Background: TGF-β1-induced cell death is known to contribute to the pathogenesis of diabetic nephropathy. Ferroptosis, a new atypical form of cell death, is an iron-dependent cell death that is distinct from apoptosis, necroptosis, and autophagy, and results from lipid peroxide accumulation. In this process, glutathione peroxidase 4 (GPX4) and glutamate/cystine antiporter (xCT) are surmised to be principally involved. Recently, ferroptosis has been reported to cause several kidney diseases. However, the impact of ferroptosis on tubular cell death under diabetic conditions has never been elucidated.

Methods: *In vitro*, rat proximal tubular epithelial cells (NRK-52Es) were cultured in DMEM media containing 5.6 mM glucose (normal glucose, NG) or NG + TGF-β1 (10 ng/ml) with or without ferroptosis inhibitors (Ferrostatin-1 and Liproxstatin-1) or iron chelator (Deferoxamine) for 12 hours. *In vivo*, 12 C57BL/6 mice were intraperitoneally injected with saline (Control, C) (N=6) or STZ (50 mg/kg/d) for 5 consecutive days (Diabetes, DM) (N=6), and were sacrificed after 6 weeks. The protein expression of GPX4, xCT, hypoxia-inducible factor (HIF)-1α, heme oxygenase-1 (HO-1), and nuclear factor erythroid 2-related factor 2 (Nrf2) were determined in cultured tubular epithelial cells and the mouse kidneys by western blot analysis. Cell viability and lipid peroxidation (MDA) were also evaluated in cultured tubular cells.

Results: Compared to NG cells, the protein expression of xCT was significantly decreased, while HIF-1α, HO-1, and Nrf2 protein expression were significantly increased in TGF-β1-stimulated renal tubular epithelial cells. In contrast, GPX4 expression was not changed in renal tubular cells exposed to TGF-β1. Moreover, MDA levels were significantly increased along with significantly decreased cell viability in TGF-β1-stimulated cells. These changes in cultured tubular cells exposed to TGF-β1 were significantly ameliorated by ferroptosis inhibitors or iron chelator treatment. A significant decrease in xCT protein expression was also observed in the kidney of DM mice compared to the C kidney.

Conclusions: These results suggest that ferroptosis is involved in renal tubular cell death under diabetic conditions and that ferroptosis inhibitor or iron chelator can be a promising therapeutic agent in patients with diabetic nephropathy.

PUB103

HIV Induces Ferroptosis in Human Podocytes Kamesh R. Ayasolla,[1] Vinod Kumar,[4] Abheepsa Mishra,[2] Ashwani Malhotra,[5] Pravin C. Singhal.[3] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY; [3]North Shore LIJ Health System, Great Neck, NY; [4]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [5]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Loss of critical number of podocytes promotes the development of focal development of glomerulosclerosis. Occurrence of cell death in adverse milieus has been repoted to incur by multiple mechanisms including apoptosis, pyroptosis, ferroptosis and necroptosis. Occurrence of podocyte apoptosis and pyroptosis has been reported in HIV-associated nephropathy; however, the role of ferroptosis in HIV-induced podocyte injury has not been investigated to date. Ferroptosis is a programmed caspase independent cell death initiated by cellular non-chelated iron and driven by altered lipid environment (reduced glutathione and lipid alterations) and condensed mitochondrial structures. We investigated whether lipid alteration mediated ferroptosis contributes to the loss of podocytes in HIV-associated nephropathy (HIVAN). To elucidate this aspect, we studied the role of sphingomyelinase (SMase) in the induction of podocyte ferroptosis in HIV milieu, in vivo as well as in vitro.

Methods: SMase activities of renal tissues of control (FVB/N, n=5) and HIVAN (Tg26, n=6) mice and vector (V/HP) - and HIV-transduced human podocytes (HIV/HPs) were determined. To examine the effect of sphingomyelinase inhibitor (GW48), V/HPs and HIV/HPs were incubated in media containing either buffer or GW48 for 48 hours. At the end of experimental period, cells were evaluated for SMase activity and lipid peroxidation. V/HPs and HIV/HPs were evaluated for cell death with or without blockers of ferroptosis, caspase-1, and caspase-3 at different time periods. Additionally, role of PKC-ζ and NF-kB on SMase-induced HIV/HPs' downstream signaling was evaluated.

Results: Renal tissues of Tg26 mice and HIV/HPs displayed several fold increase in SMase activity. HIV/HP-induced SMase activity could be effectively blocked by GW48. Additionally, HIV/HPs displayed increase in lipid peroxidation that could be inhibited by GW48. A vast numbers of HIV/HPs succumbed to death during 96 hours. The relative cell survival using blockers of ferroptosis, Caspase-1, and Caspase 3 were 35%, 45%, and

20% respectively. HIV activated PKC-ζ and NF-kB and inhibitors of PKC-ζ and NF-kB prevented HIV induced ferroptotic cell death.

Conclusions: HIV induces ferroptosis in podocytes through the activation SMase activity and associated downstream signaling.

Long Non-Coding RNA Expression Profile in Adult Renal Stem/Progenitor Cells: Role in Cell Proliferation and Differentiation Simona Simone,[1] Giuseppe De Palma,[1] Claudia Curci,[1] Alessandra Stasi,[1] Monica Rutigliano,[1] G. Lucarelli,[1] Paola Laghetti,[1] Rossana Franzin,[1] Michele Battaglia,[1] Giuseppe Grandaliano,[2] Loreto Gesualdo,[1] Giovanni B. Pertosa,[1] Fabio Sallustio.[1] *[1]University of Bari, Bari, Italy; [2]University of Foggia, Foggia, Italy*.

Background: Adult renal stem/progenitor cells (ARPC) are a cell population identified in the kidney potentially useful for the renal damage treatment. However, to fully exploit such potential it is necessary to study the conditions that regulate their behavior. Recently, long non-coding RNAs (lncRNAs) have emerged as a class of regulators of gene expression. Several lncRNAs regulate specific tissue stem cell renewal or differentiation, while others promote a differentiation program. Their functions are facilitated by protein partners that impair the ability to activate or repress gene expression or posttranscriptionally regulate other RNAs. The aim of this study was to determine the lncRNA expression profile in ARPC.

Methods: lncRNA expression profile was obtained by ARPC and renal proximal tubule epithelial cells (RPTEC) by using Agilent microarrays. Data were analyzed with GeneSpring and R software. lncRNA microarray data were validated by real time-PCR.

Results: We compared lncRNA expression in ARPC and RPTEC: 588 lncRNAs were differently modulated in ARPC compared to RPTEC (fold change >2; Q value <0.05). In particular, we found 51 upregulated lncRNAs and 53 downregulated lncRNAs. Classification analysis showed that most lncRNAs expressed in ARPC are involved in Wnt and BMP signaling pathways, activation of the immune cells and G protein-mediated signaling: processes involved in the response to cellular damage. Over-representation test demonstrated their involvement in the calcium signal transduction, cell cycle and protein glycosylation processes ($p < 0.005$). Among differentially modulated lncRNAs, LINC00263 was the most down-regulated in ARPC compared to RPTEC (fold change <3). LINC00263 is highly expressed in cerebral tissue and is involved in the differentiation inhibition and processes regulating maintenance of cytoskeleton structure, cellular adhesion, and membrane signaling. It may therefore be involved in maintaining ARPC in an undifferentiated state.

Conclusions: In conclusion, our results suggest that lncRNAs could play a role in response to cell damage and in ARPC differentiation and could represent a new therapeutic target in renal damage.

PUB105

A Systems Biology Study of Pyroptosis Gene Signatures in HIV-Associated Nephropathy Kamesh R. Ayasolla,[1] Tânia Barata,[4] Abheepsa Mishra,[2] Ashwani Malhotra,[5] Pravin C. Singhal.[3] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY; [3]North Shore LIJ Health System, Great Neck, NY; [4]CNC/UC-Biotech, Cantanhede, Portugal; [5]Feinstein Inst.Med research and NSLIJ, Manhasset, NY*.

Background: Loss of podocytes play an important role in HIV-Associated Nephropathy (HIVAN). We have recently reported that HIV induces pyroptosis in podocytes both *in vitro* and *in vivo* studies (Am J Pathol 2016, 186). We carried out systems biology approach to analyze genes associated with pyroptosis genes which overlap in HIVAN.

Methods: We used a curated set of 62 genes which make up the NOD-like receptor signaling pathway (KEGG) database. Previously published expression data sets of HIVAN were obtained from gene chip arrays (GEO). We used GSEA software parameters to achieve following variables : 1. Ranking the genes according to those differential expressed values, (ii) identifying the rank positions, (iii) calculate an enrichment score (ES), and (iv) estimating the statistical significance. The pyroptosis activation signature genes were given as input to the UniHI database. To predict the upstream regulators, transcription factors (TFs) and kinases, of genes up-regulated in pyroptosis, we used the Expression2Kinases (X2K) software, Kinase Enrichment Analysis (KEA) software and the Fisher's exact test (to score the kinases).

Results: Gene Set Enrichment analysis showed activation of pyroptosis gene signature in HIVAN. Enrichment score for the pyroptosis gene set was positive in the two independent microarray studies, indicating an activation of the pyroptosis genes in both mouse models (Tg26 and Vpr transgenic) of HIVAN. Notably, genes activated in pyroptosis formed a densely connected network (UniHi); for example association with MAPK, Toll-like receptor signaling pathway, and apoptosis. Network analyses indicated regulation of pyroptosis genes by kinases with a known role in the development of HIVAN. Using X2K, we could identify upstream regulators of pyroptosis genes, which played an important role in pyroptosis.

Conclusions: We identified transcription factors (TFs) that were connected through a network of 'intermediate proteins' by using experimentally reported protein–protein interaction network related to pyroptosis in HIVAN. There are kinases (MAPK1, MAPK3, MAPK8, HIPK2, TGFBR1 and MAPK14) in common with the previously reported top-ten kinases, most enriched in HIVAN.

PUB106

Inhibition of RON Receptor Tyrosine Kinase Attenuated Epithelial Mesenchymal Transition and Fibrosis in Human Proximal Tubular Epithelial Cells Jung Sun Park,[3] Hoon In Choi,[4] Eun Hui Bae,[1] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea; [3]Chonnam National University, GwangJu, Republic of Korea; [4]Chonnam National University, GwangJu, Republic of Korea*.

Background: Receptor tyrosine kinases plays an important role in the pathogenic processes of renal fibrosis. However, pathophysiological roles of recepteur d'origine nantais (RON), in kidney disease have not yet been identified. We investigated whether the activation of the RON and sequence-specific small interfering RNA (siRNA) induced suppression of the RON expression could regulate renal fibrosis, and examined its the underlying molecular mechanisms.

Methods: Stable cell lines for RON overexpression and the transfected cells of siRNA for RON inhibition were developed to understand the renal fibrosis and molecular mechanisms by RON in human renal proximal tubular epithelial (HK-2) cells. The protein expression of epithelial-mesenchymal transition (EMT)-related proteins, N-cadherin, E-cadherin, vimentin and fibrosis-related proteins TGF-β, α-smooth muscle actin (αSMA), fibronectin as well as Smad family and MAPK signal pathway was determined by semiquantitative immunoblotting. Staining of receptor tyrosine kinase family was evaluated using confocal laser microscopy.

Results: RON overexpression increased protein expression of EMT- and fibrosis-related proteins such as N-cadherin, E-cadherin, vimentin, TGF-β, αSMA, and fibronectin in HK-2 cells. Moreover, overexpression of RON increased phophorylation of Smad2/3 and smad-4, and Erk1/2, p38, and Jnk MAPK pathways. In contrast, RON inhibition by siRNA attenuated expression of EMT- and fibrosis-related proteins and decreased phosphorylation of Smad family and MAPK pathway. In addition, the siRNA silencing of RON attenuated expression of IGFR, VEGFR, and PDGFR.

Conclusions: Inhibition of RON may exert anti-fibrotic effect by suppression of EMT by controlling Smad and MAPK signal pathways in HK-2 cells.

PUB107

Small Interfering RNA Targeting of Recepteur d'Origine Nantais Attenuates Platelet-Derived Growth Factors Receptor (PDGFR)-Mediated Renal Fibrosis in Human Proximal Tubular Epithelial Cells Jung Sun Park,[4] Hoon In Choi,[1] Eun Hui Bae,[2] Seong Kwon Ma,[3] Soo Wan Kim.[3] *[1]Chonnam National University, GwangJu, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea; [3]Chonnam National University Medical School, Gwangju, Republic of Korea; [4]Chonnam National University, GwangJu, Republic of Korea*.

Background: PDGFR-α and β are continuously expressed in various kidney cells and PDGFR signaling is associated with inflammatory responses and fibrosis leading to acute kidney disease and chronic kidney disease. This study examined whether the sequence-specific small interfering RNA (siRNA) suppression of the RON expression could attenuate PDGFR- mediated renal fibrosis, and investigated the involved molecular mechanisms.

Methods: In vivo experiments, mouse UUO models were subjected to unilateral ureteral obstruction (UUO) for 7 or 14 days. For the in vitro study, human proximal tubular (HK2) cells were Sequence-specific RON siRNA were transiently transfected in HK-2 cells. The protein and mRNA expression of RON, PDGFR, Collagen I, Collagen IV, CTGF, JAK/STAT, PI3K/AKT, and MAPK was determined by semiquantitative immunoblotting and RT-PCR. Staining of PDGFR a and b and RON was evaluated using confocal laser microscopy.

Results: Protein expression of PDGFR was increased in the kidney of UUO compared with control kidney. Sequence-specific siRNA effectively suppressed the PDGFR α and β expression at both the mRNA and protein levels. Silencing of the RON expression significantly inhibited fibrosis-related proteins such as collagen I, collagen IV, and CTGF. In addition, phosphorylation of JAK/STAT, PI3K/AKT, and MAPK signal pathways were inhibited by transfection of RON siRNA.

Conclusions: Inhibition of RON may exert anti-fibrotic effect by suppression of PDGFR by controlling JAK/STAT, PI3K/AKT, and MAPK signal pathways in HK-2 cells.

CKD in Patients Long-Term after Liver Transplantation Marcin Adamczak, Damian Gojowy, Henryk Karkoszka, Piotr Kubis, Magdalena Gorecka, Andrzej Wiecek. *Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland*.

Background: Liver transplantation (LTx) is the only effective method of treating the end-stage failure of this organ. Coexisting chronic kidney disease (CKD) may worsen

the prognosis of these patients. The aim of this retrospective, single center, observational study was to determine the prevalence and predisposing factors of CKD in patients long-term after LTx.

Methods: Medical records of 118 patients after LTx (age 47.5±12.2 years) who completed 24 months follow-up were studied. Patients were divided into groups depending on the etiology of end-stage liver disease and on immunosuppressive therapy used after transplantation. CKD was diagnosed in patients with eGFR below than 60 mL/min/1.73m^2 or with proteinuria at least for 3 months. Results are presented as means with standard deviation.

Results: CKD has been diagnosed in 33% patients in 12. month after LTx and in 34% patients in 24. month after LTx. One, 12 and 24 months after LTx eGFR were: 79.9±34.0mL/min; 79.5±31.4mL/min; 78.0±31.2 [mL/min/kg/1.73m^2], respectively. Prevalence of CKD was lower in patients that were transplanted due to autoimmune disease (10.8%) compared to viral (41.9%) and alcohol abuse (42.9%) etiology (chi-square: p<0.05; post hoc analyses: autoimmune vs viral; p=0.02; autoimmune vs alcohol abuse; p=0.02). A significant negative correlation was found between blood concentration of tacrolimus and eGFR in 24. month after LTx (p<0.05).

Conclusions: 1. The prevalence of chronic kidney disease in patients after liver transplantation seems to be higher than in the general population. 2. Patients with autoimmune etiology of the liver disease are characterized by better renal function. 3. Treatment with calcineurin inhibitors may have an adverse influence on renal function.

Urinary Phosphorous Excretion and Kidney Disease Progression – A Retrospective Cohort Study David Levy,[1] Matthew K. Abramowitz,[2] Rebeca D. Monk,[1] David A. Bushinsky,[1] Katherine Grzesik,[1] Emily Walters,[1] Matthew Taylor,[1] Susan Messing,[1] Wei Chen.[1] *[1]University of Rochester School of Medicine, Rochester, NY; [2]Albert Einstein College of Medicine, New York, NY.*

Background: High urinary phosphate excretion may lead to tubular damage and has been shown to be associated with progression of CKD. However, there is limited evidence to support this causal relationship. Thus, the goal of the study is to test the hypothesis that high urinary phosphate excretion per GFR predicts kidney disease progression.

Methods: In this retrospective cohort study, we performed a chart review of 143 adult patients who had 24 hour urine supersaturation studies done as a part of the work up for nephrolithiasis between 3/1/2011 and 2/28/2014. We estimated urinary phosphate excretion per GFR by dividing 24 hour urinary phosphate excretion by 24 hour urine creatinine clearance (phos/CrCl). We followed these patients for 2 years to monitor kidney disease progression, which was defined as the rate of eGFR decrease (ΔeGFR per year). We used linear regression to examine the association of urinary phos/CrCl with ΔeGFR per year, while adjusting for participant demographics, diabetes, hypertension and coronary artery disease (CAD) status.

Results: The mean age was 59 ±11years (47% female, 7% black). At baseline, the mean eGFR was 76±24 ml/min/1.73m^2, the median urinary phosphate excretion was 935 (IQR 699, 1207) mg/day and urinary phos/CrCl was 8.9± 3.6 mg/day per ml/min. The mean follow up duration was 24.6±1.8 months and the eGFR declined by 1.5±5.1 ml/min/1.73m^2 per year on average. Participants with higher urinary phos/CrCl were more likely to be older, male, hypertensive, have eGFR<60 ml/min/1.73m^2 and CAD at baseline compared to those with lower urinary phos/CrCl. In the fully adjusted model, with every 1 unit increase in phos/CrCl, the eGFR increased by 0.18 ml/min/1.73m^2 per year on average but this was not statistically significant (CI -0.09, 0.45, p=0.19).

Conclusions: Our findings did not support the hypothesis that urinary phosphate excretion per GFR is an independent predictor for kidney disease progression. The study was limited by small sample size, low severity of kidney disease and short duration of follow up.

Systemic Redox Imbalance in ADPKD and IGAN Terje Apeland,[1] Ambreen Tariq,[1] Grete Jonsson,[1] Audun Slettan,[2] Chathuri P. Karunarathna weeraman,[2] Hans-Peter Marti,[3] Mohammad A. Mansoor.[2] *[1]Stavanger University Hospital, Stavanger, Norway; [2]University of Agder, Kristiansand, Norway; [3]University of Bergen, Bergen, Norway.*

Background: Oxidative stress and redox dysregulation are evident already at an early stage of chronic kidney disease (CKD). We wanted to study some redox biomarkers in autosomal dominant polycystic kidney disease (ADPKD) and IgA nephropathy (IGAN) in CKD stages 1–4.

Methods: Case-control study with two patient groups: ADPKD (n=54) and IGAN (n=58); compared to controls (n=86). Their male/female ratio were 18/36, 49/9 and 47/39, respectively (p<0.0001). Their mean age were 49.9, 49.0 and 46.1 yrs, respectively (p=0.14). Their eGFR were 61, 69 and 91 ml/min, respectively (p<0.0001). AOPP (advanced oxidation protein products, μmol/g protein), MDA (malone dialdehyde, μmol/L) and redox species of the major plasma aminothiols were analysed by HPLC. The Redox ratios were calculated as the ratio of free reduced /free oxidized (not protein bound) aminothiols (μM/μM). Hcy, i.e. homocysteine; CG, i.e. cysteinylglycine, Cys i.e. cysteine. DNA was analysed for single nucleotide polymorphisms (SNP) in ten redox related enzymes.

Results: The IGAN group had higher levels of the oxidation products AOPP and MDA (Table). Patients had lower Hcy and Cys Redox ratios than controls and this was most pronounced in the IGAN group (Table). In the patient group, there were inverse relationship between Cys redox ratio and both AOPP and MDA concentrations (simple regression, p= 0.005 and p= 0.04, respectively). The frequency of SNP *rs4880* of mitochondrial superoxide dismutase (SOD2) was significantly elevated in IGAN patients (data not shown).

Conclusions: Patients with ADPKD and IGAN had evidence of oxidative stress, and this was most pronounced in IGAN group – despite similar eGFR. Cys Redox ratio may be regarded as a measure of oxidant generation.

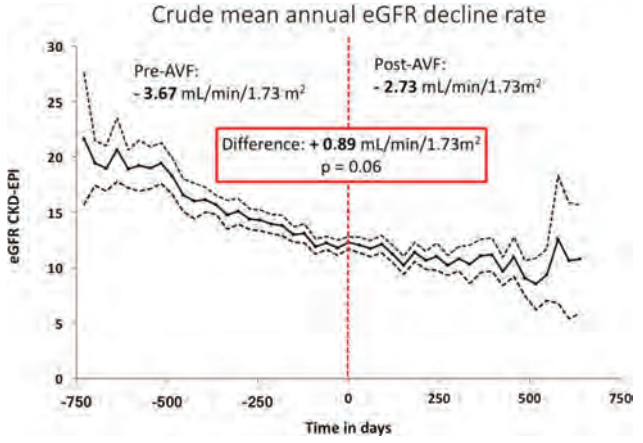
Impact of Arteriovenous Fistula Creation on Estimated Glomerular Filtration Rate Decline in Pre-Dialysis Patients Valerie Benard, Maude Pichette, Jean-Philippe Lafrance, Vincent Pichette, Naoual Elftouh, Louis-Philippe Laurin, Annie-Claire Nadeau-Fredette. *Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Arteriovenous fistula (AVF) is the vascular access of choice for hemodialysis. Recent evidence suggests that AVF creation may slow estimated glomerular filtration rate (eGFR) decline. The study objective was to assess the impact of the AVF creation on eGFR decline, after controlling for key confounding factors.

Methods: This retrospective cohort study included adult patients followed in a single-center pre-dialysis clinic between 1999 and 2017. Patients with a functional AVF for a minimum of six months were followed up to two years pre- and post-AVF creation. Patients with other vascular access, renal transplant and follow-up time exceeding two years without initiation of dialysis were excluded. Estimated GFR trajectory was reported using linear mixed models adjusted for demographic characteristics, comorbidities and medication.

Results: A total of 110 patients were studied: 68.0 (60.0-74.6) years; 48% female; 86.4% Caucasians; 59.6% with diabetes. The median eGFR at time of AVF creation was 12.4 (11.0-13.7) mL/min/1.73m^2. The annual eGFR decline tended to be lower after AVF creation (-3.65 vs. -2.73 mL/min/1.73m^2; p=0.06) (Figure 1). In adjusted analysis, the predicted eGFR was higher after AVF creation compared to before (β 0.93, 95% CI 0.55-1.31, p<0.001) when taking into account the monthly adjusted decline (-0.36 mL/min/1.73m^2). There was also a significant interaction between time and AVF creation such that eGFR decline was attenuated more each month after AVF creation (β 0.17, 95% CI 0.12-0.21, p<0.001).

Conclusions: AVF creation was associated with a time-dependent reduction of eGFR decline in pre-dialysis patients, after adjustment for potential confounders. Further prospective studies should evaluate AVF as a potential strategy to prevent progression of chronic kidney disease.



PUB113

An Endogenous Na Pump Inhibitor, Marinobufagenin (MBG), Is a Marker of CKD Severity Kristen L. Nowak,[3] Michel Chonchol,[3] Mikaela R. Malaczewski,[3] Heather Farmer-Bailey,[3] Wen Wei,[2] Christopher H. Morrell,[1] Alexei Y. Bagrov,[2] Olga Fedorova.[2] *[1]Loyola University Maryland, Baltimore, MD; [2]National Institute on Aging, Baltimore, MD; [3]University of Colorado Anschutz Medical Center, Aurora, CO.*

Background: High levels of an endogenous steroidal Na pump inhibitor MBG have been reported in CKD. MBG is a pro-hypertensive, pro-fibrotic, and implicated in cardiovascular diseases. We hypothesized that higher circulating MBG levels are associated with vascular dysfunction and relate to CKD severity.

Methods: Plasma MBG (competitive immunoassay), alkaline phosphatase (ALP) and systolic blood pressure (SBP) were measured in 11 patients with stage 3/4 CKD (9M/2F; 63±11 yrs), 8 chronic hemodialysis patients (7M/1F; 59±11 yrs), and 10 healthy controls (6M/4F; 45±17 yrs). Brachial artery flow-mediated dilation (FMD_{BA}), aortic pulse-wave velocity (aPWV), carotid intimal medial thickness (cIMT), and carotid/peripheral SBP were assessed in stage 3/4 CKD patients and controls (Table).

Results: Plasma MBG levels increased in patients with stage 3/4 CKD and in hemodialysis compared to controls (Table). Plasma MBG correlated positively with carotid and peripheral SBP, aPWV, cIMT, and ALP and negatively with FMD_{BA}. After adjustment, plasma MBG remained significantly associated with higher ALP and SBP.

Conclusions: Elevated plasma MBG in CKD and dialysis patients is associated with higher ALP, a marker of a tissue destruction and fibrosis, and with progressive kidney function decline. As a pro-hypertensive and pro-fibrotic factor, MBG may independently contribute to cardiovascular risk, be useful as a marker of severity of CKD, and represent a CKD therapeutic target.

The Effect of the Complement C3a on the Podocyte Epithelial Mesenchymal Transition and Its Mechanism with Adriamycin Nephropathy in Mice Yi Chen,[1] Jianxin Wan,[2] Jiong Cui.[2] *[1]Department of Nephrology, The First Affiliated Hospital of Fujian Medical University, FuZhou, China; [2]the First Affiliated Hospital of Fujian Medical University, FuZhou, China.*

Background: Podocyte EMT is the early reversible process of podocyte damage reaction. Podocyte have perfect C3a receptors, C3a can lead to podocyte damage, however there has been scarce research on the relationship between C3a and Podocyte EMT. we study the relationship between C3a and podocyte EMT in adriamycin nephropathy at mice.

Methods: 30 male BALB/c mice were randomized into control group, ariamycin nephrpathy group, ariamycin +3mg/kg C3a receptor antagonist (SB290157), ariamycin+10mg/kg SB290157, ariamycin +30mg/kg SB290157. On days 7, 14 and 21 after the intervene, 24-urine was collected to analyze the urine proteins. The renal tissues were obtained on 21 days to observe the podocyte using electron microscopy; the deposition of C3 on the podocyte were examined by double immunohistochemistry ;the expression of nephrin, podocin, α-SMA, FSP-1, ILK, snail were measured by immunohistochemistry, quantification of nephrin, α-SMA, snail protein was carried out by western blot.

Results: Compared with control group, in ADR group, the diffuse effacement of podocyte foot process was observed, the urine protein increased, the deposition of C3 on podocyte was increase, α-SMA, FSP-1, ILK, Snail, α-actinin-4 increased and nephrin, podocin significantly reduce, the α-SMA, snail proteins expression were increased and the nephrin podocin exprsssion reduced (P<0.05).10mg/kg SB290157 can relieve the injure of podocyte foot process and reduce 24-h urinary protein, the deposition of C3 and the expression of α-SMA, FSP-1, ILK, Snail and α-actinin-4 of podocyte and increase the expression of nephrin and podocin (P<0.05).

Conclusions: 1. There is the deposition of C3 on the podocyte in adriamycin nephropathy at mice, SB290157 can suppress the process of podocyte epithelial-mesenchymal transition in adriamycin nephropathy at mice, which indicate complement C3a can induce podocyte EMT in vivo. 2. The expression of ILK and snail were increased in adriamycin nephropathy at mice and SB290157 can reduce its expression, which indicate the important role of the ILK signing pathway in the process of complement C3a induce podocyte EMT.

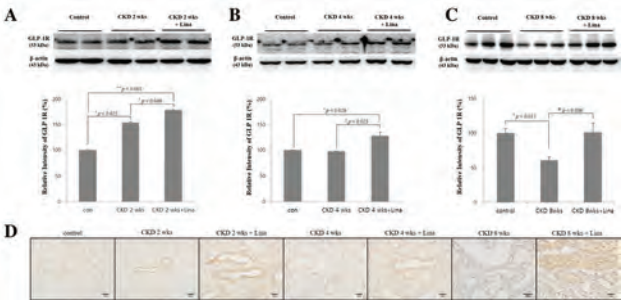
Proximal Tubular GLP-1 Receptor Activity Is Increased in CKD Rat with Myocardial Infarction Which Is Enhanced by Linagliptin Soon Kil Kwon, Hye-Young Kim, Sun Moon Kim. *Chungbuk National University Hospital, Cheongju, Republic of Korea.*

Background: Chronic kidney disease (CKD) is an important risk of ischemic heart disease. Glucagon like peptidase-1 (GLP-1) is an incretin hormone that enhances insulin secretion and GLP-1 agonist is used for glycemic control in patient with type 2 diabetes. Renal GLP-1 activity is increased in the chronic kidney disease, also GLP-1Receptor (GLP-1R) activation is related with vascular protection. We investigated difference of renal GLP-1 activity in the CKD rat with ischemic reperfusion and MI model and the change of GLP-1 receptor activity after DPP-4 inhibitor.

Methods: Sprague Dawley rat was used for CKD model with 5 each group with 5/6 nephrectomy and shame operation. For myocardial ischemia, left anterior descending coronary artery was ligated 2 weeks after 5/6 nephrectomy. 30 Minutes after ligation, we released ligated vessel for reperfusion and kept ligation for MI. CKD and MI rat were treated with oral linagliptin, renal cortical and myocardial GLP-1R was measured via IHC and Western blot (WB).

Results: Renal cortical GLP-1R activity was increased 2 wks after 5/6 nephrectomy; however, it decreased to control levels 4 wks and 8 wks after surgery. Linagliptin treatment enhanced GLP-1R expression in the renal cortex (Fig). Immunohistochemistry findings were similar with WB. Peak intensity was noted 2 weeks later, then decreased after 4 wks and 8 wks after surgery. GLP-1R in CKD with MI and CKD with ischemic reperfusion were significantly increased. WB of GLP-1R was increased in the ischemic reperfusion rats, but decreased in CKD-MI model. However, it was increased in infarcted area after linagliptin. The 5/6 nephrectomy with MI reperfusion lead to dephosporylation Akt, ERK1/2 and decreased Bcl-2, whereas linagliptin treatment reversd.

Conclusions: Expression of GLP-1R in kidney has a role in renal disease progression and GLP-1R activity may provide reno-protective effects independent of its hypoglycemic effects. Linagliptin can increase renal GLP-1R in CKD with MI rat model.



Expression of GLP-1R in the CKD rat.

PUB116

Association between Serum Na-Cl Level and Renal Function Decline in CKD Yuichi Maruta,[1,4] Takeshi Hasegawa,[1,5] Hiroki Nishiwaki,[1] Fumihiko Koiwa,[1] Enyu Imai,[2] Akira Hishida.[3] *[1]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [2]Nakayamadera Imai Clinic, Takarazuka, Japan; [3]Yaizu City Hospital, Yaizu, Japan; [4]Department of Medicine, Showa University Koto Toyosu Hospital, Tokyo, Japan; [5]Office for Promoting Medical Research, Showa University, Tokyo, Japan.*

Background: Metabolic acidosis, which reduces the serum bicarbonate level, contributes to the progression of chronic kidney disease (CKD). Total carbon dioxide (TCO_2) has spread as the direct and standard marker for the metabolic acidosis, but not popular in Japan. The difference between serum sodium and chloride (Na-Cl) may theoretically, predict serum bicarbonate levels. Therefore, the aim of our study was to evaluate Na-Cl level as a risk factor for a decline in renal function among patient in the Chronic Kidney Disease Japan Cohort (CKD-JAC) study.

Methods: The association between low Na-Cl concentration (<34 mmol/L) and renal function decline was evaluated among 1515 patients with a CKD stage G3a-4. Patients were free from malignancy and hypoalbuminemia at baseline. Predictive variables were identified using Cox regression analysis, with corresponding hazard ratios (HR) estimated after adjusting for the following covariates: age, sex, diabetes mellitus (DM), DM-associated nephropathy, cardiovascular disease, use of angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin II receptor antagonists (ARBs), cigarette smoking, body mass index, serum albumin, systolic blood pressure, urine albumin/creatinine ratio, and CKD stage. The primary endpoint was defined as a composite of initiation of any renal replacement therapy or a significant decline in eGFR (mL/min/1.73 m^2/year) from baseline. In addition, to assess which patients are more susceptible to Na-Cl, two of subgroup analyses were performed according to the CKD stages and hemoglobin concentration.

Results: A decline in renal function was identified in 289 patients. The risk for decline was higher among patients with a low serum Na-Cl level (HR, 1.428, adjusted for covariates). Subgroup analysis identified the effect of a low Na-Cl level to be stronger among patients with CKD stage G4 and those with anemia.

Conclusions: Na-Cl is easy to calculate and is an independent predictor of CKD progression, especially among patients with CKD stage G4 and those with anemia.

PUB117

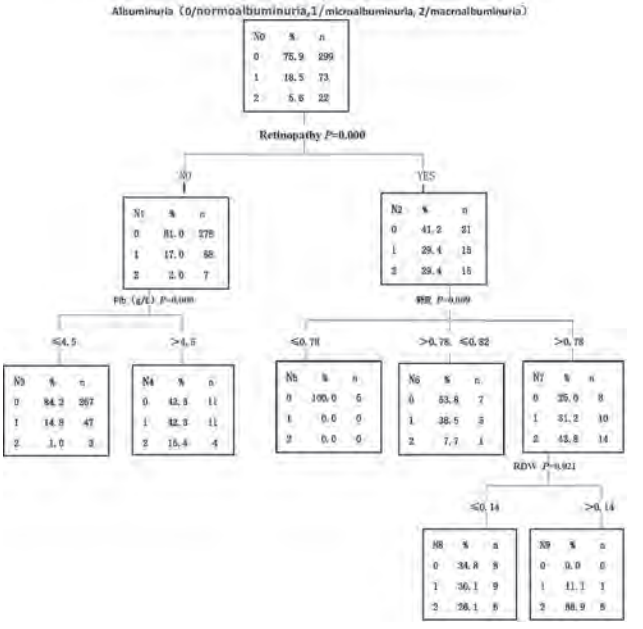
Classification Tree Model Analysis on Related Factors of Different Stages of Kidney in Type 1 Diabetic Patients Wenbo Zhao,[2] Hui-qun Li,[1] Lin Sun,[2] Cong Sun,[2] Wenhao Yang.[2] *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: To analyze the related factors of microalbuminuria and macroalbuminuria In type 1 diabetes mellitus (DM) by the classification tree model, and to screen the high risk population of Diabetic Kidney Disease.

Methods: A total of 394 patients with type 1 diabetes were enrolled in our hospital from 2008 to 2015. According to glomerular filtration rates and urine albumin quantification, the patients were divided into type 1 diabetes group (299 cases), microalbuminuria group (73 cases) and macroalbuminuria group (22 cases). The classification tree model was used to analyze the related factors to the different stages of proteinuria, and the high risk population was screened by node gain analysis.

Results: Four important explanatory variables were screened out by the classification tree model from the 23 candidate variables related to early renal damage, including retinopathy, fibrinogen waist-hip ratio (WHR), red blood cell distribution width (RDW). Retinopathy was an important factor of DKD. The probability of macroalbuminuria in retinopathy and WHR>0.82 group was 43.8%, and if at the same time RDW>0.14, the probability of macroalbuminuria was 88.9%.

Conclusions: The classification tree model can analyze the major influential factors of the different stages of proteinuria in type 1 diabetic patients effectively, to identify the characteristics of high-risk populations.



PUB118

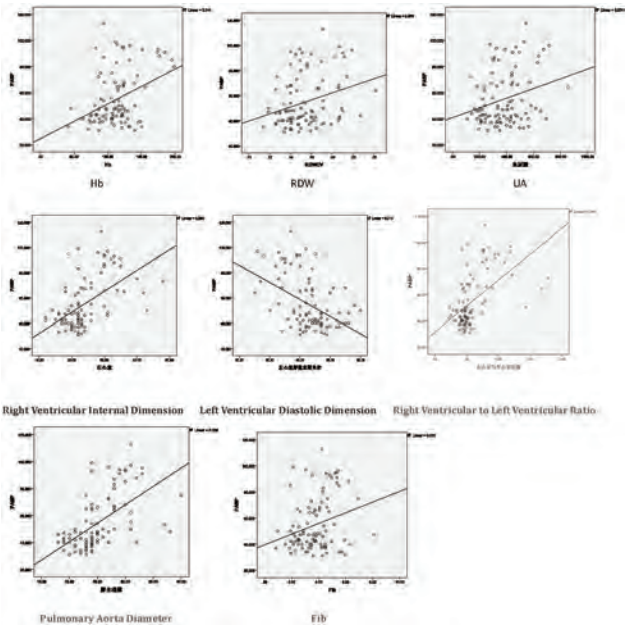
Clinical Features of Patients of Pulmonary Hypertension Associated with Lupus Glomerulonephritis Wenbo Zhao,[2] Hui-qun Li,[1] Wuyue Han,[2] Xiaomei Wu,[2] Cong Sun.[2] *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: The study was intended to analyze the clinical characters and relative factors referring to SLE related PAH in different stage.

Methods: We've studied 99 SLE patients combined with PAH and analyzed the results of hemoglobin level, platelet count, red cell distribution width (RDW), uric acid level, Fib, kidney function and cardiac ultrasonic examination, in order to understand the difference and relativity of these data among different degrees of PAH.

Results: Among all the 99 cases based on the grading scale of PAH, 58 patients had mild PAH, 20 had middle PAH and 21 had severe PAH. Result showed that Hb(r=0.379, P=0.000), RDW(r=0.294, P=0.003), Fib(r=0.265, P=0.008), blood uric acid(r=0.272, P=0.006), right ventricle internal dimension (RVID)(r=0.539, P=0.000), ratio of RVID to right ventricle internal dimension (LVID)(r=0.538, P=0.000) and pulmonary artery diameter(r=0.582, P=0.000) were positively related to the PASP level. LVID(r=-0.458, P=0.000) indicated the opposite result. Left atrial diameter(r=-0.160, P=0.114) and EF (r=-0.072, P=0.482)value were not related to the PASP level. There were significant differences in Fib (P=0.018)and PASP (P=0.011)of Logistic Analysis between the groups with or without renal damage.

Conclusions: Our study presented that the incidence of SLE combined with PAH was the highest. And higher level of Hb, RDW, blood uric acid, Fib, RVID and larger ratio of RVID to LVID and pulmonary artery diameter led to severer PAH. PASP was a related risk factor for lupus renal damage. PASP may be the main factor affecting the right ventricular function in patients with SLE. RDW, serum uric acid and Fib may be predictive factors of SLE related PAH and prognosis.



PUB119

Relationships of 24-Hour Urinary Phosphate Excretion and Serum Phosphate with Clinical Outcomes in CKD: From the Korean Cohort Study for Outcome in Patients with Chronic Kidney Disease (KNOW-CKD) Hong sang Choi,[3] Ha yeon Kim,[2] Chang Seong Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[2] Kook-Hwan Oh,[4] Curie Ahn,[4] Soo Wan Kim.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea; [3]Chonnam national university hospital, Gwang-ju, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Recent studies suggest that dietary phosphate intake is only weakly linked to its serum concentration, and the relationship the phosphate intake and clinical outcomes is not yet well studied. We investigated the relationships of dietary phosphate intake and serum phosphate with clinical outcomes in chronic kidney disease(CKD) patients.

Methods: We collected the data of 2238 CKD stage 1-5 non-dialysis patients from a prospective cohort study (KNOW-CKD). A renal event is defined by a >50% decrease in estimated glomerular filtration rate (eGFR) from the baseline values, doubling of serum creatinine concentration, or end stage renal disease. Cardiovascular event is defined as myocardial infarction, coronary revascularization, stroke and new onset or aggravation of congestive heart failure. We used cox proportional hazards models to assess the associations between baseline 24-hour urine phosphate excretion (24h-UPE) and serum phosphate concentration with clinical outcomes.

Results: Among the 2238 participants in this study, the mean age was 53.68 ± 12.24 years (range 20–75), 61.2% were male. 24-UPE was not significantly correlated with serum phosphate concentrations (r=0.016, p=0.484). Models were adjusted for age, sex, primary renal disease, eGFR, 24-hour urine protein and nitrogen excretion, body mass index, smoking, use of phosphate binder, and medical history of diabetes, hypertension and coronary artery disease. The lowest quartile of 24h-UPE (11.4-400 mg/day) was associated with renal (hazard ratio [HR] 1.734, 95% confidence interval [CI] 1.191-2.524, p=0.004) and total event (HR 1.575, 95% CI 1.146-2.165, p=0.005) when compared with third quartile of 24h-UPE (579-745 mg/day) after adjustment for confounders. The highest quartile of serum phosphate (4.2-8.8 mg/dL) was associated with renal (HR 1.743, 95% CI 1.128-2.695, p=0.012) and total event (HR 1.949, 95% CI 1.355-2.804, p<0.001) after fully adjustment.

Conclusions: Low dietary phosphate intake assessed by 24h-UPE and high serum phosphate concentration was associated with poor clinical outcome in CKD patients. Low urinary phosphate excretion and high serum phosphate concentration should be considered as important prognostic factor in CKD.

PUB120

Higher Fluid Intake Is Associated with Improved Renal and Survival Outcomes in Hypertensive Kidney Disease Robert C. Hartley,[2] Elena A. Mylroie,[2] Kalani L. Raphael.[1,2] *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: Higher fluid intake reduces kidney injury in animal models of CKD. The relationship between fluid intake and outcomes in persons with CKD is unclear. We evaluated whether urine volume, as a marker of fluid intake, is associated with death or dialysis in the African American Study of Kidney Disease and Hypertension.

Methods: We performed Cox regressions in 1093 AASK participants who submitted 24-hr urine samples at baseline to determine the association between urine volume and the composite outcome of death or dialysis. Participants were categorized into <1.5 L, 1.5 to <2.5 L, and ≥2.5 L urine volume per day groups. Models were adjusted for age, gender, randomized group, BMI, SBP, measured GFR, proteinuria, diuretic and/or ACE-i use, heart disease, and urine osmolality. Those with the lowest urine volume served as the reference. We also evaluated the association between every 500 mL higher urine volume with the composite outcome and performed cubic spline regression models using similar adjustment.

Results: The mean age was 54 yrs, 61% male, mean GFR 46 mL/min/1.73m^2, mean proteinuria 326 mg/g, and 64% used diuretics. Mean urine volume was 2.2 L (SD 0.9), and 232, 500, and 361 had urine volume <1.5 L, 1.5 to <2.5 L, and ≥2.5 L, respectively. The hazard ratios of death or dialysis were 0.68 (95% CI, 0.51-0.91) and 0.88 (95% CI, 0.68-1.13) for those with urine volume ≥2.5 L and 1.5 to <2.5 L, respectively. Each 500 mL higher urine volume was associated with 9% lower risk of death or dialysis (95% CI, 0.85-0.96). Urine volume was linearly and inversely associated with these outcomes (Figure).

Conclusions: Higher 24-hour urine volume was associated with lower risk of mortality or dialysis among African Americans with hypertensive kidney disease. An interventional study to determine whether increasing fluid intake improves outcomes in hypertensive CKD should be considered.

PUB121

Stable Isotopic Surrogates with Urinary Proteomics for Assessing Renal Tissue Damage in CKD Andrew Z. Wei, Pan Liu, Tomokazu Souma, Ellen Brooks, Craig B. Langman, Jing Jin. *Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Background: Pathologic proteinuria is the hallmark of most chronic kidney diseases (CKD), including congenital anomalies of the kidney and urinary track (CAKUT) and focal segmental glomerulosclerosis (FSGS). Often, functional kidney loss is evaluated in part by albuminuria. However, lab tests that can identify kidney-specific markers of ongoing tissue damage for the prediction of CKD progression remain unavailable. We report a novel urinary proteomic approach aimed at detecting urine proteins reflective of renal tissue damage by employing stable isotope labeling with amino acids in cell culture (SILAC, or SILAM when whole mouse serum is radiologically labelled) followed by qMS for substantiating and quantifying urine proteins.

Methods: Two CKD stage-matched urines from children with either CAKUT or FSGS were obtained with IRB approval. One patient had nephrotic syndrome secondary to biopsy proven FSGS, while the other had CAKUT associated with a neurogenic bladder. Both had significant proteinuria. To evaluate the differences in cell-derived vs. plasma-derived protein contents in CAKUT and FSGS urine, each was mixed with either 6/8 SILAC-labeled HEK293 lysate or 0/6 SILAM-labeled mouse serum. Following digestions with either trypsin or lys-C respectively, the resulting peptide fragments were analyzed by LC-MS/MS and mapped to the known human proteome.

Results: FSGS vs. CAKUT urines differed in the number overlapping proteins with the SILAC cell extract: 16 vs. 52 of cell-derived proteins, respectively, whereas serum-derived urinary proteins were more balanced (28 vs. 29 between FSGS and CAKUT). Cellular proteins that were detected in both FSGS and CAKUT urines were also markedly different in their concentrations even after being normalized against the SILAC standards. For instance, Actin that was identified in both had an abundance that was 40 times higher in CAKUT, consistent with the gross anatomical damage typically being worse in CAKUT at the late stages of CKD.

Conclusions: Our pilot using the SILAC methodology demonstrated important differences in tissue derived proteins in the urine of two subjects with CKD (FSGS vs. CAKUT). We hope that this pilot will eventually enhance the future detection of ongoing kidney tissue damage so to direct clinicians toward targeted therapeutics to treat category and tissue-specific mechanisms of CKD progression.

PUB122

The Prediction of Systolic Blood Pressure at Representative Time-Points for 24 Hour Mean Systolic Blood Pressure on 1-Year Renal outcomes in Diabetic CKD Patients

Jiwon Ryu,[1] Sejoong Kim,[6] Ran-hui Cha,[4] Hajeong Lee,[7] Jung Pyo Lee,[5] Myung jin Choi,[2] Young rim Song,[3] Yon Su Kim.[7] *[1]Cheju Halla Hospital, Seoul, Republic of Korea; [2]Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea; [3]Hallym Univ. Sacred Heart Hospital, Anyang, Republic of Korea; [4]National Medical Center, Seoul, Republic of Korea; [5]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [6]Seoul National University Bundang Hospital, Seongnam, GyeongGi-Do, Republic of Korea; [7]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Control of blood pressure(BP) in diabetic chronic kidney disease(CKD) patients is important in preventing target organ damage. 24-hour ambulatory BP measurement(ABPM) is the best known in BP monitoring, but it is not easy to use. APrODiTe study suggested systolic blood pressure(SBP) of specific time-points that can represent the 24-hour mean SBP(mSBP) were 7:00AM and 9:30PM in chronic kidney disease(CKD) patients. We followed the study 1 year later and evaluated whether SBPs at these time-points can predict renal outcomes after 1 year such as 24-hour mSBP in diabetic CKD patients.

Methods: We recruited 125 diabetic CKD patients with from 4 centers in Korea 1 year later. Baseline SBPs at 7:00AM and 9:30PM were evaluated whether they have predictive correlation for the change of renal function, proteinuria after 1 year compared with 24-hour mSBP. The renal outcomes were an increase in random urine protein/creatinine ratio than baseline value or estimated glomerular filtration rate(eGFR) deterioration which means a decrease in eGFR ≥ 5 (ml/min/1.73m²).

Results: The followed mSBPs at 7:00AM, 9:30PM and 24-hour mSBP were 135.4 ± 26.0 mmHg, 147.7 ± 131.8 mmHg and 132.9 ± 26.0 mmHg, they did not changed significantly from baseline mSBPs (paired t-test, p= 0.861; p= 0.537; p = 0.294). The SBP at 7:00AM correlated with eGFR deterioration in univariate analysis, after multivariate analysis, SBP at 7:00AM has significant association with eGFR deterioration (odds ratio: 1.026; 95% confidence interval (CI): 1.111-1.052; P = 0.046). In an association with proteinuria progression, SBP at 7:00AM has a correlation in univariate analysis, but in multivariate analysis, SBPs at any time-points has no association with proteinuria progression. In subgroup analysis, the association between SBP at 7:00AM and eGFR deterioration persisted in CKD stage 3-5 patients (odds ratio: 1.037; 95% CI: 1.005-1.070; P = 0.024).

Conclusions: These data suggested that the SBP at 7:00AM may have better prediction on 1-year eGFR deterioration in diabetic CKD patients, especially in subgroup of CKD stage 3-5 patients. Whereas SBPs at any time-points may not be correlated to 1-year proteinuria progression in diabetic CKD patients.

PUB123

Incidence of CKD and Risk Attributable to Cardiovascular Risk Factors in Two Asian Populations

Charumathi Sabanayagam,[2,3] Weng Kit Lye,[3] Kunihiro Matsushita,[1] Ecosse L. Lamoureux,[2,3] Ching-Yu Cheng,[2,3] Tien Yin Wong.[2,3] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, AL; [2]Singapore Eye Research Institute, Singapore, Singapore; [3]Office of Clinical Sciences, Duke-NUS Medical School, Singapore, Singapore.*

Background: Prevalence of chronic kidney disease (CKD) is escalating in Asian populations due to ageing and increasing prevalence of diabetes and hypertension. CKD shares many of the cardiovascular risk factors. We compared the incidence, risk factors and impact of CKD in two Asian populations with high burden of diabetes.

Methods: We analysed data from two cohorts consisting of Malay (n=1517) and Indian (n=1743) adults aged 40-80 years and free of CKD at baseline: The Singapore Malay Eye Study (SiMES, 2004-06; SiMES-2, 2011-13); the Singapore Indian Eye study (SINDI, 2007-09; SINDI-2, 2013-15). Incident CKD was defined as an (estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m²+25% decrease in eGFR at follow-up. Risk factors assessed included age, sex, education, smoking, diabetes, hypertension, dyslipidemia, cardiovascular disease, overweight/obesity, antihypertensive medication use, systolic blood pressure, HbA1c, C-reactive protein, total and HDL cholesterol and baseline eGFR. Population-attributable risks (PAR) were computed for significant risk factors.

Results: The 6-year incidence of CKD was 6.8% in Malays and 3% in Indians. At baseline, 25% of Malays and 34.7% of Indians had diabetes; 59.7% and 53.9% had hypertension. In multivariable models, among the continuous predictors, age, systolic BP, HbA1c, and lower baseline eGFR in both populations, and lower total cholesterol in Malays were significantly associated with CKD. Among the categorical predictors, diabetes (hazard ratio [95% confidence interval] = 3.47 (1.82-6.63), hypertension (3.13 [1.17-8.4]), overweight/obesity (1.79 [1.05-3.11]) in Malays and diabetes alone in Indians (2.99 [1.27-7.02]) were associated with CKD. Hypertension was not associated with CKD in Indians (1.86 [0.55-14.94]). Diabetes (13%), hypertension (7%) and overweight/obesity (3%) contributed to 23% of PAR of CKD in Malays and diabetes contributed to 4.7% of CKD in Indians.

Conclusions: Incidence of CKD in Asian Malays and Indians were similar to that of Western populations. Although the prevalence of diabetes was higher in Indians, contribution of diabetes to CKD was higher in Malays compared to Indians.

PUB124

APOL1 Genotype, Serum Bicarbonate, and Clinical Outcomes in AASK

Man Li,[5] Michael S. Lipkowitz,[1] Cheryl A. Winkler,[3] Lawrence J. Appel,[2] Kalani L. Raphael.[4,5] *[1]Georgetown University Medical Center, Washington, DC; [2]Johns Hopkins Medical Institutions, Baltimore, MD; [3]NCI, NIH, Frederick National Laboratory, Frederick, MD; [4]VA Salt Lake City Health Care System, Salt Lake City, UT; [5]Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT.*

Background: *APOL1* high-risk genotype and metabolic acidosis are individually associated with CKD progression in African Americans. *APOL1* is produced by proximal tubule cells (PTC), but its function in PTC is unclear. PTC are critically important in renal acid-base regulation. We evaluated whether the association between acidosis and outcomes in CKD is modified by *APOL1* high-risk genotypes.

Methods: We evaluated this in 639 African American Study of Kidney Disease and Hypertension (AASK) participants using multivariate Cox models (adjusted for demographics, measured GFR, proteinuria, BMI, net endogenous acid production, and percentage of European ancestry estimated by ancestry informative markers) with an interaction term and stratification by *APOL1* status. Serum bicarbonate groups were grouped as <22, 22-28 (referent), and >28 mEq/L and the primary outcome was the composite of doubling serum creatinine, dialysis, or death.

Results: Mean age was 53.5 years, 61% were women, mean GFR was 47.5 ml/min/1.73 m², mean bicarbonate was 25.2 mEq/L, 146 (22.8%) had *APOL1* high-risk genotype (two copies of the high-risk alleles). Over a mean follow-up of 4.1 years, 315 (39.7%) participants had doubling serum creatinine, dialysis, or death. The prevalence of low bicarbonate is 12.4% in *APOL1* low-risk group and 15.1% in *APOL1* high-risk group. Results of the association of baseline bicarbonate levels with the composite outcome stratified by *APOL1* status are shown in Table 1. The interaction between *APOL1* and low bicarbonate was not significant p=0.98.

Conclusions: The association between acidosis and poor outcomes in African Americans with hypertensive kidney disease is not modified by *APOL1* risk status.

Table 1. Association of baseline serum bicarbonate with the hazard of doubling serum creatinine, dialysis, or death by APOL1 status.

	APOL1 high-risk genotype (N=493)	APOL1 low-risk genotype (N=146)
Serum bicarbonate (mEq/L)	Hazard Ratio (95% CI)	Hazard Ratio (95% CI)
Normal: 22-28	REF	REF
Low: <22	1.46 (0.85, 2.51)	1.32 (0.90, 1.94)
High: >28	1.12 (0.52, 2.41)	1.31 (0.90, 1.92)

PUB125

Dyslipidemia and Renal Damage during Pregnancy in Women with Chronic Renal Disease

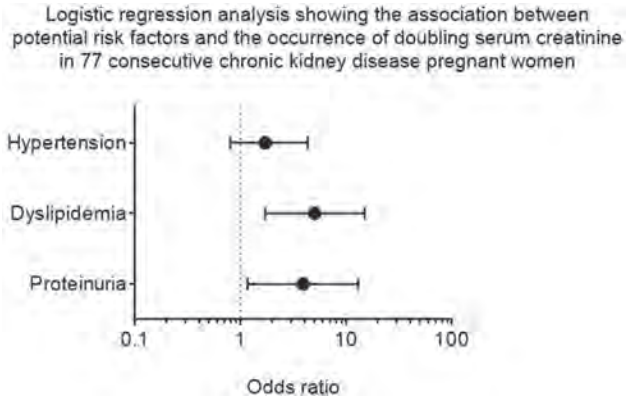
Amelia R. Bernasconi,[2] Liliana S. Voto,[1] Alicia M. Lapidus,[3] Rosa A. Waisman,[5] Ricardo M. Heguilen.[4] *[1]Obstetrics, Hospital Juan A Fernandez, Buenos Aires, Argentina; [2]Medicine, Hospital Juan A Fernandez, Buenos Aires, Argentina; [3]Obstetrics, Hospital J. A. Fernandez, Buenos Aires, Argentina; [4]Nephrology, Hospital Juan A Fernandez, Buenos Aires, Argentina; [5]Obstetrics, Juan A Fernandez, Buenos Aires, Argentina.*

Background: Cardiovascular disease (CVD) is the leading cause of death in women (W). The prevalence of hypertension (HTN) and dyslipidemia (DLP), is high among fertil W. HTN and proteinuria (Uprot) during pregnancy (P) are associated with adverse outcomes such as preeclampsia, low birth weight, etc. DLP may also have adverse effects on the fetus and mother. P W with renal disease (CKD) are at a higher risk of deterioration of GFR. The primary objective of this study was to evaluate the potential association of DLP and the occurrence of doubling serum creatinine (2xScr) from pre-P values.

Methods: Case-control study aimed at identifying risk factors worsening renal function in P W suffering from CKD. Uni and multivariate logistic regression was used to determine whether 2xScr was a dependent variable on the following potential covariates: HTN, overweight, the presence of pre-P conditions such as DLP, hyperuricemia, or Uprot, Odds ratios with the 2-sided 95% CI were reported. p values < 0.05 were considered statistically significant.

Results: Data from 77 consecutive CKD, P women recruited during a period of 3 ½ years were included in the analysis. 29 of them doubled Scr before delivery. Both groups were similar in age, BW, baseline Scr, estimated GFR; systolic or diastolic BP; uric acid levels and gestational age at the time of first visit but those who 2xScr had higher TGs levels (107.8 + 6.5 vs. 88.8 + 4.2 p< 0.01); total cholesterol (219.5 ± 8.6 vs 165.5 + 6.3 p< 0.01) and LDL levels (156.7 + 6,0 vs 115.9 + 3.1p< 0.01) or Uprot (0.7 ± 0.1 vs. 0.4 ± 0.1. Results from the logistic regression analysis is shown in Figure 1

Conclusions: DLP arise as a relevant factor associated with worsening renal function in P W with CKD. Given the health importance of identifying risk factors among CKD fertil W, DLP screening in this population is needed and aggressive treatment should be considered pre or during P in this population.



PUB126

The Efficacy of Hemodialysis in Preventing Contrast-Induced Nephropathy in Patients with Pre-Existing Renal Insufficiency: A Single Center Experience Panagiota E. Giannou,[2] Athanasia Kapota,[2] Nikolaos Magkas,[1] Feretou Katerina,[3] Aglaia Chalkia,[2] Dimitrios Petras.[2] *[1]1st Cardiology Clinic Hippokration Hospital, ATHENS, Greece; [2]Nephrology Department Hippokration Hospital, Athens, Greece; [3]Cardiology Department Hippokration Hospital, Athens, Greece.*

Background: Contrast-induced nephropathy (CIN) is defined as the impairment of renal function—measured as either a 25% increase in serum creatinine (sCr) from baseline or a 0.5 mg/dL (44 μmol/L) increase in absolute sCr value—within 48-72 hours of intravenous contrast administration. The reported incidence of CIN varies widely, largely depending upon the presence or absence of risk factors, primarily including underlying chronic kidney disease (CKD). The risk is also higher among patients with heart failure or hemodynamic instability. There are an increasing number of reports that CIN is associated with significant in-hospital and long-term mortality. The aim of the current study was to assess whether prophylactic immediate hemodialysis (HD), after intravascular contrast media administration in patients with pre existing renal insufficiency, could be used in order to preserve residual renal function.

Methods: 39 patients (30 men-9 women) who underwent procedures with administration of intravascular contrast media, were studied. Subjects had a mean value of eGFR 22.5 ml/min/1.73m^2, mean age 75.7 years and mean value daily diuresis 1.2 lt. In all patients a central venous catheter was placed and a 3hr Hemodialysis (HD) session was performed, 2 hours after contrast media administration. SerumCr levels were measured at the day of contrast media administration and 3 days after HD.

Results: None of the patients had any deterioration of their sCr value or of their daily diuresis, while no other complications were noticed during HD session.

Conclusions: In view of the limited benefit of prevention remedies such as hydration, bicarbonate and NAC, dialysis may be considered a solution. Scattered studies indicate that in patients with CKD who are undergoing coronary angiography, prophylactic HD can improve renal outcome. There are insufficient data to support the use of prophylactic HD following contrast exposure, so more multicenter, randomized studies on the subject are needed. Nevertheless a better collaboration of nephrologists and other physicians who refer patients for contrast procedures is a necessity.

Urinary Peptide Biomarkers of CKD in Dogs Valerie Brunchault,[1] Lena Pelander,[2] Benedicte Buffin-Meyer,[1] Julie Klein,[1] Benjamin Breuil,[1] Petra Zürbig,[3] Pedro Magalhães,[3] William Mullen,[4] Joost Schanstra,[1] Jonathan Elliott,[6] Harriet M. Syme,[5] Jens Häggström,[2] Ingrid Ljungvall.[2] *[1]INSERM U1048, Toulouse, France; [2]Swedish University of Agricultural Sciences, Uppsala, Sweden; [3]Mosaiques Diagnostics GmbH, Hannover, Germany; [4]University of Glasgow, Glasgow, United Kingdom; [5]Royal Veterinary College, Hatfield, United Kingdom; [6]The Royal Veterinary College University of London, London, United Kingdom.*

Background: Chronic kidney disease (CKD) is a clinically important cause of morbidity and mortality in dogs. This heterogeneous disease is insidious in onset and often not recognized until late in the course of disease. Currently available tools lack sensitivity to identify CKD in dogs.

Methods: We have analyzed the urinary peptidome of dogs with CKD with the aim to evaluate if capillary electrophoresis coupled to mass spectrometry (CE-MS)-based urinary peptidome analysis can discriminate healthy dogs from dogs with CKD with high sensitivity and specificity.

Results: Analysis of the urinary peptidome with CE-MS demonstrated the presence of ~5400 peptides in dog urine. Comparison of 15 healthy and 15 dogs with CKD identified 133 differentially excreted peptides after correction for multiple testing. Sequence information was obtained for 35 peptides out of the 133, and included 33 collagen (I and IV) and 2 uromodulin fragments, urinary peptides that were also found to be differentially excreted in humans with CKD. The 133 and 35 sequenced peptides were combined in two support vector machine classifiers called 133P and 35P, respectively. These models were validated in an independent, cohort of 20 dogs where the analyst was masked to their classification. The 133P classifier predicted CKD with a sensitivity of 80% [95%confidence interval (CI), 44 to 97%], a specificity of 80% (95% CI, 44 to 97%) and an area under the curve (AUC) of 0.88 (95% CI, 0.72 to 1.04). The 35P classifier predicted CKD with a sensitivity of 80% [95%confidence interval (CI), 44 to 97%], a specificity of 90% (95% CI, 55 to 100%) and an area under the curve (AUC) of 0.89 (95% CI, 0.73 to 1.05).

Conclusions: In conclusion, this first study of the urinary peptidome of dogs with CKD identified peptides that predicted presence of CKD in dogs with high accuracy. Future studies should validate its usefulness for early CKD diagnosis and prediction of progression in a clinical setting. [equal contribution VB and LP].

PUB128

Urinary Exosomes and the Loading of CCL2 mRNA as Biomarkers of IgA Nephropathy Patients Ye Feng, Linli Lv. *Institute of Nephrology, Zhong Da Hospital, Southeast University, Nanjing, China.*

Background: Proteinuria is the major clinical risk factor for progressive loss of renal function in immunoglobulin A nephropathy (IgAN) patients. Excessive amount of proteins enter the urinary tract which might be toxic to cells facing the urinary space and increases the exosome excretion in urine. Here we aimed to explore the role of urinary exosomes and the loading chemokine, CCL2 mRNA serving as biomarkers of IgAN.

Methods: We isolated exosomes from urine samples of IgAN patients(N=55) at the time of renal biopsy and healthy controls(N=24). Samples from 14 patients with average 19.5-month follow-up after treatment were also collected. Kidney histological damage of IgAN patients was scored according to the Oxford classification. The protein of urinary exosomes were quantified by Bradford Protein Assays and Western blotting (using Alix, CD63 as exosome markers). Exosomal RNA was extracted by miRNeasy micro kit (Qiagen) and CCL2 mRNA was quantified through RT-PCR.

Results: Interestingly, rarely exosome was detected in healthy controls through western blotting with exosomal markers including CD63 and Alix. Exosome excretion in urine was increased with increasing severity of proteinuria in IgAN patients. The level of urinary exosomal protein closely correlated with levels of proteinruria and tubular injury marker, NGAL. Follow-up studies showed significantly less exosome excretion with decreased levels of proteinuria. It indicated that overloaded protein could increased exosome excretion from tubular epithelial cells. Moreover, according to the Oxford classification of IgAN, patients with higher endocapillary hypercellularity showed remarkably larger amount of urinary exosomes. Besides, exosomal CCL2 mRNA was significantly upregulated in IgAN compared with controls, and correlated with the deterioration of renal function as determined by eGFR. Exosomal CCL2 mRNA also increased in patients with high scores of tubular atrophy and interstitial fibrosis.

Conclusions: Proteinruia is toxic to tubular epithelial cells and endocapillary damage may increase exosome excretion in urine in IgAN. Urinary exosomes production and the CCL2 mRNA might be the promising biomarkers of IgAN reflecting the deterioration of renal function and pathologic damage. Further studies are need to explore the potential role of exosomes in the progression of IgAN.

PUB129

Fibrinogen: A Possible Predictor of Microalbuminuria Stage in Type 1 Diabetic Nephropathy Wenbo Zhao,[2] Hui-qun Li.[1] *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Analysis of the correlation of fibrinogen a nd different stages albuminuria in type 1 diabetic.

Methods: nephropathyAs a Cross-sectional study, we collected hospital clinical data of 394 cases for type 1 diabetes, without albuminuria group (299 cases), microalbuminuria group (73 cases) and macroalbuminuria group (22 cases), analying albuminuria progress related influence factors for multiple factors regression.

Results: The levels of fibrinogen was in the three groups respectively for(3.06±0.78) g/L, (3.566±1.79)g/L, (4.46±1.15)g/L(P=0.000). In the without albuminuria group and microalbuminuria group, the multi-factor Logistic regression analysis showed fibrinogen (Fib) (β= 0.408, P = 0.005, OR = 1.504), and retinopathy, UA, RDW into the model. In microalbuminuria group and macroalbuminuria group, the multi-factor Logistic regression analysis showed fibrinogen (Fib) was not into the model. But retinopathy, HDL, Waist-to-hip ratio into the model.

Conclusions: Fibrinogen associated with microalbuminuria stage in type 1 diabetic nephropathy, that could be independent predictors of early renal damage in type 1 diabetic nephropathy.

PUB130

Prevalence of Co-Morbidities by Ethnicity in a UK Primary Care CKD Cohort Rupert Major,[1,2] Gang Xu,[2,3] Laura Gray,[1] Nigel J. Brunskill.[2,3] *[1]Department of Health Sciences, University of Leicester, Leicester, United Kingdom; [2]University Hospitals of Leicester, Leicester, United Kingdom; [3]Department of Infection, Immunity and Inflammation, University of Leicester, Leicester, United Kingdom. Group/Team: PSP-CKD Study.*

Background: Cardiovascular (CV) and endstage renal disease events in CKD are more common in non-white ethnicities compared to white ethnicities. The prevalence of

co-morbidities in CKD in Black and South Asian ethnicities outside of North America is poorly studies but may account for these higher renal and CV event rates.

Methods: We analysed cross-sectional data from the PSP-CKD study (ClinicalTrials.gov NCT01688141). Individuals were analysed if they had a baseline EPI eGFR <60 ml/min/1.73m^2 and an ethnicity code. The groups' baseline characteristics between ethnicities were compared using t-tests and Chi^2.

Results: 18,058 (78.1%) individuals out of 23,129 had ethnicity recorded. Of these, 17,264 (95.6%) were White, 263 (1.5%) Black and 243 (1.4%) were South Asian. Individuals of Black and South Asian ethnicities were more likely to be male and younger. Mean EPI eGFRs were similar across ethnicities but South Asians had higher mean ACR in both those with and without diabetes mellitus (DM). In Black individuals a diagnosis of hypertension (HTN) was less common but both systolic and diastolic blood pressures had higher mean values. DM was more prevalent in South Asians and HbA1c was higher too. Both Black and South Asian groups had lower rates of CV disease.

Conclusions: In South Asians with CKD, DM was present in more than 40% and glycaemic control was worse. A HTN diagnosis was less common in Black individuals but blood pressure was more poorly controlled. Both groups had lower rates of previous CV events. Targeted management of these co-morbidities in South Asian and Black populations with CKD may be warranted.

Cohort Characteristics by Ethnicity

Variable	White	South Asian	p-value	Black	p-value
n	17,264	243		263	
Female	62.9%	54.0%	0.01	55.1%	<0.01
Age	75.8 (11.1)	69.7 (11.4)	<0.001	64.5 (14.4)	<0.001
Mean EPI eGFR	50.6 (9.6)	49.9	0.23	50.6 (11.6)	0.97
ACR (mg/mmol)	6.8 (18.0)	13.3 (27.3)	0.03	12.5 (25.1)	0.10
CV Disease	17.4%	11.5%	0.02	10.7%	<0.001
HTN	91.0%	90.1%	0.65	84.8%	<0.001
Systolic BP	134.3 (16.3)	134.7 (18.9)	0.65	136.7 (18.2)	0.02
Diastolic BP	74.8 (10.0)	75.2 (10.7)	0.58	79.1 (11.3)	<0.001
DM	23.1%	44.0%	<0.001	29.3%	0.02
HbA1c % if DM	7.4 (1.4)	7.8 (1.6)	0.01	7.5 (1.5)	0.68

p-values refer to comparison to White ethnicity. For continuous variables values refer to means and figures in parentheses refer to standard deviations.

A Retrospective Analysis of Positive Predictors for the Utility of Ultrasound in the Diagnosis and Management of CKD in an Outpatient Population Erin Dohaney,[1] Martin G. Mackinnon.[2] *[1]Dalhousie University School of Medicine, Rothesay, NB, Canada; [2]Horizon health, Quispamsis, NB, Canada*.

Background: Given the economic constraints of today's health care system, there is an increasing emphasis on cost-effectiveness and judicious use of resources. Choosing Wisely is a campaign that encourages health care providers in all aspects of medicine to look for ways to reduce the use of unnecessary tests while maintaining quality care for patients. The aim of this study is to add to the existing body of "diagnostic research" by assessing the diagnostic yield and clinical utility of ultrasound in the setting of chronic kidney disease.

Methods: A retrospective multi-variant analysis was performed using data collected from 2 hospitals in New Brunswick, Canada, involving patients presenting for initial outpatient nephrology consult between January 2012 and January 2015. Data on patient presenting history and symptoms at the time of initial nephrology consult were collected via chart review. Demographic, laboratory, imaging and procedural data ranging from one year prior up to and including one year following the initial nephrology consult date was collected via electronic data extraction. A focus group attended by nephrology and radiology staff was used to determine what ultrasound findings would represent a "positive" result that would effectively change diagnosis and management. Multivariate regression analysis is being used to analyze the relationship between patient characteristics and ultrasound results.

Results: At the time of submission, of the 357 patients collected in the initial chart review, 304 (85%) were captured within our data extraction and matched to patient database demographic information with an initial nephrology consult ID and date. 221 of 304 (73%) had matches to the laboratory dataset (≥1 lab result). A total of 26,602 labs records were extracted for those 221 patients. 48 of 221 patients (22%) had ultrasounds performed. 53 ultrasounds were performed on 48 patients with 5 patients having had 2 ultrasounds. 7 of 221 (3%) had matches to pathology reports, indicating that biopsy was performed. Ultrasound findings were as follows: normal study (43%), increased echogenicity and cortical thinning (17%), re-checks with abnormalities (15%), non-obstructing calculi (8%) simple renal cysts (7%), renal atrophy (6%) and de novo lesions (4%).

PUB132

Greater Acid Retention in Patients with More Advanced CKD Is Associated with Faster eGFR Decline Nimrit Goraya,[4,5] Jan Simoni,[3] Lauren N. Sager,[1] Donald E. Wesson.[2,4] *[1]Biostatistics, Baylor Scott & White, Temple, TX; [2]Diabetes Health and Wellness Institute, Dallas, TX; [3]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX; [4]Internal Medicine, Baylor Scott and White Health, Temple, TX; [5]Internal Medicine, Texas A and M, Temple, TX*.

Background: Acid (H^+) retention measured by microdialysis causes progressive GFR decline in animal models of chronic kidney disease (CKD), even in the absence of metabolic acidosis by plasma acid-base parameters, it worsens with declining GFR, and greater H^+ retention causes faster GFR decline in these CKD models. Patients with reduced eGFR but no metabolic acidosis also have H^+ retention (Wesson, et al. AJP 300:F830) and eGFR decline rate was faster in the absence of dietary H^+ reduction in CKD patients with stage 3 (Goraya et al. KI 86:1031, 2014) compared to stage 2 (Mahajan, et al. KI 78:303, 2010) eGFR (4.3 vs. 2.4 ml/min/1.73m^2/year). We tested the hypothesis that faster eGFR decline in more advanced CKD stages is associated with greater H^+ retention.

Methods: Twenty-six CKD stage 1 (CKD 1), 40 CKD 2, and 36 CKD 3, macroalbuminuric, non-diabetic CKD subjects underwent measurement of H^+ retention by comparing the observed to the expected increase in plasma [HCO_3] in response to retained HCO_3 (dose-urine excretion) two hours after an oral $NaHCO_3$ bolus (0.5 meq/Kg bw), assuming 50% body weight HCO_3 space of distribution. Specifically, H^+ retention = [(retained HCO_3/0.5 x body weight) – observed increase in plasma [HCO_3]] x (0.5 x body weight). Cystatin C-based eGFR was measured at baseline and then yearly for five years.

Results: Baseline eGFR in ml/min/1.73m^2 was as follows: CKD 1=101±8, CKD2=76±6, and CKD 3=40±7. The yearly rate of eGFR decline, expressed as ml/min/1.73m^2/year, was faster in CKD 2 than CKD 1 (2.32±0.14 vs. 1.74±0.17, p<0.0001) and was faster in CKD 3 (3.77±0.15) than CKD 2 (p<0.0001). The Bonferroni correction required a p-value of < 0.0083 for significance among group comparisons for H^+ retention. Accordingly, H^+ retention was greater in CKD 2 vs. CKD 1 (17.4±8.9 vs. 3.0 ± 14.0 mmol, p<0.0001) and in CKD 3 (24.9±15.4 mmol) than CKD 2 (p=0.0079).

Conclusions: These data show that the faster rate of eGFR decline in CKD patients with lower initial eGFR was associated with greater H^+ retention which might mediate their more rapid progression. The data suggest that CKD patients with more advanced CKD and lower eGFR require more aggressive dietary H^+ reduction to better resolve underlying H^+ retention and thereby possibly optimize the kidney protective benefits of this therapy.

PUB133

Time-Average Proteinuria during Follow-Up and Renal Prognosis in Patients with Benign Nephrosclerosis Hoichi Amano,[5] Kentaro Koike,[2] Nobuo Tsuboi,[4] Kotaro Haruhara,[3] Makoto Ogura,[1] Takashi Yokoo.[4] *[1]Division of Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Division of nephrology and hypertension, The Jikei university school of medicine, Tokyo, Japan; [3]The Jikei University School of Medcine, Tokyo, Japan; [4]The Jikei University School of Medicine, Setagaya-ku, Japan; [5]Division of Nephrology and Hypertension, The Jikei University School of Medicine., Tokyo, Japan*.

Background: Heavy proteinuria at the time of diagnostic renal biopsy has been reported as an independent risk factor for deteriorating renal function in benign nephrosclerosis (BNS). However, few studies have investigated the relationship between the amount of proteinuria during follow-up and long-term renal prognosis in BNS. The purpose of this study was to assess the relationship between time-average proteinuria (TAP) and renal prognosis in BNS.

Methods: Patients with biopsy-proven BNS from the Jikei University Hospital participated in this study. Multivariate analysis was used to investigate the effects of TAP and other clinicopathological findings on the risk for renal events (a 30% decline in eGFR from baseline or ESRD). Proteinuria was measured every 6 months, and the mean value was used as an indicator of TAP.

Results: This study included a total of 67 BNS patients [average 51±12years old, eGFR; 51 ± 24 ml/min, urine protein excretion at baseline; 0.78 g / g Cr (0.51 - 1.79)]. The rate of renal events in patients with higher TAP was significantly elevated as compared to the rate in those with lower TAP (Figure; Log-rank trend test, P < 0.001). The adjusted model indicated a significant association between TAP and renal events (HR: 3.84, CI: 2.00-7.51), which was independent of higher baseline proteinuria, glomerulosclerosis and tubulointerstitial damage. Figure

Conclusions: These results suggest that TAP is an independent risk factor for renal prognosis in patients with BNS, indicating the significance of urinary protein excretion during follow-up in the progression of BNS.

Figure.

Angiotensin 2 and Innate and Adaptative Immunity in a Model of CKD Caused by Brief Treatment with L-NAME and Salt Overload Karin C. Oliveira, Fernanda F. Zambom, Lais Braga, Amanda H. Albino, Viviane D. Faustino, Victor F. Avila, Simone C. Arias, Camilla Fanelli, Claudia R. Sena, Vivian L. Viana, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ Sao Paulo, SP, Brazil*.

Background: We showed previously (AJPRenal 2006) that short-term NO inhibition by L-NAME (N) and salt overload (HS) promotes severe hypertension and renal injury that regress after treatment is ceased, but progress slowly to chronic kidney disease (CKD) thereafter. Here we investigated whether Ang2, innate and adaptive immunity are involved in the pathogenesis of CKD in this late phase.

Methods: Male Munich-Wistar rats received HS (2.2% Na) and N (32 mg/Kg/d) for 1 mo. Control rats (C) received HS only. Four wks after all treatments had been ceased, tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), glomerulosclerosis (GS, %), ischemic glomeruli (IG, %), interstitial collagen 1 (COLL, %), renal content of IL1β (pg/mg), as well as interstitial infiltration (cells/mm²) by macrophages (MΦ), lymphocytes (Ly), angiotensin 2+ (Ang2+) and NLRP3+ cells were assessed in 14 rats (Post-HS+N_4). All measurements were repeated in additional rats, followed for 24 wks while receiving either no treatment (Post-HS+N_{24}, n=15) or Losartan, 50 mg/kg/d (Post-HS+N+L_{24}, n=11).

Results: Mild hypertension and renal injury/inflammation, along with increased infiltration by Ang2+ cells and activation of the NLRP3 pathway, were observed in Post-HS+N_4. After 24 weeks, ALB, GS and COLL were aggravated in association with persistently high levels of MΦ, Ly, Ang2+ cells and NLRP3/IL1β. In addition, the IL1β levels correlated positively with GS, MΦ and Ang2+ cells. Losartan prevented the increase in TCP, ALB, COLL and GS, but aggravated IG. Likewise, MΦ, Ly, Ang2+and IL1β were attenuated, and IL1β correlated positively with ALB.

Conclusions: Continued activation of innate and adaptive immunity, even after the initial insult is ceased, may interact with Ang2 to mediate the development of inflammation and CKD in this model. FAPESP/CNPq

Factors Related to Proteinuria Relapse in Childhood IgA Nephropathy Yuko Shima,[1] Koichi Nakanishi,[3] Taketsugu Hama,[1] Masashi Sato,[1] Yu Tanaka,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Hiroshi Kaito,[2] Kandai Nozu,[2] Ryojiro Tanaka,[4] Kazumoto Iijima,[2] Hiroyuki Suzuki,[1] Norishige Yoshikawa.[5] *[1]Pediatrics, Wakayama Medical University, Wakayama City, Japan; [2]Dept. of Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Japan; [3]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan; [4]Pediatric nephrology, Hyogo prefectural Kobe children's hospital, Kobe, Japan; [5]Clinical Research Center, Wakayama Medical University, Wakayama, Japan.*

Background: Proteinuria remission is the most significant predictive factor for renal outcome in childhood IgA nephropathy (IgAN). Even if the proteinuria remission could be once obtained, some of the patients show proteinuria relapse during the long-time disease course. The purpose of this study is to clarify the incidence and factors related to proteinuria relapse in childhood IgAN.

Methods: Retrospective analysis of 309 cases with proteinuria remission among 538 consecutive biopsy-proven IgAN children from July 1976 to June 2013 to compare clinical and pathological findings between the patients with proteinuria relapse and others.

Results: Ninety patients (29.1%) showed proteinuria relapse during the observation period (median 7.0 [25%-75%: 4.0–11.0] years). Clinical findings showed significant differences (relapse vs non-relapse) in onset age (11.3±3.3 vs 9.9±2.8 years, p=.0005) and the duration from onset to proteinuria remission (3.0±1.9 vs 2.7±2.9, p=.01). As to the pathological findings, there were significant differences in the ratio of tubular atrophy/interstitial fibrosis present (65.4% vs. 47.4%, p=.005). The Kaplan-Meier analysis suggested that the patients with proteinuria relapse had significantly lower renal survival rates than the others at 16 years (91.9% [95%CI: 78.5-97.2] vs 99.5% [95%CI: 96.2-99.9], p<.04). Proteinuria relapse is the only significant factor for renal survival in the 309 cases that remission of proteinuria was once obtained (hazard risk 3.15e^9 [95%CI:2.8-2.8], p=.004).

Conclusions: About one third of the proteinuria remission patients showed proteinuria relapse again regardless of treatments. Tubular atrophy such as a chronic lesion was significantly related to the proteinuria relapse.

PUB136

Impact of Oral Sucrosomial Iron in Anemia of CKD Patients and Its Relation with Mineral Bone Disease Parameters Ioannis Griveas.[1,2] *[1]401 General Military Hospital of Athens, Athens, Greece; [2]RENAL CLINIC "ATHENS-NEPHROLOGY", ATHENS, Greece.*

Background: Iron deficiency is one of the main causes of anemia in patients with chronic kidney disease (CKD), and iron supplements constitute the basis of its therapy. Oral sucrosomial iron, a preparation of ferric diphosphate carried inside a phospholipidic membrane, is characterized by higher gastrointestinal absorption and bioavailability than other oral formulations, as well as lower incidence of side effects. Different biochemical abnormalities of metabolic bone disease have been associated with anemia of CKD. However, all of these abnormalities are closely inter-related and their individual effect on the development of anemia is uncertain. The study purpose was to assess the efficacy and tolerability of the treatment with sucrosomial iron in anemic patients with CKD and also to investigate the relationship between anemia, renal function and a set of metabolic bone disease biomarkers.

Methods: 30 patients (mean age 74.21years, range: 39-86 years) with CKD stage 3-5 (e GFR <60 mils/min, range: 12-48) and anemia along with iron depletion. All of the patients received oral sucrosomial iron once daily. Hematological profile, renal function and bone-mineral data were recorded at the beginning of the study and every 2 months until the end of the study protocol.

Results: We noticed that Hct levels increased from 33.3±1.87% at the beginning of the protocol to 36.61±2.72 in the end (p<0.05). Hemoglobin levels were 10.98±0.73 g/dl at the beginning of the study and ended to be 11.86±0.71 (p=NS). Ferritin levels also increased from 42.73±24.47 to 98.89±126.99 (p=NS). The above improvement of renal anemia profile drove the renal function (e GFR) of our patients to remain stable, during the 18th month period of the study. Correction of anemia helped PTH levels to decline over the study period from 359.05±447.24 pg/ml to 163.72±89.12 pg/ml (p=NS). Ca, K, Na levels remained stable without also significant changes. Oral iron was well tolerated and no significant adverse effects were recorded.

Conclusions: Oral sucrosomial iron seems to be a safe and efficacious alternative in managing CKD patients with anemia. Whether an association between PTH and hemoglobin also exists in patients with CKD is still unclear, yet in this study we noticed an association between PTH, e GFR and correction of anemia in CKD-patients.

PUB137

Clinical and Histopathological Characteristics in "Smoldering" ANCA Positive Vasculitis and Nephritis Over One Year before Burst of RPGN Eri Muso,[1,2] Youngna Kang,[2] Shuichiro Endo,[2] Yayoi Ogawa,[3] Hiroko Kakita,[1] Tomomi Endo,[1] Hiroyuki Suzuki,[1] Motoko Yanagita,[2] Tatsuo Tsukamoto.[1] *[1]Kitano Hospital, The Tazuke Kofukai Medical Research Institute, Osaka, Japan; [2]Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]Hokkaido Renal Pathology Center, Sapporo, Japan.*

Background: RPGN is most frequent phenotype of renal involvement of AAV with typical pathology of crescentic GN accompanying necrotizing vasculitis. As in most cases RPGN is the start to investigate ANCA positivity and AAV, the clinical and especially pathological information in "smoldering " phase before the burst of RPGN is limited. Some ANCA positive patients, however, could be under histological analysis due to mild but apparent urinary abnormality. Previously, the comparing those who did not develop RPGN, those developed RPGN showed positive PTCitis and arteriolar wall thickening (Kang, Muso et al, 17th ANCA Wrokshop 2015). The clinic- pathological features of further accumulated cases were analyzed.

Methods: Cases received renal biopsy due to positive nephritic urine and serum ANCA were surveyed in three different hospitals in Japan. They did not complain any systemic symptoms of vasculitis nor rapidly progressive renal dysfunction. Among them, the clinical and histological features of those developed burst of rapidly progresive glomerulonephritis(RPGN) due to ANCA associated vasculitis later were analyzed.

Results: 6 cases (female:male: 2:4 age 17-82, average: 56.1 years)showed active hematuria and proteinuria. ANCA titers were 18-880EU, Cre : 0.8-1.45mg/dl. Histologically no necrotizing lesion nor vasculitis, however, wall thickening of arteriole

were noted. At that occasion, 2 cases were diagnosed as IgA nephropathy. After average of 1.7 years during when all cases did not receive steroid therapy except one, developed RPGN. All second biopsy of 5 of them showed crescentic GN with active and necrotizing vasculitis. Before burst of RPGN, ANCA were stably high or gradually elevated.

Conclusions: At least 10 months before the burst of RPGN, inflammatory swelling of arteriole might have started in ANCA positive patients showing nephritic hematuria and proteinuria even without systemic symptom of vasculitis. The accumulation of these cases of "smoldering" AAV which later developed RPGN should be performed to propose predictive clinical or histological parameters and appropriate therapeutic approach.

PUB138

Urinary Angiotensinogen (uAOG) Levels Are Associated with Development of CKD in Type 1 Diabetes Daniel Batlle,[2] Alejandro Sanchez,[2] Sheeba H. Ba aqeel,[2] Jan Wysocki,[2] Minghao Ye,[2] Ahmed M. Khattab,[2] Alfred Rademaker,[2] Xiaoyu Gao,[1] Ionut Bebu,[1] Mark E. Molitch.[2] *[1]George Washington University, Rockville, MD; [2]Northwestern University Feinberg School of Medicine, Chicago, IL. Group/Team: For CKD Biomarkers Consortium and DCCT/EDIC Research Group.*

Background: uAOG has been reported to be increased in diabetic kidney disease (DKD) but its predictive value for DKD has not been demonstrated. Although AOG, like albumin, is filtered by a disrupted glomerular barrier, it is also produced intrarenally and thus any excess of AOG can activate the Renin Angiotensin System within the Kidney and trigger CKD progression. We examined if AOG was associated with the development of DKD using biosamples from participants in the Epidemiology of Diabetes Intervention and Complications (EDIC).

Methods: In a nested case-control design we performed a preliminary analysis of 34 cases from EDIC participants in whom GFR eventually fell to <60ml/min/1.73m^2 (Stage 3 CKD) as the study outcome. Controls were 51 EDIC subjects in whom eGFR remained well above 60ml/min/1.73m^2, followed over the same period and matched for age, gender, DM duration. Matching was done during the earliest EDIC visit where urine samples for AOG evaluation were available prior to development of CKD3 (average of ~2 yrs before CKD3, range 1-7). Analysis was by conditional logistic regression. Progressive Renal Decline (PRD, eGFR loss >3.5 ml/min/1.73m^2/yr) is an index used to predict ESRD. In a separate post-hoc exploratory analysis, uAOG levels were compared in a subset of the primary renal case/control group of 20 cases with PRD versus 53 without PRD, of whom 20 and 13 respectively were CKD3 cases. Analysis was by logistic regression with nominal p-values and AUC.

Results: The median uAOG in cases was higher than that of controls (13.9 vs 3.8µg/mg, p=0.027). uAOG was associated with the development of CKD3 after adjusting for eGFR (p=0.039) and HbA1c (p=0.043) but not for AER (p=0.50). The median uAOG in PRD decliners was higher than in non-decliners (29.8 vs 4.2µg/mg, nominal p=0.063). AOG was associated with eGFR decline after adjustment for HbA1C (p= 0.045) but not for eGFR (p=0.067) nor AER (p=0.13). The AUC for AOG was 0.77, a value not significantly better than that for AER 0.759

Conclusions: Urinary AOG is associated with the development of Stage 3 CKD. In addition, increased uAOG independently of eGFR or HbA1C is also associated with progressive renal decline, a strong index of progression to ESRD. uAOG is not significantly better than AER in predicting CKD or PRD.

PUB139

Idiopathic Nodular Glomerulosclerosis (ING) in an African American (AA) Male with Hepatitis C Nirmal K. Onteddu,[2] Anand C. Reddy,[2] Jayasri Duggirala.[3] *[2]Texas Tech University of Health Sciences, Odessa, TX; [3]Permian Research, Tampa, FL.*

Background: ING in non-diabetic patients is rare. We report this case to suggest the existence of yet unknown etiologies of ING other than previously known.

Methods: A 68-year-old AA male with BMI(22.5), hypertension and smoking presented with anasarca. His physical examination and laboratory workup showed -BP -156/96, 4+ pedal edema, hemogram was normal except for platelets117, creatinine 2.4, Urea 25, albumin 2.5, HbA1c of 5, 24hr urine protein 7.7gm, Hepatitis C antibody reactive, vasculitis workup was negative. On immunoelectrophoresis no free kappa light chains seen. Non specific increase in Alpha 2 globulins, monoclonal protein seen in gamma fraction of protein electrophoresis. Renal biopsy demonstrated nodular glomerulosclerosis. Congo red staining was negative. Immunofluorescence microscopy with human IgG, IgA, IgM, C1q, C3, albumin, fibrinogen, kappa and lambda immunoglobulin light chains was negative. No electron dense deposits.

Results:

Conclusions: Kimmelstiel and wilson described findings of nodular glomerulosis as a pathognomonic of diabetic nephropathy. Other causes of ING are diabetic nephropathy, amyloidosis, light chain disease, fibrillary and immunotactoid glomerulopathy, Collagen type 3 disease, nodular membranoproliferative glomerulonephritis and takayasu's arteritis. However our patient had a long history of smoking and hypertension, normal A1c and renal biopsy findings we diagnosed ING by exclusion. One cannot conclude that those risk factors alone caused his ING and ignore Hepatitis C antibody, MGUS as possible risk factors. He is currently treated with angiotensin converting enzyme inhibitors along with other anti hypertensive medications, smoking cessation. Long term follow up is needed to see if his renal function improve after treatment of hepatitis c and also with regular follow up on A1c as he may develop DM later.

PUB140

The Factors Influenced on Change in Systolic Blood Pressure Variability in CKD Patients: The APrODiTe-2 1-Year Follow-Up Study Jiwon Ryu,[1] Sejoong Kim,[6] Ran-hui Cha,[4] Hajeong Lee,[7] Jung Pyo Lee,[5] Myung jin Choi,[2] Young rim Song,[3] Yon Su Kim.[7] *[1]Cheju Halla Hospital, Seoul, Republic of Korea; [2]Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea; [3]Hallym Univ. Sacred Heart Hospital, Anyang, Republic of Korea; [4]National Medical Center, Seoul, Republic of Korea; [5]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [6]Seoul National University Bundang Hospital, Seongnam, GyeongGi-Do, Republic of Korea; [7]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: The blood pressure variability (BPV) may be affected by several factors such as medication, underlying disease and others. We evaluated what factors may influenced change in the BPV in the APrODiTe study in chronic kidney disease(CKD) patients.

Methods: We recruited 378 hypertensive CKD patients with 1-year follow-up from 4 centers in Korea. The Systolic BPV (SBPV) was the mean value of the differences between systolic BP at every 30 minutes for 24 hours. The factors affecting BPV were considered such as anti-hypertensive drugs, diabetes mellitus (DM), smoking, alcohol, exercise, and CKD stages.

Results: After 1-year observation period, SBPV were increased by 2.9 mmHg (Initial SBPV, 20.8 ± 11.9 mmHg; final SBPV, 23.7 ± 10.7 mmHg; $P < 0.001$ by paired t-test). SBPV in patients treated with 2 different anti-hypertensive drugs (renin-angiotensin esterase inhibitor or angiotensin receptor blockers (RAAS blocker) and beta blockers (BB), BB + calcium channel blockers (CCB)) and 3 drugs (RAAS blocker, BB and CCB) sustained over 1-year observation ($P = 0.611$, $P = 0.588$ and $P = 0.481$ by paired t-test, respectively). The type of anti-hypertensive drugs such as RAAS blocker, BB and CCB did not influence on changes in SBPV. In diabetic patients, non-smokers and patients on early-stage CKD (stage 1-2), SBPV was not changed during the observation ($P = 0.072$, $P = 0.079$ and $P = 0.281$ by paired t-test, respectively).

Conclusions: We found that SBPV in CKD patients may be increased over times, and that multiple anti-hypertensive drug users may prevent the increase in SBPV, rather than the type of anti-hypertensive drugs.

PUB141

CKD in an Underserved Population with Cardiovascular Disease Hector Alvarado verduzco,[1] Carola A. Maraboto gonzalez,[3] Avantee V. Gokhale,[1] Tarek Rashid,[4] Anjali Acharya.[2] *[1]JACOBI MEDICAL CENTER, BRONX, NY; [2]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY; [3]Jacobi Medical Center, BRONX, NY; [4]None, Fort Lee, NJ.*

Background: Chronic kidney disease (CKD) is a growing major health problem worldwide carrying a high morbidity and mortality as well as increased costs. Patients with underlying cardiovascular disease have a higher risk of CKD than the general population, however its prevalence in our diverse community hasn't been reported.

Methods: We conducted a retrospective review of our medical records to evaluate the prevalence of CKD in the Cardiology clinic during 6 months. Patients of age 18 years or older were included. Descriptive statistics were used and analysis was done using SPSS.

Results: A total of 498 patients were included: 192 (38.6%) Hispanic, 149 (29.9%) African-American, 14 (2.8%) Caucasians, 38 (7.6%) others, and 105 (21.1%) unclassified. Of this sample, 32% had CKD, which was defined according to an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m^2 calculated from the MDRD equation.

Conclusions: CKD is highly prevalent in the Cardiology clinic in our unique population with high ethnic diversity, >75% of patients belonging to US minorities. These

results should help increase the awareness of this problem in the outpatient setting to promote early diagnosis and treatment of this condition, as well as prompt referral for specialized evaluation by Nephrology.

Serum Myeloid-Related Protein 8 and 14 (MRP8/14) Are Increased in CKD Patients, Making It a Probable Novel Biomarker for Prognosis Tatsuki Matsumoto,[1] Yoshinori Taniguchi,[2] Daisuke Hashimoto,[2] Masami Ogasawara,[2] Tomohiro Eguchi,[2] Hirofumi Nishikawa,[2] Kazu H. Ode,[2] Yoshiko Shimamura,[2] Kosuke Inoue,[2] Taro Horino,[2] Yoshio Terada.[2] *[1]Kochi University, Nankoku, Japan, Japan; [2]Kochi university, Nankokushi, Japan.*

Background: Myeloid-Related Protein 8/14 complex (MRP8/14) is an endogenic ligand of toll-like receptor (TLR)-4, and is considered to be an inflammatory marker. Although it has been reported that MRP8/14 related to arteriosclerosis and coronary lesion in type 2 diabetes, there are no reports about the relationship between MRP8/14 and chronic kidney disease (CKD). We studied the association between MRP8/14 levels and renal function or the other parameter and renal prognosis in CKD.

Methods: A total of 432 patients (mean age 60±17) with CKD were enrolled. Serum samples were collected, and MRP8/14 levels were measured by using ELISA kit. Serum creatinine (Cr), blood urea nitrogen (BUN), uric acid (UA), urine protein/Cr ratio, and the other parameter of renal function were also measured. We follow up the prognosis of 250 patients for 3 years. This study was approved by Kochi Medical School review board. All patients provided written informed consent.

Results: MRP8/14 levels were positively associated with serum Cr (p=0.007, r=0.135), BUN (p<0.001, r=0.175), UA (p=0.011, r=0.127) levels, and urinary protein/Cr ratio (p<0.001, r=0.212), and Body Mass Index (BMI) (p<0.001, r=0.189). MRP8/14 levels were inversely associated with eGFR (p=0.006, r=-0.137). MRP8/14 levels significantly increased in CKD stage 5 (p<0.05; vs stage1-4). Moreover, MRP8/14 levels in CKD patients with diabetes and hypertension were significantly increased (p<0.05), compared to patients without diabetes and hypertension. Stepwise multiple regression analysis showed that MRP8/14 levels correlated well with BMI, Hb and urinary protein levels. The higher levels of MRP8/14 patients have a tendency of poor prognosis in 3 years.

Conclusions: Serum MRP8/14 significantly correlated with renal function and BMI in CKD patients, and might show that MRP8/14 is critical for disease progression and metabolic pathogenesis in CKD.

PUB143

A Parent-Child Case of Hyperlipoproteinemia and Early-Onset Obesity Complicating Obesity-Related Glomerulopathy Masanori Takaiwa,[1] Takayuki Miyai.[2] *[1]Matsuyama Red Cross Hospital, Matsuyama, Japan; [2]Okayama university, Okayama, Japan.*

Background: The relationship between the obesity-related glomerulopathy (ORG), typically characterized by proteinuria, glomerulomegaly and FSGS, and the high heritability of severe obesity is unknown. Hence, the accumulation of family cases of ORG is useful for searching the genetic factors of ORG. We report a parent-child cases of hyperlipoproteinemia with ORG combined.

Methods: Case 1: A 11-year-old Japanese boy was found to have obesity, progressive proteinuria and hematuria at the age of 3. At the time of the biopsy, he exhibited significant proteinuria (UP/CR ranging from 1.44 to 4.04). Serum albumin and eGFR were normal. CAKUT and congenital malformation syndromes were not found. He presented with obesity (BMI 33.2), hyperlipoproteinemia (triglyceride 234 mg/dl; total cholesterol 296 mg/dl). The biopsy detected glomerulomegaly and FSGS (perihilar variant). After the hospitalization receiving 2000 kCal diet, he lost weight and showed amelioration of UP/CR (from 0.61 to 1.28). He is diagnosed ORG and receiving valsartan and lisinopril. Case 2: A 46-year-old male, the father of the case 1, was diagnosed obesity, proteinuria and hematuria at the age of 14. Since renal biopsy performed at the age of 25 confirmed mild mesangial proliferation without positive immunostaining, no medication was initiated. At the age of 36, he was diagnosed obesity (BMI 26.0), hypertension, hyperlipoproteinemia (triglyceride 2225 mg/dl; total cholesterol 338 mg/dl), fatty liver, type 2 diabetes, significant proteinuria (dipstick 3+) and hematuria. He initiated exercise, nutritional guidance, glimepiride, amlodipine, telmisartan and fenofibrate. 5 years later, he maintained improved BMI (23.0), blood pressure, triglyceride (300 mg/dl), total cholesterol (138 mg/dl), and HbA1c (6.6%). In parallel, the urine dipstick analysis was normalized.

Results:

Conclusions: Although further investigation is required, this parent-child case may suggest the benefit to clarify the relationship between ORG and the genetic causes of hyperlipoproteinemia. A family history of hyperlipoproteinemia could be a potent indicator for diagnosing ORG and might avoid unnecessary use of steroids and immunosuppressants. *Vice versa,* early diagnosis of ORG might lead to a sufficiently early detection of hyperlipoproteinemia to prevent the cardiovascular complications.

PUB144

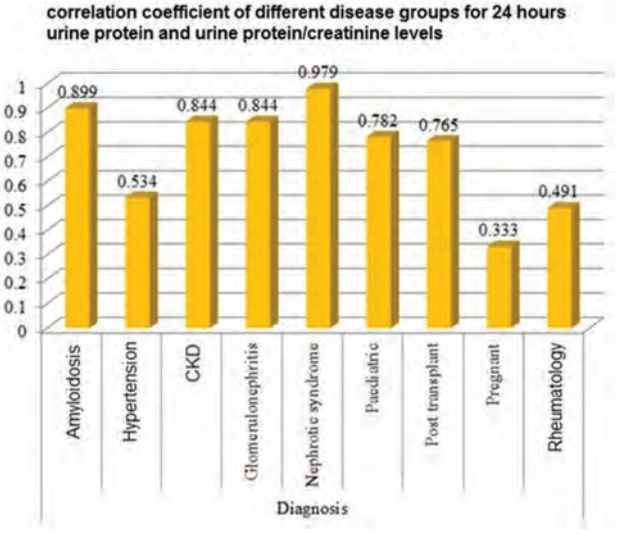
The Diagnostic Significance of Urine PR/CR Ratio and Its Replacement Capability of 24 Hours Urine Protein in Indian Non Diabetic Nephropathy Patients Hariharan R. Munganda,[1] Jitendra Kumar,[1] Punit Pruthi.[2] *[1]Asian institute of medical sciences, Faridabad, Haryana, India; [2]internal medicine, Asian Institute of Medical Sciences, FARIDABAD, India.*

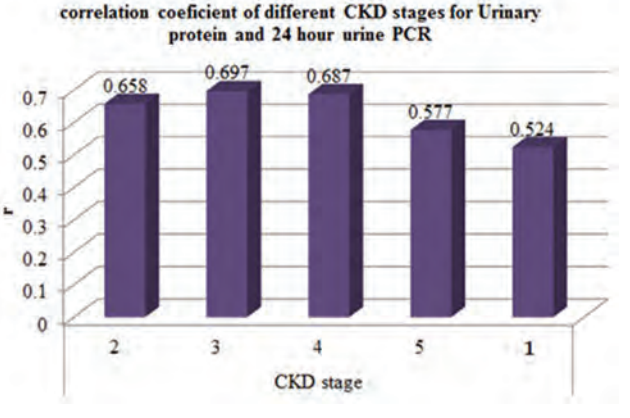
Background: The measurement of urinary protein excretion provides a sensitive marker of of kidney disease from early to advanced stages. U Pr/Cr ratio as a screening tool helps in categorisation of diseases and helps in early intervention and treatment strategy but 24 hrs urine protein still remains as a gold standard. It may be scientifically incorrect to use these tests interchangeably across all patient population.

Methods: Correlations between quantitative variables of 300 patients were evaluated using Pearson's Correlation coefficient. (SPSS) software version 15.0 was used for the statistical analysis. Diabetic nephropathy, ESRD patients on dialysis, Multiple myeloma patients were excluded

Results: Correlation between 24 hrs UP and U Pr/Cr is poor in patients with proteinuria range < 150 mg(r=0.119) and 150-300mg/24 hrs(r=0.143), this may be because the validation in international literature is mainly for albumin but in our study it was protein that was focussed, as it has varied sources. Moderate in >300 mg/24 hour (r=0.48). Best in 24 hrs UP range of 900-3000 mgs and U Pr/Cr ratio of 0.9-3.

Conclusions: U Pr/Cr ratio even in random fresh urine samples taken at any time of the day shows good correlation and seems to be an reliable alternative for 24 hrs UP. Advised 24 hours urine creatinine should be checked along with 24 hrs urine protein to know the adequacy of urination.





PUB145

In Search of Mesoamerican Nephropathy: Albuminuria as a Marker for Renal Damage in an Agricultural Community on Guatemala's Southern Coast Ever O. Cipriano,[3] Marcos Rothstein,[1] Vicente J. Sanchez polo.[2] *[1]Barnes-Jewish Dialysis Center, St. Louis, MO; [2]guatemalan social security institute, Guatemala City, Guatemala; [3]Nephrology, Instituto Guatemalteco de Seguridad Social, Guatemala, Guatemala.*

Background: In 2002, in El Salvador, a non traditional Nephropathy was described among young male adults, sugar cane workers, in the geographical region that includes Southeast Mexico, Guatemala, Belize, El Salvador, Honduras, Costa Rica and Panama. This Chronic Renal Disease of Non-Traditional Causes has claimed many lives at the Central American level and in Guatemala this entity has also been observed particularly in habitants of the coast of Pacific region of Guatemala.

Methods: OBJETIVES Identify kidney damage using albuminuria as a marker of renal damage in high risk population of southern coast in Guatemala. METHODS Cross-sectional, population-based prevalence study Conducted in the agricultural communities of El Terrero and La Gomera in Escuintla, Guatemala. All individuals ages 10 and older were included. Labs – All patients had a urinalysis. Serum glucose and creatinine was randomly checked in patients with + albuminuria on urinalysis.

Results: See the Pictures.

Conclusions: A high prevalence of albuminuria (as a marker of renal disease) was noted in the studied rural community along the Guatemalan coast. There was no observed relationship between sugar cane workers and prevalence albuminuria or hematuria. Majority of identified patients with CKD did not have diabetes.

Performance of 8 Equations to Evaluate Baseline and Postoperative eGFR Changes in Patients with Morbid Obesity Undergoing Bariatric Surgery Ricardo E. Varela, Fabiola Gallardo, Diego L. Carrillo Perez, Ricardo Correa-Rotter, Luis E. Morales-Buenrostro. *Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, Ciudad de México, Mexico.*

Background: Many current equations employed to estimate GFR do not take in account anthropometric variables. Gold standard measured GFR techniques show reduction in glomerular hyperfiltration in obese individuals after significant weight loss. The aim of this study was to evaluate the performance of 8 equations to detect eGFR changes after bariatric surgery.

Methods: We retrospectively analyzed a cohort of morbidly obese patients subjected to bariatric surgery between 2000-2014. We compared 8 eGFR equations before and 12 months after surgery. T test or Wilcoxon test were used for comparison of repeated measures.

Results: 168 patients were analyzed, mean age of 38.3 ± 9 years. All equations that included anthropometric measures showed a decrease in eGFR at 12 mo, in accordance to what has been shown with measured GFR, while all formulas that do not include anthropometric measures displayed an increase in eGFR (Table).

Conclusions: In this study, equations that included anthropometric variables demonstrated reduction in glomerular hyperfiltration, similarly to what has been reported in studies with gold-standard measured GFR. Other currently used equations standardized to a body surface of 1.73m^2 should not be employed in patients with morbid obesity. The only equation developed for obese individuals is the Salazar Corcoran, yet there is a need of eGFR concordance studies in obese individuals between measured GFR and estimation equations.

Equation	Basal eGFR Mean ± SD	12m eGFR Mean ± SD	p

Accurate eGFR Reporting in Children Independent of Height Emil Den bakker,[3] Isabelle Hubeek,[2] Joanna Van Wijk,[5] Reinoud R. Gemke,[4] Arend Bokenkamp.[1] *[1]VU Medical Center, Amsterdam, Netherlands; [2]VU university medical center, Amsterdam, Netherlands; [3]VUMC, Duivendrecht, Netherlands; [4]VUmc, Amsterdam, Netherlands; [5]Vrije Universiteit University Hospital Amsterdam, Amsterdam, Netherlands.*

Background: Background Reporting estimated GFR (eGFR) instead of serum creatinine (crea) leads to earlier recognition and more timely referral of patients with suspected kidney failure and has been implemented in current guidelines both for adults and children. Due to varying muscle mass, which is related to height, most creatinine-based equations for children require height, a patient characteristic not standard available in many settings. An approach using age-related creatinine reference data has been developed by Pottel et al (2008). Cystatin C (CysC), an alternative marker for GFR, is independent of muscle mass and CysC based eGFR equations do not require anthropometric data. Combining crea and CysC-based eGFR has been shown to significantly increase the accuracy of GFR estimation in children. <!--[endif]----> <!--[endif]----> **Aim** To study the accuracy of combining crea and CysC based *height-independent* equations for GFR estimation in children. <!--[endif]---->

Methods: Methods Single injection inulin clearance tests were done in a convenience sample of children on clinical grounds with a simultaneous serum crea and CysC measurement. GFR was estimated from crea using the CKid1<!--[endif]----> (Schwartz et al, 2012) (height-dependent) and Pottel (height-independent) equations and by the cysC-based CKid2 equation (Schwartz et al, 2012). The mean of pairs of the crea and CysC based equations was calculated and the bias and p30 accuracy analyzed.<!--[endif]---->

Results: Results A total of 459 measurements were done in 459 children (or 459 bloodsamples?) and adolescents aged 1 month to 19.5 years. Of the creatinine-based equations CKid1 (bias 4.7 ml/min/1.73m^2, p30 accuracy 82.1%) outperformed Pottel (bias -15.6, p30 accuracy 76.3%). CKiD2 (bias 14.3, p30 accuracy 80.8) performed similarly to CKid1. The combination of a crea and a CysC based equations markedly increased accuracy and decreased bias. The mean of Pottel and CKid2 (bias -0.6, p30 accuracy 87.8%), performed as well as the mean of CKid1 and CKid2 (bias 9.5, p30 accuracy 89.1%).

Conclusions: Conclusion Combining the Pottel creatinine and the CKid2 Cystatin C-based eGFR equations enables accurate allows for GFR estimation in children *independent of height* with good accuracy and which allows for direct can eGFR be reporting reported directly by the laboratory.

PUB148

CKD in HIV-Infected Patients: Relationship with Comorbidities Rosbel M. Brito,[2] Justine Johnson,[2] Eric J. Lai,[2] Rochelle E. Castro,[4] Edward A. Graviss,[3] Duc T. Nguyen,[3] Angelina Albert,[1] Ann S. Barnes,[4] Wadi N. Suki.[5] *[1]Houston Methodist, Houston, TX; [2]Houston Methodist Hospital, Houston, TX; [3]Houston Methodist Research Institute, Houston, TX; [4]Legacy Community Health, Pearland, TX; [5]None, Houston, TX.*

Background: Use of HAART has increased life expectancy in HIV-infected patients, but also is related to the development of traditional cardiovascular risk factors like HTN, dyslipidemia, and insulin resistance, among other conditions. Our aim, determine the association between HAART use, CKD, and various comorbidities frequently found in HIV-infected patients

Methods: Retrospective cohort study (2012-2016) in 3719 HIV-infected patients followed in a Federally-qualified community clinic. Prevalence of CKD (defined by the CKD-Epi Equation as eGFR<60 ml/min/1.73m^2) was determined, and its relationship with potential comorbidities examined

Results: A REDCap database was created with 3719 HIV-infected patients. CKD was present in 4.11% of the population. CKD patients were generally older, males, African American, and had HIV infection for longer. The association of different comorbidities with CKD compared with non-CKD patients was as follows:CKD patients had higher proportions of HTN (63.4% vs 27.0%,p<0.001), DM2 (15.0% vs 8.1%, p=0.003), hyperlipidemia (35.3% vs 23.3%,p=0.001), cardiovascular disease (9.2% vs 4.1%,p=0.002), cerebrovascular disease (6.5% vs 1.5%,p<0.001), HBV (9.2% vs 4.8%,p=0.02), oral candidiasis (13.7%vs8.4%,p=0.03), CMV infection (9.8%vs5.3%,p=0.02), HSV (20.9%vs15.8%, p=0.09), history of kidney stone (4.6%vs1.6%,p=0.01), and positive smoking status (40.5%vs47.4%,p=0.08). In all the 3714 patients, smoking, HTN, hyperlipidemia, and HSV infection were the most frequent comorbidities detected (47.5%, 28.5%, 23.8% and 16.0%, respectively). Other comorbidities were found in less than 10% of patients. In the CKD group, the most common comorbidity was hypertension, present in nearly two-third of the patients. On the other hand, smoking was the most common comorbidity in the non-CKD group with nearly all patients having ever smoked

Conclusions: Progressive loss of kidney function over a period of months or years, has become one of the leading causes of mortality among HIV-infected patients. HIV infection, and its treatment are often associated with comorbidities that adversely impact kidney function, such as diabetes mellitus, dyslipidemias, and hypertension. Early detection, a corrective treatment, and a meticulous follow-up of these conditions are the cornerstone of measures to decrease morbidity and mortality in HIV- infected patients

PUB149

Kidney Function in HIV-Infected Patients Seen in a Community Clinic: Characteristics and Natural History of the Disease Rosbel M. Brito,[2] Justine Johnson,[2] Eric J. Lai,[2] Rochelle E. Castro,[4] Edward A. Graviss,[3] Duc T. Nguyen,[3] Angelina Albert,[1] Ann S. Barnes,[4] Wadi N. Suki.[5] *[1]Houston Methodist, Houston, TX; [2]Houston Methodist Hospital, Houston, TX; [3]Houston Methodist Research Institute, Houston, TX; [4]Legacy Community Health, Pearland, TX; [5]None, Houston, TX.*

Background: The kidney plays a role in the metabolism and excretion of some antiretroviral drugs (ARV), and this makes it more vulnerable to various types of injury that can lead to blood and urinalysis abnormalities. Our aims were to identify patients with reduced renal function according to the KDIGO stages of kidney disease;to characterize the nature of the kidney disease encountered and to determine the rate of loss of renal function

Methods: Retrospective cohort study (2012-2016) in 3,719 HIV-infected patients seen in a Federally-Qualified community clinic. Blood and urine laboratory results were extracted from medical records. Changes in eGFR were derived from multiple serum creatinine values collected over time

Results: We measured GFR for each patient and staged patient's kidney function based on the KDIGO Clinical Practice Guideline Figure 1.153 patients (4.1%) had CKD. As compared to patients with better preserved kidney function patients with CKD were likely to have a lower level of HGB than non-CKD patients median 13.5 vs 14.4g/dl and lower level of albumin median 4.3 vs 4.4g/dL p<0.001 and higher levels of K^+ median 4.40 vs 4.30mEq/L in the non-CKD group p=0.01. Na^+ and CL^- were not significantly different between the two groups. $C0_2$ was 22mol-1 in the CKD patients vs 23mol-1 in non-CKD group p<0.001. The CKD patients also had a significantly greater decline in their eGFR, from first to the last follow-up reflecting a median percentage change of -26.5 versus 0 ml/min/1.73m^2 (IQR-9.2, 8.5) in non-CKD patients p<0.001. The median rate in eGFR changes per year was -4.0 vs -0.2 ml/min/1.73m^2/year in the non-CKD counterpart p<0.001. Data from urinalysis were insufficient for significant statistical analysis.

Conclusions: CKD was present in 4.1% of a population of HIV-patients. The disease did not appear to have any distinctive characteristics. However, in the affected patients the rate of loss of renal function appeared to be fairly rapid

Utility of Reticulocyte Haemoglobin Content as a Marker of Iron Deficiency Anaemia in Black CKD Patients in South Africa Aishatu M. Nalado,[1,3] Saraladevi Naicker.[2] *[1]Aminu Kano teaching hospital, Kano, Nigeria; [2]University of the Witwatersrand, Johannesburg, South Africa; [3]MEDICINE, Charlotte Maxeke Academic hospital, Johannersburg, South Africa.*

Background: : Anaemia is a common cause of morbidity and mortality among CKD patients. Early diagnosis of iron deficiency anaemia (IDA) is essential to initiate prompt treatment and improve prognosis. Various biochemical parameters are used to diagnose IDA with varying validity. We evaluated the ability of CHr to predict IDA in black pre-dialysis CKD patients.

Methods: : This was a cross- sectional study of 258 pre-dialysis CKD patients and 141 age- and sex-matched healthy controls at the renal outpatient clinic of Charlotte Maxeke Johannesburg Academic Hospital between 1 June 2016- 30 December 2016. Haematological and biochemical parameters were analysed, using standard laboratory methods. Univariate and multivariate logistic regression was conducted to determine the predictors of IDA. Receiver operator characteristic (ROC) curves were conducted on CHr, TSAT and Ferritin. Parametric ROC analysis was used to determine the validity of CHr in the diagnosis of IDA. The validity of CHr was compared with TSAT and Ferritin using the ROC curves.

Results: : Table 1 shows characteristics of the study population. The prevalence of IDA was 26% and the prevalence of functional IDA was 13-fold higher in CKD patients as compared to controls (18.6% vs 1.4%, P <0.001). The discriminating value of iron deficiency by CHr is fairly good (AUC=73%; sensitivity=71.2%; specificity=71.2%), but lower than that of the conventional parameter (TSAT and Ferritin) (0.88 vs 0.73; P=0.02).

Conclusions: Although the predictive value of CHr in diagnosing IDA among pre-dialysis CKD patients was lower than the conventional methods, CHr can still be proposed in our environment, when considering the trade off in terms of cost, accessibility and ease of performance.

PUB151

Sacubitril/Valsartan in CKD: A Nephrologist Point of View Borja Quiroga,[2] Antonio De santos wilhelmi,[4] David S. Sapiencia Sanjines,[3] Yamila Saharaui,[1] Antonio manuel R. Gonzalez,[3] Vicente Álvarez.[1] *[1]Hospital Universitario de La Princesa, Madrid, Spain; [2]Nephrology, Hospital Universitario de La Princesa, Madrid, Spain; [3]Hospital de La Princesa, Madrid, Spain; [4]Spanish National Health Service, Madrid, Spain.*

Background: The angiotensin receptor neprilysin sacubitril/valsartan(SV) reduces cardiovascular morbidity and mortality in patients with systolic dysfunction(SD) as shown in the PARADIGM-HF study. Renal function in patients with chronic kidney disease(CKD) has not been evaluated as a hard endpoint in clinical trials. In this study, we include patients with CKD and SD in order to assess their renal function after initiating SV.

Methods: In this prospective study, we included 41 consecutive patients with CKD and SD. We included patients with NYHA class II to IV being receiving maximal tolerated doses of optimal medical therapy including angiotensing converting enzyme inhibitors (ACEi), beta-blockers and mineralcorticoid receptor antagonist if appropriate. At baseline, comorbidities and epidemiological data was collected and low doses of SV were initiated. At month 1 and 3, doses of sacubitril/valsartan were rise up to maximal doses. At each visit (baseline, 1 month and 3 month), we evaluated renal function, estimated glomerular filtration rate (GFR) with CKD-EPI, pro-brain natriuretic peptide and changes in body composition using bioimpedance spectroscopy (BIS).

Results: Of the 41, 30 patients(73.2%) were men, with a mean age of 76±13 years. Regarding comorbidities, 39 patients (95.1%) had hypertension, 20(48.8%) were diabetic, 30(73.2%) had dyslipidemia and 5(12.2%) had history of cerebrovascular disease. Thirty six patients(87.8%) had history of ischemic heart disease, with a mean left ventricular ejection fraction of 33±8. Creatinine at baseline was 1.55±0.52 mg/dL(GFR estimated by CKD-EPI 46±20 ml/min/1.73m^2). After one month of treatment GFR improved a mean of 2.6(0.1-5.1) ml/min/1.73m^2 (p=0.03). At fourth month, renal function was stable and no differences in GFR were observed respecting baseline (p= 0.47). Diuretics were diminished or eliminated in 30 patients(73.1%). However, no differences in overhydration (measured using BIS) during the study were observed.

Conclusions: SV is safe in CKD and offers a transient improvement in renal function. Long-term clinical trials are required to confirm this results.

PUB152

Length of Stay Implications of Anemia in Patients with Heart Failure Exacerbation in an Inner-City Hospital Avantee V. Gokhale,[1,3] Samuel Mon-Wei Yu,[2] Poonam Mahato,[2] Pitchaphon Nissaisorakarn,[2] Anjali Acharya.[3] *[1]JACOBI MEDICAL CENTER, BRONX, NY; [2]Jacobi Medical Center, Bronx, NY; [3]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: Anemia is a known risk factor for poor survival, frequent hospitalization, and impaired life quality in patients with heart failure. Severe anemia [hemoglobin (Hb) < 9] is associated with poor hospital and patient outcomes in heart failure patients with chronic kidney disease. However, this relationship in patients with mild-to-moderate anemia is unclear. Hence, we assessed the relationship of admission Hb to the length of stay (LOS) during a hospitalization in patients admitted with acute decompensated heart failure (ADHF) in an inner-city hospital catering mainly to a minority patient population.

Methods: 118 consecutive patients admitted between 01/01/15 to 06/30/16 with a diagnosis of ADHF were included. Retrospective chart review was performed to gather demographics, lab data on admission and LOS. The cohort was stratified based on the presence of mild-to-moderate anemia defined by Hb levels, <12 for women and <13 for men and a lower Hb cut-off level of 9. Statistical analyses included descriptive statistics and multivariable regression analyses.

Results: Of 118 patients (mean age=69), 69 (59%) had mild-to-moderate anemia. They were older (71±13 vs. 66±14, p=0.01), but had similar gender distribution (males: 54% vs. 59%) compared to those without anemia (n=49). More anemic patients were on beta-blockers (83% vs. 63%, p=0.02). Despite similar pro-BNP levels, anemic patients had a longer LOS [median (IQR): 8 (5-14) vs. 6 (5-8); p=0.03] and a higher fraction with LOS > 7 days (54% vs. 29%; p<0.001). LOS was inversely associated with Hb levels on admission (**beta**=-0.16, p=0.01) and the association persisted beyond demographics, history of chronic kidney disease, beta blocker use, ACEi/ARB use, diuretics and BUN/creatinine on admission (**beta**=-0.18, p=0.03). Finally, compared to anemic patients, patients with normal Hb levels had lower odds of prolonged LOS (>7 days) [OR (95% CI): 0.32 (0.16-0.64), p<0.001] after adjustment.

Conclusions: In conclusion, LOS is inversely associated with admission hemoglobin in ADHF patients. even among patients with mild-to-moderate anemia. These findings confirm results of STAMINA–HF. Hence, Hb could be a modifiable risk factor for decreasing LOS, however, larger prospective studies are needed to confirm our findings.

PUB153

Global Longitudinal Strain (GLS) as Cardiac Imaging in Mid-Range Heart Failure (HF) (LVEF 40-49%) and CKD Stages 1-5ND Secundino Cigarran,[1] Jose Lomban,[2] Jesus Calvino,[3] Nicolas Menendez,[1] Ana maria Sanjurjo amado,[1] Juan Latorre,[1] Nuria C. López,[1] Lourdes Gonzalez tabares,[3] Belen Rodriguez delgado.[1] *[1]Nephrology, Eoxi Cervo-Lugo-Monforte, Burela, Spain; [2]Cardiology, Eoxi Cervo-Lugo-Monforte, Burela, Spain; [3]Nephrology, Eoxi Cervo-Lugo-Monforte, Lugo, Spain.*

Background: CKD carry a high CV risk and imaging plays a key role in assessing the severity and providing risk stratification. HF mid range LVEF 40–49% is considered that represent a grey area, most probably have primarily mild systolic dysfunction and features of diastolic dysfunction. A novel method is GLS tissue doppler imaging, which evaluate the degree of deformation in space and time of myocardial fibers during systole and diastole. The aim of this study is to assess GLS in CKD stages 1-5ND with mid range HF.

Methods: 105 pts (22.9% W, 50.5% DM2), median age 73 years. 21% CKD 1&2; 53.3% CKD 3A&3B; 25.7% CKD 4&5. All evaluated anthropometrically, and body composition was by BIVA (EFG, Akern, Fl, Ita). Anemia markers, bone metabolic disease, renal function (GFR CKD-EPI & ACR) were assessed. Peripheral arterial disease by ankle-arm-index (AAI) and carotid US and AGEs by skin autofluorescence and vascular age as well. Ecocardiography tisular doppler was performed by the same author (JAL) and derived measures were GLS, E/é, E/A & Vol LA (LAVI: VolLA/sc (m^2).

Results: Mean LVEF 45.15±2.6%. Mean GLS -12.6±3.8% (Normal: -20%). GLS was significantly higher with Charlson Index (r:.297; p=0.05), vitamin D (r:-.347; P=0.023), E/A (r: -373; p=0.039); Vol LA index (r: 268; p< 0.040). DM vs noDM (-11.80±3.5% vs -13.4±4.0; p=0.007); PAD vs NPAD (-10.2 ± 4.0% vs -13.4±3.56%; p= 0.024); atherosclerosis vs no atherosclerosis (NS).[Image1] shows GLS through CKD stages.

Conclusions: CKD from early stages, left ventricular becomes stiff and less contractile. HF mid range LVEF constitute a grey area poorly studied. In CKD may be an early mortality marker. The evolution of left ventricular functionality with GLS assess CV risk. Futher prospective studies are need to confirm these findings.

CKD and Carotid Atherosclerosis Are Associated with Symptomatic Stroke Keiko Tanaka,[3] Haruhito A. Uchida,[2] Nobuo Kajitani,[5] Yuki Kakio,[3] Masashi Kitagawa,[4] Hitoshi Sugiyama,[4] Jun Wada.[1] *[1]Okayama, Japan; [2]Okayama Univeristy, Okayama, Japan; [3]Okayama University, Okayama, Japan; [4]Okayama University Graduate School, Okayama, Japan; [5]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Symptomatic stroke is the most prevalent cardiovascular and neurological diseases in Asia. However, the relationship between stroke, atherosclerosis and chronic kidney disease (CKD) has not been fully investigated. We aimed to investigate the relationship between CKD, symptomatic stroke, and carotid atherosclerosis.

Methods: We enrolled 455 subjects who underwent carotid ultrasonography in our hospital. Three hundred eleven patients were examined with carotid ultrasonography at the onset of symptomatic brain infarction, and 144 patients without any symptoms were examined. Carotid intima-media thickness (IMT), rate of internal carotid artery vasoconstriction, and maximal plaque size were measured using high-resolution B-mode ultrasonography.

Results: The mean age was 68.5 ± 11.0 years, and the mean estimated glomerular filtration rate (eGFR) was 68.8 ± 18.2 ml/min/1.73m^2. After adjustment for cardiovascular risk factors, the mean IMT in patients with CKD showed significant progression in comparison to those without CKD. Moreover, the IMT and eGFR were negatively correlated in patients with stroke (r = -0.169, p = 0.003). The mean IMT, plaque size, and vasoconstriction area were found to be significant determinants of symptomatic stroke after the adjustment of multivariate risk factors. The eGFR was found to be a negative determinant of stroke after adjusting for risk factors (OR (95%CI) = 0.877 (0.777-0.990), p = 0.034).

Conclusions: This study demonstrated that CKD could be associated with the progression of carotid atherosclerosis in patients with symptomatic stroke.

PUB156

The Role of Peritoneal Dialysis in Congestive Heart Failure: One Center Experience Panagiota E. Giannou,[2] Athanasia Kapota,[2] Aikaterini Damianaki,[2] Giorgos Bougatsos,[2] Christina Chrysohoou,[1] Dimitrios Petras.[2] *[1]Cardiology department, Hippokration Hospital, PIKERMI RAFINA, Greece; [2]Nephrology Department, Hippokration Hospital, ATHENS, Greece.*

Background: Peritoneal ultrafiltration (PUF) could be an effective strategy for the treatment of wastewater without compromising cardiac output and thus the renal function in patients with advanced congestive heart failure (CHF). The objective of this study is to determine the therapeutic role of PD in the management of patients with advanced CHF and renal dysfunction.

Methods: We studied retrospectively 15 patients who met the following inclusion criteria: (i) at least two nonscheduled hospitalizations for acute heart failure (AHF), the last episode in the last six months (ii) functional class NYHA III / IV (iii) persistent congestion despite optimal treatment with diuretics and (iv) the presence of renal dysfunction [estimated glomerular filtration rate (eGFR) <60 ml / min/1,73 m^2].

Results: After the first 6 months patients improved the stage of heart failure (from stage NYHA III / IV in II / III), dramatically reduced hospitalizations due to cardiac symptoms, improved quality of life, maintained satisfactory diuresis (>1000ml/day) thus maintained residual renal function (mean eGFR>35 ml/min/1,73 m2), preserved hemodynamic stability, improved lower limps edema and ascites.

Conclusions: All the data gathered to date from observational studies on the role of PUF as treatment adjuvant to standard pharmacotherapy, in patients with severe CHF refractory to optimal treatment, are encouraging and indicate their efficacy as well as safety. Given that the complications such as peritonitis or leaks are relatively rare, it seems that the benefits of the therapy far outweigh its risks. The possible mechanisms of clinical improvement in patients with CHF by PUF appear to be multifactorial. The reduction of preload and clearance of vasoactive-inflammatory agents seem to be the main factors. Only the results of multicenter, randomized trials may answer the question whether PUF could extend patient's lifespan. The close cooperation of cardiologists and nephrologists could identify patients with CHF who would benefit from PD, as the method is not widely used because it does not apply to all centers, but mainly because doctors are not familiar with the process and not advice it to patients as an alternative therapy.

PUB157

Resistin as a Predictor of Hospital Admission Due to Cardiovascular Events Filipa B. Mendes,[1] Luisa H. Pereira,[1] Ana P. Silva,[2] Pedro L. Neves.[3] *[1]Centro Hospitalar do Algarve, Faro, Portugal; [2]Hospital de Faro E.P.E, Faro, Portugal; [3]Centro Hospitalar Algarve, Faro, Portugal.*

Background: The hormone resistin appear to have a relevant role on several pathological pathways in complex illness such as diabetes, cardiovascular disease, liver disease, chronic kidney disease, auto-immune disease and several inflammatory conditions. More than that, high serum resistin levels have been associated with increased risk of cardiovascular disease in the general population. Diabetic and renal impaired patients seems to present with the biggest risk. The aim of this study is to determine the role of serum resistin levels as a predictor of hospital admissions triggered by cardiovascular episodes in type 2 diabetic patients with mild to moderate CKD.

Methods: An observational study enrolled 78 diabetic patients with mild to moderate CKD which were screened and selected in an outpatient diabetic nephropathy clinic and were followed from January 2008 to December 2016.

Results: Out of the total 78 patients included, 13 were admitted at the hospital and newly diagnosed with cardiovascular pathology. There was a statistically significant result for resistin as a predictor of cardiovascular related hospital admissions (p <0.05). Laboratory parameters such as creatinine clearance, albumin, HbA1c, phosphorous, PTH, insulin resistance, CRP, resistin and active vitamin D, were positively related to cardiovascular hospital admissions.

Conclusions: Serum resistin levels demonstrated to be a valuable instrument to predict cardiovascular hospital admissions in type 2 diabetic patients with mild to moderate CKD. Also, other factors often altered in type 2 diabetics and patients with renal impairment were associated with hospital admissions but didn't prove to have any potential in predicting hospital admissions in this group.

PUB158

The Role of Proteinuria on Vascular Function in Hypertensive Patients with CKD Vagner S. Meira, Claudio P. Loivos, Mario F. Neves, Carla C. Lemos, Márcia R. Klein, Maria Ines Barreto-Silva, Rachel Bregman. *State University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: CKD is associated with cardiovascular disease (CVD), however the best marker for this alteration is not established. Proteinuria is a marker of progression of CKD and endothelial damage. Left ventricular mass index (LVMI) and arterial stiffness (AS) are related to target organ damage. Endothelial dysfunction (ED) is associated with CVD. We evaluated the association of proteinuria with CVD markers in CKD patients.

Methods: We evaluated 97 patients, eGFR: CKD-EPI (categories 3-4). Proteinuria evaluated in urine sample (mg/g). LVM evaluated by echocardiography and LVMI obtained by dividing it by the body surface area. AS evaluated by carotid-femoral (CF) pulse wave velocity (PWV). ED evaluated through the technique of flow-mediated dilation (FMD) of the brachial artery. We analyzed 4 subgroups according to age and proteinuria: Group1: age <65 years, proteinuria<300mg/g; Group2: age≥65 years, proteinuria<300mg/g; Group3: age <65 years, proteinuria≥300mg/g; Group4: age≥65 years, proteinuria≥300mg/g. All patients followed during 18 months. Statistical analysis: SPSS-20.

Results: Data for all patients: mean ± SD. Age 64 ± 10 years; 57% of males; eGFR: 30.6 ± 9.8ml/min/1.73 m^2; systolic blood pressure (SBP) : 151 ± 22mmHg; pulse pressure (PP): 70 ± 19mmHg; DMF: 10.3 ± 6.8%; CFPWV: 10.8 ± 3.4m/s; LVMI: 106.8 ± 43.5g/m^2. Median proteinuria: 320mg/g (43-4992). Proteinuria did not show association with LVMI nor FMD, and was associated with SBP after adjustment for age (p=0.0001), PP (p<0.0001) and CFPWV (p=0.001). CFPWV(m/s) values: Group1: 9.3 ± 1.6, Group2: 10.3 ± 2.6, Group3: 9.1 ± 1.9, Group4: 13.4 ± 3.6. Group 2 vs 4 p=0.03. eGFR showed a decrease >5ml/min/1.73m^2/year in 14% of the patients. Cardiovascular events: 6.2% (acute myocardial infarction or stroke); end-stage renal disease:5.2% and death:1%. All outcomes were observed in patients with higher proteinuria and CFPWV.

Conclusions: DMF was not different among the groups. AS was higher in those with higher proteinuria and independent of the eGFR. Therefore, proteinuria but not eGFR, neither age, may be associated with the AS and consequently with CVD in this population. We suggest that the simple evaluation of proteinuria, can be used as an early marker of cardiovascular disease in CKD, instead of more complex technics.

PUB159

Secondary Hyperparathyroidism Is Independently Associated with Left Ventricular Diastolic Dysfunction in Patients with CKD Il Young Kim,[2] In seong Park,[1] Min Jeong Kim,[2] Miyeun Han,[1] Harin Rhee,[1] Sang Heon Song,[1] Eun Young Seong,[1] Dong Won Lee,[2] Soo Bong Lee,[2] Ihm Soo Kwak.[1] *[1]Pusan National University Hospital, Busan, Republic of Korea; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Cardiovascular disease (CVD) is the leading cause of death in patients with chronic kidney disease (CKD). Left ventricular diastolic dysfunction is known for the predictor of CVD in these patients. Secondary hyperparathyroidism (SHPT), a common complication of CKD, contribute to cardiac dysfunction. This study aimed to evaluate the association between SHPT and left ventricular diastolic dysfunction in patients with CKD.

Methods: This study included 332 pre-dialysis CKD patients (estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2). Two-dimensional echocardiography was performed to left ventricular ejection fraction (LVEF). Tissue Doppler imaging was used to measure the early mitral inflow velocity (E) and the peak early mitral annular velocity (E'). Diastolic function was estimated by the E' and the ratio of E to E' (E/E'). The associations of echocardiographic index with clinical and laboratory variables [age, sex, diabetes, hypertension, eGFR, albumin, uric acid, calcium, phosphate, total cholesterol, hemoglobin, C-reactive protein, and intact parathyroid hormone (PTH)] were investigated by univariate (Pearson's correlation, r) and multivariate analysis (multiple linear regression analysis, β).

Results: Of the 332 patients, 198 were in CKD stage 3, 84 in CKD stage 4, and 50 in CKD stage 5. The degree of diastolic dysfunction was more severe (lower E' and higher E/E') with increasing CKD stage. There were no significant differences between the three CKD groups in LVEF. In univariate analysis, the intact PTH levels correlated with E' (r = -0.321, P < 0.001) and E/E' (r = 0.297, P < 0.001). However, they did not correlated with index of systolic dysfunction (LVEF). In multivariate analysis, the intact PTH levels were significantly associated with E' (β = -0.349, P < 0.001), and E/E' (β = 0.322, P < 0.001) after adjustment for other confounding factors.

Conclusions: Increased intact PTH levels were independently associated with decreased E' and increased E/E' in patients with CKD, suggesting that SHPT are independent predictor of left ventricular diastolic dysfunction in these patients. Further studies are needed to determine whether the treatment for SHPT could prevent left ventricular diastolic dysfunction in CKD patients.

PUB160

Diagnosis of CKD, Thrombotic Cardiovascular Events, and Prescription Trends for Aspirin and Oral P2Y12 Inhibitors among Veterans with CKD Manisha Singh,[3,2] Deepa Raghavan,[4,2] Nithin Karakala,[3] James S. Williams,[1] Nishank Jain.[2] *[1]Department of Veterans Affairs, North Little Rock, AR; [2]Little Rock VA Hospital, Little Rock, AR; [3]University of Arkansas For Medical Sciences, Little Rock, AR; [4]University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Use of aspirin and P2Y12 inhibitors (P2Y12) is standard of care for patients experiencing thrombotic cardiovascular (CV) events. However, chronic kidney disease (CKD) patients have been excluded from these trials. We explored prevalence of CKD diagnosis among Veterans, proportion of thrombotic CV events occurring in Veterans with CKD and P2Y12 prescription-trends in this Veteran population.

Methods: Using the Corporate Warehouse data from fiscal year (FY)11-15, we determined the number of Veterans with a diagnosis of CKD and thrombotic CV events using validated ICD-9 codes. We used VA pharmacy drug codes and generic names of drugs to identify prescriptions for aspirin and P2Y12. We calculated % annual increase in the number of prescriptions for P2Y12- as the difference in the prescription counts between consecutive fiscal years.

Results: The point prevalence of CKD among Veterans increased by 49% from 2.30% to 3.42%. Of 226,982 total thrombotic CV events, 56.7% occurred in Veterans with CKD. Of the 378,233 Veterans with CKD, 66.7% were on aspirin and 25% received prescriptions for oral $P2Y_{12}$ inhibitors- 97% for clopidogrel, 1% for ticagrelor and 2% for prasugrel. Half of the total prescriptions for clopidogrel and prasugrel; and two-thirds of the ticagrelor prescriptions were associated with CKD diagnosis. Prescriptions for P2Y12 increased during the observation period, with the highest increase in ticagrelor.

Conclusions: CKD is a rapidly growing chronic disease among Veterans. Thrombotic CV events are common in Veterans with CKD. There is a dramatic rise in prescriptions for P2Y12 among Veterans with CKD. Optimal use of P2Y12 needs to be defined in Veterans with CKD in order to maximize benefits, minimize risks and justify healthcare-associated costs.

Association of Blood Pressure (BP) with Proteinuria among Children with CKD Tammy M. Brady,[3] Shang-En Chung,[3] Michelle N. Eakin,[3] Andrea C. Goodman,[3] Cozumel S. Pruette,[3] Barbara A. Fivush,[3] Shamir Tuchman,[1] Susan R. Mendley,[4] Kristin Riekert.[2] *[1]Children's National Medical Center, Washington, DC; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]University of Maryland, Baltimore, MD.*

Background: Hypertension and proteinuria are risk factors for CKD progression and often occur together. We aimed to determine how various methods of BP measurement associate with proteinuria among children with CKD.

Methods: Cross-sectional analysis of the baseline visit in the CKD: Hypertension Adherence in Teens (CHAT) study. Children were 11-19 yrs, had CKD, and were prescribed ≥1 BP medication. Children had a clinic BP, 3 consecutive standardized home oscillometric BPs, and 24-hr ambulatory BP (ABPM). BP index (BPi; measured BP/95th %ile BP; BP≥1 indicates hypertension) was calculated to standardize comparisons between BP measurements. Multiple logistic regression adjusting for age, sex, race, body mass index z-score, and estimated glomerular filtration rate was used to determine how each BP measurement associated with significant [urine protein:creatinine (Upr:cr)>0.2 but <2.0] and nephrotic (Upr:cr≥2.0) proteinuria.

Results: 116 children with baseline first am Upr:cr available were included. Mean age 15.6 +/-2.6 yrs, 53% African American, 55% male, 32% hypertensive, 39% with significant proteinuria, 10% with nephrotic proteinuria. CKD Stage: I 23%; II 38%; III 26%; IV 6.3%; V 7.3%. No BP measurements were associated with Upr:Cr >0.2 but <2.0 in adjusted models. SBPi by every measurement method was associated with an increased odds of nephrotic proteinuria. Clinic DBPi was the only method of DBPi measurement not associated with nephrotic proteinuria [Table].

Conclusions: SBP by every measurement method was associated with nephrotic proteinuria. Overall, BP by ABPM was most closely associated with nephrotic proteinuria, providing additional support for its value in monitoring hypertension in progressive, heavily proteinuric CKD.

Assessment of Volume Status in Edematous CKD Patients: What to Choose Young Sun Kang,[4] Jin Joo Cha,[2] Ho jun Lee,[3] Dae R. Cha,[2] Hye sook Min.[1] *[1]Department of Internal Medicine, Wonkwang University Gunpo Hospital, Gunpo-si, Republic of Korea; [2]Korea University, Ansan, Republic of Korea; [3]Korea University Ansan Hospital, Ansan, Republic of Korea; [4]Korea University Medical College Ansan Hospital, Ansan city, Republic of Korea.*

Background: In the clinic, managements of volume overload are commonly determined by physical examination such as dyspnea and pitting edema and evaluation of signs of the disease, which could be inaccurate and lead to volume depletion. Therefore, more objective assessment of volume status is needed for management and optimization of volume status in clinically edematous patients.

Methods: We conducted a prospective observational study in patients with chronic kidney disease who visited hospital due to dyspnea and generalized edema. During hospitalization, volume status was evaluated using body composition monitor (BCM-Fresnius Medical Care) and 2D-echography. After 1 week and 1 month later, we reevaluated their volume status by BCM and 2D-echography.

Results: Of total 28 patients, mean age of the patients was 58.85±14.47. 14(50%) visited hospital due to dyspnea and 23(82.1%) due to pitting edema. Patients' edema was treated with diuretics (60.7%) and low salt diet or low salt diet only. Pitting edema, CKD stage, creatinine, NT-proBNP and UPCR(urine protein creatinine ratio) were significantly increased in relative overhydration(ROH>7%) group compared with non-relative overhydration group. 10(35.7%) patients had left ventricular hypertrophy, and 10(35.7%) patients had abnormally increased left atrial volume. At baseline and 1 week later, there were little correlations with overhyration value (OH, ECW, ECW/ICW) with ejection fraction, left atrial volume and end-diastolic left ventricle diameter. BCM value and 2D Echography were followed up after 1 month. Patients' symptoms were relieved during the treatment period with a significant weight difference (p value < 0.001). However, there were no significant differences in 2-D echo findings during 1 week nor 1 month. There were significant difference between the baseline and 1 month in overhydation value as well as body weight.

Conclusions: Current findings suggest that volume status may be more accurately assessed with bed side body composition monitor than echographic measurement.

Overhydration parameters on day 1 and 1month

Parameters	Baseline	1 Month	p value

Pathological Cardiac Remodeling Is Induced by Unilateral Urinary Obstruction (UUO) and Is Attenuated by Renin and Angiotensin Inhibition Onju Ham,[3] Lei Lei,[2] William Jin,[1] Hua A. Lu.[2] *[1]MGH, Wayland, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Massachusetts General Hospital/Harvard medical school, Boston, MA.*

Background: Cardiac hypertrophy and fibrosis are frequently observed in patients with chronic kidney failure. The mortality of cardiac disease is nearly doubled in chronic kidney disease (CKD) patients. Reno-cardio syndrome, or cardiorenal syndrome (CRS) type 4, is used to define cardiac dysfunction associated with chronic kidney injury. Despite close interactions between kidney dysfunction and cardiovascular disease, as evidenced by large amounts of clinical data, the underlying cellular and molecular mechanisms of cardiorenal syndrome remain poorly understood. Here, we report a study of cardiac remodeling in the context of chronic kidney failure, induced by unilateral urinary obstruction (UUO) in mice. CKD is induced after ligation of the left urethra for 21 days, as evidenced by the doubling of serum creatinine in treated mice. Despite no significant changes in cardiac function, we observed significantly increased cardiac mass, and enlarged cardiac myocytes, in UUO-induced CKD mice. Further examination, by trichrome and immunofluorescence staining of collagen type 1 and fibronectin, revealed the presence of significant extracellular matrix deposition in the cardiac interstitium. Significantly increased expression of ECM genes was detected by quantitative real time PCR, immunostaining, and immunoblotting. Further analysis indicated increased expression of TGF-β and TGF-β receptor 2, and increased phosphorylation of Smad 2 and 3; these suggest activation of the canonical TGF-β signaling cascade. Finally, treating animals with an angiotensin converting enzyme inhibitor (ACE I), Enalapril, significantly attenuated activation of the TGF-β signaling pathway and UUO-induced cardiac fibrosis.

Iron Therapy Is Associated with a Higher Incidence of CKD in Type 2 Diabetes Mellitus (DM2): A Retrospective Analysis of Veteran Patients in the VINCI Database Archana Goel,[5] Peter S. Wiegmann,[4] Mukut Sharma,[2] Vikas Singh,[3] Virginia J. Savin,[1] Ram Sharma,[3] Thomas Wiegmann.[6] *[1]KC VA Medical Center, Kansas City, AL; [2]KCVA Medical Center, Kansas City, MO; [3]Kansas City VA Medical Center, Kansas City, MO; [4]Midwest Biomedical Research Foundation, Kansas City, MO; [5]None, Leawood, KS; [6]VA Medical Center, Kansas City, KS.*

Background: Anemia is common with DM2 and iron therapy may exacerbate DM2. Iron is a key participant in both energy metabolism and oxidative stress with cellular damage. But it is not clear if standard iron therapy in DM2 produces a corresponding deleterious effect in the clinic. We undertook a retrospective study on the effect iron therapy on CKD progression veterans with DM2.

Methods: Data from a large cohort of veterans diagnosed with DM2 and Anemia by ICD (N=349,713) followed between 2002-2017 were used to determine the effect of iron therapy. Data from the Veterans Administration Informatics and Computing Infrastructure (VINCI) were analyzed using SQL and SAS. Patients were divided into those who did not receive iron therapy (No-Iron, N=185,272) and those who received iron therapy (Iron-Rx, N=164,441). Progression to ESRD was determined by an increase in creatinine values to above 1.5, 3.0 or 6.0 mg/dL). Groups were also compared for all-cause mortality, new onset CVA, MI and retinopathy. Significance was determined by Chi-square test.

Results: Results are outlined in the Table. Less than half of patients (47%) with anemia received iron therapy. The number of subject with creatinine values 3.0 and 6.0 were significantly higher in the Iron-Rx group (P<0.001). incidence of stroke (CVA), myocardial infarction (MI) and retinopathy was higher (P<0.001) in the Iron-Rx group. as was all-cause mortality (P<0.001).

Conclusions: Incidental or intentional iron therapy associates with significantly higher advance to ESRD and higher incidence of MI, CVA, and mortality, all consistent with advancing macro-vascular disease. Significant increased retinopath**y** signals concurrent micro-vascular disease.

Early Evidence of Intramuscular Inflammation in CKD Patients Stage 3b-4 Douglas W. Gould,[2] Alice C. Smith,[1] Emma L. Watson.[2] *[1]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]University of Leicester, Leicester, United Kingdom.*

Background: Muscle wasting is a common feature of Chronic Kidney Disease (CKD), but the precise mechanisms are not yet fully defined. However, evidence from end stage renal disease indicates an increase in protein catabolism is central to this. Intramuscular inflammation plays an important role in initiating muscle loss, but its contribution to protein degradation and impaired muscle regeneration in earlier stages of non-dialysis CKD has not been studied. Therefore, we investigated skeletal muscle cytokine gene expression and the expression of proteins involved in protein degradation and myogenesis in CKD patients stage 3b-4, compared to matched healthy controls.

Methods: Vastus lateralis muscle biopsies were collected from 10 CKD patients stage 3b-4 (mean eGFR 26, range 15-35ml/min/1.73m^2; mean age 63, range 35-75 years) and 10 healthy controls (mean age 63, range 35-75 years). IL-6, MCP-1, TNF-α, MyoD, Myogenin, Pax7, Myf5, Myostatin, activin type 2B receptor (ACVR2B), MuRF-1 and MAFbx mRNA expression were analysed by real-time PCR with 18s as internal control. Relative expression was calculated by 2^{-DCT}

Results: No differences were seen between patients and controls in the expression of any protein except IL-6 and TNF-a, which were both significantly elevated in the skeletal muscle of CKD patients by 8.7-fold (P=0.04) and 11.9-fold (P=0.01) respectively. There was a trend for increased expression of the myostatin receptor, ACVR2B, by 6.7-fold, but this fell short of significance (P=0.07).

Conclusions: This work shows marked intramuscular inflammation in non-dialysis CKD (3b-4) with elevations in mRNA expression of IL-6 and TNF-a. No significant increases were seen in MuRF-1, MAFbx or myostatin mRNA, although these were all elevated by at least 4-fold compared to the control group. This suggests that intramuscular inflammation starts early in the disease process and may play an important role in initiating muscle loss, which is known to progress with declining renal function.

PUB166

Renal Function and Infections Caused by Multidrug-Resistant Organisms in Patients Hospitalized with Infections Guobin Su,[1] Hong Xu,[1] Emilia Riggi,[3] Zhiren He,[2] Liming Lu,[2] Bengt Lindholm,[1] Gaetano Marrone,[1] Zehuai Wen,[2] Xusheng Liu,[2] Juan J. Carrero,[1] Cecilia S. Lundborg.[1] *[1]Karolinska Institutet, Stockholm, Sweden; [2]The 2nd Affiliated Hospital, Guangzhou University of Chinese Medicine, Guanghzou, China; [3]University of Pavia, Pavia, Italy.*

Background: Antibiotic resistance is a major global health threat. High prevalence of colonization and infections with multi-drug resistance organisms (MDROs) have been reported in patients undergoing dialysis. It is unknown if this finding extends to patients with mild and moderate/severe kidney disease.

Methods: An observational study included adult (≥18 years) incident patients hospitalized with a discharge diagnosis of infection, the presence of serum creatinine measurement at admission, and with microbial culture results, excluding those undergoing renal replacement therapy between 2012 and 2015, in four hospitals in China. Four categories of eGFR: eGFR≥105, 60-104 (reference), 30-59, and <30 ml/min/1.73 m^2 were compared. The odds ratio of MDROs, defined as *Staphylococcus aureus, Enterococcus spp., Enterobacteriaceae, Pseudomonas aeruginosa* and *Acinetobacter spp.*, and resistance to three or more antibiotic classes, were calculated using multivariable logistic regression model across eGFR strata, adjusting for age, sex, Charlson comorbidity index, and types of hospitalizations.

Results: We selected 9,196 the first positive cultures out of 94,445 microbial culture records. Among them, 6,356 were potential MDROs. The odds of infections by MDROs was 16% and 31% higher in those with eGFR between 30-60 ml/min/1.73 m^2 (Adjusted odds ratio (AOR): 1.16, 95% CI 1.02-1.33, P= 0.027) and eGFR <30 ml/min/1.73 m^2 (AOR: 1.31, 95% CI 1.07-1.60, P= 0.01), respectively.

Conclusions: Patients with impaired renal function have a higher risk. Kidney dysfunction at admission may be an indicator for closer attention to microbial culture results and the need of a subsequent change of antibiotics.

PUB167

Changes of Therapeutic Efficacy and Outcomes in Lupus Nephritis Patients from 1994 to 2010 in China Si-Jia Shao, Jin-Hua Hou, Cai-hong Zeng, Huixian Zhu, Ye Liu, Zhi-Hong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing China, Nanjing, China.*

Background: With more therapeutic options emerging in the management of lupus nephritis (LN) in recent decades, whether the efforts made in treatment has translated into improvement of patient outcomes remains questionable in Chinese patients. To assess trends in treatment modalities, therapeutic effects and long-term outcome of biopsy-proven lupus nephritis patients over time.

Methods: All patients aged > 14 years with biopsy-proven LN at the National Clinical Research Center of Kidney Diseases, Jinling Hospital from January 1994 to December 2010 were included. Patient characteristics, treatment regimens (including induction therapies and non-immunosuppressive therapies), and follow-up data were collected. Patients were stratified in 3 groups according to the year of renal biopsy: 1994–1998, 1999–2004, and 2005–2010. The primary end point of the study was end stage renal disease (ESRD). The treatment response and renal relapse were assessed as secondary outcomes.

Results: A total of 1945 LN patients were included in our analysis (182 from 1994-1998, 584 from 1999-2004, 1179 from 2005-2010). Use of MMF and combined therapy increased with the decline of cyclophosphamide. The cumulative probability of overall response at 12 months increased from 49.1% (95% CI, 42.0%-59.7%) in 1994-1998 to 77.8% ((95% CI, 74.2%-81.1%) in 1999-2004 and to 89.8% (95% CI, 87.9%-91.5%) in 2005-2010 ($P < 0.001$). The probability of free of renal flare increased over time ($P = 0.007$). The 10-year renal survival rates were 81.7% (95% CI, 74.2%-87.2%) in 1994-1998, 86.2% (95% CI, 82.8%-89.0%) in 1999-2004 and 89.3% (95% CI, 84.0%-92.9%) in 2005-2010 ($P = 0.006$). Compared with 1999-2004, the unadjusted hazard ratios for ESRD was in 1.13 (95% CI, 1.04-1.23) in 1994-1998 and 0.81 (95% CI, 0.73-0.90) in 2005-2010. The risk of ESRD still decreased over time after adjustment.

Conclusions: Between 1994 and 2010, treatment of LN patients improved substantially with an increasing trend in response rates to induction therapies and reduction in rates of renal relapse. It is encouraging that the long-term renal survival of LN patients have also increased over time.

PUB168

Prevalence of Reduced Bone Density in Systemic Lupus Erythematosus Patients: A Single-Center Study and a Meta-Analysis Yi Yang,[3] Gang Xu,[2] Shuwang Ge.[1] *[1]Tongji Hospital, Huazhong University of Science and Technology, WUHAN, China; [2]Tongji Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, WUHAN, China; [3]Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, Hubei, China, Wuhan, China.*

Background: The reported frequency of reduced bone mineral density (BMD) in systemic lupus erythematosus (SLE) patients vary widely. The data in Chinese SLE patients undergo minimal study. Risk factors associated are still under debate from different countries. We aimed to (1) detect the frequency and possible risk factors of reduced BMD in patients with SLE in our single center, and (2) conduct a meta-analysis concerning the frequency of reduced BMD in SLE with evidence from published studies.

Methods: We aimed to (1) detect the frequency and possible risk factors of reduced BMD in patients with SLE in our single center, and (2) conduct a meta-analysis concerning the frequency of reduced BMD in SLE with evidence from published studies.

Results: In our single-center study, 91 female SLE patients were assessed. 52.7% of the patients had low BMD, 56.0% had osteopenia and 19.8% had osteoporosis. Prevalence of osteopenia was higher in post-menopausal patients compared with pre-menopausal patients at total hip and femoral neck. Body weight was positively associated with BMD in all measured sites and menopause duration was negatively associated with lumbar spine and total hip BMD. In the meta-analysis, 71 reports with 33527 SLE patients were included. Low BMD, osteopenia and osteoporosis at any site were presented, respectively in 45%, 38% and 13% of the SLE patients. The prevalence of osteoporosis increased with the advancing of age, while U-shaped associations between age and the prevalence of low BMD and osteopenia were found. Lumbar spine was indicated to have severer bone loss compared to total hip and femoral neck in both our cross-sectional study and meta-analysis.

Conclusions: SLE Patients showed a high prevalence of reduced BMD. Low body weight, menopause duration, old age and disease-related factors might be the possible associated risk factors of bone loss.

PUB169

Effect of Intravenous Sodium Ferric Gluconate on Serial Platelet Counts in CKD Patients with Iron Deficiency Anemia Neville R. Dossabhoy,[1,2] Pallavi D. Shirsat,[1,2] Sangeeta Pal.[1,2] *[1]Medicine/Nephrology, VA Medical Center, Shreveport, LA; [2]LSU Health Shreveport School of Medicine, Shreveport, LA.*

Background: Iron deficiency often leads to reactive thrombocytosis; theoretically, its correction should lead to a lowering of the platelet count (PLT). Only a few studies have investigated this aspect, with some showing a reduction in PLT, whereas others did not. We investigated the effect of iron repletion with intravenous (IV) sodium ferric gluconate (SFG) on serial PLT counts in CKD patients with iron deficiency anemia (IDA).

Methods: We conducted a retrospective chart review, including patients with CKD and IDA who were treated with IV SFG. Patient demographics were recorded, as were baseline laboratory values for creatinine, eGFR, Hgb, iron stores and PLT. Serial, post-dose PLT values were recorded weekly for 4 weeks.

Results: A total of 118 doses of IV SFG (mean ± SD = 199±63 mg) were studied in patients with age 53±15 years, Creatinine 4.3±4.1 mg/dL, Hgb 8.7±1.8 g/dL and T-sat 12±7%. All CKD stages were represented in the study sample. Hgb and Fe stores improved post-dose. The variation in post-dose PLT over time is depicted below. All the values upto 4 weeks were elevated compared to the baseline, with the 2-week count reaching significance (P = 0.007).

Conclusions: Correction of iron deficiency did not lower PLT in CKD patients with IDA who received IV SFG. In fact, PLT were elevated compared to baseline throughout the 4-week period of follow-up, reaching statistical significance at the 2-week mark. This finding stands in contrast to some previous evidence and current popular theories. It confirms the previous report that PLT counts were not significantly reduced with IV iron dextran used as total dose infusion. Our finding may raise the possibility that increased PLT in the short-term post-dose, may contribute to the thrombotic events noted in clinical trials of erythropoiesis stimulating agents in CKD patients.

Platetet Counts

	Baseline	Week 1	Week 2	Week 3	Week 4
Mean	238	286	319	295	274
SD	163	224	209	121	136

PUB170

Loop Diuretics Associate with Greater Risk of Sarcopenia in Non-Dialysis-Dependent CKD Patients Seiko Ishikawa,[1] Shotaro Naito,[1] Shintaro Mandai,[1] Soichiro Iimori,[1] Naohiro Nomura,[1] Eisei Sohara,[1] Eiichiro Kanda,[2] Tomokazu Okado,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]Tokyo Kyosai Hospital, Meguro, Japan.*

Background: Sarcopenia is defined as progressive decline of skeletal muscle mass and function with age. Few studies have investigated the actual situation of sarcopenia in non-dialysis-dependent chronic kidney disease (NDD-CKD) patients.

Methods: We conducted a cross-sectional study comprised of 217 NDD-CKD patients over 65 years of age. Total body skeletal muscle mass was measured by dual-energy X-ray absorptiometry. Sarcopenia was diagnosed using the criteria of Asian Working Group for Sarcopenia. Adjusted odds ratios (aOR) for sarcopenia were estimated by using multivariate logistic models after stratifying the patients into 3 groups according to CKD stages.

Results: Mean age was 75.6±6.6 years, mean body mass index was 22.8±3.6 kg/m^2, and mean eGFR was 30.6±13.3 ml/min/1.73 m^2. 30.4% of the patients had diabetes mellitus (DM), 18.4% were treated with loop diuretics, and 25.3% were diagnosed as sarcopenia. Adjusted by age and gender (Model 1), the aOR in CKD5 group was 2.60 [95% confidence interval (CI) 1.04-6.50] compared to CKD 3 group. Adjusted by age, gender, and either DM (Model 2) or loop diuretics (Model 3), the aORs for CKD groups were statistically insignificant. On the other hand, each of DM and loop diuretics was associated with risk of sarcopenia [DM: aOR 2.02 (95%CI 1.01-4.07); Model 2]; [loop diuretics: aOR 3.07(95%CI 1.32-7.12); Model 3]. Furthermore, adjusted by age, gender, CKD groups, DM and loop diuretics (Model 4), the aOR for DM was statistically insignificant whereas the aOR for loop diuretics remained significant [loop diuretics: aOR 2.64(95%CI 1.10-6.33)]. In all models, age was an independent risk factor for sarcopenia.

Conclusions: Age and loop diuretics were independently associated with sarcopenia. In particular, loop diuretics were associated with increased risk of sarcopenia more than renal function and DM. Previous studies have shown that loop diuretics suppress skeletal muscle differentiation. This is the first study to show the risks of sarcopenia associated with usage of loop diuretics in a cohort of NDD-CKD patients. Since loop diuretics are commonly used in patients with advanced CKD treatment of volume overload, consideration for risk of sarcopenia may be necessary in such patients.

PUB171

The Endoscopic Findings of Double Balloon Enteroscopy in Patients with CKD and Obscure Gastrointestinal Bleeding Mohamad A. Hanouneh,[2] Steven Menez,[2] Diana S. Najjar,[2] Qiuyu Jin,[2] Ahmed El-Telbany.[1] *[1]Department of Medicine, Cleveland Clinic, Cleveland, OH; [2]Department of Medicine, Division of Nephrology, Johns Hopkins University, Baltimore, MD.*

Background: Obscure gastrointestinal bleeding is a common problem and associated with increase morbidity and mortality. Scarce data exist describing the small bowel characteristics of patients with chronic kidney disease (CKD) who present with obscure gastrointestinal (GI) bleeding. The **aim** of the study is to investigate the endoscopic findings of double balloon enteroscopy in patients with CKD who present with obscure GI bleeding.

Methods: We recruited 66 adult patients with CKD stages III-V who had obscure GI bleeding and underwent double balloon enteroscopy between 2002 and 2013. Stages of CKD were defined based on the glomerular filtration rate. Glomerular Filtration Rate (GFR) Estimate by Modification of Diet in Renal Disease (MDRD) Equation. Stage III for GFR 30-59, stage IV for GFR 15-29 and stage V for GFR <15. Obscure GI bleeding was defined as persistent or recurrent gastroentintestinal bleeding (hematemesis, melena, hematochezia or positive fecal occult blood test) with negative upper and lower endoscopies.

Results: A total of 66 patients were included in the study, of whom 37 patients had CKD stage III, 11 patients had CKD stage IV and 18 patients had CKD stage V. The median serum creatinine in the entire study population was 1.89 mg/dL [1.39, 3.28]. The source of bleeding was identified on 45 patients (68.2 %). The most common findings of double balloon enteroscopy were arteriovenous malformation (AVM) (n=30, 45.5%) of whom 18 patients had CKD stage III, 4 patients had CKD stage IV and 8 patients had CKD stage V. Overall, the most common locations of the AVM were the jejunum (73.3%). Other causes of obscure GI bleed include erosions (n=7, 10.6%) and ulcers (n=7, 10.6 %).

Conclusions: Arteriovenous malformation (AVM) is the most common finding of double balloon enteroscopy in patients with chronic kidney disease who have obscure GI bleeding.

PUB172

Correlation and Agreement between BIS-1 and CKD-EPI Equations to Estimate GFR in a Wide Cohort of Older Patients In Argentina Rosario Luxardo,[1] Maria L. Ocampo,[1] Griselda Bratti,[1] Carlos Federico Varela,[2] Alejandro Sengoku,[2] Nadia Satera,[2] Gustavo Greloni,[3] Guillermo Rosa Diez.[3] *[1]Hospital Italiano Buenos Aires, CABA, Argentina; [2]Hospital Italiano de Buenos Aires, CABA, Argentina; [3]None, Buenos Aires, Argentina.*

Background: Chronic kidney disease (CKD) is highly prevalent among older adults in Latin America. KDIGO proposes the use of Chronic kidney disease Epidemiology collaboration (CKD-EPI) equation, however this equation is not specific for patients aged over 70 years. Its application results on the inclusion of these patients on advanced stages of CKD increasing the burden on CKD programs. The Berlin Initiative Study (BIS-1) equation, compared to CKD-EPI equation, would improve the precision and accuracy of glomerular filtration rate estimation (GFRe) in patients aged over 70 years. There are limited reports of its use in Latin America and there is no data available for Argentina. Therefore, the aim of this study is to assess correlation and concordance betwween BIS-1 equation and CKD-EPI equations in a wide cohort of patients.

Methods: Plasma creatinine was measured on a cohort of 28.411 patients aged over 65 years under follow-up at Hospital Italiano of Buenos Aires. GFR was estimated with CKD-EPI and BIS-1 equations. The mean difference of GFR obtained with equations, correlation as well as the Bland-Altman analysis was calculated. The mean of GFRe was compared overall, by stages and by quartiles of age. The number of patients included on every stage was analyzed for both equations. $p<0.01$ was considered significative. A statistical analysis was performed with MedCalc Statistical Software version 16.8.4 (MedCalc Software bvba, Ostend)

Results: The mean age was 75±7 years. 65.7 % (n 18.678) female and 34.4% (n 9763) male. Mean GFR estimated by CKD-EPI was 68.3±17 ml/min/1.73m^2 and for BIS-1 was 60±15 ml/min/1.73m^2 ($p<0.01$) There was a significant correlation between both equations ($p<0.01$). BIS-1 included significative more patients on GFRe from 15 to 60 mil/min than CKD decreasing the number of patients on the rest of the stages (see Table 1). On graph 1 Bland-Altman graph showed that below 30 and above 60 mil/min the difference of the obtained results for both equations were outside the limits of concordance.

Conclusions: BIS-1 decreases the number of patients included in advanced stages of CKD (4 and 5) but, nevertheless, increases the number for stage 3B; without reducing the burden of patients on CKD programs.

PUB173

Sex, Age, and the Association of CKD with All-Cause Mortality in Buddhist Priests: A Retrospective Analysis of a Buddhist Priest Cohort in Korea Hyo Jin Kim,[1] Yunmi Kim,[1] Jae Yoon Park,[1] Sejoong Kim,[2] Ho Jun Chin,[2] Hajeong Lee,[1] Dong Ki Kim,[3] Kook-Hwan Oh,[3] Kwon Wook Joo,[3] Yon Su Kim,[3] Sung joon Shin,[1] Kyung Soo Kim,[1] Kyung Don Yoo.[1] *[1]Department of Internal Medicine, Dongguk University College of Medicine, Gyeongsangbuk-do, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, GyeongGi-Do, Republic of Korea; [3]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Buddhist priests are one of the major religious groups in Asia. Their unique life style with practicing asceticism, especially in vegetarian diet, might be influence their mortality. We explored the mortality among Buddhist priests in Korea compared with general population.

Methods: The present study is a single-center, retrospective study. Patients with Buddhist priests from Dongguk University Gyeongju Hospital from Jan, 2000 to Dec, 2014, founded by the Jogye Order of Korean Buddhism were enrolled. Standardized mortality ratios (SMR) were computed for all causes of death by comparing with the general population using national statistics (accessed at Korean Statistical Informational Service; http://kosis.kr/) in Korea. A total of 3,639 patients, 724 patients were known for baseline lavatory test including renal function. In subgroup analysis, SMR between chronic kidney disease (CKD) and non-CKD patients were analyzed. CKD was defined as dipstick proteinuria ≥1 or an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2.

Results: Among 3,639 Buddhist priests, mean age was 44.6±12.4 years old and 47.7% were male. During follow-up for 56.8±56.2 months, 152 (4.2%) patients died (102 [5.9%] in male, 50 [2.6%] in female). The SMR for all causes of death was 0.34 (95% CI, 0.29- 0.40). The SMR values for male (0.33; 95% CI, 0.27-0.40) and female (0.33; 95% CI, 0.25-0.44) were significantly smaller than general population. Among 724 patients, 74 (10.2%) patients had CKD and 3 (0.4%) patients developed end stage renal disease during follow-up period. The SMR value for non-CKD patients (0.76; 95% CI, 0.56-0.99) was significantly smaller than general population without CKD. Taking sex mortality differences into account, only female SMR value was significantly smaller (0.25; 95% CI, 0.08-0.57 *vs.* male; 0.81; 95% CI, 0.55-1.14). The SMR value for CKD patients was not significantly different comparing with general population (1.41; 95% CI, 0.85-2.21).

Conclusions: Buddhist priests showed significantly lower mortality compared with general population. Buddhist priests without CKD had significantly lower mortality, especially in female.

PUB174

Assessment of CKD Stage 3/4 Using Multiparametric Magnetic Resonance Imaging Huda Mahmoud,[3] Charlotte E. Buchanan,[1] Eleanor Cox,[1] Benjamin L. Prestwich,[2] Nicholas M. Selby,[2,3] Susan Francis,[1] Maarten W. Taal.[2,3] *[1]Sir Peter Mansfield Imaging Centre, Nottingham, United Kingdom; [2]University of Nottingham, Nottingham, United Kingdom; [3]Center for Kidney Research and Innovation, Derby, United Kingdom.*

Background: Progression of Chronic Kidney Disease(CKD) occurs secondary to inflammation and fibrosis independent of the underlying aetiology. Recent advances in Magnetic Resonance Imaging(MR) allow assessment of renal structure and function. We performed a multiparametric MR study to assess its utility and reproducibility in CKD patients.

Methods: 26 CKD Stage3-4 patients with kidney biopsies and 13 healthy volunteers(HV) had 2 multiparametric renal MR scans performed 7-14d apart on a 3T Philips Ingenia scanner. Structural assessments included renal volume, longitudinal-relaxation time(T_1) and Diffusion-Weighted Imaging(DWI) as markers of fibrosis and/or inflammation. Functional assessments included Arterial Spin Labelling(ASL) to measure renal perfusion and Blood Oxygenation Level Dependant Imaging(BOLD) as an indicator of renal oxygenation. The Coefficient of Variance(CoV) was calculated for each measure between the scans.

Results: CKD patients: mean 57±15yrs, eGFR 39±13mls/min/1.73m^3, uPCR 120±188mg/mmol. HVs were age-matched, had normal eGFR and no proteinuria. CKD cortical and medullary T_1 values were higher than HVs, 1580±92ms & 1739±78ms compared to 1396±64($p<0.0001$) & 1700±107($p<0.0001$) respectively, indicating more fibrosis/inflammation. CKDs had lower renal perfusion values($p=0.003$) and a trend for lower DWI values than HVs, no difference in volume and T_2*(BOLD) were found. Correlations were found between T_1 values and the extent of interstitial fibrosis observed on histology($p=0.02$). Reproducibility was excellent for cortical and medullary T_1(CoV 2.6% & 2.0% respectively), T_2*(CoV 2.6%), ADC(CoV 8.2%) and volumes(CV 3.0%).

Conclusions: This study demonstrates that mutiparameteric MR differentiates between HVs and CKD patients and is reproducible. The MR results reflect the known pathophysiological changes expected in CKD; reduced perfusion and the presence of fibrosis and/or inflammation, but interestingly did not demonstrate a difference in T_2* a potential marker of renal hypoxia. Further studies are required to build on this initial work to determine how best multiparametric MR can be used to assess whole kidney pathology and prognosis.

PUB175

The Risk of Hip Fracture in Patients Suffering from Different Stages of CKD Ammar Qureshi,[2] Fernando R. Aguilar,[1] Nesreen Benhamed.[3] *[1]Georgetown University Hospital, Washington, DC; [2]Internal Medicine, Marshall University, Huntington, WV; [3]Internal Medicine, MUSOM, Barboursville, WV.*

Background: Patients with CKD are at an increased risk of hip fracture than the normal population, which is attributed to the resulting vitamin D deficiency caused by the failure of the kidney to activate vitamin D. Failure in the calcium-phosphate homeostasis also adds to the poor bone condition. The aim of our study is to analyze the correlation between the stage of CKD (determined by GFR) and incidence of hip fracture.

Methods: Data was extracted from the 2005'12 nationwide sample (NIS) registry. We stratified these patients based on the stages of CKD (Stage 1 GFR > 90 mL/min; Stage 2 GFR 60-89 mL/min; stage 3 GFR 30-59 mL/min; stage 4 GFR 15-29 mL/min ; stage 5 < 15 mL/min). The incidence of hip fracture was calculated in each stage of CKD. Patients with CKD were matched with those without CKD using propensity score matching to determine the all-cause mortality in patients with hip fracture and those without hip fracture in patients with CKD.

Results: A total of 2.85 million patients were diagnosed with chronic kidney disease including ESRD in the year between 2005 and 2012. When stratifying according to the stages of CKD, stages 3 (0.54 % p<0.007 OR 0.70) and ESRD (0.76% p<0.007 OR 1.15) had the highest rates of sustaining a hip fracture when compared to the other stages of CKD. 1.35 % of these patients suffering from chronic kidney disease and hip fractures died during their hospital stay. The odds of sustaining a hip fracture with a patient suffering from chronic renal disease were 1.3 times. The difference in rates of sustaining a hip fracture between those patients diagnosed with renal osteodystrophy and those who were not was not found to be significant (p= 0.93).

Conclusions: Our data showed that patients end stage renal stage disease had a significantly higher chance of sustaining a hip fracture than patients in other stages of the CKD. Hence a worsening GFR could be correlated with the odds of sustaining a hip fracture, which means that as the stage of CKD progressed, patients were more prone to hip fractures These patients also had a higher mortality risk, however this could be a confounding factor since patients who are inflicted with both CKD and hip fracture could be sicker patients. There was no difference in the incidence of hip fractures if the patient was diagnosed with renal osteodystrophy.

PUB176

Cyclosporine as Rescue Therapy for Focal Segmental Glomerulosclerosis Who Were Refractory to Steroid Combination with Tacrolimus Xiayu Li. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: A proportion of adults with focal segmental glomerulosclerosis (FSGS) are refractory to treatment of steroid combination with tacrolimus due to persistent severe hypoalbuminemia and proteinuria. It is a challenge to find rescue therapies that are effective and safe in treating such difficult patient. Cyclosporine may be a promising alternative to tacrolimus for such patients.

Methods: In this prospective observational study, nineteen patients with adult-onset FSGS who did not respond to treatment with steroid (daily prednisone 0.5 mg/kg per day) combination with tacrolimus (target level of 4-10 ng/ml) for 12 weeks were studied from January 2013 to September 2016. Oral cyclosporine was administered (target trough level of 200-250 ng/ml) for 24 weeks, and then with tapering cyclosporine was given (target trough level of 50-100 ng/ml) for another 24 weeks. Oral prednisone was started at 0.5 mg/kg per day. Primary outcome variables were remission. Secondary outcome variables were time to remission, relapse rate, changes in serum creatinine and estimated glomerular filtration rate.

Results: One patient discontinued cyclosporine because of reversible acute nephrotoxicity, and 18 patients completed at least 12 weeks of cyclosporine therapy. Five patients (27.8%) experienced complete remission and 7 patients (38.8%) experienced partial remission. Primary resistance to cyclosporine was seen in 6 patients (33.3%). The mean time to partial remission and complete remission was 6.2 ± 3.4 weeks and 12.6 ± 4.5 weeks, respectively. After a mean follow up of 28.3 months, 33.3% (4/12) of patients who had remission experienced relapses. Two patients who were resistant to cyclosporine therapy had a doubling of serum creatinine concentration during follow-up.

Conclusions: Cyclosporine may be a suitable therapeutic option for treatment of adult-onset refractory FSGS. However, controlled studies with more patients are needed to compare the efficacy and safety of cyclosporine with tacrolimus in treating FSGS.

PUB177

Relationship between Renalase and Kidney Disease in 72 Patients with Renal Biopsy Nan Hu,[2,3] Sha Y. Huang,[2,3] Chuan-Ming Hao,[1] Xin-zhou Zhang.[2,3] *[1]Huashan Hosp., Shanghai, China; [2]Department of Nephrology, Shenzhen People's Hospital, Shenzhen, China; [3]Key Renal Laboratory of Shenzhen, Shenzhen, China.*

Background: Renalase is the only one amine oxidase that can be synthesized by a target organ. We evaluated the expression of renalase and explored the possible mechanism between renal tubular epithelial cells and renal cell apoptosis in 72 patients with renal biopsy.

Methods: The study group consisted of a total of 72 patients undergoing renal biopsy. Patient profiles and renal function were collected. Concentrations of renalase and bcl-2were measured by the IHC method. The tubular injury was detected and calculated by PAS and renal tubular epithelial cell apoptosis was assessed with TUNEL stain.

Results: The expression of renalase in renal biopsy with significantly lower levels than in patients with renal cell carcinoma of normal kidney tissue(Fig 1). In patients undergoing renal puncture biopsy, renal tubule injury index, as well as tubular epithelial cell apoptosis index showed a negative linear correlation with renalase (Fig 2). The results showed that renalase probably increase the expression of bcl-2 protein.

Conclusions: The research proved that it may reduce the renal tubular injury and apoptosis of renal tubular epithelial cells through the mitochondrial apoptosis pathway, finally achieve the purpose of delaying the progress of renal failure.

PUB178

Urine Liquid Biopsy of the Kidney Tadashi Yamamoto,[1,4] Keiko Yamamoto,[1] Yoshitoshi Hirao,[1] Bo Xu,[3] Shigeru Miyazaki.[2] *[1]Niigata University, Niigata, Japan; [2]Shinraku-en Hospital, Niigata, Japan; [3]niigata university, Niigata, Japan; [4]Shinrakuen Hospital, Niigata, Japan.*

Background: Many studies have been done to identify kidney disease biomarkers by proteomics of urine. However, urine biomarkers sufficient enough from scientific and practical views have not been identified yet. One of the reasons may come from the study designs. For example, to identify biomarkers for chronic kidney disease (CKD), urine samples collected from CKD patients with proteinuria were analyzed by proteomics, resulting that plasma proteins have mostly been identified. To overcome the problem and to identify biomarkers informing the sites of injury, we aimed to identify urine biomarkers for injury at each different tissue compartment in the kidney and to make a panel test (urine kidney biopsy), which may inform pathological changes as kidney biopsy.

Methods: Several kidney compartments (glomerulus, proximal tubule, distal tubule, collecting duct, kidney cortex and medulla) are laser-microdissected from formalin-fixed paraffin-embedded human kidney specimens and peptides digested with trypsin were collected by the on-site direct digestion (OSDD) method for mass spectrometry. These proteomes were compared each other and also with those of plasma and urine to select proteins, which were uniquely identified in each compartment and not found in the plasma but found in the urine as urine biomarker candidates for each kidney compartment injury. Then, some of these candidates (PRA2R1 and GPRC5C for glomerulus, NPR1 for proximal tubule and GGT5 for interstitium injury) were selected and quantitatively measured in urine samples from CKD patients (IgA nephropathy and diabetic nephropathy) by surface plasmon resonance method using antibodies against them (ProteOn, Bio-Rad).

Results: Concentrations of the proteins increased significantly in urine with the stage of CKD. PRA2R1 and GPRC5C excretion presumed to reflect the glomerular injury, especially, podocyte alterations, NPR1 the proximal tubule reactions and GGT5 the interstitial expansion, indicating that the urine liquid biopsy may provide more valuable information than the routine kidney function tests and more quantitative evaluation than the kidney biopsies.

Conclusions: By the urine liquid biopsy of a biomarker panel for kidney compartment events, injuries at different comartments in the kidney were individually and quantitatively evaluated by a non-invasive manner.

PUB179

A Rare Case of Granulomatous Interstitial Nephritis Associated T Cell Lymphoma Miho Karube,[1] Shintaro Masuko,[1] Hideki Shimizu,[2] Hikaru Kukimoto,[1] Shinya Kaname.[1] *[1]Kyorin University School of Medicine, Tokyo, Japan; [2]Kyorin university, Tokyo, Japan.*

Background: Introduction: Although granulomatous interstitial nephritis is known to be associated with sarcoidosis and tuberculosis, it has been rarely reported in T cell lymphoma.

Methods:

Results: A 50-year-old woman was referred to our hospital because of abdominal lymphadenopathy two years ago. Open lymph node biopsy revealed granulomatous lymphadenitis. A year and a half later, renal dysfunction was recognized by increased levels of serum Cr 1.95 mg/dl and urine β2 microglobulin 17,621μg/l, and renal biopsy was performed, showing global glomerulosclerosis in 5 out of 21 glomeruli and advanced tubulointerstitial nephritis with a marked infiltration of CD3,4,5-positive/CD20-negative, small-sized T lymphocytes and granulomatous changes. No plasma cells or eosinophils were observed. The T cell clonality test for TCRG using the renal tissues revealed T-cell monoclonality signal, thus together with a serum increase in soluble IL-2 receptor levels (2,880 U/ml), she was diagnosed with T cell lymphoma. After glucocorticoid and standard chemotherapy, renal function slightly improved and re-biopsy of the kidney showed improved T-cell infiltrations, associated with advanced tubulointerstitial changes with fibrosis.

Conclusions: Discussion: We reported a rare case of granulomatous tubulointerstitial nephritis in a patient with T cell lymphoma. T cell lymphoma should be considered in tubulointerstitial nephritis of unknown origin.

PUB180

Efficacy of AST-120 in Patients with CKD: A Systematic Review and Meta-Analysis Mei-Yi Wu,[1] Ying-Chun Chen.[2] *[1]Department of Nephrology, Taipei Medical University-Shuang Ho Hospital, Taipei, Taiwan; [2]Taipei Medical University, Shuang Ho Hospital, Taipei, Taiwan.*

Background: AST-120 (Kremezin), which is an oral spherical carbonaceous adsorbent of the precursor of indoxyl sulfate (IS), has been reported to be potential for retarding disease progression in patients with chronic kidney disease (CKD). In the present study, we aimed to evaluate its efficacy in slowing disease progression in CKD patients.

Methods: We systematically searched for clinical trials published in PubMed, Medline, and Cochrane databases. Randomized controlled trials of AST-120 in CKD patients were selected. The primary outcomes were the composite of renal outcome and all-cause mortality. The secondary outcome was the changes in serum IS level.

Results: Eight studies providing data for 3320 patients were included in the meta-analysis. Among patients treated with AST-120, the summary RR of composite of renal outcome was 0.97 (95% CI 0.88-1.07) using a random effects model (heterogeneity I^2=0%). The summary RR of all-cause mortality was 0.94 (95% CI 0.73-1.2) using a random effects model (heterogeneity I^2=0%). Change of IS level from baseline to the end of the study was higher in patients treated with AST-120 (mean difference: -0.34 mg/dL; 95% CI, -0.48 to -0.2, 4 trials) compared with placebo.

Conclusions: This review provides evidence that AST-120 can effectively lower IS level but still controversy in slowing disease progression and all-cause mortality. Further studies are needed to assess which is the optimal CKD population to be treated by AST-120.

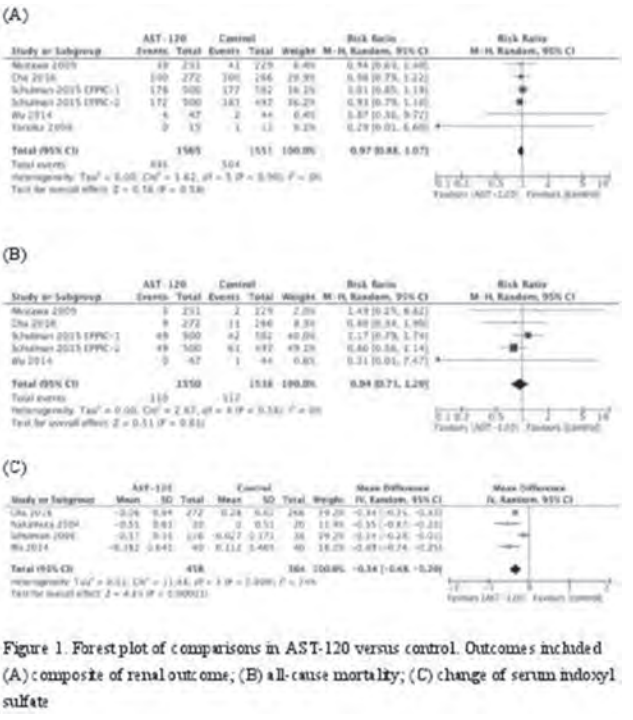

Figure 1. Forest plot of comparisons in AST-120 versus control. Outcomes included (A) composite of renal outcome; (B) all-cause mortality; (C) change of serum indoxyl sulfate

PUB181

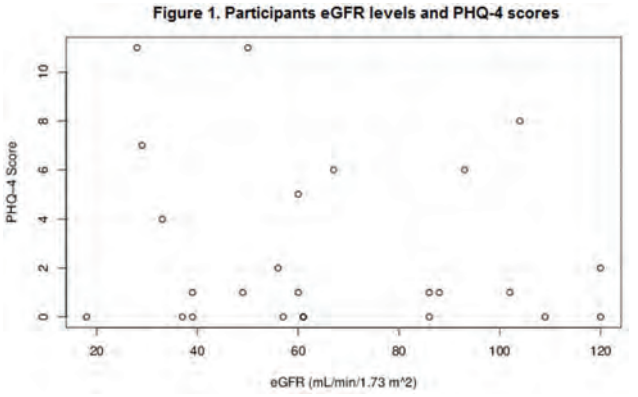
Anxiety in Patients with Autosomal Dominant Polycystic Kidney Disease Denghui Guo, Salpi S. Siyahian, Meyeon Park. *UCSF, San Francisco, CA.*

Background: The prevalence of depression and anxiety among patients with autosomal dominant polycystic disease (ADPKD) is high due to the disease's significant morbidity and uncertain prognosis. We investigated whether individuals with prognostic scores indicative of higher risk for ESRD onset and more impaired kidney function have higher levels of depression and anxiety.

Methods: We conducted a cross sectional study involving 30 individuals diagnosed with ADPKD. The PROPKD score is a prognostic tool that predicts the age of onset of ESRD for individuals with ADPKD. Participants were risk-stratified based on their PROPKD score and eGFR. We approximated the PKD mutation in the absence of genotyping using age of ESRD of a first-degree family member. The degrees of depression and anxiety symptoms were measured using the Patient Health Questionnaire 4 (PHQ-4). We calculated Spearman correlation coefficients to determine associations of PROPKD variables and eGFR with PHQ-4 scores.

Results: Median age was 52; 66.7% were male. 33.3% of study participants had mild to severe psychological distress (PHQ-4 ≥ 3). There was no significant correlation between PROPKD and PHQ-4 scores [r = -0.049, p = 0.795], or eGFR and PHQ-4 scores [r = -0.098, p = 0.642] (Figure). The two patients with the highest PHQ-4 scores both had eGFR < 60 ml/min/1.73m^2, while the patient with the lowest eGFR had a PHQ-4 score of 0 (no symptoms of depression or anxiety).

Conclusions: Symptoms of depression and anxiety are prevalent in patients with ADPKD. Neither PROPKD score nor the degree of kidney function impairment as determined by eGFR were significantly correlated with psychological distress as measured by PHQ-4 score. Understanding what contributes to anxiety in patients with ADPKD will be important to improving symptoms.



PUB182

Renadyl™: Improving GFR and Quality of Life: Results of 3rd Biannual Survey 2017 Natarajan Ranganathan,[1] Kevin M. Hanlon.[2] *[1]KIBOW BIOTECH INC, Newtown Square, PA; [2]Kibow Biotech, Newtown Square, PA.*

Background: Kibow Biotech's "Enteric Dialysis®" concept based off of the modulation of the gut microbiome to maintain healthy kidney function has proved to be helpful in many of those suffering from CKD. Kibow's product "Renadyl™" has been available since 2010 and is continually being studied to assess just how effective it is. A short survey given to 600 Renadyl customers was distributed to ascertain how their GFR changed, and the impact on their quality of life after adding the dietary supplement Renadyl™ into their standard care of therapy.

Methods: "Renadyl™," a synbiotic dietary supplement was assessed in its ability to maintain healthy kidney function (stabilize GFR), and ability to improve quality of life. A survey was distributed to 600 customers asking for GFR when they began taking Renadyl, and at their most recent doctors visit, as well as Age, Race, ethnicity, and if Renadyl™ had improved their overall quality of life or not. Statistical analyses were performed on the GFR data to estimate Renadyl's™ impact on GFR, and quality of life. Of the 600 surveys sent, 210 (35%) responses were received (116 male, 94 female).

Results: The average age of a Renadyl user was 69 years old. The average survey participant had been using Renadyl for 2.05 years. Of the surveys received, 140 contained complete information, including GFR. The lowest baseline GFR recorded was 4, the highest was 100 (ESRD to Healthy). The average baseline GFR of a survey participant was 29 (Stage IV). The most recent GFR reported varied from 5 to 102. The highest GFR impact was an increase of 65, and the largest decrease in GFR was -43. The average change in GFR for a survey participant was an increase of 2.39. Among the survey respondents, 88% reported that Renadyl™ improved their quality of life.

Conclusions: Chronic kidney disease is generally recognized as a degenerative process. However, with over 4,000 customers we sought feedback from 15% of them to assess the impact of Renadyl™ usage over an average of 2.05 years. The longest using participant used the product for 7 years, the shortest for 6 months. With the ability to stabilize and improve GFR, it may be possible to delay the progression of kidney failure at all stages. Improving quality of life in 88% of participants certainly signifies the advantages of using Renadyl™ in patients with compromised renal function worldwide.

PUB183

Chemotherapy Induced Neuropathy in CKD Patients Biruh Workeneh,[2] Louie H. Morsy,[1] He Zhou,[1] Bijan Najafi.[1] *[1]Baylor College of Medicine, Houston, TX; [2]MD Anderson Cancer Center, Houston, TX.*

Background: Chemotherapy induced neuropathy (CIPN) is a prominent feature of traditional and targeted therapy for cancer, and contributes significantly to the frailty of cancer patients. Frailty and peripheral neuropathy are also features of chronic kidney disease (CKD), and we sought to determine the influence of CKD on the severity of CIPN. We studied patients with cancer who had clinically established CIPN and screened them for an objective measure of abnormal nerve conduction with vibration perception threshold (VPT) analysis, which has been shown to predict outcomes such as falls, foot ulceration and quality of life.

Methods: We recruited 17 subjects >50 years of age with cancer who had clinically established CIPN. VPT analysis was performed on each subjects and recorded at plantar foot sites: bilaterally: heel, 5th metatarsal and big toe. We defined the CKD group by an eGFR <60ml/min at the time of testing, and recorded demographics and comorbidities.

Results: A description of both CKD and non-CKD groups are listed in Table 1. VPT scores were recorded at the following plantar foot sites and results are shown in Figure 1. The CKD consistently had lower scores across VPT testing sites, and reached significance in the right big to region. Multivariate analysis suggested that diabetes diagnosis prior to chemotherapy may be independently associated with the development of neuropathy, but did not reach significance.

Conclusions: Although preliminary, our results show that the presence of CKD is associated with a decreased severity of neuropathy and that diabetes may be independently associated with more severe neuropathy related to cancer treatment.

Immunization: An Important Addition to Standard Care in Glomerulonephritis Patients Melissa Lan, Coleman Rotstein, Rory F. McQuillan, Daniel C. Cattran. *University Health Network, Toronto, ON, Canada.*

Background: Glomerulonephritis (GN) is a group of rare kidney diseases that can progress to end stage renal failure. GN patients are at increased risk for infection given nephrotic remission/relapse pattern, exposure to immunosuppressant therapy, and/or possible progression to chronic kidney disease. Thus our focus on guidelines indicating that hepatitis B, pneumococcus, influenza, and varicella are vaccine preventable infections.

Methods: Using the model for Quality Improvement (QI), a multifaceted GN immunization protocol (GNIP) was adopted after a needs assessment found that the first 20 patient charts had no documented immunization history. Patient (N=64) preference assessment for receipt of immunizations was by family physician (FP) 65.6%, primary nephrologist 10.9%, hospital clinic 6.3%, and walk-in clinic 4.7%. Investigation of options for vaccine administration helped construct a fish bone diagram and process map that further focused the GNIP. Physician and patient communication and documentation tools were created and the protocol initiated. The GNIP assessed/recommended hepatitis B, pneumococcus, tetanus-diphtheria-acellular pertussis, varicella, and herpes zoster immunizations plus annual administration of the inactivated influenza vaccine.

Results: Outcome measures at 4-months post-GNIP implementation: 1. 73% (92/126) of patients assessed for GNIP now have documented immunization history. 2. 63.5% (80/126) of patients assessed for GNIP have now received immunization recommendations. 3. 19.4% (90/465) of the recommended immunizations have now been administered. Additional findings: 3.1% (4/130) of patients refused to participate in the GNIP; major FP issue is the high-dose hepatitis B immunization requirement; most critical is the communication links between patient, FP, and GN clinic.

Conclusions: The GNIP fulfills an unmet medical need in GN care. This QI project highlights that need and indicates a developmental process for implementation of a solution. Early results indicate improved immunization documentation, an increase in immunization administration, and the potential for increased patient infection protection.

PUB185

Depression and CKD – A Deadly Combination with Insufficient Screening Haldane Porteous,[2] Stefan C. Hemmings,[1] Daphne H. Knicely.[3] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: The prevalence of depression in the general population is approximately 7 percent but in patients with chronic kidney disease (CKD) depression rates are significantly higher, approximately 22 percent. There is a 30 percent increased risk of death in CKD patients with depression compared to CKD patients without depression. Additionally, the former are subjected to increased hospitalization rates, poorer treatment compliance, and decreased quality of life. Unfortunately, despite these known adverse associations, depression in CKD remains underdiagnosed and undertreated. Screening for depression via validated tools which are widley avialable could identify at risk patients and early intervention with pharmacological or non-pharmacological treatment could possibly improve patient outcomes.

Methods: A pre/post intervention quality improvement project involving CKD stage 3-5 patients using the validated Patient Health Questionnaire-2 (PHQ2) depression screening tool was conducted within the Nephrology Fellows' Continuity Clinic. From September 2016 to November 2016, 202 charts were audited to determine the depression screening rate of patients. The intervention phase consisted of clinician education on the importance of screening for depression as well as a built-in electronic smart phrase based on the PHQ2 tool. Between December 2016 and February 2017, 202 charts were audited

to determine the post intervention screening rate. From March 2017 and April 2017, 50 charts were audited to determine if the post-study result was sustained.

Results: Pre-intervention screening rate was 1.48 percent. Post-intervention screening rate increased to 10.45 percent. Post-study screening rate was 12.01 percent.

Conclusions: Depression is prevalent in CKD patients and is associated with increased mortality. This quality improvement project demonstrated that clinician education and an electronic smart phrase based on a validated screening tool are two metrics associated with a sustained improvement in depression screening. Research studies are needed to identify other metrics which can be used to improve depression screening so that CKD patients can receive early treatment which may reduce the risk of hospitalization and/or death.

PUB186

Advance Care Planning in the CKD Stages 3-5 Non-Dialysis Population 65 Years and Older Barbara M. Weis. *College of Nursing, University of Colorado, Aurora, CO.*

Background: In the chronic kidney disease (CKD) academic outpatient predialysis clinic, there were no identified protocols or procedures for advance care planning (ACP) for this chronic CKD stages 3-5 population 65 years and older. Research has indicated the value of ACP and the collection of advance directives in patients with chronic disease states. This quality improvement project addressed the identified gap of lack of evidence-based ACP interventions specific to this population.

Methods: The purpose of this quality improvement project was to (a) assess the effectiveness of an evidence-based educational intervention versus usual care in increasing completion of medical durable powers of attorney (MDPOAs) and advance directives by these select groups of CKD patients (b) determine the effect of independent variables on this CKD population education in completion of ACP for the purpose of tailoring an evidence-based ACP program. Pre-dialysis CKD stage 3-5 patients' (N = 60) response to an advance care planning intervention and the completion of advance directives and MDPOAs was studied. Data were analyzed using descriptive and inferential statistics (frequency distribution, Pearson's chi square planning test for independence and McNemars' test).

Results: Results indicated statistical significance ($p < .05$) in the increase in collection of advance directives in the educational versus the control group. The results also demonstrate statistical significance ($p < .05$) in the collection of MDPOAs in an outpatient CKD clinic in patients 65 years and older.

Conclusions: This quality improvement project has shown with the right resources, effective communication with staff and providers, an open clinical population, a cost effective and sustainable delivery system for ACP in an outpatient clinic in line with the organizational mission can be a reality. Ultimately, improving the process of educating patients about end-of-life care and collection of advance directives and MDPOS will improve end-of life care and decrease hospital costs related to end-of-life care as well as bring revenue to the practice.

PUB187

Provider Experience with Implementation of a Pragmatic Randomized Trial of CKD Screening in Primary Care: A Qualitative Report Martin J. Frigaard,[1] Leticia Rolon,[6] Lowell J. Lo,[2] Anna Rubinsky,[7] Delphine S. Tuot,[7] Neil R. Powe,[4] Michael Shlipak,[5] Carmen A. Peralta.[3] *[1]Kidney Health Research Collaborative, Oakland, CA; [2]None, San Francisco, CA; [3]University of California San Francisco/SFVAMC, San Francisco, CA; [4]Priscilla Chan and Mark Zuckerberg San Francisco General Hospital & University of California SF, San Francisco, CA; [5]San Francisco VA Medical Center, San Francisco, CA; [6]UCSF Medical Center, San Francisco, CA; [7]University of California, San Francisco, San Francisco, CA.*

Background: Provider burden from participation in pragmatic randomized clinical trials (RCT) is not well documented. To inform future research, we surveyed providers who had recently completed a pragmatic RCT of CKD screening in primary care. We characterized their insights and thoughts regarding perceived burden of the intervention and self-reported CKD knowledge at the end of the trial.

