is Associated with Long-Term Renal Outcomes Using Administrative Data in Children

Erin Hessey,[1] Sylvie Perreault,[2] Louise Roy,[2] Rami Ali,[1] Marc Dorais,[3] Philippe Jouvet,[2] Jacques R. Lacroix,[2] Genevieve Morissette,[2] Veronique Phan,[2] Nikki J. Rink,[1] Michael Zappitelli.[1] *[1]McGill U; [2]U de Montreal; [3]StatScience Inc., QC, Canada.*

Background: Acute kidney injury (AKI) may be a risk factor for long-term chronic kidney disease (CKD) or hypertension (HTN). Provincial administrative health data (PAHD), using International Classification of Disease codes (ICD-9/ICD-10), is a rich resource to study long-term AKI outcomes in adults, but has been poorly explored in child AKI research. We will develop a child CKD and HTN definition using PAHD and evaluate association between intensive care unit (ICU) AKI and 5-year post-discharge CKD and HTN.

Methods: Chart data from a retrospective ICU cohort (2 Montreal pediatric ICUs, 2003-2005 [n=2499]; no health care number, ICU deaths, pre-existing CKD excluded) was merged with Quebec 5-year post-ICU PAHD. Several CKD and HTN PAHD algorithms were developed (literature review, expert opinion), tested, and discussed, followed by final algorithm selection (figure 1). Exposure: KDIGO serum creatinine AKI. Outcomes: 5-year post-ICU CKD, HTN, per PAHD. Analysis: univariate AKI *vs.* non-AKI comparisons (χ^2 tests).

Results: Cohort: n=2404, 56% male, mean ± SD age=6.0 ± 5.7 years, PRISM (mortality) score=10.1 ± 7.5, 467/1934 (24.2%) ICU-AKI. 3 HTN and 17 CKD algorithms were evaluated (high sensitivity vs. specificity). The selected CKD algorithm combines the high specificity diagnostic and procedural codes, medications, and nephrology visits (figure 1). The HTN algorithm combines outpatient diagnostic codes and medications (figure 1). We found that 8.6% developed CKD (AKI: 17.6%, non-AKI: 6%, p<0.0001); 9.7% developed HTN 5 years post-ICU (AKI: 21.2%, non-AKI: 7.5%, p<0.0001).

Conclusions: Pediatric ICU-AKI is associated with 5-year post-ICU PAHD-defined CKD and HTN. Research should evaluate validity of child PAHD-defined CKD and HTN.

Figure 1: Proposed CKD definition: one or more diagnostic codes, **OR** CKD medication prescription, **OR** fulfill nephrology visit criteria.
Proposed hypertension algorithm: one or more outpatient hypertension diagnostic codes **OR** prescription for anti-hypertensive medication.

Evaluation of Height-Dependent and Height-Independent Methods of Estimating Baseline Serum Creatinine in Critically Ill Children

Erin Hessey,[1] Rami Ali,[1] Marc Dorais,[3] Genevieve Morissette,[2] Nikki J. Rink,[1] Philippe Jouvet,[2] Jacques R. Lacroix,[2] Veronique Phan,[2] Michael Pizzi,[1] Michael Zappitelli.[1] *[1]McGill U; [2]U de Montreal; [3]StatScience Inc., QC, Canada.*

Background: Baseline serum creatinine (bSCr) is required for diagnosing acute kidney injury (AKI). In children, measured bSCr is often missing. The alternative, estimating bSCr with height-based glomerular filtration rate (GFR) equations, is not always feasible. We will evaluate the accuracy of back-calculating bSCr (estimated bSCr) from height-dependent and height-independent GFR equations.

Methods: Retrospective intensive care unit (ICU) cohort (two Montreal pediatric ICUs, 2003-2005[n=2499]; excluded: no health care number, baseline renal disease). Patients with a measured bSCr, height, and ICU SCr (n=538) included. Height-dependent GFR: CKiD equation and age-based GFR norms. Height-independent method: Hoste et al equation and age-based GFR norms. Analysed bias, accuracy, and precision of estimated bSCr methods relative to measured bSCr. Calculated agreement of AKI ascertainment using measured and estimated bSCr. Performed multivariate analyses to assess the impact of estimated bSCr on AKI-outcome associations.

Results: Figure 1 shows results. Both methods slightly underestimated bSCr, had good accuracy (~30% of estimated bSCr ± 10% measured bSCr), but poor precision (wide 95% limits of agreement). Agreement of AKI defined by estimated *vs.* measured bSCr was >80% (κ>0.5). AKI was associated with longer ICU stay and mechanical ventilation, but not ICU mortality (after adjustment), by measured and estimated bSCr methods.

Figure 1: Performance of estimated bSCr methods compared to measured bSCr (n=538).

	Measured bSCr	Height-dependent	Height-independent
Mean bias, SD (95% CI) [µmol/l]	Ref	-3.4 ± 13.5 (-4.5 – -2.2)	-2.5 ± 13.5 (-3.6 – -1.4)
Mean percent bias, SD (95% CI) [%]	Ref	2.0 ± 38.0 (-1.3 – 5.2)	3.2 ± 39.5 (-0.2 – 6.5)
95% limits of agreement of percent bias [%]	Ref	-72.5 to 76.5	-74.2 to 80.6
% within ± 30% of measured bSCr	Ref	73%	72%
% within ± 10% of measured bSCr	Ref	30%	29%
Agreement - AKI (Yes/No)	Ref	82%	81%
Kappa statistic - AKI classification	Ref	0.53	0.52
Length of stay (by AKI yes/no), adjusted HR (95% CI)	0.6 (0.4-0.7)*	0.7 (0.5-0.9)*	0.7 (0.6-0.9)*
Days of mechanical ventilation (by AKI yes/no), adjusted HR (95% CI)	0.6 (0.4-0.8)*	0.6 (0.5-0.8)*	0.6 (0.5-0.8)*
Mortality (by AKI yes/no), adjusted OR (95% CI)	3.5 (1.2-9.8)*	2.2 (0.8-6.3)	1.8 (0.6-5.3)

*P<0.05

SD = standard deviation; *CI* = confidence interval; *AKI* = acute kidney injury; *HR* = hazard ratio; *OR* = odds ratio; *bSCr* = baseline serum creatinine

Conclusions: The height-dependent and height-independent formulas perform similarly for bSCr estimation. When bSCr and height are missing, AKI can be defined using bSCr estimated by a height-independent method.

TH-PO695

Neonatal Acute Kidney Injury: A Survey of Neonatologists and Nephrologists' Perceptions to Diagnosis and Follow-Up Jennifer R. Charlton,[1] Cherry Mammen,[2] Ronnie Guillet,[3] Katja M. Gist,[9] Mina Hanna,[4] Ahmad I. El Samra,[5] David T. Selewski,[7] David J. Askenazi,[8] Alison Kent.[6] *[1]Univ of Virginia; [2]Univ of British Columbia and BC Children's Hospital; [3]Univ of Rochester; [4]Univ of Kentucky; [5]Franciscan St. Elizabeth Health; [6]Canberra and Australian National Univ; [7]Univ of Michigan; [8]Univ of Alabama at Birmingham; [9]Children's Hospital Colorado.*

Background: Neonatal acute kidney injury (nAKI) is associated with increased morbidity and mortality. However, it is unclear if neonatologists and nephrologists diagnose, treat and follow up nAKI in similar ways. The aim of this study was to assess the knowledge and management of nAKI by surveying neonatologists and pediatric nephrologists.

Methods: An electronic survey containing both general questions and case-based scenarios was developed and distributed to neonatologists and pediatric nephrologists in Australia, New Zealand, Canada, USA and India on behalf of the Neonatal Kidney Collaborative (NKC).

Results: Of the 375 completed surveys 244 were returned by neonatologists (65%) and 131 by nephrologists (35%). The majority of neonatologists (60%) were unaware of the categorical definitions of nAKI. Nephrologist were more likely to recognize stage 1 AKI (80%, Neo: 60%). In the case-based scenarios, nephrologists were more likely to believe that neonates with stage 1 and 2 AKI were at risk of later chronic kidney disease (CKD). The majority of respondents (neonatologists: 92%; nephrologists: 86%) reported renal assessments were not included in their program's growth and development follow-up.

Conclusions: Pediatric nephrologists who participated in this case-based survey were more likely than neonatologists to recognize nAKI and consider it risk for the development of CKD. There is minimal renal follow-up of neonates at risk of CKD, an area for quality improvement projects.

TH-PO696

Pediatric Acute Kidney Injury after Cardiac Surgery - Incidence and Outcomes Garima Aggarwal. *Nephrology, Amrita Inst of Medical Sciences, Kochi, Kerala, India.*

Background: The aim of this study is to know the incidence of Acute Kidney Injury (AKI) in the immediate postoperative period following pediatric cardiac surgeries.To study the effect of AKI on adverse outcomes –death, mechanical ventilation and length of hospital stay, length of stay in pediatric Intensive Care Unit (PICU) and to identify the perioperative risk factors associated with AKI.

Methods: Children undergoing heart surgery in a tertiary hospital in Kerala were studied. After receiving institutional research ethics board approval, 180 consecutive children, age<18 years who underwent any type of cardiac surgery and admitted to the PICU were prospectively studied till length of hospital stay. Patients with diagnosed underlying kidney disease were excluded. Preoperative, intraoperative and postoperative possible risk factors for AKI and their relationship with adverse patient outcomes were assessed. To test the statistical significance of the association of AKI versus non AKI with different categorical variables chi squared test was applied and 21 variables were identified. Multivariate stepwise backward conditional logistic regression analysis was applied to identify significantly contributing variables with respect to presence or absence of post operative AKI.

Results: The prevalence of Acute Kidney Injury (AKI) was 32.8% in our study population. Fifty nine (developed AKI according to the pRIFLE criteria, with 12 (20.3 %), two (3.4 %), and forty five (76.3%) patients classified in the R, I, and F groups, respectively. Neonatal age group, weight ≤ 5 kg, pre operative AKI, intra operative mean arterial pressure on Cardio Pulmonary Bypass (CPB) ≤40mmHg, use of albumin during CPB, inotrope requirement for more than 48hours in the post operative period and post operative albumin use were all associated with high incidence of AKI on multivariate analysis (p=<0.05). Patients with AKI had longer duration of mechanical ventilation and longer duration of hospital stay (p=<0.05).

Conclusions: AKI is common in the postoperative period in children following cardiac surgery and is associated with adverse clinical outcomes.

TH-PO697

AKI Outcomes in Young Adults Emily Lauren Joyce,[1] Dana Y. Fuhrman,[1,2] Priyanka Priyanka,[2] John A. Kellum.[2] *[1]Dept of Pediatrics, Div of Nephrology, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]Critical Care Medicine, CRISMA Center, Univ of Pittsburgh School of Medicine, UPMC, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is associated with adverse outcomes including increased healthcare costs, morbidity and mortality. Outcomes of AKI in critically ill young adults have not been well described, and this is a unique population given that mortality is less confounded by chronic disease. The goal of this project was to assess outcomes in critically ill young adults who developed AKI.

Methods: Data was obtained from the HiDenIC database which contains > 45,000 critically ill patient records from UPMC. The cohort was divided into four age strata: young adults ages 16-25 and ages 26-35, 36-45, and 46-55. Descriptive outcomes are provided and multivariable logistic regression was used to analyze mortality.

Results: A total of 8270 critically ill adults developed AKI across all age groups, with 862 young adults. The incidence of AKI in young adults was 39.8%, and is associated with poor outcomes including prolonged hospital and ICU length of stay, and 10.4% one-year mortality. One third of the mortality occurred after hospital discharge. See table 1 for outcomes of patients with AKI stratified by age. AKI, APACHE 3 score, multiple comorbidities and vasopressor use are strong predictors of ICU, hospital, 90-day and 1-year mortality in young adults.

Outcome	Age 16-25	Age 26-35	Age 36-45	Age 46-55
Need for RRT, N (%)	46 (5.3)	77 (7)	172 (7.9)	345 (8.4)
No recovery from RRT at 90 days, N (%)	22 (47.8)	37 (48.1)	92 (53.5)	229 (66.4)
ICU length of stay (days), Mean (SD)	9.6 (10.7)	10.3 (15.1)	8.7 (11.6)	8.8 (66.4)
Hospital length of stay (days), Mean (SD)	20.1 (22.2)	21.7 (25.4)	19.5 (24.1)	19.5 (24.2)
ICU Mortality, N (%)	51 (5.9)	80 (7.3)	245 (11.2)	486 (11.8)
Hospital Mortality, N (%)	64 (7.4)	107 (9.7)	319 (14.6)	674 (16.4)
Mortality at 90 days, N (%)	67 (7.8)	123 (11.2)	390 (17.8)	860 (20.9)
Mortality at 1 year, N (%)	90 (10.4)	180 (16.4)	498 (22.8)	1145 (27.8)

Conclusions: Critically ill young adults have a high incidence of AKI with significant associated mortality.

The Prognostic Importance of Duration of Acute Kidney Injury with Mortality: A Systematic Review and Meta-Analysis Swati Mehta,[1] Achint Patel,[1] Kinsuk Chauhan,[1] Shanti N. Patel,[3] Rachel Pinotti,[1] Girish N. Nadkarni,[1] Chirag R. Parikh,[2] Steven G. Coca.[1] *[1]Nephrology, Icahn school of medicine at Mount Sinai, NYC, NY; [2]Nephrology, Yale Univ school of medicine, New Haven, CT; [3]Internal Medicine, Maimonides Medical Center, Brooklyn, NY.*

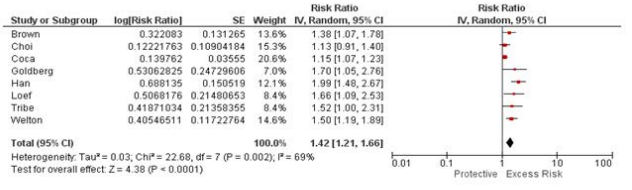
Background: Staging of AKI is based on the magnitude of peak rise in serum creatinine and does not explicitly consider the duration of AKI. We sought to determine the independent association of duration of AKI with long-Term mortality.

Methods: We performed a systematic review and meta-analysis of studies that examined the relationship between duration of AKI and long-term mortality. Medline, Embase, Cochrane library, web of science and CINAHL were searched through December 2015. Duration of AKI was categorized as "short" for AKI ≤ 2 days, medium" for durations 3-6 days, and "long" for ≥ 7 days or "non-recovered." Pooled adjusted risk ratios for duration of AKI were estimated with inverse variance method using RevMan5.3.

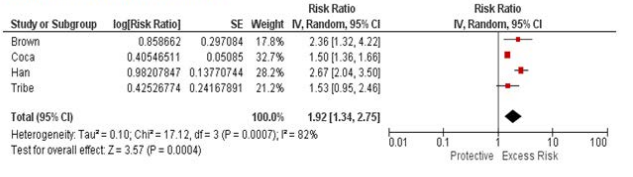
Results: Of 6209 initially identified studies, 8 were included for full review. These 8 studies were comprised of 65,080 patients with a median follow-up time of 6.4 years. The overall incidence of AKI was 21.2%, with 58% short, 18.4% medium, and 21.7% long duration. The pooled RRs demonstrated a dose response relationship with highest risk for long-duration AKI. There was considerable heterogeneity across pooled studies.

Forest plots for risk of long term mortality by duration of AKI

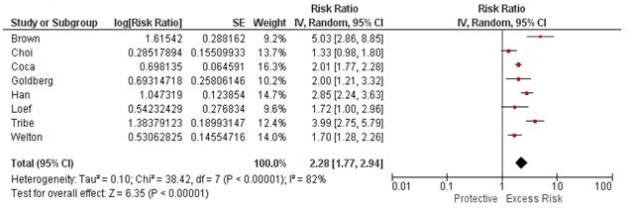
A. Short duration vs no AKI



B. Medium duration vs no AKI



C. Long duration vs no AKI



Conclusions: Duration of AKI was independently associated with long-term mortality in a graded manner. Duration of AKI should be incorporated into risk-models for long-term mortality post-AKI and possibly in staging systems for AKI.

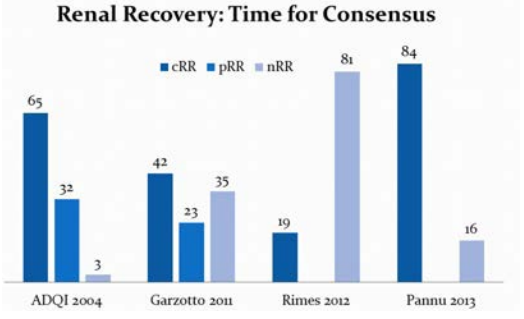
TH-PO699

Renal Recovery: Time for Consensus Maria Isabel Acosta-Ochoa, Alicia Mendiluce. *Nephrology, Hospital Clínico Univ, Valladolid, Spain.*

Background: AKI is a global public health problem, which increases mortality and bears long term consequences. We can find several definitions of renal recovery (complete cRR), partial RR (pRR) and no RR (nRR). Our aim was to compare some currently used criteria by means of rates of RR, and to describe the differences between them.

Methods: Retrospective study of hospitalized patients with diagnosis of AKI, we excluded patients who died during the index hospitalization. We tested four RR criteria: **ADQI 2004:** cRR discharge SCr <1.5x baCr, pRR >1.5x and nRR HD persistence; **Garzotto, et al. 2011** (cRR discharge SCr <1.2x baCr, pRR 1.21-1.49x and nRR >1.5x or HD persistence; **Rimes et al. 2012** (cRR return to baEGFR, nRR any alteration of EGFR; **Pannu et al. 2013** nRR, doubling baCr, and plotted the results.

Results: 342 patients were included, mean age 71.7±14, 64% males, 40% diabetes, 85% hypertension, and 53% CKD, mean Charlson Index 4±2.4, KDIGO Stage 1 (29%), 2 (13%), 3 (58%), need for HD 13%, persistence in HD 3%. We found rates of RR: **ADQI** cRR 65%, pRR 32%, nRR 3% (persistence in HD); **Garzotto:** cRR 42%, pRR23%, nRR 32% + 3% HD persistence; **Rimes:** cRR 19%, nRR 81%; **Pannu**: nRR 13%. Comparison of RR rates in figure 1.



Conclusions: We found a wide variability in renal recovery rates depending on the used author's criteria. Renal recovery after AKI lacks of standard definition and absence of unified criteria (complete, partial, and no recovery, Cr based, eEGFR based, HD dependence or not, and including vs. excluding in-hospital mortality). A consensus definition would contribute to the unification of study designs, results interpretation, refining the quest for risk and protective factors, and as public health tool in order for planning nephrology consultation needs and hemodialysis resources.

TH-PO700

Acute Kidney Injury Followed by Complete Recovery Is Associated with Higher Infection Risk Anna Jeanette Jovanovich,[1,2] Zhiying You,[2] Kyle Hiroyasu,[3] Benjamin Griffin,[2] John R. Holmen,[3] Sarah Faubel,[1,2] Michel Chonchol.[2] *[1]Denver VA Medical Center; [2]Univ of Colorado Denver; [3]Intermountain Healthcare.*

Background: Acute kidney injury (AKI) affects myriad organ systems including the immune system. Immune cells are altered in animal and human AKI. Sepsis may develop after AKI among hospitalized patients, and those with AKI requiring dialysis have a higher risk of sepsis after discharge compared to controls. We aim to determine the risk of infection in the year following a non-infectious hospital admission complicated by AKI with complete recovery in a well-matched cohort of cases and controls.

Methods: We identified 886 AKI cases (AKI Network definition) with complete kidney function recovery at the time of discharge, defined as serum creatinine <1.10 times the pre-admit baseline value, during a non-infectious hospital admission between January 1, 1999 and December 31, 2009 from an integrated health care delivery system. We matched 886 controls (no AKI during index admission) based on a propensity score including: age, sex, race, prior inpatient visits, coronary artery disease, congestive heart failure, chronic pulmonary disease, hypertension, diabetes, and admission day. The primary outcome was incident infection, defined by ICD-9 codes, during the 12 months following discharge.

Results: Baseline characteristics among the cases and controls were similar: age 62±16 years, 45% female, 94% white, serum creatinine 0.9±2 mg/dL. During the 12 months after discharge, 342 cases and controls developed infection. Post-discharge infection was more common among cases compared to controls. In the periods between 30, 60, 90, and 365 days after discharge, infection developed in 90, 53, 44, and 133 cases compared to 29, 27, 21 and 65 controls, respectively. These events correspond to greater than 2-fold higher odds of infection among cases compared to matched controls (odds ratio 2.6 [95% CI, 2.0 – 3.3]; p <0.0001).

Conclusions: Among patients from an integrated health care delivery system, non-infectious AKI followed by complete recovery was associated with an increased risk of infection in the year after discharge. These data support long-term immune dysfunction after AKI.

Funding: VA Support

TH-PO701

Risk Factors for Hospital Readmission and New-Onset CKD and Prevalence of Nephrology Follow-Up Care following AKI Grace M. Choong,[1] Mark D. Faber,[2] Denise White Perkins,[2,3] Lois Lamerato.[3] *[1]Wayne State Univ School of Medicine, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI; [3]Henry Ford Health System, Detroit, MI.*

Background: Many studies report the incidence and hospital-associated mortality of acute kidney injury (AKI) but less is known about follow-up care and longer term outcomes in this population. PURPOSE: to identify risk factors for hospital readmission and new-onset CKD, and to characterize follow up care, in hospitalized patients with AKI.

Methods: Retrospective, univariate analysis of individuals with AKI as defined by ICD-9 codes, hospitalized at 1 of 4 HFHS hospitals in 2012-2014. To enhance completeness of follow-up only patients enrolled in Health Alliance Plan of Michigan (HAP) for 6 months before and after AKI were followed. HAP is a managed care plan and subsidiary of HFHS. Individuals were 18-90 years old and excluded if they died during the index event. Subjects were followed for subsequent admissions and other aspects of care for 6 months after discharge.

Results: The study population (n=4002) had a mean age of 72.6, was predominantly male (52.5%) and non-African American (NAA) (57%). 17.7% of patients were readmitted within 30 days. Age, gender and race did not predict readmission. Readmission risk was increased by concurrent diabetes (DM), congestive heart failure (CHF), cancer, liver disease or preexisting CKD, whereas sepsis, COPD and peripheral vascular disease did not. 32.8% of individuals had CKD prior to the AKI event, while 20.6% developed CKD after the AKI. Being AA or <65 years old predicted new-onset CKD, as did having DM or CHF. Diagnoses of sepsis or hypertension were associated with a decreased risk of CKD. Despite having had AKI, only 10.6% of patients saw a nephrologist within 6 months of discharge.

Conclusions: Substantial opportunity exists to improve post discharge care of patients following hospitalization with AKI. Better understanding of risk profiles for readmission may help reduce the high and costly readmission rate. More importantly, deficient nephrology care following AKI discharge may place patients at risk for poor outcomes by denying patients the benefits of comprehensive multidisciplinary nephrology outpatient care.

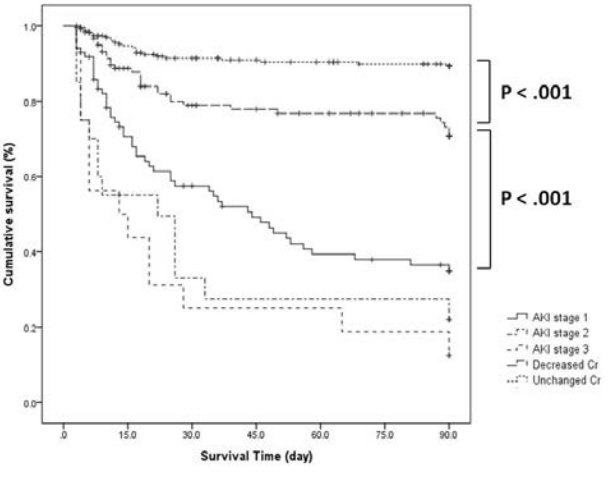
TH-PO702

Decrease in Serum Creatinine after ICU Admission Is Associated with Increased Mortality Hye Ran Kang, Sinae Lee, Jin Seok Jeon, Hyunjin Noh, Dong-Cheol Han, Soon Hyo Kwon. *Div of Nephrology, Soonchunhyang Univ Hospital, Seoul, Republic of Korea.*

Background: The elevation of serum creatinine (SCr), acute kidney injury (AKI), is associated with an increase of mortality in critically ill patients. However, it is uncertain whether decrease of SCr in intensive care unit (ICU) has an effect on outcome.

Methods: In a retrospective study, we enrolled 486 patients who admitted to an urban tertiary ICU from Jan 2014 to Dec 2014. The effect of change in SCr after ICU admission on 90 days mortality was analyzed. Patients were classified into 3 groups based on change in SCr after ICU admission: unchanged Cr group (ΔCr < 0.3mg/dL within the prior 7 days), decreased Cr group (ΔCrea ≤ -0.3 mg/dL within the prior 7 days) and increased Cr group meeting the KDIGO AKI definition.

Results: SCr decreased in 123 (25.3%) patients after ICU admission. AKI developed in 125 (24.4%) patients. The overall 90-day mortality rate was 29.0%. In a Kaplan-Meyer analysis, the mortality in the AKI group was higher than that of other groups (p<0.001). Patients with decrement in SCr showed the higher mortality rate compared to those with unchanged SCr (p<0.001).



The Cox analysis showed that decrease (HR; 3.56, 95% CI; 1.59-7.97, p=0.002) and increase in SCr were independent risk factors for death (AKI stage 1, HR; 9.35, 95% CI; 4.18-20.9, p<0.001: AKI stage 2, HR; 11.82, 95% CI; 3.85-36.28, p<0.001: AKI stage 3, HR; 17.41, CI; 5.50-55.04, p<0.001, respectively) comparing unchanged SCr group.

Conclusions: Not only increment in SCr, but also decrement in SCr was associated with mortality in critically ill patients.

TH-PO703

Evaluation of Absolute Serum Creatinine Changes in Characterizing Stages for Cirrhosis-AKI and Its Association with Long-Term Outcomes
Fangfang Zhou,[1] Qun Luo,[1] Lina Han,[1] Huadong Yan,[2] Zemin Wang,[1] Yumei Li.[1]
[1]Dept of Nephrology, Ningbo NO.2 Hospital, Ningbo, Zhejiang, China; [2]Dept of Infectious Diseases, Ningbo NO.2 Hospital, Ningbo, Zhejiang, China.

Background: Acute kidney injury (AKI) in cirrhotic patients is associated with worse outcomes. To date, there is no uniformity as to the classification for cirrhosis-AKI. We aimed to evaluate absolute serum creatinine (sCr) changes ('Delta-sCr') for characterizing stages of AKI, and its impacts onlong-term outcomes in cirrhotic patients, compared with the KDIGO criteria.

Methods: We conducted a retrospective analysis of 333 hospitalized cirrhotic patients from January 2013 through December 2014. We defined AKI stages using: 1) KDIGO criteria, and 2) the Delta-sCr, defined by the difference between the baseline and the peak sCr value during hospitalization.The Delta-sCr cut-points were defined as follows: Stage 0, sCr increase <0.3 mg/dl, Stage I, 0.3–0.7mg/dl, Stage II, 0.7–1.2 mg/dl and Stage III, ≥1.2 mg/dl. The end point was the hazard of death or readmission in one year.

Results: The 1-year mortality in cirrhotic patients with AKI was 36.67%. Multivariate analysis and Cox hazard analysis both showed that Delta-sCr was significantly associated with readmission(OR=1.008; p=0.006) and 1-year mortality (HR=1.009; p=0.000) . ROC analysis demonstrated that the Delta-sCr staging for AKI was more accurate than KDIGO staging in predicting 1-year mortality (AUC=0.825 vs 0.803; p=0.23). Though it did not achieve statistical significance, the values of specificity and positive likely radio were both higher when classifying AKI stage III. And the Delta-sCr staging also modestly improved reclassification (C-index increased from 0.6699 to 0.6803; NRI= 22.9%, p=0.04).

Conclusions: The Delta-sCr is associated with the 1-year readmission and mortality. And the Delta-sCr staging may optimize the discrimination of risk prediction, especially when classifying AKI stage III.

Acute Kidney Injury and Its Prognosis in Patients with Decompensated Cirrhosis
Gullipalli Prasad,[1] Prabhakar Doddi,[1] Mitta Ravi Kumar,[1] Raja Ramachandran.[2] *[1]Nephrology, Andhra Medical College; [2]Nephrology, PGIMER.*

Background: Acute kidney injury (AKI) occurs frequently in patients with cirrhosis. However, studies are limited on the impact of AKI on the mortality of patients with decompensated cirrhosis.

Methods: The present prospective observational study included subjects ≥ 18 years of age with cirrhosis and AKI. Patients were recruited from January 2015 to December 2015 and were followed for 90 days. Cases with Chronic kidney disease, on renal replacement therapy at the time of admission, pregnant and lactating mothers, liver transplant candidates and those with diabetes mellitus were excluded. Outcome was mortality at end of the study. Acute kidney injury network criteria were used to diagnose AKI. Hepato-renal syndrome (HRS) was diagnosed based on the 2007 Ascites Club Criteria. MELD score was used to predict severity of cirrhosis.

Results: Total 207 patients were admitted with cirrhosis and 56 patients (27%) had AKI. Mean age (yrs) was 52.12± 8.31. Mean serum creatinine(mg/dl) at admission and 48 hrs after admission was 1.84 ± 0.96 and 3.67 ± 1.29. Mean MELD score was 30.60 ± 6.47. Of the 56, patients with pre-renal azotomia(PRA) were 25 (44.64%), 15(26.78%) had acute tubular necrosis (ATN), patients with HRS were 13(23.21%) and 3 patients had other etio logies(Membranoproliferative glomerulonephritis, IgA nephropathy and acute interstitial nephritis). Fifteen patients (26.78%) died at the end of follow up. On univariate analysis, MELD score (p-0.0001), serum sodium (p-0.014), AKIN stage (0.002), serum creatinine at admission and after 48 hrs of admission (p-0.0001 and 0.0001), urine output(p-0.0001), dialysis requirement(0.007), systolic blood pressure (p-0.016) were associated with mortality. Patients with HRS had significantly high mortality when compared with PRA and ATN (p-0.004). However on multivariate analysis, only MELD score (OR- 1.308, 95% CI- 1.031-1.660) and serum sodium (OR-11.89, 95% CI-0.94-149.71) were independent predictors of mortality.

Conclusions: PRA is the most common form of AKI in patients with decompensated cirrhosis. Patients with HRS had significantly high mortality when compared with ATN and PRA. MELD score and serum sodium were independent predictors of mortality.

TH-PO705

The Study of Risk Factors for Acute Kidney Injury in 424 Patients with Decompensated Cirrhosis
Lina Han,[1] Qun Luo,[1] Fangfang Zhou,[1] Huadong Yan,[2] Zemin Wang,[1] Lailiang Wang,[1] Yumei Li.[1] *[1]Dept of Nephrology, Ningbo NO.2 Hospital, Ningbo, Zhejiang, China; [2]Dept of Infectious Diseases, Ningbo NO.2 Hospital, Ningbo, Zhejiang, China.*

Background: Acute kidney Injury(AKI) is a common complication with significant morbidity and mortality in decompensated cirrhotic patients. The aims of this study are to investigate and analyze the risk factors for AKI in these patients.

Methods: Relevant clinical data of 424 patients with decompensated cirrhosis was collected from Ningbo No.2 Hospital between January 2012 and December 2014, patients were divided into AKI group and non-AKI group according to the KDIGO criteria. Risk factors for AKI were analyzed by univariate and multivariate analysis methods.

Results: The incidence of AKI in decompensated cirrhosis is 17.7%, There were 47 men and 28 women, with a mean age of 63.04±10.21 years. The mean course of cirrhosis is 6.75±5.83 years and the average days of hospitalization were 19.20±13.90 days. The multivariate Logistic analysis showed the development of AKI in decompensated cirrhosis was correlated with increasing age(OR=1.068, P=0.003), infection(OR=8.119, P<0.001), decreasing eGFR(OR=0.919, P<0.001), ascites(OR=5.389, P<0.001),use of ACEI/ ARB(OR=7.675, P =0.028).

Conclusions: The incidence of AKI in patients with decompensated cirrhosis is high, increasing age, infection, decreasing eGFR, ascites and using of ACEI/ARB were independently associated with the development of AKI in decompensated cirrhosis.

Funding: Government Support - Non-U.S.

TH-PO706

Cholemic Nephropathy in Patients with End-Stage Liver Disease with AKI: A Postmortem Kidney Biopsy Study
Suman Nayak. *Nephrology, Inst of Liver and Biliary Sciences, New Delhi, Delhi, India.*

Background: Acute kidney injury (AKI) occurs frequently in patients with end-stage liver disease (ESLD) and portends a poor prognosis. Cholemic nephropathy (CN) is a pathological diagnosis observed in kidney biopsy of patients with jaundice and characterized by predominantly tubular epithelial injury together with intraluminal bile cast formation. Role of CN in pathogenesis of AKI is unknown. Aim of the study was to study the frequency and predictors of CN on postmortem renal biopsy among ESLD patients admitted with AKI. **Material and Methods**: We prospectively studied the post-mortem kidney biopsies of 154 ESLD patients with AKI who died between March 2012 - September 2015. Biopsies were processed and subjected to light microscopy and immunofluorescence. Bile casts were identified by light microscopy and confirmed using Fouchet's stain. We studied and divided the all biopsies into two groups Group 1 with acute tubular necrosis (ATN) and Group 2 with Cholemic Nephropathy (CN) **Results:**Of the 127 renal biopsies analyzed, 70 (55.1%) & 57(44.8%) were in group 1 and group 2 respectively. All baseline characteristics are shown on given table.

	ATN (n=70)	Cholemic (n=57)	p value
Age(yrs)	50.73 ± 11.730	43.23±12.237	.001
***Blood Urea(mg/dl)**	42 (4.10-379)	78 (8.20-352.10)	0.21
***Serum Creatinine(mg/dl)**	1.27 (0.20-7.70)	1.58 (0.23-9.65)	0.18
***Serum Bilirubin Direct(mg/dL)**	2.65(0.20-19.10)	16.27 (0.20-45.80)	**.0001**
***Serum Bilirubin Indirect(mg/dL)**	3.2 (0.60-14.80)	8.9 (0.37-42.40)	**.0001**

On multivariate analysis the predictors was total bilirubin with OR= 1.10, 95%CI (1.059-1.152, p<0.001) cut off value was 11.5 with senstivitiy and specificity as 75 and 77 respectively. Conclusions: A high clinical index of suspicion of Cholemic nephropathy should be kept in all patients who have high serum bilirubin and it was found to be a significant predictor of cholemic nephropathy on multivariate analysis.

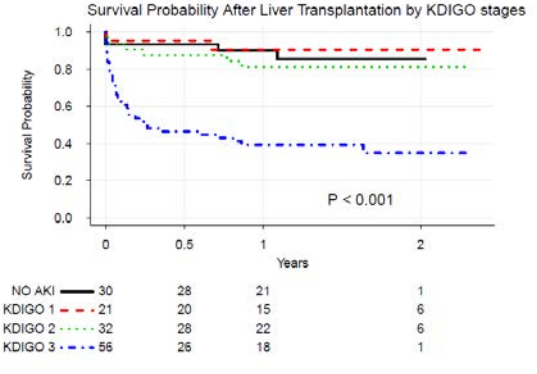
TH-PO707

Acute Kidney Injury and Long-Term Mortality after Orthotopic Liver Transplantation
Bernardo V. Reichert,[1] Ramaiane Aparecida Bridi,[1] Nzuzi Érika Mfinda,[1] Camila Eleuterio Rodrigues,[1] Igor Lepski Calil,[2] Luiz M. Malbouisson,[3] Luiz D´albuquerque,[2] Lucia Andrade,[1] Victor F. Seabra.[1,4] *[1]Nephrology; [2]Hepatology; [3]Intensive Care Unit, Univ of Sao Paulo School of Medicine; [4]Albert Einstein Hospital.*

Background: There is limited data on the association of Acute Kidney Injury (AKI) and long-term mortality after liver transplantation.

Methods: We examined the association of AKI and perioperative characteristics with long-term mortality in cases of orthotopic liver transplantation using cox proportional hazards analyses.

Results: 139 participants were enrolled for this analysis. Mean age was 55 years, 67% were men, and mean MELD-Na score was 19.6. The participants were followed for mean of 391 days [interquartile range (IQR) 97 to 610 days). The overall mortality was 33%. The figure shows the Kaplan Meier curve of probability of survival and KDIGO stages:



In unadjusted analysis, KDIGO stage 3 AKI was associated with a 6.67-fold higher risk for mortality (P <0.001; 95% confidence interval, 2.36 to 18.82) and a 6.15-fold higher risk for mortality after adjustment for other covariates (P <0.01; 95% confidence interval, 1.83 to 20.74).

Conclusions: KDIGO stage 3 is associated with long-term mortality after liver transplantation. Larger studies are needed to confirm these findings. This study was supported by FAPESP.

Funding: Government Support - Non-U.S.

TH-PO708

Association of Perioperative Characteristics and Acute Kidney Injury with In-Hospital Mortality after Orthotopic Liver Transplantation

Bernardo V. Reichert,[1] Ramaiane Aparecida Bridi,[1] Nzuzi Érika Mfinda,[1] Camila Eleuterio Rodrigues,[1] Igor Lepski Calil,[2] Luiz M. Malbouisson,[3] Luiz D´albuquerque,[2] Lucia Andrade,[1] Victor F. Seabra.[1,4] *[1]Nephrology; [2]Hepatology; [3]Intensive Care Unit, Univ of Sao Paulo School of Medicine, Brazil; [4]Albert Einstein Hospital.*

Background: There is limited data on the association of Acute Kidney Injury (AKI) and other perioperative characteristics with mortality in patients undergoing liver transplantation.

Methods: We examined the association of AKI and perioperative characteristics with in-hospital mortality in cases of orthotopic liver transplantation using logistic regression analyses.

Results: 139 participants were enrolled for this analysis. Mean age was 55 years, 67% were men, and mean MELD-Na score was 19.6. The overall mortality was 22%, the incidence of AKI was 78%, and 49% required renal replacement therapy. In univariate analysis, KDIGO stage 3 AKI was associated with higher risk of in-hospital mortality when compared with subjects without AKI (odds ratio [OR], 10.50; 95% confidence interval [CI], 2.78 to 69.03). Pre-operative (MELD-Na score, total bilirubin, serum bicarbonate levels and fulminant hepatitis) and intra-operative (number of packed red blood cells and fresh frozen plasma transfusions and prolonged anesthesia time) variables were also associated with in-hospital mortality. In multivariate analysis, the association of KDIGO stage 3 AKI and higher in-hospital mortality persisted after adjustment for other variables (OR, 13.65; 95% CI, 2.16 to 279.86). In the final model, the presence of fulminant hepatitis (OR, 8.22) and duration of anesthesia (OR, 1.32; per hour increase) were also associated with higher in-hospital mortality.

Conclusions: AKI predicts in-hospital mortality after liver transplantation. Larger studies are needed to confirm these findings. Supported by FAPESP.

Funding: Government Support - Non-U.S.

TH-PO709

Prediction of Mortality or the Need for Continued Renal Replacement Therapy following Acute Kidney Injury Requiring Dialysis

V. Shane Pankratz, Christos Argyropoulos, Orrin Myers, Mark L. Unruh. *Univ of New Mexico, Albuquerque, NM.*

Background: Managing the care of patients with acute kidney injury (AKI) remains inadequately defined. The availability of tools that simultaneously assess the probability of both mortality and continued need for renal replacement therapy (RRT) may enhance the decision making process for clinicians caring for such severely ill patients.

Methods: Using data from the VA/NIH Acute Renal Failure Trial Network, we developed a regression model that simultaneously evaluated the risk of death or continued RRT at multiple time points (28 days, 60 days, and 1 year post randomization) using the lasso shrinkage estimator on an extensive collection of data available at baseline evaluation from patients with AKI. This model was used to compute a score, which was categorized to place patients at low or high risk for each of the separate time-dependent outcomes. These scores were evaluated to assess their ability to classify patients into risk groups for the various time-dependent outcomes.

Results: The risk scores estimated for each of the time-dependent outcomes had areas under the ROC curve of roughly 0.77 for mortality risk at each of the three time points, and areas under the ROC curve of roughly 0.66 for the continued need for RRT at day 28 and day 60. The model did not identify any covariates to be associated with one-year mortality. Of those in the low risk group for all 3 mortality time outcomes, 41% were deceased at one year, while of those in the high risk group for all 3, 82% were deceased. Of those in the low risk group for the two RRT time outcomes, only 7.5% remained on RRT, and of those in the high risk group 17% still required RRT.

Conclusions: Simultaneously considering the risks for multiple outcomes at multiple future time points has the potential for being a useful tool for evaluating the ultimate status of a patient. This, in turn, has important implications for the care plans that will be implemented for the management of patients with AKI.

TH-PO710

Follow-Up to 3 Years after an Episode of Hospital Acquired Acute Kidney Injury

Anna Saurina, Irati Tapia, Monica Pou, Vicents Esteve, Veronica Duarte, Fatima Moreno, Miquel Fulquet, Jose Ibeas, Manel Ramírez de Arellano. *Nephrology, Consorci Sanitari de Terrassa, Terrassa, Barcelona, Spain.*

Background: Hospital Acquired Acute kidney Injury (HAAKI) influences in morbidity, mortality, length of hospital stay and costs. There are not enough studies of long-term monitoring.

Methods: Retrospective single-center study in two phases: Phase 1: analysis of episodes of HAAKI detected during 18 months. Phase 2: follow up at 3 years after the HAAKI. Iatrogenic HAAKI: AKI-related to medical intervention.

Results: Phase 1: 373 HAAKI. Age: 76±14. 62.5% male. Baseline creatinine: 109±30.4 µmol/L and baseline GFR(CKD-EPI): 56.3±21.6ml/min. Average recovery time: 7 days (0-60). Early recovery (1-3 d: 29 %), medium (4-9 d: 42.9 %) and late (≥10 d: 20.6%). Iatrogenic in 40.2%. At discharge: Creatinine: 125.32±57.37 µmol/L and GFR: 46.82±20.17 ml/min. 19.33% with GFR<30 ml/min. At 3 years: 167 were exitus: (E= 44.8 %), 147 alive (A= 39.4 %) and 59 had no follow-up (15.8 %). 32.2 % with GRF<30 ml/min and 2.74 % require RRT. The age of A at HAAKI was significantly lower than that in E (71.46 vs 79.86;p=0.000). The length of hospital stay: A=16 days (1-97) and E=18 days (1-128) (p=ns). Iatrogenic was observed in 42.2 % of A and 42.5 % of E (p=ns). GRF at follow up: A: 50.63 ml/min and E: 35.58 ml/min (p=0.000). Compared to baseline GFR a significant decrease of GFR at follow up was observed in A (57.47 vs 50.63 ml/min; p=0.000) and in E (52.16 vs 35.58 ml/min; p=0.005). There were also significant differences between GRF al the discharge compared to GFR at follow up in E (40.03±17.46 ml/min; p=0.000) but not in A (49.97±20.11 ml/min; p=0.811). Trend to worsening GFR (although not significant) in longer recovery time in A (p=0.869) and E (p=0.871). Patients A with iatrogenic HAAKI presented worse GFR al follow up than those without iatrogenic (p=0.02). These differences were not observed in E (p=0.556).

Conclusions: - Exitus were associated with elderly and lower baseline GFR and at discharge. - A non-significant trend to further deterioration of the RF is observed in longer recovery time. - The presence of iatrogenic is associated to worsening GFR at follow up in survivors at 3 years of follow up.

Nutritional Factors Associated to Survival in Acute Kidney Injury Patients in a Tertiary Health Care Hospital

Rosalba Sotelo-Anaya,[1] Jonathan Chavez,[2] Fabiola Martin del Campo,[1] Monica Consuelo Jimenez Cornejo,[2] Gabriela Jazmín Abundis Mora,[2] Guillermo Garcia-Garcia.[2] *[1]Dirección de Posgrados, Univ del Valle de Atemajac, Guadalajara, Jalisco, Mexico; [2]Dept de Nefrología, Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Jalisco, Mexico.*

Background: Malnutrition in hospitalized patients is associated with poor clinical outcomes.There is little evidence of KDIGO guidelines on nutritional management in AKI patients and outcomes in the hospital setting. We evaluated the impact of nutritional factors on survival on hospitalized patients.

Methods: 87 AKI patients admitted to the Hospital Civil de Guadalajara Fray Antonio Alcalde were included. Each patient had a clinical and biochemical evaluation; nutritional status was assessed by SGA, anthropometric data and 24-hour dietary recall.

Results:

Variable	Survivors n=55	Non-survivors n=32
Age (y)	51±16	56±18
Male, (%)	37(67)	25(78)
Surgical cases, (%)	20(36)	9(28)
AKI KDIGO stage, (%)*	13(24)	0
1	19(34)	11(34)
2	23(42)	21(66)
3	13(23)	21(66)
Dialysis, (%)*	10(18)	13(41)
Mechanical ventilation, (%)*	50(90)	24(75)
Non-oliguric, (%)*	6(10)	14(43)
Fasting, (%)*	37(67)	10(31)
Oral nutrition, (%)*	9(16)	4(12)
Enteral nutrition, (%)	3(5)	4(12)
Parenteral nutrition, (%)	12,8±8,6	15,1±10,7
Energy intake (kcal/kg)	0,48±0,38	0,56±0,45
Protein intake (g/kg)	26,4±6,3	25,7±6,2
BMI (kg/m^2)	25(46)	32(47)
Malnutrition SGA, (%)		

*p <0.05

Age [OR 1.032 (95% CI 1-1.06) p=<0.05], AKI KDIGO 3 [OR 3.04 (95% CI 1.37-6.77) p=0.006] and fasting [OR 7.04 (95% CI 2.12-23.29) p=0.001], increase the risk of death.

Conclusions: We conluded that fasting was associated with increased hospital mortality in patients with AKI. Aditionally a high proportion of malnutrition and poor nutrient intake was found.

TH-PO712

Effects of Acute Kidney Injury Duration on Outcomes in Critically Ill Patients

Christine K. Federspiel,[1] Theis S. Itenov,[2] Kala M. Mehta,[1] Raymond K. Hsu,[1] Morten Bestle,[2] Kathleen D. Liu.[1] *[1]UCSF; [2]Anesthesiology, Nordsjællands Hospital, Denmark.*

Background: Acute kidney injury (AKI) is a common and serious illness. Duration of AKI has been recognized as an important risk factor for adverse long-term outcomes, but less is known about the impact of AKI duration on mortality and other organ functions in critically ill patients.

Methods: We analyzed data from the NHLBI ARDS Network's "Statins for Acutely Injured Lungs from Sepsis" (SAILS), a multicenter trial of ICU patients with sepsis-associated ARDS. Patients who developed AKI over the first 5 days of enrollment were identified using the KDIGO creatinine criteria. AKI duration was defined using the number

of consecutive days at which the KDIGO creatinine criteria were fulfilled, and categorized into four groups: transient(duration 1-2days),medium(3-7days),persistent(≥7days), or death during AKI. Mann-Whitney test and Chi-square test were used to evaluate differences between the groups.

Results: Among the 249 SAILS participants who developed AKI during the first 5 days of enrollment, 77 had transient AKI, 47 had medium-duration AKI, 87 had persistent AKI, and 38 patients died while still suffering from AKI. There were no significant differences between the transient and medium-duration AKI groups in 30-day mortality, cardiovascular failure free days or ventilator free days. Patients with persistent AKI had significantly lower lengths of cardiovascular failure free days and ventilator free days.

	Transient AKI, n=77	Medium AKI, n=47	P (trans vs medium)	Persistent AKI, n=87	P (persistent, trans,medium)
Free of cardiovascular failure to day 7(mean±SD)	4.7±2.3	4.8±2.2	0.96	3.4±2.5	<0.001
Ventilator free days to day 28(mean±SD)	17.7±10.7	17.5±10.7	0.94	13.3±10.1	<0.001
30-Day Mortality	18.2%	14.9%	0.82	18.4%	0.86

Conclusions: In critically ill patients with sepsis-associated ARDS and AKI, patients with transient AKI did not have better outcomes compared to those with AKI lasting up to 7 days. Persistent AKI lasting ≥7 days was associated with worse outcomes, emphasizing the importance of developing interventions that shorten the length of renal injury to improve patient outcomes.

Model Establishing and Factor Analysis: An Insight into the Prediction of Acute Kidney Injury after Heart Surgery in China

Xin Wan, Jing Li, Changchun Cao. *Dept of Nephrology, Nanjing First Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Acute kidney injury is a common complication after cardiac surgery, known as cardiac surgery associated-acute kidney injury (CSA-AKI). This study aimed at exploring the prediction of different stages of CSA-AKI and making further efforts into factor analysis in China.

Methods: Five years of retrospective data (2008-2012, n=2811) were collected in the Division of Thoracic and Cardiovascular Surgery, Nanjing First Hospital. Variables presenting for injury and improvement of kidney function were developed to evaluate the influence of different factors. The method of Logistic Regression was applied to establish three preliminary models for predicting different stages of CSA-AKI, and with both Logistic Regression and non-parametric statistical analysis were used to analysis different factors.

Results: Among 2811 patients included in the study, incidence of CSA-AKI was 35.1%, in which the morality rate was 2.4%, double of the all-cause mortality (1.2%). Regression models for CSA-AKI from stage 1 to stage 3 showed differences in accuracy of prediction (the AUC of ROC curve: 0.676 vs. 0.759 vs. 0.813). Covariates selected in different models varied without clear evidence of stage-dependence. Factors showed significance(P<0.05) in both methods include male, age, hypertension, diabetes mellitus, insulin controlled diabetes, preoperative renal function, diagnosed chronic kidney diseases, preoperative hemoglobin, erythrocytes transfusion, duration of mechanical ventilation, ejection fraction(EF), body mass index (BMI) and surgical manner. While emergency surgery and aortic aneurysm only showed statistical significance in non-parametric test. The rank sum of factors suggested that abnormal BMI, lower preoperative hemoglobin (<130g/L in male, <120g/L in female) and lower EF (<50%) may increase the risk of postoperative AKI and lower the postoperative renal benefits.

Conclusions: The existing models for prediction may have defects in factor classification and severity evaluation; adjustment of BMI, EF and hemoglobin before elective surgery may lower the incidence of CSA-AKI and improve the prognosis.

TH-PO714

Risk Prediction Model for Kidney Injury in Two Stage Revision Arthroplasty with Antibiotic Loaded Spacers for Prosthetic Joint Infections

Anshul Bhalla,[1] Amanda K. Leonberg-Yoo,[1] Madhumathi Rao.[1] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Orthopaedics, Boston Medical Center, Boston, MA.*

Background: Two-stage revision arthroplasty using antibiotic loaded spacers (ALS) is the preferred surgical treatment for prosthetic joint infections (PJI). Acute Kidney Injury (AKI) is increasingly being identified as a known complication of this procedure. We propose a risk prediction model to predict the incidence of Kidney Injury (KI) in patients undergoing this procedure along with its validation.

Methods: Between August 2007 and December 2012 we identified all patients who underwent two-stage revision arthroplasty using antibiotic loaded spacers (Cases, N=71) and aseptic revision arthroplasty (Controls, N=110) at a single referral center. Kidney injury was defined as AKI based on KDIGO definition or >50% increase in baseline creatinine during the course of spacer implantation. We compared the two groups using univariate and multivariate analysis to identify pre-operative and peri-operative risk factors for kidney injury. Coefficients from this analysis were used to formulate the prediction model which was validated in patients with the same eligibility criteria who underwent above mentioned procedures from January 2013 to December 2015.

Results: The incidence of kidney injury according to our definition was higher in cases as compared to controls [42.3% vs 24.5%, OR 2.25 95% CI (1.18 – 4.27) p = 0.01]. Risk factors for KI on unadjusted analysis included baseline CKD, HTN, ACE inhibitor use and systemic vancomycin use. The most important baseline risk factors after multivariable adjustment that contributed to the predicted risk score included CKD (OR 2.37; 95% CI 1.17-4.82), and was compounded by spacer implantation (OR 2.25; 95% CI 1.18-4.27).

Conclusions: Kidney injury including AKI in the post-operative period as well as late kidney injury during the course of spacer implantation is significantly associated with two stage arthroplasty with ALS for PJI. The proposed risk prediction model can be used to better identify the patients at higher risk of nephrotoxic complications of the procedure.

TH-PO715

Risk Factor of Development of Acute Kidney Injury in Orthopedic Surgery

Yoo Jin Lee, Yang Wook Kim, Bongsoo Park, Sihyung Park. *Internal Medicine, Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: Postoperative acute kidney injury (AKI) is major concern to surgeons, which leads the increasing postoperative morbidity and mortality. Perioperative risk factors of AKI are well known such as underlying chronic kidney disease, exposure of iodine contrast and low hemoglobin in bypass cardiac surgery. However, there is little known about development of postoperative AKI after orthopedic surgery.

Methods: Patients underwent total hip or knee replacement surgery were enrolled from January 2011 to December 2015 in this retrospective study. A number of variables was assessed such as age, gender, preoperative glomerular filtration rate, drugs (NSAIDs, ACE inhibitor or ARB, statins), albumin, hemoglobin, type of anesthesia, amount of bleeding and infused fluid, presence of diabetes, hypertension, contrast use and chronic kidney disease (CKD). AKI was defined when postoperative creatinine increased more than or equal to 0.3 mg/dL and CKD was defined when glomerular filtration rate was under 60 ml/min/1.73m^2 by CKD-EPI equation.

Results: Overall, AKI was developed in 13 among 351 cases (3.7%). Among the examined variables, presence of hypertension (11 out of 193 cases), CKD (9 out of 66 cases), low level of albumin (3.3 g/dL vs. 3.6 g/dL), hemoglobin (11.3 g/dL vs. 12.4 g/dL) and total CO_2 (24.27 mmol/L vs. 26.53 mmol/L) content were related to AKI significantly. In subgroup analysis with CKD group, AKI was developed in 8 out of 63 cases. Low albumin (3.3 g/dL vs. 3.6 g/dL) and hemoglobin (10.58 g/dL vs. 11.7 g/dL) were related risk factor in CKD patients. Use of crystalloid fluid only or combined with colloid fluid did not have any significant meanings. Among perioperative crystalloid fluid, 2 AKI case in 5 unbalanced fluid (40%) and 6 AKI cases in 58 balanced fluid (10%) were developed.

Conclusions: We should monitor the renal function closely after orthopedic surgery if the patients have hypertension, CKD and low level of albumin, hemoglobin and total CO_2 content. The correction of albumin and hemoglobin level is needed before orthopedic surgery in CKD patients. In addition, use of balanced fluid is helpful to prevent AKI in CKD patients if there are no electrolyte abnormalities.

TH-PO716

Beta-Blocker Use and Clinical Outcome in Patients with Acute Renal Injure Requiring Dialysis

Jia-Sin Liu,[1] Ming-Huang Lin,[3] Der-Cherng Tarng,[2] Chih-Cheng Hsu.[3] *[1]Kaohsiung Medicine Univ, Kaohsiung, Taiwan; [2]Taipei Veternas General Hospital, Taipei, Taiwan; [3]NHRI, Miaoli, Taiwan.*

Background: Beta-blocker users have survival benefits in cardiovascular mortality, but its long-term effect in patients with acute renal injure (AKI) requiring dialysis is unknown.

Methods: This study was a perspective cohort study. We used National Health Insurance database in Taiwan from 2000 to 2014 to collect 13,889 patients with acute renal injure requiring dialysis. The inclusion criteria were as follows: first, they had hypertension and used anti-hypertensive drugs; second, they did not have any further dialysis recode within 1 year after the first dialysis commencement as recognized to be the AKI case.

Results: There were 6,262 beta-blocker users and 7,636 beta-blocker nonusers identified; of whom 2,200 and 3,045 died in 5 years, respectively. The 5 years mortality in beta-blocker users and nonusers were 124.1 and 146.3 case per 1,000 person-years, respectively. In Cox's proportional hazard model, after adjusting for age, gender, nephrologist care, myocardial infarction, stroke, diabetes mellitus (DM), chronic obstructive pulmonary disease, cancer, anti-hypertensive drugs used, oral antidiabetic drugs used, insulin, DM duration, statin, chronic kidney (CKD) stage, sepsis, heart failure, cardiovascular surgery, pesticide or metal poisoning, the hospital setting (treated as a cluster unit), and development of long-term dialysis (time dependent-variable), the mortality risk in beta-blocker users was 0.88 (95% confident interval: 0.83 and 0.93, p value < 0.001). In addition to the all-cause mortality, the beta-blocker users also had lower mortality risk in cardiovascular, DM and end-stage renal disease mortality. In subgroup analyses, the results in most subgroups were similar to the main results except those younger than 40, cancer patients, those with stage 5 CKD and those who developed sepsis induced AKI.

Conclusions: We conclude that for the hypertensive patients who develop AKI requiring dialysis, beta-blockers may be a preferred choice to prevent premature mortality.

Funding: Government Support - Non-U.S.

TH-PO717

Akute Kidney Injury after Cardiac Arrest Is Associated with Neurological Outcome and Mortality, an Observational Follow-Up of 10 Years Natalie M. Otto, Ralf Schindler, Anne C. Krueger, Andreas Kahl, Christian Storm. *Dept of Nephrology, Charité, Berlin, Germany.*

Background: Acute kidney Injury(AKI) is associated with early and long-term patient morbidity and mortality. In ICU patients, AKI is associated with a decrease in survival. AKI is considered a surrogate maker for illness severity and a consequence of the underlying disease. We evaluated the prevalence of AKI in cardiac arrest patients in association to their neurological outcome (according to the Cerebral Performance Categories Scale =CPC), their disease severity (APACHE Score) and hypoxia level (NSE) after administering therapeutic target temperature management at 33°C for 24hours.

Methods: Observational single center study between 2006 und 2013 in a cardiac arrest center in Berlin, Germany. All out and in hospital cardiac arrest (OHCA / IHCA) patients were included in our study. AKI was defined by the KDIGO guidelines. Main outcome was the assessment of good (CPC Scale 1-2) vs poor (CPC Scale 3-5) neurological outcome and its association with disease severity by APACHE Score, NSE levels as marker of hypoxia and AKI vs non AKI as an independent risk factor. Long term monitoring of up to 120 months assessing mortality was performed.

Results: A total of 497 patients after cardiac arrest were evaluated. Their CPC Scale obtained at discharge from ICU. 242 patients had good neurological(CPC 1-2) vs. 255 with a poor neurological outcome (CPC 3-5). The CPC 1-2 group had a NSE-level at day 3 of 18.5 vs 62.3 mg/l in the poor outcome group ($p<0.01$). The APACHE Score was similar in both groups (27.6 vs 27.9). In the CPC 1-2 group only 16.5% had an AKI vs 41.2% in the CPC 3-5 group ($p<0.001$). Patients with AKI and a poor neurological outcome had a mean survival of 0.04 years compared to patients with good neurological outcome and no AKI with a mean survival of 8.5 years.

Conclusions: AKI is a prevalent issue in critically ill patients such as survivors of cardiac arrest with long-term health issues. In addition to surviving cardiac arrest, the neurological long-term outcome remains a crucial subject. AKI is associated with mortality but also with poor neurological outcome after surviving cardiac arrest. New strategies may be needed to address this issue.

TH-PO718

Acute Kidney Injury in Asphyxiated Neonates Treated with Therapeutic Hypothermia Mariko Sawada. *Pediatrics, Kurashiki Central Hospital, Kurashiki, Okayama, Japan.*

Background: Multi-organ failure increases morbidity and mortality rates in severely asphyxiated neonates. Acute kidney injury (AKI) is one of the most severe complications in these patients, which can affect their short-term survival. In this study, we investigated the incidence and the outcomes of AKI in asphyxiated neonates treated with therapeutic hypothermia.

Methods: We retrospectively reviewed 105 cases of neonates who experienced perinatal asphyxia and treated with therapeutic hypothermia in a single neonatal intensive care unit (NICU) between June 2000 and June 2015. We used the proposed neonatal AKI definitions to classify and to establish the stage of AKI. We investigated the incidence of AKI, dialysis, mortality, and prolonged renal insufficiency.

Results: AKI occurred in 33 of 105 severely asphyxiated neonates (31.4%), and oliguric AKI was present in 57.6% of patients. Four patients (12.1%) received continuous hemodiafiltration. Overall mortality rate was 4.8%, and was much higher in those with AKI than in those without AKI (15.2% vs 0%). The mortality rate was 50% in neonates requiring dialysis. The mortality rate was 26.3% in neonates with oliguric AKI compared to 0% in those with non-oliguric AKI. Percent fluid overload was higher in the group of neonates who died than in those alive ($15.4 \pm 8.1\%$ vs $7.5 \pm 5.1\%$; $p<0.05$). The peak value of serum creatinine level was 1.7 ± 0.7 mg/dL in the former group and 2.0 ± 0.9 mg/dL in the group of neonates who died. No asphyxiated neonate developed persistent kidney dysfunction.

Conclusions: The incidence of AKI in asphyxiated neonates treated with therapeutic hypothermia was lower than previously reported. The mortality rate of neonates with AKI remains high, especially in those requiring dialysis. Oliguric AKI and higher fluid overload are associated with increased mortality rates.

TH-PO719

Impact of Therapeutic Hypothermia on Kidney Function Post Cardiac Arrest Tahir Muhammad Abdullah Khan, Armaghan Soomro, Raja Asif Masood, Shimshon Wiesel, Abdul H. Siddiqui, Anna S. Gutman, Suzanne E. El Sayegh. *IM, SIUH, Staten Island (SI), NY; Nephrology, SIUH, SI, NY.*

Background: Mortality in cardiac arrest patients remain high with limited consensus on medical management following return of spontaneous circulation (ROSC). Therapeutic hypothermia post cardiac arrest leads to better neurological outcomes however its effect on kidney function is uncertain. To better assess this, we trended serum creatinine, to determine acute kidney injury (AKI) following initiation of therapeutic hypothermia at our hospital.

Methods: A retrospective inpatient data review was conducted in patients who achieved ROSC following cardiac arrest. Patients were divided into two cohorts i.e. hypothermia and normothermia. AKI was diagnosed as per AKIN criteria. Patients who had coma prior to arrest &/or were on dialysis were excluded. Eligible patients' serum creatinine and urine output was recorded at different stages post cardiac arrest. Baseline variables in both cohorts were adjusted and multivariate regression analysis was conducted.

Results: A total of 96 patients (hypothermia n= 53, normothermia n= 43) were studied. Baseline mean serum creatinine levels in both cohorts were similar. At 24 hours after ROSC, mean serum creatinine in normothermia cohort was greater than in hypothermia cohort however was not statistically significant (2.13 vs. 1.97, p value= 0.466). Net difference of mean serum creatinine from baseline was increased more in normothermia cohort (+0.29 mg/dl, p value = 0.002), median length of stay (LOS) in normothermia group was also longer than in hypothermia group (20 vs. 7 days, p value < 0.001). Both results were statistically significant. Mortality in hypothermia group was 2.5 times higher than in normothermia group (80.4 % vs. 33.3 %, p value < 0.001).

Conclusions: Therapeutic hypothermia may have a renoprotective role in cardiac arrest patients and this may predict reduced hospital stay. Absence of AKI however may not predict improved mortality outcomes in post cardiac arrest patients treated by Hypothermia protocol.

TH-PO720

Genetic Factors of Methicillin-Resistant *Staphylococcus aureus* (MRSA) Has an Impact on the Development of AKI Yasunori Iwata, Kengo Furuichi, Yasuyuki Shinozaki, Tadashi Toyama, Akihiro Sagara, Shinji Kitajima, Yasutaka Kamikawa, Shinji Kitajima, Norihiko Sakai, Takashi Wada. *Nephrology, Kanazawa Univ.*

Background: Methicillin-resistant *Staphylococcus aureus* (MRSA) causes hospital and community acquired infection. Development of acute kidney injury (AKI) increases mortality during MRSA infection. While underlying condition of the patient are associated with the progression of infection, it is unclear whether bacterial factor, especially genetic character could contribute to the disease pathogenesis in MRSA infection. We hypothesized that whole genome analysis could reveal the key gene loci and/or gene mutation, those have the impacts on the clinical manifestation, including acute kidney injury in MRSA infection.

Methods: Whole genome sequence (WGS) of MRSA from 96 cultured samples with clinical information were analyzed with next generation sequencer. Then, we evaluated the association of clinical manifestation in MRSA infection with genomic information.

Results: WGS revealed gene mutations, those were correlated with clinical manifestation of MRSA infection. The mutation on *staphylocoagulase* locus showed the highest correlation. Among the top 50 mutations, 22 mutations were on the adhesion and biofilm related loci. Interestingly, all of the strains, those were positive for both collagen adhesion gene (*cna*)locus and SNP in *staphylocoagulase* locus, caused blood stream infection (BSI). The strains also cause AKI during BSI. Logistic regression analysis also showed the high odds ratio for AKI in the strains.

Conclusions: The cluster, that was positive for *cna* locus and SNP in *staphylocoagulase* locus showed high frequency for BSI of MRSA and high risk for AKI. These findings suggest that bacterial genotype might affect the clinical character on MRSA infection.

TH-PO721

Use of Life-Sustaining Interventions among Patients with Acute Kidney Injury Who Received Palliative Care Services prior to Death Kelly Chong, Cristian George Bologa, Herbert T. Davis, V. Shane Pankratz, David N. van der Goes, Mark L. Unruh. *Internal Medicine, Univ of New Mexico, Albuquerque, NM.*

Background: Acute Kidney Injury (AKI) is a common and serious complication of hospitalized patients without specific therapies. AKI patients requiring dialysis with unclear life expectancy and goals of care may benefit from palliative care. Palliative care (PC), focused on relief of suffering, has been shown to have many benefits, including increased patient and family satisfaction, honoring patient preferences for treatment intensity, and cost savings. Although overall use of PC is growing, little is known about PC use in the AKI patient population. In this study, we describe the use of PC among AKI patients who died during hospitalization, focusing on their use of life-sustaining interventions (LSI).

Methods: We extracted data from Cerner's Health Facts database between 2000 and 2014. We analyzed the first inpatient encounter of adult AKI patients who died during that hospitalization. We compared patient and hospital characteristics, and use of LSIs between patients who received PC with those who did not.

Results: Of 4,600 adult AKI patients who died during hospitalization, 1,089 (24%) received inpatient PC services. Mean age is slightly older for patients who received PC (75 vs. 74 years old). Among the >=90 years of age group, greater proportion of patients received PC ($p<0.0001$). PC use is significantly greater among teaching and larger hospitals, and hospital in the Northwest, West, and Midwest regions. Mean hospital length of stay is 8.9 days for the PC group compared the non-PC group (8.2 days). In the PC group, significantly less CPR, mechanical ventilation, and dialysis were used prior to death. There was no significant difference in the use of enteral feeding support between the two groups.

Conclusions: Our study reveals use of life-sustaining interventions was uniformly lower in the AKI population receiving palliative care services, except for use of feeding tube. The variations found in this study can help us gain greater understanding of providing PC to the right patients at the right time.

TH-PO722

The KDIGO Criteria Are Superior Predictors of Mortality after Non-Cardiac Major Surgery Compared to AKIN Criteria Seokwoo Park, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Internal Medicine, Seoul National Univ of College of Medicine, Seoul, Korea.*

Background: Postoperative acute kidney injury (AKI) is a serious adverse event which leads to higher mortality. Although several studies have been published on the subject, heterogeneous definitions of AKI in each study makes it difficult to synthesize study results. We evaluated which is superior between the Kidney Disease: Improving Global Outcomes criteria (KDIGO) and Acute Kidney Injury Network criteria (AKIN) in predicting patient outcomes after non-cardiac surgery.

Methods: We included adult patients who received non-cardiac major surgery (duration>1 hour) in Seoul National University Hospital from 2004 to 2013. AKI was diagnosed according to both KDIGO and AKIN criteria based on Cr measurements and initiation of RRT within 14 days after surgery. Positive predictive value (PPV) and negative predictive value (NPV) for in-hospital, 30-day, and 90-day mortality were compared using generalized score statistics. Discirimination ability was evaluated by c-statistics.

Results: Among a total of 58,919 cases, 4,092 (6.95%) and 3,347 (5.68%) were identified to be AKI by KDIGO and AKIN, respectively. KDIGO showed significantly lower PPV and higher NPV for in-hospital, 30-day, and 90-day mortality than AKIN

	PPV			NPV		
	KDIGO	AKIN	p-value	KDIGO	AKIN	p-value
In-hospital (%)	4.2	4.8	.002	99.9	99.8	<.001
90-day (%)	6.1	6.6	.006	99.2	99.2	<.001
1-year (%)	14.3	15.1	.007	96.3	96.2	<.001

The differences between C-statistics of KDIGO and AKIN were statistically significant in all 3 clinical outcomes, namely in-hospital (0.82 vs. 0.80; p=.002), 90-day (0.80 vs. 0.77; p<.001) and 1-year (0.66 vs. 0.64; p<.001) mortality.

Conclusions: KDIGO may be more useful for discriminating postoperative mortality than AKIN demonstrated by higher C-statistics. Also, considering prevalence of postoperative AKI and clinical relevance, superiority in sensitivity and discrimination power obtained by KDIGO compared to AKIN can outweigh inferiority in specificity. Implementing KDIGO criteria for defining postoperative AKI in non-cardiac surgery could prevent confusion in communication and help interpretating future studies in this field.

TH-PO723

Risk of ESRD Higher with Lower Adherence of DASH Diet in African Americans with Moderate CKD Tanushree Banerjee,[1] Deidra C. Crews,[2] Meda E. Pavkov,[3] Nilka Rios Burrows,[3] Jennifer L. Bragg-Gresham,[4] Rajiv Saran,[4] Neil R. Powe.[1] *[1]UCSF; [2]JHU; [3]CDC; [4]UM.*

Background: Dietary modifications play an important role in management of patients with CKD and ESRD. Few studies have examined the association of adherence to a DASH-type diet with risk of CKD progression among adults with moderate CKD from different race and ethnic backgrounds.

Methods: Among a cohort of 293 non-Hispanic black (NHBs) and 664 non-Hispanic white (NHWs) adults with moderate CKD (eGFR 30-59 ml/min) and with hypertension enrolled in NHANES III (1988-1994), we used 24-hour dietary recall data to determine adherence score to a DASH-type diet. Adherence was defined as score ≥4.5 out of a possible score of 9. Development of ESRD was ascertained over follow-up via linkage with USRDS. We used the Fine-Gray competing risks method separately in the NHB and NHW model for testing our hypothesis that greater DASH diet adherence would be independently associated with lower risk of ESRD.

Results: DASH diet adherence was greater among NHWs (22.3%) vs NHBs (16.1%), p value<0.05. Median DASH score in NHBs was 2.5 (Q1-Q3: 1.5-4) while in NHWs it was 3.5 (2-4). Total of 178 (18.6%) participants –103 NHB and 75 NHW--developed ESRD during a median of 11.2 years. Table shows the relative hazard of developing ESRD for race-specific models based on quintiles of DASH score. Lower scores (lower quintiles) indicate less adherence to the DASH diet

	RH (95% CI)			
	Unadjusted		Fully-Adjusted*	
DASH score (Quintiles)	NHBs	NHWs	NHBs	NHWs
1	2.9 (1.2-5.2)	2.9 (1.9-4.5)	2.5(1.1-3.5)	1.1 (0.6-1.7)
2	4.2 (2.4-6.1)	1.8 (1.0-3.2)	2.7 (1.5-4.7)	1.6 (0.9-2.8)
3	3.9 (2.0-5.8)	0.9 (0.6-1.9)	2.5 (1.3-3.9)	0.8 (0.4-1.5)
4	2.5 (0.7-4.2)	1.8 (1.2-2.9)	1.8 (0.5-2.5)	1.0 (0.6-2.0)
5	1.0 (Ref.)			

*Adjusted for age, sex, physical activity, diabetes, eGFR, and albuminuria. p trend = 0.02 for NHBs and 0.68 for NHWs.

Conclusions: Among adults with moderate CKD and hypertension, low adherence to a DASH-type diet was associated with higher risk of ESRD only among NHBs. Diet modification may be a potential target for intervention to prevent or delay progression in NHBs with CKD.

TH-PO724

Comparison of Accuracy between Pre- and Post-HD Values of Nutritonal Factors for Prediction of Mortality in Hemodialysis Patients Yoshihiko Kanno,[1] Eiichiro Kanda.[2] *[1]Tokyo Medical Univ, Japan; [2]Tokyo Kyosai Hospital.*

Background: To assess the nutritional status of patients receiving hemodialysis (HD), regularly measured pre-HD laboratory data are often used. However it has been included the problem whether the most diluted value would be appropriate to evaluate. We compared the pre-and post HD laboratory data to investigate their value to predict mortality.

Methods: 104289 maintenance hemodialysis (HD) patients (males 61.2%) were enrolled as subjects in this analysis as part of a prospective cohort study of the Japanese Society for Dialysis Therapy. The outcome events were one- and five-year mortalities. Their laboratory data included pre- and post-HD values of nutritional factors such as body mass index (BMI), and serum albumin, creatinine, and urea nitrogen levels. We compared the accuracy between pre- and post-HD values for the prediction of one- or five-year mortality using receiver operating characteristic (ROC) curves by the bootstrap resampling method.

Results: Mean age±standard deviation was 65.47±12.18 years; vintage, 8.62±7.05 years. The number of patients who died in one year was 6868 (6.6%); that in five years, 33188 (31.8%). The highest area under the ROC curve (AUCs) for the prediction of one-year mortality was post-HD serum albumin level [0.733 (95% CI 0.720, 0.746)]; and that of five-year mortality, pre-HD serum creatinine leve [0.702 (95% CI 0.699, 0.706)]. The AUCs showed that pre-HD BMI, serum creatinine and urea nitrogen levels were more accurate than post-HD values (each p<0.001). Although no statistical difference was observed between the AUCs of pre- and post-HD values of serum albumin levels for predicting one-year mortality (p=0.142), the post-HD serum albumin level was more accurate than the pre-HD level for predicting five-year mortality (p<0.0001). Stratifiction analysis based on gender, age, and diabetes mellitus as a cause of end-stage renal disease showed similar trends, that is, pre-HD BMI, and serum creatinine and urea nitrogen levels were more accurate than post-HD values.

Conclusions: Pre-HD values of nutritional factors, except serum albumin levels, were more accurate than post-HD values for predicting mortality in HD patients.

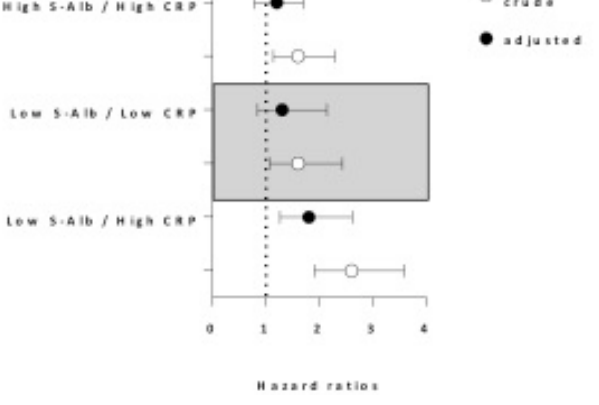
TH-PO725

Inflammatory Status Markedly Affects Ability of Serum Albumin to Predict Outcome in Chronic Kidney Disease Filipa Caeiro Alves,[1,2] Jia Sun,[2] Abdul Rashid Tony Qureshi,[2] Sunna Snaedal,[2,3] Peter F. Barany,[2] Olof Heimburger,[2] Bengt Lindholm,[2] Peter Stenvinkel.[2] *[1]Nephrology, Hospital Espírito Santo, Évora, Portugal; [2]Renal Medicine and Baxter Novum, CLINTEC, Karolinska Inst, Stockholm, Sweden; [3]Nephrology, Landspitali Univ Hospital, Reykjavik, Iceland.*

Background: The mortality predictive value of low serum albumin in patients (pts) with chronic kidney disease (CKD) is partly linked to its association with systemic inflammation but it is not clear to what extent its predictive strength depends on concomitant systemic inflammation. Here we addressed this question in pts with CKD stage 3-5.

Methods: Serum albumin (S-Alb), inflammatory status (high-sensitive C-reactive protein, CRP), cardiovascular disease (CVD) and nutritional status were assessed at baseline in 854 pts comprising: 97 pts with CKD stages 3-4 (median S-Alb 37g/L, median CRP 2.7mg/L), 523 pts with CKD stage 5 (median S-Alb 33g/L, median CRP 4.8 mg/L), 178 prevalent HD (median S-Alb 34g/L, median, CRP 6.8mg/L), and 56 prevalent PD pts (median S-Alb 31g/L, median CRP 4.4mg/L). Pts were divided into four groups according to median levels of CRP and S-Alb in each cohort: Group 1 (n=298) - High S-Alb/Low CRP; Group 2 (n=211) - High S-Alb/High CRP; Group 3 (n=218) - Low S-Alb/Low CRP; Group 4 (n=218) - Low S-Alb/High CRP. Survival over 60 months was analyzed.

Results: In Cox analysis, Group 4 (Low S-Alb/High CRP) had increased mortality risk (adjusted HR (95%CI): 1.8 (1.26 - 2.61); p<0.01), whereas the augmented risks for Groups 2 and 3 in univariate analyses were lost after adjustments for age, sex, CVD, diabetes, smoking, handgrip strength, CKD stage and renal replacement therapy.



Conclusions: Mortality risk is increased in CKD pts with low S-Alb and high CRP but not in pts with low S-Alb and low CRP or high CRP and high S-Alb, suggesting that inflammatory status should be taken into account when using S-Alb to predict outcomes in CKD patients.

TH-PO726

Net Endogenous Acid Production, an Index of Dietary Acid Load, Is Associated with the Progression of CKD Koji Toba,[1] Michihiro Hosojima,[2] Shoji Kuwahara,[3] Ryohei Kaseda,[1] Tomomichi Iida,[1] Sawako Goto,[1] Naohito Tanabe,[4] Yoshiki Suzuki,[5] Ichiei Narita,[1] Akihiko Saito.[3] *[1]Div of Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan; [2]Dept of Clinical Nutrition Science, Niigata Univ, Niigata, Japan; [3]Dept of Applied Molecular Medicine, Niigata Univ, Niigata, Japan; [4]Health and Nutrition, Univ of Niigata Prefecture, Niigata, Japan; [5]Health Administration Center, Niigata Univ, Niigata, Japan.*

Background: Recent studies have suggested that metabolic acidosis mediates the progression of CKD. Dietary acid load, a potential cause of metabolic acidosis, might be associated with CKD progression, although few studies have analyzed this. Here, we investigated the association of dietary acid load with CKD progression by evaluating the net endogenous acid production (NEAP), an index of the dietary acid load, and reviewing clinical records of CKD patients.

Methods: Subjects of this study were 96 outpatients with CKD (61 patients with diabetes; average eGFR, 53.0±18.1 mL/min/1.73 m^2) at Niigata University Hospital. We estimated their intake of foods and nutrients from the results of a self-administered dietary history questionnaire (DHQ) completed in 2011. We estimated NEAP using the following formula: NEAP (mEq/day)=54.5 (protein [g/day])/(potassium [mEq/day])-10.2 (Scialla, JJ. et al. Clin J Am Soc Nephrol 2011). Progression of CKD was assessed by comparing eGFR between 2008 and 2014.

Results: Average NEAP was 50.0±18.1 (mEq/day). Urinary pH was significantly lower in patients with higher NEAP (n=46) than in those with lower NEAP (n=50). Higher NEAP was significantly associated with intake of more meat and less vegetables, fruit, and potassium. Protein intake was not significantly associated with NEAP. Reduction of eGFR from 2008 to 2014 was significantly greater in patients with higher NEAP than in those with lower NEAP (-8.9 vs. -2.5 mL/min/1.73 m^2, p=0.038).

Conclusions: Higher NEAP could be a risk factor for CKD progression. Further studies are warranted to evaluate the protective effects of dietary acid control on CKD progression.

Funding: Government Support - Non-U.S.

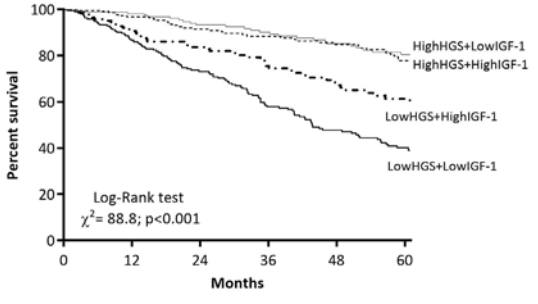
TH-PO727

Muscle Strength Interaction with Insulin-Like Growth Factor-1 (IGF-1) Influences Survival in Chronic Kidney Disease (CKD) Chen Zhimin,[1,2] Erik Nilsson,[2] Jia Sun,[2] Bengt Lindholm,[2] Olof Heimburger,[2] Peter F. Barany,[2] Peter Stenvinkel,[2] Abdul Rashid Tony Qureshi.[2] *[1]Kidney Disease Center, 1st Affiliated Hospital College of Medicine, Zhejiang Univ, Hangzhou, China; [2]Renal Medicine and Baxter Novum, CLINTEC, Karolinska Inst, Stockholm, Sweden.*

Background: CKD patients (pts) display resistance to IGF-1. Hand-grip muscle strength (HGS) is a reliable and easy-to-perform nutritional parameter. Both low IGF-1 and low HGS predict mortality. We hypothesized that concomitant presence of both conditions increases mortality risk in CKD.

Methods: IGF-1, HGS and other nutritional and inflammatory markers were measured in 724 pts (median age 58 years; 62% males) with different stages of CKD. Pts were stratified into 4 groups according to median levels of HGS and IGF-1 and all-cause mortality over 60 months was analyzed.

Results: Pts with low IGF-1 (<median) and low HGS (<median) were older and had elevated levels of high-sensitivity C-reactive protein (hsCRP), interleukin-6 (IL-6) and tumor necrosis factor (TNF) and worse survival in Kaplan-Meier analysis, see Fig 1. Multivariable logistic regression analysis adjusted for age, gender, diabetes, cardiovascular disease (CVD), HGS, subjective global assessment (SGA), albumin, smoking and hsCRP, revealed that independent predictors of lower IGF-1 were age, diabetes and low HGS. In receiver-operating characteristics curve (ROC) analysis, lower IGF-1 associated with higher mortality only in low HGS group. In Cox proportional hazards analysis, across the four HGS-IGF-1 categories, the group with low IGF-1 and low HGS had highest mortality after adjustments for age, gender, diabetes, CVD, SGA, smoking, hsCRP and albumin.



Conclusions: CKD pts with concomitant low IGF-1 and low HGS have increased mortality risk suggesting that the association of IGF-1 with mortality in CKD pts depends on nutritional status.

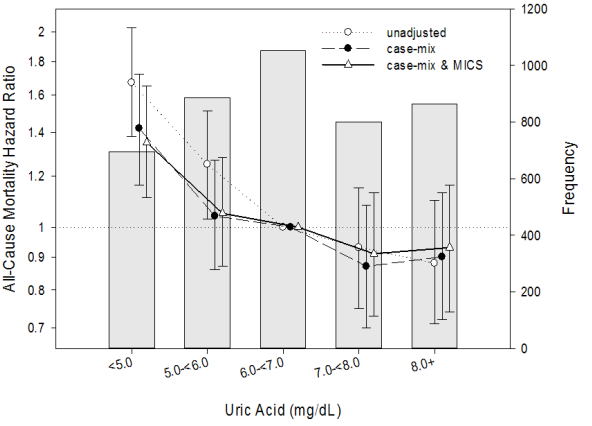
TH-PO728

Serum Uric Acid Level and Mortality in Hemodialysis Patients Christina Park, Yoshitsugu Obi, Elani Streja, Melissa Soohoo, Kamyar Kalantar-Zadeh. *UC Irvine.*

Background: Elevated uric acid concentrations are associated with cardiovascular events and mortality in the general population. However, there are scarce data regarding the mortality risk associated with hyperuricemia in the hemodialysis (HD) population.

Methods: We retrospectively examined a subcohort of 4,298 HD patients whose first serum uric acid measurements were obtained during treatment in a large dialysis organization from 2007-2011. Patients were grouped into 5 uric acid categories. Using Cox proportional hazards model, we explored the association between serum uric acid levels and time to all-cause death from first uric acid measurement with adjustments for case-mix variables (demographics, comorbidities, and spKt/V) and laboratory markers of malnutrition and inflammation (MICS).

Results: Mean age was 63±15 years and 39% were women. Mean uric acid level was 6.6±1.8 mg/dL. There was a trend toward lower mortality risk across higher uric acid levels irrespective of the adjustment models (P_{trend} <0.001); the highest category (≥8.0 mg/dL) showed non-significant lower mortality risk while the lowest category (<5.0 mg/dL) was significantly associated with higher mortality compared to the middle category (6.0-<7.0 mg/dL); case-mix adjusted HRs were 1.42 (95% CI, 1.16-1.72) and 0.90 (95% CI, 0.72-1.13), respectively. These findings were consistent across subgroups of age, gender, race, diabetes, albumin, and body mass index ($P_{interaction}$>0.1). However, mortality risk associated with low uric acid levels (<5.0 mg/dl) were significant among patients with low nPCR (<0.9 g/kg/day) but not among those with high nPCR (≥0.9 g/kg/day) ($P_{interaction}$=0.001).



Conclusions: Among HD patients, hyperuricemia may be a marker of better nutritional status, and were paradoxically related to lower all-cause mortality risk in contrast to those in the general population. Future studies are needed to investigate the mechanism behind this association.

Funding: NIDDK Support

TH-PO729

The Effect of Extended Duration Nocturnal Hemodialysis on the Human Metabolome Sahir Kalim,[1] Ron Wald,[2] Dihua Xu,[1] Anders H. Berg,[3] Eugene P. Rhee,[1] Jeffrey Perl.[2] *[1]Massachusetts General Hospital, Boston, MA; [2]St. Michael's Hospital, Toronto, ON; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Human metabolite profiling has been increasingly used to describe the small molecule disarray that arises in ESRD and several specific "uremic solutes" have been associated with adverse clinical outcomes including mortality in ESRD. In-center extended duration nocturnal hemodialysis (INHD) has been credited with a variety of clinical benefits but the impact of INHD on metabolite profiles remains unclear.

Methods: We conducted a prospective, multi-center parallel arm observational study of 53 prevalent conventional HD patients (CHD, 4 h/session, 3x/week) of whom 33 converted to INHD (7-8 h/session, 3 x/week) while 20 remained on CHD (controls). In both groups, we applied liquid chromatography-mass spectrometry based metabolite profiling at baseline and at 1-year. We examined longitudinal changes in metabolites among those who remained on CHD as compared to those who converted to INHD using Wilcoxon tests with significance thresholds adjusted for multiple comparisons using a false discovery rate correction (FDR).

Results: Among 164 polar metabolites examined, none significantly differed from baseline to study end in the control group. 27 metabolites differed in the INHD group, the majority of which actually increased with INHD (including several amino acids, including all three branched chain amino acids; all FDR adjusted P<0.05) suggesting the observed changes were not a direct effect of additional solute clearance. By contrast, several

established uremic solutes including p-cresol sulfate, indoxyl sulfate, trimethylamine N-oxide, and symmetric- and asymmetric-dimethylarginine did not change with extended duration INHD (all adjusted P>0.05).

Conclusions: INHD significantly alters metabolite profiles, however this may be a secondary effect of other metabolic and nutritional changes and not directly related to increased solute clearance. No change in several uremic solutes measured by our platform was observed.

TH-PO730

Fibroblast Growth Factor 21, a Novel Hormone, Is Associated with Lipid Metabolism and Renal Function in Nondialyzed Chronic Kidney Disease Patients Joao Victor Salgado, Maria Dalboni, Aluizio B. Carvalho, Maria Eugenia F. Canziani. *Discipline of Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Fibroblast growth factor 21 (FGF-21), a member of the endocrine FGF subfamily, is secreted mainly by the liver with critical role in glucose and lipid homeostasis. High FGF-21 levels are associated with metabolic disorders and predict kidney disease progression in patients with type 2 diabetes. However, it is still unclear what factors are truly affecting FGF-21 levels in CKD patients.

Methods: This study is *post hoc* analysis which included ninety five CKD patients stage 2-5 (age ≥ 18 and <70 yrs). Serum concentrations of total FGF-21 were quantified by enzyme-linked immunosorbent assay.

Results: Circulating FGF-21 did not change significantly with regards to age, gender and diabetes mellitus, but was different between CKD stages (2-5) (p=0.023) with highest values detectable in stage 5. Serum FGF-21 values correlated negatively with glomerular filtration rate based on the CKD-EPI equation (r=-0.28; p=0.007) and positively with serum creatinine (r=0.29; p=0.006), proteinuria (r=0.21; p=0.046), fasting glucose (r=0.21; p=0.047), triglycerides (r=0.36; p<0.001) and alkaline phosphatase levels (r=0.25; p=0.018). Multiple linear regression analysis revealed that triglycerides (β coefficient 0.395; p<0.001), GFR (β coefficient -0.309; p=0.001) and alkaline phosphatase (β coefficient 0.215; p=0.016) remained independently associated with circulating FGF-21 levels after adjustment for age, gender, BMI, and diabetes mellitus.

Conclusions: Circulating FGF-21 levels increase with CKD progression and appear to be associated with lipid rather than glucose metabolism.

Funding: Government Support - Non-U.S.

TH-PO731

Total Energy Expenditure as Estimated by Activity Trackers and Its Relationship to Hemodialysis Adequacy Schantel Williams,[1] Maggie Han,[1] Anna Meyring-Wosten,[1] Xiaoling Ye,[1] Marcee Bonner,[3] Candace Young,[3] Daniel Marsh,[3] Peter Kotanko.[1,2] *[1]Research, Renal Research Inst, New York, NY; [2]Nephrology, Icahn School of Medicine, New York, NY; [3]Research, Renal Associates Baton Rouge, Baton Rouge, LA.*

Background: While Kt/V_{urea} and urea reduction ratio (URR) are widely used indicators of hemodialysis (HD) adequacy, their conceptual flaws have been recognized. This method of evaluating adequacy may put those with low body mass index (BMI) at risk of under-dialysis. Metabolic rate, not V_{urea}, has an impact on toxin generation. Consequently, it is proposed that total energy expenditure (TEE) and metabolic rate may be more appropriate factors in determining HD dose adequacy (Singer, *AJKD* 2000). To do this, TEE needs to be measured routinely. Using activity trackers, clinically acceptable TEE can now be obtained (Murakami et al *JAMA* 2016). The aim of this study is to determine if a correlation between TEE and Kt/V exists.

Methods: Chronic HD patients wore the Fitbit® Flex™, a commercially available activity tracker, for 5 weeks. TEE, expressed in average daily calories burned, was obtained. Equilibrated Kt/V_{urea} was taken from monthly HD lab reports. Using linear regression, the relationship between TEE and eKt/V was assessed. Confounding factors, e.g. gender and BMI, were adjusted for.

Results: 44 patients, with an average age of 53.8± 11.3 years, BMI of 28.3±7.37 kg/m^2, 50% male and 75% Black were enrolled. Mean TEE was 2221± 457kcal. eKt/V_{urea} & TEE were not correlated in unadjusted (R^2 0.0149) nor adjusted (R^2 0.0153) analysis.

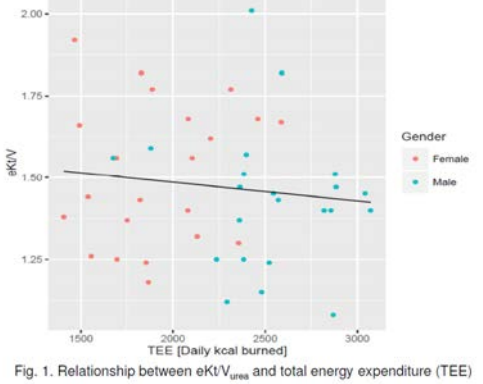

Fig. 1. Relationship between eKt/V_{urea} and total energy expenditure (TEE)

eKt/V_{urea} and TEE were not correlated in unadjusted (R^2 0.0149) nor adjusted (R^2 0.0153) analysis.

Conclusions: TEE is not related to eKt/V_{urea} and not reflected in the current assessment of HD adequacy. This may be a flaw as TEE is a proxy of determining metabolic toxin production compared to V_{urea} (Sridharan, *Hemodialysis Int'l* 2013). It is important to consider TEE when determining HD adequacy. Studies should further explore the relationship of TEE with generation of toxins. Eventually, TEE may be considered for HD dose prescription.

TH-PO732

Protein Intake Is Inversely Associated with Renal Function in Class III and IV CKD: The PROGREDIR Study Alisson Diego Machado,[1] Fernanda Silva Nogueira dos Anjos,[1] Maria Alice Muniz Domingos,[1] Maria del Carmen B. Molina,[2] Dirce Marchioni,[3] Paulo Lotufo,[4] Isabela M. Bensenor,[4] Silvia M. Titan.[1] *[1]Nephrology Div, School of Medicine, Sao Paulo Univ, Sao Paulo, Brazil; [2]Nutrition Dept, Federal Univ of Espirito Santo, Vitória, Espírito Santo, Brazil; [3]Nutrition Dept, School of Public Health, Sao Paulo Univ, Sao Paulo, Brazil; [4]Epidemiological and Clinical Research Center, Univ Hospital, Sao Paulo Univ, Sao Paulo, Brazil.*

Background: Benefits of protein restriction in CKD are still controversial. In addition, phosphorus intake could be a major confounding variable in that relation.

Methods: We evaluated the association between protein intake and baseline renal function in 454 class III and IV CKD patients (Progredir Study). A validated food frequency questionnaire was apllied and nutrient intake was estimated using USDA Database, with adjustment for energy. Models on the association between protein intake (g/kg) and renal function were built, adjusting for cardiovascular risk factors and phosphorus intake deattenuated of protein intake. Lastly, we compared participants reporting <0,8 g/kg/d of protein intake with those >0,8g/kg/d, after matching for age, sex and BMI.

Results: Tertiles of protein intake were associated to female sex, HDL, and inversely related to waist circumference (WC), BMI, hemoglobin, HOMA, alcohol, and eGFR. In linear regression, protein intake was related to log eGFR [B=-0.20 (-0.32- -0.07), p=0.002], BMI, WC and DBP. After adjustments for age, sex, hypertension, diabetes, dyslipidemia, alcohol, caloric and phosphorus intake, protein intake remained significantly associated with eGFR [B=-0.16 (-0.30 - -0.02), p=0.03]. Only 44 (9,7%) participants reported an intake of protein <0,8 g/kg/d, the KDOQI guideline. When we compared participants reporting <0,8 g/kg/d with those reporting >0,8g/kg/d after matching for age, sex and BMI, those >0,8g/kg/d presented a lower eGFR [B-4.22 (-8.18- -0.27), p=0.03], even after adjustments [B-3.93 (-8.17- -0.03), p=0.04].

Conclusions: In this cross-sectional study, higher protein intake was significantly associated with a lower eGFR, independently of phosphorus intake and other confounding variables.

The Relative Contribution of Lean and Fat Body Mass on Response to Erythropoiesis Stimulating Agents in Hemodialysis Patients Lucia Del Vecchio,[1] Valeria Aicardi,[2] Selena Longhi,[1] Vincenzo La Milia,[1] Giuseppe Pontoriero.[1] *[1]Nephrology and Dialysis, A Manzoni Hospital ASST Lecco, Lecco, Italy; [2]Nephrology and Dialysis, Clinica INDISA, Santiago del Chile, Chile.*

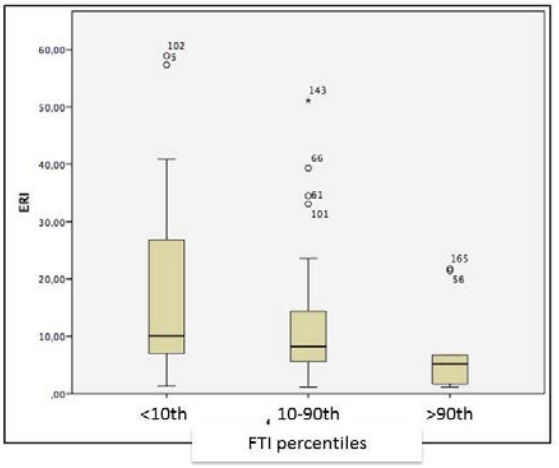
Background: High-dose ESA are associated with malnutrition and inflammation; little is known about ESA response according to lean and fat body composition.

Methods: 90 prevalent hemodialysis patients (M/F: 53/37, mean age 68.88 ± 14.01 years) on ESA therapy underwent nutritional assessment by Body Composition Monitoring. Hyporesponse to ESA defined as ERI>14.8, >75th percentile). Considering that LTI and FTI values vary according to age and gender, we analyzed the data according to Lean Tissue Index (LTI) and Fat Tissue Index (FTI) percentiles relative to an age- and sex-matched healthy population.

Results: Twenty (22%) and 19 (21%) patients had LTI and FTI values below the 10th percentile, respectively.

	ERI ≤ 14.8	**ERI > 14.8**	**P value**
BMI (Kg/m^2)	27.26 ± 4.45	25.78 ± 3.08	NS
Serum albumin (g/dl)	3.65 ± 0.51	3.13 ± 0.59	0.002
Muscular brachial area (cm^2)	55.97 ± 12.30	48.84 ± 15.74	0.078
Fat brachial area (cm^2)	20.40 ± 13.98	18.34 ± 13.41	NS
LTI (Kg/m^2)	13.16 ± 2.99	13.10 ± 2.45	NS
FTI (Kg/m^2)	13.15 ± 4.53	11.14 ± 3.59	NS

Table 1 shows main data for ERI category. Ferritin levels and TSAT were not significantly different. FTI values were inversely related to lnERI (r2= 0.094, beta -0.30, p=0.005). Patients with FTI values below the 10th percentile had higher ERI compared to the 10-90th and > 90th percentile (19.23 18.05, 11.6 ± 9.84 and 7.44 ± 7.69, respectively; p= 0.025).



The difference in mean ERI among LTI percentile categories had opposite trend (9.04 ± 7.74, 12.45 ± 11.04 and 19.63 ± 19.71 for < 10th, 10- 90th and > 90th percentile; p= 0.072).

Conclusions: In hemodialysis patients ESA hyporesponse is mainly associated with decreased fat body mass.

TH-PO734

Association of Ascorbic Acid Supplementation with Plasma Ascorbic Acid and Oxalate Levels in Prevalent Hemodialysis Patients William D. Sirover,[1] Yuguan Liu,[2] Amanda Logan,[4] Krystal Hunter,[4] Craig B. Langman,[3] Lawrence S. Weisberg,[1] Garry J. Handelman.[2] *[1]Nephrology, CMSRU, Camden, NJ; [2]Nutrition, UMASS, Lowell, Lowell, MA; [3]Nephrology, Feinberg School of Medicine, Chicago, IL; [4]Cooper Research Inst, Cooper Univ Hospital, Camden, NJ.*

Background: Ascorbic acid (AA) facilitates erythropoiesis and a plasma AA concentration (p[AA]) of at least 70 µM may be necessary to reduce erythropoiesis-stimulating agent resistance. Hemodialysis (HD) patients are commonly prescribed or take AA supplementation. Oxalate (Ox), an AA-metabolite, is excreted in the urine and is also removed during HD. Ox accumulation may limit AA use as an anemia adjuvant. When the plasma Ox concentration (p[Ox]) reaches 30 µM, Ox may deposit pathologically in organs. Plasma AA levels of 70-100 µM are not associated with p[Ox] surpassing this 30 µM threshold. We examined further the efficacy and safety of escalating degrees of AA supplementation.

Methods: In 2011, we surveyed outpatients on HD regarding AA supplement use. Pre-HD p[AA] and p[Ox] were measured in 197 patients. Moderate AA supplementation was defined as an oral AA dose of up to 120 mg/day.

Results: Median p[AA] and mean p[Ox] showed a significant positive association with escalation of AA dose (Figures 1 and 2).

	0 mg AA/ day	50-75 mg AA/ day	100-120 mg AA/day	≥150 mg AA/ day	*P*-value
AA dose (mg/ day)	0	60 (IQR 60-60)	100 (IQR 100-100)	560 (IQR 530-600)	<0.001
Albumin (gm/ dL)	3.9±0.4	4±0.4	3.9±0.3	3.9±0.4	0.74
spKt/V	1.73	1.77	1.76	1.6	0.38

Figure 1

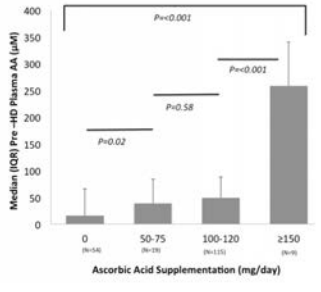


Figure 2

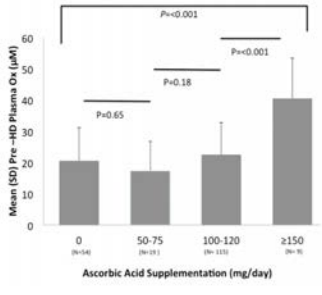

Conclusions: Moderate AA supplementation was not linked with p[Ox] surpassing 30 µM. However, this degree of supplementation was associated with a p[AA] below 70 µM. Prospective studies are needed to determine an AA dose that maintains p[AA] between 70-100 µM and, for now, HD patients should avoid an AA dose that exceeds 120 mg/day.

TH-PO735

Muscle Mass Assessment by Computed Tomography at Lumbar Vertebra: Agreement with Surrogate Methods in Chronic Kidney Disease Patients Juliana Giglio,[1] Maria A. Kamimura,[2] Antonio C. Cordeiro,[3] André Valente Bichels,[2] Nivaldo Pinho,[4] Nilian Souza,[1,4] Carla Maria Avesani.[1] *[1]Rio de Janeiro State Univ, Brazil; [2]Federal Univ of Sao Paulo, Brazil; [3]Dante Pazzanese Inst of Cardiology, Brazil; [4]National Inst of Cancer, Brazil.*

Background: The assessment of muscle mass by computed tomography (CT) has been suggested as the preferred method for analyzing skeletal muscle mass (SMM). We wish to evaluate the agreement of SMM assessed by CT at L3 with surrogates of muscle mass in chronic kidney disease (CKD) patients.

Methods: This is an ongoing study including 30 nondialyzed CKD patients (age: 59 ±9 years; 56% men; glomerular filtration rate: 12 (9 - 28) mL/min/1.73 m^2; median and interquartile range). SMM was evaluated by CT at the third lumbar vertebra for analysis of total muscle cross-sectional area (cm^2), trough the following muscles quantification: rectus abdominus, abdominal (lateral and oblique), psoas, and paraspinal (quadratus lumborum, erector spinae) using Slice-O-Matic software (v.4.3; Tomovision, Canada). Lean body mass by bioelectrical impedance (LBM-BIA) and anthropometry (skinfold thicknesses) (LBM-ANT); SMM calculated from Janssen and Baumgartner equation and midarm muscle circumference (MAMC) were selected as surrogates of muscle mass. Low muscle mass was defined as the lower P50th according to gender for each method.

Results: The kappa coefficients and sensitivity between SMM assessed by CT and surrogates (table 1) showed that the highest kappa coefficients for low muscle mass was observed for MAMC, followed by SMM-Baumgartner and LBM-ANT. The univariate association with SMM assessed by CT on the other hand were stronger for SMM-Baumgartner and LBM-ANT.

	Kappa (r;*p*)	Sensitivity (%)	Especificity (%)	Univariate association (r; *p*)
CT *vs* LBM-BIA	0.40 (0.03)	69	71	0.71 (<0.01)
CT *vs* LBM-ANT	0.46 (0.01)	75	71	0.74 (<0.01)
CT *vs* SMM Janssen	0.34 (0.06)	63	71	0.62 (<0.01)
CT *vs* SMM Baumgartner	0.46 (0.01)	75	71	0.81 (<0.01)
CT vs MAMC	0.60 (<0.01)	81	79	0.53 (<0.01)

Conclusions: Our preliminary analyzes showed that the assessment of low muscle mass in CKD patients by CT at L3 showed the best agreement with MAMC, SMM-Baumgartner and LBM-ANT.

TH-PO736

Altered Metabolism of Serum Manganese Is Associated with Low Levels of Hemoglobin in the Patients with Chronic Kidney Disease Minyoung Kim, Eun Sil Koh, Hyung Wook Kim, Seok Joon Shin, Sungjin Chung. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Manganese (Mn) is one of the essential minerals which is likely to be deficient in malnutrition. Given that malnutrition is a major issue in chronic kidney disease(CKD), Mn could be inadequate to maintain physiologic balance in CKD patients. Several reports highlighted that serum Mn level was higher in the patients with anemia. Although anemia is common manifestation of chronic kidney disease, it has been barely established whether serum Mn level have some effect on anemia in CKD patients. The purpose of this study is to analyze the relationship between serum Mn level and anemia in the patients with CKD.

Methods: This study was a cross-sectional study based on the patients with CKD. Total 300 patients with CKD were included in single center from 2014 to 2016. They were divided into two groups by serum manganese level, 8.0 ug/L, according to the reference range of the hospital laboratory policy.

Results: The median value of serum Mn and eGFR of all participants were 8.0 ug/L (interquartile range: 4.9 to 11.5 ug/L) and 12.5 ml/min 1.73 m^2 (interquartile range: 7.18 to 25.1 ml/min 1.73 m^2), respectively. The higher Mn group showed higher hemoglobin (Hb) level (11.3 ± 2.1 *vs.* 9.5 ± 1.8 g/dL ; $p < 0.001$) and higher eGFR (21.1 ± 16.8 vs. 15.71 ± 12.7 ml/min 1.73 m^2; $p < 0.001$), compared with the lower Mn group. Serum Mn level showed the significant correlation with Hb level and eGFR (r=0.474, $p < 0.001$; 0.142, p=0.014, respectively). A multivariate logistic regression analysis adjusted for age, gender, body mass index and eGFR was performed; the odds ratio was 0.173 (95% CI: 0.090 to 0.334, p<0.001) for anemia (Hb < 11.5 mg/dl), when comparing the higher Mn group with the lower Mn group.

Conclusions: In the CKD patients, higher Mn level might have positive association with hemoglobin level. Although the specific mechanism is not known yet, the role of serum Mn level may be important especially in CKD patients with an aspect of anemia management.

TH-PO737

Fetuin-A and Calciprotein Particles Profiles in Patients on Peritoneal Dialysis
Thalita Moura Santos Braga, Erica Adelina Guimarães, Rodrigo Souza Adao, Wagner Dominguez, Fabiana Graciolli, Hugo Abensur, Rosilene M. Elias, Rosa M.A. Moyses. *Nephrology, Faculty of Medicine, Univ of São Paulo, São Paulo, Brazil.*

Background: Fetuin-A is an inhibitor of mineralization that complexes with mineral apatite precursors generating high molecular weight fetuin-A-containing calciprotein particles (CPP), which are associated with aortic stiffness and all-cause mortality. CKD patients usually have low fetuin-A and high CPP, although data in peritoneal dialysis (PD) patients are scarce.

Methods: Dialysate and serum fetuin-A levels were measured in 13 patients on PD. CPP were obtained of the supernatant after high-speed centrifugation samples in both serum and dialysate. The patients were submitted to peritoneal equilibrium test (PET) and nutritional status evaluation by bioimpedance analysis.

Results: Patients aged 43 ± 15 years (69.2% women), were on PD for a median time of 23 (4-70) months. Nine patients (69.2%) were well nourished/mild nutritional risk and 8 (61.5%) patients were classified as high/high average (H/HA) transporters. Fetuin-A was 352 ± 61g/L and CPP was 29.8 ± 11.8µg/mL. The serum CPP was higher in H/HA than in low/low average transporters (34.1 ± 10.7% *vs.* 13.1 ± 1.9%, p=0.034) and correlated with dialysis vintage (r=0.579, p=0.030). The dialysate loss of fetuin-A correlated with the loss of albumin (r=0.967, p=0.0001), glucose absorption (r=0.626, p=0.022), muscle mass (r=0.620, p=0.042), cell mass (r=0.627, p=0.039), bone mass (r=0.791, p=0.004), and the percentage of fat body (r=-0.624, p=0.040).

Conclusions: The CPP appears to be higher in patients longer on PD, especially in those with H/HA transporters characteristic. Muscle reserves and nutrition status may influence this exchange.

TH-PO738

Fibroblast Growth Factor21 Is Increased in CKD Patients and React with Protein Restriction
Mio Matsuura, Hirofumi Nishikawa, Natsuki Maeda, Tatsuki Matsumoto, Yoshiko Shimamura, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Yoshio Terada. *Endcrinology, Matabolism and Nephrology, Kochi Medical School, Japan.*

Background: Fibroblast growth factor21 (FGF21) is known to play a role in glucose and lipid metabolism. Recent report showed that FGF21 expression is increased in response to starvation and ketogenic diets. However, detailed mechanism and significance of FGF21 has not been elucidated in CKD. CKD patients are taking a protein-restricted diet as the treatment. This study was designed to investigate the regulation of FGF21 of CKD patients with low-protein diet and elucidate relation FGF21 and nutritional parameters and CKD-MBD biomarkers.

Methods: We made a continuously survey of CKD patient characteristics and outcomes in Kochi prefecture (Western area of Japan) for 24 months. Patients of CKD (total N=442) were enrolled. Serum sample were collected and measured FGF21 by using an ELISA kits. In addition, serum creatinine, hemoglobin, albumin, calcium, phosphate, NTproBNP and FGF23 were measured. Therapeutic effect of the low-protein diet is determined in the BUN / Creatinine ratio. This study was approved by Kochi Medical School review board. All patients provided written informed consent.

Results: The serum level of FGF21 was negatively correlated to BUN/Creatinine ration (P<0.0001: r=-0.319). Furthermore, albumin level was negatively correlated (P<0.001: r=-0.171). FGF21 is increased in response to the protein restriction. The serum level of FGF21 elevated significantly according to the progression of CKD stage. The serum level of FGF21 was positively correlated to NTproBNP (P<0.0001: r=0.249).

Conclusions: In CKD patients, the serum level of FGF21 were increased according to CKD stages and response to the protein restriction. Our date indicate that FGF21 may play a role in CKD pathogenesis, especially in nutritional aspect.

TH-PO739

Obesity and Immunosuppressive Therapy Effects on Glucose Intolerance in Allogeneic Kidney Transplant Patients
Magdalena Barbara Kaziuk, Marek Kuzniewski. *Chair and Dept of Nephrology, Jagiellonian Univ Medical College, Krakow, Poland; Chair and Dept of Nephrology, Jagiellonian Univ Medical College, Krakow, Poland.*

Background: The population of kidney transplant patients receiving immunosuppressive treatment is particularly susceptible to glucose intolerance, and development of post-transplant diabetes in the future.

Methods: The study covered 152 patients with a functioning kidney transplant more than 6 months after the procedure (Ktx): 81 women and 71 men. The average patient age was 47.8±11.6 years. The patients received immunosuppressive dual therapy (steroids, ICN) or triple therapy (steroids, calcineurin inhibitor, proliferation inhibitor). Their body composition was assessed using the bioimpendance method (BIA) and anthropometric measurements. Nutritional status and obesity type were determined with the Waist-to-Height Ratio (WHtR) and the Waist-to-Hip Ratio (WHR). Glucose intolerance was evaluated by several measurements of fasting blood glucose levels, and its association with a specific type of obesity and glomerular filtration rate (eGFR) calculated with the MDRD formula was analysed. Patients with diabetes diagnosed before the kidney transplant procedure were excluded from the study.

Results: Glucose intolerance was diagnosed in 56% of subjects, and obesity was found in 48% of patients with hyperglycaemia and 20% of patients with correct glucose levels. The subjects with an android body type were more susceptible to glucose intolerance compared with those with the gynoid body type (p=0.004). Increased glucose blood levels were significantly correlated to cyclosporin A and tacrolimus levels (p<0.05). Furthermore, the patients with an android body type had lower eGFR compared with people with the correct body weight (p=0.004).

Conclusions: One of the basic directions for management of kidney transplant patients with glucose intolerance accompanied by abdominal obesity is reduction of their body weight combined with physical activity adapted to patients' current physical fitness. Treatment with calcinerin inhibitors (IC), particularly tacrolimus, may be a predictor for diabetes in transplant patients; therefore they should be regularly monitored.

TH-PO740

Obesity Paradox in Hemodialysis: Could Omega 3 Be the Link?
Ana Rita Mateus Martins,[1,2] Inês Filipa Moreira,[1] Ana Sofia Ferreira,[1] Iolanda Nunes Godinho,[1] Teresa Adragao,[2] Andre L. Weigert.[1,2] *[1]Davita Obidos, Davita Portugal, Portugal; [2]Nephrology Dept, Hospital Santa Cruz, Lisbon, Portugal.*

Background: In advanced chronic kidney disease (CKD), obesity is paradoxically linked with greater survival. The potential mechanisms underlying the "obesity paradox" in CKD are still not well known. Omega3 intake has been linked to many beneficial impacts in cardiovascular (CV) health, affecting lipid profile, insulin resistance, platelet aggregation. Therefore, we postulate that patients (pts) who consume large amounts of fish may have more favorable CV status.

Methods: Observational study in 155 prevalent Portuguese HD pts. We obtained baseline demographic data, blood biochemistry, comorbidities and daily diet. In order to evaluate omega 3 incorporation in red blood cell (RBC) membranes, we used frozen RBC for FAME (fatty acid methyl esters) and obtained the percentage of eicosapentaenoic (EPA) and docosahexaenoic (DHA) in total FAME.

Results: In our cohort 79 were male, mean age was 67 years, 39% had diabetes (DM) and average time on HD was 73 months. Body index mass (BIM) was 26±4.6 kg/m^2. The follow up period time was 21 months and there were 71 CV events and 52 hospitalizations. BIM was associated with RBC omega3 incorporation (*Pearson*; p=0,045). Higher BIM was associated with a lower number of CV events (*Pearson*; p=0,038) and with lower hospitalization time (*Pearson*: p=0,04). In a multivariate analysis (linear regression), a higher EPA+DHA RBC incorporation was associated with a higher BIM and albumin, in a model adjusted to time on dialysis and age (Exp(B) 0.088; p=0.05; IC 95% 0.002 to 0.177). Larger hospitalization time was correlated with lower EPA+DHA RBC incorporation (linear regression: Exp(B)-5.7; p=0.023; IC 95% -10.52 to -0.91), in a model adjusted to DM and age. In a binary regression, CV event were associated with EPA+DHA RBC incorporation (Exp(B) – 1,56; p=0.05; IC 95% -2,36 to 0.98), in a model adjusted to age, time on HD and DM.

Conclusions: There appears to be a consistent association between obesity and an higher omega3 incorporation with better clinical outcomes in our cohort of HD pts. This fact may suggest a possible explanation for the reverse obesity epidemiology in advanced CKD.

Funding: Private Foundation Support

TH-PO741

Serum Tatal Ghrelin Maybe a Biomarker for Mortality in Hemodialysis Patients
Jie Ma, Yang Yu, Xuemei Li. *Nephrology Dept, Peking Union Medical College Hospital.*

Background: Ghrelin is involved in the pathogenesis of protein-energy wasting (PEW), inflammation, and cardiovascular complications in end-stage renal disease (ESRD). Plasma ghrelin may prove to be a powerful biomarker of mortality in hemodialysis patients. The objective of this study was determined the correlation between serum ghrelin and mortality in dialysis patients.

Methods: We prospectively followed a cohort of 119 maintenance hemodialysis patients for 30 months in Peking Union Medical College Hospital dialysis center. We assessed the impact of the serum total ghrelin and free ghrelin levels on the cumulative survival rates according to the cox-regression method in the dialysis patients.

Results: A total of 119 cases were enrolled this study, male 59, female 60, age 19-90years, mean age 59.3years, with duration of dialysis for10-95 months. The mean serum total ghrelin level was detectable in all patients was 1200.11±750.19pg/mL (median 971.52pg/mL). The mean serum free ghrelin level was 122.98±75.17pg/mL (median 109.31pg/mL). Total ghrelin was significantly associated with dialysis patient mortality(P=0.032), but free ghrelin not(P=0.061).

Conclusions: Ghrelin has significant regulatory roles in energy homeostasis, systemic inflammation, and the cardiovascular system. From our study,serum total ghrelin was significantly associated with dialysis patient mortality, we considered that serum total ghrelin maybe a meaningful biomarker of mortality in dialysis patients.

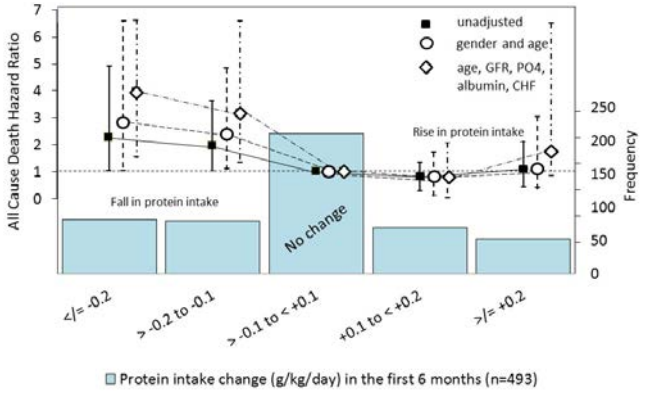
TH-PO742

Restriction of Protein Intake in Non-Dialysis Chronic Kidney Disease Patients May Be Not Beneficial when a Renal Dietitian Is Not Available Pablo Molina,[1] Sandra Beltrán,[1] Jose Roldan Iborra,[2] Marco Montomoli,[1] Belen Vizcaino,[1] Veronica Escudero,[1] Cristina Castro,[1] Jonay Pantoja Perez,[1] Ana Avila,[1] Julia Kanter,[1] Luis M. Pallardo,[1] Jose L. Gorriz.[1] *[1]Nephrology, Dr Peset Univ Hospital, Spain; [2]Dietetic Unit, Alcer Turia, Spain.*

Background: Due to safety concerns, CKD patients who are on a low-protein diet (LPD: 0.60–0.80 g/kg/d), should be carefully monitored. However, few patients receive dietary counseling before dialysis, and whether LPD without dietitian counseling is beneficial or risky remains unknown. We tested the hypothesis that LPD when an onsite renal dietitian is not available is independently associated with poor outcomes in CKD population.

Methods: The relation between dietary protein intake (DPI) and its change during the first 6 months, and mortality and kidney progression were examined in a 3-year cohort of 493 clinically stable patients with CKD stages 4-5 with a baseline DPI≥0.60 g/kg/d, using multivariate Cox models. General advice was given regarding reducing DPI, but a dietician did not routinely assess the patients. DPI was estimated by using 24-h urea nitrogen according to Maroni's formula.

Results: At baseline, the mean DPI was 0.89±0.20 g/kg/d. After a median follow-up of 31 months, there were 72 deaths and 151 required dialysis. The best survival was associated with DPI>1.0 g/kg/d, whereas DPI between 0.6 to 0.8 g/kg/d was associated with greater mortality. A decrease in DPI during the first 6 months was associated with greater death risks in the subsequent 30 months, whereas an increase in DPI tended to correlate with better survival. DPI did not predict renal progression.



Conclusions: LPD or decrease in DPI over time was associated with increased risk for death in ND-CKD patients in which counseling with a renal dietitian was not available, with no benefits on kidney progression. These results reinforce the need for predialysis dietitian care, especially when LPD is prescribed.

TH-PO743

α Ketoanalogues of Amino Acids in Patients with Chronic Kidney Disease: Experience of a Nutritional Care Center Rocio Urbina, Silvia Moran, Julia Nava, Verónica Figueroa, Rafael Montufar. *Centro de Atención Nutricional, Fresenius Kabi México, Ciudad de México, Distrito Federal, Mexico.*

Background: A low protein diet (LPD) supplemented with alpha keto analogues of amino acids (AKAAA) has a metabolic stabilizing effect, which prolongs the pre-dialysis stage and improves the quality of life.

Methods: The effects of LPD supplemented with AKAAA (sLPD) were assessed the body composition and renal function stage in patients in the stages 3,4 and 5 of chronic kidney disease. This was a retrospective, longitudinal study at the Fresenius Kabi Mexico's Nutritional Care Center (NCC); records were reviewed with AKAAA treatment periods >6 months (1 tablet per 5 to 7 kg), LPD (0.5 to 0.6 g/kg of ideal body weight). The variables measured were; anthropometry, body composition, dynamometry, blood pressure, laboratory test and creatinine clearance at 30,60 and 180 days. The information was captured and evaluated by personnel unrelated to the NCC , the software SPSS version 20 was used in the statistics evaluation.

Results: 210 cases were included; the mean age was 63.5 years, 119 male patients and 91 female patients. A cut-off data was performed after 6 months of sLPD treatment, the results were 39 patients in stage 3, 105 patients in stage 4 and 66 patients in stage 5; body weight, fat mass and fat-free mass decreased significantly; an increase in muscle strength was observed; serum albumin and total protein did not change. Blood pressure showed no difference; urea, creatinine and creatinine clearance, show a decrease levels showed significant decreases (p<0.0001) ; measures of uric acid and Ca/P declined during the study.

Conclusions: Supplemented with nutritional therapy AKAAA, allowed address metabolic abnormalities of uric acid, calcium, phosphorus, glucose, cholesterol and triglycerides. No alterations were observed in nutritional status according to anthropometric and biochemical parameters. It is proposed that this procedure may be a link in the model of comprehensive care of patients with CKD.

TH-PO744

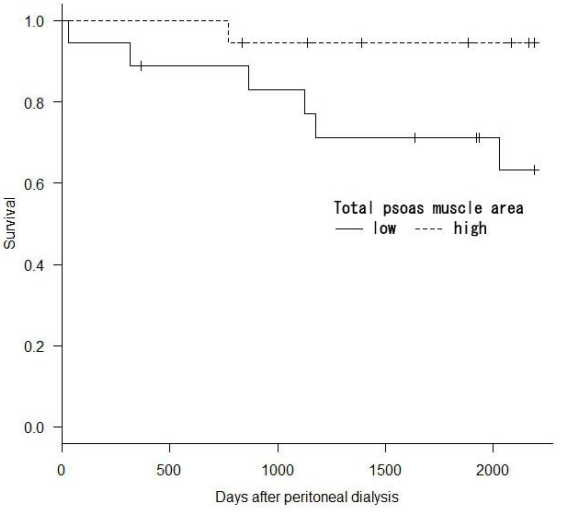
Psoas Muscle Area Predicts Mortality among Incident Peritoneal Dialysis Patients Yu Honda, Nanae Matsuo, Yukio Maruyama, Emi Kimoto, Yasuyuki Nakada, Masatsugu Nakao, Yudo Tanno, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Cardiovascular disease (CVD) is common among chronic kidney disease (CKD) patients. Malnutrition, inflammation and atherosclerosis (MIA) syndrome was reported as one of the mechanisms of a high prevalence of CVD in this population. Since it was also associated with mortality, to assess the risk of MIA syndrome is an important issue in CKD patients. Body composition, especially estimated muscle mass, has been recognized as a useful nutritional marker. Total psoas muscle area (PMA) measured by computed tomography (CT) scan is one of the methods to estimate muscle mass. Although its usefulness already has been reported among non-renal patients, studies conducted in dialysis patients are limited. The aim of this study was to evaluate whether PMA at the start of peritoneal dialysis (PD) was associated with clinical parameters and mortality.

Methods: This study included 36 male patients (59±11 years, diabetes 36%) who initiated PD between 2007 and 2008. We evaluated the associations between PMA at the third lumbar vertebra (L3) level measured by CT scan and clinical parameters. We divided the patients into two groups based on the median PMA at the L3 level and compared each cumulative survival rates using Kaplan-Meier method.

Results: The mean PMA at the L3 level was 18.41 cm^2. PMA at the L3 level was inversely correlated with serum albumin (rho=-0.352, P<0.05) and positively with body weight (rho=0.514, P<0.01) and body mass index (rho=0.454, P<0.05). 6-year cumulative survival rates were significantly lower in the low PMA group than in the high PMA group (P<0.05).

Conclusions: PMA at the L3 level was related to mortality. We suggest that PMA assessed on CT is the useful parameter of body composition among incident PD patients.



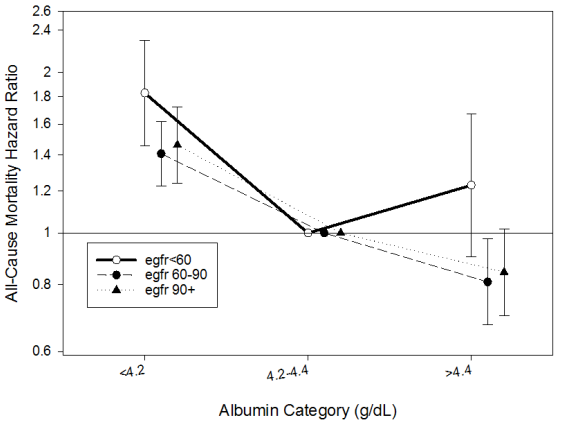
TH-PO745

Serum Albumin Concentration, Estimated Glomerular Filtration Rate, and Survival among 1999-2010 NHANES Participants Amanda R. Tortorici,[1] Elani Streja,[1] Melissa Soohoo,[1] Daniel L. Gillen,[1] Connie Rhee,[1] Keith C. Norris,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UCLA.*

Background: As a potential strong predictor of longevity in the general population and in those with chronic kidney disease, we sought to examine whether higher serum albumin (Alb) levels are associated with greater survival in the nationally representative NHANES cohort.

Methods: We identified 31,274 participants from the 1999-2010 continuous NHANES survey who had available Alb measurements and laboratory values for calculation of eGFR, as well as survival data. Follow up time began the date after Alb measurement until December 31, 2011. We analyzed the association of Alb (<4.2, 4.2-<4.4 and ≥4.4 g/dL) with mortality across strata of eGFR (<60, 60-<90, and ≥90 ml/min/1.73m^2) using Cox proportional hazards models adjusted for age, sex, race, and education.

Results: The mean±SD age of the cohort was 48±20 years, among whom 52% were female, 20% were African-American, 22% were Mexican-American, and 7% were other Hispanic American. Across all eGFR strata, participants with Alb levels <4.2 g/dL (n=11,384 people) had higher mortality rates compared to the reference group (Alb 4.2-<4.4 g/dL, n=10,793 people). In contrast, participants with Alb levels >4.4 g/dL (n=9097) and eGFR 60-90 ml/min/1.73m^2 (n=1,911) experienced lower rates. See figure for adjusted hazard ratios.



Conclusions: Among 1999-2010 continuous NHANES participants, lower Alb levels were associated with 40% to 80% greater mortality risk irrespective of the eGFR values.

TH-PO746

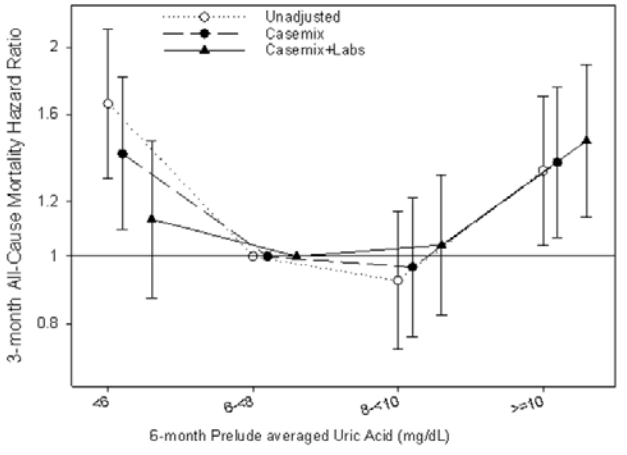
Association of Pre-ESRD Uric Acid with Post-ESRD Mortality: A Transition of Care in CKD Study

Vanessa A. Ravel,[1] Connie Rhee,[1] Elani Streja,[1] Yoshitsugu Obi,[1] Jason Chou,[1] Melissa Soohoo,[1] Daniel L. Gillen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: Although uric acid is commonly elevated in chronic kidney disease (CKD) patients, it has only recently been posited as a possible risk factor contributing to the progression of CKD. To date, most studies have focused on linking pre-ESRD uric acid to adverse pre-ESRD outcomes. We sought to examine the association between pre-ESRD serum uric acid and post-ESRD mortality among US veterans.

Methods: From a cohort of US veterans who transitioned to dialysis between 10/2007-09/2011, we identified 6,086 patients with a pre-dialysis uric acid measurement in the 6 months before transitioning to ESRD. We examined pre-ESRD uric acid as a predictor of all-cause mortality within the first 3 months post-transition using Cox proportional hazards models adjusted for case-mix covariates, BMI at prior to initiation and additional adjustments for laboratory values and eGFR (both 6-month averaged and last available before dialysis initiation).

Results: The mean age of the cohort was 67±11years old and included 2% females, 71% diabetics, and 34% African Americans. The 6-month prelude uric acid average was 8.07 ± 2.03 mg/dL. Overall, 9.3% of patients died during the first 3 months on dialysis. 6-month prelude uric acid exhibited a U-shaped association with 3-month post-ESRD all-cause mortality. Compared to the reference (6-<8 mg/dL), patients with uric acid level ≥10 mg/dL have the highest early mortality across all levels of adjustment.



Conclusions: Both low and very high serum uric acid (<6 and ≥10 mg/dL, respectively) during the prelude period to ESRD are associated with higher early all-cause mortality in US veterans. Whether this U-shaped association calls for changes to therapeutic paradigms regarding pre-ESRD hypo- and hyperuricemia warrants further studies.

TH-PO747

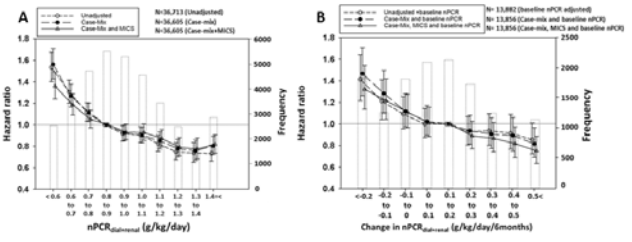
Associations of Dietary Protein Intake with Mortality in Incident Hemodialysis Patients: Using Normalized Protein Catabolic Rate Accounting for Residual Kidney Function

Rieko Eriguchi, Yoshitsugu Obi, Elani Streja, Connie Rhee, Melissa Soohoo, Kamyar Kalantar-Zadeh. *UC Irvine.*

Background: There are inconsistent reports on the association of normalized protein catabolic rate (nPCR), an index of dietary protein intake, with mortality among hemodialysis patients. This discrepancy may be partly due to not accounting for residual renal urea clearance (CLurea) among hemodialysis patients when evaluating nPCR.

Methods: Among 36,713 incident hemodialysis (HD) patients in a large dialysis organization from 1/2007 to 12/2011, we examined baseline and change in nPCR during the first 6 months of dialysis accounting for residual kidney function. Cox proportional hazard models with adjustment for case-mix covariates and markers of the malnutrition-inflammation cachexia syndrome (MICS) were used to examine associations of these nPCR markers with mortality.

Results: Patients were 62±15years old, 37% female, 28% African-American, and 47% diabetics. At baseline, median (IQR) of nPCR with CLurea was 0.94 (0.77, 1.14) g/kg/day. In the fully adjusted model, baseline nPCR< 0.7 g/kg/day was significantly associated with higher mortality, and nPCR > 1.1 g/kg/day was significantly associated with better survival compared to the reference (0.8-0.9 g/kg/day). Finally, a decrease in nPCR < 0.1 g/kg/day was associated with higher mortality whereas an increase in nPCR> 0.5 g/kg/day was associated with better survival.



Conclusions: Among incident HD patients, patients with low nPCR accounting for CLurea , and those who decreased in nPCR over the first 6 months of HD had a higher risk of death. Additional studies are needed to investigate the differences in mortality risk prediction for nPCR with and without factoring CLurea.

Metabolites Associated with Dietary Protein Intake in the Modification of Diet in Renal Disease (MDRD) Study

Casey Rebholz,[1] Morgan Grams,[1] Lawrence J. Appel,[1] Mark J. Sarnak,[2] Lesley Inker,[2] Andrew S. Levey,[2] Josef Coresh,[1] David Graham.[1] *[1]Johns Hopkins Univ; [2]Tufts Medical Center.*

Background: Dietary protein intake leads to production of a range of known and unknown metabolic effects of possible relevance to CKD symptoms and progression. Discovering metabolic consequences of diets with lower vs. higher protein intake could elucidate new pathways of protein metabolism in CKD patients.

Methods: Metabolites were measured by Metabolon (HD4 untargeted platform) using gas-chromatography-mass spectrometry and liquid chromatography-mass spectrometry in serum specimens from the 12 month follow-up visit in the MDRD study for 470 participants in study A (GFR 25-55 mL/min/1.73 m^2) and 196 participants in study B (GFR 13-24 mL/min/1.73 m^2). We used multivariable linear regression to test for differences in log-transformed metabolites (outcome) by to dietary protein intervention groups (exposure). Statistical significance was assessed at the Bonferroni-corrected threshold: $0.05/1{,}194=4.2*10^{-5}$.

Results: A total of 1,194 known and unknown metabolites were detected. After adjusting for age, sex, race, GFR, cause of kidney disease, and blood pressure intervention, 137 metabolites (86 known from 27 distinct pathways including 10 amino acid pathways and 51 unknown) were significantly different among participants randomized to the low protein diet vs. moderate protein diet in study A. Among participants randomized to the very low protein diet vs. low protein diet, 29 metabolites (20 known from 8 distinct pathways including 5 amino acid pathways and 9 unknown) were significantly different in study B.

Table. Selection[1] of Known Metabolites Associated with Dietary Protein Intake in the MDRD Study

Comparison	Metabolite	Pathway	β coefficient[2]	P-value
Study A[3]: Low Protein Diet vs. Moderate Protein Diet	tiglylcarnitine	leucine, isoleucine, and valine metabolism	-0.6	$<1.0*10^{-40}$
	1-(1-enyl-palmitoyl)-2-arachidonoyl-GPE (P-16:0/20:4)	plasmalogen	-0.4	$1.8*10^{-20}$
	6-hydroxyindole sulfate	chemical	-0.4	$2.2*10^{-13}$
	guanidinosuccinate	guanidino and acetamido metabolism	-0.8	$2.4*10^{-13}$
	indolin-2-one	food component/plant	-0.4	$9.2*10^{-11}$
Study B[4]: Very Low Protein Diet vs. Low Protein Diet	3-hydroxy-2-ethylpropionate	leucine, isoleucine, and valine metabolism	1.6	$<1.0*10^{-40}$
	creatine	creatine metabolism	-0.4	$2.1*10^{-9}$
	1-(1-enyl-palmitoyl)-2-arachidonoyl-GPC (P-16:0/20:4)	plasmalogen	-0.2	$2.6*10^{-9}$
	sulfate	chemical	-0.1	$6.3*10^{-6}$

[1] Selection of 5 known metabolites representing distinct pathways was based on statistical significance for each comparison.
[2] β coefficient represents the adjusted effect of lower vs. higher randomized protein diet on metabolite concentration.
[3] Study A: low protein diet (0.58 g/kg/day) vs. moderate protein diet (1.3 g/kg/day)
[4] Study B: very low protein diet (0.28 g/kg/day + 4-9 mg/kg/day of an essential ketoacid supplement) vs. low protein diet

Conclusions: Among CKD patients, an untargeted metabolomic platform identified multiple pathways and metabolites affected by randomized groups of dietary protein consumption. Further research is necessary to characterize unknown compounds and evaluate the ability of these metabolites to predict CKD progression.

Dietary Modifications for Adults with Chronic Kidney Disease: Meta-Analysis of Randomized Trials Suetonia Palmer,[1] Katrina L. Campbell,[2] Jonathan C. Craig,[3] David W. Johnson,[2] Marinella Ruospo,[4] Allison Tong,[3] Giovanni F.M. Strippoli.[3,4,5] *[1]Univ of Otago Christchurch; [2]Univ of Queensland; [3]Univ of Sydney; [4]Diaverum; [5]Univ of Bari.*

Background: Dietary changes are routinely recommended in patients with CKD on the basis of randomized evidence in the general population and non-randomized studies in CKD that suggest healthy eating patterns may prevent cardiovascular events (CVEs) and mortality. Patients with CKD have prioritized dietary interventions as an important treatment uncertainty. This systematic review aimed to assess the benefits of dietary modification in patients with CKD.

Methods: Meta-analysis of randomized clinical trials (RCTs) of any dietary modification in adults with CKD was conducted. Electronic databases were searched in January 2016 without language restriction. Evidence quality was assessed using GRADE.

Results: The meta-analysis included 10 RCTs (874 patients) of dietary counseling, Mediterranean diet, low-carbohydrate, polyphenol-enriched diet, or increased fruit and vegetable intake for 12 months on average. Evidence quality was very low. Dietary counseling significantly lowered diastolic blood pressure (-8.6 mmHg, CI -13.3 to -3.98) but not systolic blood pressure (-6.73, CI -16.9 to 3.44). A Mediterranean diet lowered serum LDL cholesterol levels by 1.00 mmol/l (95% CI -1.56 to -0.44) and increased serum albumin levels by 0.60 g/l (CI 0.11-1.09). Increased fruit and vegetable intake lowered systolic blood pressure by 7.10 mmHg (CI -9.60 to -4.60), while effects on diastolic blood pressure were not available. A carbohydrate-restricted diet with higher olive oil intake and lower red meat content reduced risk of serum creatinine doubling (RR 0.53, CI 0.33-0.86). Quality of life outcomes were sparse. Dietary modification had uncertain effects on ESKD, CVEs, and mortality.

Conclusions: Dietary interventions in adults with CKD have potentially beneficial effects on chronic disease risk factors including serum cholesterol, blood pressure, and serum albumin levels, but have uncertain effects on patient-level outcomes such as CVEs, ESKD, mortality, and quality of life.

TH-PO750

Reproducibility of a Test-Battery for Physical Performance and Protein-Energy Wasting in Hemodialysis Patients Manouk Dam,[1] Peter Jm Weijs,[1] Caroline Douma,[2] Brigit C. van Jaarsveld.[3] *[1]Nutrition and Dietetics, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, Spaarne Gasthuis, Hoofddorp, Netherlands; [3]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.*

Background: The assessment of physical performance (PP) and protein-energy wasting (PEW) is hampered by large variability and controversy between researchers about which tests to use. Combining different tests is advocated, but variation in test outcomes has not been studied. We studied reproducibility of a test-battery for PP and PEW in HD pts.

Methods: Two measurements with 1-2 month interval, without interventions in-between, were performed by one investigator in 33 HD pts (2-4x/wk, 3-5 hr). PP was measured by the short physical performance battery (SPPB: gait speed, chair rises, balance), 6-min walk test, handgrip strength and 7-day physical activity monitor (PAM). PEW was measured by the visual analogue scale for appetite (VAS), subjective global assessment (SGA), mid-upper arm muscle circumference (MUAMC), fat free and fat mass measured with bio-electrical impedance. Reproducibility was assessed by paired t-tests and intraclass correlation coefficients.

Results: No differences were found between the 1st and 2nd measurement, apart from a slight increase in the SPPB:

Variables	1st measurement (mean±SD)	2nd measurement (mean±SD)	*P*	ICC*
SPPB (ranking 1-12)	8.2±2.6	9.4±1.7	<0.05	0.79
6-minute walk test (m)	350.2±138.0	351.8±116.0	NS	0.93
Handgrip strength (kg)	27.4±9.9	26.5±10.2	NS	0.96
PAM activity score	14.2±4.4	13.3±5.3	NS	0.47
VAS appetite (cm)	7.6±2.1	7.4±2.2	NS	0.43
SGA (score 1-7)	5.7±0.8	5.7±0.7	NS	0.81
MUAMC (cm)	25.1±5.0	25.5±3.7	NS	0.77
Fat free mass (kg)	36.1±8.4	36.9±8.2	NS	0.81
Fat mass (kg)	31.4±14.4	33.3±13.9	NS	0.83

*ICC:<0.40 poor, 0.40-0.59 fair, 0.60-0.75 good and ≥0.75 excellent correlation.

Conclusions: The proposed test-battery to assess PP and PEW in HD pts through a diversity of parameters shows excellent reproducibility of most components. SPPB revealed a possible learning effect, necessitating a second measurement of SPPB in order to avoid overestimation of the effect on physical performance.

TH-PO751

Prediction of LBM Using One Day Urinary Creatinine Excretion and Creatinine Clearance Rate in Non-Dialysis CKD Patients Tomohito Matsunaga. *Kidney Center, Eijinkai Hospital, Osaki, Miyagi, Japan.*

Background: The assessment of Lean body mass (LBM) is quite important to monitor the nutrition status of CKD patients. And it is well known that one day urinary creatinine excretion (UCE) reflects LBM (muscle mass) strongly. The purpose of this study is to predict LBM using one day urinary creatinine excretion and creatinine clearance rate in non-dialysis CKD patients.

Methods: UCE were measured by one day urinary collection in 35 non-dialysis CKD3-5 patients (27 males, 8 females; mean age 68.4±7.7 years; 12 DM patients). Ccr was calculated by UCE and Serum Creatinine, not collected body surface area. LBM was measured using BIA (Inbody 3.0).

Results: The mean levels of UCE, Ccr and BH (Body Height) were 0.969±0.215 g/day, 27.62±16.27 ml/min and 1.62±0.08m. LBM (45.54±7.55kg) was correlated with UCE and BH ($r=0.802$ $p<0.01$ and $r=0.903$ $p<0.01$, respectively) not correlated with Ccr. Multiple linear regression analysis showed that LBM was correlated with UCE, BH and Ccr ($r=0.960$ $p<0.01$). The obtained equation of regression was as follows: estimated LBM = 17.00 x UCE + 52.77 x BH – 0.09 x Ccr – 53.95. Estimated LBM was significantly correlated with measured by BIA ($r^2=0.922$, $p<0.01$).

Conclusions: These findings suggest that LBM can be predicted using UCE, BH and Ccr in non-dialysis CKD patient.

TH-PO752

Acute Effects of Nutritional Supplementation during Hemodialysis on Hemodynamics and Symptoms Brandon Kistler,[1,2] Annabel Biruete,[2] Jin Hee Jeong,[2] Peter J. Fitschen,[2] Kevin Heffernan,[3] Karen Chapman-Novakofski,[2] Talat Alp Ikizler,[4] Ken Wilund.[2] *[1]Ball State Univ, Muncie, IN; [2]Univ of Illinois, Urbana, IL; [3]Syracuse Univ, Syracuse, NY; [4]Vanderbilt Univ, Nashville, TN.*

Background: Due to the potential for hemodynamic instability following eating during hemodialysis (HD), many clinics have restricted food in favor of oral nutritional supplements (ONS). However, the effect of ONS on treatment hemodynamics has not been examined.

Methods: 11 HD patients (47±13 years, 73% male, 64% African American) underwent resting measures of cardiac function (ejection fraction, EF) and vascular structure (carotid intima-media thickness) via ultrasound, vascular function (aortic pulse wave velocity, PWV and augmentation index, AIx) via tonometry, blood pressure (BP), and autonomic function (heart rate variability, HRV and baroreceptor sensitivity, BRS) via plethysmography, followed by standard HD treatment with and without ONS (Nepro, Abbott). Beat-to-beat hemodynamics, gastrointestinal (GI) symptoms, and efficiency were measured throughout each treatment. The delta BP (lowest BP after ONS – Pre-ONS BP) was correlated with descriptive variables.

Results: There was no interaction between sessions for any hemodynamic measure ($p>0.05$ for all), but cardiac output ($p=0.04$) and heart rate ($p=0.05$) were higher throughout the ONS session. GI symptoms (Reflux, Abdominal Pain, Indigestion, Constipation, Diarrhea) and the reduction ratio of β2-microglobulin (ONS, 37.89 ± 15.63% vs. HD, 48.97 ± 18.62%) were not significantly different between ONS and HD ($p>0.05$ for all). Aortic PWV (9.0±1.1 m/s), AIx (21.1±10.9%), albumin (4.06±0.35 g/dL), IMT (0.62±0.13mm), EF (61.1±15.6%), and ultrafiltration (8.8±2.2 ml/kg/min) were not associated with delta BP following ONS. However, BRS (Down-Down, 9.30±7.08 ms/mmHg) was correlated with the change in systolic BP and mean BP ($r=.79$ and .71, respectively; $p<.05$).

Conclusions: We found minimal hemodynamic alterations, but no significant changes in GI symptoms or efficiency in response to a renal specific ONS during HD. Measures of autonomic function were associated with the maximum change in BP following ONS and should be a future target of research.

TH-PO753

Short-Term Potato Intake and Endothelial Function Lea Borgi, John P. Forman. *Medicine, Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: Recently, potatoes have been reintroduced into food packages for the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), and restrictions on potatoes from school lunches have been lifted. In their report, the Institute of Medicine stated that evidence for adverse health effects of potatoes is lacking. However, we published that increasing consumption of boiled, baked or mashed potatoes was independently associated with an increased risk of developing hypertension in three large prospective cohort studies of US women and men. The mechanisms underlying this association are still unclear. We hypothesized that the association of potatoes with hypertension may be mediated by endothelial dysfunction.

Methods: We performed a cross-sectional analysis using data obtained from the NIH-funded ongoing Modifiable Effectors of Renin System Activation Treatment Evaluation (MODERATE) trial. Dietary information and endothelial-dependent vasodilation (EDV, a measure of endothelial function using brachial artery ultrasound) were ascertained at baseline. We used multivariable linear regression to analyze the independent association of self-reported potato intake and EDV while controlling for multiple potential confounders.

Results: By the end of the trial, 209 participants underwent brachial artery ultrasound and reported potato intake over the previous day preceding EDV measurements. Compared with participants with no intake of potatoes, those who consumed one or more servings the day before had significantly worse endothelial function after adjusting for potential confounders (difference in EDV = -1.7%, p-value=0.01). By comparison, every 10 year increase in age was associated with a 1.2% lower EDV, indicating the important magnitude of the association between potatoes and EDV.

Conclusions: We found that short-term potato intake was associated with substantially worse endothelial function. These results support the hypothesis that endothelial dysfunction may be a potential mechanism underlying the association of potatoes with hypertension.

TH-PO754

Use of a Smartphone Application to Provide Dietary Feedback in Hemodialysis Patients - A Pilot Study Brendan T. Bowman, Mitchell H. Rosner, Elaine T. Mccall, Lesley Mcphatter. *Div of Nephrology, Univ of Virginia, Charlottesville, VA.*

Background: Hemodialysis (HD) patients are required to follow strict dietary regimens with limited phosphorus and potassium intake. Despite this, 40% of HD patients have phosphorous levels above current recommendations. The purpose of this study was to assess HD patients' ability to integrate mobile technology into nutrition self-care. We developed a smartphone app to provide phosphorous and potassium content reports to HD patients based on a photographic meal log.

Methods: We recruited 16 HD patients for a 90 day trial. Patients were asked to submit, via app, photos of all meals/snacks, a brief description, and number of binders taken. Photos were graded by the unit dietitian and a score report was provided to the patient within 48 hours. Weekly and monthly summary reports were also available and the app was integrated into care rounds. We collected demographic info, a pre & post nutrition survey, laboratory data, and app usage statistics.

Results: The app was loaded on 13 Android and iOS devices with three patients withdrawing prior to start. A total of 1022 meal photos were submitted with an avg of 79 per patient (0.87 reports/day/patient). Reporting compliance averaged 17% overall. Patients used the app an average of 58 days over the course of the trial. Lab review showed no definite trends overall. Among the six highest frequency users (> 50 photos submitted); however, four had significantly decreased phos levels compared to the preceding 90 days. The other two patients had decreased phos levels over the 90 days, though not to pre-trial levels. Potassium levels were unchanged.

Conclusions: This is the first trial of a smartphone based meal log and diet counseling app in HD patients. We believe this pilot demonstrates HD patients can integrate mobile apps into their nutrition counseling. The majority of patients submitted a significant number of meal photos over a sustained time period. Though lab data did not change overall, several patients showed > 10% improvement in phos, including the majority of the frequent use group.

ACF-TEI, a Novel Oral Uremic Toxin Adsorbent, Has Potent Adsorption Profiles and Reduces Serum Indoxyl Sulfate in Rodent Models of Chronic Kidney Disease Hiroshi Shimoyama, Yasumi Nishiwaki, Yoshimasa Takahashi, Tsunefumi Kobayashi. *Pharmaceutical Development Research Laboratories, TEIJIN Inst for Bio-Medical Research, TEIJIN Pharma Ltd., Tokyo, Japan.*

Background: Uremic toxins such as indoxyl sulfate (IS) accumulate in the blood of patients with impaired renal function. Since several observation studies have demonstrated a link between serum uremic toxin levels and clinical outcomes, they have much attention as key factors in the progression of chronic kidney diseases (CKDs) and cardiovascular diseases. Spherical activated carbon (AST-120) adsorbs uremic toxins secreted or produced in the intestinal tract and excretes them out of the body with feces. These functions are effective in improving symptoms of uremia and delaying the introduction of dialysis treatment for CKD patients. However, the oral adsorbents comprising AST-120 have insufficient adsorption performance and need to be taken at high daily doses. To improve their compliance and efficacy, we focused on active carbon fiber (ACF) and have identified a novel and potent oral uremic toxin adsorbent, ACF-TEI. In this study, we examined ACF-TEI *in vitro* adsorption profiles and *in vivo* effects on reducing serum IS.

Methods: As for the *in vitro* adsorption profiles of ACF-TEI, we examined the adsorption of indole, the precursor of IS in the intestinal tract, and digestive enzymes. To evaluate the *in vivo* effects, we orally administered ACF-TEI in normal mice and CKD model (bilateral nephrectomized and renal artery ligated) rats, and measured serum IS concentrations.

Results: Compared with AST-120, ACF-TEI showed more potent capacity and speed in adsorbing indole, whereas it had a low capacity to adsorb digestive enzymes to the same extent. In normal mice, ACF-TEI showed a higher effect of reducing serum IS than that of AST-120. Moreover, administered in CKD rats, ACF-TEI dose-dependently reduced the serum IS at lower doses than those of AST-120.

Conclusions: The adsorption capacity and efficiency of ACF-TEI were superior to AST-120. In addition, it was confirmed that ACF-TEI reduced the serum IS concentrations at lower doses than those of AST-120 in the CKD models. Thus, ACF-TEI is expected to show more beneficial effects than AST-120 in clinical.

TH-PO756

Folic Acid Supplementation Reduces the Concentrations of Uric Acid in Hypertensive Adults: A Predefined Sub-Study of the CSPPT Xianhui Qin,[1] Youbao Li,[1] Binyan Wang,[1] Genfu Tang,[2] Mingli He,[3] Delu Yin,[3] Yong Huo,[4] Xin Xu,[1] Fan Fan Hou.[1] *[1]Nanfang Hospital, Southern Medical Univ; National Clinical Research Center for Kidney Disease; [2]Anhui Medical Univ; [3]First People's Hospital, Lianyungang; [4]Peking Univ First Hospital.*

Background: We aimed to test the efficacy of folic acid therapy on reducing UA concentrations in a predefined sub-study of the China Stroke Primary Prevention Trial(CSPPT).

Methods: Eligible CSPPT patients, recruited from 20 communities in China, were randomly assigned to a double-blind daily treatment with a single tablet containing 10mg enalapril and 0.8mg folic acid(n=7685) or 10mg enalapril alone (n=7679).The main outcome was change in UA concentrations, defined as the UA level at the exit visit minus that at baseline. Secondary outcomes included:(1)controlled hyperuricemia; and (2)new-onset hyperuricemia in patients with normal baseline UA concentrations(<357μmol/L). Hyperuricemia was defined as a UA concentration≥417μmol/L in men or ≥357μmol/L in women. Controlled hyperuricemia was defined as a UA concentration<357μmol/L after treatment.

Results: Mean baseline UA were 293.9μmol/L. After a median treatment duration of 4.4 years, folic acid therapy significantly reduced the UA concentrations by a mean of 4.0μmol/L(95% CI:1.6-6.5,P<0.001). Moreover, folic acid therapy resulted in a significant increase in the adjusted odds of controlled hyperuricemia (30.3% vs 25.6%; OR:1.30;95%CI:1.00-1.68;P=0.046), and a significant decrease in the adjusted odds of new-onset hyperuricemia(15.0% vs 16.3%;0.88;0.78-0.99;P=0.040). More importantly, the largest reduction in UA concentrations was observed in the highest category of baseline homocysteine(Hcy) levels(P for interaction=0.020). Furthermore, there was a significantly negative association between Hcy reduction(Hcy at baseline minus that at the exit visit) and change in UA concentrations. After further adjustment for the reduction of Hcy, the effect of folic acid therapy on the reduction of UA was attenuated and insignificant (1.3μmol/L; -0.8, 3.5;P=0.219).

Conclusions: Folic acid supplementation can significantly reduce UA concentrations among hypertensive adults. The reduction of Hcy may be an important pathway to reduce UA concentrations.

Funding: Government Support - Non-U.S.

TH-PO757

Folic Acid Supplementation Reduces the Risk of Mortality Associated with Heavy Proteinuria: Findings from a Randomized Trial Youbao Li,[1] Xianhui Qin,[1] Binyan Wang,[1] Yong Huo,[2] Fan Fan Hou,[1] Xin Xu.[1] *[1]Nanfang Hospital, Southern Medical Univ; National Clinical Research Center for Kidney Disease; [2]Peking Univ First Hospital.*

Background: We aimed to evaluate whether baseline proteinuria and eGFR levels can modify the efficacy of folic acid supplementation on the risk of all-cause mortality in the China Stroke Primary Prevention Trial (CSPPT).

Methods: A total of 20,702 hypertensive patients without a history of major cardiovascular diseases were randomly assigned to double-blind daily treatment with a single tablet daily containing 10mg enalapril and 0.8mg folic acid (n=10,348) or 10mg enalapril alone (n=10,354).

Results: During median treatment duration of 4.5 years, in the enalapril alone group, both heavy proteinuria (versus normal, 10.8% *vs*. 2.7%; HR=3.30; 95%CI:2.10-5.18) and lower eGFR levels (<60 versus ≥90 mL/min/1.73m^2, 13.0% versus. 2.2%; 1.93; 1.19-3.12) were significantly associated with increased risk of all-cause mortality. Folic acid supplementation significantly reduced the risk of all-cause mortality in patients with heavy proteinuria(6.4% in the enalapril-folic acid versus 10.8% in the enalapril alone group, HR=0.49; 95%CI:0.26-0.94), but not in those with normal or mild proteinuria (2.8% versus. 2.9%,0.99;0.84-1.17; P for interaction=0.040).

	no. of events /no. of participants(%)				
	Enalapril	Enalapril-folic acid	HR (95%CI)	P Value	P for interaction
Overall	296/9675(3.1)	279/9674(2.9)	0.94(0.80-1.11)	0.486	
Proteinuria					
Heavy	24/223(10.8)	16/249(6.4)	0.49(0.26-0.94)	0.031	ref
Normal or mild	272/9452(2.9)	263/9425(2.8)	0.99(0.84-1.17)	0.908	0.040

However, eGFR levels did significantly modify the effect of folic acid supplementation in reducing the risk of all-cause mortality(P for interaction=0.228).

Conclusions: Among hypertensive patients without a history of major cardiovascular diseases, folic acid supplementation could reduce the mortality risk associated with heavy proteinuria.

Funding: Government Support - Non-U.S.

TH-PO758

Administration of IL-1ra Does Not Affect Carbamylation Load in Hemodialysis Patients

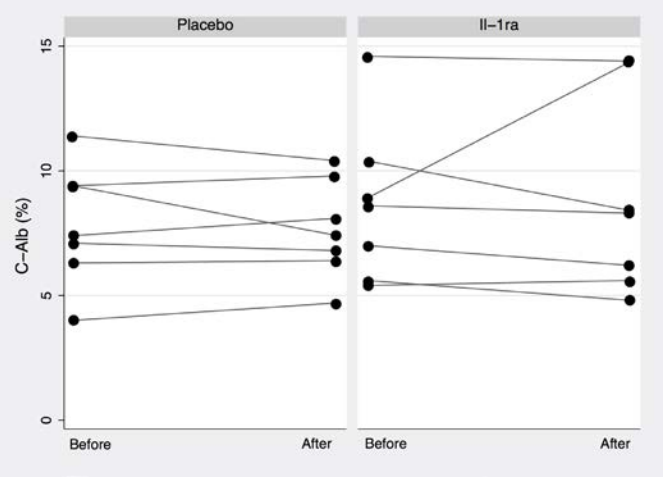
Charbel C. Khoury,[1] Adriana Hung,[2] Dihua Xu,[1] Eugene P. Rhee,[1] Talat Alp Ikizler,[2] Sahir Kalim.[1] *[1]Renal Div, Mass General Hospital; [2]Renal Div, Vanderbilt Univ Medical Center.*

Background: Protein carbamylation is strongly associated with cardiovascular complications in kidney disease and is a predictor of mortality in ESRD. This post-translational protein modification is largely driven by the nonenzymatic binding of isocyanate derived from urea. Recent reports also suggest inflammation as an alternative driver of carbamyaltion via myeloperoxidase-mediated catabolism of thiocyanate. We set out to determine whether anti-inflammatory therapy using an interleukin 1 receptor antagonist (IL-1ra) altered carbamylation burden as measured by carbamylated albumin (C-Alb) levels in ESRD patients.

Methods: This was a pilot randomized placebo-controlled trial of the administration of IL-1ra in chronically inflamed hemodialysis patients. 22 patients were randomly assigned to receive 100 mg of IL-1ra or placebo (1:1) for 4 weeks, and 14 completed the trial. The primary outcome was percent change in C-Alb and the secondary outcomes were changes in uremic metabolites captured by a metabolomics platform.

Results: The mean C-Alb change was not significantly different between the IL-1ra and placebo groups using ANCOVA models (p=0.89). This is despite a significant reduction in hsCRP and IL-6 in the IL-1ra arm. Furthermore there were no significant trends in several established uremic solutes including p-cresol sulfate, indoxyl sulfate, trimethylamine-N-oxide, symmetric- and asymmetric dimethylarginine, kynurenine and kynurenic acid.

Pre- and post-study levels of C-Alb(%) in individual study subjects



Conclusions: Administration of the immunosuppressant IL-1ra did not affect carbamylation load or levels of several uremic solutes despite significant decrease in inflammatory markers. In ESRD, inflammation may have a limited role in protein carbamylation burden. Further studies of longer duration and larger sample size are needed to confirm these findings.

TH-PO759

Effect of Diet Modification from 65% Animal-Based Protein to 70% Plant-Based Protein on Trimethylamine N-oxide (TMAO) Levels in Subjects with Stage 3-4 CKD

Catherine K. Yeung,[1,2] Jonathan Himmelfarb,[2] Sharon M. Moe,[3] Ranjani N. Moorthi.[3] *[1]Dept of Pharmacy, Univ of Washington, Seattle, WA; [2]Kidney Research Inst, Univ of Washington, Seattle, WA; [3]Div of Nephrology, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: Elevated levels of circulating pro-atherogenic uremic solutes, particularly trimethylamine N-oxide (TMAO), have been implicated in cardiovascular disease development in patients with chronic kidney disease (CKD). TMAO and precursor choline are generated from dietary phosphatidylcholine which is abundant in animal-derived high-fat foods.

Methods: We conducted a dietary intervention study in 13 subjects with stage 3-4 CKD (median GFR=26 (IQR 14.7) ml/min/1.73m^2). Protein in the baseline diet was 65% animal-based. During the 4-week study, subjects consumed a diet with 70% of dietary protein from plants and 30% protein from animals (meat, dairy, eggs), provided by the Indiana Clinical Research Institute. Plasma samples at baseline (week 0), and at 2 and 4 weeks on the study diet were analyzed for levels of TMAO and choline.

Results: Mean concentrations of both choline and TMAO trended down following diet modification; however these changes did not reach statistical significance. Concentrations of choline at 0, 2, and 4 weeks were 2.7±1.3 µg/mL, 2.5±1.4 µg/mL, and 2.2±0.6 µg/mL (p=0.22). Concentrations of TMAO at 0, 2, and 4 weeks were 2.8±3.7 µg/mL, 1.5±1.0 µg/mL, and 1.7±0.9 µg/mL (p=0.29).

Conclusions: The results of this small pilot study in patients with CKD suggest that diet modification with 70% of dietary protein from plant sources may reduce systemic concentrations of TMAO, which may be associated with increased cardiovascular risk. A larger study is warranted in order to determine if modest dietary modification can reduce TMAO concentrations in this population or if non-dietary sources of TMAO in uremia or decreased clearance prevail regardless of diet.

Implementation of a Motivational Interviewing Program to Improve Patient Engagement within a Large Dialysis Organization

Deborah A. Benner,[1] Susan W. Butterworth,[2] Sharon Brandl,[1] Jane J. Wheeler,[1] Becky Brosch.[1] *[1]DaVita Inc, Denver, CO; [2]Q-consult LLC, St. Petersburg, FL.*

Background: Engaging Patients In their Care (EPIC) is a program within a large dialysis organization (LDO) that provides training in patient-centered motivational interviewing (MI) techniques to dietitians, with the goal of fostering improved patient engagement. A small-scale pilot of the program demonstrated improvements in dietitians' proficiency in MI techniques and measurable improvements in measures of patients' phosphorus control following program completion. However, the complexity of the skill-set and the commitment level needed to build and maintain proficiency in MI are significant and we sought to assess whether the program could be successfully implemented on a larger scale across the LDO.

Methods: The EPIC program was launched LDO-wide in 2015, reaching over 1800 dietitians. Program participation involved attendance at a 1-day intensive MI training session and recorded skill-building sessions were conducted with MI experts before and after training completion. Certified MI experts used a validated, standardized assessment system to objectively measure dietitians' proficiency in MI techniques of partnering, evoking, expressing empathy, guiding, supporting activation, reflection, and strategically responding to change talk. Total MI Scores (a combination of 7 global scores) at baseline and after program completion were compared using paired-samples t-tests.

Results: Among dietitians who have completed the MI training workshop and all skill-building sessions to date (N = 639), total MI scores were significantly higher following program completion compared to baseline. Mean total MI scores were 4.35 [SD, 0.84] at baseline and 6.39 [SD, 1.01] after program completion; ($t = -10.12$, $P < 0.001$; Wilcoxon Signed-Rank test $z = -5.240$, $P < 0.001$).

Conclusions: Our findings demonstrate that a complex MI-based program can be implemented effectively across an LDO, with participating dietitians achieving levels of MI proficiency similar to those observed in the program pilot. Analyses to evaluate the impact of LDO-wide program implementation on patient engagement and clinical outcomes are ongoing.

TH-PO761

Impact of Low-Protein Diet on Protein-Energy Wasting in Diabetic CKD Patients

Vincenzo Bellizzi,[1] Patrizia Calella,[1] Silvia Moran,[2] Julia Nava,[2] Rafael Montufar.[2] *[1]Div of Nephrology, Dialysis & Transplantation, Univ Hospital, Salerno, SA, Italy; [2]Centro de Atención Nutricional, Fresenius Kabi México, Ciudad de México, Mexico.*

Background: Nutritional impact of low-protein diet (LPD) in diabetics with CKD (DM) is uncertain. We evaluated the effects of LPD supplemented with ketoacids on protein-energy wasting (PEW) in DM with moderate to advanced CKD.

Methods: 81 DM and 116 controls (CON) with CKD stages 3/5 were prescribed a LPD (0.5-0.6 g protein/kg/d), normal-high energy (30-35 kcal/kg/d) supplemented with ketoacids (Ketosteril®, 1 tab/5-7 kg/d) for at least 6 months. Metabolic status, nutrition and body composition were evaluated.

Results: DM and CON were comparable for gender (Male 59 vs 55%), age (66±9 vs 63±18 y) and renal function (eGFR 23±13 vs 24±13 mL/'). Serum urea (0/6 mo: DM 131±58 to 105±49 mg/dl, p<.05; CON 115±52 to 88±36, p<.05) and phosphate (0/6 mo: DM 4.5±1.3 to 4.1±1.2 mg/dl, p=.07; CON 4.3±1.0 to 3.7±0.8, p<.05) reduced; fasting glucose declined in DM (0/6 mo: 122±54 to 103±29 mg/dl, p<.05) without changes in insulin dose. These effects were maintained after 3 years. Serum albumin did not change in short (DM 3.7±0.6 to 3.8±0.4 mg/dl; CON 4.0±0.6 to 4.0±0.4) and long-term. Body weight (BW) (DM 68.9±14.3 kg; CON 66.6±15.1) soon declined (6 mo: DM to 65.1±12.1 kg, p<.05; CON to 64.1±15.1, p<.05) and then remained stable for 3 years. BW decline was associated with reduction of body water (-1 Lt, p<.05), fat mass (FM; -1 kg, p<.05) at 6 months; after 3 years FM was reduced (-2 kg, p<.05). Low BMI (<23 kg/m^2) and albumin (< 3.8 g/dl) were present in 30% patients at baseline and did not change during the study; cholesterol (<100 mg/dl) was always normal in all patients; low FM (<10%) prevalence raised (0/3 y: DM 14 to 60 %, p<.05; CON, 5 to 39, p<.05). Muscle strength (DM 20.8±7.9 kg; CON 25.0±7.8) did not changed at 6 month and 3 year time.

Conclusions: In DM with moderate to advanced CKD a low protein ketodiet while allowing adequate metabolic control, causes sudden BW decline which remains stable thereafter; muscle mass and muscle fitness remain stable too, while fat mass declines. No differences vs. non-diabetic CKD controls are observed.

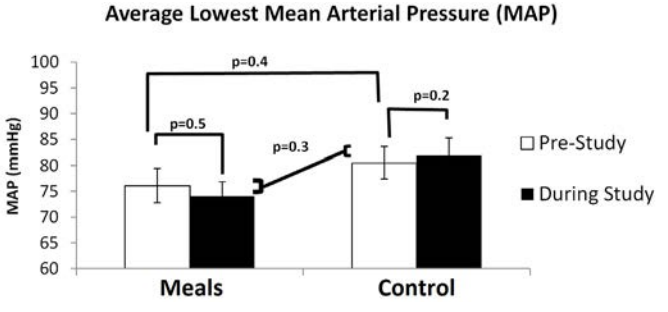
TH-PO762

Effect of High Protein Meals during Hemodialysis on Intradialytic Hypotension Mun Sun Choi,[1] Amy Wright,[1] Ranjani N. Moorthi,[2] Sharon M. Moe,[2] Kathleen M. Hill Gallant.[1] *[1]Nutrition Science, Purdue Univ, W. Lafayette, IN; [2]Nephrology, Indiana Univ School of Medicine, Indpls, IN.*

Background: High protein (PRO) meals during hemodialysis (HD) may help prevent PRO-energy wasting. However, eating during HD is often discouraged in US dialysis centers due to possible adverse events, particularly postprandial hypotension. The aim of this pilot study was to determine the effects of high PRO meals during HD on symptomatic intradialytic hypotension (SH).

Methods: 18 HD patients (N=9/group) were recruited from 2 shifts (~10AM-2PM, MWF&TTS) at 1 dialysis center for a 9-wk, non-randomized, parallel arm study. Patients received meals with 30g PRO & KDOQI guidelines for Na, K, P, & fluid, or a control social interaction at each session. Blood pressure data were collected 2mo pre-study and during study. Differences within groups for 2mo pre-study vs during study were determined by Wilcoxon signed-rank/paired t-test, and between group differences were determined by Wilcoxon rank-sum/unpaired t-test.

Results: Patients were 62±16y old, 55% female, and had dialyzed for 3.4±2.6y. In the meal group, there were 4 SH in 3 patients over 25 dialysis sessions pre-study and 12 SH in 4 patients over 25 dialysis sessions during study; in controls, there was 1 SH in 1 patient pre-study and 5 SH in 4 patients during study. Change between pre-study and during study SH was not significant for either group, both p>0.2. Average lowest MAP was not different, Fig. When asked "How interested would you be in receiving nutritious meals during dialysis?", 70% of patients responded ≥4 (5-pt scale, 5=very interested; p=NS between groups).



Conclusions: These pilot data suggest that meals during HD do not increase the frequency of SH, and patients generally have positive attitudes towards receiving meals. Larger, long-term studies are needed to confirm these results along with effects on nutritional and clinical outcomes.

TH-PO763

Effect of Low Phosphate Diet Education and Phosphate Binder Education among Maintenance Hemodialysis Patients: A Randomized Controlled Trial Eunsoo Lim, Yujeong Kim, Gyu Tae Shin, Heungsoo Kim, Inwhee Park, Jong Cheol Jeong. *Dept of Nephrology, Ajou Univ Hospital, Suwon, Kyeonggi, Korea.*

Background: Among dialysis patients, hyperphosphatemia is associated with hyperparathyroidism, mineral bone disorder and increased incidence of cardiovascular diseases. Thus, dietary education and proper intake of phosphate binder is essential.

Methods: We randomized 70 patients into education group(n=48) and control group(n=22). Phosphate binder intake education was given by pharmacists, and nutritional consultation by dietitians. Drug compliance was assessed by Morisky Medication Adherence Scales-4(MMAS-4) and bioequivalent dosage of prescribed phosphate binder. The patients' knowledge of when to take phosphate binder was assessed by questionnaire and nutritional status by using Patient-Generated Subjective Global Assessment(PG-SGA).

