Results: LN Classes were: II, III, IV, V, VI (n=9, 25, 21, 13,1). Compared to Class II, patients with Class III-V had higher MCP-1 and lower EGF/MCP-1 whereas EGF was not different. High MCP-1was independently associated with Class III-V. Patients with high activity index (AI ≥7) had higher MCP-1 and lower EGF/MCP-1 compared to patients with low AI. Patients with high chronicity index (CI≧3) had lower EGF/MCP-1 compared to patients with low CI. MCP-1 was higher in patients with wireloop, karryorhexis, tubulitis, tubular atrophy, interstitial fibrosis and EGF/MCP1 was lower in patients with PMN infiltration, wireloop, karryorhexis and cellular infiltration compared to patients without these features. In Class III-IV patients with 6 months follow-up (n= 41), 36 responded to immunosuppression and 27 were non-responders (NR). EGF was higher in Responders [EGF (ng/mg Cr): Responders: 141 (74, 283) vs NR: 57 (24, 87), p=0.025] whereas MCP-1 or EGF/MCP-1 were not different. EGF (per ng/ mg Creatinine) was independently associated with response to immunosuppression [OR (95%CI): 1.02 (1.00-1.034), p=0.034.]

Conclusions: Overall, MCP-1 was higher in LN with adverse histopathological features. Among Class III-IV patients, the response to immunosuppressive therapy at 6 months was independently associated with low baseline EGF, but not high MCP-1.

Lupus-Like Glomerular Immune Complex Deposits in a Subset of Patients with Liver Cirrhosis – Histologic Features and Clinical Correlates Anjali A. Satoskar,[2] Jessica Hemminger,[2] Vidya Arole,[2] Isabelle Ayoub,[1] Tibor Nadasdy.[2] *[1]Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH; [2]Pathology, Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Glomerular IgA deposits have been previously reported in patients with liver cirrhosis as incidental findings, mainly in autopsy studies. We recently encountered patients with liver cirrhosis presenting with acute kidney injury and large lupus-like glomerular immune deposits. None had systemic lupus erythematosus. Our aim was to systematically elucidate their clinical and biopsy features, and treatment outcomes.

Methods: We searched our kidney biopsy database over a 13-year period, from January 2004 to December 2016 for all native kidney biopsies from patients with cirrhosis.

Results: We found 118 kidney biopsies from cirrhotic patients, 76/118 had glomerular IgA staining. Nine of these 76 had large IgA, IgG and C3 containing glomerular immune complex deposits (Fig 1) and proliferative glomerulonephritis. Six of 9 patients had concomitant acute bacterial infection, prompting a biopsy diagnosis of infection-associated glomerulonephritis and treatment with antibiotics. In the remaining 3/9 patients, infectious workup was negative and were administered steroids. Overall clinical outcomes were poor among the 9 patients, but 2/6 patients treated with antibiotics (1 with liver transplant), and 1/ 3 patients on steroids recovered renal function.

Conclusions: These cases provide support to the theory that advanced liver failure can compromise the ability to clear circulating immune complexes, contributing to the build-up of large immune complex deposits in the kidney and concomitant bacterial infection probably provides a "second-hit" triggering acute glomerulonephritis in at least a subset of these patients. A trial of antibiotics is recommended and caution is advised before administering immunosuppressive treatment. Bacterial infection can be subtle and difficult to diagnose. However, both diagnosis and management of glomerulonephritis in these patients remains a challenge.

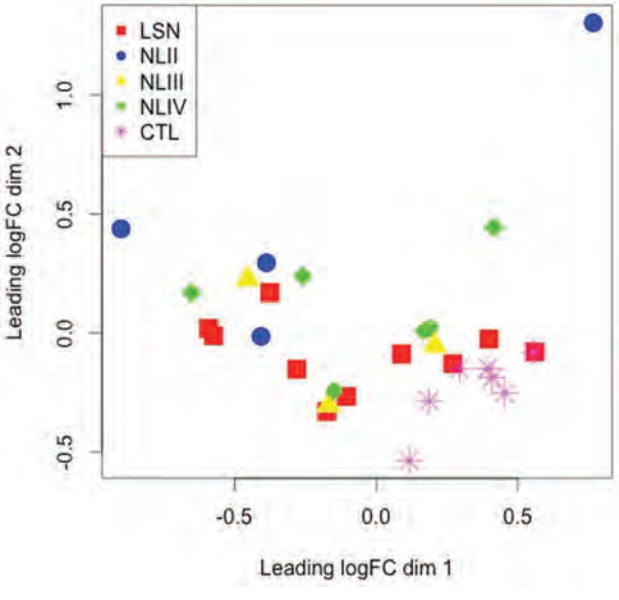
Lupus Nephropathy: Clinical-Pathological Description of 400 Cases of the Colombian Caribbean Region and Variations in the Expression of Plasma MicroRNAs Gustavo Aroca Martinez,[2,3] Alex Domínguez,[2] Elkin Navarro,[4] Henry J. Gonzalez Torres,[4] Diana Silva,[2] Juan C. Conde,[3] Lisneth Almendrales,[4] Eduardo Egea bermejo,[5] Antonio Iglesias Gamarra.[1]
[1]Universidad Nacional de Colombia, BOGOTA, Colombia; [2]Medicine, Universidad Simón Bolívar, Barranquilla, Colombia; [3]Nephrology, Clínica de la Costa, Barranquilla, Colombia; [4]Universidad Simon Bolivar, Barranquilla, Colombia; [5]Universidad del Norte, Barranquilla, Colombia.

Background: Lupus nephritis (LN) is one of the most serious manifestations of systemic lupus erythematosus (SLE). Renal biopsy allows diagnosing the histopathological classes of LN, however, it is an invasive technique associated with risk of hemorrhage. It is a priority to characterize noninvasive diagnostic tests and alterations in the differential expression of microRNAs (miRNAs) to measure LN activity. The objective was describe the clinical-pathological characteristics and to analyze the differential expression of a group of plasma miRNAs in patients with LN.

Methods: Retrospective analytical study. 400 patients are included with LN diagnosed by renal biopsy of the Caribbean Region between January 2008 and December 2016. Differentially expressed miRNAs were selected by Illumina and their diagnostic ability was validated by qPCR in 100 patients with LN.

Results: 400 patients, 86% were women. Average age of 37 ± 13.2 years. Mean follow-up time: 48 ± 20 months. Main syndromic diagnoses: nephritic syndrome (51%). Histological class: IV (70.7%), III (19.3%), II (6.5%). 234 (58%) patients did not achieve remission at 48 months. The miRNAs proposed as candidates were: miR-221-5p, miR-380-3p, miR-556-5p, miR-758-3p and miR-3074-3p, for their high sensitivity (97%) and specificity (70.3%); Positive predictive value (82.5%), negative predictive value (96%) and diagnostic efficacy (87.9%).

Conclusions: The miRNAs (miR-221-5p, miR-380-3p, miR-556-5p, miR-758-3p and miR-3074-3p) are possible diagnostic biomarkers and the differential expression pattern of miRNA would have significant implications in the pathophysiology of LN.



FR-PO733

Full House Immunofluorescence Nephropathy in Patients with Negative Clinicopathological Spectrum for Systemic Lupus Erythematosus Milagros M. Flores fonseca,[1] Arisbeth Villanueva-Perez,[1] Victor M. Martinez-Mejia,[1] Benjamin Gomez-Navarro,[1] Claudia A. Mendoza cerpa,[1] Viridiana Rodriguez,[1] Sandra F. Velasco,[2] Jorge Andrade-Sierra.[1]
[1]Nefrologia y Trasplantes, Centro Medico Nacional de Occidente (CMNO). Instituto Mexicano de Seguridad Social (IMSS), Guadalajara, Mexico; [2]Quimica, Universidad de Guadalajara, Guadalajara, Mexico.

Background: The renal histologically evidence of Systemic Lupus Erythematosus (SLE) and its classic situation for full house positive immunostaining detection; IgA, IgM, IgG, C1q and C3 deposits; occurs in lupus nephritis (LN). However, these pattern may be present in the absence of SLE on other entities such as liver disease, diabetes mellitus, infections and other glomerulonephritis (GN).

Methods: Records of 22 kidney biopsies with full-house IF nephropathy with negative clinicopathological spectrum for SLE. We evaluated at the time of renal biopsy findings including demographics, clinical presentation, laboratory data, renal biopsy findings and clinical follow up.

Results: Of the 22 full house IF nephropathy biopsies the histological diagnoses included minimal change disease (5%), focal and segmental glomerulosclerosis (13%), membranous GN (27%), IgA nephropathy (9%), membranoproliferative GN (27%), C1q GN (5%), post infectious GN (9%) and ANCA associated GN (5%). Six patients originally with full house with no SLE spectrum developed SLE in a range between 8 to 20 months of clinical follow up.

Conclusions: Full-house IF pattern it is commonly associated with morphologic evidence of LN. Although it is a characteristic not exclusively of LN, our report showed that full nephropathy is present in other type of GN. Furthermore, 6 of 22 patients on clinical follow up developed clinical and not just morphologic characteristics of SLE. Full house nephropathy is still a diagnostic challenge, may be associated with other systemic and infectious diseases. As clinicians we should insist in strict follow-up and always be alert of possible develop overt of SLE.

Idiopathic Non-Lupus Full House Nephropathy Compared to Lupus Nephritis Cristiane B. Dias,[1] Leonardo A. Testagrossa,[4] Denise M. Malheiros,[3] Lectícia Jorge,[4] Viktoria Woronik.[2] *[1]University of Sao Paulo, Brazil, São Paulo, Brazil; [2]None, Salvador, Brazil; [3]University of Sao Paulo, Sao Paulo, Brazil; [4]University of São Paulo, São Paulo, Brazil.*

Background: Full house pattern is defined by the concomitant deposition of immunoglobulins G, A and M and two components of the complement system in renal tissue identified by immunofluorescence. Non-lupus full house nephropathy (NLFN) is the patients with full house pattern but which did not fulfill criteria for the diagnosis of systemic lupus erythematosus. Due to the rarity of NLFN we studied our case series comparing with lupus nephritis.

Methods: All biopsies from January 2000 to September 2016 with full house pattern were collected from the Pathology and Nephrology Discipline at Hospital das Clinicas of São Paulo. Patients with confirmed diagnosis of Lupus Nephritis were used for comparison. Clinical and laboratory data at the time of renal biopsy and at the end of follow-up were retrieved.

Results: In this period, 16 patients had a diagnosis of non-lupus full house nephropathy, with a mean age of 36.8 ± 10.7 years, with 10 men (62.5%), median serum creatinine of 1.1 (0.8-1.0) mg/dL and mean proteinuria of 7.0 ± 4.6g/day. The most frequently optical

microscopy pattern found was membranoproliferative glomerulonephritis in 7 cases (43.80%) and membranous glomerulopathy in 4 cases (25%). Regarding the evolution, 3 patients fulfilled criteria for systemic lupus erythematosus, 2 patients were diagnosed with schistossomosis and 1 cryoglobulinemia. Ten patients with idiopathic form were compared with a group with lupus nephritis and did not have difference with respect to renal survival [Table1].

Conclusions: Non-lupus full house nephropathy is a rare condition, affecting equality men and women and has same renal survival than lupus nephritis.

Comparison of clinical and laboratory data on the diagnosis and renal outcomes of patients with idiopathic non-lupus full house nephropathy vs lupic nephritis

	Idiopathic Non Lupus Full House Nephropathy	Lupus Nephritis	p

A Novel Method of Urine Protein Isolation Allows for Identification of Kidney Disease Protein Biomarkers Using Mass Spectrometry Analysis John P. Shapiro,[1] Juan M. Mejia-Vilet,[2] Daniel J. Birmingham,[1] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: Characterization of the urine proteome using mass spectrometry (MS) provides an opportunity to identify kidney disease biomarkers. This approach has proven challenging due to salt content, pH and other physicochemical qualities that interfere with MS. We describe a novel, simple method that attenuates these properties of urine and allows for robust quantitative urine proteome characterization.

Methods: Urine (1ml) from healthy individuals (control) or patients with class IV lupus nephritis (LN-IV) was placed in Nunc MaxiSorp ELISA plates and incubated 16 hr at 4oC. Wells were washed 2x with PBS, 2x with 50 mM NH3HCO3 and incubated with trypsin in 50 mM NH3HCO3 for 7 hours at 37oC. Acetonitrile (ACN) was added to each well, mixed, collected and pooled. Peptides were dried, resuspended in 10 µl 2% ACN, 0.1% formic acid and analyzed by LC-MS/MS on a Thermo-Fisher Orbitrap XL mass spectrometer.

Results: MS identified 356 proteins, 63 of which demonstrated a ≥3-fold change in expression between control and LN-IV (all $p<0.05$). Several serum proteins such as albumin and serotransferrin were detected at higher levels in LN-IV (27-, 65-fold respectively) than control. In contrast, many proteins known to be expressed by the kidney were present in control urine but were undetectable or significantly decreased in LN-IV urine. Examples include uromodulin, extracellular sulfatase, EGF, kininogen-1, and cubulin, down-regulated (7-, 9-, 12-, 7- and 9-fold, respectively). Other attenuated proteins include amiloride-sensitive sodium channel subunit gamma and sodium/potassium-transporting ATPase subunit gamma, down-regulated 4- and 3-fold, respectively.

Conclusions: This method demonstrates the effects of lupus nephritis on urine protein profiles. As expected, serum proteins prominent in the urine of LN-IV are absent or present in small amounts in control urine. The absence or diminished expression of proteins in LN-IV urine that are present in control urine suggests specific attenuation due to LN-induced renal injury and may provide a way to assess the health of renal parenchyma. This method may provide a rapid means of preparing urine for clinical MS analysis.

FR-PO736

Pure Lupus Membranous Nephritis with Only IgG Deposits on Immunofluorescence Behaves Like Full House Pattern Gisele Vajgel,[1] Camila B. Oliveira,[1,2] Denise M. Costa,[1,2] Carolina A. Vasconcelos,[2] Maria Alina G. Cavalcante,[1] Lucila Maria Valente.[1] *[1]Nephrology, Hospital das Clinicas - UFPE, Recife, Brazil; [2]Nephrology, IMIP, Recife, Brazil.*

Background: Pure lupus membranous nephritis (LMN) may present with only IgG deposits on immunofluorescence (IF) resembling idiopathic membranous nephritis. We aim to evaluate if patients with LMN and only IgG (±C3) have the same outcome as those with IgG plus other Ig/C1q deposits.

Methods: Adult patients with a diagnosis of lupus (≥ 4 SLICC criteria) and pure LMN between 2004 and 2016 were retrospectively evaluated. Complete response, partial response and relapse were defined by KDIGO criteria.

Results: Thirty-one patients out of 42 were selected; the remaining was excluded due to lack of data or follow-up less than 12 months. Clinical characteristics are shown in Table 1. Drugs used for treatment were different between groups at the beginning (p=0.02) and at 12mo (p=0.02), but more homogeneous at the end of follow-up (p=0.15). Complete and partial response for only IgG and IgG+Ig/C1q group were not different between groups at 12mo (71.4% vs 95%; p=0.16), 24mo (83.3% vs 92.3%; p=1.0) and at last follow-up (75% vs 95.6%; p=0.16).

Conclusions: Despite lack of full house pattern on IF, lupus membranous nephritis patients with only IgG deposits seems to have the same outcome as those with typical full house or IgG plus other Ig/C1q pattern.

The Relationship between Immunological Activity Markers and the Presence of Crescents in Renal Biopsy in Patients with Lupus Nephritis Katarzyna Kanclerz,[3,4] Michal Komorniczak,[1] Barbara Bullo-Piontecka,[1] Agnieszka Perkowska-Ptasinska,[2] Alicja Debska-Slizien.[1] *[1]Department of Nephrology, Transplantology and Internal Medicine, Medical University of Gdansk, Gdansk, Poland; [2]Department of Transplantation Medicine, Nephrology and Internal Diseases, Transplantation Institute, Medical University of Warsaw, Warsaw, Poland; [3]Department of Nephrology, Transplantology, and Internal Medicine, Medical University of Gdansk, Gdansk, Poland; [4]Department of Occupational, Metabolic, and Internal Medicine, Medical University of Gdansk, Gdansk, Poland.*

Background: Among lupus nephritis (LN) patients (pts) various forms of crescents can be observed in the majority of glomeruli in renal biopsy. The objective of the study was to assess the relationship between the presence of crescents in renal biopsy and levels of immunological activity markers in LN pts.

Methods: The study group consisted of 29 W and 8 M, mean age 35.43 ± 11.22 years (range 18-66,) with biopsy proven LN. Anti-dsDNA and anti-C1q antibodies, complement component 3 (C3) and complement component 4 (C4), IgG concentrations and circulating immune complexes (C1q and C3d) represent the markers of immunological activity of the disease. Percentage of cellular crescents and percentage of all types (cellular, fibrous, fibrocellular) of crescents were evaluated in renal biopsy.

Results: The study revealed a statistically significant correlation between the percentage of all crescent types with the serum C3 level (r=-0.50; p=0.002) and anti-dsDNA antibodies (r=0.40; p=0.015). Furthermore, a substantial negative relationship between all types of cellular crescents with C3 (r=-0.55; p=0.002) and the IgG concentration (r=-0.34; p=0.039) was noted. However, no statistically important interrelation between the presence of renal crescents and anti-C1q antibodies of circulating immune complexes was found.

Conclusions: Activity of LN, evaluated using immunological markers (including a low level of C3 and a high level of anti-dsDNA), corresponds with a more aggressive form of nephropathy, associated with numerous crescents in renal biopsy.

FR-PO738

Concordance of Clinical and Histological Response on Lupus Nephritis Patients Diana A. Aguirre Campos, Jesus Arellano, Adolfo Navarro escamilla, Blanca Martinez-Chagolla, Luis A. Mariscal. *Hospital General Dr. Miguel Silva, Morelia, Mexico.*

Background: Renal response in lupus nephritis usually exclude the renal histology component. There are discordance between clinical findings and the histological activity. Recent studies has suggested that repeat biopsy after induction therapy may be useful to evaluate response to immunosuppressive therapy. The objective was to compare the concordance between clinical and histological response on proliferative lupus nephritis patients.

Methods: This retrospective study included patients between June 2010 and May 2017 with proliferative lupus nephritis who had a control biopsy after induction treatment. We evaluate complete clinical response (CCR), partial clinical response (PCR) and no clinical response (NCR) according to ACR criteria. The histological response (HR) was defined as an activity index less or equal to 3 in the control biopsy. For concordance analysis we evaluate by 2 criteria: the first (CR1) defined as Non Responders the patients with PCR and NRC. The second criteria (CR2) take as Non responders only the NRC patients. Concordance was evaluated by Kappa coefficient.

Results: We included 19 patients, 7 of them with lupus flare; 15 women (78.9%); mean age 27.4±5.79 years old and follow-up of 384±116 days. The control biopsy was performed between 6 to 12 months after the start of the treatment. At control biopsy 5 patients (26.31%) had CCR, 5 (26.31%) PCR and 9 (47.36%) NCR. Twelve patients

(63.1%) had histological response and 7 (36.8%) without histological response. The concordance between clinical and histological response was 0.53 in the CR1 criteria, and 0.47 in the CR2 criteria.

Conclusions: The study show a low concordance between clinical and histological response in proliferative lupus nephritis.

FR-PO739

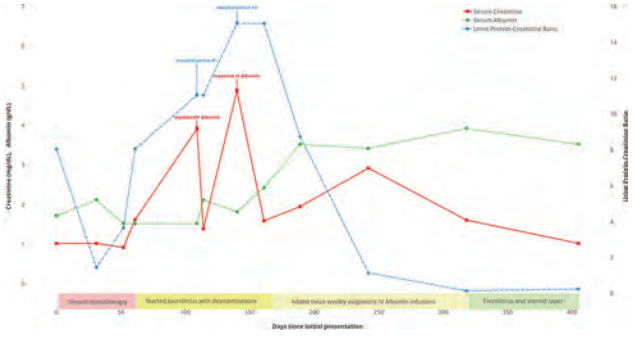
A Patient with "Albumin-Dependent" Focal Segmental Glomerulosclerosis Margaret Duffy,[2] Matthew Palmer,[1] Vishnu S. Potluri,[2] Jonathan J. Hogan.[2] *[1]Pathology, University of Pennsylvania, Philadelphia, PA; [2]Nephrology, The University of Pennsylvania, Philadelphia, PA.*

Background: Idiopathic focal segmental glomerulosclerosis (FSGS) can present with severe volume overload and acute kidney injury (AKI). Here we present such a patient with idiopathic FSGS complicated by multiple episodes of severe AKI and diuretic-resistant volume overload that was only responsive to IV albumin therapy.

Methods: A 54 year-old Jamaican woman developed nephrotic syndrome (SCr 0.86 mg/dL, UProt:Cr 8 g/g, SAlb 1.7 g/dL). A kidney biopsy revealed tip-variant FSGS. She achieved partial remission within four weeks with prednisone 120 mg/d, but then relapsed (UProt:Cr 3.6, SAlb 2.1 g/dL). She was hospitalized with oliguric AKI (Scr 3.89 mg/dL) and volume overload refractory to high-dose IV diuretics and developed candida esophagitis and *C. difficile* colitis. Steroids were tapered and she was treated with IV albumin (25%, 1 mg/kg q8h), with improvement in her SCr (1.37 mg/dL) and urine output (8L) within 24 hours (see image). Tacrolimus was started and she was discharged. She was then re-admitted for volume overload, hypoalbuminemia, and AKI that only responded to 25% IV albumin. Tacrolimus levels were undetectably low. We hypothesized that her acute anasarca led to her inability to absorb tacrolimus. We therefore treated her aggressively with 5 sessions of intermittent ultrafiltration, 5 sessions of plasma exchange therapy with albumin replacement, and pulse oral dexamethasone (40 mg/week). Her AKI again resolved and she was discharged on weekly dexamethasone, oral tacrolimus, and biweekly outpatient albumin infusions. With this therapy she achieved complete remission with target tacrolimus trough levels 6-8 µg/L. She was weaned off steroids and IV albumin. She has been in complete remission for five months on tacrolimus monotherapy.

Results:

Conclusions: We present a case of idiopathic FSGS with a rare and extreme phenotype of severe volume overload and recurrent AKI. In these cases, IV albumin therapy should be considered, particularly for patients who were previously steroid-responsive and may therefore be responsive to other immunosuppressive agents.



FR-PO740

Urinary Extracellular Vesicle-Derived Markers for Steroid Resistant FSGS Ilse M. Rood,[1] Michael Merchant,[2] Daniel W. Wilkey,[2] Johan Van der vlag,[1] Jack F. Wetzels,[1] Jon B. Klein,[2,3] Jeroen Deegens.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]University of Louisville Kidney Disease Program, Louisville, KY; [3]Robley Rex Veterans Administration Medical Center, Louisville, KY.*

Background: Urinary extracellular vesicles (uEV) contain many proteins that may serve as biomarkers in renal disease. We compared the proteome of uEV from patients with biopsy proven focal segmental glomerular sclerosis (FSGS) with a steroid resistant nephrotic syndrome (SRNS; n=3), FSGS with steroid sensitive nephrotic syndrome (SSNS; n=3), FSGS with a partial remission on steroids (PR; n=3), minimal change disease (MCD; n=3), secondary FSGS (n=3) and normal healthy controls (NC; n=3). We hypothesized that the proteome of uEV could reveal a marker to predict steroid resistance in patients with FSGS.

Methods: UEV were isolated and analyzed using a multiplexing approach (TMT-labeling) and LCMS methods (1D-RP-HPLC-ESI-LTQ-VELOS-Orbitrap and Proteome Discover Software).

Results: In total 503 different proteins were identified with at least two peptides (with peptide and protein threshold of 95% with a false discovery rate of 0.5%). Comparison of FSGS SRNS to SSNS (including FSGS-SSNS, PR and MCD) indicated changes (unadjusted t-test $p<0.05$) in abundance of 26 proteins. In FSGS SRNS 17 proteins were downregulated, of which four proteins without any overlap of abundance compared to SSNS, secondary FSGS and normal controls. Nine proteins were upregulated, of which three proteins without any overlap compared to SSNS, secondary FSGS and normal controls. Many of these are related to the complement system.

Conclusions: We identified 26 extracellular vesicle-derived proteins that were significantly different between FSGS SRNS, compared to SSNS. Further analysis will be conducted to identify (a subset of) proteins that maybe considered as candidate biomarkers for FSGS SRNS.

FR-PO741

Collapsing FSGS: Vascular Injury as a Cause of Secondary Collapsing Glomerulopathy? Francois Gougeon,[2,5] Harsharan K. Singh,[3] J. Charles Jennette,[4] Volker Nickeleit.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]UNC-Chapel Hill Nephropathology, Chapel Hill, NC; [3]University of North Carolina School of Medicine, Chapel Hill, NC; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Pathologie, Université de Montréal, Montréal, QC, Canada.*

Background: Collapsing glomerulopathy (CG) has been associated with various diseases such as infections, diabetes mellitus or auto-immune diseases. In renal allografts CG has occasionally been linked to perfusion abnormalities. At present a systematic review of CG and concurrent other renal diseases is lacking

Methods: We searched our database for a biopsy diagnosis of CG in native and transplant kidneys between 01/2011 and 01/2016. Among 7641 cases 4.4% (322) showed CG in an initial index biopsy. Tip variant FSGS 51/7641 (0.7%) served as one control cohort. Cases were grouped as: 1) "pure": no other significant kidney disease, 2) presumptive "secondary": with concurrent other significant renal diseases

Results: CG was more often secondary than the tip-variant (152/322, 47% vs. 14/51, 28%; $p<0.01$; table 1). In the study set three disease categories were significantly more often diagnosed in secondary CG: severe arterionephrosclerosis (AS; 25%), membranous glomerulopathy (MGN, 15%) and thrombotic microangiopathies (TMA, 9%; all $p<0.01$). In comparison secondary tip variant FSGS showed tightest associations with MGN and no association with TMA. In transplants, 21/30 (70%) of CG cases were classified as secondary: 7/21 had prominent vascular sclerosis and 4/21 antibody mediated rejection with microvascular injury

Conclusions: In conclusion: CG but not tip-variant FSGS is commonly associated with concurrent renal diseases. Secondary CG is significantly linked to vascular injury (AS, TMA, rejection with capillaritis). These findings further understanding of CG and pending future studies can streamline diagnostic decision making

	CG	Tip lesion	Total cohort

Clinical and Pathological Analysis of Patient Presenting Renal Lesion and Monoclonal Gammopathy: A Retrospective Study of 64 Patients with Biopsy-Proven Renal Diseases Chao Li, Yubing Wen, Hang Li, Jianfang Cai, Xuemei Li, Xuewang Li. *Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medicine Sciences & Peking Union Medical College, Beijing, China.*

Background: Patients with monoclonal gammopathy can develop a variety of related renal lesions or possibly have kidney disease unrelated to their monoclonal gammopathy. We characterized the spectrum of renal diseases associated with monoclonal gammopathy and unrelated renal diseases.

Methods: Hospitalized patients in Peking Union Medical College Hospital who underwent renal biopsy between January, 2013 and December, 2015. They had monoclonal gammopathy on Serum protein electrophoresis (SPE), serum immunofixation electrophoresis (IFE), urine IFE and/or serum free light chain (FLC). 64 patients met the inclusion criteria and were classified as MGRS (n=36), MGUS (n=17) and hematologic malignancy (n=11).

Results: Renal lesions in MGRS subgroup included light chain amyloidosis(AL) (n=28, 77.8%), light chain deposition disease(LCDD) (n=7,19.4%), and fibrillary glomerulopathy (n=1, 2.8%). Renal diseases in MGUS subgroup included membranous nephropathy (n=10, 58.8%), FSGS (n=3, 17.6%), diabetic glomerulopathy (n=1, 5.9%), Henoch-Schonlein purpura nephritis (n=1, 5.9%), anti-GBM disease concurrent with membranous nephropathy (n=1, 5.9%) and glomerulomegaly (n=1, 5.9%). Various renal lesions related/unrelated to hematologic malignancy were seen in third subgroup, including light chain cast nephropathy (n=3, 27.3%), tubulo-interstitial lesions (n=2,

18.2%), LCDD(n=1, 9.1%), IgA nephropathy (n=1, 9.1%), MesPGN (n=1, 9.1%), endocapillary proliferative glomerulonephritis (n=1, 9.1%) and acute tubular necrosis (n=1, 9.1%). Positive rate of SPE, SIFE and UIFE in MGRS subgroup were 40.6%, 52.8% and 69.4%, respectively. Positive rate of SPE, SIFE and UIFE in MGUS subgroup were 68.8%, 100% and 37.5%, respectively. Positive rate of SPE, SIFE and UIFE in hematologic malignancy subgroup were 54.5%, 72.7% and 81.8%. MGRS and MGUS subgroups differed significantly in positive rate of SIFE (P<0.001). Abnormal rates of serum FLC ratio in above three subgroups were 83.3%, 17.6% and 90.9%, respectively, in which MGUS group was significantly lower than other two groups(P<0.001,P<0.001).