Methods: The protocol required participation in the RCT between February 2016 to March 2017. All primary care providers (PCPs) received education about the study and reviewed a list of eligible patients for exclusion. Additionally, PCPs randomized to intervention reviewed CKD results, co-signed notes with CKD-related recommendations, and discussed plan of care with patients. Clinical pharmacists provided hypertension medication management and CKD education. We sent a 5-question (three yes/no, two open-ended), anonymous web-based survey to all participating providers.

Results: Of 33 providers, 20 (61%) completed the questionnaire. Among respondents, 12 (60%) answered affirmatively to "I learned how to improve care for patients with CKD" and 12 (60%) answer yes to "I changed the plan of care of one or more patients" from participation in the program. The most frequently reported changes included better understanding of CKD testing strategies, more confidence to educate patients on CKD and safe NSAID use, and addition of ACE/ARB or diuretic for hypertension treatment. The majority 16 (80%) replied "no" to whether the program increased burden. The most frequent reason for increased burden was more time spent on patient counseling about study correspondence and CKD results.

Conclusions: Providers in a pragmatic CKD screening trial in primary care didn't report substantial increases in burden. Providers also reported perceived improvements in CKD knowledge and applying practice improvements.

Assessment of Efficacy of a CKD Support Decision Making Application and Home Blood Pressure Measurement System in Patients with CKD: Study Protocol of a Randomized, Controlled Trial Shiho Kosaka,[2] Junichi Hoshino,[3] Masayuki Yamanouchi,[3] Akinari Sekine,[3] Yoshifumi Ubara.[1] *[1]Setagaya, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan; [3]Toranomon Hospital, Tokyo, Japan.*

Background: Disease management of patients with chronic kidney disease is complicated, and requires extensive time dedicated to decision making. Therefore, this study aimed to develop a support decision making application for patients with chronic kidney disease (CKD-SDM app), to prevent future disease progression and to support the decision making process regarding renal replacement therapy (RRT).

Methods: Inclusion criteria were: patient at the kidney internal medicine outpatient clinics, age over 20 years old, provision of informed consent, to be assure by doctor, RRT not yet selected, and eGFR<60. This study is a clinical, prospective, randomized, controlled trial with balanced randomization (1:1). The planned sample size is 68 participants. Participants in both groups will be followed up at 2 and 6 months after randomization. The intervention group will receive conventional care from the attending physician; the patient and physician will also be given a tablet equipped with the CKD-SDM app and an automated sphygmomanometer for home blood pressure monitoring for 2 months. The CKD-SDM app includes 61 items in three categories: "Let's study CKD", "What's about RRT?", and "Learn and consent of CKD". The control group will receive conventional care and only the automated sphygmomanometer for 2 months. The primary outcome measure is change in home blood pressure data from baseline. Secondary outcomes are renal function, spot urine test, self-efficacy for chronic illness, disease burden, knowledge level of self-management in CKD, and decision for RRT. Recruitment began in March 2017 with the last participant due to be continued.

Results:

Conclusions: This study will attempt to evaluate the effect of a self-management and support decision making intervention for chronic kidney disease. Outcome data will be used to clarify whether the new intervention prevents disease progression and improves quality of RRT selection. Trial Registration: This study is registered to UMIN Clinical Trial Registry (000025792)

Digital Tools for Complex Medication Regimens in CKD: Scoping Review Ginyoung Lee, Stephanie W. Ong. *University Health Network, Toronto, ON, Canada.*

Background: Despite advances in medical therapy, medication non-adherence remains to be a health threat causing poor clinical outcomes in patients with chronic kidney disease (CKD). Digital medication adherence tools (DMATs) may play a key role as advanced features and functionalities can be adapted to address known multifactorial barriers to medication adherence in CKD. This study examined features and functionalities of DMATs, how they specifically address barriers of medication adherence and explored currently available evidence.

Methods: A multi-step approach was undertaken including: literature search from January 2006 to 2017 using PubMed, Medline supplemented by reference lists, environmental scan using Google Search engine for available commercial DMATs and grey literature to include pre-market tools.

Results: Total of 17 studies were extracted which had distinct DMATs and met the inclusion criteria. Of these studies, DMATs ranged from digital pill systems, electronic medication container devices, electronic medication administrating devices and mobile applications. Each had unique and overlapping features and functionalities that address factors of medication non-adherence ranging from visual/auditory stimuli to act as reminders, addressing forgetfulness, organizing in Bluetooth capable dosette boxes up to allowing clinicians to remotely monitor and track medication intake. All of these factors are known barriers to medication adherence in CKD patients with complex medication regimens. It was found no single DMAT can address all factors. Evidence of use and efficacy in chronic disease are lacking at this point.

Conclusions: Available DMATs possess varying features and functionalities that address barriers of medication adherence. DMATs can play a role in promoting CKD medication taking practices if personalized and tailored use to target specific medication adherence barriers is identified. Their impact on medication adherence should be further explored in future studies.

PUB190

Cost Implications of Inappropriate Proton Pump Inhibitor (PPI) Use in Advanced CKD Amanda Chow,[1] Rory F. McQuillan,[2,1] Marisa Battistella,[1,2] Annemarie Cesta,[1] Stephanie W. Ong.[1] *[1]University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: PPIs ranked second highest drug use in Ontario, Canada. The long term use of PPIs in kidney disease has been associated with adverse clinical outcomes. Their continued use can also have impact on unnecessary drug cost burden on the patient. This study determined the proportion of advanced CKD patients who were taking PPI inappropriately and assessing this drug cost implication of inappropriate indications to the patient.

Methods: A cross sectional chart review was performed in May 2017 in outpatient renal clinics that oversee the care of patients with advanced CKD (stage 4 and 5). Data on PPI use was determined from clinic pharmacy records obtained by patient medication history. Indication for PPI use was then determined using medical charts. Indications were categorized as appropriate or inappropriate based on predetermined list of accepted long term PPI indication derived from accepted protocols. The cost of inappropriate use was then calculated from the drug list price of each PPI gathered from Ontario drug formulary list price.

Results: A total of 413 charts were reviewed. A total of 127 (31%) patients had current active documentation of PPI use. Examining the duration of PPI use, 124 patients of 127 (97.6%) had documentation of PPI use for more than 8 weeks. Seventy four (59%) patients were deemed to be using them for an inappropriate (e.g. asymptomatic GERD) or unknown indication. Cost estimates using the price per pill accounted for a total 30-day cost of $1,565.78 for these inappropriate indications. This results in a yearly cost of $18,789.37 and an average cost per patient of $147.95.

Conclusions: Inappropriate PPI use in advanced CKD not only has clinical implications but also an economic impact with respect to pill burden and associated costs incurred. PPI deprescribing protocols should be implemented to address inappropriate use and alleviate these unnecessary drug costs.

PUB191

The Expectation, Concern, and Experience of Patients towards Integrative Chinese-Western Medicine for Diabetic Kidney Disease: A Qualitative Study

Kam wa Chan,[2] Crystal Leung,[3] Gary Chan,[1] Wai Han Yiu,[2] Dickson W. Wong,[2] Bin Li,[2] Ye Li,[2] Loretta Y.Y. Chan,[2] Joseph C K Leung,[2] Sydney C. Tang.[2] *[1]Queen Mary Hospital, Hong Kong, Hong Kong, China; [2]The University of Hong Kong, Hong Kong, China; [3]Department of Family Medicine and Primary Care, Hong Kong East Cluster, Hospital Authority, Hong Kong, China.*

Background: Emerging data suggest that Chinese medicine could reduce the risk of end-stage renal kidney disease among chronic kidney disease patients by 59% in a six-year period. However, a recent cross-sectional study in Hong Kong found that only 20% of diabetic kidney disease (DKD) patients have consulted a Chinese medicine practitioner. The experience and concerns regarding integrative Chinese-western medicine management among DKD patients remains unknown and undocumented.

Methods: Focus group interviews with DKD patients were conducted to explore their experience and concerns. Patients with different age group, gender, stage of chronic kidney disease, comorbidity, knowledge and usage of western and Chinese medicine and history of herbal toxicity were purposively sampled. A trained moderator conducted the interview based on an adaptive semi-structured interview guide. Audiotaped interviews were transcribed verbatim and analysed by framework analysis by two independent researchers.

Results: The interview covered the scopes regarding 1) barrier towards integrative service, 2) motivation to seek alternative and complementary treatment, 3) experience in the use of Chinese medicine and 4) preferred mode of integrative service. Data saturation was observed at the third round of interview. Twenty-one patients with a wide spectrum of demographics were interviewed. Two to six key themes were identified under each scope with specific examples from DKD patients. Overall, patients with severe DKD tend to seek alternative options for disease management. However, the efficacy, safety, finance, convenience of access and lack of referral channels were key barriers in consulting integrative service. Organisational support from the government plays a critical role in enhancing patient's confidence in utilising integrative service.

Conclusions: Our findings document specific expectation and concerns from DKD patients over the access of integrative medicine for the future consideration of health service provision and research design. **Funding support:** The University of Hong Kong and Hong Kong Society of Nephrology Research Grant

Detection of Renal Fibrosis by CT Scanning: Results from a Primate Model

Eric P. Cohen,[1] John D. Olson,[2] John D. Bourland,[2] Mark Cline.[2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Early detection of fibrosis has a major impact on diagnosis and therapy. Renal fibrosis is a known sequel of total body irradiation (TBI).

Methods: 99 non-human-primates (NHP) have been under long term follow-up after TBI ranging from 0 to 8.5 Gy. They undergo serial follow-up with blood testing and CT scanning and a full necropsy at death. 19 died during follow-up, of which 4 were non-irradiated. Kidneys were stained for collagen with Masson trichrome, and scored twice in a masked fashion using 4 or more microscope fields at 100x. Renal cortical fibrosis was scored as absent (0), minimal (1, absent in most viewed fields), scattered (2, present in some fields), moderate (3, present in most fields), and severe (4, present in all fields). CT scanning was done by a 32 slice Toshiba Aquilion CT Scanner with parameters: 120 kV, 300mA, field of view = 320 mm, matrix = 512x512, and slice thickness = 0.5 mm. Cortex regions of interest (ROIs) were traced in three coronal slices and averaged for an average mean gray scale value for that kidney's cortex. For each ROI that was measured, the total cross sectional area of tissue penetrated was also measured to correct for x-ray beam hardening. ROIs were traced in fat, muscle, and achilles tendon for use as reference tissues to calibrate the conversion of gray scale to Hounsfield units (HU). The histological score was correlated to the HU of each kidney.

Results: There was a direct correlation of the histological fibrosis score to the CT HU of each kidney (r=0.6, p=0.003). CT HU was 90% specific and 83% sensitive for histologic fibrosis. The fibrosis scores for the irradiated NHP were significantly greater than those of the non-irradiated NHP (p=0.02). Computerized color-intensity scanning correlated with the human semi-quantitative scores. The five grades of fibrosis cannot be distinguished by analyzing the uncorrected CT images; the correction for beam hardening is required. The median BUN in the irradiated NHP was 24 and that of the non-irradiated NHP was 22 mg/dl (p=0.8).

Conclusions: Renal fibrosis can be detected by CT scanning, this requires correction for body size and beam hardening, and fibrosis can be detected before there is significant azotemia.

Proteomic Analysis of the Epithelial Secretome Implicates Jagged-1 in Tubule Dysfunction and Paracrine Communication

Jessica M. Overstreet,[1] Ming-Zhi Zhang,[2] Raymond C. Harris.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical School, Nashville, TN.*

Background: Tubulointersititial fibrosis (TIF) is a critical contributor to chronic disease strongly correlating with renal insufficiency. Persistent epithelial dysfunction is integral to TIF progression. The role of specific tubule-derived paracrine factors that crosstalk to fibroblasts is less understood.

Methods: Stable isotope labeling with amino acids in cell culture (SILAC) allowed incorporation of heavy or light amino acids into native proteins to measure their abundance in human renal proximal tubule epithelial cell (hRPTEC)-derived conditioned medium (determined from the relative mass spectrometry (MS) signal intensities). The bioinformatical program Genecodis analyzed the MS-based proteomics of the epithelial secretome in response to HB-EGF or TGF-β treatment (24h) compared to untreated cells. Biochemical approaches characterized Jagged-1 (Jag-1) as a novel tubule paracrine factor.

Results: SILAC/MS-based proteomics identified 157 and 181 secreted proteins that increased significantly in hRPTECs treated with HB-EGF or TGF-β, respectively. Genecodis analysis revealed 95 tubule paracrine factors similarly upregulated by HB-EGF and TGF-β related to signal transduction, adhesion, inflammation and negative regulation of cell proliferation pathways. Of interest, Jag-1, a ligand of the Notch pathway, was increased 15.123 and 8.2409-fold in the conditioned media of HB-EGF or TGF-β-stimulated epithelial cells, respectively. Gene silencing of Jag-1 in hRPTECs decreased HB-EGF and TGF-β-induced matrix protein CTGF and dedifferentiation regulator Snail compared to identically treated control siRNA-expressing hRPTECs. Pharmacological inhibition of γ-secretase (RO-4929097), necessary for the activation of canonical Notch signaling via NICD, also reduced TGF-β-dependent CTGF, Snail, and cell cycle regulator $p16^{INK}$ in hRPTECs. Conditioned media derived from Jag-1-depleted hRPTECs stimulated by HB-EGF or TGF-β had decreased fibroblast proliferation compared with fibroblasts incubated in conditioned media-derived from control counterparts.

Conclusions: These results suggest that activation of EGFR or TGF-β signaling in the proximal tubule promotes the secretion of paracrine factors driving epithelial dysfunction and fibroblast activation and identifies Jag-1-dependent Notch signaling as a potentially important mediator of these processes.

Ecdysone Elicits Chronic Renal Impairment via Mineralocorticoid-Like Pathogenic Activities

Minglei Lu,[2,1] Zhangsuo Liu,[1] Rujun Gong.[2] *[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]Brown Medical School, Providence, RI.*

Background: Ecdysteroids are steroidal insect molting hormones and also exist in herbs. Ecdysteroid-containing adaptogens have been popularly used for improving well-being and by bodybuilders for muscle growth. However, there is growing evidence suggesting that use of ecdysone is apparently associated with disturbed electrolyte and water balance that is manifested as water retention and body weight gain. The underlying pathogenic mechanism remains unknown and was examined in this study.

Methods: Virtual screening tools were employed to identify compounds homologous to ecdysone and putative ecdysone-interacting proteins. The kidney effect of ecdysone was examined *in vitro* and *in vivo* and compared with that of aldosterone.

Results: Computer-assisted molecular structure matching revealed that ecdysone is highly homologous to aldosterone. Moreover, virtual screening based on ccompound–protein interaction profiles identified mineralocorticoid receptor, the cognate receptor for aldosterone, as one of the top-ranking proteins with strong interaction with ecodysone. To validate the biological functionality, ecdysone was applied to inner medullar collecting duct cells, which are typical mineralocorticoid-sensitive effector cells, and induced cellular hypertrophy, accumulation of extracellular matrix, and epithelial to mesenchymal transition, marked by *de novo* expression of α-smooth muscle actin. In addition, ecdysone disrupted cellular tight junction and retarded cell motility, akin to the effect of aldosterone. *In vivo*, daily treatment of mice with ecdysone for 2 weeks resulted in body weight gain and reduced urinary sodium to potassium ratios. Moreover, increased cell apoptosis, as probed by TUNEL staining, and early signs of renal fibrogenesis, marked by deposition of collagen and fibronectin in tubulointerstitium, were noted in the kidney, reminiscent of the activity of aldosterone. The cellular and pathobiological effects of ecdysone were likely mediated by mineralocorticoid receptor as evidenced by remarkable nuclear translocation of mineralocorticoid receptor in renal tubular cells both *in vitro* and *in vivo*. Conversely, blockade of mineralocorticoid receptor by concomitant spironolactone treatment largely abolished the actions of ecdysone.

Conclusions: Our findings suggest that ecdysone possesses mineralocorticoid-like activities that impair renal function and elicit renal injury.

PUB195

Tamoxifen Attenuates Fibrosis by Suppressing PI3K/Akt and mTOR/p70S6K Pathways through Src Kinase in Obstructive Nephropathy in Rats Chang Seong Kim, Hong sang Choi, Ha yeon Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: Tubulointerstitial fibrosis is the final pathway of chronic progressive kidney diseases. Src kinase and mammalian target of rapamycin (mTOR) pathway play a critical role in the pathogenesis of renal fibrosis. Here we investigated the effects of tamoxifen on renal fibrosis and its' underlying molecular mechanisms in the obstructive nephropathy rat model.

Methods: Renal fibrosis was induced by unilateral ureteral obstruction (UUO) in male Sprague-Dawley rats for 14 days. Tamoxifen (10mg/kg) was given by oral gavage after UUO operation. We also treated human proximal tubular epithelial (HK-2) cells with tamoxifen (5 μM) in the presence or absence of tumor growth factor (TGF)-β1 (2 ng/mL), estrogen receptor (ER)-α antagonist ICI (5 μM), and ER-α receptor siRNA to examine the effects of tamoxifen treatment on TGF-β1-stimulated renal fibrosis via ER-α.

Results: Tamoxifen treatment ameliorated the UUO-induced renal fibrosis with decreased expression of α-smooth muscle actin (SMA), fibronectin and connective tissue growth factor (CTGF). Phosphorylation of Src (Tyr 416), PI3K/Akt and mTOR/p70S6K protein was also significantly decreased after tamoxifen-treated compared to vehicle-treated UUO kidneys. These renoprotective effects were not associated with inhibition of TGF-β1. In HK-2 cells, tamoxifen suppressed TGF-β1-induced protein expression of α-SMA and CTGF, and phosphorylation of Src, PI3K/Akt and mTOR/p70S6K, which was counteracted by the treatment with ICI and silencing ER-α with siRNA.

Conclusions: Tamoxifen treatment attenuates renal fibrosis in the obstructed kidney of rats with UUO. Tamoxifen-induced antifibrotic effect is associated with the suppression of Src kinase via ER-α followed by inhibition of phosphorylation of PI3K/Akt and mTOR/p70S6K signaling pathways in HK-2 cells.

PUB196

Interleukin (IL)-17 Production by Tubulointerstitial Human γ/δ T Cells in Renal Fibrosis and CKD Helen G. Healy,[1,2] Becker Meng-Po Law,[1,2] Xiangju Wang,[1,2] Katrina Kildey,[1,2] Melissa Rist,[1,2] Ray Wilkinson,[1,2] Andrew J. Kassianos.[1,2] *[1]Conjoint Kidney Laboratory, Pathology Queensland, Brisbane, QLD, Australia; [2]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia.*

Background: γ/δ T cells are effector lymphocytes recognised as having important functional roles during chronic inflammatory processes. Mouse studies suggest a pathological role for γ/δ T cells in immune-mediated models of kidney disease. This study evaluates γ/δ T cells present in human fibrotic chronic kidney disease (CKD).

Methods: We extracted γ/δ T cells from healthy kidney tissue and diseased biopsies with and without fibrosis. γ/δ T cells were identified, enumerated and phenotyped by twelve-colour flow cytometry. Localisation and production of the pro-inflammatory cytokine IL-17 by γ/δ T cells was examined by multi-colour immunofluorescent microscopy.

Results: We detected significantly elevated numbers of γ/δ T cells ($CD45^+CD3^+\gamma/\delta^+$) in diseased biopsies with interstitial fibrosis compared with diseased biopsies without fibrosis and healthy kidney tissue. The increased numbers of γ/δ T cells correlated significantly with loss of kidney function (eGFR). Furthermore, expression levels of CD161, a marker of human IL-17-producing T cells, were increased on γ/δ T cells from fibrotic biopsies compared with non-fibrotic kidney tissue. Immunofluorescent analysis of fibrotic kidney tissue localised the accumulation of γ/δ T cells within the tubulointerstitial compartment, adjacent to proximal tubular epithelial cells (PTEC), defined as tubular cells expressing aquaporin-1. Notably, we identified these tubulointerstitial γ/δ T cells as a key source of pro-inflammatory cytokine IL-17.

Conclusions: The correlation of IL-17-producing γ/δ T cells with histologically and functionally more severe CKD suggests a pathological role. Further functional dissection of renal γ/δ T cells is now required for the development of therapeutics capable of blocking this previously untargeted immune cell population.

The Protective Role of Kallistatin in Tubulointerstitial Fibrosis Ye Li,[1] Wai Han Yiu,[1] Dickson W. Wong,[1] Kam wa Chan,[1] Bin Li,[1] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Hui Y. Lan,[2] Kar Neng Lai,[1] Sydney C. Tang.[1] *[1]Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [2]Department of Medicine and Therapeutics, and Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Shatin, China.*

Background: Kallistatin, a tissue kallikrein binding protein, exerts renoprotective functions against renal fibrosis in various animal models of kidney disease. However, the underlying mechanisms remains poorly understood. Recent data suggest that kallistatin antagonizes Wnt/β-catenin signaling in cancer cells and that this signaling pathway plays a crucial role in the pathogenesis of renal fibrosis. Here, we investigated the effect of kallistatin on Wnt/β -catenin signaling and the pro-fibrotic process in renal proximal tubular epithelial cells.

Methods: Cultured human proximal tubular epithelial cells (HK-2) were transfected with kallistatin plasmid (0.5-4 μg/ml) prior to TGF-β stimulation (10 ng/ml) that is known to activate Wnt/β-catenin. The efficiency of kallistatin transfection was verified by ELISA. The induction of TGF-β-induced Wnt/β-catenin signaling and the expression of fibrotic molecules was detected by real-time qPCR and Western blotting.

Results: TGF-β activated β-catenin signaling in HK-2 cells as evidenced by increased phosphorylation of GSK3β and accumulation of β-catenin in both the cytosol and nucleus. Additionally, TGF-β significantly increased the expression of Wnt family members (Wnt5a, Wnt9a and Wnt3) and the Wnt antagonist DKK1 in HK-2 cells. Overexpression of kallistatin in HK-2 cells not only inhibited TGF-β induced phospho-GSK3β and β-catenin levels, but also decreased the expression of Wnt5a, Wnt 9a and DKK1 as well as numerous fibrosis-related genes such as TGF-β, Snail, PAI-1, Collagen I in a dose-dependent manner. Finally, the phosphorylation of Akt was increased by TGF-β, which was also abrogated by kallistatin.

Conclusions: Kallistatin attenuates the profibrotic effects of TGF-β via inhibition of Wnt/β-catenin and Akt signaling, thereby reducing the expression of fibrotic genes in tubular cells. These findings further support the renoprotective role of kallistatin and highlight its therapeutic potential in renal fibrosis. **Funding:** Research Grants Council of Hong Kong (GRF grant number 17151716)

Histone Deacetylase 6 Inhibition Counteracts Epithelial–Mesenchymal Transition of Peritoneal Mesothelial Cells and Prevents Peritoneal Fibrosis Liuqing Xu,[2] Na Liu,[2] Yingfeng Shi,[2] Shougang Zhuang.[1] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: Peritoneal fibrosis is an important pathological remodeling feature in peritoneal dialysis patients. Little is known about epigenetic regulation of its development and progression.

Methods: We examined effects of HDAC6 inhibition on epithelial–mesenchymal transition (EMT) of cultured human peritoneal mesothelial cells (HPMCs) and development of peritoneal fibrosis in a rat model induced by high glucose dialysate.

Results: In cultured HPMCs, treatment with highly selective HDAC6 inhibitor tubastatin A, or HDAC6 silencing with siRNA inhibited transforming growth factor β1 (TGF-β1)-induced EMT, manifesting as increased α-SMA, fibronectin, and collagen I expression, decreased E-cadherin expression. In a rat model of peritoneal fibrosis induced by high glucose dialysate, HDAC6 prevented submesothelial thickening and decreased collagen I and a-SMA expression. Tubastatin A treatment inhibited TGF-β1 expression and Smad-3, epidermal growth factor receptor, STAT3, and NF-κBp65 phosphorylation. HDAC6 inhibition suppressed production of inflammatory cytokines/chemokines and reduced macrophage infiltration in injured peritoneum. Moreover, tubastatin A effectively inhibited peritoneal increase of CD31(+) blood vessels and expression of vascular endothelial growth factor after high glucose dialysate injection.

Conclusions: HDAC6 inhibition may attenuate peritoneal fibrosis by inhibiting multiple pro-fibrotic signaling pathways, EMT, inflammation and angiogenesis.

Meprin Metalloproteases and Meprin Targets Secreted in the Urine of African American Men with Diabetic Kidney Injury: Insights on Underlying Mechanisms Elimelda M. Ongeri, Lei Cao, Lisa M. Felton, Ava Boston. *Biology, North Carolina A&T State University, Greensboro, NC.*

Background: Minority ethnic groups are disproportionately affected by diabetic kidney disease (DKD). Susceptibility genes identified include meprins, zinc metatalloproteases of the astacin family, which are abundantly expressed in kidney epithelial cells. Meprins are also differentially expressed in podocytes and leukocytes (monocytes and macrophages). Meprins have been implicated in the pathology of DKD in humans and rodent models. Single nucleotide polymorphisms in the meprin β gene were associated with DKD in the Pima Indians, a US ethnic group with extremely high incidence of DKD. Decreased meprin expression and activity were demonstrated in rodents with diabetic kidney injury. We recently showed that meprin deficiency enhances kidney injury in mice with STZ-induced type 1 diabetes. However, the cellular and molecular mechanisms by which meprins modulate DKD are not understood. We have gained insights from identified meprin targets in the kidney, which include modulators of inflammation (e.g IL-1β, IL-6, pro-IL18, MCP-1) and extracellular matrix (ECM) proteins (e.g collagen IV, laminin, fibronectin, and nidogen-1).

Methods: Fasting urine samples were collected from three groups of African American men aged 18-65 years; 1) nondiabetic controls, 2) diabetics, and 3) diabetics with diagnosed kidney disease. ELISA assays were used to determine the levels of albumin, creatinine, and MCP-1. Western blot analysis was used to determine the levels of meprin A, meprin B, nidogen-1, fibronectin, and laminin.

Results: Meprins and meprin targets were not detectable in the urine of non-diabetic controls or diabetics with albumin to creatinine ratios (ACR)≤10. Diabetic patients with ACR≥30 had high levels of urinary meprins, fibronectin, laminin, and nidogen-1, with a ~3-fold increase in levels for patients with ACR≥200. For nidogen-1, we detected both full-length (~136 kDa) and a 55 kDa fragment.

Conclusions: The data suggest proteolytic processing of nidogen-1 by meprins in DKD which could trigger release of other ECM proteins from the basement membrane. More importantly, this could serve to reduce ECM buildup and thus reverse the fibrosis associated with DKD. The correlation between diabetic kidney injury and the levels of meprins and meprin targets in urine suggests that they could serve as diagnostic tools for DKD.

PUB200

Fibroblast Growth Factor 23 (FGF-23) Regulates HK-2 Cell Proliferation, Migration, and Response to TGF-β1 Jack S. Lawson, Harriet M. Syme, Caroline P. Wheeler-Jones, Jonathan Elliott. *Royal Veterinary College, London, United Kingdom.*

Background: Plasma FGF-23 concentration increases early in the course of chronic kidney disease (CKD), and rises progressively with deteriorating renal function. Elevated FGF-23 is associated with progression of CKD, and may play a direct role in the development of renal injury and tubulointerstitial fibrosis. The aims of this study were to investigate the effects of FGF-23 on proliferation, migration, viability and pro-fibrotic gene expression in a human tubular epithelial cell line (HK-2), and to determine whether FGF-23 modulates the transcriptional and functional effects of TGF-β1.

Methods: HK-2 cells were incubated with FGF-23 (0.1-100 ng/ml) ± 10 ng/ml TGF-β1 for 72 h. ERK1/2 phosphorylation was measured by immunoblotting. Expression of E-cadherin, N-cadherin, connective tissue growth factor (CTGF), collagen 1α1 (col1α1) and TGF-β1 was assessed by RT-qPCR (normalised to GAPDH/RPS7). Cell migration was measured using a scratch wound healing assay, and proliferation and viability monitored by cell counting, crystal violet staining and measurement of caspase 3/7 activity. The MEK inhibitor PD184352 (1 μM) and the FGF receptor 1 (FGFR1) antagonist SU5402 (10 μM) were used to investigate involvement of MEK-ERK signalling and FGFR activation, respectively.

Results: FGF-23 increased ERK phosphorylation and stimulated cell proliferation, which was completely attenuated by PD184352. Scratch wound closure was stimulated by FGF-23 in a concentration dependent manner, and this was blocked by SU5402. TGF-β1 decreased wound closure, and this was partially ameliorated by FGF-23. FGF-23 suppressed col1α1 expression, and at 100 ng/ml partially inhibited TGF-β1-driven increases in col1α1, N-cadherin, and CTGF expression. FGF-23 and TGF-β1 each inhibited E-cadherin expression, but there was no additive inhibitory effect. FGF-23 did not modify TGF-β1 mRNA expression or TGF-β1-mediated caspase 3/7 activation.

Conclusions: FGF-23 stimulates migration and proliferation of HK-2 cells most likely through engagement of FGFR1 and MEK-ERK pathway activation, and partially reverses pro-fibrotic and anti-repair responses to TGF-β1. These results suggest FGF-23 facilitates tubular repair and regeneration processes. The relevance of these findings to progressive nephron loss in the CKD patient warrants further study to establish their translational potential.

PUB201

Direct Regulation of FGF23 on Osteoclast Growth and Activity Nan Hu,[2,3] Chuan-Ming Hao,[1] Xin-zhou Zhang.[2,3] *[1]Huashan Hosp., Shanghai, China; [2]Department of Nephrology, Shenzhen People's Hospital, Shenzhen, China; [3]Key Renal Laboratory of Shenzhen, Shenzhen, China.*

Background: In the study of CKD mechanism, FGF23 has been shown to be involved. When the disease occurs, one of the pathological causes is that osteoclasts become hyperactive. We aimed to investigate whether FGF23 can directly regulate on the growth and activity of osteoclasts, which provides another way for FGF23 to participate in CKD.

Methods: Mouse macrophage cell line RAW264.7 was routinely cultured and inducing factor RANKL (25ug/ml) and M-CSF (30ug/ml) were added for 5 days. Then TRAP staining was performed to determine osteoclasts and treatments were carried out using recombinant human FGF23 (Group A:RAW264.7; Group B-E: 1ug/ml, 100ng/ml, 10ng/ml, 1ng/ml, 0ng/ml FGF23). Then we measured the cell survival and apoptosis rate by CCK8 assay and Annexin V-FITC after 24h, 48h and 72h, respectively. Meanwhile, mRNA levels of several key factors (*NFATC1, C-FOS, RANKL, OPG, CATK*) were detected by quantitative RT-PCR after the same treatment.

Results: TRAP staining showed that cells of induced group had positive staining. RAW264.7 cell fusion began and multinucleated giant cells developed in day 5 (Figure 1-a and1-b). Results of CCK8 (Figure 1-c) showed that lower concentrations of Group E and D could promote cell proliferation and higher concentration(Group B and C) inhibited the cell activity. Annexin V-FITC staining showed that compared with control (Group A), the apoptotic rate of each group with FGF23 showed a downward trend in 24h, 48h and 72h. At the same time, mRNA levels of key factors(*NFATC1, C-FOS, RANKL, OPG, CATK*) changed significantly with different concentration of FGF23 and treatment time (Figure 2).

Conclusions: These results indicate that FGF23 can act directly on osteoclasts and provide a theoretical basis for its further involvement in the pathogenesis of CKD.

Effects of the Combination of Losartan, Mycophenolate Mofetil, and Tamoxifen on the Development of Albuminuria and Glomerulosclerosis in an Experimental Model of Hypertensive Nephrosclerosis Camilla Fanelli, Humberto Delle, Rita de Cassia Cavaglieri, Wagner Dominguez, Irene L. Noronha. *University of Sao Paulo, Brazil, São Paulo - SP, Brazil.*

Background: The renoprotective effects of tamoxifen (TAM) in CKD induced by chronic inhibition of nitric oxide (L-NAME experimental model) have previously been demonstrated. TAM has been shown to prevent albuminuria, glomerular damage and interstitial fibrosis, despite having no effect on the sustained hypertension. In the present study, we sought to determine whether the addition of an ARB (losartan; LOS) and an immunosuppressor (mycophenolate mofetil; MMF) to TAM treatment could promote further renoprotection in L-NAME-treated animals.

Methods: In 25 male Wistar rats, CKD was induced by oral administration of 70 mg/kg/d of L-NAME, accompanied by a 3.2% high-salt diet. The rats were divided into 5 groups: **L-NAME** (untreated); **LOS** (treated with LOS, 50 mg/kg/d); **MMF** (treated with MMF, 10 mg/kg/d); **TAM,** (treated with TAM, 10 mg/kg/d); and **LOS+MMF+TAM** (treated with all 3). Five additional animals only received the high-salt diet (**Control**). Blood pressure (BP), albuminuria (uALB), glomerular ischemia (GI), glomerular sclerosis (GS), interstitial fibrosis (INT) and αSMA accumulation, as well as renal cortical macrophage (ED1) and T-cell (CD3) infiltration, were evaluated after 30 days of treatment.

Results: Data are presented as Mean ± SE. For One-way ANOVA: $p<0.05$: [a]vs. Control, [b]vs. NAME, [c]vs. LOS, [d]vs. MMF, [e]vs. TAM. For Student's t-test: $p<0.05$: *vs. TAM

Conclusions: The LOS+MMF+TAM combination completely normalized the urinary albumin excretion rate and glomerulosclerosis in L-NAME-treated rats. That combination was also more effective than was TAM monotherapy in reducing hypertension and glomerular ischemia in L-NAME-treated rats. Although the LOS+MMF+TAM combination did not improve interstitial fibrosis or myofibroblast (αSMA) infiltration, it was more efficient than was TAM alone in preventing T-cell infiltration.

Table of Results

Unilateral Ureteral Obstruction Induces an Inflammatory Renal Phenotype Along with Sequential Induction of NGAL in Plasma and Peripheral Blood Mononuclear Cells Cristián A. Amador,[2] Carolina A. Lobos,[2] Mauricio A. Lozano,[2] Stefanny M. Figueroa,[2,1] Alexis A. Gonzalez.[1] *[1]Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile; [2]Universidad Autónoma de Chile, Santiago, Chile. Group/ Team: Laboratory of Renal Physiopathology*.

Background: Chronic Kidney Disease (CKD) is a worldwide health problem with poor accurate diagnostic tools, and closely linked to other major diseases. Renal inflammation has been proposed as a relevant mechanism for the CKD development, occurring at early stages of injured kidneys. Studies in patients and experimental animals have shown that the Neutrophil Gelatinase Lipocalin-Associated (NGAL) is increased in the kidney, plasma or urine during CKD progression. Whether NGAL is increased in immune cells during early stages of CKD remains unknown. We performed the unilateral ureteral obstruction (UUO), as a high throughput *in vivo* model of CKD, in order to analyze the NGAL abundance in Peripheral Blood Mononuclear Cells (PBMC) during early inflammatory stage.

Methods: Male C57BL/6 were subjected to a complete UUO (in left kidney) or Sham surgery, and sacrificed after 3 and 7 days (n=8 per group).

Results: We observed tubular dilation in obstructed kidneys sections at day 3 and 7 ($p<0.05$), without changes in plasma creatinine or plasma urea. The left kidney of UUO mice showed augmented mRNA levels of IL-1b, TGF-b1, MCP-1 and CCL5, an inflammatory chemokine, at day 3 and 7. Additionally, we observed an increase in CD68 and IL-12b mRNA levels, as markers of activated macrophages in the left kidney of UUO mice. All these changes were accompanied by the increase of NGAL mRNA abundance in left kidney from 3 to 4-fold, at 3 and 7-days respectively (*vs.* Sham, $p<0.01$), which correlated with protein expression of plasma NGAL in UUO mice (24.1 µg/L in Sham *vs.* 103.8 µg/L and 134.5 µg/L in UUO, at 3 and 7 days respectively). Finally, we observed an induction of NGAL in PBMC after 7-days of UUO, without changes in other pro-inflammatory cytokines/chemokines.

Conclusions: The inflammatory renal phenotype caused by UUO implicates the sequential up-regulation of NGAL; first in kidney and plasma, and later in PBMC. This sequential induction of NGAL suggests a role in inflammatory cells during the early stages of CKD (Supported by FONDECYT 11150542 and Research Project PUCV 039.407/2017).

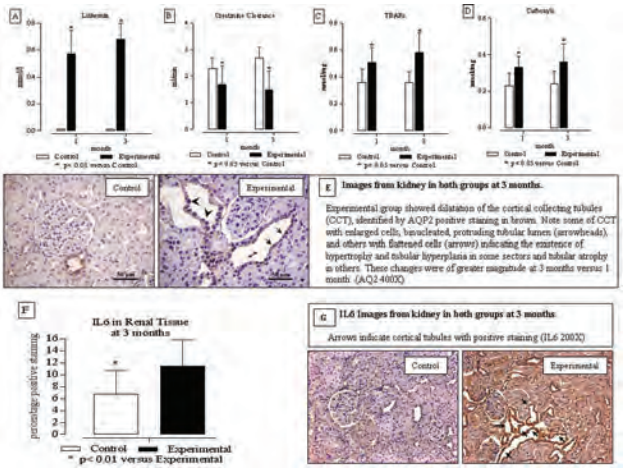
Persistent Oxidative Stress Associated with Lithium-Induced Renal Damage Jorge E. Toblli,[1] Juan M. Acosta,[2] Marisa G. Repetto,[2] Diego J. Martino,[3] Georgina P. Ossani.[1] *[1]Laboratory of Experimental Medicine Hospital Aleman, Buenos Aires, Argentina; [2]University of Buenos Aires, Buenos Aires, Argentina; [3]Institute of Cognitive and Translational Neuroscience, Buenos Aires, Argentina*.

Background: Lithium (Li) is still considered as first-line drug for therapy of bipolar disorder which requires long-term treatment. Interest in the risk of CKD and Li-induced renal failure is renewed due to some findings suggesting that both complications would be more frequent than previously estimated. This study evaluated the effect of oxidative stress on inflammatory response associated with the development of renal damage in rats treated with Li throughout the time.

Methods: Wistar male rats were fed standard diet (Control) or a containing 60 mmol lithium/kg diet (Experimental) ad libitum. This dose resulted in plasma levels of lithium equivalent to therapeutic levels in humans. Rats of each group were sacrificed after 1 or 3 months of treatment. Creatinine clearance (CrCl), lithemia, proteinuria and fractional excretion of sodium (FE_{Na}) were measured. Kidney samples were processed for: 1-oxidative stress (TBARS and carbonyls) evaluation; 2-histology (PAS and H&E); 3- immunohistochemistry: Aquaporin-2 (AQP2) in order to identify cortical collecting tubules and Interleukin-6 (IL6) as inflammatory marker protein.

Results: There were no differences in FE_{Na} and in urine protein excretion between control and experimental group at one and three months. Lithemia reached therapeutic values in the experimental group at 1 and 3 months (Fig 1A). CrCl was markedly reduced in experimental group (Fig1B). A significant increase in TBARs and carbonyls was observed in experimental group at 1 and 3 months, this indicating oxidation of lipids and proteins respectively Fig 1 C and D). Characteristics of the renal damage are shown in Fig 1 panels E, F and G.

Conclusions: Exposure to Li from 1 to 3 months to normal rats induced persistent oxidative stress expressed by lipoperoxidation/protein oxidation resulting in an increase in the inflammatory response with patent tubular damage and reduction in renal function.



PUB205

Renoprotective Effect of DPP-4 Inhibitor in Aging Mice Myung ah Ha, Tae Hyun Ban, Byung ha Chung, Bumsoon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea*.

Background: Dipeptidyl peptidase 4(DPP-4) inhibitor has been increasing evidence of diverse protective effects besides lowering glucose level, including renoprotective effect. However, the pathogenesis of the protective effects have not been clarified yet. We investigated the renoprotective effects of DPP-4 inhibitor via the RAS system in the aging mice model.

Methods: 18 month-old C57BL/6 mice were divided into two groups according to DPP-4 inhibitor administration : LIN (N=8) and CONT (N=8), followed for 24 weeks. The LIN group was administered with linagliptin 5mg/kg per oral daily. Renal function, albuminuria, activities and expressions of DPP-4 and glucagon like peptide-1 in renal tissue, neuropeptide Y and substance P in serum and renal tissue, histologic changes and expressions of angiotensin-converting enzyme (ACE), angiotensin-converting enzyme 2 (ACE2), angiotensin II (Ang II), angiotensin II type 1 receptor (AT1R), angiotensin II type 2 receptor (AT2R), prorenin receptor (PRR), Mas receptor (MasR), endothelial nitric oxide synthase (eNOS), NADPH oxidase 2 and oxidase 4 (Nox2 and Nox4), transforming growth factor-β (TGF-β), collagen IV, fibronectin, and superoxide dismutase 1 and dismutase 2 (SOD1 and SOD2) in renal tissue were analyzed. In renal histology, area of mesangial and tubulointerstitial fibrosis, collagen IV positive area and TGF- β positive area were measured.

Results: Renal function and albuminuria were not different between the two groups. In the LIN group, DPP-4 activities in renal tissue were decreased and serum substance P concentrations were increased. In renal tissue, expressions of ACE, PRR and AT1R were decreased in the LIN group compared to the CON group ($p<0.05$ for both), but ACE2, AT2R and MasR were not different. Nox2 and Nox4, TGF-β, fibronectin and collagen IV were significantly decreased in the LIN group compared to the CON group ($p<0.05$ for both), whereas expressions of phosphorylated $serine^{1177}$-eNOS and SOD1 were significantly increased ($p<0.0001$ and $p<0.05$). Area of mesangial and tubulointerstitial fibrosis, collagen IV positive area and TGF-β positive area were significantly decreased in the LIN group compared to the CON group ($p<0.001$, $p<0.0001$, $p<0.05$ and $p<0.0001$, respectively).

Conclusions: DPP-4 inhibitor may provides renoprotective effects against the aging process of the kidney via reduced PRR-ACE-AT1R axis.

PUB206

Role of Organochlorine Pesticides in Etiopathogenesis of CKD of Unknown Etiology (CKDu) – In-Vivo and In-Vitro Studies Om P. Kalra,[1,5] Rishila Ghosh,[6] Manushi Siddarth,[2] Pawan K. Kare,[3] Basu D. Banerjee,[4] Ashok K. Tripathi.[7] *[1]Nephrology, Pt. B.D. Sharma University of Health Sciences, Rohtak, India; [2]University College of Medical Science (University of Delhi) and GTB hospital, Delhi, India; [3]University College of Medical Sciences, Delhi, India; [4]University College of Medical Sciences and GTB Hospital, Delhi, India; [5]Medicine, University College of Medical Sciences, Delhi, India; [6]Biochemistry, University College of Medical Sciences, Delhi, India; [7]Biochemistry, University College of Medical Sciences, Delhi, India.*

Background: CKDu has emerged as a significant cause of morbidity and mortality and is the second commonest causes of CKD in India. Organochlorine pesticides (OCPs) are nephrotoxic agrochemicals that resist degradation and have been implicated in the etiopathogenesis of various disorders, such as diabetes mellitus, infertility, etc. The present study was designed to investigate the role of OCPs in the etiopathogenesis of CKDu and the possible underlying molecular mechanisms.

Methods: Three groups of subjects were recruited. Group 1: Healthy subjects (n= 60), Group 2: Patients with CKDu (n= 60) and Group 3: Patients with CKD of known etiology (CKDk) (n= 60). Blood OCPs levels of all three study groups were analyzed by

gas chromatography. Various OCPs included: α-HCH, β-HCH, γ-HCH, aldrin, dieldrin, α-endosulfan, β-endosulfan, p,p′-DDT and p,p′-DDE. eGFR was calculated using MDRD method. Effect of OCPs on renal cells was assessed by in-vitro studies using human renal proximal tubular epithelial cells (HK-2). The cultured cell line was treated with α-HCH, β-endosulfan and p,p′-DDE.HK-2 cells were tested for ROS generation and mRNA expression of NADPH oxidase, TGF-β1, α-SMA and E-cadherin gene.

Results: All 9 pesticides were detected in the blood samples of all study subjects; however, α-HCH, aldrin, β-endosulfan, p,p′-DDE were found to be significantly higher in CKDu group as compared to healthy controls. β-endosulfan and p,p′-DDE were found in significantly higher levels in CKDu patients as compared to CKDk patients. Increased levels of these pesticides showed significant positive correlation with urinary albumin excretion and inverse correlation with eGFR. Further, significant increase in ROS generation and increased expression of NADPH, NF- κB and TGF-β1 was observed in HK2 cell lines on exposure to OCPs. In addition to that, decreased expression of E-cadherin and increased expression of α-SMA genes were observed in HK-2 cell lines indicating significant EMT changes on exposure to the OCPs suggestive of fibrotic changes.

Conclusions: Levels of certain organochlorine pesticides, such as α-HCH, aldrin, β-endosulfan, p,p′-DDE were elevated in CKDu. These agents may result in nephrotoxicity through various mechanisms, such as activation of oxidant stress, RAAS, inflammatory and pro-fibrotic pathway.

PUB207

Repeated Dosing of Cisplatin in Mice Leads to Long-Term Loss of Kidney Function and Fibrosis Indicative of CKD Cierra Sharp,[2] Mark A. Doll,[2] Tess Dupre,[2] Levi J. Beverly,[1,3] Leah J. Siskind.[2,3] *[1]University Of Louisville, Louisville, KY; [2]University of Louisville, Louisville, KY; [3]James Graham Brown Cancer Center, Louisville, KY.*

Background: Cisplatin (CDDP) is a potent therapy used for many solid cancers. Its dose-limiting toxicity is nephrotoxicity, leading to acute kidney injury (AKI) in 30% of patients. AKI results in rapid loss of kidney function and an increased mortality rate. Longitudinal studies have indicated that AKI patients are more likely to develop chronic kidney disease (CKD), and other studies have indicated that AKI can progress to CKD. CKD is defined by development of renal fibrosis, renal function loss, and an increased mortality rate. There are no current therapies for CDDP AKI/CKD. This is due to the fact that the mouse model used to study CDDP AKI may not recapitulate the dosing regimen humans receive. Mice are administered one high dose of CDDP that leads to death 3-4 days after treatment. In contrast, patients receive low doses of CDDP over an extended period of time to curtail nephrotoxicity.

Methods: To address the limitation of this mouse model, we developed a repeated dosing regimen of CDDP (mice treated with 7 mg/kg CDDP 1x/wk for 4 wks and sacrificed at Day 24), which induces fibrosis indicative of CKD. However, CKD is a progressive disease that develops over many years in humans. Thus, we wanted to determine long-term renal outcomes of mice treated with our repeated dosing regimen of CDDP. Briefly, 8 wk old FVB mice were treated with our CDDP repeated dosing regimen.

Results: We found that mice were able to survive at least 6 months post-treatment, allowing this model to be used to look at long-term kidney outcomes. Kidney injury NGAL levels returned to baseline 6 months post-treatment in CDDP treated mice, but these mice still had elevated BUN levels compared to vehicle treated mice (1.8-fold). *Mcp-1, Pai-1,* and *Cdkn2a* mRNA levels remained elevated indicative of chronic inflammation and cell cycle arrest (6.7, 2.4, and 6.8-fold, respectively). Furthermore, fibrosis was still present as indicated by Sirius red (SR) stain and α-SMA IHC (35% SR+, 0.5% αSMA+).

Conclusions: These data suggest that while initial injury is resolved 6 months post CDDP treatment, there are long-term effects on renal function and inflammation marked by a trend towards worsened fibrosis, suggesting this model can be used as a *bona fide* model of CKD.

The Novel Kinase Inhibitor ANG3070 Improves Renal Injury in the DOCA/Salt Model of CKD Bert Oehlen,[2] Bin Duan,[1] Ping Zhou,[1] Latha Paka,[1] Prakash Narayan,[1] Itzhak D. Goldberg.[2] *[1]Angion Biomedica Corp, Uniondale, NY; [2]Angion Biomedica Corp., Uniondale, NY.*

Background: Aberrant receptor tyrosine kinase signaling has been implicated in development and progression of Chronic Kidney Disease (CKD). We investigated the effects of a novel small molecule receptor tyrosine kinase inhibitor, ANG3070, in *in vitro* and *in vivo* models of CKD.

Methods: We tested the effect of ANG3070 *in vitro* in TGFbeta-stimulated collagen production in renal fibroblasts (NRK49F cells) and on multiple endpoints in a co-culture system of human renal epithelial cells and fibroblasts. For *in vivo* studies, male Sprague-Dawley rats were uni-nephrectomized and received weekly subcutaneous injections of deoxy-corticosterone acetate (DOCA) while drinking water with 1% NaCl. After two weeks, animals were randomized to receive ANG3070 (50 mg/kg, po, bid) or vehicle. At week 6, a comprehensive panel of renal functional and histological endpoints was evaluated to assess the effect of compound treatment.

Results: ANG3070 inhibits TGFbeta-stimulated collagen production in renal fibroblasts and in a co-culture system mimicking the renal milieu, ANG3070 reduced markers of fibroblast activation (e.g. α-SMA and N-cadherin) and of fibrosis (e.g. Collagen III). Uni-nephrectomized rats treated with DOCA and salt after two weeks showed marked kidney histological damage and renal dysfunction, as shown by overt proteinuria and elevated urine levels of kidney injury marker 1 (KIM1). Compared to vehicle treated animals, treatment with ANG3070 for four weeks mitigated kidney damage and reduced renal collagen and α-SMA expression. Proteinuria, Albuminuria and urine KIM1 levels were also reduced as a result of ANG3070 treatment.

Conclusions: In preclinical experiments, the novel receptor tyrosine kinase inhibitor ANG3070 shows promise as a possible treatment for CKD.

Podocytes and Proximal Tubular Epithelial Cells Participate in ST2 Related Renal Fibrosis Yong Chul Kim,[3] Seung Hee Yang,[1] Ran-hui Cha,[2] Mi-yeon Yu,[6] Hajeong Lee,[5] Jung Pyo Lee,[4] Dong Ki Kim,[6] Suhnggwon Kim,[1] Yon Su Kim.[5,1] *[1]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [2]National Medical Center, Seoul, Republic of Korea; [3]SNUH, Seoul, Republic of Korea; [4]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea; [6]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Suppression of tumorigenicity 2 (ST2) which is the receptor of IL-33 is involved in renal inflammation and it is also correlated with disease severity in chronic kidney disease (CKD). Here, we report the ameliorating effect of the ST2 blockade as well as the role of ST2 in the progression renal fibrosis.

Methods: Serum and urine levels of sST2 were measured in 296 CKD patients. And ST2 mRNA levels were quantified in blood and urine cells. Immunohistochemistry (IHC) stain of ST2 was performed in kidney biopsy samples of CKD patients. Further, urine cells were co-stained with podocalyxin/aquaporin-1 and ST2 to characterize the cell type. And fibrosis induced by TGF-β in primary cultured podocytes and proximal tubular epithelial cells (PTECs) were evaluated with fibronectin and ST2 mRNA expressions. Anti-ST2 monoclonal antibody (mAb) was treated to evaluate the neutralizing effect of ST2 on renal fibrosis. Finally, ST2 and fibronectin mRNA expression was measured in CKD mouse model (UUO; Unilateral Ureteral Obstruction).

Results: Serum ($P = 0.002$) and urine ($P < 0.001$) sST2 levels increased as renal function deteriorated. Urine ST2 levels adjusted by urine creatinine showed the same pattern ($P < 0.001$). Serum ($P = 0.023$) and urine ($P = 0.03$) ST2 expressions were elevated in CKD stage 5 patients compared with other stages. ST2 IHC stain in CKD stage 5 showed 3-fold increase than CKD stage 1. A large portion of urine cells were ST2-rich podocytes/PTECs and we observed the proportion of these cells increased as renal function decreased in flow-cytometry. When the patients were subdivided by 0.5 g/g proteinuria, patients with more proteinuria had a higher concentration of urine ST2 ($P = 0.02$). After fibrosis induction in primary cultured podocytes/PTECs, mRNA and protein expressions of fibronectin, ST2 showed positive correlation with the fibrosis severity. And anti-ST2 neutralized the fibrosis. In UUO mouse model ST2 and fibronectin expression was increased over time ($P < 0.01$).

Conclusions: Elevated serum and urine ST2 levels are associated with the progression of CKD and podocytes/PTECs involved in this process. ST2-mediated signaling may have a considerable role in the progression renal dysfunction. And ST2 blockade is a potential therapeutic target for renal preservation.

PUB211

High Intensity Interval Training (HIIT) Attenuates Proteinuria in Nephrectomy 5/6 Rats (Nx5/6) Samuel T. Filho,[4] Luciana Jorge,[1] Natalia Reinecke,[2] Alexandre Saud,[2] Rafael Luiz,[1] Wesley Silva,[4] Rodolfo R. Rampaso,[1] Nestor Schor.[3] *[1]None, São Paulo, Brazil; [2]UNIFESP, Sao Paulo, Brazil; [3]Universidade Federal de Sao Paulo/Escola Paulista de Medicina, Sao Paulo, Brazil; [4]Universidade Federal de São Paulo, São Paulo, Brazil.*

Background: HIIT is characterized by intense and intermittent exercises, interspersed with periods of low intensity and / or rest. Recent studies suggest that HIIT stimulates physiological adaptations equal or better comparable to continuous training of moderate intensity. However, the effect of HIIT on renal function and in CKD is not well known. The aim of this study was to evaluate the effects of HIIT on renal function and physical capacity in Nx 5/6 rats.

Methods: Adult Wistar rats, divided into two groups (n=6/group): Nx 5/6 + exercise (NE) and Nx 5/6 sedentary (NS). Physical training protocol started after 7 days of surgical procedures, 3 days/week, 10 sprints at 90% of maximum capacity, 8 weeks total. To evaluate phsycal capacity, all animals underwent a maximal physical capacity test before and after training. The mean arterial pressure (MAP), proteinuria (uProt) as urea nitrogen in the blood (BUN) was evaluated.

Results: HIIT was not able to modify the MAP, but attenuated the increase in the proteinuria rate (38.2±4.4 vs.63.5 ± 1.9mg / 24h, p <0.001). Mean BUN was higher in NS in comparison to NE group. (101.2 ± 10.4 vs 83.1 ± 2.0mg / dl, p <0.01). HIIT also improved physical capacity as seen in maximal physical capacity test (27±2 vs 38±1 m/min).

Conclusions: These results suggests that 8 weeks of HIIT can minimize the impact of CKD, with lower increase of BUN and proteinuria. Thus, HIIT could have a protective effect and may be a time-efficient strategy for non-pharmacological treatment to minimize the complications of CKD.

Immunoglobulin G4 Related Disease with Polycythemia Vinaya R. Soundararajan,[3] Yameen Rashid,[2] Ramesh Soundararajan.[1] *[1]Medicine, Midwestern University College of Medicine, Downers Grove, IL; [2]St James Hospital, Chicago Heights, IL; [3]University of Illinois College of Medicine, Willowbrook, IL.*

Background: (Ig) G4-related disease is a systemic fibro-inflammatory condition characterized by a lymphoplasmacytic infiltrate rich in IgG4-positive plasma cells with elevated IgG4 Levels. The disease presents as involving one organ or may present as a systemic disease affecting multiple organs. We report a case of IgG4-related disease presenting with associated polycythemia. This combination has not been reported in the literature to the best of our knowledge.

Methods: A 41-year-old African-American male construction worker presented with a creatinine of 4.0 mg/dL and was found to have mild microscopic hematuria. His urinalysis showed 5-8 RBCs/HPF and proteinuria. His creatinine was normal 4 years ago. He had a history of hypertension and NSAID usage. Patient also recently was diagnosed with polycythemia, and his hemoglobin was 20 g/dL. Ultrasound of his kidneys suggested bilateral large lobular kidneys. He was otherwise asymptomatic. Workup showed a negative JAK 2 mutation and a urine protein of 600 mg per gram of creatinine. His vasculitis and hepatitis workups were negative, except for a low C3 and C4. The patient also had some enlarged inguinal nodes, which were biopsied but not diagnostic.

Results:

Conclusions: Patient had phlebotomy initially to decrease his hemoglobin. He underwent a kidney biopsy which showed lymphoplasmacytic infiltration of the renal interstitum, with an increased number of IgG4-positive plasma cells. Patient's creatinine decreased to 3.4 mg/dL after stopping his NSAIDs and phlebotomy. After the biopsy, patient was started on 40 mg prednisone a day. The patient's original IgG4 level was 1140 mg/dL. After 4 weeks of prednisone, the level decreased to 260 mg/dL (normal is less than 120 mg/dL). His creatinine also came down to 2.7 and his proteinuria and hematuria resolved. Prednisone is currently being tapered. His Hb decreased to 13 gm/dl IgG 4-related disease is a systemic plasma cell infiltrative disease which can involve multiple organs, including pancreas, lymph nodes and kidneys. It predominantly causes tubular interstitial infiltration in the kidney. Patient is responding well to prednisone. Other treatments including rituximab have been used to treat this disease.

Chronic Renal Fibrosis Qualified by Synchrotron Radiation-Fourier Transform Infrared Spectroscopy Jieli Huang,[2] Chen Yu.[1,3] *[1]SHANGHAI TONGJI HOSPITAL, SHANGHAI, China; [2]TONGJI HOSPITAL, SHANGHAI, China; [3]TONGJI UNIVERSITY SCHOOL OF MEDICINE, SHANGHAI, China.*

Background: Renal fibrosis is the main pathology of end stage renal disease. It includes glomerulosclerosis and tubule-interstitial fibrosis, which with the major pathological manifestations of extracellular matrix abnormal increasing and excessive deposition. Fourier transform infrared microspectroscopy and imaging are emerging excellent methodologies for biological analysis and enable nondestructive, label-free analysis of biochemical information towards the assessment of tissue functionality. We will qualify the chronic renal fibrosis by Synchrotron radiation-Fourier transform infrared spectroscopy in this study.

Methods: We used a model of unilateral ureteral obstruction and divided into two groups. Sham and UUO groups. Chronic renal fibrosis was qualified by histological examination and SR-FTIR.

Results: Histologic examination showed there were interstitial fibrosis in UUO rats, with mild or severe glomerular injury in HE staining (Fig1A) and Masson staining (Fig1B). It was found that the bands near 1000-1200 cm^{-1} are main significant differences between the sham and UUO groups. There are three feature bands near 1133.31, 1058.24, 995.2 cm^{-1} in UUO group which reflect the PO2 phosphodiesters stretch from phosphorylated molecules, glycogen and glycoprotein, and reveals that glycoprotein is increased in UUO group (Fig2A). The PCA scores plots showed a clear cluster separation between the sham and the UUO groups(Fig2B), indicating the chemical changes could be assessed by SR-FTIR.

Conclusions: The molecular structural changes of renal fibrosis had been identified and qualifying by the SR-FTIR spectra. These results showed that SR-FTIR would be a useful technique with high sensitivity to tell from the tissue fibrosis.

Funding: Government Support - Non-U.S.

Sulfatide-Selective NKT Cells Mediate M2 to M1 Polarization of Macrophage and Macrophage to Myofibroblast Transition Cell Resulting in Amelioration of Kidney Fibrosis Sunhwa Lee,[6] Hajeong Lee,[5] Jae Wook Lee,[2] Jung Pyo Lee,[4] Ran-hui Cha,[3] Dong Ki Kim,[6] Yon Su Kim,[5] Seung Hee Yang.[1] *[1]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [2]National Cancer Center, Seoul, Republic of Korea; [3]National Medical Center, Seoul, Republic of Korea; [4]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea; [6]Seoul National University Hospital, Jongno-gu, SEOUL, Republic of Korea.*

Background: Macrophage subtype polarization has been suggested as a key player related to kidney fibrosis. Moreover, myofibroblast, the principal cells that produce extracellular matrix in fibrosis, can be originated from macrophage by means of macrophage-myofibroblast transition (MMT). We investigated phenotypic skewing of these cells by sulfatide-selective type II NKT cells and its impact on kidney fibrosis.

Methods: Sulfatide-selective type II NKT cells from B6.Jα281$^{-/-}$ mice were isolated, and co-cultured with primary cultured proximal epithelial cells. In addition, sulfatide [20 or 40μg/300μl IV] was injected before unilateral ureteral obstruction (UUO) operation. Subsequently, total cellular RNA was extracted from minced kidney, lymph nodes, and fresh blood to analyze changes in transcript expression levels using quantitative real-time PCR and microarray. Furthermore, adoptive transfer of type II NKT cells was performed.

Meanwhile, the proportion of infiltrated $\alpha SMA^{+}/CD206^{+}$ double positive cells in sulfatide treated UUO kidney and CKD 3 and 5 patients were investigated.

Results: Severity of renal fibrosis and the proportion of $\alpha SMA^{+}/CD206^{+}$ double positive cells was attenuated after sulfatide injection. At the same time, sulfatide reduced senescence, shown by decreased levels of SA-β-Gal. Sulfatide stimulated polarization from M2 to M1 accompanying by increased iNOS, STAT1, SOCS3 and decreased arginase, STAT3. Pro-fibrotic transcripts, fibronectin and TGFβ, was decreased by adding sulfatide-selective NKT. The expression level of NGAL and IL-1β, a marker of kidney damage and inflammation, was attenuated. Similarly, adoptive transfer of sulfatide-selective type II NKT cells attenuated expression of αSMA and fibronectin. In stage 5 CKD patients, the density of $\alpha SMA^{+}/CD206^{+}$ double positive cells were 3.3 times higher than stage 3.

Conclusions: Sulfatide-selective NKT cell mediates macrophage polarization skewing from M2 to M1 macrophage via switching on STAT1 resulting in ameliorating renal fibrosis. Infiltration of myofibroblast cells co-expressing M2 marker are also decreased by sulfatide accompanying by reduced fibrosis. Inducing the polarization of macrophages by modulation of NKT cells can be suggested as therapeutic target for curbing fibrosis.

PUB215

A Case of Immunoglobulin G4-Related Disease in Association with Polymyalgia Rheumatica Misaki Yoshida, Kiyoaki Ito, Kazunori Yamada, Eiko Shimizu, Nobuhiro Suzuki, Takahiro Matsunaga, Takeshi Zoshima, Satoshi Hara, Ichiro Mizushima, Hiroshi Fujii, Mitsuhiro Kawano. *Kanazawa University Hospital, Ishikawa, Japan.*

Background: Immunoglobulin G4-related disease (IgG4-RD) presents with arthralgias in 10% of patients. Several case reports have described IgG4-RD in association with rheumatoid arthritis, but there has been no report of IgG4-RD in association with polymyalgia rheumatica (PMR). We report a case of IgG4-RD in a patient with PMR.

Methods: A 68-year-old man with a history of lung cancer was admitted with bilateral shoulder, wrist, and pelvic girdle pain for two months. He was found to have elevated C-reactive protein (CRP), hypergammaglobulinemia, hypocomplementemia, and a positive antinuclear antibody (ANA) test during a clinic visit one month prior to admission. The CRP level on admission was 3.7 mg/dl. He not only met the 2012 ACR/EULAR Provisional Classification Criteria for Polymyalgia Rheumatica, but also had unexplained hypocomplementemia (C3, 64 mg/dl; C4, 4 mg/dl; and CH50, 11 U/ml), hypergammaglobulinemia, and a high ANA titer (x20480). Additional blood tests showed an elevated serum IgG4 level (543.0 mg/dl) and IgG4/IgG ratio (23.4%). Computed tomography (CT) revealed swelling of the bilateral submandibular glands and enhanced CT showed multiple low-density lesions in the kidneys. Renal biopsy showed tubulointerstitial nephritis with marked infiltration of IgG4-positive plasma cells (72/high-power field). There was a clear border between affected and unaffected areas in the kidney interstitial lesions. IgG4-RD was diagnosed using comprehensive diagnostic criteria. Prednisolone 30 mg/day was initiated and the PMR symptoms rapidly disappeared.

Results:

Conclusions: This is the first reported case of IgG4-RD in association with PMR. The immunological features of PMR and IgG4-RD are different, but the reason for concurrent presentation in this patient remains unclear. One possibility is that these two diseases are related to malignancy in some cases. Further studies are needed to clarify the pathogenesis of this condition.

PUB216

Difference of Two AKI to CKD Transition Models in Mice Kengo Mayumi,[3] Daisuke Nakano,[1] Tetsushi Yamashita,[3] Yoshifumi Hamasaki,[4] Eisei Noiri,[3] Akira Nishiyama,[2] Masaomi Nangaku,[5] Kent Doi.[4] *[1]Kagawa University, Kagawa, Japan; [2]Kagawa University Medical School, Kita-Gun, Japan; [3]The University of Tokyo, Tokyo, Japan; [4]University of Tokyo, Tokyo, Japan; [5]the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Recent clinical studies have demonstrated AKI is a major risk factor for CKD. Experimental studies using animal models have been conducted so far to clarify the mechanisms underlying progression from AKI to CKD, but effects of differences between animal models on experimental results has not been sufficiently examined.

Methods: We developed two mouse AKI-to-CKD models by combining renal ischemia reperfusion and nephrectomy; unilateral ischemia-reperfusion injury with contralateral nephrectomy (UIR+UNx) and without nephrectomy (UIR), and evaluated their differences of post-ischemia injury and erythropoietin producing ability.

Results: Renal interstitial fibrosis and erythropoietin producing dysfunction in the UIR+UNx group was significantly milder than that of the UIR group. Intravital multiphoton microscopy revealed contralateral nephrectomy significantly increased blood flow of peritubular capillary (PTC) in post-ischemic kidney. Infrarenal aortic constriction (IRAC) also significantly increased PTC blood flow and reduced G2/M arrest cells and TGF-β1 expression in the ischemic kidney at subacute phase, and reduced interstitial fibrosis in chronic phase. After induction of anemia by phenylhydrazine administration, renal EPO mRNA expression in the post-ischemic kidney is higher in UIR+IRAC group than in UIR group.

Conclusions: Improvement of blood flow in PTCs in UIR+Nx group might have a significant impact on renal interstitial fibrosis and erythropoietin production. These differences suggest that careful interpretation is necessary for animal experiments that evaluate AKI to CKD progression.

Investigating a Ciliopathy – CEP164 Expression throughout Human Embryonic Development Laura A. Devlin,[1] Simon Ramsbottom,[1] Lynne M. Overman,[1,2] Susan Lindsay,[1,2] John Sayer.[1] *[1]Institute of Genetic Medicine, Newcastle University, Newcastle upon tyne, United Kingdom; [2]HDBR, Newcastle University, Newcastle Upon Tyne, United Kingdom.*

Background: Nephronophthisis-related ciliopathies (NPHP-RC) are a collection of disorders that share a common NPHP phenotype, caused by defects in the biogenesis or functioning of primary cilia. NPHP-RC are major contributors to juvenile renal failure and are often associated with neurological, retinal and hepatic abnormalities. Recessive mutations in CEP164 (NPHP15), a distal appendage centrosomal protein, have been identified in some families with NPHP-RC. These patients have a heterogeneous, multi-system phenotype, presenting with features such as retinal degeneration, Leber congenital amaurosis, developmental delay and intellectual disability.

Methods: We utilised the MRC Wellcome Trust Human Development Biology Resource (HDBR) to obtain human embryonic and fetal tissue. Immunohistochemical staining of CEP164 was completed on paraffin embedded tissue sections, from Carnegie stage (CS) 23 (approximately 8 post conception weeks (pcw)) to 19 pcw. Specifically, CEP164 expression in the kidney, eye and brain (hindbrain) were examined.

Results: In human embryonic and fetal tissues, CEP164 had a widespread expression pattern throughout development, with expression in many organs including the kidney, liver, lung and stomach. In all kidney sections analysed, CEP164 was expressed in developing renal tubules; this was maintained throughout development. CEP164 expression was also seen in retinal tissue, during all developmental stages, in defined cell layers. There was strong CEP164 expression in ependymal cells of the choroid plexus as well as cells lining the brain ventricles.

Conclusions: CEP164 has widespread, but defined expression throughout human embryonic development. There is strong expression in the kidney, retina and defined regions of the brain. This supports the multi-system pathology present in patients with Cep164 NPHP-RC.

PUB219

Three-Dimensional Reconstruction of AQP-1 and UT-A2 Expression in a 7-Day-Old Mouse Kidney Ning-Yu Liu,[1] Ling Gu,[1] Shi-Jie Chang,[2] Jie Zhang,[1] Jesper S. Thomsen,[3] Arne A. Andreasen,[3] Erik I. Christensen,[3] Xiao-Yue Zhai.[1] *[1]Department of Histology and Embryology, China Medical University, Shenyang, China; [2]Department of Biomedical Engineering, China Medical University, Shen Yang, China; [3]Department of Biomedicine – Anatomy, Aarhus University, Aarhus C, Denmark.*

Background: Mouse kidneys undergo a couple of weeks of maturation of morphology and transportation mechanisms related to the urine concentration after nephrogenesis ceases at postnatal (P) day 3. The present study investigated the location of AQP-1 and UT-A2 based on three-dimensional reconstruction of nephrons. The aim was to analyze the formation of water and urea transport in Henle's loop in developing kidneys. The morphological basis for mechanism of medullary osmotic gradient formation is discussed.

Methods: Serial 2.5-µm-thick epoxy sections from a 7-day-old mouse kidney were prepared and stained with toluidine blue. Selected sections representing different levels of the kidney were re-embedded, and cut into consecutive 0.5-µm-thick epoxy sections, on which immunohistochemistry was performed for AQP-1 and UT-A2. The location of these membrane proteins was mapped along short and long looped nephrons (SLN, LLN) and descending vasa recta (DVR). The nephrons and blood vessels were identified in 3D by computer assisted tracing on aligned images of the toluidine blue stained sections using custom-made computer software.

Results: Firstly, AQP-1 was, like in the adult kidney, expressed densely along proximal tubules (PT), except the initial part several hundreds micrometers in length. Secondly, AQP-1 were expressed in the entire length of DVR running in vascular bundles (VB) and descending thin limbs (DTL) of LLN running in the interbundle region. Thirdly, the majority of DTL of SLN did not express AQP-1. These SLN DTLs were localized in close proximity to AQP-1 positive DVR in the VB. UT-A2 was expressed alone in the last third of DTL of SLN running also in VB.

Conclusions: The distribution of AQP-1 and UT-A2 in the 7-day-old kidney is mainly consistent with that in adult kidneys. This indicates that the urine concentrating function of the kidney is at least partly established at this time point. This is especially evident in the medulla, suggesting that the morphologic and molecular basis for the intrarenal countercurrent exchange has been set up in the medulla at P7.

PUB220

Prediction of Ambulatory Hypertension Based on Clinic Blood Pressure Percentile: The SHIP AHOY Study Gilad Hamdani,[2] Elaine M. Urbina,[1] Marc Lande,[3] Kevin E. Meyers,[5] Joshua A. Samuels,[6] Mark Mitsnefes,[2] Joseph T. Flynn.[4] *[1]Cincinnati Children's Hospital, Cincinnati, OH; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]Rochester, NY; [4]Seattle Children's Hospital, Seattle, WA; [5]The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [6]University of Texas, Houston, TX. Group/Team: SHIP AHOY Study.*

Background: Ambulatory blood pressure (ABP) provides a more precise measure of BP status than clinic BP but ABP adds additional cost to evaluation for HTN. Therefore, our objective was to determine the clinic BP percentile at which the likelihood of ambulatory HTN increases to optimize application of ABP in adolescents.

Methods: We evaluated clinic BP (mean of 6 measures with auscultatory technique) and ABP (Spacelabs OnTrak), anthropometrics, and labs in 132 adolescents (mean 15.8 ± 1.4 years, 66% white, 57% male). Clinic BP percentile and ABP status (normal vs HTN) were determined by age, sex and height-specific pediatric cut-points, and patients were divided into five SBP %ile groups: <50, 50-80, 80-90, 90-95, and ≥95. Association between clinic BP percentile group and ABP status was compared using X^2. Logistic regression and receiver operating characteristics (ROC) analysis were used to determine the clinic systolic BP %ile that best predicted ambulatory HTN.

Results: Eighteen patients (14%) had ambulatory HTN. Prevalence of ambulatory HTN increased according to SBP %ile group, from 2% in subjects with normal clinic BP to 44% in hypertensives ($p<0.0001$). ROC analysis showed that casual SBP %ile predicted ambulatory HTN with an area under the curve of 0.80. The 80th % ile for SBP resulted in the best balance between sensitivity (0.78) and specificity (0.69).

Conclusions: When evaluating adolescents referred to clinic for suspected hypertension, SBP %ile of ≥80 may be the optimal threshold to perform an ABPM.

PUB221

Patterns of RAAS Blockade Use in Children with CKD Jason T. Lee,[2] Mark Mitsnefes,[1] Charles E. McCulloch,[2] Elaine Ku.[2] *[1]Cincinnati Children's Hospital, Cincinnati, OH; [2]University of California San Francisco, San Francisco, CA.*

Background: There is limited data on patterns of anti-hypertensive use in children with CKD. RAAS (renin-angiotensin-aldosterone-system) blockade is known to retard progression to ESRD. Our objective was to understand patterns of RAAS blockade use during different stages of CKD.

Methods: We analyzed data from the Chronic Kidney Disease in Children (CKiD) Study, a national observational study of children with CKD. We used mixed models to determine person-specific trajectories of renal function decline using all available eGFR measurements as means of partitioning follow-up time into distinct CKD stages (3a-5). We then determined the prevalence of ACE inhibitor (ACEi)/ARB continuation, discontinuation, or initiation for each CKD stage separately in cross-sectional analysis. We also stratified our analysis by proteinuria level (urine protein creatinine (UPC) ratio of <2.5 and UPC >2.5), using the first available measurement at entry into each CKD stage.

Results: We included 572 CKiD participants, of whom 105 had available data in stage 3a, 175 in stage 3b, 208 in stage 4, and 84 in stage 5. Across CKD stages 3a-5, 52.4%, 65.1% 59.1% and 54.8% of children were treated with ACEi/ARBs. There was significant therapeutic inertia in CKD stage 3 [Figure], whereas in CKD stage 4, 10.5% of children started ACEi/ARBs and 5.7% stopped therapy. In CKD stage 5, 6.0% started ACEi/ARB and 21.4% of children stopped therapy. No differences in potassium level were noted in ACEi/ARB users versus non-users except in CKD stage 5 where hyperkalemia was more prevalent in users of ACEi/ARB (18.8 vs. 3.9%). Patterns of ACEi/ARB use did not differ in stratified analysis by proteinuria [Figure].

Conclusions: ACEi/ARBs appear underused in the pediatric population during early stages of CKD, especially in those with significant proteinuria. Nearly half of children not on ACEi/ARB therapy were proteinuric, and therapy was not initiated until later stages of CKD which may be suboptimal for delaying progression to ESRD.

Pediatric ABPM Program: Utilizing the Electronic Medical Record for Reorganization and Improved Efficiency Monica Casillas,[1] Lieuko Nguyen,[2,1] Meghan M. Cantillon,[1] Jane Goggin,[1] Peter D. Yorgin.[2,1] *[1]Rady Children's Hospital San Diego, San Diego, CA; [2]University of California San Diego, San Diego, CA.*

Background: With increasing incidence of pediatric hypertension (HTN), early recognition and prompt diagnosis of HTN in children are critical. Ambulatory blood

pressure monitoring (ABPM) is utilized to diagnose white coat, masked, and sustained ambulatory HTN.

Methods: Hospital-wide ABPM orders at Rady Children's Hospital are completed by Nephrology department. During 2015, barriers to timely completion of ABPM included: machine malfunctions, mismatch of monitors to referrals, adequate staff time, families not returning machines in <7 days, and complicated hand calculation analysis as ABPM computer program utilized pre-set sleep times of 2200 - 0600 hour. Nephrologists took 20-45 minutes to analyze each ABPM. A new EPIC-based ABPM referral pathway was created. 11 SpaceLab Model 90227 machines were purchased in addition to our 4 models. Medical assistants, RNs, and physicians were re-trained to administer, upload, and analyze the reports. Friday afternoons are dedicated to ABPM appointments. Families sign contracts; we provide mail-in return Fed-Ex boxes. ABPM's were analyzed based on patient's actual sleep and wake times from patient activity logs. An assigned physician for the week analyzes all ABPMs completed. A new EPIC procedure note allowed for easy documentation.

Results: The number of ABPM studies completed per year increased from 280 in 2015 to 350 in 2016. The new pathway via EPIC shortened time from referral to report completion from 146 ± 112 days (March 2015) to 35 ± 14 days (March 2017), $p<0.001$. There was improved machine return rate with utilization of pre-paid Fed-Ex boxes and signed contracts. Physician's time required to analyze each ABPM was significantly decreased to 5-15 minutes.

Conclusions: New procedures for the ABPM program resulted in an improvement in timely diagnosis and workup of pediatric HTN. Improvements in program efficiency can improve patient outcomes, while reducing family and patient anxiety. We recommend working with EPIC/EMR programs to build an interface for scheduling and analyzing, which allows for decreased workload and time commitment. We hypothesize that further improvement in program efficiency can be achieved if we have more monitors, decrease the frequency of machine malfunction, and increase equipment return within 5 days.

PUB223

Impact Cases of Renin–Angiotensin Systems Gene Polymorphisms on Physiological and Pathophysiological Processes in Two Japanese Patients

Kohei Miyazaki,[1] Keisuke Sugimoto,[2] Tomoki Miyazawa,[4] Takuji Enya,[5] Hidehiko Yanagida,[3] Mitsuru Okada,[2] Tsukasa Takemura.[2]
[1]Pediatrics, Kindai University Faculty of medicine, Osaka, Japan; [2]Kindai University Faculty of Medicine, Osaka, Japan; [3]Tondabayashi Hospital, Tondabayashi, Japan; [4]Pediatrics, Kindai University School of Medicine, Sakai, Japan; [5]Kindai university school of medicine, Osakasayama, Japan.

Background: Renin–angiotensin systems (RAS) play an important role in organ development and the maintenance of physiological functions. Defects in RAS-related genes products may exhibit CAKUT including renal tubule dysplasia (RTD). The majority of children with RTD at birth may present with significantly low blood pressure leading to perinatal death. In contrast, mutations and polymorphism spectrum of the RAS-related genes to clinical outcomes exist. We present two cases of *AGT*- gene related abnormality.

Methods: Case 1 is a 4-year-old boy. He was born at 37 weeks, with a birth weight of 2374 g. After birth, he was treated for hyperventilation and cyanosis without low blood pressure. Renal dysfunction, bilateral kidney atrophy and expansion of the left renal pelvis were observed. He also had delayed mental development, low stature, and low weight. CT showed a thin skull and partial defects of the occipital region. Blood test showed evidence of increased active renin concentration (72 pg/ml [normal: 2.5–21.4 pg/ml]), although the plasma renin activity was normal. Renal biopsy showed immature glomeruli, cystic enlargement of the renal tubules. Gene analysis revealed a heterozygous mutation (C/C→T/T) in the *AGTR1* gene in exon 5. He was diagnosed with RTD caused by *AGTR1* gene abnormality. Case 2 is a 13-year-old boy. No abnormality was found in the perinatal period. Health checkup at 1 month of the age pointed out abnormalities of facial features. Screening test revealed atrophic left kidney with small cysts. Subsequently, mental retardation was recognized. He had small eyeballs and retinal dysplasia, pituitary hyperplasia as revealed in the brain MRI. Evidence of increased active renin concentration (105 pg/ml) was shown. Gene analysis revealed a homogenous M268T mutation in the *AGT* gene in exon 2. A heterozygous mutation in AGT gene was detected in the parents.

Results:

Conclusions: The RAS-related molecule is an essential factor of fetal organ development, and its abnormality shows various symptoms including extrarenal complications. Abnormalities in RAS-related molecules do not necessarily affect the circulating state of RAS-related molecules. Symptoms differ, depending on polymorphisms, suggesting that genetic mutation is potentially present in many asymptomatic patients.

PUB224

RET-Associated Renal and Extrarenal Disease: An Expanding Clinical Spectrum

Keisuke Sugimoto,[4] Tomoki Miyazawa,[5] Kohei Miyazaki,[3] Takuji Enya,[1] Hidehiko Yanagida,[2] Mitsuru Okada,[4] Tsukasa Takemura.[4]
[1]Pediatrics, Kindai University Faculty of medicine, Osakasayama, Japan; [2]Tondabayashi Hospital, Tondabayashi, Japan; [3]Pediatrics, Kindai University Faculty of medicine, Osaka, Japan; [4]Pediatrics, Kindai University Faculty of Medicine, Osaka, Japan; [5]Pediatrics, Kindai University Faculty of Medicine, Osakasayama, Japan.

Background: In *RET* gene abnormality, different symptoms are developed by gain- and loss-of-function. Gain-of-function is involved in multiple endocrine neoplasia type 2 (MEN2). The development of oligomeganephronia (OMN) is the result of loss-of-function. To date, we have reports of simultaneous occurrence of gain- and loss-of-function due to *RET* gene abnormality resulting in the merger of MEN2 in renal dysplasia, but no reports of concomitant thyroid dysfunction.

Methods: We detected two cases of *RET* gene-associated renal and extra-renal disease. Case 1: A 22-year-old woman showed renal dysfunction related to OMN and asymptomatic thyroid dysfunction with elevated thyroid-stimulating hormone (TSH) level. Gene analysis revealed a heterozygous p.T278N mutation in *RET* gene exon 4. This mutation was located in the middle of the extracellular domain of the RET molecule, suggesting the possibility of affecting its binding to GDNF/GFRα1. Case 2: A 17-year-old woman showed congenital sensorineural deafness, renal dysfunction related to OMN, and asymptomatic thyroid dysfunction with elevated TSH level. Gene analysis revealed a heterozygous T/- in *RET* gene intron 1. This mutation was present in the (intron) splice part, and it was abnormal in the polyT region at the 5' end approximately 60 bp upstream from the boundary of the exons/introns, thus possibly causing abnormal splicing of the mRNA precursor.

Results:

Conclusions: Thyroid follicular epithelial cells differentiate from thyroid stem cells, but subsequent cell differentiation is suppressed into cancer due to rearrangement of *RET/PTC* genes. Although latent hypothyroidism may be possible, the likelihood that *RET* gene mutation produces immature follicular cells and thyroid hormone and elevated TSH level as a result of negative feedback was suggested. *RET* gene abnormality in the domain affects the binding between the RET molecule and GDNF/GFRα1. GDNF gene abnormality in glomerular development in the early stage causes low nephron number with thickening of the glomerular basement membrane. In addition to podocyte structural abnormality, interestingly similar findings in the renal specimen were observed in our cases. In summary, these cases more likely caused loss-of-function in both renal and thyroid development. I propose the possibility of a new disease concept due to RET gene abnormality.

PUB225

Nephropathy in STZ-Induced Diabetic Mice: Characterization of Renal Injury and Effects of Standard of Care on Renal Dysfunction

Judi A. Mcnulty,[2] Michael P. Quaile,[2] Kathleen O. Morasco,[1] Erding Hu,[3] Denise d'Epagnier.[2]
[1]Glaxo SmsithKline, King of Prussia, PA; [2]GlaxoSmithKline, King of Prussia, PA; [3]GlaxoSmithKline Pharmaceuticals, king of Prussia, PA.

Background: Human diabetic nephropathy (DN) manifests as a complication of chronic diabetes and is characterized by a progressive decline in glomerular filtration rate, histopathologic changes, persistent albuminuria and elevated arterial blood pressure. While many promising murine models of DN populate the literature, no current model of diabetes reliably recapitulates the full spectrum of human DN phenotpye. The aim of the present study was to longitudinally characterize renal dysfunction and injury in a model combining diabetes and hyperlididemia.

Methods: Diabetes was induced in Apolipoprotein E-Knockout (ApoE) mice by multiple injections of streptozotocin (STZ) at 55 mg/kg for 5 days. Mice were considered hyperglycemic when blood glucose levels reached >250 mg/dL. Following induction of diabetes, animals received no treatment or quinapril (10, 30 mg/kg/day) for 20 weeks. Relevant urinary, plasma endpoints as well as renal morphology were evaluated.

Results: ApoE+STZ mice weighed less than ApoE controls, but there was no difference in body weight gain over 20 weeks between groups. ApoE+STZ mice exhibited stable hyperglycemia and polyuria over 20 weeks compared to controls with no quinapril effect on urine output. However, there were no biologically significant differences in renal parameters across groups over the 20 week time course. There were also no significant differences in renal morphology among groups.

Conclusions: Based on the discordance between the phenotype exhibited in this study to that of the human diabetic nephropathy condition as well as previously published literature employing this model, the ApoE-STZ diabetic nephropathy model lacks reproducibility as well as translatability to the human disease state.

PUB226

Urinary Mitochondrial Proteins and Renal Cortical Mitophagy during the Normoalbuminuric Stage of Diabetes Mellitus

Naohito Ishii,[1] Tadachika Ichioka,[1] Akemi Imoto,[1] Yoshifumi Kurosaki,[1] Pamela K. Carmines,[2] Hideki Ikenaga,[3] Yoshio Kodera,[1] Masanori Yokoba,[1] Takafumi Ichikawa,[1] Tsuneo Takenaka,[4] Masato Katagiri.[1]
[1]Kitasato University, Sagamihara, Japan; [2]University of Nebraska College of Medicine, Omaha, NE; [3]Seiikai, Tochigi, Japan; [4]International University of Health and Welfare, Tokyo, Japan.

Background: Renal cortical mitochondria are damaged by oxidative stress even during the normoalbuminuric stage of type 1 diabetes mellitus (DM) (*Clin Sci* 124:543-52, 2013). The goal of this study was to determine if this process results in mitophagy (mitochondrial autophagy) and urinary excretion of mitochondrial proteins.

Methods: Rats were injected with streptozotocin (STZ, *n*=10; 65 mg/kg i.p. to induce DM) or vehicle (Sham, *n*=10), and treatment with the angiotensin receptor blocker telmisartan (TLM; 10 mg/kg/day) was initiated in half of the rats in each group (STZ+TLM; Sham+TLM) to suppress oxidative stress. Two weeks later, blood glucose (BG), blood pressure (BP) and glomerular filtration rate (GFR) were measured in each rat. Production of 3-nitrotyrosine (3-NT; an oxidative stress marker) and levels of mitophagy-related proteins (BNIP3, LC3-II, PINK1, p62) were quantified in renal cortex. Urinary mitochondrial proteins were identified by proteome analysis.

Results: BG levels were higher in STZ rats than in Sham rats ($P<0.05$) and were unaffected by TLM. Compared with Sham, STZ rats displayed significant increases in GFR, as well as renal cortical 3-NT production, LC3-II and PINK1 levels, with these effects prevented by TLM. BNIP3 (dimer) and p62 levels did not differ among groups, nor did BP. LC/MS/MS spectral count analysis of urine from STZ rats identified four mitochondrial proteins that were not detected in urine from Sham, Sham+TLM or STZ+TLM groups: ATP synthase subunit S (ATP5S), adenylate kinase 2 (AK2), O_2-dependent coproporphyrinogen-III oxidase (gene: *Cpox*) and elongation factor Tu (TUFM).

Conclusions: During the normoalbuminuric stage of DM, targeted degradation of oxidative stress-damaged mitochondria is evidenced by a TLM-sensitive elevation in renal cortical levels of the mitophagy-related proteins, LC3-II and PINK1. This results in urinary excretion of four mitochondrial proteins that may represent early diagnostic markers for diabetic nephropathy.

PUB227

Huangkui Capsule Attenuates Podocyte Damage in Diabetic Kidney Disease by Regulating NALP3 Inflammasome and Insulin Resistance-Related Signalings Yinglu Liu, Yigang Wan. *Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China*.

Background: In China, Huangkui capsule (HKC) has been applied extensively for treatment of albuminuria in patients with early diabetic kidney disease (DKD). However, the therapeutic mechanisms still need to be elucidated. In the process of DKD, the activation of NALP3 inflammasome and the inhibition of insulin resistance (IR)-related signalings including MAPK and PI3K/Akt in kidneys lead to podocyte injury, which further result in albuminuria. Therefore this study aimed to investigate effects and mechanisms in vivo of HKC on podocyte lesions, compared with rosiglitazone (ROS) as an insulin sensitizer in clinic, via regulating NALP3 inflammasome and IR-related signalings.

Methods: Rats were randomly divided into 4 groups, the Sham-operated group, the Vehicle-given group, the HKC-treated group and the ROS-treated group. HKC, ROS and saline were daily administrated for 8 weeks after the induction of DKD by high-fat diet, unilateral nephrectomy and streptozotocin injection. Albuminuria, biochemical indicators, NALP3 inflammasome-related factors, IR-related markers (HOMA-IR), glomerular pathological changes, as well as the key signaling molecules in MAPK and PI3K/Akt pathways and podocyte structural molecules in kidneys were examined, respectively.

Results: Results showed that, urinary albumin, HOMA-IR, foot process effacement, glomerularsclerosis, the over-expressions of NALP3, active caspase-1 and active IL-1β and the decreased protein expressions of p-MAPK42/44, p-PI3K, p-Akt2, nephrin and neph1 in kidneys of the DN model rats were ameliorated in different extent after treatment of HKC or ROS. More notably, HKC synchronously inhibited NALP3 inflammasome activation, promoted MAPK42/44 and PI3K/Akt2 signalings and up-regulated nephrin and neph1 protein expressions, which is different from ROS.

Conclusions: In summary, by means of the DN model rats, we demonstrated that NALP3 inflammasome activation and IR-related signalings inhibition contribute to podocyte damage. HKC, as a natural regulator in vivo, can improve podocyte injury by inhibiting NALP3 inflammasome activation and promoting IR-related signalings.

Funding: Government Support - Non-U.S.

PUB228

Lifetime Benefits of Early Detection and Treatment of Diabetic Kidney Disease (DKD) Julia T. Snider,[1] Jeff Sullivan,[1] Emma van Eijndhoven,[1] Michael K. Hansen,[6] Nobel A. Bellosillo,[3] Cheryl Neslusan,[3] Ellen S. O'Brien,[4] Ralph A. Riley,[5] Seth Seabury,[7] Mahlet G. Tebeka,[1] Bertram L. Kasiske.[2] *[1]Precision Health Economics, Los Angeles, CA; [2]Hennepin County Medical Center, Minneapolis, MN; [3]Janssen, Pompano Beach, FL; [4]Janssen Global Services, LLC, Horsham, PA; [5]Janssen Global Services, inc., Titusville, NJ; [6]Janssen Research & Development, Spring House, PA; [7]University of Southern California, Los Angeles, CA.*

Background: DKD is a frequent complication of diabetes. The lifetime health and economic burden of DKD depends on the timing of diagnosis and subsequent management. In this study, we estimated the value that would accrue to current and future diabetes populations from earlier DKD diagnosis and treatment.

Methods: Using The Health Economics Medical Innovation Simulation (THEMIS), we modeled life expectancy and medical spending for people with diabetes. The THEMIS model uses microsimulation techniques to model cohorts aged ≥50 y over their remaining lives and project population-level health and economic outcomes through 2050. The DKD cohort was based on data from the National Health and Nutrition Examination Survey and imputed into the Health and Retirement Study. We simulated the implementation of a new biomarker test that identifies people with diabetes at an elevated risk of DKD and DKD patients at risk of rapid progression. High-risk patients receive treatment that slows the progression toward kidney failure.

Results: Compared to baseline, the prevalence of DKD is reduced 6% with the biomarker test. The test doubles the rate at which people with DKD are diagnosed because it enables identification of at-risk individuals who can be treated when appropriate. Use of the biomarker test also reduces the prevalence of stage 5 chronic kidney disease among people with diabetes by 6%. Due to reduced risk of DKD onset and progression, life expectancy gains among people with diabetes are 0.2 y with the biomarker, while per-capita annual medical spending for people with diabetes falls by 0.3%.

Conclusions: The biomarker test reduces DKD prevalence and increases life expectancy among people with diabetes. Per-capita annual medical spending for people with diabetes falls with the test, demonstrating value. The biomarker test has the potential to be more valuable when combined with more effective DKD treatment. The potential health gains are important given the rising prevalence of diabetes and DKD.

PUB229

High Glucose Induction of the GLUT1 Glucose Transporter and Mechano-Growth Factor (MGF) in Human Mesangial Cells (HMC) Portends Their Roles in Human Diabetic Nephropathy Yongxin Gao,[1] Leighton R. James,[1] Abdalagani A. Abakar Baher,[1] Nanjoo Shin,[2] Emma P. Bueno,[1] Charles W. Heilig.[1] *[1]UF COM- Jacksonville, Jacksonville, FL; [2]Univerfsity of Florida, Jacksonville, FL.*

Background: We previously reported increased mesangial cell (MC) GLUT1 and MGF expression in mouse MC in response to 20 mM (360 mg/dL) high glucose (HG) exposure. This contributed to excess MC extracellular matrix (ECM) production. We also previously reported glomerular GLUT1, NFkB and ECM are increased and/or activated in mouse models of diabetic and nondiabetic glomerulosclerosis (GS). Here, we tested HMC for potential GLUT1 and MGF responses to 20 mM high glucose which might contribute to excessive ECM production in vitro, and by implication human diabetic GS in vivo.

Methods: METHODS: 1. HMC were grown to 80 - 100% confluence at 37C, 5% CO2 in 5 mM glucose medium, then changed to 5 or 20mM glucose medium for 4 days, prior to harvest of total cell proteins or immunofluorescent (IF) staining. 2. Western blotting of HMC proteins and semiquantitation by optical densitometry with normalization of selected proteins to the endogenous housekeeping protein beta-Tubulin. 3. Immunofluorescent staining and semiquantitation of selected proteins in cultured HMC, using Alexa-Red and DAPI nuclear stain. 4. Specific antibodies were obtained against: GLUT1, MGF, fibronectin (FN), NfKB p50, NfKB p65 and CTGF.

Results: RESULTS: 1.GLUT1 protein increased 4-fold in HMC in response to 20 mM glucose, vs control 5 mM glucose, $P < .05$. 2.MGF protein increased 3.9-fold in 20 mM glucose, $P < .05$, while 3.Nuclear NFkB p50 increased 3.3-fold in 20 mM glucose, and nuclear NFkB p65 increased 2.8-fold, $P < .0005$ for both. 4.CTGF increased 3.9-fold in 20 mM glucose, $P < .0005$. 5. Resulting FN protein expression increased 6.8-fold in 20 mM glucose, $P < .05$.

Conclusions: CONCLUSIONS: 1.We found that HMC express both GLUT1 and MGF, which increased in 20 mM glucose, with NFkB activation, increased CTGF and ECM. 2.These mimic the responses we previously observed in mouse MC. 3.Increased GLUT1 and MGF portend important roles in HMC ECM production.

Extracellular Vesicles (EV) and Aerobic Exercise Improve Proteinuria in Rats with Diabetic Nephropathy Rodolfo R. Rampaso,[2] Rafael Luiz,[2] Natalia Reinecke,[2] Kleiton A. Silva,[3] Luciana Jorge,[2] Edson A. Pessoa,[1] Nestor Schor.[2] *[1]Universidade Federal de São Paulo, São Paulo, Brazil; [2]Universidade Federal de Sao Paulo/Escola Paulista de Medicina, Sao Paulo, Brazil; [3]University of Missouri, Columbia, AL.*

Background: The aim of this study was to evaluate the effects of application of extracellular vesicles with aerobic exercise training in controlling the progression of diabetic nephropathy, and its possible renoprotective effects

Methods: Adult male Wistar rats divided into 4 groups: Sedentary controls, (SED, n=8), Diabetes+Sedentary (DM-SED, n=8), Diabetes+Exercise (DM-EXE, n=8), Exercise+Controls (EXE,n=8), Extracellular Vesicles/Diabetes-Sedentary (EV/DM-SED, n=8) and Vesicles/Diabetes-Exercise (EV/DM-EXE,n=8). DM was induced with streptozotocin (STZ), 50mg/kg i.v. EV (5 aplication 80µg every 12 days/60 days) was injected into the tail vein. The physical training was done on treadmill 60 min/day, 5 days a week for 8 weeks. Weekly it was determined the Maximal Exercise Test (set at 65-70% of MEtest). Glycemia 24h post training (glycemiapt), MEtest, creatinine clearance/BW (CrCl/BW), mean arterial pressure (MAP), proteinuria (uProt)

Results:

Conclusions: Results of this study show that EV attenuates proteinuria in Diabetic rats. When physical exercise was added to the treatment, this improvement was potentialized. Both, exercise and EV reduced weight loss in Diabetic groups, but only exercised groups prevented increases in glycemia and MAP. Therefore, preliminary data suggest that aerobic exercise and application EV can minimize effects caused by diabetic and could reduce the progression to renal failure.

Astragaloside IV Synergizes with Captopril in Ameliorating Renal Fibrosis in Uninephrectomized db/db Mice Kam wa Chan, Wai Han Yiu, Haojia Wu, Dickson W. Wong, Bin Li, Ye Li, Loretta Y.Y. Chan, Joseph C K Leung, Kar Neng Lai, Sydney C. Tang. *The University of Hong Kong, Hong Kong, China.*

Background: Astragaloside IV (AS-IV) is an active ingredient of Astragalus membranaceus, the most frequently prescribed Chinese herbal medicine for diabetic kidney disease (DKD). AS-IV monotherapy has been demonstrated to ameliorate podocyte apoptosis, foot process effacement, mesangial expansion, glomerulosclerosis and interstitial fibrosis. Dual renin-angiotensin system (RAS) blockade has not been recommended for DKD due to a lack of efficacy. Since AS-IV is reported to regulate TGF-beta to ameliorate fibrosis, the prospect of combining AS-IV with renin angiotensin blockade warrants investigation.

Methods: Spontaneously diabetic db/db mice and their corresponding non-diabetic db/m littermates were uninephrectomized or sham-operated and received 8 weeks of captopril, AS-IV, combined captopril/AS-IV or vehicle control orally before sacrifice. Urine albumin-to-creatinine ratio (UACR), plasma cystatin C, blood glucose, blood pressure and expression of oxidative stress and fibrosis markers at mRNA and protein levels were determined. Histopathological changes were also examined.

Results: Uninephrectomized db/db mice developed progressive albuminuria, glomerulosclerosis, tubulointerstitial fibrosis and tubular atrophy with dilatation with upregulated cortical expression of TGF-beta, alpha-smooth muscle actin, collagen and fibronectin and NOX4. Mice that received either captopril or AS-IV treatment had ameliorated albuminuria and fibrotic lesions versus control. Mice that received combined treatment displayed the lowest glomerular injury index, tubular injury index, UACR and plasma cystatin C. Blood pressure and glucose were comparable between groups.

Conclusions: Captopril and AS-IV confer synergistic renal anti-fibrotic and anti-oxidative effects in uninephrectomized db/db mice. These findings could potentially be translated into clinical practice. Funding support: Hong Kong Society of Nephrology Research Grant

PUB232

Mitochondrial DNA in the Urine: A Potential Biomarker Reflecting Systemic Mitochondrial Stress in Type 2 Diabetes Mellitus Li Fang,[2] Jing Luo,[2] Qi Yuan,[2] Ting Cai,[2] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Both mitochondrial dysfunction and chronic sterile inflammation were the most common features in type 2 diabetes. Since extracellular mitochondrial DNA (mtDNA) could also be recognized as both a biomarker of mitochondrial dysfunction and a damage-associated molecular pattern agent, our objective was to investigate the clinical significance of mtDNA in type 2 diabetes mellitus.

Methods: In vivo, mtDNA contents extracted from the samples of both diabetic patients and diabetic mice were measured by RT-PCR. In vitro, endothelial cell lines were used to investigate the effect of mitochondrial stress trigged by high glucose on the changes of mtDNA content both inside and outside cells.

Results: As compared to the control group, we found that the plasma mtDNA contents were lower while the creatinine-adjusted urinary mtDNA contents were significantly higher in the diabetic patients. However, in STZ-induced diabetic mice, although mtDNA contents in the plasma did not change significantly, mtDNA contents extracted from the muscle, heart, liver and kidney were significantly decreased in a time-dependent manner while the creatinine-adjusted urinary mtDNA contents were increased. On this basis, the find that mtDNA could be filtrated through the dialysis membrane further suggested that the mtDNA might be released from the diabetic tissues and subsequently filtered into the urine. For exploration of the role of mitochondrial stress, in vivo, we first confirmed that high glucose could induce the increase of extracellular mtDNA contents, meanwhile, the decrease of intracellular mtDNA contents in both dose-dependent and time-dependent manners. Next, by using resveratrol to attenuate the mitochondrial oxidative stress, we found resveratrol could increase the intracellular mitochondrial content and decrease the extracellular mtDNA content.

Conclusions: Our results indicated that mtDNA might be released from the cell as a response of mitochondrial stress under diabetic conditions. Thus, mtDNA which was subsequently filtered into the urine might be a biomarker reflecting systemic mitochondrial stress in type 2 diabetes mellitus.

PUB233

Diabetic Myonecrosis: A Rare and Less Known Complication of Diabetes Sherin A. Ahmed,[2] Zeshan sharif Choudhry,[2] Smita Gunda.[1,2] *[1]Cambridge University Hospitals, Cambridge, UK, Kings Lynn, United Kingdom; [2]Renal, Queen Elizabeth hospital, Kings Lynn, United Kingdom.*

Background: We report a case of spontaneous myonecrosis and compartment syndrome involving the upper limb in a poorly controlled type1 diabetic with microvascular complications. Patient had recurrence in left thigh within a month, which was managed conservatively. To our knowledge this is the first report of Diabetic Myonecrosis(DMN) with upper limb as the index site of presentation.

Methods: 39 yr old female type1 diabetic with poor compliance, retinopathy, neuropathy and nephropathy, presented with acute onset pain and swelling of left arm. Clinically had swelling with severe tenderness, skin was intact with no redness. Limb movements were full and pulses intact. Initial bloods showed no evidence of infection Blood Glucose-50.9 mmol/L US Doppler-negative She was treated with antibiotics, anticoagulation and regular opioids for pain. CT showed significant edema with increased suspicion of compartment sydrome. Pain was rapidly worsening with decrease in range of movement and loss of pulse. Hence she was taken up for theatre and intraoperatively deltoid and triceps were found to be necrotic. Histology confirmed necrosis of individual muscle fibres consistent with DMN. Patient recovered well after surgery only to present with pain in thigh muscles within a month, when MRI showed high signal changes and intramuscular fluid consistent with DMN, needing conservative management. At a later date patient presented with fulminant hepatic failure and subsequently died.

Results:

Conclusions: DMN was first described in 1965. It is a rare and under diagnosed complication of long standing and poorly controlled diabetes. DMN is common in females and type1 diabetics, with a predilection for thigh muscles.70% cases have nephropathy. Clinially presents with acute onset pain, swelling and tenderness. Commonly misdiagnosed as cellulitis, thrombosis or fascitis. MRI is the most useful evaluation tool. Responds well to conservative management and can be self limiting but with high recurrence rate. Pathogenesis may involve atherosclerosis, hypoxia-reperfusion injury or atheroembolism. Although short term prognosis is good, long term survival is <5yrs. DMN poses a burden to health service mainly due to lack of early recognition leading to otherwise avoidable investigations and treatment. Hence a high index of suspicion is needed in long standing diabetics with acute muscle pain. Management aiming at strict blood sugar control, rest and analgesics.

PUB234

The Dissociation of Glycated Albumin (GA) and Hemoglobin A1c (HbA1c) Is Associated with Decline of Glomerular Filtration Rate (GFR) Evaluated by Inulin Clearance (Cin) in Type 2 Diabetes Akihiro Tsuda,[1] Eiji Ishimura,[2,1] Hideki Uedono,[3] Shinya Nakatani,[3] Masaaki Inaba,[3] Katsuhito Mori.[3] *[1]Department of Nephrology, Endocrinology, Metabolism, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Meijibashi Hospital, Osaka, Japan; [3]Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: It is well known that GA provides a better measure to estimate glycemic control in hemodialysis patients with diabetes melitus (DM), and that the assessment of glycemic control by HbA1c in those patients might lead to underestimation (Inaba M, et al. J Am Soc Nephrol, 2007). However, to date, no data exists regarding to the question whether and how GA and HbA1c are dissociated in those with non-dialysis chronic kidney disease (CKD) patients with DM and nonDM.

Methods: One hundred forty nine non-dialysis CKD patients (75 DM and 74 nonDM; age, 59.3 ± 13.0 years (diabetics) and 55.4 ± 13.9 years (non-diabetics); 71 males (47.7%)) were enrolled. GFR was evaluated by C_{in}. The factors related to the dissociation between GA and HbA1c in DM patients and nonDM patients were examined.

Results: There was a significant and positive correlation between GA and HbA1c in each stage of CKD in both DM(CKD 1, r=0.906, p<0.0001; CKD 2, r=0.869, p<0.0001; CKD3+4, r=0.809, p<0.0001) and nonDM (CKD 1, r=0.488, p=0.0076; CKD 2, r=0.502, p=0.0075; CKD3+4; r=0.668, p=0.0034). The regression slopes between GA and HbA1c were significantly deeper in advanced CKD stages of DM, but not in nonDM. We next evaluated the factors associated with the dissociation between GA and HbA1c. Since the dissociation of the regression line between GA and HbA1c could be represented by the GA/HbA1c ratio, we performed simple regression analyses of GA/HbA1c ratio with the various clinical parameters. There was a significant and negative correlation between GA/HbA1c ratio and GFR in DM (r=-0.452, p<0.0001), but not in nonDM. Multiple regression analyses revealed that GFR was significantly and independently associated with the GA/HbA1c ratio (ß=-0.244, p=0.0351) after adjustment with the several confounders in diabetics (R^2=0.448, p<0.0001).

Conclusions: GA and HbA1c is dissociated in diabetes, but not in non-diabetes. The dissociation of GA and HbA1c in diabetes is significantly associated with decreased GFR. HbA1c values in diabetic patients underestimate glycemic control index, particularly in those with lower GFR. Thus, evaluation of glycemic control by HbA1c in diabetic CKD patients should be carefully appreciated.

PUB235

The Renal Effect of the SGLT2 Inhibitors on the Japanese Type 2 Diabetes Mellitus Patients With Diabetic Nephropathy Kazuo Kobayashi,[1] Nobuo Hatori,[1] Hiroyuki Sakai,[1] Takayuki Furuki,[1] Masaaki Miyakawa,[1] Masao Toyoda.[2] *[1]Committee of Hypertension and Kidney disease, Kanagawa Physicians Association, Yokohama, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Some large-scale clinical trials with SGLT2 inhibitors(SGLT2i) have revealed significant improvements in cardiovascular events and diabetic nephropathy(DMN) in patients with type 2 diabetes mellitus (T2DM). However, it is not clear whether similar results are observed in Japanese patients with T2DM.

Methods: To clarify the renal effects of SGLT2i in Japanese patients, data from T2DM patients with DMN who are visiting members of the Kanagawa Physicians Association, and who were taking SGLT2i were extracted.

Results: We analyzed 592 cases (male: female = 387: 205, age 60.6 ± 12.2 years, BMI 27.7 ± 5.4). The administration period was 14.9 months on average. The distribution of eGFR(mL/min/1.73 m^2) was as follows: ≥60, 76.1%; 30–59, 23.4%; and <30, 0.5%. Six SGLT2i were used: ipragliflozin (n=190), tofogliflozin (n=113), dapagliflozin (n=92), empagliflozin (n=84), canagliflozin (n=61), and luseogliflozin (n=51). Clinical findings at the beginning of administration versus at the time of the survey are shown as mean ± SD. Body weight (kg), 76.5 ± 17.1 vs. 74.4 ± 16.5 (p<0.01); HbA1c (%), 8.1 ± 1.6 vs. 7.4 ± 1.2 (p<0.01); blood pressure (BP) at office(mmHg), 140.2 ± 20.0/79.7 ± 12.6 vs. 133.9 ± 17.2/77.5 ± 11.0 (p<0.01); BP in the early morning at home (n=55; mmHg), 130.2 ± 11.1/76.9± 10.1 vs. 128.3 ± 11.0/73.9 ± 10.2 (p<0.05). eGFR decreased from 78.2 ± 23.4 to 74.9±23.7 mL/min/1.73 m^2 (p<0.01), and the mean value of ACR significantly decreased from 96.8 to 73.9 (p<0.05). The degree of adherence with dietary treatment was divided into four groups (“very good”, ”good”, ”usual”, and ”bad”) and the change of logarithmic value of ACR were -0.43 ± 1.11, -0.20 ± 0.89, -0.19 ± 1.00, and -0.07 ± 0.93, respectively. By multiple linear regression analysis, the age, the usage of aldosterone blocker agent, “very good” adherence with dietary treatment, the usage of empagliflozin, the change of systolic BP at office were independently correlated with the change of ACR.

Conclusions: This retrospective study confirmed that the results of large-scale clinical trials were also observed in the real world. The importance of dietary therapy has also been partially accepted, and further discussion on the relationship between background factors and differences between drug treatments will be considered necessary in the future.

PUB236

Semi-Individualised Chinese Medicine Treatment as an Adjuvant Management for Diabetic Nephropathy – Preliminary Results of an Add-On, Randomised, Controlled, Multi-Centre, Open-Label Pragmatic Trial Kam wa Chan,[4] Alfred Kwong,[1] Sing-Leung Lui,[5] Tai-Pang Ip,[5] Gary Chan,[3] Benjamin J. Cowling,[4] Wai Han Yiu,[4] Dickson W. Wong,[4] Bin Li,[4] Ye Li,[4] Yibin Feng,[4] Kathryn Tan,[6] Loretta Y.Y. Chan,[2] Joseph C K Leung,[4] Kar Neng Lai,[4] Sydney C. Tang.[4] *[1]Hospital Authority, Hong Kong, China; [2]Queen Mary Hospital, Hong Kong, China; [3]Queen Mary Hospital, Hong Kong, Hong Kong, China; [4]The University of Hong Kong, Hong Kong, China; [5]Tung Wah Hospital, Hong Kong, China; [6]University of Hong Kong, Hong Kong, China.*

Background: Conventional treatment for diabetic nephropathy (DN) has achieved limited effect in preserving renal function. Recent big data studies showed that Chinese medicine (CM) could reduce the risk of end-stage kidney disease by 59% percent in a 6-year period. However, existing CM clinical guidelines are weakly evidence-based and the effect of combined Chinese and conventional medicine remains unclear.

Methods: This assessor-blind, add-on, randomized, controlled, multi-center, open-label pilot pragmatic trial evaluates the effect of an add-on semi-individualized CM treatment protocol based on expert consensus. 148 DN patients are being recruited and randomized 1:1 to a 48-week add-on semi-individualized CM treatment or standard medical care. Primary endpoints are changes in estimated glomerular filtration rate (GFR) and spot urine albumin-to-creatinine ratio (UACR) between baseline and endpoint. Outcomes are analyzed as intention-to-treat by regression models.

Results: Recruitment started in July 2015. First 25 patients have completed 24 weeks of study period. The groups are similar for demographics. Mean GFR of intervention and control group decreased by 0.06 and 3.51 mL/min/1.73m^2 respectively (95% CI: -8.08 to 1.19). Mean UACR of intervention and control group increased by 44% and 28% respectively (95% CI: -88.5% to 57%). After adjusting for age, gender, baseline HbA1c, BMI, blood pressures, GFR and UACR, intervention contributes to 3.8 mL/min/1.73m^2 increase (95% CI: -3.9 to 11.4, p=0.30) in 24-week mean GFR in treatment group versus control (47.5 vs 43.8). The model explains 88% of variability and contribution remains similar (mean diff.: 4.1, 95%CI: -4.0 to 12.2, p=0.28) when 24-week UACR is adjusted in sensitivity analysis. Adjusted 24-week mean UACR, HbA1c, blood pressures, AST, ALT levels, and incidence of serious adverse events are comparable between groups.

Conclusions: Our interim analysis suggests that add-on semi-individualized CM treatment may stabilize GFR among DN patients with macroalbuminuria independent of albuminuria, glycemic and blood pressure control. Funding: Health and Medical Research Fund (Ref:12133341)

Mortality Risk of Renal Glucosuria in a General Screening Participants in Japan Kunitoshi Iseki, Tsuneo Konta, Koichi Asahi, Kunihiro Yamagata, Shouichi Fujimoto, Kazuhiko Tsuruya, Ichiei Narita, Masato Kasahara, Yugo Shibagaki, Toshiki Moriyama, Masahide Kondo, Tsuyoshi Watanabe. *Steering Committee for the Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Check, Fukushima, Japan.*

Background: Limited data exist on the association between renal glucosuria and mortality rate in a setting of general screening.

Methods: We followed the screened participants at the2008 specific health check (N=288,528) performed in 6 district in Japan, and identified those who died by 2012. We examined the association between renal glucosuria and mortality. Diabetes Mellitus (DM) was diagnosed either HbA1c≥6.5%, fasting plasma glucose≥126mg/dl, or on medication for DM. Hazard ratio (HR) and 95% confidence interval (CI) was calculated using Cox proportional hazard analysis. Dipstick results of 1+ and higher were defined as glucosuria (+).

Results: Among the total of 294,780 subjects, we identified 3,747 fatal cases by end of 2012. The crude mortality rates were 1.2% in glucosuria (-) and 3.4% in glucosuria (+). In DM subjects with glucosuria (N=4,655), the HR (95% CI) was 1.302 (1.044-1.613, P=0.020) when compared to those without glucosuria (N=20,245). In Non-DM subjects with glucosuria (N=470), it was 2.511 (1.539-3.833, P<0.001) when compared to those without glucosuria (N=183,690).

Conclusions: Glucosuria both DM and non-DM subjects has significant impact on mortality rate among the Japanese community-based screening participants.

PUB238

Diabetic Retinopathy Can Predict the Prognosis of Patients with Type 2 Diabetes and Diabetic Nephropathy Junlin Zhang, Fang Liu, Yiting Wang. *Division of Nephrology, West China Hospital of Sichuan University, Chengdu, China.*

Background: Some patients with type 2 diabetes mellitus (T2DM) do not develop diabetic nephropathy (DN) despite the presence of diabetic retinopathy (DR). We aimed to examine the relationship between DR and the progression of DN in patients with T2DM.

Methods: In the cross-section study, 250 patients with T2DM and biopsy-proven DN were divided into two groups: 130 in the DN without DR group (DN group), and 120 in the DN+DR group. Logistic regression analysis was performed to identify risk factors for DR. Of the above 250 patients, 141 were recruited in the cohort study who received follow-up for at least 1 year and the influence of DR on renal outcome was assessed using Cox regression. Renal outcome was defined as the progression to end-stage renal disease (ESRD) or the initiation of renal replacement therapy.

Results: In the cross-section study, compared with the DN group, patients in DN+DR group had longer duration of T2DM, poorer renal function, more serious glomerular lesions and interstitial inflammation (p<0.05). The logistic regression analysis demonstrated that the severity of glomerular lesions (class IIb + III) and DM history ≥10 years were significantly associated with the odds of DR (OR, 95%CI; 3.568(1.598-7.964); p=0.002 and 2.511(1.217-5.182); p=0.013, respectively) when adjusting for baseline proteinuria, hematuria, e-GFR, interstitial inflammation. In the cohort study, a multivariate COX analysis demonstrated that the DR remained an independent risk factor for progression to ESRD when adjusting for important clinical variables and pathological findings (p < 0.05).

Conclusions: These findings indicated that the severity of glomerular was significantly associated with DR and DR was an independent risk factor for the renal outcomes in patients with DN, which suggested that DR can predict the prognosis of patients with type 2 diabetes and DN.

PUB239

Competing Risk of RRT and Death in Patients with Diabetes and CKD Who Have Undergone Renal Biopsy Ken-Soon Tan,[2] Samantha Ng,[2] Stephen P. McDonald,[1] Wendy E. Hoy.[3] *[1]ANZDATA Registry, Adelaide, SA, Australia; [2]Logan Hospital, Loganholme, NSW, Australia; [3]The University of Queensland, Brisbane, QLD, Australia.*

Background: Diabetes mellitus (DM) commonly causes chronic kidney disease (CKD). The CKD.QLD registry is an Australian state-wide registry of patients with CKD followed up in public hospital renal units who have provided informed consent. Enrollment commenced in 2011. We determined competing risk of survival to renal replacement therapy (RRT) and death without RRT in registry patients with DM and CKD who had undergone renal biopsy.

Methods: Patients with DM enrolled from 22/01/2011 - 15/11/2016 inclusive with previous renal biopsy were included. Baseline characteristics, incidence of RRT or death without prior RRT were determined. Censor date was 1/03/2017. Competing risk analysis (Fine and Gray method) was performed with RRT as the event of interest and death as the competing event. Age, eGFR and macroalbuminuria status (y/n) at enrollment were covariates.

Results: 189 patients had previous renal biopsy (58% had diabetic kidney disease present). Mean follow up at censor date was 3.1 years (586 patient-years). Mean age was 60.3years. Mean enrollment eGFR was 36ml/min (SD 17.7). 77% had macroalbuminuria. At censor date, 41 patients had commenced RRT (all dialysis). 29 died without prior RRT. Competing risk analysis revealed that only age (HR 0.94, 95%CI 0.93-0.,96) (fig1) and eGFR (HR 0.92, 95%CI 0.89-0.95) (fig2) contributed to risk of requiring RRT (both p<0.001).

Conclusions: In this high-risk group of patients receiving specialist nephrology care, younger age and lower baseline eGFR were associated with higher risk of requiring RRT.

PUB240

Changes of Parathyroid Hormone and 25 Hydroxy Vitamin D3 in Diabetic Patients with Maintenance Dialysis (MD) and Their Related Factors Chang Ying Xing, Juan Yang. *First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The differences and influences of intact parathyroid hormone (iPTH) and 25 hydroxy vitamin D3[25(OH)D3] in diabetic patients with MD are not clear.

Methods: There were 180 patients underwent maintenance hemodialysis (MHD) and 99 patients underwent peritoneal dialysis (PD). MHD patients were divided into two groups: those with DM as a diabetic hemodialysis group (DH), those without DM as a non-diabetic hemodialysis group (NDH). PD patients with DM as a diabetic peritoneal dialysis group (DP), those without DM as a non-diabetic peritoneal dialysis group (NDP). The clinical data between DH and NDH, DP and NDP were compared respectively, and analysis of possible influencing factors of iPTH and 25(OH) D3 levels were carried out.

Results: The iPTH in DH was lower than that in NDH (P<0.001). 25(OH) D3 in DH was also significantly lower than that in NDH. The level of iPTH was negatively correlated with history of diabetes, and positively correlated with dialysis years, phosphates, alkaline phosphatase (P<0.001) and 25(OH) D3 (P=0.016). The multiple linear regression (MLR) analysis showed history of diabetes (P=0.012) and years of dialysis (P=0.028) were independent factors of iPTH. The concentration of 25(OH) D3 was negatively correlated with history of diabetes (P=0.004), and positively correlated with dialysis years, phosphatase, magnesium, albumin and iPTH (P<0.05). The MLR analysis showed the history of diabetes(P=0.004) was independent factor of 25(OH)D3. The iPTH in DP group was also lower than that in NDP group [(257.7±211.1)pg/ml VS(394.7±338.9)pg/ml. In patients with PD, iPTH was negatively correlated with glycosylated hemoglobin (P<0.003), hemoglobin (P<0.045) and correction of calcium, positively correlated with serum phosphatase(P=0.000), alkaline phosphatase (P=0.013). The MLR analysis showed in patients with PD glycosylated hemoglobin (P=0.040) and serum phosphatase(P=0.024) were independent factors of iPTH. 25(OH) D3 in MPD was negatively correlated with age (P=0.044), and positively correlated with hemoglobin (P=0.007), albumin (P=0.002) and urea nitrogen (P=0.024). The MLR analysis showed that in MPD hemoglobin (P=0.009) was independent factor of 25(OH) D3.

Conclusions: Diabetic patients with dialysis have lower iPTH and 25(OH)D3. Diabetic history, Hb, albumin maybe have some effects on them,should be pay more attension on them.

PUB241

Can HbA1c Be Trusted in Anaemia or CKD? Analyses from the Copenhagen Primary Care Laboratory (CopLab) Database Rikke Borg,[4,5] Frederik Persson,[3] Volkert Siersma,[2] Bent Lind,[1] Niels D. Olivarius,[5] Christen L. Andersen.[5] *[1]Hvidovre Hospital, University of Copenhagen, Hvidovre, Denmark; [2]Research Unit for General Practice, Copenhagen, Denmark; [3]Steno Diabetes Center, Gentofte, Denmark; [4]Nephrology, Zeeland University Hospital, Roskilde, Denmark; [5]University of Copenhagen, Copenhagen, Denmark.*

Background: Glycated hemoglobin (HbA_{1c}) is used to diagnose and evaluate glycemic control in diabetes. Several clinical conditions may alter the blood glucose/HbA_{1c} relationship by affecting erythropoiesis or erythrocyte lifespan. In a large population in primary care, we investigated (1) whether we could confirm the relationship between fasting plasma glucose (FPG) and HbA_{1c} measurements, and (2) the clinical implications of anemia or CKD for the interpretation of HbA_{1c}.

Methods: From a primary care laboratory, we examined valid measurements of both HbA_{1c} and FPG, as well as measurements of hemoglobin (Hb) and eGFR. We stratified our observations according to CKD stage and according to anemia level. The prediction of the mean FPG from HbA1c alone, and jointly from HbA1c and Hb and eGFR respectively was estimated by thin plate regression splines.

Results: In 155.565 individuals (48% men), the FPG/HbA_{1c} relationship imitated the ADAG linear regression equation. The glucose/HbA_{1c} -relationship was unaffected in most patients with mild to moderate CKD and in cases of mild to moderate anemia. Only in severe hyperglycemia (HbA_{1c} >100 mmol/mol) and concurrent anemia or eGFR<45 ml/min the correlation changed, so that glucose concentration was overestimated by HbA_{1c} in anemia and underestimated in CKD (Figure 1). Very few patients in our population had eGFR <30 ml/min (0.82%) or severe anemia (0.11%), demonstrating that HbA_{1c} can be used without adjustment in primary care to estimate glycemic control.

Conclusions:

Sodium Intake Does Not Modify the Effect of Silybin and N-AC on Albuminuria in Patients with Diabetic Nephropathy Jeet Gandhi,[4,5] Manoj Bhattarai,[4,5] Subrata Debnath,[2] Sue E. Cunningham,[3,1] Shuko Lee,[1] Chakradhar Velagapudi,[3,5] Shweta Bansal.[3,5] *[1]South Texas Veterans Health Care System, San Antonio, TX; [2]University of Texas Health Science Center at San Anotonio, San Antonio, TX; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]Nephrology, University of Texas Health Science Center San Antonio, San Antonio, TX; [5]Nephrology, South Texas Veterans Healthcare System, San Antonio, TX.*

Background: Silybin, an active ingredient of Milk Thistle and anti-oxidant, reduced albuminuria in patients with diabetic nephropathy in an Iranian study. However, there was no effect of silybin administration on albuminuria in our study cohort. Dietary sodium intake modifies the effect of angiotensin inhibition on albuminuria. Whether sodium intake can influence the effect of anti-oxidant silybin and N-acetylcysteine (NAC) on

albuminuria needs to be evaluated. We hypothesize that lower sodium intake improves the beneficial effect of silybin and NAC on albuminuria.

Methods: We conducted a sub-analysis of the randomized-controlled trial where 75 subjects with diabetic nephropathy with albumin-creatinine ratio (ACR) of =/>150 mg/g and eGFR 15-60 ml/min on the background of angiotensin inhibition received either placebo or NAC or silybin or combination for 3 months to test their anti-proteinuric effect. Daily sodium intake was estimated by measuring 12-hour urinary Sodium excretion. Urinary ACR and other independent variables were measured at baseline and end of 3-month intervention.

Results: The study population was 62.97±7.48 years old, 89% male, 65% Hispanic, 27% non-Hispanic white and 7% non-Hispanic blacks, had BMI of 35.02±8.54 kg/m^2, eGFR of 36.4±13.3 ml/min, and ACR of 565 [216,1018] mg/g at baseline. None of the interventions reduced the urinary excretion of albumin (post ACR: 638 [243, 1161] mg/g). Mean sodium intake was 4064±2642 mg/d at baseline and 3816±1664 mg/d at 3-month. There was no difference in any of the demographic, clinical and laboratory parameters between the groups categorized by sodium intake. On univariate analysis, ACR correlated positively with systolic BP (r=0.3, p=0.008), and negatively with age (r=-0.25, p=0.03) and eGFR (r=-0.27, p=0.02, only at the end of intervention) but there was no correlation between ACR and daily sodium intake on both the occasions. In multivariable regression model including age, eGFR, sodium intake, use of diuretic and ACEI, different treatment arms, application of interaction term between treatment arms and sodium intake did not predict albuminuria at the end of intervention (p interaction=NS).

Conclusions: There was no modification by the daily sodium intake on the effect of silybin or NAC on albuminuria in patients with diabetic nephropathy.

GLP1RA Facilitate Improved Glycaemia, Reduction in Insulin Requirements, and Weight Loss in Renal Transplant Recipients

Kamya Kameshwar,[2] Jamie X. Cheong,[2] Shlomo J. Cohney.[1,2] *[1]Royal Melbourne Hospital, Victoria, NSW, Australia; [2]Western Health, Victoria, Australia, Melbourne, NSW, Australia.*

Background: While treatment options for diabetes have increased, there is little experience with these agents in renal transplant recipients. This study examined 13 renal transplant recipients with pre-existing diabetes mellitus (PEDM) or post-transplant diabetes mellitus (PTDM) treated with GLP1 receptor agonists (GLP1RA).

Methods: 7 PEDM & 6 PTDM patients, a mean of 60 months post-transplant were given either a B.D. preparation (Byetta) or weekly preparation (Bydureon) of exenatide.

Results: At baseline, 10 were on insulin (6 PEDM, 4 PTDM) with a mean total daily insulin (TDI) requirement of 100IU/day, 1.6 other glucose lowering agents, mean weight 88.6kg, HbA1c 8.4% and creatinine 120μmol/L. 3 patients were intolerant of Byetta, while all 8 patients on Bydureon tolerated treatment. After a median follow-up of 11 months, 4/10 patients ceased insulin (2/6 PEDM, 2/4 PTDM) with a mean reduction in TDI of 71IU/day. Weight decreased by a mean of 5kg and was greater for those who reduced TDI. Mean HbA1c at follow-up was 7.8%, with a mean reduction of 0.28%. Patients were on an average of 2.2 other agents at follow-up. Of 6 patients with documented NAFLD initially, all had improved liver function on treatment. Patient satisfaction was high, evidenced by continuation of the extra injections even when on insulin.

Conclusions: GLP1RA usage in renal transplant recipients with diabetes enabled significant reduction in TDI, weight; improved glycaemic control, and achieved greater freedom from hypoglycaemia with few adverse effects. These agents prove invaluable in managing abnormal glucose metabolism amongst transplant recipients and warrant further clinical evaluation.

Age (years)	PTDM v PEDM	NAFLD	Years post-transplant	Duration of DM (years)	Follow-up (months)	TDI (IU) prior to GLP1RA	TDI (IU) post GLP1RA	Change in weight (kg)	Change in HbA1c (%)

Rates of Hypoglycemia in Hospitalized Patients Receiving Hemodialysis

Fangfei Zheng,[1] Uvannie Enriquez,[3] Jane J. Seley,[1] Felicia A. Mendelsohn Curanaj,[1] Hyo Sook Kim,[3] Patricia Prufeta,[3] Jeffrey I. Silberzweig.[1,2] *[1]NewYork-Presbyterian/Weill Cornell Medicine, New York, NY; [2]The Rogosin Institute, New York, NY; [3]New York-Presbyterian Hospital, New York, NY.*

Background: Because of the link between inadequate nutrition and poor outcomes of hospitalized patients, we established a protocol to permit patients to eat during hemodialysis. Our clinical staff observed frequent episodes of hypoglycemia during and immediately following hemodialysis, resulting in adverse symptoms and interfering with dialysis treatment. A dialysis nurse who is a certified diabetes educator instructed nursing staff on how to calculate the amount of carbohydrate eaten from hospital meal trays. Nurses were instructed to contact physicians for insulin dose adjustments for patients consuming less than 30 grams of carbohydrate.

Methods: We received IRB approval for a retrospective cohort study to identify hypoglycemic episodes defined as any blood glucose (BG) < 90 and severe hypoglycemic episodes as a BG < 54. We reviewed medical records for additional clinical information as well as timing of insulin dosing and administration relative to dialysis. We compared the frequency of hypoglycemia using the reference value of 1-3% in the general population of patients with diabetes and 3-10% in patients admitted to non-ICU hospital settings to our population of hospitalized patients undergoing hemodialysis.

Results: Of 105 dialysis treatments between June and September 2016, 12 patients suffered 16 episodes of hypoglycemia during dialysis (15.2%); in none of these cases was hypoglycemia severe. In 9 of the 16 cases, insulin was administered based on a standard hospital order set; most more than an hour prior to initiating dialysis treatment.

Conclusions: The proportion of our patients who developed hypoglycemia was similar to that seen in a general population of hospitalized patients suggesting that it is safe for hospitalized patients to eat during hemodialysis. We propose that nutrition be more widely provided to hospitalized patients receiving hemodialysis with efforts to base insulin dosing on actual, rather than expected, carbohydrate consumption

Levels of Soluble RAGE but Not Endogenous Secretory (ES) RAGE Differ between Type 2 Diabetic versus Control Subjects in the United Arab Emirates

Abdishakur Abdulle,[3] Claire K. Inman,[6] Abdelkarim Saleh,[7] Mohamed Noshi,[8] Divya Galani,[3] Laila Abdelwareth,[1] Habiba Alsafar,[2] Abubaker Elfatih,[7] Hefsa Al shamsi,[7] Raghib Ali,[6] Huilin Li,[9] Ravichandran Ramasamy,[5] Ann Marie Schmidt,[4] Mahmoud M. Benbarka,[8] Mohamed H. Hassan.[7] *[1]Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Khalifa University, ABu Dhabi, United Arab Emirates; [3]NYU Abu Dhabi, Abu Dhabi, United Arab Emirates; [4]NYU Medical Center, New York, NY; [5]NYU medical center, New York, NY; [6]New York University Abu Dhabi, Abu Dhabi, United Arab Emirates; [7]SHEIKH KHALIFA MEDICAL CITY, ABU DHABI, United Arab Emirates; [8]SKMC, Abu Dhabi, United Arab Emirates; [9]New York University Langone Medical Center, NY, NY.*

Background: The United Arab Emirates (UAE) is experiencing increasing rates of obesity, type 2 diabetes (T2D) and its complications. We tested if soluble levels of cell surface-cleaved RAGE (sRAGE) or endogenous secretory RAGE (esRAGE), the product of alternative mRNA splicing of *AGER*, are associated with T2D and obesity in the UAE.

Methods: A case-control study was performed in the Diabetes, Endocrinology and General Medical Clinics of the Sheikh Khalifa Medical City in Abu Dhabi. 216 T2D subjects and 215 controls (mean age 57.4±12.1 vs. 50.7±15.4 years, respectively) were enrolled. Plasma sRAGE and esRAGE levels, anthropomorphic characteristics and routine chemistries were measured. The relationship between sRAGE and esRAGE with obesity and T2D status was tested using a linear regression model.

Results: Univariate analyses comparing T2D case and control subjects revealed differences in sRAGE (1,033±545.3 vs. 1,169±664.1 pg/ml, respectively; p=0.02) but not esRAGE. Covariate adjustment revealed that differences in sRAGE were significant after correction for age and sex and additionally for waist-hip ratio (WHR); total cholesterol (TC), HDL; hsCRP; Vit D; or triglyceride (TG) levels separately. In cases or controls, we tested associations of body mass index (BMI) or WHR with sRAGE and esRAGE. In controls but not T2D cases, sRAGE and esRAGE were significantly associated with BMI, after correction for age and sex and additionally for eGFR; blood pressure; TC, HDL; hsCRP; Vit D; creatinine; TG and HbA1c in a combined model. In the case of WHR, in controls and T2D cases, there were no associations with sRAGE, but only in T2D cases, WHR was associated with esRAGE after correction for age and sex and blood pressure; TC, HDL; hsCRP, HbA1c, creatinine; TG, eGFR, Vit D and TG in a combined model.

Conclusions: Levels of sRAGE but not esRAGE distinguish T2D case vs. controls in the UAE population. Genetic and unique obesity-dependent factors may underlie lack of association between esRAGE in cases vs. controls, which may affect vulnerability to T2D and its complications in the UAE.

The Cardiometabolic Risk Factor Proneurotensin Is Increased in Renal Dysfunction

Thomas Ebert,[2,3] Ming-Zhi Zhang,[1] Raymond C. Harris,[1] Dorit Schleinitz,[2] Peter Kovacs,[2,3] Anke Tönjes.[3] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]IFB AdiposityDiseases, Leipzig University Medical Center, Leipzig, Germany; [3]Department of Endocrinology and Nephrology, University of Leipzig, Leipzig, Germany.*

Background: Proneurotensin, the stable N-terminal fragment of the neurotensin precursor hormone, is significantly associated with the development of obesity, diabetes, cardiovascular disease, as well as with total and cardiovascular mortality in the Malmö Diet and Cancer Study and the Framingham Heart Study. In the present study, we investigate the regulation of the cardiometabolic risk factor proneurotensin in human and murine renal dysfunction.

Methods: Circulating proneurotensin levels were quantified by ELISA in 581 patients with chronic kidney disease (CKD cohort) covering the whole spectrum of estimated

glomerular filtration rate (eGFR) categories from G1 to G5. Furthermore, proneurotensin was measured in the German Sorbs population (N = 1041) to validate the associations with renal function in a general cohort. Moreover, *mNts* mRNA expression was investigated in an animal CKD model, i.e. eNOS$^{-/-}$ C57BLKS *db/db* mice, and compared to littermate controls without CKD.

Results: Median circulating proneurotensin levels significantly and continuously increased with deteriorating renal function (eGFR category G1: 129.0; G2: 143.8; G3: 178.3; G4: 224.9; G5: 283.6 pmol/l; $p < 0.001$) in the CKD cohort. Furthermore, proneurotensin was independently associated with eGFR and albumin/creatinine ratio in patients with CKD. In the general cohort of the Sorbs from Germany, impaired renal function remained an independent and positive predictor of proneurotensin levels. In CKD mice, *mNts* mRNA expression in subcutaneous and visceral adipose tissue, as well as in the liver and kidney, was unchanged as compared to controls.

Conclusions: The cardiometabolic risk factor proneurotensin is significantly and independently associated with renal function in both a CKD and a general cohort comprising of >1600 patients. Altered *mNts* mRNA expression might not be the cause for increased proneurotensin levels in CKD. Our results further support proneurotensin as a strong and relevant cardiometabolic risk factor in patients with renal dysfunction.

PUB247

Development of a New Mouse Model of Diabetic Kidney Disease Xiaolin He,[2] Tianzhou Zhang,[1,2] Darren A. Yuen.[2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]St. Michael's Hospital Keenan Research Centre for Biomedical Science, Toronto, ON, Canada.*

Background: Despite advances in our understanding of its pathogenesis, diabetic nephropathy (DN) remains a common and serious complication of diabetes that can progress to kidney failure, and for which few effective therapies exist. A major barrier to the development of new treatments is the lack of a mouse model that replicates key features of late stage human DN, such as interstitial fibrosis, in part because diabetic mice do not typically develop significant renin-angiotensin system (RAS) activation. **Objectives**: To develop and validate a new mouse model of diabetic nephropathy.

Methods: Mice transgenic for human renin cDNA under the control of the transthyretin promoter (TTRhRen) were employed as a model of RAS hyperactivation. Diabetes was induced in TTRhRen mice by intercrossing with diabetic Akita mice (Akita$^{+/-}$ TTRhRen$^{+/-}$mice).

Results: Both Akita$^{+/-}$ TTRhRen$^{+/-}$ and their non-hypertensive Akita$^{+/-}$ TTRhRen$^{-/-}$ controls developed hyperglycemia beginning at 6 wks of age, although Akita$^{+/-}$ TTRhRen$^{+/-}$ mice also developed increased blood pressure (151±4 vs. 91±1 mmHg), marked albuminuria (urine albumin excretion: 4114±1669 vs. 1197±246 ug/day), and an increase in serum creatinine (69±6 vs. 57±6 umol/L). Structurally, Akita$^{+/-}$ TTRhRen$^{+/-}$ mice displayed markedly increased glomerulosclerosis (glomerular picrosirius red (PSR) score: 0.56±0.11 vs. 0.37±0.06) and interstitial fibrosis (PSR intensity: 0.12±0.03 vs. 0.04±0.01) compared to their Akita$^{+/-}$ TTRhRen$^{-/-}$ controls. Fibrotic gene transcripts (COL1A1 and COL3A1) were also increased in Akita$^{+/-}$ TTRhRen$^{+/-}$ mice.

Conclusions: Taken together our results suggest that Akita$^{+/-}$ TTRhRen$^{+/-}$ mice recapitulate key features of human DN, including glomerular and interstitial fibrosis.

Uric Acid and Hemodynamic Responses to Angiotensin II Infusion in Adolescents with T1D Compared to Adults with T1D for ≥ 50 Years Yuliya Lytvyn,[4] Julie A. Lovshin,[5] Genevieve Boulet,[5] Leif E. Lovblom,[5] Hillary A. Keenan,[1] Michael Brent,[6] Narinder Paul,[2] Vera Bril,[3] Bruce A. Perkins,[5] David Cherney.[4] *[1]Joslin Diabetes Center, Boston, MA; [2]Dept. of Medical Imaging, Div. of Cardiothoracic Radiology, University Health Network, Toronto, ON, Canada; [3]Dept. of Medicine, Div. of Neurology, University of Toronto, Toronto, ON, Canada; [4]Dept. of Medicine, Div. of Nephrology, Toronto General Hospital, University of Toronto, Toronto, ON, Canada; [5]Dept. of Medicine, Div. of Endocrinology and Metabolism, Mount Sinai-University Health Network, University of Toronto, Toronto, ON, Canada; [6]Dept. of Medicine, Dept. of Ophthalmology and Vision Sciences, University of Toronto, Toronto, ON, Canada.*

Background: Plasma uric acid (PUA) is associated with activation of the renin-angiotensin-aldosterone system (RAAS), promoting hypertension and kidney disease in patients with type 1 diabetes (T1D). Our aims were to (1) compare blood pressure and renal hemodynamic responses to RAAS activation by angiotensin II (ANGII) infusion in adolescents, young adults, and adults with ≥50 years of T1D, (2) determine if PUA levels modified these responses in such T1D cohorts and (3) study the effect of exogenous ANGII on PUA levels.

Methods: Blood pressure, PUA, GFR_{INULIN} and effective renal plasma flow ($ERPF_{PAH}$) were measured during clamped euglycemia in 28 T1D adolescents, 54 young T1D adults, and 59 adults with ≥50 years of T1D at baseline and after ANGII (3 ng kg^{-1} min^{-1}). Gomez's equations were used to estimate afferent (R_A) and efferent (R_E) arteriolar resistances and glomerular hydrostatic pressure (P_{GLO}).

Results: RAAS activation with ANGII was associated with significantly greater decreases in ERPF and in renal blood flow (RBF) and greater increases in renal vascular resistance (RVR), R_A, SBP, and DBP in adolescents and young adults with T1D compared to patients with ≥50 years T1D (Fig 1). Higher PUA correlated with attenuated increases in DBP in T1D adolescents (p=0.04). ANGII decreased PUA more in those with T1D >50 years vs. adolescent T1D (p=0.02).

Conclusions: Longstanding diabetes modifies the relationship between the RAAS and PUA, resulting in renal and systemic RAAS activation.

Funding: Private Foundation Support, Government Support - Non-U.S.

PUB249

Safety and Cost-Effectiveness of In-House Preparation and Centralized Distribution of Acid Dialysis Concentrate Paolo Lentini,[1] Luca Zanoli,[2] Antonio Granata,[3] Carlo Boccato,[4] Roberto Dell'Aquila.[1] *[1]St Bassiano Hospital ULSS 7 Pedemontana, Bassano del Grappa, Italy; [2]University of Catania, Catania, Italy; [3]None, Catania, Italy; [4]Consultant, Milano, Italy.*

Background: It is important to focus the effort of the caregivers on the activities able to generate the most favourable ratio of cost/benefit: during hemodialysis(HD), basic and acid concentrate are used. Making them available at the HD machine requires a considerable efforts in terms of workload and logistic. While basic concentrate is usually provided from a cartridge of dry bicarbonate, acid concentrate is supplied to the machine in a 5-ltr bag(Single-PatientDialysisDeliverySystem-SPDDS). However, the acid concentrate can be supplied to the HD machine via a CentralConcentrateDeliverySystem(CCDS).

Methods: We adopted, 1st Center in Italy, an automated CCDS(*GranumixPlus*®, Fresenius Med. Care-DE) based on a fully mixing unit that performs the dilution of a highly concentrated ingredient in HD water, and a storage and distribution unit that stores the concentrate and distributes it to the HD machines via a dedicated tubing that runs in parallel to the HD water distribution line. Here we evaluated the1-year safety, environmental impact and cost-efficacy ratio ofCCDS.[Fig.1]

Results: CCDS was used in75pts(85%), whereas SPDD was used in10pts that require peculiar treatments with personalized HD fluid composition.11000 treatments/year were performed with CCDS in our center. CCDS was associated with a reduction of staff work-load (avoided movement/management of 59180 kg of material), more space in our storehouse (avoided disposal of 11470 kg of plastic material and 7150 kg of concentrate residuals)and a big money saved ($27544), in absence of any clinical bath-related adverse events[Tab.1].

Conclusions: CCDS is a safe,"green"and cost-effective solution to simplify the preparation of the acid HD concentrate and can reduce costs, storage and transport of the bags and dialysis staff workload.

Changes in Biomarkers of Bone and Mineral Metabolism (BMM) Associated with Cross-Over Use of Citrate (CD) and Acetate (AD) Acidified Bicarbonate-Based Dialysates Ludmila Anderson,[1] Linda H. Ficociello,[1] Paul Balter,[2] Alice Topping,[2] Claudy Mullon,[1] Robert J. Kossmann.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Institute, New York, NY.*

Background: Dialysates commonly contain acetate or citrate as the acidifying agent. This retrospective analysis of chronic hemodialysis (HD) patients who switched dialysate from AD to CD and back to AD, assessed changes in corrected serum calcium (CSC) and iPTH during these time periods.

Methods: Patients with AD treatment data for 3 months (baseline, [BL]), followed by CD for 9 months (Q1-Q3), and back to AD for 3 months (Q4) were analyzed. Mean pre-HD laboratory values were compared by quarters. Subanalyses were conducted by BL iPTH (<130, 130-600, >600 pg/ml). Changes in medications (Ca-based phosphate binders [CaPB], cinacalcet, in-center vitamin D [VitD]) were explored. Paired t-test, chi^2, α=.05 were used.

Results: Switching dialysate from AD to CD among patients with BL iPTH <= 600 pg/ml was associated with increase in pre-HD iPTH at Q1 that leveled off at Q2-Q3. Among patients with BL iPTH > 600 pg/ml, iPTH decreased (BL: 1,044.1 vs. Q3: 835.3 pg/ml). Switching dialysate from CD to AD was not associated with changes in iPTH. Minor changes in CSC followed AD to CD, and CD to AD, switches (Table). From BL to Q4, % of patients treated with CaPB (32% vs. 34%, p=1.0) and cinacalcet (46% vs. 51%, p=0.7) remained similar, and in-center VitD use increased from 71% to 78% (p<.001).

Conclusions: Clinically modest changes in iPTH and CSC followed AD to CD, and CD to AD, conversion. Patients with BL iPTH <= 600 pg/ml had mean iPTH increase in Q1 and level off at Q2-Q3, and patients with BL iPTH > 600 pg/ml had mean iPTH decrease.

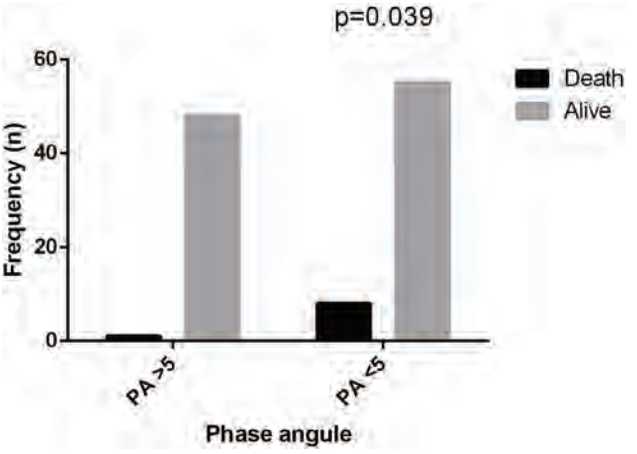
Phase Angle Is Associated with All-Cause Mortality but No Hospitalization in a Cohort of Hemodialysis Patients Javier Soto-Vargas,[1] Anel V. Barbarín vázquez,[2] Sandra L. Báez lópez,[2] Carlos alberto López lozano,[2] Miriam G. Nuño radillo,[2] Itziri P. Preciado,[2] Jesemil Navarro rodríguez,[2] Jorge fernando Topete reyes.[1] *[1]Nephrology, Regional General Hosptial 46, Mexican Institute of Social Security, Guadalajara, Mexico, Guadalajara, Mexico; [2]Clinical Nutrition, Guadalajara University, Guadalajara, Mexico.*

Background: The bioimpedance phase angle (PA) has been associated as a measure of nutritional status in maintenance hemodialysis (MHD) patients. Their relationship with hospitalization and mortality is less well stablished. Our objective is to determine the association between PA and hospitalizations and all-cause mortality in a cohort of MHD patients.

Methods: We included 121 patients in this prospective observational study. The median follow up were 24.9 months (IQR 16.2-34.1). During the follow there were lost 7 (5.8%) patients, because their denial to continue to participate. The PA was measured every 12 weeks in the day between sessions, as well and number and diagnosis of hospitalizations. For all the patients we collected HD session characteristics, demographics and relevant comorbids.

Results: There were a male predominance (60.3%). The mean age was 41 years (IQR 28.2-58.0). The media PA for trimester was 4.8±1.28, 5.1±1.31, 5.3±1.2, 5.2±1.18 and 5.2±1.16. One hundred twelve patients completed one evaluation, 89 two evaluations, 61 three evaluations, 51 four evaluations and only 33 five evaluations. There were 9 (7.4%) deaths and 26 (21.6%) patients were hospitalized during the study, 15 (12.4%) had two or more hospitalizations. The age and initial PA, were associated with mortality (p=0.036, 0.004 respectively). After adjusting for age, the PA <5 remained associated with increased risk of death (RR 1.66 CI 95% 1.24-2.23, p=0.039). The patients with PA <5 were more frequent female, and older (p<0.001 and <0.001 respectively). The change in PA values between evaluations had no impact on mortality.

Conclusions: The bioimpedance PA <5 is associated with an increased risk of death, but no with hospitalization in MHD patients.



PA <5 patients had a higher risk for all-cause death.

PUB252

ESRD and the Risk of Admissions for Recurrent Gastrointestinal Bleeding (GIB): Quality Improvement (QI) Ahmad Anjak,[3,4] Nicole Piero,[1] Charuhas V. Thakar.[2] *[1]Cincinnati VA, Cincinnati, AL; [2]University of Cincinnati, Cincinnati, OH; [3]University of cincinnati, Cincinnati, OH; [4]Cincinnati VA Hospital, Cincinnati, OH.*

Background: ESRD patients face a high risk of readmissions. GI bleed is life-threatening complication in ESRD patients; with the risk of bleeding up to 3-5 folds as compared to non-chronic kidney disease (CKD) patients. Our study aim was to evaluate the characteristics of ESRD patients experiencing GI bleed, including recurrence.

Methods: As a part of QI project, we assessed admissions under renal consult services in ESRD patients admitted to our VA facility from July –December 2016. Clinical operational data included: patients age, cause of ESRD, type of dialysis access, the source of GI bleed, the cause of GI bleed, endoscopy results and intervention, blood products requirement, anticoagulation use with hemodialysis, the use of antiplatelet and proton pump inhibitors (PPI), recurrence of GI bleed, and length of time till recurrence.

Results: During 6 months, there were 50 ESRD patients experiencing 64 admissions. Six patients with ESRD had 10 encounters with GI bleed in the 6 months period, 4 of the 6 patients had recurrent GI bleed, Three patients were diagnosed with arteriovenous malformation (AVM) as the cause of GI bleed, one with polyps and one with gastritis and one the cause of GI bleed was unknown. All patients with AVM had severe acute blood loss that needed blood transfusions, and all of them needed one or more interventions with endoscopy, all patients with AVM had recurrence of GI bleeding. The time for recurrence ranged from 1 to 3 months, recurrence occurred despite PPI use. 2 of the AVM patients also had arterio venous graft as their access, and one with tunneled catheter.

Conclusions: ESRD patients with GI bleed experience frequent recurrence. AVM as the cause of GI bleed had 100% recurrence within 30-90 days. These patients also experienced severe bleeds requiring treatment, and PPI did not reduced the risk of recurrence. Cause of AVM related bleeds in ESRD and prevention of recurrent bleeding need larger studies.

PUB253

Is the Association between Vascular Access by Catheter and Mortality in Incident Hemodialysis Patients Confounded by Sociodemographics and Comorbidities? Marcia T. Martins,[1] Marcelo B. Lopes,[2] Gildete B. Lopes,[2] Antonio A. Lopes.[2] *[1]CLINIRIM, Salvador, Brazil; [2]Federal University of Bahia, Salvador, Brazil.*

Background: Compared with access by arteriovenous fistula (AVF), access of hemodialysis (HD) by catheter for end-stage kidney disease patients has been associated with older age, greater prevalence of comorbidities and higher mortality. The present study investigated if the reported higher mortality in patients receiving HD by venous catheter than AVF could be explained by age, other sociodemographic factors and comorbidities.

Methods: The data are from a propective cohort (PROHEMO) of 421 incident HD patients treated in 4 units of Salvador, BA, Brazil. All patients were on HD for < 6 months (72% < 3 mo). To estimate hazard ratio (HR), Cox's proportional hazard models with cumulative covariate adjustments were used.

Results: Mean age was 51.0±14.9 yr. HD was performed by fistula for 119 and catheter for 302 patients. During a mean follow-up of 2.5 years, 31 deaths occurred in patients with HD by fistula (death rate=8.37/100 person-years) and 99 in patients with HD by catheter (death rate=14.73/100 person-years). The etiologic fraction of death attributed to catheter was 43.2% [(14.73-8.37)/14.73]; 95% confidence interval = 14.1%, 63.3%. The adjusted HRs of death associated with HD by catheter are shown in the Table.

Conclusions: The results of this cohort of incident HD patients add strong support against the use of catheter for vascular access. As shown the association of catheter with higher mortality was only slightly reduced after adjustments for numerous risk factors of death, including age and comorbidities.

ADJUSTED HAZARD RATIOS OF DEATH ASSOCIATED WITH HEMODIALYSIS BY CATHETER

ADJUSTED MODELS	HAZARD RATIO (95% CI)	P VALUE
Model 1	2.02 (1.33, 3.09)	0.001
Model 2	1.97 (1.27, 3.05)	0.003
Model 3	1.87 (1.18, 2.98)	0.008

CI = confidence interval; Model 1: Adjusted for age (continuous), sex, race (non-white vs white), economic class (poor/very poor vs higher), education, marital status, living with family, private health insurance and months on dialysis; Model 2: Adjusted for heart failure, ischemic heart disease, cerebrovascular disease, hypertension, diabetes, peripheral vascular disease, cancer, plus variables and model 1; Model 3: Adjusted for hemoglobin, leucocyte count, ferritin, albumin plus variables in model 2.

PUB254

Subclinical Hypothyroidism and Its Associations Observed in ESRD Patients in a Tertiary Care Hospital Sidra Saleem,[1] Syed A. Khalid,[1] Fouzia Ashraf,[2] Syed Rizwan A. Bokhari,[3] Amna Riaz,[4] Shafiq Cheema,[1] Hafiz I. Ahmad.[1] *[1]Nephrology, Allama Iqbal Medical College/Jinnah hospital, Lahore, Pakistan; [2]Pathology, Allama Iqbal Medical College/Jinnah hospital, Lahore, Pakistan; [3]Department of Nephrology and Hypertension, Tulane University, New Orleans, New Orleans, LA; [4]Endocrinology, Allama Iqbal Medical College/Jinnah hospital, Lahore, Pakistan.*

Background: Chronic kidney disease (CKD) has been known to affect thyroid hormone metabolism. End stage renal disease (ESRD) and Subclinical Hypothyroidism (SCH) are independent risk factors for cardiovascular disease (CVD) mortality. There is paucity of data regarding SCH prevalence in patients with ESRD in developing countries. We aimed to study the prevalence of SCH in our ESRD population and its correlation with patient demographics.

Methods: We enrolled all 112 ESRD patients on maintenance hemodialysis at the dialysis center of Jinnah Hospital Lahore. Thyroid function tests were performed on early morning venous samples (fasting) of all patients. Subclinical hypothyroidism (SCH) was labeled when the serum thyroid-stimulating hormone (TSH) level was high (range: 4.2-10 mIU/ml) but the corresponding serum-free thyroxine (FT_4) level was within normal limits (range: 0.93-1.7ng/dl).

Results: The mean age of the patients was 42 ± 10.86 years (range 24-60 years) and 74 (66.1%) were males. The mean duration of ESRD was 4.46 ± 1.42 years (range 1-8 years). SCH was present in 12 (10.7%) of these patients. The mean T3 and T4 values were observed to be 0.246 ± 0.072 ng/dl (range 0.04-0.49 ng/dl) and 1.05 ± 0.25 ng/dl (range 0.4-1.8 ng/dl) respectively. The mean TSH value was 2.60±4.81 mIU/L (range 0.10-40.80 mIU/L). Of these 12 patients with SCH, significant association was found between gender and presence of SCH with p-value 0.011. Eight (67%) patients were females. No significant association of SCH was found between age group and duration of ESRD (p-value 0.186 and 0.287 respectively).

Conclusions: SCH was observed in a small (10.7%) number of ESRD patients in our study and was more prevalent in females. All other variables had no significant association with the presence of SCH. Our study underscores the need to explore the correlation in terms of etiology of SCH in patients with ESRD. Treating these ESRD patients with SCH can improve their morbidity and mortality.

PUB255

Teaching Thinking of Continuing Education in the Implementation of the Integrated Management of Medicine, Nurse, and Technology for Hemodialysis Specialized Nurses Hua Liu,[2] Hongli Jiang.[1] *[1]Dialysis Center of First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi'an, Shaanxi, China; [2]First Affiliated Hospital of Medical College of Xi'an Jiaotong University, Xi'an, China.*

Background: In order to provide good quality service and achieve continuous improvement of medical quality, we carry out the integrated management of medicine, nurse and technology in the department of blood purification of the first affiliated hospital of Xi'an Jiaotong university in 2016. In this paper we discuss the influence factors and methods of the continuing education in integrated management of medicine, nurse and technology for hemodialysis specialist nurses.

Methods: With the problems of daily work and planning training in the implementation of the integrated management of medicine, nurse and technology and the planning training in department, such as, insufficient understanding of their own value, lack of professional knowledge, professional knowledge, scientific research consciousness and communication with patients, and neglect of basic nursing care outside specialist care, etc., we analyzed the influencing factors and methods in the teaching process of continuing education for hemodialysis specialist nurse.

Results: The influencing factors and improvement methods of the continuing education of dialysis specialist nurses include two aspects. The first is nurses' subjective influencing factors which focus on improving the nursing staff's own value awareness level and professional thought training, the function of nursing staff in the quality control system of staff participation, constantly playing subjective initiative, self-learning, improving professional ability knowledge, and their own value and improve the comprehensive quality. The second is continuing education development connotation which focus on the standardized training of basic nursing, professional skills, patients' health education and scientific research consciousness, and the improvement of teaching new methods, active acquisition of knowledge, the ability to analyze problems, solve problems, team collaboration, logical reasoning, literature retrieval, comprehensive evaluation, and communication and expression skills.

Conclusions: In the implementation of the integrated management of blood purification, nurses play an important role, involving all aspects of clinical quality management, we should give improve their quality, and finally implement the continuous improvement of clinical medical quality.

PUB256

The Use of Indices of Volume Status to Predict the Incidence and Severity of Sleep Disordered Breathing in Hemodialysis Patients Matthew C. Breeggemann,[3] Mark S. Bilodeau,[1] William T. Donnelly,[1] James Leiter.[2] *[1]Dartmouth College, Hanover, NH; [2]Dartmouth Medical School, Hanover, NH; [3]Dartmouth-Hitchcock Medical Center, Lebanon, NH.*

Background: Sleep disordered breathing (SDB) is a prevalent condition resulting in a considerable increase in cardiovascular related death (Mooe et al., 2001). Patients with chronic kidney disease (CKD) are known to be at an increased risk for the development of SDB, including obstructive sleep apnea (OSA), for reasons that are not entirely clear (Kimmel et al., 1989). Given the already elevated cardiovascular related morbidity that patients with CKD face, it is especially important to diagnose and treat SDB in this patient population. Defining the predictors of high risk for OSA in patients with CKD would facilitate diagnosis and treatment of OSA. The purpose of this study is to evaluate a variety of physiological factors accessible during hemodialysis to determine which of these factors is most closely associated with incidence and severity of OSA.

Methods: Participants were provided with the Watch-PAT200U Device (Itamar Medical) to assess the occurrence of apneic and hypoxic events. This device can be used to measure the respiratory disturbance index (RDI) during sleep at home. A SFB7 multi-frequency bioelectrical impedance analyzer/monitor from ImpediMed was used to measure changes in tissue water content before, during, and after hemodialysis. This allowed for objective measures of volume status in each patient in order to make indirect assessments of intravascular volume based on changes in the hematocrit during hemodialysis.

Results: All of the patients (n=5) studied have demonstrated evidence of SDB by calculated apnea-hypopnea indices (average AHI=28.50). The average AHI was higher when assessing data from Sunday nights alone (39.75). There were similar findings with oxygen desaturation indices (19.37 vs. 26.95, respectively). Weights above estimated dry weight were slightly higher on Mondays prior to hemodialysis when compared with weekly averages (2.30 vs. 2.15 kg).

Conclusions: This data supports prior findings that CKD patients are at an increased risk for SDB. Initial data from this study demonstrates that apneic and oxygen desaturation events are higher on Sunday nights, supporting the hypothesis that volume overload and potential soft tissue edema of the upper airways may be at play. Further data collection of volume status for correlation with SDB using bioelectrical impedance is underway.

PUB257

Effect of Anti-HCV Positivity on Nutritional Status and Albumin of Hemodialysis Patients Shafiq Cheema,[2] Faheem U. Sulehri.[1] *[1]Jinnah Hospital Lahore., Lahore, Pakistan; [2]Nephrology & Hypertension, Allama Iqbal Medical College, Lahore, Pakistan.*

Background: Hypoalbuminemia predicts mortality in hemodialysis patients and is assumed to result from malnutrition. The effect of anti-HCV positivity on nutritional status and hence albumin of end stage renal disease (ESRD) patients on hemodialysis (HD) is controversial. We analyzed the effect of anti-HCV positivity on serum albumin among patients with ESRD undergoing maintenance hemodialysis

Methods: All stable HD patients in our dialysis center were included. Thirty five (35) out of 128 total patients were positive for anti-HCV antibody. This included the patients with untreated active disease (positive HCV RNA) and early cirrhosis as well. Patients with decompensated liver disease were excluded. The following lab data was collected for the last 12 months, 1/1/16 till 12/31/2016, among both groups: serum albumin, calcium, phosphorus, parathyroid hormone, uric acid, URR and hemoglobulin. The differences were compared between both groups.

Results: Mean age was 51.8 years in HCV positive group and 47.2 in control group. Similarly the duration on maintenace hemodialysis was 35.6 months and 29.3 months in HCV positive and control group respectively. These differences were not significant We found statistically significant difference in serum albumin and hemoglobin level between hepatitis C positive and control groups, but the difference was non-significant in serum calcium, phosphorus, uric acid, URR and parathyroid hormone level between two groups. Mean albumin in anti-HCV positive patients was 3.55 grams /dl and in control group was 3.77 grams/dl with *p* value of 0.055. Mean hemoglobin in anti-HCV positive patients was 10.62 grams/dl and in control group is 10.02 grams/dl with *p* value of 0.043.

Conclusions: Anti-HCV positivity is associated with low serum albumin and malnutrition in ESRD patient undergoing hemodialysis. The cause of higher hemoglobulin in this group was not clear. This could be attributed to higher dosages of erythropoietin and iron used in this group.

PUB258

The Aggressiveness in Patients with Chronic Renal Failure Tomasz J. Irzyniec.[1,2] *[1]Dept. of Health Promotion and Community Nursing, Medical University of Silesia, Faculty of Health Sciences, Katowice, Poland; [2]Dept. Nephrology/ENDO, MSW i A Hospital, Katowice, Poland. Group/Team: Warchulska-Giergielewicz Team.*

Background: The aggressiveness is perceived as the feature of functioning a clearly evident predisposition to aggression. Its diversity depends on personal and situational factors. The aim was to assess the level of aggressiveness in uremic patients (CRF) and determine risk factors of aggressive behaviors.

Methods: The acceptance of illness, life satisfaction, control of emotions, depression and pain as well as total aggressiveness were examined using psychological tests and scales in 50 non-dialyzed–ND (59±16y) and 100 hemodialyzed-HD (62±14y) patients. The study attempted to select personal, clinical and biochemical features, which apply to patients with aggressiveness higher than the average (AHA) for the general population.

Results: CRF-patients characterized: the mean acceptance of the disease and life satisfaction, higher than the average control of emotions, occurrence of depression and chronic pain. The aggressiveness was similar to observed in general population. HD differed from ND in less percentage of people with depression (41% vs 64% p=0.004), occurrence of pain (38% vs 60% p<0.05) and physical aggression (16±5 vs 20±7pt p<0.007). Women differed from men in an occurrence of pain (ND-79% vs 42% p=0.004), lower suppression of anxiety (HD-20±6 vs 23±5pt p=0.002), greater acceptance of illness (ND-26±11 vs 21±10pt p=0.015 and HD-27±9 vs 21±11pt p=0.038) and less physical aggression (HD-17±5 vs 15±4pt p=0.008). ND with AHA differed from others: in age (45±13 vs 63±15y p<0.001), higher percentages of university educated (46% vs 13.5% p=0.007) and married (38% vs 16% p=0.049), absence of apathy and incidents of nausea and vomiting. A lower concentration of sodium (137±4 vs 141±4 mM/L p<0.001) was observed. HD with AHA differed from others: in percentages of men (75% vs 52%, p=0.035), married (50% vs 30% p=0.046) and time of dialysis (4±4 vs 6±7y p=0.007). They more frequently suffered from a headache (45% vs 20% p=0.02). A lower acceptance of illness (17±9 vs 25±10pt p=0.003) was also a differentiating parameter.

Conclusions: 1.The aggressiveness of uremic patients is not higher than observed among general population 2.The progression of renal insufficiency and implementation of hemodialysis lead to the reduction of aggressive behavior 3.The lower acceptance of the illness differs dialyzed patients with aggressiveness higher than the average from the others.

PUB259

Cardiovascular Autonomic Control during Early Hemodialysis Predicts Hospitalized Cardiovascular Events in Renal Failure Patients Chih-chin Kao.[1,2] *[1]Taipei Medical University Hospital, Taipei, Taiwan; [2]Taipei Medical University, Taipei, Taiwan.*

Background: Labile blood pressure (BP) was associated with increased risk of cardiovascular (CV) mortality. However, the relationship of continuous dynamics of cardiac function during hemodialysis and hospitalized CV events is not known well.

Methods: We enrolled renal failure patients who received chronic hemodialysis in Taipei Medical University Hospital. Each participant received continuous hemodynamic variability exam using ICON® (Osypka Medical. Inc, USA) during hemodialysis. The "beat-to-beat" hemodynamic parameters [heart rate (HR), stroke volume (SV), cardiac output (CO), and systemic vascular resistance index (SVRI)] were recorded. We prospectively followed these patients until the occurrence of hospitalized CV events or the end of study in May, 2017. Analysis was done by hourly basis and several approaches were carried out to explore the dynamical changes of these parameters.

Results: A total of 35 patients were included and the mean age was 57±14 years and 24 (68.6%) were male. 15 patients developed hospitalized CV events (study group), including congestive heart failure (n=5), coronary artery disease (n=8), stroke (n=1), and peripheral arterial occlusive disease (n=1). Patients with hospitalized CV events were compared to those without CV events (control group). There was significant difference in the 2nd, 3rd and 4th hourly averaged coefficient variance (standard deviation/mean) of HR between groups. No significant differences were found in hourly averaged SV, CO, and SVRI. The differences between 2nd and 1st hour coefficient variance of SV and CO was significantly higher in the control group as compared to the study group. **(Figure 1)**

Conclusions: The higher averaged coefficient variance of HR in the 2nd, 3rd, and 4th hour; and the increase of coefficient variance of SV and CO in the early hours of hemodialysis have predictive value for lower hospitalized CV events, which implies that chronic dialysis patients who have better autonomic control system may have better CV outcome.

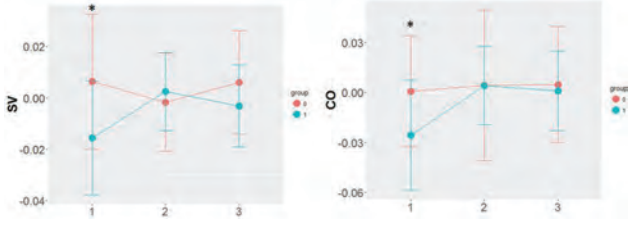

Figure 1. The differences of average [2nd-1st hour (1)], [3rd-2nd hour (2)], and [4th-3rd hour (3)] coefficient variance of SV and CO between groups.(control: 0, study: 1)

PUB260

Associations between Number of Vascular Access Providers by Geography and Catheter Rates Hao Han,[1] Sheetal Chaudhuri,[1] Tommy C. Blanchard,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Elsie Koh,[2] Murat Sor,[2] Len A. Usvyat,[1] Peter Kotanko,[3] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Vascular Care, Malvern, PA; [3]Renal Research Institute, New York, NY.*

Background: The rates of central venous catheter (CVC) use in hemodialysis (HD) patients has been relatively unaltered over the last decade. In 2016, the United States Renal Data System estimated that about 68% of incident HD patients utilize a CVC at 90 days after starting HD, and approximately 20% of patients never transition to a permanent vascular access. We aimed to study the association between the numbers of vascular access providers in a state versus the catheter rate of patients by state.

Methods: We used publically available 2014 Medicare Provider Utilization and Payment Data to determine vascular access providers who create fistulas and grafts by state. Population data for each state was gathered from 2010 Census data. To perform the analysis a new metric called "Number of Providers/Population" was created. Number of Providers who created fistulas and grafts per resident was correlated to the percentage of patients without a catheter in Fresenius Kidney Care clinics within each respective state.

Results: We found a positive correlation between the number of vascular access providers per resident who create fistulas and grafts to the percentage of patients without a catheter.

Conclusions: Out findings suggest that having access to more vascular access providers has a positive influence on catheter rates in patients. Additional studies are necessary to confirm this observation.

PUB261

Hyperkalemia and Hospitalization Rates in Hemodialysis Patients Sophia Rosen, Marta Reviriego-Mendoza, John W. Larkin, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care, Waltham, MA.*

Background: Serum potassium (K) levels are important predictors of patient outcomes in dialysis patients. While its association with mortality is well described, the relationship to hospital admissions has not been elucidated. Several methods for detecting elevated K levels include measuring mean K levels over a period of time, and assessing excursions of K levels. We aim to investigate the distribution of K levels in a large cohort of dialysis patients and its relationship to hospital admissions.

Methods: We analyzed all active patients dialyzed in the network of Fresenius Medical Care North America clinics as of Dec 31, 2015, and who were being treated in the clinics for >=6 months. Only patients who had more than six serum K levels were included in this six month analysis and ending on Dec 31, 2015. Hospital admissions data was tracked for six months after Jan 1, 2016.

Results: We analyzed data on 127,213 dialysis patients: 380 patients (0.3%) had a mean K<3.5mmol/L, 115,768 patients (91%) had a mean K>=3.5 to 5.5mmol/L, 9,707 patients (8%) had a mean K>=5.5 to 6 mmol/L, and 1,358 patients (0.7%) had a mean K>=6 mmol/L. Excursions to K>=5.5 mmol/L were more common than mean elevated K levels: 39% of patients had at least one K lab draw>=5.5 mmol/L during a six months observation period. Poisson regression models were used to compare hospital admissions and hospital days rate per patient year. Both hospital admissions and hospital days rate showed a U-shaped relationship to serum K levels, and are lowest in patients with serum K levels of 3.5 to 5.5mmol/L.

Conclusions: In this analysis we observe that, while sustained elevated serum K levels are relatively uncommon in dialysis patients, excursions to serum K levels>=5.5mmol/L are still prevalent, and impact hospitalization rates and days of stay.

PUB262

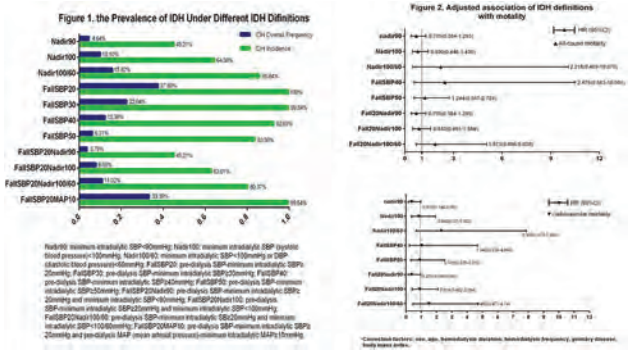
The Prevalence of Intradialytic Hypotension under Different Diagnostic Criteria and the Association with Mortality Zhiyu Wang,[1] Zijin 1. Chen,[1] Zuanhong Jiang,[2] Xiaonong Chen.[2] *[1]Dapartment of Nephrology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Division of Nephrology, Division of Nephrology, Ruijin Hospital, Shanghai Jiao Tong University, Shanghai, China, Shanghai, China.*

Background: Intradialytic hypotension (IDH) is one of the common complications during hemodialysis, however its diagnostic criteria are highly controversial. To fully understand the prevalence of IDH in our center and figure out which diagnostic criteria is better for Chinese maintenance hemodialysis (MHD) patients, we choose several IDH definitions and analyze their association with mortality.

Methods: The patients were recruited from Blood Purification Center of Ruijin Hospital undergoing hemodialysis during July 2012. Pre-, intra- and post-dialysis blood pressure were recorded. Patients' clinical characteristics, laboratory results and cardiac ultrasound results were collected. SPSS 23.0 was used to analyze data and conduct survival analysis.

Results: Totally 219 MHD patients underwent 16084 hemodialysis in 6 months. The prevalence rate, overall and individual frequency of IDH fluctuates greatly. For every IDH criteria, the patients was divided into the group IDH(+) and the group IDH(-). Survival analysis found that IDH (an absolute systolic blood pressure (SBP) < 90 mmHg or with a decrease of SBP≥ 20 mmHg) can decrease the risk of patients' cardiovascular mortality but wasn't relevant to all-cause mortality. Further analysis showed these patients had better cardiac functions mainly reflecting in lower Pro-BNP, lower prevalence rate of left ventricular hypertrophy and higher left ventricular ejection fraction than IDH(-) patients. No correlation was found between other IDH criteria and mortality.

Conclusions: The prevalence rate, overall and individual IDH frequency of IDH are of high variability when diagnosed by different IDH criterias. All IDH episodes defined by our selected definitions are of no association with all-cause mortality. An absolute SBP< 90 mmHg or with a decrease of SBP≥ 20 mmHg can decrease the risk of cardiovascular mortality due to their better cardiac function. Large scale researches should be conducted to find optimal IDH definition and explore the association of IDH and mortality.



PUB263

Evaluation of Three Hemodialysis Filters and Their Impact on Kt/V and Anti-Xa Activity in Chronic Hemodialysis Patients Hemodialyzed with Tinzaparin, a Low Molecular Weight Heparin Robert Z. Bell,[1] Michel Korkemaz,[2] Pierre Cartier,[4] Michel Vallee,[4] Naoual Elftouh.[3] *[1]Centre de recherche Hopital Maisonneuve-Rosemont, St. Lambert, QC, Canada; [2]Centre intégré de santé et de services sociaux des Laurentides, Saint-Eustache, QC, Canada; [3]Hôpital Maisonneuve Rosemont, Montreal, QC, Canada; [4]None, Montreal, QC, Canada.*

Background: Optimal usage of anticoagulant in chronic hemodialysis is fundamental in order to prevent catheter dysfunction and ensure adequate dialysis efficacy and safety. We recently switched all our patients from unfractionned heparin to tinzaparin, a low molecular weight heparin, and observed that the type of hemodialysis filter (Phylter 20 and 22) had a substantial impact on the dosage requirement of the low molecular weight heparin. Currently, there are no studies quantifying the impact of a specific hemodialysis filter type on the efficacy and safety of tinzaparin.

Methods: We conducted a subgroup analysis to determine the impact of three different hemodialysis filters on Kt/V and Anti-Xa measurements. Ten patients were hemodialysed with three different hemodialysis filters (Phylter 20 or 22, Revaclear MAX and FX 1000) for six consecutive hemodialysis sessions. The tinzaparin dosage remained the same during the evaluation of the different filters. Primary outcome was the impact of the filter type on Kt/V (efficacy) and the secondary outcome was anti-Xa activity (safety) during the HD session.

Results: The mean Kt/V was 1.30, 1.29 and 1.42 for Phylter 20 or 22, Revaclear Max and FX 1000 respectively. Anti-Xa activity is statistically higher with the FX 1000 (0.42 UI/ml) versus the Phylter 20/22 (0.33 UI/ml) and Revaclear MAX (0.34 UI/ml).

Conclusions: These preliminary results demonstrate that the type of hemodialysis filter used may have a significant impact on the efficacy and safety in regards to the type of anticoagulant that is used for hemodialysis. The data suggests that the FX 1000 filter was the most efficient filter type. We obtained the highest Kt/V (1.42) and anti-Xa activity with the FX 1000 filter. Further evaluations with a larger cohort of patients are warranted to validate our findings. This was an unsponsored study.

PUB264

Correlation of Pulmonary Hypertension with Vitamin D Deficiency in ESRD Patients Firoozeh Farahmand. *Richmond Heights, MO.*

Background: Data regarding incidence of pulmonary hypertension (PH) and its mechanisms in ESRD are scarce. PH is a devastating disease without a cure. Studies suggest oxidative stress as a mediator of PH. Vitamin D is a membrane antioxidant. Low serum vitamin D also stimulates the renin–angiotensin–aldosterone system (RAAS) resulting in vasoconstriction. The aims of this study were to evaluate the incidence of PH among patients with ESRD and its correlation with vitamin D.

Methods: A retrospective cohort of PH in ESRD patients treated with HD for at least 3 months followed in a dialysis unit. Patients without vitamin D assessment were excluded. Subject characteristics were recorded, including age, gender and race. PH was defined as an estimated systolic pulmonary artery pressure (PAP) higher than 25 mm Hg using echocardiograms performed by cardiologist.

Results: A total of 100 HD patients were included in the study. The mean of age of our patients was 59±11.4 years. The mean duration of HD was 28± 14 months. The mean ejection fraction was 45±7%. The prevalence of PHT was 51%. 59% of patients with PH were female that was statisticaly ($p<0.05$). 70% of patients with PH had a 25(OH)D level <30ng/ml ($p<0.05$).

Conclusions: Our findings demonstrate high incidence of PH among ESRD patients under maintenance HD and it is strong association with Suboptimal vitamin D. Further investigations are required to evaluate the beneficial effects of cholecalciferol in PH in ESRD patients.

PUB265

The Clinical Significance of Hyperparathyroidism Detected by Ultrasonography in Hemodialysis Patients and Analysis of Related Factors Zijin Chen,[2] Zuanhong Jiang,[3] Zhiyu Wang,[4] Xiaonong Chen.[1] *[1]Nephrology Department, Ruijin Hospital affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Ruijin Hospital affiliated to Shanghai Jiaotong University, Shanghai, China; [3]Shanghai jiaotong university, Shanghai, China; [4]Dapartment of Nephrology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: Analysis the prevalence of hyperparathyroidism detected by ultrasonography in hemodialysis patients. Combined with clinical characteristics, analysis of related factors of hyperparathyroidism, and invest the value of intact parathyroid hormone(iPTH) as a predictor of parathyroid hyperplasia.

Methods: Maintenance hemodialysis (MHD) patients were treated in Ruijin Hospital affiliated to Shanghai Jiaotong University School of Medicine in July 1st, 2015 to Dec 31th, 2015. All clinical data, sex, primary disease, dialysis vintage, biochemical data and medication were collected at baseline. Parathyroid hyperplasia was detected by Philips iE33 color Doppler sonography system (transducer with frequency 11 MHz).

Results: Totally 96 MHD patients were enrolled in this study from July 2015 to Dec 2015. Among 96 MHD patients, 54 (57.3%) patients had parathyroid hyperplasia detected by ultrasonography, including 41 (42.7%) patients with left parathyroid hyperplasia and 44(45.8%) patients with right parathyroid hyperplasia. 29 (30.2%) patients had both parathyroid hyperplasia. The prevalence of parathyroid hyperplasia in patients with dialysis vintage <36 months, 36~72months and ≥72months was 34.6%, 54.5% and 68.8%, respectively. Significant difference was between three groups (χ^2=0.018,P=0.018). Compare parathyroid hyperplasia group (n=54) and no parathyroid hyperplasia group (n=42), there was significant difference in dialysis vintage(t=-3.507,P=0.001), serum phosphorus(t=-2.591,P=0.011), intact parathyroid hormone (iPTH)(Z=-4.328,P<0.001) and active Vitamin D treatment(χ^2=11.197,P=0.001). Receiver operating characteristic(ROC) curve showed that iPTH level could predict parathyroid hyperplasia (AUC=0.758,P<0.001,95%CI 0.661-0.855). When iPTH level was over 456.9 pg/ml, the sensitivity and specificity of ultrasonography were 57.4% and 88.1%, respectively.</p>

Conclusions: Parathyroid hyperplasia is one of the common complications in uremic patients. Ultrasonography is one of the effective methods to evaluate the parathyroid gland size. Longer dialysis vintage, higher iPTH level, hyperphosphatemia and active vitamin D treatment are associated with parathyroid hyperplasia. When iPTH > 400pg/ml, it is recommended to evaluate parathyroid hyperplasia by routine parathyroid ultrasonography.

PUB266

A Case of Chronic Cerebral Edema with Recurrent Dialysis Disequilibrium Ugochi A. Osborn, Chinonye C. Ogbonnaya-Odor. *University of Texas Houston, Pearland, TX.*

Background: Introduction Dialysis disequilibrium syndrome can be defined as symptoms occurring during or after intermittent hemodialysis as a result of cerebral edema and increased intracranial pressure. The exact mechanism is unknown. However patients at risk for acute cerebral edema include patients with hepatic encephalopathy, strokes, patients with elevated BUN, hyponatremia, malignant hypertension. We present a patient with chronic cerebral edema which was unmasked by hemodialysis.

Methods: Case 40 y/o female with history of Lupus nephritis leading to End Stage Kidney Disease on hemodialysis three times a week for five years, previous ruptured anterior communicating aneurysm rupture which was surgically treated by clipping 19 years prior and hypertension. She presented after recurrent episodes of severe headaches with nausea and vomiting which was occurring 1hr into dialysis. One month prior she presented with similar intensity headaches. CT imaging revealed cystic mass with vasogenic edema and midline shift. She was initially treated with dexamethasone with mild improvements in headaches but returned after her symptoms initially resolved. Repeat CT head demonstrated radiation necrosis and hydrocephalus without obstruction. Ventriculoperitoneal shunt was placed and symptoms resolved.

Results:

Conclusions: Discussion/Conclusion This case serves as a reminder of the importance of close monitoring of patients on chronic dialysis with history of intracranial instrumentation, as cerebral edema can occur as a consequence leading to dialysis dysequilibrium syndrome.

Practices and Patterns of Hemodialysis in South Asia Sonika Puri, Gaurav Sagar. *Nephrology, Indraprastha Apollo Hospital, Delhi, India.*

Background: South Asian (SA) region faces a high burden of end stage renal disease (ESRD) and has a large gap between demand and supply for renal replacement therapy (RRT). We present the assimilated findings of a survey of nephrologists of the SA region on prevalent hemodialysis (HD) and vascular access (VA) practices in their respective units.

Methods: Nephrologists or Internal Medicine specialists running HD centers in the SA region were sent an online questionnaire. Literature was reviewed to fill gaps for missing data. Responses obtained were then converted into graphs using google survey automated software.

Results: 1700 physicians were contacted. Overall response rate was 10%. Maximum responses were from India and Pakistan (0% from Afghanistan, Bhutan and Maldives). Average cost per HD sessions varies from $10 to $100. Prevalent AV access trend: AV fistula use: 80% (India) to 40% (Myanmar) Temporary catheter use: 30% (Pakistan) to 10% (Sri Lanka). Tunneled catheter use: 30% (Sri Lanka) to 1% (Myanmar) Incident AVF use: 30% (Sri Lanka) to 3% (Bangladesh)

Conclusions: There is evident regional disparity between availability of nephrologists and HD units within this region. Few patients utilize AVF for incident HD or undergo HD three times a week. There is greater need for public-private funding to provide quality ESRD care in this region.

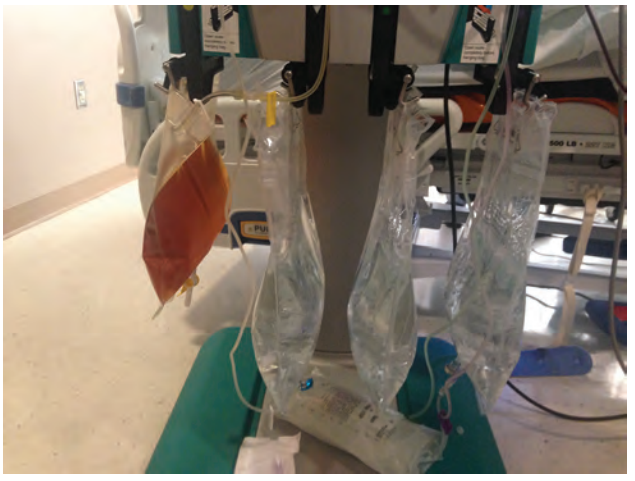
All That Is Red Is Not Blood Fahad Alobaidi, Bijin Thajudeen. *University of Arizona, Tucson, AZ.*

Background: The usual color of effluent fluid is either clear or straw colored. Occasionally there can be reddish discoloration. Common causes of reddish discoloration include hemolysis, blood leak, hyperbilirubinemia and hydroxocobalamin administration. Here we report two scenarios where effluent fluid was discolored.

Methods: 33-year-old male with history of advanced heart disease, left ventricular assist device admitted with fluid overload and acute renal failure. His hemoglobin was 6.5 gm/dl at admission and cause of anemia was thought to be due to chronic hemolysis form use of LVAD. He was started on continuous renal replacement therapy for management of volume overload. The effluent was clear for first two days. On day three he received vitamin B12 injection as part of management of anemia. Few hours following the injection there was reddish discoloration of the effluent fluid [figure 1]. A urine dipstick analysis of the fluid was negative for blood and absence of any blood leak alarm make hemoglobin less likely as the cause of discoloration. The color intensity gradually decreased and was clear by day 7. Case 2 is a 45-year male with history of end stage liver disease admitted with sepsis. He was started on CRRT for AKI, volume overload and anuria. The effluent fluid showed discoloration form the start of CRRT and persisted until CRRT was discontinued [figure 2]. There was also a yellowish discoloration of the CRRT filter. Laboratory tests showed total bilirubin of 45 mg/dl.

Results:

Conclusions: These two cases highlight the importance of checking effluent fluid color and identify the causes of discoloration.



PUB269

Clinical Features of Cardiac Surgery Associated AKI Dependent on Dialysis – A Single Center Retrospective Analysis Hongdi Cao,[1] Hong Ye,[1] Junwei Yang.[2] [1]*Center for kidney disease, Second Affiliated Hospital, Nanjing Medical University, Nanjing, China;* [2]*Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Cardiac surgery associated acute kidney injury (CSA-AKI) is one of the most common postoperative complications. CSA-AKI dependent on dialysis is closely related to the mortality. Previous CSA-AKI, particularly the incidence of dialysis dependence, has been reported differently. This retrospective analysis of the clinical characteristics of CSA-AKI dependent on dialysis is to provide a clinical reference for reducing the incidence of CSA-AKI and improving the prognosis of this population.

Methods: The clinical features of patients with CSA-AKI dependent on dialysis from January 1, 2016 to December 31, 2016 in our hospital were collected and analyzed. The basic characteristics, surgical protocols, dialysis protocols and the follow-up were recorded. Patients with chronic kidney disease were excluded. Dialysis indications were as follows: fluid overload, hyperkalemia, severe metabolic acidosis, diuretic resistance and failure of other organs.

Results: Of the 250 patients who underwent cardiac surgery, 14 with CSA-AKI (5.6%) required continuous renal replacement therapy (CRRT). In addition to a case of child with congenital heart disease, mean age of the other 13 patients was 56±17 years old, and 10 were male (76.9%). 8 patients underwent the combined heart surgery (57.1%), and 3 underwent the most complicated surgery, Bentall, aortic arch replacement, stent atrial trunk and coronary artery bypass grafting (21.4%). 2 of 14 patients were placed with intra-aortic balloon pump and 3 needed extracorporeal membrane oxygenation after operation. 6 patients received CRRT (42.8%) immediately after operation and 8 received CRRT 8-60 hours after operation. 11 patients (78.6%) underwent CRRT for at least 72 hours. 8 patients survived and the rest died in the hospital including the 3 patients who needed ECMO. The survived 8 patients were followed at least three months. 3 of them had complete recovery of renal function, the rest had persistent renal insufficiency, 1 undergoes routine dialysis.

Conclusions: CSA-AKI dependent on dialysis is a common complication after cardiac surgery, especially those undergoing combined cardiac surgery. It is one of the main factors related to the mortality after cardiac surgery.

PUB270

Use of CRRT for Myoglobin Clearance in a Patient with Rhabdomyolysis Khaled Boobes,[2] Rebecca Frazier.[1] [1]*Northwestern, Chicago, IL;* [2]*Nephrology, Northwestern University, Chicago, IL.*

Background: Myoglobin pigment released from muscle tissue in rhabdomyolysis is a known cause of acute kidney injury (AKI) in a variety of clinical presentations. Clearance of myoglobin via dialysis has been debatable. We present a case of anuric AKI secondary to rhabdomyolysis in which we used CRRT to assist with myoglobin clearance.

Methods: A 29-year-old male with a history of opioid use for back pain presented with lower extremity pain which was then attributed to a compartment syndrome of unknown etiology. He underwent fasciotomy resulting in a severe rise in his serum creatinine phosphokinase (up to 220200 units/L), with subsequent anuric AKI and hyperkalemia despite aggressive generous hydration with intravenous fluids. We proceeded with continuous renal replacement therapy (CRRT) and elected to do continuous veno-venous hemodiafiltration (CVVHDF) with a high-flux filter for highest possible clearance. We then measured myoglobin in the effluent dialysate fluid as well as in the blood on different time intervals. Myoglobin was indeed filtered into the dialysate fluid. We calculated a clearance of up to 18,000 mcg/hour. Serum CPK level came down to 167,580 units/L within 24 hours, indicating a 25% decrease. Our patient continued to require RRT for 17 days, afterward his renal function started to recover and his urine output increased to the point that he was taken off of RRT.

Results:

Conclusions: In patients with elevated serum myoglobin causing AKI, CRRT could assist in the clearance of myoglobin and other pigments that might be contributing to the renal failure.

PUB271

Cardiac Fistula: A Rare Metastatic Complication of Dialysis Access Infection Hussain Aboud, Abhilash Koratala, Robert Gibson. *University of Florida, Gainesville, FL.*

Background: While infective endocarditis is relatively common in ESRD patients, intra-cardiac fistula associated with catheter-related blood stream infection (CRBSI) is exceedingly rare and we present one such case here.

Methods: A 59-year-old man with history of ESRD on hemodialysis for 2 years has presented with intermittent chest pain and fever for 2 days. He had last hemodialysis session 1 day before via right internal jugular tunneled catheter and complained of 'feeling chilly' while on the machine. He was febrile and hypotensive at presentation. Physical examination revealed a systolic-diastolic apical murmur. Blood cultures were obtained and empiric intravenous antibiotics were started for presumed CRBSI. Cardiac markers were elevated and he was admitted and managed conservatively for non-ST elevation myocardial infarction. Cath was not done, as he was febrile. Blood cultures grew Staphylococcus epidermidis and his antibiotic therapy was adjusted accordingly. On day 5 of admission, he developed ventricular tachycardia and pulseless cardiac arrest. EKG showed ST elevation MI and cardiac catheterization showed non-obstructive coronary artery disease. Trans-esophageal echocardiogram showed findings suggestive of fulminant aortic insufficiency with possible peri-aortic abscess and a fistula connecting left ventricular outflow tract to the right atrium. [Figures 1A and 1B] His dialysis catheter was removed immediately and a temporary catheter was inserted for continuity of hemodialysis. The risks of surgical treatment were deemed to outweigh benefits and he was treated with intravenous vancomycin for 6 weeks followed by Minocycline suppressive therapy. He remained afebrile and asymptomatic throughout the hospital course.

Results:

Conclusions: In some patients with CRBSI, bacteremia leads to metastatic complications, such as endocarditis, osteomyelitis, epidural abscess, septic arthritis or other soft tissue abscesses. As metastatic complications confer high morbidity and mortality, clinicians should pay close attention to patients' symptoms and physical examination findings. In addition, early use of investigations such as trans-esophageal echocardiography whenever applicable may help in early identification of unusual complications and prompt timely interventions.

PUB272

Determinants of Successful Outcomes after Percutaneous Angioplasty of Arteriovenous Fistulas and Grafts Used for Hemodialysis Vipuj Shah,[1] Malgorzata A. Kochanek,[1] Christopher Johnson,[2] Mohammed Khadir,[2] Rakesh Navuluri,[2] Rita L. McGill,[1] Mary S. Hammes.[1] [1]*University of Chicago Medicine, Chicago, IL;* [2]*Interventional Radiology, The University of Chicago, Chicago, IL.*

Background: Arteriovenous fistulas (AVF) and grafts (AVG) may develop venous stenoses caused by neointimal hyperplasia, commonly treated with percutaneous transluminal angioplasty (PTA). We prospectively evaluated the associations of clinical characteristics with one month outcomes of PTA.

Methods: ESRD patients referred for PTA of a patent AVF or AVG from 10/2016 - 4/2017 who consented were included. Demographic, clinical data, indication for PTA and the type and location of each lesion were collected. Each stenosis was evaluated in two orthogonal planes so percentage of stenosis could be calculated as compared to a reference vessel, before and after PTA. Clinical outcomes were ascertained from dialysis unit nurse practitioners one month after PTA. Success was defined as dialyzer blood flows of 450 mL/min during dialysis, without: prolonged bleeding, cannulation pain, high venous pressure, low arterial pressure, pulling clots, infiltrations, poor clearance, infections, or swelling of the arm, neck or head.

Results: We observed 63 stenoses in 46 participants. Success at one month after intervention was seen in 33 patients who had 45 stenoses. Clinical characteristics are presented by outcome in Table.

Conclusions: Success after PTA of a hemodialysis AVF or AVG malfunction was positively associated with use of aspirin, Renin-angiotensin aldosterone inhibitors (RAAS), and referral for high venous pressures. We did not demonstrate any significant associations between procedural success and anatomic features or measurements. Future work is needed to examine longer term outcomes and clarify the role of aspirin in dialysis vascular access.

Resection of Arterial Pseudoaneurysm Followed by a Prosthetic (PTFE) Loop Graft Brachial-Basilic AV Fistula Juan Carlos Garcia Yanez, Jesús A. Nava martínez, Monica L. Mendoza. *Clinica de Accesos Vasculares, Servicios Medicos y de Equipamiento SERME, Tlalnepantla, Mexico.*

Background: This is the first case described in which is detected the presence of a pseudoaneurysm of the humeral artery at the site of anastomosis by Doppler ultrasound, is surgically resected and the same humeral artery is used for the placement of a brachio basilic graft.

Methods: A 32-year-old male patient with chronic renal disease of undetermined etiology who required renal replacement therapy. Initiates conventional hemodialysis with temporary vascular access. History of vascular access: 1. Right Internal jugular venous temporal catheter with duration of 4 months, withdrawn by change to fistula. 2. Left radial-cephalic arteriovenous fistula, which lasted 5 months, currently thrombosed. 3. Right Internal jugular venous temporal catheter placed 8 months ago, current access. 4. Left brachial-cephalic arteriovenus fistula 4 months ago, develops pulse, but does not present thrill. The presence of a pseudoaneurysm in the anastomosis site with the presence of a Ying Yang sign is evidenced by Doppler ultrasonography, and the possibility of rupture is decided to be admitted to the operating room for resection.

Results:

Conclusions: We present the case of a 32-year-old man, who came to the Vascular Access Clinic with suspicion of aneurysm. Doppler ultrasonography was performed, the presence of an arterial pseudoaneurysm was detected at the anastomosis site with a Ying Yang sign, and immediate surgical repair was considered in view of the possibility of rupture. During surgery of resection of the pseudoaneurysm, suitable diameters in the basilic vein and in the brachial artery were evidenced, so that the placement of a synthetic graft 6 mm (Advanta™ VXT PTFE Vascular Graft). The most appropriate treatment should be selected according to the cause, location, size and accessibility of the pseudoaneurysm, as well as the sequential plan of vascular accesses for each individual patient. In view of the growing number of patients with chronic renal disease on hemodialysis with multiple comorbidities, in which the sites for the creation of an arteriovenous fistula are limited, it is of vital importance to choose the optimal treatment of pseudoaneurysm by helping with the technologies available to us. Preserving permeability, decreasing recurrence and prolonging the useful life of vascular access and consequently the quality of life of patients.

PUB274

Outcome and Mechanisms of Central Vein Thrombosis Due to Catheter in Hemodialysis Patients Kazunori Oshima,[1] Naoki Ikegaya,[1] Fumiaki Nogaki,[3] Tatsuo Yamamoto,[4] Hiromichi Kumagai,[5] Takuya Yoshida,[5] George Seki,[2] Akira Hishida.[2] *[1]Dept. of Medicine, Yaizu City Hospital, Yaizu, Japan; [2]Dept. of Nephrology, Yaizu City Hospital, Yaizu, Japan; [3]Dept. of Nephrology, Shimada Municipal Hospital, Shimada, Shizuoka, Japan; [4]Dept. of Nephrology, Fujieda City Hospital, Shizuoka, Japan; [5]Dept. of clinical nutrition, Univ. of Shizuoka, Shizuoka, Japan.*

Background: Though frequent occurrences of central vein thrombosis (VT) due to hemodialysis (HD) catheters have been reported, there are little data about the anticoagulation treatment and outcome of VT. Moreover, patients with uremia exhibit altered coagulation with both increased thrombotic and bleeding risks. We evaluated the outcome of warfarin treatment and mechanisms of VT due to catheters in HD patients.

Methods: Patients requiring temporary HD access were prospectively assessed with ultrasonography prior to catheter insertion and at the time of removal. Patients with VT were treated with warfarin unless otherwise contraindicated, and evaluated with ultrasonography every two weeks after removal. Next, to analyze mechanisms of VT formation in uremia, we retrospectively compared immature platelet counts (IPC) between patients starting HD with arteriovenous fistulas and those with central venous catheters, since immature platelets are activated platelets with an increased prothrombotic potential.