Results: Baseline characteristics of two groups were similar. Primary goal was the proportion of patients who reached calcium-phosphorus product lower than 55. Among education group, 36(75%) patients achieved primary goal, compared to the 16(72.7%) of control group(*P*=0.430). The improvement of MMAS-8 score were not different between education and control group(for short term,0.26±1.12 vs 0.02±1.30,education vs. control,*P*=0.445. for long term,0.11±1.17 vs 0.30±1.29,*P*=0.555).Education non-significantly increased patients' knowledge of when to take phosphate binder(22.9% vs. 3.5%,education vs. control,*P*=0.347), and it didn't affect the amount of dietary phosphate intake per body weight(-1.18±3.54 vs. -0.88±2.04 mg/kg,education vs. control,*P*=0.851). However, it decreased dietary phosphate to protein ratio(-0.64±2.04 vs. 0.65±3.55,education vs. control,*P*=0.193). Education on phosphate restriction did not affect the PG-SGA(0.17±4.58 vs. -0.86±3.86,education vs. control,*P*=0.363), nor dietary protein intake(-0.03±0.33 vs. -0.09±0.18,education vs. control,*P*=0.569).

Conclusions: Education didn't affect the calcium phosphate product compared with control group. However, education corrected timing of phosphate binder intake and lowered dietary phosphate to protein ratio, although it wasn't statistically significant. These findings imply the importance of educational effort.

Effects of Probiotic Supplementation on Trimethylamine-N-Oxide Plasma Levels in Chronic Kidney Disease Patients Denise Mafra,[1] Natalia Alvarenga Borges,[1] Cristiane Moraes,[1] Milena Barcza Stockler-Pinto,[1] Peter Bergman,[2] Peter Stenvinkel.[2] *[1]Federal Univ Fluminense, Brazil; [2]Karolinska Inst, Sweden.*

Background: Components present in the diet can be metabolized by gut microbiota to produce metabolites like trimethylamine-N-oxide (TMAO) that play a role in cardiovascular disease in CKD patients. The objective of this study was evaluate the effects of probiotic supplementation on TMAO plasma levels in hemodialysis patients.

Methods: A randomized, double-blind trial was performed in 21 HD patients [54.8 ± 10.4 years old, 9 men, BMI 26.1 ±4.8 kg/m^2, dialysis vintage 68.5 (34.2 – 120.7) months]. Ten patients were randomly allocated to the placebo group and 11 to the probiotic group (3 capsules, with 90 billion of colony forming units per day of S. *thermophilus*, L. *acidophilus*, and B. *longum*). Plasma TMAO, choline, and betaine levels were measured at baseline and after 3 months with LC-MS/MS.

Results: The averageof TMAO, choline, and betaine plasma levels did not change after supplementation.

	Placebo Group (N= 10)		***Probiotic Group (N=11)***	
	Baseline	***Post***	***Baseline***	***Post***
Uremic toxins				
TMAO (ng/µl)	8.8 ± 4.6	6.2 ±1.9	7.4 ± 4.4	7.2 ± 4.7
Choline (ng/µl)	10.0 ±1.8	9.8 ±2.2[a]	11.4 ±2.4	12.6 ±2.7
Betaine (ng/µl)	4.3 ±2.0	4.1 ±1.6	4.5 ± 1.6	5.4 ±1.7
Biochemical parameters				
CRP (mg/dL)	3.8 (1.2 – 9.5)	2.7 (1.3 – 7.0)	3.7 (1.6 – 6.7)	5.7 (2.6 – 12.3)
Urea (mg/dL)	159.7 ± 55.3	168.3 ± 29.8	156.0± 39.0	164.4± 53.2
Hematocrite (%)	34.8 ± 5.4	33.0 ± 5.5	33,7 ±2.8	31.4 ±3.1[a]
Hemoglobin (g/dL)	11.2 ± 1.6	11.0 ± 1.6	10.9 ±1.4	10.4 ±1.7

The % of changes in the plasma levels of betaine and choline were higher in probiotic group when compared to placebo [choline - probiotic group: 2.6% (- 9.5 – 46.0) *vs* placebo group: -10.0 % (-18.7 – -0.4), p=0.03; betaine - probiotic group: 37.2% (-14.3 – 80.9) vs placebo group: 1.1% (-16.0 – 19.1), p=0.04.].

Conclusions: Short-term probiotic supplementation does not appear to influence TMAO, choline, and betaine levels in HD patients.

TH-PO765

Prediction of Fractures among Older Kidney Transplant Recipients Mara McAdams-DeMarco, Sunjae Bae, Dorry L. Segev. *Johns Hopkins.*

Background: Kidney transplantation is a growing treatment option for older adults with ESRD. Fracture risk is elevated in ESRD patients who undergo KT compared to waitlist candidates. While previous studies have identified risk factors for fractures after KT, we sought to create a post-KT fracture prediction model based on pre-transplant factors.

Methods: We studied older (aged >=55) KT recipients who were Medicare Primary (between 1/1/99-12/31/11) using SRTR data linked to Medicare claims. We estimated the cumulative incidence of a fracture (based on claims) using the Kaplan-Meier method. We developed a prediction model based on recipient, transplant and donor factors known prior to KT for the post-KT incidence of fracture using an AIC-based selection method for the Cox proportional hazards model.

Results: Using national data on 41,145 older KT recipients, we estimated the post-KT cumulative incidence of fractures to be 7.9% at 5 years and 17.4% at 10 years. We identified recipient, donor and transplant factors as predictors of post-KT fractures (C-statistic=0.65).

Predictor	HR (95% CI)	p-value
Age (5 year change)	1.18 (1.14-1.23)	<0.001
Female	1.54 (1.41-1.68)	<0.001
White Race	1.81 (1.65-1.98)	<0.001
Diabetes	2.21 (2.02-2.42)	<0.001
BMI (kg/m^2)		
<18.5	1.88 (1.35-2.63)	<0.001
25-30	1.35 (1.19-1.49)	<0.001
30-25	1.12 (1.01-1.25)	0.03
>35	Reference	
Year of KT (1 year change)	0.96 (0.95-0.98)	<0.001
Donor type		
Live	Reference	
Deceased Standard Criteria	1.12 (1.01-1.25)	0.04
ECD	1.26 (1.11-1.43)	<0.001
DCD	1.21 (0.97-1.50)	0.09
Peak PRA<80	1.14 (0.97-1.32)	0.10

Conclusions: The cumulative incidence of fractures increases to 17.4% 10 years after KT for older recipients. Recipient, donor and transplant factors obtained prior to KT can be used to predict which older recipients are at risk of post-KT fracture.

Funding: Other NIH Support - NIA, Private Foundation Support

TH-PO766

A Prospective, Randomized, Controlled Study of Cholecalciferol Supplementation in Kidney Transplant Recipients - Preliminary Results at 30 Months Cristina Jorge,[1] Teresa Adragao,[1] Patrícia Matias,[1] Margarida Bruges,[1] Rita Birne,[1] Ivo Laranjinha,[1] Jorge Azinheira,[2] Maria João Andrade,[3] Andre L. Weigert,[1] Domingos Machado.[1] *[1]Nephrology, CHLO - HSC; [2]Clinical Pathology, CHLO - HSFX; [3]Cardiology, CHLO - HSC, Portugal.*

Background: The benefits of nutritional vitD supplementation in KTR are not well defined.

Methods: We prospectively followed a group of KTR randomly allocated to receive cholecalciferol (4000 IU/day: GD, n=73) or no therapy (GC, n=68). Comparison was performed with the T test, Mann Whitney U or chi-square test; survival was analyzed through Kaplan-Meier test.

Results: The 2 groups were similar in gender (male: 57,4% vs 56,2%), age distribution (mean 51 vs 52 years), dialysis vintage (mean 46 vs 53 months(m)), cold ischemia time (average 18h17min vs 18h43min), PRA (0% of median in 2 groups), time since KT (median 46 vs. 48,5 m) and major comorbidities, respectively in GD vs. GC. Basal calcidiol levels were similar in both groups (18,7 vs. 19,1 ng/ml) and so were eGFR (EPI) (67,4 vs 63,3 mL/min/1.73 m2), Hb (12, 8 vs 13 g/dl), CRP (0,5 vs. 0,61mg/dl), iPTH (107 vs 119 pg/ml), alkaline phosphatase (72 vs 77 U/L), phosphate (P) (3.7 vs. 3.5 mg/dl) or magnesium (1.7 vs. 1.8 mg/dl) levels. However, basal serum calcium (9,8 vs. 10,2 mg/dl) was significantly lower in GD. We found a significant increase in the levels of calcidiol (ng/ml) at 6m (39,7 vs. 22,1), 12m (40,7 vs 22,1), 18m (40,6 vs 22,7), 24m (42,1 vs 22,2) and at 30m (43,5 vs 21,1), with no significant increase of calcemia, but with significant reduction in iPTH (pg/ml) at 6m (81 vs. 112), 12m (87 vs 103), 24m (76 vs 97,5) and at 30m (64,2 vs 98,6) in GD versus GC. There were no differences between the 2 groups in the evolution of excretion fraction of Ca, P, or Mg, in the urine protein/creatinine ratio, pulse pressure, left ventricular mass índex or hospitalizations. Treatment with antihypertensives (including ACEI or ARBs), active vitD or cinacalcet was similar between the 2 groups. There were no differences in graft or patient survival.

Conclusions: The dose of 4000 IU/day of cholecalciferol was safe and allowed to rise calcidiol levels of GD and reduce iPTH at 6,12, 24 and 30 months compared with the control group, without other significant results so far.

TH-PO767

FGF23/Klotho System and Vitamin D Receptor Activation in Kidney Transplant Recipients Javier Donate,[1] Fernando Henríquez-Palop,[2] Ernesto Martín,[1] Nayra Pérez-Delgado,[1] Anabel Rodriguez,[1] Carlos Marín,[1] Mercedes Muros de Fuentes,[1] Carmen Mora,[1] Juan F. Navarro-Gonzalez.[1] *[1]Univ Hospital Nuestra Señora de Candelaria (Santa Cruz de Tenerife); [2]Univ Hospital Dr. Negrin (Las Palmas de Gran Canaria).*

Background: Recent studies have demonstrated the usefulness of paricalcitol for the treatment of secondary hyperparathyroidism (SHPT) in kidney transplant recipients, also suggesting beneficial pleiotropic effects. The aim of this study was to analyze the influence of selective activation of the vitamin D receptor (VDR) on the FGF-23/KLOTHO system.

Methods: Twenty-nine renal transplant patients with iPTH >100 pg/mL were treated with oral paricalcitol (1 µg/day) for 3 months. A group of 8 patients matched for age, sex and renal function with iPTH <100 pg/mL was included as controls. Serum concentrations of FGF-23 and KLOTHO were measured by ELISA, and gene expression levels of KLOTHO (KL) were analyzed in peripheral blood mononuclear cells (PBMCs) as reflect of renal expression levels. Promoter methylation of KL was also studied.

Results: iPTH decreased in paricalcitol-treated patients (p<0.0001). Serum FGF-23 enhanced (p<0.01), whereas KLOTHO concentrations showed a trend to increase (p=0.067). KLOTHO gene expression in PBMCs increased by 45.7% in paricalcitol-treated patients (p<0.01), without change in controls. Paricalcitol administration resulted in a median percent decrease of 56% in methylated DNA levels of KLOTHO promoter (p<0.001). The ratio of un-methylated/methylated KLOTHO promoter DNA did not change in controls, but it increased by 177% in paricalcitol-treated subjects (p<0.0001). The increase in the un-methylated/methylated KLOTHO promoter ratio was independently associated with the change in serum KLOTHO (r=0.55, p<0.01) and mRNA expression levels (r = 0.40, p<0.05).

Conclusions: Paricalcitol induces an increase in KLOTHO gene expression and serum Klotho concentrations, which is significant and independently associated with a rise in the ratio of un-methylated/methylated KLOTHO promoter DNA. Long-term studies are needed to assess whether this effect may translate into beneficial clinical effects.

Funding: Government Support - Non-U.S.

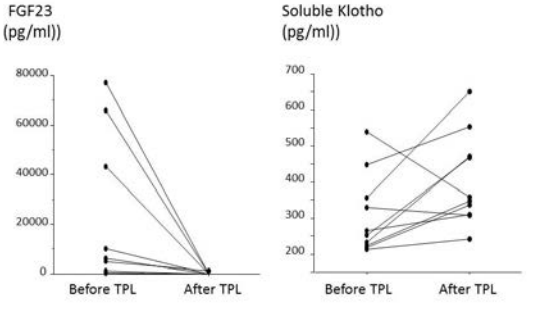
TH-PO768

Serum Levels of Soluble Klotho and Fibroblast Growth Factor-23 Changes after Renal Transplantation Yukiko Hasuike, Kosuke Mizusaki, Yuki Morikami, Yasuyuki Nagasawa, Takeshi Nakanishi. *Div Kidney and Dialysis, Dept Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: Data on serum soluble Klotho levels in chronic kidney disease after renal transplantation (TPL) are contradictory. The effects of renal TPL on serum levels of soluble Klotho and fibroblast growth factor (FGF)-23 in the recipients after TPL were investigated.

Methods: Ten renal transplant recipients underwent serum soluble Klotho (ELISA, IBL Co.,), FGF-23 (ELISA, Kinos Co.,), and 25-OH vitamin D level measurements before TPL and 1-year after TPL were examined. Correlations between serum soluble Klotho and FGF-23, vitamin D, and the other factors were also investigated.

Results: Mean age of 41.8±15.9 years. After TPL, serum level of soluble Klotho was significantly higher and FGF-23 was significantly lower than before TPL (p = 0.0469, p = 0.0051, respectively).



Vitamin D levels were not different between before and after of TPL. Serum level of soluble Klotho after TPL had a significant negative correlation with age (r = -0.721, p = 0.0187) while FGF-23 nor 25-OH vitamin D were not.

Conclusions: Serum level of soluble Klotho after TPL was associated with age. Further studies are needed to define a change of soluble Klotho level in renal TPL recipients.

TH-PO769

Urinary Calcium Excretion and Risk of Graft Failure and Mortality in Renal Transplant Recipients Jacob M. Taylor, Lyanne M. Kieneker, Else van den Berg, Martin H. De Borst, Stefan P. Berger, Jan-Stephan Sanders, Ron T. Gansevoort, Stephan J.L. Bakker. *Internal Medicine, Univ of Groningen, UMCG, Groningen, Netherlands.*

Background: Calcium and vitamin D supplementation are often prescribed to help improve bone health in renal transplant recipients (RTRs). However, high levels of urinary calcium excretion (UCaE) have been shown to increase the risk for nephrolithiasis and nephrocalcinosis. Furthermore, calcium supplements may increase the risk for cardiovascular disease. Therefore, we investigated whether high UCaE increases the risk of graft failure and mortality in a cohort of RTRs.

Methods: Urine samples were collected in a single-center, longitudinal cohort of 691 RTRs with a functioning graft for at least one year (baseline). UCa concentration was performed on a 24-hour specimen at baseline by indirect potentiometry. UCaE was measured as a continuous variable and grouped according to event-based tertiles of UCaE. UCaE was compared to graft failure (defined as restarting dialysis or re-transplantation) and mortality during follow-up.

Results: Baseline median UCaE was 95 mg/24h (interquartile range [IQR]: 46-156 mg/24h), similar between males and females. A total of 44 events of graft failure and 81 events of mortality were identified in the cohort during a median follow-up of 3.13 years (IQR: 2.66-3.87 years). After multivariable adjustment, no association was observed between UCaE and risk of graft failure during follow-up (HR: 0.88 [0.61-1.29], p=0.52, for every 1 log unit increase in UCaE). Surprisingly, an inverse association between UCaE and mortality was present (HR: 0.68 [0.53-0.88], p=0.003), with the highest risk in the tertile of subjects with the lowest UCaE. When further adjusting for other dietary factors associated with poor nutrition, a trend remained (HR: 0.79 [0.59-1.07], p=0.13), although formal statistical significance was lost.

Conclusions: High UCaE was not associated with an increased risk of graft failure or mortality in RTRs. These data do not provide evidence that calcium supplementation is harmful in RTRs.

Direct-Acting Antivirals for the Treatment of Hepatitis C Virus Infection in Kidney Transplant Recipients: A Multicenter Study
Carmen Gonzalez Corvillo, Miguel Angel Gentil Govantes, Ana Sanchez Fructuoso, Auxiliadora Mazuecos. *Nephrology, Grupo Español de Actualización en Trasplante, Spain.*

Background: HCV is a relevant negative prognosis factor for graft and transplant recipient survival.New direct-acting antivirals(DAA)allow us to solve this problem in an effective way.It is crucial to know their real impact in our daily practice.

Methods: Observational,retrospective and prospective study.We analyze treatment results with DAA,in kidney transplant(KT)recipients from 15 hospitals,regarding effectiveness,tolerance and impact on immunosuppression and renal function-proteinuria in a short-medium term.

Results: Until March 2016,119 KT recipients were included(9combined liver-kidney transplants).69.7%male;average age 54.2±9yo;KT length 11.4±10years. More than 50%showed stage 3-4 chronic kidney disease.Immunosuppressive therapies:tacrolimus(70%) or cyclosporine(18%)with MMF(76%).Predominant genotype was 1b(68.1%),1a(13.8%),3(7.8 %),4(6%) and 2(4.3%);51% had grade 3-4 of fibrosis,17%portal hypertension.The main DAA used was sofosbuvir(91%)combined with ledipasvir(55%),simeprevir(14%)or daclatasvir(13%);in 9 cases(7%)the combination of paritaprevir-ritonavir-ombitasvir-dasabuvir(3D)was employed;18% were treated with Ribavirin as coadjuvant.Side effects were limited,23.5 %,and without relevance,except for anemia caused by Ribavirin.2 patients interrupted the treatment,due to neurotoxicity caused by the interaction between 3D and tacrolimus and anemia caused by Ribavirin(both had virological response).All the patients that completed the treatment(94)are alive and show virological response in 95.6% of cases.Liver function analysis improved:74%normal vs 21%before the treatment(p<0.001).Renal function and proteinuria did not change significantly.Tacrolimus level at the end was lower with respect to the beginning(5.8±2.1 vs 7.4±1.8ng/ml,p=0.03),in spite of a slight increase in the dose(2.6 vs 2.3mg/day p=0.17).

Conclusions: DAA are highly effective in KT patients,with good tolerance,making it possible to solve the problem and having a good chance to improve the prognosis in our patients.The use of DAA in these patients requires special control and coordination with hepatologists,especially when 3D or Ribavirin is used.

TH-PO771

The Combination of Sofosbuvir Ribavirin and Interferon for Hepatitis C Virus Treatment Increases Access to Kidney Transplantation
Himanshu V. Patel, Vivek Balkrishna Kute, Minaxi Patel, Pankaj R. Shah. *Nephrology and Transplant, IKDRCITS, Ahmedabad, India.*

Background: HCV-infected renal transplant recipients have worse patient and allograft survival after transplantation compared with non-infected renal transplant recipients. However, HCV-infected patients have a lower mortality following transplantation compared with mortality on dialysis. HCV infection is not considered a contraindication to transplantation. The current AASLD and ISDA HCV guidelines state that Sofosbuvir -containing regimens can be considered for patients with CrCl < 30 mL/ min with expert consultation, as efficacy and safety data are not yet available.

Methods: We used in 22 ESRD patients (19 males and 3 females) on dialysis a combination of Sofosbuvir (400mg alternate day), Injection PEG-INF 2a 135 mcg subcutaneous once a week and ribavirin (200Mg once a day) for 12 weeks.

Results: Mean baseline HCV-RNA (QUANTITATIVE) was 409523.6 copies/ml. All patients has HCV genotype 1. HCVRNA by reverse transcription polymerase chain reaction (RT-PCR) was less than detected in 4, 8 and 12 weeks in 81.8 %(n=18), 90.9%(n=20) and 100% (n=22). All the patients had stable hemoglobin with optimization of iron, erythropoietin and anemia therapy. Blood transfusion was given in 3 patients. There have been no serious adverse events reported and no treatment-related discontinuations thus far. 8 Patients underwent kidney transplantation when HCV RNA was negative and post –transplant they were continued on combination of Sofosbuvir , and ribavirin (200Mg once a day) to complete therapy. There was no interaction with levels of tacrolimus and immune injury. There was no reactivation of HCV after completion of therapy after transplantation.

Conclusions: combination of Sofosbuvir , Injection PEG-INF 2a 135 and ribavirin for 12 weeks is safe and effective for treatment of HCV infection in CKD patients on dialysis however, frequent monitoring is warranted for patients with severe renal impairment. The combination of Sofosbuvir and ribavirin is safe and effective after kidney transplantation. Final results from this study will need to be confirmed before further recommendations can be made.

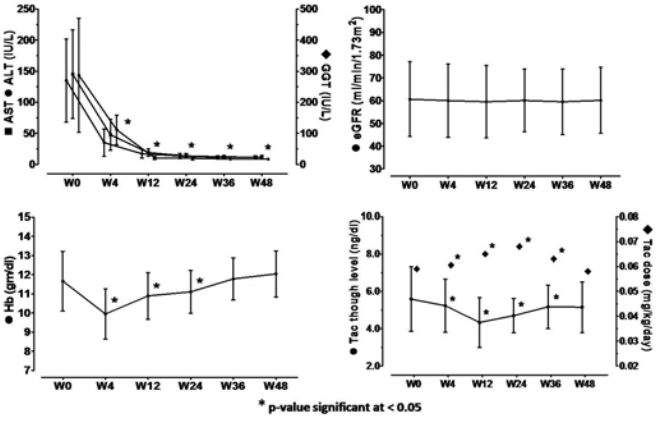
TH-PO772

Direct Acting Anti-Viral Agents in Post Renal Transplant Hepatitis C Virus infection: Efficacy and Safety
Narayan Prasad, Manas Ranjan Patel, Akhilesh Jaiswal, Dharmendra Bhadauria, Raj K. Sharma, Amit Gupta. *Dept of Nephrology, SGPGIMS, Lucknow, India.*

Background: Hepatitis C (HCV) infection in renal allograft recipient is associated with increased morbidity and mortality. Direct acting antiviral agents (DAAs) are highly effective in HCV infected liver transplant patients; however there is paucity of data on use of DDAs in renal transplant. We aimed to study the efficacy and safety of sofosbuvir based regimens to treat HCV in renal allograft recipients.

Methods: All HCV infected renal allograft recipients (n=68, 5.4%) between January 2005 to December 2015 (n=1254) were screened for HCV virus replication by PCR. Of them 28 showed active HCV replication (range 96425-24175475copies logsIU/mL) and 22 (14 genotype3;6 genotype1 and one each 2 and 4) were included in the study after exclusion of 6 patients(3 with eGFR < 30ml/min/1.73m^2, 1 with hepatic decompensation and 2 for no consent).

Results: 14 patients completed 24 weeks of treatment with dual drug (sofosbuvir and ribavirin; genotype 3, n=10; genotype 1, n=2; genotype 2, n=1; and genotype 4, n=1). Subsequently with availability newer DAAs, either daclatasvir (genotype 3, n=4 and genotype 1, n=1)or ledipasvir (genotype 1, n=3) was added to above regimen in eight patients (i.e. triple drug for a minimum of 12 weeks).A virological response with undetectable virus (i.e. Rapid 92%, End therapy 100%, and sustained VR12 of 100% and 24 of 100%) was seen in all patients.The changes in liver enzymes AST,ALT and GGT; hemoglobin, trough tacrolimus, and eGFR changes on follow up is shown in figure 1.



The treatment was well tolerated except fall in Hb and one required blood transfusion and 3 required EPO. Tacrolimus dose was increased in 10 and decreased in 2 to achieve required trough level. All had sustained remission at end of one year followup.

Conclusions: DDAs are safe and effective therapy for treatment of replicating HCV post kidney transplantation.

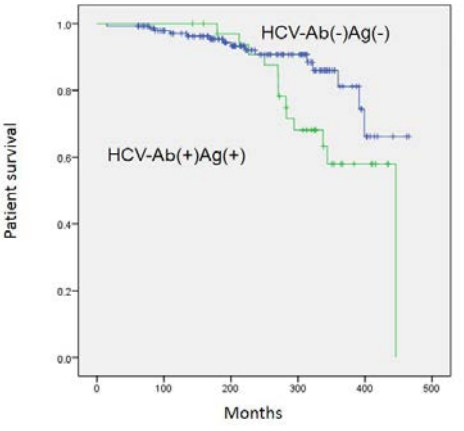
The Long-Term Outcome of Hepatitis C Viral Core Antigen-Positive Japanese Renal Allograft Recipients
Kazuaki Okino, Yuki Okushi, Kiyotaka Mukai, Keiji Fujimoto, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama. *Nephrology, Kanazawa Medical Univ School of Medicine, Kanazawa, Ishikawa, Japan.*

Background: The impact of hepatitis C virus (HCV) infection on patient survival after renal transplantation was controversial.

Methods: To clarify the long-term outcome of Japanese renal allograft recipients with HCV infection, we studied 187 cases (118 males, 69 females; 155 living-donor cases, 32 cadaveric-donor cases; mean follow-up period 249 months ranging from 0 to 466 months) who underwent the first renal transplantation in Kanazawa Medical University since 1974.

Results: In this cohort, 35 cases (18.7%) were HCV core antigen-positive, and 13 out of them (37%) were dead by liver cirrhosis (4 cases), hepatocellular carcinoma (1 case), and infections complicated with chronic hepatitis (6 cases) in chronic phase, and fibrosing cholestatic hepatitis due to HCV (1 case) after surgery. On the other hand, only 15 out of 146 (10%) recipients were lost in HCV- both core antigen and antibody negative group. The patient survival rate was significantly lower in HCV core antigen-positive group by Kaplan-Meier life table method (Log Rank test, Kay-square 4.242, p=0.039). Survival rate of HCV core antigen-positive recipients decreased rapidly 240 months after renal transplantation.



In addition, HCV core antigen-positive was a most important independent risk factor for survival times after renal transplantation by Cox proportional hazard model (Wald 6.254, p=0.012) as compared with age, gender, type of donors, serum creatinine levels on renal transplantation one year later, and Immunosuppressive therapy.

Conclusions: Continuous HCV infection was a harmful risk factor for the patient survival, especially 20 years after renal transplantation.

TH-PO774

Transplanting Hepatitis C Virus Infected Kidneys into Hepatitis C Positive Recipients in the Direct Acting Antiviral Agents Era
Juan E. Kusnir, Adriana Dejman, Kalyan Bhamidimarri, Fernando E. Pedraza, Marco A. LadinoAvellaneda, David Roth. *Medicine/Nephrology, Univ of Miami/VAMC, Miami, FL.*

Background: The availability of direct acting antivirals (DAAs) has changed the treatment of hepatitis C virus (HCV) infection. The decision to treat a HCV positive patient before or after transplant has important ramifications for patients in the deceased donor waiting list. Effective treatment can now be administered in the post-transplant period allowing for HCV infected kidneys to be allocated to HCV infected recipients. Potential benefits include significant decrease in waiting list time translating into long term benefits of decreased time on hemodialysis. Yet many questions regarding the treatment, adverse effects and potential complications remain unknown.

Methods: In this observational study of 21 HCV positive patients receiving a HCV positive kidney allograft, we reviewed the outcomes of post-transplant HCV treatment with DAAs during the 12 week treatment period. The 21 patients received induction with thymoglobulin and basiliximab, and maintenance immunosuppression with tacrolimus and mycophenolate mofetil. All patients started DAAs 60-90 days after transplant and were on Sofosbuvir with the following combinations: 13 patients on ledipasvir and ribavirin, 5 patients on ledipasvir, 1 patient on daclatasvir, 1 patient on simeprevir and 1 patient on ribavirin.

Results: The mean time on the list for these patients was 116 days. All patients that completed the prescribed DAA therapy achieved a sustained virologic response at 12 weeks (SVR12). Four patients were complicated by antibody mediated rejection while on therapy. Tacrolimus dose adjustments were required in 10 patients to maintain therapeutic levels. The response to DAA therapy was similar to that reported in the general population.

Conclusions: Accepting a kidney from a HCV positive donor dramatically reduces wait time for kidney transplantation. Complications including allograft rejection and variable tacrolimus levels will require closer monitoring of these patients and more intense immunosuppression dose adjustments. Further research into this unique population is needed to obtain better understanding and thus optimize patient care.

Treatment of Hepatitis C in Kidney Transplant Recipients with Directly Acting Antiviral Agents
Michelle Lubetzky, Maria Ajaimy, Layla Kamal, Maria Coco, Enver Akalin, Graciela De Boccardo. *Montefiore Transplant Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: With the development of new all oral, interferon-free directly acting antiviral (DAA) medications, treatment of Hepatitis C infection (HCV) in renal transplant recipients is possible, but limited data exists on its safety and efficacy.

Methods: We performed a retrospective cohort analysis of patients transplanted at our center with HCV who have been started on DAAs. Primary endpoints included sustained virologic response (SVR) as defined as negative viral load at 12 weeks post completion of therapy and allograft function.

Results: A total of 31 patients met inclusion criteria. The most commonly used regimen was sofosbuvir and ledipasvir (n=21). Upon completion of therapy, 100% had undetectable viral load. Of the 23 patients with at least 12 weeks of follow up after completion of therapy 95.7% achieved SVR. Both graft and patient survival at most recent follow up was 100%, although 2 patients now have GFR <20 ml/min/BSA. A total of 6/31 (19.3%) patients had worsening proteinuria during or shortly after therapy. Patients with more than 500mg/g of proteinuria were significantly more likely to develop worsening proteinuria than those without proteinuria at the start of therapy (p<0.001).

Conclusions: Our data demonstrates that DAAs are effective in treating HCV in patients after kidney transplantation. Patients with proteinuria and/or decreased GFR should be monitored closely.

	Prior to Therapy	After Therapy	P value
Creatinine mg/dl	1.3 ± 0.4	1.4 ± 0.5	0.25
GFR (MDRD) ml/ min/BSA	64.2±16.5	58.9±17.5	0.22
Proteinuria mg/g	0.66 ± 1.2	1.1 ± 2.0	0.10
Class I PRA	19.8 ±30.5	14.3 ± 27.5	0.45
Class II PRA	31.3±37.6	17.7 ± 34.4	0.13
AST	52.7 ±51.5	21.5±10.9	0.002
Platelets	197.8 ±75.0	216.5±73.7	0.5
Viral load	8450646.32 ±18282133.63	0	<0.001
Tacrolimus level ng/mL	6.2±1.7	6.2±2.5 (done 4-8 weeks after starting therapy)	P=0.9

TH-PO776

Sofosbuvir Based Therapy for HCV Infection in Post Renal Transplant Recipients
Vivek Pathak. *Nephrology, Kovai Medical Center and Hospital, Coimbatore, Tamil-Nadu, India.*

Background: The purpose of this study was to assess the efficacy and safety of an interferon free Sofosbuvir therapy to treat HCV infection in kidney transplant recipients .

Methods: We used sofosbuvir based therapy in 33 post transplant patients. Treatment was given for 24 weeks. Sofosbuvir and Ribavarin were given for 10, Sofosbuvir and Ledipasvir for 18 and Sofosbuvir and Daclatasavir for 3 patients.24 were suffering from genotype 1 , 07 were suffering from genotype 3 and 02 were suffering from genotype 4 infection. The median time between transplant and the start of anti HCV therapy was 60 months. They all received steroid free immunosuppression based on Tacrolimus and MMF.

Results: All the patients became negative for HCV RNA and those who were tested 12 weeks after cessation of therapy remained negative .Only one patient with genotype 1 had relapsed after stopping the treatment and he also responded well to Sofosbuvir and Ledipasvir combination. HCV infection causes significant post kidney transplant effects like new onset diabtes mellitus, Cryoglobulinaemia, chronic liver disease and infection related deaths. Sofosbuvir based therapy was found to be safe and no interaction was noted with Tacrolimus.There was no acute rejection or graft loss during the treatment. One patient required increase in Tacrolimus dose following remission of HCV infection. Mean SGPT was 74 IU/ml before and 20 IU/ml after therapy. There were 5 new onset diabetes mellitus in this group and 4 improved subsequently and anti diabetic agents were discontinued.Two patients with cirrhosis and ascites showed reversal and ascites disappeared and fibroscan became normal.There were no adverse side effects with this drug except fall in haemoglobin in those who received Ribavarin. One patient developed fungal brain abcess during the tratment but responded well to surgical drainage and Amphotericin.

Conclusions: Sofosbuvir based therapy induced remmission in 100% patients, reversed diabtes in 4 out of 5 patients and chronic liver disease with ascites in 2 patients without putting the graft at any risk. We will reduce the treatment duration to 3 months now.

TH-PO777

Short Term Effects of Hepatitis C Virus Clearance Using Direct Acting Antivirals on Markers of Glomerular Damage in Kidney Transplant Patients
Michael Reed Goetsch,[1] Ricardo Franco,[2] Ashutosh Tamhane,[2] Mohit Varshney,[2] Anuj Kapil,[2] Edgar Turner Overton,[2] Graham Towns.[3] *[1]School of Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [2]Dept of Medicine, Div of Infectious Diseases, School of Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [3]Dept of Medicine, Div of Nephrology, School of Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Hepatitis C Virus (HCV) is an independent risk factor for chronic kidney disease progression, end stage renal disease, and poorer kidney graft survival. The role of HCV clearance in long-term kidney graft survival is unknown. In this study, we examined the short-term impact of direct acting antivirals (DAAs) on markers of glomerular damage in kidney allografts.

Methods: We conducted a retrospective study of kidney transplant patients with chronic HCV infection seen at the University of Alabama at Birmingham 1917 Viral Hepatitis Clinic between January 2013 and June 2016. Of the 23 patients identified, 16 had received DAA treatment. Two patients who had achieved HCV cure were excluded due to 1) antibody mediated rejection related to low levels of immunosuppression post HCV treatment; and 2) self-limited, unexplained proteinuria post HCV treatment. Glomerular damage was assessed using serial protein/creatinine (P/C) ratios measured pre- and post- treatment.

Results: The median age of the 14 patients included was 59 years (Q1=57, Q3=64). Of these patients, 64% were African American, 36% were white, and 64% were male. Post-treatment P/C ratios (median 0.107, Q1=0.081, Q3=0.151) were significantly lower (p=0.001) than the pre-treatment ratios (median=0.176, Q1=0.165, Q3=0.385). P/C ratios decreased in 12 out of 14 patients (86%) with an absolute median decrease of 0.118 (median percent decrease=50%).

Conclusions: In this preliminary study, there was a significant trend of decrease in P/C ratios associated with HCV clearance. These results suggest a promising role for DAAs and viral clearance in improving short-term kidney graft survival. In the future, larger cohort studies will be needed to assess the long-term benefits of DAAs in this population of HCV-infected patients.

TH-PO778

Effectiveness of Direct-Acting Antivirals in Hepatitis C Infected Post-Kidney Transplant Recipients
Michelle T. Martin, Darby Rosenfeld, Grace E. Go, Todd Lee, Maya Campara, Ignatius Yun-Sang Tang. *Univ of Illinois at Chicago.*

Background: The American Association for the Study of Liver Diseases guidelines recommend the use of specific regimens for liver transplant recipients with hepatitis C virus (HCV), but do not address the treatment of HCV infected recipients of kidney alone, liver/kidney, or kidney/pancreas transplants. The objective of this study was to gain knowledge on HCV treatment response in kidney transplant recipients (KTRs).

Methods: This was a retrospective, single-center analysis of KTRs who started HCV treatment between January 1, 2014 and February 3, 2016. Electronic medical records of

patients taking direct acting antiviral (DAA) regimens of sofosbuvir + ribavirin, sofosbuvir + simeprevir, or ledipasvir/sofosbuvir + ribavirin were reviewed for demographics and laboratory values. The primary endpoint was the sustained virologic response (SVR) at 12 weeks after treatment completion.

Results: Thirty KTR patients were treated for HCV; 9 were excluded: 4 had not yet reached 12 weeks after treatment, and 5 were lost to follow-up due to transfer of care. The remaining 21 patients had a mean age of 58.3±7.3 years; 17(81%) were male, 13(62%) Black, 11(52%) cirrhotic, 12(57%) had genotype 1a, 8(38%) had 1b, and 1(5%) had 1e/1g. There were 5(24%) liver/kidney, 13(62%) kidney alone, and 3(14%) kidney/pancreas transplant patients. Eighteen (86%) patients received tacrolimus, 13(62%) had diabetes, and 13(62%) had a BMI <30 kg/m^2. During HCV treatment, immunosuppression dosage did not change for 15(71%) patients, it was increased for 2 patients, decreased for 3 patients, and changed in both directions for 1 patient. Twenty of 21 patients (95%) achieved SVR. No difference in SVR rate was found in treatment naïve or experienced (100% vs 86%, p=0.33), cirrhotic or non-cirrhotic (89% vs. 100%, p=0.429), or non-obese or obese (100% vs. 88%, p=0.99) patients. The SVR did not differ by regimen, genotype, gender, ethnicity, age, diabetes, or insurance (p>0.05).

Conclusions: DAA regimens were highly effective in KTRs. SVR did not differ by treatment or demographics; comparison across groups was limited due to small numbers. Immunosuppressive levels should be monitored closely with HCV treatment.

TH-PO779

Hepatitis B Virus(HBV) Re-Activation in HBsAg- and HBsAb-Negative and HBcAb-Positive (sAg-sAb-cAb+) Kidney Transplantation(KT) Recipients

Jae Wan Jeon, Hyosang Kim, Soon Bae Kim. *Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: According to the Korean Dialysis Registry, 5.0% of hemodialysis patients were positive for HBV. Patients who received immunosuppressive treatment commonly face the risk of HBV reactivation. sAg-sAb-cAb+ can be interpreted as low-level hepatitis B carrier or hepatitis B in remote past. European Association for the Study of the Liver Clinical Practice Guideline recommended that HBsAg-negative, anti-HBc positive patients with undetectable serum HBV DNA and regardless of anti-HBs status who receive chemotherapy and/or immunosuppression should be followed carefully by means of ALT and HBV DNA testing. However, evidences supporting these recommendations are scarce. This study was performed to evaluate the incidence of HBV reactivation in sAg-sAb-cAb+ KT recipient.

Methods: From February 1997 to March 2015, 178 sAg-sAb-cAb+ patients (M:F 130:48, 47.7+10.9 years) received KT. Forty seven patients had diabetic nephropathy. Median duration of follow-up was 83 (6~226) months. We checked liver function test (LFT) on every visit. HBsAg was rechecked in 101 patients (reason for recheck: 17 with abnormal LFT, 84 routine check) during the follow-up period.

Results: HBV reactivation was found in 6 (3.4%, 5 with abnormal LFT, 1 routine check, M:F 4:2, 50.0+7.3 years) at median 72 (8~121) months. One patient died of hepatic failure, two showed persistence of HBV DNA and three experienced HBsAg seroclearance with antiviral therapy. LFT of the 5 survivors were all normal at the final visit. Biopsy-proven acute rejection was found in 36 and Rituximab was used in 15. Fifty patients received transfusion. Eighteen patients died and graft failure was reported in 26 patients. HBV reactivation was not associated with presence of diabetic nephropathy, acute rejection, use of Rituximab, transfusion, donor HBV markers, graft failure or death.

Conclusions: We recommend LFT on every visit and HBsAg in every year in sAg-sAb-cAb+ KT recipients, however, not regular HBV DNA titer because of low incidence and high cost.

TH-PO780

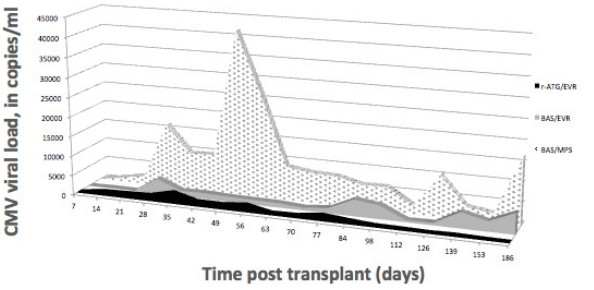
Kinetics of Cytomegalovirus Viral Load in Kidney Transplant Recipients Receiving Everolimus or Mycophenolate Sodium and No Pharmacological Prophylaxis

Geovana Basso, Alexandra Ferreira Brígido, Mayara I. Paula, Marina Pontello Cristelli, Helio Tedesco-Silva, J. Medina-Pestana, Claudia Felipe Rosso. *Hospital do Rim, SP, SP, Brazil.*

Background: Cytomegalovirus (CMV) infection is associated with morbidity and mortality after transplantation. Studies have shown that the use of mammalian target of rapamycin inhibitors are associated with lower rates of CMV infection.

Methods: The purpose is to investigate the **kinetics of CMV viral load** in kidney transplant recipients receiving tacrolimus (TAC) + everolimus (EVR) or mycophenolate sodium (MPS) and no CMV pharmacological prophylaxis. This is a comparative analysis of a **prospective**, single-center trial, in which **288** kidney transplanted patients were **randomized** to receive a single 3mg/kg dose of antithymocyte globulin, TAC, EVR and prednisone (r-ATG/EVR, n=85); basiliximab, TAC, EVR and prednisone (BAS/EVR, n=102); or BAS, TAC, MPS and prednisone (BAS/MPS, n=101). They were monitored with weekly pp65 antigenemia. CMV infection/disease were treated with intravenous ganciclovir. In a blinded fashion, samples were collected for **quantitative nucleic acid testing** (QNAT, in-house method).

Results: The incidence of first CMV infection/disease was 4.7, 10.8 and 37.6% in r-ATG/EVR, BAS/EVR and BAS/MPS (p<0.001) and the mean viral load in was 828, 1878 and 10.123 copies/ml, respectively.



Although r-ATG/EVR group had the same proportion of patients with at least one positive QNAT as BAS/MPS group (75.3 vs. 73.3%, p<0.01), the mean viral load was significantly lower in both everolimus groups (r-ATG/EVR vs. BAS/EVR, p=0.326; r-ATG/EVR and BAS/EVR vs. BAS/MPS, p<0.01).

Conclusions: The use of EVR was associated with lower incidence of CMV infection/disease and lower viral load compared to MPS. The use of r-ATG induction may have contributed to a higher proportion of patients with one episode of viremia, although its effect on vital replication was transient and mild.

TH-PO781

Adenovirus Nephritis in Kidney Transplant Recipients: Clinicopathologic Features and Correlation

Max Rollins,[1] Amy L. Adams,[2] Thomas E. Rogers,[1] Alton Brad Farris,[1] Carla L. Ellis.[1] *[1]Pathology, Emory Univ, Atlanta, GA; [2]Pathology, Dekalb Medical Center, Atlanta, GA.*

Background: Adenoviruses (AdV) are increasingly being recognized as emerging pathogens and causes of substantial morbidity in stem cell and solid-organ transplant recipients. AdV are double-stranded DNA viruses that have a reported prevalence of infection during the 1st year after kidney transplantation of 11% by urine culture and 6.5% by serum PCR. In kidney transplant recipients, certain clinical and histologic features should raise concern for adenovirus nephritis (ADN). Here we report 9 renal biopsies with ADN from seven kidney transplant recipients.

Methods: A retrospective search to identify cases of ADN in renal transplant recipients was performed.

Results: Nine biopsy reports were identified (2009-2016) from among seven patients. The median time from transplant to development of ADN was 52 days (range: 13-1,414 days). Clinically, macrohematuria was observed in 71% (5/7) of the patients, microscopic hematuria in all patients (n=7) and significant proteinuria in all patients (n=7). Serum creatinine increased by a median of 56.5% from baseline (range: 26.3%-190%). Histologically, interstitial inflammation was present in 100% (9/9), granulomas were identified in 44% (4/9), tubular epithelial necrosis was present in 78% (7/9), nuclear inclusions were seen in 22% (2/9), and obliterative tubulitis was present in 56% (5/9). Immunostaining for adenovirus showed tubular epithelial cell reactivity in 100% (9/9).

Conclusions: Granulomas and inclusions are not identified consistently and thus make the diagnosis of ADN versus acute cellular rejection difficult. Immunostaining for adenovirus is the most important diagnostic tool when clear-cut histological features of ADN are not present on the biopsy sample. Overall, a strong emphasis on the clinical presentation should be used to help with the diagnosis. Based on this review, we advocate for adenovirus immunostaining on any renal biopsy when a patient presents (especially within 1 year from time of transplant) with gross or microscopic hematuria, and histological findings of intense interstitial inflammation, obliterative tubulitis, or granulomatous inflammation.

TH-PO782

Incidence of Infection following Rituximab Use in Kidney Transplant Recipients

Lana Wong, Michael G. Ison, Chad Richardson, Aneesha A. Shetty. *Northwestern Memorial Hospital, Chicago, IL.*

Background: Rituximab is used off-label in solid organ transplant for desensitization and treatment of antibody-mediated rejection (AMR). It targets CD20 and results in B cell depletion. Although it may be beneficial in preventing or fighting rejection, it may be associated with unfavorable infectious outcomes. The purpose of this study was to evaluate the incidence of infection in kidney transplant recipients who received rituximab for desensitization or AMR treatment.

Methods: This was a single-center, retrospective analysis of living and deceased donor kidney transplant recipients at Northwestern Memorial Hospital from January 1, 2007 to October 1, 2015. The following were inclusion criteria: alemtuzumab induction; age 18 years or older; receipt of at least one dose of rituximab. Patients were excluded for: previous transplant; simultaneous organ transplants; rituximab for an oncologic indication; history of human immunodeficiency virus. The primary efficacy endpoint was incidence of infection over 1 year following first dose of rituximab. Secondary endpoints were patient and graft survival 1 year following first dose of rituximab.

Results: Of the 145 subjects included, 114 (79%) received rituximab for desensitization and 31 (21%) for treatment of AMR. Overall, there were 34 cases of fungal and viral infections. The primary endpoint is shown in table 1. Five patients had death-censored graft failure and 8 patients died within the study period, 2 which were attributed to sepsis. A sub-analysis comparing those who received rituximab for desensitization versus AMR revealed no significant difference in incidence of infection, patient survival or graft survival.

Incidence of Infection (n=145)	
Number of patients with infection, n (%)	27 (19.0%)
Incidence of viral infection CMV Viremia, n (%) BK Viremia, n (%)	 15 (10%) 17 (12%)
Incidence of fungal infection	2 (1.4%)
Overall cases of infection	34

Conclusions: Approximately 19% of patients receiving rituximab experienced a fungal or viral infection. Graft failure occurred in 3% and death occurred in 6% of patients. There were no significant differences in outcomes for patients receiving rituximab for desensitization or AMR.

TH-PO783

Post-Transplant Anemia in Kidney Transplant Recipients: Prevalence, Risk Factors, and Outcomes Venkat Sainaresh Vellanki, Pei Xuan Chen, Olusegun Famure, Yanhong Li, Joseph Kim. *Div of Nephrology and the Kidney Transplant Program, Toronto General Hospital, Univ Health Network, Univ of Toronto, Toronto, ON, Canada.*

Background: This study aims to evaluate the association between post-transplant anemia (PTA) and adverse outcomes such as cardiovascular diseases (CVDs) and total graft failure (i.e., return to chronic dialysis, preemptive re-transplant, or death with graft function) in kidney transplant recipients (KTRs).

Methods: This cohort study examined all KTRs at Toronto General Hospital from 1-Jan-2000 to 31-Dec-2013 with the development of PTA, defined as a hemoglobin level of < 11.0 g/dL. The main study endpoints were cardiovascular events and total graft failure. The study baseline was set at 3-months after transplantation. Time-fixed and time-dependent multivariable Cox proportional hazards models were used to assess the independent association of PTA with the study endpoints.

Results: A total of 1,175 (61.7% male) KTRs were included in the study. The prevalence of anemia at three-months post-transplant was 53.7%. In the time-fixed model, PTA at baseline was not associated with cardiovascular events while there was increased risk of total graft failure (HR 1.50 [95% CI: 1.10, 2.06]). In the time-dependent model, PTA was significantly associated with both cardiovascular events (HR 2.13 [95% CI: 1.51, 3.00]) and total graft failure (HR 4.39 [95% CI: 3.18, 6.03]).

Conclusions: PTA is a significant independent risk factor for cardiovascular events and total graft failure in KTRs, particularly in statistical models that properly account for the time-dependent nature of anemia.

TH-PO784

Clinical Characteristics of Parvovirus B19 Infection in Kidney Transplant Patients Chung Hee Baek, Hyosang Kim, Su-Kil Park. *Div of Nephrology, Dept of Internal Medicine, Asan Medical Center.*

Background: Parvovirus B19 is a small, nonenveloped, single-stranded DNA virus with special affinity for the erythroid progenitor cells of the bone marrow. The first case of parvovirus B19 infection(PVI) in kidney a transplant(KT) recipient was reported in 1986. Since then, the data about risk factors and specific clinical characteristics of PVI are still insufficient.

Methods: We identified PVI among all 4,392 KT recipients by parvovirus B19 polymerase chain reaction(PCR) from January 1990 to April 2016, and the clinical characteristics of patients with positive results were compared with those of age and sex-matched patients with negative results by PCR.

Results: Total 39 KT recipients showed positive parvovirus B19 PCR, and they were compared with age and sex-matched 78 patients among 563 KT recipients showed negative PCR results. The 89.7% of positive parvovirus B19 PCR was reported within the first year of KT. Bone marrow biopsies were performed in 13 patients with compatible bone marrow changes of parvovirus infection and positive parvovirus B19 PCR in bone marrow specimens. The 74.4% of patients with positive parvovirus B19 PCR were treated with intravenous immunoglobulin, and all patients were recovered from anemia. In multivariate analysis, parvovirus B19 PCR performed within 1 year of KT [relative risk(RR) 17.139, 95% confidence interval(CI) 3.989-73.641, P<0.001], deceased donor KT (RR 6.896, 95% CI 1.625–29.261, P=0.009) and hemoglobin level at the time of PCR (RR 0.438, 95% CI 0.295–0.649, P<0.001) were significantly related with positive parvovirus B19 PCR. Pancytopenia showed a trend of relation (RR 4.756, 95% CI 0.932–24.257, P=0.061). In addition, the use of tacrolimus showed a significant relationship with PVI in univariate analysis (RR 4.270, 95% CI 1.889–9.651, P<0.001), but the significance was lost in multivariate analysis. Graft survival of two groups were not different during follow up period of 111.68±54.54 months (P=0.685 by log rank test).

Conclusions: The related factors of positive parvovirus B19 PCR might be useful for suspicion and early detection of parvovirus B19 infection. Further studies are necessary to elucidate the characteristics of parvovirus B19 infection in KT.

TH-PO785

Pure Red Cell Aplasia Related to Human Parvovirus B19 Infection in Kidney Transplant Recipients: A Single Center Experience Yan Jiang, Zhechi He, Rending Wang, Jingyi Zhou, Jianghua Chen. *The First Affiliated Hospital of Zhejiang Univ, Zhejiang Univ, Hangzhou, Zhejiang Province, China.*

Background: To investigate the incidence, clinical manifestation, diagnosis and treatment of pure red cell aplasia (PRCA) related to human parvovirusB19 (HPV-B19) infection in kidney transplant recipients.

Methods: This is a retrospective cohort study of all patients who underwent kidney transplantation between January 2010 and December 2014 at kidney disease center, the first afflicted hospital of Zhejiang university. PRCA is defined by the absence of mature erythroid precursors in the bone marrow with normal white blood cell and platelet count (or deep reticulocytopeniain peripheral blood in the absence of other possible causes).We used standard real-time polymerase chain reaction (PCR) amplification to detect HPV B19 in serum sample. The clinical data of HPV-B19 PRCA patients were collected and analyzed retrospective.

Results: In the past 5 years, of 813 kidney transplant recipients, 26(3.2%) were diagnosed with HPV-B19 PRCA at a median of 46 days(range, 21days-2years) posttransplantaion. All 26 patients had severe anemia with the mean lowest hemoglobin count of 58.3±10.1 g/L.6 patients (23.1%) experienced graft dysfunction (creatitine elevation) at HPV-B19 PRCA diagnosis. 25 of 26 patients received intravenous immunoglobulin (IVIG) treatment after diagnosis. Transient serum creatinine elevating during IVIG treatment was observed in 23.1% patients.MMF was discontinued in 20(77%) patients to reduce the degree of immunosuppression. 88.3% of patients were switched from FK to CSA.Scarnet sodium was used in 5 patients as antiviral regimen (combination with IVIG in 4 patients and used alone in 1 patients).For these 25 patients who received IVIG-based comprehensive treatment, 19(80%) patients achieved long term remission after first course of IVIG treatment. 7 patients experienced HPV B19 PRCA relapse and responded well to additional IVIG courses with or withoutscarnet sodium. All 26 patients are alive with functional graft kidney at the end of follow up.

Conclusions: HPV-B19 PRCA is a rare but significant disease after kidney transplantation. Treatment with IVIG is effective in most cases.

TH-PO786

Metabolic Acidosis and Outcome in Patients Long Term after Kidney Transplantation Marcin Adamczak, Damian Gojowy, Katarzyna Skiba, Magdalena Bartmanska, Aureliusz Kolonko, Andrzej Wiecek. *Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland.*

Background: Metabolic acidosis (MA) frequently occurs in patients after kidney transplantation (KTx). Results of both experimental and clinical studies suggest that MA may contribute to faster progression of native kidney disease. It is unknown however whether or not such relationship occurs also in KTx patients. The aim of this clinical, single center, retrospective, observational study was to examine the relationship between MA and both mortality and renal outcomes in patients after KTx.

Methods: Four hundred eighty six (290 male; 196 female) patients aged 48 ± 12 years at least one year after KTx were analyzed. Blood HCO_3^- were measured and subsequently patients were observed during 3 years. MA was defined as the blood HCO_3^- concentration less than 22 mmol/L. The endpoints in survival curves analysis were death and initiation of dialysis therapy. In patients who did not reach above mentioned endpoints the difference between final (after 3 years follow-up) and initial eGFR was calculated (according to the MDRD formula). Relative risks (RR) were presented with 95% CI.

Results: MA was diagnosed in 57 (12%) patients being long term after KTx. In patients with MA the risks of death and initiation of dialysis therapy were significantly higher than in patients without MA [RR=4.11 (1,58-10,67), p=0.0038 and RR=3.58 (3,58-6,32), p<0.001; respectively]. In KTx patients with MA who did not reach above mentioned outcomes blood bicarbonate concentration at baseline correlated positively with change of eGFR values (R=0.48, p=0.002, n=36). Such correlation was not found in patients without MA (n=386).

Conclusions: 1. MA increases mortality and worsens graft survival in patients after KTx. 2. The intensity of MA is associated with faster progression of kidney dysfunction in KTx patients.

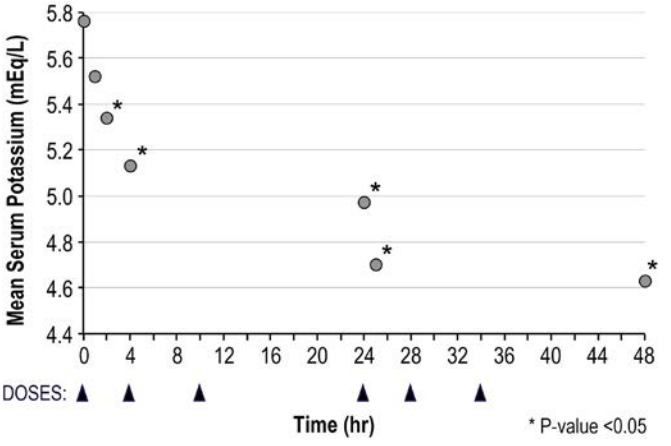
Sodium Zirconium Cyclosilicate Treatment of Hyperkalemia in CKD Patients with a Solid Organ Transplant: Data from Two Trials Mohamed A. El-Shahawy,[1] Edgar V. Lerma,[2] Wajeh Y. Qunibi,[3] Bhupinder Singh,[4] Jose A. Menoyo,[4] Henrik S. Rasmussen.[4] *[1]Academic Medical Research Inst, Los Angeles, CA; [2]Univ of Illinois at Chicago College of Medicine, Advocate Christ Medical Center, Oak Lawn, IL; [3]Univ of Texas Health Science Center at San Antonio, San Antonio, TX; [4]ZS Pharma, San Mateo, CA.*

Background: Sodium zirconium cyclosilicate (ZS-9) is a non-absorbed, selective cation trap that binds potassium (K^+) throughout the GI tract. The effects of ZS-9 in patients (pts) with a solid organ transplant have not been previously reported. This subgroup post-hoc analysis assessed the effects of ZS-9 in transplant pts with hyperkalemia (HK).

Methods: Data were pooled from two completed phase 3 prospective, randomized, placebo-controlled trials: ZS-003 and HARMONIZE. Both trials had an induction phase, where pts received 10g ZS-9 TID for 48h, and a maintenance phase.

Results: In the ZS-003 and HARMONIZE studies, 9 CKD pts had previously undergone solid organ transplants (5 kidney, 3 liver, 1 dual kidney/liver) and were receiving various immunosuppressive therapies including calcineurin inhibitors, antiproliferative agents and corticosteroids; 4 pts had heart failure and diabetes, and 5 were on RAASi therapy. Mean serum K^+ declined from 5.76 mEq/L at baseline to 4.63 mEq/L at 48h in these pts (figure); 67% and 100% of pts achieved normal serum K^+ by 24h and 48h, respectively. Median time to serum K^+ normalization was 4.0 h. None of the transplant pts experienced an adverse event (AE) during the induction phase. In the overall pt population who received 10g ZS-9 during the induction phase (n=401), the most common AEs were GI disorders (3.7%).

Figure. Mean Serum K^+ Over Time in Transplant Pts.



Conclusions: ZS-9 appeared to restore K^+ to the normal range in transplant pts with HK; the response to ZS-9 in these pts appeared to be similar to that observed in the general pt population in the trials.

Effect of Renal Transplantation on Carotid Intimal Medial Thickness and Left Ventricular Mass Index-A Longitudinal Study Sandeep Mahajan, Sucheta Yadav, Yogesh Kumar Chhabra. *Nephrology, A.I.I.M.S, Delhi, India.*

Background: Various nontraditional risk factors (NTRFs) and increased left ventricular mass index (LVMI) have been implicated for high cardiovascular (CV) mortality in CKD. Renal transplantation (RT) by correcting uremic milieu improves most NTRFs, however CV mortality remains high post RT. This has been scarcely evaluated but could be due to exacerbation of traditional & NTRFs by drugs or legacy effect of previous CKD related risk factors. Carotid intimal medial thickness (CIMT) is established marker of structural atherosclerosis & has been shown to decrease after correction of risk factors in some clinical scenarios. Only a few small, mostly pediatric studies have longitudinally assessed CIMT & LVMI post RT with inconsistent results. We for first time have prospectively looked at both CIMT & LVMI in adult CKD 5D patients just prior & at 1year post RT.

Methods: 131 consecutive, eligible & consenting adults undergoing live RT were enrolled from March 2014-15, of which 31 couldn't complete 1-year follow-up. All investigations, CIMT & LVMI assessments were done at baseline (≤1 week prior to RT) & 1-year post RT. Patients with established coronary & valvular heart disease were excluded.

Results: In study population 85.5% subjects were male, mean age was 31.8±10.7 years & median dialysis vintage was 227 days. Basic disease was unclassified in 72.5% & 6.1% were diabetic. All were on 3-drug immunosuppression of mycophenolate mofetyl, steroids & calcineurin inhibitors (94.6% Tacrolimus, 4.6% Cyclosporine). Mean Serum creatinine was 1.4±0.6 mg% at 1 year.Mean CIMT (mm) & LVMI (g/m^2)at baseline & after 1 year post RT were0.51±0.1 & 0.49±0.1 (p=0.75) & 203±48.3 & 173.1±44.7 (p<0.001) respectively. CIMT correlated significantly only with age, BMI & LVMI (p<0.001), while LVMI was significantly increased only in pateints with history of hypertension & those on >2 anti-hypertensive drugs (p<0.01).

Conclusions: In younger, low risk population we document no significant change in CIMT at 1 year post RT, while LVMI decreased by 14.7%. Further studies including more diabetic & elderly patients with longer follow up are therefore warranted.

TH-PO789

Incidence and Characteristics of Kidney Stones in Kidney Transplant Recipients: A Meta-Analysis Wisit Cheungpasitporn, Charat Thongprayoon, Michael A. Mao, Wonngarm Kittanamongkolchai, Tsering Dhondup, Stephen B. Erickson. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: The incidence and characteristics of kidney stones in kidney transplant recipients are not well studied. The objective of this meta-analysis was to evaluate the incidence and types of kidney stones after kidney transplantation.

Methods: A literature search was performed using MEDLINE, EMBASE, and Cochrane Database of Systematic Reviews from the inception of the databases through March 2016. Studies assessing the incidence of kidney stones in kidney transplant recipients were included. We used a random-effects model to estimate the incidence of kidney stones.

Results: Eighteen studies with 61,785 kidney transplant patients were included in the analyses to assess the incidence of kidney stones after kidney transplantation. The estimated incidence of kidney stones was 0.9% (95% CI, 0.6%–1.4%). The mean duration to diagnosis of kidney stones after kidney transplantation was 28 ± 22 months. The mean age of patients with kidney stones was 42 ± 8 years. Within reported studies, approximately 50% of kidney transplant recipients with kidney stones were males. 62% of kidney stones were calcium based stones (34% mixed CaOx/CaP, 18%CaOx and 10%CaP), followed by struvite stones (22%) and uric acid stones (16%).

Conclusions: The estimated incidence of kidney stones in patients after kidney transplantation is 0.9%. Although calcium based stones are the most common kidney stones after transplantation, struvite stones (also known as "infection stones") are not uncommon in kidney transplant recipients. These findingsmay impact the prevention and clinical management of kidney stones after kidney transplantation.

TH-PO790

Association between Cardio-Ankle Vascular Index, Carotid IMT and Level of FGF-21 in Renal Transplant Patients Thananda Trakarnvanich,[1] Yingchia Wang.[2] [1]*Renal Unit, Dept of Medicine, Faculty of Medicine, Vajira Hospital, Navamindradhiraj Univ, Bangkok, Thailand;* [2]*Renal Unit, Dept of Medicine, Renal Unit, Dept of Medicine, Navamindradhiraj Univ, Bangkok, Thailand.*

Background: Cardiovascular disease is the major cause of death in patients with CKD, even after renal transplantation. The major risk factor is arterial stiffness. The cardio-ankle vascular index (CAVI) was developed as an indicator of arterial wall stiffness . Fibroblast growth factor 21 (FGF-21) is a metabolic regulator and elevated FGF-21 levels have been reported in coronary heart disease and carotid artery plaque. We aimed to study the association of CAVI with FGF-21 and their relation to carotid media thickness and various parameters that can contribute to cardiovascular disease.

Methods: A total of 90 participants who underwent renal transplant were included in the study. The following measurements were done and laboratory data collected: CAVI, echocardiogram, homocysteine, hs-CRP, carotid IMT, FGF-21, medication after renal transplantation, and incidence of cardiovascular disease.

Results: The average CAVI score was 7.51±1.69. The CAVI values had a positive correlation with carotid IMT and a negative correlation with hemoglobin (r=0.214, P=0.000 and r=-0.219, P=0.044, respectively). No association was observed between CAVI and FGF-21 . FGF-21 had a positive correlation with hs-CRP, urine protein excretion, triglyceride, and a negative correlation with renal function. The average carotid IMT score in this study was 0.57±0.18. Patients with age above 60, low cholesterol and HDL, and high BMI had significantly higher carotid IMT values.

Conclusions: CAVI values after renal transplantation were within normal range and showed an association with carotid IMT. Despite the negative association with FGF-21 in this study, FGF-21 still had a positive correlation with hs-CRP, lipid profile and urinary protein excretion. This indicates that renal transplantation patients had improved arterial stiffness but still had risk factors of CVD. Close monitoring for cardiac events and risk factor modification are highly recommended even after successful renal transplantation.

TH-PO791

High-Molecular-Weight Adiponectin Inhibits the Progression of Vascular Calcification in Japanese Renal Allograft Recipients Hiroki Adachi, Yuki Matsui, Norifumi Hayashi, Keiji Fujimoto, Hideki Yamaya, Hitoshi Yokoyama. *Nephrology, Kanazawa Medical Univ, Uchinada, Ishikawa, Japan.*

Background: Adiponectin has antiatherogenic effects and prevents the development and recurrence of cardiovascular events. However, few long-term studies have been conducted on changes in serum adiponectin levels and arterial calcification in renal allograft recipients.

Methods: The effects of serum ADPN fractions on renal functions and serum lipid markers were examined in 51 Japanese patients. The calcification of abdominal aorta was examined by CT scan based on aortic calcification index(ACI) and aortic calcification area index(ACAI), in order to reveal the relationship in the rate of change between arterial calcification and serum high- and low-molecular weight (HMW-/LMW-)ADPN fractions during 8 years. Furthermore, factors influencing vascular calcification such as age were also examined.

Results: The rates of change of ACI and ACAI at the abdominal aorta were grouped into quartiles for comparison with the alteration of ADPN fractions for 8 years. As a result, the rate of change of ACI and ACAI were much lower in the highly HMW-ADPN elevated group of (p<0.01). In the multiple regression analysis, an advanced age at transplantation increased the rate of changes in ACI, while the increased the rate of changes in HMW-ADPN concentrations decreased it. In addition, an advanced age at transplantation and a history of cardiovascular complications increased the rate of changes in ACAI, while both the increase of HMW-ADPN concentrations and the improvement of eGFR decreased it. In this notion, eGFR was negatively correlated with HMW-/LMW-ADPNconcentrations (r=-0.300, p=0.033 and r=-0.380, p=0.006, respectively). BMI was positively correlated with the LDL-C/HDL-C ratio and negatively correlated with the HDL-C values (r=0.412, p=0.003 and r=-0.379, p=0.006, respectively). In a multiple regression analysis, the increased rate of changes in HDL-C was a significant factor improving the HMW-ADPN concentrations.

Conclusions: The increase of HMW-ADPN associated with HDL-C may inhibit the progression of vascular calcification at the abdominal aortaeven in Japanese renal allograft recipients during 8 years follow-up.

TH-PO792

Improvement of Arterial Stiffness Parameters after Kidney Transplantation: A Systematic Review and Meta-Analysis Aboubacar Sidibé, Catherine Fortier, Marie-Pier Desjardins, Fabrice Mac-Way, Sacha A. De Serres, Mohsen Agharazii. *Social and Preventive Medicine, Medicine, Research Center of CHU de Québec, Hôtel-Dieu de Québec Hospital, Nephrology Div, Laval Univ, Medicine, Quebec City, QC, Canada.*

Background: Chronic kidney disease is associated with increased arterial stiffness. Correction of the uremic milieu by kidney transplantation (KTx) may improve arterial stiffness. However, the results from clinical studies are not uniformly convincing. The objective of the present study is to measure the impact of KTx on the reduction of arterial stiffness.

Methods: Observational studies and randomized controlled trials with measurements of pulse wave velocity (PWV) were extracted from MEDLINE, EMBASE, COCHRANE LIBRARY, and Web of Science from their inception to January 2016. Two reviewers independently identified eligible studies comparing PWV pre to post KTx and extracted data including population characteristics, interventions and outcomes.

Results: 13 studies met our inclusion criteria. 11 Studies (408 renal transplants) have been included in meta-analysis. There was a standard mean change of PWV by -0.45 (95% CI: - 0.68; -0.20, I^2=58%) post-KTx. Both studies using aortic PWV (5 studies, 160 patients) and those using brachial-ankle PWV (3 studies, 151 patients), showed a significant decrease of PWV by -1.58 m/s (95% CI: -2.97; - 0.19, I^2= 87%) and -1.21 m/s (95% CI: - 1.89 ; – 0.54, I^2=0 %) post-KTx, respectively. Analysis of central pulse pressure and augmentation index pressure showed significant reduction post-KTx by -4.77 (95% CI: -9.19; -0.35, I2=55%) and -11.59 (95% CI:-15.64; -7.53, I2=43%), respectively. Only two studies have reported adjusted parameters for mean arterial pressure.

Conclusions: There is a significant reduction in PWV, central pulse pressure and augmentation index after KTx. Heterogeneity among studies are moderate. Further analysis is required to examine the importance of changes in different vascular beds taking into account changes in blood pressure.

TH-PO793

Clinical Outcome of Aortic Arch Calcification in Kidney Transplant Recipients – Single Center Study Yaerim Kim, Woo Yeong Park, Seong Sik Kang, Sang Mok Yeo, Kyubok Jin, Sung Bae Park, Seungyeup Han. *Internal Medicine, Keimyung Univ School of Medicine, Keimyung Univ Kidney Inst, Daegu, Korea.*

Background: Cardiovascular disease is one of the most important causes of death in kidney transplant recipients (KTR) s. Aortic calcification is a major risk factor for cardiovascular disease and associated with coronary artery disease in KTRs. The aim of this study was to evaluate the prevalence and clinical outcome of aortic arch calcification in KTRs.

Methods: We retrospectively evaluated the aortic arch calcification (AoAC) in KTRs who received kidney transplantation (KT) from 2000 to 2010, using chest radiography. AoAC was semiquantitatively estimated by calculating calcification score. The association of clinical and biochemical parameters were evaluated.

Results: A total of 258 patients were enrolled in this study and their mean age was 40.7 year-old, male: female was 135:123, diabetes was 24.4% and deceased donor KT was 36.8%. Fifty-three (20.5%) patients had AoAC at the time of transplantation and pretransplant AoAC score was 0.8 ± 2.0. Pretransplant AoAC was significantly correlated with age, serum calcium level at the transplantation and deceased donor KT. The proportion of KTRs with AoAC gradually increased to 23.3%, 26.4%, and 28.7% at 1, 3 and 5 years after transplantation, respectively. AoAC score also gradually increased to 1.0 ± 2.3, 1.2 ± 2.8 and 1.6 ± 3.1 at 1, 3 and 5 years after transplantation. During the mean follow-up duration of 101.9 months, 33 patients (12.8%) lost their grafts. Five-year graft survival rates were 97.5% in no AoAC group and 95.7% in AoAC group, but there was no statistical significance between two groups. Five-year patient survival rates were 98.0% in no AoAC group and 93.8% in AoAC group, and there was statistical significance between two groups (p=0.004).

Conclusions: AoAC is an independent predictor of poor cardiovascular outcome of KTRs. Age, pretransplant serum calcium and deceased donor KT were significantly correlated with AoAC. Regular follow-up by chest radiography could be a simple and useful method to screen the cardiovascular mortality.

TH-PO794

Endovascular Management of Transplant Renal Artery Stenosis: A Safe and Effective Treatment Ana Karoline Nobrega Cavalcanti,[1] Bento C. Santos,[1,2] Marcelino Souza Durao,[1,2] Eduardo J. Tonato,[1] Marisa Petrucelli Doher,[1] Felipe Nasser,[1] Breno Boueri Affonso,[1] Leonardo Guedes Moreira Valle,[1] Nadia Guimaraes- Souza,[1] Alvaro Pacheco-Silva.[1,2] *[1]Nephrology, Hospital Israelita Albert Einstein, São Paulo, SP, Brazil; [2]Nephrology, Univ Federal de São Paulo, São Paulo, SP, Brazil.*

Background: Transplant Renal Artery Stenosis (TRAS) is a low incidence complication, but if untreated, can lead to graft failure, refractory hypertension (HT) and reduced life expectancy. Primary stent implantation is a well-tolerated technique for TRAS treatment.

Methods: The aim of this study was to assess the safety and efficiency of TRAS endovascular therapy. The primary end point was graft survival. The secondary end points were serum creatinine level, blood pressure evolution, and the number of antihypertensive drugs (AHD) pre- and post-procedure. We performed a retrospective single-institutional review of all cases of TRAS from January 2011 to Abril 2016.

Results: From 519 renal transplant, 26 percutaneous procedures have been performed on 24 patients (68% men, 88% with HT, mean age 50 y). The median time to presentation was 169 days. Stenting was performed in all patients with 100% technical and clinical success. The major indications were acute graft dysfunction (54%) and poor function (25%); in addition to two cases of HT and three cases of delayed graft function (DGF). During a mean follow-up of 23 months, a reduction in SCr (Pre-procedure 3.05mg /dL x 30 days 1.73mg /dL x 60 days 1.62mg /dL p <0.001) with 92% graft survival was shown. We found that recovering of renal function before 30 days was an independent predictor of graft survival. All DGF patients left hemodialysis after procedure. When HT was the indication for the procedure improved blood pressure parameters and reduction in the number of AHD, was also observed in other patients (2.09x 1,50 p = 0.008). In 2 cases restenosis was observed requiring new treatment. 2 patients died from unrelated causes to the procedure.

Conclusions: The endovascular management with stent placement of TRAS is safe and presents a high rate of clinical success with low morbidity. Its impact on SCr is significant in our experience, being an effective procedure for restoring and maintaining the graft function.

TH-PO795

Detection of Silent Myocardial Ischaemia Using Radionuclide Imaging and Long-Term Outcomes after Kidney Transplantation Sanmay Low,[1] Horng-Ruey Chua,[2] Raymond C.C. Wong,[3] Angeline Goh,[1] Yue-Harn Ng,[2] Boon Wee Teo,[2] Anantharaman Vathsala.[1] *[1]National Univ Centre for Organ Transplantation, National Univ Hospital, Singapore; [2]Div of Nephrology, National Univ Hospital, Singapore; [3]Dept of Cardiology, National Univ Heart Centre, Singapore.*

Background: Silent myocardial ischemia (SMI) may predict major adverse cardiac events (MACE) which increase graft loss and mortality in kidney transplant recipients (KTRs). We aim to examine the incidence of SMI using myocardial perfusion imaging (MPI) and its association with long-term outcomes in KTRs.

Methods: Retrospective cohort study of KTRs *without* pre-transplant coronary artery disease, who underwent *post-transplant* MPI for SMI detection, defined by moderate-severe myocardial perfusion defects or post-stress cardiac ejection fraction <50%. Primary outcome (composite of all-cause mortality, graft loss, MACE) was examined over minimum 5 years post-transplantation.

Results: 135 KTRs underwent 226 MPIs post-transplant with 1.5 (1.1–2.6) years to first scan. 91 patients had two serial MPIs, with scan interval of 2.2 (2.0–2.5) years. Follow-up was 10 (7.4–12.7) years. 32% of overall total cohort and 84% of subgroup with two MPIs were diabetic. 86% of diabetics had NODAT. 110 (81%) had normal MPIs, 11 (8%) had mild perfusion defects, and 14 (10%) had SMI, of which 3 SMI were detected only on second scan. Correspondingly, primary outcome was met in 6%, 27%, 43% (p=0.04), and MACE occurred in 7%, 0%, 21% (p=0.11), respectively. Total 26 patients met the primary outcome over 4.8 (2.6–7.3) years, including 11 with MACE. On multivariate analysis, SMI (p=0.04), higher LDL (p=0.006) and proteinuria >0.3g/day (p=0.02) predicted earlier onset of primary outcome, while only SMI predicted MACE (p=0.007). Serial MPIs to detect SMI increased the positive predictive value for MACE from 17% to 25%, and correspondingly 50% to 38% for primary outcome. Absence of SMI had negative predictive value of 93% for MACE and 83% for primary outcome.

Conclusions: SMI outperforms conventional risk factors in predicting mortality, graft loss, and MACE in KTRs, with good negative but poor positive predictive value for adverse outcomes, the latter even with serial screenings.

TH-PO796

The Nocturnal BP Profile and Sleep Disordered Breathing (SDB) in Renal Transplant Patients Francesca Mallamaci, Rocco Tripepi, Daniela Leonardis, Maria Carmela Versace, Pasquale Fabio Provenzano, Angela Mafrica, Claudia Torino, Graziella D'arrigo, Giovanni Tripepi, Carmine Zoccali. *CNR-IFC, Reggio Calabria, Reggio Calabria, Italy.*

Background: Nocturnal hypertension and the non-dipping BP profile in renal transplant patients capture exposure to vascular barotrauma which is not apparent when BP is measured in the office or when the average 24h ABPM is considered (Transplantation 2015). However, risk factors for the altered nocturnal BP profile in renal transplant patients are still largely undefined.

Methods: We sought to identify the correlates of BP during night (average nocturnal BP) and of the night/day ratio, an indicator of the extent of nocturnal dipping, in 215 renal transplant patients. 24h ABPM and polysomnography recordings were performed in all patients alongside with Framingham risk factors and CKD-specific risk factors (including phosphate, the eGFR, proteinuria and CRP).

Results: In polysomnographic studies 56 patients (17%) had mild to moderate SDB [Apnea Hypopnea Index, (AHI) >5 episodes/hour <15 episodes/hour] and 19 (9%) had severe SDB (AHI >15 episodes/hour). Night-time systolic BP (r=0.19, P=0.005) and the night/day SBP ratio (r=0.18, P=0.01) were linearly related with AHI and to weaker extent with average 24h SBP and DBP (both r=0.14, P=0.04). Furthermore, high AHI associated also with older age, male gender, BMI, diabetes, high phosphate and C-Reactive Protein and CV comorbidities. In multiple regression analyses adjusting for these parameters as well as for average day-time SBP, Hb, and proteinuria, AHI remained related with average night-time SBP (beta=0.10, P=0.02) and with the night/day SBP ratio (beta=0.17, P=0.02). Of note, in these multiple regression analyses, the AHI ranked as the strongest correlate of BP during night time and of the night /day systolic BP ratio.

Conclusions: Sleep disordered breathing, as measured by the AHI, is the most powerful correlate of the altered nocturnal BP profile in renal transplant patients. Since sleep disordered breathing is highly prevalent in dialysis patients and in part regresses after renal transplantation, these associations suggests that persistence of this disturbance is a major player for the excessive nocturnal BP burden in transplant patients.

Post-Transplant Hypertension: A Potential Role of Genetic Kidney Disease

Ekamol Tantisattamo,[1] Weera Sukhumthammarat,[2] Prapaipan Putthapiban,[2] Wasawat Vutthikraivit.[2] *[1]Oakland Univ William Beaumont School of Medicine, William Beaumont Hospital; [2]Mahidol Univ.*

Background: Genetic factor plays a role in hypertension(HTN). Kidney transplantation from non-hypertensive donors may improve post-transplant HTN.

Methods: A total of 103 kidney transplantations were reviewed. There were 32 living-donor renal transplant(LDRT; 15 living-related and 17 living-unrelated) and 12 deceased donor renal transplant(DDRT) recipients, who received paired deceased donor kidneys (derived from the same donor transplanted to different recipients) leading to 5 "mate" recipient pairs.

Results: Of 44 recipients, mean age was 53.3 yrs old(21.4-79.5) and 57% were female. Mean duration of follow-up was 7.93 mo(0.6-16.3). Mean serum creatinine(SCr) was 1.4+/-0.1(LDRT 1.23±0.05 vs. DDRT 1.95±0.29,p=0.0006). Up to 93% of recipients had pre-transplant HTN, and 45% became non-hypertensive post-transplant(SBP≤140, DBP≤90, or on ≤2 BP agents regardless SBP or DBP). Mean post-transplant SBP was lower than mean pre-transplant SBP but not statistically significant(132±2.63 vs. 135±2.42,p=0.3526) as same as DBP(77±1.74 vs. 80±2.13,p=0.2406). Among 13 LRRT recipients with pretransplant HTN, 5 patients were non-hypertensive post-transplant; whereas 16 of 29(55%) recipients of unrelated recipients (LURT+DDRT) became non-hypertensive(Figure1A). Among 11 DDRT recipients with pretransplant HTN, only 4 patients(2 mate pairs) had the same post-transplant BP outcomes(Figure1B). Pretransplant BP, the number of BP medications, and normotensive kidneys were not determinants of post-transplant HTN in a logistic regression model.

Conclusions: Pre-transplant HTN may be resolved post-transplantation. Since the prevalence of post-transplant HTN trends to be lower in recipients receiving kidneys from unrelated donors (LURT+DDRT) compared to those recipient of LRRT, genetic factors may play an important role in pathogenesis of post-transplant HTN.

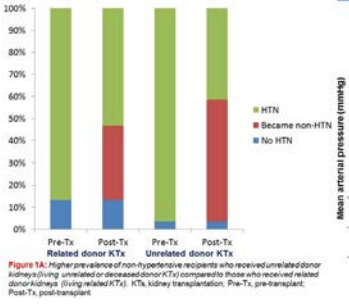

Figure 1A: Higher prevalence of non-hypertensive recipients who received unrelated donor kidneys (living unrelated or deceased donor KTx) compared to those who received related donor kidneys (living related KTx). KTx, kidney transplantation; Pre-Tx, pre-transplant; Post-Tx, post-transplant

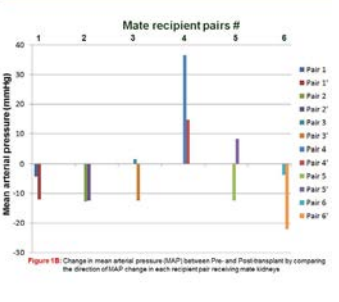

Figure 1B: Change in mean arterial pressure (MAP) between Pre- and Post-transplant by comparing the direction of MAP change in each recipient pair receiving mate kidneys

TH-PO798

Renal Artery Angioplasty Improves Short-Term Blood Pressure and Renal Allograft Function in Transplant Renal Artery Stenosis

Ekamol Tantisattamo,[1] Aneesha A. Shetty,[2] Lorenzo G. Gallon.[2] *[1]Oakland Univ William Beaumont School of Medicine, William Beaumont Hospital; [2]Northwestern Univ.*

Background: Similar to non-kidney transplant patients, the favorable outcomes of renal artery angioplasty±stenting on blood pressure(BP) control and renal function are unclear. We aim to describe these outcomes after this procedure and identify risk factors of transplant renal artery stenosis(TRAS).

Methods: An 8-year-search of medical records(2008-2015) yielded 1,919 kidney transplant recipients in whom angiography-proven TRAS was diagnosed in 19. Each of the 19 patients was individually matched to 3 subjects without TRAS based on age, gender, diabetes, and year of kidney transplantation.

Results: The TRAS group had a mean age of 50.3 years old and was 63% diabetic, 84% male, and 42% white. About 1/3 of the patients had HTN as the cause of ESRD. Median time to TRAS onset after transplant was 3.4 months(0.4-63.2), and median duration of follow-up after diagnosed TRAS was 2.16 years(0.36-6.35). SBP and serum creatinine(SCr), but not DBP were lower after transplant renal artery angioplasty±stenting (1-mo post- minus pre-angiographic differences: mean SBP 19.4±29.5 mmHg(-55 to 65,p=0.01), median SCr 0.16(-1.42 to 9.57,p=0.008), and mean DBP of 6.7±14.4 mmHg(-12 to 35,p=0.06). Median duration of follow-up from transplantation to the time when the most recent SCr were measured were 2.8 and 2.5 years in TRAS and control groups, respectively. In TRAS group, graft survival was 95% and all patients survived; whereas, graft and patient survival in control group were 93% and 91%, respectively. Compared to non-TRAS patients, history of BK viuria(OR 2.1,p=0.19) may increase the risk of TRAS; however, neither history of CMV viremia nor other potential risk factors (serum Ca, PO_4, PTH, vitamin D or donor age) was a statistically significant risk factor in a univariate conditional logistic regression.

Conclusions: Although limited to short-term follow-up, renal artery angioplasty±stenting improved BP and renal allograft function in TRAS patients. In addition, graft and patient survival do not appear lower than in non-TRAS patients. Potential risk factors of TRAS are still unclear given the small number of TRAS patients.

TH-PO799

Renal and Obstetrical Outcomes of Pregnancy in Kidney Transplant under Calcineurin Inhibitors

Juliette Perche. *Nephrology, CHRU Lille, Lille, France.*

Background: The management of calcineurin inhibitors (CNI) in renal transplant patients during pregnancy is not clearly codified. Their per-partum CNI levels physiologically decrease leading to a frequent adjustment of dose, although without evidence of a concomitant decline of the therapeutic efficiency. We here report the features of pregnancies during which CNI doses were unchanged.

Methods: This retrospective study identified 34 pregnancies with unchanged dose of CNI in 27 renal transplant patients in a French single-center from 1987 to 2014. We studied their nephrologic, obstetrical characteristics and outcome.

Results: The mean age at pregnancy was 28.5 (±4.7). The creatinine level was lower than 1.5 mg/dL in 23 patients before pregnancy (mean:1.28mg/dl±0.16). Immunosuppression regimen included tacrolimus or cyclosporine in 12 and 22 pregnancies, respectively. Mean residual levels decreased 48% for tacrolimus and 55% for cyclosporine (nadir: 30 weeks of amenorrhea, WA). Gestational hypertension occurred in 13 (38%) patients, complicated with pre-eclampsia in 6 of them. Prematurity was 44% (mean birth term: 35.5±3.7 WA) and 15 infants (47%) had a hypotrophy (mean birth weight: 2247±925 grams). HLA alloimmunization were identified in 6 patients (23%) at one year postpartum, including donor specific anti-HLA antibodies in 1 case. None acute rejection was reported and 8 patients (30%) developed a graft dysfunction within 2 years postpartum, related to immunological process, CNI toxicity or unidentified cause in 2, 2 and 4 cases respectively.

Conclusions: The no-adaptation of CNI dose according to their residual does not seems to induce more immunological complications or a poorer renal outcome. This can be explaining by the fact that circulating free drug is increased during pregnancy due to hypoalbuminemia. Considering the small size of our sample, more studies are nevertheless necessary to confirm these results.

TH-PO800

A Trial-Based Algorithm for Insulin Pump Therapy in Hyperglycemic Patients Early after Kidney Transplantation

Manfred Hecking,[1] Marcus Saemann,[1] Johannes Werzowa.[1,2] *[1]Nephrology, Medical Univ of Vienna, Austria; [2]First Medical Dept, Hanusch Hospital Vienna, Austria.*

Background: Correction of early postoperative hyperglycemia prevented posttransplantation diabetes mellitus in our previous proof-of-concept clinical trial. We hypothesized that insulin pump therapy with maximal dosing during the afternoon, in consequence of the morning administration of glucocorticoids, would further flatten the daily glucose profiles in comparison with insulin isophane.

Methods: In our multicentre study of insulin isophane versus standard of care (NCT01683331), we added a third treatment arm at a single center (NCT01680185), employing continuous subcutaneous short-acting insulin infusion therapy (CSII, Medtronic) in 24 previously non-diabetic kidney transplant recipients who had developed pre-supper glucose ≥140mg/dL.

Results: The final insulin lispro dose after up-titration of each patient was 9.6±6.0IU daily on average ± standard deviation, compared to 17.0±11.4IU overall in the previous insulin isophane group. The insulin algorithm below shows, 75.4% of the total daily dose were administered from 11am-7pm.

Hour	% of total daily insulin lispro dose [avg ± stdev]
10pm-11pm	0.4±0.3%
11pm-12am	0.3±0.1%
12am-1am	0.3±0.1%
1am-2am	0.3±0.1%
2am-3am	0.3±0.1%
3am-4am	0.4±0.1%
4am-5am	0.4±0.2%
5am-6am	0.5±0.4%
6am-7am	1.1±0.9%
7am-8am	2.0±1.7%
8am-9am	3.1±3.1%
9am-10am	3.1±1.9%
10am-11am	4.2±2.1%
11am-12pm	5.9±2.0%
12pm-1pm	8.2±2.3%
1pm-2pm	9.3±2.4%
2pm-3pm	11.7±2.9%
3pm-4pm	12.1±2.2%
4pm-5pm	11.6±2.8%
5pm-6pm	9.5±2.9%
6pm-7pm	7.1±3.4%
7pm-8pm	4.5±2.5%
8pm-9pm	2.5±1.8%
9pm-10pm	1.0±1.0%

Hypoglycemia ≥52mg/dL was observed twice. Glucose profiles in CSII patients were flatter than in the previous insulin isophane study group, and lower overall; the greatest daily decrease in glucose occured fasting.

Conclusions: The first algorithm for CSII therapy against early postoperative hyperglycemia in previously non-diabetic kidney transplant recipients was safe, employed less insulin, but provided better efficacy than previous insulin isophane treatment.

B-trace Protein as Predictor of Cardiovascular Risk in Patients with Renal Transplantation Carola-Ellen Ruiner, Roxana Werberich, Louisa Werberich, Miranda Leunga Mbouamba, Rainer Woitas. *Nephrology, Bonn Univ Hospital, Bonn, Germany.*

Background: ß-trace protein (BTP) is an alternative marker for renal function. Furthermore, it has been suggested as predictor of mortality and coronary artery disease (CAD). We determined the prognostic value of BTP for cardiovascular risk and major adverse cardiac events (MACE) in patients following kidney transplantation.

Methods: The cohort consisted of 585 consecutive patients that were kidney transplanted between March 1996 and May 2015. MACE was defined as either myocardial infarction (ST-segment elevation (STEMI) or non ST-segment elevation (NSTEMI)), stroke, intervention requiring CAD or death for cardiovascular reason. Blood samples were drawn prior to the kidney transplantation. BTP was measured by routine methods. Median observation time was 2.6 years. Data were analyzed by Mann-Whitney *U* tests, Kaplan-Meier survival and Cox regression analyses.

Results: MACE occurred in 17 % of kidney transplant recipients on average after (mean ± SD) 5.1 ± 4.4 years. Incidence of MACE in the first year following kidney transplant was highest (0.088%). Most frequently patients suffered from NSTEMI (11.7%), followed by STEMI (1.9%) and CAD (1.6%). Only 0.6 % patients died due to cardiovascular reasons. BTP was significantly higher in patients with MACE compared to the other recipients ((mean ± SD) 14.4 ± 5.7 vs 11.2 ± 5.2, p<0.001). BTP was a predictor of MACE in univariate analysis (HR 1.08, 95% Cl 1.03-1.12, p<0.01). Serum BTP was divided into quartiles: Recipients with preoperative BTP ranging from 14.8 to 32 mg/l (4th quartile, mean ± SD 19.2 ± 3.9 mg/l) had an average time to event of 7 years (95% Cl 6.1-8.3), while patients with BTP ranging from 11.2 to 14.7 mg/l (3rd quartile, mean ± SD 12.7 ± 1 mg/l) showed a mean time to event of 10 years (95% Cl 8.9-11.3) (p<0.05). BTP remained an independent risk factor (HR 1.11, 95% Cl 1.06-1.16, p<0.001) after adjustment for potential cofounders' creatinine, c-reactive protein, gender and nicotine dependence.

Conclusions: Within the first year of kidney transplantation the incidence of MACE was the highest. BTP may be used to assess renal function, but also to predict cardiovascular risk in in kidney transplant recipients' patients.

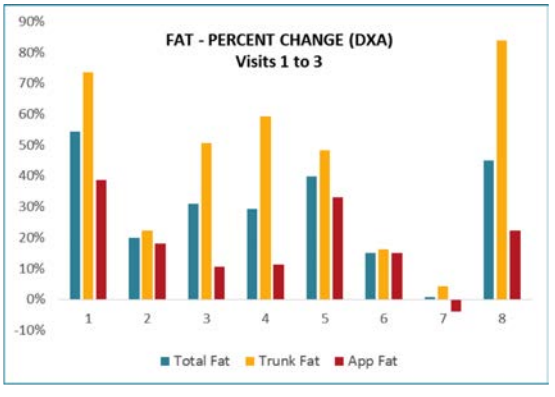
TH-PO802

Adverse Weight Gain after Kidney Transplantation Biruh Workeneh,[1] Ahmed Osama Gaber,[2] William E. Mitch.[1] *[1]Medicine/Nephrology, Baylor College of Medicine, Houston, TX; [2]Surgery, Houston Methodist Hospital, Houston, TX.*

Background: Among the most serious complications to these patients are adverse weight gain and the development of diabetes, commonly termed New-Onset Diabetes After Transplantation (NODAT) with consequent CV mortalityHowever, there no consensus about the cause of post-transplant weight gain and the metabolic determinants of body composition change.

Methods: Our aims were to determine the nature of the weight gain after Tx (i.e., relative changes in fat vs. muscle vs. fluid volume) using DXA and total body potassium and nitrogen counters, and to determine effect on insulin sensitivity. We enrolled 22 subjects who have had pre-transplant and 3mo characterization and 8 subjects who have completed the protocol.

Results:



The cumulative weight gain after after 1 year in 8 subjects was 6.8kg p<0.01. Fig 1 shows changes in body fat in 8 subjects who completed 1 year of follow-up and all but one had a significant increase in fat mass. The fat gain is primarily in the trunk (android fat distribution) than in the appendages, which has been linked to poorer cardiovascular outcomes. Insulin sensitivity quantified by Matstuda index show statistical and clinically significant worsening of insulin resistance. Changes in muscle mass does not contribute substantially to the gain of weight.

Conclusions: The results of this study will permit us to elucidate the complex metabolic underpinnings of excessive weight gain and insulin resistance that occurs frequently in kidney transplant patients and to potentially identify those at risk for adverse weight gain and develop effective interventions.

TH-PO803

Prolonged Fluoroquinolone Prophylaxis to Prevent BK Viremia in Kidney Transplant Recipients Marie Jacobs, Jaclyn Daigneault, Margaret V. Thomas, Kerry Crisalli, David Wojciechowski. *Massachusetts General Hospital.*

Background: Prophylaxis regimens for renal transplant recipients have successfully lowered the early incidence of infections such as CMV. However, 1 and 3 month courses of fluoroquinolone prophylaxis have not proven decisively successful for BK virus, despite positive in vitro evidence. It is possible that the prophylaxis duration was too short.

Methods: We retrospectively evaluated the 1 year incidence of BK viremia in a cohort of patients transplanted from 7/1/2004 to 6/30/2014 who received 6 months of ciprofloxacin or levofloxacin post kidney transplant due to a sulfa allergy (n=10) compared to a no prophylaxis cohort transplanted from 7/1/2012 to 6/30/2014 (n=69). Inclusion criteria included BK viremia screening performed at least once in months 1-6 and months 7-11, and at one year post-transplant. We compared patient and transplant demographics and immunosuppression regimens between the groups. The primary outcome was the 1 year incidence of BK viremia.

Results: The groups did not differ significantly in demographic or transplant variables or immunosuppression regimens.

	Prophylaxis (n=10)	No Prophylaxis (n=69)	P Value
Mean age, years	53.8	54.8	0.77
Male, n	4	50	0.065
Live donor, n	5	24	0.48
rATG induction, n	8	64	0.19
Mean tacrolimus trough (ng/mL)			
6 mos	7.29	6.09	0.067
12 mos	6.23	6.51	0.67
Mean MMF dose (mg)			
6 mos	1312.5	1350	0.79
12 mos	1250	1218.3	0.82
Mean prednisone dose (mg)			
6 mos	5.75	5.46	0.76
12 mos	5	5.04	0.89

The incidence of BK viremia at one year was 10% and 24.6% in the prophylaxis and no prophylaxis group, respectively (p=0.44). There were no cases of BK virus associated nephropathy in either group. Three cases of acute rejection developed in the no prophylaxis group, while none developed in the prophylaxis group (p=1.00).

Conclusions: A 6 month course of fluoroquinolone prophylaxis resulted in a numerically lower incidence of BK viremia. Our data suggest that there may be a benefit of this strategy which warrants evaluation in a larger cohort of patients. The safety of this strategy must also be assessed.

Funding: Clinical Revenue Support

TH-PO804

Low Level Serum BK Viremia Is Not Associated with Increased Risk of Rejections, Infections or Poor Graft Survival Amber Hertz-Tang,[1] Brad C. Astor,[2] Maha A. Mohamed,[2] Didier A. Mandelbrot,[2] Arjang Djamali,[2] Sandesh Parajuli.[2] *[1]Internal Medicine, Univ of Wisconsin, Madison, WI; [2]Nephrology, Univ of Wisconsin, Madison, WI.*

Background: BK virus infection is considered to be a risk factor for additional infections, increased risk of rejections and graft failure. There is limited data about association of low level BK viremia and graft outcomes.

Methods: This is a retrospective study among kidney transplant recipients (KTR) at our institution transplanted between 2006 and 2013. Serum BK polymerase chain reaction (PCR) is monitored every 2 weeks for first 3 months then every month from month 3-6 and then monthly from 6-12 months post-transplant. BK level is also checked prior to allograft biopsy. Patients were divided into three groups based on their BK level during the first year post transplant: no detectable BK level (G1), low level BK (G2)(< 1000 copies/ml) and high level of BK (G3) (> 1000 copies/ml).A level of 1000 was chosen, as this is a generally accepted cutoff for adjusting immunosuppression at our institution.Results were adjusted for donor and recipient age, gender, and race, as well as, live vs. deceased donor, HLA mismatch, CMV status, cause of ESRD, prior transplant, induction, and DGF.

Results: There were a total of 1126 KTR, 841 were in G1, 51 in G2 and 234 in G3. Comparing between G1 and G2, there were no statistically significant differences in donor or recipient age, gender, race, or type of transplants. Incidence of rejections, CMV disease, rate of graft loss and mortality were also not significantly different. Comparing between G2 and G3, G3 had significantly higher rate of infections (p= 0.004). The majority of infections were urinary tract infections. G3 had a higher trend toward increased rate of death and graft failure though not statistically significant.

Conclusions: Low level BK itself does not increase the risk of rejections, infections or graft loss compared to no detectable BK level and may predict lower rate of any infection compared to a high level BK.

TH-PO805

Prevalence of BK Nephropathy Post Allogeneic Stem Cell Transplant: Autopsy Evidence Ala Abudayyeh,[1] Rima N. Pai,[1] Ankita Tandon,[2] Miao Zhang,[1] Asha S. Multani,[1] William F. Glass.[2] *[1]The Univ of Texas MD Anderson Cancer Center; [2]The Univ of Texas Medical School at Houston.*

Background: BK virus (BKV) is known to be causally related to chronic kidney disease (CKD) in renal transplant recipients. In hematopoietic stem cell transplant (HSCT) recipients, BKV is associated with hemorrhagic cystitis. The relationship between BKV and CKD in HSCT recipients, however, is not as well established. We chose to investigate the prevalence of BKV in kidneys obtained at autopsy of patients that have undergone HSCT.

Methods: We retrospectively for patients that who had undergone a HSCT and had an autopsy performed between 2004 and 2014. Formalin fixed paraffin embedded kidney tissue blocks from these patients were analyzed by light microscopy and anti-SV40 immunohistochemistry (IHC) for detection of BKV. Cases were considered positive for BKV if moderate-to-strong staining was present in nuclei of renal tubular epithelial cells with appropriate controls and semi-quantitated based on percentage of total tubular epithelial cells affected (<25% vs. >25%). Additional clinicopathologic parameters were collected. To overcome the nonspecific staining using IHC due to autolysis in autopsy tissue we performed In situ hybridization using a BK Biotin-labeled DNA probe.

Results: A total of 46 patients were included in the study. **Sixteen patients (35%) had positive SV40 staining in ≥ 25% of tubular epithelial cells.** In situ hybridization using a BK Biotin-labeled DNA probe further confirmed the prevelance of BK in the kidney.

Conclusions: We have demonstrated tissue evidence of the prevalence of BKV in renal tissue of stem cell transplant patients. The results of this study will help shed more light on the role of BK post SCT and progression to CKD. Further research in looking in to immune predictors of the infection and a grading system to guide early intervention would be needed to improve SCT renal outcomes.

TH-PO806

Serum Levels of Uric Acid and Progression of Arteriolar Hyalinosis after Kidney Transplantation Yasuyuki Nakada,[1] Izumi Yamamoto,[1] Mayuko Kawabe,[1] Takafumi Yamakawa,[1] Haruki Katsumata,[1] Ai Katsuma,[1] Akimitsu Kobayashi,[1] Yudo Tanno,[1] Ichiro Ohkido,[1] Hiroyasu Yamamoto,[1] Masayoshi Okumi,[2] Hideki Ishida,[2] Takashi Yokoo,[1] Kazunari Tanabe.[2] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Dept of Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Arteriolar hyalinosis (AH) of the kidney is considered to be strongly associated with progression of chronic kidney disease (CKD). Aging, hypertension, and diabetes mellitus generally exacerbate the extent of AH in the native kidney. In addition, in allograft kidney, nephrotoxicity attributable to the calcineurin inhibitor (CNI) can also develop, increasing the severity of AH progression. In recent years, it has often been claimed that hyperuricemia induces AH progression and accelerates the nephrotoxicity caused by CNI. We postulated that, over time, the uric acid (UA) burden in allograft kidney recipients could influence AH progression and interstitial fibrosis/tubular atrophy (IF/TA).

Methods: We evaluated 126 recipients who received kidney transplants from January 2005 to December 2009 at the Department of Urology, Tokyo Women's Medical University. Patients with diabetes mellitus were excluded. Progression of AH and IF/TA were considered present if the Banff scores increased by two or more. To evaluate factors associated with such pathological progression, we subjected clinical parameters (age, gender, blood pressure, serum CNI concentration, baseline UA in serum[s-UA]) and the UA burden over time (the average annual level of s-UA) to logistic regression modeling.

Results: The baseline s-UA was correlated with progression of IF/TA ($p = 0.03$) but not AH ($p = 0.86$). However, the UA burden over time was associated with progression of both AH ($p = 0.03$) and IF/TA ($p < 0.01$). Of other clinical parameters, donor age was strongly associated with AH progression ($p < 0.01$).

Conclusions: Although IF/TA progression was correlated with the UA burden over the whole course of disease, the UA burden over time, but not the baseline value, induced AH progression in transplanted kidney. Therefore, we suggest that monitoring s-UA after transplantation is important to prevent AH and IF/TA progression.

TH-PO807

The Mammalian Target of Rapamycin Inhibitors and Post-Transplant Malignancy in Kidney Transplantation Lee-Moay Lim,[1] Hung-Tien Kuo.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [2]Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: Improving long-term graft and patient survival is a major challenge in kidney transplantation due to prolonged immunosuppression significantly increases the risk of malignancy, contributing to the overall morbidity and mortality. The aim of our study was to investigate the association of Mammalian Target of Rapamycin Inhibitors (mTORI) usage (early and late) with major transplant outcomes and post-transplant malignancy in kidney transplant recipients from a medical center in Taiwan.

Methods: A total of 201 adult kidney transplant recipients surviving with a functioning graft> 3 months were included. The mean follow-up days were 2368. mTORi users were categorized into early and late users at the cut-off of 6 months duration after transplantation. Odds ratios for malignancy were examined using multivariate logistic regression analysis while hazard ratios for clinical outcomes were analyzed using multivariate Cox regression analysis.

Results: The major causes of death in our cohort were cardiovascular disease, malignancy and infection. Urinary tract urothelial carcinoma (UTUC) and hepatoma comprised the major malignancy after transplantation. After adjusting for confounding factors, mTORi users has lower risk of post-transplant malignancy (adjusted OR=0.28, P=0.04).

	Reference	Adjusted OR	P-value
mTORI (n=123)	No mTORI	0.28 (0.08-0.96)	0.04
Early mTORI (n=39)	No mTORI	0.64 (0.18-2.24)	0.49
Late mTORI (n=84)	No mTORI	0.35 (0.11-1.09)	0.07

Early mTORI users have better overall graft survival (adjusted HR=0.73, P=0.52) and patient survival(adjusted HR=0.95, P=0.95) when compared to late users and non-users.

Conclusions: In our renal transplant recipients, the leading causes of death were cardiovascular disease, infection, and malignancy. The most common post-transplant malignancy were UTUC and hepatoma. The usage of mTORI was associated with a decreased risk of post-transplant malignancy.

TH-PO808

Chemoprevention of Cutaneous Squamous Cell Carcinoma (cSCC) in Long Term Renal Transplant Recipients (LRTR): A Case-Controlled Analysis Rachel Hung,[1,2] Rakesh Anand,[2] Mary Wain,[3] Antonia Cronin.[2] *[1]Renal, UCL Centre of Nephrology, Royal Free Hospital, London, United Kingdom; [2]Renal, MRC Centre of Transplantation, Guy's and St. Thomas' Hospital, London, United Kingdom; [3]Dermatology, Guy's and St. Thomas' Hospital, London, United Kingdom.*

Background: Organ transplant recipients are up to 200 times more likely to develop cSCCs than age-matched general populations. Development of NMSC in LRTR is affected by Fitzpatrick skin type, ultra-violet light exposure, and the type and duration of immunosuppression. Systemic retinoids have shown promising preventative effects against the development of cSCC, however this is associated with adverse side effects including liver dysfunction, dyslipidaemia, and use in renal impairment is cautioned.

Methods: We collected retrospective data from our cohort (n=469) of LRTR (>7 years) attending our annual review clinic, of which 108 patients had been diagnosed with NMSC. We identified patients (n=12) on treatment with the acitretin and matched them to an equal number of controls by age, total years from transplant and Fitzpatrick skin type. We compared GFR, liver function and lipid profile at 1 year pre, and 1, 3 and 5 years post commencing acitretin and the total number of cSCCs pre and post acitretin.

Results: Serum total cholesterol and LDL were significantly lower (p=0.007 and p=0.012 respectively) in patients prescribed acitretin at 5 years post treatment compared with baseline measurements. There were no other statistically significant differences in lipid profile, GFR or LFTs at baseline parameters and at 1, 3 and 5 years after starting treatment within cases or comparing cases and controls. After starting acitretin treatment the median number of new cSCCs per patient was 2 (0 - 4) which was significantly lower than the median number prior to treatment of 6 (3-10) p=0.005.

Conclusions: Acitretin usage did not adversely affect renal transplant function,liver function or lipid profiles when compared with baseline or matched untreated controls,and showed a statistically significant reduction in total number of new cSCCs during 5-year follow-up. Acitretin can be considered as a safe and effective chemoprevention agent in selected LRTR with multiple SCCs who are under regular dermatology surveillance.

TH-PO809

The Incidence of Non-Melanoma Skin Cancers in Renal Transplant Recipients - Polish Centre Experience Alicja Debska-Slizien,[1] Beata Imko-Walczuk,[2] Maria Luiza Piesiakow,[1] Slawomir Lizakowski,[1] Boleslaw Rutkowski.[1] *[1]Dept of Nephrology, Transplantology and Internal Diseases, Medical Univ of Gdansk, Gdansk, Poland; [2]Dermatology Dept, Copernicus Hospital in Gdansk, Gdansk, Poland.*

Background: Non-melanoma skin cancers (NMSCs), especially squamous cell carcinoma (SCC) and basal cell carcinoma (BCC), are the most frequent malignant neoplasms in renal transplant recipients (RTRs). SCC, due to its unusual and aggressive

clinical course in RTRs, is a diagnostic and therapeutic challenge. The aim of the study was to assess the incidence of NMSCs in Polish population of RTRs and propose methods of prevention and early diagnosis.

Methods: We included prospectively and retrospectively 77 patients with NMSCs in a group of 813 RTRs, who were patients of Nephrology, Transplantology and Internal Diseases Department of Medical University of Gdansk in years 1980-2015. Majority of study group (92.2%) underwent a single transplantation (Tx) and the mean time of observation was 12.5±5.8 years. The most frequently treatment scheme was MMF (mycophenolate mofetil)- CsA (cyclosporine A)-GS (glucocorticosteroids) 33,8%, MMF-TAC (tacrolimus)-GS - 22,1%.

Results: In 77 patients, 139 NMSCs were diagnosed. It shows more than 253-times higher risk of NMSCs development in Polish RTRs ($p<0.000001$). The median time since the Tx to cancer diagnosis was 75.5(3.0-227.0) months for BCC and 80,0(31.0-358)months for SCC. Furthermore a single lesion was diagnoses in 61.0% patients, whereas the others presented a multifocal cancers. 73,7% SCC were noticed in RTRs who received CsA as a immunosuppressive treatment and 73,3% BCC were diagnosed in patients using MMF in treatment scheme.

Conclusions: The incidence rate of skin cancer in Polish RTRS population is more than 250 times higher compared with the immunocompetent individuals (ICIs). The SCC to BCC ratio increases from 0,2:1 in general population to 0,73: 1 in our study group. Skin cancers in RTRs very often develop multicentrically.

TH-PO810

The New Method of Vesico-Ureteric Reflux Prophylactic in Kidney Transplant Recipients: Randomised Clinical Study Aleh Kalachyk, Alexei Narbin, Alexej Shkutov, Maria Kozlova. *National Center for Nephrology, Minsk, Belarus.*

Background: Vesico-ureteric reflux (VUR) is a common complication in renal transplant recipients. VUR is associated with increased risk of UTI and graft loss. The objectives of that study were to determine the incidence and risk factors of VUR, to create and prove the efficacy of new method of VUR prophylactic in kidney transplant recipients.

Methods: We conducted case-control survey of 68 patients to detect the risk factors for VUR in renal allograft. Voiding cystograms were performed to find the reflux. We checked the association of VUR with recipient's gender, age, type and duration of dialysis, residual urine volume output, cold ischemia time, ureteric stent placement, kidney function and infections. The new method of antireflux defense consists of the ureteroneocystostomy by Starzl with JJ stent placement followed by the simultaneously stent removal and endovesical submucosal injection of bulking substance on POD 30. To prove the efficacy of the new antireflux defense method we conducted a prospective, randomized clinical study. Kidney transplantation with Lich-Gregoir ureteroneocystostomy was performed in the control group. 36 kidney graft recipients were randomized in two groups. The voiding cystography was performed on POD 60 to compare the VUR rates in both groups.

Results: The cumulative incidence of VUR was found as 45/68 (66,2%). The statistically significant risk factor for VUR was residual urine volume output (50 (0-200) versus 250 (0-850)cc, p=0,006).ROC-analysis showed cut-off value 200 cc (AUC 0,71, p=0,0018). This volume was established as the cut off for the inclusion criteria for patients in control and study groups. The groups were similar in gender, age, type and duration of dialysis, residual renal function, and HLA mismatches. The incidence of VUR in the study group was found as 5/18 (28%), and it was 13/18 (72%), p=0, 0184 in the control group.

Conclusions: We found that residual renal output 200 cc is a significant risk factor of VUR in kidney transplant recipients. The Starzl ureteroneocystostomy with ureteric stenting and delayed endovesical antireflux bulking substance injection is a new effective method of VUR prophylactic in the high VUR risk kidney recipients.

TH-PO811

Urinary Tract Infections in the First Year Post Kidney Transplantation Prasanti Kotagiri,[1] Jessica Ryan,[2] Nigel David Toussaint.[1,3] *[1]Royal Melbourne Hospital, Parkville Australia; [2]Monash Health, Clayton, Australia; [3]Univ of Melbourne, Australia.*

Background: Urinary tract infections (UTI) are the commonest infectious complication in kidney transplant recipients (KTRs). Effects on graft function are unclear. No recommendations exist regarding treatment of asymptomatic bacteriuria but concern that immunosuppression and denervation of the graft masks symptoms often prompts treatment. We aimed to identify potential risk factors for UTIs, microbiological profile and role of treatment of asymptomatic bacteriuria, and effects on graft outcomes.

Methods: Retrospective analysis of UTIs in KTRs transplanted between Jan 2012 and Dec 2013 in two Australian tertiary transplant centres where patients are routinely commenced on prophylactic sulfamethoxazole/trimethoprim. Clinical and microbiological data was analysed for the first year following transplantation.

Results: 276 KTRs were evaluated, 67% male, mean age of 51yrs. 158 recipients (57%) had no bacteriuria in the first year post-transplant, 75 (27%) had only asymptomatic bacteriuria, 21 (8%) had symptomatic UTIs and 22 (8%) with UTIs developed either pyelonephritis or urosepsis. Most frequent pathogens identified were Enterococcus Faecalis and Escherichia Coli, and 36% were multi-drug resistant. Female gender was a risk factor for infection (p=0.002) and presence of a ureteric JJ stent significantly increased the risk of asymptomatic bacteriuria and symptomatic UTIs (p=0.003). Diabetes, age and prior transplantation did not increase risk. Presence of infection was not associated with increased rejection or adverse longer-term outcomes with similar renal function at 12 months. For all episodes of bacteriuria in our cohort (n=420), cases of untreated asymptomatic bacteriuria (n=185) followed by symptomatic UTI with the same organism were significantly higher (p=0.002) compared to cases of treated asymptomatic bacteriuria (n=139).

Conclusions: Treatment of asymptomatic bacteriuria in the first year post-transplant may be beneficial to prevent subsequent episodes of symptomatic UTIs.

TH-PO812

Asymptomatic Bacteriuria in Renal Transplant Patients Anna Price, Lukas Foggensteiner. *Renal Dept, Queen Elizabeth Hospital Birmingham, Birmingham, West Midlands, United Kingdom.*

Background: Patients with renal transplant are vulnerable to post-operative infection, particularly urinary tract infection (UTI). UTIs are linked with acute cellular rejection, graft loss, sepsis and death. The management of asymptomatic bacteriuria (AB) however, remains a clinical conundrum in these patients. The risk of untreated AB vs. the risk of antimicrobial side effects or overuse is unclear.

Methods: Aims: 1. Quantify the frequency and nature of AB amongst renal transplant patients at our unit. 2. Determine our management of these cases and any adverse outcomes. Methods: Between 1st January 2013 and 31st December 2013 132 renal transplant patients with AB were identified and followed up for 12 months. Demographic data was collected from electronic patient records. The urinary pathogen, bacterial count and white blood cell count of each AB was recorded from microbiology records. Patient management, admissions and subsequent urine results were retrospectively reviewed.

Results: Of the 132 patients identified, 82 patients met inclusion criteria. There were more females (n=55) than males (n=27). The mean age was 50.8 yrs. (range 17.4-79yrs). All ABs had greater than 80 white blood cells (WBC) or 10^5 bacterial organisms. Most ABs were 'Heavy mixed growth' or E.coli. Only 14 patients had complete resolution, 56 patients had AB reoccurrence and 12 patients had persistent AB throughout follow up. Of the 82 patients, 27 were treated with antibiotics. There were no related deaths or episodes of acute rejection. Only 8 admissions to hospital were associated with AB during follow up (n=1 pyelonephritis, n=4 urosepsis, n=3 symptomatic UTI). All of these patients had previously received antibiotics for AB prior to the admission. A further 12 patients during follow up later developed symptomatic UTI not requiring hospital admission (8 of which were also previously treated for AB).

Conclusions: Asymptomatic bacteriuria led to few admissions and complications. Treating patients did not seem to prevent subsequent admissions. A high proportion of 'Heavy mixed growth' may indicate incorrect collection. Practice varies widely amongst clinicians but the vast majority of ABs are not being treated.

TH-PO813

High Incidence of Arterial and Venous Thrombosis in Patients with ANCA-Associated Vasculitis Amy Kang,[1] Marilina Antonelou,[1] Anisha Tanna,[2] Nishkantha Arulkumaran,[1] Frederick W.K. Tam,[2] Charles D. Pusey.[2] *[1]Imperial College Renal and Transplant Centre, Imperial College NHS Trust, London, United Kingdom; [2]Renal and Vascular Inflammation Section, Dept of Medicine, Imperial College London, London, United Kingdom.*

Background: A few previous studies have shown an association between AAV and cardiovascular disease (CVD) and venous thromboembolism (VTE), which may be mediated by inflammation or anti-plasminogen antibody. We aimed to determine the incidence and risk factors for arterial and venous thrombosis in ANCA-associated vasculitis (AAV).

Methods: This single-centre retrospective cohort study presents the incidence of arterial thrombosis (defined as coronary events and ischaemic stroke), VTE and all-cause mortality in people diagnosed with AAV between 2005 -2014. We collected patient baseline characteristics, risk factors for CVD and VTE, and events of CVD, VTE, AAV relapse and death.

Results: 204 patients with AAV were identified with a median follow-up of 5.3 [range: 0.08-10] years or total of 1088 person-years. The overall incidence was 2.76/100 person-years for CVD (1.65 for coronary events and 1.10 for ischaemic stroke) and 1.47/100 person-years for VTE (0.83 for DVT only and 0.64 for PE with or without DVT). Two coronary events were fatal. 71 percent of our cohort had renal involvement with a median creatinine of 117 (IQR 73-268)mmol/L. On multivariate analysis only prior ischaemic heart disease was a predictor of CV events. CVD (but not VTE) was an independent predictor of all-cause mortality. When we removed patients with prior CVD the incidence of CV events was still elevated at 2.32/ 100 person-years (1.26 for coronary events and 1.06 for ischaemic stroke). When we compared these results with reported rates for the UK population, the rates in AAV patients were 17 times higher for coronary events, 10 times higher for incident stroke and 20 times higher for VTE.

Conclusions: Patients with AAV have a high incidence of arterial and venous thrombosis. These results may aid in the development of protocols to minimise thrombotic risk and improve prognosis for patients with AAV.

TH-PO814

Risk Factors of Severe Infections following Rituximab in ANCA-Associated Vasculitis Andreas Kronbichler,[1,2] Julia Kerschbaum,[2] Federico Alberici,[1,3] Rachel B. Jones,[1] David R.W. Jayne.[1] *[1]Addenbrooke's Hospital, Univ of Cambridge, Vasculitis and Lupus Clinic, Cambridge, United Kingdom; [2]Internal Medicine IV (Nephrology and Hypertension), Medical Univ Innsbruck, Innsbruck, Austria; [3]Renal Medicine and Vasculitis, San Carlo Borromeo Hospital, Milan, Italy.*

Background: Severe infections potentially leading to hospitalization are frequently observed in patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). The aim of our study was to investigate potential risk factors having an impact on severe infections following rituximab treatment.

Methods: Both univariate and multivariate logistic regression analyses were performed, using as the outcome of interest the occurrence of at least one life-threatening or severe infection. Nominal variables were compared using the chi-square test (or Fisher's exact test when appropriate), and metric variables were compared using the Mann-Whitney U. All variables showing univariate association with the dependent variable with a p-value less than 0.100 were entered into a multivariate logistic regression model.

Results: Study population consisted of 134 patients diagnosed with GPA, 28 with MPA and 30 with EGPA. 23% had a life-threatening or severe infection during 24 months of follow-up. Univariate analysis showed that lung involvement (OR 2.1; p=0.032), and especially endobronchial involvement (OR 3.824; p<0.001), COPD (OR 10.357; p=0.045), diabetes (OR 2.941; p=0.034), rituximab as a first line treatment (versus maintenance, OR 3.615; p=0.034), whereas higher levels of lymphocytes (OR 0.524; p=0.023 per unit increase) and the use of co-trimoxazole as an antibiotic prophylactic treatment (PR 0.406; p=0.04) were associated with a lower risk. Multivariate anaylsis showed that prophylactic antibiotic treatment with co-trimoxazole significantly reduced the risk of severe infections (adjusted OR 0.171; p=0.016).

Conclusions: This is the first study assessing risk factors of severe infections following rituximab treatment for AAV. Co-trimoxazole significantly reduced the risk for severe/life-threatening infections in patients with AAV. Further studies are clearly necessary to recommend antibiotic prophylaxis with co-trimoxazole in AAV.

TH-PO815

ANCA-Associated Glomerulonephritis in the Elderly - Predictors of Outcome Martin Russwurm,[1] Hermann-Josef Groene,[2] Ivica Grgic,[1] Joachim Hoyer.[1] *[1]Dept of Internal Medicine and Nephrology, Philipps Univ, Marburg, Germany; [2]Dept of Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany.*

Background: ANCA-associated Vasculitis (AAV) is the most frequent reason for biopsy proven acute kidney injury (AKI) in the elderly, however clinical data regarding outcome after standardized immunosuppression (IS) remain scarce.

Methods: All patients (pts.) >65yrs admitted to the University Hospital Marburg (Germany) undergoing a renal biopsy between 2003 and '15 were screened for AAV defined as positive serum ANCA, AKI, histomorphologically proven necrotizing GN and were enrolled in this retrospective study. Pts were observed for a period of 1-12yrs. Clinical history, histological findings and serological data were assessed. Student's t-test and Wilcoxon's rank sum test were used, where appropriate. A linear regression model was performed for analysis of predictors of renal outcome.

Results: From a total of 678 pts. 163 were older than 65yrs. In this group, AAV was the most frequent biopsy-proven cause of AKI (24.5%). In those 40 pts., median age was 76yrs and median follow-up time was 723 days (IQR 598 to 730). Nearly all pts. received standard IS (CYC, prednisolone) adjusted to GFR, age and body weight. Pts. who presented with a serum creatinine (SC) >5,0mg/dL (n=16; 40%) and/or required RRT (n=14; 35%) were additionally treated with plasma exchange (PE). Pt. survival rate after one and two years was 90% and 87.5%, respectively. Complete (SC <1.5mg/dL) and partial (SC <3mg/dl) remission was achieved in 27.5% and 55%, respectively. Mean SC decrease was 3.7 to 1.7mg/dL in pts that did not receive RRT (p<0.0001), 4.7 to 2.0mg/dL in pts that did receive RRT and recovered (p=0.012), and 5.4 to 2.0mg/dL in pts treated with PE (p=0.003). Dialysis dependency rate was 17.5% one year after diagnosis, while none of the others progressed to ESRD. Predictors of renal outcome were SC at diagnosis (p=0.001) and number of necrotic (p=0.02) and unaffected glomeruli (p=0.048).

Conclusions: Our data show that elderly pts. with AAV may also benefit from guideline-directed therapy inducing a high rate of remission.

TH-PO816

Valaciclovir to Prevent Cytomegalovirus Mediated Adverse Modulation of the Immune System in ANca Associated VAScultis (CANVAS): Results of a Randomised Controlled Clinical Trial Dimitrios Chanouzas, Michael Sagmeister, Lovesh Dyall, Charles Ferro, Paul Moss, Matthew David Morgan, Lorraine Harper. *Univ of Birmingham, United Kingdom.*

Background: CD4+CD28- T-cell expansion in patients with ANCA-associated vasculitis (AAV) is associated with increased risk of infection, cardiovascular disease (CVD) and mortality. In a linked study submitted for ASN 2016 we have shown that CD4+CD28- cells in AAV are a Cytomegalovirus (CMV) specific proinflammatory subset associated with increased arterial stiffness, a surrogate marker of CVD. We undertook a proof of concept open label randomised controlled clinical trial to determine whether controlling subclinical CMV reactivation using valaciclovir can reduce expansion of CD4+CD28- cells in patients with AAV.

Methods: 38 CMV seropositive AAV patients in remission were randomised 1:1 to 6 months valaciclovir (2g QDS; eGFR adjusted) or no additional treatment (NCT01633476). CMV reactivation (primary outcome) was assessed by quantitative plasma and urine PCR. Change in CD4+CD28- T cells was assessed by whole blood surface staining flow cytometry at baseline, 6 months and 6 months after the end of treatment.

Results: No CMV reactivation was detected in valaciclovir treated patients whereas reactivation was detected in four control patients (21.1%) (p=0.037). After 6 months valaciclovir treatment there was a significant reduction in both the mean percentage of CD4+CD28- cells (mean reduction 23% (95% confidence interval (CI) 3-39%; p=0.039) and the absolute count of CD4+CD28- cells (mean reduction 27% (95%CI 7-42%); p=0.013) whereas no significant change was seen in the control group (mean change -5% (95%CI -18% to +11%; p=0.449) and -7% (95%CI -25% to +16%; p=0.523) respectively). The reduction in CD4+CD28- cells in the valaciclovir treated group persisted 6 months after cessation of treatment. Valaciclovir was well tolerated. None of the patients had clinical CMV reactivation.

Conclusions: Blocking subclinical CMV reactivation led to a persistent reduction in CD4+CD28- cells suggesting CMV causes the expansion of this cytotoxic T-cell subset and offering novel therapeutic opportunities in AAV to reduce the risk of infection, CVD and mortality.

TH-PO817

High Incidence of ANCA-Associated Vasculitis after the Great East Japan Earthquake Yoichi Takeuchi, Ayako Saito, Tasuku Nagasawa. *Nephrology, Red Cross Ishinomaki Hospital, Ishinomaki, Miyagi, Japan.*

Background: ANCA-associated vasculitis including microscopic polyangiitis (MPA) is triggered by silica exposure. After the Great East Japan earthquake on March 11 in 2011, tsunami waves produced a huge volume of silica-containing sludge. We aimed to determine if the incidence of the MPA increased following the serious disaster.

Methods: This is an observational retrospective population-based study in a single institute. Forty-three consecutive patients were selected through the CHCC2012 criteria for the MPA from 2007 to 2015. We fitted the Poisson regression model to the incidence with the annual population of the medical district. The participants were selected during 3-year period from before (13 people) to after the disaster (20 people). The differences between the groups were analyzed by using Fisher's exact test and the Mann-Whitney *U* test. Overall survival was calculated according to the Kaplan-Meier method. All statistical data were analyzed by using EZR.

Results: The incidence of MPA per million increased after the disaster (λ= 17.4 [95%CI: 7.66 - 39.6] before the disaster and λ= 33.1 [95% CI: 17.7 - 61.7] after the disaster, P = 0.044). High Birmingham Activity Score was associated with a high incidence of MPA after the disaster (16.0 [12.0 - 18.0] before the disaster and 18.0 [16.0 - 22.0] after the disaster, P = 0.019). The overall survival of the patients with MPA declined after the disaster (P = 0.029 by log rank test).

Conclusions: The incidence of MPA increased after the Great East Japan earthquake. The patients enrolled after the disaster had severe symptoms and a high mortality rate.

TH-PO818

Restablishment of Immune Tolerance in ANCA-Associated Vasculitis: A Cohort with Both Sustained Undetectable Antibody, and Disease Free Remission Thomas Oates,[1] Fernanda Florez-Barros,[1] Sarah Katrina Todd,[1] Coen A. Stegeman,[2] Peter Heeringa,[2] Abraham Rutgers,[2] Min Chen,[3] Jan-Stephan Sanders,[2] Alan D. Salama.[1] *[1]UCL Centre for Nephrology; [2]Univ of Groningen, Netherlands; [3]Peking Univ First Hospital, China.*

Background: ANCA associated vasculitis (AAV) is associated with disease relapse in up to 50% of patients despite immunosuppression (IS). We studied patients who became persistently ANCA negative off IS without relapse to define a tolerant phenotype.

Methods: Patients at 3 centres were identified who became ANCA negative and were off IS therapy for 2 years or more. Clinical, and laboratory data were analysed. A subset of tolerant patients were compared to other remission patients and healthy controls.

Results: 35 tolerant patients were identified. Baseline characteristics are in Table 1.

Variable	**Number**
Age (years, median (range))	59 (14-74)
Female/Male	22/13
MPO/PR3/neither	17/17/1
UK/China/Netherlands	7/11/17
System	**MPO/PR3 (%)**
Renal	82/59
Lung	47/56
ENT	29/61
Eyes	6/33
Musculoskeletal	18/17

Induction regimens included steroids (97% patients) and cyclophosphamide (88%). During maintenance, 67% received azathioprine. All patients became ANCA negative and ceased IS. Median time to ANCA -ve was 5.5 months (mo) and was similar in cANCA (3mo) and pANCA (8mo; P=0.59). The cohort proportion who were ANCA -ve at 6mo was similar to patients analysed in the IMPROVE trial (P=0.67). Median time to stop therapy was 30.5mo and did not differ according to ANCA type (P=0.60). Median duration of ANCA -ve follow-up is 61mo with median duration off IS of 46mo. Analysis of PBMC in a subset of tolerant patients (n=4) demonstrated significantly higher proportion of CD24CD38+ regulatory B cells compared to non-tolerant remission patients (n=33; p=0.002)and similar levels to healthy controls (n=9). Proportions of regulatory T cells did not differ significantly. Analysis of leukocyte subsets is ongoing and may provide insight into cellular mechanisms underlying restoration of tolerance.

Conclusions: AAV patients who remain persistently ANCA -ve off IS are uncommon, are clinically similar to other remission patients, but display different molecular phenotypes.

Funding: Government Support - Non-U.S.

TH-PO819

Risk Factors of Treatment-Related Diabetes Mellitus in ANCA Vasculitis Patrick H. Nachman, Yichun Hu, Caroline J. Poulton, William Franklin Pendergraft, Ronald J. Falk, Susan L. Hogan. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

Background: Diabetes mellitus (DM) is a complication of glucocorticoid treatment which affects a third of patients with ANCA-vasculitis (ANCA-V). We describe the time course and complications of treatment-related DM and identify the independent risk factors in a large cohort of patients with ANCA-V.

Methods: Patients with ANCA-V and no prior history of DM were selected from the Glomerular Disease Collaborative Network. The association of induction IV methylprednisolone (MP) with DM was evaluated as a categorical (exposure vs no) and as continuous variable of cumulative dose. Several multivariable proportional hazard models were explored to identify independent risk factors of DM [results reported as hazards ratios (HR) with 95% confidence intervals (CI) and p-values].

Results: 454 patients were identified (median age 59 years (IQR 45, 70), 55% MPO-ANCA positive). Median follow up was 2.8 years (IQR 1.2, 6.2). 155 (34%) developed DM in a median of 0.69 months (IQR 0.07, 4.05). DM was associated with a higher frequency of severe infections. By multivariable analysis, exposure to, cumulative dose of MP, PR3-ANCA, and the combination of family history of DM *and* BMI $\geq$ 26.5 kg/m^2 were associated with an increased risk of DM. ENT disease was associated with a decreased risk.

Variable	HR (95% CI)	P value
Age (per year)	1.02(1.00,1.03)	0.012
Female Sex	1.45(0.90,2.34)	0.125
MP (exposure vs no)	1.75(1.08,2.84)	0.024
MP (cumulative dose, per g)	1.24(1.05,1.47)	0.012
No Family Hx & BMI $\geq$ 26.5*	1.59(0.88,2.88)	0.126
Family Hx & BMI < 26.5*	1.88(0.85,4.18)	0.118
Family Hx & BMI $\geq$ 26.5*	2.70(1.45,5.02)	0.002
PR3- vs MPO-ANCA	1.78(1.10,2.88)	0.019
ENT (vs no)	0.50(0.30,0.85)	0.01

*vs No Family Hx & BMI < 26.5.

Conclusions: In addition to combined obesity and family history, treatment-related DM in ANCA-V is independently associated with PR3-ANCA and exposure to induction MP. The relative benefits and risks of IV MP in treating ANCA-V are not well established. Our results support using IV MP sparingly in patients at risk of DM.

Funding: NIDDK Support

TH-PO820

Immunoglobulin Levels and Infection Risk with Rituximab Induction for ANCA Associated Vasculitis Shivani Shah, Keiko I. Greenberg, Duvuru Geetha. *Johns Hopkins Univ.*

Background: Rituximab (RTX), a B cell depleting anti-CD20 monoclonal antibody, is approved for treatment of ANCA associated vasculitis (AAV). Low immunoglobulin (Ig) levels have been observed surrounding RTX treatment. The association between the degree of Ig deficiency and infection risk is unclear in AAV patients.

Methods: AAV patients treated with RTX for remission induction in a single center (2005 to 2015) with serum Ig measurements were included. Patient characteristics, serum Ig levels, and occurrence of infections were collected retrospectively. Logistic regression models were adjusted for age at RTX administration and race.

Results: Our cohort of 28 patients had a median age of 65 years; 23 were women; 15 had GPA; and 13 were PR3 ANCA positive. Ten received concomitant cyclophosphamide. Mean IgG, IgM and IgA levels were 569.8mg/dL, 47.8mg/dL, and 123.1mg/dL, respectively. Twenty one patients had low serum IgG levels (<750 mg/dL) following RTX treatment. Over 2.4 years of follow up, 5 individuals developed infections requiring hospitalization (3 bacterial pneumonia, 1 PJP pneumonia, and 1 C. difficile colitis). IgG level $\leq$375mg/dL was associated with higher odds of infection requiring hospitalization compared to IgG level >375mg/dL (odds ratio 26.7, 95% CI: 1.6-452, p=0.023). Similarly, low IgM and IgA levels were also associated with infection.

Number of Infections Requiring Hospitalization (%)	IgG Level			p-value*
	$\geq$750 mg/dL (n=7)	376-749 mg/dL (n=14)	0-375 mg/dL (n=7)	
	1 (14%)	0 (0%)	4 (57%)	0.005
	IgM Level			
	$\geq$46 mg/dL (n=13)	24-45 mg/dL (n=5)	0-23 mg/dL (n=10)	0.093
	1 (8%)	0 (0%)	4 (40%)	
	IgA Level			
	$\geq$82 mg/dL (n=16)	41-81 mg/dL (n=9)	0-41 mg/dL (n=3)	0.004
	1 (6%)	1 (11%)	3 (100%)	

Conclusions: Lower Ig levels were associated with increased odds of infection requiring hospitalization in this cohort. Further investigation is warranted given our study is limited by small sample size, concomitant cyclophosphamide use, and variable timing of Ig measurement.

TH-PO821

Efficacy and Safety of Rituximab in Patients with ANCA Associated Vasculitis and Renal Disease in Clinical Practice Panagiota E. Giannou,[1] Konstantinos Thomas,[2] Aglaia Chalkia,[1] Aikaterini Damianaki,[1] Dimitrios Vassilopoulos,[2] Dimitrios Petras.[1] *[1]Nephrology Dept, Hippokration General Hospital, Athens, Greece; [2]Clinical Immunology-Rheumatology Unit, 2nd Dept of Internal Medicine and Laboratory, Univ of Athens, School of Medicine, Hippokration General Hospital, Athens, Greece.*

Background: Rituximab (RTX), a monoclonal antibody against CD20 is a recently approved therapeutic agent for ANCA-associated vasculitis (AAV). Our study aimed to evaluate the efficacy and safety of administration of RTX in patients with AAV and renal involvement in daily clinical practice.

Methods: Fourteen patients (57.1% males with a mean age of 59.8 years) with Granulomatosis with polyangiitis (GPA- n=8) and Microscopic polyangiitis (MPA- n=6) treated with RTX in our center, between the period of 2011 and 2015, were included. All patients had generalized disease (100%) and were followed for a mean period of 24.7 months. During follow up, disease activity, according to Birmingham Vasculitis Activity Score/WG (BVAS/WG) and adverse effects were recorded.

Results: Eight (57.1%) patients were treated with RTX due to resistant or relapsing disease and 6 (42.8%) received RTX as initial treatment. At 6 months, 71% of patients (10/14) responded to therapy. One patient (7.1%) who had not responded at 6 months, showed complete response at 9 months. Two of 14 (14.2%) patients did not respond to therapy and enrolled in hemodialysis program, possibly due to the chronicity on renal biopsy at the time of diagnosis (>50% global glomerulosclerosis). Overall during treatment, a statistically significant improvement in disease activity was observed (BVAS/WG before RTX: 5.7, 6 months: 1.3, 12 months: 1.1, p=0.01). Among responded patients (n=11), 1 (9%) demonstrated 2 relapses during follow up (one minor and one major). One patient with GPA-associated fulminant pulmonary-renal syndrome died from septic shock one month after RTX administration in combination with cyclophosphamide while in clinical remission from his AAV. No other serious infections or allergic reactions were noticed during the follow up period.

Conclusions: These real life data confirm the excellent efficacy and safety of RTX in patients with newly diagnosed or relapsing AAV.

TH-PO822

Increased Prevalence of Thyroid Disease in Patients with ANCA Associated Vasculitis Maria Prendecki,[1] Leire Martin,[1] Anisha Tanna,[1] Marilina Antonelou,[2] Charles D. Pusey.[1] *[1]Section of Renal and Vascular Inflammation, Imperial College, London; [2]UCL Centre for Nephrology, Royal Free Hospital, London.*

Background: In addition to the known association between different auto-immune diseases, ANCA associated vasculitis (AAV) has previously been associated with thyroid disease possibly due to use of anti-thyroid medications which can induce ANCA. In our clinical practice we have noted a higher prevalence of thyroid disease than would be expected in the general population.

Methods: We identified 279 patients with AAV, diagnosed between 1991 and 2014. Patients were excluded if they were diagnosed prior to 1990 or if insufficient clinical information was available. Data were collected retrospectively on ANCA type, features of vasculitis, history of thyroid disease and treatment.

Results: Thyroid disease was identified in 60 of 279 patients (21.5%); 44 patients had hypothyroidism and 5 patients hyperthyroidism. Three of the hyperthyroid patients developed subsequent hypothyroidism following treatment. Five patients had subclinical hypothyroidism and 5 had subclinical hyperthyroidism. Three patients had goitre and 2 had thyroid nodules. Forty-three patients received treatment with thyroxine, 3 patients received radio-iodine followed by thyroxine, and only 2 patients were treated with propylthiouracil. There were more female patients in the group with thyroid disease than those with AAV and no thyroid disease (73.3% vs. 45.2% female, p=0.0002 chi-squared) and patients were more likely to have anti-MPO antibodies than anti-PR3 antibodies (56.7% vs. 30.5%, p=0.0016). A greater proportion of patients with thyroid disease had evidence of renal involvement as part of their vasculitis (95% vs. 81.7%, p=0.02).

Conclusions: Our data shows a prevalence of thyroid disease of 21.5% and prevalence of hypothyroidism of 15.4% in our group of patients with AAV. This compares to a population prevalence in the UK for hypothyroidism of around 2% for females and <0.1% for males. In view of this association we suggest that patients diagnosed with AAV should be tested for thyroid disease.

TH-PO823

Myeloperoxidase Antibody Positivity in Patients without Primary Systemic Vasculitis Marilina Antonelou,[1] Lara Perea-Ortega,[2] Sally Hamour,[1] Alan D. Salama.[1] *[1]Centre for Nephrology, Univ College London; [2]Hospital General de Fuerteventura.*

Background: The combination of a pANCA immunofluorescence pattern with antibodies specific for myeloperoxidase (MPO) has been reported to have 99% specificity for the diagnosis of ANCA associated vasculitis(AAV). However, increased testing for MPO-ANCA in unselected populations can reduce the specificity for diagnosing vasculitis. The aim of this study was to gain an understanding of the frequency and associations of MPO-ANCA positivity in patients without primary AAV using current detection methods.

Methods: Retrospective review of all patients identified as MPO-ANCA positive, as determined by Luminex testing in our laboratory over a 4 year period. Case notes and laboratory results were reviewed subsequently to establish if they had a diagnosis of AAV or alternate diagnoses.

Results: Two hundred and eight patients were positive for MPO-ANCA, of whom 121(58.2%) had primary AAV. Seventy nine(37.9%) patients were anti-MPO positive without AAV. Clinical associations included other autoimmune disorders (69.6%), infections (8.9%), malignancy (5.1%) and other miscellaneous conditions(16.4%). The median(IQR) MPO-ANCA titre in this group was 16(12-30)U/ml vs 66(24-100)U/ml in the group with primary AAV ($p<0.001$). Thirty eight(48%) patients without known AAV had renal impairment defined as eGFR<60ml/min and/or uPCR ≥100. Twenty two of these patients had a kidney biopsy that ruled out the diagnosis of primary AAV. The characteristics of the 16 patients that were not biopsied are shown in Table 1.

n=16	
Age, mean(SD)	70(16)
MPO-ANCA titre, U/ml, median (IQR)	13(11-37)
eGFR/ml/min, mean(SD)	49.4(26.1)
Other antibodies	11(69%)
Clinical associations Infection/TB Autoimmunity **No association found**	 1 11 4

Conclusions: In patients with MPO-ANCA positivity, 37.9% showed a variety of underlying non-vasculitic conditions, much higher than that reported for PR3-ANCA, in which 9.7% of patients did not have AAV(1). As detectable antibodies may predate the onset of disease, unexplained ANCA findings require long-term follow up and often warrant tissue diagnosis.

Therapeutic Effect of Plasma Exchange in the Treatment of Severe Renal Damage in Anti-Neutrophil Cytoplasm Antibody Associated Vasculitis

Liping Wang. *Div of Nephrology, Fuzhou Dongfang Hospital, Fuzhou, Fujian, China.*

Background: Anti-neutrophil cytoplasm antibody-associated vasculitis (AAV) is associated with high rates of mortality due to uncontrolled disease and treatment toxicity. Small randomized trials suggest adjunctive plasma exchange(PE) may improve disease control.

Methods: ALL AAV patients presenting between 2011 and 2013 were retrospectively analyzed.The patients were divided into two groups according to the presence of PE or not. The two groups in age, sex, BVAS, serum creatinine and the level of ANCA have no statistical difference ($P > 0.05$).Patients were treated with corticosteroids, and intravenous CYP. Rate of dialysis independence at1 , 3 months and compared with theoutcome of the two groups.

Results: Forty-six patients were included. The two groups in age, sex, BVAS, serum creatinine and the level of ANCA have no statistical difference ($P > 0.05$). PE group had 23 cases ,in PE group,the level of ANCA were from[(169.1±69.8)to(92.9 ±61.8)RU/ml,P<0.05],serum creatinine from [(580.7±206.1) to (405.7±191.1)umol/L, P<0.05];In control group,the level of ANCA from[(170.6±72.4) to (105.64±62.26) RU/ml,P<0.05],serum creatinine from [(678.7±372.04)to (392.26±187.03)umol/L,P <0.05]. In PE group, 5 patients(21.7%) died at a month; 4 patients(17.2%) died in control group. 7 patients with dialysis at a month in PE group, 3 (42.9%) were dialysis independent at a month 5 patients with dialysis in the control group , 1 (20%) was dialysis independent at a month. At 3 months, 8(34.7%) patients were were dialysis independent in PE group; 3 (13%) patients were dialysis independent in control group. Follow up (21.3±8) months,no statistical difference of survival rates was found between two groups .

Conclusions: PE combined corticosteroids and intravenous CYP could effectively reduce the level of ANCA and improve renal function,rate of dialysis independence at 3 months was higher than control group. but the long-term survival In PE group was no difference from the control group.

Prevalence of Immunofluorescent Deposits in ANCA Associated Vasculitis: How "Pauci" Is "Pauci-Immune"?

Layla Alharbi, Lonnie Pyne, Michael Walsh. *McMaster Univ.*

Background: ANCA associated vasculitis is classically associated with a necrotizing, crescentic glomerulonephritis with a lack of immune deposits on immunofluorescent microscopy. We studied the prevalence and characteristics of immunofluorescent deposits in a cohort of patients with known ANCA associated vasculitis.

Methods: We performed a retrospective, single centre cohort study in Hamilton, Canada. We identified patients with a clinical diagnosis of granulomatosis with polyangiitis or microscopic polyangiitis and a renal biopsy. Biopsy records were reviewed for reports of the type, location and intensity of immune deposits on immunofluorescence. Patient characteristics were extracted from clinical charts with a standardized case report form. Biopsy and clinical characteristics were summarized using descriptive statistics. We used multivariable logistic regression to determine if there was an association between immunofluorescent staining and age, sex, ANCA type or need for dialysis at time of biopsy.

Results: We identified 69 patients with ANCA associated vasculitis and a renal biopsy. The patients were a median of 62 (IQR 54 to 70) years old, 33 (48%) were male, 16 (23%) required dialysis at the time of biopsy, 22 (32%) were anti-PR3 positive, 46 (67%) were anti-MPO positive and 1 (1%) was positive for both. Twelve (17%) were reported as pauci immune, however, IgG was found reported as at least 1+ in 23 (33%) in the mesangium and 24 (35%) in the capillaries. IgM was reported in the mesangium of 27 (39%) and in the capillaries of 22 (32%) and IgA in the mesangium of 22 (32%) and in the capillaries of 21 (30%). C3 was reported in 26 (38%) in the mesangium and 28 (41%) in the capillaries. The majority (80%) of positive immunofluorescence was reported at 3+. Male sex was associated with a 3-fold increase in the odds of positive IgG immunofluorescence ($p=0.04$ for mesangial and 0.03 for capillary) but not with age, ANCA type or need for dialysis.

Conclusions: Although the glomerulonephritis in ANCA associated vasculitis is classically described as pauci-immune, 30-40% of patients have immunofluorescence staining, most often men.

TH-PO826

Distribution of Neutrophil Extracellular Traps in the Kidney Suffering from Myeloperoxidase-ANCA Associated Vasculitis with Peritubular Capillaritis

Naoko Tsuji, Takayuki Tsuji, Naro Ohashi, Akihiko Kato, Hideo Yasuda. *Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Neutrophil extracellular traps (NETs) have been shown to contribute to development of MPO-AAV. We previously reported that peritubular capillaritis (PTC) was accompanied by 55% of patients with myeloperoxidase-ANCA associated vasculitis (MPO-AAV). We hypothesized that NETs could be found around PTC as well as crescentic formation in MPO-AAV. The purpose of this study is to reveal the distribution of intrarenal NETs in MPO-AAV with PTC.

Methods: We evaluated the distribution of NETs by immunofluorescence in paraffin-embedded tissue sections of 24 patients with MPO-AAV diagnosed by kidney needle biopsies in Hamamatsu University Hospital from January 2011 to January 2016. PTC was defined by histological findings of inflammatory cells accumulated in the peritubular capillary in association with the disruption of the capillary wall that was stained by anti-CD34 antibody. NETs were identified by colocalization of DNA and citrullinated histone and MPO with confocal immunofluorescence microscopy.

Results: PTC was found in 11 of 24 patients with MPO-AAV. There were no significant difference in ages (70.0±17.1 vs 63.1±19.1), serum creatinine (1.62 ± 1.08 vs 2.15 ± 1.52 mg/dl), MPO-ANCA titers (156.5±108.8 vs 170.1±205.4 IU/ml) between MPO-AAV with and without PTC. NETs were seen more outside glomeruli especially in and/or around PTC and less within glomeruli in MPO-AAV with PTC than without PTC (extraglomerular NETs positive fields / total fields: 33.9 ± 20.3 % vs 13.7 ± 12.8 %, $p<0.05$, NETs positive glomeruli / total glomeruli : 12.7±13.1 vs 28.7±18.7, $p<0.05$). The detection rate of extraglomerular NETs were correlated with the level of urinary α1 microglobulin excretion.

Conclusions: NETs were found around not only crescent but also PTC in the kidney suffering from MPO-AAV with capillaritis, suggesting NETs might contribute to development of PTC.

TH-PO827

Long-Term Follow-Up of a Combined Rituximab and Low-Dose Cyclophosphamide Regimen for Remission Induction in Renal ANCA-Associated Vasculitis

Stephen Paul McAdoo,[1] Nicholas R. Medjeral-Thomas,[1] Anisha Tanna,[1] Megan Griffith,[1] Jeremy B. Levy,[1] H. Terence Cook,[1] Tom Cairns,[1] Alan D. Salama,[2] Charles D. Pusey.[1] *[1]Imperial College Kidney and Transplant Centre, United Kingdom; [2]Univ College Centre for Nephrology, United Kingdom.*

Background: We have previously reported prolonged relapse-free survival in a cohort of 23 patients with renal AAV, following remission-induction treatment with a rituximab-based, cyclophosphamide-sparing regimen. We now report long-term outcomes using this protocol in an extended cohort of 66 patients.

Methods: We report long-term follow-up of consecutive patients presenting with new or relapsing renal AAV at our centre since 2006, who were treated with our published regimen of oral steroids, rituximab and low-dose pulsed intravenous cyclophosphamide. Patients who presented with alveolar haemorrhage, renal-failure requiring dialysis, or other severe disease manifestations requiring addition of plasma exchange were not included. Maintenance therapy was commenced at 3 months with azathioprine of MMF.

Results: 66 patients are included in the current analysis. The median BVAS and creatinine at presentation was 19 and 205µmol/l respectively. The median dose of rituximab and cyclophosphamide was 2g and 3g respectively. All patients achieved B cell depletion, and 95% were in remission by 6 months. At last follow-up (median 5 years; range 1-10), renal and patient survival were 94% and 84% respectively. Ten patients (15%) experienced a major relapse during follow-up, at a median time of 39 months. All were ANCA positive and 90% B cell replete at relapse. 30% of patients had an infection requiring hospital admission. No unexpected adverse events were observed.

Conclusions: These findings confirm our previous observations that this regimen affords early disease control in renal AAV, and relapse rates that are favorable compared to published controlled studies. These observations are in keeping with long-term follow-up of the RAVE trial, where sustained remission was observed without maintenance therapy following rituximab treatment. We believe this combined regimen may provide the basis to further refine remission-induction protocols in AAV, potentially by allowing early withdrawal of corticosteroids.

Funding: Government Support - Non-U.S.

TH-PO828

A Steroid-Sparing Regimen for Remission Induction Therapy in Renal ANCA-Associated Vasculitis Stephen Paul McAdoo, Rachna Bedi, Megan Griffith, Tom Cairns, Charles D. Pusey. *Imperial College Kidney and Transplant Centre, United Kingdom.*

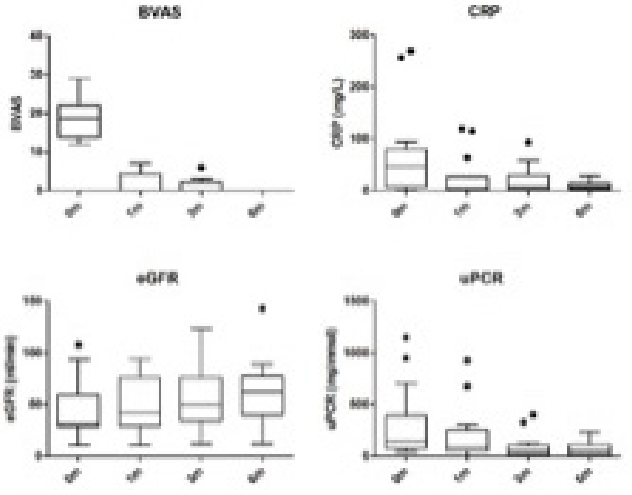
Background: The majority of early mortality in AAV is now attributed to infections, rather than active disease. Infection, along with cardiovascular disease, remains a common cause of long-term mortality. It is likely that corticosteroid exposure contributes to the risk of these adverse outcomes, and that steroid avoidance may improve outcomes in AAV.

Methods: This is a cohort study of a novel steroid-sparing regimen that has been in use for treatment of new or relapsing renal AAV at our centre since 2014 (Table 1).

Summary of the Induction Protocol		
Rituximab	1gx2	Wk 0,2
Cyclophosphamide	750mgx2; 500mgx4 pulses	Wk 0,2,4,6,8,10
iv Methylprednisolone	500mgx2	Wk 0,2
Oral Prednisolone	30mg daily	Wks 0-2 inclusive

Patients with significant alveolar hemorrhage or renal failure requiring dialysis were not included. Maintenance therapy commenced at 3 months with azathioprine or MMF.

Results: To date, 14 patients have completed at least 6 month follow-up. The median BVAS and creatinine at presentation were 17 and 180µmol/l, respectively. All patients achieved clinical remission by 6 months (Figure 1).



8 infections were seen in 6 patients, of which none were atypical. There were no new cases of diabetes and measurements of HbA1c did not change significantly (46 vs 42 mmol/mol pre- and post- treatment, respectively, p=0.23). No relapses have been observed at last follow-up 9.3 months (6.5-22).

Conclusions: Our data suggests that remission in AAV may be achieved with significantly lower corticosteroid doses than previously reported. This was not associated with early relapse, and may result in an improved adverse event profile. Controlled studies are required to establish if steroid avoidance using this, or similar, protocols will result in improved long-term outcomes in larger cohorts.

TH-PO829

Clinical Features and Outcome of Elderly Patients with Anti-Neutrophil Cytoplasmic Autoantibody-Associated Vasculitis Eun Young Seong,[1] Harin Rhee,[1] Jong Man Park,[1] Sang Heon Song,[1] Il Young Kim,[2] Dong Won Lee,[2] Soo Bong Lee,[2] Ihm Soo Kwak.[1] *[1]Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea; [2]Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) is common in elderly population, but there is few data of clinical characteristics and outcome, especially in Asia. This study aimed to investigate demographic factors, treatment and outcome in patients aged ≥65 years with AAV in Korea.

Methods: We reviewed the medical records of 228 C-ANCA or P-ANCA positive patients in a university-affiliated nephrology center from 2005 to 2016. Patients classified as having secondary vasculitis, drug-induced vasculitis, eosinophilic granulomatosis with polyangiitis and polyarteritis nodosa were excluded. A total of 69 patients were included in this study.

Results: Twenty-eight patients (40.6%) were older than 65 years old (elderly group), and 41 patients (59.4%) were younger than 65 years old (younger group). Median age at diagnosis was 71.25±4.54 years in elderly group and 47.02±13.61 years in younger group. In elderly group, initial blood urea nitrogen level and C-reactive protein (CRP) were higher and initial estimated glomerular filtration rate (eGFR) was lower than younger group. Comorbidity score and organ involvement were not different between two groups. Median follow-up was 20.74 months. Overall survival was significantly lower in elderly group (75.0%) than younger group (7.1%) (p=0.024). Older age and higher serum creatinine level were associated with higher mortality. Renal survival was 50% in elderly group and 31.7% in younger group. High serum creatinine level at diagnosis was the only significant predictor of renal survival. Patients who were treated with standard immunosuppressive therapy had same survival and renal survival in elderly group.

Conclusions: AAV is a disease with substantial mortality and morbidity among elderly patients. This study showed that standard immunosuppressive therapy may not help improve the outcome in elderly AAV patients.

TH-PO830

Management and Outcome of Anti-Glomerular Basement Membrane (GBM) Disease: A Single Centre Retrospective Case Series Anna K. Forbes, David Makanjuola, Marie B. Condon, Bhrigu Raj Sood, Fiona E. Harris. *Renal Medicine, St. Helier Hospital, London, United Kingdom.*

Background: Anti-GBM disease is a rare autoimmune condition characterised by rapidly progressive glomerulonephritis and/or pulmonary haemorrhage. Data on optimal treatment and outcomes is limited and is mainly from uncontrolled studies, with plasma exchange, corticosteroids and oral cyclophosphamide (CyP) widely accepted as induction therapy. In our centre, we routinely use pulsed intravenous (i.v.) CyP in lieu of oral, thereby reducing total CyP dose. The role of maintenance immunosuppression is less clear; where this is used, Azathioprine is our first line therapy. We present retrospective data from a cohort of patients with anti-GBM disease.

Methods: Using our local database, we identified 29 patients with anti-GBM disease presenting over a 14 year period. Data were collected from paper and electronic medical records.

Results: 16 (55%) patients were dialysis dependent at presentation. In this group, patient and renal survival were 75% and 12.5% at 1 year and 62.5% and 6.25% at last follow up respectively. Of the 13 (45%) patients who were dialysis independent at presentation, patient and renal survival were 100% and 69% at 1 year and 100% and 61.5% at last follow up. This demonstrated a significant difference in renal survival at 1 year (p = 0.014) and at last follow up (p = 0.012). The mean duration of anti-GBM antibody (Ab) persistence was 135 days. In those patients receiving maintenance immunosuppression (n=13, 45%), the duration of Ab persistence was shorter at 96 days compared with 175 days in those not receiving maintenance therapy.

Conclusions: Our findings are consistent with published data on patient and renal survival. Our data suggest that pulsed i.v. CyP may be as effective as oral. This therapeutic strategy may reduce treatment related toxicity without affecting outcome. Furthermore, our data suggest that time to Ab negativity is shorter in those receiving maintenance immunosuppression, an important consideration in potential transplant recipients. A randomised controlled trial is necessary to validate these findings.

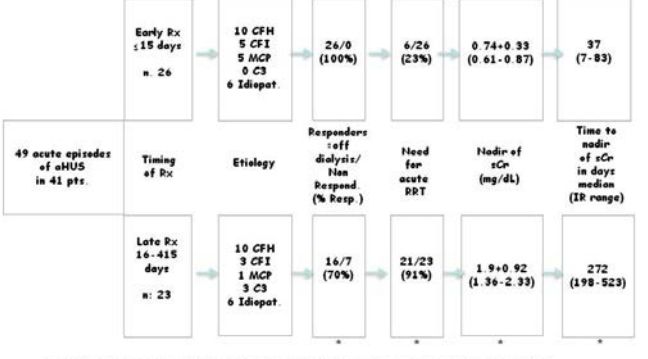
TH-PO831

Timing of Eculizumab Treatment and Renal Outcome in aHUS Gianluigi Ardissino, Francesca Tel, Donata Cresseri, Stefania Salardi, Sara Testa, Fabio Paglialonga, Michela Perrone, Martina Sgarbanti, Silvana Tedeschi, Florjan Mehmeti, Chiara Ferraris Fusarini, Piergiorgio Messa. *Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milano, Italy.*

Background: Atypical HUS (aHUS) is a severe thrombotic microangiopathy (TMA). Eculizumab (ECU) is the frontline treatment (Rx) it is not always started early after diagnosis; late Rx may result in permanent renal renal damage.

Methods: We analyze the renal outcome of patients (Pts) treated at our Center for aHUS as to timing of ECU Rx. Since 2009, at least 49 acute episodes of aHUS in 41 Pts with ongoing TMA, were treated with ECU. The 17 Pts with bone marrow transplantation-related TMA, were excluded for the different pathogenesis and the systematically different(poor) response to ECU Rx.

Results: Twelve Pts were children,25 females,4 were kidney transplant recipients,median age was 29.3 years(IR 11.7-44.2),25 episodes had been treated with plasmaexchange(PEX) before ECU and 27 required RRT. In 26 events,ECU was started within 15 days of presentation(median2.5; IR1-6) while in the remaining 23, Rx was started at a median of 43 days (IR 30-165). Five events (19%) treated early, had also been exposed to PEX before ECU compared to 20(87%) in the late Rx group. Pts' carachteristics and their renal outcome according to timing of ECU Rx, are shown in the figure.



Legends: Rx: treatment; RRT: renal replacement therapy sCr: serum creatinine; *: p<0.01

The pt who started ECU as late as415 days(the latest)after disease presentation(CFH mutation)reached a nadir of sCr as low as .7 mg/dL.

Conclusions: Early Rx provides better renal outcome as to response rate, need for acute RRT, final renal function and time to reach the nadir of sCr. The better outcome turns into lower costs for the possibility of early discontinuation of ECU, for which a good residual renal function is essential. We stress that ECU Rx can be useful even if started late, we encourage to treat Pts as long as signs of ongoing TMA are present, regardless of disease duration.

TH-PO832

A Simple and Early Prognostic Index for STEC-HUS at Presentation
Gianluigi Ardissino, Francesca Tel, Sara Testa, Fabio Paglialonga, Michela Perrone, Dario Consonni. *Fondazione IRCCS Ca' Granda Osp. Maggiore Policlinico, Milano, Italy.*

Background: STEC-HUS is an unrare, severe acute thrombotic microangiopathy (TMA) burdened with life-threatening complications (Cs), high case-fatality rate and significant long term sequels. It is important, both for patient's (Pts) management and prognosis communication, to identify Pts at high risk for severe Cs, as early as possible in the course of the disease possibly through a simple and straightforward approach. It has been demonstrated that hemoconcentration at presentation of STEC-HUS is associated with worse short- and long-term outcome.

Methods: The very first laboratoy examination with signs of TMA of Pts referred to our Center during recent years, were analyzed in order to identify and develop a reliable, as well as easy to calculate (at bedside), index to predict Cs. The following outcomes were considered together: 1. death, 2. CNS involvement, 3. need for RRT, 4. long-term renal and systemic sequels. Receiver Opereiting Characteristic (ROC) and their area under the curve (AUC) for the continuous laboratory parameters hemoglobine (Hb), serum creatinine (sCr) and LDH at presentation, were calculated, alone and in combination, after univariate and multiple logistic regression models, on the dataset of 38 patients (20 Females) with documented STEC-HUS and with a mean age of 4.9 yrars (IR 1.5-7.1).

Results: Overall there were 25 Pts (65.8%) with the listed Cs. Hb level at presentation alone proved to be the best predictor of poor outcome (AUC: 0.751). The probability of Cs increased linearly with Hb level, from about 10% at Hb of 7 gr/dL to 50% at 12 and up to 70% when Hb was 14. Frequency of Cs was 9.1% when sCr was < 1 mg/dL and 38.9% when >1 mg/dL (AUC: 0.756). The AUC for Hb and sCr combined was 0.884 (CI 0.763-0.942).

Conclusions: We conclude that in STEC-HUS, Pts with higher Hb level (>11 gr/dL) and those with high sCr, although Hb is <11 gr/dL, at presentation should be carefully evaluated, monitored and managed accordingly for the very high risk of Cs most likely related to hidden hemoconcentration in ongoing TMA.

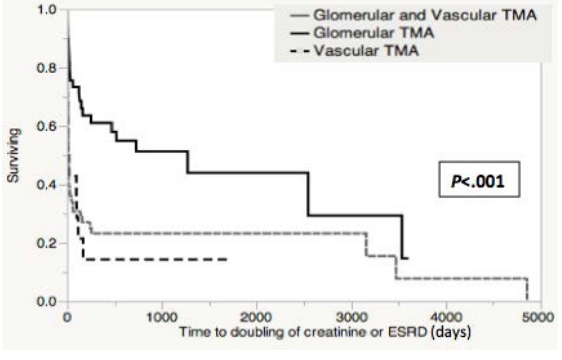
TH-PO833

Renal Thrombotic Microangiopathy in the Modern Era: A Report of 128 Cases from a Single Center
Gauri Bhutani,[1] Samar M. Said,[3] Nelson Leung,[2] Mary E. Fidler,[3] Mariam P. Alexander,[3] Lynn D. Cornell,[3] Samih H. Nasr.[3] *[1]Nephrology, Univ of Wisconsin, Madison; [2]Nephrology, Mayo Clinic; [3]Pathology, Mayo Clinic, Rochester.*

Background: Large modern series addressing renal thrombotic microangiopathy (TMA) are lacking. This study aimed to define current epidemiology, outcomes and clinicopathologic correlations in renal TMA.

Methods: We identified 128 patients with renal TMA by retrospective review of our pathology archives from 2000-14. Pathologic findings, clinical, treatment and outcome parameters were correlated. Statistical analysis employed Fisher's exact and Log Rank tests.

Results: Median age was 51 yrs (34-65); 55% were female and 84% Caucasian. Median serum creatinine (Cr) and proteinuria at renal biopsy (bx) were 2.9 mg/dL (1.8-4.2) and 2.0 g/day (0.8-4.5), respectively. The most common causes were autoimmune diseases (29%), hematologic clonal disorders (17%), drugs (13%), complement-mediated disorders (12%) and hypertension (10%). Evidence of microangiopathic hemolytic anemia (MAHA)-thrombocytopenia and peripheral schistocytes- was seen in 54% and 42%, respectively. Acute TMA on bx (fibrin thrombi and/or schistocytes) was noted in 59% and correlated with detectable MAHA (88% vs 54%, *P*<.001]. Median follow up was 752 days (169-1396) with 66% developing doubling of Cr/need for acute dialysis [median time: 13 days (4-59.5)], and 34% progressing to ESRD. TMA involved glomeruli alone, vessels and glomeruli, and vessels alone in 38%, 51%, and 11%, respectively. Vascular TMA was associated with autoimmune diseases (38% vs.16%, *P*=.01) and poor renal outcomes (Figure).



Conclusions: The epidemiology of renal TMA is evolving: autoimmune, hematologic clonal, complement-mediated disorders and drugs account for most cases. Systemic MAHA is not always present, emphasizing the importance of renal bx for diagnosis. Despite medical progress in TMA, renal prognosis remains poor, particularly with vascular involvement.

TH-PO834

Renal Prognosis of TKI Induced Thrombotic Microangiopathy, a Case Series
Keren Doenyas-Barak,[1] Avishay Sella,[2] Shai Efrati.[1] *[1]Nephrology and Hypertension, Asaf Harofeh Medical Center, Israel; [2]Oncology, Asaf Harofeh Medical Center.*

Background: Anti-VEGF tyrosine kinase inhibitors (TKIs) have substantially improved survival and quality of life of metastatic renal cell carcinoma (mRCC) patients. However, soon after the introduction of these drugs, data regarding their toxicity emerged. Renal toxicity, typically characterized by proteinuria, hypertension and renal failure, and pathologically by thrombotic microangiopathy, appears in up to 2% of patients. Most guidelines recommend withholding TKI use, but limited alternatives exist, and thus cautious continuation of TKIs may be desired. We report our three year experience treating patients with clinical TKI-induced thrombotic microangiopathy (TMA).

Methods: From the database of the nephro-oncologic clinic in Asaf Harofe Medical Center, baseline characteristics, renal progression and outcomes were extracted for Renal cell cancer patients treated with TKIs who developed proteinuria, renal failure and clinical signs of TMA.

Results: We allocated 7 patients. Their baseline characteristics included: proteinuria: 0.5 to 10.1gr (mean 5.13gr), creatinine of 1.58-4.06 mg/dl (mean 2.26mg/dl), hemoglobin of 8.4-13 mg% (mean 10.93 mg%) and platelet count of 90000-372000 (mean 193000).

TKI treatment was held in one patient due to decompensated malignant ascites, but resumed in 6 patients with mean follow-up of 22 months. Proteinuria was reduced in all patients with ACE inhibitors or ARBs treatment and tight blood pressure control.

During the follow up period creatinine blood levels were stable with mean change of 0.02mg/dl (-0.6 to +0.45mg/dl), compared to baseline. One patient with baseline creatinine of 4.06mg/dl had started dialysis simultaneously with axitinib readministration.

None of the patients developed grade III-IV anemia or thrombocytopeania, nor thrombo-embolic events.

Conclusions: TMA related to TKIs may present as an indolent disease. Careful follow up by an experienced nephrologist may enable continuation of TKI treatment.

TH-PO835

Atypical Hemolytic Uremic Syndrome: A Meta-Analysis of Case Reports
Mohit Gupta,[1] Tushar J. Vachharajani,[4] Mustafa Ascha,[2] Ramya Vajapey,[3] Rupesh Raina.[1] *[1]Dept of Internal Medicine, Akron General Medical Center, Akron, OH; [2]Clinical and Translational Science Collaborative, Case Western Reserve Univ, Cleveland, OH; [3]School of Medicine, Northeast Ohio Medical Univ, Rootstown, OH; [4]W.G. (Bill) Hefner VA Medical Center.*

Background: Atypical Hemolytic Uremic Syndrome is a life threatening thrombotic micro-angiopathy that affects the GI tract, Kidneys and the Central Nervous System. Recently, uncontrolled complement activation has been associated with aHUS. Different mutations have been linked with atypical HUS paving the way for targeted drug therapy. We will discuss the various mutations that are linked to atypical HUS, treatment modalities and their impact on prognosis.

Methods: A PubMed/Medline search for case studies including "atypical hemolytic uremic syndrome" was conducted between November 2000 and November 2015. Points reviewed were time to symptom resolution and mortality. Wilcoxon Rank Sum Test was used to compare time for symptom resolution, normalization of creatinine and platelets amongst treatment groups and mutation carriers.

Results: Between 2005 and 2015, 222 articles related to aHUS were reviewed. Patients between 2010 to 2015 had a higher severity of illness compared to the previous interval. The proportion of CFI and MCP mutations across the first 5 year interval was also higher. Use of Eculizumab has also increased from 7.5% to 48.6% over the last five years. Plasma Exchange therapy use was higher in patients with higher levels of Creatinine in comparison to those who didn't (p<0.001). Both Plasma Exchange and Eculizumab decreased mortality (p=1; p=0.25).

Conclusions: The incidence of aHUS has significantly increased over the past 5 years. Plasma exchange is the preferred modality with 65 % case studies using the same. Eculizumab was used in 35% of the case studies reviewed and was found to reduce mortality. Mutations associated with aHUS were CFH followed by MCP and CFI. Patients with CFH mutation were more likely to be involved in plasma exchange therapy. aHUS was a disease of exclusion but now has specific mutations and it's own treatment. With greater registry programs and clinical trials, we would have more clinical knowledge that would hopefully help us decrease the incidence of the disease.

TH-PO836

Renal Outcome in Primary Thrombotic Microangiopathies
Hassan A. Salameh, Jennifer C. Yui, Fernando C. Fervenza, Ronald Go, Jeffrey L. Winters, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Background: Thrombotic microangiopathy (TMA) describes a pathological process of microvascular thrombosis, microangiopathic hemolytic anemia and consumptive thrombocytopenia leading to end-organ ischemia. Any organ can be involved but patients usually present with acute kidney injury (AKI) and/or cerebral dysfunction. Literature

suggests that hemolytic uremic syndrome induces more severe renal injury than thrombotic thrombocytopenic purpura (TTP) but this is not universally found. The aim of this study is to analyze the severity of AKI and clinical outcome of patients with renal TMA in a cohort of patients from a single center's experience.

Methods: Clinical and laboratory data of 126 patients diagnosed with TMA from 2000 to 2014 were retrospectively analyzed. Patients were followed for 1 year after diagnosis and renal outcomes at 3 months and 1 year were analyzed using serum Creatinine and GFR. 43 patients were excluded due to insufficient data or loss to follow-up.

Results: Patients were subcategorized into shiga toxin producing E. Coli hemolytic uremic syndrome (STEC-HUS), TTP or atypical hemolytic uremic syndrome (aHUS) and results are summarized in table 1. Primary TMA was associated with AKI in 80.7% of patients. Atypical HUS was associated with more severe AKI with 81.8% presenting with AKIN stage 3 compared to 38% of TTP patients. Long term outcome was worse for aHUS patients with 50% requiring dialysis at one year compared to 11.3% of TTP patients.

	STEC-HUS (6)		aHUS (11)		TTP (66)	
No AKI	**0**		**0**		**24.2%**	
Stage 1 AKI	**0**		**9.1%**		**24.2%**	
Stage 2 AKI	**16.7%**		**9.1%**		**13.6%**	
Stage 3 AKI	**83.3%**		**81.8%**		**38%**	
	3 months	**1 year**	**3 months**	**1 year**	**3 months**	**1 year**
GFR >60	**33.3%**	**66.6%**	**18.2%**	**12.5%**	**45.2%**	**45.3%**
GFR 30–59	**0**	**0**	**0**	**12.5%**	**27.4%**	**26.4%**
GFR 15–29	**33.3%**	**33.3%**	**36.4%**	**12.5%**	**4.8%**	**1.9%**
GFR <15	**0**	**0**	**9%**	**0**	**1.6%**	**0**
On Dialysis	**33.3%**	**0**	**36.4%**	**50%**	**11.3%**	**11.3%**
Mortality	**0**	**0**	**0**	**12.5%**	**9.7%**	**15.1%**

Conclusions: TMA imposes a large burden on renal health. In our center's experience aHUS had worse acute and long term renal outcomes when compared with TTP or STEC-HUS. However, the number of patients in both the STEC-HUS and aHUS were small in comparison to the TTP group.