Conclusions: The significance of monoclonal gammopathy in patients with renal disease should be evaluated by other clinical data, as well as renal pathology.

FR-PO743

Clinical, Pathological, and Mass Spectrometry Analysis of AL Renal Amyloidosis

Mingxi Li, Ying Sun, Yubing Wen, Limeng Chen, Xuemei Li. *Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medicine Sciences & Peking Union Medical College, Beijing, China.*

Background: In recent years, laser micro-dissection combined with mass spectrometry (LMD/MS) has been applied in the diagnosis of renal amyloidosis, it can be used for typing of amyloid deposits where routine immunohistochemistry (IHC) is equivocal and negative, as well as finding new causes of amyloidosis, In this study, we retrospectively analysis the patients with AL amyloidosis to evaluate the significance of immunoperoxidase (IP) and establish LMD/MS technique for diagnosing renal amyloidosis.

Methods: We analyzed 45 cases of AL amyloidosis patients diagnosed by Congo Red Staining (CRS) and EM who were admitted during last 5 years in a single centre, analyzed their clinical manifestations and pathological findings, then selected 20 cases with inconclusive immunofluorescence (IF) results, performed IP and LMD/MS for amyloid typing. For IP, both κ and λ were stained. For LMD/MS analysis, 7-μm sections were prepared and CRS positive area was collected by laser microdissection, the minimum area for each case was 200,000μm^2. Sample microdissected was digested by trypsin. Peptides were quantified using Thermo Fusion Lumos mass spectrometer. MASCOT software was used for identification of proteins. Scaffold 4 software was used to integrate the results.

Results: Patients with AL renal amyloidosis had mutiple organs involvement, including kidney, liver, heart and intestinal system. Eleven (55%) of the 20 cases could be typed by IP technique. Amyloid materials could be identified in eighteen (90%) of the 20 cases by LMD/MS. Figure 1A and 1B were Mascot results of AL-κ and AL-λ amyloidosis subtyped by LMD/MS respectively.

Conclusions: Our study showed IP is superior to IF and MS-based proteomic analysis is complementary to IHC in typing of renal amyloidosis.

Sensitivity and Specificity of Immunofluorescence for Diagnosing Renal Immunoglobulin-Derived Amyloidosis Compared to Mass Spectrometry

M. Lourdes Gonzalez Suarez, Pingchuan Zhang, Samih H. Nasr, Mary E. Fidler, Insara Jaffer Sathick, Wonngarm Kittanamongkolchai, Paul J. Kurtin, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Background: Immunoglobulin light chain (AL) amyloidosis is the most frequent type of renal amyloidosis in the U.S., accounting for 81% of cases. Accurate typing is crucial for early diagnosis and treatment of immunoglobulin-derived (AIg)-amyloidosis (i.e. AL, AH (Ig heavy chain), AHL (Ig heavy and light chain)) and to avoid treating other types with potentially toxic chemotherapy. Immunofluorescence (IF) is the first step to type renal AIg-amyloidosis but the performance characteristics of this method are largely unknown. In this study, we aim to establish the sensitivity and specificity of IF for diagnosing AIg-amyloidosis in patients whose amyloid typing was performed by the current gold standard, laser microdissection/mass spectrometry (MS).

Methods: Renal biopsy pathology reports (2008-2015) from several institutions with diagnosis of amyloidosis by IF, which underwent a confirmatory diagnosis and typing by MS done at our center, were reviewed. Reported IF staining for kappa or lambda ≥ 2+, with weak or no staining (0, trace or 1+) for other antigens was considered positive for AL by IF.

Results: We reviewed 170 renal pathology reports. Of these, 104 cases were confirmed as AIg-amyloidosis on MS and 66 were non-AIg (including AA, ALECT2, AApo AI, AApo AII, AApo AIV, AGel, AFib) (table). IF sensitivity was 84.6%; 16 could not be diagnosed as AIg-amyloidosis by IF due to weak staining for all antigens. Lower sensitivity could be in part related to selection bias as cases with clear-cut IF findings of AL may not have undergone testing by MS. IF specificity was 92.4%; 5 cases were misdiagnosed as AIg-amyloidosis by IF.

Conclusions: In this study, IF failed to accurately differentiate AIg- from non-AIg amyloidosis in 12.3% of cases. Relying on IF alone for determining AIg vs. non-AIg amyloidosis may lead to misdiagnosis. Our data demonstrate that IF has inferior sensitivity and specificity as compared with MS in the typing of AIg-derived amyloidosis. Typing with MS is recommended in cases where IF is not certain.

Immunofluorescence results for the diagnosis of immunoglobulin- derived amyloidosis

Immunofluorescence	Positive MS	Negative MS	Total of cases
Positive	88	5	93
Negative	16	61	77

Rapid Reduction in Urinary sCD163 Correlates with Clinical Benefit in the CLEAR Study of C5aR Inhibitor Avacopan in ANCA-Associated Vasculitis

Jun Deng,[1] Antonia Potarca,[3] Thomas J. Schall,[2] Pirow Bekker.[3] *[1]ChemoCentryx, Inc, Mountain View, CA; [2]ChemoCentryx, Inc, Mountain View, CA; [3]ChemoCentryx, Inc, Mountain View, CA.*

Background: Avacopan (CCX168), a potent C5aR inhibitor, induced rapid clinical benefit (measured by BVAS, proteinuria, and health-related quality of life measurements) in the Phase 2 CLEAR trial in ANCA-associated vasculitis, AAV (Jayne et al, JASN, 2017). Urinary soluble CD163 (sCD163) is a macrophage cell surface molecule known to correlate with renal histopathology, and it is a useful biomarker of kidney inflammation in AAV (O'Reilly et al, JASN, 2016). We evaluated urinary sCD163 in CLEAR patients at baseline and over the 12-week treatment period.

Methods: CLEAR comprised 3 patient groups: (1)Full dose prednisone (60 mg), standard care; (2)Avacopan 30 mg b.i.d. plus low dose prednisone (20 mg); (3)Avacopan 30 mg b.i.d. plus no prednisone. All patients received either IV cyclophosphamide or IV rituximab. sCD163 (ELISA) and creatinine were measured pre-dose, and days 8, 15, 29, 57, and 85.

Results: Avacopan treatment reduced sCD163/creatinine markedly by day 8, and further over the course of 12-weeks (see table). By contrast, standard care controls with full-dose prednisone therapy did not show improvement in urinary sCD163 until day 57. The urinary sCD163/creatinine levels were highly correlated with previously reported improvements in urinary albumin/creatinine ratio and MCP-1/creatinine ratio (p<0.0001).

Conclusions: Avacopan induced a rapid reduction of sCD163, which correlated with similarly rapid improvements of kidney inflammation markers and AAV signs and symptoms in the CLEAR trial. sCD163 may provide a valuable biomarker of clinical improvements derived from avacopan. Avacopan is currently in a Phase 3 clinical trial for AAV.

Serum B-Cell Activating Factor Levels Are an Early Predictor of the Response to Rituximab in Patients with Idiopathic Nephrotic Syndrome

Manuela Colucci, Francesco Emma, Marina Vivarelli. *Bambino Gesù Children's Hospital - IRCCS, Rome, Italy.*

Background: Treatment with rituximab (RTX), a B-cell depleting anti-CD20 antibody, has a prolonged efficacy in preventing relapses in pediatric idiopathic nephrotic syndrome (INS). Length of remission following RTX correlates with length of B cell, especially memory B cell, depletion. However, some patients experience early recurrence of INS following RTX treatment. Serological predictors of response to RTX are as yet unidentified.

Methods: Levels of serum B cell-activating factor (BAFF) and of B cell subsets were serially monitored by ELISA and flow cytometry respectively in 14 steroid-dependent INS children treated with RTX up to recurrence of NS. An initial dose of RTX (375 mg/m^2), repeated at 7 days in case of incomplete depletion of B cells, was administered.

Results: Three patients relapsed after 6.1±0.2 months (R) whilst the other 11 never relapsed during this period (NR). At baseline there was no significant difference between these two groups. One month after RTX treatment, all B cell subpopulations were

completely depleted, and total $CD19^+$ B cells started to reappear at 6 months in both groups, with no significant difference in the number of total B cells between R and NR. However, serum BAFF levels and the B cell subset repopulation were different in the two groups. In the NR group, serum BAFF levels significantly rose at 1 month and remained increased during the follow-up, sustaining the significant re-emergence of transitional and mature B cells ($p<0.05$ vs 1 months). Unexpectedly, serum BAFF levels never increased in the R group, and this was reflected by the reduced recovery of transitional and mature B cells. In contrast, R patients showed a significantly increased reconstitution of memory and in particular switched memory B cells at 6 months compared to the NR group in whom the memory B cells remained depleted ($p<0.05$ compared with R at 6 months).

Conclusions: Total B cell recovery is not a good predictor of relapse in INS pediatric patients treated with rituximab, as this population is composed of several B cell subsets with different functions and different reconstitution patterns following RTX treatment. On the contrary, serum BAFF levels post-RTX treatment and the re-emergence of memory and in particular of switched memory B cells may better predict the response to RTX in pediatric INS patients.

Urine Epidermal Growth Factor, Monocyte Chemoattractant Protein-1, or Their Ratio as Biomarkers for Response to Therapy in Primary Glomerulonephritis

Eakkapat Chanrat, Supanat Worawitchawong, Nuankanya Sathirapongsasuti, Chagriya Kitiyakara. *Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Background: The balance between pro-inflammatory cytokines such as monocyte chemoattractant protein- 1 (MCP-1) and protective cytokines such as epidermal growth factor (EGF) likely determines the outcomes in primary glomerulonephritis (GN). Elevated urinary MCP-1 and decreased urinary EGF have been associated with renal fibrosis, but there is limited information on their prognostic roles. We evaluated the relationships of urinary EGF, MCP-1 or their ratio at baseline with subsequent response to therapy and renal function at 24 months in patients with primary GN.

Methods: This is a prospective study in primary GN (n=74). Urine samples were collected at the time of biopsy. MCP-1 and EGF were analyzed by ELISA kits and expressed as a ratio to creatinine (ng/mg Cr) or as EGF/MCP-1 (ng/ng). Complete remission (CR) was defined as proteinuria ≤ 0.3 g/gCr and other subjects were categorized as Not in remission (NR). The predictive role of the biomarkers and traditional clinical parameters for CR were analyzed by Cox multivariate regression analysis.

Results: The diagnoses were: IgA nephropathy (n=28), focal segmental glomerulosclerosis (n=16), minimal change disease (n=10) and membranous nephropathy (n=20). Median follow up was 20 (12, 28) months. Estimated glomerular filration rate (eGFR) at baseline correlated with positively with EGF, EGF/MCP-, and inversely with MCP-1. Proteinuria at baseline correlated positively with MCP-1, and inversely with EGF/MCP-1. After treatment with renin-angiotensin blockers and/or immune-modulating agents, 38 patients (51.4%) achieved CR. Baseline EGF and EGF/MCP-1 levels were higher in CR compared to NR, whereas MCP-1 was not different. High EGF (>75 ng/mgCr) at baseline was an independent predictor for subsequent CR (OR (95%CI): 2.86 (1.37-5.94), p=0.005). In the subset of patients (n=43) who completed 24 months follow-up, high baseline EGF (>75 ng/mgCr) had lower proteinuria at 24 months follow-up. Baseline EGF and EGF/MCP-1 correlated positively with eGFR at 24 months.

Conclusions: High urinary EGF at baseline was an independent predictor of subsequent CR. EGF and EGF/MCP-1 at baseline correlated positively with eGFR and inversely with proteinuria at 24 months. Larger studies are necessary to confirm the benefits in the management of primary GN.

Clinicopathological Implications of Urinary Soluble CD163 in Glomerulonephritis with Crescentic Formation

Hidenori Yamazaki, Tsutomu Koike, Minami Mizutani, Hayato Fujioka, Kota Kakeshita, Koichiro Kinugawa. *The Second Department of Internal Medicine, University of Toyama, Toyama, Japan.*

Background: M2 macrophages contribute to crescentic formation in various types of glomerulonephritis. A recent report suggested that the level of urinary soluble CD163 (sCD163), a marker of M2 macrophage infiltration, associated very tightly with active renal vasculitis. In this study, the association of urinary sCD163 level with indices of disease activity was analyzed in patients with glomerulonephritis with crescents.

Methods: Subjects were fifty-seven patients with biopsy proven glomerulonephritis with crescentic formation, including microscopic polyangitis (n=14), anti-GBM glomerulonephritis (n=3), IgA vasculitis (n=10), IgA nephropathy (n=22), lupus nephritis (n=6), infectious glomerulonephritis (n=2). In advance of kidney biopsy, measurements of urinary sCD163 and urinary protein excretion (UP), effective glomerular filtration rate (eGFR) were performed.

Results: 1) In all subjects, urinary sCD163 correlated positively with the percentage of glomeruli with cellular crescents ($r=0.48$, $p<0.01$). In contrast, urinary sCD163 did not associate with the percentage of glomeruli with fibrocellular or fibrous crescents. Additionally, there was a positive correlation between urinary sCD163 and UP ($r=0.41$, $p<0.05$), whereas there was no association between urinary sCD163 and eGFR. 2) In thirty subjects followed for six months after immunosuppressive treatments, the positive relationships of urinary sCD163 levels with treatment-induced changes in eGFR ($r=0.49$, $p<0.01$) or UP ($r=0.41$, $p<0.05$) were observed.

Conclusions: In conclusion, urinary sCD163 may be a novel surrogate marker for disease activity of glomerulonephritis with crescentic formation.

FR-PO749

Diagnosis of Renal Vasculitis Flare Using usCD163: A Multi-Centre Prospective Study

Sarah M. Moran,[2] Niall P. Conlon,[1] Mark A. Little.[2] *[1]Trinity College Dublin, Dublin, Ireland; [2]Trinity Health Kidney Centre, Dublin, Ireland. Group/Team: Vasculitis Ireland Network.*

Background: Urinary sCD163 displays excellent potential for active renal vasculitis detection at AAV diagnosis. The clinical utility of usCD163 is in the diagnosis of renal vasculitis flare, potentially obviating the need for biopsy and detecting active renal vasculitis prior to further injury.

Methods: AAV patients were prospectively recruited with potential renal vasculitis flares from a multicentre cohort. Physicians judged the flare probability as *High* or *Possible*. An independent committee adjudicated on renal flare diagnosis (BVAS major criteria:RBC casts &/or 30% increase in creatinine or renal biopsy). Urine creatinine-normalised sCD163 levels were measured by ELISA.

Results: 44 patients were prospectively recruited, 32% with renal flare. Creatinine was 1.7mg/dL (IQR 1.0-3.2, 78% increase from baseline) and 1.5mg/dL (IQR 1.1-1.7, 2.8% increase) in flare and non-flare (p=0.02). Median usCD163 levels were significantly higher in patients with adjudicated renal flare (469.6 ng/mmol (IQR 363.8-2974)) compared to non-flare (25.4 (IQR 3.9-80.8), p<0.0001)). Median usCD163 levels were not elevated in potential renal flare mimics, including sepsis (62.1ng/mmol IQR 27.8-155.3), acute kidney injury (22.4ng/mmol IQR 0-78.7) or systemic flare (22.4ng/mmol, IQR 21-107.7).

Conclusions: usCD163 is diagnostic of renal vasculitis flare in prospectively observed patients with AAV, and is superior to initial physician assessment and BVAS major renal criteria.

Funding: Government Support - Non-U.S.

FR-PO750

Clinical Study Results of a Real-Time Point-of-Care Glomerular Filtration Rate Measurement Richard B. Dorshow,[3] Martin Debreczeny,[1] James R. Johnson,[1] jeng-jong Shieh,[1] Thomas E. Rogers,[2] Kevin J. Martin,[4] Daniel W. Coyne.[5] *[1]MediBeacon Inc., St Louis, MO; [2]MediBeacon Inc, St Louis, MO; [3]MediBeacon Inc., Saint Louis, MO; [4]Saint Louis University Med Ctr, St. Louis, MO; [5]Washington University School of Medicine, St. Louis, MO.*

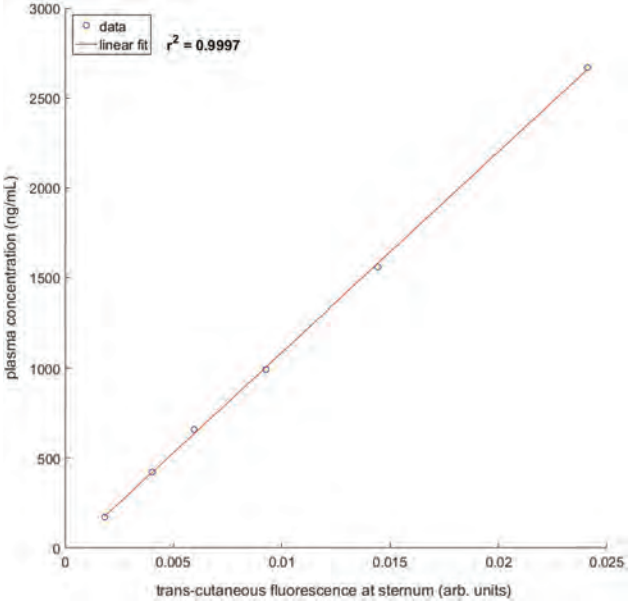
Background: Real-time point-of-care measure of glomerular filtration rate (mGFR) would permit rapid diagnosis of acute kidney injury and precise determination of CKD. Clearance pharmacokinetics of the fluorescent agent MB-102 was measured in the plasma and correlated with noninvasively measured transdermal fluorescence for subjects with normal kidney function to Stage 4 CKD.

Methods: Blood samples were taken in 60 subjects with eGFR from normal to 19 mL/min/1.73m² over a period of 12hr post simultaneous administration of MB-102 and iohexol, and urine collected to assess percent excretion. A noninvasive detection device simultaneously measured the transdermal fluorescence from MB-102.

Results: Plasma pharmacokinetics displayed the expected 2 compartment model of a vascular-tissue equilibrium phase followed by renal excretion only. The GFR measured from the MB-102 plasma pharmacokinetics was highly correlated with the GFR measured from iohexol over the entire measured range of GFR values (r^2=0.98). The time-dependence of the transdermal fluorescence from MB-102 monitored by our fluorescence detection device was highly correlated with that of the plasma (see figure from subject with normal mGFR). MB-102 was completely cleared by 12hr when mGFR was >60 mL/min/1.73m². No serious nor significant adverse events were reported.

Conclusions: Point-of-care clinically amenable measured GFR for a range of kidney function from normal to Stage 4 CKD is demonstrated using transdermal fluorescence detection of the novel fluorescence tracer agent MB-102.

Funding: Commercial Support - MediBeacon Inc.



FR-PO751

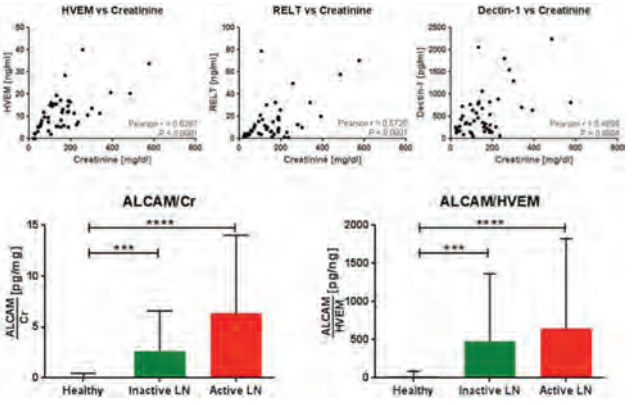
Unbiased Screening of Urinary Protein Biomarkers for Glomerular Filtration Rate Normalization Sanam Soomro, Samantha Stanley, Ramesh Saxena, Michelle Petri, Chandra Mohan. *University of Houston, Houston, TX.*

Background: To account for glomerular filtration rate, urinary creatinine is routinely used for the normalization of urine biomarkers related to disease. Because of the small size of this metabolite, antibodies are difficult and expensive to develop, limiting the applications of disease-specific urine protein biomarkers for antibody-based point of care applications.

Methods: An aptamer-based screening of 1129 proteins in 24 human urine samples (8 active lupus nephritis (LN), 8 inactive LN, 8 healthy controls (HC)) was carried out to identify urine proteins that correlated well with urine creatinine but not disease.

Results: The screen uncovered 18 proteins that correlated well with urinary creatinine but were similar in patients with or without nephritis. Further validation in an independent cohort of 48 subjects (16 active LN, 16 inactive LN, 16 HC) showed a significant positive correlation of urine HVEM, RELT, and Dectin-1 to urinary creatinine. The most promising marker, urine HVEM, was significantly correlated to urinary creatinine in both white (Pearson r = 0.7229, P = 0.0001) and black subjects (Pearson r = 0.6111, P = 0.0009). Finally, normalization of other urinary biomarker proteins against urine HVEM showed comparable fold change and statistical significance as normalization to urinary creatinine.

Conclusions: Instead of the metabolite creatinine, proteins such as HVEM, RELT, and Dectin-1 can be used for normalization of urine biomarkers. The use of proteins instead of metabolites for normalization paves the way towards novel diagnostic approaches.



Urine HVEM, RELT, and Dectin-1 were validated by ELISA and found to be significantly correlated with urinary creatinine. HVEM, the most promising marker for GFR normalization, was also used to normalize ALCAM, a biomarker for SLE, to have comparable fold change and statistical significance as normalization to urinary creatinine.

FR-PO752

Plasma Metabolomics in Steroid-Sensitive and Steroid-Resistant Nephrotic Syndrome Jessica Gooding,[3,4] Shipra Agrawal,[2,5] Susan Mcritchie,[1,4] Zachery J. Acuff,[3,4] William E. Smoyer,[2,5] Susan J. Sumner.[4,1] *[1]Nutrition Research Institute, University of North Carolina at Chapel Hill, Kannapolis, NC; [2]Center for Clinical and Translational Research, Nationwide Children's Hospital, Columbus, OH; [3]Discovery, Science and Technology, RTI International, Durham, NC; [4]NIH Eastern Regional Comprehensive Metabolomics Resource Core (ERCMRC), University of North Carolina Chapel Hill, Chapel Hill, NC; [5]Pediatrics, The Ohio State University, Columbus, OH.*

Background: Nephrotic syndrome (NS) is a common kidney disease in children. Steroids are the primary therapy; however, they are ineffective in ~20% cases. Children with steroid-resistant NS (SRNS) fail to enter remission after prolonged steroid treatment, and are at high risk for steroid-induced side effects as well as progression of disease to end-stage renal disease (ESRD) within five years. This study aimed to discover markers of steroid-resistance that could be used to predict SRNS at presentation and develop a mechanistic definition of SRNS.

Methods: Citrate plasmas (n=86) were collected from 30 steroid-sensitive NS and 15 steroid-resistant NS patients at presentation (prior to steroid therapy) and after an average of 7 weeks of steroid treatment. Broad spectrum ^{1}HNMR data was acquired, binned, and concentration fit. Multivariate analyses and hypothesis testing were used to determine the metabolites that best differentiated the phenotypic groups, and logistic regression using a stepwise variable selection method were used model the odds of steroid resistance at presentation.

Results: Treatment effects were observed between paired presentation and follow-up steroid-sensitive (SSNS) samples and between follow-up SSNS and SRNS samples. Metabolites affected by treatment included lipoproteins, adipate, tyrosine, valine, alanine, glutamine, glucose, pyruvate and creatine. After controlling for age, the step-wise logistic regression model selected glutamine (OR= 1.01; 0.99-1.02 95% CI). A similar model with children age >3 only, indicated that children with increased levels of malonate (OR=0.94; 0.89-1.00 95% CI) had an increased odds of responding to treatment.

Conclusions: Known effects of corticosteroid treatment were observed providing a proof-of-concept. The observed metabolic signature supports previous hypotheses that the proximal tubule is involved in the pathology of SRNS as reflected in circulating metabolites of renal gluconeogenesis. After controlling for age, logistic regression suggests that malonate concentration may be a potential biomarker for identifying SRNS at presentation.

FR-PO753

A Significance of Urine-Gravidity in Nephrotic Syndrome Shinichi Nishi,[1] Hideki Fujii,[1] Shunsuke Goto,[2] Keiji Kono,[1] Mikiko Yoshikawa,[1] Shuhei Watanabe,[1] Kentaro Watanabe.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Kobe University Graduate School of Medicne, Kobe, Japan.*

Background: Selectivity index (SI) has been used in the differentiation of nephrotic syndrome (NS), while the sensitivity of SI is not so high. We studied the significance of urine gravidity (UG) as an available differentiative marker for NS.

Methods: We selected 45 consecutive patients with primary NS that were admitted in Kobe University Hospital from 2012 to 2014. Secondary renal diseases associated with collagen diseases and diabetes were excluded. The cases already treated by glucocorticoid or diuretics were also excluded. We studied the relationship between histological and

clinical findings and clarified the availability of UG in the point of differentiation of NS due to MCNS, FSGS, MN.

Results: The subjective cases were comprised of 23 MCNS, 18 MN (stage 1=4), and 3 FSGS. The average age was 52.7±27.7 years-old. The means of amount of urine protein (AUP) and albumin were 8.1±3.7 g/gCr and 1.7±0.7 g/dL, respectively. Those of UG and SI were 1.032±0.013 and 0.340±0.563, respectively. We divided all cases into two groups; MCNS (n=23) and non-MCNS (n=22). In the comparison of two groups, UG was significantly higher in MCNS, 1.039±0.008 and 1.024±0.013 ($p<0.001$). SI did not show a significant difference; 0.216±0.476 in MCNS and 0.476±0.662 in non-MCNS ($p=0.9314$). In ROC analysis UG-AUC of MCNS was 0.831 and SI-AUC of MCNS was 0.796, respectively. We divided into all cases into other two groups; MCD (MCNS+stage1 MN+FSGS) and non-MCD groups. In the comparison of two groups, UG was significantly higher in MCD, 1.039±0.008 and 1.017±0.009, respectively ($p<0.001$). SI did not show significant difference in MCD and non-MCD, 0.222±0.384 and 0.574±0.787 ($p=0.943$). In ROC analysis UG-AUC of MCD was 0.978 and SI-AUC of MCD was 0.770.

Conclusions: UG was an available differentiative marker for MCNS vs. non-MCNS or MCD vs. non-MCD. When we combine UG and SI, we can effectively differentiate three groups MCNS, MN, and FSGS.

Comparison of Spot Urinary Protein to Creatinine Ratio to 24 Hours Urinary Protein at Different Time Points During the Day: Is There a Variability During the Day? Omer Sabir, Muhammad M. Riaz, Nauman Tarif, Abaid U. Rehman, Kashif Rafique, Nabiha Rizvi. *Medicine, Division of Nephrology, Fatima Memorial School of Health Sciences, University of health Sciences, Lahore, Pakistan.*

Background: 24 hours urinary protein excretion is considered gold standard for the estimation of daily urinary protein loss, although cumbersome. We compared the spot urinary protein to creatinine ratio (PCR) collected at three different time points of the day with standard 24 urine protein collection to identify the best time for sampling.

Methods: This was an observational, cross sectional study carried out at Fatima Memorial Hospital Lahore, Pakistan over four years from January 2013. Sixty-seven (67) patients who were persistently dipstick positive for protein were included and informed consent was obtained. The patients were required to collect a twenty-four hours urine sample according to standard recommendations for protein and creatinine measurement. From the same collection 10 ml aliquots of urine were separated and sent for spot urinary protein and spot urinary creatinine for PCR at different time points (Morning: 8 AM – 10 AM; Evening : 2 PM – 6 PM; Night: 8 PM – 10 PM).

Results: Mean age of the cohort was 32.91± 13.12 years and 39 (58.2%) were males. Mean Serum Creatinine was 3.24 ± 2.50 mg/dL (mean eGFR by CKD-EPI equation: 45.1 ± 37.3 ml/min. Range: 5.7 – 147.5 ml/min). 37.3% were diabetic and were clinically designated as having diabetic nephropathy whereas the rest were undergoing evaluation or had biopsy proven glomerulonephritis. Patients were classified as CKD Class I: 18.6%, Class II: 15.3%, Class III: 23.7%, Class IV: 16.9% and Class V: 25.4%. None of the patient was on renal replacement therapy at the time of cross section. Mean serum albumin of the cohort was 3.23 ± 0.63 g/dL (Range: 1.9 to 4.7 g/dL.); whereas mean 24 hours urinary protein was 2.0 ± 1.58 g/day (Range: 0.73 – 6.5 g/day). Pearson's correlations for all three spot PCR samples were significantly correlated with the 24 hours urinary protein sample, however night time spot sample was found to have strongest correlation (Pearson's r: 0.64, $p < 0.05$) as compared to early morning and evening samples ($r = 0.41$ and $r = 0.37$ respectively, $p < 0.05$ for both).