Results: Fifteen jugular and 5 femoral catheters were placed in twenty patients at the induction of HD. Thirteen patients with jugular and 1 patient with femoral catheters presented VT at the time of removal. Nine patients were treated with warfarin, and VT disappeared within 1 month in seven patients and the size of VT decreased in 2 patients. In the next study, 31 patients starting HD with catheters showed significantly increased IPC compared to 17 patients with fistulas (6920 vs. 3840 /μL, $p < 0.05$).

Conclusions: We confirmed the high frequency of VT with HD catheters and observed the possible benefits of warfarin treatment in VT due to HD catheters. Additionally, starting HD with catheters may increase thrombotic events by activating platelets.

PUB275

Patency of Arteriovenous Grafts in Hemodialysis Patients: A Single Center Retrospective Study Xueqin Bian, Hong Ye. *2nd Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: It is difficult to maintain a working access for patients on hemodialysis. Despite current Dialysis Outcome Quality Initiatives recommendations of "Fistula First", not everyone qualifies for a fistula, and those patients undergoing the treatment, a graft, can experience graft failure. The patency of arteriovenous grafts (AVG) and complication of AVG in hemodialysis patients were analysis. This study also examines factors associated with AVG patency.

Methods: From January 2014 to December 2016, maintenance hemodialysis patients underwent arteriovenous graft in our hospital were enrolled in this study. Patency of AVG was examined three times at 3,6 and 12 month after fistulation. Complications, including bleeding, infection, steal syndrome, aneurysm, thrombosis and central venous stenosis were evaluated at 12 month after fistulation. Data were collected from electronic medical records, including date of first and subsequent interventions, salvage technique, medical comorbidities, and use of antiplatelet medications. Logistic regression was used to determine the odds ratio for risk factors associated with patency. Cox proportional hazard models were used statistic analysis.

Results: A total of 155 unique patients had an AVG. Of the 155 patients 68% were female, 70% were hypertensive, and 64% were diabetic. The locations of the grafts were 31% arm and 69% forearm. Configurations, including loop and straight, were 63% and 37%, respectively. The primary patencies were approximately 90%, 69% and 59% at 3, 6 and 12 months, respectively. The cumulative patencies were 92%, 80% and 69% at 3, 6 and 12 months, respectively. The incidence of all complications is 41.9% (65 of 155) at 12 month Primary patency was not found to be different with respect to location and configuration of graft and type of intervention. Primary patency for patients with diabetes and complicated vascular access history were significantly different from other patients, with a P=0.039 and P=0.0431 respectively.

Conclusions: Arteriovenous grafts in hemodialysis patients had excellent patency and some complications. Neither location nor configuration affects the primary patency of AVGs. Diabetes and fistulation history were detrimental factors for patency of AVGs.

PUB276

Hypertriglyceridemia Associated Pancreatitis – Is Apheresis Always Required? Krishna K. Manda,[1] Syed H. Jafri,[2] Jagathi Govindu,[1] Talal K. Mahmood.[1] *[1]Swedish American Hospital, Rockford, IL; [2]Swedish American Hospital, Rockford, IL.*

Background: We present two patients with Hypertriglyceridemia associated Pancreatitis (HTGP) who recovered without Apheresis in 3 out of 4 episodes. The first patient is a 52 y/o man with a h/o hypertriglyceridemia presented with abdominal pain in Mar '14. He was diagnosed with HTGP and triglyceride (TG) level was 10186 mg/dl. Apheresis was urgently organized and after one session, TG levels improved to 977 mg/dl. TG level was 262 mg/dl at the time of discharge. He had a similar admission in June '16 and was diagnosed with HTGP and TG level was 9910 mg/dl. He was fluid resuscitated and TG level improved to 373 mg/dl in 36 hours. He did not receive intravenous Insulin or heparin. The second patient is a 32 y/o woman with a h/o poorly controlled Diabetes (HbA1c 12.5%) presented with abdominal pain in Nov '15 and was diagnosed with HTGP and TG level was 12396 mg/dl. She was fluid resuscitated and TG level improved to 4925 in 12 hours and to 1354 in 36 hours. She was discharged on Gemfibrozil but unfortunately stopped taking since Apr '16. She was again admitted in Jun '16 with HTGP and TG level was 9641 mg/dl. She was started on IV Insulin along with fluid resuscitation. TG level dropped to 1816 in 24 hours and to 926 in 48 hours.

Methods:

Results: In patients who develop HTGP, management includes conventional treatment of acute pancreatitis and decreasing the TG levels to <500 mg/dL. Various treatment modalities have been suggested including apheresis, insulin and heparin. No randomized trials have compared the efficacy of Apheresis with that of insulin and heparin for the treatment of HTGP. Many case reports and series have described benefits of apheresis for HTGP. Usual indications are TG level >1000 mg/dL plus lipase >3 times the upper limit of normal and signs of hypocalcemia, lactic acidosis or organ dysfunction. Some have reported a decrease of 41% in TG levels with one session of Apheresis.

Conclusions: As it is elucidated in our experience, HTGP does not always need Apheresis and significant reduction in TG levels can be achieved with supportive management alone. Further studies are needed, before considering Apheresis as the standard of treatment because specially trained multidisciplinary team members are needed to perform the procedure and the resources needed might not be available at all the institutions.

PUB277

Patient Preference Matters: Catheter Patients with a Successful Pregnancy Attiya Haroon,[4] Sushil Mehandru,[3] Avais Masud,[5] Mayurkumar P. Patel,[5] Loay H. Salman,[1] Elmer SADIANG-ABAY,[2] Arif Asif.[3] *[1]Albany Medical College, Albany, NY; [2]JERSEY SHORE UNIVERSITY MEDICAL CENTER, TOMS RIVER, NJ; [3]Jersey Shore University Medical Center, Neptune, NJ; [4]Jersey shore university medical center, Piscataway, NJ; [5]None, Neptune, NJ.*

Background: While an arteriovenous fistula is the best available access, many patients continue to reply on a tunneled hemodialysis catheter (TDC) for dialysis therapy. Despite the highest risk of bacteremia and associated morbidity and mortality, often patients prefer TDC to avoid pain associated with cannulation of an arteriovenous access.

Methods: We report two TDC-dependent patients (age: 33, 35) with end stage renal disease (ESRD) due to polycystic kidney disease and hypertension, respectively; who became pregnant. Pregnancy was discovered at 10 and 12 weeks of gestation. Both patients were switched to daily hemodialysis (6 sessions/week). Both patients had refused the placement of an arteriovenous access and expressed their strong preference for TDC despite vascular access education. Patient preference was acknowledged and therapy continued with TDC. Pregnancy was uneventful and both patients delivered a term healthy baby.

Results:

Conclusions: Patient preference for TDC and satisfaction is important and can result in a successful outcome in pregnant patients. Nonetheless, in keeping with the National Kidney Foundation guidelines as well as the Fistula First, an arteriovenous fistula should be offered to hemodialysis patients.

PUB278

The Use of the Early Cannulation Prosthetic Graft (Gore Acuseal) for 15 Patients as a Lower Extremity Prosthetic Hemodialysis Access

Bing Tang,[1] Yong Xu,[2] Yuanming Li,[2] Xinxin Liu,[1] Bei Hou,[1] Kun Wu.[2] *[1]Renal Division, Carnation Hospital, ChangSha, China; [2]Hemodialysis center, The third affiliated Hospital of Xiang Ya School of Medicine, Central South University, ChangSha, China.*

Background: With the life expectancy of end-stable renal disease increasing, the quality and availability of the native arteriovenous access can be limited and reduced with time, the option of using prosthetic AV will become necessary. The purpose of this study is to report the safety and effectiveness of the Gore Acuseal Graft using as a lower extremity prosthetic vascular access for chronic hemodialysis patients who have exhausted upper extremity vascular access or have central venous stenosis.

Methods: Between December 2016 and May 2017, 15 patients who underwent implantation of the Gore Acuseal prosthetic AV access were included in the study. The graft configuration all were superficial femora-saphenous. follow-up of time to first cannulation, patency rate, rates of seroma, access thrombosis, steal syndrome, pseudo-aneurysm and infection were performed and recorded.

Results: Graft implantation was technically successful in all 15 patients. No patient was lost during a mean follow-up time of 3.6±1.6 months (rang,1.7-6 months;). Mean time to first cannulation was 136.8±97.2hrs (rang, 24-384hrs). Primary functional potency rate was 93.3%. Primary blood flow rate was 200-230ml/min. First puncture time was 136.8 ± 97.2 hrs (24 -384 hrs), an average follow-up of 3.6 ±1.6 months (1.7 -6.0 months). Seroma, thrombosis, pseudo-aneurysm, or graft infection was never observed. Steal syndrome occurred in one patient. Cannulation is easier than other types of regular prosthetic access reported by nurses. Cannulation sites usually stop bleeding in 15 minutes with pressure after treatment, no hematoma was observed .12 patients were removed central venous catheter or ligated dysfunctional fistula at early stage of postoperatively days. Central venous stenosis complications were not observed. Follow-up of blood flow rate all were greater than 250ml/min.

Conclusions: Lower extremity Gore Acuseal graft implantation was safe and effective, with less complications. It can be widely applied for chronic hemodialysis patients who have exhausted upper extremity vascular access or have central venous stenosis.

PUB279

Comparison of the Early Cannulation Graft (Gore Acuseal) and Standard Graft (Gore Intering) for Prosthetic Vascular Access for Haemodialysis

Kun Wu,[1] Yuanming Li,[1] Yong Xu,[1] Xinxin Liu,[2] Bei Hou,[2] Bing Tang.[2] *[1]Hemodialysis Center, The Third Affiliated Hospital of Xiang Ya School of Medicine, Changsha, China; [2]Renal Division, Carnation Hospital, ChangSha, China.*

Background: Background: Gore Acuseal is a new early cannulation prosthetic access, it can be cannulated for dialysis within 3 days. The characteristic of this prothetic access is an attractive alternative to CVC in those requiring urgent dialysis patients. The purpose is to compare the safety and efficacy of early cannulation graft(Gore Acuseal) to standard graft (Gore Intering) for prosthetic vascular access for Haemodialysis.

Methods: This is a prospective observational study of all AVGs placed since December 2016 in our hospital. Outcomes including time to first cannulation, patency rate, rates of seroma, access thrombosis, steal syndrome, pseudo-aneurysm and infection in early cannulation graft (Gore Acuseal) comparison to standard Grafts(Gore Intering).

Results: Sixteen Gore Acuseal grafts and nineteen Gore Intering grafts were implanted in the study period. The Gore Acuseal graft configuration was superficial femora-saphenous(n=15), upper arm axillo-axillary (n= 1); The Gore Intering graft configuration was superficial femora-saphenous(n=15), upper arm brachial-axillary (n=1), brachial-cephalic or basilic (n=3). No patient was lost during a mean follow-up time of 3.6±1.6 months(rang,1.7-6 months;). Primary functional patency (Gore Acuseal 93.8% vs Gore Intering 73%), Secondary patency rate (93.8% vs 89.5%). Mean time to first cannulation was 5.6±4 days(rang, 1-16 days) vs 11 ± 8 days (rang 10-35 days), the differences were statistical significance($p<0.05$). Seroma (0 vs 64.2%, $p<0.05$), AV access infection (0 vs 21%). Steal syndrome occurred in one patient with Gore Acuseal graft. Primary blood flow rate has no difference in both grafts.

Conclusions: Comparing with Gore Interning, Gore Accuseal Graft implantation was safe and effective, early cannulation with higher patency rate, less seroma, thrombosis, and infection. It is a viable option for patients who require urgent hemodialysis instead of temporary or tunneled catheters.

PUB280

Changes in Blood Pressures, Adequacy, and Access Flow Rates before and after Arteriovenous Access Thrombectomy

Sheetal Chaudhuri,[2] Hao Han,[2] Tommy C. Blanchard,[2] Yue Jiao,[2] Marta Reviriego-Mendoza,[2] Hanjie Zhang,[1] Murat Sor,[3] Elsie Koh,[3] John W. Larkin,[2] Len A. Usvyat,[2] Peter Kotanko,[1,4] Franklin W. Maddux.[2] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA; [3]Fresenius Vascular Care, Malvern, PA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Thrombotic events are a common complication in hemodialysis (HD) patients with arteriovenous fistulas and grafts (AVFs/AVGs), and are a major cause of dialysis access failure and many negative outcomes. To date, there are no established predictors associated to thrombotic events in AVFs/AVGs. We investigated the trends in levels of pre-dialysis systolic and diastolic blood pressures (preSBP/preDBP), dialysis adequacy, and access flow rates before and after an AVF/AVG thrombectomy in attempt to identify potential predictors of thrombotic events in HD patients.

Methods: We analyzed data from 1,847 Fresenius Medical Care North America HD patients who had an AVF/AVG thrombectomy between Jan 2015 to Jan 2016. The preSBP, preDBP, Kt/V, and access flow rate was tracked in HD patients for 90 days before and after the thrombectomy, and plotted using a penalized B-spline to fit the mean with 95% confidence limits.

Results: During the 90 days prior to an AVF/AVG thrombectomy, HD patients exhibited a slight decline in mean preSBP and preDBP, declining approximately 2.5 mmHg and 2 mmHg respectively. The most precipitous decline for both preSBP and preDBP was in the final 2 weeks prior to thrombectomy. About a week after a thrombectomy, mean preSBP and preDBP increased by approximately 3.5 mmHg and 2 mmHg respectively. The preSBP at 90 days after a thrombectomy was found to increase about 1 mmHg above the levels seen 2 weeks before a thrombectomy. We observed similar findings of decreases before and increases after thrombectomy for Kt/V and access flow rates. The approximate changes after thrombectomy compared to before thrombectomy were: i) average kt/v increased 1%; ii) average access flow rate increased 10%.

Conclusions: These findings indicate that blood pressures, Kt/V, and access flow rates decline before and increase after a thrombectomy. While individual changes may be small, combining multiple variables into a comprehensive model may be useful in predicting AVF/AVG thrombotic events. Further analyses are needed to confirm these observations and assess their usefulness in thrombosis detection.

Associations between Arteriovenous Fistula/Graft Failure Rates and Catheter Rates

Sheetal Chaudhuri,[1] Hao Han,[1] Tommy C. Blanchard,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Elsie Koh,[2] Murat Sor,[2] Len A. Usvyat,[1] Peter Kotanko,[3,4] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Vascular Care, Malvern, PA; [3]Renal Research Institute, New York, NY; [4]Ichan School of Medicine, New York, NY.*

Background: The rates of central venous catheter (CVC) use in hemodialysis (HD) patients have been relatively unaltered over the last decade. In 2016, the United States Renal Data System estimated that about 68% of incident HD patients utilize a CVC at 90 days after starting HD, and approximately 20% of patients never transition to a permanent vascular access (VA). We aimed to study the correlation between vascular access surgeons who have high arteriovenous fistula/graft AVF/AVG failure rates and the catheter rates in patients within the clinics associated with the vascular access surgeons.

Methods: We obtained AVF/AVG creation and failure rates by vascular access surgeon between 2012 and 2016 using Fresenius Medical Care North America access tracking system. We calculated the failure rate for each surgeon by identifying catheter creation after successful AVF/AVG use. We identified the clinics where surgeons had highest number of patients and computed the correlations between the percentage of patients without catheters per clinic and the percentage of patients with a failed AVF/AVG.

Results: We found a negative correlation between the percentage of HD patients without catheters and the percentage of patients with failed AVF/AVG.

Conclusions: Out findings suggest that the quality of AVF/AVG creation is associated with catheter rates and outcomes in HD patients. Additional studies are necessary to confirm this observation.

PUB282

Compare the Influence of Two Kinds of Vascular Accesses on Anemia in Patients on Maintenance Hemodialysis Lirui Wang,[2] Chen Yu.[1] *[1]Shanghai Tongji Hospital, SHANGHAI, China; [2]Tongji Hospital of Tongji University, SHANGHAI, China.*

Background: Previous studies postulate that maintenance hemodialysis (MHD) patients dialyzed with tunneled cuffed catheter (TCC) have poorer outcomes compared to patients using arteriovenous fistula (AVF). This study aimed to compare the effects of two kinds of vascular accesses on anemia of MHD patients.

Methods: Thirty-five MHD patients were recruited from the dialysis center of Tongji Hospital of Tongji University. Patients were classified into two groups according to their different vascular accesses: TCC group (n=15) and AVF group (n=20). Two groups were matched for age, gender, primary disease, duration of dialysis and usage time of access. We compared hemoglobin (Hb), CRP, IL-6, TNF-α and Kt/v between the two groups.

Results: There were no significant difference in the age, gender, blood pressure, BNP, creatinine, blood lipids, albumin, PTH, calcium, phosphorus, ferritin transferrin, TSAT, SF, folic acid, VitB12 and EPO dose between the two groups. Compared to the TCC group, the Hb levels, blood flow and Kt/v in AVF group were significant increased[(112.95±7.52)vs(100.00±13.96)g/L,(215.33±12.46)vs(230.00±17.77)ml/min,(1.40±0.28)vs(1.11±0.12), $P<0.05$], while the CRP, IL-6 and TNF-α levels were significant decreased[(3.59±1.40)vs(7.31±3.41)mg/L,(4.30±2.04)vs(6.93±5.02)pg/ml,(13.70±3.25)vs(17.03±5.60)pg/ml,$P<0.05$]. There was a negative correlation between the CRP, IL-6, TNF-α levels and Hb levels (r= -0.382,-0.376,-0.380,$P<0.05$), and a positive correlation between the Kt/v and Hb levels (r=0.414,$P<0.05$).

Conclusions: Compared to the AVF, the TCC is not good for the improvement of anemia in MHD patients. That may result from increasing microinflammation state and inadequate dialysis.

PUB283

Longitudinal Patterns of Quality of Life and Dialysis Modality Use: A National Cohort Study Nwamaka D. Eneanya,[2] Dugan Maddux,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Studies comparing kidney disease quality of life (KDQOL) changes over time between end-stage renal disease patients receiving different renal replacement therapy treatments, have featured small sample sizes, short follow-up times and stable dialysis modality use over time. We investigated patterns of HRQOL by dialysis modality, as well as change in modality over time among a national cohort of dialysis patients.

Methods: We analyzed data from 22,544 PD, home HD, and in-center HD patients of Fresenius Kidney Care clinics between 1/1/2013 and 6/30/2015 who survived the first 485 days on dialysis. Only patients 18 or older years who completed a KDQOL survey during the following two periods: 1) within the first 120 days and 2) within 365 to 485 days of dialysis initiation were included. Peritoneal dialysis (PD) and home hemodialysis (HD) patients were collapsed into one "Home" group. Changes in KDQOL subscale scores were compared between patients who remained on the same modality and for patients who changed modalities between first 120 days of year 1 and year 2 on dialysis. Clinically significant changes in KDQOL domains occur when they are >=3 points.

Results: Compared to in-center HD patients, Home dialysis patients had higher mean (± SD) physical component (PCS; 40.6 ± 10.3 vs. 38 ± 10.4), symptom problem (SPS; 82.5 ± 13.5 vs. 81.0 ± 14.4), burden of kidney disease (BKD; 57.7 ± 27.5 vs. 53.6 ± 28.5) and effects of kidney disease scores (EKD. 79.5 ± 18 vs. 77.2 ± 20.4) in the first 120 days of dialysis. Mental component scores (MCS) were similar between the two groups. Over time, when comparing patients who stayed on the same modality over first 120 days of year 1 and first 120 days of year 2 ("In-center to in-center", "Home to Home") and patients who switched modalities over two periods ("In-center to home", "Home to in-center") no clinically significant changes in Physical and Mental Composite Scores occurred.

Conclusions: We observe that patients treated by a home modality have better baseline HRQOL compared to their in-center HD counterparts. No notable differences in changes in physical and mental composite scores occur between the first and second year of dialysis.

PUB284

Patients Favor Solo Home Hemodialysis to In-Center Hemodialysis – Results of a Patient Preference Survey Paul Kravitz,[1] Eric D. Weinhandl.[1,2] *[1]NxStage Medical, Inc., Lawrence, MA; [2]University of Minnesota, Minneapolis, MN.*

Background: Although many home therapies are done without a partner, there are currently no devices indicated for home hemodialysis (HHD) without a care partner ("Solo HHD") that could help address a commonly reported barrier for HHD – partner requirement. We analyzed data from a patient preference survey to determine which therapy, either Solo HHD or in-center hemodialysis (CHD), that current HHD patients would favor if they no longer had a care partner.

Methods: We designed an online survey to investigate patient preference for Solo HHD. Current HHD patients in the US were invited via unbranded email from a third-party vendor to complete the survey. We used descriptive statistics to report results in 3 groups: respondents currently performing Solo HHD; respondents favoring CHD in absence of a care partner; and respondents favoring Solo HHD in absence of a care partner.

Results: We invited 1049 patients in 129 dialysis centers to participate. The respondent cohort comprised 142 patients (response rate, 13.5%). Age was <60 years in 53% of respondents, 78% were Caucasian, 70% were male, and 31% were employed either full-time or part-time. Respondents were geographically representative. Twenty-two (15%) respondents were already performing Solo HHD. In patients performing HHD with a care partner, 73 (61%) favored Solo HHD over CHD. In those who favored Solo HHD, 40% felt comfortable treating without a care partner immediately after transitioning home, and 62% felt comfortable within 3 months of starting HHD. In patients performing HHD with a care partner, several factors were associated with a preference for either Solo HHD or CHD (table).

Conclusions: A large proportion of HHD patients favored Solo HHD over CHD in absence of a care partner. Many patients would have been comfortable with Solo HHD either immediately or shortly after starting HHD. Patient preference for Solo HHD likely reflects current experience, comfort, and confidence with HHD.

Funding: Commercial Support - NxStage Medical, Inc.

	Favors Solo HHD (N=73)	Favors CHD (N=47)	P-value
Performed a Solo HHD treatment in the past 3 months	16%	4%	0.04
Treats or is very confident in ability to treat without partner present	89%	36%	<0.01
Very confident in ability to handle issues during Solo HHD	67%	13%	<0.01
Age 60 or older	44%	64%	0.03

PUB285

A New Material for Dialysis Fluid Regeneration Dmytro Tymoshenko, Hans De brouwer, David Wimberly. *SABIC, Selkirk, NY.*

Background: Single pass dialysis systems have been used for hemodialysis therapy since they were commercially introduced in the early 1960s. Single pass systems are intrinsically water hungry and require regular and costly fluid pathway maintenance. Additionally, the necessity of "dialysis grade" pure water preparation can result in significant investments in water treatment facilities in hospital environments and stand-alone reverse osmosis units for home dialysis. An alternative therapy is sorbent dialysis, which has re-emerged as a viable water-sparing technological system enabling miniaturization, portability and potential wearability.

Methods:

Results: In this publication, we would like to present a new type of dialysate sorbent material which is under development at SABIC™. We have approached this challenge from both synthetic chemistry and impregnation/coating fronts and made significant progress towards the goal. We have examined several synthetic solutions and developed a series of porous polymer beads as novel adsorbents, which have shown moderate urea and creatinine adsorption capacity. In parallel, we have also explored an innovative impregnation/coating technique providing urea binding capacities comparable to "urease and zirconium ion exchange" technology.

Conclusions: Two innovative approaches to dialysate regeneration sorbent have been developed providing materials comparable to existing enzymatic and sorbent technologies.

PUB286

The Makings of Successful In-Centre Nocturnal Haemodialysis: Well-Being, Sleep, and Free Time Katherine L. Hull,[2,3] Darren R. Churchward,[3] Suzanne Glover,[2] Warren P. Pickering,[1] Matthew P. Graham-Brown,[3,2] James Burton.[3,2] *[1]Northampton General Hospital, Northampton, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Coventry, United Kingdom; [3]University of Leicester, Leicester, United Kingdom.*

Background: In-centre nocturnal haemodialysis (INHD) provides extended dialysis sessions, for which there is evidence of an array of potential health benefits. To enhance

our patients' experience and dialysis options, we evaluated our INHD service to better understand factors that influence the uptake and adherence.

Methods: An anonymous survey was distributed to current and previous INHD patients. The survey consisted of questions regarding: demographics, length of dialysis, quality of sleep during dialysis, and free text areas for comments regarding facilities, reasons for starting and continuing/stopping INHD, and the impact of INHD. Thematic analysis was conducted on the free text sections.

Results: 58 patients were identified as current INHD (n=24) and previous INHD (n=34) patients. From these 34 patients, 21 discontinued due to: renal transplantation (n=11), transfer to a different unit (n=3), conversion to HHD (n=1) or PD (n=1) and death (n=5). These 21 patients were not included in the survey. From those surveyed (n=36), 27 (75%) were male, the average time on HD was 52 months and the average time on INHD was 9 months. Compared to usual HD, 26 (72.2%) rated INHD as causing less disruption, 25 (69.4%) stated they preferred INHD, and 24 (66.7%) felt better on INHD. The most common reasons to start and continue INHD were to have more time during the day and for the perceived health benefits (changes to medications, better blood results, improved breathlessness and generally feeling better). The main reasons for stopping were the side effects of longer dialysis or daytime tiredness.

Conclusions: Overall patient satisfaction with INHD was high due to the positive impact on lifestyle and perceived health benefits. Those that left the programme did so due to a change in clinical care, side effects of longer dialysis or daytime tiredness. These findings have identified the benefits of INHD from the patient perspective and the modifiable factors to enhance patient experience.

PUB287

Optimal Transitions: A New Approach to Improve Home Dialysis Modality Prevalence Jose A. Morfin,[1] Alex Yang,[2] Elizabeth Wang,[2] Brigitte Schiller.[2,3] *[1]University of California, Davis, Sacramento, CA; [2]Satellite Healthcare, San Jose, CA; [3]Stanford University, Palo Alto, CA.*

Background: Home hemodialysis (HHD) and peritoneal dialysis (PD) result in better clinical outcomes, lower hospitalization rates, and improved quality of life compared to conventional in-center hemodialysis (CHD). Less than 10% of incident patients choose home dialysis, and 70% of patients report not receiving sufficient education on modality options resulting in many patients feeling unprepared to make informed decisions. The Optimal Transitions (OT) program was established to provide in-depth education in all dialysis modalities over a flexible time period. While providing clinical stabilization and self-care management opportunities, patients are empowered to choose the optimal modality based on their life plan. This study aims to determine the effectiveness of the OT program in increasing prevalence of home dialysis modalities by providing sufficient education to prepare patients for transition.

Methods: This study evaluates patients enrolled in the OT program from Oct 2016–Aug 2017. Each patient completes 6 courses over about 4 weeks. OT program consists of 4 chairs within a CHD center, admitting patients screened for their candidacy for home dialysis modalities.

Results: Outcome measures include the proportion of patients who transitioned to home dialysis upon graduation, proportion of patients who reported receiving sufficient education and felt prepared to transition to chosen modality upon graduation. To date, 67% of OT patients have chosen home modalities.

Conclusions: Key unmet needs for patients to successfully undergo home dialysis include psychosocial challenges, suboptimal education, premature decision making, and fear. OT addresses these needs by establishing a life plan, in-depth ongoing education, self-care opportunities to empower patients to choose confidently the most suitable dialysis modality. Preliminary results promise the opportunity to increase the adoption of home/self-care dialysis options.

PUB288

Evaluation of the Quality of eHR Data to Assess the Clinical Features of Anemia in Dialysis Patients Samantha St. Laurent,[1] Rafael Alfonso-Cristancho,[1] Tony Okoro,[1] J. Morel Symons,[1] Kirsten L. Johansen,[2] Laura M. Dember,[3] Vanja Sikirica,[1] Alistair C. Lindsay.[1] *[1]GlaxoSmithKline, Collegeville, PA; [2]University of California, San Franicsco, San Francisco, CA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Electronic health records (eHR) have great clinical research potential if the information is sufficiently accurate. Here, we assess the quality and completeness of data in eHR from a large dialysis organization (LDO) in the US, focusing on demographic and clinical variables.

Methods: We used Kahn's framework (*Analytic Methods*, 2012) to assess data quality from ~229,000 de-identified patients across 2,900 US centers in 2015. We focused on the following quality domains: 1) missing values and anomalies in data, 2) accurate relationships between data tables, 3) temporal relationships, and 4) logical events.

Results: Low missingness was seen for age (0.08%), sex (0.04%), and dialysis treatment (0%) data. Hemoglobin (Hb) values were assessed via quality domains 1-4. Hb labs were recorded for 96% of the LDO cohort (range 0-46.8 g/dL; mean 10.9 g/dL, same result obtained with or without zero values). Anemia (defined by Hb <13.0 g/dL for men and <12.0 g/dL for women) was observed in 99% of patients with Hb labs. Extreme Hb values (<5.0 g/dL or >20.0 g/dL) were reported for <0.17% of patients with Hb labs. Among patients with Hb labs, 78% had non-zero Hb values <10.0 g/dL (the KDIGO threshold for anemia of CKD treatment). Of these patients, 11% were below this threshold for a span of at least 90 days based on subsequent lab draw dates, and 3% were below it for 180 days. Of patients with Hb <10 g/dL, 98% were receiving an erythropoietin stimulating agent.

Conclusions: Using Kahn's framework, an objective analysis of eHR from an LDO found that certain demographic features, treatment, and Hb levels were consistently recorded. 99% of all patients were anemic; 78% of patients with Hb labs had a Hb level mandating treatment (<10 g/dL, the KDIGO hemoglobin criteria). Although 98% of these patients were given an erythropoietin stimulating agent, 11% remained anemic for at least 90 days. Future work will assess mortality data linkages, and temporal data relationships between clinical variables, lab tests, and subsequent clinical treatments.

PUB289

Automation Anemia Management Algorithm System for Hemodialysis Patients Reduces the Staff Resources Yuuki Yoshioka,[1,2] Tadashi Otsuka,[3,2] Ryuzi Aoyagi,[2] Takashi Yokoo.[1] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Tachikawa general hospital, Nagaoka, Japan; [3]Niigata University, Niigata, Japan.*

Background: Anemia treatment in hemodialysis(HD) patient involves adequate supply of iron and an erythropoiesis stimulating agent (ESA). We have used Darbepoetin Alfa as ESA from 2007 and managing anemia using an algorithm from 2010. Then facility-level hemoglobin(Hgb) was improved(11.2±0.9g/dl, mean±SD). Our anemia management algorithm requires the following variables: Hgb, ferritine, Hgb Trend (HgT), ESA dose. HgT is calculated as the differential between the average of Hgb during the most recent two months and the two month-period immediately prior to that. All datas were aggregated manually. The doctor confirms the algorithm and sets each patient's next dose. These sequence still influences the potential for human error, inaccuracies, and burden on staff.

Methods: We have designed the Automation Anemia Management Algorithm System(AMAS) which digitalizes the paper-based algorithm. AMAS is connected to the Hospital Information Systems to automatically capture Hgb and ferritin data. HgT is calculated automatically. The doctor verifies the results of AMAS and gives orders via AMAS. The nurse confirms the order on the tablet device.

Results: Before starting AMAS, the nurse evaluated the algorithm of all patients (n=188) using a total average of 168 minutes. The doctor issued dose prescriptions to an average of 98 patients over an average of 83 minutes. The nurse confirmed orders over the total average of 143 minutes(total 394 minutes). There were an average of 0.8 errors per evaluation. After starting AMAS, the doctor verified AMAS results for all patients over an average of 32 minutes. The nurse confirmed orders over the total average of 128 minutes(total 160 minutes). There was no error after the introduction.

Conclusions: Staff resources devoted to anemia management decreased significantly as a result of utilizing AMAS.

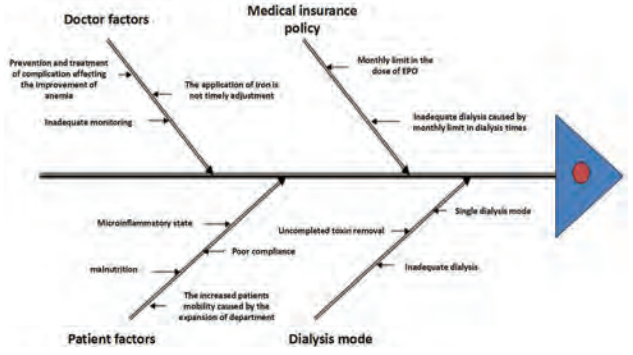
Application of Continuous Quality Improvement in Anemia Management of Maintenance Hemodialysis Patients Hua Liu,[2] Hongli Jiang.[1] *[1]Dialysis Center of First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi'an, Shaanxi, China; [2]First Affiliated Hospital of Medical College of Xi'an Jiaotong University, Xi'an, China.*

Background: In recent years, with the continuous improvement of dialysis technology, the focus of dialysis management is gradually changing over to improve the treatment quality of hemodialysis patients. Plan-do-check-act (PDCA) is the scientific procedures which should be followed by the comprehensive quality management. We used PDCA cycle to explore the clinical effect of the continuous quality improvement on anemia management of the MHD patients.

Methods: After we found the general standard rate of anemia in outpatients in 2014 (37.8%) was lower than that in 2013 (39%), we choose overall anemia (HGB≥100g/L) from 2014 to 2016 for MHD patients in the First Affiliated Hospital of Xi'an Jiaotong University, based on application of PDCA cycle management model, used the fishbone diagram as a management tool to analyze the reasons. Then,we analyzed clinical stage index comparative.

Results: Based on PDCA medical quality improvement for the doctor factors, health care policy, patient factors, dialysis and so on, we adopt the following methods, including strengthening the monitoring efforts, standardizing application of iron; strengthening the follow-up and treatment of new patients, paying attention to prevention and treatment of hyperparathyroidism and other complications, strengthening the patient's propaganda, improving the drug compliance and disease attention, improving malnutrition and the dialysis adequacy, providing different patients with individual dialysis choice, improving the dialysis adequacy and other measures to improve the microinflammatory state in patients. After these methods, the overall standard ratio increased 10.7% in 2015 (48.5%) and 14% in 2016 (51.8%) compared with 2014 (37.8%).

Conclusions: Continuous quality improvement management can promote the improvement of chronic complications in MHD patients such as anemia. We need to continue to make efforts to train staff, technical standards, and quality management in the treatment of MHD patients.



PUB291

The Effect of Ferric Citrate on Inflammation and Lipid Levels in Patients on Hemodialysis Nawsheen Chowdhury,[2] Youngjun Park,[3] Candace D. Grant,[1] Shayan Shirazian.[1] *[1]Winthrop University Hospital, Mineola, NY; [2]Winthrop university hospital, Mineola, NY; [3]Winthrop-University Hospital, Mineola, NY.*

Background: Cardiovascular mortality in hemodialysis patients is up to 20 times that of the general population. This increased mortality has been thought to occur partly due to chronic inflammation and accelerated atherogenesis. The purpose of this ongoing study is to examine the potential of ferric citrate (FC), a recently FDA approved phosphate binder, to improve cardiovascular risk by decreasing inflammatory markers and lipid levels in patients on hemodialysis (HD).

Methods: This is a prospective, non-controlled trial with a target enrollment of 30 participants. Inclusion criteria were HD for ≥ 6 months, phosphate binder use, maintenance intravenous iron (IV Fe) use, dialysis via a fistula, and serum phosphorus (Phos) level between 2.5 to 8.0 mg/dl. Patients with signs of ongoing inflammation, blood transfusion within 3 months, and IV Fe loading within 2 weeks were excluded. After a 2-week wash-out period from their current phosphate binder, FC was initiated and dosed by study investigators according to a previously published protocol. Anemia management was left to the discretion of the subject's nephrologist. Serum levels of ferritin, other inflammatory markers (c-reactive protein, homocysteine, TNF-alpha, IL-6 and IL-8), lipid levels, and Phos were measured at 0 and 6 months. ESA and IVFe requirements in the 6 months prior to the study and during the study period were calculated.

Results: 18 patients have completed the required 6 months. The average age of the completing participants was 58 years, 78% were male, and 61% were white. Phos levels declined significantly from 6.92 ±1.61 to 5.38±1.22 mg/dl (p=0.002). Cumulative IV Fe dose used during the 6 months of the study as compared to the 6 months prior to the study decreased by 46% (p=0.011). There were no significant changes in ferritin levels, inflammatory markers, lipid levels or ESA use.

Conclusions: This study found that while improving Phos, FC significantly decreased the amount of IV Fe used in HD patients during the 6 months of the study as compared to the 6 months prior to the study. Participants were able to maintain their iron stores as there were no significant changes in ferritin levels. Larger trials are needed to confirm these effects.

PUB292

Quality of Life with Reference to Haemoglobin Levels and Erythropoietin Use in a Rural Tertiary Care Centre Beena Unnikrishnan. *SMIMS, Kulashekaram, Trivandrum, India.*

Background: The relationship between quality of life and anemia has been the subject of recent debates. The study was done in a rural setting where major number of patients cannot afford medications and let alone dialysis. The participants of this study are undergoing twice and thrice weekly hemodialysis. Yet most of them are independent.

Methods: This study examines the relationship between Kidney Disease Quality of Life questionnaire domains(KDQOL) and Hemoglobin (Hgb) levels in 157 patients with ESRD on Hemodialysis followed in Sree Mookambika Institute Of Medical Sciences over the period of six years. QofL measures were compared in a stepwise fashion for Hemoglobin levels of <8, 8- <10, 10 to <12, 12 to 13, and ≥13. Student t test was used to examine the relationship between quality of life scores and Hgb level, age, and albumin level; a history of diabetes, congestive heart failure, or myocardial infarction; use of erythropoetic stimulating agents (ESA); and the level of hemoglobin level and ESA. Out of the 157 patients who participated, only 60 (38%) of them are taking erythropoietin. Even among the 60 only 15 (25%) are taking regularly.

Results: The increasing Hb levels are statistically significant correlation with increases in kidney disease domain scores on the kidney disease component of the questionnaire (p=0.042). About the SF36 component, the difference between 5 groups of Hb levels were significant in the general health (p=0.023), role emotion (p=0.015), social functioning (p=0.008), and mental component summary scores (p=0.039). The most dramatic improvements in these various domains occurred between the 8- <10, and the 10 to <12 group. Quality of life was better among those who are taking erythropoietin compared with the haemoglobin levels but the difference was not statistically significant (P=0.018)

Conclusions: The difference of the Hb levels were statistically significant with differences in the effects of kidney disease, general health, role emotion, and social function scores, and mental component summary scores of the KDQOL-SF questionnaire. Long-term assessment should be considered. These findings have implications for the care of hemodialysis patients in terms of the Hb target and the of erythropoietin (EPO) therapy. It has been suggested that the treatment of anemia of ESRD patients should be individualised.

PUB293

Influence of Iron Deficiency on Contractility in Dialysis Patients Gustavo Laham,[1] Maximo A. Schiavone.[2] *[1]None, Buenos Aires, Argentina; [2]Medicina Interna, Universidad Austral, Pilar, Argentina.*

Background: The major cause of mortality is cardiac arrytmia and sudden death. The key factors are in the cardiac and vascular function. We postulate the rol of anemia and iron load related to this cardiac disfunction. We analyze the prevalence of anemia and iron deficiency on dialysis patient and establish teh rol of iron in ventricular contractility.

Methods: 102 patients attended the interdialysis day to undergo a hemodynamic evaluation. Iron metabolism was measured: serum iron, ferritin and transferrin saturation (TSAT). The patients were then classified into 2 groups according to the presence (Group 1) or not (group 2) of anemia, (hemoglobin (hb) < 13 g / l men and < 12 g / l women, in order to evaluate subgroup separately. In assessing the interaction of iron metabolism on ventricular contractility (d2z / d2t) were considered as dependent variable, adjusting by age, gender, BP, anthropometric variables, TFC, dialysis time and medication to through a multiple regression (Backward Stepwise Regression). Multiple regressions were performed on the total sample and on each subgroups separately

Results: We included 91 patients (age: 58.89, SBP: 143 mmHg, DBP: 80.83 mmHg, women 53.8%, LVMI: 149.63, EPR 0.525,% FEY 63.15, Ferremia 66.44, Ferritin 368.8, TSAT 26.593). 43,96 % patients had anemia, corresponding to group 1. In group 2, 51 patient (56.04%). In the multiple regressions were significant: hb (p = 0.016, serum iron (p = 0.009), TSAT (p=0,038). In the specific analysis of group 1: Hb (p = 0.011), serum iron (p = 0.05), TSAT (p = 0.03). For group 2, Ferritin (p = 0.026), serum iron (p = 0.01) and TSAT (p=0,018) were significant as independent variables for contractility.

Conclusions: In this study we demonstrated the association of iron on contractility regardless of the presence or not of anemia in dialysis patients. These findings correlate with those studies performed in patients with heart failure, except that our population has a conservative ejection fraction, with the majority of studies with patients with decreased ejection fraction.

PUB294

The Relationship between Peripheral Artery Disease and Frailty in Patients with Chorionic Hemodialysis Hidemi Takeuchi,[2] Michihiro Okuyama,[2] Haruhito A. Uchida,[1] Yuki Kakio,[2] Yuka Okuyama,[2] Ryoko Umebayashi,[2] Hitoshi Sugiyama,[3] Jun Wada.[1] *[1]Okayama Univeristy, Okayama, Japan; [2]Okayama University, Okayama, Japan; [3]Okayama University Graduate School, Okayama, Japan.*

Background: The clinical condition of frailty is a common problem in the elderly population. Chronic hemodialysis (HD) patients often have peripheral artery disease (PAD) as a vascular complication. However, the relationship between PAD and frailty in HD patients remains unknown. The aim of this study was to identify the relationships among PAD and risk factors in chronic HD patients.

Methods: This study was a multi-center, cross-sectional and observational investigation which was conducted at 6 institutions. Subjects were all chronic HD patients. To evaluate frailty, we used the modified Fried's frailty phenotype adjusted for Japanese as the self-reported questionnaire, and measured each physical domain. Furthermore, we calculated ankle-brachial index (ABI) to define PAD. PAD was defined according to the definition of TASC II (Trans-Atlantic Inter-Society Consensus II).

Results: Of the 542 patients in all institutions, 362 were enrolled in this study. Sixty-two patients (17.1%) were categorized as PAD group and 300 patients (82.9%) as non-PAD group. In the PAD group, the prevalence of frailty was significantly higher than that in the non-PAD group (34% vs 18%, P = 0.010). Non-shunt side grip strength was

significantly stronger in the non-PAD group compared to PAD group (23.6 kg vs 17.0 kg, P < 0.001). Thigh circumferences (the mean of both sides) were also significantly larger in the non-PAD group compared to PAD group (41.7 cm vs 39.7 cm, P = 0.005). Univariate regression analyses showed that frailty, age, number of oral medicine, and history of myocardial infarction (MI) had significant correlations with PAD. Multivariate logistic regression analysis demonstrated that the factors independently associated with PAD were as follows: frailty (OR = 2.061, 95% C.I. 1.091-3.894, P =0.030) and MI (OR = 3.742, 95% C.I. 2.051-6.831, P < 0.001).

Conclusions: PAD is associated with frailty in HD patients.

PUB295

Assessment of Fluid Shifts of Dialysis Patients Using Plasma Water Index to Predict Intradialytic Hypotension Tadashi Otsuka, Ryohei Kaseda, Yoshikatsu Kaneko, Ichiei Narita, Yuuki Yoshioka. *Niigata University, Chuo-ku, Niigata, Japan.*

Background: Intradialytic hypotension (IDH) is the major risk factor for mortality in hemodialysis (HD), which often occurs when plasma fluid removal outpaces the rate of refilling in the patient whose dry weight (DW) is underestimated to prevent congestive heart failure (CHF). There is no standard measure of ultrafiltration on fluid shifts in the extra- and intracellular fluid spaces. We aimed to put plasma weight index (PWI) into practical use for probing relevant DW, as a marker of plasma refilling rate, and categorized patient's fluid shifts in combination with hANP, an intravascular volume marker. In addition, relationships between those markers and pretibial edema (PTE) just before HD, as an interstitial fluid marker, were examined.

Methods: This study retrospectively examined records of 156 dialysis patients from December 30, 2015, to January 5, 2016 in Tachikawa medical hospital. IDH was defined by current KDOQI guidelines [a decrease in either systolic BP (SBP) ≥ 20 mmHg or mean arterial pressure≥10 mmHg as well as associated symptoms]. CHF group was defined as patients with dyspnea and lower SpO2 level (<96%).

Results: IDH and CHF occurred in 28.2% and 7.7% of all patients respectively. Patients with IDH had higher PWI levels than those without IDH (1.71±2.40 vs. 2.65±1.70, P = 0.007). PWI > 2.0 was predictive of high incidence of IDH (OR = 2.40, 95%CI, 1.12-5.12, P = 0.020), but not associated with incidence of CHF (OR 1.00, 95%CI, 0.30-3.30, P = 1.000). On the other hand, hANP >100 pg/ml was predictive of high incidence of CHF (OR 3.52, 95%CI, 1.06-11.71, P = 0.004), but not associated with incidence of IDH (OR 0.79, 95%CI, 0.37-1.71, P = 0.5504). We subdivided the patients into 4 groups by the two cut-off points of PWI and hANP. In the PWI < 2.0/hANP < 100 pg/ml group, there was no CHF occurrence and incidence of IDH was relatively low (23.7%). PWI of patients with PTE was lower than those without PTE (1.68±2.34 vs. 3.07±1.51, P < 0.001), and hANP had no significant difference between those with or without PTE (62 pg/ml; IQR 39-128 vs. 52 pg/ml; IQR 27-93, P = 0.060).

Conclusions: Assessment of fluid shifts by PWI and hANP would be useful for determination of DW. Moreover, PTE keeps fluid in interstitium and become a reservoir to intravascular volume during HD. Thus, PTE is possible to keep blood pressure during HD.

PUB296

Association of Oral Mucosal Lesions with Mortality in Patients Treated with Hemodialysis: The Oral-D Multinational Cohort Study Marinella Ruospo,[1] Suetonia Palmer,[2] Jorgen B. Hegbrant,[1] Giovanni F. Strippoli.[1,3] *[1]Diaverum, Lund, Sweden; [2]University of Otago, Christchurch, New Zealand; [3]University of Bari, Bari, Italy. Group/Team: ORAL-D investigators.*

Background: Oral mucosal lesions are highly prevalent and frequently severe in patients with CKD, but little is known about the association of oral mucosal lesions such as precancerous or infectious lesions with adverse clinical outcomes in haemodialysis patients. We evaluated the association of oral mucosal lesions with all-cause and cardiovascular mortality in the setting of hemodialysis.

Methods: The ORAL-D study was a multinational prospective cohort study involving haemodialysis patients from 7 countries in Europe and Argentina. Oral and mucosal lesions were evaluated at baseline by trained dentists using calibrated WHO standardized protocols. The association of oral mucosal disease with total and cardiovascular mortality was estimated by random-effect Cox regression models adjusted for age, gender, smoking, MI, stroke, diabetes, albumin, phosphorus, time on dialysis, BMI, blood pressure, occupation, and country. Sensitivity analysis utilized a shared frailty model clustering by country.

Results: The ORAL-D study involved 4,205 patients (61.6±15.6 years, 58% men) during July 2010-February 2012. Median follow up was 23.7 months. Prevalence of pre-malignant lesions was: leukoplakia (3.5%); erythroplakia (4%); neo-formations (2%). Prevalence of oral infections was: thrush (4.6%); herpes (0.5%). Other lesions included scrotal tongue (10.7%), geographical tongue (4.9%), petechial lesions (7.9%), and ulcers (1. 7%). In unadjusted survival analysis, any oral precancerous or infectious mucosal lesion was associated with all-cause mortality (HR 1.32, 95% CI 1.08-1.63 and 1.28, 0.99-1.65) and cardiovascular mortality (1.60, 1.22-2.09 and 1.39, 0.98-1.97). After adjustment, there was no association between oral precancerous lesions and total (HR 0.79, 95% CI 0.53-1.17) and cardiovascular (0.75, 0.42-1.32) mortality. Similarly, no association was found between infectious lesions with total (1.30, 0.81-2.07) or cardiovascular (1.63, 0.87-3.02) mortality. Results were similar when clustered by country.

Conclusions: Oral precancerous or infectious lesions were not associated with all-cause or cardiovascular mortality after 2 years in dialysis patients.

PUB297

Fruit Intake and Cardiovascular and All-Cause Mortality in Adults on Hemodialysis: The DIET-HD Multinational Cohort Study Valeria M. Saglimbene,[1,3] Germaine Wong,[1] Jonathan C. Craig,[2] Jorgen B. Hegbrant,[3] Giovanni F. Strippoli.[4,3] *[1]University of Sydney, Sydney, NSW, Australia; [2]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [3]Diaverum Medical Scientific Office, Lund, Sweden; [4]University of Bari, Bari, Italy. Group/Team: For DIET-HD investigators.*

Background: High fruit intake is associated with reduced cardiovascular risk in the general population, but it is generally discouraged in hemodialysis due to risks associated with hyperkalemia.

Methods: Using data from the DIET-HD study, a prospective cohort study (January 2014-January 2016) in 9757 adults treated with hemodialysis in Europe and South America, fruit intake (portions/day) was measured by the validated GA²LEN food frequency questionnaire. Adjusted cox regression analyses clustered by country were conducted to evaluate the association of fruit intake with cardiovascular and all-cause mortality.

Results: During a median follow up of 1.5 years (8108 person-years), there were 1214 deaths including 515 attributable to cardiovascular causes. Overall there was no association between total fruit intake (one portion (70 g) increase per day) and cardiovascular (adjusted hazards ratio 1.00, 95% confidence interval 0.97-1.02) and all-cause mortality (0.99, 0.97-1.00). Apple consumption (≥ 1 apple per day versus none) was associated with lower risks of cardiovascular (0.67, 0.52-0.88) and all-cause (0.83, 0.69-0.98) mortality. Higher consumption (one fruit increase per day) of avocados (2.75, 1.28-5.91) and apricots (1.84, 1.26-2.69) was associated with increased cardiovascular mortality.

Conclusions: There was no overall association between fruit consumption and all-cause and cardiovascular mortality for patients on hemodialysis, but daily apple consumption may be associated with lower mortality in this clinical setting.

PUB298

Clinical Profile and Survival of Children and Adolescents under Renal Replacement Therapy in a Single Center in Brazil Maria Goretti M. Penido,[2,4] Celina F. Rezende,[3] Andre S. Alvarenga,[3] Mariangela L. Cherchiglia,[1] Viviane L. Nery.[3] *[1]Federal University of Minas Gerais, Belo Horizonte, Brazil; [2]Pediatric Nephrology Unit, Santa Casa de Belo Horizonte Hospital, Belo Horizonte, Brazil; [3]Nephrology Center, Santa Casa de Belo Horizonte Hospital, Belo Horizonte, Brazil; [4]Pediatric Nephrology Unit, Federal University of Minas Gerais, Belo Horizonte, Brazil.*

Background: There are few available data that estimate the clinical profile and survival of pediatric renal replacement therapy (RRT). The aim of this study was to outline the clinical profile and survival of 82 children and adolescents under RRT followed at the Nephrology Center of Santa Casa Hospital in Belo Horizonte, from 2008 to 2016.

Methods: Cohort study with children and adolescents <18 years old with at least 3 months of registration to cohort admission. Patients excluded were those who died in the first 3 months under RRT, acute patients and those ≥18yrs. The databases of the Center as well as patient records were consulted. The following statistic tests were used: Student t, Mann Whitney, Wilcoxon, Fisher exact test and Kaplan-Meyer curves.

Results: We evaluated 82 pediatric patients (52M) with the median age of 9.5 years. 57% showed low height-for-age-and-gender and the BMI was normal in 88%. The primary diagnosis was glomerulonephritis (36.6%), 82% were followed by nephrologists before beginning RRT, and 64.5% presented residual diuresis. Comparison between the admission exams vs 6 and 12 month exams after the beginning of the RRT, showed significant statistical growth of hemoglobin, albumin, alkaline phosphatase, parathyroid hormone and calcium levels. Hemodialysis was the main treatment modality (71%). The long-term double-lumen catheter was the most used vascular access (49%). During the study, 34 patients (41.5%) were transplanted and 94% received the graft from deceased donors. The median waiting time in RRT until the transplant was 20 months, and the median age of transplantation was 12 years of age. The survival rate in 8 years was 80.6%, with sepsis being the main cause of death (56%).

Conclusions: The majority of our patients were male, with glomerulonephritis, followed by nephrologists before starting RRT, on hemodialysis, with the long-term double-lumen catheter for vascular access. 34 patients were transplanted and received the graft from deceased donors. The median time on a waiting list and the age of transplantation was 20 months and 12 years, respectively. The survival in 8 years was 80.6%, with sepsis as the main cause of death. More studies are needed to improve the quality of care provided to pediatric RRT patients.

PUB299

Epidemiological, Social, and Economic Profile of Children and Adolescents under Renal Replacement Therapy in a Single Center in Brazil Maria Goretti M. Penido,[2,3] Celina F. Rezende,[4] Andre S. Alvarenga,[4] Mariangela L. Cherchiglia,[1] Viviane L. Nery.[4] *[1]Federal University of Minas Gerais, Belo Horizonte, Brazil; [2]Pediatric Nephrology Unit, Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [3]Pediatric Nephrology Unit, Federal University of Minas Gerais, Belo Horizonte, Brazil; [4]Nephrology Center, Santa Casa de Belo Horizonte, Belo Horizonte, Brazil.*

Background: Pediatric chronic kidney disease is a long-term disease and is associated with morbity, premature death and low quality of life. The progressive decline of renal function compromises all organs of the organism as well as psyche, behavior, family dynamics and income. The aim of this study was to outline the epidemiological, social and economic profile of 82 pediatric patients under renal replacement therapy (RRT) followed at the Nephrology Center of Santa Casa Hospital in the city of Belo Horizonte from 2008 to 2016.

Methods: Cohort study with children and adolescents <18 years old with at least 3 months of registration to cohort admission. Patients excluded were those who died in the first 3 months under RRT, acute patients, and those ≥18 years of age. The databases of the Center as well as patient records were consulted. The following statistic tests were used: Student t, Mann Whitney, Wilcoxon and Fisher exact test.

Results: We evaluated 82 pediatric patients (52M) with the median age of 9.5 years and the following age ranges: infants (16%), preschoolers (22%), school-aged (28%), adolescents (34%). Fifty-seven patients did not live in Belo Horizonte and the mother was the caretaker in 80.5%. The *per capita* income was ≤1 minimum wage in 89%, 95% of the patients received RRT from the government, 60% use government transportation for their treatment, and the majority (94%) are enrolled at the primary care unit and received the majority of their medicines from those units. Among those at scholastic age (54), 85% attended school regularly. Fifty-seven percent showed low height-for-age-and-gender and the body mass index was normal in 88%. Hemodialysis was the main treatment modality (71%).

Conclusions: The profile of our pediatric patient was: a boy with low height, on hemodialysis, older than 7 years of age, not living in the city, *per capita* income was ≤1 minimum wage, enrolled at primary care unit, receiving RRT and transportation from the government, attending school regularly, cared for by their mothers. More studies are needed to improve the understanding of the epidemiological, economic and social characteristic of pediatric RRT.

PUB300

Agreeability between Dialysis Unit Blood Pressure and Ambulatory Blood Pressure Monitoring in Dialysis Patients Paras Dedhia, Rachana H. Jasani, Viswanath Billa, SHRIRANG BICHU, Rajesh B. Kumar. *Apex Kidney Foundation, Mumbai, India.*

Background: Hypertension in dialysis population is associated with increased cardiovascular mortality and morbidity. Majority of therapeutic decisions are taken based upon dialysis unit blood pressure (BP) readings.

Methods: Ambulatory BP monitoring (ABPM) was performed for 44 hours in between 2 dialysis sessions beginning immediately post-dialysis. ABPM was recorded every 20 min during the day (7 am to11 pm) and every 30 min during night (11 pm to 7 am) on non-fistula arm. ABPM data with less than 70% readings were excluded from the study. Hourly means were averaged to obtain interdialytic systolic and diastolic blood pressure readings over 44 hours. Pre and post dialysis blood pressure were recorded by dialysis personnel using oscillometric device attached to dialysis machine. These pre and post dialysis unit BP measurements were averaged over one week. Agreement between dialysis unit blood pressure and interdialytic ABPM were assessed by Bland-Altman plot and Lin's concordance correlation coefficient (CCC).

Results: Of 40 patients, 68% were males. Average age was 54.5± 12.3 years. Mean dialysis vintage was 2.85± 2.9 years. About 49% were diabetic, 97% were hypertensive and 23% had IHD. Mean 44 hour ABPM reading was 142.9 ± 18.6/ 82.6±13.8 mm Hg. Limits of agreement between dialysis unit blood pressures and ABPM were wide across all BP parameters by bland-altman plot. Lin's CCC (see table) also showed poor agreement between two readings (ABPM and dialysis unit readings).

Conclusions: There is a disagreement between dialysis unit blood pressure and ABPM. Irrespective of BP parameter, agreement remains poor between 2 measurements. We suggest assessing out of dialysis unit BP readings to make therapeutic decisions in dialysis patients.

Agreement between dialysis unit BP and ABPM

Blood pressure parameters	Limits of agreement	Lin's CCC
Pre dialysis SBP	-31.6 to 25.7	0.70
Pre HD DBP	-16 to 21.7	0.70
Post HD SBP	-36.4 to 32.3	0.64
Post HD DBP	-16.2 to 21.5	0.75
1 week average pre and post HD SBP	-28.7 to 23.6	0.74
1 week average pre and post HD DBP	-11.8 to 17.1	0.81

PUB301

Intradialytic Bioimpedance Cardiography Measurement to Assess Cardiovascular Responses during Hemodialysis Jining Wu, Hong Ye, Junwei Yang. *Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: In hemodialysis, extracorporeal circulation is applied to remove accumulated uremic toxins, electrolyte and fluid in plasma into the dialysate through a membrane during a 4h HD session 3 times a week. The rate of exculsion in 4h is approximately 10 times faster than that of previous accumulation for 2 or 3 days. Hemodynamic stress during HD results in recurrent segmental ischemic injury that drives cumulative cardiac damage. We performed an observational study of the cardiovascular effect of dialysis sessions using intradialytic thoracic bioimopedance cardiography to examine the acute effects of standard HD in stable patients.

Methods: In this observational study, we enrolled 114 patients from a single hemodialysis unit. Bioimpedance cardiography measurements included cardiac index, stroke volume index, systemic vascular resistance index, acceleration index and thoracic fluid content.

Results: Patients had mean±SEM ultrafiltration rates of 3.8±2.9 ml/kg per hour during HD. All measures of systolic contractile function fell during HD, with partial recovery after dialysis. Interestingly, during the first 5 mins of hemodialysis, cardiac index and stroke volume index reduced obviously compared to the base lever before dialysis. All patients experienced some degree of segmental left ventricular dysfunction, with severity proportional to ultrafiltration rate and BP reduction.

Conclusions: It suggested that bioimpedance cardiography could assess the acute cardiac effects of dialysis during hemodialysis treatment. And fluid overload could in part explain the fell of cardiac index during dialysis.

Funding: Government Support - Non-U.S.

PUB302

Monitoring Volume Status Using Bioelectrical Impedance Analysis in Chronic Hemodialysis Patients So-hee Jeong, Jin Ho Hwang, Su Hyun Kim, Jung-ho Shin. *Chung-Ang University Hospital, Seoul, Republic of Korea.*

Background: Fluid overload can be an independent risk factor of cardiovascular events and all-cause death in end-stage renal disease (ESRD) patients on chronic hemodialysis. We performed a retrospective study to investigate whether intermittent control of fluid status decreases the rate of these complications using bioelectrical impedance analysis (BIA).

Methods: In ESRD patients on chronic hemodialysis, we identified the ratio of extracellular water to total body water (ECW/TBW) every 6 months using InBody S10 (Biospace, Seoul, Korea), which was measured within 30 minutes after dialysis initiation on the first dialysis day of the week. The uncontrolled group included 57(40.1%) patients with all ECW/TBW measurements ≥0.40; in contrast, the controlled group included 85 (59.9%) with any measured ECW/TBW <0.40.

Results: Included patients were followed for 29 (12, 42) months. The risk of cardiovascular events was higher in the uncontrolled group (HR 2.4, 95% CI 1.2–5.1; $P < 0.05$) than it was in the controlled group; however, this difference disappeared after adjusting for age, sex, and Charlson comorbidity index (not significant). On the other hand, the patients in the uncontrolled group had a higher risk of all-cause death than did those in the controlled group, independent of age, sex, and Charlson comorbidity index (HR 4.7, 95% CI 1.4 – 16.1; $P < 0.05$).

Conclusions: Monitoring volume status using BIA may help to predict all-cause death in chronic hemodialysis patients. Further controlled studies are needed to confirm that strict volume control could reduce the rates of cardiovascular events and mortality in this population.

PUB303

Increased QRS Width Predicts Mortality in Patients on Maintenance Haemodialysis Tony Amin,[4] Lawrence P. McMahon,[3] Matthew A. Roberts,[1] Md nazmul Karim,[2] Catherine Brumby.[3] *[1]Eastern Health, Blackburn, VIC, Australia; [2]Monash University, Melbourne, NSW, Australia; [3]None, Box Hill, VIC, Australia; [4]Renal, Eastern Heath Service, Melbourne, Melbourne, VIC, Australia.*

Background: Cardiovascular mortality is the leading cause of death in haemodialysis patients. We assessed the association of QRS width and corrected QT interval (QTc) on a 12 lead electrocardiography (ECG) with mortality and cardiovascular events (CVE).

Methods: We analysed ECGs performed as part of routine care between March 2013 and June 2014 in 104 maintenance haemodialysis patients. The QRS and QTc duration were calculated by the ECG software and recorded. All-cause-mortality and CVE were determined between December 2013 and December 2015. CVE was defined as a new acute coronary syndrome and or sudden cardiac death. Predictors of mortality and CVE were identified through univariate association and were confirmed by multivariate logistic regression, thus adjusting for possible confounders.

Results: During the 2-year follow-up, 24 deaths and 19 CVE occurred. Patients who died had a significantly higher QRS (119.1 ± 30.8 msec) than patients who survived (99.6±25.0 msec; P=0.002). Similarly, patients with CVE (121.7±35.6 msec) had significantly higher QRS than patients with no CVE (100.1±23.9 msec; P=0.002). QTc Duration did not differ significantly across death or CVE status. The odds of all-cause mortality (OR 1.026, 95% CI 1.006,1.047; p=0.012) and CVE (OR 1.028, 95% CI

1.005,1.051; p=0.016) were increased for each msec increase in QRS width, adjusted for age, gender, duration on dialysis, coronary artery disease status, diabetes status and urea reduction rate (URR).

Conclusions: Prolonged QRS is significantly associated with all-cause mortality and cardiovascular events in patients receiving maintenance haemodialysis.

PUB304

Stakeholder Priorities for Cardiovascular Outcomes for Trials in Hemodialysis Emma O'Lone,[4,7] Andrea K. Viecelli,[1] Martin Howell,[6] Allison Tong,[2] Jonathan C. Craig,[5] David C. Wheeler.[3] *[1]Sir Charles Gairdner Hospital, Perth, NSW, Australia; [2]The University of Sydney, Sydney, NSW, Australia; [3]University College London, London, United Kingdom; [4]University of Sydney, Sydney, NSW, Australia; [5]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [6]University of Sydney, Sydney, NSW, Australia; [7]Renal Department, Royal North Shore Hospital, Sydney, NSW, Australia. Group/Team: SONG-HD Cardiovascular Disease Expert Working Group.*

Background: Cardiovascular disease (CVD) is life-threatening and critically important for patients on hemodialysis, their caregivers and health professionals but has been measured inconsistently and variably across trials in hemodialysis.

Methods: In an international online survey (available in English, Hindi), participants rated the importance of ten cardiovascular outcomes (derived from a systematic review) on a 9-point Likert Scale, with a score of 7-9 suggesting critical importance. To determine relative importance participants also completed a best-worst scale. Means, medians and proportions were analyzed for each outcome.

Results: In total, 395 participants (including 105 [27%] patients/caregivers) from 51 countries participated. The mean rating and mean preferences scores (both with 95% confidence intervals) are shown in Figure 1 and 2. In absolute terms, all outcomes were rated as critically important (mean score >7), by both patients and healthcare professionals. On relative preference, myocardial infarction was found to be the most important outcome by all stakeholders.

Conclusions: Patients and health professionals identify all cardiovascular outcomes as important but myocardial infarction as the most important outcome to be measured in hemodialysis trials.

Aldosterone and Insulin Resistance: A Vicious Combination in Patients on Maintenance Hemodialysis Hitoshi Minakuchi,[3] Shu Wakino,[1] Hiroshi Itoh.[2] *[1]Keio University, Tokyo, Japan; [2]Keio University School of Medicine, Tokyo, Japan; [3]school of medicine, Keio University, Tokyo, Japan.*

Background: We recently showed that in patients with chronic kidney disease, insulin resistance (IR) is associated with an increase in plasma aldosterone levels (Kidney Int., 2013). However, the role of this association in patients on maintenance hemodialysis has not been determined.

Methods: A total of 128 patients on hemodialysis were enrolled. The associations of plasma aldosterone or insulin resistance with various parameters were examined. Blood specimens were collected after overnight fasting and IR was evaluated by the homeostasis model of insulin resistance (HOMA-IR). We defined the patients both of whose aldosterone and HOMA-IR were above the tertile of each parameter in this cohort as HH group. Various clinical parameters in HH group were compared to those in control group both of whose aldosterone and HOMA-IR were below the median of each parameter.

Results: Aldosterone levels were associated with age, HbA1c levels, HOMA-IR, and plasma levels of albumin, creatinine, potassium, uric acid, and insulin. Multiple regression analysis showed that the HOMA-IR was independently associated with aldosterone levels. Aldosterone levels were also associated with cardiac hypertrophy and with carotid artery stenosis. The HOMA-IR was associated with age, sex, past history of diabetes or dyslipidemia, body mass index, HbA1c, platelet count, hemoglobin, white blood cell count, and Kt/V, plasma levels of total protein, creatinine, uric acid, phosphorus, high-density lipoprotein, triglycerides, and aldosterone. Multiple regression analysis showed that age, sex, uric acid, body mass index, and aldosterone were independent risk factors. The HOMA-IR was associated with cardiac hypertrophy. HH group exhibited more severe cardiac hypertrophy, contractile dysfunction and carotid artery stenosis as compared with control group.

Conclusions: In patients on maintenance hemodialysis, plasma aldosterone levels and insulin resistance are closely interrelated, each of which is associated with cardiovascular tissue damages. The constellation of increased aldosterone levels and insulin resistance is related to severe cardiovascular damages.

PUB306

Geographical Variations of Comorbidities in ESRD Patients Yue Jiao, Marta Reviriego-Mendoza, John W. Larkin, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Patients with end stage renal disease (ESRD) are known to commonly suffer from several comorbidities including anemia, vascular diseases, and diabetes. National benchmarks exist for many comorbidities in ESRD patients, yet geographical profiles have not been defined. We characterized the prevalence of common comorbidities in dialysis patients by geography in the United States and investigated whether geographical variations exist.

Methods: Data from patients treated at Fresenius Kidney Care clinics in 2016 was analyzed. We characterized the 17 common comorbidities in patients: anemia, cardiac dysrhythmias, diabetes, hepatitis, infection, peripheral or arterial vascular disease, congestive heart failure, hyperparathyroidism, chronic obstructive pulmonary disease, pneumonia, ischemic heart disease, myocardial infarction (including cardiac arrest), cerebrovascular disease, cancer (except skin neoplasm), drug or alcohol dependence, HIV/AIDS and gastrointestinal bleed. Patients were stratified according to the number of comorbidities: ≥1, ≥4, ≥8 or ≥12. We calculated the mean, maximum, and minimum percentages of patients with the selected comorbidities within each of the 50 states in the United States.

Results: Data from 246,903 patients was analyzed. Of the 17 comorbidities investigated, we observed nationally that a mean of 91.2% of patients had ≥1 comorbidity (range: 68.2% to 96.4%), 20.9% had ≥4 comorbidities (range: 4.5% to 35.5%) and 0.81% had ≥8 comorbidities (range: 0% to 2.8%). We identified considerable variations in the number of comorbidities affecting patients in differing states. For instance, in West Virginia 35.52% of patients suffered from ≥4 of the comorbidities, while in North Dakota only 4.55% had ≥4 of the comorbidities. For cardiac dysrhythmias, we found that in patients residing in New Hampshire exhibited the highest prevalence (17.9%) and those in New Mexico (4.3%) had the lowest prevalence. Similar disparities were identified among the 17 comorbidities investigated.

Conclusions: Our analysis indicates that profiles of comorbidities affecting ESRD patients vary by geography. These findings may be useful for the development of improved management strategies that account for regional health disparities.

PUB307

Effect of Albumin on the Efficacy of Fluid Removal in Hypoalbuminemic Patients Donia Ahadian,[1] Etienne Macedo,[1] Bethany E. Karl,[1] Ravindra L. Mehta.[2] *[1]University of California San Diego, San Diego, CA; [2]University of California San Diego Medical Center, San Diego, CA.*

Background: Intradialytic hypotension limits adequate fluid removal in hypoalbuminemic patients with acute kidney injury (AKI) or end stage renal disease (ESRD). Intravenous albumin has been used in such patients with varying results.

Methods: We are conducting a prospective cohort interventional study that included 31 patients with albumin levels less than 3 g/dl with AKI or ESRD who required fluid removal with hemodialysis. In this cross-over design patients were randomized to receive 100mL of either 0.9% sodium chloride or 25% albumin intravenously prior to their first dialysis session and alternated between the two solutions until up to 6 sessions. Patients' vital signs and ultrafiltration removal rate were recorded every 30 minutes during dialysis. 116 dialysis sessions were completed in total, 60 received normal saline and 56 received albumin.

Results: Intradialytic hypotension was defined as a decrease in systolic blood pressure by ≥ 20 mm Hg or a decrease in mean arterial pressure by 10 mm Hg. In total, 77 hypotension episodes (48 in saline and 29 in albumin groups) occured in 39 dialysis sessions (20 in saline and 19 in albumin groups). The median total number of hypotension episodes was 2 for saline and 2 for albumin group (p value=0.68). Hypotension occurred 30 minutes after the start of dialysis in saline versus 37 minutes in the albumin groups (p

value=0.81). The median hypotension duration was 45 minutes for saline and 30 minutes for albumin groups (p value 0.32). In the 48 saline hypotension episodes, 24 (50%) were accompanied by hypotensive symptoms, 11 (22.9%) required saline administration, and 16 (33.3%) required the ultrafiltration rate to decrease or to stop as therapeutic interventions. In the 29 albumin hypotension episodes these numbers were 12 (41.4%), 3 (10.3%), and 8 (27.6%), respectively. In albumin sessions more ultrafiltration fluid was removed compared to saline sessions (-2000 mL in albumin versus -1700 mL in saline).

Conclusions: In hypoalbuminemic patients who need hemodialysis, addition of albumin prior to dialysis results in later onset of hypotension, less incident of hypotensive symptoms, fewer hypotension therapeutic interventions such as saline administration or ultrafiltration rate decrease, shorter duration of intradialytic hypotension, and larger volume of fluid removed. However, these results were not statistically significant.

PUB308

Associations of Endothelial Function, Arterial Stiffness, and Heart Rate Variability with Physical Activity Anoop Sheshadri,[3] Piyawan Kittiskulnam,[1] Kirsten L. Johansen.[2] *[1]Chulalongkorn university, Bangkok, Thailand; [2]University of California, San Franicsco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA.*

Background: In the general population, higher levels of PA are associated with lower cardiovascular risk and better endothelial function, but it is not clear whether the association holds at the lower end of the PA spectrum. We sought to determine whether PA is associated with endothelial function and heart rate variability.

Methods: We recruited 55 dialysis patients ≥18 years of age receiving in-center hemodialysis (HD, n=47) or peritoneal dialysis (PD, n=8), on dialysis for ≥3 months and able to walk. We measured PA by pedometer. We tested endothelial function (reactive hyperemia index or RHI), using the EndoPAT-2000, which measures flow-mediated dilation after a 5-minute arterial occlusion, and also measures arterial stiffness (augmentation index adjusted to heart rate of 75 or AI75), and heart rate variability (standard deviation of NN intervals or SDNN). All measurements were taken before HD sessions for those patients on HD.

Results: Participants' median age was 58 years and 80% were male. Overall, PA was low at 2631, IQR 1361-5176 steps per day. RHI was impaired for the group as a whole (median RHI and IQR 1.57, 1.34 – 1.87), as was SDNN at 20.55, IQR 12.55 – 31.92. AI75 was not substantially impaired at 11, IQR -2 – 22%. After adjusting for age and sex, PA was not statistically significantly associated with endothelial function, augmentation index, or heart rate variability, despite positive associations in the general population and other populations with chronic disease. Adding vintage, diabetic status, and coronary artery disease status to the model did not affect this association.

Conclusions: It is likely that other factors beyond PA dominate in contributing to less traditional cardiac risk factors such as endothelial dysfunction and heart rate variability in patients treated with dialysis, although it is also possible that the majority of patients occupied too low a stratum of PA to generate a meaningful association.

PUB309

The Relation between Fibroblast Growth Factor 23, Cardiovascular Risk, and Body Composition in Patients Undergoing Hemodialysis Marta Olszewska, Krzysztof Hoppe, Krzysztof Schwermer, Malgorzata Kaluzna, Ewa Baum, Krzysztof Pawlaczyk, Andrzej Oko. *Poznan University of Medical Sciences, Poznan, Poland.*

Background: Fibroblast growth factor 23 (FGF23) is a key player in regulation of bone-mineral homeostasis. Bone mineral disease is associated with negative cardiovascular outcomes in patients with chronic kidney disease. The aim of the study was to assess the relation between FGF23, cardiovascular risk and body composition in patients undergoing hemodialysis (HD).

Methods: This study included a group of 74 HD patients (mean age 62.9±11.8 years, male n=40), divided into 2 subgroups (gr1>1109.88; gr2≤1109.88 [pg/ml]) depending on the median FGF23 value. Serum FGF23 was measured with ELISA. Markers of body composition featured overhydration, adipose and lean tissue mass measured with bioimpedance (BIA, Fresenius BCM). CV injury was assessed with NT-proBNP and troponin T. Other routinely measured laboratory markers featured CRP, hemoglobin, triglicerides, calcium, phosphates (PO4) and PTH. Subjective Global Assessment and Charlson's Comorbidity Score were also carried out. Statistical analysis was performed using Statsoft Statistica 12.5. P-value <0.05 was considered statistically significant.

Results: There were no statistically significant differences in terms of age and sex distribution. The groups differed in terms of residual diuresis (gr1 vs. gr2: 550±800 vs. 150±500 [ml/24h]; p=0.014), HD vintage (2.7±2.7 vs. 5.2±9.2 [years]; p<0.001), NT-proBNP (6130±14056 vs. 9005±30431 [pg/ml]; p=0.040). There were significant differences in PO4 (4.9±1.8 vs. 6.8±2.1 [mg/dl]; p<0.001), ferritin (408.5±840.0 vs. 708.7±674.0; p=0.022) and preHD systolic blood pressure (160±30 vs. 140±35 [mmHg]; p=0.033). FGF23 was correlated with such parameters as: diuresis (r=-0.351, p=0.003), HD vintage (r=0.414, p=0.001), NT-proBNP (r=0.282, p=0.016), PO4 (r=0.658, p<0.001), PTH (r=0.288, p=0.017), and ferritin (r=0.304, p=0.011).

Conclusions: In conclusion, this study seems to confirm the connection between FGF23 and other markers of bone-mineral balance. However, our results may also suggest a potential relation between FGF23 and HD vintage, decreasing residual renal function and it's complications such as iron management dysregulation, blood pressure elevation and cardiac strain. Further research is required to investigate the value of FGF23 as a prognostic marker for patients on maintenance HD.

PUB310

Association between Pre-Dialysis Electrolytes and Incidence of Arrhythmia in Long Interdialytic Interval among Chronic Hemodialysis Patients Kampantong Tangweerapong. *Renal Division, Bhumibol Adulyadej Hospital, Saimai, Thailand.*

Background: End stage renal disease patients have high risk of cardiovascular death. Mortality rate is higher in long interdialytic interval compare to short interdialytic interval and one of the main cause is cardiac arrhythmias.

Methods: A prospective, single-center study was performed among thrice a week-hemodialysis patients without documented arrhythmias to compare the incidence of arrhythmias between long and short interdialytic intervals and determine the associated factors which relate to the events. 24-hour Holter monitoring was done twice in long and short interdialytic intervals within one week. Holter diagnoses were defined by the ACC/AHA guidelines. Patient's baseline data and pre-dialysis serums were collected.

Results: The data analysis of 28 patients who were studied, showed that there were 18 (64.3%) males and 10 (35.7%) females with mean age of 63 years. Non-sustained ventricular tachycardia (VT) was detected in 3 of 28 patients (10.7%) and only occurred in long interdialytic interval. In 8 of 28 patients (28.6%) had higher incidence of overall arrhythmias in long interdialytic interval while the left patients had no significant arrhythmias or no difference of arrhythmias in both intervals. Only male patients had higher incidence of both non-sustained VT and supraventricular arrhythmias in long interdialytic interval. Lower predialysis serum potassium (4.64 ± 0.40 compared to 5.45 ± 1.49, p-value 0.035), lower predialysis calcium (8.26 ± 1.05 compared to 8.95 ± 0.51, p-value 0.027) and lower predialysis serum magnesium (1.91 ± 0.32 compared to 2.34 ± 0.33, p-value 0.004) were found as independent factors for patients who had higher incidence of arrhythmias in long interdialytic interval.

Conclusions: Higher incidences of arrhythmias during long interdialytic interval occasionally occurred in chronic hemodialysis patient. Low serum potassium, low serum calcium and low serum magnesium might be associated factors.

PUB311

30-Day Readmissions in ESRD Patients with Heart Failure Linda-Marie Ustaris, Sandeep K. Mallipattu. *Stony Brook Medicine, Stony Brook, NY.*

Background: The overall number of hospitalizations for ESRD on hemodialysis in 2013 was 1.7 admissions per patient year. Rehospitalization rates for Medicare beneficiaries greater than 66 years old without kidney disease compared to those with ESRD are 15.8% and 34.8%, respectively. This study's objective is to identify the modifiable and non-modifiable risk factors associated with increased readmission rates in ESRD patients.

Methods: 1,534 ESRD patients corresponded to 28,695 encounters with an ICD 9 code for ESRD at a university hospital from 2010-2014. Inclusion criteria: more than one inpatient encounter (admission or ER visit) within a 30-day period. Outpatient, ambulance, and duplicate visits were excluded. Each hospital encounter within 30 days from the last discharge was reviewed for reason for admission: dialysis related (HTN, volume overload, electrolyte abnormality and access complication) or non-dialysis related. Baseline demographics and clinical data were collected, including ejection fraction and the presence of left ventricular (LV) dysfunction on echocardiogram. We calculated the proportion of dialysis related visits within each group. Chi square Fisher's exact test calculated the p-value.

Results: 1,184 ESRD (445 females, 739 male) patients and 4,358 encounters met the inclusion criteria. Average number of encounters per patient year was 0.73, with an unadjusted 30-day readmission rate of 0.56 per patient year. Table 1 shows the association of dialysis and non-dialysis related 30-day readmissions with systolic and diastolic dysfunction. There was no statistical significance (p-value: 0.6) between the type of readmission and the subtypes of LV dysfunction.

Conclusions: Our preliminary data suggests that the presence of both systolic and diastolic dysfunction is associated with more dialysis related encounters compared to those without LV dysfunction.

Funding: NIDDK Support

Visit types in ESRD patients with and without LV dysfunction

	No LV dysfunction	Diastolic LV dysfunction	Systolic LV dysfunction	Both systolic and diastolic LV dysfunction
Sex (Male:Female)	1:1	15:12	8:4	5:3

Peritoneal Dialysis (N=1)	0	1	0	0
Transplant (N=1)	1	0	0	0
# of dialysis related visits (N=196)	27 (14%)	173 (88%)	58 (30%)	63 (32%)
# of non-dialysis related visits (N=210)	37 (18%)	195 (93%)	74 (35%)	82 (39%)
Total Visits (N=406)	64 (16%)	368 (91%)	132 (32%)	145 (36%)

PUB312

Correlation Analysis between GNRI and LVMI, RDW, PDW, and OSTA in Maintenance Hemodialysis Patients Wenbo Zhao,[2] Hui-qun Li.[1] *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Malnutrition was a common condition in maintenance hemodialysis patients and increased mortality. The purpose of this study was to investigate the correlation between nutritional risk index (GNRI) and LVMI, RDW, PDW and OSTA in patients with maintenance hemodialysis

Methods: We enrolled 91 cases of maintenance hemodialysis patients (female 42 cases, male 49cases, dialysis time: 3.31±3.34 years). The nutritional risk index (GNRI) was correlated with the red blood cell distribution width (RDW), the platelet distribution width (PDW), the left ventricular mass index (LVMI), Osteoporosis Self-assessment Tool for Asians (OSTA).

Results: GNRI range (93.87 + 7.92), RDW (0.146 + 0.015), PDW (11.46 + 1.65), LVMI (145.23 + 39.56), OSTA, (0.50 + 3.98). GNRI, with a higher risk of RDW, PDW, LVMI, related to the increase of OSTA level ($P < 0.05$), a higher risk of GNRI and RDW ($r=-0.317$, $P=0.002$), PDW ($r=-0.203$, $P=0.045$), LVMI ($r=-0.201$, $P=0.04$), negative correlation, positive correlation with OSTA ($r=0.353$, $P=0.001$)

Conclusions: For maintenance hemodialysis patients, GNRI was closely related to cardiac function, blood cell morphology and degree of osteoporosis. It was important to evaluate the nutritional status of routine hemodialysis patients for routine GNRI to improve the survival state.

PUB313

Mean Platelet Volume as a Determinant of Abdominal Aortic Calcification Myung jin Choi,[2] Jiwon Ryu,[1] Eun young No.[2] *[1]Cheju Halla Hospital, Seoul, Republic of Korea; [2]Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.*

Background: Mean platelet volume (MPV) is a marker of platelet activation. Increased MPV has been reported with the development of thrombotic events such as coronary artery occlusive disease, cardiovascular mortality and vascualr access failure in chronic kidney disease (CKD) patients. However, abdominal aortic calcification (AAC) is also correlated with cardiovascular events in dialysis patients. The effects of MPV on arterial calcification is not known. This study was designed to determine the predictor for AAA in hemodialysis (HD) patients.

Methods: Eighty-nine chronic HD patients (age 59.7 ± 10.4 years, male 51.7 %, diabetes 53.9 %, mean dialysis duration 48.7± 40.9 months) were enrolled. With collection of clinical and laboratory parameters, ambulatory blood pressure monitoring, ankle-brachial index test with pulse wave velocity, echocardiography and lateral lumbar radiography were performed. Quantitative analysis of AAA score was assessed.

Results: Median AAA score were 4.63 ± 4.6. Patients with AAC score (≥ 1) were found in 71 (79.7 %) patients, and they were older ($p=0.000$) and had longer periods of HD ($p=0.018$). They also showed lower levels of pre-HD diastolic blood pressure (BP) and higher levels of sleep diastolic BP and serum ferritin. AAA score showed a significantly positive association with age, HD vintage, diabetes, previous cardiovascular disease, serum calcium and MPV level in univariate analysis. In the multivariate analysis, AAC score was independently associated with MPV level ($\beta=1.466$, $p=0.032$) as well as HD vintage ($\beta=0.028$, $p=0.008$) and serum calcium ($\beta=1.459$, $p=0.004$).

Conclusions: MPV value, HD vintage and serum calcium level are important determinants of AAC in HD patients. MPV may be a potential marker for prediction of not only atherosclerosis but also arterial calcification in dialysis patients.

PUB314

Relationship of Neighborhood Walkability and Dialysis Patient Characteristics and Outcomes John W. Larkin,[1] Maggie Han,[3] Schantel Williams,[3] Xiaoling Ye,[3] Len A. Usvyat,[1] Peter Kotanko,[3] Franklin W. Maddux,[1] Roberto Pecoits-Filho.[2] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [3]Renal Research Institute, New York, NY.*

Background: Higher levels of physical activity are known to be associated with dialysis patients achieving better outcomes. A recent study identified that neighborhood walkability scores are positively correlated with the mean daily steps walked by dialysis patients (Han M et al. 2017). We aimed to investigate whether there are correlations in walkability scores and an array of dialysis patient clinical characteristics and outcomes.

Methods: We obtained data on Walk Scores (www.walkscore.com) in 10,000 zip codes in the United States (US) and identified dialysis patients treated at Fresenius Kidney Care (FKC) clinics residing in the same zip codes during June of 2016 to May of 2017. The Walk Score measures neighborhood walkability on a scale of 0 (poorest walkability) to 100 (greatest walkability) based on access to key destinations (e.g. grocery stores, restaurants, retail stores). We calculated the correlation coefficients between the walkability score in the zip code of each patient's residence and 56 clinical and non-clinical variables.

Results: We analyzed data from 89,551 FKC patients living in 8,351 zip codes throughout the US. Of 56 parameters investigated, 17 were positively correlated with higher walkability scores. These included higher KDQOL physical composite scores, albumin, and creatinine levels, and lower rates of infection, rates of hepatitis, potassium levels, a younger dialysis vintage, and others (all $p<0.05$). Black, Asian, and Hispanic patients tend to live in areas with higher walkability. We found 23 parameters negatively correlated with walkability scores, including older age and higher prevalence of cardiac diseases and diabetes, as well as higher intradialytic weight gain. Also, a lower adequacy, treatment time, and body mass index was inversely correlated to walkability scores (all $p<0.05$).

Conclusions: These findings indicate that the walkability score where patients reside is related to physical composite scores, disease states, and many clinical markers of optimal patient management. Identification of surrogate measures of physical activity and overall infrastructure could assist in designing geographically specific support systems.

PUB316

Treatment of Dialysis-Related Amyloidosis with Lixelle Weeraporn Srisung,[1] David L. Epstein,[2] Jeffrey I. Silberzweig.[2] *[1]New York-Presbyterian, Weill Cornell Medical Center, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: Dialysis-related amyloidosis (DRA) arises in patients on dialysis, typically for more than 10 years. DRA develops from deposition of amyloid fibrils comprised of beta-2-microglobulin (B2M) primarily in bones and joints of the hips, knees, shoulders, wrists, and spine, but it can also involve visceral organs. In Japan, DRA patients have been treated with Lixelle B2M apheresis columns, which utilize beads with micropores which allow molecules smaller than 30,000 daltons to pass through them. Additionally hydrophobic hexadecyl alkyl ligands on the beads bind B2M. This two-year research trial evaluates the efficacy and side effects of Lixelle in the United States.

Methods: The first US patient treated with Lixelle is a 68 year-old African American man with end-stage renal disease of unclear etiology who started hemodialysis in 1968. A short time later, he underwent bilateral nephrectomy to manage hypertension. He received deceased-donor renal transplants in March 1969, which lasted until February 1970, and in April 1970, which lasted until April 1973. He has been treated by hemodialysis since then except for one year of peritoneal dialysis. He was diagnosed with DRA in 1986. At the time of initiation of Lixelle treatment, he had documented amyloid deposits throughout his body including right shoulder, left hand, colon, small bowel, and buttocks. Due to joint involvement causing weakness, he uses a wheelchair for mobility. He began Lixelle

treatment in August 2016; initial clinical data demonstrated significantly increased removal of B2M with Lixelle (56.7% reduction ratio compared to 27.9% with high flux dialysis alone); he reported reduction in the size of his amyloid deposits. In late April 2017, he developed lightheadedness and hypotension during dialysis. The Lixelle column was held on April 24, 2017. During the course of treatment, his hemoglobin decreased to 9.5 g/dL, and therefore his erythropoietin-stimulating agent dose was increased.

Results:

Conclusions: Our patient started treatment with Lixelle in August 2016 as part of a clinical trial. It is unclear what caused the change in tolerance but the additional extracorporeal volume may contribute to hypotension in predisposed patients. His tolerance of the columns for greater than 7 months suggests that this clinical change is independent of Lixelle.

Low Triiodothyronine Syndrome Is Associated with High Beta 2 Microglobulin in Hemodialysis Patients Hong joo Lee. *Seoul Red Cross Hospital, Seoul, Republic of Korea.*

Background: Low circulating triiodothyronine (T3) levels, known as the low T3 syndrome, are the most frequently encountered thyroid functional test derangement in end-stage renal disease (ESRD) patients on hemodialysis. Beta-2 microglobulin (β2M) is a prototypical middle molecule uremic toxin that associate with a higher mortality in hemodialysis patients. Hence, we conducted a study to elucidate the interacting factors between β2M and a low T3 level in ESRD patients on hemodialysis.

Methods: All hemodialysis patients in Red Cross Hospital within a period of one year were included in the study. The participants were divided into two groups based on the level of T3. We evaluate relationships between T3 level and the variables showing malnutrition, inflammation, comorbidity, and β2M. Statistical analysis was carried out by using SPSS.

Results: Among the 56 cases, 44.6% of the patients had the low T3 syndrome. The patients with the low T3 syndrome had lower weight and body mass index (BMI) than the patients with normal T3 level. In addition, the T3 level was associated significantly with the level of ferritin, total iron-binding capacity (TIBC) and albumin/globulin (A/G) ratio. We observed a negative correlation between the level of T3 and β2M. However, blood urea nitrogen, creatinine, and lipid profiles including total cholesterol, high density lipoprotein and low density lipoprotein cholesterol, and triglyceride were not related to the level of T3.

Conclusions: Therefore, the intensive hemodialysis for clearing β2M may have an advantage for normal T3 in hemodialysis patients.

PUB318

Lowest Attainment of Guideline Targets Is Associated with Higher Morbimortality in European Haemodialysis Patients (EURODOPPS) Sophie Liabeuf,[4] Ayesha Sajjad,[1] Brian Bieber,[3] Keith McCullough,[3] Ronald L. Pisoni,[3] Fergus J. Caskey,[5] Christian Combe,[6] Bruce M. Robinson,[3] Kitty J. Jager,[1] Ziad Massy.[2] *[1]Academic Medical Center, Amsterdam, Netherlands; [2]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [3]Arbor Research Collaborative for Health, Ann Arbor, AL; [4]Clinical research center Amiens University hospital and INSERM U1088, Amiens, France; [5]UK Renal Registry and University of Bristol, Bristol, United Kingdom; [6]CHU de Bordeaux, Bordeaux, France.*

Background: Haemodialysis patients experience a wide variety of intermediate complications, such as anaemia, hypertension and mineral bone disease (MBD). We aimed to compare survival and hospital admissions in patients according to the simultaneous attainment of different guideline targets (hypertension, anaemia and MBD) in a large European cohort of dialysis patients.

Methods: EURODOPPS is part of DOPPS, an international, prospective cohort study of adult, in-centre haemodialysis patients, with clinical data extracted from patient records. For this analysis, 6317 patients from seven European countries were included between 2009 and 201. Quality of guidelines target attainment was considered high if 4 or 5 targets of the 5 evaluated targets were attained, moderate if 2 or 3 targets were attained and low if 0 or 1 target were attained (Table1). Fully adjusted multivariate Cox models investigated the relationship between quality of guideline targets attainment and mortality or first hospital admission.

Results: At baseline, attainment of guidelines was considered as low in 1751 (28%) patients, moderate in 3803 (60%) and high in 763 (12%) patients. In the fully adjusted model using time dependent covariates, low attainment was associated with higher all-cause mortality (Table 2) and with higher risk of hospitalizations (HR = 1.20; 95% CI, 1.11 – 1.30), whereas high attainment was only associated with lower all-cause mortality (Table 2) and not with risk of hospitalization (HR = 1.09; 95% CI, 0.96 – 1.23).

Conclusions: Given the large proportion of patients with low attainment, we may argue that amelioration of guidelines application could improve patient outcomes.

Table 1: Definition of clinical targets, clinical biochemical targets

	Targets
CKD-MBDs	1. A serum phosphate level between 3.5 and 5.5 mg/dl 2. An intact PTH level between 150 and 600 pg/ml 3. A serum calcium level between 8.4 and 10.2 mg/dl
Hypertension	4. A mean of three blood pressure measurements <140/90 mmHg (pre-HD) and <130/80 mmHg (post-HD)
Anaemia	5. A serum Hb level between 11 and 12 g/dl

Table 2 : Association between quality of guidelines attainment and mortality during the study follow up

Target attainment	Baseline No. of observations=6315 HR (95% CI)	Time-varying covariates No. of observations=33,881 HR (95% CI)

The Non-Calcium Based Phosphate Binder Ferric Citrate May Increase Serum Calcium in Patients on Hemodialysis (HD) Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Tayo Kawazu,[1] Osamu Sasaki,[1] Hiroshi Ichinose,[1] Kenji Sawase,[1] Makiko Yamashita,[1] Yoko Obata,[2] Tomoya Nishino,[2] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki University School of Medicine, Nagasaki, Japan.*

Background: Hypercalcemia caused by calcium overload is associated with mortality and cardiovascular disease in HD patients, and recent studies reported reduction in mortality with non-calcium-based phosphate binders compared with those with calcium-based phosphate binders. We therefore conducted a study to compare ferric citrate and other non-calcium based metal-type phosphate binders for their serum calcium profiles.

Methods: After informed consent was obtained from all subjects, they were adequately informed about the 3 different non-calcium based metal-type phosphate binders to be studied, i.e. lanthanum carbonate, sucroferric oxyhydroxide and ferric citrate, and were asked to choose between these reagents. Relevant serum parameters including calcium were monitored during 16-week follow-up. Their concomitant dosing of calcium basedphosphate binder, vitamin D and HD were not altered.

Results: Thirteen subjects were enrolled in the lanthanum carbonate group, 7 in the sucroferric oxyhydroxide group and 16 in the ferric citrate group. As shown in figure, the serum calcium level was significantly increased only in the ferric citrate group after 8 weeks of treatment.

Conclusions: Of the two intestinal calcium absorption processes involved, an active transcellular process and a passive paracellular process in the small intestines, enhanced calcium chelation and permeation by ferric acid may explain our results.

PUB321

Relationship Between Vascular Access (VA) Performance Evaluated with a Triage System and Clinical Events in Haemodialysis (HD) Maria luisa Muci,[1] Silverio Rotondi,[4] Lida Tartaglione,[3] Sandro Mazzaferro.[2] *[1]Policlinico Umberto I Roma, Roma, Italy; [2]Sapienza University of Rome, Rome, Italy; [3]sapienza university of rome, Rome, Italy; [4]Nephrology and Dialysis Unit, ICOT hospital, Polo Pontino, Sapienza University, Rome, Italy*.

Background: VA type and performance affect morbidity and mortality in HD. Routine does not allow standard monitoring of VA. We developed a system of VA triage to be representative of average monthly performance. We evaluated the relationship between VA triage and clinical events

Methods: In any session of every patient, nurses report weights, BP, HR, Blood flows, VA pressures, symptoms, clots and, monthly, KT/V. Records generate a score that, according to thresholds, triages the VA as Green (G), Yellow (Y) or Red (R). We retrieved clinical events (admissions and deaths) of those patients whose VA had been triaged for >3 months in the period between 1/1/2014 and 12/31/2016. For each patient we considered the average triage during the whole available follow-up.

Results: We followed 131 patients (78 AVF and 52 CVC) for 21±11 months and recorded 18 deaths and 217 hospital admissions lasting 19±30 days. Prevalence of events was greater in CVC *vs* AVF patients (83% vs 78%, X^2=4,6; p<.05). For statistical purposes, given the unbalanced distribution of triage (70 G; 52 Y; 8 R), we merged the two pathologic classes (Y+R). The incidence rate of events was lower in the G group (1,9/1000 pt/days vs 4,0/1000 pt/days; p<.001)(tab. 1) as compared to the Y+R group, despite similar age, dialysis vintage and diabetes. We confirmed this difference in the two VA subroups (AVF: G=1,1 events/1000pt/days vs Y+R=3,4 events/1000 pt/days; p<.001; CVC (G=2,9 events/1000 pt/days vs Y+R=5,5 events/1000 pt/days; p<.001), separately. CVC patients with G triage had lower death rates than those with the Y-R triage (8% vs 33%; X^2=3,9; p<.05).

Conclusions: We confirm the different impact of VA type on morbidity. Our Triage system allowed to identify patients at increased risk of any clinical event independently of VA type. In patients with CVC VA triage also identifies cases at increased risk of mortality. Our triage is simple and reliable as a sensor of VA performance and labels patients at increased clinical risk.

Long-Term Competing Risk for ESKD and Death in a Large Austrian Cohort Emanuel Zitt,[1,2] Constanze Pscheidt,[3] Reinhard Kramar,[4] Raphael S. Peter,[3,5] Hans Concin,[3] Jan Beyersmann,[5] Karl Lhotta,[1,2] Gabriele Nagel.[3,5] *[1]Academic Teaching Hospital Feldkirch, Feldkirch, Austria; [2]VIVIT, Feldkirch, Austria; [3]aks gesundheit GmbH, Bregenz, Austria; [4]Austrian Dialysis and Transplant Registry, Kematen, Austria; [5]Ulm University, Ulm, Germany*.

Background: Knowledge of metabolic risk factors for end-stage kidney disease (ESKD) in the general population is limited, especially when considering the competing event death before ESKD in risk analysis. Aim of our study was to investigate competing risks for ESKD and death in a large general population-based cohort with long-term follow-up.

Methods: In this prospective, longitudinal observational study participants were recruited between 1988 and 2005 within a community-based health monitoring and prevention program (VHM&PP) in the Austrian state of Vorarlberg. This cohort was linked to the Austrian Dialysis and Transplant Registry and the Vorarlberg Mortality Registry. Every adult above the age of 20 years was invited to participate in the program after providing written informed consent. 177,255 participants (53.8% women; mean age 42.5 (SD 15.4) years) were included. Body mass index, fasting blood glucose, systolic and diastolic blood pressure, total cholesterol, triglycerides and γ-glutamyltransferase (GGT) were determined as continuous and obesity, diabetes mellitus, hypertension, hypertriglyceridemia, hypercholesterolemia and GGT elevation as categorized variables. We calculated the risk for ESKD and death applying cause-specific Cox proportional hazards models and subdistributional regression models.

Results: Over a mean follow-up of 16.0 years 358 participants reached ESKD (38% women) and 19,512 participants died. In the fully adjusted cause-specific risk models (HR, 95% confidence interval) diabetes mellitus (4.62, 3.54 -6.03), hypertension (2.89, 2.22-3.77), hypertrigylceridemia (2.08, 1.32-3.28) and hypercholesterolemia (1.61, 1.29-2.00) were associated with a higher risk for ESKD than for death, whereas elevated GGT was associated with an increased all-cause mortality risk (1.49, 1.44-1.54). Subdistribution models supported cause-specific findings.

Conclusions: Components of the metabolic syndrome are associated with a higher risk for ESKD than for its competing event death in a large general population-based cohort of middle-aged adults, whereas elevated GGT levels indicate a higher risk for all-cause mortality. These findings might help improve the design of renal risk factor modification trials and kidney disease awareness and prevention programs in the general population.

PUB323

Elevated Outdoor Temperatures Are Associated with Increased Mortality and Hospitalization Events among Hemodialysis Patients in Northeastern US Cities Richard V. Remigio,[3,5] Alice Topping,[4] Jochen G. Raimann,[4] Peter Kotanko,[4] Franklin W. Maddux,[2] Patrick Kinney.[1] *[1]Boston University School of Public Health, Boston, MA; [2]Fresenius Medical Care, Waltham, MA; [3]Maryland Institute of Applied Environmental Health, School of Public Health, University of Maryland, College Park, College Park, MD; [4]Renal Research Institute, New York, NY; [5]Epidemiology & Biostatistics, Dornsife School of Public Health, Drexel University, Philadelphia, PA.*

Background: Few studies have focused on the effects of heat-related stress on populations living with chronic diseases, more specifically end-stage renal failure. In this work, we sought to examine the effects of weather conditions on mortality and hospitalization risks among hemodialysis patients treated at Fresenius Medical Care North America (FMC-NA) clinics in Boston MA, New York, NY, and Philadelphia, PA.

Methods: Time-stratified case-crossover analyses were applied to estimate short-term effects of weather on mortality and hospitalization using maximum air and heat index daily temperatures for each city. We considered same-day and one-day lag (before reported event) exposures on patients receiving treatment between 2001 and 2012. We accounted for varying rate denominators inherent with a dynamic cohort. Extreme heat was categorized with respect to upper percentiles of temperature and tested to determine risk.

Results: One-day lag heat wave events (above 97.5th percentile) exhibited statistically significant (p<0.05) associations with mortality across all three cities (Fig 1A). We estimated a 55- to 98-percent increase in the risk of death among patients within a day of a heat wave event. Same-day extreme heat exposures also had a significant effect on mortality rates in Boston and NYC (Fig 1B). On hospitalization, we found that increasing air temperatures had a positive, however modest, effect in all three cities. Extreme heat events demonstrated a null association with hospitalization events.

Conclusions: Heat effects on the mortality and hospitalization of hemodialysis patients varied among the three urban areas. However, extreme heat may have an effect on hemodialysis patients residing in Northeastern USA. The rate of hospitalization does not appear to be associated with extreme heat. Additional factors such as pre-existing co-morbidities and prior infection need to be considered.

Mortality risk estimates for same-day (A) and one-day lag (B) heat waves with respect to location

PUB324

National Trends in Medicare Advantage Insurance Coverage for ESRD Jeffrey Pearson,[1,2] Richard A. Hirth,[2] Marc Turenne,[1] Bruce M. Robinson,[1] Rajiv Saran.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI*.

Background: Nearly all ESRD patients are entitled to Medicare coverage, but they have been restricted to traditional fee-for-service (FFS) and barred from Medicare Advantage (MA) health plans, with the exception of beneficiaries who develop ESRD while already in MA. Outside ESRD, the MA program has grown dramatically over the last decade and now covers almost one in three Medicare beneficiaries. Beginning in 2021, the 21st Century Cures Act will allow ESRD patients to join any MA health plan. This study examines recent trends in MA and ESRD.

Methods: USRDS data were analyzed to identify Medicare beneficiaries who had developed ESRD from 1996-2015. MA enrollment at ESRD onset and at one year was obtained from the Medicare Enrollment Database. Multivariate logistic regression was used to identify predictors of MA at incidence (compared to FFS) and predictors of MA beneficiaries switching from MA to FFS.

Results: Out of 1,337,786 patients with Medicare coverage at ESRD onset, 19% were in MA (12% of age <65, 22% of age ≥65). A 2005 change to the Medical Evidence Form (CMS-2728) added MA as a prior insurance choice but since 2006 only 43% of MA enrollees were reported as MA. Patients in MA were more likely to be older, male, black, Hispanic/Latino, and have diabetes as cause of ESRD. At one year after ESRD onset, 28% of MA patients had died, similar to FFS. Among those still alive, 13% have switched to FFS (15% of age <65; 12% of age ≥65). Those more likely to switch to FFS were young, female, from racial/ethnic minorities and with diabetes as cause of ESRD.

Conclusions: Consistent with increasing use of MA in the general Medicare population, an increasing number of patients have MA at the onset of ESRD. Most patients in MA at ESRD onset who survive to one year remain in MA. Patients in MA differ from patients in FFS, and thus any comparisons will need to be risk-adjusted. Policy changes promote additional use of MA for the ESRD population; future research should examine the effect MA plans can have on access, quality, cost, and health outcomes.

PUB325

Demographics and Hospitalization Rates of Dialysis Patients Prescribed the Ten Most Common Drugs Tommy C. Blanchard,[1] Yue Jiao,[1] David A. Hart,[2] Savannah R. Clary,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]FreseniusRx, Franklin, TN.*

Background: End stage kidney disease patients commonly suffer from multiple comorbidities and are on average prescribed 12 concomitant medications. We aimed to identify the most common drugs prescribed to dialysis patients, and characterize the patient demographics and hospitalization rates by medication type.

Methods: We analyzed data on all dialysis patients treated at Fresenius Kidney Care clinics as of December 2016, and located the ten most common drugs. We then characterized patient demographics by analyzing age, body mass index (BMI), vintage, gender, and hospital admission rate in each drug group and compared them to the whole patient population.

Results: We studied data from 170,560 dialysis patients. We found that the ten most commonly prescribed drugs were: sevelamer carbonate, aspirin, cinacalcet, calcium acetate, amlodipine, carvedilol, atorvastatin, hydralazine, gabapentin, and furosemide. Patients taking aspirin and atorvastatin were the oldest, with a median age of 66. Patients taking cinacalcet had the longest median vintage (4.8 years, compared to 3.1 in the whole population). Hospital admission rate was the lowest for patients taking carvedilol (2.68 per patient year (ppy)) and furosemide (2.96 ppy), and was the highest for those taking hydralazine (4.06 ppy).

Conclusions: Our results indicate that patients on certain medications may have increased hospitalization rates. This worsened morbidity is likely due to indication, yet appears useful for pinpointing patients that might require more attention. More analyses to identify a potential connection between medication utilization and outcomes are warranted.

Changing Burden of Comorbidities Over Last 20 Years among Incident US Hemodialysis Patients and Rate of First-Year Mortality Jennifer L. Bragg-Gresham,[4] Keith McCullough,[1] Rita L. McGill,[3] Kevin He,[2] Rajiv Saran.[4] *[1]Arbor Research Collaborative for Health, Ann Arbor, AL; [2]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [3]University of Chicago Medicine, Chicago, IL; [4]University of Michigan, Ann Arbor, MI.*

Background: Mortality among HD patients during their first year of renal replacement therapy remains very high, although there is a trend toward declining death rates in recent years. We sought to determine the potential impact of changing patient characteristics and comorbidity burden at initiation of HD on first-year mortality, over the last 20 years.

Methods: A total of 1,885,074 first-time incident HD patients between January 1996 and December 2015 were included and analyzed by year of HD initiation. Age, race, ethnicity, sex, and comorbid conditions were taken from the Medical Evidence Form (MEF), collapsing diabetes and cardiac diagnoses into single variables to align data between the 1995 and 2005 MEF. Cox models, stratified by year, were run to determine the association between each comorbid condition and mortality. The dot product of these model estimates and the means of each covariate by year were used to calculate the log hazard ratios associated with demographic and comorbid differences, versus the reference year 1996. Follow-up was censored at 1 year.

Results: Cardiovascular disease (CVD), stroke, cancer, diabetes (DM), lung disease, and peripheral vascular disease (PVD) showed little change in their impact on mortality over time. Compared to 1996, the aging of the HD population increased the first-year mortality risk 8%, which slowed after 2002. Although the prevalence of hypertension (HTN) rose from 68% to 88% during this period, this increase was associated with lower log hazards of first year mortality over time (HR=0.67, p<0.0001), which drove the overall mortality trend downward.

Conclusions: Increasing age of incident HD patients was associated with an increased risk of first-year mortality, but risk associated with comorbid conditions decreased over time, especially for HTN. The overall risk of first-year mortality decreased from 2010 onwards, suggesting improving health status of incident HD patients over time, which may help explain decreasing first-year mortality rates over the past 2 decades.

PUB327

Sucroferric Oxyhydroxide: A Novel Phosphate Binder Only or Something More? Ioannis Griveas.[1,2] *[1]PRIVATE DIALYSIS UNIT "NEFROIATRIKI", ATHENS, Greece; [2]NEPHROLOGY, 417 VETERANS ARMY ADMINISTRATION HOSPITAL OF ATHENS, ATHENS, Greece. Group/Team: Private Dialysis Unit "NEFROIATRIKI".*

Background: Hyperphosphatemia is a hallmark of advanced chronic kidney disease (CKD). A majority of chronic dialysis patients have also hyperparathyroidism. Different biochemical abnormalities of metabolic bone disease (MBD) have been associated with anemia in hemodialysis (HD) patients. This study was aimed to investigate sucroferric oxyhydroxide (PA21) in terms of efficacy and safety in HD patients with MBD and to assess the relationship between phosphate control, nutrition, anemia, lipids and a set of metabolic bone disease biomarkers in a cohort of adult patients with advanced dialysis-dependent CKD.

Methods: In this study HD patients with hyperphosphataemia were received PA21 for 10 months. The primary outcome was estimation of serum phosphate concentration at the end of treatment. Secondary outcomes were monitoring of haematocrit (Hct), hemoglobin (Hb), corrected serum calcium, albumin, cholesterol, triglycerides, intact-parathyroid hormone (PTH) concentrations. Ferritin levels were monitored also. Adverse events were evaluated.

Results: 31 HD patients were enrolled with mean age 61. 35 years (range: 35-87). 9 patients were naïve regarding phosphate medication, 18 were receiving sevelamer before and 4 lanthanum. All of the patients were taken 2-3 pills of PA21. 6 patients were withdrawn. We noticed significant reduction of the phosphate levels from the first month (from 6.54±1.27 to 5.05±1.01 mg/dl, p<0.05). This trend carried out until the end (4±0.90 mg/dl, p<0.05). PTH levels significantly reduced (PTH at first 698±564 pg/ml, 6th month 433±409 pg/ml, p<0.05) which carried out until the end (383±115 pg/ml). Ferritin levels remained stable. 2 months since the beginning we noticed increase of Hct (35.9% vs 37.41 %, p=0.097) until the end (37.47%). Cholesterol levels tended to reduce (175±34 mg/dl beginning vs 160±15 mg/dl, at the end, p=0.213). Albumin and triglycerides levels remained stable. Calcium levels had also unremarkable differences.

Conclusions: In conclusion, sucroferric oxyhydroxide is a valuable treatment option for hyperphosphataemia in CKD patients on dialysis, providing an effective and generally well tolerated noncalcium-based phosphate binder therapy and the potential for improved treatment adherence in MBD in general. Apart from that, it seems that it helps HD patients holistically since it favours stability of Hct and nutrition improving lipids parameters at the same time.

PUB328

Association between Estimated Glomerular Filtration Rate Equations at Hemodialysis Initiation and Survival in Chinese ESRD Patients YING LIU. *nephrology, The First Affiliatied Hospital of Dalian Medical University, Dalian, China. Group/Team: CHDSE study.*

Background: Accurate estimating glomerular filtration rate (GFR) is one of the important indicators in assessment of dialysis initiation. There are several commonly used GFR estimating equations, while no equation is considered superior for assessing the initiation of dialysis in Chinese end stage renal disease (ESRD) patients. This study aims to examine the association between estimated GFR (eGFR) at the time of hemodialysis initiation and survival using different estimating equations in Chinese ESRD patients.

Methods: 1997 patients with ESRD, commenced hemodialysis between 2008 and 2015 from 24 hemodialysis centers all around mainland China, were enrolled in the study. The eGFR at the initiation of hemodialysis were calculated by the Cockcroft and Gault (CG), the Modification of Diet in Renal Disease (MDRD), Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) and the Chinese-MDRD (C-MDRD) equation. The cohort was respectively grouped by tertiles according to the eGFR calculated by four equations.

Results: The greatest agreement was between the GFR estimated by the CG and CKD-EPI equations with the difference of 0.6 ml/min/1.73m^2 (limits of agreement=-1.1-2.2 ml/min/1.73m^2), and the closest was between the MDRD and CKD-EPI equations, with the difference of 2.6 ml/min/1.73m^2 (limits of agreement=-1.5-6.7 ml/min/1.73m^2). The agreement between the GFR estimated by C-MDRD, MDRD and CKD-EPI equations was similar. After adjustment for age, sex, diabetes mellitus, signs and symptoms at the initiation and laboratory data, there were no significant difference in survival between eGFR tertiles calculated by CG, MDRD, CKD-EPI and C-MDRD.

Conclusions: There were differences between GFR estimated by C-MDRD and other three equations for the assessment of hemodialysis initiation. eGFR at the initiaition of hemodialysis was not associated with patient survival no matter which estimating equation was used.

PUB329

Analysis of Factors Regarding Life Prognosis at the Time of Dialysis Initiation among Late-Stage Elderly Patients Starting Hemodialysis Tsutomu Inoue, Ono Atsushi, Koji Tomori, Hirokazu Okada. *Saitama Medical University, Iruma-gun, Saitama, Japan.*

Background: The life prognosis of elderly patients after the initiation of dialysis is not always favorable. Predictive indicators for prognosis provide valuable information for patients and their families when making decisions regarding the initiation of dialysis. The purpose of this study was to investigate the factors regarding life prognosis at the time of dialysis initiation among late-stage elderly patients aged 75 or over starting hemodialysis.

Methods: A single center, retrospective, observational study was conducted. A total of 91 late-stage elderly patients (the mean age: 80.4±1.41 years; the mean observation duration of dialysis: 34.1±24.7 months) who received hemodialysis at our hospital during the period from April 1, 2011 to March 31, 2014 were included in the study. Examination items included age, sex, blood tests at the time of dialysis initiation, ADL at admission and discharge, family structure, as well as all the physical, social, and medical factors.

Results: During the follow-up, 31 patients died (causes of death by fatalities: sepsis, heart disorder, and cancer). With time to death being taken into consideration, a multivariate analysis was performed to identify factors of death using a Cox proportional-hazards model. The followings were found to be significant independent factors: ADL at admission (aHR: 0.36; 95% CI : 0.17~0.73), emergency dialysis initiation (aHR: 3.54; 95% CI: 1.36~6.85), and history of ischemic heart disease (aHR: 2.80; 95% CI : 1.38~5.68) as social and physical factors; serum albumin (aHR: 0.47; 95% CI : 0.282~0.78) and serum phosphorus (aHR: 0.72; 95% CI : 0.54~0.95) as laboratory values at the time of dialysis initiation. In a model wherein the above-mentioned 5 factors as well as age and sex were defined as independent factors, ADL, serum albumin, and serum phosphorus were statistically significant.

Conclusions: ADL independence and nutritional status at the time of dialysis initiation were considered to be independent factors regarding life prognosis after dialysis initiation among late-stage elderly patients. These results suggest that a prospective study is required to further investigate the relevant factors in the future.

PUB330

Efficacy and Safety of Ferric Citrate in Hemodialysis Patients: A 2-Year Retrospective Cohort Study Kazunori Yamada,[5] Mizuho Wada,[3] Minoru Kaneko,[3] Toru Shibata,[3] Satoshi Hara,[4] Ichiro Mizushima,[5] Hiroshi Fujii,[1] Remon Otake,[3] Akira Junicho,[3] Masatsune Hasegawa,[3] Mitsuhiro Kawano,[2] Mikio Namiki,[3] Toru Hasegawa.[3] *[1]Division of Rheumatology, Department of Internal Medicine, Kanazawa University Graduate School of Medicine, Kanazawa, Kanazawa, Japan; [2]Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan; [3]Hasegawa Hospital, Toyama, Japan; [4]Kanazawa Graduate School of Medicine, Kanazawa, Japan; [5]Kanazawa University Graduate School of Medicine, Kanazawa, Japan.*

Background: Long-term effects of ferric citrate (FC) in hemodialysis patients (pts) have not been studied. We evaluated the efficacy and safety of FC in hemodialysis pts.

Methods: We enrolled 132 Japanese hemodialysis pts who underwent HD between July 2014 and October 2016, categorized into two groups: FC group (FCG, n=30) and non-FC group (non-FCG, n=102). All FCG pts discontinued intravenous iron use after FC treatment. Baseline clinical data were obtained between July and September 2014. We retrospectively analyzed serum phosphorus (P), iron, ferritin, hemoglobin (Hb) levels, and the dose of erythropoietin stimulating agent (ESA), which was calculated as darbepoetin a. Bowel movement (BM) disorders were evaluated using Constipation Scoring System (CSS).

Results: Baseline demographics showed that FCG pts were significantly older (60.9 ± 2.7 vs. 66.0 ± 1.3, P=0.020), had a higher serum P level (6.0 ± 0.3 vs. 5.4 ± 0.1, P=0.015), and lower ferritin level (63.6 ± 14.6 vs. 113.1 ± 15.4, P=0.008) compared to non-FCG pts. After FC treatment, serum P level did not significantly differ. Serum ferritin level after 24 weeks (wks) was significantly higher in FCG than in non-FCG (104 wks; 158.7 ± 37.1 vs. 86.5 ± 11.8, P<0.001). Baseline Hb level in both groups was almost the same; however, Hb level in FCG became significantly higher than in the non-FCG between 24 and 72 wks, without a change in the non-FCG. The ESA dose in FCG was significantly lower than in the non-FCG after 24 wks (104 wks; 6.8 ± 1.2 vs. 19.7 ± 1.7, P<0.001), indicating that iron supplied by FC improved anemia, and led to dose reduction of ESA. CSS started to improve at 12 wks in FCG. CSS values at 48, and 104 wks in FCG were significantly lower than in the non-FCG (1.6 ± 0.5 vs. 4.4 ± 0.4, P=0.005, 2.4 ± 0.4 vs. 4.3 ± 0.4, P=0.039, respectively). The most frequent adverse event (AE) was loose stool (n=4). No severe AE was seen.

Conclusions: FC lowered P levels and improved anemia and constipation, indicating that pts with iron deficiency and BM disorder may additionally benefit with use of FC.

PUB331

Effects of a Progressive Inspiratory Muscle Training on Pulmonary Function in Hemodialysis Patients Hsin-Yu Fang, Brett Burrows, Luis M. Perez, Ken Wilund. *University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Pulmonary abnormalities are prevalent in hemodialysis (HD) patients and the increased pulmonary capillary permeability associated with fluid overload may be one of the causative factors of impaired respiratory function. Inspiratory muscle training (IMT) helps improve respiratory performance in other populations, but there are relatively few studies investigating its treatment effects in patients on HD. This pilot study aimed at assessing the efficacy of a progressive IMT intervention on pulmonary function in HD patients.

Methods: Nine HD patients were recruited from two outpatient clinics in central Illinois with spirometry assessments for pulmonary function at baseline and 8 weeks (immediately post intervention). During the 8-week IMT intervention period participants engaged in thrice weekly training sessions during dialysis by progressively increasing both the training duration and resistance of the IMT breathing device.

Results: All nine patients completed the 8-week intervention for a 100% compliance rate. Baseline patient characteristics were (mean±SD): age = 61±12, BMI = 35.8±19.2 kg/m2, 56% male, 56% AA; 56% smoker. No statistically significant difference was found in patient characteristics from baseline to 8-weeks. For pulmonary function, significant decreases were observed in forced expiratory volume in first second (FEV1, from 2.08 ± 0.506 to 2.01 ± 0.460; p = 0.005) and forced vital capacity (FVC, from 2.60 ± 0.762 to 2.36 ± 0.715; p < 0.005), while a significant increase in peak expiratory flow (PEF, from 311 ± 78.3 to 339 ± 67.7; p = 0.007) was also shown. The FEV1/FVC ratio increased significantly (from 0.813 ± 0.094 to 0.873 ± 0.085; p = 0.017) post training, which was attributed to a decreased FVC level as the denominator.

Conclusions: The present study showed no favorable effects of the 8-week progressive IMT intervention on several pulmonary function test parameters. Because fluid overload is associated with pulmonary malfunction in HD patients, whether IMT intervention is preferable to HD patients with better fluid control remains to be tested. Further studies are needed.

PUB332

The Impact of Patient-Centered Pharmacist Care on Pharmacoadherence in Hemodialysis (HD) Patients: A Quasi-Experimental Study Sherine Ismail,[2,3] Abrar F. Al-Subhi,[2] Eman Y. Ahmed,[2] Medhat S. Ahmed,[2] Abdullah H. Almalki,[2] Diane Seger,[4] Andrew Seger,[1] Earl Francis Cook.[3,1] *[1]Brigham and Women's Hospital, Boston, MA; [2]King Abdullah International Medical Research Center, King Saud Bin Abdulaziz University for Health Sciences, Ministry of National Guard Health Affairs, Ministry of National Guard Health Affairs, King Abdulaziz Medical city, Jeddah, Saudi Arabia; [3]Harvard T.H. Chan School of Public Health, Boston, MA; [4]Partners Healthcare System, Somerville, MA.*

Background: Pharmacoadherence is a public health problem in patients with chronic illness (WHO 2003). Non-Pharmacoadherence in HD patients varies from 12.5-98.6%, which leads to poor clinical outcomes. There is a paucity of data determining the influence of pharmacist on pharmacoadherence in our setting; therefore we aim to assess the impact of patient-centered pharmacist care to improve pharmacoadherence in HD patients.

Methods: The study was conducted at king Abdulaziz Medical City from Oct 2016-Apr 2017. Ambulatory HD patients were included if age ≥18 years and on HD for at least 3 months and excluded if they have no mental capacity to participate. Primary outcome is change in pharmacoadherence assessed by medications' self-report vs. records and pre-dialysis serum phosphorus before and after intervention. Secondary outcomes include changes in systolic blood pressure (SBP), glycosylated hemoglobin (A1c), serum low-density lipoprotein (LDL) and prevalence of Medication-related problems (MRPs) pre and post intervention. Pharmacists interviewed patients monthly and intervention (Medication Therapy Management & motivational interview) occurred at month 3 and 5. An estimated sample of 60-77 patients to provide 20-25% change in adherence from 72 %, power of 80% and alpha 0.05. Linear mixed regression analysis was used to assess mean changes in primary and secondary outcomes and Wilcoxon signed-rank test for assessing prevalence of MRPs pre and post intervention.

Results: A sample of 72/ 98 patients recruited. Median (IQR) of age is 59 (47-67.5), males are (52.8%), mean recorded tablets and median (IQR) self-reported tablets are (11.3 ± 5.5) and 7 (5-11) respectively. Mean changes in self-report medications and serum phosphorus were -0.07, 95% CI [-0.36 - 0.22], *p= 0.348 and -0.01 mmol/L, 95% CI [-0.11-0.09], *p =0.68 respectively. Mean change in SBP and A1c were not significant, *p= 0.08 and *0.11 respectively, however mean change in LDL was -0.2154 mmol/L, 95% CI [-0.35 -(-0.08)], *p=0.0016. There were 4.3 MRPs per 7 medications at month 3 vs. 2.27 at month 5 (p=0.0015). (*p for trends)

Conclusions: Patient-centered pharmacist care may improve pharmacoadherence in HD patients. Although it was not statistically significant, it's crucial to identify and mitigate Medication-related problems.

PUB333

Assessing the Microeconomic and Psychosocial Impact of Dialysis for ESRD in Kerala, India Christina L. Bradshaw,[1,2] Shuchi Anand,[1] Noble Gracious,[3] Manjula Kurella Tamura,[1] Glenn M. Chertow.[1] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Centre for Chronic Disease Control, Gurgaon, India; [3]Nephrology, Government Medical College, Thiruvananthapuram, India.*

Background: A diagnosis of end-stage renal disease (ESRD) carries with it significant financial and psychosocial ramifications, especially in low and middle-income countries where social safety nets are typically limited in scope. In the absence of universal insurance coverage, persons with ESRD often have to resort to extreme measures in order to fund their care, frequently without full understanding of their disease trajectory and prognosis. As one of the most rapidly developing nations in the world with large numbers of persons with chronic kidney diseases, India is at the forefront of this issue. Our study aims to understand the financial and psychosocial burdens experienced by South Asians with ESRD, beginning with preliminary findings from the region of Kerala, India.

Methods: We conducted a cross-sectional multi-site study of persons with ESRD on maintenance hemodialysis in Kerala. Using an interview-based questionnaire, we collected data on demographics, dialysis history, understanding of and engagement in therapy and financial status. The microeconomic impact of dialysis will be quantified in terms of distress financing and catastrophic health spending. We will conduct follow-up interviews at 6 months and one year to determine dialysis status and, if applicable, reason(s) for discontinuation. We will aim to determine significant correlates of dialysis withdrawal, with a focus on financial status and psychosocial needs.

Results: We contacted nephrologists at 12 sites across Kerala and are actively recruiting study participants at 3 sites at this time. We are awaiting ethics approval from 4 other sites. To date, 112 patients have been interviewed. We anticipate available baseline data on 600 persons by November 2017.

Conclusions: Economic development and associated lifestyle changes have shifted the burden of disease in low and middle income countries toward non-communicable diseases, including CKD. Understanding generic and region-specific needs of patients with advanced CKD and ESRD will allow for more compassionate care processes, and could help to promote innovation to reduce the burden of CKD and ESRD worldwide.

PUB334

Gender Difference in the Outcomes of Dialysis Dependent Patients Requiring Hospitalization – A Nationwide Analysis Yumeng Wen,[1,2] Di Pan,[1,2] David Mariuma,[1,2] Marcelo X. Hernandez cuchillas,[1,2] Michael Gramuglia,[3] Ira S. Meisels.[1,2] *[1]Division of Nephrology, Department of Medicine, Mount Sinai St. Luke's and Mount Sinai West Hospitals, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Montefiore Medical Center, Scarsdale, NY.*

Background: End Stage Renal Disease (ESRD) is a major cause of worldwide mortality and morbidity. ESRD requiring chronic dialysis is associated with high mortality and morbidity, requiring frequent hospitalization for complications from dialysis and comorbidities. The aim of this study is to determine if gender plays a role with regard to in-hospital outcomes in patients with ESRD on chronic dialysis requiring hospitalization.

Methods: This is a retrospective cohort study using the 2014 National Inpatient Sample, the largest publically available inpatient database in the United States. The inclusion criteria were age>18 years and an ICD-9 CM code for diagnosis of ESRD on chronic dialysis. Patients hospitalized for elective procedures were excluded. The primary outcome was in-hospital mortality. The secondary outcomes were morbidities, as measured by the development of shock and acute respiratory failure, as well as resource utilization including length of hospital stay (LOS) and total hospitalization charges. Analysis was performed by using Stata, version 14.2. Odds ratio (OR) and means were adjusted for the following confounders using multivariate logistic models and multivariate regression models: age, gender, race, Charlson Comorbidity Index, early dialysis in hospital (defined as receiving hemodialysis or peritoneal dialysis within 1 day of admission), primary insurance, hospital region, hospital bed size, household income and admission day.

Results: 934,575 patients with ESRD on chronic dialysis were included in the study. The mean age was 61 years and 47% of patients were female. Female dialysis dependent patients had a reduced in-hospital mortality rate (OR 0.90, p<0.001), lower rates of shock (OR 0.85, p=0.02) and acute respiratory failure (OR 0.85, p<0.001) compared with male patients. There were also a significantly reduced total hospital charges ($69,815 vs $76,025, p<0.001) and a trend in shorter length of hospital stay (6.83 vs 6.95 days, p=0.054) in female patients.

Conclusions: Female patients with ESRD on chronic dialysis requiring hospitalization had lower rates of mortality, shock and acute respiratory failure compared to males. Total hospital charges were also lower in female patients.

PUB335

Association between Physical Activity and Symptoms among Patients on Dialysis Anoop Sheshadri,[2] Piyawan Kittiskulnam,[1] Kirsten L. Johansen.[3] *[1]Chulalongkorn university, Bangkok, Thailand; [2]University of California, San Francisco, San Francisco, CA; [3]University of California, San Franicsco, San Francisco, CA.*

Background: Patients treated with dialysis report very low levels of physical activity (PA) and functional status. Although it is logical to consider that PA might be associated with the heavy burden of symptoms dialysis patients experience, there is little data. We sought to determine whether PA is associated with specific symptoms on a modified version of the Dialysis Symptoms Index (DSI).

Methods: We recruited 55 dialysis patients ≥18 years of age receiving in-center hemodialysis (HD, n=47) or peritoneal dialysis (PD, n=8), on dialysis for ≥3 months and able to walk. We measured PA by pedometer. We administered the DSI, which contains 30 items, each targeting a specific physical or emotional symptom. Patients are asked to report the presence of each symptom at any time during the previous week and if present, report the degree to which the symptom is bothersome on a five-point Likert scale.

Results: Fatigue was the most commonly reported symptom at 71% of patients surveyed, and the most bothersome. After adjusting for age, and sex, PA was inversely associated with the severity of fatigue (-0.24 points per 1,000 daily steps). PA appeared to have a slight negative association with muscle soreness, but this association did not reach statistical significance after adjustment for age and sex. PA did not appear to be associated with insomnia, bone or joint pain, or muscle cramping.

Conclusions: It is possible that improving PA in patients treated with dialysis may improve fatigue, the symptom that is consistently most common and bothersome to patients.

Funding: NIDDK Support, Veterans Affairs Support, Private Foundation Support

Table 1. Linear Regression with Average Daily Step Count (per 1,000 steps) and Specific Symptoms on the DSI

Symptom	Unadjusted (95% CI)	Regression Coefficient adjusted for age and sex (95% CI)
Fatigue ("Feeling Tired" or "Having Low Energy")	-0.26 (-0.47 - -0.05)	-0.24 (-0.47 - -0.10)
Muscle Soreness	-0.09 (-0.18 – 0)	-0.09 (-0.18 – 0.01)
Muscle Cramping	0 (-0.11 – 0.12)	0.02 (-0.10 – 0.15)
Insomnia ("Trouble Falling Asleep or "Trouble Staying Asleep")	-0.07 (-0.29 – 0.15)	-0.13 (-0.37 - 0.93)
Bone or Joint Pain	-0.02 (-0.16 – 0.11)	-0.01 (-0.16 – 0.13)

PUB336

Evaluation of Cognitive Functions in Hemodialysis versus Peritoneal Dialysis Treatment Patients in CKD Aclan Ozder,[1] Zeyneb I. Yüksel salduz,[2] Yelda Deligoz bildaci,[1] Rumeyza Kazancioglu.[1] *[1]Bezmialem Vakif University, Istanbul, Turkey; [2]Bezmialem Vakif University, Istanbul, Turkey.*

Background: Chronic kidney disease (CKD) is the disease characterized by the elevation of serum creatinine which had been described in five stages depending of the levels. Renal replacement therapy is required for the patients in last stage which can be done with kidney transplantation, hemodialysis (HD) or peritoneal dialysis (PD). Impaired cognitive function usually accompanies to worsening kidney functions. In this study our aim is to compare cognitive functions of patients which are on either HD or PD versus healthy control groups.

Methods: Our study group was patients who were on renal replacement therapy with either HD or PD in Bezmialem Vakif University Hospital and Haseki Hospital. Patients who did not know reading or writing, who had visional impairment were excluded. Totally 35 (HD:9, PD: 26) patients had Montreal Cognitive Assesment Test (MoCA) with their demographic properties noted as well as their etiology of CKD. Age and gender matched healthy control group also had MoCA test. We compared results renal replacement therapy group vs control group and the differences between dialysis modalities.

Results: Patients on renal replacement therapy showed a rate of mild cognitive impairment (MCI) as 28,57% compared to 8,57 % in control group (p <0,05). There is no difference found between HD versus PD in terms of MCI (p>0,05).

Conclusions: In our study we found that MCI is more often in patients on dialysis therapy compared to patients who are not. There is no differences of MCI scores in between dialysis modalities. We believe that with larger studies to come, our results will be backed up.

PUB337

Outcomes in Patients with Chronic Renal Disease Undergoing Peritoneal Dialysis versus Hemodialysis Fernando R. Aguilar,[2] Ammar Qureshi,[3] Mark A. Nader,[1] Nesreen Benhamed.[2] *[1]None, Germantown, DC; [2]Internal Medicine, Marshall University Medical Center, Huntington, WV; [3]Internal Medicine, Marshall University, Huntington, WV.*

Background: Renal transplant allows a higher life expectancy for patients with end-stage renal disease(ESRD). However, due to the dearth of renal transplant donors, patients with ESRD are treated with dialysis. The 2 most common modalities for dialysis are peritoneal and hemodialysis. Peritoneal dialysis is cheaper, but its use has declined. Some studies have shown that peritoneal dialysis has a higher adjusted mortality rate than hemodialysis and some have shown otherwise. The aim of this study was to compare the demographics and mortality rates between the patients receiving hemodialysis and peritoneal dialysis.

Methods: Data was extracted from the 2005-2012 nationwide sample (NIS) registries. Patients with a diagnosis of Chronic Kidney Disease and ESRD were included in this study. We compared the comorbidities such as diabetes mellitus and hypertension, all-cause mortality, the length of stay between the 2 groups. Pediatric population and those patients who received both hemodialysis and peritoneal dialysis were excluded. The population with chronic kidney disease was stratified based on their glomerular filtration rates and hence stages based on ICD 9 codes and compared the 2 groups.

Results: The NIS registry showed 2.85 million patients diagnosed with ESRD disease between 2005 and2012. Out of this, 1.07 million received either hemodialysis or a peritoneal dialysis. Patients who were receiving a hemodialysis had a higher mortality rate (4.69%) as compared to those receiving peritoneal dialysis (4.69% vs. 3.28%, p<0.0001; OR= 1.45 (95% CI 1.37-1.54). Mean length of stay in patients receiving hemodialysis was significantly higher than those receiving peritoneal dialysis (7.85+/- 10.69 vs. 6.40+/- 6.89, p< 0.0001). More patients in the earlier stages of chronic kidney disease (CKD stages 1-4) received hemodialysis, while peritoneal dialysis was seen to administered more in those diagnosed with stages V and ESRD.

Conclusions: Our results clearly showed that the all crude mortality rate and length of stay were significantly higher in those patients receiving hemodialysis as compared to those receiving peritoneal dialysis. However, since it was also seen that patients with a later stage of chronic kidney disease were more likely to receive hemodialysis, it could explain the higher mortality associated with hemodialysis.

PUB338

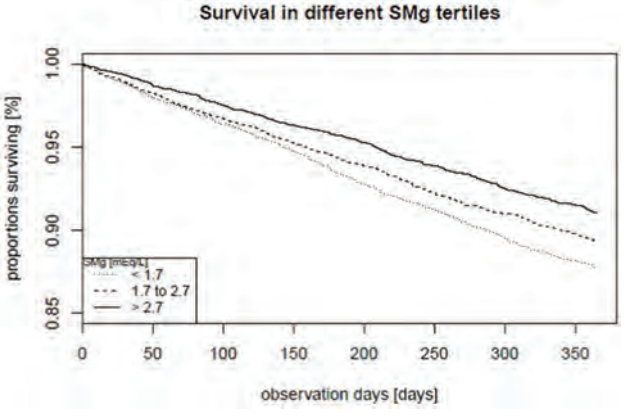
Effects of Dialysate Magnesium Concentration on Serum Magnesium Concentrations and Mortality: A Retrospective Cohort Study of the Monitoring Dialysis Outcomes Initiative Xiaoling Ye,[7] Adrian M. Guinsburg,[2] Cristina Marelli,[3] Bernard J. Canaud,[1] Stefano Stuard,[2] Xiaoqi Xu,[4] Jeroen Kooman,[6] Frank van der Sande,[6] Albert J. Power,[8] Len A. Usvyat,[5] Yuedong Wang,[9] John T. Daugirdas,[10] Peter Kotanko,[7] Jochen G. Raimann.[7] *[1]FMC Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care, Moron, Argentina; [3]Fresenius Medical Care Argentina, buenos Aires, Argentina; [4]Fresenius Medical Care Asia Pacific, Hong Kong, China; [5]Fresenius Medical Care North America, Melrose, MA; [6]Maastricht University Medical Centre, Maastricht, Netherlands; [7]Renal Research Institute, New York, NY; [8]Richard Bright Renal Unit, Bristol, United Kingdom; [9]University of California - Santa Barbara, Santa Barbara, CA; [10]University of Illinois College of Medicine, Burr Ridge, IL. Group/Team: MONDO initiative.*

Background: Serum magnesium(SMg) is known to associate with mortality and lower levels, in particular, are associated with a risk of adverse outcomes (Lacson, AJKD 2015). We investigated the relationship between SMg and all-cause mortality in data from the global MONitoring Dialysis Outcomes Initiative.

Methods: For this analysis, we used data from hemodialysis patients between 2000 and 2012 from the international MONDO database initiative. Following the first available data point on SMg we established a 3 month baseline using averages of included parameters for subsequent analyses, and followed outcomes over one year of follow-up. Survival analyses were conducted after stratification of the entire population into tertiles (G1: <1.7, G2 1.7 to 2.7 and G3 >2.7 mEq/L). Kaplan Meier survival curves, Log Rank test and Cox regression analysis adjusted for age, gender, albumin, catheter and dialysis vintage, were employed for the survival analysis.

Results: We studied 20,362 patients (59.0±16.7 years, 58% males, 70% diabetics, 25% catheter. Uni- and multivariate survival analysis showed significant differences in all-cause mortality between the lowest tertile of serum magnesium and the two higher tertiles (**Figure 1**).

Conclusions: Low SMg associates with worse outcomes as compared to higher levels, even after adjustment for relevant parameters possibly confounding the relationship. Frequent magnesium measurements may be indicated and if levels are found to be low and oral or dialytic magnesium supplementation may be beneficial for some patients. Prospective studies investigating the effects of magnesium supplementation on outcomes are needed.



PUB339

Difference in Mortality in Diabetic Patients Receiving Peritoneal versus Hemodialysis Fernando R. Aguilar,[1] Ammar Qureshi,[3] Mark A. Nader,[2] Nesreen Benhamed.[4] *[1]Georgetown University Hospital, Washington, DC; [2]None, Germantown, DC; [3]Internal Medicine, Marshall University, Huntington, WV; [4]in, MUSOM, Barboursville, WV.*

Background: Diabetic patients (DM) often develop end-stage renal disease (ESRD) requiring renal replacement therapy in the form of hemodialysis (HD) or peritoneal dialysis (PD). Studies comparing the outcomes and difference in in-hospital mortality between these 2 groups are sparse. We set our objective to determine the dialysis modality with a better in-hospital survival rate among diabetics with ESRD (ESRD-DM).

Methods: Data was extracted from the 2005 to 2012 Nationwide Inpatient Sample (NIS). Using propensity score matching, ESRD-DM patients on PD were matched with patients on HD at a 1:1 ratio. Analyses were performed using SAS version 9.3 (SAS Institute, Cary, NC, USA).

Results: Among 586,238 patients with incident ESRD, 568,469(96.97%) and 17,769(3.03%) were initiated on HD and PD, respectively, during the hospitalization. HD-DM patients had a significantly higher in hospital mortality compared with PD, however after matching both groups, it appears PD- DM have a much higher mortality (3.0 % vs 2.52% p<0.0001).

Conclusions: Diabetic patients with ESRD who undergo PD have significantly higher in-hospital mortality, favoring HD as the modality of choice.

PUB340

President Trump's Executive Order 13769: A Nephrology Perspective Scott Reule,[3,2] Mark E. Rosenberg,[2] Paul E. Drawz,[2] Areef Ishani,[1] Robert N. Foley.[2] *[1]None, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN; [3]Medicine, Veterans Affairs Health Care System, Minneapolis, MN.*

Background: With the recent signing of Executive Order (EO) 13769 restricting travel from 7 designated countries, we set out to describe associations between providers originally from the countries designated (EO providers) and clinical outcomes.

Methods: Physician data obtained from AMA Masterfile combined with USRDS and Medicare claims from 2010-2012 was used to determine associations between providers and outcomes including mortality, listing for, and receipt of kidney transplantation.

Results: A total of 8,025 providers cared for 361,454 patients on renal replacement therapy (RRT), with 7,304 patients receiving care from 174 EO providers compared to 346,450 patients receiving care from the remaining providers. Overall, EO providers were less likely to be female (12.5% vs. 25.2%) and more likely to practice in the Midwest (22.2% vs. 18.8%). EO providers delivered care in less densely populated areas, defined as the highest tertile of population density (32.2% vs. 36.3% for non-EO providers; > 3006.4 people/sq. mi.) and in populated areas with lower median household incomes ($44,126 vs. $49,443 for non-EO providers). Patients receiving care from EO providers were younger than 65 years of age (37% vs. 39.5%), more likely receive care > 12 months prior to initiation of renal replacement therapy (27.9% vs. 25.1%), and more likely to utilize peritoneal dialysis (8.9% vs. 7.9%) as a primary modality. At a mean follow up of 5.8 years, 31.4% of the cohort died. Overall, no significant differences in mortality (AHR 0.97; CI 0.87-1.08), listing for kidney transplantation (AHR 0.95; CI 0.88-1.02), or receipt of kidney transplantation (AHR 0.97; CI 0.84-1.11) were found.

Conclusions: EO providers are tasked with the care of patients in less populated, lower income areas with no impact on important clinical outcomes.

Developing an Energy Budgeting Education Program to Improve Fatigue Self-Management in Adults on Chronic Dialysis Janine Farragher,[2,1] Sarbjit V. Jassal,[1,2] Sara Mcewen,[2,3] Helene Polatajko.[2] *[1]University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Background: Fatigue is one of the most common and disabling symptoms found among people with end-stage renal disease on long-term dialysis. Energy budgeting is a novel approach to fatigue self-management, that focuses on strategies such as planning, pacing, and prioritizing to promote optimal use of available energy during everyday tasks. The approach has demonstrated positive effects in other clinical populations, such as multiple sclerosis, but has not yet been tried in the dialysis patient postulation. The objective of this project is to develop an energy budgeting intervention, that limits the deleterious effects of fatigue on life participation for adults on dialysis with fatigue.

Methods: Energy budgeting principles were combined with an established approach to problem-solving (the Cognitive Orientation to Occupational Performance) to form the theoretical framework of the intervention. Learning principles were applied to make educational material concise, simple and easy to learn. Key informant feedback was sought after initial prototype development to guide further program revisions.

Results: The P.E.P. (Personal Energy Planning) program is a two-part fatigue self-management program for adults on dialysis. In Part 1, patients learn general concepts about fatigue and energy budgeting during two concise, self-administered web modules. In Part 2, patients apply the concepts with the guidance of a healthcare professional to create and test personalized energy plans that address their unique goals. The content and design of the program have been largely endorsed by key informants (2 CKD patients, a dialysis nurse coordinator, and a health education specialist), who provided several minor recommendations for further enhancement.

Conclusions: After key informant feedback is implemented, the PEP program will be ready to undergo efficacy testing to explore its effects on fatigue and life participation in adults on chronic dialysis.

Intra-abdominal Non-Communicating Pseudocyst in a Peritoneal Dialysis Patient Devan Makati,[2] Sana R. Akbar.[1] *[1]None, Morgantown, WV; [2]West Virginia University, Morgantown, WV.*

Background: Introduction Intraperitoneal pseudocyst formation is a rare complication found in peritoneal dialysis (PD) patients. Thus far the cases reported involve the pseudocyst enclosing the Tenchhoff catheter tip (1).

Methods: Case 66 yr old male with a past medical history of Diabetes, cerebral stroke and end stage renal disease on continuous ambulatory PD for 2 years was being treated with intravenous antibiotics for pneumonia. On hospital day 8 due to patient's abdominal pain CT abdomen pelvis was performed showing a 16.1 x 9.0 cm rim-enhancing loculated fluid collection in the right abdomen. Fluid analysis showed creatinine and urea matching serum samples leading to the conclusion that the fluid was fibrin entrapped dialysate. Serum BUN 49mg/dL, creatinine of 7.92mg/dL, fluid BUN was 51mg/dL, fluid creatinine was 8 mg/dL.

Results:

Conclusions: Discussion Our patient's case is rare, due to a lack of communication between the pseudocyst and catheter, making it hard to diagnose as no outflow obstruction was noted. Diagnosis was established only after IR guided fluid drainage due to escalating peritonitis. CT peritoneography is considered superior to traditional CT scans (2). After 24 hours the drain was removed and cultures remained negative. Due to worsening condition and PD cell count the catheter was removed and transitioned to hemodialysis. Patient improved after removal of PD catheter. Non-communicating pseudocyst is a rare complication that occurs in PD patients. We recommend in patients with PD found having loculated fluid collection on imaging; to send cell count, culture and analysis in order to diagnosis a pseudocyst. Our case differ from those reported by Baer et al as there was no outflow obstruction and the signs of peritonitis were masked by the antibiotics for the patient's pneumonia. 1: *Abdominal Pseudocyst following peritoneal dialysis-associated peritonitis: A Report of 3 cases Gernot Baer, MD, Albrecht Wagner, MD, Jochen Selbach, MD, Mike Otto, MD, and Stefan M. Pattern of Late Catheter Dysfunction in Automated Peritoneal Dialysis Patients Detected through Remote Patient Monitoring and Its Impact in Therapy Total Time Mario R. ---,[2] Victor A. Mercado,[2] Manuel Abraham Ramirez Almazan,[1] Manuel G. Lopez de Nava,[1] Pedro Jimenez,[1] Alfonso Ramos.[1] *[1]Baxter Mexico, San Jer?nimo Chicahualco, Mexico; [2]Internal Medicine, Hospital Dr Belisario Domínguez, Mexico, Mexico.*

Background: Despite progress made in the management of patients in peritoneal dialysis and in spite of improvements in technique survival, Tenckhoff catheter dysfunction remains a common problem of peritoneal dialysis. The aim of this report is to show the impact on draining and infusion times as well as on the total therapy time in a group of patients with Tenckhoff catheter dysfunction through remote monitoring and to compare them to a group of patients with functional standard catheters

Methods: A group of patients with an abnormal pattern of drainage time, which affected the total amount of effective therapy time, was detected during the initial assessment. We conducted an evaluation of, 4 patients (3 males, 1 female) (group 1) with an average time on therapy of 24 months. In order to assess the impact, 10 patients (6 male, 4 female) (group 2) who did not show abnormal findings were randomly selected and then, we measured the actual therapy time (min), infusion times (min), drainage times (min), nightly UF (ml) and total UF (ml) in both groups. Descriptive statistics were used, and the differences in the variables between patients in group 1 and 2 were performed using t test for continuous variables and X^2 distributions or Fisher exact test for discrete variables or according its distribution.

Results: The median total therapy time was 335 vs 409 minutes for group 1 and group 2, respectively ($p< 0.02$); the median drainage time was 179 vs 92 minutes ($p< 0.007$); the median infusion times was 46.5 vs 36 minutes ($p< 0.05$); and the median UF was 594 ml vs 1187 ($p=$ NS). A linear regression between UF and total therapy time showed a positive correlation of 0.61. Beta coefficient showed that an increase of one minute in the total therapy time is associated with an increase of the UF of 5.69 ml ($p<0.05$)

Conclusions: Remote patient monitoring in APD patients allows early detection of disturbances in filling and drainage patterns during dialysis. An interesting finding is the correlation between the total time of therapy and the UF

PUB345

Difference in Consideration of Patient Eligibility for Peritoneal Dialysis between Nephrologists and Other Medical Staffs – Using a Conjoint Analysis Hisako Yoshida,[2] Kazuhiko Tsuruya.[1] *[1]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Clinical Research Center, Saga University Hospital, Saga, Japan.*

Background: In patients with incident end-stage renal disease, selection of renal replacement therapy (RRT) modality is affected by consideration of medical staffs. Very few studies have investigated the consideration of medical staffs regarding RRT modality selection. Thus, we conducted a web questionnaire study for nephrologists (Neph) and other medical staffs (OMS) to elucidate their consideration of RRT modality, especially regarding eligibility for peritoneal dialysis (PD), using conjoint analysis (CA).

Methods: CA is a method for understanding the preferences for such as services over a set of multi-attribute alternatives (Clark MD, *et al. NDT* 2016). According to CA procedure, 21 simulation cases were created to quantify the relative importance of hypothetical patient attributes as the 6 categories: sex (male, female); age (40, 55, 70, 85 years old); primary diseases (diabetic nephropathy, chronic glomerulonephritis, polycystic kidney disease); abdominal condition (normal, post-surgery, hernia, diverticulum); necessary for support (independent or dependent of family support); and self-care status (good, poor dietary control, or poor sanitary control). For each case vignette, the Neph and OMS who were working at the PD clinic of Kyushu University Hospital and its related facilities were asked to indicate whether they would recommend PD for their patients using a five-point scale. This research was performed using a web response system (https://questant.jp). Relative importance rates and partial utility scores were calculated via CA. We compared these values between Neph and OMS using Wilcoxon signed-rank test.

Results: A total of 98 respondents (42 Neph and 56 OMS) answered our web questionnaire. We calculated the relative importance which means the strength of influence for respondents' evaluation, and the utility score means weight for decision making within each factor. In Neph compared to OMS, the relative importance was higher in "primary diseases" (p=0.002) and lower in "self-care status" (p=0.023). In "age", the utility score of 85 years old was higher (p<0.001), while in "self-care", good self-care was lower (p=0.041), in Neph than OMS.

Conclusions: The consideration of eligibility for PD was significantly different in age and self-care status between Neph and OMS.

PUB346

Effectiveness of Chlorhexidine, Mupirocin, and Conventional Exit-Site Care for the Prevention of Peritoneal Dialysis-Related Infections (COSMO-PD): A Preliminary Result of a Randomized Trial surapon nochaiwong,[5,6] Chidchanok Ruengorn,[2,6] Kajohnsak Noppakun,[7] Kiatkriangkrai Koyratkoson,[3,6] Chayutthaphong Chaisai,[3,6] Ratanaporn -. Awiphan,[1,6] Wilaiwan -. Chongruksut,[7,6] Sirisak Nanta.[4,6] *[1]Chiangmai University, Chiangmai, Thailand; [2]Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; [3]Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; [4]Maesai District Hospital, Chiang Rai, Thailand, Chiang Rai, Thailand; [5]Pharmaceutical Care, Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; [6]Pharmacoepidemiology and Statistics Research Center (PESC), Chiang Mai University, Chiang Mai, Thailand; [7]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand. Group/Team: Thai Renal Outcomes Research (THOR) Investigators.*

Background: Topical antibacterials, antiseptics, and cleansing agents for exit-site care has potential to decrease the risk of PD-related infections-the most common cause of technical failure, morbidity, and mortality in PD patients. Evidence is limited to guide the choice of exit-site care agents for the prevention of PD-related infection. We evaluated whether daily local application of chlorhexidine gluconate (CHG)-impregnated patch would decrease the rate of PD-related infections compared with topical mupirocin ointment or conventional exit-site care.

Methods: In a randomized, double-blind, multicenter trial, we study the effectiveness of three exit-site care agents; 2% CHG-impregnated patch, 2% mupirocin ointment, and conventional exit-site care by normal saline solution among adult PD patients. Participants were recruited from three tertiary PD centers in Thailand, from June 2016 (enrollment is ongoing). The primary pre-specified outcome was a composite of PD-related peritonitis and exit-site infection (ESI). Secondary outcomes included rates of catheter removal, adverse events, and all-cause mortality. The study has been registered as NCT02547103.

Results: Of 215 participants screened, 44, 43, and 43 were randomized to receive CHG, mupirocin, and conventional exit-site care, respectively. No difference of characteristics among groups were observed. With the numbers available, there was no differences of primary and secondary outcomes (all P>0.05) among the study groups, as well as safety profiles.

Conclusions: A preliminary result revealed that no statistically significance in efficacy and safety of three exit-site care agents. However, results may change as the study reaches closure, longer follow-up is warranted.

Funding: Government Support - Non-U.S.

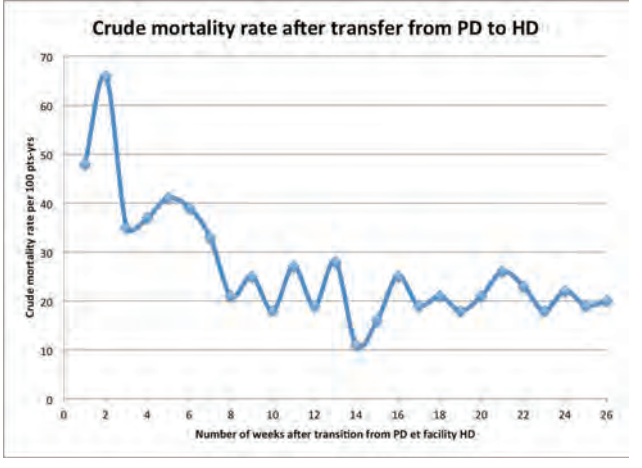
Group/Team: On behalf of INTEGRATED Study Group.*

Background: Transition of patients with end-stage kidney disease (ESKD) between peritoneal dialysis (PD) and hemodialysis (HD) is both common and associated with a heightened risk of adverse events. This study aimed to assess rates and predictors of early death after transfer from PD to facility HD.

Methods: All incident Australian and New Zealand ESKD patients initiated on PD between 2000 and 2014 and with a transition between PD and HD were included. Weekly crude mortality rates were calculated using a Poisson model for the first 26 weeks after the transition and predictors of early death (≤ 50 days after switch to HD) were assessed in an adjusted Cox proportional hazard model, censoring for transplantation, change of modality and end/loss of follow-up.

Results: The study included 5577 patients with a transition from PD to facility HD. Crude mortality rate was highest during the second week after transfer to HD (66 deaths per 100 patient-years, 95% CI 52-84) and stabilized 8 weeks after the switch. (Figure 1). Predictors of early death after transition included older age (HR 1.25, 95% CI 1.18-1.32, per 5 years), diabetic kidney disease (HR 1.41, 95% CI 1.01-2.0 compared to glomerulonephritis), and longer dialysis duration (HR 1.16, 95% CI 1.10-1.24, per year). In contrast, male gender (HR 0.68, 95% CI 0.54-0.85), Asian race (HR 0.58, 95% CI 0.35-0.94 compared to Caucasian), and recent era (HR 0.63, 95% CI 0.43-0.91 for year 2010-2014 compared to 2000-2004) were associated with a lower risk of early death after transition.

Conclusions: The first weeks following transition from PD to HD are associated with a high death rate. Further studies should evaluate whether this vulnerability is mostly related to the reason behind PD completion or to the transition process, and target interventions to mitigate transition-associated risks.



PUB348

Bedside Peritoneal Dialysis Catheter Repositioning – A Novel Technique Santosh Varughese, Suceena Alexander, Anna T. Valson, Shailesh T. Kakde, Anjali Mohapatra, Vinoi G. David. *Christian Medical College, Vellore, India*.

Background: Malfunction of peritoneal dialysis (PD) catheters usually need surgical repositioning, requiring anesthesia, operating time, surgical expertise and longer hospital stay. Where successful, this novel percutaneous technique obviates need for open surgical repositioning.

Methods: The abdomen is scrubbed and cleaned. The PD catheter distal to the exit site is meticulously cleaned, the titanium adaptor and transfer set removed, the former soaked in povidone-iodine. A guide wire is passed through catheter into the peritoneal cavity. After infiltrating skin over the previous healed incision scar with local anesthetic, a 5mm incision is made. The soft tissue is dissected until the deep cuff is visible. With blunt dissection, the cuff is gently separated from the subcutaneous tissue where it had become anchored. Taking care to retain guide wire's position inside the peritoneum, the intra-peritoneal part of the PD catheter is removed. The external portion of the guide wire is advanced through the PD catheter till free from the catheter. The proximal end of the guide wire is thus in the peritoneum and distal end is free. Occluding clots, which may contribute to catheter malfunction, if present, are gently removed and the catheter flushed with saline. A dilator is advanced along the guide wire to ensure adequate space for the PD catheter at the linea alba and below. The peel-away sheath and dilator are then advanced into the peritoneum. The dilator and guide wire are removed leaving only the sheath in place. The catheter is then re-introduced into the peritoneum through the sheath, which is separated leaving the catheter in place. The peritoneal cavity is filled with PD fluid and good inflow and outflow are ensured. The subcutaneous tissue and skin are closed in layers.

Results:

Conclusions: In the 18 patients with PD catheter malfunction in whom percutanous repositioning was done, we had immediate success in 100% and a month later 12 catheters were functioning well. Six months later, they remained functional but one patient had died due to cardiac disease. In a significant proportion of cases, this novel procedure will help to obviate surgical repositioning, saving money, decreasing hospital stay and not necessitating personnel with surgical expertise. This promises to be exceptionally useful in resource-poor settings of South Asia.

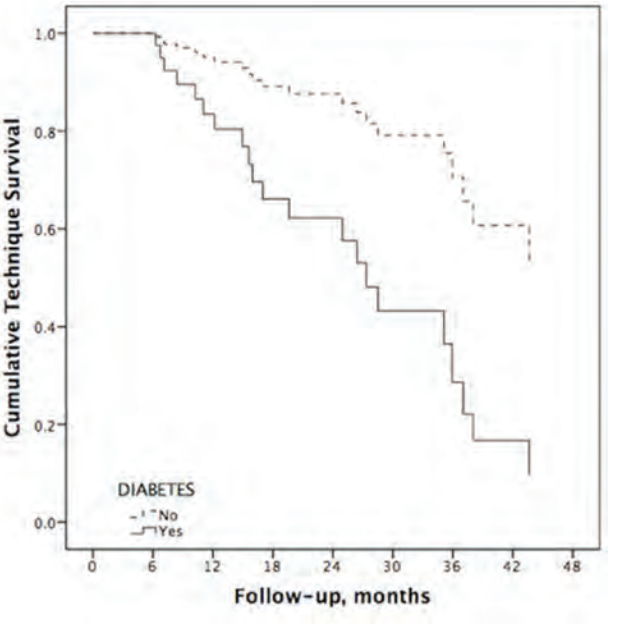
Reasons for Dropout from Peritoneal Dialysis in Contemporary Days Guilherme P. Santa Catharina, Gabriel C. Barsotti, Erica A. Guimarães, Rodrigo S. Adao, Camila Dosse, Bruno C. Silva, Benedito J. Pereira, Rosilene M. Elias, Hugo Abensur. *Universidade de Sao Paulo, Sao Paulo, Brazil*.

Background: Peritoneal dialysis (PD) is a worldwide spread technique that provides comparable mortality with hemodialysis. Technique survival, however, is limited due to patient dropout. Since several advances in peritonitis prevention and treatment occurred over the last few years, we hypothesized that the main patient dropout cause was no longer peritonitis.

Methods: We collected data from patients starting PD between December 2010 and May 2017 in an academic center, including demographic, clinical, and laboratorial variables. Reasons for dropout were classified as catheter-related, PD-related or patient-related problems.

Results: We included 136 patients (age 48±19 years, 51% male, and 29.6% diabetic). During a median follow-up of 10.6 months there were 18 kidney transplants and 67 dropouts: 15 (22.4%) catheter-related, 39 (58.2%) PD-related (20 transfer to hemodialysis due ultrafiltration failure and volume overload and 19 peritonitis), and 13 (19.4%) patient-related (4 recovery of renal function, 2 patient burnout and 7 deaths). Diabetics had a higher technique failure rate (RR 3.6, p=0.008), in a model adjusted for age and renal function at PD entry (Figure 1). Patients with catheter-related problems had a higher body mass index (26.8±4.5 vs. 23.7±4.0 kg/m 2, p=0.017).

Conclusions: Since peritonitis and membrane failure are the main causes for dropout from PD, all efforts should be done in order to preserve renal function and avoid infection. Further investigation is warranted to confirm that overweight patients have more catheter-related problems.



PUB351

Case of Encapsulating Sclerosing Peritonitis in a Renal Transplant Recipient Anam Siddiqui. *Northwell, Elmhurst, NY*.

Background: Encapsulating Sclerosing Peritonitis is an uncommon form of peritoneal inflammation characterized by fibrous thickening of the visceral and parietal surfaces of the peritoneum. PD treatment is the major risk factor for EPS, with specifically the duration of the treatment most crtically linked to EPS development. EPS is categorized by the adhesion of intestines and the subsequent capsule, composed primarily of Fibrin, formed around the adhered lesion. The clinical indicators of patients developing EPS while on PD treatment are ineffective clearance and ultrafiltration failure. Patients who were previously withdrawn from PD treatment and are developing EPS, present with small bowel obstruction.

Methods: We report a case of a 49-year old male, former PD patient of 5 years, with history of HTN, on metoprolol, and a renal transplant recipient. Patient presented 1-2 years after renal transplantation with a month-long history of abdominal discomfort, nausea, and vomiting. CT imaging revealed a small bowel obstruction. Patient received conservative management with an improvement in symptoms and was discharged home. After one week, the patient presented again with similar symptoms. He was again found to have a high-grade small bowel obstruction. Despite the initial conservative treatment, for persistence of symptoms, he underwent surgical treatment. A biopsy then revealed EPS as the cause of his recurrent small bowel obstruction.

Results: Our patient received a diagnosis of EPS, a rare disease which caused him to have SBO. Our patient's history of long term PD treatment was the main cause leading him to develop EPS. Another known contributor to EPS is the use of betablockers. While the specific mechanism remains unclear, one possible explanation is that betablockers have an inhibitory effect on surfactant release. The role of surfactant in the peritoneum may compare to that of surface-active phospholipids, which prevent intra-abdominal adhesions. Surgical treatment is the exclusive recommendation for patients with EPS. This patient population has a relatively poor prognosis with a mortality rate of 25-55%

Conclusions: In more than half of all cases, EPS occurs following PD withdrawal, as was observed with our patient. Thus, despite its rarity, it is imperative to strictly monitor a long-term PD patient upon withdrawal from PD therapy for symptoms of intestinal obstruction.

PUB352

Scope and Heterogeneity of Outcomes Reported in Randomized Trials in Patients Receiving Peritoneal Dialysis Karine E. Manera,[3,5] Allison Tong,[3,5] Jonathan C. Craig,[4,5] Roberto Pecoits-Filho,[1] Benedicte Sautenet,[6] David W. Johnson.[2] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Princess Alexandra Hospital, Brisbane, QLD, Australia; [3]The University of Sydney, Westmead, NSW, Australia; [4]University of Sydney/ Children's Hospital, Sydney, NSW, Australia; [5]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [6]Department of Nephrology and Clinical Immunology, University François Rabelais, Tours, France. Group/Team: On behalf of SONG-PD Steering Group.*

Background: Randomized trials can provide evidence to inform decision-making for improved care and outcomes but this may be limited if the chosen outcomes are not relevant to patients and clinicians, and are reported inconsistently.

Methods: Medline, Embase, the Cochrane Kidney and Transplant Specialized Register and clinicaltrials.gov were searched for RCTs involving adults receiving PD published from 2011 to 2016. All outcome domains and measurements were extracted. The frequency and characteristics of the reported outcome domains and measures were analyzed.

Results: From 85 included trials, 1346 different measurements of 60 different outcome domains were reported, with a median of 5 per trial (interquartile range 3 to 10). Overall, 27 (45%) domains were surrogate, 23 (38%) clinical and 10 (17%) patient-reported. The six most commonly reported domains were PD-related infection (37 [44%]), mortality (32 [38%]), renal function (31 [36%]), dialysis solute clearance (26 [31%]), protein metabolism (25 [29%]) and technique failure (25 [29%]). Quality of life (14%) and fatigue (4%) were reported infrequently. The most frequently reported clinical outcome, PD-related infection, had 69 different outcome measures, with only 11 of these being used in more than one trial.

Conclusions: Trials in PD include important clinical outcomes such as mortality and infection, but these are measured and reported inconsistently; and patient-reported outcomes are infrequently reported. Nearly half of the outcome domains were surrogate or biochemical outcomes.

PUB353

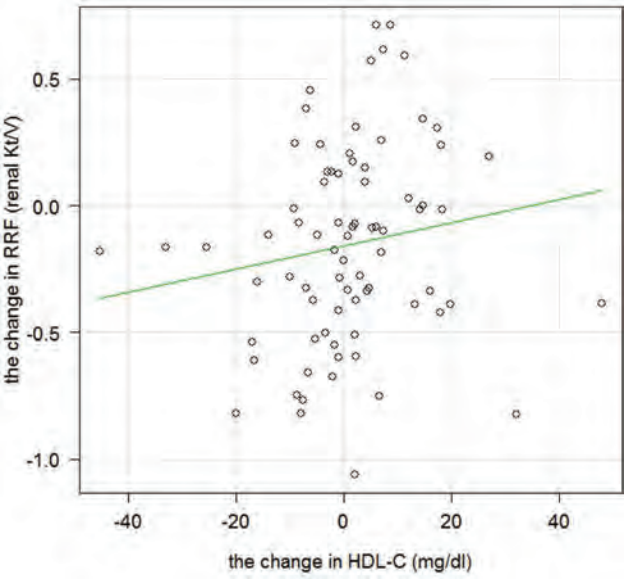
Association between Lipid Profile and Residual Renal Function in Incident Peritoneal Dialysis Patients Yu Honda, Yukio Maruyama, Masatsugu Nakao, Nanae Matsuo, Yudo Tanno, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Preserving residual renal function (RRF) is known to be related to mortality in peritoneal dialysis (PD) patients. It has been reported that lipid profile is associated with the incidence and progression of chronic kidney disease, whereas it is not clear whether lipid profile is associated with the decline of RRF in incident PD patients. The aim of this study was to evaluate the association between lipid profile and RRF in incident PD patients.

Methods: This was a retrospective cohort study of 78 patients (58±14 years, male 68%, diabetes 41%) initiating PD between 2006 and 2015 in the three centers. We analyzed the relationship between lipid profile and the alteration of RRF, expressed as renal Kt/V, during 1 year.

Results: The change in renal Kt/V during 1 year was inversely correlated with high-density lipoprotein cholesterol (HDL-C) at PD initiation (rho=-0.28, P<0.05) and positively with the change in HDL-C (rho=0.24, P<0.05) during 1 year. On the other hand, there was no significant correlation between the change in renal Kt/V during 1 year and light-density lipoprotein cholesterol.

Conclusions: Our results demonstrated the association between HDL-C and deterioration of RRF in incident PD patients. Further study is needed to clarify the effect of medication for dyslipidemia on preserving RRF in PD patients.



PUB354

Long-Term PD Patients in Greece: Are There Any Special Characteristics? Emilios Andrikos,[2] Paraskevi Tseke,[3] Olga Balafa,[1] George I. Tsirpanlis,[4] Christina Melexopoulou,[6] Vasileios Liakopoulos,[10] Christos Katsinas,[5] Chrysostomos Dimitriadis,[7] Marios Theodoridis,[8] Ploumis Passadakis.[9] *[1]Nephrology, University Hospital of Ioannina, Ioannina, Greece; [2]Hatzikosta, General Hospital, Ioannina, Greece; [3]MESOGEIOS Dialysis Center, ATHENS, Greece; [4]Nephrology, G.Genimatas, General Hospital Of Athens, Athens, Greece; [5]Nephrology, Bodosakio, General Hospital, Ptolemaida, Greece; [6]Nephrology, Laiko, General Hospital, Athens, Greece; [7]Nephrology, Ippokrateio, General Hospital, Thesaloniki, Greece; [8]Nephrology, University Hospital of Alexandroupolis, Alexandroupolis, Greece; [9]Nephrology, University Hospital of Alexandroupolis, Alexandroupoli, Greece; [10]Nephrology, AXEPA, General Hospital, Thessaloniki, Greece.*

Background: The Hellenic Peritoneal Dialysis (PD) Registry started setting up at the beginning of 2017 in order to evaluate the special characteristics of PD patients (pts) in Greece and to enhance the practical experience of PD physicians and nurses.

Methods: A group of nephrologists with great experience in PD in co-operation with biostatisticians designed a database to record all prevelant PD pts in Greece. All PD physicians were informed for the development of the registry and asked to participate.

Results: Until today, 182 prevalent PD patients from 7 centers have been recorded, 39 of whom are on PD for more than 5 years. Long-term PD survivors (23 male and 16 female) have a median time on PD of 72 months (range from 60-145) and their mean age at start of dialysis was 54.5±15.9. The majority of pts was married (76.3%) and was followed by nephrologists prior to PD initiation (half of them for almost 4.5 years). The educational level was low to basic for 57% of these pts and 1 out of 3 of them lived in islands and rural areas. Training on PD was performed by institutional PD nurses or properly educated employees of PD companies. The latter was significantly associated with longer PD training period (mean training time was 11.5 vs 6.4 days, p=0.004) and shorter time on PD (median time on PD was 60 vs 74 months, p=0.05). Initial PD regimen which was CAPD in 75% and APD in 25% did not significantly affect the total time on PD. However, the odds for peritonitis was significantly reduced in those on APD (OR: 0.12, p=0.023). Noteworthy, 37.5% of the total pts had none or 1 episode of peritonitis in a median time of 67 months and overall peritonitis rate was 3.5 episodes per pt-year. 39.5% of these pts are candidates for kidney transplantation, which is strongly associated with the age at the start of PD treatment (p=0.006) and Charlson's Co-morbidity Index (p=0.008).

Conclusions: As this is the first report of an ongoing study limitations may exist as further findings are expected to fully explore the PD map in Greece.

PUB355

Surgical Outcomes of Tenchkoff Catheter Insertion in a Tertiary Center Gerard Low,[2] Jia rui Kwan,[1] Gabriel W. Low,[2] Chieh-suai Tan,[3] Tze tec Chong.[3] *[1]Nanyang Technological University, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]Singapore General Hospital, Singapore, Singapore.*

Background: Peritoneal Dialysis is a cost-effective form of renal replacement therapy. The initiation of PD requires the insertion of a Tenchkoff catheter and this is most commonly performed by a surgeon in our center. We aim to report the surgical outcomes of Tenchkoff catheter insertion in our center and factors affecting outcomes.

Methods: This is a single-centered retrospective study of all patients receiving Tenchkoff catheter between January 2011 and January 2016 in Singapore General Hospital. Electronic medical records of the patients were reviewed and followed up for 1 month after initiation of peritoneal dialysis.

Results: A total of 470 Tenchkoff catheters were inserted. Most were inserted using an open technique (403/470, 85.7%) while the remainder were inserted laparoscopically (67/470, 14.3%). The mean age of the study population was 61.6 ± 14.3 years, 49.8% Male, 75.5% Chinese, 18.9% Malay, 4.9% Indian with a median BMI of 24.0. Diabetes Mellitus (58.5%), Hypertension (87.2%) and Ischemic Heart Disease (41.1%) were the 3 most common comorbidities among patients. Majority of patients did not have any previous abdominal surgery (392/470, 82.6%). More than half of the patients (289/470, 61.5%) were started on hemodialysis before Tenchkoff insertion. Tenchkoff catheter insertion was successful in all patients with no mortality attributable to surgical mishap. Early complications within 30 days of Tenchkoff insertion include bleeding (31/470 with 3 requiring operative hemostasis), leak (3/470 with none requiring operation), flow-related issues requiring re-operation (20/470; migration 3.0%, obstruction 0.8%, poor flow 0.4%) and infection (22/470; PD peritonitis 3.2%, Exit-site infection 3.0%, Tunnel tract infection 0.2%, Incision site infection 0.2%). Early complications were not related to the method of insertion, patient comorbidities or BMI on multivariate analysis.

Conclusions: Tenchkoff catheter can be successfully inserted in majority of patients. Flow-related complications are the most common indication for re-intervention within 30 days. Further studies of composite endpoints are required to improve Tenchkoff insertion outcomes.

PUB356

Icodextrin as an Alternative to Glucose to Evaluate Peritoneal Membrane Transport Pattern Lucas D. Pereira,[2] Rosilene M. Elias,[1] Hugo Abensur,[1] Erica A. Guimarães,[2] Benedito J. Pereira,[3] Rodrigo S. Adao.[2] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade de São Paulo, Salvador, Brazil; [3]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Peritoneal equilibration test (PET) is considered the gold standard method to classify transport pattern among patients on peritoneal dialysis (PD). Classically, ultrafiltration (UF) volume obtained after a dwell of 4.25% glucose can estimate peritoneal membrane capacity. Icodextrin is a dialysis solution that promotes UF mainly through the small pores and weather icodextrin can substitute glucose in predicting peritoneal membrane characteristics is unknown. We have compared UF volume with a 4-hour dwell period with icodextrin (UF-ICO) and 4.25% glucose solutions (UF-Glucose), correlating the results with PET.

Methods: We included 35 patients (47±17 years, 51.4% male), on PD for a median time of 9.2 months. Each patient underwent 3 assessments: standard PET, UF-ICO and UF-Glucose.

Results: UF volume, and PET classification according to dialysate 4h/0h glucose and dialysate/plasma creatinine are shown in Table 1. Patients were divided into two groups: low (L) + low average (LA) and high (H) + high average (HA) pattern. Dialysate/plasma creatinine correlated with UF-Glucose (r=-0.383, p=0.023) and with UF-ICO (r=-0.531, p=0.001). ROC estimated the best cut=off point to predict H/HA transport pattern with ICO was 141ml based on PET classification by 4h/0h glucose (sensitivity 69% and specificity 91%) and 141ml based on PET classification by dialysate/plasma creatinine (sensitivity 77% and specificity 95%). (Observe table)

Conclusions: Icodextrin-based solutions promote an equal or better capacity to predict peritoneal membrane pattern. Further studies are warranted to confirm these results in a larger sample size.

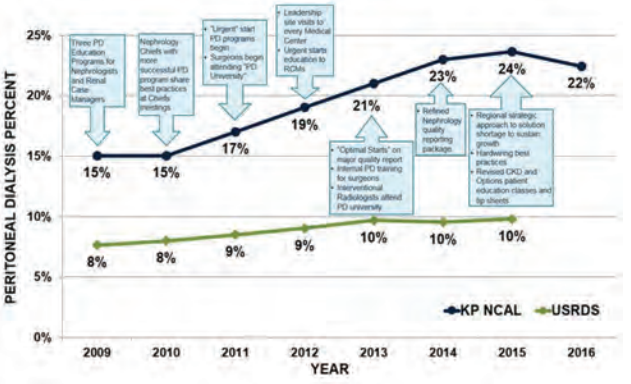
Organizational Performance Improvements in a Successful PD Program Leonid Pravoverov,[1] Sijie Zheng,[3] Joanna Mroz,[3] Neelam M. Bhalla.[2] *[1]Kaiser Permanente, Walnut Creek, CA; [2]None, Fremont, CA; [3]The Permanente Medical Group, Oakland, CA.*

Background: Peritoneal Dialysis (PD) is an underutilized renal replacement modality (RRT) in the United States; currently only 10 % of ESRD patient are on PD (USRDS, 2016). Kaiser Permanente Northern California (KPNC), an integrated health care system consists of 15 Medical Centers with unique Nephrology Departments, providing care to the population of over4 million members. Approximately 1300 KPNC patients initiated dialysis from March 2016 to March 2017. Among them, 27% started on PD and around 24% remained on PD.

Methods: Since 2009, KPNC has developed a multidisciplinary approach to PD promotion including: Patient and Family Education, Provider and Organizational education, multiple operational improvements with monitoring and continuous quality improvement projects. We analyzed the PD incidence and prevalence since 2009 to determine the trend for the past 8 years.

Results: Significantly higher incidence and prevalence of PD in KPNC was achieved by implementation of comprehensive multidisciplinary approach in promotion of home dialysis. Despite our highly effective multi-disciplinary program focusing on "home therapies first", we have recently seen a plateau with our PD penetration.

Conclusions: In a fully integrated health care system, despite continuous organizational efforts to increase PD incidence and prevalence, we observe slowing down of growth in some medical centers. Multiple factors are likely contributing, including socio-economic, demographic, patient composition and changes in healthcare landscape. We evaluate strategies to sustain growth of our home dialysis population by continuous provider education, ongoing evaluation of operational needs of local medical centers and use of technology to support patient education and engagement.



PUB358

Arnos Protein-Energy Wasting Score (ARNOS PEWS): Does It Work in Peritoneal Dialysis (PD) Patients? David Attaf. *Fresenius medical care, Frenes, France.*

Background: A score of PEW named "ARNOs PEWS" is graded from 0 (worse) to 4 (normal) and derived from Alb, BMI, Creat, nPCR. It predicts survival in HD patients. Any increase of the score is associated with increase of survival. It identifies subgroups of patients with higher risk of mortality. We aim to assess retrospectively if the score of PEW is applicable in PD patients

Methods: 76 PD patients (03/05 - 06/16), datas available for 58 patients. We define 4 categories of patients : Score 0-1 (Gr.1:severe wasting); Score 2 (Gr. 2: moderate wasting) ; Score 3 (Gr 3: Slight Wasting) and Score 4 (Gr 4: normal Wasting). We assessed the score changes during the follow-up and analyzed the association with biological and clinical outcomes.

Results: The table below provides clinical and biological parameters according to PEW score. Moderately and severely wasted groups (Gr 1 and 2) included 34 patients i.e. 58% of the global population. All parameters were significantly impaired in Gr 1 versus grp 4, except for the renal Kt/V.

Conclusions: ARNos PEWS is associated with morbidity and survival in PD. Longer follow up and higher number of patients are needed to know if this score will help in PD to identify subgroups of patients with higher risk of mortality in which nutrition support is mandatory.

Evolution of Small Solute Transport in a Patient Treated for 18 Years with CAPD Restricting Hypertonic Glucose Dominique C. Pagniez, Jean-baptiste Beuscart. *Nephrology, Centre Hospitalier Universitaire, Lille, France.*

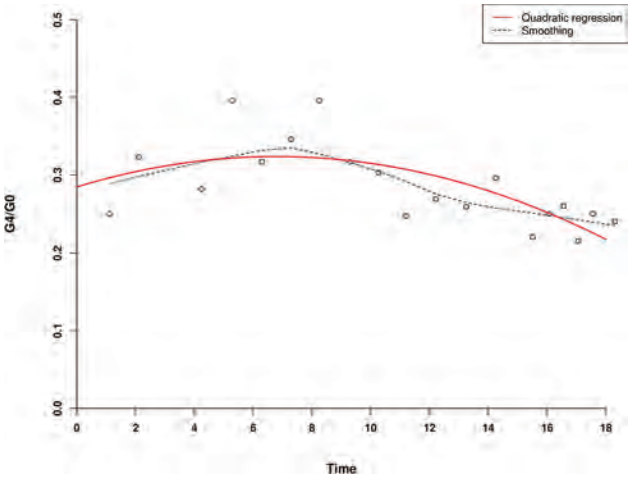
Background: We report on the evolution of Small Solute Transport (SST) in a patient treated for 18 years in our center, where the use of hypertonic (3.86%) glucose solutions has been persistently restricted.

Methods: A 44-year-old female patient started CAPD in August 1994. She used only 1.36% glucose bags until one bag of icodextrin per day was started in December 2006. A second was started in December 2009. She had an early cluster of peritoneal infections leading to a catheter exchange in January 1998, and a late peritoneal infection in September 2009, which was difficult to cure. She received a living donor kidney transplant in January 2013, and is currently doing well. An equivalent of the PET test, using 3.86% glucose, was performed after 6 months of CAPD, and then every 12 months.

Results: As the interference of glucose with creatinine measurement varied widely in the 18-year period, we used the D4/D0 ratio of peritoneal glucose concentrations after

dwell times of 4 and 0 hours as an index of SST. The D4/D0 ratio actually *increased* (SST decreased) until 2004; it then slowly decreased, and was .25 in March 2012, its initial value. There had been a gradual decrease of the effluent volume for both the 1.36% glucose and icodextrin bags since 2010.

Conclusions: This particular case suggests that persistently avoiding exposure to hypertonic glucose may prevent for up to 10 years the increase in SST linked to vascular proliferation.



PUB360

Evaluation of the Nutritional Status in Peritoneal Dialysis Patients: Interactions with Mental Psychological State and Appetite Valerio Vizzardi,[1] Scilla Maghella,[2] Massimo Sandrini.[1] *[1]ASST-Spedali Civili, Brescia, Italy; [2]University of Brescia, Brescia, Italy.*

Background: Malnutrition (MN) is a risk factor in peritoneal dialysis (PD) patients and it's correlated with a major risk of morbidity, mortality and a worsening of quality of life.

Methods: 41 prevalent PD patients were included. The aim was to evaluate nutritional status (NS) testing Malnutrition Inflammation Score (MIS) and correlated it with appetite and mental psychological state (MPS); appetite was assessed by the Council Nutritional Assessment Questionnaire (CNAQ), MPS was assessed by the Mental Component Scale (MCS) of short form-12 (SF-12) questionnaire. MIS and CNAQ were submitted at the first meeting (T_0) and six months later (T_1), MPS at T_1.

Results: The percentage of malnourished depended on the method used for the evaluation both at T_0 and T_1. MIS was negatively correlated with nephelometric albumin and cholesterol at T_0 ($p<0.001$, $p<0.01$) and T_1 ($p<0.001$, $p<0.05$) and with triglyceride at T_0 ($p<0.05$). MIS was positively correlated with C-Reactive Protein (CRP) at T_1 ($p<0.05$). Appetite resulted reduced in 46% at T_0 and 49% at T_1. CNAQ at T_0 didn't correlate with weight loss from T_0 to T_1 and CRP. However higher CNAQ at T_0 (better appetite) correlate with lower MIS at T_1 (better NS) ($p<0,05$). We also studied the relation between MIS and CNAQ at T_0 (Figure 1): we obtained a scatterplot with four boxes: good NS and good appetite (box A), bad NS and good appetite (box B), good NS and bad appetite (box C), bad NS and bad appetite (box D). Analyzing the average CRP value for each box, the highest one was the value of box B. Another factor that can influence the NS is the MPS: lower MCS was related to highest MIS ($p<0,01$), lower nephelometric albumin ($p<0,05$) and lower CNAQ ($p<0,005$).

Conclusions: This study demonstrates that MIS can be used to evaluate the NS of PD patients which resulted influenced by inflammation, appetite and MPS. The latter influenced also the appetite.

PUB361

The Effect of Core Fucosylation on Rat Peritoneal Fibrosis Longkai Li. *First affiliated hospital of Dalian Medical University, China, Dalian, China.*

Background: To investigate the effect of core fucosylation (CF) on rat peritoneal fibrosis.

Methods: SD rats were divided into control, peritoneal fibrosis, Ad-Fut8shRNA, Ad-con and imatinib (PDGFR inhibitor) group. We used peritoneal fibrosis rat model induced by peritoneal dialysate. Fut8shRNA recombinant adenovirus was used to inhibit CF. We detected pathologic lesion, observed Collagen I and III, and examined TGFβ and PDGF signaling. We also compared the difference between inhibition of CF and imatinib.

Results: There is increased CF expression in rats with peritoneal fibrosis. After inhibition of CF, pathological lesion and functional changes in Fut8shRNA group were alleviated, compared with peritoneal fibrosis and Ad-con group. Collagen I and III in Fut8shRNA group were also alleviated. In TGFβ signaling, TGFβ receptor I and II and Smad were all increased, p-Smad was significantly decreased in the Fut8shRNA group. In PDGF signaling, PDGF receptor αand βand ERK were all increased, p-ERK was significantly decreased in Fut8shRNA group. Compared with imatinib group, pathological and functional changes, and Collagen I and III were all alleviated in Fut8shRNA group.

Conclusions: Blockage of CF inhibited PF, its effect is better than imatinib.

Physical Activity in Patients Treated with Peritoneal Dialysis: A Systematic Review Tharshika Thangarasa,[1] Rameez Imtiaz,[3] Swapnil Hiremath,[1] Deborah Lynn Zimmerman.[2] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Medicine, Ottawa Hospital, Ottawa, ON, Canada; [3]University of Ottawa, Ottawa, ON, Canada.*

Background: End-stage kidney disease (ESKD) treated with peritoneal dialysis (PD) are less active than sedentary individuals in the general population. The actual effects of physical activity with or without structured exercise programs for these patients remain unclear. Our objective was to more completely define the risks and benefits of physical activity in the ESKD population treated with PD.

Methods: With the help of a skilled librarian, a search was conducted using MEDLINE, EMBASE, CINAHL and Cochrane Central Register of Controlled Trials for randomized trials and observational studies to identify research articles examining the effects of physical activity on ESKD patients treated with PD. The primary outcomes of interest were improvements in mental health, physical function, fatigue, quality of life (QOL) and adverse events. Studies reporting adult end-stage kidney disease patients

treated with peritoneal dialysis that have participated in an exercise training program or had their level of physical activity assessed directly or by self-report were included.

Results: A total of 1828 manuscripts were identified; 13 were found to fit the inclusion criteria. Eight of the studies were observational (6 used an accelerometer/ pedometer, 1 used self-reported measures of physical activity and 1 used occupation type as a measure of physical activity), the remaining studies were interventional. Most of the interventional studies assessed aerobic exercise programs. There was evidence from 3 studies to suggest that physical activity resulted in increased levels of physical functioning, 1 study suggested an increased quality of life, and 1 study provided evidence for decreased mortality rates. Biochemical markers improved in majority of studies in which they were measured. However in 1 study, physical activity did not affect fatigue or physical performance.

Conclusions: There is limited evidence to suggest that physical activity in PD patients is associated with important benefits. Most of the studies is small and have important methodological limitations. There is a need for future randomized control trials examining the impact of exercise programs (both aerobic and resistance) in PD patients.

PUB363

Peritonitis in Mexico: Comparison of CAPD and APD Population Ruben G. Roldan. *Instituto Nacional de Cardiologia Ignacio Chávez, Mexico city, Mexico.*

Background: Peritonitis is the major cause of morbidity and mortality in patients on PD. PD infection is associated with peritoneal membrane damage and technique faillure. Following a single episode of peritonitis, the risk of further peritonitis episodes, haemodialysis transfer and death are greatly increased and remain significantly elevated for up to 6 months.

Methods: In this retrospective study we aimed to evaluate patients with peritonitis episode between october 2014 to december 2016 catered in the "National Institute of Cardiology Ignacio Chávez" in Mexico city under continuos ambulatory peritoneal dialysis (CAPD) and automated peritoneal dialysis (APD). Using electronic database we found 71 patients with peritonitis. Clinical and biochemical data were evaluated.

Results: 36 (50.7%) patients were female sex with a median age of 50 years. 54 (76.1%) on CAPD and 17 (23.9%) on APD. The principal etiology of CKD were diabetic nephropathy in 34 (45.1%), 17 (23.9%) with chronic kidney disease of unknow origin and 6 (8.5%) with focal segmental glomerulosclerosis. 28 patients (39.4%) with no history of peritonitis and the principals comorbidities were chronic hypertensión (47.9%), isquemic heart disease (16.9%) and chronic heart faillure (8.5%). The principals organism identified on cultures were S aureus in 23 (32.4%) of patients, E coli in 7 (9.9%), S marcescens in 5 (7%), S epidermidis with 5 (7%) cases and Candida in 5 patients (7%).

Conclusions: The results demostrate a less commonly cases of peritonitis in the APD poblation, with the highest number of cases caused by S. aureus (39.4%). From the patients with mechanical dysfunction (10) only 1 correspond to the APD poblation, and from the deads recorded (5) only 1 was part of the APD modality. We emphasize the results above-mentioned, were the level of albúmin and BUN demonstrated a statistical significance. Posible related to a properly nourished population, whom presented the less mortality and better outcome, in relation to a close follow up in the course of the treatment.

Variable	Outcome	Median	P
Albumin	Alive Dead	3.11 2.3	0.012
BUN	Alive Dead	65.88 36.92	0.02
Leucocytes	Alive Dead	8.47 21.16	0.05
Lymphocytes	Dead Alive	1.21 0.97	0.36
Age	Dead Alive	49.27 57.80	0.62
Cellularity	Dead Alive	2567 2262	0.83

PUB364

Tracheostomy Dependent Long Term Dialysis Patients Jack Rubin,[1] Jacqueline Bogo.[2] *[1]None, Long Beach, CA; [2]none, Los Alamitos, CA.*

Background: Since April 2014 we have been treating tracheostomy dependent patients(pts) at our dialysis unit (ventilator and former continous ventilator). We wish to report salient features of our experience to May 2017.

Methods: Data were retrieved from the dialysis charts. The data from the last available chart entry are presented. All data are presented as mean ± sd unless stated otherwise. Differences between groups were evaluated by 2 tailed t test with Bonferroni correction for multiple comparisons.

Results: There were 38 pts (18F/20M) Their mean age was 68 ± 14 years with a mean time on dialysis at our unit of 171 ± 219 days (median 92). These pts were on dialysis prior to coming to us. They had suffered a medical catastrophe or transferred from a long term acute facility after developing renal failure that did not resolve. KT/V 1.4 ± 0.3, hg 9 ± 1 g%, albumin 3.1 ± 0. 6 g%, calcium 9.3 ± 0.9 mg% and phosphorus 4.3 ± 2.2 mg%. Ten (9F, 1M) (A) are on dialysis 185 ± 300 (median 185) days and 28 have deceased (D) after 112 ± 148 days (median 50). By 2 tailed t test creatinine mg% (A 6.7 ± 1.1;D 4.8 ± 1.4) was significantly lower in those who died (p<0.007). Cholesterol mg% (A 128 ± 50; D 88 ± 31 P<0.009)) and albumin g% (A 3.3 ± 0.6; D 2.9 ± 0.5 P<0.07) almost reached significance (negative after Bonferroni correction). KT/V (A 1.6 ± 0.3; D 1.4 ± 0.3), bun mg% (A 88 ± 39; D 100 ± 34), hemoglobin g% (A 9.9 ± 1.1; D 8.9 ± 1.2), prealbumin mg% (A 20 ± 8; D 16 ± 9), calcium mg% (A 9.5 ±1,1; D 9.4 ±0.8), phosphorus mg% (A 4.6 ± 1.5; D 4.4 ± 2.4) and hg A1c % (A 5.8 ± 1.1; D 6.1 ± 0.9) were not significantly different.

Conclusions: The laboratory differences observed between Alive and Deceased pts may reflect diminished muscle mass (lower creatinine) and malnutrition (lower albumin and cholesterol) as heralds of clinical deterioration prior to death. Upon taking on treatment of this group of pts one must expect a lower star rating as most require catheters and are frequently admitted for infection, bedsores or pulmonary complications. The logistics of transporting patients and ensuing ambulance traffic can be challenging. Funding may be a problem for ambulance service companies. To sustain these selected pts requires a dedicated staff of nurses, respiratory technicians and ambulance services.

PUB365

A Prospective Observational Study on Prevalence of Hepatitis C Virus Infection and Its Risk Factors in CKD Patients on Hemodialysis at Faridabad, Delhi NCR, India Hariharan R. Munganda,[1] Jitendra Kumar,[1] Punit Pruthi.[2] *[1]Asian institute of medical sciences, Faridabad, Haryana, India; [2]internal medicine, Asian Institute of Medical Sciences, Faridabad, India.*

Background: Chronic renal disease patients on haemodialysis are at increased risk of infection by hepatitis C virus (HCV). Subjects undergoing treatment in dialysis centres without nephrologists and improper viral marker screening, dialysis at more than one centre and no separate dialysis machine for HCV positive patients, unscreened blood transfusion are at risk of cross contamination. Thus, there is a need to screen these subjects for prevalence of HCV seropositivity and study the impact of HCV positivity on clinical course of the disease.

Methods: Aim of our study:was to assess prevalence of HCV positivity in CKD on hemodialysis subjects. Also to assess various characteristics of HCV positive subjects compare them with HCV negative CKD subjects.**Methodology**:In our Asian tertiary care hospital dialysis unit a total of 100 CKD subjects were recruited for the study and after informed written consent, further detailed history, socioeconomic and clinical parameters including dialysis related parameters were analysed and compared between the Hepatitis C seropositive and Seronegative subjects. Hepatitis C positivity was assessed using chemoluminiscence.

Results: Prevalence of seropositivity was found to be 16% in CKD subjects. Only 2% of the subjects have turned HCV positive from contaminated blood transfusion and dialysis at multiple centres while 14% have acquired HCV infection from same dialysis centre and by usage of same dialysis machine.

Conclusions: High prevalence of HCV infection exists in CKD subjects. Though CDC doesn't recommend HCV patient isolation/segregation, we in our study strictly recommend use of separate dialyzer for HCV positive patients under expert nephrologists supervision to contain the HCV infection. **References :** 1) CDC may call for HCV screening in hemodialysis, But not likely to recommend patient isolation, Suzanne Cotter, MD, medical epidemiologist in the CDC; https://www.ahcmedia.com/articles/44946-cdc-may-call-for-hcv-screening-in-hemodialysis 2) Recommendations for prevention and control of hepatitis C virus (HCV) infection and HCV-related chronic disease. PUB367

Reporting Feasibility of the Use of a Real-Time Data Reporting Tool to Improve Outcomes of Haemodialysis Catheter Complications across Australia (REDUCCTION) Sradha S. Kotwal,[7,8] Girish S. Talaulikar,[6] Nicholas A. Gray,[5] Kevan Polkinghorne,[3] Stephen P. McDonald,[1] Alan Cass,[2] Martin P. Gallagher.[4] *[1]ANZDATA Registry, Adelaide, SA, Australia; [2]Menzies School of Health Research, Darwin, NSW, Australia; [3]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [4]None, Sydney, NSW, Australia; [5]Sunshine Coast University Hospital, Birtinya, NSW, Australia; [6]The Canberra Hospital, Carran Act, NSW, Australia; [7]Renal and Metabolic, The George Institute of Global Health, Sydney, NSW, Australia; [8]Prince of Wales Clinical School, UNSW, Sydney, NSW, Australia.*

Background: Patients with kidney disease are susceptible to healthcare associated infections, especially in association with dialysis catheter use. These catheters are a major driver of blood stream infection and the higher mortality in dialysis patients. Dialysis catheter care in Australia is managed by individual renal units, without real-time reporting and limited national benchmarking. Tools to analyse clinical variation and mount an effective timely response are lacking. Data on the total extent of catheter use and outcomes is limited.

Methods: This project has developed standardised definitions around dialysis catheter usage and complications, validated for accuracy by a central committee. Development of a custom-designed data collection tool used by clinical staff has enabled real-time data collection. The data collection tool was designed and developed using an iterative consultative process with participating renal units. Regular feedback meetings have been conducted since the launch of the data collection tool with changes/updates made using the feedback.

Results: The first phase of this study has involved the design, implementation and uptake of the data collection tool. Of the 36 units involved in the study, 28 are currently entering data. We have data on 696 participants, 427 active catheters with 41033 total catheter days. We expect data on approximately 9000 participants by the end of the study in 2020.

Conclusions: Early involvement of renal units, with regular feedback sessions, is invaluable when pursuing an implementation project at this scale. Meaningful representation with effective engagement from each state is essential to implement change nationally.

PUB368

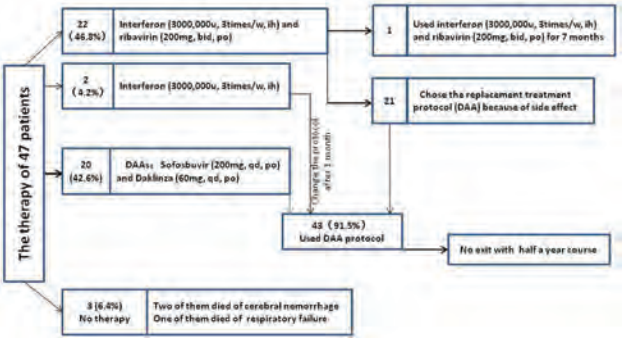
Hepatitis C Virus Outbreak in a Primary Hospital: Infection Investigation and Treatment Follow-Up Hua Liu,[2] Jinhong Xue,[1] Hongli Jiang.[1] *[1]Dialysis Center of First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi'an,Shaanxi, China; [2]First Affiliated Hospital of Medical College of Xi'an Jiaotong University, Xi'an, China.*

Background: To investigate the status of hepatitis C virus (HCV) infection, related factors and treatment follow-up in MHD patients in a primary hospital.

Methods: We monitored the HCV-RNA situation and HCV genotyping of 47 patients with positive anti-HCV antibody. The epidemiological investigation, infection risk factors were analyzed, and treatment response and tolerance of different patients were followd up.

Results: From the analysis of various aspects of HCV transmission in hemodialysis: 1) Regulations on the use of disposable articles are not strictly enforced; 2) The infection consciousness of medical staff is dim, and the conception of asepsis is not strong; 3) the hospital system is not perfect; 4) Infection index monitoring is defective. In the 47 patients, 2 patient were not detected HCV-RNA. The genotype 2a were 32 cases (68.1%), 1b were 9 cases (19.1%), and 2a mixed 1b were 4 cases, 2 (4.25%) patients did not measure genotype has started treatment, overall genotype proportion is different from the common HCV mainly in 1b type. 22 patient (46.8%) used the protocol of interferon and ribavirin (PR protocol) in the beginning, but 21 patients of those were changed to the DAA protocol (Sofobuvir and Daklinza) because of the side effect. 20 cases used the DAA protocol at the beginning. All of the patient used the DAA protocol not only first using but also the replacement, there were no patient exiting because of the intolerance. The negative conversion time of HCV-RNA between the PR and DAA protocol (67.75±8.71 vs 27.93±5.32, P<0.05)was different.