TH-PO837

Hypertension-Associated Thrombotic Microangiopathy and Complement Dysregulation Sjoerd Timmermans,[1] Myrurgia Abdul-Hamid,[2] Jan Damoiseaux,[3] Pieter Van Paassen.[1] *[1]Nephrology and Clinical Immunology, Maastricht UMC, Netherlands; [2]Pathology, Maastricht UMC, Netherlands; [3]Central Diagnostic Laboratory, Maastricht UMC, Netherlands.*

Background: Renal thrombotic microangiopathy (TMA) can be both cause and consequence of severe hypertension, ultimately leading to renal failure. Underlying pathophysiological mechanisms differ among the diverse TMA syndromes with great impact on treatment options and prognosis. We hypothesized that dysregulation of the alternative pathway (AP) is a treatable, but often unrecognized cause of hypertension-associated TMA, particularly in patients without biochemical signs of TMA, and that the prognosis resembles atypical hemolytic uremic syndrome (aHUS).

Methods: Consecutive patients with hypertension-associated TMA, defined as severe hypertension (BP ≥180/120 mmHg) and biopsy-proven renal TMA, were screened for AP abnormalities, including genetic and serological testing. Renal biopsies were stained for complement components.

Results: Ten patients were identified, including 8 patients without biochemical signs of TMA. *C3* (*n*=3), *CFI* (*n*=1), *CD46* (*n*=1) and/or *CFH* (*n*=2) mutations either with or without Δ*CFHR1-CHFR3* (*n*=2) and/or at-risk *CFH* haplotypes (*n*=5) were found in 7 patients. C3c and C5b-9 deposits along the vasculature and glomerular capillary wall confirmed complement activation in vivo. Patients with genetic AP abnormalities invariably presented with end-stage renal disease (ESRD), while ESRD did not occur among patients without complement defects. Remarkably, disease recurrence developed in 4 out of 5 allografts (*n*=3), which was associated with graft loss; recurrence-free survival was achieved in a single patient who received eculizumab after transplantation, however.

Conclusions: AP abnormalities can be found in a subset of patients with hypertension-associated TMA even though biochemical signs of TMA are mostly absent. Renal survival is poor and TMA recurrence appeared common, indicating that these patients fall into the spectrum of aHUS. Genetic testing for AP abnormalities should therefore be performed in patients with hypertension-associated TMA, particularly in those not responding to treatment and/or prior to renal transplantation.

TH-PO838

Clinical Features of Primary Membranoproliferative Glomerulonephritis in Japan: An Analysis of the Japan Renal Biopsy Registry (J-RBR) Naoki Nakagawa,[1] Motoshi Hattori,[2] Michio Nagata,[3] Hitoshi Yokoyama.[4] *[1]Nephrology, Asahikawa Medical Univ, Japan; [2]Tokyo Women's Medical Univ; [3]Tsukuba Univ; [4]Kanazawa Medical Univ.*

Background: The clinical features of primary membranoproliferative glomerulonephritis (MPGN) in an adequate sample of patients has not been studied in detail. We therefore surveyed the features of primary MPGN based on data from the Japan Renal Biopsy Registry (J-RBR).

Methods: A cross-sectional survey of 332 patients with primary MPGN registered in the J-RBR between 2007 and 2015 was conducted. Clinical parameters of blood pressure (BP), and blood and urine laboratory findings at diagnosis were compared between children (< 20 years), adults (20-64 years) and elderly persons (≥ 65 years). Factors affecting declining renal function in adult and elderly patients were assessed using multiple regression analysis.

Results: Mean age was 51.6 ± 24.6 years, mean systolic BP 137.9 ± 22.4 mmHg, mean proteinuria 3.8 ± 3.4 g/day, mean serum albumin 2.97 ± 0.80 g/dL and mean eGFR 49.9 ± 26.1 ml/min/1.73m^2. The clinical features were significantly more severe in elderly patients, especially systolic BP (children, 112.8 ± 15.8; adult, 136.0 ± 18.1; elderly patients, 148.2 ± 20.3 mmHg; P<0.001), proteinuria (children, 1.8 ± 2.2; adult, 4.0 ± 3.2; elderly patients, 4.2 ± 3.6 g/day; P<0.001), low albumin levels (children, 3.5 ± 0.9; adults, 3.0 ± 0.8 g/day; elderly patients, 2.8 ± 0.7 g/dL; P<0.001), and low eGFR (adults, 59.6 ± 28.7; elderly patients, 40.2 ± 18.6 ml/min/1.73m^2; P<0.001). The rate of clinically classified nephrotic syndrome was significantly higher in adults (48.8%) and elderly patients (62.9%) than children patients (16.7%), whereas the rate of chronic glomerulonephritis was significantly higher in children (76.7%) than adults (46.5%) and elderly patients (29.4%). Multiple regression analysis revealed that high systolic BP and high proteinuria were independent factors associated with decreased eGFR in adult and elderly patients with primary MPGN.

Conclusions: In Japan, the clinical features of adults and elderly patients with primary MPGN were more severe than those of children. Further investigation is needed to explore the clinical outcomes in patients with primary MPGN.

TH-PO839

Immune-Complex Mediated Membranoproliferative Glomerulonephritis: A New Approach to a Forgotten Entity Paola Rodríguez, Enrique Morales, Evangelina Merida, Eduardo Gutierrez-Martinez, Manuel Praga. *Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: The better understanding of membranoproliferative glomerulonephritis (MPGN) based on immunofluorescence has changed its therapeutical approach. Idiopathic immune-complex mediated MPGN is a partially known entity. The aim of this study was to analyze the clinical presentation, treatment and outcome of this disease.

Methods: Retrospective review ofpatients diagnosed of idiopathic immune-complex mediated MPGN at our Nephrology Department from 1976 to 2015.

Results: Twenty-three patients (10%) of our 228 MPGN patients were labeled as idiopathic immune-complex mediated MPGN (56.5% males), with a mean age 41±25 (10-81) years. The mean follow-up was 215±203 (1-489) months. Acute kidney injury was present in 50% of the patients at time of diagnosis. The most common clinical presentation was nephrotic syndrome (60.8%) with a mean proteinuria of 4.2±3.1 (0.10-12.0) g/day. When we compared patients according the decade of diagnosis, patients diagnosed after 2003 (N=12) were older (55.8±29.8 vs 20.4±7.7 years, p < .001), with more severe kidney impairment (1.7±0.9 vs 0.9±0.4 mg/dl, p = .044), higher systolic blood pressure (BP) (152±26 vs 124±13 mmHg, p = 0.009), and proteinuria (4.8±3 vs 2.9±2.2 g/day, NS). Thirteen patients (52%) received immunosuppression (100% steroids, 90% mycophenolate mofetil and 42% Rituximab®) due to a more aggressive clinical presentation. Elderly patients (> 65 years, N=6) presented worse baseline SCr (2.5±0.8 vs 1.0±0.4 mg/dl, p < .005), higher systolic BP (168±7 vs 130±22 mmHg, p < .005), and proteinuria (6.2±4.1 vs 3.6±2.6 g/day, NS), and reached ESRD more frequently (66.7% vs 11.8%, p < .008) compared with young patients (N=17). Six patients (26%) progressed end stage renal disease (ESRD) in a mean time of 35.3±39.8 (2-84) months.

Conclusions: The clinical presentation of idiopathic immune-complex mediated MPGN has dramatically changed, affecting older patients with more severe renal impairment and poor response to immunosuppressive therapies. Further prospective studies are needed for a better knowledge of this entity.

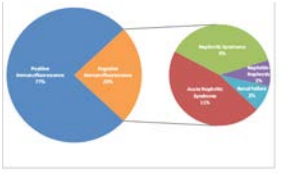
TH-PO840

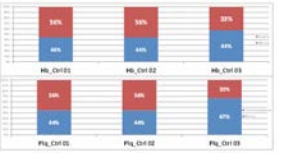
Membranoproliferative Glomerulonephritis and Negative Immunofluorescence: A Clinicopathological Study Luis A. Castillo,[1,2,3] Eduardo I. Navarro,[2] Gustavo Aroca Martinez,[2,3] Henry J. Gonzalez Torres.[2] *[1]Nephrology, Univ Cooperativa de Colombia, Santa Marta, Magdalena, Colombia; [2]Nephrology, Univ Simón Bolívar, Barranquilla, Atlantico, Colombia; [3]Nephrology, Clínica de la Costa, Barranquilla, Atlantico, Colombia.*

Background: Membranoproliferative GN (MPGN) represents a pattern of injury seen on light microscopy. Recent advances in understanding of the underlying pathobiology have led to a proposed classification scheme based on immunofluorescence findings. Given recent advances in our understanding of the role of the alternative pathway of complement in MPGN, a practical approach is to view MPGN as either immune complex– or complement-mediated. If neither of these causes is present (null complement and immune complex), then chronic thrombotic microangiopathy may be the cause of the MPGN.

Methods: Cross-sectional study. The data were extracted from NefroRed ©, a software platform that contains the socio-demographic, clinical and laboratory data of 1200 kidney biopsies. It was selected for the study those patients that showed the pattern of MPGN and negative immunofluorescence. Each biopsy was studied by light microscopy and immunofluorescence. Frequency tables and graphics were performed on relevant into R (figure 1).

Results: The average age of men was 33.8 years and for women was 33.6 years. The 1200 Biopsies showed 58 injuries MPGN (5%) of these 58 cases only 23% lesions showed negative immunofluorescence. The Acute Nephritic Syndrome was the most common clinical presentation (46%), Nephrotic Syndrome (38%), and Acute kidney Injury (8%) (figure 2).





Conclusions: 23% of patients with MPGN have negative immunofluorescence either immune complex o complement. The presence of anemia and thrombocytopenia in several patients during clinical evolution suggest the presence of a thrombotic microangiopathy. The most common clinical presentation was acute nephritic syndrome.

TH-PO841

Determinants of Long-Term Outcomes in Monoclonal Immunoglobulin Deposition Disease Florent Joly,[1] Camille Cohen,[2] Vincent Javaugue,[1] Bertrand Arnulf,[3] Mathilde Nouvier,[4] Vincent Audard,[5] Francois Provot,[6] Dominique Nochy,[7] Bertrand Knebelmann,[2] Arnaud Jaccard,[8] Jean-Paul Fermand,[3] Frank Bridoux.[1] *[1]CHU Poitiers; [2]Hôpital Necker, Paris; [3]Hôpital Saint Louis, Paris; [4]CHU Lyon; [5]Hopital Henri Mondor, Creteil; [6]CHU Lille; [7]HEGP Paris; [8]CHU Limoges, France.*

Background: Monoclonal immunoglobulin deposition disease (MIDD) is a rare complication of plasma cell disorders, defined by linear Congo red-negative deposits of monoclonal light chain (LCDD), heavy chain (HCDD) or both (LHCDD) along basement membranes. Treatment strategies and long-term outcomes are poorly defined.

Methods: We retrospectively reviewed 176 French patients (pts) with biopsy-proven LCDD (n=143), HCDD (n=18) and LHCDD (n=15). Renal response (defined by >50 % decrease in 24h-proteinuria without a >25 % decrease in eGFR) and patient survival were compared with hematological response after chemotherapy.

Results: Median age at diagnosis was 63 years. Renal involvement was constant, with median eGFR of 18 ml/min/1.73m², proteinuria of 1.8 g/d, microhematuria (68%) and hypertension (64%). 55 pts had extra-renal disease, with heart (n=18), peripheral nerve (n=18) or liver (n=8) involvement. Hematologic diagnosis was multiple myeloma in 42% and MGRS in 57%. Serum free light chain (FLC) ratio was abnormal in all 113 tested pts. Among 169 pts who received chemotherapy, based on bortezomib and/or alkylating agents, 60% achieved hematological response (HR), as defined by post-treatment dFLC <40 mg/L. Median overall survival in pts with and without HR was 169 months and 78 months (p=0.001), with a median renal survival of 216 months and 108 months, respectively (p=0.05). Median overall survival was 169 and 64 months in pts who achieved or not a renal response (p<0.001). Predictive factors of renal response were baseline eGFR >30 ml/min/1.73 m², post-treatment dFLC <40 mg/L, bortezomib-based therapy, and severity of renal interstitial fibrosis/vascular lesions.

Conclusions: Achievement of dFLC <40 mg/L translates into improved renal and patient survival in MIDD. Renal response is associated with higher patient survival. Due to their efficacy and good tolerance profile, bortezomib-based regimens should be considered as first-line therapy.

TH-PO842

Hereditary Aα Fibrinogen Amyloidosis: The French Cohort Marc Ulrich,[1] Lara Meyer,[2] Sophie Valleix,[3] Hélène François,[2] Laurence Vrigneaud.[1] *[1]Néphrologie, Dialyse et Médecine Interne, CH Valenciennes, Valenciennes, Nord, France; [2]Néphrologie et Transplantation, Hopital Kremlin Bicetre, Le Kremlin Bicetre, France; [3]Génétique Médicale, Hopital Necker Enfants Malades, Paris, France.*

Background: Aα-Fibrinogen amyloidosis (AFib) is the most frequent renal hereditary amyloidosis in Northern Europe characterized by rapidly progressive chronic kidney disease (CKD), high proteinuria and massive glomerular deposits.

Methods: French AFib patients were identified from a genetic registry (S. Valleix), complemented with a national call on members of the French nephrological society to report cases.

Results: Data were collected on 21 families: 30 patients with E526V mutation (n=22), R554L (n=2), Δ 517-522 (n=2) and not reported in the medical file (n=4). Mean age at presentation was 54.33 years. A family history of nephropathy was present in 10 cases, 7 of whom were amyloidosis. Four patients died, with a mean time from diagnosis of 109 months. Principal characteristics were rapidly progressive CKD with hypertension (63%) and proteinuria (4g/d), often nephrotic range (30%). Renal biopsy consistently showed massive glomerular amyloid deposits. Fibrinogen immune-staining was positive in 7 cases and negative in 8 cases. End-stage renal disease occurred in all symptomatic patients (mean time from diagnosis 29 months). Fourteen patients underwent transplantation, 11 renal and 3 hepato-renal grafts. There were 5 recurrences on isolated renal graft, leading to graft lost in 3 cases, in a mean time of 109.2 months.

Conclusions: This first French series confirms phenotypical and histological presentation of AFib, with a predominance of E526V variant and a poor renal prognosis. Extra-renal manifestations seem limited. Assessment of family is a key point and can lead to early diagnoses. The only certain diagnostic tool is genetic assessment, although the massive glomerular deposits and family history may lead to suspect an AFib. Renal graft survival is about 10 years in case of renal transplantation, whereas there is no recurrence in hepato-renal transplantation. Renal transplantation is the best choice in most cases. For the youngest patients hepato-renal transplantation affords the best long-term outcomes.

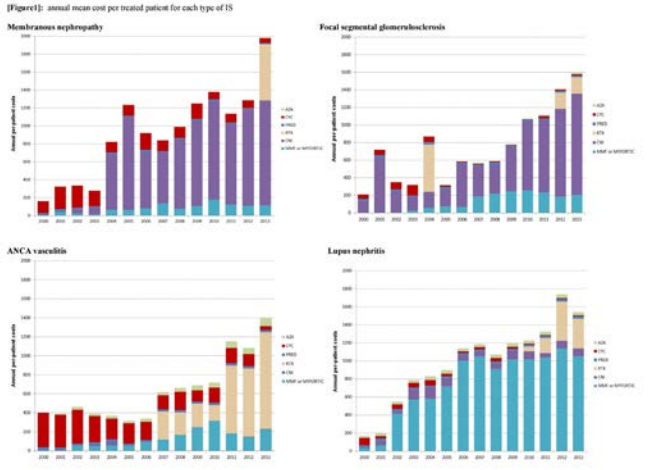
TH-PO843

The Population-Level Costs of Immunosuppression Treatment for Glomerulonephritis Are Increasing over Time Sean Barbour,[1,2] Clifford Lo,[1] Gabriela Espino-Hernandez,[1] John Feehally,[3] Sharareh Sajjadi,[2] Jagbir Gill.[1,2] *[1]BC Renal Agency, Canada; [2]Univ of BC, Canada; [3]LGH, Leicester, United Kingdom.*

Background: To date, there has been no assessment of the real-world cost of immunosuppression (IS) treatment for glomerulonephritis (GN). Given the chronic nature of GN, and advances in treatments that are more safe and effective, but also more expensive, the cost of treating GN is likely substantial. In renal transplant, the use of newer IS treatments resulted in a doubling of medication costs over time. We hypothesize a similar trend exists in GN as a result of a transition to newer more expensive therapies.

Methods: A population-level incident GN cohort (n=2983) was created by linking 3 provincial databases in British Columbia: pathology (includes all kidney biopsies), renal (includes clinical and laboratory characteristics) and PharmaNet (includes all medications with costs). This cohort captures the treatment costs of all GN patients in BC from 2000-2013.

Results: The annual IS treatment cost per patient increased 6.8x from $205 in 2000 to $1,394 in 2013 (p<0.001). The contribution of each medication to increasing costs over time varied by GN type.



Overall, the yearly cost of azathioprine per patient increased slightly ($12 to $32 p<0.001), whereas prednisone/cyclophosphamide decreased ($32-125 to $22 p=0.002 and <0.001). MMF, calcineurin inhibitors and rituximab had the largest cost increases ($0-26 to $417-455 each, p<0.001). In 2000, they constituted only 17.6% of costs; this increased to 94.5% in 2013 but was used to treat only 40.8% of patients.

Conclusions: We describe for the first time the real-world population-level cost of IS treatment for GN, and have demonstrated a striking increase in costs due to the use of newer/more expensive therapies. Our results suggest that efforts to improve cost-effectiveness will need to focus on the minority of patients treated with disproportionately expensive therapies.

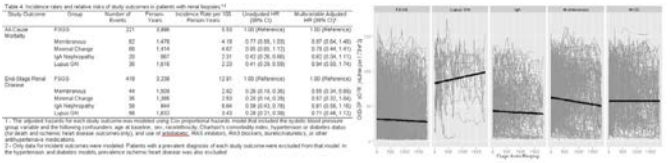
TH-PO844

Incident ESRD and eGFR Decline among the Most Common Glomerulopathies (GN): The Kaiser Permanente Southern California (KPSC) Cohort John J. Sim,[1] Michael Batech,[2] Teresa N. Harrison,[2] Sally F. Shaw,[2] Sejal Vora,[3] Aviv Hever.[1] *[1]Nephrology and Hypertension, Kaiser Permanente Los Angeles Medical Center; [2]Research & Evaluations, Kaiser Permanente Southern California; [3]Mallinckrodt Pharmaceuticals.*

Background: While GN is an important contributor to ESRD and morbidity/mortality outcomes, the clinical course is often variable among and within different GN. Within an integrated health system, we sought to evaluate and compare eGFR decline and incident ESRD rates in patients with focal nephrosclerosis (FSGS), membraneous GN (MGN), minimal change disease (MCD), IgA nephropathy (IGAN) and lupus nephritis (LN).

Methods: Retrospective longitudinal cohort study in the period 1/1/2000 through 12/31/2013 among patients within KPSC who had biopsy proven primary GN, were characterized and followed using serial laboratory measurements until they reached the outcome of ESRD (hemodialysis, peritoneal dialysis, transplant). All eGFR's measured at and subsequent to biopsy were used to evaluate trend of eGFR. Medications prescribed within 180 days of biopsy were extracted.

Results: Among 2226 GN patients (FSGS 46%, MGD15%, MCD12%, IGAN12%, LN15%) with mean follow up of 3.9yrs, 609 (27%) progressed to ESRD. Preemptive transplant occurred in 2.6%. Steroids (39.6%), calcineurin inhibitors (4.6%), MMF (3.3%) and alkylating agents (2.7%) were the most frequent initial treatments. FSGS had the highest ESRD incidence rate at 12.9 followed by IGAN 6.6, LN 3.4, MGN 2.9, and MCD 2.5 (per 100 person-yrs). LN was the only GN that had improvement in eGFR slope after biopsy whereas MGN had the steepest decline.



Conclusions: Among a large racially/ethnically diverse GN population within a routine treatment environment, FSGS patients had the highest rate of progression to ESRD, while MGN patients were observed to have the steepest decline and LN patients appeared to have the best treatment response based on eGFR trends.

TH-PO845

Light Chain Amyloidosis and Light Chain Deposition Disease - Single Centre Treatment Results Elena Zakharova.[1,2] *[1]Nephrology, City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation; [2]Nephrology, State Univ of Medicine and Dentistry n.a. A.I. Evdokimov, Moscow, Russian Federation.*

Background: Treatment approaches to AL amyloidosis and Light Chain Deposition Disease (LCDD) evolved over last decades. In 2012-2013 the term "monoclonal gammopathy of renal significance" (MGRS) was introduced, and treatment strategies for MGRS recommended by International Kidney and Monoclonal Gammopathy Research Group.

Methods: We analysed retrospectively the data for patients with biopsy-proven AL amyloidosis and LCDD, treated with chemotherapy in 2001-2015. Study group of 49 patients was divided in 3 treatment subgroups: 1) oral melphalan-based regimens - 20 (40.8%); 2) high-dose melphalan/autologous stem cell transplantation (HDM/ASCT) - 7 (14.2%); 3) bortezomib-based regimens - 22 (44.8%).

Results: 26 (53%) males and 23 (47%) females, median age 59 [48; 64.5] years, median duration from the disease onset 12 [6; 24], median follow-up 12 [4; 29] months. Clinical presentation shown in Table.

Kidneys only pts n (%)	14 (28.5)
Kidneys and heart pts n (%)	11 (22.4)
Multiorgan involvement n (%)	24 (48.9)
Nephrotic syndrome pts n (%)	39 (79.5)
Median proteinuria g/L	5.0 [3.2; 6.7]
CKD stage 2-4 pts n (%)	23 (46.9)
Median serum creatinine μmol/L	121.5 [95.2; 176.7]
Nephrotic syndrome and CKD stage 2-4 pts n (%)	16 (32.6)

46.9% achieved haematological remission (HR), 36.7% - organ remission (OR). Rate of HR was significantly higher in the subgroup 2 compared to subgroups 1 and 3 (85.7% vs 40.0% and 40.9% respectively, p<0.05), OR rate did not differ between the subgroups. 5-year kidney survival was 73%, 100% and 70%, patient's survival - 32%, 33% and 70%, cumulative patient's and kidney survival - 14%, 33% and 14% in the subgroups 1, 2 and 3 respectively, all differences were not significant.

Conclusions: Majority of our patients presented with severe nephrotic syndrome, impaired kidney function and multiorgan damage. However, under chemotherapy about half of them achieved haematological remission, and more than one third - organ remission, with significantly better results after HDM/ASCT. 5-year cumulative patient's and kidney survival did not exeed 33% even in HDM/ASCT subgroup.

TH-PO846

Long Term Renal Outcomes and Clinical Associations of Scleroderma Renal Crisis: A Retrospective Case/Control Study Sarah M. Gordon, Dustin J. Little, Rodger S. Stitt, Wayne Bailey, Jess D. Edison, Stephen W. Olson. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Scleroderma (SSc) has a heterogeneous clinical presentation with potential multisystem organ involvement and known associations with cancer and thyroid disease. Scleroderma renal crisis (SRC) is a severe complication of SSc. Few previous studies have compared SRC cases to SSc without SRC disease controls (SSc w/o SRC DC) and none have reported the long term renal outcomes for SRC patients not requiring renal replacement therapy (RRT) or characteristics at the time of SSc diagnosis that associate with future SRC.

Methods: 53 SRC cases and 204 SSc w/o SRC DC were identified, and comprehensive clinical and laboratory data was collected using the military electronic medical record. Comparisons were made between SRC cases and SSc w/o SRC DC for multiple clinical and laboratory findings both at SSc diagnosis and throughout disease progression. Fisher's Exact test and the student's t-test were used for statistical analysis.

Results: SRC cases that did not require chronic RRT experienced a similar mean change in GFR per year compared to SSc w/o SRC DC (+0.3 vs. -0.02 cc/min/yr, p=0.7). SRC patients had a higher incidence of proteinuria (75% vs. 6%, p<0.001), a higher median ESR (37 vs 12, p<0.001), and a lower hemoglobin (11.7 vs. 13.7, p<0.001) at initial SSc diagnosis than SSc w/o SRC DC. SRC cases had higher lifetime rate of cancer (21% vs. 7%, p<0.001), thyroid disease (38% vs. 14%, p<0.001), pulmonary hypertension (39% vs. 17%, P<0.001), pericarditis (23% vs. 6%), and anti-RNA polymerase III antibody (39% vs. 14%) than SSc w/o SRC DC.

Conclusions: SRC patients that do not require chronic RRT have stable long term renal function. Proteinuria, anemia, and elevated ESR at initial SSc diagnosis are associated with future SRC. SRC is specifically associated with cancer, thyroid disease, and pulmonary hypertension. Our retrospective findings could be utilized to develop a model to more accurately identify SSc patients at high risk for SRC. Patients with an SRC diagnosis may benefit from earlier and more aggressive screening for cancer and thyroid function. Prospective confirmation is required.

TH-PO847

The Diagnosis of Renal Amyloidosis Using Laser Microdissection and Liquid Chromatography–Mass Spectrometry Michiko Aoki, Dedong Kang, Ai Katsuma, Yusuke Okabayashi, Takafumi Kanemitsu, Yusuke Kajimoto, Kiyotaka Nagahama, Akira Shimizu. *Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: In our department, renal amyloidosis of kidney biopsies have been diagnosed by congo-red stain, immunofluorescence (IF) for immunoglobulin light (L) and heavy (H) chains, immunostaining for amyloid A, transthyretin, and β2-microglobulin. Recently liquid chromatography tandem mass spectrometry (LCMS/MS) technique began to be performed to detect the amyloid precursor proteins.

Methods: We selected 18 cases of AL amyloidosis that were diagnosed by serum immunoelectrophoresis (SIEP) and biopsy samples with congo-red stain, IF, and immunostaining for amyloid A, from a series of renal biopsies in our department from 1999 to 2014. We examined the component proteins in deposited amyloid in formalin fixed paraffin embedded tissues using laser microdissection of glomeruli and LCMS/MS. These results were compared with the results of SIEP and findings of IF.

Results: In AL amyloidosis which was previously diagnosed using SIEP and biopsy samples with congo-red stain, IF, and immunostaining for amyloid A, LCMS/MS detected AL amyloidosis in 12/18 cases (66.7%), AHL amyloidosis in 5 /19 cases (27.8%), and AH amyloidosis in 1/18 cases (5.5%). In 5 cases (27.8%), monoclonal immunogloburin in serum could not detected by SIEP. Furthermore, in IF, all cases had irregular non-specific immunoglobulin L and H chains and complement components in our cases. LCMS/MS could detect the component proteins in amyloid deposition even in the cases that had less than 5% area of amyloid deposition in glomeruli.

Conclusions: In our cases, non-specific staining for immunoglobulin L and H chains was seen in AL amyloidosis. In addition, ALH and AH amyloidosis could not be diagnosed by SIEP and IF for immunoglobulin L and H chains. LCMS/MS is very helpful for diagnosis of amyloidosis, especially for AHL and AH amyloidosis.

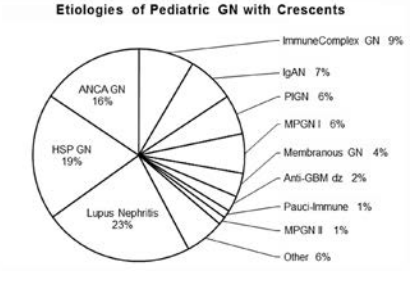
TH-PO848

Crescentic Glomerulonephritis in Children: A Midwest Pediatric Nephrology Consortium Study Joseph George Maliakkal,[1] Michelle N. Rheault,[3] Jason Misurac,[4] Joseph T. Flynn,[5] William E. Smoyer,[2] Scott E. Wenderfer,[1] Guillermo Hidalgo.[6] *[1]Pediatric Nephrology, Baylor College of Medicine, Houston, TX; [2]Nationwide Children's Hospital, Columbus, OH; [3]Univ Minnesota, Minneapolis, MN; [4]Univ Iowa, Iowa City, IA; [5]Seattle Children's Hospital, WA; [6]East Carolina Univ, Greenville, NC.*

Background: Crescents on kidney biopsy predict poor prognosis in acute glomerulonephritis (GN). The clinical presentation and etiology of crescentic GN in children have not been well studied for over 30 years.

Methods: Children <21 years old from 4 centers who presented after Jan. 2004 with >1 crescent on kidney biopsy were enrolled in a multi-center registry. Demographic, clinical, laboratory, and kidney biopsy findings were collected.

Results: The registry includes 83 patients (40% Hispanic, 36% Caucasian, 21% African American), with median age at presentation of 12 years (range 1-18). At presentation, 64% were hypertensive and 21% had pulmonary involvement. Estimated GFR was <60mL/min/1.73m2 in 58% of patients at time of biopsy. Median proportion of glomeruli with crescents was 16% (IQR 8-28%). Histological diagnoses are listed in the Figure.



Patients with anti-glomerular basement membrane (GBM) disease had the greatest proportion of crescents (66%). Renal replacement therapy (RRT) at presentation was required in 11% of all patients and in 50% of patients with anti-GBM disease. The proportion of crescents on biopsy was significantly higher in patients requiring RRT at presentation (58%) compared to those who did not (21%, p=0.002).

Conclusions: The prevalence of glomerular diseases in US children that manifest with crescentic glomeruli is changing. The proportion of crescents was associated with a need for RRT at presentation. Continued investigation of this cohort will improve our understanding of the presentation, optimal evaluation and management of pediatric patients with crescentic GN.

TH-PO849

Recruitment of Plasmacytoid Dendritic Cell to Renal Ectopic Germinal Center in Primary Sjögren Syndrome with Tubulointerstitial Injury

Jing Wang,[1] Mengyu Zhou,[1] Yubing Wen,[1] Wen Zhang,[2] Xuemei Li,[1] Limeng Chen.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Rheumatology, Peking Union Medical College Hospital, Beijing, China.*

Background: Renal involvement of Primary Sjögren syndrome (pSS) is predominated by tubulointerstitial injury (pSS-TIN). Large sample clinicopathological studies are sparse and mechanisms underlying renal damage remain to be elucidated. This study aimed to evaluate ectopic germinal center (EGC) formation, recruitment of pDC and mDC, and activation of B cell chemokine CXCR5 in pSS-TIN, and to analysis the factors affecting eGFR long term prognosis.

Methods: From 1993 to 2015, 64 pSS patients were diagnosed with tubulointerstitial lesions by renal biopsy in a single center of Beijing. EGC ($CD21^+$), pDC ($BDCA\text{-}2^+$), mDC ($DC\text{-}SIGN^+$) and CXCR5 were identified by immunohistochemistry staining. Peripheral pDC ($Lin\text{-}^-HLADR^+CD123^+$) and mDC ($Lin\text{-}^-HLADR^+CD11c^+$) were evaluated by flow cytometry.

Results: pSS-TIN patients were mostly middle-aged female. eGFR (56.3±29.5ml/min/1.73m^2) was independently correlated with age (R^2=0.102, 95%CI(-1.592, -0.357), p=0.003), glomerular sclerosis index (R^2=0.099, 95%CI(-77.261, -12.381), p=0.008) and tubulointerstitial leision (R^2=0.457, 95%CI(-20.780, -2.306), p=0.016). 15.6% had EGC in renal interstitium. Both pDC and mDC were detected in EGC, but only pDC had a higher prevalence (semiquantatively scoring 2.0±0.9 vs. 1.1±0.3, p=0.025) comparing to patients without EGC. Peripheral pDC decreased significantly in pSS with renal involvement than health control (0.01±0.00% vs. 0.07±0.05%, p=0.001). $CXCR5^+$ cell infiltration was more prominent in the presence of EGC and was mainly near the adjacent vessels. 93.8% received glucocorticoid and 45.3% received immunosuppresant treatment. Patients were followed up for median 38.0 monthes. eGFR improved from 56.3±29.5 to 72.3±26.7ml/min/1.73m^2 in 1 year and remained stable in the following 3 years. eGFR at renal biopsy is the sole risk factor affecting long term renal function (R^2=1.024, 95%CI(1.012, 1.036), p<0.001).

Conclusions: EGC were detected in renal interstitium of pSS-TIN, with pDC recruitment from peripheral blood and increased CXCR5 expression. It may participate in renal tubulointerstitial injury.

TH-PO850

Genetic Changes Predisposing to Complement Dysregulation and Infection May Play Role in a Case of Atypical Hemolytic Uremic Syndrome

Elena Volokhina,[1] Birendra Singh,[2] Martin Kömhoff,[3] Marcin Okroj,[4] Nicole Van De Kar,[1] Kristian Riesbeck,[2] Anna Blom,[2] Lambertus P.W.J. Van den Heuvel.[1,5] *[1]Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Lund Univ, Malmo, Sweden; [3]Univ Medical Centre Groningen, Groningen, Netherlands; [4]Medical Univ of Gdansk, Gdansk, Poland; [5]Univ Hospitals Leuven, Leuven, Belgium.*

Background: Hemolytic uremic syndrome (HUS) is a major cause of renal failure in childhood. Most cases are caused by infection with Shiga-toxin producing *Escherichia coli* (STEC). In 5-10% of cases, HUS is not preceded by the STEC infection and is considered atypical (aHUS). These cases are strongly associated with genetic defects leading to dysregulation of the complement system. Often aHUS is triggered by a non-STEC infection, however, genetic predisposition to such infections in aHUS has not yet been sufficiently addressed. Here we present genetic analysis of a 2 months old patient with *Bordetella pertussis* infection, followed by aHUS.

Methods: DNA analysis was performed by Sanger sequencing, analysis of autoantibodies to CFH was performed by ELISA. Recombinant vitronectin variants were produced in HEK293T cells, purified and used in hemolytic assay with sheep erythrocytes and purified C5b-6, C7, C8 and C9 complement proteins.

Results: The patient carried a previously described p.Ala43Thr variant in thrombomodulin that alters complement regulation, but had no abnormalities in CFH, CFI, MCP, C3 and CFB or autoantibodies to CFH. In search of the new genes in etiology of aHUS, we screened the patient´s DNA for aberrations in complement inhibitor vitronectin and discovered a rare heterozygous variant p.Arg229Cys. Prediction software (SIFT, PolyPhen-2) indicated it as likely pathogenic. *In vitro* experiments using recombinant vitronectin variants have shown that this mutation enhances complement inhibition.

Conclusions: A rare vitronectin change could have contributed to the severe development of *B. pertussis* infection. Our work indicates that a genetic cause may contribute to aHUS not only by a well-known effect of complement dysregulation, but also by enhancing vulnerability to infections.

TH-PO851

The CureGlomerulonephropathy (CureGN) Cohort Study: Enrollment Characteristics to Date

Laura H. Mariani, Andrew S. Bomback, Michelle A. Hladunewich, Michelle N. Rheault, Dana Rizk, Michael F. Flessner, Lisa M. Guay-Woodford. *On Behalf of the CureGN Consortium.*

Background: In minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), and IgA nephropathy (IgAN)/Henoch-Schonlein Purpura (HSP), challenges to studying underlying mechanisms, biomarkers and new therapies include the rarity of each diagnosis and slow progression, which together may require decades of follow-up to measure the effectiveness of interventions on ESKD or death.

Methods: CureGN is a 64-center prospective cohort study of children and adults with biopsy-proven MCD, FSGS, MN or IgAN/HSP. Target recruitment is 2,400 patients with first diagnostic kidney biopsy within 5 years of enrollment. Patients with ESKD, other organ transplant, or secondary causes of kidney disease (diabetes, lupus, HIV, active malignancy, hepatitis B or C) are excluded. Study visits occur 4 times in the first year and 3 times per year thereafter.

Results: As of May 2016, 1,223 (255 MCD, 306 FSGS, 221 MN, 441 IgAN including 87 with HSP) patients have been enrolled. 32% (n=396) are 'incident,' as defined by diagnostic biopsy within 6 months of enrollment. Median (IQR) of time since biopsy is 1.2 (0.3-2.8) yrs at enrollment. 36% are <18 years old (n=445 pediatric patients; 166 MCD, 107 FSGS, 17 MN, 155 IgAN/HSP). 41% are male, 13% Hispanic, 68% White/Caucasian, 15% Black, 7% Asian and 2% multi-race. 27% reported a family history of kidney disease. Table 1 provides an overview of medication exposure, enrollment kidney function and proteinuria by diagnosis.

TABLE 1	Overall* (n=930)	MCD (n=198)	FSGS (n=214)	MN (n=176)	IgAN** (n=342)	HSP (n=73)
% Exposed to immunosuppression prior to enrollment	74%	94%	71%	76%	62%	82%
% On immunosuppression at enrollment	52%	79%	55%	47%	39%	60%
eGFR*** (median [IQR], mL/min/1.73m2)	85 (47, 113)	114 (89, 136)	67 (36, 100)	66 (42, 95)	85 (44, 112)	108 (88, 119)
UPCR (median [IQR], mg/mg)	1.3 (0.2, 3.6)	0.5 (0.1, 4.4)	2.1 (0.6, 4.6)	2.6 (1.1, 5.3)	0.7 (0.2, 1.8)	0.6 (0.2, 2.2)

*Participants with completed enrollment visit
**Excludes IgAN with HSP
***CKD-Epi formula for participants ≥18yo; modified CKiD-Schwartz formula for <18yo

Conclusions: CureGN enrollment now exceeds 50% of target. Robust clinical data combined with serial biosamples from a diverse group of adults and children with MCD, FSGS, MN, and IgAN will be a valuable resource for researchers in glomerular disease and platform for ancillary studies.

TH-PO852

Safety and Effectiveness of Restrictive Eculizumab Treatment in Atypical Hemolytic Uremic Syndrome

Kioa L. Wijnsma,[1] Elena Volokhina,[3] Nicole Van De Kar,[1] Jack F. Wetzels.[2] *[1]Pediatric Nephrology, Radboudumc, Nijmegen, Netherlands; [2]Nephrology, Radboudumc, Nijmegen, Netherlands; [3]Laboratory Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, but severe form of thrombotic microangiopathy, characterized by hemolytic anemia, thrombocytopenia, and acute renal failure, as a consequence of complement dysregulation. Atypical HUS has a poor outcome with mortality up to 10% and over 50% of patients developing end stage renal disease. Since the end of 2012, these outcomes have drastically improved with the introduction of eculizumab. The European Medicines Agency has approved eculizumab as lifelong treatment in aHUS patients. However, there is no hard evidence to support this advice. Historically, a substantial number of aHUS patients were weaned of plasma therapy, often without disease recurrence. Moreover, the long-term consequences of eculizumab treatment are unknown. Here we describe a case series of 16 aHUS patients treated with a restrictive treatment regimen of eculizumab.

Methods: All patients with aHUS who presented in the Radboudumc in the Netherlands, between 2012-2016, and who received eculizumab treatment, according local practice, are described. Clinical, diagnostic, genetic and follow up data were gathered and reviewed.

Results: Of the 16 patients (10 adults, 6 children) who presented with aHUS since 2012, 15 received restrictive eculizumab therapy. Therapy was either gradually withdrawn (n=4) or discontinued (n=11). Two patients, both known with factor H mutation, experienced recurrence of aHUS after therapy discontinuation. Due to close monitoring, recurrence was detected early, eculizumab was restarted, and no clinical sequela such as proteinuria or diminished kidney function were detected subsequently. In total, eculizumab could be safely discontinued in 9 patients of which 6 are event free for over a year now. With this strategy approximately €7.5 million has been saved.

Conclusions: A restrictive eculizumab regimen in aHUS is safe and effective. Future studies should focus on finding reliable predictors of disease recurrence.

TH-PO853

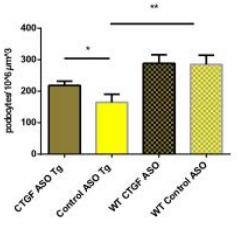
Investigating the Role of Connective Tissue Growth Factor (CTGF) Antagonism on Renal Outcomes in Cryoglobulinaemia

Gayathri K. Rajakaruna,[1] Kelly L. Hudkins,[2] Charles E. Alpers,[2] Roger M. Mason,[3] Alan D. Salama.[1] *[1]UCL Centre for Nephrology, London, United Kingdom; [2]Dept of Pathology, Univ of Washington, Seattle; [3]Renal Section, Imperial College London, London, United Kingdom.*

Background: Transgenic thymic stromal lymphopoeitin (TSLP Tg) mice develop membranoproliferative nephritis secondary to cryoglobulinaemia. We have shown high circulating levels of CTGF in these animals and attenuation of disease following use of CTGF antisense oligonucleotide(ASO) therapy in a pilot study. We now describe the impact of CTGF antagonism on renal parameters.

Methods: 32 TSLP Tg animals were treated with weekly ip CTGF or control ASO therapy (50mg/kg) for 10 weeks. Renal parameters were evaluated.

Results: Mice that received CTGF ASO had significantly lower proteinuria for the duration of therapy compared to control ASO ($p<0.001$). Glomerular mesangial expansion score was significantly reduced in CTGF ASO compared with control ASO treated (1.456 ±0.3105 vs 2.078 ±1.038, p=0.0159) Podocytes were identified by IHC for p57, and their density morphometrically quantitated



WT mice had preserved podocyte density that was unaffected by ASO therapy (CTGF ASO treated 288.3 +/- 67 vs control ASO treated 285+/- 73 podocytes/10^6 µm^3), while TSLP-Tg control ASO mice had significantly reduced podocyte density which was significantly ameliorated by CTGF ASO treatment (control ASO treated 164.8 +/- 57vs CTGF ASO treated 218 +/- 35 podocytes/10^6 µm^3). In addition, podocyte CTGF expression was significantly lower in CTGF ASO treated mice compared with untreated mice(proportion glomeruli with CTGF expression 0.3333 ± 0.5164 vs 0.8333 ± 0.4082, p=0.0462 respectively).

Conclusions: This study demonstrates that antagonism of CTGF leads to amelioration of glomerular injury and podocyte preservation in cryoglobulinaemic MPGN and may represent a future therapeutic target.

TH-PO854

Clinical and Histological Differences between PR3-ANCA and MPO-ANCA Vasculitis in a Spanish Cohort Montserrat M. Diaz Encarnacion,[1] Helena Marco,[2] Xavier Fulladosa,[3] Gema Fernandez Juarez,[4] Luis F. Quintana,[5] Manuel Praga,[6] Jose Ballarin.[7] *[1]Fundacio Puigvert, Barcelona; [2]H.U Germans Trias i Pujol, Barcelona; [3]H.U Bellvitge, Barcelona, Barcelona; [4]H.U Foundation Alcorcón, Alcorcon, Madrid; [5]HU Clínic, Barcelona; [6]H.U 12 Octubre, Madrid; [7]Fundacio Puigvert, Barcelona.*

Background: There are significant differences between patients with ANCA-PR3 and MPO, which have been reinforced by genetic studies in recent years. The aim of this study is to analyse demographics difference and prognostic values of ANCAS Serotypes in a Spanish cohort.

Methods: 304 patients with positive ANCA vasculitis diagnosed in 12 Spanish centers between 1978-2014. Clinical/laboratory variables, renal function, renal biopsy, presence of recurrences, severe infections, leukopenia and renal / patient survival are evaluated. Chi-square test, likelihood ratio test, Kruskal-Wallis test and the Kaplan-Meier curve when appropriate is used.

Results: 304 patients, 82% MPO ANCA-positive and 18% ANCA-PR3 positive patients were included. PR3 positive patients were younger ($p = 0.001$) and higher proportion of men ($p <0.001$) than MPO positive patients. PR3 patients had a higher number of affected organs ($p <0.001$), highlighting a greater involvement of lungs ($p <0.001$) and respiratory tract ($p <0.001$) compared MPO. No differences in initial mean creatinine levels between PR3 and MPO, although renal biopsy showed more active lesions in PR3 patients. There was no difference in the need for dialysis during follow-up (29% vs 34%, $p = 0.519$), although we observed a higher percentage of patients with GFR> 60 ml / min in PR3 patients (31.9% vs14.6% $p = 0.01$). PR3 patients had more relapses than MPO patients (36% VS19% $p = 0.014$). There were no differences in the presence of other complications or patient survival.

Conclusions: These results show that clinical presentation and histology class are different depending on ANCAS serotype. Also we have found a higher rate of relapse in patients PR3, This could have therapeutic implications, specially at the level of maintenance therapy.

TH-PO855

Long Term Outcomes of Kidney Transplantation in Patients with End Stage Renal Disease due to Pauci-Immune Glomerulonephritis Sophia Lionaki,[1] Konstantinos Panagiotellis,[1] Nikolaos Altanis,[1] Ilias Makropoulos,[1] George Liapis,[2] Georgios Zavos,[3] John N. Boletis.[1] *[1]Nephrology, Laiko Hospital, National & Kapodistrian Univ of Athens, Faculty of Medicine, Athens, Greece; [2]Pathology, Laiko Hospital, Athens, Greece; [3]Transplantation Unit, Laiko Hospital, Athens, Greece.*

Background: To evaluate the long term outcomes of kidney transplantation (KTx) in patients with end stage renal disease (ESRD) due to pauci-immune glomerulonephritis (PIGN), in comparison with patients with primary diseases (PD) of non-autoimmune nature.

Methods: We retrospectively studied all patients with ESRD due to PIGN, transplanted in our hospital between 1995-2014, with a follow up of 1 year post KTx or more. Demographics, clinical, and laboratory data were recorded. For comparisons reasons, a control group, consisted of patients with PD of non-autoimmune origin, matched for age, gender, donor source, and KTx date was selected.

Results: 21 patients with PIGN as PD were identified. Of these, 12(95.2%) were ANCA positive at PIGN diagnosis. 14(66.5%) had developed rapidly progressive disease at presentation. The baseline characteristics of the two groups were similar.

Parameter, (mean±sd) or %	Patients with PIGN N=21	Control group N=71	p-value
Donor age (years)	55.4(±14.25)	53.95(±16.6)	0.74
Time in dialysis (months)	78.3(±69.6)	57(±38.9)	0.08
Induction with anti-CD25	95.2	93	0.88
Maintained with a calcineurin inhibitor, mycophenolic acid and steroids	85.7	97.2	0.28
Follow up (fup) post KTx (months)	81.9(±55.6)	65.0(±27.3)	0.06
Ser.creatinine at end of follow up (mg/dl)	1.9(±1.4)	1.4(±0.7)	0.03
Acute rejection	10.5	15.7	0.7
Survival with functioning graft	90.5	97	0.24
Graft failure	9.5	1.5	0.14
Infection requiring hospitalization	95.2	51.5	0.0004

Serum creatinine and eGFR were lower in patients with PIGN compared to controls, but graft survival was similar between them.

Conclusions: Graft function of patients with ESRD due to PIGN, was inferior from that of patients with a PD of non-autoimmune origin at end of follow up, but this fact had no impact on graft survival. Infections requiring hospitalization were more frequent among patients with PIGN.

TH-PO856

Fast Development of Iron Deficient Anemia and Heart Failure in a Rat Model of CKD-MBD: A Suitable Model to Study the Cardiorenal Syndrome Anja Verhulst, Ellen Neven, Patrick C. D'Haese. *Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: Cardiorenal syndrome (CRS) is an umbrella term covering disorders of the heart and the kidneys whereby dysfunction of the one organ may induce dysfunction of the other. Despite advances in treatment of both (chronic) kidney disease (CKD) and cardiovascular disease (CVD), CRS remains a major health problem. The current study aimed at optimizing an animal model mimicking CRS in order to allow experimental evaluation of new treatment strategies.

Methods: An adenine (0.25%) supplemented, high phosphate (P) diet was administrated to 56 male Wistar rats, which were sacrificed at different time-points: 3,4,5,6,7 and 8wks (n= 8 or 10/group) after start of adenine treatment. Control animals (n=4, standard diet) were sacrificed at 8wks. Blood samples were taken at 2,4,6 and 8wks. The following aspects of CRS where studied: CKD, mineral-bone disorder (MBD), CVD and (iron deficient) anemia. Hereto the following parameters were followed-up during the study: serum creatinine (crea), -Ca, -P, -FGF23, dynamic bone parameters, aortic Ca deposits, heart weight, serum NT-proANP, Hct, Hb, retyculocytes, spleen iron, serum hepcidin.

Results: Serum crea, P and FGF23 showed a statistically significant increase and –Ca a decrease after respectively 2,6, 4 and 2wks. These parameters became more severe during the course of the study and thus evidenced the development of a severe CKD and disturbed mineral balance. CKD-related complications developed from week 5 on; significantly increased bone turn over and aorta calcification (von Kossa positive staining). Moreover the animals promptly (wk2) developed a serious iron deficient anemia as evidenced by significantly steep decreases in Hct, Hb and reticulocyte levels and significant, steep increases in serum hepcidin and spleen iron. Finally the animals developed heart failure as demonstrated by significantly and steadily increasing heart weight (relative to whole body weight) and significantly increased NT-proANP levels.

Conclusions: The proposed animal model for the first time will allow to study CRS in all its aspects and will be useful to concomitantly evaluate effects of new treatment strategies on the various aspects of CRS.

Funding: Government Support - Non-U.S.

TH-PO857

Inadequate Vitamin D and Risk for Anemia in the CKiD Cohort Kathleen Elizabeth Altemose,[1] Juhi Kumar,[2] Anthony A. Portale,[3] Bradley Warady,[4] Susan L. Furth,[5] Jeffrey J. Fadrowski,[1] Meredith A. Atkinson.[1] *[1]Johns Hopkins Univ; [2]Weill Cornell Medical College; [3]Univ of California San Francisco; [4]Children's Mercy Hospital; [5]Children's Hospital of Philadelphia.*

Background: Inadequate 25-hydroxyvitamin D (25D) levels are common in children with chronic kidney disease (CKD), and are associated with increased risk for anemia in healthy children. This association has not been explored in children with CKD.

Methods: Cross-sectional analysis of 25D and hemoglobin (Hgb) in 580 children in the Chronic Kidney Disease in Children (CKiD) study. Anemia = Hgb < 5th%ile for age/sex. Inadequate 25D = 25D < 30 ng/ml. GFR measured via plasma disappearance of iohexol. Linear regression analyses examined the association between Hgb, risk for anemia and 25D level. Logistic regression analysis examined the association between risk for anemia and inadequate 25D. Models adjusted for race, BMI, GFR, treatment with iron or an ESA, and age/sex (linear models with Hgb only).

Results: Median (IQR) age of cohort was 11 (8,15) yrs, 63.1% male. Median 25D was 28.3 (19.8, 35.3) ng/ml with 57.6% inadequate.

Median (IQR) or %	25D <30 ng/ml (n=334)	25D Sufficient (n=246)	p-value
Age (yrs)	13 (9,15)	9 (6,13)	<0.001
Male	64.1	61.8	0.57
Race			<0.001
W	58.4	81.1	
B	23.7	3.7	
Other	18	14.2	
BMI (kg/m^2)	20.1 (16.7, 24.4)	17.2 (15.8, 19.3)	<0.001
GFR (ml/min/1.73m^2)	48.1 (28.9, 67.6)	43.1 (28.2, 62.9)	0.09
Hgb (g/dL)	12.7 (11.6, 13.7)	12.8 (11.9, 13.6)	0.37
Anemic	28.4	17.1	0.001
On ESA	9.9	10.6	0.79
On iron	23.4	30.1	0.07

In linear regression, each 1 ng/ml increase in 25D was associated with a 0.2 g/dl increase in Hgb (p=0.001) and decreased anemia risk (OR 0.97, 95% CI 0.95-0.99, p<0.01). Inadequate 25D was associated with twice the risk for anemia compared to subjects with 25D levels >= 30 ng/ml (OR 2.02, 95% CI 1.29-3.17, p<0.01). Further adjustment for ferritin/TSAT among 285 subjects with levels available showed the increased risk for anemia in those with inadequate 25D remained significant: OR 2.15, 95%CI 1.05-4.40, p=0.04.

Conclusions: Inadequate 25D is associated with increased risk for anemia in children with CKD, identifying it as a potentially modifiable risk factor for the anemia of CKD.

TH-PO858

Anemia Profiles by Chronic Kidney Disease Stage in a Large National Cohort of Patients Yue Jiao,[1] Dugan Maddux,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Tomislav Kovacevic,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Vifor Fresenius Medical Care Renal Pharma, Zurich, Switzerland.*

Background: Profiles of anemia in the different stages of chronic kidney disease (CKD) have not been fully defined. We aimed to determine the levels of hemoglobin (Hgb) and ferritin (Fer) by CKD stage in a large national cohort of patients who did not require dialysis.

Methods: The Fresenius Medical Care CKD Data Registry was utilized to analyze data from 349,420 patients from 2013 to 2015. For CKD stage 3, 4, and 5 patients, we calculated the mean annual Hgb and Fer levels, as well as, the percent (%) of patients with Hgb <11g/dL, Hgb <12g/dL, Fer <100ng/mL, Fer <200ng/mL, Hgb <11g/dL & Fer <100ng/mL, Hgb <11g/dL & Fer <200ng/mL, Hgb <12g/dL & Fer <100ng/mL, and Hgb <12g/dL & Fer <200ng/mL.

Results: Overall, we observed that Hgb levels decrease, and Fer levels rise with advancing CKD. In CKD stage 5, 70% of patients exhibit Hgb levels are under 11g/dL, while 13% have Fer levels below 100ng/mL (Figure 1A). We also noted an inverse relationship between Hgb and Fer measurements; average Hgb levels decrease from 12.6 to 10.6g/dL as the patients' CKD stage progress from 3-5, while average Fer levels increase from about 200 to >400ng/mL from CKD stage 3 to 5 (Figure 1B).

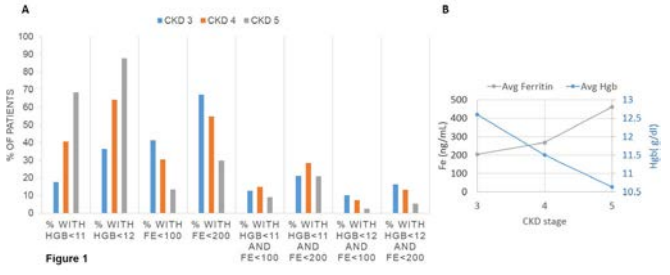

Figure 1

Conclusions: Our data shows a persistent decrease in Hgb levels with the progression to later stages of CKD in patients not on dialysis. Despite this, Fer levels increase with the advancement of CKD; this may be reflecting an increasing inflammatory status with the progression of CKD, or could be secondary to intravenous (IV) Fer regimens. Unfortunately, medication data was not readily available in this registry. Further investigations are needed to define the practice patterns for administration of ESA therapies and IV Fer therapies in pre-dialysis CKD stages 4 and 5.

Association between 25-Hydroxyvitamin D Deficiency and Rapid Chronic Kidney Disease Progression Ha Yeon Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [2]Dept of Internal Medicine, Seoul National Univ, Seoul, Korea.*

Background: 25-hydroxyvitamin D [25(OH)D] deficiency is highly prevalent in the chronic kidney disease (CKD) population, which is linked with cardiovascular events and mortality. Here we evaluated the relationship between 25(OH)D deficiency and the rapid declining in estimated glomerular filtration rate (eGFR) using KNOW-CKD cohort data.

Methods: In total, 1063 CKD patients were measured for the concentrations of 25(OH)D and creatinine with a follow-up of 4 years in a prospective multi-center cohort study of CKD patients in Korea. We divided the patients into two groups according to their serum 25(OH)D levels (deficiency group: 25(OH)D < 15 ng/ml, vs. non-deficiency group: 25(OH)D ≥ 15 ng/ml). Rapid progression was defined by the decline of eGFR over 5 ml/min/1.73m^2 per year (N=326) and as controls if decline of eGFR was under 1 ml/min/1.73m^2 per year (N=609).

Results: The average of decline in eGFR was 1.82 ml/min/1.73m^2 per year, maximum value of which was 53.8 ml/min/1.73m^2 per year. The mean of 25(OH)D was 16.8 ng/ml in the rapid progression groups, while that of the control group was 18.5 ng/ml. Univariate linear regression analysis showed that the rapid CKD decline was correlated with age, diabetes, serum albumin, 25(OH)D deficiency, cystatin C, and the albumin-to-creatinine ratio. Multiple analysis revealed that age, hypoalbuminemia, 25(OH)D deficiency, diabetes, and macroalbuminuria associated with rapid progression.

Conclusions: Vitamin D deficiency was associated with rapid eGFR decline in CKD patients. The results of this prospective cohort study suggest that vitamin D supplementation may significantly help the preservation of renal function in CKD patients.

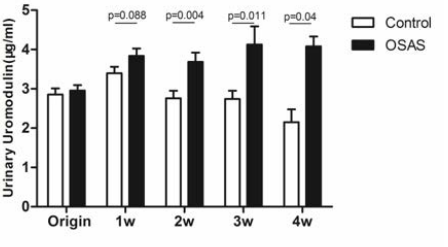
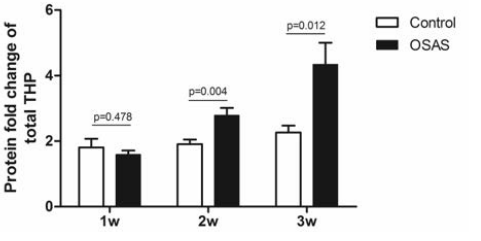
Uromodulin Mediated Hypoxia Induced Renal Injury Yaqin Wang, Kunjing Gong, Min Xia, Ying Liu, Yuqing Chen. *Dept of Nephrology, Peking Univ First Hospital, Beijing, China.*

Background: Increased urinary uromodulin level associated with high risk of CKD in general population. And excretion of uromudulin also increased in children with obstructive sleep apnea syndrome . Thus we hypothesized that uromodulin may be an earlier indicator of hypoxia injury to kidney and involved in the pathogenesis of hypoxia induced renal injury.

Methods: Totally eighty 12-week-old male SD rats were divided into OSAS and control groups. Rats in OSAS groups lived in a designed chamber, in which oxygen level changed from normal to low (10%) every 60 s for 8 h during daytime. We got 24-h urine and kidney tissue after 1, 2, 3 and 4 weeks. EM and LM were used to view structure of the rat kidney. Western blot was used to assay the expression of uromodulin. Rat urinary uromodulin level was determined using ELISA. We also use the cultured mIMCD3 to explore the regualtor of uromodulin under hypoxia.

Results: After 3-weeks of OSAS condition, no obvious injury was visualized under light microscope. However, we found more foot process fusion of podocytes, and more secondary lysosomes, vacuoles and mild swelling of mitochondria in tubular cells. We also identified an increased uromodulin secretion into urine and expression in tubuli after 1 week hypoxia in OSAS groups compared with controls.





In cultured mIMCD3 cells, the expression of uromodulin also started to increase after exposure of hypoxia condition for 6h, and continue to rise after 12h, 24h and 36h. HNF-1B is one of the transcription factors regulating UMOD transcription. Thus we inhibited HNF-1B expression of mIMCD3 cells with siRNA, but expression of uromodulin still increased under hypoxia condition.

Conclusions: Uromodulin increased earlier after kidney injury induced by hypoxia. Hnf-1b may not play a key role in hypoxia induced uromodulin expression.

Urinary miR-196a as a Risk Predictor for Progression to ESRD in Patients with FSGS Changming Zhang, Shao-Shan Liang, Shuiqin Cheng, Xia Wang, Cai-Hong Zeng, Chun-Xia Zheng, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: miR-196a is predominantly expressed in kidney and plays an important role in renal fibrosis, which is a factor for evaluating the prognosis of FSGS. Moreover, our previous study indicates correlation between urinary miR-196a and FSGS activity. In the present study, we attempted to investigate whether urinary miR-196a can serve as a predictor of disease progressionin patients with FSGS.

Methods: Urinary and plasma miR-196a were compared in patients with active FSGS (FSGS-A), FSGS in complete remission (FSGS-CR) and normal controls (NCs) using both testing set and validation set. Urinary miR-196a levels at the time of renal biopsy were also measured by qRT-PCR in 231 FSGS patients. The relationship between urinary miR-196a and the prognosis of FSGS was analyzed using Kaplan-Meier and Cox regression analysis.

Results: Urinary miR-196a levels were significantly increased in FSGS-A patients as compared with FSGS-CR patients and NCs in the testing set, as well as in the validation set. However, plasma miR-196a levels were similar among the three groups and there was no correlation between urinary and plasma miR-196a, suggesting that the change of urinary miR-196a was not due to the change of plasma miR-196a. Of the 231 patients, 43 patients developed ESRD during the follow-up period for at least 3 years. Urinary miR-196a levels were significantly higher in patients who progessed to ESRD than those with stable renal function. Urinary miR-196a at the time of renal biopsy was associated with proteinuria, eGFR, tubulointerstitial damage and the occurrence of ESRD. Kaplan-Meier analysis showed patients with higher urinary miR-196a levels had a worse renal outcome than those with lower urinary miR-196a levels. Multivariable Cox regression analysis additionally demonstrated urinary miR-196a was an independent risk factor for progression to ESRD.

Conclusions: Urinary miR-196a may serve as a potential biomarker for risk classification of FSGS patients, facilitating early identification of those who will subsequently develop ESRD.

TH-PO862

Urinary MicroRNAs as Biomarkers for Early Prediction of Radiation Nephropathy Sagar Bhayana, Feifei Song, Naduparambil K. Jacob. *Radiaton Oncology, The Ohio State Univ, Columbus, OH.*

Background: The risk of chronic kidney disease (CKD) is strongly associated with treatment associated late toxicities in cancer survivors. The early predictive biomarkers detecting kidney toxicity are still lacking. There has been heightened interest in the utility of extracellular miRNAs as minimally invasive biomarkers for early detection of a wide range of human pathologies. The goal of our study was to investigate miRNAs as potential early indicators of radiation induced kidney damage in rodents.

Methods: Three kinds of TBI regimen were used: 7.7 Gy (LD50 dose) for evaluation of time dependent changes, sublethal to lethal dose (2, 4, 6 & 8 Gy) for evaluation of dose response and a more complex fractionated regimen that was applied in clinic. Cell free miRNAs isolated from urine and serum were subjected to expression profiling using an amplification free hybridization based nCounter assay. Selected high counts miRNAs were further analyzed for their expression and localization by *in situ* hybridization.

Results: Over 40 miRNAs were detected in urine samples collected from mice and over 80 miRNAs were detectable in serum. Following acute single dose TBI, the expression of most microRNAs peaked at 6-8 hours post irradiation. Among them, miRNA-1224 and miRNA-714 were of particular interest because they also showed increase in their urinary levels in response to increase in doses (2, 4, 6, and 8 Gy) of TBI. Moreover, miRNA-1224 and miRNA-714 exhibited dose and time dependent changes following exposure to fractionated myeloablative regimen (6 x 2 Gy= 12 Gy). Specifically, the urinary miRNA-1224 and -714 were shown to be localized in the outer medulla by *in situ* hybridization, suggesting their proximal tubular origin.

Conclusions: Systematic profiling of cell-free urinary and serum miRNAs haveidentified biomarkers with potential to develop as biomarkers of toxicity response after TBI. In particular, our study demonstrated that outer medulla is the source of origin for molecules such as miRNA-1224 and miRNA-714 that exhibited clear dose response. Cell-free miRNAs detectable in urine and serum can serve as bioindicators of kidney toxicity in response to radiation and potential early predictors of late effects.

The Effect of Renin-Angiotensin-Aldosterone System Inhibitors on Clinical Outcomes in Severe Advanced Chronic Kidney Disease Yun Jung Oh,[1] Sun Moon Kim,[2] Su Mi Lee,[3] Ae Jin Kim,[4] Han Ro,[4] Jae Hyun Chang,[4] Hyun Hee Lee,[4] Wookyung Chung,[4] Ji Yong Jung.[4] *[1]Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Dept of Internal Medicine, Chungbuk National Univ Hospital, Cheongju, Republic of Korea; [3]Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; [4]Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea.*

Background: The renin-angiotensin-aldosterone system (RAAS) blockades have been considered to slow renal progression in chronic kidney disease (CKD) patients. However, whether the habitual use of RAAS inhibitors affects renal progression and outcomes in pre-dialysis advanced CKD patients remains uncertain.

Methods: From a total of 2,076 pre-dialysis patients with advanced CKD stage 4 or 5, RAAS blockade users were paired with non-users for analyses using inverse probability of treatment weighted (IPTW) and propensity score (PS) matching. The outcomes were renal death, all-cause mortality, hospitalization for hyperkalemia, and interactive factors for composite outcomes.

Results: RAAS blockades were prescribed for 1,236 (59.6%) patients with CKD stage 4 to 5. RAAS blockade users showed an increased risk of renal death in PS matching (HR, 1.381; 95% CI, 1.071-1.781; P =0.013), in agreement with the result of IPTW analysis (HR, 1.298; 95% CI, 1.123-1.500; P <0.001). The risk of composite outcomes (renal death, all-cause mortality and hospitalization for hyperkalemia) was higher in RAAS blockade users, but did not reach a statistically significant level (HR, 1.243; 95% CI, 0.996-1.550; P =0.054), in PS matched analysis level. However, the result of IPTW adjustment showed significant increased risk of composite outcomes (HR, 1.154; 95% CI, 1.016-1.310; P =0.027).

Conclusions: The use of RAAS blockades may hasten the onset of renal death without a benefit in all-cause mortality in pre-dialysis advanced CKD patients. Further studies were warranted to determine whether the withholding it may lead to better outcomes in this patients.

TH-PO864

Low Molecular Weight Serum Filtration Markers as Predictors of Acute Kidney Injury and CKD Progression in Adults with Chronic Kidney Disease Meredith C. Foster, Andrew S. Levey, Josef Coresh, Amanda Hyre Anderson, Jiang He, Edward J. Horwitz, Chi-Yuan Hsu, Amy B. Karger, Paul L. Kimmel, John W. Kusek, James P. Lash, Robert G. Nelson, Haochang Shou, Raymond R. Townsend, Vasan S. Ramachandran, Sushrut S. Waikar, Xiaoming Zhang, Lesley Inker. *CKD Biomarkers Consortium and the CRIC Study.*

Background: The low molecular weight (LMW) serum filtration markers β-trace protein (BTP) and β-2 microglobulin (B2M) are independently associated with ESRD in adults with chronic kidney disease but less is known about their associations with acute kidney injury (AKI) and CKD progression.

Methods: We studied participants in the Chronic Renal Insufficiency Cohort Study (N=3609, mean age 58 yrs, 45% women), a prospective cohort study of adults with CKD. Cox proportional hazards regression was used to evaluate associations of measured GFR (mGFR) and estimated GFR (eGFR) using CKD-EPI equations for creatinine, cystatin C, BTP, B2M (eGFRcr, eGFRcys, eGFRBTP, eGFRB2M) with subsequent AKI (first hospitalization with AKI ICD codes [584.x]) and CKD progression (30% decline in eGFRcr from baseline) during follow-up. Hazard ratios are presented for a 30mL/min/1.73m^2 lower baseline GFR. We used seemingly unrelated regression to compare the magnitude of associations to that observed for eGFRcr.

Results: Participants were followed a median of 6.7 yrs for AKI and 4.3 yrs for CKD progression (**Table**). For all measures lower GFR was associated with higher risks for AKI and CKD progression in MV adjusted models. For AKI, eGFRcys, eGFRBTP and eGFRB2M had stronger associations than eGFRcr, which persisted with mGFR adjustment. For CKD progression only eGFRBTP and eGFRB2M had stronger associations than eGFRcr, which persisted with mGFR adjustment.

Conclusions: Estimated GFR from serum LMW proteins are independently associated with increased risk of AKI and CKD progression in adults with moderate CKD, beyond that of eGFRcr or mGFR.

Table: Multivariable° adjusted associations for AKI and CKD progression. Hazard ratios (HR) are presented for a 30mL/min/1.73m^2 lower baseline mGFR or eGFR in each model.

Outcome: Acute Kidney Injury (905 events/3609 population at risk)

TH-PO865

Proteinuria without Impairment in Kidney Function or Kidney Scarring Potentiates Atherosclerosis Yohei Tsuchida,[1] Jianyong Zhong,[1] Macrae F. Linton,[2] Agnes B. Fogo,[3] Haichun Yang,[3] Valentina Kon.[1] *[1]Pediatrics, Vanderbilt Univ Medical Center, Nashville, TN; [2]Medicine, Vanderbilt Univ Medical Center, Nashville, TN; [3]Pathology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: CKD is a well-established risk for cardiovascular disease (CVD) with an inverse relationship between degree of kidney impairment and CVD. This relationship may reflect accumulation in uremic toxins that activate proatherogenic pathways. CKD is often accompanied by proteinuria. We now examine if proteinuria without other renal functional impairment or renal structural injury impacts development of atherosclerosis.

Methods: NEP25 transgenic mice express the human CD25 receptor on podocytes and develop proteinuria when injected with LMB2 toxin. NEP25/ApoE-/- mice were generated by cross-breeding. NEP25/ApoE-/- female mice were injected with LMB2, and compared to littermates not receiving toxin. All mice were fed a high fat diet. Body weight, as an index of edema, and albuminuria, assessed as spot urine albumin:creatinine ratios (ACR) were assessed weekly until sacrifice 4 weeks later. BUN was assessed at sacrifice. Atherosclerosis was measured by Oil-Red-O staining of proximal aortae, and kidney morphology was assessed.

Results: NEP25/ApoE-/- mice had increased ACR after LMB2 toxin compared to control (289.6±125.1 vs 28.4±8.6ug/mg, $p<0.05$). Although ACR was persistently elevated in NEP25+/ApoE-/-, the mice had no change in body weight and BUN was unchanged in toxin-exposed vs control (24.0±9.3 vs, 24.9±1.8mg/dl). Renal light microscopic morphology remained normal. NEP25+/ApoE-/- with LMB2 toxin had significantly greater atherosclerotic area than control that did not receive LMB2 (416954.0±111754.5 vs 235807.1±39861.2um^2, $p<0.05$). The degree of elevation in ACR correlated with the magnitude of atherosclerotic plaque burden (R^2=0.7213).

Conclusions: In summary, even in the absence of changes in BUN or histological damage, proteinuria per se amplifies atherosclerosis and the degree of proteinuria correlates with extent of atherosclerotic plaques. Additional studies are needed to further clarify the atherogenic mechanisms augmented by disruption in the glomerular filtration barrier.

TH-PO866

Low-Grade Albuminuria Predicts Age-Related GFR Decline in the General Non-Diabetic Population Toralf Melsom, Marit D. Solbu, Jørgen Schei, Vidar T.N. Stefansson, Trond G. Jenssen, Bjorn Odvar Eriksen. *Metabolic and Renal Research Group, UiT The Arctic Univ of Norway, Tromso, Troms, Norway.*

Background: Rapid age-related loss of GFR is a risk factor for chronic kidney disease (CKD), cardiovascular disease and mortality. Albuminuria, defined as an albumin-creatinine-ratio (ACR) >3.0 mg/mmol, predicts steeper age-related GFR decline in the general population. However, whether an ACR level below this cut off also constitute a risk of GFR decline is unknown. We investigated this hypothesis in a general non-diabetic population.

Methods: In the Renal Iohexol-clearance Survey in Tromsø 6 (RENIS-T6) we measured GFR as iohexol-clearance in a representative sample of 1562 middle-aged persons from the general population without baseline diabetes, cardiovascular disease or albuminuria. A total of 1274 (82%) had a repeated GFR measurement after a median of 5.6 years in the RENIS-Follow-Up (FU). ACR was measured in urine samples collected on three separate days at baseline.

Results: The median (interquartile range) ACR at baseline was 0.2 (0.1 – 0.5) mg/mmol and the mean (standard deviation) GFR decline rate was 0.95 (2.23) mL/min/year. One standard deviation higher baseline log-transformed ACR was associated with a 1.85 (95% CI: 0.48 to 3.21) mL/min higher baseline GFR and a 0.15 (95% CI: 0.26 to 0.04) mL/min/year steeper GFR decline rate during follow up in a linear mixed model ($P < 0.01$). We adjusted for sex and baseline height, weight, blood pressure, fasting glucose, LDL-cholesterol, triglycerides, smoking and the use of antihypertensive medications. A similar association was found after excluding those with high normal ACR defined as ACR>1.1 mg/mmol (>10 mg/g).

Conclusions: We conclude that higher ACR levels within the normal range predict accelerated age-related GFR decline in the general non-diabetic population.

TH-PO867

Renal Hyperfiltration Predicts a Steeper GFR Decline in the General Non-Diabetic Population Toralf Melsom, Jørgen Schei, Vidar T.N. Stefansson, Trond G. Jenssen, Marit D. Solbu, Bjorn Odvar Eriksen. *Metabolic and Renal Research Group, UiT The Arctic Univ of Norway, Tromso, Troms, Norway.*

Background: An abnormally elevated glomerular filtration rate (GFR), or hyperfiltration, has been proposed as a risk factor for subsequent GFR decline and chronic kidney disease (CKD) of different origins. Treatments that cause an initial drop in GFR, such as ACE-inhibitors in hypertension and sodium-glucose co-transport inhibitors in diabetes, have been associated with a slower GFR decline in the long term. We hypothesized that higher baseline GFR levels predict a steeper age-related GFR decline rate in the general non-diabetic population.

Methods: We measured GFR at baseline and follow-up in the Renal Iohexol Clearance Survey Follow-up (RENIS-FU). A total of 1594 middle-aged persons without diabetes or CKD were investigated at baseline and 1324 (83%) had a follow-up after 5.6 years. A random sample of 88 persons had a third GFR measurement within the RENIS-FU, which allowed us to use a linear mixed model to investigate the GFR decline rate. This method overcomes the problems of mathematical coupling and regression to the mean when investigating the relationship between initial value and change.

Results: Mean (SD) baseline GFR was 104.0 (20.1) mL/min and mean GFR decline rate was 0.95 (2.23) mL/min/year. Male sex, tobacco smoking, higher body weight, and higher fasting glucose were associated with a higher baseline GFR (a higher intercept), in multivariable adjusted linear mixed regressions with random intercept and slope ($p<0.001$). The correlation (95% CI) between the random intercept and the random slope was -0.32 (-0.40 to -0.23), demonstrating that high baseline GFR values were associated with a subsequent steeper GFR decline.

Conclusions: This study indicates that renal hyperfiltration is a risk factor for accelerated age-related GFR decline in the general population.

Funding: Pharmaceutical Company Support - Main funding from the Northern Norway Health Authority; additional grant from Boehringer-Ingelheim, Government Support - Non-U.S.

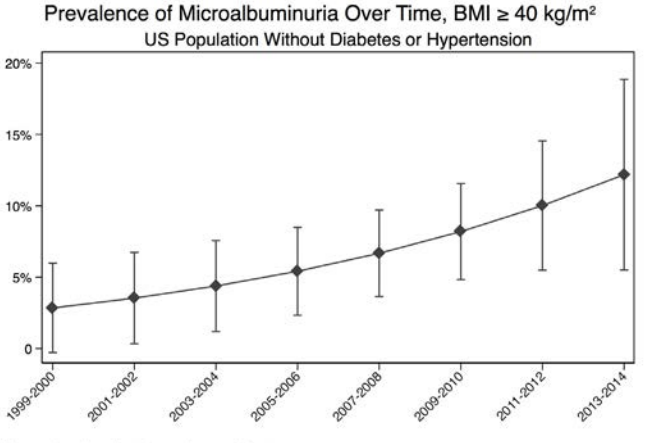
TH-PO868

Prevalence of Albuminuria among Obese U.S. Adults without Other Comorbid Conditions Meera Nair Harhay,[1] Andrew Stokes,[3] Eun Ji Kim,[3] Justin C. Brown,[2] Michael Oscar Harhay.[2] *[1]Medicine, Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA; [2]Univ of Pennsylvania; [3]Boston Univ.*

Background: Obese individuals without evidence of obesity-related metabolic abnormalities may not be routinely screened for proteinuria. The prevalence of proteinuria among non-hypertensive and non-diabetic obese adults is unknown.

Methods: Our study sample was derived from the multi-ethnic, nationally representative sample of US adults (age>18 years) from eight waves (1999-2014) of the National Health and Nutrition Examination Surveys (NHANES). We included adults with estimated glomerular filtration rate>90 ml/min/1.73m^2, no history of diabetes or hypertension, glycated hemoglobin<6.5%, and blood pressure<140/90 mmHg. We estimated age- and gender-adjusted prevalence over time of microalbuminuria and macroalbuminuria (urine albumin:creatinine >30 and <300 mg/g, and >300 mg/g, respectively) in this subsample, by body mass index (BMI) category.

Results: 22,476 NHANES participants met inclusion criteria. From 1999-2014, the age-adjusted prevalence of obesity (BMI>30 and <40 kg/m^2) in this sample increased from 21% to 25% (p=0.02), and morbid obesity (BMI>40 kg/m^2) increased from 2.4% to 5.8% (p<0.001). The overall age- and gender-adjusted prevalence of microalbuminuria increased from 6.8% (95% CI: 5.3-8.1%) to 7.1% (6.0-8.2%), p=0.04 for trend. The overall prevalence of macroalbuminuria also rose over time, from 0.3% (0.1-0.6%) to 0.7% (0.5-1.0%), p=0.01 for trend. The age and gender-adjusted prevalence of microalbuminuria among morbidly obese participants increased from 2.7% (0.0-5.8%) in 1999-2000 to 11.6% (5.0-18.3%) in 2013-2014 (p interaction=0.08).



Conclusions: The prevalence of microalbuminuria has been increasing over time among morbidly obese US adults without evidence of other commonly assessed proteinuria risk factors.

TH-PO869

High-Normal Albuminuria Predicts the Incidence of Chronic Kidney Disease in a Nondiabetic Population Aki Sanada, Toshinori Ueno, Ayumu Nakashima, Shigehiro Doi, Takao Masaki. *Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Microalbuminuria is considered to be one of the predictors of the incidence in decline of glomerular filtration rate (GFR). However, little is currently known about the relationship between high-normal albuminuria and chronic kidney disease (CKD) developing in the general population without diabetes mellitus.

Methods: A 10-year follow-up retrospective cohort study was preformed involving 1364 Japanese men (mean age, 44 years) who were free of CKD and diabetes mellitus. CKD was defined as an estimated GFR (eGFR) of <60 ml/min per 1.73 m2 or urine albumin to creatinine ratio (ACR) of ≥30 mg/g. Multivariate stepwise analysis was used to assess independent predictors of the baseline ACR. Logistic regression approaches were then used to assess determinants of the incidence of CKD. Receiver operator characteristics curve (ROC) analysis was used to determine the optimal cut-off value of the ACR as a predictor of incident CKD.

Results: At the baseline examination, eGFR, hypertension, age, body mass index, and the presence of hematuria were independently associated with the ACR. Among 1364 participants, 182 (13.3%) complied with our definition of incident CKD through 10 years of follow-up. The rate of decline in eGFR was higher with increasing quartiles of the ACR. Participants who had an ACR in the highest quartile (5.9 to 28.9 mg/g) were more likely to develop microalbuminuria (odds ratio 13.2, 95% CI 5.1 to 44.7) and CKD (odds ratio 3.7, 95% CI 2.3 to 6.0) than those who had an ACR in the lowest quartile (1.3 to 3.6 mg/g). These results were unchanged after adjustment for age, eGFR, hematuria, body mass index, and smoking status, as well as the presence of hypertension, hyperuricemia, and dyslipidemia. In ROC analysis, the area under the curve was 0.62 and an albuminuria level of 7.0 mg/g was decided as the cut-off value of incident CKD.

Conclusions: Our study shows that high-normal albuminuria is associated with incident CKD in the nondiabetic population.

TH-PO870

The Clinical Association among Urinary Albumin Excretion within Normal Range, Left Ventricular Diastolic Functional and Structural Change in General Korean Population Dong-Young Lee,[1] Hyun Sun Park.[1] *[1]Internal Medicine, VHS Medical Center, Seoul, Korea; [2]Total Healthcare Center, Kangbuk Samsung Hospital, Sungkyunkwan Univ, School of Medicine, Seoul, Korea.*

Background: Urine albumin creatinine ratio (UACR) is a reliable index of urinary albumin excretion and getting great attention on its association with cardiovascular disease. Nonetheless, the clinical association between UACR within normal range and subclinical left ventricular (LV) change was not clearly identified. Therefore, this study was designed to examining the clinical association between normal range of UACR and subclinical LV change.

Methods: A total of 31,334 apparently healthy Korean who received medical health check up including echocardiography in Kangbuk Samsung hospital were enrolled in this study. Study population was stratified by 3 groups according to their UACR (Tertile 1<3.17, Tertile 2: 3.17-4.95, Tertile 3≥4.95). The odd ratios (ORs) with 95 % confidence interval (CI) of abnormal LV relaxation, LV remodeling, and hypertrophy were compared among 3 groups using the multivariable logistic regression analysis. We also analyzed the adjusted mean value of parameter associated with LV diastolic function and structure.

Results: When tertile 1 group was set as reference, the adjusted ORs (95%CI) for abnormal LV relaxation showed proportional relationship with UACR levels within normal range [OR; 0.86 (95% CI 0.59 – 1.22) in underweight, 1.81 (95% CI 1.63 – 2.00) in overweight, 2.75 (95% CI 2.49 - 3.03) in obese, and 4.34 (95% CI 3.65 - 5.16) in severe obese]. Adjusted ORs for abnormal LV relaxation significantly increased with UACR levels. [tertile 2 (1.72; 1.15-3.08) and tertile 3 (2.18; 1.24-3.87)], even after adjusting for other covariates. Adjusted ORs for LV remodeling and hypertrophy were also significantly associated with UACR levels [tertile 2 (1.54; 0.93-2.16) and tertile 3 (1.94; 1.31-2.63)].

Conclusions: Elevated UACR, even within normal range, was significantly associated with the risk of LV diastolic functional and structural abnormality.

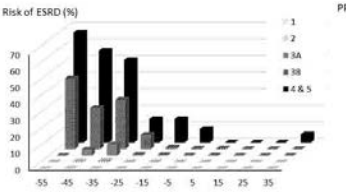
TH-PO871

Evaluation of Glomerular Filtration Rate Change as Surrogate Endpoint for End-Stage-Renal Disease Eiichiro Kanda,[1] Tomoko Usui,[2] Naoki Kashihara,[3] Chiho Iseki,[4] Kunitoshi Iseki,[4] Masaomi Nangaku.[2] *[1]Tokyo Kyosai Hospital; [2]The Univ of Tokyo; [3]Kawasaki Medical School; [4]Okinawa Heart and Renal Association, Tomishiro Center Hospital.*

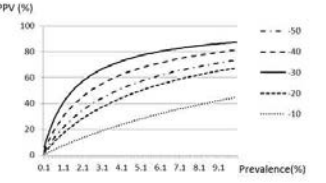
Background: Chronic kidney disease patients have high risks of death and end-stage renal disease (ESRD). Although more clinical studies are needed to improve their prognosis, good surrogate endpoints for ESRD have been required, because it takes a long time and involves large costs until true endpoints occur.

Methods: Subjects with data on serum creatinine level for a baseline period over 1 to 3 years were enrolled (n=69248) in this community-based prospective cohort study in Okinawa, Japan, and followed up for four years. The percent of estimated glomerular filtration rate (%eGFR) change converted into 2 years (%/2 years) was calculated on the basis of the baseline period.

Results: Among the subjects recruited, 15.81 % had low-eGFR (eGFR<60ml. min/1.72m^2), and 0.11 % developed ESRD. Subjects with a range of -40 ≤ %eGFR change < -30 %/2 years had the highest risks [high-eGFR (60ml.min/1.72m^2≤eGFR) group adjusted odds ratio (aOR), 12.8 (95 % confidence interval 3.4, 48.3); low-eGFR group, aOR 53.9 (13.3, 219.0)]. Cumulative population attributable risk percent showed that %eGFR change < -30 %/2 years contributed to the ESRD population. The positive predictive value for ESRD was highest at %eGFR change -30 %/2 years.



A Risk distribution of ESRD and CKD stage. The risk of ESRD sharply increases from %eGFR change -30 to -40 %/2 years.



B Positive predictive value of ESRD based on a cutoff value of % eGFR change. -30% was highest at %eGFR change -30 %/2 years.

The accuracy of prediction of ESRD based on %eGFR change [AUC 0.93 (0.89, 0.98)] was higher than those based on the change in eGFR slope [0.85 (0.80, 0.90)].

Conclusions: %eGFR change is associated with the risk of ESRD. %eGFR change -30%/2 years can be a surrogate endpoint for ESRD in the Japanese population.

TH-PO872

Performance of Creatinine-Based Equations to Assess Glomerular Filtration Rate Decline - The NephroTest Cohort Study Marieke H.C. Van Rijn,[1,2] Marie Metzger,[1] Jan A.J.G. van den Brand,[2] Martin Flamant,[3] Jean-Philippe Haymann,[4] Pascal Houillier,[5] Marc Froissart,[1] Benedicte Stengel.[1] *[1]Inserm U1018, France; [2]Radboud Univ Medical Center, Netherlands; [3]Bichat Hospital; [4]Tenon Hospital; [5]InsermU1138 & European G. Pompidou Hospital, France.*

Background: One point performance of creatinine-based estimated glomerular filtration rate(eGFR) equations has been extensively analyzed, but little is known on their ability to evaluate GFR trajectories. We studied the performance of the MDRD and CKD-EPI equations in estimating GFR decline over time.

Methods: We included 1955 stage 1 to 4 CKD adult patients who underwent up to 13 simultaneous IDMS-calibrated serum creatinine and GFR measurements (mGFR; ^{51}Cr-EDTA renal clearance). We estimated absolute and relative slopes for mGFR and both MDRD and CKD-EPI eGFR equations using linear mixed models. Performance was assessed by the bias and 95% limits of agreement (LoA) between mGFR and eGFR slopes, overall and by patient subgroups.

Results: Patients underwent a total of 5515 visits; 60% had at least two over a median 3.4-yr follow-up (IQR: 2.0-5.6). The bias for the absolute slope was close to zero for both equations.

	GFR at baseline (mL/min/1.73m^2)	Absolute GFR slope (mL/min/1.73m^2/year)			Relative GFR slope (% change per year)		
	mean (sd)	mean (sd)	Mean Bias	95% LoA	mean (sd)	Mean Bias	95% LoA
mGFR	44.0 (19.0)	-1.56 (0.90)			-4.33 (3.10)		
CKD-EPI eGFR	46.4 (22.2)	-1.52 (1.10)	-0.04 (0.86)	(-1.72, 1.64)	-3.74 (2.77)	-0.59 (1.82)	(-4.16, -0.67)
MDRD eGFR	44.5 (20.9)	-1.31 (1.04)	-0.25 (0.82)	(-1.87, 1.36)	-3.32 (2.65)	-1.01 (1.90)	(-4.72, 2.71)

Using relative slope yielded greater bias, which was stronger for the MDRD than the CKD-EPI equation. The LoA were wide for both absolute and relative slopes, indicating low precision. Performance of equations varied by subgroups defined by baseline GFR, age, gender and hypertension.

Conclusions: In CKD patients, both equations were very accurate in estimating the absolute GFR decline at the population level, but their precision was low, indicating large differences at the individual level. Patient and disease characteristics may impact equation longitudinal performance.

TH-PO873

Within-Person Variability of Albuminuria and Glomerular Filtration Markers in CKD Sushrut S. Waikar, Casey Rebholz, Chi-Yuan Hsu, Harold I. Feldman, Dawei Xie, Kathleen D. Liu, Lesley Inker, Theodore E. Mifflin, John H. Eckfeldt, Paul L. Kimmel, Vasan S. Ramachandran, Joseph V. Bonventre, Josef Coresh. *CKD Biomarkers Consortium, NIDDK.*

Background: We conducted a study to determine the short-term within-person variability and reference change values for albuminuria and four filtration markers used for GFR estimation in CKD.

Methods: We collected 3 repeat plasma samples and 5 urine samples (2 first morning and 3 random spot) from 49 patients with CKD over 1 month. Inclusion criteria were diagnosis of CKD; attendance at a nephrology clinic; and eGFR <60 ml/min/1.73 m^2 or

albumin:creatinine ratio (ACR) >100 mg/g. We measured albumin and creatinine in urine samples, and the filtration markers creatinine (SCr), cystatin C (CysC), β-trace protein (BTP), and β_2-microglobulin (B2M) in plasma samples, in single batches with blind split replicates to measure assay variability. Reference change values (RCV) at 95% confidence level were calculated from median values of within-person coefficient of variation (CV) from non-log transformed values.

Results: The distribution of CKD stages was 13% stage 5, 24% stage 4, 31% stage 3b, 20% stage 3a, 4% stage 2, and 2% stage 1; the distribution of albuminuria was 28% normo-, 28% micro-, and 43% macroalbuminuria. Analytic CVs for urine albumin, creatinine, and all four filtration markers were <2%. The Table shows medians, ranges, CV, and RCV for each analyte.

	ACR, mg/g		SCr, mg/dL	CysC, mg/dL	BTP, mg/L	B2M, mg/L
	First morning	Random				
Median conc. (range)	162 (0 - 3,557)	173 (0 - 4,006)	1.77 (0.62 - 9.41)	1.88 (0.82 - 4.39)	1.26 (0.28 - 4.91)	4.54 (1.62 - 15.54)
Median CV, % (range)	31.1 (0.2 - 95.1)	31.0 (13.6 - 76.8)	5.5 (0.8 - 69.3)	4.1 (0.4 - 52.2)	7.3 (1.1 - 49.4)	5.7 (0.2 - 54.9)
RCV, %	86	86	15	11	20	16

Conclusions: In CKD patients, albuminuria exhibits substantial within-person variability with RCVs exceeding 50%, which has been proposed in proteinuric kidney diseases as part of the definition for partial remission. The within-person variability of filtration markers in CKD appears comparable to reports in healthy individuals and does not exceed thresholds commonly used to define CKD progression.

TH-PO874

Screening for CKD Risk in the General Population in Belgium Using the QKidney®-2014 Risk Calculator Eric E. Gheuens, Koenraad Peter Bouman, Ronald Daelemans. *ZNA Kidney Clinic, Ziekenhuis Netwerk Antwerpen, Antwerpen, Belgium.*

Background: On World Kidney Day 2015 we launched the QKidney®-2014 risk calculator (www.qkidney.org) to screen for risk for developing chronic kidney disease (CKD) or end stage renal disease (ESRD) in the general population.

Methods: A webpage was created and launched on march 12th 2015, followed by a Facebook® advertising campaign in February 2016.

Results: In one year more than 60.000 records were created.

Characteristics of the population	Women	Men
n	31580	31085
Median age [IQR], years	52 [44, 60]	56 [45, 64]
BMI, Mean (SD)	26 (4,62)	26 (4,62)
Smoking status, n(%)		
Ex Smoker	1485 (4,70)	2058 (6,62)
Heavy Smoker	1147 (3,63)	1975 (6,35)
Light Smoker	1568 (4,97)	1399 (4,50)
Moderate Smoker	2948 (9,34)	2060 (6,63)
Non Smoker	24432 (77,37)	23593 (75,90)
Clinical conditions, n(%)		
Type 1 diabetes	331 (1,05)	795 (2,56)
Type 2 diabetes	1193 (3,78)	1859 (5,98)
Cardiovascular disease	1401 (4,44)	2623 (8,44)
Congestive heart failure	1217 (3,85)	1867 (6,01)
Peripheral vascular disease	1522 (4,82)	1654 (5,32)
Treated hypertension	7018 (22,22)	8635 (27,78)
Kidney stones	3381 (10,71)	4431 (14,25)
Family history of kidney disease	5308 (16,81)	3958 (12,73)

We included only complete records for our final analysis (21162 women, 21581 men). The 5-year risk score (mean [95%CI]) for CKD is 1,92 [1,83-2,02] for women, 4,39 [4,25-4,54] for men. For ESRD this is 0,75 [0,68-0,82] and 1,72 [1,60-1,84] respectively. 417 (1,97%) women and 1260 (5.84%) men have a slightly elevated risk for developing ESRD within 5 years (scores between 3-15). 171 (0.81%) women and 425 (1,97%) men have a high risk for developing ESRD within 5 years (scores >15).

Conclusions: The risk for developing CKD or ESRD is low in the general population. In our population the risk is higher for males than for females, explained by the higher age and presence of comorbidities. The use of the Qkidney risk calculator allows detection of high risk persons, eligible for screening.

TH-PO875

Hematuria as a Risk Factor for the Progression of Chronic Kidney Disease Paula Ferreira Orlandi,[1] Naohiko Fujii,[1] L. Lee Hamm,[3] James H. Sondheimer,[4] Chi-Yuan Hsu,[5] Michael J. Fischer,[2] Harold I. Feldman.[1] *[1]Center for Clinical Epidemiology and Biostatistics, Univ of Pennsylvania, Philadelphia, PA; [2]Renal Div, Univ of Illinois Hospital and Health Sciences Center, Chicago, IL; [3]School of Medicine, Tulane Univ School of Medicine, New Orleans, LA; [4]School of Medicine, Wayne State Univ, Detroit, MI; [5]School of Medicine, Univ of California, San Francisco, CA.*

Background: Hematuria from nephrogenic causes is associated with oxidative stress and inflammation, which may mediate further structural damage to the nephron. Despite its inexpensive and universally accessible assessment, hematuria has rarely been explored as a risk factor for CKD progression.

Methods: In the Chronic Renal Insufficiency Cohort (CRIC) Study, we evaluated the relationship of hematuria with CKD progression. Presence of hematuria was defined as a positive dipstick in one urinary sample during patient enrollment. All 3272 participants for whom hematuria was assessed were included. Hazards ratios for the development of ESRD over a median follow-up of 5 years were estimated for patients with and without hematuria. Analyses were stratified by eGFR (<30; 30-44.9; 45-59.9, >=60 ml/min/1.73m2), history of diabetes and proteinuria (<0.10; 0.10 -0.49; 0.50- 1.49; >=1.50g/dl).

Results: From all participants, 1145 (29%) presented hematuria at screening. Groups with and without hematuria differed on racial distribution (22% of Hispanics in the group with hematuria vs. 9.5% in the group without), proportion of diabetes (55.72% vs. 47.6%), eGFR (40.2 vs. 45.3 ml/min/1.73m2) and presence of proteinuria at baseline (34.8% vs. 8.5% presented at least 1.5g/day). For patients with diabetes, hematuria was associated with the development of ESRD within the first year (Hazard Ratio: 2.43; 95%CI: 1.18-5.00, p=0.016) and second year of follow-up (Hazard Ratio: 1.68; 95%CI: 1.11-2.54, p=0.013), and this relationship was attenuated over time.

Conclusions: In a large adult cohort with CKD, hematuria was associated with a significantly greater risk of CKD progression. These results suggest the potential role of hematuria as a predictor of CKD progression.

TH-PO876

The Chronic Kidney Disease Metabolome - Untargeted Metabolomics in Living Kidney Donors, Kidney Transplant Patients, Chronic Kidney Disease Patients and Various Dialysis Modalities Brad Urquhart,[1,2] Thomas Velenosi,[1] Benjamin Kervin Thomson,[2,3] Amit X. Garg,[2] Andrew A. House.[2] *[1]Physiology and Pharmacology, Western Univ; [2]Medicine, Div of Nephrology, Western Univ, London; [3]Medicine, Div of Nephrology, Queens Univ, Kingston, ON, Canada.*

Background: Although a number of studies have assessed metabolic changes in chronic kidney disease (CKD), this study aimed to evaluate overall metabolic changes in living kidney donors, CKD, transplant and various dialysis modalities as well as before and after dialysis using an untargeted metabolomics approach.

Methods: Plasma was collected from living kidney donors prior to and one year following kidney donation. Age-matched control plasma was collected in the same time frame. Dialysis patient plasma was collected prior to and immediately following dialysis for conventional dialysis (Conv. HD), nocturnal intermittent peritoneal dialysis (NIPD) and a number of home hemodialysis (Home HD) modalities including: frequent nocturnal (FN), short-hours daily (SHD), intermittent conventional (IC) and intermittent nocturnal (IN). Plasma from CKD and transplant patients was collected during routine follow-up appointments. Untargeted metabolomics analysis of plasma samples was performed using reverse phase (RPLC) and hydrophilic interaction liquid chromatography (HILIC) coupled to mass spectrometry.

Results: All pre-dialysis and CKD samples demonstrated more than 250 significantly different metabolites compared to control patients by both RPLC and HILIC analysis. Transplant samples resulted in less than 35 metabolites significantly different than controls in by RPLC and HILIC analysis. Principal component analysis demonstrated clustering of control, living donor and transplant patient samples compared to CKD and all dialysis modalities. When comparing pre and post dialysis samples, NIPD resulted in minimal metabolic changes. The largest change in metabolite levels during dialysis was seen in Home HD FN samples.

Conclusions: Plasma metabolic profiles of living kidney donors and kidney transplant patients were not distinguishable from controls by principal component analysis for both RPLC and HILIC data further supporting kidney transplant as ideal renal replacement therapy.

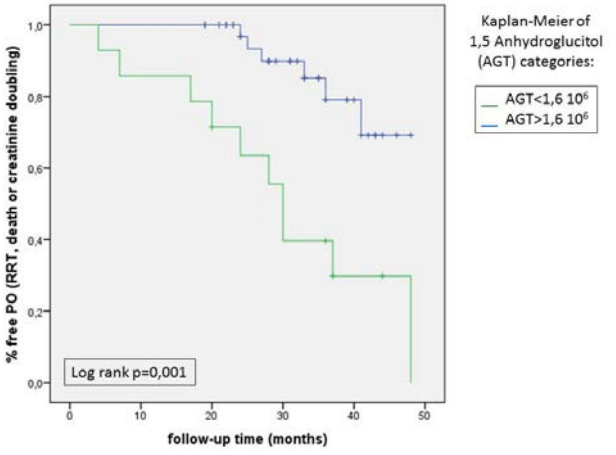
1,5-Anhydroglucitol Predicts CKD Progression in Macroalbuminuric Diabetic Kidney Disease: Results from Non-Targeted Metabolomics

Gesiane Fernandes Tavares,[1] Gabriela Venturini,[2] Kallyandra Padilha,[2] Roberto Zatz,[1] Alexandre Costa Pereira,[2] Eugene P. Rhee,[3,4] Silvia M. Titan.[1] *[1]Nephrology Div, School of Medicine, Sao Paulo Univ, Sao Paulo, Brazil; [2]Laboratory of Genetics and Molecular Cardiology, Heart Inst, Univ of São Paulo Medical School, Sao Paulo, Brazil; [3]Nephrology Div, Massachusetts General Hospital, Boston, MA; [4]Metabolite Profiling, Broad Inst, Cambridge, MA.*

Background: In DKD, few biomarkers of disease progression are available, besides eGFR and albuminuria. Metabolomics is a new tool that allows exploration of novel biomarkers.

Methods: Non-targeted metabolomics was done on plasma of 56 DKD patients in Brazil. After a follow-up of 2.5y, the primary outcome (PO: dialysis need, doubling of serum creatinine, or death) occurred in 17 patients (30.3%). Samples were derivatized by methoximation and MSTFA, and analyzed by GC-MS Agilent 5977A/7890B. Data was processed using Agilent MassHunter with NIST 11 and Fiehn A.01.00 compound library. Metaboloanalyst 3.0 and SPSS 20.0 were used for analysis.

Results: After cleaning, 186 metabolites were left for analysis. Of those, 14 were associated with the PO (Mann-Whitney test). In Cox regression, only 1,5-anhydroglucitol (AGT) (HR 0.10; 95%CI 0.01-0.63, p=0.01), norvaline and L-aspartic acid where associated with the PO. After adjustments for baseline eGFR and glycated hemoglobin, AGT remained significantly and inversely associated with the PO (HR 0.05; 95%CI 0.01-0.33, p=0.002). A significant KM curve is shown in Figure 1.



Conclusions: Our results show that 1,5-anhydroglucitol, an inverse marker of hyperglycemia, is a significant predictor of CKD progression in DKD. Notably, a recent study highlighted AGT as a marker for new onset CKD among African Americans. Our findings extend this association to established DKD, in a racially diverse population.

Funding: Government Support - Non-U.S.

TH-PO878

Ceruloplasminuria Predicts Progression of CKD and Precedes the Development of Macroalbuminuria

Elwaleed Elnagar,[1] Kelly J. Hunt,[2] Alison Bland,[2] Christian Herzog,[1] Michael G. Janech,[2] Maria Lopes-Virella,[2] John M. Arthur.[1] *[1]UAMS; [2]MUSC.*

Background: We previously used a discovery proteomic analysis to identify ceruloplasmin (Cel) as a candidate marker to predict decline in renal function in diabetic patients. This is an initial validation study to determine if Cel predicts progression of CKD in diabetic patients.

Methods: We used 258 urine samples from the VA Diabetes Trial that were collected when patients had normo or microalbuminuria with normal serum creatinine (Cr). The median urine albumin to Cr ratio (ACR) was 11.5 mg/g. The primary outcome measure is a 50% rise in serum Cr from baseline during follow-up. Secondary outcomes are a 3.3% decline in eGFR per year and development of macroalbuminuria. Ceruloplasmin (Cel) was measured in urine samples collected as part of the VADT study using ELISA. Urine creatinine (Cr) was measured using a kinetic Jaffe assay. Results adjusted for treatment groups and use of ACE inhibitors.

Results: 13.4% of subjects had a 50% increase in serum Cr. As predicted from the discovery proteomic analysis, urine Cel concentration is associated with the risk of future decline of renal function in patients with normal renal function at baseline. For each 1 standard deviation increase in Cel, the odds ratio (OR) for a 50% increase in Cr is 1.33 (CI 1.01-1.75p=0.045, AUC 0.56). Standardizing Cel to urine Cr concentration using a Cel to Cr ratio (CCR) the OR for CCR is 1.51 (CI 1.14-1.99, p=0.004, AUC 0.61). For comparison the OR for ACR is 1.68 (CI 1.22-2.30, p=0.001, AUC 0.64). To examine whether the combination of ACR and CCR could improve prediction, we divided subjects into 4 groups based on the median splits of ACR and CCR and compared the risk of reaching the primary outcome in each of these groups to using the low ACR and low CCR group as the referent group. When compared to the referent group, all other categories had statistically significantly elevated risk. Subjects that had both high ACR and high CCR had the nominally highest risk.

Conclusions: Ceruloplasminuria can identify type 2 diabetic patients with an increased risk of loss of renal function. The combination of ACR and CCR may enhance prediction. Hence, CCR may be useful as a clinical predictor in combination with ACR.

TH-PO879

Urinary Activin A as a Valuable Biomarker Reflecting the Activity of Various Kidney Diseases

Akito Maeshima, Anastasie Tshilela Kadiombo, Ken Kayakabe, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: Activin A, a member of TGF-β superfamily, is known to regulate cell growth and differentiation in various tissues. It has been reported that activin A modulates ureteric bud branching in kidney development, inhibits tubular regeneration after renal ischemia, and acts as a potent inducer of renal fibrosis in rodents. However, the role of activin A in kidney diseases remains unknown in human. To address this issue, we analyzed renal biopsy specimens and urine from patients with various kidney diseases.

Methods: Patients with IgAN (n=81), lupus nephritis (n=80), ANCA-associated vasculitis (n=32), glomerulosclerosis (n=31), minimal change nephrotic syndrome (n=21), and others (n=147) who were treated in our department from 2011 and 2015 were included in this study. Urinary concentration of activin A, follistatin (activin antagonist), N-gal, KIM-1 and serum activin A were measured by ELISA. The localization of activin A in renal biopsy specimens was examined by immunostaining. Normal kidney specimens from patients who underwent nephrectomy were used as controls.

Results: Urinary activin A was almost undetectable in healthy volunteers (9.6 ± 2.3 ng/gCr), but was significantly increased in patients with acute kidney injury (257.9 ± 174.6), lupus nephritis type IV (51.7 ± 15.0), and ANCA-associated vasculitis (120.4 ± 38.7). Urinary activin A levels of these patients was rapidly decreased after the initiation of treatment. There was a significant correlation of urinary activin A level with urinary N-gal, KIM-1 and serum activin A. Urinary activin A level was negatively correlated with eGFR and hemoglobin. Activin A was localized in the cytoplasm of distal tubules of normal kidneys. In contrast, activin A was present not only in distal tubules, but also in the apical lumen of proximal tubules, infiltration macrophages, and vascular smooth muscle cells in patients with kidney diseases.

Conclusions: These data suggest that urinary activin A is a valuable biomarker reflecting the activity of various kidney diseases.

TH-PO880

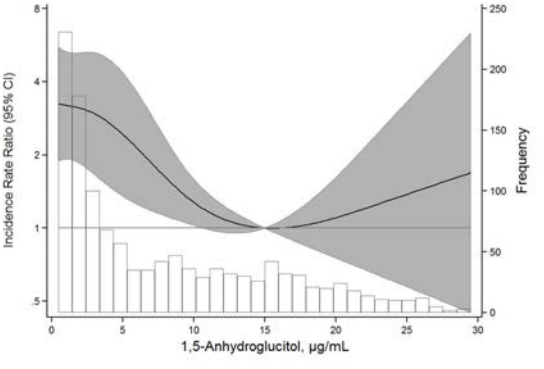
Serum Levels of 1,5-Anhydroglucitol and Risk of Incident End-Stage Renal Disease

Casey Rebholz,[1] Morgan Grams,[1] Yuan Chen,[2] Alden Lawrence Gross,[1] Yingying Sang,[1] Josef Coresh,[1] Elizabeth Selvin.[1] *[1]Johns Hopkins Univ; [2]Columbia Univ Mailman School of Public Health.*

Background: Low 1,5-anyhydroglucitol (1,5-AG) is a biomarker of hyperglycemic excursions that has recently been associated with early stages of kidney disease. However, it is unknown if low 1,5-AG levels can lead to more advanced stages of kidney disease independent of kidney function and glycemia (e.g., hemoglobin A1c).

Methods: Blood levels of 1,5-AG, other glycemic markers, and filtration markers were measured in 13,279 Atherosclerosis Risk in Communities (ARIC) Study participants. End-stage renal disease (ESRD) was defined as entry into the U.S. Renal Data System registry from baseline through 2011. Structural equation modelling was used to estimate the association between 1,5-AG and ESRD with latent variables for kidney function (creatinine, cystatin C, β_2-microglobulin) and glycemia (diabetes, fasting glucose, hemoglobin A1c, fructosamine, glycated albumin), and adjusting for demographics and established risk factors.

Results: During a median follow-up of 20 years, there were a total of 271 incident ESRD cases. After adjusting for age, sex, race, hypertension, body mass index, smoking status, and the latent variable for kidney function, the linear spline terms representing 1,5-AG levels <6 µg/mL (IRR: 0.80, 95% CI: 0.71-0.95) and 6-<10 µg/mL (IRR: 0.76, 95% CI: 0.66-0.87) were significantly associated with ESRD. After additionally adjusting for the glycemia latent variable, low levels of 1,5-AG (<6 µg/mL) were no longer significantly associated with ESRD (IRR: 0.92, 95% CI: 0.81-1.05).



Conclusions: Low levels of 1,5-AG are associated with higher risk of incident ESRD independent of baseline kidney function but not glycemia. 1,5-AG is a marker of hyperglycemia and glucose variability, an important metabolic pathway that accelerates progression to ESRD.

Two Forms of Urinary Megalin Excretion Are Novel Predictors of the Progression of Early-Stage Diabetic Nephropathy in Type 2 Diabetes Mellitus

Tomomichi Iida,[1] Michihiro Hosojima,[2] Keiko Kabasawa,[3] Kazutoshi Nakamura,[4] Shoji Kuwahara,[5] Tomomi Ishikawa,[1] Ryohei Kaseda,[1] Yoshiki Suzuki,[6] Hiroyuki Kurosawa,[7] Yoshiaki Hirayama,[7] Ichiei Narita,[1] Akihiko Saito.[5] *[1]Clinical Nephrology and Rheumatology, Niigata Univ, Niigata, Japan; [2]Clinical Nutrition Science, Niigata Univ, Niigata, Japan; [3]Health Promotion Medicine, Niigata Univ, Niigata, Japan; [4]Preventive Medicine, Niigata Univ, Niigata, Japan; [5]Applied Molecular Medicine, Niigata Univ, Niigata, Japan; [6]Health Adiministration Center, Niigata Univ, Niigata, Japan; [7]Denka Co., Ltd., Tokyo, Japan.*

Background: Megalin is an endocytic receptor at the apical membrane of proximal tubules. We established sandwich ELISA to measure urinary (u-) excretion of the ectodomain and full-length forms of megalin, A- and C-megalin, respectively. Here, we examined the significance of these markers to predict the progression of early-stage diabetic nephropathy.

Methods: We analyzed 175 cases with type 2 diabetes mellitus (T2DM) (103 men; median age 68 [IQR, 58–75] years) with a median observation period of 3.97 (2.10–4.12) years. Cases were selected according to the u-albumin/creatinine (Cr) ratio (ACR, mg/g) and eGFR (mL/min/1.73m^2). We evaluated u-A- and C-megalin in relation to the risks of eGFR reduction (≥20% of initial data) and the escalation of ACR stages (from normo- [ACR<30] to microalbuminuria [30≤ACR<300], or from micro- to macroalbuminuria [ACR≥300]),using Cox's proportional hazard analysis.

Results: U-A-megalin/Cr was found to be a predictor of the escalation of the ACR stage in 69 microalbuminuric cases with eGFR≥30 (HR, 9.71 [95% CI, 1.34–70.67]) and of eGFR reduction in 120 cases with eGFR≥ 60 (HR, 6.31 [95% CI, 1.48–26.82]), even after adjusting for sex, age, HbA1c, eGFR, body mass index, and u-markers including ACR, β_2-microglobulin/Cr, and NAG/Cr. U-C-megalin/Cr was also a predictor of the escalation of the ACR stage in 62 normoalbuminuric cases with eGFR≥60 (HR, 2.45 [95% CI, 1.02–5.86]).

Conclusions: A- and C-megalin are novel u-biomarkers, independent of albumin, β_2-microglobulin, and NAG, that can predict particularly the progression of diabetic nephropathy in T2DM at micro- and normoalbuminuric stages, respectively.

TH-PO882

Effects of Oxidative Stress on the Relationship between Hyperuricemia and Intrarenal Arteriolar Lesions in Chronic Kidney Disease

Tsuyoshi Miyagi,[1] Kentaro Kohagura,[1] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Okinawa, Japan; [2]Tomishiro Central Hospital, Okinawa, Japan.*

Background: We previously reported that hyperuricemia (HU) is related to intrarenal arteriolar lesions in patients with chronic kidney disease (CKD). Here we investigated whether oxidative stress affects this relationship.

Methods: After excluding patients with vasculitis, we recruited a total of 139 patients (mean age, 44 years; 55 females; 84 males) who had undergone renal biopsy at our department. Hyalinized intrarenal arteriolar lesions were semi-quantitatively evaluated (grades 0–3). Relative oxidative stress was calculated using the formula: reactive oxygen metabolites-derived compounds (d-ROMs) ÷ biological antioxidant potential (BAP) value × correction coefficient (5.8). A result of ≥1 indicated a state of increased oxidative stress (OS). Subjects were divided into four subgroups according to the presence or absence of HU and OS (HU-/OS-, HU+/OS-, HU-/OS+, and HU+/OS+), and arteriolar lesions were compared between each group.

Results: The highest mean hyalinization grade was found in the HU+/OS+ group; this grade and differed markedly from that found in the HU-/OS- group. However, only a relatively small difference was detected between the HU+/OS- and HU-/OS- groups. Multivariate analysis was also used to investigate factors that may be associated with severe arteriolar hyalinization (values above the median grade), including age, gender, systolic blood pressure, HbA1c level, and HU/OS subgroup. Results indicated that HU+/OS+ (Ref: HU-/OS-) was a significant factor (Odd's ratio: 3.7; 95% CI, 1.0–14.6) and that the HU+/OS+ group exhibited the lowest%FMD.

Conclusions: Results indicated that the relationship between HU and intrarenal arteriolar hyalinized lesions may become more prominent in CKD patients when OS increases and endothelial dysfunction occurs.

TH-PO883

Urinary Markers of Oxidative Stress Do Not Accelerate the Age-Related GFR Decline Rate in the General Non-Diabetic Population

Jørgen Schei,[1,3] Ole-Martin Fuskevåg,[2] Vidar T.N. Stefansson,[3] Marit D. Solbu,[1,3] Trond G. Jenssen,[3,4] Bjorn Odvar Eriksen,[1,3] Toralf Melsom.[1,3] *[1]Dept of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; [2]Laboratory Medicine, Univ Hospital of North Norway, Tromsø, Norway; [3]Metabolic and Renal Research Group, UiT The Arctic Univ of North Norway, Tromsø, Norway; [4]Dept of Nephrology, Oslo Univ Hospital, Oslo, Norway.*

Background: Oxidative stress plays an important role in the pathogenic process of age-related chronic diseases. The urinary levels of 8-oxo-7, 8-dihydro-2'-deoxyguanosine (8-oxodG) and 8-oxo-7, 8-dihydroguanosine (8-oxoGuo) are well-established markers of oxidatively damaged DNA and RNA, and have been associated with chronic kidney disease (CKD) in animal studies and progression of diabetic nephropathy in humans. However, whether increased urinary levels of 8-oxodG and 8-oxoGuo predict an accelerated age-related GFR decline in the general population is unknown.

Methods: We measured GFR using iohexol clearance at baseline and follow-up in the Renal Iohexol Clearance Survey Follow-Up study (RENIS-FU). The cohort included 1,591 middle-aged subjects without diabetes, cardiovascular-, or kidney disease at baseline. After a median of 5.6 years, 1,298 subjects were included in the follow-up study. Baseline urinary levels of 8-oxodG and 8-oxoGuo were measured with LC-MS/MS.

Results: Mean (SD) annual GFR decline was -0.95 (2.23) mL/min/year. The median (IQR) urinary 8-oxodG/creatinine and 8-oxoGuo/creatinine ratios were 1.36 (1.04-1.74) and 3.45 (2.68-4.44) nmol/mmol, respectively. In multivariable adjusted mixed models, the log-transformed 8-oxodG/creatinine and 8-oxoGuo/creatinine were not associated with the GFR decline rate. When using 8-oxodG and 8-oxoGuo not corrected for urinary creatinine, one nmol/L higher concentration was associated with a slower GFR decline of 0.19 (95% CI: 0.03-0.35) and 0.16 (95% CI: 0.01-0.30) mL/min/year, respectively.

Conclusions: We found that the urinary concentrations of 8-oxodG and 8-oxoGuo predicted a slower GFR decline in a cohort representative of the general population. This does not support the hypothesis that oxidative stress plays an important role for an accelerated age-related GFR decline.

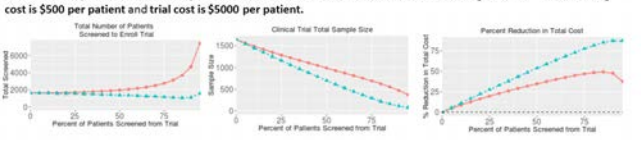
Evaluating Biomarkers for Prognostic Enrichment of Clinical Trials

Kathleen F. Kerr,[1] Jeremy Roth,[1] Kehao Zhu,[1] Allison Meisner,[1] Heather Thiessen Philbrook,[2] Francis Perry Wilson,[2] Steven G. Coca,[2] Chirag R. Parikh.[2] *[1]Biostatistics, Univ of Washington, Seattle, WA; [2]Yale Univ.*

Background: Although there is broad agreement that biomarkers should be evaluated with respect to their intended use, little has been written about how to evaluate a biomarker for prognostic enrichment of clinical trials.

Methods: For an intervention intended to reduce the occurrence of some unwanted clinical event, a prognostically enriched trial enrolls only patients at relatively higher risk of experiencing the event without the intervention. The rate of the unwanted event is higher in the "enriched" study population, which implies that a smaller sample size can be used in a clinical trial while maintaining adequate power to detect a treatment effect.

Results: We developed methods for evaluating biomarkers for prognostic enrichment of clinical trials. These methods are implemented in free software called BioPET (**Bio**marker **P**rognostic **E**nrichment **T**ool). A BioPET analysis evaluates a prognostic biomarker for its impact on clinical trial sample size, the total of trial patient costs and the costs of screening, and calendar time to enroll the trial. Depending on the performance of the biomarker and its cost to measure, the cost of a prognostic enrichment trial strategy can increase or decrease with the stringency of screening. Modestly performing biomarkers typically increase the calendar time to enroll a prognostically enriched trial, but high performing biomarkers will decrease the time. We demonstrate methods with examples in ESRD and ADPKD.



Conclusions: BioPET provides investigators with tools to assess biomarkers for prognostic enrichment. BioPET addresses several competing dimensions in trial design, including sample size, cost, time for enrollment, and ethical considerations. BioPET is available as a webtool and as a package for the R statistical platform, which has extended functionality.

TH-PO885

A Risk Scoring Model to Predict Progression of Renal Dysfunction in Patients with Chronic Kidney Disease Complicated with Contrast-Induced Nephropathy Seung Don Baek,[1] Mun Jang,[1] Wonhak Kim,[1] Eun Kyoung Lee,[2] Jai Won Chang.[1] *[1]Dept of Internal Medicine, Asan Medical Center, Seoul, Korea; [2]Dept of Internal Medicine, Dankook Univ College of Medicine, Cheonan-si, Korea.*

Background: The contrast-induced nephropathy (CIN) occurs more frequently in patients with lower estimated glomerular filtration rate (eGFR). Since CIN may be associated with the progression of chronic kidney disease (CKD), it would be important to predict the risk of irreversible renal damage prior to contrast-enhanced CT.

Methods: We retrospectively analyzed 18,278 enhanced CTs performed in 9,097 CKD patients with eGFR less than 60 mL/min/1.73 m^2 for at least 3 months, from January 2013 to December 2014. The progression of renal dysfunction was defined as reduction of eGFR >25%. We investigated 1-year renal outcomes in CKD patients complicated by CIN (increase ≥25% and/or ≥0.5 mg/dL in serum creatinine within 3 days after CT) and compared the outcomes between the progression and the non-progression groups. A risk score of 4, 5, 6, 7, or 7 was assigned to diabetes, baseline eGFR <45 mL/min/1.73 m^2, hypertension, repeated contrast exposure, and congestive heart failure, respectively.

Results: The overall occurrence of CIN was 5.8% (1,051/18,278) of all enhanced CTs performed, in 7.6% (689/9,097) of the total CKD patients. Among 689 patients, 465 were excluded due to follow-up loss or death. Among the remaining 224 patients, 70 (31.3%) patients had progression of renal dysfunction. The aggravation of azotemia compared with baseline serum creatinine level, was more severe in the progression group (1.84 ± 0.75 mg/dL *vs.* 2.46 ± 1.13 mg/dL, $p < 0.001$) than in the non-progression group (1.67 ± 0.60 *vs.* 1.69± 0.83, $p = 0.827$) at 1-month later after CIN. The risk scoring model demonstrated that the risk of progression of renal dysfunction increased with the sum of risk score in CKD patients complicated by CIN (*c* statistic = 0.735).

Conclusions: Although our risk scoring model needs to be validated in another population, our study suggested the possibility of predicting the risk of progression of renal dysfunction in CKD patients prior to contrast administration.

TH-PO886

Validation of a Systems Biology Derived Model to Predict Renal Disease Progression in Diabetes Mellitus Gert J. Mayer,[1] Hiddo Jan Lambers Heerspink,[2] Constantin Aschauer,[3] Judith Sunzenauer,[3] Georg Heinze,[4] Alexander Kainz,[3] Paul Perco,[5] Michelle Pena,[2] Peter Rossing,[6] Dick de Zeeuw,[2] Rainer Oberbauer.[3] *[1]Internal Medicine IV, Medical Univ Innsbruck, Innsbruck, Austria; [2]Dept of Clinical Pharmacy and Pharmacology, Univ Medical Center Groningen, Groningen, Netherlands; [3]Dept of Nephrology, Medical Univ of Vienna, Vienna, Austria; [4]Center for Medical Statistics, Informatics and Intelligent Systems (CeMSIIS), Section for Clinical Biometrics, Medical Univ of Vienna, Vienna, Austria; [5]Emergentec Biodevelopment, Vienna, Austria; [6]Steno Diabetes Center, Gentofte, Denmark.*

Background: Progression of renal function loss in diabetes mellitus (DKD) has a complex molecular pathophysiology. We aimed to identify a panel of biomarkers able to predict the individual eGFR decline using a systems biology derived model and validated the markers in a large sample of patients at various stages of DKD.

Methods: We used publicly available -omics data to develop a molecular process model of DKD and identified a representative parsimonious set of 9 biomarkers (CHI3L1, GH1, HGF, MMP2, MMP7, MMP8, MMP13, TIE2, TNFR1), which were measured in baseline plasma samples of 1765 patients recruited into two large clinical trials with baseline eGFRs of 87.2 (IQR 16.4) and 33.5 (9.5) ml/min/1.73m2 (DIRECT-2 and SUN Macro). The prediction of eGFR decline by biomarkers, clinical risk factors (including baseline eGFR and albuminuria) and both combined was evaluated by mixed linear regression models for longitudinal data.

Results: A combination of molecular and clinical predictors achieved an explained variability (R^2) of longitudinal eGFR values of 35 and 63% for patients with >60 and <60 ml/min/1.73m^2 respectively. The contribution to R^2 by molecular predictors was 15 and 34% for clinical predictors 20 and 29% respectively.

Conclusions: We conclude that a small set of plasma protein biomarkers identified by a systems biology approach enhances the prediction of renal function loss by standard clinical variables in patients with a wide range of baseline eGFR. Furthermore the biomarkers reflect a molecular model of DKD and thus might allow patient stratification based on pathophysiology providing an opportunity to apply targeted therapy.

TH-PO887

Prediction of Six Months Progression to End Stage Renal Disease Hao Han,[1] Yuedong Wang,[2] Sheetal Chaudhuri,[1] Terry L. Ketchersid,[1] Dugan Maddux,[1] Sophia Rosen,[1] John W. Larkin,[1] Peter Kotanko,[3,4] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Univ of California Santa Barbara, Santa Barbara, CA; [3]Renal Research Inst, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The progression of chronic kidney disease (CKD) to end stage renal disease (ESRD) is difficult to predict in routine management of patients (Pts). We aimed to understand the performance of four CKD progression predictive models using sensitivities and specificities.

Methods: We used data from 28,608 CKD Pts from 2000 to 2011 in the Fresenius Medical Care CKD Data Registry to construct two linear and spline models that utilize up to 6 months of historic estimated glomerular filtration rates (eGFRs) data, or logarithm of eGFRs (log-eGFRs), for prediction of CKD progression to ESRD. We excluded CKD stage 5 Pts and those with a kidney transplant. Prediction performance was assessed using alpha of 0.1 for sensitivities and specificities segregated by historical eGFR sample sizes (n) to identify adequate sample numbers for the models; groups are as follows: 5≤ n <10, 10≤ n <20, 20≤ n <30, 30≤ n <40, and n ≥40.

Results: The performance of the models is detailed in Figure 1. All models performed well for prediction with n <20 eGFR samples. For eGFR samples n ≥20, sensitivities and specificities were unreliable secondary to a limited Pts that progressed to ESRD.

Figure 1			sensitivities				specificities			
eGFR sample n	Pt number	Progressed to ESRD	Linear eGFR (95%CI)	Spline eGFR (95%CI)	Linear log-eGFR (95%CI)	Spline log-eGFR (95%CI)	Linear eGFR (95%CI)	Spline eGFR (95%CI)	Linear log-eGFR (95%CI)	Spline log-eGFR (95%CI)
5≤ n <10	3,254	73	0.897, (0.840 0.955)	0.832, (0.761,0.903)	0.877, (0.815,0.940)	0.755, (0.673,0.837)	0.683, (0.594,0.771)	0.704, (0.617,0.790)	0.788, (0.710,0.866)	0.785, (0.707,0.864)
10≤ n <20	1,309	42	0.857, (0.765,0.949)	0.804, (0.700,0.908)	0.732, (0.616,0.848)	0.786, (0.678,0.893)	0.759, (0.647,0.871)	0.733, (0.617,0.849)	0.843, (0.747,0.938)	0.830, (0.731,0.928)
20≤ n <30	192	8	0.545, (0.251,0.840)	.818, (0.590,1.00)	0.455, (0.160,0.749)	0.636, (0.352,0.921)	0.842, (0.626,1.00)	0.851, (0.641,1.00)	.911, (0.743,1.00)	0.901, (0.724,1.00)
30≤ n <40	45	2	0.667, (0.133,1.00)	0.667, (0.133,1.00)	0.667, (0.133,1.00)	0.667, (0.133,1.00)	0.615, (0.065,1.00)	0.654, (0.115,1.00)	.731, (0.229,1.00)	0.769, (0.292,1.00)
n ≥40	43	0	NA	NA	NA	NA	0.929, (0,1.00)	0.786, (0,1.00)	0.929, (0,1.00)	0.857, (0,1.00)

Conclusions: The four prediction models for determining six month risk for progression to ESRD were found to have good sensitivity and reasonable specificity. While our modeling efforts rely on historic eGFR values, other models, with similar c-statistics, use multiple factors to predict future eGFR.

TH-PO888

GDF-15 and Risk of Decline in Kidney Function in Patients with Chronic Kidney Disease Viji Nair,[1] Cassianne Robinson-Cohen,[2] Michelle R. Smith,[1] Keith A. Bellovich,[3] Zeenat Yousuf Bhat,[4] Maria Bobadilla,[5] Frank C. Brosius,[1] Ian H. De Boer,[2] Ivan Formentini,[5] Crystal A. Gadegbeku,[6] Debbie S. Gipson,[1] Jennifer Joyce Hawkins,[1] Jonathan Himmelfarb,[2] Bryan R. Kestenbaum,[2] Matthias Kretzler,[1] Maria Chiara Magnone,[5] Susan P. Steigerwalt,[1] Wenjun Ju,[1] Nisha Bansal.[2] *[1]UM; [2]UW; [3]St. John; [4]Wayne; [5]Roche Pharmaceutical; [6]TU.*

Background: Growth differentiation factor-15(GDF-15)is a novel biomarker of cardiac inflammation and remodeling.The association with progression of kidney disease is less certain and may identify a novel risk factor for loss of kidney function.In two prospective cohort studies of chronic kidney disease ,C-PROBE and SKS,we tested the association of circulating levels of GDF-15 with rapid decline in kidney function, and correlation with kidney tissue expression of GDF-15 mRNA.

Methods: We investigated the association of serum GDF-15 level with progression to a composite endpoint(ESRD or 30% reduction from baseline eGFR)using Cox models and continuous eGFR decline using GEE model in the C-PROBE (n=224) and SKS (n=297). We examined the correlation of intrarenal expression of *GDF-15* mRNA with the serum GDF-15 levels in matching samples (n=24,C-PROBE).

Results: 32% participants progressed to kidney disease,median F/U: 3.5yrs (C-PROBE)/4yrs(SKS).Higher GDF-15 concentration significantly associated with a greater risk of progression of kidney disease.Similarly, every doubling of GDF-15 associated with a 5.8%/year and 3.0%/year rapid decline in eGFR in C-Probe and SKS respectively (p<=0.01).

Figure1: Association of GDF-15 with progression to ESRD or loss of30% of eGFR

C-PROBE			SKS Study		
GDF-15 (pg/mL)	Events[$]	HR (95% CI)	GDF-15 (pg/mL)	Events[$]	HR (95% CI)
437 – 1307	08 (2.6)	1.0 (ref)	403 – 1636	15 (6.5)	1.0 (ref)
1307 –1938	13 (4.5)	2.24(0.90, 5.59)	1636 – 2338	17 (7.4)	0.76 (0.35,1.64)
1938 –2891	20 (7.2)	2.13(0.87, 5.18)	2338 – 3508	30 (13.5)	1.48 (0.68,3.21)
2891 – 8444	31 (11.1)	3.25(1.26, 8.36)*	3508 – 9549	33 (18.3)	2.56 (1.15,5.72)*

[$]Incidence Rate, per 100 person – years
Adjusted :CVD, diabetes, SBP, & anti-hypertensive medication. *pvalue <0.02

Circulating GDF-15 concentrations significantly correlated (p=<0.01) with intrarenal GDF15mRNA(r=0.54) and baseline eGFR(r=-0.57).

Conclusions: Elevated GDF-15 was associated with increased risk of rapid decline of eGFR in two independent CKD cohorts.There was a strong correlation of circulating GDF-15 with intrarenal tubulointerstitial *GDF15* mRNA.These data suggest that GDF-15 may be a novel mechanistic biomarker of CKD progression.

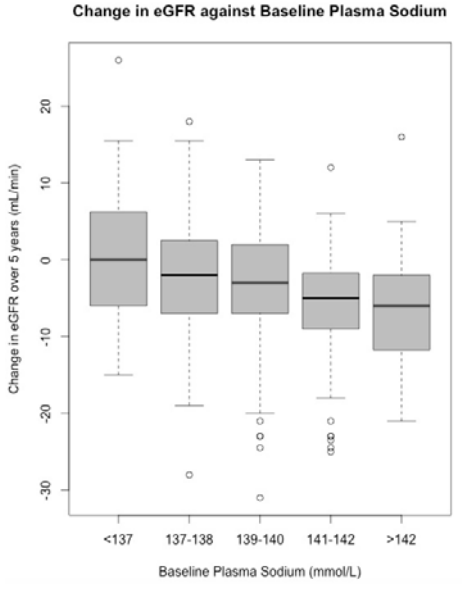
TH-PO889

Relationship between Plasma Sodium Concentration and Chronic Kidney Disease Progression Nicholas I. Cole,[1] Rebecca Suckling,[1] Feng J. He,[2] Pinnaduwage Vipula De Silva,[1] Pauline A. Swift.[1] *[1]South West Thames Renal Unit, St. Helier Hospital, London, United Kingdom; [2]Wolfson Inst of Preventative Medicine, Queen Mary Univ of London, London, United Kingdom.*

Background: Observational and experimental studies have demonstrated that small increases in plasma sodium concentration (PNa) are associated with increased blood pressure and changes to endothelial function. Increases in PNa may therefore contribute to the adverse renal and cardiovascular outcomes observed in those with chronic kidney disease (CKD).

Methods: This was a retrospective study of data collected between January 2009 and December 2014. We included patients known to our renal service with a minimum of three blood tests taken every two years and an estimated glomerular filtration rate (eGFR) of <60 mL/min at baseline. Exclusion criteria were renal replacement therapy, diabetes mellitus, heart failure, decompensated liver disease, and significant fluctuations in renal function.

Results: 7,063 blood results from 309 patients were included in the study. The mean PNa at baseline was 139.7 mmol/L (SD 2.0). We found no relationship between baseline PNa and eGFR, and no significant change in PNa occurred over time in those with progressive CKD. However, there was a significant correlation between baseline PNa and the change in eGFR over time (r = -0.2, P <0.001). After adjustment for age, gender, ethnicity, CKD stage and diagnosis, a 1 mmol increase in baseline PNa was associated with a 0.70 mL/min decrease in eGFR over 5 years (P < 0.001, 95% CI 0.29-1.12).



Conclusions: This study is the first to identify an association between PNa and the progression of CKD. Small increases in PNa, within the normal physiological range, were associated with a greater rate of eGFR decline during the study period. The cause of this association is uncertain but increased PNa may be associated with higher blood pressure, problems with salt and water regulation, and endothelial dysfunction.

TH-PO890

Serum Osmolarity Is an Independent Risk Factor for Chronic Kidney Disease; 5 Year Cohort Study in Japan Masanari Kuwabara,[1,2,3] Miguel A. Lanaspa,[1] Carlos Alberto Roncal-Jimenez,[1] Ana Andres-Hernando,[1] Tamara Milagres,[1] Thomas Jensen,[1] Richard J. Johnson.[1] *[1]Div of Renal Diseases and Hypertension, Univ of Colorado Denver, Aurora, CO; [2]Dept of Cardiology, Toranomon Hospital, Tokyo, Japan; [3]St. Luke's International Hospital, Tokyo, Japan.*

Background: Epidemics of chronic kidney disease (CKD) not due to diabetes or hypertension have been observed among individuals working in hot environments in several areas of the world. Experimental models have confirmed that recurrent heat stress and water restriction can lead to CKD, and the mechanism may be mediated by hyperosmolarity that activates pathways (vasopressin, aldose reductase-fructokinase) that can induce renal injury. Here we tested the hypothesis that elevated serum osmolarity may be an independent risk factor for the development of CKD.

Methods: This study was a large-scale, single-center, retrospective 5-year cohort study at St. Luke's International Hospital Center for Preventive Medicine, Tokyo, Japan, between 2004 and 2009. We analyzed 13,201 subjects who underwent annual medical examination at the hospital. Of those, 12,041 subjects were enrolled who were between 30 years and 85 years old in 2004 without diabetes mellitus and/or CKD. This analysis evaluated age, gender, body mass index, abdominal circumference, hypertension, dyslipidemia, hyperuricemia, and calculated serum osmolarity.

Results: After adjusted regression analysis, the risk factors for developing CKD were as follows: age [Odds Ratio (OR): 1.07 per 1 year increased, 95% confidence interval (CI): 1.06-1.08], body mass index (OR: 1.12 per 1 kg/m^2 increased, 95% CI: 1.08-1.16), abdominal circumference (OR: 0.96 per 1cm increased, 95% CI: 0.95-0.98), hyperuricemia (OR: 1.68, 95% CI: 1.44-1.95), and serum osmolarity (OR: 1.04 per 1 mOsm/L increased, 95% CI: 1.03-1.05). Compared with the lowest serum osmolarity quartile, the highest quartile had a higher adjusted OR for new onset CKD, being 1.52 fold (95% CI: 1.23-1.88) in men and 1.34 fold (95% CI: 1.04-1.72) in women.

Conclusions: Elevated serum osmolarity is a strong independent risk factor for development of CKD. This result indicates the importance of limitation of high salt diet and prevention of dehydration to prevent CKD.

Anion Gap Associated with Risk of Progression to ESRD in Adults with Moderate CKD Tanushree Banerjee,[1] Deidra C. Crews,[2] Sharon Saydah,[4] Nilka Rios Burrows,[4] Brenda W. Gillespie,[3] Rajiv Saran,[3] Neil R. Powe.[1] *[1]Medicine, Univ of California, San Francisco; [2]Medicine, Johns Hopkins Univ; [3]Medicine, Univ of Michigan, Ann Arbor; [4]Centers for Disease Control and Prevention.*

Background: Anions that accumulate during the course of CKD, including unmeasured anions (e.g. p-cresol sulfate and indoxyl sulfate), may accelerate the progression of CKD. Whether undetermined anions, as indicated by the anion gap, are associated with risk of progression to ESRD in adults with moderate CKD has not been elucidated.

Methods: We analyzed data from 1,286 adults with moderate CKD (eGFR 30-59 ml/min/1.73 m^2) enrolled in National Health and Nutrition Examination Survey III (1988-1994). Anion gap was determined from laboratory tests (serum Na-(serum Cl +serum bicarbonate). The development of ESRD was ascertained over a median of 10.4 years of follow-up via linkage with USRDS. We used a proportional hazards regression model to test the association between anion gap and risk of ESRD after adjusting for demographics (age, gender, race/ethnicity), clinical factors (diabetes and hypertension), eGFR, and albuminuria.

Results: The mean baseline anion gap was 9.5 mEq/L. A significant elevation in the tertiles of anion gap was found with eGFR 45-59 ml/min/1.73 m^2 compared to eGFR 30-44 ml/min/1.73 m^2. Demographics and clinical factors of diabetes and hypertension did not differ by anion gap tertile (p>0.05). During the follow-up period, 16.7% developed ESRD. Compared to the lowest, the highest tertile of anion gap was associated with an increased risk of ESRD when adjusted for demographics, clinical factors, eGFR, and albuminuria (Relative hazard [95% CI]: 1.81 [1.01-3.08]). There was no significant risk of ESRD noted comparing the middle to the lowest tertile of anion gap (RH [95% CI]: 1.10 [0.52-2.04]).

Conclusions: In a nationally representative sample of adults with CKD, we observed that anion gap was independently associated with risk of ESRD. These data highlight the anion gap as a potential therapeutic target for slowing CKD progression.

TH-PO892

Association between Water Intake and Kidney Function: The Korea National Health and Nutrition Examination Survey Mina Yu. *Nephrology, Seoul Seonam Hospital, Seoul, Republic of Korea.*

Background: The effect of plain water intake on kidney function is not yet clear. Chronically low fluid intake may induced vasopressin up-regularion and increased GFR via tubuloglomerular feedback and hyperfiltration. However, some data reported that water intake may prevent GFR decline.

Methods: The population-based, cross-sectional study analyzed, total 37,753 participants from the Korea National Health and Nutrition Examination Survey conducted in 2008-2011. the water intake (cup=200 m/dayl) was estimated by asking the question " how much water do you usually cosume per day?". Dietary water intake (g/day) was estimated by 24hr dietary recall.The 24-hr urinary sodium values were estimated from sodium and creatinine values of random urine samples using Tanaka's equation. CKD was defined 4 groups as an GFR (GFR<30, 30=<GFR<60, 60=<GFR<90, GFR>=90). Data was splitted into ages by 10 years.

Results: Of 26,955 adults (range 19-96yrs), CKD defined (GFR<30: 56[0.2%],30<GFR<60:829[2.1%],60<GFR<90:8824[26.7%]. As ages urine specific gravity was significantly reduced (1.022 vs.1.202 vs. 1.019 vs.1.018 vs.1.017 vs. 1.016, 19 =<Age<30/30-39/40-49/50-59/60-69/70-96 (p<0.05)). The estimated amount of sodium excretion (mmol/d) increased to 60s decreased from 70s (18,426 vs. 19,317 vs. 19984 vs. 20847 vs. 21294 vs. 20476 (p<0.05)), showed a similar pattern is also sodium intake (g/d) estimated from food (4.876 vs. 5.414 vs. 5.513 vs. 5.197 vs, 4.547 vs. 3.603(p<0.05)). Fair water intake (cups/day) and total water intake from diet (g/day) were not differ between ages, In each ages group, average water consumption (cups/da) was decreased with decreased GFR, at 60s and 70s, low water intake is associated with low GFR group significantly. (60s; water intake 7.61vs. 5.57vs. 5.05 vs.5.53, 70s; 11.7 vs. 6.5vs. 4.2 vs.4.2 in GFR>90/60<GFR<90/30<GF=<60/GFR<30).

Conclusions: This result suggest that water intake associated with CKD significantly in elderly people.

TH-PO893

Effect of Homocysteine on Intestinal Permeability in Rats with Adenine-Induced Experimental Uremia Shanshan Liang, Hongli Jiang. *Dialysis Dept of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong Univ.*

Background: Previous studies have revealed increased levels of plasma and intestinal homocysteine(Hcy) in Chronic Kidney Disease (CKD). However, whether Hcy is involved in increased intestinal permeability and barrier dysfunction of CKD remains unclear. This study aimed to investigate the effect of Hcy on intestinal in rats with adenine-induced uremia and elucidate its possible mechanism.

Methods: SD rats were divided into four groups:normal, Hcy, adenine, adenine +Hcy. Experimental uremia was induced by adenine and Hcy were injected subcutaneously. The serum creatinine, urea nitrogen as well as the renal pathological tissue staining were tested to assess the model. The serum C-reactive protein, IL-6 and TNF-α, Hcy, endotoxin, intestinal epithelial permeability and intestinal tissues Hcy, SOD and MDA levels were assessed. The fibrosis releated protein of MMP-9,α-SMA and TGF-β were assessed by Western blot.

Results: The serum biochemical parameters and renal pathological show a success of animal model (Fig1). the serum inflammatory factors, endotoxin, Hcy ,endotoxin and intestinal permeability were shown in Figure 2, and intestinal tissue levels of Hcy ,SOD and MDA in Figure 3.The change of MMP-9,α-SMA and TGF-β protein abundance were shown in Figure 4.Compared with normal and adenine group, the serum inflammatory factors, endotoxin, Hcy and intestinal permeability, and intestinal tissue levels of Hcy and MDA were significantly higher, with the SOD activity markedly decreased in adenine+Hcy group. In adenine group and adenine+Hcy group , the protein expression were significantly increased than normal group.

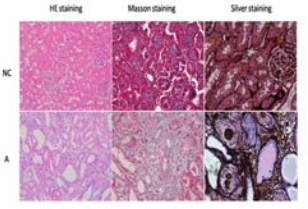

Figure 1 Renal pathological changes of group NC and group A by HE, Masson and Silver staining. (× 200)

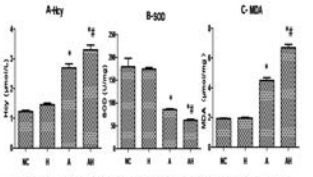

Figure 3 Levels of Hcy, SOD and MDA of each group. *P < 0.05 compared with group NC; #P < 0.05 compared with group A.

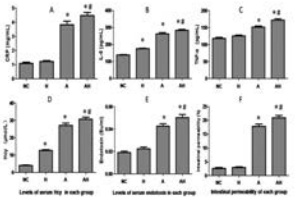

Figure 2 Levels of inflammatory biomarkers (IL- 6, CRP, and TNF-α), Hcy ,endotoxin, and intestinal permeability of each group. *P < 0.05 compared with group NC; #P < 0.05 compared with group A.

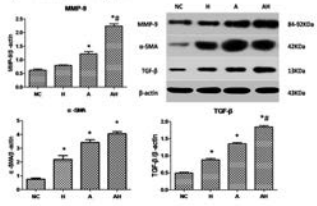

Figure 6 Relative protein expression levels of MMP-9, α-SMA and TGF-β in colonic tissue of each group, and were normalized to β-actin. * p < 0.05 vs. the NC group; # p < 0.05 vs. group A.

Conclusions: Hcy can increase intestinal permeability and aggravate inflammatory damage in adenine-induced uremia rats.The underlying mechanisms of which may be attributed to its effects of promoting the expression of fibrosis related factors.

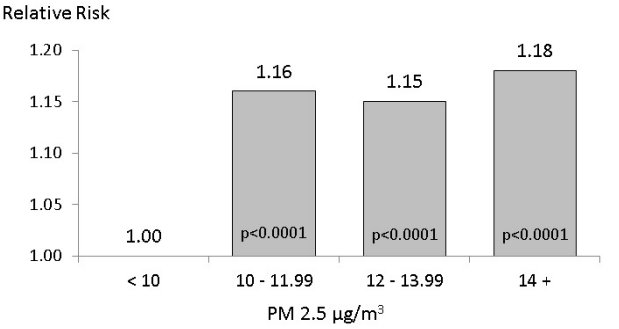
TH-PO894

County-Level Air Quality and the Incidence of ESRD in the U.S. Population Jennifer L. Bragg-Gresham, Patrick Albertus, Hal Morgenstern, Robert D. Brook, Peter X.K. Song, Rajiv Saran. *Univ of Michigan, Ann Arbor, MI.*

Background: Considerable geographic variation exists in the incidence of ESRD across the U.S. Higher rates have been noted along the Ohio and Mississippi river valleys and in more industrialized parts of the country. We explore the association between air quality and ESRD incidence by county in the US.

Methods: Using data on all incident cases of ESRD from the USRDS data base (2012-2014: n=338,042), the US Census (2013), and 2006 EPA air-quality data, we examined the association between a county-level measure of air pollution—particulate matter ≤2.5 μm (PM2.5), which includes toxic particulates, such as heavy metals—and the incidence of ESRD, for all U.S. counties with complete data (n=3,053). Poisson regression was used to estimate the relative risk of new cases of ESRD (per county population) by county PM2.5 level, adjusting for potential country-level confounders—mean age, proportion male, and proportion Black, Asian, and Native American.

Results: The crude incidence rate of ESRD ranged from 0 to 2,341 new cases per 1,000,000 population among counties (median =335) in the full sample and 69 to 1,581 (median=367) in a sample of counties with at least 10 new cases, after adjusting for age, sex, and race of the county. Treating PM2.5 level a continuous variable, the adjusted RR for an increase of 4 μg/m^3 was 1.10 (95% CI = 1.09-1.11; $p < 0.0001$). The results when categorizing PM2.5 by quartiles suggest a possible detrimental threshold effect at PM2.5 level of 10 μg/m^3, which is below the current EPA guideline of 12 μg/m^3.



Conclusions: We found that poorer air quality was associated with higher incidence rate of ESRD. However, the ecological design and lack of individual exposure data precludes causal inference. Future investigations should include measures of multiple air pollutants and individual exposure, as well as more extensive control of confounding.

APOL1, Sickle Cell Trait (SCT), and Risk of Chronic Kidney Disease (CKD) in the Jackson Heart Study (JHS) Bessie A. Young,[1,2,3] Alex Reiner,[3] L. Ebony Boulware,[4] Neil R. Powe,[5] Bryan R. Kestenbaum,[2,3] Nora Franceschini,[7] Nisha Bansal,[2] Adolfo Correa,[6] Jonathan Himmelfarb,[2] Ronit Katz.[2] *[1]Hospital and Specialty Care, VA Puget Sound Health Care System, Seattle, WA; [2]Kidney Research Inst and Div of Nephrology, UW, Seattle, WA; [3]Epidemiology, UW, Seattle, WA; [4]Medicine, Duke, Surham, NC; [5]Medicine, UCSF, San Francisco, CA; [6]Medicine, UMC, Jackson, MS; [7]Epidemiology, UNC, Chapel Hill, NC.*

Background: *APOL1* high-risk variants and SCT have been shown to be associated with increased risk of CKD among African Americans (AA). Little is known regarding risk of development of CKD/ESRD among AA with one risk variant compared to none; or whether there is an association with SCT. We determined the association between *APOL1* risk variants, SCT, and development of CKD among AA. of JHS.

Methods: JHS is a prospective cohort study of 5306 AA. Participants were enrolled at baseline (2000-2004), and followed at exam 2 (2005-2008) and 3 (2009-2012). The primary outcomes of interest were incident CKD (eGFR <60ml/min/m^2), incident albuminuria (albumin to creatinine ratio (ACR) ≥ 30mg/g), incident ESRD or rapid kidney function decline (defined as ≥30% decline). Multivariable models (Cox, logistic, and linear) were adjusted for age, sex, diabetes (DM), hypertension (HTN), SCT, and ancestry informative markers.

Results: Baseline creatinine and genetic information on *APOL1* variants and/or SCT were available for 2300 AA. Of those, 41.3% had zero, 52.0% had one, and 6.7% had two *APOL1* variants; SCT was found in 8.5% (199/2299). Subjects with one (HR=1.41, 95% CI 1.00-1.99) and two (HR=1.97, 1.12-3.47) *APOL1* risk alleles had increased risk of incident ACR that remain significant after adjustment, while incident ESRD was significant for only those with two alleles (aOR 11.89, CI 2.10-67.45). Continuous decline in eGFR and rapid decline in eGFR>30% were significant for those with two but not one alleles.

Conclusions: Among AA, the presence of one or two *APOL1* risk alleles was associated with increased risk of incident ACR in a graded fashion. Those with two alleles also had increased risk of incident ESRD, continuous decline, and rapid decline of eGFR independent of DM, HTN or SCT.

TH-PO896

Insulin Requirement Is a Risk Factor for End-Stage Renal Disease (ESRD) Independent of Hemoglobin (Hb) A1C Levels in Type 2 Diabetes Mellitus (T2DM) Rabia Nadeem Kiani,[1] R. E. Boucher,[1] Guo Wei,[1] Debra Lynn Simmons,[1] Linda F. Fried,[2] T. S. Bjordahl,[1] Tom Greene,[1] Srini Beddhu.[1] *[1]Univ of Utah, SLC, UT; [2]VA, Pittsburgh.*

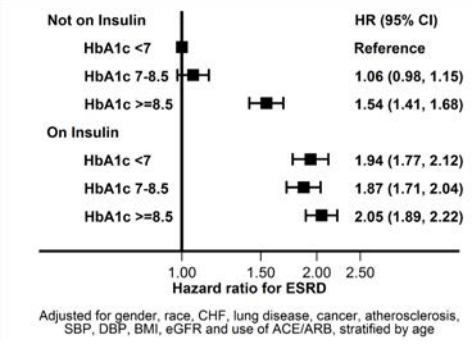
Background: As the need for insulin might be a reflection of insulin resistance, we hypothesized that independent of HbA1c levels, insulin use might be a risk factor for ESRD in T2DM.

Methods: In a cohort of 1,561,876 veterans with serum creatinine and serum HDL-cholesterol measured within 3 months of each other from Jan 1, 2000 to Dec 31, 2008, we analyzed 188,544 veterans with T2DM (defined by ICD9 codes). Data on filled medications were obtained from outpatient pharmacy database. Laboratory data were obtained from routine clinical labs. Follow-up was until 10/1/2011. ESRD data were obtained by linking to USRDS. Based on HbA1C levels and the use of insulin, 6 groups were defined. Using the HbA1c< 7 and no insulin as the reference group, the risk of ESRD in the other groups were examined in Cox regression models.

Results:

	Without insulin			With insulin		
HbA1c%	<7 N=81470	7-8.5 N=42782	>8.5 N=26184	<7 N=9292	7-8.5 N=12933	>8.5 N=15883
Age (yr)	67±11	66±11	61±11	66±11	66±10	60±11
Male(%)	97	98	97	98	98	97
AA(%)	15	16	24	19	18	28
SBP(mmHg)	140±21	142±21	142±21	141±22	141±22	141±22
DBP(mmHg)	75±12	77±12	80±12	73±13	74±13	78±13
Atherosclerosis(%)	40	40	30	48	49	40
CHF(%)	8.2	7.8	6.0	14.9	15.0	12.2
BMI(kg/m^2)	30.7±5.9	31.3±6.0	31.6±6.2	31.6±6.6	31.9±6.5	31.7±6.7
ACEI/ARB(%)	63.3	67.5	64.4	72.8	76.2	73.8
eGFR(ml/min/1.73m^2)	72±21	73±21	82±21	66±26	68±24	76±25

There were 5757 ESRD events over 1,463,762 years of follow-up.



Conclusions: A limitation is the lack of data on duration of T2DM. However, even in those with HbA1C < 7, need for insulin was associated with increased ESRD risk. Interventions that ↓ the need for insulin might ↓ the risk of ESRD in T2DM.

TH-PO897

Deoxycholate, a Gut-Microbiome Derived Bile Acid Is Elevated in Patients with Diabetic Kidney Disease Adil Jadoon, Anna V. Mathew, Jaeman Byun, Farsad Afshinnia, Subramaniam Pennathur. *Div of Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: Diabetic Kidney Disease (DKD) is the most common cause of end stage renal disease in the United States but underlying mechanisms of DKD initiation and progression remain unclear. Bile acids are a diverse group of aliphatic compounds which modulate gene transcription and may play a critical role DKD as evidenced by recent murine studies. In this study, we sought to explore the association of plasma bile acid profiles in patients with DKD compared to those with non-diabetic kidney disease to identify potential mechanisms and markers of DKD development and progression.

Methods: Our study population consisted of 34 DKD and 34 subjects with non-diabetic CKD. Bile acids were extracted from fasting plasma from the study subjects and subjected to highly sensitive and specific liquid chromatography/mass spectrometry (LC/MS) to measure 25 primary and secondary bile acids .We then explored the differences in the bile acid profiles between the two study groups using logistic regression modeling in SPSS.

Results: Bile acid profiles were compared by t-test followed by multivariable logistic regression. Most bile acid levels were significantly higher in DKD subjects ($p<0.0001$). Multivariable logistic regression revealed deoxycholate to be the top differentially regulated compound that independently differentiated the two clinical groups after correction of confounding variables.

Conclusions: Deoxycholate is an unconjugated bile acid derived from metabolism of bile acids by the gut microbiota and thus not under the control of the biosynthetic machinery of the host. Our data concludes that bile acid levels in subjects with chronic kidney disease are much higher among those with DKD and Deoxycholate can precisely identify those with CKD due to diabetic nephropathy. This data also suggests a potential role for gut microbiota and altered bile acid metabolism in DKD which needs to be further evaluated in future mechanistic studies.

TH-PO898

Guanidinylations of Albumin Decreased Binding Capacity of Hydrophobic Metabolites Vera Jankowski, Joachim Jankowski. *Inst for Molecular Cardiovascular Research, Univ Hospital RWTH Aachen, Aachen, Germany.*

Background: Since post-translational modifications of proteins may have an impact on the pathogenesis of diseases like atherosclerosis, diabetes mellitus and chronic kidney disease (CKD), post-translational modifications are currently gaining increasing interest. In this study, a comprehensive method for analysis of these post-translational modifications is established for the clinical diagnostic routine.

Methods: Here, we analysed albumin –the most abundant plasma protein in human– isolated from CKD patients and healthy controls by chromatographic steps and identified by MALDI mass-spectrometry.

Results: Albumin isolated from plasma of CKD patients but not from healthy control subjects was specifically post-translationally modified by guanidylation of lysines. After identification of guanidylations as post-translational modifications of albumin isolated from CKD patients, these modifications were quantified by mass-spectrometry demonstrating a significant increase in the corresponding mass-signal intensities in CKD patients compared to healthy controls. The relative amount of guanidylation in CKD patients was determined as 63 ± 32 %. Subsequently, we characterized the pathophysiological impact of the post-translational guanidylation on the binding capacity of albumin for representative hydrophobic metabolic waste products. *In-vitro* guanidylation of albumin from healthy control subjects caused a decreased binding capacity of albumin in a time-dependent manner. Binding of indoxyl sulfate (protein bound fraction) decreased from 82 ± 1 % of non post-translationally modified albumin to 56 ± 1 % after *in-vitro* guanidylation ($p < 0.01$). Thus, *in-vitro* post-translational guanidylation of albumin had a direct effect on the binding capacity of hydrophobic metabolites like indoxyl sulfate and tryptophan.

Conclusions: We used a mass spectrometry-based method for the characterisation of post-translational modification and demonstrated the pathophysiological impact of a representative post-translational modification of plasma albumin. The data described in this study may help to elucidate the pathophysiological role of protein modifications.

TH-PO899

Reported Randomized Controlled Trial Results in Nephrology Are Fragile: An Analysis Using the Fragility Index Lani Shochet, Peter G. Kerr, Kevan Polkinghorne. *Dept of Nephrology, Monash Health, Clayton, Victoria, Australia.*

Background: The Fragility Index (FI) is a tool for testing the robustness of randomized controlled trial (RCT) results for dichotomous outcomes. It describes the minimum number of patients in whom changing an event status would alter a statistically significant result to a non-significant result.

Methods: A systematic literature search identifying all RCT in 5 nephrology (JASN, cJASN, AJKD, NDT and KI) and 5 general journals (NEJM, Lancet, BMJ, JAMA and Annals of Internal Medicine) from 2005-2014 was performed. RCT reporting at least one dichotomous positive outcome ($p<0.05$) were eligible for inclusion. FI was calculated using the Fischer exact test. FI, total event number and sample size were log transformed. Multiple linear regression were performed to assess factors independently associated with FI.

Results: 129 RCT were included (111 nephrology, 18 general). Six studies had a FI of zero and were excluded from further analysis. Of the remaining 123 studies, median sample size was 132 (range 22-11506) with 18 (range 0-1243) events in the intervention group. Median FI was 3 (range 1-166) indicating that in half of the studies the addition of 3 events to one of the treatment arms rendered the result non-significant. A doubling in total event number and sample size independently increased median FI by 30% and 16% respectively ($p<0.001$ and $p=0.009$). Compared to a reported p-value of >0.01-<0.05, those reporting 0.01-0.001 and <0.001 had a 74% ($p<0.001$) and 497% ($p<0.001$) increase in the median FI. After adjusting for event number, sample size and p-value, the median FI was 58% lower in general medical journals compared to renal journals ($p=0.007$). Finally, of the studies reporting loss to follow-up (n=106), 41% had a FI < total loss to follow-up indicating potential to change a trial result had all subjects been accounted for in the study.

Conclusions: Reported nephrology RCT results are fragile, with half of the studies' results susceptible to changes in small numbers of events. This study highlights the need for larger RCT with accurate accounting for loss to follow-up to adequately guide evidence-based practice.

TH-PO900

Scope and Consistency of Outcomes Reported in Randomized Trials Conducted in Children with Chronic Kidney Disease Camilla Sara Hanson,[1,2] Lauren Chong,[1,2] Benedicte Sautenet,[1,2] Allison Tong,[1,2] Jonathan C. Craig.[1,2] *[1]School of Public Health, The Univ of Sydney; [2]Centre for Kidney Research, The Children's Hospital at Westmead.*

Background: Randomized controlled trials (RCTs) have been conducted to improve outcomes in children with chronic kidney disease (CKD), but the outcomes reported may not be relevant to children, families or clinicians, and variability in outcome domains and measures make it impossible to assess the comparative effectiveness of interventions. We assessed the scope and consistency of outcomes reported in RCTs of interventions for children in any stage of CKD.

Methods: The Cochrane Renal Register of Controlled Trials was searched for all RCTs in children across all stages of CKD published before March 2016. The frequency of reporting of each outcome domain, and the measurement characteristics were evaluated.

Results: From the 205 trials, 99 different outcome domains were reported including 37 and 44 domains specific to transplantation and dialysis, respectively. Across all outcome domains, 50 (51%) were surrogate, 40 (40%) were clinical, and 9 (9%) were patient-reported. The median number of domains per trial was 15 (IQR 9-26). The five most commonly reported domains were: blood pressure (75 [37%] trials), medication use/duration (73 [36%] trials), relapse/remission (72 [35%]), kidney function (66 [32.2%]) and infection (61 [30%]). Mortality was reported in 28 (14%) trials. Cardiovascular disease and quality of life were reported very infrequently, in 8 (4%) and 2 (1%) trials, respectively. There was inconsistency of measures and time points used across all trials. Across the 99 domains, 1671 different measurements were reported. For blood pressure and medication use/duration, 76 and 54 measures were used across trials, respectively.

Conclusions: The outcomes reported in RCTs involving children with CKD primarily report surrogate outcomes, rather than clinical and patient-centered outcomes such as mortality, cardiovascular disease, quality of life and cognition. The multiplicity and heterogeneity of outcomes at all levels – domain, measurement, threshold, and time points - deters efforts to compare the effectiveness of interventions and use trial evidence in decision-making.

TH-PO901

Effects of Ferric Citrate (FC) in Adults with Non-Dialysis-Dependent Chronic Kidney Disease and Iron-Deficiency Anemia (IDA): Ph 3 Clinical Trial

Steven Fishbane,[1] Geoffrey A. Block,[4] Pablo E. Pergola,[5] Lisa Loram,[3] John F. Neylan,[3] Katrin Uhlig,[3] Glenn Matthew Chertow.[2] *[1]Hofstra Northwell Health, Great Neck, NY; [2]Stanford Univ, Palo Alto, CA; [3]Keryx Biopharmaceuticals, Boston, MA; [4]Denver Nephrologists PC, Denver, CO; [5]Renal Associates PA, San Antonio, TX.*

Background: Iron deficiency anemia is common and consequential in non-dialysis-dependent chronic kidney disease (NDD-CKD). Efficacy and tolerability of conventional oral iron supplements are mixed; intravenous (IV) iron administration is associated with finite but important risks.

Methods: 234 patients were randomized 1:1 to FC and Placebo (P) in a double blind clinical trial comparing the safety and efficacy in patients with NDD-CKD stages 3-5 and IDA. The starting dose of 3 tablets/day was increased every 4 weeks if hemoglobin (Hgb) was not >1g/dL above baseline. IV or oral iron, erythropoeisis stimulating agents, blood transfusions and other phosphate binders were not permitted during the trial. The primary endpoint was the proportion of patients who achieved ≥1.0 g/dL increase in Hgb at any time during a 16-week randomized period. Patients who completed the 16-week period were asked to participate in an 8-week open label extension period.

Results: Patients randomized to FC were significantly more likely to achieve the primary endpoint [52.1% (61/117) *vs* 19.1% (22/115), p<0.001]. All secondary endpoints also reached statistical significance, including the mean relative change in Hgb (0.84 g/dL, 95% confidence interval 0.58 to 1.10 g/dL, p<0.001) and the proportion of patients who achieved a sustained increase in Hgb [≥0.75 g/dL over any 4-week time period during the randomized trial period] [48.7% (57/117) *versus* 14.8% (17/115), p<0.001). Gastrointestinal disorders were the most commonly observed adverse events, with diarrhea reported in 24 (20.5%) and 19 (16.4%), nausea in 13 (11.1%) and 3 (2.6%) and constipation in 22 (18.8%) and 15 (12.9%) patients treated with FC and P, respectively. The rate of serious AEs was similar across groups (12 FC vs 11.2 % P) and no SAEs or deaths were related to study drug.

Conclusions: The study demonstrated that in patients with NDD-CKD, FC is well tolerated and may be an efficacious treatment for IDA.

TH-PO902

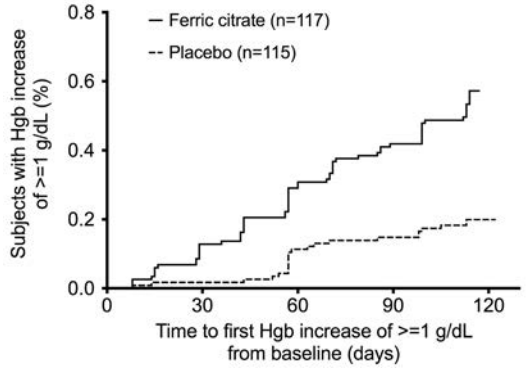
Hemoglobin Response to Ferric Citrate (FC) in Subjects with Non-Dialysis Dependent (NDD) Chronic Kidney Disease (CKD) and Iron Deficiency Anemia (IDA): Data from a Phase 3 Clinical Trial

Glenn Matthew Chertow,[1] Steven Fishbane,[2] Pablo E. Pergola,[3] Katrin Uhlig,[4] John F. Neylan,[4] Geoffrey A. Block.[5] *[1]Stanford Univ, Palo Alto, CA; [2]Hofstra Northwell Health, Great Neck, NY; [3]Renal Associates, San Antonio, TX; [4]Keryx Biopharmaceuticals, Boston, MA; [5]Denver Nephrologists, Denver, CO.*

Background: The hemoglobin (Hgb) response to Ferric Citrate (FC) in a Phase 3 clinical trial in subjects with NDD-CKD and IDA was further explored.

Methods: 234 subjects were randomized 1:1 to FC and placebo (P) in a 16 week Randomized treatment period. The dose of FC or placebo was started at 3 tablets/day and up-titrated if Hgb had not risen by >1 g/dL provided that the subject's increase in Hgb from baseline is ≤1.0 g/dL at any titration time point. The rate and durability of Hgb response and the effect of baseline Hgb is evaluated here.

Results: We have reported elsewhere a significant increase in Hgb from baseline to the end of 16 wk for FC compared to P (p<0.001) and that 52.1% of FC achieved ≥ 1 g/dL rise in Hgb (primary end point of the trial) compared to 19.1% in P (p<0.001). Time to first ≥1 g/dL rise in Hgb is shown in the Figure.



In the last 4 weeks of the trial, 33.3% of those on FC vs 6.1% on P achieved ≥0.75 g/dL increase from baseline in Hgb (p<0.001) suggesting that the increase in hemoglobin is durable. A logistic analysis to determine whether baseline hemoglobin (≤ 10.5 vs >10.5 g/dL) predicted the response of Hgb showed that the response to FC treatment was independent of baseline Hgb (p=0.768). Treatment failure was characterized as Hgb <9.0 g/dL for 2 visits in a row at least 7 days apart and occurred in less subjects in the FC group (4.3%) versus (8.7%) in the P group.

Conclusions: In patients with NDD-CKD and IDA, FC increased and maintained hemoglobin levels independent of baseline Hgb.

Funding: Pharmaceutical Company Support - Keryx Biopharmaceuticals

TH-PO903

Effects of Ferric Citrate on Parameters of Mineral and Bone Metabolism in Patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) Treated for Iron Deficiency Anemia (IDA)

Geoffrey A. Block,[1] Steven Fishbane,[2] Pablo E. Pergola,[3] Katrin Uhlig,[4] John F. Neylan,[4] Glenn Matthew Chertow.[5] *[1]Denver Nephrology, Denver, CO; [2]Hofstra Northwell Health, Great Neck, NY; [3]Renal Associates, San Antonio, TX; [4]Keryx Biopharmaceuticals, Boston, MA; [5]Stanford Univ, Palo Alto, CA.*

Background: Ferric citrate (FC) is an approved iron-based phosphate binder. A recent Phase 3 Clinical trial was completed to evaluate the efficacy and safety of FC for the treatment for IDA in NDD-CKD. Here we evaluate the effect of FC on serum phosphate (Phos), intact parathyroid hormone (PTH) and fibroblast growth factor (FGF)-23 levels when FC dose was titrated to hemoglobin (Hgb).

Methods: 234 subjects randomized 1:1 to FC and Placebo (P) were included in a 16 week Randomized period followed by an 8 week Extension period. Subjects with serum Phos <3.5 mg/dL at screening were excluded. The starting dose of 3 tablets/day was increased at fixed intervals if Hgb at any time point had not increased by ≥1g/dl AND if serum Phos was > 2.5 mg/dL. Between-group changes in serum Phos, PTH, c-terminal and intact FGF-23 were evaluated from baseline to the end of 16 week using MMRM (parametric data) and Wilcoxin Rank-Sum test (non-parametric data).

Results: Data for serum Phos, PTH and FGF-23 are presented in the Table.

	FC (n=117)		P (n=115)		P-value
	BL	EOT	BL	EOT	
Serum Phosphate (mg/dL) mean ± SD	4.23±0.08	3.72±0.06	4.12±0.06	3.86±0.08	0.02
i-FGF23 (pg/mL) median [IR]	134 [90,233]	105 [67,180]	134 [83,202]	120 [82,213]	< 0.001
c-FGF23 (RU/mL) median [IR]	364 [198,601]	233 [137,397]	306 [177,484]	309 [186,503]	< 0.001
PTH (pg/mL) median [IR]	103 [67,171]	84 [58,173]	92 [62,168]	90 [62,148]	
BL- baseline, EOT, end of 16 week randomized period					

During the Randomized Period, 4 (3.4%) and 3 (2.6%) subjects on FC and P, respectively, had serum Phos <2.5 mg/dL.

Conclusions: In patients with NDD-CKD, FC given in doses to raise Hgb, reduced serum Phos, with infrequent excursions below normal. FC also lowered PTH, c-terminal and intact FGF23 levels.

TH-PO904

Predictors of Hemoglobin Response to Ferric Citrate in Patients with Non-Dialysis Dependent Chronic Kidney Disease and Iron Deficiency Anemia

Pablo E. Pergola,[1] Steven Fishbane,[2] Geoffrey A. Block,[3] John F. Neylan,[4] Katrin Uhlig,[4] Glenn Matthew Chertow.[5] *[1]Renal Associates PA, San Antonio, TX; [2]Hofstra Northwell Health, Great Neck, NY; [3]Denver Nephrologists, Denver, CO; [4]Keryx Biopharmaceuticals, Boston, MA; [5]Stanford Univ, Palo Alto, CA.*

Background: Ferric citrate (FC), an approved iron-based phosphate binder, raised hemoglobin (Hgb) in a phase 3 trial of iron deficiency anemia (IDA) in patients with Non-Dialysis Dependent CKD (NDD-CKD).We examined demographic and clinical factors and routinely available laboratory tests as determinants of hemoglobin (Hgb) response.

Methods: In the 16 week randomized period, 61/117 FC treated subjects had an increase in Hgb of ≥ 1g/dL at any point (defined as "responders"). We compared baseline characteristics and laboratory changes of responders and non-responders. Laboratory variables (Hgb, TSAT, ferritin, eGFR, phosphate, calcium, bicarbonate, PTH, and albumin) identified as candidate predictors of Hgb change in univariate analyses (with a p-value of ≤0.1) were entered into multivariable linear regression analysis. PTH was log transformed.

Results: Baseline demographic and clinical characteristics did not differ by responder status. In univariate analyses, TSAT, ferritin, eGFR, and phosphate were identified as candidate predictors of Hgb change. TSAT and eGFR combined provided the best fitting multivariate model. A 5% lower TSAT was associated with a 0.2 g/dL (95% confidence interval 0 to 0.35, p=0.029) greater increase in Hgb; a 10 ml/min/1.73 m2 higher eGFR with a 0.2 g/dL (0 to 0.35, p=0.036) greater increase in Hgb. Responders relative to non-responders experienced larger increases in TSAT (20% versus 11%, p=0.01) and ferritin (164 versus 117 ng/dL, p=0.045) during the trial.

Conclusions: Patients with NDD-CKD and IDA respond to FC with an increase in Hgb regardless of degree of iron deficiency and renal impairment. Patients with more pronounced iron deficiency (lower TSAT) and better kidney function (higher GFR) experience a more robust Hgb response to FC associated with repletion of iron stores, as reflected by greater increases in TSAT and ferritin among responders.