Conclusions: Our study shows that nighttime sampling for spot PCR may better correlate with 24 hours urinary protein excretion. Further studies in different CKD stages and ethnicities could confirm the findings of our study.

FR-PO755

Prediction of Pathologic Type of Primary Nephrotic Syndrome Using a Machine Learning Algorithm Hui Xu. *Nephrology Department, Xiangya Hospital, Central South University, Changsha, Hunan, China, Changsha, China.*

Background: Renal biopsy is the gold standard to determine the pathologic type of primary nephrotic syndrome. However, renal biopsy cannot be performed in some cases. Based on this, we tried to using a machine learning algorithm to predict the pathologic type in primary nephrotic syndrome patients without renal biopsy.

Methods: Clinical data and pathologic types of 203 patients with primary nephrotic syndrome were collected. We trained and validated a machine learning algorithm using data from 203 patients. Then the model was tested prospectively on another 63 biopsy-confirmed patients with primary nephrotic syndrome. Thirdly, Compared with the pathologic results of renal biopsy, the predictive effectiveness of the model was further verified.

Results: Overall accuracy of prediction from the retrospective set of 203 patients was 62.2% across all types of nephrotic syndrome. Among them, minimal-change disease (MCD), 52.2%; non-IgA mesangial proliferative glomerulonephritis, 64.1% (Non-IgAN); IgA nephropathy (IgAN), 57.1%; membranous nephropathy (MN), 76.1% and focal segmental glomerulosclerosis (FSGS), 10.5%. The accuracy of model prediction for the prospectively collected dataset of 63 patients was 61.9%. MCD, 85.7%; Non-IgAN, 60%; IgAN, 80%; MN, 63.6% and FSGS, 0%. Meanwhile, the algorithm identified 17 of 33 variables as contributing strongly to type of renal pathology. Among them, age, hemoglobin and serum creatinine were the top three(Figure 1).

Conclusions: The method has high precision and can be used to help those patients who are not suitable for renal biopsy to predict the pathologic type of primary nephrotic syndrome, which can guide the diagnosis, choice of treatment and evaluation of prognosis of primary nephrotic syndrome.

Urinary Podocyte mRNA and Urinary Podocalyxin Protein: Different Excretion Pattern between Proliferative and Non-Proliferative Glomerular Diseases Akihiro Fukuda,[1,2] Akihiro Minakawa,[2] Masao Kikuchi,[2] Yuji Sato,[2] Hiroyuki Kurosawa,[3] Masanori Hara,[4] Shouichi Fujimoto.[2] *[1]Oita University, Yufu, Japan; [2]University of Miyazaki, Miyazaki, Japan; [3]Denka Seiken Co., Ltd, Gosen, Japan; [4]Niigata Wellness (Iwamuro Health Promotion Center), Niigata, Japan.*

Background: Podocyte depletion causes glomerulosclerosis, and persistent podocyte loss drives progression to end-stage kidney disease in most forms of glomerular diseases. Podocytes are resident on the urinary space side of the glomerular basement membrane, so that as they detach or die, their products can be identified in urine. Thus, the podocyte products in urine might be potential biomarkers to monitor glomerular disease activity and progression. Recently, both the urinary pellet podocyte (u-pod) mRNA excretion rate and urinary podocalyxin (u-PCX) protein levels have been used to monitor disease activity in various glomerular diseases. However, differences in these markers between various pathologies have not yet been investigated. By comparing the u-pod mRNA excretion rate to u-PCX protein levels in biopsy-proven glomerular diseases, we examined the significance of these markers in various glomerular diseases.

Methods: From January 2013 to March 2016, early morning urine samples were collected from 12 healthy volunteers and 184 patients with various kidney diseases (minor glomerular abnormality, n=15; MCNS, n=16; MN, n=17; IgAN, n=62; crescentic GN, n=24; lupus nephritis, n=11; others, n=39). We examined the u-pod mRNA excretion rate, u-PCX protein levels and urinary protein/creatinine ratio (u-PCR).

Results: The u-pod mRNA excretion rate was statistically correlated with u-PCX protein levels ($r=0.37$, $p<0.001$). Both the u-pod mRNA excretion rate and u-PCX protein levels were statistically correlated with u-PCR ($r=0.52$, $p<0.001$ and $r=0.32$, $p<0.001$, respectively). Interestingly, the u-pod mRNA excretion rate was significantly increased in crescentic GN, IgAN and LN (especially class IV) compared with controls but not in MCNS and MN, whereas the u-PCX protein levels were significantly increased in MN and LN (tendency for class V) compared with controls but not in other glomerular diseases.

Conclusions: Although the u-pod mRNA excretion rate and u-PCX protein levels were positively correlated, a higher u-pod mRNA excretion rate and higher u-PCX protein levels might be associated with proliferative glomerulonephritis and non-proliferative glomerulonephritis, respectively.

A Swine Model of Tunneled Dialysis Catheter (TDC) Infection and Dysfunction: Opportunities for Therapeutic Innovation Diego Celdran-Bonafonte,[1] Begoña Campos,[2] Aous Jarrouj,[1] Li H. Wang,[1] Lindsay N. Kohler,[1] Jaroslav Janda,[1] Keith L. Saum,[2] Frank C. Brosius,[1] Prabir Roy-Chaudhury.[1,3] *[1]University of Arizona, Tucson, AZ; [2]University of Cincinnati, Cincinnati, OH; [3]SAVAHCS, Tucson, AZ.*

Background: TDC infection and dysfunction are important causes of morbidity and mortality in hemodialysis patients, with no truly effective therapies. An important reason for this is the absence of a validated large animal model. We herein describe a swine model that closely mimics the human condition.

Methods: TDC's were placed in the right jugular vein of 6 Yorkshire pigs. Blood was flushed in and out of each lumen twice weekly in order to mimic dialysis and assess for the onset of dysfunctional flow. Animals were monitored daily for infection. Blood cultures (BC) were obtained and antibiotics started when the temperature was > 103 degrees F. Animals were euthanized if they did not respond to treatment. Data on the time to infection (fever), dysfunction, and sacrifice, as also the BC profiles were collected. Data collection has been completed on 3 pigs and is ongoing in the others. We will present the available data from all 6 pigs.

Results: The average time to fever (infection) and TDC dysfunction was 9.2±5.2 and 8±6.2 days respectively. The arterial line was dysfunctional first in 83% of cases. Compacted fibrin sheaths were present in all sacrificed animals (Figure), together with jugular and central venous wall thickening. Importantly, the bacterial profile correlated with standard human data, showing growth of Klebsiella, Pseudomonas and Beta hemolytic strep (and from an earlier study Staphylococcus aureus).

Conclusions: We have, for the first time, described a large animal model of TDC infection and dysfunction which mimics the human condition. We believe that the availability of this model, with its well defined end points, will incentivize the product development pathway for novel, safe and effective therapies that target both TDC infection and dysfunction.

Upper Extremity Swelling in ESRD: DVT or Central Venous Disease Adam Safdi,[1] Monnie Wasse.[2] *[1]Medicine, Northwestern University, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.*

Background: Among end-stage renal disease (ESRD) patients, upper extremity deep vein thrombosis (DVT) and central venous disease (CVD) defined as stenosis or occlusion, may have similar clinical presentations, commonly a swollen arm ipsilateral to a functional dialysis access. However, management is different. Anticoagulation is prescribed for acute DVT, whereas angioplasty might be necessary for CVD. The objective of this study was to examine ESRD patients presenting with arm swelling who received a diagnosis of upper extremity DVT, the proportion undergoing central venous angiogram, and an alternate CVD diagnosis.

Methods: We retrospectively reviewed the medical records of all ESRD patients receiving hemodialysis admitted to a tertiary academic medical center between January 1, 2013 and June 30, 2015, and received a diagnosis of upper extremity DVT by ICD-9 code. Charts were reviewed to determine: 1) if duplex ultrasound was performed, 2) if referral was made for dialysis access angiogram and if CVD was determined, and 3) whether the patient was discharged on anticoagulation.

Results: An upper extremity ultrasound was ordered in 102 ESRD patients over 124 admissions, and one or more acute or chronic DVT was diagnosed in 118 of the 124 admissions. The most common vein location for DVT was the internal jugular (75%), followed by axillary (44%), subclavian (34%), brachial (23%), and brachiocephalic (14%). 25 of the 118 DVT cases (21.2%) were referred for angiography. Of these, only 4 of the 25 cases (16%) were diagnosed with DVT. In contrast, 18 of the 25 cases (72%) referred for angiogram had CVD. Of note, angiography was not always performed on the vessel noted to have a DVT by duplex ultrasound. Of 19 cases diagnosed with a DVT and subsequently studied with angiography, CVD was present in 18 cases (94.7%) and DVT was only observed in 4 cases (21.1%), all of whom had concurrent CVD. 39 of the 118 cases (33%) diagnosed with a DVT were discharged with a new prescription for anticoagulation.

Conclusions: Our retrospective study shows that when hemodialysis patients with ESRD receive a diagnosis of upper extremity DVT by ultrasound, and also have upper extremity venogram, they more often have CVD than DVT. This suggests that duplex ultrasound leads to an incorrect clinical diagnosis when hemodialysis patients present with a swollen arm, and suggests patients may be receiving inappropriate anticoagulation.

FR-PO759

Incidence and Risk Factors for Central Venous Stenosis in Haemodialysis Patients Anamika Adwaney,[1] Neill D. Duncan,[2] Damien Ashby.[1] *[1]Imperial College, London, United Kingdom; [2]Imperial College Renal and Transplant Centre, London, United Kingdom.*

Background: Central venous catheters have traditionally provided haemodialysis access when a fistula is declined or not achieved, but are increasingly advocated as an acceptable option for older or more comorbid patients. Adverse effects of this type of dialysis access include central vein stenosis (CVS), which can lead to significant morbidity including access dysfunction or failure. The pathogenesis and risk factors for CVS are incompletely understood.

Methods: All patients starting haemodialysis in a single centre between December 2005 and February 2015 were prospectively identified. From this cohort, a random sample of patient records were retrospectively analysed for the presence of CVS, defined by cross-sectional or angiographic imaging.

Results: Out of 300 patients (aged 19 - 91, 64.7% male) followed for up to 10 years, CVS developed in 23 (7.67%). All CVS patients had a history of tunneled dialysis catheter use. Compared to those unaffected, patients with CVS had a larger number of previous catheters (2.3 vs 1.2, $p<0.001$) but not a greater duration of previous catheter use (28.7 vs 32.1 months). Non-dialysis risk factors, more frequent in patients with CVS, included pacemakers (13.0 vs 2.2%, $p=0.024$) and prior intensive care admission (56.5 vs 11.9%, $p<0.001$). There was no significant effect of ethnicity, but in older patients (over 70 at dialysis initiation, 35.0% of the group) the development of CVS was much less common (2.9 vs 10.3%, $p=0.023$).

Conclusions: In haemodialysis patients with prior tunneled catheter use, a significant minority may develop CVS, with the number of catheters, rather than catheter duration, being the primary risk factor, though non-dialysis risk factors are also important. The finding that patients over 70 at dialysis initiation are less likely to develop CVS, supports the selective use of tunneled catheters in some older patients.

FR-PO760

Tunneled Catheter-Related Bacteremia Preventive Protocol: Results Analysis Carmen Gonzalez corvillo, Maria angeles Rodriguez-Perez, Mercedes Salgueira. *NEPHROLOGY, HUVMACARENA, SEVILLA, Spain.*

Background: The increasing use of tunneled catheters for hemodialysis is associated with a number of complications, particularly catheter-related bacteremia(CRB). The implementation of a pre-emptive protocol during the preimplantation period and maintenance care could reduce the rate, although there is no consensus in the bibliography. Since 2006, our department has had a preimplantatory protocol, developed by nephrologists and infectologists, it includes nasal decolonization in case of staphylococcal aureus colonization, complete cleansing with chlorhexidine gel and prophylactic cefazolin before the procedure. We analyze the results obtained in our department regarding CRB in tunneled catheter implants in the last 11 years.

Methods: Our protocol has been implemented in 246 tunneled catheters, implanted in 107 patients. Mean age:63 years. Mean follow-up period for each catheter:132 months. Incidence of bacteremia, time of appearance of the bacteremia after the implantation, bacteria types and associated complications were analyzed.

Results: - Location:right jugular vein 71.1%, left subclavian 16.3%, right subclavian 11%, femoral 1.6% - 72 catheters were removed in 15(6.1%) cases, with infection being the main reason for removal. - 64 cases of catheter-related bacteremia were diagnosed, representing an incidence rate of 0.48 cases per 1000catheters per day. Mean time for appearance of CRB:579± 441 days after implantation(median 513days, minimum 42, maximum 1623) - Most frequent microorganisms: Staph. Epidermidis 36.7%, MSSA 26.5%, MRSA 6.1% Staph. Warneri 4%, pantoea agglomerans 4%, strep viridans 4%, candida 2%, pseudomonas 2%, cloacae 2%, klebsiella 2%, corynebacterium 2%, serratia 2%. - Infection recurrence was 26% in a mean time of 276 days. The most frequently recurring microorganisms were Staph. Epidermidis 31% and MSSA 26%. - Septic complications: 9 cases (1 septic arthritis, 1 spondylodiscitis, 4 endocarditis and 4 septicemia)

Conclusions: In our experience, the rate of tunneled CRB is in fact lower than reported in the bibliography. Implementation of our preemptive protocol has delayed the incidence of CRB, with the primo-infection presenting more than 1 year after tunneled catheter implantation. The recurrence rate was high and the most frequent microorganism was Staph. Epidermidis. The incidence of other complications and the need to remove the catheter is low.

FR-PO761

Efficacy of Alteplase (tPA) 1 mg versus 2 mg in Restoring Hemodialysis Catheter Function: A Randomized Double-Blind Controlled Study Albert Kadri,[1] Wasim El Nekidy,[2] Derrick Soong,[3] Maher M. El-Masri.[4] *[1]Windsor Regional Kidney Care Center, Windsor, ON, Canada; [2]Cleveland Clinic - Abu Dhabi, Windsor, ON, Canada; [3]Windsor Regional Hospital, Windsor, ON, Canada; [4]University of Windsor, Windsor, ON, Canada.*

Background: Hemodialysis catheters (HDC) are used to provide vascular access to patients with Chronic Kidney Disease on hemodialysis (HD). Late thrombus formation can result in HDC occlusion leading to its malfunction. Data about optimal alteplase (tPA) dose required to restore HDC is scarce. The purpose of the study was to examine the effectiveness of the commonly used tPA dose of 2 mg as compared to 1mg in restoring HDC function

Methods: A double blind, randomized, controlled clinical trial was conducted on hemodialysis patients who required tPA use to restore their HDC function. Eligible consented patients were randomly assigned to either of the two study groups (tPA 2 mg or 1 mg). Patients were included if they: were ≥ 18 years of age at the time of the study, were receiving HD using HDC, and had no medical contradiction for tPA use.

Results: Forty eight consenting patients contributed a total of 252 observations that were allocated to either group A (2 mg) or group B (1mg) based on randomization. Given the clustered nature of the observation, randomization was observation-based as opposed to patient-based. The rate of clot resolution at the catheter site in the A group was 85.7% as opposed to 84.9% with an insignificant absolute risk reduction of only 0.8 % percentage ($p = 0.5$). There were only six catheter removals; three of which were related to catheter malfunction. Catheter stripping was documented in 10 of the 252 observations. Kaplan Meier results indicated that the median time to occlusion after tPA resolution of the first catheter occlusion was 192 and 120 days for groups A and B, respectively (Log rank = 0.499; p = 0.480). Cox regression analysis indicated no difference in the hazard of occlusion between the two groups (p = 0.267; HR = 0.72; 95% CI 0.40–1.3). Further, correlated logistic regression with generalized estimating equations on all 252 observations indicated no difference in the rate of post tPA clot resolution (p = 0.336; OR = 2.4, 95% CI 0.399-14.6) between the two groups.

Conclusions: tPA 1 mg is as effective as 2 mg in restoring HDC function. The use of the lower dose will result in significant cost reduction in hemodialysis units.

FR-PO762

Infections of Tunneled and Non-Tunneled Central Venous Catheters Associated with the Use of 10% Povidone-Iodine versus 2% Chlorhexidine in Chronic Hemodialysis Mauricio Arvizu-Hernandez,[2] Olynka Vega,[1] Ricardo Correa-Rotter.[2] *[1]National Institute of Medical Sciences, Mexico, Mexico; [2]Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute Salvador Zubiran, México city, Mexico.*

Background: Vascular access (VA) infections are a problem in patients on hemodialysis (HD), representing the second cause of morbidity and mortality. The ideal VA is the arterio-venous fistula, in our environment a high number of patients start and stay for a longer than desired on catheters. The use of 2% chlorhexidine solution (2% CHX) for the management of exit site of VA on HD can impact positively the number of catheter infections.

Methods: Retrospective cohort study performed in our Institute HD unit, where 10% povidone-iodine solution (PI) was previously used and since March/2015, was substituted by 2% CHX. We assessed the rate of VA (cathether related) infections from Sep/13 to Aug/16 (Sept/13-Feb/2015 PI and Mar/15-Aug/16 use of 2% CHX). Incidence of infections was analyzed on a monthly basis, identifying number and clinical characteristics of the infection. We calculated the rate of infections per 1000 days/cath/patient. The use of PI vs 2% CHX periods were compared.

Results: During the 36 month study period, a total of 33 infections were identified (0,91 infect/month). The highest infection rate was observed during the use of the PI, both in tunneled and non-tunneled catheters. On the basis of cumulative incidence rates, calculating the RR; the use of PI in both types of catheters, as compared to use of 2% CHX, has a RR of 4.0 (tunneled RR=3.6 and non-tunneled RR=7.0).

Conclusions: Our study demonstrated clearly that the use of 2% CHX in patients with temporary cathether vascular accesses on HD, reduces the risk of infection of both the tunneled and non-tunneled catheters.

FR-PO763

Substitution of Citrate with Tissue Plasminogen Activator (rt-PA) for Catheter Lock Does Not Improve Patency of Tunneled Hemodialysis Catheters Pavlina Richtrova,[1,2] Jan Mares,[1,2] Lukas Kielberger,[1,2] Jan Klaboch,[1,2] Jaromir Eiselt,[1,2] Tomas Reischig.[1,2] *[1]1st Medical Department, Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic; [2]Biomedical Centre, Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic.*

Background: The study aim was to establish if substitution of citrate with rt-PA for catheter lock once weekly can reduce the incidence of catheter-related blood stream infections (CR-BSI) or improve patency of tunneled hemodialysis catheters.

Methods: All incident patients undergoing insertion of a tunneled hemodialysis catheter were screened and included except those suffering infection or using anticoagulation. Study participants were randomized into two arms according to the solution applied as catheter lock: receiving either trisodium citrate (Citra-Lock™ 4%) only or rt-PA (Actilyse® 1mg/ml) on the middle session each week with citrate used on the first and third sessions. The incidence of CR-BSI (confirmed by positive blood culture), catheter non-function (complete obstruction), and malfunction (blood flow <250ml/min) was recorded. Statistical significance was tested with ANOVA, post hoc analysis was performed by means of multiple linear regression.

Results: Totally, 20 patients were included and followed during 655 hemodialysis sessions. No episode of CR-BSI was detected while 6 catheter non-functions (0.9% sessions) and 101 malfunctions (15.4% sessions) were recorded. The incidence of both events was equal between the study arms: 4 non-functions and 55 malfunctions in the rt-PA arm and 2 non-functions and 46 malfunctions in the citrate arm ($p=0.47$ and $p=0.24$, respectively). Additionally, the mean blood flow achieved did not differ significantly between the arms: 326±1,8 and 326±1,9 ml/min ($p=0.95$) in rt-PA and citrate arms, respectively. Post hoc analysis identified time elapsed since previous session ($\beta=0.12$, $p=0.005$) and malfunction on previous session ($\beta=0.25$, $p<0.001$) as significant factors affecting the occurrence of malfunction. By contrast, the study arm, rt-PA application on previous session, and catheter vintage did not enter the model.

Conclusions: Substitution of citrate with rt-PA for catheter lock does not reduce the incidence of catheter malfunction neither does it affect the blood flow achieved during hemodialysis. Catheter patency is related rather to the time interval between sessions and to previous malfunction. The incidence of CR-BSI within pre-selected hemodialysis population is sporadic (less than 1 per 4.3 patient years in our sample).

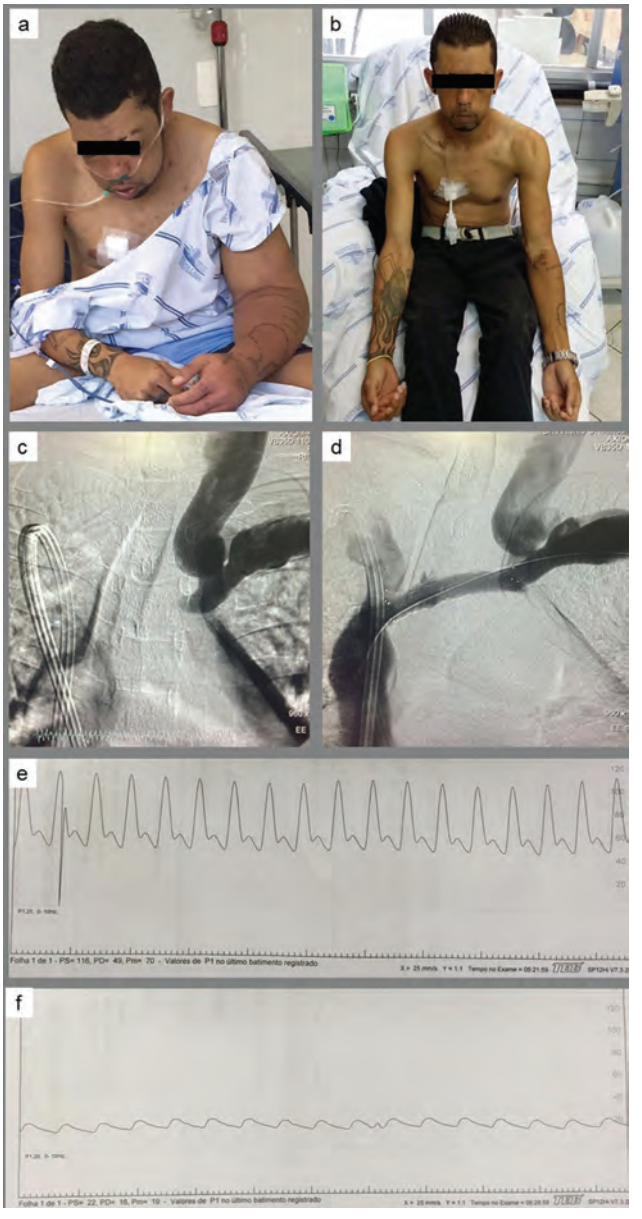
Sharp Recanalization of Central Venous Occlusions in Hemodialysis Patients Carlos rafael A. Felipe,[2] Andre S. Alvarenga,[2] Gerson M. Pereira jr,[2] Ana elisa S. Jorge,[2] Antonio carlos M. Bedeti.[1] *[1]Santa Casa, Belo Horizonte, Brazil; [2]Santa Casa de Belo Horizonte, Belo Horizonte, Brazil.*

Background: Central venous occlusion (CVO) is a severe vascular complication that causes massive upper extremity swelling and dysfunctional dialysis access. Management is aimed at providing symptomatic relief and maintaining hemodialysis access site patency.

Methods: A total of 14 hemodialysis patients with massive upper extremity swelling and dysfunctional dialysis access, who underwent endovascular recanalization for CVO at our institute between November-2013 and May-2016 were examined. We evaluated procedure sucess rate, complication rate, primary and secondary patency rate.

Results: There were 12 occlusions in brachiocephalic veins and 2 in suclavian veins. Until this procedure, each patient had lost on average 5.1 vascular access. First, we tried to traverse the occlusion using soft tip of hydrophilic wire under angiographic catheter (conventional technique); if failure, we switched to sharp recanalization technique using stiff end of hydrophilic wire to puncture the fibrotic cap to create a channel that was crossed by the soft tip of same hydrophilic wire. The procedure was considered successful when residual lesion was <30%. Succes of conventional technique were 28.6%. Switch to sharp recanalization resulted in overall success rate of 85.7% without any major complications. It maintained the patency of dialysis access and relieved the symptoms in all cases. At 12 months, the primary and secondary patency rates were 75% and 83.3% respectively. At an average follow-up of 12.8 months, there was one death not related to the procedure.

Conclusions: Sharp recanalization of symptomatic central venous occlusions in hemodialysis patients was an effective and safe method to maintain the patency of dialysis access and to relieve the symptoms.



FR-PO765

Predicting Vascular Access Thrombosis Using Vasc-Alert™ Based Scoring Algorithm Jeffrey J. Sands,[2,3] Brad C. Astor,[1] Kim Hirschman,[3] John B. Kennedy,[3] Anatole Besarab.[4] *[1]University of Wisconsin, Madison, WI; [2]Renal Systems Consulting LLC, Orlando, FL; [3]Vasc-Alert LLC, Evanston, IL; [4]Stanford University, Palo Alto, CA.*

Background: We evaluated a Vasc-Alert™ based multifactorial scoring algorithm to estimate the risk of developing vascular access (VA) thrombosis within the subsequent 60-days. Vasc-Alert™ VA surveillance utilizes data from each dialysis treatment (Tx) to calculate intra-access venous (VAPR) and arterial (AAPR) pressure ratios to identify those VA at high risk for thrombosis needing further evaluation ± elective intervention. Alerts are generated when the VAPR>0.55 or the AAPR>0.65 (AVF) and >0.60 (AVG) on 3 consecutive Tx.

Methods: We identified 985 patients (263 AVF; 722 AVG), including 304 (81 AVF, 223 AVG) who experienced VA thrombosis (TH) and 681 (182 AVF, 499 AVG) without TH (N-TH), from 86 HD facilities with electronic download of Tx and VA intervention data with up to 120 days Tx data/patient. Records were divided into 15 day intervals (total intervals = 7655; 2049 AVF and 5606 AVG) and assessed to determine outcome (TH vs N-TH) within the subsequent 60 days. Bivariate repeated-measures logistic regression identified 5 factors significantly associated ($p<0.05$) with TH (mean AAPR, mean VAPR, VAPR slope, #VAPR alerts, #Tx with delivered/prescribed blood flow rate <90%). Risk scores were then assigned for specific ranges of each factor based upon their predictive value for TH (0-1 for Mean AAPR, VAPR slope, Tx Blood Flow Rate (BFR)<90% prescribed; 0-3 for mean VAPR) and summed for each interval resulting in an assigned cumulative risk score from 0-7.

Results: A total of 15.3% intervals were associated with thrombosis in the subsequent 60 days. The cumulative incidence of thrombosis was greater with higher cumulative score (see table below). Scores ≤1 were associated with a relatively low incidence (9.5% AVF, 13.0% AVG) and scores ≥3 with a high incidence (AVF: 25.4%, AVG: 23.2%) of thrombosis.

Conclusions: Risk scores based upon a Vasc-Alert™ scoring algorithm successfully identified VA with low or high probability of developing thrombosis within the next 60 days. Because these scores are Tx record based, they may be easily automated to help guide VA patient care through a population management model.

FR-PO766

A Randomised Controlled Trial of Interrupted versus Continuous Suturing Techniques for Radiocephalic Fistulae: 3-Year Follow-Up Data Emma L. Aitken, David Kingsmore. *NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Continuous suturing techniques have conventionally been used for the end-to-side anastomoses of radiocephalic fistulae (RCF), however only 50-60% of RCF retain patency at one-year. We hypothesised that interrupted sutures (utilised in many microsurgical procedures) may improve outcomes of fistulae constructed from small vessels by optimising anastomotic compliance.

Methods: Three year follow-up of a randomised controlled trial comparing interrupted (n=36) vs. continuous (n=42) suturing techniques for RCF is presented. Patients were excluded if vessels were <1.8mm diameter or if previous ipsilateral fistula had been attempted. The primary end point was primary patency at 6 weeks (assessed by a blinded observer for the presence of thrill and bruit). Secondary end points were functional patency (clinical and ultrasonographic) at 6 weeks and primary/ secondary patency at 1 and 3 years (NCT01704313).

Results: Groups were comparable for basic patient demographics, operating surgeon and vessel diameter (mean age: 58.9(13.3) yrs; 67.9% male). Primary patency at 6 weeks was higher in the interrupted group (71.4% vs. 47.2%; OR 2.9 P=0.01). There was no significant difference in functional patency at 6 weeks (52.4% vs. 36.1%; OR 2.0 P=0.18). At 3 year follow-up 34.6% of patients (n=27) had died, 24.3% (n=19) had been transplanted and only 34.6% (n=27) of the patients remained on haemodialysis. Primary patency at 1 year was comparable between the two cohorts (53.3% [16 of 30 patients] vs. 45.9% [17 of 37 patients]; OR 1.34, P=0.17 for interrupted and continuous cohorts respectively). Similarly 3 year patency rates were 50.0% [13 of 26 patients] vs. 60.0% [15 of 25 patients]; OR 0.67, P=0.54).