Conclusions: Strengthen the control measures, and strictly implement the infection control system is an important measure to prevent hemodialysis patients from HCV infection. DAAs scheme for MHD patient with HCV-infection has better tolerance, which is a good choice for patients with intolerance of PR protocol, and have better antiviral effect, but also need a lot of guidance for clinical use in clinical data support.



PUB369

Maintaining a Low Peritonitis Rate in Peritoneal Dialysis Patients Sankar Chinnugounder,[2] Stephen B. Craven,[2] Mark E. Stoker,[1] Nishanth Girija kumar,[2] Robert Mark Black.[1] *[1]Reliant Medical Group, Worcester, MA; [2]ST VINCENT HOSPITAL, WORCESTER, MA.*

Background: Peritoneal dialysis (PD) is an efficient, cost effective home modality for renal replacement therapy. In developing countries, PD has increased in numbers possibly due to the lack of hemodialysis (HD) but it has been declining in developed countries (Jain AK et al. J Am Soc Nephrol. 2012 Mar; 23(3): 533–544). The risk and poor outcomes in patients who develop peritonitis may be a major cause of this decline. The International Society of Peritoneal Dialysis (ISPD) position paper (Beth Piraino et al. Peritoneal Dialysis International, Vol. 31, pp. 614–630) considers the difference in incidence rates of peritonitis to be primarily due to disparities in training technique and infection prevention protocols. We strongly concur and propose that the remarkably low peritonitis rate in our program is secondary to a dedicated PD team.

Methods: We conducted an IRB approved retrospective review of data for all patients on PD at our institution between March 2014 and March 2017. Peritonitis during hospitalizations was also included. Our peritonitis rate was expressed as episode per patient per year. We also calculated the peritonitis rate for each organism. We compared the peritonitis rate with the target recommended by ISPD and also with the reported national (United States) level prevalence.

Results: We had an average of 22 patients on PD contributing to a total of 702 patient months. We recorded 7 episodes of peritonitis, which translates to one episode per 100.2 total patient months, which corresponds to 0.12 episodes per patient per year. This is half of the peritonitis rate (0.25 episodes per patient year) in the Unites States (Qamar et al. Advances in Peritoneal Dialysis, Vol. 25, 2009).

Conclusions: We strongly believe that our superior outcomes are due largely to the availability of our PD nurse, our nurse's presence in the operating room at the time of catheter insertion, the use of an experienced surgeon and prompt communication amongst the nephrologist, surgeon and dialysis nurse. We recommend that this process be initiated whenever possible at all PD facilities.

PUB370

Intra-Abdominal Collection and Catheter Removal as a Complication in Mexican Peritoneal Dialysis Patients Guadalupe R. Ramirez,[1] Luis I. Bonilla,[1] Diego E. De la fuente,[2] Elisa M. Guerrero Gonzalez.[1] *[1]Nephrology, University Hospital Dr. José Eleuterio Gonzalez, Monterrey, Mexico; [2]Facultad de Medicina UANL, Monterrey, Mexico.*

Background: Peritonitis continues to be the most frequent cause of Peritoneal dialysis (PD)failure. All dialysis treatments include a certain risk of infection because decreased immune activity in established renal failure. PD is associated with a high risk of infection of the peritoneum, subcutaneous tunnel and exit site. PD patients with severe peritonitis require catheter removal. It is often assumed that this approach, together with antibiotics, would eradicate the infection; however, some patients present further complications despite catheter removal. It is broadly known that developing countries, such as Mexico, are still using proportionally more PD than the rest of the world.

Methods: This was a Retrospective descriptive study about peritonitis on peritoneal dialysis patients. In a period of 40 months nephrology service implanted 238 peritoneal catheters by interventional technique following by predialysis education. Characteristics of the study cohort are described using medians ranges, and moass ranges for the continuous variables and proportions for the categorical variables. The differences between the groups were calculated using chi-square test.

Results: 238 patients were included. The median age was 50.3 years. 12 (52.2%) were male. 62 % were diabetic, 17 (70.8%) had 1 episode and 6 (25%) had 2 episodes of peritonitis. During the study period, 44.1% required catheter removal and 25% developed recurrent peritoneal collection that required percutaneous drainage. In most of cases (85%) the cause of removal catheter was the presence of abdominal collections and 1 patient had several hypoalbuminemia and associated shock, X2[2]= 3,489 p <0.077. *Pseudomonas* species were the microbiological causes of the peritonitis episodes in most of cases (20%). Of the 238 patients, 2 patients died within 24 months, 1 due to pneumonia and 1 due to myocardial infarction.

Conclusions: The formation and the persistence of intra-abdominal fluid collections of different sizes and localizations is not a rarely encountered phenomenon in peritoneal dyalisis patients. Catheter removal represents high cost in developing countries, and implies a low chance of successful return to peritoneal dialysis. Effective education and training in pre - dialysis should improve outcomes and avoid catheter removal.

PUB371

Gram-Negative Bacteraemia (GNB) in Hemodialysis Patients with Tunnelled Dialysis Catheters (TDCs) Quan Yao Ho. *Tan Tock Seng Hospital, Singapore, Singapore.*

Background: The clinical, microbiological characteristics and management of Gram-negative bacteraemia (GNB) in hemodialysis patients with tunnelled dialysis catheters (TDCs) has not been clearly defined.

Methods: Patients who underwent TDC-related procedures from 2014 to 2016 were reviewed and patients who developed GNB while on hemodialysis via TDCs were included.

Results: 599 patients were either newly initiated on dialysis via a TDC (n=424) or converted to hemodialysis via a TDC – either due to failed arterio-venous access (n=138) or conversion from peritoneal dialysis (n=37). On follow-up to 31 March 2017, 121 episodes of GNB developed in 99 patients while on dialysis via TDCs, including 16 episodes of polymicrobial bacteremia, The attributed sources of GNB were TDC (66.9%,n=81), musculoskeletal (6.6%,n=8), respiratory (5.8%,n=7), hepatobiliary (5.0%,n=6), urinary (5.0%,n=6), other gastrointestinal sources (4.1%,n=5) and others (6.7%,n=8) The principal organisms isolated were Pseudomonas (22.4%,n=31), Klebsiella (17.4%,n=24), Escherichia coli (15.9%,n=22), Enterobacter (11.5%,n=16) and Acinetobacter (7.2%,n=11). Among the all isolates tested, 29.1% were resistant to ceftriaxone, 12.6% to ceftazidime, 16.5% to cefepime, 16.5% to piperacillin/tazobactam, 14.1% to carbapenems, 22.7% to gentamicin, 13.6% to amikacin, 23.4% to ciprofloxacin, 32.0% to co-trimoxazole. 82.6%(n=100) of the cases had abdominal imaging (Computer tomography or ultrasound) performed, of which 19.8%(n=24) revealed at least 1 infective focus. 90-day mortality was 17.4%(n=21). 17.4%(n=21) of the cases required Intensive Care Unit (ICU) care; amongst these cases the 90-day mortality rate was 76.2%(n=16). 90-day mortality was associated with ICU admission (OR=15.2, 95%CI 6.28-37.0, p<0.01); a higher median Pitt Bacteraemia Score (3 vs 1; p<0.01); hospital-acquired (>48hours from admission) GNB (OR=3.40, 95%CI 2.13-5.42); source not attributed to TDC (OR=3.18, 95%CI 2.08-4.85, p<0.01) finding of at least 1 infective focus on imaging (OR=2.83, 95%CI 1.48 to 5.41. p<0.01) and management without a line-free period (TDC exchange or no line removal) (OR=1.78, 95%CI 1.18-2.70, p<0.05).

Conclusions: GNB in patients on hemodialysis via TDCs is associated with high morbidity and mortality. Abdominal imaging may be useful in prognostication and TDC removal may be associated with improved survival.

PUB372

Diabetic "MALA"dy – A Tale of a Patient with Diabetes Who Survived Metformin Associated Lactic Acidosis Twice Krishna K. Manda, Sameer Ansar. *OSF St Anthony Medical Center, Rockford, IL.*

Background: We present a case of a 54 y/o man with a h/o Type 2 Diabetes mellitus and Chronic Kidney Disease who was fortunate enough to survive Metformin Associated lactic Acidosis (MALA). He was admitted in June '16 with weakness, nausea and vomiting. Initial investigations revealed Acute Kidney Injury (AKI) with Creatinine (Cr) of 7.3 mg/dl, severe acidosis with Lactic acid greater than 13.3 mmol/L and pH was 7.01. As he was on Metformin, this was thought to be related to MALA amongst other etiologies. He was urgently started on hemodialysis. Renal functions improved and Cr was 1.33 at the time of discharge in July '16. He was again admitted in Feb '17 with increasing lethargy. Labs were notable for AKI with a Cr of 7.1 mg/dl, severe Lactic acidosis >13.3 mmol/L and pH was <6.8. Hemodialysis was emergently initiated. Metformin level was checked which was later found to be elevated at 31 mcg/ml (therapeutic range 1-2). Renal functions gradually recovered and Cr was 1.79 at the time of discharge in March '17.

Methods:

Results: Metformin is one of the most commonly used oral agents in Diabetes. It decreases insulin resistance, decreases hepatic glucose output and increases peripheral glucose uptake. The elimination half-life of Metformin in patients who take multiple doses and have good renal function is approximately 5 hours. Metformin is actively excreted, unmetabolized, via transporters in the proximal tubules of the kidneys and may accumulate in renal failure. The mechanism of MALA is complex. Metformin promotes the conversion of glucose to lactate in the splanchnic bed of the small intestine. Metformin also inhibits mitochondrial respiratory chain complex 1, leading to decreased hepatic gluconeogenesis from lactate, pyruvate, and alanine. This results in additional lactate and substrate for lactate production. Metformin plasma concentrations exceeding 5 mcg/mL are generally associated with MALA. Multiple case series have reported a high rate of mortality with MALA, some approaching 45%. Hemodialysis is indicated if lactate level >20 mmol/L or severe metabolic acidosis (pH ≤7.0)

Conclusions: As Metfomin usage in renal impairment has increased since the removal of rigid serum Cr levels, careful consideration of ongoing usage should be done in order to prevent this potentially life threatening "MALA"dy.

PUB373

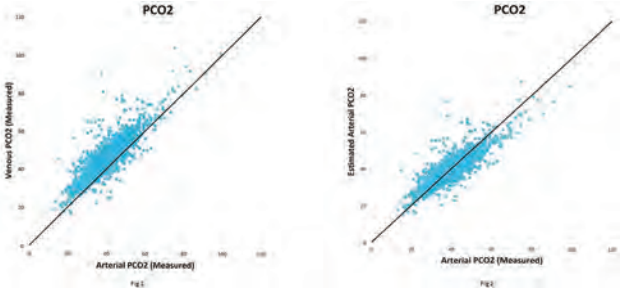
Leveraging "Big Data" Towards a Better Estimation of Arterial pCO2 from Venous pCO2 in the Clinical Settings Sheeba H. Ba aqeel, Alejandro Sanchez, Daniel Batlle. *Northwestern University Feinberg Medical School, Chicago, IL.*

Background: Arterial blood samples are often difficult to obtain owing to technical difficulties and pain associated with the procedure. Venous blood gas is increasingly used instead and there are formulas that transform venous pCO_2 to arterial pCO_2 generated from careful studies which, however, were based on limited data. Moreover, the data originated from specific settings, especially ICU and sometimes obtained using central venous blood etc. In addition, data points from a full spectrum of values within the lower and higher pCO_2 range were usually lacking in previous studies.

Methods: We analyzed a de-identified database of all the venous and arterial blood gases performed in the clinical lab of our hospital (Northwestern Memorial Hospital, Chicago, USA) between November 2003 and November 2016. We selected 3931 values from 11934 observations where both the arterial and venous samples had the same time of blood extraction. These observations were from 2430 males and 1501 females of ages ranging from 17 to 90 yrs and from all clinical settings and departments within the hospital.

Results: The expected relationship between venous and arterial pCO_2 (venous>arterial) was found with r^2= 0.74 (Fig 1). From this relationship the arterial pCO_2 could be recalculated from venous pCO_2 using the least squares formula: $ApCO_2$=0.82 x $VpCO_2$ + 2.19. Based on this relationship the estimated arterial pCO_2 re-plotted as a function of measured arterial pCO_2 was close to the line of identity (Fig 2)

Conclusions: The arterial pCO_2 estimated from venous pCO_2 from thousands of concurrent observations, from different clinical settings, encompassing a wide range of pCO_2 can replace measured arterial pCO_2 with a reasonable level of precision. With this improved estimation of arterial pCO_2 from measured venous pCO_2 the recalculation of arterial pH will likewise also be more accurate.



PUB374

The Pain of Fighting a Shadow: 5-Oxoproline Acidosis as a Clinical Diagnosis Alisha Smith, Franco H. Cabeza Rivera, Desiree Garcia Anton, John Bridges. *University of Mississippi Medical Center, Madison, MS.*

Background: Anion gap metabolic acidosis (AGMA) in the critically ill is a frequent cause of Nephrology consultation. While in most the cause is easily identified, in otherwise unexplained acidosis a high level of suspicion of specific conditions as well as availability of laboratory resources are needed. Despite being recognized as a cause of AGMA for decades, 5-oxoproline (5-OP) acidosis attention seems to have spiked recently with more cases being reported; yet, it is not well characterized and remains underdiagnosed.

Methods: A 79 year-old female with history of anxiety, depression, and COPD was admitted with vertebral and rib fractures after a fall. She was started on scheduled acetaminophen 650 mg PO every six hours for pain. Hospital course was complicated by respiratory failure and hemodynamic instability. Shortly after admission her serum bicarbonate (CO2) level began to fall: from 24 meq/L it decreased daily to a nadir of 14. At the time of consultation, 14.9 g of acetaminophen were administered to the patient over 7 days. ABG: 7.26/35/101; serum chemistry (mEq/L): sodium 137, potassium 4.1, chloride 109, CO2 14, BUN/creatinine 16/0.74 mg/dl (within her baseline), glucose 169 mg/dl, anion gap 17, albumin 2.7 g/dl; lactate normal, no ketones. With negative work-up for common causes of acidosis, discontinuation of acetaminophen was recommended and urine organics acids were ordered. Urine 5-OP level was 17 mmol/molCr. One day after stopping acetaminophen her CO2 improved to 18 and normalized within 72 hours.

Results:

Conclusions: 5-oxyproline acidosis remains a rare cause of AGMA. While mainly diagnosed in women with chronic use of acetaminophen, hospital-acquired cases have been reported. Given the transient nature of the elevation of 5-OP levels and the delay in obtaining confirmatory results, laboratory confirmation should not delay treatment when suspected clinically. In our case, clinical characteristics like gender, age, nutritional status, critical condition and more importantly the temporal correlation between acetaminophen intake and increase in anion gap provided a strong evidence for causality. The resolution of the acidosis after discontinuation of the drug also supports our diagnosis. Even when 5-OP levels in urine were not significantly elevated, its presence represents a pathological condition as it is rarely seen in healthy controls.

PUB375

Easy to Miss but Treatable Cause of High Anion Gap Metabolic Acidosis Priyamvada Singh,[3] Jean M. Francis,[1] Craig E. Gordon.[2] *[1]Boston University Medical Center, West Roxbury, MA; [2]None, Natick, MA; [3]Renal, Boston University, Boston, MA.*

Background: Acquired 5-oxoprolinuria secondary to excessive acetaminophen ingestion is a rare, and underdiagnosed cause of anion gap metabolic acidosis.

Methods: A 59-year-old female with CKD stage 3 (baseline creatinine 1.3 mg/dL, eGFR 41ml/min/1.73m2), diabetes, hypertension, and ischemic heart disease was admitted for bilateral foot gangrene and underwent left saphenofemoral endarterectomy. Her hospital course was complicated by delirium, *Clostridium difficile* colitis, AKI (peak creatinine 1.6mg/dL), and high anion gap metabolic acidosis (AGMA). AKI was attributed to ATN in the setting of high vancomycin levels and hypotension. She was treated with an isotonic bicarbonate infusion. Workup of the etiology of the high AGMA was unrevealing with no evidence of ketoacidosis and normal D and L-lactate values. Additional workup revealed elevated urinary 5-oxoproline (305 mmol/mol of creatinine, normal 15-59) through quantitative urine organic acid testing. In retrospect, we discovered she was treated repeatedly with acetaminophen during the hospital course (total 56 grams over 1 month). We recommended discontinuation of acetaminophen which resulted in improvement in her AGMA and delirium.

Results:

Conclusions: An under-recognized cause of high AGMA is acquired pyroglutamic (5-oxoproline) acidosis due to excessive acetaminophen ingestion. Acetaminophen disrupts the gamma-glutamyl cycle causing depletion of glutathione stores, and leading to accumulation of 5-oxoproline. Normally, glutathione results in a negative feedback by inhibiting gamma-glutamyl cysteine synthetase. With glutathione depletion, the negative feedback is removed resulting in upregulation of this enzyme, leading to increased gamma-glutamyl cysteine, a precursor to 5-oxoproline. Acquired 5-oxoproline acidosis is more common in elderly women with multiple comorbidities, in whom baseline glutathione levels may already be low. This likely is an underdiagnosed condition because measurements of serum and/or urinary 5-oxoproline levels are not readily available. Usually, treatment of the condition is to discontinue acetaminophen. Also, N-acetyl cysteine is shown to be of some benefit likely as it augments glutathione levels. Our case thus illustrates the need for keeping a high clinical suspicion and checking 5-oxoproline levels regularly in patients with unexplained AGMA as it is an easily treatable condition.

PUB376

The Bay Rum Diaries: False Assumptions about Rum and Kidney Function in a Case of Isopropyl Alcohol Ingestion Daniel Corbally, Avrum Gillespie. *Temple Medical School, Philadelphia, PA.*

Background: Isopropyl alcohol ingestion presents with a unique array of clinical and laboratory findings that challenge the understanding of both physiology and clinical chemistry. Isopropyl alcohol is a common ingredient in rubbing alcohol and aftershave products marketed as Bay Rum. Current packaging of Bay Rum often resembles that of common ethanol containing rums. We describe a case of mistaken ingestion of Bay Rum, the multiple abnormalities discovered, and their implications for treatment.

Methods: A Spanish speaking woman was brought to the hospital by her son after she drank Bay Rum. A week prior, the patient had been admitted for a fall related to beer potomania. Her son took away her alcohol so she ingested Bay Rum. On exam she was frail, lethargic, behaving unusually; oriented to only person and place. She was normotensive and euvolemic without neither nystagmus nor flank tenderness. Her Na+ was 123 mEq/L, BUN 47 mg/dl, creatinine 2.54 mg/dl, glucose 75 mg/dl, ethanol < 5 mg/dl, and a calculated osmol gap of 27 mOsm/kg. She was treated with normal saline, thiamine, and folate. Subsequent laboratory results showed osmol gaps of 18 mOsm/kg and 8 mOsm/kg respectively. Pseudo-renal failure was considered as acetone interferes with the creatinine assay, increasing it by 1 mg/dl for every 100 mg/dl of acetone. We calculated serum acetone of 98 mg/dl, which would falsely increase her creatinine by 0.98 mg/dl from her baseline of 0.6 mg/dl. Her elevated creatinine (2.54 mg/dl) cannot be attributed to acetone alone. Her fractional excretion of Na+ was 3.3%, suggesting acute tubular necrosis (ATN). Her creatinine improved slowly to 1.38 mg/dl on discharge.

Results:

Conclusions: This case highlights the importance of understanding and managing the elevated creatinine levels in isopropyl alcohol toxicity. It is critical that kidney function be carefully assessed and the laboratory phenomenon of pseudo-renal failure thought of as a diagnosis of exclusion. When managing toxic alcohol ingestions in the setting of chronic alcohol abuse, volume status and sodium levels must be monitored closely. Furthermore, it is important to understand the toxicity of common household products, and recognize that language barriers may lead to hazardous misunderstandings with such products.

PUB377

Cell Phone Application for Improved Point of Care Urine Concentration Measurement Laura E. Walawender,[3] John Ketz,[1] Vijay Saxena,[3] Andrew L. Schwaderer.[2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Westerville, OH; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: Inadequate hydration may have deleterious effects including cyst progression in ADPKD patients or urinary stone formation. However, markers to evaluate hydration status have not been well studied in children. The objective of this study is to assess pediatric patients' urine osmolality compared to markers of thirst and/or urine concentratrion.

Methods: Children age 12-17 years were eligible for enrollment. Exclusion criteria were CKD > stage 1, concentrating defects, diuretic use, gross hematuria, and medication known to change urine color. Patients reported thirst perception by Visual Analog Scale. Patients and 4 research team members independently matched the patient urine to the urine color scale. Urine specific gravity (SG) was measured by automated dipstick analysis and refractometer. Urine osmolality was measured by osmometer. Linear regression compared urine osmolality to the other hydration markers. The technology department developed a cell phone camera app to to measure light penetrance into urine which was tested on 25 random anonymized urine samples.

Results: Twenty-one patients were enrolled. Linear regression comparing osmolality to hydration markers resulted in the following R squared values: SG (automated dipstick), 0.358; SG refractometer, 0.954; urine color scale (patient), 0.137, urine color scale (research group) 0.026-0.311; and light penetrance, 0.593. The slopes of the SG (automated dipstick), SG refractometer and light penetrance were significantly deviated from a zero-slope line. The refractometer SG had a significantly higher correlation to osmolality than the automated dipstick SG, p= 0.0046. Urine color scales vs. osmolality correlation slopes that significantly deviated from a zero-slope line in 2/4 research team members, but none of the patient or research group member's urine color scale vs. osmolality slopes differed significantly when compared to each other.

Conclusions: Specific gravity by refractometer, but not by urine dipstick correlated closely with urine osmolality. Additionally, there is poor correlation between thirst perception and hydration status. The cell phone application may be a more accurate point of care tool for urine concentration measurement than automated specific gravity dipstick, subjective thirst, and urine color scale, but lags behind specific gravity measured by refractometer.

PUB378

Proteomic Analysis of the Liver with Vacuolar Degeneration from AQP11 Deficient Mice Tatsuya Saito, Sei Sasaki, Kenichi Ishibashi. *Meiji Pharmaceutical university, Tokyo, Japan.*

Background: Aquaporin-11 (AQP11) is expressed at the membrane of intracellular organelles such as endoplasmic reticulum (ER). AQP11-null mice revealed a striking phenotype of multiple large intracellular vacuoles in the proximal tubule and the hepatocyte which are derived mostly from dilated rough ER. However, the mechanism for the vacuole formation is not clear. We employed a proteomic approach to identify key molecules for the hepatic vacuole degeneration before developing kidney dysfunction with polycystic kidneys.

Methods: Mouse livers from three week old AQP11-null mice and their wild-type littermates were compared. Tissue samples were sonicated and digested in sodium deoxycholate buffer to increase hydrophobic protein solubility and trypsin action. After labeling with tandem mass tag (TMT) 6-plex, mixed samples were fractionated by C18-strong cation exchange stop and go extraction tip and separated by nano-flow HPLC followed by mass spectrometer, Q-Exactive.

Results: From the analysis of six livers in each group, 1509 proteins were identified. Around 40 each differently expressed proteins (>1.3 and <0.7 fold) were identified. The enhanced proteins in AQP11-null were Metallothionein2 (binding various heavy metals), Cytochrome P450 4A (20-HETE synthase and fatty acid ω-hydroxylase activities), Thymidine phosphorylase (angiogenic factor), RNA-binding protein3 (anti-apoptotic), Fatty acid-binding protein (cellular antioxidant), Ceruloplasmin (copper-carrying protein), and Calpastatin (membrane fusion inhibitor). The decreased proteins in AQP11-null were RNA helicase DDX39A (cell growth), Cnot3 (cell growth, fat storing), Insulin-like growth factor-binding protein 4 (growth modulator), and Carbonic anhydrase 3 (fat storing). Moreover, KEGG pathway analysis revealed the decreased biosynthesis of antibiotics and nitrogen/lipid metabolism in AQP11-null.

Conclusions: Our proteomic study on AQP11-null liver revealed active cell survival molecules and membrane fusion inhibition with poor growth stimulation and nitrogen/fat metabolisms leading to grown retardation even before kidney failure. The results also

suggested the presence of abnormal heavy metal metabolism relevant to putative metal permeation of AQP11 as some AQPs permeate metals.

PUB379

Nocturnal Polyuria: An Unusual Cause of Nocturia Umair S. Ahmed. *Lavale, MD.*

Background: Nocturnal polyuria is a syndrome in which more than 33 % of the total daily urine output occurs at night. We present an elderly patient who presented with nocturnal polyuria.

Methods: Patient is a 77 years old female with hypertension who was seen in Nephrology clinic for excessive urination at night. Patient had been experiencing an increased urine frequency and volume overnight for 2 years. Patient kept a voiding diary and was voiding approximately 1.5 liters of urine between midnight and 6:00 in the morning. Urine output during the day was less than 1 liters. Patient denied any consumption of caffeine or alcohol. Work up done included a normal sleep study, no evidence of a urinary tract infection, diabetes mellitus, hypokalemia or hypercalcemia. Transthoracic echocardiogram showed grade 1 diastolic dysfunction. Bilateral lower extremity duplex was unremarkable. Patient was started on Lasix 20 mg every morning without any improvement in symptoms. Desmopressin was discussed as a therapeutic option which was declined by patient due to concerns for hyponatremia, reported to be a risk in elderly patients on Desmopressin.

Results:

Conclusions: Causes of nocturnal polyuria include nephrotic syndrome, congestive heart failure and venous insufficiency which can result in development of interstitial edema during the day. Mobilization of this interstitial fluid can result in nocturia. Patients with chronic kidney disease are unable to maximally concentrate their urine. Neurological diseases including Alzheimer's and Parkinson's disease can result in alterations of the usual diurnal secretion of antidiuretic hormone and natriuretic peptides. Often nocturnal polyuria is idopathic and thought to be related to a decreased production of antidiuretic hormone which is usually elevated at night. Treatment options include non-pharmacological measures such as reducing fluid intake in the evening, avoiding use of caffeine and alcohol and use of compression stockings. Pharmacological options include use of topical estrogen, loop diuretics 6 to 10 hours before sleeping and Desmopressin. Desmopressin is a synthetic analog of anti-diuretic hormone and can reduce nocturnal polyuria by promoting water reabsorption overnight. Side effects of Desmopressin include headache, nausea, peripheral edema and hyponatremia. Severe hyponatremia have been reported in the elderly.

PUB380

Refractory Hypophosphatemia in a Young Asian Man with Cholangiocarcinoma Nattawat Klomjit,[2] Ma Clarisse T. Santos.[1] *[1]Renal Physicians Hawaii, LLC, Honolulu, HI; [2]Medicine, John A. Burns School of Medicine, University of Hawaii., Honolulu, HI.*

Background: Hypophosphatemia is a relatively uncommon electrolytes abnormality in hospitalized patients. Common causes of hypophosphatemia include refeeding syndrome, malnutrition and renal phosphate wasting. Excess parathyroid hormone-related peptide (PTHrP) is one of the causes of renal phosphate wasting. Squamous cell carcinomas are most commonly associated with PTHrP secretion, although there are rare case reports from other solid organ tumors. We present a rare case of refractory hypophosphatemia due to PTHrP from cholangiocarcinoma.

Methods: A 34-year-old man with medical history significant for hypertension and obesity who presented with progressive right upper quadrant pain and significant weight loss. Physical exam was remarkable for hepatomegaly and right upper quadrant tenderness. Initial labs were notable for mild hypercalcemia (13.9 mEq/L), hypophosphatemia (1.8 mEq/L), normal renal function (serum creatinine 0.7 mg/dL) and mildly elevated transaminases. CT pelvis and abdomen showed innumerable hypodense masses in caudate and left lobe of liver. US-guided liver biopsy revealed intrahepatic cholangiocarcinoma. Further work-up showed PTH 7 pg/ml (Low), 25-OH vitamin D 14 ng/ml(Low), 1,25-OH vitamin D 35 pg/ml (Normal) and PTHrP 87 pg/ml (High). Fractional excretion of phosphate was high at 20.46% consistent with urinary phosphate wasting. Hypercalcemia was treated with intravenous fluids, intranasal calcitonin and subsequently IV pamidronate. The patient was also persistently hypophosphatemic despite aggressive phosphorus repletion. He was started on chemotherapy since he was a poor surgical candidate due to an extensive disease. Nonetheless, he developed acute hepatic failure with progressive clinical deterioration. The patient and his family subsequently decided to pursue hospice care and he was then discharged to a nursing home.

Results:

Conclusions: In cancer patients who present with hypercalcemia and hypophosphatemia, excessive PTHrP production should be in the differential regardless of tumor type. Since the identification of PTHrP in 1987, there were less than 15 cases reported and most of them were from Japan. Interestingly, our patient developed cholangiocarcinoma with PTHrP at a relatively young age compared to all prior cases reports wherein patients were older than 50 years old. The presence of excessive PTHrP secretion in cholangiocarcinoma portends dismal prognosis.

PUB381

Acute Intermittent Porphyria as a Cause of Syndrome of Inappropriate Anti-Diuretic Hormone in a Young African American Woman Serena Bhela,[4] Dheeraj Kaul,[2] Gary R. Briefel,[1] Mary C. Mallappallil,[2] Moro O. Salifu.[3] *[1]Kings County Hospital, Brooklyn, NY; [2]Medicine, SUNY Downstate, Brooklyn, NY; [3]SUNY Downstate Medical Center, Brooklyn, NY; [4]Medicine, SUNY Downstate, Brooklyn, NY.*

Background: Acute intermittent porphyria (AIP) is a rare genetic disorder of the synthesis of heme caused by a deficiency in hydroxymethylbilane synthase (HMBS), resulting in the overproduction of the porphyrin precursors δ-aminolevulinic acid and porphobilinogen. When present it can result in hyponatremia and chronic kidney disease. Although identified in all main ethnic groups, it is less common in African Americans.

Methods: A 21 year old African American female with no previous medical history was admitted for three days of vomiting and abdominal pain. Physical exam at the time of admission revealed an elevated blood pressure, normal mental status and bilateral lower quadrant abdominal tenderness. Laboratory data on admission were unremarkable however 2 days into her hospitalization, patient had a witnessed tonic-clonic seizure and repeat lab work was remarkable for severe hyponatremia. She was found to have a normal creatinine with a serum sodium of 113, serum osmolality of 258, urine osmolality 807 and urine sodium of 245. Her TSH and T4 were normal. A diagnosis of SIADH was made and patient started on fluid restriction, Lasix and salt tablets with no improvement in her sodium level. Patient was started on 3% hypertonic saline with correction of her sodium. Given the patients abdominal pain, hypertension and SIADH, the diagnosis of acute intermittent porphyria was suspected. A 24 hour urine sample was collected and she was found to have increased levels of δ-aminolevulinic acid and porphobilinogen. Patient was discharged with labetalol for blood pressure control and advised to avoid medications that precipitate an acute attack. Two years later, the patient had another episode of hyponatremia consistent with SIADH and which responded to Lasix and salt tablets. She has experienced a progressive decline in her renal function, her last estimated glomerular filtration rate was 40ml/min with a serum creatinine of 1.8mg/dL and her urinalysis had mild proteinuria, a finding consistent with tubular damage possibly from porphyrin precursors that result in endoplasmic reticulum stress and apoptosis.

Results:

Conclusions: As there is a low prevalence of acute intermittent porphyria in the United States, the diagnosis should be considered in young females who presents with abdominal pain and SIADH of unclear etiology.

PUB382

An Asian Woman with Chinese Herbal Medicine Induced Transient Fanconi Syndrome Resulting in Rhabdomyolysis and Complicated by Severe Hyponatremia Nattawat Klomjit,[1] Noah M. Solomon,[2] Rick Y. Hayashi.[1,3] *[1]Medicine, John A. Burns School of Medicine, University of Hawaii., Honolulu, HI; [2]Nephrology, Straub Clinics and Hospital, Honlulu, HI; [3]Nephrology, Pali Momi Medical center, Honolulu, HI.*

Background: Fanconi syndrome is a rare disorder with multiple etiologies that is characterized by generalized proximal renal tubular dysfunction. Patients could develop hypophosphatemia, hypokalemia, tubular proteinuria, normoglycemic glycosuria and non-anion gap metabolic acidosis with bicarbonaturia. A potential cause of Fanconi syndrome, more commonly seen in Asia, is Chinese herbal medicine nephropathy.

Methods: A 55 year-old Japanese woman who presented with obtundation, abdominal pain, nausea, and vomiting without history of diarrhea. She was found to have hypotonic hyponatremia with initial serum sodium of 104 mmol/L, hypokalemia (3.3mmol/L), hypophosphatemia (1.1mg/dL) and a non-anion gap metabolic acidosis. Urine studies revealed proteinuria, positive urinary anion gap and glycosuria but with relative normoglycemia. These findings were consistent with generalized proximal renal tubular dysfunction otherwise known as Fanconi syndrome. Renal functions were normal with serum creatinine between 0.5-0.6 mg/dL. However, she had developed rhabdomyolysis with elevated creatine kinase up to 10,586 Units/L. Rhabdomyolysis was likely from hypophosphatemia and hypokalemia as a result of Fanconi syndrome and possible component of severe hyponatremia. The rhabdomyolysis improved after repletion of serum phosphorus and potassium. Possible etiologies of Fanconi syndrome had been ruled out. After an improvement of her mental status, she revealed that she had been taking Chinese herbs with the intention of weight loss starting 1 year prior to the admission. Serum phosphorus and potassium had been improved and were normalized prior to discharge. Sodium level was appropriately improved after 3% NaCL infusion. It is uncommon for Fanconi syndrome to present with severe hyponatremia. Abdominal pain and nausea might contribute to appropriate increased ADH production causing hyponatremia. The temporal relationship between the electrolytes recovery and discontinuation of the Chinese herbs suggests a possible causal role in the patient's transient Fanconi syndrome.

Results:

Conclusions: We reported a rare case of transient Fanconi syndrome associated with Chinese herbal medicine use. Chinese herbs containing aristolochic acid have been known to cause aristolochic nephropathy which could present with Fanconi syndrome.

PUB383

When the Hospitalist Meets the Nephrologist: A Case of a Mixed Acid-Base Disorder in the Ward Alexandra C. Bell,[1] Amr E. Mohamed,[2] Javier A. Neyra,[3] Fabrizio Canepa-Escaro.[2] *[1]Univeristy of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky, LEXINGTON, KY; [3]University of Kentucky Medical Center, Lexington, KY.*

Background: Mixed acid-base disorders are often found in hospitalized patients. We report a case of non-anion gap metabolic acidosis (NAGMA) resulting from rapid correction of severe metabolic alkalosis in a patient with acute kidney injury (AKI) receiving total parenteral nutrition (TPN).

Methods: A 37-year-old woman with TPN dependency after total small bowel resection and chronic percutaneous gastrostomy (PEG) tube presented with altered mental status. On admission, she had severe metabolic alkalosis with concomitant respiratory acidosis and AKI. Urine electrolytes were obtained after fluid resuscitation with 2.5 L of 0.9% NaCl and a dose of Diamox (250 mg) in the ED. History revealed her PEG tube was placed to continuous drainage for several days. On the wards, the patient continued to receive IV 0.9% NaCl and was briefly on BiPAP. Her mental status, kidney function and metabolic alkalosis improved after IV fluids. Home TPN (amino acids 1.6 g/kg/day) was then resumed without adjustments. Subsequently, the patient's serum $HCO3^-$ trended down with a normal serum anion gap and positive urine anion gap. The patient was diagnosed with post-AKI tubulopathy impairing the ability of the kidney to excrete HCl^- from amino acid metabolism in the context of high-protein TPN and relative dilutional hyperchloremic metabolic acidosis from aggressive administration of chloride-rich solutions. Patient was discharged on Bicitra and follow-up in Renal Clinic.

Results:

Conclusions: Post-AKI tubulopathy may affect acid-base homeostasis in patients exposed to high-protein TPN. Recognition of mixed acid-based disorders is critical for the management of patients with PEG tubes and TPN.

Cases of Obstructive Uropathy Causing Hyponatremia Victoria Gutgarts,[2,1] Ilya Glezerman.[1] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Nephrology, Weill Cornell, New York, NY.*

Background: The most common cause of hyponatremia in hospitalized patients is syndrome of inappropriate antidiuretic hormone (SIADH). In older male patients, the etiology may be related to urinary obstruction, with improvement in serum sodium seen after relief of the obstruction.

Methods: Case 1: 63 year old man with prostate cancer and brachytherapy implantation three days prior to admission for altered mental status and penile swelling. He had no focal neurologic deficits on exam. Blood work showed serum osmolarity of 243 mOsm/L and sodium of 116 (136-144) mEq/L. Random urine sodium was 160 mEq/L and osmolarity 500mOsm/L. A urinary catheter was placed and 1600 ml of urine was drained. The serum sodium gradually improved, but patient required 5% continuous dextrose infusion to avoid overcorrection. His mental status improved and returned to baseline. Patient was discharged with indwelling urinary catheter and plan for future trial of void. Case 2: 60 year old man with invasive urothelial cancer who underwent radical cystoprostatectomy, bilateral ureteroileal ureterostomy and creation of neobladder two weeks prior to hospital admission. Patient was brought in for lethargy and poor oral intake. On exam, he was normotensive, lethargic but oriented, and had a urinary catheter draining yellow urine. Blood work notable for serum sodium of 99 mEq/L and creatinine of 4.4 (0.6-1.3) mg/dl from baseline of 0.9mg/dl. Urine studies showed random urinary sodium of 26 mEq/L and osmolarity of 157mOsm/L. Further imaging revealed a large pelvic fluid collection causing displacement of the neobladder and urinary catheter anteriorly. Drainage of the collection improved renal function to 1.3mg/dl with normalization of serum sodium.

Results:

Conclusions: In both cases, urinary retention, either secondary to recent prostate instrumentation or extrinsic compression of the bladder from a pelvic collection, was the direct cause of hyponatremia. Relief of the obstruction with placement of a urinary catheter or drainage of the pelvic collection, respectively, caused improvement in serum sodium. The possible mechanism of SIADH involves antidiuretic hormone release from pain related to distention of the bladder exacerbated by excessive free water intake to counter low urine output. Obstructive uropathy is a reversible cause of hyponatremia that should be considered as part of investigations particularly in the setting of recent urologic procedures.

PUB385

Surreptitious Alcohol Intake in a Hospitalized Patient Victoria Gutgarts,[2,1] Ilya Glezerman.[1] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Nephrology, Weill Cornell, New York, NY.*

Background: The serum osmolal gap is a useful tool to evaluate for additional solutes in the blood apart from sodium, glucose, and urea. If the difference between measured and calculated osmolality exceeds 10 mosmol/L, an alternative solute should be considered. Common causes include ethanol intoxication, methanol, ethylene glycol, or isopropyl alcohol. An anion gap can be calculated to differentiate these causes.

Methods: 30 –year-old gentleman with a history of Hodgkin's Lymphoma, Myelodysplastic syndrome, and allogenic stem cell transplant one year ago, presented with bilateral upper extremity tremor and diaphoresis for three days. Tremor was initially thought to be a side effect of cyclosporine, but despite dose reduction and lower serum levels of the cyclosporine, the tremor persisted. Hospital course was complicated by hypernatremia and nephrology was consulted for further evaluation on day 4 of admission. Patient complained of feeling thirsty, and drank two bottles of water daily. He was normotensive, not tachycardic, and afebrile. Physical exam was notable for an essential tremor of the bilateral upper extremities. Otherwise, patient was alert and oriented to person, time, place, but slow to answer and tangential. Recorded urine output was 1.3 liters in 24 hours but patient reported non-compliance with measurement of the output. Blood work was significant for a serum sodium of 154 (136-144) mEq/L and a serum osmolarity of 397 (280-295) mosmol/L. The calculated serum osmolarity was 326 mosmol/L with serum osmolal gap of 71. An anion gap was not present. A more thorough social history was reviewed but patient denied use of alcohol, ingestion of antifreeze, methanol, or alcohol derivatives. Upon further investigation, patient was found to have several empty alcohol containers under his bed.

Results:

Conclusions: Ethanol is the most common cause of an elevated serum osmolal gap. When presented with an elevated serum osmolality, it is important to calculate the osmolarity to investigate whether an osmolal gap is present. Hypernatremia is another clue to ethanol use, since it can cause diabetes insipidus through a transient inhibitory effect on anti-diuretic hormone (ADH) release. When presented with this scenario, a thorough social history and search need to be performed in order to effectively rule out a hazardous cause.

PUB386

Transient Paralysis: Rare Case of Ectopic ACTH Syndrome in Metastatic Prostate Cancer Leading to Severe Hypokalemia Sushma Munugoti, Jennine Michaud. *VA EAST ORANGE, EAST ORANGE, NJ.*

Background: Ectopic ACTH syndrome (EAS), due to malignancy, can lead to severe hypokalemia and metabolic alkalosis. The prognosis depends on tumor type and severity of symptoms. We describe a rare case of transient paralysis due to severe hypokalemia from EAS in metastatic prostate cancer.

Methods: 71 year old African American male with history of hypertension and castration resistant prostate adenocarcinoma, Gleason 9, treated with radical prostatectomy, followed by androgen deprivation therapy and chemotherapy for late recurrence, presented with severe leg weakness. Labs showed serum potassium of 2.2 mEq/L and bicarbonate 33mEq/L. Further studies showed pH of 7.52, PSA 491ng/mL and urine potassium 141mmol/L. Despite initial improvement with potassium repletion, potassium again dropped to 2.2mEq/L resulting in lower extremity paralysis. He concurrently developed progressive lower extremity edema, worsening hypertension, and hyperglycemia. Further work up revealed elevated serum cortisol 47.5 mcg/dL, ACTH 114.4 pg/mL, and 24 hour urine free cortisol 1772 ug. Lack of cortisol suppression after high dose dexamethasone administration confirmed EAS. Ketoconazole was added to potassium supplementation and spironolactone therapy. Paralysis resolved and potassium normalized in just over 24 hours. Ketoconazole was discontinued due to worsening liver function and changed to octreotide. He was discharged on hospice and died 6 weeks after initial evaluation.

Results:

Conclusions: EAS is a clinical state due to prolonged, inappropriate exposure to excessive endogenous secretion of cortisol and excess circulating free cortisol, with loss of the normal feedback mechanisms of the hypothalamo-pituitary-adrenal axis and the normal circadian rhythm of cortisol secretion. Advanced prostate cancer has been shown to dedifferentiate leading to a paraneoplastic syndrome. Inappropriate repression or expression of certain genes, presumably similar to those in normal pituitary corticotropes, can cause tumors to secrete ACTH. Treatment options include ketoconazole, which inhibits adrenal corticosteroid production, and octreotide which has a direct effect on tumor production of ACTH. Despite aggressive therapy, prognosis is poor for unresectable disease.

PUB387

A Curious Course of Hypercalcemia in Rhabdomyolysis Pace Romney,[2] Josephine Abraham.[1] *[1]University of Utah, Holladay, UT; [2]University of Utah Medical Center, Salt Lake City, UT.*

Background: Hypocalcemia and hypercalcemia are common occurrences with rhabdomyolysis, but can mask underlying calcium metabolism disorders.

Methods: A 77 year old white man with a history of atrial fibrillation presented to the emergency department after sustaining a fall and remaining down for an unknown

period of time. He was diagnosed with rhabdomyolysis and was treated with intravenous fluids (CK 28,000 units/L). Despite appropriate interventions, CK continued to increase, hyperkalemia ensued and calcium decreased to 6.5 mg/dL with an ionized calcium 0.91 mmol/L. Intermittent hemodialysis was initiated for progressive renal insufficiency with hyperkalemia and oliguria. After three days of persistently low calcium, the calcium levels started to increase and was within the normal range at day six. However, over the following two weeks, serum calcium elevated to a peak level of 15.8mg/dL. He underwent further investigation. PTH was found to be elevated at 108 pg/mL. 25-OH Vitamin D was 35 ng/mL and 1, 25 Vitamin D was 13 pg/mL. PTHrp was elevated at 5.2pmol/L. Serum and urine were negative for paraprotein. The patient was given calcitonin, cinacalcet, and denosumab and calcium levels improved. In addition, his renal function recovered, and dialysis was discontinued. A tumor evaluation was conducted with a whole body PET scan that revealed increased metabolic activity at the site of muscle injury and ensuing calcinosis. Further review of his chart revealed a previous diagnosis of hyperparathyroidism due to a right inferior parathyroid adenoma seven years before. He declined surgery then and was lost to follow up.

Results:

Conclusions: This case illustrates the difficulties involved in the interpretation and management of calcium levels during acute rhabdomyolysis and ensuing shift of calcium between the muscle and the vascular compartments. Management principles include supportive fluid and calcium management along with renal replacement therapy. In this case, an underlying cause became apparent following correction of the acute metabolic sequelae of rhabdomyolysis. We believe the elevation of PTHrp is unexplained and likely false positive finding.

PUB388

Design and Methods of a Randomized Controlled Trial of Metformin in ADPKD (TAME-PKD) Stephen L. Seliger,[4] Kaleab Z. Abebe,[5] Kenneth R. Hallows,[1] Dana Miskulin,[2] Ronald D. Perrone,[2] Terry J. Watnick,[3] Kyongtae T. Bae.[5] *[1]Keck School of Medicine of USC, Los Angeles, CA; [2]Tufts Medical Center, Boston, MA; [3]University of Maryland School of Medicine, Baltimore, MD; [4]University of Maryland School of Medicine, Baltimore, MD; [5]University of Pittsburgh, Pittsburgh, PA.*

Background: Preclinical studies suggest that metformin may be efficacious for preventing progression in ADPKD by activating the metabolic sensor AMP-activated protein kinase (AMPK). However, the effect of metformin on disease progression in human patients with ADPKD, and the long-term tolerability of this medication in these patients, is unknown.

Methods: This is a phase 2 double-blind placebo-controlled multicenter randomized clinical trial to evaluate the safety, efficacy, and tolerability of metformin in ADPKD patients over a two-year treatment period. Participants (N=96) are adults with ADPKD with estimated GFR ≥50 ml/min/1.73m2, without contraindication to MRI or metformin treatment. Participants are randomized in 1:1 ratio to metformin - beginning at 500mg daily and titrating over 6 weeks to maximally tolerated dose up to 1 gram twice daily - or matching placebo. Follow-up evaluations occur every 2 weeks for 2 months, monthly for 4 more months, and then every 3 months for 24 months total. Metformin dose will be reduced to 500mg twice daily if eGFR declines <45 ml/min/1.73m^2, and will be discontinued if eGFR declines <30 ml/min/1.73m^2 or if increased serum lactate occurs. The primary safety/tolerability outcomes are: proportion of participants experiencing serious adverse events; gastrointestinal symptom rating scale severity; and maximally tolerated dose of study medication. Treatment efficacy is assessed by comparing the annual rate of changes in a) height-adjusted total kidney volume on MRI performed every 6 months and b) eGFR. Mechanistic outcomes include the changes in activity of key glycolytic pathway enzymes, metabolite concentrations, and activity of AMPK pathway enzymes measured in urine. An independent Data Safety Monitoring Board provides study oversight.

Results: Through May 2017, 57 participants have completed screening, of whom 55 were eligible. Of these, 48 were randomized, and 45 remain in active follow-up for a median 4.5 months.

Conclusions: Results of this phase 2 multicenter clinical trial will provide important evidence on the safety, tolerability, efficacy and effects on renal metabolomic biomarkers of metformin in patients with ADPKD. Such evidence will be crucial to support and plan a phase 3 multicenter efficacy trial.

PUB389

Assessment of PROPKD Score in Chilean ADPKD Families to Predict Renal Outcome Paola Krall,[3] Daniela Ubilla,[3] Daniela P. Nualart,[3] Rocio P. Saenz,[1] Claudio A. Flores,[3] Patricio Downey,[2] Leopoldo G. Ardiles,[3] Sergio A. Mezzano.[3] *[1]Centro de Dialisis Dialsur, Osorno, Chile; [2]Pontificia Universidad Catolica, Santiago, Chile; [3]Universidad Austral de Chile, Valdivia, Chile.*

Background: ADPKD is a genetic kidney disease with a highly variable clinical presentation between individuals, even if they share the same mutation within a family. A clinical-genetic prognostic model, PROPKD score, is available to predict renal outcomes in ADPKD patients that needs to be assessed in developing countries with low health care resources.

Methods: 20 unrelated Chilean families with clinical ADPKD diagnosis were recruited between 2015 and 2017. Genetic analysis of *PKD1/PKD2* was performed in the index case and offered to relatives after identification of a pathogenic variant. Clinical data were collected in individuals carrying a pathogenic variant and scored: being male (1pt), hypertension or first urologic event <35 years (2 pt each one), non-truncating (2 pt) or truncating (4 pt) PKD1 mutation. Relationship between risk categories (low, intermediate or high) of progression to ESRD and age of ESRD was analyzed. Association between position of truncating mutations and hypertension was evaluated.

Results: A genetic basis was confirmed in 18 out of 20 Chilean families. 16 different pathogenic PKD1 mutations were identified that predicted protein truncation (n=11), in frame-deletion (n=1) or missense changes (n=4). PROPKD score was estimated in 51 participants (median ESRD age = 49 years) that resulted with low, intermediate or high risk, with median ages for ESRD of 56, 49 and 48 years, respectively (p=NS). 55% (11/20) of patients carrying truncating mutations before exon 26 had hypertension <35 years, whereas only 21% (4/19) of patients carrying truncating mutations after exon 26 had this condition, suggesting that early truncating mutations are associated with early hypertensive phenotype [p=0.048; OR 4.58; 95% CI 1.12-18.8].

Conclusions: Our findings indicate that PROPKD score seems to predict renal outcome in Chilean ADPKD patients, with the same tendency as described in other cohorts. *GANAB* might be considered as third candidate gene in the two families with negative results. Truncating mutations before the first PKD1 TM domain (exon 26) are associated to hypertension and, secondarily, might be important for renal outcome. We expect to recruit more ADPKD families and monitor young affected relatives to be able to predict ESRD with a high predictive value. FONDECYT #11140242

Overweight and Obesity Are Predictors of Progression in Early Autosomal Dominant Polycystic Kidney Disease Kristen L. Nowak,[8] Zhiying You,[8] Berenice Y. Gitomer,[8] Godela M. Brosnahan,[8] Vicente E. Torres,[3] Arlene B. Chapman,[5] Ronald D. Perrone,[4] Theodore I. Steinman,[1] Kaleab Z. Abebe,[7] Frederic F. Rahbari-Oskoui,[2] Alan S. Yu,[6] Peter C. Harris,[3] Kyongtae T. Bae,[7] Michel Chonchol.[8] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Emory University School of Medicine, Atlanta, GA; [3]Mayo Clinic, Rochester, MN; [4]Tufts Medical Center, Boston, MA; [5]University of Chicago, Chicago, IL; [6]University of Kansas Medical Center, Kansas City, KS; [7]University of Pittsburgh, Pittsburgh, PA; [8]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Similar to the general population, body-mass index (BMI) in individuals with autosomal dominant polycystic kidney disease (ADPKD) has been increasing over recent decades. Surprisingly, the association of overweight and obesity with progression in patients with ADPKD has never been described. We hypothesized that overweight and obesity would be associated with faster progression in early-stage ADPKD patients.

Methods: 455 non-diabetic participants with ADPKD and estimated glomerular filtration rate (eGFR) >60 ml/min/1.73m^2 who participated in HALT Study A were categorized based on BMI as normal weight (18.5-24.9 kg/m^2; reference group; n=170), overweight (25.0-29.9 kg/m^2; n=176), or obese (≥30 kg/m^2; n=109). The longitudinal (5-year) association of overweight and obesity with change in height-corrected total kidney volume (htTKV) by magnetic resonance imaging was evaluated using multinomial logistic regression and mixed effects linear regression models.

Results: Mean±s.d. age was 37±8 years, annual percent change in htTKV was 7.4±5.1%, and BMI was 27.1±5.1 kg/m^2. The annual percent change in htTKV was greater with increasing BMI category (normal weight: 5.4±4.2%, overweight: 7.8±4.7%, obese: 9.5±6.0%; p<0.0001). After adjustment for demographics, randomization group, systolic blood pressure, eGFR, urinary albumin excretion, and baseline htTKV and liver volume, overweight and obesity were associated with increased odds of annual percent change in htTKV ≥7% compared to <5% (overweight: OR: 3.07, [95% CI: 1.79, 5.27], obese: OR: 4.86 [2.54, 9.30]). In the fully adjusted mixed effects regression model, htTKV across all time points (0, 24, 48, and 60 months) was greater in both the overweight (p=0.01) and obese (p=0.005) group compared to the normal weight group.

Conclusions: Overweight, and particularly obesity, are strongly and independently associated with rate of htTKV progression in early-stage ADPKD.

Adaptations to Increased Flow in Polycystic Kidney Disease Elizabeth Y. Chen,[2] Marcelo F. Cassini,[1] Vijayakumar R. Kakade,[1] Richard Torres,[2] Lloyd G. Cantley.[2] *[1]Yale University, New Haven, CT; [2]Yale University School of Medicine, New Haven, CT.*

Background: Previous studies have demonstrated that the loss of polycystins results in unopposed cilia dependent cyst activating signaling, which leads to pathologic tubule remodeling. Because it has been hypothesized that the polycystin complex can function as a flow sensor in cilia, we evaluated the effect of increased GFR on tubule diameter in mice with either normal PC1 expression or Pkd1 haploinsufficiency.

Methods: We employed a nephrectomy model to induce compensatory hyperfiltration in the remaining kidney in both wild-type and Pkd1 heterozygous mice (which have approximately a 50% reduction of PC1 expression). To analyze tubule morphology we used multiphoton confocal microscopy and optimized the Z-stack image analysis techniques to accurately detect morphological changes in response to hyperfiltration.

Results: One week after unilateral nephrectomy, wild-type mice exhibited a 18.02% increase in tubule diameter (718.84±118.38 um vs. 848.37±119.06 um, $p<0.01$, n=20 tubules). Similarly, Pkd1 heterozygous mice exhibited a 20.45% increase in diameter at the same time point (688.48±102.58 um vs. 829.30±153.41 um, $p<0.01$, n=20 tubules).

Conclusions: These studies support a model of tubular adaptation to increased flow, but demonstrate that Pkd1 haploinsufficiency does not impact the magnitude of external remodeling.

Tuberous Sclerosis: Clinical Characteristics and Renal Management Strategies – A Single Centre Experience Rajkumar Chinnadurai, Peter H. Clough, Jude Allen, Martin N. Punter, David I. New. *SALFORD ROYAL NHS FOUNDATION TRUST, Manchester, United Kingdom.*

Background: Tuberous Sclerosis(TS) is a rare genetic disorder affecting multiple organ systems including Kidneys, where it presents as Angiomyolipoma(AML) and Cysts. With the advent of mTOR inhibitors, the management of this condition has taken a new dimension. As our institution is a tertiary renal and neurological centre, we have a growing cohort of TS patients followed-up in our multi-speciality and multi-disciplinary(MDT) TS clinic.

Methods: A cross-sectional observational study of all patients registered in our TS database. Clinical characteristics and Management strategies were reviewed.

Results: Currently 25 patients are registered in our study database. Mean age of our cohort is 40 with 14 males and 11 females. So far: 22/25 had some form of imaging (MR or CT Scan) of their Abdomen/Kidneys. Of these 22 patients, 13(59%) had a size of AML>3cm and qualified for mTOR inhibitor therapy based on current international guidelines. 5 had AML size <3cm and 4 with no renal involvement. Mean eGFR of our sample was 74.6ml/min/1.73m^2 with the mean haemoglobin 130mg/dl. eGFR did not correlate with the number of AMLs. There a linear increasing trend noted in the size of AMLs with age. Of the 13 eligible for mTOR inhibitor treatment, eight are on sirolimus, one on everolimus and rest under assessment. On review of neurological manifestations, 84%(16 of the available 19) had radiological evidence of cortical tubers in the brain, 11 had Sub Ependymal Nodules, 7 had SEGA(Astrocytoma). Phenotypically, 14 of 25 had an intellectual disability with 23 of the 25 patients having active epilepsy; generalised onset in 18 with co-existent focal onset in 17. The seizure type was unclassified in 5 patients. All 25 were on at least two antiepileptic medications.

Conclusions: Our study and database have given a better insight of our patient characteristics and management strategies, including a plan for timely imaging. With expanding indications of the use of mTOR inhibitors an MDT approach would be the appropriate management strategy. Plans also include the use of Physiologically Based Pharmacokinetic Modelling(PBPK) in guiding mTOR inhibitor dosing to overcome challenges in drug level monitoring due to intellectual disabilities and enzyme inducing anti-epileptic medications.

PUB393

The Effect of Hydration Advice on Urine Specific Gravity as a Marker of Vasopressin Suppression in Polycystic Kidney Disease Ragada El-Damanawi,[3,4] Anita Sarker,[1] Caroline M. Robinson,[2] Richard N. Sandford,[2] Fiona E. Karet,[2,3] Thomas F. Hiemstra.[3,4] *[1]Clinical Biochemistry, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [2]Medical Genetics, University of Cambridge, Cambridge, United Kingdom; [3]Renal Medicine, Cambridge University Hospital NHS Foundation Trust, Cambridge, United Kingdom; [4]Cambridge Clinical Trials Unit, Cambridge, United Kingdom.*

Background: Vasopressin receptor antagonism (VRA) slows ADPKD progression, but access to this treatment is restricted to a small number of developed economies. High water intake suppresses vasopressin production and may offer an alternative therapeutic approach. Trials of high water intake are needed, but the effectiveness of high water intake advice on urine specific gravity (uSG), a surrogate marker for vasopressin suppression (uSG≤1.010), is unknown.

Methods: We evaluated the effectiveness of high water intake advice in reducing uSG in a cohort of incident patients with ADPKD attending a specialist renal genetics clinic. In this single-centre cohort study, we abstracted data from the health records of all ADPKD patients referred between 2010-2015. We compared uSG after provision of fluid intake advice to baseline values.

Results: Data were available for 77 patients. The mean age (±SD) at baseline was 45±16 y, and 32±16 y at diagnosis. 51% (39) were female, 84% (65) White British, and 49% (38) had a *PKD1* mutation. The mean eGFR was 75±24(SD) ml/min/1.73m^2 and 68% (44/65) of those with imaging data were at high risk of progression (kidney length ≥16cm or Total Kidney Volume ≥750mls). The median uSG at baseline was 1.015 (IQR 1.010-1.020) and 36% (28) had uSG≤1.010. This was not significantly different at follow-up: after high water intake advice 31% (24) achieved uSG≤1.010, p=0.50 (Table). Only 13% (10) had achieved a reduction in uSG from baseline, while uSG increased in 18% (14).

Conclusions: Fluid intake advice was ineffective in increasing the proportion of ADPKD patients attaining dilute urine. Additional strategies that promote adherence to high fluid intake are necessary to achieve vasopressin suppression. This should be taken into account when designing high water intake trials.

Number ± SD	Baseline Visit	Follow-up Visit	P value
Achieved uSG ≤ 1.010	28 (36%)	24 (31%)	0.50
Mean Creatinine umol/L	104±50	106±52	0.21
Mean eGFR ml/min/1.73m2	75±24	73±24	0.32
Mean Arterial Pressure mmHg	101±12	100±11	0.51
Mean Sodium mmol/L	139±3	140±2	1.00

PUB394

Clinical Characteristics of ADPKD Patients Requesting Pre-Implantation Genetic Diagnosis Erin L. Murphy, Madeline Droher, Neera K. Dahl. *Yale School of Medicine, New Haven, CT.*

Background: Patients with Autosomal Dominant Polycystic Disease (ADPKD) have a 50% chance of transmitting the disease to their offspring. Preimplantation genetic diagnosis (PGD) reduces this risk to 1-2%. We hypothesized ADPKD patients of childbearing potential who are at high risk of clinical progression are likely to pursue PGD to conceive. Common clinical features that may predict high risk of clinical progression to end stage renal disease (ESRD) in ADPKD patients include genotype, early onset of hypertension, and large kidneys or increased total kidney volume (TKV). In addition, patients may have a family history of intracranial aneurysms or complications of hepatic cysts which may further inform the decision to pursue PGD.

Methods: After IRB approval, we performed a retrospective medical record review of eight patients diagnosed with ADPKD who attempted PGD with IVF. We collected family history and patient characteristics and, including genotype, presence of hypertension, extra-renal manifestations of PKD, and TKV when available.

Results: See table.

Conclusions: 7 patients had novel mutations, 4 patients had truncating PKD1 mutations, and 4 patients required additional testing of family members to determine disease associated short tandem repeats (STRs). 1 patient had a mutation near an exome splice site which may cause a truncating mutation, 1 patient had predicted pathogenic mutation in an intronic region. All 8 patients were at high risk of clinical progression, and considered and/or underwent PGD with IVF to conceive.

Thermal Radiofrequency Ablation (RFA) in Renal Cancer of Von Hippel Lindau (VHL) Patients: A Case for Renal Mass Preservation in a Multiple Renal Tumor Setting Javier De Arteaga,[3,4] Pehuén Fernández,[3,4] Jorge De la fuente,[2,4] Walter Douthat.[1] *[1]Hospital Privado Universitario, Córdoba, Argentina; [2]HTAL. PRIVADO DE CORDOBA, BUENOS AIRES, Argentina; [3]Hospital Privado Universitario de Córdoba, Cordoba, Argentina; [4]Universidad Catolica de Cordoba, Cordoba, Argentina.*

Background: VHL can present with a devastating clinical picture that may include ESRD for surgical procedures of multiple renal carcinoma Until not far, open or laparoscopic surgery has been the only therapy considered. Termal RFA is a percutaneous less invasive procedure that allows targeting small nodules (less than 3.5 cm usually) Objective: to perform thermal RFA in VHL patients to avoid open surgery with unnecessary loss of renal tissue.

Methods: 3 VHL patients wih renal nodules between 2.5 (smallest) and 4.2 cm (largest) were subjected to thermal RFA under light sedation and local anaesthesia. A percutaneous tumor biopsy was realized during the procedure.2 patients had a previous unilateral nephrectomy for renal cancer.

Results:

Conclusions: Thermal RFA is a valuable and non agressive alternative therapy to open surgery in the setting of multiple and bilateral kidney cancer of VHL 3 patients that had been previously multioperated with loss of renal parenchima (pts: 2 and 3). and a 3rd one with an extremely fragile condition were treated successfully and without complications with this modality Follow up time was of 2.5 years (pt 1), 9 months (pt 2) and 3 months (pt 3) confirms small changes in renal function (table 1) Percutaneous renal tumor biopsy was a safe procedure and confirmed the diagnosis of clear cell carcinoma in all 3

Patients

Cases	Age	Sex	Tumors (n)	Previous unilateral nefrectomy	CKD-EPI pre RFA (ml/min x 1,73 m2)	CKD-EPI post RFA (ml/min x 1,73 m2)	Follow-up (months)

Urinary Citrate Excretion, a Renal Bioenergetic Source, Is Reduced in Autosomal Dominant Polycystic Kidney Disease Matthew Lanktree,[1] Peili Chen,[2] Anna L. Zisman,[2] Bharathi V. Reddy,[2] Kristin J. Bergsland,[2] Fredric L. Coe,[2] Elaine M. Worcester,[2] Arlene B. Chapman.[2] *[1]Nephrology division, McMaster University, Hamilton, ON, Canada; [2]University of Chicago, Chicago, IL.*

Background: Increased renal metabolism is a feature of autosomal dominant polycystic kidney disease (ADPKD). Hypocitraturia occurs in ADPKD and has been ascribed to reduced glomerular filtration rate (eGFR) and defects in renal tubular acidification. We hypothesize that ADPKD patients have hypocitraturia independent of these abnormalities.

Methods: 16 APDKD and 16 age-, sex-, and eGFR-matched controls with relatively intact kidney function (mean eGFR=64 ml/min/1.73m²) provided a 24-hour and a fasting morning urine and plasma sample in a Clinical Research Center setting. Serum creatinine, electrolytes and citrate, and urine pH, creatinine, electrolytes, and citrate were obtained, and eGFR, fractional excretion of citrate (FE_{Cit}), gastrointestinal alkali absorption (GIAA), net endogenous acid production (NEAP), and net acid excretion (NAE) were calculated.

Results: Unadjusted urinary citrate and FE_{Cit} were significantly lower in ADPKD vs. controls (327 ± 221 vs. 548 ± 199 mEq/day, P=0.006; 4.6 ± 2.4 vs. 11.5 ± 5.4 %, P=0.002). No difference in plasma citrate, GIAA, NEAP, or NAE were observed between ADPKD and controls (3.8 ± 1.1 vs. 3.9 ± 1.2 mmol, P=0.9; 18.5 ± 24.7 vs. 26.2 ± 19.6 mEq/day, P=0.4; 38.5 ± 19.5 vs. 28.8 ± 15.1 mEq/day, P=0.3). No difference in 24-hour urine pH or bicarbonate (5.8 ± 0.5 vs. 6.1 ± 0.5, P=0.2; 3.5 ± 4.8 vs. 3.1 ± 2.7 mEq, P=0.3), serum bicarbonate or potassium concentration (25.0 ± 2.1 vs. 25.2 ± 1.9 mmol/L, P=0.3; 4.2 ± 0.3 vs. 4.3 ± 0.9 mmol/L, P=0.5) were observed. Linear regression modelling demonstrated that ADPKD status contributed independently to 24 hr urinary citrate excretion and FE_{Cit} beyond eGFR, GIAA, NEAP, and urinary potassium, chloride, and ammonium excretion (R^2 = 0.56, F-statistic = 10.0, P<0.001).

Conclusions: ADPKD status associates with decreased urinary citrate excretion. Decreased FE_{Cit} in the setting of unchanged plasma citrate concentration indicates an enhanced proximal tubule uptake of citrate. Citrate provides 10% of energy for renal metabolism under normal conditions. Given epithelial proliferation, cyst growth, expansion and the increased metabolic demands of kidneys in ADPKD, urinary citrate uptake may provide additional epithelial energy substrate.

PUB397

Clinical Outcome of Patients with Autosomal Dominant Polycystic Kidney Disease Receiving Renal Replacement Therapy Seong Sik Kang,[1,2] Hayeon Park,[1] Sang Mok Yeo,[1] Woo Yeong Park,[1,2] Kyubok Jin,[1,2] Sung Bae Park,[1,2] Seungyeup Han.[1,2] *[1]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic cause of kidney disease in patients receiving renal replacement therapy (RRT). However, there are few reports of clinical outcomes of patients with ADPKD receiving RRT. Herein, we evaluated clinical characteristics and outcomes of patients with ADPKD.

Methods: We retrospectively reviewed the medical records of 253 patients with ADPKD at Keimyung university hospital between January 1989 and January 2017. We analyzed risk factors for renal disease progression and survival rates in patients with ADPKD receiving RRT.

Results: The mean age at diagnosis was 43.2 ± 13.2 years (range, 10-75). Males were 129 (51%) and patients with a family history of ADPKD were 93 (37%). Average duration of follow-up was 76 ± 74.5 months (range, 1-280). Among the 253 patients, 125 (49%) progressed to CKD stage 5 and 100 (40%) received RRT. The mean duration from diagnosis to receiving RRT was 8.8 ± 7.8 years (range, 0-32). In a multivariate analysis, hypertension (HR 2.154, $P = 0.016$), cardiovascular disease (HR 4.325, $P = 0.023$), cyst infection (HR 5.317, $P < 0.001$) were independent risk factors for progression to end-stage renal disease (ESRD). The number of patient receiving hemodialysis, peritoneal dialysis, and kidney transplantation (KT) was 72, 2, and 26, respectively. Twelve (46%) of the 26 KT recipients (KTRs) were treated prior to transplantation. Four underwent simultaneous bilateral nephrectomy and 8 underwent renal artery embolization. The 5-year survival rate of patients without RRT and KTRs were 94.3 ± 2.3% and 96 ± 3.9%, respectively, which was higher than that of 82 ± 5.2% in hemodialysis patients ($P = 0.021$). The 5-year survival rate of allograft kidney in KTRs was 88 ± 8.1%.

Conclusions: Hypertension, cardiovascular disease, and cyst infection were independent risk factors for progression of renal disease in ADPKD. In order to slow the progression to ESRD, best efforts to properly manage hypertension and cardiovascular disease are required. Nevertheless, when progressing to ESRD, KT can be recommended as treatment of choice.

PUB398

ADPKD Prevalence in the Italian Province of Modena Suggests That Is a Rare Condition Francesca Testa,[1] Andrea Solazzo,[1] Marco Busutti,[2] Luciana Furci,[1] Silvia Giovanella,[1] Giulia Ligabue,[1] Giacomo Mori,[1] Gianni Cappelli,[1] Marco Leonelli,[1] Riccardo Magistroni.[1] *[1]Division of Nephrology, Dialysis and Transplant, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Italy; [2]UO Nefrologia, Dialisi e Trapianto, Dipartimento di Medicina Specialistica e Sperimentale, Ospedale Sant'Orsola-Malpighi, Alma Master Studiorum Università di Bologna, Bologna, Italy.*

Background: Available estimates of ADPKD's prevalence in literature are conflicting. One of the main difficulties is the complete identification of all affected subjects. The aim of this study was defining the prevalence adjusted for missing diagnosis in a geographically defined population(Province of Modena, Italy). A descriprion of the clinical characteristics of affected subjects is provided.

Methods: The prevalence is calculated considering alive ADPKD patients at the date of 31/Oct/2016. All possible sources of information, including electronic databases, clinical notes of nephrologic clinics, register of RRT patients, have been checked. Index cases were asked to sign the consent and have been clinically evaluated. At risk subjects were invited to partecipate in the study as well. Missing data were imputed through a mixed linear model. The diagnosis of at risk patients without clinical information was predicted through a binary logistic regression. The risk curve was modeled on the population characteristics of the province of Modena extracted from the last census(ISTAT, 2016)

Results: The population of the Province of Modena is 701,642 inhabitants (ISTAT, 2016).254 affected subjects were identified. The point prevalence of ADPKD subjects is 3.63:10,000(IC 95% = 3.010-3.758). Estimated prevalence adjusted for missing diagnosis is 4.82:10,000(IC 95% =4.160- 4.987).81% of patients are in renal replacement therapy (41.9% hemodialysis, 11.6% peritoneal dialysis, 46.5% transplant).42 subjects underwent to a molecular genetic evaluation that showed the involvement of PKD1 in 83% of cases and PKD2 in the remaining 17%.Renal survival is worse in patients with truncated PKD1 mutations(25° survival age 48 years), followed by PKD2 mutations(25° survival age 59 years)and finally by PKD1 missense mutation(25° survival age 64 years).

Conclusions: The prevalence of ADPKD in the Province of Modena is lower than frequently reported in the literature. In our analysis the point prevalence is 3.63:10,000 inhabitants, while predicting missing ADPKD subjects in the cohort of at risk subject produces an estimated prevalence of 4.82:10,000. These estimates are compatible with the definition of rare disease adopted by the European Medicines Agency and Food and Drug Administration.

PUB399

Gastroparesis in Polycystic Kidney Disease – Emphasis on Early Diagnosis Rhea Bhargava,[1] Shradha Gupta,[2] Theodore I. Steinman.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Saint Vincent Hospital, Worcester, MA, Worcester, MA.*

Background: Malnutrition can lead to poor outcomes in renal patients. Early satiety is a well known symptom of polycystic kidney disease. Most of these cases do not undergo an extensive outpatient workup for their GI symptoms and this can lead to unnecessary hospital visits.

Methods: 42 year old male who was diagnosed with polycystic kidney disease at 17 years of age after undergoing a renal ultrasound because of high blood pressure and a history of PKD in the family. His mother developed renal failure and underwent a transplant in 2001. His sister, 2 years older than him is presently on hemodialysis and was also diagnosed with PKD. He has a diagnosis of hypertension since childhood, which has been managed with lisinopril 20 mg daily. Reports decreasing energy levels for the past 2-3 years with associated early satiety and loss of appetite. He was unable to tolerate full meals and had nausea after each meal. Seen by several physicians and had 2 hospital stays for hypovolemia leading to acute kidney injury. No history of hematuria, dysuria, increase in abdominal girth, fever or chills. He has never had any stones or UTIs. He has associated polycystic liver disease as well. Several EGD studies did not reveal any pathology and systemic examination is unremarkable except pallor. He has lost 8 kg over 3 years. Cr has been stable at 1.2 mg/dl for the past 5 years. No other laboratory abnormalities were noted except anemia with a Hb of 11 g/dl. Gastric emptying study showed delayed gastric emptying. Further workup with a CT scan was pursued and this was significant for several right renal cysts providing extrinsic compression on the descending portion of the duodenum. This was thought to be the cause of early satiety. The patient was started on a 6 part small feeding diet and has been followed for 6 months with stable weight and no hospitalizations.

Results:

Conclusions: Mechanical complications of PKD have not been well decsribed and sometimes are undiagnosed. Early screening and close monitoring of these patient with extrinsic bowel compression from cysts can avoid unnecessary procedures and prolonged hospital stays. This can also help in mantaining adequate nutrition which is of utmost importance in these patients. Working in conjuction with urologists to relieve severe symptomatic compression by unroofing cysts has been described.

PUB400

A Rare Case of Distal Renal Tubular Acidosis Complicated with Hypokalemic Nephropathy Xiaoyu Liu, Xuhui Zhong, Jie Ding. *Peking University First Hospital, Beijing, China.*

Background: To report a rare case of distal renal tubular acidosis boy complicated with hypokalemic nephropathy, and analyze the association of hypokalemia, renal tubular acidosis and renal cysts. Detailed clinical data were collected and analyzed. Renal ultrasound and MRI were detected to follow up the change of renal cysts.

Methods: A 9 years old boy, first presented to hospital with a complaint of poor growth and motor retardation at 9 months old. Initial blood investigations showed hypokalemia, hyperchloremic acidosis, with urine PH >5.5. Renal ultrasound showed calcinosis. Renal tubular acidosis and inborn metabolic error were suspected, but no positive was result shown in metabolic screening test. Treatments of sodium bicarbonate, potassium citrate were started, but the follow-up was irregular and the treatment of potassium citrate was not persistent. Other problems, such as growth retardation, rickets, consistent muscle weakness, polyuria and polydipsia developed, and he had experienced several episodes of paralysis which could be relieved by potassium chloride infusion. At the age of 8, urine analysis showed alkalinuria, low titratable acid and FeHCO3. Urine anion gap was 37.39mmol/L. So the diagnosis was type I renal tubular acidosis. But the lab investigation also showed small molecular proteinuria, aminoaciduria and increase of calcium, phosphorus and potassium in urine. Multiple cysts were found in a latest renal ultrasound. In consideration of his long term hypokalemia, a diagnosis of hypokalemic nephropathy was made. After treatment of sodium bicarbonate, potassium citrate and phosphorous salts, his symptom improved with correction of hypokalemia and metabolic acidosis. After 6 months' follow up, his urine protein was negative and the size of renal cysts was decreased.

Results:

Conclusions: Persistent hypokalemia might induce to hypokalemic nephropathy, which manifest as renal tubular injury and renal cysts. Doctors should pay attention to hypokalemia and correct it as soon as possible.

PUB401

Prognostic Assessment of Polycystic Kidney Disease by Urine N-Acetylglucosaminidase Excretion Kaori Takayanagi, Yuta Kogure, Hiroaki Hara, Minoru Hatano, Yumiko Nakamura, Saeko Sato, Takatsugu Iwashita, Taisuke Shimizu, Tomonari Ogawa, Koichi Kanozawa, Hajime Hasegawa. *Nephrol and Hypertens, Blood Purification Center, Saitama Med Center, Saitama Med Univ, Kawagoe, Japan.*

Background: For the adequate therapeutic strategy, especially decision of Tolvaptan indication, prognostic assessment of autosomal dominant polycystic kidney disease (ADPKD) is critical. At present, kidney growth rate (KGR)>5%/year is considered as most reliable parameter in this regard, however, repeated CT/MRI scanning with one year

interval is required to assess KGR. This study aimed to investigate the prognostic efficacy of urine N-aithcetylglucosaminidase-to-Cr ratio (NAG index), conventional parameter for tubulo-interstitial nephropathy (TIN), in patients with ADPKD.

Methods: Clinical data of ADPKD patients who received CT scanning twice or more, before beginning to use Tolvaptan in our facility (n=60) were studied by the prospective analysis based on the past time-point. Predictor of latest KGR was explored by focusing clinical data sampled one year prior to the latest CT scanning.ers in one year prior to the latest CT scanning based on the analytical approach of prospective observation from the past.

Results: Average or median value of age, total kidney volume (TKV), KGR, eGFR and NAG index were 50.2 of age, 1351.7 ml of median value, 5.4% per year of median growth, 47.4±20.3 ml/min and 5.47 IU/mgCr. Stratified analysis by the median value of KGR showed the significant difference in NAG index, but not TKV and eGFR. Univariate analysis showed that NAG index, but not TKV nor eGFR, significantly correlated with KGR (R=0.46, p=0.016), and multivariate analysis also showed that the NAG index would be a predictor of future KGR (partial regression coefficient=0.46, standard error=0.76, p=0.015). In addition, ROC analysis showed that the cut-off value of NAG index for the prediction of ≥5%/year of KGR was 5.06 U/mgCr which is almost equivalent to the upper limit of generally accepted normal range of the NAG index (AUC 0.670, 95% CI 0.461-0.880, sensitivity 76.9%, specificity 57.1%).

Conclusions: NAG index might be a useful clinical parameter for the assessment of ADPKD prognosis and indication of Tolvaptan, which might be reasonable when it would be considered that ADPKD is a typical disease setting causing TIN.

PUB402

A Japanese Patient with Autosomal Dominant Polycystic Kidney Disease Suffering Sustained Liver Injury by Tolvaptan Misaki Yoshida,[8] Kazunori Yamada,[4,9] Kiyoaki Ito,[7] Nobuhiro Suzuki,[8] Takahiro Matsunaga,[5] Takeshi Zoshima,[6] Satoshi Hara,[3] Ichiro Mizushima,[4] Hiroshi Fujii,[1] Takeshi Sawada,[9] Mitsuhiro Kawano.[2] *[1]Division of Rheumatology, Department of Internal Medicine, Kanazawa University Graduate School of Medicine, Kanazawa, Kanazawa, Japan; [2]Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan; [3]Kanazawa Graduate School of Medicine, Kanazawa, Japan; [4]Kanazawa University Graduate School of Medicine, Kanazawa, Japan; [5]Kanazawa University Hospital, Ishikawa, Japan; [6]Kanazawa university hospital, Kanazawa, Japan; [7]Kanazawa universtiy, Kanazawa, Japan; [8]Kanazawa University, Kanazawa, Japan; [9]Department of Advanced Research in Community Medicine Kanazawa University Graduate School of Medical Sciences, Kanazawa, Japan.*

Background: The TEMPO 3:4 Trial described that the elevation of AST and ALT were 3.2% and 4.9%, respectively. However, the whole picture of liver injury by tolvaptan has not been well clarified. Here, we reported an autosomal dominant polycystic disease (ADPKD) patient with drug-induced liver injury (DILI) due to tolvaptan.

Methods: A 37-year-old woman with ADPKD admitted to our hospital due to sustained liver injury. She was administered tolvaptan six months before admission. She had been administered no drug except for tolvaptan. Her hepatic enzymes had been normal for four months after tolvaptan initiation, but they suddenly elevated (ALT 166 IU/L and g-GTP 53 IU/L). Tolvaptan was discontinued, however, her hepatic enzyme had been increasing for two weeks. She was consulted to gerontologist and close examinations were performed. Blood tests showed that hepatitis viruses and auto antibodies were also all negative in addition of normal value of C-reactive protein. Computed tomography showed only a few lever cysts. DILI due to tolvaptan was suspected, although drug lymphocyte stimulation test was negative. Ursodeoxycholic acid was started, but her liver injury did not ameliorate four weeks after discontinuation of tolvaptan (ALT 302 IU/L and g-GTP 180 IU/L). She was admitted our hospital to perform liver biopsy to exclude other disease such as acute onset autoimmune hepatitis. Liver biopsy showed that lymphocytes, neutrophils, a few eosinophil infiltrations were existed. Necrosis with many pigment-phagocyte cells were seen around centrilobular zone. She was diagnosed with acute hepatitis due to tolvaptan. Corticosteroid (30 mg/day) was initiated and her liver function ameliorated. Conclusions: The detail mechanism and the clinical course of liver injury by tolvaptan has not been well understood, and the liver biopsy is ordinary difficult due to liver cysts in ADPKD patients. Therefore, this patient seemed to give some important information to clarify the pathogenesis of liver injury by tolvaptan.

Experience with Tolvaptan in Patients with Autosomal Dominant Polycystic Kidney Disease Eiichi Sato,[1,2] Tsukasa Nakamura,[2] Takao Ono,[2] Manaka Degawa,[2] Hongmei Lu,[2] Daisuke Matsumura,[2] Mayumi Nomura,[2] Mayuko Amaha,[2] Akiko Fujii,[1] Yuko Ono,[1] Yoshihiko Ueda.[1] *[1]Dokkyo Medical University, Koshigaya Hospital, Koshigaya, Saitama prefecture, Japan; [2]Shinmatsudo Central General Hospital, Matsudo City, Japan.*

Background: The aim of this study was to demonstrate the treatment of autosomal dominant polycystic kidney (ADPKD) with Tolvaptan.

Methods: 15 confirmed cases of ADPKD were included in a cohort between July 2014 to June 2016. Cases were defined according to total kidney volume exceeding 750 ml and with an approximate 5% increase in volume per year by subject. Cases were commenced on 45mg/day of Tolvaptan but the dose was decreased as kidney function deteriorated over time.

Results: Cases were aged between 29-71 years old (average ± standard deviation 52.1 ± 13.1) and comprised 9 males and 6 females. There were 9 patients with a family history of ADPKD. 9 cases were complicated with hypertension, and 5 cases were complicated with cerebral aneurysm including subarachnoid hemorrhage. Hepatic dysfunction, fatty liver, ulcerative colitis, and chronic rheumatism were also observed in this cohort. The eGFR was 54.7 ± 25.6 mL/min/1.73m^2 and the total kidney volume was 1732.7 ± 1052.3 mL at baseline. Cases received a maximum dose of 90 mg/day Tolvaptan and eGFR was recorded as being an average of 49.4 ± 25.6 mL/min/1.73m^2, and mean decrease of 4.99±22.17 % of the total kidney volume/age 6 months after prescription of Tolvaptan.

Conclusions: These cases are typical of patients that are admitted due to kidney disease and are a feature of this cohort. Patients were treated with Tolvaptan for a period of 6 months and we noted a reduction in total kidney volume with Tolvaptan. We also noted that symptoms improved over this 6-month period and we present the effects of this drug on ADPKD including its utility as a biomarker.

PUB404

Predictors of Progression to ESRD in a Cohort of Hispanic Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) Sonia Rodriguez,[1] Jesús A. Cedillo,[1] Ricardo Correa-Rotter,[2] Rodrigo J. Rosado.[1] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [2]Institutor Nacional de la Nutricion, Mexico City, Mexico.*

Background: Introduction: ADPKD is the most common monogenic kidney disease and one of the most frequent causes of ESRD. Its characteristics in Hispanic population are poorly described.

Methods: Purpose and Methods: To identify the factors associated with advanced chronic kidney disease (CKD), defined as eGFR ≤45 mL/min at the time of presentation and rapid progression of CKD, defined as the fall of GFRe >5 mL/min/y for two consecutives years or 10 mL/min in one year. We employed univariate and multivariate analysis.

Results: Results: Single-center cohort of 222 patients, of whom 139 were women (62%), at a National Institute of Health in Mexico City. Median follow-up of 74 months (24-180 IQR), mean age at diagnosis 41 (SD ±14 y). There were 67 patients (43%) with eGFR <45 mL/min and 17 patients (8%) that had renal replacement therapy requirement (RRT) at diagnosis. In addition, during the follow up period 94 patients (42%) required RRT. The median age at the start of RRT was 63 years old and 68 patients (60%) showed a rapid progression of CKD. The indicators at time of diagnosis that predicted progression to an eGFR <45 employing the univariate analysis were: male sex (p 0.01) and presence of systemic hypertension (p 0.02), while age and tobacco use showed only a trend. In the multivariate analysis, the only factors independently associated to progression were male sex (OR 2.6 CI 95% 1.27 – 5.63, p 0.009) and systemic hypertension (OR 2.4, 95% CI 1.2 – 9.2, p 0.015).

Conclusions: Conclusion. In our cohort, advanced CKD was presented in almost half of patients at the time of diagnosis which may imply a late referral to nephrological care. In addition, we observed a high frequency of rapid progressors to CKD. The hypertension and male sex were associated factors to advanced CKD at diagnosis, more studies are needed to explain this last finding.

PUB405

Developing a Computable Phenotype for Autosomal Dominant Polycystic Kidney Disease (ADPKD) Reem Mustafa,[2,4] Kerri A. McGreal,[1] Alan S. Yu.[3] *[1]None, Prairie Village, KS; [2]Nephrology and Hypertension, Univeristy of Kansas Medical Center, Kansas City, KS; [3]University of Kansas Medical Center, Kansas City, KS; [4]Mcmaster University, Hamilton, ON, Canada.*

Background: Polycystic kidney disease includes inherited diseases that cause chronic kidney disease (CKD) and permanent worsening in kidney function. Autosomal dominant PKD (ADPKD), despite being a rare condition, is the most common genetic cause of CKD. We at University of Kansas Medical Center (KUMC) are leading the ADPKD Research Interest Group (RIG) and aim to develop computable phenotype for ADPKD. This effort is through the PCORNet Kidney Health Collaborative Research Group (CRG).

Methods: We identified patients with potential ADPKD using an algorithm that utilizes ICD9 codes 753.12 and 753.13, and ICD10:Q61.2 and Q61.3. This algorithm was developed through an iterative process by expert clinical nephrologist at KUMC. We used a de-identified patient information in i2b2 data access platform to search for patients with the potential diagnosis of ADPKD. Two reviewers independently determined whether patients had ADPKD or not using strict established criteria.

Results: We identified 496 patients using the ADPKD computable phenotype. we performed chart reviews of a random sample of 283 patients to determine if they had ADPKD or not. ADPKD was confirmed in 236 out of 283 charts reviewed. The ADPKD computable phenotype using ICD9 and 10 codes provides a positive predictive value (PPV) of 83.4 % (95% confidence interval 78%-88%). In four charts the diagnosis of ADPKD was unclear due to missing information. A sensitivity analysis was performed to determine whether classifying the excluded patients as having ADPKD, or as not having ADPKD, and it did not meaningfully change the results.

Conclusions: Identifying ADPKD patients using ICD 9 and 10 code has reasonable PPV. We are in the process of assessing the accuracy of the computable phenotype on a

sample of all patients at KUMC which will allow us to determine other accuracy measures including the Sensitivity, Specificity and Negative Predictive Values of the computable phenotype. We also plan to validate the computable phenotype in other electronic medical record systems. In a condition like ADPKD, future research should focus on developing probabilistic phenotyping which may allow for consideration of radiology reports and/or family history that can enhance and improve the accuracy of the computable phenotype.

Criteria for diagnosing ADPKD

PUB406

Rapid Loss of Kidney Function Due to MYH9 Nephropathy: A Case Report Fellype C. Barreto, Gabriela Sevignani, Sibele S. Milano, Giovana M. Pavanelli, Maria A. Pachaly, Mauricio Carvalho. *Universidade Federal do Paraná, Curitiba, Brazil.*

Background: Mutations in the non-muscle myosin heavy chain gene (*MYH9*) are characterized by congenital macrothrombocytopenia, hearing loss, cataracts and glomerulonephritis. We sought to describe a case of rapid loss of kidney function in a young male patient due to *MYH9* nephropathy.

Methods: Data were extracted from medical records.

Results: A 20-year-old male has been followed up at the Clinic Hospital of Federal University of Paraná due to medical history of epistaxis, ecchymoses and petechiae since infancy. At first, Bernard-Soulier Syndrome was suspected due to macrothrombocytopaenia and tendency of bleeding. When he was 17 years old, hearing loss and hypertension were detected along with mild renal failure [creatinine: 1.2mg/dl; CKD-EPI estimated glomerular filtration rate (eGFR): 88 ml/min/1.73m^2], microhaematuria and nephrotic-range proteinuria (7.5g/24h). Renal biopsy could not be performed due to the risk of bleeding (platelets: 7000/µl). Cataracts were excluded by ophthalmological evaluation. Due to the clinical suspicion of *MYH9* nephropathy, genotyping of the patient and of his parents was performed: a *de novo* missense mutation in exon 1 of *MYH9* [c.287C>T; p.Ser(TCG)96(TTG)Leu] was detected. Enalapril was initiated for renoprotection. The patient did not adhere to treatment and lost follow-up. Two years later, he returned to the Nephrology outpatient clinic complaining of foamy urine, peripheral edema and hypertension (160/120 mmHg). Laboratory tests detected worsening of renal function (creatinine: 3.2 mg/dl; eGFR: 36.4 ml/min/1.73m^2) and persistent proteinuria (9.6g/24h). Table shows the evolution of proteinuria and eGFR.

Conclusions: In conclusion, although *MYH9* mutation is a rare cause of nephropathy, awareness of rare genetic disorders is essential to ensure accurate diagnosis and proper management. There is yet no proved effective treatment for *MYH9* nephropathy. Its early recognition is important to avoid unnecessary diagnostic procedures and potential harmful treatment, such as immunosuppressive agents.

Molecular Inversion Probes (MIPs) Are a Highly Scalable, Lower Cost Method for Targeted Sequencing of Kidney Disease Genes Brendan Crawford,[3] V Vega-Warner,[3] D Fermin,[3] Rasheed A. Gbadegesin,[2] Simone Sanna-Cherchi,[1] Jacob O. Kitzman,[3] Matt G. Sampson.[3] *[1]Columbia University, New York, NY; [2]Duke University Medical Center, Durham, NC; [3]University of Michigan, Ann Arbor, MI.*

Background: Targeted sequencing is being used to diagnose patients with putative Mendelian forms of kidney disease. As the number of target genes & patients available for sequencing grows, we are challenged to use affordable and accurate sequencing strategies. Molecular inversion probes (MIPs) is a relatively new method that uses oligonucleotides to perform hybridization-based target capture for subsequent sequencing. MIPs can be massively multiplexed and do not require proprietary technology, thus reducing cost and enhancing scalability. But its performance versus other established methods is less understood. Here, we describe our experience establishing MIPs to screen implicated & candidate Mendelian nephrotic syndrome (NS) genes in a patient cohort.

Methods: We designed an array of 12,000 MIPs for 115 genes (55 previously implicated & 60 candidates). We did a pilot study of 192 NS patients (including 56 previously sequenced) & two 1000 Genomes (1000G) reference samples. Sequences underwent alignment, variant calling, and pathogenicity filtering; Sanger confirmation of qualifying variants was used. We assessed the depth of coverage achieved across the targets, sensitivity in detecting known variants, and depth of coverage needed for acceptable accuracy. We also identified factors impacting acceptable genomic coverage.

Results: The estimated cost was $30/patient, ~5x less expensive than microfluidic based amplification strategies. Sensitivity to detect known variants was 89-94% for 1000G and 100% for previously discovered mutations in NS cases (17/17). Overall, 3.8% of the target region (~23,000 bp) had low coverage, defined as <8X read depth in >10% of samples. Of these regions, 29% also had poor coverage in the Exome Aggregation Consortium dataset, suggesting these are, in general, challenging areas for sequencing. Creating 1500 "rescue" probes resulted in recovery of over 50% of low-coverage regions.

Conclusions: MIPs can be massively multiplexed on arrays, and incorporation of single-molecule tagging permits analysis of unique capture events, reducing the depth necessary at each site to achieve acceptable sensitivity. Provided that there is good DNA quality and rescue of poorly performing regions, MIPs is an accurate and cost-effective method for targeted sequencing studies.

PUB408

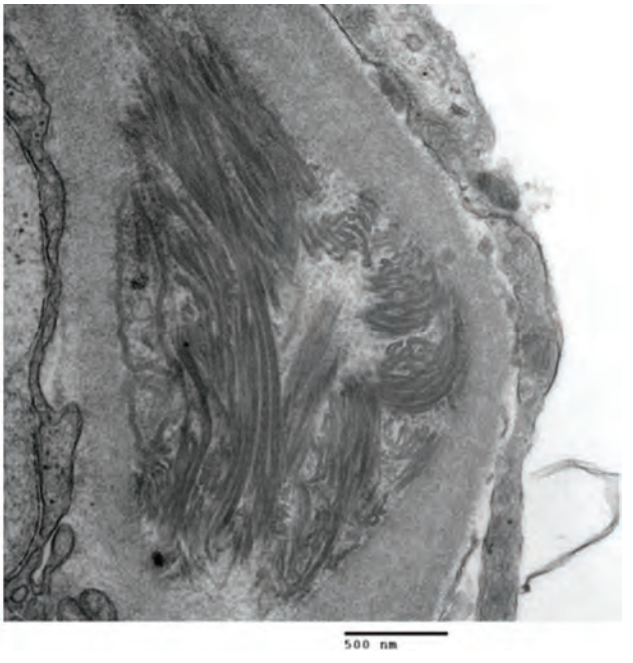
LMX1B Associated Nephropathy with Type III Collagen Deposition in Glomerular and Tubular Basement Membranes Nicole K. Andeen, Jennifer Schleit, Christopher D. Blosser, Fuki M. Hisama, Kelly D. Smith. *University of Washington, Seattle, WA.*

Background: Variants in LIM homeobox transcription factor 1 beta (*LMX1B*) gene cause Nail-Patella Syndrome (NPS). Renal involvement is characterized by incorporation of thick bundles of collagen resembling type III collagen into glomerular basement membranes (GBMs). Recently, variants in *LMX1B* have been associated with renal-limited disease lacking skeletal, joint and nail findings of NPS.

Methods: The patient is a 39 year old man with a family history of kidney disease who presented for transplant evaluation. A kidney biopsy performed 10 years prior when he presented with hypertension, nephrotic syndrome of 5-6 years, and no other physical abnormalities revealed focal and segmental glomerulosclerosis (FSGS). Ultrastructural examination revealed aggregates of electron dense fibrils within thickened GBMs (image) and infrequently in mesangial regions. Some fibrils demonstrated a regular periodicity of 60 nm. Uninvolved GBMs had normal architectural organization and thickness. Several tubular basement membranes were thickened and contained similar fibrils. Immunofluorescence studies were negative. Next generation exome sequencing was performed 10 years later. A total of 66 genes associated with FSGS and steroid resistant nephrotic syndrome were examined. A pathogenic variant in one allele of *LMX1B* (c.737G>A (p.Arg246Gln)) was identified.

Results:

Conclusions: This case highlights the importance of clinical, pathologic, and genomic correlation, and has the novel finding of type III collagen deposition in tubular basement membranes in *LMX1B* associated nephropathy. *LMX1B* variants should be considered as a potential cause of sporadic and hereditary forms of FSGS and steroid resistant nephrotic syndrome, especially in cases where electron microscopy studies reveal incorporation of bundles of type III collagen into basement membranes, regardless of the presence or absence nail or skeletal findings associated with NPS.



PUB409

Autosomal Dominant Interstitial Disease of Kidney – Father and Son Underwent Transplantation Pradeep P. Deshpande. *Hyderabad, India.*

Background: In a village, in India, with 5000 population, around 500 people are suffering from kidney disease. Out of which 100 are on Hemodialysis and 35 underwent kidney transplantation. One family of the same village, in which 6 of the family members are suffering from kidney disease. Father underwent kidney transplantation in 2006 and son underwent kidney transplantation in 2013. Genetic analysis was done for family

members which showed Autosomal Dominant Interstitial Disease of Kidney, mostly due to Mucin -1 gene mutation.

Methods: 34 years old male, kidney transplant recepient, ABO-Compatible(O +ve) on triple drug immunosuppression with Prednisolone 10mg, Tacrolimus 4mg and Mycophenolate 1000mg, on regular follow-up with normal renal functions, serum Creatinine value of 1.3mg/dL. He was initiated on Hemodialysis in February 2013. Underwent unrelated altruistic donor kidney transplantation in July 2013 (due to unsuitability of family members). Family History:Father aged 59 years, underwent kidney transplantation in 2006, doing well and on regular follow-up, with creatinine value of 1.8mg/dL. His two Sisters, 38 and 36 years, who were biopsied and were found to have chronic interstitial disease of the kidney. One having creatinine of 3mg/dl and other having creatinine of 8mg/dl, who has been planned for Deceased donor transplantation. Serum Uric acid levels high in all the affected members.

Results:

Conclusions: To highlight the prevalence of chronic interstitial disease of the kidney in a large population in some districts of India. This family, who had 6 members suffering from chronic interstitial disease, out of which, two, father and son underwent kidney transplantation. Genetic analysis is desirable in such cases to find out the mutation. However, environmental toxins in the soil and water in the villages needs to be studied in detail.

Modulation of Angiotensin II Binding and AT1 Receptor Expression in Experimental Alport Mouse Kidney Christopher Neagra,[2,1] Hong weng Pang,[2] Andrea Linares lopez,[2] Judith T. Molina David,[3] Alessia Fornoni,[3] Robert C. Speth.[2,4] *[1]Palmetto General Hospital, Hialeah, FL; [2]College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL; [3]Katz Family Drug Discovery Center and Division of Nephrology, University of Miami, Miami, FL; [4]Dept. Pharmacology and Physiology, Georgetown University, Washington, DC.*

Background: Alport Syndrome (AS) is a progressive renal glomerular disease that causes kidney failure and hearing and visual impairment, affecting as many as 3% of children and 0.2% of adults with end-stage renal disease (ESRD). It is caused by mutation of a Type IV collagen gene. Angiotensin converting enzyme inhibitors (ACE-I) and angiotensin receptor blockers (ARB) are currently the only treatments that slow progression towards ESRD in AS.

Methods: Eight-week-old Col4a3 -/- (KO) and wild-type (WT) mice were utilized. AT_1 receptors were assayed using ^{125}I-sarcosine^1, isoleucine^8 Ang II (^{125}I-SI Ang II) by saturation binding assay and receptor autoradiography to determine receptor density, distribution and binding affinity.

Results: There was a significant 48% decrease ($p < 0.01$) in AT_1 receptor binding in KO compared to WT mouse kidneys (fmole/mg initial wet weight). However, when expressed as fmol/mg protein, the decrease in the Bmax for AT_1 receptor was 31%, which was not significant ($p = 0.11$).). Interestingly, there was a 24% decrease in mg protein/g wet weight in the Col4a3 -/- when compared to WT kidneys ($p < 0.05$). K_D values were not statistically different between the two groups. Receptor autoradiography did not reveal a difference in AT_1 receptor density in KO versus WT kidneys (153 versus 149 fmoles/g wet weight). However the pattern of AT_1 receptors was more diffusely distributed in the Alport model kidney compared to the wild-type kidney.

Conclusions: The density and affinity of AT1 receptors in the whole kidney cortex are reduced or not altered in experimental AS. This suggests that renoprotection with ACEi-ARB in AS is not linked to overexpression of AT_1 receptors in the kidney or to increased receptor binding. If and how the different distribution of AT1R may contribute to disease progression remains to be established.

PUB411

Renal Manifestations of Deficiency of Adenosine Deaminase 2 Marika Manolopoulou, Ed Gould, Julia Lewis. *Vanderbilt University Medical Center, Nashville, TN.*

Background: First described in the literature three years ago, deficiency of adenosine deaminase 2 (DADA2) has since been appreciated to have a myriad of clinical phenotypes. DADA2 is a disease defined by loss of function mutations in the CECR1 gene, leading to inflammatory activation and early-onset vasculopathy. To date, the renal phenotypes observed in this genetic disease have yet to be fully described in the literature. Here, we introduce one patient diagnosed with DADA2 and characterize her renal phenotype.

Methods: An 18-year-old Caucasian female with DADA2 was referred to renal clinic for evaluation of mildly elevated serum creatinine and low serum bicarbonate. She initially developed manifestations of cutaneous polyarteritis nodosa with livedo reticularis at age two. Despite successful remission with methotrexate, she had several periods of disease relapse over the following decade. Her pre-pubertal serum creatinine (sCr) was 0.3 - 0.4 mg/dL. Between the ages of 8 and 10, her sCr rose to 0.8 - 0.9 mg/dL. At age 14 she was recognized to also have neutrophil aberrancies, cytopenias and relative immunodeficiency; she was managed with non-sucrose based IVIg. This constellation of signs and symptoms prompted referral to the NIH for evaluation. At age 17, shortly after DADA2 was described in the literature, she underwent confirmatory genetic testing. Given the complexity of her case, she was referred to renal clinic to consider possible disease manifestations in her kidney. Her renal workup in our clinic – which has been conducted during a period of relative disease quiescence – has demonstrated a stable sCr (0.9-1.0 mg/dL), an inactive urinary sediment, and a mild metabolic acidosis (serum bicarbonate 18-20 mmol/L) likely driven by a distal renal tubular acidosis.

Results:

Conclusions: Adenosine deaminase 2 is primarily active in the extracellular space and seems to have a variety of roles, including serving as a modulator of the extracellular inflammatory milieu. The vasculopathy observed with DAD2 deficiency likely also manifests in the renal vasculature. In our patient, we suspect that her mild renal insufficiency stems from renal vasculopathy during periods of disease activity in her youth. Given the rarity of this disease, we support centralizing a patient database for additional investigation and characterization of the renal specific phenotypes that can be observed.

PUB412

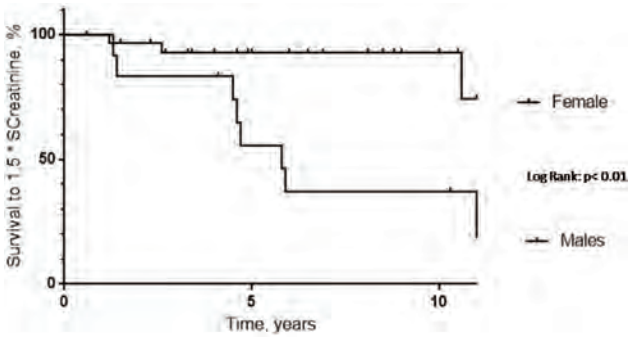
Long Term Renal Function in Patients with Fabry Disease Ricardo M. Heguilen,[3] Juan Politei,[4] Gustavo H. Cabrera,[1] Amelia R. Bernasconi.[2] *[1]Del Viso Medical Group, Buenos Aires, Argentina; [2]Hospital Fernandez, Buenos Aires, Argentina; [3]Hospital Juan A Fernandez, Buenos Aires, Argentina; [4]Department of Neurology, Laboratorio Chamoles, Buenos Aires, Argentina.*

Background: Proteinuria and progressive renal dysfunction, along with cardiovascular and neurological conditions are major findings in patients with Fabry disease (FD). In order to prevent progressive organ failure, enzyme replacement therapy (ERT) should be started early to remove substrate deposition in target tissues. In this study we analyze the renal outcome of a cohort of individuals followed-up throughout a period of almost 15 years from the diagnosis of FD

Methods: Prospective cohort study analyzing the time until an increase in serum creatinina (Screat) 1.5 times from baseline. Proportional hazard (Cox) regression was used to determine whether such outcome was a dependent variable on the following potential covariates: gender, age, hypertension (HTN), diabetes, tobacco use, overweight (OW) or the presence of dyslipemia, Odds ratios with the appropriate 2-sided 95% CI were reported. Kaplan-Meier and the Log-Rank test were used to compare survival curves. All tests were 2 sided, and p values < 0.05 were considered statistically significant.

Results: 44 individuals (13 male) fullfilling the inclusion criteria were followed-up for a time ranging from 1 - 15 years; most of them (80%) receiving ERT from 1 through 13.5 years. The age at diagnosis of FD was 35 ± 2.1 y, baseline creatinine (SCr) was 0.9 ± 0.1 and GFR 89.5 ± 5.0. Ten individuals (6 M) developed the outcome; the median time until the occurrence of the main outcome was 4.6 y, ($p< 0.01$ for gender difference). Male gender (OR 8.9 - 95% CI 1.2-66.8), HTN (10.2; 1.1 – 95.5) and OW (28.7; 1.6 – 50.6) were associated with worsening renal function

Conclusions: Renal involvement in FD is frequent, and the main findings are proteinuria, decreased GFR and tubular dysfunction. ERT may be important to lessen the burden of the disease but is also mandatory to remove other modifiable risk factors that play a major role in the progression of renal involvement



PUB413

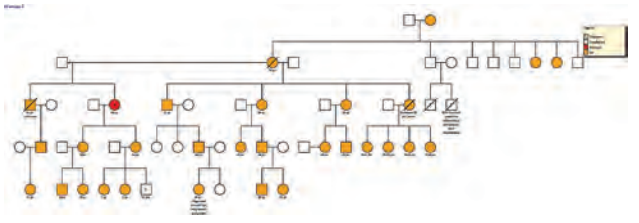
Familial Neurohypophyseal Diabetes Insipidus (FNDI) Spanning Five Generations Denaly S. Chen, Rafia I. Chaudhry, Anum Bilal, Loay H. Salman, Mauricio Monrroy. *Albany Medical College, Albany, NY.*

Background: FNDI is a rare genetic mutation in the AVP gene on chromosome 20p13, resulting in misfolded AVP precursors within the endoplasmic reticulum of hypothalamic neurons, causing cell death. Progressive neuronal degeneration can delay onset of symptoms, however polyuria and polydipsia usually manifest before age 6. Inheritance is autosomal dominant (AD), although autosomal recessive (AR) and X-linked inheritance have been reported. We present a middle-aged patient diagnosed with FNDI, unveiling 5 generations of affected individuals in her family.

Methods: A 56 year old woman with polydipsia and nocturnal enuresis since infancy consulted nephrology following a diagnosis of FNDI in her daughter during pregnancy complicated by dehydration, hypokalemia, and congestive heart failure. Our patient recalled headaches, dizziness, nausea and fatigue with decreased water intake. She had exacerbation of symptoms with limitation of oral intake at the time of a cholecystectomy and ovarian cystectomy. Family hx was positive for polydipsia (siblings) and nocturnal enuresis (daughters). Of note, despite a BMI of 28.8, and full term pregnancies, the patient delivered low birth weight babies (5lb 13 oz and 5 lbs). Initial labs: Cr 0.6 mg/dL, Na 138 meq/L, Ur SG <=1.005. Overnight water deprivation test revealed a Ur osmolality of 398, Sr osmolality 297, serum Na 146 meq/L. Intranasal desmopressin was initiated, Ur SG increased to 1.015, consistent with central DI. Panel gene sequencing of the AQP2 and AVPR2 genes was normal, while the patient was heterozygous in the AVP gene for a sequence variant (c.232_234delGAG), which results in the deletion of one amino acid (p.Glu78del). This mutation is pathogenic for AD FNDI.

Results:

Conclusions: Patients with Central DI have an inability to conserve free water, and FNDI can present with chronic bedwetting, polydipsia and polyuria resulting in growth retardation in childhood, or insidious symptoms with severe electrolyte disturbances during stress (e.g. pregnancy). Genetic screening is essential in patients with Central DI as FNDI affects multiple generations and can have AD, AR or X-linked inheritance.



PUB414

Late Onset Variant N215S GLA Mutation Is Associated with Fabry Nephropathy Behzad Najafian,[2] Mona Maghsoodi-Deerwester,[2] Michael Mauer.[1] *[1]University of Minnesota, Minneapolis, MN; [2]University of Washington, Seattle, WA.*

Background: Fabry disease (FD) is a heterogeneous condition with >700 GLA gene mutations/variants. Characterization of phenotype severity can guide FD treatment. Late onset variants are believed to cause milder phenotypes compared with classical mutations. We compared glomerular lesions, renal function and structural-functional relationships (SFR) in Fabry patients with late onset N215S vs. classical GLA mutations.

Methods: 7 (M/F=4/3) Fabry patients with N215S mutations, age 39(7-54), median (range) years were compared with 7 age and sex matched patients with classical mutations. Fractional volumes of globotriaosylceramide (GL3) inclusions per endothelial [Vv(GL3/Endo)] and mesangial cells [Vv(GL3/Mes)] and podocytes [Vv(GL3/Podo)] were estimated using electron microscopy stereology. Renal function data included urine albumin and protein creatinine ratios (ACR and PCR) and GFR.

Results: All patients had microalbuminuria. GFR, ACR or PCR were not different between classical and N215S patients. N215S was associated with lesser Vv(GL3/Endo) ($p=0.03$) and Vv(GL3/Mes) ($p=0.03$). Vv(GL3/Podo) was numerically greater in classical (0.35±0.16) than in N215S mutations (0.20±0.21) regardless of sex, but the difference was not significant. There was marked variation in Vv(GL3/Podo) among N215S patients regardless of sex, but in patients with classic mutations, variation in Vv(GL3/Podo) was restricted to females. While PCR was strongly associated with Vv(GL3/Podo) ($r=0.78$; $p=0.04$) and Vv(GL3/Endo) ($r=0.86$; $p=0.01$) in the classical group, such SFRs were not seen in the N215S group. Among the clinical symptoms, corneal opacities and gastrointestinal complications were more frequent in the classical compared with the N215S groups.

Conclusions: Late onset N215S variant, typically associated with residual enzyme activity, is associated with less GL3 inclusions in endothelial and mesangial cells, and shows remarkable variation in GL3 content in podocytes compared with classical mutations. This study suggests that, despite delayed onset and milder symptoms with the N215S mutation, these patients may develop substantial Fabry nephropathy with podocyte injury and microalbuminuria.

PUB415

The Distribution Characteristic of Monoclonal Antibody against Triple Helix of Type IV Collagen α Chains in Epidermal and Renal of X-Linked Alport Syndrome Patients with Different Genotypes Xiaoyu Liu, Fang Wang, Jie Ding. *Peking University First Hospital, Beijing, China. Group/Team: National Key Research and Development Program of China.*

Background: To investigate the distribution characteristic of monoclonal antibody against triple helix of type IV collagen α chains in epidermal and renal basement membranes of X-linked Alport syndrome boys with different genotypes.

Methods: Indirect IF staining of monoclonal antibody angainst type IV collagen α5 chain and monoclonal antibody against triple helix of type IV collagenα5α6α5(IV) were performed on the frozen sections of X-linked Alport syndrome boys and nomal controls. And the phenotype and genotype of X-linked Alport syndrome boys were analysed.

Results: In 10 X-linked Alport syndrome boys whose staining of α5(IV) was negative on the EBM, the staining pattern of monoclonal antibodies against triple helix of type IV collagen α5α6α5(IV) on the EBM was negative in 5 patients but positive in the other 5 patients. No definite relationship between genotype and the staining pattern was found. In 5 X-linked Alport syndrome boys whose staining of α5(IV) was positive on their EBM and GBM, the staining pattern of monoclonal antibodies against triple helix of type IV collagen α5α6α5(IV) was positive.

Conclusions: Mutations in the COL4A5 gene producted abnormal α5(V) chain, and the abnormal α5(V) chain can assemble triple helix type IV collagen protomers with other α chains. But the mechanism of how the abnormal protein distribute to the basement membranes and assemble triple helix type IV collagen protomers was still unknown.

PUB416

Diffusion Restriction of Kidney Medulla in Gitelman Syndrome Patients Detected by the New Diffusion Kurtosis Imaging of MRI Xiaoyan Peng,[1] Gu-Mu-Yang Zhang,[2] Yan Liu,[1] Dongli Tian,[1] Hao Sun,[2] Limeng Chen.[1] *[1]Department of Nephrology, Chinese Academy of Medical Science, Peking Union Medical College Hospital, Beijing, China; [2]Department of Radiology, Chinese Academy of Medical Science, Peking Union Medical College Hospital, Beijing, China.*

Background: Gitelman syndrome (GS) is an inherited tubulopathy with Na^+-Cl^- cotransporter (NCC) dysfunction. Regular imaging techniques including magnetic resonance imaging (MRI) could not detect any changes in kidney of GS. Diffusion kurtosis imaging (DKI) is a new method of MRI which could disclose more precise tissue structure and non-Gaussian water diffusion. This study first applied this novel technique in GS patients to observe the potential biostructural and functional abnormity of the kidney.

Methods: Sixteen genetically diagnosed GS patients and 24 healthy subjects were enrolled and underwent Diffusion-Weighted imaging of the kidney at a 3 Tesla. Region-of-interest measurements were performed to determine apparent diffusion coefficient (ADC), kurtosis (K) and diffusivity (D) value of the kidney cortex and medulla. Pearson or Spearman correlation was used to evaluate the association between DKI-derived parameters and clinical data, including serum and urine electrolyte levels, plasma upright RAAS levels, and the in vivo NCC function evaluated by the thiazide test.

Results: The mean age of GS patients was 30.0±10.8y and 50% were males, with a mean onset age of 23.4±12.7y. At admission, the median duration of hypokalemia was 24(12, 126) months and the mean serum K^+ was 3.25±0.6 mmol/L, the urinary K^+ excretion was up to 91.1±32.9 mmol/24h. Compared to healthy subjects, lower ADC (1.417±0.189 vs. 1.547±0.115, $P=0.022$) indicating greater diffusion restriction was observed in the renal medulla of GS, but ADC was similar in the cortex. ADC of the cortex was associated with plasma upright AngII concentration ($r=-0.529$, $P=0.035$) and mean blood pressure ($r=-0.598$, $P=0.014$). Among GS patients, D indicating the observed non-Gaussian behavior and K reflecting the more peaked distribution of tissue diffusivities correlated well with serum Cl^- (D: $r=-0.733$, $P=0.001$; K: $r=-0.664$, $P=0.005$), HCO_3^- (D: $r=0.603$, $P=0.014$; K: $r=0.621$, $P=0.010$) and actual base excess. In the medulla, only K value associated with serum Cl^-($r=-0.562$, $P=0.023$). No correlations were observed between DKI-derived parameters and serum potassium or urinary electrolytes excretion.

Conclusions: In GS patients, diffusion restriction of water molecular in kidney medulla was observed by the novel DKI-MRI and associated well with hypochloremia and metabolic alkalosis.

PUB417

Erdheim-Chester: A Rare Multi-System Disease Mohamed Razeem,[2] Smita Gunda.[1] *[1]Cambridge University Hsospitals, Cambridge, UK, Kings Lynn, United Kingdom; [2]Queen Elizabeth Hospital King's Lynn, Swaffham, United Kingdom.*

Background: A case of Erdheim-Chester disease which demonstrates the classic features of the disease including BRAF gene mutation. We have followed up the patient for over 8 years. We aim to demonstrate the challenges in diagnosis and management of a rare disease.

Methods: 55 year old normally fit and well man presented with tiredness and weight loss and underwent investigations for anaemia. Gastroscopy did not find any abnormalities. Upper gastrointenstinal biopsies only showed metaplastic changes. He was then found to be in acute kidney failure with a Creatinine of 199 umol/l but no significant proteinurea or microscopic haematuria. A CT scan of abdomen demonstrated retroperitoneal disease, mesenteric soft tissue mass, left adrenal mass and bilateral hydronephrosis. A laparoscopic biopsy of peritoneal tissue confirmed the suspicion of retroperitoneal fibrosis. Vasculitic screening has been negative. Patient underwent bilateral ureteric stents for urinary obstruction due to fibrosis and kidney function remained stable during this time. Two years after initial presentation, patient developed bilateral exophthalmos with associated double vision. A biopsy of retro-orbital mass was not diagnostic but excluded malignant causes. Patient received various different imuune suppression tretament including rituximab, bot showed no response. A diagnosis of IgG4 was excluded from the differentials and Erdheim-chester disease was considered as a possible differential diagnosis. Based on this, X-rays of limbs showed diffuse medullary and cortical sclerosis within the long bones that is classical of Erdheim-chester disease. An MRI of heart showed a cardiac pseudo-tumour. Since a diagnosis of Erdheim-chester was made, patient was started on treatment with Pegylated Interferon therapy for which a good response was shown clinically and on imaging. unfortunately this had to be discontinued due to drug related hepatitis. Genetic testing came positive for BRAF gv600E mutation that has been associated with Erdheim-chester disease. At present he is off treatment and awaiting funding for Vemurafenib.

Results:

Conclusions: Erdheim-chester is an extremely rare multi-system disease. A little is known about the disease and reported cases in literature is limited. There has been significant chanllenges in diagnosis. Awarenessa and high index of clinical suspicion of disease is helpful in diagnosis and timely management.

PUB418

Fabry Disease Screening: Report of a Hemodialysis Center in Paris - Turin France Nader Bassilios, Angela Balsa, Mahdi Abtahi, Jacques Becart. *CLINIQUE TURIN, PARIS, France.*

Background: Fabry's disease (FD) is an X-linked lysosomal disease due to a deficiency of alpha-galactosidase A, the enzyme responsible for degradation of globotriaosylceramide (Gb3). The accumulation of Gb3 leads to multisystemic deficiency. The renal involvement is a combination of proteinuria and progressive fall in glomerular filtration rate (GFR) resulting in chronic end-stage renal failure in most male patients at around the age of 40 years old, usually requiring haemodialysis (HD). The purpose of the study was to determine the prevalence of FD patients of a hemodialysis center in Paris.

Methods: A total of 51 patients in HD have been included in the study after signing their informed consent. This is a single prospective study. This cohort consisted of 31 male patients aged between 27 and 65 years and 20 female patients aged between 35 and 65 years. 4 patients had past history of renal transplantation (1 male; 3 female). The length of history of dialysis for male patients ranged from 3 to 97 months and from 6 to 159 months for female patients. Residual enzyme activity of α-GAL was tested in men. For women α-GAL activity combined with testing for Lyso Gb3 levels was performed. The genetic test will be performed if the enzyme activity and/or if the Lyso Gb3 value is reduced.

Results: No patient among 51 was diagnosed with FD. In a female patient the α-GAL enzyme activity was extremely low: 1.4 µmol/l/h (cut-off < 2 µmol/l/h). The Lyso Gb3 value was within normal ranges 0.6 ng/ml (normal range 0.00 -3.5). A request for genotyping was made and no mutations were found in the GLA gene.

Conclusions: In this study, 51 patients undergoing HD were included to test for Fabry's disease although no patients were diagnosed. A review of the international literature suggests a prevalence of FD in patients with end-stage renal failure (ESRF) near 1%. However some studies reported a prevalence of 0%. It is important to change our practice and routinely investigate for Fabry's disease in patients in ESRF of indeterminate cause. Multi-disciplinary care is required and particularly a medical visit with geneticists and genetic counsellors in order to establish a family pedigree to screen other members of the family.

Hereditary Renal Amyloidosis Caused by Variant Lysozyme W64R in a Chinese Family Hui Xu,[1] Suxia Wang.[2] *[1]Xiamen University Chenggong Hospital, Xiamen, China; [2]Peking University First Hospital, Beijing, China.*

Background: Lysozyme amyloidosis was first described by Pepys in 1993. It is a rare form of hereditary amyloidosis with heterogeneous phenotype including gastrointestinal(GI) symptom, hepatic rupture, sicca syndrome, petechiae and purpura, renal failure and lymphadenopathy, among which gastrointestinal symptom is the most typical manifestation. Here we report a lysozyme amyloidosis caused by variant lysozyme W64R in a Chinese family with renal impairment, whereas GI was not involved.

Methods: A 42-year-old man of Chinese ancestry presented with a 1-year history of hypertension and high creatinine. He denied any gastrointestinal symptoms. He had a family history of renal disease. Physical examinations and laboratory studies revealed an abnormal kidney function. No monoclonal immunoglobulin bands were detected by immunofixation electrophoresis. Renal biopsies were positive for amyloid deposits in the renal glomerulus and blood vessel wall on Congo red staining. Immunohistochemistry(IHC) and proteomic analysis confirmed the deposits was lysozyme. Sequence analysis of exon 2 of the lysozyme gene showed heterozygous double peaks with single base transversion from T to A at the first position of codon 64 (TGG/CGG), indicating a heterozygous W64R mutation in the mature protein.

Results:

Conclusions: According to the family history and the results of IHC, proteomic analysis and DNA sequencing, this patient was diagnosed as hereditary renal amyloidosis caused by variant lysozyme W64R. To date, less than 30 families associated with lysozyme amyloidosis have been reported and the geographic kindreds of these families are United Kingdom, France, Canada, Swedish and Germany. This is the first case report about a Chinese family with lysozyme amyloidosis whose dominant involved organ is renal, whereas GI was not involved.

PUB420

Whole Exome Sequencing to Identify Causal Variants for Familial IgA Nephropathy Caragh P. Stapleton,[3] Sharon N. Cox,[2] Claire Kennedy,[1] Neil Fennelly,[1] Gianpiero Cavalleri,[3] Francesco P. Schena,[2] Peter J. Conlon.[1] *[1]Beaumont Hospital, Dublin, Ireland; [2]Department of Emergency and Organ Transplantation, University of Bari Aldo Moro, Bari, Italy; [3]Department of Molecular and Cellular Therapeutics, Royal College of Surgeons, Dublin, Ireland.*

Background: IgA nephropathy (IgAN) is the most common form of glomerular nephritis in the world. Difference in prevalence between ethnicities and familial inheritance patterns indicate a strong genetic component. The advent of next generation sequencing has accelerated the discovery of risk variants underlying familial disorders. We set out test whether damaging variants in known kidney disease genes explain a proportion of cases diagnosed with IgAN.

Methods: We recruited and performed exome sequencing in 8 Italian and 6 Irish families with at least one case of biopsy proven IgAN and at least one other 1st degree relative with either biopsy proven IgAN or end stage renal disease. Candidate causal variants were identified based on 1) being shared between affected family members, 2) frequency in the general population, 3) function and 4) predicted pathogenicity. Qualifying variants were confirmed using Sanger sequencing.

Results: We identified candidate causal variants in three of the Irish families. In one family, we identified a pathogenic variant (according to American College of Medical Genetics standards) in *COL4A5* (known to cause Alport syndrome). The variant was present in two of the three sequenced affected family members and segregated with the disease in five other family members indicating that there may be two similar diseases present in the one family. In another family, we identified a likely pathogenic variant in *COL4A3*. This variant segregated with the disease in two unaffected and two affected family members. In the third family, we identified a variant in *LMX1B*, a gene associated with Nail-patella syndrome. This variant also segregated with the disease however its significance remains uncertain. The same variants associated with kidney disease were not present in the Italian families.

Conclusions: Exome sequencing is a powerful tool for diagnosing unexplained disease. We identified a number of pathogenic and likely pathogenic variants in 14 families who were originally diagnosed with IgAN. This suggests that exome sequence may help improve diagnosis in patients with familial IgAN.

A Girl with Autosomal Recessive Alport Syndrome Due to Segmental Paternal Isodisomy Zihua Yu,[1,2] Lizhu Chen.[1,2] *[1]Department of Pediatrics, Dongfang Hospital, Fuzhou, China; [2]Department of Pediatrics, Xiamen University Affiliated Dongfang Hospital, Fuzhou, China.*

Background: Autosomal recessive Alport syndrome (ARAS), characterized by hematuria, progressive end-stage renal disease, sensorineural hearing loss and ocular abnormalities, is caused by mutations in either the *COL4A3* gene or the *COL4A4* gene. ARAS may be caused by uniparental disomy, which is composed of two homologous chromosomes from one parent or a duplicate of one chromosome, i.e. isodisomy. A man with ARAS due to segmental maternal isodisomy has been reported. Here we report a girl with ARAS due to segmental paternal isodisomy.

Methods: A four years old girl presented with microhematuria at 25 months old, proteinuria at 28 months old and episodic gross hematuria. Her father age 32 years old and younger brother age 2 years old also presented microhematuia, and her mother had neither hematuria nor proteinuria. Her parents are non consanguineous. A homozygous mutation, 1496G>A (G499E), in exon 21 of the *COL4A3* gene was identified in the girl. The same heterozygous mutation, G499E, was found in both her father and younger brother, but it wasn't detected in her mother. Quantitative PCR analysis showed that she has two copies of exon 21 of the *COL4A3* gene. Chromosomal microarray analysis revealed segmental uniparental isodisomy in her chromosome region 2p25.3-2q37.3 that includes the *COL4A3* gene. She was diagnosed with ARAS due to segmental paternal isodisomy.

Results:

Conclusions: The identification of isodisomy in the patient with ARAS helps to give accurate genetic counseling for the patient's parents. The risk of future child of the patient's parents with affected ARAS is negligible because the recurrence risk for isodisomy is very low.

IL-4 Receptor Gene Polymorphism in Childhood Idiopathic Nephrotic Syndrome

Amal A. Al-eisa. *Pediatrics, Kuwait University, Kuwait, Kuwait.*

Background: Idiopathic Nephrotic syndrome (INS) is an immune-mediated disease with a well-documented association with atopy. IL-4 is a vital cytokine involved in atopic symptoms mediated through its receptors (IL-4R). Gene polymorphism of IL-4 receptor (IL-4R) controls the expression and function of IL-4 and therefore might have an effect on the pattern of INS. The aim of this study is to determine the frequency and the association of IL-4R gene polymorphisms with idiopathic nephrotic syndrome (INS) and its effect on the disease pattern in Kuwaiti children.

Methods: Genotypes of the IL-4R gene polymorphisms were analyzed using PCR-RFLP in 151 INS patients and 59 age and sex- matched controls. Clinical data of all subjects were reviewed.

Results: A total of 151 INS (129 steroid-sensitive and 22 steroid- resistant) patients with a mean age was 7.6±4.3 years were studied. Male: Female ratio was 2:1. The CC genotype of IL-4R gene polymorphism was detected in 64% of the INS patients compared to 69.5% of the controls (P=0.57). The heterozygous CT genotype was detected in 30% of INS patients compared 25.5% of the controls (P =0.61). The TT-genotype was detected in 6% of INS patients and 5% of the controls (P =1.00). The C-allele frequency in homozygous and heterozygous forms was found in 94% of INS patients compared to 95% of the controls (P =1.00). The T-allele frequency in homozygous and heterozygous forms was found in 35.7% of INS patients compared to 30.5% of the controls (P =0.57). No significant difference was found in any of the allele frequencies between SS and SR sub-groups when compared with each other or when compared to the controls.

Conclusions: Our data shows no role of IL-4 receptor gene polymorphisms on the clinical pattern or response to steroids in Kuwaiti children with INS

PUB423

The Prevalence of Fabry Disease in Hemodialysis Patients of Jeju island

So Mi Kim, Jong tae Cho, Chang hyun Park, Eun kyoung Lee, Jihyen Jeon. *Division of Nephrology, Department of Internal Medicine, Dankook University Hospital, Dankook University, College of Medicine, Cheonan, Chungnam, Republic of Korea.*

Background: Fabry disease (FD) is an X-linked genetic disorder, caused by mutation in the GLA gene which encodes lysosomal enzyme, a-galactosidase A (α -Gal A). The deficiency of α-Gal A could cause renal failure, but its diagnosis is completely missed at times. Although the prevalence of FD in dialysis patients are known to be between 0.16% and 1.2%, the higher prevalence was expected in island area in terms of genetic disorder. Therefore, we tried to investigate the prevalence of FD in hemodialysis patients of Jeju island.

Methods: A total of 9 artificial kidney units participated in the study. We measured plasma α-Gal A activity before starting hemodialysis. In patients with low level of plasma α-Gal A activity, we analyzed the GLA gene, under patient's agreement.

Results: A total of 663 patients with hemodialysis were enrolled in the study. The mean age of patients was 57 year, and the male was 64 %. Among them, the 39 (5%) patients showed the low α-Gal A activity with < 0.45 nmol/min/mg protein. The gene analysis was performed in all patients with low α-Gal A activity. In genetic analysis, no definite GLA mutation was found. But E66Q mutation, controversial whether it is a functional variant or FD, was found in 3 female patients. Although their presumptive clinical cause of renal failure was DM in one of the 3 patients, unknown etiology in other 2 patients, the kidney biopsy was not performed.

Conclusions: Although the prevalence of FD was 0%, the E66Q mutation showed 0.04 % in hemodialysis patient of Jeju island. More accurate diagnostic tool for FD and follow-up of prognosis of patient with E66Q mutation are needed.

PUB424

Saudi Children Have High Prevalence of Genetic Related Atypical Hemolytic Uremic Syndrome and Better Renal Recovery with Eculizumab Therapy

Abdulaziz A. Bamhraz, Abdulkarim S. Alanazi, Khawla A. Rahim. *Pediatric Nephrology Department, king Fahad medical city, Riyadh, Saudi Arabia.*

Background: Atpical hemolytic uremic syndrome (aHUS) is ultra-rare disease, characterized by microangiopathy hemolytic anemia, thrombocytopenia and renal impairment. Genetic defects that determine uncontrolled activation of the alternative complement pathway have been well documented, it accounts for about 40%–60% of the cases. Recent studies demonstrate the effectiveness of Eculizumab in aHUS treatment. In Saudi Arabia, there is up to 56% of consanguinity marriage resulting in higher prevalence of genetic diseases. We are reporting the experience of a tertiary care center in Saudia for children with aHUS who were treated with plasma therapy and or Eculizumab, their outcome and genetic background.

Methods: This is a retrospective study, from January 2010 till May 2017 in a tertiary care center comparing children with aHUS who had received plasma therapy to those received Eculizumab therapy which was introduced at our center in 2014. We report our data in regard to demographic, clinical presentation, the length of hospital stay, need for dialysis, renal recovery and genetic mutations.

Results: 21 Saudi children who have similar demographic background diagnosed with aHUS, 12 (57%) of them showed complete renal and hematologic recovery (67% in the Eculizumab group versus 33 % in plasma therapy group). Six cases (29 %) reached End Stage Renal Disease (ESRD), four patients (67 %) of these cases from the plasma therapy group; two patients (33%) from Eculizumab group reached ESRD, their genetic mutations were not related to complement dysregulation system. Two of the 21 cases (17%) developed disease recurrence while receiving plasma therapy but no recurrence developed after using Eculizumab. Hospitalization was reduced by 10.6 days in Eculizumab group. 11 (69%) of the 16 cases who underwent genetic testing have identified gene mutations.

Conclusions: In our 21 cases with aHUS, Eculizumab was superior to plasma therapy in inducing, maintaining remission, and associated with better renal recovery. Genetic mutations detected among our patients were higher than reported for this ultra-rare disease, most probably related to the high prevalence of consanguinity marriage.

PUB425

Prohibitin-2 Gene Polymorphism and ROS Tolerance in Frequent Relapsing Nephrotic Syndrome

Keisuke Sugimoto,[5] Kohei Miyazaki,[4] Tomoki Miyazawa,[3] Takuji Enya,[1] Hidehiko Yanagida,[2] Mitsuru Okada,[5] Tsukasa Takemura.[5] *[1]Pediatrics, Kindai University Faculty of medicine, Osakasayama, Japan; [2]Tondabayashi Hospital, Tondabayashi, Japan; [3]Pediatrics, Kindai University Faculty of Medicine, Osakasayama, Japan; [4]Pediatrics, Kindai University Faculty of medicine, Osaka, Japan; [5]Kindai University Faculty of Medicine, Osaka, Japan.*

Background: Patients with minimal change nephrotic syndrome (MCNS) often also have allergic diseases. Imbalances between reactive oxygen species (ROS) and antioxidants have been implicated in MCNS and progression of atopic dermatitis (AD). ROS, produced mainly within mitochondria, subject cells to oxidative stress, while prohibitin 2 protects mitochondria by increasing tolerance to ROS.

Methods: An 18-year-old male patient who developed nephrotic syndrome at 3 years of age subsequently was diagnosed with MCNS by histologic examination. Disease manifestations have recurred 12 times. He had given the various immunosuppressants. At present, proteinuria has abated during treatment with prednisolone and MMF. Eczema has appeared on the patient's face, trunk, and 4 limbs, beginning at 2 months after birth, and worsening of intractable skin eruptions has accompanied or preceded increases in proteinuria. The serum IgE concentration was 18670 IU/L, representing a marked increase. Sensitization to fungi and staphylococcal enterotoxin was detected by ImmunoCAP-specific IgE. Among Th2 cytokines, increases in IL-4 and IL-13 were marked. High value of the dROM represent high oxidative stress and slight reduction of BAP, indicating low antioxidant activity. On exome sequencing analysis detected a heterozygous *prohibitin 2* polymorphism, c.873-3_873-2 delCA (rs111523336). This mutation in exon 9 located on chromosome 12 caused frameshifts in regions connected to splicing sites, where they could disrupt transcription of *prohibitin 2*. Frequency of this polymorphism in exon 9 is 7.3% among Japanese.

Results:

Conclusions: Increase in peripheral blood ROS even MCNS remission state suggests the heterozygous prohibitin 2 variant may contribute to give more susceptibility towards the recurrence of MCNS as well as AD. This increase may have progression of AD, which sometimes heralded. The prohibitin-2 polymorphism may reduce ROS tolerance in glomerular epithelium and led to high local exposure to ROS, increasing permeability of the GBM to result in proteinuria. Imbalance between ROS and antioxidants together with failure of signal transduction in the glomerular slit membrane caused by prohibitin 2 abnormality could have contributed to NS patients. Prohibitin 2 analysis is needed in additional MCNS patients with concomitant allergic disease.

PUB426

The Interaction Effect of rs4077515 and rs17019602 Increases the Susceptibility to IgA Nephropathy

Changwei Wu,[2] Li Wang,[2] Guisen Li.[1] *[1]Renal Division and Institute of Nephrology, Sichuan Academy of Medical Sciences and Sichuan Provincial People?s Hospital, Chengdu, China; [2]Sichuan Provincial People?s Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.*

Background: Immunoglobulin A nephropathy (IgAN), the most common form of primary glomerular diseases worldwide, is a complex multifactorial disease. Previous genome wide association studies (GWAS) reported that variants CARD9 and VAV3 genes were associated with immunoregulation and susceptibility to IgAN.

Methods: In this study, we further validated the associations and explored the interaction effect of rs4077515 and rs17019602 in IgAN patients.

Results: There was no significant correlation between the two variants and IgAN (P>0.05). The analysis of disease risk score showed that rs4077515 and rs17019602 had interaction effect on the susceptibility to IgAN, and the more the number of risk alleles, the higher the risk of IgAN. For additive interaction, the CT or TT of rs4077515 and GG of 17019602 genotype combination conferred a 2.556-fold risk of IgAN reference to CC

of 4077515 and AA of 17019602 (OR=2.556, 95% CI: 0.976-6.694, P=0.049). There was no significant association between genotype distribution and clinical characteristics in IgAN patients (P>0.05).

Conclusions: The interaction effect of the variants of CARD9 and VAV3 genesincreases the susceptibility to IgAN.

PUB427

The Association Between Frailty and Quality of Life in CKD Andrew Nixon,[1,2] Theodoros M. Bampouras,[3] Alastair R. Petrie,[3] Atinuke J. Afolabi,[3] Neil Pendleton,[1] Sandip Mitra,[4] Ajay P. Dhaygude.[2] *[1]University of Manchester, Manchester, United Kingdom; [2]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [3]University of Cumbria, Lancaster, United Kingdom; [4]Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom*.

Background: Frailty is associated with an increased mortality in chronic kidney disease (CKD). Smaller studies that used modified versions of the frailty phenotype have demonstrated that frailty is also associated with a worse quality of life (QoL) in CKD. Further studies are needed to validate this association.

Methods: Fifty-eight patients with dialysis-dependent CKD and pre-dialysis stage 4 and 5 CKD were recruited. Frailty was assessed using the original frailty phenotype (FP). Patients were categorised as robust, pre-frail or frail. QoL was assessed using the 36-Item Short Form Survey (SF36). Between group differences in SF36 scores were assessed using the Kruskal–Wallis test. A p value of <0.05 was considered statistically significant. Linear regression analysis was performed to assess the magnitude of associations between FP scores and SF36 domains.

Results: Median age was 70 years old (IQR: 58.75-77.00) with 28 male participants. Half were receiving haemodialysis. Mean Charlson Comorbidity Index (CCI) score was 3.12 (SD: 1.29). Frailty and pre-frailty prevalence was 24% and 47%, respectively. The frail group had the lowest median scores across all SF36 domains. There were significant differences between FP categories for all SF36 domains except 'emotional well-being'. Table 1 demonstrates linear regression coefficients. Adjusting for age, CCI score and CKD stage did not substantially alter coefficients. An increase in frailty score by 1 point had the greatest effect on the 'physical functioning', 'role limitations due to emotional problems' and 'pain' SF36 domains.

Conclusions: Frailty is associated with a worse QoL in CKD and influences both physical and emotional aspects of QoL. Nephrology services should routinely assess frailty and offer additional support for those considered frail.

Table 1. Frailty and Quality of Life: Linear Regression Analysis.

SF36 Domain	Regression Coefficient	95% Confidence Intervals	p value	Adjusted Regression Coefficient	95% Confidence Intervals	p value
Physical Functioning	-14.95	-19.18 to -10.71	0.00	-13.98	-18.45 to -9.52	0.00
Role Limitations due to Physical Health	-11.98	-18.82 to -5.13	0.00	-11.43	-18.96 to -3.90	0.00
Role Limitations due to Emotional Problems	-9.76	-17.30 to -2.22	0.01	-12.90	-21.05 to -4.75	0.00
Energy/Fatigue	-9.86	-13.12 to -6.60	0.00	-10.61	-14.16 to -7.06	0.00

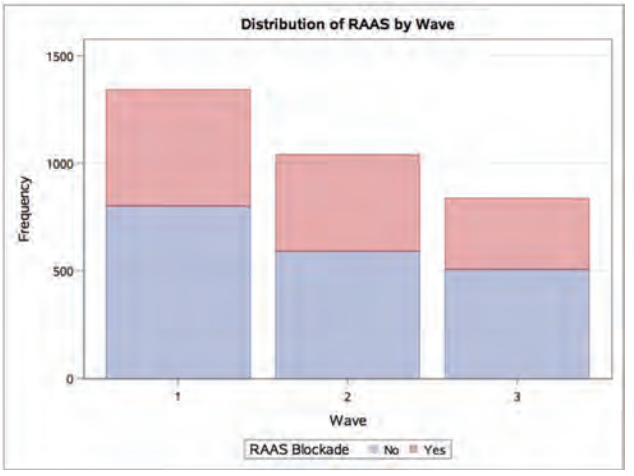
RAAS Blockade in Community Dwelling Elders and the Importance of "Sick Day Rules" Donal J. Sexton,[2,1] Mark Canney,[2] Rose Anne M. Kenny,[2] Mark A. Little,[3] Conall M. O'Seaghdha.[2,1] *[1]Nephrology Department, Beaumont Hospital, Dublin, Ireland; [2]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland; [3]Trinity Health Kidney Center, Trinity College Dublin, Dublin, Ireland*.

Background: Acute kidney injury contributed to by continued RAAS blockade during episodes of intercurrent illness is common. We set out to define the size of the population denominator for AKI due to ACE inhibitors or ARBs by defining the frequency of their use in community dwelling individuals ≥ 75.

Methods: TILDA is a nationally representative prospective longitudinal cohort study of community-dwelling adults aged ≥ 50 years resident in the Republic of Ireland. Random sampling of geographical clusters was used to select households. Data collection involved an in-home interview (CAPI) (N=8175) and a health assessment undertaken in the health center or in the respondent's home (N=5751). Mean follow up for TILDA was 3.4 years. Our study-utilised data from wave 1 (completed July 2011), wave 2 (March 2013) and wave 3 (December 2015) TILDA.

Results: In those aged ≥ 75 yrs (N=1342), mean age 80.2 (4.36), 598 Male, 745 female. At wave 1 TILDA (of 218,309 population) 41% were on some form of RAAS blockade, 7.1% were taking prescription NSAIDS, 3% were taking both RAAS blockade and NSAIDS. At wave 3 follow up, 20% were on an ACE, 18.9% were on an ARB, 38.4% on any RAAS blockade. 53.9% had hypertension, 9.2% previous MI, 11.2% diabetes, 3.2% stroke, 5.2% TIA, 1.7% CHF. Of those aged ≥ 75 and eGFR < 60 ml/min, 38.4% were on some form of RAAS blockade, 15.2% were on both RAAS blockade and diuretics.

Conclusions: The prescription of RAAS blockade medication is widespread in community dwelling elders. Given the prevalence of CHF, previous myocardial infarction and CKD in the population, it is likely that the majority of RAAS blockade prescribing is related to hypertension treatment in the community. Awareness of the importance of sick-day rules in primary care merits emphasis.



Cross sectional prevalence of RAAS blockade prescriptions in community dwelling individuals aged ≥ 75 years over the first three waves of TILDA.

PUB429

Erythropoietin Resistance May Just Be Diagnostic Complacency Jack Rubin,[1] Lihong Wu.[2] *[1]None, Long Beach, CA; [2]none, LOS ALAMITOS, CA*.

Background: We reviewed our dialysis units data to identify patients (pts) whose hemoglobin (hg) did not increase with increasing doses of erythropoietin (epo)(our functional definition of epo resistance). 21 of 123 patients fulfilled this criteria. 8 of the 21 are pts who came to dialysis after medical catastrophes requiring feeding tubes and tracheostomies, 1 patient is noncompliant with dialysis, 1 has short bowel and cardiomyopathy and 2 had hematologic illness. The rest remained unexplained. We wish to report on the pts with hematologic illness.

Methods: Mr. Y, aged_75 developed membranous nephropathy and eventually required dialysis. He was started on peritoneal dialysis and converted to hemodialysis after he developed an inguinal hernia (9/12-3/15). He has coronary artery disease with past bypass surgery and a recent stent placement. His main complaint is the sensation that he is cold all the time and has no energy, especially when his hg is less than 9 g %. He remained throughout the course requiring large doses of erythropoietin up to 10000 units thrice weekly. After 4 years we requested a hematology consult because he developed thrombocytopenia. Bone marrow found myelodysplastic syndrome with a 20q deletion. Chemotherapy was started with Dacogen. After 2 cycles of treatment hg and platelet count improved. Mrs. X, An 82 year old pt with renal insufficiency secondary to diabetes mellitus and congestive heart failure started hemodialysis 9/2015 initially to control congestive heart failure. Within a month she developed facial zoster. She has been maintained on dialysis twice weekly. She remained anemic. After 18 months she had a sudden marked drop in hemoglobin from 9 to 6 g% with associated rectal bleeding. A gastrointestinal workup was unrevealing. A hemolytic anemia was eventually diagnosed and thrombocytopenia noted culminating in a bone marrow biopsy diagnosing mantle cell lymphoma. Chemotherapy was started with single agent Rituxin and after 4 doses she is in remission.

Results:

Conclusions: In summary 17% of our pts (21/123) failed to respond to increasing doses of epo. Of these 21 pts a satisfactory explanation could be found for 11 of the 21 pts. When pts are found to have epo resistance differential diagnosis needs to be broadened beyond iron deficiency, bleeding without a source or an "inflammatory state" causing anemia of chronic disease.

PUB430

Frailty Is Predictive of Future Adverse Outcome in Incident Elder Patients with ESRD: A Prospective Cohort Study in Korea Soojin Lee,[1] Sung Woo Lee,[2] Anna Lee,[3] Ho Jun Chin.[3] *[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Eulji General Hospital, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seong nam, Republic of Korea*.

Background: Little is known for the clinical significance of frailty in elderly patients with end stage renal disease (ESRD).

Methods: We prospectively enrolled 46 elder patients with incident ESRD in a dialysis center of tertiary hospital between May 2013 and March 2015. Frailty was assessed using comprehensive geriatric assessment protocol and was defined as ≥ 10 of the multidimensional frailty score. The main outcome was composites of all-cause death or cardiovascular hospitalization determined at June 2016.

Results: Of 46 participants, median age was 71.5 years and 63.0% was men. During median 17.7 months' follow-up, the rate of composite outcome was 17.4%. In

multivariate logistic regression analysis, after adjusting for age, sex, diabetes, body mass index (BMI) and time of pre-dialytic nephrologic care, women and increased BMI were associated with increased and decreased odds of frailty, respectively. In multivariate Cox proportional hazard analysis, after adjusting for age, sex, diabetes, BMI and time of pre-dialytic nephrologic care, frailty was significantly associated with composite adverse outcome. In repeated frailty assessment, the multidimensional frailty score was significantly improved 12 months after dialysis initiated, which was largely relied on the improved alimentation.

Conclusions: Frailty is associated with increased risk of adverse outcome in elder patients with incident ESRD. Dialysis may improve frailty, particularly relying on the improved alimentation in elder ESRD patients. Future large studies need to confirm our study results.

PUB431

Coordinating Values for Shared Decision Making in Dialysis: Patient and Provider Perspectives Ann E. Vandenberg,[2] C. Barrett Bowling,[1] Janice P. Lea,[2] Leigh Nadel,[2] David Byrd,[3] Amelia Lambeth,[3] Brian D. Jones,[3] Laura Plantinga.[2] *[1]Durham VA Medical Center, Decatur, GA; [2]Emory University, Atlanta, GA; [3]Georgia Institute of Technology, Atlanta, GA.*

Background: Patient values are a core component of shared decision making (SDM). Less often identified, provider values also influence SDM. Little is known about dialysis patient or provider values. As part of the development of a report on dialysis patient functional status using geriatric assessments to facilitate SDM, we examined patient and provider values with respect to dialysis care.

Methods: Four 90-minute focus groups were conducted, two with patients (n=17, patient group) and two with providers (n=9, MD group – physicians and physician-extenders; n=8, non-MD group – social workers, registered nurses, and dietitians). Transcripts were analyzed within and across stakeholder groups for concordance and discordance of expressed values.

Results: All groups shared the values of patient function, individualized care, social service support, and patient personal responsibility in treatment. All attributed the value of efficiency to other groups to explain a streamlined, non-individualistic approach to dialysis care. The patients and the non-MD group shared many values, including access to quality patient-provider meetings, family support in care, cost-savings within the medical system, and patient family responsibility, work, independence, effort, and hope. Hope, or focusing on possibilities rather than limitations in function, was repeatedly expressed by both patient groups. Patients but not providers emphasized the importance of their own physical comfort within and outside the clinic; using knowledge of their own body to inform treatment, including medication adherence; and freedom away from dialysis. Providers but not patients valued objectivity in functional assessment and biomedical knowledge (i.e., lab results, medications) for treatment decisions. The MD group attributed the value of body knowledge to patients and saw it as a barrier to patient adherence to treatment recommendations.

Conclusions: These findings may facilitate SDM by informing dialysis providers about the presence of and allegiance to values across stakeholder groups in dialysis clinics. By attending to the values of patient hope, effort, and family responsibility, nephrologists might increase their persuasiveness with patients with regard to the shared value of personal responsibility in adhering to treatment recommendations.

Six-Month Impact on Quality of Life and Functional Assessment of Elder Patients with ESRD Undergoing Hemodialysis David Escamilla-Illescas,[4] Jorge Rivera reyes,[5] Mario A. Sebastian-Diaz,[2] Michael E. Wasung,[3] Mario A. Cerecedo rosendo,[6] Guillermo Cardenas.[1] *[1]General Hospital Manuel Gea Gonzalez, Mexico, Mexico; [2]None, MEXICO, DF, Mexico; [3]Hospital Angeles de Acoxpa, Mexico City, Mexico; [4]Hospital Central del Sur de Alta Especialidad PEMEX, Mexico City, Mexico; [5]PEMEX, Mexico City, Mexico; [6]PEMEX SERVICIOS MEDICOS, Mexico City, Mexico.*

Background: Hemodialysis improving survival rates of Chronic Kidney Disease (CKD) patients but not Quality of Life (QoL) is an important problem. This aggravates in the elder. We describe the impact in QoL and functional assessment of 6-months hemodialysis treatment.

Methods: Single center prospective study, applying the Kidney Disease Quality of Life (KDOQOL-36™) in Spanish, Katz Index, Barthel Index, Lawton and Brody Scale and Karnofsky Performance Status to patients with CKD KDIGO 5D, aged 65 years or older at Hospital Central Sur de Alta Especialidad PEMEX (Mexico) on October 2016. We applied the surveys again on May 2017 to the same population. We presented the general view in mean and standard deviation and analyzed with Studen's t-test.

Results: At the beginning of the study there were 22 elder patients in hemodialysis, 59% men with an average age of 72.9 (±5.9) years old and a time in hemodialysis of 27.1 (±24.1) months. Six-months later we had 18% deaths, 9% changed their residency and 73% were still active, 62.5% men. Mean values from the different scales are represented in Table 1. We compared the media of each subscale after six months with Student's t-test but there were no significant variables.

Conclusions: We observed a decrease in all subscales of KDOQOL-36™ and functional assessment evaluation with no statistical differences. The first evaluation was higher than previous hemodialysis reports on QoL in Mexico, but it turned out to be quite similar in the second analysis. One important limitation is that we don't know the bias of applying the same survey, also the proper means of measuring QoL in chronically patients are unclear. We suggest the continuous evaluation of QoL in geriatric population to get a global perspective.

Scale	2016 Mean (SD) / Mode	2017 Mean (SD) / Mode

Effects of Global TRPC6 Knockout on Passive Anti-GBM Nephritis in Sprague-Dawley Rats: No Effects on Renal Fibrosis or Overall Renal Function but Reduced Glomerulosclerosis Stuart E. Dryer, Eunyoung Kim. *University of Houston, Houston, TX.*

Background: TRPC6 channels have been implicated in familial forms of FSGS. There are reports that TRPC6 knockout in mice reduces renal fibrosis[1]. Here we examined this question in a global constitutive TRPC6 knockout in Sprague-Dawley rats using a model of immune complex nephritis.

Methods: Nephritis was induced by a single i.v. injection of sheep anti-rat GBM (Probetex, San Antonio, TX). Rats were not previously immunized with anti-sheep IgG. Renal phenotypes were characterized by standard biochemical and histological methods. All experiments were approved by the University of Houston IACUC.

Results: Rats injected with nephrotoxic serum had robust IgG and complement deposition within glomeruli measured 28 days after injection. This was the same in $TRPC6^{+/+}$ and $TRPC6^{-/-}$ littermates. TRPC6 knockout had no effect on 24-hr urine albumin excretion measured 4, 18 or 28 days after immunization. At 28 days after immunization, TRPC6 knockout had no effect on serum creatinine, BUN or circulating procollagen type I peptide, all of which were significantly elevated in immunized animals, and which reflected a decline in renal function and an ongoing fibrotic process. TRPC6 knockout also had no effect on the abundance of CD68, vimentin, or α-smooth muscle actin in renal cortex, or on kidney weight: body weight ratio. Tubulointerstitial fibrosis as assessed by PAS and Masson's trichrome staining was severe in this model, and there was no protective effect of TRPC6 knockout on tubules or in the interstitium. However, close examination of glomeruli in PAS-stained sections showed less severe glomerular disease and a reduced percentage of glomeruli with crescentic lesions in $TRPC6^{-/-}$ rats ($P < 0.05$). Basal TRPC3 abundance in renal cortex was increased in $TRPC6^{-/-}$ rats compared to $TRPC6^{+/+}$ controls. However TRPC3 did not increase further during anti-GBM nephritis. None of the manipulations in this study affected TRPC5 channels.

Conclusions: TRPC6 knockout had a partial protective effect on glomeruli in Sprague-Dawley rats during anti-GBM glomerulonephritis. However, it failed to reduce tubulointerstitial fibrosis and did not have any effect on the decline of overall renal function in this model. 1. Wu et al. *Kidney Int.* 91: 830-841, 2017.

PUB434

Detection of Convertase-Stabilizing Factors in Patients with Complement-Mediated Renal Diseases Marloes Michels,[1] Marcin Okroj,[2] Sanne van Kraaij,[3] Nicole Van De Kar,[1] Elena Volokhina,[1,3] Bert Van den heuvel.[1,4] *[1]Pediatric Nephrology, Radboud university medical center, Nijmegen, Netherlands; [2]Medical Biotechnology, Intercollegiate Faculty of Biotechnology, Medical University of Gdansk, Gdansk, Poland; [3]Laboratory Medicine, Radboud university medical center, Nijmegen, Netherlands; [4]Pediatrics, University Hospitals Leuven, Leuven, Belgium.*

Background: The autoantibody C3 nephritic factor (C3NeF) plays a pathogenic role in C3 glomerulopathy (C3G) by stabilizing the key enzyme of complement activation, the C3 convertase. However, reliability of currently used assays to detect C3NeF is limited. Recently, we developed a method to measure convertase stability in human serum. We now optimized the method for simple detection of convertase-stabilizing factors such as C3NeF in large patient cohorts.

Methods: Convertase stability was measured in a hemolytic assay using the C5-blocking agent eculizumab to separate the alternative pathway (AP) into two steps: formation of C3/C5 convertases by test sera in a time-variable step 1 and formation of lytic membrane attack complexes in a standardized step 2 for readout. Samples of 15 controls and 29 patients with C3G were analyzed. In addition, convertase stability was assessed in a family with complement Factor B (FB) mutation (p.Lys323Glu) and atypical hemolytic uremic syndrome (aHUS), a complement-mediated disease not associated with C3NeF.

Results: Healthy controls were tested to define the normal convertase activity profile: maximal convertase activity was observed after 10-15 min and after 30 min the activity of all controls had returned to background levels. When serum or purified Ig fraction containing C3NeF was added to control serum, convertase activity was increased at t=30 ($P<0.001$). Thus, detectable convertase activity at t=30 min or later was chosen as a marker for presence of convertase-stabilizing factors such as C3NeF. In our cohort, 16 out of 29 (55%) patients showed increased convertase stability. Interestingly, prolonged convertase activity was also detected in an aHUS family and segregated with the FB mutation in affected and non-affected family members.

Conclusions: We present optimization of a simple, reliable, and cost- and time-effective assay for detecting convertase-stabilizing factors (C3NeF and some mutations) in patients with various complement-mediated renal diseases. This study may give insight in disease pathogenesis and treatment strategies in these patients.

PUB435

Alterations in Circulating Lymphoid Cell Populations in Systemic Small Vessel Vasculitis Are Non-Specific Manifestations of Renal Injury Barbara Fazekas,[7] Ana D. Moreno,[6] Yvelynne P. Kelly,[1] Paul O'Hara,[3] Susan L. Murray,[4] Alan Kennedy,[6] Niall P. Conlon,[5] Dearbhaile Dooley,[8] Eóin O'Brien,[2] Sarah M. Moran,[4] Derek G. Doherty,[6] Mark A. Little.[6] *[1]Beaumont Hospital, Dublin 9, Co. Cork, Ireland; [2]St. James' Hospital, Dublin, Ireland; [3]HSE, Limerick, Ireland; [4]None, Dublin 8, Ireland; [5]St. James's Hospital, Dublin, Ireland; [6]Trinity College Dublin, Dublin, Ireland; [7]Trinity Health Kidney Centre, Trinity College Dublin, Dublin 8, Ireland; [8]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland.*

Background: Innate lymphocyte populations, such as innate lymphoid cells (ILCs), γδ T cells, invariant natural killer T (iNKT) cells and mucosal associated invariant T (MAIT) cells are emerging as important effectors of innate immunity and are involved in various inflammatory and autoimmune diseases. The aim of this study was to assess the frequencies and absolute numbers of innate lymphocytes in peripheral blood from a cohort of ANCA associated vasculitis (AAV) patients.

Methods: Flow cytometry was used to enumerate circulating ILC subsets (ILC1, ILC2, ILC3, LTi), γδ T cell subsets (Vδ1, Vδ2, Vδ3), iNKT cells, MAIT cells, $CD4^+$, $CD8^+$ and $CD4^-CD8^-$ T cells, B cells, natural killer (NK) cells and monocytes in 29 AAV patients and 19 healthy and disease controls. Recruited patients with AAV were sampled both with and without immunosuppressive treatment, and in the setting of both active and remission disease.

Results: The frequencies of MAIT and ILC2 cells were significantly decreased in all disease groups, including the disease control group, compared to healthy controls. These reductions in the AAV patients remained during remission. B cell numbers and frequencies were significantly lower in AAV in remission compared to patients with active disease and disease controls. Despite the strong Th2 preponderance of eosinophilic granulomatosis with polyangiitis, we did not observe increased ILC2 frequency in this cohort of patients. The frequencies of other cell types were similar in all groups studied.

Conclusions: Reduction in circulating ILC2 and MAIT cells seen in patients with AAV are not specific for AAV, but are more likely to be due to non-specific manifestations of renal impairment and chronic illness. Reduction in B cells in remission AAV is almost certainly therapy related.

Funding: Government Support - Non-U.S.

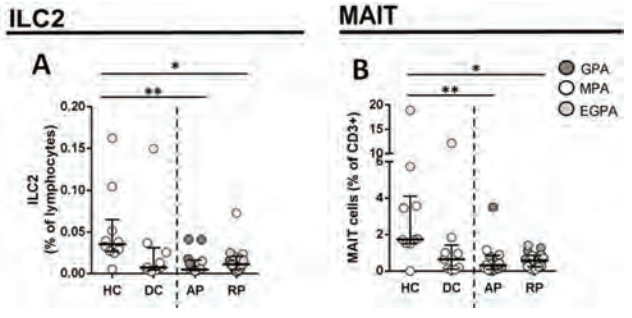

Figure 1. ILC2 and MAIT cells are persistently depleted in AAV patients and disease controls.

Renal CD141+ Dendritic Cell Infiltration in Crescentic Glomerulonephritis in Humans and Mice Titi Chen,[6,7] Qi Cao,[1] Padmashree Rao,[5,3] Guoping Zheng,[4,7] Yiping Wang,[2] David C. Harris.[3,7] *[1]Centre for Transplant and Renal Research, Westmead Millennium Institute, University of Sydney, Sydney, NSW, Australia; [2]Centre for Transplantation and Renal Research, Westmead Millennium Institute, The University of Sydney, Westmead, NSW, NSW, Australia; [3]Sydney Medical School - University of Sydney, Terrey Hills, NSW, Australia; [4]The University of Sydney, Sydney, NSW, Australia; [5]Westmead Millenium Institute for Medical Research, Parramatta, NSW, Australia; [6]School of Medicine, University of Sydney, Westmead, NSW, Australia; [7]Centre for Transplant and Renal Research, Westmead Institute for Medical Research, Westmead, NSW, Australia.*

Background: CD141+ dendritic cells (DCs) have recently been identified as a unique myeloid DC subset that play a significant role in immune regulation. CD103+ DCs, their murine homologue, have been shown to play an important role in murine crescentic glomerulonephritis (GN). However, little is known about expression of CD141+ DC in human crescentic GN. We aim to investigate the relationship between CD141+ DC infiltration and clinicopathologic features in human crescentic GN, and to investigate possible underlying mechanisms of injury in a murine model.

Methods: Adult patients with a sole diagnosis of crescentic GN were enrolled in the study. Patients were excluded if they received immunosuppressant therapy before renal biopsy. Anti-GBM disease was induced in C57BL/6 mice by injection of sheep anti-mouse glomerular basement membrane serum. Mice were examined at week 1 and week 3.

Results: In normal human kidney, CD141+DCs were rarely present. However, the number significantly increased in patients with crescentic GN (P=0.021). Higher CD141+ DC density was associated with worse serum creatinine (P=0.029) and proteinuria (P=0.038). In contrast to previous studies, which showed myeloid DCs were mainly present in the interstitium, we also found a high number of CD141+ DCs in glomeruli. Similar to humans, we found CD103+ DCs constituted only 2% of total leucocytes in normal murine kidneys. In murine anti-GBM disease, the number and proportion of kidney CD103+ DCs was significantly increased (P=0.021), and CD103+ DCs were mainly present in the interstitium. We are examining pathological correlations and pathogenic mechanisms of CD 103+ DCs in this model.

Conclusions: Our data suggest that CD141+ DCs may play an important role in crescentic GN.

PUB437

Urinary Cytokines/Chemokines as Prognostic Markers in Crescentic Glomerulonephritis Patients Receiving Immunosuppressive Therapy Junseok Jeon,[1] Minjung Kim,[1] Do Hee Kim,[2] Jung eun Lee,[1] Wooseong Huh,[1] Dae Joong Kim,[1] Yoon-Goo Kim,[1] Ha Young Oh,[1] Hye Ryoun Jang.[1] *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Chungbuk National University College of Medicine, Cheongju, Republic of Korea.*

Background: Immunosuppressive therapy is considered to be the standard treatment for crescentic glomerulonephritis (CrGN). However, timely kidney biopsy and initiation of aggressive immunosuppressive therapy is not always feasible in cases such as very old age or serious comorbidities. In this study, we investigated the clinical usefulness of urinary cytokines / chemokines as non-invasive prognostic markers for predicting the treatment response in patients with CrGN.

Methods: A total of 87 patients with biopsy-proven CrGN from 2002 to 2015 were included. In 38 patients, both urine and serum samples were collected on the day of kidney biopsy. A panel of cytokines / chemokines were measured as follows: regulated on activation, normal T cell expressed and secreted (RANTES), fractalkine, interferon-γ, interleukin (IL)-4, IL-6, IL-10, monocyte chemoattractant protein-1 (MCP-1), tumor necrosis factor-α (TNF-α), and vascular endothelial growth factor (VEGF). Urine cytokine / chemokine levels were adjusted with urinary creatinine levels. Baseline estimated glomerular filtration rate (eGFR), urinary protein to creatinine ratio (uPCR), and the proportion of non-albumin proteinuria were also analyzed in all patients. The primary outcome was uPCR and renal function at 1 year after kidney biopsy. Good response was defined as a decrease in proteinuria to < 50% without significant renal function deterioration. Mann Whitney U-test and logistic regression analysis were used as appropriate.

Results: The median age of patients was 65 years and 47% were male. Baseline eGFR was 18.7 ml/min/1.73m^2 and uPCR was 1.87 mg/mg Cr. The proportion of the good response group was 50%. In all patients, baseline eGFR was identified as a predictor of good response to immunosuppressive treatment. In 38 patients whose urinary and serum cytokines / chemokines were analyzed, baseline urinary RANTES (P = 0.016), fractalkine (P = 0.044), and MCP-1 (P = 0.041) levels were higher in the good response group

Conclusions: Our study demonstrated the importance of early initiation of immunosuppressive treatment before renal function deterioration in patients with CrGN for improving renal outcome. Urinary MCP-1, RANTES and fractalkine may be of prognostic value as non-invasive markers predicting treatment response.

PUB438

Cross-Reactivity of Neutralizing Anti-Rituximab Antibodies and New Anti-CD20 Monoclonal Antibodies: An Alternative Therapy in Primary Membranous Nephropathy? Sonia B. Boyer,[1] Sylvia Benzaken,[2] Ghislaine Bernard,[2] Vincent L. Esnault,[1] Barbara Seitz-Polski.[2,1] *[1]Nephrology, Nice University Hospital, Nice, France; [2]Immunology, Nice Univertsity Hospital, Nice, France.*

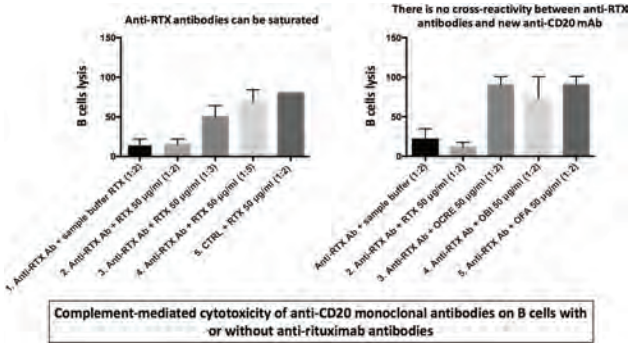
Background: Rituximab (RTX) is a murine / human chimeric monoclonal antibody (mAb) directed against CD20, a surface marker expressed on B cells (BC). RTX induced clinical remission in 60 to 80% of patients with primary membranous nephropathy (MN) in several non-randomized studies. However, mAb as RTX can elicit an unwanted antibody response in a substantial number of patients, resulting in a loss of efficacy of treatment. In MN, we showed that some patients develop neutralizing anti-RTX antibodies. We therefore investigated whether a cross-reactivity existed with new anti-CD20 mAb (humanized or fully human).

Methods: We studied complement-mediated cytotoxicity of anti-CD20 mAb on BC in the presence or absence of anti-RTX antibodies. Tested anti-CD20 mAb were: RTX with increasing concentrations, ocrelizumab (OCR) and obitunuzumab (OBI) (humanized anti-CD20 mAb), ofatumumab (OFA) (fully human anti-CD20 mAb).

Results: In presence of anti-RTX antibodies, RTX cytotoxicity is close to zero, demonstrating the neutralizing character of these antibodies. We observe a dose-response effect in RTX cytotoxicity, related to anti-RTX antibodies saturation. In the case of OCR, OBI and OFA, cytotoxicity is evaluated above 80-100% in the presence of anti-RTX antibodies. There is no neutralizing effect of anti-RTX antibodies on the three new anti-

CD20 mAb tested, even for low dose tested. Our work demonstrates the absence of cross-reactivity with three anti-CD20 mAb currently studied: OCR, OBI and OFA. Moreover, these third-generation mAb might be less immunogenic and less responsible for treatment resistance.

Conclusions: We find no cross-reactivity of anti-RTX antibodies with last-generation of anti-CD20 mAb. These humanized or fully human anti-CD20 mAb could be an alternative therapy to RTX in MN for patients with anti-RTX antibodies. Searching for neutralizing anti-RTX antibodies could also be extended to other autoimmune diseases.



Complement-mediated cytotoxicity of anti-CD20 monoclonal antibodies on B cells with or without anti-rituximab antibodies

PUB439

Zebrafish Embryos and ANCA-Associated Glomerulonephritis: Initial Steps towards a New Animal Model Malu Zandbergen, Hans J. Baelde, Jan A. Bruijn, Ingeborg M. Bajema. *Leiden University Medical Center, Dept. Pathology, Leiden, Netherlands.*

Background: The titre of Antineutrophil Cytoplasmic Autoantibodies (ANCAs) in the serum of patients with ANCA associated vasculitis (AAV) does not always correspond to clinical disease activity, although a pathogenic role for these antibodies has been described in several studies. Currently, there is no model available to predict the disease activity in patients with AAV. The zebrafish (*Danio rerio*) embryo model has been used successfully to study leukocyte migration and inflammatory processes *in vivo.* Here, we report our initial proceedings into investigating whether the zebrafish embryo model can be used to predict disease activity in patients with AAV.

Methods: Frozen sections of 4dpf zMPO:GFP transgenic zebrafish embryos were stained with polyclonal anti-human MPO antibody. 4dpf zMPO:GFP transgenic zebrafish embryos were injected with sera from AAV patients with high anti-MPO levels. Zebrafish embryos injected with sera from healthy controls and PBS served as controls. A local inflammation was induced 1 hour after injection by tail transection. At different time points, ~30 embryos were fixed and the number of zMPO:GFP cells responding to the site of injury was scored.

Results: The zebrafish myeloperoxidase (zMPO) and human MPO protein, one of the best-documented autoantigen targets of ANCA, share 76,5% similarity. However, there was no substantial binding detectable of conventional MPO-ANCA assays on zebrafish zMPO:GFP positive cells. An increased number of zMPO:GFP cells was observed at the site of injury from 2 to 6 hours after tail transection, however, there was no statistically significant difference over the groups (controls versus those injected with AAV serum).

Conclusions: Although we have been able to replicate in our zebrafish model previous findings of leucocyte migration to sites of injury, we have not been able to enhance this effect by injection of human AAV sera. We are currently focussing on leucocyte priming in parallel to previously described animal models of AAV where this was a major component for optimization of the model.

PUB440

Effects of Classical CKD Treatments and Quantification of Inflammatory Cell Infiltrates in the Nephrotoxic Nephritis Model Maria K. Ougaard,[1,2] Henrik Søndergaard,[1] Henrik E. Jensen,[2] Peter H. Kvist.[1] *[1]Novo Nordisk A/S, Måløv, Denmark; [2]University of Copenhagen, Frederiksberg, Denmark.*

Background: Renal inflammation is central in the pathogenesis of chronic kidney disease (CKD) and studies of renal inflammation and its treatment response might clarify the impact of the infiltrating cell types during disease development and could help improve therapy of CKD. The nephrotoxic nephritis (NTN) model is a model of CKD which could provide a robust inducible model where significant inflammation is associated with CKD. In this study, the inflammatory cell infiltration in the kidney in the NTN model was quantified over time and the effect of the ACE-inhibitor; enalapril and the angiotensin receptor blocker; losartan were evaluated.

Methods: NTN was induced by injecting CD1 female mice with 50 µl nephrotoxic serum containing anti-GBM sheep IgG on day 0, 1, and 2. Sheep IgG and inflammatory cell infiltrates (CD45+, CD3+, and F4/80+) were visualised by IHC on day 7, 42, 63, and 77 and quantified with Visiopharm software. In a 6 week study, enalapril (15, 30 mg/kg/day) and losartan (15, 30 mg/kg/day) were administrated via the drinking water from day -1, and their effect on CKD readouts was evaluated.

Results: In the NTN model a significant infiltration of CD45+, CD3+, and F4/80+ cells were present in the kidneys on day 7, 42, 63, and 77 compared to the controls. The CD3+ and F4/80+ cells comprised approximately 25% of the CD45+ cells indicating an infiltration also of other hemopoietic cells. The renal inflammatory cells were significantly reduced on day 63 and 77 compared to day 42 which was associated with a decrease of GBM-bound sheep IgG observed post day 42. Treatment with enalapril ($p<0.0001$) and losartan ($p<0.0001$) significantly reduced UAER on day 7-8 and 36-37 after NTN induction compared to the vehicle group, suggesting an important effect of the renin-angiotensin axis in preservation of protein-loss in the NTN model in the context of inflammation. Further analysis is currently ongoing to evaluate effects on mesangial expansion and the inflammatory response.

Conclusions: The NTN model of CKD shows significant inflammatory infiltration of CD3+, F4/80 and other hemopoietic cells which appear to follow the presence of GBM-bound IgG. Treatment with enalapril and losartan significantly reduced UAER, suggesting a key role of RAS-blockade in inflammation-associated CKD.

PUB441

The Presence and Function of Anti-Neutrophil Extracellular Trap Antibody in Patients with Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis Fumihiko Hattanda,[1] Kanako Watanabe,[1] Daigo Nakazawa,[1] Saori Nishio,[1] Tatsuya Atsumi,[1] Akihiro Ishizu.[2] *[1]Department of Rheumatology, Endocrinology and Nephrology Faculty of Medicine and Graduate School of Medicine Hokkaido University, Sapporo, Japan; [2]Faculty of Health Sciences, Hokkaido University, Sapporp-shi, Japan.*

Background: Although anti-neutrophil cytoplasm antibody (ANCA) is the major autoantibody in patients with ANCA-associated vasculitis (AAV), previous studies have suggested the presence of anti-neutrophil extracellular trap (NET) antibody in some AAV patients. However, the prevalence and function of anti-NET antibody in AAV patients remain elusive. The aim of this study is to determine the prevalence and function of anti-NET antibody in AAV patients.

Methods: We determined the presence or absence of anti-NET antibody in 11 AAV patients by indirect immunofluorescence, and assessed the relationship of anti-NET antibody with the serum abilities of NET induction and degradation.

Results: Anti-NET antibody was present in 6 out of 11 AAV patents. Since anti-NET antibody was not absorbed by myeloperoxidase (MPO), anti-NET antibody seemed to be distinct from MPO-ANCA. NET induction and degradation abilities were not different between the anti-NET antibody-positive sera and anti-NET antibody-negative sera. Although NET degradation ability in the sera without anti-NET antibody was significantly increased by addition of DNase I, the increase was not observed in some sera with anti-NET antibody. In addition, NET degradation ability in some sera with anti-NET antibody was markedly increased by depletion of IgG from the serum.

Conclusions: The collective findings demonstrate that a part of AAV patients produce anti-NET antibody and suggest that some of them possess the inhibitory function against DNase I.

PUB442

Tissue Resident Macrophage in the Kidney Kazunori Karasawa, Takahito Moriyama, Ken Tsuchiya, Kosaku Nitta, Keiko Uchida. *Tokyo Women's Medical University, Tokyo, Japan.*

Background: Tissue resident macrophages are subset of macrophages that are present at steady state. It is considered to be a heterogeneous population of immune cells having tissue-specific functions including Kupffer cells, Langerhans cells of the skin, and alveolar macrophages. In the kidney, we have several subsets of tissue resident macrophages, but their pathological roles are not fully understood. We are trying to reveal the role of novel subset macrophage in kidney.

Methods: Wild type mouse kidney was analyzed using immunohistochemical stainning and flowcytometer.

Results: Previously, we reported that the localization of $F4/80^+$ macrophage, $CD169^+$ macrophages, $CX3CR1^+$ macrophage, respectively, was clarified by immunohistochemical staining at steady state in kidney interstitium. Furthermore, we found that $CD206^+$ macrophages are localized in the mesangial region of glomeruli. To ensure that these $CD206^+$ macrophages are resident macrophages in the mesangial region, we co-stained with CD140b, which is a pericyte marker that lines blood vessels from the outside. Most of the $CD206^+$ macrophages co-localized with CD140b. From the staining results, we hypothesized that mesangial cells are heterogenous even at steady state. We decided to focus on CD206 and CD140b double positive resident macrophages in glomeruli. For further analysis, we isolated the glomeruli using Dynabeads and then analyzed using flowcytometer. Flowcytometry analysis with CD206 and CD140b antibody revealed that mesangial cells were distinguished into three fractions. However, expression of molecules characteristic of macrophages such as F4/80 and CD11b was not recognized in CD206 and CD140b double positive macrophages.

Conclusions: Our results suggest that mesangial cells are heterogenous even at steady state. CD206 and CD140b double positive cells in mesagial region may be a very specific tissue resident macrophage subset having the functions of macrophage and pericyte.

Timing the Effect of Rituximab on Peripheral CD 20+B cells: An In Vivo Experience Dario Roccatello,[1] Savino Sciascia,[2] Roberta Fenoglio.[1] *[1]Ospedale San GIovanni Bosco, Torino, Italy; [2]Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Torino, Italy*.

Background: B-lymphocyte antigen CD20 is an activated-glycosylated phosphoprotein expressed on the surface of all B-cells starting at the pro-B phase and progressively increasing in concentration until maturity. CD20 is the target of the monoclonal antibodies (mAb) rituximab (RTX), which is an active agent in the treatment of many immuno-mediate diseases. RTX can induce killing of CD20+ cells through multiple mechanisms. RTX direct effects include complement-mediated cytotoxicity and antibody-dependent cell-mediated cytotoxicity; the indirect effects include structural changes and apoptosis. In all disease states in which RTX has been given, there has been a rapid elimination of circulating B cells. However, the timing of the complete depletion of CD19/CD20+ after RTX administration is still unknown. In this study, we aimed to investigate in vivo the timing of the effect of rituximab on peripheral CD 20+B cells during the first infusion of RTX

Methods: We evaluated 8 pts during the first infusion of RTX at the dosage of 375 mg/m^2 or 1 gr. B-cell levels (CD19/CD20+cells) were measured by flow cytometry in peripheral bloodat various intervals after initiation of treatment (baseline, 10, 20, 60, and 180 minutes). The depletion was defined as a number of CD19/CD20+<10 cell/mm^3.

Results: White blood cells (n.v. 4000-9000 x 10^3) and lymphocytes counts were normal at baseline. B-cells expressing CD19/CD20+ were not detectable in the peripheral blood in any pts within 1 h after initial treatment with Rituximab; in 5 pts (62.5%) they were not detectable within 20 minutes. The complete depletion of CD19/CD20+ was confirmed in all pts after 180 minutes.

Conclusions: This is the first study investigating in vivo the timing of the effect of RTX on peripheral CD CD19/CD20+ B during RTX therapy. Of high interest, we observed a very rapid B-cells depletion during RTX administration. The association of peripheral CD CD19/CD20+ B depletion with tissue levels of still remain to be investigated.

PUB444

IRF5 Polymorphisms Do Not Predict Interferon Signature nor the Presence of Tubuloreticular Inclusions within the Glomerulus in Patients with Biopsy Proven Lupus Nephritis Romy C. Lawrence,[1] Britte C. Beaudette-Zlatanova,[1] Hanni Menn-Josephy,[3] Ramon G. Bonegio.[2] *[1]Boston Medical Center, Roxbury, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]None, Newton, MA.*

Background: Several Interferon Regulatory Factor 5 (IRF5) polymorphisms have been shown to be associated with the development of autoimmune diseases including systemic lupus erythematous (SLE). The polymorphism rs77571059 is thought to be a gain of function variant and is reported to cause higher levels of IRF5 and type 1 interferons. Tubuloreticular inclusions (TRI) are distinctive intracellular structures found in the cytoplasm of endothelial cells and lymphocytes within the glomerulus. These structures are markers of systemic stimulation by interferons and their presence raise diagnostic suspicion for autoimmune disease or viral infections. We hypothesized that patients who are homozygous for the rs77571059 SLE risk polymorphism would have a higher rate of TRI within their glomeruli and this could serve as a predictor of their interferon signature and thus response to treatment with interferon inhibition.

Methods: The authors extracted DNA from 59 patients with SLE and amplified the rs77571059 polymorphism using PCR. This DNA was sequenced and patients were divided based on their genotyping results into those who are homozygous for the risk allele, homozygous for the protective allele, and heterozygous patients. The presence of TRI was recorded from previous renal biopsies and compared to patients within these 3 groups.

Results: The risk allele frequency in SLE patients was 39%. Patients with nephritis had a similar risk allele frequency (36%) to those without (40%). Seventy two percent of patients with nephritis had tubular reticular structures reported on biopsy. The genotype of the patients at the rs77571059 locus was not associated with the presence of TRI as similar rates of TRIs were found in patients who were homozygous for the SLE risk allele (100%), homozygous for the protective allele (71%) and heterozygous patients (67%).

Conclusions: TRI are common in the biopsies of lupus patients, occurring in about 72% of lupus patients. This is in keeping with the reported rate of high interferon signature within lupus patients. IRF5 variants may influence the level of type 1 interferon but do not predict the presence of TRI in the glomeruli. Therefore, we propose that IRF5 genotyping alone may not be sufficient to predict response to interferon inhibition.

Butyrate Ameliorates CKD by Improving Gut Permeability and Inflammation Austin J. Gonzalez,[3] Siddhartha S. Ghosh,[2] Daniel E. Carl,[2] Richard Krieg,[1] Shobha Ghosh,[1] Todd W. Gehr.[3] *[1]VCU, Richmond, VA; [2]VCU Medical Ctr, Richmond, VA; [3]Virginia Commonwealth University, Fredericksburg, VA.*

Background: Changes in intestinal microbiota in CKD alters intestinal permeability. This change increases paracellular transport of inflammatory toxins such as lipopolysaccharide (LPS). LPS in the circulation leads to inflammation which aggravates CKD. Short chain fatty acids such as butyrate produced by colonic bacteria have anti-inflammatory properties and may correct intestinal permeability. We hypothesized that butyrate treatment in CKD animals can improve gut permeability and will alleviate renal failure.

Methods: 5/6 nephrectomy was done in ten Sprague dawley rats to induce CKD and divided into 2 groups, untreated (CKD) and butyrate treated (CKD+BU). Control were sham operated. Na Butyrate (250 mg/100ml) was given in drinking water for 6 weeks to BU. After 6 weeks animals were sacrificed. Plasma was used measure renal function, LPS, and TNF∝. Kidney and colon were collected for western blots for NFkB, IL-10, Colon was stained with alacian blue to determine mucin expression.

Results: Our results show that butyrate improves renal function, sclerosis and inflammation in CKD animals. Although butyrate improved tubular dilatation it was not significant.

Conclusions: Mucins protects the gut from bacteria and inflammation and is regulated by anti-inflammatory cytokine IL-10. We show that in CKD animals there is lowering of IL-10 and mucin production which results in loss of colonic tight-junction protein ZO1 leading to increased LPS in circulation and inflammation. Butyrate's modulation of biomolecules of colonic mucosa may contribute to its anti-inflammatory and reno-protective effect.

Differential Effects of Acthar® Gel and Methylprednisolone in a Preclinical Rodent Model of FSGS Kyle Hayes, Elizabeth A. Warner, Chris Bollinger, Dale Wright, Richard M. Fitch. *Mallinckrodt Pharmaceuticals, Hazelwood, MO.*

Background: Repository corticotropin injection (RCI: H.P. Acthar® gel) contains a purified porcine pituitary ACTH-analogue, and is an FDA-approved treatment to induce remission of proteinuria in idiopathic nephrotic syndrome. The hypothesis that RCI (30IU/kg) treatment may be effective on progressive glomerulosclerosis was evaluated in a rat puromycin (PAN) induced model of FSGS. Effects of RCI or methylprednisolone (2mg/kg/day) on proteinuria, kidney histopathology, serum and urine biomarkers, were compared to treatment with placebo gel, saline or Enalapril (ACEi). RCI treatment was beneficial for expression of previously reported biomarkers of podocyte injury, podoplanin (Pdpn) and Wilms tumor-1 (Wt1), as determined by IHC and quantitative image analysis. A certified pathology read demonstrated treatment with RCI notably decreased renal fibrosis, tubular degeneration, and glomerular injury, compared to saline controls and steroid treatment (Severity Score= 0-5, Mean +/- SD).

Methods:

Results:

Conclusions: Compared to saline, RCI significantly reduced overall proteinuria and serum creatinine at all time-points, at day-28 ($p< 0.05$). In addition, RCI reduced serum creatinine ($p<0.05$, day-28), cholesterol ($p< 0.05$, day-28 and 56), and urine kidney injury molecule (Kim-1) ($p< 0.05$, day-28). In contrast, treatment with methylprednisolone resulted in overall increased proteinuria, serum creatinine, serum cholesterol and triglycerides, compared to saline. Methylprednisolone treatment had no effect on disease induced tubular injury, and resulted in increases in renal fibrosis and glomerular injury, as determined by the pathologist. In this rat model of FSGS, RCI suppressed disease endpoints compared to saline, while treatment with methylprednisolone was associated with increased disease severity, biomarkers, and progression.

Activation of Mineralocorticoid Receptor by the Adaptogenic Ecdysteroids Promotes Glomerular Injury Minglei Lu,[1,2] Zhangsuo Liu,[1] Rujun Gong.[2] *[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]Brown Medical School, Providence, RI.*

Background: Anabolic steroids are commonly used by bodybuilders to achieve impressive muscular physiques. Among these, ecdysteroids, represented by ecdysone, are insect molting hormones and have been marked as natural anabolic agents and popularly used as adaptogenic dietary supplements. However, ecdysone is likely problematic for health as indicated by occasional case reports associating its use with disorders manifested as proteinuria or renal impairment. The renal effect of ecdysone and related mechanisms were examined here.

Methods: The renal effect of ecdysone was examined *in vivo and in vitro*. *In-silico* modeling system was applied to screen proteins with the highest probability of interacting with ecdysone.

Results: In mice, daily treatment with ecdysone for 2 weeks incurred an increasingly elevated albuminuria, associated with glomerular injury, marked by glomerular cell apoptosis, mesangial expansion, podocyte injury featured by a variable degree of foot process effacement on electron microscopy, diminished glomerular expression of podocyte marker proteins like podocin and synaptopodin, and augmented expression of desmin. This pathogenic effect was likely due to an autonomous glomerular injury, because addition of ecdysone to cultured glomerular cells caused substantial cytopathic changes, including cellular hypertrophy, increased apoptosis, lessened expression of podocyte differentiation proteins like WT-1, and activation of mesangial cells as evidenced by increased expression of α-smooth muscle actin and extracellular matrix. To explore the molecular target of ecdysone, *in-silico* modeling system of compound–protein interaction was carried out and identified mineralocorticoid receptor (MR) as one of the top-ranking proteins with putative interactions with ecdysone. In consistency, the molecular structure of ecdysone was found to be highly homologous to mineralocorticoids, like aldosterone. Indeed, ecdysone was capable of activating MR, as probed by MR nuclear translocation in glomerular podocytes and mesangial cells both *in vitro* and *in vivo*. Conversely, spironolactone, a selective blockade of MR, largely abolished the cytopathic effect of ecdysone in glomerular cells *in vitro* and attenuated albuminuria and glomerular lesions in ecdysone-treated mice.

Conclusions: The adaptogenic ecdysone is able to activate MR and thereby promote glomerular injury and proteinuria.

PUB449

Is Histone Deacetylases 2 Associated with Steroid Resistance in Childhood Nephrotic Syndrome? Narayan Prasad,[1] Harshit Singh,[1] Vikas Agarwal,[3] Saurabh Chaturvedi,[3] Akhilesh Jaiswal.[2] *[1]NEPHROLOGY, SGPGIMS, Lucknow, India; [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India; [3]CLINICAL IMMUNOLOGY, SGPGIMS, LUCKNOW, India.*

Background: Glucocorticoids (GCs) are first line therapy for Nephrotic Syndome(NS). The activated glucocorticoid receptors interact with co-repressor molecules to impair NFκB-associated coactivator activity, which reduces histone acetylation. Reduction in histone acetylation occurs through recruitment of histone deacetylase HDAC 2 to activated inflammatory gene complex by activated glucocorticoid receptor, resulting in suppression of activated inflammatory genes within the nucleus. Epigenetic phenomenon may be associated with steroid response. We hypothesize that reduction in HDAC2 may lead to steroid resistance.

Methods: Immunohistochemical HDAC-2 expression was analyzed on renal biopsy samples in SRNS patients (n=15, M=9, mean age 8.4±2.59), and healthy control (n=6, M=3, mean age 12.14± 5.26). Controls were biopsy proven Nephrectomy samples. Remission (SSNS) (n=25, M=15, mean age 9.85±3.08) for at least 6 months without steroid were recruited. All definitions are as per the criteria of International Study of Kidney Diseases in Childhood. RNA was isolated from Peripheral blood mononuclear cells (PBMCs) using trizol method. Real time quantitative PCR was performed using SYBR green.

Results: S.Albumin (SSNS=2.87±.98, SRNS=2.27±.79, p=0.012) was lower and proteinuria (SSNS=13.18±3.09, SRNS=284±193.45, p<0.001) was higher in SRNS as compared to SSNS. HDAC2 nuclear expression was significantly lower in SRNS group as compared to control and steroid dependent group(86.67%), (p=0.002). HDAC2 mRNA expression was also significantly lower in SRNS- fig.1.

Conclusions: Lower HDAC2 nuclear and gene expression is associated within steroid resistance in NS. The inducers of HDAC 2 may lead to restoration of glucocorticoid response and prevent GCs resistance.

Endostatin Concentration in Mice with Advanced Glomerulonephritis Phenotype Measured with a Specific and Robust ELISA Jacqueline Wallwitz,[2] Gabriela Berg,[3] Dagmar Stoiber.[1] *[1]Ludwig Boltzmann Institute of Cancer Research, Vienna, Austria; [2]The Antibody Lab GmbH, Vienna, Austria; [3]Biomedica, Vienna, Austria.*

Background: Endostatin is a 20 kDa protein produced by proteolytic cleavage of collagen XVIII. It is one of the most potent endothelial cell-specific inhibitors of angiogenesis with influence on proliferation, migration and apoptosis. Vav-BCL2 transgenic mice (BCL2tg) are prone to suffer from follicular lymphoma with age and can develop kidney disease, i.e. glomerulonephritis. A synergism between the ETV6/RUNX1 fusion product and BCL2 was identified by intercrossing single transgenic mice for BCL2 and ETV6/RUNX1.

Methods: We developed an immunoassay for the detection of mouse and rat endostatin. The assay was validated according to ICH and EMEA guidelines. Serum concentration of endostatin and also blood urea nitrogen as an established kidney marker were measured in mouse samples with impaired kidney function caused by glomerulonephritis.

Results: The novel endostatin ELISA is optimized for 1 µl mouse serum or plasma and all validation parameters like specificity (>98%), precision (<10% CV), dilution linearity (88-109%), accuracy (91-97%), sample stability, LOD (0.24 nmol/l) and LLOQ (0.5 nmol/l) meet the quality standards. The glomerulonephritis phenotype of ETV6/RUNX1 and BCL2 transgenic mice is accompanied with higher endostatin serum concentration, which seem to better reflect progression of impaired kidney function than the established kidney biomarker BUN.

Conclusions: Detection of endostatin with a reliable and accurate ELISA may give new perspectives within the biomarker research in the field of kidney disease progression.

PUB451

Transcutaneous Measurement of Glomerular Filtration Rate in a Mouse Model of Diabetic Kidney Disease Asim B. Dey, Leah L. Porras, Shannon M. Harlan, Josef G. Heuer, Mark Kowala, Matthew D. Breyer, Mark Rekhter. *Eli Lilly and Company, Indianapolis, IN.*

Background: ReninAAV treated unilaterally nephrectomized (uNx) *db/db* mice is a novel model of progressive diabetic kidney disease (Abstract MP16: SM Harlan, AHA 2015). It features major risk factors: type 2 diabetes (db/db mice), nephron loss (uni-nephrectomy) and arterial hypertension (over-expression of human renin delivered by adeno-associated virus). The model is characterized by proteinuria, increased serum creatinine and renal pathology reminiscent of human DKD. In addition, previous characterization has also demonstrated reduced glomerular filtration rate (GFR) by analysis of FITC inulin clearance. In this study, we applied novel non-invasive technology to analyze longitudinal changes of GFR in this model.

Methods: 20 week-old, unilaterally nephrectomized female db/db mice received single retro-orbital injection of AAV-Renin or LacZ (mock-transfection). The animals were randomized to two groups: vehicle and Lisinopril (30mg/L) in the drinking water. GFR was analyzed every two weeks. The mice were injected FITC-sinistrin (a polysaccharide exclusively eliminated through the kidneys). Plasma disappearance curve, reflecting glomerular filtration, was measured by a skin-mounted detector (Medibeacon).

Results: Significant hyperfiltration (31%) has been observed in db/db uninephrectomized mice compared to the age-matched lean animals. While lacZ injected mice continued hyperfiltering, GFR was decreased by 22% in hypertensive (renin-overexpressing) animals. Progressive GFR decline was accompanied by proteinuria and

increase in serum creatinine. After 4 weeks of drug treatment, Lisinopril significantly reduced proteinuria and serum creatinine and inhibited GFR decline.

Conclusions: Novel method of GFR analysis can be used for animal model characterization and analysis of pharmacological treatment.

Renal Thrombotic Microangiopathy in Rat Models after Bone Marrow Transplantation and Irradiation Sae Aratani,[3,1] Takafumi Kanemitsu,[2] Shinya Nagasaka,[1] Shuichi Tsuruoka,[3] Akira Shimizu.[1] *[1]Analytic Human Pathology, Nippion Medical School, Tokyo, Japan; [2]University of Tokyo, Bunkyo-ku, Japan; [3]Nephrology, Nippon Medical School Hospital, Tokyo, Japan.*

Background: Thrombotic microangiopathy (TMA) is a renal complication after allogenic hematopoietic stem cell transplantation. We previously established a rat model of renal TMA after bone marrow transplantation (BMT), and concluded that chronic graft versus host disease could induce renal TMA. However, the influence of irradiation on the development of TMA has not been fully evaluated. In this study, we used radiation nephropathy model to investigate the role of irradiation in developing TMA, and compared the clinical and pathological characteristics to renal TMA after BMT.

Methods: According to the previous methods, TMA after BMT was induced in DA rats. In brief, bone marrow cells ($6x10^{-7}$ cells) from Lewis rats were transplanted to DA rats, which received 10 Gy of whole body irradiation before BMT. Radiation nephropathy was induced in DA rats by irradiation of 10 Gy (low dose irradiation) or 18-20 Gy (high dose irradiation) with shielding of hind legs and sternal bone by lead block. The clinical and pathological findings were examined at 36 weeks after BMT or irradiation.

Results: In rat with BMT, pathological renal TMA was observed, as previously reported. On the contrary, rat with high dose irradiation (18-20 Gy), but not low dose (10 Gy), developed proteinuria, hematuria, and increased serum Cr level. Hemolytic anemia and hypertension were not evident. Pathological findings revealed diffuse endothelial cell injuries, including swollen endothelial cells with loss of fenestra and diffuse double contour of glomerular basement membrane (GBM) with widening subendothelial spaces. The pathological findings were most consistent with renal TMA. Notably, these clinical and pathological characteristics observed in high dose irradiation were quite similar to those seen in renal TMA after BMT. In high dose irradiation, loss of capillaries was seen concomitant with podocyte injury which was indicated by positive stain for Desmin.

Conclusions: High dose irradiation could cause renal TMA with proteinuria, hematuria, and renal dysfunction, but without hemolytic anemia and hypertension, as similar as TMA after BMT. However, low dose irradiation (10 Gy) alone, which was used in BMT, did not contribute to the development of renal TMA. Irradiation might induce a direct endothelial injury, developing pathological renal TMA.

PUB453

Glomerular Volume Does Not Increase with Age after Accounting for Comorbidities Aleksandar Denic, Jerry Mathew, Mariam P. Alexander, R. houston Thompson, Bradley Leibovich, Walter K. Kremers, John C. Lieske, Lilach O. Lerman, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: A stipulation that glomerular volume increases with aging has been largely based on studies that included patients with comorbidities. Conversely, we and others have observed no change in glomerular volume with aging among healthy living kidney donors. We hypothesized that an increased prevalence of comorbidities with age may account for this discrepancy.

Methods: We studied biopsies from living kidney donors (n=2054) and patients who underwent a radical nephrectomy for a renal tumor (n=749). Periodic acid-Schiff stained kidney biopsy sections were scanned into high-resolution images. Non-sclerotic glomeruli (NSG) profiles were manually traced and mean NSG volume calculated using the Weibel-Gomez stereological formula. NSG volume was regressed on age and comorbidities known to affect glomerular volume.

Results: Compared to donors, nephrectomy patients were older, more male, obese, diabetic, hypertensive, and had a 12% larger NSG. In both populations male gender, obesity, taller height, and hypertension were associated with larger NSG. In the combined dataset, independent predictors of larger NSG were male sex, obesity, diabetes, and hypertension. After adjusting for comorbidities, the NSG volume did not significantly differ between donors and tumor nephrectomy patients and instead of increasing with age trended towards decreasing with age (**Table**).

Conclusions: Older age alone is not an independent determinant of increasing glomerular volume, while several comorbidities increase it. A decrease in metabolic demand for glomerular function with age may explain the lack of compensatory increase in glomerular volume with age-related nephron loss.

Funding: NIDDK Support

Characteristics associated with NSG volume

Characteristic	Unadjusted		Adjusted for each other characteristic

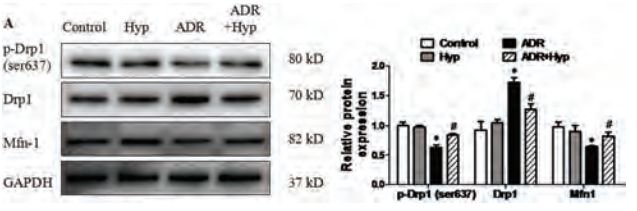
The Protective Role of Hyperoside in Adriamycin-Induced Nephropathy in Mice Chang Ying Xing,[2] Zhuyun Chen.[1] *[1]First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Department of Nephrology, First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Hyperoside (HYP) is a major active flavonoid glycoside extracting from *Abelmoschus manihot (L.) Medik.* which is a traditional Chinese medicine. Hyperoside has various effects on several diseases, like antidiabetic, antioxidant, anti-inflammatory, anticancer and anticoagulant. In vivo and vitro study showed that HYP can reduce myocardial cell ischemia-reperfusion injury through decrease reactive oxygen species (ROS) and improve the activity of antioxidant enzymes. The balance of mitochondrial fission/fusion is very important. Unbalanced fission or fusion led to mitochondria injury. Mitochondrial fission usually observed at the early stage of mito MtD. We assume that HYP has protective effect to podocyte through inhibiting mitochondrial fission and dysfunction.