Efficacy and Safety of Sevelamer Carbonate in Hyperphosphatemic Pediatric Patients with Chronic Kidney Disease Sahar A. Fathallah-Shaykh,[1] Mark R. Benfield,[2] Dorota Drozdz,[3] Joseph T. Flynn,[4] Randall Jenkins,[5] Katherine Wesseling-Perry,[6] Sarah J. Swartz,[7] Craig S. Wong,[8] Beverly Accomando,[9] Gerald F. Cox,[9] Bradley Warady.[10] *[1]U of Alabama at Birmingham, Birmingham, AL; [2]Pediatric Nephrology of Alabama, Birmingham, AL; [3]Dept of Pediatric Nephrology, JU MC, Krakow, Poland; [4]Seattle Children's Hosp, Seattle, WA; [5]Oregon Health & Science U, Portland, OR; [6]Children's Health Center, UCLA, Los Angeles, CA; [7]Texas Children's Hosp, Houston, TX; [8]U of New Mexico HSC, Albuquerque, NM; [9]Sanofi Genzyme, Cambridge, MA; [10]Children's Mercy Hosp, Kansas City, MO.*

Background: No currently marketed oral phosphate binders are FDA-approved for management of hyperphosphatemia in children with chronic kidney disease (CKD). This phase 2 study (NCT01574326) evaluated safety and efficacy of sevelamer carbonate (SC) in hyperphosphatemic pediatric patients with CKD before/on dialysis.

Methods: After 2–4 week screening/washout, children with serum phosphorus (SP) higher than age-appropriate levels were randomized to receive SC/placebo in 0.4–1.6 g doses based on body surface area for a 2-week fixed-dose period (FDP) followed by a 6-month single-arm open-label dose titration period (DTP). Primary efficacy endpoint: change in SP from baseline to end of FDP (ANCOVA); secondary efficacy endpoint: change in SP from baseline to end of DTP (descriptive statistics). Adverse events (AEs) were recorded.

Results: Of 101 patients enrolled at 29 centers, 66 completed the study (74% adolescents [mean age=14.1 years]; 77% on dialysis); renal transplant was the main reason for discontinuation. Mean overall baseline SP was 7.16 mg/dL. SC significantly reduced SP levels from baseline during FDP (–0.90 mg/dL,*P*=0.001) and DTP (–1.18 mg/dL,*P*<0.0001). SP became age-appropriate in 8% patients on SC during FDP and overall 27% patients at end of DTP. Safety/tolerability of SC was comparable to placebo during FDP; mild gastrointestinal AEs occurred in DTP. No clinically relevant changes occurred in vital signs and in calcium/bicarbonate levels.

Conclusions: Sevelamer carbonate lowered SP significantly in hyperphosphatemic children with CKD, with no significant safety issues identified.

Low Rate of Early Response to Oral Iron in Patients with Non-Dialysis Dependent CKD (ND-CKD) Iain C. Macdougall,[1] Andreas H. Bock,[2] Fernando Carrera,[3] Kai-Uwe Eckardt,[4] Carlo A. Gaillard,[5] David B. Van Wyck,[6] Yvonne Meier,[7] Sylvain Larroque,[7] Simon D. Roger.[8] *[1]King's College Hospital, London, United Kingdom; [2]Kantonsspital Aarau, Aarau, Switzerland; [3]Eurodial, DaVita, Leiria, Portugal; [4]Uni. Erlangen-Nürnberg, Erlangen, Germany; [5]Uni. Medical Centre Groningen, Groningen, Netherlands; [6]DaVita Healthcare Partners Inc, Denver, CO; [7]Vifor Pharma, Glattbrugg, Switzerland; [8]Renal Research, Gosford, NSW, Australia.*

Background: Hematopoietic response rates to oral iron in ND-CKD are low. Understanding the likelihood of a subsequent response after initial non-response could guide decision-making.

Methods: *Post hoc,* 626 iron-deficient patients with ND-CKD and anemia, randomized (2:1:1) in the FIND-CKD trial to oral iron or IV ferric carboxymaltose (FCM, targeting higher or lower ferritin) were assessed for response (Hb increase ≥1 g/dL from baseline [BL]) during the first 8 weeks, when additional anemia therapy was permitted only for rescue. Patients without Hb data at BL and week 4 (W4) for the W4 analysis, or BL and weeks 4 and 8 for the week 8 (W8) analysis were excluded. Data from the FCM groups are shown for comparison.

Results: At week 4, the response rate was 22% with oral iron. BL Hb, ferritin and TSAT were higher in W4 non-responders vs responders (Table). With oral iron, only 11% of patients with no response at W4 responded by W8. Among W4 non-responders, 4.4% of patients received rescue therapy by W8 under oral iron.

Conclusions: Hematopoietic response to oral iron was achieved in ~20% of ND-CKD patients with anemia and iron deficiency by W4. Thereafter, ~10% of early non-responders responded by W8. Earlier intervention for non-response to oral iron may improve anemia management.

	Oral iron	High ferritin FCM	Low ferritin FCM
Hb response at W4, n (%)*	63/292 (22%)	61/149 (41%)	20/144 (14%)
Hb response at W8 in week 4 non-responders, n (%)*	20/180 (11%)	23/73 (32%)	17/104 (16%)
Baseline values:W4 responders vs non-responders			
Mean Hb, g/dL	9.9 vs 10.5	10.1 vs 10.5	9.8 vs 10.5
Mean ferritin,ug/L	37 vs 61	41 vs 65	37 vs 57
TSAT, %	12 vs 17	12 vs 19	15 vs 16

*Excluding patients with rescue therapy.

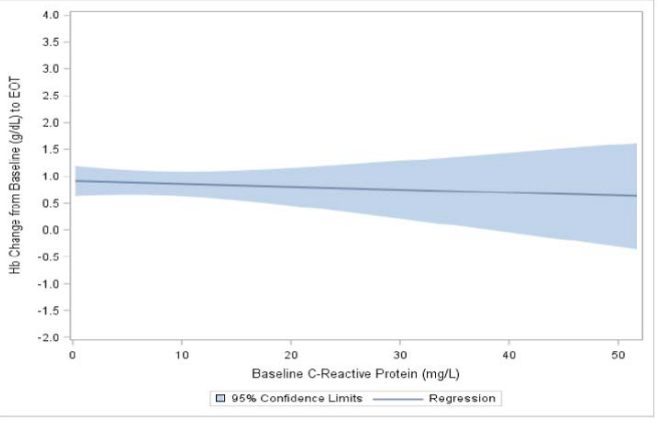
Efficacy and Dose Requirements of Vadadustat Are Independent of Systemic Inflammation and prior Erythropoiesis-Stimulating Agent (ESA) Dose in Patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) Volker H. Haase,[1] Bruce S. Spinowitz,[2] Pablo E. Pergola,[3] Zeeshan Khawaja,[4] Jason Chan,[4] Qing Zuraw,[4] Bradley J. Maroni,[4] Ramin Farzaneh-Far.[4] *[1]Vanderbilt Univ, Nashville, TN; [2]New York Presbyterian Queens, Flushing, NY; [3]Renal Associates PA and Univ of Texas, San Antonio, TX; [4]Akebia Therapeutics, Inc., Cambridge, MA.*

Background: CKD is associated with systemic inflammation, which in turn is linked to worsening anemia and high ESA dose requirements. Vadadustat is a novel, once-daily, oral, hypoxia-inducible factor prolyl-hydroxylase inhibitor in development for the treatment of renal anemia.

Methods: A randomized, double-blind, placebo-controlled study was conducted to assess the hemoglobin (Hb) response to 20 weeks of vadadustat dosing in NDD-CKD patients with anemia. Patients were randomized (2:1) to receive vadadustat (n=138; 450mg QD) or placebo (n=72). A post-hoc analysis was performed to explore correlations between final vadadustat dose, mean change in Hb, markers of inflammation (hepcidin and C-reactive protein [CRP]), and weekly ESA dose prior to study entry.

Results: Baseline inflammatory markers and weekly ESA dose (prior to study entry) did not correlate with vadadustat dose at Week 20 (p=0.4). The magnitude of the mean increase in Hb (from baseline to Week 20) was independent of baseline hepcidin (p=0.6), ESA dose (p=0.9) and CRP (p=0.6; figure). In addition, vadadustat treatment maintained Hb within target range (p<0.0001 vs placebo), with few Hb excursions above 13g/dL (6/138; 4%).

Change in Hb from baseline to Week 20 (end-of-treatment) was independent of the baseline CRP levels



Conclusions: The Hb response and vadadustat dose requirement for correction and maintenance of Hb are independent of underlying systemic inflammation and baseline ESA dose in patients with NDD-CKD.

Daprodustat, a HIF-Prolyl-Hydroxylase Inhibitor, Increases and Maintains Hemoglobin over 24 Weeks in Anemic Chronic Kidney Disease Subjects Louis Holdstock,[1] Borut Cizman,[1] Amy M. Meadowcroft,[1] Nandita Biswas,[1] Delyth Jones,[1] Brendan M. Johnson,[2] John J. Lepore,[1] Sung Gyun Kim,[3] Alexander Ralph Cobitz.[1] *[1]GlaxoSmithKline; [2]Roivant Sciences; [3]Hallym Univ, South, Korea.*

Background: The efficacy and safety of daprodustat (GSK1278863) was evaluated in 252 chronic kidney disease (CKD) subjects over 24 weeks (w).

Methods: rhEPO-naïve subjects were randomized 3:1 and rhEPO-users 1:1 to daprodustat (1–4mg, based on starting hemoglobin [Hgb; g/dL] for rhEPO-naïve subjects; 2 mg for rhEPO-users) or control groups (CTRL; rhEPO per investigator discretion; 91% of rhEPO naive subjects and all rhEPO users received at least 1 rhEPO dose). For rhEPO-naïve subjects, entry Hgb was 8-10 (group [G] 1) or 8-11 (G2); for rhEPO-users, entry Hgb was 9-10.5 (G1) or 9-11.5 (G2). Study drug was titrated to maintain Hgb in a target range (TR) of 9–10.5 (G1) or 10–11.5 (G2).

Results: In rhEPO naïve subjects, mean Hgb increased from 9.6 to 10.2 (G1) and 10.1 to 11.0 (G2) in the daprodustat groups, and from 9.6 to 10.6 (G1) and 10.2 to 11.1 (G2) in CTRL. Median percent of time within Hgb target range was 81% for the combined daprodustat groups and 47% for combined CTRL. In rhEPO users, Hgb was maintained in both daprodustat groups, whereas Hgb in CTRL increased by 0.7 (G1) and 0.4 (G2). The median percent of time within Hgb target range was 94% for the combined daprodustat groups compared to 88% for the combined CTRL. In rhEPO naïve subjects, hepcidin decreased from baseline at 24 w by 19.3% in the daprodustat group and increased by 6.7% in CTRL. In rhEPO users, hepcidin decreased by 9.9% at 24 w in the daprodustat group, and by 17.1% in CTRL. Daprodustat did not effect plasma EPO or VEGF levels throughout the study. There were no differences between groups in blood pressure or eGFR. Daprodustat was well tolerated with an adverse event profile consistent with the CKD population.

Conclusions: In patients with CKD, daprodustat safely and effectively enabled rhEPO users to achieve target Hgb levels and maintained target Hgb levels in over a 24-w period. Daprodustat reduced hepcidin, and did not change plasma EPO or VEGF levels. These data support future long-term clinical studies of daprodustat to treat anemia of CKD.

High versus Low Dose Erythropoiesis-Stimulating Agents in People with End-Stage Kidney Disease Treated with Hemodialysis (C.E. DOSE Trial): A Pragmatic, Multicenter, Randomized Controlled Trial

Valeria M. Saglimbene,[1,2] Suetonia Palmer,[3] Marinella Ruospo,[1,4] Gabrielle J. Williams,[2] Jonathan C. Craig,[2] Jorgen B.A. Hegbrant,[1] Giovanni F.M. Strippoli.[1,2,5] *[1]Diaverum Medical Scientific Office; [2]Univ of Sydney; [3]Univ of Otago Christchurch; [4]Amedeo Avogadro Univ of Eastern Piedmont; [5]Univ of Bari, on behalf of the C.E. DOSE Investigator.*

Background: The increased risks of death and adverse cardiovascular events with erythropoiesis-stimulating agent (ESA) therapy targeting a higher hemoglobin level in patients with ESKD are established, but it is unclear whether these adverse effects can be mitigated and quality of life benefits maintained when a fixed treatment dose approach is used.

Methods: The C.E. DOSE trial was a multicenter, pragmatic, non-blinded, randomized, controlled, parallel-group trial allocating 656 hemodialysis patients with anemia to receive either high dose (18,000 IU epoetin alfa or epoetin beta or 90 mcg darbepoetin alfa per week) or low dose (4000 IU epoetin alfa or epoetin beta or 20 mcg darbepoetin alfa per week) ESA. The primary outcome was a composite of death or a CV event (non-fatal myocardial infarction, non-fatal stroke, or hospitalization for acute coronary syndrome, transient ischemic attack, unplanned percutaneous coronary intervention or peripheral revascularization). ClinicalTrials.gov, number NCT00827021.

Results: High dose ESA did not increase the primary outcome by 12 months (55 [17%] *vs* 46 [14%] patients; hazard ratio [HR] 1.19, 95% CI 0.81–1.77), death (40 [12%] *vs* 35 [11%]; HR 1.21, 95% CI 0.77–1.91), or myocardial infarction (8 [2%] *vs* 4 [1%]; HR 1.78, 95% CI 0.52-6.08), and had no impact on HRQOL (mean difference in physical composite score at 12 months 1.70, 95% CI -0.95 to 4.35).

Conclusions: In this fixed-dose trial of ESA treatment for anemia in patients with ESKD, a high dose strategy had uncertain effects on mortality, CVEs, and health-related quality of life. Funding: Italian Medicines Agency.

Efficacy of Add-On Tolvaptan in the Very Early Treatment Phase of Congestive Heart Failure Complicated by Advanced CKD

Naoto Tominaga,[1] Keisuke Kida,[2] Takayuki Inomata,[3] Naoki Sato,[4] Tohru Izumi,[5] Yoshihiro J. Akashi,[2] Yugo Shibagaki.[1] *[1]Div of Nephrology and Hypertension, St. Marianna Univ, Japan; [2]Div of Cardiology, St. Marianna Univ; [3]Dept of Cardio-angiology, Kitasato Univ; [4]Cardiology and Intensive Care Unit, Nippon Medical School Musashi-Kosugi Hospital; [5]Div of Cardiology, Niigata Minami Hospital.*

Background: The aim of this subanalysis was to investigate the efficacy of add-on tolvaptan (TLV) in congestive heart failure (CHF) patients complicated by advanced CKD with or without hyponatremia (HN) in the very early treatment phase.

Methods: The Kanagawa Aquaresis Investigators Trial of TLV on HF Patients with Renal Impairment was a multicenter, open-labeled, randomized, and controlled prospective clinical study consisting of 81 Japanese patients with CHF and residual signs of congestion despite oral furosemide (FUR) treatment (≥40 mg/day). They were randomly assigned to 7-day treatment with either ≤15 mg/day of newly added TLV or ≤40 mg/day of increased FUR. A subanalysis was conducted for 73 patients, except those for whom some results were not available within 2 days from baseline (day 1). We classified these patients into two groups according to their serum sodium level (sNa): non-HN (sNa>135 mEq/L, n=58) and HN (sNa≤135 mEq/L, n=15). Subsequently, each group was stratified into two subgroups (increased FUR/added TLV, n=32/26 in non-HN group; n=5/10 in HN group), and the differences (Δ) of urine and serum parameters between day 1 and 3, were compared between the subgroups in each group.

Results: ΔUrine volume (UV) was greater in TLV subgroups than in FUR subgroups (472.3±158.2 vs 78.9±60.1 mL/day in non-HN group, P=0.024; 446.0±139.6vs 202.2±246.4 mL/day in HN group, P=0.426), and ΔuOsm was also greater in TLV subgroups (-100.2±25.3 vs -21.0±8.9 mOsm/kg in non-HN group, P<0.001; -96.5±15.9 vs -16.8±23.6 mOsm/kg in HN group, P=0.019). As a result, ΔsNa was greater in TLV subgroups (2.0±0.5 vs 0.1±0.3 mEq/L in non-HN group, P=0.003; 2.7±1.3 vs 0.7±0.5 mEq/L in HN group, P=0.154).

Conclusions: In this subanalysis, add-on TLV increased UV, decreased uOsm and improved sNa more than increased FUR in the very early treatment phase of CHF complicated by advanced CKD.

NT-proBNP Levels Predict the Individual Drug Response to Aliskiren in Patients with Type 2 Diabetes at High Cardio-Renal Risk

Hiddo Jan Lambers Heerspink,[1] Frederik I. Persson,[2] Hans-Henrik Parving,[3] Dick de Zeeuw.[1] *[1]Univ Medical Center Groningen, Netherlands; [2]Steno Diabetes Center, Denmark; [3]Rigshospitalet, Univ of Copenhagen, Denmark.*

Background: The individual response to renin-angiotensin-system (RAS) intervention is blunted in the setting of volume overload. Diuretic treatment or low sodium diet is often required to enhance the response to RAS intervention. We investigated whether NT-proBNP, a biomarker of volume expansion, can be used to predict the individual response to aliskiren.

Methods: A post-hoc analysis was performed in the ALTITUDE trial, a double blind randomized controlled trial comparing the effect of aliskiren 300 mg/d vs. placebo on cardio-renal endpoints in 8561 patients with type 2 diabetes at cardio-renal risk. Data from 5081 patients with available NT-proBNP measurements were used. The primary endpoint was a composite of CV death, resuscitated sudden death, MI, stroke, hospitalization for heart failure, end-stage renal disease (ESRD), or doubling of serum creatinine. We investigated variation in the effect of aliskiren on the cardio-renal endpoint based on baseline tertiles of NT-proBNP in Cox proportional hazard regression models using an interaction term (treatment*NT-proBNP).

Results: Median NT-proBNP levels by tertiles were 50, 157, and 534 pg/ml, respectively. During a median follow-up of 2.5 years, 840 (16.4%) patients experienced a cardio-renal event. There was a statistically significant trend across NT-proBNP tertiles, with a lower risk of events in the aliskiren group, compared with placebo, in patients with a lower NT proBNP and the converse in patients with a higher NT proBNP (Table). Similar trends were observed for the cardiovascular and ESRD endpoints.

Conclusions: Elevated NT-proBNP levels, reflecting volume overload, predict a poor response to aliskiren in patients with type 2 diabetes at cardio-renal risk. These data highlight the importance of achieving adequate extracellular volume control by diuretic treatment or dietary sodium restriction.

Extracellular Volume	NT proBNP Tertiles	Hazard Ratio Cardio-Renal Endpoint	P trend
Low	≤ 94	0.80 (0.58 – 1.10)	
Mid	95 - 266	0.98 (0.76 – 1.26)	0.009
High	> 266	1.25 (1.04 – 1.51)	

Funding: Pharmaceutical Company Support - Novartis sponsored the ALTITUDE trial

Effect of Direct Renin Inhibitor Aliskiren Compared with Angiotensin II Receptor Blockers on Clinic and Ambulatory Blood Pressure Profiles in Hypertensive Chronic Kidney Disease Patients

Kazushi Uneda, Hiromichi Wakui, Kengo Azushima, Sona Haku, Ryu Kobayashi, Kohji Ohki, Kotaro Haruhara, Sho Kinguchi, Masato Ohsawa, Kouichi Tamura. *Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.*

Background: Increasing evidence indicates that appropriate control of blood pressure (BP) is critical in the management of hypertensive patients with chronic kidney disease (CKD). The direct renin inhibitor aliskiren (DRI) reportedly exert comparable BP lowering effects in hypertension. However, the clinical evidence of DRI in hypertensive patients with CKD is insufficient as compared to that of angiotensin II receptor blockers (ARBs). In the present study, we compared effects of DRI and ARBs on clinic and ambulatory BP profile in hypertensive patients with CKD.

Methods: Hypertensive patients with CKD who have already been treated with ARBs therapy were eligible for the study. After the 4-week run-in period, eligible patients were randomized either to DRI replacement group (DRI group) or control ARBs group (ARB group) during the 24-week active treatment period. Clinic BP and ambulatory BP profiles were evaluated at baseline and after the protocol therapy.

Results: 36 patients were enrolled and randomly assigned to DRI group (n=18) or ARB group (n=18). One patient in each group withdrew consent. The baseline clinic BP levels and the after-treatment/baseline (A/B) ratios of clinic BP levels, estimated after 24-week treatment period, were similar in both groups. However, with respect to the effects on ambulatory BP, the A/B ratios of the daytime and nighttime systolic BP in DRI group were significantly higher than those in ARB group (DRI vs ARB: daytime systolic BP, 0.99±0.11 vs 0.92±0.08, *P*=0.041; nighttime systolic BP, 1.03±0.12 vs 0.91±0.12, *P*=0.010). Concomitant anti-hypertensive medication was comparable in both groups during 24 weeks of treatment.

Conclusions: The results of the present study suggest that DRI therapy is not superior to ARB therapy in lowering ambulatory BP in hypertensive CKD patients, in spite of comparable clinic BP lowering effects.

TH-PO913

Effect of Spironolactone on Vascular Stiffness in Hemodialysis - A Randomized Crossover Study

Michael Eklund,[1] Hans Furuland,[2] Olof Hellberg,[1] Erik Nilsson.[1] *[1]Internal Medicine, Örebro Univ Hospital, Örebro, Sweden; [2]Nephrology, Uppsala Univ Hospital, Uppsala, Sweden.*

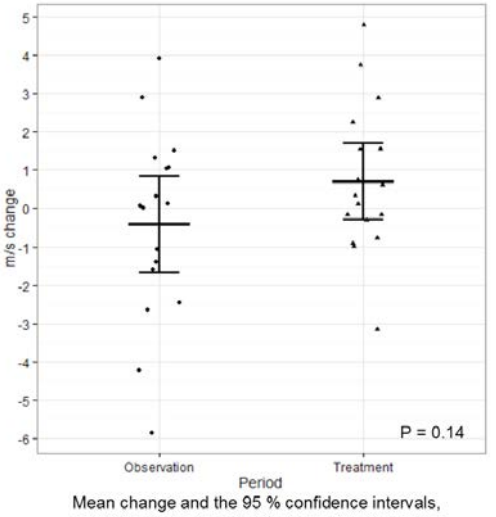
Background: Hemodialysis (HD) is associated with high cardiovascular mortality and increased vascular stiffness is a known risk factor for cardiovascular events. Spironolactone treatment is associated with improved survival in HD and in other populations vascular

stiffness has been reduced. This study investigates possible cardiovascular actions of spironolactone in HD and we hypothesized that spironolactone would affect vascular stiffness as measured by pulse-wave velocity (PWV) in HD.

Methods: This was a two center, open, randomized crossover study. Primary end-point was based on long-term ECG changes and the present sub-study represents a secondary hypothesis. Subjects on HD (n = 30) were randomly allocated using sealed envelopes into two study arms starting with either treatment with spironolactone 50 mg daily or observation for twelve weeks, then a six week wash-out period followed by cross-over for another twelve weeks. PWV was measured before and after treatment and observation, respectively. Difference in PWV change during the two periods was analyzed using confidence intervals (CI) and paired Student's t-test.

Results: Complete PWV data was available for 17 participants and included in the analysis. Mean PWV change was 0.71 (95 % CI: -0.28 – 1.71) m/s during treatment and -0.42 (-1.69 – 0.85) m/s during observation. The difference between periods was not statistically significant, p = 0.14. No adverse events were considered associated with the intervention.

Figure 1: Change in Pulse Wave Velocity



Mean change and the 95 % confidence intervals, calculated from the t-distributions. P-value for the difference between periods. n = 17.

Conclusions: PWV increased slightly after treatment with spironolactone but compared with the observation period the change was not statistically significant. Although this study has low power for detecting changes in PWV, results indicate that spironolactone does not have a clinically significant positive effect on vascular stiffness in HD.

Funding: Government Support - Non-U.S.

TH-PO914

Impact of Vitamin D on Cardiac Structure and Function in Chronic Kidney Disease: A Randomised Controlled Trial Debasish Banerjee,[1] Nihil Chitalia,[1] Kristel E. Medina-Rodríguez,[1] Laura E. Tooth,[1] Evan Appelbaum,[2] Ravi I. Thadhani,[2] Juan Carlos Kaski,[1] David Goldsmith.[3] *[1]St. Georges Univ of London; [2]Harvard Univ; [3]Guys Hospital.*

Background: CKD is associated with cardiac hypertrophy. We examined impact of oral cholecalciferol supplementation on cardiac structure and function, in a double-blind, placebo-controlled randomised trial.

Methods: After screening 84 stable, non-diabetes, CKD stage 3-4 patients on ACEi/ARB, with vitamin D concentrations <75 nmol/L, 48 patients with left ventricular [LV] mass in the upper tertile of normal range, were randomised to receive either 6 directly-observed doses of 100,000 units of cholecalciferol or matched placebo over 42 weeks. Cardiac MRI and echocardiography were performed at baseline and 52 weeks.

Results: The clinical characteristics were well matched at baseline between vitamin D and placebo groups as follows: age 52±12 vs 52±11 years (p=0.94); eGFR 35±11 vs. 34±11 (p=0.75); calcium 2.4±0.1 vs 2.4±0.1 (p=0.37); phosphate (1.1±0.2 vs 1.0±0.3; p=0.42). The vitamin D concentrations in the vitamin D and placebo groups; at baseline, 24 weeks and 52 weeks, were 43±18 vs. 43±20 [p=0.95], 77±14 vs. 49±27 [p<0.001], 78±24 vs. 43±21 nmol/L [p<0.001] respectively. The left ventricular mass by MRI scan at baseline and 52 weeks, in the vitamin D and placebo groups were 104±39 vs. 100±29 gm [p=0.97] and 108±39 vs. 96±27 gm [p=0.28]. At 52 weeks there were no difference in LV volumes, RV volumes and mass, RA area, LA area, Mitral valve E/A ratio, E/e' ratios at septum and lateral wall, pulmonary artery systolic pressure between the vitamin D and placebo groups [see table 1].

Conclusions: Cholecalciferol supplementation over 52 weeks increased vitamin D levels but did not have an impact on cardiac structure of function in stable, non-diabetic, CKD patients with low vitamin D.

Table 1: The outcome variables at 52 weeks

Outcome measures	Placebo	Vitamin D	p value
LV ED Mass (gm)	96±26	108±39	0.28
LV stroke volume (ml)	96±21	95±23	0.86
LV ED Volume (ml)	149±36	154±36	0.67
LV ES Volume (ml)	108±29	118±46	0.25
RV Stroke Volume (ml)	97±24	98±33	0.74
RV ED volume (ml)	161±43	162±39	0.92
RV ES Volume (ml)	66±26	64±15	0.69
RV ejection fraction (%)	59.9±7.0	59.8±8.6	0.97
RA Area (cm^2)	20±5	20±4	0.68
LA Area (cm^2)	21±3.7	22±3.7	0.63
MV e/a ratio	1.02±0.22	0.96±0.27	0.41
E/e' lateral wall	9.68±4.50	7.6±2.80	0.93
E/e' septum wall	10.8±3.1	9.9±3.2	0.92
PA systolic pressure (mmHg)	22.5±8.0	22.4±5.3	0.96

Legend: LV=left ventricle, RV=right ventricle, RA=right atrium, LA=left atrium, PA=pulmonary artery, ED=end diastolic, ES=end systolic, MV=mitral valve

TH-PO915

Prospective Trial of Exogenous Growth Hormone Administration on Circulating Concentrations of α-Klotho in Healthy and Chronic Kidney Disease Subjects Aaltje Ymkje Adema,[1] Camiel L.M. de Roij van Zuijdewijn,[1] Joost Hoenderop,[2] Martin H. De Borst,[3] Pieter M. Ter Wee,[1] Marc G. Vervloet.[1] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Noord-Holland, Netherlands; [2]Physiology, Radboud Univ Medical Center, Nijmegen, Gelderland, Netherlands; [3]Internal Medicine, Div of Nephrology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: Chronic kidney disease (CKD) is characterized by a decline in soluble α-Klotho levels, which may play a role in adverse outcomes. Cross-sectional studies demonstrated that growth hormone (GH) and α-Klotho concentrations are associated.This work represents the first study reporting on the effect of exogenous GH administration on α-Klotho concentrations in patients with mild CKD and healthy subjects.

Methods: A prospective, single-center open label case-control pilot study was performed involving 8 patients with mild CKD and 8 healthy controls matched for age and sex. All participants received subcutaneous GH injections (Genotropin®, 20 mcg/kg/day) for 7 consecutive days. α-Klotho concentrations were measured at baseline, after 7 days of therapy and 1 week after discontinuation of the treatment.

Results: Three women and five men were included in both groups (mean age 46.9±12.9 and 44.5±11.4 years; eGFR 57±17 and 100±8 ml/min/1.73m^2 in CKD and healthy controls respectively). At baseline, α-Klotho concentrations were not significantly different between CKD-patients and controls (529±132 vs. 646±338 pg/mL, P=0.38). GH therapy successfully increased IGF-1 concentrations from 26.8±5.0 nmol/L to 61.7±17.7 nmol/L (P<0.001) in the pooled cohort, as well as in both groups (26.3±2.8 to 59.8±20.5 nmol/L (P=0.002) in CKD and 27.3±6.8 to 63.6±15.6 nmol/L (P=0.001) in healthy controls). However, α-Klotho concentrations did not increase significantly after GH, neither in the pooled cohort (588 ± 255 to 669 ± 286 pg/mL, P=0.10) nor in each treatment group (529±132 to 625±325 pg/mL (P=0.29) and 646±338 to 712±256 pg/mL (P=0.19) in CKD and healthy controls respectively).

Conclusions: Exogenous growth hormone therapy does not increase α-Klotho concentrations in patients with mild CKD or healthy controls.

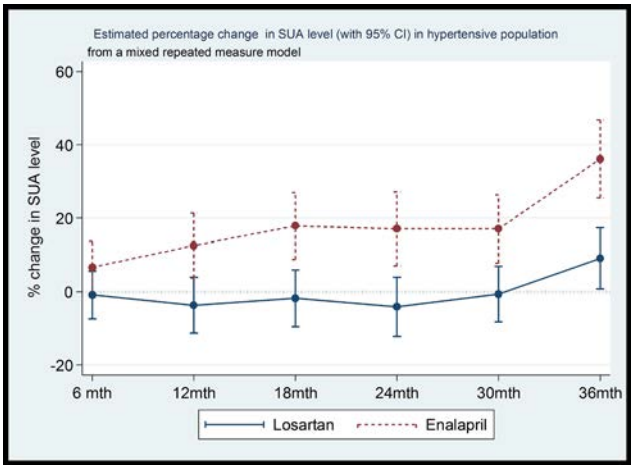
Losartan Significantly Lowers Serum Uric Acid in Hypertensive Children with Proteinuria Charlotte Bryant,[1] Azita Rajai,[2] Ronald J. Hogg,[3] Nicholas J. Webb.[1] *[1]Royal Manchester Children's Hospital, United Kingdom; [2]Central Manchester Univ Hospital, United Kingdom; [3]Texas A&M Health Science Center College of Medicine.*

Background: Serum uric acid (SUA) has emerged as a potentially modifiable risk factor for the progression of chronic kidney disease (CKD). We have previously reported the results of a randomised controlled trial showing that losartan and enalapril are comparable in their efficacy and safety in reducing proteinuria in children with CKD (KI 2012;82:819).

Methods: In a post-hoc analysis of these patients, we determined the effect of losartan vs. enalapril on SUA over 36 months in 201 normotensive and 47 hypertensive children with CKD and examined the change in estimated glomerular filtration rate (eGFR).

Results: Despite no overall difference between the two treatment groups, change in SUA was significantly different between losartan and enalapril in the hypertensive population at 12 months (3.69% decrease [95% CI -3.93%, 11.31%]) vs. 12.57% increase [3.72%, 21.41%], p=0.007). This significant difference remained after 24 and 36 months of treatment.



This effect was not observed in normotensive patients. The change in SUA showed a statistically significant negative correlation with change in eGFR at each time point over 36 months p<0.001.

Conclusions: Compared to enalapril, losartan significantly lowers SUA in hypertensive children with CKD and this is correlated with change in eGFR. Studies are needed to evaluate whether changes in clinical practice, such as the preferential use of losartan over other antihypertensive agents, will slow progression in children with CKD.

TH-PO917

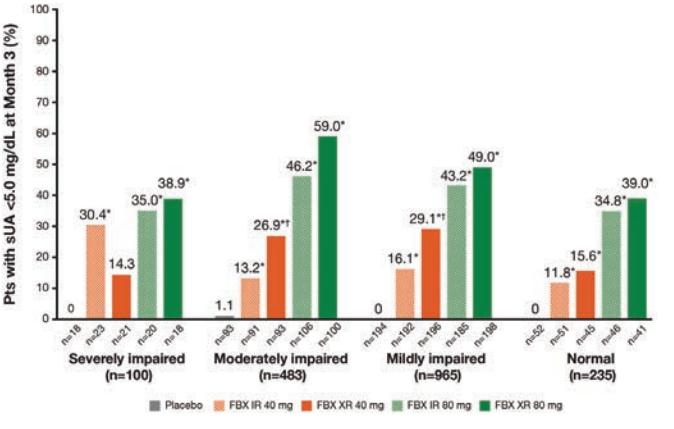
Impact of Baseline Renal Function on Efficacy and Safety of Febuxostat Extended and Immediate Release Formulation in Patients with Gout

L. Gunawardhana,[1] M. Becker,[2] K. Saag,[3] B. J. Hunt,[1] M. Castillo,[1] D. Kim,[1] A. Whelton.[4] *[1]Takeda Pharmaceuticals, Deerfield, IL; [2]Univ of Chicago, Chicago, IL; [3]Univ of Alabama at Birmingham, Birmingham, AL; [4]Johns Hopkins Univ, Baltimore, MD.*

Background: Phase 1/2 data suggest that febuxostat (FBX) extended release (XR) may provide equal or better reduction in serum urate level (sUA), with reduced exposure vs currently marketed FBX immediate release (IR) in patients (pts) with gout. This Phase 3 study compared the efficacy and safety of XR vs IR in pts with gout stratified by baseline (BL) renal function.

Methods: In a multicenter, randomized, placebo-controlled, double-blind study, 1783 pts with gout (sUA ≥8.0 mg/dL; estimated glomerular filtration rate ≥15 mL/min; ≥1 gout flare within previous 12 months [mos]) received placebo or XR 40 mg, XR 80 mg, IR 40 mg, or IR 80 mg once daily for 3 mos; ≥30% of pts had moderate-to-severe BL renal impairment. The primary endpoint was the percentage of pts with sUA <5.0 mg/dL at 3 mos.

Results: In the primary analysis, more pts achieved sUA <5.0 mg/dL at 3 mos with XR 40 vs IR, p<0.001. Although the difference was not statistically significant after multiplicity adjustment, more XR 80-mg treated pts achieved the primary endpoint compared with IR 80 mg. By BL renal function, more pts with mild or moderate renal impairment achieved sUA <5 mg/dL with XR 40 mg vs IR (p<0.05); there was a non-statistically significant trend for XR 80 mg vs IR (**Figure**). Treatment-emergent adverse events were infrequent and did not differ among renal function subgroups.



*p<0.05 vs placebo; †p<0.05 vs equivalent dose IR formulation

Normal renal function = eGFR ≥90 mL/min; Mild renal impairment = eGFR ≥60 to 89 mL/min;
Moderate renal impairment = eGFR ≥30 to 59 mL/min; Severe renal impairment = eGFR ≥15 to 29 mL/min

eGFR = estimated glomerular filtration rate; FBX = febuxostat; IR = immediate release; pts = patients; sUA = serum urate; XR = extended release

Conclusions: More XR-treated pts achieved sUA targets of <5 mg/dL vs IR-treated pts with mild or moderate renal impairment. There were no meaningful differences in safety data for XR vs IR in pts with gout stratified by BL renal function. Both FBX formulations were efficacious in reducing sUA and well tolerated.

The Comparison of Febuxostat and Allopurinol in Chronic Gout Patients with Chronic Kidney Disease, a Randomized Prospective Study

Yong Chul Kim, Hajeong Lee, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim. *Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: The aim of this 12-week, open-label, non-inferiority trial was to compare the safety and efficacy of febuxostat with allopurinol in treating chronic gout patients with chronic kidney disease (CKD).

Methods: Patients were randomized to febuxostat (n= 53; 40mg daily for the first 4 weeks, 80mg thereafter) or allopurinol (n=53; dose adjusted based on ones kidney function), and both groups were stratified by baseline serum uric acid (SUA) 10.0 mg/dL. SUA was checked for 4 times (week2, 4, 8, 12) The primary end point was the proportion of SUA below 6.0 mg/dL at the end of the study. The non-inferiority margin for the difference in rates *(of SUA below 6.0 mg/dL)* was defined as -15 %. Efficacy analyses were done both by intention-to-treat (ITT) and per protocol (PP).

Results: Uric acid control with febuxostat (n= 49, 94.2 %) was non-inferior to that achieved with allopurinol (n= 13, 26 %), difference 0.68 [97.5 % CI 0.54 to ∞]. The proportion of SUA below 6.0 mg/dL at week 2 was 57.69 % (febuxostat) and 12% (allopurinol), respectively. And the rate increased in both group to 94.23 % (febuxostat), 26 % (allopurinol) at week 12 (p<0.0001).

	Febuxostat (N=53)	Allopurinol (N=50)	P=value
ITT group			
Initial SUA < 10 mg/dL At week 12 SUA < 6.0 mg/dL, N (%)	31 (93.94)	10 (33.33)	< 0.0001
Initial SUA > 10 mg/dL At week 12 SUA < 6.0 mg/dL, N (%)	18 (94.74)	3 (15)	< 0.0001
PP group			
Initial SUA < 10 mg/dL At week 12 SUA < 6.0 mg/dL, N (%)	28 (100)	10 (38.46)	< 0.0001
Initial SUA > 10 mg/dL At week 12 SUA < 6.0 mg/dL, N (%)	17 (94.44)	15 (83.33)	< 0.0001

The difference rate of SUA compared with baseline SUA increased with time in febuxostat, but not in allopurinol (at week 12: -47.13±15.1 % vs -24.34±11.45 %, p<0.0001). The rate of GFR change or incidence of AKI had no difference in both group. Skin eruption was observed in 1 case with allopurinol, but was tolerable.

Conclusions: Febuxostat was as effective as allopurinol in reducing SUA in chronic gout patients with CKD, with a similar safety profile.

TH-PO919

Orally Administered Complement 5a Receptor Inhibitor CCX168 Shows Ex Vivo Anti-Thrombogenic Activity in a Phase 2 Study in End-Stage Renal Disease Patients with Atypical Hemolytic Uremic Syndrome (ACCESS Study)

Valentina Portalupi,[1] Miriam Galbusera,[1] Piero Luigi Ruggenenti,[1] Nadia Rubis,[1] Sara Gastoldi,[1] Serena Bettoni,[1] Pirow Bekker,[2] Thomas J. Schall,[2] Marina Noris,[1] Giuseppe Remuzzi.[1] *[1]Mario Negri Inst, Italy; [2]ChemoCentryx, Inc.*

Background: The primary objective of this study is to evaluate whether CCX168 treatment of patients with atypical hemolytic uremic syndrome (aHUS) dampens the ex vivo thrombogenic properties of the serum on cultured microvascular endothelial cells.

Methods: Up to 10 patients with aHUS on stable peritoneal or hemodialysis for ≥6 mo are dosed at 30 mg CCX168 b.i.d. for 2 wks. Blood samples are collected during the study for ex vivo thrombogenesis assay (Ruiz-Torres MP et al, Thromb Haemost 2005;93:443-52).

Results: Five patients with aHUS (CFH, C3, CFI mutations: n=1 each, no mutations: n=2) have been treated to date. Mean±SD age: 50.6±8.96, male 1, female 4; 2 on peritoneal and 3 on hemodialysis. All patients showed a decrease in thrombus size (mean -83%); 3 showed 100% inhibition of thrombus formation at Day 14; 2 showed >30% inhibition. When CCX168 treatment was stopped, the thrombogenic activity returned to baseline levels (see table).

Treatment Period (N=4)	Thrombus Size (pixel²) mean ± SEM
Baseline	8690 ± 4811
Day 2	12582 ± 3018
Day 14	3964 ± 3960 *
No Treatment Follow-up Period	
Day 16	4364 ± 2367
Day 21	9680 ± 4504
* P = 0.016 versus baseline for paired t test	

Not unexpectedly, serum C3, C4, and plasma C5b-9 levels were unchanged. Two patients had low platelet counts which increased on CCX168 (163 to 223/μL and 152 to 196/μL). One patient, with a high cardiovascular event risk because of diffuse coronary calcifications and several cardiovascular risk factors related to long history of uremia and

a previous failing kidney transplant had a serious adverse event during a peritoneal dialysis session on Day 4 of cardiac asystole resulting in death. This event was not considered related to CCX168 use.

Conclusions: CCX168 was effective in reducing aHUS-induced thrombus formation in an ex vivo thrombogenesis assay, with all 5 patients showing an inhibition and 3 of 5 patients showing a complete inhibition.

A Multi-Level Intervention among Low-Income Patients with Chronic Kidney Disease to Improve Blood Pressure Control: Kidney Awareness Registry and Education Pilot Trial

Delphine S. Tuot,[1,2] Anna Rubinsky,[2] Alexandra Velasquez,[1] Charles E. McCulloch,[1] Dean Schillinger,[1] Chi-Yuan Hsu,[1,2] Neil R. Powe.[1] *[1]Univ of California, San Francisco, San Francisco, CA; [2]Kidney Health Research Collaborative, Univ of California, San Francisco, San Francisco, CA.*

Background: Low patient awareness and provider recognition of CKD can impede efforts to slow CKD progression and lead to adverse outcomes. A randomized control pilot trial entitled Kidney Awareness Registry and Education (KARE, NCT01530958) examined the impact of 1) a primary care CKD *Registry* with point-of-care provider notifications and quarterly feedback, 2) a patient-facing CKD *self-management support (CKD-SMS)* program, and 3) their combination, on systolic blood pressure (SBP) among low-income patients with CKD, eligible by eGFR or albuminuria, compared to a control group without either intervention.

Methods: Among patients with SBP recorded at baseline and 12 months (n=121/137), we examined the impact of each intervention (*Registry*, n=22; *CKD-SMS*, n=29; *Registry+CKD-SMS*, n=34) compared to usual care (n=36) on change in SBP using linear regression models adjusted for baseline SBP.

Results: KARE enrolled racially/ethnically diverse patients (7% White, 42% Black, 36% Hispanic, 15% Asian). Mean age was 56 years; 49% were male; 40% were non-English speaking. Mean eGFR was 47.6 (SD=9.5) ml/min/1.73m^2; mean baseline SBP was 130 (SD=21.8) mmHg. Compared to patients receiving usual care whose average SBP decrease was -0.24 mmHg, patients in the three intervention arms had larger non-statistically significant decreases in SBP (-3.6 for *Registry*; -3.1 for *CKD-SMS*; -2.8 for *Registry+CKD-SMS*). There was no evidence of effect modification by baseline SBP ($p_{interaction}$= 0.16), but decreases in SBP were non-statistically larger among patients with baseline SBP >140 mmHg (n=40) randomized to the intervention groups compared to usual care: -5.2 for usual care; -21.6 for *Registry*; -12.1 for *CKD-SMS*; -9.9 for *Registry+CKD-SMS*.

Conclusions: The KARE pilot study suggests that multi-level interventions can improve SBP among low-income patients with CKD. A trial with greater power comparing these interventions among patients with CKD and SBP >140 mmHg is warranted.

Patient Navigators and Enhanced Personalized Health Records in Kidney Disease: A Randomized-Controlled Pragmatic Clinical Trial

Sankar D. Navaneethan,[1] Stacey Jolly,[2] Jesse D. Schold,[2] Susana Arrigain,[2] Victoria Konig,[2] Georges Nakhoul,[2] Jennifer Hyland,[2] Barbara H. Tucky,[2] Priscilla Davis Dann,[2] Yvette K. Burrucker,[2] Joseph V. Nally.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Cleveland Clinic, Cleveland, OH.*

Background: Patient navigators have been shown to improve quality of care delivered to cancer patients; their impact on CKD care is unclear.We developed a CKD Patient Navigator program adapting the chronic care model and an electronic health record (EHR)-based enhanced personal health record (PHR) to disseminate CKD stage-specific goals of care and education. We report the results of a randomized clinical trial examining the clinical outcomes of a CKD Patient Navigator or enhanced PHR, and their combination compared to usual care among CKD Stage 3b/4 patients.

Methods: 209 patients with CKD from 6 outpatient clinics were randomized in a 2x2 factorial design. Primary outcome measure was the change in eGFR over a 2-year follow-up period. We also evaluated secondary outcome measures including: acquisition of appropriate laboratory measures, appropriate specialty referral and hospitalization rates. Outcomes were captured using EHR and telephone interviews without in-center visits.

Results: Median age of the study population was 68.5 years with 75% being Caucasians. Literacy score (STOFLA) was adequate in 97% of the study population. Prior to enrollment, 54% of patients were followed by nephrologists and 88% of them were on ACEI/ARBs. During 2-year follow-up, eGFR decline was similar across the four groups (p=0.81). Measurement of CKD-related laboratory data were not statistically significantly different between study groups. Further, referral for dialysis education and vascular access placement, emergency room visits and hospitalization rates were not statistically significantly different between the four study arms.

Conclusions: We successfully developed a patient navigator program and an enhanced PHR for CKD population.However, there were no differences in eGFR and quality care metrics between study groups in this randomized clinical trial. Longer follow up is needed to see a potential difference and additional analyses are needed to evaluate patient-specific benefits of the interventions.

Efficacy and Safety on Traditional Chinese Medicine Niaoduqing Particles in Delaying Moderate/Severe Renal Dysfunction: A Randomized Controlled Trial

Xiang-Mei Chen,[1] Ying Zheng,[1] Hong Li Lin.[2] *[1]Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases; [2]Dept of Nephrology, First Affiliated Hospital of Dalian Medical Univ.*

Background: Traditional Chinese medicine Niaoduqing particles can delay renal dysfunction, but there is no high-quality evidence. The present study aimed to determine the efficacy and safety of Niaoduqing particles in delaying renal dysfunction.

Methods: The study was a prospective, randomized, double-blind, placebo-controlled, multi-centered clinical trial (Clinical Trial registration number: ChiCTR-TRC-12002448). 300 adult patients with estimated glomerular filtration rate (eGFR) 20~45 mL/min per 1.73 m^2 were enrolled form 22 hospitals in China.The test group was given 3 doses of 5g Niaoduqing particles during the day and 10g Niaoduqing particles before bedtime; the control group was given placebos with same mode. Primary efficacy indicators included comparing serum creatinine and eGFR values and the change of values before and after treatment between the two groups. Endpoint event was defined as doubling of creatinine and/or commencing renal dialysis.

Results: At the end of treatment, there was no significant difference (P>0.05) in serum creatinine and eGFR between the two groups. However, compared with baseline, the value change of serum creatinine after treatment was significantly different between the two groups (ΔScr median was 1.1 μmol/L in test group versus 11.7 μmol/L in control group, P=0.008); compared with baseline, the value change of eGFR after treatment was also significantly different between the two groups (ΔeGFR median was -0.2 mL/min/1.73m^2 in test group versus -2.21mL/min/1.73m^2 in control group). 6 patients in test group and 4 patients in control group had creatinine doubled, and 1 patient in test group and 2 patients in control group started renal dialysis. In terms of adverse events, there was no significant difference (P>0.05) between the two groups.

Conclusions: For the first time, this study has determined that Niaoduqing particles could effectively delay renal dysfunction in CKD3b-4 patients.

TH-PO923

Analysis of the Paediatric Investigation Plans (PIP) of the EMA in Nephrology

Reinhard Feneberg,[1] Ineta Sosare,[2] Michael Marx.[1] *[1]ICON, Frankfurt, Germany; [2]ICON, Riga, Latvia.*

Background: To assess the requirements of the European Medical Agency (EMA) for paediatric clinical trials in nephrology we assessed the decisions on PIPs, which are required to get approval for new drugs. Clinical trials are needed in order to base therapy on evidence, but the relevant population can be very small in paediatric nephrology.

Methods: All 20 decisions on PIPs published by the EMA for nephrology were included. Data are presented as proportions (categorical data) and median (range) (numerical data).

Results: 7 of the published decisions granted a full waiver (i.e., no pediatric studies required). For the remaining 13, a PIP was agreed. For 6 of those 13 PIPs, a partial waiver was granted for certain ages (0-6 months (2x), 0-5, 0-6, 0-8, 12-18 yrs. The PIPs require the conduct of 0 – 3 (median 1) quality studies, 0 – 2 (median 0) non-clinical studies, and 1 – 6 (median 3) clinical studies. As there are ca. 9 paediatric dialysis subjects per million of all paediatric subjects, roughly ca. 400 patients in EU. At least 4 PIPs require inclusion of paediatric dialysis subjects, requiring 14 clinical studies, i.e., ca. 14 subjects are available for each of those studies. There are no concessions in powering the studies, and therefore, the required numbers will be much higher than the available number of subjects in EU. The time between start of the procedure and the decision of the PdCo/EMA was 103 days (35 – 468 days). The time between the date of decision of the PdCO/EMA and the date of the required completion of the PIP ranged from 0.03 yrs – 13.47 yrs (median 4.84 yrs).

Conclusions: In summary, we show some imbalances: a) All partial waivers affected the lowest age groups. Although the youngest age groups need an evaluation of new substances most, the granted partial waivers indicate how difficult it is to conduct trials in this group. b) Only 4 of the 13 PIPs are concerned with frequent indications, while 9 of those aim at rare. For those 9, a median of 3 studies are required. It is unlikely that the required subjectss can realistically be recruited. c) The required studies make the timely conduct (median 4.84 yrs) and completion at the same time adult studies questionable, which could delay approval.

TH-PO924

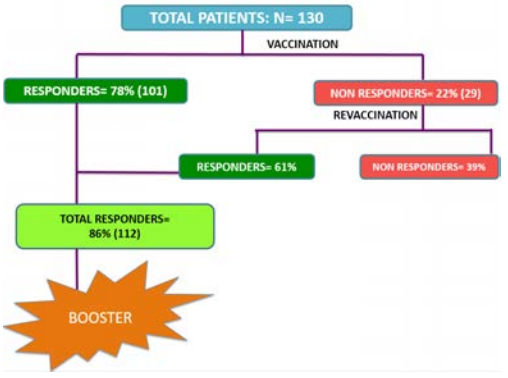
Response to Vaccination against Hepatitis B and Antibody Evolution in 130 Hemodialysis Patients Followed during Six Years

Angel Cristobal Santacruz, Maria Gabriela Santacruz, Juan Cristobal Santacruz, Zury A. D'Amelio. *Nefrologia, Clinica De Los Rinones Menydial, Quito, Pichincha, Ecuador.*

Background: Hemodialysis(HD) patients have a higher susceptibility to infections with Hepatitis B virus because of their advanced age,immunosuppressed state,increased transfusion requirements as well as because of the staff"s failure to strictly abide by published preventive universal precautions. This makes vaccine provided prevention particularly important in this population of patients.

Methods: In this manuscript we describe our observations in 130 HD patients-81 males (62%) and 49 females (38%) median age 53 years (range between 20-81 years), and median time on HD of 40 months (range 6-84 months). All patients were at onset AgHbs and anticore antigen negative. Vaccination was provided with double doses of

recombinant vaccine (Euvax-B) 40 ug IM deltoid muscle at 0, 30 and 180 days.Those who were classified as responders(anti Hbs antibody titer > 100 IU/ml) received an additional 40 ug booster annually.



Results: With this regimen, at the conclusion of the initial course of vaccination **78%** of the patients achieved an adequate level of antibody with a mean of **777** IU//ml. The response was highly heterogeneous, including the failure of **22%** following the first vaccination.This group underwent a second course of three double doses 40µg of vaccine on days 0-30 and 180. Following this,as many as 61% achieved adequate seroconversion, while the other 39% remained resistant.

Conclusions: Conclusion employing the approach described herein 86% of HD patients can attain adequate immunization against Hepatitis B virus.Increasing age is associated with decreased antibody response,but neither time on dialysis nor the underlying etiology of the renal disease significantly impacted the immunologic response.The persistence along the time of the immunization in normal range depend on the initial high answer to the vaccine.

TH-PO925

Implementing Teaching Guidelines on Quality of Life and Adaptation on Hemodialysis Patients

Tarek Abdellatif Ghonemy. *Nephrology Unit, Zagazig Univ Hospital, Zagazig, Al-Sharqyia Governorate, Egypt.*

Background: Health Related Quality of life (HRQOL) of patients with End Stage Renal Disease (ESRD) is influenced by the disease itself and by the type of replacement therapy. Clinical practice guidelines were established to provide recommended ranges for parameters associated with management of ESRD patients. The aim of this study is to assess the QOL and adaptation in patients with ESRD on regular HD and to study the implantation of teaching of the European best practice guidelines on those types of patients.

Methods: Prospective study which was carried out on 95 patients. Two different tools were used in data collection to all subjects: Tool 1: Assessment sheet consists of four parts includes patients' socio demographic criteria, medical history, clinical data and laboratory investigations. Tool 2: QOL and adaptation assessment using Arabic form of SF-36 and brief cope.

Results: There were statistically significant improvement of HB, creatinine level, urea reduction ratio, phosphorus and albumin level after teaching of the guidelines. There were no statistically significant improvement of WBC, PLT, calcium level, kt/v and PTH level. There was statistically no-significant increased QOL in all domains after teaching of guidelines. There was sever decrease in all QOL domains . Median range of physical function was 54.50 (27.70 – 100) and mean limitation due to both physical health and emotional problems was 51.35 ± 21.08 and 51.40 ± 20.61 respectively. While mean energy feeling, Emotional wellbeing, Social functioning, Pain, General health were 48.91 ± 18.13, 49.56 ± 18.33, 43.83 ± 18.76, 58.20 ± 23.86 and 55.10 ± 18.89 in order.

Conclusions: : HRQOL is much lower in HD patients. The implementation of teaching guidelines has a positive effect on the studied patients' total knowledge and most of laboratory parameters while it has no significant effect on HRQOL for the studied patients regarding almost all domains. Continuous education should be provided by the healthcare team for HD patients.

Funding: Government Support - Non-U.S.

TH-PO926

A Quality Improvement Initiative Assessing Factors Improving Inadequate Hemodialysis in Hospitalized Patients

David M. Dewolfe, Robert S. Brown. *Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Hemodialysis (HD) adequacy is associated with a number of clinical outcomes, including hospitalizations and death. The adequacy of HD treatments in hospitalized patients is usually not measured and may not be achieved. This quality improvement (QI) study aimed to measure the adequacy of inpatient HD treatments and analyze the factors associated with improvement over time.

Methods: We performed a quality improvement initiative with retrospective cohort analysis of hospitalized patients undergoing HD in 2009, 2010 and 2015. The intervention was a comprehensive education initiative for nephrology fellows and attending physicians in prescribing adequate HD. The primary outcome was the frequency of adequate HD treatments defined as single pool Kt/V >1.2. Subsequently, we retrospectively compared factors affecting spKt/V to explain the observed improvement.

Results: Outside of the QI initiative, HD adequacy was not being routinely assessed throughout all time periods. The initial phases of the study in 2009 found only 44% of HD treatments were adequate with insignificant improvement in 2010. However, after initiation of a comprehensive education initiative, 94% of HD treatments were adequate in 2015 (P< 0.001 vs 2009) with mean spKt/V of 1.6±0.37 in 2015 compared to 1.1± 0.34 in 2009 (P<0.001). Retrospective analysis found no difference between 2009 and 2015 in patient size (81.87±28.05 Kg vs 73.46±19.68 Kg, P=0.13) or HD time (213.9±42.74 minutes vs 220.9±28.91 minutes, P= 0.47). A significant difference was observed in blood flow rates (344.4±39.66 ml/min vs 385.8±46.70 ml/min, P< 0.001) and in dialyzer size with only 13% of treatments in 2009 vs 75% in 2015 utilizing dialyzers with surface area ≥ 1.8 m^2 (P<0.001).

Conclusions: Inpatient HD adequacy was not being measured and initially found to be quite poor. Adequacy was improved by a focused QI program with more intensive training in HD prescriptions which lead to increased use of larger dialyzers and greater blood flow rates. To ensure that hospitalized patients receive adequate HD, measurements of adequacy should be undertaken to detect whether corrective action is necessary.

TH-PO927

The Association of Bilirubin and Mortality in Patients Underwent Regular Hemodialysis

Yen Chung Lin.[1,2] *[1]Div of Nephrology, Dept of Internal medicine, Taipei Medical Univ Hospital, Taipei, Taiwan; [2]Dept of Internal Medicine, School of Medicine, College of Medicine, Taipei Medical Univ, Taipei, Taiwan.*

Background: Bilirubin has the effect of anti-oxidation and anti-inflammation, benefiting in cardiovascular events, which is very common in end stage renal disease patients (ESRD) underwent regular hemodialysis. However, the association between mortality and bilirubin level in ESRD patients was not clear.

Methods: A total 102,599 patients in TWRDS, a national-wide end state renal disease registration system in Taiwan were surveyed. After deleting 45865 patients with an abnormal higher bilirubin >1.2 mg/dl or extremely lower bilirubin level <0.1 mg/dl. Finally, 47560 patients were analyzed in this study. Multi-variates adjusted cox proportional analyses were used to find out the relationship between the bilirubin groups (low <0.3 mg/dL, reference 0.3-0.7 mg/dL, high >0.7 mg/dL) and mortality during a 8 years follow-up.

Results: There were no obvious demographic difference between the groups of bilirubin levels. In the contrary, higher bilirubin was correlated with higher all-cause mortality. The cox proportional hazard ratio for death in high bilirubin group was 1.15 times (95 % CI 1.09-1.22, p < 0.01) higher than the reference group (bilirubin between 0.3-0.7 mg/dL). Every 1mg/dl increase in bilirubin had a 1.39 times (95% CI 1.26-1.53, p <0.01) higher the mortality risk.

Conclusions: Surprisingly, this study revealed that bilirubin had a negative impact on mortality in HD patients. Further solid evaluations are warranted to support this point of view.

TH-PO928

The Association between Dialysis Session Time and the Risk for Hospitalization and Death in Maintenance Hemodialysis Patients

Takahiro Kuragano, Takeshi Nakanishi. *Dept of Internal Medicine Div of Kidney and Dialysis, Div of Kidney and Dialysis, Nishinomiya, Japan.*

Background: Recently, dialysis efficiency was dramatically improved by using super flux dialysis membrane. However, in the condition of the common use of high flux dialysis, it has not been well studied the relationship between treatment time and adverse events or survivals of maintenance hemodialysis (MHD).

Methods: Subject: 805 patients undergoing MHD. Study design period: prospective, observational multi-center study of 3 years. Measurement: We measured serum levels of urea nitrogen (UN), creatinine (Cr), β2microgroblin (MG), total protein, albumin, prealbumin, high sensitive C reactive protein (hCRP) every 3month. We also evaluated body mass index (BMI), and Kt/V. The associations between dialysis intensity and adverse events or death were investigated with the cox proportional hazards model for time-dependent variables.

Results: Although there was no significant correlation between pre-dialysis levels of β2MG or UN and adverse event or survival, high pre-dialysis Cr level was associated with lower risk of hospitalization (HR:0.89, P=0.003) and death (HR:0.71, P=0.002). Moreover, high Kt/V was also associated with lower risk for cerebrovascular and cardiovascular disease (CCVD) (HR:0.37, P=0.039) and hospitalization (HR:0.55, P=0.026). There was no significant difference in serum levels of prealbumin, albumin, Cr, Kt/V and hCRP levels among 3 groups of treatment time (<4hours(h), 4-5h, >5h). On the other hand, BMI in the patients treated with >5h was significantly (p=0.012) higher than those of patients treated with <4h. In time dependent cox hazard model, the risk of hospitalization (HR:0.43, P=0.001) and death (HR:0.49, P=0.013) of patients treated with 4-5h were significantly lower than that of patients treated with <4h. Moreover, the risk of death in patients treated with >5h was significantly (HR:0.45, P=0.024) lower than that of treated with <4h.

Conclusions: Higher Kt/V was associated with lower risk of CCVD and hospitalization of MHD patients, but not pre-dialysis level of β2MG levels. Shorter dialysis session time (<4 hr) was associated with higher risk of hospitalization or death than that of longer treatment time.

TH-PO929

Vegetarian Diets Reduce Advanced Glycosylation End Product Deposition in the Skin in Chronic Hemodialysis Patients Arkom Nongnuch,[1,2] Andrew Davenport.[2] *[1]Renal Unit, Dept of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand; [2]UCL Centre for Nephrology, Royal Free Hospital, Univ College London, London, United Kingdom.*

Background: Advanced glycosylation end products (AGEs), are protein-bound uremic toxins and associated with increased risk of developing cardiovascular disease and mortality in HD patients. As AGEs are deposited in the skin, they can be measured by skin autofluorescence (SAF). Vegetarian diets potentially reduce AGEs formation, thus we desired to determine whether vegetarian diets reduce AGEs deposition.

Methods: Prospective repeated measurements were made in 180 prevalent hemodialysis patients in North London between June 2012 and September 2013. Clinical data and serial laboratory data were collected and were analysed by linear mixed effects model.

Results: A total of 180 HD patients were studied. Sixty-six percent were male and 45% had diabetes. The mean increased in SAF after 12 months was 0.27 ± 0.12 AU. Univariate analysis showed age, history of diabetes, peripheral vascular disease, prescription of lanthanum carbonate (LC), clopidogrel, insulin, warfarin, elevated CRP, vitamin D and HbA1c were positively associated with an increased in SAF, whereas non-Caucasian ethnicity, urine output >250 ml/day, serum albumin and vegetarian diets reduced skin AGEs deposition. Multivariate analysis revealed the usage of warfarin, LC, insulin and age significantly associated with increased in SAF, whereas urine output > 250 ml/day and vegetarian diet were associated with attenuated accumulation in SAF.

	Univariate analysis		Multivariate analysis		
Factors	Coefficient	P value	Coefficient	Confidence interval	P value
lantanum	0.37	0.006	0.36	0.11 to 0.6	0.004
clopidogrel	0.29	0.046			
Insulin use	0.211	0.10	0.29	0.055 to 0.52	0.016
Diabetes	0.274	0.022			
History of PVD	0.311	0.073			
Chronological age	0.01	0.018	0.013	0.005 to 0.02	0.002
Vegetarian	-0.7	0.001	-0.59	-0.96 to -0.21	0.002
Ethnics					
Asians	-0.419	0.003			
African-carribeans	-0.756	0.001			
urine output > 250/d	-0.229	0.072	-0.258	-0.49 to -0.2	0.033
vit D level	0.0035	0.052			
CRP	0.002	0.062			
albumin	-0.0219	0.049			
HbA1C	0.005	0.005			
Warfarin	0.6	0.024	0.62	0.14 to 1.1	0.012

Conclusions: Vegetarian diets and residual renal function (RRF) lessen AGEs accumulation in HD patients. Strategies to preserve RRF with low AGEs diets may reduce AGEs deposition and potentially reduced CVD risk in HD patients.

TH-PO930

Time-Varying Changes in Serum Albumin and Cytokines Predict HD Patient Mortality Paul L. Kimmel,[1] Kenneth J. Wilkins.[2] *[1]DHUHD, NIDDK NIH, Bethesda, MD; [2]Biostatistics Program, NIDDK NIH, Bethesda, MD.*

Background: High baseline circulating pro-inflammatory cytokine levels (CLs) are linked to ESRD hemodialysis (HD) patient (PT) mortality. Whether HD PT CLs are stable over time is unknown. Whether changes in CLs predict mortality, adjusting for known longitudinal predictors is unstudied.

Methods: We studied interleukin (IL)-1, IL-6 and Tumor-Necrosis Factor-α (TNF-α) CLs in 234 HD PTs (75 incident, 159 prevalent), followed a mean of 3.3 y with a median of 3 assessments at 3 centers in Washington, DC (total 763 person-y followup). CLs were skewed, ranging over 6 natural logs. Scatter plots revealed high and low groups for all cytokines at baseline. This ad hoc univariate grouping was assessed for each cytokine at baseline to have >90% accuracy by multivariate methods (K-means cluster, quadratic discriminant and principal components analyses). Groupings were then assessed for how well each predicted mortality using Cox models (adjusting for known time-varying predictors such as serum albumin [SAlb]), to compare the use of ad hoc high/low values, with log 4 as a threshold, as an alternative to clustering by baseline values or trajectories, with models using time-varying prediction by actual values.

Results: In the low IL-1 group (n=157), only 5% exhibited post-baseline values >4 log (54.6 pg/mL). In the high IL-1 group (n=77), only 13% exhibited values <4 log. A majority of CLs remained roughly constant over follow-up. 81% of variability is explained by individual mean CLs, with similar findings for IL-6 and TNF-α. Exceeding 4 logs of these levels predicted mortality using time-varying Cox models, even after adjusting for baseline CLs and trends in SAlb since the previous cytokine measure (HR, 95% CIs] IL-1: 3.3 [2.1, 5.3]; IL-6: 3.4 [2.2, 5.4]; TNF-α: 3.3 [2.1, 5.3]). No residual variation in events appears correlated with baseline CLs.

Conclusions: CLs exhibit limited variability over time in the majority of HD PTs. Longitudinal cytokine levels can be characterized as "high" or "low," according to baseline measurements with negligible misclassification, and predict mortality or survival. Such characterization will be useful in stratifying PTs for interventional trials.

A Novel Risk Factor for Hospitalization in Patients with ESRD Buthayna A. Dinary,[1] Jasmine Harris,[2] Nivetha Subramanian,[2] Michael S. Simonson,[1] Sharmeela Saha.[1] *[1]Nephrology and Hypertension, Univ Hospitals Case Medical Center and Case Western Reserve Univ School of Medicine, Cleveland, OH; [2]Case Western Reserve Univ School of Medicine, Cleveland, OH.*

Background: In the US dialysis population, the overall hospitalization rate in 2012 was 1.73 per patient year. 35.2% of prevalent hemodialysis patients were readmitted within 30 days of discharge. These readmission rates are twice that of the general Medicare population. Cognitive impairment (CI) may be a contributor. There are currently no standardized screening guidelines for the end-stage renal disease (ESRD) population. Our aim is to identify modifiable risk factors for re-hospitalization in a hemodialysis-treated ESRD population at a tertiary-care center.

Methods: We conducted a retrospective cohort study of hemodialysis patients greater than 18 years of age years at UHCMC between January 2015 and November, 2015, and followed until December 31, 2015. The primary outcome was the number of any-cause hospitalizations following the index admission. We collected information regarding patient demographics, comorbidities, medications and Mini-Cog score. The Mini-Cog test was used to assess whether or not a patient suffered from CI.

Results: A cohort of index admissions (n=40) was analyzed for a primary outcome of any-cause hospitalization per person. The most common causes of hospitalization were hypertensive emergency, cardiovascular, infection, access related issue, and hypervolemia. Lower serum albumin levels and higher systolic blood pressure strongly predicted higher hospitalization rate in a multivariate linear regression model (P = 0.003) adjusted for age, female sex and black race. In addition, hospitalizations were 2.3-fold higher in hemodialysis patients with cognitive impairment (P = 0.019). Cognitive impairment predicted hospitalizations independent of age, sex, and black race.

Conclusions: Our findings suggest that ESRD patients with cognitive impairment are at higher risk for hospitalization. Mini-Cog performance is a novel marker of re-hospitalization risk. Future studies will assess whether identification of CI and use of alternative learners reduces hospitalizations in hemodialysis patients.

Current Status of Hemodialysis in China, 2015 Xiang-Mei Chen, Ying Zheng. *Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Medical Quality Control Center for Kidney Diseases, MOH, Beijing.*

Background: In order to further understand the the current status of the patients of ESRD and hemodialysis in China, in May 2010, the first nationwide, web-based prospective renal data registration platform, the Chinese Renal Data System (CNRDS) was launched in China. The goal of the study was to determine the current status of hemodialysis in China by analyzed the data from CNRDS.

Methods: Data in CNDRS includes demographic, clinical, and laboratory data for dialysis cases. We analyzed the data from CNRDS by the end of 2014.

Results: There were 4089 domestic hemodialysis centers were registered by the end of 2015. On Dec. 31, 2015, 385055 prevalent cases were receiving hemodialysis therapy. Compared to 2014, the number increased by 45307 cases. The unadjusted prevalence (proportion) was 281.5 per million in the Chinese population. The number of incident cases receiving hemodialysis therapy in 2015 was 61790, which was the lowest since 2011. The unadjusted incidence rate was 45.2 per million/year. In the prevalent cases, 59.0% were male, the mean age and dialysis time was 55.7years and 46.7 months, respectively. Both of the age and dialysis time continue to increase since 2011. Though the proportion of glomerulonephritis declined to 54.2% in 2015, it was still the leading causes of ESRD who receiving hemodialysis therapy in prevalent cases. The proportion of diabetic nephropathy in incident cases was 21.2%, the number continues to rise. 13839 cases were died in 2015. 58.3% of them were male. The mean age and dialysis time was 62.7 years and 41.2 months, respectively. Both of the two number in mortality cases continue to increase since 2011. The main causes of death were cardiovascular events and stroke.

Conclusions: In recent years, the hemodialysis in China has made a great progress. As Chinese National Health and Family Planning Commission have enhanced the basic medical security system on hemodialysis, the population and prevalence of hemodialysis rose sharply during 2011-2015.

TH-PO933

Involuntary Discharges (IVDs): Analysis of Case Characteristics of End Stage Renal Disease (ESRD) Network 2 in New York before and after Bundled Payment Implementation by Centers for Medicare and Medicaid Services (CMS) Ranjeet Singh,[1] Brittany Kalosza,[1] Syeda Hussain,[2] Chaim Charytan,[2] George N. Coritsidis.[1] *[1]Nephrology, Elmhurst Medical Center, Elmhurst, NY; [2]Nephrology, New York-Presbytarian, Queens, NY.*

Background: Dialysis providers are authorized to involuntarily discharge patients under certain circumstances, as set forth in Medicare's Conditions of Coverage. We wanted to analyze how etiologies for the rate of IVDs have changed since the CMS prospective payment system for ESRD in 2011.

Methods: We collected IVD data reported to ESRD Network 2 from Jan-2007 to December-2015. Being the first year of the CMS changes 2011 data was excluded. Reasons for IVDs and patient characteristics were reviewed.

Results: 153 IVDs were identified. The number of IVDs increased following CMS bundled payment model from 66 patients (16.5 IVDs/year) to 87 patients (21.8 IVDs/year). Male patients had a significantly higher IVD rate before and after bundled payment. Rate of IVD of African Americans decreased after the CMS bundle (78.8 % vs 59.8 % respectively). The major reason for discharge continue to be behavioral issues (76.7%) followed by non-payment (19.3%).

Involuntary Discharge for Network 2	Total N = 153	2007-2010 43.14%(n=66)	2012-2015 56.86% (n=87)	p-value
Rate of IVD per Year		**16.5**	**21.8**	
Age	51.5	52.2	51.0	0.485
Sex, male, %(n)	71.2(109)	71.2(47)	71.3(62)	0.994
Race,%(n) Caucasian	30.1(46)	19.7(13)	38.0(33)	0.015
African American	68.0(104)	78.8(52)	59.8(52)	0.013
Asian	1.3 (2)	1.5(1)	1.2 (1)	0.382
Ethnicity, Latino %(n)	13.8 (21)	12.1(8)	15.1 (13)	0.596
Reason for Discharge,%(n)				
Behavioral	76.7(115)	81.0(51)	73.6(64)	0.291
Non-payment	19.3(29)	16.0(10)	21.9(19)	0.361
Non-Compliance	1.3 (2)	3.2 (2)	0.0	0.094

Conclusions: Analysis of data for NY reveal higher IVD rates after the bundled payment changes. IVD patients were younger than ESRD patients as a whole and IVD was predominantly due to behavioral issues. More Caucasians and fewer African Americans were IVDs after the CMS bundle, possibly indicating that racial disparities are equalizing.

TH-PO934

Intermediate Care Outcomes before and after Switching to Nocturnal In-Center Hemodialysis Adam S. Wilk,[1] Kristen Senetar,[1] Laura Plantinga,[1] Janice P. Lea.[2] *[1]Emory Univ; [2]Emory Dialysis Centers, Emory Healthcare.*

Background: Nocturnal dialysis (ND) can support longer sessions with lower ultrafiltration (UF) rates, compared to traditional (daytime) in-center hemodialysis. We compare dialysis care traits and intermediate health outcomes for ND patients before and after they initiate ND treatment.

Methods: Among patients undergoing hemodialysis at a medium-sized dialysis organization, we identified ND patients as those for whom at least 80% of dialysis sessions over a 3-month window (≥20 sessions) began at 6:30pm or later and lasted 5 hours or more. For these patients, we extracted dialysis treatment orders and session records, demographics, and other electronic health record data relevant for within 90 days of ND transition. We estimated session-level ordinary least squares regression models of key intermediate outcomes—session duration, UF rate, completed session rate (fraction with at least 90% of treatment order time), pre-session blood pressure (systolic [SBP] and diastolic [DBP]), and lowest recorded intradialytic SBP and DBP—to identify conditional effects of post-transition ND care status, clustering standard errors within patients.

Results: We identified 55 ND patients (3.9% of 1,420 patients in care), with 1,065 pre-transition sessions and 1,877 post-transition ND sessions. Relative to pre-transition sessions, post-transition ND sessions were 3.2 hours longer ($p<0.001$), had UF rates 4.9 ml/h/kg lower ($p<0.001$), and were completed equally often ($p=0.9$). Likewise, patients' SBP and DBP levels, both pre-session and lowest intradialytic, were not significantly different pre- vs post-transition, though we observed small but statistically significant declines over time across post-transition ND sessions in nearly all SBP and DBP outcomes.

Conclusions: ND treatment sessions were longer than pre-transition hemodialysis sessions and had lower UF rates, but ND did not affect patients' session completion rates or absolute SBP and DBP levels. For patients selecting into ND, the effect appears to be as intended.

TH-PO935

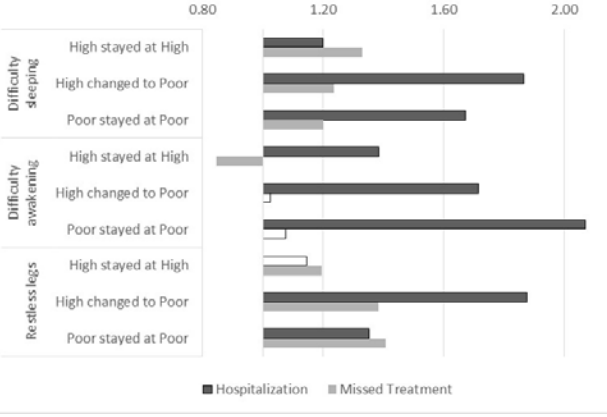
Improved Sleep Quality Is Associated with Reduced Hospitalization Rate and Increased Treatment Adherence in Hemodialysis Patients Nien-Chen Li, Felicia N. Speed, Marta Reviriego-Mendoza, John W. Larkin, Norma J. Ofsthun, Stephanie Johnstone, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Patients (pts) with end-stage renal disease often suffer from sleep disorders. We investigated if a social worker (SW) quality improvement program effects sleep quality (SQ), and subsequently alters rates of hospitalizations and treatment adherence in a cohort of hemodialysis (HD) pts.

Methods: HD pts (869) enrolled in an 8-week SW program between 7/1/2013 and 2/28/2014 were provided a 5-item SQ questionnaire before and after the SW intervention. Using a factor analysis, 5 items were reduced to 3: difficulty sleeping, difficulty awakening, and restless legs during sleep. For each item, SQ was defined as "high" for scores better than the baseline median and "poor" otherwise. Hospitalization and missed treatment data were captured 1 year before and after intervention. Rate ratios (RR) in hospitalization and missed treatment, stratified by changes in SQ were analyzed using Poisson regression, offset with the length of exposure period and adjusted for baseline hospitalization or missed treatment count, age, gender, race, diabetes, coronary artery disease (CAD), and congestive heart failure (CHF).

Results: Pts had a mean age of 55.3 ± 14.1 years, 51.8% males, 69.7% white, and 58.6% with diabetes, 19.5% CAD, and 38.1% CHF. The impact of changes in SQ parameters on hospitalization and missed treatment rates are detailed in Figure 1. That is, in almost all cases, RR > 1 indicating higher risk in hospitalization and/or missed treatment when comparing with SQ improved from poor to high after intervention.

Figure 1. RR (Rate Ratio) in Hospitalization and Missed Treatment by Change in SQ Before and After Intervention (Ref: SQ changed from Poor to High, all RR are significant p<.05 unless no fills)



Conclusions: The findings suggest that the SW program was associated with improvements in SQ and, in turn, with reductions in hospitalization risk and better adherence to HD treatments. Implementing a strong QS program in HD clinics may improve HD pts' outcomes.

TH-PO936

Associations between Sleep Quality and Quality of Life, Stress, and Depressive Symptoms in Hemodialysis Patients Nien-Chen Li, Stephanie Johnstone, Felicia N. Speed, Marta Reviriego-Mendoza, John W. Larkin, Norma J. Ofsthun, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: We investigated if implementing a social worker (SW) quality improvement program resulted in better sleep quality (SQ) and thus, improved depressive symptoms, psychosocial stress, pain perception and Kidney Disease Quality of Life (KDQOL) scores in HD pts.

Methods: We analyzed data from 869 pts at Fresenius Medical Care North America enrolled into the 8-week SW program between 7/1/13 and 2/28/14. SQ was assessed before and after the SW program. The original SQ 5-item assessment was reduced to 3-items by way of factor analysis: difficulty sleeping, difficulty awakening and restless legs during sleep. We used the following questionnaires: the center for epidemiologic studies depression scale-10 (CESD-10), KDQOL, Psychosocial Stressor Screening tool, and Comfort Barriers Screening tool (pain items). Paired t-tests were used to compare means of Pt data before and after implementing the SW program. Regression analysis was used to assess associations of changes in questionnaire scores and SQ, adjusted for baseline score, age, gender, race, and diabetes, coronary artery disease (CAD), and congestive heart failure (CHF).

Results: Pts in the study had mean age of 55 ± 14 years, 52% males, 70% white, and 59% with diabetes, 20% CAD, and 38% CHF. Results show that SQ improved after SW intervention (all $p<0.05$). We found that: i) improvements in CESD, mental component score (MCS), burden of kidney disease, and stress indicators were significantly associated

with improvements in difficulty sleeping (all p<0.01), ii) improvements in CESD and heath symptoms and loss/grief stressors were associated with improvements in difficulty awakening (all p<0.01), and iii) improvements in CESD and financial/insurance and family/relationships stressors were associated with less restless legs during sleep (p<0.02).

Conclusions: Our study indicates that improvements in SQ are associated with improvements in depressive symptoms, psychosocial stress, MCS, and KDQOL measures in HD patients. SW interventions may aid in improving pts' SQ and, consequently, HD outcomes.

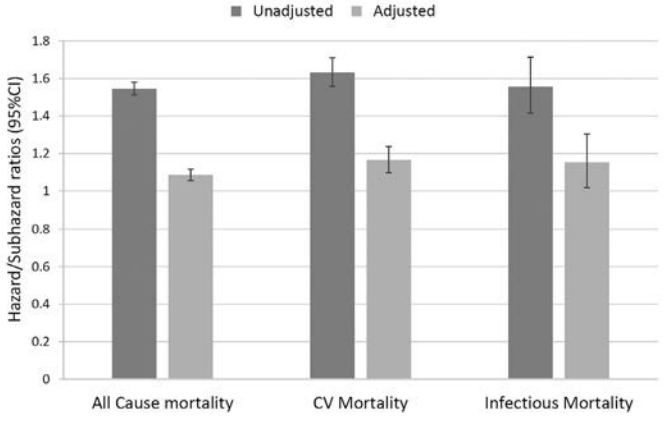
TH-PO937

Outcomes Associated with Inpatient versus Outpatient Hemodialysis Initiation in a Large Incident ESRD Cohort Faisal M. Arif,[1] Miklos Zsolt Molnar,[1] Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Jun Ling Lu,[1] Geeta G. Gyamlani, Fatima Hassan,[1] Fridtjof Thomas,[1] Elani Streja,[2] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine; [3]VA Medical Center, Memphis, TN.*

Background: The setting (Inpatient vs. Outpatient) of chronic HD initiation could be determined by medical (e.g. comorbidities) or other factors (e.g. no available mature vascular access). It is unclear if the setting of HD initiation is associated with mortality risk in the post-dialysis period.

Methods: We examined the association of inpatient (vs. outpatient) HD initiation with all-cause and cause-specific mortality in 48,261 US veterans transitioning to HD between 10/2007-09/2011. Associations were examined in Cox (all-cause mortality) and competing risk regression models (cause-specific mortality), adjusted for demographics, comorbidities, vascular access type, predialysis Nephrology care and medication use, and pre-ESRD eGFR and hemoglobin.

Results: 22,338 (46.3%) patients started HD as inpatients. Inpatient HD start was associated with older age, presence of a tunneled catheter, and more comorbidity. Higher hemoglobin, lower eGFR and predialysis use of active vitamin D were associated with outpatient HD start. 32,323 patients died over a median follow up time of 2.1 years (mortality rate, 95%CI: 290/1000 patient-years, 287-293). Inpatient vs. outpatient HD start was associated with significantly higher crude all-cause, CV and infectious mortality. These associations were substantially attenuated, but remained significant after multivariable adjustment (Figure).



Conclusions: Veterans who transitioned to HD in a hospital setting experienced significantly higher mortality following dialysis initiation. Better predialysis care may allow more patients to initiate HD as outpatient. Future studies are needed to examine the impact of this on mortality.

Funding: NIDDK Support, VA Support

TH-PO938

Outbreak of Gram Negative Bacilli Non Fermenters Associated to the Lack of Chlorine in Pre-Treated Water for Hemodialysis Cinthia Sobral Vieira, Claudio Stadnick, Ethel Ribas, Rozeli Biedrzycki, Andressa Kowal, Gisele Lobato, Gabriela Sobral Vieira. *Nephrology Unit, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.*

Background: Bacteremia presented during dialysis can lead to harmful outcome to patients. Varied reasons are cited, long associated with the use of catheters. When in outbreak the whole process must be thoroughly analyzed. Our purpose is to report possible causes of bacteremia and the subsequent assessment of the outbreak occurred in a hemodialysis service.

Methods: Between March and April 2016, there were 20 cases of bacteremia in patients under hemodialysis therapy in a private hospital in South of Brasil The blood cultures showed Gram-negative bacilli non fermenters (GNBNF) commonly associated to water contamination. Physical-chemical, microbiological analyses of all materials used for hemodialysis were carried out including water. At the same time, sanitization, deodorization and exchange resins in water purification system were realized.

Results: 20/98 patients with bacteremia presented GNBNF. They were *Stenotrophomonas maltophilia, Burkholderia cepacia, Ralstonia mannitolilytica and Ralstonia pickettii*. Reverse osmose were used for water treatment and the dialyzers were manually reprocessed. The microbiological tests showed that the growth of colonies occurred after activated carbon. The potable water produced during the epidemic period, had chlorine concentrations below the desirable standards imposed by the guide of best practices in dialysis in Brasil which requires 0.5 mg/l maximum for chlorine. The chlorine free water was arriving very hot to the reverse osmose, suggesting that chlorine evaporated during passage through the external plumbing and favoring the bacterial growth. It was a very hot summer with long distance from the water tower to the reverse osmose suggesting a mixture with water from central boiler. Individualized plumbing (exclusively from public water system) and an extra 10.000 liters water tank were installed before water treatment room and no more cases were seen.

Conclusions: It is imperative to monitor all procedures involving the water used in the process of hemodialysis. Cases are avoided when the focus of the outbreak quickly and effectively is found.

Funding: Private Foundation Support

TH-PO939

Negative Correlation of Serum Adiponectin Level with Peripheral Artery Disease in Hemodialysis Patients Yu-Hsien Lai,[1] Bang-Gee Hsu.[2] *[1]Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]Buddhist Tzu Chi General Hospital, Hualien, Taiwan.*

Background: Adiponectin is a fat-derived hormone produced and secretedexclusively by adipocytes that have anti-atherosclerotic effects. Peripheral arterial disease is associated with an increased risk of death in hemodialysis (HD) patients. The aim of this study was to evaluate the relationship between serum adiponectin levels and peripheral artery disease by ankle-brachial index (ABI) in HD patients.

Methods: Blood samples were obtained from 100 HD patients. The ABI values were measured using an ABI-form device (VaSera VS-1000). Serum adiponectin levels were measured using a commercial enzyme-linked immunosorbent assay kit. Left or right ABI values that were < 0.9 were included in the low ABI group.

Results: Among 100 HD recipients, 18 patients (18.0%) were in the low ABI group. Compared with patients in the normal ABI group, patients in the low ABI group had higher prevalence of diabetes (p = 0.043), older age (p = 0.027), and lower serum adiponectin level (p = 0.003). HD patients with diabetes mellitus (DM) had lower serum adiponectin level than non-DM HD patients (p = 0.016). According to multivariable forward stepwise linear regression analysisshowed that waist circumference (β: -0.216, p = 0.029), log transformed triglyceride (log-TG) (β: -0.230, p = 0.019), and log transformed C-reactive protein (log-CRP) (β: -0.241, p = 0.008) were the independent predictors of adiponectin level in HD patients, and multivariate logistic regression analysis, adiponectin (Odds ratio [OR]: 0.927, 95% confidence interval [CI]: 0.867-0.990, p = 0.025) and age (OR: 1.054, 95% CI: 1.002-1.109, p = 0.043) was the independent predictors of peripheral arterial disease in HD patients. The sensitivity, specificity, positive predictive value, negative predictive value, and area under the receiver-operating characteristic (ROC) curve predicting peripheral arterial disease in HD patients were 72.22%, 64.63%, 36.68%, 99.92%, and 0.691 (95% CI: 0.591-0.780, p = 0.008), and the adiponectin cut-off value was 43.27 μg/mL.

Conclusions: In this study, serum adiponectin level was proved to be involved in the pathogenetic process of peripheral arterial disease in HD patients.

TH-PO940

Impacts of Insurance Type on Hospitalization and Mortality Rates in Hemodialysis Patients Xiaoling Ye,[1] John W. Larkin,[2] Marta Reviriego-Mendoza,[2] Len A. Usvyat,[2] Peter Kotanko,[1,3] Franklin W. Maddux.[2] *[1]Renal Research Inst, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Insurance types may be associated with outcomes in chronic hemodialysis (HD) patients (Pts). We compared outcomes in Pts who initiated and remained on HD with commercial insurance (COM) to matched Medicare fee-for-service Pts with comparable demographic and clinical parameters.

Methods: We analyzed data from 2008 to 2014 on 16,357 Pts at FMCNA who initiated and survived 6 months(mo) on HD with COM as primary coverage. Pts with Medicare primary coverage who survived 6mo on HD were identified using 1:1 nearest neighbor matching on logit of propensity score for race, gender, HD initiation year, and 15 comorbidities, as well as number of in-center treatments, hospitalization rate, adherence rate, treatment time, pre-HD SBP, IDWG, and Kt/V in first 6 mo of HD. We performed exact matching for: age, race, diabetes, % of treatments with catheter, mean albumin, and mean BMI during first 6mo of HD; Pts without an exact match were excluded. We compared 12mo hospitalization and mortality rates per patient year (ppy) in groups after first 6mo of HD.

Results: Data from a total of 3,280 HD Pts was analyzed (1,640 COM & Medicare Pts each). We found Pts starting the first 6mo of HD covered by COM had 0.45 (95 CI,0.44–0.46) less hospitalizations ppy, compared to matched Medicare Pts (p<0.001) [figure1]. Similarly, we observed 1.49 (95%CI,1.41-1.60) fewer deaths ppy for COM Pts versus Medicare patients (p<0.001).

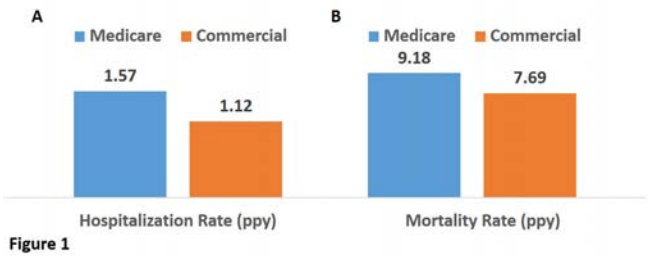


Figure 1

Conclusions: Our analysis suggests that Pts who initiate and remain on HD with COM may have lower hospitalization and mortality rates when compared to their Medicare peers. Further analyses are warranted to understand these differences in outcomes and whether patient characteristics or plan benefits are involved.

TH-PO941

Effect of Interdialytic Time on Outcomes in Chronic Hemodialysis Patients

Jalal E. Hakmei, Wayne R. Fitzgibbon, Michael E. Ullian. *Nephrology (Medicine), Medical Univ of South Carolina, Charleston, SC.*

Background: Most chronic hemodialysis (HD) patients dialyze on MonWedFri or TueThuSat. Prior studies suggest that the risk of cardiovascular events (CVEs) is highest after the weekend, ie Mon and Tue, respectively. Since our Veterans Administration (VA) Hospital HD unit is closed on weekends, non-traditional HD schedules were created, ie 3-day weekends (compared to the usual 2-day weekend). We wondered if more frequent CVEs and greater mortality occurred after longer inter-HD time intervals.

Methods: We reviewed charts of all chronic HD patients since 2002, when the VA electronic medical record was initiated. Patients were placed on a HD schedule randomly. Those dialyzed for at least 3 months (4 - 144, median 21) without change in HD schedule were studied (n = 85). Those dialyzing on MonWedFri and MonTueFri (n = 29) constituted the short-weekend group (SWG), and those dialyzing on MonWedThu, MonTueThu, TueWedFri, and TueThuFri (n = 56) constituted the long-weekend group (LWG). Outcomes consisted of all-cause mortality, CVEs requiring hospital visits, and day in HD schedule when CVEs occurred: D-0, during and after HD; D-1, 1st day after last HD; D-2, 2nd day after last HD; D-3, 3rd day after last HD; D-4, 4th day after last HD.

Results: Demographics and co-morbidities of the 2 groups were similar, except for more coronary artery disease ($p < 0.03$) and higher serum phosphorus concentration ($p < 0.001$) in SWG. All-cause mortality was not different between groups, even after normalization for coronary artery disease and serum phosphorus level. For each group, we compared observed CVE rates to expected CVE rates (null hypothesis: CVEs were expected to occur at the same rate on D-0, D-1, D-2, D-3, and D-4). For D-0, we observed 56% more CVEs than expected in SWG, and we observed the expected rate of CVEs (-4%) in LWG. In SWG, we observed 52% fewer CVEs than expected on D-1, 22% fewer on D-2, and 340% more on D-3; in LWG, we observed 67% fewer CVEs than expected on D-1, 52% fewer on D-2, 227% more on D-3, and 352% more on D-4 (both $p < 0.05$ for trend).

Conclusions: In chronic HD patients, CVEs occur more frequently after longer inter-HD intervals.

Cytokine Removal by Different Dialysis Membranes

Markus Storr, Michael Hulko, Julia Gauss, Rose Speidel, Bernd Krause. *Dialyzer R&D, Gambro Dialysatoren GmbH (Part of Baxter International Inc.), Hechingen, Germany.*

Background: The purpose was to compare the removal efficiency of inflammatory and cell activating molecules by different types of dialysis membranes with a standardized in vitro test system.

Methods: Mini-dialyzers (membrane area 360 cm²) were prepared from commercial dialyzers Polyflux Revaclear (PR), Fresenius Cordiax (FC), highflux membranes with extended permeability (MCO1, MCO4) and HCO1100 (HCO). They were tested in an in vitro dialysis setup with 220 ml recirculating human serum on blood side (10 ml/min) and 220 ml recirculating bicarbonate dialysis fluid on dialysate side (25 ml/min) in countercurrent flow without net ultrafiltration at 37°C for 90 min. Serum solution was prepared from LPS activated whole blood as uniform solution divided into identical fractions. Samples were analyzed with an Interleukin-6 (IL6) ELISA kit. Dialysate samples were added to 3 different cell systems and cell activation was studied. Tubular epithelial cells (TEC) and normal human dermal fibroblasts (NHDF) were analyzed for IL6 generation; and human whole blood was FACS analyzed for CD11b expression on granulocytes.

Results: Serum IL6 decrease, IL6 recovery in dialysate and cell activation of TEC, NHDF and granulocytes by dialysate samples at 90 min are displayed in table below. IL6 starting concentration was 8667 pg/ml. Numbers are given as mean +/- standard deviation of 3 independent runs.

Membrane type	Serum IL6 decrease [pg/ml]	Dialysate IL6 recovery [pg/ml]	TEC IL6 [ng/10^6 cells]	NHDF IL6 [ng/10^6 cells]	CD11b on granulocytes [GeoMean signal]
PR	687 ± 310	399 ± 57	14 ± 0.6	643 ± 71	376 ± 16
FC	37 ± 107	190 ± 66	12 ± 0.8	584 ± 178	325 ± 18
MCO1	1047 ± 109	744 ± 111	20 ± 0.6	866 ± 115	417 ± 27
MCO4	1366 ± 371	1302 ± 136	28 ± 0.5	930 ± 41	496 ± 61
HCO	2175 ± 734	2075 ± 268	35 ± 3.6	831 ±18	651 ± 46
Dialysis fluid control	na	na	3 ± 0.1	1 ± 0.1	437

Conclusions: In a standardized test system different membranes were compared by their removal efficiency of specific pro-inflammatory mediators like IL6 and their general capacity to remove cell activating molecules measured by cell responses in 3 cell assays.

TH-PO943

MCO Dialyzer: Enhanced High-Flux Membrane with Expanded Toxin Removal

Markus Storr, Adriana Boschetti-de-Fierro, Manuel Voigt, Michael Hulko, Bernd Krause. *Research & Development, Gambro Dialysatoren GmbH, Hechingen, Germany.*

Background: MCO is a newly designed high-flux dialyzer providing improved selectivity that extends the spectrum of toxins removed during treatment. The purpose of this study is to compare the MCO in-vitro plasma clearances of different middle molecules to those for different high-flux dialyzers.

Methods: Middle/large molecule clearances of Theranova 400 (MCO, Gambro), Revaclear 400 (HF-PAES, Gambro), Optiflux F180NR (HF-PSu, Fresenius) and Elisio 17H (HF-PES, Nipro) dialyzers were compared. HD treatments were simulated with Q_B=400 ml/min and Q_D=700 ml/min. In each experiment (n=3), 1 L of uniform human plasma (octaplasLG, protein concentration 60 g/L) was recirculated for 60 min and followed by a 60 min simulated treatment. Markers (human) were spiked into the plasma pool after 55 min of recirculation: β2-microglobulin (5 mg), myoglobin (500 µg), and κ-FLC (~300 mg), while interleukin 6 is comprised in plasma. Pool and dialysate samples were taken after defined time intervals. Each marker concentration was measured by nephelometry and the clearance was calculated from the first order kinetics for the pool concentration variation with time.

Results: In vitro clearances for the MCO dialyzer in HD were consistently higher than those shown by all other dialyzers investigated. For κ-FLC and IL-6, the largest markers, all regular high-flux dialyzers showed only one-digit clearance values.

Devices	Surface area [m²]	Clearances Q_B=400 ml/min [ml/min]			
		b2m	Myo	κ-FLC	IL-6
		12 kDa	17 kDa	22.5 kDa	20-26 kDa
MCO	1.7	93 ± 5	61 ± 1	20 ± 1	12 ± 2
HF-PAES	1.8	71 ± 2	19 ± 2	6 ± 1	5 ± 1
HF-PSu	1.8	44 ± 3	4.2 ± 0.3	0.1 ± 0.1	2 ± 3
HF-PES	1.7	71 ± 1	17.5 ± 0.1	5 ± 1	3 ± 1

Conclusions: MCO delivers slightly better in vitro plasma clearances for β2m to that of HF-PES and HF-PAES, and larger than that of HF-PSu. Additionally, MCO shows superior removal of molecules in the range between 15 and 30 kDa against all comparators. This expanded toxin removal is in good agreement with the results from pilot clinical studies recently conducted in Europe [Krieter et al, ERA-EDTA 2016].

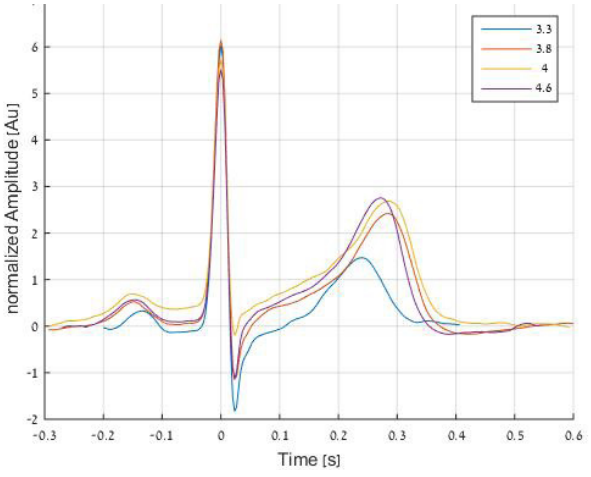
Bloodless Potassium Measurement Using Mathematically-Processed, Signal-Averaged Electrocardiography

John J. Dillon,[1] Zachi I. Attia,[2] Omar Ziad Yasin,[2] Christopher G. Scott,[6] Jennifer Dugan,[2] Gaurav Satam,[4] Dorothy J. Ladewig,[4] Michael J. Ackerman,[2] Virend K. Somers,[2] Kevin E. Bennet,[5] Dan Sadot,[3] Paul Friedman.[2] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN; [3]Electrical and Computer Engineering, Ben-Gurion Univ of the Negev, Beer Sheva, Israel; [4]Mayo Clinic Ventures, Mayo Clinic, Rochester, MN; [5]Engineering, Mayo Clinic, Rochester, MN; [6]Statistics, Mayo Clinic, Rochester, MN.*

Background: Detecting hyperkalemia is limited by the need for blood testing. We have described non-invasive K measurement using the 12-lead, surface ECG. We now describe using these methods with a smartphone-based, single-lead device.

Methods: 14 adult hemodialysis patients had serum K and simultaneous, 2 minute ECG's recordings before dialysis, at 30 minutes, at 60 minutes at the end of dialysis, and optionally, on a non-dialysis day. ECG's (lead 1 only) were obtained by placing both hands on a 2-lead, Kardia device attached to the back of an Android smart phone. Using advanced signal processing, we used (t right slope)/(t amplitude)$^{1/2}$ from the first dialysis to create individual templates which were used to predict subsequent K values.

Results: 4 patients had inadequate data due to hand tremors or poor, lead-1 t wave morphology. Among the other 10 patients, mean K during the 1st dialysis was 5.2±0.7 maximum and 3.6±0.5 minimum. Subsequent K values were similar. For the predicted values, the mean absolute error (observed - predicted) was 0.4±0.2 mmol/L. Processed ECG changes between K 3.3 and 4.6 in one patient are shown in figure 1.



Conclusions: With signal processing, single-lead ECG can be used to bloodlessly measure potassium with clinically meaningful resolution. This enables remote and/or continuous K monitoring. Some patients require a device that is not affected by hand tremor or that can monitor a lead other than lead 1.

TH-PO945

Influence of Membranes and Hemodialysis Technique on Phenol and P-Cresol Clearance Jose A. Herrero, Mariana Garbiras, Amir Shabaka, Isabel Ortega, Mj Torrejon, Fernando Tornero, Virginia López de la Manzanara Pérez, Jesús Delgado-Domínguez. *Nephrology, Hospital Clinico San Carlos, Madrid, Spain.*

Background: Binding of Phenol and p-Cresol to proteins hinders their clearance in hemodialysis (HD). Our objective was to determine phenol and p-Cresol clearance with membranes of different adsorption and filtration capacity with different HD techniques.

Methods: In 16 patients, 13 males, mean age 62±17.5 years, Phenol and p-Cresol clearance was determined with; a)Toray polysulfone(PS) 2.1 m^2 Kuf 55 ml/h/mmHg on conventional HD(PS-HD), b)PS on online postdilutional hemodiafiltration(PS-HDF) c) Polymethyl methacrylate 2.1 m^2 Kuf 43 ml/h/mmHg (Great adsorption capacity) on HD(PMMA-HD), d)PMMA on HDF(PMMA-HDF). Each session lasted 4 hours and Phenol, p-Cresol, β_2-microglobulin(β_2-m), albumin and urea serum levels were determined before and after each session. Post-HD β_2-m, phenol and p-cresol levels were adjusted for variations in serum albumin. Their percentage reduction(PR), total processed blood volume(PBV) and infusion volume in HDF, and KT were measured.

Results: There were no differences in total PBV between the four procedures. Infusion volume in HDF was higher with PS than with PMMA (26.1±2.4 vs. 17.6±2.3 l/session,p=<0.001). There were no differences in Phenol and p-Cresol clearance between HDF and HD when using the same membrane. Phenol clearance was higher than that of p-Cresol in all combinations(p<0,001). Phenol and p-Cresol clearance was higher with PS than with PMMA in both HD and HDF. β_2-m clearance differed with different membranes and techniques.

	PMMA-HD	PMMA-HDF	PS-HD	PS-HDF
PR Phenol(%)	61.3±8.9	62.4±12.1	69.0±10.6[a]	68.7±8.9[b]
PR p-Cresol(%)	39.8±10.5	39.7±10.0	46.5±10.0	45.0±7.2
PR β_2-m(%)	53.1±5.2[c]	65.9±4.7[c]	70.9±3.8[c]	81.8±3.2[c]
KT(l)	54.0±4.4	56.1±4.9	56.7±3.7	59.9±3.3[d]

a)p=0.025 vs PMMA-HD;b)p=0.045 vs PMMA-HDF;c)p<0,05 in all values of β_2-m;d)p=0.02 vs the rest.

Conclusions: 1) In HD and HDF Phenol clearance is higher than that of p-Cresol. 2) PS membranes achieve a higher Phenol and β_2-m clearance than PMMA in both HD and HDF. 3) HDF does not increase Phenol or p-Cresol clearance compared to HD with neither PS nor PMMA.

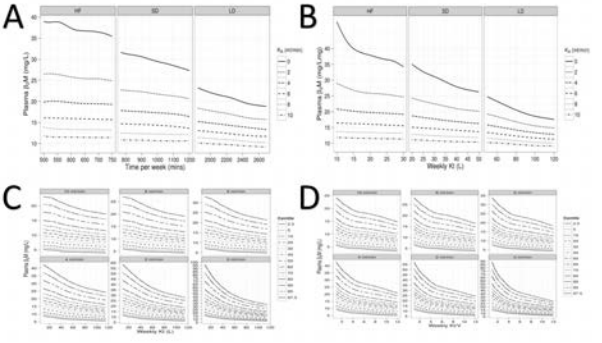
TH-PO946

Simplified Kinetic Indices and Population Exposures to Middle Molecules across the Range of Residual Renal Functions Hafiz Ali Sroya, Christos Argyropoulos, Maria-Eleni Roumelioti, Mark L. Unruh. *UNM School of Medicine.*

Background: Beta 2 Microglobulin (β2M) is a uremic toxin that accumulates in ESRD patients. Elevated plasma β2M concentrations is linked to higher mortality in patients undergoing hemodialysis. The population kinetics of β2M has been described in the literature but the application of available kinetic models to predict dialysis induced changes in β2M concentrations has been limited.

Methods: We did a quantitative patient-level review of available data of β_2M population kinetic models to predict plasma β2M concentrations in a population of simulated ESRD patients on hemodialysis with different levels of residual renal functions. We compared dialyzer clearance in patients receiving high flux dialysis under different regimes; conventional thrice weekly dialysis (HF), short daily (SD) and long daily (LD) sessions. We also examined the ability of simplified kinetic indices to quantify the effects of different dialysis schedules on plasma β_2M concentrations across the range of residual renal functions.

Results: Longer weekly dialysis time resulted in lower β_2M concentrations irrespective of dialysis regimes. There was a sharp reduction in mean predialysis β_2M concentration in patients with K_R < 4ml/min as Kt increased from 10 to 15 L, followed by a gradual decline. At population level, the effect of fixed Kt (or Kt/V) was different depending on residual renal functions. Only 2.5% of patients with K_R =10ml/min had β_2M >20mg/L versus 80% of patients with KR =0ml/min. The effect of Kt/V on population centiles of β_2M appeared to be biphasic, the steeper effect at Kt/V < 4 and less steeper at Kt/V >4.



Conclusions: While weekly Kt (or Kt/V) can be used to quantitate the effects of different dialysis regimes, understanding of its effect at population level can effectively be used prescribing dialysis dose across the population of patient at different residual renal functions.

TH-PO947

Hemodialysis Water Purification, Disinfection and Monitoring Practices in Bangladesh Sadiq Ahmed. *Nephrology, Univ of KY, Lexington, KY.*

Background: To provide ESRD patients with safe dialysis is a challenge due to technical & economic constraints in Bangladesh. In Bangladesh the numbers of ESRD patients are doubled in recent years. Most of these patients are on HD with very high mortality. Proper water purification is essential for providing safe HD treatment.This study looks at the dialysis water chemical composition and the disinfection protocols and monitoring practices in two major dialysis units in Dhaka, Bangladesh.

Methods: In 2015 two major chronic HD units, A & B, in Bangladesh were visited. The technicians and Nephrologists were interviewed. The samples of feed water and the final products before the dialysis was analyzed by Spectra lab USA. Some of the chemicals of the waters from units A & B in table: I and the water monitoring practices of the units are in table II. Table I shows that unit B has high levels of certain chemicals in the purified water. Table II shows that a routine disinfection and monitoring protocol is not followed.

Results: Table I

Analytes	A	B	Normal range mg/L
Aluminum	<.005	**0.184**	0.000-0.010
Arsenic	<.005	<0.005	0.000-0.006
Calcium	1.986	**6.699**	0.000-2.000
Copper	<.005	0.067	0.000-0.100
Fluoride	<0.10	<0.10	0.00-0.20
Lead	<0.002	**0.011**	0.000-0.005
Magnesium	0.737	1.190	0.000-4.000
Zinc	<.005	**0.644**	0.000-0.100

Table II

Water maintenance	Unit A	Unit B	USA
Check Chlorine and Chloramine	No	No	Yes. Before each shift
Routine check for endotoxin and bacterial culture	No	No	Yes
Chemical analysis	yearly	6 month	6 month
Routine disinfection of RO	No	No	Yes
Check Ph. and conductivity by a separate meter	No	No	Yes
Nephrologist involved in the process	None or minimum	None or minimum	Yes

Conclusions: Proper purification and disinfection protocols with routine monitoring of water quality is essential for safe hemodialysis. This is a challenge in the developing nations like Bangladesh due to cost but more due to lack of awareness. Routine monitoring of water quality & following disinfection protocols are not very expensive as the technology is locally available. Organizations like ISN or WHO can take initiatives to provide education & help in this area.

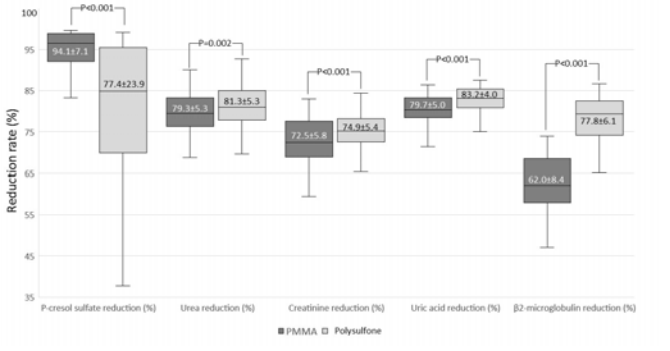
Combining Difussion, Convection and Absorption: A Pilot, Cross-Over Study of Polymethylmetacriylate versus Polysulfone High-Flux Dialysis Membranes in the Removal of P-Cresol Sulfate by On-Line Hemodiafiltration

Pablo Molina,[1] Julio Peiró-García,[2] Cristina Esteller Beltrán,[2] María Amparo Martínez Gómez,[3] Sandra Beltrán,[1] Belen Vizcaino,[1] Mercedes Gonzalez,[1] Irina Sanchis,[1] Luis M. Pallardo,[1] Francisco Maduell.[4] *[1]Nephrology, Dr Peset Univ Hospital, Spain; [2]Clinical Analysis, Dr Peset Univ Hospital, Spain; [3]Pharmacology, Dr Peset Univ Hospital, Sri Lanka; [4]Nephrology, Hospital Clinic Barcelona, Spain.*

Background: Only a few studies have examined how to improve the protein-bound toxins removal by extracorporeal strategies. This study tested the hypothesis that polymethylmetacriylate *(*PMMA) dialysis membranes with a high adsorptive capacity increase P-cresol sulfate removal compared to standard high-flux (HF) membranes, by on-line hemodiafiltration (OL-HDF).

Methods: 40 stable hemodialysis patients were enrolled in a prospective, cross-over study and treated with PMMA and polysulfone HF membranes by OL-HDF with postdilutional infusion. One session with each dialyzer was performed (PMMA BG2.1U, and polysulfone TS2.1). Primary end point was serum p-cresol sulfate reduction rate, determined by chromatography. Secondary end points included the convective volume achieved and the β_2-microglobulin (β2M) and small solute clearances. Dialysis procedures remained unchanged during both sessions.

Results: PMMA membrane achieved significantly greater p-cresol sulfate reduction ratio (94.1 vs. 77.4%; p<0.001). There was no difference in Kt/V (2.2±1.0 Vs. 2.2±0.4; p=0.325) although small molecules removal was better with polysulfone. The convection volume (20.4±3.3 Vs. 31.4±8.4 L/session; p<0.001) and β2M reduction ratio (62.0 Vs.77.8%; p<0.001) were significantly lower with PMMA membrane.



Conclusions: P-cresol sulfate removal by OL-HDF was superior with PMMA membranes, appearing to be a good dialysis strategy for improving dialytic clearance of p-cresol, enabling an adequate β2M and small solute clearances.

TH-PO949

Assessment of Inpatient Dialysis Adequacy Using On-Line Clearance: A Fellow Quality Improvement Project

Deewan Deewan,[1,2] William D. Paulson,[1,2] N. Stanley Nahman,[1,2] John Jason White.[1,2] *[1]Medicine, Augusta Univ, Augusta, GA; [2]Specialty Care, Charlie Norwood VA Medical Center, Augusta, GA.*

Background: A Hemodialysis (HD) single-pool Kt/V target of > 1.4 (Kt/V) is widely accepted as the minimum standard for outpatients dialyzing thrice weekly. Studies evaluating HD adequacy in hospitalized patients suggest worse outcomes when Kt/V is below standard outpatient goals. However, HD adequacy is rarely assessed in hospitalized settings. Online clearance monitoring (OCM) by sodium dialysance can accurately estimate urea clearance. In this project, we assessed OCM derived adequacy in hospitalized ESRD patients treated with HD.

Methods: Data were prospectively collected on all ESRD patients treated over a 2 week period. HD was performed on a Fresenius 2008T machine with Optiflux 180 dialyzer at Qb = 400 ml/min & Qd = 800 ml/min. Session durations were based on outpatient prescriptions or 4 hours when not available. Urea volume of distribution (Vd) was estimated by the Watson formula. OCM derived Kt/V values were recorded at the end of each HD session. Data are mean +/- (SEM).

Results: 21 patients were treated with 62 HD sessions. There were 10 AVF, 2 AVG, and 9 CVC responsible for 30, 8, and 24 treatments respectively. Treatment times were 227 +/- 31 min. OCM data indicated only 42% (26/62) of treatments achieved Kt/V ≥ 1.4 with 22% (14/62) having Kt/V < 1.2. Analysis of patients' initial HD treatment suggests high Vd and CVC access are associated with failure to meet Kt/V goal.

Kt/V Goal	Access	Vd (L)	Time (min)	UF vol (L)	spKt/V	eKt/V
Met n = 10	20% CVC	36.7 (1.1)	232 (6.3)	2.1 (0.4)	1.65 (0.07)	1.43 (0.06)
Fail n = 11	64% CVC	49.7 (2.7)	228 (8.0)	2.8 (0.5)	1.20 (0.06)	1.03 (0.05)
P-value	0.04	0.0003	0.34	0.16	0.06	0.05

Conclusions: These data suggest that inpatient HD frequently fails to achieve adequacy standards. OCM was easy to perform and only required calculation of Vd. We postulate that OCM directed therapy has the potential to improve HD delivery in the inpatient setting and possibly improve outcomes. Based on our results,we plan to utilize OCM in future determinations of dialysis session length.

TH-PO950

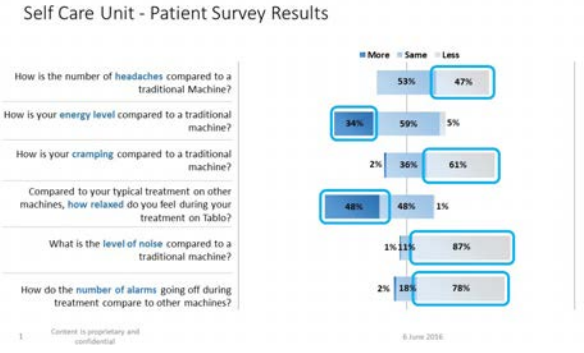
Early Patient Experience with the Tablo™ Hemodialysis System

Luis Alvarez,[1] May L. Yau,[2] Glenn Matthew Chertow.[3] *[1]Div of Nephrology, Dept of Medicine and Nephrology, Palo Alto Medical Foundation, Palo Alto, CA; [2]Clinical Operations, Outset Medical, Inc., San Jose, CA; [3]Div of Nephrology, Dept of Medicine and Nephrology, Stanford Univ School of Medicine, Stanford, CA.*

Background: Patients on in-center hemodialysis (ICHD) often experience a range of symptoms and disturbances during, immediately following, and between dialysis sessions. A goal for any innovation in hemodialysis is to minimize those symptoms. This study reports on the early patient experience using a new technology aimed at enabling in-center self-care hemodialysis (ICSCHD), the Tablo™ Hemodialysis System.

Methods: A subset of patients (n=33) from three dialysis centers, representing 152 treatments using the Tablo™ System were asked to complete surveys on their experience with Tablo™ compared to their previous dialysis machine.

Results: Patients reported experiencing 47% fewer headaches (n=54), 61% less cramping (n=92), 34% having more energy (n=53) and 48% being more relaxed (n=74). In addition, patients reported that the Tablo™ System was 87% quieter (n=129) and 78% had fewer alarms (n=119) compared to their previous dialysis machine.



Conclusions: Preliminary, uncontrolled results suggest that patients report a more favorable dialysis experience with the Tablo™ Hemodialysis System compared to their conventional ICHD device. These results may encourage patients to choose in-center self-care for which the device is designed.

Funding: Pharmaceutical Company Support - Outset Medical, Inc.

Protein-Bound Uremic Toxin Adsorption by Hexadecyl-Immobilized Cellulose Beads in Hemodialysis

Suguru Yamamoto,[1] Mami Sato,[1] Takuya Wakamatsu,[1] Yoshimitsu Takahashi,[1] Akira Iguchi,[2] Kentaro Omori,[3] Yasushi Suzuki,[2] Isei Ei,[4] Junichiro James Kazama,[1] Fumitake Gejyo,[1] Ichiei Narita.[1] *[1]Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Saiseikai Niigata Daini Hospital, Niigata, Japan; [3]Omori Clinic, Niigata, Japan; [4]Santo Scond Clinic, Niigata, Japan; [5]Dept of Nephrology and Hypertension, Fukushima Medical Univ, Fukushima, Japan.*

Background: Protein-bound uremic toxin (PBUT) accumulation causes uremia-related complications. We examined the PBUT removal ability of a hexadecyl-immobilized cellulose bead-containing column for patients undergoing hemodialysis.

Methods: *In vitro,* adsorption of indoxyl sulfate (IS), a representative PBUT (0.25–2.0 mM), to hexadecyl-immobilized cellulose beads (1.0 g) for 0–4 hours was compared

with that to polysulfone (PS) and polymethyl methacrylate (PMMA). Clinically, patients undergoing hemodialysis (4–5 h for regular dialysis, thrice weekly) (n= 29) were randomly divided into 2 groups: one (n=15) used the hexadecyl column for direct hemoperfusion with a regular hemodialyzer for 2 weeks; the other (n=14), a PS or PMMA dialyzer. Patient sera before and after dialysis, and before and after passing the column, were assessed to measure clinical effects and adsorption performance, respectively. Serum IS, indoleacetic acid (IAA), phenyl sulfate (PhS), p-cresyl sulfate (PCS), β_2-microglobulin (β_2-m), urea nitrogen, and albumin levels were measured.

Results: Compared to PS and PMMA, hexadecyl-immobilized cellulose beads dose-dependently adsorbed more IS in vitro (7.5±0.6% vs. 55.4±1.4% adsorption of 1 mM IS for 1 hour, P<0.01). Only the hexadecyl column decreased protein-unbound IS, IAA, PhS, and PCS levels (by 34.4±30.0%, 34.8±25.4%, 28.4±18.0% and 34.9±22.1%, respectively), but did not significantly decrease their pre-dialysis serum levels after 2-week treatment. The hexadecyl column strongly adsorbed β_2-m (92.9±2.5%) but not urea nitrogen and albumin.

Conclusions: Hexadecyl-immobilized cellulose beads removed PBUTs by adsorption. Regular hemodialysis with adsorption treatment is an attractive blood purification treatment to increase PBUT and water-soluble intermediate removal.

TH-PO952

Intradialytic Kinetics of β-2-Microglobulin and κ Free Light Chains: Diffusion-Adjusted Regional Blood Flow Model J. Ken Leypoldt,[1] Markus Storr,[2] Baris U. Agar,[1] Adriana Boschetti-de-Fierro,[2] Manuel Voigt,[2] Michael Hulko,[2] Angelito A. Bernardo,[1] Alexander H. Kirsch,[3] Alexander R. Rosenkranz,[3] Detlef H. Krieter,[4] Bernd Krause.[2] *[1]Baxter Healthcare Corporation, Deerfield; [2]Gambro Dialysatoren GmbH, Hechingen, Germany; [3]Medical Univ of Graz, Graz, Austria; [4]Univ Hospital Wuerzburg, Wuerzburg, Germany.*

Background: The kinetics of β_2-microglobulin (b2m) during hemodialysis (HD) have been shown to be consistent with either a conventional two-compartment model (Ward et al, Kidney Int 2006) or a diffusion-adjusted regional blood flow model (DA-RBF, Maheshwari et al, Ann Biomed Eng 2011). Recent work has shown that a two-compartment model cannot be used to describe the kinetics of middle molecules with molecular weight (MW) larger than that for b2m unless the compartment volume from which dialyzer clearance occurs is less than plasma volume. We hypothesized that a DA-RBF model can adequately describe the kinetics of b2m (MW=11.8 kD) and kappa free light chains (κFLC, MW=22.5 kD).

Methods: Intradialytic serum and dialysate concentrations of b2m and κFLC were measured in 34 HD patients treated by Theranova (high flux with extended permeability) dialyzers during 2 prospective clinical trials (NCT02377570 & NCT023776222). Overall dialyzer clearance (K_{ovr}) was evaluated by total mass removed in the dialysate. In vitro experiments using human plasma spiked with κFLCs evaluated membrane adsorption of κFLC to the dialysis membrane (N=3). A DA-RBF model, including dialyzer clearance by membrane transport and adsorption, was used to estimate intercompartmental clearance (K_{ip}), total distribution volume (V_{tot}) and the blood flow percent to the high flow tissue region (f_h).

Results: Assuming the volume percent in the high flow region to be 5-20%, calculated model parameters expressed as medians for this range were:

Middle Molecule	K_{ip} (mL/min)	V_{tot} (L)	f_h (%)
β_2-microglobulin	61.3-62.0	15.3-17.9	90.7-94.0
κFLC	4.8-5.6	9.7-9.8	97.6-98.0

As expected, K_{ip} was higher for b2m than κFLC, but blood flow percent to the high flow tissue region was similar for both b2m and κFLC.

Conclusions: A DA-RBF model provides a physiological basis for intradialytic kinetics of both b2m and κFLC.

Funding: Pharmaceutical Company Support - Baxter Healthcare Corporation

TH-PO953

Middle Molecule Kinetics during Hemodialysis and Hemodiafiltration Based on a Two-Compartment Model J. Ken Leypoldt,[1] Markus Storr,[2] Baris U. Agar,[1] Adriana Boschetti-de-Fierro,[2] Angelito A. Bernardo,[1] Alexander H. Kirsch,[3] Alexander R. Rosenkranz,[3] Detlef H. Krieter,[4] Bernd Krause.[2] *[1]Baxter Healthcare Corporation, Deerfield; [2]Gambro Dialysatoren GmbH, Hechingen, Germany; [3]Medical Univ of Graz, Graz, Austria; [4]Univ Hospital Wuerzburg, Wuerzburg, Germany.*

Background: The kinetics of β_2-microglobulin (b2m) during hemodialysis (HD) are well described by a two-compartment (2C) model where clearance by the dialyzer is from a central compartment volume (V_1) that approximates plasma volume and a total distribution volume (V_{tot}) that approximates extracellular volume. The kinetics of middle molecules with molecular weight (MW) larger than b2m have not been extensively studied.

Methods: Intradialytic serum and dialysate concentrations of b2m (MW=11.8 kD), myoglobin (16.7 kD), and complement factor D (27.0 kD) were used to estimate 3 kinetic parameters from a 2C model (intercompartmental clearance or K_{12}, V_{tot} and V_1) in HD patients during 2 prospective clinical trials (NCT02377570 & NCT023776222) comparing the performance of high flux dialyzers/diafilters and medium cut-off (high flux with extended permeability) dialyzers. In this analysis, the results from all treatments were combined. Overall dialyzer clearance (K_{ovr}) was evaluated by total mass removed in the dialysate. In total, 345 sets of kinetic parameters from 35 patients were determined.

Results: K_{ovr} was dependent on MW and dialyzer; median (interquartile range) for the combined data was 49.5 (28.9-70.0) mL/min. Results are tabulated:

Middle Molecule	N	K_{12} (mL/min)	V_{tot} (L)	V_1 (L)
β_2-microglobulin	135	95.4 (78.2-115.8)	17.8 (13.8-21.6)	2.8 (2.1-3.6)
myoglobin	109	68.1 (56.5-88.2)	21.8 (15.4-31.7)	2.1 (1.1-2.6)
complement factor D	101	52.3 (38.0-75.6)	14.8 (11.6-19.1)	1.2 (0.6-1.6)

Although K_{12} and V_1 were smaller at larger MW, the strongest dependence of these parameters was on K_{ovr}. For the combined data: K_{12} vs. K_{ovr}, R=0.444, P<0.001 & V_1 vs. K_{ovr}, R=0.745, P<0.001. V_{tot} was independent of K_{ovr} (P=0.09).

Conclusions: A 2C model can only describe the kinetics of middle molecules with MW larger than b2m if the central compartment volume is small and dependent on dialyzer clearance.

TH-PO954

Performance of Hemodialysis with Novel Medium Cut-Off Dialyzer Alexander H. Kirsch,[1] Lars-Goran Nilsson,[3] Werner Beck,[4] Michael Amdahl,[5] Christoph Wanner,[2] Alexander R. Rosenkranz,[1] Detlef H. Krieter.[2] *[1]Clinical Div of Nephrology, Medical Univ of Graz, Graz, Austria; [2]Div of Nephrology, Univ Hospital Würzburg, Würzburg, Germany; [3]Baxter Renal Therapeutic Area, Lund, Sweden; [4]Baxter Renal Therapeutic Area, Hechingen, Germany; [5]Baxter Healthcare Corporation, Round Lake, IL.*

Background: Compared to high-flux dialysis membranes (hfD), novel medium cut-off (MCO) membranes are more permeable for larger middle molecules.

Methods: In two prospective, open-label, controlled, randomized crossover pilot studies (NCT02377570, NCT02377622), 39 prevalent HD patients were studied in mid-week dialysis treatments using Theranova 400 AA dialyzer in HD (MCO HD) in comparison to, study 1, FX CorDiax 80 dialyzer in HD (hfHD) and, study 2, hfHD and high-volume hemodiafiltration (HDF; FX CorDiax 800; convective vol 24L). Instantaneous clearances (K_{inst}) at 30 and 120 minutes and reduction ratios (RR) of free light chains (FLC) and other larger middle molecules were analyzed with a mixed model.

Results: Study 1 (Q_B=300 ml/min): At 30min MCO HD provided higher FLC K_{inst} (κFLC, LS mean [SE]: 38.0 [3.63]; λFLC (15.2 [1.59] mL/min) compared to hfHD (20.1 [3.63] and 0.0 [1.59] mL/min, respectively); both P <0.001. At 120min κFLC K_{inst} was still significantly greater for MCO HD while λFLC K_{inst} was not. Also, FLC RR was higher with MCO HD (κFLC: 66.3% [1.85]; λFLC: 42.5% [2.06]) than hfHD (36.4% [1.88] and 12.9% [2.10] respectively); both P<0.001) Study 2 (Q_B=400 mL/min): MCO HD showed higher K_{inst} (30min) of λFLC compared to HDF (19.1 [2.65] vs. 6.6 [2.65] mL/min; P<0.001), while there was no difference in κFLC. Also, there was a significantly higher λFLC RR in MCO HD compared to HDF (48.1% [1.72] vs. 37.9% [1.76]; P<0.001). Additionally, MCO HD provided significantly better removal of β_2-microglobulin compared to hfHD and of myoglobin and complement factor D compared to both hfHD and HDF. Albumin loss to dialysate was moderate with MCO, but greater than in high-flux HD and HDF.

Conclusions: MCO HD effectively removes a wide range of middle molecules, substantially better than high-flux HD. It even exceeds the performance of HDF for several large solutes.

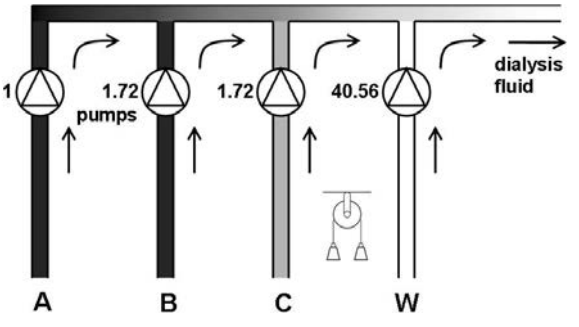
TH-PO955

A Novel Method of Widening the Range of Dialysis Fluid [Na] Using a 4-Stream Approach Susie Q. Lew,[1] Yuk Lun Cheng,[2] Todd S. Ing.[3] *[1]Medicine, George Washington Univ, Washington, DC; [2]Medicine and ICU, Alice Ho Miu Ling Nethersole Hospital, Hong Kong, China; [3]Medicine, Stritch School of Medicine, Loyola Univ Chicago, Maywood, IL.*

Background: The conventional, 45X, 3-stream, bicarbonate-based dialysis fluid (DF) delivery system consists of an acid concentrate stream (CS), **A**; a bicarbonate (BIC) CS, **B**; & H_2O stream, **W**. The flow rate ratios (FRR) for **A**:**B**:**W** are: 1:1.72:42.28 (totaling 45 or 45X). This system provides a DF [Na] range of 125-150 mM.

Methods: We devised a 4-stream DF delivery system to expand the [Na] range by adding a NaCl CS, **C**. An electronic pulley-like mechanism sits between **C** & **W.** Contributions to the final DF include: **A:** Chloride salts of Na(63 mM), K, Ca & Mg, & dextrose; **B**: 37 mM $NaHCO_3$; **C:** 37 mM NaCl; & **W**: H_2O. The FRR for **A**:**B**:**C**:**W** under normal conditions are: 1:1.72:1.72:40.56 (45 or 45X).



Results: To change the DF Na level, the FRR of **C** changes 1 way, & **W** changes by the same magnitude but in the opposite direction. For example, if **C**'s FRR decreases by

0.2 to 1.52 then **W**'s FRR will increase by 0.2 to 40.76. **C** will deliver less NaCl & **W** will deliver more H_2O to the final DF; lowering [Na] in the final DF. The opposite sequence of events will occur if **C**'s FRR increases. Patients with dysnatremia can be dialyzed with a wider range of DF Na levels without associated changes in BIC, K, Ca, Mg, & dextrose concentrations. Thus averting central pontine myelinolysis or cerebral edema, normally seen with rapid changes in serum [Na]. The ingredients in **A** & **B** remain unchanged because the sum of the FRR for **C** & **W**, a fluid volume that normally dilutes the ingredients of **A** & **B**, remains unchanged.

Conclusions: A pulley between **C** & **W** permits a wider DF [Na] range. The final concentrations of BIC, K, Ca,& Mg are not affected since the total volume of fluid that dilutes these elements remains intact.

TH-PO956

Acute Extracellular Calcium Regulation Is Independently Associated with Serum Undercarboxylated Osteocalcin in Chronic Hemodialysis Patients

Markus Pirklbauer, Ramona Schupart, Gert J. Mayer. *Internal Medicine IV, Nephrology and Hypertension, Medical Univ Innsbruck, Innsbruck, Tyrol, Austria.*

Background: In order to avoid excessive calcium (Ca) loading in hemodialysis (HD) patients, current guidelines suggest a dialysate calcium concentration (dCa) of 2,5 mEq/l based on relatively stable intradialytic serum Ca levels. However, the latter do not account for possible Ca storage in acutely accessible pools. A rapidly exchangeable Ca pool located at the bone level has been proposed to be involved in acute extracellular Ca regulation.

Methods: To obtain clinical evidence for a rapidly exchangeable Ca pool and its contribution in the maintenance of serum Ca levels we assessed dialysate-sided ionized Ca mass balance (iCa_{MB}) and change in extracellular fluid ionized Ca mass (ΔiCa_{ECF}) during two HD sessions in chronic HD patients using a dCa of 3,5 (n=28) and 2,5 (n=10) mEq/l. Acute calcium buffer capacity was calculated by setting ΔiCa_{ECF} in relation to iCa_{MB}. ELISA-based measurements of serum osteocalcin, the most abundant non-collagenous bone protein, were conducted prior to the first HD session.

Results: Considering pre- to postcapillary dialysate bicarbonate decline, iCa_{MB} was invariably positive for both 2,5 and 3,5 mEq/l dCa, with a mean of 434 (±125) and 725 (±162) mg/HD, respectively (p<0,001). The mean amount of intra-dialytic Ca load buffered (i.e. iCa_{MB} - ΔiCa_{ECF}) was 410 (± 116)mg/HD at 2,5 mEq/l dCa and 565 (±130)mg/HD at 3,5 mEq/l dCa (p<0,001). Acute Ca buffer capacity was 95 (±8)% and 78 (±7)% (mean at 2,5 and 3,5 mEq/l dCa) (p<0,001). Using 3,5 mEq/l dCa, acute Ca buffer capacityunivariately correlated with undercarboxylated osteocalcin (Glu-OC) (r=0,49, p<0,01), patient dry weigth (r=-0,47, p<0,05) and body mass index (r=-0,45, p<0,05). Multivariate regression analysis showed an independent association of acute Ca buffer capacity with Glu-OC (ß=0,512, p=0,002) only.

Conclusions: Our study revealed high Ca burden with standard dCa and provides strong evidence for the existence of a rapidly exchangeable calcium pool that counteracts acute serum Ca deviations. Our data provide - for the first time - experimental evidence for the involvement of bone in acute extracellular Ca regulation in vivo.

Validation of a Novel Mathematical Model of Protein-Bound Uremic Toxins Kinetics in Hemodialysis Patients

Vaibhav Maheshwari, Stephan Thijssen, Xia Tao, Doris H. Fuertinger, Peter Kotanko. *Renal Research Inst, New York City, NY.*

Background: While accumulation of protein-bound uremic toxins (PBUTs) such as indoxyl sulfate (IS) and p-cresyl sulfate (pCS) is associated with mortality, their removal in conventional hemodialysis (HD) is limited. We developed a novel mathematical model to better understand PBUT kinetics. We validated the model with *in vivo* data on the dialytic removal of PBUTs (Deltombe *et al*. 2015), and *in vitro* data studying the effect of increased dialysate flow with concomitant increase in dialyzer size (K_oA) (Meyer *et al*. 2004).

Methods: The model comprises a multi-compartmental representation of the patient and a spatiotemporal representation of the dialyzer and accounts for albumin-toxin dynamic equilibrium. The model was calibrated using IS, PCS, and urea data from Eloot *et al*. (2016). A total of 6 model parameters, namely, (i-ii) mass transfer coefficients between plasma and interstitium ($K_{ip,T}$) and between interstitium and intracellular space ($K_{ic,T}$), (iii) the association constant (k_1), (iv-vi) and plasma, extracellular, and intracellular volumes (V_{pl0},V_{ex0},andV_{ic0}) were estimated.

Results:

Toxin	$K_{ip,T}$ (L/min)	$K_{ic,T}$ (L/min)	k_1 ($M^{-1}min^{-1}$)	V_{pl0} (L)	V_{ex0} (L)	V_{ic0} (L)
IS	1.55	0.3	3.72×10^5	2.5	12.4	24.7
pCS	1.44	0.26	4.36×10^5			
Urea	-	0.35	-			

Our model reproduces the published data accurately. During HD, the bound fraction of IS increases with time and across the dialyzer. The reduction ratio for the free fraction is much more pronounced compared to that of the total concentration (Figure 1A). Our model also describes the response to changing Q_d and K_oA (Figure 1B).

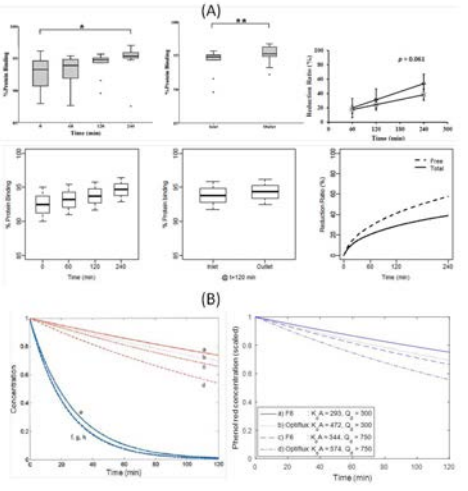

Figure 1: (A) Comparing indoxyl sulfate (IS) *in vivo* data (top row) (Deltombe *et al.* 2015) with model predictions depicted in bottom row. (B) Effect of and Q_d on removal of phenol red. Comparing Meyer *et al.* (2004) (left) and model simulations (right). In left panel: (a-d) in figure legend refers to same dialyzers, Q_d and combinations as in right panel. Plasma flow rate Q_b was 200 mL/min for all four scenarios.

Conclusions: The proposed model reproduces existing literature data closely. This model can be used for testing new approaches for removal of PBUTs such as pre-dilution hemodiafiltration and effect of enhanced removal by binding competitors.

TH-PO958

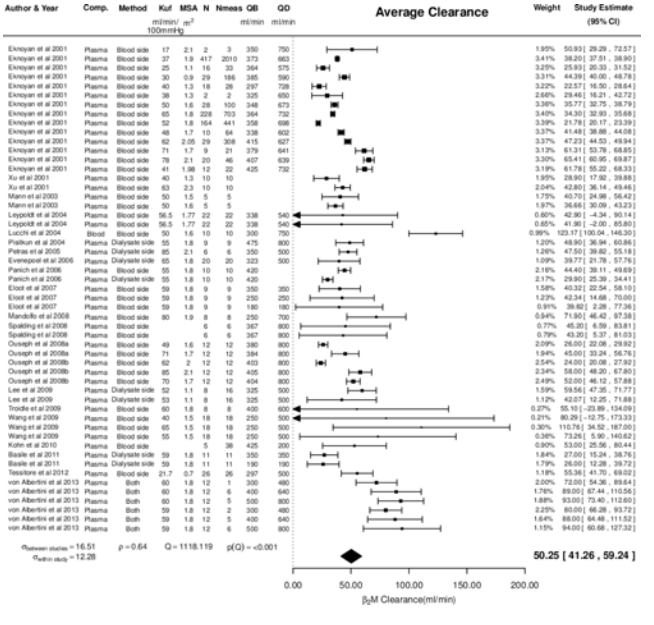
β-2 Microglobulin Removal by High-Flux Dialysis: A Meta-Analysis

Rocio Figueroa,[1] Maria-Eleni Roumelioti,[1] Gregory S. Trietley,[2] Thomas D. Nolin,[2] Yue-Harn Ng,[1] Zhi Xu,[1] Mark L. Unruh,[1] Christos Argyropoulos.[1] *[1]Internal Medicine-Nephrology, UNMHSC, Albuquerque; [2]Pharmacy and Therapeutics, Univ of Pittsburgh, Pittsburgh.*

Background: Elevated beta-2 microglobulin (B2M) levels with adverse cardiovascular and infectious outcomes. There is limited quantitative data about the ability of high flux dialyzers (HF) to remove B2M.

Methods: We used ProQuest to search EMBASE and MEDLINE, for randomized controlled trials and observational studies in HF dialysis between 2001-2013. Clearance measurements at blood side and/or dialysate side were included and reported via random effects meta-analysis.

Results: Average clearance was 50.2 ml/min with substantial heterogeneity among the 37 studies identified.



In meta-regressions, we found a significantly lower B2M clearance for Polysulfone and Cellulose membranes.

	estimate	se	p-val
Intercept	22.2	14.2	0.1
Membrane Kuf (ml/min/100mmHg)	0.2	0.2	0.2
Membrane Surface Area (m2)	0.5	6.7	0.9
Blood (vs. plasma) clearance	58.7	13.3	**<0.001**
Dialysate (vs. blood side) clearance	-13.3	6.7	**0.05**
Blood flow (ml/min)	0.1	0.03	**0.04**
Membrane material (polyarylethersulfone is referent)			
Polysulfone	-17.6	3.6	**<0.001**
Cellulose	-19.17	8.01	**0.02**
Polyacrylnitrile	-13.36	6.88	**0.05**
Polymethylmethacrylate	-22.50	11.57	**0.05**
Secular trend	0.57	1.24	0.64

Adjusted dialysate-side and plasma clearances were lower than whole blood clearances. B2M reduction ratio was significantly higher for PS (-8.62 ± 4.28, p = 0.04 [-17.01, -0.22]) compared to other membrane materials.

Conclusions: Membrane material (e.g. PAES), but not surface area, plays a significant role in the efficient clearance of B2M. Due to methodological heterogeneity, this observation should be confirmed in prospective studies with highly standardized methods of analysis.

Combination of Sodium and Ultrafiltration Step-Down Is More Effective and Much Safer in Aged in Comparison to Younger Population Rather Than Any Alone

Ahmed G. Adam, Rania Awad, Asharaf Adel. *Dept of Internal Medicine, Nephrology, Dialysis & Transplantation Unit, Faculty of Medicine, U of Alexandria, Alexandria, El Salvador.*

Background: Intradialytic hypotension is the most common complication of haemodialysis (HD). This study on the effect of profiled hemodialysis on intradialytic hypotension(IDH) and related symptoms,nursing interventions during dialysis . Evaluated intradialytic hypotension related symptoms included muscle cramps, dizziness, headache,nausea and vomitting. Evaluated nursing interventions included saline infusion,decrease or stop ultrafiltration(UF) and session failure. In this study interdialytic weight and serum sodium concentration were evaluated also.

Methods: This study included 24 patients on maintenance haemodialysis who experienced frequent episodes of intradialytic hypotension were recruited. There were 17 female and 7 male patients.

Results: There was significant improvement of IDH (p<0.001) ,cramps(p<0.001) ,dizziness(p<0.001) , headache(p<0.001),saline infusion (p<0.001),decrease or stop UF (p<0.001), session failure (p<0.001). No significant difference in interdialytic weight gain, serum sodium concentration, nausea and vomiting.

	standard	profiled
Saline Bolus n (%)	69 (24%)	29 (10%)
Decrease of D/C UF n (%)	121 (42%)	45 (15.6%)
Session Failure n (%)	35 (12%)	10 (3.5%)
Hypotension n (%)	108 (37.5%)	41 (14.3%)
Cramps n (%)	38 (13.2%)	9 (3.2%)
Dizziness n (%)	62 (25.5%)	20 (7%)
Headach n (%)	44 (15%)	13 (4.5%)
Nausea & Vomiting n (%)	17 (5.9%)	14 (4.7%)

Conclusions: In conclusion, combination of step-down sodium and ultrafiltration profiles are simple and cost effective methods which improve the homodynamic stability with modulating the sodium dialysate and removal of fluids, so decreases the incidence of IDH and related symptoms (dizziness,cramps,headache) . Also decreasing all nursing interventions (saline infusion,decreasing or stopping ultrafiltration, session failure) with improvement of dialysis tolerance. Without significant interdialytic weight gain or sodium gain. Therefore combination of sodium and ultrafiltrationprofiles is recommended for IDH prevention.

TH-PO960

Vadadustat Maintains Hemoglobin (Hb) Levels in Dialysis-Dependent Chronic Kidney Disease (DD-CKD) Patients Independent of Systemic Inflammation or prior Dose of Erythropoiesis-Stimulating Agent (ESA)

Volker H. Haase,[1] Zeeshan Khawaja,[2] Jason Chan,[2] Qing Zuraw,[2] Ramin Farzaneh-Far,[2] Bradley J. Maroni,[2] Peter A. McCullough.[3] *[1]Vanderbilt Univ, Nashville, TN; [2]Akebia Therapeutics, Inc., Cambridge, MA; [3]Baylor Univ Medical Center, Dallas, TX.*

Background: DD-CKD is associated with systemic inflammation. Vadadustat is a novel, oral, hypoxia-inducible factor prolyl-hydroxylase inhibitor in development for the treatment of renal anemia.

Methods: A randomized, Phase 2, multicenter, open-label study assessed the Hb response to 3 starting doses of vadadustat over 16 weeks in 94 DD-CKD patients who were maintained on ESAs prior to study entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300mg once daily (QD); 450mg QD; and 450mg three times weekly (TIW). From week 8, vadadustat dose could be adjusted (150-600 mg) as needed to maintain Hb. A post-hoc analysis was performed to explore the relationship between final vadadustat dose, mean change in Hb, baseline markers of inflammation (hepcidin and C-reactive protein [CRP]), and weekly ESA dose prior to study entry.

Results: No correlation was observed between the final vadadustat dose and baseline markers of inflammation or ESA dose. (Tables 1, 2). Vadadustat maintained Hb independent of baseline CRP (p=0.07) and hepcidin (p= 0.11).

Table 1. QD vadadustat dose

	Mean baseline hepcidin (ng/mL)		Mean baseline CRP (mg/L)		Weekly ESA dose prior to study entry (Units/week)	
Final dose (mg/day)	n	Mean±SD	N	Mean±SD	n	Mean±SD
150	6	144.1±106.1	6	18±19	6	4816±4256
300	18	106.5±53.2	18	8±9	18	5005±3699
450	20	116.5±53.5	20	12±28	20	7025±4963
600	19	100.6±42.6	19	10±15	19	8152±4834
P-value based on ANOVA	p=0.4		p=0.6		p=0.3	

Table 2. TIW vadadustat dose

	Mean baseline hepcidin (ng/ml)		Mean baseline CRP (mg/L)		Weekly ESA dose prior to study entry (U/week)	
Final dose (mg/TIW)	n	Mean±SD	n	Mean±SD	n	Mean±SD
150	1	87.9	1	7.9	1	8000
300	4	88.4±33.0	4	6.1±3	4	6750±5909
450	12	125.1±62.0	12	26.3±47	12	8075±7561
600	14	94.4±30.7	14	11.5±19	14	6742±4754
P-value based on ANOVA	p=0.3		p=0.6		p=0.9	

Conclusions: The Hb response and vadadustat dose requirements for Hb maintenance are independent of underlying systemic inflammation and baseline ESA dose in patients with DD-CKD.

A Mirror in Time - Path to Dialysis from Education to Experience

Sagar Jujjavarapu, Prasad Rajendran, Biju John, Terence Samuel, Shiva Kumar. *Renal Medicine, Dudley Group of Hospitals, Dudley, United Kingdom.*

Background: All CKD patients starting dialysis should ideally have the opportunity to receive timely pre-dialysis education to make an informed choice about their preferred modality of long term renal replacement therapy (RRT), enabling dialysis start through a permanent access created ahead of its requirement for use. Our study aims were to review patients who started dialysis during a 12 month period and analyse trends and timelines in their decline in renal function, referral to our Pre-dialysis education service, access creation and transplant work up.

Methods: 39 patients commenced long term dialysis during the period between October 2014 and September 2015. Data was collected from electronic clinic letters for timelines of and blood results obtained from hospital IT system in January 2016. The data was analysed using EPI-INFO 7.

Results: 26(67%) patients were male. The mean age was 61. 34(87%) were white. 10 patients had diabetic nephropathy(25%) and 5 had IgAN(13%). 18 patients started haemodialysis through a line of whom 7 had chosen PD as their modality of choice for RRT. **No correlation was observed between the eGFR at referral for pre-dialysis education and start of RRT with haemodialysis catheter**.

Timeline & eGFR Trend	Mean ± SD	Median	Range
eGFR at referral for education – ml/min	13.5 ± 3.72	13	5 to 20
Time to access referral - months	11.2 ± 18.1	5	0 to 95
eGFR decline/change at access referral – ml/min	4.6 ± 3.56	3	0 to 9
Time to access creation after access referral - months	4.9 ± 11.1	1	0 to 47
Time to dialysis start after education - months	16.4 ± 22.9	13	-1 to 99
eGFR at dialysis start – ml/min	5.5 ± 1.83	5	3 to 11

Conclusions: Wide variability in the time interval from pre-dialysis education to the start of RRT could be explained by the variable rate of decline in eGFR, comorbid factors, patient concordance and other acute inter-current events. In spite of timely referral for primary definitive access based on individual assessment and clinical judgement, the risk of acute decompensation probably should prompt earlier definitive access although problems arising with definitive access could also be unpredictable.

TH-PO962

Anti-Aging Factors, Sirtuin 1 and αKlotho Concentration in Hemodialysis Patients

Edyta Zbroch, Ewa Koc-Zorawska, Jolanta Malyszko. *2nd Dept of Nephrology with Hypertension and Dialysis Centre, Medical Univ, Bialystok, Poland.*

Background: SIRT1 acts as an anti-aging protein due to anti-apoptotic, anti-oxidative and anti-inflammatory effect and is implicated in several diseases as diabetes or cardiovascular problems. SIRT1 renal overexpression indicates oxidative stress. Similarly,

Klotho was originally discovered as anti-aging factor. It is primary produced in kidney. It's deficiency is associated with renal disease progression and heart disease by affecting cardiac remodeling. The aim of the study was to asses the Sirtuin1 and αKlotho plasma concentration in hemodialysis (HD) patients comparing to healthy volunteers in regard to age, blood pressure control, residual renal function (RRF), diabetes, cardiovascular disease, time of dialysis and type of dialyzer.

Methods: The plasma level of SIRT1 and αKlotho was evaluated using ELISA tests in 103 HD patients, median age 62 years and in 21 volunteers. The blood pressure, residual diuresis, echocardiography and some dialysis parameters was assessed. HD group was divided according to the presence of residual diuresis.

Results: Plasma SIRT1 level was higher (Me=28.42 vs 2.71 ng/ml, p<0.0001) and αKlotho was lower (Me=433.9 vs 756.63 pg/ml, p<0.0001) in HD group comparing to control one. αKlotho was lower in those without RRF. There were no differences in SIRT1 concentration regarding residual diuresis. SIRT1 positively correlated with duration of hemodialysis. αKlotho negatively correlated with left ventricular posterior wall thickness. There were no significant relationship between SIRT1 and αKlotho level and age, blood pressure control, type of dialyzer, Kt/V and the diabetes.

Conclusions: The elevated SIRT1 concentration is associated with impaired kidney function as well as lowered αKlotho level. The decreased αKlotho level may also indicate the heart hyperthrophy and cardiac problem in maintained dialysis. Though, the role of SIRT1 and αKlotho as biomarkers/predictors of oxidative stress, inflammation and cardiovascular diseases needs further examination.

TH-PO963

Prediction of Intradialytic Arterial Oxygen Saturation in Chronic Hemodialysis Using Patient Characteristics Hanjie Zhang,[1] Israel Campos,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Research, Renal Research Inst, New York, NY; [2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Recent evidence indicates that intradialytic arterial oxygen saturation (SaO2) is associated with inflammation, resistance to erythropoiesis stimulating agents, hospitalization, and all-cause mortality in hemodialysis (HD) patients (Meyring-Wosten, CJASN 2016). While SaO2 can be measured easily with the Critline monitor (CLM; Fresenius Medical Care, Waltham, MA), only a minority of HD facilities have deployed that technology. Therefore we explored if SaO2 can be predicted from demographic, clinical and laboratory data.

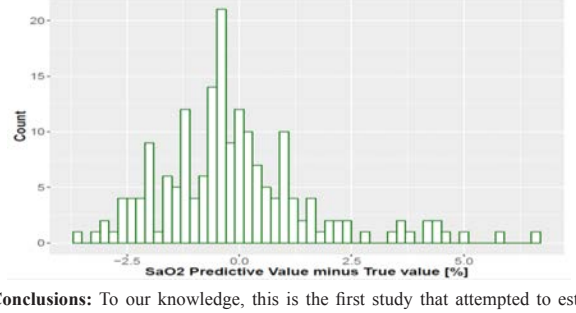
Methods: We studied HD patients with arterio-venous vascular access who had their SaO_2 measured by CLM during HD. Generalized linear model (GLM), generalized additive model (GAM), gradient boosting methods (GBM) and random forest (RF) were used to predict SaO_2 based on 16 predictors, including age, gender, race, body mass index, HD vintage, serum albumin, hemoglobin level, and comorbidities. We randomly sampled 80% of the data (derivation cohort) for model building; the remaining 20% were used as validation cohort.

Results: We studied 28,065 HD sessions in 910 chronic HD patients (mean age 61.5, 59% males, 51% white). Average SaO2 was 92.6% (SD 1.94%). There was no material difference in the predictive performance of the 4 models (Figure 1A; a histogram of GLM results is shown in Figure 1B).

Figure 1A: Predictive performance of the 4 models

	GAM	GBM	GLM	Random forest
Difference (prediction – measured) [% SaO2]	-0.07	-0.09	-0.09	-0.17
Standard deviation of the difference [% SaO2]	1.73	1.68	1.73	1.73
R^2	0.10	0.12	0.12	0.14

Figure 1B: Result of the GLM model



Conclusions: To our knowledge, this is the first study that attempted to estimate intradialytic SaO_2 using patient characteristics. While only 10-14% of the SaO2 variability could be explained by these models, the predicted SaO2 still provided a better SaO_2 estimate for an individual patient than the population average. Future studies need to explore additional biological predictors of SaO2, such as the degree of fluid overload.

Characteristics of Markets and Patients Served by ESRD Seamless Care Organizations (ESCOs) R. Hirth,[1] J. M. Messana,[1] Brighita Mona Negrusa,[2] Court Q. Melin,[3] Yi Li,[1] G. Marrufo.[2] *[1]School of Public Health & Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]The Lewin Group, Falls Church, VA; [3]The Lewin Group, Eden Prairie, MN.*

Background: The Comprehensive ESRD Care Model (CEC) establishes ESCOs as an innovative care delivery structure, based on concepts of accountable care organizations with a focus on the complex needs of dialysis patients. Operations began 10/1/2015 with 13 ESCOs in 17 Core-based Statistical Areas (CBSAs). Because of CEC participation requirements (e.g., 350+ dialysis patients in each ESCO within 1-2 CBSAs and dialysis facilities and nephrologists willing to accept financial risk), the markets in which ESCOs choose to operate and consequently the patients they serve may differ from those not served by ESCOs. To project the model's scalability, we explored whether ESCOs' markets and patients are typical of the broader Medicare ESRD population.

Methods: We compared characteristics of CBSAs with and without ESCOs in 2015 in terms of size, Medicare spending, demographics and health system characteristics. ESCO-aligned and non-aligned patients were compared on demographics, comorbidities, Medicaid status and Medicare spending in 2014.

Results: ESCO CBSAs had substantially more Medicare ESRD beneficiaries than non-ESCO CBSAs (median 1851 vs. 122), had fewer white patients (60% vs. 81%), higher average household income ($51,345 vs. $43,815), higher Medicare Advantage penetration (24% vs. 18%), and more primary care physicians (7.1 vs. 6.3 per 10,000 Medicare beneficiaries) and specialists (8.3 vs. 4.8 per 10,000). Patients aligned to ESCOs were more likely to be treated in an urban area (98% vs. 84%), had higher monthly Medicare Parts A and B spending in 2014 ($6,118 vs. $5,703), and had comparable prevalence of most comorbidities (largest differences for Alzheimer's 16% vs. 10%, and rheumatoid arthritis 28% vs. 25%). All reported differences were significant with p<0.05.

Conclusions: By creating incentives for more effective care coordination, the CEC model has the potential to improve outcomes and reduce costs. To date, participation has been limited to larger markets, suggesting that the ability to extend the model to smaller markets should be monitored.

TH-PO965

Starting Dialysis: From Refusals to Regrets, How Strong Is the Misperception? Mabel Habib Aoun,[1,2] Leony Antoun,[3] Dania Chelala.[2] *[1]Nephrology, Saint-Georges Hospital, Ajaltoun, Lebanon; [2]Nephrology, Saint-Joseph Univ, Beirut, Lebanon; [3]Internal Medicine, Kaslik Univ, Lebanon.*

Background: Dialysis is life-sustaining for end-stage renal disease (ESRD) patients and a way to better quality of life (QoL). Nephrologists try to convince patients of starting dialysis but may propose palliative care for elderly with reduced survival and QoL scores. The challenge is to discover what patients really want and whether their choices change. We studied 71 chronic haemodialysis (HD) patients, their initial refusal of dialysis, later regret, QoL and survival time in 3 age-groups.

Methods: Patients on HD in April 2015 were included and administered 2 questionnaires: (1) demographic data, dialysis refusal, later regret, major complaint; (2) Short Form 36 (SF-36) for QoL scores: physical functioning (PF), role limitations due to physical problems (RP), bodily pain (BP), general health perceptions (GH), energy/vitality (VT), social functioning (SF), role limitations due to emotional problems (RE) and mental health (MH).

Results: Patients were divided in 3 groups according to age at dialysis start: < 70, 70-80 and > 80 [table 1]. 28% refused dialysis but changed their mind later. One regretted starting dialysis. 27% complained of the long sessions. Patients < 70 had longer survival on dialysis (p=0.001). QoL: No significant difference was found in SF-36 scores between the 3 groups.

Age	<70 (N=41)	70-80 (N=24)	>80 (N=6)	TOTAL (N=71)
M/F	27/14	14/10	4/2	45/26
Time on dialysis (months)	77.4	34	44.6	60
Refusal (N)	11	9	0	20
Regret (N)	1	0	0	1
No complaints	20	12	1	33
PF	45.5	38.9	14.1	40.6
RP	29.2	21.8	16.6	25.7
RE	35.3	29.1	0	30.2
VT	47.4	53.7	46.6	49.4
MH	50.2	54.9	60.8	52.7
SF	51.8	55.7	41.6	52.2
BP	53.2	51.3	42	51.6
GH	49.3	56.2	44.9	51.2

Conclusions: Higher prior refusals compared to negligible later regrets point out to the probable patients' misperception of dialysis. Age doesn't seem to affect patients' final choice as long as QoL scores are similar through different age-groups. Nephrologists should not be influenced by patient's old age and initial refusal of dialysis.

TH-PO966

Intradialytic Exercise May Not Break the Vicious Cycle of Frailty Hannah M.L. Young,[1] Daniel Scott March,[1] Darren R. Churchward,[1] Charlotte E. Grantham,[1] Patrick J. Highton,[1,2] Matthew P.M. Graham-Brown,[1,2] Alice C. Smith,[1] James Burton.[1] *[1]Dept of Infection, Immunity & Inflammation and John Walls Renal Unit, Leicester General Hospital; [2]School of Sport, Exercise and Health Sciences, Loughborough Univ; [3]Dept of Cardiac & Pulmonary Rehabilitation, Glenfield Hospital.*

Background: Frailty is associated with poor outcomes for hemodialysis (HD) patients. Intradialytic cycling is recommended, but effective interventions in the frail elderly include a wider range of exercises; the components of a program suited to frail HD patients are unknown. The purpose of this study is to examine the influence of frailty on exercise capacity, function, activity levels and exercise behaviors to inform a specific frailty intervention.

Methods: Frailty status was measured in 43 patients (30 male, 13 female, age 58, IQR 27.25). Exercise capacity was measured using walking tests (ISWT and ESWT), muscle endurance using the Sit to Stand 60 (STS60) and step count using accelerometry. Function and exercise behavior were assessed using the Duke Activity Status Index (DASI), exercise self-efficacy questionnaire and exercise benefits and barriers scale (DPPEBBS).

Results: 13 (30%) of the participants were 'robust', 23 (52%) 'pre-frail' and 7 (16%) were frail. Patients were well matched for age, vintage and co-morbidity. One-way ANOVA showed lower exercise and functional capacity (ISWT, $P<0.05$; ESWT, $P<0.05$; DASI, $P<0.05$) and muscle endurance (STS60, $P<0.05$). Post hoc analyses showed a significant decrease in ISWT distance in the frail group compared with robust (-294m,$p<0.05$) and pre-frail groups (-168m, $p<0.02$), in ESWT time between pre-frail and robust groups (-406s, $p<0.05$),in STS60 scores between frail, robust (-17.03, $p<0.02$) and pre-frail groups (-12.66, $p<0.02$) and between frail and robust groups (-21.95, $p<0.003$) for the DASI. Weekly steps were low in all groups (21436, IQR 29732), but self-efficacy was moderate and the DPPEBBS indicated that patients generally perceived more exercise benefits than barriers (66.11 ± 7.68).

Conclusions: This study reveals a high prevalence of frailty amongst HD patients and suggests that that a multi-component exercise program, rather than intradialytic cycling, may best address frailty in this population.

TH-PO967

The Spectrum of Symptoms Induced by Hemodialysis Kevin Quach,[1] Jennifer M. MacRae,[2] Braden J. Manns,[2] Michael Walsh.[1] *[1]McMaster Univ; [2]Univ of Calgary.*

Background: Hemodialysis induces symptoms in many patients that take time to recover from (recovery time). The symptoms induced and how they vary over time and between patients is unclear. We conducted a prospective cohort study to describe how recovery time symptoms vary over time and between patients.

Methods: We recruited prevalent in-center hemodialysis patients and measured their recovery time using multiple instruments. Instrument A presented a global question regarding how long it took to recover from the last dialysis treatment. Instrument B addressed the recovery time for each of 10 symptoms. Participants completed each instrument for each dialysis treatment for one week. We compared the distribution of recovery time found with each instrument.

Results: One hundred twenty participants from 2 centres completed 914 recovery time assessments. Fewer participants required no recovery time with Instrument A (14 to 17% of participants depending on day of week) as compared with identifying no symptoms with Instrument B (20 to 34% of participants depending on day of week) ($p=0.002$ for difference between groups). However, the maximum recovery time from any symptom in Instrument B (median 10 hours) was longer than the recovery time identified with Instrument A (median 3 hours) ($p=0.001$). Lack of energy was the most common symptom following dialysis (69% of all patients), with muscle cramps (41%), bone and joint pain (36%), shortness of breath (26%), and muscle soreness (33%)the next most frequent. Recovery time measured with instrument A correlated with the KDQoL Burden of Disease ($p=0.003$), Effects of Kidney Disease ($p=0.01$) and Mental Composite Score ($p=0.01$) but individual symptoms did not consistently correlate with domains of the KDQoL.

Conclusions: Recovery time is a complex of different symptoms that vary in duration. Further research is required to understand how dialysis induces each type of symptom in order to reduce recovery time.

TH-PO968

Prospective Study of the Gut Microbiome and Effects of P-Inulin in ESRD: Early Experience of the NIDDK Hemodialysis Novel Therapies (HDNT) Consortium Dominic S. Raj,[1] Ali Ramezani,[1] Hongzhe Li,[2] J. Richard Landis,[2] David M. Charytan,[3] Talat Alp Ikizler,[4] Jonathan Himmelfarb,[5] Alan S. Kliger,[6] Paul L. Kimmel,[7] John W. Kusek,[7] Laura M. Dember.[2] *[1]George Washington U; [2]Univ Pennsylvania; [3]Brigham & Women's Hospital; [4]Vanderbilt U; [5]U Washington; [6]Yale U; [7]NIDDK.*

Background: Preliminary evidence suggests that alterations in the gut microbiome contribute to ESRD-associated inflammation and cardiovascular disease. Prior to conducting clinical trials of interventions, such as pre- or pro-biotics, to restore microbial symbiosis, it is necessary to characterize the composition, function, and stability of the gut microbiome in ESRD patients.

Methods: The NIDDK HDNT Consortium is performing a non-randomized, open label, crossover study of at least 10 patients receiving maintenance hemodialysis at 4 centers. The study protocol requires intensive sampling of stool (1-2X/wk) and blood (1X/wk) during 3 phases: 1) pre-treatment-8 wks; 2) treatment with p-inulin pre-biotic, 8 g 2X/day-12 wks; and 3) post-treatment-8 wks. Microbiome composition will be assessed at the overall microbial diversity and individual taxon levels, and microbiome function will be assessed with metabolomic profiling and targeted metabolite measurements. 16S rRNA gene sequencing, metabolomic studies, and analytical approaches are being piloted in a sub-set of samples collected at wks 2 and 8 (phase 1) and wks 14 and 20 (phase 2).

Results: Of 12 patients enrolled, 2 withdrew (1 for transplantation; 1 for unwillingness to provide samples). The remaining 10 patients, followed for 143 pt-weeks thus far, have provided 152 of 154 (99%) blood samples and 157 of 161 (98%) stool samples, and have processed their stool samples generating 1564 of 1594 (98%) aliquots. Adherence to p-inulin as assessed by packet counts is 74% of the recommended dose. Analytical approaches to high-dimensional, repeated measures data have been developed to evaluate within-person variability of microbiome composition and function, and effects of p-inulin on both parameters.

Conclusions: The feasibility of intensive stool and blood sample acquisition and the tolerability of p-inulin both appear to be sufficient to generate data needed to design future clinical trials targeting the gut microbiome in ESRD.

TH-PO969

Disorders in Thyroid Morphology Observed in ESRD Patients on Maintenance Hemodialysis Syed Rizwan A. Bokhari,[1] Maria Rizwan Bokhari,[2] Syed A. Khalid,[1] Muhammad Zaman Khan Assir,[3] Abeera Mansur.[4] *[1]Nephrology, AIMC/JHL, Pakistan; [2]Radiology, AIMC/JHL, Pakistan; [3]Nephrology, DHMC, Pakistan.*

Background: Chronic kidney disease has been associated with changes in thyroid gland morphology and thyroid hormone metabolism. Goiter and thyroid nodules have been reported with increased frequency in end-stage renal disease (ESRD) patients, however its frequency is not known in developing countries. We aimed to study the thyroid gland morphology in our ESRD population and its correlation with patient demographics.

Methods: We enrolled 74 patients on maintenance (HD) at the dialysis center of Jinnah hospital Lahore. Two patients (3%) with preexisting thyroid disease were excluded. Thyroid ultrasound was done on all to assess thyroid volume, nodules and its echotexture.

Results: Total of 72 end stage renal disease (ESRD) patients on maintenance hemodialysis were included. Median age was 50 years (range 17-82 years). Fourty six (64%) were male. Twenty-two (31%) had DM ,43 (60%) had HTN, 4 (5%) patients had evidence of obstructive uropathy and 3 (4%) patients had ADPKD as the cause of ESRD. 32 (44%) had HCV infection. Median duration on hemodialysis was 3.5 years (range 1-12 years). 60 (83%) patients were on thrice weekly hemodialysis. Median thyroid volume was 8 ml (range 3-24ml). Thyroid nodules were seen in 31 (43%) patients. Significantly higher number of females (57%) had thyroid nodules as compared to males (32%) p-value 0.035, odds ratio 2.8 (95% CI 1.062-7.48). Twelve patients (17%) had single thyroid nodule, 14 patients (19 %) had 2-5 nodules, 5 patients (7%) had more than 5 nodules. Echotexture of thyroid gland was homogenous in 70 (95%) and heterogeneous in 4 (5%) patients.

Conclusions: There is high prevalence of thyroid nodules in our dialysis patient's population. Higher frequency was observed in female patients. No correlation was found with PTH levels, preexisting co morbidities, frequency and duration of hemodialysis, co-existing presence of renal cysts. Ultrasound evaluation of thyroid gland morphology should be considered in patients on maintenance hemodialysis.

TH-PO970

Routine Pre- and Post-Hemodialysis Blood Pressure as a Screening Tool for the Use of Ambulatory Blood Pressure Monitoring Yannick Begin, Simon Desmeules, Mohsen Agharazii, Sebastien Savard, Fabrice Mac-Way, Sacha A. De Serres. *Néphrologie, CHUQ- Hotel-Dieu de Quebec, Quebec, QC, Canada.*

Background: Routine pre- and post-hemodialysis (HD) blood pressure (BP) are poor indicators of BP control. Ambulatory blood pressure monitoring (ABPM) remains the gold standard for diagnosis and treatment of hypertension, but its availability is limited and it is especially uncomfortable in HD population. The aim of this study is to define pre- and post-HD blood pressure cut-offs where an ABPM would not be required for the assessment of blood pressure control.

Methods: In a single center cross-sectional retrospective study, we studied all complete routine ABPM that were performed in an HD population from April 2013 to February 2016. High BP was defined as a 44h ABPM systolic BP> 135 mmHg. ROC curve analysis, specificity, sensitivity, positive and negative predictive value (PPV and NPV) analysis were performed.

Results: There were 271 complete ABPM. The average of routine pre- and post-HD systolic BP (HD systolic BP) provided the best AUC (0.881) for an ABPM BP control of < 135 mm Hg. For a HD systolic BP threshold of 130 mmHg, sensitivity, specificity and NPV were respectively 97%, 42% and 94%. For a HD systolic BP threshold of 165 mmHg, sensitivity, specificity and PPV were respectively 45%, 97.4% and 94%. Overall, using these two thresholds, 45% of ABPM were in the zones of very high NPV or PPV.

Conclusions: To assess high BP, our study indicates that limiting ABPM use to patients with average of pre- and post-HD systolic BP of between 130-165 mm Hg reduces the use of ABPM by 45%. These findings could be useful for the management of health care resources and for the reduction of the level of intrusiveness.

TH-PO971

Impact of a Multi-Disciplinary Intensive Management Clinic on Incident Hemodialysis Patients in Singapore Priscilla P. How,[1,2] Catherine Ho,[1] Jia Jia Lee,[1] Hersharan Sran.[2] *[1]Dept of Pharmacy, National Univ of Singapore; [2]Dept of Medicine (Nephrology), National Univ Hospital.*

Background: Multidisciplinary models of care have been shown to be beneficial for patients with end-stage renal disease. The Hemodialysis Initiation and Transition (HIT) clinic provides consistent, intensive, multidisciplinary care to incident hemodialysis (HD) patients, and is the first of such clinic in Singapore. This study aimed to determine the clinical impact of this clinic.

Methods: Adult patients newly initiated on chronic HD from January 2013 to December 2014 were enrolled in this cohort study. Laboratory parameters, medication profiles, dialysis access, vaccination status, hospitalizations and mortality were assessed and compared between patients managed by the HIT clinic vs. conventional care.

Results: A total of 303 patients (216 HIT patients and 87 conventional care – control group) were included in the study. HIT patients achieved higher mean hemoglobin, corrected calcium and albumin levels (P<0.05). More HIT patients achieved albumin goals (HIT vs control 87.1% vs 65.8%, P<0.05), were using AV fistula (HIT vs control 54.2% vs 33.3%, P=0.008) and received Hepatitis B, influenza and pneumococcal vaccines (all P<0.05). More HIT patients were prescribed with renin-angiotensin-aldosterone blockers (HIT vs control 36.5% vs 20.9%), phosphate binders (HIT vs control 92.1% vs 77.6%) and IV iron (HIT vs control 81.5% vs 37.3%; all P<0.05). Fewer infection-related hospitalizations were observed among HIT patients (HIT vs control 0.3±0.6 vs 0.6±1.2, P=0.018) within the first 6 months of HD initiation although they had more access-related hospitalizations (HIT vs control, 0.3±0.8 vs 0.1±0.4, *P*=0.010), likely due to increased vigilance and follow-ups. No differences in mortality were observed between the groups (P>0.05).

Conclusions: Targeted multidisciplinary care can improve the morbidity, as well as management of ESRD-related complications, vaccination status and permanent access placement of our local incident HD patients.

TH-PO972

Clinical Significance of Serum Soluble α-Klotho Levels in Maintenance Hemodialysis Patients Shinya Nakatani,[1,2] Eiji Ishimura,[1] Mari Sakura,[2] Yu Tateishi,[2] Hideki Uedono,[1] Akihiro Tsuda,[1] Norihiko Usui,[2] Masaaki Inaba.[1] *[1]Nephrology, Osaka City Univ Graduate School of Medicine, Osaka, Japan; [2]Nephrology, Ishikiriseiki Hospital, Japan.*

Background: Humans with CKD exhibit markedly reduced serum soluble alpha-klotho (sαKl), progressively decreasing as renal function declines. However, in end-stage renal disease, the role of sαKl in pathogenesis of CVD, DM and CKD-MBD has not been fully studied.