Conclusions: An interrupted suturing technique yielded higher early primary patency rates for RCF. Less than one third of the original cohort remained on dialysis at three year follow-up. The early improvements in patency observed in the interrupted arm were not seen at 1 and 3 year follow-up. This may be the result of a small sample size (the study was not powered for secondary end-points). This study highlights the high attrition rate and short survival of patients with end-stage renal disease and brings into question whether autologous access is appropriate for ever patient.

FR-PO767

Buttonhole Versus Stepladder Cannulation for Arteriovenous Fistulas for Home Hemodialysis Patients: A Randomized Controlled Feasibility Trial Deborah Lynn Zimmerman,[8] Jennifer M. MacRae,[7] Brittany Hollingsworth,[3] Christopher T. Chan,[5] Gihad E. Nesrallah,[4] Philip McFarlane,[2] Michael A. Copland,[6] Shih-Han S. Huang.[1] *[1]London Health Sciences Centre, London, ON, Canada; [2]St. Michael's Hospital, Toronto, AB, Canada; [3]The Ottawa Hospital Research Institute, Ottawa, ON, Canada; [4]The University of Western Ontario, Toronto, ON, Canada; [5]Toronto General Hospital, Toronto, ON, Canada; [6]University of British Columbia, Vancouver, BC, Canada; [7]University of Calgary, Calgary, AB, Canada; [8]Medicine, Ottawa Hospital, Ottawa, ON, Canada.*

Background: The need for more rigorous studies to address the uncertainty about the risk and benefits of buttonhole versus stepladder cannulation for arteriovenous fistula (AVF) was highlighted in the recently published Canadian Society of Nephrology guidelines on intensive home hemodialysis (HHD). Therefore, our purpose was to determine the feasibility of doing a multi-centre randomized controlled trial of buttonhole versus step-ladder cannulation in patients training to do HHD with an AVF.

Methods: Patients were to be recruited from 7 tertiary care Canadian hospitals with expertise in home hemodialysis. Inclusion criteria were 1) adult patients training for HHD, 2) AVF, 3) life expectancy greater than 12 months, and 4) able to give informed consent. Exclusion criteria were: 1) potential loss to followup within 12 months of training, 2) allergy to mupirocin, 3) need for intradermal lidocaine, 4) short segments or aneurysms in the AVF that the care team felt required buttonhole cannulation, and 5) mechanical heart values. For our feasibility outcome, we determined that 70% of eligible patients needed to be randomized.

Results: Patients were recruited from November 2013 to Sept 2015. A total of 167 patients began training for HHD; average age 54 (±15) years, 55% male, 53% had a central venous catheter (CVC) or arteriovenous graft (AFG). Sixty patients were eligible to participate; only 14 (23%) were randomized. Of the eligible patients that we not randomized, the majority either declined study participation (16) or stated a preference for buttonhole cannulation (12). Of the 107 patients who were ineligible to participate 79 patients had a CVC and 10 patients had an AVG. Other reasons for exclusion included; did not complete training (8), potential to be lost to followup (6), buttonhole required (4), stepladder required (1), and mechanical heart values (1).

Conclusions: In spite of the stated equipoise about the optimal cannulation technique for patients with an AVF who are training for HHD, we were unable to demonstrate that a randomized controlled trial would be feasible in Canada.

FR-PO768

Protecting Patients from Venous Needle Dislodgement (VND): An Improved AV Fistula Set PATRICK ROUSCHE.[1,2] *[1]Hemotek Medical Inc., Rohnert Park, CA; [2]Bioengineering, University of Illinois, Chicago, IL.*

Background: Venous needle dislodgement (VND) is a serious patient risk for any dialysis session at home or in the clinic. Inadvertent removal of the venous line during dialysis therapy is at very least inconvient, leading to spilled blood. At worst, even just one minute of unmitigated VND at 400 mL/min can lead to hemorrhagic shock; if the VND goes undetected for 5 minutes, patients can die from exsanguination. Clinics are faced with biohazard exposure, therapy disruption and patient injury/death. Hemodialysis machines are programmed to automatically detect pressure variations between fully inserted and dislodged needles during therapy, but often fail to accurately detect VND. We introduce here a patent-pending AV fistula modification which protects patients from the risks of VND.

Methods: The standard butterfly design of traditional AV fistulas was modified to incorporate a small 'sensing' feature on the underside of the needle used to determine if the inserted AV fistula remains in close contact with patient skin. When the system detects VND, flow through the needle is immediately restricted, resulting in quick and automatic shut-off of the machine pump. The needle is otherwise designed to look and feel the same as a traditional AV fistula needle.

Results: Essential to performance testing of the new AV fistula, is its ability to pass normal amounts of fluid flow in the 'ON SKIN' condition and its ability to restrict flow when in the 'OFF SKIN' position. We used a benchtop flow system to determine the forces associated with flow termination during simulated VND. Results suggest fluid flow disruption of up to 95% through the V-Needle during simulated 'dislodgement' is achievable with closing forces of ~15 grams, a force level that can easily be tolerated on the human skin over the typical dialysis therapy.

Conclusions: The V-Needle offers a simple and elegant solution to the problem of Venous Needle Dislodgement. Fluid flow termination in the event of dislodgement can be achieved with low forces, allowing a product solution which is easily implemented in the clinic or home.

Hemotek Medical's V-Needle protects patients from VND

FR-PO769

Environmental and Patient Specific Factors Associated with Absolute AVF Blood Flow David H. King,[4] Michael G. Taylor,[5] Mo Al-Qaisi,[4,3] Sumith C. Abeygunasekara,[2] Abdelgalil A. Ali.[1] *[1]Broomfield Hospital, Chelmsford, United Kingdom; [2]Broomfield hospital, Chelmsford, United Kingdom; [3]Imperial College London, London, United Kingdom; [4]Renal, Mid Essex Hospitals, Chelmsford, United Kingdom; [5]Kings College London, London, United Kingdom.*

Background: AVF blood pressure measurement using a novel monitoring device BluedopTM combined with Color Duplex blood flow measurement has been used to identify the incidence of Normal and Failing Arteriovenous Fistulae 1. The study protocol has been repeated in two widely different environments, Europe (UK) and Africa (Sudan).

Methods: A patented algorithm based on blood velocity waveform shape, was used to calculate mean distal brachial artery blood pressure P proximal to the a-v anastomosis. Dividing flow Q by pressure P yields venous conductance VC. A value of less than 10ml per minute per mmHg correlates with a significant venous outflow stenosis of 60% or greater.

Results: There were 54 dialysis patients in the Sudan cohort of which 9 were failing according to VC criteria leaving 45 normally functioning AVF. There were 68 dialysis patients in the UK cohort of which 10 were failing, leaving 58 normally functioning AVF in the study. There was no significant difference in the percentage of failing AVF in either group (Sudan = 17%, UK = 15%). Table 1 shows Mean ± 1SD for P, Q and VC in normally functioning AVF. AVF blood flow in the Sudanese cohort was 69% greater than the UK cohort. This is a highly significant difference. The following dependencies were tested and shown to be minor or not significant NS. The tests shown here were on the Sudanese cohort: AVF Flow vs Age = NS (R2= 0.0019), AVF Flow vs Gender = NS (female vs male = 1578 ± 567ml/min vs 1882 ± 910 ml/min). In contrast published values for minimum seasonal ambient temperatures show Khartoum is approximately 14 deg C hotter than London throughout the year, supporting the concept of a temperature related association with AVF development.

Conclusions: Further research into the influence of a range of low, medium and high seasonal temperatures on AVF blood flow may supply insight into early AVF failure as well as early maturation. [1] Volume blood flow, static pressure ratio and venous conductance in native arterio-venous fistulae: three surveillance methods compared: J Vasc Access 2015;16(3);211-217

Table 1

Location	P mmHg	Q ml/min	VC ml/min/mmHg
Sudan normal AVF	50 ± 19	1797 ± 843	38.8 ± 21.3
UK normal AVF	48 ± 11	1062 ± 543	22.4 ± 11.1

FR-PO770

Identifying a Core Vascular Access Outcome for All Trials in Hemodialysis: An International Survey with Patients and Health Professionals Andrea K. Viecelli,[1,2] Martin Howell,[3] Allison Tong,[3] Jonathan C. Craig,[3] David W. Johnson,[1,2] Carmel M. Hawley.[1,2] *[1]Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [2]School of Medicine, University of Queensland, Brisbane, QLD, Australia; [3]University of Sydney, Sydney, NSW, Australia.*

Background: Vascular access is an essential component for the care of patients requiring hemodialysis, yet clinical trials report a large and diverse range of vascular access outcomes that often cannot readily be compared across trials and have no clear relevance to patients and clinicians. This survey aims to identify a core outcome for vascular access, with the expectation that this will be measured and reported in all trials involving patients requiring hemodialysis, based on the shared priorities of patients/caregivers and health professionals.

Methods: Based on a systematic review, qualitative research and meetings with vascular access experts, 12 vascular access outcomes were included in an online survey conducted in English, Chinese, Spanish and Malay. Participants rated the absolute importance of outcomes using a 9-point Likert scale (7-9 being critically important), and the relative importance was determined by a Best-Worst Scale (BWS) using multinomial logistic regression.

Results: The survey was completed by 772 participants (187 [24%] patients/caregivers and 585 [76%] health professionals) from 58 different countries. Across both groups, the top two outcomes were function (mean 8.4, top 1 on BWS) and infection (mean 8.1, top 2 on BWS). There was consistency in the prioritization of outcomes between both groups but health professionals rated outcomes overall higher than patients/caregivers (mean differences ranging from 0.09 for interference with activities to 1.3 for access maturation) with the exception of aneurysms which was ranked higher by patients/caregivers (mean difference 1.1, top 3 vs 7 on BWS).

Conclusions: For patients/caregivers and health professionals, there was consensus on the primary importance of vascular access function. A core outcome measure for function will now be developed to improve the consistency and relevance of vascular access outcomes reported in trials in hemodialysis.

Age Is Not Everything – Vascular Access for Hemodialysis in the Elderly Dallit Mannheim, Tatiana Tanasiychuk, Victor Frajewicki. *Carmel Medical Center, Haifa, Israel.*

Background: Old patients are the fastest growing incidence dialysis age-group, having increased by 57% over the last decade. Indeed, people aged more than 75 are now over 1/5 of dialysis patients. Even though arteriovenous fistulas (AVF) are the preferred vascular access for hemodialysis, with the lowest rate of morbidity and mortality, the best vascular access in the elderly is still unclear. This controversy is further accentuated by a longer maturation time of AVF and shorter life expectancy. To promote a better planning and follow-up of patients undergoing operations for vascular access at our center we initiated a multi-disciplinary clinic: every single patient is routinely evaluated before and after the operation at least by a vascular surgeon and a nephrologist.

Methods: The goal of this study was to retrospectively evaluate the outcome in patients assessed by a multi-disciplinary clinic which have undergone operations for the creation of a vascular access during 2015-2016. Primary endpoint was the rate of a functioning mature vascular access, either a fistula or a graft.

Results: During the period 291 operations for vascular access were done. All patients were evaluated by a vascular surgeon and nephrologist before the operation. Patients without clinical obvious arm or forearm cephalic veins were further evaluated by venous mapping. Male:female ratio was 3:1, Diabetes was present in 58%. 119 patients (41%) were evaluated before onset of dialysis. A primary fistula was created in 92% of cases; radio- cephalic 39%, brachio- cephalic 43%, brachio- basillar in 11%. In 17 (6%), grafts were inserted. Five patients experienced post-operative complications (including 4 cases of steal syndrome and 1 of venous hypertension). Of these, only 1 was an elder patient. Maturity was achieved in 202 accesses (73%). In 2 cases an angioplasty was needed to assist maturation. Age did not correlate with maturation as both a categorical as well as a continuous parameter for all age groups (including over 75, 80 or 85)

Conclusions: Implementation of a multi-disciplinary trained team to take care of the growing elderly population requiring dialysis is highly advised. This kind of program not only leads to a higher rate of successful vascular access but also avoids unnecessary surgical interventions and complications in patients that will not enjoy from such procedures.

FR-PO772

Keep or Remove? Arteriovenous Fistula Functionality in Patients Returning to Haemodialysis after Transplant Failure Sarah Blakey,[1] Damien Ashby.[2] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College, London, United Kingdom.*

Background: The arteriovenous fistula is the preferred access type for haemodialysis patients, but following transplantation many patients are concerned about the appearance or potential for long-term complications with a fistula, particularly since it may no longer be functional should dialysis be required years later. Little is known about the long-term patency of fistulae when redundant, or the likelihood of functionality at the point of transplant failure.

Methods: In a prospectively identified cohort of haemodialysis patients with a fistula undergoing renal transplantation between April 2007 and October 2015, records were retrospectively analysed to identify those who returned to hemodialysis, and their vascular access at the time.

Results: Out of 224 patients (aged 19-77 at transplantation, 75.4% male) followed for up to 10 years (mean 49.1 months), 24 (10.7%) died with a functioning transplant and 21 (9.4%) returned to haemodialysis after a mean of 34.3 months post-transplantation (range 0-85.5). Of the 21 patients returning to haemodialysis, 15 (71.4%) were able to use their pre-transplant fistula. Compared to those returning to dialysis with a functional fistula, those requiring new access had a longer transplant duration (66.6 vs 21.3 months, p=0.007), but there was no difference in age at transplant failure (47.8 vs 56.1, p=0.2). All patients re-starting haemodialysis within 24 months of transplantation had a functional fistula, compared to only 40% of those returning to dialysis beyond 2 years. Of the 6 patients whose fistula was non-functional, 3 had undergone excision due to fistula complications (2 aneurysms and 1 high-output heart failure), 2 spontaneously failed, and 1 required alternative access whilst a procedure was performed to recover fistula functionality.

Conclusions: Following a period of haemodialysis via fistula and subsequent transplantation, around 10% of patients return to dialysis over 4 years. The majority of these will still have functional access, but fistula patency declines with time, due to fistula complications and spontaneous failure. These data may be helpful to those making fistula decisions with transplant patients.

FR-PO773

Maintaining Vascular Access for Haemodialysis after First Vascular Intervention Pablo Justo avila,[2] Terrina Abd rahim,[1] Kumar Abayasekara,[2] Lindsay J. Chesterton,[2] Richard J. Fluck.[2] *[1]Kettering General Hospital, Leicester, United Kingdom; [2]Royal Derby Hospital, Derby, United Kingdom.*

Background: Vascular access (VA) teams struggle with VA patency as they can stenose or thrombose entailing vascular intervention (VI). We explore predicting factors for prolongation of VA function following VI and the role of antiplatelet or anticoagulant medications (AAM) on primary (PGS) and secondary graft survival (SGS).

Methods: We analysed VA formations from Oct09 to Dec15, with follow-up ending Dec16. Patient demographics, comorbidities, cause of ESRD and medications were collated. We identified location of VA, first time of VI, number of VI, failure date and cause of HD withdrawal.

Results: 427 patients (260 M and 167 F) underwent VA formation. Mean age was 63 years. 168 had DM (39.3%) and 247 had HTN (57.8%). Causes of ESRD were unknown (41.0%), DM nephropathy (30.4%), GN (21.6%), PKD (3.75%) and HTN nephropathy (3.28%). 315 were on AAM; 19 (3.9%) on warfarin (W), 17 (3.5%) on clopidogrel (CL), 253 (52%) on aspirin (AP), 17 (3.5%) on AP and CL and 9 on W and AP. 538 VA were formed (209 radiocephalic [RC], 229 brachiocephalic [BC], 87 brachiobasilic [BB] and 13 AVGs); 487 usable for HD. Mean follow-up was 850 days (SD 718). 286 (58.7%) required VI; (8 revisions [RV], 278 angioplasty [AG], 33 RV and AG) comprising 116 RC, 109 BC, 51 BB and 10 AVG. Median time to AG was 371 days; while to RV was 443 days. Mean PGS was 356 days (SD 372). Median AG performed was 2.8 (SD 2.25). 153 patients discontinued HD due to death (24.8% [71]), thrombosis of VA (21.7% [62]) and functioning transplant (7%[20]). SGS was 760 days (SD 528). We excluded patients who died or received transplant from analysis. We found no correlation between having DM or HTN, cause of ESRD, and type of VA with graft patency. VI in the first 6 months after VA formation was associated with worse patency rates (27.27% vs 53.97% [p < 0.001]). HTN was associated with longer SGS (697.73 vs 550.76 days [p 0.004]) whilst DM was associated with shorter SGS (578.76 vs 673.12 days [p 0.039]). AAM was not associated with improved patency (59.09% vs 70.96% [p 0.076]) or SGS (626 vs 656 days [p 0.178]).

Conclusions: 1. VI in the first 6 months after VA formation is associated with worse patency rates. 2. Less stringent BP control but tight glycaemic control could potentially

increase patency rates of VAs. 3. AAM is not directly associated with higher patency rates or prolongation of SGS.

FR-PO774

Pre-Dialysis Cognitive Impairment and Pre-Emptive Placement of Dialysis Access: Findings from the Chronic Renal Insufficiency Cohort Study Meera N. Harhay,[16] Dawei Xie,[15] Chi-yuan Hsu,[9] Alan S. Go,[4] Jing Chen,[7] James P. Lash,[11] Sanjeev Akkina,[5] Xiaoming Zhang,[14] Eric Vittinghoff,[10] Stephen M. Sozio,[3] Stephen L. Seliger,[12] Mirela A. Dobre,[1] Jacob B. Blumenthal,[2] Rajat Deo,[13] Peter P. Reese,[13] Kristine Yaffe,[8] Manjula Kurella Tamura.[6] *[1]Case Western Reserve University, Cleveland, OH; [2]Department of Veterans Affairs, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD; [4]Kaiser Permanente Northern California, Oakland, CA; [5]Loyola University Medical Center, Chicago, IL; [6]Stanford University, Palo Alto, CA; [7]Tulane School of Medicine, New Orleans, LA; [8]UCSF, San Francisco, CA; [9]University of California San Francisco, San Francisco, CA; [10]University of California, San Francisco, San Francisco, CA; [11]University of Illinois at Chicago, Chicago, IL; [12]University of Maryland School of Medicine, Baltimore, MD; [13]University of Pennsylvania, Philadelphia, PA; [14]University of Pennsylvania School of Medicine, Philadelphia, PA; [15]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA; [16]Drexel University College of Medicine, Philadelphia, PA. Group/Team: CRIC Study Investigators.*

Background: Cognitive impairment (CI) is a common finding in late-stage chronic kidney disease (CKD), but few studies have examined its direct impacts on dialysis preparedness. We assessed the independent association of pre-dialysis CI on the probability of pre-emptive permanent access placement among participants from the Chronic Renal Insufficiency Cohort (CRIC) Study who started dialysis.

Methods: We identified 630 CRIC participants who initiated dialysis. We defined pre-dialysis CI as a Modified Mini-Mental State Examination score < 80 measured prior to dialysis initiation. We estimated the association between CI and access placement using logistic regression models for the probability of 1) having permanent access placed before dialysis initiation, and 2) using the permanent access at the first dialysis session.

Results: The cohort had a mean age of 59 years (SD 12 years) and mean eGFR of 16 ml/min/1.73m^2 (SD 3 ml/min) at the pre-dialysis cognitive assessment. Pre-dialysis CI was present in 14% (n=89) of the cohort. Compared to participants without CI, more participants with CI reported low income status (64% vs 38%, p<0.001) and low educational attainment (71% vs 22%, p<0.001). Pre-emptive access was placed in 75% of the cohort (n=473), and 45% of participants initiated dialysis using a permanent access (n=279). After adjustment for eGFR slope, demographics, diabetes, hypertension, vascular disease, functional status, and smoking, pre-dialysis CI was associated with a 48% lower probability of pre-emptive access placement (aOR 0.52, 95% CI 0.29-0.91) and a 45% lower probability of starting dialysis using a permanent access (aOR 0.55, 95% CI 0.32-0.97). After adjustment for socioeconomic variables including income, these associations were no longer statistically significant.

Conclusions: In this study, we found an association between pre-dialysis CI and suboptimal access outcomes, though this finding was not independent of socioeconomic status. Given the known relationship between socioeconomic status and CI, future studies may consider incorporating measures of pre-dialysis CI when evaluating strategies to reduce disparities in dialysis preparedness.

FR-PO775

A Meta-Analysis of Randomized Clinical Trials of Blood Flow and Stenosis Surveillance of Hemodialysis Access Seon Deok Hwang,[1] Seoung Woo Lee,[2] Moon-Jae Kim.[3] *[1]Inha University College of Medicine, Incheon, Republic of Korea; [2]Inha University Hospital, Inchon City, Republic of Korea; [3]Kidney Center, Inha University Hospital, Incheon City, Incheon, Republic of Korea.*

Background: Regular vascular access blood flow (Qa) surveillance is recommended to detect graft or fistular stenosis. However, published studies have reported conflicting results of its utility that led healthcare professionals to doubt the benefits of this surveillance method. We find to access blood flow monitoring lowers the risk of AV access thrombosis or stenosis and that the outcomes differs between arteriovenous(AV) fistular (AVF) and arteriovenous graft (AVG)

Methods: We performed a systematic review of the available literature according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses. An electronic search was conducted using the MEDLINE, EMBASE, and Cochrane Library databases from 1980 to 2017 for 9 RCTs involving dialysis access blood flow measurement. All studies combined included a total of 981 patients with hemodialysis vascular access of whom 649 had AVF and 332 had AVG.

Results: The estimated overall pooled risk ratio (RR) of thrombosis was 0.782 (95% confidence interval [CI], 0.553 to 1.107) favoring access blood flow monitoring. The pooled RR of thrombosis were 1.104 (95% CI, 0.672 to 1.816) in the AVG group. However, In AVF subgroup, the pooled RR of thrombosis statistically significant decrease surveillance group 0.562 (95% CI, 0.346 to 0.915).

Conclusions: The benefit of AV access surveillance using access blood flow monitoring to lower the risk of thrombosis is uncertain in AVG group. But, using access AVF surveillance is effective method in hemodialysis patients.

FR-PO776

Which Test Is Best for Detecting Stenosis and Predicting Thrombosis in Arteriovenous Graft? A Diagnostic Accuracy Comparative Study Nicola Tessitore,[2] Giuseppina Pessolano,[2] Giovanni Lipari,[3] Giancarlo Mansueto,[1] Valeria Bedogna,[2] Alberto Contro,[1] Albino Poli,[1] Antonio Lupo.[2] *[1]AOUI Verona, Diagnostics & Public Health Dpt, Verona, Italy; [2]AOUI Verona, Nephrology Unit, Verona, Italy; [3]AOUI Verona, Surgery Dpt, Verona, Italy.*

Background: Guidelines recommend regular screening of grafts for significant >50% stenosis (St) by surveillance (access blood flow[Qa], static venous pressure ratio[sVPR] or Duplex Ultrasound [D]) and state that there is insufficient evidence to prefer one tool over another due to the lack of studies comparing vis-a-vis all of the options

Methods: To identify optimal criteria for St detection and elective repair, we compared in 52 PTFE grafts the Area under Receiver Operator Curve (AUC[95%CI]), sensitivity (SE) & false positive rate (FPR) of clinical monitoring (M), Qa by ultrasound dilution (QaU), sVPR, & D to detect >50% St (StD) and measure Qa (QaD) for >50% St at angiography (StA) and incipient thrombosis (within 4-mo).

Results: Prevalence of StA was 52%. M could not detect StA (AUC 0.60[0.45-0.76]), while all surveillance tools had a similarly significant accuracy for StA: StD (AUC 0.91[0.79-0.97]; SE 85%, FPR 4%), QaU (AUC 0.89[0.77-0.96]; Qa<1300 ml/min: SE 78%, FPR 8%), sVPR (AUC 0.78[0.65-0.89]; sVPR>0.7: SE 89%, FPR 40%), QaD (AUC 0.73[0.59-0.84]; Qa<1300 ml/min: SE 76%, FPR 48%). 31 thromboses occurred during the follow-up. Only QaU (AUC 0.75[0.64-0.84], p<0.001; QaU<1200: SE 68%, FPR 29%), QaD (AUC 0.67[0.53-0.80], p<0.03; QaD<1300: SE 87%, FPR 57%) & StA (AUC 0.61[0.50-0.72], p<0.05; SE 73%, FPR 47%) were equally significant predictors of thrombosis, though their AUC was similar to StD (AUC 0.60[0.46-0.72]) & sVPR (AUC 0.59[0.47-0.70]). At Cox's multivariate analysis (in a model including StA or StD, QaU or QaD, sVPR, M & acute symptomatic Hypotension during the follow-up) the only significant & independent predictors of incipient thrombosis were Hypotension (with a 4-fold [95%CI:2-18] increased risk, p=0.001), QaU or QaD (with a 20% [95% CI:10-40] greater risk for each 100 ml/min drop in Qa, p<0.01). At univariate analysis, the risk of thrombosis increased significantly at QaU<1200 ml/min (RR 3.7 [95%CI:1.7-8.7], p<0.001) or QaD<1300 ml/min (RR 4.1 [95%CI:0.9-37.1], p<0.05).

Conclusions: Our comparative study suggests that in graft an effective screening program should be based on Qa surveillance (QaU or QaD) & the risk of thrombosis may be contained by avoiding acute hypotension & electively repairing St at a QaU<1200 ml/min or QaD<1300 ml/min.

FR-PO777

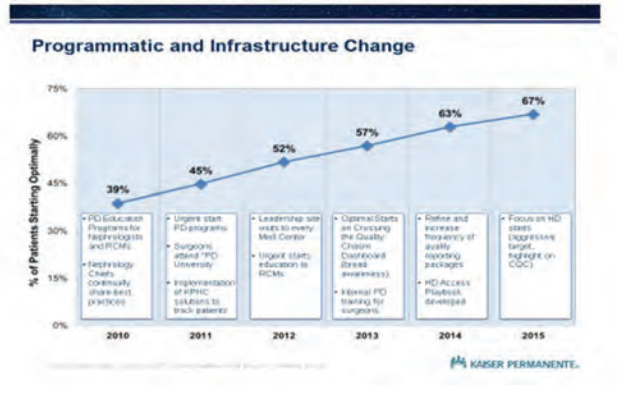
Optimal ESRD Starts as an Organizational Metric Enabling Reduction in CVC Use Leonid Pravoverov,[1] Sijie Zheng,[2] Joanna Mroz.[2] *[1]Kaiser Permanente, Walnut Creek, CA; [2]The Permanente Medical Group, Oakland, CA.*

Background: Patients who initiate dialysis with central venous catheters are associated with higher rate of infection, death and hospitalization. However in the United States, on average 80% of patients started hemodialysis are using central venous catheter instead of a matured AVF/AVG. Kaiser Permanente Northern California (KPNC) is an integrated health care system of 4 million members with an average of 1300 patients starting renal replacement therapy every year. Through a systemic multi-discipline approach, KPNC was able to gradually increase patients with and "optimal start" to 67% and reduce incident patients using CVC to initiate dialysis to 33%.

Methods: Since 2009 KPNC adopted Optimal ESRD Starts metric, targeting to (1) increase use of home dialysis modalities, Peritoneal Dialysis (PD) and home hemodialysis (HHD), (2) increase use of AVF/AVG in hemodialysis population and (3) increase number of pre-emptive transplants.

Results: Throughout systematic approach and advantages of integrated healthcare system, we are able to reduce use of CVC as an initial access for dialysis to less than 33%.

Conclusions: It is feasible to decrease CVC in patients starting renal replacement therapy by systemic and multi-disciplinary approach.



FR-PO778

Efficacy of Peri-Vascular Anesthesia in Dialysis Access Procedures – Experience from Saudi Arabia Danyal Hassan. *DaVita Saudi Arabia, Jeddah, Saudi Arabia.*

Background: Early and late venous stenosis within a dialysis access is a common complication requiring endovascular intervention. These procedures are typically done under sedation because of pain and discomfort to the patients. On the other hand use of sedation is associated with higher risk of complications.

Methods: We describe the use of peri-vascular local anesthesia (PVA), in a free standing vascular access center (VAC), to treat area of stenosis in dysfunctional dialysis access. The area of the stenosis was identified using standard angiogram and PVA was provided under ultrasound guidance. The pain experienced by the patients was recorded on a numeric score from 0-10; during the procedure and at the time of discharge. This was then divided into adequate, moderate and poor pain control.