Methods: Balb/c mice(22-28g,aged 8 weeks) were randomly divided into 4 groups: Control group, HYP group, ADR group and ADR+HYP group. ADR group and ADR+HYP group were injected with 10 mg/kg of Adriamycin through tail vein at day 0. HYP group and ADR+HYP group were treated by hyperoside by intraperitoneal injection for 14 days. Urine were collected by metabolic cage at day 14 after the injection of adriamycin. All mice were sacrificed on day 15 after the injection. Drp1 expression was detected by western blot and real-time PCR and located by laser scanning confocal microscopy. Other proteins were measured by western blot.

Results: ADR increased mice urine microalbumin and decreased the expression of nephrin and podocin. Glomerular sclerosis and protein casts were markedly increased under light microscopy. As observed via transmission electron microscope(TEM) foot process effacement was extensive. Drp1 expression was increased and Mfn-1 was decreased on the contrary. Hyperoside treatment can reverse part of kidney injury. The expression of podocyte markers like nephrin and podocin were increased compared with ADR group. And Drp1 decreased, Mfn-1increased(Fig A). Drp1 fluorescence was collocated with Synapotodin, and markedly increased in ADR group. After treatment of hyperoside the fluorescence was reduced.

Conclusions: ADR causes mice podocyte injury and increased mitochondrial fission. The injury can be reversed by hyperoside.



PUB455

Optimizing Experimental Animal Models of Nephrotic Syndrome Jiro Kino,[1] Melinda A. Chanley,[1] William E. Smoyer,[1,2] Shipra Agrawal.[1,2] *[1]CCTR, The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Pediatrics, The Ohio State University, Columbus, OH.*

Background: Puromycin aminonucleoside (PAN)- induced nephropathy has become the animal model of choice for minimal change nephrotic syndrome, due to its hallmarks of podocyte flattening and nephrotic-range proteinuria. However, there is no standard way to use this model and it exhibits many inherent variabilities leading to wide-ranging results. The aim of this study was to optimize PAN utilization with respect to species, strain, dosage, administration and treatment response.

Methods: Wistar and Sprague Dawley (SD) rats were injected with PAN (i.v.; tail vein) in saline at 0, 50, 75 and 100 mg/kg (N=3-15/group). Wistar rats were additionally injected with PAN (i.p.) at 0, 75, 100 and 150 mg/kg. Steroid efficacy was measured in PAN- injected (i.v. and i.p.) Wistar rats by treating them with glucocorticoids (GC) (15 mg/kg/d i.p.). Proteinuria (spot urine protein/creatinine ratio) was measured at baseline and days 7 and 11 by Antech (GLP lab). Additionally, sv129 mice were injected with vehicle, 150 mg/kg PAN (i.v.) alone or in combination with albumin overload (400mg/day, i.p.) for 4 days and proteinuria analyzed till day 5.

Results: Comparable proteinuria was induced in both SD (Day11;UPC=39.7±5.5mg/mg,$P<0.01$) and Wistar (Day11;UPC=56.3±10.5mg/mg,$P<0.01$) rats with a single dose

of PAN (i.v.) at 75 mg/kg. Proteinuria varied in range but increased with PAN dosing i.v. [50, 75 and 100 mg/kg; UPC=28.0±9.0, 56.3±10.5 and 101.0±11.2mg/mg, respectively] as well as i.p from 75 to 100 mg/kg (UPC=14.6±10.2, 83.4±16.9mg/mg) which plateaued at 150 mg/kg (UPC=73.3±35.7mg/mg) in Wistar rats. Notably, higher i.p. doses produced similar result as lower i.v. doses (i.v. 75mg/kg vs i.p. 100mg/kg,*P*=0.13). Moreover, GC treatment reduced proteinuria significantly in i.v. PAN at 50 and 75 mg/kg (74%,*P*<0.01 and 78%,*P*<0.01 respectively), moderately in i.p. PAN at 75 mg/kg (75%,*P*=NS), but significantly in i.p. PAN at 100 mg/kg (70%,*P*=0.04). Additionally, PAN injection + albumin overload resulted in massive proteinuria in PAN-resistant mice.

Conclusions: Strain differences play a minimal role in PAN sensitivity in rats. Moreover, although i.v. PAN injection leads to a wider range of proteinuria, it is more responsive to GC than i.p. PAN. Finally, PAN resistant mice can be made susceptible by a second insult with albumin overload which may create useful models to study genetic deletions.

The Inhibition of D-Site Binding Protein (DBP) Contributes to the Proliferation of Mesangial Cells in Experimental Anti-Thy1 Glomerulonephritis

Lei Chen,[2] Hongli Jiang.[1] [1]*Dialysis Center of First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi'an, Shaanxi, China;* [2]*Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: Mesangial proliferative glomerulonephritis (MsPGN) is one of the most common glomerular diseases worldwide. It is characterized by mesangial cell proliferation accompanied by ECM expansion. Anti-Thy1 antibody-induced glomerulonephritis is a classical experimental model of MesGN. Our previous study demonstrated that D-site binding protein (DBP) was involved in the inflammatory response at the early stage of the anti-Thy1 nephritis. However, the role of DBP on the proliferation of mesangial cells (MCs) remains unclear.

Methods: 8-week old SD rats were injected with anti-Thy1 antibody (2.5 mg/kg body weight) though tail venous to induce anti-Thy1 nephritis. The rats in negative control (NC) group were received PBS injection. Specimens of the NC group were collected at 0d after the injection, while those of other groups were collected at 7d and 14d after the injection, respectively. Renal cortex slices were obtained for histological and immunohistochemistry assessment. Glomeruli were isolated by the differential-sieving method. The expression of DBP in tissues was detected by Westen blotting. In vitro study, RMCs with DBP overexpression and DBP knockdown were conducted by DBP plasmid and siRNA transfection, respectively. Cell cycles were examined by flow cytometry. Westernblotting were used for detecting the expression of DBP, p27, p21 and Cyclin D1.

Results: In the anti-Thy 1 nephritis, mesangial proliferation and ECM accumulation peaked at 7d and decreased subsequently at 14d after anti-Thy1 antibody injection. The positive rates of PCNA in glomerulus were also significant rised at 7d and then decreased 14d. Compared with NC group, the expression of DBP at 7d in glomerulus was significantly reduced at 7d and then increased at 14d. Flow cytometry results demonstrated that the knockdown of DBP promoted G0/G1-G2/S transition in RMCs, whereas, the overexpression of DBP arrested cell cycle at G0/G1 phase. Furthermore, we found the knockdown of DBP reduced the expression of p27 and p21,and increased the expression of Cyclin D1. The complete contrary results were observed in the DBP-overexpressed RMCs.

Conclusions: DBP has an effect on the G1 phase to G2/S phase transition in RMCs though regulating the expression of p27, p21 and Cyclin D1, and finally affects the proliferation of RMCs.

PUB457

Endothelial Cell Injury Plays an Important Role in the Mechanism Developing Nephrotic Syndrome in Proliferative Lupus Nephritis: Immunohistochemical and Messenger RNA Analysis

Aya Nawata,[3,4] Toshiyuki Nakayama,[1] Satoshi Hisano,[2] Yoshiya Tanaka,[4] Shohei Shimajiri.[5] [1]*Department of Pathology, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan;* [2]*Fukuoka University School of Medicine, Jonan-ku, Japan;* [3]*Department of Pathology, University of Occupational and Environmental Health, Kitakyushu, Japan;* [4]*The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan;* [5]*Department of Pathology, University of Occupational and Environmental Health, Kitakyushu, Japan.*

Background: Nephrotic syndrome (NS) is a major feature of lupus nephritis (LN) and reflects podocyte injury. Although slit diaphgram protein molecules are important for the integrity of the filtration barrier in NS, these studies in lupus nephritis are lacking. The aim of our study is to clarify whether the damage of podocyte or slit diaphragm protein molecules or endothelial cell injury plays a central role in developing nephrotic syndrome in proliferative LN (lupus III/IV) and membranous LN (lupus V).

Methods: Sixty-six patients with nephrotic syndrome including minimal change nephrotic syndrome (MCNS), primary membranous nephropathy (PMN), lupus III/IV and lupus V were enrolled in the study. Glomerular expression of podocyte or slit diaphragm molecules including Wilms tumor protein 1 (WT1), nephrin, synaptopodin and podocalyxin was evaluated in renal tissue by immunohistochemistry (IHC) and quantitative RT-PCR. Endothelial cell injury was evaluated by electron microscopy (EM) and CD31-immunostaining. In EM study, the number of capillary loop which shows subendothelial space enlargement was counted.

Results: WT1, nephrin and synaptopodin expression were reduced in PMN, lupus III/IV and lupus V by IHC and mRNA analysis. Podocalyxin expression was reduced in MCNS, lupus III/IV and lupus V. CD31-expression was significantly reduced alone in lupus III/IV. The percentage of endothelial cell injury with subendothelial space enlargement was significantly higher in lupus III/IV group than lupus V group on EM. Foot process effacement was found only along the glomerular loop showing endothelial cell injury in lupus III/IV.

Conclusions: Our results first demonstrate that endothelial cell injury plays a pivotal role in nephrotic syndrome of lupus III/IV. In lupus V, reduction of slit membrane protein molecules of synaptopodin, nephrin and podocalyxin may be associated with developing nephrotic syndrome.

PUB458

Effect of Long-Term Rapamycin Treatment on Kidney Parameters in Mice

Christopher L. O'Connor, Cindy Chu, Hongyu Zhang, Roger C. Wiggins, Markus Bitzer. *University of Michigan, Ann Arbor, MI.*

Background: Podocyte depletion causes glomerulosclerosis. Age-associated glomerulosclerosis in humans is also associated with decreasing podocyte density caused by glomerular volume increase and podocyte number reduction (Hodgin, Bitzer et al JASN 2015). Rapamycin (RAPA), like calorie intake reduction, extends lifespan in nematodes and mice and slows the rate of glomerular hypertrophy in rodent models. We therefore evaluated kidney and glomerular parameters in a large cohort of mice (n=152) aged to >22 months to compare the effects of rapamycin and calorie restriction initiated at 4 months.

Methods: A four-way cross of genetically heterogeneous mice (UM-HET3) was used to reduce impact of strain-specific characteristics on outcome. Treatments included ad-libitum fed (ad-lib), rapamycin-treated (RAPA), and caloric restricted (CR) (PMID27923560). A pilot cohort of 5 male mice per group was assessed. 50 randomly selected glomeruli were analyzed per mouse using FFPE tissue sections stained with PAS and WT1 IHC, computer-assisted image analysis was used to estimate glomerular volume and podocyte density.

Results: Kidney to body weight ratio is highly preserved in nature and remains so in this study (n=152, r=.54, p<0.0001) with the notable exception of the RAPA-treated cohort where this relationship was lost (n=21, r=-.09, p=0.69). During aging the rate of body weight gain of ad-lib and RAPA groups were not different, although both were greater than the CR group (p<0.01). In parallel, ad-lib and RAPA groups had significantly increased kidney weight compared to the CR group (P=0.01). Glomerular volume correlated with kidney weight (p=0.002, r=.65) and was highest in RAPA-treated mice and statistically increased in both ad-lib and RAPA groups compared with the CR group (P<0.05). As a result of the RAPA-associated glomerular volume increase this group also showed a significantly lower podocyte density compared to either ad-lib (p=0.02) or CR (p=0.008) groups.

Conclusions: Reduction in podocyte density during aging is predicted to be associated with increased prevalence of glomerulosclerosis. Therefore, the observation that glomerular volume is increased in association with long term rapamycin treatment in adult mice raises a question about the potential use of rapamycin to prevent aging in humans. Additional quantitative morphometric and transcriptomic studies are planned.

Nicotine Induces Podocyte Apoptosis through Increasing Mitochondrial Pro-Apoptotic Proteins

Xiqian Lan,[1] Abheepsa Mishra,[3] Seyedeh Shadafarin Marashi Shoshtari,[5] Rukhsana Aslam,[2] Ashwani Malhotra,[1] Pravin C. Singhal.[4] [1]*Feinstein Institute for Medical Research, Great Neck, NY;* [2]*Feinstein Institute for medical research, Glenoaks, NY;* [3]*Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY;* [4]*North Shore LIJ Health System, Great Neck, NY;* [5]*The Feinstein Institute for Medical Research, Manhasset, NY.*

Background: Cigarette smoking is considered to be the most important cause of preventable mortality in many developed countries, including the United States. It is also an independent risk factor for chronic kidney disease (CKD) including diabetic nephropathy (DN). Nicotine, one of the highly active compounds in cigarette smoke, is required for smoking-accelerated CKD. Our previous studies have confirmed that nicotine causes podocyte apoptosis; however, the underlying detailed molecular mechanisms are still poorly understood. In this study, we examined the effect of nicotine on mitochondrial pro-apoptotic proteins.

Methods: We cultured human podocytes in both normal (5mM) and high glucose (25 mM) medium, and then treated them with nicotine at different concentrations (0.1, 1, and 10 μM). Occurrence of cell apoptosis was determined with morphologic assays (condensed and fragmented nucleus), and the expression of mitochondrial pro-apoptotic proteins was determined with real-time PCR and Western blotting.

Results: Nicotine significantly induced podocyte apoptosis in a dose-dependent manner in both normal and high glucose milieus. It also increased the expression of mitochondrial pro-apoptotic molecules such as Bax, Bim, and Nox4, at both RNA and protein levels.

Conclusions: Nicotine may induce podocyte apoptosis through enhancing the expression of pro-apoptotic proteins in mitochondria. The present study provides insight for further studies on the molecular mechanisms involved in smoking associated progression of chronic kidney disease.

PUB460

Role of SMPDL3b in Sphingolipid Biosynthesis and in Glomerular Diseases Shamroop Kumar Mallela,[1] Alla Mitrofanova,[1] Eden Rosenfeld-Gur,[2] Tony Futerman,[2] Alessia Fornoni.[1] *[1]Katz Family Division of Nephrology and Hypertension, University of Miami Miller school of medicine, Miami, FL; [2]Weizmann Institute of Science, Rehovot, Israel.*

Background: Research suggests an important role of sphingolipids in the pathogenesis of kidney diseases. We demonstrated that decreased Sphingomyelinase phosphodiesterase like 3b (SMPDL3b) expression in post reperfusion kidney biopsies from patients with focal segmental glomerulosclerosis (FSGS) predicted recurrence of nephrotic range proteinuria suggesting that SMPDL3b may be a susceptibility factor contributing to the pathogenesis of FSGS. Others have shown that in macrophages, SMPDL3b is a glycosylphosphatidylinositol (GPI) anchored protein that is localized to lipid rafts and affects ceramide species composition of the plasma membrane thus regulating the inflammatory response. However, if SMPDL3b affects the ceramide species composition of the plasma membrane in podocytes thus contributing to podocyte injury remains to be established. Sphingolipids have various cellular functions. Ceramide and sphingosine can induce cell cycle arrest and promote apoptosis whereas ceramide-1-phosphate (C1P) and sphingosine-1-phosphate (S1P) promote cell survival and proliferation. Similarly to SMPDL3b, C1P was also shown to regulate inflammatory processes. We have generated preliminary data supporting the fact that SMPDL3b expression in podocytes regulates C1P levels, an observation that led us to test the hypothesis that SMPDL3b regulates C1P levels by directly dephosphorylating C1P or by inhibiting the activity of ceramide kinase (CERK).

Methods: Mass spectrometry analysis of lipids was performed. Phosphatase activity of SMPDL3b was determined *in vitro*. Co- and endogenous immunoprecipitation experiments were used to investigate a potential interaction of CERK and SMPDL3b.

Results: We observed an increase in C1P levels in siSMP podocytes when compared to SMPDL3b overexpressing podocytes. We show that CERK and SMPDL3b interact in transfected HEK293 cells and in glomeruli isolated from mice. Finally, we demonstrate that SMPDL3B can dephosphorylate C1P *in vitro*.

Conclusions: Our results identify an important role of SMPDL3b in regulating podocyte C1P levels. Further experiments to understand the exact mechanism by which SMPDL3b controls C1P levels in podocytes are underway.

A High Degree of Sulfation of Heparin Triggers Differentiation of Cultured Podocytes Eishin Yaoita,[1] Yutaka Yoshida,[2] Hiroki Takimoto.[1] *[1]Department of Structural Pathology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Institute for Research Promotion, Niigata University, Niigata, Japan.*

Background: We have succeeded in establishing culture conditions in which cultured podocytes exhibit phenotypes close to those *in vivo* morphologically and in gene expression (JASN 2016; 27: 153A). Heparin is indispensable to the culture conditions. In this study, we have tried to clarify the role of heparin more precisely.

Methods: Rat primary cultured podocytes were subcultured and used for experiments. The effect of heparin was examined by changing the period of addition to culture media or comparing with effects of other polysaccharides having some structural similarities to heparin.

Results: When the presence of heparin was limited to the first 24 hours after subculture instead of the entire time during culture, interdigitating cell processes and foot process-like staining of podocin were also formed five days after as shown by the figures below. Changes of gene expression consistent with differentiation *in vivo*, marked upregulation of podocyte-specific genes and downregulation of classic cadherins, were completed within the first 24 hours. Without heparin, such phenotypic changes were not observed. It is likely that heparin serves as a trigger for phenotypic changes. Heparan sulfate is less sulfated than heparin, but has the same polysaccharide structure as heparin. Sulfated dextran is highly sulfated, but has polysaccharides different from heparin. Sulfated dextran substituted for heparin, but heparan sulfate did not show such trigger effects.

Conclusions: A high degree of sulfation is crucial for the effect of heparin to trigger differentiation of cultured podocytes.

Ultra-Miniaturized Podocyte Cell-Based High-Content Screening (HCS) Assay Ha Won Lee,[2] Jean-Michel Saffin,[3] Mehmet M. Altintas,[1] Jochen Reiser,[2] Vineet Gupta.[2] *[1]Rush University, Chicago, IL; [2]Rush University Medical Center, Chicago, IL; [3]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.*

Background: Podocytes are established targets for therapeutic development for glomerular diseases. Podocyte morphology is essential for their physiological functions. We have previously shown that automated high-content imaging based assays can quantitatively discriminate between healthy and damaged podocytes. We also utilized this methodology to screen a library of ~2000 compounds with podocytes in a 96-well format and identified novel podocyte-protective compounds. However, the 96-well format is not ideal for screening larger chemical libraries, thus necessitating further miniaturization. Here, we describe our efforts towards miniaturization of the cell-based phenotypic assay to 384- and 1536-well formats.

Methods: Differentiated mouse podocytes were seeded in collagen-I coated multi-well plates. Cells were fixed with paraformaldehyde, permeabilized with Triton X-100, and blocked with donkey serum. Then, cells were stained with CellMask Blue, anti-paxillin antibody, and phalloidin. Images were taken using Opera HCS system. Morphologic parameters were quantified using Columbus software and analyzed by Genedata Screener software.

Results: Optimization of seeding density and culture conditions of podocytes in 384- and 1536-well plate formats provided reproducible results. Quantification of cellular phenotypes showed dose-dependent changes in cellular parameters upon treatment with puromycin aminonucleoside (podocyte injury-inducing agent). Co-treatment with mizoribine (podocyte protective compound) showed dose-dependent protection of podocytes from injury, as observed in the 96-well plate format. The assay also showed *Z'*-values similar to those in 96-well format, indicating the robustness of our assay.

Conclusions: We have optimized our podocyte based HCS assay in the ultraminiaturized 1536-well format for high throughput screening. This miniaturized HCS format quantitatively discriminates between healthy and injured podocytes. The ultraminiaturized assay will allow us to screen large and diverse chemical libraries to identify novel podocyte-protective compounds. With the miniaturized format, an in-house library of >300,000 compounds will be screened.

PUB463

Concurrent Treatment with Growth Hormone and Transforming Growth Factor Beta Exacerbates the Epithelial-to-Mesenchymal Transition in Mouse and Human Podocytes Alison L. Brittain. *Biological Sciences, Ohio University, Athens, OH.*

Background: Previous research has indicated that both growth hormone (GH) and transforming growth factor beta (TGFβ) can individually promote the epithelial-to-mesenchymal transition (EMT) in several different cell types. One such cell type is the podocyte. Podocyte EMT enhances foot process effacement and causes loss of podocytes from the basement membrane, ultimately leading to glomerular dysfunction and albuminuria. The purpose of this research was to test the effect of combined GH and TGFβ on mouse and human podocytes in terms of the EMT process.

Methods: To test the relationship between GH, TGFβ and the EMT process, we administered these two growth-promoting peptides individually or concurrently to immortalized mouse podocytes and primary human podocytes. We performed qPCR to evaluate EMT-related gene regulation, Western blotting to evaluate relevant second messengers, immunofluorescence and confocal microscopy to view structural proteins, and colony and scratch assays to evaluate cell phenotype.

Results: Our results show that individual administration of either GH or TGFβ causes an increase in markers of EMT and promotes a mesenchymal phenotype in both cell lines. Our results also show that compared to GH and TGFβ administration alone, combined administration of these growth factors results in further enhancement of EMT, as evidenced by regulation of EMT-specific genes and proteins such as E-cadherin, N-cadherin and Vimentin. Our results also suggest dual GH or TGFβ administration

results in significant actin rearrangement, as well as enhanced cell migration and colony formation.

Conclusions: These results suggest that GH administration may exacerbate preexisting kidney disease, as would be the case in pediatric patients with chronic kidney disease who are given GH to treat short stature.

COL4A Immunofluorescent Staining in the Diagnosis of Autosomal Alport Syndrome

Abdurrahman M. Hamadah, Samih H. Nasr, Kamel A. Gharaibeh, Ziad El-Zoghby. *Mayo Clinic, Rochester, MN*.

Background: Alport syndrome (AS) is an inherited disorder due to mutations in genes *COL4A1 -5* encoding type IV collagen alpha chains. Transmission of AS is mainly X-linked (*COL4A5* gene on X chromosome) (80% of cases), and less commonly autosomal (*COL4A3* or *COL4A4* genes) (20% of cases). We present a case of AS where we established the mode of inheritance by staining pattern of COL4A.

Methods: A 24-year-old woman, with history of microscopic hematuria since age of three presented with worsening renal function. She was thought to have benign hematuria and did not undergo kidney biopsy previously. She had a recent creatinine of 1.5 mg/dL, hematuria on urinalysis, and proteinuria of 5 grams/24 hours. She denied systemic symptoms such as hearing or eye complaints. Family history was significant for hematuria in paternal grandmother, father, and sister, but none had kidney failure. Physical exam was unremarkable. Workup revealed a creatinine of 1.3 mg/dL. Urinalysis showed hematuria and lipiduria. A 24-hour urine revealed 3.2 g of protein. She underwent kidney biopsy with light microscopy showing mild thickening of the glomerular basement membranes (GBM). No significant abnormalities were seen on Immunofluorescence (IF). Electron microscopy revealed thickened GBM with scalloping and lamellation. IF staining with antibody to COL4A5 was negative in glomeruli and positive in tubular basement membranes (TBM) and Bowman's capsule (BC), suggesting autosomal Alport disease due to a mutation in *COL4A3* or *COL4A4* genes. Normal IF staining for COL4A2 was observed in GBM, TBM, and BC. She was initiated on ACE inhibitor.

Results:

Conclusions: The history and biopsy findings of this patient are consistent with AS, with a pattern of staining with antibodies against alpha 5 of collagen IV consistent with autosomal type. In X-linked AS, there is loss of COL4A5 staining of GBM, BC, and distal TBM, whereas in autosomal AS, there is loss of COL4A5 staining of GBM with intact staining of BC and distal TBM. Because of the large size of the COL4 genes and many disease-causing mutations (1900 variants in COL4A5), staining for COL4 chains maybe a useful adjunct for diagnosis and determination of mode of inheritance. In summary, this case illustrates the unique ability of specific alpha chain staining in identifying the underlying defect in AS and its associated mode of inheritance.

PUB465

Clinico-Pathologic Scoring System Predicting Renal Outcome in IgA Nephropathy

Kornchanok Vareesangthip,[1] Ngoentra Tantranont,[3] Boonyarit Cheunsuchon,[4] Ratana Chawanasuntorapoj.[2] *[1]Division of Nephrology, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand; [2]Division of Nephrology, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand; [3]Department of Pathology, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand; [4]Department of Pathology, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand*.

Background: Prediction of prognosis in IgA nephropathy (IgAN) is still limited and the Oxford classification of IgAN is required the validation in different ethnicity. This study aimed to establish the predictors of renal outcome in IgAN in Thai patients.

Methods: The 327 patients diagnosed IgAN by renal biopsy in Siriraj Hospital between the year 1996-2014 were retrospectively followed. The clinical parameters were collected and the pathologic lesions were evaluated and scored with the Oxford classification.

Results: At the time of renal biopsy, the patients' mean age was 39 years, 64.5% was female and the median creatinine was 1.4 mg/dL. The median renal survival was 155 months, and 114 of 327 patients developed ESRD during the median follow up time of 89 months. From multivariate analysis, age (≤ 30 years: HR 2.28, 95%CI 1.24 to 4.19), serum creatinine at 6 months follow up (Cr 1.2-2.99 mg/dL: HR 4.77, 95%CI 1.96 to 11.59; Cr ≥ 3 mg/dL: HR 16.94, 95%CI 5.73 to 50.12), proteinuria at 6 months follow up (HR 2.03, 95%CI 1.17 to 3.52), tubular atrophy/interstitial fibrosis (T2: HR 3.80, 95%CI 1.54 to 9.38) and ≥ 30% crescent (HR 4.32, 95%CI 1.77 to 10.55) were independent risk factors for the time to ESRD. These variables were used to create a clinico-pathologic scoring system for 5-year ESRD risk. This scoring system demonstrated a good discrimination with a c-statistic of 0.85 (95%CI 0.79 to 0.89).

Conclusions: Our study showed that IgAN in Thailand had a rather high ESRD outcome. The risks of ESRD were young age, high serum creatinine, high proteinuria, high T score from the Oxford classification and high percentage of crescent. With these factors included in the scoring system, 5-year ESRD risk score can be predicted. Further study to validate this clinico-pathologic scoring system is being investigated.

PUB466

Characterization of a Sandwich ELISA for the Quantification of Total Soluble Human Neuropilin-1

Gabriela Berg,[1] Elisabeth Gadermaier,[2] Jacqueline Wallwitz.[2] *[1]Biomedica, Vienna, Austria; [2]The Antibody Lab GmbH, Vienna, Austria*.

Background: Neuropilin-1 (NRP1) functions as co-receptor for several extracellular ligands. It exists as 103 kDa transmembrane NRP1 isoform 1, and as 72 and 68 kDa soluble NRP1 (sNRP1) isoforms 2 and 3, that are generated by alternative splicing. NRP1 and sNRP1 expression was demonstrated in the kidney, e.g. in visceral glomerular epithelial cells. An alteration of NRP1 expression with reduced NRP1 levels was described in diabetes and diabetic nephropathy. The measurement of circulating levels of the soluble forms of NRP1 have proven to be difficult due to the lack of a reliable technique to accurately quantify the analyte. In addition, to our knowledge, it is also not yet known if soluble NRP1 circulates free or as a ligand-bound form. In order to investigate the potential of sNRP1 as a renal biomarker we developed a highly specific and sensitive assay for the quantification of total soluble Neuropilin-1 in peripheral blood.

Methods: We developed a sandwich ELISA that is able to detect total sNRP1 employing polyclonal and monoclonal anti-human NRP1 antibodies. Linear epitopes were mapped with microarray technology and compared between the soluble NRP1 isoforms. Assay parameters like specificity, dilution linearity, and spike recovery were assessed.

Results: The monoclonal detection antibody binds to a linear epitope located in the N-terminal CUB 1 domain of human NRP1. The multiple linear epitopes recognized by the polyclonal coating antibody are distributed over the whole NRP1 sequence. All mapped linear epitopes are conserved between the two known human sNRP1 isoforms. The assay is calibrated with sNRP1 isoform 2, and it detects total sNRP1 in human serum and plasma (heparin, EDTA, citrate) samples. All assay characteristics (specificity, dilution linearity, spike recovery) meet the international standards of acceptance.

Conclusions: Our novel ELISA provides a reliable and accurate tool for the quantitative determination of total soluble human Neuropilin-1 in healthy and diseased samples and it could help to investigate the role of this biomarker in chronic kidney disease.

PUB467

A Spectrum and Clinical Course of Focal Segmental Glomerulosclerosis Variants by Colombia Classification in Japanese Patients

Akihiro Tsuchimoto,[3] Yuta Matsukuma,[3] Kosuke Masutani,[3] Kazuhiko Tsuruya,[4] Shigeru Tanaka,[2] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Fukuoka, Japan; [2]Fukuoka Dental College, Fukuoka, Japan; [3]Kyushu University, Fukuoka, Japan; [4]None, Fukuoka, Japan*.

Background: Focal segmental glomerulosclerosis (FSGS) is divided into 5 pathological variants by Columbia classification. A spectrum of FSGS variants and the utility of this classification to predict a response to treatment and patient outcome have not been fully investigated in Asian patients.

Methods: This is a retrospective cohort study consisted of 151 patients aged 1–87 years who were diagnosed as FSGS from 1993 through 2016 in 9 nephrology centers in Japan. The patients were divided into 5 subgroups according to the Columbia classification. Interobserver reproducibility of pathological diagnosis was tested using kappa statics by two independent observers, blinded for clinical courses. We compared patients' clinical characteristics and renal composite outcome defined serum creatinine doubling and/or development of end-stage kidney disease.

Results: A distribution of FSGS variant was as follows: not otherwise specified (NOS), 60% (n = 90); perihilar, 15% (n = 23); cellular, 13% (n = 19); tip, 7% (n = 11); and collapsing, 5% (n = 8). Interobserver reproducibility of pathological diagnosis was good (kappa statics 0.71). Urinary protein excretion at kidney biopsy was severer in the tip and collapsing variants than the other three subtypes. Renal function was comparable among the five subtypes. With regard to the response to treatment, proteinuria and serum creatinine at 6 months were lower in patients with tip variant. In the collapsing group, renal composite outcome was significantly worse than NOS variant [adjusted hazard ratio (95% confidence interval), 5.05 (1.42–18.0); p=0.024), while it was similar among the other three groups.

Conclusions: In this study, a frequency of collapsing variant was lower and cellular variant was higher as compared with previous studies reported from the United States and Europe. Good treatment responsiveness of tip variant and poor prognosis of collapsing variant were similar with previous studies.

Myeloma Cast Nephropathy with Light Chain Proximal Tubulopathy, Renal Extramedullary Hematopoiesis, and Collapsing FSGS Virginie Royal,[1,2] Richard Leblanc,[1,2] Annie-Claire Nadeau-Fredette,[1,2] Louis-Philippe Laurin.[1,2] *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]University of Montreal, Montreal, QC, Canada.*

Background: Light chain cast nephropathy is a common etiology of acute kidney injury associated with multiple myeloma. Presence of albuminuria in patients with multiple myeloma is usually related to a concomitant glomerulopathy such as AL amyloidosis or MIDD. Collapsing FSGS has been caused by various etiologies, including infections (e.g. HIV, CMV), lupus and pamidronate therapy, but has not been frequently described in patients with myeloma with proximal tubular injury.

Methods: We described a 45-year Caucasian woman who presented with severe renal failure, albuminuria (1364 mg/mmol) and severe hypercalcemia (17.1 mg/dL), requiring dialysis therapy. Serum kappa/lambda ratio was 2632 at initial presentation. Kidney biopsy showed extensive light chain cast nephropathy (Figure 1A), light chain proximal tubulopathy (Figure 1B) along with extramedullary hematopoiesis. Collapsing FSGS was also seen on light microscopy (Figure 1C). Kappa staining was observed on pronase-digested paraffin sections. EM showed intraluminal cast formation and intracytoplasmic electron dense crystals in proximal tubular cells only. Bone marrow biopsy showed 80% plasma cells. The patient was treated with cyclophosphamide, bortezomib and dexamethasone with significant improvement of renal function which resulted in end of dialysis therapy.

Results:

Conclusions: We describe an unusual case of light chain cast nephropathy and proximal tubulopathy with extramedullary hematopoiesis, and concomitant collapsing FSGS. There was no direct light chain deposition in podocytes to explain collapsing FSGS.

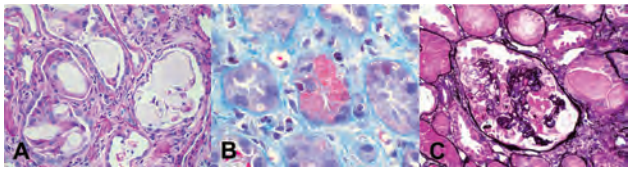

Figure 1. A) Myeloma cast nephropathy: fractured, PAS negative casts, surrounded by cellular reaction, 400x. B) Light chain proximal tubulopathy: Trichrome red intracytoplasmic crystals in proximal tubular cells, 60x. C) Collapsing FSGS: Silver stain showing collapsus associated with podocyte hypertrophy and hyperplasia, 40x.

PUB469

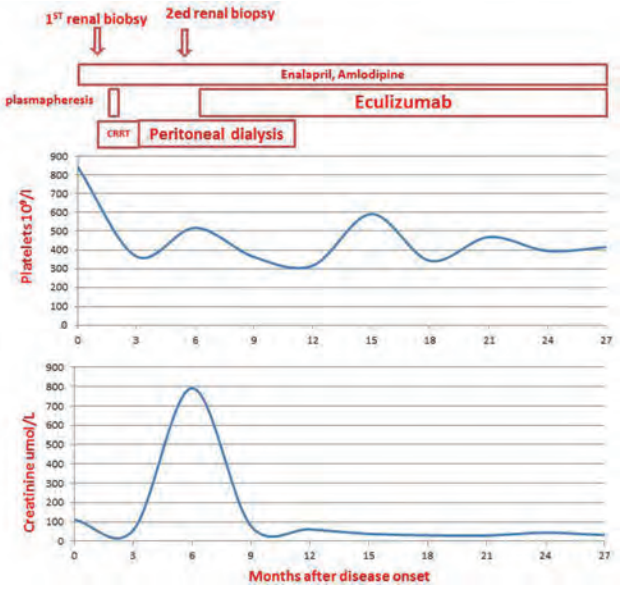
Eculizumab Resulted in Complete Renal Recovery after 9 Months of Dialysis in a Child with Atypical Hemolytic Uremic Syndrome Saeed M. Al zabli,[2] Khawla A. Rahim,[1] Abdulkarim S. Alanazi.[1] *[1]King Fahad Medical City, Riyadh, Saudi Arabia; [2]King Fahed Medical City, Riyah, Saudi Arabia.*

Background: Atypical haemolytic uraemic syndrome (aHUS) is rare, life-threatening, genetic disease characterized by microangiopathic hemolytic anemia, thrombocytopenia, and renal injury. Plasma therapy was the mainstay of treatment, with over 50 % of patients either died or developed permanent kidney damage within the first year. Eculizumab is a monoclonal antibody that blocks the cleavage of C5. Prospective trials demonstrated its effectiveness in management of aHUS

Methods: We report a 3 year old boy, with partial aHUS presented with renal impairment, anemia, normal platelets, low C3, low Complement Factor I and B (CFI & CFB). First kidney biopsy showed proliferative glomerulonephritis, vascular changes without obvious thrombosis. Genetic analysis came positive for mutations in CFI and C3 genes. Second biopsy while on dialysis was consistent with aHUS Steroid pulse therapy and plasmapheresis were ineffective to control the disease, peritoneal dialysis then started. Despite vigorous antihypertensive treatment and improved fluid overload with dialysis, HTN persisted. Eculizumab was given after 4 months of dialysis

Results:

Conclusions: Eculizumab resulted in renal recovery and cessation of prolonged dialysis. Renal function improved after the second dose. PD catheter was removed after 9 months of dialysis. Currently, after 24 months of Eculizumab therapy, disease is in remission and renal function is normal Partial HUS to be considered; diagnosis to be confirmed by biopsy and or gene mutations



PUB470

Atypical Hemolytic Syndrome (aHUS) Presenting as Acute Pulmonary-Renal Syndrome Preceded by Ocular Manifestation: A Very Rare Presentation Sanjeev Gupta,[1] Savneek S. Chugh,[2] Magdi H. Abdelrahman,[1] Anastasios Papanagnou,[1] Praveen N. Chander.[3] *[1]Dept. of Nephrology, Westchester Medical Center, Valhalla, NY; [2]Dept. of Nephrology, New York Medical College, Valhalla, NY; [3]Dept. Of Pathology, New York Medical College, Valhalla, NY.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a systemic disease characterized by excessive complement activation in the microvasculature. Kidneys are most commonly involved organ while pulmonary and retinal involvement is very rare and usually discovered at autopsy. We present a case of aHUS mediated acute pulmonary-renal syndrome with ocular involvement.

Methods: A 32-year-old man with a history of Crohn's disease s/p bowel resection was admitted with seizures, acute respiratory failure and acute kidney injury (creatinine-8.5 mg/dl). He also had a very recent history of bilateral eye blindness, resolved with steroid treatment. Laboratory findings showed hemoglobin 6.8 g/dl and platelet count 96,000). Chest X-ray showed diffuse bilateral interstitial infiltrate; bronchoscopy revealed diffuse pulmonary hemorrhage with a normal ejection fraction noted on echocardiogram. A diagnosis of pulmonary-renal syndrome was considered and he was started on IV steroids, Cytoxan, plasmapheresis, and hemodialysis. Further workup revealed low C3 at 57, normal C4 and negative MPO Ab, PR3 Ab, ANA, hepatitis panel, anti-GBM Ab, anticardiolipin Ab, SSA Ab, SSB Ab and blood cultures. ADAMTS-13 activity was 43. Renal biopsy showed changes of thrombotic microangiopathy (TMA) with glomerular immunofluorescence staining strongly for C3 compatible with a diagnosis of possible C3 nephropathy (GN). Given his multi-organ involvement, low serum C3, TMA and C3 GN on renal biopsy, and hematologic findings, a diagnosis of aHUS was made. The patient was lost to follow-up so genetic testing and complement blockade therapy could not be initiated.

Results:

Conclusions: Diagnosis of aHUS is based on clinical and laboratory findings. Extrarenal manifestations of aHUS are seen in about 20% of cases and often involve the skin, cardiovascular, and central nervous system. To our knowledge, there is only one case reported thus far of aHUS presenting as an acute pulmonary-renal syndrome; this was successfully treated with steroid and plasmapheresis. Although renal involvement with pulmonary hemorrhage is a rare manifestation of aHUS, it should be included in the differential diagnosis of pulmonary-renal syndrome, as early treatment is crucial for the better clinical outcome.

PUB471

Immunotactoid Glomerulopathy with Masked Monotypic Immunoglobulin Deposition Tsubasa Fukuoka,[2] Shunichi Shibazaki,[2] Makoto Araki,[2] Katuji Tuda,[2] Takashi Ehara.[1] [1]*Matsumoto University Graduate School of Medicine, Nagano, Japan;* [2]*Suwa Central Hospital, Nagano Pref., Japan.*

Background: Immunotactoid glomerulopathy (ITG) is a rare disease characterized by organized, Congo red-negative immunoglobulin deposits. ITG often has a monotypic light chain restriction because of a possible association with lymphoproliferative disorders, but 31% of ITGs are kappa and lambda immunoglobulin positive.

Methods: An 80-year-old woman with deteriorating renal function since 6 months presented with proteinuria of 1.5 g/day, creatinine levels, 0.92 mg/dl, and a mild decrease in C3 (76 mg/dl). Serology and urine protein electrophoresis assay and anti-nuclear antibody were normal. A renal biopsy revealed membranoproliferative glomerulonephritis. Congo red staining was negative. Immunofluorescence staining of the frozen tissue was IgG and C3 positive in the mesangial and subendothelial regions, with no differences in kappa/lambda. Electron microscopy revealed a 30-nm deposition of microtubules with a hollow core. The diagnosis was ITG. As additional checks, Serum immunofixation indicated trace amounts of IgG-kappa M protein and a normal serum free kappa/lambda light chain ratio of 1.99, (65.2/32.8). Serum cryoglobulin was negative on quintuplicate assay; bone marrow aspiration did not show excess plasma cells. Computed tomography findings were normal. Because it has recently been reported that monoclonal proteins occasionally show false negative staining by routine immunofluorescence of the frozen tissue, we tried to study light microscopic immunohistochemistry of trypsin-digested section from epon-embedded tissue. As a result, it revealed obvious subepithelial deposition of kappa. After 6 months of immunosuppressive therapy, creatinine level was 1.21 mg/dl and urinary protein concentration was 1.3 g/g Cr without any evidence of lymphoproliferative disorders.

Results:

Conclusions: ITG is a monoclonal gammopathy of renal significance, but monoclonal deposition may not be confirmed if the three-dimensional structure of the antigenic site is masked. In this patient, light microscopic immunohistochemistry of trypsin-digested section revealed monotypic kappa deposition, even though direct immunofluorescence staining of frozen tissue was both kappa and lambda positive. This would provide evidence that the monoclonal protein is the cause of ITG and would justify treating with chemotherapy

PUB472

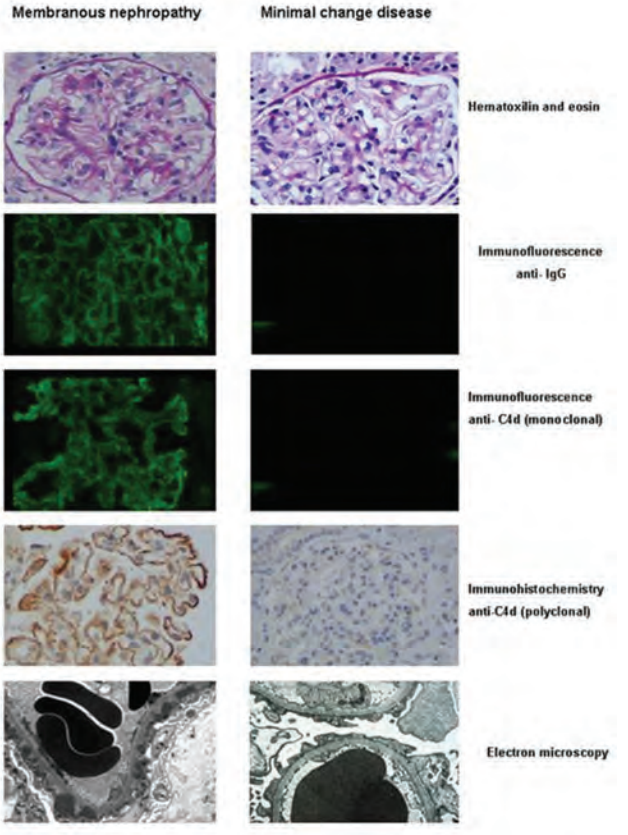
C4d Is an Important Diagnostic Tool in Membranous Nephropathy Cristina Rabasco, Mario Espinosa. *UGC Nephrology, University hospital Reina Sofía, Cordoba, Spain.*

Background: Idiopathic membranous nephropathy (MN) is the most frequent cause of the nephrotic syndrome in adults. The diagnosis is based on typical findings observed via electron microscopy (EM) and immunofluorescence (IF) studies. Recent advances have shown that MN is a kidney specific autoimmune disease induced by antibodies specific for podocyte antigens. Complement plays an important role, even if mechanisms of activation have not been clarified yet. C4d is a fragment of C4 that is produced during activation of the classical or lectin complement pathway. We might therefore expect to find C4d deposition as a marker of complement activation in MN. The aim of our study was to determine whether immunohistochemical detection of C4d in patients with MN could be useful as a diagnostic tool.

Methods: All adult patients diagnosed with idiopathic minimal change disease (MCD) and MN biopsied in our unit between January 2001-December 2016 were considered for inclusion in the study. Diagnoses of MCD and MN were based on histological assessment of renal biopsy tissue with LM, IF and EM studies. 51 patients with MCD and 91 with MN were finally included.

Results: No C4d deposition was observed in any of the glomeruli of patients with MCD, and 100% of these patients were classified as "negative". C4d was detected in 100% of patients with NM in the form of a uniform granular distribution that outlined all the capillary loops and spared the mesangium. Detectable C1q deposits by IF were detected in only two patients with MN.

Conclusions: The demonstration of C4d by means of immunohistochemical techniques can thus be used as a tool for the differential diagnosis of MN and MCD. The deposit of C4d and no C1q deposit suggest that the alternative and/or lectin pathways might be predominantly involved in complement activation and formation of the C5b-9 complex in MN.



PUB473

Atypical Myeloperoxidase Anti-Neutrophil Cytoplasmic Antibody (MPO-ANCA) Associated Crescentic Glomerulonephritis (GN) with Immune Deposits Overlap with CREST Celeste S. Chang, Yorg Al Azzi. *Nephrology, NY medical college at Westchester Medical Center, Valhalla, NY.*

Background: Pauci-immune crescentic GN is defined as few or no immune deposits on renal biopsy. However, some reported an overlap of pauci-immune pathology with immune deposits in the setting of anti-MPO-ANCA. CREST is typically associated with thrombotic microangiopathy (TMA) like renal lesion and only a handful of case reports associated between ANCA vasculitis and CREST. Here, we present a rare case of atypical MPO-ANCA associated crescentic GN on light microscopy with immune deposits on electron microscopy, overlap with CREST.

Methods: 74 F from El Salvador presented with tea-colored urine, proteinuria (Urine protein/Cr ratio: 8) and AKI with positive ANA (centromere), Anti- MPO Ab, negative HbsAg, reactive Anti-Hbs and Anti-Hbc. History of HTN, pulmonary nodules, mild restrictive pulmonary disease, pulmonary HTN, arthralgia and latent syphilis. Renal biopsy revealed crescentic and focal necrotizing GN with mesangial and subendothelial deposits on EM. There are IgG, IgA, C3, fibrillary segment, both kappa and lambda light chains on IF staining. Thrombi are present in some glomeruli, suggestive of TMA with possibility of overlapping with autoimmune disease. She was started on steroid and cyclophosphamide, required hemodialysis for fluid overload and worsening of AKI. However, she recovered renal function and came off from dialysis without any plasmapheresis. Her HbsAg became positive after cyclophosphamide.

Results:

Conclusions: This is a very unusual and rare case of pauci-immune GN with evidence of immune deposits on EM which could be related to atypical lupus nephritis with positive ANCA vs ANCA vasculitis with unusual immune deposits from possible contribution of latent syphilis and latent hepatitis B infection, the latter was unmasked by immunosuppression. All these superimposed on an element of thrombotic microangiopathy, probably secondary to CREST.

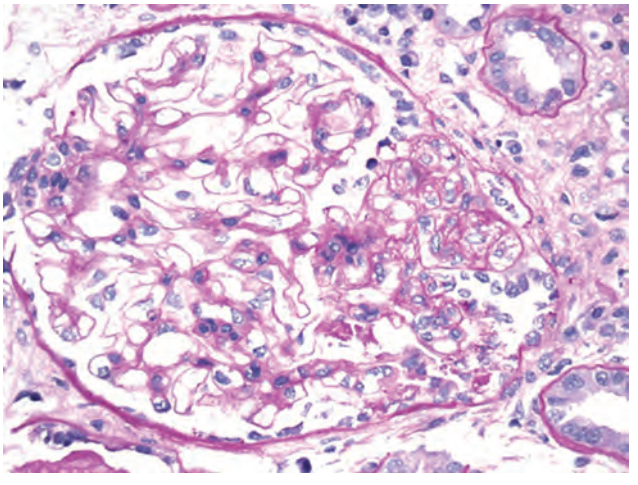
Lithium: Mood Stabilizer That Made Us Dialyze Her Anna S. Gutman, Shimshon Wiesel, Madeeha Abdul Ghaffar, Militza K. Kiroycheva. *Staten Island University Hospital, Staten island, NY.*

Background: Despite its toxic effects, lithium continues to be used for the management of bipolar disorder. We present a case of acute and chronic lithium nephrotoxicity.

Methods: A 43-year-old woman with bipolar disorder, who had been taking lithium for over 11 years, presented with lethargy and decreased oral intake. She was alert but disoriented, and had bilateral lower extremity edema. Serum creatinine was 3.5 mg/dL, from a normal baseline, with large proteinuria. Her spot urine total protein:creatinine was 54g/mg, albumin 2.0 g/dL, and serum Li^+ 3.2mmol/L, which did not improve with intravenous fluids. Intermittent hemodialysis was started, with frequent monitoring of her Li^+ levels. A renal biopsy showed focal segmental and global glomerulosclerosis, interstitial fibrosis, and multiple distal tubular cysts. Li^+ was discontinued, but the patient remained hemodialysis dependent.

Results:

Conclusions: Renal biopsies of patients with chronic lithium use and nephrotic range proteinuria show tubulointerstitial nephropathy, minimal change disease, focal segmental, and global glomerulosclerosis. Despite discontinuing lithium, as many as 75% of patients progress to end stage renal disease. Our patient had routine monitoring of her serum lithium and creatinine levels, however she progressed to ESRD. We recommend frequent quantification of proteinuria for closer monitoring of lithium induced nephrotoxicity.



Glomerulus with FSGS tip variant

PUB475

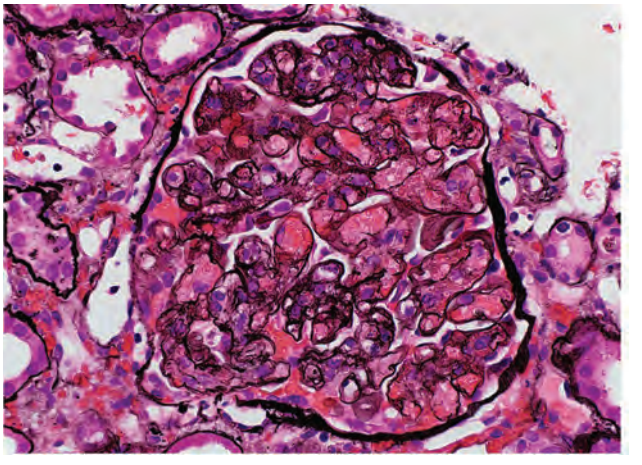
Rare Case of Catastrophic Anti-Phospholipid Syndrome Iyad S. Mansour. *Banner university medical center/ university of arizona, Tucson, AZ.*

Background: Catastrophic Anti-Phospholipid Syndrome (CAPS) is a rare life threatening form of APS. Acute thrombotic microangiopathy is the most common histological finding on kidney biopsy in this disease

Methods: A 48 year old male with PMH of Idiopathic thrombocytopenic purpura, pulmonary embolism, and recent diagnosis of arthritis, presented with 4 day history of lower back and left flank pain. P/E: vitals are stable, lung exam: scattered crackles, mild left flank and left mid- abdomen tenderness, +1 lower extremities edema, intermittent confusion, patient has been oliguric. Labs showed Hb: 13.2, WBC 10.7, plat:85,000, serum Cr: 2.8 mg/dl, AST:71, ALT:57, D.D:16.6, PT:15, PTT:39.9, blood smear showed thrombocytopenia with normocytic RBC, no hemolysis, MRI abdomen showed left adrenal hematoma. Urine AX: 100 mg/dl protein, 41 RBC and 4 WBC, 2 granular cast, serological For HIV,HCV,HBV,ANA, ASMA, Anti-DsDna, ANCA were negative, anticardiolipin antibody IgG: 18, lupus anticoagulant :2.02 (High). ADAMTS13 activity: 54%, C3, C4: both low, Kidney biopsy showed acute and chronic thrombotic microangiopathy, acute tubular injury, negative immune fixation. This patient had involvement in kidneys, adrenal glands, liver and probable CNS involvement. So he fulfilled the criteria of probable CAPS. He was treated with steroids, anticoagulation, plasma exchange and rituximab, with good response

Results:

Conclusions: APS is autoimmune disease, characterized by arterial and venous thrombosis, Catastrophic antiphospholipid syndrome (CAPS) is a rare life threatening form associated with disseminated vascular thrombosis results in multiorgan ischemia and failure. Kidney are involved in 73% of patient with CAPS, TMA is the most common histological finding in this disease. It is a life threatening disease that requires aggressive treatment strategies, and all patient with CAPS should be treated with steroids, anticoagulation, and possibly plasma exchange, in refractory and relapsing cases, Rituximab and Eculizumab may be an option.



PUB476

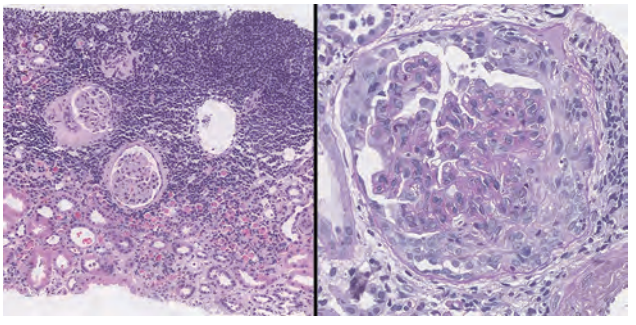
Unusual Cause of Nephrotic Syndrome with AKI: Membranoproliferative Glomerulonephritis (MPGN) with Concurrent Chronic Lymphocytic Leukemia/Small Lymphocytic Lymphoma (CLL/SLL) Infiltration in Kidney Shubha Ananthakrishnan,[1] Kuang-Yu Jen,[3] Kevin D. Marquez.[2] *[1]UC Davis, Sacramento, CA; [2]University of California Davis Medical Center, Sacramento, CA; [3]University of California, Davis, Sacramento, CA.*

Background: Renal manifestations in patients with CLL/SLL have been reported, with MPGN being the most common glomerular finding. Here we describe a patient with history of CLL/SLL who presented with new onset nephrotic syndrome and renal impairment.

Methods: The patient is a 74-year-old Caucasian male, previously treated for CLL/SLL with a rituximab-based regimen. He was off treatment for 2 years but presented with new onset ascites, requiring frequent paracentesis. On exam, he was chronically ill-appearing with marked ascites but had no peripheral edema. Labs were significant for rise in serum creatinine to 2.6 mg/dl (baseline of 1 mg/dl) and low albumin of 1.7 g/dl. Liver enzymes were normal and he had no evidence of viral hepatitis. Ascitic fluid cytology was negative for malignancy. Urine protein excretion was ~10 grams/24 hrs. Urine microscopy showed many dysmorphic red blood cells. A renal biopsy was performed that revealed CLL/SLL infiltrating the renal parenchyma with concurrent MPGN showing focal crescent formation. MPGN deposits displayed IgG1-kappa restriction, correlating to the phenotype of the patient's malignancy.

Results:

Conclusions: This is an unusual case of a patient with a history of CLL/SLL with multiple simultaneous renal manifestations - ascites related to nephrotic syndrome that was caused by MPGN secondary to CLL/SLL and AKI related to crescent formation and parenchymal infilration by CLL/SLL.



Kidney biopsy showing infiltration of parenchyma by CLL/SLL as well as MPGN with crescent formation.

PUB477

Membranous Nephropathy Secondary to Syphilis Deepa Nagaraja, Himanshu Vashistha, Shirisha Bodana, Damodar R. Kumbala. *Ochsner Health System, New Orleans, LA.*

Background: Membranous nephropathy is one of the most common causes of nephrotic syndrome in the adult population. Although in the majority of cases an inciting event can't be identified, in about a third, an association with autoimmune disease, drugs, or infections is usually found. Syphilis is a rare infectious cause of membranous nephropathy and usually presents nephrotic range proteinuria (X). In the last fifteen years, there has been a reemergence in the cases of primary and secondary syphilis in the United States (CDC), which could lead to a greater number of patients affected by this sexually transmitted disease seeking medical help due to renal involvement.

Methods:

Results: We described the case of a 41 year-old African American man without known prior medical history that presented to the hospital with the chief complaint of one-week history of gradual, incapacitating, bilateral lower extremity edema. High-risk conduct for sexually transmitted disease was identified during the history. A physical exam revealed a maculopapular rash on his palms and soles. Initial laboratories showed rapid plasma regain dilution of 1:128, serum creatinine of 1.2mg/dl, and spot urine to protein creatinine ratio of 5.7. Kidney biopsy was consistent with membranous nephropathy. After four weeks of antibiotic treatment for secondary syphilis, there was a complete resolution of his nephrotic picture.

Conclusions: Although syphilis is rarely associated with membranous nephropathy, the increasing incidence of secondary syphilis will invariably lead to a greater number of patients that are present with renal involvement. Healthcare providers must remain aware of the association of syphilis with renal disease and its possible presentations. History and physical findings suggestive of this sexually transmitted disease in a patient presenting with proteinuria and/or nephrotic syndrome should point towards accurate diagnosis. Resolution of the associated nephropathy is seen after antibiotic treatment against *Treponema pallidum*.

PUB478

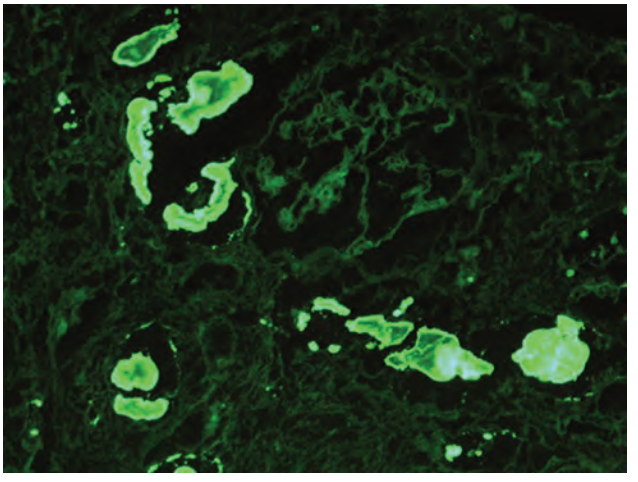
A Case of Myeloma Kidney with Glomerular C3 Deposition Asif Khan, Suzanne E. El Sayegh, Elie El-Charabaty. *Medicine, Staten Island University Hospital, Staten Island, NY.*

Background: Myeloma cast nephropathy and monoclonal immunoglobulin deposition disease are the most common renal complications of multiple myeloma (MM). Up to 50% of MM patients present with renal impairment at diagnosis: 20% may present with acute kidney injury, and 10% require dialysis. Light chains can precipitate in the proximal and distal tubules causing inflammation leading to secondary interstitial fluid involvement. Moreover, mutations or autoantibodies such as C3 nephritic factor (C3Nef) against complement regulatory proteins promote the erratic activity of the complement cascade, causing glomerular deposition of C3 without marked deposition of classical complement components and with minimal, or no immunoglobulin deposits resulting in tissue damage. These disorders are described as C3 glomerulopathy(C3G).

Methods: We report the case of a 59-year-old man Trinidadian man who presented to the emergency with acute kidney injury, hyperkalemia, anemia, serology positive for anti-dsDNA antibody and low levels of C3 with normal C4. Kidney biopsy showed cast nephropathy with mesangial staining for C3. A bone marrow biopsy showed CD56 positive plasma cell myeloma (42% IgG Lambda). Four months after the initial biopsy, the patient remained dependent on hemodialysis therapy and required multiple blood transfusions. Evaluation of the alternative complement pathway showed normal activity level.

Results:

Conclusions: Currently, there are no effective disease-specific treatments for C3G. Clinicians should be aware of isolated glomerular deposits that stain weakly or dominantly for C3 might represent an unusual complication of plasma cell dyscrasia, related to complement activation through an autoantibody activity of the monoclonal Ig against complement regulatory proteins.



Immunofluorescent revealed 3+ staining for lambda in the distribution of the atypical casts with weak granular mesangial staining for C3. Staining for IgA, IgG and C1 were negative.

PUB479

Podocytic Infolding Glomerulopathy: A Case Report Pin Zhang,[2] Daqing Hong,[3] Yurong Zou,[4] Guisen Li.[1] *[1]Renal Division and Institute of Nephrology, Sichuan Academy of Medical Sciences and Sichuan Provincial People?s Hospital, Chengdu, China; [2]Sichuan Provincal People's Hospital, Chengdu, China; [3]Sichuan Provincial People's Hospital, CHENGDU, China; [4]Sichuan provincial people's hospital, Chengdu, China.*

Background: Podocytic infolding glomerulopathy (PIG) has recently been proposed as a possible new pathological entity. In PIG, microtubules or microspheres, or both, are associated with the infolding of cytoplasmic processes of podocytes into the glomerular basement membrane (GBM). Most of PIG cases have been reported in Japan, and it is unclear whether this lesion indicates a new disease entity or a transient morphological finding of a well-known disease.

Methods: Here, we report a PIG case of a 57-year-old Chinese female. The patient presented nephrotic syndrome without renal functional impairment or other systemic diseases. Glomeruli were normocellular, but GBMs were diffusely and mildly thickened. Immunofluorescent staining was negative for immunoglobulin, complements, fibrinogen and light chain. Electron microscopy showed diffuse distribution of microtubules and microspheres within thickened GBM in association with segmental infolding of cytoplasmic processes of podocytes into the GBM. The patient was treated with steroids for 6 weeks, resulting in proteinuria less than 1 g/day.

Results:

Conclusions: The presented case demonstrates a rare and peculiar glomerulopathy, the podocytic infolding glomerulopathy. The pathogenic mechanism of PIG should be multiple, more cases of PIG are needed to be analyzed in order to better understand this lesion.

Early Recognition and Intervention Improves Outcome in HELLP-HUS: A Case Report Rakesh Kumar,[1] Dhanashri Kohok,[3] Ramesh Adhikari,[2] Manish Gera.[1] *[1]Internal Medicine Nephrology, INC, Terre Haute, IN; [2]Union Hospital, Terre Haute, IN; [3]Internal medicine, Union Hospital, Terre Haute, IN.*

Background: Atypical hemolytic uremic syndrome (aHUS) with Hemolysis elevated liver enzyme and low platelet (HELLP) syndrome is a rare complication of pregnancy. It is associated with high morbidity and mortality. Renal survival is dismal and renal dysfunction is the rule.

Methods: A 23-year-old Caucasian female pregnant at 32 weeks gestation age was admitted with epigastric pain. She was hypertensive at presentation and had proteinuria. Fetal distress led to an emergent cesarean section. Post delivery of fetus her vital signs stabilized. She had hemolysis, elevated liver enzymes, and low platelets. At the time of presentation serum creatinine was 0.6 mg/dL. Preeclampsia with HELLP syndrome was diagnosed. Post-partum she became oliguric and had renal failure. Haptoglobin and Lactate dehydrogenase (LDH) were < 10 mg/dL and 2450 U/L respectively. Schistocytes were present in peripheral blood smear. Urinalysis showed hematuria and proteinuria (greater than 3 grams/day). She was diagnosed with preeclampsia with HELLP syndrome and post-partum atypical HUS. Deregulated alternative pathway has been implicated in the pathogenesis of HELLP and aHUS so plasmapheresis was given within a few hours of diagnosis and eculizumab was given within twenty-four hours of diagnosis. Her urine output slightly improved with first session of plasmapheresis. Her serum creatinine trended up to 5.5 mg/dL. She needed 3rd session of plasmapheresis on 7th day due to worsening renal function. Supplemental dose of eculizumab was given after 3rd plasmapheresis. None of the genetic variants of 10 genes associated with aHUS were present. Lupus anticoagulants and Hepatitis screen were negative. After 2 weeks of hospital stay, her serum creatinine improved to 1.2 mg/dL and LDH started trending down but remained high at 539 U/L. Platelets improved from 53000 /uL to 386000 /uL. Hemoglobin levels also started improving but she remained anemic. She never required dialysis.

Results:

Conclusions: The association of preeclampsia, HELLP syndrome and post-partum aHUS suggest that these may be a spectrum of single disease process i.e. abnormal alternative complement activation. Early recognition of HELLP/ aHUS and treatment with plasmapheresis and eculizumab may improve renal outcome.

PUB482

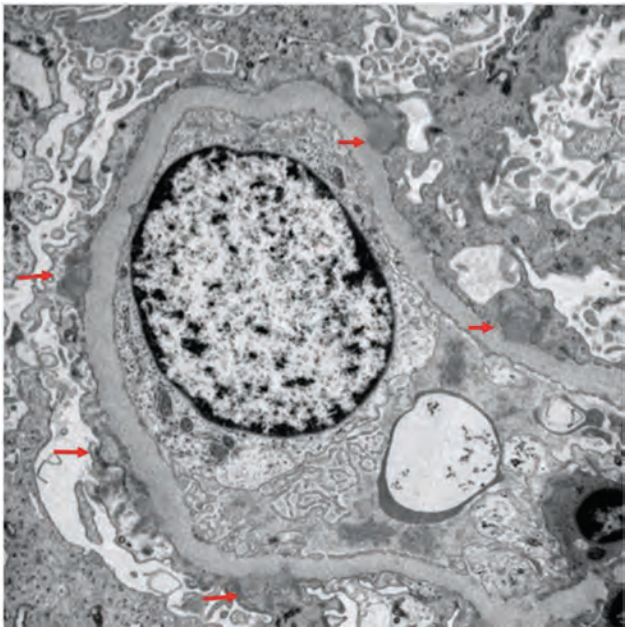
The Great Imitator: An Unusual Cause of Reversible Nephrotic Syndrome Arundati Rao,[2] Sarthak Virmani,[2] Christine B. Vigneault,[1] Michael N. Moustakakis.[1] *[1]Greater Hartford Nephrology, Bloomfield, CT; [2]University of Connecticut, Hartford, CT.*

Background: Sudden onset of nephrotic syndrome in HIV infected patients has a broad differential including HIV associated nephropathy/FSGS. Immune deposition mediated nephrotic syndrome due to co-infections is an unusual etiology in such patients.

Methods: A 52-year-old male with PMH of HIV infection on HAART presented with a 3 day history of periorbital edema, bilateral lower extremity swelling, weight gain and a urine dipstick showing 3 + proteinuria. Exam was notable for a BP of 140/85mmHg and anasarca. Investigations revealed BUN 21mg/dL, S.Cr. 1.3mg/dL, albumin 1.7g/dL, total cholesterol 422mg/dL and Triglycerides 374mg/dL. A urine protein:creatinine ratio was 5266.75mg/g and the 24 hour urine protein was quantified at 13.3g. He was diagnosed with nephrotic syndrome and started on an ACE inhibitor. Workup revealed normal levels of ANA, ANCA, complements and negative hepatitis serologies. FSGS was the working diagnosis and a renal biopsy was performed that showed immune complex GN suggestive of an infectious etiology. On further questioning, he reported a 1 day history of self limiting rash and fever following treatment with ceftriaxone for recently diagnosed gonorrhea 2 weeks prior to presentation. This was presumed to be a Jarisch-Herxheimer reaction. Subsequently, RPR and FTA-ABS were found to be positive and he was treated for secondary syphilis with penicillin. This led to complete resolution of his nephrotic syndrome clinically with a S.Cr. of 0.8mg/dL, albumin 3.2g/dL and an undetectable urine:protein creatinine ratio.

Results:

Conclusions: Syphilitic infection causing nephrotic syndrome in HIV infected patients is unusual but completely treatable and reversible. It is recommended that patients with a similar clinical picture be tested for co-infection with syphilis.



Sub-epithelial immune complex deposits on EM

PUB483

A Case of Cronkhite-Canada Syndrome Complicated by Membranous Nephropathy Christine Parsons,[1] Leslie F. Thomas,[2] Lucinda A. Harris,[1] Maxwell L. Smith.[1] *[1]Mayo Clinic, Scottsdale, AZ; [2]Mayo Clinic Arizona, Phoenix, AZ.*

Background: Cronkhite-Canada syndrome (CCS) is a very rare disorder with less than 500 reported cases. It is characterized by extensive gastrointestinal polyposis and various ectodermal anomalies including alopecia, cutaneous hyperpigmentation, and onychodystrophy. Only a few cases of associated kidney disorders (namely membranous nephropathy) have been reported.

Methods: A 71-year-old male with a history of calcium pyrophosphate deposition disease and recently diagnosed CCS presented for evaluation of proteinuria. The patient initially presented with abdominal discomfort, a 45-pound weight loss, dysgeusia, skin hyperpigmentation, alopecia and dystrophic nails. Radiologic and endoscopic evaluation was significant for widespread gastrointestinal nodular inflammation and colonic polyps. Histopathology was consistent with CCS. He was treated with prednisone and antacids, followed by steroid sparing therapy with azathioprine. He had moderate clinical improvement, but developed proteinuria, which progressed to nephrotic-range (4.4 grams on 24-hour urine collection). Renal biopsy showed membranous glomerulonephritis, and cyclosporine and losartan were initiated. The patient had significant improvement in his CCS manifestations; however, his proteinuria did not resolve and eventually worsened

coincident with declining glomerular filtration rate. Rituximab was added to his regimen of cyclosporine and azathioprine, which resulted in remission of his MN, marked improvement in his polyposis, and near resolution of his cutaneous symptoms.

Results:

Conclusions: CCS is a rarely encountered disorder in which associated renal disease, such as membranous nephropathy, uncommonly manifests. After a careful review of the literature, only three cases of CCS have been associated with MN. To our knowledge, this is the first reported case of CCS with MN as well as any case of CCS treated with rituximab. The excellent response observed for both CCS and MN recommends consideration of this treatment, especially for resistant disease. The use of cyclosporine was reported as successful in another case of CCS with MN. Steroid-resistant CCS is scarcely reported, but some success has been noted with cyclosporine, azathioprine, and infliximab. Cyclosporine in the present case evoked a response superior to azathioprine.

PUB484

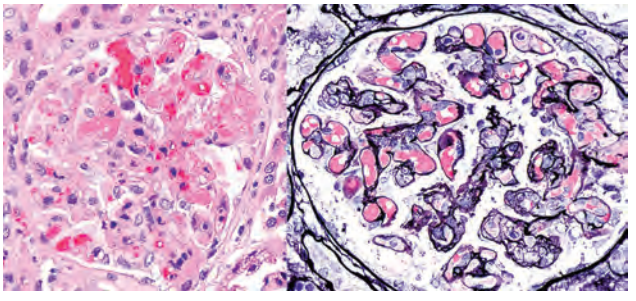
Combined Tacrolimus and Sorafenib-Associated Thrombotic Microangiopathy Voravech Nissaisorakarn,[1] Weeraporn Srisung,[1] Steven Salvatore,[1] Vesh Srivatana.[2] *[1]Weill Cornell Medical Center, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: Thrombotic microangiopathy (TMA) is an inflammatory and thrombotic disease of the microvasculature, which often occurs in hematopoietic stem cell transplantation (HSCT) population. Risk factors of TMA in HSCT include chemotherapy, radiation, calcineurin inhibitors (CNI), anti-vascular endothelial growth factor (anti-VEGF) therapies, graft-versus-host disease, and infections. Tacrolimus and sorafenib have been individually associated with TMA, however, to our knowledge there have been no reports of TMA with the combination of the two drugs. We report the first case of tacrolimus and sorafenib-associated TMA.

Methods: Our patient is a 57-year-old woman with acute myeloid leukemia who underwent HSCT. She had been taking sorafenib for seven weeks and stopped one week prior to HSCT. The post-HSCT immunosuppression consisted of antithymocyte globulin, mycophenolate mofetil, and tacrolimus. Thirteen weeks after HSCT, she had an acute kidney injury (AKI) from tacrolimus toxicity. The renal function improved after a temporary discontinuation of tacrolimus. Seventeen weeks after HSCT, sorafenib was started on top of concomitant use of tacrolimus. Two weeks later she developed severe oliguric AKI from biopsy-proven TMA (figure 1). Despite therapy with eculizumab, she died from complications of sepsis after a prolonged hospital course. Autopsy confirmed the diagnosis of TMA involving the cardiac and renal tissue.

Results:

Conclusions: We observed that TMA developed when the patient was taking both tacrolimus and sorafenib but not when they were taken individually. The concept of two drugs having synergistic effects to cause TMA has been demonstrated in dual anti-VEGF inhibition but not with the combination of CNI and anti-VEGF therapy. We hypothesize that tacrolimus and sorafenib combined may have caused a severe endothelial injury initiating the pathogenesis of systemic TMA. Despite early and aggressive therapy, the patient died. Due to emerging indications for combined use of these drugs in HSCT population, intensive monitoring for early signs of TMA is critical for optimizing outcomes.



PUB485

A Case of Sjogren Syndrome Related Cryoglobulinemic Glomerulonephritis Tramanh Phan, David Levy, Rickinder Grewal, Bruce Goldman, Scott E. Liebman. *University of Rochester Medical Center, Rochester, NY.*

Background: Sjogren syndrome is the most common cause of non-hepatitis C virus (HCV)-related cryoglobulinemia. Here, we report a case of Sjogren syndrome associated cryoglobulinemic glomerulonephritis (GN) that responded to treatment with steroids, rituximab and mycophenolate.

Methods: A 43 year-old woman with Sjogren syndrome (with hypocomplementemia, positive cryoglobulins, ANA, anti-Ro and anti-La antibodies and on hydroxychloroquine) presented with nephrotic syndrome (protein to creatinine ratio of 3.7 g/g, albumin of 2.5 g/dL). Other than peripheral edema, the physical exam was unremarkable. Further workup revealed an elevated serum free light chain (FLC) ratio of 5.78, and serum immunofixation was positive for IgM kappa. CT of the neck, chest, abdomen and pelvis did not reveal lymphadenopathy. Bone marrow aspirate was negative for multiple myeloma. Renal biopsy showed type II cryoglobulinemic GN (Fig.1). Congo red stain was negative. There was no evidence of HCV or current or previous hepatitis B infection. Thus, she was diagnosed with Sjogren syndrome associated cryoglobulinemic GN. Initial treatment was with high dose steroids followed by rituximab infusion. She continued hydroxychloroquine and was on lisinopril as tolerated by kidney function. Several months later the patient developed myopathy. Steroids were tapered off in favor of mycophenolate and continued rituximab. The protein to creatinine ratio peaked at 13.36 g/g but decreased to 0.23 g/g at six months. Serum cryoglobulins are no longer detectable, FLC ratio has decreased to 1.77 and serum creatinine is normal.

Results:

Conclusions: Although rare, cryoglobulinemic GN should be considered in Sjogren syndrome patients with nephrotic syndrome. The combination of steroids, rituximab and mycophenolate is a potential therapy for biopsy proven cryoglobulinemic GN in this setting.

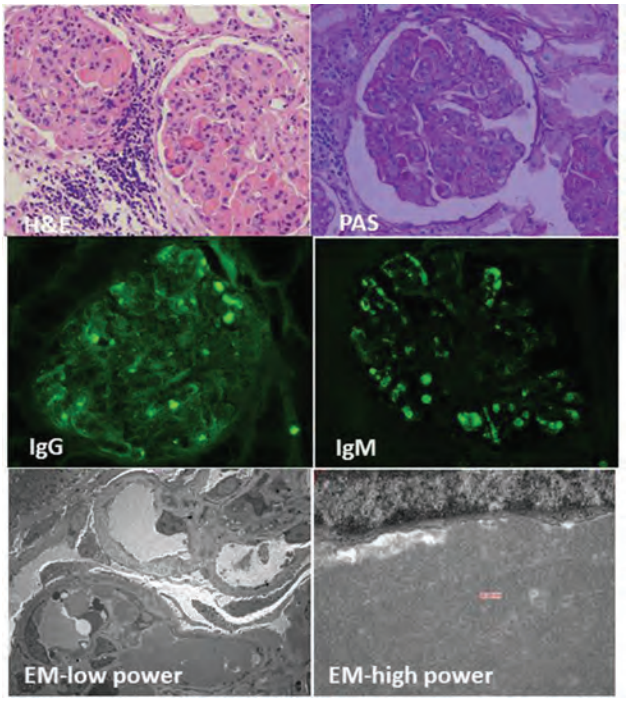


Fig.1. Renal biopsy: light microscopy (H&E,PAS), immunofluorescence (IgG, IgM), and electron microscopy (EM)

PUB486

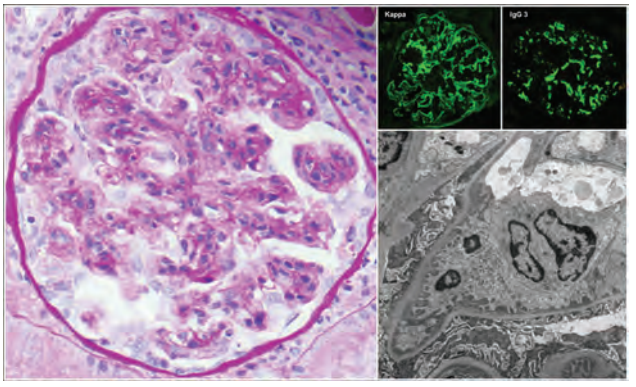
A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Early after Renal Transplantation Yasir Alfi, Scott D. Cohen, Muralidharan Jagadeesan. *Division of Renal Diseases & Hypertension, George Washington University, Washington, DC.*

Background: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) was first described by Nasr et al. in 2004 as a form of renal involvement by monoclonal gammopathy resembling immune-complex glomerulonephritis. Here we describe a case of PGNMID early after renal transplantation in a patient with a prior history of multiple myeloma in remission.

Methods: A 66 year old male with a past history of treated IgG lambda multiple myeloma who presented with abnormal renal function 5 months after a deceased donor renal transplant with a serum Cr of 1.3 mg/dl up from a baseline Cr of 0.9 mg/dl and a new nephrotic range proteinuria with a spot UPCR of 9.5 g/g. The patient was first diagnosed with MM 13 years prior to kidney transplant and achieved remission following autologous stem cell transplant. His native kidney biopsy at that time showed lambda light chain cast nephropathy and amyloidosis. Serological workup showed no evidence of a monoclonal paraprotein. A kidney biopsy was remarkable for glomerular mesangial matrix expansion with increased cellularity and segmental double contours. IF stained for IgG3 and kappa light chains, but not for lambda light chains. EM showed subendothelial and mesangial electron dense deposits. The patient was subsequently treated with Bortezomib and Dexamethasone with improvement of GFR to baseline and slight improvement in proteinuria to 4.1 g/g.

Results:

Conclusions: There are only limited case reports of PGNMID in renal allografts. It can present as a recurrence of the native kidney disease usually early after the transplantation or as a *de novo* glomerulonephritis years after the kidney transplant. We report a case of PGNMID that presented early after kidney transplantation in a patient who had myeloma cast nephropathy and amyloidosis on his native renal biopsy. The optimal treatment of PGNMID is unclear with mixed results using Rituximab. Early treatment with Bortezomib and high-dose Dexamethasone may be effective for the treatment of PGNMID but needs further study.



PUB487

Three Year Follow Up Results of Severe IgAN with CKD Treated by MP-Pulse Therapy and Autologous Adipose Derived SVF Byoung-Soo Cho,[1] Hyaejin Yun,[1] Sung min Jung,[1] Wang kwang Hong,[2] Daeyoung Kim.[3] *[1]Mirae Kidney Center, Seoul, Republic of Korea; [2]ByulE plastic surgery, Seoul, Republic of Korea; [3]N-biotek, Seoul, Republic of Korea.*

Background: As yet there is no specific method of treatment in severe IgAN associated with CKD, but giving ACEi, ARB, Omega-3, etc., however most patients eventually progress to ESRD and need RRT. Recently stem cell/SVF(stromal vascular fraction) therapy has been suggested as a promising option for CKD, attenuation of renal ischemia and reperfusion injury especially by SVF and adipose-derived mesenchymal stem cells. Our group have been reported a shorterm result of MP pulse therapy and adipose derived SVF at the ASN(2015,2016) in IgAN with CKD3. The mechanisms underlying this beneficial effect are still a matter of debate, therapeutic strategies aimed at correcting the potential of stem cells based on the administration of SVF. In this report we summarized 3 years follow up results as follows.

Methods: Case 1. : A 27-year-old male was diagnosed as IgAN with 24% glomerulosclerosis. Follow up renal biopsy after 10 cycles of MP followed by SVF in 1 year showed markedly decreased immune deposits without lesions of sclerosis. Laboratory results showed BUN/Cr 6.9/1.08, urine protein/Cr 0.974. Follow up lab after 2 years showed BUN/Cr 16.5/1.04, urine protein/Cr 0.145. Case 2. : A 45-year-old female was diagnosed as IgAN grade IV(HS Lee Classification) with 61% sclerotic glomeruli. Follow up renal biopsy after 10 cycles of MP followed by SVF in 1 year showed 41% sclerotic glomeruli with disappearance of IgA and C3 deposition. Initial serum Cr and GFR was 1.77mg/dl and 35ml/min. Follow up lab after 3 years showed 1.03mg/dl and 61ml/min. Case 3. : A 36-year-old female was diagnosed as IgAN grade V with 67% glomerular sclerosis. Follow up renal biopsy after 10 cycles of MP pulse followed by SVF in 1 year showed stage IV with 33% glomerulosclerosis. Initial serum Cr and GFR was 1.39mg/dl and 43ml/min. Follow up lab after 3 years showed 1.32mg/dl and 48ml/min.

Results:

Conclusions: In conclusion, although further longterm studies are needed, 3 years follow up of MP pulse followed by SVF treatment in severe IgAN with CKD might be promising new therapeutic strategies without noticeable side-effects or complications.

PUB488

State of Rituximab in Treatment of Minimal Change Disease: A Systematic Review Chandra M. Jha,[1] Hormaz D. Dastoor,[3] Ehab A. Elshukri,[4] Alind Kumar.[2] *[1]Nephrology, Gulf Diagnostic Center Hospital, Abu Dhabi, United Arab Emirates; [2]Nephrology, Julekha Hospital, Dubai, United Arab Emirates; [3]Nephrology, Rahba Hospital- Johns Hopkins International, ABU DHABI, United Arab Emirates; [4]Nephrology, Burjeel Hospital, Abu Dhabi, United Arab Emirates. Group/Team: ADHARR.*

Background: 90% of childhood &10-15% of adult Nephrotic Syndrome is caused by primary minimal change disease (MCD). Corticosteroid has remarkable success. Around 25% of patients have frequently relapse & 30% become steroid dependent. Chimeric monoclonal antibody Rituximab (RTX) induces B cell depletion. The pathophysiology & mechanistic involvement of B cells in MCD is poorly understood. Yet Rituximabb is reported to be used in its management. We aimed to review the literature to find answers about: 1. Efficacy of Rituximab in Frequently relapsing Nephrotic syndrrome due to MCD / FSGS in children and adult; 2. Dose & duration of RTX used for MCD; 3. Side effects / complications associated with its use.

Methods: We searched PUBMED, Chochrane Review Database and Govt. Trial Registry for the search term “rituximab in minimal change disease”, “rituximab in proteinuria” and “Rituximab in Glomerular diseases” during the period 1st January 1998 to 31st March 2017. We excluded the publications for membranous nephropathy, IgA nephropathy and secondary MCD. All publications including case reports, prospective and retrospective cohorts studies were included. Data was pulled from full text articles by lead author and independently verified by 2nd author. Revman 5 was used for review.

Results: There were 11 case reports & 3 case series (25 patients), two retrospective cohort studies (total 29 patients) and 16 prospective cohort studies (309 patients). There was one prospective randomized control study involving 48 patients. Few cases of FSGS in some studies were not excluded. RTX dose employed varied from single dose of 375 mg/M² two such doses, to 500 ng every sixth month for duration of two years. Rituximab was effective in bringing remission, reducing requirement of immunosupressives and reducing the recurrences. Treatment with mycophenolate was associated with poor response to Rituximab. FSGS was more prone to early relapse. Commonest side effect was infusion reaction, hypopropeinemia, lymphopenia & neutropenia, rash & fever.

Conclusions: Rituximab appears to be effective treatment without any serious complication in relapse or steroid dependent MCD. RTX requires to be evaluated as a second line of therapy if it could bring permanent or prolonged remission & less steroid dependence. Long term effect of RTX if any is unknown and observation in this direction is very much required.

PUB489

An Unusual Case of Unilateral Sensorineural Hearing Loss Associated with IgA Vasculitis Chuan Jiang, Jordan L. Rosenstock. *Nephrology, Lenox Hill - Northwell Health, New York, NY.*

Background: Immunoglobulin A vasculitis (IgAV), also known as Henoch-Schonlein Purpura, is a systemic disorder characterized by immune complex glomerulonephritis, arthalgias, leukocytoclastic vasculitis manifesting as palpable purpura, and abdominal pain. There are case reports and series in the pediatric literature highlight neurological manifestations such as headaches, seizures, central and peripheral neuropathies. We describe a case with unilateral sensorineural hearing loss associated with onset of renal biopsy proven IgAV. This association has not been previously reported.

Methods: A 28 year old Caucasian male without significant medical history was evaluated for renal insufficiency and edema. Clinical history revealed the patient had an upper respiratory infection about one month prior to evaluation that was treated with amoxicillin and followed by an extensive palpable purple leg rash associated with arthralgia, nausea, and anasarca. Concurrently, the patient also reported sudden hearing loss in his right ear associated with tinnitus. Workup revealed creatinine of 1.38g/dL, albumin 2.1 g/dL, and nephritic urine sediment (10 RBC/hpf) with 8.4g/g of proteinuria. Serologic evaluation was unrevealing. Renal biopsy revealed diffuse endocapillary proliferative glomerulonephritis, acute tubular injury, diffuse granular mesangial and glomerular capillary wall staining for IgA and C3, and electron microscopy demonstrated 70% podocyte foot process effacement. MEST scores M1, E1, S0, T0, C0. He also received ENT evaluation that identified severe sensorineural hearing loss in his right ear. MRI was unrevealing for intracranial pathology. Creatinine rose to 2.4mg/dL that likely reflected tubular injury due to the severe podocytopathy. High dose prednisone (1mg/kg dosing) and aggressive diuresis were initiated with improvement in renal function but the hearing loss has not yet improved.

Results:

Conclusions: Neurological manifestations are known sequelae of small vessel vasculitis such as IgAV. However, there are no cases in the literature describing an association with unilateral sensorineural hearing loss. This report extends the observed constellation of symptoms with IgAV to include unilateral sensorineural hearing loss, which has not yet resolved in our patient.

PUB490

Unusual Presentation of Secondary Syphilis Syed Rizwan A. Bokhari,[1] Adrian J. Baudy,[2] Myra A. Kleinpeter,[4] Laura R. Kidd,[3] Eric E. Simon.[2] *[1]Tulane School of Medicine, New Orleans, LA; [2]Tulane University, New Orleans, LA; [3]Tulane University Medical School, New Orleans, LA; [4]Tulane University School of Medicine, New Orleans, LA.*

Background: Nephrotic syndrome with secondary Membranous glomerulonephritis (MGN) is frequently encountered with autoimmune diseases, diabetes mellitus, exposure to toxins, malignancies and infectious agents. Infection-related MGN, secondary to syphilis is rarely seen with advancement of healthcare in developed countries.

Methods: We describe a case of 21-year-old African American HIV positive male with severe renal dysfunction and no known co-morbidities admitted with a 1 week complaints of epigastric pain, nausea, vomiting and diarrhea. Review of systems, family and allergic history were insignificant. Sexual history was positive for a single male partner of less than a year. Examination revealed maculopapular rash on trunk, few small axillary and inguinal lymph nodes, epigastric tenderness and perianal tenderness on palpation. Labs showed normal complete blood count, BUN and creatinine of 53 mg/dl and 7.1 mg/dl (baseline 1.1) respectively, with no electrolyte or liver function test abnormalities. Urinalysis showed 4+ protein, 2+ blood, negative for nitrite and bacteria. Urine microscopy and culture were unremarkable. Urine protein/creatinine was 7.3 g/g, Infectious profile was positive for HIV with viral load 1917 copies/mL, CD 4 count 306 cells/mm³ and strongly positive RPR. Autoimmune profile, complement levels, thyroid function tests, lipid profile, coagulation profile, serum and urine electrophoresis were all within normal limits. Renal ultrasound and CT abdomen were unremarkable, except for few abdominal lymph nodes. Patient received penicillin G benzathine 2.4 M units IM and percutaneous renal biopsy was consistent with early MGN and a patchy interstitial mononuclear cell infiltrate composed of predominately plasma cells. A treponemal (spirochete) immunohistochemical stain was very focally positive for spirochetes within the areas of plasma cell-rich interstitial infiltrate. Significant improvement in renal function was noted in a week with complete return to baseline within one month of discharge.

Results:

Conclusions: Syphilis has been traditionally associated with MGN with infrequent presentation in the current era, our case described the rare biopsy features of tubular involvement and interstitial inflammation. These findings are not always seen in the MGN

secondary to syphilis, however, if present, they are almost always associated with plasma cell rich infiltrate.

PUB491

Predictive Significance of Indicated Repeat Biopsy in Patients with Lupus Nephritis Krishan Lal L. Gupta, Joyita Bharati, Hari A. Prasad, Raja Ramachandran, Manish Rathi, Aman Sharma, Ritambhra Nada. *Postgraduate Institute of Medical Education & Research, Chandigarh, India.*

Background: Lupus nephritis, an important cause for morbidity and mortality in systemic lupus erythematosus, is characterized by remissions and relapses. Although repeat renal biopsy in a flare/resistant disease is suggested in almost all guidelines, few conclusive studies have investigated its role. We analysed the contribution of repeat renal biopsy in treatment decision and assessed various predictors of renal outcome.

Methods: Sixty-four patients who underwent repeat renal biopsy from January 2013 to January 2017 were included. Renal biopsy was done only when clinically indicated. The clinical and histological parameters at initial biopsy and repeat biopsy were compared. Multivariate regression analysis was used to determine factors significantly affecting renal outcome at last visit. Renal relapse and outcome (complete remission, partial remission, resistant) were defined based on KDIGO (Kidney Disease: Improving Global Outcomes) guideline.

Results: Repeat biopsy was done for relapse in 56% and for resistant disease in 44% of patients (56/64 underwent one repeat biopsy, 8/64 underwent 2 repeat biopsies). The median age of patients was 29 ± 9.6 years at initial biopsy and male to female ratio is 1:3. Nine (17%) out of 52 patients with baseline proliferative histology converted to non-proliferative disease while 3/12 (25%) with non-proliferative lesion converted to proliferative disease. After the second biopsy, 84% of patients had therapy changed. In multivariate analysis, the factors statistically significant for non-response at last visit are non-responsive disease to second line of therapy, non-nephrotic severe relapse, presence of IFTA (Interstitial fibrosis/tubular atrophy) at first biopsy, IFTA >25% at second biopsy, presence of diffuse glomerular basement membrane thickening and TMA (thrombotic microangiopathy) at second biopsy. With a median follow-up of 146 months, 48/64 (75%) patients have responded to therapy after the second biopsy, with 17/64 (26.5%) in complete remission and 5/64 (7.8%) needing renal replacement therapy.

Conclusions: Tubulointerstitial and vascular involvement in repeat biopsy were associated with poor response to therapy. This indicates ineffectiveness of current induction therapy in lupus nephritis. The practice of repeat renal biopsy is still an important and decisive tool.

PUB492

Survey of Deceased Children with Shiga Toxin-Associated Hemolytic Uremic Syndrome in Japan Shuichi Ito,[1] Mayumi Sako,[2] Takashi Igarashi.[2] *[1]Department of Pediatrics, Graduate School of Medicine, Yokohama City University, Yokohama, Japan; [2]National Center for Child Health and Development, Setagaya-ku, Japan.*

Background: In patients with Shiga toxin-producing *Escherichia coli* (STEC)-related hemolytic uremic syndrome (HUS), known major causes of death are encephalitis or intestinal perforation, but few studies have analyzed clinical features of deceased children.

Methods: We conducted a nation-wide retrospective survey of deceased children due to STEC-HUS between 2000 and 2014. We sent a questionnaire to 1100 institutes in Japan. We analyzed collected data.

Results: Eighteen patients (males 11; females 7) were studied. The median age at onset was 4 years (2.2-14.6 years) and the median weight was 13.5 kg (12–47 kg). O antigens of *E. coli* were O157 (n=10), O111 (n=4), O26 (n=2), and unknown (n=2). All patients developed AKI and thrombocytopenia. Convulsion and conscious disturbance were observed in 18 and 14 patients, respectively. Six patients developed acute cardiac failure and 5 had arrhythmia. The median day of death was 3 days from the onset of HUS (1-181days). Primary causes of death were encephalopathy (n=12), encephalopathy with acute cardiac failure (n=1), cardiac failure (n=4), and AKI (n=1). Types of intervention were dialysis (n=11), plasma exchange or infusion (n=8), anticoagulation (n=14), methylprednisolone pulse therapy (n=1), and antibiotics (n=14). The median day from onset of diarrhea to death was 20.7 days in patients treated with antibiotics (n=14), but 4 days in those who were not (n=4) (p=0.047). There were no significant differences in laboratory data and characteristics of patients at the diagnosis of HUS between those who died within 3 days (n=10) and after 3 days (n=8).

Conclusions: Most patients had rapid and devastating clinical course, and the median day from onset of HUS to death was only 3 days. The second main cause of death was acute cardiac failure. The time from onset of diarrhea to death was significantly longer in antibiotic-treated patients than in non-treated patients. Risks and benefits of antibiotics have not been clarified, but survival was improved in antibiotic-treated patients in an outbreak of O104:H4 in Germany (BMJ 2012). Significant efficacy of methylprednisolone pulse therapy against STEC-HUS encephalopathy was recently reported (Neurology 2014). A combination of antibiotics and methylprednisolone pulse therapy may improve outcome of patients with severe STEC-HUS.

PUB493

Hydroxychloroquine Induced Phospholipidosis Satya Sai V. Bhupathi,[1] Franco H. Cabeza Rivera,[2] Jorge L. Castaneda.[1] *[1]University Of Mississippi Medical Center, Madison, MS; [2]University of Mississippi Medical Center, Ridgeland, MS.*

Background: Systemic Lupus Erythematosus (SLE) is a systemic disease, can manifest as Lupus Nephritis and shown to overlap with other diseases. SLE is treated by a combination of steroids, immune-suppression and anti-malarial like Chloroquine (CQ) and Hydroxychloroquine (HCQ). Fabry is a X-Linked disease due to inactivation of Lysosomal Alpha-galactosidase (GAL) enzyme, renal biopsy is characterized by Zebra bodies on electron microscopy. We report a case of SLE on HCQ with zebra bodies and negative genetic testing.

Methods: A 35 y.o. AA woman is known to have SLE for 17 years, with Asthma, Myositis, HTN, Lupus Anticoagulant, PE on Warfarin. SLE treated with Azathioprine, Prednisone and HCQ. Noted to have increased proteinuria and hematuria. FH significant for SLE. She is non-smoker, no alcohol/drug use. Exam only positive for leg edema. Labs showed normal blood counts, sCr 0.8, electrolytes and C3/C4. Urine showed protein >300 mg/dL and RBC 50-100, 24 hr collection showed 2.42 gm of protein. HIV, Hepatitis B/C were negative and ANA/dsDNA positive. Protein electrophoresis and light chains were normal. Renal Biopsy showed areas of Mesangial depostis, rare sub-epithelial deposits and tubulo-reticular inclusion consistent with Class I LN. Abundant Zebra Bodies of varying sizes were noted in the visceral epithelial cell cytoplasm, characteristic of Fabry Disease. Further tests showed normal Plasma Lyso-Gb3 level and negative genetic GLA sequencing, ruled out Fabry. After discontinuation of HCQ, proteinuria improved and renal function stable.

Results:

Conclusions: Zebra bodies are mostly seen in primary renal phospholipidosis but described with various drugs like CQ, amiodarone and silicon. CQ induced Phospholipidosis was first described as CQ Keratopathy in 1977. CQ Cardiotoxicity was describe in a Mayo study in 2002. The first description of CQ Renal Phospholipidosis was reported in German in 2002. More recently HCQ has been associated with similar findings. Being a weak base HCQ is concentrated in lysosomes and inhibits enzymes like alpha-galactosidase, cathepsin, acid hydroxylase and phospholipases leading to Iatrogenic Phospholipidosis. Accumulation is higher in patients on higher doses of HCQ, prolonged exposure and renal failure. Fabry needs to be ruled out to establish diagnosis. Only few case reports of this association are reported and clinicians need to be aware of Drug Induced Phospholipidosis.

PUB494

Complete Remission of Severe Nephrotic Syndrome and AKI in Collapsing FSGS with a Combination of ACTH Gel and Abatacept – A Case Report Rebeca D. Monk. *University of Rochester, Rochester, NY.*

Background: Focal segmental glomerulosclerosis (FSGS) is now the most prevalent primary nephrotic disorder. The collapsing variant of FSGS often portends a poor prognosis. Patients develop severe nephrotic syndrome (NS) with ensuing kidney failure despite therapy. This case demonstrates success using combination therapy with Abatacept and ACTH gel.

Methods: A previously healthy 32 year old florist presented with 3+ leg edema. Initial creatinine (Cr) was 0.99. Alb 2.0, Cholesterol 404, 24h urine, protein:creat ratio were both consistent with 8 g of proteinuria. Kidney biopsy revealed FSGS-- collapsing variant with Ki-67 immunostaining. She was treated with 1 mg/kg prednisone, lisinopril and furosemide. She developed AKI and hyperkalemia with no improvement in anasarca. Due to high K (5.9) and Cr (to 2' s), calcineurin inhibitors were not felt safe to use. Cellcept was initiated with iv diuretics in the hospital. Steroids were continued. She suffered numerous medications side effects including proximal myopathy, severe anemia on cellcept and methemoglobinemia from Dapsone. Months later she was 45 lbs greater than baseline weight of 100 lbs. Cr was 3 (GFR 19) and protein:creatinine ratio remained 30 to 50. B7-1 stain was ordered and Abatacept was started. 3 weeks later insurance for ACTH gel (Acthar ®) was approved. B7-1 staining was negative but both medications were continued for 9 months. Over the first 2 months she lost 40 lbs. One months later, Cr decreased to 0.83, MA:creat ratio 766. Eight months after initiation MA:creat ratio was 255. 3 years later she remains disease free and pregnant with her first child.

Results:

Conclusions: This patient with no response to prior therapy of collapsing FSGS had a surprising full recovery of disease with combined ACTH gel and Abatacept. ACTH stimuates melanocortin receptors including MC1R on podocytes. Activation of MC1R may have a variety of podocyte protective effects but few pts with FSGS have had complete remissions with ACTH. Theoretically, Abatacept inhibits B7-1 binding to β-1 integrin, an action that prevents podocyte migration and proteinuria. However, our patient was B7-1 negative. The mechanism by which one or both of these drugs led to complete remission in this case is not clear. Further studies may elucidate the benefits of this therapy.

PUB495

Spontaneous Resolution of Histiocytic Glomerulopathy in a Patient with Secondary HLH after a Presumed Acute Viral Illness Bhavin Chokshi, Kisra Anis. *Jacobi Hospital Medical Center, Bronx, NY.*

Background: Hemophagocytic lymphohistiocytosis (HLH) is a syndrome of excessive immune activation leading to massive infiltration of activated macrophages.

Following first description in 1939, substantial advances have been achieved in the understanding the pathophysiology and clinical course leading to identification of growing number of cases. Despite this, renal complications of HLH remain poorly documented. Immunosuppression remains the mainstay of treatment and spontaneous resolution have not been shown so far.

Methods: Our patient is a 33-year-old female with history of hypothyroidism, who was admitted with puffiness of face, fever and pitting leg edema. Laboratory work up revealed acute kidney injury with albuminuria of 5.1 grams, elevated liver transaminase, bicytopenia, elevated ferritin, low fibrinogen and active urine sediments with granular and hyaline casts and oval fat bodies. Ultrasound showed normal sized kidneys with normal echogenicity. The kidney biopsy revealed glomeruli with prominent infiltrating monocytes/histiocytes & endothelial swelling, most consistent with histiocytic glomerulopathy. Following kidney biopsy, she received supportive care as her renal function started to improve. She was discharged home six days after biopsy with clinical improvement and kidney function reaching baseline and albuminuria of 123 mg. She was followed up in the out patient clinic and has normal GFR with no albuminuria six months post discharge.

Results:

Conclusions: HLH is often triggered by infectious, autoimmune, neoplastic diseases and sometimes multiple causes exist. Most recent modification of diagnostic criteria include three of four clinical findings (fever, splenomegaly, cytopenia, hepatitis) plus one of four immune markers (hemophagocytosis, increased ferritin, hypofibrinogenemia, absent or very decreased NK cell function). We report a case of HLH after a presumed acute viral illness, who fulfilled criteria of HLH with histiocytic glomerulopathy and had spontaneous, rapid resolution of nephrotic syndrome and renal insufficiency in the absence of immunosuppressive therapy. Our case highlights the potential reversibility of the secondary HLH in clinically stable patient. Further research is needed to understand more about this rare disease and reporting of clinical presentations and outcomes of all cases are recommended.

PUB496

Glomerular Inflammatory and Lipid Related Genes Correlate with Clinical Variables in Patients with FSGS Undergoing a Kidney Transplant Sandra M. Merscher,[1] Lilian A. Otalora,[1] Efren A. Chavez,[2] Daniel J. Watford,[2] Lissett Tueros,[3] Mayrin Correa,[4] Viji Nair,[5] Phillip Ruiz,[3] Sean Eddy,[5] Matthias Kretzler,[5] George W. Burke,[3] Alessia Fornoni.[1] *[1]Katz Family Division of Nephrology and Katz Family Drug Discovery Center, University of Miami, Miami, FL; [2]Jackson Memorial Hospital, Miami, FL; [3]Department of Surgery, University of Miami, Miami, FL; [4]Department of Pathology, University of Miami, Miami, FL; [5]Dept. of Internal Medicine and Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI.*

Background: Focal segmental glomerulosclerosis (FSGS) is a common glomerular disorder and recurrence of nephrotic range proteinuria (REC) post transplantation (PT) occurs in up to 70% of high risk patients. Podocyte foot process effacement (FPE) in post-reperfusion (PostR) biopsies can be detected early and correlates with REC. We previoulsy showed that decreased Sphingomyelinase phosphodiesterase-like 3b (SMPDL3b) expression in PostR kidney biopsies predicted REC and was associated with foot process effacement (FPE) suggesting that SMPDL3b may be a susceptibility factor intrinsic to podocytes contributing to the pathogenesis of FSGS. The current study was aimed at confirming our previous observations and at identifying mechanisms by which SMPDL3b may contribute to the REC in FSGS.

Methods: Serum, urine and glomerular biopsies from forty-six patients with FSGS undergoing kidney transplantation were obtained. Microarray analysis, immunohistochemistry (IHC) and electron microscopy (EM) were performed using Pre (PreR) and PostR biopsy samples. Serum samples were also used for *in vitro* studies. Correlation analysis between genes important in modulating lipid metabolism and the immune response and morphometric variables such as FPE in PT kidney biopsies and clinical variables (proteinuria, estimated GFR) was performed.

Results: SMPDL3b expression was not significantly modulated in PostR kidney biopsies but weakly correlated with eGFR at 1 year. Inflammatory and lipid related pathways were highly regulated in glomeruli of PostR kidney biopsies and in podocytes exposed to the sera obtained from a subset of patients with FSGS.

Conclusions: We identified a small set of glomerular inflammatory and lipid related genes that correlated with clinical variables and may be utilized to stratify patients for PT REC and decline of GFR.

Proliferative Glomerulonephritis with Monoclonal Immune Deposits Associated with a Bladder Mass Ranine Ghamrawi,[2] Arjun Sekar.[1] *[1]Cleveland Clinic Foundation, University Heights, OH; [2]Hurley Medical Center/Michigan State University, Flint, MI.*

Background: A new entity called proliferative glomerulonephritis with monoclonal immune deposits (PGNMID) has been added to the spectrum of monoclonal gammopathies of renal significance (MGRS). The pathogenesis and management of this entity have not yet been clearly described. We report a case of PGNMID with an associated bladder mass.

Methods: 76 y old male patient with hypertension and diabetes mellitus type 2 presented with dyspnea, generalized swelling of the body and acute kidney injury (AKI). Physical examination was significant for confusion, edema and asterixis with stable vitals. Creatinine(Crea) was 3.7 up from a baseline of 1.1. Complete blood count(CBC), and electrolytes were within normal limit. Protein/Crea ratio was 4.4. Serology for hepatitis B and C, anti- neutrophilic cytoplasmic antibodies (ANCA), anti-nuclear antibody (ANA), anti-histones, anti – double stranded DNA were all negative. C3, and C4 and serum cryoglobulins were normal. Serum kappa and lambda, and M proteins were not elevated. Renal ultrasound and chest x- ray were normal. Renal biopsy was done and showed 19 glomeruli with 5 sclerosed. There was marked endocapillary hypercellularity with subepithelial and subendothelial immune complex deposits and 10-20% fibrosis. Immunofluorescence (IF) was positive for IgG3, C3c, C1q, and kappa light chains. Electron Microscopy (EM) showed focal subendothelial and subepithelial electron dense immune complex deposits. The biopsy was suggestive of PGNMID as there was IgG3 staining of mesangium and capillary loops. The patient was started on steroids, with improvement in the confusion, dyspnea and kidney function (Crea down to 1). Work up for malignancy included CT scan which showed a large bladder mass. Biopsy of the mass was deferred as the patient was later switched as per request to palliative care.

Results:

Conclusions: PGNMID is a newly recognized entity caused by monoclonal deposition of IgG. The diagnosis and treatment is made by histology and robust data is lacking. Different immunomodulators particularly steroids have been tried successfully and some cases reported complete remission. PGNMID has also been occasionally associated with different malignancies, mostly hematological. This case demonstrates a case of PGNMID associated with a solid bladder mass that showed initial improvement by steroids within one week of treatment.

PUB498

Association of Mesangial IgM Deposits with Rapidly Progressive Diabetic Nephropathy Bronwyn Leblanc,[4] Juan Carlos Q. Velez,[5] Mark Lusco,[1] Meghan E. Kapp,[2] Ivo Lukitsch.[3] *[1]Pathology, Vanderbilt University School of Medicine, Nashville, TN; [2]Pathology, Vanderbilt University Medical Center, Nashville, TN; [3]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [4]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [5]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Classic diabetic nephropathy (DN) is characterized by progressive proteinuria and decline in kidney function over a period of 10-15 years. However, when the clinical course does not fit the norm, a kidney biopsy is often performed to confirm the diagnosis. Whether the tissue specimens of those who require kidney biopsy and are found to have DN disclose additional unique pathological findings is not well established.

Methods: We performed a retrospective review of clinical data and kidney biopsy results from patients with long-standing type 2 diabetes mellitus who underwent kidney biopsy for the following indications: 1) rapid onset or worsening of proteinuria uncharacteristic for DN (n=5) and 2) positive serum protein electrophoresis for monoclonal gammopathy (n=3) suspicious for plasma dyscrasia; and were found to have pathologic evidence of DN.

Results: Eight cases were identified. The mean age of the cohort was 62 years, predominantly African American (62%), with equal percentage of men and women. The mean serum creatinine, estimated glomerular filtration rate (eGFR) and urine protein-to-creatinine ratio values at the time of the biopsy were 2.39 mg/dL, 30.1 ml/min and 8.7 g/g, respectively. Glomerular findings consistent with DN and arterionephrosclerosis were present in all cases. In addition, varying degrees of mesangiopathic changes were noted by light microscopy, along with mesangial IgM deposition by immunofluorescence and electron microscopy. Five patients had a rapidly progressive course (decline in eGFR > 10ml/min/year) and three of them required renal replacement therapy within one year post biopsy. The median rate of decline of kidney function was estimated at -11 ml/min/year (range: +3.2 to -28.0).

Conclusions: Although IgM mesangial deposition is often associated with minimal change disease or focal segmental glomerulosclerosis, evidence of its association with DN is sparse. Our results suggest that mesangial IgM deposition may be found in individuals with DN exhibiting an unusual clinical course and this finding could be associated with an accelerated course of DN. Further investigation is warranted to better characterize this entity.

PUB499

All the Right Hits: APOL1, CMV, and Collapsing Focal Segmental Glomerulosclerosis Stephenie Le, Ritu Modi, Anum Bilal, Rafia I. Chaudhry, Richard J. Blinkhorn, Loay H. Salman, Krishnakumar D. Hongalgi. *Albany Medical College, Albany, NY.*

Background: Collapsing focal segmental glomerulosclerosis (FSGS) is the main pathologic feature of HIV associated nephropathy. Non-HIV collapsing FSGS is much less common, but increasingly recognized. We present a case of collapsing FSGS in a patient, 11 months postpartum, with sickle hemoglobinopathy, APOL1 gene mutation, and cytomegalovirus (CMV) viremia.

Methods: A 31 year old African American female with SC hemoglobinopathy presented with fever, sore throat, sinus congestion, myalgia, vomiting, and dark urine. There was no illicit drug or NSAID use. Creatinine (Cr) 2.3 mg/dL, hemoglobin 9.5 g/dL, respiratory viral panel positive for parainfluenza virus. Spot urine protein/Cr was 9.8 g/g. Cr eventually peaked at 7.2 mg/dL. Plasma CMV by PCR was 2594 IU/mL, and CMV IgM antibody titer was >240 AU/mL. Tests for HIV, hepatitis B, hepatitis C, and parvovirus B19 were negative. Renal biopsy showed collapsing of capillary loops, prominent overlying epithelial cells, and extensive foot process effacement on

EM, without endothelial deposits. Immunostaining was negative for viral inclusions in glomeruli. APOL1 genotyping showed heterozygosity for G1 and G2 alleles. The patient was treated with corticosteroids and ganciclovir, with subsequent improvement: Cr to 1.1 mg/dL (without renal replacement therapy), CMV by PCR became undetectable, and proteinuria declined to 3 g/g.

Results:

Conclusions: While collapsing FSGS is traditionally associated with HIV, non-HIV viruses are now emerging as potential triggers. A "two hit" mechanism has been proposed; wherein genetically susceptible hosts with the APOL1 gene polymorphism, subsequently exposed to an environmental trigger, such as viral infection, results in activation of the immune system and local podocyte destruction. Our patient had heterozygous APOL1 genotype and CMV viremia leading to collapsing FSGS. Collapsing FSGS is typically associated with poor renal outcomes and progression to end stage renal disease, however, early recognition and prompt treatment of CMV with ganciclovir and corticosteroids for FSGS resulted in clearance of viremia and renal recovery in our patient.

PUB500

Fibrillary Glomerulonephritis (FGN): A Rare Clinical-Pathologic Entity, Not Always with Poor Renal Outcomes! Swati Mehta,[1] Anum Bilal,[1] Arif Asif,[4] Llewellyn A. Foulke,[2] Adam Austin,[3] Rafia I. Chaudhry.[5] *[1]AMC, Albany, NY; [2]Albany Medical Center, Albany, NY; [3]Albany Medical College, Albany, NY; [4]Jersey Shore University Medical Center, Neptune, NJ; [5]None, Albany, NY.*

Background: FGN is a renal deposition disease characterized by 10-30 nm thickness, disorganized, straight fibrils in the mesangium and glomerular basement membrane (GBM) on electron microscopy (EM). FGN is reported in 0.5-1% of native renal biopsies.

Methods: 5 cases of FGN presented to Albany Medical Center (AMC) over the last 12 years.986 native renal biopsies were performed in this period, confirming an incidence of 0.5% of FGN amongst native renal biopsies at AMC. We present 3 cases (follow-up data missing in the remaining 2).

Results: Mean age of diagnosis was 66 years, 2 Caucasians, with male to female ratio 2:1. Presenting features: nephrotic syndrome (2/3), AKI (2/3) with mean Cr 1.4mg/dL, hematuria (3/3) and hypertension (3/3). 1 patient (Pt) was diagnosed with Multiple Myeloma. LM revealed mesangial GN (1/3), membranous GN (1/3), and membranoproliferative GN (1/3), with polyclonal IgG and C3 on IF for all 3, and IgG4 subclass in 1. EM was diagnostic with 10-30 nm fibrils in mesangium and GBM, and sub epithelial deposits. All 3 patients received RAS blockade, and during a 35 month follow up: Pt 1(initial Cr 1 mg/dL, 11 gms proteinuria): progressed to ESRD despite immunosuppression (IS) with rituximab. Pt 2 (initial Cr 0.6 mg/dL, 6.8 gms proteinuria): partial remission with corticosteroids and tacrolimus. Pt 3 (initial Cr 2.7): did not receive IS, and Cr stabilized at 2.7.

Conclusions: FGN predominates in Caucasians, and most patients are 40-60 yrs old, presenting with nephrotic range proteinuria, with or without renal insufficiency and hematuria. Previously considered an idiopathic disease, FGN may herald systemic illnesses, with autoimmune conditions or malignancy found in a third of cases in a large Mayo clinic series. Histologic findings are widely variable, although mesangial GN and MPGN are reported in most cases, along with diagnostic fibril deposits. The therapeutic strategy remains poorly defined, and renal survival is poor, with 50% patients reaching ESRD despite RAS blockade and IS. Prospective, controlled studies are limited by the rarity of the disease, and data on optimal therapeutic regimen is lacking.

PUB501

Unusual Presentations of Anti-GBM Disease: A Case Series Anum Bilal,[1] Adam Austin,[1] Loay H. Salman,[1] Arif Asif,[2] Swati Mehta,[1] Llewellyn A. Foulke,[1] Roman Zuckerman,[2] Rafia I. Chaudhry.[1] *[1]Albany Medical College, Albany, NY; [2]Jersey Shore University Medical Center, Neptune, NJ.*

Background: Anti glomerular basement membrane (anti-GBM) disease is a small vessel vasculitis with antibodies (Ab) to the basement membrane of pulmonary and renal capillaries. The prevalence of anti-neutrophil cytoplasm antibodies (ANCA) with anti-GBM, i.e. double positive disease, is estimated at 30%.

Methods: We present 10 cases of anti-GBM disease diagnosed by renal biopsy for RPGN from 2009-2017 at Albany Medical Center. 60% were male, 90% Caucasian, aged 15-82 yrs. 2 patients had pulmonary hemorrhage; both non-smokers, with prior history of asthma in 1. 40% tested positive for ANCA (all P-ANCA: 3 MPO, 1 PR3), consistent with the reported prevalence of double positive disease. 8 of 10 patients required hemodialysis (HD) and only 1 had renal recovery, while 7 progressed to ESRD. Both cases that did not require HD, and the only case of renal recovery, had double positive disease. All patients received cyclophosphamide, corticosteroids and plasmapheresis. One patient was switched to rituximab due to pancytopenia, and a subsequent diagnosis of multiple myeloma. Anti-GBM titers decreased with plasmapheresis in all cases. 5 patients received renal transplants without recurrence of anti-GBM disease. Anti-GBM Ab prior to transplantation were negative in all cases, consistent with data suggestive of decreased risk of recurrence post-transplant with low pre-transplant anti-GBM Ab titers.

Results:

Conclusions: Anti-GBM classically has a bimodal age distribution with peak incidence in the 3rd and 6th decades. Our series does not support this pattern, with at least 1 case in every decade of life (between age 10-90), except the 8th (70-79 yrs). Prior reports demonstrate mixed renal outcomes in double positive disease, including a correlation with poor renal prognosis in some studies. However, the 30% renal survival in our series was amongst double positive cases. The low incidence of pulmonary hemorrhage may be due to screening based on renal biopsy, while notably both cases were non-smokers. We did not note a seasonal pattern to the disease (only 50% presented in the warmer months). Despite the severity of anti-GBM disease, and associated high mortality, we have 100% patient survival to date.

PUB502

A Rare Etiology of Renal Failure in Chronic Hepatitis C Viral Infection Arun Rajasekaran,[1] Mario A. Mendoza,[2] Edward T. Casey.[2] *[1]University of Central Florida College of Medicine, Kissimmee, FL; [2]Nephrology, Orlando VA Medical Center, Orlando, FL.*

Background: Chronic hepatitis C viral (HCV) infection is strongly associated with immune mediated glomerular diseases, including membranoproliferative glomerulonephritis (MPGN), and rarely fibrillary glomerulonephritis. We describe a case of fibrillary MPGN in a patient with HCV infection, with no improvement in renal function despite achieving sustained virologic response after anti-viral therapy.

Methods: A 60-year-old white male with treatment-naïve HCV infection presented with a four month history of progressive leg swelling. He was taking high doses of non-steroidal anti-inflammatory (NSAIDs) agents for pain relief. On examination, there was pitting edema in the legs. Serum creatinine was 4.1 mg/dl (1.2 mg/dl a year ago), urine studies showed hematuria and nephrotic range proteinuria. HCV RT-PCR returned at 405,073 IU/ml (normal <12), and testing revealed genotype-1a. Serology revealed normal ESR and complement levels. HIV, ANA, ANCA, and cryoglobulins were negative. NSAIDs were stopped and his hypertension treated. A kidney biopsy showed normal sized glomeruli with a mesangial matrix expansion that stained positive for H&E and PAS. There was severe widespread tubular atrophy and interstitial fibrosis, along with severe intimal fibrosis of blood vessels. On immunofluorescence, there was global mesangial and capillary wall "smudged" deposits staining 3+ for IgG, 2+ for C3 and 2-3+ for kappa and lambda light chains. Electron microscopy showed ill-defined fibrillary deposits within an expansile mesangium, and glomerular basement membrane global thickening with severe foot process effacement of the visceral epithelial cells. These findings were consistent with a fibrillary MPGN. 12 week treatment with elbasvir-grazoprevir lead to undetectable viral loads; however his renal function progressively worsened to chronic kidney disease stage V.

Results:

Conclusions: Fibrillary MPGN is a rare cause of renal failure, manifestations range from nephrotic syndrome to overt renal failure. Few cases of this renal disease have been associated with HCV infection and elevated viral titers. The patient's kidney biopsy showed severe glomerular sclerosis, tubular atrophy and interstitial fibrosis that predicted a poor renal response to treatment of his HCV. This case highlights an unusual renal manifestation of HCV infection, along with the need for early recognition and treatment of HCV.

PUB503

Persistent, Heavy Proteinuria Despite Discontinuation of VEGF Inhibitors for Renal Cell Carcinoma Dheeraj Kaul,[3] Himabindu Valluru,[2] Philip Goldwasser,[2] Gary R. Briefel,[1] Man S. Oh,[2] Ian L. Provancha.[4] *[1]Kings County Hospital, Brooklyn, NY; [2]None, Brooklyn, NY; [3]Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; [4]SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Axitinib is an antineoplastic tyrosine kinase inhibitor targeting VGEF receptors used against renal cell carcinoma. Proteinuria, hypertension and renal dysfunction are known adverse effects, but nephrotic range proteinuria rarely continues after the medication is discontinued. We report a case of nephrotic range proteinuria within 10 days after initiation of axitinib.

Methods: A 66 year old man with type 2 diabetes, hypertension, hyperlipidemia and obstructive sleep apnea and stage 3b CKD with a diagnosis of renal cell cancer treated with left nephrectomy in 2001. In 2015, lung metastases from renal cell cancer were found, for which sunitinib was started. Prior to the start of sunitinib, a 24 h urine albumin was 383 mg/day and protein 754 mg/day. Because of neutropenia, sunitinib was discontinued on October 2015. Axitinib 5 mg daily was started on 1/1/16. On 2/29/16, protein excretion was 16.7 g/day. Axitinib was increased to 5mg BID on 3/16/16. On 3/31/16, albumin excretion was 18.0 g/day and urine protein 23.3 g/day. Although Axitinib was discontinued that day, the heavy proteinuria persisted: 15.2 g/day (Apr. '16), 11.1 g/day (Nov '16), 16.3 g/day (Feb '17).

Results:

Conclusions: Proteinuria induced by tyrosine kinase inhibitors directed against VGEF receptors is usually mild to moderate, but occasionally severe enough to cause nephrotic syndrome. Proteinuria usually improves upon discontinuation of the drug. The persistence of severe proteinuria could be due to another mechanism, but a solitary kidney prevented diagnostic biopsy.

PUB504

Membranoproliferative Glomerulonephritis and the "Lollipop" Lymph Node Follicles Manish K. Saha,[4] Ritika Ohri,[2] Denyse Thornley-Brown,[1] Huma Fatima.[3] *[1]UAB, Birmingham, AL; [2]University Of Alabama at Birmingham, Hoover, AL; [3]University of Alabama at Birmingham (UAB), Birmingham, AL; [4]Medicine, University of Alabama at Birmingham, Birmingham, AL.*

Background: Membranoproliferative glomerulonephritis (MPGN) is a pattern of glomerular injury which is either immune-complex or complement mediated, based on immunofluorescence (IF). We describe a rare case of MPGN with a negative IF for any immunoreactant.

Methods: A 44-yr-old woman presented with abdominal distension and anasarca. Physical examination revealed ascites, lower extremity edema, parotid enlargement, and diffuse adenopathy. Hemoglobin was 7.7 gm/dL, platelet count 110-192 x 10^3 /μL, serum creatinine 2.3 mg/dL, spot urine protein/creatinine ratio 0.4 mg/mg; urinalysis showed 3-10 red blood cells per high-power field. Serum LDH, complements and haptoglobin levels were normal. Significant radiographic findings included: diffuse lymph node enlargement in the neck, chest, abdomen and pelvis, hepatomegaly, and ascites. Ultrasound of the kidneys was normal. Immunoelectrophoretic studies, autoimmune and infectious disorders were negative. The kidney biopsy showed a classic membranoproliferative pattern of glomerular injury (MPGN) by light microscopy. No specific staining for immunoglobulins or complements was identified by immunofluorescence. Electron microscopy was negative for immune-complex deposits. These morphologic features in the absence of immune-complex deposits were consistent with chronic thrombotic microangiopathy (TMA). Lymph node biopsy showed "lollipop" appearance of lymph node follicles: concentric layers of small lymphocytes in the mantle zone penetrated by a hyalinized blood vessel. Multicentric Castleman's Disease (MCD) was diagnosed based on systemic findings, lymph node and renal histology.

Results: .

Conclusions: MCD is a group of lymphoproliferative disorders which may have renal involvement due to amyloidosis, MPGN, and interstitial nephritis. Circulating levels of IL-6 and VEGF were elevated in our patient, which are thought to be the mediators of inflammation and microangiopathy, respectively. Our patient was initially treated with the IL-6 inhibitor siltuximab; however, creatinine continued to rise, and peaked at 4.8 mg/dL. She was subsequently treated with rituximab, with improvement of creatinine to 1.0 mg/dL. Although uncommon, MCD should be on the differential diagnosis of a patient with immunoglobulin and complement negative MPGN and systemic findings of lymphadenopathy, fever and hepato-splenomegaly .

PUB505

Leukocytoclastic Vasculitis Heralding Immunoglobulin G4-Related Kidney Disease Anubhav Kumar, Jia hwei Ng, Jehan Z. Bahrainwala. *Nephrology, Penn-Presbyterian Medical Center, Philadelphia, PA.*

Background: Immunoglobulin G4-related disease (IgG4-RD) is a systemic inflammatory disorder that can affect multiple organs. IgG4 related kidney disease (IgG4-RKD) is a rare cause of kidney disease, though it is becoming more widely recognized as a cause of serious renal morbidity. It most commonly manifests as tubulointerstitial nephritis. We describe a case of IgG4-RKD preceded by leukocytoclastic vasculitis of the skin.

Methods: A 70 year-old Caucasian female with no prior history of kidney disease was directly admitted to our institution for acute kidney injury. Over the course of one year prior to admission, she experienced unintentional weight loss, lower extremity purpuric macules and submandibular swelling. Her serologies were notable for low C4 (11 mg/dl) and C3 (75mg/dl), high RF (>600 IU/ml). She had negative SSA/SSB, ANCA, Hepatitis B, Hepatitis C and HIV serologies. A skin biopsy was consistent with leukocytoclastic vasculitis. A salivary gland biopsy was not diagnostic. She was treated briefly with prednisone that improved her symptoms. On routine blood work prior to admission, her creatinine was 3.8 mg/dl; an increase from 1 mg/dl two months prior. She was admitted for urgent work up. Her creatinine peaked at 4 mg/dl. Her repeat serologies were negative. Her spot urine to protein creatinine ratio was 1.4 g/g. Her IgG4 levels were elevated at 419 mg/dL (1-123). Renal imaging showed large kidneys, 15 cm each, without hydronephrosis. Her kidney biopsy showed a diffuse dense infiltrate of plasma cells and lymphocytes; > 50 IgG4-positive cells in a single high-powered field, without evidence of lymphoproliferative or plasma cell disorders, consistent with IgG4-RKD. She was pulsed with methylprednisolone and discharged on high dose oral prednisone with a plan to taper over 12 weeks. Her creatinine decreased to 1.86 mg/dL within two weeks of diagnosis.

Results:

Conclusions: IgG4 related skin disease is typically due to IgG4 plasma cell infiltration in the skin lesions but other non-specific, inflammatory skin lesions have been described. This case represents a rare case of IgG4-RKD associated with leukocytoclastic vasculitis. Early recognition of the disease is important as it commonly responds rapidly to steroid therapy.

PUB506

ANCA Associated Vasculitis: Experience of a Tertiary Care Referral Center Rafia I. Chaudhry,[1] Anum Bilal,[1] Adam Austin,[1] Swati Mehta,[1] Loay H. Salman,[1] Paul J. Feustel,[1] Llewellyn A. Foulke,[1] Roman Zuckerman,[2] Arif Asif.[2] *[1]Albany Medical College, Albany, NY; [2]Jersey Shore University Medical Center, Neptune City, NJ.*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) is a small-vessel vasculitis that encompasses Granulomatosis Polyangitis (GPA), Microscopic Polyangitis (MPA) and Eosinophilic GPA. U.S. incidence estimates are limited, and European data suggest 10-20 cases per million per year. Renal manifestations of AAV include rapidly progressive glomerulonephritis. While the gold standard for diagnosis is pauci immune glomerulonephritis on renal biopsy, the term AAV is coined from associated circulating antibodies detected by neutrophil immunofluorescence demonstrating cytoplasmic (cANCA), perinuclear (PANCA) or atypical patterns in a majority of these vasculitides.

Methods: We identified 54 cases of AAV from 986 renal biopsies (5.47% of total biopsies) performed at Albany Medical Center (AMC) from January 2005 to April 2017. 41 cases met inclusion criteria: 18 GPA, 19 MPA and 4 Dual Positives, i.e. anti-GBM with ANCA positivity.

Results: 90% were Caucasians, 56% male, and mean age 52.41. The mean values for laboratory data were: Sr creatinine 3.9 mg/dL, albumin 2.7 g/dL, and hemoglobin 9.7 g/dL. 73% of the cases had hypertension, 17% had nephrotic range proteinuria, and hematuria was present in 100%. 32% (13 cases) required hemodialysis (HD), and of these, 7 came off HD by week 24. Statistical significance: C-ANCA positivity in GPA vs MPA ($p<0.001$), P-ANCA in MPA vs GPA ($p<0.001$), C-ANCA-PR3 pairing in GPA ($p=0.003$), P-ANCA-MPO in MPA ($p=0.003$). All 4 Dual Positive cases were seropositive for P-ANCA. 4 cases did not have ANCA positivity, and met criteria for AAV based on biopsy and clinical features. Of note, 8 of the 41 cases presented in 2016, and 16 presented from within a 15-mile radius.

Conclusions: Our data suggests that AAV is seen at a significantly higher rate in patients meeting criteria for renal biopsy at AMC. We postulate that this may reflect an increased regional incidence of AAV in the Capital District. In addition to the clustering of AAV, there appears to be a temporal relationship, with a higher number of cases in certain years. Prior studies suggest interplay of environmental and genetic factors resulting in varying incidence of AAV, which may explain the higher numbers of AAV presenting to our hospital.

PUB507

Recurrent Atypical Anti-Glomerular Basement Disease in a Kidney Transplant Patient Samir A. Brahmbhatt,[3] Basheer A. Kummangal,[1] Leal C. Herlitz,[1] Richard A. Fatica,[4] Saul Nurko.[2] *[1]Cleveland Clinic, Cleveland Heights, OH; [2]Cleveland Clinic Foundation, Cleveland, OH; [3]Cleveland Clinic Foundation, Cleveland, Ohio, Beachwood, OH; [4]The Cleveland Clinic, Cleveland, OH.*

Background: Atypical anti-glomerular basement disease (anti-GBM) is a rare variant of anti-GBM disease characterized clinically by an indolent course usually. Compared to typical anti-GBM, there is no circulating alpha-3NC1 antibody, no diffuse crescentic and necrotizing glomerulonephritis, and quasi-linear IgG staining on a kidney biopsy. Here we report a case of a recurrence in a renal transplant.

Methods: 23 year old Caucasian female with end-stage renal disease attributed to membranoproliferative glomerulonephritis, status post living related donor kidney transplant, on Tacrolimus, Mycophenolate Mofetil, Prednisone, with last known stable graft function with serum creatinine (SCr) 1.8 mg/dL one year ago. After 5 years and 1 month of her transplant, she presented with nausea, vomiting x 3 days, low-grade fever and acute kidney injury with SCr 5.88 mg/dL. Initial basic work up showed no evidence of obstruction and there was no significant improvement in graft function after intravenous hydration. There was a high suspicion of a rejection as she was found to have 2 ng/mL Tacrolimus trough levels, so a transplant kidney biopsy was performed. It showed diffuse endocapillary proliferative with membranoproliferative features and focal crescentic formations. Immunofluorescence showed diffuse linear positivity of GBM with IgG, kappa and lambda, suggestive of atypical anti-GBM nephritis. In addition, there was Banff Grade 1B acute cellular rejection and acute antibody-mediated rejection. She had a negative serum anti-GBM antibody. She was treated with plasmapheresis, intravenous Methylprednisone, then 60 mg Prednisone orally daily and Rituximab infusions, continued on Tacrolimus and stopped Mycophenolate Mofetil. She did not require dialysis. Her SCr improved to 3.53 mg/dL with estimated glomerular filtration rate 16 mL/min/1.73m2 on 2 months follow up.

Results:

Conclusions: This is the only 3rd reported case of recurrent atypical anti-GBM disease in a renal transplant patient. Optimal therapy for atypical anti-GBM disease in both native kidneys and after recurrence in the transplant remains controversial, as this is a rare disease entity. Further studies are needed to characterize the molecular architecture of GBM auto-antigens in these patients and establish optimal therapy.

PUB508

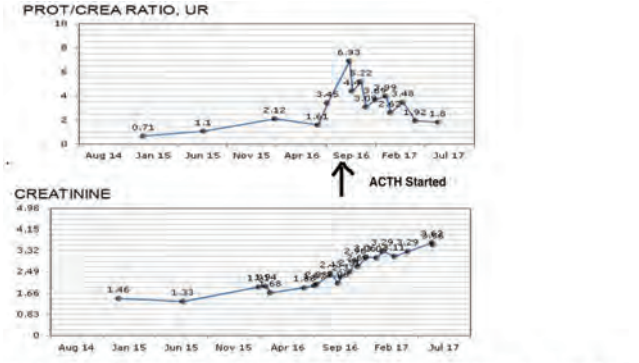
Acthar® (ACTH) Therapy in Post-Transplant De Novo IgA Nephropathy (IgAN) Asma Hasan, Nelson P. Kopyt. *Lehigh Valley Hospital, Allentown, PA.*

Background: IgAN has been reported to recur Post-Transplant as well as De Novo. We present a case of De Novo IgAN treated with 6 months of ACTH.

Methods: 32 YO F presented with AKI at age 18 due to Hemolytic Uremic Syndrome: native renal biopsy revealed acute thrombotic microangiopathy with extensive ATN. Immunofloresence (IF) staining was negative for IgA. Despite aggressive treatment with pulse steroids/plasmapheresis (pre eculizumab) failed to recover and started HD until receiving a LRKT from mother in 2004. Induction: Basiliximab & steroids, maintenance Tacrolimus (Tacro), Steroids, and MMF with steroid taper a year later. Creatinine (Cr) stable (1–1.4) with urine Protein/Cr ratio (UPCR) 0.5 g/g. In 2013 developed progressive Proteinuria (Pr) (See graph) and Cr ↑ to 2.26 mg/dL. Serological w/u negative. Biopsy showed FSGS changes with 1+ IgA / 2+ IgM deposits in mesangium (20% tubular atrophy & interstitial fibrosis along with ATN and vacuolization of tubules (possible calcineuronal effect). No rejection. Suggestive but not diagnostic of IgAN. Tacro dose adjusted to keep level 3-5 ng/ml. Started Losartan titrated to 100 mg daily. MMF stopped for a year due to gastroparesis, able to resume low dose a year later. On Losartan UPCR ↓ to 0.71 g/g and Cr stabilized at 1.4 mg/dL. In 2016 Cr again worsened to 1.9 mg/dL and UPCR ↑ to 2.12 g/g so repeat biopsy done, revealing IgAN, global sclerosis (4/8 glomeruli) and worsening parenchymal chronicity from 20 to 50-70%. Of note, biopsies prior to 2014 showed no IgA positivity. Donor (mother) was rechecked and again had no microhematuria or Pr. May 2016, she stopped losartan trying to conceive. Her status worsened and UPCR ↑ as noted below to a peak of 6.9 g/g. Cr ↑ to 2.6-3.3 mg/dL, losartan restarted. After lengthy discussion with patient regarding options, started on ACTH therapy for 6 months with a partial remission as noted below in Pr and stabilization in the Cr. Pr continues to improve despite being off ACTH since March most recently 1.37 g/g. She is currently undergoing a w/u for a second transplant and remains Dialysis free.

Results:

Conclusions:



We have demonstrated a significant improvement in Pr and stabilization of Cr with ACTH in this young woman with De Novo IgAN with primary disease HUS.

PUB509

Lung Involvement on Patients with ANCA Associated Renal Disease Hiroki Mizuno, Yoshifumi Ubara, Akinari Sekine, Yoichi Oshima, Masahiko Oguro, Masayuki Yamanouchi, Keiichi Sumida, Junichi Hoshino. *Nephrology Center, Toranomon Hosp., Tokyo, Japan.*

Background: ANCA-associated vasculitis is a systemic vasculitis affecting multi-organ systems. Although analyses of each organ damage has already been published, the interaction between kidney and lung involvement has not been analyzed in detail.

Methods: We reviewed clinical data and high resolution lung CT (HRCT) on forty eight patients who were diagnosed as ANCA-associated renal disease by the kidney biopsy between April 2007 and December 2015. Glomerular lesions were classified according to the classification published by Berden *et al.* in 2012 and lung involvements were classified into 5 categories; (1) airway lesion; bronchial wall thickening, bronchiectasis, bronchiolitis, (2) pleural lesion; pleural thickening, pleural effusion, (3) alveolar lesion; pure ground-glass opacity, mixed ground-glass opacity, consolidation, (4) focal lesion; nodular lesion, cavity, (5) interstitial lung disease. We conducted statistically analysis about the association between those findings and clinical data.

Results: Median age was 72 (IQR: 60.5-78.5) years old, and eighteen cases were men. Forty-four (91.7%) were MPO-ANCA positive. Serum creatinine level was 1.525 (0.75-3.51) mg/dL, urine protein excretion was 0.715 (0.335-1.895) g/day. Glomerular lesion was seen in forty-six (95.8%). Eight (16.7%) cases were classified as sclerotic type; twelve (25%) cases, crescentic type; seven (14.6%) cases; focal type; nineteen (39.6%) cases, mixed type. On 95.8 percent of total patients with ANCA-associated renal disease, lung involvement including five categories (category 1; 62.5%, 2; 62.5%, 3; 41.7%, 4; 31.3%, 5; 43.8%) were detected. Median BVAS was 18(IQR: 15-24). Although there is no statistical association between renal and lung lesion categories, the alveolar lesion was significantly associated with heart failure($p<0.01$); the nodular lesion, the glomerular fibrinoid necrosis($p=0.01$); the interstitial pneumonitis, hematuria ($p=0.02$). In patients with interstitial pneumonitis, lung involvements proceeded renal dysfunction.

Conclusions: Almost of all patients diagnosed as ANCA-associated renal disease by the kidney biopsy had some lung involvements detected by HRCT, dividing into 5 categories. Though 50% of patients with AAV in Japan is renal-limited type, ANCA-associated renal disease was considered to have some relation with lung involvement.

PUB510

The Significance of Renal Repeat-Biopsy in Non-Remitting IgA Nephropathy to Navigate Treatment Shinako Miyano,[2] Tomo Suzuki,[1] Mikako Hisamichi,[1] Daisuke Ichikawa,[1] Sayuri Shirai,[1] Yugo Shibagaki.[1] *[1]Division of Nephrology and Hypertension, St Marianna University Hospital, Kawasaki, Japan; [2]St. Marianna University School of Medicine, Tokyo, Japan.*

Background: The renal outcome of Immunoglobulin A nephropathy (IgAN) depends on clinical features (impaired renal function, hypertension, proteinuria etc.), and a renal biopsy (Glomerular mesangial hypercellularity, atorophy/interstitial fibrosis etc.). After a long-term treatment of IgAN, some patients do not lead to a remission. It is uncertain that a renal repeat-biopsy is useful to get a further prognosis prediction and a decision of treatment. Aim: The significance of a repeat-biopsy in non-remitting IgAN was evaluated by comparing 1st biopsy and re-biopsy specimen in those received steroid + tonsillectomy and those only with conservative treatment.

Methods: We retrospectively observed 13 non remitting IgAN patients who had received a re-biopsy followed more than 1 year from their initial biopsy at our hospital. Six patients received only with renin-angiotensin system (R group) and seven patients experienced steroid therapy with tonsillectomy (A group). With two classification (Japan and Oxford), we compared clinical changes with historical grade between R and A groups.

Results: Both A and R groups were not significantly different clinically (proteinuria: A group 2.6 ±1.4 g/g Cre R group 2.6 ± 1.5 g/g Cre, eGFR : A group 51.8 ± 6.1 ml/min/1.72m^2 R group 50.6 ± 6.6 ml/min/1.73m^2). With The Oxford classification, the specimen in both groups appeared to recover by C score and to worsen by S and T scores. However, with Japanese classification, it seems that the re-biopsy specimen of A group do not tend to reflect clinical stages directly The concordance rate was 42.9% in A group and 66.7% in R group. In A group, in particular, two cases showed totally opposite results (worse clinical staging with good histological staging.

Conclusions: Impressive: The discordant results between clinical prognostic parameters and pathological findings indicated the significance of a repeat biopsy to better navigate appropriate treatment. We suggest that a repeat biopsy in R group may be unnecessary.

PUB511

Efficacy of Induction Immunosuppression in Ethnic Minorities with Membranous Lupus Nephritis Aniesh Bobba, Jayasree Krishnan, Ambarish Athavale, Amit J. Joshi, Setri Fugar, Peter D. Hart. *John H stroger hospital of cook county, Chicago, IL.*

Background: Thirty eight percent of patients with systemic lupus have kidney disease, 20% of those with membranous lupus nephritis (Class V LN) experience decreased GFR after 7-12 years. Current guidelines recommend treating Class V LN in the presence of nephrotic range proteinuria with immunosuppressant in addition to steroids. We investigated the 6 months clinical outcome of induction treatment with Cyclophosphamide or Mycophenolate Mofetil (MMF) in patients with Class V LN.

Methods: Retrospective review of kidney biopsy database at Stroger Cook County Hospital from Jan 2000- April 2017 identified 28 patients with class V LN. Baseline characteristics including age, gender, race, serum creatinine(sCr) and urine protein/creatinine ratio(uP/Cr) at the time of initiation of therapy and after 6 months of therapy were obtained. Baseline characteristics were compared using descriptive statistics and categorical variables were compared using Chi-square analysis.

Results: There was no difference in sCr or proteinuria at 6 months in patients receiving induction treatment with MMF or cyclophosphamide (Table 1). After 6 months of therapy, MMF group (4/22) and cyclophosphamide group (3/6) had either partial or complete response. 50% patients in cyclophosphamide group had partial or complete response however only 6 patients received cyclophosphamide. Complete response was defined as sCr to baseline plus Pr/Cr < 500 mg/g. Partial response is sCr improve >25% plus 50% reduction in P/Cr and Pr/Cr < 3000 mg/g.

Conclusions: Mycophenolate is less effective than Cyclosphosphamide for inducing remission in ethnic minority patients with class V LN. An RCT is needed to compare MMF to cyclophosphamide for induction of remission in this patient population.

Table 1

Induction therapy	MMF(n=22)	Cyclophosphamide(n=6)	p value

Renal and Cutaneous ANCA Positive Vasculitis: Be Aware to Illicit Cocaine-Levamisole Use Even Though the Patient Denies Elvino J. Guardao barros,[3,2] Veronica V. Antunes,[2] Gustavo G. Thomé,[2] Joao B. Saldanha de castro filho,[2] Fernando S. Thomé,[2] Dirceu R. Da silva,[2] Pedro E. Schaefer,[2] Viviane Sebben,[1] Alberto Nicolella,[1] Francisco V. Veronese.[2] *[1]Centro de Informações Toxicológicas do Rio Grande do Sul, Porto Alegre, Brazil; [2]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [3]Nephrology Division, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.*

Background: Adulterated cocaine with levamisole in different concentrations has been increasingly used during the last decades. Levamisole can cause skin lesions, intravascular thrombosis, neutropenia, and crescentic nephritis. Physician awareness is essential for ensuring a proper diagnosis, because patients frequently deny the use of illicit drugs.

Methods: We describe a series of five patients with anti-neutrophil cytoplasmic antibody (ANCA)- associated vasculitis secondary to levamisole-adulterated cocaine, which were prospectively followed at a single hospital. Demographics and clinical characteristics are presented.

Results: Urine toxicology was all positive for cocaine and levamisole, tested by immunochromatography and gas chromatography-mass spectrometry. Three patients brought a sample of the cocaine powder (1 g), in which the presence of cocaine and levamisole was confirmed (levamisole: 32%, 1,2% and 0,5% in each powder). Demographics and clinical characteristics are presented in Figure 1. No patient quit cocaine use. End-stage renal disease (ESRD) developed in one patient; the worst outcome was death due to vasculitic mesenteric necrosis and sepsis, that occurred in another patient.

Conclusions: In conclusion, cocaine/levamisole-induced vasculitis should be suspected in patients with renal and skin lesions, even when illicit drug use is denied. A urine drug toxicology screen is necessary to confirm the diagnosis and must be done during follow-up to ascertain drug abstinence. This condition can induce poor outcomes, as ESRD and death.

PUB513

A Case of Familial Type III Hyperlipoproteinemia with Severe Foam Cell Mesangial Infiltration and Endothelial Injury Hirokazu Marumoto, Kentaro Koike, Naoko Nakaosa, Akihiro Shimizu, Nobuo Tsuboi, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Division of nephrology and hypertension, The Jikei university school of medicine, Tokyo, Japan.*

Background: Apolipoprotein E (apoE) serves as a ligand for the low-density lipoprotein (LDL) receptor and other cell-surface receptors of the LDL receptor gene family. Type III hyperlipoproteinemia in patients homozygous for *apoE2* is associated with increased levels of apoE, but there are few reports on the occurrence of glomerulopathy in *apoE2* homozygotes.

Methods: A 67-year-old female was admitted to our hospital with renal insufficiency and abnormal urine test results. Her laboratory data on admission were as follows: serum creatinine level, 1.69 mg/dl; urinary protein excretion, 2.7 g/24 h; urinary red blood cell, 0-1/high-power field; LDL-cholesterol level, 44 mg/dl; and triglyceride level, 346 mg/dl. Her family history included an older brother with renal insufficiency who had been on hemodialysis since the age of 34 years. In a genetic screening, a genetic mutation was not detected in *apoE*. Thus, the genotype was apoE2/E2, and the patient was diagnosed with familial type III hyperlipoproteinemia. Of the seven glomeruli evaluated in the renal biopsy specimen, none showed global sclerosis; rather, most were hypertrophic and infiltrated by numerous foam cells, which were immunohistochemically positive for CD68. The capillary walls showed segmental duplication. Electron microscopy revealed endothelial cell injury and lipid deposition in the mesangial area. Mild thickening of the glomerular basement membrane was also seen. There were no electron-dense deposits, and an immunofluorescence analysis showed no significant glomerular deposits.

Results:

Conclusions: The glomerulopathy seen in our patient was characterized by abundant foam cell infiltration of the glomeruli and endothelial damage. Unlike in lipoprotein glomerulopathy, however, lipoprotein thrombi with lamella formation were not observed. Although the mechanism remains to be elusive, this case is an important cue to better understand the pathogenesis of glomerulopathy related to familial type III hyperlipoproteinemia.

PUB514

Nephrotic Syndrome Secondary to Chronic Thrombotic Microangiopathy without Pathognomonic Clinical or Laboratory Features Arun Rajasekaran,[2] Najam A. Siddiqui,[1] Pran M. Kar.[3] *[1]Lake Erie College of Osteopathic Medicine, Lake Worth, FL; [2]University of Central Florida College of Medicine, Kissimmee, FL; [3]Nephrology, Orlando VA Medical Center, Orlando, FL.*

Background: Thrombotic microangiopathy (TMA) encompasses small-vessel thrombosis, consumptive thrombocytopenia, and microangiopathic hemolytic anemia (MAHA) that leads to global ischemia. Severe hypertension may promote TMA within the renal vasculature. We describe the first case of chronic thrombotic microangiopathy as a cause of nephrotic syndrome, not associated with clinical or laboratory features suggestive of TMA.

Methods: A 71-year-old Arab male with well-controlled hypertension (on amlodipine), CKD stage 4 (baseline serum creatinine 1.4 mg/dl), and anemia of chronic disease (baseline hemoglobin 12 mg/dl) presented with a one-month history of worsening lower extremity swelling. He was alert, afebrile, normotensive, and had pitting edema in his legs. Hemoglobin was 12 mg/dl, albumin 2.1 mg/dl, and serum creatinine 1.4 mg/dl. A 24-hour-urine collection revealed 10 grams of protein. Platelet counts, liver enzymes, coagulation parameters, lactate dehydrogenase, haptoglobin, ESR, serum complements and immunoglobulins were normal. HIV, ANA, ANCA, RF, hepatitis B and C serologies, cryoglobulins, anti-GBM and antiphospholipid antibodies, and direct Coombs test were negative. No schistocytes were seen in the blood smear. Renal biopsy revealed glomeruli with extensive double-contour formation, mesangiolysis, and severe interstitial fibrosis and tubular atrophy. Severe arteriosclerosis and arteriolar hyalinosis were seen. Immunofluorescence revealed negative staining for IgG, IgM, IgA, C3, C4, C1q, albumin, fibrinogen, and kappa and lambda light chains. Electron microscopy depicted thickened and irregular basement membranes due to extensive double-contour formation. These features suggested a chronic TMA. Workup for an occult malignancy was negative. He was given intravenous albumin for the next 3 days and low-dose Lisinopril was added. After a month, his proteinuria markedly improved with a spot urine protein-to-creatinine ratio being 0.455.

Results:

Conclusions: We report the first case of biopsy-proven chronic TMA as a cause of nephrotic syndrome with significant improvement of proteinuria, in an individual with well-controlled hypertension, not associated with clinical or laboratory features suggestive of TMA. Further studies on this phenomenon are warranted to better understand the pathophysiology of renal damage in TMA.

PUB515

Treatment of Proteinuria Due to Treatment Resistant or Treatment Intolerant Idiopathic Focal Segmental Glomerulosclerosis: A 2 Part Prospective Study of H.P. Acthar® Gel (PODOCYTE) James A. Tumlin,[4] Brad H. Rovin,[2] Richard A. Lafayette,[3] Enxu Zhao,[1] Patrice Becker,[1] Leah Patel,[1] Susan Vanmeter.[1] *[1]Mallinckrodt Pharmaceuticals, Ellicott City, MD; [2]Ohio State University Wexner Medical Center, Columbus, OH; [3]Stanford University, Stanford, CA; [4]University of Tennessee College of Medicine, Chattanooga, TN.*

Background: Focal segmental glomerulosclerosis (FSGS) is a glomerulopathy with a high rate of progression to end stage renal disease; prior FSGS studies show that 16 weeks of therapy with glucocorticoids (GCs), calcineurin inhibitors (CNIs) and other agents have a limited ability to induce sustained remission. H.P. Acthar® Gel (repository corticotropin injection, RCI) contains a highly purified porcine ACTH analogue, and is indicated to induce remission of proteinuria in idiopathic nephrotic syndrome. Its mechanism of action is incompletely understood, though preclinical studies suggest activation of melanocortin receptors in the kidney and modification of circulating immune cells may reduce proteinuria via steroid-dependent and independent pathways.

Methods: Approximately 236 patients with FSGS, nephrotic range proteinuria (urine protein to creatinine ratio [uPCR] > 3.5 g/g) who are refractory or intolerant to GCs or CNIs will start open-label RCI 80 units (U) subcutaneously 3x/week. After 24 weeks, patients taper to 80 U 2x/week; those with complete (CR), partial (PR) or fractional remission of proteinuria (uPCR ≤ 0.3 g/g; uPCR ≤ 3.5 g/g and ≥ 50% reduction from baseline; uPCR > 3.5 g/g and ≥ 50% reduction from baseline, respectively) at Week 24 are randomized 1:1 to RCI 80 U 2x/week or placebo for 24 weeks. Subjects who do not achieve remission may continue RCI in an open-label extension to investigate possible delayed response. Efficacy will be assessed by change in proteinuria at Weeks 24 and 50; safety will be assessed by collection of AEs, changes in vital signs and labs.

Results:

Conclusions: This is the largest study to date in refractory FSGS patients and will investigate the efficacy of RCI to induce CR or PR; also, it will determine the efficacy of prolonged therapy on response rates.

PUB516

Improvement of Clinical Outcome in Kidney Diseases via the On-line Thai Glomerular Disease Registry: Lupus Nephritis Ratana Chawanasuntorapoj,[5] Boonyarit Cheunsuchon,[4] Warangkana Pichaiwong,[3] Bancha Satirapoj,[2] Siribha Changsirikulchai.[1] *[1]Medicine, Srinakharinwirot University, Bangkok, Thailand; [2]Medicine, Phramongkutklao hospital, Bangkok, Thailand; [3]Medicine, RAJAVITHI HOSPITAL, Bangkok, Thailand; [4]Pathology, Siriraj hospital, Bangkok, Thailand; [5]Medicine, Siriraj Hospital, Bangkok, Thailand. Group/Team: Thai Glomerular Disease Collaborative Network (TGCN).*

Background: Lupus nephritis (LN) is the most common glomerular disease causing the end stage renal disease (ESRD) in Thailand. The data on epidemiology and outcomes of LN are limited in few medical schools. Thai Glomerular Disease Collaborative Network (TGCN) was established to investigate the epidemiology and clinical outcomes in Thai glomerular disease patients.

Methods: The data collected prospectively from TGCN included adult patients with biopsy-proven LN during July 2014 to March 2017. The clinical, laboratory and renal pathology data were obtained via online record.

Results: We found that LN was the most common pathological finding from TGCN (522 from 1,556 cases, 33.5%). Female was 89.3%. The median serum creatinine(sCr) was 1.06 mg/dL(0.7-9.2), and median urine protein creatinine ratio(UPCR) was 3.72 g/g.Cr(0.1-24.7). The percentage of class I, II, III, IV, V, III+V, IV+V, and VI was 0.4, 2.1, 15.5, 42.9, 15.7, 10.9, 11.1, and 1.3. The initial sCr≥1.2 mg/dL was found in class IV 60.7, VI 57, IV+V 53.4, III 37, III+V 29.8%. Crescentic formation>50% was found in class IV 11.2% and IV+V 10.3%. The median activity index (AI) in class III, IV, V, III+V, IV+V, and VI was 5, 8, 1, 3, 9 and 2, whereas the median chronicity index(CI) in class class III, IV, V, III+V, and IV+V was 3, 3, 2, 3, 3 and 10, respectively. During 32 months follow-up period, overall clinical response was not different among LN class. The % of partial response/complete response in proliferative LN (III, IV), V, and III+V, IV+V were 34.8/41.2, 39.2/27.5, and 38.7/40.7. Focus on LN III and IV, the multivariate analysis showed that sCr≥1.2 mg/dL, and CI≥4 were the independent factors of none renal response with HR (95%CI) of 0.48 (0.29,0.82), 0.44 (0.21, 0.91). Additionally, the predicting factor for renal response in LN V was only the interstitial fibrosis. During this period, ESRD was found 6.1% in class III and IV.

Conclusions: Our study described the LN class IV was the most common renal findings and severe renal impairment at the time of biopsy in SLE patients. The clinical manifestation and renal response were comparable with the other studies. The independent unfavorable factors for renal response in LN III, IV were sCr≥1.2 mg/dL, and CI≥4, whilst in LN V was the high interstitial fibrosis.

An Unkind Cut: A Case of Pauci-Immune Crescentic Glomerulonephritis Associated with Suspected Exposure to Levamisole-Adulterated Cocaine Robert Lorch,[1] Susanne F. Mclaughlin,[2] Sreedhar A. Mandayam.[1] *[1]Baylor College of Medicine, Houston, TX; [2]None, Bellaire, TX.*

Background: Levamisole (LEV) is a ubiquitous cocaine adulterant in the United States and has been implicated in an ANCA-associated vasculitis syndrome which commonly manifests as purpuric skin lesions, agranulocytosis, and thrombocytopenia. An increasingly recognized effect of LEV is kidney injury in the form of pauci-immune glomerulonephritis (GN). Our understanding of LEV-induced kidney injury is limited, and it can be difficult to differentiate ANCA-associated GN secondary to LEV from primary ANCA-associated vasculitis based on serology and biopsy. The implications for prognosis and treatment in this scenario are unclear.

Methods: We present the case of a 57-year-old man with stage 3 CKD and an approximately 20-year history of regular intranasal cocaine use, who presented with 8 weeks of myalgias and chills, as well as several days of new-onset dyspnea. He had last used cocaine 2 days prior. Physical exam was remarkable only for bibasilar crackles and bilateral scattered rhonchi in the lungs, mild abdominal distension, and no abnormal skin findings. Initial laboratory testing revealed a creatinine of 5.1 mg/dL (baseline creatinine of approximately 2 mg/dL), blood urea nitrogen of 66 mg/dL, and urine testing positive for cocaine. Bilateral patchy airspace opacities were seen on chest CT. Renal biopsy demonstrated pauci-immune crescentic GN, and serologic testing was suggestive of microscopic polyangiitis (anti-MPO positive, anti-PR3 negative). Due to his significant history of cocaine use, LEV-induced vasculitis could not be ruled out as a cause of rapidly progressive GN. He was treated with corticosteroids, rituximab, and plasma exchange; although he ultimately progressed to dialysis-dependent renal failure.

Results:

Conclusions: Up to 80% of cocaine in the United States now contains LEV, and this case highlights the growing public health concern of LEV exposure. Our current knowledge of the clinical, laboratory, and biopsy findings specific for LEV-induced GN is often too limited to differentiate this form of drug-induced vasculitis from primary vasculitis, especially in otherwise medically complicated cases and when clinical stakes are high. A better understanding of the effects of LEV on the kidney is needed so that improved methods to diagnose and treat levamisole-induced glomerulonephritis may be developed.

Improvement of Clinical Outcome in Kidney Diseases via the On-line Thai Glomerular Disease Registry: The Third-Year Report Ratana Chawanasuntorapoj,[6] Boonyarit Cheunsuchon,[5] Ngoentra Tantranont,[4] Warangkana Pichaiwong,[3] Bancha Satirapoj,[2] Siribha Changsirikulchai.[1] *[1]Medicine, Srinakharinwirot University, Bangkok, Thailand; [2]Medicine, Phramongkutklao hospital, Bangkok, Thailand; [3]Medicine, Rajavithi hospital, Bangkok, Thailand; [4]Pathology, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [5]Pathology, Siriraj hospital, Bangkok, Thailand; [6]Medicine, Siriraj Hospital, Bangkok, Thailand. Group/Team: Thai Glomerular Disease Collaborative Network (TGCN).*

Background: End stage renal disease (ESRD) affects the quality of life and causes the high cost in health care system. The prevention of ESRD is the early recognition and appropriate treatment. Glomerulonephritis is the third most common cause of ESRD in Thailand. Thai Glomerular Disease Collaborative Network (TGCN) was established to evaluate the epidemiology and clinical outcomes in the glomerular diseases and helped to promote the good system to taking care of these patients.

Methods: TGCN originally consists of 9 tertiary care centers and expands to 20 hospitals. We conducted a prospective cohort study in the adults' native kidney biopsy proven glomerular diseases between July 2014 and Mar 2017. The clinical and laboratory parameters at the time of biopsy, pathologic findings, treatment regimens and clinical outcomes were recorded via on-line registry.

Results: We recruited 1,556 patients performed native kidney biopsy during Jul 1, 2014 to Mar, 2017. The female to male ratio was 1.88:1. The average age, creatinine, albumin, and cholesterol were 43.4 (18-87) years, 1.48 (0.4-16.2) mg/dL, 2.9±0.8 g/dL, and 294±131 mg/dL in respectively. The median proteinuria was 3.7 (0.02-25.3) g/day. The patients presented with 40% of nephrotic syndrome, 21.7% of nephritis, 19.4% of nephrotic nephritis, and 60.8% of renal impairment (creatinine≥1.2 mg/dL). The renal pathological findings showed 33.9% of LN, 13.5% of IgAN, 10.9% of FSGS, 7.4% of minimal change disease(MCD), and 7.1% of membranous nephropathy (MN). The mean age of LN, IgAN, FSGS, MCD, and MN were 34.9, 39.4, 47.3, 46.5 and 52.6 years. The median creatinine at biopsy of LN, IgAN, FSGS, MCD, and MN were 1.08, 1.76, 1.7, 1.02 and 0.98 mg/dL.

Conclusions: Our study described the common renal pathological findings including LN, IgAN, FSGS, MCD, and MN. The clinical outcomes and predicting factors of renal response were described in the separate articles. *Funding: Health Systems Research Institute, and Nephrology Society of Thailand support*

Renal Complications of Hematopoietic Stem Cell Transplantation (SCT) and Glomerulopathies in Patients with Leukemia Receiving SCT: MD Anderson Cancer Center's Experience Ali Ziaolhagh,[6] Umut Selamet,[1] Laila S. Lakhani,[5] Amanda Tchakarov,[2] William F. Glass,[3] Ala Abudayyeh.[4] *[1]MD Anderson Cancer Center, Houston, TX; [2]University of Texas Medical School at Houston, Houston, TX; [3]University of Texas – Houston Medical School, Houston, TX; [4]The University of Texas MD Anderson Cancer Center, Houston, TX; [5]UT Houston, Houston, TX; [6]University of Texas health science center at Houston, Housotn, TX.*

Background: Variety of kidney diseases as such as nephrotic range proteinuria and glomerulonephritis, acute and chronic kidney disease are associated with Hemoatopoeitic stem cell transplant. We present our experience in our Institute in patients with undelying leukemia who were managed with hematopoetic stem cell transplant. Glomerular diseases were confirmed by renal biopsy. Reason for biopsy were acute kidney injury and in some patients were nephrotic range proteinuria.

Methods: After we obtained IRB (institutional review board) approval, renal biopsy reports from year 2000- 2017 were obtained from pathology department. Patients with leukemia who had stem cell transplant were selected. Medical charts were reviewed. We collected date on base line serum creatinine, serum creatinine at the time of biopsy, degree of proteinuria, urinalysis and renal pathology report.

Results: We reviewed 15 cases with leukemia including AML, ALL, CLL, and diffuse large B-cell lymphoma. We had 3 cases with BK nephropathy, 3 cases with thrombotic microangiopathy which might represent graft-versus-host disease, 1 case with membranous nephropathy, 1 with mesangioproliferative glomerulopathy, 3 with Acute Tubular Necrosis, 1 with FSGS and 1 with moderate to severe chronic interstitial fibrosis. 1 specimen was disregarded due to inadequate sample. 5 patient had nephrotic range proteinuria between 3-20 g proteinuria.

Conclusions: Hematopoietic stem cell transplant is associated with variety of kidney diseases. Some patients develop nephrotic range proteinuria with different glomerulopathies.

PUB520

Novel Approaches Based in Current Evidence in ANCA-Associated Vasculitis with Renal Involvement Treatment Vanina Vazquez,[2] Gabriela González,[3] Javier E. Robaina Sindin.[3] *[2]Simplemente Evita Hospital, Buenos Aires, Argentina; [3]División Nefrología, Hospital de Clínicas José de San Martín, Universidad de Buenos Aires, Buenos Aires, Argentina.*

Background: ANCA-associated vasculits (AAV) are a group of autoinmune diseases characterized by inflamation and necrosis in small and medium vessels. AAV could respond to diferent therapeutics protocols depends on levels of clinical severity. Early treatment could improve the outcome. In spite of recognized efficay of regimens with cyclophosphamide and corticosteroids to control the AAV, efforts to minimize drugs-related toxicity led to consider targeted therapies. Considering novely and currently therapies evidence proposed to AAV and severity of renal presentation, we suggest new rational approaches emphasizing targeting B-cells therapy and preventing disease relapse.

Methods: Latest quality evidence was identified by methodological search filters, assessed evidence quality with Cochrane Renal Goup check list, determinated the strenght of recommendations by Levels of Evidence (Oxford Centre for Evidence-based Medicine)

Results: Rituximab (RTX), a monoclonal anti-CD 20antibody, is the biologic agent more using in AAV in current evidences. Unlike latest Guides and Recommendations published, RTX would be recommended in induction and maintenance AAV with renal involvement treatment (Table 1)

Conclusions: Current therapies for AVV with renal involvement shows that emerging therapies like RTX could improve rates of relapses and treatment-related toxicity. Further studies would provide target-therapeutical options. **References:** Vazquez V et al. Medicina (Buenos Aires)2015;75 Suppl 1:1-38;Mukhtyar C et al. ANCA Associated Crescentic GN with Infective Endocarditis: Hold the Immunosuppression and Treat the Cause Pradeep Chaganti,[2] Mubasshar Rehman,[2] Purva D. Sharma,[2] Ira S. Meisels,[3] Steven D. Smith.[1] *[1]Icahn School of Medicine at Mount Sinai/St Luke's-Roosevelt Hospital Center, New York, NY; [2]Mount Sinai Saint Luke's and mount Sinai West, Bronx, NY; [3]None, Brooklyn, NY.*

Background: Infective endocarditis can mimic ANCA associated vasculitis with positive serological markers. We report a case of infective endocarditis associated pauci-immune crescentic glomerulonephritis with positive PR3, which improved clinically and serologically with treatment of endocarditis, without any immunosuppression

Methods: 63 y/o man with AIDS on ART, HCV+ (treated and HCV RNA negative), ex-IVDU, CKD III (baseline creat 1.6 mg/dl), h/o epistaxis, first presented to an outside hospital with fever and was found to have Granulicatella adiacens MV endocarditis and AKI with high titer cANCA (PR3-Ab) requiring hemodialysis, transferred to our hospital for MVR. At the time, his urine sediment was active with multiple dysmorphic RBCs and RBC casts along with granular casts. He received antibiotics and underwent successful bioprosthetic MVR. His renal function improved and he was able to come off dialysis in 2 weeks without any immunosuppressive therapy with a creatinine of 4.5 on discharge. He presented again after 3 weeks to the outside hospital with epistaxis without any other symptoms. Creatinine at the time was 2.6 with persistent subnephrotic proteinuria. ENT evaluation revealed multiple telangiectasias and a nasal biopsy showed inflammation without any granulomas/micro abscess, followed by a renal biopsy that showed a pauci-immune focal crescentic GN with moderate IFTA. On completion of 6 weeks of antibiotics and negative blood cultures, his acute kidney injury resolved with resolution of proteinuria. His last labs showed PR-3 Ab levels decreased from 76 AU/ml to 33 AU/ml, no proteinuria and a Cr of 1.74.

Results:

Conclusions: Infective endocarditis associated GN can present as diffuse necrotizing and crescentic GN with or without associated ANCA positivity and its recognition is crucial to prevent inadvertent therapy with immunosuppressive medications

PUB522

A New Kid in the Paraffin Block R hea Bhargava,[3] Isaac E. Stillman,[3] Nikhil Agrawal,[3] Himmat Grewal,[2] Christina Chen,[1] Samer S. Nasser.[1] *[1]None, Watertown, MA; [2]Saint Vincent Hospital, Worcester, MA, Watertown, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: ‘MGRS’ (monoclonal gammopathy of renal significance) is a newly described entity. This is thought to be from a non malignant cell clone. ESRD and recurrence after kidney transplantation has been described.

Methods: 68 year old female presented with lower extremity edema for 6 months. Trialed on diuretics as an outpatient with inadequate response prompting inpatient admission. Cr increased from 0.7 to 4.5 mg/dl over 7 months with a urine protein/cr ratio of ~12mg/mg. Systemic examination was unremarkable except for 2+ pitting edema in bilateral lower extremities. Urine sediment demonstrated red cells with several acanthocytes, multiple granular and hyaline casts. She underwent a kidney biopsy which demonstrated endocapillary proliferative glomerulonephritis with substructured deposits suggestive of paraprotein deposition. Pronase digested paraffin sections showed capillary wall staining for kappa while IgG and lambda were negative. Prior to admission, was on losartan with inadequate improvement in proteinuria and persistent lower extremity edema. Serology showed a negative anti GBM, ANCA, ANA, SPEP/UPEP, cryoglobulins, hepatitis panel and a normal rheumatoid factor. Further studies showed a negative PET scan, bone marrow biopsy and peripheral flow cytometry. The decision to start immunosuppressive therapy was made. IV cyclophosphamide(300mg/m2- 50% reduced dose) with mesna was initiated along with prednisone 60 mg daily with a taper. She has recieved 3 IV cytoxan infusions and is presently on 20 mg daily prednisone with a Cr of 1.7 mg/dl and a urine protein/cr ration of 4.4 mg/mg.

Results:

Conclusions: MGRS is diagnosed by the presence of monoclonal immunoglobulin deposition in the kidney. Since the treatment can vary depending on the cell clone identified and the type of immunoglobulin found (IgG versus IgM) it is imperative to do a thorough workup including peripheral flowcytometry, PET scan and bone marrow biopsy if protein electrophoresis is negative. In our patient, no single cell clone was indentified and non-IgM deposits were present. Cyclophosphamide was initiated since it targets both B-cells and plasma cells and a good response has been noted. Early diagnosis and treatment may prevent poor renal outcomes that have been reported in literature. A collabrative approach and further prospective trials will be helpful to further elucidate treatment options in this disorder.

PUB524

Clinical Utility and Prognosis of Standardizing Chronic Changes in Renal Biopsies with CKD Laura Fuentes, Ivan Rosero. *Hospital General de Mexico, Distrito Federal, Mexico*.

Background: Renal biopsy still is controversy in patients with chronic kidney disease, chronic changes are predictors of renal outcomes because predicts prognosis, guides and assess treatment. We correlate the histological findings classiffied with severe damage by interstitial fibrosis and tubular atrophy (IFTA) and add the proposed in a previous consensus (glomeruloesclerosis, arterioesclerosis) with outcomes such as improve in renal function, CKD, ERSD, renal replacement therapy and mortality.

Methods: We retrospectively reviewed the records of 348 adult patients who underwent kidney biopsies between 01/01/12 and 06/01/17, focused only in patients with IFTA >50% including demographic, clinical, laboratory, ultrasonography and renal histopathological characteristics.

Results: The population was 49 men and 45 women, age 41.5± 14.2 years, kidney size 97.78 ± 12.3 mm for right and 98.72 ± 12.0 left, nephrotic in 37.2% and rapidly progressive syndrome in 28.7%, 22.3% patients were in RRT before the biopsy, and the main comorbidities were HTA, DM, SLE, at the diagnosis 97.9% were in CKD and 46.8% in ESRD, we found SGN in 61.7% (n:58), diabetic nephropathy in 22 (23.4%), lupus 19 (20.2%), vasculitis 11 (11.7%), GSFS as the main cause in PGN in 13.8%, followed by IgAN and membranous, there were and overlap seen in diabetics and FSGS and also PGN with tubulointersticial nephritis in 25%, 22 patients received inmunossupresive therapy because the underlaying cause with recovery and withadrawal of renal replacement therapy in 28.7%, using the classification with the glomerular and vascular damage can classify the patient to offer treatment or delay progression factors with more accuracy compared to previous classification for mortality and progression to ESRD in 19.5%.

Conclusions: The renal biopsy in CKD patients is still debated but it is a irrepleaceable tool that may help clinicians stablish a therapeutic strategy to slow down progression of kidney injury, in previous studies don't take the overlap between PGN and SGN with another pattern of glomerular damage and it is very important to differenciate it because the prognosis in renal outcome treating both diseases. Also a postbiopsy treatment change in 25% of CKD patients. Therefore, even if only speculative, it indicates that biopsy has been useful to decide the therapy for these patients so the criteria should be expanded.

PUB525

Minimal Renal Affection in Patients with Systemic Lupus Erythematosus: Characteristics and Evolution Eva Rodriguez,[5] Tarek C. Salman,[2] Maria Jose Soler,[6] Clara Barrios,[4] Jordi Abelló,[1] Julio Pascual.[3] *[1]Hospital del Mar, Barcelona, Spain; [2]Rheumatologist, Hospital del Mar, Barcelona, Spain; [3]Hospital del Mar, Parc de Salut Mar, Barcelona, Spain; [4]Hospital del Mar. Institut Mar d?Investigacions Mediques. Barcelona. Spain., Barcelona, Spain; [5]Nephrology, Parc de Salut Mar, BARCELONA, Spain; [6]Parc de Salut Mar. Fundació IMIM, Barcelona, Spain.*

Background: Lupus nephritis (LN) is the most common organ involvement in Systemic Lupus Erythematosus (SLE). Indications of renal biopsy (RB) are deterioration of renal function and / or activity in sediment and / or proteinuria> 0.5g / 24h or urine protein: creatinine ratio (P:C ratio) > 0.5 (SEN consensus 2012). There are patients who show data of "minimal renal involvement" (MRI) without indication of RB. Our objective is determine if these patients present clinical and analytical characteristics that allow them to differentiate from patients with LN.

Methods: We reviewed 171 patients with SLE diagnosis, classifying them as MRI if they showed> 3 occasions at least 1 year, proteinuria determinations = 0.3 g / 24h or P:C ratio= 0.3, ruling out urologic pathology. We have compared clinical and analytical variables of MRI vs LN at the time of SLE diagnosis, at renal involvement diagnosis and last visit.

Results: We identified 38 (18.7%) patients with MRI and 41 (24%) patients with LN. At the time of SLE diagnosis, the MRI group had a lower titer of anti-DNAds (14.8% vs 42.1%, p = 0.01), anti-Sm (12% vs 32.2%, p = 0.04), lupus anticoagulant (38%, p = 0.01) and anticardiolipin IgG (11% vs 38%, p = 0.01), less severe C3 hypocomplementemia (70 ± 34 vs 86.9 ± 32.7 mg / dl, p = 0.04), C4 (14 ± 10 vs 17 (p = 0.04) and CH50 (33.3 ± 15 vs 49.6 ± 17.4 mg / dl, p = 0.04); and lower inflammatory parameters: ESR (23.1 ± 20 vs 58.9 ± 42 mg / dl, p = 0.01), CRP (12.7±11.8 vs 27.3±17 mg/dl, p=0.02). At the diagnosis of the renal involvement, these results were confirmed (Table) and we observed that, in MRI patients, proteinuria appeared at an older age, with a higher evolution of SLE (12.7 ± 11.8 vs 27.3 ± 17 mg / dl, p = 0.02) and with absence of previous immunosuppressant therapy. After a mean follow-up of 10 ± 6.6 years, no MRI patient presented a renal flare, maintaining stable the renal function.

Conclusions: Our results showed that patients with MRI had a lower clinical and biological SLE activity, both at SLE diagnosis and at the diagnosis of renal involvement. No MRI patients presented a LN flare during the follow-up although it is difficult to know the role played by the immunosuppressant treatment

PUB526

Proliferative Glomerulonephritis with Monoclonal IgG Deposits: Successful Treatment with Steroids, Bortezomib, and Plasma Exchange Olga Baraldi, Giorgia Comai, Vania Cuna, Matteo Ravaioli, Maria Cappuccilli, Gaetano La Manna. *University of Bologna, Bologna, Italy*.

Background: Kidney impairment is frequent in plasma cell dyscrasias and it is characterized by polymorphic histology mainly related to the physicochemical properties of the pathological monoclonal component. Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is a newly discovered pathological entity. The diagnosis of renal alterations is based on histology, and the patients with compromised renal function are commonly treated with standard hematology chemotherapy protocols.

Methods: Case description. We report a case of a 64-year-old man with nephrotic syndrome, normal renal function, negative immunological and viral tests (in particular anti-PLA2R antibodies). Serum electrophoresis for detection of IgG light chain monoclonal proteins revealed: monoclonal component 3.4%, kappa 92.6 mg/L, lambda 23.7 mg/L, kappa/lambda ratio 3.7. Magnetic resonance was negative for spine injuries. Bone-marrow biopsy revealed a monoclonal gammopathy of undetermined significance (MGUS) with an IgG/kappa clone. Echocardiogram showed no features of cardiac amyloidosis. Renal biopsy histology displayed diffuse and global membranoproliferative glomerulonephritis with linear single IgG monoclonal deposition at immunofluorescence. Electron microscopy disclosed the presence of subendothelial deposits with granular and non-organized morphology. The patient was treated with steroids (dexamethasone 40 mg for 3 days), bortezomib (1.3 mg/m^2, weekly) and plasma exchange with albumin reinfusion. ACE-inhibitor and furosemide therapy was also administered. After 2 months, the clinical conditions were better, renal indices were slightly improved (creatinine 1.2 mg/dL, eGFR 47 mL/min/1.73m^2), urine protein excretion was 2 g/day, and kappa chains levels dropped to half of the initial level (44.9 mg/dL).

Results:

Conclusions: In patients with multiple myeloma (MM) or amyloidosis, established chemotherapy protocols are regularly used, whereas no consolidated therapy exists for the treatment of MGUS with renal impairment. The described patient affected by PGNMID with MGUS was successfully treated with a therapy regimen associated with plasma exchange consistent with those used in MM.

PUB527

Critical Value of Early Diagnosis to Restore Renal Function in Thrombotic Microangiopathy Induced by Severe Lupus Nephritis: A Case Report Haijing Hou,[3] Jiasheng Huang,[2] Jiawei He,[2] Suyuan Peng,[2] Guobin Su,[1] Chuan Zou,[3] Fuhua Lu.[3] *[1]Karolinska Institutet, Stockholm, Sweden; [2]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [3]Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China*.

Background: Thrombotic microangiopathy (TMA) is a pathological process based on microangiopathic hemolytic anemia, thrombocytopenia and microvascular occlusion, with an incidence of 0.5/100000 in adults. It is rare but severe in lupus nephritis (LN).

Methods: A 28-year-old Chinese woman with a previous history of anemia was admitted with swelling legs and recurring fever for a month. Initial lab findings indicated acute renal failure, thrombocytopenia, infection and severe LN with the high SLEDAI scoring of 20, ruling out antiphospholipid syndrome and thalassemia. After receiving sufficient dose of cyclophosphamide (accumulated to 1.8g), methylprednisolone therapy (0.5g/qd*3d) and hemodialysis for 2 weeks. her renal function was still progressively declining (Scr 6.04mg/dL VS 1.99mg/dL at baseline) with a low count of platelet (62*10^9/L, baseline 113*10^9/L) and anuria. Bearing the risk of uncontrolled bleeding due to thrombocytopenia, a renal biopsy was performed to guide the treatment. The renal biopsy showed endocapillary fibrin thrombi and crescent. The diagnosis of TMA was established based on renal biopsy, the ADAMTS13 activity level of 50.4% and RBC schistocytes of the peripheral blood smear. Plasmapheresis was initiated, combined with Traditional Chinese Medicine (TCM), which aimed to reduce the risk of infection during the CTX therapy. At discharge, her urine output improved and did not require dialysis (ADAMTS13: above 100%, Scr: 1.93 mg/dL and platelet counts: 164*10^9/L). In 6 months follow-up, she reports improvement in symptoms with stable renal function.

Results:

Conclusions: TMA is an uncommon LN-related disorder, early diagnosis of patients is critically important for treatment and prognosis of LN patients. This case highlights the need to have a broad differential diagnosis for hematological system damage of LN and TMA. Plasmapheresis combined with TCM in the treatment of LN with TMA deserved further study.

PUB528

Complete Remission of Immunotactoid Glomerulopathy Following Rituximab Jacqueline Raicek,[1] Jason R. Pettus,[2] Elizabeth J. Brant.[2] *[1]Dartmouth Hitchcock Medical Center, Hanover, NH; [2]Dartmouth-Hitchcock Medical Center, Lebanon, NH.*

Background: Immunotactoid glomerulopathy (ITG) is a rare cause of glomerular disease characterized by large (30-50 nm) non-amyloid microtubule-like ultrastructural deposits in glomeruli. It can be associated with a lymphoproliferative disorder but is usually idiopathic. Optimal treatment is not defined.

Methods:

Results: The patient was a 68-year-old woman with no significant medical history who presented in 9/2015 with a 5-month history of proteinuria and gross hematuria. Prior cystourethroscopy and CT urography were negative. Physical examination was unremarkable. Dysmorphic hematuria and oval fat bodies were seen on urine microscopy. Serum creatinine was 0.57, urine protein-to-creatinine ratio 10.6 (13.1 in 10/2015), total cholesterol >400 and LDL >200 (previously normal). SPEP showed two faint IgG kappa restrictions; UPEP was negative. Kidney biopsy revealed a diffuse segmental proliferative glomerulonephritis on light microscopy; global staining for IgG(1+), C3(2-3+), trace IgA, kappa(1+), and lambda(1+) on immunofluorescence. Electron microscopy showed predominantly subepithelial electron-dense deposits in the mesangium and periphery of glomeruli, which were characterized by discrete microtubule-like organization (~30-35 nm in diameter), consistent with a diagnosis of ITG. Bone marrow biopsy demonstrated normocellular marrow with trilineage hematopoiesis and <0.1% of clonal B-cells. PET scan was negative. She was treated with rituximab 1g IV in 10/2015 and 11/2015 with prompt resolution of hematuria. Proteinuria was 5g, less than one month after rituximab and has remained <1g since 6/2016. She received rituximab 500 mg IV in 8/2016 upon repopulation of B cells. Creatinine has been stable.

Conclusions: Immunotactoid glomerulopathy is a rare cause of kidney disease that is associated with microtubule-like organized deposits in glomeruli. It can be associated with a lymphoproliferative disorder but is often idiopathic, as in our patient. Prognosis is often poor, with as many as 50% of patients progressing to end-stage renal disease. Optimal treatment has not been defined. Rituximab may be an effective therapy, as demonstrated in our case. Normal renal function at presentation may have played a role in the overall positive outcome. Thus, early diagnosis and treatment are important in potentially changing the course of the disease.

PUB529

Association between Cardio-Ankle Vascular Index and Various Pathological Lesions in Patients with IgA Nephropathy Hideo Okonogi, Tetsuya Kawamura, Akihiro Shimizu, Shinya Yokote, Masahiro Suyama, Kei Matsumoto, Kentaro Koike, Nobuo Tsuboi, Yoichi Miyazaki, Masato Ikeda, Makoto Ogura, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.*

Background: Cardio-ankle vascular index (CAVI) is a non-invasive index of arterial stiffness and, theoretically, independent of blood pressure at the time of measurement. Recently, association of arterial stiffness with decline in renal function has discussed, however, few studies have examined the association between arterial stiffness and pathological lesions. Therefore, we examined the association between CAVI at the time of renal biopsy (RBx) and pathological lesions in patients with IgA nephropathy (IgAN).

Methods: We included 27 IgAN patients, who were diagnosed by first time RBx and whose renal biopsy specimens contained afferent arterioles and ≥6 glomeruli. The presence of mesangial hypercellularity (MH), endocapillary hypercellularity (EH), segmental glomerulosclerosis (SG), tubular atrophy or interstitial fibrosis (≥20%) (TI), and hyaline change of afferent arterioles (HA) were analyzed.

Results: As a result, the percentage of patients who had MH, EH, SG, TI and HA lesion were 37%, 11%, 19%, 56% and 63%, respectively. In SG, TI and HA lesions, CAVI value of lesion-positive groups were significantly higher than those of lesion-negative groups ($p<0.05$, $p<0.05$ and $p<0.05$, respectively). However, in MH and EH lesions, there was no significant difference of CAVI value between lesion-positive groups and lesion-negative groups. Relative cumulative frequency of the presence of SG, TI, and HA lesions became higher in accordance with increase of CAVI value. Furthermore, the forms of three graphs closely resembled each other, and 58%, 53% and 53% of SG, TI and HA lesion-positive patients had CAVI value below 8.

Conclusions: These results indicate that CAVI reflects the presence of SG, TI and HA lesions in IgAN patients. Moreover, these pathological legions have begun to appear in kidney of IgAN patients with relatively low CAVI value which correspond to systemically normal value.

PUB530

LECT2 Renal-Hepatic Amyloid with Associated Primary Biliary Cholangitis and Rheumatoid Arthritis Sabitha Eppanapally. *kern medical, Bakersfield, CA.*

Background: Introduction: Amyloidosis represents a varied group of diseases which result from the misfolding and aggregation of autologous proteins which are deposited in diverse tissues in the form of amyloid fibrils; one of the most recently recognized of these is Amyloid Leukocyte Chemotactic Factor 2 (LECT2). In LECT2 amyloidosis, leukocyte chemotactic factor 2 is the precursor protein, which is involved in chemotaxis, cell proliferation, inflammation, immunomodulation and carcinogenesis. We present a case with primary biliary cholangitis and rheumatoid arthritis that subsequently was diagnosed with LECT2 amyloidosis with demonstrated liver, renal and bone marrow involvement.

Methods: Case Report: The patient is a 70-year old Hispanic female with history of rheumatoid arthritis and primary biliary cholangitis. Due to complaints of persistent hematuria and worsening renal function, patient underwent a renal biopsy which showed amyloidosis which involved the interstitium and arterioles, which may represent leukocyte chemotactic factor 2 associated amyloidosis (LECT2); biopsy was negative for light chains. Liver biopsy showed features consistent with primary biliary cholangitis with bridging fibrosis and amyloid deposition; the globular amyloid pattern with LECT2 amyloidosis; no features of plasma cell neoplasm identified. Bone marrow biopsy was also positive for Congo red stain for amyloid, indicating the possibility of LECT2 associated amyloidosis. Patient is also followed by hematology for plasma cell dyscrasia-related amyloidosis with plans to start immunomodulatary therapy. She has family history significant for renal disease in her sister, who died from lupus nephritis requiring dialysis complications; also, patient's mother who had renal failure of unknown etiology.

Results:

Conclusions: Conclusion: LECT2 is a multifunctional cytokine and its precise functions and mechanisms are unclear and currently being investigated. LECT2 has been linked to multiple pathologic conditions such as liver disease. Globular amyloid consists of large circular globules with extracellular deposits within the sinusoids or as intracellular deposits within hepatocytes. Our patient had this globular amyloid deposition confirming the diagnosis of ALECT2 amyloidosis, involving the liver and kidney.

PUB531

A Comparative Study of Lupus Podocytopathy versus Primary MCD or FSGS Jason Cobb,[2] Titilayo O. Ilori.[1] *[1]Nephrology, University of Arizona, Tucson, AZ; [2]Nephrology, Emory University School of Medicine, Atlanta, GA.*

Background: Lupus podocytopathy has been described as minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) in patients with SLE with or without mesangial involvement but without proliferative or membranous lupus nephritis features. Outcomes of patients with lupus podocytopathy (a secondary podocytopathy) have not been compared to patients with idiopathic or primary MCD and FSGS. We present a retrospective comparison of lupus podocytopathy patients and primary MCD/FSGS patients in our institution.

Methods: We collected kidney biopsies from our academic system from 2000-2016. We identified fifteen patients with lupus podocytopathy and randomly chose sixteen patients with primary MCD or FSGS. We collected demographic variables (age, gender, race, duration of SLE), laboratory data (serum creatinine, albumin, degree of proteinuria, presence of hematuria, complement levels), pathology data (light microscopy, immunofluorescence, and electron microscopy) and clinical data (treatment, treatment response, duration of follow-up).

Results: In the lupus podocytopathy group of patients there were 14 females and 1 male patient. In the primary MCD/FSGS group there were 8 females and 8 males. In the lupus podocytopathy group there were 10 black, 3 Caucasian, 1 hispanic, and 1 middle eastern patient. In the primary MCD/FSGS group there were 8 black and 8 Caucasian patients. In the lupus podocytopathy group 6 of the patients were FSGS and in the other group 5 of the patients had FSGS. The average initial peaked creatinine was 3.08 mg/dL in the lupus podocytopathy group and 1.72 mg/dL in the primary MCD/FSGS group ($p=.037$). The average final creatinine was 1.25 mg/dL in lupus podocytopathy (excluding one ESRD patient) and the average final creatinine was 1.64 mg/dL in the primary MCD/FSGS patients ($p=0.16$). The average protein per day was 9.3 g/day in the lupus podocytopathy and 9.4 g/day in the primary MCD/FSGS group ($p=0.19$). The average age was 36.2 years in the lupus podocytopathy group and 42.6 years in the primary MCD/FSGS group ($p=0.15$).

Conclusions: We presented the first comparative study of lupus podocytopathy patients and patients with primary MCD/FSGS. The lupus podocytopathy group was more likely to be female and had a higher initial peaked creatinine in comparison to primary MCD/FSGS patients. There were similar levels of proteinuria (average > 9 g/day) and age.

PUB532

Renal Biopsy Should Not Delay Treatment Initiation in Suspected Lupus Nephritis Astrid Baumann, Ravindra Rajakariar. *Renal, Royal London Hospital, London, United Kingdom.*

Background: Renal biopsies are considered the gold standard in diagnosing lupus nephritis (LN). Since the publication of ALMS, the largest randomized trial in LN, Mycophenolate Mofetil (MMF) has been standard therapy in proliferative LN, but there may be delays in obtaining a histological diagnosis due to practical considerations. Renal biopsy also has a recognized complication rate. We therefore investigated whether histological findings influenced treatment in patients with SLE and clinical features consistent with LN.

Methods: Histopathology and renal databases were used to identify all cases of new biopsy-proven active LN, diagnosed between Feb 2012 and Nov 2016 and managed at the Barts Lupus Centre (n=62). Patients were divided into subgroups based on their renal function (eGFR > or ≤50 ml/min/).

Results: The mean age at LN diagnosis was 37 years (+-13 SD). 55 patients were female (88%) whilst 7 were male (12%). The ethnic distribution: 46% South Asian, 34% Black, and 11% Caucasian. The histological class was either pure proliferative (class III or IV) or mixed proliferative (with additional class V) in 24 cases (39%). 42 (68%) patients had an eGFR > 50mL/min at presentation with a mean albumin and urine PCR of

30 g/dL and 520 mg/mmol respectively. Of this group, 37 patients (88%) received MMF, 3 patients were treated with cyclophosphamide (1- clinician decision, 2- severe extra renal manifestations) and the remaining two patients received Azathioprine (sub-nephrotic proteinuria). At six months 85% of LN patients were either in partial remission defined as proteinuria below 200 mg/mmol (44%) or complete remission defined as proteinuria below 50 mg/mmol (41%). The treatment choice was different in the group with eGFR ≤50mL/min, with 13 (65%) of these patients receiving cyclophosphamide.

Conclusions: Current guidelines strongly recommend performing a kidney biopsy in every patient presenting with suspected LN. Our findings indicate that in patients with preserved renal function and significant proteinuria, treatment decision is not influenced by biopsy result. We therefore propose, that induction treatment with MMF should not be delayed until a renal biopsy result is available. This study also questions the necessity of baseline histology in LN patients with preserved renal function and raises the possibility that biopsy could be reserved for patients who are resistant to induction therapy.

PUB533

Retrospective Review of Lupus Nephritis in African Americans from an Academic Hospital Ravi K. Thimmisetty,[1] Obead Y. Yaseen,[2] Zeenat Y. Bhat,[1] Yahya M. Osman Malik.[3] *[1]Wayne State University, Detroit, MI; [2]Wayne State University/ Detroit Medical Centre, LaSalle, ON, Canada; [3]Wayne State University Medical School, Detroit, MI.*

Background: Lupus Nephritis is one of the most common forms of secondary glomerulonephritis causing nephrotic syndrome and progressive loss of renal function. We examined the relation between proteinuria class of nephritis and level of chronicity in renal biopsies. We also evaluated the response to therapy as well as one year's outcome.

Methods: We reviewed medical records of biopsy proven lupus nephritis (n= 26, ISN/RPS 2003 class I-VI) from the year 2012 to 2016 with one year follow-up after initiation of immune-suppressive therapy. This included correlation between proteinuria, histological class, severity and chronicity on renal biopsies, as well as one year follow-up of proteinuria and eGFR following initiation of immuno-suppressive therapy.

Results: The mean follow up was 12 months. The population was predominantly African American groups (92% were African American groups, and 92% female). Baseline mean proteinuria was 4.97 ± 4.75 g/24h and eGFR was 74.19 ± 41 ml/min/1.73m2. Majority received cyclophosphamide as an induction therapy. Out of 26 patients, most of them were found to have class III to V at the time of diagnosis. The mean proteinuria following immune-suppressive therapy has dropped to 2.08 g/24 h, This is more than 50% reduction with a p-value of 0.006. However, there was a weak correlation between proteinuria and the histological classes of lupus (correlation coefficient is 0.201; p- value 0.324) and also to disease activity index (correlation coefficient is 0.353; p- value 0.07). A moderate correlation was found between chronicity and degree of proteinuria and this was statistically significant (correlation coefficient is 0.528; p- value 0.006). Pre-treatment eGFR and one-year post-treatment, did not demonstrate any significant change[75.5,78.9 ml/minute respectively]with a p-value of 0.409.)

Conclusions: The magnitude of proteinuria is a reasonable predictor of severity of chronicity, among other factors. Measurement of eGFR may not be a sensitive parameter to monitor the response to immune-suppressive therapy when compared with proteinuria. Our results showed that reduction of proteinuria within one year of therapy was statistically significant and may be a good prognostic marker for monitoring lupus nephritis.

PUB534

Successful Treatment of Membranous Lupus Nephritis with Rituximab Andres Serrano. *Mount Sinai Hospital, Chicago, IL.*

Background: Rituximab has been proven to be a safe and effective therapy for idiopathic membranous nephropathy. In regards of lupus nephritis, there have been reports of rituximab to be efficacious when used as a combined therapy. However, in a large randomized study, rituximab did not improve the response of mycophenolate mofetil. I am reporting a case of membranous lupus nephropathy successfully treated with rituximab alone.

Methods: The patient is a 38 year-old African-American woman who was sent for evaluation of nephrotic syndrome. At the initial visit her only symptom was progressive peripheral edema, which advanced over the course of 4 weeks. Her past medical history included intra-cranial hemorrhage, seizure disorder and sickle cell trait. The only medication she was taking was levetiracetam for her seizure disorder. On physical exam her blood pressure was normal, and she had severe lower extremities edema. Work up ordered showed a serum creatinine of 0.5 mg/dl, and a serum albumin of 1.5 mg/dl. The urinalysis reported >500 mg/dl of protein, and the urine protein/creatinine was 5.1 gm/gm. A complete serological work up was negative. Patient underwent a transcutaneous ultrasound-guided kidney biopsy, which revealed membranous lupus nephritis. Because of lack of symptoms suggestive of systemic lupus erythematous and a negative serological work up, I decided to treat the patient with rituximab 1 gm IV every 14 days for a total of 2 doses, along with oral prednisone. Patient had a mild allergic reaction during the first dose. Two months after completing the last dose of rituximab, the urine protein/creatinine decreased to 1.0 gm/gm and the serum albumin increased to 2.3 mg/dl. Six months later the patient was in complete remission, urine protein/creatinine decreased to 0.1 gm/gm, and serum albumin increased to 3.8 mg/dl.

Results:

Conclusions: In patients with lupus nephritis rituximab does not add any additional benefit when used as a combined therapy. The case I presented achieved a full remission using rituximab alone. The patient had serological-negative membranous lupus nephritis. It is possible this group of patients have a clinical course similar to idiopathic membranous nephropathy. Hence, the response to Rituximab.

PUB535

Single Centre Report of Outcomes of Treatment of ANCA Vasculitis from a Large Cohort of Patients David Makanjuola,[1] Eirini LIOUDAKI.[2] *[1]St. Helier Hospital, Carshalton, United Kingdom; [2]ST HELIER HOSPITAL, Surrey, United Kingdom.*

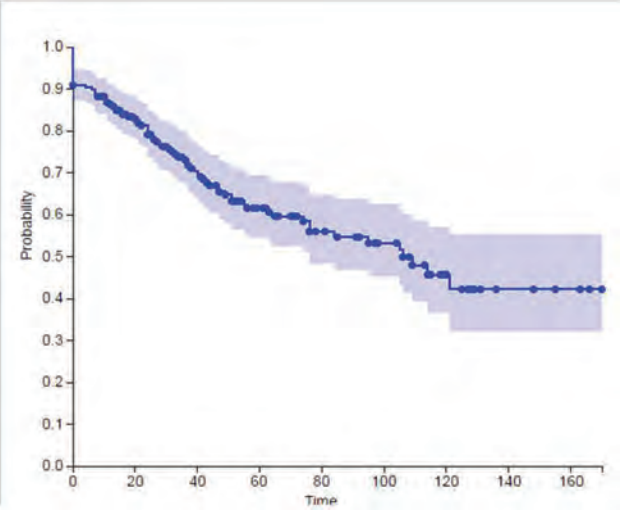
Background: The aim of treatment of patients with ANCA associated vasculitis is to induce a remission and then to maintain it. The challenge then is to wean the dose of immunosuppression to minimise toxicity from exposure to the immunosuppressive therapy, and balance this against the risk of relapse. We present the outcomes following treatment in a cohort of patients in whom remission was achieved with standard induction treatment, followed by maintenance therapy with Azathioprine (Aza) as first line agent, or Mycophenolate mofetil (MMF).

Methods: Data were collected from paper and electronic medical records of patients over a 13 year period.

Results: 220 patients with ANCA associated vasculitis successfully completed induction treatment and started maintenance treatment. 45% female, 91% Caucasian, age range 19 – 89 yrs (median 68). 112 (51%) had PR3 antibodies and 108 (49%) had MPO antibodies. 55 (25%) had a creatinine of > 500μmol/l at presentation. 27 (12.2%) patients died. 154 (70%) patients were relapse free at median follow up of 57 months (range 6-170). 66 (30%) experienced 1 or more relapses; data were available on 62 (Table 1). The presence of PR3 was more frequently associated with relapse - odds ratio (OR) 2.523 (95% CI 1.362 to 4.676) compared to MPO (p=0.004). MMF as maintenance treatment was also more frequently associated with relapse compared with Aza (OR 2.733; 95% CI 1.328 to 5.626, p=0.0068). The probability of event free survival (censored for death and/or relapse) is shown in figure 1.

Conclusions: Using our treatment protocol, 70% of patients had no relapse during the follow up period. In those who relapsed, we found, as has been described in other studies, that PR3 positivity was associated with an increased risk of relapse and that MMF also was inferior to Aza at maintaining remission.