Methods: Stable maintenance HD patients (n=188, 114 men and 74 women, 66.5 ±11.1 years, HD duration, 101±90 months) were enrolled. Serum sαKl levels were measured by recently developed ELISA methods (Yamazaki Y, et al. Biochem Biophys Res Commun. 2010).

Results: Serum sαKl levels in HD patients were 445±158 pg/ml, which was lower than those of healthy Japanese subjects (740 pg/ml; Yokoyama K, et al. Clin Nephrol. 2012). Although some previous studies have showed significantly correlations between sαKl and CKD-BMD parameters, serum sαKl levels in the present study showed no significant correlations between any of these markers. (FGF23: r=0.045, p=0.54; intact PTH: r=-0.06, p=0.44; phosphorus: r=0.01, p=0.89; calcium: r=0.06, p=0.46, respectively) When compared to DM *vs*. non-DM, and with CVD histories *vs*. without CVD histories, serum sαKl levels were not significantly different (DM; 447±170 *vs*. 444±148 pg/ml, p=0.75, CVD; 436±135 *vs*. 490±174 pg/ml, p=0.61, respectively). However, in HD patients with DM and CVD histories (n=38), these were significant correlations between serum sαKl and glycated albumin, a useful marker of glycemic control, (r=0.44, p=0.006), plasma glucose (r=0.32 p=0.005), calcium (r=0.34, p=0.004) and alkaline phosphatase (r=0.33, p=0.005). A multiple regression analysis showed that serum sαKl levels showed significant, independent associations with glycated albumin (β=0.40, p=0.006) and calcium (β=0.30 p=0.04) (R^2=0.43 p=0.0002).

Conclusions: In the presents study, clinical significance of measurement of serum sαKl is expected to be seen in HD patients with DM and CVD histories, which might reflect the parameters of anti-aging and/or anti-cachectic effects of alpha-Klotho. Clinical significance of serum sαKl levels on CKD-MBD may be smaller than that of anti-aging and/or anti-cachectic effects of alpha-Klotho.

TH-PO973

Residual Renal Function and Inflammation in Hemodialysis Patients Patricia De Sequera,[1] Elena Corchete,[1] Marta Albalate,[1] Rafael Perez-Garcia,[1] Lourdes Bohorquez,[3] Matilde Alique,[3] Jose M. Portoles,[2] María Marques Vidas,[2] Rafael Ramirez.[3] *[1]Nephrology, Univ Infanta Leonor Hospital; [2]Nephrology, Univ Puerta de Hierro Hospital; [3]Physiology, Univ Alcala de Henares, Madrid, Spain.*

Background: Residual renal function (RRF) contributes to overall clearance in dialysis patients. Previous studies have shown the relationship between inflammation and mortality in chronic kidney disease (CKD) patients. It has been described an increase in the percentage of proinflammatory monocytes CD14+/CD16++ in CKD stages 4-5, even without clinical evidence of inflammation and a reduction in the percentage of these monocytes by on-line hemodiafiltration (OL-HDF). Our objective was to investigate the relationship between RRF and inflammatory parameters in HD patients.

Methods: Prospective, observational, cross sectional study in 69 adult patients in chronic HD for at least 6 months. Epidemiological data and laboratory parameters were collected. RRF was measured by calculating average clearance of urea and creatinine in 24-h urine ((CCr+CU)/2). If>1 ml/min or urine>100 ml/day presence of RRF was considered. C-reactive protein (CRP) were quantified using nephelometry. Proinflammatory CD14+/CD16++ were measure with monoclonal antibodies followed by analysis in a flow cytometer.

Results: Average age:70.9 y, 38(55%) were male and 25(36.2%) diabetics. The average ((CrC+CU)/2):1.8 ml/min and urine V: 454(569) ml/day. RRF was associated with shorter renal replacement therapy vintage (39.7 vs 95.9 m;p=0.002); and lower OL-HDF prescription (56.6 vs 82%;p=0.021). There were no differences in vascular access, dialysis time, interdialitic weight gain or ultrafiltration (p Ns). Hemoglobin levels and predialysis systolic arterial blood pressure in patients with RRF were higher (11.8 vs 11.2 g/dl;p=0.024 and 144.2 vs 128.4;p=0.005) than in patients without it. Patients with RRF had lower β2microglobulin (19.9 vs 26.5 mg/l;p=0.0001), CRP levels (6.2 vs 21.4 mg/l;p=0.038) and proinflammatory CD14+/CD16++ percentage (17 vs 36.6%;p=0.006).

Conclusions: Patients with RRF in our study have lower inflammatory parameters. This is another reason to consider its preservation as a key objective in hemodialysis patients.

TH-PO974

Survival of People on Dialysis by Age Group between 1990 and 2010 in U.S.A., Australia and New Zealand Amy Kang,[1,2,3] Tadashi Toyama,[1,3] Yoichiro Hirakawa,[1] Vlado Perkovic,[1,2] Meg J. Jardine.[1,2] *[1]The George Inst for Global Health, Sydney, Australia; [2]ANZDATA Registry; [3]Equal Contribution.*

Background: The causes of death in End Stage Kidney Disease (ESKD) may reflect processes common to general population health and those specific to ESKD. We aimed to determine trends in absolute and relative mortality for people receiving dialysis compared with the general population in different age categories within the established dialysis healthcare systems of the USA, Australia (Aus) and New Zealand (NZ).

Methods: The included countries reported comparable publicly available age-specific annual mortality outcomes from 1990 to 2010. Annual mortality was derived from the dialysis registries and from national population statistics for young (0-44years), middle-aged (45-64years), senior (65-74years) and elderly (≥75years) people. Relative risks were calculated using a log-binomial model, with years included as piecewise-defined spline terms. Local regression using log relative risks was performed and slopes compared before and after each timepoint.

Results: Our study included 2,305,140 people receiving dialysis for a total of 7,334,427 person-years. Absolute mortality rates were higher for the dialysis and general populations in the US compared with Aus and NZ. For all groups in the USA, middle aged in Aus and NZ relative mortality worsened between 1990 and 2000 and then improved between 2000 to 2010. For seniors in Aus outcomes worsened between 1990 to 2000 and then did not change between 2000 to 2010. For young and elderly in Aus and young, senior and elderly in NZ there was no significant change in outcomes over the entire time period. Limitations include a relative lack of power for the young and elderly age groups in Aus and NZ.

Conclusions: Relative mortality rates for middle aged dialysis patients were stable overall between 1990 and 2010, after a transient worsening driven by a lag between improvements in the general and dialysis population mortality. Relative mortality rates for Australian senior dialysis patients appear to have worsened.

TH-PO975

Age-Stratified Incidence Rates of Cardiovascular Morbidity and Mortality in Both Diabetic and Non-Diabetic Dialysis Patients. Results from a 5-Year Prospective Study Masaki Ohsawa. *Dept of Internal Medicine, Iwate Medical Univ, Morioka, Japan.*

Background: It has not been sufficiently examined to what extent diabetic dialysis patients (DM) have the higher risk of cardiovascular events than the risk in non-diabetic dialysis patients (non DM).

Methods: A prospective study of 1,204 dialysis patients (DM (n=916) and non DM (n=298)) was conducted. Subjects were subdivided into four age categories (20-44, 45-64, 65-74, 75 years of age or older). Outcomes included all-cause death (ACD), cardiovascular death (CVD), incident heart failure (HF), incident stroke and incident acute myocardial infarction (AMI). Crude incidence rates and sex-and age-adjusted hazard ratios (95% confidence intervals) of outcomes using non-diabetic group as the reference were estimated in each group.

Results: There were 4793 observed patient-years (mean 3.9 years). Crude incidence rates (per 1000 patient-years) and hazard ratios (95% confidence intervals) are shown in the table.

age category	subjects (n)	ACD	CVD	HF	stroke	AMI
20-44 years	non DM (n=116)	19.0	9.5	24.4	7.7	0
	DM (n=21)	55.4	33.3	66.9	36.1	0
	HR (95% CI)	3.39 (1.12-10.2)	4.38 (1.00-19.3)	2.69 (0.94-7.67)	2.88 (0.52-15.9)	-
45-64	non DM (n=437)	52.1	29.0	50.9	37.9	10.7
	DM (n=142)	104.4	59.4	79.6	54.3	12.9
	HR (95% CI)	1.75 (1.26-2.44)	1.83 (1.18-2.85)	1.34 (0.91-1.98)	1.34 (0.75-2.40)	0.89 (0.37-2.13)
65-74	non DM (n=233)	108.8	36.3	99.3	71.5	8.9
	DM (n=96)	155.8	67.6	151.1	66.9	20.9
	HR (95% CI)	1.45 (1.03-2.05)	2.00 (1.15-3.47)	1.56 (1.06-2.30)	0.77 (0.32-1.83)	2.65 (0.92-7.62)
75+	nonDM (n=130)	269.8	133.5	169.4	114.9	28.4
	DM (n=39)	324.2	152.6	182.5	103.9	0
	HR (95% CI)	1.26 (0.85-1.86)	1.20 (0.85-1.86)	1.16 (0.68-2.11)	4.63 (1.10-19.5)	-

Conclusions: DM had significantly higher risks of ACD and CVD than the risks in non DM among patients aged less than 75 years. DM also had a higher risk of HF than the risk in non DM with marginal significance among patients aged less than 75 years. The risk ratio becomes lower with advance of age.

TH-PO976

Cardiovascular Outcomes in Young Adults with ESRD: An Analysis of the USRDS Yee Lu,[1] Nan Ji,[2] Alissa Kapke,[2] Xue Dietrich,[2] Zubin J. Modi,[1] David T. Selewski,[1] Kevin C. Abbott,[3] Brett W. Plattner,[1] Brahmajee K. Nallamothu,[1] Douglas E. Schaubel,[1] Rajiv Saran,[1] Debbie S. Gipson.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Arbor Research, Ann Arbor, MI; [3]NIH/NIDDK, Bethesda, MD.*

Background: Little is known about cardiovascular (CV) morbidity and mortality in young adults (YA) with end stage renal disease (ESRD).

Methods: Using national end stage renal disease (ESRD) data in the USRDS, all patients ages 1-29 yrs at ESRD initiation (2003-2013) were identified and grouped by age at ESRD initiation (1-11, 12-21, 22-29 yrs). CV mortality (CVM) events were identified from ESRD Death Notification Forms. Patients were censored if they died due to non-cardiovascular events, lost to follow-up, recovered or survived to the end of the study period (12/31/2014). Cox proportional hazards models were fit to determine the risk of CVM in YA (age 22-29), compared to patients age < 22 at initiation.

Results: Over 10 years, 1,787 (5.4%) of the 33,159 study patients experienced CVM. YA had the highest probability of CVM, as early as 3 months post initiation of ESRD. Characteristics associated with CVM are summarized in Table. Compared to YA with ESRD, the risk of CVM was lower among patients < 22 with cystic/hereditary/congenital (CHC) disease and children <12 with glomerulonephritis (GN) as the primary cause of ESRD.

Adjusted Hazard Ratios for CVM among Young Adults with ESRD

Variable	Hazard Ratio (95% CI)	p-value
Female	1.26 (1.14,1.38)	<0.001
Race (vs. White):		
Black	1.44 (1.3,1.59)	<.0001
Other	0.92(0.74, 1.14)	0.43
Incident Modality (vs. Transplant):		
HD	5.76 (3.71,8.94)	<.0001
PD	3.75 (2.37,5.93)	<.0001
Pre-ESRD Nephrology Care (vs. None)	0.88 (0.80,0.97)	0.01
Insurance (vs. Private):		
Public	1.73 (1.54,1.94)	<.0001
None	1.14 (0.98,1.32)	0.08
CHC ESRD Etiology (vs. age 22-29)		
Age 1-11	0.37 (0.18,0.76)	0.007
Age 12-21	0.58 (0.35,0.95)	0.03
GN ESRD Etiology (vs. age 22-29)		
Age 1-11	0.33 (0.16,0.70)	0.004
Age 12-21	1.02 (0.84,1.23)	0.88
Other ESRD Etiology (vs. age 22-29)*		
Age 1-11	0.58 (0.39,0.84)	0.004
Age 12-21	0.58 (0.48,0.70)	<.0001
Co-Morbidities at ESRD Initiation		
Congestive heart failure	1.78 (1.55,2.04)	<.0001
CV disease	1.37 (1.14,1.65)	0.001
Other cardiac disease	1.82 (1.53,2.16)	<.0001
Diabetes	2.16 (1.93,2.43)	<.0001

*Other: DM, Interstitial nephritis/pyelonephritis, Hypertension/large vessel disease, neoplasms/tumors, and miscellaneous. CVD: atherosclerotic heart disease, cerebrovascular disease/CVA/TIA, peripheral vascular disease; Other cardiac disease: as defined by Medical Evidence Form (CMS-2728)

Conclusions: In the setting of ESRD, YA have higher CVM than children. African Americans, dialysis at initiation, absent pre-ESRD nephrology care, public insurance, ESRD etiology, and pre-ESRD history of CV disease or diabetes mellitus are risk factors for CVM. These factors suggest areas for future research to improve CV survival.

TH-PO977

Epidemiology and Mortality of Pulmonary Embolism: A Comparison between Chronic Dialysis Patients and the General Population Chih-Chiang Chien. *Dept of Nephrology, Chi-Mei Medical Center, Tainan City, Taiwan.*

Background: Pulmonary embolism (PE) is associated with increased mortality, but it is not clear whether end-stage renal disease (ESRD) dialysis patients have a higher incidence and mortality than dose the general population not on dialysis, especially in Asian.

Methods: Using the Taiwan National Health Insurance Research Database, we did a comparative cohort study on 45,040 incident ESRD patients undergoing dialysis and 90,080 gender- and age- matched (1:2) patients not on ESRD dialysis, between 2000 and 2005. The follow-up period was from the index date to PE, the date of death, the end of dialysis, or December 31, 2008. Multivariate Cox proportional hazards models were used to estimate the relative hazards, and the models were adjusted for demographic parameters and comorbidities.

Results: The incidence rate of PE was 18.96/100,000 person-years in general population not on dialysis and 40.44/100,000 person-years in ESRD dialysis cohort. After multivariate analysis, there were no significant differences between the two cohort (HR: 1.364; 95% CI: 0.942-1.974). Older age (HR: 1.028; 95% CI: 1.015-1.041), peripheral vascular disease (HR: 1.897; 95% CI: 1.104-3.261), and atrial fibrillation (HR: 2.084; 95% CI: 1.037-4.191) were independent risks for PE. The overall in-hospital mortality rate after PE was 13.3%. ESRD dialysis patients had almost twice (97%) the mortality risk after PE than did the non-ESRD cohort (HR: 1.972; 95% CI: 1.083-3.590).

Conclusions: In conclusion, no significant difference in the incidence rates of PE between patients on and not on ESRD dialysis in Taiwan. However, patients on ESRD dialysis had a higher mortality risk after PE.

TH-PO978

B-lines on Lung Ultrasound: A Biomarker for Cardiac Events and Mortality in Hemodialysis Patients Jeanne Kamal,[1] Wissam Mansour,[1] Marc M. Saad,[2] Boutros Karam,[1] Elias Moussaly,[1] Saqib Hussen Abbasi,[1] Elie El-Charabaty,[3] Suzanne E. El Sayegh.[3] *[1]Internal Medicine Dept, Staten Island Univ Hospital, Staten Island, NY; [2]Nephrology Dept, Emory Univ Hospital, Atlanta, GA; [3]Nephrology Dept, Staten Island Univ Hospital, Staten Island, NY.*

Background: Volume overload in End Stage Renal Disease (ESRD) patients on hemodialysis (HD) is an independent risk factor for death from cardiovascular events. B Lines detected on Lung ultrasound (BLUS) assess extravascular lung water and correlate with the physical performance of HD patients. This raises interest in its prognostic ability predicting cardiac events and mortality in this population.

Methods: 81 HD patients underwent lung Ultrasound (US) after achieving their dry weight and had their B Line scores categorized as mild (0-14), moderate (15-29), severe (30-59) and very severe (>60). 10 were lost to follow up (6 transferred to another unit; 4 had renal transplant). 71 were followed for cardiac events (myocardial infarction; electrocardiogram(ECG)-documented angina episodes; heart failure; ECG-documented arrhythmia; cerebrovascular accident or transient ischemic attack) and death.

Results: 71 subjects were followed for a mean duration of 1.19 years. 50 were males, mean age 60. 9 patients died, 20 had an incident cardiac event. A Kaplan-Meier survival analysis demonstrated an interval decrease in survival times in all-cause mortality and cardiac events with increased BLUS scores (p 0.0049). Multivariate cox regression analysis showed the independent predictive value of BLUS for mortality and cardiac events: patients in moderate and severe classes (grouped) and very severe classes had hazard ratios of 2.98 and 7.98 respectively compared to patients in mild class (p 0.025 and 0.013). The average hospitalization rate (1.88) was not significantly different between the categories (p 0.1).

Conclusions: BLUS is an independent risk factor for death and cardiovascular events in HD patients. Chest US helps detecting lung congestion among ESRD patients on HD even at its early stage when clinically asymptomatic. The application of chest US in this population may improve patients' clinical outcome and help refine prognosis.

TH-PO979

Extravascular Lung Water Monitoring in Low Cardiovascular Risk Hemodialysis Patients Dimitrie Cristian Siriopol,[1] Luminita Voroneanu,[1] Ionut Nistor,[1] Mihai Onofriescu,[1] Simona Hogas,[1] Mugurel Apetrii,[1] Mehmet Kanbay,[2] Adrian Covic.[1] *[1]Nephrology, "Grigore T. Popa" Univ of Medicine and Pharmacy, Iasi, Romania; [2]Medicine, Koc Univ School of Medicine, Istanbul, Turkey.*

Background: Fluid overload is one of the most common modifiable risk factor associated with the increased mortality risk observed in hemodialysis (HD) patients, but the precise assessment of hydration status in these patients remains a major challenge for nephrologists. Our study aimed to explore whether combining two bedside methods, lung ultrasonography (LUS) and bioimpedance, may provide complementary information to guide treatment in specific HD patients.

Methods: In total, 250 HD patients from two dialysis units were included in this randomized clinical trial. Patients were randomized 1:1 to have a dry-weight assessment based on clinical (control) or LUS and bioimpedance (active) guided protocol. The primary outcome was to assess the difference between the two groups on a composite of all-cause mortality and first cardiovascular event (CVE) - including death, stroke, and myocardial infarction.

Results: During a mean follow-up period of 21.3±5.6 months, there were 54 (21.6%) composite events in the entire population. There was a non-significant 9% increase in the risk for this outcome in the active arm (HR=1.09, 95%CI 0.64-1.86, p=0.75). Similarly, there were no differences between the two groups when analyzing separately the all-cause mortality and CVE outcomes.

Conclusions: This study shows that a LUS guided dry-weight adjustment protocol, as compared with clinical evaluation, doesn't reduce all-cause mortality and/or CVE in HD patients.

Volume Overload Hospitalization Identification among Hemodialysis Patients Using Administrative Claims Magdalene M. Assimon, Thuy Minh Nguyen, Suzanne L. Katsanos, Jennifer E. Flythe. *Univ of North Carolina, Chapel Hill, NC.*

Background: There is growing interest in fluid management practices and consequently a need to identify, quantify and monitor volume-related hospitalizations among hemodialysis (HD) patients. Administrative claims databases (e.g. the U.S. Renal Data System) are often used to study such outcomes, but these data are generated for billing purposes and may not capture clinical nuance. We conducted a validation study to assess the accuracy of claims-based definitions for volume overload (VO) hospitalizations.

Methods: We examined a random sample of 315 adult maintenance HD patients admitted to a large U.S. academic medical center from 2010-13. We performed standardized chart reviews to clinically adjudicate VO admissions. Using the medical center's administrative billing data, we built claims-based definitions for VO hospitalizations by combining various fluid-related ICD-9 discharge diagnosis codes. We computed the prevalence of claims-identified VO admissions and estimated validity metrics for each definition using adjudicated VO as the reference standard.

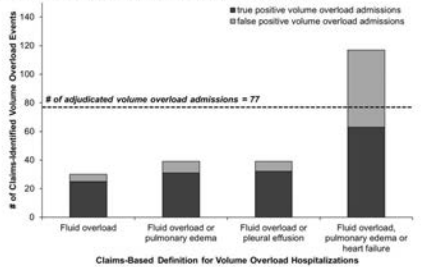
Results: Seventy-seven admissions (24.4%) were adjudicated as VO hospitalizations. The prevalence of claims-identified VO admissions varied across definitions (9.5-37.1%). Claims-based definitions tended to have low sensitivity and high specificity (**Panel A**). Definitions containing heart failure ICD-9 codes captured the most false positive events (**Panel B**). In sensitivity analyses, we added dialysis procedure codes to diagnosis code-based definitions and assessed validity. Small gains in definition specificity and decrements in sensitivity were observed (data not shown).

Panel A. Validity of Administrative Claims Definitions for Volume Overload Hospitalizations

Claims definition description	ICD-9 diagnosis codes*	Sensitivity (95% CI)[a]	Specificity (95% CI)[a]	PPV (95% CI)[a]	NPV (95% CI)[a]
Fluid overload	276.6, 276.69	32.5% (22.2%, 44.1%)	97.9% (95.2%, 99.3%)	83.3% (65.3%, 94.4%)	81.8% (76.8%, 86.1%)
Fluid overload or pulmonary edema	276.6, 276.69 or 514, 518.4	40.3% (29.2%, 52.1%)	96.6% (93.4%, 98.5%)	79.5% (63.5%, 90.7%)	83.3% (78.4%, 87.5%)
Fluid overload or pleural effusion	276.6, 276.69 or 511.9	41.6% (30.4%, 53.4%)	97.1% (94.0%, 98.8%)	82.1% (66.5%, 92.5%)	83.7% (78.8%, 87.9%)
Fluid overload, pulmonary edema or heart failure	276.6, 276.69 or 514, 518.4 or 402.x1, 404.x1, 404.x3, 428	81.8% (71.4%, 89.7%)	77.3% (71.5%, 82.5%)	53.8% (44.4%, 63.1%)	92.9% (88.4%, 96.1%)

*Definitions were constructed using ICD-9 discharge diagnosis codes billed in any position.
[a]Clinically adjudicated volume overload served as the reference standard.
Abbreviations: CI = confidence interval; NPV = negative predictive value; PPV = positive predictive value.

Panel B. Number of Claims-Identified Volume Overload Hospital Admissions



Conclusions: Claims-based VO definitions are imperfect. Investigators and regulators must carefully consider the implications of missing and misclassifying events when evaluating and monitoring HD patient VO admissions with administrative data.

Management of Overhydration Using Bioelectrical Impedance Analysis in Chronic Hemodialysis Patients Chae Rim Kim, Jung-Ho Shin, Jin Ho Hwang, Su Hyun Kim. *Dept of Internal Medicine, Chung-Ang Univ Hospital, Seoul, Korea.*

Background: Fluid overload is common in end-stage renal disease (ESRD) patients receiving maintenance hemodialysis, and it may be an independent risk factor for cardiovascular events and all-cause death. Recently, bioelectrical impedance analysis (BIA) has been widely used as a non-invasive method to estimate volume status. We retrospectively investigated whether management of overhydration can reduce the rate of cardiovascular event and mortality in chronic hemodialysis patients.

Methods: ESRD patients who had been treated with outpatient hemodialysis were recruited. Using BIA, the ratio of extracellular fluid to total body fluid (ECF/TBF) was obtained every 6 months. Patients were divided into two groups according to ECF/TBW: the uncontrolled group included those with all measured ECF/TBW ≥0.40; and the controlled group included those with any measured ECF/TBW <0.40.

Results: A total of 142 patients (85 [59.9%] in the controlled group and 57 [40.1%] in the uncontrolled group) were included, and were followed for 29 (12, 42) months. The baseline ECF/TBW was 0.39 ± 0.01 in the controlled group and 0.42 ± 0.01 in the uncontrolled group, respectively (P < 0.001), this difference persisted during the study period (all P < 0.05 from baseline to 48 months). Patients in the uncontrolled group was older, and had higher Charlson comorbidity index and higher systolic blood pressure, compared to those in the controlled group (P = 0.006, P < 0.001 and P = 0.009, respectively). The risk of cardiovascular event was higher in the uncontrolled group (HR 2.4, 95% CI 1.2–5.1; P = 0.020), but it was disappeared after the adjustment with age, Charlson comorbidity index and systolic blood pressure (P = 0.344). On the other hand, patients in the uncontrolled group had higher risk of all-cause death, independent of age and Charlson comorbidity index (HR 3.6, 95% CI 1.1–11.5; P = 0.033).

Conclusions: Management of overhydration according to the ECF/TBF may be beneficial to prevent all-cause death in ESRD patients with maintenance hemodialysis.

TH-PO982

Does Fluid Balance or Rapid Fluid Removal Affect Outcome in Incident Hemodialysis Patients? Sandra Seidenfaden,[1] Runolfur Palsson,[1,2] Olafur S. Indridason.[2] *[1]Univ of Iceland; [2]Landspitali - the National Univ Hospital of Iceland, Reykjavik, Iceland.*

Background: Recent studies have shown that fluid balance affects survival in prevalent hemodialysis (HD) patients and that end-dialysis overweight (EDOW) of ≥0.3 kg and ultrafiltration rate (UFR) of more that 10-13 ml/kg/hr have been associated with decreased survival. In this study we examined if factors related to fluid balance are associated with survival in incident HD patients.

Methods: This was a retrospective study of all patients initiating HD at a University Hospital's Dialysis Unit and surviving for at least 3 months during 2003-2014. Data were obtained from medical records, including estimated dry weight, weight before and after dialysis, dialysis duration, blood pressure during dialysis and vascular access. The mean of values for each patient during the fourth month of HD (8-12 consecutive HD sessions) were used. Volume removed and fluid removal rate was calculated and EDOW was defined as the difference between attained post-dialysis body weight and dry weight. Kaplan-Meier method and Cox regression analysis were used to assess survival.

Results: A total of 197 patients began hemodialysis treatment during the study period. 153 patients survived for at least 3 months and had a full set of data available; 98 (64.0%) were men. EDOW ≥0.3 kg was observed in 36 (23.5%) of the HD patients , 63 (41.1%) spent ≤3.5 hours in each dialysis session. Sixty-five (42.3%) had UFR >10 ml/kg/hr and 20 (13.0%) >13 ml/kg/hr. The type of vascular access was a native fistula in 98 patients (64.0%), a HD catheter in 37 (24.2%) and a synthetic graft in 18 patients (11.8%). Cox regression analysis, adjusting for age, sex, access type, albumin and URR did not show association between survival and EDOW ≥0.3 kg (HR 0.7, 95% CI, 0.34-1.41), UFR >10 ml/kg/hr (HR 1.0, 95% CI, 0.60-1.69) or URF >13 ml/kg/hr (HR 1.18, 95% CI, 0.44-3.12).

Conclusions: The previously described association between UFR and EDOW does not appear to affect survival of incident HD patients. Residual kidney function could not be accounted for in our model but may be of importance in incident patients.

TH-PO983

A Higher Ultrafiltration Rate Is Associated with Worsening of the Echocardiographic Left Atrial Volume Index in Incident Hemodialysis Patients Jwa-Kyung Kim,[1] Sun Ryoung Choi,[2] Jae-Won Lee,[3] Sung Gyun Kim.[1] *[1]Internal Medicine, Kidney Research Inst, Hallym Univ Sacred Heart Hospital, Anyang, Korea; [2]Internal Medicine, Sahmyook Medical Center, Seoul, Korea; [3]Internal Medicine, G Sam Heart Hospital, Anyang, Korea.*

Background: Optimal fluid management is essential in caring hemodialysis patient. However, too rapid fluid removal and the resultant higher ultrafiltration rate (UFR) disadvantageously promote hemodynamic instability and cardiac injury. We evaluated the effects of the rapid UFR on the changes of echocardiographic left atrial volume index (LAVI) over period.

Methods: A prospective observational study was conducted with 124 patients who newly started hemodialysis. Echocardiography was performed at baseline and repeated 19.7 (11.3-23.1) months apart. Changes in LAVI per year (ΔLAVI/yr, mL/m$^{2.7}$/year) were arithmetically calculated, and the 75th percentile of the ΔLAVI/yr distribution was regarded as a "significant" increment. UFR was expressed in terms of mL/hr/kg , and we employed a mean UFR over 30 days (approximately 12-13 treatment).

Results: The meaninter-dialytic weight gain was 1.88±0.94 kg, and the UFR were 8.01±3.87 mL/h/kg. The significant pathological increment point in ΔLAVI/yr was 4.87 mL/1.73m^2/yr. Correlation analysis showed that ΔLAVI/yr was closely related to the baseline blood pressure (BP), hemoglobin level, residual renal function, and UFR. According to the ROC curve, the best cut-off of value of UFR for the predicting the pathological increment was 10 mL/h/kg, with the area under the curve of 0.712. In multivariate analysis, systolic BP, a history of coronary artery disease, hemoglobin <10 g/dL, and high UFR were significant predictors. An increase of 1 mL/h/kg in the UFR was associated with a 22% higher risk of a worsening of the LAVI (odds ratio, 1.22; 95% confidence interval, 1.05–1.41).

Conclusions: For patient starting hemodialysis, a rapid UFR over 10 mL/h/kg may be associated with maladaptive worsening of the LAVI, a strong predictor of long-term adverse outcomes.

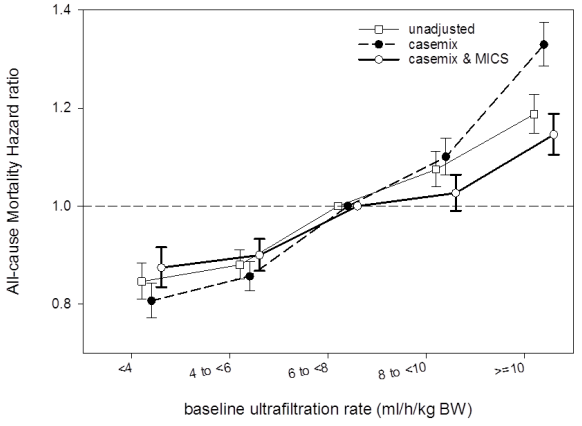
TH-PO984

Association of Ultrafiltration Rate with Mortality in Incident Hemodialysis Patients Tae Woo Kim,[1] Tae Ik Chang,[1] Tae Hee Kim,[1] Elani Streja,[1] Melissa Soohoo,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.*

Background: High ultrafiltration rate (UFR; ml/h/kg BW) may have a deleterious effect on survival in maintenance hemodialysis (MHD) patients. The main determinants of UFR are ultrafiltration and dialysis treatment time. Several studies have reported higher UFR was associated with increased all-cause and cardiovascular (CV) mortality in prevalent hemodialysis (HD) patients. However, the association of UFR with mortality in incident HD patients is not well known.

Methods: We examined a 5-year cohort of 110,880 patients who initiated MHD in the US from January 2007 to December 2011. UFR levels were divided into 5 ordinal categories (<4, 4 to <6, 6 to <8, 8 to <10, ≥10 ml/h/kg BW). We examined the association of UFR and all-cause mortality using Cox proportional hazard models with hierarchical adjustments for demographics, comorbidities and markers of malnutrition-inflammation-cachexia syndrome (MICS).

Results: The mean age of patients was 63±15 years, and included 43% females, 32% African Americans, 58% diabetics. In the case-mix and MICS adjusted model, higher baseline UFR was linearly associated with higher all-cause mortality risk. In addition, there were consistent and, incrementally higher associations of UFR with mortality irrespective of different urine volume, dialysis treatment time and post-dialysis systolic blood pressure categories.



Conclusions: High UFR is independently associated with increased all-cause mortality in incident HD patients. These results suggest that longer or more frequent dialysis therapy is needed to improve outcome for patients with high UFR.

TH-PO985

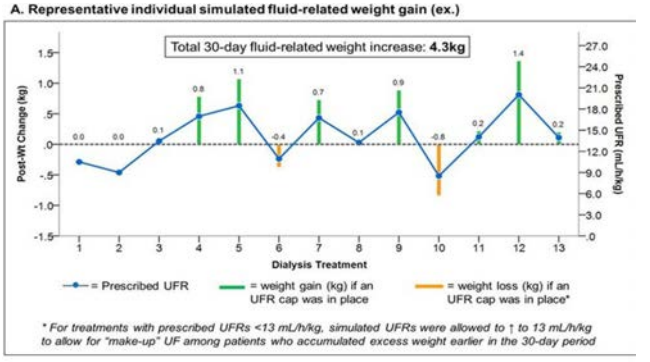
Weight Gain following Ultrafiltration (UF) Rate Threshold Implementation Jennifer E. Flythe, Magdalene M. Assimon. *Univ of North Carolina Kidney Center, Chapel Hill, NC.*

Background: Good fluid management is critical for optimal hemodialysis (HD) care. In 2015 the National Quality Forum endorsed an UF rate threshold quality measure but did not endorse a proposed companion target weight achievement measure. Lowering UF rates requires treatment time (TT) extension or interdialytic weight gain (IDWG) reduction. Often, patients are opposed to longer TTs and have difficulty with diet restrictions. In a national cohort we 1) examined target weight achievement, and 2) simulated weight gain over a 30-day period in the setting of UF rate threshold implementation without concurrent TT extension or IDWG reduction.

Methods: Using large dialysis organization data from 112,373 patients (1,754 facilities) in 2012, we analyzed facility-level target weight achievement according to the Kidney Care Quality Alliance-proposed target weight measure (post-HD weight ≥1 kg above or below target weight). Among 61,796 patients with complete pre- and post-HD weight and TT data, we simulated cumulative 30-day weight gains if UF rates were capped at 13 mL/h/kg without concurrent TT extension or IDWG reduction (Panel A).

Results: Facilities had, on average, 27.6 ± 10.1% of patients with post-HD weights ≥1 kg above or below target weights per KCQA measure specifications. Facilities in the highest target weight measure quartile (≥33.5% of patients with missed target weight) tended to be larger, located in the western U.S., and had more black patients and patients with shorter TTs (vs. lower quartile facilities). Overall, at the patient-level, implementation of an UF rate cap of 13 mL/h/kg with unchanged TTs and IDWGs resulted in a mean 30-day cumulative weight gain of 3 ± 4 kg. Panel B displays facility-level simulation results.

A. Representative individual simulated fluid-related weight gain (ex.)



** For treatments with prescribed UFRs <13 mL/h/kg, simulated UFRs were allowed to ↑ to 13 mL/h/kg to allow for "make-up" UF among patients who accumulated excess weight earlier in the 30-day period*

B. Facility-level % of patients with various 30-d weight changes after UF rate cap imposition.[a]

	% of Patients with 30-d Cumulative Difference in Post-HD Wt	% of Patients with 30-Day Cumulative Difference in Post-HD Wt	
	Overall	(-) Heart Failure	(+) Heart Failure
30-Day Cumulative Difference in Post-HD Wt	Mean ± SD Median (Q1, Q3)	Mean ± SD Median (Q1, Q3)	Mean ± SD Median (Q1, Q3)
≥ +2 kg	35 ± 15 35 (25, 45)	34 ± 17 33 (23, 44)	40 ± 26 39 (25, 54)
≥ +3 kg	28 ± 14 26 (17, 37)	26 ± 16 25 (15, 36)	32 ± 25 29 (15, 46)
≥ +4 kg	22 ± 13 21 (13, 30)	21 ± 14 19 (11, 29)	26 ± 23 23 (9, 39)

[a] Interpretation: Facilities had, on average, 35 ± 15% of patients with cumulative weight gains ≥2 kg 30 days after imposition of an UF rate cap of 13 mL/h/kg without TT extension or IDWG reduction.

Conclusions: Failure to balance UF rate thresholds with target weight achievement policies may lead to substantial weight gain if TTs are not extended and/or IDWG is not reduced.

TH-PO986

Association of Hemoglobin Levels Corrected by Interdialytic Weight Gain on Mortality in Japanese Hemodialysis Patients Tatsunori Toida,[1,2] Takashi Iwakiri,[2] Yuji Sato,[3] Hiroyuki Komatsu,[2] Kazuo Kitamura,[2] Shouichi Fujimoto.[1] *[1]Dept of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki; [2]Fist Dept of Internal Medicine, Univ of Miyazaki Hospital; [3]Dialysis Div, Univ of Miyazaki Hospital.*

Background: Hemoglobin (Hb) levels are affected by a change in the body fluid status, the relationship between Hb levels and mortality while taking interdialytic weight gain (IDWG) at blood sampling into account has not yet been examined in hemodialysis (HD) patients.

Methods: Study design: Cohort study. Setting, Participants: Data from 1375 prevalent HD patients (median age (interquartile range), 69 (60-77) years; 42.3% female). Predictor: Patients were divided into 5 categories according to baseline Hb levels and two groups based on IDWG rates at blood sampling. Outcomes: All-cause and cardiovascular mortality during a 3-year follow-up. Measurements: Hazard ratios (HRs) were estimated using a Cox model for the relationship between Hb categories and mortality, and adjusted for potential confounders. Patients with Hb levels of 9-9.9g/dL were set as our reference category.

Results: 246 patients (18%) died of all-cause mortality, including 112 cardiovascular deaths. Lower Hb levels (<9.0g/dL) were associated with all-cause mortality, while Hb levels were not associated with cardiovascular mortality. When patients with IDWG 5.4% were divided into two groups using the median value of IDWG, the correlation between lower Hb levels and all-cause mortality disappeared in high IDWG patients (IDWG≥5.4%), but was maintained in low IDWG patients (<5.4%). Furthermore, about the cardiovascular mortality, a significant correlation was observed in both lower Hb levels in low IDWG patients and higher Hb levels in high IDWG patients (Table).

Conclusions: In HD patients, target Hb levels need to be selected in consideration of IDWG at blood sampling.

	Hb level (g/dL)				
	<9	9-9.9	10-10.9	11-11.9	≥12

Association between Central Venous Oxygen Saturation and Ultrafiltration Volume in Chronic Hemodialysis Patients Lili Chan,[1] Hanjie Zhang,[2] Anna Meyring-Wosten,[2] Stephan Thijssen,[1,2] Peter Kotanko.[2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Renal Research Inst, New York, NY.*

Background: Hemodialysis (HD) patients with congestive heart failure have higher mortality than those without. At rest with other factors being stable, central venous oxygen saturation ($ScvO_2$) can be used as a surrogate for cardiac output. Our goal was to examine if ultrafiltration volume corrected for post HD body weight (cUFV) is correlated with $ScvO_2$ at the end of HD and to assess the association between this correlation and mortality.

Methods: We conducted a retrospective study between 1/2012 and 8/2015 in 232 HD patients with central venous catheters as HD access. A 6-month baseline period with at least 10 HD treatments with $ScvO_2$ recordings preceded a 36-month follow-up. The $ScvO_2$ values during the last 10 minutes of treatments were averaged to obtain an end-HD $ScvO_2$. A slope was then obtained per patient between end-HD $ScvO_2$ and cUFV across all treatments. Survival was assessed with Kaplan Meier and spline analysis.

Results: 70% of the patients showed an inverse relationship between end-HD $ScvO_2$ and cUFV. During follow-up, there were 54 deaths. On spline analysis, there was no association between slope and mortality. Patients were then divided into groups of negative and positive slopes. Kaplan-Meier analysis indicated no survival difference between groups.

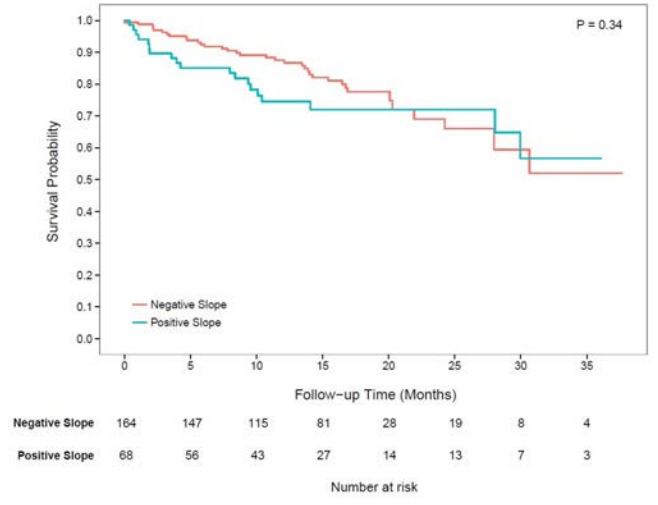

Figure 1: Kaplan-Meier estimates for survival probabilities between negative slope (red) and positive slope (green) patients, respectively. The number of patients at risk is indicated in the table below the graph.

Conclusions: As $ScvO_2$ is reflective of cardiac output at rest, the negative correlation of $ScvO_2$ with cUFV suggests that a majority of HD patients respond with a drop in cardiac output in the face of ultrafiltration. Patients with a negative slope did not have increased mortality. Further research is necessary to clarify the complex relationship between $ScvO_2$, UFV and cardiac output, in hopes of identifying a modifiable intradialytic target to improve outcomes in HD patients.

TH-PO988

Association between Peridialytic Systolic Blood Pressure Changes and Arterial Oxygen Saturation: Results from a Large U.S. Hemodialysis Cohort Anna Meyring-Wosten,[1] Ya Luo,[2] Hanjie Zhang,[1] Stephan Thijssen,[1] Yuedong Wang,[2] Peter Kotanko.[1,3] *[1]Renal Research Inst, New York; [2]Univ of California - Santa Barbara; [3]Icahn School of Medicine at Mount Sinai, New York.*

Background: While the physiological basis for peridialytic systolic blood pressure (SBP) decline has been studied extensively, the factors underlying a paradoxical SBP rise are not fully understood. Recent research indicated that 10% of chronic hemodialysis (HD) patients suffer from prolonged intradialytic hypoxemia [Meyring-Wösten, CJASN 2016]. Since hypoxemia induces a sympathetic response we entertained the hypothesis that SBP changes (ΔSBP) and intradialytic arterial oxygen saturation (SaO_2) may be associated.

Methods: We retrospectively analyzed intradialytic SaO_2 and ΔSBP (calculated as post-HD SBP minus pre-HD SBP) in chronic HD patients with arterio-venous vascular access. SaO_2 was recorded by Crit-Line® monitor (Fresenius Medical Care, Waltham, MA). Patients were followed over 6 months. Linear mixed effects models (LME) were used to explore associations between ΔSBP and (a) HD treatment time spent below 90% SaO_2 as well as (b) mean intradialytic SaO_2.

Results: We assessed 982 patients (29,869 HD treatments, 61% males; 52% whites). In patients with SaO2 > 90% during HD treatments mean ΔSBP was -10.24 mmHg (95% confidence interval -10.57 to -9.90). In contrast, in patients in whom SaO2 was < 90% throughout the entire treatment time mean ΔSBP was -6.04 mmHg (95% confidence interval -8.15 to -3.93). LME revealed that for every percent point increase of time spent below 90% SaO_2 ΔSBP increased by 0.03 mmHg (p=0.004) and that with every percent point increase in mean SaO_2 the ΔSBP decreased by 0.46 mmHg (p<0.001).

Conclusions: We observed an inverse relationship between intradialytic arterial oxygen saturation and the blood pressure response to HD. These findings support the notion that hypoxemia activates mechanisms that partially blunt the intradialytic blood pressure decline. We speculate that sympathetic surges resulting from intermittent hypoxemia may play a role. To further explore that hypothesis specifically designed prospective studies are required.

TH-PO989

Joint Effect of Pre-Dialysis Systolic Blood Pressure and Peridialytic Systolic Blood Pressure Change on Survival in Chronic Hemodialysis Patients Anna Meyring-Wosten,[1] Hanjie Zhang,[1] Ya Luo,[2] Alice Topping,[1] Jochen G. Raimann,[1] Yuedong Wang,[2] Franklin W. Maddux,[3] Peter Kotanko.[1,4] *[1]Renal Research Inst, New York; [2]Univ of California at Santa Barbara, CA; [3]Fresenius Medical Care North America, Boston, MA; [4]Icahn School of Medicine at Mount Sinai, New York.*

Background: Previous studies in chronic hemodialysis (HD) patients indicate an association between pre-HD systolic blood pressure (preSBP) and peridialytic SBP change (ΔSBP) on mortality. Yet, analyzing these two variables separately may not fully explore the nature of the interaction.

Methods: PreSBP and ΔSBP (post- minus pre SBP) were analyzed between 1/2001 and 2/2010. Baseline was defined as months 4-12 in the first year of HD, follow-up terminated at death, loss to follow-up, or the end of the study. Only patients who survived the baseline and had no missing covariates were included. We fitted Cox proportional hazard model with a bivariate spline for the main predictors, preSBP and ΔSBP, and adjusted for age, gender, diabetes, access type, relative interdialytic weight gain, body mass index and albumin.

Results: 5866 patients remained for final analysis (56% males; 50% whites). 1649 (28.1%) patients died during follow-up. Median follow-up time was 1.74 years. While with high preSBP, a SBP increase was associated with higher hazard ratio (HR), with low preSBP, a SBP increase was associated with lower HR (Fig.1). The results indicate a "trough" region of low HR.

Conclusions: Peridialytic SBP changes and pre-HD SBP are jointly associated with all-cause mortality in HD patients. While a peridialytic SBP increase may be particularly harmful in patients with high pre-HD SBP, it may be beneficial in those with low pre-HD SBP.

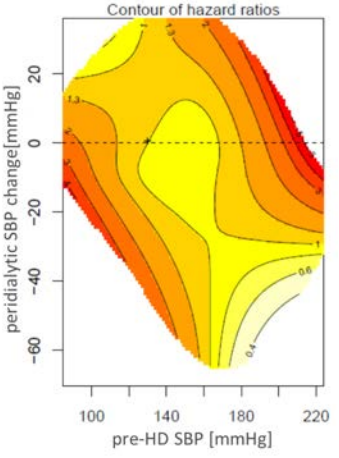

Figure 1: Contour plot showing the relationship between preSBP, ΔSBP and hazard ratios (HR) for all-cause mortality. Contour lines indicate discrete HR levels.

TH-PO990

Geographical and Seasonal Patterns of Blood Pressure in Hemodialysis Patients: A EURODOPPS Study Flore Duranton,[1] Anneke Kramer,[2] Brian Bieber,[3] Ziad Massy,[4,5] Christian Combe,[6] Francesca Tentori,[3] Kitty J. Jager,[2] Angel Argiles.[1,6] *[1]RD-Nephrologie, France; [2]ERA-EDTA Registry, AMC Amsterdam, Netherlands; [3]Arbor Research Collaborative for Health; [4]CHU Ambroise Paré and Inserm U1018, France; [5]CHU Bordeaux, France; [6]NDSG Sète, France.*

Background: In HD patients, we found that blood pressure (BP) before dialysis sessions was associated with seasons and outdoor temperature in a single facility. We wanted to extend our study to assess the geographical influences on BP.

Methods: Clinical data were obtained from the Dialysis Outcomes and Practice Patterns Study (DOPPS) phases 3-4 (2005-2011) for patients from 7 European countries (Sweden, United Kingdom, Belgium, Germany, France, Italy, Spain). Climate records corresponding to HD facilities were obtained. BP level was analyzed using mixed models with location (country or latitude), climate (season or outdoor temperature) and interactions as fixed effects, adjusting for study design and repeated measures.

Results: The study included 9655 HD patients from 151 locations and over 50 000 observations. Across Europe, pre- and post-dialysis BP were significantly lower in Southern places (fig-left, P≤0.02). Pre-dialysis BP was lower in summer and higher in winter (P<0.001) and was inversely associated with outdoor temperature (fig-right, P<0.01). Post-dialysis BP showed no clear association with seasons (P≥0.09) or temperature (P>0.1). The effect of temperature on preSBP was more pronounced in southern or warmer locations (P_{int}<0.01).

Conclusions: In Europe, patients from southern locations have lower pre- and post-dialysis BP. Pre-dialysis BP is lower in summer and with warmer temperature, and this effect is more pronounced in southern/warmer locations. There is a need to consider this variability when studying BP.

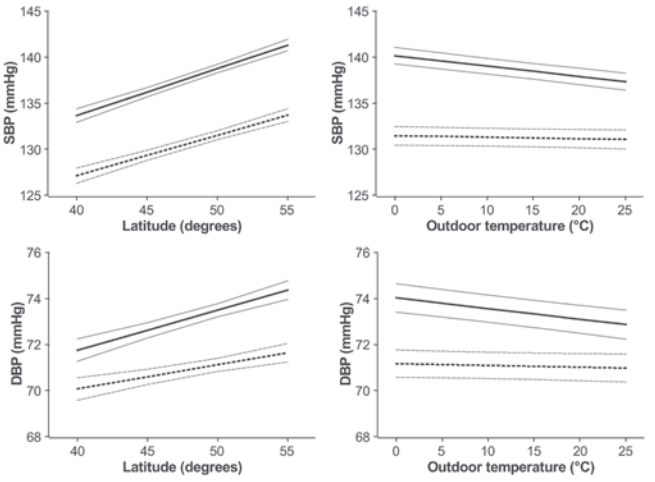

Fig: Pre-dialysis (solid line) and post-dialysis (dashed line) BP level by latitude and temperature. Estimates and 95% CI from mixed models.

Adequately Controlled Systolic Blood Pressure Is Significantly Associated with Better Survival Rate, Irrespective of Number of Antihypertensive Agents in Prevalent Dialysis Patients

Boyoung Nam,[1] Jong Hyun Jhee,[2] Ji Min Park,[1] Youn Kyung Kee,[2] Tae-Hyun Yoo.[1,2] *[1]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Republic of Korea.*

Background: The object of this study is to investigate optimal blood pressure (BP) target and adequate management of BP in prevalent dialysis patients group.

Methods: The data were retrieved from End-stage Renal Disease-Clinical Research Center (ESRD-CRC) which dialysis patients were prospectively enrolled from 2009 to 2014. Total 2,299 prevalent dialysis patients were analyzed. Eligible patients were assigned to five groups according to distribution of SBP (SBP<110, 110-129, 130-149, 150-169, and ≥170 mmHg). The primary outcome was all-cause mortality.

Results: The mean SBP in each group was 99.2, 119.7, 137.1, 155.9, and 179.2 mmHg, respectively (P<0.001). Baseline characteristics among the groups did not show significant differences except number of AHAs (1.3±1.4, 1.7±1.5, 1.9±1.4, 2.2±1.4, and 2.4±1.3 pills in each group, P<0.001). During a median follow up of 4.5 years, all-cause mortality was significantly higher in SBP <110 and ≥170 mmHg group [Hazard ratio (HR) 1.96, 95% confidential interval (CI) 1.40-2.74, P<0.001; HR 1.49, 95% CI 1.05-2.11, P=0.026], compared to reference group. Multivariate Cox analysis revealed that SBP <110 and ≥170 mmHg group had significantly higher risk of all-cause mortality after adjustment for age, sex, history of diabetes and cardiovascular events, duration of dialysis, serum albumin (HR 2.06, 95% CI 1.44-2.93, P<0.001; HR 1.53, CI 1.07-2.19, P=0.020). However, the number of AHAs being taken was not associated with survival rate in subgroup analysis with each BP group.

Conclusions: This study showed that lowest (<110) or highest (≥170 mmHg) SBP group had significantly higher risk of all-cause mortality, irrespective of number of AHAs. BP control with optimal target is significantly associated with better survival rate.

TH-PO992

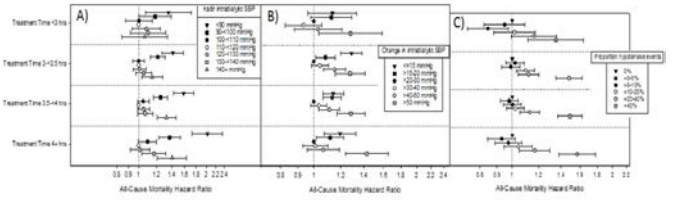
Impact of Hemodialysis Treatment Time on the Association of Intradialytic Hypotension and Mortality in Hemodialysis Patients

Jason Chou,[1] Elani Streja,[1] Connie Rhee,[1] Yoshitsugu Obi,[1] Melissa Soohoo,[1] Csaba P. Kovesdy,[2] John J. Sim,[3] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ of Tenn.; [3]Kaiser Permanente SC.*

Background: Intradialytic hypotension (IDH) occurs frequently and is associated with poor outcomes in hemodialysis (HD) patients. The HD treatment time (TT) may also be associated with survival. We hypothesize that longer TT attenuates the association of IDH with mortality.

Methods: We examined the association of nadir and change in intradialytic SBP (niSBP and ΔiSBP, respectively) and frequency of IDH with all-cause 5-year (2007–2011) mortality stratified by TT in a cohort of 112,015 incident (first 91 days of HD) adult HD patients using Cox regression models with adjustment for case-mix, comorbidities, and lab covariates. ΔiSBP was defined as pre-HD SBP minus niSBP. Frequency of IDH was defined as the proportion of HD treatments where patient's niSBP was < 90 mmHg.

Results: We found that lower and higher niSBP (< 100 and ≥ 140 mmHg, respectively) were incrementally associated with higher mortality. Frequency of IDH had an incremental quadratic association with death starting with > 20% frequency. Longer TT in these groups exhibited an increased IDH-mortality association. ΔiSBP of ≤15 and ≥ 50 mmHg were consistently associated with increased mortality while longer TT groups did not consistently show this trend. All associations were robust to adjustment for demographics, laboratory values and comorbidities.



Conclusions: Under longer hemodialysis TT, the IDH events and/or lower niSBP have a greater mortality risk. Further studies are needed to identify optimal niSBP goals and corresponding treatment times.

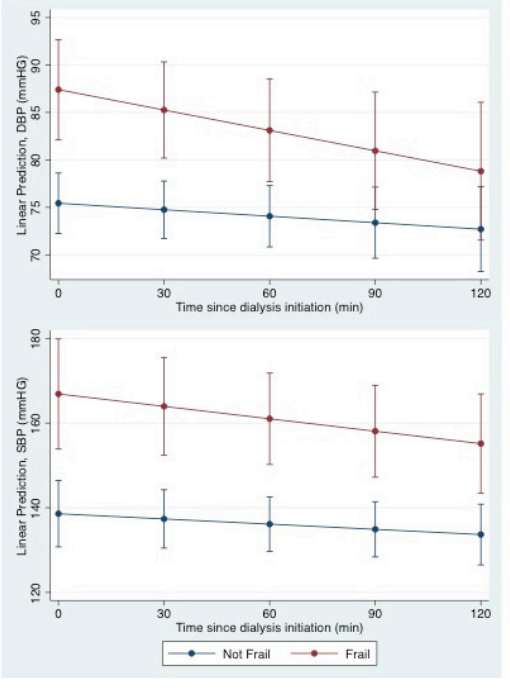
Frailty and the Blood Pressure Response to the Stressor of Hemodialysis among Older Patients

Mara McAdams-DeMarco, Qiong Huang, Hao Ying, Israel O. Olorundare, Morgan Grams, Dorry L. Segev. *Johns Hopkins.*

Background: Frailty is described as a multi-system dysregulation resulting in a vulnerability to stressors; yet evidence for this hypothesis is lacking. Hemodialysis represents a great stressor for older adults with ESRD. Sympathetic nervous system (SNS) activation is an essential compensatory mechanism for intradialytic blood pressure (iSBP/iDBP) maintenance. We hypothesized that frail dialysis patients have worse changes in BP while undergoing hemodialysis.

Methods: Frailty was measured on 163 older hemodialysis patients and pre- and post-dialysis BP measures were collected. We used adjusted linear regression to test for a difference in the pre- and post-dialysis change in SBP and DBP and adjusted logistic regression to test for a pre- and post-dialysis change of 15mmHg of SBP and 5mmHG of DBP by frailty. In a separate cohort, frailty was measured on 15 hemodialysis older patients who had 10 intradialytic BP measures and we used an adjusted linear growth curve model to test the association between frailty and iSBP/iDBP.

Results: Frail dialysis patients also had a greater change in their SBP (-4mmHg; p=0.24) and DBP (-7mmHg; p=0.001) while on dialysis. In adjusted analyses, those who were frail were had a 1.95-fold (95%CI:1.01-3.76; p=0.047) increased odds of a 15mmHg decline in SBP and 3.7-fold (95%CI:1.89-7.33; p<0.001) increased odds of a 5mmHG decline in DBP while on dialysis. For those who were frail, the rate of iSBP change was -2.93mmHG/30minutes (p=0.05) compared to -1.23mmHG/30minutes (p=0.22) for those who were nonfrail. Similar results were observed for iDBP (-2.15mmHG/30minutes [p=0.01] vs. -0.68mmHG/30minutes [p=0.21]).



Conclusions: Frailty represents a state of SNS dysregulation for patients in which adults undergoing the stressor of hemodialysis have a poor SBP and DBP response. This is the first evidence of SNS dysregulation among frail patients with ESRD.

TH-PO994

Mannitol for the Prevention of Intra-Dialytic Hypotension - A Pilot Randomized Double-Blind Placebo-Controlled Trial

Finnian R. Mc Causland,[1,2] Brian Claggett,[1,2] Heather E. Croy,[1] Sara J. Abrahams,[1] Sushrut S. Waikar.[1,2] *[1]Brigham and Women's Hospital; [2]Harvard Medical School.*

Background: Intra-dialytic hypotension (IDH) is a common complication of hemodialysis (HD) and may be related to relatively rapid shifts in plasma osmolality. Interventions to minimize intra-dialytic changes in osmolality may prevent IDH.

Methods: In this double-blind single center RCT, patients requiring initiation of RRT for acute or chronic kidney disease were randomized to receive mannitol 0.25g/kg/hr or a similar volume of 0.9% saline during their first three HD sessions. Blood pressure was measured in a standardized fashion pre-, post- and every 30 minutes during HD. The primary endpoints were: 1) the average decline in systolic blood pressure (SBP); and 2) the proportion of total sessions complicated by IDH (SBP drop of ≥20 mmHg).

Results: A total of 52 patients were randomized, contributing to 156 study visits.

Baseline Characteristic	Placebo (n=27)	Mannitol (n=25)	P
Male, n (%)	14 (52)	12 (48)	0.78
Race, n (%)			0.90
Black	8 (29)	6 (24)	
White	18 (67)	18 (72)	
Other	1 (4)	1 (4)	
Age, yrs	58 ± 15	53 ± 17	0.34
Diabetes, n (%)	13 (48)	11 (44)	0.76
Heart Failure, n (%)	9 (33)	7 (28)	0.68
ESRD, n (%)	22 (82)	23 (92)	0.27
Catheter, n (%)	16 (59)	15 (60)	0.96
Pre-dialysis SBP, mmHg	144 ± 21	149 ± 26	0.48

There were no differences in the mean SBP decline between the mannitol and placebo groups (15.3±11.4 vs. 19.2±15.6 mmHg; P=0.31). This remained non-significant after adjusting for the pre-dialysis SBP (P=0.27). The proportion of total sessions complicated by IDH was lower in the mannitol group compared with placebo (25.3% vs. 43.2%), with a trend towards fewer repeated sessions complicated by IDH (OR 0.38; 95%CI 0.13-1.06; P=0.06).

Conclusions: In this pilot RCT for patients requiring the initiation of HD, we found no difference in the absolute SBP decline between those who received mannitol versus placebo. However, there were fewer overall IDH events and a trend towards lower risk of repeated sessions being complicated by IDH in the mannitol group. A larger multi-center RCT is warranted.

TH-PO995

Additional Volume Reduction Will Improve IDH Only in the Patients with Higher Pre-Dialytic BP

Chen Yu, Zhang Yingying. *Dept of Nephrology, Tongji Hospital, Tongji Univ School of Medicine, Shanghai, China.*

Background: This study was conducted to investigate the main causes in intradialytic hypertension (IDH) patients, and whether additional volume reduction will result in improvement in either blood pressure (BP) or other benefits among IDH patients.

Methods: A prospective, open-label, single center study of 22 HD patients with IDH were involved in this study.IDH means an increase of blood pressure (ΔSBP>10mmHg) during dialysis session. 11 patients with normal pre-dialytic BP were entered in Group A, and other 11 patients with higher pre-dialytic BP were in Group B. Another 18 HD patients with normal BP were selected as CON. The whole study was lasted for 4 weeks. The blood samples of all patients were collected before dialysis at session 1st, 13th. Serum Ang-II, ALD, ACE, ET-1, NO and ADMA at same time were measured. Besides the control group, an additional weight loss of 0.1-0.2Kg body weights was prescribed per dialysis till additional ultrafiltration was not tolerated.

Results: The ultrafiltration of each dialysis session of IDH patients was higher than the CON, especially in Group B ($p < 0.05$). The serum levels of ACE, ALD , ET-1 and ADMA significantly increased in IDH patients than control group ($P < 0.05$). In Group A, the dry weight was reduced by 0.18Kg at 12 sessions and resulted in -3.18mmHg change in pre-SBP (p=0.973). In Group **B**, the dry weight was reduced by 0.67Kg at 12 sessions and resulted in 12.82 mmHg change in pre-SBP (p=0.021). The decrease of SBP was associated with decrease in the level of serum ACE, ALD, ET-1 and ADMA. However, the additional ultrafiltration treatment had no effects on diastolic blood pressure and blood pressure variability in these two groups.

Conclusions: (1) The reduction of dry weight is an efficacious maneuver to improve IDH patients with volume excess charactered with higher pre-dialytic BP. (2) The reduction of dry weight has no effect on IDH patients with normal pre-dialytic BP. (3) Activation of RAAS and endothelial dysfunction are the main causes that relate to intradialytic hypertension in MHD patients. (4) SBP may play a role in the effect on the decreasing of vascular contraction materials released.

TH-PO996

Correlation of Weight Loss and Fluid Removal via Ultrafiltration in Patients with Acute Decompensated Heart Failure

Abhilash Koratala, S. Irfan Qadri, Amir Kazory. *Div of Nephrology, Hypertension and Renal Transplantation, Univ of Florida.*

Background: Changes in weight and daily fluid balance are commonly used in clinical practice to monitor decongestive therapy in patients with acute decompensated heart failure (ADHF). It has recently been proposed that there exists a significant discrepancy between fluid balance and weight loss in ADHF patients who are managed with diuretics. The performance of these metrics has not been evaluated in patients undergoing ultrafiltration (UF) therapy.

Methods: Available data from clinical trials of UF in ADHF performed between January 2000 and March 2016 were included in the analysis. These studies evaluated decongestion both through weight change and fluid removal. Pertinent data were extracted and using Pearson product-moment correlation, the degree of linear dependence and correlation between these two variables was determined.

Results: A total of 14 studies (6 randomized controlled trials) with a total of 797 patients were evaluated. The mean age was 65.4 years. There existed substantial variation across studies in the reporting of surrogates of decongestion such as net and total fluid removal. Weight loss ranged from 2.6 to 10.7 Kg (mean 6.3 ± 2 Kg) and fluid removal ranged from 2.6 to 18.7 L (mean 8.6 ± 3.8 L). There was a strong positive correlation between weight loss and fluid removal (r = 0.87, 95% CI of Correlation 0.64-0.96, p = 0.00003).

Conclusions: Currently available evidence suggests that there is a strong correlation between weight loss and fluid removal in patients with ADHF who undergo UF therapy. Therefore, both markers may reliably be used to determine the degree of decongestion. These findings stand in contrast to patients who receive diuretics in ADHF. Future studies are needed to clarify whether this discrepancy is related to the inherent differences in sodium content of the ultrafiltrate versus urine sodium concentration or other less well explored factors such as local practice patterns and data collection.

TH-PO997

Renal Perfusion Falls during Hemodialysis: An Explanation for the Loss of Residual Renal Function in Dialysis Patients

Raanan Marants,[1] Claire J. Grant,[2] Ting Lee,[1,3] Christopher W. McIntyre.[1,2,3] *[1]Dept of Medical Biophysics, The Univ of Western Ontario, London, Canada; [2]The Kidney Clinical Research Unit, The Univ of Western Ontario, London, Canada; [3]Lawson Health Research Inst, London, Canada.*

Background: Maintenance of residual renal function (RRF) has consistently been shown to confer survival benefit in hemodialysis (HD) patients, even in those with minimal urine output (UO). However, strategies for preservation are few, largely due to an inadequate understanding of the pathophysiology behind the characteristic rapid decline in RRF. The aim of this study was to directly examine the hypothesis that intradialytic circulatory stress results in significant ischemic challenge to the remnant kidney.

Methods: 12 patients with UO<500mL/24hrs underwent renal imaging before, during and after a session of dialysis. Detailed study of renal perfusion was performed using a novel dynamic-contrast imaging algorithm, in conjunction with a latest generation 256-slice CT scanner (GE Revolution). Images were analyzed offline to create functional maps for perfusion across the entire kidney. Echocardiography was done at baseline and prior to the end of dialysis to detect myocardial stunning, as a reference organ system for ischemic response to HD-induced circulatory stress (detected as regional changes in longitudinal strain using speckle tracking).

Results: Baseline renal perfusion was markedly reduced (48.2±26.4mL/min/100g), compared to normal control values, and was related to dialysis vintage (r=-0.67, p=0.01). HD resulted in significant reduction in renal perfusion to 25.9±16.1mL/min/100g (p=0.001) at peak stress (3 hrs). 10/11 patients in whom perfusion fell also exhibited myocardial stunning (>2 segments with >20% reduction in longitudinal strain), whereas stunning was not seen in the patient whose renal perfusion did not fall.

Conclusions: An acute drop in renal perfusion is observed during HD and is related to demonstrable organ injury in another vulnerable vascular bed. Cumulative exposure to circulatory stress may be a key pathophysiological factor in the loss of RRF observed in HD patients. Longitudinal studies are needed to examine whether amelioration of circulatory stress during HD helps to preserve RRF.

TH-PO998

Paradoxical Fluid Diversion into the Hepatic Circulation with Hemodialysis

Claire J. Grant,[1] Trevor Wade,[2] Charlie Mckenzie,[2] Christopher W. McIntyre,[1,2] Guido Filler,[1] Shih-Han S. Huang.[1,2] *[1]The Kidney Clinical Research Unit, Western Univ, London, Canada; [2]Dept of Medical Biophysics, Western Univ, London, Canada.*

Background: The hepatic circulation is involved in adaptive systemic responses to circulatory stress. However, it is vulnerable to both chronic hypervolemia and changes in cardiac function. The influence of hemodialysis (HD) and fluid removal upon the liver has never been specifically studied. We therefore conducted a detailed initial study to characterize the effects of HD upon liver water content and stiffness, referenced to peripheral fluid mobilization, total body water and cardiovascular stability.

Methods: We studied 55 established in-centre chronic HD patients without liver disease. To measure hepatic stiffness and body composition, all subjects underwent transient ultrasound-based elastography (Fibroscan®) in combination with bioimpedance

assessment (BIA) pre and post-HD. 16/55 patients also consented to additional magnetic resonance imaging (MRI) before and after HD, to determine changes in water content in both the liver and calf.

Results: Mean ultrafiltration (UF) volume was 26.3±14mL/kg. Fluid removal was accompanied with effective mobilization of peripheral water (measured with MRI within calf) from 0.84±0.3mL/g to 0.75±0.2mL/g, and reduction in total body water (36.8±7.7L to 35.5±9.1L, p<0.001), measured by BIA. However, MRI directly-measured liver water content increased (0.57±0.1mL/g to 0.79±0.3mL/g) accompanied by an increase in liver stiffness, measured by ultrasound elastography (5.65±2.5 vs. 6.31±2.9kPa, p=0.02). This increase was not proportional to UF volume, but was blunted in those with higher baseline stiffness (r=-0.37, p=0.006). The degree of liver water content increase was associated with significantly lower diastolic BP during HD (r=0.67, p=0.04).

Conclusions: Whilst fluid removal reduced peripheral and total body water content, liver water content (measured directly by MRI and indirectly by elastography) increased post-HD, consistent with movement of blood to the hepatic circulation. This novel observation suggests that there is a unique hepatic response to HD with UF and that the liver may play a more important role in HD response than currently appreciated.

TH-PO999

The Hepatic Response to Hemodialysis: Consequences for Uremic Toxin Exposure and Multi-Organ Injury Claire J. Grant,[1] Raanan Marants,[2] Nicholas Tonial,[3] Thomas Velenosi,[3] Brad Urquhart,[3] Ting Lee,[2,4] Christopher W. McIntyre.[1,2,4] *[1]The Kidney Clinical Research Unit, Western Univ, London, Canada; [2]Dept of Medical Biophysics, Western Univ, London, Canada; [3]Dept of Pharmacology, Western Univ, London, Canada; [4]Lawson Health Research Inst, London, Canada.*

Background: The liver provides the final functional barrier between gut-derived uremic toxins and the circulation. Hemodialysis (HD) has been demonstrated to result in widespread recurrent ischemic injury to vital organs (heart, brain). However, the liver's functional vulnerability has not been studied. To investigate potential metabolic and systemic hemodynamic consequences we performed a comprehensive evaluation of hepatic perfusion, excretory function and cardiac response during HD.

Methods: 15 patients underwent serial assessment of liver perfusion during HD using dynamic-contrast imaging with a latest generation 256-slice CT scanner [GE Revolution]. This allowed direct quantification of total liver (LBF), portal (PV) and hepatic arterial blood flow. Hepatic excretory function was measured with indocyanine green (ICG) clearance. HD-induced myocardial stunning was detected with serial echocardiography. Markers of tissue-specific endothelial stress and uremic toxin levels were measured.

Results: Total LBF was maintained over the course of dialysis. However, stability of LBF occurred at the expense of PV flow increasing, marked reduction in excretory function (ICG clearance falling from 916±423 to 789±350mL/min, p=0.002) and associated significant perfusion-dependent cardiac injury. Myocardial stunning was present in 80% of patients and severity was proportional to LBF (r=0.57, p=0.03) and degree of excretory function loss (ICG clearance, r=-0.64, p=0.02).

Conclusions: Failure of excretory function during HD, with concomitant increased delivery of uremic toxin-laden portal blood, results in increased systemic toxin exposure. Hepatic blood flow preservation occurs at the expense of concurrent critical organ injury. This maladaptive response to circulatory stress may be of central importance to understanding the limitations of current clearance measures to explain observed uremic symptoms as well as the pathophysiology of HD-induced organ injury.

TH-PO1000

The High Prevalence of Silent Myocardial Ischemia and Ventricular Arrhythmias Detected by Holter Monitoring during a Single Hemodialysis Session in a Brazilian Sample: An Exploratory Investigation of Associated Factors Marcia T.S. Martins,[1] Jean M. Monteiro,[1] Lucas Hollanda Oliveira,[3] Inaia A. Teixeira,[2] Pedro Guimarães Silva,[1] Marcelo Barreto Lopes,[1] Luis Claudio Correia,[2] Antonio Alberto Lopes.[1] *[1]Federal Univ of Bahia; [2]Escola Bahiana de Medicina; [3]Hospital São Rafael, Salvador, Brazil.*

Background: Maintenance hemodialysis (HD) patients seem to be highly susceptible to silent myocardial ischemia (SMI) and ventricular arrhythmia (VA). We used Holter monitoring during a single HD session to estimate prevalences of SMI and VA and to explore associations of echocardiographic findings and intradialitic hemodynamic changes with these outcomes.

Methods: Data (2013-2016) from 95 patients (mean age 51.1 yr, 73.7% males, 88.5% non-whites, 21.1% diabetics, median vintage=49 mo.) enrolled in the Prospective PROHEMO cohort in Salvador, Brazil. SMI was defined as ST depression at J-point ≥0.1mV. Cardiac function was assessed by echocardiography. Odds ratio (OR) and 95% confidence interval (95%CI) were estimated by logistic regression with adjustments for demographics, vintage and diabetes.

Results: Prevalences of both SMI and VA were 57% but VA prevalence did not vary by SMI diagnosis P=0.478). VA, but not SMI, increased steadily with age from 31.6% for 18-40 yr to 74.1% for ≥60 yr (P=0.005). VA prevalence was slightly higher in those with coronary artery disease (CAD) diagnosis (68.2 vs 53.4%), but SMI prevalence and ischemic load did not differ by CAD history. Adjusted odds of VA were positively associated with heart failure (OR=3.18, 95%CI=1.08-9.38) and echocardiographic findings: left ventricular volume index>28/mL/m^2 (OR=6.76, 95%CI=1.98-23.00), moderate-to-greater degree left atrial size (OR=3.85, 95% CI=1.47-10.12) and aortic insufficiency (OR=3.20, 95%CI=1.11-9.29). Fall in systolic BP during HD session was the hemodynamic variable strongest associated with VA (OR by 10% reduction=2.54, 95%CI=0.95-6.72). Associations of hemodynamic changes during HD session with SMI were not observed.

Conclusions: This study in MHD patients suggests that the high prevalences of SMI and VA in the HD session are driven by different mechanisms. It is likely that intradialytic SMI is largely caused by mechanisms other than CAD.

TH-PO1001

High Dialysate Calcium Concentration Is Associated with High Risk of Dialysis-Induced Myocardial Stunning Vitor B. Silva,[1] Thiago Andrade Macedo,[3] Luciano F. Drager,[1,3] Fabiana Graciolli,[1] Wagner Dominguez,[1] Rosa M.A. Moyses,[1,2] Rosilene M. Elias.[1] *[1]Nephrology, Univ de Sao Paulo, São Paulo, Brazil; [2]Univ Nove de Julho (UNINOVE), Brazil; [3]Cardiology, Inst do Coração, Brazil.*

Background: Myocardial stunning is associated with high ultrafiltration and consequent intradialytic hypotension. High dialysate calcium concentration (Ca 1.75 mmol/l) is associated with better hemodynamic tolerability, but whether this dialysate would reduce the risk of myocardial stunning during conventional hemodialysis (HD) is unknown.

Methods: In this randomized trial, patients under regular HD were assigned to two consecutive mid-week HD sessions, with high (Ca 1.75 mmol/l) and low (Ca 1.25 mmol/l) dialysate calcium concentration, and the same ultrafiltration. All patients performed transthoracic echocardiographybefore HD and at peak HD. Global longitudinal strain (GLS) and segmental strain were calculated by a single observed, blinded to the calcium concentration status.

Results: Nineteen patients were included (6 men, 44±13 years). The pre dialysis weight, systolic, diastolic and mean blood pressure (MBP) were similar between two HD sessions. Despite the same delta of weight (p=0.280), HD with low calcium had a greater drop of MBP (p=0.006), and was associated with more intradialytic hypotension and cramps (p=0.001). Segmental strain values were significantly worst in the peak HD with high calcium in almost all segments, except for basal inferolateral and mid-inferolateral. The GLS before HD was -19.8 ± 3.7 and went to -17.3 ± 2.9 and -16.1 ± 2.6% in HD with low and high calcium, respectively (p<0.0001). Post-test revealed that GLS during HD with high calcium was even worse than with low calcium (p=0.018). GLS was also worse among patients with parathyroid hormone >300pg/ml. GLS correlated with the delta of weight, ultrafiltration, serum transferrin, serum aldosteron and C-reative protein (all p values <0.005).

Conclusions: Although low dialysate calcium concentration may determine worse short-term hemodynamic tolerability, it may also lead to low risk of dialysis-induced myocardial stunning. Further studies are necessary to elucidate how the calcium delivered during HD may interfere with myocardial contractility.

TH-PO1002

Progressively Increased QTc Dispersion Was Associated with Sudden Cardiac Death in Patients with End Stage Renal Disease on Hemodialysis Dong-Ryeol Ryu, Seung-Jung Kim, Duk-Hee Kang, Kyu Bok Choi. *Dept of Internal Medicine, Ewha Womans Univ.*

Background: Patients with end stage renal disease (ESRD) on hemodialysis (HD) have a high risk of sudden cardiac death (SCD) due to serious ventricular arrhythmias. We performed an electrocardiogram wave pattern analysis of patients with ESRD on HD to find risk factors for predicting SCD.

Methods: We conducted a retrospective study involving 36 HD patients who died from SCD (SCD-HD) and 314 HD patients well controlled (Non-SCD) from January 2010 to June 2015 in 3 general hospitals (multi-centers). The QT interval, QT dispersion, and QT peak-end interval on all 12 leads, as well as some other 12-lead ECG parameters, were measured. We evaluated the first and last ECGs in 350 patients on HD.

Results: The SCD-HD patients were older (69.0±12.2 vs. 60.8±13.8 years, p=0.001) than the Non-SCD patients, while there was no significant difference in the gender, underlying disease, or body surface area between the two groups among the enrolled 350 patients (50.0% male, 61.7± 13.9 years) (p>0.05). However, a decreased QT peak-end interval (OR 0.961, p<0.001) in all pre-cordial leads (V1-V6) and a prolonged QTc dispersion (OR 1.023, p<0.001) were associated with an increase in SCD. The QTc dispersion increased progressively compared to those at the time of initial HD during mean follow-up duration of 2.5 years. (from 38.8±15.2 to 49.5±25.0ms, p=0.037). A multivariate analysis also revealed that prolonged QTc dispersion (OR 1.1, p=0.003) was an independent predictor of SCD in HD patients, and the area under the curve (AUC) for QTc dispersion was 0.653 in the receiver operator curve (ROC) analysis.

Conclusions: A decreased QT peak-end interval and prolonged QTc dispersion were independent predictors of SCD in patients with ESRD on HD. Therefore, serial ECG monitoring may have important clinical implications in patients with ESRD on HD.

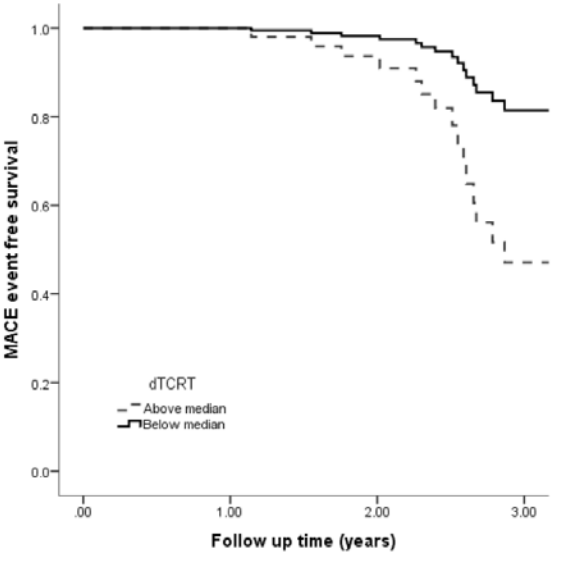
TH-PO1003

Longitudinal Change in QRS-T Angle Is More Significantly Associated with Cardiac Outcome in Hemodialysis Patients Than Standard ECG Parameters Darren Green,[1] Katerina Hnatkova,[2] Sofia Skampardoni,[1] Philip A. Kalra,[1] Marek Malik,[2] Dimitrios J. Poulikakos.[1] *[1]Salford Royal Foundation Trust, United Kingdom; [2]Imperial College, London, United Kingdom.*

Background: Wide QRS-T angle calculated from the surface digital ECG reflects global repolarisation heterogeneity and increase in QRS-T angle over time is linked with higher arrhythmic risk in the general population. We hypothesised that longitudinal changes in QRS-T angle would also be associated with adverse cardiac outcome in hemodialysis patients.

Methods: ECG was performed prospectively on adult haemodialysis patients on two occasions 1 year apart, both on midweek non-dialysis days. QRS-T angle was calculated from the ECG as total cosine R-to-T expressed in degrees (TCRT) using singular value decomposition with the aid of custom software. Follow up was until a major cardiac event (MACE: acute coronary syndrome, coronary revascularization, heart failure, arrhythmia, sudden cardiac death), or censored at transplant. Univariate associations of above vs below median annualised changes in TCRT and other ECG parameters with MACE was calculated using Cox regression, except for QRS which was adjusted for ultrafiltration volume due to potential confounding.

Results: There were 74 patients, age 62±14 years. Baseline TCRT was 86 ± 36° and median (range) annualised change was 5 (-84 to +127)°. The values for QRS were 107±16ms and +1 (-40 to +25)ms, for QT_c were 440±23ms & -1 (-194 to +108)ms, and for heart rate were 72±13 bpm and -1 (-19 to +40)bpm. Follow up was 2.3±0.7 years. There were 17 MACE end points. The hazard ratio for MACE in above versus below median change in TCRT (dTCRT) was 3.67 (1.27–10.60, p=0.036, see figure), for dQRS was 2.04 (0.77–5.41, p=0.148), for dQT_c was 1.15 (0.44–3.06, p=0.771), for dHR was 3.44 (0.98–12.03, p=0.053).



Conclusions: Longitudinal changes in QRS-T angle (dTCRT) may improve risk prediction in hemodialysis patients.

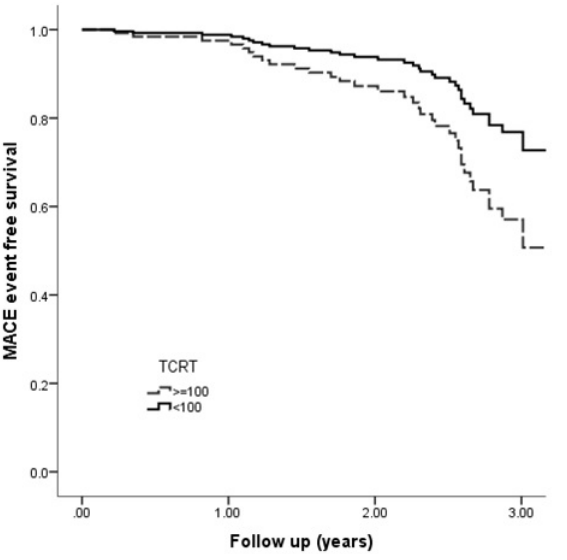
TH-PO1004

Global Electrical Heterogeneity as a Predictor of Mortality and Major Cardiac Events in Hemodialysis Patients Darren Green,[1] Katerina Hnatkova,[2] Sofia Skampardoni,[1] Philip A. Kalra,[1] Marek Malik,[2] Dimitrios J. Poulikakos.[1] *[1]Salford Royal Foundation Trust, United Kingdom; [2]Imperial College, London, United Kingdom.*

Background: Wide spatial QRS-T angle calculated from digital 12 lead ECG is a marker of global cardiac repolarization heterogeneity associated with worse prognosis in high cardiac risk populations. We assessed its prognostic value in hemodialysis patients.

Methods: Echocardiography and ECG were performed on adult hemodialysis patients on midweek non-dialysis days. QRS-T angle (TCRT) was calculated from the ECG as total cosine R-to-T using singular value decomposition aided by custom software, and expressed in degrees. Abnormal TCRT was defined as ≥100°. End points were death and major cardiac events (MACE: acute coronary syndrome, coronary revascularization, heart failure, arrhythmia, sudden cardiac death). The association of TCRT ≥100° with these was calculated by Cox proportional hazard models adjusted for age, gender, time on dialysis, left ventricular ejection fraction (LVEF), and left ventricular mass indexed to height (LVMI). Follow up was censored at transplant.

Results: There were 170 patients: age 61±15 years, time on dialysis 4±7 years, 66% male, LVEF 66±12%, LVMIht 50±19g/$m^{2.7}$, TCRT 88±39°. 70 patients (41%) had TCRT ≥100°. Follow up was 2.1±0.8 years with 40 deaths (24%) and 40 MACE. The adjusted hazard ratio (HR) for death if TCRT ≥100° was 0.80 (0.40–1.59), p=0.52). The HR for MACE was 2.1 (1.0–4.4), p=0.04.



For death, the significant variables were age (HR 1.02 [1.04-1.12], p,0.01), LVEF (HR 0.97 [0.94-0.99], p=0.04), and LVMI (HR 1.03 [1.01-1.05], p<0.01). For MACE, LVEF and LVMI were not significant but age was (HR 1.03 [1.00-1.03], p=0.04).

Conclusions: Wide QRS-T angle (TCRT) appears to be a better prognostic marker of risk for cardiac events than standard echocardiography. This likely reflects its association with arrhythmia and may become a useful prognostic indicator.

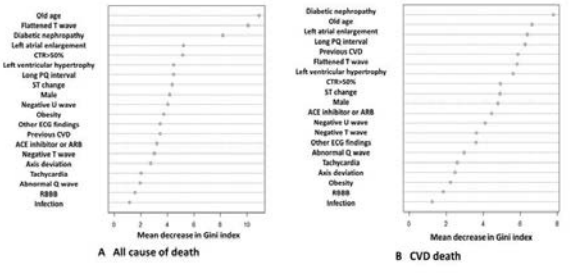
TH-PO1005

Evaluation of 15-Year Mortality Based on Electrocardiogram in Hemodialysis Patients Using Random Forest Machine Learning Algorithm Eiichiro Kanda,[1] Bogdan I. Epureanu,[2] Hiroshi Kawaguchi,[3] Yoichiro Tabata,[4] Noriyoshi Murotani,[5] Tomoko Maeda,[6] Hidetaka Itoh,[7] Haruki Itoh.[8] *[1]Tokyo Kyosai Hospital; [2]Michigan Univ; [3]Tokiwa-kai Medical Corporation; [4]Meysey-kai Medical Corporation; [5]Japan Community Health Care Organization Chiba Hospital; [6]Sakakibara Heart Inst Clinic; [7]Toranomon Mutual Aid General Hospital; [8]Sakakibara Heart Inst.*

Background: Cardiovascular disease (CVD) is a leading cause of death in hemodialysis (HD) patients. The aim of this 15-year prospective cohort study of HD patients in Japan was to determine which resting electrocardiography (ECG) findings are associated with long-term prognosis.

Methods: We developed a random forest which was an ensemble of 500 decision trees, to predict each patient's survival from a random subset of training data (N=304). Moreover, the ECG findings effective for identifying patients with a high risk of cause-specific death were identified from the mean decrease in the Gini index on a test dataset (N=305).

Results: Mean age and vintage were 52.5 and 5.6 years, respectively. 67.8% of the patients died. The random forest showed an estimation of sensitivity of 73.6% and specificity of 40.1%. Old age (>65 years) was the most discriminative variable for all-cause death, followed by flattened T waves, diabetic nephropathy, and left atrial enlargement.



Ranking of variables for prediction of death

Cox proportional hazard models adjusted for baseline characteristics showed that these ECG findings were associated with all-caused death; flattened T wave, adjusted hazard ratio (aHR) 1.32 (95% CI 1.03, 1.70); left atrial enlargement, aHR 1.25 (1.01, 1.54). Another random forest showed that the important ECG findings for the prediction of CVD-caused death were left atrial enlargement, long PQ interval, and flattened T wave.

Conclusions: In this study, we showed the importance of ECG findings for HD patients' prognoses. If changes in ECG findings are observed, detailed cardiac examination should be carried out.

TH-PO1006

Interplay between Arterial Functional and Structural Alteration and Their Contribution to Cardiac Abnormalities in Hemodialysis Patients

Jin Hee Jeong,[1] Annabel Biruete,[2] Brandon Kistler,[3] Pei-Tzu Wu,[4] Bo Fernhall,[5] Ken Wilund.[1] *[1]Kinesiology, Univ of Illinois, Urbana, IL; [2]Nutrition Science, Univ of Illinois, Urbana, IL; [3]Dietetics and Nutrition, Ball State Univ, Muncie, IN; [4]Medicine, Univ of California, Los Angeles, CA; [5]Kinesiology, Univ of Illinois, Chicago, IL.*

Background: Hemodialysis (HD) patients often have altered arterial and cardiac features. The aim of this study is to examine the relationship between arterial structure and function and their contribution to left ventricular (LV) dysfunction and hypertrophy in HD patients.

Methods: 118 HD patients (55±12yr, BMI:32±8 kg/m², 59% males, 46% diabetes) were tested for blood pressure (BP), arterial wave reflection (AIx75), arterial stiffness (aortic pulse wave velocity (PWV), pulse pressure (PP) and β-stiffness), carotid artery lumen diameter (D), carotid intima-media thickness (IMT), subendocardial viability ratio (SEVR), LV ejection fraction (EF), LV early diastolic flow-tissue ratio (E/E') and LV mass (LVM) on a non-dialysis day.

Results: The presence of LV hypertrophy, systolic dysfunction (EF<40%) and diastolic dysfunction were 84.6% (concentric: 79.5% and eccentric: 10.7%), 17.7% and 45.6% respectively. There were positive associations between β-stiffness and IMT and between D and LVM and a negative association between AIx75 and LV EF (p <.05 for all). With adjustments for age and diabetes status, each of brachial and aortic systolic BP and aortic PP were independently associated with E/E', the severity of LV diastolic dysfunction and SEVR (p< .05 for all). The combination of aortic systolic BP and PP, but not individually, significantly predicted increased LVM (r=.319, p=.047).

Conclusions: This study confirms pathophysiological arterio-ventricular coupling in HD patients. Increased arterial wave reflection was accompanied with impaired LV systolic function. Augmented arterial stiffness was associated with arterial wall thickening, progression of LV diastolic dysfunction and LV enlargement. These findings may result in potential therapeutic interventions to prevent the progression of cardiovascular diseases in HD patients.

TH-PO1007

N-3 Polyunsaturated Fatty Acid (N-3 PUFA) Dietary Intake and All-Cause and Cardiovascular Mortality in Adults on Hemodialysis: The DIET-HD Multinational Cohort Study

Valeria M. Saglimbene,[1,2] Germaine Wong,[2] Marinella Ruospo,[1,3] Suetonia Palmer,[4] Katrina L. Campbell,[5] Vanessa Garcia Larsen,[6] Patrizia Natale,[1] Jorgen B.A. Hegbrant,[1] Jonathan C. Craig,[2] Giovanni F.M. Strippoli.[1,2,7] *[1]Diaverum Medical Scientific Office; [2]Univ of Sydney; [3]Amedeo Avogadro Univ of Eastern Piedmont; [4]Univ of Otago; [5]Princess Alexandra Hospital; [6]Imperial Collge London; [7]Univ of Bari on behalf of the DIET-HD Investigators.*

Background: N-3 PUFA intake is a protective factor for cardiovascular (CV) risk in the general population, but data in dialysis are scant. We investigated the association between n-3 PUFA dietary intake and CV and all-cause mortality in hemodialysis (HD).

Methods: The DIET-HD study is a cohort study (n=9235) conducted between January 2014-2016 in 11 countries in Europe and South America. It aims to examine the association between nutrition and dietary patterns with major health outcomes in HD patients. Participants received a food frequency questionnaire validated for N-3 PUFA. We used adjusted Cox regression analyses clustered by country to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for CV and all-cause mortality associated with N-3 PUFA dietary intake.

Results: 8142 patients (88%) provided complete responses. 3433 (42%) were women, mean age 63.1 years (SD: 15.0), median n-3 PUFA intake 1.2 g/wk (IQR: 0.3-2.4). During a mean follow up of 16.2 (5.3) months (8112 person-years), there were 1232 deaths, 520 from CV causes. N-3 PUFA was inversely associated with CV (adjusted HR 0.88; CI 0.79-0.99 per SD increase in log transformed g/wk intake) and all-cause mortality (HR 0.93; CI 0.86- 1.01). Adjusted HRs for CV and all-cause mortality for patients in the highest n-3 PUFA tertile (≥2.6 g/wk), compared with those in the lowest (<0.37 g/wk), were 0.71 (0.52- 0.97) and 0.84 (0.70-1.01), respectively. Higher (≥2.6 g/wk) compared to lower (<0.37 g/wk) n-3 PUFA intake was associated with an absolute risk reduction of 21 CV deaths per 1000 patients over 1 year.

Conclusions: Higher n-3 PUFA dietary intake is associated with lower CV mortality in HD patients. Strategies supporting dietary n-3 PUFA intake are potential candidate interventions for large-scale randomized trials in the dialysis setting.

TH-PO1008

The Effect of Polyunsaturated Fatty Acids Supplementation on Cardiovascular Risk Factors in Patients with End-Stage Renal Disease: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Li Yao, Tianhua Xu, Chuang Ren, Xing Fan, Li Sun, Linlin Liu, Jiangmin Feng, Jianfei Ma, Lining Wang. *Nephrology, The First Hospital of China Medical Univ, ShenYang, LiaoNing, China.*

Background: Previous observational studies suggest that omega-3 fatty acids are associated with lower cardiovascular risk factors in adults; however, this association in patients with end-stage renal disease (ESRD) remains controversial. Therefore, the aim of the present study was to summarize the evidence from the investigations of randomized controlled trials (RCTs) related to omega-3 fatty acids supplementation on the major cardiovascular risk factors.

Methods: We performed electronic searches in PubMed, EmBase, and the Cochrane Library to identify RCTs on major cardiovascular risk factors through June 2015. Standard mean difference (SMD) and a random-effect model were used to measure the effect of omega-3 fatty acid supplementation on the risk of triglyceride, total cholesterol, LDL, HDL, homocysteine, SBP, DBP, and glucose. The analysis was further stratified by factors that could affect the treatment effects.

Results: We included 19 prospective studies reporting data on 1,415 patients with end stage renal diseases. Overall, omega-3 fatty acid supplementation produced a reduction of 0.68 mg/dl (SMD: -0.68; 95%CI: -1.10 to -0.26; P=0.001) for triglyceride, and a reduction of 0.36 mg/dl (SMD: -0.36; 95%CI: -0.69 to -0.03; P=0.033) in LDL. However, omega-3 fatty acid had no significant effect on total cholesterol (SMD: -0.31; 95%CI: -0.72 to 0.09; P=0.127), HDL (SMD: 0.49; 95%CI: -0.03 to 1.01; P=0.066), homocysteine (SMD: -1.41; 95%CI: -3.07 to 0.24; P=0.095), SBP (SMD: -1.07; 95%CI: -3.14 to 1.01; P=0.313), DBP (SMD: -1.52; 95%CI: -4.95 to 1.90; P=0.383), and glucose (SMD: 0.20; 95%CI: -0.46 to 0.85; P=0.560). Finally, a sensitivity analysis suggested that omega-3 fatty acid might be associated with lower total cholesterol (SMD:-0.42; 95%CI: -0.81 to -0.04; P=0.030).

Conclusions: Omega-3 fatty acid supplementation was associated with lower cardiovascular risk for patients with ESRD.

TH-PO1009

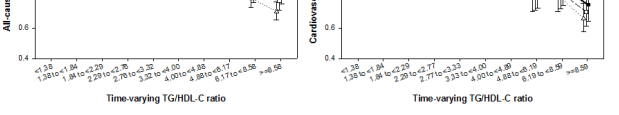
Elevated Nonfasting Serum Triglyceride to High-Density Lipoprotein Cholesterol Ratio Is Associated with Improved Outcomes in Incident Hemodialysis Patients

Tae Ik Chang,[1] Elani Streja,[1] Connie Rhee,[1] Moti L. Kashyap,[2] Nosratola D. Vaziri,[1] Kamyar Kalantar-Zadeh,[1] Hamid Moradi.[1,2] *[1]UC Irvine; [2]VA Long Beach.*

Background: Elevated serum triglyceride to high-density lipoprotein cholesterol (TG/HDL-C) ratio has been identified as a risk factor for cardiovascular (CV) disease and mortality in the general population. However, the association of this important CV marker with mortality has not been fully examined in patients with end stage renal disease (ESRD) on hemodialysis. Here we evaluated the association of nonfasting serum TG/HDL-C ratio with all-cause and CV mortality in incident patients with ESRD on maintenance hemodialysis.

Methods: We studied the association of nonfasting serum TG/HDL-C ratio with all-cause and CV mortality in a nationally representative cohort of 50,673 incident hemodialysis patients during 1/1/2007-12/31/2011. Association of baseline and time-varying TG/HDL-C ratios with mortality was assessed using Cox proportional hazard regression models.

Results: In fully adjusted models with case-mix and surrogates of malnutrition and inflammation complex, elevated TG/HDL-C ratios showed paradoxical association with better survival, in which the highest decile group (reference: 6th deciles) had a significantly lower risk of all-cause (HR, 0.88 [95% CI, 0.81-0.96] in baseline and 0.82 [0.75-0.90] in time-varying models) and CV mortality (0.81 [0.71-0.94] in baseline and 0.75 [0.64-0.87] in time-varying models). These associations remained consistent and significant across various subgroups.



Conclusions: Contrary to the general population, elevated TG/HDL-C ratio was associated with better CV and overall survival in hemodialysis patients. Our findings provide further support that the nature of CV disease and mortality in patients with ESRD is unique and distinct from other patient populations.

The Sit to Stand 60 Associates with Cardiovascular Fitness and Physical Activity in Hemodialysis Patients

Daniel Scott March,[1,2] Hannah M.L. Young,[1,2] Darren R. Churchward,[1,2] Charlotte E. Grantham,[1,2] Patrick J. Highton,[3] Matthew P.M. Graham-Brown,[2,3] James Burton.[1,2] *[1]Dept of Infection Immunity and Inflammation, Univ of Leicester, Leicester, Leicestershire, United Kingdom; [2]John Walls Renal Unit, Univ Hospitals Leicester NHS Trust, Leicester, Leicestershire, United Kingdom; [3]National College of Sport and Exercise Medicine, Univ of Loughborough, Loughborough, Leicestershire, United Kingdom.*

Background: The relationship between physical function, levels of physical activity and cardiovascular fitness in patients undergoing Hemodialysis (HD) is not well defined. The aim of this study is was to assess the association between physical function, physical activity and haemodynamic measurements in HD patients.

Methods: Sit to stand 60 (STS60), hemodynamic measurements and 7 day total steps (7DTS) data was collected for 36 prevalent HD patients. Demographic was collected

prospectively on all patients. Hemodynamic measurements (cardiac index {CI}, stroke volume index {SVI}, total peripheral resistance index {TPRI}, mean arterial pressure {MAP}, systolic blood pressure {SBP} and diastolic blood pressure {DBP}) were collected using the NICOM™, immediately prior to the second HD session of the week. StS60 was measured on a non-dialysis day. Pearson's correlation coefficient was performed to assess correlations between variables. Statistical significance was accepted at $P < 0.05$ level.

Results: STS60 significantly associated with CI (r=0.633, P<0.001), SVI (r=0.669, P<0.001), TPRI (r=-0.675, P<0.001) and SBP (r=-0.397, P<0.001). There were no significant associations between STS60 and DBP (r=-0.18, P<0.920) and MAP (r=-.250, P=0.168). STS60 was also significantly associated with 7DTS (r=0.702, P<0.001).

Conclusions: STS60 is a clinically relevant test significantly associated with cardiovascular fitness and levels of physical activity in HD patients. This highlights the relationship between physical function, physical inactivity and cardiovascular health in HD patients. Further research should investigate whether a concurrent improvement in cardiovascular fitness is observed when lower extremity strength is ameliorated in this patient population.

TH-PO1011

Two Years of Regular Perdialytic Exercise Is a Protective Cardiovascular Factor in ESRD Patients Myriam Rouchon Isnard, Céline Coutard. *AURA Auvergne, Chamalières 63 400, France.*

Background: The aim of the study was to show the effectiveness of Physical Activity (PA) during dialysis as a protective treatment against cardiovascular (CV) diseases.

Methods: Eighty volunteer patients were included in this multicentric prospective study and followed for two years: 40 patients in the Exercise group (EX), 40 patients in the Control group (CON). CV risk factors: Total Cholesterol, HDL Cholesterol (HDL-c), LDL cholesterol (LDL-c), Triglycerides (TG) and Hemoglobin (Hb), were checked at M0 (Month 0) and M24 (Month 24). The number of antihypertensive treatments and the Erythropoietin Stimulating Agent (ESA) required doses were collected too. We noted for each group during the follow-up the hospitalizations and their etiologies.

Results: At Year two, there are 35 patients left in the CON group: 4 deaths and 1 renal transplantation; 31 patients left in EX: 7 deaths and 2 transplantations [figure1]. We observed a significant decrease of Total Cholesterol in EX between M0 and M24: 1.82 ± 0.47 vs 1.6 ± 0.26 g/l (p<0,05) [figure1]. TG decreased significantly in EX after two years (1.63 ± 0.9 vs 1.44 ± 0.74 g/l) [figure1]. HDL, LDL Cholesterol and Hb remained stable in the 2 groups, but the required doses of Erythropoietin Stimulating Agent (ESA) decreased in EX between M0 and M24: 110,83 ± 70,8 vs 75,7 ± 69,7 µg/month. The number of antihypertensive drugs per patient decreased significantly ($p < 0.05$) in the EX group between M0 and M24 (1.85 ± 1.08 vs 0.75 ± 0.84 at M24).

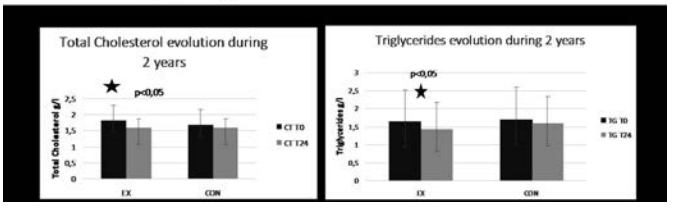
ESA doses	89,63 ± 77,3	75,5 ± 70	110,83 ± 70,8	75,7 ± 69,7
Cardiovascular hospitalizations		**14**		**5**
Renal transplantation		**1**		**2**
Cardiovascular Death		**2**		**2**

Values are mean ± SD. CON : Control group ; EX : exercising-group
*: difference between EX and CON at M24, p< 0,05



The EX patients were 3 times less frequently hospitalized for cardiovascular reasons: 5 hospital stays in EX versus 14 for CON.

Conclusions: Our study demonstrates that an intradialytic aerobic cycling training program promotes beneficial effects on cardiovascular protection: Lipids and HTA control. PA also reduced CV events in our population during two years follow-up.

TH-PO1012

Intradialytic Exercise Does Not Alter the Frequency or Severity of Ventricular Arrhythmias Charlotte E. Grantham,[1,2] Darren R. Churchward,[1,2] Daniel Scott March,[1,2] Matthew P.M. Graham-Brown,[1,2,3] Hannah M.L. Young,[1,2] Patrick J. Highton,[1,2,3] Alice C. Smith,[1,2] Anna-Marie Marsh,[4] James Burton.[1,2,4] *[1]Dept of Infection, Immunity & Inflammation, Univ of Leicester; [2]John Walls Renal Unit, Leicester General Hospital; [3]National Centre for Sport and Exercise Medicine, Loughborough Univ; [4]Leicester Cardiovascular Biomedical Research Unit, Glenfield Hospital.*

Background: Haemodialysis (HD) patients are prone to ventricular arrhythmias, a leading cause of sudden cardiac death. Given that HD and exercise are known to be pro-arrhythmogenic, the safety of intradialytic exercise (IDE) warrants further attention. We aimed to assess whether IDE altered the characteristics of ventricular arrhythmias.

Methods: Twelve HD patients underwent two 48-hour Holter recordings starting immediately before a resting dialysis session and before a dialysis session including 45 minutes of moderate intensity intradialytic cycling. Recordings were analysed for frequency of premature ventricular complexes (PVC; % overall beats). Complex Ventricular Arrhythmias (CVA) were classified as Lown class 3 and above. Ultrafiltration volume (UF) was recorded for all studied sessions. Data were analysed using Wilcoxon sign rank, Fisher's exact test or Spearman correlation as appropriate.

Results: The average recording was 36±15 hours. PVCs were detected in 75% (9) patients with 56% (5) classed as having CVAs during the baseline recording. Similarly, 66% (8) patients had PVCs present with 75% (6) having CVAs during the exercise recording. During the baseline recordings, frequency of PVCs was higher during dialysis than the post-dialysis phase (0.04% vs. 0.008%, P=0.02). Exercise on dialysis did not significantly alter frequency of PVC (0.05% vs. 0.002%, P=0.21) or CVAs (P=0.67). UF was not associated with frequency or severity of ventricular arrhythmias ($P \geq 0.649$).

Conclusions: Our results confirm previous findings that HD is potentially arrhythmogenic however the addition of moderate intensity exercise during dialysis did not significantly alter frequency of PVCs or CVAs. Similarly, increasing UF was not associated with PVCs or CVAs. These data support the hypothesis that IDE is a safe strategy to improve cardiovascular health in HD patients.

TH-PO1013

10-Year Trends in Kidney Dialysis and Transplantation Treatment for Patients with End-Stage Kidney Disease in Canada Juliana Wu,[1] Michael Terner,[1] Kevin Quach,[1] Kelvin Lam,[1] Joseph Kim,[2] Scott Klarenbach.[3] *[1]Canadian Inst for Health Information, Toronto, ON, Canada; [2]Univ of Toronto, Toronto, ON, Canada; [3]Univ of Alberta, Edmonton, AB, Canada.*

Background: The Canadian Organ Replacement Register (CORR) — a pan-Canadian information system for organ failure — is an important resource for examining trends in end-stage kidney disease (ESKD) and renal replacement therapies in Canada.

Methods: CORR data was used to calculate incidence and prevalence rates for ESKD patients who received dialysis or kidney transplants. Data from 2005 to 2014 for all provinces and territories in Canada, except Quebec, was included. Rates were calculated using the Statistics Canada population estimates.

Results: The number of patients starting dialysis in Canada has been increasing steadily over the past 10 years, rising from 4,244 (172 RPMP) in 2005 to 5,269 (193 RPMP) in 2014; prevalent number of patients has also similarly increased. Since 2005, patient survival for those on dialysis has increased marginally, with the most notable increase being 5-year survival for peritoneal dialysis patients (47.0% in 2005 and 52.5% in 2009). The number of deceased-donor kidney transplants has increased steadily over the past 10 years; whereas the increase in the number of living-donor kidney transplants has been much smaller. Both the number on the waiting list and the number of transplants performed steadily increased over the past 10 years, with a persistent 2.5 times differential gap between the two.

	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014
Waiting List	2035	2198	2159	2026	1981	2399	2431	2505	2629	2665
Kidney Transplants	816	947	990	939	968	1019	987	1071	1043	1085

Conclusions: The need for renal replacement therapy is steadily rising in Canada, and increases in kidney transplantation have not kept pace with demand. This puts pressure on the health care systems to improve the efficiency of kidney transplantation and the organ donation process while ensuring all dialysis modalities are accessible for ESKD patients.

TH-PO1014

End Stage Renal Disease Patients in Asia-Pacific from 2005 to 2015: A Trend Towards Concern Xiaoqi Xu, Yun Shi. *Medical Affairs, Fresenius Medical Care Asia Pacific, Hong Kong, China.*

Background: The number of end-stage renal disease patients (ESRD) has continuously grown worldwide although multiple prevention strategies were implemented over the decades. There are many international registries have provided valuable demographic and epidemiologic information for ESRD. But there were very few information for entire Asia Pacific (AP) region.

Methods: ESRD patient information was collected and covers 25 AP countries in 2015 (AUS, BGD, BTN, BRN, KHM, CHN, HKG, IND, IDN, JPN, LAO, MAC, MYS, MDV, MMR, NPL, NZL, PAK, PHL, KOR, SGP, LKA, TWN, THA and VNM). The country surveys performed at the end of each calendar year focus on the total number of ESRD patients, treatment modality, products, patient care structure and funding. This report is the summary of 2005-2015.

Results: The total population in the survey comprised 3,916 million people which are more than 50% of world population in 2015. During the period numbers of ESRD and dialysis patients have been doubled to about 1.35 million and 1.25 million, respectively, with similar annual growth rate (AGR) around 10%. The ESRD prevalence increased from 153 per million population (pmp, 2005) to 345 (pmp) and dialysis prevalence reached 319 from 136 (pmp). While the transplantation (Tx) rate is rather low about 26 pmp in 2015 (17 pmp, 2005) and AGR is 6%. The individual dialysis prevalence ranged from 307 to 3,210 pmp (versus 40-1,807pmp in 2005). TWN has the highest rate followed by JPN, KOR, MYS and SGP (over 1100 pmp). 83% patients have received hemodialysis, 9% peritoneal dialysis and 8% Tx in 2015. PD has grown fast and steadily in this region with AGR about 12%. THA, CHN and MYS have higher AGR (38%, 25%, 13%) driven by favored policy or professional advocacy. CAPD is the dominant regimen but APD has been gradually adopted (more common in HKG, KOR and SGP) with proportion of 12% PD patients in 2015.

Conclusions: The dialysis prevalence has been rising with the economic development and inclusion of dialysis into healthcare plans in AP over the last decade. The impact on healthcare burden will be significant given the large number of population in this region.

TH-PO1015

Association of Community Health Indicators with Late Nephrology Referral, Health Status and Subsequent Outcomes in Patients Reaching End-Stage Renal Disease Jung-Im Shin, Mari Palta, Brad C. Astor. *Univ of Wisconsin School of Medicine and Public Health.*

Background: Previous studies have focused on individual-level factors to identify patients reaching end-stage renal disease (ESRD) at higher risk of late nephrology referral. The relationship of environmental and socioeconomic conditions of communities in which patients live with late nephrology referral and subsequent clinical outcomes remains unclear. Such data are necessary to develop effective interventions.

Methods: We assessed the association of community health indicators with late nephrology referral (n=590,710), health status at the start of renal replacement therapy (i.e. hypoalbuminemia (n=455,063), inadequate management of anemia (n=539,712), and arteriovenous fistula (AVF)/catheter use (n=535,307)), and mortality after dialysis (n=393,255) using data from the United States Renal Data System in 2005-2012 merged with County Health Rankings database. Multivariable multilevel logistic and Cox proportional hazards regression models were used to assess the independent association of community risk factors with outcomes of interest, accounting for the clustering of individual patients within communities.

Results: A significant dose-response relationship of community risk score with late nephrology referral was found, with an adjusted odds ratio (OR) of 1.28 (95% confidence interval [CI]: 1.08-1.53) for the highest ($\geq 90^{th}$ percentile) vs. lowest-risk ($<10^{th}$ percentile) communities. Higher community risk score also was associated with hypoalbuminemia (adjusted OR =1.38; 95% CI: 1.20-1.58), inadequate management of anemia (1.23; 1.13-1.33), AVF use (0.76; 0.67-0.88), and catheter use (1.24; 1.09-1.41). Higher community risk also was associated with mortality following initiation of dialysis (adjusted hazard ratio=1.23; 95% CI: 1.17-1.28).

Conclusions: Higher community risk is significantly associated with greater risk of late nephrology referral, poorer health status and vascular access preparation at initiation of dialysis, and subsequent mortality, independent of individual-level factors. Community risk may be an important consideration for developing interventions to improve access to pre-ESRD nephrology care and subsequent clinical outcomes.

TH-PO1016

Improved Access to Pre-End Stage Renal Disease Nephrology Care among Beneficiaries of the Military Health System Evan I. Fisher,[1] Christina M. Yuan,[1] Lawrence Agodoa,[2] Kevin C. Abbott,[2] Robert Nee.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Insts of Health, Bethesda, MD.*

Background: Pre-end stage renal disease (ESRD) nephrology care is associated with lower rates of morbidity and mortality. We hypothesized that patients in the Department of Defense's Military Health System (MHS), a model of an integrated universal healthcare enterprise in the US, would have better access to pre-ESRD nephrology care.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 2,073,543 patients initiated on maintenance dialysis from January 2, 1995 through December 31, 2014, of whom 2,096 (0.1%) were MHS incident dialysis patients. We assessed care by a nephrologist and dietitian, erythropoietin use and type of vascular access upon dialysis initiation, based on the Centers for Medicare and Medicaid Services Form 2728. We also conducted multivariable logistic regression, adjusted for demographics and comorbid factors, using the individual pre-ESRD care components as the outcome variable.

Results: The proportions of MHS and non-MHS patients who were under the care of a nephrologist were 82.2% and 64.4%, respectively (p<0.001). 62.3% of MHS patients were under the care of a kidney dietitian versus 11.6% of non-MHS patients (p<0.001). 52.3% of MHS patients received erythropoietin pre-ESRD versus 29.4% of non-MHS patients (p<0.001). 29.0% of MHS patients used an arteriovenous fistula (AVF) on dialysis initiation versus 14.8% of non-MHS patients (p<0.001). On logistic regression analysis, MHS patients were significantly more likely to have had pre-ESRD nephrology care (adjusted odds ratio [aOR] 2.5; 95% confidence interval [CI] 2.0-3.0); pre-ESRD dietary care (aOR 13.9; 95% CI 11.8-16.3); pre-ESRD erythropoietin use (aOR 2.5; 95% CI 2.3-2.8); and AVF on dialysis initiation (aOR 2.2; 95% CI 1.8-2.6).

Conclusions: Compared to the broader ESRD population, MHS patients have greater access to pre-ESRD nephrology care which may improve morbidity and mortality.

TH-PO1017

Decisions about and Use of Renal Replacement Therapy in the U.S. Department of Veterans Affairs, 2000-2011 Susan P.Y. Wong,[1] Paul L. Hebert,[2] Chuan-Fen Liu,[2] Nilka Rios Burrows,[3] Ann M. O'Hare.[2] *[1]Univ of Washington; [2]VA Puget Sound Health System; [3]Centers for Disease Control and Prevention.*

Background: It is not known what proportion of US patients with advanced chronic kidney disease (CKD) do not receive renal replacement therapy (RRT). In other developed countries, receipt of RRT is highly age-dependent and is the exception rather than the rule at older ages.

Methods: We conducted a retrospective study of a national cohort of 28,568 adults who had a sustained estimated glomerular filtration rate <15 ml/min/1.73m^2 between January 1, 2000 and December 31, 2009 and were receiving care within the Department of Veterans Affairs (VA). We used linked administrative data from the US Renal Data System, VA and Medicare to identify cohort members who received RRT (n=19,165). For a random 25% sample of the remaining 9,403 patients, we performed an in-depth review of clinical progress notes in the VA-wide electronic medical record to understand their clinical course.

Results: Two-thirds (67.1%) of cohort members received RRT based on administrative records. Based on the results of chart review, we estimate that an additional 7.5% (95% CI 7.2-7.8) of cohort members had in fact received dialysis, 10.9% (95% CI 10.6-11.3) were preparing for or discussing dialysis but had not started dialysis at most recent follow-up and, in 14.5% (95% CI 14.1-14.9), a decision had been made not to pursue dialysis. The percentage of cohort members who received or were preparing to receive RRT ranged from 96.2% (95% CI 94.4-97.4) for those <45 years to 53.3% (95% CI 50.7-55.9) for those aged ≥85 years. Results were similar after stratification by level of comorbid burden.

Conclusions: In this large US cohort of patients with advanced CKD, the majority received or were preparing to receive RRT. These findings suggest more liberal use of RRT among older members of this cohort as compared with other developed countries.

Figure. RRT uptake among patients with advanced CKD.

TH-PO1018

Developing a Set of Core Outcomes for Trials in Hemodialysis - An International Delphi Survey Nicole Evangelidis,[1] Allison Tong,[1] Braden J. Manns,[2] Brenda Hemmelgarn,[2] David C. Wheeler,[3] Tess Harris,[4] Wim Van Biesen,[5] Wolfgang C. Winkelmayer,[6] Jonathan C. Craig.[1] *[1]Univ of Sydney; [2]Univ of Calgary; [3]Univ College London; [4]PKD International; [5]Ghent Univ Hospital; [6]Baylor College of Medicine.*

Background: Survival and quality of life for patients on hemodialysis (HD) remain poor despite substantial research efforts. Existing trials often report surrogate outcomes that may not be relevant to patients and clinicians. The purpose of this study is to generate a consensus-based, prioritized list of core outcomes for trials in HD. A core outcome set that reflects stakeholder priorities would improve the relevance, efficiency, and comparability of HD trials.

Methods: In an online Delphi survey, participants rated the importance of outcomes using a 9-point Likert scale. In Round 2 and 3, participants reviewed the scores and comments of other respondents and re-rated the outcomes. For each outcome, we calculated the median, mean, and proportion rating 7-9 (critically important).

Results: 1,181 participants (202 [17%] patients/caregivers, 979 health professionals) from 73 countries completed Round 1 and 838 (150 [18%] patients/caregivers) completed Round 3 (71% response rate). Outcomes achieving consensus as high priorities across both groups were: vascular access complications, cardiovascular disease (CVD), mortality, dialysis adequacy and fatigue. Patients/caregivers rated four outcomes higher than health professionals: ability to travel (mean difference 0.9), dialysis-free time (0.5), dialysis adequacy (0.3), and washed out after dialysis (0.2). Health professionals rated 11 outcomes higher: mortality (1.0), hospitalisation (1.0), drop in blood pressure (1.0), vascular access complications (0.9), depression (0.9), CVD (0.8), target weight (0.7), infection (0.4), potassium (0.4), ability to work (0.3), and pain (0.3).

Conclusions: The top stakeholder prioritized outcomes were vascular access problems, CVD, mortality, dialysis adequacy and fatigue. Patients/caregivers gave higher priority to lifestyle-related outcomes than health professionals. This prioritized set of outcomes can inform the establishment of a core outcome set, to improve the value of trial evidence to support decision-making for people on HD.

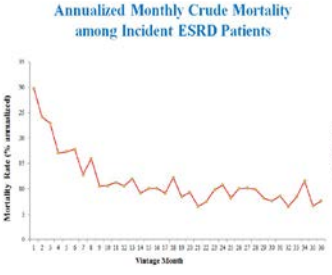
TH-PO1019

Pre-ESRD (Prelude) eGFR and the Relationship to Post-ESRD Mortality Outcomes among the Kaiser Permanente Southern California (KPSC) CKD Cohort John J. Sim,[1] Hui Zhou,[1] Jiaxiao Shi,[1] David K. Yi,[1] Shayna L. Henry,[1] Sally F. Shaw,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[3] Steven J. Jacobsen.[1] *[1]Nephrology & HTN / Research and Evaluations, Kaiser Permanente Southern California; [2]Univ of Tennessee Health Science; [3]Univ of California Irvine Medical Center.*

Background: The eGFR values prior to transition to ESRD may provide insights on indications for starting renal replacement and also prognosticate early mortality after ESRD transition. We sought to evaluate the post ESRD mortality outcomes among a large diverse CKD population based on prelude eGFR values.

Methods: A retrospective cohort study over 13 years (1/1/2002-12/31/2014) within the KPSC health system of all incident CKD patients (eGFR<45 using serial measurments) who transitioned to ESRD [hemodialysis (HD), peritoneal dialysis (PD), or kidney transplant (TX)]. Post ESRD mortality outcomes were determined relative to the first outpatient ESRD treatment as the index date.

Results: A total of 5,476 CKD patients transitioned to ESRD (86% HD, 13% PD, 1% TX). Mean age 63yrs with 59% males. DM (53%) and HTN (19%) were most common ESRD causes. Prelude (pre-ESRD) eGFR was >15ml/min in 19% of the cohort at transition. This group had the highest rate of cardiac events, acute kidney injury (84%), and inpatient ESRD starts but the lowest fistula rates (16 vs 34%). This group also had the highest pre-emptive TX (1.9 vs 0.5%). Post transition mortality was highest immediately upon transition to ESRD and rates declined and stabilized around month 9 (Figure 1). The prelude eGFR groups >20 and 16-20 had the highest rate of mortality up to 1 yr compared to prelude eGFR <15 ml/min.



Conclusions: Among a CKD cohort who transitioned to ESRD, patients with a prelude eGFR >15 experienced the highest short term mortality. This subgroup is a potential area of focus in terms of CKD management strategies which may or may not include transition to ESRD.

TH-PO1020

Improved Early Survival Rates among Patients Initiated on Maintenance Dialysis in the Military Health System Robert Nee,[1] Evan I. Fisher,[1] Christina M. Yuan,[1] Lawrence Agodoa,[2] Kevin C. Abbott.[2] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Insts of Health, Bethesda, MD.*

Background: Previous reports have indicated increased mortality in the early period after initiation of maintenance dialysis in the general end stage renal disease (ESRD) population. We hypothesized that ESRD patients in the Department of Defense's Military Health System (MHS), a model of an integrated universal healthcare enterprise in the US, would have better survival rates during this early high-risk period.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 2,073,543 patients initiated on maintenance dialysis from January 2, 1995 through December 31, 2014, of whom 2,096 (0.1%) were MHS incident dialysis patients. We conducted Cox regression analyses by sequential multivariable adjustment with all-cause mortality as the outcome variable. Covariates include demographic and clinical characteristics and other co-morbid conditions from the Medical Evidence Form 2728.

Results: MHS patients had significantly lower mortality rate compared to non-MHS patients during the first 12 months of dialysis initiation (17 vs. 26 per 100 patient-years [PY], respectively; p<0.001). Mortality rates peaked from the 4th to 8th week for both MHS and non-MHS patients (25 vs. 40 per 100 PY, respectively). The basic Cox model showed significantly lower death rates among MHS vs. non-MHS patients at 3 months (adjusted hazard ratio [AHR] 0.64; 95% confidence interval [CI] 0.52-0.79) and at 6 months (AHR 0.62; 95% CI 0.53-0.73). However, these differences in mortality rates were nonsignificant after further adjustment for pre-ESRD nephrology care and type of dialysis vascular access, becoming significant only at 12 months (AHR 0.79; 95% CI 0.64-0.98).

Conclusions: Compared to the broader ESRD population, MHS patients had better survival rates during the first 12 months after starting maintenance dialysis, likely due to improved access to predialysis care. Mortality was highest at week 4 to 8 for both cohorts but attenuated among MHS patients.

TH-PO1021

Co-Morbid Conditions of Incident Dialysis Patients Rita L. McGill, Eduardo K. Lacson, Robin Ruthazer, Klemens B. Meyer, D. Miskulin, Daniel E. Weiner. *Nephrology, Tufts Medical Center, Boston, MA.*

Background: US dialysis patient survival has improved. From 2004-2013, adjusted USRDS patient mortality fell by 22% for hemodialysis (HD) and 34% for peritoneal dialysis (PD). We examined trends in the comorbid diagnoses for incident patients, 2005-2011.

Methods: Cohorts of incident HD and PD patients with 2 years of prior Medicare were constructed for each 1-year period, so claims could be used to determine comorbid diagnoses present before dialysis initiation. Time trends in the proportions of each co-morbid condition were evaluated with logistic regression, with odds ratio (OR) >1 representing an increased frequency over the seven year period. Overall proportions of each diagnosis were compared between HD and PD patients using chi-square.

Results: 265,900 HD patients and 12,268 PD patients were assessed in 7 HD and 7 PD cohorts. Median age was 74 (IQR: 67,80) for HD and 72 (IQR: 67, 78) for PD. For each diagnosis, the percentage of affected patients was greater for HD than PD patients (P<0.001 for all).

Overall Prevalences and Odds Ratios for Trend over Seven Years for Each Comorbid Condition

	Hemodialysis			Overall Prevalence		Peritoneal Dialysis		
	Odds Ratio	95% CI	*P*	HD	PD	Odds Ratio	95% CI	*P*
Cardiac Disease	0.94	0.91, 0.97	0.007	62	53	0.98	0.84, 1.15	0.8
Diabetes	1.09	1.05, 1.13	<0.001	57	52	0.96	0.82, 1.13	0.6
Peripheral vascular disease	0.98	0.94, 1.02	0.3	26	20	0.94	0.77, 1.14	0.5
Chronic lung disease	1.03	0.99, 1.07	0.2	22	16	1.02	0.82, 1.26	0.9
Stroke	1.08	1.02, 1.14	0.004	13	9	1.34	1.02, 1.76	0.04
Cancer	1.06	1.00, 1.13	0.06	10	8	0.98	0.74, 1.30	0.9
Gastrointestinal (GI) bleeding	0.87	0.80, 0.94	<0.001	4	2	1.02	0.60, 1.74	0.9
Liver disease	1.35	1.22, 1.50	<0.001	4	2	1.21	0.69, 2.13	0.5
No comorbid diagnoses	1.03	0.98, 1.07	0.3	17	22	0.98	0.81, 1.18	0.8

Time trends in HD revealed small decreases in cardiac disease and GI bleeding, and increases in diabetes, liver disease and stroke; PD patients had increased stroke.

Conclusions: The large improvements in dialysis patient survival cannot be explained by the observed trends in the case-mix variables of incident patients. PD patients may have less pre-existing comorbid disease at dialysis initiation.

TH-PO1022

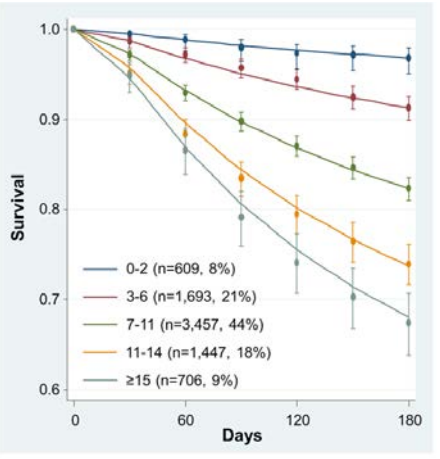
A Novel Comorbidity Score for Predicting Early Mortality upon Transition to ESRD among Incident Dialysis Patients Yoshitsugu Obi,[1] Elani Streja,[1] Connie Rhee,[1] Melissa Soohoo,[1] John J. Sim,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Kaiser Permanente SC; [3]Univ of Tenn.*

Background: Mortality is exceptionally high during the first 6 months after transition to dialysis therapy. Development of a new comorbidity score for predicting early mortality by using pre-ESRD conditions may have important clinical and epidemiological implications.

Methods: In a nationwide cohort of 28,100 US veterans who transitioned to dialysis therapy between Oct 2007–Sep 2010, we derived a new comorbidity score comprised of primary ESRD causes and 16 comorbid conditions prior to ESRD by using a Cox model with adjustment for demographics(Full model). We evaluated the model fitness, discrimination, and calibration using 5 groups of the new comorbidity score (Score model), and then validated the model among those 7,912 who transitioned to dialysis Oct 2010–Sep 2011.

Results: The median comorbidity score was 9 (IQR, 6–12), ranging from 0 to 30. Compared to the middle risk group, adjusted HR(95%CI) for 6-month mortality in the lowest and highest risk groups were 0.37 (0.30–0.44) and 1.96 (1.81–2.12), respectively. C-index and adjusted R_D^2 were 0.69 and 0.20 in the Full model and 0.68 and 0.19 in the Score model, respectively. The difference in Akaike's information criterion was <0.01% between models. In the validation cohort, we observed consistent findings and also confirmed a good calibration by comparing predicted survival probability versus observed Kaplan-Meier estimates. Compared to Charlson comorbidity index, the new score appeared to have higher C-index (0.70 vs. 0.68) and adjusted R_D^2 (0.21 vs. 0.19).

Primary cause of ESRD	
Diabetic Nephropahty	2
Hypertension	3
GN/PKD	0 (Ref)
Others	6
Comorbidities	
Diabetes as non-primary cause of ESRD	0
Myocardial infarction	2
Congestive heart failure	5
PVD	0
CVA/TIA	1
Dementia	3
Paraplegia/Hemiplegia	3
COPD	2
Connective tissue dis.	0
Peptic ulcer	1
Liver disease	
Mild	1
Moderate/Severe	9
Cancer	
w/o metastasis	1
with metastasis	4
AIDS/HIV	5



Conclusions: The new pre-ESRD comorbidity score would provide important clinical information for patients transitioning to dialysis given a high predictive ability of early mortality among incident dialysis patients. It may also be useful for decision algorithms and comparisons in future early mortality analyses.

TH-PO1023

Long Term Survival in End Stage Renal Disease Patients Compared to General Population on a General Intensive Care Unit Ingi Elsayed. *Renal Dept, Sheffield Teaching Hospitals, United Kingdom.*

Background: Prevalence of chronic kidney disease (CKD) worldwide is increasing. UK Renal Registry reported an incidence rate of 109 per million population (pmp) of end stage renal disease (ESRD) in 2013. Mortality is higher in ESRD patients compared to general population. 1.3% of admissions to adult ICUs in UK between 1995 & 2004 were ESRD patients. Knowledge of long term mortality rates in this group of patients remains deficient. We sought to quantify long term outcomes of ESRD patients admitted to our ICU.

Methods: We retrospectively analysed prospectively collected data from all adult (>18 years) patients admitted to our 44-bed general ICU between Oct 2008-Oct 2013. ESRD patients were identified from renal database, as requiring long term renal replacement therapy prior to ICU admission. Patients were followed up for maximum of 6.25 years from admission to ICU. We used cox-regression analysis to examine survival and adjust for possible confounders.

Results: Study population comprised 132 ESRD & 3534 general patients admitted to ICU. 58% were male, median age 62 years (IQR 50-74), median APACHE II score 17 (IQR 12-22). 116 (82%) of ESRD patients survived to ICU discharge. Unadjusted Kaplan-Meier survival showed that long term mortality was significantly higher among patients with ESRD compared to general ICU patients (p=.00). There was no statistically significant difference in long term mortality between ESRD & general ICU patients (p=0.590, 95%CI: 0.753-1.175); when adjusting for age & APACHE II scores; using Cox-regression analysis. Age and APACHE II scores were independently associated with worse long term mortality (HR: 1.01, 95%CI 1.01-1.02, p=0.00 and HR: 1.07, 95% CI 1.06-1.08, p=0.00; respectively).

Conclusions: Our cohort suggests that significant proportion of ESRD patients admitted to ICU survive to unit discharge. In our cohort long term mortality was not different among ESRD compared to general ICU patients. This reflects improved mortality among ESRD patients over the years including those requiring higher intensity level of care. Our data can be useful in preoperative risk stratification.

TH-PO1024

Prognosis and Related Risk Factors of ANCA-Associated Vasculitis Patients on Maintaining Dialysis Fei Han, Xishao Xie, Ying Xu, Jianghua Chen. *Kidney Disease Center, First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: We retrospectively analyzed the prognosis and related risk factors for ANCA-associated vasculitis (AAV) patients on maintaining hemodialysis or peritoneal dialysis.

Methods: AAV patients on maintaining peritoneal dialysis (PD) or hemodialysis (HD) treated in our center from June 2007 to June 2015 were included, and their data were retrospectively compared and analyzed by Kaplan-Meier analysis and Cox regression model to know their survival rate and the risk factors.

Results: A total of 123 cases were included, with an average duration of dialysis for 1005 ± 739 days, and with 88 cases (71.5%) on HD and 35 cases (28.5%) on PD. Seventy-one patients (57.7%) were under the age of 65 years old and 52 patients (42.3%) were more than 65 years old. At the median follow-up time of 36 months, 39 patients (31.7%) were died. The main causes of death were cardiovascular events (30.8%) and infection (23.1%). COX regression analysis showed that patients older than 65 years old, with cardiovascular disease or interstitial pneumonia at the disease onset were independent risk factors affecting survival.

Conclusions: The factors including age older than 65 years, pre-dialysis cardiovascular disease and interstitial pneumonia were independent risk factors affecting survival of AAV patients on maintaining dialysis, and infections and cardiovascular events were the main causes of death.

TH-PO1025

Epidemiology and Outcome of Acute Pancreatitis in End-Stage Renal Disease Dialysis Patients: A 10-Year National Cohort Study Chih-Chiang Chien. *Dept of Nephrology, Chi-Mei Medical Center, Tainan, Taiwan.*

Background: To determine the incidence and severity of acute pancreatitis (AP) in end-stage renal disease (ESRD) patient on dialysis and whether the dialysis modality [hemodialysis (HD) vs. peritoneal dialysis (PD)] confers a higher risk for AP as well as complications or mortality related to AP.

Methods: We analyzed data from the Taiwan National Health Insurance Research Database and included 67,078 ESRD patients who initiated dialysis between 1999 and 2007. The follow-up period was from the start of dialysis to death, end of dialysis, or December 31, 2008.Cox proportional hazards models were used to identify the related risk factors.

Results: The cumulative incidence rates of AP were 0.6%, 1.7%, 2.6%, 3.4%, and 4% at 1-, 3-, 5-, 7- and 9-year, respectively. The incidence of AP was 5.11 per 1,000-person years for those on HD and 5.86 per 1,000-person years for those on PD. Independent risk factors for AP on ESRD patient were elderly, being female, biliary stone, liver disease and on PD. Severe AP occurred in 44.9% of HD patients and in 36% of PD patients. Patients with AP on HD had a higher incidence of upper gastrointestinal (UGI) bleeding than did those on PD (p=0.002). In contrast, patients with AP on PD had a higher incidence of total parenteral nutrition (TPN) use than did those on HD (p=0.072).The overall in-hospital mortality was 8.1%. Furthermore, mortality after AP was associated with male gender, increasing age, severity of AP, and the presence of DM or liver disease.

Conclusions: Patient on PD had a higher risk than patient on HD for AP attack. UGI bleeding more commonly occurred in HD patients and TPN use was more common in PD patients.

TH-PO1026

Survival Outcomes of Children Starting Renal Replacement Therapy in the Second Year of Life Akira Ashida,[1] Mayumi Sako,[2] Eisuke Inoue,[2] Daishi Hirano,[3] Masataka Honda,[4] Shori Takahashi,[5] Motoshi Hattori.[6] *[1]Osaka Medical College, Osaka, Japan; [2]National Center for Child Health and Development, Tokyo, Japan; [3]The Jikei Univ School of Medicine, Tokyo, Japan; [4]Tokyo Metropolitan Children's Medical Center, Tokyo, Japan; [5]Nihon Univ School of Medicine, Tokyo, Japan; [6]Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Renal replacement therapy (RRT) for children with end-stage renal disease (ESRD) has been used for several decades; however, survival data for small children who start RRT are limited.

Methods: The Japanese Society for Pediatric Nephrology (JSPN) performed a cross-sectional, nationwide survey of Japanese patients aged less than 20 years who were newly diagnosed as having ESRD. This survey started in 2012 (Clin Exp Nephrol 19:933, 2015) and collected information every 3 years. The present study was performed using data from the JSPN survey database from January 1 2006 to December 31 2013, and examined survival outcomes of children starting RRT in the second years of life.

Results: A total of 152 patients who had been younger than 2 years of age at the start of RRT were identified. Among them, 112 patients had started RRT at 0 to 1 years of age; 52.0% were boys, and 88.8% had started with peritoneal dialysis. ESRD was mostly caused by congenital anomalies of the kidney and urinary tract (42.7%), followed by congenital nephrotic syndrome (12.5%) and cystic kidney disease (9.2%). A total of 21 deaths occurred during 520.7 patient-years (py), equivalent to a mortality rate of 40.3 deaths per 1000 py. The main known cause of death was infection (33.3%). The overall survival rate at 5 years was 81.0% (95% confidence interval (CI) 73.2-89.2%). The 5-year survival rates in the 0-1 year, and 1-2 year age groups were 76.8% (95%CI 67.7-87.0%) and 94.9% (95%CI 88.3-100%), respectively. Mortality was higher in children aged 0-1 year (49.1 deaths per 1000 py) than in children aged 1-2 years (14.9 deaths per 1000 py).

Conclusions: The present study indicates that the survival rate in children aged less than 1 year was poor. Specific therapeutic challenges continue to exist for children with ESRD aged less than 1 year who undergo RRT.

TH-PO1027

Racial/Ethnic Variations in Mortality Rates for End-Stage Renal Disease (ESRD) Patients Treated in U.S. Territories Compared to U.S. 50 States Keith C. Norris,[1] Guofen Yan,[2] Wei Yu,[2] Lawrence Agodoa.[3] *[1]UCLA; [2]Univ of Virginia; [3]NIH-NIDDK, Bethesda, MD.*

Background: Health outcomes for racial/ethnic minorities with ESRD treated in US territories may differ from patients treated in the US 50 states.

Methods: Using USRDS we examined 1,547,438 patients ≥18 years, with no prior transplantation and first dialysis between 4/1/1995 and 9/28/2012. Hazard ratios (HR) for death were calculated from the date of first ESRD treatment to 9/30/2012, censored at transplant. Adjustments included **Model 1**: demographics, yr of dialysis initiation, cause of ESRD, insurance and eGFR at ESRD onset; **Model 2**: Model 1 with addition of comorbidities and dialysis modality.

Results: Of 22,828 dialysis patients treated in territories (American Samoa, Guam, Puerto Rico, Virgin Islands), 321 were white, 666 black, 20,299 Hispanic, and 1,542 Asian. Of 1,524,610 US 50 states patients, 838,736 were white, 444,066 black, 182,994 Hispanic, and 58,814 Asian. After adjustments, the risk for death for white dialysis patients in the territories was 25% lower than US 50 states, but did not differ for black patients. Hispanic and Asian patients in the territories had 61% and 95% greater risk for death (Table). Using matched subcohorts significantly affected only whites, likely due to large differences in age; final HR 0.96 (p=0.72).

	Model 1		Model 2	
	HR for Territories vs. 50 States (95% CI)	P value	HR for Territories vs. 50 States (95% CI)	P value
White	0.69 (0.60-0.79)	<0.001	0.75 (0.65-0.86)	<0.001
Black	1.05 (0.96-1.16)	0.296	1.04 (0.94-1.15)	0.446
Hispanic	1.63 (1.60-1.66)	<0.001	1.61 (1.58-1.63)	<0.001
Asian	1.93 (1.81-2.06)	<0.001	1.95 (1.82-2.08)	<0.001

Conclusions: Mortality rates for ESRD patients in the US territories differ substantially by race/ethnicity compared to 50 US States. After matching, mortality risk did not differ for whites or blacks, but remained greater for Hispanics and Asians. A better understanding of these differences could lead to important health policy recommendations.

TH-PO1028

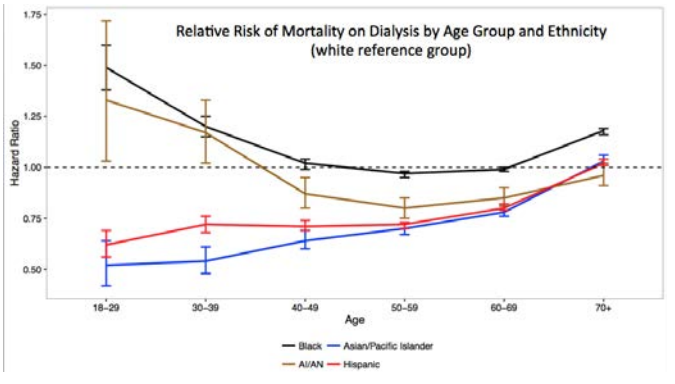
Ethnicity and Survival of Patients with End-Stage Renal Disease on Dialysis

Abdulkareem Agunbiade, Abhijit Dasgupta, Mohammed R. Chowdhury, Michael M. Ward. *NIAMS, NIH, Bethesda, MD.*

Background: End-stage renal disease disproportionately affects ethnic minorities, particularly blacks and Hispanics. Minorities have longer survival on dialysis than whites, but the reasons are unclear. Differences in rates of renal transplantation partially account for the survival difference, but differences in the rate of discontinuation of dialysis have not been explored as a contributor. We examined if ethnic differences in the rate of elective discontinuation from dialysis and in transplantation account for the survival advantage of ethnic minorities on dialysis.

Methods: We conducted a retrospective cohort study of the United States Renal Data System from 2003 and 2014, which included 1,131,409 adults with incident ESRD. We performed a multivariate survival analysis with two competing risks. Our primary independent variable was ethnicity (white, black, Hispanic, Asian, and American Indian/Alaska Native). The outcome was survival on dialysis.

Results: Both transplantation and discontinuation of dialysis were more common among whites than blacks and Hispanics. In multivariate survival models with two competing risks, mortality risks were higher for blacks compared to whites in those age 18-29 years (subdistribution hazard ratio 1.49, 95% CI [1.38, 1.60]), 30-39 years (1.20 [1.15, 1.25]), and 70 years and older (1.18 [1.16, 1.19]), while risks were similar in middle-age. American Indians/Alaska Natives also had higher mortality risks than whites among patients age 18-29 and 30-39 years. Hispanics and Asians had lower mortality risks than whites in all but those age 70 years and older.



Conclusions: Blacks with ESRD have no survival advantage on dialysis compared to whites after accounting for ethnic differences in renal transplantation and elective discontinuation of dialysis. Hispanics and Asians have lower risk of mortality on dialysis than whites among patients younger than 70 years.

TH-PO1029

Impact of Race and HCV Co-Infection on HIV+ Dialysis Patient Survival

Deirdre L. Sawinski,[1] Jayme E. Locke,[2] Jordana B. Cohen,[1] Kimberly Autumn Forde,[3] Peter P. Reese.[1] *[1]Renal Medicine, Univ of Pennsylvania, Philadelphia, PA; [2]Surgery, Univ of Alabama at Birmingham, Birmingham, AL; [3]Gastroenterology, Univ of Pennsylvania, Philadelphia, PA.*

Background: Historically HIV+ dialysis patient survival has been inferior to HIV- patients. The effect of antiretroviral therapy on dialysis survival in the modern era is unknown. Since the removal of HIV as a comorbidity from the CMS 2728 form in 2005 it has been impossible to study outcomes for HIV+ dialysis patients using national registry data.

Methods: We obtained data from a national dialysis provider (Davita). Using home medications and laboratory data we identified 5356 HIV+ and 1864 HIV+/HCV+ patients who were compared to 411,363 HIV-/HCV- patients dialyzed from 2004-2014. Survival on dialysis was modeled using cox regression.

Results: HIV+ patients were younger (median age 46), more often male (67%) and black (74%). We found effect modification by race (p<0.001). In a model stratified by race accounting for age, sex, diabetes, dialysis exposure and modality, white HIV+ patient survival was similar to HIV-/HCV- (HR 1.05, 0.93-1.19) but non-white HIV patients had increased risk of death (HR 1.50, 1.42-1.58). HIV+/HCV+ patients had an increased risk of death regardless of race (white HR 1.59, 1.26-2.00; non-white HR 1.72, 1.62-1.87).

	White			Non-white		
	HR	p value	95% CI	HR	p value	95% CI
HIV-/HCV-	ref			ref		
HIV+	1.05	0.40	0.93-1.19	1.50	<0.001	1.42-1.58
HIV+/HCV+	1.59	<0.001	1.26-2.00	1.72	<0.001	1.62-1.87
Age (cont)	1.03	<0.001	1.03-1.03	1.04		
Male	1.04	<0.001	1.02-1.05	0.98	0.07	0.96-1.00
Diabetes	1.16	<0.001	1.14-1.17	1.14	<0.001	1.11-1.14
PreDavita dialysis exposure	1.30	<0.001	1.27-1.32	1.28	<0.001	1.25-1.31
PreDavita dialysis in years	0.99	0.004	0.99-0.99	1.01	<0.001	1.01-1.02
Hemodialysis	ref			ref		
Peritoneal dialysis	0.74	<0.001	0.72-0.77	0.81	<0.001	0.78-0.84

Conclusions: Race is an important modifier of survival on dialysis for HIV+ patients, but co-infection with HCV also contributes to increased mortality for that group.

TH-PO1030

The Impact of Gender on Prescription and Use of Vascular Access in Elderly Patients on Hemodialysis: A European Hemodialysis Multicenter Analysis

Andre L. Weigert,[1] Stefan H. Jacobson,[2,3] Werner Kleophas,[4] Mahesh Krishnan,[5] Abdulkareem Alsuwaida,[6] Fatima Ferreira Silva,[1] Maciej B. Drozdz.[7] *[1]DaVita, Portugal; [2]Karolinska Inst, Stockholm, Sweden; [3]DaVita, Europe; [4]DaVita, Germany; [5]DaVita Inc; [6]DaVita, Saudi Arabia; [7]DaVita, Poland.*

Background: The elderly constitute a substantial and growing fraction of the end stage renal disease population. Elderly patients on hemodialysis are a heterogeneous group with a high prevalence of comorbidities that reduce life expectancy. Although women have a survival advantage in the general population, women on hemodialysis do not survive longer than men.

Methods: In this analysis we included 1,247 patients on maintenance hemodialysis from Portugal (n=730) and Poland (n= 517) and focused on treatment prescription, use of vascular access and achievement of KDIGO targets in women and men ≥80 years of age respectively.

Results: Elderly patients (≥80 years) on hemodialysis were prescribed lower Qb and shorter treatments, but despite this they achieved significantly higher Kt/V and significantly better control of phosphorus and PTH. The proportion of CVC's was significantly higher and AVF's lower in the elderly. Women ≥80 years had lower prevalence of AVF than men, but there were no differences in the prescription of hemodialysis in relation to gender in the elderly. Elderly women had a higher Kt/V and lower body weight than corresponding men. Mean arterial BP pre HD, Charlson comorbidity index and ESA doses were similar in relation to both age and gender.

	Age yrs	Vint months	Bw post	Kt/V	TT min	Hb g/dl	Ferrit ug/l	Alb g/l	Ca mg/dl	P mg/dl	iPTH pg/ml	Qb ml/min	Tx blood volume	CVC %	AVF %
<80 yrs	63	61	72	1.8	732	11	586	42	8.8	4.5	588	377	1.32	14	80
>80 yrs	84	60	65	1.9	717	10.8	669	38	8.9	3.8	478	368	1.38	26	68
p	***	*NS*	***	***	***	*	*	*NS*	*NS*	***	***	**	**	***	***
Male >80 yrs	84	59	67	1.8	715	10.9	487	38	8.8	3.8	464	370	1.25	24	69
Female >80 yrs	84	61	63	2.0	719	10.7	698	38	8.9	3.8	495	366	1.28	22	57
p	NS	NS	**	***	NS	NS	NS	NS	NS	NS	NS	NS	NS	NS	*

t-test *=0.05, **=0.01, ***=0.001

Conclusions: This indicates that there are no or small differences in clinical practice in relation to gender in elderly patients on hemodialysis in Portugal and Poland.

Funding: Pharmaceutical Company Support - DaVita

TH-PO1031

Racial-Ethnic Disparities in Indices of Bone and Mineral Metabolism in the Pediatric Dialysis Population

Marciana Laster,[1] Melissa Soohoo,[2] Elani Streja,[2] Keith C. Norris,[1] Isidro B. Salusky,[1] Kamyar Kalantar-Zadeh.[2] *[1]UCLA; [2]UC Irvine.*

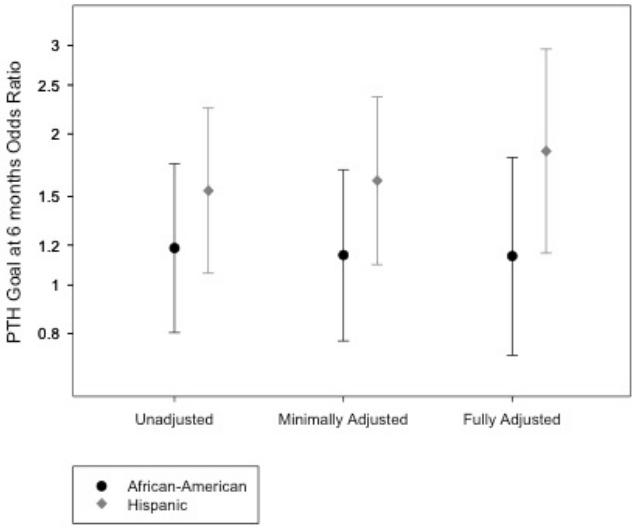
Background: Studies of healthy black adolescents show higher parathyroid hormone (PTH) and lower alkaline phosphatase (AP) levels when compared to white adolescents. Similarly, studies of adult dialysis patients have shown higher PTH in Black patients when compared to White patients. Little is known about racial-ethnic differences in markers of mineral bone metabolism (MBM) in the pediatric dialysis population.

Methods: In a pediatric dialysis population of 661 patients from a large dialysis organization, we explored racial-ethnic differences in MBM markers within the first 90 days after dialysis initiation. All lab values were provided from samples processed in a central laboratory. Using logistic regression, we explored the odds of reaching a PTH level between 200pg/ml to 600pg/ml by 6 months.

Results: Mean age of the cohort was 17±4 years of which 34% were White, 31% Black and 35% Hispanic. 68% of patients were treated with HD and 32% with PD. Black and Hispanic patients had significantly higher median PTH values than white patients. AP levels were lower in Black patients, while higher in Hispanic patients.

	White	Black	Hispanic	p
PTH (pg/ml)	368[203,584]	411[236,737]	471[277,779]	0.0048
S-Ca (mg/dl)	9.3±0.7	9.2±0.7	9.1±0.7	0.0008
S-P (mg/dl)	5.9±1.5	5.6±1.5	5.7±1.3	0.0937
AP (IU/L)	90.0[66.0,145.0]	82.0[64.7,115.3]	104.8[75.3,169.7]	<0.0001

In a model adjusted for baseline PTH, calcium, phosphorous, AP , binder type, 1,25$(OH)_2$D use, Cinacalcet use, modality, spKt/V and cause of ESRD, Hispanic ethnicity was associated with higher odds of meeting the PTH goal at 6 months (OR 1.85 [1.16, 2.95]).



Conclusions: Racial-ethnic differences in MBM exist in the pediatric dialysis population. Further studies are needed to evaluate how these differences affect the management of MBM in pediatric dialysis patients.

Funding: Other NIH Support - Ruth L. Kirschstein National Research Service Award

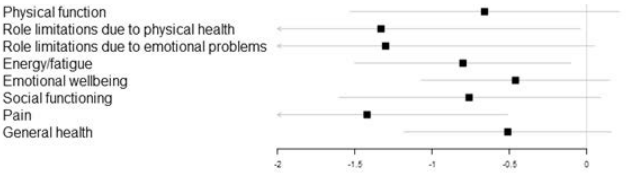
TH-PO1032

Thyroid Functional Disease, Quality of Life, and Mental Health in a Prospective Hemodialysis Cohort Connie Rhee,[1] Yanjun Chen,[1] Amy Seung You,[1] Csaba P. Kovesdy,[2] Steven M. Brunelli,[3] Gregory Brent,[4] Kamyar Kalantar-Zadeh,[1] Danh V. Nguyen.[1] *[1]UC Irvine; [2]Univ of Tennessee Health Science Center; [3]DaVita Inc; [4]UCLA.*

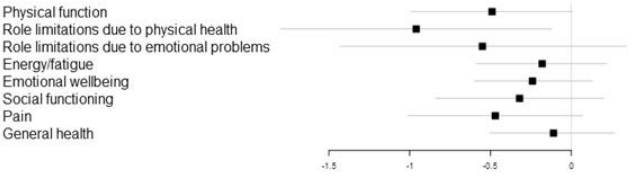
Background: In the general population there is increasing recognition of the impact of hypothyroidism on patient-centered outcomes such as health-related quality of life (HRQOL) and depression. While hypothyroidism is highly prevalent in hemodialysis (HD) patients, there has not been a prior study to determine if thyroid dysfunction is a risk factor for impaired HRQOL or mental health in this population.

Methods: Among 450 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Kidney Disease* study, we examined the association of thyroid status defined by TSH with HRQOL and depressive symptoms over time. Patients were recruited from 17 HD facilities and underwent protocolized TSH testing and administration of Short-Form 36 (SF-36) surveys and Beck Depression Inventory-II (BDI-II) every 6 months over 2013-15. We examined the association of baseline and time-varying TSH with the 8 SF-36 domains as longitudinal outcomes using case-mix+laboratory adjusted linear mixed effects models. Analogous methods were used to examine baseline and time-varying TSH with BDI-II score.

Results: Higher baseline TSH levels (+Δ1mIU/L) were associated with lower (worse) scores across the SF-36 domains of role limitations due to physical health (β=-1.33, p=0.04), energy/fatigue (β =-0.80, p=0.03), and pain (β=-1.42 p=0.002). Higher time-varying TSH (+Δ1mIU/L) was associated with lower role limitations due to physical health scores (β=-0.96, p=0.03). Baseline and longitudinal TSH levels were not associated with BDI-II score.



Change in SF-36 domain score associated with +Δ1mIU/L higher baseline TSH



Change in SF-36 domain score associated with +Δ1mIU/L higher time-varying TSH

Conclusions: In HD patients higher TSH levels are associated with impaired HRQOL across domains of physical health, energy/fatigue, and pain. Future studies are needed to determine if thyroid-modulating therapy improves the HRQOL of hypothyroid HD patients.

Use of a Symptom-Reporting Survey in Renal Clinic Jeremy T. Moskovitch,[1,2] Peter F. Mount,[1,2] Matthew R.P. Davies.[1,2] *[1]Austin Health Nephrology Dept, Melbourne, Victoria, Australia; [2]Univ of Melbourne, Victoria, Australia.*

Background: Previous studies have reported a high prevalence of symptoms in dialysis patients. The POS-renal survey identifies the presence and severity of 17 symptoms in ESKD patients. Whether identification of symptoms with a survey leads to an improvement in symptoms has not been studied. Thus, the aims of this study are: To determine the prevalence and change in symptoms experienced by dialysis patients following introduction of a symptom-reporting survey in renal clinic, and to evaluate nephrologists' satisfaction with this survey.

Methods: This is a prospective observational study of 110 prevalent dialysis patients (HD and PD). POS renal surveys were collected at baseline and follow-up (median 3 months). Surveys were completed by patients and results were available to nephrologists at clinic appointments. An anonymous survey was distributed to nephrologists to determine satisfaction.

Results: Baseline prevalence of individual symptoms ranged from 17-66% (95%CI 11-26% and 57-75%). Most common symptoms were fatigue (66%) and trouble sleeping (55%).Median number of symptoms was 7/17 (IQR 4-10). 49% of patients rated at least one symptom as severe or overwhelming. On multivariate analysis PD was associated with an increased risk of vomiting and drowsiness. Restless leg syndrome was associated with diabetic nephropathy primary renal disease (OR 9, p<0.05). On average, an improvement in severity of individual symptoms identified at baseline was seen in 55% of patients (range 30-89%, 95%CI 18-46% and 67-98%). The symptoms which improved most commonly were GI symptoms (62-89%) and itch (60%). The percentage of patients rating at least one symptom as severe or overwhelming was reduced (p<0.05), but remained high at 39%. The median number of symptoms was unchanged at 7/17 (IQR 3-10). Overall, nephrologists found that the survey was useful for symptom identification, but were unsure if its use helped improve symptom management.

Conclusions: Use of the POS-renal survey in renal clinic identified a high symptom burden in dialysis patients, and may be associated with an improvement in symptom severity. However, overall symptom burden at follow-up remained high.

TH-PO1034

Subjective Symptoms and Feelings for Daily Lives Are Not so Deteriorated in Maintenance Dialysis Patients Compared with Non-Dialyzed General Population Ikuto Masakane, Minoru Ito. *Nephrology, Yabuki Hospital, Yamagata, Japan.*

Background: Quality of life of chronic dialysis patients are generally recognized to be severely deteriorated because of inevitable and endless dialysis sessions and uremia itself. However, there are fewer reports which directly compared QOL and subjective symptoms between dialysis patients (HD) and non-dialyzed general population (ND). We have evaluated the dialysis related subjective symptoms and QOL of chronic dialysis patients twice a year since 2005. We compared the subjective symptoms and feelings for daily lives between HD and ND.

Methods: 213 HD and 157 ND were enrolled into the study. The average age were 65 years old in HD and 66 years old in ND. The original assessment sheet for subjective symptoms and QOL for dialysis patients which is called "Patient-oriented Dialysis (POD sheet) were used for the current study. POD sheet contains 19 questions about dialysis related symptoms and feelings for daily lives. The 7 questions indicated only to HD such as "pain at cannulation", "intradialytic hypotension" and so on were not provided to ND.

Results: Skin itchiness and general fatigue were observed more often in HD than ND; 20.2% vs. 10.2% in itchiness, 17.8% vs. 8.3% in fatigue. A lack of satisfied feeling for daily life was also higher in HD than ND; 18.8% vs. 5.7%. However, irritation feeling was lower in HD than ND; 6.6% vs. 14.1%. Other subjective symptoms such as constipation, insomnia and depressive sense which were reported as to be closely related to dialysis were not different between 2 groups. The total POD score were not different between HD and ND; 13.0 vs, 11.1.

Conclusions: Overall subjective feelings evaluated by the total POD score were not so deteriorated in HD compared with ND in the current study. Skin itchiness and general fatigue were uniquely related to dialysis itself and they could be good markers to evaluate the dialysis quality. However, actual prevalence rate of skin itchiness and insomnia in HD were significantly lower in our facilities than that of the previous reports. We believe our dialysis prescription policy based on patient's symptoms could improve the QOL of chronic dialysis patients.

TH-PO1035

Analysis of Symptoms Suffered by Patients on Haemodialysis and Peritoneal Dialysis Hari Dukka, Madhavan S. Menon, Simon J. Davies, Dominic Detakats, Mark Lambie. *Renal, Univ Hospitals North Midlands, Stoke on Trent, United Kingdom.*

Background: Dialysis patients both on haemodialysis (HD) and peritoneal dialysis (PD) suffer from multitude of symptoms, irrespective of their clearances on dialysis. We analysed symptoms suffered by dialysis patients attending dialysis clinics prospectively.

Methods: A validated dialysis symptom index questionnaire published in the journal of pain and symptom management,modified to suit the local patient population has been used. The original questionnaire had 30 symptoms out of which 18 commonly complained symptoms were used. 123 patients answered the questionnaire before the doctor's consultation in the clinic. Parameters including age, co-morbidities and urea clearances were recorded.

Results: The mean age (Mean±SD) was 62±14 years.73% of the study group were patients on HD and remaining 27% were on PD. The top 5 symptoms among all patients were post dialysis tiredness (77.7%),joint and muscle pains (66.9%),feeling tired all the time (66.1%),itching (63.6%), breathlessness (61%).Among HD patients post dialysis tiredness (84.9%), joint and muscle pains (72.1%),feeling tired all the time (68.6%), muscle cramps (66.7%), itching (65.1%), were more common. In patients on PD, feeling tired all the time (59.4%), joint and muscle pains (59.4%), feeling low (59.4%) itching (59.4%), low appetite and breathlessness (54.5%) were more common. We did not find any correlation between the comorbid index, age or urea clearances and the number of symptoms complained. About 5 patients on PD and 12 on HD complained of uraemic symptoms defined as a combination of nausea, itching and loss of appetite, but had adequate urea clearances.

Conclusions: Dialysis patients complain of multitude of symptoms which may be unrelated to urea clearances, age or comorbid index. Thorough consultations and appropriate investigations should be conducted to identify different pathological processes which may be causing symptoms and possible solutions provided.

TH-PO1036

Patients on Dialysis following a Failed Renal Transplant Have Significantly Higher Levels of Depression as Identified by the Beck Depression Inventory and the Patient Health Questionnaire PHQ-9: The ASSERTID Study Michael K. Almond,[1] Karin Friedli,[2] Joseph Chilcot,[3] Andrew Davenport,[4] Ayman Guirguis,[2] Benjamin Spencer,[5] Ken Farrington.[2] *[1]Renal Unit, Southend Hospital, Essex, United Kingdom; [2]Centre for Life Sciences, Univ of Hertfordshire, Hatfield, Hertfordshire, United Kingdom; [3]Psychology Dept, Kings College, London, United Kingdom; [4]Centre for Nephrology, Royal Free Hospital, London, United Kingdom; [5]Psychiatry, Maudsley Hospital, London, United Kingdom.*

Background: The diagnosis of depression in the presence of End Stage Renal Failur, is difficult. There is evidence that depression affects the outcome (survival) of patients on haemodialysis. The impact of a previous failed renal transplant in this group is poorly documented.

Methods: 1110 haemodialysis patients from five UK centres were invited to take part in a screening programme for depression using the Beck Depression Inventory (BDI-II) and Patient Health Questionnaire – 9 (PHQ-9) and the results compared with social, demographic, physical and biological markers. The presence of a failed transplant was documented. 709 patients (64%) consented to screening.

Results: 114 of 709 patients (16.1%) had been transplanted. 699 patients completed the BDI and 702 the PHQ-9. A significant number of patients had a high BDI-II (≥ 16) and high PHQ-9 (≥ 10) (33% and 28% respectively). Patients with a failed transplant and now back on haemodialysis were more likely to score highly on both tools for depression than those never transplanted. Median BDI-II score in previously transplanted patients was 13.5 (IQR 20) and 10 (IQR 13) in the non-transplanted group (p = 0.022). Comparable scores for PHQ-9 were 8 (IQR 11) vs 5 (IQR 8) (p = 0.018). More patients with a failed transplant had a high BDI-II score (46% vs 31%: p = 0.002). The same was true for high PHQ-9 (40% vs 26%: p=0.001). A failed transplant was a significant predictor of high BDI-II (Odds Ratio 1.88: p= 0.035) and high PHQ-9 (Odds Ratio 1.97: p =0.026).

Conclusions: Depression is common in patients on dialysis. Having a failed transplant increases the likelihood of patients having high depression scores. Patients with a failing transplant likely to return to haemodialysis may benefit from intervention.

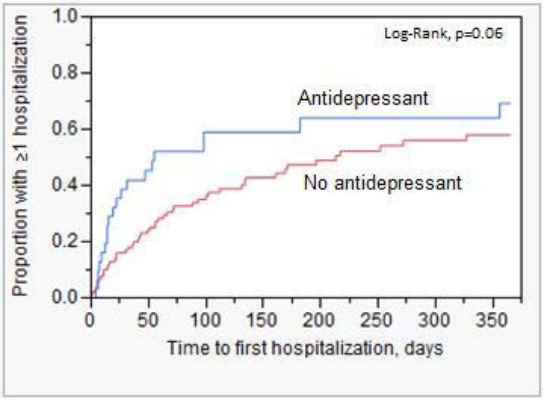
TH-PO1037

Young Adult Hemodialysis (HD) Patients: Antidepressant Use and Healthcare Utilization in the First Year Diana L. Vork,[1] Ziad El-Zoghby,[2] Robert C. Albright,[2] Sandra Herrmann,[2] Maria Lapid,[3] Terry D. Schneekloth,[3] LaTonya J. Hickson.[2] *[1]Mayo Medical School, Mayo Clinic; [2]Nephrology, Mayo Clinic; [3]Psychiatry, Mayo Clinic, Rochester, MN.*

Background: Despite having less comorbidity than older patients, young adult HD patients have high healthcare utilization. Depression and other psychosocial factors may contribute to this observation, and the relationship between antidepressant medication use and healthcare use in young adults has not been well described.

Methods: Retrospective cohort study of patients aged 18-44 years who initiated HD (01/2001-12/2013) and remained on dialysis ≥30 days at a single institution. Primary outcomes were hospitalization and ED visit rates within the 1st year of HD based on antidepressant use at baseline.

Results: Among 131 young adult HD patients, 31 (24%) were receiving ≥1 antidepressant for a mood indication at the time of HD initiation. The antidepressant group was more likely to have diabetes (61% vs. 32%), coronary artery disease (29% vs. 11%), heart failure (32% vs. 14%), and illegal drug use history (32% vs. 14%; all p<0.05). Time to 1st hospitalization was not different (Figure), but hospitalization rate was higher in the antidepressant group (0.0085 vs. 0.0035 per person days, p=0.003). This difference remained even when controlling for diabetes (p=0.01), coronary artery disease (p=0.01), heart failure (p=0.01), and illegal drug use history (p=0.03). Psychiatric hospitalizations were uncommon (1 event). ED visit rate was similar between groups (0.0022 vs. 0.0016 per person days, p=0.46).



Conclusions: Antidepressant use is common among young adult HD patients and is associated with a higher hospitalization rate during the 1st year compared to patients not on an antidepressant at initiation. Further studies may clarify the direct impact of depressed mood on healthcare use versus antidepressants as a marker of medical comorbidities.

TH-PO1038

Impact of Fluid Overload on Quality of Life in Haemodialysis Patients Carlos Adrián Chávez-Mendoza, Jose Luis Ortega Vargas, Olynka Vega, Ricardo Correa-Rotter. *Nephrology and Mineral Metabolism, National Medical Science and Nutrition Inst Salvador Zubiran, Mexico City, Mexico.*

Background: The overhydration (OH) in patients with end stage renal disease (ESRD) is associated with multiple outcomes. The aim of this study was to evaluate the effect of OH in quality of life (QoL) in Mexican prevalent chronic haemodialysis (HD) patients.

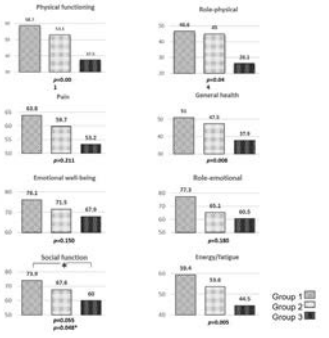
Methods: Observational comparative study that included 133 prevalent HD patients from 3 centers from Mexico City. Hydration status and body composition was assessed by bioimpedance spectroscopy employing BCM, Fresenius®. The degree of OH was defined by estimating the fluid overload/extracellular water (OH/ECW) index dividing the population into tertiles, being Group 1 with no OH and Group 3 with highest degree of OH. The cut off threshold for the definition of OH was set to 15% (OH/ECW index >0.15, Group 3). QoL was measured using KDQOL-36 instrument. Data analysis was carried out through descriptive and inferential statistics.

Results: General characteristics are shown in Table 1. No differences between groups were present in: age, Charlson index, time on dialysis, type of vascular access, and hospitalization days in the last year. Overhydrated HD patients had a higher prevalence of DM (p=0.02). The KDQOL-36 specific kidney disease composite summary was lower in Group 3 (p=0.01). The score of the group with the mayor overhydration was lower for all KDQOL-36 generic dimensions (Figure 1). The SF-12 physical and mental composite was lower in the subgroup with OH (Physical: 38.5, 38.1, and 33.7 (p=0.07), and, Mental: 52.4, 49.4, and 48.9 (p=0.3) in groups 1, 2 and 3 respectively).

Table 1. Differences between overhydrated and euvolemic patients in chronic HD

	Group 1	Group 2	Group 3	p
Age, years	51.7 ± 15.5	53.3 ± 17.8	53.7 ± 14.3	0.827
Sex (female), %	25 (40.9)	22 (36.1)	14 (22.9)	0.042
Diabetes Mellitus, %	18 (28.6)	16 (25.4)	28 (46)	0.018
Charlson index	4.5 ± 2.6	4.5 ± 2.6	5.1 ± 2.3	0.416
Body mass index, kg/ m²	26.5 ± 5.6	26.2 ± 4.7	24.4 ± 3.9	0.088
Interdialytic weight gain, mL/ kg	34.4 ± 15.3	33.3 ± 50.1	36.6 ± 15	0.890
Kt/V	1.4 ± 0.4	1.4 ± 0.3	1.4 ± 0.3	1.000
MAP predialysis, mmHg	100 ± 18.9	98.8 ± 21.1	101.6 ± 13.7	0.775
MAP postdialysis, mmHg	93.3 ± 14	96.5 ± 16.8	100.4 ± 13.1	0.077
OH/ECW	0.02 ± 0.04	0.11 ± 0.02	0.21 ± 0.05	<0.05
Lean tissue index [LTI], kg/ m²	14.7 ± 4.1	13.2 ± 3.4	13.5 ± 3.3	0.127
Fat tissue index [FTI], kg/ m²	12.1 ± 7.6	13 ± 6.7	10.3 ± 3.6	0.133
Body cell mas [BCM], kg	21.3 ± 8.9	18.9 ± 7.3	19.8 ± 7.1	0.351
Handgrip strength, kg	28.1 ± 9.9	27.9 ± 9.9	24.1 ± 8.8	0.237
Haemoglobin, mg/ dL	10.3 ± 1.3	10.1 ± 1.8	10 ± 1.7	0.737
Albumine, mg/ dL	3.6 ± 0.4	3.6 ± 0.3	3.5 ± 0.4	0.446
Cholesterol, mg/ dL	170.9 ± 35.7	159.5 ± 41.2	145.6 ± 39.7	0.025
Serum creatinine, mg/ dL	11.3 ± 3.8	10.6 ± 2.6	10.5 ± 2.6	0.394

Figure 1. Quality of life in chronic HD patients. KDQOL-36 generic dimensions (SF-36)



Conclusions: Quality of life is lower in patients with overhydration compared with euvolemic patients in HD. All dimensions that assess the components of SF-36 (generic) had lower scores in the subgroup patients with OH; not, in those specific dimensions of kidney disease.

TH-PO1039

The Association between Perceived Social and Family Support with Comorbidity and Clinical Outcome in Incident Hemodialysis Patients Seonghun Kim,[1] Su-Young Jung,[2] Ji Min Park,[1] Hyoungnae Kim,[2] Tae-Hyun Yoo.[1,2] *[1]Dept of Internal Medicine, College of Medicine, Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Republic of Korea.*

Background: The aim of this study was to investigate the association between the social and family support with charlson comorbidity index (MCCI) and mortality in dialysis patients.

Methods: A total 1,155 incident HD patients were prospectively enrolled in Clinical Research Center for End-Stage Renal Disease cohort from August 2008 to April 2013. The social support was assessed using by perceived support and family scale that are expressed by a range of scores from 1 to 4. The patients were categorized into three groups according to the summation of perceived social and family support; group 1, fully independent; group 2, partially dependent; group 3, fully dependent, respectively. The primary outcome was defined as all-cause mortality.

Results: The mean age was 58.5±14.4 years. Group 3 showed significantly higher MCCI (4.59±2.03 vs. 5.44±2.25 vs. 5.62±2.3, P=0.001) and lower mean arterial pressure (MAP, 103.82±16.6 vs. 99.66±14.7 vs. 97.59±14.80, P=0.007) compared to group 1 and 2. In multiple linear regression analysis, social and family support was closely related to MCCI (β=0.095, P=0.038) after adjustment for confounding factors. In multiple Cox analysis, group 3 revealed significantly higher all-cause mortality rate (HR, 3.28; 95% CI, 1.54-7.00; P=0.002) compared to group 1 even after adjustment for age, sex, education status, MCCI, serum albumin, Hb, and PTH levels.

Conclusions: The incident dialysis patients needed social and family support are significantly associated with high MCCI and low MAP, and associated with higher all-cause mortality.