Results: Data was collected for 83 patients who underwent 112 encounters over a period of 15 months. Mean age of the patients was 54 years, with 51% male patients. There were 54 cases of outflow stenosis, 34 inflow stenosis, 10 cases of both inflow and outflow stenosis treated during the same procedure, and 14 thrombectomy cases including 12 AVF thrombectomy and 2 AVG thrombectomy. During procedure 4 covered stents were placed, 2 of them to treat complications. Overall adequate pain control (0-3) during the procedure was achieved in 91 patients (81%), moderate pain control in 16 patients (14.2%) and poor pain control in 5 patients (4.4%). Post procedure 97% of the patient reported adequate pain control and 3% reported moderate pain control. For thrombectomy procedures 6 (43%) patients reported adequate, 6 (43%) reported moderate and 2 (13%) reported poor pain control. Overall procedure success rate was 98%, with 3 procedures related complications including two Grade I hematomas and one Grade II hematoma. In one case the procedure was stopped due to poor pain control, leading to anxiety, chest pain and transfer to the ER. No PVA related complications were reported except for mild local infiltration and erythema.

Conclusions: In this series, ultrasound guided PVA provided good pain control for endovascular procedures in outpatient setting with minimal complications. In case of thrombectomy, PVA should be decided on case to case basis, due to a higher moderate and poor pain control during the procedure.

FR-PO779

Correlation of Intradialytic Blood Pressure Variability with Vascular Access Outcomes in Hemodialysis Patients Hye mi Seo, Hyunwoo Kim, Ji young Kim, Miyeon Kim. *Jeju National University Hospital, Jeju City, Republic of Korea.*

Background: Hemodialysis vascular access dysfunction is a major cause of morbidity and hospitalization in patients on hemodialysis. Identifying risk factors of vascular access failure is important because it will likely allow early intervention for dysfunctional hemodialysis fistulas. Recent studies has shown that blood pressure variability during dialysis are associated with increased cardiovascular morbidity and mortality. But there have been no studies related to effect of intradialytic BPV on vascular access outcomes. This study aimed to investigate the correlation of intradialytic BPV with vascular access outcomes in hemodialysis patients.

Methods: We examined 130 end stage renal disease patients with created vascular access between January 2009 and December 2016 in our hospital. Blood pressure data were collected three month after the start of hemodialysis for adaptation period. We examined 12 dialysis session per patient and recorded five times blood pressure for each session. Blood pressure variability (BPV) was assessed using the standard deviation of the residual derived from linear regression model. The primary outcome was primary vascular access patency defined as time to first intervention including angioplasty or surgical revision. Cox proportional hazards regression anlysis was used to access the risk of primary outcome (reintervention) or secondary ouctome (failure).

Results: Patients were followed up an average of 3.7 years. Patient's mean age was 62 years. Among these, 64% of patients were male, 53% of patients had DM. We devided patients into two groups according to intradialytic blood pressure variability. The mean time to primary patency of high BPV group was 750 ± 131 days and low BPV group was 1613 ± 190 days. After adjustment for demographics, comorbidities and medications, high BPV was significantly associated with worse primary outcome (HR, 2.30; 95% CI 1.39-3.82; p = 0.01) and worse secondary outcome. (HR,2.81; 95% CI 1.14-6.93; p = 0.025)

Conclusions: We observed a significant correlation between intradialytic BPV and vascular access patency. Lowering Intradialytic BPV is important to improve vascular access patency in hemodialysis patients.

FR-PO780

Association between Post-Dialysis Hemoglobin Level and the Survival of Vascular Access Hiroki Nishiwaki,[7] Takeshi Hasegawa,[7] Naoto Tominaga,[3] Masahiko Yazawa,[1] Hiroo Kawarazaki,[6] Tatsuyoshi Ikenoue,[5] Yugo Shibagaki,[2] Shingo Fukuma,[4] Shunichi Fukuhara.[4] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, St.Marianna University School of Medicine, Kawasaki, Japan; [2]Division of Nephrology and Hypertension, St Marianna University Hospital, Kawasaki, Japan; [3]Georgetown University Medical Center, Washington, DC; [4]Kyoto University, Kyoto, Japan; [5]Kyoto University Graduate School of Medicine and Public Health, Kyoto, Japan; [6]None, Tokyo, Japan; [7]Showa University Fujigaoka Hospital, Yokohama, Japan.*

Background: Although a few dialysis facilities conduct a complete blood cell count for some patients at post-dialysis, including hemoglobin, clinical findings supporting the interpretation of results are scarce. The aim of this study was to investigate the association between post-dialysis hemoglobin level and vascular access failure with clinical data.

Methods: Study Design: Case crossover design Setting: Japanese dialysis facilities which routinely take post-dialysis blood samples, including complete blood cell counts at least once a month. Participants: Hemodialysis patients who experienced vascular access failure in Jan. 2010- Dec. 2014. Exposure: Post-dialysis hemoglobin level Main outcome: Vascular access failure treated with endovascular treatment or operation. Statistical analysis: Self-matched odds ratios and 95% confidence intervals were estimated by comparing post-dialysis hemoglobin just before events ("case") with levels at 6 and 12 months before events ("control") using conditional logistic regression, and presented with restricted cubic spline.

Results: 230 hemodialysis patients with vascular access failure were identified. Mean post-dialysis hemoglobin level before the failure was 11.8 g/dl (standard deviation 1.7). The spline curve showed that higher post-dialysis hemoglobin levels above 11.8 g/dl had a greater odds ratio for vascular access failure. Post-dialysis hemoglobin levels and odds ratios (95% Confidence Interval) for vascular access failure relative to the reference value (Hb 11.8 g/dl) were Hb 12.0 g/dl, 1.1 (1.0-1.1); Hb 14.0 g/dl, 3.3 (1.3-8.3); and Hb 16.0 g/dl, 12.7 (1.8-89.4).

Conclusions: A higher post-dialysis hemoglobin level was associated with vascular access failure. Higher post-dialysis Hb could be a factor which triggers vascular access failure.

FR-PO781

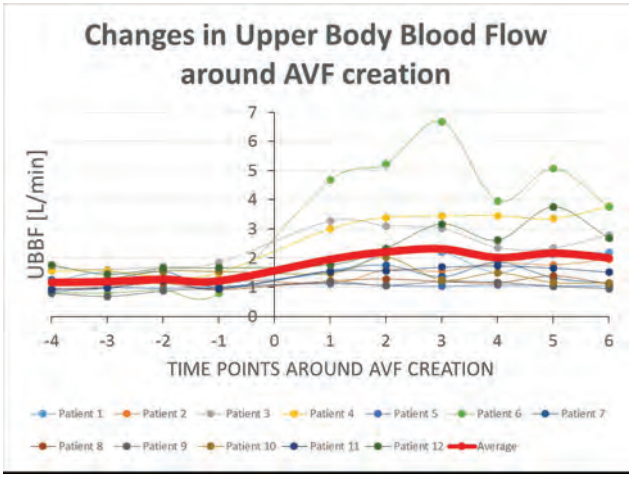
Changes in Upper Body Blood Flow after AV Fistula Creation in Hemodialysis Patients Israel Campos,[1] Hanjie Zhang,[2] Priscila Preciado,[1] Stephan Thijssen,[1] Peter Kotanko.[1] *[1]Renal Research Institute, Morelia, Michoacán, Mexico; [2]Renal Research Institute, New York, NY.*

Background: Hemodynamic changes occurs after AV fistula (AVF) creation. Cardiovascular adaptive mechanisms allow adequate AVF maturation, usually accompanied by an increase in cardiac output (CO). In hemodialysis (HD) patients with a central-venous catheter (CVC), upper body blood flow (UBBF) can be estimated [Campos et al., WCN 2017]. UBBF is expected to increase after AVF placement in the presence of normal AVF maturation and adequate adaptation

Methods: We estimated UBBF around AVF creation using averaged central-venous oxygen saturation and hemoglobin data from the Crit-Line® Monitor (CLM) (FMC, Waltham, MA) in HD patients from Renal Research Institute clinics. Brain mass was calculated using the Mehrpour formula [J Forensic Leg Med. 2010]. Arm muscle mass was set at 2.3kg for males and 1.2kg for females [Abe T, Br J Sports M. 2003]. Tissue-specific O2 consumption rates were taken from Sokoloff L [Handbook of Physiology. 1960]. Arterial O2 saturation was taken from a large HD population [Meyring-Wösten, CJASN. 2016]. We compared the four closest UBBF values before AVF creation, the first three UBBF estimates after AVF creation and the last three UBBF estimates before first AVF cannulation

Results: We analyzed 12 patients (8 males), mean age 60±12 y. While individual UBBF trajectories differed between patients, UBBF did rise on average after AVF creation (Figure). The average UBBF before and after AVF creation was 1.21±0.03L/min, and 2.15±0.76L/min respectively, and UBBF before the first AVF cannulation was 2.06±0.62L/min

Conclusions: Hemodynamic changes related to AVF creation can be detected non-invasively in HD patients using the CLM. As expected, UBBF increases on average after AVF creation. A prospective study with AVF flow rate measurements alongside UBBF estimation would be insightful and help define the expected UBBF trajectory in well-maturing AVFs



FR-PO782

Characteristics of Permanent Vascular Access of Young Children (≤12 Years Old) on Chronic Hemodialysis Reut R. Pagi, Gaurav Kapur, Rudolph P. Valentini, Amrish Jain, Tej K. Mattoo, Rossana Baracco. *Children's Hospital of Michigan, Detroit, MI.*

Background: Hemodialysis (HD) is the most commonly used dialysis modality in children with end stage renal disease. Because of perceived proximity to transplantation and smaller blood vessels in children, central venous catheters (CVC) remain the most commonly used access for children in the United States and are more frequently used over a permanent access: either an arteriovenous fistula (AVF) or arteriovenous graft (AVG). The aim of this study was to compare efficacy and complications of these HD accesses in young children.

Methods: This was a retrospective chart review of patients who started chronic HD at age ≤12yo from 2008 to 2016. Data collected and compared included age and weight of the patient, infectious and non-infectious complications and hospital admissions related to the access; as well as treatment characteristics at 6 months including adequacy of dialysis (Kt/V), hematocrit, albumin, erythropoietin dose and calcitriol dose.

Results: There were 39 accesses used by 19 patients (16 CVC's, 16 AVF's and 7 AVG's). Medians were 8 years (1 – 12) for age and 23.4kg (6.6 – 110.7) for weight. Median days on HD per patient was 696 (317 – 1826). Treatment characteristics at 6 months showed that Kt/V was 2 for permanent access and 1.42 for CVC (p=0.03). Albumin and hematocrit were not significantly different between the 2 groups. Patients with CVC required 33% more erythropoietin and 100% more calcitriol than the patients with permanent access, however, this difference was not statistically significant. Patients using permanent access had lower rates of infectious complications, total complications, hospital admissions and shorter hospital stays (p<0.01 for all categories).

Conclusions: Commitment to using permanent access (AVG or AVF) in young children on chronic HD led to more cost-effective care in view of decreased complications, hospitalizations and better adequacy of dialysis.

Access Related Complications per 100 Days of HD (mean)

	CVC	Permanent access	P value
Bloodstream infections (BSI)	0.61	0.03	<0.001
Hospital days secondary to BSI	2.32	0.13	<0.001
Antibiotic treatment days secondary to BSI	9.32	0.50	<0.001
Admissions related to access complications	0.95	0.40	<0.001
Total complications	0.93	0.52	<0.001
Hospital days related to access	3.05	1.21	<0.001

FR-PO783

Impact of a Compressive Therapy via Arm Sleeve on High Flow Arteriovenous Fistula and Cardiac Output in Patients with ESRD Jong-Hwan Jung, Seon-Ho Ahn. *Wonkwang University Hospital, Iksan, Republic of Korea.*

Background: Heart failure is among cardiac complications in patients with end-stage renal disease (ESRD) undergoing hemodialysis via arteriovenous fistula (AVF). AVF creation may result in several cardiac dysfunctions, such as increase of left ventricular end-diastolic diameter, left ventricular hypertrophy, and high output heart failure, particularly in patients with AVF flow over 2000 ml/min. Surgical reduction of AVF to improve cardiac dysfunctions may often result in complications, such as access thrombosis. Thus, we suggests non-invasive compressive method via arm sleeve to reduce blood flow of high flow AVF.

Methods: Data were collected from total 30 patients with ESRD and high flow AVFs. All patients have autologous AVFs and have undergoing hemodialysis of three times sessions per week. All patients also have high flow AVFs with blood flow rate over 1200 ml/min. Arm sleeve (Nambuk Surgical®, Seoul, Korea) with pressure of 30~40 mmHg was applied during 8 hours on non-hemodialysis dates for three months in only fifteen patients. We performed comparative analysis for changes of AVF flow rates, cardiac output, and arm edema after application of arm sleeve in two groups.

Results: The average change of AVF flow rate in group which arm sleeve was applied was – 60 ml/min. On the contrary, average change of AVF flow in control group was 19.33 ml/min. The average AVF flow rate in group which arm sleeve was applied decreased statistically significant. (p <0.001) Also, arm edemas decreased significantly in patient which arm sleeve was applied. (-0.28 ± 0.28 vs 0.23 ± 0.26, -0.32 ± 0.25 vs 0.12 ± 0.24, -0.36 ± 0.37 vs 0.31 ± 0.21, -0.37 ± 0.30 vs 0.31 ± 0.32, and -0.45 ± 0.44 vs 0.33 ± 0.34; p <0.001) We analyzed changes of cardiac output. However, there was no significant difference concerning of change of cardiac output in two groups. (-0.01 ± 0.005 vs 0.005 ± 0.17, p =0.091)

Conclusions: The non-invasive compressive method reduced arm edema and AVF flow rate in patients with high flow AVFs. High flow rate over 2000 ml/min of AVF can be a risk factor of development of high output heart failure in patients with AVFs. Although there was no an effective impact of the non-invasive compressive method on cardiac output, reduction of edema and AVF flow rate might inhibit development of high output heart failure in patients with high flow AVFs

FR-PO784

Acetate Free Dialysis and Mortality in the French Renal Epidemiology Information Network Registry (REIN) Lucile Mercadal,[1,6] Abdoulaye Ndoye,[4] Marie Metzger,[3] Christian Jacquelinet,[2] Benedicte Stengel.[5] *[1]nephrology, AP-HP, Pitié Salpetrière hospital, Paris, France; [2]Agence de la biomedecine, Saint-Denis La Plaine, France; [3]CESP U1018, INSERM, Villejuif, France; [4]INSERM, Villejuif, France; [5]Inserm ? CESP, Villejuif, France; 6team 5, INSERM-CESP, Villejuif, France.*

Background: We previously found a reduced mortality associated with the use of acetate free dialysis (AFD) in subjects older than 70 years old. As the use of these dialysates made with chlorhydric or citric acid steadily increases since 2010, we wonder whether this result can be reproduced in the last recent years.

Methods: All patients who started HD from 2010 to 2013 were classified according to their exposure to AFD: exposed in a 100% AFD dialysis center, exposed in a mixed center (both standard and AFD) and unexposed. Cox survival analysis was performed in 26 304 incident patients, adjusted for 15 baseline co-morbidities and biological data and accounting for patient clustering within facilities. Exposure to AFD and hemodiafiltration (HDF) status were analyzed as time-dependent variables. Analysis was censored at Dec 31, 2014, or at kidney transplantation, lost to follow-up, dialysis weaning or transfer to peritoneal dialysis. The Cox model was used for the overall population and by age group, <70 or ≥70 years.

Results: During the study period, 16 124 subjects were exclusively dialyzed in centers with standard dialysate, 380 in 100% AFD centers, 7538 in mixed centers and 6481 had a change in their AFD exposure. Being dialyzed in mixed centers was associated with a mortality HR of 0.53 (0.47-0.60) for subjects <70years old and of 0.57 (0.52-0.62) for those ≥70. Being dialyzed in 100% AFD centers was associated with a mortality HR of 0.80 (0.59-1.09) for subjects <70 years old and of 0.68 (0.54-0.87) for those ≥ 70. The Cox on the overall population found a mortality HR of 0.56 (0.51-0.61) for being dialyzed in mixed centers and of 0.73 (0.6-0.89) for 100%AFD centers.

Conclusions: Using an entirely new data set of subjects exposed to AFD in the REIN registry, we confirm that being dialyzed with AFD is associated with a reduced mortality risk. In a larger AFD exposed population, the mortality reduction seems more constant with age.

FR-PO785

Forecasts for 2030 for the ESRDDialysis Workforce in the US Ivo Abraham,[2] Chinmayee Katragadda,[2] Michael Katz,[2] Brian Erstad,[2] Karen Macdonald.[1] *[1]Matrix 45, Tucson, AZ; [2]University of Arizona, Tucson, AZ. Group/Team: For ESRD Workforce Investigators.*

Background: The continued rise in patients requiring renal replacement therapy impacts the ESRD/dialysis workforce demand. We aimed to estimate for 2030, on the demand side, the number of patients requiring dialysis; and on the supply side, workforce requirements for nephrologists, nurses (registered nurses and advanced practice nurses) and technicians (licensed practical/vocational nurses and dialysis technicians).

Methods: We forecasted the demand and supply sets using time series analysis with autoregressive integrated modeling (ARIMA). We used annual 2008-2014 USRDS data for the number of dialysis patients, dialysis centers, and FTE nurses and technicians; and 2008-2016 ASN data for nephrologists. We assumed similar dialysis practice patterns in 2014 and 2030.

Results: Forecasting models projected the following for 2030; all with adequate to superior goodness-of-fit. On the demand side, 689693 patients and 9911 centers. On the supply side 13107 nephrologists, 51381 FTE nurses, and 62243 FTE technicians. By 2030 the ratio of patients:nephrologist will have increased to 52.6:1; of patients:nurse to 13.4:1; and of patients:technician to 11.1:1. The supply differential of nephrologists is projected to be -386 shortage; of nurses +5679 surplus; and of technicians -2276 shortage.

Conclusions: Significant shortages of nephrologists and FTE technicians are anticipated by 2030 to meet the demand of patients requiring dialysis and the centers providing this dialysis. The shortage in centers can be addressed by enhanced operational efficiency and increased volume, but the latter is constrained by the need for geographically equitable access. Though the emerging use of advanced practice nurses may enable shifting some responsibilities' from nephrologists, in general nurses can assume few if any nephrologists' responsibilities. In addition to potentially being inappropriate professionally, wage differences make nurses fulfilling tasks of technicians economically not feasible. Funding for nephrology fellowship training needs to be

diversified and recruitment intensified (inter)nationally; while novel training programs between the dialysis sector and community/technical colleges are required to address the technician demand.

FR-PO786

Relative Blood Volume Changes and Mortality among Hemodialysis Patients Priscila Preciado, Hanjie Zhang, Stephan Thijssen, Peter Kotanko. *Renal Research Institute, New York, NY.*

Background: Ultrafiltration during hemodialysis (HD) is the only means to remove excess fluid. In most HD sessions the ultrafiltration rate exceeds the refilling rate (UFR), leading to decreased blood volume and potentially intradialytic hypotension and increased morbidity. While relative blood volume (RBV) monitoring is widely used, the relationship between RBV levels and outcomes is ill-defined

Methods: Retrospective multi-center study in HD patients from 17 Renal Research Institute (RRI) clinics between 1/2012-12/2016. A 6-months baseline period preceded follow-up period. Hematocrit-based RBV was reported 1x/minute by the Crit-Line® Monitor (CLM;Fresenius Medical Care, Waltham, MA). Hourly RBV levels were defined as the mean RBV between treatment minutes 50 and 70,110 and 130, and 170 and 190. The relationship between mortality and hourly RBV levels was analyzed using Cox proportional hazards models with spline terms

Results: We included 842 patients with 28,119 HD treatments (mean age 61.0±14.8 years, 50% whites, 62% males, 56% diabetes mellitus, 22% congestive heart failure). Median follow-up was 2.7 years. Hazard ratios for all-cause mortality were significantly reduced in patients who achieved RBV levels [%] of 93-96 at 1 hour, 89-94 at 2 hours, and 86-92 at 3 hours. Subgroup analysis by age, gender, race, comorbidities, pre-HD blood pressure, and UFR showed similar results

Conclusions: To our knowledge this is the first study to examine the relationship between achieved intradialytic RBV levels and all-cause mortality in a large and diverse HD population. Our key finding is the association of specific RBV levels with reduced mortality. Prospective studies are warranted to test the hypothesis that attainment of these levels improve outcomes

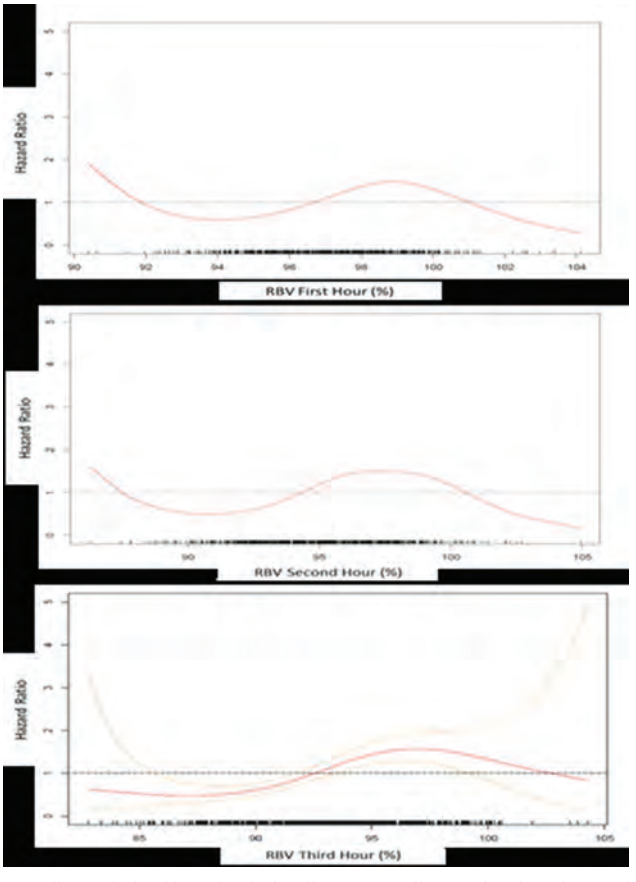


Fig 1 Spline analysis of hazard ratio for all-cause mortality as a function of RBV after 1, 2, and 3 hours

FR-PO787

Effects of Post-Dilution High Volumen On-line Hemodiafiltration in Comparison to High-Flux Hemodialysis: A One-Year Prospective and Controlled Study Fernando F. Hadad-Arrascue,[1,2] Gabriela I. Pimentel,[1,2] Barbara Fernandez-Lopez,[1,2] Maria D. Algaba,[1,2] Marisol Poma tapia.[3] *[1]Nephrology, Clinica RTS Murcia VII, Murcia, Spain; [2]Nephrology, Hospital Universitario Reina Sofia, Murcia, Spain; [3]Nephrology, Hospital Universitario Clinico San Carlos, Madrid, Spain.*

Background: It is suggested that post-dilution on-line Hemodiafiltration (OL-HDF) may improve clinical outcomes. Currently, the world-wide acceptance of HDF is low because higher costs and its benefits have not been well demonstrated. The aim of this prospective and controlled study was to compare the effects of post-dilution OL-HDF and conventional high-flux HD during one year.

Methods: One-hundred fifteen clinically stable HD patients were randomized in two groups: OL-HDF group (55 patients, ages 29-81 years, mean time on dialysis 5.2 years) and HD group (60 patients, ages 39-95 years, mean time on dialysis 6.5 years). All patients were scheduled sessions thrice weekly with a stable arteriovenous fistula, blood flow rate (QB) 364 ml/min (316-410 ml/min) in OL-HDF and QB 356 ml/min (306-400 ml/min) in HD. The same Polysulfone membrane high-flux dialysers and Artis Physio dialysis machines for both groups were used during the entire study period. OL-HDF procedure was performed in the post-dilution mode and the substitution volume was targeted to be above 20 L per session.

Results: During follow-up, there were no significant differences in mean hemoglobin (11.7±1.5 g/dl OL-HDF vs. 11.74±1.45 g/dl HD), mean transferrin saturation (24.6±14.3% OL-HDF vs. 22.9±16.4% HD), but the mean prescribed erythropoietin (EPO) dosage was significantly lower in OL-HDF than HD (14676±2889 vs. 15300±4550 U/month, P<0.05). The mean prescribed intravenous iron dosage was not different among the groups. OL-HDF group was lower the mean ferritin (483.3±45.7 ng/mL vs. 601.6±35.6 ng/mL, P<0.005), mean high-sensitivity C-reactive protein (0.42±0.1 mg/dL vs. 0.62±0.15 mg/dL), mean intact parathyroid hormone (327.09±45.7 pg/mL vs. 346.95±35.6 pg/mL, P<0.05), despite similar calcium (8.82±0.14 mg/dL vs. 8.89±0.16 mg/dL) and phosphorus (4.09±0.16 mg/dL vs. 4.01±0.11 mg/dL, P>0.05). The β-2 microglobulin remained lower (23.53±12.1 mU/mL vs. 26.94±12.43 mU/mL, P<0.05) and mean Kt was significantly higher (53.12±1.9 vs. 48.18±1.87, P< 0.05) in OL-HDF, despite the mean eKt/V was similar in both groups.

Conclusions: Post-dilution OL-HDF is a safe and well-tolerated treatment, increased dialysis dose, reduced inflammation and needed lower requirement for EPO to correct anemia compared with high-flux HD.

FR-PO788

Increased Levels of Extracellular Nucleosomes, Biomarkers of Cell Death, in Stage 5 Chronic Kidney Hemodialysis (CKD5-HD) Are Independent of Circulating Tissue Factor Microparticle Complex Vinod K. Bansal,[1] Trung Phan,[1] Ryan Mcmillan,[1] Amanda Walborn,[2] Debra Hoppensteadt,[1] Jawed Fareed.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Medical Center, Maywood, IL.*

Background: Extracellular nucleosomes in plasma (PNs) are complexes of DNA and histones that are released during cell death. In both the chronic and acute kidney injury, there is an increased release of nucleosomes with decreased nucleosome clearance. Nucleosomes mediate inflammatory and thrombotic responses and could serve as biomarkers in chronic kidney diseases. Microparticle-associated tissue factor (MP-TF) are released during cell death and mediate thrombotic responses.

Methods: Plasma levels of PNs in CKD5-HD patients (n = 90) and healthy volunteers (n = 50) were measured using the Cell Death Detection ELISA PLUS assay (Roche Diagnostics, Mannheim, Germany). MP-TF levels were measured using the ZYMUPHEN MP-TF kit (Hyphen BioMed, Neuville-sur-Oise, France). The levels of both PNs and MP-TF were also correlated with WBCs, RBCs and platelets to determine the origin of measured PNs.

Results: In comparison to the plasma from healthy volunteers (6.74 ± 13.7 Arbitrary Units (AU)), the levels of PNs in CKD5-HD patients were higher (15.5 ± 14.1 AU; $p < 0.0001$). Similarly, MP-TF levels were elevated in CKD5-HD patients (3.00 ± 1.42 pg/mL; $p < 0.0001$) compared to normal (0.363 ± 0.263 pg/mL). There was no correlation between PNs and MP-TF in CKD5-HD patients ($r = 0.077$; $p = 0.501$). Moreover, there was no correlation between PNs and platelets ($r = 0.067$; $p = 0.543$) and RBCs ($r = 0.083$; $p = 0.447$). However, the PNs showed a positive correlation with WBCs ($r = 0.223$; $p = 0.042$). There was no correlation between MP-TF and WBCs ($r = -0.057$; $p = 0.632$) and RBCs ($r = -0.042$; $p = 0.722$), but a positive correlation was observed between MP-TF and platelets ($r = 0.237$; $p = 0.042$).

Conclusions: PNs were elevated in CKD5-HD patients, indicating an increased release of nucleosomes, suggesting increased cell death. The observed correlation between PNs and WBCs suggests that the detected PNs are derived from WBCs. A lack of correlation between PNs and MP-TF suggests that the MP-TF increase is independent of the pathophysiologic processes responsible for abnormal PN generation in CKD5-HD patients.

FR-PO789

The Interdialytic Creatinine Rise Is a Novel Marker of Volume Overload and Mortality Risk in Hemodialysis Patients Ljubomir M. Ilic, Robert S. Brown, Roger B. Davis, Stewart H. Lecker. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Volume overload is a major contributor to morbidity and mortality in maintenance hemodialysis (HD) patients. Since serum creatinine increases between HD treatments, we theorized that the Interdialytic Creatinine Rise (IDCR), a change dependent upon net creatinine retention and dilution by fluid intake, might be used to evaluate volume overload and predict patient mortality. IDCR is calculated using two serum creatinine values from the same interdialytic period obtained at least 18h apart.

Methods: Three analyses were undertaken. A prospective cohort of 47 maintenance HD patients admitted to our hospital had IDCRs measured serially over a period of one week. IDCR change with time and after HD sessions were analyzed using mixed effects model. A prospective cohort of 25 outpatient maintenance HD patients was followed for 2 weeks with determination of the sensitivity and specificity of different IDCR cutoff values using patient volume assessments by their nephrologist as the gold standard. A retrospective cohort of 39 maintenance HD patients was studied longitudinally during inpatient admissions from 2012 until 2017 or death. The data were analyzed using Cox proportional hazards model with IDCR as a time varying covariate. In the same cohort, mixed effects logistic regression was used to correlate IDCR with mortality risk.