Treatment at time of relapse	Prednisolone only	Aza or MMF only	Prednisolone and Aza or MMF	None
Number who relapsed	6 (9.5%)	14 (22.5%)	34 (55%)	8 (13%)
Average time (months) to relapse	38 (18-51)	38 (4-84)	29 (7-109)	89 (51-121)



PUB536

The Circadian Clock Provides Beneficial Effects against the Endothelial Dysfunction to Promote Atherogenesis by Regulating LKB1/AMP-Activated Protein Kinase Activation Hideyuki Negoro. *Harvard Medical School, The Graduate School of Project Design, Tokyo, Japan.*

Background: The circadian clock is a molecular mechanism that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence the protein levels of LKB1, a serine/threonine kinase, the phosphorylation of its downstream target AMP-activated protein kinase (AMPK) and plasminogen activator inhibitor (PAI)-1 generation which play an important part in the progression of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of LKB1, AMPK and PAI-1 in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was an increase in LKB1, AMPK and PAI-1 expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display premature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include LKB1, AMPK and PAI-1, which are significantly elevated in Bmal1 KO mice. We also confirmed that LKB1, AMPK and PAI-1 levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating LKB1, AMPK activation and PAI-1 generation. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

PUB537

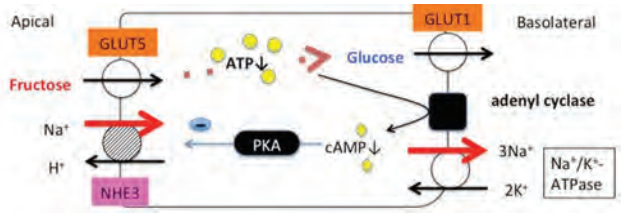
High-Fructose Diet Induces the Dysfunction of Energy Metabolism (ATP Depletion) and Hypertension Hiroaki Hara, Kaori Takayanagi, Minoru Hatano, Kento Hirose, Takatsugu Iwashita, Taisuke Shimizu, Tomonari Ogawa, Koichi Kanozawa, Hajime Hasegawa. *Department of Nephrology, Hypertension, Blood Purification, Saitama Medical center, Saitama Medical University, Kawagoe, Japan.*

Background: Consumption of fructose is revealed to evoke an acceleration of obesity, hypertension, insulin resistance, and uric acid production. Recently, it is known that fructose activates sodium–hydrogen exchanger 3 (NHE3) through the reduction of cyclic AMP in the proximal tubule. It would be highly assumed that the uni-directional fructose metabolism-induced ATP-consumption may be involved in the development of energy dysfunction, however, it has not been directly demonstrated yet. Here, we investigated the fructose-induced changes in the renal salt handling and ATP levels.

Methods: Male SD rats (7 weeks old) were fed by food containing 60% glucose (GLU) and food containing 60% fructose (FRU) for 3 and 6 and 12weeks (n=5 in each group). Calorie per unit-weight was adjusted in all three kinds of food. Tissue ATP concentration was assayed by use of assay kit (Abcam plc, Cambridge, UK). No difference of calorie and salt intake of individual animal was daily confirmed by the measured weight of remaining food.

Results: Body weight was not different in both groups at all time-points. Mean blood pressure of FRU was significantly higher than that of GLU at 6 and 12-weeks (6w-GLU: 85.9 ± 1.2 mmHg, 6w-FRU: 90.1 ± 1.4 mmHg, 12w-GLU: 94.8 ± 3.4 mmHg, 12w-FRU: 103.7 ± 1.2 mmHg), however, it was not different at 3-week. Fractional excretion of sodium (FENa) of FRU at 6-weeks was significantly higher than that of GLU (6w-GLU: 0.100 ± 0.016%, 6w-FRU: 0.042 ± 0.09%, 12w-GLU: 0.084 ± 0.011%, 12w-FRU: 0.059 ± 0.08%). The NHE3 immunostaining positive area of FRU at 12-weeks was significantly higher than that of GLU (12w-GLU: 5.31±0.490%, 12w-FRU:6.55±0.369%). Renal cortical ATP concentrations of FRU was significantly low comparing to GLU at 6 and 12-week (12w-FRU: 6.15 ± 1.11 nmol/mg protein, 12w-GLU: 10.81 ± 1.99 nmol/mg protein) whereas no significant difference was observed at 3-weeks.

Conclusions: We demonstrated that fructose intake might cause the elevation of blood pressure and salt reabsorption through the ATP consumption being independent on calorie and salt intake in the present study.



PUB538

Inhibition of Both NFκB and NLRP3/IL1β Pathways Affords Better Renoprotection in Chronic NO Blockade/Salt Overload Fernanda F. Zambom, Karin C. Oliveira, Viviane D. Faustino, Orestes Foresto-Neto, Victor F. Avila, Simone C. Arias, Flavia G. Machado, Camilla Fanelli, Claudia R. Sena, Vivian L. Viana, Denise M. Malheiros, Niels O. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ Sao Paulo, SP, Brazil.*

Background: NO inhibition with L-NAME along with salt overload (HS) lead to severe hypertension (HT), albuminuria (ALB), glomerulosclerosis (GS) and interstitial fibrosis. We investigated whether activation of the NFκB and/or NLRP3 pathways is involved in the pathogenesis of renal injury in this model.

Methods: Adult male Munich-Wistar rats receiving oral NAME (32 mg/kg/d) and HS (HS+N) were given Allopurinol (Allo) as NLRP3 inhibitor, 36 mg/kg/d ($HS+N_{Allo}$), or Pyrrolidine Dithiocarbamate (PDTC), a NFκB inhibitor, 60 mg/kg/d ($HS+N_{PDTC}$). After 4 wk, we assessed: tail-cuff pressure (TCP, mmHg), ALB (mg/d), GS (%), renal uric acid (rUA, mg/g), interstitial collagen 1 (COLL, %), macrophages (MΦ, cells/mm²), NLRP3+ cells (/mm²) and the renal content of IL1β (pg/mg), TLR4, nuclear p65 (NFκB) and Superoxide Dismutase (SOD2) (xHS).

Results: HS+N rats developed HT, ALB and renal injury, along with inflammation, oxidative stress (OS), TLR4/NFκB and NLRP3/IL1β activation. Allo lowered rUA and inhibited NLRP3/IL1β, without changing OS, in association with amelioration of HT, ALB and interstitial inflammation/fibrosis, but not GS. Besides diminishing rUA and NLRP3/IL1β, PDTC prevented OS and NFκB, and exerted a more efficient antiinflammatory and nephroprotective effect than Allo.

Conclusions: NLRP3/IL1β and NFκB act in parallel to promote renal injury/inflammation and must be simultaneously inhibited for best nephroprotection in the chronic NO blockade/salt overload model. FAPESP/CNPq

Evaluation of Further Cardiovascular and CKD Risk Factors Screening in an Apparently Healthy Population Attilio Di Benedetto,[3] Annalisa Ciotola,[3] Fabrizio Cerino,[3] Annamaria Colao,[4] Stefano Stuard,[2] Bernard J. Canaud.[1] *[1]FMC Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]NephroCare, Naples, Italy; [4]University Federico II Naples, Naples, Italy.*

Background: Cardiovascular disease(CVD) prevalence is on the rise in industrialized countries, presenting a significant societal and economic burden. We report the results of a screening program in an apparently healthy population

Methods: In 2013,2014 and 2015, during prevention events, a large sample of apparently healthy people were evaluated for cardiovascular and kidney risk factors. The following parameters were assessed:blood pressure, weight, height, waist circumference, BMI and Body Composition (BC). Lean(LTI) and Fat(FTI) tissue indexes and ECFO were evaluated by multi-frequency bioimpedance spectroscopy(BIS). Results are reported as mean and standard deviations or percentages for continuous and categorical variables in different age group and gender, respectively.

Results: 1081subjects were evaluated: 416(38.5%)were male(m),665(61,5%)were female(f);mean age was 54.46(±15.9) years in m, 50.17 (±15.2) years in f;5.5% m and 6.8% f referred dyslipidemia;4.3%m and 2.4%f referred diabetes;21.6%m and 13.4%f were hypertensive;2.6% m and 0.5% f referred heart disease;0% m and 2.6% f referred hypothyroidism;1.2% m and 1.5% f referred CKD.Mean systolic blood pressure(SBP)was 125.38(±19.18)mmHg, mean diastolic blood pressure (DBP)was 75.85 (±11.3)mmHg. BMI levels were: <20 kg/m²: 2(0.5%) in m and 30 (4.5%) f ; 20-24 kg/m²: 104(25.0%) m and 276(41.5%) f; 25-29 kg/m²: 208 (50.0%) m and 210 (31.6%) f; >30 kg/m²:102 (24.5%)m and 149 (22.4%) f.FTI and LTI were evaluated according to normal distribution adjusted by age and gender.

Conclusions: In a large sample of apparently healthy population a relevant proportion of male compared to female had more risk factors as higher SBP, ECFO, FTI, but also additional CVD/CKD risk factors such as obesity, dislipidemia, smoke, diabetes. In stratifying general population for risk factors, body composition appears to be an important method to evaluate FTI and ECFO risk factors.

Effect of Aliskiren on Arterial Stiffness, Compared with Angiotensin-Converting Enzyme Inhibitors and Angiotensin II Receptor Antagonists in Hypertensive Patients: A Meta-Analysis Georgios Spanos,[1] Rigas Kalaitzidis,[2] Evangelos Evangelou,[3] Kostas Siamopoulos.[2] *[1]Department of Nephrology & Renal Transplantation Unit, Laiko General Hospital, National & Kapodistrian University of Athens, Medical School, Athens, Greece; [2]Department of Nephrology, University Hospital of Ioannina, Ioannina, Greece; [3]Department of Hygiene and Epidemiology, University of Ioannina, Medical School, Ioannina, Greece.*

Background: The degree of arterial stiffness (AS) is correlated with the risk of cardiovascular disease and it is a powerful predictor for morbidity and mortality. Inhibition of the renin-angiotensin system (RAS) is associated with an important decrease in cardiovascular risk, while classic RAS inhibitors have shown to improve AS indices. We sought to compare the relationship of direct renin inhibitor aliskiren versus classic RAS inhibitors on AS in mild to moderate hypertensive patients.

Methods: PUBMED, MEDLINE, and Cochrane library searches were performed until March 1st, 2017 for potential related articles. Inclusion criteria were i) randomized controlled trials in adult hypertensive patients, ii) comparison of aliskiren with other agents that inhibit the RAS, iii) reported data for blood pressure, pulse wave velocity (PWV), augmentation index (AIx) and iv) Study duration over 4 weeks. We calculated the summary standardized mean difference (SMD) from all studies using a random-effects

model using an inverse variance approach. Heterogeneity was quantified using the I^2 which ranges between 0-100% and describes the percentage of the variability in the effect estimates (e.g standardized mean differences in our case) that is due to heterogeneity rather than chance. Values >50% represent substantial heterogeneity.

Results: A total of 40 articles were found through database searches. These articles included 4 randomized controlled studies involving a total of 160 participants who met all pre-defined criteria. The SMD calculated did not indicated any significant differences with summary estimates including the null. Specifically, for PWV the summary effect size derived from the random effects model was 0.01 (95% CI: -1.00- 1.02) with no observed heterogeneity (I^2=0%). For AIx the summary effect was -0.21 (95% CI: -5.14-4.72) with no observed heterogeneity ((I^2=0%)

Conclusions: Aliskiren when compared to other RAS inhibitors have similar effect on arterial stiffness indices in hypertensive patients.

PUB541

Anti-Vascular Endothelial Growth Factor Agent Bevacizumab Use for Diabetic Retinopathy in a Hemodialysis Patient Dheeraj Kaul,[3] Serena Bhela,[1] Moro O. Salifu,[2] Mary C. Mallappallil.[1] *[1]None, Brooklyn, NY; [2]SUNY Downstate Medical Center, Brooklyn, NY; [3]Nephrology, SUNNY Downstate Medical Center, Brooklyn, NY.*

Background: In diabetic patients microvascular disease could present as diabetic retinopathy, nephropathy and or neuropathy. Among diabetics, diabetic macular edema (DME) is the most common cause of vision loss. While in the past, laser photocoagulation significantly reduced moderate vision loss and was the gold standard treatment for DME. Recently, with the use of anti-Vascular Endothelial Growth Factor drugs (Bevacizumab, Ranibizumab, and Aflibercept), better outcomes were obtained in terms of visual acuity gain and decrease in macular thickness as monotherapy. As the dose of the agent used in intravitreal injection is small the systemic side effects of progression of thrombosis is rare.

Methods: We present a case of a woman with primary open angle glaucoma, diabetic retinopathy and nephropathy who presented with diabetic retinopathy since 2006. She developed diabetic macular edema and successfully treated with focal laser photocoagulation with repeated treatments of both eyes in 2008, 2010, 2012 and intravitreal bevacizumab in 2008, 2010, 2011 and 2012. Pan retinal photocoagulation was performed in 2012. With the progression of her diabetic nephropathy, chronic hemodialysis was initiated in April 2016. She continued her treatment of diabetic retinopathy safely with bevacizumab in July 2016 and got repeated treatments for her non proliferative diabetic retinopathy with the agent in 2017 without any systemic side effects. With the treatments her visual acuity and optical coherence tomography showed improvement with as objective measures being a decrease in macular thickness in both eyes (512 to 412 and 610 to 440 Micrometers).

Results:

Conclusions: Macular laser therapy may still play an important role as an adjuvant treatment because it is able to improve macular thickness outcomes and reduce the number of injections needed. There are no case reports in the literature of the use of anti-VEGF intraocular injection therapy in hemodialysis for diabetic retinopathy either as monotherapy or combination with focal or pan retinal laser therapy.

Better Late Than Never Anjuman A. Howlader, Bijin Thajudeen. *University of Arizona, Tucson, AZ.*

Background: Acute renal arterial occlusion due to a stent thrombosis is common. The management options include endovascular or surgical revascularization. When the renal artery is occluded, a revascularization decision is sometimes deferred depending on the size of the kidney or extent of chronicity based on imaging or biopsy. Here we present the case of a patient who had total occlusion of renal artery in the presence of solitary kidney and who responded to revascularization.

Methods: 73-year-old female with history of right renal arterial stenosis, status post stent placement, congenital atrophic left kidney, hypertension, and chronic kidney disease presented with reduced urine output of 3 days duration. She also has a history of chronic kidney disease. Laboratory tests showed serum creatinine of 17 mg/dl and potassium of 7.4 meq/L. Emergency hemodialysis was started. Subsequent evaluation showed occlusion of right renal arterial stent. A renal angiogram revealed total occlusion of the renal arterial stent and attempt for revascularization failed. In view of the small size of kidneys (8.5 cm), thin cortex and loss of corticomedullary differentiation it was deemed that a surgical vascularization may not be of benefit. Hence, she was discharged home with recommendations to continue the hemodialysis. But 2 weeks later she presented to the ER with back pain and was found to have a ruptured aortic aneurysm on CT angiogram. CT angiogram also showed presence of contrast in the mid renal artery despite the total occlusion which suggested ongoing perfusion of the kidney. An endovascular repair of the aortic aneurysm was done using a synthetic graft. Since there were some signs of perfusion to that kidney a revascularization bypass procedure was done using PTFE graft connecting the aortic graft used for repairing the aortic aneurysm and renal artery distal to the thrombosed stent. Following the bypass procedure there was reestablishment of circulation to the kidney and improvement in urine output. Hemodialysis was discontinued. Serum creatinine was 1.8 mg/dl 2 weeks after the procedure. A post procedure duplex showed heterogenous perfusion to the kidney although a similar study was not available prior to procedure to compare.

Results:

Conclusions: This case highlights the importance of considering revascularization procedure in presence of renal vascular occlusion irrespective of the size of the kidney especially in patients with solitary kidney.

Uremia Alters Vascular Gene Expression in Pig Carotid Artery and Jugular Vein Jaroslav Janda,[2] Begoña Campos,[4] Frank C. Brosius,[2] Aous Jarrouj,[1] Keith L. Saum,[4] Lindsay N. Kohler,[2] Prabir Roy-Chaudhury,[2,5] Diego Celdran-Bonafonte.[3] *[1]Banner-University of Arizona, Tucson, AZ; [2]University of Arizona, Tucson, AZ; [3]University of Arizona / BIO 5 Institute, Tucson, AZ; [4]University of Cincinnati, Cincinnati, OH; [5]Southern Arizona VA Healthcare System, Tucson, AZ.*

Background: Uremia induces multiple pathologic changes in vascular tissues leading to enhanced cardiovascular disease and increased mortality in patients with advanced chronic kidney disease and end-stage kidney disease. To identify key pathogenic molecules in this process we have utilized a uremic pig model and have specifically determined the expression of 8 genes associated with endothelial and vascular dysfunction, at different arterial and venous sites.

Methods: Yorkshire pigs (n = 4 in each group) were made uremic by 5/6 nephrectomy]. Arterial (carotid, aorta) and venous (jugular, inferior vena cava) segments were removed under anesthesia 6 wk post-surgery and processed for total RNA isolation and cDNA synthesis. Quantitative real time-PCR was performed for ICAM, VCAM, NOS3, NOX4, KLF2, CCL2, MMP2, and MMP9.

Results: NOX4 and MMP2 expression was reduced ~2-fold in uremic vs. normal carotid artery ($p < 0.05$). NOS3, CCL2 and VCAM demonstrated non-significant reductions in gene expression in uremic carotid artery vs. non-uremic carotid artery.

In jugular vein, KLF2 and ICAM were reduced ~7-fold ($p<0.05$) in uremic veins. No significant changes in gene expression were found in the 8 genes studied in uremic aortas or inferior vena cavas vs. their non-uremic counterparts.

Conclusions: Uremia is associated with a reduction in expression of vascular genes in both carotid artery and jugular vein. Such reductions may alter signaling and vascular adaptation in uremia. Ongoing and future studies will characterize the functional effect of these gene changes through a systematic evaluation of genome-wide expression in uremic vessels, together with an evaluation of changes in uremic and non-uremic vessels in response to vascular stress/injury.

A Case of Renal Artery Dissection in a Patient with Fibromuscular Dysplasia and Rheumatoid Arthritis Aditya S. Pawar,[2] Stephen B. Erickson.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN, ROCHESTER, MN.*

Background: Fibromuscular dysplasia (FMD) is a non-inflammatory and non-atherosclerotic angiopathy, most commonly seen in renal arteries. Here, we present a case of renal artery dissection in a patient with FMD and Rheumatoid Arthritis (RA) presenting with flank pain.

Methods: 59-year-old male with past medical history of RA and HTN controlled with hydrochlorothiazide presented to emergency room with severe flank pain. His vitals were stableand had no prior history of kidney disease. EKG and echocardiogram were unremarkable. Laboratory test showed hemoglobin of 13 g/dL, WBC 6.8 x 10^9/L, serum creatinine 1mg/dL. Electrolyte panel, ESR, CRP, UA and microscopy were unremarkable. CT angio showed a dissection of the left mid renal artery with wedge shaped infarction of lateral upper/mid left kidney (Figure1). Additionally, beaded irregularity was seen in the mid and distal renal arteries, which supported diagnosis of FMD. MRA of neck and brain was unremarkable. Kidney function remained stable during his hospital stay. He was discharged on low dose aspirin with outpatient follow up with Nephrology and hypertension.

Results:

Conclusions: Flank Pain can be one of the presenting symptom of FMD (17%). FMD can mimic atherosclerotic disease and vasculitis. Minority of FMD patients develop aneurysm and dissection. Treatment is focussed on control of hypertension and anti-platelet therapy. The next most common arterial bed involvement after renal arteries is cerebral and vertebral arteries. RA, which is a pro-inflammatory condition and has been shown to accelerate atherogenesis from endothelial dysfunction may predispose to a dissection of FMD involved arteries. In our case, having RA might have predisposed our patient to develop a dissection and subsequent infarction. It is important for physcians to be aware of the complications of FMD as timely intervention can prevent further damage.

PUB546

Physicians' Perception of Blood Pressure Control in Patients with CKD and the Target BP Achievement Rate Ran-hui Cha,[2] Hajeong Lee,[4] Jung Pyo Lee,[3] Young rim Song,[1] Yon Su Kim.[4] *[1]Hallym Univ. Sacred Heart Hospital, Anyang, Republic of Korea; [2]National Medical Center, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Blood pressure (BP) control is the most-established method for the prevention of chronic kidney disease (CKD) progression. However, the ideal BP target for CKD patients is still in debate.

Methods: We performed a questionnaire survey of regular members registered in the Korean Society of Nephrology to determine the physicians' perception of BP control in patients with CKD. And we evaluated the target BP achievement rate using data from the APrODiTe-2 study.

Results: Two-thirds of physicians considered the target BP for CKD to be < 130/85 mmHg. The SBP thresholds for diabetic CKD, proteinuria ≥ 300 mg/day, 30 ≤ GFR < 60 ml/min/1.73 m^2, age < 60 years, and the presence of atherosclerotic (ASO) complications were significantly lower than the SBP thresholds of the opposite parameters. The four major hurdles to controlling BP were non-compliance to life-style modification and medications, self-report of well-controlled home BP, and co-prescription from other specialties. 78.6% and 97.3% of physicians prescribed home and ambulatory BP monitoring to less than 50% of their patients, respectively. The target BP achievement rates using the SBP thresholds in this survey were as follows: non-diabetic (69.3%); diabetic (29.5%); proteinuria < 300 mg/day (72.3%); proteinuria > 300 mg/day (33.7%); GFR ≥ 60 (76.4%); GFR < 30 (47.8%); no evidence of ASO (67.8%); and the presence of ASO (42.9%).

Conclusions: The target BP was lower in patients with higher cerebro-cardiovascular risks, including diabetic CKD, lower GFR, higher proteinuria, and the presence of ASO. These patient groups also showed lower target BP achievement rates. We also found a relatively lower application and clinical reflection rate of home or ambulatory BP monitoring.

PUB547

A Pharmacist-Guided Patient-Driven Interdisciplinary Program to Improve Blood Pressure Control in Patients with Hypertension Charles W. Hopley,[6] Emily Andrews,[3] Patrick M. Klem,[5] Zhiying You,[1] Michelle Jonjak,[2] Diana I. Jalal.[4] *[1]UC Denver, Aurora, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado Denver, Aurora, CO; [4]University of Colorado Denver Health Science Center, Aurora, CO; [5]University of Colorado Heospital, Aurora, CO; [6]University of Colorado SOM, Denver, CO.*

Background: Hypertension is a major risk factor for kidney and cardiovascular disease and mortality. Yet, approximately 2/3rds of patients treated for hypertension do not meet blood pressure goals. Patient-driven self-titration of blood pressure (BP) medications and lifestyle modifications are both reportedly effective and safe in the management of hypertension. We launched a quality improvement project implementing a pharmacist-guided patient-driven self-titration protocol and standardized dietary counseling to improve BP control in the chronic kidney disease (CKD) clinic.

Methods: Patients with uncontrolled hypertension on 3 or fewer antihypertensive agents were included. BP goals were established based on individual risk factors. Patients were referred to the clinical pharmacist who devised a personalized plan for BP medication titration based on home BP monitoring and provided dietary education. Patients were required to enter their BP readings via electronic medical records (EMR) every 2 weeks. The following outcomes were evaluated: adherence and effectiveness (entry of home BP readings via EMR), adverse events, and appeal to patients and providers.

Results: Nineteen patients have been enrolled and 3 patients have completed 6 month follow-up visits. 72.2% have entered home BP readings regularly in EMR. 2 of the 3 patients completing 6 month follow-up had significant improvement in blood pressure (avg 16.26 mmHG). Preliminary assessment of current patients demonstrates that of 13 patients actively entering readings, six patients have already met pre-specified blood pressure goals. One patient has reported episode of hypotension associated with a transient increase in serum creatinine, the patient was instructed to withhold diuretics and the symptoms resolved without further intervention. No other adverse events have been reported. Program provider surveys suggest favorable acceptance by the renal providers.

Conclusions: Patient-driven self-titration of BP medications and dietary counseling is feasible, safe, and well received from providers. Early results from patients completing the protocol appear to be promising and future plans include transitioning recruitment to the clinic staff, expanding it to all patients with hypertension, and expanding it to the primary care setting.

Prevalence and Treatment of Hypertension in Hemodialysis Patients in Three Time Points – 2006, 2011, and 2016 Piotr Skonieczny,[1,2] Zbigniew Heleniak,[1] Klaudia Piechowska,[1] Bartosz Pakula,[1] Marta Ksi??ek,[1] Monika Michalczuk,[1] Marek Karowiec,[1] Przemyslaw Rutkowski,[3,4] Leszek Tylicki,[1] Alicja Debska-Slizien.[1] *[1]Department of Nephrology, Transplantology and Internal Diseases, Medical Univeristy of Gdansk, Gdansk, Poland; [2]Department of Physiology, Medical University of Gdansk, Gdansk, Poland; [3]Department of General Nursery, Medical University of Gdansk, Gdansk, Poland; [4]Diaverum Poland, Gdansk, Poland.*

Background: Hypertension is a major problem among hemodialysis patients. The aim of the cross-sectional, observational study was to evaluate the prevalence, antihypertensive treatment and control of blood pressure according to JNC and K/DOQI recommendations in hemodialysis patients.

Methods: 227 patients hemodialyzed in Diaverum Dialysis Unit in three distinct periods of time 2006,2011 and 2016 were enrolled to the study. The analysis of the antihypertensive treatment was based on the medical files and it consisted of a comparison of the mean blood pressure results reported during the six consecutive HD sessions.

Results: The characteristic of study popualtion was showed in table 1. The mean blood pressure before HD session was 133/77,130/74 and 140/76mmHg, after HD session was 123/73,126/72 and 139/77mmHg in 2006,2011 and 2016 respectively and the values differed in three distinct periods of time. Percentage of patients using single, double, triple and multidrug therapy (4-6) were 23.6,18.2,28,12.5 in 2006, 14.8,34.6,24.7,17.2 in 2011 and 12.8,18.7,29,23.3 in 2016. The differences between single and double therapy were statistically significant. The most often used drugs were ß-blockers, diuretics and calcium channel blockers.

Conclusions: 1.Target of blood pressure control according to recommendations was achieved more often in 2006 probable as a result of differences in group characteristics 2.ß-blockers, diuretics and calcium channel blockers were the most common hypertensive drugs used in 2006,2011 and 2016 3.Percentage of patients using triple and multidrug therapy increased in 2016 in comparison to 2006 and 2011

Changes in Day- and Night-Time HRV during Acute Phase of ARB Therapy Masashi Mizuno,[1] Michio Fukuda,[1] Yoshiaki Ogiyama,[1] Hiroko Shibata,[1] Tetsuhei Matsuoka,[1] Ken Mizuguchi,[1] Hiroya Shimogushi,[1] Ken Kiyono,[3] Yoshiharu Yamamoto,[4] Hiroyuki Kobori,[5] Junichiro Hayano,[2] Nobuyuki Ohte.[1] *[1]Department of Cardio-Renal Medicine and Hypertension, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; [2]Department of Medical Education, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; [3]Department of Mechanical Science and Bioengineering, Osaka University, Osaka, Japan; [4]Department of Physical and Health Education, University of Tokyo Graduate School of Education, Tokyo, Japan; [5]International University of Health and Welfare, Tokyo, Japan.*

Background: Enhanced renal tubular absorption (tNa) cause sodium sensitivity of BP and non-dipper circadian BP rhythm. We had clarified that angiotensin receptor blockers (ARBs) can suppress “inappropriately increased intrarenal RAAS” to inhibit tNa, resulting in increase of daytime natriuresis and restoration of circadian BP rhythm. Recently, we have reported that the increase in daytime natriuresis with ARB treatment was accompanied by intrarenal dopamine secretion. However, in that study some individuals demonstrated restoration of circadian BP rhythm without alteration of natriuresis.

Methods: 24h-holter ECG data was analysis to investigate changes in sympathetic (non-Gaussianity index λ2s) and parasympathetic (HF and deceleration capacity, DC) nervous activity in 20 patients with CKD during acute phase (2 days) of ARB (azilsartan).

Results: At baseline, 5 patients had dipper and 15 nondipper BP rhythm. HF was a determinant of night/day BP ratio (β = -0.50, F = 5.8), rather than DC or λ2s. Five patients out of 15 non-dipper patients had decrease in daytime λ2s. (0.49±0.50→0.47±0.05, p=0.04). Other 5 patients of 15 nondippers, who did not get decrease in night/day BP ratio, nighttime λ2s augmented.

Conclusions: In summary, diminished parasympathetic nervous activity was related to nondipper BP rhythm in CKD, but restoration of the BP rhythm with ARB was derived from its sympathoinhibitory effect.

PUB550

Saving the Pulseless Kidney! Rahul Kumar,[1] Ali Mehdi,[1] Georges Nakhoul.[2] *[1]Internal Medicine, Cleveland Clinic Foundation, Cleveland, OH; [2]Nephrology, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Takayasu’s arteritis (TAK) also known as the pulseless disease, is a granulomatous large-vessel vasculitis. It primarily affects women of age 10 to 40 years. In patients with TAK, the prevalence of hypertension varies from 23% to 76% across the world and about half of them are secondary to renal artery involvement. In this case report, we present a patient with difficult to control hypertension and worsening renal function due to TAK induced bilateral renal artery stenosis refractory to medical therapy.

Methods: A 39-year-old Caucasian female presented with sudden onset chest pain. The patient was found to have an anterior ST-elevation myocardial infarction. Coronary angiography revealed 99% ostial stenosis of the left anterior descending as well as high-grade stenosis of the proximal left subclavian and bilateral renal artery. The patient underwent an urgent coronary artery bypass graft. On detailed history, she reported intermittent left arm shooting pain, muscle ache, fatigue, poor appetite and 50-pound weight loss over the past year. She has a past medical history of multiple sclerosis, ulcerative colitis, and cigarette smoking. On exam, blood pressure was 110/72 mmHg in the right arm and 88/70 mmHg in left arm, heart rate 86 bmp. A left subclavian bruit was present. Patient has a normal right radial pulse but a feeble left radial pulse. Patient labs showed ESR 59 and CRP 1.1. A CT angiogram showed severe stenosis of the proximal left subclavian artery, SMA, IMA, celiac and bilateral renal artery (80% RRA and 90% LRA). A clinical diagnosis of Takayasu’s arteritis was made. The patient was discharged on prednisone and methotrexate. At a six-month follow-up visit, MRA abdomen showed a completely occluded RRA with atrophied right kidney. Renal Duplex US showed an occluded RRA and 60-99% LRA proximal stenosis with a PSV of 768 cm/sec. An aortogram confirmed the RRA occlusion. The patient underwent a left aorto-renal bypass graft of her solitary kidney. A six-month follow-up showed stable kidney function with better control of blood pressure.

Results:

Conclusions: Takayasu’s arteritis is a rare cause of renovascular hypertension. Our patient was prevented from becoming dialysis dependent by timely recognition and intervention. In TAK with advanced renal artery stenosis refractory to medical therapy, surgical revascularization is the treatment of choice. Patient management must include a well-coordinated multidisciplinary approach.

PUB551

Rapid Progressive Visual Loss Due to Macular Edema and Cotton Wool Spots in a Pediatric Patient Receiving Peritoneal Dialysis Takahiro Namba,[1] Akira Ashida,[1] Hideki Matsumura,[1] Yuko Fujii,[1] Hyogo Nakakura,[1] Akihiko Shirasu,[1] Satoshi Yamazaki,[1] Tsunehiko Ikeda,[2] Motoshi Hattori,[3] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Japan; [2]Ophthalmology, Osaka Medical College, Takatsuki, Japan; [3]Pediatric Nephrology, Tokyo Women’s Medical University, Tokyo, Japan.*

Background: End-stage renal disease (ESRD) may lead to unique ocular complaints or exacerbate any underlying ocular disease. These ocular manifestations are a result of uremia, abnormal electrolyte balance, loss of fluid homeostasis, anemia, and hypertension. Although typical ocular symptoms in pediatric patients with ESRD include red, irritated eyes, ocular pain and changes in visual acuity, rapid progressive vision loss is relatively rare. Here, we report an unusual case of acute bilateral vision loss due to bilateral macular edema and cotton wool spots in a patient receiving peritoneal dialysis for ESRD.

Methods: A 15-year-old boy visited our clinic because of rapidly progressive blurring of his central vision. The patient had no history of diabetes, and had end-stage renal disease caused by focal glomerulosclerosis. Peritoneal dialysis had been started at the age of 14 years, and then six months later he had been admitted for readjustment of his dialysis conditions due to hypertension. However, because of non-adherence to dialysis, his blood pressure continued to increase. After a further two months, rapid progressive blurring of his central vision occured. On examination, his visual acuity was 0.5 in the right eye and 0.35 in the left. An ocular fundus examination revealed bilateral disk edema, macular edema, and cotton wool spots. Macular edema was confirmed by optical coherence tomography. As the patient’s blood pressure was found to have increased to 197/114 mmHg on admission, we changed the conditions of his peritoneal dialysis to improve water overload and administered additional antihypertensive drugs. After one month of treatment, his blood pressure was reduced to 100/60 mmHg and his visual acuity was improved to 1.5 in both eyes.

Results:

Conclusions: Irrespective of whether ocular symptoms are present, ophthalmological screening is necessary for pediatric patients with ESRD, as early ophthalmological diagnosis and treatment may restore vision and reverse any retinal anatomic changes without the need for surgical intervention.

PUB552

Frequency of Multi-Drug Treatment for Pediatric Hypertension Bethany Crawford,[2] Christopher Cates,[2] John Lin,[4] Nichaela A. Hoffman,[1] Thomas K. Davis,[3] Vikas R. Dharnidharka,[3] Laura Hesemann.[2] *[1]Barnes Jewish Hospital, St. Louis, MO; [2]University of Missouri School of Medicine, Columbia, MO; [3]Washington University School of Medicine, St Louis, MO; [4]Washington University in St. Louis, St. Louis, MO.*

Background: Hypertension (HTN) is increasingly prevalent among children and adolescents. Data regarding treatment of pediatric HTN is increasing but remains limited. Up to 75% of adult patients require multiple medications for blood pressure (BP) control. Knowledge of this guides adult practitioners regarding expected outcomes and gives a rationale for rapid titration of medication. The goals of this study were to determine the frequency with which children require multi-drug therapy to attain BP control and to identify risk factors for needing multiple BP medications.

Methods: All patients with HTN seen between May 2012 and April 2013 at a pediatric nephrology clinic in an academic center were evaluated. Patients with resolved HTN, ESRD, or history of kidney transplant were excluded. Data were collected for BP control as assessed by the treating physician, number of medications needed to achieve control, and risk factors including race, gender, BMI, CKD, and diabetes mellitus.

Results: Of 126 subjects, 92 (73%) were prescribed 1 medication. The remaining 34 (27%) were prescribed 2 or more medications. The groups were not significantly different with regard to the presence of any of the identified risk factors (table 1). Adequate BP control was achieved in 81% of subjects on 1 medication, which was not statistically different from the 82% who required multiple medications (p=0.883). In logistic regression, none of the identified risk factors correlated with the need for multiple anti-hypertensive medications.

Conclusions: Similar to findings in adult patients, a significant proportion of hypertensive children require multi-drug therapy to achieve BP control. The need for multi-drug therapy was independent of the evaluated risk factors and may not be an indication for more intensive evaluation. None of the factors evaluated predicted the need for multi-drug therapy. Further studies are needed to validate these findings in larger cohorts.

HTN risk factor assessment by number of medications used

	1 medication (N=93)	2+ medications (N=33)	p-value
male	61%	64%	0.812
AA	35%	24%	0.236
CKD	24%	33%	0.277
DM	6%	15%	0.134
BMI > 85%	63%	61%	0.906

Relationship between Angiogenesis Inhibitors and Pediatric Hypertension: A Case-Series Marissa Lipton,[4] Laura jane Pehrson,[3] Suzanne M. Vento,[2] Howard Trachtman,[1] Laura Malaga-Dieguez.[4] *[1]NYU Langone Med Ctr, New York City, NY; [2]NYU Langone Medical Center, New York, NY; [3]NYU School of Medicine, New York, NY; [4]New York University School of Medicine, New York, NY.*

Background: Angiogenesis inhibitors have an emerging role in the treatment of pediatric cancers. CNS tumors have high concentrations of pro-angiogenic factors and neo-vascularization. Much of what is known about angiogenesis inhibitors comes from adult studies, where they have been more widely used. Hypertension is a common side effect of this new drug class in adults. Limited information is available about the safety of these medications in children.

Methods: A single center, retrospective chart review was conducted. Twenty-eight patients under 25 years of age with CNS tumors, who were followed by the Division of Pediatric Hematology and Oncology at NYU Medical Center, were identified who had received angiogenesis inhibitors developed hypertension. Chart review was conducted in 12 cases. The other cases met exclusion criteria or access to full EMR was unavailable.

Results: Seven (56%) patients developed hypertension within 9 months of initiation of the drugs, with most occurring in the first 3 months. Four were treated with bevacizumab, 2 axitinib, and 1 pazopanib. While one patient's symptoms resolved, the remaining 6 children required treatment with anti-hypertensive agents. Only two patients were referred to pediatric nephrology and were treated with amlodipine. The remaining patients were all given diuretics by the oncology team, with 3 requiring use of a second antihypertensive agent (ACE inhibitors).

Conclusions: Our findings are consistent with the adult literature and indicate that secondary hypertension is a frequent complication of angiogenesis inhibitor therapy. Poorly controlled hypertension in children has the potential to track into adulthood and is a major risk factor for cardiovascular morbidity and mortality. Identification and treatment of pediatric hypertension is an important health focus for pediatric oncology patients. Timely referral to a pediatric nephrologist should be coinsidered for treatment of angiogenesis inhibitor-associated hypertension.

PUB554

Identification of Factors Modulating Hypertension in CKD: A Pilot Study Mochammad Thaha,[6] Maulana A. Empitu,[5] Ika N. Kadariswantiningsih,[1] Cahyo wibisono Nugroho,[4] Muhammad Amin,[7] Haerani Rashid,[3] Muhammad Yusuf.[2] *[1]Department of Microbiology, Airlangga University School of Medicine, Surabaya, Indonesia; [2]Department of Cardiology, Airlangga University School of Medicine, Surabaya, Indonesia; [3]Department of Internal Medicine, Hasanuddin University, Makassar, Indonesia; [4]Department of Internal Medicine, Airlangga University Hospital, Surabaya, Indonesia; [5]Department of Pharmacology, Airlangga University School of Medicine, Surabaya, Indonesia; [6]Department of Internal Medicine - Nephrology Division, Airlangga University School of Medicine, Surabaya, Indonesia; [7]Institute of Tropical Disease, Airlangga University, Surabaya, Indonesia.*

Background: Hypertension and chronic kidney disease interact in multifaceted dimension. Hypertension is regarded amongst leading causes of CKD. In contrast, hypertension is frequently developed in previously normotensive CKD patients. As hypertension also progress with kidney disease, it becomes urgent to identify factors which modulate the development of hypertension in CKD patients. Therefore, we conduct an observational study to investigate the contribution of nutritional status, quality of sleep, inflammation, and oxidative stress to the progression of hypertension in CKD.

Methods: During the first phase of recruitment, 35 consented stable CKD patients who enrolled in outpatient or haemodialysis clinics at a private and a government hospital in Surabaya, Indonesia were included. The nutritional status were evaluated using anthropometric measurement, Malnutrition-Inflammation Score (MIS) and Dialysis Malnutrition Score (DMS), while sleep quality were examined using Pittsburgh Sleep Quality Index (PSQI). Blood biochemical and cytological parameters represented with inflammation and oxidative stress were measured at baseline level. The medication and medical history were documented.

Results: The baseline characteristics of the study participants were aged 52.6±14.3 years with Cystatin-C adjusted eGFR 36.6±43.2 ml/minute per 1.73 m^2. Partial least squares - discriminant analysis on 49 different factors including clinical and biochemical parameters, revealed that 21 measured parameters significantly contributed ($Qi^2 > 0.8$, CI 95%) to the projection of hypertension. Among factors those significantly contributed in this model were eosinophil counts (VIP=2.27), renal function (VIP=1.80), Total Iron Binding Capacity (VIP=1.12), percentage of body weight change during the last 3 months (VIP=1.10), MIS score (VIP=1.06), the presence of sleep disturbance (VIP=0.91), and sleep latency (VIP=0.89±0.63).

Conclusions: The analysis result might consist of factors related to hypertension in CKD. However due to the limited numbers of data, the model used in this study needs to be validated along with this ongoing study recruiting more subjects.

Evaluation of Blood Bicarbonate Levels and Gas Analysis in Hemodialysis Patients Who Switch from Lanthanum Carbonate to Sucroferric Oxyhydroxide Aristeidis Stavroulopoulos,[1,2] Vasiliki V. Aresti,[1,2] Christoforos Papadopoulos,[3,2] Panagiotis Nennes,[2] Polyxeni G. Metaxaki,[2] Anastasios Galinas.[4,2] *[1]IASIO Hospital - General Clinic of Kallithea, Athens, Greece; [2]Dialysis Unit "ATTIKOS NEPHROS", Athens, Greece; [3]Dialysis Unit "ATHINAIKO KENTRO NEFROU", Athens, Greece; [4]417 NMTS Hospital, Athens, Greece.*

Background: Different phosphate binders have different effects on acid-base status of hemodialysis patients. We sought to examine possible alterations in acid-base parameters in patients switching from lanthanum carbonate (LC) to sucroferric oxyhydroxide (SOH).

Methods: Fifteen stable patients, on bicarbonate hemodialysis, switched from LC to SOH. However, only 9 continued on SOH; 3 returned to LC and the other 3 switched to sevelamer carbonate due to side effects of SOH. The later 6 patients served as a control group to the SOH group of 9 patients. Blood was sampled from the "arterial needle" of the vascular access, on the 3-day and the last 2-day interval of the week prior to switching and 6 weeks after, at the same intervals. Bicarbonate levels (HCO_3), pH, pO_2, pCO_2 were measured, and the mean of the 2 measurements (3-day and 2-day interval) was calculated. Dialysate, medications and hemodialysis prescription (except of ultrafiltration) were remained unchanged throughout the study.

Results: Comparing pre-switching to post-switching measurements in the SOH group, no statistically significant differences were found in any of the parameters studied. Mean pre-switching HCO_3 levels were 22.41 ± 1.66 mmol/L and post-switching 22.62 ± 2.25 mmol/l (P=0.743). Respectively, mean pH= 7.384 ± 0.028 vs. 7.388 ± 0.03 (P=0.723), mean pCO_2= 38.41 ± 3.29 vs. 38.37 ± 3.62 mmHg (P=0.971), Phosphate = 4.65 ± 0.85 vs. 4.21 ± 1.19 mg/dL (P=0.194) etc. No significant differences were found even when we analyzed the data for the 3-day and the 2-day intervals. There were not any significant differences when we performed the same analyses in the control group, or between SOH and control group. In addition, no correlations were found, either between pre-switching daily LC daily dose, or between post-switching daily dose of the new binder and the measured parameters. Only, pH and HCO_3 were significantly lower at the 3-day vs. 2-day interval, as expected.

Conclusions: In our small study, switching from LC to SOH did not have any significant effect on blood bicarbonate levels and gas analysis, indicating that there is no need to change hemodialysis prescription regarding these parameters. However, monitoring of serum bicarbonate levels is part of good clinical practice.

PUB556

Does Intravenous Iron Therapy Decrease Serum Phosphorus Levels? Frieda Wolf, Vladimir Poletaev, Mazen Elias. *Emek Medical Center, Afula, Israel.*

Background: Several intravenous iron formulations have been reported to increase phosphaturia, causing dangerously low serum phosphorus levels. This may lead to osteomalacia and fractures, more so in people with vitamin D deficiency. This phenomenon has been observed with saccharated ferric oxide, a preparation commonly used in Japan, and with iron polymaltose. It has also been observed with iron carboxymaltose There is no information in the literature about phosphorus levels after treatment with iron sucrose or ferric gluconate, which we use most frequently for individuals with iron deficiency anemia, with or without kidney disease.

Methods: . We checked serum phosphorus levels in 48 individuals with iron deficiency anemia, before and after iron treatment. Comparisons of phosphorus levels prior to and after treatment were done using students' t-test.

Results: Forty seven received iron sucrose. Only three individuals had vitamin D deficiency. Average phosphorus level pre- treatment was 3.46±0.5 mg/dL, with a mean PTH level of 62.59 pg/mL and mean vitamin D level of 40.67 nmol/L. Average phosphorus level was 3.47±0.55 mg/dL post-treatment.

Conclusions: We conclude that iron sucrose is a safe and effective treatment for iron deficiency, and does not reduce serum phosphorus levels.

Funding: Clinical Revenue Support

Laboratory values before and after iron treatment

	N	Mean value ±SD before iron	N	Mean value ±SD after iron
Phosphorus mg/dL	48	3.46 ±0.5	48	3.47 ±0.55
Hemoglobin g/dL	46	9.33 ±1.5	30	11.79 ±1.33

Nephrocalcinosis Secondary to Total Parenteral Nutrition Gayatri D. Nair,[2] Laura Ferreira Provenzano,[1] Leal C. Herlitz.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH.*

Background: Nephrocalcinosis is a rare complication of TPN and has only been reported in prenatal infants to date. Here we report a case of a middle aged woman who was found to have microscopic nephrocalcinosis with calcium phosphate deposition seen on renal biopsy which was due to high amounts of phosphorus she was receiving via TPN.

Methods: A 55 year old female with a history of Ulcerative colitis and total colectomy at the age of 6 followed by a diverting loop jejunostomy and end ileostomy in 2012 requiring TPN since then, presented to nephrology clinic in 2016 for elevated serum creatinine (SCr). Her baseline SCr was 0.6-0.8 mg/dL a year prior to presentation and had been slowly rising to a SCr of 1.8 mg/dL on initial evaluation. She had a history of recurrent episodes of dehydration secondary to high ostomy output which was an ongoing problem at the time of presentation. Her intake was adjusted to match output and protein content of TPN was decreased but SCr continued to rise and reached 2.29 mg/dL. Further labs showed an elevated phosphorous of 6.9mg/dL, PTH 329 pg/mL and low normal calcium, suggesting secondary hyperparathyroidism. Urine analysis showed no significant proteinuria or hematuria with some amorphous crystals seen on microscopy. 24 hour urine showed elevated phosphorus (1300 mg/24hr). Renal ultrasound was normal. Biopsy revealed chronic tubulointerstitial inflammation with moderate interstitial fibrosis and tubular atrophy. Moderate amounts of crystals consistent with calcium phosphate deposition were scattered throughout the interstitium. On further investigation it was found that the patient was receiving very high levels of phosphorus via TPN and had intermittent episodes of hyperphosphatemia in the prior year. The phosphorus content of TPN was substantially decreased and over the next few months SCr improved to 1.4mg/dL.

Results:

Conclusions: The mechanism of nephrocalcinosis due to TPN is related to the calcium phosphate ratio required for maintaining a neutral or positive calcium balance in order to prevent bone disease. Usual adult parenteral dose of phosphorus is 27-53 meq/day, our patient was receiving very high levels of phosphorous(95-180meq/day) for an extended period of time which led to calcium phosphate crystal deposition causing renal injury. Thus, in patients with renal dysfunction receiving TPN this is an important consideration.

PUB558

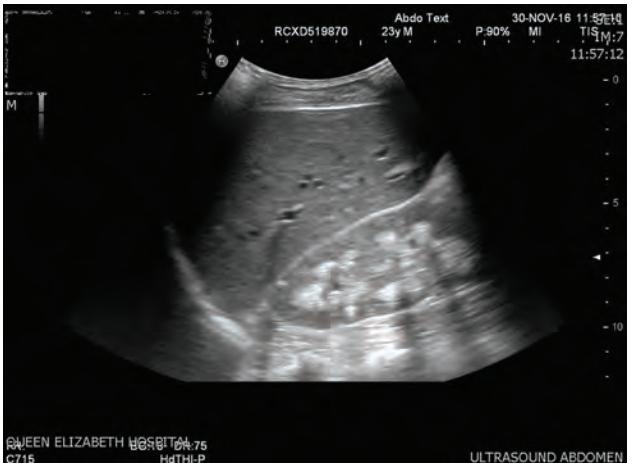
Medullary Sponge Kidney and Primary Hyperparathyroidism – An Enigma Zeshan sharif Choudhry,[2] Sherin A. Ahmed,[3] Smita Gunda.[1] *[1]Cambridge University Hsospitals, Cambridge, UK, Kings Lynn, United Kingdom; [2]NATIONAL HEALTH SERVICES, Kings Lynn, United Kingdom; [3]NHS, Cambridgeshire, United Kingdom.*

Background: Medullary sponge kidney is considered as congenital disorder usually characterised by malformation of collecting ducts which manifest as medullary cysts with sparing of cortex. It is thought to be a developmental abnormality with limited evidence of genetic transmission. It is usually asymptomatic and picked up as incidental finding on imaging but some times presents with hematuria, UTIs and renal colic with overall good prognosis with preserved renal function.

Methods: 23 year old gentleman with no past medical history. Presented to GP with 12 months history of increasing tiredness and fatigue, negative family history of any endocrinopathy. Normal physical examination. Routine blood tests revelaed raised alkaline phosphatase and therefore an abdominal ultrasound was arranged. This was suggestive of medullary sponge kidney and he was referred for nephrology review. Nephrology review and subsequent investigations showed a raised calcium 3.42mmol/l, high parathyroid hormone 28.7 pmol/l, urinary calcium 2.87 mmol/l, negative myeloma screen, normal ACE/vitamin D levels, normal range urinary metanephrines, normal pituitary profile and no symptoms of hypercalcaemia. CT urogram did not show renal stones and confirmed medullary sponge kidney. Clinical impression was of primary hyperparathyroidism which was treated with fluids and pamidronate. MIBI scan later confirmed right sided parathyroid adenoma which was surgically excised.

Results:

Conclusions: There is limited evidence in literature regarding association of primary hyperparathyroidism with medullary sponge kidney. There are suggestions that primary hyperparathyroidism can cause medullary sponge kidney but on other hand it is well proven fact that naphrocalcinosis can cause medullary sponge kidney. Association and mechanism of primary hypeparathyroidism as causative factor for medullary sponge kidney still remains an enigma.



PUB559

A Case Study of a Patient with CKD-Metabolic Bone Disorder with Concomitant Ectopic Primary Parathyroid Adenoma Joseph T. Leeds,[2] Abubakr Abdelaziz,[2] Tushar Chopra.[1] *[1]None, Nashville, TN; [2]University of Virginia, Charlottesville, VA.*

Background: We report an outpatient referral of a patient with chronic kidney disease (CKD) and normal to borderline elevated Calcium (Ca) with elevated PTH who presented to our outpatient clinic being referred by his Primary Physician.

Methods: 65-year-old Caucasian male with a past medical history of CKD Stage 3 likely secondary to presumed underlying type II diabetes mellitus (DM), and hypertension (HTN) who presents with fatigue, constipation and cold intolerance. Physical examination was unremarkable. Serum creatinine (Cr) had been elevated at 1.4-1.6 mg/dl since August of 2015 along with intermittent hypercalcemia since 2012 with peak Ca of 11.9mg/dl in January 2013. Most recent labs revealed serum PTH of 174 pg/ml, calcium of 11.1 mg/dL, 25-Hydroxy Vitamin D of 16ng/ml, and phosphorus of 1.8 mg/dL. Renal ultrasound was inconclusive. A sestamibi scan revealed an abnormal uptake due to an ectopic retrosternal parathyroid. A diagnosis of primary hyperparathyroidism (HPT) along with some element of secondary hyperparathyroidism related to renal insufficiency was made. Subsequently, he was referred for a surgical excision, while being medically managed with cinacalcet.

Results:

Conclusions: Ectopic parathyroid adenoma has a prevalence of 5%[1-3]. Common locations include mediastinum, retropharyngeal, carotid sheath, and intrathyroidal. Most common symptoms include renal colic, frequent urination, abdominal pain, nausea, vomiting, impaired memory, personality changes, and constipation. Primary HPT is often overlooked in Chronic Kidney Disease patients. Our case highlights the importance of persistent hypercalcemia with normal or low serum phosphorus levels as a biochemical clue in diagnosing primary HPT with ectopia in patients with suspected secondary hyperparathyroidism from CKD and Vitamin D deficiency. Imaging approach includes a sestamibi scan which is not necessary in all cases. It is important to remember the need for a sestamibi or 4-dimensional CT as ultrasound alone could miss ectopic adenomas, especially with inexperienced ultrasonographers.[5] Treatment approach includes surgery. The indication for parathyroidectomy in our case was elevated calcium values 1mg/dl above normal along with CKD. Whether the ectopic parathyroid is the hyper-functioning nodule can only be confirmed by excision and following PTH levels.

PUB560

Rebound Hypercalcemia Post Denosumab Exposure Mohammed Z. Mohialdeen,[1] Karim M. Soliman.[2] *[1]NEPHROLOGY, MUSC, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC.*

Background: Hypercalcemia is an oncological emergency with an estimated incidence of 10–20% in adult patients with cancer. Denosumab is a humanized monoclonal antibody to RANKL approved for treatment of osteoporosis and prevention of skeletal-related events from bone metastases. RANK ligand (RANKL) is a cell surface protein involved in many cellular processes, including osteoclastogenesis. Receptor activator of nuclear factor κ-B ligand (RANKL) is a cell surface molecule that plays an important role in bone resorption and bone remodeling through its effect on osteoclasts.

Methods: We describe a 68 year old female with a pmhx of polymyalgia rheumatic (PMR), hypothyroidism, osteoarthritis, osteopenia, liver cirrhosis with Bx proven NASH, right breast cancer without bone metastasis, diagnoised 3 years earlier, who underwent bilateral mastectomy. She did not undergo chemo- or radiation therapy. She adjuvant therapy initially with letrozole which was changed to tamoxifen. Patient presented with generalized weakness and change in mental status. One week earlier, she was found to have a Ca2+ of 12. On admission, Ca2+ was 14 with albumin of 3.1. She received one dose of Denosumab for her known osteoporosis 6 month ago. Other outpatient medications included vit d 2000 U and Centrum silver once Labs:- CBC: Hgb 9.3, wbc 3.6, plt 76. BMP :- Na 144, k 2.8, Cl: 108, HCo3 27, AG 9, BUN: 16, CR: 1.3 BS: 107, EGFR:42,

Ca: 14., ALB: 3.1, Ionized Ca 1.35, PTH: 21.1. MG: 0.9 BIL/T 2.2, AST 29, ALT 11, ALK: 53, P: 6.1. UPEP:NL, SPEP:NL, K/LCR: 2.05, ACE: 66, 25-Hydroxy: 9.6,25, D3:30.3, 25-D : 39.9. AMMONIA: 15.1, VIT A: 0.07, PTH-RP: 0.8, CALCIUM, URINE: 14.6 Radiology:- Skeletal survey : Neg. Bone scan :Neg. Sestamibi scan: neg During her hospitalization course, she was treated with IV hydration, calcitonin. We stopped her vit D and supplement since admission. Corrected her Mg level and re-measure PTH with no significant changes. After that we re-introduce her Denosumab with significant improvement in her calcium level and PTH was up to 54.7 from 21

Results:

Conclusions: In previous case reports Denosumab was associated with clinically significant disturbances of mineral metabolism both while on treatment and after discontinuation. In all reported cases hypercalcemia was due to increased bone resorption from osteoclast activity following loss of denosumab inhibitory effect. in our case there was no bone metastasis

Sevelamer Crystals in Injured Colonic Mucosa – Causative Agent or an Innocent Bystander?

Antonin Jaros,[3] Fazia Mir,[2] Susan Hudson,[1] Saeed K. Shaffi.[4] *[1]DCI, Albuquerque, NM; [2]Presbyterian Hospital, Albuquerque, NM; [3]UNM, Albuquerque, NM; [4]University of New Mexico, Albuquerque, NM.*

Background: Sevelamer carbonate is a polymeric amine that is used as a phosphorus binder in patients with advanced chronic kidney disease (CKD) and end-stage renal disease (ESRD). We report a case of colitis in a patient with ESRD where sevelamer may have been responsible for colonic mucosal injury.

Methods: A 48 year old female with ESRD on hemodialysis presented to the hospital with abdominal pain, nausea and diarrhea. Laboratory evaluation revealed leukocytosis. A Computed Tomography(CT) scan of abdomen and pelvis was notable for right sided colonic wall thickening with associated luminal narrowing. Initial colonoscopy revealed severely edematous bluish mucosa of the cecum and ascending colon. Pathology report on obtained biopsy was consistent with ischemic colitis. Abdominal CT angiogram showed patent vasculature. She received supportive care and was discharged home with improvement in her symptoms. Two weeks after discharge, she presented to the hospital with epigastric and left sided abdominal pain, nausea and dark stools. Evaluation revealed hypotension, anemia and leukocytosis. Patient underwent colonoscopy with finding of ulcerated, friable mucosa from cecum to splenic flexure. Pathology report was notable for presence of granulation tissue, sevelamer crystals and associated foreign body inflammatory response. No features of acute ischemia were found. Sevelamer was discontinued with improvement in her symptoms. Repeat colonoscopy 18 months later revealed ulcerated long stricture in ascending colon preventing passage of 10mm colonoscope. Biopsy showed chronic colitis with mild activity.

Results:

Conclusions: Sevelamer induced colitis can be a cause of chronic diarrhea in selected cases resulting in stricturing disease over time. This has been reported previously in the literature. Further studies are needed to establish whether sevelamer is responsible for mucosal injury or whether sevelamer can exacerbate injury in an already damaged colonic mucosa. This infrequent adverse effect should be kept in mind in any patient treated with sevelamer having otherwise unexplained colitis.

PUB562

Hypercalcemia in a Patient with Cholangiocarcinoma (CC): Diagnosis and Management (CC)

Pablo Garcia,[1] Kartik Kalra,[1] Nabil Ghani,[1] Simranjit S. Randhawa,[2] Ayan De.[1] *[1]Saint Peter's University Hospital, New Brunswick, NJ; [2]Sir Ganga Ram Hospital, New Delhi, India.*

Background: Hypercalcemia is a common problem. It can occur when there is an increase in bone resorption, excessive GI absorption, or decreased renal excretion of calcium. Primary hyperparathyroidism comprises the majority of hypercalcemic patients among the ambulatory population, but malignancy accounts for up to 65% of such patients in the hospital. Humoral hypercalcemia of malignancy (HHM) has been rarely documented in patients with CC. Here we present an unusual case of hypercalcemia secondary to cholangiocarcinoma.

Methods: 62 year-old female, was admitted with weakness, constipation, 20 pound weight loss, and decrease oral intake for about two months. PMH of HTN, DM, HLD and restless leg syndrome. Medications as outpatient were diltiazem, colace, losartan, tramadol and alogliptin. In the ER the initial blood work showed serum Ca of 15.4 mg/dl, creatinine of 2 mg/dl and magnesium of 1.4 mg/dl. She was admitted for further investigation. On further investigation PTH was 22 pg/ml and ionized calcium was 14 mg/dl. CT scan of the abdomen showed multiple metastatic lesions in the liver. Liver biopsy was done on day 3 of hospitalization, it showed morphologic and immunohistochemical features of cholangiocarcinoma. PTHrP levels were elevated which is consistent with HHM secondary to cholangiocarcinoma. Multiple myeloma and metastatic disease workup was negative. Patient was treated with intravenous hydration, calcitonin and zolendronic acid. On day 3 of hospitalization calcium was 10. 7 and patient was discharge with a calcium level of 8.4. Patient symptoms resolved, and it was discharge on calcitonin and we have been following as outpatient with calcium levels 8.2 – 9 mg/dl.

Results:

Conclusions: Increased calcium levels, decreased PTH levels and absence of metastatic bone disease in the setting of CC suggest the diagnosis of HHM. Management of hypercalcemia due to HHM should be started as soon as possible to improve the symptoms.

PUB563

Report of Recombinant Parathyroid Hormone Therapy (Forteo) in a 18 Year Old Patient with Fanconi Syndrome and Osteomalacia

Ivie O. Okundaye, Aparna Natarajan, Julia Schneider. *Loyola University Medical Center, Maywood, IL.*

Background: An 18-year old woman with Fanconi Syndrome due to an unknown genetic mutation initially presented with proximal renal tubular acidosis, hypokalemia and hypophoshatemia resulting in osteomalacia and pathologic fractures. Patient presented to the ER with sudden onset right leg pain and inability to bear weight. Imaging showed diffuse osteopenia, left transverse femoral shaft fracture, multiple prior stress fractures and a right ulnar fracture. Labs notable for K 3.0, Phos 1.7, HCO3 16, Ca 7.7, Ionized Ca 1.15 PTH 129, and normal serum creatinine. There was no evidence of nephrolithiasis. 24 hour urine did not show hypercalciuria. Alkaline Phosphatase 1004, Vitamin D 25-OH 16. Vitamin D- 1,25 within normal limits. Dexa Scan revealed Z score -5.5 consistent with osteomalacia for her age.

Methods: Vitamin D was repleted but due to severe chronic bone pain and poor fracture healing, use of recombinant parathyroid hormone analogue, Forteo was initiated. Interestingly, alkaline phosphatase, bone alkaline phosphatase, levels improved after Forteo therapy, and patient has not had additional fractures after therapy. She also reports marked pain improvement. Patient remains on calcium 600 mg, calcitriol 1ug BID, and ergocalciferol 50,000 IU every other week, kphos packets TID.

Results:

Conclusions: Forteo is known to expedite bone healing however its use in young patients with Fanconi syndrome and hypophosphatemic rickets has not been studied. This drug is typically used for treatment of osteoporosis in elderly patients or those taking corticosteroid medications. Some studies show acceleration of bone healing from fractures in patients with osteoporosis. Here we present a case of hypophosphatemic rickets resulting in debilitating bone fractures successfully treated with Forteo. Forteo in combination with calcium and phosphorous replacement therapy demonstrates a novel approach in treatment of Fanconi syndrome associated hypophosphatemic rickets with pathologic fractures.

PUB564

A Case of Sagliker Syndrome

Julia Brown,[2] Rebecca Frazier.[1] *[1]Northwestern, Chicago, IL; [2]Nephrology, McGaw Medical Center of Northwestern University, Chicago, IL.*

Background: Sagliker Syndrome is a recently described entity in which patients with chronic renal failure and uncontrolled hyperparathyroidism develop severe bone deformities including teeth, maxillary and mandibular bone, skull, finger, and height changes. These abnormalities are more severe than expected with high parathyroid hormone levels. It is often associated with lack of medical care. This syndrome likely has an underlying genetic basis although the genes are not yet identified.

Methods: A 36-year-old male on dialysis for 11 years presented with progressive skeletal abnormalities and bone pain. He had normal stature and musculoskeletal development until he developed renal failure in his early 20s. Over the next few years, he developed many deformities including bilateral leg fractures, bowing of the legs and arms, curvature of the spine, mandibular hypertrophy, and angulation of the distal phalanges. These changes caused progressive immobility; on presentation he was bedridden. He was found to have a parathyroid hormone level of 2410 pg/mL, phosphorus 6.8 mg/dL, calcium 9.4 mg/dL, and alkaline phosphatase 727 U/L. X-rays revealed diffuse demineralization, cystic changes, and cortical sclerosis consistent with severe osteitis fibrosa cystica. Parathyroid ultrasound demonstrated enlarged parathyroids, and sestamibi scan revealed parathyroid hyperplasia. His case is consistent with Sagliker Syndrome. The patient was treated with subtotal parathyroidectomy with forearm autotransplatation of 3 mm^3 of parathyroid gland. Bone pain resolved post-operatively, however, he developed hungry bone syndrome requiring a total of 67g of intravenous calcium and 24g of oral calcium in the first 72 hours post-operatively. His PTH level after parathyroidectomy was 8 pg/mL.

Results:

Conclusions: Early recognition of skeletal changes and strict control of hyperparathyroidism is crucial in preventing devastating bony deformities in those predisposed to Sagliker Syndrome.

PUB565

Serum Calcitriol Concentrations and Kidney Function Decline, Heart Failure, and Mortality in Community-Living Persons: The Health, Aging, and Body Composition Study Umut Selamet,[1] Ronit Katz,[2] Dena E. Rifkin,[1] Linda F. Fried,[3] Stephen Kritchevsky,[4] Andrew N. Hoofnagle,[2] David A. Drew,[5] Tamara Harris,[6] Anne B. Newman,[3] Orlando M. Gutierrez,[7] Mark J. Sarnak,[5] Michael Shlipak,[8] Joachim H. Ix.[1] *[1]UCSD, San Diego, CA; [2]Univ of Washington, Seattle, WA; [3]Univ of Pittsburgh, Pittsburgh, PA; [4]Wake Forest Sch of Med, Winston-Salem, NC; [5]Tufts Med Center, Boston, MA; [6]NIA, Bethesda, MD; [7]UAB Sch of Med, Birmingham, AL; [8]UCSF, San Francisco, CA.*

Background: Lower 25-hydroxyvitamin D concentrations have been associated with kidney function decline, heart failure (HF), and mortality, but calcitriol has been less studied as a risk factor in community-living individuals. We evaluated the associations of plasma calcitriol concentrations with kidney function decline, HF, and mortality in the Health ABC Study of participants aged 70 to 79 years.

Methods: We used a case-cohort design and we measured baseline calcitriol in a random sub-cohort of 479 participants, and also among incident cases with kidney function decline (≥ 30% decline in eGFR from baseline [n=397]) and HF (n=207). In addition, 136 of the 479 participants in the sub-cohort died during 8.6 years mean follow-up.

Results: After adjusting for demographics, kidney function, traditional cardiovascular risk factors, calcium, phosphate, intact parathyroid hormone (iPTH) and fibroblast growth factor (FGF)-23 concentrations, each standard deviation (SD) lower calcitriol concentration was associated with 33% higher risk of kidney function decline (95% CI 1.07, 1.66; p=0.012) during 10 years follow-up. Calcitriol was not significantly associated with incident HF (HR 1.19 [0.94, 1.51]) or mortality (HR 1.05 [0.84, 1.30]) in adjusted analyses. We observed no significant interactions by chronic kidney disease status, or baseline iPTH and FGF-23 levels. We also evaluated associations of 25-hydroxyvitamin D with the same clinical end-points and in fully adjusted models, we did not observe statistically significant associations of 25-hydroxyvitamin D levels with any of the outcomes.

Conclusions: Lower concentrations of calcitriol were independently associated with kidney function decline but not with incident HF or mortality among community-living older adults.

The Impact of Smoking on the CKD-MBD Biomarkers Geuza D. Dos santos,[2] Rosilene M. Elias,[3] Emilia M. Soeiro,[2] Camila Dosse,[3] Luciene dos Reis,[3] Wagner Dominguez,[3] Fabiana Graciolli,[3] Giovanio V. da Silva,[3] Ivone B. Oliveira,[3] Vanda Jorgetti,[3] Maria Dalboni,[1,2] Rosa M. Moyses.[2,3] *[1]Universidade Federal de São Paulo, São Paulo, Brazil; [2]Universidade Nove de Julho, São Paulo, Brazil; [3]Nephrology, Universidade de São Paulo, São Paulo, Brazil.*

Background: Chronic kidney disease and smoking are considered a public health problem and are associated with an increased risk of cardiovascular disease. CKD-BMD also presents a high cardiovascular risk for CKD patients. However, the potential association of smoking and CKD-MBD is unknown. A previous study has shown that smoking habits among CKD patients is associated with higher serum c-terminal FGF-23, although the mechanism has not been elucidated. In this study, we aimed to confirm whether intact FGF-23 would be elevated in CKD patients who smoke. We hypothesized that an elevation of FGF-23 would be related to a decrease in serum Klotho or an increase in hypoxia inducible factor 1α (HIF1α). The latter is usually increased among smokers and has been recently described as a regulator of FGF-23 production, in experimental models.

Methods: We have evaluated 92 patients divided into three groups: Control without CKD, CKD stages III and IV on conservative treatment, and dialytic group, with smokers and non-smokers. We collected data from August 2016 to January 2017. Measurements of HIF-1α, Intact FGF-23 and Klotho were performed using commercial ELISA assays, according to manufacturers' protocols.

Results: Smokers performed less time of physical activity than the other groups. Serum phosphate was lower among patients on conservative treatment with smoking habits (3.10 ± 0.5 vs. 3.6 ± 06 mg/dl; $p < 0.05$). Serum uric acid was also lower in smokers, regardless the CKD stage (6.1± 1.5 vs. 6.8 ± 1.6 mg/dl; $p < 0.05$). No differences were found for calcium, 25-vitamin D, parathormone or alkaline phosphatase. FGF-23 was higher in dialysis patients than in conservative patients, but no differences were found between smokers and non-smokers. There were not any significant differences in Klotho and HIF1α levels among these groups.

Conclusions: We found no argument to support our preliminary hypotheis, as there were no significant differences in FGF-23, Klotho and HIF1α levels when comparing patients with and without smoking habits. As an aditional finding however, the effect of cigarette smoking on plasma uric acid and phosphate levels deserves further investigation.

PUB567

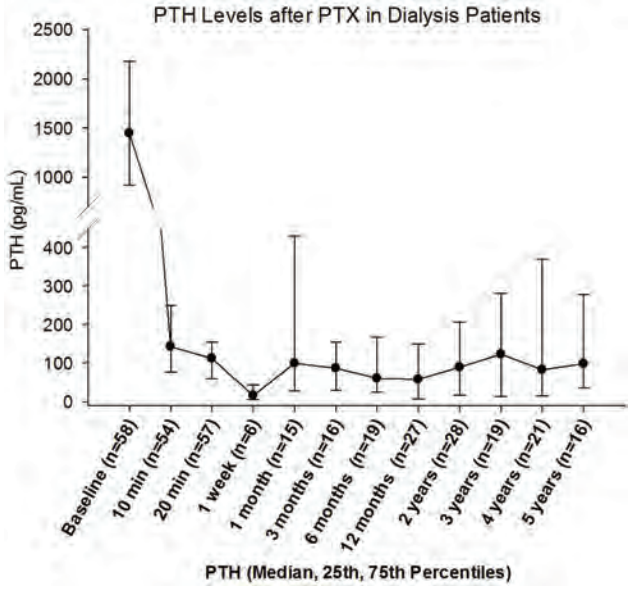
The Value of Intra-Operative PTH Assay during Parathyroidectomy in Dialysis Patients with Refractory Hyperparathyroidism Adeleye A. Edon, Kevin Wang, David Saxon, Florence Lima, David Sloan, B. Peter E. Sawaya, Amr E. Mohamed. *University of Kentucky, LEXINGTON, KY.*

Background: In dialysis patients with secondary and tertiary hyperparathyroidism (HPT), the correlation of intra-operative parathyroid hormone (ioPTH) measurement during parathyroidectomy (PTX) with long-term PTH level is unknown. The present study aims at evaluating the value of ioPTH measurements on long-term outcome of PTX in dialysis patients in a single center study.

Methods: The ioPTH was measured in 57 hemodialysis patients (33 females and 24 males) who underwent PTX between 2005 and 2015 because of refractory HPT. Near-total PTX was performed in 43 patients, total PTX in 15 patients (one patient underwent second PTX within 3 months because of failure of the first PTX). The ioPTH monitoring included 3 samples: pre-intubation (pre-ioPTH), 10- and 20-minute post PTX (10- ioPTH and 20-ioPTH). The patients were followed for up to 5 years (mean ± SD: 2.2 ± 2.1 years.

Results: The median (25th-75th percentile) pre-, 10- and 20-ioPTH levels were: 1447 pg/ml (969-2168), 143 pg/ml (78-244) and 112 pg/ml (59-153), respectively. There was no significant difference between 20-ioPTH and any subsequent PTH measurements (P=0.8, Figure). Sixteen patients (28%) were readmitted within 90 days due to significant hypocalcemia. One patient was readmitted for post-PTX hematoma evacuation. No patient required repeat PTX because of recurrent HPT.

Conclusions: The 20-ioPTH is a good indicator of long-term PTH values. Hypocalcemia is a common complication and the main reason for readmission after PTX. No patient required second PTX due to recurrent HPT.



PUB568

A Three-Year Experience with 201 Cases of Denosumab: Risk Factors and Precautions of Severe Hypocalcemia, Particularly in CKD Patients Rio Noto,[1] Hideki Yokoi,[2] Akihiro Yoshimoto,[1] Motoko Yanagita.[2] *[1]Kobe City Medical Center General Hospital, Kobe, Japan; [2]Kyoto University Graduate School of Medicine, Kyoto City, Japan.*

Background: Denosumab, a human monoclonal antibody to the receptor activator of nuclear factor-κB ligand (RANKL), has good evidence for preventing osteoporotic fragility fractures, so that the demand increases. On the other hand, cases of denosumab-associated hypocalcemia are reported more frequently.

Methods: We searched patients receiving denosumab from August 2013 to December 2016 in our hospital, and verified the frequency and risk factors of hypocalcemia.

Results: A total of 201 patients, including 84% female and 16% male, were treated by denosumab. The mean (±SD) age was 73.0 (±12.6) years, 28% of patients took steroid and 37% suffered from systemic autoimmune diseases. The baseline estimated GFR (eGFR, mL/min/1.73 m2) was as follows; ≧60 (67%), ≧45 to <60 (18%), ≧30 to <45 (8%) and <30 (7%). Adjusted calcium level decreased in 48%, increased or unchanged in 36%, and could not be compared in 16%. In 43 cases who underwent the second blood test within 2 weeks after injection of denosumab, lower baseline eGFR and steroid use were significantly associated with the decline of adjusted calcium levels (eGFR; p=0.0082, steroids; p=0.0157). Among them, 4 patients had side effects. eGFR of these patients was under 30 in 3 of 4 cases, one of which underwent intensive care, including artificial ventilator and intermittent hemodialysis, because of coma and acute respiratory failure induced by severe hypocalcemia. In every 4 cases, there was room for improvement for prescription. For example, a CKD patient was prescribed with natural vitamin D and calcium compounds as preventive medicine for hypocalcemia.

Conclusions: Renal dysfunction and steroid therapy were risk factors of denosumab-associated hypocalcemia. If denosumab is administered to patients with severe CKD, close monitoring and adequate supplementation of active vitamin D and calcium compounds is required to avoid the development of hypocalcemia.

Is the Efficacy of Nutritional Vitamin D (Cholecalciferol) Comparable to Active Vitamin D (Calcitriol) as Maintenance Therapy in Dialysis Dependent CKD Patients? (CHOLCAL) Chau Wang Ng,[1,2] Mathew C. Mathew,[1] Rajesh Raj.[1] *[1]Nephrology, Peninsula Health, Frankston, VIC, Australia; [2]Medicine, Launceston General Hospital, Launceston, TAS, Australia.*

Background: Dialysis dependent chronic kidney disease patients have reduced renal 1-α-hydroxylase and consequently insufficient active vitamin D activity, which is often manifested as hypocalcaemia. Calcitriol is traditionally used as not needing further renal conversion. However, it can cause increased phosphate absorption from gut. There is evidence of persistent extra-renal 1-α-hydroxylase activity in these patients. Hence, cholecalciferol has been proposed as potential alternative therapy. This study investigated cholecalciferol's efficacy in maintaining serum calcium in adult dialysis dependent chronic kidney disease patients.

Methods: This twelve-week pilot prospective interventional cohort study was conducted across three dialysis units in Northern Tasmania, Australia. Adult dialysis patients on pre-existing calcitriol with normal serum calcium were enrolled. Their calcitriol was then changed to cholecalciferol. Bloods including calcium, phosphate, parathyroid hormone, alkaline phosphatase, 25-hydroxyvitamin D_3 and 1,25-dihydroxyvitamin D_3 were sampled at baseline, 4-week, 8-week and 12-week post therapy change. Therapy success was defined as ability of cholecalciferol to maintain serum calcium, and the successful proportion was calculated.

Results: From February till April 2016, 112 patients were screened and total 13 patients were enrolled. 12 of 13 participants succeeded cholecalciferol therapy at end of study. When compared to baseline, there was no significant difference to serum calcium, phosphate and parathyroid hormone at end of study. There was statistically significant rise in serum alkaline phosphatase (mean increase 19.1 U/L, P=0.004) and 25-hydroxyvitamin D_3 (mean increase 24.7 nmol/L, P<0.001) at week 12. Serum 1,25-dihydroxyvitamin D_3 showed significant initial drop at week 4 (mean reduction 28.1 pmol/L, P<0.001) and week 8 (mean reduction 20.2 pmol/L, P<0.001), but exhibited no significant difference by week 12.

Conclusions: Cholecalciferol can maintain serum calcium in a worthwhile proportion of adult dialysis dependent chronic kidney disease patients.

Ultrasound Guided Ablation Therapy for Treatment of Severe Secondary Hyperparathyroidism Elias J. Baied, Marc J. Alonzo, Stuart M. Sprague. *NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: The successful management of severe secondary hyperparathyroidism in patients with chronic kidney disease (CKD) is difficult to accomplish with medical therapy alone due to complications of drug treatment, medication intolerance and non-compliance. Thus, many patients still require surgical parathyroidectomy. Ultrasound guided percutaneous ethanol (US-EtOH) injection has been successfully used in a few centers, especially in Japan, however, widespread acceptance of this procedure has not yet occurred. The aim of this analysis is to review patients in our center who underwent US-EtOH therapy.

Methods: Charts of patients who underwent US-EtOH therapy between 2013 and 2017 were reviewed. Data analyzed included basic demographic information, pre-ablation parathyroid hormone (PTH), calcium (Ca), number of ablations, and 6-9 month follow up PTH and Ca concentrations.

Results: A total of 20 patients were identified, however, data was only available on 16 (5 males). Four of the patients were post-transplant, 1 undergoing hemodialysis and 11 with CKD. In 56%, PTH concentrations decreased by > 25 % at 8 ± 2 month. Mean Ca decreased from 10.4 ± 1.9 to 9.9 ± 0.07, p< 0.05.

Conclusions: US-EtOH therapy may be helpful in controlling secondary hyperparathyroidism in selected patients with CKD. Further experience and prospective studies are needed.

The Contralateral Kidney Is Protected against Fibrosis in Unilateral Ureter Obstructed (UUO) Rats Anders Nordholm,[1] Maria L. Mace,[1] Eva Gravesen,[2] Jacob Hofman-Bang,[2] Klaus Olgaard,[2] Ewa Lewin.[1] *[1]Department of Nephrology, Herlev Hospital, University of Copenhagen, Copenhagen, Denmark; [2]Department of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.*

Background: Emerging concepts propose that circulating factors released from an injured kidney, might cause vasculopathy, bone disease, and kidney fibrosis. We examined the expression of genes related to fibrosis and Wnt signaling in the contralateral, untouched kidney (CON) to unilateral obstructed kidney (OBS) in UUO rats with unilateral nephrectomized (UNX) and normal rats as controls.

Methods: UUO rats (n=48) were studied at 0, 2, 4, 6 hr, 1, 3, 4 and 10 days (D) in parallel with UNX control rats (n=30) and normal rats (n=6). Kidney expression *of Klotho, BMP7, TGF-β, Periostin, Sclerostin, DKK-1 and ActivinA* were examined as well as plasma (p) levels of Sclerostin and ActivinA.

Results: *ActivinA* mRNA was undetectable in normal kidney but highly induced in OBS (Baseline:0.09±0.01, D3:1.38±0.22, D10:2.94±0.55, p<0.01). However gene expressions in CON were similar to that of UNX and normal kidney. P-ActivinA doubled at day 10 in UUO rats compared to baseline and UNX (B:217±14, UNX 10D:254±18, UUO 10D:413±44, p<0.001) indicating that ActivinA is released from the injured kidney. P-sclerostin was similar in UNX and UUO rats (B:142±18, UNX 10D:284±42, UUO 10D:313±60, p<0.05). Kidney *sclerostin* mRNA was undetectable in all groups indicating non-renal source of sclerostin. *DKK-1* mRNA was similar in OBS and CON. In the OBS kidney there was a down-regulation of anti-fibrotic factors *Klotho* and *BMP7* already at day 1 (p<0.001) but not at 0-6 hr. Simultaneously in the OBS kidney a progressive up-regulation of pro-fibrotic *TGF-β* and induction of *Periostin* were evident from day 1 (p<0.01). All genes were similar in CON, UNX and normal kidneys at all time points.

Conclusions: A rapid decrease in anti-fibrotic factors and an increase in pro-fibrotic factors is observed in the OBS kidney of UUO rats. Induction of ActivinA in OBS kidney may contribute to its elevated plasma levels and could potentially represent a circulating factor that drives kidney fibrosis. However, gene expressions of pro - and anti-fibrotic factors in the CON kidney are maintained normal, indicating protection against circulating fibrotic factors.

PUB572

Increased Bioactive Sclerostin Levels in Kidney Transplant Recipients Detected with a New and Well-Characterized ELISA Jacqueline Wallwitz,[1] Gabriela Berg,[2] Elisabeth Gadermaier.[1] [1]*The Antibody Lab GmbH, Vienna, Austria;* [2]*Biomedica, Vienna, Austria.*

Background: Over the past years there is an increasing knowledge about the relationship between mineral and bone disorder (MBD) and cardiovascular diseases in patients with chronic kidney disease (CKD). One of the key regulators identified in CKD-MBD is sclerostin a 190-amino acid glycoprotein, which is mainly secreted by osteocytes. It was shown that circulating sclerostin levels are increased in CKD-MBD patients. Sclerostin is an inhibitor of the osteoanabolic Wnt signaling pathway achieved by binding with its second loop to the LRP5/6 complex. The measurement of this bioactive site of sclerostin may be helpful to further investigate its role within CKD-MBD disease progression and in the assessment of therapeutic effectiveness.

Methods: We have developed an immunoassay for the detection of the bioactive binding site of sclerostin in human serum and plasma samples. The antibodies were characterized and assay performance was validated according to ICH and EMEA guidelines. Plasma concentration of bioactive sclerostin was measured in apparently healthy controls and renal transplant recipients.

Results: The recombinant monoclonal coating antibody recognizes an epitope within the second loop of sclerostin, whereas the polyclonal detection antibody has five linear epitopes distributed throughout the molecule. Both antibodies have good binding kinetics of k_{dis} of <1.0E-07 s^{-1} for the monoclonal antibody and 1.19E-05 s^{-1} for the polyclonal antibody, respectively. The validation parameters were within the required quality standards. Bioactive sclerostin concentration was significantly increased from 87 +/- 41.7 pmol/l (apparently healthy) to 166.5 +/- 68.0 pmol/l in renal transplant recipients.

Conclusions: This ELISA provides a reliable and accurate tool for the quantification of the bioactive site of the sclerostin molecule in healthy and diseased human and may give a new perspective within CKD-MBD research.

Two-Year Cortical and Trabecular Bone Loss in CKD-5D: Biochemical and Clinical Predictors Hartmut H. Malluche, Florence Lima, Marie-Claude M. Faugere, Conor Lowry, Daniel Davenport. *University of Kentucky, Lexington, KY.*

Background: This prospective two-year study of CKD-5D patients assessed cortical and trabecular bone loss at the hip and spine and examined potential demographic, clinical and serum biochemical predictors of bone loss.

Methods: Eighty-nine CKD-5D patients had baseline, year 1 and year 2 bone mineral density (BMD) measurements using dual X-ray absorptiometry (DXA) and quantitative computed tomography (QCT); concurrent blood samples were drawn and clinical variables recorded. No study treatments occurred.

Results: The two-year total hip BMD changes were -5.9% by QCT and -2.7% by DXA ($p < .001$). Spinal BMD was unchanged. QCT total hip cortical mass and volume decreased by -7.3% and -10.0%; trabecular volume increased by 5.9% (all $p < .001$). BMD changes did not vary with age, BMI, race, diabetes, smoking, or exercise. Patients with longer dialysis vintage and more negative baseline t-scores lost less BMD ($p < .05$, Figure 1A). Vitamin D analogs and phosphate binders were not protective against bone loss; cinacalcet was protective by univariate but not by multivariable analysis. CNS-affecting anti-hypertensives were protective against loss of BMD, cortical mass, cortical volume and trabecular mass (all $p < .05$, Figure 1B). These effects remained after adjustment for baseline t-score and dialysis vintage. BSAP correlated with changes in BMD, cortical mass and volume (all $p < .01$) as did sclerostin (inversely, all $p < .01$).

Conclusions: In CKD-5D patients, there is severe cortical bone loss at the hip best recognized by QCT. Patients with shorter dialysis vintage and less pre-existing bone loss lose more bone, calling for early diagnosis and treatment. BSAP and sclerostin are useful markers of bone loss. These are the first data showing a protective effect of CNS-acting anti-hypertensives against bone loss in these patients.

PUB575

Secondary Hyperparathyroidism Treated with a Novel Vitamin D Prohormone, Extended-Release Calcifediol, in a Renal Allograft Patient with CKD Jack E. Rubin. *Encino, CA.*

Background: Patients with advanced CKD have secondary hyperparathyroidism (SHPT), arising from vitamin D insufficiency and derangements of mineral and bone parameters such as caclicum, (CA), phosphorus (P). PTH elevation in these patients causes demineralization of bone and increases the risk of cardiovascular morvidity and mortality. While calcitriol and active vitamin D analogs are effective in lowering elevated PTH levels, they are associated with increased risk of hypecalcemia and hyperphosphatemia and increased FGF-23 levels. Addtionally, the problem of correcting vitamin D insufficiency remains unaddressed with these therapies. Rayaldee (extended-relase calcifediol, 25-OH-D3), a prohormone of the active form of Vitamin D3, has recently been approved by the FDA for the treatment of SHPT and vitamin D insufficiency in CKD stages 3 or 4, the only vitamin D producted indicated to treat elevated PTH and insufficient Vitamin D levels, correcting both disorders.

Methods: Here, I present a 57 year old African-American male who had a renal allograft placed 8 years ago and now has stage 4 CKD due to chronic allograft nephropathy. He also has type 2 diabetes mellitus, hypertension, hyperlipidemia, pulomonary artery hypertension, anemia of CKD and hypertension.

Results: His PTH reached its apex of 266 pg/ml on 11/7/16 and his Vitamin D level was at its nadir then at 20.1 ng/dl. He was then taken off calcitriol 0.25 mg and placed on Rayaldee, calcifediol ER (CER) 30 mcg hs. After 4 months of treatment on CER, on 4/27/17, his PTH fell to 97.2 ng/dl, a 36% reduction. His Vitamin D level rose to 36.7, a 83% increase. During this time period his serum creatinine increased from 3.3 mg/dl to 3.6 mg/dl, a 9% increase.

Conclusions: There are no case reports of CER being used to treat SHPT in renal allograft recpients with CKD in the literature. This patient had a reduction of his elevated PTH level of 36% with no untoward clinical events. As his PTH was significantly reduced, an expected amelioration of his bone-induced SHPT bone disease would occur. This case report shows that CER is a safe and more effective option to treat SHPT in renal allograft patients with CKD. However, a large randomized controlled study utilizing calcifediol ER for the treatment of SHPT in patients with renal allografts is needed.

PUB576

Effect of Cinacalcet Combined with Low Dose Calcitriol on Clinical Outcome and Bone Metabolism in Patients on Hemodialysis with Severe Secondary Hyperparathyroidism Fang Yuan,[1] Hong Liu,[3] Xing Chen,[1] Fu-You Liu.[2] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; [2]The Second Xiangya Hospital, Changsha, China; [3]Departments of nephrology, Second Xiangya Hospital Central South University, Changsha, China.*

Background: Secondary hyperparathyroidism(SHPT) is a common complication observed in maintenance hemodialysis (MHD) patients, characterized by multi system damage, calcium-phosphorus metabolism disorders and bone disease. Several clinical studies have confirmed that SHPT is closely related to the high risk of cardiovascular disease and mortality. Our study is To observe the clinical outcome and the effect of bone metabolism of cinacalcet hydrochloride combined with low dose calcitriol in MHD patients with severe SHPT.

Methods: Thirty MHD patients were enrolled to receive treatment of cinacalcet combined with low dose calcitriol, with inclusion criteria as follows: maintenance on HD>6 months;serum intact parathyroid hormone(iPTH)>600 pg/ml; parathyroid glands had more than 1 nodules by ultrasonography; traditional therapy is not effective. All patients were given cinacalcet 25-75 mg and 0.5 μg calcitrol dialy. Serum Ca, P, iPTH, bone metabolic markers and bone density were measured before and after treatment. The clinical symptoms and their improvement were investigated.

Results: The baseline levels of iPTH,Ca,and P were 1787.3±1321pg/mL, 2.54±0.19 mmol/L, and 2.06±0.15 mmol/L, respectively. After 2 weeks of treatment, serum phosphorus decreased by 20%; after one and three month, iPTH decreased by 35% and 70% compared with before treatment. Ca and P fell to 2.39±0.17mmol/L and 1.56 ±0.50mmol/L(P<0.05) after one month, respectively. The symptoms of the patients relieved. The above indicators remained stable after one year. Moreover, the bone metabolism index showed alkaline phosphatase, osteocalcin and β-Cross levels were decreased by 50%, 37% and 49% respectively than that before treatment after 6 months. Patients' bone density decline was inhibited. No severe adverse events were observed.

Conclusions: Cinacalcet hydrochloride combined with low dose calcitriol can improve high calcium, high phosphorus and high iPTH in MHD patients with severe SHPT, relieve symptoms, improve bone metabolism. It can be used as a favorable choice for the treatment of SHPT.

PUB577

Predictive Factors for PTH Control in Hemodialysis Patients with Secondary Hyperparathyroidism Treated with Cinacalcet in Real-World Clinical Practice: MIMOSA Study Pablo A. Urena,[3] Jacques B. Rottembourg,[5] Catherine Michel,[1] Abdelaziz Hamani,[4] HEBIBI Hedia,[2] Thomas Guincestre.[6] *[1]AURA, Paris, France; [2]nephrologist, THIAIS, France; [3]Dialysis, Clinique du Landy, Saint Ouen, France; [4]Hôpital privé Athis Mons, Athis Mons, France; [5]Paris, France; [6]Hopital Victor Provo, Roubaix, France. Group/Team: Study Group MIMOSA.*

Background: Secondary hyperparathyroidism (SHPT) is frequent in hemodialysis (HD) patients. Oral cinacalcet provides a way to decrease and control PTH but we lack real-life data based on KDIGO guidelines. Our goal is to assess the percentage of cinacalcet-treated HD patients for 12 months (M12) with controlled SHPT (PTH < 9xULN).

Methods: We performed a retrospective observational study in HD patients with SHPT treated by cinacalcet between 2005 and 2015 and dialyzed in 7 French HD centers using the HEMODIAL database.

Results: The study includes 1,268 patients with a mean follow-up of 21±12 months. Their mean dialysis vintage was 4.3±5.6 years. Phosphate binders were used in 335 (52%), active vitamin D in 289 (45%) patients throughout the study. Among the 645 patients with PTH values available at M12, 58.9% had controlled SHPT and 41.1% uncontrolled.

Conclusions: In this real-life study, 41% of HD patients with SHPT treated with cinacalcet retained a PTH above the KDIGO recommended target after 12 months of treatment. Apart from the possibility of non-compliance, the severity of SHPT appears to be a major factor, reinforcing the importance to treat SHPT at earlier stages.

PUB578

Possible Role of Hydroclorotiazide Suppressing PTH on Peritoneal Dialysis Antonio A. Portela Neto,[2] Lilian Cordeiro,[2] Erica A. Guimarães,[3] Benedito J. Pereira,[2] Hugo Abensur,[2] Rosa M. Moyses,[1,2] Rosilene M. Elias.[2] *[1]Universidade Nove de Julho, São Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil; [3]Universidade de São Paulo, São Paulo, Brazil.*

Background: In peritoneal dialysis (PD), there is a safety concern regarding influx of calcium (Ca), which becomes challenging while treating patients starting therapy with low parathyroid hormone (PTH). The use of low dialysate calcium concentration [Ca]d and the avoidance of Ca-based binders are recommended. Despite this, PD patients are more prone to have adynamic bone disease. We have assessed the behaviour of CKD-MBD markers in patients on PD, focusing on incident patients with PTH <150pg/ml.

Methods: Patients starting PD between January 2009 and December 2016 in an academic center, with demographic, clinical and laboratorial data available on alkaline phosphatase(AP), PTH, Ca, 25vitamin D and phosphate(P) were included.

Results: Sixty-nine patients (47±18 years, 46.4% male, 80% hypertensive, 23% diabetic) were included. Mean ionized and total Ca, and phosphate were 4.8±0.4mg/dl, 8.8±0.8mg/dl, and 4.7±1.2mg/dl, respectively. AP was 81 (67,119)UI/l and PTH was 226(98, 461)pg/ml. 25vitamin D was 19.9±9.6ng/ml (59.4% had levels <15ng/ml).[RC1] Patients who started PD with PTH<150pg/ml (N=28, 40.6%) presented higher iCa (p=0.036), higher glicemia (0.027), lower P (p=0.0001), lower AP (p=0.004), and a similar percentage of vitamin D deficiency (0.373) and diabetes (p=0.322), as compared to those with PTH>150pg/ml. None of the patients with low PTH were taking calcium-based binder and 3 have received low d[Ca]; after a median of 26 months of follow-up, 11 patients (39.3%) remained with PTH <150pg/ml. This subset of patients differed from those whose PTH increased because a higher percentage of patients were taking hydrochlotiazide (p=0.040) and because of a tendency toward avoiding low d[Ca] (p=0.06). Another additional 18 patients reduced PTH to as low as <150pg/ml, because hyperparathyroidism treatment. Neither clinical nor demographic characteristics, including the use of hydrochlotiazide differed patients whose PTH decreased overtime.

Conclusions: Besides traditional factors such as Ca-based phosphate binders, calcitriol and high d[Ca], hydroclorotiazide seems to supress PTH in patients on PD. Although this finding is already described in CKD on conservative management, further studies are warranted to confirm the mechanism in PD.

PUB579

The Usefulness of Fracture Risk Assessment through FRAX without BMD in Hemodialysis Patients Heeryong Lee, Woochul Lee. *Good Samsun Hospital, Busan, Busan, Republic of Korea.*

Background: According to the Improving Global Outcomes (KDIGO) CKD-MBD (chronic kidney disease-mineral and bone disorder) guideline update 2017, there is a recommendation that the risk of fractures in CKD 3a-5 stage patients can be evaluated by BMD (bone mineral density). The Fracture Risk Assessment Tool (FRAX) is a computerized algorithm that determines fracture probability by integrating important individual risk factors for fracture and mortality, with or without the addition of femoral neck BMD. We would like to evaluate whether FRAX without BMD can replace BMD in fracture risk assessment.

Methods: Total 56 dialysis patients aged 40 years or older were included in the study. The mean age was 61.06 ± 11.39 years and the duration of hemodialysis was 57.11 ± 57.33 months. We calculated the 10-year probabilities of fracture (%) using the Korean FRAX models with or without femoral neck BMD. We then performed comparative analyses 10-year probabilities of major/hip osteoporotic fractures depending on BMD values.

Results: The mean 10-year probabilities of major osteoporotic fractures and hip fractures using the FRAX model without BMD were 4.63 ± 3.08 % and 1.37 ± 1.48 %. When the BMD value was assigned to the FRAX, the 10-year probabilities of fracture were 5.31 ± 4.57 % and 1.90 ± 2.64 %. A statistically significant difference in major osteoporotic fractures was not observed for FRAX in individuals with femoral neck BMD versus without femoral neck BMD. Also there was no statistical significance in hip fracture (95% confidence intervals; p=0.22 and p=0.23).

Conclusions: This study showed that Even if BMD is not measured in hemodialysis patients, the risk of 10-year bone fracture can be predicted only through FRAX.

Mineral and Bone Disease Management in the Hemodialysis Unit: Improvement Care Model Fadwa S. Al-Ali,[2] Tarek A. Fouda,[2] Mohamed amin Khalil elesnawi,[2] Saifatullah Khan,[1] Tarek A. Ghonimi,[1] Abdullah Hamad,[1] Khulood Kasem,[1] Khulood Awadh,[3] Fadumo Y. Yasin,[4] Aisha Abdulla,[5] Rania A. Ibrahim,[1] Mohamed Y. Mohamed.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Hamad medical cooporation, Doha, Qatar; [3]Hamad Medical corporation, Doha, Qatar; [4]Hamad medical coorporation, Doha, Qatar; [5]HMC, Doha, Qatar*.

Background: Chronic kidney disease affects mineral and bone metabolism in Hemodialysis(HD) patients, so patients are often vulnerable to deterioration of mineral and bone disorder (MBD) long term complications that influencing morbidity and mortality. We developed a proactive interventional protocol to improve MBD management to achieve better PTH level control in HD population as per KDOQI/ KDIGO recommendation

Methods: We developed a new care model for MBD management (Nurse based model under nephrologist supervision)HD patients were selected randomly and gradually from Fahad Bin Jassim Kidney Center over 12 month of period. MBD blood laboratory parameter monitored (PTH, Ca, Po4 level as per protocol. Assigned dialysis nurse played important active role in the care coordination, planning, communication and education

Results: In March 2016 we started with 23 pts. And gradually increased number to 152 in March 2017. Percentage of pts. With target PTH level (150-300 ng/ml) increased by 23%. And the extreme PTH level (>800 ng/ml) decreased by 16%. The new care model also controlled the other parameters (Ca, Po4, and CPP). Minimize the utilization of special calcium dialysate bath

Conclusions: The new MBD care model was developed and implemented successfully. We achieved, and maintained patients within target PTH level (150-300 ng/ml)

Funding: Government Support - Non-U.S.

MBD care model

Criteria	care model (152 pts.)	control group (152 pts.)
Pts. in target PTH level (150-300 ng/ml)	40%	24%
Pts. in target carcium level (2.1-2.37 mmol/l)	68%	52%
Pts. in target phosphorus level (1.13-1.8 mmol/l)	59%	52%

Iliac Crest Biopsy Performed by Interventional Radiologists: A New Way to Improve Access to Bone Biopsy in Patients with CKD Lori Asselin-Thompstone, Fabrice Mac-Way. *Qu?bec, QC, Canada*.

Background: Mineral and bone disorder (MBD) is a major health issue among patients with chronic kidney disease (CKD). It is associated with an increased risk of fracture, cardiovascular disease and mortality. The 2009 Kidney Disease Improving Global Outcomes guidelines recommend performing iliac crest biopsies to aid in the diagnosis and management of CKD-MBD. Unfortunately, the procedure is rarely performed because many clinicians lack the technical ability required to carry out the intervention. In order to increase access to this procedure, we suggest that it be performed by interventional radiologists rather than nephrologists.

Methods: A nephrologist familiar with the procedure first trained two interventional radiologists at CHU de Québec - Hôtel-Dieu de Québec Hospital in November 2016. The Rochester bone biopsy kit was used and the samples were sent for bone histomorphometric analysis. In contrast to the traditional blind technique, radiologists used a new fluoroscopy-guided approach. This novel procedure provided direct visualization of the outer and inner cortical bone during the intervention (Figure 1). This standardized technique allowed for easier identification of the preferred bone biopsy site.

Results: All of the iliac crest biopsies currently being performed at Hôtel-Dieu de Québec Hospital are being carried out by interventional radiologists. So far, more than 10 fluoroscopy-guided biopsies have been obtained and no complications have been observed. There were no cases of pain, hematoma, infection or neuropathy following the intervention. Furthermore, all of the bone specimens were adequate and sufficient for analysis.

Conclusions: Iliac crest biopsies performed by interventional radiologists will increase nephrologists' access to bone specimens in patients with CKD-MBD. Moreover, the addition of a standardized, image-guided technique will lower the risk of possible complications.

Renal Osteodistrophy: A Weird Case of Leontiasis Ossea Emiliana Ferramosca,[2] Annarita Valletta,[1] Vilma Martella,[1] Marcello Napoli.[1] *[1]ASL Lecce - V. Fazzi Hospital, Lecce, Italy; [2]Nephrology Dialysis and Transplantation, ASL Lecce - V. Fazzi Hospital, Lecce, Italy.*

Background: Renal osteodystrophy (ROD) is a common complication in dialysis patients (pt), due to disorders of mineral and bone metabolism secondary to a longstanding hyperparathyroidism (HPT), resulting in both skeletal and extraskeletal consequences. The combination between high bone turnover and mineralization defects lead to an increased risk of bone fractures and deformities. ROD affects several sites (long bones, ribs, spine), but the cranio-facial localization is rather rare. At this site, the more dramatic pattern is *leontiasis ossea.* Radiological examination of the skeleton is a non-invasive tool for the identification of ODR, with high specificity but low sensitivity, since it only recognizes the advanced forms of the disease.

Methods: We report a case of a 45 y/o man on regular HD. History: coronary artery disease treated with CABG, hypertension, COPD, severe secondary HPT non responder to medical therapy, with parathyroid gland hyperplasia detected by ultrasound and scintigram. The pt presented vertebral osteoporosis with multiple vertebral collapses. His high cardiovascular risk contraindicated a parathyroidectomy. Due to the rapid onset of facies alterations, with macrognathia and severe facial deformity, the pt underwent cranio-facial CT. This test showed marked morphostructural bone alterations, with symmetrical bone remodelling, affecting both the trabecular structure and cortical one. At this level we found widespread erosions with symmetrical involvement of bone structures. Multiple lytic and sclerotic areas representing brown tumourss were also observed in the maxilla and mandible. This aspect was compatible with fibrocystic osteitis. Extensive vascular and soft tissue calcification were also found.

Results:

Conclusions: Todate, despite the numerous therapeutic options, high-efficiency dialysis, and parathyroidectomy, ODR still remains a complication in dialysis pt. Leontiasis ossea is a rare or maybe undiagnosed condition. Its early recognition is fundamental in order to intensify intervention strategies and improve pt outcome.

PUB583

Vitamin D and Stone Burden in Calcium Phosphorus Kidney Stone Formers Xuerong Wen,[2] Jie Tang.[1] *[1]University Medicine - Nephrology, Brown University, Providence, RI; [2]University of Rhode Island, Kingston, RI.*

Background: Vitamin D is important in regulating calcium and phosphorus homeostasis, but its effects on the risk of kidney stone and stone burden among calcium phosphorus (CaP) stone formers are not clear.

Methods: We conducted a retrospective cross-sectional study of a cohort of prevalent CaP stone formers, from a large academic hospital in Rhode Island. Both plasma 25-hydroxy-vitamin D (25D) and 1,25-dihydroxy-vitamin D (1,25D) were measured and the stone burden (calculated as the cumulative stone size) was assessed by ultrasound. The associations between plasma vitamin D measurements and kidney stone burden were assessed after adjusting for demographic and other clinical characteristics.

Results: A total of 36 CaP stone formers were identified for the study. Among them, 18 (50%) were female, 30 (83%) were caucasian, 14 (39%) had history of hypertension, 8 (22%) had diabetes, 14 (39%) had hyperlipidemia, 2 (6%) were taking allopurinol, 6 (18%) were taking potassium citrate, and 6 (18%) were taking thiazide diuretic. Mean body mass index (standard deviation (SD)) was 30.3 (6.9). The stone burden were higher in older subjects (p=0.003), among women (p=0.004), in those without hypertension (p=0.001), in those with hyperlipidemia (p=0.02), in those not taking allopurinol (p=0.001) or thiazide (p=0.006), and in those had either higher urine phosphorus (p=0.04) or lower urine citrate (p=0.001). For the final analyses, we included a total of 66 laboratory measurements of vitamin D, with corresponding other blood and urine tests as well as stone burden assessment. Mean plasma 25D (SD) was 26.4 ng/ml (9.9), mean plasma 1,25D (SD) was 58.1 pg/ml (16.6), and median stone burden was 6.6 mm (Interquartile range: 2.5 - 11.0 mm). Plasma 25D did not associate significantly with plasma 1,25D (p=0.7). Neither plasma 25D nor 1,25D showed significant associations with measurements of blood intact parathyroid hormone (p=0.8, 0.9 respectively), 24-hour urine calcium (p=0.5, 0.7 respectively) and phosphorus (p=0.8, 0.1 respectively), as well as CaP supersaturation (p=0.7, 0.3 respectively). Finally, neither plasma 25D nor 1,25D had significant effect on stone burden after adjustment for demographics and 24-hour urine sodium, potassium, pH, citrate, volume, and medication use (allopurinol, thiazide), p=0.3 and 0.4 respectively.

Conclusions: Neither 25D nor 1,25D, appears to affect kidney stone burden among prevalent CaP stone formers

MCP-1 and NGAL-Positive Urinary Extracellular Vesicles Associate with Calcium Oxalate Stone Former Status Robin S. Chirackal, Xiangling Wang, Muthuvel Jayachandran, Samuel Edeh, Zejfa Haskic, Majuran Perinpam, Timothy M. Halling, Ramila A. Mehta, John C. Lieske. *Mayo Clinic, Rochester, MN, Rochester, MN.*

Background: Randall's plaque (RP) appears to be an important precursor of kidney stone disease. However, RP cannot be noninvasively detected. Thus we investigated potential biomarkers on urinary extracellular vesicles (EVs) of stone formers (SFs) with high (≥ 5% papillary surface with plaque) and low (< 5% surface area) amounts of RP compared to controls.

Methods: RP were assessed via videotaping and quantitative image processing in 64 consecutive idiopathic calcium oxalate SFs undergoing percutaneous surgery for stone removal. Cell-free urinary EVs from SFs and controls (n=40) derived from different segments of the nephron were quantified in bio- banked urine by digital flow cytometry using fluorophore conjugated antibodies. Candidate protein biomarkers of renal fibrosis (MCP-1), injury (NGAL) and RP (OPN) were selected for study.

Results: Data are presented as median (25th, 75th percentile). Overall the number of EVs positive for MCP-1 and NGAL differed significantly in SFs compared to controls (Table), but not between low and high plaque SF. OPN-positive vesicles were similar in all 3 groups.

Conclusions: EVs carrying MCP-1 and NGAL may contribute to stone pathogenesis and /or reflect inflammatory or injury processes ongoing during stone formation. Hence further validation of EV associated biomarkers including MCP-1 and NGAL as a noninvasive tool to access those at risk of urinary stone disease are warranted.

Expression of urinary EVs positive for MCP-1 & NGAL among Controls vs Cases.

Nephron Segment	Marker 1	Marker 2	Controls (n-40)	Cases (n-64)	P-value
Proximal	MCP-1	URAT1	13.2 (3.4, 44.9)	4.6 (1, 21.1)	0.05
Thin Loop	MCP-1	AQ1	29.2 (7.6, 96.3)	5.0 (0.2, 26.0)	<0.01
Thick Loop	MCP-1	UROM	3.7 (1.5, 19.7)	3.4 (1, 12.2)	0.40
Distal	MCP-1	SLC12A3	2.1 (0.6, 10.2)	2.8 (0.6, 11.9)	0.96
Collecting Duct	MCP-1	AQ2	26 (8.3, 93.5)	16.2 (3.6, 67.3)	0.15
Renal Pelvis	MCP-1	CK-19	14.5 (3.2, 48.4)	2.5 (0.7, 12.2)	<0.01

Clinical Characteristics and Tolerability of ALLN-177 in Phase 2 Studies of Patients with Secondary Hyperoxaluria Sagar U. Nigwekar,[3] James E. Lingeman,[2] Gyan Pareek,[1] Annamaria T. Kausz.[4] *[1]Brown University, Providence, RI; [2]IU Health Physicians Urology, Indianapolis, IN; [3]Massachusetts General Hospital, Boston, MA; [4]Allena Pharmaceuticals, Newton, MA.*

Background: Secondary (2°) HOx is caused by excess oxalate absorption from diet due to enteric disorders (enteric HOx, EH) or is unexplained (idiopathic, IH), and can lead to kidney stones and other sequelae including oxalate nephropathy. Presently there are no approved pharmacotherapies for HOx. ALLN-177 is a novel oral formulation of crystalline oxalate decarboxylase that degrades oxalate in the gastrointestinal (GI) tract, thereby reducing urinary oxalate (UOx).

Methods: Three phase 2 trials have been conducted in patients with 2°HOx and history of kidney stones to evaluate effect of ALLN-177 on 24-hour UOx. In study 396, 16 subjects received 7500 u/meal of ALLN-177 3x/d for 4d. In study 649, 32 subjects were randomized to 1500, 3000 or 7500 u/meal ALLN-177 or placebo 3x/d for 7d, then crossed over to an alternate arm for 7d. In Study 713, 67 subjects were randomized to 7500 u/meal ALLN-177 or placebo 3x/d for 28d. In Studies 649 and 713, CT scans were obtained at baseline to assess kidney stone burden.

Results: A total of 115 subjects were enrolled across the three studies; mean age range was 54 -61 years; 70.4% were male and 33 (28.7%) had EH. Across Studies 649 and 713, subjects reported on average 7.6 stones in the past 5 years and had 2.3 stones on CT scan. Compared with IH, subjects with EH had higher baseline UOx (mean 98.9 vs 57.5 mg/24h) despite lower dietary oxalate intake (mean 248 vs 315 mg/d). EH patients also had more kidney stones on CT (2.85 vs 2.02). Across the studies, adverse events (AE) were reported in 50-56.3% of ALLN-177 subjects vs. 25-62.9% placebo. The most frequently reported AEs were GI AEs, with no notable difference in rates between ALLN-177 and placebo. There were no drug-related serious AEs or drug-related AEs that led to withdrawal in the ALLN-177.

Conclusions: Despite lower dietary oxalate intake, EH patients have higher UOx and more kidney stones than IH patients. The characteristics of subjects in ALLN-177 clinical trials highlight the need for an effective therapy, especially in EH patients. ALLN-177 was well-tolerated and has the potential to address this unmet need.

Polycystic Ovary Syndrome, Testosterone, and Urinary Stone Risk: A Matched Case Comparative Study Donald C. Fedrigon, Kareem Alazem, Sri Sivalingam, Juan C. Calle. *Glickman Urological & Kidney Institute, Cleveland Clinic, Cleveland, OH.*

Background: Polycystic ovary syndrome (PCOS), a common endocrine disorder characterized by androgen excess, has been suggested as a potential risk factor for kidney stone formation based on past evidence indicating a relationship between elevated testosterone and urinary stone risk. Our goal was to evaluate the relationship between PCOS, elevated testosterone, and stone formation from the perspective of stone composition and 24-hour urine metabolic stone risk.

Methods: We retrospectively identified 74 patients diagnosed with PCOS. A matched case cohort of female stone formers in our stone registry was generated at a 3:1 ratio, matched by age and BMI for a total of 222 control patients. Additionally, PCOS patient

data was compared based on normal and high testosterone categorization. Primary endpoints were 24-hour urinary metabolic panels and stone composition and both cohorts were compared using Pearson chi-square and Student T-tests. The PCOS-testosterone cohort was also compared using multivariable analysis adjusted for age, BMI, and metformin status.

Results: For the case-control cohort PCOS patients had both significantly lower urinary sodium excretion (p=0.015) and lower frequency of hypernatriuria (28.9% vs 50.9%, p=0.009). Within the PCOS-testosterone cohort, high testosterone patients had both significantly higher urinary citrate values (p=0.041, table 3) and significantly lower odds of having hypocitraturia (36.7% vs 54.2%, OR=0.2, p=0.042). These patients also had higher urinary sodium (p=0.058) with significantly higher odds of having hypernatriuria (40.0% vs 13.6%, OR=13.3, p=0.021). Stone composition analysis for either cohort did not reveal any statistically significant patterns.

Conclusions: When compared to matched cohort of healthy stone formers PCOS patients did not demonstrate significant enough changes in 24-hour urine and stone composition to indicate PCOS is an independent risk factor for stone formation. Elevated free testosterone in PCOS patients has a significant association with higher urinary citrate and sodium values; findings that in and of themselves do not confirm the hypothesized increased risk of stone formation. This patient cohort may provide deeper insight into the interplay between androgens and stone risk, however, further study is needed to fully confirm any hypothesized increased risk of stone formation in PCOS.

PUB587

A Pilot Randomized Study Comparing Blumea Balsamifera (Sambong) and Terpenes on Ureterolithiasis Rommel P. Bataclan. *Medicine, San Antonio District Hospital, San Antonio, Philippines.*

Background: Other agents have been proposed to be given in the management of kidney or ureteral stones. This study aims to investigate the safety and efficacy of *Blumea balsamifera* (Sambong) in comparison with a terpene combination drug as treatment for ureterolithiasis.

Methods: Patients with clinically stable kidney function and ureter stones of ≤5mm were randomised to receive a special terpene combination (Rowatinex®; 2 capsules three times daily) or Blumea balsamifera 500mg tablet (2 tablets three times daily). The study consisted of a 12-week active treatment phase, in addition to standard management. All patients had a physical examination, and diagnosis of kidney stones was made by ultrasound at baseline and after 6 and 12 weeks of treatment. Primary outcomes are change in stone size and stone-free status, defined as obviously successful expulsion of calculi/fragments, documented by ultrasound.

Results: After 6 weeks, 5 patients in the Sambong group and 6 individuals in the Terpene group were stone free (p-value 0.90). After 12 weeks, 6 in Sambong group and 8 in the Terpene group were stone free (p-value 0.31). In terms of stone size, there was significant decrease in the mean value of stone size after 6 weeks (1.81+2.01mm, p-value 0.008) and 12 weeks (1.12+1.43mm p<0.005) in the Sambong group, and also with the Terpene group (At 6 weeks 1.24+1.43mm, p<0.005; at 12 weeks 0.74+0.70, p<0.005). However, there were no differences between the two groups. Urine pH also significantly increased in both groups compared to baseline but no statistical difference when comparing both arms, Frequency of pain, hematuria, change in serum parameters were also not statistically significant and no other adverse events were noted.

Conclusions: Treatment with Blumea balsamifera and Terpene combination are well tolerated and safe in patients with Urolithiasis. Further studies may be warranted, with inclusion of other urine parameters.

	Stone Size (mm)		Stone Free		Stone Unchanged		Stone Decrease Size		Urine pH	
	Sambong	Terpene	Sambong	Terpene	Sambong	Terpene	Sambong	Terpene	Sambong	Terpene
Baseline	2.98±1.02	3.01±0.88							5.82±0.34	5.85±0.55
6 weeks (p vs baseline)	1.81±2.01 (0.008)	1.24±1.43 (<0.005)	5	6	3	1	9	11	6.64±0.30 (<0.005)	6.41±0.35 (0.02)
P-value in 2 groups	0.22				0.9				0.23	
12 weeks (p vs baseline)	1.12±1.43 (<0.005)	0.74±0.70 (<0.005)	7	8	3	3	8	6	6.64±0.14 (<0.005)	6.58±0.19

Oxalate Nephropathy: A Systematic Review and Individual Patient Data Meta-Analysis of Case Reports and Case Series Nuttha Lumlertgul,[1] Monchai Siribumrungwong,[2] Paweena Susantitaphong,[1] Bertrand L. Jaber.[3] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Lerdsin Hospital, Bangkok, Thailand; [3]St. Elizabeth's Medical Center, Boston, MA.*

Background: Little is known of oxalate nephropathy. The aim of this systematic review and individual patient data meta-analysis is to perform an in-depth review on the state of the evidence on oxalate nephropathy and its association with oxalate intake, and provide a more precise estimate of clinical characteristics and outcomes through pooling of aggregate data and analysis of individual patient data.

Methods: The following electronic databases were searched for relevant citations: PubMed, Ovid, and the Cochrane Central Register of Controlled Trials (inception to November 2016). We included case reports, case series, case control studies, and retrospective and prospective cohort studies that describe individual cases or cohorts of patients with evidence of biopsy-proven oxalate nephropathy in the setting of native or transplanted kidneys.

Results: Seventy-nine case report and case series (150 patients) were included. Twenty-three (15%) cases involved kidney transplant recipients. The mean age was 51.3±17.0 years. Increased dietary oxalate intake through excessive consumption is the most common cause (52%) followed by increased oxalate availability in the colon due to decreased intestinal calcium availability from fat malabsorption (47%), 3% resulted from decreased intestinal oxalate degradation due to decreased intestinal colonization with oxalate-degrading bacteria and only 1% resulted from increased colonic permeability to oxalate. Seventy-seven percent had acute kidney injury, 9% had acute-on-chronic kidney disease, 3% had chronic kidney disease and 11% had stones. Sixty percent needed dialysis and 29% had complete recovery, 25 % had partial recovery, 46% had non-recovery of kidney function and 31% required dialysis dependence. The mortality rate was 22%.

Conclusions: The main etiology cause was the increased dietary oxalate intake through excessive consumption. Most people had acute kidney injury, needed dialysis requirement, and did not have renal recovery. Therefore, the prevention should be considered.

PUB589

A Systematic Literature Review to Understand the Impact of Calcium-Containing Phosphate Binders and Sevelamer on Mortality and Cardiovascular Calcification in Patients with Kidney Disease Charles Piwko,[3] Elizabeth M. Uleryk,[4] Leora Kurtz,[1] Philip McFarlane.[2] *[1]CHP Pharma Inc, Thornhill, ON, Canada; [2]St. Michael's Hospital, Toronto, AB, Canada; [3]CHP Pharma Inc, Thornhill, ON, Canada; [4]E.M. Uleryk Consulting, Mississauga, ON, Canada.*

Background: Phosphate binders are pivotal in managing hyperphosphatemia in patients with kidney disease. Calcium containing phosphate binders (CPBs) may be effective and perceived to be less expensive but more likely to cause hypercalcemia, vascular calcification (VC) and mortality compared with non-CPBs, such as sevelamer. The objective was to compare the effects of phosphate binders on patients with chronic kidney disease and bone mineral disorders (CKD-MBD) in regard to VC and mortality.

Methods: A systematic literature search was conducted. Two independent reviewers identified and reviewed relevant references. Included were any peer-reviewed randomized studies that presented research on the impact of CPBs and sevelamer (hydrochloride or carbonate) on VC and mortality. Patients had to be >18 years. Papers in any language published after 1995 were accepted. Studies where outcomes of interest were part of pooled analyses or post-hoc analyses were excluded.

Results: From the 1,690 identified references, 17 and 5 studies that reported outcomes for VC and mortality, respectively, were included for data summary. Only 3 studies did not report advantages of sevelamer concerning CV calcification. In regard to (all-cause) mortality, all studies reported advantages of sevelamer versus CPBs.

Conclusions: Based on this literature review it can be concluded that sevelamer has advantages versus CPBs with respect to vascular calcification and mortality and should therefore be considered preferentially to CPBs for the management of hyperphosphatemia in CKD patients. Furthermore, a Rapid Response published by the Canadian Agency for Drugs and Technologies in Health suggests that sevelamer is less costly and more clinically effective than calcium-carbonate in all scenarios involving a subset of pre-dialysis or non-dialysis-dependent CKD patients.

Atypical Case of Calciphylaxis in a Renal Transplant Recipient Brittany L. Schreiber, Muhammad A. Mujtaba. *University of Texas Medical Branch, Galveston, TX.*

Background: Calciphylaxis is a rare, life-threatening condition with insidious onset and significant mobidity and mortality. Traditionally, it is associated with chronic kidney disease-mineral bone disease, hyperparathyroidism, high calcium phosphate product, and vitamin D administration. We present a unique case of calciphylaxis in a renal transplant recipient with normal renal function.

Methods: A 42-year-old female with a history of secondary hyperparathyroidism status-post parathyroidectomy and ESRD on hemodialysis for 10 years status-post renal transplant with normal renal function presented with a few week history of intractable lower extremity pain followed by a non-healing cutaneous ulcers 4 months after transplantation. Initially she was referred to dermatology and underwent a punch biopsy which showed epidermal and dermal necrosis with acute inflammation and leukocytoclasia. Infectious work up was negative. One week later she was admitted to the hospital for worsening pain and presence of new ulcerations. Repeat punch biopsy at that time showed results consistent with prior biopsy. She received a taper of steroids and was discharged with wound care and analgesics. For the next 2 months, she was admitted multiple times with extensive work-up including vascular studies, bone scan, and EMG/Nerve conduction studies performed for lower extremity pain and weakness, all of which were unremarkable. Despite low intact-PTH and calcium-phosphate product levels ranging from 13.7 to 20.4 pg/mL and 20.8 to 36.5 respectively, based upon high clinical suspicion a diagnoses of calciphylaxis was entertained and the patient was started on sodium thiosulfate. A repeat punch biopsy was performed which revealed vascular congestion in the dermis and subcutis with focal calcification consistent with a diagnosis of calciphylaxis.

Results:

Conclusions: A diagnosis of calciphylaxis should be considered as part of the differential for ulcer in post transplant patients despite normal renal function and calcium phosphate product. Recognition and diagnosis with prompt initiation of therapy in a setting with high clinical suspicion is crucial in patients with atypical mineral profiles or negative biopsy as delay in therapy can lead to worse outcomes with increased morbidity and mortality.

PUB591

Calciphylaxis in Patients after Bariatric Surgery Charbel C. Khoury,[3,1] Lauren N. Ko,[4] Ravi I. Thadhani,[3,4] Sagar U. Nigwekar,[3,4] Daniela Kroshinsky,[2,4] Malcolm K. Robnson.[1,4] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: Calciphylaxis is a rare disease of dysregulated calcium-phosphorous metabolism predominantly seen in patients (pts) with CKD/ESRD. Recent observational studies have identified potential risk factors such as hypercoagulability, warfarin intake, as well as diabetes and obesity. However, calciphylaxis has rarely been reported in pts after bariatric surgery.

Methods: This study includes 9 pts with a history of bariatric surgery who were referred to the calciphylaxis clinic or admitted to the inpatient service at the Massachusetts General Hospital from 2012-2017. Data was abstracted from electronic medical records.

Results: Median age was 49 (IQR 44,65) years, 4 pts were women, and 8 were white. At the time of diagnosis, 1 pt had normal kidney function, 1 had AKI, 4 pts had CKD stage 2-3, and 3 pts were on maintenance dialysis (with a vintage of 6 months, 3 years, and 4 years). Bariatric surgery consisted of Roux-en-Y gastric bypass (n=6), sleeve gastrectomy (n=2), and laparoscopic banding (n=1). The mean (SD) maximal weight loss was 45.6 (3.7)%, excess body weight loss was 81.8 (8.1)%. Comorbidities included diabetes (n=5), NAFLD (n=5), hypercoagulable state (n=3). No pts were on warfarin. Laboratory testing was notable for a mean serum(SD) calcium level of 8.8 (1.4)mg/dL, phosphate 4 (1.2)mg/dL, 25-HO vitamin D 21.7 (13.9)ng/mL, and parathyroid hormone 173 (203.2)pg/mL. Calciphylaxis ulcers were located mainly on the abdomen, breast, and thighs. The lesions of 3 pts resolved following intralesional/intravenous sodium thiosulfate, 2 pts required surgical debridement. Three pts died; however the causes of death were unrelated to infection of their ulcers.

Conclusions: To our knowledge this is the largest series of pts with calciphylaxis following bariatric surgery. While calciphylaxis is thought to occur more commonly in women, our series had almost equal number of men and women. There were more pts with normal kidney function or early stages of CKD, and bone mineral disease markers did not reflect the nutritional vitamin D deficiency recorded. These findings, along with the significant weight loss noted suggests a potential role for nutritional deficiencies in the pathogenesis of calciphylaxis. Sample size and characteristics of pts included in our study limit generalizability to overall bariatric population and warrant examination in larger independent studies.

Ginkgo Biloba Extract Inhibits High-Phosphorus-Induced VSMC Calcification by Interfering with Sclerostin/Lrp4 Li Yao,[1] Jian Wang,[1] Tianhua Xu,[1] Zitong Sheng,[1] Lining Wang.[2] *[1]The First Affiliated Hospital of China Medical University, Shenyang, China; [2]The First Hospital of China Medical University, ShenYang, China.*

Background: To investigate whether Ginkgo biloba extract(GBE) inhibits high calcium-induced calcification of VSMC by interfering with sclerostin/Lrp4.

Methods: Extraction of SD rat aortic vascular smooth muscle cells(VSMCs) and identification. Divided into normal control group, high phosphorus induced calcification group(10mmol/Lβ-glycerophosphate + 50ug/ml ascorbic acid),high phosphorus induced calcification+GBE intervention group(10mmol/Lβ-glycerophosphate+50ug/ml ascorbic acid+0.5mg/ml GBE),and the medium was induced for 14 days. Vonkossa staining and alizarin red staining were used to detect the calcification of VSMCs. The expression of BGP mRNA was detected by real time PCR, the expression of sclerostin and Low density lipoprotein receptor relatd protein 4(Lrp4) was detected by western blot.

Results: Vonkossa staining and alizarin red staining showed that there was significant calcium deposition in VSMC calcification group compared with normal control group, and calcium salt deposition in GBE was significantly reduced compared with calcification group. The mRNA expression of BGP in VSMC calcified group was significantly higher than that in other groups ($P<0.05$) and it was significantly lower in GBE than that in calcification group ($P<0.05$). Western Blot showed that the expression of sclerostin protein in VSMC calcified group was significantly higher than that in other groups ($P<0.05$), and the expression of Lrp4 protein was significantly lower than that of other groups ($P<0.05$). The expression of sclerostin protein in GBE was significantly lower than that in calcified group ($P<0.05$), and the expression of Lrp4 protein was significantly higher than that of calcification group ($P<0.05$).

Conclusions: High phosphorus can induce VSMC calcification. Sclerostin/Lrp4 is involved in hyperphosphine-induced VSMC calcification and plays an important role. GBE can inhibit high phosphorus induced VSMC calcification by interfering with Sclerostin/Lrp4.

PUB593

Establishment of Novel Mouse Model to Exhibit CKD – Mineral and Bone Disorder Associated with Hyperphosphatemia Takashi Tani,[3,1] Hideo Orimo,[1] Akira Shimizu,[2] Shuichi Tsuruoka.[3] *[1]Department of Metabolism and Nutrition, Nippon Medical School, Bunkyo-ku, Japan; [2]Department of Analytic Human Pathology, Nippion Medical School, Bunkyo-ku, Japan; [3]Department of Nephrology, Nippon Medical School, Bunkyo-ku, Japan.*

Background: CKD - mineral bone disorder (CKD-MBD), which mainly represents medial arterial calcification (MAC) and renal osteodystrophy, is a serious complication and risk factor of CKD-related mortality. Our aim was to develop a novel mouse model of CKD using an adenine-fed procedure to investigate the clinical course of MBD.

Methods: Eight-week-old C57BL/6J male mice were assigned to the following groups: the control group, fed a standard chow for 6 or 12 weeks (C6 an C12); the CKD-normal phosphorus (NP) group, fed a chow containing 0.2% adenine, with normal (0.8%) phosphorus, for 6 or 12 weeks (A6 and A12); and the CKD-high phosphorus (HP) group, fed 6 weeks with the 0.2% adenine/0.8% phosphorus diet, followed by a chow with 1.8% phosphorus for 2 weeks, 4 weeks or 6 weeks (A6P2, A6P4 and A6P6). At sacrifice, aorta and femur bone were scanned by computed tomography (CT) imaging and were evaluated histologically, while plasma was drawn for biochemical findings. mRNA expressions of aortic lysates were quantified by qRT-PCR analysis.

Results: Blood levels of urea nitrogen and serum creatinine were elevated in both CKD-NP and CKD-HP group than control, while serum phosphorus and intact parathyroid hormone were significantly increased in the CKD-HP than CKD-NP mice and control. MAC was confirmed only in CKD-HP mice by histological (positive Von-Kossa and Alizarin Red staining) and CT imaging, and the volume of MAC increased with longer exposure to the high phosphorus feed. MAC formation in CKD-HP mice was associated with upregulation in runt-related transcription factor 2 (Runx2), tissue non-specific alkaline phosphatase (TNAP) and osteopontin (OPN), indicative of osteoblastic trans-differentiation of vascular smooth muscle cells. CT and histological imaging revealed that the cortex of the femur was particularly thinned in CKD-HP mice; significant depletion in mineral density/volume of the cortical bone of the femur in CKD-HP mice was observed.

Conclusions: Our results support a previously-reported strong influence of hyperphosphatemia for the formation of CKD-MBD. Our novel CKD-MBD model is enhanced by its recapitulation of CKD-MBD in patients with end-stage renal disease in practice, without any surgical or transgenic interventions. We expect this model to be of value advancing research in the field of CKD.

PUB594

Vascular Calcification and Cardiac Function According to Residual Renal Function in Patients on Hemodialysis with Urination Dong Ho Shin,[1] Jung-woo Noh,[3] Jeonghwan Lee.[2] *[1]College of Medicine, Hallym University, Seoul, Republic of Korea; [2]Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [3]Hallym University, Seoul, Republic of Korea.*

Background: Vascular calcification (VC) is common and may affect cardiac function in patients with end-stage renal disease (ESRD). However, little is known about the effect of residual renal function (RRF) on VC and cardiac function in patients on hemodialysis (HD).

Methods: This study was conducted between January 2014 and January 2017. One hundred six patients with RRF on maintenance HD for 3 months were recruited. We used residual renal urea clearance (KRU) to measure RRF. First, abdominal aortic calcification score (AACS) and brachial-ankle pulse wave velocity (baPWV) were measured in patients on HD. Second, we performed echocardiography and investigated new cardiovascular events after study enrollment.

Results: The median KRU was 0.9 (0.3 – 2.5) mL/min/1.73m^2. AACS (4.0 [1.0 – 10.0] vs. 3.0 [0.0 – 8.0], $p = 0.05$) and baPWV (1836.1 ± 250.4 vs. 1676.8 ± 311.0 cm/s, $p = 0.01$) were significantly higher in patients with a KRU < 0.9 mL/min/1.73m^2 than a KRU ≥ 0.9 mL/min/1.73m^2. Log-KRU significantly correlated with log-AACS (ß = -0.33, $p < 0.001$) and baPWV (ß = -0.23, P = 0.01) after factor adjustment. The proportion of left ventricular diastolic dysfunction (LVDD) was significantly higher in patients with a KRU < 0.9 mL/min/1.73m^2 than with a KRU > 0.9 mL/min/1.73m^2 (67.9 % vs. 49.1%, $p = 0.05$). Patients with a KRU < 0.9 mL/min/1.73m^2 showed a higher tendency of cumulative cardiovascular events compared to those with a KRU > 0.9 ml/min/1.73m^2 ($P = 0.08$).

Conclusions: RRF was significantly associated with VC and LVDD in patients on HD.

PUB595

Evaluation of Major Factors for Vascular Calcification in Patients with Hemodialysis Yoshihito Nihei, Hitoshi Suzuki, Masao Kihara, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Vascular calcification is the common complication in patients with end-stage of kidney disease (ESKD) and is high risk of cardiovascular disease and stroke. In present study, we investigated the clinical parameters for vascular calcification in patients with hemodialysis.

Methods: The vascular calcification was quantified as an Aortic Arch Calcification Score (AoACS) by chest X-ray, as previously reported (Hemodial Int 2009). AoACS was measured in forty hospitalized patients with hemodialysis. Forty patients were divided into two groups depending on the AoACS; high AoACS group as ≥ mean + 1SD, low

AoACS group as < mean -1SD. The cause of ESKD, complications, age, duration of hemodialysis, serological data including Ca, P and intact PTH were analysed its association with AoACS.

Results: In high AoACS group, major causes of ESKD were mainly diabetes and nephrosclerosis. Meanwhile, the major cause in low AoACS group was glomerulonephritis. The high AoACS group had a long history of smoking, dialysis treatment, and hypertension. In addition, higher levels of P as well as product of Ca and P was significantly higher in the high AoACS group (P<0.05).

Conclusions: Vascular calcification is one of the major risks of cardiovascular diseases in hemodialysis patients and well associate with mortality. The strict management of hypertension and arteriosclerosis in addition to treatment of Ca and P are necessary to prevent the vascular calcification.

PUB596

1.25-VitD Is Independently Associated to CAC in CKD Patients

Janaina d. Ramalho,[3] Luz M. Gómez,[1] Isabela M. Bensenor,[4] Paulo Lotufo,[4] Rosa M. Moyses,[3,2] Silvia M. Titan.[3] *[1]Laboratory of Genetics and Molecular Cardiology, Heart Institute (InCor), São Paulo, Brazil; [2]Universidade Nove de Julho, São Paulo, Brazil; [3]Nephrology Division, Faculty of Medicine, University of São Paulo, São Paulo, Brazil; [4]Clinical Research Center, Universitary Hospital, University of São Paulo, São Paulo, Brazil.*

Background: Vascular calcification (VC) is highly prevalent in CKD patients and is an independent predictor of cardiovascular morbidity and mortality. CKD-MBD may contribute to VC. Although several studies have addressed the association of 25-VitD with VC, 1.25-VitD has been less studied.

Methods: CKD-MBD measurements and clinical data from 372 participants in the Progredir Study were used. CAC was assessed by CT. Univariable and multivariable logistic regression models on the risk of Agatston score ≥ 400 and gamma models using CAC as a continuous variable were built.

Results: Mean eGFR was 36 (IQR 26 – 46) ml/min/1.73m^2 and median CAC was 165 (IQR 7 – 784), with only 17% of participants with CAC of zero. As expected, higher CAC was associated to age, sex, race, diabetes, lipids and smoking. In the logistic regression and gamma models, 1.25-VitD (inversely) was significantly associated with CAC, while other CKD-MBD biomarkers like PTH and FGF-23 were not, even after adjustments for age, sex, race, diabetes and smoking. 1.25-VitD remained significantly and inversely associated with CAC after additional adjustment for 25-Vit D (Table1).

Conclusions: Our results demonstrate that 1.25-VitD is inversely related to CAC in CKD patients not on dialysis. The identification of ideal ranges of 1.25-VitD and the benefits of strategies to achieve those levels in preventing and treating VC should be explored in future studies.

Carotid Calcium Score Is Associated with Coronary Calcium Score in Patients with ESRD on Hemodialysis

Chi-Young Choi,[1] Nam-Jun Cho,[1] Hyo-Wook Gil.[2] *[1]Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea; [2]Soonchunhyang university Cheonan Hospital, Cheonan, ChungcheongNam-do, Republic of Korea.*

Background: In patients with end-stage renal disease (ESRD) on hemodialysis (HD), the degree of coronary calcium score is associated with cardiovascular risk and mortality. Those with higher degree of carotid calcium score are known to have higher cerebrovascular risk and mortality. However, there is no study which evaluates a correlation between coronary artery calcium score and carotid calcium score

Methods: This is a cross-sectional study involving ESRD patients who were dialyzed in Soonchunhyang Cheonan Hospital and agreed to participate in the study. Brain computed tomography (CT) and heart CT were performed to evaluate the carotid and coronary calcium score, and the routine laboratory data in artificial kidney center were analyzed.

Results: Total 49 patients were included. A mean age of the group was 58.5 ± 12.1 year, and a mean duration of HD 67.7 ± 44.2 months. Serum calcium, phosphorus, intact parathyroid hormone, and alkaline phosphatase (ALP) levels were 8.9 (8.6 – 9.1) mg/dL, 4.1 ± 1.4 mg/dL, 241.5 ± 173.9 pg/mL, and 63 (46 – 87) IU/L, respectively. Carotid and coronary calcium score were noted as 125.7 (23.3 – 366.7) and 172.6 (7.2 – 798.7), respectively. The patients were divided into two groups, < 50 or ≥ 50 percentile, based on carotid calcium score. Among the variables, there was a significant difference in age (< 50 percentile, 51.5 ± 8.9; ≥ 50 percentile, 65.2 ± 10.9 year) between the two groups. The partial correlation analysis showed that a correlation between coronary calcium score and carotid calcium score was statistically significant (r = 0.556, p < 0.001), when the age was set as confounding variables.

Conclusions: In patients with ESRD on HD, coronary calcium score was correlated with carotid calcium score in patients with ESRD on HD

Prevalence of CKD-Mineral Bone Disorder (CKD-MBD) in Mexico

Enrique Rojas-Campos,[1] Laura Cortes-Sanabria,[2] Clementina E. Calderon Garcia,[3] Alejandra Silva Ocegueda,[3] Alfonso M. Cueto-Manzano.[4] *[1]INSTITUTO MEXICANO DEL SEGURO SOCIAL, GUADALAJARA, Mexico; [2]Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; [3]Mexican Social Security Institute, Guadalajara, Mexico; [4]Zapopan, Jalisco, Mexico. Group/Team: Unidad de Investigación Médica en Enfermedades Renales.*

Background: CKD-MBD includes bone alterations (remodeling/mineralization), biochemical, (calcium, phosphorus, 25-OH-vitamin D, parathormone), and presence of extra bone calcifications. It is not completely known the epidemiology of MBD-CKD in México. Aim: To determinate the prevalence of MBD-CKD in our country.

Methods: Cross-sectional analytical study, performed in 333 patients with diagnosis of Chronic Kidney Disease with renal function replacement therapy whit hemodialysis or peritoneal dialysis, between January of 2014-June of 2016. There was no distinction between gender or causes of CKD. The comparisons were performed with c^2 or Student's T. A *p* value <0.05 was considered adequate.

Results: Fifty one percent (n 168) was men, 38% in hemodialysis and 62% in peritoneal dialysis. The prevalence of vascular calcification was 48%; hyperparathyroidism (PTH >300 pg/mL) was 62%, and the prevalence of deficiency of vitamin D (<15 ng/ml) was 27%.

Conclusions: The prevalence of vascular calcification was similar to the results of other national studies. The prevalence of hyperparathyroidism was close to two thirds. The deficiency of vitamin D was just in one of each four patients.

Coronary Artery Calcium (CAC) Score, CAC Volume, and CAC Density in Relation to Cardiovascular Disease (CVD) and Mortality in CKD Patients

Dai Lu,[1] Hideyuki Mukai,[1] Chen Zhimin,[1,2] Bengt Lindholm,[1] Jonaz Ripsweden,[3] Torkel Brismar,[3] Olof Heimburger,[1] Peter F. Barany,[1] Peter Stenvinkel,[1] Abdul Rashid T. Qureshi.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Djursholm, Sweden; [2]1st Affiliated Hospital College of Medicine, Zhejiang University, Hangzhou, China; [3]Medical Imaging and Technology, Karolinska Institutet, Stockholm, Sweden.*

Background: A high content of CAC measured by computed tomography (CT) associates with increased mortality with Agatston score of CAC being weighted upward for greater calcium density. However, increased calcium density in plaques may be CVD protective. Here we investigated association of CAC score, CAC volume and CAC density with presence of CVD and all-cause mortality risk in CKD patients (pts).

Methods: In 201 CKD pts (median age 56 years old, 66% male, 22% diabetes; 97 non-dialyzed, 104 on dialysis) who underwent multi-slice CT, CAC parameters (CACP) were estimated by *Calcium Scoring* (S). Framingham's CVD risk score (FRS) and CACP were analyzed as classifiers of CVD and as predictors of all-cause mortality. Agreement between CAC score and FRS was assessed by weighted kappa calculation. Kaplan Meier and multivariate Cox models evaluated association of mortality with CACP and FRS. During follow-up for a median of 25 months, there were 34 deaths.

Results: CAC score (S) and CAC volume (S) associated with FRS (rho=0.72), CVD (rho=0.43), hsCRP (rho=0.37) and IGF-1 (rho=-0.38; n=149) and various nutritional markers. CAC density was associated with male sex (rho=-0.20). In AUC calculation, classifier of CVD by CAC score (S) (AUC=81), Volume (S) (AUC=0.81) and Density (S) (AUC=0.70). AUC for predictor of all-cause mortality CAC score (S) (AUC=0.81), Volume (S) (AUC=0.81) and Density (S)(AUC=0.62). The ln(log) CAC volume and density scores in the same multivariate model, the lnCAC volume showed an independent association with all-cause mortality, with a HR of 6.93 (95%CI, 2.25-21.33) per 1-SD increase. Conversely, CAC density showed an independent inverse association, with an HR of 0.27 (0.08-0.93) per 1-SD increase.

Conclusions: Whereas high CAC volume predicted increased mortality, high CAC density independently associated with decreased mortality suggesting that CAC density should be considered in evaluations of CAC scoring.

Professionalism and Privacy of Pediatric Residents' Facebook Profiles Melinda Carpenter,[1] Katherine W. Herbst,[1] Cynthia J. D'Alessandri-Silva.[1,2] *[1]Connecticut Children's Medical Center, Hartford, CT; [2]Pediatrics, University of Connecticut Health Center, Farmington, CT.*

Background: Social media has progressed more rapidly than regulatory guidelines have emerged. Professional, regulatory and educational organizations have started to disseminate social media guidelines. This study's aim was to rate pediatric residents' Facebook profiles on privacy and professionalism.

Methods: Pediatric residency programs were randomly selected from the 2016-2017 ACGME list. Facebook was queried in May 2017 to determine if residents had private or public profiles. If public, profiles were reviewed for gender, residency year (PGY), residency program affiliation, and professional rating. Professionalism was rated as: 1) Professional (P)-no evidence of unprofessional content; 2) Potentially unprofessional (PU)-images of alcohol/tobacco in hand, political commentary, religious statements, or weapons; or 2) Clearly unprofessional (CU)-HIPAA violation, inappropriate language, binge drinking, drug use, racist or sexist content, and sexual content.

Results: Of 327 resident names searched, 232 (71%) had a Facebook profile. Neither gender nor year of residency was associated with having a profile (p>0.05). The majority (96%) of profiles were public with information from the bio "info" section, photo albums, friends, likes, groups and locations viewable. Almost half of residents (48%; n=111) affiliated with their current residency program. Three-quarters of the profiles were rated as professional (n=174). Of 55 profiles rated as unprofessional, over half (n=29) were holding an alcoholic drink and one quarter had images of alcohol. Three profiles were rated clearly unprofessional due to sexual and alcohol-related content.

Conclusions: Social media guidelines and institutional policies are needed in order to guide resident behavior as public posts could pose risk to themselves and their affiliated institutions. Facebook privacy features need to be reviewed and judiciously applied given the widespread popularity in current culture.

CT-Guided Renal Biopsy: A Useful Technique in the Hands of Trained Nephrologists Sadiq Ahmed,[1] Hani Alkhankan.[2] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.*

Background: Percutaneous kidney biopsy has a crucial role in the diagnosis & management of renal diseases. Nephrologists typically perform the biopsies with ultrasound but it is often difficult to biopsy the native kidney of an obese patient. On the other hand the CT-guided renal biopsies are much more precise. As obesity becomes an epidemic it is important for more nephrologists to learn the techniques of CT-guided renal biopsy. Here we share the experience of 42 consecutive CT guided native kidney biopsies performed by nephrologists in our center

Methods: The patient is placed in prone position. With a CT scanner the kidney is localized, overlying skin is marked and the distance to the surface of the kidney is measured. Skin is cleaned with antiseptic solution & draped. The skin and track to the renal surface is anesthetized with 1% Lidocaine. A 15G introducer is inserted up to the surface of the kidney with CT guidance. A 16G Biopsy gun is inserted through the introducer & 2-3 cores are collected. Post-biopsy patient rested for 8 hours with vitals monitored.

Results: All 42 patients had adequate samples. (Table) In 32 out of 42 Patients post-biopsy mean arterial pressure (MAP) remained unchanged compared to pre-biopsy. In 8 out of 42 Patients MAP dropped 10 mmHg post-biopsy and in 2 Patients it dropped 20 mmHg. Out of these 42 Patients 35 (> 83%) had less than 1 g/dl drop of hemoglobin (Hgb) measured on the following morning post biopsy. In 7 Patients Hgb dropped 1-2g/dl & in 1 other Patient it dropped > 2 g/dl. 2 Patients needed PRBC transfusion (4.7%) & 1 of them needed coiling of the bleeding vessel by the interventional radiologist. There was no loss of kidneys, injury to the adjacent organs or death. Average radiation exposure is 350-380 DLP.

Conclusions: CT-guided renal biopsies yield adequate tissue with acceptable complication rate even in morbidly obese patients. More nephrologists are encouraged to learn this technique as obese patients are commonly encountered. The renal fellowship training programs should incorporate performing CT-guided kidney biopsies in training of future nephrologists.

Awareness of AKI Risk Factors and Perspective toward Its Practice Guideline Numan Alabdan,[3,5] Abdelhameed Mohammed,[2] Rami Bustami,[4] Yousef A. Alrajhi.[1] *[1]KAMC-MNHGA-ksa, Riyadh, Saudi Arabia; [2]KSAU-HS, Riyadh, Saudi Arabia; [3]Pharmaceutical care, King Abdulaziz Medical City, Riyadh, Saudi Arabia; [4]King Saud Bin Abdul-Aziz University for Health Sciences (KSAU-HS), Riyadh, Saudi Arabia; [5]College of Pharmacy, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

Background: There is an increasing need for awareness of acute kidney injury (AKI) risk factors and its risk assessment because it is a crucial step towards early detection and possible intervention to prevent or minimize AKI and its associated adverse outcomes. Our aim is to assess awareness, and risk assessment of healthcare professionals regarding AKI risk factors. Also, to assess perspective toward Kidney Disease Improving Global Outcomes (KDIGO) AKI Practice Guidelines.

Methods: Cross sectional survey-based by using online survey program which let us to create a link that can be electronically mail it to a healthcare professionals (physicians and pharmacists) during Dec 2016 – Feb 2017 at King Abdulaziz Medical City (KAMC), Riyadh, Saudi Arabia

Results: 117 physicians and 135 pharmacists completed the survey. The vast majority of respondents were aged ≤ 38 years (78%), 57% were males, and had < 9 years of experience (70%). Among 25 risk factors of AKI and 15 drugs may cause AKI, there was a large variation between respondents in term of awareness of AKI risk factors and the drugs that may cause AKI e.g.96% were aware of nephrotoxic medication whereas 20% agreed on female gender and 92% agreed on aminoglycoside but 47% agreed on ciprofloxacin. In general, significantly higher percentage of physicians identified individual AKI risk factors than pharmacists, however significantly higher percentage of pharmacists identified individual AKI causing drugs than physicians. Variations were observed between the 2 professions and the profession level. Although the majorities face AKI cases in their practice (77%), only half of them do AKI risk assessment, 42% stratify patients' AKI risk according to their offending risk factors, or document AKI as past medical history. 71% agreed that practice guidelines improve patient outcome and 69% thought that these guidelines help standardized care and ensure that patients are treated in a consistent way.only 69 % defined AKI as per KDIGO AKI criteria. 87% did not receive any continuous medical educations hours on AKI.

Conclusions: While the majority of respondents had a positive perspective toward AKI guidelines, a large variation in awareness of AKI risk factors, risk assessment, and the drugs that may cause it was detected. Educational efforts are needed to raise awareness and knowledge to reduce the variation.

Formative Learning in Medicine Integrated to the Primary Health Care: Pedagogical Innovation for the Prevention of CKD in Brazil Joao M. Penido,[3] Adriana M. Figueiredo,[3] Maria Goretti M. Penido,[1] Thaís B. Finotti,[2] Allana S. Mamedio,[2] Aline S. Oliveira.[2] *[1]Pediatric Nephrology Unit, Department of Pediatrics, Federal University of Minas Geraisl, Belo Horizonte, Brazil; [2]Universidade Federal de Ouro Preto, Carangola, Brazil; [3]Federal University of Ouro Preto, Ouro Preto, Brazil.*

Background: Health education practices reflect the pillars of Primary Health Care. Health teams need to develop strategies to assist families and communities in understanding mechanisms for health assurance and disease prevention. The aim of this study is to present a educational strategy to prepare medical students and all health team to identify individuals at risk for developing chronic kidney disease (CKD).

Methods: Teachers from medical public school located in southeast of Brazil developed integrated teaching strategies to primary care units for CKD prevention. Those strategies were: health team training, education of the local community on CKD and its risk factors, a survey of the population at risk of becoming ill was conducted, educational videos and booklet for the population and health team on CKD and its risk factors.

Results: Medical students have learned on an integrated and contextualized situation how to clinically to identify kidney disease in the community, focusing on early detection and combining educational practices to promote family health as prevention of disease. Learning was meaningful and collaborative. Also, the medical team learned how to identify individuals at risk to developed chronic kidney disease.

Conclusions: Integrated and collaborative learning between medical students and the health team could be an essential tool for reducing the incidence of CKD in low-income population with difficult access to more developed centers. More studies are necessary to

improve the understanding about how to prevent the CKD and how to identify early risk factors for developing CKD.

PUB604

Lifestyle Management for People with CKD Suyuan Peng, Jiasheng Huang, Jiawei He, Yifan Wu. *The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China. Group/Team: Second Clinical College of Guangdong Provincial Hospital of Chinese Medicine.*

Background: Self-management program involves initiative participation in the daily care of their discomforted symptoms, medical treatments, as well as maintainance healthy lifestyles and prevention of progression of diseases for the patients with chronic diseases. Patient engagement and self-management are the cornerstones of optimal chronic disease management. These programs are designed to encourage patients to be expert patients so as to improve outcomes.

Methods: The Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, EMBASE, PubMed, Chinese National Knowledge Infrastructure(CNKI), China Biology Medicine disc(CBM), and China Biology Medicine disc and Chinese Scientific Journals full text database (CQVIP) were searched(up to January 2017) for randomized controlled trials (RCTs)assessing the effectiveness of lifestyles related self-management programs for people with chronic kidney disease(CKD) by two independent authors. Meta-analysis was conducted to compare the effects of interventions.

Results: Eight studies (n=585 patients) were included. Across these trials, Self-management programs resulted in a significant difference in glomerular filtration rate(GFR, Mean Difference 2.27, 95% CI 1.90 to 2.65 ml/min; I^2=4%). Compared with usual care only, the intervention resulted in -7.97(95% CI -1.82 to -1.58) and -2.98(95% CI -3.28 to -2.69)mmHg mean changes in systolic and diastolic BPs, with moderate heterogeneity across the included studies(I^2 = 42%, P = 0.18) and a mean change of -2.80(95% CI -3.31 to -2.28)mg/L in C-reactive protein(CRP) with no evidence of heterogeneity (I^2 = 0.0%, P =0.58). Meta-analysis results for total cholesterol(TC), low-density cholesterol(LDL-C) and hemoglobin failed to show a difference between the lifestyle related self-management intervention of CKD and the usual standard care.

Conclusions: To date, there have been very few randomized trials testing Self-management interventions targeting lifestyle care with the goal of delaying the progression of CKD. Those conducted to date have shown a clinically moderate but significant impact, longer follow-up is needed to determine if these findings will translate into delaying the progression of CKD. Suggesting that other strategies, or multi-faceted interventions, may be required to enhance the management of risk factors for patients with CKD in the community.

PUB606

Winning the Fight against a Progressive Hereditary Disease: An 87-Year-Old Patient with ADPKD Freddy R. Malpartida, Abhilash Koratala, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common inherited diseases that frequently progresses to end-stage renal disease (ESRD) at a relatively young age. Herein, we present a case of an 87-year old man with ADPKD in whom optimal management of risk factors for progression of chronic kidney disease (CKD) has halted the progression of his disease.

Methods: In 2001, a 71-year old Caucasian man was seen for flank pain after a fall. He was found with hypertension, renal dysfunction, and enlarged kidneys that were filled with innumerable cysts on the ultrasound as well as multiple cysts in the liver. Family history was positive for ADPKD; at least 2 of the siblings were known to have renal cysts (father had died at the age of 55 in an accident). He had no children. At that time, no family members were diagnosed with ESRD but over the next 10 years, one brother and one sister started dialysis. He quit smoking, was advised to increase his water intake to suppress cyst formation, and his hypertension was treated with an angiotensin-converting enzyme inhibitor (ACE-I) and a thiazide diuretic with optimal control. Three years later, he developed a hemorrhagic cyst that could be managed conservatively. Since then, the patient has been doing excellent: although he is 87 years old, the rate of progression of his CKD could be significantly reduced due to optimal management of risk factors (e.g. blood pressure 120-140/60-70, albuminuria 180 mg/g of creatinine, and bicarbonate level 25 mmol/L). His estimated glomerular filtration rate has reached 21 ml/min.

Results:

Conclusions: The severity of renal involvement varies considerably among ADPKD patients implying the importance of factors that are independently associated with worse renal outcomes (e.g. male gender and hypertension). Although clinical symptoms of renal disease can appear at any age, the first symptoms most often appear in the 4th or 5th decade and then progress rapidly; the mean age of ESRD has been reported between 56 and 69. This case represents one of the oldest patients with ADPKD whose CKD progression rate could be successfully reduced, underscoring the importance of modifiable risk factors in management of this hereditary disease that is known to be progressive.

PUB607

A Rare Side Effect of the Commonly Used Anti-Hypertensive Medication Indirakshi Jamalpur,[1] Abhilash Koratala.[2] *[1]Sri Padmavathi Medical College for Women, Tirupati, India; [2]University of Florida, Gainesville, FL.*

Background: Drug-induced gingival enlargement (DIGE) was first described in patients taking anti-convulsive drug, Phenytoin. The three most common classes of medications implicated are anti-convulsives, calcineurin inhibitors and calcium channel blockers (CCBs). In patients who are on predisposing medications, DIGE should be suspected when they present with enlarged gums.

Methods: A 50-year-old male has presented to the clinic complaining of enlarged gums in the upper and lower front jaws for 2 months. His medical history was significant for hypertension and diabetes mellitus type 2. He denied any fever, bleeding from the gums, loosening of the teeth, use of any prosthesis or dental braces. He did not have any history of dental procedures in the recent past. His medications included enalapril 10mg bid, amlodipine 10mg per day (for 6 months), sitagliptin 100mg per day and glipizide 20mg per day. Oral examination revealed marginal and interdental gingival enlargement, predominantly involving maxillary and mandibular anterior teeth [Figure 1A]. The enlargement was firm, non-tender with no bleeding on probing. Poor dental hygiene was noted. Laboratory tests were unremarkable including a negative HIV test. We diagnosed Amlodipine induced gingival enlargement and the patient showed slight but notable improvement in 4 weeks after switching amlodipine to long acting thiazide diuretic [Figure 1B].

Results:

Conclusions: While DIGE is a well-known side effect of CCBs, the incidence varies among different agents. For example, in a study by Ellis et al., the risk for developing clinically significant gingival enlargement was found to be higher in those treated with nifedipine (6.3%), compared to patients taking either amlodipine (1.7%) or diltiazem (2.2%). Treatment primarily consists of withdrawing the offending agent whenever possible in addition to maintenance of good oral hygiene. It may take from 1 -8 weeks for resolution of gingival overgrowth after discontinuing the drug.

PUB608

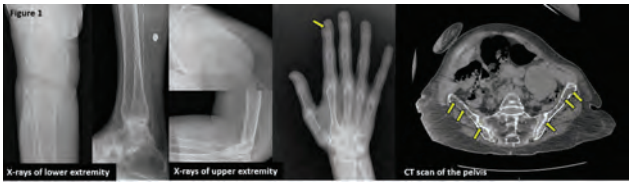
Forgotten, but Not Gone: Bone Manifestations of Secondary Hyperparathyroidism Muhannad Leghrouz, Abhilash Koratala, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: In the current era of early detection of chronic kidney disease and efficient therapeutic options for management of its complications, skeletal manifestations of renal hyperparathyroidism are increasingly rare. Herein, we present a case of secondary hyperparathyroidism that presented with brittle bones and characteristic radiographic changes.

Methods: A 31-year-old female patient presented for evaluation of pain in the left forearm, right hand, right knee, right hip and lower back following a fall sustained 3 days prior to presentation. She had a past medical history notable for ESRD on hemodialysis for the past 15 years, hypertension, diabetes, and congestive heart failure. She was wheelchair bound due to disabling diabetic neuropathy and chronic leg pain. She reported multiple prior fractures that were managed conservatively. Review of the medical records revealed that she had poor compliance with her diet, medications, and dialysis treatments. Labs were significant for marked elevation in serum parathyroid hormone level (1735 pg/mL) as well as hyperphosphatemia and normal serum calcium levels. X-ray images showed generalized severe demineralization of the extremities with the pelvic CT scan revealing presence of diffuse brown tumors [Figure 1]. In addition, she had insufficiency fractures of the extremities that left her incapacitated and had to be managed conservatively due to her poor functional status and ongoing severe hyperparathyroidism. Unfortunately, the patient refused surgical removal of the parathyroid glands and was hence treated with a high dose phosphate binder and a calcimimetic agent together with reinforcement of compliance.

Results:

Conclusions: Our case highlights the importance of metabolic assessment of patients presenting with unexpected bone complications and can be used to raise awareness of the physicians on the extreme cases of mineral bone complications secondary to renal disease that are observed rarely.



PUB609

Silent Hyperoxaluria Contributes to CKD Progression in a Patient with Short Bowel Myriam C. Vela-Ortiz,[2] Li Li,[4] Suzanne Boyle,[3] Suganthi Soundararajan.[1] *[1]Drexe lUniversity, Philadelphia, PA; [2]Nephrology, Drexel University, Philadelphia, PA; [3]Drexel University College of Medicine, Philadelphia, PA; [4]DrexelUiversity Colleg of Medicie, Philadelphia, PA.*

Background: Hyperoxaluria is common in patients with short bowel syndromes due to enhanced colonic resorption of soluble oxalate, which can result in symptomatic calcium-oxalate nephrolithiasis and nephrocalcinosis. There are also reports of subtle calcium oxalate crystal deposition contributing to progressive CKD.

Methods: A 75 year-old white female presented with elevated creatinine. She had a history of left nephrouretectomy and ileal resection secondary to urothelial carcinoma and carcinoid syndrome; HTN; and anxiety/depression. She reported frequent loose stools following meals for which she took diphenoxylate-atropine. She denied flank pain, dysuria, and kidney stones. She limited her liquid intake in order to reduce the frequency of bowel movements. Creatinine was 1.4 mg/dl prior to nephrouretectomy and gradually rose to 2.5 mg/dl over 4 years. Renal ultrasound revealed a 9.6 cm right kidney with normal echotexture and no nephrolithiasis. The left renal fossa was replaced by scar tissue. Kidney biopsy had hypertensive glomerular changes with moderate interstitial fibrosis and tubular atrophy. Few tubular oxalate crystals were present with focal extravasation into the interstitium with granulomatous inflammation. No immune complexes were detected. Discontinuation of a PPI, chlorthalidone, and fluoxetine and addition of a short course of steroids for the nephritis failed to improve the creatinine. A 24-hour urine assessment showed hypocalciuria; hyperoxaluria (63 mg/day; normal < 45); hypocitraturia; urine pH of 5.7; volume of 1.4 L.

Results:

Conclusions: Chronic calcium oxalate deposition in the tublointerstitium can lead to nephritis. While this patient's progressive CKD was multi-factorial, including hyperfiltration of a solitary kidney and HTN, the calcium oxalate crystal deposition was likely contributing. Despite a significantly reduced GFR, hyperoxaluria was evident on 24 hour urine collection. Due to the absence of symptomatic and radiologic nephrolithiasis, interstitial calcium oxalate deposition might otherwise be excluded from the differential diagnosis in this setting. This underscores that with ileal resection and CKD, hyperoxaluria should be considered. Early implementation of hyperoxaluric therapy might mitigate CKD progression

PUB610

Water Is Toxic Kartik Kalra,[1] Nabil Ghani,[1] Simranjit S. Randhawa.[2] *[1]Internal Medicine, Saint Peters University Hospital, New Brunswick, NJ; [2]Sir Ganga Ram Hospital, New Delhi, India.*

Background: Water intoxication can occur in a variety of clinical settings but is more commonly associated with chronic schizophrenics. The condition may go unrecognized in the initial stages when the patient may have symptoms of confusion, syncope and changes in psychotic symptoms. Early detection is crucial to prevent severe hyponatremia, which can be life-threatening. This is a case of a young schizophrenic male who had hyponatremia secondary to Psychogenic Polydipsia (PPD).

Methods: A 38 year old male with a 5 year history of seizure disorder currently on Levetiracetam/Oxcarbazepine and Citalopram, past history of schizophrenia admitted after syncope while micturition and mild confusion. Vitals and Physical examination on arrival in ER were not suggestive of volume depletion. Further questioning revealed patient had been drinking >5 liters water/day for a week. Labs revealed serum sodium(Na)-123 mEq/L, Creatinine-0.7 mg/dL, Serum osmolality(osm)-275 mOSm/kg, Urine osm-106 mOsm/kg, and Urine Na-18mEq/L. Given his labs, clinical history, and physical exam findings, hyponatremia was attributed to PPD. Water restriction was started and sodium corrected to 134mEq/L within 8 hrs. Patient was given DDAVP and D5W to reverse rapid correction. On day 2 sodium was stable at 134mEq/L, and patient was discharged home with education about need to avoid excess water.

Results:

Conclusions: PPD occurs in 25% of patients with schizophrenia. Pathophysiology is complex and multifactorial - malfunction of the hypothalamic thirst center likely contributes. It usually occurs in three phases- Beginning with polydipsia and polyuria, followed by hyponatremia (water is retained as the kidneys fail to excrete the excess fluid) and finally water intoxication leading to symptoms secondary to movement of fluid into brain cells. Symptoms range from confusion, vomiting, syncope and can eventually lead to seizures, coma and death. Differentials include other cause of hyponatremia especially SIADH. PPD usually has low urine osmolality in contrast to SIADH (Urine osm>100). Water restriction remains main stay of treatment. In severe cases, however, hypertonic saline solution is recommended. Sodium should be closely followed and rapid correction may have to be reversed with DDAVP to prevent osmotic demyelination syndrome. PPD thus is an unusual cause of hyponatremia that may go unnoticed without an appropriate clinical history that carries high mortality.

PUB611

Granulomatous Interstitial Nephritis in Diet-Controlled Crohn's Disease Kabir O. Olaniran,[2] Ivy A. Rosales,[2] Astrid Weins,[1] Nwamaka D. Eneanya.[2] *[1]Brigham & Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Crohn's disease (CD) is a chronic recurrent inflammatory condition with rare renal involvement. CD associated granulomatous interstitial nephritis (GIN) is even more rare and has only been described in a few case series and reports. CD associated GIN typically occurs in the setting of recent mesalamine exposure, new onset CD, or exacerbation of existing CD. We report a case of GIN due to CD in the absence of clinically apparent GI symptoms.

Methods: A 19-year-old male with a history of biopsy-proven CD and hypertension (HTN), both well controlled with dietary modifications, presented for a second opinion regarding acute kidney injury (AKI). One month prior, his serum creatinine (Cr) had increased from a baseline of 1.3mg/dL to 2.6mg/dL. He did not have recent nephrotoxin exposure, new or chronic medication use, chronic cough or acute illnesses. His physical exam was unremarkable, he was asymptomatic and normotensive (not on medications). Urine studies showed microscopic hematuria (1+) and microalbuminuria (48.7mg/g). Serum calcium, sedimentation rate and calcitriol levels were normal. Renal imaging with Doppler analysis was unremarkable. Serologic work-up for a nephritic process was negative. The kidney biopsy showed diffuse non-caseating granulomatous inflammation with no immune complex deposition or microorganisms. Vessels were unremarkable. Based on these findings, we determined that his GIN was due to CD. He received pulse steroids and his serum Cr decreased to 2.04 mg/dL. Due to steroid dependence, adalimumab was initiated. Steroids were tapered off and his serum Cr decreased to 1.6mg/dL after 5 months on adalimumab.

Results:

Conclusions: This case emphasizes the need to recognize and further explore the association between CD and GIN given the potential long term adverse renal outcomes if treatment is delayed. Early nephrology consultation may be advisable in CD patients with mild renal dysfunction or abnormal urine studies regardless of CD symptom control.

PUB612

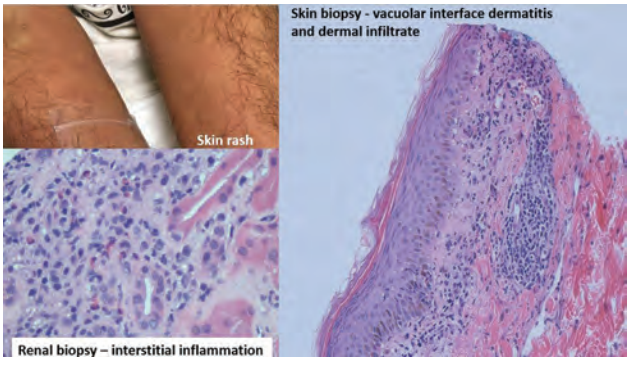
Cefepime Induced DRESS Syndrome without Eosinophilia S. Irfan Qadri, Xu Zeng, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Background: Approximately 60-70% cases of acute interstitial nephritis (AIN) are drug-induced. Multiple agents from different drug classes can cause AIN and the clinical presentation and laboratory findings vary based on the class of drug. We report a case of AKI and drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome without eosinophilia, associated with cefepime.

Methods: A 62-year-old man with poorly controlled diabetes mellitus developed osteomyelitis of the foot and was prescribed intravenous antibiotic therapy with vancomycin 1g every 12 hours and cefepime 6g continuous infusion for an intended duration of 6 weeks. The patient tolerated this regimen well until a few days prior to the end of therapy. He presented to the hospital with fatigue, anorexia, morbilliform rash and fever. Labs demonstrated AKI with a SCr of 3.6 mg/dL (baseline 0.8), transaminitis and leukocytosis. Peripheral smear revealed vacuolated neutrophils and atypical lymphocytes, but no eosinophilia. Urine microscopy revealed multiple WBC casts. He was diagnosed with DRESS. Serum complements were normal and was started on empiric steroid therapy with prednisone 1mg/kg/day. SCr continued to worsen requiring dialysis. After 10 days of prednisone therapy, the patient's renal function began to improve and he is currently off dialysis. Renal biopsy was consistent with AIN and skin biopsy with DRESS [Figure 1].

Results:

Conclusions: DRESS is an idiosyncratic hypersensitivity response to drugs defined by presence of at least 3 of the following findings: cutaneous eruption, fever, lymphadenopathy, systemic symptoms involving internal organs, hematologic abnormalities (atypical lymphocytes, eosinophilia). Cefepime is a rare cause of DRESS syndrome and can present without eosinophilia. Although there are no clear guidelines regarding dose and duration of steroid therapy, early initiation of steroid therapy has been shown to hasten recovery of renal function in drug-induced AIN.



PUB613

Adult Diagnosed Tuberous Sclerosis Complex with Renal Cell Carcinoma Amit Reddy,[2] John C. Henegan,[1] Teja Poosarla.[1] *[1]Hematology/ Oncology, University of Mississippi Medical Center, Jackson, MS; [2]Pathology, University of Mississippi Medical Center, Jackson, MS.*

Background: Tuberous sclerosis complex (TSC) is a rare autosomal dominant connective tissue disorder involving multiple systems that affects roughly 1 in 10,000 live births. Approximately 2-4% of people with TSC are diagnosed with renal cell carcinoma (RCC), typically with an onset 20 to 30 years earlier than in the general population. The diagnosis of TSC is established by either clinical findings (i.e. physical examination and/or radiological imaging) or the identification of a pathogenic variant in either *TSC1* or *TSC2*. The presentation of the disease varies substantially and because of this the diagnosis of TSC can be missed during childhood. Here we present a case of TSC diagnosed in an adult.

Methods: A 56-year-old African American female with history of end stage renal disease on intermittent hemodialysis, coronary artery disease, and RCC with a right nephrectomy 14 years earlier presented for a routine follow up. Physical examination showed multiple small lesions on her bilateral cheeks consistent with angiofibromas. CT scan showed multiple bilateral 2-3 mm scattered stable pulmonary nodules, evidence of a prior right nephrectomy, stable extensive mixed density masses in the left kidney, and persistent edematous changes with soft tissue infiltration into the left renal pelvis and proximal ureter with enlargement of a left retroperitoneal lymph node. Previous magnetic resonance imaging of the brain revealed a subependymal nodule. The presence of both the subependymal nodule and angiofibromas are major criteria for TSC, confirming its clinical diagnosis. Subsequently, the patient was referred for an echocardiogram and ophthalmic evaluation based on this new diagnosis.

Results:

Conclusions: Certain findings should prompt testing for hereditary syndromes when assessing patients with RCC, including bilateral/multifocal RCC, family history of RCC, certain renal tumor histologies, and clinical manifestations of known hereditary RCC syndromes. Clinicians should also consider hereditary RCC syndromes such as TSC in all patients with RCC diagnosed at an age less than 47 years-old, like the case presented. Many hereditary RCC syndromes have a subtle presentation which may delay their diagnosis. Identifying hereditary RCC syndromes is important as their diagnosis may lead to downstream testing for associated clinical manifestations as well as cascade family testing with appropriate genetic counseling.

PUB614

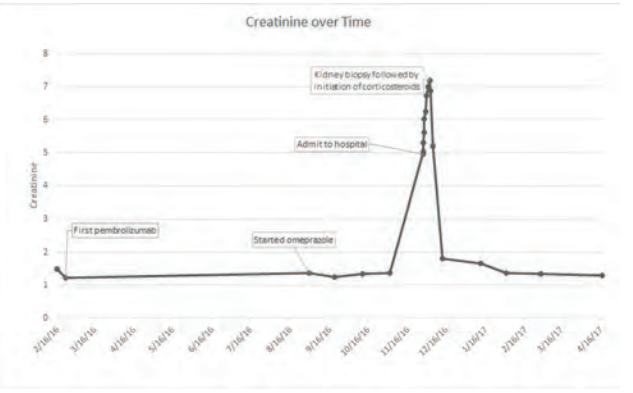
Acute Interstitial Nephritis in a Patient with Urothelial Carcinoma on Pembrolizumab: A Programmed Cell Death 1 Inhibitor Anthony N. Muiru, Patrick Ahearn, Thuy M. Nguyen, Santhi Voora, Diana Mina, Christopher A. Carlos, Yuenting D. Kwong, Terence W. Friedlander, Lawrence Fong, Meyeon Park. *UCSF, San Francisco, CA. Group/Team: UCSF First Year Fellows.*

Background: Pembrolizumab, a PD-1 inhibitor was recently approved for all solid tumors with a specific genetic biomarker. There are several case reports of PD-1 inhibitors induced acute interstitial nephritis (AIN) in the setting of lung, melanoma, and pancreatic cancers. We present a patient with AIN while being treated with pembrolizumab for urothelial carcinoma.

Methods: A 61-year-old man with a history of atrophic left kidney, CKD 3a, and urothelial carcinoma developed AKI. Nine months after starting Pembrolizumab serum creatinine increased from 1.3 mg/dl to 5 mg/dl (figure). His 14th cycle was held due to vomiting, diarrhea, and AKI, and he was hospitalized. Examination was notable for BP of 103/59 mm hg, HR 59 beats/min, and dry mucous membranes. Urine sediment showed non-dysmorphic RBCs, clumps of WBC, and no casts. Renal ultrasound showed mild right hydronephrosis and atrophic left kidney. A Foley catheter was placed for decompression. He was volume resuscitated, omeprazole and losartan were discontinued, but creatinine continued to rise. After discussion regarding the higher than typical risk, a kidney biopsy was performed. The biopsy revealed AIN. Corticosteroids were started with improvement in serum creatinine (figure).

Results:

Conclusions: Although rare, treatment with PD-1 inhibitors has been associated with AIN. Similar to previous case reports, our patient was also taking a second medication associated with AIN, omeprazole. Researchers hypothesize that PD-1 inhibition may lower the threshold for concomitant immunogenic agents like proton pump inhibitors to cause AIN. Despite high risk, biopsy was especially necessary prior to treatment of AIN in setting of chronic sterile pyuria related to urothelial carcinoma. Steroids and discontinuation of the PD-1 inhibitor have been shown to be effective in management of PD-1 induced AIN.



Creatinine prior to, during, and after hospitalization

PUB615

Calcified Vessels: A Disastrous Complication of ESRD S. Irfan Qadri, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Background: Calciphylaxis is a clinical syndrome of arterial calcification with resultant tissue necrosis, most commonly seen in patients with end-stage renal disease (ESRD) on dialysis. This condition carries a high mortality rate mainly due to infection. Helpful interventions include adequate dialytic therapy, medical management of hyperparathyroidism, hyperphosphatemia and intravenous sodium thiosulfate therapy. Herein we present a case with extensive arterial calcification associated with calciphylaxis.

Methods: A 54-year-old woman with obesity, diabetes mellitus and ESRD on hemodialysis presented with exquisitely painful lesions on her extremities. Examination revealed necrotic lesions at the tips of right index and ring fingers and toes, with surrounding inflammation. There was no obvious infection. Labs demonstrated serum calcium of 8.3 mg/dL (8.4-10.2), albumin 3.0 g/dL (3.5-5.0), phosphorus 7.7 mg/dL (2.7-4.5), and parathyroid-hormone (PTH) 348 pg/ml (150-300 for ESRD). Her PTH was apparently 'very high' several months ago. X-rays of the hand and foot revealed extensive arterial calcifications suggestive of calciphylaxis [Figure 1].

Results:

Conclusions: Risk factors for calciphylaxis include high calcium-phosphate product, elevated PTH, hypoalbuminemia, diabetes, obesity, warfarin use, female sex and protein C or S deficiency. Most lesions occur in legs though uncommon sites such as breast have been reported. It has been proposed that calciphylaxis and vascular calcification are a continuum of extra-skeletal osteogenesis and the clinical manifestations depend upon the location of the affected artery. Our patient was treated with sodium thiosulfate and intensification of dialysis regimen which resulted in modest improvement of the lesions.

PUB616

Not All That Is Black on Kidney Ultrasound Is Hydronephrosis Abhilash Koratala,[2] Deepti Bhattacharya.[1] *[1]University of Florida, Gainesville, FL; [2]Nephrology, Hypertension and Renal Transplantation, University of Florida, Gainesville, FL.*

Background: As point-of-care renal ultrasound is being increasingly performed by Nephrologists, it is important to have a thorough understanding of renal anatomy and the sonographic appearance of normal kidneys, including normal anatomical variants.

Methods: A 73-year-old woman with hypertension and heart failure has presented with generalized weakness for about 2 weeks leading to a fall at home. She was found to have severe hypercalcemia with a serum calcium of 16 mg/dl and acute kidney injury. CT scan of the chest was obtained to exclude malignancy. In addition to multiple pulmonary nodules, the upper abdominal slices of the scan demonstrated fullness of the left renal pelvis suspicious for hydronephrosis. Renal ultrasound was obtained to evaluate this finding, which demonstrated a large hypoechoic mass just outside the renal sinus but with no distension of the calyces or the ureter [Figure]. This finding was consistent with extrarenal pelvis, which is often confused with hydronephrosis.

Results:

Conclusions: An extrarenal pelvis is a normal anatomical variant that is predominantly outside the renal sinus and is larger and more distensible than an intrarenal pelvis that is surrounded by sinus fat. Extrarenal pelvis can easily be misinterpreted as hydronephrosis, especially on a quick bedside exam as it appears as a black mass. Close attention to detail can help differentiate between these two conditions. Hydronephrosis appears as branching, 'interconnected' areas of decreased echogenicity that show sonographic evidence of fluid. As the obstruction continues, renal parenchyma becomes compressed with loss of corticomedullary differentiation. On the other hand, extrarenal pelvis is not associated with dilated calyces, parenchymal thinning or hydroureter as in our case. In the figure, a medullary pyramid (line arrow) can be seen just above the central echogenic portion of the kidney suggestive of preserved corticomedullary differentiation and absence of compression. While extrarenal pelvis is asymptomatic in most cases, complications such as infection and stone formation have been reported.

PUB617

Escitalopram Induced Hyponatremia in a Young Post-Surgical Patient: Case Report Rommel P. Bataclan. *Medicine, University of the East Ramon Magsaysay Medical Center, Quezon City, Philippines.*

Background: Hyponatremia is a rare adverse effect of Selective Serotonin Reuptake Inhibitors (SSRI). These are medications given to individuals with Depressive Disorders and Panic Disorders. This presentation highlights the association of hyponatremia and use of Escitalopram in a post-surgical young patient without medical co-morbidities.

Methods: Patient is a 28-year old male who was admitted due to abdominal surgery from injuries incurred in a vehicular accident. Patient had panic attacks and was given Escitalopram. He was referred post-surgical due to restlessness and change of sensorium. Physical exam reveals a pale-looking patient with multiple abrasions and hematoma. He was drowsy, unable to respond from verbal cues. No focal deficits were noted. Serum Sodium was 121 mmol/l, Serum Osmolality 265 mOsm/kg, Urine Sodium 56 mmol/l and Urine Osmolality was 210 mOsm/kg. Rest of bloodworks and Cranial CT Scan were unremarkable. Escitalopram was discontinued, advised fluid restriction and 0.9% saline solution intravenously was given. Serum Osmolality was noted to be 265 mOsm/kg, Urine Sodium was 56mmol/l and Urine Osmolality was 210 mOsm/kg. On the initial 24 hours Escitalopram was discontinued, Serum Sodium was monitored three times, with values of 122, 124 & 125 mmol/l. Serum Sodium was normal (135 mmol/l), 72 hours after Escitalopram was discontinued. Diazepam was started as the anxiolytic drug, and patient's subsequent course was unremarkable and discharged on 15th hospital day.

Results:

Conclusions: SSRI-induced hyponatremia is attributed to a syndrome of inappropriate antidiuretic hormone (SIADH) secretion induced by a non-osmotic release of anti- diuretic hormone. Risk factors for SSRI-induced SIADH include advanced age, female gender, concomitant diuretics, hyperkalemia, baseline hyponatremia, and lower body mass index, all of which are not present in our patient. The only definitive treatment for drug-induced SIADH is removal of the offending agent. Most cases resolve promptly upon drug discontinuation. This case, together with the other previous reports highlight the need to monitor serum sodium and other electrolytes when anti-psychotic medications is started. Monitoring of serum sodium concentrations at baseline and 1 to 2 weeks after initiation of SSRIs may be warranted in individuals at risk of SIADH.

PUB618

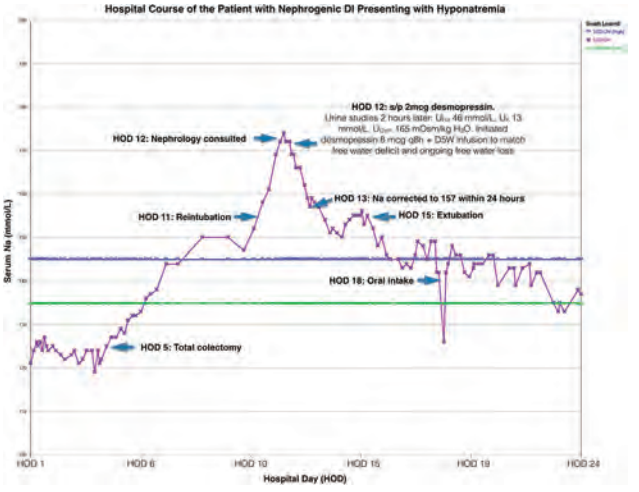
Hypovolemic Hyponatremia Masking Nephrogenic Diabetes Insipidus (DI) Maria Clarissa Tio,[1] Jiten Patel.[2] [1]*Department of Medicine, University of Texas Southwestern Medical Center, Dallas, TX;* [2]*Division of Nephrology, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: DI typically presents with hypernatremia and polyuria. We report a unique case of a patient with an unknown history of DI presenting with hyponatremia in the setting of abdominal compartment syndrome and septic shock.

Methods: A 50-year old white female with bipolar disorder, remotely treated with lithium, presented with a week of bloody diarrhea. She was found to be in severe septic shock from *C. difficile* colitis and AKI. On admission: Na 121 mmol/L, Cr 4.63 mg/dL, Serum osmolality 280 mOsm/kg H_2O, Urine Na (U_{Na}) <20 mmol/L, Urine osmolality (U_{Osm}) 298 mOsm/kg H_2O. She developed oliguria, acidemia, increasing pressor requirements, and respiratory failure. Bladder pressure was 21 cm H_2O. She underwent emergent total colectomy on hospital day (HOD) 5. Post-op, her renal function improved and urine output (UOP) increased to 4ml/kg/hr. Serum Na rose from 130s to 152 mmol/L and was managed with fluids and free water. On HOD 11, she aspirated and was reintubated. Serum Na increased from 152 to 174 mmol/L within 24 hours with concurrent 8L of UOP. Cr 1.14 mg/dL, U_{Na} 32 mmol/L, U_K 6 mmol/L, Uosm 107 mOsm/kg H_2O. Desmopressin (2 mcg IV) was given, 2 hours later: U_{Na} 46 mmol/L, U_K 13 mmol/L, U_{Osm} 165 mOsm/kg H_2O. Nephrogenic DI was diagnosed. Given the acute rise in Na, we lowered it equally rapidly to 157 with 5% dextrose (D5W) and supraphysiologic desmopressin (4 mcg q8h). Daily U_{Osm} measurements thereafter ranged from 120-180 mOsm/kg H_2O. The patient was successfully extubated on HOD 15 and tolerated oral intake on HOD 18. On HOD 20, serum Na was 142 mmol/L, desmopressin was stopped, and D5W was weaned off. Hydrochlorothiazide was initiated.

Results:

Conclusions: We report a case of nephrogenic DI presenting with hyponatremia from abdominal compartment syndrome and septic shock. Subsequent abdominal decompression, resolution of sepsis, and eventual loss of free water access from reintubation unmasked this previously unknown history of nephrogenic DI.



PUB619

Granulomatosis with Polyangiitis (GPA) Presenting as Renal Vasculitis in a Patient with Crohn's Disease Judi M. Graham,[1,2] Melissa S. Nataatmadja,[1,2] Linda G. DeLuca.[2] [1]*Nephrology, University of British Columbia, Vancouver, BC, Canada;* [2]*Nephrology, St Paul's Hospital, Vancouver, BC, Canada.*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA), most commonly perinuclear ANCA (P-ANCA), is associated with inflammatory bowel disease (IBD), usually without evidence of systemic vasculitis. We describe a case of GPA with Crohn's disease (CD) presenting as rapidly progressive glomerulonephritis.

Methods:

Results: A 51 year old man presented with fever and headache. Past history included chronic kidney disease with creatinine 120umol/L and normal urinalysis 6 months prior. CD was diagnosed 30 years earlier but had been quiescent for many years. On presentation, blood pressure was 187/87mmHg, creatinine 454umol/L, urine albumin/creatinine ratio (ACR) 66mg/mmol and dysmorphic erythrocytes seen in urine. C-ANCA was 160 and PR3 115U. Renal biopsy showed pauci-immune proliferative glomerulonephritis with a cellular crescent. Treatment commenced with intravenous then oral steroids, and oral cyclophosphamide- later replaced by rituximab due to bone marrow toxicity. Ten weeks later, creatinine was 197umol/L, PR3 10U, ACR 4.6mg/mmol with no urine erythrocytes.

Conclusions: CD, a granulomatous disease of the gut, may manifest extraintestinally as musculoskeletal, ocular, mucocutaneous and lung disease. In GPA, granulomas typically form in the respiratory tract and kidneys but involve the gut in 20-30% of cases. Thus, extra-intestinal CD may masquerade as GPA, and extra-pulmonary GPA as CD. ANCA, without evidence of ANCA-associated vasculitis (AAV), is well described in IBD however rare cases of these diseases occurring together have been reported; mostly with pulmonary involvement. One group reported coexistence of eosinophilic granulomatosis with polyangiitis (EGPA) with UC, and GPA with CD, but no cases of EGPA with CD, or GPA with UC. As with other autoimmune diseases, they may coexist in "clusters", thus there may be a yet unknown immune or genetic predisposition in affected individuals. Data suggests that EGPA and UC are both mediated by Th2. Conversely, both GPA and CKD are considered granulomatous diseases and primarily mediated by Th1. Future research may reveal more about the relationship of these diseases and could provide opportunities for gene based therapy. Currently, immunosuppression is the mainstay of therapy in both CD and AAV, however differentiating the two diseases is important to guide treatment, prognosis and risk of relapse.

PUB620

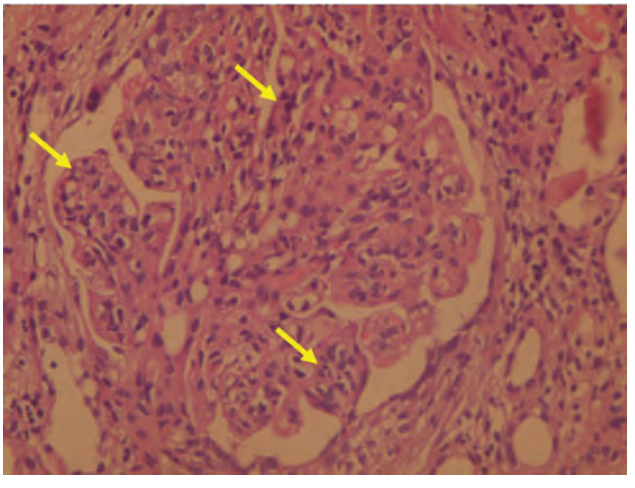
Diffuse Membranoproliferative Glomerulonephritis with Focal Sclerosis and Renal Amyloidosis in an Adult Male with Autosomal Dominant Dystrophic Epidermolysis Bullosa Karim M. Soliman,[1,2] David W. Ploth.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Nephrology, Cairo University, Cairo, Egypt.*

Background: Previous reports of glomerular disease in adult patients with autosomal dominant dystrophic epidermolysis bullosa are limited and include post-infectious glomerulonephritis, IgA nephropathy, amyloidosis and leukocytoclastic vasculitis. To our knowledge, membranoproliferative glomerulonephritis (MPGN) has not been described.

Methods: A 39 year old male with autosomal dominant dystrophic epidermolysis bullosa, presented with leg swelling of one week duration. There was no other significant past medical history. Physical examination was remarkable for scars and erosions over all body areas, all extremities with blisters and ulcers, bilateral lower extremity edema (Fig.1) and absent finger and toenails. Serum creatinine (Cr) was 0.9 mg/dl, albumin 1.3 gm/dL, and urine protein excretion 3.7 gm/24hr. Viral markers (Hepatitis B, C and HIV), C3, C4 and immune profile were all negative. Renal ultrasound and echocardiogram were normal. Renal biopsy showed fourteen glomeruli, all with proliferation of mesangial and endothelial cells and expansion of the mesangial matrix (arrows in Fig.2), focal segmental sclerosis, and amorphous homogeneous eosinophilic deposits which were positive with Congo red staining.

Results:

Conclusions: We recommend physicians consider the possibility of MPGN and secondary amyloidosis in patients with epidermolysis bullosa especially with the availability of new treatment modalities for the latter.



PUB621

Steroid-Free Regimen for Primary Membranous Nephropathy with High Antibody Titer Roxana A. Jurubita, Bogdan Obrisca, Bogdan M. Sorohan, Vlad T. Berbecar, Andreea Andronesi, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania.*

Background: Primary membranous nephropathy (pMN) remains a leading cause of adult nephrotic syndrome (NS). Multidrug regimens in patients with contraindications to corticosteroid therapy have never been evaluated. Additionally, patients with high antibody titer are less likely to obtain a spontaneous remission and would benefit from early immunosuppressive therapy (IS). Therefore, we report a case of pMN treated with cyclophosphamide and low-dose cyclosporine.

Methods: A 34-years old male is admitted with a relapse of the NS. His past medical history included pMN diagnosed 2 years ago and bipolar disorder that precluded the use of corticosteroids. Therefore the patient was started on cyclosporine (5 mg/kg/day), while being on adequate RAS blockade, and the clinical course was fluctuating with partial remissions and relapses of the NS (proteinuria levels between 3 and 10 g/day). However after 18 months of therapy the patient voluntarily stopped the cyclosporine and soon after the NS relapsed. At the time of admission he presented edemas, normal BP, while the laboratory results showed hypoalbuminemia (1,9 g/dl), proteinuria 8g/day and eGFR of 87 ml/min. The patient was started on monthly cyclophosphamide pulse-therapy (0.75 g/m2) and low-dose cyclosporine (100 mg/d), while being on adequate RAS blockade for the past 18 months. After 2 months of multidrug regimen, proteinuria and antibody titer significantly decreased to 1,3 g/day and 210 IU/ml, respectively. Subsequent check-ups are shown in the table.

Results:

Conclusions: The podocyte targeted effect of low-dose cyclosporine (rapid decline of proteinuria) in addition to the immunosuppressive effect of cyclophosphamide (decreased antibody titer) is associated with a rapid response in this particular patient. This multidrug regimen could be useful in patients with contraindications to corticosteroids and high antibody titer, but it needs to be validated in large clinical trials.

Patient Follow-up

Variable	Baseline	Month 1	Month 2	Month 3
eGFR (ml/min)	97	70	102	97
Serum Albumin (g/dl)	1.9	3.3	3.3	3.6
Proteinuria (g/day)	8	3.84	1.3	1.2
Anti-PLA2R antibody titer (IU/ml)	1041	770	210	198
Cyclosporine level (ng/ml)	30	26	28	21

PUB622

Oxalate Nephropathy Leading to ESRD Following Roux-en-Y Gastric Bypass Erika Drury, Ali Poyan-Mehr. *BIDMC- Division of Nephrology, Boston, MA.*

Background: Hyperoxaluria is a common and underappreciated complication of gastro-intestinal bypass surgeries. Calcium oxalate nephropathy is known to occur following jejunoilial bypass, and case series have reported oxalate nephropathy after Roux-en-Y gastric bypass. Here we report a case of calcium oxalate nephropathy occurring after Roux-en-Y gastric bypass for gastric adenocarcinoma leading to severe renal failure and end stage renal disease and outline potential strategies for prevention of future events.

Methods: An 83-year-old male with hypertension, type 2 diabetes mellitus, systolic heart failure (EF 45%), stage III CKD, and gastric adenocarcinoma status-post gastrectomy and Roux-en-Y esophagojejunostomy four months prior was admitted to our hospital with acute renal failure. He described new weakness, dysphagia, and loose stool. His creatinine was 9.3 mg/dL and arterial pH was 7.07. Renal ultrasound demonstrated a left-sided 1.3 cm non-obstructing stone. Urinary sediment showed rare renal tubular epithelial cells and granular casts. ANA, ANCA, C3, C4, SPEP, and UPEP were normal. He rapidly developed oliguria and uremia and was initiated on hemodialysis. Renal biopsy demonstrated advanced interstitial fibrosis, tubular atrophy, and calcium oxalate and calcium phosphate deposition. He never recovered renal function and was discharged on dialysis.

Results:

Conclusions: While hyperoxaluria is known to occur after gastric bypass, oxalate nephropathy and severe renal failure are less frequently reported. Our patient developed ESRD four months after surgery. Prior series have reported acute renal failure developing at a mean of thirty-three weeks after surgery. One study reported progression to ESRD within three months of identification of renal failure in 72% of patients. We identified several factors that may have contributed to this rapid and severe course including underlying CKD, diuretic use, post-operative AKI, diarrhea, and poor oral intake. In light of this case and prior reports, we propose the following considerations for patients undergoing gastric bypass: a) heightened clinical suspicion post-operatively, b) patient and provider education on the risks of hyperoxaluria and oxalate nephropathy, particularly in states of volume depletion, c) close monitoring of volume status and post-operative renal function, and d) early referral to nephrology, particularly for at-risk patients.

PUB623

Idiopathic Acute Renal Infarction Sandheep Venkataraman, Shruti Polu, Lin N. Lwin. *Montefiore Medical Center, Bronx, NY.*

Background: Renal infarction (RI) is a rare and under-diagnosed condition resulting from a sudden disruption of blood flow in the renal artery. Estimated incidence is about 0.004%– 0.007%. We report a case of RI presenting with no identifiable cause.

Methods: A 51 year old man with a history of hypertension, diabetes, and nephrolithiasis, presented with sudden onset, severe left flank pain radiating to the left groin. He had never smoked/used illicit drugs. He was afebrile and hypertensive(181/104 mm Hg) on presentation. EKG was normal. Labs: leukocytosis, high LDH(730 U/L) and CRP(33 mg/L). Urinalysis showed proteinuria and small blood. CT abdomen with contrast showed a region of non-enhancement in the left upper renal pole, suggestive of infarction. No aorto-renal vascular pathology was noted. Trans-esophageal echo was normal. Holter monitoring was uneventful. He had severe uncontrolled hypertension, requiring 4 medications including a calcium channel blocker. He was subsequently discharged on oral anti-coagulation.

Results:

Conclusions: RI usually occurs between the 6th and 8th decades of life. It commonly presents as abdominal/flank pain, nausea and vomiting, with leukocytosis, elevated LDH, and microscopic hematuria. Severe and difficult-to-control hypertension is often seen in these patients, which is thought to be renin-dependent due to renal ischemia. Most patients have a history of prior cardio-embolic events such as atrial fibrillation(AF), valvular heart disease, ventricular aneurysm, endocarditis, and dilated cardiomyopathy. AF is the most common risk factor, found in about 64% cases. Other possible etiologies include vasculitis, coagulopathies, aorto-renal vascular pathology, and trauma. However, the cause may remain undetermined in up to 29% of the cases. Clinical diagnosis of RI is difficult due to its non-specific presentation. Ultrasound is very low yield. Contrast-enhanced CT is the gold standard, which shows a wedge-shaped area of low attenuation within an otherwise normal appearing kidney. No clear treatment strategy for RI has yet been established. The current practice is to anticoagulate these patients similar to a patient with AF. However, the duration and mortality benefit is unknown given the scarcity of data available about this condition. In conclusion, RI must be considered in a patient with acute flank pain, and high levels of LDH, especially in the presence of risk factors for thromboembolic events.

PUB624

Malignant Hypertension/Thrombotic Microangiopathy: The Basis for Irretrievable Renal Failure in a Patient with SLE Brian R. Stotter,[1,2] Lisa Teot,[4] Ghaleb H. Daouk,[1] Seymour Rosen.[3,4] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Div of Nephrology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [3]Dept of Pathology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [4]Dept of Pathology, Boston Children's Hospital, Harvard Medical School, Boston, MA.*

Background: Renal vascular abnormalities are common in systemic lupus erythematosus (SLE) nephritis, but not part of the ISN/RPS 2003 classification. We present a case of SLE nephritis in a girl whose renal biopsies showed endocapillary proliferative glomerulonephritis, glomerular ischemia, and evolving vascular injury from acute phase intimal edema to occlusive intimal fibrous obliteration. These changes reflect injury from severe malignant hypertension/TMA.

Methods: A 16-year-old girl of African ancestry was admitted with arthralgias, blurry vision, edema, and BPs in the 190s/110s. Ophthalmologic exam revealed hypertensive retinopathy. She had anemia, thrombocytopenia, low C3 and C4, elevated anti-dsDNA titers, and AKI with sCr 1.7 mg/dL. She received steroids, MMF, and Cytoxan for induction. After two weeks, sCr peaked at 5.3 mg/dL and she started HD. Her first renal biopsy showed endocapillary proliferative glomerulonephritis with low level immune complex (IC) deposition consistent with SLE nephritis, but with extensive glomerular ischemia, intimal edema of the vasculature, and myofibroblastic proliferation in the interlobular arteries **(Figure A)**, consistent with malignant hypertension/TMA. A repeat biopsy after a course of eculizumab had similar glomerulonephritis, but the arterial changes became chronic and occlusive **(Figure B)**. Her BPs remained poorly controlled, despite maximizing five antihypertensive agents, and she underwent bilateral nephrectomy.

Results:

Conclusions: Disease burden in SLE nephritis is commonly classified by glomerular pathology and IC deposition. This case illustrates that in rare situations, malignant hypertension/TMA can drive disease progression and lead to chronic, irreversible renal vascular changes with poor renal outcomes.

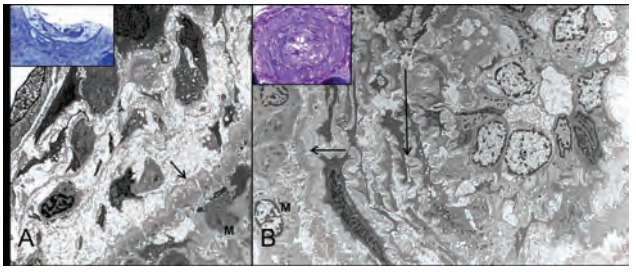


Figure A: First biopsy. Larger interlobular artery with edematous intima (arrow – internal elastic lamina; M – media). EM, inset 1 micron section.**Figure B:** Second biopsy. Interlobular artery with thickened occlusive intima (horizontal arrow – internal elastic lamina; vertical arrow – reduplicated elastica; M – media). EM, inset 1 micron section.