TH-PO1040

Improvement of Quality of Life in Hemodialysis Patients with Uremic Pruritus as Measured by the Skindex-10 Questionnaire: Effect of a Novel κ Opioid Receptor Agonist, CR845 Vandana S. Mathur,[1] Robert H. Spencer,[2] Jiaan Illidge,[2] Joseph W. Stauffer,[2] Catherine Munera,[2] Frederique Menzaghi.[2] *[1]MathurConsulting, Woodside, CA; [2]Cara Therapeutics, Stamford, CT.*

Background: Uremic pruritus (UP) is a chronic systemic itching disorder frequently reported in hemodialysis (HD) patients, which causes suffering that negatively impacts quality of life (QOL). CR845 is a selective kappa opioid receptor agonist with combined anti-pruritic and anti-inflammatory effects. We aimed to examine the effects of itch reduction on QOL as measured by the Skindex-10 Questionnaire and its sensitivity to discriminate between CR845 and placebo in producing an improvement in QOL.

Methods: We evaluated intravenous CR845 (post-HD) in a double-blind, placebo-controlled trial in 65 HD patients with moderate-to-severe UP [i.e. ≥ 40 mm on a visual analog scale (VAS) of 0 mm (no itch) to 100 mm (worst imaginable itch)] for 2 weeks. Itch intensity (VAS) and QOL (Skindex-10, i.e., bothersomeness, emotional distress, and reduced social functioning due to itching) were recorded.

Results: 32 were randomized to placebo and 33 to CR845.Patients receiving CR845 (1 mcg/kg) had significant reductions in Skindex-10 score compared to those receiving placebo (p=0.031), demonstrating improvement in QOL. The mean change in the Skindex-10 score at week 2 correlated significantly with the itch intensity after CR845 treatment (r=0.83 p<0.001). Patients with both moderate (i.e. VAS ≥40 and <70 mm) and severe itch (i.e., VAS ≥70 mm) at baseline responded equally to CR845, suggesting that CR845 was similarly effective regardless of the itch severity. In a responder analysis, 63% of the CR845-treated patients had a change in Skindex-10 score greater than 30% from baseline compared to 39% in the placebo group.

Conclusions: Improvement in itching intensity with CR845 significantly improved QOL in HD patients with UP, regardless of baseline itch severity. The Skindex-10 correlated strongly with the measurement of itch intensity, and discriminated between treatments in QOL responses. CR845 shows promise as a treatment for UP and the Skindex-10 appears to be a useful instrument for quantifying QOL changes in this population.

TH-PO1041

Antipruritic Effect of the Long-Acting Peripheral κ Opioid Receptor Agonist CR845: A Novel Approach for the Treatment of Uremic Pruritus in Hemodialysis Patients Robert H. Spencer,[1] Michael E. Lewis,[1] Joseph W. Stauffer,[1] Vandana S. Mathur,[2] Frederique Menzaghi.[1] *[1]Cara Therapeutics, Inc., Shelton, CT; [2]MathurConsulting, San Francisco, CA.*

Background: Despite the availability of off-label treatments, patients with uremic pruritus (UP) continue to be afflicted by this debilitating condition with no treatment approved in the US. Although the etiology of UP is unknown, it is likely multi-factorial, including systemic inflammation and deficiency in the kappa endogenous opioid system.

Methods: Non-clinical and clinical studies were conducted to demonstrate that the novel potent and selective kappa opioid receptor (KOR) agonist CR845 may be effective for the symptomatic treatment of UP in hemodialysis (HD) patients.

Results: CR845 is a small, synthetic peptide with full agonist activity at rodent and human KORs (EC_{50} = 0.16 nM) with no other detectable off-target activities. A sustained anti-itch activity (>24 hours) was demonstrated for CR845 using mouse models of itch. Additionally, CR845 demonstrated anti-inflammatory properties in rodents and human macrophages. CR845 was not detectable in the central nervous system, therefore CR845 is likely to activate KORs expressed in peripheral neurons and on immune cells. CR845 is primarily excreted unchanged in urine, resulting in prolonged exposure in patients with renal dysfunction compared to normal healthy subjects (up to >10-fold increase in half-life). In HD patients, CR845 was well tolerated at doses ranging from 0.5 to 2.5 mcg/kg with plasma levels remaining constant after a single injection post-HD until cleared at the following dialysis. HD patients with moderate to severe UP treated with intravenous CR845 (1 mcg/kg) post-HD for 2 weeks had a 50% decrease in itch intensity as measured by a visual analog scale of 0 to 100 (n=33) with a significant difference compared to placebo-treated patients (n=31, p=0.016).

Conclusions: These results suggest that peripheral kappa opioid receptors play an important role in the modulation of itch signals and represent a target for the development of novel antipruritic agents. The profile of CR845 makes this compound a suitable and promising candidate for the treatment of UP.

TH-PO1042

Efficacy and Safety of Pregabalin for the Treatment of Neuropathic Pain in Patients Undergoing Hemodialysis Tomoyasu Otsuki, Masanori Abe, Seishiro Baba, Noriaki Maruyama, Kazuyoshi Okada. *Divs of Nephrology, Hypertension and Endocrinology, Dept of Internal Medicine, Nihon Univ School of Medicine, Tokyo, Japan.*

Background: Pregabalin is a gamma aminobutyric acid derivative administered for neuropathic pain. It binds to α2Δ subunits of voltage-dependent calcium channels, and inhibits calcium inflow of synapses and the release of excitatory neurotransmitters. This study investigated the safety and efficacy of pregabalin in patients with peripheral neuropathic pain undergoing maintenance hemodialysis.

Methods: This prospective, open-label, single-arm, multi-center trial screened 257 patients. A total of 45 patients with peripheral neuropathic pain were included, of whom 35 patients (men, 23; women, 12; age, 71.5 ± 6.1 years; duration of dialysis, 64 ± 35 months) were analyzed. Patients were treated with an initial dose of pregabalin at 25 mg; this was then increased up to a maximum of 150 mg depending on the patient during a 12-week study period. Visual analogue scale (VAS), Short Form Health Survey (SF-8), and laboratory data were collected at baseline and the end of the study.

Results: The final mean dose of pregabalin was 50.7 mg daily. Mean VAS scores significantly decreased from 52.4 mm at baseline to 34.1 mm at the end of the study (P<0.01). Scores for all eight categories of the SF-8 significantly increased compared with baseline. Both physical and mental component summary scores of the SF-8 also significantly increased. There were no significant differences in serum urea nitrogen, albumin, electrolytes, lipid profiles, or C-reactive protein levels during the study period. Ten patients were withdrawn from the study due to drowsiness, dizziness, and invalidity; however, no serious adverse drug reactions were recorded.

Conclusions: If adverse effects are carefully monitored and administered dosage prudently determined, pregabalin can be an effective treatment for peripheral neuropathic pain, even in patients undergoing hemodialysis.

TH-PO1043

Association of Neuropathy and Physical Parameters in People on Maintenance Haemodialysis: A Prospective Study Ying Wang,[1] Cathie Sherrington,[1] Arun V. Krishnan,[2] Martin P. Gallagher,[1] Alan Cass,[3] Meg J. Jardine.[1] *[1]The George Inst for Global Health, Camperdown, NSW, Australia; [2]Prince of Wales Clinical School, Univ of New South Wales, Randwick, NSW, Australia; [3]Menzies School of Health Research, Darwin, NT, Australia.*

Background: Physical parameters are associated with physical quality of life (QOL) among people with end stage kidney disease (ESKD) on dialysis. While clinical or subclinical neuropathy affects 70-100% of dialysis patients, its effects upon physical parameters (muscle strength and mobility) remain poorly understood.

Methods: We recruited adult maintenance haemodialysis patients to this single centre prospective study. muscle strength (ankle dorsiflexion) and mobility performance (Short Physical Performance Battery, SPPB) were assessed at baseline, 12 and 36 months. Baseline neuropathy was assessed using total neuropathy score (TNS), a structured score for neurological symptoms, signs and nerve conduction study results. QOL was assessed using the SF-36 physical and mental component scores (PCS, MCS). Associations between variables at baseline were assessed with linear regression models.

Results: Thirty-one maintenance haemodialysis patients commenced this study and completed 12 months follow up. Among them, twenty patients (64.5%) completed 36 months follow up. At baseline, study participants had a mean age of 65.7 years (SD 11.4), with a median dialysis vintage of 43 (IQR 26-101) months. The majority of participants were male (17 participants, 55%). Diabetes was the most common cause for ESKD (38.7%). The mean baseline TNS was 7 (SD 6). Baseline QOL data were available for 29 (93.5%) participants, with mean PCS of 35.5 (SD 6.3) units and MCS of 35.4 (SD 10.1) units. In multivariate analysis, baseline TNS was not associated with QOL. Deterioration in patient mobility at 12 and 36 months was predicted by higher baseline TNS (i.e. more severe neuropathy). TNS was not a predictor of deterioration in muscle strength over time.

Conclusions: Severity of baseline neuropathy predicted subsequent deterioration in mobility but not muscle strength at 12 and 36 months. Further larger studies assessing the association of neuropathy, physical parameters and clinical events are needed.

TH-PO1044

Opioid Use, Morbidity and Mortality in U.S. Dialysis Patients

Paul L. Kimmel,[1] Kevin C. Abbott,[1] Chyng-Wen Fwu,[2] Paul W. Eggers.[1] *[1]DKUH, NIDDK, NIH, Bethesda, MD; [2]Social & Scientific Systems, Silver Spring, MD.*

Background: Pain is important for ESRD patients (PTs), linked to depression and diminished quality of life. Aggressive ESRD PT pain treatment has been advocated. Medicare prescription drug benefits allow tracking ESRD prescriptions and linkage to outcomes, but few data exist regarding outcomes associated with pain and opioid medication prescription (OMP) in ESRD. New Centers for Disease Control guidelines recommend caution in OMP. We assessed maintenance dialysis ESRD PT OMP prevalence, and determined associations between OMP and mortality, dialysis discontinuation and hospitalization, using 2006–2010 USRDS data.

Methods: We limited the study sample to continuously treated (≥365 d) dialysis PTs with full Medicare Part A, B, and D coverage in each study year to ensure complete PT claims. OMP was confirmed from Part D prescription claims. Cox proportional hazards regression models examined associations of OMP in 2010 with subsequent all-cause death, dialysis discontinuation, and hospitalization in the 2010 prevalent cohort (N=153,758), controlled for demographics, ethnicity, comorbidity and residence.

Results: Approximately 20% of PTs had a prescription for 90 d opioids yearly. The most common OMP in 2010 contained hydrocodone (11.7%), oxycodone (5.4%) and tramadol (2.5%). Compared with non-users, short-term (1-89 d supply) and chronic use (≥90 d) PTs had increased risk of death (adjusted HR: 1.04 [95%CI, 1.02-1.07], 1.27 [1.23-1.30], respectively), dialysis discontinuation (1.13 [1.04-1.22], 1.37 [1.26 -1.50]) and hospitalization (1.13 [1.11-1.14], 1.31 [1.29-1.33]). All opioid drugs were associated with increased death risk except for codeine, including class IV agent tramadol. Codeine was associated with increased hospitalization. Rural residents with OMP had higher mortality risk than urban PTs with OMP.

Conclusions: Opioid drug prescription is associated with increased dialysis PT risk of death, dialysis discontinuation and hospitalization. While causal relationships cannot be inferred, and opioid prescription may be an illness marker, efforts to treat pain effectively in dialysis PTs with less toxic interventions deserve consideration.

TH-PO1045

Executive Dysfunction among HD and PD Patients: A Comprehensive Long-Term Prospective Study

Valentina Corradi,[1,2] Ornella Gambero,[3] Lucia Meligrana,[3] Sara Samoni,[2] Mariangela Mettifogo,[1,2] Carlotta Caprara,[2] Massimo de Cal,[1,2] Elisa Scalzotto,[2] Alessandra Brendolan,[1,2] Carlo Crepaldi,[1,2] Francesco Perini,[3] Fiorenza Ferrari,[2] Claudio Ronco.[1,2] *[1]Nephrology, San Bortolo Hospital; [2]IRRIV, San Bortolo Hospital; [3]Neurology, San Bortolo Hospital.*

Background: Cognitive impairment (CI) can range from a mild cognitive impairment to dementia. CI may be most prominent in pts with concurrent vascular disease, particularly among chronic kidney disease pts undergoing to dialysis. Mild CI may affect as many as 64% of dialysis pts and it is displayed by worse performances on tests of processing speed and executive function. Trials that examine long-term effects of chronic dialysis are needed. The aim of this study is to evaluate the 1-year progression of executive dysfunction in HD and PD pts.

Methods: We enrolled pts in chronic dialysis (HD or PD) from at least 3 months. Executive dysfunction was assessed by a Montreal Cognitive Assessment (MoCA) Equivalent Score (ES) <18,29. Statistical analysis was performed with SPSS20 software.

Results: We screened 207 dialysis pts: 73 were excluded and 133 were enrolled (mean age 64,09±13,65 yrs; 71% M) at T0. We performed MoCA test in 58 HD pts [mean age 64,90±14,27 yrs, 71% M, median dialysis time 5,66(2,70-10,97) yrs]and in 75 PD pts (63,46±13,22yrs, 71% M, 1,94(1,15-3,56)]. Median values of MoCA (ES) are shown in table 1.

MoCA (ES) median (25th-75th)	T0	T1	*p* value
ALL	23.33 (20.63-25.71)	23.37 (20.07-26.11)	0.056
HD	23.69 (20.28-25.70)	22.98 (19.40-25.60)	0.050
PD	23.33 (21.15-25.98)	23.72 (21.35-26.62)	NS
MoCA (ES) <18,29			
ALL	12%	14%	<0.001
HD	16%	19%	0.009
PD	9%	9%	NS

At T0 a MoCA(ES) <18,29 was present in 16% of HD pts and in 9% of PD pts. After a median follow-up of 1.02 (0.99-1.09) yrs, the rate of HD pts with a MoCA(ES) <18,29 significantly increased (19%), while no significant variations occurred in PD pts.

Conclusions: Median MoCA(ES) was not different between HD and PD pts, while the rate of pts characterized by MoCA(ES) < 18,29 was significantly different between T0 and T1 in HD pts. Our findings suggest that long-term HD pts develop a deterioration of the executive function.

TH-PO1046

Dementia as a Risk Factor for Mortality and Ischemic Stroke in Elderly Korean Patients on Hemodialysis

Sung Min Jung, Seung-Jung Kim, Duk-Hee Kang, Kyu Bok Choi, Dong-Ryeol Ryu. *Dept of Internal Medicine, College of Medicine, Ewha Womans Univ, Seoul, Korea.*

Background: Cognitive dysfunction and dementia is common in ESRD patients on hemodialysis (HD). It is associated with worse quality of life and higher risk for mortality. This study aimed to investigate the incidence of major adverse cardiac and cerebrovascular event (MACCE) in elderly Korean patients initiating HD with dementia.

Methods: Using the database from the Health Insurance Review & Assessment Service, we analyzed 10,171 patients aged 65 years or older who had initiated dialysis from 2005 to 2008 and had followed up until 2009. MACCE was defined as a composite outcome including all-cause mortality, nonfatal acute myocardial infarction, target vessel revascularization, and nonfatal stroke. Kaplan-Meier method was used to compare the incidence of MACCE among elderly ESRD patients with and without dementia. The risk factors for all-cause mortality were identified by Cox proportional hazards model. In addition, we matched 1:2 patient pairs with similar propensity scores to reduce biases due to nonrandomization and then performed further comparisons.

Results: A total of 303 elderly patients (3.0%) starting HD had dementia. In all elderly incident HD patients, dementia was a significant predictor for MACCE (HR, 1.258; 95% CI, 1.088 – 1.454; P = 0.002) after adjustment of all eligible confounding variables. Dementia was also a risk factor for all-cause mortality (HR, 1.334; 95% CI, 1.140 – 1.562; P < 0.001), whereas it was not a risk factor for other endpoint of MACCE. However, when we perform analyses in propensity-score matched groups, dementia was an independent predictor for nonfatal ischemic stroke (HR, 1.492; 95% CI, 1.027 – 2.168; P = 0.036) as well as all-cause mortality (HR, 1.301; 95% CI, 1.053 – 1.607; P = 0.015).

Conclusions: Dementia is an independent risk factor for mortality and ischemic stroke in elderly ESRD patients initiating HD. Dialysis providers should pay more attention to patients with dementia to reduce the risk for mortality and ischemic stroke.

TH-PO1047

Frailty Is Correlated with Increased Length of Hospitalization and Death in Hemodialysis Patients

Garyfalia Perysinaki,[1] Panagiota Papadaki,[1] Stavroula Douna,[1] Spiros Paparidis,[1] Maria Psoma,[1] Kourmouli Evangelia,[1] Georgios Vlachopanos,[1] Symeon Panagiotakis,[2] Eirini Ntaountaki.[1] *[1]Rethymnon Hospital; [2]Heraklion Univ Hospital Greece.*

Background: Research on prognostic indices in hemodialysis (HD) patients is of great importance. Frailty, a geriatric syndrome not adequately studied in HD patients is characterized by reduced physical and cognitive reserve under stress. It is correlated with increased health services utilization and death. We investigated the association of frailty with hospitalization and mortality in HD patients.

Methods: Forty nine (67.3% males) single unit HD patients were enrolled for this observational prospective (12 months) study. Patients were classified as nonfrail, prefrail, and frail according to the SHARE-FI instrument. Demographic, social, physical, and HD related data, medication, comorbidities and functional and nutritional status were recorded. The end points were death and days of hospitalization.

Results: At study beginning the mean (95% confidence interval: CI) age, Charlson Index, Barthel Index, Karnofsky scale, Kt/V, nPCR, serum albumin and CaXP were 76.7 (63.1–72.3)years, 3.2 (2.8–3.7), 18 (16.8–19.3), 73.6 (67.6–79.6), 1.24 (1.18–1.30), 0.98 (0.88–1.08), 3.8 (3.7–3.9) and 46.2 (42.8–49.6) respectively. Sixteen patients (30.6%) were nonfrail, 16 (32.7%), prefrail and 17 (34.7%) frail. Older age was associated with higher frailty rates (P<0.04). Subscapular skin fold thickness was larger in frails and prefrails (P≤0.04). Frailty was not associated with the gender, the lean body weight, the serum albumin, the Kt/V, the nPCR and the CaXP. One nonfrail, three prefrails (18.8%) and six frails (35.3%) died during the follow-up period. Lower serum albumin (P=0.02) and frailty (P=0.042) was associated with mortality. Mortality was not associated with the Kt/V, the nPCR and the CaXP. The mean (95% CI) length of hospitalization was significantly longer in the frails vs in the nonfrails 15.8 (7.5-24) vs 9.3 (0.2–18.3) days respectively.

Conclusions: Frailty was correlated with age among HD patients. Mortality and length of hospitalization within 12 months were significantly correlated with frailty.

TH-PO1048

Frail Elderly Patient Outcomes on Dialysis: An Update on the Longitudinal Study Osasuyi A. Iyasere,[1] Edwina A. Brown.[1] *[1]Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom; [2]Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

Background: Assisted peritoneal dialysis (aPD) enables home dialysis for older patients. The Frail Elderly Patient Outcomes on Dialysis (FEPOD) study is a prospective 2 year longitudinal study comparing quality of life (QoL) between HD and aPD. Baseline analysis showed no differences between dialysis modality and that frailty was predominant predictor of poor outcomes.

Methods: 206 (106 aPD; 100 HD) patients > 60 years, on dialysis for > 3 months and hospitalisation free for 30 days were recruited from 20 UK centres. HD patients (requiring hospital transport) were matched to aPD recruits by age, sex, diabetes status, dialysis vintage, ethnicity and postcode Index of Deprivation. Frailty was assessed using the Clinical Frailty scale. QoL was assessed using Hospital Anxiety and Depression Scale (HADS), SF-12, Palliative Outcomes Symptom scale (renal) and Illness Intrusiveness Rating Scale (IIRS). Physical function was assessed using Barthel's score. Assessments were performed for 2 years, at 3 monthly intervals.

Results: There were 121 dropouts (death -59, study withdrawal-61, transplant -5). After linear mixed model analysis, dialysis modality was not associated with any QoL measures in patients completing 2 year follow-up except SF12 MCS. In the aPD cohort, SF12 MCS decreased with increasing frailty scores (PD* Frailty score ; effect estimate = -1.74, p = 0.032) . In the cox regression survival model, survival was poorer in female HD patients compared to female PD patients (Female Gender * PD vs HD, Exp B = 0.28, p =0.012) . The interaction between HD and male gender was not significant. The principal predictor for survival, though, was frailty (hazard increased by factor of 1.38 for unit increase in frailty score, p = 0.008).

Conclusions: There is no significant difference in QoL over time between matched older patients on aPD and HD. Survival is associated with frailty but may also be poorer in older female patients on aPD. These findings suggest that assisted PD should be considered as a valid alternative to HD in older patients, at least from a QoL viewpoint.This would allow for true patient choice.

TH-PO1049

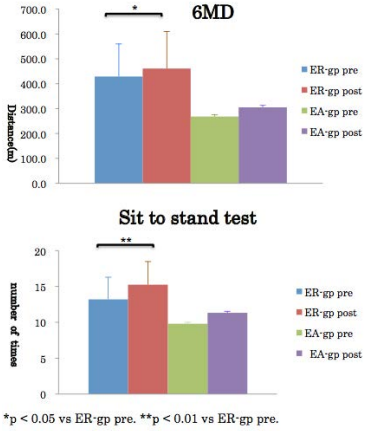
Comparing the Effect of Electric Bicycle Training and Conventional Exercise on Physical Function of End-Stage Renal Disease Patients Undergoing Hemodialysis Misa Miura,[1] Ryo Yoshizawa,[2] Aki Hirayama,[1] Osamu Ito,[3] Masahiro Kohzuki,[3] Shigeru Owada,[2] Teruhiko Maeba.[2] *[1]Health, Tsukuba Univ of Technology, Tsukuba, Ibaraki, Japan; [2]Asao Clinic, Kawasaki, Kanagawa, Japan; [3]Tohoku Univ Graduate School of Medicine, Sendai, Japan.*

Background: While chronic kidney disease (CKD) is common in older adults, approaches to treat geriatric patients with CKD remain undefined. However, exercise training for hemodialysis patients has been shown to improve fitness, physical function, quality of life, and cardiovascular disease markers such as arterial stiffness. This study aimed to determine whether aerobic training or electrical bike exercise for 12 weeks could improve physical function and/or relevant biochemical results in geriatric patients with end-stage renal disease (ESRD).

Methods: This controlled clinical trial consisted of 71 ESRD patients (38 males, 33 females;71.0 ± 7.3 years), randomized to receive 12 weeks of hemodialysis and concurrent aerobic training (ER-gp: n = 22), electrical bike training (EA-gp: n = 10), or no specific intervention (Con-gp: n = 39). The Borg scale was employed to control training intensity. At baseline and study completion, primary outcome measures included exercise tolerance, grip strength, quad muscle torque, balance, 10-m maximum walking and variousbiochemical outcomes.

Results: In the ER-gp, lower muscle endurance and exercise tolerance increased significantly

Figure 1. Result of 6-minute walk distance (6MD) test and sit-to-stand test



*p < 0.05 vs ER-gp pre. **p < 0.01 vs ER-gp pre.

Such effects were not observed in the Con-gp. Although quad muscle torque decreased in the EA-gp, other parameters were not significantly altered.

Conclusions: In this study, the safety and efficacy of aerobic training and electrical bike exercise during hemodialysis were confirmed without sudden drop of blood pressure or any other side effects. Therefore, training during hemodialysis sessions for 12 weeks may improve ESRD patient physical function by eliciting specific whole-body and local effects.

TH-PO1050

The Effect of Intradialytic Exercise on Daily Physical Activity and Sleep Quality in Maintenance Hemodialysis Patients Ji-Hyung Cho, Jun Chul Kim. *Dept of Internal Medicine, CHA Gumi Medical Center, CHA Univ, Gumi-si, Gyeongsangbuk-do, Republic of Korea.*

Background: Physical inactivity and sleep disturbances are frequently observed and shown to relate with poor quality of life (QoL), higher rates of hospitalization and mortality in dialysis patients. We aimed to investigate the effect of intradialytic exercise (IDE) on daily physical activity (DPA) and sleep quality measured by accelerometer in maintenance hemodialysis (MHD) patients.

Methods: This study randomly assigned ambulatory MHD patients aged ≥20 years on dialysis ≥6 months, without hospitalization history for the previous 3 months to 4 groups: aerobic (AE), resistance (RE), combination exercise (CE), and control (CG). Stationary bike was used for AE and TheraBand®/theraball for RE. Twelve-week IDE program (3 times/week) was completed in AE (n=11), RE (n=10), and CE (n=12). CG (n=13) received warm-up stretching. At baseline and 12-week follow up, DPA and sleep quality were measured by a 3-axis accelerometer (wActiSleep-BT, ActiGraph LLC) during continuous 7-day wear period.

Results: Patients were 55±12 years of age (mean±SD) on MHD for 64±72 months, 50% female, 44% diabetic. We observed a significant increase of MET (Metabolic Equivalent; kcal/h/kg) in AE (1.02±0.03 vs 1.04±0.04, *P*=0.04) and CE (1.06±0.05 vs 1.09±0.08, *P*=0.003) at 12-week compared with baseline. When comparing between-group changes to MET there was a significant increase in CE (0.03±0.03 vs -0.01±0.04, *P*=0.014) compared with CG. The total number of sedentary bouts (per week) decreased significantly in AE (200±37 vs 174±36, *P*=0.016) and CE (180±45 vs 152±46, *P*=0.031) at 12-week compared with baseline. The average sleep fragmentation index indicating poor sleep quality decreased significantly at 12-week compared with baseline in AE (51.4±8.0 vs 44.5±9.6, *P*=0.041) and RE (52.3±7.3 vs 40.0±15.4, *P*=0.017).

Conclusions: These findings suggest that IDE may play a significant role in the improvement of DPA and sleep quality in MHD patients, although future studies with more study subjects and longer intervention duration are needed to confirm our findings and if this would also lead to improvement of clinical outcomes, such as QoL, hospitalization, and mortality.

TH-PO1051

Pattern of Dermatoses in Chronic Hemodialysis Patients Maria Soledad Ferrari,[1] Rodrigo Sarantes,[1] Paula Gauronas,[1] Andrea Nicola,[2] Silvana Mazzolini,[2] Lidice Dufrechou,[2] Patricia Larre Borges,[1] Alejandra Larre Borges,[2] Miguel Martinez,[2] Oscar A. Noboa.[1] *[1]Centro de Nefrologia; [2]Catedra de Dermatologia, Hospital de Clinicas, Univ de la Republica, Uruguay.*

Background: Skin diseases are highly prevalent in dialysis patients but are frequently overlooked. The aim of this study was to diagnose dermatoses in renal replacement therapy patients treated with hemodialysis (HD-RRT) and analyze the association with background, laboratory data and treatment.

Methods: A descriptive cross-sectional multicenter study was performed in a convenience cohort of patients over 18 years old in HD-RRT for more than 6 months. The Hospital ethic committee approved the study. Patients with previous renal transplant were excluded. Dermatologist performed systematic evaluation of skin.

Results: We evaluated 195 patients, 98 females (50.2%), mean age 64.4±0.9 years (31-94). The average time on HD-RRT was 3.9±0.3 years (0.75-25). At least one skin disease was diagnosed in 98.5 % (n=192) of patients. Xerosis 79% (n=154), pruritus (n=65, 33.7%), yellowish tint (n=60, 30.8%), onycholysis (n=55, 28.2%), purpura (n=53, 27.2%). Non melanoma skin cancer was diagnosed in 15 patients (7.6 %) and 2 patients were diagnosed with melanoma. The age of patients with non melanoma skin cancer was significantly higher (p=0.02). Time on HD-RRT was related with diffuse alopecia (p=0.034) and acquired perforating dermatitis (p=0.029), yellowish tint was related with hyperphosphatemia (p=0.038) and loss of hair shine with anemia (p=0.01).

Conclusions: Skin diseases were present in 98.5 % of the patients. Most prevalent dermatoses were xerosis and pruritus. Of note is the high prevalence of skin cancers with 7.6% with non melanoma skin cancer and 2 cases of melanoma. This data indicates the relevance of periodic skin assessment in patients treated with HD-RRT.

TH-PO1052

Higher Risk of Malignant Neoplasms in Young Adults with End-Stage Renal Disease under Hemodialysis: A Nationwide Population-Based Study Heng-Chih Pan. *Nephrology, Chang Gung Memorial Hospital, Keelung, Taiwan.*

Background: Malignant neoplasm is prevalent in elderly and negatively impacts patient outcomes. Previous investigations have shown that end-stage renal disease (ESRD) is associated with an increased risk of malignancies. Our study was designed to explore the contribution of ESRD for incidence of malignancy in patients with different ages.

Methods: We analyzed a nationwide cohort, retrieved from Taiwan's National Health Insurance Research Database(NHIRD), to study the incidence of malignancy in patients with and without receiving hemodialysis (HD). We obtained 1,000,000 random subjects and followed them from 2005 to 2013. 3086 of them developed ESRD and received regular HD during this period. For each HD patient, four age- and gender-matched control, a total of 12344 patients, were selected from the NHIRD. We further stratified the patients according to different ages. The study endpoint was the occurrence of malignancy.

Results: The incidence of malignancy was 6.71% and 4.42% for HD, and control patients, respectively. Among HD patients aged younger than 40 years, 40 to 49 years, 50 to 59 years, and 60 to 69 years, the incidence rate of malignancy was 4.15%, 4.72%, 6.22%, and 8.12%, which were significantly higher than that of control group. After adjustment for known risk factors, HD had the highest odds ratio of developing malignancy.

Conclusions: ESRD patients who received HD had a significantly higher risk of malignancy, especially in a relative young age. Based on the results of our study, we believe that the development of ESRD signifies higher risk of malignancy in young adults.

TH-PO1053

Risk of Skin Cancer in Chronic Haemodialysis Patients: A Nationwide, Population-Based Study in Taiwan Yuh-Mou Sue,[1] Chia-Chen Wang.[2] *[1]Div of Nephropathy, Dept of Nephrology, Taipei Medical Univ-Wan Fang Hospital, Taipei, Taiwan; [2]Dept of Dermatology, Cardinal Tien Hospital, New Taipei City, Taiwan.*

Background: Chronic haemodialysis (HD) patients have a higher incidence of cancer. However, the risk of skin cancer in this population has rarely been investigated. The purpose of this study is to investigate the risk of non-melanoma skin cancer (NMSC) and cutaneous melanoma in chronic HD patients and explore the associated risk factors.

Methods: We performedretrospective cohort and nested case-control studies using records in the Taiwanese National Health Insurance Research Databasebetween 1999 and 2013. The HD cohort included 79,668 incident HD patients, of which the standardized incidence ratios (SIRs) for incident NMSC and cutaneous melanoma were determined. In the nested case-control study, HD patients with NMSC were matched to those without skin cancers. The impact of various factors on the development of NMSC was determined by conditional logistic regression analysis.

Results: Of the 79,668 HD patients, 248 cases of NMSC and 22 of cutaneous melanoma occurred after a mean 4.95 years of follow-up. The SIRs for NMSC and cutaneous melanoma in HD patients were 1.58 (95% confidence interval [CI], 1.39–1.79) and 1.44 (95% CI, 0.91–2.19), respectively. Of the patients with HD, a higher risk of NMSC was found in men (1.5-fold), South Taiwan residents (2-fold), and patients with uremic pruritus after long-term antihistamine treatment (1.53-fold). However, the incidence of NMSC was not increased in patients with uremic pruritus receiving ultraviolet-B (UVB) phototherapy.

Conclusions: Chronic HD patients are at higher risk of NMSC. Uremic pruritus further increases the risk of NMSC, which might be prevented by UVB phototherapy.

TH-PO1054

Cancer Diagnosis and Treatment for Patients under Hemodialysis; Multicenter Surveillance Takeshi Matsubara, Tatsuo Tsukamoto, Motoko Yanagita. *Dept of Nephrology, Kyoto Univ Graduate School of Mediciine, Kyoto, NA, Japan.*

Background: Cancer is the third leading cause of death among end-stage renal disease (ESRD) patients in Japan. However, little is known about the diagnosis and treatment of them. Therefore, the aim of this study is to clarify the clinical practice of cancer patients under hemodialysis (HD).

Methods: This retrospective case series study enrolled HD patients who subsequently developed cancer from 2010 to 2012 in 20 institutions. The clinical courses were reviewed in each patient with the cancer at the following primary sites: kidney, colorectum, stomach, lung, liver, bladder, pancreas, and breast. Data were collected about the cause of ESRD, time between initiation of HD and the diagnosis of cancer, disease status based on its surgical resectablity, and the primary therapy, anemia (Hb<10g/dL), hypoalbuminemia (ALB<3.0g/dL). The primary end point was death.

Results: From 686 patients enrolled at baseline, 509 patients registered. The main primary cancer sites were kidney (32%), followed by colorectum (17%), and stomach (14%). In all patients, the median time for cancer diagnosis after the beginning of HD was 74 months. Notably, median time was significantly longer in kidney cancer than others (142 vs 54 months, respectively). 391 (77%) cancers were assessed to be surgically resectable, and 366 (72%) cases underwent operation. On the other hands, 44 (8.6%) and 39 (7.7%) patients underwent chemotherapy and best supportive care, respectively. After a median follow-up of 25 months, there were 130 deaths, including 66 patients (51%) died of causes other than cancer. 2-year survival in all cancer was 75%. Kidney cancer showed better survival than other cancers (HR 0.43: 0.27-0.65, p<0.01). After multivariate adjustment for sex, cause of ESRD, cancer primary site, disease status and hypoalbuminemia, anemia was independently associated with mortality (HR: 1.64: 1.10 to 2.41, p=0.01) .

Conclusions: This is the first and largest study about cancer patients under HD in Japan. Kidney cancer had longer interval between HD initiation and diagnosis of cancer, but better prognosis than other cancers. Anemia could be a good predictor of the cancer mortality in HD patients.

Pregnancies in Patients on Dialysis: A Multi- Center Retrospective Study on Outcomes and Prognosis Factors Gabrielle Laetitia Normand,[1] Xu Xiao Li,[3] Marine Panaye,[1] Anne Jolivot,[1] Sandrine Lemoine,[1] Fitsum Guebre-Egziabher,[4] Muriel Doret,[2] Laurent Juillard.[1] *[1]Service de Néphrologie, Hospices Civils de Lyon, Lyon, France; [2]Service de Gynécologie- Obstétrique, Hospices Civils de Lyon, Lyon, France; [3]Service de Néphrologie, CHU d'Amiens, Amiens, France; [4]Service de Néphrologie et Transplantation, CHU Grenoble, Grenoble, France.*

Background: Pregnancies in hemodialysis (HD) patients are rare and often associated with maternal and fetal complications. We aimed to determine pregnancies outcomes in HD patients and to identify maternal and fetal prognosis' risk factors.

Methods: This is a descriptive, retrospective, multi center study. Pregnant women on HD from 1985 to 2015 in France were included. A favorable fetal outcome was defined as a living infant discharged from hospital.

Results: We identified 100 pregnancies in 84 women on HD, from 41 centers, with a mean age of 30 years (± 5). Mean delay between initiation of dialysis and onset of pregnancy was 44.7 ± 59.7 months . Fourteen patients (14.9%) began chronic HD during their pregnancy explaining a high rate of catheter (19.8%) and a preserved residual diuresis for 43 patients (50%). Mean weekly dialysis time was 14.6 ± 4.6 hours, 19.1 ± 4.1 hours and 20.4 ± 3.9 hours for the first, second and third trimester respectively. Seventy- six (89.4%) women performed daily dialysis during the third trimester. Fetal survival was 78% with a mean gestational age of 33 ± 3.9 weeks and a mean birth weight of 1719 ±729 g. Fetal outcome worsened after 2010 with a fetal loss of 16% for pregnancies between 2010 et 2015, compared to 9% before 2010. No significant correlation was found between a lower urea concentration or a higher hemoglobin value and a favorable fetal outcome.

Conclusions: Our study is one of the largest series of pregnancies in HD patients. Its long observation period, multi center and retrospective design could explain the lack of correlation between classical prognosis factors and fetal outcome. The worsening of fetal outcome after 2010 could be explained by an increase in pregnancies number due to a better acceptance of these pregnancies by the medical community. Nevertheless, these pregnancies remain at high risk, reinforcing the need for an early nephrologist- obstetrician dialogue.

TH-PO1056

Dialysis Facility Variation in Primary Care Physician (PCP) Involvement in the Care of Chronic Dialysis Patients in the U.S. Vahakn B. Shahinian, Patrick Albertus, Sai Hurrish Dharmarajan, John Z. Ayanian, R. Hirth, William H. Herman, Rajiv Saran. *Univ of Michigan, Ann Arbor, MI.*

Background: We previously demonstrated increasing involvement of PCPs in the care of dialysis patients, and that PCP involvement is associated with greater delivery of preventive care compared to a nephrologist alone. In this study, we examined dialysis facility variation in PCP involvement.

Methods: Using the United States Renal Data System (USRDS), prevalent dialysis patients in 2013 with Medicare as primary insurer were identified. PCP involvement was based on ≥1 claim for an outpatient (non-dialysis) visit with a family practice, general medicine or geriatrics physician. The % of patients with ≥1 PCP visit for each facility was plotted in rank order. A multilevel logistic regression model was performed to examine facility level predictors (size, profit status, free-standing/hospital-based, % below poverty line in county of facility) of PCP involvement, adjusted for patient age, sex, race, and comorbidities. An intra-class correlation (ICC) was calculated to assess clustering by facility, unexplained by observed patient and facility level predictors.

Results: A total of 219,260 patients were assigned to 6,226 facilities. There was wide facility variation in PCP involvement (Figure). The median facility had 65% of its patients with PCP involvement, with interquartile range from 53 to 76%. The only significant facility level predictor was county poverty (Odds ratio 0.89 [95%CI 0.85,0.93] for ≥20% of residents below poverty line vs above). The ICC was 0.09, suggesting a moderate degree of clustering at the facility level.

Conclusions: Facilities in areas with greater poverty were less likely to have patients with PCP involvement. Substantial unexplained variation at the facility level may reflect differences in attitudes of nephrologists regarding who should be responsible for primary care of dialysis patients.

The Challenges of Achieving Universal Health Coverage for Chronic Conditions in Low Income Settings: A Case Study of Dialysis Outcomes in India Vivekanand Jha,[3] Oommen John,[3] Sradha S. Kotwal,[1] Martin P. Gallagher,[1] John Knight.[1] *[1]The George Inst for Global Health, Sydney, New South Wales, Australia; [2]The George Inst for Global Health, Delhi, India; [3]Medanta Hospital, New Delhi, India; [4]Post Graduate Inst of India, Chandigarh, India.*

Background: India has set itself the target of achieving universal health coverage by 2022. The provision of financial protection from the costs of treating high cost chronic conditions such as kidney disease is one of many challenges. Little is known about the economic impacts of maintenance dialysis in India. We conducted a prospective observational cohort study of incident dialysis patients to understand the household economic impact of dialysis, barriers to treatment continuation and the extent to which existing insurance programs provide financial protection.

Methods: Incident patients commencing hemodialysis at two North Indian centers are followed prospectively for 12 months. Baseline demographic and clinical outcome data were collected as well as data on direct, indirect costs and economic impact on the patient and family.

Results: Here we present the results of the 6 month interim analysis. A total of 119 patients (82 male, 37 female) have been enrolled thus far, 70 at a public hospital (Chandigarh) and 49 at a private hospital (Delhi). Median age at enrollment was lower at the public hospital compared to the private (37.5 yrs cf 60 yrs). Baseline Median monthly income was USD$90 at the public hospital and USD$377 in the private hospital. Of the 94 patients at the 6 month interim analysis, 18(19%) have died, 19(20%) have been transplanted , 47 (50%) remain on dialysis and 10 (11%) patients have discontinued dialysis. Median total monthly expenditure for dialysis was USD$231 in the public hospital and USD$1526 in the private hospital.

Conclusions: These relatively young Indian dialysis patients have high mortality and dialysis discontinuation rates but also a high rate of transplantation. Costs were high relative to income and are likely to impact upon ongoing treatment decisions and survival. The high and ongoing nature of such costs pose particular challenges to how risk protection programs are designed, particularly given the limited capacity to pay of its beneficiaries.

TH-PO1058

Undocumented with End Stage Renal Disease: Characteristics and Outcomes Associated with Delayed Initiation Nova Hou,[1] Chandan Vangala,[2] Rajeev Raghavan.[2] *[1]McGovern Medical School, Houston, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Most undocumented patients with ESRD in Houston, TX rely on emergent dialysis treatments. Each day, 50% of the patients who present to the hospital for dialysis are either admitted due to critical illness or are turned away without treatment. For this reason, physicians delay initiation of dialysis until absolutely necessary. This abstract characterizes the undocumented population at initiation and compares them to a representative cohort of patients in the United States Renal Data System (USRDS).

Methods: There were 155 undocumented patients who initiated dialysis at the county hospital system in Houston, TX between July 2009 and July 2014. Data was obtained from chart review. A standard mortality rate (SMR) was calculated for the 92 patients who received emergent dialysis for one year (2013) and this was compared to a representative USRDS cohort (Hispanics in Texas). Six of the 18 patients 'lost to follow-up' were presumed dead.

Results: The average Charlson Comorbidity Index (CCI) for the undocumented patients at initiation is 4.36 (±2.26). Data is presented in Table 1. The p-value was <0.05 for all comparisons except female gender and Hispanic race.

	Undocumented (n=155)	USRDS Cohort (n=18,411)
Demographics		
Age at Initiation (yrs)	44.7	60.2
BMI	26.7	29.8
Female*	40.6%	46.0%
Hispanic*	96.8%	100.0%
Etiology of ESRD		
Diabetes Mellitus	48.4%	68.0%
Unknown	20.0%	1.8%
Labs at Dialysis Initiation		
Albumin (g/dL)	2.86	3.08
Hemoglobin (g/dL)	7.81	9.26
Serum Creatinine (mg/dL)	13.94	6.93
Mortality		
Standard Mortality Ratio (SMR)	1.72	1.00

Conclusions: The undocumented patients who begin dialysis in Houston, TX have a high CCI score, which is correlated with increased mortality in the established ESRD population. These patients have significantly reduced hemoglobin and albumin levels at initiation; these biomarkers have an established correlation with increased mortality. Critical illness at initiation, along with inconsistent access to dialysis, places this population at a high risk of mortality despite younger age.

TH-PO1059

Effect of Citizenship Status on Hemodialysis Adherence Ishita Rajnish,[1] Tina Adjei-Bosompem,[1] Christopher Dijanic,[1] Gary Kwo,[2] Ellena A. Linden,[1] George N. Coritsidis,[1] Joani Pantiz,[2] Priya Pai.[2] *[1]Nephrology, Icahn School of Medicine- Elmhurst Hospital Center, Elmhurst, NY; [2]Broadway Dialysis Center.*

Background: Previous studies have shown that undocumented ESRD patients (UPs) tend to be younger and continue working once on hemodilaysis (HD). We explored whether UPs have difficulty with adhering to HD treatments by reviewing various clinical markers of adherence.

Methods: Records of all our adult HD patients were reviewed for one full year beginning 4/1/15. Yearly Kidney Disease Quality of Life (KDQOL) questionnaire was reviewed. Documentation status was determined by presence or absence of a social security number. Variables analyzed included sex, age, ethnicity, phosphorous (P), parathyroid hormone (PTH), potassium (K), interdialytic fluid gains, hospitalizations, missed and shortened treatments.

Results: 158 patients were analyzed: 44% of all patients were UPs (n=70). Hispanics made up majority of UPs (74%). PTH, P levels were higher in the UPS. UPs were more likely to shorten treatments. KDQOL was similar in both groups except for a higher score on physical health assessment in UPs.

Demographics	N=158(%)	Documented N=88(%)	UPs N=70(%)	p-values

Average fluid gain, L		2.2	2.3	0.4
KDQOL	142			
Physical component summary score		37.9	40.9	**0.05**
Mental component summary score		44.9	47.1	0.2

Conclusions: UPs are less adherent with HD prescription as seen by higher P, PTH, greater likelihood of shortened treatments despite having higher physical health scores. Given similar KDQOL scores we postulate that the difficulty with adherence may be due to work burden and age.

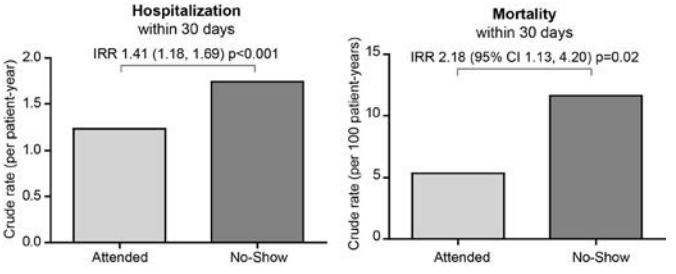
TH-PO1060

In-Center Hemodialysis Absenteeism: Prevalence and Association with Outcomes Steven M. Brunelli, Kathryn S. Gray, Dena E. Cohen. *DaVita Clinical Research, Minneapolis, MN.*

Background: Patients with end-stage renal disease often miss in-center hemodialysis (ICHD) treatments. Here, we estimated the percentage of missed treatments that were attributable to hospitalization, emergency department (ED) visit, or out-patient procedure, versus no identifiable cause ('no-show'), and estimated the impact of a single no-show on the short-term risk of hospitalization and mortality.

Methods: In one analysis, we retrospectively aligned treatment attendance records for calendar year 2012 with claims data for adult Medicare Parts A and B enrollees who received ICHD on a Monday/Wednesday/Friday (MWF) schedule at a large US dialysis organization (LDO). In a second analysis, we considered prevalent adult Medicare beneficiaries receiving MWF ICHD at the LDO who had not missed dialysis or been hospitalized between 21 Apr and 20 May 2012. We identified patients who had a no-show on 21 May 2012 and propensity matched them (1:5) to patients who attended treatment on that date. We compared hospitalization and death over the subsequent 30 days. The process was repeated for 23 and 25 May 2012, and data were pooled for all three dates.

Results: Of 462,028 missed treatments observed in 2012 (15.31 per patient-year at risk), 45.1% coincided with a hospitalization; 1.9% with an ED visit, and 0.1% with a procedure. The remaining 52.8% were no-shows. A single no-show (vs. attending the treatment) was associated with a significantly increased risk of hospitalization (adjusted odds ratio [aOR] 1.41, 95% confidence interval [CI] 1.18-1.69) and death (aOR 2.18, 95% CI 1.13-4.20).



Conclusions: In conclusion, over half of missed hemodialysis treatments are no-shows; ie, not resulting from hospitalization, ED visit, or procedure. Dialysis no-shows are potently and significantly associated with greater short-term risk of hospitalization and death. Reducing no-show rates may improve patient outcomes.

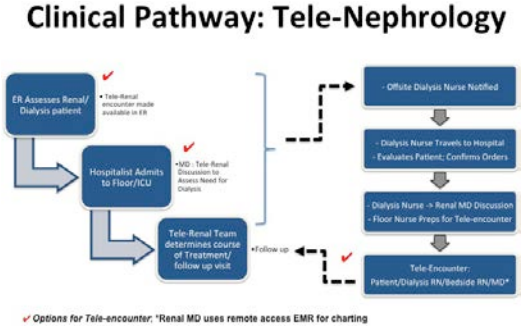
TH-PO1061

Tele-Nephrology: Delivering Acute Dialysis in Rural Hospitals via Telehealth Charuhas V. Thakar,[1,4] Mahmoud T. El-Khatib,[1] Amit Govil,[1] Doug Johnson,[2] Robert Parker,[3] Pam Kimmel,[1] Anya Sanchez.[1] *[1]Nephrology/Medicine, Univ of Cincinnati/UC Health, Cincinnati, OH; [2]Dialysis Clinics Incorporated, Nashville, TN; [3]Meadowview Regional Medical Center, Maysville, KY; [4]Cincinnati VA Medical Center, Cincinnati, OH.*

Background: 38% of the 4,926 community hospitals in the U.S.A. are designated as rural hospitals. Although dialysis use is similar across rural and urban areas (3.9 /1000 residents); 77% of remote rural counties lack an in-county dialysis facility. Only a third of rural hospitals offer acute dialysis due to lack of dialysis and/or renal providers.

Methods: We describe the development of a tele-nephrology program, partnering with a national dialysis provider (Dialysis Clinics Inc.), and Meadowview Regional (rural hospital) in Maysville, KY. Lack of dialysis providers had forced transferring of patients requiring acute dialysis to larger hospitals, resulting in transportation costs and real/intangible costs to patients.

Results: Key elements of implementation included: 1. Planning (needs assessment; technology; dialysis provider; contracting); 2. Stakeholders (business, nursing, informatics, hospitalist, pharmacy, renal). Metrics of success include: A. Clinical performance; B. Patient satisfaction; C. Provider satisfaction; D. Opportunity cost savings. After careful planning, the program went live in January 2016. Clinical pathway is shown in Fig 1. To date, we have treated 12 patients (32 bed-days; 20 dialysis treatments) via tele-health for conditions requiring medical/surgical/critical care. 67% of patients were successfully treated and discharged from the rural hospital.



Conclusions: By applying innovative technology, we demonstrate surmounting traditional barriers to deliver specialty renal care at rural/critical access hospitals. This patient-centered program plans to build a hub-and-spoke model for specialty care, and can be emulated nationally.

TH-PO1062

Processes of Care and Outcomes of End Stage Renal Disease Hemodialysis Patients during a Man Made Disaster Majd Isreb,[1,7] Lina Murad,[3,7] Akram Almakki,[4,7] Mohamad Alhosaini,[5,7] Kamel Hatahet,[6,7] Mohamed A. Sekkarie.[2,7] *[1]PeaceHealth Medical Group, Vancouver, WA; [2]Nephrology & Hypertension Associates, Bluefield, WV; [3]Metropolitan Access Center, Washington, DC; [4]Indiana Univ Health System, West Lafayette, IN; [5]Loyola Univ, Springfield, IL; [6]Temple Univ Hospital, Philadelphia, PA; [7]Syrian National Kidney Foundation, Panama City, FL.*

Background: The health of dialysis patients is negatively impacted by natural disasters. The degree of this impact in the setting of war is not well known. Herein we compare processes of care and outcomes, including survival, in two ESRD hemodialysis facilities in Syria. Both units are charitable but one is located in a besieged area (B) where getting supplies and medications is very difficult, and the other has a fairly free access to these items (NB).

Methods: Baseline characteristic of all the patients dialyzing in the facilities on 1/1/2015, including demographics, etiology of ESRD, type of vascular access, smoking history, and history of major cardiovascular disorders were collected retrospectively. Follow up was for a maximum of one year and included data collection on availability of medications, dialysis duration and frequency, and survival.

Results: There were no statistically significant differences in patients' demographics, smoking history, and dialysis vascular access type. The average patient age was 47 years. Less than 5% of the patients dialyzed 3 times a week. Data on medications availability, dialysis duration and frequency, and outcomes are shown in the table.

Facility	WG > 4kg	Duration ≤ 3 hours	Once a week HD	ESA not available	HB < 8 gm/dl	V D not available	Died
B (N=31)	39%	97%	47%	65%	55%	71%	48%
NB (N=29)	0%	0%	7%	0%	48%	0%	21%
P value	.001	.001	.002	.001	NS	.001	.03

(B: besieged, NB not besieged, WG: Interdialytic weight gain, V D: active vitamin D, Statistics: two tailed Fisher exact test).

Conclusions: War has a strong negative impact on the health of ESRD hemodialysis patients especially when access to medications and supplies is restricted by beseigement. The renal community should be more involved in guaranteeing access of care to the vulnerable population of ESRD patients.

TH-PO1063

Increased Hospitalizations and Costs Associated with Suboptimal Initiation of Chronic Dialysis Edwin J. Anand,[1] Kabir Jalal,[2] Brian M. Murray,[1] Pradeep Arora,[3] Rocco C. Venuto.[1] *[1]Nephrology, Univ at Buffalo, Buffalo, NY; [2]Biostatistics, Univ at Buffalo, Buffalo, NY; [3]Nephrology, VA Medical Center, Richmond, VA.*

Background: Initiation of maintenance dialysis with a catheter is associated with increased mortality. Nearly 80% of patients start dialysis with a catheter, despite concerted efforts to increase fistula use. Using data from a large 3rd party payer, we studied the comorbidities leading to increased hospitalizations and costs in the first 12 months after starting chronic dialysis.

Methods: We used data (costs, hospitalizations, labs, billing codes) from a large 3rd party payer in NY State from 2007-14. We identified patients with CKD based on eGFR <60 for at least 90 days. Patients with CKD who were started on dialysis formed our study cohort. Dialysis crash was defined as starting dialysis with a catheter. We performed logistic regression of factors associated with hospitalizations and costs over the 12 month period following dialysis initiation.

Results: Of the 1.3 million patients in the database, 38,857 had CKD. Of these, 1298 developed ESRD. There was a significantly higher rate of hospitalization (2.3 vs 1.9 P=0.008), as well as total medical costs in the first year ($104,674 vs $81,575) in patients who crashed vs those who did not . Presence of a fistula (mature or maturing) was associated with reduced hospitalizations (1.5 vs 2.1 P=0.001). Other variables that were associated with increased hospitalizations and costs on multivariate analysis were COPD, asthma, substance abuse and mental illnesses.

Variables	RR	Confidence internal
Crash	1.19	1.05-1.37
Fistula	0.70	0.56-0.87
COPD/Asthma	1.46	1.27-1.70
Depression	1.56	1.35-1.80
Substance abuse	2.25	1.8-2.78

Heart disease and diabetes were not associated with increased hospitalizations.

Conclusions: 1. Dialysis initiation with a catheter is associated with increased hospitalizations and costs 2. More effective interventions to increase fistula rates would reduce avoidable hospitalizations 3. Care coordination of ESRD patients with experts in respiratory diseases and mental illness should reduce hospitalizations and costs for this population.

TH-PO1064

Impact of Dialysis Access Modality on Emergency Department Utilization

Brendan P. Lovasik, Rebecca H. Zhang, Justin D. Schrager, Stephen O. Pastan, Rachel E. Patzer. *Emory Univ, Atlanta, GA.*

Background: Initiation of dialysis with an arteriovenous fistula (AVF) is associated with lower costs and improved patient survival. However, the impact of dialysis access modality on ED utilization among a national ESRD patient population has not been examined.

Methods: We examined a cohort of 103,155 incident adult ESRD patients in the United States Renal Data System data from 2005-2011. ED utilization, hospital admission, and diagnoses were obtained from the USRDS and Medicare Physician/Supplier and Inpatient databases for Medicare Part A/B claims. Multivariable Poisson regression was conducted to assess the association of relevant patient variables with ED utilization.

Results:

	ED Visits	ED Visits/Patient-Year	Multivariable Analysis		
			Rate Ratio	95% Confidence Interval	P-Value
All ESRD N=769,228	1,782,441	2.89			
AV Fistula N=94,801 (13%)	146,527	1.83	REF	REF	REF
Graft N=23,532 (3%)	53,078	2.63	1.220	1.213-1.228	<0.0001
Catheter N=550,737 (71%)	1,394,263	3.22	1.122	1.110-1.134	<0.0001
Peritoneal & Other N=100,158 (13%)	188,573	2.25	1.235	1.203-1.267	<0.0001

In the first year of ESRD, 55% of patients presented to the ED, with a total of 1,782,441 ED visits among 422,738 unique ESRD patients. The median Medicare claim for an ED visit by an ESRD patient was $466 (IQR:$274-$745). Extrapolating this cost yields an annual ED cost of $668 million for first-year ESRD patients. Only 13% of ESRD patients initiated dialysis with a mature AVF; AVF patients had the lowest rate of ED utilization (1.83 visits per patient year [PY]). Catheter-based dialysis patients had the highest rate of ED utilization (3.22 per PY). In multivariable analysis controlling for sociodemographic and clinical factors, patients with a graft (RR: 1.22; 95% CI:1.21-1.23) or catheter (RR:1.12; 95% CI:1.11-1.13) for dialysis access had higher rates of ED utilization compared to those with an AVF.

Conclusions: Despite Fistula-First guidelines, AVFs remain an underutilized dialysis access modality, with significant deleterious patient outcome and healthcare resource utilization implications. Initiatives to increase pre-ESRD nephrology referrals may improve AVF rates.

TH-PO1065

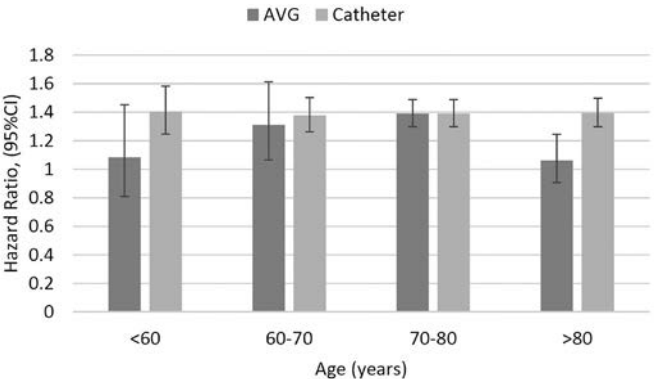
Vascular Access and Mortality in Elderly Incident ESRD Patients

Tarek H. Saleh,[1] Miklos Zsolt Molnar,[1] Keiichi Sumida,[1] Jun Ling Lu,[1] Praveen Kumar Potukuchi,[1] Elani Streja,[2] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]VA Medical Center, Memphis, TN.*

Background: Creating a mature AV fistula (AVF) can be challenging in elderly individuals. It is unclear if elderly incident HD patients derive a survival benefit from an AV fistula (AVF) over an AV graft (AVG) or a tunneled catheter (TC).

Methods: We examined 46,748 US veterans who transitioned to dialysis between 2007 and 2011 using an AVF, AVG or TC. We examined the association of AVG and TC (vs. AVF) with all-cause and cause-specific mortality in Cox and competing risk regression models adjusted for age, race, comorbidities and pre-dialysis Nephrology care in patients aged <60, 60–<70, 70–<80, and ≥80 years old. Effect modification by age was examined with interaction terms.

Results: Upon dialysis transition, patients were 70±12 years old, 94% male, 25% African-American, and 58% diabetic. 8,936 (19%) started HD with an AVF, 1,232 (3%) with an AVG, and 36,580 (78%) with a TC. 31,354 patients died (mortality rate 290/1000 patient-years, 95%CI: 287-293) over a median follow-up of 2.1 years. Use of a TC was associated with significantly higher all-cause mortality in all age groups (Figure), with no significant age interaction (p=0.6). TC use was also associated with both higher infectious mortality (HR 1.76, 95% CI 1.33 - 2.32) and CV mortality (HR 1.54, 95% CI 1.37 - 1.74) in patients ≥80 years old. Use of an AVG was not associated with higher risk of all-cause, infectious or CV mortality in patients >80 years old.



Conclusions: Staring HD with a TC is associated with higher mortality in all age groups, the risk being highest for infectious mortality. Use of an AVG appears to be associated with similar outcomes as an AVF in patients ≥80 years old. A catheter-last approach should be advocated in elderly incident HD patients.

Predictors of Adverse Outcomes of Permanent Vascular Access (PVA) in Pediatric Hemodialysis (HD) Patients: A MWPNC Study

Ali Mirza Onder, Ellen G. Wood, Craig B. Langman, Chryso P. Katsoufis, Marissa J. Defreitas, Joseph T. Flynn. *Midwest Pediatric Nephrology Consortium.*

Background: Few data exist on what factors contribute to success or failure of PVA in pediatric HD. We investigated predictors of adverse outcomes of PVA in a large cohort of pediatric HD patients.

Methods: Retrospective chart reviews were performed in 20 participating centers. Variables collected included duration and number of non-permanent vascular access (NPVA), type of PVA, complications, interventions, and final outcome.

Results: PVA were created in 117 children during the study period: 103 (88%) were AV fistulas and 14 (12%) were AV grafts. AVF demonstrated better primary patency rates compared to AVG (p =0.0391, Wilcoxon signed rank test). Primary failure occurred in 16 PVA (13.6%). AVF's were about 2 times more likely to have primary failure compared to AVG (Odds ratio= 2.1). Secondary failure occurred in 14 PVA (12.2%). AVG's had about 3 times increased risk for secondary failure compared to AVF's (Odds ratio=3.334). As the number of NPVA increased, the probability of secondary failure decreased (p=0.0343, inverse correlation). Longer NPVA duration directly correlated with increased risk for secondary failure (p=0.0501). As Kt/V at the time of permanent vascular access creation increased, the probability of secondary failure increased (p=0.0263). There were 196 interventions in total. AVF's were more likely to be intervention-free (p=0.0456, Odds ratio=4.84). Twenty-seven interventions resulted in non-functional PVA. Both Intervention-free survival (p=0.0252, Odds ratio=0.093) and the total number of interventions were able to predict secondary failure (p=0.0006). For each additional intervention, the odds of having secondary failure increase by 1.535. Finally, intervention-free survival directly correlated with overall survival of PVA (p=0.0197, Spearman correlation coefficient = 0.28028).

Conclusions: We found that both the number and duration of NPVA, and baseline Kt/v may affect the outcomes of AVF and AVG. While most interventions were able to salvage the function of PVA, both the intervention-free survival and total number of interventions were predictive of secondary failure.

TH-PO1067

Predictors of Maturation Time for Permanent Vascular Access (PVA) in Pediatric Hemodialysis (HD) Patients: A MWPNC Study

Ali Mirza Onder, Ellen G. Wood, Matthew M. Grinsell, Larry T. Patterson, Jennifer G. Jetton, Joseph T. Flynn. *Midwest Pediatric Nephrology Consortium.*

Background: Maturation time is one of the limiting factors in using PVA for children on HD.Our objective was to investigate the predictors of maturation time of AVF's and AVG's in a large cohort of pediatric HD patients.

Methods: Retrospective chart reviews were performed in 20 participating centers. Variables collected included duration and number of non-permanent vascular access (NPVA), type of PVA, patient demographics, baseline laboratory findings at time of placement and final outcome.

Results: PVA were created in 117 children during the study period: 103 (88%) were AV fistulas and 14 (12%) were AV grafts. The average maturation time was 3.7± 3.9 months. AVG's had significantly shorter maturation times when compared to AVF's after exclusion of the 2 outlier centers (p=0.0028). In the logistic regression model for the predictors of maturation time, there were 4 predictors; Study site (p=0.0165), duration of NPVA (p<0.0001), number of previous NPVA (p=0.0061, inverse correlation),and age at placement (P<0.0001). When AVF and AVG were separately analyzed, these predictors were only significant for AVF's. The overall PVA survival was 23.9± 13.9 months, with AVF's being statistically indifferent from AVG's (p=0.8270). Maturation time could not predict secondary failure of either access type (p=0.8817). There was no difference in maturation times between PVA with secondary failure and those that were still functional at the end of the observation period (p= 0.3675).

Conclusions: We demonstrated that the study site, both the duration and number of NPVA and age at placement may affect the maturation times for AVF's. AVG's had significantly shorter maturation times and none of the variables could predict their maturation times. Time to maturation was not a predictor of secondary failure of PVA in this cohort.

TH-PO1068

The Role of Vascular Access on Medicare Reimbursement among Patients with Incident End-Stage Renal Disease Receiving Hemodialysis

Sarah H. Yi,[1] Sophia Kazakova,[1] Duc B. Nguyen,[1] Ibironke W. Apata,[1,2] John A. Jernigan,[1] Priti R. Patel.[1] *[1]Div of Healthcare Quality Promotion, Centers for Disease Control and Prevention, Atlanta, GA; [2]School of Medicine, Emory Univ, Atlanta, GA.*

Background: Previous studies suggest better outcomes among patients with end-stage renal disease (ESRD) initiating hemodialysis (HD) with arteriovenous fistulas (AVFs) versus central venous catheters (CVCs). We sought to compare Medicare reimbursements during the first year of HD by vascular access at initiation.

Methods: A retrospective cohort of patients with incident ESRD in 2011 or 2012 was selected from a 5% sample of all Medicare beneficiaries. We included patients aged ≥67 years, covered by traditional fee-for-service Medicare two years before and one year after HD initiation, and alive one year after HD initiation. Initial vascular access was identified using the first modifier code (V5-V7) on an outpatient hemodialysis claim in the initial 60 days of HD. Inpatient, outpatient, and other claims were utilized to obtain reimbursement data. Medicare reimbursement in the first year of HD was modeled as a function of vascular access, age, sex, race, healthcare setting of first HD, and reimbursement in the year prior to HD as a proxy for baseline health status and utilization using a generalized linear model.

Results: Of 1,635 included beneficiaries, 23% and 77% started hemodialysis with AVF and CVC, respectively. In the year prior to HD initiation, crude median reimbursements were $15,452 and $19,026 among those initiating via AVF and CVC. In the year after HD initiation, crude median reimbursements were $58,604 and $91,165 among those initiating via AVF and CVC. Adjusted reimbursement was 18% lower (0.82, 95% CI: 0.77-0.87, *P*<.0001) among beneficiaries initiating with fistula compared with CVC.

Conclusions: Among a fully covered Medicare ESRD cohort surviving the first year of HD, those with fistula had lower total Medicare reimbursements during the first year of care even after adjusting for baseline reimbursement and other characteristics. These findings suggest a missed opportunity to prevent excess healthcare costs to Medicare associated with HD initiation with CVC.

TH-PO1069

Effect of Hemodialysis on Anterior Chamber Biometric Structure and Intraocular Pressure in Non-Diabetic Patients with End-Stage Renal Disease

Wei Shen. *Zhejiang Provincial People's Hospital, Dept of Nephrology, Hangzhou, China.*

Background: To evaluate the short-term changes in the ophthalmologic findings after low-flux hemodialysis in non-diabetic end-stage chronic renal failure (CRF) patients.

Methods: Forty-three patients (86 eyes) selected so as not to have glaucoma or history of glaucoma were studied. We observed the patients on maintenance hemodialysis therapy more than 6 months. Their clinical characteristics and medical records before and after hemodialysis were reviewed through the way of self-control study. Detailed ophthalmologic examinations together with tomometre (intraocular pressure, IOP), A/B scan(lens thickness) and ultrasound biomicroscopy(central anterior chamber depth) were performed immediately before and after HD sessions. Demographic information including age, gender, underling systemic diseases, hemodialysis duration, and levels of body weight, blood urea nitrogen, and creatinine before and after hemodialysis were recorded.

Results: The mean age of the patients at the time of dialysis was 49.7±12.0 (range 33 to 65) years. 53.5%(23) were men.After hemodialysis treatment, the blood urea nitrogen, creatinine, patient weight decreased significantly *(P*<0.01); There was no significant difference in the change of serum calcium, serum phosphorus, serum albumin and hemoglobin after the treatment(*P*>0.05). Mean central anterior chamber depth also decreased significantly after HD, from 2.46±0.38 to 2.38±0.36 mum (paired t test, *P*<0.01). Mean lens' thickness significantly increased from 4.23±0.22 mm before HD to 4.30±0.12mm after HD (*P*<0.01) in group. However, Mean IOP increased from 12.32±4.31 mmHg to 14.31±2.98mmHg after HD (paired t test, P<0.01).

Conclusions: Conventional hemodialysis can affect the ophthalmologic findings. Patients with chronic renal failure should be checked of their anterior chamber structure and be given corresponding treatment before haemodialysis.

TH-PO1070

Persistent Disparities in Hemodialysis Vascular Access

Jonathan H. Segal, Sehee Kim, Shu Chen, Jeremy J. Phipps, Jennifer Sardone, J. Affholter, C. Dahlerus. *Univ of Michigan Kidney Epidemiology and Cost Center.*

Background: Despite gains over the past decade with AV fistula (AVF) creation, concerns remain about vascular access (VA) disparities. Prior studies are limited by sample size or ability to adjust for clinical risk factors that influence AVF creation. Using data on Medicare ESRD patients we analyze the impact of patient demographic factors on likelihood of different VA types after adjusting for incident and prevalent comorbidities.

Methods: We used 2014 CROWNWeb for monthly VA data for all Medicare hemodialysis patients in the US. Incident comorbidities were obtained from the CMS 2728, and prevalent comorbidities from the prior 12 months of Medicare claims. Multivariate generalized logistic regression modeled odds of AVF/AV graft (AVG)/catheter (CVC) use associated w/ demographic and clinical factors.

Results: Of 2,920,145 patient-months AVF and AVG were used in 65% and 21% of patient-months. After adjusting for ethnicity, BMI, nursing home status, pre-ESRD care, duration of ESRD and 12 categories of comorbidities those aged 75+ were 19% and 15% less likely to have an AVF versus (V) AVG and CVC. Black patients were 47% and 16% less likely to have AVF V AVG or CVC compared to whites/other race. Hispanic ethnicity was associated with higher AVF use V CVC. Females were 52% and 46% less likely than males to have AVF V AVG or CVC.

	AVF v CVC	AVF v AVG	AVG v CVC
	OR	*OR*	*OR*
25-≤59	0.97	***1.2***	***0.81***
Age Ref: 60-75	-	-	-
75+	***0.85***	***0.81***	1.02
Black race	***0.84***	***0.53***	***1.58***
Hispanic eth.	***1.28***	1.06	1.24
Female sex	***0.54***	***0.48***	1.12
Vintage Ref: 1-4y	-	-	-
5-≤8y	1.03	***0.77***	***1.32***
9+y	***0.76***	***0.48***	***1.50***

p<0.01

Conclusions: We observed differences in AVF use by demographic characteristics. After adjustment for patient comorbidities, patients >75y, of black race, and females were less likely to have an AVF compared to AVG or CVC. Absent strong biological bases for barriers to achieving optimal vascular access outcomes by race and sex, caution is required in considering these risk adjustment factors as part of public reporting to avoid masking potential care disparities.

Funding: Other U.S. Government Support

TH-PO1071

Timing of Arteriovenous Fistula Creation prior to Hemodialysis Start in the Veterans Affairs Healthcare System

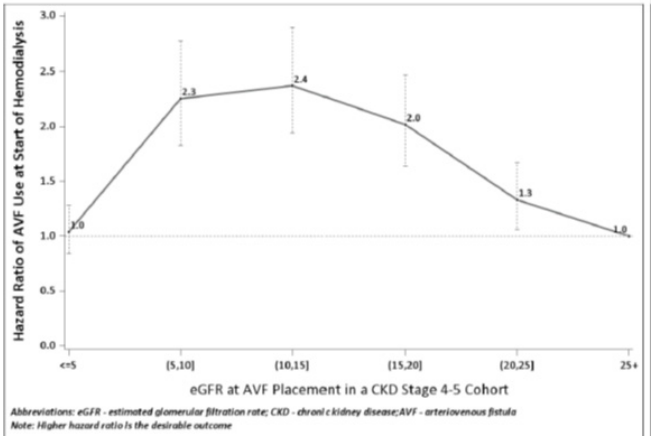
Rajiv Saran,[1] Anca Tilea,[1] Sai Hurrish Dharmarajan,[1] John Stephen,[1] Aaron Pearson,[1] Diane Steffick,[1] Brenda W. Gillespie,[1] Hal Morgenstern,[1] Eric W. Young,[1] Edward D. Siew,[2] Michael J. Fischer,[2] Karen Sovern,[2] Daniel F. Balkovetz,[2] Susan T. Crowley,[2] Vahakn B. Shahinian.[1] *[1]Univ of Michigan; [2]Veterans Affairs Healthcare System.*

Background: For quality assessment/improvement of VA clinical practice we analyzed existing data from the national Veterans Affairs Renal Information System (VA REINS) to determine incident HD vascular access rates and timing of AVF placement in VA that best predicts AVF at HD start.

Methods: VA 'user' is defined as ≥1 VA contact in 3 yrs. Users with eGFR <30 ml/min/1.73m^2 at any time (2008-13) were identified. Using procedure codes in VA, vascular access placements with corresponding eGFR (±3 mo) after the date of user entry into CKD stage4-5 were identified. Incident HD users and their access were identified from Medical Evidence Form 2728. Cox regression assessed predictors of AVF use at HD start. ESRD with access other than AVF (including those with catheters with maturing AVF) and pre-ESRD death were treated as competing risks. Adjustors were: age, sex, race, comorbidities, closest eGFR within 3 mo of AVF placement.

Results: Among the 349,020 users with CKD Stage4-5, 150,635 died; 40,313 patients started HD (16,968 with AVF; 1,723 AV Graft; 21,622 catheters). Wide variation in rates of AVF or Catheter with maturing AVF (34-64%) was observed across geographic areas. The estimated hazard ratios (HR), comparing eGFR values at the time of AVF placement are in Figure. The range of eGFR associated with highest HRs for Veterans starting HD with an AVF was 5-20ml/min/1.73m^2.

Figure: Adjusted HR (95% CI) for successful AVF use at HD start, by category of eGFR vs. eGFR ≥25 ml/min/1.73 m^2 (ref) at time of AVF placement in CKD Stage4-5.



Conclusions: In VA Healthcare System**,** placement of AVF early (eGFR>20) or late (eGFR <5) in users with CKD stage4-5 was associated with lower success in AVF use at HD start.The optimal window for AVF placement was eGFR in the 5-20 range. Geographic variation in VA AVF placement warrants further review.

Funding: VA Support

TH-PO1072

Use of a Vascular Access Coordinator to Increase Arteriovenous Fistula (AVF) Prevalence and Decrease Tunneled Catheter Duration and Use in an Inner City Hemodialysis Clinic Cesar Y. Cardona, Marquetta L. Faulkner. *Internal Medicine and Nephrology, Meharry Medical College, Nashville, TN.*

Background: The National Kidney Foundation, Kidney Disease Outcomes Quality Initiative (NKF, KDOQI) push for dialysis practice standards envisioned a goal of <10% catheter use and >66% AVF use for each hemodialysis (HD) unit.[1] A major component of First Fistula Breakthrough Initiative is use of AVF within 90 days of first dialysis treatment to minimize time a tunneled catheter is present while awaiting AVF or arteriovenous graft (AVG) maturation in patients dialyzing via a tunneled catheter.[2] Goals of study are to establish, evaluate a protocol that can be replicated to minimize catheter use and maximize AVF prevalence and cannulation of AVFs or AVGs within 90 days of tunneled catheter placement.

Methods: In June, 2007 we designed a pilot program to increase prevalent AVF use from baseline of 19.9 % to greater than 60% by using a vascular access coordinator to coordinate care and monitor access creation and maturation.[3,4] We enrolled 60 patients based on inclusion criteria of GFR of less than or equal to 30 mL/min (assessed by MDRD equation) who were followed in the nephrology clinic or those who were referred to our clinic and met inclusion criteria or deemed appropriate by attending nephrologist for referral for vascular access placement. Patients were enrolled beginning June, 2007 to November, 2014.

Results: We were able to increase prevalent AVF use in our hemodialysis clinic from 19.9% to 56.9% (p<0.0001) and decrease catheter use for greater than 90 days from 32.5% to 12.6% (p<0.0001) and our total patients with catheters decreased to 18.9% from 42.5% (p<0.0001).

Prevalence June 2007	Prevalence February, 2015
AVF 19.9%	AVF 56.9%
Total Catheter (TC) 42.5%	TC 18.9%
Catheter > 90 days (C>90) 32.5%	C>90 12.6%

Conclusions: Use of a VAC helped increase AVF use and decrease both total tunneled catheter use and catheter use of greater than 90 days in an inner city hemodialysis clinic and results were statistically significant despite not reaching goals established by NKF and KDOQI.

Funding: Pharmaceutical Company Support - DCI helped support the funding for the position of the Vascular Access Coordinator

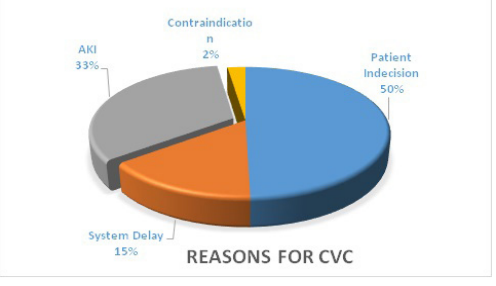
TH-PO1073

Why Not "Fistula First"? The Obstacles Sijie Zheng, Andrea Remeta, Joanna Mroz, Leonid Pravoverov. *The Permanente Medical Group, Oakland, CA.*

Background: In the US, 80% of patients initiate maintenance HD with a central venous catheter (CVC). One reason for low incidence of AVF/AVG was attributed to late referral. Kaiser Permanente Northern California (KPNC) is an integrated health care system providing health care to 3.9 million members. The East Bay service area provides health care to approximately 400,000 members with an estimate of 40,000 CKD patients.

Methods: A retrospective analysis was conducted of CKD patients who initiated dialysis in the KPNC East Bay Service Area from 2013 to 2015. For patients who initiated hemodialysis with a CVC, we analyzed the reasons for not having a matured AVF/AVG upon hemodialysis initiation.

Results: A total of 199 patients initiated HD from January 1, 2013 to December 31, 2015. Among them, 127 (63.8%) patients used CVC as their dialysis access upon initiation. 57 (28.6%) patients had a matured AVF at the start of dialysis and 15 (7.5%) patients had a matured AVG. We analyzed the reasons for failure to have a matured AVF/AVG and classified them into 4 categories: (1) delays due to patient indecision (63 patients, 49.6%), (2) system related delays (19 patients; 15%), (3) patients with Acute Kidney Injury (42 patients; 33.1%) and (4) medically contraindicated (3 patients; 2.4%).



Conclusions: In our integrated health care system, incident hemodialysis patients have lower CVC rates compared with the national average. Delays due to patient indecision and unexpected AKI requiring immediate dialysis initiation represent the majority of cases when permanent access is not established prior to initiation of dialysis. Patient education and close monitoring in the pre-dialysis period will likely have the highest effect in decreasing CVC rates in the future. In our integrated organization, system related delays represent a smaller overall opportunity to increasing the use of AVF/AVG as a primary access at initiation of dialysis.

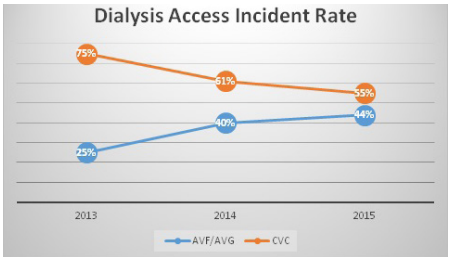
TH-PO1074

Strategies to Increase Incident AVF/AVG in Hemodialysis Patients Sijie Zheng, Andrea Remeta, Joanna Mroz, Leonid Pravoverov. *The Permanente Medical Group, Oakland, CA.*

Background: Despite higher mortality and complications associated with central venous catheter (CVC) use, 80% of incident HD patients in US are using CVC as their dialysis access. Kaiser Permanente Northern California (KPNC) is an integrated health care system providing health care to 3.9 million members. The East Bay service area provides health care to approximately 400,000 members with an estimate of 40,000 CKD patients.

Methods: We strengthened the collaboration between nephrologists and vascular surgeons by instituting a designated dialysis access nurse coordinator. Since June 2013, a dialysis access nurse coordinator to prospectively monitor patients approaching CKD 5. Patients with eGFR $\leq$ 25 ml/min/1.73 m^2 were referred for evaluation for AVF/AVG placement if they choose hemodialysis (HD). Protocols were developed to create consistent patient education about risks and benefits of various dialysis access types, uniform process of referral for vein mapping, pre-operative evaluation and operating room scheduling. In addition, the dialysis access nurse coordinator involved patient's caregivers, educating them on the importance of timely preparation for dialysis, thus improving adherence to appointments. Once the AVF/AVG was placed, a vascular surgeon examined the patient at 2 weeks and 8 weeks to ensure successful maturation of the AVF/AVG. The nurse coordinator ensured patient has follow up appointments with the vascular surgeons, nephrologists, duplex studies and AVF/AVG revision surgeries as needed.

Results: The incident AVF/AVG rate increased from 25% to 44% since 2013 to 2015, and the incident CVC rate decreased from 75% to 55% during the same period of time.



Conclusions: By increasing the overall integration of the pre-existing team of providers, an access nurse coordinator is able to significantly and consistently reduce rate of CVC in patients initiating hemodialysis in our integrated health care system.

TH-PO1075

Quality Improvement Project for Permanent Dialysis Access Rates in End-Stage Renal Disease Elliot M. Charen, Naitik Sheth, Chiarra Marie Ornillo, Nikolas B. Harbord. *Div of Nephrology and Hypertension, Mount Sinai Beth Israel, New York, NY.*

Background: Dialysis patients with central venous catheters (CVC) are expected to have more interventions for access dysfunction at higher cost, worse patency rates, and higher morbidity and mortality. Many incident dialysis patients initiate dialysis in the hospital and do not meet the expectation from NKF-KDOQI of CVC free by 90 days of dialysis initiation; many new-start dialysis patients have not consulted with a surgeon prior to initiation of dialysis.

Methods: New start chronic dialysis patients initiated while hospitalized and followed by the renal consult service were included. The retrospective first phase of data collection (January-March, 2014) involved a study of incident End-Stage Renal Disease (ESRD) patients who ultimately were discharged to an out-patient dialysis center. The hospital record (PRISM) was checked to see if the patient had a permanent dialysis access placed, a surgical consult for access was completed, or an out-patient office visit was scheduled. The prospective second phase (5 non-contiguous months from 2014-2015) involved teaching all new start ESRD patients about options for dialysis including the benefits of a permanent access and surgical evaluation with possible access placement.

Results: In the implementation phase as compared to the study phase, a greater percentage of patients had in-patient surgical consults (56% versus 29%, p=0.38) and out-patient surgical appointments (67% versus 43%, p=0.38). The amount of permanent dialysis accesses were no different between the two groups (28% versus 29%, p=1). The most common reason for not having an access placed during hospitalization was patient choice (n=7/18). The most common medical reason for not having an access placed was cardiac risk (n=3/18).

Conclusions: Patient education can be improved during an incident ESRD patient's hospitalization, but access planning education in the hospital may not allow patients sufficient time to make decisions about venous access placement.

TH-PO1076

AV Fistula Creation by Nephrologist: An Indian Experience Vinant Bhargava, Ritesh Kauntia, Devinder S. Rana, Anil Bhalla, Ashwani Gupta, Manish Malik, Anurag Gupta. *Nephrology, Sir Gangaram Hospital, New Delhi, India.*

Background: AV fistula is the preferred vascular access for long term hemodialysis as it has higher patency rates and lower infection rate, morbidity and mortality. The aim of the study was to assess the outcomes and primary patency rates of radiocephalic AV fistulae created by nephrologists.

Methods: A retrospective analysis of AV fistulas created by nephrology team in the year 2013 in Sir Gangaram Hospital, New Delhi, India was done. USG Doppler for forearm vein mapping was performed in cases where physical examination with tourniquet failed to reveal a cephalic vein of adequate diameter. Patients who did not have adequate caliber of cephalic vein were referred to vascular surgeon for brachial AV fistulae. Data was collected over telephonic conversation with the patients as well as physical examination in nephrology outpatient clinics.Primary failure was defined as an AV fistula which did not mature and could not be used for hemodialysis.

Results: 301 patients underwent AV- fistula surgery. 260 patients underwent 270 AV-fistula creation. 10 patients underwent AV fistula revision in view of primary failure. Data regarding maturation was not available for 41 patients. Analysis of 270 AV-Fistulae was done for primary maturation .The mean age of patients was 50.6±15.3years. 73.3%were males. 41.8% of patients had diabetes mellitus. Preexisting coronary artery disease was present in 20% and peripheral vascular disease was present in 1.85% of the patients. On follow up, 204 (75.56%) of AV fistula created had successful maturation. Primary failure was seen in 66 (24.44%) patients. Primary failure in patients with diabetes was seen in 38 out of 66 (57.57%) and 75 out of 204 (36.76%) had successful maturation (p=0.002). Coronary artery disease was present in 20 out of 66 (30.3%) patients with primary failure and 34 out of 204 (16.67%) patients with successful maturation (p=0.016).

Conclusions: This study shows that AV fistulae created by nephrologists have comparable success rates of maturation. Diabetes mellitus and coronary artery disease are significant risk factors for AV fistula primary failure.

TH-PO1077

Pre-Operative Venography and the Identification of Forearm Veins Compared to Ultrasound Vein Mapping Patrick McGlynn, Dirk M. Hentschel. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: The KDOQI guidelines advocate the creation of forearm over upper arm arteriovenous fistulas (AVFs), as these typically last longer and are associated with fewer access and systemic complications. In addition, forearm AVFs increase the success of secondary accesses created more proximally. Duplex ultrasound is the preferred method for pre-operative vessel mapping and has increased the successful creation of AVFs when compared to physical exam alone. However, in clinical practice many patients without a suitable forearm vein by US do in fact have forearm access options. Here, we describe the use of peripheral venography (PV) with serial released tourniquets to visualize the veins of the upper extremity and compare the peripheral vein findings from PV to that of ultrasound vein mapping (UVM).

Methods: The Brigham and Women's Interventional Nephrology Database was used for this study to identify a historical cohort of patients who received pre-operative PV and UVM between January 2008 and December 2015. The UVM and PV reports were reviewed for appropriate forearm veins to be used in AVF creation by Silva criteria. The presence of suitable veins was recorded as a dichotomous outcome. The extremities were treated as paired data-points and evaluated using McNemar's test.

Results: During the study period, 426 extremities were evaluated with peripheral venography in 246 patients. 202 extremities were evaluated using both PV and UVM, 44 forearm AVF created, and 49 extremities did not have an access created. PV identified 76 extremities with OR 4.38 (2.37-8.73). UVM recommended forearm AVF in 10 of the 44 created and venography recommended 18 of 44 created. The use of PV increased forearm AVF, however without clinical significance (p=0.06). The primary failure rate was similar in forearm accesses recommended by PV or UVM, 28% vs. 22% respectively.

Conclusions: This suggests the use of PV is associated with identifying more forearm veins to be used in the creation of AVFs, with similar primary failure rates.

TH-PO1078

The Use of Peripheral Venograms in Evaluating the Central Veins in Preparation for Permanent Dialysis Access Creation Patrick McGlynn, Dirk M. Hentschel. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: Ultrasound vein mapping (UVM) is the preferred method for pre-operative vessel mapping, and its use has increased the number of patients in whom an arterial venous fistula (AVF)is able to be placed. Despite pre-operative steps to optimize outcomes, 20-60% of AVFs are never usable for dialysis. The creation of an AVF requires a suitable outflow conduit, and central vein (CV) stenosis can impair maturation. Previous studies report that UVM can be used to assess the CVs for evidence of occlusion, with an 81% sensitivity and 97% specificity. Here, we describe the use of peripheral venography (PV) to visualize the CVs and compare CV findings from PV to that of UVM.

Methods: All patients with pre-operative PV between January 2008 and January 2016 at Brigham and Women's Hospitals were included. Images and reports were reviewed for the ability to visualize the CVs for patency, stenosis, or obstruction. PV used three serially released tourniquests (last in the axilla), and terminal, passive arm elevation to "dump" pooled contrast into the CVs (method established by Tom Vesely). The ability to visualize the CVs was recorded as 3= comparable to dedicated central venogram, 2= visible with confidence, 1=visible, but outline not distinct. CV were also evaluated via PV and UVM for evidence of CV stenosis or obstruction. The results were treated as paired data, and McNemar's test was used to evaluate a difference in detection in CV abnormalities.

Results: 426 extremities were evaluated via PV in 246 patients. 225 extremities were also evaluated with UVM. PV confirmed patency of the Superior Vena Cava 87% & 70%, Brachiocephalic 93% & 85%, and Subclavian veins 98% & 96% of the time on the right and left respectively. PV and UVM detected 52 and 5 extremities with CV stenosis or obstruction respectively. Only 2 of the 52 (4%) stenosis or occlusions detected with PV were identified with UVM (sensitivity=4%, specificity=98%). The use of PV was significantly associated with identifying CV stenosis with p= 0.00.

Conclusions: The use of PV can be used to evaluate the central veins. The utility of UVM in evaluating the CVs may be less useful than previously reported.

TH-PO1079

Prominent "V" at Elbow Is a Predictor of Successful Median Basilic to Brachial Artery Arteriovenous Fistula Sachin Soni.[1,2] [1]*Interventional Nephrology, United Ciigma Hospital, Aurangabad, Maharashtra, India;* [2]*Nephrology, MGM Medical College, Aurangabad, Maharashtra, India.*

Background: A functioning Arteriovenous fistula (AVF) is key to survival of patients on maintenance hemodialysis. In this study, we have looked at the outcome of side to side median basilic vein to brachial artery AVF. All surgeries are performed by the Nephrologist independently.This type of AVF is not discussed in literature frequently, but is technically very simple as the vein and the artery lie in close proximity just below the elbow crease.

Methods: In this prospective study, all patients undergoing median basilic vein to brachial artery AVF, were analysed for primary outcome of successful vascular access, defined as cannulable cephalic vein above elbow giving doppler flow more than 450 ml/min on surveillance monitoring and blood flow of more than 350 ml/min during dialysis after 3 weeks of surgery. We also looked at predictors of successful AVF and complications. Based on author's personal experience patients with prominent "V" at the elbow were taken for this type of fistula. (Prominent V at the elbow is formed by median basilic and median cephalic veins,).

Results: During the study period 122 patients underwent median basilic vein to brachial artery AVF. Of the study group 12 patients were lost to the follow up and 6 patients died before completing three weeks of post operative period. Of 104 patients, 96 patients (92.3%) patients had successful AVF. Male outnumbered females (66 males and 48 Females). Hypertension (78.8 %) was the most frequent co-morbidity, followed by Diabetes Mellitus (39.4%). Failure of maturation was seen in 8 patients and arm edema in 4 patients.

Conclusions: Side to side median basilic vein to brachial artery arteriovenous fistula is promising vascular access. Prominent "V" at the elbow is a strong predictor for success of such AVF.

TH-PO1080

Could Very Small Arteriovenous Fistulas Last Long Even in the Elderly on Hemodialysis? Hitoshi Iwabuchi, Manabu Asano, Kenichi Oguchi. *Bousei Hospital, Saitama, Japan.*

Background: The number of elderly patients who need hemodialysis treatment has been increasing here in Japan. Arteriovenous fistulas (AVFs) are the preferred choice for vascular access (VA); however, there is a debate over the utility of AVFs in older patients, particularly concerning fistula patency. We continued to make AVFs much smaller for preventing incidental load on the heart. The aim of this study was to verify that smaller size AVF might be appropriate for elderly patients.

Methods: A retrospective study was carried out on one hundred hemodialysis patients who underwent creation of a smaller size AVF. An average age of the subjects was 72.1±10.8 years, with 61 males and 39 females. Forty-seven of whom were lower than 75 years (GroupI) and the others were over 75 years (GroupII). The autologous radiocephalic fistulas at distal forearm were created by a single surgeon under the same method. The

anastomosis size by side to side was limited to just 3 mm. Primary VA patency was defined as the time to first VA intervention, and secondary patency as the time to creation of a new VA. Kaplan-Meier curves of primary and secondary AVF patency were generated. Also, comparisons between the two groups were performed using a log-rank test. Results were considered significant at P<0.05.

Results: The primary patency rates were 88.0% and 77.9% for GroupI and GroupII at 12 months, also 71.2% and 37.2% (p=0.03) at 36 months, respectively. The secondary patency rates for each were 92.2 % and 85.4 % at 12 months, also 78.6% and 59.8% at 36 months. Secondary AVF patency did not show any significant difference (p=0.34).

Conclusions: Our results disclosed lower patency rate of smaller AVFs in elderly patients. Although excessive blood flow must be unfavorable for any dialysis patient, our attempts to make AVF smaller were not able to show a new additional value for the elderly from the viewpoint of lives of VA.

TH-PO1081

Procedural Burden during Arteriovenous Fistula Maturation following Operative Placement: An Analysis of the United States Renal Data System Kenneth J. Woodside,[1] Kaitlyn Ratkowiak,[2] Purna Mukhopadhyay,[2] Sai Hurrish Dharmarajan,[1] Brett W. Plattner,[1] Douglas E. Schaubel,[1] Rajiv Saran,[1] Ronald L. Pisoni.[2] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

Background: Over the last decade, the number of arteriovenous fistula (AVF) in the prevalent hemodialysis (HD) population has increased. We sought to determine the procedural burden required for successful AVF maturation in the incident United States HD population.

Methods: Using the United States Renal Data System (USRDS) Medicare claims and CROWNWeb data, we analyzed patients incident to HD from 7/1/12 to 6/30/13 with first-time AVF placements (after HD start) from 7/1/12 to 6/30/2014. Successful maturation was defined as documentation of first AVF use in CROWNWeb by 12/31/2014.

Results: Among the 102,703 incident HD patients, there were 24,416 first-time AVF placements of which 70.7% were successfully utilized, 25.5% failed to mature and 3.9% were lost to follow-up. Of those AVF that successfully matured, 44.2% required interventions during the maturation phase, with half of these interventions requiring angioplasty. Interventions were performed on 50.8% of AVFs that failed to mature. Not surprisingly, thrombectomies were carried out much more often in those with AVF maturation failure. Rates of interventions per patient (pp) are summarized in the Table.

Table. Interventions during AVF maturation.

	Successful Maturation	Failed Maturation
Patients	17,270	6,223
Patients with Interventions	7,629	3,271
Interventional Procedures	11,949 (0.69 pp)	9,685 (1.56 pp)
Diagnostic Fistulogram Only	2,659 (0.15 pp)	1,694 (0.27 pp)
Angioplasty	5,803 (0.34 pp)	3,154 (0.51 pp)
Thrombectomy	897 (0.05 pp)	3,601(0.58 pp)
Revision	2,144 (0.12 pp)	846 (0.14 pp)
Other	446 (0.03 pp)	390 (0.06 pp)

Conclusions: While there have been improvements in AVF utilization in the prevalent HD population, interventions on these AVF were exceedingly common during maturation. As such interventions are resource intensive, additional studies investigating patient and center level predictors of maturation success and interventional effectiveness are ongoing.

TH-PO1082

Risk Factors for Arteriovenous Fistula Nonmaturation in a European Cohort Bram M. Voorzaat, Koen E.A. van der Bogt, Jan Van Schaik, Friedo W. Dekker, Joris I. Rotmans. *Nephrology, Surgery and Clinical Epidemiology, Leiden Univ Medical Center.*

Background: Nonmaturation of permanent vascular access (VA) conduits is a significant burden for hemodialysis (HD) patients. European data about the current prevalence of nonmaturation are lacking. This study evaluated outcomes of VAs in a large Dutch retrospective cohort.

Methods: Clinical charts from 2004-2015 in 8 hospitals were retrospectively reviewed. Data were collected on VA configuration, procedures to improve maturation, medication and comorbidities. Maturation was assessed by clinical use of the VA. Risk factors for nonmaturation were identified through multivariable analysis. Next, the prediction model for nonmaturation by Lok, et al. was validated.

Results: 1383 arteriovenous fistulas (AVF) and 273 grafts (AVG) were included, for a total of 1656 vascular accesses in 1221 patients. Nonmaturation was defined as primary fistula failure. In patients requiring hemodialysis (HD), 24% (149/617) of radiocephalic AVFs (RCAVF) were never used for HD. For brachiocephalic AVFs (BCAVF) and AVGs these numbers were 11% (54/511) and 6% (13/229) respectively. Nonmaturation of RCAVFs was 23% (66/287) in prevalent HD patients and 25% (83/330) in pre-dialysis patients (p=0.533). Of RCAVFs used for HD, 21% (98/468) required additional procedures to assist maturation. A Lok-score over three did not predict nonmaturation of RCAVFs (score ≤ 3: 25%, score >3: 22%, p=0.505) or nonmaturation for all AVF configurations together. Female gender was a significant risk factor for nonmaturation, whereas age and diabetes were not.

Conclusions: This large cohort demonstrates a high incidence of nonmaturation in RCAVFs, with one out of every four RCAVFs never used, even in pre-dialysis patients. Female gender is associated with an increased incidence of nonmaturation. The Canadian Lok-score did not predict nonmaturation in this cohort.

TH-PO1083

A Prospective Cohort Study of Predictors of Upper Extremity Arteriovenous Fistula Maturation Aiza Waheed,[1] Agnes Masengu,[2] Tomas Skala,[3] Guiyun Li,[3] Jacek Jastrzebski,[4] Nadia Y. Zalunardo.[4] *[1]Dept of Medicine, Univ of British Columbia, Vancouver, BC, Canada; [2]Regional Nephrology Unit, Belfast City Hospital, Belfast, United Kingdom; [3]Vancouver General Hospital, Vancouver, BC, Canada; [4]Div of Nephrology, Univ of British Columbia, Vancouver, BC, Canada.*

Background: A substantial proportion of AVFs fail to achieve functional patency and cannot be used for hemodialysis (HD). We evaluated demographic and ultrasound data, and postoperative clinical assessment as predictors of AVF failure.

Methods: Prospective cohort study of patients with CKD at the Vancouver General Hospital (Canada) vascular access clinic who had an AVF created from April 2009 - April 2013. Vessel mapping was performed by an experienced vascular access nurse. The primary outcome was failure to achieve functional patency (HD with 2 needles, blood pump speed >=350 for 12 consecutive treatments). Stepwise logistic regression was used for multivariable analysis.

Results: Functional patency was assessed in 200 patients (of 247 total; 13 died, 21 remain CKD-ND) of which 123 (61.5%) were radiocephalic. At AVF creation: 54.5% were CKD-ND, mean age 63.1 yrs, 62.5% male, 47.5% white, 62.0% diabetes. 26.5% of AVFs failed (34.1% of lower arm vs. 14.3% of upper arm AVFs, P=0.002). Univariate predictors of AVF failure included: older age (P=0.03), female sex (P=0.05), smaller arterial diameter (P=<0.001), lower artery volume flow (P=0.04), smaller vein diameter (P=0.01), previous CVC or pacemaker (P=0.07). In multivariable analysis, age (OR 1.03, 95% CI 1.004-1.057), and artery diameter (OR 0.41, 95% CI 0.27-0.65) remained significant predictors of AVF failure; ischemic heart disease, peripheral vascular disease, race, and previous AVFs were not significantly associated. Vascular access nurse assessment 6 weeks postoperatively correctly predicted outcome in 83.8% of AVFs that achieved functional patency and 65.0% of AVFs that failed (kappa 0.45, p<0.0001).

Conclusions: Older age and smaller artery size predict a higher risk of AVF failure. Failure to achieve functional patency is common for radiocephalic AVFs despite use of preoperative ultrasound mapping. Further studies are needed to determine which patients should proceed directly to an upper arm AVF.

TH-PO1084

Maturation of Arteriovenous Fistula and Parameters That Predict Failed or Delayed Maturity - A Single Centre Study Pek Ghe Tan, Gail Theresa Read, Lisa S. Jeffs, Geoffrey S. Kirkland, Cheong Tatt Yew, Richard Yu, Matthew D. Jose. *Nephrology, Royal Hobart Hospital, Hobart, Tasmania, Australia.*

Background: Arteriovenous fistula (AVF) is the best vascular access for long-term haemodialysis. However, many fistulae (28-53%) never mature to support dialysis. The majority of these were salvageable with interventions. In our center, all fistulae have maturity assessment conducted by vascular access nurse between week 6 and 8. Those with maturation failure were investigated and/or discussed with primary vascular surgeon for appropriate early salvaging interventions.

Methods: We conducted a single center study to evaluate AVF maturation. Prospective data collected by vascular access nurse on all AVF created between January 2010 and December 2015 was reviewed. Patients who died before AVF maturity assessment were excluded. Clinically matured AVF was defined using the Kidney Disease Improving Global Outcomes (KDIGO) rule of 6's. Secondary outcomes evaluated include: causes of maturity failure; numbers of salvaging interventions performed and their success rate; and clinical predictors (e.g. age, gender, site of AVF, body mass index (BMI), venous and arterial diameter) for delayed maturity.

Results: 159 patients (71 females; mean age of 65) had primary AVF created and 42% (67/159) failed to mature. Significantly more female patients had failing to mature fistulae (p<0.05). There was no difference in mean age, diabetes, AVF site, arterial diameter and venous diameter. 78% of failed to mature fistulae (52/67) underwent salvaging interventions with 90% matured subsequently. Causes of maturity failure include: stenosis (44%), thrombosis (33%) steal syndrome (9%), accessory veins (4%) and deep AVF (13%). Factors associated with delayed maturation (>12 weeks, with or without salvaging interventions) were female gender (OR2.5; 95%CI1.2-5.2), obesity (BMI>30) (OR3.0; 95%CI1.4-6.4) and distal AVF (OR4.1; 95%CI1.3-12.5).

Conclusions: Failure to mature is a common issue with AVF but the majority is salvageable. Clinical assessment to detect early AVF failure is critical to improve rate of eventual maturation. Female gender, obesity and distal AVF were associated with delay maturation of AVF.

TH-PO1085

Correlation of AV Fistula Maturation with Scoring System - A Prospective Study from Developing Nation with Non White Population Hemant J. Mehta, Jhoomar R. Makhija, Soham Gohil, Wasi Shaikh. *Nephrology, Lilavati Hospital and Research Center, Mumbai, India.*

Background: Choosing the most appropriate vascular access site is guided by many factors. We investigated the clinical predictors of AV Fistula (AVF) Failure to mature (FTM) and applied an existing clinical risk prediction model for AVF FTM. The main objective of this study was to identify clinical risk factors that are related to Failure to Mature (FTM) AVF and whether such model can be applied to non white population.

Methods: A prospective study was designed that included all patients undergoing AVF creation between February 2014 and February 2016 in a single centre of a city from developing nation, whose functional AVF outcome was observed 6 weeks after creation of fistula. The preoperatively determined FTM predicted risk model (Lok et al) was applied to our cohort.

Results: Out of 113 AVF, 72 (63.7%) matured and 41 (36.3%) failed to mature at 6 weeks. The FTM scoring was applied to our cohort. The variables that were considered were age ≥65 years, Coronary Artery Disease and Peripheral Vascular Disease. In our study all patients were non white race, the scores ranged between 3-10.5 There were no patients in the low risk category because all patients start with a score of 3. In the moderate risk category (score 3); 44/59 fistulas matured and 15 did not. In the high risk category (score 3.1-6.9), 25/47 fistulas matured and 22 did not. In the very high risk category (score ≥7), 3/7 matured and 4 did not. Thus non maturation rates in the moderate, high and very high risk categories were 25.4%, 46.8% and 57.1% respectively, which was statistically significant (p=0.037).

Conclusions: Factors associated with AVF FTM are likely to vary from population to population. It is important to investigate local rates of AVF FTM and associated predictors of AVF patency in order to guide appropriate vascular access decision making. Clinical predictors of AVF FTM may not be sufficient on their own to improve vascular access functional patency rates. We suggest that the FTM score be revised as per population, and the categories be changed as follow for non white population: Low to moderate, moderate to high and very high risk categories.

TH-PO1086

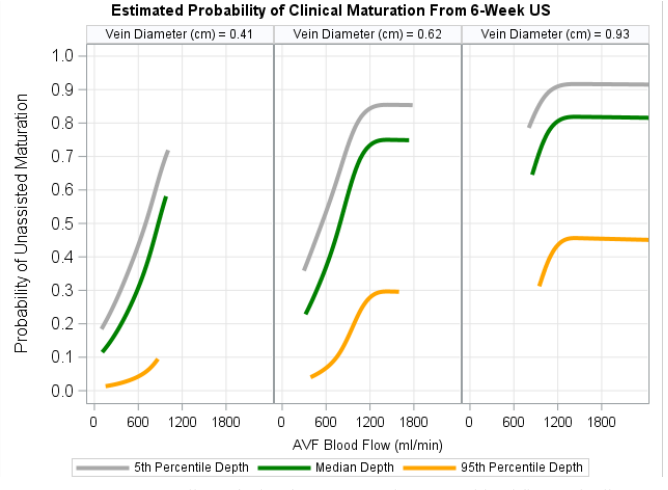
Prediction of AVF Clinical Maturation from Postoperative Ultrasound (US)

Michelle L. Robbin, Tom Greene, The HFM Study Group. *NIDDK, NIH.*

Background: The utility of early US measurements to predict AVF clinical maturation is uncertain. Primary unassisted and overall (assisted + unassisted) clinical AVF maturation were related to centrally measured US parameters.

Methods: We explored the prognostic accuracies of clinical maturation prediction from US parameters at 1 day, 2 and 6 weeks after AVF creation in 602 study participants of the 7-center Hemodialysis Fistula Maturation Study. A backward selection algorithm chose independent US predictors of unassisted and overall maturation among AVF blood flow, mean vein diameter, vein depth, arterial diameter, presence of stenosis, and presence of accessory veins, accounting for AVF location (upper arm vs. forearm), 5 case mix factors (age, sex, AVF location, diabetes, dialysis status) and clinical center. Missing US measures were multiply-imputed.

Results: At each time point, AVF flow, diameter, and depth were predictive of both unassisted and overall maturation (Figure). Accounting for AVF flow, diameter and depth, none of the remaining US parameters, AVF location, or case mix factors improved prediction, but maturation probabilities differed significantly among clinical sites after accounting for all these parameters. Cross-validated areas under ROC curves for prognostic models based on only the three US parameters increased from 0.69 at 1 day to 0.74 and 0.79 at 2 and 6 weeks for primary unassisted clinical maturation, and 0.69, 0.71, and 0.76 respectively for overall maturation. The US-prognostic models classified 6%, 11%, and 19% of subjects as having < 20% probability of unassisted clinical maturation at 1 day, 2 and 6 weeks.



Conclusions: Regardless of other factors, 6-week US AVF blood flow, vein diameter and depth are moderately predictive of clinical maturation.

Ultrasound-Guided Evaluation of Fistulas Safely Decreases Time to Cannulation and Catheter Removal

Orlando Nicholas Machado,[1,2] Farzin Farpour,[1,2] Tina Adjei-Bosompem,[1] George N. Coritsidis.[1,2] *[1]Div of Nephrology, Elmhurst Hospital, Icahn School of Medicine at Mt. Sinai, Queens, NY; [2]Broadway Dialysis Center, Queens, NY.*

Background: Use of bedside ultrasonography (USG) has dramatically increased in Medicine. Our dialysis center has used USG to evaluate arterio-venous fistula (AVF) maturation. Retrospective data from our center show significant improvement in time to cannulation without increased complications. We now present prospective data using USG as an aid to cannulation.

Methods: AVF cannulation based on physical exam alone from 2012-2014 was compared to AVF cannulation using USG 2014- 2016. AVF maturation criteria were: Diameter ≥6mm, Depth ≤6mm, Length ≥6cm. If by 4 weeks these criteria were not met the AVF was classified as failure of maturation (FOM). Examinations were done by fellows after completing the Emory renal-ultrasound course. Need for interventional radiology was considered a complication (early, 0-3 months; late, 4-12 months).

Results: 8/13 patients had USG for AVF cannulation compared to 12/29 as control. The remainder were FOM. Age and ethnic makeup were similar. USG examined AVFs had the shortest time to cannulation (17 days earlier, p< 0.05) and dialysis catheter (DC) removal (>100 days earlier, p<0.005). FOM results using USG were similar, except for fewer complications (0 vs. 10, p<0.05). Bloodstream infection rates were similar.

	UM with USG N=8	UM Control N=12	FOM with USG N=5	FOM control N=17
Female sex	25%	17%	20%	47%
Average Age	51±15	57±13	52±7	51±13
Race				
African American	12.5%	8.3%	20%	6%
Asian	12.5%	16.6%	40%	75%
Latino	75%	75%	40%	18%
White	0%	0%	0%	0%
PMH of DM	62.5%	50%	100%*	35%
Cannulation time, days	41±17*	58±18	81	150
DC removal time, days	70±34**	180±72	247±111	364±155
Early complications	1/8	8/12	0/5*	10/17
Late complications	3/8	8/12	1/5	7/17
Bacteremia, patients	2/8	2/12	2/5	10/17
Bacteremia, number	3	2	2	17
*p<0.05, **p<0.005				

Conclusions: USG resulted in early and safe AVF cannulation and earlier removal of DCs. USG also helped identify FOM allowing for earlier cannulation in this group (p 0.07).

TH-PO1088

Central Venous Oxygen Saturation as a Novel Means to Monitor Arterio-Venous Fistula Maturation

Israel Campos,[1] Hanjie Zhang,[1] Schantel Williams,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Inst, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Most patients start hemodialysis (HD) with a central-venous catheter (CVC) as vascular access. Whenever possible, an arterio-venous fistula (AVF) is created, which will serve as a permanent vascular access after an appropriate maturation time. Progress of fistula maturation is primarily evaluated clinically. Central venous oxygen saturation ($ScvO_2$) can be measured using Crit-Line® monitor in HD patients with a CVC. The main objective of this study was to assess the change in $ScvO_2$ after AVF creation.

Methods: We analyzed $ScvO_2$ measurements before and after AVF creation using Crit-Line® monitor (Fresenius Medical Care, Waltham, MA). We compared the four closest values of $ScvO_2$ before AVF creation, the first three $ScvO_2$ measurements after AVF creation and the last three $ScvO_2$ measurements before AVF cannulation; finally we compared these values with the first two $ScvO_2$ measurements after AVF cannulation day.

Results: We studied 6 patients. Mean $ScvO_2$ before AVF creation was 63.2 ± 0.3% and increased to 74.1 ± 0.8% after AVF creation. The average $ScvO_2$ of the final 3 HD sessions immediately preceding the first AVF cannulation was 76.1 ± 0.8%. After AFV cannulation arterial and no longer central venous blood circulated in the extracorporeal system with a mean oxygen saturation of 92.9 ± 0.2% (Figure 1).

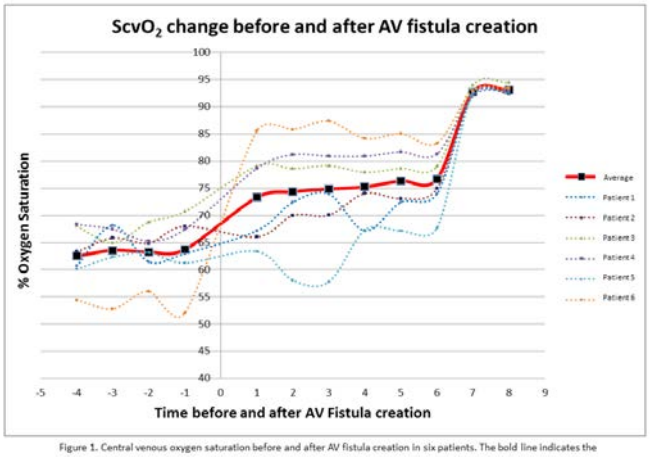

Figure 1. Central venous oxygen saturation before and after AV fistula creation in six patients. The bold line indicates the group average.

Conclusions: AVF creation results in increased contribution of arterial blood to the central venous backflow to the right heart. This increase in $ScvO_2$ is recorded by the Crit-Line® device. Prospective studies are warranted to further explore the feasibility of monitoring AVF maturation – or the failure thereof – using $ScvO_2$. We observed a $ScvO_2$ rise after AVF creation. If successful, $ScvO_2$ values could be used as a novel means to objectively track the AVF maturing process.

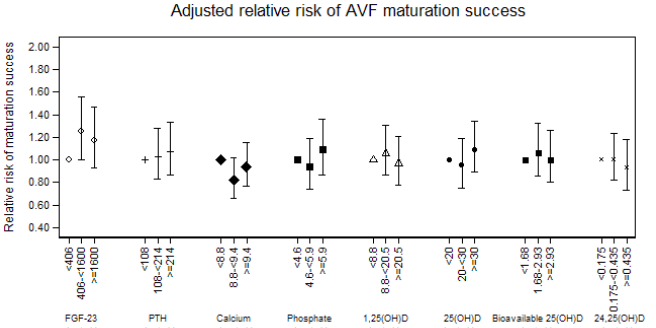
Mineral Metabolism Markers and Arteriovenous Fistula Maturation

Rachel W. Kubiak,[1] Bryan R. Kestenbaum,[1] Leila R. Zelnick,[1] Jonathan Himmelfarb,[1] Gerald J. Beck,[3] The HFM Study Group.[2] *[1]Univ of Washington; [2]NIDDK, NIH; [3]Cleveland Clinic Foundation.*

Background: The arteriovenous fistula (AVF) is central for providing life sustaining hemodialysis treatments. However, half of all AVFs fail to mature within the toxic environment of end stage renal disease (ESRD). Disturbances in mineral metabolism affect most ESRD patients and may impair AVF maturation by disrupting endothelial function and promoting vascular calcification. We hypothesized that lower serum concentrations of vitamin D metabolites and higher concentrations of FGF-23 and phosphate would be associated with AVF maturation failure.

Methods: We evaluated 562 participants from the Hemodialysis Fistula Maturation study, a multicenter study of ESRD patients undergoing planned AVF creation. At the pre-surgical study visit, we measured serum concentrations of 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, and 24,25-dihidroxyvitamin D using liquid chromatography-mass spectrometry, fibroblast growth factor-23 (FGF-23) and parathyroid hormone (PTH) using immunoassays, and phosphate and calcium. We used Poisson regression with robust errors to estimate associations of mineral metabolism markers with unassisted AVF maturation within nine months of surgical placement.

Results: A total of 263 participants (47%) achieved unassisted AVF maturation. In continuous analyses, serum concentrations of vitamin D metabolites, FGF-23, PTH, calcium, and phosphate were not associated with AVF maturation after basic adjustment. Further evaluation of associations with more complete adjustment and using restricted splines demonstrated no association of any markers with AVF maturation. Similarly, the calcium*phosphate product was not associated with AVF maturation.



Conclusions: Serum concentrations of mineral metabolism markers prior to surgery are not associated with AVF maturation in a large prospective cohort study of ESRD patients.

Postoperative Medial Fibrosis Predicts Maturation Failure in Two-Stage Arteriovenous Fistulas

Laisel Martinez,[1] Juan Camilo Duque Ballesteros,[2] Marwan Tabbara,[1] Angela Paez,[1] Guillermo Selman,[1] Loay H. Salman,[3] Roberto I. Vazquez-Padron.[1] *[1]DeWitt Daughtry Family Dept of Surgery, Leonard M. Miller School of Medicine, Univ of Miami, Miami, FL; [2]Dept of Medicine, Miller School of Medicine, Univ of Miami, Miami, FL; [3]Section of Interventional Nephrology, Miller School of Medicine, Univ of Miami, Miami, FL.*

Background: The purpose of this study is to evaluate the impact of vascular fibrosis on arteriovenous fistula (AVF) outcomes.

Methods: Native vein and juxta-anastomotic AVF biopsies were obtained from patients undergoing two-stage AVF creation. Pre-existing, postoperative and change in intimal and medial fibrosis (% area of collagen) were quantified in Masson's trichrome stained cross-sections using color thresholding methods. Associations between vascular fibrosis and clinical outcomes (maturation failure and unassisted primary patency) were assessed using logistic regressions and Cox proportional hazards models adjusted for sex.

Results: Intimal and medial fibrosis in native veins (n=63) ranged from 10.1 to 71.7% and 16.2 to 64.4%, respectively. Nonetheless, neither measure of pre-existing fibrosis was associated with AVF outcomes. Postoperative intimal and medial fibrosis in AVF (n=78) ranged from 16.5 to 66.7% and 25.7 to 74.3%, respectively. Increased postoperative medial fibrosis, but not intimal fibrosis, predicted maturation failure (odds ratio [OR] 1.078, p=0.022), and this effect was more pronounced using the collagen/cell area ratio (OR 1.368, p=0.038). None of the measures of postoperative fibrosis were associated with primary patency. Change in fibrosis over time was assessed in 54 patients from whom both vein and AVF biopsies were available. Supporting the postoperative fibrosis association, a higher increment in medial fibrosis, but not intimal fibrosis, predicted maturation failure (OR 1.106, p=0.032) but not primary patency.

Conclusions: Our results suggest that elevated fibrosis and loss of medial smooth muscle cells are signatures of adverse AVF remodeling and predispose for early access failure. In contrast, increased fibrosis does not appear to determine the long-term patency of working fistulas.

TH-PO1091

Association between Preoperative Venous Medial Collagen Fiber Configuration and Arteriovenous Fistula Development

Yan-Ting E. Shiu,[1] Silvio H. Litovsky,[2] Alfred K. Cheung,[1,3] Daniel Pike,[1] C.S. Jason Tey,[1] Y. Zhang,[1] Carlton J. Young,[2] Michael Allon.[2] *[1]U of Utah; [2]U of Alabama; [3]VASLCHCS.*

Background: Arteriovenous fistula (AVF) maturation requires an increase in the diameter and blood flow of the fistula vein following its creation. The native vein wall's microstructure may affect the magnitude of these changes. We hypothesized that the orientation of collagen fibers in the venous media modulates the vein's capacity to dilate and mature.

Methods: Veins used for anastomosis were sampled during AVF creation surgery. The second harmonic generation (SHG) signals of collagen fiber bundles in vein samples were analyzed for anisotropy index (AI) and orientation angle (OA). AI ranged from 0 (random fiber network) to 1 (completely aligned fiber network). OA ranged from 0° (parallel to lumen) to 90° (perpendicular to lumen). The fiber configuration index (FCI) was defined as the product of AI and sin(OA). Unadjusted gamma regressions with natural cubic splines were used to model the association of the FCI in 84 patients and their 6-week AVF blood flow assessed using ultrasound.

Results: Venous medial collagen fiber patterns varied among patients with end-stage renal disease (Fig. 1A). The 6-week AVF blood flow was positively associated with the collagen FCI (per 0.1 unit difference in FCI: Δ blood flow = 131 ml/min; 95% CI, 8 to 254 ml/min; p=0.038) (Fig. 1B). The FCI of clinically matured AVFs (those successfully used for dialysis) was significantly higher than that of non-matured AVFs (0.13±0.07 vs. 0.08±0.05, p=0.02).

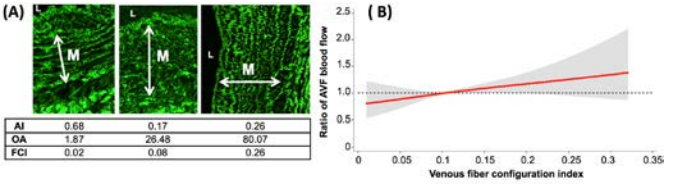

Fig. 1. (A) Representative SHG images of difference fiber patterns and FCI in the venous medial (M) layers. L: lumen. **(B)** The y coordinate is the ratio of the unadjusted geometric mean 6-week AVF blood flow at the indicated FCI to the unadjusted geometric mean 6-week AVF blood flow rate at the median FCI reference. N=84.

Conclusions: The venous medial collagen fiber orientation was associated with subsequent AVF development. Veins with collagen fibers more uniformly aligned perpendicular to the lumen were associated with higher AVF blood flow and clinical maturation by yet undefined mechanisms.

Uremic Regulation of Endothelial Krüppel-Like Factor 2 in Arteriovenous Fistula (AVF) Maturation Failure

Keith Louis Saum,[1] Begoña Campos,[1] Diego Celdran-Bonafonte,[2] Albert Phillip Owens,[1] Prabir Roy-Chaudhury.[2]
[1]Univ of Cincinnati; [2]Univ of Arizona.

Background: AVF maturation failure resulting in prolonged dialysis catheter exposure, is an important cause of clinical morbidity and mortality. The endothelial transcription factor Krüppel-like factor 2 (KLF2) is an important regulator of vascular homeostasis linking changes in hemodynamics to inflammation, vasodilation, and vascular remodeling. While KLF2 expression plays a critical role in atherogenesis, little is known about its role in AVF maturation failure. Our objective was to determine how endothelial KLF2 is regulated in-vitro by uremic metabolites and translate these findings into a uremic mouse model of AVF maturation failure.

Methods: Human umbilical vein endothelial cells (HUVECs) were cultured with uremic toxins, including carboxymethyl lysine (CML), an advanced glycation end product (AGE), and analyzed for KLF2 expression by qPCR and western blotting. In addition, C57BL/6J mice underwent 5/6 nephrectomy to produce renal insufficiency followed by AVF creation (after 14 days). The venous segment of the AVF was harvested 14 days post-AVF creation and KLF2 expression assessed by immunohistochemistry (IHC) and qPCR.

Results: CML treatment of HUVECs decreased KLF2 mRNA and protein expression, which was rescued by siRNA-RAGE ablation. Similarly, KLF2 was decreased in the endothelium of uremic versus non-uremic mice (IHC). Interestingly, KLF2 was upregulated (IHC) in the neointima of uremic mice, which corresponded to a three-fold increase in KLF2 venous segment mRNA expression in uremic versus non-uremic mice.

Conclusions: Our results suggest that uremia can suppress *endothelial* KLF2 in-vitro and in-vivo. However, uremia increases KLF2 expression within the neointima *(smooth muscle cells)* of the AVF. Ongoing studies utilizing endothelial and myeloid-specific KLF2 knockout mice will further delineate these mechanisms and also identify the specific roles of KLF2 in AVF stenosis. These data could then be used to develop novel therapies that target the KLF2 pathway in order to enhance AVF maturation rates.

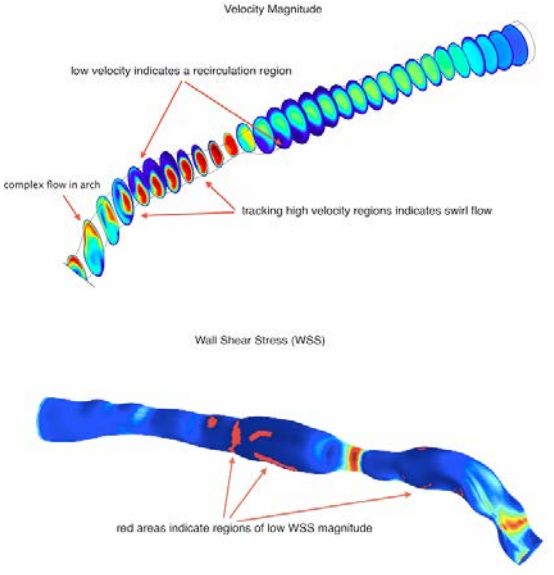
Computational Modeling from Intravascular Ultrasound in Arteriovenous Fistula Access

Mary S. Hammes,[1] Kevin Cassel,[2] Michael Boghosian,[2] S.M. Javid Mahmoudzadeh A.[2] *[1]Univ of Chicago; [2]Illinois Inst of Technology.*

Background: While angiography provides two-dimensional lumeography, the intraluminal surface of an arteriovenous fistula (AVF) is often a complex three-dimensional structure. Intravascular ultrasound (IVUS) is a technique using a high frequency ultrasound transducer on the tip of a catheter inserted directly into a blood vessel to obtain a series of high-resolution three-dimensional images. The aim of the current study was to reconstruct three-dimensional images of the cephalic arch in patients with brachiocephalic fistula access as the basis for computational modeling of the hemodynamics.

Methods: 13 IVUS procedures were performed in 8 subjects. A Doppler for blood flow velocity, venogram and blood sample were collected for whole blood viscosity. An IVUS catheter was then inserted into the cephalic arch to the axillary vein and pull back measurements were made. Image analysis and reconstruction with computational modeling were performed to determine the hemodynamics, including wall shear stress (WSS), velocity and pressure profiles.

Results: An example of a three-dimensional reconstruction is shown. The graphic on the top shows velocity magnitude contours highlighting regions of interest such as abnormally low and high velocities and locations of recirculation and swirl.



The graphic on the bottom shows WSS contours on the vein intimal surface. Areas of WSS below the normal range are indicated by a solid red color. WSS above the normal range are observed at the constriction.

Conclusions: The ability to assess vessel wall morphology and luminal characteristics of diseased veins in an AVF is a novel application of IVUS and may ultimately improve the understanding of hemodynamic determinates of AVF function.

TH-PO1094

Quantification of Venous Adaptation in Patients with Brachiocephalic Fistula Access

Mary S. Hammes,[1] Kevin Cassel,[2] Michael Boghosian,[2] S.M. Javid Mahmoudzadeh A.[2] *[1]Univ of Chicago; [2]Illinois Inst of Technology.*

Background: An autogenous arteriovenous fistula (AVF) is the optimal vascular access for hemodialysis. A brachiocephalic fistula (BCF) is often placed, but unfortunately cephalic arch stenosis (CAS) commonly develops leading to access failure. We have hypothesized that a contribution to fistula failure is low wall shear stress (WSS) (less than 0.076 *Pa*), resulting in neointimal hyperplasia (NIH) leading to venous stenosis. The aim of this investigation is to develop a novel graphical method to assist in characterization of vein adaptation response mechanisms which lead to CAS.

Methods: 12 patients that had BCF placed were included in this study. A venogram, Doppler to measure blood flow velocity, and whole blood viscosity measurement were performed at baseline, time of AVF maturation and when CAS was evident. Computational modeling was performed to determine areas of low WSS and geometric parameters. Zonal plots were created showing the relationship between local diameter change and WSS at various time points.

Results: WSS in a cephalic venous arch prior to AVF creation ranged from 0 *Pa* to 2.5 *Pa*. The majority of WSS measurements fell within the normal range (0.076 to 0.76 *Pa*) with an average WSS of 0.22 *Pa*. Post-fistula plots at time of maturation and beyond showed 4 scenarios: decrease in diameter change with WSS < 0.076 *Pa* (**NIH**); increase in diameter change with WSS < 0.076 *Pa* (**aneurism**); increase in diameter change with WSS > 0.076 *Pa* (**excess dilation**); decrease in diameter change with WSS > 0.076 *Pa* (**inward remodeling**). As an AVF matures, these zonal plots depict which of the mechanisms dominate locally, with particular emphasis on vein adaptation via NIH following maturation.

Conclusions: WSS outside the physiologic range 0.076 to 0.76 *Pa* predicts abnormal venous adaptation in an AVF. As an AVF matures, the optimal geometry of the cephalic arch is altered via NIH in an attempt to bring the WSS back within the physiologically acceptable range. The very mechanism that is intended by the body to mitigate the undesirable low WSS "over adapts" because of the excessively high blood flow velocity created when an AVF is placed, which is found to lead to CAS in a large proportion of patients.

TH-PO1095

In Vitro Analysis of Vascular Access Flow by Laser Doppler Vibrometry

Camille Johnson,[1] Israel Campos,[1] Schantel Williams,[1] Jie Ma,[1] Laura Rosales,[1] Fansan Zhu,[1] Peter Kotanko.[1,2] *[1]Renal Research Inst, New York, NY; [2]Icahn School of Medicine at the Mount Sinai Hospital, New York, NY.*

Background: A contact-free assessment of arterio-venous access (AVA) flow is currently elusive. Laser Doppler vibrometry provides a novel means to quantitate flow-induced AVA vibrations ("thrill") and may thus assist in diagnosing AVA malfunction.

Methods: We engineered an AVA bench model (Fig. 1) to systematically study the effects of lumen stenosis on radial velocities of an artificial AVA conduit. Flow (*Qa*) was provided by a pump delivering pulsatile patterns resembling arterial flow (Model 1423, Harvard Apparatus. Holliston, MA, USA). We kept *Qa* constant at 1500 mL/min (stroke volume 30 mL; stroke rate 50/min). AVA conduit inflow and outflow stenoses were applied by graduated lumen constrictions (Fig. 1). Stenoses were either partial (50% stenosis), or complete (100% stenosis). AVA conduit radial velocities were measured by laser Doppler vibrometry (PDV-100, Polytec, Waldbronn, Germany). Radial velocity data are presented in mm/s and as mean±SD.

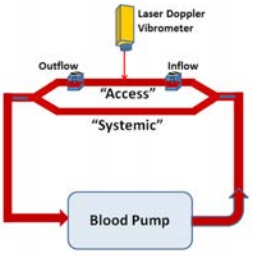

Fig. 1: AVA Bench Model

Table 1: Summary of velocity

Access Radial Velocity (mm/s)				
		Inflow Stenosis		
		None	Partial	Complete
Outflow Stenosis	None	0.21±0.014	0.19±0.03	0.08±0.021
	Partial	0.29±0.015	0.17±0.03	0.16±0.015
	Complete	0.47±0.02	0.44±0.02	0.05±0.015

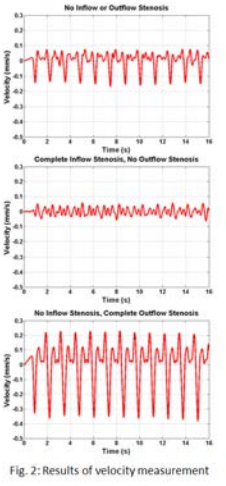

Fig. 2: Results of velocity measurement

Results: The highest radial velocities were observed with complete outflow stenosis and concurrent absent or partial inflow stenosis. Irrespective of the degree of outflow stenosis, any inflow stenosis drastically reduced radial conduit velocities (Table 1; Fig. 2).

Conclusions: This bench research shows that both inflow and outflow stenosis affects the radial velocities of AVA conduits to an extent that can be quantified by laser Doppler vibrometry. Moreover, this study indicates that laser Doppler vibrometry can potentially distinguish between inflow and outflow stenosis. While these results are encouraging, in vivo studies are warranted to determine if these experimental findings can be replicated in a clinical setting. To that end, analysis of access flow pressures and thrill frequency spectra may add to our understanding of the system dynamics.

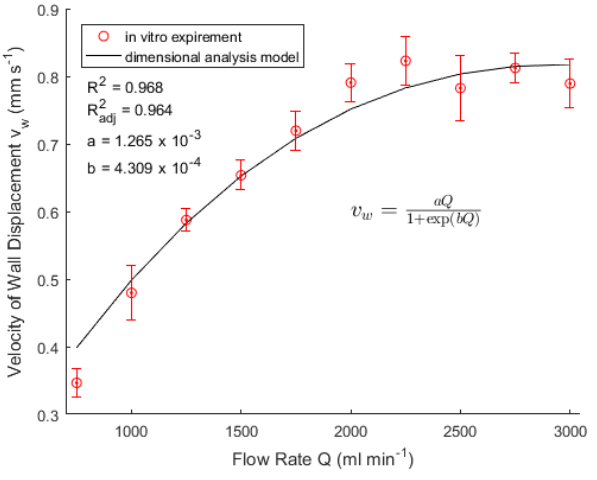
TH-PO1096

A Novel Mathematical Model to Non-Invasively and Contact-Free Assess Arterio-Venous Access Characteristics Alhaji Cherif,[1] Doris H. Fuertinger,[1] Vaibhav Maheshwari,[1] Israel Campos,[1] Camille Johnson,[1] Schantel Williams,[1] Jie Ma,[1] Laura Rosales,[1] Fansan Zhu,[1] Peter Kotanko.[1,2] *[1]Renal Research Inst, New York, NY; [2]Icahn School of Medicine, Mount Sinai Hospital, New York, NY.*

Background: While clinically desirable, a non-invasive and contact-free assessment of arterio-venous (AV) access characteristics is elusive. The aim of the current work is to assess the applicability of a novel theoretical model with laser Doppler vibrometer (LDV) data to analyze AV access characteristics.

Methods: We engineered a bench model where a pump (Model 1423, Harvard Apparatus. MA) produced pulsatile flow with arterial characteristics in a tube that resembled an AV access. The vibrations ("thrill") the AV access model were then quantitated with LDV (PDV-100, Polytec, DEU). Using dimensional analysis informed by a 1D Navier-Stokes equation describing the relationship between flow and cross-sectional area of a compliant vessel, we derive an expression (Fig. 1) relating the radial velocity of the vessel wall (V_w) and the flow rate (Q) with characteristic parameters $a=1/(2*pi*R_0*L)$ and $b=mu/(E*h)$, where R_0, L, E, h and μ are reference radius, vessel length, Young's modulus, wall thickness, and fluid viscosity, respectively.

Results: Using LDV signals, we fit the model to the data and estimated the characteristic parameters with goodness of fit coefficients R^2=0.968 and adjusted R_{adj}^2=0.964 (Fig. 1). The results show the relationship between the V_w and Q exhibits a functional shape where the velocity increases linearly until the vessel compliance (viscoelasticity) dominates.



Conclusions: The preliminary results illustrate the use of LDV and modeling to evaluate AV access characteristics with a good model-data fit. Further studies and modeling efforts are needed to explore the robustness of the modeling framework to identify the characteristics of AV access both in bench and clinical studies.

TH-PO1097

De Novo Induction of Mineralocorticoid Receptors in Vascular Tissue Mediates Hemodialysis Fistula Dysfunction Pei Wang,[1,2] Andrew S. Brem,[1] Xianhui Liang,[1] Minglei Lu,[1] Zhangsuo Liu,[2] Rujun Gong.[1] *[1]Nephrology, Brown Univ; [2]The First Affiliated Hospital of Zhengzhou Univ, China.*

Background: Fistula stenosis is a major cause of vascular access failure in patients undergoing maintenance hemodialysis (HD). Since mineralocorticoids can induce inflammation and fibrosis in vascular tissues, we hypothesized that these steroids may play a role in fistula failure.

Methods: Mineralocorticoid receptor (MR) expression was examined in normal human veins and in the dysfunctioning fistulae by immunohistochemistry. The effects of aldosterone were also measured in cultured vascular smooth muscle cells (VSMC) programmed to over express MR. Lastly, as a clinical correlation, HD patients on spironolactone because of cardiac disease were compared to age matched controls on HD and fistula patency was evaluated.

Results: Dysfunctioning stenotic fistulae exhibited a marked thickening of the intima and media, with affected VSMC demonstrating proliferation [staining for proliferating cell nuclear antigen (PCNA)] and hypertrophy [large cellular size plus staining for phosphorylated p70S6K, a transducer of the mTOR pathway associated with cellular hypertrophy]. While normal veins express minimal MR, a marked increase in MR expression was observed in affected VSMC with a pattern of distribution across all tunicae layers of the fistula, and this positively correlated with the intima-media thickness. Cultured VSMC over expressing MR (GFP-MR-147) showed excessive cellular proliferation [measured by the tetrazolium assay and PCNA expression] and hypertrophy [measured by protein to DNA ratios and expression of phosphorylated p70S6K] after exposure to aldosterone (10 nM). These effects were largely abolished by the MR antagonist spironolactone (1 μM). Lastly, patients on HD who received spironolactone exhibited an improved rate of fistula patency compared to control HD patients.

Conclusions: MR is induced in fistula VSMC probably from baro-trauma associated injury. Excess expression of MR in the presence of physiologic concentrations of aldosterone promotes cell proliferation and hypertrophy leading to fistula stenosis. MR antagonism may be a promising therapy for retarding the progression of fistula stenosis in patients on HD.

TH-PO1098

Association of Genetic Polymorphisms of Renin–Angiotensin–Aldosterone System-Related Genes with Arterio-Venous Fistula Malfunction in Hemodialysis Patients Chih-Ching Lin.[1,2] *[1]Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, National Yang Ming Univ, Taipei, Taiwan.*

Background: Hemodialysis (HD) is the most commonly-used renal replacement therapy for patients with end-stage renal disease worldwide. Arterio-venous fistula (AVF) is the vascular access of choice for HD patients with lowest risk of infection and thrombosis. In addition to environmental factors, genetic factors may also contribute to malfunction of AVF. Previous studies have demonstrated the effect of genotype polymorphisms of angiotensin converting enzyme on vascular access malfunction.

Methods: We conducted a multicenter, cross-sectional study to evaluate the association between genetic polymorphisms of renin-angiotensin-aldosterone system and AVF malfunction.

Results: Totally, 577 patients were enrolled. Their mean age was 60 years old and 53% were male. HD patients with AVF malfunction had longer duration of HD (92.5 ± 68.1 *vs.* 61.2 ± 51.9 months, $p < 0.001$), lower prevalence of hypertension (44.8% *vs.* 55.3%, $p = 0.025$), right-sided (31.8% *vs.* 18.4%, $p = 0.002$) and upper arm AVF (26.6% *vs.* 9.7%, $p < 0.001$), and higher mean dynamic venous pressure (DVP) (147.8 ± 28.3 *vs.* 139.8 ± 30.0, $p = 0.021$). In subgroup analysis of different genders, location of AVF and DVP remained significant clinical risk factors of AVF malfunction in univariate and multivariate binary logistic regression in female HD patients. Among male HD patients, right-side AVF and upper arm location are two important clinical risk factors. In addition, two single nucleotide polymorphisms (SNPs), rs275653 (Odds ratio 1.90, $p = 0.038$) and rs1492099 (Odds ratio 2.29, $p = 0.017$) of angiotensin II receptor 1 (*AGTR1*), were associated with increased risk of AVF malfunction. After adjustment for age and other clinical factors, minor allele-containing genotype polymorphisms (AA and CA) of rs1492099 still remained to be a significant risk factor of AVF malfunction (Odds ratio 3.63, $p = 0.005$).

Conclusions: In conclusion, we demonstrated that rs1492099, a SNP of *AGTR1* gene,could be a potential genetic risk factor of AVF malfunction in male HD patients.

Oxidative Stress-Induced High Mobility Group Box 1 (HMGB1) Stimulates Monocyte Chemoattractant Protein-1 (MCP-1) Expression in the Human Umbilical Vein Endothelial Cells (HUVECs) Jeong-Sun Han, Yaeni Kim, Yong-Soo Kim. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea College of Medicine, Seoul, Korea.*

Background: Oxidative stress and inflammation are the main causes of vascular intimal hyperplasia and subsequent stenosis of hemodialysis arteriovenous fistula. In our previous study, oxidative stress directly stimulated the MCP-1 expression. In this study, we studied whether HMGB1 was involved in the process of oxidative stress-induced MCP-1 expression.

Methods: HMGB1 mRNA and MCP-1 mRNA were measured by quantitative real-time PCR. MCP-1 protein was measured by ELISA. HMGB1 protein, MAPK, NF-κB and AP-1 activities were measured by western blot. Glycyrrhizin or a monoclonal antibody to TLR4 was used to inhibit HMGB1.

Results: After treating HUVECs with H_2O_2, MCP-1 mRNA and protein expression was significantly increased in a time- and dose-dependent manner. In addition, after treating HUVECs with H_2O_2, HMGB1 mRNA and protein expression was significantly increased in a time- and dose-dependent manner. When the cells were pre-treated with inhibitors of p38 (SB203580), JNK (SP60012), NF-κB (PDTC), or AP-1 (curcumin), H_2O_2–induced HMGB1 mRNA expression was significantly decreased. When the cells were treated with HMGB1, the MCP-1 mRNA and protein expression was significantly increased in a time- and dose-dependent manner. When the cells were pre-treated with glycyrrhizin or a monoclonal antibody to TLR4, the HMGB1-induced MCP-1 expression was blocked in a time- and dose-dependent manner. HMGB1 treated cells stimulated phosphorylation of p38, JNK, c-jun and p-65 together with a decrease in IkBa.

Conclusions: Oxidative stress-induced MCP-1 expression in HUVECs is partially mediated by HMGB1 via the TLR4/p38/JNK/NF-κB/AP-1 pathways. This study suggests that HMGB1 inhibition in vein endothelial cells might be a challenge to prevent venous neointimal hyperplasia in hemodialysis arteriovenous fistula.

High-Mobility Group Box Protein 1 (HMGB1) Induces Endothelial-to-Mesenchymal Transition (EndMT) in Human Umbilical Vein Endothelial Cells (HUVECs) Jeong-Sun Han, Yaeni Kim, Yong-Soo Kim. *Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea College of Medicine.*

Background: Myofibroblasts are the major cells within the venous neointima in stenosed hemodialysis vascular access. However, the origin of the myofibroblasts has not been clealy determined. In our previous study, oxidative stress stimulated HMGB1 expression in HUVECs. In this study, we investigated whether HMGB1 induced EndMT in HUVECs.

Methods: After stimulating the HUVECs with HMGB1, the key biomarkers for endothelial and mesenchymal cells were evaluated by fluorescent immunocytochemistry and western blot. EndMT transcription factors (snail1, snail2, and twist1) were measured by western blot. Role of HMGB1 receptors (TLR4 and RAGE) and TGF-β1 in the mechanism of HMGB1-induced EndMT was studied.

Results: HUVECs were normal round shape with cobble stone appearance with strong labeling of CD31, VE-cad, and vWF, but a-SMA was not expressed in the cells. When the cells were exposed to HMGB1, cells changed into the spindle shape with decreased expression of CD31, VE-cad, vWF and high expression of a-SMA. Western blot revealed same changes in biomarkers before and after HMGB1 treatment. When the cells were pre-incubated with antibodies to HMGB1 receptors, TLR4 or RAGE, the changes in the HMGB1-induced endothelial and mesenchymal biomarkers were reversed in a dose dependent manner. HMGB1 stimulated the expression of EndMT transcription factors (snail1, snail2, and twist1)in a dose dependent and in a time dependent manner up to 48 hours. In addition, HMGB1 stimulated the expression of TGF-β1, and the phosphorylation of smad2/3 and NF-κB p65. When the cells were pre-treated with anti-RAGE antibody or Glycyrrhizin, the expression of TGF-β1 by HMGB1 were reduced. When the cells were pre-incubated with SB431542, the changes in the HMGB1-induced endothelial and mesenchymal biomarkers were reversed in a dose dependent manner.

Conclusions: To our knowledge, this is the first report showing that HMGB1 induces EndMT via the RAGE/TGF-β1signaling in the venous endothelial cells. These data might provide a mechanism of myofibroblasts accumulation within the venous neointima in stenosed hemodialysis vascular access.

Selecting End Points for Pivotal Hemodialysis AV Fistula Clinical Trials - Anatomical Surrogates versus Functional Suitability Maria V. DeVita,[1] Eric S. Chemla,[2] Konstantine B. Kipiani,[3] Sriram Iyer.[4] *[1]Div of Nephrology, Lenox Hill Hospital, New York, NY; [2]Vascular Surgery, St. George's NHS Trust, London, United Kingdom; [3]Vascular Surgery, Georgian Center of Angiology and Surgery, Tbilisi, Georgia; [4]Vascular Therapies Inc, Cresskill, NJ.*

Background: Although an ultrasound (US) vein diameter (VD) of 4mm and AVF blood flows >500mL/min are often proposed/used as surrogates to support fistula functionality, these parameters have never been validated in large clinical trials. Anatomical AVF patency, a "success metric" in pre-dialysis patients, correlates poorly with functional use; in the DAC study 45% of AVF not suitable for dialysis (D) were anatomically patent.

Methods: 30 pts undergoing AVF surgery [22 Radiocephalic (RCF), 8 Brachiocephalic (BCF)] received a Sirolimus eluting collagen implant around the anastomosis. Serial US exams were performed. Cannulation decisions were based on clinical exam.

Results: Pre op mean±VD for RCF and BCF were 2.7±0.5 and 3.9±0.6mm. 4 RCF thrombosed within 2 weeks(w); 26 AVF (87%) were successfully cannulated for D (Mean 7w). Relative to cannulation, VD in 22/26 AVF (85%) was ≥6 mm (Range: 5.1-10.1mm), there were no infiltrations. At 12mos 74% of AVF maintained *functional patency*.

US Timing	6-8hrs Post-op	2w	4w	6w	8w		
VD ≥4mm (n=26) RCF n=18 BCF n=8	22/28*(79%) 14(70%) 8(100%)	24/26(92%) 16(89%) 8	25(96%) 17(94%) 8	26(100%) 18(100%) 8			
VD ≥6mm (n=26) RCF n=18 BCF n= 8	2/28*(7%) 0 2/8(25%)	8/26(31%) 2(11%) 6(75%)	16(62%) 8(44%) 8(100%)	21(81%) 13(72%) 8	26(100%) 18(100%) 8		
Cannulation success (n=26) RCF n=18 BCF n= 8			21 14 7			3 2 1	2 2
Time to cannulation			4 - 8w			8-10w	>12w
* 2 RCF thrombosed soon after surgery							

Conclusions: 1. 85% of cannulated AVF had VD ≥6.0mm; none were <5.1mm. 2. Absent surrogate validation, pivotal clinical trials evaluating the impact of a new treatment on AVF outcomes should use clinical end points that require demonstration of AVF cannulation and show continued functional durability during later time points. This would necessitate excluding patients not on dialysis at the time of AVF surgery.

TH-PO1102

The Effect of Beraprost Sodium to Treat Primary Hemodialysis Vascular Access Failure Hyun Woo Kim,[1] Miyeon Kim,[1] Tae Hee Kim.[2] *[1]Dept of Internal Medicine, Jeju National Univ, School of Medicine, Jeju National Univ Hospital, Jeju-si, Jeju-do, Korea; [2]Dept of Internal Medicine, Inje Univ College of Medicine, Busan, Korea.*

Background: Hemodialysis vascular access dysfunction is a major cause of morbidity and hospitalization in the hemodialysis patients. The major cause of hemodialysis vascular access dysfunction is venous stenosis as a result of neointimal hyperplasia. Although several studies suggest a role for antiplatelet agents in the prevention of hemodialysis vascular access failure, it has not been complete. It has been reported that prostaglandin I_2 has pleiotropic effects including antiplatelet, vasodilating, anti-inflammatory and anti-atherogenic properties. In addition, several studies have shown that prostaglandin I_2 can inhibit the neointimal formation generated after vascular injury.

Methods: The purpose of this study was to research the effects of beraprost sodium, an oral synthetic analog of prostaglandin I_2 on vascular access patency in hemodialysis patients with primary hemodialysisvascular access failure. The primary outcome was secondary vascular access failure. Between April 2013 and February 2014, forty-nine patients with end stage renal disease on hemodialysis were prospectively chosen for this study. Twenty-three patients were assigned to be treated with 120 μg/day of beraprost sodium and the other patients (n=26) were assigned to a control group.

Results: After a median follow-up of 3.0 years (interquartile range 1.8-3.1 years), the secondary vascular access failure was detected in twelve patients (46%) in control group andfour patients (17%) inberaprost sodiumgroup, respectively (P = 0.032). Analysis of covariables indicated that this effect occurred principally as a result of beraprost sodium administration. No life-threatening adverse event or severe bleeding was recorded in both groups.

Conclusions: Our data indicated that oral prostaglandin I_2 analog is effective and safe for the prevention of secondary vascular access failure in hemodialysis patients with primary vascular access failure.

Palliative and End of Life Care for End Stage Renal Failure Patients Managed without Dialysis in Denmark. A National Survey Jens Kristian Madsen,[1,2] Fliss E. Murtagh.[2] *[1]Dept of Renal Medicine, Aarhus Univ Hospital, Aarhus, Denmark; [2]King's College London, Cicely Saunders Inst, London, United Kingdom.*

Background: In Denmark, there is a growing focus on conservative kidney management (CKM) for older frail patients with end stage renal failure (ESRF). This survey aimed to assess the current provision of palliative and end of life (EOL) care to Danish patients with ESRF following a non-dialytic pathway or discontinuing dialysis.

Methods: An electronic questionnaire was sent to all Danish hospital-employed nephrologists and department nurses (15 centres). Data were handled anonymously. Descriptive statistics were used for analyses.

Results: 140 senior renal staff were invited. The response rate was 83%, including 93% (14/15) of medical directors/head physicians. All units had CKM patients, but numbers were mostly unknown. When asked whether nephrologists had same practice regarding choice of CKM for ESRF patients, 24% of respondents answered 'yes', 58% answered 'no', and 18% answered 'don't know'. Criteria of patients' suitability for CKM were similar. Criteria for timing discussion of CKM with patients differed (at a certain level of renal function, 33%; at low-clearance clinic referral, 17%; not known, 15%; when symptoms, 11%; other, 24%). One renal centre had a dedicated clinic, one centre had treatment guidelines, and 12% staff had training in CKM. Follow-up mostly occurred in general renal outpatient clinics (75%). Advance care planning (ACP) was formally practiced in two units. One third of respondents reported involvement of specialist palliative care (SPC) with CKM patients at EOL and when stopping dialysis. Only 7% did not see a future role for SPC for ESRF patients. Suggestions for improvement were more education (87%), better collaboration (67%), and implementation of ACP (64%).

Conclusions: Great variation exists in practice patterns of delivery of palliative and EOL care for Danish ESRF patients managed without dialysis or discontinuing dialysis. Formal CKM pathways are not yet developed. Nephrologists report that SPC is under-utilized among Danish ESRF patients at the end of life. Education and better collaboration between specialties are key elements in further development.

TH-PO1104

The Practice of Withholding of and Withdrawing from Dialysis Treatment to Patients with Persistent Vegetative State in Affluent Arabic Countries: Renal Physician Survey Omran Bakoush,[3] Ahmed Chaaban,[1] Mona Alrukhaimi,[2] Bassam Bernieh.[1] *[1]Nephrology Dept, Tawam Hopsital, Al Ain, AbuDhabi, United Arab Emirates; [2]Internal Medicine, Dubai Medical College, Dubai, United Arab Emirates; [3]College of Medicine and Health Sciences, United Arab Emirates Univ, Al Ain, AbuDhabi, United Arab Emirates.*

Background: Persistent vegetative state (PVS) is severe disability which requires full nursing care and is associated with poor outcome. The number of dialysis patients with persistent vegetative state (PVS) is increasing worldwide. In United Arab Emirates, 29 patients out of 650 patients on regular dialysis treatment were in PVS. This study aimed to explore the practice patterns of withhold and withdrawal of dialysis in patients with PVS in affluent Gulf Arabic countries.

Methods: Settings: Renal physicians taking care of dialysis patients in public and private sectors in Gulf Arabic counties. Interventions: A 24-item online self-administered questionnaire based on ASN Shared Decisions clinical practice guidelines. Primary and secondary outcome measures: The renal physicians' approach to manage PVS patients with severe kidney failure.

Results: The survey was completed by 29 nephrologists taking care of patients with ESKD. 83% of respondents will continue dialysis if a dialysis patient went into persistent vegetative state, furthermore dialysis will be initiated by 55% of respondents if a PVS patient developed severe renal failure. Institutional haemodialysis is most common dialysis modality (81%) offered to PVS. The respondents identify the cultural background (76%), the local policy (72%), and the religious background (65%) to be the major impacts on the decision making process for ongoing dialysis treatment for patients with PVS.

Conclusions: The contextual sociocultural factors and the preferences of the patient's proxy strongly influence the physician decisions for initiation and continuation of dialysis treatment for patients in PVS. Early integration of quality palliative care within the health care system for such severely ill patients is required to face the increasing burden of PVS in such developing affluent countries.

TH-PO1105

'La Familia es lo mas Importante': Palliative Care Perspectives of Latinos on Dialysis Lilia Cervantes,[1,2] Claudia Camacho,[2] Maria Francisca Zabalaga Palma,[2] Stacy M. Fischer.[1] *[1]Univ of Colorado; [2]Denver Health.*

Background: Patients with end-stage renal disease (ESRD) have a high symptom burden and mortality yet palliative care is often overlooked. Hispanics have a nearly 2-fold higher incidence of ESRD and suffer disproportionately at end-of-life (EOL) compared to non-Hispanic whites. The purpose of our study was to understand the palliative care experiences and preferences of Hispanics on dialysis.

Methods: We conducted qualitative, semi-structured interviews with Hispanic ESRD patients. We used an interview guide with open-ended questions to elicit the patient's palliative care preferences and experience with advance care planning. Interviews were audio-recorded, transcribed, and then analyzed by four members using a deductive approach.

Results: We interviewed 20 Hispanic ESRD patientsbetween October 2015 and January 2016. Our qualitative theme analysis yielded five main themes: Family, advance care planning (ACP), advance directives (AD), fatalism, and hospice. Patientsprioritizefamily needs over personal needs, and EOL preferences are thus centered around family. Patients express that ACP decisions should be made by the family as a whole. Patients also feel it is important to have ACP conversations early on before extreme illness, and as long as the provider initiating conversations maintained a positive outlook. Some patients feel that because their family is aware of their wishes, there is little value in signing an advance directive. For those with a documented signed AD, few were able to recall any details of their decisions. Fatalistic attitudes and a resignation to illness were expressed, such as illness being a punishment for past personal or parental behavior. Patients also feel that death and the process of death is predetermined and beyond their control, and thus take a passive disposition towards ACP. Regarding hospice, patients prefer to die at home with family.

Conclusions: With respect to palliative care, patients express the importance of integrating their family in ACP decision-making and describe barriers such as fatalism.

Improving Comfort with Comfort Care Discussions Juliya Hemmett,[1,2] Elena Qirjazi,[1,2] Faisal Rehman,[1,2] Valerie Schulz,[2,3] Norman Muirhead.[1,2] *[1]Nephrology, London Health Sciences Centre, London, ON, Canada; [2]Schulich School of Medicine & Dentistry, London, ON, Canada; [3]Perioperative Medicine & Anesthesia, London Health Sciences Centre, London, ON, Canada.*

Background: Previous studies have demonstrated a gap in nephrology training on end of life discussions. We addressed this deficiency in the curriculum by creating a goals of care (GOC) discussions workshop using role plays and didactic teaching.

Methods: We designed and implemented a 3 hour workshop consisting of a didactic session on an evidence based approach to GOC discussions in chronic kidney disease patients, followed by small group simulations to practice this approach. Participants included nephrologists, a palliative care physician, nurses, social workers, Standardized Patients (SP) and nephrology fellows. Small group participants were divided into four teams led by a pre-selected staff nephrologist. Nephrology fellows led one, and observed one, of two simulated family meetings discussing: 1) withdrawing from dialysis in a frail patient and 2) conservative management in end-stage renal disease. At the end of each scenario the fellows received constructive feedback from the other participants. Participants evaluated their experience using anonymous surveys containing 7 questions evaluating the effectiveness of the workshop using a 5 point Likert scale and additional space for comments.

Results: 14 out of 16 participants completed the anonymous surveys. The workshop was ranked "very useful," "important," and "relevant" to their practice. In particular, the use of SPs was highlighted. Constructive feedback included providing the scenarios ahead of time and further clarifying the roles of the allied health. Importantly, nephrology staff leaders identified knowledge gaps such as what happens to patients when they stop dialysis, and were able to address them.

Conclusions: Our workshop is the first in Canada to teach GOC discussions using didactic teaching and dynamic simulations involving the main stakeholders in nephrology. This educational intervention proved to be effective in improving current knowledge and comfort levels of care providers.

TH-PO1107

Factors Influencing Supportive Care Discussions in Hemodialysis Patients Billie Axley, Michael R. O'Connell, Dugan Maddux, Marta Reviriego-Mendoza, John W. Larkin, Stephanie Johnstone, Michelle L. Gilliland, Rebecca L. Wingard, Tammy C. Green, Franklin W. Maddux. *Fresenius Medical Care North America.*

Background: Advanced care planning has been reported to be rarely discussed, despite that most hemodialysis (HD) patients desire better communication for supportive care needs (Goff SL, et al. 2015). We explored what factors are considered influential to initiating these discussions by surveying a group of HD nurses (RNs).

Methods: In March of 2016, a voluntary, electronic survey was offered to RNs at a Fresenius Medical Care nursing focused meeting. Survey questions and responses are as outlined in Figure 1. Questions 1 & 2 had 116 responses, and questions 3 & 4 had 68 responses.

Results: Based on this survey of dialysis clinic RNs, decreased quality of life (QOL) and multiple comorbidities were the most common reasons for care providers to have initiated conversations about supportive care (88% & 52%, respectively) (Figure 1A). Similarly, the patients/family members reported to have initiated conversations due to decreased QOL, followed by symptom burden from HD (89% & 49%, respectively) (Figure 1B). Responses from questions 3 & 4 found that 70% of RNs believe a private talking area could better enable clinic staff to initiate a supportive care discussions, followed by educational courses and materials for staff (Figure 1C). It was identified that the staff also believe patients would benefit from more educational materials (Figure 1D).

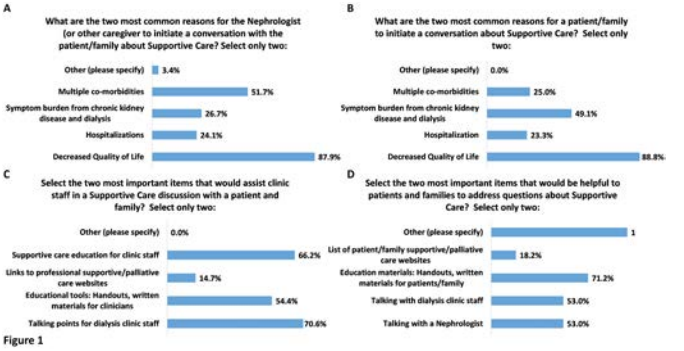

Figure 1

Conclusions: The survey results suggest that decreased QOL is the most common reason for patients and/or families to initiate supportive care discussions. The study also reveals tools that clinic staff and patients/families may find helpful to facilitate discussions on supportive care options. Overall, these survey findings reinforce the need for strategies that support patient's values and wishes in regards to supportive care.

TH-PO1108

International Variation in Dialysis Discontinuation: Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Sarbjit Vanita Jassal,[1] Maria Larkina,[2] Kitty J. Jager,[3] Fliss E. Murtagh,[4] Ann M. O'Hare,[5] Manjula Kurella Tamura,[6] Norio Hanafusa,[7] Richard D. Swartz,[8] Hal Morgenstern,[8] Friedrich K. Port,[2] Keith McCullough,[2] Francesca Tentori.[2] *[1]Univ Health Network, Toronto; [2]Arbor Research, MI; [3]Academic Medical Center, Amsterdam; [4]King's College London; [5]VA, Seattle; [6]Stanford Univ; [7]Univ of Tokyo Hospital; [8]Univ of MI, Ann Arbor.*

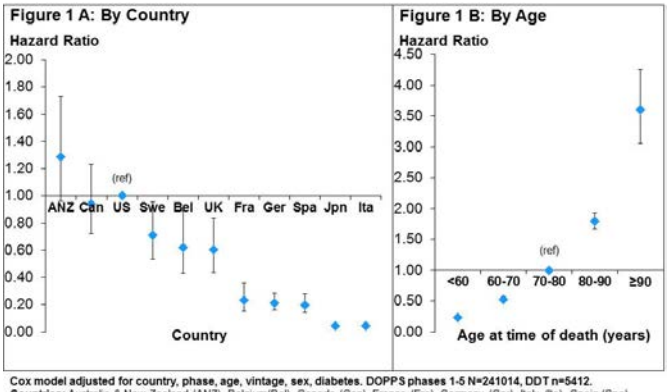
Background: Dialysis is a burdensome and difficult treatment. In some cases, patients, their families, or their healthcare team may consider discontinuation of dialysis therapy (DDT). DOPPS provides an opportunity to assess international variability in DDT across 12 countries and associated clinical characteristics.

Methods: Staff identified the reason each patient left a DOPPS facility, with DDT (n=5412) as an option (v. death, transfer, etc.) from 1996 to 2015. Adjusted Cox regression tested associations of DDT with country, age, sex, dialysis vintage, DOPPS phases, and diabetes status.

Results: Adjusted DDT HRs varied greatly, with 30-fold variation across countries (fig 1A) and 15-fold variation across age groups (fig 1B). DDT rates were highest within 4 months of dialysis initiation (HR[95% CI]=1.4[1.3, 1.5] v. >1 year), and those with diabetes (1.2[1.1,1.2]). No consistent era effect over DOPPS phases was seen.

Conclusions: The wide variation of DDT amongst 12 countries suggests sociocultural determinants are important contributor to DDT, and over how DDT is designated and accepted. The strong association of DDT with age and vintage may imply different considerations and practices with respect to DDT for different patient populations. Enhancing our understanding of DDT, particularly during the first few months of dialysis therapy, may help align practices when considering dialysis initiation and help us better understand the need for palliative renal care services.

Adjusted association of country and age with dialysis discontinuation



Cox model adjusted for country, phase, age, vintage, sex, diabetes. DOPPS phases 1-5 N=241014, DDT n=5412.

TH-PO1109

Dialysis Nurses' Perspectives on Advance Care Planning Katharine L. Cheung,[1] Bette J. Gilmartin,[2] Ann S. Laramee,[3] Prema R. Menon,[4] Robert Macauley,[5] Allison Tong.[6] *[1]Medicine-Nephrology, Univ of Vermont College of Medicine, Burlington, VT; [2]Dialysis & Apheresis, Univ of Vermont Medical Center, Burlington, VT; [3]Medicine- Cardiology and Palliative Care, Univ of Vermont Medical Center, Burlington, VT; [4]Medicine- Pulmonary/Critical Care, Univ of Vermont Medical Center, Burlington, VT; [5]Pediatrics, Univ of Vermont Medical Center, Burlington, VT; [6]School of Public Health, The Univ of Sydney, Sydney, New South Wales, Australia.*

Background: Advance care planning (ACP) is recommended for dialysis patients and yet there has been no systematic implementation. Dialysis nurses often spend more time with patients than other providers, and have the potential to contribute to ACP. We aimed to describe nurses' perspectives on their role and challenges of ACP in the dialysis setting.

Methods: Nurses with experience in dialysis from a university hospital network participated in face-to-face semi-structured interviews. Transcripts were coded using investigator triangulation. Results were based on grounded theory and thematic analysis.

Results: We interviewed 26 dialysis nurses, median age 55 (range 32-72), with 18 (1-45) years of dialysis experience. We identified five themes: advocating for patients (witnessing suffering, coaching healthy behaviors, facilitating communication); dispersed knowledge (operating in clinical silos, sense of helplessness, managing prognostic uncertainty); navigating family-like relationships (respecting patient's struggles, maintaining professionalism, expressing compassion); juxtaposition of frailty and resilience (working to survive, locus of control, balancing hope with anticipatory fear, chronicity of illness) and community of nurses (pooled wisdom and shared bereavement).

Conclusions: Nurses viewed themselves as advocates seeking to protect patients from worsening illness, and to prepare them for death by creating opportunities to explore their fears and wishes. At the same time, nurses sought to preserve hope and felt conflicted when patients survived acute illness. Although nurses had support from each other, they hoped for a greater sense of community and palliative care training.

Abstract Withdrawn

TH-PO1111

A Novel Communication Skills Curriculum to Improve Shared Decision Making among Nephrology Fellows Jehan Z. Bahrainwala,[1] Niharika Ganta,[2] Nina R. O'Connor,[2] Karen M. Warburton,[1] Denise Lamarra,[3] Jeffrey S. Berns.[1] *[1]Renal, Electrolyte and Hypertension Div, Hospital of the Univ of Pennsylvania, PA; [2]Palliative Care Program, Div of General Internal Medicine, Hospital of the Univ of Pennsylvania, PA; [3]Standardized Patient Program, Perelman School of Medicine at the Univ of Pennsylvania.*

Background: Nephrologists are often faced with difficult conversations regarding goals of care. Most nephrology training programs lack formal communication training. Here we describe a novel communication skills curriculum aimed at improving shared decision making regarding dialysis and end of life care.

Methods: Curriculum: The curriculum included a one hour workshop conducted by palliative care faculty that was attended by 12 first and second year nephrology fellows. A new framework called "SUPER" (Setup, Understanding, Priorities, Explain, Review) was introduced to guide goals of care conversations. Fellows then participated in role play sessions with standardized patients (SP) to practice their skills. These sessions were observed by renal and palliative care faculty who provided real-time feedback. A debriefing session was conducted by renal and palliative care faculty 1 week later. **Measures:** Fellows completed self-assessment surveys measuring their comfort with goals of care communication prior to the workshop, immediately following the SP experience, and 6 weeks later.

Results: A comparison of the scores obtained across subjects during three time points (pre-workshop, post-workshop, 6 weeks post curriculum) demonstrated significant differences among their distributions (p=0.015). Post-hoc *t*-tests revealed a significant improvement in self-assessment scores in post-curriculum scores when compared to the pre- curriculum scores (p=0.02). This improvement was sustained as evidenced by the significant improvement in 6 weeks post-curriculum scores when compared to pre-curriculum scores (p=0.02).

Limitations: small sample size, self-reported rather than objective skills assessment, lack of control group.

Conclusions: A novel curriculum to enhance communication skills for nephrology fellows improved self-reported scores in communication.

TH-PO1112

Racial Disparities in the Utilization of Palliative Care in Dialysis Patients from the United States Renal Data System Haytham Alkhaimy,[1] Jennifer L. Waller,[1] Mufaddal F. Kheda,[1] Jake Everett Turrentine,[1] Rhonda E. Colombo,[1] N. Stanley Nahman,[1,2] Lu Y. Huber.[1] *[1]Augusta Univ, Augusta, GA; [2]Charlie Norwood VAMC, Augusta, GA.*

Background: CMS has approved payment for voluntary end-of-life counseling as part of its 2016 Medicare physician fee schedule. We queried the USRDS to investigate how palliative care (PC) has been utilized in the ESRD population.

Methods: All deaths of incident dialysis patients from 2004–2011, age 18-100, were queried. Those with an ICD-9 code V66.7, received hospice care or discontinued dialysis at least 4 days before death were defined as having received PC. Basic descriptive statistics were calculated. Kaplan-Meier analysis was used to estimate survival. Generalized linear models were used to estimate the relative risk (RR) of PC.

Results: Among the 874,777 incident dialysis patients, 459,679 (52%) died by the end of 2012. 30% (136,917) of deaths had PC, with increasing usage from 2004 to 2011 (2%, 6%, 9%, 11%, 13%, 15%, 17%, 20%, respectively). Compared to those who did not undergo PC (NPC), the PC group was significantly older at initiation of dialysis (72±12 vs. 67±14 years) and at time of death (74±12 vs 69±15), more likely to be female (47% vs. 44%), and be on HD when died (92% vs 78%). There were only 17% Blacks in PC comparing with 28% in NPC. The final multivariable model found that older age (RR=1.02), female (RR=1.09), death in more recent years (RR>1.06 for 2005-2012), and more hospitalizations (RR=1.04) were associated with use of PC, while being black (RR=0.65) or of "other" race (RR=0.73) were less likely to have PC. Cause of death for PC was less likely to be coded as cardiac (RR=0.39), GI (RR=0.42), infection (RR=0.52), metabolic (RR=0.83) or vascular causes (RR=0.62). There was no difference in time to death by PC status.

Conclusions: Age, gender, race and underlying chronic conditions all appear to influence the use of PC. Despite increasing utilization of PC since 2004, there has been a racial disparity in the employment of PC, with less frequent use in non-white patients. The reasons for this difference cannot be determined from this study; however, cultural and/or socioeconomic variables may play a role.

TH-PO1113

Patient Perspectives on Choosing Conservative Management of End-Stage Renal Disease Katherine Roza,[1] L. Ebony Boulware,[2] Ion D. Bucaloiu,[3] Frank Daniel Davis,[4] Patti Ephraim,[5] Christina Yule,[3] Jamie Alton Green.[3] *[1]Dept of Medicine, Geisinger Medical Center, Danville, PA; [2]Dept of Medicine, Duke Univ School of Medicine, Durham, NC; [3]Dept of Nephrology, Geisinger Medical Center, Danville, PA; [4]Bioethics, Geisinger Medical Center, Danville, PA; [5]Dept of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Welch Center for Prevention, Epidemiology and Clinical Research, Baltimore, MD.*

Background: Little is known about what factors are important in patients' decisions about conservative management of end-stage renal disease (ESRD).

Methods: We conducted semi-structured, telephonic interviews of patients with advanced chronic kidney disease (stages 4-5) who have opted not to pursue dialysis or have a renal transplant. We recruited patients from nine nephrology clinics in a large integrated health system in rural Pennsylvania. We asked patients to discuss 1) important factors in their decision about conservative management, 2) educational needs and resources, 3) support from family, friends, and providers, 4) decision-making ambivalence, and 5) advance care planning. We audio-recorded interviews for analysis.

Results: Of 13 eligible individuals, six (46%) patients completed interviews. Mean age was 81 years (range 74-88), and four (67%) were male. Factors reported as important in patients' decision to choose conservative management included: advanced age, impact of dialysis on health and quality of life, inconvenience of dialysis, desire to maintain independence, and desire to lessen caregiving burden. Religious faith and support of the healthcare team and loved ones aided decision-making. All interviewees felt they had enough information and support during the decision-making process to opt for conservative management and expressed satisfaction with their decision. Most (83%) had engaged in advanced care planning discussions.

Conclusions: Patients identified key factors in their decision to pursue conservative management. Our findings can inform interventions to improve shared decision-making and communication between patients and providers about conservative management of ESRD.

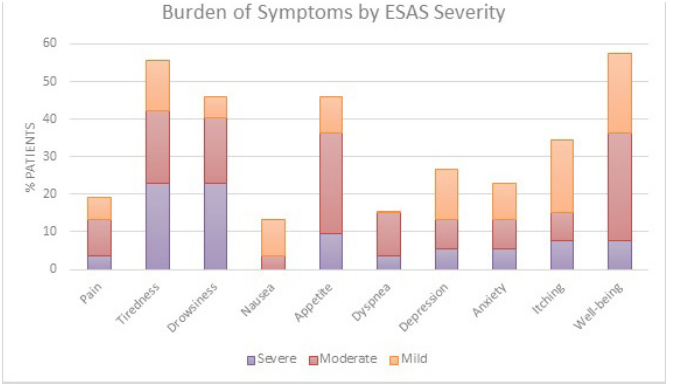
TH-PO1114

Symptom Burden in Veterans on Chronic Hemodialysis Matthew Tyler,[1] Joshua Hauser,[1] Shubhada N. Ahya.[2] *[1]Medicine - Palliative Care, Northwestern Memorial Hospital, Chicago, IL; [2]Medicine - Nephrology, Northwestern Memorial Hospital, Chicago, IL.*

Background: The Coalition for Supportive Care of Kidney Patients (CSCKP), a national organization of renal and palliative care health professionals, patients, and families, suggests "meticulous pain and symptom management" for ESRD patients. However, there is no consensus on what symptom assessment instrument to use or how to implement it at the point of care. This quality improvement project sought to assess the feasibility of administering the Edmonton Symptom Assessment Scale (ESAS) during a veteran's regularly scheduled outpatient hemodialysis (HD) session. We also sought to catalogue the physical symptom burden of our veterans receiving routine HD.