Results: IDCR decreases, changing by –0.014 per day without HD (95%CI –0.017, –0.010; p<0.001) due to volume gain. IDCR increases by 0.013 from before to after each successive hemodialysis session (95%CI 0.008, 0.017; p<0.001) due to fluid removal by ultrafiltration. An IDCR cutoff value of ≤ 0.1 mg/dL/h has a sensitivity of 82 %, specificity of 79 %, and accuracy of 80 % in diagnosing volume overload with AUC of ROC curve = 0.78 (95%CI 0.59, 0.97). The hazard ratio of death for each 0.01 mg/dL/h decrease in IDCR is 1.64 (95%CI 1.31, 2.07; p<0.001). If IDCR decreases to less than 0.05 mg/dL/h, the odds ratio of death within 2 months is 38 (95%CI 8, 131; p<0.001).

Conclusions: IDCR decreases with volume retention, can help detect volume overload, and has excellent prognostic value in identifying HD patients who are at high risk of dying over the following 60 days.

FR-PO790

The Effect of Isohydric Hemodialysis on Uremic Retention Solutes Jerome Lowenstein,[1] Aleksey Etinger,[2] Sumit R. Kumar,[3] William Ackley,[3] Leland R. Soiefer,[2] Eric B. Grossman,[1] Albert Matalon,[1] Robert Holzman,[5] Bjorn Meijers.[4] *[1]New York University Medical Center, New York, NY; [2]New York University School of Medicine, New York, NY; [3]Yale New Haven Hospital, New Haven, CT; [4]University Hospitals Leuven, Leuven, Belgium; [5]NYU School of Medicine, New York, NY.*

Background: There is growing evidence that the accumulation of protein- bound uremic retention solutes, such as indoxyl sulfate (IS), p-cresyl sulfate (PCS) and kynurenic acid (KA), play a role in the accelerated cardiovascular disease seen in patients undergoing chronic hemodialysis. Protein-binding, presumably to albumin, renders these solutes poor-dialyzable. We had previously observed that the concentration of free solute and its unbound fraction were markedly reduced at the end of hemodialysis. We hypothesized that solute binding might be pH-dependent and the changes attributable to the higher serum pH at the end of hemodialysis. *In vitro*, acidification of uremic plasma to pH 6 greatly increased the proportion of unbound indoxyl sulfate.

Methods: We tested our hypothesis by reducing the dialysate bicarbonate buffer concentration to 25 mEq/L for the initial half of hemodialysis ("isohydric dialysis"). Eight stable hemodialysis patients underwent "isohydric dialysis" and, midway, were switched to standard buffer (37 mEq/L). A second dialysis, 2 days later, employed standard buffer throughout.

Results: We found a clearcut separation of blood pH and bicarbonate concentrations 90 minutes following "isohydric dialysis" (pH = 7.37, HCO3 =22.4 mEq/l) and standard dialysis (pH= 7.49, HCO3 = 29.5). Analysis of free and bound concentrations of uremic retention solutes confirmed our prediction that binding of solute is affected by pH. However, in mixed models analysis, we found that the *reduction in total uremic solute concentration* during dialysis accounted for a greater proportion of the variation in free concentration, presumably an effect of saturation binding to albumin, than did the *relatively small change in pH* produced by isohydric dialysis.

Conclusions: These findings suggest that modification of dialysis technique that would expose blood to a transient decrease in pH might increase the free fraction of solute and enhance the efficacy of hemodialysis in the removal of protein-bound uremic retention solutes.

FR-PO791

Intra-Dialytic Syndrome and Time to Recovery in Patients on In-Center Hemodialysis Luis Alvarez,[3,4] Sarah S. Prichard,[2] Dean Hu,[5] Glenn M. Chertow.[1] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]Advisor role, Outset Medical, San Jose, CA; [3]Nephrology, Palo Alto Medical Foundation, Palo Alto, CA; [4]Outset Medical Inc, San Jose, CA; [5]Outset Medical, San Jose, CA.*

Background: Patients on hemodialysis (HD) experience a variety of symptoms during dialysis described here as Intradialytic Syndrome (IDS). Patients also feel unwell for a period of time post HD. The purpose of this study was to assess frequency and severity of intradialytic symptoms and time to recovery post dialysis in a broad cross section of HD patients.

Methods: An online questionnaire was sent to patients in the National Kidney Foundation database via email. Patients included were adults on in-center hemodialysis 3 times/week for 3 or more months. Demographic and basic clinical data were obtained. A 12-item symptom questionnaire asked about the type and severity of symptoms during HD sessions in the previous week. Severity was rated on a 5-point Likert scale - 1 "not severe" to 5 "very severe". It also asked how long it took to resume normal activities post dialysis, if they ever stopped dialysis early because of intradialytic symptoms, and for which symptoms they stopped.

Results: 5,000 e-mails were sent. 98 patients met the screening criteria and completed the questionnaire. Mean age 65±14 yrs, 39% female, 61% male, 65% White, 28% Black/African American, 46% diabetic, 35% history of coronary artery disease, and 87% with hypertension (100% on meds). 88% had intradialytic symptoms in the previous week, with a mean severity of 2.7 (range: 1 - 5). The most common adverse events are shown in Table 1: The median (10%, 90%) time to recovery and resume normal activities was 180 minutes (30 minutes, 13 hours). 35% reported having stopped dialysis early for symptoms. The most common symptom-related reasons to stop dialysis early were cramps and low blood pressure.

Conclusions: 88% of a broad based sample of in-center HD patients reported having symptoms during dialysis. Because intradialytic syndrome can cause patients to terminate dialysis prematurely, innovation in dialysis should target reducing these symptoms.

Exploring Walking Pace, Physical Activity, and Readiness to Change in ESRD Yan Song,[1] Patrick J. Highton,[3] Amy L. Clarke,[1] James Burton,[1] Alice C. Smith.[2] *[1]University of Leicester, Leicester, United Kingdom; [2]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [3]Loughborough University, Leicester, United Kingdom.*

Background: Reduced physical function and walking speed in end stage renal disease (ESRD) patients are associated with increased morbidity and mortality and high healthcare costs. Physical activity (PA) and regular exercise may optimize physical function, but the majority of ESRD patients are sedentary. This study explored walking speed, PA and exercise, and readiness to change exercise behavior in patients on haemodialysis (HD).

Methods: 1156 patients (M: F 1.8:1, median (IQR) age 63.01(21.00) years) from 16 disparate HD networks completed a series of validated questionnaires: GP Physical Activity Questionnaire (GPPAQ providing Physical Activity Index [PAI] and Walking Speed [WS]), Leisure Time Exercise Questionnaire (LTEQ, providing an exercise Health Contribution Score (HCS) based on METS) and Stage of Change Questionnaire (SoCQ, defining readiness to change exercise behaviour).

Results: The distribution of PAI, WS, HCS and SoC are shown in Table 1. Walking pace was negatively associated with older age, female sex (P<0.01) and longer dialysis vintage (P<0.05), and positively associated with behavioural factors (physical activity, leisure time exercise), and readiness to change (all P<0.01).

Conclusions: GPPAQ and LTEQ responses highlight the inactive lifestyle of HD patients. The majority have slow walking speed which is a strong predictor of poor outcome and indicates the need for functional improvement. Exercise interventions have been shown to improve walking speed in older frail adults and may be beneficial for ESRD patients. However, walking speed was positively associated with stage of change indicating that the most vulnerable patients (slow walking pace, older age, female, low PA) may require targeted support to engage in exercise programmes to improve outcomes.

Funding: Private Foundation Support

FR-PO793

Intradialytic Systolic Blood Pressure and Hemodynamics Are Predominantly Controlled by Baroreflex Mechanisms Dvora Rubinger, Michal Dranitzki Elhalel, Dan Sapoznikov. *Hadassah University Medical Center, Jerusalem, Israel.*

Background: Systolic blood pressure (SBP) is believed to be controlled by both baroreflex (BARO) and non-baroreflex (NON-BARO) sympathetically mediated central mechanisms.

Methods: To assess the relative contribution of these mechanisms during hemodialysis (HD), beat-to-beat SBP and interbeat interval (IBI) monitoring using Finometer device was performed during a 4 hr regular HD session in 51 non-diabetic patients, age 52±16 y. BARO and NON-BARO activity episodes were evaluated by the calculation of the slope of between IBI and SBP in 1 min sequences; a positive correlation coefficient (r>0.5) was considered to be representative of BARO activity, whereas a negative correlation was considered to represent NON-BARO sympathetic activity. LFα coefficient, a measure of predominantly BARO function was calculated as the square root of the ratio between average IBI power and average SBP power in the low frequency band (0.04-0.15 Hz). Cardiac output (CO), stroke volume (SV) and total peripheral resistance (TPR) were calculated using the Modelflow simulation method.

Results: The averaged variables for the 1st and the 4th HD hr (median and interquartile range) are shown in Table 1.(see table below) During HD, LFα increased from 3.76 (2.34) in the 1st to 4.17 (3.37) the last hr (p=0.013).

Conclusions: Our data show: 1. At the begining of HD, SBP is dually controlled by both BARO and NON-BARO mechanisms. 2. During ultrafiltration, the maintenance of constant SBP is achieved by predominant BARO activation. 3. The decrease in CO and SV during ultafiltration is compensated by an increase in TPR. The intradialytic hemodynamic stability seems to be dependent on the adequacy and the strength of the BARO response.

Table 1.

	HD 1st hr	HD 4th hr	p
SBP (mmHg)	133 (22)	131 (26)	NS
IBI (ms)	805 (129)	796 (183)	NS
% BARO episodes	62(61)	96 (67)	0.003
% NON-BARO episodes	38 (61)	4 (67)	0.003
CO (L/min)	6.78 (2.10)	5.64 (2.58)	0.001
SV (ml)	89 (28)	73 (38)	0.001
TPR (mmHg.s/ml)	0.875 (0.310)	1.009 (0.530)	0.001

FR-PO794

Hemodialysis Prescription Patterns in a Large Cohort of Pediatric Patients on Maintenance Hemodialysis Verena Gotta,[1] Olivera Marsenic Couloures,[3] Marc Pfister.[2] *[1]University of Basel Children's Hospital, Basel, Switzerland; [2]University of Basel Children's Hospital, Basel, Switzerland, Hilterfingen, Switzerland; [3]Yale University School of Medicine, New Haven, CT.*

Background: Hemodialysis (HD) prescription is relatively standardized in adults, compared to children. Limited systematic data on HD prescription behavior in children and adolescents is available. We aimed to provide reference ranges of real-life pediatric HD prescriptions.

Methods: This descriptive cohort study included 53903 HD sessions of 1852 patients <30 years on chronic HD since childhood, receiving thrice weekly HD between 2004 and 2016 in outpatient DaVita dialysis (6075 patient-years, 1-29 years, 8.3-168 kg). Median and 10th to 90th percentiles (80% reference ranges) of prescriptions were calculated over age and weight-bands of 10 kg, from median individual prescriptions per year for: blood flow (Q_B), dialysate flow (Q_D), mass-transfer coefficient for urea (*KoA)*, duration of HD session, resulting dialytic clearance for urea (K_D) and single pool variable-volume Kt/V (spKt/V). Both absolute and weight-normalized flows were investigated. Means ±standard deviation were summarized over five larger age and weight groups.

Results: Prescription parameters were correlated with age and weight, and showed non-linear dependencies. Inter-individual variability was larger between patients of same age (larger reference intervals) than of same weight. Systematic prescription differences were however more pronounced between patients of different weight (see Table). Generally, low-weight patients had higher weight-normalized Q_B, Q_D, KoA, K_D and spKt/V. More than 90% (70%) of patients 10-80 kg achieved target spKt/V of ≥1.2 (≥1.4). spKt/V was steadily decreasing with higher weight, with only 75% (36%) of patients 110-120 kg achieving target values of ≥1.2 (≥1.4).

Conclusions: HD prescription components are systematically different in children compared to adults, with smaller patients routinely receiving more intensified treatments. Adolescents and young adults with weight >80 kg appear to be at higher risk of receiving suboptimal HD treatment as compared to children ≤80 kg.

Weight	<25kg	25-50kg	50-75kg	75-100kg	>100kg
Q_B (mL/min/kg)	8.2±2.9	7.8±1.6	6.5±1.2	4.8±0.8	3.5±0.6

FR-PO795

Use of a Validated Algorithm to Estimate Potentially Avoidable Readmissions in Hemodialysis Patients Matthew R. Sinclair,[1] Anna Mathew,[1] Lisa M. Rosen,[2] Jody-Ann McLeggon,[1] Steven Fishbane.[1] *[1]Northwell Health, Commack, NY; [2]The Feinstein Institute for Medical Research, Manhasset, NY.*

Background: Hemodialysis (HD) patients face up to 35% 30-day readmission, with associated anxiety and financial costs. There is no validated measure to identify potentially avoidable readmissions (PAR) in HD patients. In the general medicine population, the SqLape computer algorithm identifies PAR with 96% sensitivity and specificity. The aim of this study is to validate SqLape in the HD population.

Methods: We used chart review as the validation gold standard. We randomly selected 100 charts of HD patients with a 30-day readmission in Northwell Health, ending 9/30/2015. SqLape identified patients with a PAR and chart reviewers, blinded to algorithm results, conducted a simultaneous chart review. PAR chart review criteria was developed *a. priori*. To assess reliability of PAR classification by chart review, a second reviewer adjudicated a random 20% of charts. A 2x2 table cross classified algorithm and chart review identified PAR. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated. All analysis used SAS version 9.4.

Results: The kappa statistic for inter-rater reliability of readmission classification was 0.667 (substantial agreement). 19% and 72% of readmissions were classified as potentially avoidable by chart review and algorithm, respectively. The sensitivity and specificity of SqLape was 60.0% (95% CI: 26.2, 87.8) and 25.6 (95% CI: 13.5, 41.2), respectively. The PPV and NPV was 15.8% (95% CI: 6.0, 31.3) and 73.3% (95% CI: 44.9, 92.2), respectively (Table 1).

Conclusions: We assessed the use of an algorithm to identify PAR in HD patients. The algorithm performed well to identify the proportion of patients without a potentially avoidable readmission, with acceptable sensitivity and NPV. Specificity and PPV of the algorithm were poor, perhaps related to unique causes of PAR in HD patients(i.e fluid and electrolyte abnormalities, vascular access issues). Future studies should focus on development of an accurate measure of potentially avoidable readmissions in HD patients, as a foundational starting point for further study of this topic.

Table 1: Classification of 30-Day Potentially Avoidable Readmission

		From chart review	
		PAR	Non-PAR
From Algorithm	PAR	6	32
	Non-PAR	4	11

PAR: 30-day Potentially Avoidable Readmission

FR-PO796

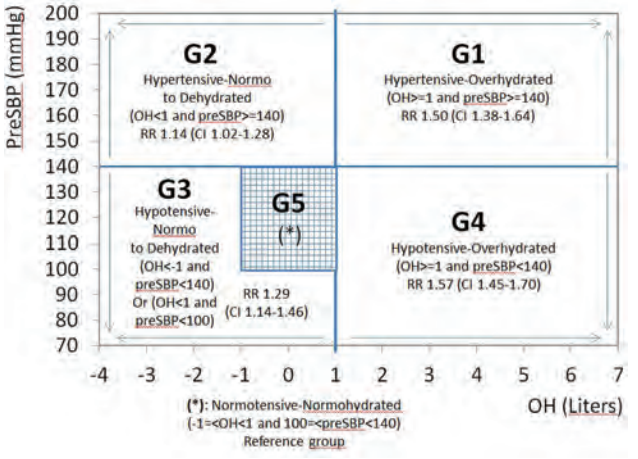
Relationship between Hydration Status (HS), Blood Pressure (BP), and Survival in Hemodialysis (HD) Patients (Pts) Marcelo D. Ferder, Adrian M. Guinsburg, Cristina Marelli. *Fresenius Medical Care Argentina, Buenos Aires, Argentina.*

Background: HS and BP are key factors to control in HD pts due both are closely related to mortality. We aimed to study their association with mortality in a large HD pts cohort from Fresenius Medical Care Latinamerica (FMCLA).

Methods: Pts undergoing HD at FMCLA between 09/2008 and 12/2016 were included. HS was assessed by multifrequency bioimpedance spectroscopy using a body composition monitor device (BCM©, FME Deutschland GmbH). Predialysis systolic BP (pSBP) was obtained as mean of 6 consecutive treatments prior to HS assessment (baseline). Lab data at baseline was used. Values expressed as mean±SD. All pts were assigned to one of five groups (G) based on pSBP and overhydration (OH). G1: Hypertensive-Overhydrated (OH>=1+pSBP>=140); G2: Hypertensive-Normo/Dehydrated (OH<1+pSBP>=140); G3: Hypotensive-Normo/Dehydrated (OH<-1+pSBP<140) or (OH<1+pSBP<100); G4: Hypotensive-Overhydrated (OH>=1+pSBP<140); G5 (Ref): Normotensive-Normohydrated (-1=<OH<1+100=<pSBP<140). Time at risk was counted between HS assessment and death or Dec 31, 2016. A Cox model was constructed to analyze independent relationship between groups and mortality.

Results: 43,786 pts were included. Age 57.9±16.1 yrs, vintage 3.1±4.3 yrs, male 58.2%, OH 1.76±2.15 lts, pSBP 140.4±23.4 mmHg, Alb 3.8±0.5 (g/dl), Hgb 10.8±1.9 g/dl, serum Ca 8.8±0.9 mg/dl, serum P 4.7±1.4 mg/dl, serum Na 137.8±4.0 mEq/l, eKt/V 1.36±0.30, DBT 30.9%, CVD 8.0%, Cancer 1.0%. Mean follow up time was 4.45 yrs and 5,864 death events were observed. After controlling for demographic, comorbid and lab values, RR of death was G1 1.50 (1.38-1.64), G2 1.14 (1.02-1.28), G3 1.29 (1.14-1.46) and G4 1.57 (1.45-1.70).

Conclusions: Our study suggests that any combination of OH and pSBP outside the box of reference (-1<OH<1 and 100<pSBP<140) increases risk of death. Excesive OH (OH>=1) combined with pSBP<140 (G4) as well as >140 (G1) are groups at higher risk.



presence of additional colon-derived solutes for which chemical structures remain to be determined. Efficient renal clearance for many of these compounds, which are presumably of microbial origin, is achieved by tubular secretion. The large number of colon-derived solutes complicates the problem of identifying their potential toxicity.

Developing an Organized Approach to Symptom Screening, Assessment, and Management for Hemodialysis Patients in Ontario: A Pilot Project Alysha Glazer,[1] Marnie MacKinnon,[1] Esti Heale,[1] Carey Moolji,[1] Peter G. Blake,[2] Michael Walsh.[3] *[1]Ontario Renal Network, Toronto, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]McMaster University, Hamilton, ON, Canada.*

Background: People living with chronic kidney disease (CKD) requiring dialysis experience a high degree of symptom burden. Symptom assessment, particularly the assessment of chronic symptoms, is not typically done systematically as routine care which may result in a care gap. A provincial approach to routine symptom assessment that can be customized by renal programs may provide an opportunity to improve patient-provider communication and patient experience with dialysis care. To improve the experience of people treated with in-facility hemodialysis and their care team by providing an organized approach to routine symptom screening, assessment, and management.

Methods: Eight Regional Renal Programs in Ontario were selected to participate in a one year pilot project. Participating Programs will routinely assess patients undergoing in-facility hemodialysis with the Edmonton Symptom Assessment Scale Revised – Renal (ESAS-r:Renal), a self-reported symptom questionnaire. The project is being developed by a Task Group with multi-institutional and multi-sectoral representation utilizing a co-design model that engages patients, healthcare providers, and administrators in project planning and development.

Results: Each pilot site has developed a new clinical workflow that includes symptom screening, assessment, and management every four to six weeks. Healthcare providers will be educated on symptom assessment and management through a train-the-trainer approach and the use of evidence-based clinical symptom management guides. Patients will also be educated about the project and use of the screening tool through various resources, including one-on-one education from the care team. Finally, an extensive evaluation framework was developed to guide the evaluation of the pilot project.

Conclusions: This pilot project will help determine the feasibility of a provincial approach to symptom screening, assessment, and management in Ontario. Furthermore, the project will increase awareness of CKD patient symptom burden.

Numerous Colon-Derived Solutes Are Efficiently Cleared by the Kidney Robert Mair,[1] Tammy L. Sirich,[1,2] Natalie Plummer,[1,2] Timothy W. Meyer.[1,2] *[1]Stanford, Palo Alto, CA; [2]VAPAHCS, Palo Alto, CA.*

Background: Previous studies have identified solutes derived from colon microbes that are normally excreted in the urine. The current study employed metabolomic analysis to identify additional solutes in this class and profile their renal clearance.

Methods: Samples from patients with total colectomies (n=12) and age matched controls (n=17) were analyzed using an established metabolomic platform. Solutes were considered colon-derived if they met both of the following criteria: 1) mean excretion rate was greater than four-fold higher in individuals with colons than without colons 2) the difference in excretion between the groups was assigned significance with a false discovery rate (q value) < 0.05.

Results: 91 urinary solutes were identified as colon-derived. Of these, 46 were named compounds with known structure and 45 were unnamed compounds without confirmed chemical structure. Only 11 of the 46 named compounds identified as colon-derived in the current study had previously been shown to be be colon-derived. Binding to plasma proteins allowed a urinary clearance expressed in terms of the free, unbound solute concentration. Plasma levels in normal subjects were sufficient to estimate clearance values for 53 of the 91 colon-derived solutes. As shown in the figure, the estimated urinary clearance exceeded the creatinine clearance for the great majority of these solutes, consistent with tubular secretion.

Conclusions: Comparison of patients with and without colons identified 35 novel colon-derived solutes which are normally excreted by the kidneys and revealed the

FR-PO799

Effects of Intradialytic Cycling on Exercise Capacity, Quality of Life, and Physical and Cardiovascular Function: A Systematic Review and Meta-Analysis Hannah M. Young,[4] Daniel S. March,[3] Matthew P. Graham-Brown,[4] Arwel W. Jones,[5] Ffion Curtis,[5] Charlotte E. Grantham,[3] Patrick J. Highton,[1] Alice C. Smith,[4] Sally J. Singh,[2] Chris Brile,[5] James Burton.[3] *[1]Loughborough University, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS FT, Leicester, United Kingdom; [3]University of Leicester, Leicester, United Kingdom; [4]University of Leicester and University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [5]University of Lincoln, Lincoln, United Kingdom.*

Background: There is growing interest in intradialytic cycling (IDC), to address a range of health & wellbeing issues associated with haemodialysis (HD). The aim of this systematic review was to identify & synthesise the available evidence on the effects of IDC on exercise capacity, quality of life (QOL), physical & cardiovascular function.

Methods: Databases of published, unpublished & ongoing studies (Medline, EMBASE, CINAHL, LiLACS, Web of Science, Sports Discus, PsycINFO, PEDRO, AMED, Cochrane, PROSPERO, DARE, BIOSIS previews, Index to Scientific & Technical Proceedings, Conference Papers Index, CENTRAL, ClinicalTrials.gov, Current Controlled Trials) were searched for randomised controlled trials (RCTs) of prevalent adult HD patients, comparing cycle training during HD to usual care. Sources were searched until March 2017 & supplemented by internet, hand searching & consultation with experts. No limits were placed upon publication language.

Results: Fourteen RCTs were eligible, but 5 did not provide data interpretable for use in meta-analyses. The remaining 9 RCTs included 187 participants and the length of IDC interventions ranged from 8-26 weeks. Most studies had an overall high risk of bias. Meta-analysis of available evidence indicated no significant change in VO_2 peak (MD 1.84, 95% CI -0.90 to 4.59 p=0.19), physical (mean change -0.06, -0.69 to 0.58 p=0.86) or mental component (mean change 1.68, -6.30 to 9.65 p=0.68) scores of the SF36, or pulse wave velocity (MD -0.36, -1.54 to 0.43, p=0.38) following IDC. IDC did lead to a mean improvement of 85m (25 to 144, p=0.005) on the six-minute walk test. The limited number of studies in the meta-analyses precluded planned sensitivity & subgroup analyses & assessment of publication bias.

Conclusions: There is insufficient evidence to support the use of IDC to influence exercise capacity, QOL, cardiac or physical function in practice. The point estimates of the meta-analyses on the 6MWT are greater than the smallest clinically important difference, but the imprecision of the individual study estimates means further RCTs are needed. The strength of the evidence could be greatly enhanced via transparent reporting & consensus on validated measures.

FR-PO800

Coronary Artery Bypass Grafting (CABG) Is Not Associated with Worse Outcomes in Dialysis Patients Sirlei Silva, Rosa M. Moyses, Rosilene M. Elias. *Universidade de São Paulo, SAO PAULO, Brazil.*

Background: CABG is currently a good option of treatment for dialysis patients with multivessel coronary artery involvement. However, whether this population has a higher risk of Hospital worse outcomes than patients with normal renal function and patients with chronic kidney disease (CKD) not on dialysis is still debatable.

Methods: This is a prospective observational study to compare hospital mortality of patients who underwent elective CABG. Consecutive non-selected patients were included in the group with normal renal function (control; N=167), CKD with eGFR 30-60 ml/min (CKD30-60; N=78) and on maintenance dialysis (CKD5D; N=31). Demographic, clinical, biochemical and also fluid balance were evaluated in all patients from the day 1 (surgery) to the day 30 of admission. Sequential Organ Failure Assessment (SOFA) scores at intensive care unit (ICU) admission were also assessed.

Results: Age was similar among control, CKD30-60 and CKD5D groups (63±10, 63±9 and 65±6 years, respectively, p=0.585). Patients from the control group had less diabetes (p=0.019) and Hypertension (p=0.010) than other groups, although dyslipidemia, smoking and previous history of coronary disease did not differ significantly. Initial SOFA scores were higher when renal component was considered (0.3±0.6, 1.1±0.8 and 4.2±1.0 in groups control, CKD30-60 and CKD5D respectively, p=0.0001), though this difference disappeared when renal component was dismissed (p=0.507). Surgery time was similar among groups (p>0.05); endotracheal intubation time was shorter in the control group (p=0.001) as well as intensive care discharge time (p=0.002). There were 17 deaths in 30 days of admission that occurred in the ICU (7 from control, 7 from CKD30-60 and 2 patients from CKD5D; p=0.264). Kaplan-Meier curve showed no 30-day hospital mortality difference among groups (log-rank test 0.977), which was confirmed by Cox-regression survival analysis adjusted for age, diabetes and initial SOFA.

Conclusions: The CABG predictable short-term mortality seems not to be inferior among selected patients on maintenance dialysis. This is probably due to quality improvements in the in cardiologic centers and also because dialysis can be routinely planned in this population.

FR-PO801

Small Animal Study and Hemocompatibility of Small Form Factor Microfluidic Filtration System with Nitride Membranes

Dean G. Johnson. *University of Rochester, Rochester, NY.*

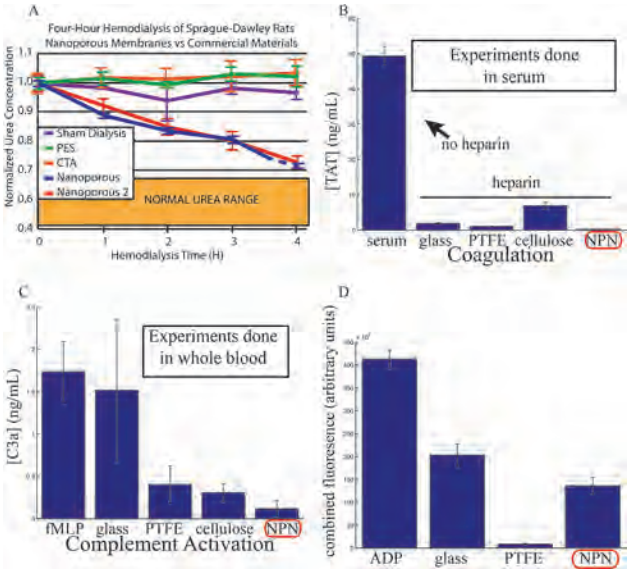
Background: Improving the health outcomes for End Stage Renal Disease (ESRD) patients on hemodialysis (HD) requires new technologies for wearable HD such as a highly efficient membrane that can achieve standard toxic clearance rates in small device footprints. Our group has developed nanoporous silicon nitride (NPN) membranes which are 100 to 1000 times thinner than conventional membranes and are orders-of-magnitude more efficient for dialysis.

Methods: Devices were constructed with polydimethylsiloxane (PDMS) and two NPN membrane chips. Uremic rats were dialyzed for 4 hours under anesthesia. The concentration of thrombin-anti-thrombin complex (TAT) and C3a complement was used as the indicator of coagulation and immune activation. For platelet adhesion and activation, platelet rich plasma (PRP) was incubated in microchannels then incubated with antibodies.