Renal Limited TMA in Patients with HSCT: Endothelial Variant of Graft versus Host Disease Nupur N. Uppal,[1] Rimda Wanchoo,[1] Douglas H. Allison,[3] Cristie Scott,[2] Meina Fung,[2] Richard L. Barnett,[1] Ruthee Bayer,[2] James M. Pullman,[3] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra Northwell School of Medicine, Great Neck, NY; [2]Hematology/Oncology, Hofstra Northwell School of Medicine and Northwell Health, Lake Success, NY; [3]Pathology, Montefiore Medical Center, Bronx, NY.*

Background: Thrombotic microangiopathy (TMA) and graft versus host disease (GVHD) are well-recognized complications of hematopoietic stem cell transplantation (HSCT). TMA in HSCT (TA-TMA) is preceded by endothelial injury triggered by chemo-radiotherapy, infections or immunosuppressive drugs. Recent data suggests that GVHD itself may be a trigger of TA-TMA. We report 2 cases where GVHD in HSCT was associated with renal-limited TMA.

Methods: A 58-year-old female with a second allogenic HSCT one year ago, and on cyclosporine treatment for gastrointestinal GVHD was admitted with acute kidney injury (AKI), worsening hypertension (HTN), nephrotic range proteinuria and early hemolysis. Serum creatinine (Scr) increased from 1 to 1.8mg/dl over 4 months. AKI worsened requiring dialysis despite discontinuation of cyclosporine. A kidney biopsy confirmed acute on chronic TMA with minimal fibrosis, and she received 2 doses of rituximab. AKI resolved over the course of 6 weeks. However, she expired due to sepsis. Another patient, a 58-year-old-female with a second HSCT on tacrolimus therapy for skin GVHD, had AKI 1 year after transplant with HTN, proteinuria, and signs of hemolysis. Scr worsened from 1.1 to 3.8mg/dl despite discontinuation of tacrolimus. A kidney biopsy revealed chronic TMA, with tubular reticular inclusion bodies (TRIs) without any viral etiology demonstrable by serology or immunohistochemistry.

Results:

Conclusions: A relationship between GVHD and TA-TMA has been previously described but is confounded by calcineurin inhibitor use, infections, heterogeneous study populations, and retrospective study designs. Our findings suggest a possible link between GVHD and TA-TMA. One patient's GVHD and TA-TMA improved following anti-B cell therapy (rituximab) and the other showed evidence of a high interferon state (TRIs), as seen in GVHD. Our results suggest that TA-TMA represents a form of "renal GVHD" or "endothelial GVHD". However, more research is needed to understand the exact mechanism of development of GVHD associated TA-TMA

PUB626

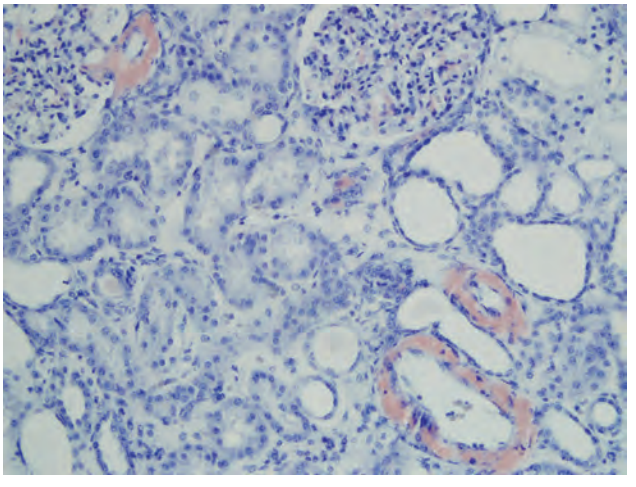
An Unusual Cause of Gross Hematuria Divya Raghavan, Monica P. Revelo Penafiel, Frederic Clayton, Mazdak A. Khalighi, Josephine Abraham. *University of Utah, Murray, UT.*

Background: Amyloidosis refers to the deposition of amyloid fibrils in various tissues. AL amyloidosis is seen in plasma cell dyscrasias.

Methods: A 42-year-old man was transferred from an outside hospital for persistent hematuria after a fall which had resulted in splenic laceration and proximal ureteral injury. He had undergone cystoscopy, embolization, and finally nephrectomy. His serum creatinine rose from 1.8 mg/dl on admission to 4.4 mg/dl by day 4. Urine dipstick was positive for protein and blood. Ultrasound showed right hydronephrosis and he underwent cystoscopy, bladder biopsy and ureteric stent placement. His renal function worsened, necessitating dialysis. Immunofixation electrophoresis revealed an M-spike. Echocardiogram showed infiltrative cardiomyopathy. Bladder biopsy revealed vascular AL amyloidosis. Patient underwent endomyocardial biopsy followed by bone marrow biopsy. Renal function eventually improved and dialysis was stopped. The endomyocardial biopsy showed AL-lambda type amyloidosis. Nephrectomy tissue obtained from the outside hospital showed vascular amyloidosis. Bone marrow aspirate showed 10-15% plasma cells and focal vascular amyloid deposition. Patient was started on chemotherapy. He was readmitted a week later with a gastrointestinal bleed. He developed a cardiac arrest requiring resuscitation. Angiography showed bleeding from a branch of the inferior mesenteric artery and left renal stump. His condition worsened despite aggressive therapies, and the patient was transitioned to comfort care per family wishes. A post mortem demonstrated amyloidosis in the brain, lungs, lymph nodes, thyroid, stomach, bowel, liver, spleen, adrenals and testes in addition to the heart, kidney and bladder.

Results:

Conclusions: Gross hematuria is a relatively rare presentation of renal amyloidosis. Proteinuria (often nephrotic range) is the most common manifestation.



Kidney specimen with Congo red positive vascular deposits

PUB627

Tumor Lysis Syndrome with Extremely High Serum Uric Acid and Phosphate Abhilash Koratala, Hussain Aboud. *University of Florida, Gainesville, FL.*

Background: The tumor lysis syndrome (TLS) occurs when tumor cells release their contents into the bloodstream, typically in response to chemotherapy, leading to the characteristic findings of hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia. We report a case of TLS who presented with extremely high serum uric acid (34.6 mg/dL) and phosphate (32 mg/dL) and to the best of our knowledge, such high numbers were never reported before.

Methods: A 51-year-old woman with history of chronic lymphocytic leukemia (CLL) and hypertension has presented to the hospital with fatigue, nausea, vomiting and decreased urine output. She received the first cycle of chemotherapy one week ago, which consisted of Fludarabine and Cyclophosphamide. She was not taking her allopurinol and not able to stay hydrated because of vomiting. The patient was found to be having acute kidney injury with a serum creatinine of 12.3 mg/L (baseline <1) and was slightly hypervolemic. Other labs were suggestive of TLS [Table1]. In response to chemotherapy, the WBC count has dropped from 165 thou/mm^3 a month ago to 3.5. Interestingly, review of her renal ultrasound images revealed twinkle artefacts on color doppler, which possibly represent calcium phosphate deposits [Figure1, arrows]. She later improved with hemodialysis.

Results:

Conclusions: Patients at high risk for the tumor lysis syndrome need to be closely monitored with labs and should be instructed to seek medical attention immediately if they do not feel well. Initial low-intensity chemotherapy may be considered in suitable individuals for slower lysis of the cancer cells allowing renal homeostatic mechanisms to clear metabolites before they accumulate and cause organ damage.

Table 1: Labs at presentation

	Results	Reference range
White blood cell count (thou/mm^3)	3.5	4-10
White blood cell count (thou/mm^3) – one month prior to presentation	165.6	4-10
Hemoglobin (g/dL)	8.8	12-16
Platelets (thou/mm^3)	220	150-450
Sodium (mmol/L)	124	136-145
Potassium (mmol/L)	7.8	3.4-5.1
Chloride (mmol/L)	81	98-107
Bicarbonate (mmol/L)	8	22-30

A "Muddy Brown" Herring Mona Shaban,[1] Jeremy J. Sorkin,[2] Gerald A. Hladik,[3] Alexei V. Mikhailov,[1] Kawan A. Swain.[2] *[1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC.*

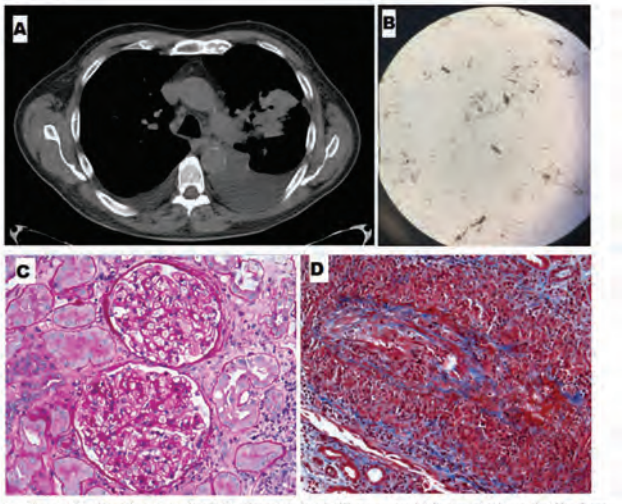
Background: Examination of the urinary sediment is a powerful tool in the diagnostic evaluation of acute kidney injury (AKI). However, the specificity of the urinary sediment exam is imperfect and can dissuade clinicians from considering alternative diagnoses. We present a case of ANCA-associated vasculitis manifest as AKI associated with muddy brown casts.

Methods: A 73-year-old man was seen in consultation for AKI. His serum creatinine (SCr) had risen from 1.2 mg/dl to 2.6 mg/dl. He was recently hospitalized with fever, hypoxia, and multifocal pulmonary infiltrates that initially improved with antibiotic therapy, however symptoms recurred. Follow up imaging revealed persistent multifocal infiltrates and bilateral pleural effusions (Figure 1A). Bronchoscopy demonstrated purulent exudate emanating from the left upper lobe without hemorrhage. The urinary sediment revealed 6 to 10 "muddy brown" casts per low power field (Figure 1B). PR3-ANCA was positive at >200 U/ml. Kidney biopsy showed severe, widespread necrotizing vasculitis, but minimal glomerular changes and only one small, segmental cellular crescent (Figure 1C/D). Immunofluorescence microscopy showed mesangial C3 deposition, but otherwise negative. These findings were in the spectrum of a pauci-immune ANCA-associated small vessel vasculitis. The SCr peaked at 4.2 mg/dl and patient required one hemodialysis treatment for hypervolemia. The patient gradually improved after implementation of corticosteroids, plasmapheresis, and IV cyclophosphamide. The SCr was 1.7 mg/dl at discharge and 1.4 mg/dl 6 months later.

Results:

Conclusions: ANCA-associated vasculitis can present with minimal glomerular involvement. In this case, the "muddy brown" casts were most likely indicative of "downstream" ischemic tubular injury resulting from severe vasculitis. This case highlights the importance of maintaining a high index of suspicion for underlying vasculitis in patients with persistent pulmonary renal syndrome even in the absence of glomerular hematuria.

Figure 1



A. Chest CT showing patchy left upper lobe infiltrate and bilateral pleural effusions.
B. "Muddy brown" casts seen on wet prep of urine sediment. Magnification × 100
C. Glomeruli with only minimal changes with minimal mesangial matrix expansion. One glomerulus of 28 showed a small segmental cellular crescent (not shown).
D. Dramatic segmental fibrinoid vascular wall necrosis and segmentally accentuated transmural inflammation with circumferential intimal lymphocytic infiltrates consistent with small vessel vasculitis. The lumen is obliterated by edematous intimal thickening.

PUB629

Light Chain Deposition Disease (LCCD) Manifesting as Monoclonal Gammopathy of Renal Significance (MGRS) in a Patient with B-cell Marginal Cell Lymphoma Leah M. McIntosh,[2] Barry M. Wall,[1] Geeta G. Gyamlani.[1] *[1]Veterans Affairs Medical Center, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: MGRS includes renal disorders caused by monoclonal immunoglobulin (MIg) secreted by a a clonal population of plasma cells or B-cells. Athough patients with MGRS often do not meet criteria for overt multiple myeloma or lymphoma, they can have significant renal disease due to MIg deposition. MGRS is associated with a wide spectrum of glomerulopathies, classified by type, localization, and organization of the deposited MIg. Kidney biopsy is indicated to determine the exact lesion and to evaluate its severity. Early recognition is crucial, as suppression of Mig secretion by chemotherapy often improves outcomes. We present a case of LCCD, manifesting as MGRS in a patient with B-cell marginal cell lymphoma.

Methods: 74-year-old male presented with progressive renal dysfunction: baseline creatinine 2.0 mg/dL in 2014 which increased to 2.4 mg/dL in 2017. Blood pressure was normal and there was no edema. Urinalysis was bland with no protein on qualitative exam. Urine protein creatinine ratio was 292 mg/g. Viral and autoimmune etiologies were ruled out. Renal ultrasound was unremarkable. Serum protein electrophoresis revealed a monoclonal spike in the gamma region, immunofixation electrophoresis showing IgG kappa. Serum free light chain (K/L) ratio was 9 and 24 hour urine free light chain (K/L) ratio was 100. Flow cytometry on bone marrow aspirate was positive for malignant low-grade B cell lymphoma. Bone marrow biopsy showed an indolent marginal zone lymphoma. Kidney biopsy showed mesangial expansion without nodules, IF showed linear kappa light chain deposition along glomerular and tubular basement membranes. He was treated with rituximab weekly for 4 weeks along with oral chlorambucil. Susequently, creatinine has improved to 2.1 mg/dL and serum free light chain ratio has improved 4.5.

Results:

Conclusions: The association of marginal zone B cell lymphoma with LCDD is extremely uncommon. Kidney biopsy is indicated in patients with renal impairment and MIg to diagnose MGRS. There may be a benefit of plasma cell or lymphoma directed therapy for decreasing the risk of chronic kidney disease, even in the presence of low levels of clonal cells. This case highlights the importance of diagnosing MGRS and related kidney disease, such that the paraprotein secreting clone can be optimally treated.

PUB630

Unmasking the Culprit: Valproic Acid Induced Thrombotic Microangiopathy Sean Hebert, Rita Swinford, Christian L. Erikson. *McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX.*

Background: Thrombotic microangiopathy (TMA) is a serious, sometimes life-threatening disorder marked by the presence of endothelial injury and microvascular thrombi. One specific TMA syndrome, Drug-induced TMA (DI-TMA) can occur following drug exposure via drug-dependent antibodies or direct tissue toxicity. Examples include TMA secondary to calcineurin inhibitors Tacrolimus and Cyclosporine and the antineoplastic Gemcitabine. To the best of our knowledge, this is the first reported case of DI-TMA from VPA toxicity.

Methods: An adolescent male with difficult to control epilepsy was admitted for impaired hepatic function while on valproic acid therapy. On the third hospital day, he developed severe metabolic lactic acidosis and multiorgan failure, prompting transfer to the pediatric intensive care unit. Progressive anemia and thrombocytopenia instigated an evaluation for thrombotic microangiopathy, where confirmed by hemolysis with schistocytes, elevated lactate dehydrogenase (LDH), low haptoglobin, and oliguric acute kidney injury. Thrombotic thrombocytopenic purpura was less likely with adequate ADAMTS13. Discontinuing valproic acid reversed the anemia, thrombocytopenia, and normalized the LDH and haptoglobin, supporting a drug-induced cause for the TMA.

Results:

Conclusions: TMA syndromes are extraordinarily diverse. Universally, they are incited by microvascular endothelial cell injury leading to arteriolar and capillary thrombosis and subsequent organ injury. We propose VPA's ability to modify cellular membranes served as the nidus for DI-TMA. Swift recognition and VPA discontinuation likely saved this patient from escalation to plasma exchange and/or hemodialysis. Our case features the first reported case of DI-TMA with VPA toxicity. We suggest increasing awareness of VPA as a TMA culprit will assist in identifying future cases.

PUB631

Sterile Peritonitis with Monocytic Predominance in a Peritoneal Dialysis Patient Ryan Spiardi,[2] Myriam C. Vela-Ortiz,[1] Jaime A. Baynes-Fields,[1] Lissa B. Levin Mizrahi,[3] Sandeep Aggarwal,[2] Rebecca K. Seshasai.[3] *[1]Drexel University, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA; [3]None, Philadelphia, PA.*

Background: PD peritonitis presents with cloudy fluid, abdominal pain, and dialysis effluent WBC > 100/ml with > 50% neutrophils (PMNs). In sterile peritonitis, infectious and non-infectious causes must be considered. We present a PD patient with sterile peritonitis with monocytic predominance of cells.

Methods:

Results: 53 year old female with history of kidney-pancreas transplant in 1999 with bladder exocrine drainage. Renal allograft failed, she began PD in 2016. She continued low dose tacrolimus and cellcept. Pancreas allograft showed reduced function: elevated serum amylase (176 IU/l) and lipase (102 IU/l), fasting hyperglycemia, HgA1C 6.2% and C-peptide level 5.2 ng/ml. She used both CCPD and CAPD and did not use icodextrin. She first presented with cloudy PD fluid and abdominal pain with effluent WBC 335 with 42% PMNs and 44% monos. She received IP antibiotics. Cultures were negative and repeat fluid cell count at one week showed WBC 71 with 23% PMNs and 64% monos. Empirically she received two weeks antibiotics for sterile peritonitis and symptoms resolved. Six weeks later she again presented with cloudy effluent and cell count showed WBC 150 with 25% PMNs and 67% monos. She received antibiotics initially but they were stopped at 3 days when cultures were again negative and repeat cell count was WBC 153 with 5% PMNs and 75% monos. All bacterial, fungal and mycobacterial cultures were negative. CT abdomen showed heterogenous pancreas, possibly consistent with pancreatitis, kidney allograft anatomy and blood flow normal. PD fluid amylase was not elevated (27 IU/l), making pancreaticoduodenocystostomy leak in the setting of bladder drained pancreas unlikely. Symptoms improved without antibiotics and have not recurred after 3 months. Differential includes inflammation of juxtaperitoneal organ, mild graft rejection of pancreas and presence of intraperitoneal air. On review of patient technique, we found she was not properly priming the line during CAPD and infusing air into her peritoneal cavity.

Conclusions: There is a wide differential for sterile monocytic peritonitis. The patient is now asymptomatic and doing well. One must consider less common infectious causes as well as non-infectious causes in complicated patients who are immunosuppressed and have multiple organ transplants.

PUB632

The Man with the Large Tongue – A Case Report Kyrstin Alexander, Sathish Karmegam, Renuka Chowdhury. *Methodist Dallas Medical Center, Dallas, TX.*

Background: Introduction: AL amyloidosis is a clonal plasma cell disorder that causes systemic symptoms secondary to deposition of amyloid in multiple organs. AL amyloidosis can present with abnormalities, such as macroglossia, carpal tunnel syndrome, hepatosplenomegaly, heart failure, nephrotic range proteinuria, neuropathy and bleeding diathesis.

Methods: Case Description: A 78-year-old Hispanic man presented with progressive fatigue, SOB and lower extremity edema. PMH included DM, CAD, diastolic heart failure, recurrent pleural effusions, and BPH. He further complained of poor oral intake because of difficulty swallowing. He was hypotensive and hyponatremic at 127 mmol/L prompting a nephrology consultation. He appeared chronically ill with significant difficulty in articulation. He had significant macroglossia with ulcers along the margins of the tongue and stigmata of multiple biopsies to rule out malignancy. His teeth had been "shaved to fit the big tongue better" by an OMF surgeon. His urine protein was >600 mg/dL and protein/creatinine ratio of 20 grams. Given the macroglossia, proteinuria and diastolic CHF, amyloidosis was suspected. Serological work up including hepatitis, ANA, RPR, HIV, ANCA, SPEP and UPEP were unremarkable. Free light chain analysis showed IgG Lambda chain of 30.60 mg/dL and a kappa/lambda ratio of 0.05. BM Bx did not indicate a plasma cell dyscrasia but there were abnormal cytogenetic findings by FISH. Amyloidosis was diagnosed on kidney and tongue biopsies as Congo red staining resulted positive. Liquid chromatography tandem mass spectrometry was performed on peptides extracted from Congo red positive micro-dissected areas of kidney specimen to diagnose AL amyloidosis. He was started on Dexamethasone and Bortezomib but continued to become progressively weaker and was placed on hospice.

Results:

Conclusions: Discussion: AL amyloidosis has a poor prognosis when detected at an advanced stage. Treatment varies with the eligibility of the patient to pursue high dose melphalan followed by autologous hemopoietic cell transplantation. Our patient did not meet the eligibility criteria. Despite his macroglossia for more than one year and multiple biopsies to rule out malignancy, amyloidosis was not considered. High clinical suspicion is required to diagnose this rare life threatening disorder.

PUB633

Hemolysis Associated with Continuous Renal Replacement Therapy Aala Jaberi,[2] Samer Abujaber.[1] *[1]Mount Auburn Hospital, Cambridge, MA; [2]Internal Medicine, Mount Auburn Hospital, Harvard Teaching Hospital, Cambridge, MA.*

Background: Hemolysis is a rare, but potentially life-threatening complication of hemodialysis. Patients undergoing long-term hemodialysis seldom develop this complication, and even less so in critically ill patients undergoing Continuous Veno-Venous Hemofiltration (CVVH). We present a case of a critically ill patient undergoing CVVH who developed acute hemolytic anemia.

Methods: A 65-year-old female was admitted to the intensive care unit with severe pancreatitis, with progression to multiorgan failure, including acute kidney injury (AKI), requiring CVVH. After 48 hours from CVVH initiation, high return circuit pressure developed with significant clot burden in the circuit. The dialysis catheter was exchanged confirming adequate flow; however, elevated return pressures and filter pressures persisted. Nursing staff noted blood in the effluent fluid with continuous system alarm signals. The circuit was disconnected without blood return to the patient. Hemolysis labs were urgently drawn and the dialysate filter was sent to the manufacturer for analysis. CVVH was reinitiated with a new filter pending; however, within an hour of treatment the effluent fluid demonstrated blood and the treatment was discontinued. Laboratory studies revealed: significant drop in hemoglobin to 7g/dL and significant thrombocytopenia to 50 K/UL. elevated LDH at 600 U/L with low to normal haptoglobin. While CVVH was on hold, the patient received a Furosemide infusion for management of volume overload, with improvement in urine output and electrolyte abnormalities. After 24 hours from CVVH discontinuation, the patient's hemoglobin level rose to 8.9g/dL and her platelets to 105 K/UL, with further improvement noted at 48 hours.

Results:

Conclusions: The diagnosis of CVVH induced hemolysis, although rare, requires a high level of suspicious in critically ill patient, given their increased propensity for pro-inflammatory and hypercoagulable states. Thrombus formation and cytokine aggregation can result in filter clot formation and elevated circuit pressures. This clot burden can result in significant hemolysis due to the shearing forces on red blood cells as they travel throughout the extracorporeal circuit and roller pump. Hemolysis can also result from treatment-induced electrolyte abnormalities, such as hypophosphatemia, hyponatremia, and hypokalemia. With significant hemolysis, pigment-induced nephropathy can occur causing further renal injury.

PUB634

Granulicatella adiacens Causing Infective Endocarditis with Crescentic Glomerulonephritis Bhupinder K. Prajapati,[1] Katie Bean,[3] Manoj Das,[1] Imran F. Fatani,[2] Daniel E. Carl,[1] Jason M. Kidd.[2] *[1]VCU, Henrico, VA; [2]VCU Medical Center, Richmond, VA; [3]Virginia Commonwealth University Health Systems, Richmond, VA. Group/Team: VCUrine.*

Background: Rapid progressive glomerulonephritis is manifested by evidence of glomerular disease in the urine, rapid progressive deterioration renal function and is characterised morphologically by formation of crescents. Granulicatella Adiacens(GA) is designated as a nutritionally variant streptococci (NVS) the transmission of which from mouth is a noted cause of infective endocarditis(IE). NVS can cause severe infections in immunocompetent and immunosuppressed hosts.

Methods: A 32 year old white male with history of congenital heart defect presented with fevers, chills, night sweats for 6 months. Recently, he noted decreased urine output and 30 pound weight loss. On admission, he was febrile. Initial labs were significant for a creatinine of 7 mg/dl (previously normal). His urinalysis was significant for hemautria and proteinuria. Blood cultures grew Granulicatella Adiacens and transesophageal echocardiography showed vegetation on the pulmonary valve. Renal biopsy was performed which showed crescentic glomerulonephritis. Electron microscopy showed sub-endothelial electron dense deposits. His crescentic glomerulonephritis was attributed to infectious endocarditis. His renal function began to slowly improve with the initiation of antibiotics and he never required renal replacement therapy. With treatment, his serum creatinine was steadily improving, and was 3.8mg/dL at discharge.

Results:

Conclusions: This case highlights two unique features. First, GN associated with IE historically occurred with Streptococcus viridans but with the advent of prophylactic antibiotic coverage in IE, it is currently most commonly seen in Staph aureus IE. Antibiotics are the cornerstone of treatment for these patients, but in some cases, immunosuppression has been utilized. Granulicatella Adiacens is a rare cause of infective endocarditis. In 2015 Eduardo et al found only 25 cases of IE caused by granulicatella species and none of them were associated with nephritis. We present the first reported case of post infectious glomerulonephritis related to this uncommon organism. Secondly, this case highlights the diverse glomerular pathological patterns associated with Infectious GN, as crescentic glomerular lesions are uncommonly seen with PIGN but are typical for GN with IE.

PUB635

A Case of Water Intoxication with Transient SIADH After Seizure Shinichi Tanaka,[1] Takaya Sasaki,[1,2] Masahiro Okabe,[1,2] Yu Honda,[1,2] Masahiro Ishikawa,[1,2] Takashi Yokoo.[2] *[1]KAWAGUCHI MUNICIPAL MEDICAL CENTER, Saitama, Japan; [2]The Jikei University School of Medicine, Tokyo, Japan.*

Background: Water intoxication is caused by excessive water ingestion and a fatal disorder and usually shows hypotonic urine. We report a case of water intoxication with transient hypertonic urine and a relatively high antidiuretic hormone (ADH) level.

Methods: A 54-year-old Japanese man presented to our hospital with seizure and unconsciousness. After cessation of seizure, his Glasgow Coma Scale score was 11(E2V4M5). Blood pressure, heart rate, and body temperature are 136/67 mmHg, 90 / min, and 36.4 degrees centigrade, respectively. Blood tests revealed hyponatremia (108 mmol/L) and hypo-osmolality (227 mOsm/L). Urinalysis showed hypertonic urine (U-Na 97 mmol/L, U-K 18 mmol/L, and U-osm 416 mOsm/L). He was treated with 3% sodium chloride solution for about 36 hours until hypotonic urine (U-Na 32 mmol/L and U-K 9 mmol/L) was observed. Subsequent treatment with half normal saline to prevent overcorrection gradually improved hyponatremia. After regaining consciousness he had consumed at least 6 liters of water over 3 hours due to adaptation disorder. His blood ADH concentration was relatively high (3.1 pg/mL). Magnetic resonance imaging focusing on pituitary and laboratory tests for pituitary hormones indicated no other clinically significant pituitary abnormalities. He was diagnosed with water intoxication augmented by secondary syndrome of inappropriate secretion of ADH (SIADH) after seizure. He was discharged without abnormal neurological findings on the 14th day.

Results:

Conclusions: Water intoxication often occurs in patients with psychiatric disorders in a setting of abnormal thirst or SIADH caused by antipsychotics. While water intoxication is usually associated with hypotonic urine, patients with SIADH administered antipsychotics, often show hypertonic urine. Our patient showed a transiently high ADH level and hypertonic urine despite hypotonic hyponatremia with euvolemia. Because he had no history of antipsychotic medication intake, it was assumed that he demonstrated a transient secondary SIADH after seizure. Hyponatremia rapidly improved after his urine changed from hypertonic to hypotonic. A rapid increase of serum sodium concentration predisposes to osmotic demyelination syndrome. Thus it is necessary to frequently confirm serum and urinary electrolytes and promptly adjust the content of infusion therapy.

PUB636

A Case of Severe Hyponatremia Managed with Prolonged 3% Saline in a Patient with Acute Intermittent Porphyria Sayed S. Ahmed,[2] Dia R. Waguespack.[1] *[1]UTHealth, Houston, TX; [2]Renal Diseases and Hypertension, McGovern Medical School at UTHealth, Houston, TX.*

Background: Acute Intermittent Porphyria (AIP) results from partial deficiency of heme biosynthetic enzyme porphobilinogen deaminase. Among various clinical manifestations, severe hyponatremia is a possible clinical presentation. Hyponatremia can occur from variety of entities including syndrome of inapprpriate antiduretic hormone (SIADH), losses from the gastrointestinal tract and renal sodium wasting. We report a case of severe hyponatremia in patient with AIP managed with aggressive and prolonged 3% saline replacement.

Methods: A 21 year old woman presented with generalized body pain. She had a history of rhabdomyolysis one month ago. During that admission she was managed with intravenous fluid and pain control. This admission she presented with similar symptoms, however her creatinine phosphokinase level was normal. Nephrology was consulted for severe hyponatremia (serum sodium level of 116 meq/L) that was consistent with SIADH on laboratory work up. She was initially treated with 3% saline boluses. Despite this her sodium level continued to decline. She was then transitioned to a continous 3% saline infusion at 25-30 ml/hr. The treatment goal was to maintain goal sodium correction of 6 meq/24hrs. During this time confirmatory tests for the diagnosis of AIP returned. She was started on directed treatment of AIP. Over next several days hypertonic saline therapy was discontinued as sodium level stabilized between 130-140 meq range with the treatment of her AIP.

Results:

Conclusions: This case was notable because of continued use of 3% saline over approximately 2 week period due to SIADH/salt wasting etiology. This case also demonstrates refractory hyponatremia in AIP requiring aggressive and prolonged repletion with 3% saline and eventual stabilization of sodium level after treating underlying etiology.

PUB637

From an Implantable Venous Access Device to the Kidneys: Staphylococcus Infection-Associated Glomerulonephritis Fatima B. Cintron-Rosa,[1] Martin Gorrochategui,[1] Ileana E. Ocasio Melendez,[1] Jannice M. Arroyo,[1] Krystahl Z. Andujar,[1] Sulimar Rodriguez.[2] *[1]Nephrology, University of Puerto Rico, San Juan, PR; [2]Gastroenterology, University of Puerto Rico School of Medicine, Guaynabo, PR.*

Background: IgA nephropathy (IgAN) is a mesangial proliferative glomerulonephritis characterized by diffuse mesangial deposition of IgA. It has been associated with inflammatory bowel disease (IBD); in addition, IgA-dominant glomerular deposition occurs with Staphylococcus infection-associated glomerulonephritis (SAGN). We present a case of a patient with IBD and staphylococcal infection with nephritic syndrome and acute kidney injury (AKI).

Methods: A 57-year-old female with perianal Crohn's disease receiving infliximab infusions via an implantable venous port presented with a two-week history of diarrhea. She was admitted and her evaluation was significant for a prerenal AKI. Urinalysis was positive for protein, leukocyte esterase, white blood cells and red blood cells. Urine culture and blood cultures were remarkable for methicillin sensitive staphylococcus aureus (MSSA). Renal sonogram and echocardiogram were negative for obstruction and endocarditis, respectively. She was initiated on intravenous fluids and piperacillin-tazobactam for urinary tract infection and bacteremia and showed clinical improvement from kidney function and infection. Two weeks later, she developed nephritic syndrome. Laboratory workup for glomerular disease with low complement C3 levels, suggestive of infectious glomerulonephritis. The implantable port was removed and its culture yielded MSSA. New echocardiogram was negative for endocarditis. The kidney biopsy reported immune complex mesangial glomerulonephritis with IgA deposition suggestive of IgAN. SAGN was diagnosed and antibiotic therapy was completed. Bacteremia was eradicated with further improvement of AKI.

Results:

Conclusions: SAGN is an unusual immune complex-mediated disease that presents with a *Staphylococcal* infection associated with edema, hematuria, leukocyturia, proteinuria, hypocomplementemia and AKI. The infection site may be the skin, heart, lung or indwelling catheter. Recently, a SAGN study showed a wide spectrum of IgA staining, trace or negative C3 staining and a much lower prevalence of subepithelial "humps". This case represented a diagnostic challenge due to biopsy features of two entities, SAGN versus IgAN secondary to IBD. In SAGN, infection needs to be appropriately treated with antibiotic therapy instead of immunosuppression.

PUB638

Is There a Role for High Intensive Angiotensin Blockade in Mesangial Proliferative Glomerulonephritis? Ana F. Gomes da silva, Maria N. Pestana, Miguel Goncalves, Pedro M. Vieira, José M. Durães, Luís Resende, Jose N. Guimaraes Rosa, José Teixeira, Gil Silva. *Hospital Central do Funchal, Funchal, Portugal.*

Background: Idiopathic mesangial proliferative glomerulonephritis (MPGN) may represent a variant of minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS), but some believe that they are separate conditions.

Methods: A 38 year old male was referred to our nephrology department consultation with non-nephrotic proteinuria and serum creatinine (sCr) of 1.26mg/dL. He was assimptomatic and had no personal or family history of kidney disease. Laboratory findings revealed sCr level of 1.31 mg/dL and urinary albuminuria and proteinuria levels were 2.535 g/24h and 3.61 g/24h, respectively. Creatinine clearance (CrCl) was 103.6 ml/min. A renal biopsy was performed and its histological analysis revealed mesangial cell proliferation with mesangial granular deposits of IgG (+), IgA (-), IgM (-), C3 (+/-), C1q (+), kappa (+/-) and lambda (+/-). The patient was treated with prednisolone (PDN) 60 mg/day and ramipril 5 mg/day. The initial response was oscillating with the need for successive increases in ramipril dose up to 40mg/day. 2 years later, with PDN progressive

reduction and suspension, he presented with persistent cough and ramipril was replaced with losartan 50mg/day. In the following months there was a new rise in albuminuria requiring increasing doses of losartan up to 200mg/day and currently the patient remains clinically stable with this therapy.

Results:

Conclusions: MPGN can be secundary to a variety of diseases including lupus nephritis, IgA nephropathy, and mild postinfectious glomerulonephritis. In this case report, no cause was found responsible for mesangial proliferation. The immunofluorescence microscopy revealed deposits of IgG (+) and C1q (+) without the predominance of one of them, which excluded C1q nephropathy. The majority of patients with MPGN respond initially to PDN and an antiproteinuric drug. The treatment of our patient was particularly challenging since he needed a prolonged corticotherapy (during 2 years) and the use of high doses of angiotensin blockers.

PUB639

A Case of Concurrent Catastrophic Antiphospholipid Syndrome and IGA Nephropathy Kristine Soltanpour, Tiffany N. Caza, Paul F. Shanley, Apurv Khanna. *SUNY Upstate Medical University, Clay, NY.*

Background: Antiphospholipid syndrome (APS) can be a cause of CKD over time due to repeated formation of microthrombi and their dissolution. Although an association of antiphospholipid antibodies and Henoch-Schonlein purpura has been recognized, few cases of APS and IgA nephropathy have been reported. Here we show a rare case of concurrent thrombotic microangiopathy (TMA) due to catastrophic antiphospholipid syndrome (CAPS) and IgA nephropathy.

Methods: A 42 year old morbidly obese male patient with an 18 year history of antiphospholipid syndrome due to B2 glycoprotein and anti-cardiolipin antibodies, complicated by bilateral deep venous thromboses on warfarin, presented with abdominal pain, AKI, and acute hypoxic respiratory failure. A prior episode of CAPS resulted in AKI due to TMA and required dialysis and plasmapheresis. After recovery from this episode, he had CKD stage III with his baseline creatinine being in the mid-1 range. Upon admission, he was found to have acute pancreatitis with a lipase of 764 and AKI on CKD with a serum creatinine of 4.5 g/dL. Review of systems was positive for mouth sores, dry eyes, nausea, abdominal pain, 100 lb weight loss, and arthralgias. Physical exam was significant for left lower quadrant tenderness. He had a nephritic presentation with microscopic hematuria with 25-50 RBC/hpf, 3+ hemoglobinuria, and a protein-to-creatinine ratio of 2.34. He had anemia and thrombocytopenia. A CT of the abdomen showed splenomegaly and no obstructive uropathy. His clinical presentation was concerning for recurrent catastrophic antiphospholipid syndrome requiring a renal biopsy. Biopsy showed both evidence of TMA and a mesangiocapillary proliferative glomerulonephritis with IgA-containing immune complexes consistent with IgA nephropathy. There was acute on chronic TMA with severe ischemic tubulointerstitial damage, interstitial hemorrhage, infarction, occlusion of glomerular capillaries, endothelial damage, and subendothelial widening. He was treated with plasmapheresis and high dose steroids, discharged with a steroid taper and hydroxychloroquine, and recovered with a creatinine of 1.9.

Results:

Conclusions: Here we present a case of catastrophic antiphospholipid syndrome and IgA nephropathy overlap treated successfully with plasmapheresis, anticoagulation, and steroids.

PUB640

Severe AKI in a Sickle Cell Patient Taking Deferasirox Bair Cadet,[1] Amarpali Brar,[1] Okwudili Nnaji,[3] Mary C. Mallappallil,[1] Hanan K. Tawadrous,[1] Moro O. Salifu.[2] *[1]Nephrology, SUNY- Downstate School of Medicine, Brooklyn, NY; [2]SUNY Downstate Medical Center, Valley stream, NY; [3]SUNY downstatemedicsl center, Brooklyn, NY.*

Background: Introduction Acute kidney injury (AKI) occurs in five to seven percent of hospitalized patients. Deferasirox is an iron chelating agent used in treatment of chronic iron overload. Here we report a case of severe AKI associated with use of Deferasirox in a patient with sickle cell disease and iron overload.

Methods: Case description A 24-year-old man with Moya Moya disease, sickle cell disease who was dependent on chronic blood transfusions, stroke associated with bilateral extremities weakness presented with 3 days of non-bloody diarrhea and vomiting. He was found to have AKI on admission. His medications at home included lisinopril, deferasirox, levetiracetam, carbamazepine and folic acid. Laboratory investigation revealed calculated fractional excretion of sodium to be 1.7 %, creatinine on the day of admission was 7.18 mg/dl with baseline creatinine of 0.83 mg/dl recorded 2 weeks prior. Urinalysis was noted for a pH 6.0, RBCs <1, WBCs 3 and negative for protein. Renal ultrasound showed normal echogenicity without any acute renal pathology.

Results:

Conclusions: Discussion In this case, the patient who was treated with deferasirox for iron overload developed AKI. Recognized mechanism of renal injury include decrease prostaglandin synthesis, inhibition of tubular reabsorption of solute and direct mitochondrial injury. The discontinuation of the deferasirox and lisinopril resulted in the serum creatinine decreasing to 0.88 mg/dl. Deferasirox should be used with caution in patient on ACE inhibitor with rapid discontinuation in the setting of dehydration.

PUB641

Biopsy-Proven HIV-Associated Nephropathy in a Patient with Untreated HIV/AIDS and Non-Nephrotic-Range Proteinuria Diana Mina. *UCSF Division of Nephrology, San Francisco, CA.*

Background: Renal involvement in patients with HIV/AIDS has been described since the mid-1980s, and can directly cause glomerular and tubulointerstitial injury, or can be associated with renal infection, renal involvement by neoplasm, or can be secondary to anti-retroviral medications. The histopathologic lesion termed HIV-associated nephropathy (HIVAN) is characterized by a collapsing form of focal and segmental glomerulosclerosis (FSGS) with coexistent tubulointerstitial disease and classically presents with heavy proteinuria and chronic renal failure, but must be considered in the differential diagnosis for all patients with HIV/AIDS who present with renal failure.

Methods: A 37 year old male with HIV/AIDS, not taking anti-retroviral medications, was brought to the hospital by family members due to several days of altered mental status. Cerebral spinal fluid studies revealed CNS lymphoma and the patient was treated with anti-retroviral medications, high dose steroids, and rituximab. Records from the 4 months prior to admission suggested a baseline creatinine of 1.5, with several prior episodes of acute kidney injury during hospitalization for opportunistic infections, but degree of albuminuria (0.6 g/g) and proteinuria (1.5 g/g) on admission made sepsis-related ATN or possible renal infection, such as by CMV, appear to be more plausible etiologies for renal failure than HIVAN per se. Complete serologic work-up was unremarkable and renal ultrasound revealed large kidneys with increased echogenicity. Renal biopsy revealed collapsing FSGS with coexistent tubulointerstitial disease. Interestingly, after several weeks on anti-retroviral therapy and continuous renal replacement therapy, renal function improved significantly, though patient remained dialysis dependent in the context of a CMV-related gastrointestinal bleed and clinical deterioration. The patient remains critically ill and dialysis-dependent.

Results:

Conclusions: Though anti-retroviral treatment has significantly reduced the prevalence of HIVAN, and though it classically presents with high-grade proteinuria, it must be considered in the differential diagnosis of all HIV/AIDS patients presenting with renal failure. The degree of recovery depends on the extent of the renal injury, and prompt recognition of HIVAN and initiation of anti-retroviral therapy is critical for preventing progression to end-stage renal disease.

PUB642

AKI Secondary to Sunitinib in a Renal Allograft Patient Sean Verma, Kayla Shirley, Claude Bassil. *University of South Florida, Tampa, FL.*

Background: Sunitinib is a multiple tyrosine kinase inhibitor used in advanced renal cell carcinoma (RCC) and gastrointestinal stromal tumor. Nephrotoxicity is a rare side effect that was not reported during clinical trials

Methods: A 64-year-old man with a living related donor renal transplant due to focal segmental glomerulosclerosis and stage 4 metastatic RCC of native left kidney was found to have acute kidney injury (AKI) with creatinine of 3.5 mg/dL (baseline 1.4 mg/dL). He was on cyclosporine and prednisone, while myceophenolate mofetil was held over last 3 months with the discovery of RCC. He completed a 14 day course of sunitinib 4 days prior to routine labs showing AKI. Labs showed potassium 6.1 meq/L, bicarbonate 14 meq/L, albumin 2 mg/dL. A cyclosporine trough was within normal limits. Urinalysis showed 100 mg/dL protein. Urine eosinophils, BK, and JC viruses were negative. Renal ultrasound of the transplant showed no hydronephrosis and patent vasculature. Creatinine peaked at 3.7 mg/dL the next day. A spot protein/creatinine ratio showed nephrotic range proteinuria at 4.75 g protein/g creatinine. Over the following days his creatinine remained stable at 3.5-3.7 mg/dL but he became oliguric. After discussion, he declined renal replacement therapy and opted for palliative care. He was discharged with hospice and passed away 15 days after admission.

Results:

Conclusions: Sunitinib targets multiple cell factor receptors that are involved in growth regulation, neoangiogenesis, differentiation, and cell survival, most notably vascular endothelial growth factor receptor (VEGFR). Renal side effects seldomly implicated with sunitinib include, acute interstitial nephritis, thrombotic microangiopathy, tumor lysis syndrome, new or worsening hypertension, edema, and proteinuria. 7 case reports describe a pre-eclamptic like condition, in which patients developed hypertension, edema and proteinuria. VEGFR is important in the function of podocytes and glomerular epithelial cells. VEGFR inhibition may result in decreased endothelial fenestration formation, effacement of podocyte foot processes, and disturbance of the glomerular filtration barrier leading to proteinuria, hypertension, and AKI. Treatment is supportive with intravenous fluids, stopping the sunitinib, and avoiding any additional renal insults. Sunitinib is not cleared through hemodialysis. Renal biopsy can be considered if safe to proceed.

PUB643

Valerian Root Interaction with Statins: Another Cause of Rhabdomyolysis-Associated AKI Alexander Borrero-Arvelo,[7] Enrique E. Acosta Oruna,[1] Stefano Coppola fasick,[3] Jacobo J. Loyola,[7] Eddie M. Rodriguez,[7] Migdoel Cruz rodriguez,[6] Carlos J. Perez-Lopez,[5] Lorena D. Morales,[4] Elvin Soto,[2] Carlos S. Rosado-Rodriguez.[7] *[1]Internal Medicine Resident, San Juan, PR; [2]VA Caribbean Healthcare System, San Juan, PR; [3]VA Caribbean healthcare system, Guaynabo, PR; [4]VA caribbean Healthcare System, San Juan, PR; [5]VA caribbean Healthcare sytem, San juan, PR; [6]VA healthcare system, Patillas, PR; [7]Veterans Affairs Caribbean Healthcare System, Toa Baja, PR.*

Background: Valerian root is an herbal supplement used to treat insomnia, anxiety and muscle tension. It has a complex mixture of chemical compounds including valeric acid and its derivatives. Valeriana root has been shown to decreased the CYP3A gene expression by nuclear receptors in an experimental model but interactions with drugs metabolized by the CYP450 has not been clearly established. We report a patient who presented with severe rhabdomyolysis and oliguric acute renal failure coincident with the use of Valerian root and Rosuvastatin.

Methods: An 88 year old man was brought to the ED with 3 day history of general malaise, hypoactivity, poor oral intake and decrease urine output. He had history of CKD Stage 3b associated to HTN, T2DM, CVA with residual right hemiparesis, prostate hypertrophy, and hyperlipidemia. He was on Rosuvastatin, Losartan and Terazosin. No recent medication dose changes was documented. He was also taking Melatonin and Valerian root herbal supplement for insomnia. Vital signs: BP: 110/70 HR: 60/min. The patient was alert, but disoriented. Physical exam was remarkable for bilateral leg pitting edema. Initial laboratory data at the ED revealed: S Creat: 14.9, BUN 118 mg/dl, and Glucose: 216 mg/dl; Na: 123 K: 8.6, Cl: 90, TCO2: 15 meq/l. Blood pH: 7.20 pCO2: 37.3. Elevated total CPK(See Table). Urinalysis was not taken since anuria. A diagnosis of acute kidney injury due to rhabdomyolysis was made. The patient required acute RRT. There were no signs of urinary tract obstruction in imaging studies. Clinical picture was complicated by development of respiratory failure due to bilateral pneumonia. He also had episode of allergic reaction to Sulfa. The patient was discharged home 3 weeks later on hemodialysis treatments since there no significant recovery of renal function.

Results:

Conclusions: Development of acute renal failure due to rhabdomyolysis may have been precipitated by Valerian root interaction with hepatic metabolism of Rosuvastatin.

Funding: Veterans Affairs Support

Two Cases of Successful Percutaneous Transluminal Angioplasty to Treat Immature Arteriovenous Fistulas Due to Non-Thrombotic Occlusions Takeshi Tosaki,[1] Takaya Sasaki,[1,2] Yu Honda,[1,2] Masahiro Okabe,[1,2] Masahiro Ishikawa,[1,2] Takashi Yokoo.[2] *[1]Kawaguchi Municipal Medical Center, Kawaguchi-shi, Saitama, Japan; [2]The Jikei University School of Medicine, Minato-ku Tokyo-to, Japan.*

Background: Percutaneous transluminal angioplasty (PTA) to stenosis of an immature arteriovenous fistula (AVF) serves as an effective treatment. A non-thrombotic occlusion of a mature AVF is also treated with PTA, and a high patency rate has been reported. However, the effectiveness of PTA for the treatment of an immature AVF due to non-thrombotic occlusion is still unknown. We report two cases of successful PTA for treatment of immature AVF caused by non-thrombotic occlusion.

Methods: Case 1 examines a 75-year-old man with end-stage renal failure due to benign nephrosclerosis. The patient underwent an AVF operation on his left forearm, and dialysis was started. The main trunk of the AVF in the cephalic vein was poorly developed, and a collateral vein was used for dialysis. Arteriography was performed one month after the operation because of insufficient blood flow for dialysis, showing a non-thrombotic complete obstruction in the main trunk. The main trunk was expanded completely without any complications, and blood flow became sufficient. Case 2 involves a 79-year-old man with end-stage renal failure due to diabetic nephropathy who underwent an AVF operation on the left tobacco fossa. Seven months later, pulsation of the AVF in the cephalic vein and hand edema appeared, and venous hypertension syndrome and an immature AVF were suggested. Arteriography showed a complete non-thrombotic occlusion of the main trunk of AVF; thus, PTA was performed on the occlusion. After the PTA, the pulsation of the AVF and hand edema disappeared. The expanded vein has been fully patent in both patients.

Results:

Conclusions: Although PTA is usually performed for complete non-thrombotic occlusions, few studies have been reported. Especially, there is no evidence for the developmental failure of the AVF due to non-thrombotic obstructions. We have reported here that PTA could be effective for immature AVF treatment due to complete non-thrombotic occlusion of the main trunk.

PUB645

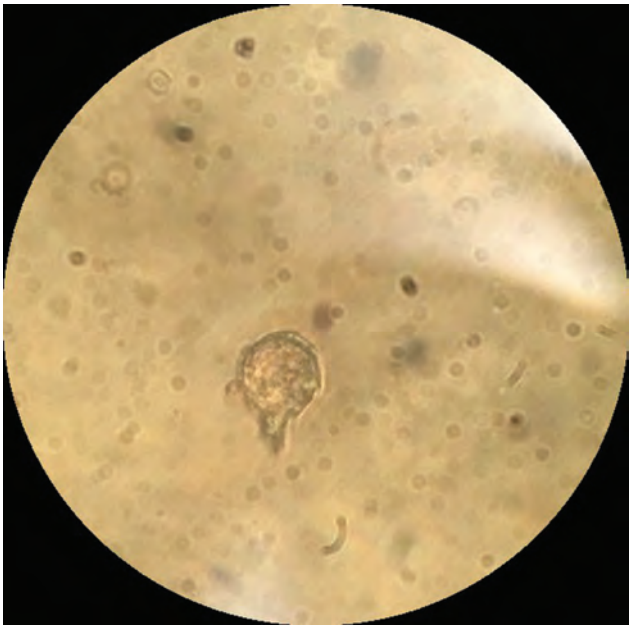
Urinary Schistosomiasis Aala Jaberi,[2,3] Jasvinder S. Bhatia.[1] *[1]Boston University Medical Center, Brookline, MA; [2]Nephrology, Boston Medical Center, Boston, MA; [3]Internal Médicine, Mount Auburn Hospital, Cambridge, MA.*

Background: Schistosomiasis, also commonly known as bilharzia, is a water-born parasitic infection most common in developing countries. It has been estimated that more than 97% of all schistosomiasis cases occur in Africa. In areas endemic for urinary schistosomiasis, bladder cancer is the most commonly diagnosed malignant neoplasm. Genitourinary schistosomiasis can present early with microscopic hematuria. In chronic infection, granulomatous inflammation leading to fibrosis and calcification of the bladder wall with the development of pseudopolyps can result. Early diagnosis of S. haematobium is based on identification of embryonated ova in the urine. The eggs are elongated at 110 μm to 170 μm in length by 40 μm to 70 μm in width. Here we present a case of a 24-year-old male with history of chronic hematuria.

Methods: 24-year-old Egyptian male with no significant past medical history, presented for evaluation of two-year history of terminal painless gross hematuria. He was a recent immigrant to the united states from Egypt, however he denied illicit drug use. He smoked cigarettes occasionally. Lab studies were significant for 16%eosinophils, creatinine 0.74mg/dL, normal C3, C4, undetectable Hepatitis C RNA. Urine sediment revealed nondysmorphic RBCs and the egg of Schistosoma hematobium. Further lab studies revealed positive IgG antibodies to both Schistosoma hematobium and Schistosoma Mansoni. Renal ultrasound revealed a 1.2cm bladder mass, which was resected on cystoscopy. The patient was treated with Praziquantel, with complete resolution of his gross and microscopic hematuria.

Results:

Conclusions: Urine microscopy is an essential tool in the diagnosis of urinary schistosomiasis. Prompt recognition can result in early referral for further investigations and expedited treatment and management.



PUB646

Monoclonal Gammopathy of Renal Significance: An Unresolved Dilemma Abhilash Koratala,[3] Don H. Esprit,[2] Volodymyr Chornyy.[1] *[1]UF Department of Nephrology, Gainesville, FL; [2]University of Florida, Gainesville, FL; [3]University of Florida, Gainesville, FL.*

Background: Monoclonal gammopathy of renal significance (MGRS) encompasses all renal disorders caused by a monoclonal immunoglobulin secreted by a nonmalignant B-cell clone. Patients with MGRS do not meet the criteria for overt multiple myeloma by definition. Management of these patients remains a clinical dilemma at this time.

Methods: A 33-year-old woman was referred for evaluation of CKD. She did not have any significant medical history except for hypokalemia and hypophosphatemia, noted about a year ago, requiring supplements. Vital signs were stable and the laboratory data at presentation is shown in figure1. In brief, she had mild reduction in GFR, hypokalemia, hypophosphatemia, non-anion gap metabolic acidosis and glycosuria without hyperglycemia suggestive of proximal renal tubular acidosis with Fanconi syndrome. In addition, there was discrepancy between urine protein and albumin excretion. Serum protein electrophoresis revealed an M-spike in the gamma region (2 g/dL). Bone marrow biopsy demonstrated hypercellular marrow (70%) with 20% of plasma cells with abnormal phenotype. Congo red stain was negative for amyloid. Skeletal survey was negative for lytic bone lesions. Based on current definitions, she was labelled as ‘smoldering myeloma’. We chose to monitor her renal function expectantly for now

without chemotherapy based on the fact that baseline GFR is a major determinant of renal outcome in most types of MGRS.

Results:

Conclusions: While the pathologic spectrum of renal diseases in MGRS is wide, the role of a kidney biopsy in changing the management is questionable. Moreover, the benefit of early initiation of chemotherapy in patients with 'stable' renal function is not established and chemotherapy has significant side effects on the other hand. There is no one-size-fits-all approach for the treatment of this entity at present and consensus on the pathological definition of the MGRS spectrum is needed in order to design future collaborative studies.

Thrombotic Microangiopathy: The Importance of Early Identification and Differentiation Otis H. Brunson,[2] Christopher T. Perry,[1] Sabrina G. Bessette.[2] *[1]University of South Alabama, Mobile, AL; [2]University of South Alabama College of Medicine, Daphne, AL.*

Background: The differentiation of Thrombotic Microangiopathy (TMA) is difficult due to overlapping features in presentation. Malignant hypertension-induced TMA (MH TMA) and atypical Hemolytic Uremic Syndrome (aHUS) are two of the more difficult etiologies of TMA to distinguish. Both can present with severely elevated blood pressures and classic TMA features: microangiopathic hemolytic anemia, thrombocytopenia, and renal failure. Rapid recognition of aHUS is important due to the vast improvement in prognosis with early Eculizumab initiation.

Methods: Presentation: A 59-year-old African American Female with PMH of hypertension presented with renal failure, anemia, and thrombocytopenia. Diagnosis: A diagnosis of TMA was made based on lab findings and schistocytes on peripheral smear. Intervention: Patient was initially treated for HTN emergency due to BP 181/115 mmHg on admission. She was then started on plasma exchange therapy, while ADAMSTS13 level was sent to rule out TTP. After ADAMSTS13 returned normal, an additional diagnosis of aHUS was considered. The decision was made to start Eculizumab while awaiting confirmatory aHUS genetic panel. The patient was treated with five weekly doses of Eculizumab. Outcomes: Hematologic parameters and renal function improved on Eculizumab. Genetic panel returned normal, thus aHUS ruled less likely. The patient's TMA was thus determined to be solely due to severe hypertension. The patient was discharged after blood pressure control and stabilization of Creatinine.

Results:

Conclusions: Our case highlights an important clinical point; in patients presenting with TMA and severe hypertension it is important to consider aHUS as a potential underlying diagnosis. Research shows that a subset of patients diagnosed with MH TMA have proven complement dysfunction, suggesting a close association between MH TMA and aHUS. Early treatment with Eculizumab is warranted due to better outcomes in kidney function and decreased progression to ESRD. Treatment with Eculizumab should be initiated as early as possible and before confirmatory genetic testing is completed.

PUB648

Recurrence of Primary FSGS in Renal Allograft Kartik Kalra,[1] Nabil Ghani,[1] Simranjit S. Randhawa.[2] *[1]Internal Medicine, Saint Peter's University Hospital, New Brunswick, NJ; [2]Sir Ganga Ram Hospital, New Delhi, India.*

Background: Focal segmental glomerulosclerosis (FSGS) refers to a histologic pattern that is a characteristic of various distinct underlying etiologies sharing a common theme of podocyte injury and depletion. Recurrent FSGS usually presents in the early post-transplantation period with re-emergence of proteinuria and progressive graft dysfunction. This is a case of a 52-year-old gentleman with progressive renal failure secondary to FSGS in renal allograft.

Methods: 52-year-old gentleman with past medical history of Left Nephrectomy (1981), End-stage renal disease (ESRD) secondary to primary FSGS status post (s/p) Living donor transplant (2016) currently on Tacrolimus, Mycophenolic Acid and Prednisone presented with 1 week history of progressive bilateral lower extremity swelling, and orthopnea (5 months s/p transplant). Vitals and Physical Examination were significant for Blood Pressure 172/100 mm Hg, +3 pitting pedal edema. Labs revealed Creatinine(Cr) 5.15 mg/dL (Baseline 2.3 - 2.5 mg/dL), Albumin 2.8 g/dL, Total Cholesterol 280 mg/dL, Spot Urine Protein:Cr Ratio 4.87 gram/gram. Subsequently, renal biopsy showed progressive scarring of glomeruli suggestive of FSGS. Histologic Variant - Not otherwise specified. The patient was managed conservatively on renin-angiotensin blockade and dietary sodium restriction. Corticosteroid and immunosuppressive therapy were continued.

Results:

Conclusions: Recurrence of primary FSGS is remarkably common in transplanted kidneys and may recur in up to 50% of the cases. Factors thought be associated with higher risk of recurrence include: Rapid progression of initial disease, White race, history of recurrence in a prior allograft. Case reports of recurrence have been reported for podocin and TRP6 mutations. The pathogenesis is thought to be possibly related to a circulating factor in majority of the cases. No definite treatment is available yet, though usual strategies include plasmapheresis to remove the "possible circulating factor", calcineurin inhibitors for their anti-proteinuric effects by stabilizing actin cytoskeleton in podocytes. Rituximab use has also been reported and is thought to have a direct action on the podocytes in addition to interference with the presentation of B cell antigens. Future research exploring pathogenic molecular pathways will lead to more insight into pathophysiology and FSGS classification and thus will lead way for improved treatment strategies.

PUB649

An Old Friend Strikes Again: A Rare Case of CMV Acute Tubulointerstitial Nephritis in a Transplant Recipient with AKI Sathish Karmegam,[2] Kosunarty Fa,[2,1] Jose A. Castillo-Lugo.[2,1] *[1]Dallas Nephrology Associates, Dallas, TX; [2]Nephrology, Methodist Dallas Medical Center, Dallas, TX.*

Background: Introduction: Cytomegalovirus (CMV) infection remains one of the most important etiology for the morbidity and mortality of transplantation patients. The impact on patients depends on the form of CMV infection. About 10% to 50% develop symptomatic disease while solid organ involvement (e.g. CMV nephritis) have a deleterious outcome and requires histopathology testing. This is a rare case of CMV presenting as acute tubulointerstitial nephritis.

Methods: Case Description: A 65 y/o male, recipient of a deceased-donor kidney transplant 8 months prior to admission presented with progressively worsening diffuse abdominal pain for 3 days, associated with nausea, vomiting, and diarrhea. CMV status at transplantation was CMV D+/R+, and baseline serum Cr was 1.2 mg/dl. Immunosuppression regimen consisted of tacrolimus, MMF, and prednisone. He received valgancyclovir prophylaxis for 3 months post-transplant, after which it was discontinued as per protocol. CT of abdomen/pelvis on admission was unremarkable. An US of the transplanted kidney showed some fullness around the allograft. Stool workup was negative. His tacrolimus level was elevated at 19 ng/mL and it was held. He became febrile and CXR showed RML infiltrate prompting the use of broad spectrum antibiotics. His CMV viral load returned at 2.9 million copies/ml. He was started on IV ganciclovir for CMV disease. All cultures and cytology were unremarkable. On day 8, his Cr started to increase up to 5.0 mg/dl with a benign sediment and therapeutic tacrolimus levels. A kidney biopsy revealed acute interstitial nephritis with viral inclusions but no signs of rejection. He was started on IV methylprednisolone 500 mg daily and his Cr started to downtrend to 0.9 after 5 days. His CMV viral load dropped to 9492 copies/mL. He received a total of 25 days of IV ganciclovir and then transitioned to oral route to be continued for a total of 6 months as ID recommended a long duration of induction therapy.

Results:

Conclusions: Discussion: CMV infections in renal allograft recipients constitute an important cause of renal graft dysfunction. There is an increasing incidence coinciding with more potent immunosuppression regimens. CMV nephritis can present as glomerulopathy and tubulointerstitial disease. High clinical suspicion and vigilance required for diagnosis and prompt treatment.

PUB650

An Interesting Case of Hypercalcemia from HTLV-1 Associated Adult T-Cell Lymphoma Krishna Sury,[1] Namrata Krishnan.[1,2] *[1]Section of Nephrology, Yale University School of Medicine, New Haven, CT; [2]Section of Nephrology, Department of Veterans Affairs, West Haven, CT.*

Background: Adult T-cell leukemia/lymphoma (ATL) is a rare form of non-Hodgkin lymphoma involving regulatory T cells. Human T-cell lymphotropic virus type 1 (HTLV-1) is a known risk factor. ATL is rarely seen in the United States, but is prevalent in endemic areas such as Japan, South America, Central Africa, and the Caribbean islands. We present a case of severe, symptomatic hypercalcemia in a Jamaican man who was ultimately diagnosed with HTLV-1 associated ATL.

Methods: A 71-year old Jamaican man with hypertension, diabetes, and stage 2 chronic kidney disease presented with one month of fatigue, unintentional sixteen-pound weight loss, and polyuria. Laboratory data showed an elevated creatinine of 3.1 mg/dl (from baseline 1.5 mg/dl), and hypercalcemia (ionized calcium 8.53 mg/dl) that was unchanged after saline therapy and required calcitonin and intravenous pamidronate. Workup included negative SPEP/UPEP, normal angiotensin converting enzyme level (28 mg/l), low Vitamin D (<13 ng/ml), suppressed PTH (12 pg/ml), and elevated PTHrP (40 pg/ml). Total-body CT scan showed no adenopathy, but FDG-PET revealed increased metabolic activity in lymph nodes throughout the neck, chest, abdomen, and pelvis. On biopsy, the bone marrow was hypercellular with atypical lymphocytes. Peripheral blood flow cytometry showed T cells with an abnormal immunophenotype, and a T-cell

gene rearrangement study confirmed monoclonality. HTLV-1 IgG antibody testing was positive. Final diagnosis was HTLV-1 associated adult T-cell leukemia/lymphoma. Sadly, due to distrust of the medical system, the patient refused care. Weeks later, he was found dead in his home.

Results:

Conclusions: Severe hypercalcemia is present in less than 4% of lymphomas, yet 70% of acute ATL cases are complicated by severe (often resistant) life-threatening hypercalcemia. PTHrP plays a pathologic role. Although HTLV-1 associated ATL is rare in the United States, given the high frequency of international travel, diseases endemic to other parts of the world must be considered during diagnostic evaluation. The asymptomatic carrier state and long latency period (decades) between infection with HTLV-1 and onset of ATL makes the diagnosis challenging and requires a high index of suspicion.

PUB651

Dense Deposit Disease – A Clinical Case Report Sofia S. Coelho, Ana Fernandes, Elsa S. Soares, Patrícia V. Santos, Ana Farinha, Ana Natario. *Nephrology, Centro Hospitalar de Setúbal, Setubal, Portugal.*

Background: Dense deposit disease (DDD) and C3 glomerulonephritis (GN) are rare forms of renal disease both in children and adults. Initially classified as a subgroup of membranoproliferative GN type II, these conditions have recently been re-classified as *complement-associated glomerular disease*. Both DDD and GN result from an abnormal regulation of the alternative complement pathway, with variable pathological mechanism and clinical presentations.

Methods: We report the case of a 48-year-old Caucasian man with smoking habits and a 2 years history of arterial hypertension. No individual or family history of kidney disease was known. The patient was referred to the Nephrology department 2 months after the detection of rapidly progressive kidney failure, nephrotic syndrome, hematuria and poorly controlled hypertension. At physical examination, acquired partial lipodystrophy was observed, and the ophthalmologic observation revealed a macular drusen suggestive of DDD. The blood tests revealed a quite frankly low C3, with the remaining being negative for autoimmune disease, monoclonal gammopathy or viral infection. The renal ultrasound showed normal kidneys' features. In order to clarify the etiology of the renal disease, a renal biopsy was taken, which showed glomerulonephritis associated with dense deposits, exclusively of C3; cellular crescents, endocapillary proliferation, moderate interstitial fibrosis and tubular atrophy were also present. A rapid worsening of renal function, requiring hemodialysis, followed. Given the presence of active lesions in the histology, combined immunosuppression therapy with steroids plus mycophenolate mofetil, was started. Later on, the the complement analisys revealed a nonsense pathogenic mutation of the complement factor B gene (c.1424dupT, p.Ser476Glufs*43) not previously described and a homozygous haplotype for the complement factor H gene, known to confer risk for atypical haemolytic uraemic syndrome (CFH3-tgtgt).

Results:

Conclusions: DDD is a rare disease with a poor renal prognosis; renal failure requiring dialysis at the time of presentation is a predictor of progression to end stage renal disease. Randomized clinical trials designed to establish the better therapeutic options are needed.

PUB652

Podocytopathy in Anabolic Steroid User Rapidly Responsive to Steroids Melissa C. Fajardo,[1] Beenish Noor,[2,1] Suhaib A. Andrabi,[1] Jeffrey D. Wallach,[1] Sudhanshu Jain.[1] *[1]Harlem Hospital, New York, NY; [2]Harlem Hospital Centre, NY, NY.*

Background: Focal segmental glomerulosclerosis (FSGS) is a commonly found histologic lesion that underlies nephrotic syndrome in adults. It can be classified into primary and secondary variants. Primary FSGS, is thought to be a result of injury to the podocyte, with involvement of parietal epithelial cells. Secondary FSGS, is usually a result of an adaptive response to hyperfiltration and glomerular hypertrophy that comes about from scarring from previous injury or from another glomerular abnormality. Secondary FSGS has been well linked to obesity, drugs, infections amongst other things. Recently, a link to long term anabolic steroid use and development of secondary FSGS was identified. Our case describes a patient who was on chronic anabolic steroids and presented with nephrotic syndrome.

Methods: 29 y/o AAM with no known past medical history who presented with complaints of progressive B/L LE swelling, scrotal swelling and abdominal distention for 2 weeks. He denied any recent illness, previous similar episode, sick contacts, recent travel. He c/o increased urinary frequency, foamy urine, vomiting and DOE. He had taken a supplement called Halo X, to build muscle for 6 months intermittently amongst other supplements years before. Negative family history, no toxic habits, was a body builder. O/E- BP-142/80, HR-70 RR- 16, he was afebrile;he had bilateral gynecomastia; abdomen was distended, soft; there was ++scrotal/penis edema, LE- 4+edema B/L to upper thigh, erythema,+tenderness. Investigations-K- 5.2, BUN/creatinine were 24/1.6, total protein-4.1 and albumin-1.5, UA-3+ protein, CK-1167, UACR-3938mg/g UPCR-4.2g/g;urine sediment was bland. CystatinC-0.98 Initial management-IV diuretics and albumin infusion;serologic studies were sent and were negative, kidney biopsy was scheduled but not done. Later, he came to clinic c/o of worsening LE swelling and pain. O/E-edematous, tense, erythematous LE, scrotal swelling. He was admitted, given IV diuretics. Labs- BUN/creatinine of 39/2.2, albumi n 1.0; UACR-3995 and UPCR-4.0 Renal bx- 80% foot process effacement, consistent with primary FSGS, tubular atrophy.

Results:

Conclusions: Management- 120mg of prednisone qod, diuretics; No ACE/ARB-high K. Initial outpatient follow up (3 weeks) showed- 31kg weight loss, no cushingoid features, BUN/Creat-20/1.71UACR-267, UPCR-0.4;albumin-4.5 K was normal, ARB was initiated.

PUB653

Isolated Renal Injury: A Case of Monoclonal Light Chain Deposition Disease Enrique E. Acosta Oruna,[7] Alexander Borrero-Arvelo,[7] Stefano Coppola fasick,[4] Jacobo J. Loyola,[2] Elvin Soto,[3] Eddie M. Rodriguez,[1] Lorena D. Morales,[5] Carlos S. Rosado-Rodriguez.[6] *[1]None, San Juan, PR; [2]VA Caribbean Health Care System, Camuy, PR; [3]VA Caribbean Healthcare System, San Juan, PR; [4]VA Caribbean healthcare system, Guaynabo, PR; [5]VA caribbean Healthcare System, San Juan, PR; [6]Veterans Affairs CAribbean Healthcare System, Guaynabo, PR; [7]Veterans Affairs Caribbean Healthcare System, San Juan, PR.*

Background: Monoclonal light-chain deposition disease (MLCDD) is a systemic disease that typically presents initially with isolated renal injury related to a glomerular lesion associated with nonamyloid electron-dense granular deposits of monoclonal light chains with or without heavy chains.

Methods: A 69 year-old male was brought to the emergency department with the chief complaint of combined lower extremity, scrotal, and penile swelling of one week of evolution. Past medical history includes HTN, obesity, dyslipidemia, prostate cancer treated with local radiotherapy, radiation cystitis, and GERD. His medication profile included nifedipine, atorvastatin, and omeprazole. Physical examination revealed elevated blood pressure 169/75mmHg and anasarca. Laboratories showed AKI with an increase in creatinine from 1.2mg/dl to 2.0mg/dl, anemia of 8.3g/dl, proteinuria of >500mg/dl by dipstick, and microscopic hematuria. A urine 24-hour collection was performed and showed nephrotic range proteinuria. Further lab results reported hypocomplementemia, elevated rheumatoid factor, and positive IgG schistosoma titers. In view of this, patient was trated with praziquantel. However, eosinophilia, anasarca, and elevation in serum creatinine persisted despite treatment. Secondary causes of nephrotic syndrome were ruled out. Hepatitis workup, Strongyloides, and HIV with negative results. SPEP and UPEP without monoclonal spikes. Renal biopsy was requested and light microscopy remarkable for thickened capillary loops and membranes which suggested a membranoproliferative pattern. Electron microscopy revealed subendothelial deposits with mesangial widening and diffuse efacement of podocyte foot processes. Immunofluorescence positive focal granular deposits of low intensity for IgG and lambda light chains, moderate intensity for IgM, and high intensity for C3. All deposits were mesangial and subendothelial in origin. Bone marrow biopsy negative for multiple myeloma. PET scan negative. Serum free light chains were elevated with a high kappa/lambda ratio. Patient was diagnosed with MLCDD.

Results:

Conclusions: MLCDD is a rare entity that should be considered in the differential diagnosis of patients with nephrotic syndrome. A delay in diagnosis worsen renal outcomes due to the rapid progression of disease.

PUB654

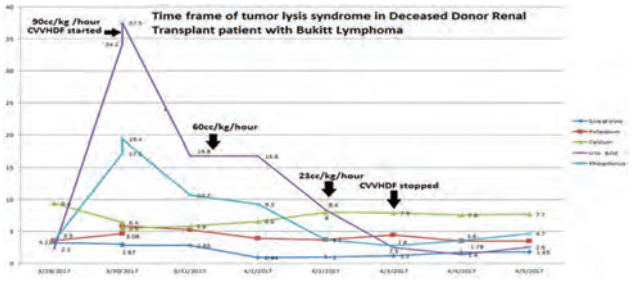
Successful Treatment of Severe Tumor Lysis Syndrome in a Deceased Donor Renal Transplant Recipient Massini Merzkani, Jamil Ibrahim, Richard L. Barnett, Vinay Nair. *Northwell, Mineola, NY.*

Background: The recent use of more effective targeted agents enhances the risk of developing Tumor Lysis Syndrome(TLS). The mortality in TLS is 66% in patients who present with AKI. Few cases has been reported in patients with renal transplantation. We present a case in a patient with deceased donor renal transplantation(DDRT) with severe TLS refractory to medical management which was successfully treated with CVVHDF.

Methods: A 39 year old female with history of DDRT 15 years ago, diabetes mellitus and recent pregnancy 4 months ago presenting with abdominal pain and AKI. Initial creatinine was 3.7 mg/dL. The CT abdomen revealed multiple lymph nodes in the peritoneum. A biopsy revealed Burkitt lymphoma. Epstein Barr serum PCR was 195322 IU/ml. Her immunosuppression was changed, by increasing prednisone to 10 mg PO daily and discontinuing tacrolimus. The patient initiated chemotherapy with rituximab (678 mg). The following day the patient had oliguria. Her serum calcium decreased to 6.4 mg/dL, uric acid increased to 34.3 mg/dL, serum phosphorus increased to 19.2 mg/dl and serum potassium rised up to 5.9mmol/L. Her EKG revealed peaked T waves, widening QRS 0.15 sec and prolonged QTc 0.55 sec. She received multiple infusions of calcium gluconate, fluids and rasburicase 6mg. EKG changes and electrolyte abnormalities did not reverse with medical management. High dose CVVHDF was initiated (90cc/ kg / hour) with immediate improvement of electrolytes (figure). Subsequent CVVHDF dose was decreased to 60 cc/kg/hour on day 2 and 3 then 23cc/kg/hour on day 4. On day 5 urine output increased and CVVHDF was discontinued. Serum Creatinine normalized to 1mg/dL

Results:

Conclusions: This is one of the few cases reported with TLS in a renal transplantation recipient. This case showed severe hyperkalemic EKG changes despite mild hyperkalemia enhanced by hypocalcemia. In this case high dose CVVHDF was started immediately as she was refractory to medical management. High clearance CVVHDF may not only be lifesaving but was associated with excellent recovery in the renal transplant.



PUB655

Thrombotic Microangiopathy in the Kidney Transplant Population: An Emergency That Requires a Quick Diagnosis and Treatment Hassaan Rasheed,[1] Aleksandra De Golovine.[2] *[1]UT Houston, Houston, TX; [2]UTHSC-H, Houston, TX.*

Background: Thrombotic microangiopathy (TMA) is a histopathological term that describes glomerular, arteriolar or interlobular artery lesions, characterized by patchy distribution, with intimal cell proliferation, thickening and necrosis of the wall, thrombi and narrowed lumens.(1) These lesions are rare, but can be devastating in kidney transplants if the processes that cause them are not stopped. Post kidney transplant TMAs can be recurrent, often the result of genetic mutations or de novo, attributed to drugs, infections or rejection. Quick diagnosis is key to the survival of the graft. We describe three cases of TMA in renal transplant recipients.

Methods: The first case is a 35-year-old African American man who underwent a living unrelated kidney transplant complicated by delayed graft function. A kidney biopsy was done and showed no evidence of rejection. He was readmitted 4 months later for sepsis secondary to a urinary tract infection and CMV colitis. He also had severe acute kidney injury requiring temporary hemodialysis. A kidney transplant biopsy was repeated which revealed focal segmental glomerular platelet thrombi, consistent with disseminated intravascular coagulation. Electron microscopy showed segmental intracapillary platelet aggregates consistent with microthrombin and TMA. The infections were treated and his kidney function recovered. The second case is a 40-year-old white female with atypical hemolytic uremic syndrome on eculizumab, who underwent a living unrelated kidney transplant. She was found to have a rising creatinine and a transplant kidney biopsy revealed TMA, likely secondary to atypical hemolytic uremic syndrome despite being on eculizumab. She was found to have CMV colitis. She was treated and her calcineurin inhibitor was discontinued. Her kidney function stabilized. The third case is a 60 -year- old African American female with a history of active hepatitis C who underwent a deceased donor kidney transplant from a hepatitis C positive donor and developed acute kidney injury. Transplant kidney biopsy revealed HCV related cryoglobulinemia and TMA. Her hepatitis C was treated and her kidney injury resolved.

Results:

Conclusions: Discussion: Early recognition and accurate diagnosis of TMA in kidney transplant recipients improves graft survival. 1) Ponticelli C, Banfi Giovanni. Thrombotic microangiopathy. *Transplant Int*

PUB656

An Unusual Case of Membranoproliferative Glomerulonephritis Due to Culture Negative Peritonitis Ahmed O. Giwa,[2] Silvi Shah.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]Internal Medicine, University of Cincinnati, Cincinnati, OH.*

Background: Membranoproliferative glomerunephritis (MPGN) is a type of chronic nephritis. Viral infections (e.g. hepatitis C) and chronic bacterial infections (e.g. endocarditis) are the most common reported infectious causes. We report a rare case of MPGN due to culture negative peritonitis.

Methods: 41-year-old female initially presented with a 3-day history of diffuse abdominal pain, abdominal swelling and acute kidney injury (AKI). Her medical history was significant for orthotropic liver transplant 13 years back complicated by chronic rejection, cirrhosis and ascites requiring frequent paracentesis. Vitals were stable. Physical examination revealed ascites and bilateral lower extremity swelling. Blood work showed a white cell count of 3.8 10E3/microL and elevated creatinine of 3.5 mg/dl (baseline creatinine of 1.2 mg/dl). Urinalysis showed 100 RBC's with dysmorphic RBC's seen on urine microscopy. Spot urine protein/creatinine ratio was 8.4. Albumin was 3.2g/dl. Complement C3 was low (57mg/dl) but C4 was normal (22mg/dl). Workup for Hepatitis and HIV were negative. No monoclonal or cyroglobulins were detected. Renal ultrasound showed normal sized kidneys with no hydronephrosis. Paracentesis revealed 372 TNC's and 75% neutrophils. A diagnosis of spontaneous peritonitis was made and patient was started on broad-spectrum antibiotics. Both ascitic fluid culture and blood culture remained negative. Due to worsening oliguric AKI (creatinine peaked to 4.3mg/dl on day five of admission), renal biopsy was done; that showed a proliferative glomerular lesion with evidence of immune complex deposits, predominantly IgG and C3 in the mesangial region and the capillary walls, representing features consistent with MPGN. Etiology of MPGN was attributed to culture negative peritonitis. Patient was started on dialysis, but was dialysis free at time of discharge with creatinine of 3.3mg/dl and stable electrolytes.

Results:

Conclusions: This case underscores an unusual cause of MPGN due to culture negative peritonitis, as compared to the well-documented cases secondary to Hepatitis C, bacterial endocarditis and fungal infections. Clinicians should be mindful of this to avert renal complication of peritonitis.

PUB657

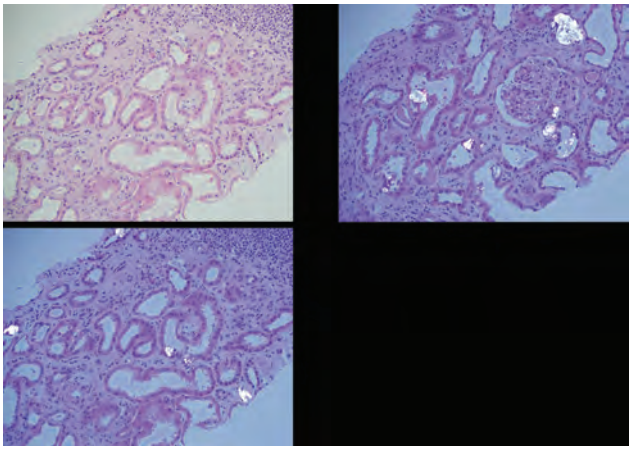
Oxalate Nephropathy: A Case of Acute Renal Failure from Chronic Pancreatitis Trevor R. Smith,[2] Monica P. Revelo Penafiel,[1] Josephine Abraham.[1] *[1]University of Utah, Holladay, UT; [2]Nephrology, University of Utah, Salt Lake City, UT.*

Background: Acute oxalate nephropathy (AON) is a rare form of secondary enteric hyperoxaluria that can result in renal failure.

Methods: A 78 year old white male presented with an elevated creatinine from a baseline of 1.8 mg/dL. He has a history of acute gallstone pancreatitis with necrosis and pseudocysts; acquired diabetes; hypertension; and carcinoid tumor of the appendix status-post resection 5 years prior. He was complaining of chronic explosive watery diarrhea for 2 months associated with a 70 lb weight loss over 12 months. Physical exam was significant for mild abdominal distension and no fluid wave, and non-blanching purpuritic rash on the bilateral lower extremities. Urinalysis was unremarkable. Serologic studies revealed a creatinine of 4.98 mg/dL, cystatin C of 3.1 mg/L, phosphate 6.1 mEq/L, total calcium 8.5 mg/dL. Monoclonal spike of 0.59 g was found on serum protein electrophoresis with kappa/lambda serum free light chain ratio of 2.15. CT of the abdomen and pelvis showed pancreatic calcifications, but was otherwise negative. Renal biopsy showed diffuse oxalate crystals with associated tubular damage, AIN with scattered eosinophils, 30% interstitial fibrosis and tubular atrophy, moderate hypertensive nephrosclerosis. Additionally, basement membrane thickening and mesangial expansion was found. Immunofluorescence was negative for kappa or lambda light chains or IgG4. Congo red stain was negative. Bone marrow biopsy showed plasma cell dyscrasia (5% plasma cells), and a small population of monoclonal B-cells (1.5% by flow cytometry). The patient was treated with pancrealipase enzyme replacement with improvement of his diarrhea. His creatinine stabilized to ~ 4.

Results:

Conclusions: Case series of acute oxalate nephropathy with pancreatic insufficiency have been described. Here we describe a case of unknown exocrine pancreatic insufficiency where the diagnosis of oxalate nephropathy lead to alternative treatment of his pancreatic disease.



PUB658

A Case of Asymptomatic Hydralazine-Induced ANCA Vasculitis Eric Chang, Jeffrey M. Turner. *Yale University, New Haven, CT.*

Background: ANCA vasculitis covers a wide spectrum of different disorders, typically microscopic polyangiitis, granulomatosis with polyangiitis and eosinophilic granulomatosis with polyangiitis. Less commonly seen is drug-induced vasculitis. We report a case of asymptomatic hydralazine-induced ANCA vasculitis.

Methods: A 32-year-old female with history for viral cardiomyopathy with past cardiogenic shock and subsequent recovery of heart function, who presented with new, progressive renal dysfunction. Renal injury occurred within 6 months of presentation with creatinine increasing from 0.85 mg/dL to 1.96 mg/dL and then 2.32 mg/dL. She had no significant symptoms at time of presentation, only seasonal allergy symptoms of itchy eyes and rhinorrhea. She was exposed to antibiotics for a root canal procedure 3 months prior to presentation. She recently had several medications tapered off by her cardiologist, including hydralazine, isosorbide dinitrate, losartan and carvedilol. Review of systems was negative for chest pain, shortness of breath, nausea, vomiting, diarrhea, muscle aches, joint pains and rashes. Urine sediment revealed several dysmorphic RBCs and >300 proteinuria on dipstick. Further diagnostic testing showed normal C3/C4, negative hepatitis B/C and HIV, positive ANA at 1:320, elevated dsDNA antibody level of 252 IU/mL, elevated anti-histone antibody of 3.4, positive p-ANCA with anti-MPO level of 553.6 CU, and 8.66 g/g proteinuria with normal urine immunofixation. Renal biopsy demonstrated necrotizing glomerulonephritis with chronicity consistent with

pauci-immune crescentic glomerulonephritis, and presence of acute interstitial nephritis. Treatment to date has included prednisone, resumption of losartan and rituximab.

Results:

Conclusions: Hydralazine has been associated with two rheumatic syndromes: drug-induced lupus and ANCA vasculitis. Drug-induced lupus rarely involves the kidneys, and our patient did not exhibit any symptoms suggesting lupus. On the other hand, hydralazine-induced ANCA vasculitis frequently has renal involvement. Notable differences between hydralazine-induced ANCA vasculitis and idiopathic ANCA vasculitis include presence of several different antibodies: anti-histone, anti-lactoferrin, anti-elastase and antiphospholipid. This case serves to shed light on a rare condition, and to highlight the importance of rigorous review of patient medications for potential sources for renal disease.

PUB659

Men in Our Own Backyard: Case Reports of ESRD from Suspected Mesoamerican Nephropathy Susanne F. Mclaughlin,[2] Sreedhar A. Mandayam.[1] *[1]None, Missouri City, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX.*

Background: There is a mysterious cluster of renal failure without obvious etiology in young agricultural workers from Central America. Potential risk factors including pesticide exposure, heat stress, NSAID use, and contaminated water are being implicated. As part of a larger study at Baylor College of Medicine investigating Mesoamerican Nephropathy, we are conducting demographic surveys on immigrant patients with ESRD who come to our ER for dialysis. Here we present a selection of case reports illustrative of Mesoamerican Nephropathy.

Methods: ESRD patients who have emigrated from Mexico or Central America volunteer for a survey about their work and living conditions in their native country. Those with a known cause of ESRD are excluded. Data is then compiled to look for commonalities in their environmental exposures. The following are representative cases from our study population. A 54 y/o M from Guatemala, who spent 30 years working as a banana farmer, developed ESRD at the age of 48. He reports chemical exposures, NSAID use, drinking home-brewed liquor, and several incidences of heat stress. His water source was unfiltered irrigation tubes in the fields. He rarely washed his hands prior to eating. His father, who was also a banana farmer, died from renal failure at the age of 80. A 37 y/o M from El Salvador, who spent 13 years working in sugar cane and cotton fields, developed ESRD at the age of 34. He reports chemical exposures, NSAID use, and dehydration. His water was unfiltered from a spigot at home. His father and uncle, both of whom worked cutting sugar cane, died from renal failure, both at the age of 56. A 53 y/o M from Mexico, who spent 25 years working in fields growing corn, tomatoes, and bananas, developed ESRD at the age of 40. He reports chemical exposures, NSAID use, local herbal use, and several incidence of heat stress.

Results:

Conclusions: Unfortunately there is no known treatment for Mesoamerican Nephropathy. The suspected pathogenesis of ESRD is progressive damage from repeated episodes of acute kidney injury. It is our hope that our work will contribute to the body of evidence that elucidates definitive risk factors for Mesoamerican Nephropathy. Intervention strategies directed at environmental and occupational exposures can then be implemented in efforts to prevent this malady, which is demonstrating increasing prevalence, morbidity, and mortality.

PUB660

IgA Nephropathy: A Diagnostic Dilemma Roshni Radhakrishna,[3] Manish K. Saha,[2] Volker Nickeleit,[1] Patrick H. Nachman.[4] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]University of North Carolina, Carrboro, NC; [4]University of North Carolina School of Medicine, Chapel Hill, NC.*

Background: Primary IgA Nephropathy (IgAN) is the most common form of glomerulopathy, while secondary causes of IgAN include inflammatory bowel diseases (IBD), infections and liver disease among others. It usually presents as glomerular hematuria and proteinuria with variable progression of kidney disease; crescentic rapidly progressive glomerulonephritis (RPGN) is an uncommon presentation. Other possible differential diagnoses in this setting include IgA ANCA vasculitis, IgA dominant infectious glomerulonephritis (AIGN) and lupus nephritis.

Methods: 67 year old female with Ulcerative colitis with complex surgical history including total colectomy, partial small bowel resection, multiple infections and fistulas was admitted with poor oral intake and abdominal pain. She was found to have septic shock from enterocutaneous fistula and Enterococcal UTI which was treated with antibiotics. Subsequently, she was found to have a gradual rise in creatinine from baseline of 0.6-0.8 to 3.8 mg/dl with an active urinary sediment with acanthocytes and UPCR of 12mg/mg. Review of past records since 2012 showed low grade proteinuria and microscopic hematuria which had not been evaluated. C3 was low at 80 mg/dl with elevated circulatory IgA levels at 855 mg/dl. Kidney biopsy revealed diffuse proliferative IgA glomerulonephritis with features of MPGN and associated focal and segmental cellular and fibrocellular crescents. She was subsequently started on steroids. For progressive renal failure she was initiated on dialysis.

Results:

Conclusions: This case highlights the dilemma in diagnosis of a RPGN presentation of IgAN in the setting of systemic infections. Our patient has had multiple infections with gram-negative organisms prior to this presentation, although not diabetic or elderly. She had evidence of consistent low grade hematuria and proteinuria, years before this presentation, pointing towards possible underlying secondary IgA nephropathy associated with IBD; in addition, the elevated ratio of IgA: C3 (ratio>10) was consistent with this diagnosis. The lack of C3 predominance staining over IgA, maintenance of lambda/kappa staining, absence of subepithelial humps may suggest crescentic IgAN rather than AIGN. It is essential to differentiate these two conditions as treatment differs. We propose that presence of low grade hematuria and proteinuria be evaluated for underlying glomerular diseases in patients with IBD.

PUB661

Smoldering C3 Glomerulonephritis Exacerbated by Blood Transfusion and Inactivated after Immunosuppression Therapy Hatem Elabd, Rushi K. Nayak, Tarek Rashid. *Jacobi Medical Center, New York, NY.*

Background: C3 glomerulonephritis (C3GN) is a separate form of proliferative glomerulopathy under category of C3 glomerulopathies, which is characterized by isolated or predominantly C3 deposits. It is associated with dysregulation of the complement alternative pathway (AP) secondary to acquired autoantibodies and/or genetic mutation of complement proteins.

Methods: We report a case of a 49-year-old male, presenting with bilateral lower extremity swelling, hypertension, plasma creatinine of 1.2mg/dl, protein-to-creatinine ratio 5.4 gm/g and bland urine, markedly depressed C3 level of 7mg/dl [90-180], normal C4, and normal ASO titer. A renal biopsy was planned. In the meantime, the patient received a blood transfusion, after which he became acutely febrile, developed a non-oliguric acute kidney injury (AKI) with creatinine peak of 3.1mg/dl, worsened proteinuria, and dark urine with an active sediment. Therefore pulse steroids were commenced then oral steroid 1mg/kg maintained. Renal pathology shows evidence of C3 glomerulonephritis. Further AP workup revealed presence of Factor H autoantibodies 28 Unit/mL [<=22], C3 nephritic factor (C3NeF) 38 units/ml [<=0] and markedly elevated soluble membrane attack complex serum C5b-9 >1700 [Reference Range: <=244 ng/mL]. Patient underwent Plasma exchange for 7 sessions, then rituximab two weekly doses (0.5 and 1 gm), and maintained on prednisone. Patient improved clinically, creatinine stabilized at 1.2mg/dl, proteinuria decreased. In addition factor H autoantibodies normalized, C3NeF decreased to 6 units/ml, serum C5b-9 went to 546 ng/ml and C3 increased to 55mg/dl. Mycophenolate introduced at this time and steroids tapered.

Results:

Conclusions: An underlying genetic or acquired complement alternative pathway abnormality can be possibly exacerbated by triggering immune complement system which subsequently triggers an unbalanced excessive continual driving of complement terminal pathway activation. In our case, blood transfusion might have led to induction of complement cascade activity either through classical or alteranative pathway dysregulation. There is limited evidence and no randomized trials to inform therapeutic decisions in C3GN. In our case, the therapeutic regimen may mitigate AP pathway activity and normalize factor H autoantibodies.

PUB662

Complications of Therapy for Pauci-Immune Rapidly Progressive Glomerulonephritis Syeda A. Raza,[1] Melanie Powell,[2] Leigh K. Hunter.[3] *[1]Methodist Health System, Dallas, TX; [2]Methodist Dallas Medical Center, Dallas, TX; [3]Methodist Hospitals of Dallas, Dallas, TX.*

Background: Rapidly progressive glomerulonephritis (RPGN) is a clinical syndrome resulting from damage to the glomeruli and is characterized by progressive loss of renal function over a short period of time. RPGN is classified into three categories, each based upon the immunofluorescence patterns. Type III, also known as pauci-immune RPGN, accounts for about 50% of RPGN cases.

Methods: A 68-year-old Hispanic female with history significant for P-ANCA-associated pauci-immune RPGN and Type II Diabetes Mellitus presented with complaints of weakness, worsening lower extremity edema that was refractory to outpatient diuretics and dysuria. Patient had been on an immunosuppresant (Rituxan) and steroids (Prednisone 40mg/day) with plans to taper. On physical examination, the patient was noted to have Cushingoid features (moon facies) along with 3+ pitting edema to the mid shins bilaterally with bruising apparent in the bilateral feet and ankles. Lab work was notable for leukocytosis and urinalysis positive for urinary tract infection. Patient was admitted for management of the multiple side effects related to prednisone therapy including marked edema refractory to oral diuretics, muscle weakness, and urinary tract infection. Patient was treated with IV diuretics for the lower extremity edema and antibiotics for the urinary tract infection. Patient had improvement of her symptoms and was sent home with a steroid taper to follow up with nephrology outpatient.

Results:

Conclusions: Treatment of RPGN relies on the use of corticosteroids. This case illustrates the importance of recognizing side effects seen with therapy and assessing the short-and long-term effects of such therapy.

PUB663

ACEI Induced Anaphylactoid Reactions in Polysulfone Dialyzers Anthony F. Iluyomade,[2] Hema Manickam.[1] *[1]None, Granite Bay, CA; [2]University of California Davis Medical Center, Sacramento, CA.*

Background: Gone are the days of severe anaphylactic reactions to Ethylene oxide and non-biocompatible membrane dialyzers; with the new era of using polysulfone and other synthetic dialyzers. Hypersensitivity reactions to these synthetic dialyzers are also on the rise. Reports of Anaphylactoid reactions in patients on ACEI dialyzing via PAN (AN69) dialyzer is widely known to occur from bradykinin effects but similar reactions

in patients on ACEI's using non – PAN (AN69) is not well known. We hereby present a case of anaphylactoid reaction to two different manufacters polysulfone dialyzers in a patient on ACEI.

Methods: A 53 year old male with a history of ESRD on HD for 3 years, HTN on Lisinopril 10mg daily, CAD S/P CABG X 3 stents and type 2 DM with retinopathy, transferred to the ER from his HD unit due to sudden shortness of breath symptoms with 86% O2sats and becoming restless about 12 minutes after starting his regular dialysis session. He was dialyzed on rexeed - 18R, a reusable dialyzer and was on the 9th re-use that day. He also endorsed similar symptoms about 3 days prior to presentation by the 8th use but these were self limiting. Patient had always tolerated his HD sessions and was initially on Revaclear polysulfone dialyzer briefly. He had been on Lisinopril treatment for hypertension management for years. No prior allergy to food or medications. Chest xray evaluation showed mild pulmonary edema, cardiac work up including an ECHO and Cardiac Cath were negative. Patient had similar reactions the next day after hospital admission when revaclear polysulfone dialyzer was used. His symptoms resolved with supplemental O2 treatment and was able to complete his dialysis session. He had not received his Lisinopril since admission given hyperkalemia and was able to tolerate dialysis from the 3rd day onward. Patient's Lisinopril was eventually discontinued and he is back to his outpatient HD unit using the same rexeed polysulfone dialyzer and has not had any recurrent symptoms.

Results:

Conclusions: ACEI triggered anaphylactoid reactions have not been commonly reported in patients using non-PAN dialyzers and literature review shows very few cases of similar reactions in ACEI and Polysulfone dialyzers. With the wide spread use of both Polysulfone dialyzers in HD units and increasing number of dialysis patients on ACEI, knowledge of such possible reactions can help in the management of our dialysis patients.

PUB664

Histoplasmosis in a Renal Transplant Patient: A Case Report Fernanda T. Ferreira,[2] Antonio A. Portela Neto,[7] Laura Onuchic,[6] Marcella M. Frediani,[1] Precil D. Neves,[3] Flavio De paula,[4] Elias David-Neto.[5] *[1]USP, Sao Paulo, Brazil; [2]University State of São Paulo, São Paulo, Brazil; [3]University of S?o Paulo, S?o Paulo, Brazil; [4]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [5]University of São Paulo School of Medicine, São Paulo, Brazil; [6]Universidade de São Paulo, São Paulo, Brazil; [7]University State of São Paulo, São Paulo, Brazil.*

Background: Transplant success depends on achieving the ideal doses of immunosuppressants capable of avoiding rejection while still maintaing sufficient immune level to prevent opportunistic infections. Histoplasmosis is a fungal disease, with a incidence <0.5% in transplant patients and clinical manifestation may vary from common cold-like symptoms to generalized systemic infections, lethal if left untreated

Methods: A 39-year-old female kidney transplant recipient due to lupus nephritis, underwent a second unrelated live donor transplant 12 years ago. Initial immunosuppression include thymoglobulin and maintenance consisted on everolimo, mycophenolate mofetila and prednisone. She had been recently diagnosed with transplant glomerulopathy during investigation of chronic graft dysfunction. She presented enterorrhagia 4 days after admission and a significant fall in hemoglobina: 8.5-> 5.0 g/dL and was, therefore, hospitalized. She was investigated with upper digestive endoscopy, abdominal and chest tomography and blood cultures; all normal. She underwent colonoscopy, which revealed an ulcerated lesion in the ascending colon, compromising ¾ of the colon circumference and biopsies were performed. During hospitalization, the patient progressed with worsening of renal function and infectious parameters, returning to the chronic hemodialysis program and starting treatment with Levofloxacin, Clarithromycin, Etambutol and Amphotericin B, according to our infectology guidelines for empiric coverage, without effective clinical improvement, and maintenance therapy was scheduled for 12 months. Although digestive haemorrhages caused by intestinal infections are most commonly associated with cytomegalovirus or herpes simplex, in our patient such agents were not identified. The colonic biopsy showed active granulomatous colitis with fungal structures of Histoplasma sp, as well as a positive BAAR. Treatment was modified to Itraconazole. The patient was discharged from hospital using this medication after clinical improvement.

Results:

Conclusions: We described a very rare case that shows the importance of extensive investigation in the presence of renal dysfunction, fever or other systemic manifestations in immunosuppressed patients, since they may present atypical pathologies and clinical manifestations, with potentially tragic evolution.

PUB665

Lung Cancer in the Kidneys, Blood in the Urine Brad Long, Mazdak A. Khalighi, Josephine Abraham. *University of Utah, Salt Lake City, UT.*

Background: Metastatic squamous cell lung cancer is a lethal disease that can involve any organ in the body. Most frequent sites of metastases are bone, liver, brain, and adrenal glands. Rarely, the kidney is involved. We present a case of metastatic SCC of the lung involving the kidneys presenting with gross hematuria and AKI.

Methods: A 68 year old male with metastatic squamous cell lung carcinoma admitted to the acute care oncology clinic with four days' progressive shortness of breath and gross hematuria and passage of a large clot. Creatinine was elevated to 2.75mg/dL from a baseline of 1.0mg/dL. Renal ultrasound showed enlarged kidneys bilaterally, with loss of normal corticomedullary differentiation and small bilateral cystic structures. CT scan from four months prior showed large kidneys with infiltrative process present in the right kidney, with obliteration of the superior pole collecting system.

Results: Recent kidney biopsy revealed poorly differentiated squamous cell carcinoma metastatic from the lung. AKI during this admission was felt to be due to infiltration of the renal parenchyma by tumor cells. Glomerulonephritis due to chemotherapy was considered though felt unlikely.

Conclusions: Renal invasion by primary lung cancer is rare and can present with hemorrhage leading to gross hematuria and impaired renal function. Hematuria and acute kidney injury should also prompt consideration of chemotherapy-related effects. In any event, lung cancer that invades the kidneys carries a very poor prognosis.

IgA-Dominant Post Infectious Glomerulonephritis and IgA Nephropathy: Different Diseases with Similar Mechanisms? Brenden D. Connor,[1] Swati Rao,[1] Duncan B. Johnstone,[1] Manjula Balasubramanian,[2] Iris J. Lee.[1] *[1]Temple University School of Medicine, Philadelphia, PA; [2]Einstein Medical Center, Philadelphia, PA.*

Background: IgA glomerular deposition is a hallmark of IgA nephropathy (IgAN). Rarely, isolated IgA- deposition is observed in post infectious glomerulonephritis (PIGN) instead of IgG. IgA-dominant PIGN, more common in elderly with diabetes mellitus (DM), has a guarded prognosis with 40% progression to ESRD. Due to similar findings in clinical and histological presentations, the differentiation of IgA dominant PIGN from IgAN can be challenging. Both diseases can present with hematuria, proteinuria, acute kidney injury, and have mesangial and endocapillary proliferation with IgA and C3 deposits on biopsy. When present, evidence of staphylococcal infection, low complements, large subepithelial deposits and polymorphonuclear (PMN) cellular infiltrates on biopsy favor IgA dominant PIGN. We report a case of IgA dominant PIGN with challenging diagnostic features.

Methods: A 75 y/o Cuban female with DM presented with gross hematuria and 2 weeks of fatigue and weight loss, without other symptoms. No findings were notable on physical exam. Labs demonstrated creatinine (Cr) of 5.3mg/dL (baseline 0.9mg/dl), hemoglobin 8.3g/dL, normal platelets, 1 gm proteinuria and dysmorphic RBC on urine microscopy. There was no clinical or laboratory evidence of infection. Ultrasound of the kidneys was normal. Serologic work up was negative and complement levels were normal.

Renal biopsy demonstrated glomerulitis, with infiltrating PMN in multiple glomeruli, mild mesangial proliferative disease, interstitial inflammation and acute tubular necrosis. Immunofluorescence was positive for IgA and C3. Electron microscopy showed mild effacement of podocyte foot processes, PMN in glomerular capillary loops, and minimal electron dense deposits in the mesangium. The lack of classic clinical and histological features of PIGN in our patient presented a diagnostic dilemma. The acute presentation with no prior known renal disease and striking glomerulitis led us to a diagnosis of IgA-dominant PIGN. After a steroid pulse, hematuria resolved and Cr improved from 6.7mg/dl to 2.63mg/dl.

Results:

Conclusions: IgA dominant PIGN is an uncommon disease and is very challenging to diagnose and manage. Interestingly, both IgA and IgA dominant PIGN can be triggered by infection, supporting similar underlying pathological mechanism but different clinical disease patterns.

PUB667

Minimal Change Disease Relapse after Influenza Vaccination Olusola Isikalu, Ruth C. Campbell, Roberto Pisoni. *Medical University of South Carolina, Charleston, SC.*

Background: Minimal change disease (MCD) is a major cause of idiopathic nephrotic syndrome (NS) accounting for 15% of idiopathic NS cases in adults. It is characterized by severe proteinuria, hypoalbuminemia, and hypercholesterolemia leading to edema. MCD onset and relapse following vaccinations has been described in the literature since 1966, but only few cases due to influenza vaccination are reported.

Methods: We report a case of MCD relapse after influenza virus immunization. Patient was a 45-year-old white woman with MCD diagnosed in December 2014 after presenting with abrupt onset of bilateral hand, facial, and lower extremity edema, and frothy urine. She had no significant past medical or allergy history and no signs of systemic infection. She was normotensive. Urinalysis (UA) showed 3+ protein and urine protein-to-creatinine (UPCR) was 6.5 g/g. Serum albumin was 1.5g/dL, total cholesterol 465 mg/dL, WBC 6.79K/mm^3, hemoglobin (Hgb) 14.5 g/dL, platelets 417K/mm^3, BUN 20 mg/dL, creatinine 1.0 mg/dL, AST 29IU/L, ALT 20 IUL/L, C3 155mg/dL, and C4 29.3mg/dL. RPR, hepatitis B & C serologies, and ANA were negative. After approximately 2 weeks, UPCR worsened to 12 g/g. A kidney biopsy showed MCD and oral prednisone 1mg/kg daily was started in addition to torsemide 5mg/day and rosuvastatin 5mg/day. Complete remission of proteinuria was documented 2 weeks later and persisted after completing a 6-month course of prednisone. Patient remained in complete remission until October 2016 when, just after receiving influenza vaccine, she developed periorbital edema and frothy urine. She denied recent infections or NSAID use. She was normotensive. Renal and hepatic chemistries were normal with creatinine 0.7 mg/dL except for serum albumin of 3.0 g/dL. UA showed protein 100 mg/dL and 24 hour proteinuria was 1.5 g. Relapse of MCD was attributed to recent influenza vaccination in the absence of other potential triggers of MCD. She was treated with oral prednisone 50mg/day and proteinuria resolved within 21 days.

Results:

Conclusions: Our case as well as previous anecdotal reports suggest that influenza vaccination and the resulting stimulation of the immune system may cause MCD. This finding demands further investigation in the pathophysiology of MCD and also requires consideration of further vaccinations in this patient population.

PUB668

An Uncommon Cause of Hypertension in Sepsis Jin Lee,[1] Sharad Virmani.[2] *[1]Gwinnett Medical Center Internal Medicine Residency Program, Lawrenceville, GA; [2]Georgia Nephrology, LLC, Lawrenceville, GA.*

Background: Pheochromocytoma is responsible for 0.1% of hypertension cases. Oftentimes, the classic triad of palpitations, headache, and diaphoresis can be overlooked or even absent. Pheochromocytoma should be considered in patients presenting with resistant hypertension, paroxysmal hypertension or labile blood pressure. We present a case pheochromocytoma masked by sepsis.

Methods: A 52 year-old Korean female with no past medical history presented to Gwinnett Medical Center with sepsis secondary to pneumonia. On admission, BP was 86/43mmHg and pulse was 124bpm. The patient was started on broad spectrum antibiotics with IV fluid resuscitation. The patient clinically improved with resolution of pneumonia but she remained tachycardic with labile blood pressure (SBP 68-200, DBP 37-93mmHg). She required intermittent Norepinephrine and Nicardipine for management of her dramatic BP fluctuations. Further questioning of her medical history revealed two years of intermittent episodes of flushing and palpitations which she believed to be related to menopause, thus she did not seek medical assistance. Evaluation for secondary causes of hypertension revealed a 4.8x4x5.37cm right adrenal mass on renal duplex. This raised a suspicion for pheochromocytoma and a 24 hour urine metanephrine analysis was performed resulting in normetanephrine levels of 5208mcg/24h, metanephrine levels of 11807mcg/24h, and vanillymadelic acid levels of 51.4mcg/24h, all elevated. Confirmatory MRI with gadolinium showed a 5cm heterogenous, cystic supra-renal mass with central necrosis. She was immediately started on phenoxybenzamine. Optimization of BP was achieved and was deemed stable for discharge with plans for operative removal of the tumor after two weeks of alpha blockade.

Results:

Conclusions: Pheochromocytoma can be an underdiagnosed condition due to nonspecific historical and physical exam findings. Upon diagnosis, initiation of alpha blockade to stabilize blood pressure prior to resection of the adrenal tumor is critical to avoid lethal intraoperative blood pressure fluctuation. Our case highlights the importance of a thorough history to identify a rare disorder overlapped by a common presentation of sepsis.

PUB669

Crescentic IgA Nephropathy (IgAN) in a Patient with Underlying Crohn's Disease – A Treatment Challenge Alinda M. Sarma,[1] Anca C. Vlasie.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Comprehensive Kidney Care, Westlake, OH.*

Background: Crescentic IgA Nephropathy (IgAN), defined as >50% crescentic glomeruli on kidney biopsy, is a common cause of rapidly progressive glomerulonephritis (GN), but a rare manifestation of IgA vasculitis. We present a case of IgAN in a chronically immunosuppressed patient.

Methods: A 49 year old female was admitted for profound malaise, found to severe acute kidney injury (AKI). Her past medical history was significant for Crohn's disease and secondary inflammatory arthritis treated with prednisone, mesalamine, 6-mercaptopurine, methotrexate and infliximab over the years, recurrent skin rash with biopsy suggestive of leucocytoclastic vasculitis, chronic sinusitis. Physical examination was significant for purpuric rash on lower extremities. Laboratory work-up revealed serum creatinine of 2.9 mg/dl, BUN of 57 mg/dl, WBC of 13.06 k/ul, ESR of 111 mm/hr and CRP of 20.6 mg/dl, urinalysis with dysmorphic RBCs and RBC casts. P-ANCA, C-ANCA, Anti-proteinase 3, Anti-myeloperoxidase, ANA were all negative, and serum complement levels were normal. Kidney biopsy showed focal endocapillary proliferative and crescentic GN with IgA-dominant deposits, and electron microscopy confirmed the presence of mesangial and peripheral capillary wall immune deposits. Differential diagnoses included large vessel vasculitis/cutaneous vasculitis in setting of Chrohn's disease, cutaneous vasculitis and GN secondary to medications (infliximab or TNF alpha inhibitor), and IgA vasculitis. Patient was started on pulse dose steroids and oral cyclophosphamide. After three months, creatinine was 1.5 mg/dl, with resolution of hematuria and rash.

Results:

Conclusions: The Oxford Classification of IgAN does not account for glomerular crescents and there are no specific guidelines for treating crescentic IgAN. Crescentic GN is usually associated with ANCA – associated vasculitis or anti-GBM disease. While isolated case reports suggest good response to treatment that includes pulse steroids, cyclophosphamide and plasma exchange, others show no benefit from aggressive treatment. Our patient presented with all the acknowledged risk factors for IgA progressive disease: serum creatinine >1.35 mg/dL, proteinuria >1 g/day, fibrinoid necrosis, and responded well to aggressive treatment. Further guidelines on managing crescentic IgAN would greatly improve the care of these challenging patients.

PUB670

Antiphospholipid Syndrome Started with Microangiopathy and Developed Right Renal Infarction and Left Renal Artery Stenosis Maiko Nagata, Takayuki Fujii, Kaiji Saito, Mizuki Shinozaki, Mayu Morimoto, Noriko Terasaki, Hiroaki Tanaka, Satoshi Suzuki. *Seirei Sakura Citizen Hospital, Chiba, Japan.*

Background: The kidney is one of the organs that is involved in patients with primary antiphospholipid syndrome (APS). Renal involvement in APS is characterized by non-inflammatory occlusion of renal vessels ranging in size from large vessels to intrarenal microvasculature. However, there are no reports of these lesions over time.

Methods: This is a case of a 48-year-old woman, who was previously in good health presented to our department for the investigation of proteinuria when she was 44 years old. She did not have hypertension. The serum creatinine level was 0.5 mg/dl. Urinalysis showed no microscopic hematuria and mild proteinuria (0.5 g/day). Imaging did not show renal artery stenosis. When she was 45 years old, renal biopsy was performed for continuous mild proteinuria (0.5 g/day). Renal biopsy showed fibrous intimal hyperplasia of arterioles and segmental glomerular basement membrane reduplication. Immunofluorescence showed IgG deposits in her capillaries. She was suspected of membranous nephropathy and prescribed angiotensin receptor blocker. Three years later, she admitted to our hospital due to right back pain, and her contrast computerized tomography (CT) scan revealed right renal infarction and left renal artery stenosis. APS was considered the most likely diagnosis because her lupus anticoagulant, anticardiolipin antibody, and anti-β2 glycoprotein I antibody were positive. There was no thrombosis in other organs. Because she was not suspected systemic lupus erythematosus, only anticoagulation treatment was started. A retrospective analysis shows that renal biopsy three years ago showed microangiopathy which might be a pathological feature of APS nephropathy.

Results:

Conclusions: This is a rare case that we were able to observe APS started with microangiopathy and developed right renal infarction and left renal artery stenosis. This might be a process of development from intrarenal microvasculature to large vessels in renal involvement in APS.

PUB671

A Case of Bilateral Renal Artery Thromboembolic Disease of Unknown Etiology Franklin Lam,[1] Samah Musa,[1] Matthew J. Bruha,[2] Krishnakumar D. Hongalgi.[1] *[1]Albany medical center, Albany, NY; [2]Albany Medical College, Albany, NY.*

Background: Renal artery thrombosis usually presents unilaterally and is treated with anticoagulation therapy or endovascular repair. We present a case of bilateral renal artery thromboembolic disease of unknown etiology.

Methods: This patient is a 56 year old female with history of COPD and current smoker who presented with hemoptysis and hematuria. She had no other complaints. Lab work showed elevated creatinine of 3.5 mg/dL. Baseline creatinine was normal. Urinalysis was noteable for 3+ protein and RBCs and WBCs in urine sediment. Twenty four hour protein was 1.7gm A renal ultrasound showed absent vascular flow suggestive for renal vein thrombus. Anticoagulation was initiated with IV heparin and was also started on Coumadin. Her renal function continued to decline and creatinine increased to 6.8 mg/dL. On day 4 MRI of abdomen which showed striking bilateral heterogeneous signal abnormality involving half of the left kidney and a third of the right kidney which represents multiple embolic infarcts of the kidneys in setting of an infrarenal aortic thrombus. On day 6 a right renal biopsy was obtained which revealed diffuse tubular degenerative changes consistent with ATN. When correlated with the MRI, the possibility of unsampled renal vascular injury including thromboembolic processes vs. structural, vasoactive or inflammatory vascular insults should be considered. Patient required hemodialysis on day 5. She developed intracranial hemorrhage and status epilepticus requiring intensive care unit stay and intubation for a period of time. Anticoagulation was stopped and she was extubated and has been hemodialysis dependant Work up for cause of thromboembolic state so far revealed no evidence of atrial fibrillation, and TTE was negative for thrombus or valvular disease. Further investigation yielded the following results: positive ANA, C3 & C4 were normal, pANCA & cANCA negative, Hepatitis panel negative, negative Factor V Leiden, and negative antiphospholipid syndrome. The patient also demonstrated an elevated homocysteine level. JAK 2 mutation is negative.

Results:

Conclusions: This is a case of bilateral renal artery thromboembolic disease of unclear etiology. Once the patients intracranial hemorrhage resolved by CT imaging she was initiated on IV heparin and her neurological status was monitored closely.

PUB672

TINU Syndrome: A Diagnosis of Exclusion Malavika Kapuria, Natasha N. Dave, Rajeev Raghavan. *Baylor College of Medicine, Spring, TX.*

Background: With little over 250 cases reported, the diagnosis of Tubulointerstitial Nephritis and Uveitis (TINU) syndrome requires a high index of suspicion. Variable clinical presentations, poorly understood underlying mechanisms and lack of specific laboratory markers make its diagnosis all the more complex. We report the case of a young female who presented with AKI, anterior uveitis and systemic symptoms, initially misdiagnosed as pyelonephritis, and subsequently diagnosed and treated for TINU syndrome.

Methods: A 33 year-old Hispanic female with no significant past medical history presented with an 11 days history of fever, fatigue, headache, epigastric pain, dysuria, polyarthralgias and bilateral conjunctival injection. CT scan showed bilateral striated nephrogram with perinephric stranding. She was diagnosed with pyelonephritis and discharged on empiric antibiotics. She presented again 2 days later with no improvement in symptoms. Physical examination was notable for bilateral conjunctival erythema without drainage, epigastric tenderness and wrist synovitis. Serum creatinine was 2.5 mg/dl increased from 1.5 mg/dl 2 days prior (baseline Cr 0.8). Further work-up including urinalysis revealed a loss of concentrating ability (specific gravity 1.005 decreased from previous 1.023 in 2011) with 'few' urine eosinophils. Urine microscopy revealed WBC casts. Renal ultrasound showed preserved kidney sizes with bilateral heterogeneous poor corticomedullary differentiation. Other pertinent labs included elevated CRP (8.94) and ESR (76), negative ANA, and mildly elevated C3 (154) and C4 (46.9). Ophthalmologic evaluation found anterior uveitis with conjunctival injection. A kidney biopsy showed acute TIN with eosinophils and non-caseating granulomas. Additional work-up for syphilis, tuberculosis, Sjogren's, HLA-B27, MPO/PR3 ANCA and chest x-ray were negative. The patient had excellent response to steroids (pulse dose IV steroids for 3 days, followed by PO steroid taper) with improvement in renal function back to baseline within 14 days. She was treated for a total of 6 weeks and remains asymptomatic 2 months post-hospitalization.

Results:

Conclusions: TINU is a rare, idiopathic syndrome and remains a diagnosis of exclusion. This case exemplifies the variety of presenting signs/symptoms and the degree of renal dysfunction associated with TINU, and highlights the need for a systematic approach to ruling out alternative diagnoses.

PUB673

Underdiagnosis of Adrenocortical Adenoma Franklin Lam,[2] Rafia I. Chaudhry,[2] Loay H. Salman,[1] Mauricio Monrroy.[2] *[1]Albany Medical College, Albany, NY; [2]None, Providence, RI.*

Background: Primary hyperaldosteronism, described by Conn in 1956 as an aldosterone-secreting adrenal adenoma results in resistant HTN. Less than 1% of cases with HTN were initially attributed to Conn's syndrome. Recent data indicates a higher incidence of Conn's syndrome of up to 5-15% in pts with HTN, suggesting considerable underdiagnoses.

Methods: 33 yr-old Caucasian male, with PMHx of obesity and HTN, referred for HTN, hypokalemia in 2013. BP 178/100 mmHg on Amlodipine 10 mg. Funduscopic exam revealed bilateral retinal AV nicking. Sr Cr 1.0 mg/dL, K 3.3 mmol/L, and CO_2 32 mmol/L. Renal US unremarkable, doppler US negative for renal vein stenosis. Plasma aldosterone concentration (PAC) 7.7 ng/dL, plasma renin activity (PRA) 0.86, 24-hr Ur aldosterone (ALD) 40.50, Ur Na 182. MRI negative for adrenal abnormality. BP remained marginally controlled on Amlodipine, Telmisartan, and Amiloride. CPAP was started for OSA. HTN remained sub optimally controlled HTN 3 yrs later, and repeat studies consistent with hyperaldosteronism (PAC 37.8, 24-hr Ur ALD 40.50, PRA 4.81 and 6.17). CT adrenal mass protocol revealed 1.1-cm left adrenal nodule. Adrenal venous sampling (AVS) confirmed lateralization to left adrenal gland, and adrenalectomy will be pursued.

Results:

Conclusions: Adrenal CT scan has superior spatial resolution than MRI to detect adrenal adenoma. If CT scan is negative, or demonstrates bilateral abnormalities, or unilateral abnormality in pt > age 35, AVS can confirm unilateral disease to explore the role of surgical intervention for primary hyperaldosteronism.

Time (minutes)	Left AV Aldosterone	Right AV Aldosterone
Baseline	166 ng/dL	26 ng/dL
5	4310 ng/dL	42 ng/dL
10	2990 ng/dL	48 ng/dL
15	2930 ng/dL	60 ng/dL

PUB674

The Role of Continuous Renal Replacement in the Management of Type B Lactic Acidosis Due to Hemophagocytic Lymphohistiocytosis Ryan Mullane, Scott G. Westphal. *University of Nebraska Medical Center, Omaha, NE.*

Background: Hemophagocytic Lymphohistiocytosis (HLH) is a rare, life-threatening complication of excessive immune activation caused by uncontrolled release of inflammatory cytokines from activated macrophages and T lymphocytes. Type B lactic acidosis due to HLH is extremely rare with few case reports; therefore, the optimal treatment strategy is unknown. We present a case of type B lactic acidosis due to HLH where continuous renal replacement therapy (CRRT) and sodium bicarbonate infusion were incorporated in the successful management of the lactic acidosis.

Methods: A 64-year-old female with chronic lymphocytic leukemia and anaplastic large cell lymphoma was admitted for pancytopenia and hyponatremia. Examination was notable for splenomegaly and recurrent fevers. Extensive evaluation into an infectious etiology was unremarkable. Further testing revealed hypertriglyceridemia (triglyceride level of 362 mg/dL), hyperferritinemia (ferritin level of 60,917 ng/mL), transaminitis, and an elevated soluble IL-2 receptor level (111,000 pg/mL); given her presentation, she was diagnosed with HLH. Over the next 24 hours, despite remaining normotensive with relatively unchanged renal function, she developed lactic acidosis with a maximum lactate level of 16.6 mmol/L and profound acidemia. She was started on CHOP chemotherapy and we initiated treatment for her lactic acidosis with IV sodium bicarbonate and continuous venovenous hemodialysis (CVVHD) with a high dialysate flow rate of 5,000 mL/hour (~60 mL/kg/hour) to control the acidosis. The patient's lactic acidosis resolved over the following days and her sodium bicarbonate infusion and CRRT were both discontinued.

Results:

Conclusions: Type B lactic acidosis and HLH both have poor survival rates. Historically, the use of renal replacement therapy and bicarbonate infusion for lactic acidosis is controversial with limited evidence of benefit in Type B lactic acidosis. Our patient had resolution of lactic acidosis due to HLH following chemotherapy initiation and treatment with CRRT and sodium bicarbonate infusion. Concurrent with chemotherapy, sodium bicarbonate infusion with CRRT may be a potential novel management approach for type B lactic acidosis due to HLH.

PUB675

Cases of Intimal Arteritis with Phantom Etiology John T. Nguyen,[2] Aleksandra De Golovine.[1] *[1]UTHSC-H, Houston, TX; [2]University of Texas Houston Medical School, Houston, TX.*

Background: V lesions in transplant renal biopsy have shown to be important in our ability to diagnose and prognosticate graft failure. The conventional thought is that V lesions represent T cell-mediated rejection however there is concern that V lesions may be present in antibodymediated rejection as well. We report three cases of renal transplant patients who underwent indicated renal biopsy that demonstrated isolated intimal arteritis.

Methods: The first case is a 55 year old male with end stage renal disease after he donated a kidney and developed renal cell carcinoma in his remaining kidney. He underwent deceased donor transplant on 10/31/2016. The patient had delayed graft function which resulted in a biopsy on 11/3/2016 that showed 3 arteries with intimal arteritis that was almost obliterative. The patient was clinically diagnosed with atypical HUS and started on eculizumab shortly after. The patient's renal function stabilized but

worsened three months later. Repeat transplant renal biopsy on 3/3/2016 that revealed isolated V lesion of a single artery with no significant tubulointerstial inflammation, tubulitis or peritubular capillaritis, no interstitial fibrosis and C4d was negative. The second case involves a 41 year old male with a history of dilated cardiomyopathy status post heterotypic transplant in 1992. The patients was admitted in 05/2016 for decompensated heart failure and developed acute on chronic kidney disease requiring hemodialysis. The patient underwent simultaneous heart and kidney transplant on 1/22/2017. Post operative course was complicated by respiratory failure, recurrent C. difficile colitis, influenza and renal graft insufficiency. Patient had a transplant renal biopsy on 2/17/2017 that showed isolated intimal arteritis, no tubulitis, no peritubular capillarities, and no C4d positivity. The third case involves a 49 year old male with a medical history of end stage renal disease, congestive heart failure, and hypertension. He underwent living unrelated transplant on 12/09/2016. There was delay of graft function and transplant renal biopsy was performed on 12/16/2016 which showed intimal arteritis in four arteries but with negative C4d and no tubulitis.

Results:

Conclusions: These cases are notable because they demonstrate how isolated V lesions are present in acute rejection but there needs to be continued efforts to further define their role in diagnosis and prognostication of graft failure.

PUB676

Hypophosphatemia and Cardiac Arrest in an Elderly Hemodialysis Patient Joanne Cooke, Amina Khan, Munis A. Mattu, David E. Webb, Virginia J. Savin. *Kansas City VA Medical Center, Kansas City, MO.*

Background: About 40% of hemodialysis (HD) patients funded by Medicare are ≧ 65 years old. Both hyper- and hypo-phosphatemia are associated with increased mortality in HD patients. Hyperphosphatemia is the primary concern for younger patients, while hypophosphatemia is more common in elderly patients and is associated with higher all-cause and cardiovascular mortality.

Methods: A 77 yo man with malnutrition and hypophosphatemia prior to starting HD received a liberal diet, nutrition supplement (Nepro) and tid oral NA/K/PO_4 (Neutraphos) and no PO_4 binders. Dialysis was 3.5 h tiw. 18 months later he had asystole at the end of HD. Plasma PO_4 after cardiac arrest was 1.8 mg/dl. He was hospitalized for 26 days and DC'd on dialysis 3 h tiw, with a Life Vest ™ and plan for ICD. He received IV $NaPO_4$, 30 mM at each HD for 4 months (~1350 mM total). Predialysis PO_4 rose from 2.5 to 4.5.

Results:

Conclusions: Of 34 HD patients in our VA HD unit, 7 (21%) had pre-dialysis PO_4 ≦3.5. Pre- and post-dialysis PO_4 were 3.1±0.7and 1.2±0.5 (Mean±SD), respectively. Decrease in PO_4 during dialysis was 1.9±0.9 (59±18%). Hypophosphatemic patients had lower Hgb and BUN than others. Each had lost weight in prior 3 months (2.2±1.9%). Five were hospitalized in the prior month. After recognizing low PO_4 as a potential risk, PO_4 binders were stopped in these patients. Predialysis PO_4 increased by a mean of 0.75 mg/dL within 30 days. Two patients resumed PO_4 binder at a lower dose and have maintained predialysis PO_4 ≧ 3.5. Hypophosphatemia increases mortality in continuous and intermittent therapies. It is a challenge in geriatric care as well as during intensive treatments in acutely ill persons. Measurements of dialysis adequacy focus on removal of organic compounds, but depletion of inorganic compounds occurs simultaneously. PO_4 drops during HD and, although it rebounds within 5 hours, dynamic changes may increase the risk of cardiac events. Increasing predialysis PO_4 by including foods with intrinsically higher nutrient:PO_4 ratio (dairy, legumes) and limiting PO_4 binders can increase predialysis PO_4 and reduce risk. Recognizing the high incidence of hypophosphatemia may alter prescriptions and improve outcomes in the elderly.

A Variability Study of Two Leading Metabolomics Platforms in CKD Eugene P. Rhee,[3] Sushrut S. Waikar,[1] Casey Rebholz,[2] Regis Perichon,[4] Clary B. Clish,[10] Julian R. Avila-Pacheco,[6] Michelle Denburg,[7] Amanda H. Anderson,[8] Harold I. Feldman,[8] Paul L. Kimmel,[5] Josef Coresh.[9] *[1]Harvard Medical School, Boston, MA; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Massachusetts General Hospital, Boston, MA; [4]Metabolon, Durham, NC; [5]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [6]The Broad Institute of MIT and Harvard, Cambridge, MA; [7]The Children's Hospital of Philadelphia, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [8]University of Pennsylvania, Philadelphia, PA; [9]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [10]Broad Institute of MIT and Harvard, Cambridge, MA. Group/Team: On behalf of NIDDK CKD Biomarkers Consortium.*

Background: Non-targeted metabolomics can measure thousands of low molecular weight biochemicals, but important gaps limit its utility for biomarker discovery in CKD. These include the need to characterize technical and intraperson analyte variation, to pool data across metabolomics platforms, and to outline relationships between the metabolome and GFR.

Methods: Plasma from 49 individuals with CKD (eGFR <60 mL/min/1.73m2 and/or ≥1g proteinuria) was examined over two study visits; 20 samples were repeated as blind replicates. To enable comparison and synthesis across two non-targeted metabolomics platforms, samples were profiled at the Broad Institute and Metabolon.

Results: The Broad (B) platform reported 681 known metabolites and 28,630 unknown ion features. The Metabolon (M) platform reported 896 known metabolites and 46,212 unknown ion features. Median CVs across blind replicates were 6.3% (B) and 14.6% (M) for knowns, and 24.5% (B) and 35.1% (M) for unknowns. Median CVs for day-to-day variability were 24.9% (B) and 29.0% (M) for knowns, and 36.7% (B) and 40.9% (M) for unknowns. 343 knowns were shared across platforms, with a median Pearson correlation of 0.91. Many metabolites were negatively correlated with eGFR-Cr at p<0.001: 8.8% (B) and 19.1% (M) of knowns, and 12.4% (B) and 9.0% (M) of unknowns.

Conclusions: Nontargeted metabolomics quantifies thousands of analytes with low technical CVs (lower for known metabolites than unknown ion features). Substantial intraperson variation and correlation with eGFR underscore the need for careful selection of potential metabolite biomarkers. Agreement for overlapping metabolites across two leading platforms is excellent, setting the stage for future cross-platform meta-analyses.

A Simplified Protein-Energy Wasting Scoring System for Survival Prediction in Korean Incident Hemodialysis Patients Young Eun Kwon,[1] Hye Min Choi,[1] Dong-jin Oh,[1] Shin-Wook Kang.[2] *[1]Department of Internal Medicine, Myoungji hospital, Seonam University College of Medicine, Goyang-si, Gyeonggi-do, Republic of Korea; [2]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Even though protein-energy wasting (PEW) is a crucial risk factor for survival in end-stage renal disease (ESRD) patients, a convenient and reliable assessment method to determine PEW in ESRD patients has not been established. However, a recent study proposed a simplified PEW scoring system based on the PEW diagnostic criteria, which was predictive for European ESRD patients' survival. This study aimed to validate the prognostic significance of the simplified PEW score in Korean incident hemodialysis patients.

Methods: Data were retrieved from a prospective cohort study from the Clinical Research Center for ESRD in Korea. The simplified PEW scoring system is graded from 0 (the worst) to 4 (the best), which consists of four components: serum albumin, body mass index, serum creatinine/body surface area, and normalized protein nitrogen appearance. Since the number of patients in the PEW score 0 group was too small (n=14), the PEW score 0 and 1 groups were combined into a same group. The survivals of the four groups (PEW score 0~1, 2, 3, and 4) were compared by Kaplan-Meier plot, and multiple Cox regression analysis was performed to identify the association between the PEW score and patients' survival.

Results: A total number of 430 patients were included in this study. The numbers of patients in the four score groups were 77 (score 0~1), 158 (score 2), 145 (score 3), and 50 patients (score 4). The mean age was 61.1 years and male was 59.8%. Kaplan-Meier plot revealed that the lowest PEW score group had the worst cumulative survival or there was a significant difference in patient survival across the groups (log-rank test, P<0.001); 2-year mortality rates of 15.6% in the score 0~1 group, 8.2% in the score 2 group, 1.4% in the score 3 group, and 2.0% in the score 4 group. In multiple Cox regression analysis, moreover, PEW score was a significantly independent factor for mortality even after adjusting for confounding variables (PEW score 0~1 as a reference; PEW score 2, hazard ratio [HR] 0.450, 95% confidence interval [CI] 0.262–0.772, P=0.004; PEW score 3, HR 0.165, 95% CI 0.070–0.385, P<0.001; and PEW score 4, HR 0.101, 95% CI 0.013–0.760, P=0.026).

Conclusions: A simplified PEW scoring system is a practical and reliable method for predicting mortality in Korean incident hemodialysis patients.

Short and Long Term Effects of Renal Rehabilitation on Oxidative Stress Aki Hirayama,[1] Misa Miura,[1] Yo Hirayama,[2] Go Yasuda,[3] Yumiko Nagano,[3] Atsushi Ueda,[4] Akihito Nishida,[1] Hirofumi Matsui,[3] Kazumasa Aoyagi,[1] Masahiro Kohzuki,[5] Shigeru Oowada.[6] *[1]Tsukuba University of Technology, Tsukuba, Japan; [2]HIRAYAMA HOSPITAL, Chiba, Japan; [3]University of Tsukuba, Ibaraki, Japan; [4]Tsukuba University Hospital Hitachi Medical Education and Research Center, Hitachi, Ibaraki, Japan; [5]Tohoku University Graduate School of Medicine, Sendai, Japan; [6]Asao Clinic, Kawasaki, Japan.*

Background: To evaluate the risk of renal rehabilitation, we investigated short (3 months) and long (6 to 9 months) term effect of exercise program for hemodialysis (HD) patients on oxidative stress

Methods: Total 39 stable HD patients, 22 with and 17 without the exercise program, were examined. The renal rehabilitation program was; aerobic training with lower limb ergo-meter, Borg scale 11 to 13, twice a week during HD, and the work time15 to 60 min. Oxidative stress was evaluated by serum scavenging activities against multiple reactive

oxygen species, measured by an electric spin resonance-based method, and inflammatory cytokines.

Results: No severe unfavorable effects were confirmed during the program. The patients received the renal rehabilitation showed significant increase of daily activity, exercise tolerance and muscular strength, and decrease of blood pressure, LDL and HDL. The program significantly increased serum scavenging activity against alkylperoxyl radical ($ROO^{\cdot}$) within the first 3 months, then against hydroxyl radical ($^{\cdot}OH$) within the next 6 months. Contrary, superoxide ($O_2^{\cdot-}$) scavenging activity was decreased within the first 3 months, and then alkoxyl radical ($RO^{\cdot}$) scavenging activity was decreased within 9 months. An increase of TNF-α was detected in the patients with the exercise program.

Conclusions: Our study revealed that the renal rehabilitation gradually improved oxidative stress over time. The effects on antioxidant system are not uniform and their timing window are various. Most of these results are favorable, while there still remains negative effects including TNF-α and $RO^{\cdot}$ scavenging activity. The change of $O_2^{\cdot-}$-scavenging activity may be the result of an adaptation against already increased oxidative stress in HD patients.

PUB681

Evaluation of Peridialytic Change in Body Composition Using Three Bioimpedance Devices Ohnmar Thwin,[1] Fansan Zhu,[1] Priscila Preciado,[1] Xia Tao,[1] Laura Rosales,[1] Jochen G. Raimann,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Body mass (BM) can be divided into fat mass (FM) and lean body mass (LBM). Skeletal muscle mass (SMM) is a major component of LBM. In general, the ratio of LBM to total body water (TBW) is approximately 0.73. LBM can be calculated if TBW is known. The aim of this study was compare 3 commercially available bioimpedance devices with respect to (1) measurements of peridialytic BC changes and (2) BC measurements in healthy subjects (HS).

Methods: Ten HD patients (8 males, age 58.1±12 years) and 12 HS (7 females, 33.3±5.6 years) were studied. Measurements were performed pre and post HD in patients and once in HS. We used three multi-frequency bioimpedance devices: InBody 770 (InBody USA, Cerritos, CA), Seca mBCA 514 (Seca North America, Chino, CA), and Hydra 4200 (Xitron Technologies, San Diego, CA). InBody and Seca report TBW, FM, LBM, and SMM. Hydra provides FM, LBM, and SMM using a model (Chamney, Am J Clin Nutr, 2007). We analyzed peridialytic BC changes and BC in HS.

Results: All devices reported a significant peridialytic decrease in BM, TBW and LBM (**Fig.1 a, c, d**). However, FM results differed between the devices: InBody reported no change, while Seca reported increased with a high variability and Hydra found decreased (**Fig 1 b**). The pre HD FM-to-BM ratio (%FM) was higher with Hydra compared to InBody and Seca, respectively (**Table 1**). In HS, however, %FM was significantly higher with Seca compared to Hydra and InBody, respectively. In both HD and HS LBM was reported lower with Hydra compared to InBody and Seca, respectively. In HD patients and HS SMM was reported lower with Hydra compared to InBody.

Conclusions: In this pilot study the peridialytic FM increase suggests that LBM may be underestimated due to use of a constant TBW/LBM ratio (0.73). This ratio may not correct in dialysis patients.

Table 1

	Pre FM (kg)	Pre %FM (%)	Pre LBM (kg)	Pre SMM (kg)	FM-HS (kg)	%FM-HS (%)	LBM-HS (kg)	SMM-HS (kg)

Status of Nutrition in Hemodialysis Patients Survey: SNIPS Talia R. Weinstein,[2,3] Odile Azoulay,[4] Mona Boaz.[1] *[1]Ariel University, Ariel, Israel; [2]Tel Aviv Medical Center, Tel-Aviv, Israel; [3]Tel Aviv University, Tel Aviv, Israel; [4]Rabin Medical Center, Petach Tikva, Israel.*

Background: Protein-energy wasting (PEW) is prevalent in hemodialysis (HD) patients, due to inadequate dietary intake and an increased catabolic state. Adverse outcomes include increased hospitalization, morbidity and death. The prevalence ranges from 18-70%, depending on the method used for PEW definition. Expert panels have recommended dietary modifications intended to prevent PEW in this population. The primary objective of this study was to survey nutrition intake in Israeli HD patients and to estimate the PEW prevalence; additionally, the study measured patients' mean energy and nutrient intake, and their adherence to dietary recommendations.

Methods: This multi-center, cross-sectional study included a representative sample of HD patients treated at 9 hospitals throughout the country. At each center, the population was stratified for age; sex; ethnicity; dialysis vintage (< 1 year >); dialysis shift; and diabetes. Patients were proportionally randomly sampled from each strata. Dietary intake was assessed using the 24-hour recall. Biochemistry, demographic data, prescription list and anthropometric data were extracted from the electronic medical record.

Results: The study included 378 HD patients, mean age 64.8±12.7 years, mean dialysis vintage 2.4±4.9 years, Kt/V 1.4±0.29, 52% female, 80% Jews. Comorbidities included hypertension (65%); dyslipidemia (35%) and diabetes (33%). Serum albumin was 3.7±0.4 g/L, serum phosphorous was 5.1±1.5 mg/dl and c-reactive protein was 11.7±25.9 mg/dl. Total energy intake, energy intake per kg/ideal body weight and protein per kg/ideal body weight were all significantly below recommendations. Only 19% consumed adequate calories, 29% consumed adequate protein. Almost 70% of patients had below-normal serum albumin levels; 58% of the study population was classified as having PEW. Only 8.2% of the study population overall and only 15.5% of patients with PEW received nutrition supplementation. Almost 50% of patients were categorized as overweight or obese.

Conclusions: PEW is common in Israeli HD patients. Compliance with nutrition recommendations and guidelines is poor. Despite this, use of nutrition supplementation was limited. Paradoxically, almost half of the patients were overweight or obese. Further studies must be conducted to reconcile these seemingly incongruous states; additionally, studies investigating methods to enhance dietary compliance must be carried out.

Biomarker Profiling in Stage 5 CKD Hemodialysis Patients with Reference to Apparent Metabolic Syndrome and Vascular Manifestations Vinod K. Bansal,[1] Leonidas Skiadopolous,[1] Ryan Mcmillan,[1] Debra Hoppensteadt,[1] Jawed Fareed.[2] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University medical center, Maywood, IL.*

Background: Stage 5 Chronic Kidney Disease Hemodialysis (CKD5-HD) represents a complex syndrome in which a variety of inflammatory factors contribute to its pathogenesis and progression. Vascular disorders and metabolic syndrome are common comorbidities in CKD5-HD patients. The purpose of this study is to profile inflammatory biomarkers to determine their role in pathogenesis of CKD5-HD and how they relate to apparent metabolic syndrome and vascular disorders.

Methods: Ninety patients (45 male, 45 female) with documented CKD5-HD on maintenance hemodialysis were included in the study. The control group consisted of 50 healthy individuals (25 male, 25 female; George King Biomedical, Overland, KS). Plasma from the CKD5-HD and control groups were used to measure levels of Vitamin

D, PTH, Endocan, Endothelin-1, NGAL, PDGF-BB, IL-18, NT-proBNP, MPTF, KIM-1, Lp(a), Heparin anti-Xa, and PF4.

Results: All biomarker levels were elevated in the CKD5-HD cohort compared to the healthy controls, except for Vitamin D. Of the 90 CKD5-HD patients, 48 (53%) were found to have a history of vascular disease, of CKD5-HD which 36 (40%) had coronary artery disease and 19 (21%) had peripheral vascular disease; 38 (42%) were determined to have apparent metabolic syndrome. A correlation was found between Vitamin D and Endothelin-1 ($p=0.037$, $r= 0.220$) in all 90 CKD5-HD patients as well as in the vascular disease group ($p=0.023$, $r= 0.328$). Lp(a) levels were significantly elevated in the vascular disease patients ($p=0.032$, % change =21.2%) and in the PVD patients ($p=0.002$, % change=35.9%). Endothelin-1 was also found to be statistically significantly increased in the 38 patients with apparent metabolic syndrome ($p=0.002$, % change =42.9%) as was PF4 ($p=0.005$, % change=16.8%) and platelet count ($p=0.025$, % change= 24%).

Conclusions: Decreased plasma Vitamin D levels, along with increased PTH, Endocan, and Endothelin-1 levels in the CKD5-HD patients compared to the healthy controls suggests that these biomarkers may play a role in the pathogenesis of CKD5-HD. The correlation found between Vitamin D and Endothelin-1 in the CKD5-HD cohort as well as in the vascular disease group suggests that the mechanism behind this vascular endothelial dysfunction may in part occur through the upregulation of Endothelin-1 levels.

PUB684

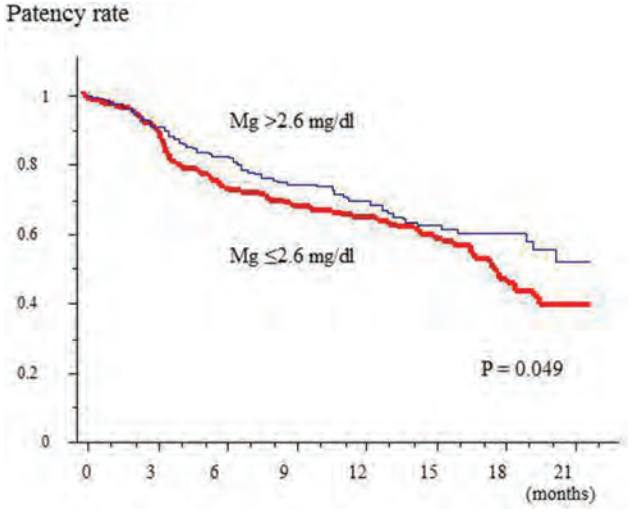
Higher Serum Magnesium Effect on Second Patency Rates of Vascular Access in Patients on Hemodialysis Yukiko Hasuike, Naoto Kakita, Kiyoko Yamamoto, Kosuke Mizusaki, Takahiro Kuragano, Takeshi Nakanishi. *Internal Medicine, Division of Kidney and Dialysis, Nishinomiya, Japan.*

Background: Vascular access (VA) is essential for the patients on HD. However, VA failure is often occurred even after VA intervention therapy (VAIVT). Several studies suggested a possible association between hypomagnesemia and vascular change. The purpose of this study was to examine the factors affecting VA patency after VAIVT, including Mg, and factors related to oxidative stress, inflammation, and uremia.

Methods: Blood samples were taken from 518 HD patients at the VAIVT. Among them, 391 patients (75.5%) had native arteriovenous fistula. Routine blood chemistries and factors related to mineral-bone metabolism (Mg (xylidyl blue method, 1.9 to 2.6 mg/dl), corrected calcium, phosphate, parathyroid hormone-intact), oxidative stress (8-hydroxy-2'-deoxyguanosine, GSH/GSSG), inflammation (CRP, interleukin-6, tumor necrosis factor-α), and uremia (body mass index, albumin, urea nitrogen, hemoglobin) were measured. The end point of study was the re-vascularization or re-operation of VA during the observational period after VAIVT (mean follow-up periods 289 days). Cox proportional hazards models for the end point was used.

Results: During follow-up period, re-vascularization was performed in 96 patients and re-operation in 88 patients. The median value of serum Mg concentration was 2.5 mg/dl in all patients. The patients with VA failure had lower serum Mg compared with the patients without VA failure. There was no significant difference in other factors. The Kaplan-Meier analysis showed that the patents with lower Mg (≤2.6 mg/dl) was associated with higher incidence of VA failure ($p=0.049$, [figure1]). Cox regression analysis also revealed that lower Mg (adjusted hazard ratio 1.365, 95% confidential interval 1.013 to 1.839, $p=0.041$) was linked to VA failure.

Conclusions: Lower serum Mg was associated with the poor event-free patency of VA after VAIVT, and affected the second patency rates of VA.



PUB685

Effect of Gender on Obesity-Associated Renal Dysfunction and Involvement of Adipokines Blanche Martin,[1] Chloé Wilkin,[1] Inès Jadot,[1] Olivia Botton,[1] Anne-Emilie Decleves,[2] Nathalie Caron.[1] *[1]Laboratory of General Physiology - URPHYM, University of Namur, Namur, Belgium; [2]Laboratory of Molecular Biology, University of Mons, Belgium, NIMY (MONS), Belgium.*

Background: Obesity incidence has dramatically increased during the last few years. This disease, characterized by an excessive fat accumulation, has for consequences an alteration of adipose tissue function and a chronic inflammation status, leading to metabolic disturbances. It is also well described that an excess of fat can be considered as a risk factor for kidney disease development. Today, most researches focus on males. However, it is imperative to determine how the sex difference can affect metabolic homeostasis and obesity syndrome. Indeed, differences, such as adipose tissue distribution, have been highlighted between sexes. Moreover, sexual hormones are involved in lipid and glucose metabolism. Adipose tissue has been to shown to play endocrine functions by the secretion of adipokines, such as chemerin, adiponectin, leptin and TNF-α. In obese patients, secretion of these adipokines is impaired. In the present study, we investigated the role of adipokines in obesity progression in males and in females and its impact on obesity-induced kidney alterations.

Methods: C57BL/6 male and female mice were randomized to a low fat diet (LFD) or a high fat diet (HFD) for 16 weeks.

Results: We demonstrated that male mice fed a HFD developed obesity, as illustrated by an increase in body weight, kidney hypertrophy and glucose metabolism disorders. Regarding kidney function, we observed that HFD mice tend to develop renal functional impairment as they exhibited proteinuria and a slight increase in albuminuria. These observations were associated with a mesangial matrix expansion in glomeruli and vacuolated tubular cells. We also observed effects of HFD on adipokine concentrations, inflammation and fibrosis process in kidney. Finally, HFD mice presented a moderated oxidative stress. Female mice, on the other hand, seem less affected by HFD according to metabolic data. Moreover, kidney lesions were less important than in male. However, female mice exhibited important inflammation, fibrosis and oxidative stress modifications compared with male fed a HFD and LFD.

Conclusions: In summary, we demonstrated appearance of obesity as well as associated kidney failure in HFD male and female mice. However, according to our results, gender seems to influence the obtained data, highlighting roles of sexual hormones in obesity physiopathological mechanisms.

PUB686

Hepatocyte Nuclear Factors as Possible Mediators of Inflammation in Experimental Chronic Renal Failure Elzbieta Sucajtys-Szulc, Marek Szolkiewicz, Boleslaw Rutkowski, Ryszard Milczarek, Alicja Debska-Slizien. *Medical University of Gdansk, Gdansk, Poland.*

Background: The molecular background of CKD-related inflammatory state is rather obscure, though the most potent inflammatory biomarkers (CRP, IL-6) are linked with the pathogenesis of many CKD-related disorders, including cardiovascular diseases. Recently, we found that hepatocyte nuclear factors (HNFs) involved in the transcriptional regulation of large number of genes, were up-regulated in liver of CRF rats. In this paper, we analyze the interplay between HNFs, IL-6 and CRP synthesis in experimental CRF.

Methods: Rats with experimentally induced CRF (5/6 nephrectomy), pair-feds and controls (sham-operated) were used in the study. Persistent inflammation was induced in additional group of healthy animals by implanting a subcutaneous slow-release ALZET osmotic pump to infuse 1 mg/kg/d of lipopolysaccharide (LPS). *Crp, Il-6, Hnf1α* and *Hnf4α* genes expression in liver and WAT were determined using real-time RT-PCR (mRNA) and Western blotting analysis (protein). Serum level of CRP and IL-6 were estimated by immunoassay.

Results: We found a significant up-regulation of *Crp, Il-6* and *Hnf1α* and *Hnf4α* genes expression (mRNA and protein amount) in liver and WAT of CRF rats, when compared with pair-feds and controls. This was accompanied by the elevated CRP and IL-6 serum levels in animals with CRF. We also observed significant positive correlations between serum CRP or IL-6 and creatinine levels. Moreover, *Crp* gene expression (at the level of mRNA, protein amount and serum level) significantly positively correlated with *Hnf*s (mRNA and protein amount) gene expression in both liver and WAT. And finally, a serum creatinine concentration in LPS-treated healthy rats remain low, but we found the identical pattern of changes concerning liver and WAT *Crp, Il-6, Hnf1α* and *Hnf4α* genes expression (mRNA, protein amount, serum level) like in rats with CRF, and the same correlations between these genes expressions and circulating CRP.

Conclusions: The presented results suggest that overexpression of genes encoding *Crp, Il-6* and *Hnf1α* and *Hnf4α* are linked to each other, and are tightly associated with kidney function. It seems that CRF-related inflammatory state is a crucial these genes up-regulator, and HNFs may be an essential element of its molecular background.

PUB687

Interventions to Increase Nutrition Referrals in Patients with CKD Stefan C. Hemmings, Haldane Porteous, Daphne H. Knicely. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: The prevalence of malnutrition in patients with chronic kidney disease (CKD) is high. Nephrologists are inadequately trained in nutrition education and lack

the time during clinic visits to adequately address the nutrition aspects of patient care. Inadequate documentation of nutrition status of patients with CKD in our Nephrology fellows' clinic lead to the design of a quality improvement (QI) project to improve documentation of nutrition status for CKD patients and making appropriate referrals to nutrition services.

Methods: Charts for patients with CKD stage G3a to G5 seen in the Nephrology fellows' clinic during December 2016 were audited by peer review to assess nutritional status within this population. Clinic notes were reviewed for documentation of nutrition data and referrals. Late December 2016, fellows were given a CKD nutrition lecture addressing clinical indicators for nutrition and an electronic health record (EHR) template or "smart phrase" for nutrition was designed to capture surrogates of nutritional status. In January and February 2017, charts were audited to determine nutrition referral rates. After completion of the project, fellows were sent a survey regarding the nutrition QI project and dilemmas with managing nutrition.

Results: A total of 80 charts were reviewed pre-intervention, and 121 charts were reviewed post-intervention. 49.5% of patients were either obese with BMI ≥30 kg/m² or undernourished with BMI <18.5kg/m². Serum albumin was documented in 150 charts, 23% of which had an albumin level <3.5mg/dL. The pre-intervention nutrition referral rate was 5%. Post-intervention, nutrition referrals were higher in each of the two subsequent months at 15% and 33%, respectively. The fellow survey identified major barriers to nutrition referrals, including lack of clinic time, low importance of nutrition compared to other clinical measures, and insurance coverage for referrals.

Conclusions: Obesity and hypoalbuminemia indicating poor nutritional status is prevalent in CKD patients. This QI project demonstrated that fellow education and an EHR "smart phrase" was associated with a sustained improvement in nutrition referrals. Further study is needed to determine what parameters increase a patient's chance of nutrition referral and if such referrals and adherence to diet plans improve patient outcomes.

PUB688

Profile of High Sensitivity C Reactive Protein in AKI and CKD Abhishek Goel, Tushar A. Dighe, Atul Mulay, Charan B. Bale, Ashwini Sharma, Jayraj Korpe, Nilesh Shinde, Vajed Mogal, Pratik Shete, Atul Sajgure. *Nephrology, Dr. D Y Patil Medical College, Pune, India.*

Background: Prevalence of chronic kidney disease (CKD) is around 10% worldwide, while that of acute kidney injury (AKI) has not been systematically examined. Inflammation has been identified as an important factor of co morbidities in AKI and CKD. High sensitivity C reactive protein (hsCRP) assay is useful for detection of inflammatory state. We studied the profile of serum hsCRP in patients of AKI and CKD on hemodialysis (CKD_{5D}) and the correlation of hsCRP with other inflammatory markers.

Methods: A prospective observational single tertiary care centre study from western India. Serum hsCRP, serum ferritin and serum albumin levels were checked on initiation of hemodialysis for both AKI and CKD subjects. All were dialyzed with a low flux dialyzer. Sample was collected for hsCRP, pre and post hemodialysis. All subjects were divided into AKI, CKD and Acute on CKD groups. HsCRP was analyzed using the Immuno Turbidimetry method with Cobas Integra 400 plus fully automatic analyzer. Unpaired t test was used to denote the statistical significance. Correlation between different inflammatory markers was calculated using the Pearson's correlation coefficient.

Results: A total of 106 subjects were enrolled, which included 78 (73.6%) males. The mean age of participants was 49.90±15.22 years. 74 (69.8%) were CKD, 17 (16%) in Acute on CKD and 15 (14.2%) subjects in AKI group. Serum hsCRP in AKI group (65.23±47.25 mg/l) was significantly higher (p=0.023) compared to CKD (31.93±52.60 mg/l). On comparing AKI with Acute on CKD (39.87±37.11 mg/l, p=0.106) and Acute on CKD with CKD (p=0.47), were not statistically significant. Serum hsCRP was not found to correlate with serum ferritin level in AKI (R=0.43, p=0.11), Acute on CKD (R=0.23, p=0.37) and CKD groups (R= -0.04, p=0.73). Correlation was also not found with serum albumin levels in AKI (R= -0.9,p=0.73), Acute on CKD (R= -0.33, p=0.198) and CKD (R= -0.13, p=0.26). A two tailed paired samples t test on pre and post hemodialysis values of hsCRP revealed that the hsCRP level does not change with hemodialysis (p=0.128).

Conclusions: Serum hsCRP is higher in subjects with AKI as compared to CKD, while no difference was found on comparing both the groups with acute on CKD. Serum hsCRP does not correlate with other inflammatory markers and is not dialyzable.

PUB689

Sources of Dietary Phosphorus in Patients on Dialysis Margareth L. Fornasari,[1,2] Yvoty A. Sens.[1] *[1]Santa Casa de São Paulo School of Medical Sciences, São Paulo, Brazil; [2]Nutrition, Sao Judas Tadeu University, Sao Paulo, Brazil.*

Background: Phosphorus control in the diet of end stage renal disease patients involves restriction of foods that contains phosphorus additives, processed foods with inorganic phosphorus that has high bioavailability. Dietary counseling focuses on education as a key component of hyperphosphatemia management. However, despite long-standing recommendations to limit phosphorus additives from foods most patients consume too much. The purpose of the study was to verify the contribution of foods with natural phosphorus versus foods with phosphorus additives.

Methods: A total of 67 adults with hyperphosphatemia and end-stage renal disease patients on hemodialysis for ≥6 months at a single center were evaluated. Three record-assisted 24-hour dietary recalls were collected from each participant to capture eating for a weekday on dialysis, and one recall for a weekday without dialysis. Post recall included calculating the total phosphorus amount in the diet and the identification of sources of processed foods with phosphorus additives. To verify if processed foods contained phosphorus additives food labels of each food referred was observed.

Results: The mean age were 56±13 years; 32(47%) were women and 35 (53%) were men. Phosphorus-containing foods additives contributed to 23% of the total sources of phosphorus in the diet on dialysis day and 21% on weekday without dialysis. Total phosphorus intake on dialysis day was 789±298 mg/d for total sample and was statistically different between women 789±298 mg/d and men 803±301 mg/d (p<0.001) while in a weekday without dialysis was 811±260 mg/d and was statistically different between women 811±259 mg/d and men 822±263 (p<0.001). There weren't differences between women and men and day of the week concerning foods with phosphorus additives; women 2.4±1.4 foods and men 2.4±1.4 foods on dialysis day ((p=0.87); and women 2.4±1.5 foods and men 2.4±1.5 foods (p=0.81) with phosphorus additives on a day without dialysis.

Conclusions: Foods that have natural phosphorus were the highest contributor to phosphorus in the diet but phosphorus-containing foods additives were present in the diet of all patients of this study regarding educational tools.

PUB690

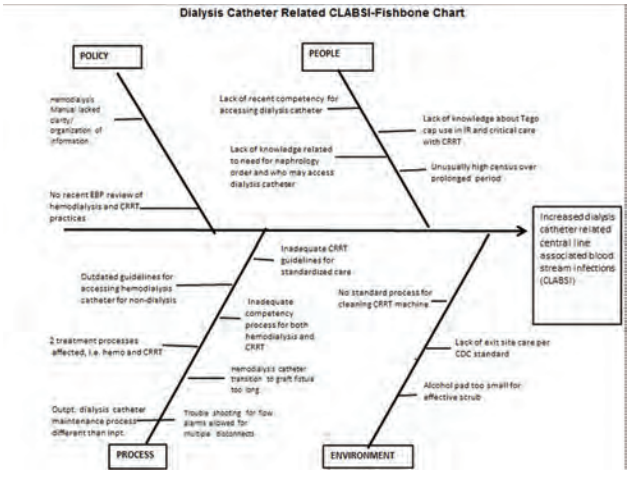
Interdisciplinary Approach to Mitigate Harm Related to Dialysis CLABSIs Robert S. Gayner. *Nephrology, St Lukes University Health Network, Bethlehem, PA.*

Background: Central Line Associated Blood Stream Infections (CLABSI) are associated with increased mortality, morbidity and cost. CLABSIs result annually in 84,551-203,916 preventable infections, 10,426-25,145 preventable deaths, and 1.7-21.4 billion dollars in avoidable cost. CLABSIs are preventable when EBM guidelines are followed. In the 1st quarter of CY 2015, we experienced a sudden increase in dialysis CLABSIs. The goal of our project was to reduce dialysis CLABSIs by 50% within 6 months and achieve sustained results.

Methods: EBM literature review, CLABSI task force creation, root cause analysis, benchmarking, human factor learning, developing clinical competencies, education and guidelines for catheter care were methods used to decrease dialysis CLABSIs

Results: Achievement: We met and surpassed our goal to reduce CLABSIs related to dialysis catheters by 50% within 6 months and achieve sustained results over time. Financial Implications: For CY2016 2016 we had 3 dialysis CLABSIs versus a spike of six in the 1st quarter of 2015. Annual cost saving is estimated at $137,442 (3 x $45,814 compared to CLABSI spike, $962,094 if initial CLABSI spike was pro-rated over 1 year. Another financial component to be considered is avoidance of Hospital-Acquired Condition (HAC) penalties. Statistical Significance: Calculating a p value would not add to what was an obvious and clinically significant reduction.

Conclusions: Hemodialysis associated CLABSIs are a significant contributor to patient associated morbidity and cost of care. This will become particularly important with Pay for Value Reimbursement and HAC penalties. Despite establishing a program of low CLABSI rates, this can change at anytime and needs to be constantly moniotred. Establishing a rapid cycle task force, updating EBM guidelines, employing human factor learing and updating clinical competencies are some core factors in preventing dialysis associated CLABSIs



PUB691

Renal Failure and Death by Hydrogen Peroxide Lori Shah,[3] Neil S. Sanghani,[2] Amit K. Rajput.[1] *[1]None, Nashville, TN; [2]Vanderbilt Nephrology, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Hydrogen peroxide is frequently used in alternative medicine as a treatment for autoimmune disease, infections including HIV, atherosclerotic plaques, cancers, and COPD.

Methods: A 43 year old female with scleroderma and Sjogren's presented with lethargy, vomiting, and diarrhea and was found to have multi-organ failure after use of 3% IV hydrogen peroxide infusions as therapy for her autoimmune disease. She had received

2 one-liter infusions over the preceding 3 weeks. CRRT was started for acute renal failure found to be due to multiple renal microinfarctions. Splenic and pulmonary microinfarcts were also noted on CT. She had hypertensive emergency, subarachnoid hemorrhage, DIC, severe lactic acidosis, and respiratory failure. After suffering one PEA arrest with successful CPR, she had a second arrest from which she was not resuscitated.

Results:

Conclusions: Hydrogen peroxide is a caustic oxidizing agent which can cause severe damage when infused, ingested, or inhaled. The more commonly used 3% solutions cause mild inflammation when ingested, however when used in an infusion form they can cause oxygen gas embolization to the brain and other organs, compromised cardiac output due to excessive oxidation, and disseminated intravascular coagulation. Public education on the risks of hydrogen peroxide is needed, as this toxic agent is often recommended in alternative medicine treatment regimens.

Visible renal, splenic, and occasional hepatic microinfarcts caused by hydrogen peroxide. These microinfarcts were the cause of renal failure.

PUB692

Perception of Quality of Life in Patients with Lupus Nephritis Gustavo Aroca Martinez,[3,4] Alvaro A. Martinez Bayona,[1] Henry J. Gonzalez Torres,[2] Alex Domínguez,[5] Santos Depine.[2] *[1]Fundación de Lupus del Caribe, Barranquilla, Colombia; [2]Universidad Simon Bolivar, Barranquilla, Colombia; [3]Medicine, Universidad Simón Bolívar, Barranquilla, Colombia; [4]Nephrology, Clínica de la Costa, Barranquilla, Colombia; [5]Universidad Simón Bolívar, Buenos Aires, Argentina.*

Background: Patients with Lupus Nephritis (LN), in addition to the pathophysiological factors associated with the disease, present other aspects that are of clinical interest, such as their Quality of Life - QL. Objective: to perceive the QL of 30 patients under follow-up under the risk management model of LN at an institution in the Colombian Caribbean region.

Methods: Analytical, longitudinal and retrospective study. Patients with a diagnosis of LN were included. To measure the quality of life of the patients, the GENCAT quality of life instrument was used, which evaluates eight dimensions. Emotional Well-Being, Interpersonal Relations, Material Well-being, Personal Development, Physical Well-Being, Self-Determination, Social Inclusion and Rights. For the application of the instrument, 3 controls were performed, first control at the time of being diagnosed with LN and each year during two years follow-up.

Results: 30 LN patients that were controlled, 28(93%) were women and 2(7%) were men. The results found in the different dimensions of the scale allowed us to determine that patients with LN did not obtain a high level of quality of life (Material Welfare (16.9%), Interpersonal Relations (66.7%), Personal Development (50.7%), Physical Well-being (10.9%), Self-Determination (69.1%), Social Inclusion (33.9%). From the first control the overall scores increased, being more noticeable; In those where the score was higher than the average, that improvement in the other aspects of their quality of life was also significant, especially for Emotional Welfare, Interpersonal Relations, Physical Well-Being and personal rigth.

Conclusions: The quality of life studied with the Gencat scale showed at the beginning the presence of depression and low self-esteem. Many of them failed to maintain good interpersonal relationships, they can not project their goals for their future, associated with poor self-care. From the third controls, the change was significant. Patients reported achieving and maintaining better self-esteem and self-perception. These findings could be related to a good response to treatment. At the beginning, the stress situation that affected the patients, motivated by their illness, their precarious economic situation and the deterioration of interpersonal relations, generated a vicious circle of psychological affectation.

PUB693

Upper Extremity Weight Lifting by Hemodialysis Patients with Mature Upper Extremity Arteriovenous Fistulas: Safety Considerations and the State of the Science Randi Bates.[1,2] *[1]Dennison Renal Care, Inc., Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Exercise, including resistance training and weight lifting, has been demonstrated to provide hemodialysis patients with mature arteriovenous fistulas (AVFs) with numerous health-related benefits. However, it is not known how much weight these patients can safely lift with their upper extremities while simultaneously having a mature upper extremity AVF. To better understand this patient safety concern and state of the science, I conducted a comprehensive review of published, empirical research.

Methods: I comprehensively searched Cochrane Central Register of Controlled Trials, Embase, and MEDLINE using the following search phrase "(arteriovenous AND fistula) AND exercise AND dialysis." I also searched the bibliography of relevant articles. I then scanned articles' title, abstract, and/or full-text for relevance.

Results: A total of three empirical studies resulted from the search, but two studies described the same results from the same population. Thus, two empirical studies with a total of 71 patients were identified for this review. One study was a randomized control trial and reported no serious adverse events, but did not report how much weight the dialysis patients lifted. The other study was a non-randomized controlled crossover trial, but did not discern exactly how many patients had an AVF. This study found that patients lifted up to 8.8 +/- 4.5kg (mean +/- SD) on the chest press and up to 6.7 +/- 1.1kg on the biceps curl with three sets of 12-15 repetitions each, three times per week (up to 26 weeks) without experiencing any serious adverse events.

Conclusions: A lack of well-defined randomized controlled trials limit the ability to conclude how much weight a hemodialysis patient with a mature upper extreimity AVF can safely lift with their upper extremities. Further trials are needed to better investigate this patient safety concern.

PUB694

The Causes of Dysuria after Renal Biopsy Hui-qun Li. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Background: To prevent the risk of bleeding, routine care after renal biopsy requires that the patients should be in bed rest for 24 hours, and at the initial 6 hours the patients are required to be in supine position. Patients often suffer from dysuria during bed rest. Nurses can use the quality control circle (QCC) to analyze the causes of dysuria and to carry out continuous quality improvement of nursing care.

Methods: Methods: Retrospective analysis of 288 cases with renal biopsy was involved (149 male, 139 female). Urination status of the patients undergoing renal biopsy was analyzed, including preoperative training, postoperative urination, induced urination and the time of postoperative urination. QCC activity was used in this survey.

Results: Results: This retrospective survey showed that the incidence of dysuria after renal biopsy was 14.5%, training implementation rate of the preoperative supine urination was only 46.7%. 35.7% patients with hot compress and glycerol enema were still unable to urinate, eventually indwelling catheter was carry out. Pareto Chart analysis showed three major causes of dysuria after renal biopsy, including poor preoperative education, supine position and back pain. Among them, the reasons of poor preoperative education mainly included nurses' education methods, busy tasks and patients causes (such as the training was not been carried out or ignored). And sometimes bad privacy ward environment and the lack of standard health education materials were the reasons. Finally, the forced supine position after renal biopsy, and patients failed to complete the bed urination training also led to dysuria operation; in addition, postoperative puncture site pain and back pain were the reasons of dysuria.

Conclusions: Conclusion: Many causes of dysuria after renal biopsy were founded in this survey. The nurse's efforts can be carried to reduce the incidence of dysuria after renal biopsy.

PUB695

Effect Bisection Time and Administration Interval of Evolocumab Frieder Keller. *University Hospital, Ulm, Germany.*

Background: In the FOURIER trial, subcutaneous evolocumab was given with 140 mg every 14 days or with the pharmacodynamic equivalent of 420 mg every 28 days. The pharmacokinetic equivalent of 280 mg every 28 days was found less efficient. The effect of evolocumab is measured by the decrease in circulating proprotein convertase subtilisin/ kexin type 9 concentrations (PCSK9). This direct effect on circulating PCSK9 concentrations is immediate and lasts for 20 days until 50 % of initial concentrations are restored. The PCSK9 inhibition translates into an indirect response by the decrease in LDL cholesterol with a time delay of 10 days for the strongest effect.

Methods: With 140 mg, the maximum unbound evolocumab concentration is 20 μg/ml but with 420 mg the C_{max} is 50 μg/ml. Since the systemic clearance is 0.26 l/day and the apparent volume 2.6 liters, the elimination half-life ($T_{1/2}$) can be estimated with 7.5 days. Based on the published data, the perplexing dosing experience with evolocumab can be explained by the effect bisection time (TED_{50}). The TED_{50} is a new pharmacodynamic parameter that relates the time of effect duration to the elimination half-life (T1/2), the Hill coefficient (H) and the concentration producing 50 % of maximum effect (CE_{50})

according to the pharmacodynamic E_{max} model. $TED_{50} = T_{1/2} \times (1.44 / H) \times \ln[2 + (C_{max} / CE_{50})^H]$

Results: The TED_{50} equation was used to find a numerical solution for the pharmacodynamic parameters H with 1.4 and for CE_{50} with 4 μg/ml. The low Hill coefficient might indicate that evolocumab action is concentration-dependent and not time-dependent, allowing for an administration interval longer than the half-life. From our parameter estimates the TED_{50} is calculated with 19 days for the 140 mg evolocumab dose, but with 28 days for the 3-fold higher dose of 420 mg in complete agreement with the published 28 days administration interval. With the only two-fold higher dose of 280 mg, however, the effect bisection time will be estimated with 25 days and less than twice the normal 14 days administration interval.

Conclusions: The present formula for the effect bisection time TED_{50} allows to estimate exact pharmacodynamic parameters that could be used for the most rational evolocumab dosing.

PUB696

Automated Approach to Calculating Total Daily Dose of Tacrolimus in the Million Veteran Program Using the Electronic Health Record Adriana Hung,[1,2] Cecilia P. Chung,[2] Victoria Whitfield,[2] Csaba P. Kovesdy,[3] Christianne Roumie,[1] Todd L. Edwards,[2] Edward D. Siew,[1,2] Digna R. Velez edwards,[2] Ayush Giri,[2] Michael E. Matheny,[1] Kelly A. Birdwell.[2,1] *[1]TVHS Veterans Administration, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Memphis VA Medical Center, Memphis, TN. Group/Team: On behalf of VA Million Veteran Program.*

Background: Tacrolimus dosing is complex, often requiring the combination of two pills of two different strengths that are generated concurrently with the same date/time stamp. For a study of tacrolimus pharmacogenomics in the Veterans Affairs Million Veteran Program (MVP), we aimed to develop informatics algorithms to abstract accurate dosing of tacrolimus.

Methods: Using the VA corporate data warehouse we assembled a retrospective cohort of veterans with a prescription of tacrolimus following kidney transplant. We used pharmacy files to identify dispensed prescriptions, date filled, days supplied, number of pills and dosage, and the printed bottle instructions. We built two automated algorithms to ascertain the number of pills per day per prescription and calculate the total daily dose of tacrolimus, confirming 10% by manual chart review. We then used them to confirm each other for accuracy.

Results: We identified 28,081 prescriptions of tacrolimus. **Method 1:** used the automatically printed bottle instructions prescription instructions to generate a repository of distinct text. We found 2612 distinct texts and converted them into their numeric equivalent of pills per day. **Method 2:** used structured data to identify the pill strengths, number of pills dispensed, and the number of days' supply. We divided the number of pills by the number of days supplied to get the number of pills per day. Methods 1 and 2 were compared to verify if the number of pills per day matched for each individual prescription and 90% perfectly matched, with Method 1 being the most accurate. Discrepancies were primarily caused by providers adjusting doses in the clinic without writing a new prescription.

Conclusions: Method 1, a repository of distinct texts of automatically printed bottle instructions, allowed more accurate recognition of complex prescriptions. Printed instructions are generic and can be used in the context of any prescription and will be of great use for pharmacoepidemiological and pharmacogenomics studies of other drugs.

PUB697

Pharmacokinetics of Vancomycin in Pediatric Patients Receiving Hemodialysis and Hemodiafiltration Erin Chung,[1,3] James A. Tjon,[1,3] Rosaleen M. Nemec,[2,5] Nadya Nalli,[1,3] Elizabeth A. Harvey,[2,6] Christoph Licht,[2,4] Winnie Seto.[1,3] *[1]Department of Pharmacy, The Hospital for Sick Children, Toronto, ON, Canada; [2]Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; [3]Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada; [4]Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada; [5]Division of Nephrology, University Health Network (Toronto General Hospital), Toronto, ON, Canada; [6]Faculty of Medicine, Department of Paediatrics, University of Toronto, Toronto, ON, Canada.*

Background: Vancomycin is commonly used for bacteremia, but optimal dosing in pediatric patients requiring hemodialysis (HD) or hemodiafiltration (HDF) remains unknown. This study aims to characterize vancomycin pharmacokinetics, monitor its efficacy and safety, explore effects of various factors on vancomycin pharmacokinetics and derive an optimal vancomycin dosing regimen for pediatric patients on HD/HDF.

Methods: A therapeutic drug monitoring (TDM) guideline was implemented for pediatric patients on HD/HDF. Eligible patients received vancomycin 10mg/kg/dose post-dialysis and a series of serum vancomycin concentrations were collected pre-, immediately-post-, 1-h-post- and 4-h-post-dialysis. The pharmacokinetic parameters were estimated using a single compartment model and nonlinear least-squares algorithm. Monte Carlo simulations (MCS) were performed to assess dosing regimen of vancomycin.

Results: 42 courses from 16 patients were included. The average drug removal was 56.38%, rebound was 23% and net drug removal was 43% using HD/HDF. Nine courses from 6 patients with pharmacokinetic profiles were included in our pharmacokinetic model. While on HD/HDF, the median elimination constant (k_e) was $0.32h^{-1}$, and clearance was 0.18L/kg/h. When off dialysis, the median k_e was $0.013h^{-1}$, clearance was 0.0066L/kg/h and volume of distribution was 0.64L/kg. We found that duration of HD/HDF session, and type of dialysis (HD vs. HDF) may be important determinants of vancomycin pharmacokinetics. All vancomycin courses dosed at 10mg/kg/dose post-dialysis followed by TDM to assess re-dosing appeared effective based on white blood cell count, temperature and culture results. No adverse effects were reported except for one case of Redman syndrome. MCS demonstrated that the current regimen is optimal to reach therapeutic range for 4-hour post-dialysis concentrations (for central nervous system infections: 10-15mg/L or other: 5-12mg/L) and 24-hour area under the curve over minimum inhibitory concentration (AUC/MIC) ≥400 if MIC is 0.5mg/L.

Conclusions: Vancomycin is significantly removed by HD/HDF with rebound occurring at 4 hours post-dialysis. However, time to maximum rebound remains unknown due to sparse blood sampling. The current vancomycin dosing regimen is optimal for pediatric patients on HD or HDF at this institution.

PUB698

A Case of Levofloxacin Induced Choreiform Movements in a Hemodialysis Patient Muhammad Saad,[1] Shehryar Mehershahi,[1] Kalpana A. Uday,[2] Rabih Nasr.[1] *[1]Bronx Lebanon Hospital Centre, Bronx, NY; [2]Bronx-Lebanon Hospital Center, Irvington, NY.*

Background: Neurotoxic effects of quinolones have been described and are considered as second most common adverse effects after gastrointestinal side effects. Risk factors associated with enhanced adverse effects are renal impairment, old age, higher doses and interaction with other medications especially theophylline. We report a case of reversible involuntary movement (choreiform movements) in end stage renal disease (ESRD) patient secondary to levofloxacin.

Methods: 63-year-old man with known history of hypertension, end stage renal disease (ESRD), on alternate day dialysis schedule, diastolic heart failure presented with complain of generalized tremors and intermittent twitching of face and extremities for the past 2 days. Patient was compliant to his usual anti-hypertensive medications and dialysis. Four days prior to his presentation patient was started on levofloxacin 750 mg daily for treatment of upper respiratory tract infection. No history of fever, headache, photophobia, sensory or motor deficit, new medication, alcohol/drug exposure, recent travel was reported. On physical examination, his vitals were within normal limits. He was fully alert and oriented with no neurological deficit. Of significance, he was noted to have coarse tremors in all his extremities. Choreiform movements of face and tongue tremor on protrusion were also identified. No nystagmus or cerebellar signs were found. His Laboratory tests including cell count, electrolytes were completely normal and renal functions were stable. Computed Tomography(CT) head did not show any acute abnormality. Levofloxacin was stopped and hemodialysis was given as per his regular schedule. His tremors drastically improved with complete resolution within one week.

Results:

Conclusions: Although rare, Central Nervous System (CNS) toxicities such as orofacial dyskinesia, choreiform movements, myoclonus and Chorea Like movement have been reported with levofloxacin. Clinicians should be vigilant of renal adjusted doses in treating infections especially in the setting of renal failure. Conservative management with treatment of symptoms has been suggested.

PUB699

Dialysis-Induced Ventricular Tachycardia? A Reappraisal of Quinidine Clearance with Modern Dialyzers Graham T. Gipson,[2] Daniel E. Carl,[2] Jason M. Kidd.[1] *[1]VCU Medical Center, Richmond, VA; [2]Virginia Commonwealth University, Richmond, VA.*

Background: We studied the pharmacokinetics of quinidine in order to establish or refute its culpability in hemodialysis-associated breakthrough ventricular tachycardia.

Methods: 74-year-old white gentleman who was admitted to the ICU for management of recurrent ventricular tachycardia (VT). He required intermittent hemodialysis (HD) for acute kidney injury. A pattern developed wherein each HD treatment was associated with breakthrough VT despite treatment with quinidine. After determining that electrolyte and hemodynamic abnormalities were not likely the cause of this breakthrough VT, we hypothesized that intradialytic quinidine clearance might drop the blood quinidine concentration outside of the therapeutic range. Little data is available regarding the transport characteristics of quinidine with newer generation hemodialysis membranes like Revaclear MAX (used for this patient). Thus we performed a quinidine pharmacokinetic study during HD. Venous blood quinidine concentrations were assessed under steady-state conditions immediately prior to an oral maintenance dose (300 mg), thereby providing "trough" concentrations. The quinidine trough concentration for this patient was reliably 3.5 μg/mL. The patient then received a routine oral maintenance dose (300 mg), a venous blood sample was collected, and HD was started. The peak blood quinidine concentration was 4 μg/mL. Paired inflow and outflow venous blood samples were collected hourly for the duration of the HD treatment. Dialysate flow rate was set at 600 mL/min, and blood flow rate was 350 mL/min. Quinidine clearance, computed using the Fick method for blood clearance, was 25.6 mL/min, or 0.179 mL/min/kg (using an average body weight during HD equal to 142.7 kg). This computation does not account for the effect of convective clearance driven by ultrafiltration. The final venous blood quinidine concentration was 3.2 μg/mL, well within the accepted therapeutic range. The patient did not suffer breakthrough VT during this HD treatment.

Results:

Conclusions: Reported quinidine hemodialysis clearances are quite variable and our data does neither accords with nor stands out from previously published data. While older drugs find increased use in modern clinical practice we should reappraise the historical

dialyzability data for these drugs in light of the transport characteristics of newer hemodialysis membranes.

PUB700

Pharmacokinetics of Oral ZYAN1 across Indian and Australian Healthy Subjects Kevinkumar A. Kansagra,[4] Deven Parmar,[5] Mukul R. Jain,[6] Devang P. Parikh,[2] Harilal V. Patel,[3] Nuggehally R. Srinivas,[1] Vrajesh B. Pandya.[5] *[1]Cadila Health Care Ltd, Ahmedabad, India; [2]Cadila Healthcare Ltd., Ahmedabad, India; [3]Cadila Healthcare limited, Ahmedabad, India; [4]Cadila healthcare lmt, Ahmedabad, India; [5]Zydus Cadila, Ahmedabad, India; [6]Zydus Research Centre, Ahmedabad, India.*

Background: Hypoxia inducible factor (HIF)-prolyl hydroxylase inhibitors are being developed for the treatment of anaemia in chronic diseases. ZYAN1- a HIF prolyl hydroxylase inhibitor stabilized the HIF alpha and stimulated endogenous erythropoietin production and raise HB level in preclinical studies. This study was conducted to evaluate safety and compare the pharmacokinetics of ZYAN1 at an oral dose of 150 mg in Indian and Australian healthy human subjects.

Methods: Randomized, double-blind, placebo-controlled, single dose study included a total of 16 subjects; 6 subjects in each Indian and Australian group received ZYAN1 150 mg and 2 subjects in each group received matching placebo. The data were evaluated based on the blood concentration vs. time profile of ZYAN1 and the pharmacokinetic parameters were estimated using non-compartmental model.

Results: Mean age (years) and BMI (kg/m²) of Indian and Australian subjects were 28.00±4.00, 22.90±3.04 and 30.88±12.38, 22.91±1.77, respectively. There was no statistically significant difference in pharmacokinetic parameters of Indian subjects compared to Australian subjects with 150 mg dose as presented in Table.

Conclusions: Pharmacokinetics of ZYAN1 150 mg was comparable between Indian and Australian subjects. ZYAN1 150 mg was safe and well tolerated in healthy volunteers.

Vancomycin Dosing in Short Daily Hemodialysis (SDHD) Using the NxStage System One Machine Mohan Ramkumar,[2,1] Brooke K. Decker,[2,1] Paul M. Palevsky.[2,1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Medicine Specialty, VA Pittsburgh HCS, Pittsburgh, PA.*

Background: Vancomycin is a glycopeptide antibiotic that is commonly used for treatment of Gram-positive pathogens. Both renal and non-renal clearance of vancomycin is markedly diminished in patients with decreased kidney function. Its molecular weight (~ 1450 KD), volume of distribution (~0.4-1 L/kg) and limited binding to protein (~50%) allow for significant clearance during hemodialysis using modern high flux dialyzers. Use of SDHD as a modality of home dialysis is increasing; however there are no published data to guide vancomycin dosing in patients on SDHD using the NxStage System One machine.

Methods: We evaluated the pharmacokinetics of intravenous vancomycin in an anephric patient on SDHD (30L/session, dialysate flow~ 200 ml/min, 6 days a week) using the NxStage System One machine at home. We measured vancomycin levels pre- and post- hemodialysis (HD) on numerous occasions. The volume of distribution (V), clearance (K) and half-life on HD($T_{1/2}$) were calculated assuming a single compartment model (C_0 is the pre-HD vancomycin concentration, C_t is the post-HD concentration and t is the time on dialysis): $C_t = C_0 e^{-Kt/V}$ $C_t = C_0 e^{-0.693/T½}$ Dose = V. C_0

Results: Using a loading dose of 20mg/kg followed by a maintenance dose of 500mg (~ 6mg/kg) after each SDHD session pre-HD vancomycin levels were 23-30 mg/L with post-HD (trough) levels of 15-20 mg/L. V = 0.76L/kg, K = 192 ml/min, $T_{1/2}$ = 226 minutes. Limitations: This is a limited pharmacokinetic study with data from a single anephric patient; these data will need to be confirmed in additional patients. For logistical reasons, peak vancomycin levels were not obtained 1-2 hours after vancomycin infusion; in this anephric patient we used pre-HD levels as a surrogate for peak levels.

Conclusions: To our knowledge, this is the first published report of vancomycin pharmacokinetics in patients on SDHD using the NxStage System One machine. Although the results need to be confirmed in a larger number of patients, our data provide a basis for prescription of vancomycin in patients treated with SDHD.

Toxic Epidermal Necrolysis Induced by Febuxostat: A Case Report Xiaoxuan Hu,[1] Jiawei He,[2] Jiasheng Huang,[3] Suyuan Peng,[3] Haijing Hou,[1] La Zhang,[1] Fuhua Lu.[1] *[1]Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China; [2]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [3]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.*

Background: Toxic epidermal necrolysis (TEN) is a rare, life-threatening drug-induced skin disease with a mortality rate of 25-70%. The precise mechanism is still unclear. Clinically, the Nikolsky's sign, erosions of the mucous membranes and extensive detachment of the epidermis should be an alarm for us. Specific drugs like nonsteroidal anti-inflammatory, antimicrobial drugs and allopurinol seem to be the main predisposing factors for TEN. Additionally, population's genetic background such as human leukocyte antigen (HLA) status is associated with the disease. The purpose is to describe a hyperuricemia woman, with HLA-B*5801 negative, developing the TEN after using Febuxostat.

Methods: A 64-year-old Asian woman was hospitalized with proteinuria and high serum creatinine level. Referring to her medical history, urinary color Doppler ultrasound as well as some laboratory findings, we argued that renal dysfunction was caused by chronic glomerulonephritis by the means of exclusion. She was initially treated with Febuxostat-a potent non-purine selective xanthine oxidase inhibitor against her high level of serum uric acid. However, erythematous plaques first appeared on her buttocks soon afterward. Lesions rapidly coalesced and became tense bullae. With the progression of the disease, they formed large confluent areas of epidermal detachment. Mucosal involvement occurred in her oral cavity simultaneously. All the suspect drugs were erythematous discontinued immediately. She was treated with the corticosteroid, intravenous immunoglobulins, blood transfusions, and antibiotics, along with other supportive therapies. Eventually, extensive epidermal detachment improved. It was a pity that because of the heart failure and sustained limb swelling, she accepted hemodialysis from then on.

Results:

Conclusions: What depress us most is the mortality of the disease. The most important therapeutic measures are identification and withdrawal of the suspect drugs. In this case, our patient used various kinds of medicine including traditional Chinese medicine. We listed all the medicines and sorted them according to the literature review and other drug-induced adverse reactions reports. Additionally, a genetic test was arranged but what surprised us was that her HLA-B*5801 negative, which meant drugs causing allergies'mechanism between Febuxostat and Allopurinol was different.

PUB703

Decreased Tremor and Improvement of Quality of Life after Switching to Prolonged Release Formulation of Tacrolimus in Kidney Transplant Patients Marisol Poma tapia,[2] Natividad Calvo,[2] Fernando F. Hadad-Arrascue,[3] Ana Sanchez fructuoso,[2] Isabel I. Perez-Flores.[1] *[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Clínico San Carlos, MADRID, Spain; [3]Clinica RTS Murcia VII, Murcia, Spain.*

Background: Tacrolimus is the immunosuppressant of choice in kidney transplant patients, one of the most common side effects is tremor occurring at peak serum tacrolimus blood concentrations. Tremor is associated with a significant decrease in the quality of life (QOL) of transplant patient. Our objective was to determine the change in tremor severity using the Fahn-Tolosa-Marín (TMF) scale and QOL using the quality of life questionnaire (QUEST), after switching from immediate release formulation of tacrolimus to prolonged release formulation of tacrolimus.

Methods: There were 11 stable Kidney transplant patients. They had tremors that affected their QOL. Tremor pre and one month post conversion was evaluated using the FTM scale, patients completed the QUEST. We measure levels Cmin (minimum concentration) and Cmax (maximum concentration) pre and after switching from immediate release to prolonged release formulation of tacrolimus.

Results: The mean age of patients was 58 +/- 11 y. After switching from immediate release tacrolimus to prolonged release tacrolimus there was a decrease in tremor in the absolute FTM test from 26.82 to 18.36 (-8.46 P <0.012) as an improvement in the parts of the FTM test: tremor location/severity 9.45 to 5.64 (-3-81P <0.07), specific motor tasks 12.9 to 10.2 (-2.6P <0.04), functional disability as a consequence of tremor 4.4 to 2.6 (-1.81P <0.1). Regarding the QUEST QOL test in the self-evaluation, there was a subjective decrease in tremor from 7.45 to 4.18 (-3.27 P <0.03) and an increase in the quality of life assessment from 58.6 to 65.9 (-7.2P<0.027). As for immediate release tacrolimus levels in Cmin 8.1 ng/ml and Cmax (at 2 hours) 13.6 ng/ml, unlike prolonged-release tacrolimus with Cmin 7.1 and Cmax (at 8 hours) 10.8 ng/ml. There was a 30% reduction in the total dose of tacrolimus when switching to prolonged-release tacrolimus. The renal function, serum and urinary magnesium levels did not produce statistically significant differences.

Conclusions: Results suggest after switching from immediate release formulation of tacrolimus to prolonged release formulation of tacrolimus there is decrease objectively and subjectively in the tremor and there is an improvement in the quality of life of Kidney transplant patients affected by tremor.

PUB704

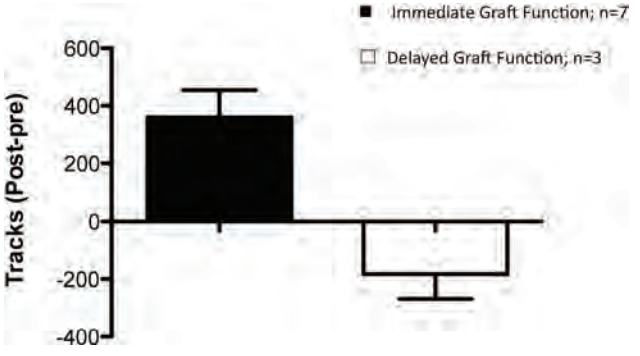
Successful Kidney Transplantation Normalizes Platelet Function Claire Kennedy,[4,5] Limy Wong,[4] Donal J. Sexton,[3] Jonathan J. Cowman,[2] Martin Kenny,[5] Peter J. Conlon,[1] Dermot Kenny.[2] *[1]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [2]RCSI, Dublin, Ireland; [3]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland; [4]Nephrology, Beaumont Hospital, Dublin, Ireland; [5]Royal College of Surgeons in Ireland, Dublin, Ireland.*

Background: Uremic platelet dysfunction is poorly understood largely because of inadequate platelet function assays. We have developed an assay of platelet function that accurately measures platelets translocating across von Willebrand factor (VWF) at arterial shear rates (DPFA). The aim of this study was to investigate the impact of kidney transplantation (KTX) on platelet function using the DPFA.

Methods: Blood samples from ten patients before and after KTX surgery and nine healthy controls at two different time points were assayed using the DPFA. Multiple parameters of platelet behavior and platelet-VWF interactions were recorded using customized platelet tracking software. The assay was repeated 3-8 weeks post-transplant.

Results: Platelet-VWF interactions were markedly reduced in the ten pre-transplant patients compared to the healthy controls. They normalized post-transplant in the seven patients with immediate graft function (despite a small drop in hemoglobin and hematocrit) but remained markedly abnormal in the three patients with delayed graft function (DGF).

Conclusions: This is the first demonstration of normalization of platelet function with reversal of uremia by KTX. Early normalization of platelet-endothelial interactions did not occur in those with DGF. This has important clinical consequences, as patients with DGF are more likely to undergo invasive procedures including transplant biopsies and insertion of central venous catheters.



Change in platelet interactions following transplantation as measured by differences between post-transplant and pre-transplant platelet tracks (ie the number of platelets interacting with VWF over the course of 500 frames)

PUB705

Value of the Immune Cell Function Assay in Pediatric Kidney Transplantation Lokesh N. Shah,[2] Joann M. Carlson,[1] Lynne S. Weiss,[1] Anna Petrova.[1] *[1]Rutgers RWJMS, New Brunswick, NJ; [2]Thomas Jefferson University Hospital, AI DuPont Hospital for Children, Wilmington, DE.*

Background: End-stage renal disease (ESRD) is associated with long-term complications and alteration of quality of life in affected children. Kidney transplantation is widely accepted for the management of ESRD in pediatric patients. The immune cell function (ICF) assay that measures CD4 lymphocyte ATP activation has been suggested to assess the level of immunosuppression, which is essential to reduce the risk for both rejection and complications of immune dysfunction.

Methods: We analyzed ICF level and clinical data on 20 children aged 3 to 20 years who underwent kidney transplantation. A total number of 75 ICF levels were analyzed to identify an association with the white blood counts (WBC), blood level of tacrolimus, and month after renal transplant (from 1 to 145). In addition, the ICF level was analyzed with respect to the therapeutic regiments: Group 1 (tacrolimus, mycophenolate/mycophenolic acid, and prednisone and Group 2 (tacrolimus and prednisone). Data is presented as mean with 95% Confidence Interval (95%CI) and correlation coefficient (r). *P*-value <0.05 was considered significant.

Results: A total number of 56 ICF levels were measured in Group 1 and 19 in Group 2 of studied patients. We found no difference in ICF levels [Group 1 (336.5, 95% CI 288.6-384.7) vs. Group 2 (359.4, 95%CI 248.8-469.9), P=0.65]. The ICF was correlated with WBC (r=0.66, P<0.01). There was no correlation with ICF and tacrolimus levels, nor was there an association between the ICF and the month after transplantation. ICF measures analyzed during post-transplantation follow-up were low, moderate and high in 23.2%, 64.3%, and 12.5% in Group 1 and in 42.1%, 31.6%, and 26.3% of those in Group 2 (P<0.05).

Conclusions: Immunosuppression therapy including mycophenolate or mycophenolic acid is more likely to maintain a moderate immunosuppression status, and the WBC may be used as surrogate measurement of immune-suppression in pediatric patients followed kidney transplantation.

PUB706

Predictors of Persistent Hyperparathyroidism Post Renal Transplantation – A Single Centre Experience Mayank Chawla,[1] Sobhana Thangaraju.[2] *[1]singapore general hospital, SINGAPORE, Singapore; [2]renal medicine, singapore general hospital, SINGAPORE, Singapore.*

Background: Hyperparathyroidism improves after kidney transplantation (KTR). However, persistent- hyperparathyroidism (PH) may occur and is associated with a higher risk of cardiovascular events, fractures, allograft failure, and all-cause mortality. Pre-transplant parathyroidectomy (PTX) has been advocated to prevent the risk of PH and complications of post-transplant PTX. However, there is no defined criteria for the timing of pre-transplant PTX. This study seeks to identify predictors of PH following transplantation to guide timely intervention

Methods: All first KTR performed in our tertiary care center, between January 2005 and July 2015 with follow-up of until 12 months and pre-transplant dialysis of more than 3 months were recruited for analysis (n=169). PH was defined as serum corrected calcium (cCA) of > 2.50 mmol/L and serum iPTH > 6.5pmol/L at 12 months post-transplant Baseline demographic and biochemical data were compared between groups with and without PH. Univariate analysis was performed and significant predictors of PH were further analyzed with multivariate regression analysis

Results: Mean age of study population was 45.8 years. The mean dalysis vintage was 88 months (36-140) and 84% were on hemodialysis. 68% of patients received deceased donor KTR. PH was diagnosed in 65 patients (38 %). On univariate analysis, patients with PH were older (48 (7.9) vs 44.4 (10.8), p=0.025), had longer dialysis vintage (108 vs 77 months p= 0.002), and higher pre-transplant cCA (2.51 (2.34, 2.68) vs. 2.29 (2.07, 2.51), p<0.0001), alkaline phosphatase (127.0 (114.0, 140.0) vs. 88.0 (38.0, 105.0), p=0.016), iPTH (90.2 (29.0, 127.2) vs. 38.0 (11.7, 49.9), P=0.0002), and phosphate (1.90(1.38,2.42) vs 1.66(1.14,2.18), P=0.0056) levels. Estimated GFR was lower in patients with PH at 12 months (54.5 (34.5, 75.0) vs. 61.0 (42.0, 80.0), P=0.0001). Following multivariate adjustment, longer dialysis vintage (HR = 1.011, 95% CI=(1.001,1.021)), higher pre-transplant cCa (HR=1.647, 95% CI=(1.296, 2.177)), and higher pre transplant iPTH (HR=1.015, 95% CI=(1.006,1.026)) remained significant

Conclusions: Longer dialysis vintage, higher pre-transplant iPTH and pre-transplant hypercalcemia are important predictors of PH following kidney transplantation

PUB707

A Unique Case of Disseminated Nocardia Infection and Post Transplant Lymphoproliferative Disorder in a Renal Allograft Recipient Dilini M. Daswatta,[1] Rohan V. Mehta,[1] Stephen O. Pastan,[1] Rahul Mehta.[2] *[1]Emory University School of Medicine, Atlanta, GA; [2]University of Virginia, Charlottesville, VA.*

Background: Nocardia infections most commonly present 1 to 6 months after solid organ transplantation with acute or subacute pneumonia, but hematogenous spread to brain, bone, eye and rarely skin and subcutaneous tissue have been reported. Inhanced Immunosupression, particular exposure to antilymphocytic antibody preparations may potentially increase the risk of such infections.

Methods: A 55 year old asian man with a history of Deceased Donor Renal Transplant of 2 years and stable Post Transplant Lymphoproliferative Disorder(PTLD) presented with left leg swelling for 2 weeks. About 6 months prior, he was diagnosed with biopsy proven metastatic CNS PTLD managed with systemic Rituximab, Intracranial radiation and Decadron. His maintenace immunosupression which included Belatacept was held and the dose of Cellcept was reduced after the diagnosis. The right parietal brain lesion was stable and liver metastasis had resolved after completion of therapy. He also had a history of Acute Rejections managed with Predniosne and Thymoglobulin in the past.

Results: CT scan of the leg reveals intramuscular fluid collection in the adductor and vastus group of muscle suggeting cellulitis / abscess, while Chest CT shows consolidation of the right upper and lower lobes. A new ring enhancing lesion suggestive of infection is discovered in the right temporal lobe of the brain on MRI, after the patient develpos altered mental status. Tissue biopsy from the leg grows Nocardia Farcinica. A CT guided drain is placed in the leg. The patient is started on Bactrim and Meropenem. Bactrim is later replaced with Linezolid. A repeat CT of the leg is suggestive of reduction in the fluid collection and the patient shows clinical improvement.

Conclusions: We present a case of Disseminated Nocardia Farcinica Infection in the setting of PTLD complicating a Deceased Donor Renal Transplant. We highlight the risk factors leading to these complications and discuss potential therapeutic options.

PUB708

Clinical Predictors of Recurrent Focal Segmental Glomerulosclerosis in Renal Transplantation Anita Shah,[3] Juan M. Gonzalez,[1,2] Sandra Barrow.[2,3] *[1]Houston Methodist Hospital, Houston, TX; [2]Nephrology, Dialysis & Transplantation Associates PA, Houston, TX; [3]J. C. Walter Jr. Transplant Center, Houston Methodist Hospital, Houston, TX.*

Background: Focal segmental glomerulosclerosis (FSGS) is a clinicopathologic syndrome involving scarring of the glomerulus and nephrotic range proteinuria[1]. Approximately 30% of patients have recurrent FSGS after renal transplantation[1], and these patients are at high risk of losing their graft. This recurrence, if not halted, ultimately leads to failure of the renal transplant and either dialysis or retransplantation. While some studies have shown risk factors associated with recurrence, there is no consensus on which patients are at greatest risk[1-3]. Our aim is to describe factors that help predict FSGS recurrence in transplant recipients.

Methods: A retrospective, observational case-control study was conducted on 24 patients (15 males) with idiopathic FSGS who had received a renal transplant at the Methodist Hospital between 2011 to 2015. All patients underwent a renal transplant biopsy. Baseline characteristics such as age at transplant, sex, race, immunosuppressive regimen, donor type, proteinuria, and creatinine were compared between those with and without FSGS recurrence. Continuous data were expressed as mean ± standard deviation (range) and analyzed with a Mann-Whitney test, while categorical data was analyzed by Fisher's exact test.