Methods: A palliative care physician administered the ESAS to each patient during their routine HD session at a VA hospital-affiliated dialysis center in a major metropolitan area. The physician also documented the time to complete each ESAS and the patient's self-perceived difficulty with completing the ESAS.

Results: Fifty-two patients completed an ESAS during their routine dialysis session. Of these, 36 (69%) patients reported at least 1 moderate to severe symptom, with 40% of patients endorsing at least 3 moderate to severe symptoms. Tiredness was the most commonly reported symptom, endorsed by 56% of patients. Thirty-eight (73%) patients were able to complete an ESAS in less than 5 minutes. Most patients (85%) did not find the ESAS challenging to complete, with the rest (15%) only finding it somewhat challenging.



Conclusions: Symptom burden in patients on chronic hemodialysis is high. The ESAS is an easy to use symptom inventory that most patients can complete in less than 5 minutes during their routine dialysis session. Implementation of routine symptom screening should be a high priority for dialysis centers but does not need to be resource-intensive.

TH-PO1115

Improving Palliative Care Communication Skills in Nephrology Training: Description and Outcomes of the NephroTalk Communication Program Jane O. Schell,[1] Jamie Alton Green,[2] Robert A. Cohen.[3] *[1]Nephrology, Univ of Pittsburgh Medical Center, Pittsburgh, PA; [2]Nephrology, Geisinger Health System, Danvillle, PA; [3]Nephrology, Beth Isreal Deaconess, Boston, PA.*

Background: Effective communication is essential to being a competent nephrologist. We describe NephroTalk communication curriculum for nephrology fellows and report educational outcomes utilizing two years of data. The three-day course includes didactics and small group practice with simulated patients addressing palliative care communication tasks in nephrology. The primary objective was to evaluate skill acquisition using a validated communication checklist analyzing pre- and post-training standardized patient encounters. Secondary objectives included fellow satisfaction with the course and changes in self-reported preparedness.

Methods: Nineteen first and second year fellows from six academic nephrology programs participated in Nephrotalk in 2014 and 2016. Audio-recorded pre- and post-training encounters with standardized patients giving bad news were evaluated using a modified communication checklist. Skill acquisition was measured using paired T-tests. Fellow experience and perceived improvement were measured using a 5-point Likert scale.

Results: Over half of participants were male and in the second year of fellowship. Sixty-five percent reported no formal education in either how to discuss conservative management or dialysis in a patient who may not do well. Training resulted in a significant increase in the total number of checklist communication skills used compared to pre-training encounter ($p = 0.002$). Fellows were more likely to respond to emotional cues with empathic statements in post-training compared to pre-training encounter ($p < 0.05$). Fellows were highly satisfied with the training and recommended it be part of routine fellowship education.

Conclusions: Our three-day communication course demonstrated increased communication skill acquisition, particularly in fellows responding to emotional cues using a modified validated communication checklist. These findings demonstrate the efficacy of palliative care education and communication skills training during nephrology fellowship.

TH-PO1116

Development of a Question Prompt Sheet for Patients with Advanced Kidney Disease to Promote Shared Decision Making Regarding Dialysis and Transplantation Arouna Senthilkumar,[2] Swati Lederer,[1,2] Hira T. Khan,[2] Michael J. Fischer,[1,2] Howard S. Gordon,[1,2] Anuradha Wadhwa,[2] Subhash Popli,[2] Elisa J. Gordon.[2,3] *[1]Jesse Brown VAMC and Univ of Illinois, Chicago, IL; [2]Hines VA Hospital, Hines, IL; [3]Northwestern Univ, Chicago, IL.*

Background: Patients with advanced chronic kidney disease (CKD) commonly receive suboptimal education about treatment options for end-stage kidney disease (ESKD). Thus, many information needs are unmet. Active participation in discussions can prepare patients for renal replacement therapy and improve health outcomes. Question prompt sheets (QPS) can increase patient involvement in discussions during crucial phases of their illness. No QPS is available for patients nearing ESKD.

Methods: We conducted a cross-sectional study with semi-structured interviews to develop a QPS for patients with advanced CKD. Initial interviews among patients with moderate to severe CKD assessed their general CKD information needs. Patients' feedback informed the development of a 53-item QPS. A new cohort of patients with ESKD from one VA facility were interviewed to assess the importance of asking each QPS question (on a 5-point Likert Scale) and to provide open-ended feedback about each of the 53 items. We used a mixed methods approach to analyze responses and refine QPS items.

Results: In all, 45 patients completed interviews for a 46% participation rate. Most were male (98%), white (51%), and the mean age was 64 years. Most patients were either on dialysis (62%) or had a kidney transplant (38%). The final QPS included 35 items divided into 2 key themes (dialysis, transplantation). Patients reported being 'completely' or 'very' willing to use an ESKD-QPS in their doctor visits (89%) and recommended that patients receive dialysis and transplant questions at the same time (68%).

Conclusions: Advanced CKD patients expressed interest in using an ESKD-QPS. Future research should evaluate the feasibility of using an ESKD-QPS in nephrology clinics and whether our 35-item QPS addresses patient information needs, fosters patient communication with care teams, and improves outcomes.

Funding: VA Support

TH-PO1117

Using Storify as a Learning Tool in Nephrology: The NephJC Experience Hector M. Madariaga,[1] Swapnil Hiremath,[2] Nikhil A. Shah,[3] Matthew A. Sparks,[4] Joel Topf.[5] *[1]Div of Nephrology, Univ of Maryland Medical Center, Baltimore, MD; [2]Div of Nephrology, Univ of Ottawa, Ottawa, ON, Canada; [3]Dept of Nephrology and Immunology, Univ of Alberta, Edmonton, AB, Canada; [4]Nephrology Div, Duke Univ, Durham, NC; [5]Nephrology Div, St. John's Providence Hospital, Detroit, MI.*

Background: Social media (SoMe) is increasingly being used in medical education and information is scattered across SoMe. It is difficult to bring information together, hence the importance of using hashtags (#). Storify is a tool that enables users to curate information from Social Networks, creating a digital narrative of events, media and tweets. We use it in our twice-a-month Twitter-based nephrology journal club, NephJC, to curate discussions and generate a narrative for others to review.

Methods: We performed an analysis to determine the utilization of Storify in the dissemination of tweetchats by examining the number of times people viewed each NephJC Storify and by performing a survey asking participants how they review NephJC information. We have hosted 50 chats since April 2014. Pageviews were quantified on www.storify.com through May 2016. Each tweetchat has two Storify versions: American and European chat.

Results: We have had a total of 2744 participants during the 50 discussions, with a total of 26521 tweets and average of 530 tweets per discussion. Storify narratives condense this down to a mean of 115 tweets per discussion. The total number of NephJC Storify page views was 6212, average of 124 page views per Storify and median 95(interquartile range 60,145). 13% of respondents said they interact with NephJC primarily through Storify.

Conclusions: Storify is an online tool to help users to gather information across SoMe by using hashtags and share. At NephJC we use it to preserve critical elements of chat discussions and make them easier to review. Without the curated Storify version, most of the individual conversational threads would be hard to retrieve and follow. Storify is a compelling tool for organizing and archiving real-time tweets for enriching the online continuing medical education experience.

TH-PO1118

Queen's Nephrology E-Learning: WhatsApp - Q-NEW Study Muhammad A. Bukhari, M. Khaled Shamseddin. *Nephrology, Queen's Univ, Kingston, ON, Canada.*

Background: Competency based medical education (CBME) is gaining more attention. E-learning is becoming a central modality of medical education. Social media applications are not yet a regular source of e-learning. WhatsApp Messenger allows exchange of messages and media, and holds promise as a CBME teaching tool.

Methods: We performed a pilot study of Nephrology Clinical Case problems sent to volunteers (Internal medicine trainees) via WhatsApp in an effort to assess and improve Nephrology competency. Responses were requested at 5 days. Answers and explanations were then sent out. Pre- and post-study surveys reported Trainees self-assessed competency in managing Nephrology topics.

Results: 29 (46%) out of 63 trainees enrolled (48% Females; 14, 10, & 5 PGY-1, 2, & 3, respectively). On a scale of 5; 1: very unconfident, 5: very confident, Trainees self-reported competency managing the problems. Scores improved significantly post-study, in specialized fields of Nephrology (e.g. Transplantation, Nephritis and Dialysis). There was no significant improvement in scores in more common areas like acute kidney injury.

Management	Post-Study Mean ± SD	Pre-Study Mean ± SD	95% CI Lower	95% CI upper	P Value
Acute Kidney Injury	4.00±0.54	3.93±0.46	-0.32	0.46	0.72
Acute Interstitial Nephritis	3.40±0.63	2.87±0.52	0.12	0.95	0.02
Nephritis	3.27±0.46	2.60±0.74	0.13	1.21	0.02
Nephrotic Syndrome	3.40±0.63	3.73±0.70	0.09	1.25	0.03
Electrolyte	3.53±0.64	3.27±0.70	-0.12	0.66	0.16
Hemodialysis	3.60±0.83	3.00±0.93	0.02	1.19	0.04
Peritoneal Dialysis	3.27±0.70	2.67±0.72	0.14	1.06	0.01
Chronic Kidney Disease	3.20±0.56	2.67±0.72	0.07	0.99	0.03
Transplantation	2.93±0.70	2.00±0.66	0.54	1.32	0.000
Hypertension	3.33±0.62	3.13±0.52	-0.23	0.63	0.33
Overdoses	3.20±0.0.68	2.80±0.86	-0.15	0.95	0.14

Conclusions: Trainees' competency improved using WhatsApp as a tool to enhance critical thinking. Most Trainees reported interest in e-learning and WhatsApp to learn Nephrology; however, the Trainee response rate diminished with time questioning the durability of using such a teaching method.

TH-PO1119

Enhancing Renal Physiology and Pathophysiology Education Using a Novel Mobile Learning Platform R. Lance Miller. *Medical Education, Inquizica LLC, Penn Valley, PA.*

Background: Optimal learning occurs when content is given in small, digestible chunks, which are followed up with regularly spaced out practice assessments to maximize retention. Our innovation leverages technology to make it easy for students to engage in the best educational practices, anywhere, anytime, and on any device and it makes it easy for medical educators to supplement in class lectures and track student progress in real-time to optimize content to maximize learning and promote a flipped classroom.

Methods: Using smartphone technology we automatically "feed" students content via text-messages containing links to 5 minute learning modules, i.e., videos or assessments. The student or educator can choose from the content library and enter associated exam dates, i.e., quizzes, mid-terms, and finals, our SMS-notification/scheduling system then automatically "feeds" the student content, in spaced out intervals. Results are reported by question and quiz and logged to the user's and/or educator's dashboard. If the student scores below a certain percentage, the system sends a text message with a link for remediation.

Results: We tested our platform on first year medical students (n=20) and undergraduates (n=15). After completing the mobile learning modules on first-year renal physiology (i.e., acid-base physiology, renal hemodynamics, and urine concentration mechanisms), medical students and undergraduate students scored 92 ± 3% and 83 ± 4% on the 25 question multiple choice quiz.

Conclusions: Greater than 90% of students found this approach highly favorable and thought it would be a helpful supplement to in class lectures. This novel mobile learning platform represents a viable approach to supplementing in class lectures and improving retention of difficult material, like renal physiology and pathophysiology.

TH-PO1120

The Acute Dialysis Orders Objective Structured Clinical Examination (OSCE): A Formative Assessment for Nephrology Fellows Lisa K. Prince,[1] Sam W. Gao,[2] Christopher J. LeBrun,[3] Dustin J. Little,[1] David L. Mahoney,[4] Robert Nee,[1] Mark C. Saddler,[5] Maura A. Watson,[1] Christina M. Yuan.[1] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Naval Medical Center, Portsmouth, VA; [3]Baptist Memorial Hospital Golden Triangle, Columbus, MS; [4]Private Practice, Fairfax, VA; [5]Mercy Regional Medical Center, Durango, CO.*

Background: Few quantitative, validated, Nephrology-specific simulations assess fellow competency. We developed and validated a formative OSCE to assess medical knowledge, patient care, and systems-based practice in acute dialysis.

Methods: There are 3 scenarios: acute CRRT in a septic, hypotensive oncology patient; chronic dialysis initiation in a volume-overloaded, moderately uremic patient; and acute dialysis in a ESRD patient with hyperkalemia and volume overload. Fellows use institutional protocols and order sets. The test was developed by 5 academic military nephrologists, and refined by 4 nephrologists (2 in rural practice and 2 in urban/suburban practice). Test committee members were board certified/participating in MOC. There were 49 test items, and 58 possible points. Passing score was determined by Ebel's method applied to each item. Passing threshold was 46/58 points. No item had median relevance less than "important", and 42/58 (72%) were of easy or medium difficulty.

Results: The test was validated by 10 external volunteers who were not on the test committee. All trained in the WRNMMC program; 7/10 were in the military. All were board certified in nephrology; a median 3.5 years (1-11) from graduation. Median time to take the test was 75 minutes. Mean score was 49 (95% CI 46-51). Interrater reliability: Kappa 0.68 (95% CI 0.59-0.77).

Conclusions: We will administer the test to first and second year fellows at the end of the 2016 training year. We hypothesize that performance will be significantly better in second vs. first year fellows, and associate with ITE score. We will also analyze performance on evidence-based questions. *The views expressed are those of the authors and do not necessarily reflect the official policy or position of the Department of the Navy, the Department of the Army, the Department of Defense, nor the US Government.*

TH-PO1121

Best Practices to Increase Medical Student Interest in Nephrology: A Qualitative Study Stephen M. Sozio,[1] Kurtis Pivert,[2] Hitesh H. Shah,[3] Harini A. Chakkera,[4] Katlyn Leight,[2] Mark G. Parker.[5] *[1]Johns Hopkins U; [2]American Society of Nephrology; [3]Hofstra Northwell School of Medicine; [4]Mayo Clinic; [5]Maine Medical Center.*

Background: Interest in nephrology as a career has been declining. Understanding practices of medical schools that successfully generate nephrology interest is sorely needed.

Methods: This "Best Practices Project" was as an initiative designed by the ASN Workforce Committee to increase nephrology interest. Medical school graduates from 2002-2009 who became board certified in nephrology were identified through the AMA Masterfile. From the top 10 producing medical schools, renal educators were asked to participate in 1 of 4 directed focus groups inquiring about key factors in each school's success. Transcripts were analyzed using thematic content analysis with inductive reasoning.

Results: Of the 10 schools, 3 were in the Northeast, 3 Midwest, and 4 South. Median medical school class size was 185 students; 26% of graduates chose Internal Medicine. 18 educators from 9 institutions were recruited. Programs identified aspects in their renal course, rotations, research, and faculty that made them successful.

TOP THEMES	REPRESENTATIVE QUOTE
Early exposure	*Some of our medical students have the opportunity to work with us at the clinical and basic research level. I think it's a very early stage, but it makes an impact on them.*
Clinical relevance	*What seems to get students interested is getting the students early and making sure they already feel like they're mastering the pathophysiology. And then connecting that with the clinical case. That seems to be a good way to get students to realize the connection between what they're learning and clinically doing.*
Faculty interaction	*The faculty present a very good role model and good mentorship, so that when they do electives, we have good relationships with them and they get to see quite a bit of us.*
Variety	*Medical students rotate through nephrology, both inpatient as well as outpatient clinics, even early on in their third year rotation. So it does expose them to nephrology in various aspects.*

Conclusions: Early and consistent clinical experience and faculty contact with medical students are important to help generate interest in nephrology.

TH-PO1122

Outcomes of Tunneled Hemodialysis Catheters Insertion by Nephrology Fellows in Singapore Alicia Ong,[1] Ru Yu Tan,[2] Kian Guan Lee,[2] Suh Chien Pang,[2] Pei Loo Tok,[2] Chieh-Suai Tan.[2] *[1]Duke-NUS Medical School, Singapore; [2]Renal Medicine, Singapore General Hospital, Singapore.*

Background: Increasingly, nephrology fellows (NF) in Singapore are beginning to insert tunneled hemodialysis catheters (THC) under fluoroscopic guidance. This is done with the supervision of interventional nephrologists as part of fellowship training. Data on THC insertion outcomes are however lacking. This study aims to report their outcomes and complications rates.

Methods: In a single-center retrospective study of THC insertion performed from March 2015 to February 2016, outcomes of catheter insertion by NF and accredited proceduralists (AP) comprised of Interventional Radiologists, Vascular Surgeons, and Interventional Nephrologists were compared. Data were collected from electronic medical records and procedural reports. Patients were followed up from the time of insertion until hospital discharge. Primary outcomes evaluated included bleeding and infection. Secondary outcomes included procedural fluoroscopy time and patient radiation exposure.

Results: THCs were successfully inserted under fluoroscopic guidance in combination with real-time ultrasound cannulation in 140 patients (mean age of 61 ± 13 years old, 51.4% male, 69.3% Chinese). The majority of the insertions (n=91; 65%) were performed by AP although NF placed more catheters in newly diagnosed end stage renal failure patients compared to AP (65.3% vs. 46.2%, p=0.02). The right internal jugular was the preferred site of insertion in both groups (89.8% vs. 83.5%, p=0.37). There were no differences in post-procedural bleeding (6.1% vs 4.4%, p=0.47) and infection within 24 hours of placement (4.1% vs 2.2%, p= 0.44). In insertions done by NF, median fluoroscopy time [1.3mins (0.3, 17.9) vs. 1.1mins (0.1, 38.4), p=0.42] was higher whereas the median radiation exposure [57.6mGycm2 (5.6, 2207.9) vs. 102.5 mGycm2 (7.4, 8129.0), p=0.17] was lower although these differences did not reach statistical significance.

Conclusions: In carefully selected patients, tunneled hemodialysis catheter can be safely inserted by nephrology fellows with minimal complications rates and radiation exposure. Larger studies are necessary to validate our findings.

TH-PO1123

Development and Validation of a Clinical Competence Test for Dietitians Regarding Early Chronic Kidney Disease (CKD) Roxana Marquez-Herrera, Laura Cortes-Sanabria, Hector Martinez Ramirez, Alfonso M. Cueto-Manzano. *Unidad de Investigación Médica en Enfermedades Renales, Inst Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: CKD is a serious public health issue. Appropriate nutritional care may help to prevent CKD onset in patients at risk, and slow progression in those at early stage. To improve care of patients with early CKD, it is mandatory to know the dietitian's clinical competence; however, no adequate tool to measure this issue has been published. Aim: to develop and validate a test to evaluate dietitian's clinical competence about nutritional care in patients with early CKD.

Methods: Development and evaluation of the test was performed as follows: 1) A group of experts in psychometrics and nutrition of early CKD was integrated; 2) Clinical competence and its dimensions were defined; 3) Four real clinical cases and questions (based on the latter) were elaborated; 4) content validity was established; 5) Test was applied to dietitians with or without previous CKD training; 6) Reliability assessment by question exclusion, based on internal consistency and discrimination index, was established. A Cronbach's alpha ≥0.70 and discrimination index ≥0.30 were considered adequate.

Results: Dietitians with previous training obtained higher scores than those with no training (123 *vs* 92, respectively, p<0.0001), confirming test validity criterion. As a first step to increase reliability, questions were dropped according a correlation coefficient cutoff value <0.15 (item/total correlation); from the latter, discrimination capacity of remaining questions was controlled by elimination of those with discrimination index <0.15. Final test contained 92 from the original 239 questions, increasing Cronbach's alpha value from 0.83 to 0.91, and discrimination index from 0.15 to 0.34.

Conclusions: The clinical competence test developed for dietitians is a consistent and suitable instrument to identify dietitians with or without adequate competence in nutritional care of early CKD patients. The availability of a reliable test to measure dietitian's clinical competence may help to improve care of early CKD patients.

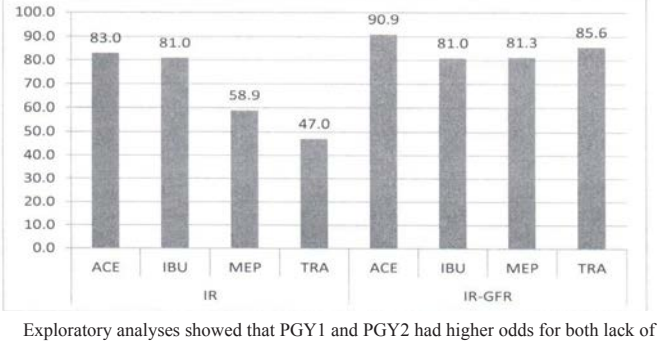
TH-PO1124

Awareness and Knowledge among House-Staff for Dose Adjustment of Analgesic Medications in Chronic Kidney Disease Chadi Y. Saad,[1] Joshua Fogel,[2] Sofia Rubinstein.[1] *[1]Nephrology and Hypertension, Nassau Univ Medical Center, East Meadow, NY; [2]Business Management, Brooklyn College, Brooklyn, NY.*

Background: Drug dosing errors result in adverse patient outcomes and are more common in patients with chronic kidney disease (CKD). As internists treat the majority of patients with CKD and pain is common in those with CKD, we study if Internal Medicine (IM) house-staff have awareness and knowledge about the correct dosage of commonly used analgesic medications for those with CKD.

Methods: We performed a cross-sectional survey of 353 IM house-staff. Our outcomes are the awareness of whether a medication needs dose adjustment in patients with CKD and whether there was knowledge at what level of glomerular filtration rate (GFR) a medication needs to be adjusted.

Results: There were high percentages for lack of awareness and knowledge. Lack of awareness and knowledge was highest for acetaminophen at 83.0% and 90.9%, respectively.



Exploratory analyses showed that PGY1 and PGY2 had higher odds for both lack of awareness and knowledge. Also, more Nephrology training and exposure was associated with lower odds for both lack of awareness and knowledge.

	Incorrect Response		Incorrect Response at GFR level			
Variables	Tramadol OR	95% CI	Acetamino-phen OR	95% CI	Mepered-ine OR	95% CI
PGY3	1.00		1.00		1.00	
PGY1	**2.37**	**1.22-4.62**	2.10	0.65-6.82	**4.01**	**1.81-8.89**
PGY2	**2.34**	**1.16-4.72**	2.29	0.64-8.12	**3.30**	**1.44- 7.59**
Nephrology rotation medical school	0.78	0.44-1.36	**0.37**	**0.14-0.99**	**0.41**	**0.2-0.83**

Conclusions: There is a poor awareness and knowledge among IM house-staff for dose adjustment of analgesic medications in CKD patients. Internal medicine house-staff should receive more Nephrology exposure and formal didactic training during residency to better manage complex treatment regimens and prevent medication dosing errors.

TH-PO1125

Health Literacy of Nephrology Patients and Their Family Caregivers Jamie Alton Green,[1] Deserae N. Clarke,[2] Amanda Young,[3] Jennifer L. Wolff,[4] Rebecca A. Stametz.[2] *[1]Nephrology, Geisinger Medical Center, Danville, PA; [2]Center for Clinical Innovation, Geisinger Medical Center, Danville, PA; [3]Biostatistics, Geisinger Medical Center, Danville, PA; [4]Health Policy and Management, Johns Hopkins Univ, Baltimore, MD.*

Background: Many patients with kidney disease rely on assistance from a family or informal caregiver to help manage their care. The presence of a caregiver may compensate for patient difficulties related to limited health literacy; however, little is known about what proportion of nephrology patients receive help from a caregiver, the health literacy of their caregivers, or how caregiver health literacy corresponds to that of the patient.

Methods: Patient-caregiver dyads were identified and surveyed utilizing a health information technology enabled process embedded into clinical nephrology care at a large integrated health system in Pennsylvania. Health literacy was assessed using a single item screening question, "How confident are you filling out medical forms by yourself" with response options of extremely, quite a bit, somewhat, a little bit, or not at all. A response of "somewhat" or less was used to define limited health literacy.

Results: Of 790 patients surveyed, 466 (59%) reported they receive help from a family caregiver with at least one health related activity. Caregivers were most often a spouse (61%) or an adult child (12%). Among 316 complete dyads, patients were overall more likely to have limited health literacy than caregivers (45% vs. 19%, p<0.01). Patient-caregiver dyad health literacy varied with 103 (33%) consisting of a patient with limited health literacy and a caregiver with adequate health literacy, 22 (7%) consisting of a patient with adequate health literacy and a caregiver with limited health literacy, 39 (12%) where both had limited health literacy, and 152 (48%) where both had adequate health literacy.

Conclusions: More than half of nephrology patients receive help from a family caregiver. Both patients and caregivers are at risk for limited health literacy which should be considered when providing patient instructions or education. Future studies should examine how patient and care giver health literacy affect patient outcomes.

Funding: Private Foundation Support

TH-PO1126

Primary Care Provider Education in Nephrology - Improving Chronic Kidney Disease Care on the Front Lines Rob Rope,[1] Nhat M. Pham.[2] *[1]Internal Medicine/Nephrology, Stanford Univ, Palo Alto, CA; [2]Internal Medicine/Nephrology, Santa Clara Valley Medical Center, San Jose, CA.*

Background: The majority of CKD care takes place in the primary care setting. Effective treatment can reduce disease progression and cardiovascular complications but is underutilized. This project demonstrates cost-effective educational outreach to PCPs designed to increase provider knowledge in CKD care.

Methods: The intervention consisted of five small-group lectures covering topics in CKD care: diagnosis/referral; preventing progression; cardiovascular disease; managing complications; and dialysis/post-transplant care. Lectures were given at 3 primary care sites within a county health system. Fifteen providers attended 4-5 talks. A control group of 9 providers received a review article only. 80% of participants were IM physicians with the remainder FM or NPs. The intervention was evaluated in 3 ways: a survey evaluating provider confidence in, and knowledge of, CKD management; chart reviews of all patients referred from the physicians in the intervention and control groups; and chart reviews of patients with CKD from the intervention and control clinics.

Results: 13 providers (intervention) and 7 (control) took the knowledge survey before and after the intervention. McNemar (paired Chi-square) testing indicated that knowledge improved in the intervention group (17% improvement, $p < 0.05$) but not in the control group (2% improvement, $p = 0.38$). Analysis of the confidence data is pending. Chart review of referrals for the year prior showed that 80% of referrals in both groups met KDIGO indications for referral. Chart review of care for patients with CKD revealed that < 75% of all patients were prescribed RAASi or statins and < 66% of patients were controlled to an SBP of < 140.

Conclusions: This project demonstrates that specialist led education can be effective in improving knowledge in CKD care. We also identified significant need for improvement in referrals to nephrology and CKD care. Follow-up data one year after the intervention will assess for improvements in the appropriateness of referrals as well as markers of CKD care (use of RAASi, use of statins, and BP control to < 140/90 mmHg).

Funding: Other NIH Support - Stanford University Division of Nephrology, T32 Training Grant provided funding for Rob Rope's salary

TH-PO1127

Replacement Modality Choice Knowledge in the Non-Renal Multidisciplinary Team - Experience from a Single UK Centre Fatima Abdelaal, Hatem Ali, Jyoti B. Baharani. *Renal Medicine, Birmingham Heartlands Hospital - Heart of England NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Chronic Kidney Disease (CKD) is a common health problem which is on an upward trend. Dialysis treatment remains the mainstay for patients with End Stage Renal disease (ESRD). In the UK there has been a significant decline in home dialysis despite its benefits and cost effectiveness. There are many reasons for this including lack of awareness about availability and effectiveness of home dialysis by both patients and healthcare professionals. Patients with CKD often have multiple co-morbidities and are known to other medical specialties who they may continue to consult when approaching the need for dialysis. We wished to assess home dialysis awareness among the non renal Multi-Disciplinary Team (MDT).

Methods: Home dialysis awareness was assessed by an on-line survey sent to the choosing specialties likely to deal with CKD patients at our centre.The questionnaire aimed to assess knowledge of these individuals regarding home dialysis and establish whether further targeted education was warranted.

Results: 364 questionnaires were sent out with a 26.4% response rate. 69.32% of respondents were working in common specialties dealing with CKD patients (geriatrics 15.9%, cardiology 14.8%, haematology 10.2%, endocrinology 10.2%, urology 10.2% and vascular surgery 8%). 81.5% of non-renal MDT did not feel confident in discussing home dialysis options with patients despite seeing a large number of CKD patients. 70% felt that their knowledge about Home Haemodialysis (HHD) was poor and 74.5% felt that they needed further education about home dialysis.

Conclusions: Knowledge of home dialysis among the non-renal MDT is poor and they lack the confidence to discuss this with CKD patients. In our sample, respondents felt they would benefit from further education. This may increase the uptake of home dialysis by the multi-morbid CKD patient who has a consistent message delivered to them by all relevant healthcare teams about the benefits of home dialysis.

TH-PO1128

Early Validation of a Low-Literacy Smartphone and Web-Based Application on Chronic Kidney Disease Knowledge and Self-Management Maria E. Ferris,[1] Nina Jain,[1] Meaghan Nazareth,[1] Stephen James,[2] Melanie Livet,[2] Jordan Richards,[1] Alex Phillips,[1] Stephen R. Hooper,[1] Janey Sturtz McMillen.[2] *[1]UNC Chapel Hill, Chapel Hill, NC; [2]3C Inst, Durham, NC.*

Background: Effective disease self-management requires knowledge about chronic kidney disease (CKD). The effectiveness of patient education delivered via smartphone applications remains to be determined.

Methods: English-speaking adolescents and young adults (AYA) who attended the UNC Kidney Center utilized Planet K, a low-literacy smartphone and web-based application designed to teach about kidney function, chronic kidney disease (CKD) stages and self-management skills via interactive games. Pre-post performance on the Self-management and Transition to Adulthood with Rx=treatment ($STAR_x$) Questionnaire (Ferris 2015) was an outcome examined for patients using Planet K. In addition to completing the STARx Questionnaire before and after using the app, participants completed a pre-post 19-item CKD knowledge measure that was designed for this project.

Results: To date, 26 AYA aged 12-17 years (μ 15.2 ± 2.2) with CKD stages 1-5 had the following characteristics: 65% males, 61% White, 23% African American; mean age at diagnosis was 6.1 yrs (±5.7, range 0-17 yrs). The pre- and post-STARx Questionnaire scores on disease knowledge and resources utilization significantly increased after the use of Planet K. Knowledge (p=0.046) and resource utilization (p=0.028) were normally distributed and displayed significant increases when t-tests were used to compare pre- and post- scores after use of the application. The <a>mean knowledge score from the 19-item CKD knowledge measure increased from 0.77 to 0.88 (p<0.001).

Conclusions: The low-literacy smart phone and web-based Planet K application appears to have early findings of efficacy and utility for AYA with CKD. Further evaluation is underway.

Assessment of Clinical Practices in the Management of Hyperkalemia Edward L. Jackson, Don Blatherwick, Karen Badal. *Medscape Education, LLC.*

Background: Concerns regarding hyperkalemia may contribute to the underuse of renin-angiotensin aldosterone system (RAAS) inhibitor therapies.The current study was developed to assess gaps in knowledge and competence of nephrologists regarding assessment and management of hyperkalemia.

Methods: A continuing medical education (CME)-accredited clinical practice assessment survey consisted of 25 multiple-choice questions, self-assessing knowledge, confidence and barriers with regard to hyperkalemia management. Hosted on the Medscape Education website, participant responses were collected between September 22, 2015 and November 22, 2015. Responses were de-identified and aggregated prior to analysis to maintain confidentiality. Questions were based on clinical trials, guidelines, and expert faculty recommendations.

Results: Data were collected from 394 nephrologists who participated during the study period. Key findings include: •While 88% correctly recognized that impaired potassium excretion was the primary cause of chronic hyperkalemia, only 55% correctly identified physiologic details of normal potassium regulation •Although 89% recognized that the presence and severity of CKD was the strongest associated risk factor for hyperkalemia, only 47% were able to correctly identify key predictors of risk •In a scenario of a patient with stage 3 CKD and type 2 diabetes, without effective treatments 40% opted for discontinuation of RAAS therapy in the event of an elevation in potassium, with a lower percentage (35%) instead opting for dose-reduction •Less than one-half (46%-49%) recognized the mechanisms of action for novel potassium binders •Only 57% of respondents were familiar with clinical trial data for a novel potassium binder •Among confidence and barrier questions, 93% of respondents indicated a likelihood to maximize RAAS therapy provided there were better treatment options for hyperkalemia, and 55% selected knowledge of new agents for hyperkalemia as the area of greatest educational need.

Conclusions: While general knowledge and confidence among nephrologists are high in several areas of hyperkalemia, gaps in the detailed understanding of clinical aspects remain. Educational efforts in management, tailored to nephrologists, are warranted to address these gaps.

Iron Deficiency Anemia in Chronic Kidney Disease: Educational Effects from a Case-Based Online Intervention Edward L. Jackson, Don Blatherwick, Anne Le. *Medscape Education, LLC.*

Background: A study was conducted to determine whether an online educational intervention could address an underlying care gap in the area of evaluation and management of iron deficiency anemia in patients with chronic kidney disease (CKD).

Methods: The educational intervention consisted of a video panel discussion activity for nephrologists and primary care physicians (PCPs), with two case scenarios to guide discussion. Educational impact was assessed by comparing each participant's responses to the same 4 questions asked both pre- and post-education. A paired 2-tailed t-test was used to assess whether the mean post-assessment score was different from the mean pre-assessment score for each question. McNemar's χ^2 statistic was used to measure changes in responses to individual questions. Probability values (*P* values) were also calculated for both t-test and χ^2 statistics to determine significance, with a $P < .05$ as meeting statistical significance. Cramer's V was used to calculate the effect size of the intervention, with large effect sizes defined as $V > .30$.

Results: For nephrologists (n = 113) and PCPs (n = 214) who participated in the online activity and completed all pre- and post-education assessment questions, comparison of responses to pre- and post-education assessment questions demonstrated statistically significant improvements (P <.05) and a large effect (nephrologists, V = 0.321; PCPs, V = 0.319). Significant absolute increases in correct responses were observed in several specific areas of managing iron-deficiency anemia in CKD (all $P < .05$), including: •Contributors to iron-deficiency anemia in CKD (Nephrologists, 37%; PCPs, 41%) •Appropriateness of oral iron compounds for treatment (Nephrologists, 18%; PCPs, 27%) •Risks from intravenous iron replacement in CKD patients who are also being treated for comorbidities (Nephrologists, 27%; PCPs, 15%) •Options for iron replacement therapy (Nephrologists, 42%; PCPs, 44%).

Conclusions: As a result of participation in this case discussion-based educational activity in a video format, significant improvement in knowledge of nephrologists and PCPs was demonstrated in several important aspects of managing iron-deficiency anemia in patients with CKD.

TH-PO1131

Assessment of Current Clinical Practices in the Diagnosis and Management of Hepatorenal Syndrome Edward L. Jackson, Don Blatherwick, Susan Smith. *Medscape Education, LLC.*

Background: Hepatorenal syndrome (HRS) is a potentially devastating form of acute renal injury seen in clinical practice. The current study was conducted to assess gaps in knowledge and competence of nephrologists regarding diagnosis and management of patients with HRS.

Methods: A continuing medical education (CME)-certified clinical practice assessment survey was developed comprising 20 multiple-choice questions that assessed knowledge, attitudes, and confidence with regard to the diagnosis, clinical course, treatment, and management of patients with HRS. The survey questions were based on clinical trials, guidelines, and expert faculty recommendations. The survey was launched on August 14, 2015, and hosted on the Medscape Education website, and participant responses were collected through October 11, 2015. Confidentiality was maintained and responses were de-identified and aggregated prior to analyses.

Results: Data were collected from 198 nephrologists who participated in the survey during the study period. When asked about diagnosing HRS, 85% correctly recognized HRS as a diagnosis of exclusion, yet only 38% reported being fully confident in making the diagnosis. With respect to evaluation and staging, only 37% of nephrologists correctly recognized the most appropriate tests for evaluating kidney function in patients with cirrhosis and, when presented with a case scenario and laboratory test result, only 40% were able to properly stage the HRS presentation. In the area of HRS management, a majority of nephrologists (79%) correctly recognized that HRS is potentially reversible and 75% correctly stated that liver transplantation is the definitive treatment. However, only about one-half (54%) were able to identify the most appropriate pre-transplantation management strategy, and less than one-quarter (24%) were able to correctly answer a question related to effectiveness of therapeutic options.

Conclusions: Low self-reported confidence among nephrologists in establishing a diagnosis of HRS was substantiated by responses to specific questions on diagnosis and staging. Further gaps were identified in the area of pre-transplant management options. Educational efforts tailored to nephrologists are warranted to address these gaps.

Identifying Utility and Challenges for an Established Online Journal Club: The NephJC Experience Swapnil Hiremath, Matthew A. Sparks, Thomas Oates, Francesco Iannuzzella, Paul J. Phelan, Hector M. Madariaga, Michelle N. Rheault, Matthew P.M. Graham-Brown, Nikhil A. Shah, Edgar V. Lerma, Graham E. Abra, Anna Marie Burgner, Ian Logan, Suzanne M. Norby, Joel Topf. *Medicine, Univ of Ottawa.*

Background: Online journal clubs have become widespread as a method for dissemination and discussion of new research. Since its inception in April 2014, the online twitter based journal club #NephJC, has conducted more than 50 tweet-chats. We developed a survey to characterize participants and better understand the perceived benefits and potential barriers to participation.

Methods: The online survey was conducted using the Google forms platform. We invited individuals to participate by a direct message to @NephJC Twitter followers, including a link in the weekly NephJC email digest for 2 weeks and displaying a link prominently on nephrology blogs. Institutional review board approval was obtained.

Results: 328 individuals responded to the survey: 221 men (68%), from North America (49%), Europe (25%), and rest of world (26%). 178 (54%) were practicing physicians, 81 trainees (25%) and the remainder being other healthcare professionals (44, 14%) or interested citizens (24, 7%). The responding physicians were mostly nephrologists (147, 82%). The overwhelming majority of the respondents (> 90%) compared it favorably to traditional journal clubs. There was considerable interest in discussing non-traditional articles, such as guidelines (220, 67%) and interesting case reports/series (131, 40%). Despite only 10 respondents working in basic science, there was enthusiasm for discussing basic science articles (120, 37%). The major barrier to active chat participation was lack of time in general (50%). Hence, 64 respondents (20%) actively participate in the live tweetchat, and most others follow the feed passively (34%) or review individual tweets (46%) or curated versions (13%). Others noted issues regarding the specific time of the chat (31%).

Conclusions: NephJC , the online journal club, has near-unanimous positive feedback. We identify lack of time as the most important barrier to participation. Online journal clubs are a promising tool which interest MDs and non-MDs alike from different specialties and training levels.

TH-PO1133

The Renal Interactive Learning Module (ILM): A Novel Nephrology Curriculum for Interns Karen M. Warburton,[1] Dan Negoianu,[1] Jordana B. Cohen,[1] Serena Cardillo,[2] David J. Aizenberg.[2] *[1]Nephrology, Perelman SOM, Philadelphia, PA; [2]Medicine, Perelman SOM, Philadelphia, PA.*

Background: Interest in nephrology among US medical graduates is in decline, and this may be due to inadequate exposure to the more appealing aspects of this field during residency. It has been suggested that more exposure to ambulatory nephrology may stimulate interest in nephrology among residents. A dedicated nephrology ambulatory experience could highlight the longstanding relationships we often have with our patients and better demonstrate the variety in the clinical experience.

Methods: The Penn IM residency program recently adopted a 6+2 scheduling model, providing an opportunity for curricular innovation in the realm of ambulatory subspecialty experiences. Interns' schedules are templated such that they have 6 weeks of inpatient time, followed by two weeks of ambulatory time. The "+2" ambulatory time has been organized into six themed blocks called interactive learning modules (ILMs). As nephrology is relatively underrepresented in the clinical and didactic portions of our training experience, we included an immersive renal ILM into the curricular framework.

Results: All interns participated in the renal ILM course, repeated four times in succession to allow for standardized curriculum delivery to all four cohorts of interns. Components of the course included in-person themed content, subspecialty clinic experiences, core readings, and an interactive online forum. The in-person themed content consisted of a series of core lectures on topics relevant to ambulatory nephrology. Ambulatory experiences included the following clinics: transplant, complex hypertension, glomerular diseases, chronic kidney disease, home dialysis, in-center dialysis, and stones. The online forum provided an opportunity to review challenging cases and exchange questions and ideas regarding controversies in hypertension management.

Conclusions: Using the ILM framework, we supplemented traditional classroom-based experiences and provided our interns with exposure to a variety of career opportunities in nephrology. Future work will examine whether we were successful in quantifiably improving interest in nephrology as a career among residents.

TH-PO1134

Applying the Flipped Classroom Model in the Outpatient Renal Clinic: A Pilot Study Amir Kazory, Abhilash Koratala, Maryam Sattari. *Univ of Florida College of Medicine.*

Background: Suboptimal exposure to outpatient nephrology has been proposed as an important driving force for the fading interest in this subspecialty. We hypothesized that development of a focused educational activity for medical residents can increase their knowledge and interest. This pilot project was designed to evaluate the impact of a flipped classroom model and "Snapshot Exposure" in the outpatient nephrology setting on the knowledge of internal medicine residents about chronic kidney disease (CKD).

Methods: As part of the ambulatory rotation at the University of Florida, internal medicine residents attended a half-day CKD clinic between May 2013 and December 2015. A curriculum was developed focusing on evidence-based management of CKD. The flipped classroom model consisted of e-mailing the developed pre-clinic reading material to the residents prior to the clinic. The "Snapshot Exposure" consisted of a structured clinic session with the faculty nephrologist and a fellow. The baseline knowledge of residents was assessed at the beginning of the clinic through a multiple-choice pre-test. A post-test was administered at the end of the activity to assess the benefit of the clinic exposure. Student's t-test was used to compare the scores.

Results: Thirty seven medicine housestaff participated in this pilot study, attended the CKD clinic, and completed both the pre- and post-tests. The mean pre-clinic score was 3.87 + 0.38 out of 6 (range = 2-6) and the mean post-clinic score was 5.6 + 0.18 (range= 4-6). A statistically significant increase was seen in participants' knowledge as evaluated by the difference between the post-clinic versus pre-clinic scores (d=1.73; $P < 0.001$).

Conclusions: The main finding of this pilot study is that a snapshot exposure to CKD clinic can have a positive impact on the learners' knowledge. Moreover, the low pre-activity score implies that the conventional hand-out teaching might have limited impact on the knowledge of the learners. The next step would be to validate these findings in a larger population, and to evaluate the impact of this educational method on the interest and attitude of the learners regarding career choices.

TH-PO1135

Acute Kidney Injury (AKI) and Chronic Kidney Disease (CKD) Are amongst the Most Common Clinical Renal Questions Asked by Primary Care Providers (PCPs). Easily Identifiable Causes of AKI Are Frequently Missed Raimund H. Pichler,[1] Nancy M. Harris,[1] Maureen Germani,[1] Elizabeth A. Mattox,[1] Lauren Beste,[1] Michael F. Chang,[2] Bessie A. Young.[1] *[1]Dept of Veterans Affairs, Puget Sound Healthcare System, Seattle, WA; [2]Dept of Veterans Affairs, Portland Healthcare System, Portland, OR.*

Background: The Department of Veterans Affairs (VA) has used various forms of Telemedicine to improve care for Veterans. In 2010, the VA launched a form of electronic consultations (or non-visit consults (NVCs)) involving electronic medical record review of patients by specialists. To date there are little data on what renal clinical questions are most commonly asked by PCPs in referrals.

Methods: We conducted a qualitative chart assessment of NVCs (n=402) submitted to a Nephrology service; Using chart review, we determined clinical characteristics of the referred patients and qualitatively extracted the primary clinical question for referral.

Results: Of the 402 NVC referrals, 53% were for urban, 43% rural, 3% highly rural and 1% unknown patients. The most commonly asked clinical questions in descending order were regarding acute kidney injury (AKI) (25.7%), followed by AKI-on-chronic kidney disease (CKD) (18.7%), CKD (14.1%), request for medication review (13.4%), hypertension (10.5%), abnormal renal imaging (7%), and electrolyte imbalances (3.9%). Of all patients with AKI alone, 17% had a low blood pressure as defined by a systolic blood pressure of less than 120mm Hg, while 11% were taking non-steroidal anti-inflammatory drugs (NSAIDS). Consults for"renal imaging" referred to renal ultrasound reports that commented on "medical renal disease" and/or "renal cysts".

Conclusions: NVCs serve a relatively rural patient population. AKI and CKD are the most common clinical questions posed by PCPs in NVCs. Interestingly, low blood pressure and NSAID use appear to be overlooked causes of AKI amongst PCPs. Frequently reported and clinically insignificant abnormalities on renal imaging reports also prompt specialty consultation. The above results will help refine ongoing renal education outreach programs to address common knowledge gaps amongst PCPs.

Funding: VA Support

TH-PO1136

A Re-Evaluation of Pain Assessment in Hemodialysis Patients Tatiana Tanasiychuk, Muhammad Abd Elhalim, Daniel Kushnir, Victor Frajewicki. *Dept of Nephrology and Hypertension, Carmel Medical Center, Haifa, Israel.*

Background: Patients suffering from Chronic Kidney Disease treated by hemodialysis often complain about pain. The presence of chronic pain greatly impacts on patients quality of life (QOL) and may have effects on morbidity and mortality. The prevalence and severity of pain (acute or chronic) in this population and its influence on QOL is not well recognized. Although many sites use the Visual Analogue Scale (VAS) which includes just one question about the presence of current pain and its intensity, the best method for pain assessment has not be established.

Methods: VAS is routinely performed every treatment by our dialysis nurses. A modified Brief Pain Inventory (BPI) questionnaire includes 18 questions about localization, intensity and response to pain. BPI was given to our chronic hemodialysis patients. VAS results were obtained from the patients electronic files for the same session.

Results: 67 patients completed the questionnaire during the first week of 2016. Mean age was 73.5 years. 58% were diabetics, 68% were male. Average vintage on dialysis was 37.3 months. Only 1.5% of patients reported pain in VAS. In contrary, the BPI showed that 25% of patients had pain at that dialysis session and 61% suffered from pain for the previous 24 hours. Intensity of pain was significantly higher ($P<0.01$) with the BPI than with VAS. No significant differenced were detected between genders or diabetics/non-diabetics. In 52% of cases musculoskeletal pain was reported. Half of patients noted pain related reduced QOL defined by walk capability (54%), sleep disorders (57%), bad mood (64%), work disability (51%) or interference in familiar relationships (49%). Almost half of patients use any kind of analgesics and 10% use narcotics. Only 13% of patients reported to be pain free under analgesics treatment.

Conclusions: Pain is a frequent and debilitating condition in chronic hemodialysis patients, affecting all aspects of life, including not only the dialysis session. Standard short VAS may underdiagnose this problem leading to undertreatment and impairement of QOL. The use of a comprehensive pain tool may improve the outcomes.

TH-PO1137

Restless Legs Syndrome in Chronic Kidney Disease: Association with Objective Measures of Sleep/Wake Behaviors Maria-Eleni Roumelioti, Mark L. Unruh, Orrin Myers. *Internal Medicine, Div of Nephrology, UNM, Albuquerque, NM.*

Background: Restless legs syndrome (RLS) is a common sleep disturbance among patients with kidney failure and leads to severe initiation insomnia, daytime sleepiness and increased mortality risk. In this cross-sectional study we examined the prevalence of RLS and its effect on objective measures of sleep/wake behavior among patients with CKD (stages 4b-5) and chronic dialysis patients.

Methods: Objective measures of sleep/wake behavior included one in-home polysomnography and wrist actigraphy for two weeks. Presence of RLS was estimated with the Hopkins RLS Questionnaire.

Results: We studied 96 patients with stages 4b-5 CKD, 159 hemodialysis (HD) and 29 peritoneal dialysis (PD) patients. Average age was 54.7y, 60.2% were men, 64.4% were white. RLS was found in 36.8% of CKD, 28.7% of HD, and 44.4% of PD patients. Increased risk of RLS was associated with higher BMI, presence of DM and hyperglycemia .

	All	No RLS	RLS	p-val
Age	54.7(15.1)	56(16)	54(13)	0.2
Males(%)	60.2	62	57	0.4
Whites(%)	64.4	61	69	0.1

PSG data				
TSA(min)	336(111)	344(106)	325(117)	0.3
AHI	21.2(25.3)	20.2(24.6)	23.4(26.8)	0.4
PLMI	4.4(4.9)	3.9(4.5)	5.1(5.4)	0.1
Actiwatch data				
AvgOf ACSLPTOT	337(93)	344(102)	327(76)	0.2
AVGOFACWASO	81(34)	76(29)	89(39.5)	0.06
AvgOfACSE	69(11)	70(14)	67(14)	**0.04**
AvgOfACSL	43(46)	41(50)	46(42)	0.06

RLS was associated with decreased average of actigraphy scored sleep efficiency (SE), and with a trend towards increased actigraphy-scored wake after sleep onset and sleep latency.

Conclusions: RLS is common across the whole spectrum of CKD and is associated with decreased actigraphy-measured SE. Assessing appropriately and treating RLS in obese patients with CKD, especially due to DM, may improve their sleep and long-term outcomes.

TH-PO1138

Predicting 1-Year Mortality in Peritoneal Dialysis Patients by the Surprise Question, Palliative Care Screening Tool, and Clinical Risk Score Cheng Ching I,[1] Chun-Fu Lai.[2] *[1]Dept of Nursing, National Taiwan Univ Hospital and National Taiwan Univ College of Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [2]Renal Div, Dept of Internal Medicine, National Taiwan Univ Hospital and National Taiwan Univ College of Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Identifying potential candidates is an important issue to facilitate palliative care into the dialysis population. This study aimed to develop risk models to predict the 1-year mortality risks of patient under peritoneal dialysis (PD).

Methods: A total of 422 adult patients under PD for ≥ 3 months were recruited in March 2015. In addition to obtaining clinical characteristics and parameters, each patient was evaluated by the "surprise question" and the "palliative care screen tool" by the primary care nurse in the PD unit. Subjects were followed up from April 1, 2015 until March 31, 2016 for the outcome of all-cause mortality. The developed using Cox proportional hazards regression.

Results: During the 1-year follow-up, 34 (8.06 %) patients died. Kaplan-Meier analysis showed significantly worse survival in patients of the "no, not surprised" group or those with a score ≥ 4 of the palliative care screening tool (both log-rank $P<0.0001$).The area under the receiver operating characteristic curve (AUROC) to predict 1-year mortality by the two methods were comparable (0.743 v.s. 0.763, P=0.59). We also defined a clinical risk model that included gender, malignancy, Karnofsky Performance Status score, hemoglobin, white blood cell count, fasting serum glucose, serum creatinine, and intact parathyroid hormone level with good discrimination to predict 1-year mortality. Combining the above clinical model with the surprise question and the palliative care screen tool increased the AUROC to 0.938.

Conclusions: These results underscored the values of the surprise question and the palliative care screen tool to identify vulnerable patients undergoing PD.

Funding: Government Support - Non-U.S.

TH-PO1139

Medication Related Hospitalizations in Hemodialysis Patients Harold J. Manley, Jessica L. Baugh, Margaret Mcnamara, Doug Johnson. *Dialysis Clinic Inc, Albany, NY.*

Background: Hemodialysis (HD) patients' medication regimens are complex with 10-12 medications daily and medication related problems (MRPs) are common. The frequency and preventability of medication-related hospital (MED-HOSP) admissions in HD patients is unknown.

Methods: An observational study was conducted Sept. 2014-Sept 2015. MED-HOSP frequency, preventability (definite, possible, not-preventable), associated MRPs, length of stay (LOS) and potential risk factors were determined via ≥ 75% consensus within a group (3 pharmacists and 1-2 pharmacy students, 1-2 nurses). Reviews included information from discharge summaries and corresponding electronic medical record information (e.g., lab results, medical diagnoses, medications, progress notes). Patient age, number of medications prescribed, hospitalization type (index or readmit) and LOS for each event was recorded.

Results: A total of 343 (194 index; 149 readmit) hospitalizations in 218 unique patients (55.4% female; 59.2±15.1 yr) were included. Overall 35.3% (n=121) hospitalizations were MED-HOSP. Index admissions were less likely to be MED-HOSP events compared to readmits; 29.4% versus 42.9% respectively (p=0.012). MED-HOSP were considered definitely (35.4%), possibly (61.2%), or not-preventable (3.3%) of time. MRPs contributing to a MED-HOSP were dosing errors [27.3%; high (19%) or low (8.3%)], adverse drug event (24.8%), failure to receive drug (24.8%), indicated drug not prescribed (16.5%), different drug needed (3.3%), drug interaction (1.7%), and drug without indication (1.7%). MED-HOSP events were not predicted by gender (p=0.50) or number of medications (p=0.21). However, MED-HOSP events was associated with younger age (57.3±18 v. 61.4±13 yr; p=0.037) and had shorter LOS (5.8±4.7 v 7.3±7.8 days, p=0.026) compared to non-MED-HOSP events.

Conclusions: MED-HOSP events occur frequently and are preventable in HD patients. Dosing errors, adverse drug events, and failure to receive prescribed therapy (e.g., adherence) are the most common causes of MED-HOSP events. The impact of structured medication reviews to reduce MED-HOSP warrants investigation.

TH-PO1140

Fixing the Gap in Vancomycin Use among Patients on Hemodialysis at a Dialysis Center Nishkarsh Saxena, Laura J. Maursetter. *Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Vancomycin is the first line antibiotic for resistant gram positive infections, particularly MRSA. Its dosing should be guided by serum trough level with therapeutic goal of 15 to 20 mcg/mL. 30 to 40% of the drug is removed during 3 to 4 hour session of hemodialysis (HD). Pre-HD drug level can be used to guide vancomycin dose after accounting for extracorporeal elimination of the drug.

Methods: We first determined if there is a gap in dosing and monitor of vancomycin in patients on HD at a dialysis center [Wisconsin Dialysis, Inc. (WDI): WDI East (WDI-E) and WDI,Fitchburg (WDI-F)]. Among patients on HD at WDI who received vancomycin within a three month period (10/1/15 - 12/31/15), we calculated: a) Percentage of serum vancomycin level drawn to the total number of dose given. b) Percentage of serum vancomycin level within therapeutic range (15 to 20 mcg/mL).

Results: Among patients on HD at WDI who received vancomycin within a three month period (10/1/15 - 12/31/15), serum vancomycin level was drawn only 23% of the time and only 36% of the serum drug levels were within therapeutic range (15 - 20 mcg/mL).

	Serum vancomycin level drawn % (n;N)	Therapeutic range (15 - 20 mcg/mL) % (n;N)
WDI-F	23.59% (n=21; N=89)	38.09% (n=8;N=21)
WDI-E	25% (n=4;N=16)	25% (n=1;N=4)
WDI-E + WDI-F	23.8 (n=25;N=105)	36% (n=9;N=25)

Conclusions: Of the small percentage of serum vancomycin levels drawn, only 36% fell in the therapeutic range with a potentially much larger group that were not monitored falling outside the target range as well. The gap in care can lead to sub-optimal treatments and complications including multidrug resistant organisms, recurrent infections and increased mortality. To overcome this gap, we plan to implement a protocol and train the dialysis staff to use the protocol for vancomycin dosing for patients on HD at WDI.

Loading dose (LD) algorithm

Dry body weight (kg)	Vancomycin LD (20-25 mg/kg)✢
< 60	1250 mg IV

Targeted Deprescribing in an Outpatient Hemodialysis Unit: A Study to Decrease Polypharmacy Marisa Battistella,[1,2] Caitlin McIntyre,[1,2] Chaim Bell,[3] Rory F. McQuillan.[3] *[1]Nephrology, Univ Health Newwork, Toronto, ON, Canada; [2]Pharmacy, Univ of Toronto, Toronto, ON, Canada; [3]Medicine, Univ of Toronto, Toronto, ON, Canada.*

Background: Polypharmacy in hemodialysis patients can result in a higher risk of non-adherence, adverse drug events, hospitalizations, and mortality. Deprescribing tools can reduce polypharmacy yet no method exists for an outpatient hemodialysis population. We aimed to (1) develop a deprescribing tool for target medications with poor evidence for efficacy and safety; (2) determine its effectiveness in decreasing polypharmacy; and (3) monitor patient safety and satisfaction.

Methods: In a single-center prospective observational study, a deprescribing tool for specific medications was developed, validated, implemented and evaluated in a tertiary care center - outpatient hemodialysis unit. All 240 patients in the unit were screened using the deprescribing tool. The primary outcome was the proportion of target medications completely deprescribed at 6 months. Patient safety and satisfaction were monitored during the trial using drug-specific monitoring parameters outlined in the tool.

Results: Five medication classes were selected: quinine, diuretics, alpha-1 blockers, proton pump inhibitors, and HMG Co-reductase inhibitors (statins). There were 171/240 (71%) patients prescribed at least one of the five target medications and 71 patients (80 medications) underwent a deprescribing trial. After applying the tool, 35/40 (88%) eligible patients initiated a deprescribing trial. There were 31 of 40 (78%) target medications successfully deprescribed. Six months after the trial, only 5/31 (16%) medications discontinued were re-prescribed. This decreased the average number of medications per patient [from 13.4 ± 4.3 (SD) to 12.7 ± 4.4 medications in 35 patients]. No adverse events were observed.

Conclusions: Deprescribing tools can be applied successfully in an outpatient hemodialysis unit to reduce polypharmacy while maintaining patient safety and satisfaction.

Prolonged Intravenous Antibiotic Use in Hemodialysis Patients Evamaria Anvari, Laura Ferreira Provenzano. *Nephrology and Hypertension, Cleveland Clinic.*

Background: Infection is common in hemodialysis patients. The presence of a hemodialysis catheter and a weak immune system are recognized risk factors. Infections could be bacterial or non-bacterial, and bacterial infections include blood stream infections, pneumonia, urinary tract infections and others. Recognizing which patients to treat with antibiotics is essential, as bacterial infections are the second most common cause of death in hemodialysis patients, but treating patients with antibiotics when not needed, might lead to many adverse events. Despite this, many hemodialysis providers prescribe empiric antibiotics when patients are found to be febrile on hemodialysis, assuming a bacterial blood stream infection, sometimes without a clinical evaluation. In addition, many times blood cultures are not checked and prolonged antibiotic courses are given.

Methods: We analyzed blood culture and antibiotic use data from 10 hemodialysis units from a single dialysis provider in the Cleveland area, from January to November 2015. Patients were under the care of both private and academic practice physicians.

Results: During this period, 279 patients had blood cultures sent. Of these patients, only 49 had positive cultures. (17.6 %) and 230 were negative (84.4%). A total of 124 patients received antibiotics during hemodialysis, 75 of which ended having negative blood cultures. 33/75 of culture negative patients received more than 3 doses of antibiotics (range: 1-24 doses). Of the 49 patients with positive blood cultures, 33 had catheters.

Conclusions: Our data shows that there is significant variability in antibiotic use and duration in patients in hemodialysis. We found significant number of patients that received antibiotics without a clear indication. Protocols to help providers could help identify patients that require antibiotics in hemodialysis are needed, to avoid improper or prolonged use of antibiotics in the dialysis units.

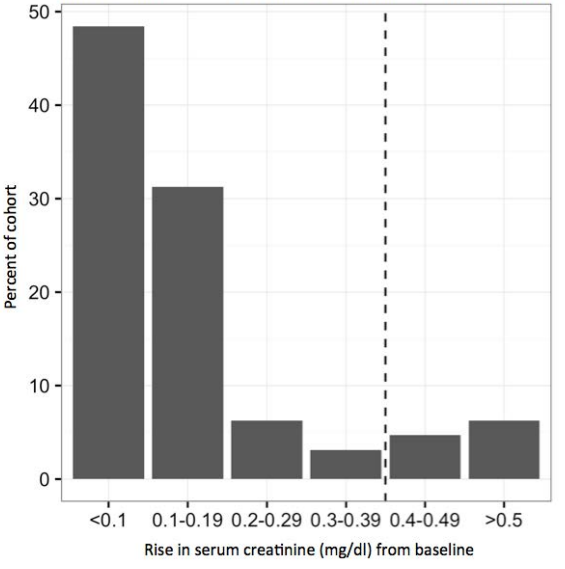
Safety and Efficacy of Novel Direct-Acting Antiviral Therapies in Patients with Chronic Kidney Disease Meghan E. Sise,[1] Gregory L. Hundemer,[1] Guillermo Ortiz,[1] Elke Backman,[2] Donald Chute,[3] Joseph Brancale,[3] Ravi I. Thadhani,[1] Raymond T. Chung.[3] *[1]Medicine/Nephrology, Massachusetts General Hospital, Boston, MA; [2]Pharmacy, Massachusetts General Hospital, Boston, MA; [3]Medicine/Gastroenterology, Massachusetts General Hospital, Boston, MA.*

Background: Sofosbuvir-based therapy has revolutionized the management of Hepatitis C Virus infection; however, little is known about the safety of this medication in patients with chronic kidney disease (CKD). The active metabolite of sofosbuvir, GS-331007, is renally eliminated. Recent studies suggest that patients with baseline CKD may experience adverse events including nephrotoxicity when treated with sofosbuvir.

Methods: Retrospective study of patients with CKD who began DAA treatment (tx) between 11/01/2013 - 12/31/15. CKD defined by mean eGFR < 60mL/min or albuminuria > 30mg/g in the 6months prior to tx. Safety, tolerability and laboratory results were assessed by chart review. Mean and standard deviation (SD) are presented.

Results: 107 subjects were included. Mean age 62 years (SD 8), 77% male, 46% White, 19% Black. 45% had diabetes, 86% hypertensive, 12% HIV co-infected, 37% were cirrhotic, 33% prior liver or kidney transplant recipients. 50% were HCV tx naïve. Regimens used were SOF/simeprevir 42%, SOF/ledipasvir 24%, and SOF/ribavirin 34%. 6% had a transient creatinine rise of >= 0.5mg/dL during tx.

Figure 1. Peak Rise in serum creatinine during direct acting antiviral therapy



Despite transient rises on therapy, average creatinine 12 weeks after therapy was 1.24mg/dL (SD 0.8) compared to baseline 1.26mg/dl (SD 0.37). SVR was 81%. Causes of renal and other serious adverse effects are presented, with discussion of relationship to DAA tx.

Conclusions: SOF-containing DAA regimens are effective and appear relatively safe in patients with CKD, although side effects were common; significant nephrotoxicity was noted in 6% percentage of cases.

The Drugs That Mostly Frequently Induce Acute Kidney Injury: A Case-Non-Case Study of a Pharmacovigilance Database Sophie Liabeuf,[1,2] Marion Pierson Marchandise,[1] Julien Moragny,[1] Kamel Masmoudi,[1] Valérie Gras.[1] *[1]Regional Pharmacovigilance Centre, Div of Clinical Pharmacology, Amiens Univ Hospital, Amiens, France; [2]Inserm U1088, UPJV, Amiens, France.*

Background: Acute kidney injury (AKI) is associated with a high hospitalization rate, accelerated long-term decline in kidney function and a high mortality rate. Adverse drug reactions (ADRs) constitute one of the most important modifiable factors in the context of AKI. Most studies of drug-induced AKI have focused on a sole drug class. The objective of the present survey was to establish a comprehensive overview of drug-induced AKI on the basis of ADRs spontaneously reported in the French national pharmacovigilance database (FPVD).

Methods: We performed a case/non-case study of drug-induced AKI. Cases of AKI were reported in the FPVD between January 1st, 2015, and December 31st, 2015. The non-cases corresponded to all other reports during the same period. Data were expressed as a reporting odds ratio (ROR) with its 95% confidence interval.

Results: Of the 38782 ADRs recorded in the FPVD during the study period, 3.2% were classified as cases of AKI. A total of 1254 patients experienced AKI (males: 55%; mean ± standard deviation age: 68.7 ± 15.0; median age: 70). Two or more concomitantly administered drugs were involved in 66% of the cases of AKI. The most frequently implicated drug classes were antibacterials for systemic use (29.5%), diuretics (18.5%), agents acting on the renin-angiotensin system (16.3%), antineoplastic agents (10.2%) and anti-inflammatory agents (5.4%). Gentamicin, eplerenone, spironolactone, candesartan, cisplatin and aciclovir had the highest RORs (>10).

Conclusions: Drug-induced AKI is a preventable event. A comprehensive study of a national pharmacovigilance database enabled us to identify the drug classes that most frequently induced AKI. Even though most of the identified drugs were already known to induce AKI, the present work should raise physicians' awareness of the compounds responsible for triggering this potentially life-threatening condition.

TH-PO1145

Incidence of Hyperphosphatemia and Hypocalcemia Secondary to Phosphate Enema Administration Javier Villacorta, Ana M. Tato, Gema Fernandez Juarez. *Nephrology, Hospital Fundacion Alcorcon, Alcorcon, Spain.*

Background: The use of sodium phosphate solutions as a purgative implies an exogenous phosphorus administration 8 times the normal daily intake. This overload of phosphorus can lead to a significant increase in phosphatemia within the first 24 hours, which is usually accompanied by a decrease in serum calcium levels. This has been demonstrated in patients undergoing bowel preparation with oral phosphate solutions, but few studies have analyzed electrolyte abnormalities after the use of phosphate enemas.

Methods: This study aim to analyze changes in serum phosphorus and calcium levels following the administration of sodium phosphate enemas in a cohort of hospitalized patients. During a follow-up period of three months, all patients admitted in the Foundation Hospital Alcorcon who recieved sodium phosphate enemas were studied prospectively. Serum phosphorus and calcium determinations were performed 48 hours before and 24 hours after sodium phosphate enema exposure.

Results: Changes in serum calcium and phosphorus levels were studied after 22 exposures to phosphate enemas in fourteen patients. In most cases a single enema (dosage of 8 gr of sodium phosphate; Casen Fleet Enema 250 cc) was administered. The average serum concentration of phosphorus and calcium before enema administration was 2.94 +/- 0.46 and 8.3+/-0.65 mg/dl, respectively. The average concentration of phosphorus and calcium after sodium phospate exposure was 3.2 +/- 0.67 and 8 mg/dL+/-0.61, respectively. In fourteen patients (63.5%) the sodium phosphate enema led to positive phosphorus balance and negative calcium balance. The mean increase in serum phosphorus was 0.34 mg/dl after administration of the enema, and the mean decrease in plasma calcium was - 0.2 mg/dl. Two patients (9%) developed mild hyperphosphatemia and 5 patients (22.7%) with previous normal calcium levels developed relevant hypocalcemia.

Conclusions: The use of sodium phosphate enemas led to an increase in serum phosphorus levels and decrease in serum calcium levels in a high percentage of patients. These electrolytes changes are mild and transient in most cases, but may determine the onset of significant hyperphosphatemia or hypocalcemia in a significant number of patients.

TH-PO1146

Monitoring Urinary Protein Excretion in Patients with Heart Transplant Receiving mTor Inhibitors-Need for Raising Awareness Negiin Pourafshar,[1] Ashkan Karimi,[2] Jon A. Gregg,[1] Amir Kazory.[1] *[1]Div of Nephrology, Univ of Florida, Gainesville, FL; [2]Div of Cardiovascular Medicine, Univ of Florida, Gainesville, FL.*

Background: The inhibitors of the mammalian target of rapamycin (mTORi) are used in the setting of orthotopic heart transplantation (OHT) mainly to avoid the nephrotoxicity of calcineurin inhibitors (CNI) or to slow the progression of allograft vasculopathy. Proteinuria is a well-recognized complication of mTORi use in the renal transplant recipients but there is limited data in the OHT population. We studied the monitoring of patients with OHT who received mTORi-based regimens with respect to development of proteinuria.

Methods: This is a retrospective study of patients who underwent OHT between January 2000 and December 2015 at our institution. Patients on mTORi, whether de novo or following conversion from a CNI-based regimen, were included. The clinical and laboratory records were reviewed and monitoring of urinary protein excretion through qualitative (urine analysis) or quantitative measurements were explored before and after the initiation of mTORi.

Results: A total of 411 OHT patients were studied, of which 91(22%) received mTORi (72 Sirolimus and 19 Everolimus). mTORi was started de novo in 32/91 (35 %) of patients. Prior to the initiation of mTORi, urine protein excretion had been assessed in 56/91 (62%) of the patients with either urinalysis (26/91 [29%]) or quantitatively (30/91 [33%]). After the initiation of mTORi therapy only 60/91 (66%) had at least one-time evaluation for proteinuria during follow-up by urine analysis 26/91 (29 %) or quantitatively 34/91 (37%). Among patients who received mTORi, 31/91 (34%) patients had no assessment of proteinuria throughout follow-up.

Conclusions: This single-center study reveals that a significant subset of OHT recipients who are treated with an mTORi-based regimen may not undergo assessment of proteinuria prior to or following initiation of mTORi, possibly resulting in underdiagnosis. Raising awareness regarding regular screening and timely diagnosis of this complication may conceivably lead to long-term preservation of renal function and overall improvement in the outcomes of these patients.

TH-PO1147

Management of Hyperkalemia in Emergency Department: Computerized Physician Order Entry Reduces Hypoglycemia Associated with Insulin-Dextrose Treatment Bairbre A. McNicholas, Mai Huong Pham, Chang Huei Chen, Hien Pham. *Div of Nephrology, Univ of Washington, Seattle.*

Background: Hyperkalemia is commonly treated in the ED (emergency department) with insulin-dextrose being a cornerstone of treatment. The use of insulin can result in clinically significant hypoglycemia. Computerized physician order entry (CPOE) has been shown to reduce preventable adverse events. We assessed use of CPOE for hyperkalemia management on hypoglycemia incidence in the ED.

Methods: Two retrospective studies of hyperkalemia management at Harborview Medical Center ED were carried out, an initial study from June-December 2013 and a follow up study from July 2015 to January 2016. Following the initial study, Education sessions were provided to ED staff on CPOE for hyperkalemia management. For both studies, data related to presentation, laboratory values and pharmacological management of hyperkalemia (K^+>6mEq/L) was collected using chart review for each patient.

Results: In the initial study, 125 patients had 155 presentations of K^+>6mEq/L compared to 98 patients with 116 presentations in the follow up study. In the initial study, pharmacological treatment was used in 99(63%) of cases with management in 62(62%) ordered using CPOE for hyperkalemia. 75(75%) patients were treated with insulin-dextrose. In the follow-up study, pharmacological treatment was used in 68(58%) of cases and 51(75%) were ordered using CPOE for hyperkalemia. 66(97%) patients were treated with insulin-dextrose. When subjects with hyperkalemia associated with hyperosmolar hyperglycemia (blood glucose>600mg/dl) were excluded from treated groups (n=3 for initial study, n=3 for follow up study), the number of cases managed using CPOE for hyperkalemia trended higher on follow-up (62/96 (64%) vs 51/65(78%), p=0.07). The number of cases of hypoglycemia associated with insulin treatment was reduced at follow up (21/76 (27.6%) vs. 7/66 (10.6%), p=0.02) and there were no cases with blood glucose <40mg/dl compared to 3 cases in the initial study.

Conclusions: Increased use of CPOE for management of hyperkalemia was associated with a reduction in number of patients with hypoglycemia associated with insulin-dextrose treatment.

TH-PO1148

Atypical Hemolytic Uremic Syndrome: Quality Measures for Detection Jibran Ahmed,[1] Hussein Hamad,[2] Olha Huzo,[3] Carolyn S. Brecklin.[4] *[1]Internal Medicine, John Stroger Hospital of Cook County, Chicago; [2]Internal Medicine, John Stroger Hospital of Cook County, Chicago; [3]Saint James School of Medicine; [4]Nephrology, John Stroger Hospital of Cook County, Chicago.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a major thrombotic microangiopathy (TMA). TMA include aHUS, Shiga-toxin producing E.Coli (STEC) associated HUS and thrombotic thrombocytopenic purpura (TTP). It is essential to differentiate aHUS from TTP as these two entities require different treatment. We conducted a retrospective study to determine whether patients receiving plasma exchange for TMA had appropriate initial testing done.

Methods: We identified 30 patients who received plasma exchange for presumed TTP between January 2010 and June 2015 at an inner city hospital and recorded socio-demographic, clinical and laboratory data. Mean values were calculated, univariate analysis was conducted.

Results: Male patients accounted for 73% of the group and 73% were African-American. Diarrhea at presentation was recorded in 16% (5 pts) of which only 2 (6.6%) had testing for STEC sent. Cancer (26.7%) and infection (23.7%) were the two most common risk factors. The mean platelet count (plts) at diagnosis was 31,600 and the mean creatinine (Cr) was 3.46 mg/dl. Haptoglobin was checked in 23 pts (76.6%) and was not low in 4 pts (13.3%). ADAMTS 13 was checked in only 20 pts (66.6%) and levels below 5% were observed in only 5 pts (16%). Normalization of plts after 10 sessions of plasma exchange occurred in about 50% of patients and 16% had relapse by 1 month. Dialysis was required in 16%. Cr level at diagnosis did not correlate with plts normalization after 10 sessions of plasma exchange (p=0.088) or with relapse at one month (p=0.76) but did correlate with the need for dialysis (p=0.003).

Conclusions: Our review showed that appropriate pre-plasma exchange labs were not always performed when TTP was presumed, including STEC test, haptoglobin and most importantly ADAMTS13 level. The relapse at one month, although not unexpected, should raise the question of the accuracy of initial TTP diagnosis and the provision of ADAMTS13 level testing is crucial. Further studies should help define the recommended testing algorithms for TMA.

TH-PO1149

Effectiveness of UV Light in the Disinfection of Peritoneal Dialysis Catheter Connections

Julia Rasooly, John Ashley, Ian Tran, Glenn Matthew Chertow. *PuraCath Medical, Inc., Fremont, CA.*

Background: The purpose of the current study was to evaluate the microbiological performance (log reduction) of a modified ultraviolet (UV) light-based peritoneal dialysis catheter connection system. The system included an enhanced UV light generating device which provides greater coverage for the UV transparent connector incorporated into the transfer set and a modified UV transmissive connector which improves patient ease of use.

Methods: Prior to being coupled to the non-UV transmissive Y-set connector with a membrane sealing the distal lumen which is attached to a PD solution bag, each UV transparent transfer set was inoculated with 10µl of cultured inoculum consisting of either *S. aureus, E. coli,* or *C. albicans*. After being inoculated, the Y-set connector was attached to the transfer catheter connector creating a sealed chamber, then placed in a UV generating device, and the chamber was exposed to a UV light dose of approximately 350-400 mJoules/cm^2. After being exposed to the UV light, the membrane seal was broken, the plunger valve on the UV transmissive transfer catheter was pushed to the open position, and 10 mL of dialysate was flushed through the connection over 7 seconds. The flushed solution was collected, diluted, and plated on agar medium matched to the organism. All plates were incubated for a 24 hour period (48 for C. albicans). Sample results were compared to positive controls which were collected in an identical manner but without exposure to the UV light.

Results: Twenty-nine (29) separate test samples, 3 positive controls, and 1 negative control were collected for each organism. All positive control samples had significant bacterial growth and negative controls had no growth following the 24 hour incubation period. All test samples exposed to UV light had complete kill of bacteria. Log reduction ranged from 4.93 in the *C. albicans* group, to 5.56 in the *S. aureus* group, to 6.24 in the *E. coli*.

Conclusions: The application of 400 mJ/cm^2 of UV light (254nm) combined with an easier to use UV transmissive transfer catheter connector produces a germicidal effect upon microorganisms which have been found to be associated with peritonitis in patients receiving peritoneal dialysis.

TH-PO1150

Application of Comfeel Hydrocolloid Transparent Dressing Combined Specific Electromagnetic Wave in the Patients with Arteriovenous Fistula Complicated with Subcutaneous Hematoma

Hui-Qun Li,[1] Wenbo Zhao,[1] Geng-Xi Sun,[2] Hui Peng,[1] Tan-Qi Lou.[1] *[1]The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong; [2]Affiliated Hexian Memorial Hospital, Southern Medical Univ, Guangzhou, Guangdong.*

Background: Comfeel transparent dressing is a hydrocolloid dressing which can promote local blood circulation, relieve pain and Reduce inflammatory reaction. And Teding Dianci Pu (TDP) special electromagnetic wave irradiation instrument can diminish inflammation and promote the growth of the local epithelial tissue. The purpose of this study is to explore the effect of Comfeel transparent dressing combined TDP irradiation treatment in the chronic kidney disease patients with arteriovenous fistula (AVF) complicated with subcutaneous hematoma.

Methods: 30 patients (14 male, 16 female) were involved in this study. All the patients were randomly divided into observation group (n=15) and control group (n=15). There was no significant difference in gender, age, primary disease, use time of AVF and the size subcutaneous hematoma between the two groups. The methods of control group included clean the local skin and use the Hirudoid ointment to massage, 3 times a day, but not to use within 6 hours after hemodialysis. The methods of observation group included clean the skin, paste the Comfeel transparent dressing (No.3533), and use TDP irradiation for 15 minutes, twice a day, but not to use TDP within 24 hours after hemodialysis. The transparent paste was replaced every 3 days. The effect of treatment was recorded daily, and the skin ecchymosis, swelling, local pain (NRS Pain Assessment Scale), AVF tremor and patient satisfaction were assessed after 1 week.

Results: The subsidence of the skin ecchymosis and swelling was faster ($P < 0.05$) in the observation group. And the pain assessment showed pain scores of observation group were lower than the control ones ($P < 0.05$). There were no differences in the AVF tremors and patient satisfaction ($P > 0.05$).

Conclusions: The research results show that use of Comfeel transparent paste combined TDP irradiation can effectively relieve the local pain, and promote the subsidence of the skin ecchymosis and swelling. It is worthy to be popularized in clinic practice.

TH-PO1151

Beyond the Bundles: Reducing Central Line Related Infections - Permanent Catheter (PC) in Haemodialysis (HD) Patients at Five Community-Based Dialysis Centres (CB-DCs)

Jamilah Jantan. *Quality Management/Infection Control, National Kidney Foundation, Singapore.*

Background: Catheter Bundles were implemented for PC care over five year period to reduce infections at NKF. Changes included hand hygiene compliance, barrier precautions, use of alcohol based 2% chlorhexidine antisepsis, patient education and ensuring PC dressing is intact/dry The Catheter Bundles decreased infection rates, however it did not approach zero after interventions. Reducing catheter infection rate is essential for safe care and patient safety. This study adopts CDC Approach to Bloodstream Infections (BSI) Prevention in Dialysis Facilities. Aim of the study is to determine the contributing factors for catheter-related infections, develop creative solutions and reduce the PC infections at NKF.

Methods: From Jan 2014 to Dec 2014, 115 HD patients had catheter - related infections. Five CB-DCs had surpassed PC infection rate equal and above 4.32 per 100 patient months. Catheter Bundles Audit (4th Quarter 2014) showed 90% compliance rate. AS-IS Diagram, three starbursts were identified; hand hygiene non-compliance, lack of patient education and poor "Scrub The Hubs" technique. Interventions includes training on "Dialysis Catheter Workshop" was conducted in Feb 2015 with participations from 42 clinicians, development of patient educational brochure, video on "Catheter Care", PC "E" kit to promote self management and Catheter Bundle Audit to monitor the compliance with procedures.

Results: Results revealed catheter-related infection rate declines from 7.14 per 100 patient months in Nov 2014 to 1.23 per 100 patient months in Apr 2015, reduction in hospitalisation episodes from 16 to 9 cases, cost savings and increase compliance with Catheter Bundles from 90% to 94%.

Conclusions: This study promotes compliances through catheter management with standardisation of PC training (video), patient educational brochure and PC "E" kit. While the national average is 4.32 per 100 patient months, ours is down to around overall average 2.10 per 100 patient months in Apr 2015. Active surveillance, sharing of catheter-related infection rates and catheter bundle audit results with clinicians helps to raise awareness on the importance of PC care.

TH-PO1152

Efficacy and Cost-Effectiveness of DDAVP Administration prior to Renal Biopsy when eGFR Is Below 30: A Retrospective Chart Review

Michael J. Rogers,[1] Elise J. Barney.[2] *[1]Internal Medicine, Banner Univ Medical Center, Phoenix, AZ; [2]Nephrology, Phoenix VA Healthcare System / Univ of Arizona COM, Phoenix, AZ.*

Background: Renal biopsy is an essential diagnostic tool in management of renal disease. Life-threatening bleeding, while uncommon, is a serious and feared complication. Higher serum creatinine has been shown to predict postbiopsy bleeding (Whittier et al.). In 2011, Manno et al. found a 0.45 relative risk reduction in postbiopsy bleeding with DDAVP compared to placebo. In 2014, our Radiology Department implemented a protocol giving 0.3mcg/kg of IV DDAVP to all patients with eGFR below 30 prior to ultrasound-guided renal biopsy.

Methods: A retrospective chart review was done for all patients who underwent a renal biopsy one year prior to and after protocol implementation. We collected data on patient age, baseline blood pressure, hemoglobin, renal function, coagulation and evidence of minor or major bleeding. Minor bleeding is defined as: perinephric hematoma and gross hematuria. Major bleeding is defined as the need for angiography or embolization.

Results: Of 156 patients who did not receive DDAVP, 24 were noted on imaging to have a perinephric hematoma and 5 required renal artery embolization. Of 144 patients who did receive DDAVP, 13 had a hematoma and none required angiography or embolization.

Conclusions: Despite what appear to be promising outcome trends with the administration of DDAVP, our findings were not statistically significant. We believe our analysis is limited primarily by sample size. However, at an institution cost of $2/mcg, the total cost of DDAVP given to our treatment group was $7,041. This is far less than Medicare reimbursements (HCPCS36253) for one renal angiogram. Therefore, given the favorable trend toward bleeding prevention, if administration of DDAVP prevents at least 1 embolization, it proves to be a cost-effective adjunct therapy in a higher risk population.

TH-PO1153

Arterial Stiffness Is an Independent Risk Factor for Anemia after Percutaneous Native Kidney Biopsy

Keiko Tanaka, Masashi Kitagawa, Akifumi Onishi, Tatsuyuki Inoue, Koki Mise, Toshio Yamanari, Hitoshi Sugiyama, Jun Wada. *Dept of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama Univ Graduate School, Okayama, Japan.*

Background: Bleeding is the most common complication after renal biopsy. There are many previous reports on the predictors of bleeding. While physicians can perform procedures carefully, anemia is frequently unavoidable. Whether arterial stiffness affects bleeding complications remains unclear.

Methods: We performed an observational study of the renal biopsies that were performed over an approximately 6-year period (March 2010 to March 2016) at our Division. They were all percutaneous ultrasound-guided biopsies. The clinical and laboratory factors were analyzed to reveal the risk factors associated with bleeding, with a focus on anemia (defined as a ≥10% decrease in hemoglobin (Hb) after biopsy). The brachial-ankle pulse wave velocity (baPWV) was measured to evaluate the arterial stiffness.

Results: This study included 462 patients (244 males, 218 females). Of these, 2 patient (0.43 %) required a blood transfusion after the biopsy; no patients required nephrectomy

due to continuous bleeding. Macrohematuria occurred in 5 patients (1.0 %), and perirenal hematoma was observed on ultrasonography in 386 patients (85.0 %). The median decrease in Hb was 0.33 g/dl. Anemia (defined above) was observed in 54 patients (11.7 %). The risk of anemia was higher in women, older patients, and patients with lower serum albumin, lower eGFR and lower diastolic blood pressure after biopsy. A multivariate analysis revealed that anemia was strongly associated with female gender, lower serum albumin, and lower diastolic blood pressure after biopsy. Next, we performed a further analysis in 187 patients for whom baPWV data was available. A higher baPWV value was found to be a risk factor of anemia. The ROC analysis for predicting anemia revealed baPWV 1839 m/s to be the best performance (AUC 0.689, $p < 0.005$).

Conclusions: An increase in the baPWV, which is non-invasive parameter of arterial stiffness, was the factor significantly associated with anemia after biopsy, and thus may be a more valuable predictor of bleeding complications than any of the other reported risk factors.

TH-PO1154

Outpatient Percutaneous Native Renal Biopsy: Safety Profile in a Large Monocentric Single Operator Cohort Dario Roccatello, Savino Sciascia. *Nephrology Dept, San Giovanni Bosco Hospital, Torino, Italy.*

Background: Debate exists on the appropriate observation period after percutaneous native renal biopsy. We evaluated the safety of performing renal biopsy as an outpatient procedure compared to the traditional inpatient policy.

Methods: We retrospectively studied native kidney biopsies performed in our Institution (Jan 2000-Nov 2015).Since Jan 2012, we began performing renal biopsies as outpatient procedures. Two groups of patients were considered; Group I: biopsy was performed and followed by at least 1-day hospital admission;Group II: biopsy was performed as outpatient and followed by 6 hours' observation period and then by outpatient visits. All biopsies were performed by a single nephrologist with the use of real-time ultrasound and automated biopsy needle (18 gauge),following a structured protocol.

Results: 462 biopsies were reviewed, 210 (45.5%) of patients were female and the mean age was 54.7±17.9 years. 129 (27.9%) of these biopsies were performed in outpatients. A total of 36 (7.8%) of patients developed a complication, and of those 9 (1.9%) suffered for a major complication [arteriovenous fistula (6 cases,1.2%), ischaemic stroke (2, 0.4%), thromboembolic pulmonary embolism (1, 0,2%)] and 27 (5.8%) for minor [macroscopic haematuria (12 cases, 2,6%), haematomas on sonography not requiring intervention (15 cases, 3,2%)]. When comparing the complication rate between group I and II, no statically difference were observed [overall 24/333 (7,2%) complications in group 1 and 12/129 (9,3%) in group II; 5/333 (1,5%) and 4/129 (3,1%) major, 19/333 (5,5%) and 8/129 (6.2%) minor complications, respectively in group I and II]. When analysing together both groups, after multivariate analysis, serum creatinine >3 mg/dl (OR 2.03 95%CI 1.18-6.81) and known severe hypertension (OR 2.01 95%CI 1.2-4.7) were found to be independent risk factors for minor and major complications, respectively. We found no association of risk with the biopsy passes, gender, age, diagnosis, presence of haematuria before the kidney biopsy nor the degree of proteinuria.

Conclusions: Outpatient biopsy could be a valuable, safe, and perhaps cost-effective method of obtaining diagnostic renal tissue in the majority of patients.

TH-PO1155

Complications of Percutaneous Renal Biopsy Performed by Nephrology Fellows: Analysis of 1071 Procedures Manuel Alejandro Marquez,[1] Monica Chapa,[2] Ricardo Correa-Rotter,[1] Juan M. Mejia-Vilet.[1] *[1]Nephrology, Inst Nacional de Ciencias Médicas y Nutrición, Mexico; [2]Radiology, INCMNSZ, Mexico.*

Background: The performance of percutaneous renal biopsies(PRB) is a key element for renal diagnosis and nephrology training. The aim of this study was to evaluate safety and efficacy of PRB performed by nephrology fellows(NF) in an academic training program and to determine risk factors for major complications(MC).

Methods: All PRB performed by NF between 2008-2015 were analyzed.PRB procedures were ultrasound-guided and supervised by staff.In all patients, a doppler ultrasound(US) was performed 10min after the procedure. MC were defined as those requiring medical intervention(blood transfusion, renal angiography, surgery or death). Chi-square, t-student or Mann-Whitney tests were used for comparison of those with or without MC. A predictive model for MC was constructed by logistic regression.

Results: A total of 1071 PRB were analyzed,≥10 glomeruli were obtained in 989(92%) and were appropriate for diagnosis in 1067(99.6%). MC presented in 33(3.1%). All corresponded to hematomas requiring blood transusion, 3(0.3%) renal angiography and 1(0.09%) patient died after a laparotomy due to severe hemorrhage. Predictors of MC in the logistic regression model are shown

Risk factor	Prebiopsy Risk factors			+ Post-biopsy ultrasound		
	OR	95% CI	p Value	OR	95% CI	p Value
Female	3.68	1.21-11.2	0.022	3.27	1.04-10.2	0.042
Blood urea nitrogen>50mg/dl	4.82	2.15-10.8	<0.001	5.09	2.18-11.9	<0.001
Hemoglobin <11g/dl	4.23	1.73-10.4	0.002	3.39	1.34-8.58	0.010
Platelets <150 per mm3	6.00	2.76-13.0	<0.001	5.04	2.20-11.5	<0.001
Hematoma in ultrasound	--	--	--	8.23	3.35-20.2	<0.001

The predicting AUC was 0.89. There were no differences in MC in 28 patients who had total anticoagulation(suspended prior to PRB). The absence of a renal hematoma in the immediate post-procedure US had a NPV of 99%. The addition of postprocedure US to the model improved the AUC to 0.92.

Conclusions: The study allowed the identification of specific high-risk factors for selection and decision of performance of a PRB. The absence of a renal hematoma in the immediate postprocedure US had a high NPV for MC. RPB is a safe procedure when performed by NF, as MC presented in a similar pattern and percentage as compared to large published series.

TH-PO1156

Safety of Outpatient Kidney Biopsies Bojana Gardijan, Mihaela Gunjaca, Branislav Cingel, Mladen Knotek. *Renal Div, Dept of Medicine, Univ Hospital Merkur, Zagreb, Croatia.*

Background: Kidney biopsy (bx) is an essential part of nephrological diagnostic work-up. In our center it is frequently performed as an outpatient procedure. Aim of this study was to evaluate the safety of bx in the outpatient setting.

Methods: We analysed native and transplant kidney bx performed from July 2013 to June 2015. 255 bx performed in the outpatient setting were identified. There were 216 bx in transplant pts, and 39 native kidney bx, including 3 solitary kidney bx. All were performed under US guidance using a 16G or 18G needle. In all patients with eGFR<30ml/min desmopressin (0.4 µg/kg BW i.v.) was administered prior to the procedure. Patients were observed for 6 h before discharge, with a CBC and a urine test performed after 4 hours. Ultrasonography was performed upon attending clinician discretion. Study outcomes were minor complications, defined as macrohematuria, significant reduction in Hb levels (>10% without need for RBC transfusion), local hemorrhage or major complications, defined as hemorrhage requiring therapeutic intervention including RBC transfusion.

Results: There were 71 female and 184 male patients. Average age was 42.6 ±16.1yrs. Indications for native kidney bx included nephrotic syndrome (51%), subnephrotic proteinuria with hematuria (29%), follow-up bx (15%), and other (5%). From 216 transplant bx 31% were indication and 69% were protocol bx. The glomerular yield in 96.9% of bx was sufficient for analysis. There were no major complications. In 18% of patients there was a Hb rise after biopsy. Average postbx Hb decline in the other 82% was 5% (1-16%). In 13.3% pts there was >10% reduction in Hb level, with no evident bleeding, including by US. In 2% of the patients postbx macrohematuria was present, without requirement for intervention or blood transfusion. In univariate analysis age, gender, serum creatinine, prebx Hb and indication for bx were not predictive for postbx Hb decline. There were no therapeutic interventions required for bx complications.

Conclusions: We found that kidney biopsy performed in an outpatient setting in select patients is only rarely associated with adverse events and is a safe procedure.

TH-PO1157

Self-Monitoring Creatinine after Kidney Transplantation: Reliability of Patient Reported Data Céline Lianne van Lint,[1] Wenxin Wang,[2] Sandra Van Dijk,[1,4] Ton Rovekamp,[3] Ton J. Rabelink,[1] Willem-Paul Brinkman,[2] Paul J. Van der Boog.[1] *[1]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Computer Science, Delft Univ of Technology, Delft, Netherlands; [3]Technology in Healthcare, Prevention and Health (TNO), Leiden, Netherlands; [4]Health, Medical and Neuropsychology & Behavioural Sciences, Leiden Univ, Leiden, Netherlands.*

Background: Our previous study shows that self-monitoring creatinine can significantly decrease the high number of outpatient visits in the first year post-transplantation without compromising on quality of care. In the current study we analyzed data from this same self-management RCT to investigate the reliability of patient reported measurements.

Methods: During the first year post-transplantation 54 patients registered their self-measured creatinine values in an online Self-Management Support System (SMSS) which provided automatic feedback (e.g. contact hospital). Values registered in the SMSS were compared to those logged in the creatinine device to study reliability of registered data. Adherence to measurement frequency was determined by comparing number of requested with number of performed measurements. To study adherence to provided feedback, SMSS logged feedback and information from the electronic hospital files were analysed.

Results: Level of adherence was highest during month 2-4 post-transplantation with over 90% of patients performing at least 75% of the requested measurements. Ninety percent of all registered creatinine values was entered correctly, although values were often registered several days later. In case more measurements were performed than registered on a single day (10%), registered values were significantly lower than unregistered values ($p < .05$) suggesting selection of lower creatinine values. Adherence to SMSS feedback ranged from 53-85% depending on the specific feedback.

Conclusions: Self-monitoring creatinine enables the high number of outpatient visits to be reduced. However, patients' tendency to postpone registration and to select lower creatinine values for registration and the suboptimal adherence to the SMSS provided feedback might challenge safety. These issues can mostly be overcome by transferring measured data automatically.

TH-PO1158

Eradication of Chronic *Helicobacter pylori* Infections in Immigrant Patients with Chronic Renal Insufficiency Alexander M. Swan, Kay Thwe Kyaw. *NHRTRT, LLC, Avenel, NJ.*

Background: Based on some epidemiological studies, there are more frequent infection rate of Helicobacter pylori (H. pylori) in children of developing nations. Surprisingly, more than 50 % of second-generation immigrants are infected with H. pylori. Some studies showed that those differences are somewhat related to socioeconomic status. Most route of transmission of H pylori is either oral-to-oral or fecal-to-oral contacts. Some patients with

H pylori do not present symptoms. When comes to treatment, triple therapy regimen is the first line treatment of H. Pylori. It is critical to aware of known complications of H. pylori such as gastric adenocarcinoma, gastric MALToma, and squamous cell esophageal cancer.

Methods: This study is a non-randomized parallel clinical trials study design. The study population was selected from renal failure patients who were H. Pylori Ig G Ab positive after treated with standard triple regime, consisting of 88 participants of renal failure ranging from CKD Stage one to five, with age between 20 to 65, 80 participants finished and 8 drops out from the study. There are 16 participants contributed in each chronic kidney disease stage from one to five. The participants were given the new treatment, which includes Nitazoxanide 500 mg PO twice daily; Omeprazole 40 mg capsule delayed release daily; Levaquin 500 mg tab daily; and Doxycycline 100 mg twice daily, and the renal dose adjustments were done according to creatinine clearance. The duration of new treatment was 4 weeks. H. pylori Ig G Ab levels were measured before and after new treatment.

Results: At the end of the study, H. Pylori Ig G Ab of all patients in the study population was reduced to "0". The outcome measure is a complete resolution of symptoms of H. Pylori and the disappearance of H. pylori Ig G antibody.

Conclusions: There is evidence that the new treatment regimen reduced H. pylori Ig G level to 0, and clearly showed that more effective in eradication of H pylori infection in patients who have chronic renal failure. The drawback of the new treatment is expensive. However, more researches with larger populations are needed for developing a new guideline for eradication of H pylori in all patients to prevent complications H. pylori infections.

TH-PO1159

Improving Post-Kidney Transplant Immunisation: A Clinical Practice Improvement Project

Sanela Redzepagic,[1,2,3] Angus G. Ritchie,[1,2] Martin P. Gallagher.[1,2,4] *[1]Concord Hospital, Sydney, Australia; [2]Univ of Sydney, Australia; [3]Kolling Inst of Medical Research, Sydney, Australia; [4]The George Inst, Australia.*

Background: Kidney transplant recipients (KTR) are at increased risk of influenza and invasive pneumococcal disease. Audit after 2 cases of pneumococcal infection in KTR at our institution identified low prevalence of pneumococcus (35%) and influenza (30%) vaccination. We devised a quality improvement program in partnership with primary care, who manage vaccination in Australia, to improve up-to-date vaccination to>90% in this population.

Methods: We conducted a single centre prospective clinical practice improvement study on a KTR cohort over 3 years (2013-15). The diagnostic phase indicated low awareness of vaccination importance, non-adherence to local immunisation guidelines and suboptimal communication with primary care doctors. Two interventions of annual reminders to primary care doctors with local immunisation guidelines were devised. The primary outcome was up-to-date vaccination reported in annual surveys. A logistic regression model using Generalized Estimating Equations was used in analysis. The study was approved by our ethics board.

Results: Surveys were sent to the primary care doctors of 59 KTR. Responses were received to 48/59(81%) and 37/59(63%) surveys to interventions 1(2014) and 2(2015) respectively. For pneumococcus 34% of eligible patients were reported to have received vaccination in the period prior to baseline survey, increased to 69% by the second survey; while up-to-date influenza vaccination increased from 45% to 59% in the same period. KTR were significantly more likely to have up to date vaccination by the second survey for pneumococcus, OR 3.4 (95% CI:1.8–6.4; p<0.001) but not influenza, OR 1.8 (95% CI:0.9–3.5; p=0.09). No reported cases of IPD during the study.

Conclusions: The clinical practice improvement method resulted in significant improvements in reported vaccination documentation and up-to-date status but overall rates remain sub-optimal.

TH-PO1160

Emergency Preparedness in the Kidney Transplant Community

Shimi Sharief, Daniel J. Freitas, Nicole Rich, Deborah B. Adey, James A. Wiley. *UCSF.*

Background: In the ten years since Hurricane Katrina, the Centers for Medicare and Medicaid Services and KCER (Kidney Community Emergency Response) Coalition have taken several steps to regulate and mandate emergency preparedness planning in dialysis units. Similar steps have not been taken to ensure the safety of kidney transplant patients who rely on specialized pharmaceuticals to maintain the function of their allografts. The objective of this study was to develop and pretest a self-administered questionnaire to assess the disaster preparedness of a cohort of kidney transplant recipients in an earthquake-prone region of the United States.

Methods: Based on information obtained from the National Kidney Foundation Planning for Emergencies handbook, we designed a preliminary questionnaire. We recruited 10 Bay Area patients and 5 kidney transplant providers from the transplant clinic at the University of California San Francisco and the general nephrology clinic at San Francisco General Hospital. Our two-step protocol included a self-administered questionnaire followed by an interview regarding attitudes and barriers around preparedness and feedback on the survey. Three researchers coded and analyzed the data and categorized the responses into themes.

Results: The questionnaire was easily readable but subjects had difficulty in understanding the context of the questions. Most defined disasters as man-made terrorism instead of the intended meaning of natural disasters. Patients reported lack of salience and relevance of the issue and lack of access to information as major barriers to disaster preparation. Providers cited their patients' education and motivation as key determinants of their level of preparedness. We modified the questionnaire to include a hypothetical scenario to frame the questions, and organized the questions into sections. Providers' deficiencies in understanding and recognizing transplant patients as a vulnerable population contributed to their complacence in providing them with preparedness information.

Conclusions: We noted serious deficiencies in disaster awareness and planning in the kidney transplant community. Ongoing research and collaboration between medical and city services are necessary to ensure safety in disaster-prone regions.

Funding: NIDDK Support

Digital Urine Sediments: Keeping the Attending in the Loop

Kilsy Alexandra Cuello-Pichardo,[1] John Ahn,[1] Nardos Belayneh,[1] Jusmin Patel,[1] Azeem Mohammed,[1] Deewan Deewan,[1] Lu Y. Huber,[1,2] John Jason White,[1,2] Pamela J. Fall,[1] N. Stanley Nahman.[1,2] *[1]Nephrology, Augusta Univ, Augusta, GA; [2]Nephrology, Charlie Norwood Va Hospital, Augusta, GA.*

Background: Busy nephrology fellowships may necessitate that fellows assess the urine sediment (U-Sed) without faculty presence. This may dilute the educational and clinical value of findings. To address this, we theorized that smart phone digital pictures of the U-Sed, taken by fellows and texted to faculty, may enhance educational and clinical value. To address this, we assessed a random group of U-Sed images for quality, discrimination of elements, and diagnostic utility.

Methods: Three fellows submitted U-Sed images from the inpatient consult service for assessment. U-Sed were photographed through the microscope eye piece. In a group PowerPoint session, fellows and faculty (all blinded to the diagnosis) scored each image for 17 variables, including image quality (acceptable or not), diagnostic utility (yes/no), casts (presence + 5 types), cells (presence + 3 types), and other (yeast, crystals, or debris).

Results: 45 U-Sed images were assessed by a group of 5 faculty and 5 fellows. Control images were carefully scrutinized and classified by 2 faculty prior to the session. Results are in the table.

	Parameter recognized or scored		
Parameter	All	Faculty	Fellows
Image quality (acceptable)	73%	80%	66%
Diagnostic use (useful)	44%	44%	44%
Elements seen			
Casts	42%	39%	45%
Cells	24%	21%	28%
Crystals	16%	16%	15%
Debris	37%	66%	30%
Candida	4%	6%	2%
Control images			
Muddy brown casts	NA	100%	96%
Crystals	NA	100%	88%
Debris	NA	100%	60%
Red cells	NA	100%	100%
Candida	NA	88%	20%

Conclusions: Most smart phone digital images of U-Sed are of acceptable quality. Muddy brown casts, crystals, and red cells can be recognized, but candida is less obvious. Sampling error may occur based on the experience of photographer. Keeping faculty in the loop by sharing U-Sed images may be of educational and clinical utility.

FR-PO001

Infectious Endocarditis Mimicking ANCA Associated Pulmonary-Renal Syndrome with Crescentic Necrotizing Glomerulonephritis
Samer Mohandes,[1] Anjali A. Satoskar,[2] Tibor Nadasdy,[2] Lee A. Hebert,[1] Isabelle Ayoub.[1] *[1]Medicine, The Ohio State Univ, Columbus, OH; [2]Pathology, The Ohio State Univ, Columbus, OH.*

Introduction: Pulmonary renal syndrome (PRS) is a life threatening disease requiring early diagnosis and prompt treatment. Its most common cause is ANCA- associated pauci immune crescentic Glomerunephritis (Granulomatosis with polyangiitis, GPA). Treatment usually involves high dose steroids, an immunosuppressant, and plasmapheresis. However, ANCA- associated pauci immune crescentic GN can also be the result of infection. This case illustrates the dilemma of medical management until these forms of PRS can be clearly differentiated.

Case Description: A 57- year old white man with bioprosthetic aortic valve placement 5 years earlier transferred to our medical center with altered mental status and PRS. Diagnostic work up was significant for oliguria with Scr 3.5mg/dl, anemia, thrombocytopenia, positive PR3-ANCA, low complements and diffuse alveolar hemorrhage by bronchoscopy. He received hemodialysis, plasmapheresis and intravenous methylprednisolone. Kidney biopsy showed severe crescentic and necrotizing glomerulonephritis with C3 and IgM mesangial staining on immunofluorescence and rare paramesangial electron dense deposits. While on steroids, he develops fever. Blood cultures from the referring hospital showed MRSE. A transesophageal echocardiogram showed vegetations on the aortic and mitral valve along with a perivalvular aortic abscess. Appropriate antibiotic coverage was begun. Plasmapheresis and immunosuppression were stopped. He was too unstable for surgical intervention. The family decided to withdraw care. He died seven days later.

Discussion: PRS due to infection can be difficult to distinguish from GPA. In this case clues to the presence of infection included low complement (C3 32, C4 <8) and fever after starting immunosuppression.

FR-PO002

Proteinuria, Edema, and Hypertension: A Case of Lupus Podocytopathy
Farah Daccueil,[1] Kathleen Leger,[1] Nobuyuki (Bill) Miyawaki,[1] Joseph Mattana,[1] Vivette D. D'Agati,[2] James Drakakis.[1] *[1]Medicine, Winthrop Univ Hospital, Mineola, NY; [2]Pathology and Cell Biology, Columbia Univ Medical Center, New York, NY.*

Introduction: Lupus podocytopathy is an emerging subgroup classification of lupus nephritis with proteinuria but there is no immune deposition or endocapillary proliferation on biopsy. The biopsies are often diagnosed as minimal change disease (MCD) or FSGS. We report a case of lupus podocytopathy as per American College of Rheumatology proposed diagnostic criteria, with co-existing focal glomerular tip lesion on biopsy.

Case Description: 39 year old male with hypertension for 12 years presented with abdominal pain, facial and leg edema. He was found to have blood pressure readings consistently over 160/80 despite two blood pressure medications. Blood work showed a creatinine of 1.08mg/dL, cholesterol of 392, triglyceride of 530, serum albumin of 2.2g/dL with normal HgA1C. Two days after our office visit he was hospitalized with flank pain and found in acute kidney injury with a creatinine of 2.9mg/dL. Hospital work up showed normal anti-DNA, complement level, HIV, hepatitis profile, immunofixation and ANCA. Laboratory result showed proteinuria of 2.9 gram/gram of creatinine, positive anti-Smith antibody and ANA>1280. He admitted to NSAID use in the last month. With his worsening kidney function, a kidney biopsy was performed. Biopsy showed podocytopathy, focal glomerular tip lesion approximating minimal change disease. There was accompanying speckled nuclear positivity for IgG, suggesting characterization as a lupus podocytopathy. A formal diagnosis of lupus based on systemic and serologic findings is being strongly considered by rheumatology. High dose steroid was initiated and thus far creatinine has improved to 1.2mg/dL.Rrepeat proteinuria quantification is pending.

Discussion: Lupus podocytopathy is an emerging subgroup classification of lupus nephritis, where there is no immune deposition or endocapillary proliferation on biopsy, but significant proteinuria and MCD or FSGS is noted. Ongoing literary work and case reports have aimed at defining lupus podocytopathy as its own entity in order to better categorize the disease and provide directed treatment plan.

FR-PO003

A 61 Year Old Male with Dense Deposit Disease and Monoclonal Gammopathy of Undetermined Significance
Farah Daccueil,[1] Nobuyuki (Bill) Miyawaki,[1] Vivette D. D'Agati,[2] Naveed N. Masani.[1] *[1]Medicine, Winthrop Univ Hospital, Mineola, NY; [2]Pathology and Cell Biology, Columbia Univ Medical Center, New York, NY.*

Introduction: Dense deposit disease (DDD) is a rare cause of glomerulonephritis (GN), predominantly seen in children and young adults. Dysregulation of the alternative complement pathway (AP) is implicated in the development of DDD. Monoclonal gammopathy of undetermined significance (MGUS) has been linked to AP activation. Here we report a case of biopsy proven DDD in an adult male with MGUS.

Case Description: A 61 year old Caucasian male presented with newly diagnosed hypertensive urgency and acute kidney injury with an increase in serum creatinine to 2.7 mg/dL from baseline of 0.8 mg/dL after a recent URI. Exam was significant for a BP of 160/80 and lower extremity edema. Urinalysis was significant for 2+ protein, 3+ blood, 3-10 RBC/hpf, no red cell casts. Spot quantification revealed approximately 3.2 grams of proteinuria per gram of creatinine. Serum immunofixation was remarkable for IgG kappa with a normal serum kappa:lambda ratio. Further work up done at the time, showed normal/negative ANA, anti-dsDNA, C3, C4, CH50, HBsAg, HCV, ANCA and anti-GBM. Renal biopsy findings included membranoproliferative and exudative pattern of glomerulonephritis, with isloated C3 deposits, and highly electron dense deposits, consistent with DDD. Subsequent bone marrow biopsy demonstrated a 3% clonal population Patient was treated with high-dose prednisone and rituximab induction. Seven months post treatment, patient appears to be in remission with a negative urinalysis, no significant proteinuria on spot sample, and a serum creatinine of 1.96 mg/dL. Patient is due for maintenance rituximab therapy. Complement testing for alternate pathway dysregulation is underway.

Discussion: DDD is a rare cause of GN, attributable to dysregulation in the alternative pathway of the complement system. MGUS has been linked to AP dysregulation. This case report demonstrates a patient with DDD & MGUS successfully treated with prednisone and B-cell depleting therapy (rituximab) leading to short term remission of GN.

FR-PO004

Concomitant Diagnosis of Fibrillary Glomerulonephritis Secondary to Multiple Myeloma and Mycosis Fungoides: Simultaneous Diagnosis of B and T Cell Malignancies
Farah Piracha, Neeraj Sharma, Michael Yudd, Jennine Michaud. *Nephrology, East Orange Veterans Affairs, East Orange, NJ.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare proliferative glomerulonephritis associated with malignancies including Multiple Myeloma (MM). B cell disorders including MM and T cell lymphomas including Mycosis fungoides (MF) occur concomitantly at a higher rate than expected by chance.

Case Description: 71 year old African American male underwent a kidney biopsy for nephrotic syndrome and hematuria. His creatinine was 1.2 mg/dL, serum M spike of 0.5g/dL, 24 hour urine protein 4 grams, urine M spike of 4.5%, C3 was low at 53 mg/dL. Renal biopsy revealed C3 and monoclonal IgG κ deposits on immunofluorescence with randomly arranged, Congo Red negative, fibrils 15-23nm in diameter in a mesangioproliferative pattern. Bone marrow biopsy revealed 4% plasma cells; flow cytometry showed 0.4% IgG κ restricted plasma cells. Serum κ free light chains were 7730 mg/L with a serum free light chain (SFLC) ratio of 228, establishing the diagnosis of MM. Several large hyperpigmented lesions were noted on his trunk; biopsy proven to be MF. MM was treated with cyclophosphamide, bortezomib and dexamethasone; topical steroids for MF. After 4 cycles, serum free κ decreased to 3110 mg/dL, SFLC ratio to 142; proteinuria decreased to 1.2 grams.

Discussion: FGN is seen in 0.5-1% of kidney biopsies with 10% having monoclonal deposits; an M spike can be seen in up to 17% of patients. A contemporaneous cutaneous T cell lymphoma was found in the this patient. A 2009 review from the Mayo Clinic found a higher than expected incidence of concomitant B and T cell disorders which can present simultaneously or sequentially. Proposed theories for this include immunosuppressive medication for one malignancy stimulating another, direct immune suppression of one malignancy leading to a second malignancy, genetic predisposition or release of stimulatory cytokines. In this review, 23 were patients identified with B and T cell disorders, 11 having MM and Amyloidosis; however there were no cases of FGN identified. To our knowledge, this is the first case of MM with FGN and simultaneous MF.

FR-PO005

Collapsing Glomerulopathy Secondary to Schitosoma Mansoni: A Case Report
Precil Diego Miranda de Menezes Neves,[1] Ramaiane Aparecida Bridi,[1] Bernardo V. Reichert,[1] Janaina de Almeida Mota Ramalho,[1] Lectícia Jorge,[1] Luis Yu,[1] Viktoria Woronik,[1] Leonardo Abreu Testagrossa,[2] Denise M. Malheiros,[2] Cristiane B. Dias.[1] *[1]Nephrology Div, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Pathology Div, Univ of Sao Paulo, Sao Paulo, Brazil.*

Introduction: Schistosomiasis is a disease caused by Schistosomiasis mansoni (SM). In the kidney, the glomerulus is the main site of lesion and the most frequent patterns of histologic lesion are Membranoproliferative Glomerulonephritis and Focal Segmental Glomerulosclerosis. At our knowledge, no cases of Collapsing Glomerulopathy (CG) were described. We report a case of CG secondary to SM.

Case Description: Male, 35-years old, previously healthy, complaining for eight months of lower limbs edema, foamy urine and increased abdominal girth. He had had a recent diagnosis of schistosomiasis, with hepatosplenic involvement and had been treated with Praziquantel (50mg/kg). Laboratory tests: urea: 51mg/dL, serum creatinine: 1.8mg/dL (CKD-EPI:54ml/min/1.73m^2), no electrolyte/acid-base disorders, no hematuria/leukocyturia, 24h-proteinuria: 6.56g, serum albumin: 1.9g/dL, total cholesterol: 531mg/dL, LDL: 426mg/dL, hemoglobin: 13.8g/dL, leukocytes: 6440/mm^3, platelets: 115000/mm^3, normal serum complement proteins. Autoantibody and serologic tests (hepatitis B, hepatitis C and HIV) were negative. The aspect of kidney were normal at ultrasonography. Light microscopy at renal biopsy revealed 16 glomeruli (2 completely sclerotic), mesangial hipercellularity, hipertrophy and hyperplasia of podocytes, 25% of glomeruli presenting synechiae, tubules with mycrocistic dilatation, diffuse interstitial fibrosis and arteriolar hyalinosis. Immunofluorescence stain was positive to IgM:+2/+3 e C3:+3/+3, with granular, focal and segmental pattern. Ultrastructural findings at electron microscopy supported the diagnosis of CG. As the treatment of parasitic disease had been taken, we started Prednisone 1mg/kg/d. In spite of treatment, patient undergone progressive end-stage renal disease and need of renal replacement therapy.

Discussion: Despite a rare disease, CG must be kept in mind as a differential diagnosis of nephrotic syndrome in patients with SM.

FR-PO006

Fibrillary Glomerulonephritis in a Patient with Systemic Lupus Erythrematosus Mohit Gupta, Rupesh Raina, Karla Detoya. *Internal Medicine, Akron General Medical Center, Akron, OH.*

Introduction: Fibrillary Glomerulonephritis (FGN) is a rare disorder that is characterized by nephrotic range proteinuria, hematuria and reduced renal function. It has a reported incidence of 0.6 – 1.5% in adults and carries a poor prognosis. It is rarely associated with systemic disorders but has been recently linked to Systemic Lupus Erythrematosus (SLE). Herein, we report a case of a patient who presented with worsening kidney function and was found to have fibrillary glomerulonephritis associated with SLE.

Case Description: A 70 year old Female with a known history of CKD III initially presented to us with a complaint of progressive diarrhea. Upon presentation she was found to have a Creatinine of 5.3 mg/dL significantly above her baseline of 1.5 mg/dL. She was started on IV Fluids for a suspected pre-renal injury. Creatinine improved initially but not to baseline. During the next 2 days, she worsened clinically and developed bilateral pleural effusions. She was consequently diuresed for worsening oxygen requirements. Urinalysis showed proteinuria in excess of 3.8g/day. ANA pattern was positive with nucleolar pattern and a titre of 1:80. She remained oliguric despite diuretics and was transitioned to renal replacement therapy. Renal biopsy was planned for suspected Lupus nephritis and she was placed on pulse dose steroid therapy. Biopsy revealed the presence of extensive Congo Red Negative electron dense deposits arranged in fibrils measuring 20 to 25 nm along the mesangium and glomerular walls. This was consistent with a diagnosis of fibrillary glomerulonephritis associated with SLE. She was discharged with renal replacement therapy, but later opted for comfort care only.

Discussion: SLE associated fibrillary glomerulonephritis is a rare disorder and only a handful of cases have been reported till date. It differs from other forms of fibrillary glomerulonephritis in that fibrils are generally arranged in a fingerprint pattern of concentrically curved lines. Immunosuppressive therapy with cyclophosphamide, steroids and recently Rituximab have been used in the treatment of this disorder. However, given its rare incidence and lack of studies, the treatment of the same still remains a therapeutic challenge.

FR-PO007

Thin Basement Membrane Disease or Alports Syndrome Albara Said, Cybele Ghossein. *Nephrology, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Introduction: Thin basement membrane disease (TBMD) is characterized by diffuse thinning of the glomerular basement membrane (GBM). It is a common disorder that is frequently familial in nature and is caused by genetic defects in COL4A3 or COL4A4, genes that encode type IV collagen. These same alleles are affected in patients with Alports. In fact biopsies done early in patients with Alports frequently reveal diffusely thin GBMs as seen in TBMD. Clinically, however, TBMD has a much more benign course. TBMD patients typically present with hematuria and mild proteinuria while Alports frequently progresses to end stage renal disease (ESRD). We present a patient with presumed familial TBMD and no family history or ESRD whose biopsy revealed Alports.

Case Description: A 29 year-old male with a history of TBMD presented to our clinic for evaluation. The patient had been followed yearly from early childhood for hematuria and proteinuria. He states his mother, brother, and sister have the same disease and they all were given the presumptive diagnosis of TBMD. There was no family history of kidney dysfunction or hearing loss. None of his family members had ever undergone a kidney biopsy. Labs revealed a creatinine of 0.84 mg/dL and a 24 hour urine protein of 2400mg. A renal biopsy was performed and this revealed variably thickened basement membranes from 130nm to 780nm consistent with Alports. Genetic testing was performed and an in-frame deletion of three amino acids in the triple helix repeat domain of the COL4A5 protein was found. This variant has been reported to cause Alports.

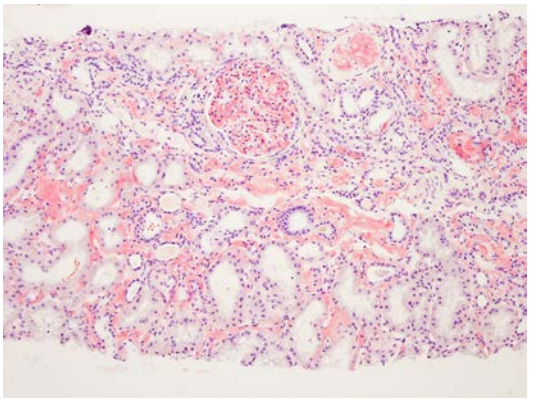
Discussion: TBMD is an often familial GBM disease that causes hematuria. Patients with this disease tend to follow a benign course, have minimal proteinuria, and almost never have kidney disease progression. For this reason biopsies are rarely performed and the diagnosis is frequently a clinical one. However it is important to consider alternative diagnoses if the clinical picture isn't clear. Our patient exhibited a higher than expected level of proteinuria and thus a biopsy was performed revealing Alports. This diagnoses will help with genetic counseling in our patient and may affect future management.

FR-PO008

Leukocyte Cell-Derived Chemotaxin 2(ALect2) Associated Renal Amyloidosis: A Case Report Benjamin Kwesi Sarsah,[1] Amy Nicole Sussman,[1] Erika R. Bracamonte,[2] Bijin Thajudeen.[1] *[1]Nephrology, Banner Univ of Arizona Medical Center, Tucson, AZ; [2]Pathology, Banner Univ of Arizona Medical Center, Tucson, AZ.*

Introduction: ALect2-associated renal amyloidosis(RA) is a recently recognized and distinctive clinicopathologic type of amyloid manifested in adults by varying degrees of impaired kidney function and proteinuria. There are limited number of cases reported in the literature.

Case Description: We present a 64-year-old Hispanic female with a history of hypertension who was referred for CKD management. Review of her laboratory tests revealed a serum Cr of 1.5-1.8 mg/dl and microalbuminuria (in the presence of a bland urine sediment) in the past one year. She denied any history of diabetes, rheumatologic disorders or exposure to intravenous contrast, NSAIDs, herbals and heavy metals. Serological work up was negative. A renal biopsy was performed. Light microscopy showed diffuse infiltration of glomerulus with pale eosinophilic material strongly positive for Congo red stain. A similar eosinophilic material was present throughout the interstitium



Immunofluorescence study was negative. Electron microscopy showed marked infiltration of mesangium, capillary loops and interstitium with haphazardly arranged fibrillary deposits. Liquid chromatography tandem mass spectrometry was performed on peptides extracted from Congo red positive, microdissected areas of the paraffin- embedded kidney specimen and showed ALect2-type amyloid deposition.

Discussion: ALect-2 amyloidosis should be suspected in renal biopsy specimens exhibiting extensive and strong mesangial as well as interstitial congophilia. Individuals with ALect2 RA have varying prognosis depending on the extent and rate of deposition. Therapeutic options include supportive measures (including dialysis when necessary) and consideration of kidney transplant from a histocompatible donor for those with ESRD.

FR-PO009

A Case of Waldenstrom's Macroglobulinemia Presenting as Acute Renal Failure and Nephrotic Syndrome Sumeet Munjal, Edwin J. Anand. *Div of Nephrology, Univ at Buffalo, NY.*

Introduction: Waldenstrom's macroglobulinemia (WM) is a rare B-cell disorder characterized by bone marrow (BM) infiltration of B lymphocytes and plasma cells along with a serum monoclonal immunoglobulin M (IgM) component. Renal involvement is uncommon compared to other dysproteinemias. We report a case of WM presenting with severe acute kidney injury (AKI) and Minimal change disease (MCD).

Case Description: A 56 year old WF with no history of renal disease developed shortness of breath and anasarca of 4 weeks duration. Clinical exam showed signs of volume overload and labs showed severe AKI (below). She was admitted and diuresed. CXR showed a large left pleural effusion and ECHO showed a normal EF. Admission creatinine was 7.5 mg/dl, Hemoglobin 9 gm/dl and 24hr urine protein was 18.4 grams. ANCA and ANA were negative. SPEP and UPEP showed monoclonal spike and IFE labeled it as IgM kappa. Serum IgM levels was elevated at 1940 mg/dl and free kappa level was 667.Kappa to lambda ratio was 56. Bone marrow biopsy confirmed a lymphoplasmacytic lymphoma consistent with WM. Renal biopsy showed minimal glomerular changes (MCD), immunofluorescence showed dominant IgM deposition with kappa light chain restriction in the subendothelial space and no amyloid. Our patient did not have neurological symptoms and serum cryoglobulins were negative ruling out hyperviscosity. She was started on plasmapheresis with a rapid reduction in serum IgM to 204. She received bortezomib, rituximab and steroids without improvement in renal function and needed dialysis. Chemotherapy for B-cell lymphoma (cyclophosphamide, rituximab, steroid) was given for 6 cycles. She achieved full remission of lymphoma, and was weaned off dialysis.

Discussion: Renal involvement in WM is rare and is usually due to amyloidosis. We report this case of WM with AKI requiring dialysis and MCD caused by IgM kappa in the glomeruli and no amyloidosis. There are only a few cases in the literature with a similar presentation. We also show that the renal injury could be permanent despite full remission of the WM with aggressive chemotherapy and plasmapheresis.

FR-PO010

ANCA-Negative Pauci-Immune Necrotizing Glomerulonephritis in a Patient with Multicentric Castleman's Disease Dilini M. Daswatta, John J. Doran. *Nephrology, Emory Univ.*

Introduction: Castleman's Disease is a rare lymphoproliferative disorder first described by Dr. Benjamin Castleman in 1956 in patients with lymphadenopathy having hyalinized follicles and interfollicular vascular proliferation. It is classified as unicentric (UCD) or multicentric disease (MCD) where MCD presents with lymphadenopathy, hepatosplenmegaly and fevers and is associated with Human Herpes 8 (HH8) in HIV infection. Kidney involvement in MCD is unusual and case reports have noted various lesions, mostly amyloidosis, membranoproliferative glomerulonephritis (GN) and thrombotic microangiopathy. Other lesions were rarely seen less including 3 cases of crescentic GN. We describe a case of MCD disease with HHV 8 presenting with hematuria, proteinuria, and near normal renal function whose kidney biopsy showed Pauci-immune necrotizing GN with cellular crescents.

Case Description: A 55-year-old African American male patient with HIV and wasting came to Grady Memorial Hospital with fevers, and weight loss. CT chest and abdomen

showed diffuse lymphadenopathy (LAD). An infectious workup ruled out JCV, HSV, CMV, cryptococcos and tuberculosis. Five months later, he developed lower extremity edema, was diagnosed with a deep venous thrombus and was discharged on lovenox. He was readmitted for gross hematuria, thought secondary to lovenox, but it persisted despite discontinuation. CT of chest/abdomen/pelvis showed a ureterolith thought recently passed and worsening LAD. Lymph node biopsy revealed MCD, with positive HHV-8 staining. Cystoscopy and bladder cytology were negative. Cr ranged 0.6 to 1.0 mg/dL and urine showed dysmorphic RBCs and 1.5 g/g proteinuria. ANA, ANCA and anti-GBM AB were negative. Kidney biopsy showed pauci-immune, focal, necrotizing GN with cellular crescent formation. Global or focal sclerosis was mild (14%) with little interstitial fibrosis or tubular atrophy. Treatment was begun with prednisone and Rituximab. Urinalysis demonstrates resolution of proteinuria and hematuria. 5 months later Cr remained stable at 0.9mg/dL.

Discussion: Kidney involvement in MCD is unusual, and we report a case of ANCA-negative crescentic pauci immune GN in a HHV-8 positive HIV patient.

FR-PO011

A BPI-ANCA Associated Rapidly Progressive Glomerulonephritis with Immune Complexes: A Case Report Bojana Gardijan,[1] Danica Galesic Ljubanovic,[2] Zeljka Jurekovic,[1] Branislav Cingel,[1] Mladen Knotek.[1] *[1]Renal Div, Dept of Medicine, Univ Hospital Merkur, Zagreb, Croatia; [2]Dept of Pathology, Univ Hospital Dubrava, Zagreb, Croatia.*

Introduction: Antineutrophil cytoplasmic antibodies are a major cause of rapidly progressive glomerulonephritis (RPGN). Routinely tested ANCA are MPO and PR3. A number of atypical ANCA is also known, such as anti-bactericidal/permeability-increasing protein(BPI) ANCA, which is a well-described cause of vasculitis. Overlap syndromes of pauci-immune ANCA GN and immune complexes (IC)-mediated GN have been reported. After a review of literature, this is the first reported case of BPI-ANCA associated RPGN with IC.

Case Description: A 35-year-old Caucasian male with cryptogenic liver cirrhosis was referred to our hospital with the diagnosis of hepatorenal syndrome. At admission, the pt was dialysis-dependent and oliguric. An active urine sediment (E >50, L 15, casts) was noted with P/C 2.6 (g/g). Kidney biopsy was performed. The finding was diffuse endocapillary proliferative glomerulonephritis, active, without signs of chronicity. Immunoflorescence (IF) was positive for IgG, IgM, C3, κ and λ chains. ANA, ENA, dsDNA, RF, anti-CCP, LAC, cardiolipin IgG and IgM, beta-2 glycoprotein were negative. Serum C3 was 0.53 g/L (0.90-1.80) and C4 0.15g/l (0.10-0.40). Testing for HCV, HBV and HIV was negative, as well as bacterial respiratory and urine cultures. ANCA was positive by IF (1:640), with negative ELISA for PR3- and MPO-ANCA. ANCA was specified as BPI-ANCA. The pt was treated with combination of PEX, steroid pulses and iv cyclophosphamide (CYC). After 4 PEX, ANCA declined to 1:160. After 10 days the pt was no longer dialysis-dependent. He received in total 6 CYC pulses. After a follow-up of 6 months, his eGFR is 115ml/min/1.73m^2, without pathological proteinuria.

Discussion: This is to our knowledge the first described case of BPI-ANCA-associated RPGN with IC. Pathohistology corresponded to lupus grade IVa nephritis (lupus-like nephritis, as serology was negative). Due to ANCA, PEX was added to steroids and CYC. This is an educational case demonstrating the presence of BPI-ANCA in a pt with IC GN. ANCA testing by IF is important for detection of atypical ANCA.

FR-PO012

Two Cases of Cryoglobulinemic Glomerulonephritis after Successful Hepatitis C Treatment Nupur Gupta,[1] Allon N. Friedman,[1] Melissa D. Anderson.[1] *[1]Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [2]Pathology, Indiana Univ School of Medicine, Indianapolis, IN; [3]Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [4]Nephrology, Indiana Univ School of Medicine, Indianapolis, IN.*

Introduction: Chronic hepatitis C viral (HCV) infection are associated with cryoglobulinemic glomerulonephritis. With recent HCV- anti-viral therapy, sustained virologic response rates have diminished risk of kidney disease. We report two cases which both developed Cryoglobulinic Glomerulonephritis after being treated by antivirals.

Case Description: Case I 63 y/o man with successfully treated HCV infection using Harvoni, presented with recurrent hematuria, proteinuria, low serum complements, worsening creatinine and palpable purpura. Given his clinical presentation kidney biopsy was done which demonstrated cryoglobulinemic glomerulonephritis with immune complex deposition. Repeat testing for serum cryoglobulins was positive. Case II 58 y/o male presented clinic for evaluation of chronic kidney disease. He had past medical history of hepatitis C treated with ribavirin, interferon alpha and telaprevir. He initially presented with Raynaud's phenomenon and biopsy proven leucocytoclastic vasculitis. His Complement 4 level was low. It was felt he had a positive serum cryoglobulins and was diagnosed with mixed cryoglobulinemia related to hepatitis C. His hepatitis C viral load was negative. He had proteinuria and worsening kidney function. In order to assess etiology of his kidney disease, kidney biopsy was done. The Immune complex glomerulonephritis with organized deposits , compatible with cryoglobulinemic glomerulonephritis.

Discussion: Patients with Cryoglobulinemic Glomerulonephritis who have sustained virologic and vasculitic response continue to be negative for cryoglobulins. We had ruled out other causes of cryoglobulinemia such as parvo virus and rickettsial infection. These cases illustrate the possibility of emerging renal pathology in anti- viral therapy treated patients. The postulated mechanism is molecular mimicry for HCV Antigen which triggers immune response despite HCV RNA negative.

FR-PO013

Can We Chalk It All up to Myeloma? Hans Jensen,[1] Mitchell P. Sternlieb,[2] Lia Desposito,[2] Vishnu S. Potluri.[2] *[1]PCOM; [2]Lankenau Medical Center.*

Introduction: Multiple Myeloma (MM) is a disease diagnosed utilizing the CRAB score (hypercalcemia, renal failure, anemia, bone lesions) in addition to serologic and pathologic testing. We present a case of hypercalcemia where the diagnosis was complicated due to a history of parathyroidectomy with supplemental calcium use and volume depletion, thereby upending the basis of calcium and creatinine levels for diagnosis.

Case Description: A 65-year-old Caucasian woman with a distant history of a total parathyroidectomy presented with dizziness, constipation and abdominal pain for 2 weeks. She reported a 3-day history of anorexia and clumsiness. Her family added that she had confusion and slurred speech. Home medications notable for hydrochlorothiazide and furosemide for hypertension, calcitriol, 4000 mg daily Ca^{2+} and metformin. Vitals were BP 137/76 mmHg, HR 104 bpm, RR 20/min and SpO_2 of 95%. On exam, she was obese and lethargic but non-toxic, mildly confused with dry mucous membranes. She had mild epigastric tenderness without peritoneal signs; neurological exam was notable for slurred speech. BMP revealed corrected Ca^{2+} of 15.6 mg/dL, markedly elevated lipase, total protein of 9.6 g/dL and albumin of 3.9 g/dL. CT showed peri-pancreatic fat stranding. BMP 4 days prior was completely normal. The admission working diagnosis was acute pancreatitis and mental status change due to acute hypercalcemia from milk-alkali syndrome and thiazides. She received aggressive IV fluids and her Ca^{2+} completely normalized. Subsequent workup consisted of serum protein electrophoresis with immunofixation and serum free light chain ratio, which showed IgG monoclonal protein and K:λ of 39.3. Bone marrow biopsy had 20% clonal plasma cells, but skeletal survey did not reveal any lytic lesions.

Discussion: Presented is a case with acute pancreatitis, likely secondary to acute hypercalcemia that was, in and of itself, multifactorial in etiology—undiagnosed MM, high dose calcium ingestion, and hypovolemia while on a thiazide diuretic. This case illustrates how medical and surgical history impact interpretation of CRAB criteria in the recognition of new malignancy. It further evidences the importance of thorough medication reconciliation when creating a differential diagnosis and treatment strategy.

FR-PO014

Bacteremia Caused by Campylobacter Upsaliensis in a Patient with Minimal Change Disease following Rituximab Treatment Sachiko Fukushima,[1] Naoki Takahashi,[1] Seiji Yokoi,[1] Kyoko Hisada,[2] Yukio Hida,[2] Yukie Morikawa,[1] Mamiko Kobayashi,[1] Daisuke Mikami,[1] Hideki Kimura,[2] Kenji Kasuno,[1] Masayuki Iwano.[1] *[1]Div of Nephrology, Fukui Univ, Fukui, Japan; [2]Dept of Clinical Laboratories, Univ of Fukui Hospital, Fukui, Japan.*

Introduction: *Campylobacter upsaliensis* (*C. upsaliensis*) infection is a cause of sporadic gastrointestinal disease. The colonization of *C. upsaliensis* was found in more than 50% of house hold pets, the pet ownership is a risk factor for *C. upsaliensis* infections. Recently, successful treatment of rituximab (RTx) injection at an interval of 6 months for minimal change disease (MCD) in adults was reported. Although the efficacy of RTx for various renal diseases was reported, the immunocompromised status may be the risk of disease transmissible from animals to humans. Here, we report a patient diagnosed with bacteremia caused by *C. upsaliensis* with MCD following RTx treatment.

Case Description: A 30-year-old man was admitted to our hospital with fever. He had been diagnosed with steroid resistant and frequently relapsed MCD at the age of 28. He has been treated with cyclic RTx and low dose predonine for these 2 years and complete remission was maintained. Four months before admission, he had paroxysmal fever higher than 38 degree without gastrointestinal symptoms and C reactive protein was elevated and naturally decreased. Physical examination findings were normal expect moderate atopic dermatitis. Hematological tests revealed moderate leukocytosis and no B-lymphocyte. Urinalysis revealed normal findings. Systemic enhanced computed tomography and FDG-PET showed no particular lesion. *C. upsaliensis* was detected by his blood culture. After minocycline treatment and lactic acid bacterium administration was started, he became afebrile.

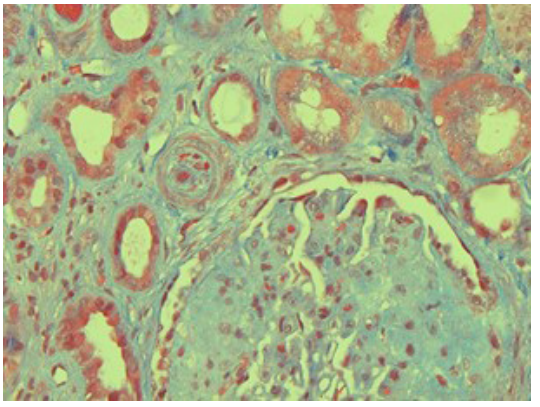
Discussion: To our knowledge, this is the first report of a patient with bacteremia caused by *C. upsaliensis* with MCD following RTx treatment. We suppose that *C. upsaliensis* may be transmitted from his house hold dog and bacterial translocation by his immunocompromised status may lead to bacteremia. We should take *C. upsaliensis* infection into consideration in fever of unknown origin following RTx treatment.

FR-PO015

Recurrent aHUS Post Kidney Transplantation Leading to Kidney Allograft Loss Despite Treatment with Terminal Complement Blockade Elwaleed Elnagar, Wael S. Hassan. *UAMS.*

Introduction: Complement disorders and aHUS are now increasingly recognized as causes of morbidity and mortality, leading to ESRD and, in kidney transplant recipients, to kidney allograft loss. Eculizumab, a terminal complement inhibitor, was found to improve renal parameters, leading to discontinuation of dialysis, and transplant protection[1].

Case Description: A 56 years old woman, with ESRD due to TTP, received a DDKT 3 years later and was treated with Prednisone, Mycophenolate Mofetil, and Prograf. A year later, a kidney allograft biopsy showed TMA. Prograf was switched to monthly Belatacept. Her kidney function returned to baseline. She did well until two years later when she was admitted with a second episode of AKI. She was anemic, with few schistocytes, low haptoglobin, increased LDH, and mild thrombocytopenia. ADAMTS13 activity was 87% (Normal >70%). C4 was normal and C3 was very low. CFH and CFB were low, CFI was normal, and anti CFH antibodies were not detected. A transplant kidney biopsy again showed a TMA



Genetic testing for complement factors revealed a mutation in CFH gene. She was started on Ecluzimab. Unfortunately, 12 months later she is still requiring intermittent hemodialysis.

Discussion: In Eculizumab trials in aHUS, younger age, higher baseline LDH and lower baseline hemoglobin were associated with greater eGFR improvements. Early Eculizumab initiation led to improved renal recovery. Mean eGFR change from baseline at 1 year was significantly higher in patients treated in ≤7 days than >7 days (57 vs. 23 ml/min/1.73 m^2, p = 0.0098). After 1 year, 17/21 and 36/76 patients in the ≤7 and >7 day groups, respectively, achieved a sustained increase in $eGFR^2$. Retrospectively, in this patient, he delay in initiation of Eculizumab may have impacted our patient, leading to non-recovery. Also, Eculizumab is a terminal (C5) complement blocker that may not work better in higher complement disorders.

FR-PO016

Membranous Nephropathy and Autoimmune Hemolytic Anemia in a Patient with a History of Hodgkin Lymphoma and Immune Thrombocytopenic Purpura

Molly Fisher, Yelena Rekhtman Drexler. *Nephrology, Montefiore Medical Center, Bronx, NY.*

Introduction: We report the first known case of a patient with a history of Hodgkin lymphoma and immune thrombocytopenic purpura (ITP), both in remission, who developed membranous nephropathy (MN) and autoimmune hemolytic anemia (AIHA) in the absence of any overt clinical signs of a lymphoma recurrence.

Case Description: 41 year-old female with a history of Hodgkin lymphoma and ITP who presented with nephrotic syndrome. In 2010, she was diagnosed with Stage II Hodgkin lymphoma and was treated with rituximab and radiation therapy, resulting in a complete remission. In 2014, she was diagnosed with ITP, which remitted with IVIG and steroids. In June 2015, she presented with two months of gradual onset lower extremity edema, 40-lb weight gain, and foamy urine. Labs showed serum albumin 1.8 g/dL, total cholesterol 586 mg/dL, 16g of protein on a 24hr urine collection, and serum creatinine 0.5 mg/dl. Serologic evaluation, including SPEP, ANA, and testing for HIV and hepatitis B and C, was negative. Renal biopsy showed MN with extensive subepithelial and a few mesangial deposits and negative glomerular staining for PLA2R. She had no evidence of lymphoma recurrence, and age-appropriate cancer screening was negative. She was treated with an ACE inhibitor without improvement in proteinuria. Therefore, tacrolimus was started, but proteinuria remained at 14 g/day. A CBC performed in anticipation of starting cyclophosphamide revealed a macrocytic anemia with hemoglobin 5.6 g/dL compared to 11.1 g/dL five months prior. A direct Coombs test was positive, consistent with a diagnosis of AIHA. Prednisone was initiated, followed by rituximab to treat both MN and AIHA. She received rituximab 375 mg/m^2 weekly for four weeks, resulting in an improvement in her hemoglobin to 11.4 g/dL, albumin to 3.8 g/dL, and proteinuria to 2.7 g/day.

Discussion: Rare cases of MN associated with Hodgkin lymphoma, ITP, or AIHA have been described but this is the first reported co-existence of all four diseases. We suspect these diseases may share a common autoimmune basis. Treatment with rituximab resulted in a complete remission of AIHA and a partial remission of membranous nephropathy.

FR-PO017

De Novo Collapsing Glomerulopathy in Renal Allograft: A New Potential Culprit?

Yorg Al Azzi, Oluremi Williams, David J. Cohen. *Medicine, Columbia Univ, New York, NY.*

Introduction: Collapsing glomerulopathy(CG) is a disease than can recur post-transplantation however its occurrence de novo is very rare. Case reports described de novo CG in renal allografts and in most of them no etiology was identified. We report a case of de novo CG in a renal allograft recipient with CMV being the potential culprit.

Case Description: 34yo AAF with ESRD 2/2 HTN on HD for 7 years s/p DDRT 07/14 from 20yo AAM (COD:GSW,KDPI 33%,multiple HLA-I and II DSA,EBV and CMV IgG D+/R+). She was induced with alemtuzumab, Rituximab and IVIG and maintained on tacrolimus and mycophenolic acid with rapid steroid withdrawal. Post-reperfusion bx showed ATN and diffuse glomerular fibrin thrombi. On 7/23/14, 1-wk protocol bx showed AMR and features of acute TMA(SCr 10.4). Started plasmapheresis 3 times/week with IVIG repletion and tacrolimus was switched to belatacept. She was re-biopsied after 6 sessions of PP(no rejection,no TMA,no more DSAs). She was maintained on belatacept,mycophenolic acid,prednisone 5mg daily. SCr reached 0.92. On 7/14/15, 1-yr protocol bx revealed CG (CMV stain neg). Urine P/C ratio 5.3 and SCr 0.9. No events of renal ischemia, no new medications including no OTC medications. Viral serologies including HIV, parvoB19,adenovirus.BK,CMV and EBV PCRs were sent. CMV PCR resulted 5033 IU/mL, she was started on valganciclovir 900mg BID and followed with weekly labs. By the following week, CMV PCR levels were decreased to 353 IU/mL, and on the 3rd week CMV PCR was negative and remains negative to date.

	Urine protein/creatinine ratio	Serum creatinine (mg/dL)
August 2014	0.4	1.4
October 2014	0.3	0.89
November 2014	0.2	0.88
January 2015	0.3	0.83
July 2015	5.3	0.9
September 2015	0.7	0.88
December 2015	0.6	0.94
January 2016	0.5	0.89

Discussion: To our knowledge, this is the first case report of de novo CG occurring in a renal allograft in the setting of CMV viremia. The timing of CMV viremia and development of proteinuria as well as resolution of the viremia with improvement of the proteinuria, in the absence of history of FSGS, addition of new medications and episodes of hypotension and renal ischemia, suggest that CMV might be the potential etiology of this de novo CG.

FR-PO018

Idiopathic Collapsing FSGS Presenting as "Forme Fruste" Lupus

Thalia Salinas, Karim El Hachem, Steven D. Smith. *Nephrology, Icahn School of Medicine at Mt. Sinai St. Luke's, New York/NY, NY.*

Introduction: Patients with SLE commonly develop lupus nephritis during their disease course. Only a subset of patients have been described to have lupus podocytopathy, a form characterized by a full nephrotic syndrome in the setting of overt SLE with diffuse and severe foot process effacement on Electron Microscopy, in the absence of subendothelial or subepithelial immune deposits.

Case Description: A 45-year-old African American man on hemodialysis presented for shortness of breath and was found to have a large pericardial effusion with a tamponade physiology. He underwent pericardiocentesis with drainage of 700 cc of exudative fluid. His laboratory studies and his clinical presentation allowed a diagnosis of active SLE. Six years prior he presented with nephrotic syndrome and kidney failure requiring hemodialysis. His biopsy revealed collapsing FSGS presumed to be ideopathic at which time he did not meet clinical or serologic criteria for lupus.

Test	Admission year 0 (Renal Failure)	Admission year 6 (Lupus Flair)
ANA	1:640	1:160
anti-dsDNA (0-29 IU/mL)	26.0	>300
C3 (90-180 mg/dL)	101	55
C4 (10-40 mg/dL)	34.7	20
Platelets (150-450 K/uL)	238	87
HIV	negative	negative
Hepatitis C antibody	negative	negative
Hepatitis B surface Antigen	negative	negative
Serum Albumin (3.4-5.4 g/dL)	2.0	3.1
Urine protein to creatinine ratio	3.34 gm	--
TB quantiferon gold	Negative	Negative

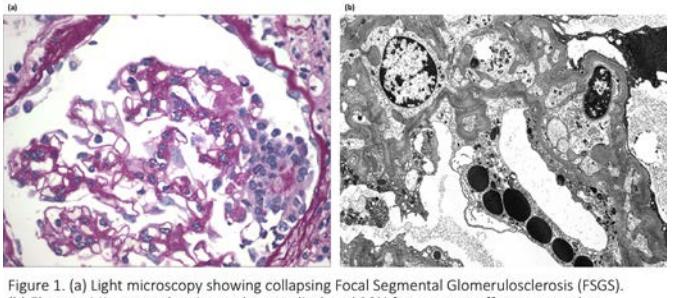


Figure 1. (a) Light microscopy showing collapsing Focal Segmental Glomerulosclerosis (FSGS). (b) Electron Micrscopy showing podocytes displayed 90% foot process effacement and, no immune type electron dense deposits or endothelial tubuloreticular inclusions. The patient's immunofluorescence was negative.

Discussion: This case illustrates that idiopathic collapsing FSGS could represent a lupus podocytopathy in the absence of overt lupus on initial presentation. We suggest following patients with idiopathic collapsing FSGS closely for possible subsequent development of SLE and perhaps treating them similarly to LN classes 3 and 4.

FR-PO019

Recurrent Atypical Anti-Glomerular Basement Membrane Disease after Successful Kidney Transplantation: A Rare Case Masaaki Yamada,[1] Andres G. Chiesa-Vottero,[2] Leal C. Herlitz,[2] Richard A. Fatica.[1] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Pathology, Cleveland Clinic, Cleveland, OH.*

Introduction: Renal anti-glomerular basement membrane (GBM) disease typically presents with rapid renal dysfunction and crescentic glomerulonephritis. Several published reports describe an indolent variant of anti-GBM disease with atypical clinical and pathological features compared to classic anti-GBM disease. Patients with atypical anti-GBM disease manifest a smoldering disease course with hematuria, proteinuria, and more gradual decline in GFR.

Case Description: The patient was a 53 year-old never-smoker Caucasian female with a long history of microscopic hematuria whose serum creatinine rose from 0.7 to 1.3 mg/dL over 5 years. She developed proteinuria (1.4 g/day) and hypertension around the onset of renal dysfunction. All serological evaluations were negative including RF, ANA, ANCA, complements, hepatitis B and C, HIV, anti-GBM antibody. Kidney biopsy revealed a sclerosing glomerulonephritis without crescent formation. Immunofluorescence showed strong linear GBM staining for IgG and lambda with negative kappa. Electron microscopy showed no electron-dense deposits but was notable for lucent subendothelial expansion and mesangial interpositioning suggestive of glomerular microangiopathy. Further tests; Scl-70, SS-A, SS-B, antiphospholipid, repeat anti-GBM antibodies, and M protein, were negative and no clinical evidence of a systemic thrombomicroangiopathy. Her renal function was steady for the first 5 years, but started to decline over the next 3 years despite a trial of oral prednisone. Repeat kidney biopsy showed findings similar to the initial biopsy and no crescents were seen. She was preemptively transplanted from a three antigen HLA mismatched living-related donor. She had an excellent graft function but microscopic hematuria persisted. A 2-year post-transplant biopsy revealed focal segmental mesangial and endocapillary proliferation and linear IgG and lambda staining again in the GBMs. Atypical anti-GBM disease was diagnosed and retrospectively considered her original disease.

Discussion: This is the second reported case of recurrent atypical anti-GBM antibody disease after renal transplant.

FR-PO020

Collapsing Glomerulopathy due to Lupus Podocytopathy: Successfully Treated - A Case Report Arani D. Nanavati,[1] Leal C. Herlitz,[2] Juan C. Calle.[1] *[1]Nephrology, Cleveland Clinic Foundation; [2]Pathology, Cleveland Clinic Foundation.*

Introduction: Collapsing glomerulopathy (CG) is described in SLE patients and represents a severe form of lupus podocytopathy (LP). The diagnosis of LP requires podocyte effacement without peripheral capillary wall immune deposits. We report a case of CG superimposed on membranous (class V) lupus nephritis (LN V) who was successfully treated and became dialysis free.

Case Description: A 49 year old African American male, recently diagnosed with SLE, presented initially with proteinuria of 2 gm/day and serum creatinine (SCr) of 0.9 mg/dL. Renal biopsy at that time revealed LN V. Therapy with mycophenolate mofetil and prednisone was recommended; however he was lost to follow up and did not comply with treatment. He presented again one month later with confusion, weakness. Lab studies revealed SCr of 9.75 mg/dl, urine protein-cr ratio of 4.1. He was started on dialysis for anuric renal failure with uremia and was empirically treated with intravenous (IV) pulse methylprednisolone. Repeat renal biopsy revealed CG superimposed on the previously documented LN V. There was no evidence of endocapillary proliferation, necrosis or glomerular basement membrane rupture. Work up for HIV, EBV, parvovirus and CMV was negative. In the absence of known infectious causes of CG the diagnosis of LP was favored. The patient was treated with pulse IV cyclophosphamide. After 4 weeks of hemodialysis and within 12 days of IV cyclophosphamide dose, renal function began to recover. His SCr continued to trend down to 1.1 mg/dL. He continues to have proteinuria with recent urine protein/cr ratio of 2.7.

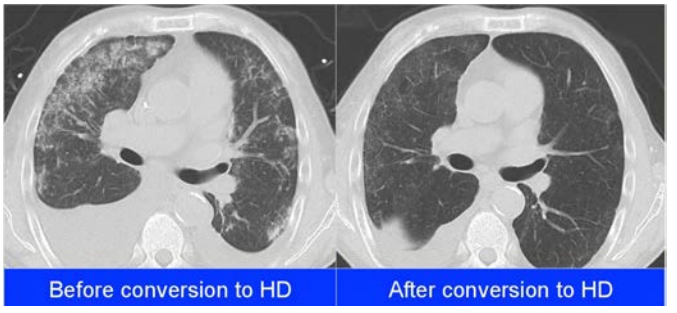
Discussion: The diagnosis of LP in this case is somewhat controversial given the underlying membranous changes. However, the presence of collapsing features, which are not seen in membranous lupus alone and the dramatic clinical deterioration supported the diagnosis of collapsing LP superimposed on class V lupus nephritis. While collapsing glomerulopathy is typically aggressive with poor outcomes, our case demonstrates that an excellent clinical response to the immunosuppressive regimen of cyclophosphamide and steroids is possible.

FR-PO021

Metastatic Pulmonary Calcification with Progressive Respiratory Failure in the Course of Peritoneal Dialysis Yuna Onozawa, Yosuke Nakagawa, Naoto Hamano, Masahiro Koizumi, Takehiko Wada, Masafumi Fukagawa. *Dept of Nephrology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan.*

Introduction: Metastatic pulmonary calcification is characterized by deposition of calcium salts in the normal alveoli and is commonly caused by end-stage renal disease (ESRD). It is often asymptomatic, but can develop respiratory failure.

Case Description: A 56 year-old male peritoneal dialysis (PD) patient was referred to our hospital due to progressive shortness of breath with pulmonary abnormal shadow on chest X-ray. He had been on PD for 10 years and had uncontrolled secondary hyperparathyroidism (SHPT). His intact PTH level stayed around 500 pg/mL despite of a year-long treatment with cinacalcet. The abnormal shadow on chest X-ray had been observed for a year. Initially he was asymptomatic, however, he presented with progressive dyspnea just before the referral. Chest computed tomography (CT) showed consolidation in bilateral lungs with diffuse calcification as well as cardiac enlargement and pleural effusion. Bone scintigraphy revealed intense uptakes in bilateral lungs. Taken together, he was diagnosed as metastatic pulmonary calcification and chronic heart failure. In echocardiogram anterior wall motion was decreased and coronary artery calcification score (CACS) was calculated to over 3,000 in multi-detector CT, indicating severe coronary artery stenosis due to metastatic calcification. In order to control his SHPT, he was switched to hemodialysis (HD) to improve his dialysis efficiency. In addition, percutaneous coronary intervention was performed to improve his cardiac function. Respiratory failure gradually improved although he remained on oxygen therapy. On a follow-up CT at 3 months after the conversion to HD, the calcification was obviously diminished.



Discussion: This case suggested that improved dialysis efficiency might reverse metastatic pulmonary calcification.

FR-PO022

Lupus Podocytopathy and Collapsing Glomerulopathy in a Patient without Nephrotic Syndrome Delin Wang, Lance D. Dworkin. *Nephrology, Brown Univ, Providence, RI.*

Introduction: Lupus podocytopathy is an unusual type of lupus nephritis characterized by nephrotic syndrome with podocyte foot process effacement and mesangial electron-dense deposits. We encountered a patient with lupus-like disease whose kidney biopsy showed pathological features of lupus podocytopathy and collapsing glomerulopathy but only exhibited microalbuminuria.

Case Description: A 39-year-old African-American female with history of hypertension, hypothyroidism, and obesity status post gastric bypass surgery presented with an elevated serum creatinine (sCr) at 1.83 mg/dL, eGFR 31 mL/min/1.73m^2, which had increased from 1.62 mg/dL 4 months prior. She was transiently on Chlorthalidone which was discontinued due to normalization of blood pressure (BP). Physical exam was remarkable for BP of 154/82 and frontal alopecia. Urine microalbumin-to-creatinine ratio (UMCR) was 265mg/gm. Serologic tests revealed high-titer antinuclear antibody (1:2560) with normal complements C3/C4 and anti-dsDNA (<1:10). Antiphospholipid antibodies were negative. Patient underwent a kidney biopsy which showed collapsing focal segmental glomerulosclerosis with podocyte foot process effacement and mesangial electron-dense deposits. Viral studies including HIV, Hepatitis B/C, Epstein-Barr virus, Parvovirus B19, and Cytomegalovirus were negative. Because of progressive renal failure, she was treated with Mycophenolate Mofetil (MMF) 3 grams/day, Prednisone 60mg/day, and an angiotensin-converting-enzyme inhibitor (ACEI). Bactrim was used for prophylaxis. After four months of therapy, her sCr has increased to 2.27 mg/dL, although Bactrim may be contributing. In contrast, microalbuminuria has declined to 43 mg/gm per UMCR.

Discussion: To our knowledge, this is the first published case of a patient with collapsing lupus podocytopathy who lacks nephrotic range proteinuria. Although lupus podocytopathy often responds to immunosuppressive therapy, the limited number of reported patients with collapsing glomerulopathy have had a much poorer response. Additional patients and longer term follow-up are needed to determine whether the combination of MMF, steroid and ACEI helps induce remission and prevent progressive renal failure in patients with the collapsing variant.

FR-PO023

Renal Limited Polyarteritis Nodosa with Positive Anti Myeloperoxidase Darwish Naji, Rupal Mehta. *Nephrology Dept, Northwestern Medicine, Chicago, IL.*

Introduction: Polyarteritis Nodosa (PAN) is a systemic necrotizing vasculitis that typically affects medium-sized muscular arteries.

Case Description: M.W. is a 71-year-old Caucasian female with no past medical history who complained of fatigue, decrease urine output, lower extremity swelling, weight gain of 53 pounds over 2 months, and new elevated blood pressure. Laboratory investigation demonstrated an elevated creatinine of 4.6 mg/dL (baseline of 0.51 mg/dL one month prior). Urinalysis demonstrated non-dysmorphic red blood cells with no casts. Antinuclear antibody, complement levels, Hepatitis panel, serum and urine protein electrophoresis were unremarkable. Renal ultrasound revealed one incident microanuerysm and normal size kidneys. Renal biopsy demonstrated fibrinoid necrosis with little glomerular involvement (Figure 1A). Renal angiogram to investigate the microanuerysm demonstrated numerous microanuerysms (Figure 1B). Serology later returned with a positive anti-neutrophil cytoplasmic antibody (ANCA) titer of 1:640 and positive anti-myeloperoxidase (MPO) at 91 units. M.W. was started on pulse dose steroids and Cyclophosphamide for treatment of PAN.

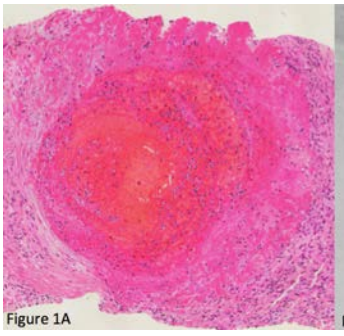


Figure 1A

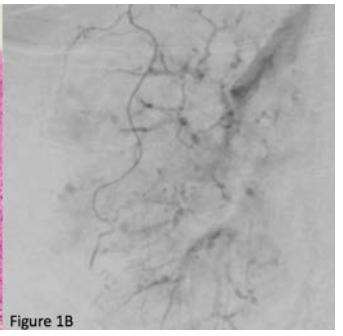

Figure 1B

Discussion: We describe an atypical presentation of PAN, which manifested with acute renal failure and positive serologies, without any other systemic organ involvement.All prior reported cases of MPO-ANCA positive PAN manifested with systemic involvement. Our patient presented with renal-limited disease with a moderate to strong positive MPO-ANCA. She was diagnosed with renal limited PAN based on renal angiogram findings of diffuse bilateral small aneurysms. Biopsy findings of arterial fibrinoid necrosis and no glomerulonephritis confirmed our diagnoses and helped guide treatment.

FR-PO024

A Case of C4 Dense-Deposit Disease Keisuke Kawashima,[1] Saori Nishio,[1] Mitsuru Yanai,[2] Yozo Ishikawa,[1] Fumihiko Hattanda,[1] Minoru Makita,[1] Yoshihiro Kusunoki,[1] Junya Yamamoto,[1] Yasunobu Ishikawa,[1] Yuichiro Fukazawa,[2] Tatsuya Atsumi.[1] *[1]Medicine 2, Hokkaido Univ Hospital, Sapporo, Japan; [2]Pathology, Sapporo City Hospital, Sapporo, Japan.*

Introduction: Traditionally, Membranoproliferative Glomerulonephritis (MPGN) was categorized into three subtypes according to the location of electron dense deposits. Recently, MPGN has been classified into immune complex-mediated GN and complement-mediated GN (dense deposit disease; DDD and C3 nephropathy). This classification is grounded upon etiology and immunofluorescence(IF) findings of each case. We experienced a case of MPGN presented in none of the classification.

Case Description: 63-year-old man with hypertension presented with hematuria and nephrotic-range proteinuria (urinary protein-to-creatinine ratio of 4.4). His renal function was normal. He had mild hypocomplementemia. Urinalysis showed dysmorphic erythrocytes. Evaluation for autoimmune disease, hepatitis and monoclonal gammopathy gave negative results. He was asymptomatic. Renal biopsy was performed. Microscopic evaluation showed MPGN, with diffuse mesangial and endocapillary hypercellularity. Periodic acid-Schiff stain showed diffuse thickening of capillary wall, proliferation of mesangial cells and endocapillary cells. Jones silver-methenamin stain showed reduplication of glomerular basement membrane(GBM). IF showed bright staining for C4d along the capillary walls, and no glomerular staining for IgG, IgM, IgA, C1q, C3, kappa or lambda light chain. Electron microscopy showed ribbon-like subendothelial dense deposits lining the GBM. No deposits along Bowman capsule or tubular basement membranes were visible. We performed ELISA to access the acitivity of each complement pathway.ELISA showed abnormal activation of lectin pathway. The diagnosis was C4 glomerulopathy(C4 DDD). He was treated with valsartan and immunosuppressive drugs. Nephrotic range proteinuria was prolonged, but his renal function remained unchanged.

Discussion: Recently, it has been reported that C4d deposition serves as a marker for complement (especially lectin pathway)-mediated GN, and clinical entity 'C4 glomerulopathy', C3-negative proliferative GN characterized by C4d deposition is proposed. This is the first case report of C4 DDD in Asian population.

FR-PO025

MGUS-Acquired Von Willebrand Disease Transitioning to Myeloma and Presenting as Type 1 Croglobulinemic Vasculitis and RPGN Mohamed Elsayed,[1,2] Ahmed Alghali,[1,2] Alaa M. Ali,[1,2] Arunkumar Aruna Udayakumar,[1,2] Muhammad Umair Sharif,[1,2] Austin G. Stack.[1,2,3] *[1]Graduate Entry Medical School, Univ of Limerick; [2]Nephrology Dept, Univ Hospital Limerick; [3]Health Research Inst, Univ of Limerick, Ireland.*

Introduction: Cryoglobulinemia type 1 vasculitis (CryoVas1) is a rare manifestation of Multiple Myeloma.Reports of renal involvement as RPGN in this setting are very scarce. Moreover,the emergence of such presentation from a longstanding MGUS causing acquired Von Willebrand disease(vWD)has to our knowledge never been reported.

Case Description: A70-year old woman with a15 year history of acquired vWD associated with life-threatening bleeding episodes and a long term history of IgG λ MGUS, presented with a painful purpuric rash on both legs confirmed to be leukcytoclastc vasculitis on skin biopsy.Initial studies showed normal kidney function(Creat 0.85 mg/dl),and benign urine sediment.Vasculitis work up revealed type 1 cryoglobulinemia. Hepatitis B and C serology was -ve.She was started on oral steroids but presented 2 weeks later with worsening rash,microscopic hematuria,nephrotic-range proteinuria and RPGN with low C3&C4 levels.She became anuric and her creatinine peaked over 6.2 mg/dl necessitating urgent dialysis.The vWD bleeding disorder posed a challenge to invasive procedures due to low FVIIIc&vWF levels,which were poorly responsive to IVIG and vWF replacement.A kidney biopsy was deemed unsafe.She received pulse IV steroid therapy and 7 plasmapharesis sessions.A bone marrow biopsy confirmed 30%plasma cells and she was started on (CyBorD)regimen.After 2 cycles of chemotherapy & 4 weeks on dialysis, the rash resolved,renal function recovered (Creat 0.66 mg/dl)& cryoglobulins were no longer detected in serum.vWF levels normalized with no further bleeding or need for replacement therapy.

Discussion: MGUS-acquired vWD presenting as CryoVas1 and RPGN is extremely rare and is associated with poor outcome.Rapid identification of croglobulins and confirmation of MM allowed a multi-pronged approach of steroids,plasmapharesis and bortezomib chemotherapy with an excellent outcome.An early aggressive approach to management of MGRS is warranted especially when associated with vWD or features of cryovasculitis.

FR-PO026

Strongyloid-Associated Membranous Nephropathy Josef Bautista, Katherine Mikovna Scovner. *Section of Kidney Diseases and Hypertension, Brown Univ - Rhode Island Hospital, Providence, RI.*

Introduction: Secondary membranous nephropathy may be caused by drugs, malignancy or infection. While it is known that infections can cause renal diseases little is known about the associations between parasitic infections and specific nephrotic syndromes. Here we present the first reported association between strongyloid infection and membranous nephropathy.

Case Description: This is a 65-year-old Nigerian man with history of hypertension on lisinopril and hydrochlorothiazide who was referred for proteinuria and elevated creatinine. The patient reported chronic diarrhea. Physical examination showed gross leg edema. Serum creatinine was 2.2 mg/dl, and his urine protein/creatinine ratio was 7 g/g. Renal biopsy showed mesangial proliferation and thickened glomerular basement membrane. Anti-PLA2R immunofixation was negative, and electron microscopy showed intramembranous deposits. Final biopsy read was membranous nephropathy. The patient denied NSAID use or use of other medications associated with membranous nephropathy. His age-appropriate cancer screening was up-to-date. Interestingly, his blood differential showed persistent eosinophilia of 20%. This prompted an investigation for a parasitic cause of his membranous nephropathy. Strongyloid antibody was positive, and the patient received ivermectin. His antihypertensive medications were continued. One-month follow-up showed improvement in his proteinuria to 4 g/g and creatinine to 1.4 mg/dl.

Discussion: This case demonstrates the first reported association between strongyloid infection and membranous nephropathy. While strongyloid infection is known to cause nephrotic syndrome, most of the biopsies show minimal change disease. Strongyloid parasitemia may induce type 2 T helper cells to produce eosinophils, interleukin 5 and IgE which results in a nephritogenic immune response and subsequent membranous nephropathy.

FR-PO027

IVIG as First Line Therapy for Thrombotic Microangiopathy Triggered by Ischemia-Reperfusion Injury Post-Kidney Transplant Kamel Hatahet,[1] Swati Rao,[1] Mythili Ghanta,[1] Duncan B. Johnstone,[1] Ashish Gummadi,[1] Serban Constantinescu,[1] Avrum Gillespie,[1] Crystal A. Gadegbeku,[1] Xu Zeng,[2] Iris J. Lee.[1] *[1]Section of Nephrology and Transplantation; [2]Pathology, Lewis Katz School of Medicine at Temple Univ, Philadelphia, PA.*

Introduction: Thrombotic microangiopathy (TMA) is a severe complication post kidney transplant (KT). Allograft biopsy findings include arteriolar and intraglomerular capillary thrombosis/occlusion with fibrin deposition. Calcineurin inhibitors (CNI) and antibody-mediated rejection (AMR) are the most common etiologies of *de novo* TMA. Prolonged allograft ischemia causes ischemia-reperfusion injury (IRI), which increases the risk for post-transplant TMA. Therapeutic plasma exchange (TPE) is the mainstay of treatment for severe cases of TMA. Intravenous immunoglobulin (IVIG) is used in conjugation with TPE only in cases of AMR related TMA, with Eculizumab reserved for resistant cases. We present a case of post-transplant TMA due to extensive IRI managed by IVIG monotherapy.

Case Description: A 60 yr old male with ESRD on hemodialysis underwent cadaveric KT. During the surgery, recipient's external iliac artery dissected requiring re-implantation of the allograft after arterial repair. In the first week post-KT, patient had delayed graft function and developed severe anemia and thrombocytopenia. TMA was diagnosed with elevated lactate dehydrogenase (900 units/L), low haptoglobulin (<6 mg/dl), and schistocytes. Allograft biopsy revealed TMA without features of rejection. CNI had not been initiated. There were no donor specific antibodies and normal level of ADAMTS13. Due to patient's critical condition, TPE/Ecluzimab were withheld and IVIG therapy was initiated. Platelets and hemoglobin rapidly improved to normal.

Discussion: Our case represents TMA triggered by extensive IRI of the allograft. The proinflammatory cytokine milieu likely caused endothelial cell activation and injury resulting in activation of the complement cascade. IVIG inhibits C3 activation and mitigates C5b-9 mediated tissue injury. Interestingly, IVIG is not recommended as first line therapy for TMA. We propose that for TMA that appears to be complement mediated, IVIG should be further investigated as a primary or additional therapy.

FR-PO028

A Necrotizing Glomerulonephritis Associated with Mantle Cell Lymphoma Mamta Shah, Valerie Jorge Cabrera, Anushree C. Shirali. *Dept of Nephrology, Yale School of Medicine, New Haven, CT.*

Introduction: Mantle cell lymphoma (MCL) is a rare and aggressive B-cell non-Hodgkin's lymphoma. The association of MCL with glomerulonephritis (GN) is uncommon. We report here a case of necrotizing GN in a patient with MCL.

Case Description: A 72-year-old man with recently diagnosed MCL presented with a serum creatinine (Cr) of 4.1 mg/dL, from a prior baseline of 1.1mg/dL. On exam, blood pressure was 144/77 mmHg and cervical and axillary lymphadenopathy was noted. Urine microscopy showed dysmorphic red blood cells. Spot urine protein/creatinine ratio was 0.3 g/g and serologies were unrevealing. Kidney biopsy showed a focal and segmental necrotizing GN with an active interstitial nephritis. Immunofluorescence (IF) was positive for IgM, IgG, C3, C1q, kappa, lambda and fibrinogen. No electron dense deposits were identified on electron microscopy. His Cr rose to 7.2 mg/dL despite receiving high dose steroids, and plasmapheresis was initiated. He received a total of 7 plasmapheresis sessions along with R-CHOP chemotherapy (rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone). He didn't require dialysis and his Cr subsequently improved to and has stayed stable at 2 mg/dL. He is currently on maintenance rituximab every 3 months and his lymphoma is in remission.

Discussion: Renal involvement in lymphoma occurs through direct or indirect mechanisms. Direct mechanisms include lymphomatous infiltration or obstruction. Indirect effects include GN, paraproteinemia and cryoglobulinemia. Kidney injury secondary to tumor lysis, drugs or infections may also occur. The first case of MCL associated GN was reported in 1999 and since then, only 14 cases have been reported in the literature. The most common presentation is proliferative GN, with or without crescent formation. IF typically includes IgG, IgM and C3 staining. In most cases, chemotherapy leads to resolution or improvement of MCL associated GN. In conclusion, MCL associated GN can precede, coexist or occur following the diagnosis of lymphoma. Decline of renal function and microscopic hematuria should increase the suspicion for a glomerular process in patients with MCL and prompt a renal biopsy.

FR-PO029

Focal Segmental Glomerulosclerosis in a Patient with Multiple Myeloma and Autologous Hematopoietic Cell Transplantation Bogdan Obrisca, Roxana Adriana Jurubita, Marina Felicia Paraschiv, Andreea Gamala, Andreea Andronesi, Gener Ismail. *Nephrology and Internal Medicine, "Carol Davila" Univ, Bucharest, Romania.*

Introduction: Glomerulopathies occur less often in recipients of autologous as compared to allogeneic hematopoietic cell transplantation (HCT) and, therefore, renal pathology in this setting is less well characterized.

Case Description: A 54 year-old man is admitted for the evaluation of a nephrotic-range proteinuria. His past medical history included a λ light chain secreting multiple myeloma (MM) diagnosed 4 years ago, treated with bortezomib and dexamethasone. Two years ago, the patient underwent autologous HCT. During the past two months, proteinuria at subsequent check-ups was 3,9 g/day and 4,8 g/day, respectively. A relapse of MM was ruled out by bone marrow biopsy. At the time of admission, the clinical examination was unremarkable. Initial testing showed a proteinuria of 5,6 g/day, but without other signs of NS (normal serum albumin and lipid panel). Urinalysis was unremarkable, the renal function was normal, the serologic and virological studies were negative and there were no signs of active MM. The patient underwent a kidney biopsy that revealed perihilar focal and segmental glomerulosclerosis (FSGS) and was started on cyclosporine 5 mg/kg/day. After 4 months of immunosuppressive therapy, the patient experienced a partial remission (proteinuria of 2 g/day).

Discussion: Glomerulopathies occurring after allogeneic HCT reveal a close temporal relationship between the onset of NS and the diagnosis of chronic graft-versus-host disease (GVHD), indicating a possible pathogenic link. Similarly, in autologous HCT, GVHD-like manifestations have been described as a result of a possible immune dysregulation. Review of the literature reveals several cases of membranous nephropathy and minimal-change disease occurring after autologous HCT, but, to our knowledge, FSGS in this setting wasn't described before. As in previous reported cases of glomerulopathies diagnosed after autologous HCT, our patient didn't show any sign suggestive of a GVHD-like manifestation. Whether there is a pathogenic link or it is just a coincidental finding remains debatable.