Results: The clearance results from the commercial membranes and the sham dialysis showed no reduction in urea concentration (Figure 1A). The NPN membranes from SiMPore, on the other hand reduced the urea by 26%. Albumin was retained during the 4-hour HD session (n=3) as expected. This indicates that the molecular weight cut-off was somewhere between the size of urea (60.06 Da) and that of albumin (66.5 kDa). The hemocompatibility results are shown in Figure 1B-D.

Conclusions: We had positive results from the NPN membranes clearing Urea better than commercial materials. Significantly, urea was cleared with very little membrane surface area. The favorable hemocompatibility results of the native silicon nitride are encouraging.

Funding: NIDDK Support



A: Sham dialysis, PES, and CTA membrane dialysis – no reduction in serum urea. 50 nm and 75 nm NPN membranes show a 24% decrease in serum urea. B: Coagulation (TAT) n = 3 C: Immune activation (C3a) n = 3 D: Platelet activation (CD62P) n = 15 for ADP, glass, and NPN; n = 5 for teflon.

FR-PO802

Bringing Down the Phosphorus: A Novel Approach to Improve the Quality of Hemodialysis Phosphate Management

Alexander Brauer,[1] Laura J. Maursetter.[2] *[1]UWSMPH, Madison, WI; [2]University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: High phosphate levels are associated with vascular calcifications, osteodystrophy and an increased risk of cardiac mortality. According to major investigations such as the Dialysis Outcomes and Practice Patterns Studies, approximately 50% of dialysis patients have hyperphosphatemia. Hyperphosphatemia is both a common and serious complication for patients receiving dialysis therapy. Despite this fact, clinical management of hyperphosphatemia remains subpar. This is thought to be largely due to patient compliance with binders, cost of therapy and dietary constraints.

Methods: In this single center quality improvement project looking at the prevalence of phosphorus control and the willingness of patients to make a change. The serum phosphate levels from the previous 6 months were evaluated. Patients were classified into 3 groups: good control (phosphorus <6), fluctuating control (phosphorus with 2-3 values >6) or poor control (phosphorus >6 for more than 4 values). Anyone in the fluctuating or poor control group was scheduled into 4 weekly meetings for the purpose of using behavioral change theory, an intervention that has been shown effective in dialysis patients. Management modifications were developed by the patients based on the perceived needs. These included changes that have been proven effective such as specific dietary consultation, economic concerns, and meal planning/preparation. The intervention was documented for the patient.

Results: 115 patients that were included in this evaluation, 46 (40%) of patients fell into the fluctuating or poor control group; 21 in the poor control and 25 in fluctuating control. 96% of these patients were willing to meet regularly and 100% of these developed an intervention. The patients reported a positive view of this program.

Conclusions: Using theories of behavioral change, this interdisciplinary intervention showed that patients with poor or fluctuating control of phosphorus were willing to meet and create a plan for change. Belief that poorly controlled phosphorus patients would not care to make changes was disputed by these results. This model actively included the patient as part of the management plan and could be applied to many parts of the hemodialysis treatment to improve adherence to management guidelines.

FR-PO803

Risk Factors Associated with Early Mortality in Patients Commencing Maintenance Hemodialysis: A Systematic Review

Adil M. Hazara,[1] Sunil Bhandari.[2] *[1]Hull and East Yorkshire Hospitals NHS Trust, Hull, United Kingdom; [2]Hull and East Yorkshire Hospitals NHS Trust and Hull York Medical School, East Yorkshire, United Kingdom.*

Background: Early mortality rates are reported to be high in patients starting hemodialysis (HD) for end-stage renal disease (ESRD). We have conducted a systematic review of literature in order to evaluate the risk factors associated with early mortality in this patient population.

Methods: Medline and EMBASE databases were searched for studies published in English language between 1/1/1985 and 31/7/2015. Early mortality was defined as deaths within 180 days of starting HD. Case-control and cohort studies involving adult subjects commencing HD for ESRD were included. The Quality in Prognosis Studies tool was used to assess risk of bias in individual studies. Data extracted from the studies included information on population characteristics and settings. In addition, patient or treatment related factors studied with reference to their relationship with the risk of early mortality were documented. The findings were summarised and a narrative account was drawn from the available evidence.

Results: 21 studies with a combined population of 1,016,646 new dialysis starters were included (median number of subjects: 825; range: 148 - 498,566). There were 15 cohort and 6 case-control studies. Risk of bias was low, medium and high in 5, 3 and 13 studies respectively. A total of 39 different risk factors for early mortality were extracted; broadly, these belonged in 4 categories: clinical, demographic, laboratory and socioeconomic risk factors. Early mortality was associated with patient age, serum albumin at the start of dialysis, not starting HD with functioning arteriovenous fistula, having diabetes as the cause of ESRD, history of heart failure or malignancy, increased frailty, absence of previous nephrological care and deficiency of 25-OH vitamin D. Factors that were not associated with early mortality were gender, having diabetes (as a comorbid condition), serum haemoglobin, parathyroid hormone levels, serum calcium and phosphate.

Conclusions: This systematic review identifies several important modifiable risk factors for early mortality. Studies examining the effects of modification of these risk factors are urgently needed.

FR-PO804

In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH CAHPS) Survey Non-Responder and Responder Characteristics

Taimur Dad,[2] Hocine Tighiouart,[2] Megan Grobert,[1] Eduardo K. Lacson,[2,1] Klemens B. Meyer,[2] Dana Miskulin,[2] Daniel E. Weiner,[2] Michelle M. Richardson.[2] *[1]Dialysis Clinic Inc, Boston, MA; [2]Tufts Medical Center, Boston, MA.*

Background: The In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH CAHPS) Survey assessing patient experience is a

performance metric in the End Stage Renal Disease Quality Incentive Program administered twice yearly to adult, in-center hemodialysis patients. Response rates currently are approximately 35% and little is known about characteristics of non-responders.

Methods: Cross-sectional analysis of ICH CAHPS administration in 2012 to all ICH patients in Dialysis Clinic, Inc. (DCI) facilities nationally who met AHRQ eligibility criteria for survey administration (over 18 years old and receiving HD at their facility for at least 3 months). Patient-level covariates include demographic, clinical, laboratory, and functional characteristics. Outcome was survey response using AHRQ's definition of response (no proxy help and answers to at least 50% of pre-defined key questions).

Results: Among 11,055 patients eligible for ICH CAHPS, 6,541 (59%) did not return the mail survey or complete the alternative phone survey and 5,372 (82%) of these had complete covariate data. Of 3,918 responders with complete data (87% of responders), 549 (14%) did not meet AHRQ's definition of response. Using random effects multivariable logistic models, non-responders were more likely to be men, non-white, younger, single, dual Medicare/Medicaid eligible, less educated, non-English speaking, not active on the transplant list, have longer ESRD vintage, lower BMI, lower serum albumin, worse functional status, and more hospitalizations, missed treatments, and shortened treatments. Similar associations were found using more parsimonious multivariable analyses and after imputing missing data.

Conclusions: In 2012, survey non-responders significantly differed from responders raising concern for bias in survey results. Future research should assess and address reasons for non-response to improve survey applicability.

FR-PO805

World-Wide Early Mortality Rates after Commencement of Hemodialysis: A Systematic Review and Meta-Analysis

Adil M. Hazara,[1] Sunil Bhandari.[2] *[1]Hull and East Yorkshire Hospitals NHS Trust, Hull, United Kingdom; [2]Hull and East Yorkshire Hospitals NHS Trust and Hull York Medical School, East Yorkshire, United Kingdom.*

Background: In the care of patients with progressive decline in renal function, the start of maintenance hemodialysis (HD) marks a critical turning point. Mortality rates are reported to be high in this period due to multiple treatment and patient related factors. Our aim was to estimate world-wide early mortality rates after commencement of HD in patients with end-stage renal disease.

Methods: Medline and EMBASE were searched for studies published between 1/1/1985 and 7/31/2015 in English. Early mortality was defined as deaths within 180 days of starting HD. Case-control and cohort studies involving adult subjects commencing HD were included. Number of deaths within the early period were extracted and converted in to annualised mortality rates (expressed in 100 person-year). The Quality in Prognosis Studies tool was used to assess risk of bias in studies.

Results: 25 studies were included (population of 1,000,014 patients from 12 countries). Median follow-up: 90 days representing 255,079 person-years of observation. Mortality rates varied from 15.7 to 122.0 per 100 person-year (meta-analysis: 31.6 per 100 person-year [95% CI 31.0-32.2], figure 1). Rates were highest in studies based in Africa (87.2 vs Europe: 15.9 per 100 person-year), lower income countries (87.2 vs high income countries: 31.5 per 100 person-year), studies that restricted recruitment to elderly (37.5 vs unselected: 31.6 per 100 person-year), those that started recruiting in earlier decades (1970's: 37.3 vs 2000's: 31.6 per 100 person-year) and those with low risk of bias (33.6 vs high risk: 22.6 per 100 person-year).

Conclusions: High rates of early mortality after commencement of HD is a global phenomenon. Studies showing lowest rates generally carried high risk of bias suggesting likely under-reporting and incomplete follow-up.

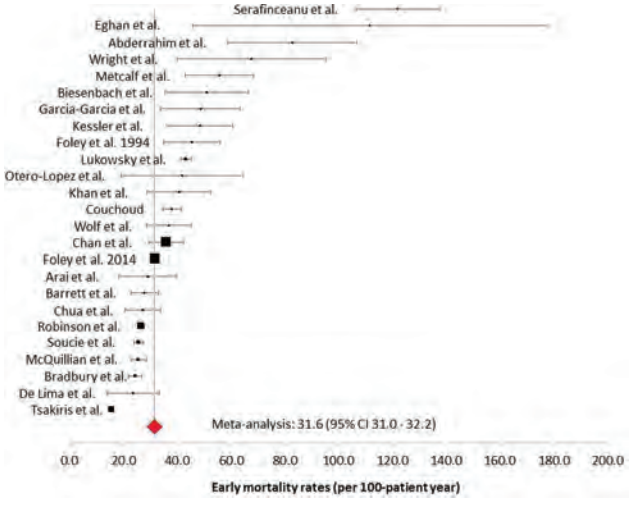

Figure 1: Meta-analysis of early mortality rates in patients newly started on hemodialysis

FR-PO806

Assessment of Wear Compliance, Differences in Step Counts, and Activity Levels of Fitbit and Jawbone Devices to the Actigraph GT3X+ in Hemodialysis Patients

Luis M. Perez, Hsin-Yu Fang, Brett Burrows, Sean P. Mullen, Ken Wilund. *University of Illinois, Urbana, IL.*

Background: The Actigraph GT3X+ (ACT) is a research standard in measuring steps and physical activity, but does not have the convenience of newer commercial devices. The objective of this study was to determine wear compliance and compare differences in steps counts of the Fitbit Flex (FLX), Fitbit Charge HR (CHR), and Jawbone Up2 (JWB) to the ACT in hemodialysis (HD) patients.

Methods: We recruited 29 HD patients (age: 53±10 y, BMI: 32.4±11.4 kg/m2, sex: 67% M) to simultaneously wear the ACT (hip), FLX, CHR, & JWB (wrist) for 7 days. A total of four days (2 dialysis & 2 non-dialysis) were selected for validation. We used self-reported wear-time and a validated algorithm to identify and select valid days for steps and sedentary, light, and moderate-to-vigorous (MVPA) activity.

Results: Adherence rate was for patients wearing and completing 4 days of valid data was 50% (13 excluded & 3 drop-outs). The average daily steps by device were: ACT=2666±1202, FLX=3735±1869, CHR=3660±1728, JWB=3041±1801; with a significant mean difference in steps from the ACT to the FLX & CHR ($p<0.01$), but not for the JWB ($p=0.35$). Regression of the mean steps to the difference in steps was significant for the FLX, CHR, & JWB to the ACT (all $p<0.05$). Patients had a greater step count on average for non-dialysis days compared to dialysis days. Each device had a significant correlation in steps to the Actigraph (FLX $r=0.84$, $p<0.01$; CHR $r=0.81$, $p<0.01$, JWB $r=0.67$, $p=0.01$). The correlation of light activity (min.) was significant for the FLX ($r=0.72$, $p<0.01$) & CHR ($r=0.67$, $p<0.01$) was significant, but not for sedentary & MVPA activity. Furthermore, the mean difference in light time was not significantly different for the FLX & CHR.

Conclusions: The FLX, CHR, & JWB provided similar step estimates, but each device overestimated steps compared to the Actigraph. The devices provided similar estimates of time spent in light activity, but not sedentary or MVPA activity. It is possible that the algorithms or different positioning of the devices contributed to this discrepancy. Additional studies are needed to confirm these data.

FR-PO807

Effect of Twice Weekly Hemodialysis on Plasma Levels of Uremic Solutes Normally Cleared by Secretion

Sheldon Leong, Natalie Plummer, Timothy W. Meyer, Tammy L. Sirich. *Stanford University/VAMC Nephrology, Palo Alto, AL.*

Background: Current guidelines allow twice weekly hemodialysis (HD) in patients with residual function. They require that patients receive a target standard Kt/V_{urea} (stdKt/V) calculated by combining the residual urea clearance (Kru) with dialytic dose assessed by Kt/V_{urea}. This urea-based calculation does not take into account the native kidney's secretory function. We hypothesized that because secretory function is not replicated by dialysis, plasma levels of normally secreted solutes may be better controlled in patients with residual function on twice (2X) weekly HD than in anuric patients on thrice (3X) weekly HD.

Methods: Dialytic clearance (Kd), residual clearance (Kr), and plasma levels for urea and 4 solutes normally cleared by secretion were measured in patients on 2X weekly HD with average stdKt/V 2.35 ± 0.49. Plasma solute levels were compared to those measured in anuric HEMO Study patients on 3X weekly HD with similar stdKt/V of 2.22 ± 0.24.

Results: Maintenance of secretion in the residual kidney was reflected by higher ratios of residual clearance to dialytic clearance (Kr/Kd) for the secreted solutes than for urea. The plasma levels for indoxyl sulfate, hippurate, and phenylacetylglutamine in the 2X weekly patients were significantly lower than in the 3X weekly anuric patients, while the plasma level for p-cresol sulfate was not different between the two groups (Table).

Conclusions: Residual kidney function removes a larger portion of secreted solutes than of urea. The plasma levels of secreted solutes may therefore be better controlled in patients with residual function on 2X weekly treatment than in anuric patients on 3X weekly treatment receiving the same weekly dose as assessed by Kt/V_{urea}. Consideration of secretory function may allow refinement of prescription guidelines for patients with residual kidney function.

Healthcare Provider Experiences in Emergent Dialysis of Undocumented Immigrants Areeba Jawed,[2] Alexia Torke,[3] Lucia Wocial.[1] *[1]Indiana University Health, Indianapolis, IN; [2]Wayne State University, Grosse Pointe Woods, MI; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: No national standards exist for chronic dialysis in undocumented (UD) immigrants posing a unique ethical dilemma for providers. The purpose of this survey was to explore provider perspectives.

Methods: Cross Sectional Internet Survey in April 2016 of Nephrology, ICU, ER, IM, Palliative Care nurses and physicians at a safety-net hospital. The last 4 open ended survey questions were included in this analysis (table 1). All authors individually explored the textual data inductively using an approach based on grounded theory to generate codes and broader themes. Coders then developed a shared code list. All responses were assigned ≥ 1 theme. We then calculated the number of participants with each of the codes.

Results: 299/765 participants completed the survey of which 185 included free texted comments. Nurses comprised 47% of the respondents. 483 responses were coded. The predominant coping mechanisms to moral distress were venting and team approach to patient care. We found that responses to the last 3 questions had overlapping themes. So, these items were coded using the same list of codes. Many participants spoke to the negative consequences of emergency dialysis for UD immigrants. This was noted to have a negative effect on providers, UD patients, other patients and the health system. Emotional and psychological distress was common (73.5%) along with concerns for emergent dialysis causing harm to UD immigrants (38.9%). Although far less common, some providers did note positive consequences of their experience caring for UD patients, most common being taking pride in provider role (13%). Attitudes about the right approach to this issue varied widely with both support (36.2%) for and opposition (7.6%) to dialysis for UD patients. Importantly emotions ran very high among those who supported regularly scheduled 3x\week dialysis and those who opposed dialysis altogether.

Conclusions: Provision of inadequate dialysis causes significant emotional distress in providers with varying attitudes towards the current practice of emergent dialysis. Policies need to be balanced with the strong ethical and moral commitments of providers.

How do you cope with the the Moral Distress that you encounter?
What do you perceive to be consequences of moral distress on you?
What Impact does providing care to UD immigrants have on you?
Please provide any other comments about the care of ESRD patients who are UD immigrants

FR-PO809

Socioeconomic Determinants of Outcomes among Patients Receiving Hemodialysis in India Abhinav Bassi,[1] Vivekanand Jha,[1] Kamal D. Shah,[3] Oommen John,[2] Venkatraman G,[3] Sumathi Kolli.[3] *[1]George Institute for Global Health, New Delhi, India; [2]The George Institute for Global Health, New Delhi, India; [3]NephroPlus Dialysis Centres, Hyderabad, India.*

Background: Dialysis in India is associated with a relatively higher mortality and early dropout when compared to developed countries. Poor clinical outcomes of dialysis patients are associated with socio-demographic predictors that have received limited attention thus far.

Methods: Data from a cohort of 9,058 subjects receiving HD between April 2014 and December 2016 at 92 centres of NephroPlus, India's largest dialysis center network was analysed retrospectively. We retrieved baseline demographics, medical history, treatment cost, dialysis frequency and erythropoiesis stimulating agent (ESA) use from the patient records. Univariate Cox proportional hazards model was used for the calculation of mortality and dialysis discontinuation hazard ratios (HR).

Results: The mean age of the subjects was 51±14 years. Subjects were predominantly male (70%), from metropolitan cities (37%) and paying out of pocket for dialysis (61%). A total of 16% of the subjects died, 46% discontinued dialysis and 37% continued dialysis. Out of the 1494 deaths, 60% and 75% subjects died within the 1st and the 2nd year from their first dialysis, respectively. Of the 4181 subjects discontinuing dialysis, 21% and 76% discontinued within the 1st and the 2nd year from their first dialysis respectively. Subjects younger than 40 years (HR 0.55, 95% CI, 0.47-0.65), residing in a metropolitan city (HR 0.56, 95% CI, 0.49-0.63), undergoing dialysis three times per week (HR 0.91, 95% CI, 0.84-0.98), on erythropoiesis-stimulating agents (ESAs) (HR 0.88, 95% CI, 0.78-0.99) and paying dialysis cost through health insurance (HR 0.89, 95% CI, 0.66-0.90) had lower mortality HR. Subjects not receiving ESAs (HR 2.56, 95% CI, 2.18-3.03) and paying out of pocket for dialysis (HR 1.15, 95% CI, 1.03-1.27) had higher odds of discontinuing dialysis. Gender was not found to be a predictor of outcomes.

Conclusions: The findings of the analysis of the data from this large cohort show high mortality and dropout rates and highlight the associated socio-economic and treatment related factors that will need to be addressed to reduce inequity in dialysis access and improve outcomes in India.

FR-PO810

A Simulation of Demand-Supply Imbalance in Dialysis Care in India Achintya Ray,[2,3] Bhabendra Putatunda.[1] *[1]Nephrology Associates PC, Murfreesboro, TN; [2]Tennessee State University, Nashville, TN; [3]Kidney Clinics and Research Centers International, Inc., Murfreesboro, TN.*

Background: About 10% of India's 1.3 Billion people suffer from Chronic Kidney Disease (CKD). An average of 15% of urban Indian population suffers from CKD. That number rises to 50% for some cities. Demand (CKD/ESRD treatment including dialysis) is growing at a rate of about 31% in India (compared to about 6% in the USA and 8% in the rest of the world.) About 30% of the CKD cases are estimated to be caused by diabetes and about 20% by hypertension. India has over 70 Million diabetes patients, a number that is estimated to double by 2040. A third of the diabetes cases will develop CKD. About 200,000 patients develop ESRD in India per year of which 70%-80% start dialysis treatment while about two-thirds of them are eventually ceasing the treatment due to resource limitations leading to premature death.

Methods: Published studies are used to extract economically meaningful numbers that can be used to draw quantifiable data measuring the demand-supply imbalance. Various projection methods are used to arrive at measures of long-term (through 2035) prevalence in the country for diabetes, dialysis and CKD cases. Furthermore, published studies are used to estimate the lower and upper bounds of CKD prevalence. Sparse evidences are scanned to estimate the number of dialysis centers and machines in different parts of the country and their abilities to meet the current demands. Reasonable assumptions are made to simulate the demand and supply of dialysis treatment based on the upper and lower bounds of the CKD estimates.

Results: About 87% to 93% of the demand for dialysis treatment may not be currently met in India. These estimates may be conservative. It is estimated that about 40,000-68,000 additional dialysis machines may be needed to serve India's current demand. These numbers may increase by 200%-300% by 2035 under various scenarios.

Conclusions: This study is of the first to harness a sparse and widely varying literature on the state of dialysis treatment to make meaningful estimates of demand-supply imbalance in Indian dialysis care market. The sparseness of the existing studies and the gravity of the magnitude of the imbalance point to need for more in-depth studies involving population health and healthcare marketplace data in India.

FR-PO811

Weight Perception in African-American Hemodialysis Patients Varun Gupta,[1] Milda R. Saunders,[2] Rita L. McGill,[2] Michelle A. Josephson.[2] *[1]Creighton University, Northbrook, IL; [2]University of Chicago, Chicago, IL.*

Background: The epidemic of obesity in the United States has been linked to greater risks of cardiovascular disease, diabetes, and kidney disease. However, in dialysis patients, increased body mass index (BMI) is paradoxically associated with better survival, as is African American race. We sought to determine the perception of ideal BMI in African American hemodialysis patients.

Methods: We surveyed African American hemodialysis patients at three dialysis facilities on the South Side of Chicago in June-July 2016. Patients were asked about ideal weight, exercise, eligibility for kidney transplant, and lifestyle. BMI was calculated from measured values. Results were tabulated into a descriptive analysis.

Results: Among 127 patients, 52% were female, and 82% had completed 12 or more years of school. Mean age was 57±16 years. Mean BMI was 28.8±7.3, 32 patients (25%) were overweight, and 50 patients (39%) were obese; proportions did not differ by sex. BMI>38 (our center maximum for transplant eligibility) was seen in 14 (11%). Among patients with normal BMI, 43% perceived a need to gain weight; among overweight patients, 79% wanted to maintain or gain weight (Table). The majority (70%) of obese patients wanted to lose weight.

Conclusions: African American hemodialysis patients perceive BMI of 25-30, which is classified as overweight, to be desirable. Further work is needed to determine whether this weight preference is in part responsible for African Americans' improved hemodialysis survival.

Funding: NIDDK Support

Perceived Need to Lose or Gain Weight, by BMI

BMI Category, n (%)	Should Lose	Should Maintain	Should Gain	Total
Underweight (BMI<18.5)	0	0	3 (100)	3
Normal/Ideal (BMI=18.5-24.9)	1 (2)	23 (55)	18 (43)	42
Overweight (BMI 25-29.9)	7 (22)	20 (63)	5 (16)	32
Obese (BMI>30)	35 (70)	14 (28)	1 (2)	50
Total	43	57	27	127

FR-PO812

Use of Poisson Regression Analysis with Restricted Cubic Splines Facilitates Cross-Sectional Comparisons of Mortality in a Large Provider Antonia Harford,[2] R. Schrader,[1] S. Paine,[1] Ambreen Gul,[1] Philip Zager.[2,1] *[1]DCI, Albuquerque, NM; [2]UNM, Albuquerque, NM.*

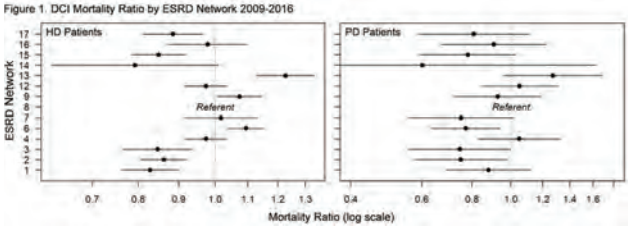
Background: Dialysis Clinic, Inc. (DCI) is a large not-for-profit provider. Assessing mortality across geographic regions served by a large provider is complicated by differences in demographics and local variations in overall healthcare. The use of Poisson regression analysis with restricted cubic splines may facilitate cross-sectional comparisons of mortality that are not influenced by differences in distributions of race, sex, age, vintage and diabetes.

Methods: We assessed mortality for HD and PD patients treated in DCI facilities in different geographic regions across the country for the years 2009 to 2016 combined. We used ESRD Networks to define the geographic regions. We conducted Poisson regression analysis using the rms package in R. Instead of using USRDS categories we used restricted cubic splines, which have flexible shapes, determined by the data. Models contained categorical (race, sex, and diabetes) and continuous (age, vintage, and year) variables. We fit all 2-way interactions among race, sex, diabetes status, and interactions

between age and vintage. Network 8, which has the largest number of DCI patients, was the referent.

Results: Standardized mortality ratios by ESRD Networks for HD and PD patients for the years 2009-2016 are shown. Results are expressed as ratios of mortality within a given Network to that in the referent Network. Among HD patients, clinics in Networks 1, 2, 3, 15, and 17 had lower mortality ratios vs. Network 8. Among PD patients, clinics in Networks 2 and 3 had lower mortality ratios vs. Network 8.

Conclusions: Within DCI there were significant variations in mortality across ESRD Networks for both HD and PD patients. The use of Poisson regression analysis, with restricted cubic splines, facilitates assessing mortality across different geographic regions served by a large provider. This technique provides estimates that are not influenced by demographic differences.



FR-PO813

Efficacy of Percutaneous Etelcalcetide Injection into the Parathyroid Glands on Serum Parathyroid Hormone (PTH) in Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT): A Pilot Study Satoshi Funakoshi,[1] Takuhisa Uchino,[1] Subodh J. Saggi,[2] Yoko Obata,[3] Tomoya Nishino,[3] Jyunichiro Hashiguchi,[1] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]SUNY Downstate Medical Center, New York, NY; [3]Nagasaki University Hospital, Nagasaki, Japan.*

Background: The most popular treatment for SHPT in HD patients is oral administration of cinacalcet in Japan. Nausea and high cost limits its use long term. Etelcalcetide is a novel injectable calcimimetic agent that has a similar mechanism of action as cinacalcet. Direct injection of etelcalcetide into the PTH gland may prove to be cost effective as compared to its systemic administration.

Methods: HD patients with SHPT who complained of nausea while on cinacalcet for >2 years were enrolled in this study after their informed consent was obtained. Cinacalcet was withdrawn from all patients for > 2 weeks, and 1.0ml (2.5mg) of etelcalcetid for 1.25ml gland volume was injected under direst real-time ultrasonographic guidance, and serum PTH was determined for up to 8 weeks.

Results: Seven patients (mean age, 68.4±11.8 years old; median HD duration, 12 years; mean PTH 270.6±155.5 pg/ml; participated in the pilot trial. Four achieved >50% reduction in serum PTH up to 4 weeks as shown in figure. Three patients had no response to this therapy, but their PTH was promptly decreased with systemic etelcalcetide administration, suggesting the presence of undetected hyperactive glands by Ultrasound. Direct administration was safe and not associated with any hematoma or laryngeal nerve paresis as has been reported for direct ethanol injection.

Conclusions: Percutaneous etelcalcetide injection into the parathyroid glands appears to be cost effective, safe, and a superior option for the treatment of SHPT in HD patients.

Mortality Prediction in Hemodialysis Patients According to Dietary Protein Intake to Serum Phosphorus Ratio Dana Bielopolski,[1,4] Yoshitsugu Obi,[2] Elani Streja,[1] Kamyar Kalantar-Zadeh.[3] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of California Irvine, Orange, CA; [3]University of California Irvine, School of Medicine, Orange, CA; [4]Nephrology and Hypertension, Rabin Medical Center, Petah-Tikva, Israel.*

Background: Lowering serum phosphorus (P) in maintenance hemodialysis (MHD) patients may improve survival. However, prior studies have shown that restricting dietary protein intake (estimated by "normalized protein catabolic rate", nPCR), a major source of phosphorus, is associated with higher mortality. We hypothesized that combing these two risks, nPCR and P, in the form of a new score can improve survival prediction.

Methods: Dividing the variables by one another enabled them to influence the metric equally. We divided phosphorus by 5.8, to create nP, so that distribution ranges of the two variables better overlap. Then new metric R, was formulated: R=nPCR/nP Analysis was carried in 63,016 MHD pts, who were followed for 5 years (2007-11). Survival models were adjusted for case-mix and malnutrition-inflammation cachexia syndrome (MICS).