Results: At the time of biopsy, patients with FSGS recurrence illustrated, as expected, a significantly higher creatinine (p=0.010) and amount of proteinuria (p=0.001). However, no significant difference in age, sex, race, immunosuppressive regimen, or donor type could be identified between the two groups.

Conclusions: Surprisingly, there was no association between age, sex, race, immunosuppressive regimen, or donor type and recurrence, which differs from prior studies[1-3]. Future longitudinal studies monitoring idiopathic FSGS patients prior to and after transplantation can lead to proper screening of high-risk patients. 1. Shimizu, A, Higo, S, Fujita, E, et al. Focal segmental glomerulosclerosis after renal transplantation. Clin Transplant 2011; 25(Suppl. 23): 6-14. 2. Vinai, M, Waber, P, Seikaly, MG. PUB709

Severe AKI Due to AMR Rescued with Eculizumab Mark J. Lerman,[1] Michael B. Kuperman,[3] Afzal Nikaein,[2] Judson M. Hunt,[1] Salman Khan.[1] *[1]Dallas Nephrology Associates, Dallas, TX; [2]Texas Medical Specialty, Dallas, TX; [3]Johns Hopkins, Baltimore, MD.*

Background: Antibody mediated rejection (AMR) in transplant recipients may cause graft dysfunction and decreased graft survival. Current treatment options for AMR include plasma exchange (PP), intravenous immunoglobulin (IVIG), and anti--CD 20 therapy. Patient's with severe forms of AMR usually do not respond to these treatments. We present one case of very severe acute antibody mediated rejection which was resistant to conventional therapy but responded to Eculizumab.

Methods: 45-year-old AA man status post deceased donor kidney transplant in 2013, baseline creatinine 1.2. Patient presented with a serum creatinine > 20 in 2015. A biopsy revealed severe diffuse peritubular capillary C4d staining. Donor specific antibodies were present against DQ9 MFI 13153 at 1:32 dilution. Hemodialysis was initiated. A repeat renal biopsy after 5 doses of IV SoluMedrol and 5 treatments of plasma exchange and low-dose IV IgG continued to show diffuse peritubular capillary C4d deposition. Light microscopy remained essentially unremarkable. DSA to DQ9 remained high at MFI 12837 at 1:32 dilution. He remained on tacrolimus and mychophenolate. Eculizumab was begun at 1200 mg IV every week x 4. After 4 weeks and 4 doses of Eculizumab, renal function was clearly improving with a serum creatinine of 3 and a GFR of 25 mL/min/1.73m2. Dialysis was discontinued and a third renal biopsy showed complete resolution of C4d staining and very mild tubulitis with about 30% interstitial fibrosis. Patient received Eculizumab 900 mg every 2 weeks for another 4 doses. He has remained dialysis free for the last 19 months.

Results:

Conclusions: To our knowledge, prior to this case, no patient with a serum creatinine above 20 has responded to antirejection therapy and been able to discontinue dialysis. Our patient remains stable with serum creatinine 2.5 and has not required dialysis after almost 19 months. We believe even severe acute renal failure due to AMR requiring dialysis, may respond to Eculizumab. Allograft biopsy demonstrating absence of chronic changes and particularly thombosis maybe an important predictor for responsive patients regardless of renal dysfunction.

PUB710

The Risk of Inadequately Low First Tacrolimus Trough Level with Currently Recommended Reduced Drug Dosing in Kidney Transplant Recipients Aureliusz Kolonko, Andrzej Wiecek, Jerzy Chudek. *Medical University of Silesia, Katowice, Poland.*

Background: Nowadays, reduced tacrolimus (Tc) initial daily dose (0.1-0.15 mg/kg) is recommended for the majority of kidney transplant recipients (KTR). The aim of the study was to check the safety of such a regimen including the risk of first inadequately low tacrolimus blood level, acute rejection occurrence and delayed graft function (DGF).

Methods: In 2011, we introduced a modified (reduced from 0.2 to 0.1-0.15 mg/kg/day) initial tacrolimus dosing regimen in older (>55 years) and/or overweight KTR. To assure the safety of this protocol we have monitored the risk of inadequately low blood Tc level (<6 ng/ml) and incidence of acute rejection or DGF. The historical cohort (n=319) served as a control group.

Results: The mean Tc daily dose in 79 KTR (group with reduced dosing) was 0.13±0.02 mg/kg and was significantly lower than the standard, previously prescribed dose (0.19±0.02 mg/kg). The dose reduction resulted in slight, nonsignificant decrease in first blood Tc trough level (15.6±7.8 vs. 16.1±7.2 ng/ml). There were 6.3% (n=5) versus 5.3% (n=17) first Tc trough levels below 6 ng/ml and 45.6% (n=36) versus 48.9% (n=156) above 15 ng/ml in reduced and standard dosing groups, respectively. These differences were not significant. The incidence of acute rejection (7.6 vs. 6.0%) and DGF (26.6 vs. 28.5%) was similar in both groups.

Conclusions: 1. The currently recommended reduction in Tc initial dosing does not increase the risk of inadequate immunosuppression and does not affect the early graft function. 2. Regardless of Tc dose reduction, there is still a greater risk for Tc overdosing in older and overweight kidney transplant recipients.

PUB711

Rapid Graft Loss Due Recurrence of Undiagnosed Primary Hyperoxaluria Saffa M. El awad.[1,2] *[1]NEPHROLOGY, HAMAD MEDICAL COORPORATION, DOHA, Qatar; [2]TRANSPLANTATION, UNIVERSITY OF LIVERPOOL, LIVERPOOL, United Kingdom.*

Background: Primary hyperoxaluria (PH) is a rare autosomal recessive disorder leading to systemic deposition of calcium oxalate crystal causing nephrocalcinosis, nephrolithiasis, and chronic kidney disease. A case record of a young woman with end-stage renal disease is being presented who underwent paid organ transplantation and developed allograft loss at two weeks due to recurrence of undiagnosed PH.

Methods: Case Records: The patient is a 28-year-old female patient, was known to have hypertension and hyperlipidaemia for few years. She presented with end-stage renal disease and commenced on haemodialysis in December 2014. She was found to have bilaterally small kidneys; hence kidney biopsy was not performed. In February 2016, she received kidney transplantation from donor a 38 years old paid male donor (no further information available). Post-operative period was complicated with severe bacterial sepsis and development of a lymphocele. Two weeks later there was a consistent decline in graft function, and eventually, she required maintenance haemodialysis. Renal allograft biopsy showed extensive calcium oxalate crystals deposition, suggestive of recurrence of primary hyperoxaluria. Genetic studies confirmed the diagnosis of primary hyperoxaluria type 1. Moreover, patient contracted hepatitis C and developed severe erythropoietin-resistant anaemia

Results:

Conclusions: Recurrence of PH is recognised, leading to graft loss. Despite this in 10% of patient diagnosis is done retrospectively. This case demonstrated the need for careful screening of PH in young patients prior to transplantation. There is a dire need for pre-transplant counselling to increase awareness of life-threatening situations in unregulated health care sector, where money is the sole aim. The exploitation of donors and recipient is rampant and unabated where cross-infections are common. Acquisition of hepatitis C is not surprising.

PUB712

Urinary Tract Infection in Kidney Transplant Recipients, Experience of the Hospital Specialties, Western National Medical Center, Mexican Institute of Social Security Victor M. Martinez-Mejia,[1] Jorge Andrade-Sierra,[1,2] Benjamin Gomez-Navarro,[1] Milagros M. Flores fonseca.[1] *[1]Nephrology, Instituto Mexicano Del Seguro Social. Centro Medico Nacional de Occidente, Guadalajara, Mexico; [2]Physiology, University of Guadalajara, Guadalajara, Mexico.*

Background: URINARY TRACT INFECTIONS (UTI) ARE THE MAIN CAUSE OF INFECTIOUS COMPLICATIONS AFTER KIDNEY TRASPLANT. THE INCIDENCE REPORTED OF UTIs RANGES FROM 21% TO 79%. GRAM NEGATIVE BACTERIA ACCOUNT FOR MOST OF 70% OF UTI; E. COLI IS THE MOST UROPAHOGEN. THE RISK FACTORS FOR THE DEVELOPMENT OF POSTTRANSPLANT UTIS ARE MULTIFACTORIAL AND ARE DETERMINED BY THE INTERACTION BETWEEN HOST FACTORS, PATHOLOGIC AGENTS AND ANATOMICAL ABNORMALITIES.

Methods: WE PERFORMED COHORT STUDY INCLUDING ALL THE ADULT PATIENTS WHO RECEIVED A RENAL TRANSPLANT AT HOSPITAL OF SPECIALTIES, WESTERN NATIONAL MEDICAL CENTER, MEXICAN INSTITUTE OF SOCIAL SECURITY FROM JANUARY 2013 TO APRIL 2015. WE DEFINED AS UTI PATIENTS WITH URINE CULTURE WITH >10 5 CFU/ML. PRINCIPAL OUTCOME: TO DETERMINE THE INCIDENCE OF UTIs IN THE FIRST YEAR POSTTRANSPLANT. SPECIFIC OUTCOMES. TO RECOGNIZE RISK FACTORS, PATHOLOGIC AGENTS.

Results: THE POPULATION CONSISTED OF 631 PATIENTS, WITH MAJORITY RECEIVING ALLOGRAFT FROM LIVING DONORS (86%). A TOTAL OF 192 PATIENTS (30.4%) DEVELOPED AT LEAST ONE EPISODE OF UTI. SIGNIFICANT RISK FATORS FOR POSTTRASPLANT UTIs WERE FEMALE GENDER (OR 2.8; CI 95%:1.7-4.3; P <0.001) CADAVERIC DONOR (OR 2.2; CI 95%:1.4-3.6; P <0.001), DIABETES MELLITUS 2 (OR 2.8; CI 95%:1.3-6.0; P <0.001), DURATION BLADDER CATHETERIZATION MORE THAN FOUR DAYS (OR 6.4; CI 95%:3.1-13.3; P <0.001)URETERAL CATHETER PLACEMENT(OR 3.1; CI 95%:1.9-5.1; P <0.001) AND ANATOMICAL ALTERATIONS (OR 9.7; CI 95%:4.86-19.5; P <0.001).

Conclusions: IN THIS COHORT OF PREDOMINANTLY LIVING DONOR RENAL TRANSPLANT RECIPIENTS, THE INCIDENCE OF UTI IS SIMILAR TO THAT REPORTED IN OTHER STUDIES. ISOLATED PATHOGENS AS IN OTHER REPORTS CORRESPOND TO GRAM-NEGATIVE BACILLI. RISK FACTORS THAT WE COULD DETERMINED WERE FEMALE SEX, CADAVERIC DONOR, PROLONGED URETHRAL CATHETER STAY, URETERAL CATHETER PLACEMENT AND ANATOMICAL ALTERATIONS.

Procalcitonin for Diagnosis of Bacterial Infections and Rejection in the Early Post-Renal Transplant Period Shefali Gupta,[3] Pradeep Jaswani,[2] Kashi nath Prasad,[2] Narayan Prasad,[2] Amit Gupta,[1] Chinmoy Sahu.[2] *[1]Department of Nephrology, Lucknow, India; [2]SGPGI, Lucknow, India; [3]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Infection and rejection are leading causes of morbidity and mortality in renal transplant recipients. Since patients with infection and rejection have similar clinical presentation, differentiating the two can pose a diagnostic challenge for transplant clinicians. We evaluated the utility of PCT in differential diagnosis of rejection and infection in renal transplant recipients.

Methods: In this study, serum PCT concentrations were monitored in 146 renal transplant recipients from the day of transplant to 15 days after transplant. The PCT estimation was done using ELECSYS BRAHMS PCT kit. Recipients were grouped into Group 1: non-infectious and Group 2: infectious group. Group 2 was further subdivided into: graft rejection (Group 2a) and non-rejection (Group 2b) cases. SPSS (V.20) was used for statistical analysis. PCT levels > 0.5 ng/ml were consideredclinically significant. Rejection was proven with biopsy.

Results: Out of the total 146 patients, 111 (group 1) did not develop a bacterial infection while 35 (group 2) suffered bacterial infections within 15 days of renal transplant. Among the group 2 patients, 13 (group 2a) suffered acute graft rejection while 22 (group 2b) did not. Receiver operating characteristic (ROC) analysis showed the area under thecurve (AUC) for predicting infection above PCT level of 1.9 ng/ml was 0.89, (95% confidence interval [CI]: 0.83-0.94; p = <0.0001). For differentiating group 2a patients from group 2b, AUC was 0.65 (95% CI: 0.46-0.83; p = 0.1).

Conclusions: PCT levels can improve diagnostic accuracy of bacterial infections in patients in the early post–renal transplant period with adequate sensitivity and specificity. It does not, however, reliably exclude the co-occurrence of rejection in patients who have also developed bacterial infections. Larger, multicenter studies would be useful to validate the PCT cutoff values.

PUB714

A Case of Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN) and De Novo Donor Specific Antibodies (dnDSA) after Kidney Transplantation in a Patient with Polycystic Kidney Disease Syed Hammad Alam,[4] John E. Leggat,[2] Paul F. Shanley,[2] Vikram Aggarwal,[1] Oleh G. Pankewycz.[3] *[1]SUNY UPSTATE MEDICAL UNIVERSITY, NEW YORK, Syracuse, NY; [2]SUNY Upstate Medical University, Syracuse, NY; [3]SUNY, Upstate Medical University, Syracuse, NY; [4]Upstate Medical University, Syracuse, NY.*

Background: Immune mediated glomerular disorders in transplant recipients include recurrent GN, post-infectious GN and antibody mediated rejection. Different GNs usually do not occur simultaneously as they imply either over-immunosuppression (IS) i.e. infection or under-IS i.e. alloantibodies. We now describe an unusual case of IC-MPGN with concurrent dnDSA in a patient with ESRD due to APKD.

Methods: A 61 year old man with a panel reactive antibody level of 0% received a kidney transplant from a non-Public Health Service defined high risk donor. Both recipient and donor were negative for hepatitis C virus (HCV). Rabbit anti-thymocyte globulin was given with maintenance IS on cyclosporine, mycophenolate and prednisone. Allograft function was excellent with creatinine levels of 1.0-1.2 mg/dl. The patient was often noncompliant with therapy due to adverse drug effects. Fourteen months after transplant the patient developed nephrotic range proteinuria (4.6-6.9 gr), microscopic hematuria and a creatinine of 1.4 mg/dl. Allograft biopsy showed typical changes of IC-MPGN with double contouring of glomerular basement membrane accompanied by glomerular and mesangial dense deposits, C3, C1q, IgG, IgA and IgM staining by immunofluorescence and microtubular aggregates by EM. An evaluation revealed the presence of anti-HCV antibodies, serum cryoglobulins and a low C3 level, however HCV viral copies were undetected. Peritubular capillaritis and C4d staining were also observed. The recipient was also found to have anti-Class II dnDSA (DR1, DQ2 and DQA105) and anti-Class I (A1) dnDSA. High dose steroid therapy, apheresis and IVIG were started with resultant improvement in proteinuria and return of serum creatinine to prior baseline. Anti-HCV antibodies and cryoglobulins were negative on repeat testing.

Results:

Conclusions: Without anti-viral therapy, post-transplant HCV infection is associated with IC-MPGN and the HCV infection by itself rarely remits and leads to high rates of graft loss and patient mortality. Our patient represents an unusual case of a presumed spontaneously resolved HCV infection with cryoglobulins due to under-IS as evidenced by the presence of dnDSA.

PUB715

Long-Term Outcome of Renal Transplantations in Two Patients with ADCK4-Associated Glomerulopathy Zihua Yu,[1,2] Si Wang.[1] *[1]Department of Pediatrics, Dongfang Hospital, Fuzhou, China; [2]Department of Pediatrics, Xiamen University Affiliated Dongfang Hospital, Fuzhou, China.*

Background: Mutations in the *ADCK4* gene can cause *ADCK4*-associated glomerulopathy. Patients with *ADCK4*-associated glomerulopathy can be treatable with CoQ10 at the early stage because the transcript of *ADCK4* encodes a protein of the CoQ10 biosynthetic pathway, which localizes to the mitochondria in podocytes. The patients with *ADCK4*-associated glomerulopathy who progress to end-stage renal disease (ESRD) require dialysis or renal transplantation. It has reported that some patients with *ADCK4*-associated glomerulopathy received renal transplantations. However, long-term outcome of transplantations in the patients with *ADCK4*-associated glomerulopathy is unknown. Here, we report the long-term outcome of two cases with *ADCK4*-associated glomerulopathy who received cadaveric renal transplantations at more than 10 years of follow up.

Methods: The two patients harbor a compound heterozygous mutation (532 C>T; R178W and 748 G>C; D250H) in the *ADCK4* gene. Case 1, a boy presented with steroid-resistant nephrotic syndrome (SRNS) at 7 years old and had mesangial proliferative glomerulonephritis lesions on renal biopsy at 8 years old. He received a cadaveric renal transplantation at 16 years old when he progressed to ESRD. The avenues in the immunosuppressive treatment included the use of mycophenolate mofetil, tacrolimus plus prednisone. His renal examination retained normal at 11 years of follow-up. His last urinalysis showed normal. His serum creatinine was 114 μmol/L and urea nitrogen 7.9 mmol/L. Case 2 (older sister of case 1), a girl presented with SRNS and had focal segmental glomerulosclerosis on renal biopsy at 10 years old. She received a cadaveric renal transplantation at 14 years old when she progressed to ESRD. She received the same avenues after transplantation. Her renal examination also retained normal at 15 years of follow-up. Her last urinalysis also showed normal. Her serum creatinine was 81μmol/L and urea nitrogen 5.5mmol/L.

Results:

Conclusions: Long-term outcome of renal transplantations is good in the patients with *ADCK4*-associated glomerulopathy who progress to ESRD.

PUB716

Triglyceride Metabolism in Japanese Kidney Transplant Recipients Makoto Tsujita. *Nagoya Daini Red Cross Hospital, Nagoya, Japan.*

Background: Residual risk factors such as triglyceride (TG) cause cardiovascular disease. TG metabolism after kidney transplantation remains unclear.

Methods: Sixty-three consecutive stable recipients just one year after kidney transplantation were included in the study at Nagoya Daini Red Cross Hospital from January to September in 2014. We performed cookie test(this cookie consists of 75 g carbohydrate and 25 g fat) to evaluate TG metabolism. TG, Blood sugar (BS), remnant like particle-choresterol (RLP-C), serum insulin were measured at fasting (f) and 2 and 4 hours (h) after ingestion. Low density lipoprotein cholesterol (LDL-C) and high desity lipoprotein cholesterol (HDL-C) and apoB were measured at fasting.

Results: Figure 1 summarizes the clinical and metabolic characteristics of this study. Mean TGf and RLP-Cf were 139.4±62.6 mg/dl and 5.6±3.4 mg/dl within normal range, however, both mean TG2h and TG4h were above 200 mg dl, and both mean RLP-C 2h and RLP-C 4h were above 9 mg/dl. A negative correlation was seen between TGf and eGFR (r=-0.48 p<0.001). TGf had positive correlation with RLP-C, non HDL-C, LDL-C/apoB ratio, BMI (r=0.80 p<0.001, r=0.47 p<0.001, r=0.48 p<0.001, r=0.38 p=0.002, respectively). BMI had positive correlations with RLP-C (r=0.35, p<0.001) and a negative correlation with HDL-C and LDL-C/apoB ratio (r=0.48 p<0.001, r=0.30 p=0.016, respectively). LDL-C levels were under control because of statin use, but LDL-C/apoB ratio levels in 50% of recipients were below 1.2, meaning the rate of small dense LDL-C in LDL-C increased. TG metabolism in non DM group was similar with that in DM group. In Everolimus (EVR) group, TGf levels were higher than that in non EVR group (p=0.04).

Conclusions: Prevalence of postprandial hypertriglyceride among kidney transplant recipients was high, however, whether it should be treated remained unknown.

The Relationship Between Intra-Patient Tacrolimus Variability and Immunosuppression Regimens in Kidney Transplant Patients: A Comparative Multi-Centre Retrospective Study Vitaliy Androshchuk. *Oxford University Hospitals NHS Foundation Trust, Bristol, United Kingdom. Group/Team: Transplant Audit Collaborative (UK).*

Background: It is increasingly recognised that high tacrolimus trough level intra-patient variability (IPV) is a predictor for poor long-term outcome after renal transplant. The relationship between IPV and the use of induction and maintenance immunosuppressive agents has not been previously evaluated.

Methods: Database records of all kidney transplant recipients on standard-release Tacrolimus were interrogated across 5 UK transplant centres (Oxford, Manchester, Liverpool, Glasgow and King's College London) between 2009 and 2014. Each centre compared trough level IPV in patients on different immunosuppression during the 6-12 month post-transplant (T1) and the last 12 months of follow-up (T2) using Kruskal-Wallis analysis. Patients were excluded if they received dual-organ transplants or modified release tacrolimus and if death or graft loss occurred within two years of transplantation.

Results: 1066 patients were included from 5 UK centres (Table 1). There was no significant difference in tacrolimus IPV between patients receiving induction with basiliximab or alemtuzumab and those on maintenance mycophenolate and Azathioprine during T1 and T2 (p>0.05 for all comparisons). In Oxford and King's College London, patients receiving steroids had significantly higher IPV in T2 (p=0.0001 and p=0.013 respectively) compared to those on steroid-free regimen. A similar trend was seen in other centres but the difference in IPV did not reach significance.

Conclusions: This study represents the first multicentre comparative evaluation of tacrolimus IPV in kidney transplant patients on different immunosuppression across the UK. Our results demonstrate an association between the use of steroids and higher tacrolimus IPV in 2 out of 5 centres. Further study of pooled data is awaiting ethical approval.

Funding: Commercial Support - Educational grant from Astellas Pharma Ltd

Five Year Outcomes of Adult and Pediatric Kidney Transplantation: A Single Center Experience from Guatemala Alejandro Lucas. *Tlalpan, Mexico.*

Background: The Latin American Dialysis and Transplant Registy, indicates that the overall kidney tranplant rate increased from 3.7 per million population (pmp) in 1987 to 19.4 pmp in 2013, neverthless Guatemala is a country with very low rate of kidney transplant (5.6 pmp), and this rate has not changed during the last ten years. This study presents the experience of kidney transplants from foundation Amor, this is a nongovernmental and noprofit institution that provides renal transplants in adults and childrens without social security. This is the first report of long term follow up kidney tranplants to our country. The objetive is determine 5 years graft and patient survival and factors asociated to graft lost.

Methods: It includies all transplants peformed between December 2011 to December 2016. Data were expressed as mean ± s.d. or medians, percentages. Patient and graft survival rates were estimated by theKaplan–Meier method. Log rank test were used to compare graft and patient survival rates. Cox regression analisys used to determine hazard ratio to graft failure. The SPSS 18 was used to analize the data.

Results: A total of 131 kidney transplants were performed between observation period, the distribution was 82 adults(62.6%) and 49 pediatrics(37.4%). Mean follow-up time adult graft survival was 28.5 months DE ± 19.9 (0-65), in pediatrics was 32.3 months DE ±19.5 (1-63). A total of 30 grafts were losts in the follow-up time, 19 (23.2%) in adults, in pediatrics were 11 (22.4%). Graft adult survival at 1, 3 and 5 yeas was 87%, 71% and 71% respectly. In pediatric group the graft survival at 1,3 and 5 years was 92%, 80% y 69% respectly Klaplan meier analisys of patients survaivor showed no diferences between adulst an pediatric (p:0.2). Adult patient survaivor was at 1 year 97 % and 5 year 94%. Pediatric patient survaivor was at 1 year 96% and 5 year 91%. Analisys of Cox regresión to determine hazard ratio of factors associates to graft lost showed in adult patients, got social security in follow-up is a protector factor to lost, Hazard ratio 0.2 IC 95% (0.06-0.60) p: 0.006.

Conclusions: Kidney transplants in adults and pediatrics patientes had good outcomes at 5 year follow up time in our center.

PUB719

Access to Kidney Transplant: Limitations from the Patient's Perspective in Jalisco, México Daniel Murillo brambila,[1,2] Monica C. Jimenez cornejo,[1,2] Karina Renoirte,[1,2] Gabriela J. Abundis Mora,[1,2] Guillermo Garcia-Garcia.[1] *[1]Hospital Civil De Guadalajara, University of Guadalajara, Guadalajara, Mexico; [2]PISA SANEFRO, Guadalajara, Mexico.*

Background: CKD is a major public health problem in Mexico, the incidence is 421 per million inhabitants according to the latest 2016 USRDS report. Renal replacement therapy is expensive and in the majority of low and middle-income countries is prohibitive. Renal transplantation is the treatment of choice for patients with ESRD. Objetive is evaluate the main obstacles encountered by prevalent hemodialysis patients to undergo a kidney transplant.

Methods: A cross-sectional study of 200 prevalent hemodialysis patients in Jalisco. Insured and uninsured patients were included. Demographic variables, time on hemodialysis, social security status and main reasons to undergo or refuse the kidney transplant protocol, The data are shown in numbers, percentages, mean and standard deviation.

Results: Only 72 (36%) patients were under a kidney transplant protocol; 78% of these patients belonged to the Social Security: 32 (44.4%) had completed the protocol, with an average time of 8.8 months for completion, and an average waiting time for surgery of 12.4 months. 128 (64%) patients were not on the transplant protocol; 103 (80.4%) of patients are insured. Main reasons were 46 (36%) were medically unsuitable candidates, 21(16.4%) did not have a compatible living-related donor, 20 (15.6%) were afraid of being transplanted; 20 (15.6%) were not offered transplant, 18 (14.1%) lacked financial resources

Conclusions: Being medically unsuitable candidate, lack of a compatible living-related donor, fear of transplantation, not offered the option of transplantation, lack of financial resources, and lack of relatives not willing to donate were the most commonly identified obstacles to kidney transplantation. The findings were similar among the insured and non insured populations.

Tuberculous Constrictive Pericarditis after Renal Transplantation: Case Report Larissa G. Andrade,[6] Alexandre D. Pinto,[6] Diogo B. Cabral,[4] Gisele Vajgel,[6] Guilherme G. Danzi,[6] Joaquim O. Borba,[5] Marclebio M. Dourado,[3] Maria carolina R. Coêlho,[2] Zaira R. Menezes,[6] Filipe C. Aguiar.[1] *[1]Federal University Of Pernambuco, Recife, Brazil; [2]Hospital das Clínicas HC - UFPE, Recife, Brazil; [3]UFPE, Recife, Brazil; [4]UNIVERSIDADE FEDERAL DE PERNAMBUCO, RECIFE, Brazil; [5]Ufpe, Recife, Brazil; [6]Universidade Federal de Pernambuco, Recife, Brazil.*

Background: Constrictive pericarditis (CP) results from chronic scarring caused by inflammation of pericardium. The main causes of CP are idiopathic, viral, or after cardiac surgery, acute pericarditis or radiation therapy. Tuberculosis (TB) is still an important cause of pericarditis in developing countries and imunossuppressed patients.

Methods: A 35-year-old male patient with end-stage renal failure of unknown etiology received a live donor renal transplant(Tx) in 2001 after 3 years undergoing hemodialysis. His tuberculin skin test was negative before Tx. He received cyclosporine, prednisone and azathioprine as maintenance medications and no induction. Baseline serum creatinine was 1,4mg/dL. In 2012 changed to sirolimus and prednisone due to pelvic chondrosarcoma. In 2016 the patient was admitted to Hospital with dyspnea. Physical examination revealed hepatomegaly and distended jugular veins. Chest X-ray revealed pericardial calcification (figure 1). Echocardiogram showed increased brightness of the pericardium and biatrial dilatation. Polymerase Chain Reaction (PCR) to TB were positive in blood and urine. He started rifampicin, isoniazid, pyrazinamide and ethambutol. Despite initial treatment, symptoms worsened and he underwent anterior pericardiectomy. Histopathological examination showed diffuse fibrosis, but PCR to TB was negative. Patient improved symptoms and was discharged under antituberculous drugs.

Results:

Conclusions: TB has a high incidence in Brazil and is 14 times more common in Tx patients. The incidence of CP following kidney Tx is unknown, and there are only few case reports in literature. CP is a serious sequel of TB pericarditis. CP has progressive course causing congestive heart failure and high cardiovascular mortality risk. This patient had a good response after surgery. Pericardiectomy is indicated once the diagnosis of CP is made.

Warfarin Related Nephropathy Complicating Management of IgA Nephropathy in a Patient with Cirrhosis Leading to Combined Liver and Kidney Transplant: A Case Report Yougandhar Akula,[2] Satya Sai V. Bhupathi,[1] Juan A. Medaura.[2,1] *[1]University Of Mississippi Medical Center, Madison, MS; [2]Nephrology, Univ of mississippi medical ctr, JACKSON, MS.*

Background: Warfarin related nephropathy or its broader term Anticoagulant related nephropathy is known to cause AKI in patients with supratherapeutic INR. The predominant mechanism seems to involve hemorrhage, heme induced free radical injury and inflammation. We report a case of AKI in a pt with cirrhosis caused by Warfarin in a pt with IgA nephropathy leading to combined kidney, liver transplant

Methods: Pt is a 47 y/o white male with PMH of Liver Cirrhosis and Hepatitis C, who was transferred from community hospital for the management of SBP. In spite of treatment of SBP his creatinine continued to rise. Pt had red cells in his urinalysis. This was thought to be secondary to Warfarin for portal vein thrombosis. Due to concern for IgA nephropathy versus membranoproliferative glomerulonephritis a kidney biopsy was done. The biopsy was complicated by post biopsy hemorrhage. He was discharged and later readmitted for combined liver and kidney transplant. His kidney biopsy revealed IgA nephropathy, probably secondary to the patient's hepatitis C related cirrhosis, with focal segmental endocapillary proliferative glomerulonephritis (in 2 of 15 glomeruli). No segmental or global glomerulosclerosis present. No significant interstitial fibrosis. Erythrocytes were present within a number of tubular lumen some of which are degenerate. There is one small focus in which the tubules show mild thickening of their basement membranes compatible with some early tubular atrophy.

Results:

Conclusions: Anticoagulant-related nephropathy has been associated with warfarin and dabigatran use. The mechanism of AKI was shown to be secondary to 1) injury to tubular epithelial cells caused by reactive oxygen species and lipid peroxidation generated by free hemoglobin in the tubular lumen 2) intracellular uptake of hemoglobin by tubular epithelial cells leading to activation of caspases and induction of apoptosis 3) intracellular hemoglobin activates proinfalmmatory pathways. The risk of AKI occurs at an INR threshold of >3; It appears that supratherapeutic INR alone may not be sufficient. AKI is more likely to occur in the setting of pre-existing glomerular damage like IgA nephropathy as in our patient.

PUB722

The Role of Resilience in Healthcare Transitions among Adolescent and Young Adult Kidney Transplant Recipients Sheila M. Quinn,[3] Hilda E. Fernandez,[1] Frances K. Barg,[2] Kenneth R. Ginsburg,[3] Sandra Amaral.[3] *[1]NYP-CUMC, NYC, NY; [2]University of Pennsylvania, Philadelphia, PA; [3]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Adolescent and young adult (AYA) kidney transplant (KT) recipients experience high rates of premature allograft loss, believed in part to be due to the healthcare transition (HCT) process. Yet, most AYA with KT navigate the HCT successfully. There is a critical need to identify the protective factors associated with stable HCT. Resilience--the ability to thrive in the setting of adversity-- is a learned and dynamic process with known positive impact on health outcomes. This study is the first to examine the novel role of resilience as a protective factor in securing stable HCT.

Methods: This is a retrospective mixed methods study of AYA with KT who transitioned from a single pediatric center between 2008-2016 to adult nephrology care. Medical record data stratified participants into stable or unstable HCT groups. (Unstable = loss-to-follow-up, missing ≥50% of adult nephrology visits in the first 12 months (mo) post-transfer, or unexpected dialysis initiation in 12 mo post-transfer). Semi-structured interviews were conducted in adult clinics at least 6 mo post-transfer to investigate the role of key constructs of the American Academy of Pediatrics Resilience Framework (confidence, competence, connection, character, contribution, coping, control). Qualitative analysis used a grounded theory approach, with transcripts coded in a blinded fashion using NVivo11Pro.

Results: 23 of an estimated 30 necessary participants (55% male, median age 24.4 years (yrs), median time since KT 10.6 yrs, median 3.2 yrs since transfer) have enrolled. 16 participants with stable HCT endorsed strong character and personal control over their medical condition. Thematic saturation is not yet achieved in the 7 participants with unstable HCT, but they preliminarily seem to lack the aforementioned character and control, and instead emphasize competence as a leading mediator in HCT. Coping skills and a meaningful connection with an adult appear salient in both groups.

Conclusions: Resilience constructs can be supported and enhanced, and therefore are potentially modifiable mediators of HCT. Here, AYA with KT endorsing a strong sense of character and personal control over their medical condition appear to have more stable HCT. Our findings suggest that enhancing sense of personal control while finding supportive connections may support stable HCT.

PUB723

Have Kidney Transplants from Uncontrolled Donation after Circulatory Death (uDCD) Different Cardiovascular Risk Factors after Transplantation? Maria Molina, Enrique Morales, Manuel Praga, Esther Gonzalez monte, Amado Andres. *Nephrology Department, Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Cardiovascular diseases (CVD) are the most frequent cause of mortality in kidney transplant (KT) recipients, and 50% of these deaths are due to ischemic heart disease (IHD). The recipients of KT from uDCD received more frequently induction therapy with lymphocytes depleting antibodies and higher dose of inhibitor of calcineurin. The incidence of CVD after this kind of KT is unknown. **Aim**: To analyse the prevalence and the incidence of CVD events in our program of KT from uDCD after 100 months of follow up and to determinate the risk factors that are involved in the development of this complication.

Methods: We included 237 RT from uDCD between 2005 and 2013. We reviewed donors, recipients, procurement and evolution characteristics. We reported CVD eventes: IHD, cerebrovascular accidents and peripheral vascular disease (PVD) or death attributable to CVD.

Results: Recipient's age was 48±11 y and 141 (59.5%) were male. Pretransplantation cardiovascular risk factors were: 77.2% (183) hypertension, 22.8% (54) diabetes mellitus and 39.2% (93) dyslipidemia. CVD pretransplantation were: 5.5% (13) IHD, 4.6% (11) stroke and 3.8% (9) PVD. Mean follow up was 44±27 (25-63) months. The prevalence of CVD was 8.8% and the incidence was 27 cases/1000 patient-years. Of the 21 CVD events in 20 patients, 55% (11) were IHD, 35% (7) stroke and 10% (3) PVD. Multivariable analysis shown the following risk factors to develop for any CVD event: pretransplantation IHD (HR: 9.2 (3.2-26.8) p<0.001), pretransplantation PVD (HR: 4.2 (1.1-15.4) 0=0.02), previous cerebrovascular accidents (HR: 4.2 (1.4-12) p=0.008), recipient's age at transplantation (HR: 1.05 (1.006-1.1) p=0.04), body mass index of recipient at transplantation (HR: 1.12 (1.004-1.2) p=0.04), diabetes mellitus (HR: 2.8 (1.03-7.9) p=0.04), dyslipidaemia (HR: 2.5 (1-6.1) p=0.05) and serum creatinine at 6 month (HR: 2 (1.1-3.5) p=0.02). Hepatitis C, donor gender or proteinuria … didn't increase CDV risk.

Conclusions: The incidence of CVC events following renal transplantation of uDCD donors is low and is related to the previous CVD factors and renal function at 6 months. Then, renal transplant recipients with pre-KT CVC events require a wide pre-transplant vascular study and a close post KT follow-up.

PUB724

Hypophosphatemia Post Kidney Transplant – A Single Centre Experience Pablo Justo avila,[3] Terrina Abd rahim,[2] Shafi Malik.[1] *[1]Renal Medicine, Leicester General Hospital, Leicester, United Kingdom; [2]Kettering General Hospital, Leicester, United Kingdom; [3]Renal, Royal Derby Hospital NHS Trust, Derby, United Kingdom.*

Background: Hypophosphatemia (HP) is a common complication after kidney transplant (Tx). It requires correction by either oral or intravenous phosphate (PO_4). We aim to identify predisposing factors for developing HP post-Tx.

Methods: We identified 57 kidney Tx recipients from Nov14 to Dec15. We collated demographics, cause of ESRD, prevalent RRT pre-Tx, type of Tx, duration of admission, serum phosphate (SPO_4) levels 3 days post-Tx and at discharge, requirement of PO_4 supplementation and Tx function for the period of 6 months. We defined HP as SPO_4 levels <0.8 mmol/L and delayed graft function (DGF) as requiring RRT 7 days post-Tx.

Results: Mean age was 47.2 years. Causes for ESRD were GN (31.6%), unknown aetiology (22.8%), hereditary (19.3%), interstitial nephritis (14%), renovascular (7%) and DM nephropathy (5.3%). Prior to Tx, 47.4% and 29.8% were on HD or PD respectively. 10 patients received a living donor Tx (LD) (17.5%), 32 deceased brain-death Tx (DBD) (56.1%) and 14 deceased cardiac-death Tx (DCD) (24.6%). Mean duration of admission was 9.4 days (SD 9.3). 28 presented with drop in SPO_4 levels of >0.3 mmol/L 3 days post-Tx. Mean SPO_4 at discharge was 0.94 mmol/L (SD 0.3). 10 (17.5%) had normal graft function, 45 (78.9%) had DGF and 2 (3.5%) had primary graft dysfunction. Mean SCr at Day 1, 1,3 and 6 months post-Tx were 561.7 μmol/L (SD 248.2), 150.3 μmol/L (SD 102.4), 159.1 μmol/L (SD 100) and 147.5 μmol/L (SD 71.7) respectively. At the end of follow-up, 37 patients presented HP. 27 (47.37%) required oral PO_4, 3 (5.26%) required IV PO_4 while 7 (12.28%) required both. Mean dose of PO_4 supplementation was 44.34 mmol/day (SD 44.74) for oral and 130 mmol (SD 48.3) for IV. There is a correlation between HP and type of Tx (p 0.018); (LD 70%, DBD 78%, DCD 35.7%); SPO_4 level at discharge ($p < 0.01$) and Tx function in the 1st, 3rd and 6th months post-Tx (p values 0.023, 0.021, 0.05). We found no correlation between HP and cause of ESRD, prevalent RRT, Tx function 1 day post-Tx, initial drop of PO_4 levels 3 days post-Tx and presence of DGF.

Conclusions: 1. Probably, DBD and LD Tx are more likely to develop HypoP in comparison with DCD Tx. 2. Improved Tx function is associated with higher incidence of HypoP, close monitoring of these patients is advisable to prevent complications. 3. The presence of DGF and initial monitoring of renal function are not reliable factors to predict the onset of HypoP.

PUB725

The Coefficient of Variation (CV) and the Mean Absolute Deviation (MAD) Are Both Acceptable Measures of Intrapatient Variability (IPV) in Tacrolimus Trough Levels Petra M. Goldsmith. *Royal Liverpool Hospital, Lymm, United Kingdom. Group/Team: UK Transplant Audit Collaborative.*

Background: Tacrolimus is the preferred first line immunosuppressant following renal transplant in the UK. It has a narrow therapeutic index which is measured by serum trough levels. Studies have shown that a high IPV (the variability observed in a patient's trough level over time) is associated with poorer outcomes post-transplant. In previous studies IPV has been inconsistently calculated using CV or MAD. CV is calculated using the square value of differences from the mean whereas the MAD uses the absolute difference. We hypothesised that because of this difference in formula, the CV method would overestimate IPV when compared with MAD.

Methods: Patients transplanted in 5 UK centres between 2009-2014 and who were taking standard release Tacrolimus preparations were included in the study. IPV data was captured for each patient from 2 predetermined time points – 6-12months post-transplant and the most recent 12 months, with a minimum of four separate trough levels for each time point. MAD and CV were calculated for both time points and a rank correlation performed using Spearman's Rho Test.

Results: The results are shown in table 1: Although the values calculated for IPV are higher using CV when compared to MAD, there is a very high rank correlation observed in all centres between both tests.

Conclusions: We conclude either method is a valid measure of IPV. In practical terms CV is generally simpler to calculate, especially using an automated reporting system. However, CV would need to be used with caution where there are isolated high outlying values, such as a mistimed post-dose sample.

Comparison of CV versus MAD in 5 UK Renal Transplant Centres

Hospital	N= IPV Calculations (Participants)	Median (IQR) CV	Median (IQR) MAD	Spearman's Rank Order Correlation
Liverpool	342 (171)	20 (13.62, 28.45)	15.64 (11.11, 22.03)	Rs=0.9847 P <0.0001
Glasgow	334 (167)	17.96 (13.02, 26.31)	14.76 (10.89, 21.25)	Rs=0.9827 P <0.0001
Oxford	568 (284)	20.7 (14.01, 29.52)	15.6 (10.4, 23.15)	Rs=0.9839 P <0.0001
King's College (London)	264 (132)	20.22 (13.77, 29.97)	14.82 (10, 22.21)	Rs=0.964 P <0.0001
Manchester	624 (312)	20.47 (14.74, 30.41)	15.57 (11.11, 23.04)	Rs=0.983 P <0.0001

PUB726

Intrapatient Tacrolimus Level Variability Can Vary Significantly During Separate Time Periods, Depending on Transplant Centre: A Multicentre UK Retrospective Study Philip Nash. *King's College Hospital NHS Trust, London, United Kingdom. Group/Team: UK Tacrolimus Audit Collaborative.*

Background: Tacrolimus is the first choice primary immunosuppressant used after kidney transplantation in the UK. It has a narrow therapeutic range, and its successful use requires regular monitoring of serum trough levels. There is emerging evidence that low levels of intra-patient variability (IPV) in tacrolimus levels during the first year after kidney transplantation are associated with improved outcomes in the short term. Longer term data examining IPV and its association with outcomes is limited. It is also not known whether transplant recipients tend to maintain a consistent IPV over longer time periods or not.

Methods: Five UK Transplant Centres calculated IPV from trough tacrolimus levels during two separate time periods; months 6-12 after transplantation (T1) and the most recent 12 months of follow up (T2). Hospital databases were interrogated to provide demographic details and laboratory results for all recipients of kidney transplants between 1 January 2009 and 31 December 2014. Patients were excluded if they received duel-organ transplants, if they died or lost graft function within two years of transplantation, if their immunosuppression regimens were not based on tacrolimus or if they were given modified release tacrolimus preparations. Each centre examined the correlation of IPV during the two time periods and results between centres were compared. The means from each time period were compared using a paired t test.

Results: Data from 1063 eligible transplant recipients were included. Follow up periods ranged from two to five years. Results are summarised in table 1.

Conclusions: This unique national retrospective study demonstrates that at 3 centres there was no significant difference between the tacrolimus IPV during T1 and T2. However, recipients from Glasgow and Oxford had statistically significant differences in IPV during the two time periods. These results are inconsistent across centres, and this prompts further study. Relatively small sample sizes limit the power of the inidividual analyses. We propose to combine the data after gaining ethical approval, which we hope will expand upon these findings.

Adenovirus Nephritis in Kidney Transplant Recipients: Features of Clinical Presentation and Management Shalini Bumb, Varun K. Phadke, Carla L. Ellis. *Emory University, Atlanta, GA.*

Background: Adenoviruses (AdV) are double-stranded DNA viruses that are rare, but well recognized causes of morbidity and allograft dysfunction in transplant recipients. We have previously shown that adenovirus nephritis (AdN) can present with granulomatous or neutrophilic tubulointerstitial nephritis in kidney biopsies. There are many options to management, ranging from supportive therapy to the use of AdV-directed therapy. Here we report 7 cases of AdN in kidney transplant recipients and their associated clinical outcomes.

Methods: We performed a retrospective search to identify cases of AdN in renal transplant recipients from 2009-2016 at our institution.

Results: The diagnosis of AdN was confirmed by immunostaining of kidney transplant biopsies in 6/7 cases. The diagnosis of AdN was made serologically in the remaining case as the biopsy was not an adequate sample. The median time from transplant to the development of AdN was 50 days. All patients presented with complaints of dysuria, hematuria, and proteinuria. Additionally, 5 presented with fever, 5 with diarrhea, and 2 with respiratory symptoms. The peak serum creatinine increased by a median of 83% from baseline. Treatment in these cases varied from supportive care (2), ribavirin (3), ribavirin/IVIG (1), and brincidofovir (1). Of the 2 that did not receive AdV-directed therapy, 1 had resolution of the viremia after 42 days. Viremia clearance was not documented for the second, although the clinical course was benign. The 4 who received ribavirin cleared at a median of 78 days. The 1 who received brincidofovir cleared at 22 days. Proteinuria and hematuria improved or resolved in all patients. 3 of the 7 were treated for rejection. As such, the immunosuppression regimens were titrated and quite variable. 6 of the 7 cases were also noted to have CMV, BK, EBV, or parvovirus at the time of their management for AdN.

Conclusions: Our case series summarizes the clinical features and management of AdN. Treatment varies, but clinical resolution was noted in all cases and was most profound with brincidofovir. Despite the morbidity of AdN, if managed and monitored closely, resolution can be achieved with good outcomes in renal function in kidney transplant recipients. Additional study of cases of AdN without AdV-directed therapy are required before supportive therapy can be considered a universally viable option.

PUB728

JC Nephropathy in Renal Transplant Patients: Review of Two Cases Harleen Aujla,[4] Jose A. Morfin,[2] Ling-Xin Chen,[1] Kuang-Yu Jen.[3] *[1]None, West Sacramento, CA; [2]University of California Davis, El Dorado Hills, CA; [3]University of California, Davis, Sacramento, CA; [4]UC Davis, Sacramento, CA.*

Background: JC and BK viruses are polyomaviruses that commonly infect humans but become latent in immunocompetent individuals. In immunocompromised patients such as transplant recipients, polyomavirus can become reactivated and result in infection of the renal parenchyma with associated allograft dysfunction. Polyomavirus nephropathy (PVAN) is primarily associated with BK virus while JC nephropathy is a very rare complication in transplant patients. Here we report two transplant patients with evidence of JC nephropathy.

Methods: Review of transplant biopsy records from our institution from 07/2016-05/2017 showed three cases with biopsy-proven PVAN but without significant plasma BK viral loads. Subsequent plasma JC viral load was quantified and two of the cases exhibited substantial JC DNA levels.

Results: The two renal transplant patients were noted to have rises in serum creatinine from baseline several years post-transplant. Both underwent allograft biopsies, which revealed evidence of PVAN with positive SV40 immunohistochemical (IHC) staining in tubular epithelial cells. One case showed viral cytopathic changes including viral inclusions. The other case did not show definitive viral cytopathic changes. Moderate to severe chronicity and severe chronic vascular disease were noted in the biopsies as well. No evidence of rejection was identified. Serologically, neither patient had BK viremia but JC viral loads were found to be elevated. Subsequent JC virus in situ hybridization (ISH) on the biopsy material was positive. Each patient underwent reduction in immunosuppression regimen with decreased JC viral loads.

Conclusions: JC nephropathy may be missed both clinically and on biopsy if one is not aware of this entity. In some cases, no viral cytopathic changes are identified on biopsy although SV40 IHC may reveal allograft infection. Although BK nephropathy typically occurs early in the post-transplant period, our cases of JC nephropathy were detected late in the transplant course. JC virus screening should be considered in patients with PVAN and negative BK serologies.

	Time post-transplant	Immunosuppression	Plasma BK viral load	SV40 IHC	JCV ISH	Plasma JCV DNA
Case 1	6.0 years	Tacrolimus Myfortic Prednisone	<500 copies/mL	Positive	Positive	75,046 copies/mL
Case 2	6.5 years	Tacrolimus Mycophenolate	<500 copies/mL	Positive	Positive	48,387 copies/mL

PUB729

Belatacept Conversion and Improved eGFR in Transplant Recipients with Calcineurin Inhibitor Intolerance Harleen Aujla, Andrew I. Chin, Victoria Chung, Brian J. Gallay. *UC Davis Medical Center, Sacramento, CA.*

Background: Calcineurin inhibitors (CNIs) are the mainstay of immunosuppressive therapy after renal transplant, but nephrotoxicity has been thought to limit long term allograft survival. Belatacept, a chimeric CTLA4-IgG fusion protein which blocks T cell costimulation has been shown to afford superior composite patient and graft survival after transplant when used de novo after kidney transplant. We report our experience with 19 patients converted from CNI-based maintenance immunosuppression to belatacept for CNI intolerance.

Methods: Nineteen transplant patients from 2009 to 2016 underwent conversion from tacrolimus or cyclosporine to belatacept.

Results: The majority of patients (68%, n=13) were switched to belatacept due to biopsy-proven or suspected CNI renal toxicity. Excluding 3 patients with eGFR of >60 mL/min/1.73 m^2 before and after conversion, eGFR increased after the switch (30.9 ± 11.1 vs 36.1 ± 13.8, p=0.031) at a median of 43 months from initial transplantation.

Conclusions: In patients with CNI intolerance or renal toxicity, our series suggest an improvement in short and long-term eGFR for most patients converted to belatacept. This warrants a randomized trial comparing late conversion to belatacept to continued maintenance of CNI in recipients with evidence of chronic allograft injury.

Age/Sex	Initial Immunosuppression	Reason for switching	eGFR before switch mL/min	eGFR after switch (mL/min)

GFR and Biomarkers of CKD in Diabetic and Prediabetic Rhesus Monkeys Yinan Liang,[1] Zhenyan Yang,[1] Zunyuan Yang,[1] Bc Hansen,[2] Li Gong,[1] Wen Zeng.[1] *[1]Chengdu Primed Huaying Bio-tech Co., Ltd., Chengdu, China; [2]Dept Int Med, Univ of So Florida, Tampa, FL.*

Background: In view of the known similar renal physiology and fundamental mechanisms of diabetic kidney disease between humans and nonhuman primates, rhesus monkeys with chronic kidney disease (CKD) have been proven to provide an excellent large animal model to validate the efficacy of drugs targeting nephropathy. Research on biomarkers is providing improved experimental methods to assess early stage CKD status before the disease becomes irreversible.

Methods: Forty one adult male rhesus monkeys were studied for the purpose of examining the relationships between glomerular filtration rate (GFR determined by the Iohexol clearance with five-point plasma method) and plasma biomarkers that may detect early CKD. Creatinine (Cr), receptor for advanced glycation end products (RAGE), kallikrein B1 (KLKB1), vascular endothelial growth factor (VEGF), homocysteine (HCYS), Cystatin-C (CYSC), high sensitivity C reactive protein (hsCRP) were measured. Pearson's correlation was performed.

Results: GFR was significantly negatively correlated with Cr (r=-0.599, p<0.01), HCYS (r=-0.319, p<0.05) and CYSC (r=-0.478, p<0.01). Cr was moderately correlated with CYSC (r=0.312, p<0.05). RAGE, KLKB1 and VEGF were highly correlated between each pair (RAGE vs KLKB1, r=0.998, p<0.01; RAGE vs VEGF, r=0.995, p<0.01; and KLKB1 vs VEGF, r=0.996, p<0.01).

Conclusions: Cr and CYSC were broadly used in both the MDRD and CKD EPI equations to calculate the estimated GFR in patients. Cr, HCYS and CYSC were all significantly negatively related to GFR. These biomarkers will help to diagnose early stage CDK in monkeys.

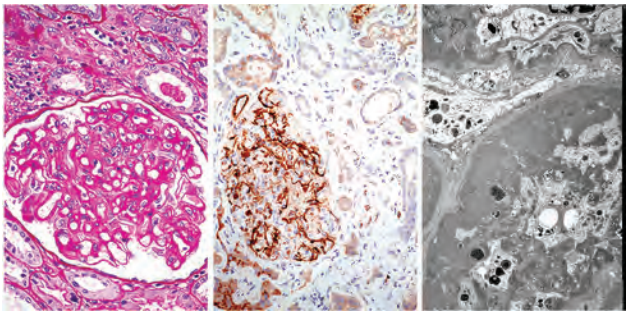
Coexisting Recurrent Lupus Nephritis and Chronic Antibody-Mediated Rejection in Renal Allograft: A Case Report Watcharapong Treesinchai, Bunyong Phakdeekitcharoen, Suchin Worawichawong, Punlop Wiwattanathum. *Ramathibodi Hospital, Mahidol university, Ratchatewi, Thailand.*

Background: Chronic antibody-mediated rejection (ABMR) is one of the common causes of late allograft dysfunction and play a major role in allograft loss. On the other hand recurrent lupus nephritis (RLN) is uncommon but it also causes allograft dysfunction and failure. There have been limited reports about these two distinct processes on the same allograft. Herein we reported a case that had two concurrent diseases on allograft.

Methods: A 32 year-old female with ERSD from lupus nephritis (LN) underwent a kidney transplantation from her mother in July 2010. Serum creatinine was 1.0 mg/dl at discharge. Five years after KT, she developed progressive increase proteinuria and serum creatinine to 2.7 mg/dL while having good compliance and tacrolimus level was in target range. The allograft biopsy revealed diffuse endocapillary proliferation, wire-loop lesion and focal basement membrane reduplication in glomeruli with focal tubulitis and peritubular capillaritis. The immunofluorescence (IF) showed full house pattern. Electron microscopy (EM) demonstrated electron dense deposits in subendothelium and mesangium with focal basement membrane reduplication. The immunoperoxidase staining for C4D was positive in glomeruli and peritubular capillaries. These findings were compatible with lupus nephritis class IV-G (A/C) combined with chronic antibody-mediated rejection. The blood tests showed positive for donor specific antibody Class I&II but negative for ANA and anti-DNA and complement within normal range. Therapies were offered with methyl prednisolone and plasmapheresis in keeping with raise level of tacrolimus and mycophenolate mofetil. Serum creatinine was stable of 2.2 mg/dl.

Results:

Conclusions: The additional tests including IF, EM and serologic markers may helping for diagnosis these overlapping histological finding.



PUB732

Impact of Prostate Cancer (PCa) on Waiting Time for Transplant and Mortality in ESRD Nagaraju Sarabu,[3] Nicholas K. Schiltz,[1] Donald E. Hricik.[2] *[1]Case Western Reserve University, Cleveland, OH; [2]University Hospitals Case Medical Center, Rocky River, OH; [3]Medicine, University Hospitals Cleveland, Cleveland, OH.*

Background: Prostate cancer is a very slow growing cancer with a low mortality. It is unclear if kidney transplant should be delayed after a diagnosis of prostate cancer and how it affects mortality post-transplant.

Methods: This study included incident cases of end-stage renal disease for males 40-79 years old from the 1999-2012 United States Renal Data System, linked with Medicare claims data. Our main study variable of interest was prostate cancer as indicated through an ICD-9-CM diagnosis code. Primary outcomes of interest were time to kidney transplant and mortality. We used propensity score matching control to for selection bias, and Cox proportional hazards models and Kaplan Meier curves to compare the risk between men with prostate cancer and those without.

Results: Figure 1 shows that the baseline characteristics are all well matched between prostate cancer group, and the control group except that the prostate cancer has slightly more patients in the older age groups. Prostate cancer was associated with a better survival compared to controls (HR:0.82; CI:0.78-0.86), and signifcantly chances of transplant (HR:0.61; CI:0.52-0.72). Kidney transplantation significantly reduced the mortality regardless of prostate cancer status, figure 2.

Conclusions: Kidney transplant improves survival in prostate cancer patients and should not be delayed.

Acute Brucellosis in Renal Transplant Patient Muddassar Mahboob,[4] Sana Hasan,[1] Ebadur Rahman,[4] Mohammed F. Akhtar,[5] Ashraf A. Attia,[3] Syed Rizwan A. Bokhari.[2] *[1]Prince Sultan Military Medical City, Riyadh, Saudi Arabia; [2]Tulane School of Medicine, New Orleans, LA; [3]kfsh&rc, Riyadh, Saudi Arabia; [4]Prince Sultan Military Medical City(PSMMC), Riyadh, Saudi Arabia; [5]Prince Sultan military Medical City, Riyadh, Saudi Arabia.*

Background: Brucellosis is common in developing countries and is usually transmitted by the consumption of unpasteurized milk or direct exposure with the infected animals. Very few cases have beed reported regarding the incidence of Brucellosis in the renal transplant patients. We are reporting a case of Brucellosis in the renal transplant patient presenting to Prince Sultan Militart Medical City, Riyadh.

Methods: We report a case of 61-year-old male, known case of living related kidney transplant 7 years ago with co-morbid conditions including Diabetes (DM), Hypertension (HTN) and Coronary Artery Disease (CAD). Presented to emergency department with constitutional symptoms of fever, burning micturation, dizziness and headache. Examination was positive for epigastric tenderness only. Labortary workup showed normal complete blood count, ESR 167, CRP 10, BUN 60 mg/dl and Creatinine 3.3 mg/dl, with no other electrolyte or liver function test abnormalities. Urinalysis, microscopy and culture were negative. Acute rejection panel was unremarkable. Infectious profile revealed Blood culture positive for gram-negative Coccobacillus with negative viral studies. Renal Doppler ultrasound was unremarkable. Patient recieved empirical antibiotics in addition to his routine immunosuppression, while mycophenolate mofetil (MMF) was held for three days. Further work up showed positive Brucellosis titre 1:10240, which was negative before kidney transplant. Patient was treated with doxycycline and ciprofloxacin with marked clinical improvement and biochemistry returned to normal in a week.

Results:

Conclusions: Brucellosis is a rare zoonotic disease in renal transplant recpients especially in endemic areas however timely diagnosis and appropriate treatment results in complete recovery.

Results of a Pediatric Kidney Transplantation Cohort in Brazil Maria Goretti M. Penido,[2,3] Karina C. Zocrato,[2] Andre S. Alvarenga,[1] Carolina M. Leite,[1] João vitor S. Cortez,[2] Mariana G. Paula,[2] Marcelo S. Tavares.[2] *[1]Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [2]Pediatric Nephrology Unit, Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [3]Pediatric Nephrology Unit, Federal University of Minas Gerais, Belo Horizonte, Brazil.*

Background: Pediatric kidney transplantation (TxPed) is the renal replacement therapy (RRT) of choice in pediatrics. The aim of this study was to outline the results of the pediatric kidney transplantation in a single center in Brazil.

Methods: Analysis of a retrospective cohort of 48 TxPed conducted between 2011 and 2017.

Results: There were 47 TxPed with deceased donors and 1 with living donor, and their main results are shown in table 1. There was signficant increase of the mean z score for height with 1 month of Tx (Z = -3,3) and after 12 months of Tx (Z = -2,3) (Figure 1). Graft survival was 82.5% at 30 months. There was no difference between the patients with and without graft failure regarded age, sex of the recipient, type of RRT before trasnplantation, type of induction, delayed graft function, KDPI or preemptive TxPed. AUROC of KDPI for graft lost was 0,54. Interestingly, linear regression analysis showed an inverse correlation between KDPI and 3 months eGFR(p=0,037).

Conclusions: The graft survival rate of pediatric TxPed at the analyzed center is similar to other centers. KDPI was not a valuable index to predict graft loss in children. There was significant improvement in stature with 1 year of TxPed.

PUB735

BK Virus in Renal Transplantation Patients Using Alemtuzumab for Induction Immunosuppression Katie L. Korneffel, Bradley B. Gehring. *University of Toledo College of Medicine, Toledo, OH.*

Background: Alemtuzumab (Ale) is a monoclonal antibody that targets CD52+ lymphocytes, causing profound B- and T-cell depletion. The use of potent immunosuppressive agents poses an increased threat of BK virus infection in organ transplants. We sought to determine the impact of Ale immunodepletion, with steroid freedom for low risk patients, on the incidence of BK virus viremia and associated patient outcomes.

Methods: An IRB-approved retrospective analysis was performed on 676 patients at the University of Toledo Medical Center who underwent renal transplantation between 3/06 and 11/15. All patients were induced with Ale. BK Viremia was defined as clinically significant BK infection confirmed by PCR.

Results: Median patient age was greater for BK (53.3 years vs 60.5 years, p=0.041). Median patient BMI was not significant (28.2 without BK and 27.7 with BK, p=0.743). A greater percent of elderly patients (defined as >65 years) had BK (8.2% vs 3.8%; p=0.035). No other demographic factors were significant for BK. BK was associated with increased 1 year rejection (21.2% vs. 34.5%; p=0.049). However, clinically positive BK was not significantly associated with overall increased rejection, although it was close (OR 2.01, 95% CI 0.96-4.19, p=0.064). There was no association of BK with death-censored graft survival (DCGS) or patient survival. (Table 2)

Conclusions: The median age of patients with BK was greater than patients without BK. A greater percent of elderly patients than non-elderly patients had BK. Overall, clinically positive BK was not associated with increased rejection. BK was not associated with increased DCGS or patient survival.

Incidence of Rejection, DCGS, and Patient Survival in BK and No BK Patients

	BK Viremia (n, % of total)	Control (n, % of total)	Significance
Rejected (total)	13 (41.9%)	169 (26.2%)	0.063
90 day rejection	6 (19.4%)	94 (14.6%)	0.44
1 year rejection	10 (34.5%)	130 (21.1%)	0.049
3 year rejection	13 (47.2%)	154 (25.9%)	0.104
5 year rejection	13 (47.2%)	165 (29%)	0.143
1 year DCGS	27 (100%)	499 (93.9%)	0.39
3 year DCGS	14 (91.8%)	342 (87.8%)	0.381
5 year DCGS	8 (78.2%)	253 (83.5%)	0.671
1 year patient survival	27 (100%)	584 (95.6%)	0.622

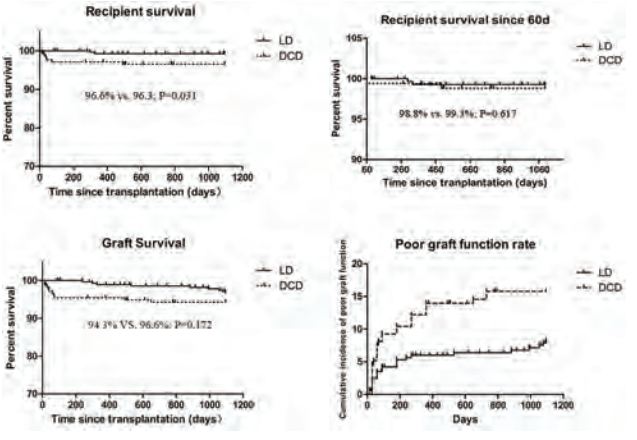
Comparison of 3-Year Graft Outcome between Donation after Cardiac Death (DCD) and Living Donor Kidney Transplantation Xing Zhang,[2] Jianyong Wu.[1] *[1]The First Affiliated hospital of Zhejiang University School of Medicine, Hangzhou, China; [2]Kidney disease center, The First Affiliated hospital of Zhejiang University School of Medicine, Hangzhou, China.*

Background: DCD and living donor kidney transplantation become main kidney transplant forms in China at present. There is few study special focusing on comparison of graft outcome between DCD and living donor kidney transplantation.

Methods: We retrospectively compared graft outcome between 176 DCD and 284 living donor kidney transplant recipients. 3-year graft survival, death-censored graft survival, recipient survival and graft function were compared. The relationship of DCD kidney transplantation with poor kidney function defined as the composite of death censored graft failure or two consecutive eGFRs less than 45 mL/min/1.73m2 occurring within 3 years was evaluated.

Results: Delayed graft function (DGF) was more common in DCD kidney transplantation (14.20% vs. 0.35%; P<0.001). 3-year graft survival (94.3% vs. 96.6%; P=0.172) and death-censored graft survival (97.1% vs. 97.3%; P=0.757) were similar between DCD and living donor kidney transplantation. The recipient survival was similar between two groups once DCD kidney transplantation recipients survived over 2 months (98.8% vs. 99.3%; P=0.617). The graft function assessed by eGFR at 3 years after transplantation for DCD kidney transplantation was better than living donor kidney transplantation (mean, 71.08 vs. 62.72 ml/min/1.73m2; P<0.001). DCD kidney transplantation was an independent risk factor of poor kidney function in multiple-variables analysis of Cox proportional hazards regression models, although it had similar 3-year graft survival and superior 3-year gaft function compared with living donor kidney transplantation.

Conclusions: In spite of higher DGF rate, 3-year kidney survival of DCD is comparable with that of living kidney transplantations. And 3-year graft function for DCD is superior to living donor kiney transplantation. DCD kidney transplantation remained to be an independent risk factor of poor kidney function.



Comparison of outcome between DCD and living donor kidney ransplantation

PUB737

Page Kidney after Kidney Transplant Biopsy: A Case Series Camilo Cortesi, Mai Sedki, Giselle Guerra, Adela D. Mattiazzi. *University of Miami/Jackson Memorial Hospital, Miami, FL.*

Background: Page Kidney (PK) is a rare but serious complication that is seen in kidney transplant (KT) recipients after renal allograft biopsy. PK results from a large perinephric collection compressing the allograft parenchyma, characterized by a triad of hypertension (HTN), perinephric collection, and creatinine (Cr) elevation. This condition has been poorly described in KT recipients with a few cases reported in the literature. This is a case series of 3 patients that developed PK after KT biopsy (KTb). We provide a full demographic description of each patient in Table1.

Methods: Case 1: 66-year-old (yo) woman with deceased donor kidney transplant (DDKT) due to ESRD from HTN and diabetes mellitus (DM) was admitted with elevated Cr. Ultrasound (US)-guided KTb was done, the next day she developed HTN up to 205/95 mmHg, lower abdominal pain and anuria. US of the KT revealed a large hematoma measuring 7x4cm. Patient was taken to the OR for exploratory surgery with drainage of 500mL of blood. After the procedure, Cr was 6.08mg/dL resolving 2 weeks later at 1.6mg/dL. Case 2: 45 yo man with DDKT due to ESRD from FSGS underwent US-KTb given high donor specific antibodies. Three days after biopsy he presented with diffuse abdominal pain, HTN up to 192/83 mmHg, and Cr elevation from 2.54 to 11.41mg/dL. CT scan showed a subcapsular hematoma of the KT measuring 6.7x2.5x10.1cm and 17.5x10.9x16.4cm retroperitoneal collection. Patient underwent exploratory surgery with removal of 3L; one month later Cr was 3.4mg/dL. Case 3: 56 yo man with DDKT due to ESRD from HTN and DM had an elevated Cr, he underwent US-KTb to rule out allograft rejection. Immediately after, he had pain at the site of KT and HTN up to 202/82 mmHg. Subsequently patient became anuric and Cr rose from 2.1 to 13.2mg/dL. CT scan unveiled

a perinephric hematoma measuring 8.7x4.5x10.9cm which was then percutaneously drained. Patient required dialysis indefinitely after this event.

Results:

Conclusions: PK diagnosis relies mainly on clinical suspicion and the use of appropriate imaging. Once PK is diagnosed, aggressive management is often necessary to ensure optimal viability of the allograft. This highlights the importance of identifying risk factors associated with this complication. Large cohort studies are needed to adequately assess the risk.

Characterization of H2-Blocker and Proton Pump Inhibitor Prescribing Practices in Maintenance Care of Kidney Transplant Recipients Vicki K. Sandys, Amy Hudson, Catherine M. Brown, Sean F. Leavey. *Nephrology, University Hospital Waterford, Waterford, Ireland.*

Background: Antacids, either histamine type 2 receptor-blockers (H2Bs) or proton pump inhibitors (PPIs) are routinely prescribed post-transplant. Interactions with immunosuppressants occur in the case of PPIs, through the inhibition of cytochrome P-450 and alteration of the gastric milieu. Of concern, evidence linking PPIs to acute interstitial nephritis now shows an association with progressive chronic kidney disease.

Methods: Active prescriptions for patients attending transplant clinic at UHW on Jan 15 th 2017, were extracted from the electronic health record (EMedrenal), with demographic, clinical and laboratory covariates. A variable describing the sum of all non-immunosuppressive medications per patient (excluding antacids)was created as an indicator for polypharmacy. Descriptive and both univariate and multivariate inferential analysis was undertaken using SPSS (version 23).

Results: 1540 prescriptions identified in 168 patients. 75% of patients were on antacids (41.7% (70) on H2B; 33.3% (56) on PPI). Significant positive associations with any antacid use ($p<0.05$) were found in univariate analysis for older age, male gender, immunosuppressant type, anticoagulant, statin and polypharmacy. Lower eGFR indicated preference for PPI over H2B ($p<0.05$). In multivariate modelling, the prescription of prednisone, MMF and each additional non-immunosuppressant independently increased the Odds of antacid prescribing by 4.7, 3.8 and 1.4 fold.

Conclusions: There is a high prevalence of antacid use. Polypharmacy and immunosuppressant use independently influence prescribing. The use of PPIs long-term, post-transplant may have clinical implications for graft survival. The factors influencing the indication for and choice of antacid post-transplant merits further study.

Association between Vascular Access Type in Hemodialysis Patients and Subsequent Kidney Transplant Outcomes Medha Airy,[1] Colin R. Lenihan,[3] Monnie Wasse,[2] Wolfgang C. Winkelmayer.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Rush University Medical Center, Chicago, IL; [3]Stanford University School of Medicine, Palo Alto, CA.*

Background: Type of vascular access is associated with outcomes in patients with end-stage kidney disease undergoing hemodialysis. Whether associations exist with outcomes after kidney transplant is unknown. Potential mechanisms towards worse outcomes include patency of residual peripheral accesses potentially contributing to heart failure as well as retained vascular grafts that may cause chronic inflammation.

Methods: A retrospective cohort study of hemodialysis patients receiving a first kidney transplant was done using merged data from the US Renal Data System and a large dialysis organization. We ascertained the access used for the last hemodialysis prior to transplantation: arteriovenous fistula (AVF); arteriovenous graft (AVG); central venous catheter (CVC). Patients were followed from kidney transplant for all-cause mortality, kidney allograft loss from any cause, and allograft loss not from death.

Results: Among 9291 patients who underwent kidney transplantation between 2006-2011, 65.3% had an AVF and 20.4% had an AVG and 14.3% used a CVC. Cox proportional hazards regression models adjusted for demographic, comorbidity, and transplant characteristics, as well as laboratory parameters indicated no associations between vascular access type and all-cause mortality or all-cause allograft loss (Table). Central venous catheter use was associated with a 30% higher risk of allograft loss from causes other than death compared to use of an arteriovenous fistula (HR=1.30; 95% CI, 1.06-1.57).

Conclusions: No clear associations between vascular access use for dialysis and subsequent transplant outcomes were identified. The association of central venous catheter use with allograft loss from all causes other than death lacks a plausible explanation and requires confirmation.

*Adjusted HR (95% CI)	AVG vs AVF	CVC vs AVF
All-cause mortality	1.13 (0.97, 1.33)	1.00 (0.83, 1.21)
Allograft loss	1.13 (1.00, 1.28)	1.12 (0.96, 1.29)
Allograft loss from cause other than death	1.17 (0.98, 1.39)	1.30 (1.06, 1.57)

*Adjusted for demographic variables, comorbidities, transplant characteristics, and laboratory parameters

Twelve-Year Experience in ABO Incompatible Kidney Transplantation: Differences in Infection Rate and Short-Term Outcomes between Hemodialysis and Peritoneal Dialysis Patients Georgios Spanos,[1] Christina Melexopoulou,[1] Chrysanthi Skalioti,[1] Smaragdi Marinaki,[1] John Bokos,[2] Georgios Zavos,[2] John N. Boletis.[1] *[1]Nephrology Department & Renal Transplantation Unit, Laiko General Hospital, National & Kapodistrian University of Athens, Medical School, Athens, Greece; [2]Renal Transplantation Unit, Laiko General Hospital, National & Kapodistrian University of Athens, Medical School, Athens, Greece.*

Background: The use of intensfied desensitization protocols in ABO-incompatible kidney transplantation (ABOi KTx) seems to increase postoperative infection rates. Currently, no clear consensus has emerged regarding whether the peritoneal dialysis (PD) catheter should be removed at the time of transplant surgery or not, in the event dialysis is required in the immediate post-transplant period. The purpose of this study was to audit infectious complications and outcomes in ABOi KTx in PD patients and compare them with heamodialysis (HD) patients.

Methods: A single centre prospective cohort of ABOi KTx patients from June 2005 till May 2017 with a desensitization protocol including the use of rituximab 30 days pre-KTx, immunoadsorptions, intravenous immunoglobulin and double oral immunosuppression administered 15 days pre-KTx was followed up for one year post KTx.

Results: The cohort included 42 patients (14% PD patients, 76% HD patients and two preemptive) with a mean age of 37.4 ± 10.8 years, 26% female. No significant difference was observed in baseline characteristics between two groups. One episode of peritonitis during desensitization period was successfully treated causing rescheduling the KTx date, while one episode of central venous catheter related septicemia was observed during follow up. The incidence of post-KTx bacterial infections leading to hospitalization, viral infections (cytomegalovirus and polyoma virus) and surgical complications were similar between the two groups. There was no significant difference in serum creatinine at the end of follow up (1.73±0.5 vs 1.51±0.35, p=ns), and patient and graft survival was 100% vs 100% and 100% vs 97.6% in the PD vs HD group, respectively (p=ns). Furthermore, the rate of biopsy-proven acute rejection was comparable. Two patients in the PD group and 3 in the HD group had acute cellular rejection, treated successfully. Only one HD patient developed acute antibody-mediated rejection and graft loss in the immediate post KTx period.

Conclusions: Peritoneal dialysis and hemodialysis patients undergoing ABO incompatible kidney transplantation have comparable infectious complication rate and short term outcomes.

PUB741

Kidney Autotransplantation as an Effective Alternative to Percutaneous Transluminal Renal Angioplasty for Renal Artery Stenosis: A Case Report Hirofumi Sumi, Atsuko Uehara, Tsutomu Sakurada, Yugo Shibagaki. *St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: Acute kidney injury (AKI) caused by renal artery stenosis is common. The most common treatment is percutaneous transluminal renal angioplasty (PTRA); however, this procedure is technically difficult in some cases. In these cases, the indications and effectiveness of kidney autotransplantation (AutoTx) remain unclear. We describe the case of a patient with renal artery in-stent restenosis successfully treated with kidney AutoTx.

Methods: The patient was a 76-year-old woman with a right solitary kidney attributable to left renal thromboembolism. Two years prior to admission, she underwent an endovascular aortic aneurysm repair with a stent graft for infrarenal aortic aneurysm, which led to ostial occlusion of the right renal artery. She underwent PTRA and stenting. Two days prior to admission, she developed leg edema and hypertension, and thus visited the hospital. Her serum creatinine level was 2.4 mg/dL (baseline, 1.0 mg/dL). AKI due to renal artery in-stent restenosis was suspected, and re-angioplasty was attempted on hospital day 2 but was unsuccessful because of technical failure. Her renal function did

not improve, and anuria persisted, so hemodialysis was initiated on the same day. The size of the right kidney was preserved (8.6 cm) relative to her body size, with only mild cortical atrophy and Doppler ultrasonography and mercaptoacetylgriglycine scan showing a minimal but significant perfusion of the right kidney. Thus, we considered that the kidney perfusion was not arrested and that renal function could be reversed. On hospital day 25, we proceeded with right kidney AutoTx to the right iliac fossa to reestablish an adequate renal perfusion and reverse the need for dialysis. Soon after the procedure, the patient started passing urine. Her renal function improved and serum creatinine level decreased to 1.0 mg/dL on hospital day 33. Hemodialysis was discontinued after the surgery.

Results:

Conclusions: Our findings indicate that kidney AutoTx can be a treatment option for patients with renal artery stenosis who have undergone an unsuccessful PTRA.

Acute Tacrolimus Toxicity Successfully Treated with Phenytoin Tasleem Katchi,[2] Kavneet Kaur,[1] Savneek S. Chugh,[1] Sanjeev Gupta,[3] Muhammad R. Mustafa.[2] *[1]New York Medical College, White Plains, NY; [2]Westchester Medical Center, White Plains, NY; [3]Westchester county medical center, White Plains, NY.*

Background: Tacrolimus is an integral part of immunosuppression following solid organ transplantation. We present a case of acute tacrolimus toxicity in a renal transplant recipient successfully treated with phenytoin.

Methods: A 55-year old male with history of end-stage renal disease due to tuberous sclerosis and polycystic kidney disease who had undergone a living related renal transplant 17 years ago was transferred to our facility for evaluation of acute kidney injury (AKI). The patient was admitted to a psychiatric facility for suicidal ideations and had recently been initiated on multiple psychotropic drugs including haloperidol, quetiapine, benztropine, hydroxyzine, citalopram and fluoxetine. Anti-psychotic therapy was held due to AKI. Upon arrival, the patient had progressive worsening of generalized body tremors. Vitals signs were normal and physical examination was unremarkable. Laboratory results revealed a serum chloride concentration of 113 mEq/L, bicarbonate 11 mEq/L, blood urea nitrogen 98 mg/dl, creatinine 3.42 mg/dl (increased from baseline of 1.7 mg/dl). Serum trough tacrolimus level was >30 ng/ml. Within a few hours, the patient had worsening mental status and was intubated for airway protection. Tacrolimus was held and he was started on phenytoin 100 mg every 8 hours. On hospital day 3, tacrolimus levels dropped to 7.5 ng/ml and creatinine was 1.7 mg/dl. The patient became more alert, his tremors resolved and he tolerated extubation. Phenytoin was stopped and tacrolimus was restarted at a dose of 2 mg twice daily.

Results:

Conclusions: Calcineurin inhibitors form the backbone of immunosuppression in solid organ transplant recipients. Tacrolimus is metabolized by the Cytochrome P450 (CYP) 3A4 enzyme and levels ranging from 5-15 ng/ml are recommended post-transplant. Clinical features of tacrolimus toxicity can vary from complete absence of symptoms to renal failure and neurotoxicity. Our patient developed tacrolimus toxicity likely due to drug interactions with multiple psychotropic drugs given without checking tacrolimus levels. This in turn led to the AKI and worsening body tremors. Very few cases of tacrolimus toxicity treated with phenytoin have been reported in the literature. Phenytoin is an inducer of the CYP system. It increases the metabolism of tacrolimus, and can be considered in cases where rapid decrease in tacrolimus levels is desired.

PUB743

Hyperammonemia after Lung Transplant, an Often Fatal Complication Pace Romney,[2] Laith Al-Rabadi,[3] Nirupama Ramkumar,[1] Josephine Abraham.[1] *[1]University of Utah, Holladay, UT; [2]University of Utah Medical Center, Salt Lake City, UT; [3]University of Utah hospital, Salt Lake, UT.*

Background: Hyperammonemia after lung transplantation is a rare complication which is frequently fatal. The etiology is unclear and early recognition is important for survival.

Methods: A 69 year old man with a history of alpha-1 antitrypsin deficiency underwent lung transplantant with an initial uneventful post operative course and discharge on day 14. He was induced with basiliximab and maintained on mycophenolate, tacrolimus, corticosteroids, with routine antimicrobial prophylaxis. Day 17 he complained of fatigue, lightheadedness, and decreased mental acuity. Day 23 he had hyponatremia but improved mentation and energy. However day 31 he was unable to ambulate, was admitted to the hospital, and was found to have continued hyponatremia and an ammonia level of 200. Due to worsening encephalopathy, he was intubated shortly after admission. Management for hyperammonemia included broad-spectrum antibiotics, hemodialysis, bowel decontamination, amino acid supplementation, and nitrogen scavengers. Tacrolimus and mycophenolate were stopped. Ammonia levels and mentation improved and he was extubated, but despite this improvement and ongoing therapy, hyperammonemia recurred. He was reintubated due to worsening hypoxia and initiated on pressors for hypotension. Despite aggressive hemodialysis, ammonia levels continued to increase. Palliative consult followed due to the patient's continued decline and care was withdrawn. Consent for autopsy was obtained and a lung sample was notably positive for Ureaplasma parvum.

Results:

Conclusions: Hyperammonemia is a rare occurrence after lung transplant affecting 1-4% of these patients and the etiology is unknown. Proposed mechanisms include unmasking of partial urea cycle disorders, immunosuppressive agents, and infection with urea-splitting organisms such as Ureaplasma or Mycoplasma. Goals of treatment include minimization of ammoniagenesis and increased nitrogen removal. Strategies to reduce ammonia production include protein restriction, bowel decontamination and amino acid supplementation. Nitrogen removal is achieved through hemodialysis and use of nitrogen scavengers such as sodium benzoate and sodium phenylacetate. Empiric treatment for urea-splitting organisms with a fluoroquinolone and macrolide is recommended. Despite therapy, mortality is high and a high index of suspicion is required for early diagnosis and prompt initiation of therapy.

PUB744

Monoclonal IgG4/2-Kappa Deposition Following Eculizumab Therapy for Recurrent Atypical Hemolytic Uremic Syndrome (aHUS) in Kidney Transplantation Priyamvada Singh,[5] Hui Chen,[1] Craig E. Gordon,[7] John M. Sloan,[2] Karen Quillen,[4] Vipul C. Chitalia,[6] Amitabh Gautam,[3] Joel M. Henderson,[4] Jean M. Francis.[4] *[1]BMC, Boston, MA; [2]Boston MEdical Center, Boston, MA; [3]Boston Medical Center, Boston, MA; [4]Boston University Medical Center, Boston, MA; [5]Renal, Boston University Medical Center, Boston, MA; [6]Boston University School of Medicine, Boston, MA; [7]None, Natick, MA.*

Background: Eculizumab is emerging as a promising therapy for aHUS. We present a patient with rapid resolution of recurrent aHUS after kidney transplantation following eculizumab therapy but with evidence of monoclonal IgG4/2-kappa deposition on repeat kidney biopsy

Methods: A 22-year-old male with CKD stage 5 of unknown etiology underwent preemptive living related kidney transplantation from his sister. His post-operative course was complicated by thrombocytopenia on day 3 after transplant (nadir platelet count: 36k/ul) and delayed graft function. Testing revealed elevated LDH (673 U/L, normal 171-308), low haptoglobin (<7 mg/dL, normal 44-184), and schistocytosis on peripheral blood smear. Eculizumab was initiated for possible recurrent aHUS on day 3 post-transplant. Kidney biopsy performed on day 5 post-transplant following a recovery of thrombocytopenia confirmed the diagnosis of acute thrombotic microangiopathy (TMA). Hematological parameters improved rapidly following treatment but the renal function did not improve as expected. A repeat kidney biopsy performed after 5 doses of eculizumab demonstrated complete resolution of TMA features on a background of essentially normal renal parenchyma. Interestingly, immunofluorescence microscopy revealed monoclonal staining for IgG4/2-kappa in glomeruli, vasculature, and focally in tubular basement membranes. The deposits suggest eculizumab deposition because eculizumab is a hybrid monoclonal immunoglobulin comprised of IgG4/2-kappa chains. IgG4/2-kappa deposits are rare pathological findings seen following eculizumab therapy.

Results:

Conclusions: Early identification and treatment of recurrent TMA after transplantation require a high clinical suspicion but result in improved graft function and patient outcome. IgG4/2-kappa deposits are a rare pathological finding following effective eculizumab therapy but the long-term effects of these deposits on renal function remain unknown.

PUB745

Cytomegalovirus Infection and Hemophagocytic Lymphohistiocytosis in a Renal Transplant Recipient Brittany L. Schreiber, Muhammad A. Mujtaba. *University of Texas Medical Branch, Galveston, TX.*

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, life-threatening hyper-inflammatory syndrome characterized by hypercytokinemia, histiocytic proliferation and hematophagocytosis. Renal transplant recipients (RTRs) are at increased risk of developing HLH due to chronic immunosuppression and high prevalence of opportunistic infections including cytomegalovirus (CMV). We present a unique case of HLH due to CMV infection in a renal transplant recipient.

Methods: A 75-year-old female with a history of polycystic kidney disease status post renal transplantation 12 years prior to presentation, maintained on tacrolimus, mycophenolate mofetil, and prednisone presented with watery diarrhea and generalized weakness. Initial work-up revealed thrombocytopenia, acute kidney injury and tacrolimus toxicity with a serum level of 29 ng/mL. Tacrolimus was held and levels returned to therapeutic range after administration of rifampin. After 7 days of hospitalization, the patient became lethargic, febrile and hypotensive. Mycophenolate was held, empiric antibiotics were started, and the patient was resuscitated with intravenous fluids. Laboratory work-up at that time showed worsening pancytopenia, rising transaminases, elevated ferritin and coagulopathy with hypofibrinogenemia. Despite multiple blood product transfusions the pancytopenia persisted and hematology was consulted and a bone marrow biopsy was performed revealing hemophagocytosis, dyserythropoiesis and dysgranulopoiesis. CMV polymerase chain reaction returned showing over 33 million viral copies/mL. The patient was diagnosed with HLH secondary to disseminated CMV infection and was started on intravenous ganciclovir with resolution of viremia and improvement in clinical condition.

Results:

Conclusions: RTRs are at high risk for CMV infection, a known precipitant of HLH. These patients are most susceptible during periods of intense immunosuppression, particularly in the early post-transplantation period. Unlike HLH in non-transplant patients, etoposide is not a mainstay of therapy and treatment remains controversial with little consensus on the role of immunosuppression. Intensive supportive care and organism-directed antimicrobials are essential in patient survival. Prognosis remains poor despite therapy making early diagnosis and prompt initiation of directed therapy crucial in this population.

PUB746

Is There an Association between Frailty and Relative Telomere Length in Pre-Renal Transplant Recipients? Vasantha M. Muthuppalaniappan,[2] Kieran Mccafferty,[1] Muhammad M. Yaqoob.[2] *[1]NHS, LONDON, United Kingdom; [2]William Harvey Research Institute, London, United Kingdom.*

Background: Both telomere length (TL) and frailty is associated with aging. Frailty is emerging as an important risk factor for adverse renal transplant (RT) outcomes and increasingly recognized as potential tools in risk stratifying RT candidates. Strong associations between frailty and relative TL (rTL) have been reported but sparse data is found in renal transplantation. The aim of the study was to assess the association of frailty in RT recipients with rTL and outcome in this cohort.

Methods: This was a single centre prospective study from October 2016 - April 2017. Frailty was measured as defined and validated by Fried based on 5 components at admission for RT. Non-frail was defined as a score of 0 or 1; intermediate frailty as a score of 2 and frail if the score was ≥3. TL was measured from peripheral white blood cell pre-transplant using quantitative PCR (T/S ratio) using a modified Cawthon protocol. Data on co-morbidities, complications, and length of stay in hospital and readmissions were recorded.

Results: 33 recipients (14 male, 19 female) were recruited prior to RT. Ages ranged from 26-77 year with a median age of 47.97 ± 12.84. Cadaveric transplantation was performed in 66.7% of patients and 33.3% had living donor transplant. 66.7% of patients were non-frail (68.2% cadaveric, 63.6% living donor); 24.2% were intermediately frail (18.2% cadaveric, 36.4% living donor) and 9.1% were frail (13.6% cadaveric) at the time of RT. There was no correlation between age and length of stay (R^2= 0.03). A higher Charlson co-morbidity index was strongly associated with longer length of stay post RT (p=0.001). Length of stay post RT was increased with shorter rTL but this was subsequently found not to be significant (p=0.392). There was no significant association with raised frailty scores and increased hospital admissions (p= 0.35). There was no association between frailty score and rTL was found in this study. Dialysis vintage was inversely proportional to RTL (p=0.046). rTL was also significantly shorter in RT recipients on haemodialysis in comparison to peritoneal dialysis (p< 0.001).

Conclusions: Despite literature suggesting a correlation between frailty and shorter rTL, our study failed to replicate these findings. There was no significant association between frailty index and rTL, however a small sample size may be the limiting factor.

PUB747

Clinical Features, Treatment, and Outcomes of Kidney Transplant-Associated Thrombotic Microangiopathy: A Single-Center Experience Kohei Unagami,[2] Masayoshi Okumi,[2] Hideki Ishida,[1] Kosaku Nitta,[2] Kazunari Tanabe.[2] *[1]Tokyo Women's Meedical University, Tokyo, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan.*

Background: Thrombotic microangiopathy (TMA) is a dangerous disorder characterized by fragmented red blood cells, decreased platelet count, and organ failure due to thrombosis. In recent years, atypical HUS has been reported to present such a state. Furthermore, TMA was also considered to present the same state, so strict differentiation between the two conditions is difficult. Kidney transplant-associated TMA (TA-TMA) presents a severe state; thus, rapid differential diagnosis is required.

Methods: We conducted a retrospective study of kidney transplantations performed between January 1999 and December 2015 at our institution, and investigated and evaluated diagnoses, treatment, and graft survival.

Results: 1,109 renal transplantations were performed, and 24 recipients were diagnosed as having TA-TMA (Table1). The prevalence of ABO incompatible cases with TA-TMA was higher than that of ABO compatible cases (odds ratio, 2.39; p = 0.03). We confirmed pathological findings of TMA in 23 cases, including rejection in 11 cases. Using our proposed TA-TMA diagnostic scoring system (Table2), 23 cases were diagnosed as TMA (95.8%). By contrast, the positivity rate without TMA was 0%. As treatments, plasma exchange therapies were performed in almost all the cases. In 3 cases, eculizumab infusion was given. We confirmed the disappearance of TMA in 13 (54.2%) of the 24 cases via biopsy examination. Except 2 cases, all cases showed good graft survival, with a creatinine level of 1.87 ± 0.81 mg/dL.

Conclusions: Prompt diagnosis and treatment based on diagnostic criteria may lead to good treatment results.

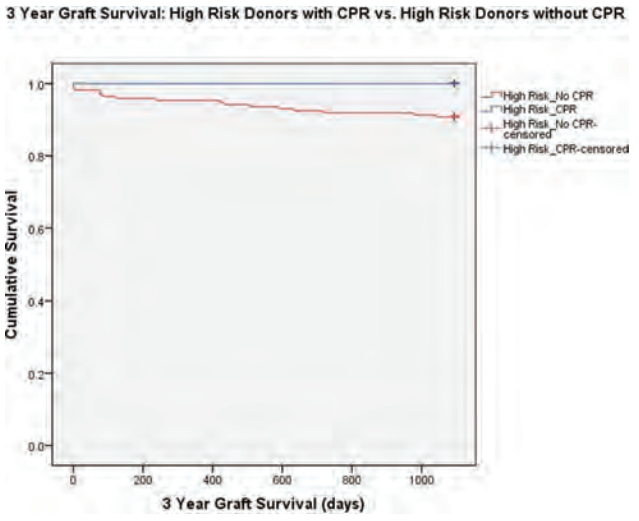
CPR in High-Risk DCD and ECD Donors for Kidney Transplantation Jacentha L. Buggs,[1] Victor Bowers.[2] *[1]Transplant Surgery, Tampa General Medical Group, Tampa, FL; [2]Transplant Surgery, Tampa General Medical Group, Tampa, FL.*

Background: The demand for organs for kidney transplantation compels the use of high risk (HR), donation after circulatory death (DCD) and extended criteria donors (ECD) in addition to standard criteria and living donors to expand the donor pool. Most studies suggest DCD and ECD kidney transplants (KTX) may be associated with inferior graft survival. Many cadaveric donors receive CPR as a lifesaving method to return the patient to baseline function but the literature does not address the consideration of donor CPR as an additional tangible benefit to graft survival when selecting donors for KTX. We hypothesize that donor CPR correlates with improved graft survival with HR DCD and ECD KTX thus providing additional information when evaluating a potential donor.

Methods: We retrospectively analyzed consecutive cadaveric KTX recipients and their donor data from January 1, 2008 to December 31, 2013.

Results: A total of 646 cadaveric donors (498 SCD, 55 DCD, and 93 ECD) facilitated 910 cadaveric KTX. Within the 148 HR donors, 31 received CPR and 117 did not. There were 223 cadaveric KTX performed at our center from HR donors. The mean age of HR donors was 45 yrs. with CPR and 53 yrs. without CPR (p-value 0.010). There was no difference in HR donor gender, race, and BMI with or without CPR. The KTX recipients of HR donors revealed no significant difference in BMI, LOS, discharge Cr, CIT or DGF with and without CPR although the LOS and discharge Cr were lower, and the CIT was greater with CPR vs. without CPR. Graft survival at 3 years was significant with 0 failures out of 50 KTX from HR donors with CPR vs. 16 graft failures out of 173 KTX from HR donors without CPR (p-value 0.026).

Conclusions: Our study is limited as a single center retrospective study, however the result of significant 3 year graft survival in high-risk donors who received CPR suggests donor CPR should be considered when assessing organs for transplantation.



PUB749

Acute Antibody Mediated Rejection Associated With the Use of the New Anti-HCV Medications – A Case Report Khaled Karkout,[1] Saleema Sharief,[2] Qutaiba Hussain,[1] Yousef Boobes.[1] *[1]Tawam hospital, Al Ain, United Arab Emirates; [2]Tawam Hospital, Al Ain, United Arab Emirates.*

Background: Hepatitis C virus (HCV) infection is prevalent in renal allograft recipient and associated with increased morbidity and mortality. The new direct acting antiviral agents (DAAs) are highly effective in clearing the virus and considered safe for use in kidney transplant patients, no acute graft rejection has been reported so far after their use. Here we are reporting for the first time a case of biopsy-proven acute graft rejection after the use of DAAs.

Methods: We report a case of a 47-year-old, type 1 diabetic male, who had a living unrelated kidney transplant in 2006. Prior to his transplant, he acquired HCV infection. In 2009, he was found to have 12 million copies of HCV, with a deranged liver function test. In 2015, the patient showed F3 fibrosis on fibro-scan. However, due to the risk of graft rejection he wasn't started on INF therapy, he was kept on low immunosuppressive treatment consists of cyclosporine (CYC) 75/50 mg daily, mycophenolic acid 180 mg twice daily and prednisolone 5 mg daily. Recently, DAAs became available and he was started on Daclatasvir 60 mg daily with Sofosbuvir 400 mg daily. Creatinine level (Cr) was maintained mostly around 1.4-1.5 mg/dL. About 3 months after initiating anti-HCV treatment, his Cr raised to 2.4 mg/dL, and kept rising steadily reaching 4.78 mg/dL. During the course DAAs treatment CYC trough level was kept always therapeutic (140-180 ng/mL), a renal biopsy was done almost three month after starting DAAs, and revealed the presence of acute anti-body mediated rejection (AMR) as well as features of advanced diabetic nephropathy and severe interstitial fibrosis and tubular atrophy. He received methylprednisolone IV pulses and CYC was replaced by tacrolimus together with increasing the dose of mycophenolic acid. The AMR responded with gradual improvement of his serum Cr

Results:

Conclusions: In our patient, the use of DAAs was associated with biopsy proven acute AMR raising the need to be more cautious when using these medications in kidney transplant patients. More studies are needed to establish the link between this treatment and graft rejection.

PUB750

Long-Term Spontaneous Operational Tolerance after Deceased-Donor Kidney Transplantation: A Case Report Denaly S. Chen, Loay H. Salman, Rafia I. Chaudhry, Mauricio Monrroy. *Albany Medical College, Albany, NY.*

Background: Operational Tolerance (OT) is defined by the maintenance of stable allograft function in the absence of immunosuppressive drugs for at least one year in kidney transplant recipients. OT does not imply a complete paucity of anti-donor reactivity, but the absence of clinically detectable, deleterious immune responses directed against the allograft. This highly desirable phenomenon has been linked to an increase in expression of B cell associated genes, and changes in B cell subsets, with an increase in naïve and decrease in memory B cells. Less than 200 kidney transplant recipients have been reported to develop spontaneous OT after discontinuing immunosuppressive medications, and these patients maintained allograft function without rejection for years. Almost all of the reported cases were living-donor kidney recipients.

Methods: A 25yo WM presented to the ED for left flank pain. He had a history of ESRD due to bilateral congenital kidney dysplasia and underwent living donor kidney transplant from his mother at age 4, with early graft failure due to vascular thrombosis. He underwent a second kidney transplant from a cadaveric donor at the age of 7, and was followed at our institution until 19 yrs of age. His baseline creatinine was 1.9 mg/dL, immunosuppressive regimen included Prednisone, Myfortic and Rapamune. The patient was then lost to follow-up and eventually stopped all immunosuppressive therapy at the age of 20 due to noncompliance. 5 years after discontinuing immunosuppressive agents, the patient remained normotensive, with an unremarkable physical exam. His creatinine impressively remained at 1.8 mg/dL, UA was positive for trace protein only.

Results:

Conclusions: Although factors such as pre-sensitization against HLA antigens and previous rejection episodes have not prevented the subsequent emergence of spontaneous tolerance, most reported cases of OT are recipients well matched to their donor. In this case, the development of OT to a cadaveric donor kidney is remarkable, with an impressively stable renal function, and urine sediment without evidence of ongoing kidney injury after 5 years off immunosuppression.

PUB751

Impact of Pre-Implant Biopsy Findings on Short-Term Kidney Graft Function and Maintenance Immunosuppression Management Sanjeev Akkina, Ewa Borys, Amishi S. Desai, Raviprasenna K. Parasuraman. *Loyola University Medical Center, Chicago, IL.*

Background: The role of procurement biopsies or pre-implant biopsies on renal allograft outcomes is unclear. Altering maintenance immunosuppression (IS) by calcineurin-inhibitor (CNI) reduction or conversion to non-CNI regimens based on donor histology may improve allograft function. In this study, we hypothesize that pre-implant biopsy (bx) histology may predict the need for changes in maintenance IS early after transplant.

Methods: In this retrospective, single-center review, we have 24 individuals had a pre-implant bx between January 2016 and March 2017. We collected donor characteristics including the reported histological findings from the donor bx prior to procurement. We assessed for glomerulosclerosis, tubular atrophy, interstitial fibrosis, and arterial hyalinosis as the primary predictors. Our outcomes of interest were serum creatinine at 1, 4, and 8 weeks after transplant and changes that occurred in maintenance IS. Linear and logistic regression was used to determine which factors were associated with allograft function and changes in maintenance IS.

Results: Of the 24 individuals that had a pre-implant bx, 18 had a donor bx prior to procurement. The mean donor age was 42±15 years with a mean KDPI of 57±25. Cause of death was anoxia or trauma in 71% of the donors while 50% had hypertension and an additional 17% had both hypertension and diabetes. Mean terminal creatinine was 1.6±1.2mg/dL with a cold ischemia time of 17±5 hours. Of the 24 recipients, 4 had alterations in their maintenance IS within the first 8 weeks after transplantation (CNI reduction for 2, conversion to belatacept for 2) with an average reduction of 40% in creatinine within 4 weeks after the change. Creatinine at 8 weeks was associated with arteriolar hyalinosis on the pre-implant bx (2.8±3.4 vs 1.2±0.3mg/dL, p=0.076). Creatinine was not associated with other histological parameters or donor KDPI. Logistic regression of bx findings did not predict alterations in maintenance IS.

Conclusions: In our study, we found that arterial hyalinosis on pre-implant biopsies was associated with higher 8 week creatinine level but there were insufficient data to predict who would benefit from early changes in maintenance IS.

PUB752

Drug Resistant CMV Infection in Post Kidney Transplant Recipients – High Dose Gancyclovir as a Safe Treatment Option Swetha Rani Kanduri,[2] Desiree Garcia Anton,[1] Pradeep Vaitla.[2] *[1]University of Mississippi Medical Center, Ridgeland, MS; [2]Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: Resistant cytomegalovirus infection (CMV) is a significant problem in kidney transplant recipients with an incidence of 0.54%–1%. The factors that promote the emergence of resistance include CMV donor-positive recipient-negative status. (D+/R–), receipt of potent immunosuppression, prolonged exposure to anti-CMV agents and high CMV virus load. There are multiple reports of poor graft survival and increased mortality with resistant CMV infections noted in literature. Here we present a case of gancyclovir (GCV) resistant CMV infection and its successful treatment.

Methods: 28-year-old African American female, with end stage renal disease underwent disease donor renal transplant secondary to hypertensive nephrosclerosis. She received thymoglobulin induction along with Mycophenolate mofetil, Tacrolimus and Prednisone. She is low risk for CMV with both donor and recipient being positive for CMV IgG. 3 months post-transplant, patient was diagnosed with CMV colitis after she completed valgancylovir prophylaxis. Received treatment with high dose oral valgancyclovir. CMV PCR levels initially decreased however trended back up and had persistent leukopenia. Genetic testing noted to have GCV resistant CMV viremia. Resistance testing showed mixed CMV population with resistance at UL97 gene target. Available treatment options were induction with Foscarnet vs Cidofovir vs high dose Gancyclovir. Foscarnet and Cidofovir have adverse nephrotoxic profiles along with electrolyte abnormalities and Fanconi picture. They also cause significant disease burden with need for IV fluids and close monitoring of labs. Option of high dose GCV induction was chosen for two weeks followed by high dose oral valgancyclovir. Colitis and leukopenia improved along with significant decrease in CMV PCR levels.

Results:

Conclusions: Resistance to GCV can be explained by mutations in two CMV genes: UL97, encoding a kinase responsible for the initial phosphorylation and activation of GCV; and UL54, encoding the viral DNA polymerase. Therapeutic options for GCV-resistant CMV are limited and with some therapeutic options being extremely toxic. So far, we have no controlled trial data to support the best alternative therapy. The use of

higher doses of IV GCV 10 mg/kg twice daily has been been one of the successful options considering side effect patterns of other options.

PUB753

Utility of Day 0 Urine Screening Protocol in Predicting Early Onset Urinary Tract Infection after Renal Transplantation Anil Mishra, Olanrewaju Aboderin, Bradley B. Gehring, Katie L. Korneffel, Graham Mitro. *University of Toledo College of Medicine, Toledo, OH.*

Background: Urinary tract infection (UTI) limits allograft survival and is the most common form of bacterial infection in patients who undergo renal transplantation. Many hospitals including the University of Toledo Medical Center routinely screen patients via urinalysis (UA) and/or urine culture (UC) for nitrites or bacteria prior to operation (Day 0) in order to address this issue. Our study investigates the utility of this protocol in predicting the onset of UTI within two weeks of transplantation (early onset UTI).

Methods: An IRB-approved retrospective cohort study was conducted on 675 patients who received renal transplantation between 03/2006 and 11/2015 at the University of Toledo Medical Center. Day 0 through Day 14 UA and UC data were collected and analyzed. A positive UA was defined as a UA containing nitrites and positive UC as a UC containing greater than or equal to 10^5 colony forming units per milliliter (Cfu/mL). All patients were induced with Alemtuzumab.

Results: Of the 675 patients, 227 (33.3%) received screening on Day 0. Eleven of these patients (1.6% of total) had a positive UA and/or positive UC within two weeks of transplantation. Only one patient (0.15% of total) was positive on Day 0, and this patient did not have another positive result within two weeks of transplant. 448 patients (66.4%) did not receive Day 0 screening, and this group was used as a control. Twelve of these patients (1.8% of total) had a positive UA and/or positive UC within two weeks of transplantation. Day 0 urine screening was not a significant predictor of early onset UTI in patients (p=0.143).

Conclusions: Based on our single-center study at UTMC, the practice of Day 0 Urine screening is not a significant predictor of UTI within two weeks of renal transplantation. Hospitals should re-evaluate this protocol and further investigate its utility at their local site before permanently implementing.

Day 0 Urine Screen and the Development of UTI (14 days after Transplant)

	No UTI	UTI	Total
Without Day 0 Urine Screen	436 (64.6%)	12 (1.8%)	448 (66.4%)
With Day 0 Urine Screen	216 (32.0%)	11 (1.6%)	227 (33.6%)
Total	652 (96.6%)	23 (3.4%)	675 (100%)

Early Acute Antibody Mediated Rejection in a Simultaneous Liver Kidney Transplant Patient Requiring Bortezomib Therapy Winston A. Ally,[2] Gayle M. Vranic,[2] Karen M. Warburton,[2] Angie G. Nishio-Lucar,[2] Peter I. Lobo,[2] Alden M. Doyle.[1] *[1]University of Virginia, Charlottesvillle, VA; [2]University of Virginia Health System, Charlottesville, VA.*

Background: In simultaneous liver kidney transplantation, the liver is traditionally thought to be protective of the kidney. Herein, we present the case of early acute antibody mediated rejection in a simulatenous liver kidney transplant patient.

Methods: A 61 year old female with a history of hepatitis C cirrhosis and type 2 hepatorenal syndrome on hemodialysis was admitted for deceased donor simultaneous liver kidney transplantation. This was a donation after brain death donor with a positive low level donor specific antibodies (DSA) at the time of transplant (MFI: A68=1487, A24=343, B61=280, B35=269 DR4=3044, DR11=1360, DR52=1243, DR53=544, DQ7=136, DP4=2080). The patient received induction immunosuppression with 1.5 mg/kg rabbit anti-thymocyte globulin, methylprednisolone 500 mg IV and 3 g/kg IVIG (2g/kg in OR and 0.5 g/kg on POD1 and 4). Maintenance immunosuppression included steroid taper and mycophenolate with tacrolimus initiated on POD5. The patient had delayed graft function of the kidney requiring renal replacement therapy (RRT). On POD 11, the kidney allograft biopsy revealed marked peritubular capilliritis and robust C4D staining associated with elevated DSAs (DQ7=9977 on POD 11 vs. 150 on POD4) consistent with antibody mediated rejection. Therapy was initiated including 9 sessions of plasmapheresis followed by IVIG 0.5 g/kg. Although the patient no longer required RRT by POD 35, kidney function remained poor with serum creatinine ranging from 3.1 to 3.9 mg/dl. Repeat biopsy on POD 47 was significant for ongoing antibody mediated rejection, DSAs remained elevated (DQ7=14011 on POD 47 vs. 11500 on POD 40). Due to the lack of response, treatment with four sessions of plasmapheresis and bortezomib therapy (4 doses of 1.3 mg/m^2) was initiated on POD48 with continued improvement in renal allograft function.

Results:

Conclusions: This represents a case of early acute antibody mediated rejection in a simultaneous liver kidney transplant patient non-responsive to extended IVIG/plasmapheresis therapy, now requiring treatment with bortezomib, a proteasome inhibitor targeting plasma cells. Although the liver is thought to be protective in simultaneous liver kidney transplantation, close monitoring and careful consideration of induction therapy as warranted, as this is not always the case.

PUB756

Hemophagocytic Syndrome Associated with Acute Renal Allograft Dysfunction Milagros M. Flores fonseca,[1] Claudia A. Mendoza cerpa,[1] Sandra F. Velasco,[2] Benjamin Gomez-Navarro,[1] Viridiana Rodriguez,[1] Jorge Andrade-Sierra.[1] *[1]Nefrologia y Trasplantes, Centro Medico Nacional de Occidente. Instituto Mexicano de Seguridad Social., Guadalajara, Mexico; [2]Quimica, Universidad de Guadalajara, Guadalajara, Mexico.*

Background: Although there are few reports of hemophagocytic syndrome (HPS) and histoplasmosis infection, we present two cases of renal allografts that developed acute allograft dysfunction.

Methods: **Case 1.** A 31-year-old male with chronic kidney disease (CKD) of unknown etiology, kidney transplant recipient, kidney biopsy with an acute cellular rejection (ACR) 1A receiving IV methylprednisolone, hospitalized with fever and diarrhea, paraclinical exams with pancytopenia, serum creatinine (SCr) 3.7mg/dl, hyperferritinemia, hypertriglyceridemia, hypofibrinogenemia and abdomen tomography showed hepatosplenomegaly. Bone marrow reports sporadic hemophagocytosis (Figure 1). Discontinuing immunosuppresive therapy, followed by amphotericin and itraconazole. He clinically improves, discharged SCr 2.3mg/dl, and restarting immunosuppressive therapy. **Case 2.** A 25-year-old male with CKD of unknown etiology, kidney transplant recipient, kidney biopsy with an ACR 1A receiving thymoglobulin, hospitalized complaining of fever and productive sputum, bicytopenia, SCr 2.2 mg/dl, hyperferritinemia, hypertriglyceridemia, chest tomography with areas of consolidation, and abdominal ultrasound with hepatosplenomegaly. Positive culture for Histoplasma capsulatum. Peripheral blood smear revealed megaloblastic changes and hemophagocytosis. Immunosuppressive therapy was suspended, administer amphotericin and itraconazole. Clinically improving and discharged SCr 1.7 mg/dl.

Results:

Conclusions: We report two cases of HPS with acute allograft dysfunction, followed by ramped up immunosuppressive treatment after ACR episodes, initially unfavorable evolution, discharged patients with a partially recovered renal function. These findings suggests a reasonable management strategy might be discontinued immunosuppressive drugs and considering additional treatment with antifungals, IVIg or high-dose steroids.

Posttransplant Hypercalcemia Associated with Cryptococcal Pneumonia Katherine I. Lemming,[1] Winston A. Ally,[2] Gayle M. Vranic,[2] Karen M. Warburton,[1] Angie G. Nishio-Lucar,[1] Alden M. Doyle.[1] *[1]University of Virginia Health System, Charlottesville, VA; [2]University of Virginia Health System, Charlottesville, VA.*

Background: Hypercalcemia associated with cryptococcal infections is a rarely reported complication. Herein, a kidney transplant patient with cryptococcal pneumonia who develops significant hypercalcemia post-transplant is presented.

Methods: A 64-year-old male with a history of hypertension, focal segmental glomerulosclerosis, and end-stage kidney disease presented 8 months after successful deceased donor kidney transplant with cough, malaise, and low grade fever. Patient had been maintained on tacrolimus, mycophenolate mofetil, and prednisone with stable kidney allograft function and a baseline creatinine of around 1.7 mg/dl. During his initial posttransplant period he had been maintained on low dose calcitriol with PTH values of 300-500, and serum calcium of 9.5-10.1 and serum phosphorus of 2.2-3.1. Patient was found to have right middle and lower lobe opacities and was started on antibiotics. Work up revealed a positive Cryptococcal antigen (1:160), the diagnosis of Cryptococcal pneumonia was confirmed by bronchoscopy. During his admission, his calcium levels rose. Despite discontinuation of his vitamin D supplementation and administration of IV fluids and furosemide, his calcium level rose to a zenith of 12.9 mg/dl associated with an ionized calcium of 6.9 mg/dl and a marked fall in his PTH levels. His vitamin D 1,25-dihydroxy level was found to be 85 pg/ml. Patient received hydrocortisone, calcitonin, and a single dose of pamidronate with improvement to a current serum calcium level to 10.6.

Results:

Conclusions: Cryptococcal infections are a rare but important cause of posttransplant hypercalcemia that are felt to be related to 1-hydroxylation of vitamin D.

PUB758

Long-Term Outcome after Multimodal Treatment of Kidney Transplant Rejection with Microvascular Injury Ksenija Vucur,[3] Bojana Maksimovic,[3] Zeljka Jurekovic,[3] Danica G. Ljubanovic,[2] Mladen Knotek,[3] Stela Bulimbasic.[1] *[1]University Hospital Center Zagreb, Zagreb, Croatia; [2]University of Zagreb School of Medicine, Clinical Hospital Dubrava, Zagreb, Croatia; [3]Department of Nephrology, University of Zagreb School of Medicine and University Hospital Merkur, Zagreb, Croatia.*

Background: Microvascular injury (MVI) (peritubular capillaritis (ptc) and/or glomerulitis (g) with DSA is common histopathological feature of acute and chronic active AMR, but MVI can also be found in TCR. Some studies reported that MVI was independently associated with graft loss. The aim of the study was to analyze patient (pt) survival, death-censored graft survival, and overall graft survival after treatment of kidney rejection with MVI.

Methods: Retrospective analysis included all pts who had kidney tx (KT) or simultaneous pancreas and kidney tx (SPKT) at Merkur hospital between 2007 and 2016. We found 75 pts (68 KT and 7 SPKT) who had a rejection episode with MVI. 87% KT were from deceased donors. In induction, 75% pts received anti IL-2 receptor antibody, with TAC, MMF ± steroid maintenance.

Results: The mean time from tx to index bx was 1.1±4.1 mos (median 0.3 mos). 64% pts experienced early graft rejection (within 90 d from tx). Index biopsies were classified as: TCR (49%), borderline (28%), and AMR (23%). Cumulative treatment included steroids (79%), plasmapheresis (27%), anti-thymocyte globulin (23%), IVIG (15%), bortezomib (13%), and rituximab (6%). Last follow-up bx after the treatment revealed persisting rejection in 42% pts (borderline 32%, TCR 4%, and AMR 6%). Average number of bx per pt was three. Time from index to last bx was 6.2±9.6 mos (median 3.9 mos). During follow up period of 33.3±27.4 mos pt survival was 93.3%, death-censored graft survival was 78.4%, and overall graft survival was 74.3%. In univariate analysis v-score in the index bx, ptc in the last bx, i-score in the last bx, steroids, and rituximab were associated with death censored graft survival, but none of these factors was found to be significant in multivariate analysis (Tbl).

Conclusions: Neither MVI, nor Banff classification of rejection was independently associated with long-term death-censored graft loss regardless of the onset and the type of the rejection, possibly reflecting effect of a multimodal cumulative rejection treatment pts have received based on follow up bx.

Univariate and multivariate Cox proportional-hazards regression analysis for death-censored graft surival

Tolvaptan Slows eGFR Decline in Later-Stage ADPKD Vicente E. Torres,[1] Arlene B. Chapman,[8] Olivier Devuyst,[10] Ron T. Gansevoort,[7] Ronald D. Perrone,[6] Gary G. Koch,[9] John Ouyang,[2] Robert D. Mcquade,[11] Jaime Blais,[4] Frank S. Czerwiec,[3] Olga Sergeyeva.[5] *[1]Mayo Clinic, Rochester, MN; [2]Otsuka Pharm. Dev. & Comm., Rockville, MD; [3]Otsuka Pharma. Devel. & Comm., Inc., Rockville, MD; [4]Otsuka Pharmaceutical Development and Commercialization, Princeton, NJ; [5]Otsuka Pharmaceuticals, Princeton, NJ; [6]Tufts Medical Center, Boston, MA; [7]UMC Groningen, Groningen, Netherlands; [8]University of Chicago, Chicago, IL; [9]University of North Carolina at Chapel Hill, Chapel Hill, NC; [10]University of Zurich, Zurich, Switzerland; [11]Otsuka Pharmaceutical Development and Commercialization Inc, Rockville, MD. Group/Team: REPRISE Trial Investigators.*

Background: In subjects with autosomal dominant polycystic kidney disease (ADPKD) and relatively early disease (estimated creatinine clearance ≥60 mL/min) the vasopressin V2 receptor antagonist tolvaptan slowed kidney growth and estimated glomerular filtration rate (eGFR) decline, but also caused more frequently transaminase and bilirubin elevations. Tolvaptan efficacy and safety in later-stage ADPKD are unknown.

Methods: REPRISE is a phase 3, multi-center, randomized withdrawal, placebo controlled, double-blind trial. After an 8-week pre-randomization period including sequential placebo and tolvaptan treatments, 1,370 ADPKD subjects, 18–55 years with eGFR 25-65 mL/min/1.73 m^2 or 56–65 years with eGFR 25-44 mL/min/1.73 m^2, were randomized 1:1 to tolvaptan or placebo and treated for 12 months. Safety assessments were conducted monthly.

Results: The primary endpoint, annualized eGFR change from pre-treatment baseline to post-treatment follow-up, was -2.34 mL/min/1.73 m^2 with tolvaptan versus -3.61 mL/min/1.73 m^2 with placebo, indicating a 35% reduction in rate of eGFR decline (P<0.001). The secondary endpoint, annualized eGFR slope was -3.16 mL/min/1.73 m^2 versus -4.17 mL/min/1.73 m^2 (P<0.001). Alanine aminotransferase elevations (>3 x upper limit of normal, ULN) occurred in 5.6% or 1.2% of subjects receiving tolvaptan or placebo, respectively. Transaminase elevations were reversible and no subjects showed bilirubin elevations >2 x ULN.

Conclusions: Compared with placebo, tolvaptan slowed eGFR decline by 35% over 1-year in subjects with later-stage ADPKD. While transaminase elevations occurred more frequently with tolvaptan treatment, these were reversible after withdrawal of tolvaptan, without concurrent bilirubin elevation, and none met Hy's laboratory criteria, likely due to more frequent transaminase monitoring and earlier discontinuation.

Bardoxolone Methyl Improved GFR Measured by Standard Inulin Clearance: The TSUBAKI Study Masaomi Nangaku,[1] Ryutaro Shimazaki,[2] Tadao Akizawa.[3] *[1]the University of Tokyo School of Medicine, Tokyo, Japan; [2]Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan; [3]Showa University School of Medicine, Tokyo, Japan.*

Background: Bardoxolone methyl (BARD), an Nrf2 activator, consistently and significantly increased the estimated glomerular filtration rate (eGFR) in multiple clinical studies in patients with diabetic kidney disease (DKD). A prior Phase 3 study (BEACON) was terminated prematurely due to early-onset fluid overload, however, post-hoc analyses identified risk factors for fluid overload. We have therefore conducted a study that excluded at-risk DKD patients, known as the TSUBAKI study. In the study, we used the inulin clearance method, which is the gold standard for measuring GFR, to determine if changes in eGFR were reflective of true changes in GFR.

Methods: This was a randomized, double-blind, placebo-controlled, multi-center Phase 2 trial in patients with stages G3 and G4 DKD without identified risk factors for fluid overload such as baseline BNP > 200 pg/ml and prior history of heart failure. Patients were administered BARD or placebo with a titration scheme from 5 to 15 mg orally once daily for 16 weeks. Primary efficacy endpoint was the change in GFR measured by standard inulin clearance after 16 weeks of treatment in patients with stage G3 in a pre-specified interim analysis. The safety of BARD was evaluated in patients with both stages.

Results: A total of 120 patients with stages G3 and G4 were treated. In patients with stage G3, 85 patients were randomly assigned to either BARD or placebo with a 1:1 allocation; three patients discontinued before treatment started. GFR was evaluated in 40 patients (BARD: n=17; placebo: n=23). The mean eGFR and GFR at baseline were 46.7 (32.9 to 58.8) and 48.5 (27.9 to 64.8) ml/min/1.73 m^2, respectively. A significant improvement in GFR was seen in the BARD compared to the placebo group (6.6 ml/min/1.73 m^2, p=0.008). Data also showed that BARD significantly improved eGFR compared to placebo. In patients with stage G4, all 38 patients completed their treatment period. For patients with both stages, BARD was well tolerated, and no signs or symptoms of fluid overload were observed.

Conclusions: BARD improved renal function assessed by inulin clearance. The results suggest among preselected patients, BARD may yield significant treatment benefits without safety concerns.

Kidney Injury After Intravenous or Intracoronary Contrast Agents for Noninvasive or Invasive Coronary Angiography: An Industry-Independent, Phase 3, Randomized Controlled Trial Marc Dewey,[1] Peter Martus,[2] Maria Bosserdt,[1] Elke Zimmermann,[1] Michael Laule,[1] Eva Schönenberger.[1] *[1]Charité, Berlin, Germany; [2]UKT Tübingen, Tübingen, Germany. Group/Team: CAD-Man Study Group.*

Background: X-ray contrast agents can have nephrotoxic effects, while it is unknown whether acute kidney injury is more likely after intracoronary or intravenous administration of these agents and whether contrast-induced acute kidney injury is associated with impaired chronic kidney function.

Methods: In this randomized controlled trial, patients with suspected coronary artery disease were recruited. Patients without known coronary artery disease and a clinical indication for invasive coronary angiography (ICA) based on atypical chest pain were eligible. Patients were randomly assigned (1:1) to ICA with intracoronary contrast or coronary computed tomography angiography (CTA) with intravenous contrast. The same low-osmolar non-ionic contrast agent was used for ICA and CTA. The primary outcome of this analysis was contrast-induced acute kidney injury within 3 days following contrast agent administration defined as an increase in serum creatinine of ≥0.5 mg/dL or 25% after 18-24 hours or 46-50 hours. Laboratory investigators were masked to randomization group.

Results: Between February 18, 2009, and August 2, 2015, 162 and 165 patients were randomly assigned and underwent ICA and CTA. Follow-up creatinine after 18-24 hours or 46-50 hours was available for 159 patients (98%) in the ICA group and 161 (98%) in the CTA group. Baseline estimated glomerular filtration rates were not significantly different between patients in the CTA (84.3±17.2 mL/min/1.73 m^2) and the ICA group (87.1±16.7 mL/min/1.73 m^2; p=0.14). There were 30 cases of contrast-induced acute kidney injury overall: 9 in the CTA group (6%, 95% CI 3-10%) and 21 in the ICA group (13%, 95% CI 8-19%, p=0.023; OR 2.57, 95% CI 1.14-5.80). Long-term serum creatinine follow-up was available in 97% of patients (311 of 320) after a median duration of 1.9 years, and a greater proportion of patients with acute kidney injury still had increased creatinine (38%) compared with those without acute kidney injury (6%; p<0.001).

Conclusions: In patients with suspected coronary artery disease, acute kidney injury seems to be less likely after intravenous than after intracoronary contrast agent administration and contrast-induced acute kidney injury was associated with impaired chronic kidney function.

Efficacy and Safety of QPI-1002 (QPI) for Prevention of AKI Following Cardiac Surgery David Corteville,[5] Robert J. Still,[9] Gabor Szabo,[7] Madhav Swaminathan,[3] Vasant Jayasankar,[1] Andre Lamy,[6] Lukas J. Lehner,[10] Matthias Thielmann,[8] Craig D. Brown,[4] Ec Squiers,[2] U Schwertschlag,[2] A Potts,[2] A Patel,[2] E K. Messersmith,[2] D Rothenstein,[2] D J. Odenheimer,[2] S Erlich.[2] *[1]Cardiothoracic and Vascular Surgical Assoc, Jacksonville, FL; [2]Quark Pharmaceuticals, Inc., Fremont, CA; [3]Duke University Medical Center, Durham, NC; [4]New Brunswick Heart Centre, Saint John, NB, Canada; [5]McLaren Northern Michigan, Petoskey, MI; [6]McMaster University, Hamilton, ON, Canada; [7]University of Heidelberg, Heidelberg, Germany; [8]West-German Heart and Vascular Center Essen, University Duisburg-Essen, Essen, Germany; [9]JCCR, Jacksonville, FL; [10]Department of Nephrology and Medical Intensive Care, Charité - Universitätsmedizin Berlin, Berlin, Germany. Group/Team: QRK209 AKI Study Group.*

Background: QPI, a siRNA targeting p53, is being developed for prevention of Delayed Graft Function (DGF) following renal transplantation (ReGIFT Phase 3 Study, NCT#02610296) and for acute kidney injury (AKI). AKI is a major complication of cardiac surgery (CS) that increases morbidity and mortality. No treatments are approved for the prevention of AKI following CS.

Methods: The efficacy and safety of QPI, was studied in a global Phase 2 double-blind study (N=341: QPI=165, Placebo (PL)=176) undergoing CS at 41 sites (NCT#02610283). Subjects undergoing non-emergent CS at risk for AKI were enrolled (risk factors included: Age ≥ 70 years; eGFR ≤ 60 mL/min/1.73m^2, diabetes, proteinuria, congestive heart failure). Subjects were stratified by eGFR (≥ vs < 60mL/min/1.73m^2). A single IV dose of either QPI (10mg/kg) or PL was given 4 hours post-CS. Safety assessments included clinical and laboratory exams and adverse events (AEs). Efficacy endpoints included the rate of AKI determined by serum creatinine according to AKIN (primary), RIFLE and KDIGO (secondary) criteria assessed through Day 5. Secondary endpoints also included duration and grade of AKI, and the composite of death, renal replacement therapy (RRT) and 25% reduction of eGFR at Day 90.

Results: Demographics and AE profiles were similar between treatment groups and consistent with CS. QPI treatment resulted in a 26% relative risk reduction (RRR) of AKI (AKIN): (37% QPI vs. 50% PL; p=0.020). Risk reductions were consistently observed across predefined populations (age, diabetes, CS type, gender, baseline eGFR). Treatment with QPI improved AKI across all AKIN grades (by 18%–61%; p=0.012). Duration of AKIN AKI from Days 0-5 was shorter with QPI (p=0.013). QPI significantly impacted AKI incidence, grade and duration by RIFLE and KDIGO criteria. The composite of Death, RRT and Reduction of eGFR by 25% at Day 90 favored QPI in a subpopulation (N=241) with either proteinuria, and/or low base line eGFR, and/or diabetes, (37% QPI vs 51% PL; RRR=29%; p=0.024).

Conclusions: In this study, QPI reduced the incidence, grade and duration of AKI in high risk subjects following CS. Further development of QPI for the prevention of AKI is warranted.

The Pivotal Multicenter Trial of Ultrasound Guided Percutaneous Arteriovenous Fistulae for Hemodialysis Access Jeffrey E. Hull,[1] William C. Jennings,[2] Randy I. Cooper,[3] Umar Waheed,[3] Matthew E. Schaefer,[4] Rajeev Narayan.[4] *[1]Richmond Vascular Center, North Chesterfield, VA; [2]Univ OK Med Col, Tulsa OK, Tulsa, OK; [3]Southwest Kidney Institute, PLC, Tempe, AZ; [4]San Antonio Kidney Disease Center, San Antonio, TX.*

Background: Arteriovenous fistulae for hemodialysis are usually created by a surgical procedure. Percutaneous creation of an arteriovenous fistulae with a thermal resistance anastomosis device (TRAD) in an office based vascular center is emerging as an alternative to surgery.

Methods: One hundred seven patients were enrolled in a prospective, non-inferiority trial at 5 sites. Patients underwent ultrasound guided anastomosis creation between the proximal radial artery and perforating vein with the Ellipsys® Vascular Access System followed by seperate maturation procedures. All procedures were performed in outpatient vascular centers. The primary endpoints were brachial artery flow volume ≥ 500 mL/min and vein diameter ≥ 4 mm in > 49% of patients, and absence of device related complications at 90 days.

Results: Arteriovenous fistulae with fused anastomoses were created in 95% (102/107) patients. Maturation procedures included anastomotic balloon dilation in 72% (77/107), brachial vein embolization in 32% (34/107), cubital vein ligation in 27% (29/107), and surgical transposition in 26% (28/107). The primary flow and diameter endpoints were achieved in 86.0% (92/107) of the patients exceeding the performance goal of 49% ($p < 0.0001$). There were no major adverse events attributed to the device. Cumulative patency was 96.1%, 93.7%, 91.0 % at 90, 180, and 360 days, respectively. The target dialysis vein was the cephalic, basilic, and brachial veins in 74% (73/99), 24% (24/99), 2% (2/99), respectively. 2-needle dialysis was achieved in 88% (71/81) of patients on hemodialysis at a mean 113.1 ± 72.0 days. Functional patency was 98.4%, 98.4%, and 92.3% at 90, 180, and 360 days, respectively.

Conclusions: The Ellipsys® Vascular Access System met the primary safety, and efficacy endpoint goals in the United States pivotal trial.

Primary Results of the Time to Reduce Mortality in End-Stage Renal Disease (TiME) Trial: A Pragmatic Trial Demonstration Project of the NIH Health Care Systems Research Collaboratory Laura M. Dember,[12] Eduardo K. Lacson,[9] Steven M. Brunelli,[2] Jesse Y. Hsu,[11] Alfred K. Cheung,[14] John T. Daugirdas,[10] Tom Greene,[14] Csaba P. Kovesdy,[13] Dana Miskulin,[8] Ravi I. Thadhani,[5] Wolfgang C. Winkelmayer,[1] Allen R. Nissenson,[3] Franklin W. Maddux,[4] Michael F. Flessner,[6] Kevin C. Abbott,[7] J. R. Landis.[11] *[1]Baylor College of Medicine, Houston, TX; [2]DaVita Clinical Research, Needham, MA; [3]DaVita Healthcare Partners Inc., El Segundo, CA; [4]Fresenius Medical Care, Waltham, MA; [5]Massachusetts General Hospital, Boston, MA; [6]NIDDK, NIH, Bethesda, MD; [7]The National Institutes of Health, NIDDK, Bethesda, MD; [8]Tufts Medical Center, Sommerville, MA; [9]Tufts University School of Medicine, Boston, MA; [10]University of Illinois College of Medicine, Burr Ridge, IL; [11]University of Pennsylvania, Philadelphia, PA; [12]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [13]University of Tennessee Health Science Center, Memphis, TN; [14]University of Utah, Salt Lake City, UT. Group/Team: TiME Trial Study Group.*

Background: Observational studies of patients receiving maintenance hemodialysis suggest that mortality is lower with dialysis sessions longer than 4 hours but this hypothesis has not been evaluated in a randomized trial, and broad acceptability of longer treatments has not been established.

Methods: Cluster-randomized trial fully embedded in clinical care delivery with no on-site research staff or primary data collection. 266 dialysis units operated by two US dialysis providers were randomized to Intervention or Usual Care. Intervention units were to adopt a default hemodialysis session duration of ≥4.25 hours (255 minutes) for incident patients. Usual Care units had no trial-driven approach to duration. The primary outcome was mortality. The major secondary outcome was hospitalization rate.

Results: 7035 incident patients highly representative of the US dialysis population were enrolled between 12/18/13 and 9/30/16. The trial was discontinued at a median follow-up of 1.1 years after an interim analysis showed a smaller than targeted group difference in session duration and no difference in outcomes. For the primary analysis population (patients with Watson V≤42.5L), per-patient mean session durations were 219 and 210 minutes for Intervention and Usual Care, respectively, and there was no difference in mortality (HR 0.97, 95% CI 0.84, 1.12; p=0.69) or hospitalization rate (204 vs 213 per 100 patient-yrs, p=0.44). Findings were similar for the full analysis population (all patients).

Conclusions: A partnership between academic investigators and multiple dialysis providers and a highly pragmatic design resulted in successful and efficient participant enrollment, data acquisition, and trial monitoring but uptake of the intervention was insufficient to determine whether longer hemodialysis sessions improve clinical outcomes. The TiME trial results demonstrate feasibility of several aspects of large-scale pragmatic trials in dialysis. However, effective strategies for engaging clinicians and patients are required to evaluate interventions fully incorporated into routine care delivery. NCT02019225

A Multi-Center Randomized Controlled Trial of Rituximab versus Cyclosporine in the Treatment of Idiopathic Membranous Nephropathy (MENTOR) Fernando C. Fervenza,[4] Pietro A. Canetta,[7] Sean Barbour,[13] Richard A. Lafayette,[10] Brad H. Rovin,[9] Nabeel Aslam,[6] Michelle A. Hladunewich,[16] Heather N. Reich,[11] Paul E. Brenchley,[3] Debbie S. Gipson,[15] Matthias Kretzler,[12] Jai Radhakrishnan,[2] Lee A. Hebert,[8] Patrick E. Gipson,[15] Leslie F. Thomas,[5] Ellen T. McCarthy,[14] Gerald B. Appel,[1] J. Ashley Jefferson,[17] Nelson Leung,[4] Daniel C. Cattran.[11] *[1]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [2]Columbia University Medical Center, New York, NY; [3]Manchester Royal Infirmary, Manchester, United Kingdom; [4]Mayo Clinic, Rochester, MN; [5]Mayo Clinic Arizona, Phoenix, AZ; [6]Mayo Clinic Florida, Jacksonville, FL; [7]None, New York, NY; [8]Ohio State University Medical Center, Columbus, OH; [9]Ohio State University Wexner Medical Center, Columbus, OH; [10]Stanford University, Stanford, CA; [11]Toronto General Hospital, Toronto, ON, Canada; [12]U.Michigan, Ann Arbor, MI; [13]University of British Columbia, Vancouver, BC, Canada; [14]University of Kansas Medical Center, Kansas City, KS; [15]University of Michigan, Ann Arbor, MI; [16]University of Toronto, Toronto, ON, Canada; [17]University of Washington, Seattle, WA.*

Background: Membranous nephropathy (MN) remains the leading cause of nephrotic syndrome in Caucasian adults. Cyclosporine (CSA) is successful in reducing proteinuria, but its use is associated with a high relapse rate. Rituximab (RTX) is effective in reducing proteinuria but whether RTX is as effective as CSA in inducing and maintaining complete (C) or partial remission (PR) of proteinuria in MN is unknown. The MENTOR trial hypothesized that B-cell targeting with RTX is non-inferior to CSA in inducing long-term remission of proteinuria.

Methods: Patients with proteinuria ≥5g/24h, estimated GFR ≥ 40 ml/min/1.73m2 and ≥3-months of AII blockade were randomized into a 12-month treatment period with IV RTX, 1000 mg (2 infusions, 14 days apart; repeated at 6 months if proteinuria reduction >25% at 6-months or oral cyclosporine 3.5-5mg/kg/day for 6-months (continued for another 6-months if a substantial reduction in proteinuria (equal to or >25%) is seen at 6-months). Treatment efficacy was assessed by an intention-to-treat analysis of remission status (C or PR) at 24-months post-randomization. At the 6-month post-randomization, patients who did not have proteinuria reduction ≥25% were considered treatment failures and exit the study. Follow up was at 3, 6, 9, 12, 18 and 24 months, and included quantification of creatinine clearance, serum albumin, 24h proteinuria, anti-PLA2R antibodies levels as well as quality of life assessment.

Results: One hundred and eighty one were screened and 130 patients (mean age 52 ± 12.4 SD; 76.9% male) were randomized. Mean BP 125/76 ± 14 mmHg. Median SCr 1.2 mg/dl (range 0.5-2.5), serum albumin 2.6 g/dl (range 1.6-4.1), proteinuria 10.3 g/24h (range 8.9-27-5).

Conclusions: Last patient randomized was September 2015 and follow-up will be completed on 9/11/2017. We guarantee that will be able to present preliminary results by the time of the ASN.

Initial Data Report from "CARDINAL": A Phase 2/3 Study of Bardoxolone Methyl in Patients with Alport Syndrome Geoffrey A. Block,[1] Pablo E. Pergola,[2] Lesley Inker,[3] Peter A. McCullough,[4] Melanie Chin,[5] Colin J. Meyer,[5] Michelle N. Rheault,[6] Clifford E. Kashtan,[6] David G. Warnock.[7] *[1]Denver Nephrology, Denver, CO; [2]Renal Associates PA, San Antonio, TX; [3]Tufts Medical Center, Boston, MA; [4]Baylor University Medical Center, Dallas, TX; [5]Reata Pharmaceuticals, Irving, TX; [6]University of Minnesota, Minneapolis, MN; [7]UAB, Birmingham, AL.*

Background: In previous studies that enrolled over 2,600 patients, primarily including patients with CKD caused by type 2 diabetes, bardoxolone methyl (BARD) improved estimated GFR (eGFR) and inulin clearance. A Phase 2/3 trial (CARDINAL, NCT03019185) was initiated to test the hypothesis that BARD will improve eGFR in patients with Alport syndrome (AS).

Methods: The Phase 2 open-label portion of the study was designed to enroll 30 patients on stable RAAS blockade, ages 12 to 60 years, with confirmed diagnosis of AS, eGFR values from 30 to 90 mL/min/1.73 m^2 [calculated using CKD-EPI or Bedside Schwartz (age < 18 years) equations], and urinary albumin to creatinine ratio (UACR) ≤ 3500 mg/g. Patients received BARD at 5 mg, to dose-escalate as tolerated to 10 mg at Week 2, 20 mg at Week 4, and for patients with baseline UACR > 300 mg/g, to 30 mg at Week 6. The primary efficacy endpoint was change from baseline in eGFR after 12 weeks of treatment. Interim results are described herein.

Results: 30 patients were enrolled (mean age 44 years, 60% female, 73% X-linked AS). Data were extracted after the first 8 patients had received 12 weeks of treatment. From a mean baseline eGFR of 54.7 mL/min/1.73 m^2, treatment with BARD produced mean improvements of 6.9 mL/min/1.73 m^2 at Week 4 (n=19; p<0.0005), which further increased to 12.7 mL/min/1.73 m^2 at Week 12 (n=8; p<0.00005), as of July 24th, 2017. Over 80% of patients demonstrated clinically meaningful improvement in eGFR of at least 3.0 mL/min/1.73 m^2 by Week 8. eGFR improvements were associated with mean decreases in BUN, uric acid, and phosphorous. Median UACR increased, however, UACR/eGFR ratios were unchanged from baseline. Blood pressure was unchanged. The most commonly reported adverse event (AE) was muscle spasms, which were generally mild to moderate in severity, with no laboratory evidence of muscle toxicity. No patients have discontinued from the study and no serious AEs have been reported so far, in this ongoing trial.

Conclusions: BARD was generally well tolerated and improved kidney function in patients with AS. The Phase 3 double-blind, randomized, placebo-controlled portion of the trial that will enroll up to 150 patients has been initiated.

FR-PO1054

A Phase 1/2 Trial of ALN-GO1: An Investigational RNAi Therapeutic for Primary Hyperoxaluria Type 1 Yaacov Frishberg,[1] William van't Hoff,[2] Sally Hulton,[3] Patrick Haslett,[4] David V. Erbe,[4] Tracy Mcgregor,[4] Georges Deschênes.[5] *[1]Shaare Zedek Medical Center, Jerusalem, Israel; [2]Great Ormond Street Hospital, London, United Kingdom; [3]Birmingham Childrens' Hospital, Birmingham, United Kingdom; [4]Alnylam Pharmaceuticals, Cambridge, MA; [5]Hospital Robert Debre, Paris, France.*

Background: In Primary Hyperoxaluria Type 1 (PH1) alanine-glyoxylate aminotransferase deficiency leads to excessive hepatic oxalate production. This results in nephrocalcinosis, recurrent calcium oxalate stones, and progressive renal impairment, ultimately with multi-organ damage from systemic oxalosis. ALN-GO1 is an investigational RNAi therapeutic which suppresses hepatic glycolate oxidase, decreasing the conversion of glycolate to glyoxylate, a required substrate for oxalate production. Previously released study data from healthy adult volunteers showed that single dose ALN-GO1 was well tolerated with dose-dependent elevations in plasma glycolate. Here we report initial outcomes of patients with PH1 in the Phase 2 portion of the study.

Methods: This randomized, placebo controlled, single blind, multicenter trial is ongoing (ClinicalTrials.gov: NCT02706886). To be eligible, patients with PH1 must have urinary oxalate ≥0.7 mmol/24h/1.73m^2 and eGFR >45 ml/min/1.73m^2. One of four patients in each cohort is randomized to 3 doses of placebo prior to dosing with ALN-GO1. The first cohort received 1 mg/kg ALN-GO1 subcutaneously every 28 days x 3 doses, with the second cohort receiving 3 mg/kg ALN-GO1. The primary endpoint is safety, and secondary endpoints include change in 24 hour urinary oxalate excretion from baseline.

Results: ALN-GO1 has demonstrated acceptable safety and tolerability to date with no treatment related serious adverse events or discontinuations from the study. Preliminary results reveal that all three patients randomized to ALN-GO1 in the first cohort experienced >50% decrease in urinary oxalate excretion from baseline. Two of the three patients achieved levels within the normal range. The patient randomized to placebo in the first cohort shows a similar trend after initial dosing with ALN-GO1. Data from the second cohort are forthcoming.

Conclusions: ALN-GO1 is an investigational RNAi therapy which has been well tolerated while showing promising activity in lowering urinary oxalate excretion in patients with PH1. These preliminary data support continued development of ALN-GO1 as a potential therapeutic approach to alleviating the pathologic overproduction of oxalate in this devastating disease.

FR-PO1056

IV Cyclophosphamide vs Tacrolimus and Azathioprine as Induction in Proliferative Lupus Nephritis: A Randomized Controlled Trial Arpita Roychowdhury,[2] Dipankar Sircar.[1] *[1]IPGMER, SSKM HOSPITAL, KOLKATA, India; [2]Nephrology, IPGMER, Kolkata, India.*

Background: Therapy for proliferative lupus nephritis is limited to cyclophosphamide or mycophenolate as induction regimens. We present a randomized controlled trial of a regimen comprising of tacrolimus, azathioprine and steroids compared to IV cyclophosphamide and steroids for induction of lupus nephritis.

Methods: Patients of lupus nephritis (classes III, IV, V+III or V+IV), age 15-60 years were included. Exclusion criteria included patients with biopsy proven class IIIC/IV C lupus nephritis, an estimated glomerular filtration rate (eGFR) of <30ml/min/1.73m^2, severe infections or contraindications to any drugs. All patients received 3 pulses of methylprednisolone (500 mg). Subsequently, prednisolone was given at doses of 0.5 mg/kg/day and tapered. The Triple Drug regimen group received tacrolimus (0.075 mg/kg; trough 5-10 ng/ml) and azathioprine (2mg/kg). The control group received IV cyclophosphamide, 500 mg/m^2 monthly. All patients received hydroxychloroquine. The primary end point was achievement of complete renal remission. Secondary end points included decrease of proteinuria, decrease in disease activity scoring(SLEDAI Score) and incidence of severe adverse events.

Results: 137 patients were screened and 92 patients were randomly assigned to both arms and of them 65 completed the study for first 6 months induction phase. There were 33 patients in group 1and 32 patients in group 2. Complete remission occurred in 22/33 patients in the triple drug group and 22/32 patients in the IV Cyc group (p=0.857). Secondary end points were also similar between treatment groups- Group1 & Group2. Major infective complications requiring hospital admission in the Group1 (2/33) were less in number than in group 2 (5/32) had significant adverse effect but it did not reach significance (p= 0.183)

Conclusions: The novel triple therapy comprising of TAC-AZA-PRED as induction therapy in proliferative lupus nephritis is comparable to IV cyclophosphamide with respect to efficacy and safety.

Funding: Government Support - Non-U.S.

Rituximab (RTX) Treatment of Fibrillary Glomerulonephritis (FGN): A Pilot Study Stephen B. Erickson,[1] Mariam P. Alexander,[2] Samih H. Nasr,[2] Fernando C. Fervenza.[1] *[1]Division of Nephrology, Mayo Clinic, Rochester, MN; [2]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: FGN is a rare glomerular disease for which no standard treatment is available. Renal survival is poor with nearly 50% of patients progressing to ESRD within 4 yrs.

Methods: We recruited 11 patients with biopsy proven idiopathic FGNs into an open-label study testing the efficacy of RTX in reduction of proteinuria and preservation of kidney function. Patients' age ranged from 35 to 77 yrs, mean 58.5. Eight were females. All patients received 2 doses of RTX 1 gm each, at day 1 and day 14 with identical retreatment at 6 mos. Prespecified end points included 24 hr creatinine clearance (CrCl) and proteinuria at 12 mos. A logarithmic transformation was applied to CrCl values at each time point prior to comparing the values using a paired t-test. No serious adverse events.

Results: All patients completed 12 mos of the study. There was no significant change in CrCl: 47.73 (SD 24.02) at baseline, 43.73 (SD 23.08) ml/min/SA at 12 mos, p=0.21 [Fig 1]. Proteinuria decreased from 3824.7 (SD 1468.8) to 2650.5 (SD 1692.2) mg/24h, or nephrotic to non-nephrotic p=0.068. A subgroup of 3 (27%) patients had a dramatic response[Fig 2]. CD-19 B cells, the RTX target, dropped from an avg of 158.9 cells/mcL pre-RTX to nearly 0 at day 28 post-RTX. With the exception of patients 1 and 6 who had rebound by day 180 after both RTX treatments, all patients remained CD-19 cell depleted throughout the study.

Conclusions: Following 4 doses of RTX, patients had stable renal function. There was a tendency for proteinuria to decrease although it did not quite meet statistical significance(p= 0.068). A subgroup of patients showed remarkable reduction in proteinuria. For a previously untreatable disease, this is good news.

Canagliflozin and Renal Outcomes in Type 2 Diabetes: Data from the CANVAS Program Vlado Perkovic,[1,2] Dick de Zeeuw,[3] Kenneth W. Mahaffey,[4] Greg Fulcher,[2] Ngozi Erondu,[5] Wayne Shaw,[5] Terrance D. Barrett,[5] Michele Weidner-Wells,[5] Hsiaowei Deng,[5] Norm Rosenthal,[5] Mehul Desai,[5] David R. Matthews,[6] Bruce Neal.[1] *[1]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [2]The Royal North Shore Hospital and University of Sydney, Sydney, NSW, Australia; [3]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [4]Stanford Center for Clinical Research (SCCR), Stanford University, Department of Medicine, Stanford, CA; [5]Janssen Research & Development, LLC, Raritan, NJ; [6]University of Oxford, Oxford, United Kingdom. Group/Team: CANVAS Program collaborative group.*

Background: Canagliflozin (CANA) is an SGLT2 inhibitor that may have beneficial effects on the kidney in people with diabetes. The effects of CANA on prespecified renal outcomes in people with type 2 diabetes (T2D) and an elevated risk of cardiovascular (CV) disease were assessed in the CANagliflozin cardioVascular Assessment Study (CANVAS) Program.

Methods: The CANVAS Program consists of 2 double-blind, randomized trials conducted in 10,142 people with T2D and elevated CV risk (defined by the presence of documented CV disease or ≥2 risk factors), who received CANA (pooled analysis of 100 and 300 mg doses) or matching placebo (PBO). The prespecified exploratory renal outcomes were changes in urinary albumin:creatinine ratio (UACR), estimated glomerular filtration rate (eGFR), and composite clinical outcomes.

Results: At baseline, median UACR was 12.3 mg/g and mean eGFR was 76.5 mL/min/ 1.73 m^2. Urinary albumin excretion was 18% lower in participants treated with CANA versus PBO overall (95% CI 16%-20%), and 34% (95% CI 29%-38%) and 36% (95% CI 28%-43%) lower in participants with micro- and macroalbuminuria, respectively. Annual rate of eGFR decline was also reduced (difference 1.31 mL/min/1.73 m^2/year, 95% CI 1.15-1.48). The composite outcome of end-stage kidney disease, doubled serum creatinine, or renal death occurred less frequently in the CANA group (hazard ratio 0.53, 95% CI 0.33-0.84). Rates of renal adverse events were similar with CANA and PBO.

Conclusions: CANA reduced urinary albumin excretion, slowed eGFR decline, and reduced the risk of substantial loss of kidney function.

FR-PO1059

Vascular Adhesion Protein-1 Inhibitor (VAP-1i) Reduces Albuminuria in Diabetic Kidney Disease Dick de Zeeuw,[2] Ronny Renfurm,[1] Tobias E. Larsson.[1] *[1]Astellas Pharma Europe B.V., Leiden, Netherlands; 2University Medical Center Groningen, Groningen, Netherlands. Group/Team: ALBUM investigators.*

Background: Many diabetic kidney disease (DKD) patients treated with Angiotensin Converting Enzyme inhibitors (ACEi) or Angiotensin Receptor Blockers (ARB) have residual albuminuria and high risk for disease progression. We investigated the efficacy of a novel and specific VAP-1i, ASP8232, for reducing albuminuria on top of ACEi or ARB treatment in DKD. VAP-1 is an amine-oxidase with pro-inflammatory and pro-oxidative stress actions that is elevated and predicts cardiovascular risk in diabetes.

Methods: ALBUM was a randomized, double-blind, placebo-controlled, Phase 2 study in 45 European centers, enrolling 125 patients with type 2 diabetes and DKD. Inclusion criteria included Urinary Albumin Creatinine Ratio (UACR) ≥200 mg/g, eGFR 25-75 ml/min/1.73 m^2, and stable ACEi or ARB and anti-diabetic treatment for ≥3 months. After a 5-week screening/run-in, patients were randomized to ASP8232 40mg or placebo once daily for 12 weeks. Primary endpoint was change from baseline to end of treatment in first morning void (FMV) UACR. Secondary endpoint was change in 24-h albuminuria. A sample size of 110 was sufficient to detect 30% UACR reduction vs placebo with 80% power at a significance level of 5%.

Results: Of 406 patients screened, 125 were randomized and 120 were included in the analysis. Mean age was 69 yr, BMI 32 kg/m^2, HbA_{1c} 7.5%, BP 139/75 mmHg, eGFR 39.7 ml/min/1.73m^2, UACR 715 mg/g. Randomization was balanced. Use of ACEi (48.3% vs 53.3%), ARB (50.0% vs 43.3%), and combination (1.7% vs 3.3%) therapy was similar among ASP8232 vs placebo groups, respectively. Effects of ASP8232 vs placebo are shown in the table. ASP8232 reduced $UACR_{FMV}$ by 19.5% (p=0.033), $albuminuria_{FMV}$ by 26% (p=0.004), and 24h albuminuria by 20.0% (p=0.094). Reduction in UACR of ≥30% was observed in 37% of ASP8232 vs 22% of placebo patients (p=0.109). ASP8232 was safe and well tolerated; no serious drug-related adverse events were reported.

Conclusions: The VAP-1i ASP8232 yielded a clinically meaningful reduction of residual albuminuria in patients with DKD on stable ACEi/ARB treatment compared with placebo after 12 weeks of treatment.

A Multicentre, Stepped-Wedge Cluster Randomised Trial of a Complex Intervention to Reduce Harm Associated with AKI Nicholas M. Selby,[6,8] Anna Casula,[5] Laura Lamming,[9] John Stoves,[3] Yohan P. Samarasinghe,[2] Andrew J. Lewington,[4] Russell Roberts,[3] Nikunj Shah,[1] Richard J. Fluck,[8] Mel J. Johnson,[7] Natalie Jackson,[7] Carol A. Jones,[1] Fergus J. Caskey.[5] *[1]Ashford & St Peters Hospitals NHS Foundation Trust, Chertsey, United Kingdom; [2]Frimley Park Hospital, Camberley, United Kingdom; [3]Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom; [4]Leeds Teaching Hospitals, Leeds, United Kingdom; [5]UK Renal Registry, Bristol, United Kingdom; [6]Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom; [7]Yorkshire & Humber Improvement Academy, Bradford, United Kingdom; [8]Department of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [9]University of Bradford, Bradford, United Kingdom. Group/Team: Tackling AKI investigators.*

Background: Acute kidney injury (AKI) is common and associated with poor outcomes. We sought to evaluate the effectiveness, at the hospital level, of a package of measures to reduce harm associated with AKI.

Methods: A multi-centre, pragmatic, stepped-wedge cluster randomised trial (SWCRT) was performed in five UK hospitals. The organisation-wide intervention consisted of AKI alerts, a care bundle and an educational program that was introduced sequentially across fixed three month periods until all hospitals were ultimately exposed to the intervention. The sequence was determined by random number generation. All patients with AKI aged ≥18 years hospitalised for >1day were included. Chronic dialysis was the only exclusion criterion. Data were collected in 3 month periods, with a minimum of 2 pre-exposure (control), one transition and a minimum of one exposed periods per site. The primary outcome was 30-day mortality associated with AKI, with pre-specified secondary endpoints and a nested evaluation of care process delivery.

Results: 24,059 AKI episodes were studied (incidence 7.6 cases/100 admissions); mean age was 72±17yrs; 62% had AKI stage 1, 21% AKI stage 2, 17% AKI stage 3. Overall 30d mortality was 24.5%, with no difference between control and intervention periods (OR 1.07, 95% CI 0.93-1.24). Hospital length of stay (LoS) was reduced in the intervention period; -0.2days (95% CI -0.4 to 0.1), -0.7days (-1.3 to -0.1) and -1.3days (-2.7 to 0.1) for tertiles with low, middle and high LoS, respectively. The incidence of AKI increased in the intervention period, likely reflecting improved AKI detection. Process measures were assessed in 1042 patients. In the intervention period, improvements were seen in several metrics including AKI recognition, medication optimization, fluid assessment and urinalysis; care bundle usage was 40% with variation between centres

(range 15-68%). The degree of improvement differed between centres, which will be explored in a qualitative analysis.

Conclusions: A complex, hospital-wide intervention to reduce harm associated with AKI resulted in improvements in delivery of care, improved AKI detection and a modest reduction in LoS, but did not alter AKI mortality.

Fenoldopam in in Shiga Toxin-Related Hemolytic Uremic Syndrome

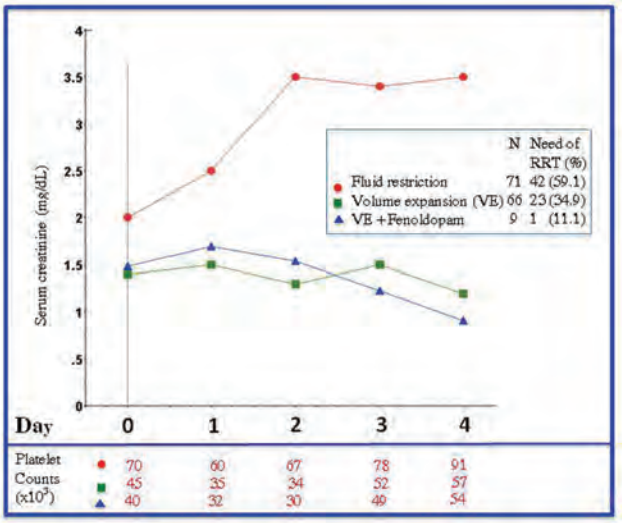
Gianluigi Ardissino,[3] Antenore Giussani,[5] Francesca Tel,[1] Sara Testa,[8] Fabio Paglialonga,[1] Silvia Consolo,[6] Cristiano Gandini,[4] Luisa Napolitano,[7] Emilio Fossali,[8] Dario Consonni.[2] *[1]Fondazione Ca' Granda Osp. Maggiore Policlinico, Milano, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Center for HUS Prevention, Control and Management, Pediatric Nephrology and Dialysis Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy; [5]Fondazione IRCCS Cà granda policlinico Milano, Milano, Italy; [6]Fondazione IRCCS Ospedale Maggiore Policlinico, Milano, Italy; [7]Ospedale Maggiore Policlinico Cà Granda, San Donato Milan, Italy; [8]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Background: The pathogenic sequence leading to renal damage in Shiga toxin-related hemolytic uremic syndrome (eHUS) includes endothelial injury, intravascular thrombi formation, microvascular occlusion and ischemic tissue injury. Early volume expansion (VE) reduces the number and severity of complication most likely by increasing organ perfusion. Fenoldopam (F), a dopamine-1 receptor agonist, is being widely used as an off-label treatment (T) for AKI as it induces renal vasodilation and favours perfusion, but we are unaware of its assessment in eHUS.

Methods: We describe our experience with F, in combination with VE, to treat 9 children with eHUS. FT was started immediately after eHUS was diagnosed. Renal resistance index (RRI) was measured on and off F. The disease course was compared with that observed in a cohort of patients receiving standard T(n=71) or early VE(n=66).

Results: Mean (SD) RRI decreased from 0.82(0.04) to 0.73(0.06) on F(-10.4%;p<0.00001). The figure compares the time-course of median serum creatinine during the initial 5 days of disease with the 3 T strategies, together with the platelet counts and the rate of RRT. An important reduction to 11.1% of the need of RRT was observed in patients treated with F(actually, a single patient required a single dialysis session) compared to either the standard T(59.1%) or the VE(34.9%) group. No patient treated with F showed signs of central nervous system involvement or any other complication and renal fuction quikly and fully recovered in all of them without sequels. No adverse event was observed. Despite the clearly ongoing and severe thrombotic microangiopathy (as evidenced by platelets count), combined T with F and VE was associated with an impressive favourable outcome.

Conclusions: If confirmed on a larger scale, FT may become an important addition to VE for improving the outcome of eHUS with important lifesaving potentials.



FR-PO1064

Results of a Randomized Multicentre Pilot Study of Sacubitril/Valsartan versus Irbesartan in Patients with CKD: United Kingdom Heart and Renal Protection (UK HARP)-III Trial

Richard Haynes,[1] Parminder K. Judge,[1] Natalie Staplin,[2] Martin J. Landray,[1] Colin Baigent.[1] *[1]MRC Population Health Research Unit, University of Oxford, Oxford, United Kingdom; [2]Clinical Trial Service Unit, University of Oxford, Oxford, United Kingdom. Group/Team: UK HARP-III Collaborative Group.*

Background: Angiotensin Receptor Neprilysin Inhibitor (ARNI) therapy inhibits the renin-angiotensin system (RAS) and increases concentrations of natriuretic and other vasoactive peptides. ARNI therapy may delay progression of kidney disease and prevent cardiovascular events. Trials among patients with heart failure have shown that treatment with ARNI significantly reduces the risk of cardiovascular events. However, the potential benefits in patients with CKD have not been studied. UK HARP-III is a randomized trial comparing the effects on kidney function, safety and tolerability of the ARNI sacubitril/valsartan (S/V) versus irbesartan (IRB) in patients with CKD.

Methods: Patients ≥18 years of age with either (i) an estimated glomerular filtration rate (eGFR) of ≥45 <60 mL/min/1.73m̊ and urine albumin:creatinine ratio (uACR) >20 mg/mmol; or (ii) eGFR ≥20 <45 mL/min/1.73 m² (regardless of uACR) were eligible to participate. After 4-7 week placebo run-in (including washout of RAS inhibitors), participants were randomly assigned S/V 97/103 mg twice daily or IRB 300 mg once daily. The primary outcome was measured glomerular filtration rate (mGFR) at 12 months. Other outcomes include effects on uACR, change in eGFR over time and the short-term safety and tolerability of S/V.

Results: 414 participants were randomized. Mean eGFR was 35.4 ml/min/1.73m² and median uACR was 54 mg/mmol. Allocation to S/V had no effect on mGFR at 12 months (difference -0.1 [SE 0.7] ml/min/1.73m²) nor eGFR at any time point. Allocation to S/V led to a non-significant 9% (95% CI -1 to 18) reduction in uACR. S/V was well-tolerated and was not associated with excess of any serious adverse events. Allocation to S/V reduced study average systolic and diastolic blood pressure by 5.4 (3.4-7.4) and 2.1 (1.0-3.3) mmHg respectively. There was a non-significant excess of hyperkalaemia (>5.5 mmol/l) among those allocated S/V vs IRB (32% vs 24%; p=0.10).

Conclusions: Compared to irbesartan, S/V had no measurable effect on GFR or uACR. S/V was well-tolerated and no major hazards were observed. A large randomized trial is required to assess the effects of S/V on cardiovascular and renal outcomes.

Aspirin Treatment in Primary Cardiovascular Prevention and Renal Disease Progression in CKD Patients: A Randomized Clinical Trials (AASER Study)

Marian Goicoechea,[3] Maria soledad Garcia de vinuesa,[3] Borja Quiroga,[6] Ursula Verdalles,[5] Enrique Morales,[1] Patricia De Sequera,[7] Gema Fernandez Juarez,[2] Eduardo Verde,[3] Jose Luno.[4] *[1]HOSPITAL 12 DE OCTUBRE, MADRID, Spain; [2]HOSPITAL DE ALCORCON, ALCORCON, Spain; [3]Hospital General Universitario Gregorio Marañon, Madrid, Spain; [4]Hospital General Universitario Gregorio Marañón, Madrid, Spain; [5]Hospital Gregorio Marañon, Madrid, Spain; [6]Hospital de La Princesa, Madrid, Spain; [7]University Hospital Infanta Leonor, Madrid, Spain.*

Background: Aspirin (ASA) use for primary cardiovascular disease (CV) prevention is controversial in general population. Chronic kidney disease (CKD) patients have a high CV risk but no evidence is available about the use of aspirin in CKD patients to decrease CV risk and to reduce renal disease progression.

Methods: We conducted a prospective, multicentric open randomized trial that included 111 patients with estimated GFR (eGFR) <60 ml/min (stage 3 and 4) without previous CV events. Patients were randomly assigned to treatment with aspirin 100 mg/day (*n*: 50) or to continue the usual therapy (*n:61*). Mean follow up time was: 63.6±16.4 months. Outcomes: The primary end-point was a composite of non-fatal cardiovascular events and mortality. Secondary end-points included progression of renal disease doubling of serum creatinine, ≥50% decrease in estimated glomerular filtration rate or renal replacement therapy and bleeding episodes

Results: During long-term follow-up, 16 and 5 participants in control and ASA groups respectively suffered from a CV event (p=0.05). Eight patients suffered from a fatal or non-fatal coronary event in the control group and no patient in the ASA group experienced a coronary event (log rank 5.997, p=0.014). Seventeen patients in the control group reached the renal outcome in comparison with 3 patients in the ASA group (log rank: 5.849 p=0.016). Aspirin treatment decreased renal disease progression in a model adjusted for age, baseline kidney function and diabetes mellitus (HR, 0.272; 95% CI, 0.075-0.955; p= 0.045). No differences were found in bleeding episodes (2 in standard and 3 in ASA group) Limitations: Small sample size and not double blind trial.

Conclusions: Long-term treatment with low dose aspirin decreases coronary events and may slow the rate of progression of kidney disease.

FR-PO1066

CKD Antidepressant Sertraline Trial (CAST) Susan Hedayati,[5] Lucile Parker Gregg,[5] Thomas Carmody,[4] Nishank Jain,[2] Marisa S. Toups,[3] Augustus J. Rush,[1] Robert D. Toto,[6] Madhukar Trivedi.[4] *[1]Duke-NUS, Santa Fe, NM; [2]Little Rock VA Hospital, Little Rock, AR; [3]UT Dell Medical School, Austin, TX; [4]UT Southwestern Medical Center, Dallas, TX; [5]University of Texas Southwestern, Dallas, TX; [6]University of Texas Southwestern Medical Center, Dallas, TX*.

Background: Major Depressive Disorder (MDD) is prevalent in CKD patients and associated with morbidity and mortality. Efficacy and safety of selective serotonin reuptake inhibitors in these patients are unknown. CAST (Clinicaltrials.gov NCT00946998) is the first well-powered, randomized, double-blinded, placebo-controlled trial in nondialysis stages 3-5 CKD patients to determine if treatment with sertraline improves depression and quality of life (QOL) and is safe and tolerable.

Methods: After a 1-week placebo run-in, 201 patients with MDD, established by the Mini Neuropsychiatric Interview, were randomized to 12 weeks of 50 mg/day of sertraline or matching placebo, escalated to a maximum tolerated dose of 200 mg/day. The primary prespecified outcome was improvement in depression severity from baseline by the Quick Inventory of Depression Symptomatology Clinician-Rated scale (QIDS). Secondary outcomes were safety and improvement in QOL.

Results: Intention-to-treat analysis included 193 patients (CKD stages 3a, 3b, 4, and 5: 11%, 36%, 36%, 17%) who received at least one post-randomization outcome assessment. The baseline QIDS score was 14.0 ±2.4 in the sertraline (N=97) and 14.1 ±2.4 in the placebo (N=96) group. The median participation time was 12.0 weeks and median achieved dose 150 mg/day, not different between groups. The QIDS score changed by -4.1, 95% CI (-5.1, -3.1) in the sertraline and -4.2 (-5.0, -3.5) in the placebo group; between-group difference, -0.1 (-1.3 to 1.1), *P*=.82 (Figure). Serious adverse events and changes in QOL were comparable between groups. Nausea or vomiting (23 vs. 10%, *P*=.03) and diarrhea (13 vs. 3%, *P*=.02) occurred more frequently in the sertraline vs. placebo arm.

Conclusions: In nondialysis CKD patients, treatment with sertraline did not improve depression or QOL and increased adverse events. These data do not support the use of sertraline to treat depression in CKD, which can have significant impact on clinical practice. (Funding: 1R01DK085512)

Rapid Bedside Plasma Volume (PV) and Measured GFR (mGFR) in Normal and CKD Subjects Dana Rizk,[4] Daniel Meier,[1] Ruben M. Sandoval,[3] Teresa Chacana,[5] Erinn S. Reilly,[1] Jesse C. Seegmiller,[6] Emanuel Denoia,[2] James S. Strickland,[1] Joseph Muldoon,[1] Bruce A. Molitoris.[3] *[1]FAST BioMedical, Carmel, IN; [2]Icon, San Antonio, TX; [3]Indiana University School of Medicine, Indianapolis, IN; [4]University of Alabama, Birmingham, AL; [5]University of Alabama at Birmingham, Birmingham, AL; [6]University of Minnesota, Minneapolis, MN*.

Background: Quantitative measurement of plasma volume (PV) and glomerular filtration rate (mGFR) remain arduous clinical tasks having wide ranges for individual subjects. Estimated GFRs (eGFRs), derived from endogenous markers such as creatinine, are commonly employed in both clinical AKI and CKD studies to evaluate severity of injury and disease progression. However, at the present time the eGFR results typically suffer in the healthy and end stage renal disease populations.

Methods: FAST BioMedical has developed a rapid PV and mGFR technique based on the plasma disappearance following a single IV injection containing a large 150kDa (12 mg) rhodamine derivative monitored as a signature of PV and small 5kDa fluorescein carboxy methylated dextrans (35mg) for mGFR determination, respectively. PV is quantified after only 15 minutes following injection by dilution of the large dextran which is stable for over 6 hours allowing repeat determinations without redosing.

Results: In a recently finished phase 2b study, involving 16 normal subjects and 8 CKD III and 8 CKD IV patients, injections were well tolerated and no SAEs were reported. A 24 hour repeat dose measurement in 8 healthy subjects showed PV reproducibility of better than +/- 5% and mGFR within 5%. In response to intravenous infusion of a 350 ml 5% albumin over 30 minutes the increase in PV, measured using dilution principles of the 150kd carboxy methylated dextran, was on average plus 290ml at 30 minutes post infusion. mGFR determination required three 0.5 ml blood draws over 2.5 hours and values compared well, +/- 5%, with standard Iohexol plasma disappearance studies using samples taken over 6 hours for all patients.

Conclusions: Use of this FAST BioMedical approach allows for the rapid bedside determination of PV, changes in PV with clinical maneuvers, accurate measurement of GFR and renal reserve (stimulated maximal GFR) while maintaining patient safety, measurement accuracy and reproducibility.

FR-PO1068

Effect of Drinking More Water on Kidney Function Decline in Adults with CKD: A Randomized Clinical Trial William F. Clark. *London Health Sciences Center, London, ON, Canada. Group/Team: Water Intake Trial (WIT) Investigators*.

Background: Drinking more water is associated with a slower rate of kidney function decline in animal experiments and human observational studies. We conducted a clinical trial to determine whether drinking more water slows the decline in estimated glomerular filtration rate (eGFR) over one year in patients with chronic kidney disease (CKD).

Methods: Design: Randomized controlled trial. **Setting**: Nine centers in Ontario, Canada (2013–17). **Participants**: Adults with stage 3 CKD and microalbuminuria. **Intervention**: The hydration group was coached to drink more water above their usual fluid intake and the control group to maintain usual fluid intake. **Analysis:** The primary outcome was the one-year change in eGFR. Secondary outcomes included the one-year change in plasma copeptin, 24-hr urine albumin, 24-hr creatinine clearance, and health-related quality of life. In the primary analysis patients were analyzed according to random assignment (intention to treat), and in additional analyses by protocol adherence, defined using 24-hr urine volume (per-protocol).

Results: Of 631 randomized patients (mean age 65, men [63%], diabetes [48%], mean eGFR 43 mL/min/1.73m^2) 2% died within one year and 95% of survivors provided one-year follow-up measurements. At 12 months, the 24-hr urine volume was 0.6 L/day higher in the hydration group than the control group (95% CI, 0.5 to 0.7; p<0.001). The average one-year decline in eGFR was 2.2 mL/min/1.73m^2 in the hydration group and 1.9 mL/min/1.73m^2 in the control group, and the adjusted between-group difference in change was -0.3 mL/min/1.73m^2 (95% CI, -1.7 to 1.2; p=0.74). Results were similar in the per-protocol analysis. No significant between-group difference in one-year change was seen for 24-hour urine albumin or health-related quality of life. However, at one year, plasma copeptin concentrations were lower in the hydration group than the control group (the between-group difference in one-year change was -2.3 pmol/L [95% CI, -3.9 to -0.6; p=0.009]), while 24-hr creatinine clearance was higher in the hydration group compared to the control group (the between-group difference in one-year change was 3.6 mL/min/1.73m^2 [95% CI, 0.8 to 6.5; p=0.012]).

Conclusions: Among patients with stage 3 CKD, the average one-year change in eGFR did not differ in patients who drank more water compared with those who continued their usual fluid intake.

An Integrated Smartphone Application Improves Patient Safety and Intervention Adherence: A Randomized Controlled Trial (RCT) with an Active Control Group Sarbjit V. Jassal,[3,2] Stephanie W. Ong,[3] Kelly Min,[3] Akib Uddin,[3] Eveline C. Porter,[3] Joseph A. Cafazzo,[3] Emily Seto,[2] George Tomlinson,[3,2] Alexander G. Logan.[1,2] *[1]Mount Sinai Hospital, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada*.

Background: There are a large number of applications (apps) available for chronic kidney disease (CKD) management, but few have been rigorously evaluated in a RCT. We previously published the efficacy of the eKidneyCare App when used to monitor blood pressure (BP), medications, labs and symptoms (CJASN 2016). To establish the clinical effectiveness of using an integrated app system and including customizable algorithms to send real-time feedback we completed a 1-year prospective RCT comparing eKidneyCare (Active) to MyMedRec (Active Control), a widely-recommended, commercially available app that records similar medical information without providing feedback.

Methods: We randomly assigned patients with CKD 3b-5 or 5D, attending an outpatient renal clinic at UHN, to a mobile-health monitoring kit consisting of a Bluetooth-enabled home blood pressure(BP) monitor, and a smartphone preloaded with either the eKidneyCare or MyMedRec app. The primary outcome was the number of medication discrepancies at 1 year. Secondary outcomes included adherence to monitoring regime, use of the app over time, BP at study exit and feedback from patient-questionnaires.

Results: Between May and Sept 2016, a total of 182 adults (mean age, 57 years; 65% (n=118) men; 31% (n=57) diabetics) underwent randomization (93 MyMedRec; 89 eKidneyCare). Median follow up was 11.4 months (84% completed, 10% medical exit, 6% patient withdrawal). Medication discrepancies were more common in the MyMedRec group (mean 7.3, 5.1 in MyMedRec and eKidneyCare respectively; difference -2.2, 95% CI, -3.8 to -1.1). The number of BP readings taken per month was sustained longer and at significantly higher rates in the eKidneyCare group (median readings per month 16.8 vs 8.6, p<0.0001).

Conclusions: In this study, patients allocated to the eKidneyCare app participated more in self-monitoring behaviours and had fewer medication discrepancies than those

using the commercially available app. Our results suggest that integration and real-time feedback features in the app are critical components for success.

DIALOGUE Phase 2 Extension Studies of BAY 85-3934, Molidustat, a HIF-PH Inhibitor with Daily Oral Treatment in Anemic Subjects with CKD Tadao Akizawa,[2] Iain C. Macdougall,[3] Jeffrey S. Berns,[4] Thomas Bernhardt,[5] Thilo Krueger,[5] Megumi Taguchi,[1] Eriko Ogura,[1] Kazuma Iekushi.[6] *[1]Bayer Yakuhin, Ltd., Osaka, Japan; [2]Showa University School of Medicine, Tokyo, Japan; [3]King's College Hospital, London, United Kingdom; [4]University of Pennsylvania School of Medicine, Philadelphia, PA; [5]Bayer AG, 13353 Berlin, Germany; [6]Bayer Yakuhin, Ltd, Osaka, Japan.*

Background: Renal anemia is one of the most frequent complications of chronic kidney disease (CKD). Traditionally renal anemia is treated with erythropoiesis stimulating agents. The Hypoxia-inducible factor (HIF)-prolyl hydroxylase (PH) inhibitor, molidustat (BAY 85-3934), is developed for the oral treatment of anemia in subjects with CKD.

Methods: The clinical program included 3 randomized, multicenter main studies and 2 controlled, parallel group, open-label, multicenter extension studies, one in non-dialysis and one in dialysis subjects with anemia associated with CKD. Subjects enrolled in the main studies were planned to enter the 2 extension studies to prove long-term safety and efficacy of molidustat for a period of up to 36 months as measured by the change from baseline to post-baseline time points in Hb levels.

Results: In the hemodialysis study, mean Hb values at baseline were similar in the molidustat group (10.40 g/dL) and in the epoetin group (10.52 g/dL). Mean (SD) Hb values during treatment were 10.52 (0.557) g/dL in the molidustat group and 10.37 (0.471) g/dL in the epoetin group. Similar rates of subjects reported a TEAE in the molidustat group (91.2%) compared with the epoetin group (93.3%). In the non-dialysis study, mean Hb values at baseline were similar in the molidustat group (11.28 g/dL) and in the darbepoetin group (11.08 g/dL). Mean (SD) Hb values during treatment were 11.10 (0.508) g/dL in the molidustat group and 10.98 (0.571) g/dL in the darbepoetin group. Similar rates of subjects reported a TEAE in the molidustat group (85.6%) compared with the darbepoetin group (85.7%).

Conclusions: The oral HIF-PH inhibitor, molidustat may offer potential benefits for managing anemia in both dialysis and non-dialysis subjects. Future Phase 3 studies of larger size will be executed to further assess the effects of molidustat.

FR-PO1071

Head-to-Head Efficacy and Safety Comparisons of a Novel Calcimimetic Agent (Evocalcet) with Cinacalcet in Japanese Hemodialysis Patients with Secondary Hyperparathyroidism: A Randomized Clinical Trial Masafumi Fukagawa,[1] Ryutaro Shimazaki,[2] Tadao Akizawa.[3] *[1]Tokai University School of Medicine, Kanagawa, Japan; [2]Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan; [3]Showa University School of Medicine, Tokyo, Japan. Group/Team: the Evocalcet Study Group.*

Background: Cinacalcet is a potent calcimimetic agent used to treat secondary hyperparathyroidism (SHPT) in hemodialysis (HD) patients. Because there are many refractory patients who cannot tolerate cinacalcet owing to gastrointestinal (GI) symptoms, we developed evocalcet, a new oral calcimimetic agent. Here, we compared the efficacy and safety between evocalcet and cinacalcet in Japanese HD patients with SHPT.

Methods: This was a multicenter, randomized, double-blind, double-dummy, parallel-group, phase 3 trial. Evocalcet and cinacalcet were administered within the dose ranges of 1–8 mg/day and 12.5–100 mg/day, respectively. The primary efficacy endpoint was the non-inferiority of evocalcet to cinacalcet at achieving the target intact parathyroid hormone (iPTH) level of 60–240 pg/mL (target range in Japan) during weeks 28–30 (non-inferiority margin, 15% in the per protocol set (PPS)). For safety, adverse events (AEs) related to GI symptoms (abdominal discomfort, nausea, vomiting, abdominal distension, and decreased appetite) and serum calcium levels were evaluated.

Results: In total, 639 subjects were randomized. Among 519 patients in the PPS, the proportion of patients who achieved the target iPTH level was 72.7% (184/253) and 76.7% (204/266) in the evocalcet and cinacalcet groups, respectively. The estimated intergroup difference in the achievement rate was −4.0% (95% CI −11.4%, 3.5%, p=0.002 for non-inferiority). The proportion of patients who achieved a ≥30% reduction in iPTH level from baseline was comparable. GI AEs were observed in 18.6% (evocalcet) vs 32.8% (cinacalcet) of patients (difference −14.2% [95% CI −20.9%, −7.5%], p<0.001). The rates for decreased serum calcium level from baseline were comparable.

Conclusions: Non-inferiority of evocalcet to cinacalcet was verified in terms of PTH suppression, with a lower incidence of GI AEs in the evocalcet group. Our results suggest that evocalcet may be a potent alternative to existing calcimimetics with a wider safety margin for management of SHPT.

FR-PO1072

Effect of Phosphate Binders on Biochemical and Vascular Outcomes in Patients with Non-Dialysis Dependent CKD Csaba P. Kovesdy,[1] Jun Ling Lu,[1] Zhongji Han,[1] Fridtjof Thomas,[1] Leigh D. Quarles,[1] Nabil Jarmukli.[2] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Salem VAMC, Salem, VA.*

Background: Abnormal phosphate (P) homeostasis develops early in CKD and is associated with adverse clinical outcomes. It is unclear if normalization of P homeostasis results in improved clinical outcomes in patients with non-dialysis dependent (NDD) CKD.

Methods: We randomized 120 patients with CKD stages 3-4 in a 1:1:1 ratio to open-label lanthanum carbonate, calcium acetate or dietary phosphorus restriction for one year (3 months titration and 9 months maintenance). The co-primary outcomes were month 12 (vs. baseline) biochemical (serum and urinary P, PTH, calcium, bone-specific alkaline phosphatase [bALP], and FGF-23) and vascular parameters (coronary artery calcium [Agatson score], arterial stiffness [pulse wave velocity, PWV] and endothelial dysfunction [reactive hyperemia index, RHI]) in all patients. Secondary outcomes were between-treatment differences in change for each parameter between month 12 and baseline. All analyses were intention-to-treat.

Results: Patients were 66.1±11.4 years old, 87% male, 52% African American, 55% diabetic, and their baseline eGFR was 32±10 ml/min/1.73m^2. Baseline characteristics were similar between the intervention arms (p>0.5). 107 of 120 (89%) randomized patients completed 12 months of follow-up. Differences were not significant at month 12 (vs. baseline) for any of the outcomes (**Table**) except bALP and FGF-23. Changes for all outcomes were similar in the three arms except for PTH, which was suppressed more effectively by calcium acetate (p<0.001, data not shown).

Conclusions: A 1-year intervention to limit P absorption using dietary restriction or two different P binders resulted in decreased bALP suggesting improvement in bone turnover, but no other significant changes in biochemical or vascular parameters in patients with NDD CKD. (NCT01357317)

Funding: Veterans Affairs Support, Commercial Support - Shire

	Baseline	Month 12	p
Phosphorus (mg/dl)	3.8±0.6	3.7±0.8	0.15

FR-PO1073

Comparison of Lanthanum Carbonate with Calcium Carbonate for the Progression of Coronary Artery Calcification in Hemodialysis Patients Hiroaki Ogata,[2] Masafumi Fukagawa,[3] Hideki N. Hirakata,[1] Tatsuo Kagimura,[4] Tadao Akizawa.[2] *[1]Fukuoka Renal Clinic, Fukuoka City, Japan; [2]Showa University School of Medicine, Yokohama, Japan; [3]Tokai University School of Medicine, Isehara, Japan; [4]Translational Research Informatics Center, Kobe, Japan. Group/Team: On behalf of the LANDMARK Study Group.*

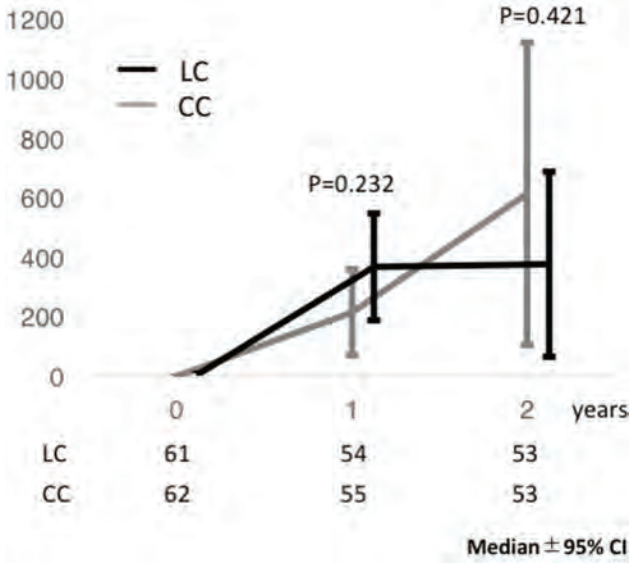
Background: The LANDMARK study is a multicenter, randomized, open-label, parallel assignment study comparing the effects on cardiovascular mortality and morbidity of a non-calcium phosphate (P) binder, lanthanum carbonate (LC), with calcium carbonate (CC) in hemodialysis patients. This adjunct study (LANDMARK-SS) investigated whether LC delayed the progression of coronary artery calcification compared with CC.

Methods: Adult hemodialysis patients with at least one risk factor for vascular calcification (age >65 years, postmenopausal women, type 2 diabetes mellitus), were randomly assigned to receive LC or CC. Doses of LC and CC were titrated to achieve target serum P levels of 3.5–6.0 mg/dL. If this was not achieved with the maximum tolerated dose, other non-calcium-based P binders were added in the LC group and P binders other than LC in the CC group. The primary endpoint was the change in Agatston coronary artery calcification score (CACS) from baseline.

Results: Median changes in CACS in the LC and CC groups were 360 (95% confidence interval [CI], 180–541) and 211 (95%CI 77–366), respectively, at 1 year, and 368 (95%CI 57–680) and 611 (95%CI 105–1118) at the end of the 2-year study. The increase in CACS appeared to lessen after 1 year with LC, but these differences were not statistically significant, and stratified analysis based on concomitant treatment, age, and baseline CACS also showed no significant differences in CACS progression between groups.

Conclusions: We conclude that LC did not significantly attenuate calcification in comparison with CC over 2 years in hemodialysis patients.

Funding: Commercial Support - Bayer Yakuhin, Ltd.



Changes in total Agatston CACS from baseline

FR-PO1074

Efficacy and Safety of Short-Term Treatment with Sodium Zirconium Cyclosilicate (ZS-9) for Hyperkalemia: Open-Label, Phase 3 Trial David K. Packham,[1] Steven Fishbane,[2] Pablo E. Pergola,[3] Edgar V. Lerma,[4] Javed Butler,[5] Stephan Von haehling,[6] Scott H. Adler,[7] Bhupinder Singh,[8,9] Philip T. Lavin,[10] Peter A. McCullough,[11] Mikhail Kosiborod,[12] Bruce S. Spinowitz.[13] *[1]U. of Melbourne, Melbourne, NSW, Australia; [2]Hofstra Northwell Health School of Med., Great Neck, NY; [3]Renal Associates PA, San Antonio, TX; [4]UIC/ Advocate Christ, Oak Lawn, IL; [5]Stony Brook U., Stony Brook, NY; [6]U. of Göttingen Medical Centre, Göttingen, Germany; [7]AstraZeneca, Gaithersburg, MD; [8]ZS Pharma Inc., part of AstraZeneca, San Mateo, CA; [9]University of California, Irvine, Irvine, CA; [10]Boston Biostatistics Research Foundation, Framingham, MA; [11]Baylor U. Medical Center, Dallas, TX; [12]Saint Luke's Mid America Heart Institute, Kansas City, MO; [13]New York Presbyterian Queens, New York, NY.*

Background: Correction of hyperkalemia (HK) is important for the clinical management of patients (pts). Sodium zirconium cyclosilicate (ZS-9) is a selective, inorganic, potassium (K)-binder. We report results of ≤72h of ZS-9 treatment from the largest study of treated HK pts to date.

Methods: This international, open-label, single-arm trial with no dietary K or RAASi restrictions enrolled 751 outpatients (≥18y) with HK (K≥5.1mmol/L). Pts received 10g ZS-9 TID for 24–72h until normokalemic (K3.5–5.0 mmol/L; blood K measured by point-of-care device [iSTAT]). Treatment decisions were based on iSTAT K, generally considered to be highly accurate; efficacy endpoints were based on serum K from central lab per usual practice. Endpoints were achievement of normokalemia, overall response rate (%), change in K from baseline (ΔK), and adverse events (AE).

Results: 99.3% of pts completed. By 24h, ΔK was -0.8 mmol/L (iSTAT, -14.9%; from 5.5 to 4.7 mmol/L) and -0.7 mmol/L (serum, -12.7%; from 5.6 to 4.9 mmol/L). Overall, 99.5% (95% CI [99%, 100%]) of pts achieved normokalemia by iSTAT and 77.9% (95% CI [75%, 81%]) by serum K. 100% of pts experienced a reduction in K (regardless of measurement method) with 92% having K reductions ≥0.5 mmol/L; 0.4% of pts had iSTAT K>5.0mmol/L and 22% had serum K>5.0mmol/L (Figure). 4.1% of pts experienced an AE. Most common were nausea (0.5%) and urinary tract infection (UTI; 0.5%); 1 pt each had peripheral edema and serum K3.0-<3.5mmol/L. UTI was the 1 SAE (resulting in the only hospitalization), and 2 pts discontinued due to AEs (UTI, flatulence, and upper abdominal pain). No deaths occurred.

Conclusions: ZS-9 rapidly and reliably normalized K in nearly all HK pts, with a safety profile similar to prior studies.

FR-PO1075

Novel Intermittent Pneumatic Compression Device Promotes Early Cannulation Tej M. Singh.[1,2] *[1]Palo Alto Medical Foundation, Los Altos Hills, CA; [2]Fist Assist Devices, LLC, Los Altos Hills, CA.*

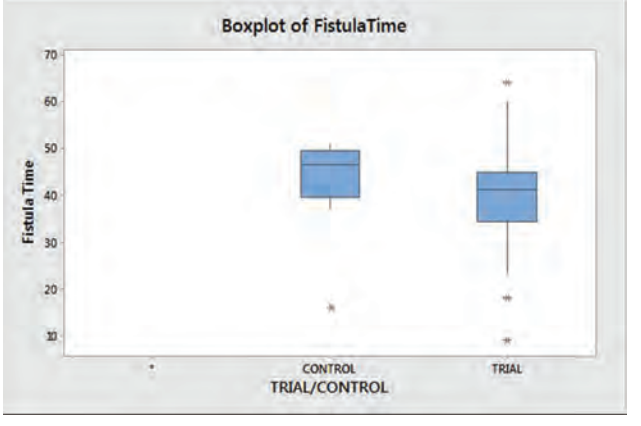
Background: Arteriovenous fistulas (AVF) are the preferred for hemodilaysis access. However, AVF maturation has been poor globally. Poor maturation often leads to increased catheter contact time and costs. Intermittent compression of upper arm veins may aid in forearm vein dilation. Early use of non-invasive devices may help in maturation and possible early AVF needle cannulation.

Methods: After AVF creation, an intermittent pneumatic compression device [Fist Assist® (FA)] was applied to allow cyclic compression of 60 mm Hg daily for 90 days. Fourty (n=40) AVF patients were in the study arm to test vein dilation with FA and needle cannulation time. Of these patients, twenty-four (n=24) had brachiocephalic fistulas (BCF), while seventeen (n=16) had radiocephalic fistulas (RCF). Controls (n=16) used a sham device. Vein size was measured and recorded at baseline and after 90 days by duplex measurement. Clinical results (percentage increase) were recorded and tested for significance. Time to fistula cannulation was recorded as the difference between surgery date and needle placement.

Results: After three months, the mean percentage increase in vein diameter in the FA treatment group with RCF was significantly larger than those with BCF at proximal locations of 5 cm, 10 cm, and 15 cm from the anastomosis (p=0.000, 0.000, and 0.017, respectively) compared to the control group. Fistulas treated with the FA device were cannulated sooner by 4 days in the clinic (Control: 43.8±8/7 days vs. FA: 39.2±9.6) [Table 1]. All fistulas treated with FA are still functional with no reported thrombosis or extravasations.

Conclusions: Improved AVF maturation is important for vascular access care and has been an important goal. Early application of an intermittent pneumatic compression may be successful in AVF maturation at longer time points as demonstrated in this comparative study. Pneumatic devices may assist in early cannulation of AVF.

Funding: Private Foundation Support



MEAN FISTULA TIME A significant decrease in mean fistula time was observed for the Treatment group vs. Control group

FR-PO1076

Prospective, Randomized, Multi-Center, Double-Blind, Controlled, Two-Period, Two-Treatment, Crossover, Phase II Trial to Evaluate the Safety and Efficacy of Alanyl-Glutamine in Peritoneal Dialysis

Andreas Vychytil,[3] Klaus Kratochwill,[1] Rebecca Herzog,[2] Christoph Aufricht.[4] *[1]Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Medical University of Vienna, Vienna, Austria; [2]Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Medical University of Vienna, Vienna, Austria; [3]Medicine III, Nephrology and Dialysis, Medical University of Vienna, Vienna, Austria; [4]Pediatric Nephrology and Gastroenterology, Medical University of Vienna, Vienna, Austria.*

Background: Recent meta-analyses concluded that the past 20 years development of dialysis fluids with low concentration of glucose degradation products did not lead to improved peritonitis rates, membrane failure or technique drop out of peritoneal dialysis (PD) patients. In early clinical testing, addition of alanyl-glutamine (AlaGln) to a single dwell of glucose-based PD fluids restored peritoneal cellular stress responses and leukocyte function. This study tests effects of a novel AlaGln supplemented PD fluid on relevant biomarkers in a nation-wide trial.

Methods: In a prospective, double-blinded, cross-over design (EudraCT-2013-000400-42) stable PD outpatients were enrolled to undergo 16 weeks of treatment, 8 weeks with standard PD fluid (Physioneal 40, Baxter) and 8 weeks with AlaGln supplemented standard PD fluid (Physioneal 40 and Dipetiven [Fresenius-Kabi]), in a randomized order. As primary outcome parameters cancer-antigen 125 (CA-125) appearance rate as marker of peritoneal cell mass and ex-vivo stimulated interleukin 6 (IL-6) release as marker of peritoneal immune competence were assessed in effluents of standard peritoneal equilibration tests at 1h (IL-6 release) and 4h (CA-125).

Results: Out of 54 enrolled PD patients in 8 Austrian centers, 50 patients were randomized. In the full analysis set (n=41), addition of AlaGln significantly increased CA-125 appearance rate (mean treatment difference: 46.7 U/min [95% CI: 23.5-69.9], p=0.0001) and log 10 of ex-vivo stimulated IL-6 release (mean treatment difference: 0.15 [95% CI: 0.04-0.26], p=0.004). Higher levels of stimulated TNFα release and lower levels of peritoneal protein loss supported the beneficial effect of intraperitoneal AlaGln supplementation. No adverse events or safety signals were observed with AlaGln, all peritonitis episodes in the safety population (n=47) occurred during standard PD fluid treatment.

Conclusions: A novel AlaGln-supplemented PD fluid improves important biomarkers of mesothelial cell status and peritoneal immune competence compared to treatment with a standard dual-chamber PD fluid.

Twelve Weeks of Home-Based Exercise Training Improves Strength, Function and Quality-of-Life Measures in Elderly Hemodialysis Patients

Khin N. Chan,[1,2] Payam Massaband,[1,2] Yiming Lit,[1,2] Yu Chen,[1,2] Tieming Niu,[1,2] Jonathan N. Myers.[1,2] *[1]VA Palo Alto Health Care System, Stanford, CA; [2]Stanford University, Palo Alto, CA.*

Background: Maintenance hemodialysis (MHD) patients exhibit significantly impaired physical function and skeletal muscle wasting. We examined whether 12 weeks of home-based exercise training improves cardiopulmonary function, muscle mass, strength, QOL, and cognitive function in elderly MHD patients.

Methods: Twenty-three elderly MHD patients (66 ± 7.7 yrs) were randomized to either a 12-week home-based exercise program (n=9) or usual care (n=14). Measures of peak VO_2, thigh muscle quality (percentage intramuscular fat [IMF]) evaluated by magnetic resonance imaging (MRI), body composition by DXA scan, upper and lower body strength, six-minute walk test (6MWT), and QoL were determined.

Results: Peak VO_2 (ml/kg/min) increased 13% in the exercise group while no significant changes occurred among controls. Exercise time improved 44% in the exercise group while there was 14% reduction among controls (p=0.06). There were no significant changes in thigh muscle IMF % by MRI or leg fat % by DXA in either group. Distance covered during the 6MWT was marginally improved in both groups. Number of sit-to-stand repetitions in 1 minute was improved by 10% in the exercise group and was unchanged in usual care. Exercised patients improved 12 % in lower body strength. Both physical and mental component scores were improved by approximately 12% in the exercise group.

Conclusions: In this interim analysis, we observed that 12 weeks of exercise training is potentially effective in improving cardiopulmonary function, strength and quality of life in elderly MHD patients.

Safety and Cardiovascular Efficacy of Spironolactone (SPL) in Dialysis-Dependent ESRD (SPin-D): A Pilot Trial of the NIDDK Hemodialysis Novel Therapies Consortium

David M. Charytan,[1] Jonathan Himmelfarb,[3] Talat Alp Ikizler,[8] Dominic S. Raj,[2] Jesse Y. Hsu,[6] J. R. Landis,[6] Paul L. Kimmel,[5] John W. Kusek,[4] Alan S. Kliger,[9] Laura M. Dember.[7] *[1]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA; [2]GWU Medical Faculty Associates, Washington, DC; [3]Kidney Research Institute, Seattle, WA; [4]NIDDK, Bethesda, MD; [5]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [6]University of Pennsylvania, Philadelphia, PA; [7]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [8]Vanderbilt University Medical Center, Nashville, TN; [9]Yale New Haven Health System, New Haven, CT.*

Background: Small trials suggest that SPL reduces cardiovascular events in maintenance hemodialysis patients but the optimal dose for a large, clinical outcomes trial is unknown.

Methods: Multicenter, randomized, double-blind placebo(PL)-controlled trial of SPL at 12.5, 25, or 50 mg per day for 36 weeks for patients receiving maintenance hemodialysis. The trial aimed to evaluate safety (primary) and generate estimates of efficacy on cardiac structure and function. Randomization was based on a 2:1 ratio for PL vs each SPL dose.

Results: 129 patients were randomized. Hyperkalemia and hypotension events were more frequent with SPL 50 mg/day than with lower doses, but did not result in more frequent study drug reduction or discontinuation than PL (Table). There were no differences in change from baseline to week 36 in the primary efficacy measure of diastolic function.

Conclusions: SPL appears to be reasonably safe at doses ranging from 12.5 to 50 mg per day in a clinical trial setting with regular monitoring. The greater rate of hyperkalemia at 50 mg suggests that safety measures such as dose titration/reduction algorithms should be incorporated in a clinical outcomes trial if a 50 mg dose is used.

Effect of Hemodialyzer Characteristics on the Prognosis of Elder Dialysis Patients with Early Dialysis Stage (E-HOPED Study)

Ikuto Masakane,[1] Jun Minakuchi,[2] Hideki Kawanishi,[4] Kosaku Nitta.[3] *[1]Honcho-Yabuki Clinic, Yamagata, Japan; [2]Kawashima Hospital, Tokushima, Japan; [3]Tokyo Women's Medical University, Shinjuku-ku, Japan; [4]Tsuchiya General Hospital, Hiroshima, Japan. Group/Team: E-HOPED Study Group.*

Background: Increasing older dialysis patients have to continue dialysis because of few chances of renal transplantation so that it has been an urgent issue what kind of

dialysis prescription could ameliorate QOL and survival rate of them. In recent years high flux dialysis have been universally performed, however, its evidences have not been established especially for elder dialysis patients.

Methods: Eight hundred and two incident dialysis patients as greater than 70 years old were recruited to the study. The patients were randomly assigned to the following 2 groups; Group A as treated with low flux ethylenevinylalcohol (EVAL) membrane, Group B as treated with high flux synthetic membranes mainly of polysulfone (PS). 5-year survival rate as the primary outcome was compared between Group A and Group B by Kaplan-Meier Analysis. Secondary outcomes such as body weight, serum creatinine, serum albumin and hemodynamic indices during dialysis were also evaluated. Safety evaluation were performed on cause of death, CVD event, hosipitalization and vascular access failure.

Results: Seven hundred thirty-four patients, 363 patients in Group A and 371 patients in Group B, were analyzed for survival rate as a full analysis set. The mean age in each group was 78.1 in Group A and 77.9 in Group B. One-year, 2-year, 3-year, 4-year and 5-year survival rates in each group were 95.6%, 87.1%, 80.1%, 67.7% and 60.9% respectively in Group A; 95.3%, 89.3%, 84.9%, 79.4% and 68.9% in Group B. There were no differences between Group A and Group by Kaplan Meier analysis (Log-rank P value, 0.089). Secondary outcomes and safe aspects were not different between Group A and Group B.

Conclusions: In the current study, we did not find beneficial effects of high flux dialysis on the elder dialysis patients survival. Recently several adverse effects of PS membrane have been reported such as anaphylaxis, thrombocytopenia and deterioration in peripheral circulation during dialysis session and these could be recognized to be related to the bioimcopmpatibility of PS membrane. EVAL membrane is biocompatible especially for hemodynamic stability during dialysis session. Biocompatible aspect of EVAL membrane might have modified the outcome of elder dialysis patients even if it is a low flux membrane.