FR-PO030

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin G Deposits in Pediatric Patients: A Possible Differential Diagnosis of Membranoproliferative Glomerulonephritis Eiji Nakano,[1,2] Ken-Ichiro Miura,[1] Shoichiro Kanda,[2] Yuji Tomii,[1] Keiichi Takizawa,[1] Naoto Kaneko,[1] Tomoo Yabuuchi,[1] Kiyonobu Ishizuka,[1] Hiroko Chikamoto,[1] Yuko Akioka,[1] Yutaka Harita,[2] Yutaka Yamaguchi,[3] Motoshi Hattori.[1] *[1]Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan; [2]Dept of Pediatrics, the Univ of Tokyo, Bunkyo-ku, Tokyo, Japan; [3]Yamaguchi's Pathology Laboratory, Matsudo-shi, Chiba, Japan.*

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is a newly described entity of glomerulonephritis, which is characterized by glomerular staining for a single light-chain isotype and a single heavy-chain subtype. In adults, the biopsy incidence of PGNMID is 0.17%, and the most frequent histologic pattern is membranoproliferative glomerulonephritis (MPGN) (56.8%). To date, reports of PGNMID in pediatric patients are very limited.

Case Description: The patient was a 15-year-old boy. At the age of 9, mild hematuria and proteinuria were notedby chance during a school urine screening test. The amount of urinary protein gradually increased and a renal biopsy was performed at 15 years old. Light microscopy showed MPGN pattern, and immunofluorescence (IF) revealed granular staining for monoclonal immunoglobulin of IgG3-kappa along the glomerular capillary loops. On electron microscopy, glomerular immune deposits were predominantly subepithelial. There was no clinical and serological evidence of cryoglobulinemia. Based on these results he was diagnosed as PGNMID. Next, 14 pediatric cases diagnosed as MPGN in our hospital between 1994 and 2013 were examined for monoclonal IgG deposits using IF staining. Two patients (14.3%) showed glomerular deposits staining for a single light chain isotype and a single heavy chain subtype (IgG3-kappa in one patient and IgG3-lambda in the other), which was suggestive of a diagnosis of PGNMID.

Discussion: We experienced a pediatric case of PGNMID. Furthermore, our preliminary study found two cases with PGNMID pattern in pediatric MPGN patients. Further studies are clearly needed; our data indicate that pediatric patients showing MPGN may require immunostaining for monoclonal IgG deposits for a definite diagnosis.

FR-PO031

An Exceptional Case of Lyme Disease Associated MPGN Shraddha Rana, Apurv Khanna, Tiffany Nicole Caza, Sylvia L. Betcher. *Nephrology Dept, Syracuse VA Medical Center, Syracuse, NY; SUNY Upstate Medical Univ, Syracuse, NY.*

Introduction: Lyme disease, an endemic multisystem disorder caused by the tick-transmitted spirochete *Borrelia burgdorferi*, is known to cause glomerulonephritis in canine species. It has been postulated that the chronicity of this infection leads to an initial IgM response with polyclonal B cell activation with possible formation of cryoglobulins with eventual IgG response against spirochete polypeptide. Injury is mediated by the classical complement pathway. In the few cases of Lyme disease related glomerulonephritis reported in humans, patients had systemic manifestations of classical Lyme disease.

Case Description: A 70 year old man presented with increasing creatinine and proteinuria over 4 months. PMH included DM type II, HTN, Hyperlipidemia, chronic hematuria with negative urological work up and recent history of tooth extraction for dental infection. He denied usual symptoms of Lyme disease. Exam was significant for a obese male with BP of 169/75 mmHg and mild lower extremity edema. Laboratory data showed creatinine 3.2 mg/dl, urine protein:creatinine ratio = 8, albumin 2.5 mg/dl, microscopic hematuria. Serology work up revealed ESR 120 mm/hr, CRP 3.59 mg/dl, RF 1:1 titer, C4 <1.5, C3 96.1, C-ANCA <1:20, P-ANCA 1:320, anti PR3 8.6 U/ml, MPO 11.8 U/ml, cryoglobulins positive. Kidney biopsy showed immune complex crescentic MPGN with mostly fibrocellular but a few active cellular crescents, tubular atrophy, interstitial fibrosis and IF staining positive for IgG, IgM, C3, C1q. Extensive work up to rule out infectious process or malignancy was negative except for a positive Lyme screen with confirmation Immunoblot positive. Hemodialysis had to be initiated due to declining renal function.

Discussion: This case is unusual as our patient has positive Lyme serology and MPGN with circulating cryoglobulins and positive ANCA antibodies, but absence of the usual symptoms of Lyme disease. This case highlights that Lyme disease may manifest as renal limited and should be considered when unexplained MPGN occurs where Lyme disease is endemic.

Kirmizis D, *et al*. AJKD 43:544-551, 2004; Finnian R, *et al*. Nephrol Dial Trans. 26:3054–3056, 2011.

FR-PO032

A Novel Case of Renal Pathergy Reaction in a Behçet's Disease Patient Complicated by IgA Vasculitis Takaaki Higashihara,[1] Akira Okada,[2] Akira Shimizu,[3] Hideki Takano.[1] *[1]Nephrology, Tokyo Teishin Hospital, 2-14-23, Fujimi, Chiyoda-ku, Tokyo, Japan; [2]Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, 7-3-1, Hongo, Bunkyo-ku, Tokyo, Japan; [3]Analytic Human Pathology, Graduate School of Medicine, Nippon Medical School, 1-1-5, Sendagi, Bunkyo-ku, Tokyo, Japan.*

Introduction: A pathergy reaction is defined as a hyperreactivity of the skin in response to minimal trauma, which is important in the diagnosis of Behçet'sdisease (BD). However, a pathergy reaction may not be restricted to the skin, and little is known about whether an invasive medical procedure can induce the reaction. Here we present a pathergy reaction induced by renal biopsy, an invasive procedure.

Case Description: A 46-year-old man who was diagnosed with IgA vasculitis (IgAV) at the age of 38 was treated with prednisolone and mizoribine. However, complications such as common carotid arteritis or recurrent oral ulcer suggested the possibility of another pathophysiology. Later, increasing urine protein developed, suggesting disease aggravation. However, renal biopsy showed arteriosclerotic changes caused by hypertension and diabetes mellitus, negating exacerbation. After renal biopsy, his renal dysfunction and body temperature fluctuated, and detailed examinations revealed recurrent oral and genital ulcers and a folliculitis-like rash on his scrotum. Later, he complained of myodesopsia caused by hemorrhage in the ocular fundus due toocclusive vasculitis. Complete BD was diagnosed after development of the symptoms, and he was treated with prednisolone and colchicine.

Discussion: Co-occurrence of BD with IgAV is very rare and may be associated with immune disorders. Interestingly, a renal biopsy revealed BD, which was masked by the presence of IgAV, and elucidated the etiology of the unexplainable symptoms. To the best of our knowledge, this is the first report of renal pathergy. This case enlightens clinicians to the fact that not only a needle stimulation but also an invasive procedure can cause a pathergy reaction, and we should perform focused history-taking and physical examinations when some signs and symptoms in a patient cannot be explained fully by one form of vasculitis, for example, IgAV.

FR-PO033

Lupus Flare Presenting as Acute Pericarditis in a Patient with Stage V CKD on Hemodialysis Secondary to Lupus Nephritis Sai Prasad Gadapa,[1] Siwadon Pitukweerakul,[2] Sree V. Pilla.[3] *[1]Internal Medicine, St. Francis Hospital, Evanston, IL; [2]Internal Medicine, St. Francis Hospital, Evanston, IL; [3]Internal Medicine, St. Francis Hospital, Evanston, IL.*

Introduction: Development of end-stage renal disease (ESRD) does not always result in resolution of the extra-renal manifestations of Systemic Lupus Erythematosus (SLE). Lupus flare is the cause of pericarditis in a patient with stage V CKD on hemodialysis secondary to lupus nephritis until proven otherwise.

Case Description: A 41-year-old AA woman with a medical history of SLE, HTN, Gout, HLD and CKD stage V on hemodialysis presenting with one day duration severe chest pain, pleuritic in nature. Her last lupus flare was more than three years. She is on hemodialysis for more than one year. Her medications include amlodipine, metoprolol tartrate, sevelamer, prednisone 5 mg, and atorvastatin. On examination, the patient had temp. of 99.9 F. Her HR was 102/minute, BP 93/50 mm Hg, RR 28/minute, and oxygen saturation 98% on room air. The BUN level 36 mg/dL. Chest XR revealed marked cardiomegaly. The EKG revealed sinus tachycardia. 2D echo revealed moderate posterior pericardial effusion with borderline tamponade. She received naproxen. Pt also received intensive hemodialysis. Despite above treatment her symptoms did not improve, pericardial rub was heard, her 2D echo also showed no improvement of pericardial effusion. On hospital day 4, SLE studies and inflammatory studies revealed dsDNA Ab 79 IU/mL, C3 complement 67 mg/dL, C4 complement <8 mg/dL and C - reactive protein level 22.5 mg/dL. Naproxen was switched to oral prednisone 20 mg twice daily. On hospital day 7 2D echo revealed small pericardial effusion with no tamponade.

Discussion: Uremic pericarditis occurs in 6-10% of patients with advanced uremia just before initiation of dialysis or immediately after; it is associated with high blood urea levels (>60 mg/dL). SLE activity tends to decrease overtime in patients on dialysis. However, a number of papers report a high rate of flare in dialysis patients. This case report underscores the importance of close follow up of SLE patients on hemodialysis for lupus activity. It also helps making decision regarding renal transplantation.

FR-PO034

Nephrotic Syndrome with Cancer Immunotherapies Abhijat Kitchlu,[1] Warren Fingrut,[1] C. Avila-Casado,[2] Heather N. Reich.[1] *[1]Div of Nephrology, U. of Toronto, Canada; [2]Lab. Med. & Pathobiology, U. of Toronto, Canada.*

Introduction: Oncologic immunotherapy utilizes a patient's immune response to eliminate tumour cells by disruption of immune checkpoints, including programmed cell death 1 (PD-1) and cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) pathways. Autoimmune sequelae, including cases of acute kidney injury from interstitial nephritis have been reported; however glomerular disease appears rare. Here we describe two cases of nephrotic syndrome in patients treated with these agents.

Case Description: Patient 1, a 43 year old male, received the anti PD-1 antibody pembrolizumab, after a 9 year history of Hodgkin's lymphoma. Following his second dose he developed edema and nephrotic syndrome (proteinuria 5.6 g/d) and acute kidney injury (creatinine 4.9 mg/dL). Renal biopsy showed diffuse foot process effacement and mild acute tubular injury. Following cessation of pembrolizumab and corticosteroid treatment he had resolution of his proteinuria and renal insufficiency. Patient 2, a 45 year old male with melanoma, received the CTLA-4 antibody ipilimumab. Following four cycles he developed anasarca and nephrotic syndrome (proteinuria of 9.5 g/d) with normal kidney function. Biopsy was compatible with minimal change disease. Ipilimumab was stopped and proteinuria resolved following corticosteroid treatment. Two years later ipilimumab was restarted as salvage therapy, and he developed recurrent proteinuria. Both patients ultimately died from their underlying cancer.

Discussion: These cases provide insights into the pathogenesis of nephrotic syndrome. While affecting T cell regulation at different stages of T cell activation, both the PD-1 and CTLA-4 pathways modulate T cell activation through signals involving antigen presenting cell CD80 (B7.1). These cases may support the hypothesis of a 'permeability factor' causing podocyte injury. Release of T cell regulation by these drugs may have promoted production of such a factor and subsequent foot process effacement. However a more direct effect on podocyte CD80 engagement cannot be excluded and merits investigation. Given the increasing prevalence of these therapies, monitoring patients for renal sequelae as well as potential early biopsy and intervention may be warranted.

FR-PO035

Nephrotic Syndrome after Autologous Hematopoietic Stem Cell Transplant: A Manifestation of Graft-versus-Host Disease? Madhuri Ramakrishnan,[1] Siva Sagar Taduru,[1] Omkar U. Vaidya,[3] Rakesh Gaur.[2] *[1]Internal Medicine, Univ of Missouri, Kansas City; [2]Hematology/Oncology, Saint Luke's Hospital, Kansas City; [3]Nephrology, Univ of Missouri Kansas City, Kansas City.*

Introduction: Renal involvement in Graft-vs-Host Disease (GVHD) is rare, but has been described following allogenic hematopoietic stem cell transplant (HSCT). Recently, GVHD is being identified as a complication of autologous-HSCT, especially in association with Multiple Myeloma. The manifestations of this type of GVHD are similar to those after allogenic-HSCT, though no cases involving the kidney are described. We describe a case of Nephrotic Syndrome in a patient after autologous-HSCT for Multiple Myeloma.

Case Description: The patient is a 58 year old African American female diagnosed with Multiple Myeloma, who underwent chemotherapy with Bortezumib, Lenalidomide, and Dexamethasone, and subsequent autologous-HSCT. A 100 day bone marrow biopsy revealed no disease process, and the patient was in complete remission. She presented 5 months after transplant with increased weight, lower extremity and facial edema. Initial labs showed AKI- Cr of 3, a 24-hour urine protein of 22 gram (previous urine Protein/Creatinine ratio was normal 4 years prior), and a serum albumin of 2.0. Work up for her Nephrotic Syndrome, including ANA, dsDNA, and ANCA were negative. A renal biopsy was performed, that showed Focal Segmental Glomerulo-Sclerosis, with no evidence of myeloma deposits. Following biopsy results, she was started on high dose Prednisone-120 mg every other day. Her kidney function improved, with Cr of 1.2, and serum albumin improved to 3.8.

Discussion: Given that no other secondary causes were identified, and the temporal relation with transplant, we consider that our patient's Nephrotic Syndrome could be a manifestation of GVHD after autologous-HSCT. Renal manifestations of GVHD are rare, but have been described, though only in patients undergoing allogenic-HSCT. Since GVHD is now also being described in patients undergoing autologous-HSCT, especially for multiple myeloma, kidney disease in relation to this, if presents, is worth investigating. Recognition of more cases is required to elucidate the renal pathophysiology involved.

FR-PO036

A Case of Secondary Membranous Glomerulonephritis Rami Mouayad Azem,[1,2] Minesh Rajpal,[1] Georges Nakhoul,[1] Leal C. Herlitz,[1] James F. Simon.[1] *[1]Nephrology, Cleveland Clinic Foundation, Cleveland, OH; [2]Internal Medicine, Summa Health System, Akron, OH.*

Introduction: Membranous Glomerulonephritis (MGN) is the second leading cause of nephrotic syndrome in adults. MGN can be a primary disease or secondary to underlying etiologies such as autoimmune diseases, including Sjogrens disease. Secondary MGN has also been attributed to IgG4 related disease (IgG4-RD), an immune-mediated disease that involves lymphoplasmacytic infiltration with IgG4 enriched plasma cells.

Case Description: A 61 year old female with past medical history of Sjogrens disease, IgG4-RD, CKD Stage III (baseline creatinine [Cr] 1.0-1.2), retroperitoneal fibrosis with history of bilateral hydronephrosis requiring stent placement and ureterolysis, presented with sore throat, shortness of breath, and productive cough. Cr was 2.4 mg/dL on admission and increased to 4.5 mg/dL within 2 days, accompanied by urine protein/Cr (P:Cr) ratio of 2.5, and an active urinary sediment. There was no evidence of recurrent ureteral obstruction. She was treated for pneumonia with antibiotics and started on pulse dose solumedrol 1 gram daily for 3 days with prednisone subsequently. CRP was 1.5, with negative HIV, ANA, C3, C4, c-ANCA, p-ANCA, DS-DNA, syphilis IgG, phospholipase A2-receptor antibody (PLA2R), and abnormal elevations in IgG subclasses I-IV. IgG subclass IV levels were normal at 113.6, however were elevated 3 weeks prior at 195.5. Renal biopsy showed MGN with focal mesangial and subendothelial deposits, but no IgG4 tubulointerstitial nephritis. She responded to solumedrol with a decrease in Cr from 4.5 mg/dL on 4/21 to 2.76 mg/dL on 5/3, and 1.46 mg/dL on 6/1. Her urine P:Cr ratio however increased from 2.4 on 4/23 to 9.6 on 6/1.

Discussion: This patient had biopsy proven MGN with mesangial and subendothelial deposits and negative anti PLA2R serologies, strongly favoring a secondary form of MGN. While PLA2R testing along with histology can help exclude primary MGN, there is no reliable way to differentiate between secondary MGN due to Sjogrens disease versus IgG4-RD. This case underscores the need for a more thorough understanding of how the many secondary causes of MGN cause this pathology so that therapy can be targeted appropriately.

FR-PO037

Acute Parvovirus B19-Associated Nephrotic Syndrome in a Patient with Sickle Cell Disease Nupur N. Uppal, Jeny Varghese, Hitesh H. Shah. *Nephrology, Hofstra Northwell School of Medicine, Great Neck, NY.*

Introduction: Human parvovirus B19 (HPV B19) infection is a common cause of transient aplastic crisis (TAC) in patients with sickle cell disease (SCD). However, nephrotic syndrome (NS) has been rarely associated with acute HPV B19 infection in patients with SCD. We present an interesting case of abrupt onset severe NS and AKI secondary to acute HPV B19 infection.

Case Description: 37-year-old AA female with history of SCD was hospitalized with fever and severe anemia. Both serum creatinine (Scr) and albumin were normal on admission. Pt. was found to have TAC secondary to acute HPV B19 infection. HPV B19 DNA by PCR was elevated (1.8×10^8 IU/ml). HPV B19 IgM was positive. Scr increased to 1.9 mg/dL during hospitalization. Pt. was thought to have prerenal AKI secondary to hemodynamic changes. There was no obstructive uropathy on renal ultrasound. Pt. received IV fluids and Scr decreased to 1.8 mg/dL on the day of discharge. Five days later, pt. presented to the clinic with worsening lower extremity (LE) swelling, abdominal distention and 35 lbs weight gain. Pt. was noted to have significant LE edema on exam. Urinalysis showed proteinuria. Spot urine total protein to creatinine ratio (TP/CR) was elevated at 56. Serum albumin was low (1.8 g/dL). Scr remained elevated at 1.8 mg/dL. Serological work up for NS including HIV infection was negative. Pt. was subsequently rehospitalized for management of generalized body swelling that was resistant to oral diuretic therapy. Pt. received IV albumin and diuretic therapy during hospitalization. Kidney biopsy performed subsequently revealed collapsing FSGS that was thought to be secondary to acute HPV B19 infection. Scr peaked to 3.4 mg/dL during that hospital stay. Three months after initial presentation, Scr however remains elevated at 2.7 mg/dL. Pt. also continues to have significantly elevated spot urine TP/CR (21.5) and NS despite decreasing HPV B19 DNA levels.

Discussion: Collapsing FSGS as a result of acute HPV B19 infection has been rarely described in patients with SCD. Optimal therapy and renal outcomes in such cases are unknown. Our patient continues to have significant renal failure and severe NS, 3 months after initial presentation.

FR-PO038

Resolution of Hepatitis C Related Membranoproliferative Glomerulonephritis after Treatment with Combination Ledipasvir/ Sofosbuvir Hayden Novak, Kosunarty Fa. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Advent of new medications indicated for the treatment of Hepatitis C has drastically changed the landscape of end- stage liver disease. With the increased use of these new modalities their effect on other virus- related pathologies has yet to be fully established.

Case Description: KB is a 56 year old female with end- stage liver disease secondary to chronic hepatitis C cirrhosis listed for orthotopic liver transplant. December 15, 2014 patient is noted to have apparently normal kidney function with creatinine 0.94. However by mid- January her creatinine is noted to be increased and on January 23 2015 she is admitted with shortness of breath, anasarca, and acute kidney injury, leading to a preliminary diagnosis of nephrotic syndrome (16.7 grams proteinuria). Creatinine peak was 4.1 on 30 January 2015. Renal biopsy did show membranoproliferative glomerulonephritis (MPGN) and acute tubular injury without vasculitis. She did later develop a vasculitic rash of both legs. In addition to treatment with solumedrol, plasmapheresis, and rituximab, ledipasvir/ sofosbuvir (Harvoni) therapy was initiated on 30 January 2015. In April 2015, creatinine had improved to 1.2 and vasculitic rash resolved. 24 hour collection in June 2015 showed 245 mg proteinuria. In November 2015 patient completed 24 weeks' duration of ledipasvir/ sofosbuvir treatment, and creatinine was 0.89.

Discussion: This report of biopsy- proven MPGN in the setting of cryoglobulinemia related to HCV, with recovery to baseline of renal function after ledipasvir/ sofosbuvir treatment is unique in the current literature. The resolution of MPGN in this patient enabled evaluation for single organ transplant in lieu of double organ transplant. With this association, new avenues for investigation are opened into the treatment and management of end- stage renal disease secondary to HCV- associated conditions.

FR-PO039

PLA2R-Antibody Positive Membranous Nephropathy Associated with Inflammatory Demyelinating Radiculopathy after Hepatitis B Vaccination Reejis Stephen, Evamaria Anvari, Laura Ferreira Provenzano. *Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Introduction: PLA2R is a biomarker of idiopathic membranous nephropathy (MN). However, it can be positive in some secondary cases, including hepatitis B (HBV) associated MN. MN has also been associated with inflammatory demyelinating diseases, but the nature of the association remains unclear. This case describes a case of PLA2R positive MN associated with an inflammatory demyelinating polyradiculopathy in the background of a recent HBV vaccination.

Case Description: A 56-year-old Caucasian male was referred for a second opinion regarding MN. He initially presented with joint pain and bilateral extremity paresthesias. He soon developed marked edema and hypertension, with over 20 lbs weight gain, associated with weakness and unsteady gait. No preceding illness was reported, but he had received hepatitis B vaccination one month prior. He had taken NSAIDs for pain but no other medications. He was found to have 17 grams of proteinuria/24 hs and was diagnosed with nephrotic syndrome. His renal function was normal. Serological workup including C3/ C4, ANA, RF, ANCA, anti-GBM antibodies, hepatitis panel, SPEP, UPEP was negative. A screening colonoscopy 6 years prior and a PSA level were normal. Renal biopsy showed membranous nephropathy. PLA2R was positive (1:40). Concomitantly, he was diagnosed with inflammatory demyelinating polyradiculopathy and was started on prednisone 60 mg daily. Over the next several months he showed neurological improvement, and the steroid dose was titrated down. Proteinuria also improved (<1g /24 hrs) and the nephrotic syndrome resolved. Repeat PLA2R levels have been negative.

Discussion: To our knowledge, this is the first case of MN associated with a inflammatory demyelinating radiculopathy with PLA2R positivity. The time correlation with the hepatitis B vaccination series raises the possibility that the HBV antigen triggered the autoimmune response.

FR-PO040

Crescentic and Necroziting Glomerulonephritis with IgA Depositions and Circulating IgG and IgA ANCA Sonia Brigitte Boyer,[1,2] Elizabeth Alderman McInnis,[1] Volker Nickeleit,[1] Patrick H. Nachman.[1] *[1]UNC Kidney Center, Univ of North Carolina; [2]Dept of Medicine, CHU Nice, Nice, France.*

Introduction: Several observations of crescentic and necroziting glomerulonephritis (CNGN) with IgA depositions and IgG ANCA have been reported in literature, suggesting an overlap between IgA nephropathy (IgAN) and ANCA-associated vasculitis (AAV). In this situation, we evaluate the presence of ANCA of IgA isotype.

A 22 year-old male with no previous medical history presented with acute kidney injury (serum creatinine 3mg/L). His symptoms were nausea and one episode of vomiting. Workup was significant for active urine sediment (red blood cell casts, dysmorphic hematuria and oval fat bodies), urine protein/creatinine ratio was 2.78g/g. PR3-ANCA was positive at 185.7U/mL(normal < 20U/mL), ANA was negative and complement was in normal range.

Kidney biopsy revealed diffuse CNGN involving 80-90% of glomeruli and diffuse acute tubular injury with scattered tubular red blood cell casts. Immunofluorescence showed 2+ for IgA and C3 staining in mesangial regions. Initial treatment included methylprednisolone 500mg IV x 3, cyclophosphamide 15mg/kg and 7 plasmapheresis sessions. The patient responded to treatment, with improved serum creatinine to 1.3mg/L.

We investigated the presence of IgA-ANCA by indirect immunofluorescent (IFI) on ethanol fixed neutrophils and western blot electrophoresis on purified MPO, PR3 and Neutrophil extract. The IFI was positive for cytoplasmic staining. The western blot substantiated the presence of an circulating IgA anti-PR3.

Discussion: Only 19 cases of AAV and associated IgAN have been reported in the literature. These patients presented with systemic symptoms in 60% of cases, had a proteinuria > 2g/24h and ANCA were mostly anti-MPO subtype. Morever, studies found that proteinuria is higher in CNGN-ANCA than in crescentic IgAN. A recent study comparing CNGN-ANCA to ANCA-vasculitis showed greater proteinuria in CGCN-ANCA. IgA-ANCA have the capacity to modify neutrophils degranulation and so, could play a role in CGCN-ANCA pathogenesis. Our observation suggests an overlap between IgAN and AAV, and IgA-ANCA could be involved in the physiopathology of this entity.

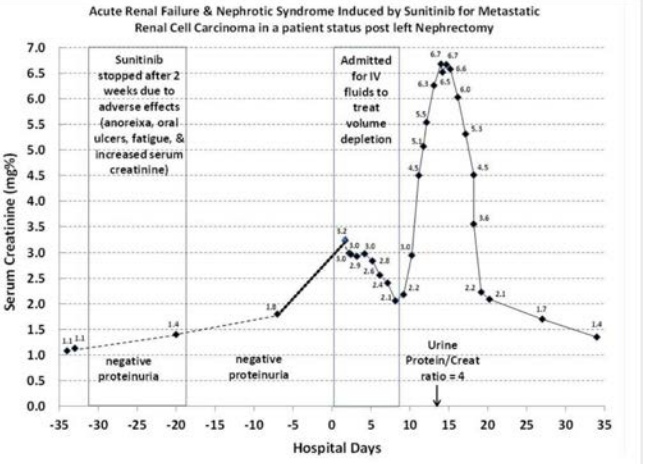
FR-PO041

Severe but Reversible Acute Renal Failure (ARF) and Nephrotic Syndrome (NS) Induced by Sunitimib (Sutent), an Inhibitor of Receptor Tyrosine Kinase (RTK) Used to Treat Metastatic Renal Cell Carcinoma (m-RCC) Sushanta K. Goswami,[1,2] Kai Lau.[1,2] *[1]Dept of Nephrology, Univ of Oklahoma, Oklahoma City, OK; [2]Medical Service, VA Medical Center, Oklahoma City, OK.*

Introduction: Sunitinib is a multi-target RTK inhibitor including VEGFR. Used in many advanced cancers (breast, lung, colon and RCC), it has many extra-renal & renal side-effects. We here report a 51 year old man with m-RCC, prior left nephrectomy, admitted for severe ARF & NS evolved over 4-5 weeks.

Case Description: We reviewed all clinical & lab data in this man consulted for ARF & NS. His hypertension & hyperuricemia were controlled. We excluded all potential causes like NSAID, contrast dye, sepsis, obstruction, rhabdomyolysis & tumor lysis. 2 weeks into 50 mg/d of sunitinib, he developed diarrhea & steadily climbing serum creatinine (Scre) from a stable baseline of 1.1 mg%.

Afebrile, his vital signs & exam were normal. Hydronephrosis was absent. Chest X rays, urine & blood cultures were negative. Hgb was 9 g%, WC 8 k, platelet 21 k (normal bone marrow). Liver function, LDH, CPK, haptoglobin, troponin were normal. IV fluid yielded only mild transient drop in Scre. Initial urinalysis was normal but NS soon emerged. Anasarca was resolved by diuresis, thrombocytopenia by N-plat. 3 weeks after peak Scre of 6.7, his ARF spontaneously & largely resolved.



Discussion: 1. RTK inhibitors, like sunitinib, could cause nephrotoxicities, including thrombotic microangiopathy, interstitial nephritis, proteinuria & mild-to-moderate ARF. Among the dozen reported cases, ours seemed to have the worst renal failure compounded by NS that spontaneously resolved by supportive care & stopping sunitibnib. 2. Given the growing use of these agents in many cancers, we would call attention to these hitherto little described renal toxicities & urge regular monitoring of renal functions.

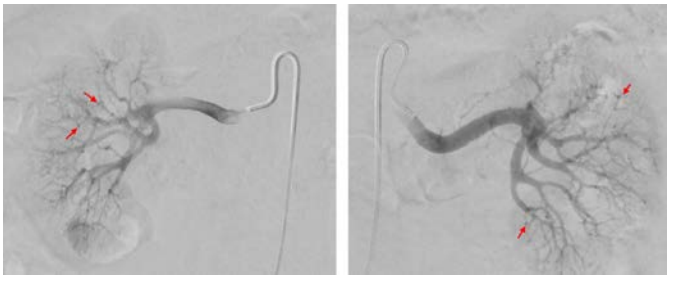
FR-PO042

A Case of Isolated Renal Involvement of Polyarteritis Nodosa Successfully Treated with Steroid Monotherapy Negiin Pourafshar, Eric S. Sobel, Mark S. Segal. *Univ of Florida, Gaineville, FL.*

Introduction: Polyarteritis nodosa(PAN) is a systemic necrotizing vasculitis that typically affects medium-sized arteries, with occasional involvement of small arteries. Renal involvement would frequently result in variable degrees of renal insufficiency, proteinuria and hypertension.

Case Description: A 75-year-old man was referred for management of uncontrolled hypertension and worsening renal function. Patient recently developed uncontrolled HTN as well as renal function impairment. Further work-up of hypertension was unremarkable. A renal angiogram was then obtained due to suspicion for renal artery stenosis which revealed patent renal arteries, marked irregularity of the interlobar branches of the renal arteries with multiple areas of strictures as well as numerous microaneurysms involving interlobar branches of renal arteries (figure 1), suspicious for PAN.



He was initially started on prednisone 40 mg/day which was subsequently increased to 60 mg/day. While on the increased dose of steroids, his hypertension and renal impairment improved. He did not require anti-hypertensive therapy.

Discussion: Renal failure and uncontrolled hypertension could represent renal involvement in PAN. Diagnosis of PAN is based on the recognition of a vasculitic syndrome with supportive evidence deriving from radiologic or pathologic studies or both. Biopsy of an organ is ideal for verifying the diagnosis of vasculitis. However, angiography is similarly valuable or even preferable to tissue sampling for diagnosis. We believe that our patient's worsening renal function and uncontrolled hypertension resulted from diffuse renal necrotizing vasculitis with occlusive lesions of small-sized arteries. Our case report demonstrates successful treatment of renal failure and hypertension with steroid monotherapy.

FR-PO043

The Importance of Adrenal Venous Sampling in Young Patients with Primary Aldosteronism Mamta Shah,[1] David Geller.[2] [1]*Dept of Nephrology, Yale Univ School of Medicine, New Haven, CT;* [2]*Dept of Nephrology, Yale Univ School of Medicine/Veteran Affairs, West Haven, CT.*

Introduction: Primary aldosteronism (PA) is a leading cause of resistant hypertension, which can be treated with surgical removal of a unilateral adenoma. Previous recommendations held that adrenal venous sampling (AVS) was not necessary in patients ≤ 40 years of age with evidence of PA and unilateral adenoma on adrenal imaging, on the premise that nonfunctioning adrenocortical adenomas are rare in young people.

Case Description: A 39 year-old man with a 7-year history of difficult to control hypertension and mild hypokalemia presented for initial evaluation. He had serum and urinary laboratory parameters suggestive of hyperaldosteronism and CT adrenal imaging showed adrenal nodularity on the left consistent with microadenoma vs. hyperplasia with no abnormality on the right. However, AVS demonstrated clear lateralization to the right side. He eventually underwent right adrenalectomy based on AVS, with resultant better blood pressure control on one anti-hypertensive agent and normalization of the serum potassium.

Discussion: Current guidelines advocate the use of AVS in addition to adrenal imaging before considering unilateral adrenalectomy. Based on previous recommendations, this patient might not have had AVS given his age, clinical evidence of PA, and the CT findings, but that would have resulted in the removal of functionally normal gland. A recent study showed AVS changed management in 30% of patients ≤40 years of age. Newer recommendations state AVS should be done in PA patients over 35 years of age. We believe that AVS should ideally be performed in all patients with PA in whom surgical treatment is a consideration.

FR-PO044

The Crystal Clear Answer to Methotrexate Toxicity? Mamta Shah, Juan Calderon, Anushree C. Shirali. *Dept of Nephrology, Yale School of Medicine, New Haven, CT.*

Introduction: Methotrexate (MTX) is a potent anti-cancer drug that antagonizes active division of tumor cells. This often comes at the expense of nephrotoxicity with an incidence of 2-10% with use of high-dose MTX (>500mg/m2). Treatment approaches for toxic MTX levels include high-flux hemodialysis (HF-HD) and Carboxypeptidase-G2 (CPDG2) administration. While HF-HD is more often employed for clearance of MTX, rebound of MTX levels post dialysis has been a concern. We report here a case of MTX toxicity treated with CPDG2 alone, with no rebound of MTX levels after treatment.

Case Description: A 72 year-old man with newly diagnosed Diffuse Large B-cell Lymphoma and baseline serum creatinine (Cr) of 1.0 mg/dL was initiated on MTX at a dose of 2gm/m^2 with leukovorin rescue and intravenous sodium bicarbonate. Within 6 hours of the infusion, he was oliguric with a Cr of 1.6mg/dL, which continued to rise to 3.4mg/dL in 24 hours and 5.5mg/dL in 72 hours. His vital signs and physical exam were unremarkable. No mucositis was noted. MTX levels at 24 and 48 hours were 51μmoles/L and 17μmoles/L respectively. The patient received one dose of CPDG2 at 72 hours with a drop in MTX levels to <1μmole/L which did not rebound. He did not require renal replacement therapy. Cr peaked at 6.5mg/dL the following day and then improved to 1.8mg/dL over the next ten days.

Discussion: In our patient, treatment with CPDG2 resulted in prompt clearance of MTX. Importantly, no rebound was observed and the patient did not require any dialysis. MTX is a small molecule which is 50% protein-bound with a large volume of distribution. This makes it an acceptable drug for dialytic clearance. However, it is an invasive procedure which can put cancer patients at higher infection and bleeding risk. Additionally, post-HD drug levels frequently rebound, requiring repeated dialysis sessions. CPDG2 is fairly well tolerated, is noninvasive and is not associated with rebound. When access to either approach is readily available, use of CPDG2 to treat toxic MTX levels may be more favorable than HF-HD.

FR-PO045

Successful Revascularization of Critical Proximal Renal Artery Stenosis with Early Bifurcation with Two Kissing Coronary Stents Sonali Biligiri, Navneet Kaur, Sandeep Aggarwal, Ellie Kelepouris. *Internal Medicine, Div of Nephrology, Drexel Univ College of Medicine, Philadelphia, PA.*

Introduction: RA stenting is treatment of choice for RAS with uncontrolled hypertension, pulmonary edema, rapid deterioration of renal function and preservation of renal mass. According to living donor studies, renal artery anomalies including accessory renal arteries are present in 30%-47% cases. Usually the accessory RA is non-dominant and is "sacrificed" during intervention without significant loss of renal mass. We present a case of severe RAS of a solitary kidney and very short early bifurcating main RA with 2 co-dominant segmental arteries after successful endovascular revascularization using 2 side by side "kissing" coronary stents.

Case Description: 66 year old black female presented for management of uncontrolled hypertension and worsening renal function with serum creatinine increasing from 2.6 to 3.3 mg/dL in 1 month; her BP had been >180 mmHg systolic despite multiple anti-hypertensives including a diuretic. NM MAG3 scan showed a non-perfused small left kidney with right kidney contributing 100% of renal function suggestive of solitary functional right kidney. Renal doppler showed parvus tardus waveform and normal RI (<0.7) in the right RA suggestive of critical stenosis with preserved parenchyma. An angiogram confirmed severe right renal artery ostial stenosis with near immediate bifurcation into 2 co-dominant segmental arteries. A single stent could not be placed since length of stent would be longer than main renal artery leading to stenting of one segmental artery with potential sacrifice of co-dominant renal artery. Two balloon expandable "kissing" coronary stents were successfully deployed in upper and lower pole renal arterial branches in main renal artery. Patient had marked improvement in BP and renal function with patent stents on post-procedure doppler.

Discussion: Our patient's presentation with progressive kidney dysfunction and uncontrolled hypertension warranted immediate intervention. Her atypical anatomy with immediate renal artery bifurcation proved a challenge for stent placement, but clinical improvement successfully achieved with a unique solution of two "kissing" stents.

FR-PO046

Therapeutic Plasma Exchange for Amlodipine Overdose Latoya L. Brathwaite,[1] Mahwash Kamal,[1] N. Ganesh Yadlapalli.[1] [1]*Nephrology, Univ of Cincinnati Medical Center, Cincinnati, OH;* [2]*Nephrology, Univ of Cincinnati Medical Center, Cincinnati, OH.*

Introduction: Amlodipine is the most prescribed long-acting dihydropyridine calcium channel blocker (CCB). Amlodipine toxicity is associated with poor outcomes and largely treated with supportive therapies. There are no recommended treatments for enhanced removal of CCBs from blood. We report a case of Amlodipine toxicity treated with total plasma exchange (TPE).

Case Description: A 62 year old Caucasian female was admitted with Amlodipine overdose. She was unconscious, hypotensive with bradycardia on admission. She ingested about 500mg of amlodipine. She developed oliguric acute kidney injury, anion gap metabolic acidosis and concomitant respiratory acidosis which required continuous renal replacement therapy. The patient required large amounts of pressor support to maintain hemodynamics. She received high dose IV calcium, IV glucagon, high dose insulin and fat emulsion infusions. After five days of continued high pressor requirements despite aggressive management, she received 1 session of TPE with 1 volume exchange and 100% replacement with 5 % albumin. Amlodipine level prior to TPE was 140ng/ml and after 1 session of TPE, the level had decreased to 70ng/ml. The patient's pressor requirements decreased. At this point, the patient's family decided to withdraw care. We were unable to conduct the second session of TPE as planned. We were also not able to get repeat levels to evaluate a post TPE rebound effect.

Discussion: Amlodipine is 93% protein bound with a large volume of distribution and unable to be removed by hemodialysis. Its long half-life of 30-50hours increases in setting of overdose and places the patient at risk of a prolonged hospitalization requiring a high pressor support requirement and the associated adverse outcomes. In our case, we noticed reduction in pressor requirement after a decrease in amlodipine level with TPE. There is not much data that exist about drug removal with TPE except a few case reports. This case report supports TPE as a modality for removal of highly protein bound substances like amlodipine. The use of TPE earlier in the treatment course may improve outcomes.

FR-PO047

Non-Steroidal Anti-Inflammatory Drugs for Treatment of Severe Refractory Orthostatic Hypotension: Thinking Outside the Box! Julia Brown, Rie Hirai, Anil K. Bidani, Kavitha Vellanki. *Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Orthostatic hypotension is recognized as a paraneoplastic effect of bronchial carcinoma, reported in 10-20% of patients with the disease. While the exact pathophysiology is unknown, the role of vasodilatory peptides secreted by the tumors has been explored. Here we present a unique case of refractory orthostatic hypotension in a patient with lung carcinoma in which symptomatic relief was achieved with non-steroidal anti-inflammatory drugs (NSAIDs).

Case Description: A 66 year old male with a recent diagnosis stage IIIb squamous cell lung carcinoma presented with complaints of generalized weakness. He was found to be orthostatic and remained orthostatic despite aggressive fluid resuscitation. His blood urea nitrogen and creatinine were stable. Cisplatin-induced salt wasting nephropathy

was ruled out (fractional excretion of sodium <1% repeatedly). He continued to be symptomatic despite receiving salt tablets 4 grams 3 times daily, midodrine 5 mg 3 times daily, fludrocortisone 0.1 mg twice daily, an abdominal binder, and thigh-high compression stockings. We hypothesized that systemic and renal vasodilatation, possibly paraneoplastic in origin, were playing a role in the patient's severe orthostatic hypotension. Low systemic vascular resistance calculated from the patient's echocardiogram further reinforced our hypothesis. We therefore started ibuprofen, after which there was a dramatic improvement in the patient's clinical symptoms and he was able to walk after being bed bound for more than a week (Table 1).

Discussion: In appropriate clinical conditions, NSAIDs can be considered for treatment of severe refractory orthostatic hypotension.

	Supine BP	Standing BP	Supine HR	Standing HR
Prior to NSAID	123/88	96/76	77	111
	133/89	117/76	86	121
	128/82	83/56	84	140
	113/64	91/63	95	145
	139/84	92/74	80	126
	85/57	70/49	96	142
	117/64	121/78	85	121
	106/67	74/53	95	142
	125/86	96/64	87	140
After ibuprofen 400mg twice daily	138/86	115/79	82	109
	131/81	103/75	84	123
	133/90	111/82	80	126
After ibuprofen 400mg three times daily	138/90	125/91	82	129

FR-PO048

Reversible Heart Failure and Nephrotic Syndrome Associated with Massive Protein Intake in a Bodybuilder

Khaled Boobes, Robert M. Rosa, Cybele Ghossein, Daniel Batlle. *Nephrology/Internal Medicine, Northwestern Univ, Chicago, IL.*

Introduction: High protein diet in addition to anabolic steroid ingestion is common among bodybuilders to promote muscle development/hypertrophy. Acute tubular necrosis and focal segmental glomerulosclerosis have been described in the setting of high protein intake and anabolic steroid use.

Case Description: We present a case of a previously healthy 42 year-old African American male bodybuilder, on anabolic steroid supplements, who was consuming a 150g of protein/kg/day diet -for a total intake of >1500 g of protein a day- who was hospitalized for decompensated heart failure.

On evaluation, he was found to have a decreased ejection fraction (EF) of 15% and proteinuria of 6g/day. Serum protein electrophoresis did not show any gammapathies, and Urine protein electrophoresis revealed that his urinary protein consisted mainly of albumin. His GFR based on creatinine clearance was 113ml/min. A renal biopsy to evaluate proteinuria showed mild chronic tubule-interstitial disease without acute tubular necrosis. His myocardial biopsy showed hypertrophied myocytes, but no specific etiology for his heart failure. Five days later, while still an inpatient, his proteinuria decreased to 2g/day while on a hospital low protein diet. He was started on an ACE inhibitor and asked to modify his lifestyle. Six months later his proteinuria was reduced to 115mg/day and his EF has improved to 45%.

Discussion: This unique case highlights a rarely recognized cause of heavy proteinuria and acute heart failure attributable to massive protein intake and possibly anabolic steroids use. In addition to the reversible heart failure associated with myocyte hypertrophy our case illustrates that chronic tubular interstitial nephropathy can develop as well. The proteinuria and tubular damage observed in this case resembles the overload proteinuria caused experimentally by albumin infusion to rodents.

FR-PO049

Secretory Paraganglioma of the Head and Neck

Muddasser Saiyed-Javed, Christopher R. Provenzano, Keith A. Bellovich. *Nephrology, St. John Hospital & Medical Center, Detroit, MI.*

Introduction: Paragangliomas are rare neuroendocrine extra-adrenal tumors of sympathetic or vagal ganglion cells. Catecholamine secreting Paragangliomas are present mostly in the abdominal para-aortic region (75 percent). Nonsecreting vagal Paragangliomas (95 percent) are located mainly in the head and neck.

Case Description: We report a 58 year old gentleman with the diagnosis of panic disorder for 7years was referred to Hypertension clinic with labile hypertension. He was on appropriate therapy(Lisinopril 40mg daily, Indapamide 1.25mg daily, Verapamil 240mg daily, Carvidolol 25mg twice daily, Olmesartan 40mg daily) but was experiencing episodic fluctuations in blood pressures with panic attacks. Work up for pheochromocytoma was initiated and his plasma free Normetanephrines was 16nmol/L (Normal <0.90). The 24 hour urine Normetanephrine was 32,340 nmol/L. CT scan of Abdomen and pelvis was negative. I-123MIBG was also negative. With high clinical suspicion F-18-FDG PET scan was performed and showed localized left cervical Paraganglioma. CT Angiography of the Head/Neck confirmed a heterogeneous mass 4x2x5.6 cms at the base of the skull. He underwent selective Left neck dissection with excision of Para-pharyngeal mass and lymph nodes. Pathology was consistent with malignant paraganglioma with negative lymph nodes. Repeat Plasma Normetanephrines were 1.2 nmol/L.

Discussion: Catecholamine secreting Paragangliomas of head and neck are rare (3 percent). F-18-FDG PET scan is more sensitive then I-123MIBG scan (85 versus 52 percent) in diagnosing Paraganglioma of the neck.

FR-PO050

The Mysterious Polish Supplement: A Case Report of Cardiac Glycoside Poisoning with Lily of the Valley Extract

Payam Pourhassani, Christopher Richard Kern, Hasan Arif. *Internal Medicine, Drexel Univ College of Medicine, Philadelphia, PA.*

Introduction: The plant *convallaria majalis* (Lily of the Valley) contains multiple cardiac glycosides similar to those found in the pharmaceutical drug Digoxin, derived from the *digitalis lanata* (foxglove) plant. These plants are responsible for a number of cases of acute poisonings yearly. We report a case of cardiotoxicity, AKI, and hyperkalemia in an elderly female caused by the health supplement Cardiol-C, which contains Lily of the Valley extract.

Case Description: An 86-year-old Polish female with history of CAD and HTN presented to the ED with nausea, vomiting, and weakness for 5 days. While her cardiac medications were at first unknown, she admitted to a 3-month use of Cardiol-C. Her BP was as low as 64/32 and heart rate 42bpm. Initial EKG showed junctional bradycardia with old LBBB. Labs revealed potassium level of 7.2 mMol, creatinine 3.8 mg/dL (baseline unknown), bicarbonate of 17 mMol. She was given atropine and DigiFab with improvement of hemodynamics, symptoms, and EKG, and transferred to the ICU for monitoring of possible symptom recurrence secondary to xenobiotic redistribution. Her potassium normalized with temporizing measures, including intravenous fluids and diuretics; her discharge creatinine was 1.59 mg/dL.

Discussion: Although the degree of hyperkalemia correlates with cardiotoxicity in acute ingestion, special care was made not to lower the potassium drastically as hypokalemia can enhance the effect of cardiac glycosides. Our patient's glycoside-induced hyperkalemia was likely exacerbated by a prerenal AKI and her use of medications known to induce hyperkalemia. This case illustrates the importance of asking patients about over-the-counter (OTC) supplement use as there can be lethal consequences, most of which patients are unaware of. Cardiol-C also contains Hawthorn extract, which has been shown to interfere with digoxin immunoassay measurements and compete with Na+/K+ ATPase. Given the narrow therapeutic index of cardiac glycosides, extreme caution—if not complete avoidance—should be used with their non-standardized use as toxicity often occurs even with close monitoring.

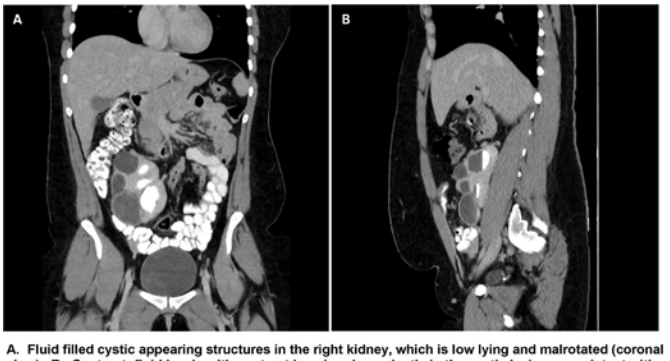
FR-PO051

An Unusual Case of Hypertension and Acute Kidney Injury during Pregnancy and Postpartum Course

Mahrukh Rizvi, Sai Subhodhini Reddy, Andrea Zynda-Weiss, Guan Wu, Wei Chen. *Univ of Rochester School of Medicine.*

Introduction: New onset hypertension (HTN) complicates 6-8% of pregnancies. Approximately 20% of women remain hypertensive beyond 3 months postpartum. We present an interesting case of new onset HTN and acute kidney injury (AKI) during pregnancy that persisted beyond 3 months postpartum.

Case Description: A 28 year old Hispanic woman with no significant past medical history was referred to Nephrology for persistent HTN and elevated creatinine (Cr 1.1mg/dL, baseline 0.7) 3 months postpartum. During the third trimester, she developed HTN with blood pressure (BP) in 140/90's (baseline BP 120/70's), proteinuria (~400 mg/day) and AKI with a peak Cr of 1.4 mg/dL. She was diagnosed with pre-eclampsia and induced at 38 weeks. Despite delivery, she continued to have HTN with a mean BP of 150/90's. This prompted work up for secondary HTN. Renal ultrasound showed bilateral renal cysts. Follow up CT scan and MRI revealed malrotated right pelvic kidney, bilateral ureteropelvic junction configurations with moderate to severe hydronephrosis and areas of cortical thinning.



A. Fluid filled cystic appearing structures in the right kidney, which is low lying and malrotated (coronal view). B. Contrast- fluid levels with contrast layering dependently in the cystic lesions consistent with contrast filling the dilated collecting system. Right kidney demonstrated slightly delayed enhancement compared to the left kidney (sagittal view). Both images were obtained 6 minutes after contrast administration.

She subsequently underwent right ureteral stent placement and pyeloplasty. Cr and BP remained stable after the surgical intervention.

Discussion: New onset HTN during pregnancy that persists >3-6 months postpartum warrants further evaluation. Our work up led to the unexpected diagnosis of significant congenital anomalies (bilateral ureteropelvic junction configurations and right pelvic kidney) requiring surgical intervention. The congenital anomalies, pre-existing hydronephrosis and

increasing fetal size (which could exacerbate the hydronephrosis) likely all contributed to the development of preeclampsia and AKI. Interestingly, the hydronephrosis was first thought to be renal cysts on ultrasound. This highlights the importance of pursuing further workup for multiple renal cysts in young individuals.

FR-PO052

Canagliflozin (Invokana) Induced Ketoacidosis and Proximal Renal Tubular Acidosis in the Setting of Euglycemia following Sugery

Robert Fleyshman, Christopher Richard Kern, Hasan Arif. *Hahnemann Univ Hospital, Philadelphia, PA.*

Introduction: Canagliflozin, a selective sodium glucose cotransporter-2 (SGLT-2) inhibitor, works by blocking glucose reabsorption at the proximal tubule. Its most significant side effect is hypoglycemia. A rarer side effect in type 1 diabetics improperly labeled as type 2 diabetics is normoglycemic diabetic ketoacidosis. We present a case of canagliflozin-induced ketoacidosis and proximal renal tubular acidosis (RTA2) following surgery in the setting of euglycemia in a patient with type 2 diabetes mellitus (DM2).

Case Description: 55 year old female with past history of DM2 (diagnosed 4 years prior) and left breast cancer status post mastectomy was admitted for left breast reconstruction surgery. Her home medications included anastrozole, insulin glulisine and insulin detemir. Metformin and canagliflozin were added several weeks prior and last taken one day prior to surgery. On post-operative day 2, she was noted to have pH of 7.08, serum chloride 114 mmol/L, serum bicarbonate of 6 mmol/L, anion gap of 16, serum potassium of 3.2 mmol/L, serum calcium of 7.1 mg/dL, blood sugar of 155 mg/dL and normal lactic acid. After surgery, she reported nausea along with decreased appetite and oral intake. Elevated beta-hydroxybutyric acid on day 3 confirmed likely euglycemic DKA, accounting for her significant gap acidosis. Her abnormal delta ratio, revealing a concurrent non-gap acidosis, was thought to be secondary to a canagliflozin-induced RTA2, in the setting of glucosuria and abnormal urinary electrolytes. She was treated with IV bicarbonate and sliding scale insulin until her anion gap closed on post-operative day 5. Her hypokalemia, hypophosphatemia, and hypomagnesemia were treated with aggressive electrolyte repletion; each derangement normalized by post-operative day 7.

Discussion: Canagliflozin is approved for DM2. Most common side effects include genital mycotic infections and urinary tract infections. A rare, but significant side effect, is hypoglycemia when used with other diabetic medications. Our case illustrates a rare but serious side effect of ketoacidosis and RTA2 in the setting of euglycemia following surgery and decreased oral intake.

FR-PO053

Severe Metabolic Acidosis as a Complication of an Oral SGLT-2 Inhibitor

Benjamin Griffin, Charles L. Edelstein. *Nephrology, Univ of Colorado, Aurora, CO.*

Introduction: Sodium-Glucose Cotransporter 2 (SGLT-2) inhibitors, a novel class of anti-glycemics, work by inhibiting the SGLT-2 cotransporter in the proximal tubule, leading to significant glucosuria. There is also evidence that they increase insulin sensitivity and decrease gluconeogenesis. Canagliflavin was approved by the FDA in 2013 for Type II Diabetes Mellitus (DM), but is occasionally used as an off-label treatment for Type I DM as well.

Case Description: KR is a 40 year old lady with a past medical history of Diabetes Type I and hypertension who presented to the hospital with two days of nausea, vomiting, abdominal pain, and confusion. Blood glucose levels at home had not been elevated. Physical exam was remarkable for tachycardia, dry mucous membranes, and abdominal tenderness, but was otherwise unremarkable. Laboratory investigations revealed an arterial pH of 6.845, pCO2 of 25, bicarbonate of 3, anion gap of 28, glucose of 222, creatinine of 1.24 (from a baseline of 0.8), small ketones in the serum, and 3+ ketones on urinalysis. She was treated for Diabetic Ketoacidosis (DKA) with an insulin drip and fluid repletion. Creatinine peaked at 1.7, and then recovered to baseline over the course of one week. Upon further questioning, she was on an insulin pump for diabetic control, and also on Canagliflavin orally. Because her blood glucose levels were normal, she had not been receiving an adequate dose of subcutaneous insulin, which was thought to be the trigger of her DKA episode.

Discussion: This case illustrates the recently described phenomenon of euglycemic DKA in the setting of Canagliflavin use. This medication is currently only approved for use in type II DM, and caution must be exercised if used off-label in type I DM. In this case, the patient was not receiving an adequate amount of insulin because serum glucose levels were within normal limits, and developed DKA. Recognition of this disorder in the euglycemic patient is important in order to avoid delays in diagnosis and treatment.

FR-PO054

Lactic Acidosis: A Potential Complication of SGLT2 Inhibitors

Bilal Z. Iqbal, David Levy, Sai Subhodhini Reddy. *Nephrology, Univ of Rochester, Rochester, NY.*

Introduction: SGLT2 inhibitors have been shown to improve glycemic control in patients with diabetes mellitus type 2 (DM2). These agents have been show to increase the risk of ketoacidosis, however lactic acidosis is not currently a known complication.

Case Description: JG is a 48 year old female referred to nephrology in April 2015 for further evaluation of CKD and metabolic acidosis. At that time she was taking Metformin and Invokana for DM2. She was advised to stop Metformin and sodium bicarbonate was started. Seven months later, she was noted to have worsening metabolic acidosis. She was taking the sodium bicarbonate; however she also continued the Metformin and Invokana. At this point she agreed to stop taking both medications. Repeat labs showed improved serum bicarbonate and normal lactic acid. Four months later, her endocrinologist restarted her Invokana due to poor glycemic control. Two months after Invokana was restarted, she developed worsening metabolic acidosis and lactic acid was elevated (see table). Although she was asymptomatic she was referred to the ED for further evaluation. Repeat labs showed persistent lactic acidosis. Workup for DKA, sepsis, and hypoperfusion was negative. Furthermore there was no clear cause of the lactic acidosis. Invokana was stopped and repeat labs showed that her lactic acid and serum bicarbonate had normalized.

Date:	Serum Bicarbonate (mmol/L)	Serum Cr (mg/dl)	Anion Gap	eGFR (ml/min/1.73m2)	Lactic Acid (mmol/L)	Medications	Changes
4/10/15	21	1.28	12	50	-	Metformin Invokana	NaHCO3 started
11/12/15	16	1.38	19	45	-	Metformin Invokana NaHCO3	Metformin/ Invokana stopped
11/25/15	22	1.27	15	50	1.3	NaHCO3	Invokana restarted
5/2/16	18	1.28	17	49	-	NaHCO3 Invokana	Labs repeated
5/12/16	16	1.62	20	37	4.2	NaHCO3 Invokana	Hospitalized, Invokana held
5/14/16	21	1.16	11	55	1.6	NaHCO3	Discharged, Invokana not restarted

Discussion: Although ketoacidosis has been reported as a potential complication of SGLT2 inhibitors, to our knowledge this is the first reported case of lactic acidosis secondary to Invokana. Clinicians should be aware of this potential complication among patients taking SGLT2 inhibitors.

FR-PO055

Oxymorphone Hydrochloride (Opana) Related Acute Kidney Injury with Lamellated Bodies in Podocytes

Yan Yatsynovich,[1] Anjali A. Satoskar,[3] Natallia Maroz,[2,5] Dmiri Souzdalnitski,[4] Glenn R. Rech.[4] *[1]Kettering Medical Center, OH; [2]Wright State Univ, RPI, OH; [3]Ohio State Univ, OH; [4]Western Reserve Hospital, OH.*

Introduction: Opana (Oxymorphone hydrochloride) is a semi-synthetic oral opioid analgesic used for management of severe pain. While side effects of CNS, respiratory and GI depression are well known, acute kidney injury (AKI) is generally not expected.

Case Description: A 61yo white male presented with a two-month history of progressive peripheral edema and dyspnea. He had underling CKD stage III A, related to prolonged use of NSAID's. He had baseline creatinine of 1.6 mg/dl in the absence of proteinuria. He was abstinent from NSAID's for the last 2 years. On physical examination he had weight gain of 20 lb and +2 edema of LE extending to the abdominal wall. There was an acute rise in creatinine of 2.4 mg/dl. UA showed proteinuria 0.4 mg/gm without hematuria. Serological work up, evaluation of thyroid, liver and heart function was unremarkable. Review of the medications revealed recent modification of his pain regimen with substitution of extended release morphine (MS Contin) by Oxymorphone hydrochloride (Opana), occurring 4 months prior to presentation. Renal biopsy was performed. Electron microscopy showed presence of lamellated lipid containing curvilinear bodies in the cytoplasm of podocytes referred to as "myeloid or zebra bodies". Alpha galactosidase activity in serum was normal. Therefore, drug induced podocyte injury was suspected. Opana was discontinued, with resolution of edema and creatinine improvement to prior baseline.

Discussion: Opana has been described to cause thrombotic microangiopathy in the kidney. This case illustrates an unusual link between the use of Opana and development of AKI. Lamellated bodies in the podocytes were first described in Fabry's disease. Similar structures with curvilinear appearance have been later described in association with drug toxicity from Chloroquine, Hydroxychloroquine and Amiodarone but never associated with Opana. Importantly, discontinuation of Opana has led to resolution of edema and AKI. While renal complications from use of opioid analgesics are uncommon, awareness of this rare nephrotoxicity is important.

FR-PO056

Cola-Colored Urine and Acute kidney Injury after Type A Aortic Dissection Repair

Hema Vishwanath Sheelvanth,[1] Khaleel Sayeed,[1] William Luke Whittier.[1] *[1]Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Nephrology, 1, Chicago, IL; [3]Nephrology, 1, Chicago, IL.*

Introduction: Hemolysis after mechanical heart valve replacement is caused by trauma from shearing force on red blood cells (RBCs) resulting in release of RBC products and acute kidney injury (AKI). We report a case of hemolysis presenting with cola-colored and AKI nine days after surgical repair of type A aortic dissection.

Case Description: A 57 y/o man presented with fatigue, dyspnea, and cola-colored urine, nine days after repair of an aortic dissection with hemi-arch placement and re-suspenison of native aortic valve. UA color was black, with large prot, large bld, 70 RBCs. Urine p/c ratio 1.48 g/g, Hgb 5 g/dL and serum creatinine (SCr) 2.4 from 1.1 mg/dL post-operatively. LDH 3,116 U/L, myoglobin 207 ng/mL, CPK 960 U/L, reticulocytes 7.26%, unconjugated bili 2.1 mg/dL, haptoglobin < 4, normal G6PD, ADAMTS13, ANA, ANCA, C3, C4. He received RBC transfusions without improvement in his Hgb. MRI showed focal kinking of the ascending aortic graft with resultant turbulent jet (see Figure).

His SCr increased to 4.1 mg/dL despite therapy with IV fluids and metoprolol. He was taken back to surgery and found to have a portion of the aortic hemashield graft wrapped around the distal aorta. The mean gradient pressures decreased by 50% after surgical release of the wrap graft. Intraoperatively, within minutes of the revision, urine color turned from black to amber and six hours later, was yellow. In the ensuing days, hemolysis resolved and his SCr improved to 1.9 mg/dL.

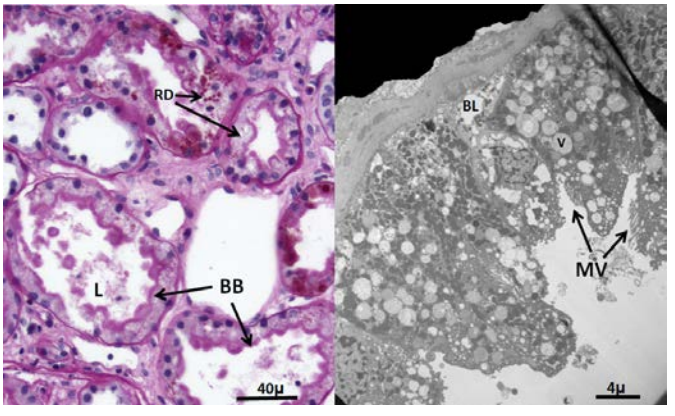
Discussion: We present a patient with hemolysis and AKI after repair of an aortic dissection due to focal kinking of the ascending aortic graft causing a turbulent blood flow. Hemolysis improved and dialysis was avoided after surgical repair.

FR-PO057

Alirocumab (Praluent) Induced Renal Injury: A Novel Side Effect of a Novel Drug Valerie Suzanne Barta,[1] Kenar D. Jhaveri,[1] James M. Pullman.[2] *[1]Nephrology and Hypertension, NorthShore-LIJ Health System, Great Neck, NY; [2]Pathology, Montefiore Medical Center, Bronx, NY.*

Introduction: We report the first case of biopsy-proven acute tubular injury (ATN) associated with alirocumab, a monoclonal antibody against proprotein convertase subtilisin/kexin type 9 (PCSK9), shown to be a valuable treatment of hypercholesterolemia.

Case Description: A 62 year old AA woman recently started on alirocumab 75 MG/ML SQ every 2 weeks. Medications included aspirin, metoprolol succinate, rosuvastatin, doxazosin, clopidogrel and ramipril. 2 weeks later her creatinine rose to 5 mg/dl from baseline 2.3mg/dl and continued to rise despite holding ramipril. Kidney biopsy on light microscopy (LM) showed ATN in a background of chronic hypertensive nephropathy with secondary FSGS. Electron microscopy (EM) confirmed tubular injury, with features of toxicity.



Proximal tubule injury. Left, LM: sloughing of necrotic proximal tubule epithelial cells into the lumen (L), absorption droplets (RD), degeneration of brush border (BB). PAS stain 20X. Right, EM: proximal tubule with only residual brush border microvilli (MV) and basolateral processes (BL), numerous cytoplasmic vacuoles (V). 2700X.

Discussion: The clinical picture, pathology and time course of ATN coincided with alirocumab as the cause, and renal function returned to baseline 1 month following cessation of this agent. A mechanism of alirocumab-induced ATN may be suppression of the PCSK9 overexpression in the kidney that occurs during inflammation, likely a cellular protective response to injury. CKD may be an additional risk factor. Of note, ATN was also documented as an effect of SPC5001, an antisense oligonucleotide which interferes with PCSK9 expression. Internists, cardiologists and nephrologists need to be aware of ATN as a potential side effect of alirocumab, and possibly other drugs that downregulate PCSK9 expression.

FR-PO058

Combined Anti-CTLA-4 and Anti-PD1 Immunotherapy Induced AIN Valerie Suzanne Barta,[1] Nupur N. Uppal,[1] Rimda Wanchoo,[1] James M. Pullman,[2] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra Northwell School of Medicine; [2]Pathology, Montefiore Medical Center.*

Introduction: Both anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) and anti-program death 1 (PD-1) have been used more frequently to combat an increasing variety of cancers. Their nephrotoxic side effects are only recently being discovered. We present a case of acute interstitial nephritis (AIN) caused by combined treatment of nivolumab and ipilimumab.

Case Description: A 62 year old male with metastatic melanoma was started on nivolumab 5 months prior to consultation for acute kidney injury (AKI). He experienced arthritis and dermatitis as side effect treated and resolved with course of prednisone. His baseline creatinine (SCr) was 1.2 mg/dL throughout treatment. Within 2 weeks of starting combination therapy with addition of ipilimumab, Cr rose to 1.6mg/dL and absolute eosinophils (AEC) went from 0 to 0.9 K/uL. There were no other new medications started in this time and no exposure to contrast or other nephrotoxins aside from occasional use of NSAIDS in the past. Urine eosinophils were positive and serological work up for AKI was negative. SCr and eosinophil increases coincided temporally post infusions of combined immunotherapy. SCr peaked at 1.8 mg/dL. A kidney biopsy confirmed moderate interstitial fibrosis and tubular atrophy with focal chronic inflammation and eosinophils suggestive of chronic interstitial nephritis. Both agents were held after third cycle secondary to AIN and prednisone 1mg/kg was initiated. SCr decreased to 1.38 mg/dL and AEC back down to 0 K/uL. Currently, the patient's cancer is not progressing.

Discussion: Immune checkpoint inhibitors such as nivolumab and ipilimumab are known to cause AIN. Their combined use seems to confer an increased risk. Only one prior case exists of combined therapy leading to AIN in a native kidney. AIN appears to be related to an immune response to the kidney. It is essential for nephrologists and oncologists to understand this risk. Frequent monitoring of Scr during treatment and swift referral to nephrology for AKI can aid in early diagnosis of this newly recognized side effect and early initiation of treatment to prevent continued renal damage in these patients.

FR-PO059

Cytokine Storm and T-Cell Dysregulation Drives Acute Tubular Necrosis and Glomerular Disease in an SLE Patient with Hemophagocytic Lymphohistiocytosis (HLH) Ashish Gummadi, Iris J. Lee, Swati Rao, Kamel Hatahet, Xu Zeng, Duncan B. Johnstone. *Nephrology, Temple Univ Hospital, Philadelphia, PA.*

Introduction: HLH is a rare condition of dysregulated activation of the innate immune system and abnormal T-cell function that can result in multi-organ failure and death. Renal involvement in HLH is not well characterized, but few cases report findings of acute tubular necrosis (ATN) and variable podocyte injury. Diffuse podocyte effacement and collapsing glomerulopathy have been described. We report a case of HLH in a woman with systemic lupus erythematous (SLE) who presented with nephrotic range proteinuria and acute kidney injury (AKI).

Case Description: A 57 year old Caucasian female with history of hepatitis C cirrhosis was admitted to hospital for fever and placed on broad spectrum antibiotics. An extensive work up for infection was negative. The patient had a non-blanching erythematous macular rash, pancytopenia, splenomegaly, mental status changes and continued fevers. Peripheral smear and bone marrow biopsy were non-diagnostic. Ferritin levels >7500ng/ml, prompted consideration of HLH. Clinical findings and levels of soluble IL-2 Receptor (5295U/ml), later confirmed HLH. Treatment was started with steroids, IVIG and Etoposide. Inflammatory markers, CRP and Ferritin improved, but patient then developed AKI and nephrotic range proteinuria (5 grams) with microscopic hematuria. Serologies were positive for ANA (1:160), P-ANCA (1:80), and low complements. Renal biopsy confirmed a diagnosis of SLE, but only demonstrated class II lupus nephritis. A severe nephrotoxic ATN was seen on biopsy.

Discussion: We found both features of ATN and nephrotic range proteinuria in our patient with SLE and HLH. Our patient unexpectedly showed minimal glomerular damage related to SLE, as we only found class II lupus nephritis, which uncommonly presents with severe nephrotic range proteinuria. It has been proposed that in HLH, a soluble factor, and/or yet to be identified cytokine or lymphokine may contribute to podocyte damage and modifications resulting in nephrotic range proteinuria which was present in our patient.

FR-PO060

Severe Cisplatin Induced Renal Salt Wasting Pavani Reddy,[1] Ashvin Kamath,[1] Golriz Jafari,[1] Phuong-Thu T. Pham,[2] Phuong-Chi T. Pham.[1] *[1]OVMC; [2]UCLA.*

Introduction: Cisplatin is known to induce Fanconi syndrome and renal salt wasting (RSW). RSW typically only requires transient normal saline (NS) support. We report a severe RSW case that required >12L of 3% saline.

Case Description: A 57-year old woman with limited stage small cell cancer was admitted for cisplatin (80 mg/m^2) on day 1, and etoposide (100 mg/m^2) daily, day 1, 2, and 3 . On day 3, patient's serum sodium (SNa) decreased from 133 to 125 within 24 hours. A diagnosis of syndrome of inappropriate antidiuretic hormone secretion was made. Urine studies revealed osmolality (Uosm) 693 mosm/kg, UNa 205 mEq/L, and potassium (UK) 40 mEq/L. While plan for strict free H_2O restriction was being placed, patient's SNa fell to 119 within 5 hours in association with acute onset of headaches, nausea, and dizziness. Given the rapid fall in SNa and rapid onset of neurological symptoms, 3% saline (3%S) was initiated to raise SNa by 5%. Despite the initial 3%S infusion, her SNa continued to

decrease in association with increasingly high volume of hypertonic urine (average 100-150 mL/h, up to 600 mL/h of urine with UNa+UK up to 265+73 mEq/L respectively). Higher 3%S infusion rates up to 1400 mL/day were required to maintain SNa at 135. Empirical fludrocortisone 0.1 mg bid did not ameliorate the natriuresis. Thyroid stimulating hormone was 1.5 mIU/L. Studies to evaluate for Fanconi syndrome revealed glucosuria up to 70 mg/dL in the absence of serum hyperglycemia and hypophosphatemia at 2.7 mg/dL (baseline phosphorus level was 4 mg/dL). The natriuresis slowed down by 2.5 weeks, but 3%S support was continued for a total volume of 12L over 3.5 weeks. Patient was eventually discharged on NaCl 2g bid. During the natriuretic phase, other attempts to slow down her glomerular filtration included ibuprofen 200 mg tid and benazepril 10 mg bid.

Discussion: Fanconi syndrome and RSW have been reported with cisplatin. Our data were consistent with both conditions following a one time use of cisplatin. To our knowledge, this is the most severe case of RSW ever reported with cisplatin. With the exception of 1 case where 3%S was required for 3 days, all other reported cases only required NS infusion. Our patient required over 12L of 3%S over a prolonged course of 3.5 weeks.

FR-PO061

A Rare Case of Harvoni (Ledipasvir with Sofosbuvir) Induced Acute Interstitial Nephritis Dilek Yarar,[1] Jean Luc Franck,[1] John J. Doran,[1] Carla L. Ellis.[2] *[1]Nephrology Dept, Grady Memorial Hospital, Atlanta, GA; [2]Renal Pathology Dept, Emory Univ, Atlanta, GA.*

Introduction: Harvoni is a novel agent approved by the FDA for the treatment of hepatitis C infection. Scant data concerning Harvoni and its nephrotoxicity profile are available; we report a case of biopsy proven acute interstitial nephritis (AIN) associated with Harvoni.

Case Description: A 62-year-old female with hypertension, insulin dependent diabetes mellitus, chronic liver disease secondary to hepatitis C infection and chronic kidney disease stage 3 was admitted to Grady Memorial Hospital due to a recent rise in her serum creatinine level. Beside starting on Harvoni four weeks prior to presentation, the patient denied other changes in her medications which included insulin, amlodipine, hydralazine and losartan. She denied use of non-steroidal anti-inflammatory agents or herbal products. Her physical examination was only remarkable for a bilateral lower extremity pitting edema. Admission labs were notable for a creatinine level of 2.5 from a baseline of 1.7. Urine sediment analysis showed presence of white blood cells casts. Those findings prompted a renal biopsy which was performed. Histopathological findings showed mild to focally moderate acute interstitial nephritis with focally increased interstitial eosinophils and neutrophils and evidence of diabetic nephropathy. The decision to hold Harvoni was made, and on follow up the patient had near complete resolution of her acute kidney injury with her creatinine almost back to baseline.

Discussion: Harvoni is a novel medication for the treatment of chronic hepatitis C infection. To our knowledge this is the second case of biopsy-proven AIN induced by Harvoni reported. This case emphasizes the need for nephrologists and hepatologists to be aware of this potential side effect of Harvoni.

FR-PO062

Bile Acid Nephropathy Successfully Treated with Plasmapheresis Sam Kant,[1] Orla M. Crosbie,[2] Syed Akbar Zulquernain,[2] Liam Plant.[1] *[1]Dept of Renal Medicine, Cork Univ Hospital, Cork, Ireland; [2]Dept of Gastroenterology, Cork Univ Hospital, Cork, Ireland.*

Introduction: Anabolic steroids are well documented to cause cholestatic jaundice. With the institution of supportive care, predominantly withdrawal of offending agent, recovery usually ensues. Concomitant acute kidney injury secondary to bile acid nephropathy, is increasingly being recognised in this cohort of patients.

Case Description: A 44 year old man presented with severe jaundice and pruritis. He had been consuming testosterone enthanate and oxymetholone for the past 12 weeks. Of note, his sister has a history of end stage liver disease, on the waiting list for a liver transplant, and 8 first degree relatives (including a 15 year old daughter) have a history of cholecystectomy. On admission, bilirubin was 513 umol/L and creatinine 113 umol/L. Subsequent Magnetic Resonance Cholangipancreatography did not reveal any biliary duct pathology, along with negative viral, autoimmune and hereditary liver disease screens. Liver biopsy demonstrated severe cholestasis with neutrophilic infiltrate around bile ducts and central veins. Concomitantly, creatinine worsened and in the absence of clear etiology, a renal biopsy was performed, which demonstrated evidence of tubular injury with bile acid casts in the distal tubules. In light of progressive worsening of bilirubin, pruritis and renal function(creatinine peaking at 650 umol/L)- plasmapheresis was initiatated. He underwent 7 cycles , which led to a progressive improvement in the bilirubin and creatinine levels and offsetting the need for dialysis.

Discussion: Anecdotal evidence exists that plasmapheresis help reduce bile acid-associated pruritis, and a recent case report, demonstrated success in a very similar setting of bile acid nephropathy. With respect to our patient, sustained improvement in overall clinical status was noted post plasmapheresis. A hypothesis for a genetic bile transporter defect, considering family history, is being entertained. This case highlights that plasmapheresis can be an effective treatment to arrest acute kidney injury secondary to bile acid nephropathy, which in turn emanates from cholestatic jaundice, especially in a population that consumes predisposing agents.

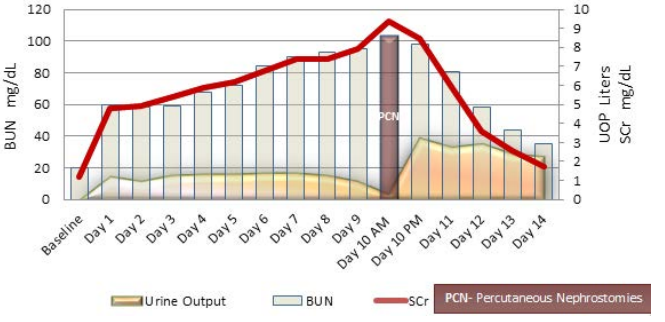
FR-PO063

Progressive AKI after Relief of Urinary Tract Obstruction Volodymyr Chornyy, Muna T. Canales. *Nephrology, Hypertension and Renal Transplantation, Univ of Florida, Gainesville, FL.*

Introduction: Urine output (UOP) is not a good indicator of urinary tract obstruction (UTO) as damage to the kidney may occur in the presence of only partial obstruction. Herein we present a case of partially relieved UTO with adequate UOP which progressed over days to complete renal failure.

Case Description: An 82 year old man with history of CKD stage 3 and chronic urinary retention due to enlarged prostate requiring clean intermittent self-catheterizations (CISC) presented with generalized weakness & 20 lbs unintentional weight loss over 6 months. He was able to void naturally 3-4 x/day & while being busy on his farm, decreased the number of CISC. He presented with elevated serum creatinine (SCr) of 4.8 mg/dL from baseline of 1.2 mg/dL 6 months prior. Ultrasound demonstrated severe bilateral (b/l) hydroureteronephrosis. Upon decompression with Foley catheter, 1500 cc of urine was evacuated. Given history of non-adherence with CISC, post-obstructive uropathy was diagnosed & recovery was anticipated. However, despite urinary output (UOP) of ~1500 cc/day, his renal function continued to deteriorate

Figure 1. SCr and Urine Output Trend



All work-up for intrinsic causes of AKI was negative. Within 10 days, he developed uremic symptoms, his urine output decreased. Urology (GU) attempted retrograde ureterograms which revealed obstruction at the level of b/l ureteral orifices. After placement of b/l percutaneous nephrostomy tubes, immediate post obstructive diuresis ensued with steady recovery of renal function. Follow-up GU evaluation revealed high grade prostate cancer infiltrating both ureteral orifices.

Discussion: We report the evolution from partial UTO with satisfactory UOP to complete UTO over 2 weeks. To avoid irreversible renal damage, physicians should have a high index of suspicion for ongoing partial UTO in the setting of progressive renal failure despite apparent decompression of UTO.

FR-PO064

Candida Glabrata Pyelonephritis Leading to Bilateral Renal Papillary Necrosis and End Stage Renal Disease Katherine Akers, Beatrice P. Concepcion, Julia Lewis. *Vanderbilt Univ Medical Center.*

Introduction: Candiduria often represents contamination or colonization in otherwise healthy individuals. However, *Candida spp.* can cause severe, invasive infections of the urinary tract. We present a case of invasive *C. glabrata* pyelonephritis that led to bilateral renal papillary necrosis and ESRD in a diabetic.

Case Description: 57/F with DM I, HTN, CAD, nephrolithiasis presented in 5/2010 with irritative voiding symptoms and sterile pyuria despite several courses of empiric antibiotics. Urine culture ultimately grew *C. glabrata*. She developed ARF and hydronephrosis which did not resolve despite ureteral stenting and Voriconazole. She had multiple hospitalizations for *C. glabrata* pyelonephritis with repeated episodes of acute on CKD and initiated dialysis 1/2012. Patient was admitted in 5/2012 with another episode of *C. glabrata* pyelonephritis. CT showed bilateral hydronephrosis, pyelonephritis, papillary necrosis, and a fungus ball in the renal collecting system. Patient was treated with Amphotericin and Flucytosine, and maintained on high dose Fluconazole for suppressive treatment. Cystoureteroscopy from 10/2012 showed necrotic debris containing degenerating fungal forms. Due to persistent flank pain and low grade fever, she underwent staged bilateral nephrectomies. Pathology showed caseating granulomas with associated degenerating fungal forms and necroinflammatory debris within the right collecting system. PCR of fungal forms was consistent with *C. glabrata* but cultures remained negative.

Discussion: Patients with genitourinary abnormalities, instrumentation of the urinary tract, diabetes, and immunosuppression are at increased risk for invasive fungal urinary tract infections. Fungal infections should be on the differential for recurrent or persistent UTI symptoms despite antibiotic treatment or in the setting of "sterile pyuria." While fungal species can grow from bacterial urine cultures, the sensitivity for detecting fungal UTIs is higher with urine fungal cultures. Particularly in high risk patients, fungal UTIs should be taken seriously; if not treated in a timely manner they can become invasive, difficult to treat, and can lead to serious complications including papillary necrosis and ESRD.

FR-PO065

Estimation of Renal Function in Patients with Acute Kidney Injury or Chronic Kidney Disease Who Are Receiving Dolutegravir Hafiz Ali Sroya, Faisal Anwar, Christos Argyropoulos. *UNM School of Medicine.*

Introduction: Dolutegravir (DTG) is integrase inhibitor used for the treatment of HIV infection. Data suggests that DTG increases serum creatininine by inhibiting organic cation transporter 2, which is responsible for tubular secretion of creatinine. It has been shown that DTG can decrease creatinine clearance (CrCl) by 14% in healthy individuals. However in patients with impaired renal function (either AKI or CKD), the effect of DTG on CrCl is likely to be quantitatively more important, as tubular secretion contributes significantly in CrCl under these conditions. Measuring CrCl and using eGFR equations in this situation may significantly underestimate the GFR that can adversely affect the patient's management. We present a case that illustrates these points.

Case Description: A 57 YO female with HIV/AIDS and CKD3bA3 was admitted with non-oliguric AKI on CKD. Her HIV/AIDS was controlled since diagnosis on a regimen of Tribild (cobicistat/elvitegravir/emtricitabine/tenofov) with most recent CD4 count 393 and viral load <20. A native kidney biopsy was consistent with ATN and mild tubular atrophy. She was started on hemodialysis due to worsening metabolic acidosis, uremia and hyperkalemia. Stribild was discontinued and a regimen of Abacavir, Lamivudine & Dolutegravir was started. She remained dialysis dependent with no signs of renal recovery based on pre & post dialysis creatinine levels. Her eGFR calculated by MDRD equation was consistently <2ml/min and 24h urine CrCl that was 1ml/min. We measured serum Cystatin C level (3.4 mg/l) and did eGFR calculations using CKD Epi, CKD Epi Cystatin C, CKD Epi Cys-Cr equations with eGFR 7, 14 and 10ml/min respectively. Finally, we did NM GFR measurement using Tc-99m DTPA that was 22 ml/min/1.73sq-m. We stopped dialysis and patient remained stable for 2 weeks but her recovery was complicated by another episode of AKI necessitating initiation of dialysis.

Discussion: Dolutegravir's effect on CrCl is probably more pronounced in patient with low eGFR. GFR should be calculated using compounds that are freely filtered, not secreted or reabsorbed instead of eGFR or CrCl for correct estimation of renal function in patients with AKI or CKD receiving dolutegravir.

FR-PO066

Gemcitabine Associated Interstitial Nephritis Maryam Gondal,[1] Namrata Krishnan.[2] *[1]Nephrology, Yale New Haven Hospital, New Haven, CT; [2]Nephrology, VA, West Haven, CT.*

Introduction: Gemcitabine is widely used as a first line chemotherapeutic agent for various solid organ malignancies. Nephrotoxicity with this agent is rare and typically presents as hemolytic uremic syndrome (HUS). Acute interstitial nephritis (AIN) has not been previously reported with its use. We describe a case of gemcitabine induced AIN.

Case Description: A 69 year old male diagnosed with pleomorphic rhabdomyosarcoma of the neck and left supraclavicular fossa with osseous metastases was started on Adriamycin/ifosfamide and Mesna for treatment. He developed severe biopsy proven acute tubular injury(ATI) and acquired fanconi syndrome related to ifosfamide use within 3 months of starting treatment. Ifosfamide was stopped and patient was switched to gemcitabine for further therapy of his sarcoma. After receiving 3 cycles of gemcitabine, he was found to have evidence of further acute kidney injury (creatinine rose from 2.9mg/dl to 5.9mg/dl) associated with the development of a morbilliform, diffuse, skin rash. Urine sediment was noted to be bland. Renal US showed mild stable bilateral hydronephrosis secondary to mild benign prostatic hyperplasia. No evidence of HUS was found. Renal biopsy revealed areas of robust acute and chronic interstitial nephritis with a mixed infiltrate (neutrophils/ lymphocytes/ eosinophils) along with persistent severe ATI from previous ifosfamide exposure. Patient was diagnosed with a gemcitabine induced AIN. He was pulsed with IV solumedrol and transitioned to a 3 month oral prednisone taper. His creatinine improved down to 2.9mg/dl-3.1 mg/dl after completion of therapy.

Gemcitabine was approved in early 1990's and is included among first-line treatments in some adjuvant and palliative settings for non–small cell lung, ovarian, breast, and pancreatic cancers. It is generally well tolerated with minimal complications. It causes rare nephrotoxicity typically manifested as a hemolytic uremic syndrome (incidence 0.015–1.4%). To our knowledge, our case is the first reported in the literature of gemcitabine induced AIN.

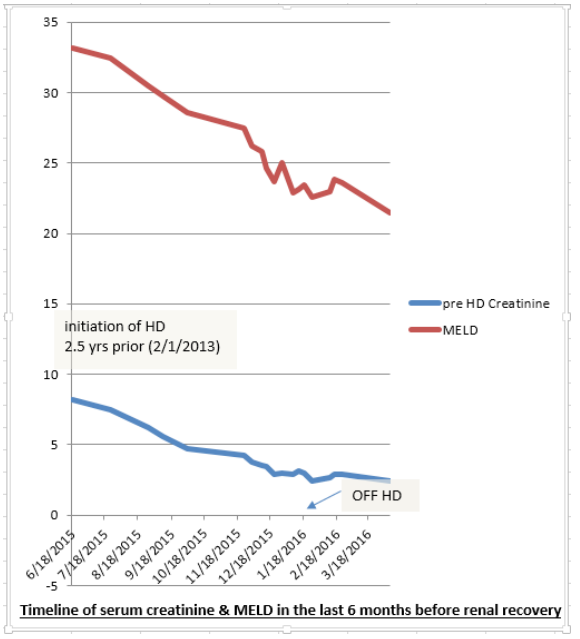
Discussion: Interstitial Nephritis should be considered in the differential diagnosis of patients with acute kidney injury on Gemcitabine therapy.

FR-PO067

Kidney Recovery after Three Years of Dialysis for Hepatorenal Syndrome Type I Louisette Soussan, Sandeep Aggarwal, Gregory Malat, Ellie Kelepouris, Alden Michael Doyle. *Transplant Nephrology, Drexel Univ College of Medicine.*

Introduction: Kidney recovery from Hepatorenal Syndrome (HRS) type 1 that requires dialysis is unusual but is sometimes possible with the combination of albumin, octreotide and midodrine; terlipreressin, or norepinephrine. HRS is generally felt to be irreversible after 8 weeks of dialysis therapy is required but has occasionally been described after months of dialysis in the setting of successful liver transplantation. Here, we describe a case of kidney recovery after 3 years of dialysis without transplantation.

Case Description: Patient is a 51 y/o M with a history of alcoholic cirrhosis, hepatic encephalopathy, esophageal varices, portal hypertension, and ascites requiring paracentesis, who presented with decompensated liver failure. Patient had a MELD score of 42, woresening jaundice, ascites, thrombocytopenia, coagulopathy, hyponatremia and AKI. He was oligoanuric with a serum creatinine of 9 mg/dL, low urine sodium, bland UA and a normal kidney USG. Patient was diagnosed and treated for HRS type I with albumin, octreotide, and midodrine. Despite therapy, patient remained oliguric and required dialysis. Patient was listed for simultaneous liver and kidney transplant and was discharged to our outpatient dialysis unit where he remained stable but virtually anuric. Over the next 3 years, patient was abstinent from alcohol and had slow but steady improvement in liver function and decreased MELD score.



Timeline of serum creatinine & MELD in the last 6 months before renal recovery

Patient started to make more urine and was given a trial off dialysis. Patient now has stage IIIB CKD with a 24-hour creatinine clearance of 34 mL/min with appropriate metabolic changes.

Discussion: Late recovery of severe kidney injury is possible after HRS type I. In this era of rapidly expanding options for direct acting anti-viral therapies, nephrologists should be aware of this possibility in patients whose MELD scores are improving while on dialysis.

FR-PO068

Rare Cause of Granulomatous Acute Interstitial Nephritis Ankita Tandon,[1] Jaya Kala,[1] Amit Lahoti,[2] Ala Abudayyeh.[2] *[1]Div of Renal Disease and Hypertension, UT Health Science Center at Houston-McGovern Medical School, Houston, TX; [2]Section of Nephrology, UT-MD Anderson Cancer Center, Houston, TX.*

Introduction: With the emergence of new novel myeloma drugs, there has been increasing interest on their effects of the kidneys. We present a case of bortezomib induced granulomatous acute interstitial nephritis as a rare cause of acute kidney injury.

Case Description: A 73-year-old man with myeloma diagnosed three years ago presented with a creatinine of 1.8 mg/dl along with an increase in the light chain. Patient was started on bortezomib. A week later, he presented with nausea,vomiting and hematuria. His creatinine was 6.4 mg/dL, urine showed large blood, 300 protein, >100 WBC, >100 RBC and positive urine culture that he was treated for with ceftriaxone. Free kappa light chains were 10,964 mg/L. The kidney dysfunction was presumed to be due to myeloma kidney. He was started on hemodialysis due to persistent hyperkalemia. He was continued on bortezomib due to persistence of the untreated myeloma. Unclear etiology for AKI prompted kidney biopsy, which showed acute granulomatous tubulointerstitial nephritis with diffuse kappa light chain-dominant glomerular and tubular basement membrane highlighting. The patient was started on prednisone which did not help improve renal function. Patient remained on bortezomib while on dialysis and when completed his cycle, started urinating and came off dialysis within a week. Creatinine a month later is at 1.4 mg/dl.

Discussion: Bortezomib treatment is used extensively in patients with Multiple Myeloma, and in trials on patients with immunological diseases. However, there has been only one case report of Bortezomib induced acute interstitial nephritis with granulomas reported thus far. The patient was being treated for his C3 Glomerulonephritis. To the best of our knowledge, this is the second case of biopsy proven granulomatous acute interstitial nephritis secondary to bortezomib. A high index of suspicion is necessary to recognize this as there are multiple etiologies of acute kidney injury in multiple myeloma. Discontinuation of the offending agent will be of utmost importance in the patient to keep them off potential need for renal replacement therapy.

FR-PO069

A Very Rare Case of HARVONI Causing Acute Tubular Necrosis
Rameen Hashemiyoon, Savneek S. Chugh, Rahul N. Pawar. *Nephrology, New York Medical College, Valhalla, NY.*

Introduction: With the approval of the newer agents, patient with hepatitis C virus (HCV) are now having an effective cure. One of these agents is HARVONI, a combination pill containing Ledipasvir and Sofosbuvir, an effective and more importantly an interferon free regimen. It was approved in 2014 for the treatment of hepatitis C genotype 1 virus infection with sustained virological response of more than 95%. Although there were no cases of Acute Kidney Injury (AKI) seen in the trial phase, lately some case reports of HARVONI induced AKI have surfaced. Recently, one case of Acute Interstitial Nephritis was published but we are reporting another unique case of Acute Tubular Necrosis mediated by HARVONI.

Case Description: 58 year old female with history of HCV on HARVONI, Hypertension and DM, presented to the ER with 5 days of dysphagia and odynophagia. She was subsequently found to be in AKI with serum creatinine (SCr.) of 11.06 and potassium of 7.2. She had no known history of kidney disease with baseline SCr. 0.9mg/dl. She was eventually started on hemodialysis. Urinalysis showed 1+ protein but no blood which on quantification was 625mg in 24 hours and negative for monoclonal pattern on immunofixation. Serum HCV quantitative was less than 15, cryoglobulins were negative, and C3, C4 were normal respectively. ANA was elevated at 63.3 yet double stranded DNA antibodies were negative. Her renal ultrasound showed normal size kidneys with no evidence ofhydronephrosis. She underwent percutaneous renal biopsy which revealed acute tubular injury associated with widespread oxalate deposits and very scant eosinophils. Eventually the patient was weaned off dialysis and discharged with SCr. of 2.5mg/dl.

Discussion: Our patient had a normal creatinine just a few months ago and the only new drug introduced to her was HARVONI, thus it is most likely caused the ATN and responsible for the AKI. It is a very effective medication and with its growing use, more and more of these cases are being discovered. We are reporting, to our knowledge, the first ever case of ATN caused by this agent. The exact mechanism is unclear and more studies should be done in pursuit of clearly identifying the renal adverse effects of this highly marketable drug.

FR-PO070

Worcestershire Sauce Induced Nephropathy: Case Report
Juan Camilo Trimino,[1] Bernardo Moguel.[2] [1]*Internal Medicine, Hospital Espanol de Mexico, Mexico City, DF, Mexico;* [2]*Nephrology Div, Hospital Espanol de Mexico, Mexico City, DF, Mexico.*

Introduction: Histopathology damage by Worcestershire sauce was unknown; however, the excessive use causes oxalate deposit. Acute oxalate nephropaty (AON) due Worcestershire sauce is a rare cause of kidney failure. It's secondary to calcium oxalate crystals deposits that induce chronic tubular damage, tubulointerstitial fibrosis and progressive kidney failure. A high load of oxalate, causes hyperoxaluria that increases the risk of nephrolitiasis and nephrocalcinosis; also, triggers like dehydration and/or metabolic acidosis, could cause acute kidney injury.

Case Description: 51-year-old latin american male, without past medical history, presented to the emergency room with a 2 week history of diarrhea, approximately 10 stools per day, with abdominal cramping during defecation. Blood Chemistry: Creatinine: 23.06 mg/dL, BUN: 117.5 mg/dL, Na: 134.8 mmol/L, K: 4.22 mmol/L, Cl: 96.8 mmol/L, Albumin: 3.47 g/dL, BUN/Cre: 5.09. Chest X-Ray: Bilateral pleural effusion of approximately 30%. 24-hour urine protein: 9820 mg. Urine protein/creatinine ratio: 12.27 g/g. Renal ultrasound: Normal size and anatomy. Acute hemodialysis treatment and later a kidney biopsy were performed: acute oxalate nephropaty and fibrosis grade 0. Directed inquiry approach, the patient reported consuming 400 ml of Worcestershire sauce per week. The patient received 8 hemodialysis sessions with partial renal recovery. Hospital's discharge with hemodialysis requirements during 1 month and high dose of piridoxine. In the follow up, the patient had renal recovery with creatinine leves of 1.49 mg/dL, without proteinuria. He was discharged from hemodialysis clinic with subsecuent follow up.

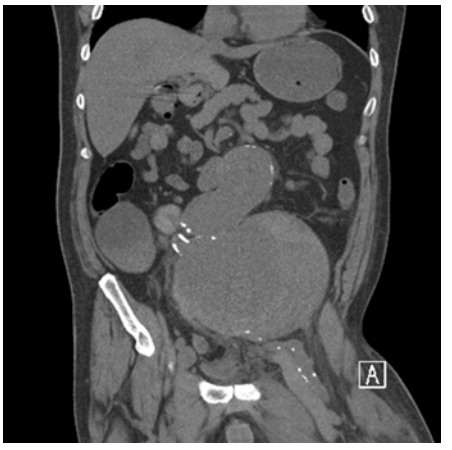
Discussion: Only 5 cases reported since 1971, 3 of them had bilateral nephrolithiasis and aminoaciduria; 1 had malignant hypertension and end-stage kidney disease; the remaining patient had mild to moderate kidney damage that reverted upon suspending the consumption of Worcestershire sauce. Although it is a rare cause of kidney failure, Worchestershire sauce induced nephropathy should be intentionally inquired if there isn't any other apparent cause.

FR-PO071

Acute Renal Failure, Aneurysm and Deep Vein Thrombosis - Connecting the Dots
Naga Goparaju,[1] Pavan Annamaraju,[1,2] Seyed-Ali Sadjadi.[2] [1]*Internal Medicine, Loma Linda Medical Center;* [2]*Loma Linda VAMC, Loma Linda, CA.*

Introduction: Anuric Acute kidney injury (AKI) is uncommon but it can be seen with acute tubular necrosis, renal cortical necrosis and bladder outlet obstruction. Herein we report an unusual case of anuric AKI.

Case Description: A 62-yr-old man with a solitary left kidney, presented to the ER, with complaint of left thigh pain and anuria for 4 days . His past history included, R nephrectomy, HTN & CKD stage 3 with eGFR 53ml/min. On exam, BP was 165/110mmHg; with swelling and pain of left hip and thigh. Lab values were: K 6.5 meq/l, BUN 119mg/dl, Cr 13.1mg/dl. A Foley catheter insertion did not yield urine. The Patient was given insulin- D50, kayexalate & IV $NaHCO_3$. Renal US showed left kidney length of 16 cm, with moderate hydronephrosis. US duplex of left thigh veins showed DVT extending from left common femoral vein to the trifurcate veins. Nephrology consult recommended a non-contrast CT scan of the abdomen and pelvis, repeat doses of kayexalate, insulin-D50 & and $NaHCO_3$ IV drip The CT scan showed a ruptured left common iliac artery aneurysm(IAA), a large retroperitoneal hematoma (17.7 cm x 14.7 cm) and a bilobular infrarenal AAA of 5.8 cm", causing obstruction of the left ureter and DVT of the left femoral vein.



Emergent laparotomy confirmed a massive left IAA and thrombosis of the thigh veins. The patient underwent open repair of AAA and the left IAA with a bifurcated prosthesis along with placement of a ureteral stent. At 3-month follow-up, eGFR was 50ml/min suggesting a favorable outcome.

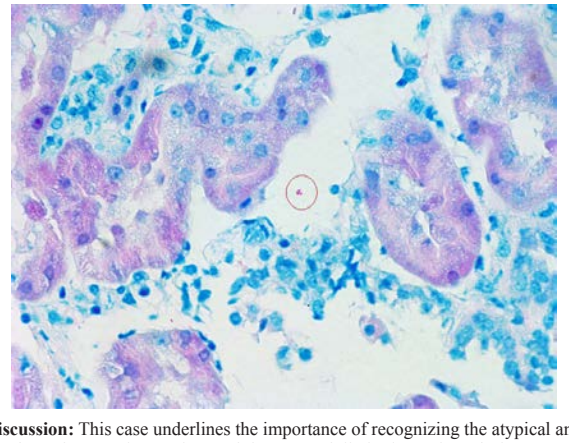
Discussion: Obstructive anuria from IAA (in a solitary kidney) is rare, with only 4 cases reported in the literature. Our case illustrates IAA should be considered in the differential diagnosis of anuric AKI. This case emphasizes the utility of CT scan of abdomen and pelvis as a diagnostic tool in the evaluation of anuric AKI.

FR-PO072

A Rare Cause of AKI in a Renal Allograft: A Case Report
Yorg Al Azzi, Jillian Daleo, Geoffrey K. Dube. *Nephrology, Columbia Univ, New York, NY.*

Introduction: AKI is common complication in renal transplant recipients. Differential diagnosis is broad and includes multiple infectious etiologies. However, it is rare for mycobacteria to infect the allograft and cause AKI. We present here the case of a renal transplant recipient who presented with an FUO and was diagnosed with disseminated MAC with renal allograft involvement.

Case Description: 50yo M ESRD 2/2 PCKD is s/p LURT (alemtuzumab induction,rapid steroid withdrawal,maintained on tacrolimus and mycophenolate). No history of acute rejection and his creatinine stabilized at 1.5. Twenty months post-transplant, he presented with 2wk of worsening fevers (99-103F in past 3 months) and dry cough. No weight loss, dyspnea, or GU symptoms. Routine blood work was notable for AKI (Cr 2.2),Chest CT with left paraortic mass and an enlarged retroperitoneal lymph node. Lymph node biopsy was positive for acid fast bacilli, NAAT testing neg for TB). Blood and urine cx were negative, IGRA indeterminate and Fungitell positive. He was started on azithromycin, ethambutol and rifampin. His Cr rose to 3. Renal allograft biopsy showed severe interstitial inflammation,lymphocytic tubulitis and rare acid fast bacilli identified on special stain. At this time MAC speciated from the lymph node biopsy. By hospital day 11, Cr decreased to 2.2. IVIg was given for treatment of possible concurrent allograft rejection. High grade fevers persisted throughout the 2wk admission. He was discharged on a 12mo course of Rifampin, Ethambutol, and Azithromycin. Cr was 1.8 upon discharge. Blood cultures sent on admission ultimately were positive for MAC. Three months after his initial presentation, he was clinically improved, with resolution of fevers. His Cr had decreased to 1.7.



Discussion: This case underlines the importance of recognizing the atypical and rare causes of AKI in a renal transplant recipient, especially in the setting of a known ongoing infection.

FR-PO073

Prolonged AKI Caused by Severe Rhabdomyolysis due to Genetic Disorder of Muscle ATP Metabolism Kilian Steden, Sahana R. Kamalanabhaiah, Joachim Hoyer. *Internal Medicine and Nephrology, Univ Marburg, Marburg, Hessen, Germany.*

Introduction: Carnitine Palmitoyltransferase (CPT) II deficiency is an autosomal recessive disorder characterized by a disruption of mitochondrial oxidation of long-chain fatty-acids, thus leading to an impaired ATP catabolism. First clinical symptoms of the myopathic form are observed in childhood and are characterized by weakness, exercise-induced muscular pain and myoglobunuria often triggered by fasting, lengthy muscular activity, viral infection or cold temperature.

Case Description: A 54 year old female physiotherapist returns from a skiing trip, complaining of pain in the proximal lower limbs as well as brown coloured urine. Laboratory reports showed an fulminant rhabdomyolysis (CK 235.000 U/l) accompanied by an acute kidney failure (serum creatinine 10,3 mg/dl). Treatment included alkalization of urine and volume management. As kidney function only slowly recovered, a more thorough evaluation of the underlying cause of rhabdomyolysis was performed. The patient did not report any trauma, chronic alcohol abuse, steroid medication or neoplasia. Serological testing ruled out autoimmune disorders. MR imaging showed disseminated muscular edema and signs of myositis. The muscle biopsy showed single fibre necrosis and type-II-fibre-hypotrophy with no signs indicating myositis or mitochondrial disease. We considered a genetic disorder. The patient reported of occasionally suffering from muscular pain since childhood. Testing for genetic myopathies revealed CPT II deficiency due to two heterozygous mutations in exon 1 and 3 of the CPT II gene. Over a prolonged time period of 5 weeks kidney function improved significantly with an almost normalized kidney function to this date (GFR 75 ml/min).

Discussion: Besides common causes for rhabdomyolysis such as trauma, arterial thrombosis, infections and autoimmune diseases, genetic disorders need to be considered in inconclusive or complex cases. CPT II deficiency is a rare disorder (currently 300 reported cases), but should be considered as differential diagnosis. Therapy includes strict low-fat diet high on carbohydrates in addition to oral intake of L-carnitine to prevent rhabdomyolysis and muscle pain.

FR-PO074

Hand2 Inhibits Kidney Specification while Promoting Vein Formation within the Posterior Mesoderm Elliot Perens. *Div of Biological Sciences and Dept of Pediatrics, Univ of California, San Diego, La Jolla, CA.*

Background: The kidneys and urinary tract are derived from the intermediate mesoderm (IM), yet the regulatory pathways that determine precise IM dimensions and that separate the IM from neighboring portions of the posterior mesoderm are poorly understood.

Methods: To study the genetics of early kidney development, we are using zebrafish. Like mammalian kidneys, zebrafish kidneys are derived from the IM, which expresses the same conserved transcription factors (such as *lim1* and *pax2*) as the mammalian IM. Using a combination of loss-of-function and gain-of-function analysis, we have sought to determine the role of *hand2* in IM development.

Results: We have found that the bHLH transcription factor Hand2 limits the size of the embryonic kidney by refining IM dimensions. In zebrafish *hand2* mutants, the IM is expanded, and it is diminished when *hand2* is overexpressed. *hand2* is expressed within the posterior mesoderm, laterally adjacent to the IM. A set of venous precursors arise at the interface between these two territories, and *hand2* promotes their development while suppressing IM formation in this region. Furthermore, Hand2 and the similarly localized zinc-finger transcription factor Osr1 have functionally antagonistic influences on pronephron formation.

Conclusions: Together, our data illuminate a previously unrecognized regulation of IM development and suggest a model in which *hand2* functions in opposition to *osr1* to balance the formation of IM and venous progenitors by regulating cell fate decisions in the posterior mesoderm. Our findings have implications for understanding the genetic basis of congenital anomalies of the kidney and urinary tract (CAKUT) and for developing new approaches in regenerative medicine.

FR-PO075

Heterozygosity for Six2 Increases Ureteric Branching and Final Nephron Number Alexander N. Combes,[1,2] Sean Wilson,[2] Belinda Phipson,[2] Brandon Binnie,[3] Ali Ju,[4] Cristina Cebrian Ligero,[5] Sarah L. Walton,[6] Karen M. Moritz,[6] Alicia Oshlack,[2] Melissa H. Little.[2,7] *[1]Anatomy and Neuroscience, Univ of Melbourne, Melbourne, Vic, Australia; [2]Murdoch Childrens Research Inst, Melbourne, Vic, Australia; [3]Inst for Molecular Bioscience, Univ of Queensland, Brisbane, Qld, Australia; [4]Translational Research Inst, Univ of Queensland, Brisbane, Qld, Australia; [5]Dept of Internal Medicine, Univ of Michigan, Michigan, MI; [6]School of Biomedical Sciences, The Univ of Queensland, Brisbane, Qld, Australia; [7]Dept of Paediatrics, Univ of Melbourne, Melbourne, Vic, Australia.*

Background: SIX2 is a transcription factor that regulates the maintenance of progenitor state within the cap mesenchyme (CM) during kidney development. Complete loss of *Six2* in mouse results in premature differentiation of the CM.

Methods: In this study, we examined kidney development in mice heterozygous for *Six2 (Six2*$^{GCE/+}$*)* using quantitative multiscale imaging and transcriptional profiling.

Results: *Six2* mRNA and SIX2 protein levels were reduced by 50% in the *Six2* Het. Surprisingly, these mice had an average of 18% more niches than wild-type mice from 15.5 dpc to postnatal day (P)2. Total glomerular number was also 18% higher. RNA-Seq of *Six2* Het kidneys revealed a decrease in genes associated with the uninduced CM state, including *Cited1*, *Crym*, and *Meox1*. Several renal vesicle-enriched genes, such as *Tcf23* and *Pcdh8,* were upregulated but there was no evidence of ectopic nephogenesis. *Six2* Het mice had increased CM and ureteric tip proliferation and upregulation of CM-expressed genes associated with proliferation and metabolism. Direct and dose-sensitive SIX2 targets were identified by further analysing transcriptional changes in CM from 11.5 dpc *Six2* KO and Het kidneys, with these genes showing high overlap with published SIX2 ChIP data.

Conclusions: In summary, this represents a rare example of a genetic change resulting in increased nephron number by subtly shifting the molecular regulation of proliferation and differentiation in the CM. It also suggests a dose-sensitive separation between the role of SIX2 in regulating CM proliferation and the maintenance of CM identity.

FR-PO076

Increased Hedgehog Signaling in Renal Progenitors Disrupts Stromal Cell Development and Nephrogenesis Norman D. Rosenblum, Sepideh Sheybani-Deloui. *Div Neph, Dev and Stem Cell Biol, Depts Ped and Physiology, Hosp Sick Children, U Toronto, Toronto, Canada.*

Background: *Foxd1+* stromal cells are essential for renal development. Abnormal stroma is a signature feature of CAKUT. While *Foxd1+* stromal as well as *Six2+* nephrogenic cells both arise from *Osr1+* and their daughter *Sall1+* progenitor cells, the molecular mechanisms that control the specification and the relative proportion of *Foxd1+* and *Six2+* cells are undefined. Since renal injury causes Hedgehog (HH)-dependent proliferation of stoma-derived cells, we hypothesize that HH signaling controls specification of *Foxd1+* cells during embryogenesis.

Methods: HH signaling was activated in a temporal manner in vivo with Tamoxifen (TM) in mice expressing *Ptc1*^{loxP}and *Sall1-Cre*^{ERT2} or *Osr1-GFP-Cre*^{ERT2} alleles. Lineage tracing was performed using a *ROSA*^{tdTomato} allele. Cell proliferation was analyzed using Ki-67 and phospho-histone H3. *Osr1+GFP+* cells were purified from metanephric mesenchyme by FACS.

Results: TM injection at E9.5 in *Sall1-Cre*^{ERT2}*;ROSA*^{tdTomato} mice induced TOMATO expression in both SIX2+ nephrogenic and PBX1+ stromal cells. TM injection at E9.5 in *Sall1-Cre*^{ERT2}*;Ptc1*$^{loxP/-}$ mice decreased *Ptc1* mRNA by 50% and increased expression of the HH signaling reporter, *Ptc1-lacZ*, in situ. E14.5 mutant kidneys demonstrated a 78% increase in PBX1+ cells and ectopic expression of *Raldh2* in the medulla and presumptive ureteropelvic junction. Also at E14.5, PBX1+ cells associated with ureteric bud tips were mis-patterned and were increased in number by 20% (n=4, $p<0.05$). Proliferation of PBX1+ cells was not significantly changed. The number of NCAM+ nephron progenitor structures and WT1+ glomeruli was decreased by 28% and 20%, respectively (n=4, $p<0.01$). Yet, the number of SIX2+ cells was not significantly different than controls. In *Osr1+* cells isolated from metanephric mesenchyme of E11.5 *Osr1-Cre*^{ERT2}*;Ptc1*$^{loxP/-}$ mice injected with TM at E9.5, *Foxd1* mRNA was increased by 60% but *Six2* mRNA was unchanged compared to that in control *Osr1+* cells (n=5, $p<0.05$).

Conclusions: Increased HH signaling in renal progenitor cells increases generation of stromal cells, disrupts stromal patterning, and decreases nephron formation.

Funding: Government Support - Non-U.S.

FR-PO077

Bim Gene Dosage Is Critical in Modulating Nephron Progenitor Survival in the Absence of Dicer Activity Debora Malta C.S. Santos, Andrew J. Bodnar, Yu Leng Phua, Neil A. Hukriede, Jacqueline Ho. *Dept of Pediatrics, Children's Hospital of UPMC, Pittsburgh, PA.*

Background: Low nephron endowment has been implicated in an increased risk of hypertension and chronic kidney disease. We have previously reported that in *Six2-TGC*$^{Tg/+}$; *Dicer*$^{flx/flx}$ mutant kidneys, nephron progenitors lacking mature miRNAs undergo increased apoptosis, and express increased levels of the pro-apoptotic protein, Bim.

Methods: In this study, we investigated the functional significance of increased Bim expression in *Six2-TGC*$^{Tg/+}$; *Dicer*$^{flx/flx}$ mutant kidneys. To address this question, we generated a mouse model with conditional deletion of both *Dicer* and *Bim* from nephron progenitors in the developing kidney.

Results: While mutant kidneys exhibited a reduced number of nephron progenitors and developing nephron structures, the deletion of a single allele of *Bim* was sufficient to reduce the apoptotic rate of nephron progenitors and improve nephron formation. Next we used bioinformatics tools to identify potential binding sites for the nephron progenitor-enriched miRNAs, *miR-10a*, *miR-17*, *miR-24-1* and *miR-106b*, in the 3'-untranslated region (3'-UTR) of *Bim*. All four miRNAs negatively modulated the endogenous expression of Bim and the activity of a luciferase reporter containing the intact *Bim* 3'-UTR *in vitro*. Furthermore, *pri-mmu-miR-10a*, *pri-mmu-miR-17*, *pri-mmu-miR-24-1* and *pri-mmu-miR-106b* repressed EGFP expression in *Xenopus laevis* embryos injected with a synthetic mRNA containing the *EGFP* sequence fused to mouse *Bim 3'-UTR*.

Conclusions: Together these data suggest that the coordinated action of *miR-10a*, *miR-17*, *miR-24-1* and *miR-106b* sets a threshold of Bim expression, regulating the balance between apoptosis and survival in nephron progenitors.

Funding: NIDDK Support

FR-PO078

Temporal Down-Regulation of Spontaneous Calcium Activity in Metanephric Mesenchymal Cells Inhibits Branching Morphogenesis
Jacopo Maria Fontana,[1] David Unnersjö-Jess,[1] Hans Blom,[1] Hjalmar Brismar,[1,2] Anita Aperia.[2] *[1]Applied Physiscs, Royal Inst of Technology, Stockholm, Sweden; [2]Women's and Children's Health, Karolinska Inst, Stockholm, Sweden.*

Background: Calcium signaling is of fundamental importance for the development of early vertebrates, but little is known about the role of calcium in mammalian embryogenesis.
Methods: We have used explanted kidneys from 14-day-old rat embryos cultured for 1 or 2 days to study calcium activity in metanephric mesenchymal (MM) cells, branching morphogenesis and synaptotagmin expression.
Results: We have recorded spontaneous calcium activity, characterized by stochastic calcium spikes of different amplitude and shape, in MM cells. This pattern of irregular calcium spikes is compatible with the calcium activity observed in cultured mesenchymal cells exposed to mechanical forces. Spontaneous activity was abolished following inhibition of the SERCA pump in the endoplasmic reticulum (ER) membrane, but remained intact during acute exposure of the kidney to calcium free medium. Partial depletion of ER calcium stores for 24 hours caused a temporal down-regulation of the spontaneous calcium activity. This resulted in deformation of ureter buds, significant reduction of ureter branching points and order and fewer newly formed renal vesicles. Proliferation of MM cells remained intact. We have hypothesized that metanephric spontaneous calcium activity is required for secretion of the morphogenic factors that mediate the reciprocal interaction between the MM cells and the ureter bud, a prerequisite for ureter branching morphogenesis and nephron formation. In support of this hypothesis we demonstrate expression of the calcium dependent excretory protein synaptotagmin 1 in MM cells.
Conclusions: This study has identified calcium as a novel indispensible link in the events involved in development of the mammalian kidney.

The Transcription Factor tfap2a Directs Progenitor Fate Decisions during Nephron Development
Brooke E. Chambers, Gary Gerlach, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: Vertebrate kidney development consists of the differentiation and intricate patterning of specialized epithelial cells into discrete segments that form the nephron. However, the molecular and genetic pathways involved in cell fate decisions during nephrogenesis are poorly understood. The zebrafish provides a powerful, conserved system to discover developmental mechanisms driving nephron formation.
Methods: By performing a forward genetic screen and utilizing whole mount *in situ* hybridization to assess nephron segmentation, we isolated a mutant line with abrogated distal segment development. Whole genome sequencing revealed that the genetic lesion disrupted splicing of *transcription factor AP-2 alpha* (*tfap2a*), which has been described as essential for neural crest and epidermis differentiation, but was not known to be active during renal ontogeny.
Results: We found that *tfap2a* exhibits a dynamic expression pattern in renal progenitors, eventually restricting to the distal segments of developing nephrons. Deficiency of *tfap2a* recapitulated the mutant phenotype, and *tfap2a* mutants also failed to complement a previously characterized *tfap2a*^{m819} strain, which encodes a missense mutation that also disrupts transcript splicing. In addition to distal tubule defects, *tfap2a* abrogation was associated with a significant increase in multiciliated cells, which supports the hypothesis that *tfap2a* may mediate cell fate choice within the nephron. Taken together, these studies support a novel role for *tfap2a* in epithelial cell fate decisions during nephrogenesis. Interestingly, during mouse embryogenesis, *tfap2a* expression is abundant within the developing urogenital tract encompassing structures such as the ureteric tip, early tubule, and late tubule.
Conclusions: Thus, our continuing efforts to characterize the molecular activities of *tfap2a* in renal progenitors may uncover aspects of nephron formation that are relevant to human kidney development and disease states.

Hopx-Expression Marks a Multipotent Progenitor Cell Pool during Kidney Development in Mice
Nikhil Singh,[1] Rajan Jain,[2,3] Li Li,[3] Lloyd G. Cantley,[1] Jonathan Epstein.[2,3] *[1]Section of Nephrology, Yale Univ, New Haven, CT; [2]Dept of Cell and Developmental Biology, Univ of Pennsylvania, Philadelphia, PA; [3]The Cardiovascular Inst, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: The homeodomain-containing transcription factor Hopx has been recently identified as a marker of progenitor cells in a variety of embryonic and adult tissues, including the lung, skin, heart, brain, taste bud and gut. We sought to determine whether Hopx-expression marks a progenitor cell population during kidney development.
Methods: We used quantitative PCR and a Hop3xF-GFP reporter mouse to analyze the expression of Hopx during murine nephrogenesis. We used a Hop-Cre and a tamoxifen-inducible Hopx-ER-Cre line to fate map Hopx-derivatives during embryonic development.
Results: We found that Hopx is expressed in the metanephros as early as E13.5, with expression increasing through gestation and peaking postnatally at P7. At E13.5, Hopx-positive cells localize to the condensing metanephric mesenchyme and by E14.5, these cells expand in number and are surrounded by Wt1-positive podocyte precursor cells. Hopx-positive cells at E13.5 stain for mesenchymal markers, and these cells fate map to mesangial cells and the Renin-expressing cells of the juxtaglomerular apparatus - suggesting a common progenitor for these two cell populations. In the postnatal mouse, Hopx-expression is maintained in mesangial and Renin-positive cells, as well as in scattered proximal tubular cells and cells in the renal papilla; the latter two areas having previously been cited as potential stem cell niches in the adult.
Conclusions: Hopx-expression marks a progenitor cell pool during embryogenesis that gives rise to Renin-expressing cells in the JGA as well as intraglomerular mesangial cells. Hopx is also expressed in several putative stem cell niches in the postnatal murine kidney, an area which requires further investigation.

mTORC1 Activity in Renal Progenitor Cells Is Correlated with Nephrogenesis and Kidney Size
Oded Volovelsky,[1,2] Raphael Kopan.[1] *[1]Developmental Biology, Cincinnati Children's Hospital Medical Center; [2]Div of Nephrology, Cincinnati Children's Hospital Medical Center.*

Background: Low nephron number is correlated with adverse health outcomes, including hypertension and chronic kidney disease in adulthood. mTORC1 complex is a member of the serine/threonine kinase family and is a central regulator of cell metabolism, growth, proliferation and survival. TSC1 is an inhibitor of the mTORC1 complex together with TSC2. Although mTORC1 has been shown to regulate stem cells of the hematopoietic system, its role in regulating stem cells in the kidney and nephrogeneis has not been defined.
Methods: Knockout of mTORC1 or TSC1 in progenitor cells in embryonic mice was achieved using Cre-LoxP technology. Six2-CREGFP:mTORC1$^{+/F}$ or Six2-CREGFP:TSC1$^{+/F}$ males were mated with mTORC1lox/lox or TSC1lox/lox respectively females to generate embryos carrying a homozygous deletion or CD1 females to generate heterozygous deletion. Kidney weight was measured relative to the body mass. Kidney morphology was evaluated and nephron counts were determined using acid digestion. In addition, kidney function was measured using serum urea at 5 to 6 months.
Results: Tissue specific deletion of mTOC1 in renal cell progenitors led to renal agenesis and severe dysplasia of the kidney, resulting in death a few days after birth. Analysis of mTOR+/F animals reduction in nephron endowment compared to control mice. Furthermore, kidney function in mTOR+/F animals was reduced as well. On the other hand, complete deletion of TSC1 led to significant increase in kidney size and their death few days of birth but apparently secondary to tubular injury. Heterozygous deletion of TSC1 led to significant nephromegaly compared to control type in addition to 50% increase in nephron numbers compared to controls. Kidney function in adult mice with heterozygous deletion of mTORC1 or TSC1 has decreased kidney function as measured by urea level.
Conclusions: Our results indicate that mTORC1 pathway plays an important role in kidney development, and mTORC1 is a significant regulator of nephrogenesis.

PPAR Signaling Regulates Nephron Development
Joseph M. Chambers, Shahram Jevin Poureetezadi, Eric Donahue, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: At present, the genetic and molecular mechanisms directing nephron segmentation during kidney development are not well understood. Embryonic zebrafish have a simplified kidney, the pronephros, comprised of proximal and distal segments that display conservation with mammalian nephrons, including humans.
Methods: Through a novel chemical genetic screen, we discovered that peroxisome proliferator-activated receptor (PPAR) signaling is essential for normal nephron segment development. PPARs are a group of nuclear receptor proteins that are activated by agonists such as fatty acids and act as transcription factors by heterodimerization with retinoid X receptor (RXR) to regulate cell differentiation and, in addition, have diverse roles in metabolism.
Results: We found that treatment with the PPAR agonist bezafibrate during nephrogensis resulted in a decreased length of the distal tubule while increasing the proximal straight tubule domain. Interestingly, the co-activator, *ppargc1a*, which binds to activated PPARs to regulate transcription of target genes, is expressed specifically in renal progenitors. To test the functional role of this co-activator during nephron segmentation, we knocked down *ppargc1a* and found deficiency reduced distal tubule formation. Next, we examined nephron development in ppargc1a^{sa13186} mutant zebrafish and found that the distal tubule was likewise abrogated.
Conclusions: Taken together, our studies reveal for the first time that PPAR activity is required for nephrogenesis. These findings may lead to a better understanding of the therapeutic value of PPARs in relation to the human kidney, as they have been shown to have renoprotective properties.

FR-PO083

Genetic Mechanisms of Multiciliated Cell Genesis during Renal Ontogeny
Amanda N. Marra, Shahram Jevin Poureetezadi, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The differentiation of multiciliated cells (MCCs) has become an increasingly attractive area of research because of their association with fluid flow and disease across tissues, including the kidney. There is evidence for a core, conserved pathway of MCC development that includes the Notch signaling pathway as an inhibitor to MCC fate.

Methods: The embryonic zebrafish kidney, or pronephros, has emerged as a useful tool to study MCC genesis, where the transcription factor *mecom* acts upstream of Notch to restrict MCC development while Retinoic Acid (RA) signaling promotes MCC fate by inhibiting *mecom* and promoting expression of the ETS transcription factor *etv5a*. Here, we report phenotype analysis of the *etv5a*^{sa16031} allele, which encodes a nonsense mutation in the ETS binding domain of *etv5a*.

Results: Embryos with one copy of this allele displayed a reduced number of MCCs, suggesting that *etv5a* is a haploinsufficient gene. Next, we found that *mecom* inhibits *etv5a* expression in the kidney, as knockdown of *mecom* caused an expansion of the *etv5a* domain. Further, we uncovered a novel role for prostaglandin (Pg) signaling in MCC development. Treatment with the Pg agonist PgE2 increased average MCC number in the pronephros, where inhibition of the Pg pathway via Indomethacin or concomitant knockdown of the Pg biosynthesis enzymes Cox1 and 2 reduced MCC number. Importantly, PgE2 treatment also increased the *etv5a* domain in the pronephros. Conversely, *mecom* expression was reduced after PgE2 treatment.

Conclusions: In conclusion, we have discovered a novel relationship between the Pg pathway, *etv5a*, and *mecom* during MCC genesis in the pronephros. Ongoing studies will further examine the epistatic relationship between these factors to illuminate the mechanism by which *etv5a*, *mecom*, and Pgs direct MCC development.

FR-PO084

Multiciliated and Transporter Cell Fate Decisions Are Regulated by the Iroquois Transcription Factors irx2a/3b during Nephrogenesis Christina N. Cheng, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The genetic mechanisms that control cell fate decisions during kidney development remain poorly understood. The zebrafish pronephros provides a simplified yet genetically conserved model for renal ontogeny, being composed of segments with two major epithelial populations, transporter and multiciliated cells (MCCs). The expression of solute carriers within the transporter cells is used to demarcate distinct segments, and the MCCs are distributed in a "salt-and-pepper" fashion throughout the pronephros. Previous research in *Xenopus* revealed that *Iroquois (irx) homeobox 3* regulates tubule segment formation, whereas *irx1/2* were implicated to have redundant downstream functions during nephrogenesis. Furthermore, *irx3b*, the zebrafish paralog of *irx3,* was found to have conserved roles in proximodistal segmentation.

Methods: Here, we have used a combination of expression and functional studies to study the roles of *irx* genes during nephrogenesis.

Results: We report that *irx2a* and *irx3b* influence MCC fate as the loss of *irx2a* or *irx3b* resulted in decreased MCC density. Interestingly, the proximal straight tubule became expanded in *irx2a* or *irx3b* deficient embryos suggesting that these genes may help modulate the balance between MCC versus transporter cell lineages during kidney development. Our current work also implicates interplay between *irx3b* and *single-minded family bHLH transcription factor 1a (sim1a)* in the patterning of the proximal tubule cells and the corpuscles of Stannius, endocrine glands that control calcium homeostasis and are closely associated with the kidney lineage. Ongoing epistasis experiments aim to further delineate *irx2a/3b* redundancy and their relationship to *sim1a,* Notch signaling and *etv4/5a*, which are important regulators of nephrogenesis.

Conclusions: This study reveals exciting novel roles for *irx2a/3b* during renal epithelial cell specification. Further investigation of the genetic regulators involved in these events will enhance our overall understanding of the molecular pathways that govern kidney development, and may have significant implications for CAKUT therapies and renal reprogramming in the near future.

New Strategy for Kidney Regeneration Using DiSCAS: The Drug-Induced Specificity Cell Ablation System Shuichiro Yamanaka, Toshinari Fujimoto, Susumu Tajiri, Kei Matsumoto, Makoto Ogura, Takashi Yokoo. *Internal Medicine (Nephrology and Hypertension), Jikei Univ School of Medicine, Japan.*

Background: The kidneys develop through reciprocal and sequential interactions between the ureteric bud (UB) and surrounding cap mesenchyme (CM). To date, the cell transplant to a nephrogenic niche has achieved very low engraftment efficiency, and the competition with the existing native host cell occupying a niche is considered to be its underlying cause. We demonstrated the development of living scaffold for kidney regeneration using the drug-induced specificity cell ablation system (DiSCAS). We found that DiSCAS is an efficient kidney regeneration method to eliminate the existing native nephron progenitor cells (NPCs) that behave competitively in the nephrogenic niche.

Methods: We generated a mouse model with ablation only NPCs using an induction drug. Subsequently, metanephros (MN) was isolated from the embryos and an induction drug was added to the organ culture dish for the elimination of native NPCs only. MN through DiSCAS provided a scaffold mainly comprising living UBs. Donor mouse NPCs that were not affected by the drug were then transplanted into MN through DiSCAS. We examined donor NPC engraftment to CM and their differentiation to a neo nephron. We analyzed the organ culture of MN using immunostaining.

Results: Donor NPCs were noted in the broad engraftment in CM, which ablated native NPCs using the drug. In addition, regenerative nephrons comprising only transplant cells were provided. The neo nephron expressed glomerular and tubular markers. We observed the connection with host collecting ducts and neo nephrons. The engraftment range of the transplant cells accounted for 48.7% of MN with DiSCAS and obtained a wide range of neo nephrons.

Conclusions: Using DiSCAS, it was shown that competing native NPCs were completely replaced by transplant cells in CM. Furthermore, the replaced transplant cells displayed reciprocal interactions with the host UB, and a complete differentiation to nephrons. Living scaffolds in DiSCAS were considered to have the ability to organize neo nephrons from transplant cells and to have good biological compatibility. The new method may facilitate the regeneration of kidneys in future.

FR-PO086

Human Nephrogenesis from Single Cell Suspension - A New Model for Renal Toxicity Studies? Amnah Alharbi,[1] Mona Elhendawi,[2] Jamie Davies,[2] Paul Winyard.[1] *[1]Inst of Child Health, London, United Kingdom; [2]Univ of Edinburgh, Edinburgh, United Kingdom.*

Background: Recent research used predominantly mouse renal tissues aimed at engineering new kidneys from early dissociated renal cells has resulted in a method for generating multiple nephron segments, in a 3-dimensional structure.In theory, it should also be possible to form kidneys using directly isolated human renal progenitor cells. If this can be achieved, with demonstrable renal function, then these neo-organs may provide a better model to assess nephrotoxicity and identify nephroprotective strategies.

Methods: Early renal progenitor samples were dissociated into single cells then re-aggregated into cell clumps by centrifugation.These potential mini-kidneys were cultured for 5-6 days and morphologically analysed by dual immunofluorescence microscopy labelled with nephrogenic markers delineating early and later stages of nephrogenesis. Function was assessed by measuring anion (6 carboxyfluorescein) and cation (DAPI) uptake.

Results: Dissociated human kidney progenitor cells were able to self-organise into nephron-like structures.These structures contained diverse normal nephron tubule segments including proximal tubules and distal tubules, as assessed using Lotus tetragonolobus lectin binding and e-cadherin immunohistochemistry respectively, and putative glomeruli with rounded clusters of WT-1 positive cells suggestive of glomerular podocytes. Specific organic anion and cation transport was demonstrated in histologically-identified proximal tubule segments during the fifth day of culture. This was subsequently lost despite persistent morphological and immunohistochemical evidence of numerous proximal tubules.

Conclusions: We have shown that early human renal progenitor cells can self-organise from single cell suspension to develop nephron structures with demonstrable proximal tubule transport activity. Future studies will aim to maintain transport activity over the full length of culture and test other functions in different nephron segments. These mini-kidneys represent a novel potential model to study both human nephrogenesis and nephrotoxicity.

Prostaglandin Signaling Regulates Nephron Proximo-Distal Cell Fate Decisions Shahram Jevin Poureetezadi, Christina N. Cheng, Joseph M. Chambers, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: Despite several discoveries furthering our understanding of nephrogenesis, the factors that influence segmentation decisions remain largely unknown. The zebrafish forms a simple embryonic kidney organized in a proximal-distal pattern of contiguous segments that are conserved with the human nephron.

Methods: Here, we performed a multiplex chemical genetic screen to determine factors that regulate proximal and distal nephron fate choices.

Results: Employing this method we identified prostaglandins as a major player in nephrogenesis, which have been previously shown to dictate liver versus pancreas cell fate. Prostaglandin agonists restricted distal segment formation and expanded the proximal segment lineage during nephrogenesis. Genetic abrogation or inhibition of the prostaglandin producing Prostaglandin-endoperoxide synthase 1 or 2a (also known as Cox-1, Cox-2), or the Prostaglandin E receptor 2a or 4a (Ptger2a, Ptger4a), which we found to be expressed in renal progenitors, triggered an alteration in the balance of distal segment fates. Notably, distal segment fate in Ptgs1 or Ptgs2a deficient embryos was rescued by exogenous prostaglandin treatment. Further, we saw that modifying levels of prostaglandin pathway components significantly altered renal progenitor expression domains, including *sim1a*, *irx3b*, and *mecom* - which are required for proximal and distal tubule patterning. Epistasis studies revealed that prostaglandin signaling is working upstream of these transcription factors.

Conclusions: Taken together, these findings show for the first time that prostaglandin signaling is an essential component of nephron cell fate choice, suggesting that prostaglandins may have considerable implications for therapeutic treatment of congenital kidney diseases as well as end stage renal disease.

Funding: NIDDK Support

FR-PO088

The Transcription Factor emx1 Is Required for Distal Segment Formation during Nephrogenesis Elvin E. Morales, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The developmental pathways that establish nephron segment identities from renal progenitors are poorly understood. The zebrafish embryo forms a simple two-nephron pronephros that possesses a conserved segment anatomy with higher vertebrates. *emx1* is a homeobox gene that has an essential role in brain development, and although it is also expressed in the pronephros, its role in nephrogenesis has not been established.

Methods: Here we characterized the spatiotemporal expression of *emx1* in renal progenitors and performed functional analyses.

Results: Using whole mount *in situ* hybridization, we found that *emx1* is dynamically expressed in renal progenitors, becoming localized to the distal segments. *emx1* deficient embryos had a normal distal nephron territory, but had alterations of the individual segments within it, with an expanded distal early (DE) segment and a reduced distal late (DL) segment. These data suggest that *emx1* is essential to promote the DL, and that it may restrict the DE and/or negotiate the site of the DE/DL boundary. *emx1* deficient embryos had reduced expression domains of several components that direct distal nephron segmentation, such as *irx3b* and *sim1a*, suggesting *emx1* acts upstream of these factors. However, expression of *mecom* was unchanged in *emx1* deficient embryos, suggesting *mecom* acts upstream or independently of *emx1*. Furthermore, *emx1* expression in renal progenitors was responsive to changes in retinoic acid (RA), a morphogen which is essential to induce proximal segments and repress distal segments during nephrogenesis. RA treated embryos had a restricted *emx1* domain, while exposure to the RA biosynthesis inhibitor DEAB conversely expanded *emx1* expression, indicating that RA signaling acts to negatively regulate *emx1* expression within renal progenitors.

Conclusions: Taken together, this work reveals for the first time that *emx1* has essential roles in distal nephron patterning. As expression of *Emx1* has also been annotated in the mouse metanephros, and because of the similarity between the zebrafish and mammalian genomes, this research can provide insights into regulatory networks that direct renal progenitor patterning during nephron formation.

FR-PO089

Differential Usage of Enhancers for Bmp7 in Different Lineages of Kidney Development In Vitro Taro Tsujimura,[1,2] Osamu Takase,[1,2] Masaomi Nangaku,[2] Keiichi Hishikawa.[1,2] *[1]Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo Hospital, Tokyo, Japan; [2]Nephrology and Endocrinology, The Univ of Tokyo Hospital, Tokyo, Japan.*

Background: BMP7 plays pivotal roles in kidney development and diseases. The function of the gene is critically determined by its expression pattern. Therefore, unveiling the regulation is essential to better understand the process. We previously reported that the downstream region of the gene is dispensable for development of the kidney. In addition, an element within the intron 1 of *Bmp7* was identified as an enhancer active in the ureteric bud (UB), but not in the metanephric mesenchymes (MM), during development. However, enhancers essential for the *Bmp7* expression in these different cell-types remain elusive. To deepen our understanding, we explored the *cis*-regulatory regions of the locus.

Methods: We first investigated the publically available ChIP-seq data from ENCODE of H3K27ac marks around the locus in the kidney at different stages. We next generated deletion lines of mouse ES cells each for the upstream and downstream regions of the *Bmp7* gene body, and for the UB enhancer. Then we applied two differentiation protocols towards kidney lineages to test the functionality of the deleted regions.

Results: We found that the pattern of H3K27ac mark changes considerably, suggesting that different enhancers are utilized for the *Bmp7* expression at different times and spaces. Upon differentiation towards interemediate mesoderm via activation of Osr1 (Mae et al. 2013), the deletion of the intron1 enhancer showed significant reduction of the *Bmp7* expression, while those of the others did not. Interestingly, however, none of the deletions changed the expression level of *Bmp7* upon differentiation specifically towards UB lineage (Takasato et al. 2015).

Conclusions: Taken together, these results show that different enhancers, particularly within the introns that were not tested yet, appear to regulate the expression of *Bmp7* in different cell types of the kidney. Deletion of these elements individually *in vivo* should further clarify their roles in regulation as well as the precise functions of BMP7 secreted from different domains of the kidney.

FR-PO090

The Basic Helix-Loop-Helix Transcription Factor, Tcf21/ Pod1 in Renal Stroma Is Essential for Crosstalk between Nephrons and Interstitia Shintaro Ide,[1] Yoshiro Maezawa,[1] Rizaldy P. Scott,[3] Tuncer Onay,[3] Yoshihiro Akimoto,[2] Kana Ide,[1] Minoru Takemoto,[1] Susan E. Quaggin,[3] Koutaro Yokote.[1] *[1]Clinical Cell Biology and Medicine, Chiba Univ Graduate School of Medicine, Chiba, Chiba-ken, Japan; [2]Dept of Anatomy, Kyorin Univ School of Medicine, Mitaka, Tokyo-to, Japan; [3]Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Background: Renal stromal cells provide a supportive scaffolds for nephrons and the collecting duct system, produce erythropoietin, undergo myofibroblast-like transformation to induce renal fibrosis.Tcf21/Pod1 is a bHLH transcription factor highly expressed in both renal stromal and nephron progenitor population. A standard Tcf21 KO mouse dies in the perinatal period with disrupted nephron development and disorganized interstitial patterning. However, given the complexity of the Tcf21 KO phenotype and early lethality, the precise role of Tcf21 in stromal cells remains unclear.

Methods: In order to clarify the role of Tcf21 in renal stromal development and function, Tcf21 floxed mice were bred with FoxD1Cre mice that provide specific gene deletion in renal stromal cells and its derivatives.

Results: Mice that lack Tcf21 in renal stroma ($Tcf21^{str/str}$) develop massive polyuria with significantly reduced urinary creatinine and osmolarity, increase of urinary sodium and chlorine excretion. Mutant kidneys are significantly smaller, show disorganized stromal structure, and prominent decrease in collecting ducts and loops of Henle. Ultrastructural analysis show thinning of endothelial cells, morphological changes of interstitial fibroblasts, and accumulation of extracellular matrices. Expression profiling using RNA-seq reveals possible downstream targets of this transcription factor including type 6 and type 7 collagens.

Conclusions: Together, these data demonstrate a crucial role of stromal Tcf21 in the development of tubular/collecting duct system. Identification of direct targets of this transcription factor could provide a novel insight into the interaction between stromal compartment and nephrons.

FR-PO091

Stromally Expressed B-Catenin Controls Proper Differentiation of the Medullary Stroma Felix Julien Boivin, Darren Bridgewater. *Pathology and Molecular Medicine, McMaster Univ, Hamilton, ON, Canada.*

Background: The renal stroma is a population of fibroblast cells essential for proper kidney development. Yet, stromal lineage formation, maintenance, and differentiation are poorly understood. In stromal progenitors, β-catenin is essential for establishing cortico-medullary patterning and formation of the medulla. While deletion of β-catenin specifically in stromal progenitors results in the absence of medulla, its underlying mechanism is not clear. **We hypothesize stromal β-catenin is essential to regulate differentiation of the medullary stroma.**

Methods: We generated mice with a β-catenin deficiency in stromal progenitors ($\beta\text{-cat}^{S-/-}$).

Results: The overall stromal population in $\beta\text{-cat}^{S-/-}$ kidneys revealed a 16.67% reduction using the stromal nuclear marker Pbx1 at E15.5. Analysis of the cortical stroma using FoxD1 and Tn-C did not reveal significant changes in their expression in $\beta\text{-cat}^{S-/-}$ by IF and qPCR, suggesting β-catenin is not essential for cortical stroma progenitor formation. In contrast, the analysis of medullary stroma markers Pod1, Wnt4, Bmp4, and p57Kip2 revealed marked reductions of medullary stroma in $\beta\text{-cat}^{S-/-}$. To further investigate the contribution of β-catenin to the regulation of genes essential for medullary stroma formation, we developed a mouse model where β-catenin is overexpressed in stromal cells ($\beta\text{-cat}^{GOF-S}$). The levels of Wnt4 and Bmp4, genes necessary for medullary stroma formation,were significantly increased in $\beta\text{-cat}^{GOF-S}$ in an expanded cell population overexpressing β-catenin. This demonstrates β-catenin regulates the expression of genes essential for medullary stroma differentiation and medulla formation. Considering the reduced medullary stroma in $\beta\text{-cat}^{S-/-}$, we suspected stromal cells that did not differentiate properly to form the medullary stroma were eliminated by apoptosis. Analysis of apoptosis revealed a significant increase in TUNEL and Casp3+ stromal cells. These apoptotic cells were found in clusters below the nephrogenic zone just prior to medullary stromal formation.

Conclusions: Taken together, our results suggest β-catenin specifically regulates medullary stroma differentiation and survival by regulating *Bmp4* and *Wnt4* for proper medulla formation.

FR-PO092

Loss of Zeb2 in Stromal Progenitors in Developing Mouse Kidney Leads to Renal Fibrosis Sudhir Kumar, Hila Milo Rasouly, Richa Sharma, Xueping Fan, Weining Lu. *Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Renal fibrosis is a leading cause of chronic kidney disease and renal failure worldwide and is characterized by fibroblasts to myofibroblasts transition and deposition of fibrillary matrix such as collagen. ZEB2 is a SMAD-interacting transcription factor expressing in stromal cells and fibroblasts in developing kidney. However, the link between ZEB2 and renal fibrosis is not known.

Methods: We generated *Zeb2* stroma-specific conditional knockout mice (cKO) by crossing *Zeb2* flox mice with *Foxd1Cre* mice and analyzed the phenotype of homozygous $Zeb2^{flox/flox}$;$Foxd1Cre^{+}$ mice (*Zeb2* cKO) and their wild-type littermate controls. Kidney histology, renal function, and lifespan were studied in *Zeb2* cKO. Protein expression analyses were performed by immunostaining of ZEB2, Phospho-SMAD3 and several markers for stromal progenitors, fibroblasts, and myofibroblasts in *Zeb2* cKO and wild-type controls.

Results: We found that ZEB2 is highly expressed in FOXD1+ renal stromal progenitors and PDGFR-β+ fibroblasts during mouse kidney development. Deletion of *Zeb2* flox allele using *Foxd1Cre* mice leads to growth retardation, renal failure, and early mortality in homozygous cKO. Immunohistochemical analysis showed that newborn *Zeb2* homozygous cKO kidneys have reduced expression of PDGFR-β and Tenascin-C, two stromal cell and fibroblast markers. At 3 weeks of age, interstitial fibroblasts showed markedly increased expression of α-smooth muscle actin indicating fibroblast to myofibroblast transition. Increased myofibroblasts lead to renal fibrosis with expanded collagen deposition as measured by Masson trichrome, picrosirius red and collagen-1 staining. Further analysis showed that *Zeb2* homozygous cKO mice have increased number of p-SMAD3+ interstitial cells suggesting enhanced TGF-β/SMAD3 signaling activation.

Conclusions: ZEB2 is important for renal interstitial fibroblast development and loss of *Zeb2* in stromal progenitor cells during mouse kidney development leads to fibroblast to myofibroblast transition and renal fibrosis via enhanced TGF-β/SMAD3 signaling.

Prorenin Receptor Controls Renal Branching Morphogenesis via Wnt/β-Catenin Signaling Renfang Song, Adam T. Janssen, Yuwen Li, Samir S. El-Dahr, Ihor V. Yosypiv. *Pediatrics, Tulane Univ, New Orleans, LA.*

Background: The prorenin receptor (PRR) is a receptor for renin and prorenin, and an accessory subunit of the vacuolar proton pump H^+-ATPase. Renal branching morphogenesis, defined as growth and branching of the ureteric bud (UB), is essential for mammalian kidney development. Previously, we demonstrated that conditional ablation of the *PRR* in the UB in $PRR^{UB-/-}$ mice causes severe defects in UB branching, resulting in marked kidney hypoplasia at birth (PLoS ONE, 2013).

Methods: Here, we investigated UB transcriptome using whole-genome-based analysis of gene expression in UB cells FACS-isolated from $PRR^{UB-/-}$and control kidneys at birth (P0) to determine the primary role of the PRR in terminal differentiation and growth of UB-derived collecting ducts.

Results: Three genes with expression in UB cells previously shown to regulate UB branching morphogenesis, including *Wnt9b*, *β*-catenin and *Fgfr2*, were upregulated, whereas the expression of *Wnt11*, *Bmp7*, *Etv4* and *Gfrα1* was downregulated. We next demonstrated that infection of immortalized UB cells with shPRR *in vitro* or deletion of the UB *PRR* in double-transgenic $PRR^{UB-/-}/BatGal^{+}$ mice, a reporter strain for *β*-catenin transcriptional activity, *in vivo* increases *β*-catenin activity in the UB epithelia. In addition to UB morphogenetic genes, the functional groups of differentially expressed genes within the downregulated gene set in UB cells FACS-isolated from $PRR^{UB-/-}$ mice included genes involved in molecular transport, metabolic disease, aminoacid metabolism and energy production.

Conclusions: Together, these data demonstrate that UB PRR performs essential functions during UB branching and collecting duct morphogenesis *via* inhibition of *β*-catenin signaling and control of hierarchy of genes that control UB branching and terminal differentiation of UB-derived collecting duct cells.

Grainyhead-Like 2 Regulates Urinary Concentrating Ability by Facilitating Collecting Duct Barrier Function Christian Hinze,[1,2] Janett Ruffert,[2,3] Katharina Walentin,[2] Jonathan M. Barasch,[4] Kerim Mutig,[1] Sebastian Bachmann,[1] Nina Himmerkus,[6] Markus Bleich,[6] Kai M. Schmidt-Ott.[1,2] *[1]Charité, Berlin, Germany; [2]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [3]Urological Research Laboratory, Berlin, Germany; [4]Columbia Univ, New York; [5]Univ of Kiel, Kiel, Germany.*

Background: The transcription factor grainyhead-like 2 (Grhl2) is highly expressed in renal collecting ducts. Mice with collecting duct-specific Grhl2 deficiency show a decreased ability to concentrate urine and are more susceptible to water restriction and prerenal acute kidney injury. The leading causes for this phenomenon, however, remain unknown. Potential explanations include alterations of the epithelial barrier or of cellular water transport. Here, we investigated the differential impact of Grhl2 on transepithelial resistance and on cellular water transport in freshly isolated collecting ducts.

Methods: We generated Hoxb7/Cre; $Grhl2^{flox/-}$ mice, which exhibit a deletion of functional Grhl2 protein in most cells of the collecting duct. Collecting ducts (CD) from the inner stripe of the outer medulla were freshly isolated and perfused using a double-barreled perfusion system with electrodes inside and outside the CD to analyze transepithelial resistance. To evaluate the relevance of Grhl2 to water transport, we imaged CD after lowering the basolateral solution osmolality inducing water influx and consecutive swelling of the cells. Afterwards, we exposed the CD to forskolin inducing deswelling of cells due to apical insertion of aqpaporin 2.

Results: Our data show that the transepithelial resistance of ISOM collecting ducts of Hoxb7/Cre; $Grhl2^{flox/-}$ conditional knockout mice is reduced by 52% when compared to littermate controls (control vs. knockout: 107.6 vs. 51.2 Ωcm², no. animals, no. ISOM CD: 5 vs. 5, 9 vs. 14, $p<0.001$). However, dynamics of swelling and deswelling showed no difference between Grhl2 knockout animals and controls.

Conclusions: In the renal collecting duct, Grhl2 is primarily required to maintain the transeptithelial barrier, but is dispensable for cellular water transport dynamics. This might be of relevance to diseases involving defective renal responses to water deprivation and conditions of prerenal acute kidney injury.

The Role of Planar Cell Polarity Signaling in Nephric Ciliogenesis and Tubulogenesis Rachel Katherine Miller,[1,2,3] Bridget D. Delay,[1] Vanja Stankic,[1,2] Mark E. Corkins,[1] Tanya A. Baldwin,[2] Malgorzata Kloc,[3,4] Pierre D. Mccrea,[2,3] Andrew B. Gladden.[2,3] *[1]Pediatrics-Research Center, Univ of Texas McGovern Medical School, Houston, TX; [2]Univ of Texas Graduate School of Biomedical Sciences, Houston, TX; [3]Genetics, Univ of Texas MD Anderson Cancer Center, Houston, TX; [4]Immuno-Biology Laboratory, Houston Methodist Research Inst, Houston, TX.*

Background: Kidney tubules consist of a ciliated epithelium, and disruption of cilia polarity leads to aberrant nephrogenesis and cyst development. Recent work suggests that planar cell polarity (PCP) genes influence the development of cilia, but the mechanism behind this involvement is unknown. Daam1, a component of the PCP pathway is expressed during nephrogenesis, and knockdown of Daam1 leads to decreased kidney tubulogenesis in *Xenopus laevis* (frog) embryos. Dishevelled, a component upstream of Daam1 in the PCP pathway, is known to influence ciliogenesis. We hypothesize that Daam1 modulates kidney tubule formation through formation of cilia.

Methods: Using *Xenopus laevis* (frog) embryos, supplemented polarized mammalian kidney cell (MDCK), we assess the roles of PCP components in kidney tubule ciliogenesis and morphogenesis utilizing knockdown, CRISPR/Cas9-mediated knockout, overexpression, immunostaining, yeast 2-hybrid and biochemical techniques.

Results: Our preliminary data suggest that knockdown of Daam1 leads to reduction of cilia in *X. laevis* kidneys and MDCK cells, supporting a working hypothesis that a reduction in kidney cilia may contribute to nephrogenesis defects. Our initial assessments using CRISPR/Cas9-mediated knockout of Daam1 support its role in ciliogenesis and nephric morphogenesis. Yeast 2-hybrid screening and co-immunoprecipitation assays indicate that Daam1 interacts with Tuba, a component of the exocyst complex that is required for primary ciliogenesis. Our recent data also suggest that knockdown of Tuba in the kidney results in reduced tubulogenesis and that CRISPR-Cas9-mediated Tuba knockouts also have defects in nephrogenesis.

Conclusions: Together, these results indicate that PCP signaling is necessary for tubulogenesis within the developing kidney, in part due to effects upon ciliogenesis.

Genetic Analysis of Mutations Affecting Kidney Development Audra White, Gary Gerlach, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: How the segment cell types of the nephron arise remains a major unresolved question in the field of nephrology. The zebrafish embryonic kidney, or pronephros, has become a progressively prevalent model to analyze renal development and disease. The zebrafish pronephros is composed of two nephrons that contain a series of functional proximal and distal segments, comparable to mammals.

Methods: To discover the repertoire of genes that direct nephron segmentation, a novel haploid forward genetic screen was conducted after random mutagenesis with ethylnitrosurea.

Results: The screen was performed on approximately 700 genomes and resulted in the collection of 15 mutant lines to date. Ongoing complementation studies have suggested that these mutations represent at least 12 different nephrogenesis genes. The kidney phenotypic classes include models of podocyte deficiency, as well as expansions or reductions in the domains of individual proximal and distal tubule segments. Here, we report the characterization of several recessive, embryonic lethal mutations affecting kidney development. For example, line 363 lacks the proximal straight tubule, such that the proximal convoluted tubule and distal tubule form adjacent to one another. Current efforts are directed at identifying the genetic lesion underlying mutation 363. In comparison, line 154 had reduced proximal and expanded distal segments, hallmarks of a defect in retinoic acid (RA) biosynthesis. To test this, we performed complementation analysis with *aldehyde dehydrogenase1a2* ^{nz15} (*aldh1a2*), as well as rescue studies, which revealed that 154 is a novel allele of *aldh1a2*.

Conclusions: This collection of kidney mutations will provide a useful resource to uncover the genes that direct nephrogenesis pathways and may provide new models to study human congenital kidney defects.

Genetic Networks of Distal Tubule Patterning during Nephrogenesis Bridgette Drummond, Yue Li, Nicole Handa, Amanda N. Marra, Christina N. Cheng, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: The nephron is composed of a variety of cell types that are arranged into distinguishable proximal and distal segments. Previous studies have utilized the simplified nephron system of the zebrafish embryo to identify novel components of nephrogenesis, such as the key roles for retinoic acid (RA) signaling in inducing proximal nephron fates, and the transcription factor encoded by *mecom*, which is required for distal segment formation.

Methods: In this study, the T-box transcription factors *tbx2a* and *tbx2b* were found to be expressed by renal progenitors that give rise to the distal tubule. Loss of function studies revealed that deficiency of *tbx2a*, *tbx2b* or both *tbx2a/b* led to similar reductions in distal tubule formation.

Results: Interestingly, knockdown of *tbx2a* reduced the domain of *tbx2b* expression in renal progenitors, and distal tubule development in *tbx2a* deficient embryos was partially rescued by *tbx2b* overexpression, indicating that *tbx2a* acts upstream to induce or maintain *tbx2b* during distal tubule development. To test the relationship of *tbx2a/b* with the RA pathway, wild-type embryos were treated with exogenous RA or a RA biosynthesis inhibitor, which revealed that *tbx2a/b* are negatively regulated by RA signaling. Next, using *in situ* hybridization, we found that *mecom* transcripts maintained a consistent expression domain in the distal segments of *tbx2a*, *tbx2b*, and *tbx2a/b* deficient embryos. In contrast, *mecom* deficient embryos had significantly decreased *tbx2a* and *tbx2b* domains. Further, the diminished distal tubule typically seen with loss of *mecom* was partially rescued by coninjecting *tbx2a/b* capped RNA. This indicates that *mecom* acts to promote *tbx2a/b* expression, which in turn promotes the formation of the distal tubule.

Conclusions: Taken together, these findings demonstrate that *mecom, tbx2a,* and *tbx2b* are necessary and sufficient factors for distal tubule development, which is pertinent for other developmental and regenerative medicine studies.

FR-PO098

Elf5 Is a Principal Cell Lineage Specific Transcription Factor That Contributes to Normal Expression of Aqp2 and Avpr2 Kameswaran Surendran, Malini Mukherjee, Jennifer DeRiso. *Children's Health Research Center, Sanford Research, Sioux Falls, SD.*

Background: The collecting ducts of mammalian kidneys are populated by intermingled intercalated and principal cells that are critical for water, electrolyte and acid-base homeostasis. Comparison of the gene expression profiles of normal developing mouse kidneys versus kidneys with Notch-signaling-deficient collecting ducts, in which most duct cells are aberrantly fated to become intercalated instead of principal cells, led us to identify Elf5 as a potential principal cell specific transcription factor. We have determined whether Elf5 is an early principal cell lineage specific factor and whether it is required for principal cell differentiation.

Methods: We determined the renal *Elf5* expression pattern using transgenic mice in which GFP or reverse tetracycline transactivator (rtTA) are expressed under the control of the Elf5 regulatory region and mice in which LacZ is knocked into the Elf5 locus. Lineage tracing experiments were performed to determine the fate of Elf5 expressing cells using Elf5->rtTA;Tet-o-Cre; Rosa $^{+/tdtomato}$ mice. We performed dual luciferase assays to test the ability of Elf5 to promote the transcriptional activity of proximal promoters of principal cell specific genes. We also analyzed mice with conditional inactivation of *Elf5* in the collecting ducts.

Results: *Elf5* is expressed prior to Aquaporin-2 within the developing collecting ducts as early as E14.5. Lineage tracing of *Elf5*-expressing cells between E16.5 and E17.5 revealed that *Elf5*-expressing cells develop into mature principal cells expressing Aquaporin-4, and Aquaporin-2. Elf5 mildly activates the proximal promoters of *Aqp2* and *Avpr2* in cultured principal cells, consistent with a 20% reduction in *Aqp2* and *Avpr2* gene expression levels in the kidneys with Elf5-deficient collecting ducts.

Conclusions: Although Elf5 is expressed early in the developing collecting ducts and becomes restricted to the principal cell lineage by E16.5, the contribution of Elf5 to regulation the of principal cell specific genes is minimal. The Elf5->rtTA mice will be useful for genetically labeling principal cells and inactivating genes specifically in the principal cell lineage.

Prenatal Renal Tract Abnormalities in Murine Models of Spina Bifida Overexpressing Grainyhead-Like 2 and Grainyhead-Like 3 Daniyal Jalil Jafree,[1,2] Oleksandr Nychyk,[1] Nicholas Greene,[1] Andrew Copp,[1] Paul Winyard.[1] *[1]UCL Inst of Child Health, Univ College London, London, United Kingdom; [2]Div of Surgery and Interventional Sciences, Univ College London, London, United Kingdom.*

Background: Given the prenatal manifestation of spina bifida, associated renal tract abnormalities may originate prenatally. Mouse fetuses with spina bifida overexpressing the *grainyhead-like* genes, *grainyhead-like 2* (*Grhl2*) and *grainyhead-like 3* (*Grhl3),* could serve as a model of the human condition. The present study aimed to use this murine model to assess the potential for prenatal renal tract abnormalities in spina bifida.

Methods: Matings were performed of heterozygous *Axd* mice, which overexpress *Grhl2* (*Grhl2^{Axd}*) and transgenic *curly tail* mice, which overexpress *Grhl3* (*Grhl3*;Tg). Renal tracts were dissected from fetuses at embryonic day (E)18.5, embedded, sectioned at 3 μm and analyzed using histology and immunohistochemistry.

Results: Of *Grhl2^{Axd}* fetuses with spina bifida at E18.5, 2 / 4 (50.0%) had abnormal kidney morphology, with no histological abnormalities. 7 / 9 (77.8%) *Grhl3;*Tg fetuses with spina bifida exhibited ureteral tortuosity (n = 4, 44.4%) or dilation (n = 3, 33.3%) at E18.5. Ureteral dilation was also observed in 2 / 5 (40.0%) *Grhl3*;Tg fetuses without spina bifida. Immunohistochemistry suggested indistinguishable innervation and smooth muscle differentiation in bladders and ureters of *Grhl3;*Tg fetuses with spina bifida (n = 2) compared to controls (n = 2). No renal tract abnormalities were observed in heterozygotes at E18.5, but 2 / 4 (50.0%) fetuses carrying both the *Axd* allele and the *Grhl3* transgene had spina bifida and renal pelvic dilation.

Conclusions: In conclusion, spina bifida is a feature of mouse fetuses overexpressing either *Grhl2* or *Grhl3* at E18.5, but associated renal tract abnormalities result from *Grhl2* and *Grhl3* overexpression, not from spina bifida itself. This is suggested by the observation of renal tract abnormalities in fetuses without spina bifida, the variation in defects between strains and evidence of innervation in renal tracts of fetuses with ureteral abnormalities. This study provides insight into the importance and interaction of *Grhl2* and *Grhl3* during renal tract development.

The Establishment of Horseshoe Kidney Animal Model Induced by Retinoic Acid and Its Possible Molecular Mechanism Yuansheng Xie,[1] Yan Qi,[1] Panpan Hu,[1,2] Qinggang Li,[1] Xiang-Mei Chen.[1] *[1]Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, China; [2]Dept of Nephrology, Civil Aviation General Hospital.*

Background: Horseshoe kidney(HSK) is a common renal fusion malformation, and disorders in cell adhesion and migration during kidney development may involve in its formation. In this study, we established HSK models of fetal mice with retinoic acid (RA) and tried to reveal the underlying mechanism.

Methods: Eight-week-old mature female ICR mice were mated with male ones, and the identification of a vaginal semen plug was defined as embryonic day 1 (E1d). At E8d, pregnant mice were injected with RA at a dose of 25mg/kg intraperitoneally. Fetal mice were taken out by cesarean delivery at E13d, E15d and E17d, respectively. The morphology of fetal mice and their kidneys were observed and recorded. Five factors including RA receptor β(Rarβ),Wnt5a,Tcf3,Snai2 and Rhob which related with RA signaling pathway,non-canonical Wnt signaling pathway,cell adhesion and migration were selected as candidates through literature review. Real-time PCR was used to detect their expression in normal and horseshoe kidneys as well as normal and RA stimulated embryonic renal cells.

Results: Among all the 11 fetal littermate mice acquired at E13d, 3 of them had HSK, 2 of them were unclear and 6 of them had normal renal morphology. As for the 4 fetal littermate mice acquired at E15d, all of them had HSK. Two pregnant mice were killed at E17d, one had 13 fetal mice, 3 of them had HSK, 1 was unclear and 9 had normal morphology. And the other had 12 fetal mice, 8 of them had HSK and 4 had normal morphology. Up-regulation of Rarβ, Wnt5a, Tcf3 and Snai2 and down-regulation of Rhob were found in HSK and RA stimulated embryonic renal cells compared with fetal kidneys in normal morphology and unstimulated cells.

Conclusions: RA can induce HSK models of fetal mice which can be used to investigate its molecular mechanism. RA induced HSK maybe related to the promotion of cell adhesion and inhibition of cell migration throughnon-canonical Wnt signaling pathway.

Cubilin/AMN-Mediated Protein Reabsorption in Nephrocytes Affects Drosophila Lifespan through Regulating the Senescence of Brain and Muscle Tissues Fujian Zhang, Xiaoming Feng, Qiuxia Fan, Fan Fan Hou. *Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guang Zhou, Guang Dong, China.*

Background: Living-kidney donors have an increased risk of cardiovascular, ESRD and all-cause mortality compared with matched healthy nondonors. However, the underlying mechanism is unknown . The *Drosophila* nephrocyte shares remarkable anatomical, molecular and functional similarity to the glomerular podocyte for protein ultrafiltration, and the renal proximal tubule for protein reabsorption. In this study, we aimed to elucidate the effect of Cubilin/AMN-mediated protein reabsorption on lifespan in Drosophila and its underlying molecular mechanism.

Methods: First, we established Cubilin/AMN knock-down flies and examined the effect of protein reabsorption defect on lifespan. Then, we investigated the effect of enhanced protein reabsorption on lifespan with over-expressing AMN receptor in nephrocytes. We also examined the effect of protein reabsorption on the neuronal and muscular function using negative geotaxis assay. We monitored the proteostasis in hemolymph and tissues using proteomic approach. Furthermore, we performed the immuno-staining and H&E staining to evaluate the effect of protein reabsorption on the senescence of other organs.

Results: We found that defect in nephrocyte protein reabsorption leads to shortened lifespan, whereas, enhanced protein reabsorption in nephrocytes extends *Drosophila* lifespan. We also found that nephrocyte protein reabsorption affects the proteostasis in hemolymph using proteomic approach. Furthermore, we also observed declined neuronal and muscular activities in flies with protein reabsorption defect. Finally, we found that protein reabsorption defect in nephrocytes impairs proteostasis and organ ageing in muscle and brain tissues, suggesting that Cubilin/AMN-mediated protein reabsorption in nephrocytes may affect the senescence of other organs via the tele-proteostasis mechanism.

Conclusions: This study not only discovered the effect of protein reabsorption in nephrocytes on lifespan and its underlying molecular mechanism, but also laid the foundation for the investigation of the effect of tele-proteostasis on aging and its molecular mechanism.

FR-PO102

Cakutome, a High-Throughput Tool for Molecular Diagnosis and Identification of Novel Genes for Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) Laurence Heidet,[1] Vincent Moriniere,[2] Lara De Tomasi,[3] Charline Henry,[3] Raphaelle Campait,[2] Olivier Alibeu,[4] Cecile Fourrage,[5] Remi Salomon,[1,3] Sophie Saunier,[3] Cecile Jeanpierre.[3] *[1]Pediatric Nephrology Dept, Reference Center MARHEA, Necker Hospital, Paris, France; [2]Genetic Dept, Necker Hospital, Paris, France; [3]Inserm UMR1163, Imagine Inst, Paris Descartes Univ, Paris, France; [4]Genomic Platform, Imagine Inst, Paris, France; [5]Bioinformatic Platform, Paris Descartes Univ, Paris, France.*

Background: CAKUT are major causes of chronic kidney disease in children. They are phenotypically and genetically heterogeneous diseases, with more than 50 genes reported as mutated in patients, mostly in syndromic forms. Most of the mutations are heterozygous, with autosomal dominant inheritance and variable expressivity. The most frequently mutated genes are *HNF1B, PAX2, EYA1* and *SIX1,* all encoding transcription factors. Many of the other genes are mutated in only few patients and their implication is sometimes elusive.

Methods: To improve molecular diagnosis and identify new causative genes, we developed a targeted exome sequencing strategy (" cakutome ") focusing on 388 genes including known causative or likely causative genes, genes whose knock-out in mouse lead to CAKUT, genes involved in cellular processes/signaling pathways relevant for kidney development, as well as candidates that we had previously identified by whole exome sequencing of CAKUT familial cases. 214 unrelated patients were analysed, 63 previously tested for *HNF1B*, *PAX2*, *EYA1* and/or *SIX1* mutations by Sanger sequencing, and 151 new cases.

Results: Mutations/deletions of *HNF1B, PAX2, EYA1* or *SIX1* were identified in 23 of the 151 cases. This rate is nearly similar to that obtained by Sanger sequencing. We identified mutations in *ANOS1* (Kallmann syndrome), *GATA3* (hypoparathyroidism, deafness and kidney disease) and *SALL1* (Townes-Brocks syndrome) in 6 isolated cases. Moreover, we identified variants in several genes never reported as mutated in CAKUT patients, whose pathogenicity is currently being tested.

Conclusions: This approach is suitable for diagnosis and should allow us to validated new CAKUT causative genes.

Low Nephron Number in Japanese Subjects without Overt Renal Disease: The Effect of Race and Hypertension Go Kanzaki,[1,2] Victor G. Puelles,[1] Luise A. Cullen-McEwen,[1] Wendy E. Hoy,[3] Yusuke Okabayashi,[2] Nobuo Tsuboi,[2] Akira Shimizu,[4] Takashi Yokoo,[2] John F. Bertram.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Australia; [2]Dept of Internal Medicine, The Jikei Univ School of Medicine, Japan; [3]Centre for Chronic Disease, The Univ of Queensland, Australia; [4]Dept of Analytic Human Pathology, Nippon Medical School, Japan.*

Background: Nephron number in normal human kidneys varies widely and some racial groups with low nephron number have a higher incidence of hypertension and chronic kidney disease (CKD). In Japan, CKD has reached epidemic proportions, but the reasons for this remain unclear.

Methods: Autopsy kidneys from 18 male Japanese subjects without overt kidney disease were collected at Nippon Medical School, Tokyo, Japan and were carefully age-matched to archival data from 18 Caucasian Americans from Mississippi, USA. Demographic data were obtained from autopsy reports and medical records. Total nephron number and mean glomerular volume were estimated by design-based stereology. Glomerulosclerosis was determined using a standardized glomerulosclerotic index.

Results: Significant differences were found between Japanese and Caucasian Americans for height, weight, and thereby BSA ($P<0.001$ for all). Japanese kidneys weighed 21.8% less than those from Caucasian Americans ($P<0.01$). Caucasian American kidneys (955,843±52,781) contained 42.4% more nephrons than Japanese kidneys ($P<0.01$, 550,392±41,787). This difference was still present after adjustment for BSA. Glomerular hypertrophy was observed in association with hypertension ($P=0.04$), but not race. Interestingly, kidneys of hypertensive subjects contained fewer nephrons than normotensives in both races ($P= 0.002$, Japanese; $P= 0.046$, Caucasian Americans) even after glomerulosclerosis adjustment.

Conclusions: This study shows for the first time that Japanese subjects have fewer nephrons than Caucasian Americans, and also indicates that hypertension is associated with lower nephron number. Although it remains unclear whether Japanese subjects were born with fewer nephrons and/or show accelerated nephron loss, the lower nephron number in Japanese people would be compatible with their susceptibility to CKD.

Loss of the Planar Cell Polarity Gene Fuzzy Causes Severe Renal Hypoplasia Elena Torban, Yanran Wang. *Medicine, Div of Experimental Medicine, McGill Univ and McGill Univ Health Center Research Inst, Montreal, QC, Canada.*

Background: Fuzzy is a PCP effectors gene, originally identified in Drosophila, where it regulates actin organization in wing cells. Disruption of Fuzzy in mice causes severe malformations including neural tube defects, polydactyly and facial defects among others. In vertebrates, Fuzzy also affects ciliogenesis by interacting with other PCP effectors to regulates recruitment of some intraflagellar group A transport proteins. Thus, Fuzzy may affect organogenesis by acting both on planar cell polarity signaling and on ciligenesis, two processes important for kidney development.

Methods: Fuzzy gene-trap embryos were harvested at E14.5 and genotyped. Fuzzy homozygous mutants and matching controls were paraffin-embedded, sectioned and processed for immunofluorescent microscopy with various markers: calbindin (ureteric bud), Six2 (nephron progenitors), N-CAM (early mesenchyme-derived nephron structures), WT1 (glomerular podocytes). Hematoxilin and eosin were used to conduct morphometric studies. PNCA and Tunnel assay were used to visualize proliferating and apoptotic cells. In situ hybridization was used to ascertain Fuzzy localization in kidney structures.

Results: We found that E14.5 Fuzzy-/- mutants display severe kidney hypoplasia (~ 50% of the size of control animals) accompanied by ~ 50% reduction in the ureteric bud structures and corresponding 50% reduction of early glomeruli. However, the size of the Six2-positive progenitor pool, the proportion of early nephron structures and the number of podocytes per glomeruls were unaffected. Proliferation and apoptosis within mesenchymally-derived structures were similar to control, yet proliferation and apoptosis within the ureteric bud structures were affected. ISH study revealed that Fuzzy is highly expressed in the collecting duct and at a lower level in other structures.

Conclusions: Our studies indicate that defective UB branching is the major cause of renal hypoplasia in Fuzzy-/- mutants. We will investigate whether loss of Fuzzy affects c-Ret/GDNF, Wnt and/or Shh signaling, Hippo kinase pathway and causes aberrant tubular elongation in the collecting duct lineage.

Vitamin D Effect on the Disturbances of Renal Function and Structure Induced by Losartan Exposure during Lactation in Rats Lucas Ferreira Almeida, Heloisa Francescato, Cleonice Silva, Terezila Machado Coimbra. *Physiology, Univ of Sao Paulo, Ribeirao Preto, Sao Paulo, Brazil.*

Background: Renal development in rats is completed between 10 and 15 days after birth. Rat exposure to angiotensin II antagonists during lactation presents disturbances in renal development. Vitamin D (Vit D) has been envolved with cellular differentiation and inflammation and in the regulation of renin gene. Besides this the lack of tubular differentiation in losartan treated rats can affect the Vit D activation. This study evaluates the effect of Vit D in the renal changes provoked by losartan exposure during lactation.

Methods: Male Wistar rats were divided in 4 groups: 1-Control and 2-Control+Vit D, pups treated or not Vit D, 3-Losartan and 4-Losartan+Vit D, pups treated or not Vit D from dams that received losartan. Treatment with losartan (100 mg/kg/day) was conducted during lactation. Vit. D (6 ng/day,calcitriol-*Abbott*), administered by a mini-osmotic pump (*Alzet*), was introduced on day 30 after birth and continued until day 60. Blood pressure (BP) was determined 60 after birth, and blood and urine samples collected to measure creatinine levels. The kidneys were removed for morphometric and immunohistochemical studies.

Results: The animals exposed to losartan presented higher blood pressure (140±0.77 mmHg), decreased glomerular filtration rate (0.56±0.12 ml/min/100g) and albuminuria (80.78±3.80 mg/24h), compared to control. These alterations were attenuatted by Vit D treatment (129.5±0.74 mmHg, 0.77±0.16, 49.93±3.00, respectively, $p<0.05\%$). Rats treated with losartan also showed decreased glomerular area media (5,800 μm^2), higher interstitial area (21.1±1.66%), macrophage number (13.5±0.47/0.100 mm^2), and incresead score for fibronectin and alfa-SM-actin expression in renal cortex (1.4±0.08, 1.9±0.18 respectively). These alterations less intense in Losartan+Vit D group (6,300 μm^2, 15.8±1.75%, 8.9±0.49, 1.0±0.08, 1.3±0.10, respectively).

Conclusions: Vit D treatment reduced the BP and the renal disturbances provoked by losartan exposure during lactation. These effects were associated with renal cellular differentiation and decrease of inflammation in the rats treated with Vit D.