Results: Patients were divided to 5 groups according to R value. Group 1 had high phosphorus and low nPCR, the opposite of patients in group 5. After 1 year follow-up survival difference between groups was according to numerical order. Association of R with mortality was strengthened with adjustment for case-mix variables. Adjusting HR to albumin improved prediction of patients with good prognosis.

Conclusions: The novel protein to phosphorus ratio score can predict mortality in MHD patients and may allow a better phosphorus monitoring while adequate protein intake is ensured.

Survival estimates according to fivR5 after 1 year 63,016 CEFDIM patients

FR-PO815

Effects of Citrasate® and Citrasate Dry ® on Serum Calcium and iPTH Robert J. Kossmann,[1] Ludmila Anderson,[1] Linda H. Ficociello,[1] Paul Balter,[2] Alice Topping,[2] Claudy Mullon.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Institute, New York, NY.*

Background: Citrasate and Citrasate Dry provide hemodialysis dialysates (CD) containing 2.4 mEq of citric acid (citrate) per liter. Citrate binds calcium and is rapidly metabolized in the liver. The objective of this analysis was to explore CD effects on corrected serum calcium (CSC) and iPTH in chronic kidney disease patients on thrice weekly hemodialysis (HD) who were converted from acetate acidified dialysates without citrate (AD) to CD.

Methods: Data for CD treated patients from 18 clinics were analyzed. Mean pre-HD laboratory values for the last three months of AD were compared with mean values for the first three months of CD (paired t-test, McNemar, chi^2, α=.05). Subanalyses were carried out by CSC (<8.4, 8.4-9.5, 9.6-10.2, >10.2 mg/dl) and iPTH (<130, 130-600, >600 pg/ml) ranges during the three months of AD. Changes in concomitant medications (in-center vitamin D [VitD], Cinacalcet, Ca-based phosphate binders [CaPB]) were explored.

Results: In total, 1,321 patients were analyzed. Mean pre-HD values for three months of AD and changes following the CD conversion are summarized in the Table.

Conclusions: On average, CSC decreased -5.6% and iPTH increased +4.4% during the first three months of CD. Subanalyses indicated that observed changes in CSC and iPTH varied according to their range during the last three months of AD. Limitations of the analysis include the cross-sectional nature of our assessment and inability to account for all clinical practices.

Measured versus Prescribed Dialysate Sodium Using Dialysis Machines from Different Manufacturers Ambreen Gul,[1] Dana Miskulin,[2] Antonia Harford,[3] R. Schrader,[1] S. Paine,[1] Walter L. Bender,[4] Bijin Thajudeen,[5] Philip Zager.[3,1] *[1]DCI, Albuquerque, NM; [2]Tufts Medical Center, Sommerville, MA; [3]UNM, Albuquerque, NM; [4]Dialysis Clinic Inc., Kansas City, MO; [5]University of Arizona, Tucson, AZ.*

Background: The optimal dialysate sodium (DNa) is unknown. We previously reported that differences (measured - prescribed DNa) in facilities using Fresenius and Gambro machines ranged from +13 mEq/L to - 6 mEq/L (mean + 2.5 mEq/L), which may contribute to the disparate results of published studies. We extended these observations by assessing differences in facilities using B. Braun machines.

Methods: We studied 2 DCI facilities that use B.Braun Dialog+ machines with either NaturaLyte or Diasol dialysate. Technicians entered DNa orders into the machine, which were verified by a nurse. We turned on dialysate machines ≥ 30 minutes prior to sampling. We clamped the saline line and sampled dialysate from the dialysate port 10 minutes prior to the start of dialysis in clinics 5 (24 machines, 97 treatments) and 6 (25 machines, 54 treatments). We sampled dialysate 10 minutes prior to end of dialysis in clinics 5 (n=91) and 6 (n=54). The DCI lab measured DNa concentrations with an indirect ion selective electrode. We assessed the differences (measured- prescribed DNa) by computing least square means with a linear mixed model that accounted for random machine effects and repeated measures.

Results: Measured DNa was 3.36 mEq/L (95% CI 2.69 – 4.02) and 1.82 mEq/L (95% CI 1.08 – 2.56) higher than prescribed in Units 5 and 6, respectively. The percentages of DNa measurements within 2 mEq/L of that ordered were 22.2% and 59.5% in Unit 5 & 6, respectively. DNa in late in dialysis was also higher than prescribed in clinics 5 (4.14 mEq/L [95% CI 3.54 – 4.73]) and 6 (1.81 mEq/L, [95% CI 1.15 – 2.47]). Measured DNa in samples drawn pre- and late- dialysis were similar. In clinic 5 26 pairs (28.6%) matched and 67 (73.6%) were within 1mEq/L. Corresponding numbers in clinic 6 were 22 (40.7%) and 47 (87%). The weighted kappa was 0.63 indicating good agreement between pre- and late dialysis DNa.

Conclusions: Measured DNa is higher than prescribed with Fresenius, Gambro, and B.Braun machines. QAPI programs should incorporate measurements of DNa to ensure adherence to the dialysis prescription.

FR-PO817

The Amino Acid Losses Are Lower during Pre-Dilution On-Line HDF Than HD Shunichiro Urabe,[1,2] Yukie Kitajima,[3] Motoko Kato,[1] Asami Kurii,[1] Emi Hiyama,[1] Takashi Hosono,[1] Toru Hyodo,[4] Makoto Kitamura,[4] Miho Hida,[4] Yasuhisa Kurata,[4] Kenichi Kokubo.[5] *[1]Clinical Engeenering, Eijin Clinic, Hiratsuka, Kanagawa, Japan; [2]Kitasato University Graduate School of Medical Sciences, Sagamihara, Japan; [3]Tokyo Healthcare University, Tokyo, Japan; [4]Kurata Hospital & Eijin Clinic, Hiratsuka, Japan; [5]Kitasato University School of Allied Health Sciences, Sagamihara, Japan.*

Background: We analyzed the amino acid losses that occur on performing pre-dilution on-line HDF (O-HDF) and HD because the amino acid kinetics of O-HDF has been unknown until now.

Methods: We compared the total amino acid level, total non-essential/essential/branched-chain amino acid levels, urea/Cr removal amount, reduction rate, and Kt/V (urea) between 10 patients undergoing O-HDF (8 males, 5 diabetic, mean age: 70.5±2.11 years) and 10 patients receiving HD (7 males, 5 diabetic, mean age: 73.6±5.87 years). The mean blood flow rate in the former and latter was 240±20 and 200 mL/min, respectively. The dialysate flow rate was 347±26.4 and 450 mL/min, respectively. The replacement fluid flow rate was 253±26.4 and 0 mL/min, respectively. The replacement fluid volume was 57±6.0 and 0 L, respectively.

Results: In the O-HDF group, the total and total non-essential amino acid losses (6,097±1,507* and 4,070±967* mg, respectively) were significantly lower than in the HD group (9,093±1,965 and 6,529±1,469 mg, respectively) (* $p < 0.01$). Urea and Cr removal amount in the O-HDF group was 12.4±1.48 and 1.59±0.367 g, respectively. In the HD group, the values were 12.5±3.59 and 1.63±0.332 g, respectively. The values showed no significant differences between the O-HDF and HD group. In the O-HDF group, the urea and Cr reduction rates were 65.1±6.68 and 71.2±6.80%, respectively. In the HD group, the values were 64.2±5.95 and 70.6±6.01%, respectively. The values showed no significant differences between the O-HDF and HD group. The Kt/V (urea) values in the former and latter were 1.50±0.289 and 1.49±0.314, respectively; there was no significant difference.

Conclusions: Under the same dialysis dose of Kt/V for urea, the amino acid losses were lower during O-HDF than HD, suggesting that O-HDF is more favorable as a blood purification method from the viewpoint of nutrition.

FR-PO818

Adjustment of Target Weight Based on Absolute Blood Volume Reduces the Frequency of Intradialytic Morbid Events Daniel SCHNEDITZ,[3] Susanne Kron,[1] Til Leimbach,[2] Klemens Budde,[1] Joachim Kron.[2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]KfH Kidney Center Berlin-Köpenick, Berlin, Germany; [3]Medical University Graz, Graz, Austria.*

Background: Adequate ultrafiltration (UF) avoiding intradialytic morbid events (IME) remains a core problem in current hemodialysis (HD) therapy. The aim of this study was to investigate the suitability of absolute blood volume (Vs, in mL/kg) to prescribe UF volume and to reduce the frequency of IME.

Methods: Following a 4 week baseline phase to quantify the frequency of IME, volume status was determined in a specified HD study during which relative blood volume (RBV, %) was measured by the blood volume monitor (BVM), Vs was measured using on-line dialysate dilution, and volume overload (Vo, L) was measured using bioimpedance spectroscopy. Symptomatic IME was defined as a drop in systolic blood pressure (PSYS) by more than 20 mmHg, or a PSYS below 90 mmHg, or the occurence of symptoms such as dizziness, light-headedness, sweating, or cramps. Suitability of different variables to discriminate for IME was examined by analysis of receiver-operator-characteristics (ROC-analysis) and calculation of the area under the ROC-curve (AUROC). Target weight was then increased or decreased based on measured Vs, Vo, and occurence of IME, and the frequency of IME was recorded during 4 weeks of follow-up.

Results: 45 patients participated in this study. 22 (49%) patients experienced 66 IME in 12% of HD treatments during baseline. In 15 (33%) patients who experienced IME during the volume assessment study Vs (60.7±4.0 vs. 73.7±11.3 mL/kg, $p<0.001$) and Vo (1.1±0.9 vs. 2.5±1.8 L, $p<0.01$) was lower than in stable patients, while RBV (87.9±4.4 vs. 90.2±4.2%, p=n.s.) was comparable. AUROC was 0.92, 0.80, and 0.61 for Vs, Vo, and RBV, respectively. The sensitivity, specificity, and accuracy of the Vs≤65 mL/kg threshold to predict IME was 87%, 100%, and 91%, respectively. Target weight was increased (+1.5 kg) or decreased (-5kg) in 32 patients. The frequency of IME fell to 0.9% of all HD sessions in the following 4 weeks ($p<0.001$).

Conclusions: Absolute blood volume (Vs, mL/kg) is more accurate in assessing the risk for IME-prone patients than relative blood volume (RBV, %). Adjustment of target weight based on information of Vs, Vo, and IME appears as a feasible approach to reduce the frequency of IME.

FR-PO819

Use of Lung Ultrasonography to Determine the Accuracy of Clinically Estimated Dry Weight in Chronic Hemodialysis Patients Chuan Jiang, Satyam Patel, Andrew A. Moses, Maria V. DeVita, Michael F. Michelis. *Medicine / Nephrology, Lenox Hill Hospital / Northwell Health, New York, NY.*

Background: The use of lung ultrasound (LUS) to identify extravascular lung water has received increasing acceptance. Sonographic B-lines, discrete vertical lines that originate from the pleura, represent pulmonary interstitial edema and are correlated with the accumulation of fluid. The goal of this study was to evaluate the utility of LUS to determine the accuracy of prescribed dry weight (DW) in chronic hemodialysis (HD) patients admitted to our dialysis unit and to ascertain the adequacy of fluid removal.

Methods: LUS was performed pre and post HD in 20 patients. The HD prescription and DW challenge were done independent of the results of the LUS. The presence of B-lines was tabulated and compared to the intradialytic ultrafiltration parameters.

Results: The mean age of the patients was 66.4 ± 13.5 years, with 55% male, and a mean dialysis vintage of 70.2 ± 8.0 months. Of the 20 patients, 3 did not exhibit B-lines at the beginning of the dialysis session. Among the other 17 patients, B-lines disappeared in 7 patients at the end of the HD session (mean B-lines 4.2 to 0). One patient was 0.3kg away from the prescribed dry weight, but the mean variance in the other 6 patients was 1.7kg below the prescribed weight. Of the remaining 10 patients, eight decreased but did not eliminate the B lines (mean B-lines 15.5 to 3.8) and were 3.8kg below DW post HD. Two patients could not reach DW or eliminate the B-lines (mean B-lines 24.5 to 10.0) and were 3.2 kg above DW post HD. Both patients exhibited more cardiac insufficiency than initially recognized. Correlation analysis showed a statistically significant correlation ($P < 0.05$) between the intradialytic percent change in B-lines and the percent change in total body weight ($r = 0.40$) and ultrafiltration rate ($r = 0.33$). Seven of 10 patients with clear chest x-rays pre HD exhibited B-lines.

Conclusions: This study supports the hypothesis that reduction of B-lines during HD can provide accurate information regarding changes in pulmonary fluid content. Further, LUS is an invaluable diagnostic tool for recognizing both the adequacy of fluid removal and the occurrence of error in the estimation of dry weight by usual clinical parameters.

FR-PO820

Use of Lung Ultrasonography for Assessment and Follow Up of Asymptomatic Pulmonary Congestion in Hemodialysis Patients Salah S. Naga. *Nephrology, Alexandria Faculty of Medicine, Alexandria, Egypt.*

Background: Chronic fluid overload is a common problem in ESRD patients on HD. Even asymptomatic lung congestion results in increased cardiovascular morbidity and mortality. Lung ultrasound provides a non-invasive tool to assess fluid overload. The aim of the study was to assess asymptomatic pulmonary congestion using lung ultrasonography and to evaluate the effect of increasing hemodialysis dose on improvement of the lung comet scores.

Methods: One hundred patients were enrolled. Based on ultrasound lung comets (ULC) score, patients were divided into group A (65 patients) with no or mild pulmonary congestion (ULC<14) and group B (35 patients) with moderate to severe (ULC>14). Group B was further subdivided into group B1 (18 patients) who were subjected to intensified HD and group B2 (17 patients) who were maintained on their conventional HD, and both subgroups were followed for three months.

Results: Baseline ULC score showed a significant positive correlation with LAP (r=0.808, p <0.001), LAD (r=0.519, p<0.001), IVCD (r=0.669, p<0.001), SBP (r=0.578, p<0.001) and DBP (r=0.435, p<001) and a strong negative correlation with EF (r=0.542, p<0.001) and inferior vena cava collapsibility index (IVCCI) (r=0.571, p<0.001). After intensified HD, Group B1 showed a significant decrease in the ULC score (25.44±6.13 to 9.17 ± 3.65, p<0.001), left atrial pressure (LAP) (16.22 ± 1.72 to 12.16 ±1.90, p<0.001), left atrial diameter (LAD) (41.33 ± 4.06 to 39.53 ± 2.73, p=0.003), inferior vena cava diameter (IVCD) (12 .65 ± 1.74 to 9.86 ± 1.61, p<0.001), SBP (146.67 ± 17.15 to 130.0 ± 12.83, p<0.001) and DBP (87.22 ± 6.96 to 82.22 ± 4.28, p=0.001) in comparison to group B2.

Conclusions: The present study demonstarted that lung ultrasonography guided intensified HD dose improved patients lung comets score, LAP, LAD, IVCD, IVCCI and blood pressure. ULC monitoring is an easy tool to detect asymptomatic lung congestion and allows tailoring dialysis to treat it.

FR-PO821

Intradialytic Hemodynamics and Cerebral Perfusion Dawn F. Wolfgram. *Zablocki VA Medical Center, Milwaukee, WI.*

Background: Persons with end-stage renal disease on hemodialysis (HD) have significant cerebral ischemic disease and atrophy noted on brain imaging. Hemodynamic instability during HD may lead to cerebral hypo-perfusion and resultant ischemic injury. Risk of cerebral hypo-perfusion may be higher in a subset of HD persons with increased drop in blood pressure during HD. We sought to describe the changes in cerebral perfusion during HD and the relationship to changes in intradialytic blood pressures (BP) in a cohort of HD patients.

Methods: We used a clinically validated method of continuous cerebral oximetry monitoring as a marker of cerebral perfusion during HD. Demographic variables and co-morbidities were collected on each participant, along with hemodialysis variables of intradialytic BP, fluid removal and duration of HD session. Descriptive statistics and linear regression analysis was used to analyze the data.

Results: Thirteen participants were enrolled with 11 participants completing the study and included in the analysis. The mean (SD) age was 66.8 (7.7) years. All participants had hypertension and 73% had diabetes. Diabetes was the cause of ESRD in 55% of participants. The mean (SD) change in cerebral oximetry during HD was -3.5% (2.6). In participants with greater than 20mmHg drop in SBP during HD (n= 7) the mean (SD) change in cerebral oximetry was -4.1% (3.2) vs -2.6 (0.8) in those with less than 20mmHg drop in SBP (p = 0.39). In participant with diabetes the mean (SD) change in cerebral oximetry was -4.2 (3.2) vs -2.3 (1.3) in participants without diabetes (p = 0.24). In participants with both diabetes and a greater than 20mmHg drop during dialysis there was a change in cerebral oximetry of -5.1 (3.1) vs -2.2 (1.3) in participants not meeting both criteria (p = 0.06). In four participants there was a significant association between SBP and cerebral oximetry during HD.

Conclusions: On average cerebral oximetry declines during HD and in some participants the decline may be related to drop in systemic BP during HD. Greater intradialtyic drop in BP in the setting of diabetes may increase risk of cerebral hypo-perfusion and ischemic injury. Analysis of our data was limited due to small sample size and increase in participant number is needed to determine the relationship between changes in intradialytic blood pressures and cerebral oximetry.

FR-PO822

Evaluation of Intradialytic Hypertension Using Bioelectrical Impedance Combined with Echocardiography in Maintenance Haemodialysis Patients Hongqi Ren. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: Although intra-dialytic hypertension(IDH) has been noted in clinical setttings for many years, its pathogenesis remains unclear. In this cross-sectional study, we aimed to analyze IDH incidence in our center and the correlation between postdialysis volume state and IDH.

Methods: 131maintenance haemodialysis (MHD) patients were enrolled in our study with bioelectrical impedance (BIA) and echocardiography (ECG) recorded. Demographic data was collected and laboratory examination was conducted. The patients were grouped into four groups according to the changes of systolic blood pressure (SBP) between postdialysis and predialysis.

Results: The incidence of IDH was10.7%. The proportion of extracellular water to total body weight (ECW/TW) evaluated by BIA, in the IDH group was significantly higher than those of the other three groups both in pre-and post- dialysis comparison. In particular, postdialysis SBP was highest in the highest tertile interval of ECW/TW. In addition, left ventricular volume (LVV) in the IDH group was the highest among all four groups. By binary logistic analyses, we found that predialysis SBP, postdialysis ECW/TW and LVV were independent risk factors of intradialytic hypertension. When predicting the probability of ECW/TW combined with LVV, ROC curve showed a AUC (0.752, 95 % CI was 0.613-0.896)was higher than the LVV and ECW/TW alone.

Conclusions: In this study, we found that the volume expansion of ECW and intravascular compartments after the dialysis measured by the combination of bioelectrical impedance and echocardiography in patients with MHD. Our study further showed that post-dialysis volume expansion is an important factor for the development of IDH.

Baseline Muscle Strength, Dry Weight, and Physical Activity Are Associated with Muscle Strengthening of Lower Extremities after 6-Month Resistance Training in Patients with Maintenance Hemodialysis Yoshifumi Moriiyama,[2] Sae Aratani,[3] Masahiko Hara,[4] Hideaki Ishikawa.[1] *[1]Konan Kosei Hospital, Konan, Japan; [2]Nagoya kyoritsu hospital, Nagoya, Japan; [3]Nippon Medical School Hospital, Tokyo, Japan; [4]Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Rapid muscle wasting is a common complication in patients with maintenance hemodialysis, and it is associated with the risk of pratfall as well as with poor quality of life and survival.

Methods: We included 271 patients who underwent 6-month resistance training program during hemodialysis. Primary outcome measure was change in percent knee extension muscle power to body weight (pKEMP-BW; mean of right and left) during 6-month. We divided our patients into 2 groups; improve vs deteriorate groups. Multivariable logistic regression model was employed to evaluate parameters which are associated with improvement of pKEMP-BW at 6-month, using indices shown in the Table as explanatory variables such as baseline pKEMP-BW or short physical performance battery (SPPB).

Results: Median age was 71 (quartile 64-77) years old, 144 patients (53.1%) were men, and median dry weight was 54.2 (47.5-61.6) kg. After 6-month training, pKEMP-BW was improved in 177 patients (65.3%), and pKEMP-BW changed from 42.0 (32.4-52.3) % to 43.4 (34.8-55.0) % in total (p<0.001). As shown in the Table, baseline lower dry weight, higher handgrip, lower pKEMP-BW, and higher SPPB were associated with an improvement of pKEMP-BW at 6-month.

Conclusions: Six-month resistance training improved pKEMP-BW. Baseline lower dry weight, higher handgrip, lower pKEMP-BW, and higher SPPB were associated with an improvement of pKEMP-BW at 6-month in patients with maintenance hemodialysis.

Urea Clearance Modelling Using 300 ml/min of Dialysate Flow J. Ken Leypoldt,[1] Sarah S. Prichard,[3] Glenn M. Chertow,[2] Luis Alvarez.[1] *[1]None, Menlo Park, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Outset Medical, San Jose, CA.*

Background: High dialysate flow rates (Q_D) of 500-700 mL/min are generally used in the outpatient setting to maximize urea removal in a time efficient manner. Lower dialysate flows of 100-200 mL/min are often employed in critically ill patients and in patients at high risk of dialysis disequilibrium. There are few data describing the use of a mid-rate Q_D (300mL/min) in a modern outpatient dialysis setting. We present urea kinetic modeling of 300 mL/min dialysate flow rates and investigate differential urea clearances between 300 and 500 mL/min Q_D.

Methods: Urea kinetic models were used to predict urea clearances at 300 mL/min dialysate flows. Using the FHN trial group urea model assumptions in combination with published dialyzer characteristics (KoA), a weekly urea concentration profile was obtained. The model was then applied to patients of different weights and volumes of distribution (VOD) at blood flows (Q_B) of 400 mL/min. Finally, a clearance relationship for spKt/V of 300 vs. 500 mL/min Q_D was obtained.

Results: Table 1 shows modelled spKt/V when Q_D is 300mL/min or 500 mL/min at the same Q_B of 400 mL/min. Across VOD, the model demonstrates a Q_D of 300 mL/min results in a predicted spKt/V that meets urea clearance targets. There was a small difference in spKt/V between a Q_D of 300 mL/min and 500 mL/min Q_D. Use of a larger KoA (LKoA) dialyzer and 15 minutes of additional time narrows the spKt/V difference.

Conclusions: A Q_D of 300mL/min can be expected to achieve urea clearance targets. Decreasing dialysate flow rate to 300 mL/min results in a modest, but clinically insignificant, spKt/V difference. For patients with clearance challenges at 500mL/min Q_D, the use of a 300 mL/min Q_D with a larger KoA dialyzer and incremental time can be considered, which may itself allow for lower rates of ultrafiltration and better-tolerated hemodialysis therapy.

In-Vitro Dialysis Clearances Using Dharma, the EasyDial Portable Hemodialysis Machine Timothy R. Mcnamara,[2] Osman S. Khawar,[1] Sarah L. Foster.[2] *[1]Balboa Nephrology Medical Group, Escondido, CA; [2]EasyDial, Irvine, CA.*

Background: Dharma is a unique, fully portable dialysis machine, which uses only 5 Liters of dialysate during each treatment. To determine the efficacy of Dharma in clearing blood waste products, in-vitro dialysis tests were run utilizing bovine blood.

Methods: Twenty-three treatments were conducted and all met the defined parameters of an effective dialysis over 90 – 120 minutes. A common protocol was utilized. Amendments were made for differences between studies inclusive blood flow rates, dialysate, reinfusion solutions and rates. Dharma machines were prepared with consumables (dialyzer, blood and dialysis circuit cassettes, blood and dialysate lines) and primed. Five liters of dialysate were added to a reservoir and warmed to 37 degrees centigrade. Five liters of bovine blood was spiked with urea, creatinine, potassium, calcium, magnesium and glucose to levels commonly found in dialysis patients. The blood was added to a vessel connected to the arterial line through a 16-gauge needle or a 10 French catheter. Treatments were run by dialysis technicians. Serum samples for waste products were collected at baseline, every 15 minutes and at the end of dialysis. Dialysate pH and conductivity were monitored.

Results: Desired clearances of waste products was achieved at all timepoints (Table 1). Mean clearances were: BUN 77.1% (126.3 mg/dL (±26.4) to 28.93 mg/dL(±6.89), creatinine clearance 88.9% (15.9 mg/dL (±4.2) to 1.76 mg/dL (±0.89) and urea clearance was of 77.5% (225.5mmol (±47.2) to 50.74 mmol (±19.03). Clearances for waste products were greater than 70% at all timepoints and were greatest in the 120-minute treatment group for BUN (78.6%), creatinine (89.5%) and urea (78.7%).

Conclusions: These results verify in-vitro efficacy of Dharma in dialysis treatments. Dharma offers the unique features of portability (18 lbs.), no fixed water connection (5 L dialysate) and the possibility for significantly reducing dialysis treatment times. These features may allow for improving the quality of life and reducing the burden of illness in ESRD patients on dialysis.

African American ESRD and Medication Adherence: What Are the Effects of Everyday Racism? Tamara Savage. *Social Work, UNC Pembroke, Pembroke, NC.*

Background: Poor medication adherence leads to increased hospitalizations, morbidity, and mortality in end-stage renal disease (ESRD) patients. African American ESRD patients have poorer rates of medication adherence when compared to Whites. Studies have not investigated the impact of broader social issues such as everyday racism on this racial disparity. This is the first study to explore how everyday racism within the healthcare system contributes to this disparity in medication adherence. A mixed methods study was conducted to investigate the relationship between everyday racism and medication adherence within the African American ESRD community.

Methods: Primary data were collected from 46 African American ESRD patients. All participants completed a questionnaire comprised of demographic information, a medication adherence survey, and an everyday racism in the healthcare setting survey. Additionally, 27 of the total sample (N=46) participated in in-depth interviews which lasting approximately one hour. Participants were recruited from attendees at two patient-centered meetings in Greensboro, NC and Nashville, TN. Pearson's Correlation was used to analyze quantitative data and Constructivist Grounded Theory was used to identify themes that emerged from interview transcripts.

Results: A statistically significant negative relationship was found between medication adherence and everyday racism in the healthcare system (r = -.477, p < .01). As everyday racism increased, medication adherence decreased. Furthermore, interviews revealed that everyday racism perpetuated within the healthcare system negatively affected participants' medication adherence. Three themes were identified: 1) Concern that medical providers were not knowledgeable about the medications they were prescribing 2) Concern that the medication was not safe 3) Information about medication and lab results withheld or given to participants without further consultation.

Conclusions: These findings provide the basis for development of future research that could lead to interventions with healthcare systems and professionals to address the medication adherence disparity.

FR-PO827

Methylguanidine in Normal Subjects and ESRD Patients Ahmed Z. Alkhathlan,[1] Xin Hai,[2] Mirela A. Dobre,[2] Timothy W. Meyer,[3] Thomas H. Hostetter.[2] *[1]University Hospitals Case Medical Center, Beachwood, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Stanford University, Palo Alto, CA.*

Background: Methylguanidine (MG), a guanidino compound, is a small water-soluble solute that accumulates in uremic patients and has been implicated in some uremic toxicities. We studied the behavior of MG in end-stage renal disease patients on chronic dialysis compared to normal controls.

Methods: We studied six normal controls and seven chronic hemodialysis patients. Blood and 24-hour urine samples collected from the control group; while blood and dialysate samples were collected from the dialysis group (start, mid, and end of dialysis sessions). Urea, creatinine (Cr), and MG were measured by a LC-MS/MS method. Mean levels, clearance, and production/excretion rates were calculated assuming first order kinetics, and statistical methods (Student's t test, Pearson correlation coefficient) were used for data analysis. Results are expressed as mean ± standard deviation (SD).

Results: The mean predialysis plasma MG level in chronic dialysis subjects was significantly higher (more than 100-fold) than in the control group (5.17 ± 2.61 vs. 0.047 ± 0.01 μM, respectively; P = 0.0005). In comparison, the mean predialysis urea level was only three-fold the normal level (44.05 ± 23.06 vs. 14.89 ± 3.23 mg/dL, respectively; P = 0.02), and Cr was 13-fold the normal level (10.8 ± 3.1 vs. 0.83 ± 0.18 mg/dL, respectively; P = 0.0001). The mean production rates of MG were 47.12 (± 13.6) and 4.21 (± 3.4) μmol/day in chronic dialysis patients and healthy individuals, respectively (P < 0.05). The effective clearance rates for urea and Cr in dialysis patients were 239 (± 69) and 173 (± 51) ml/min, respectively; which were significantly higher than the effective clearance rate for MG 122 (± 26) ml/min (P < 0.05).

Conclusions: MG accumulates to more than 100 fold the normal level in ESRD patients. This accumulation likely reflects 1) its clearance rate (and therefore its reduction ratio) is significantly less than that of urea and Cr, which is likely due to its previously described large distribution volume, and 2) increased production from Cr oxidation.

Table 1. Solute Plasma Levels, Clearance and Excretion Rates in Controls and ESRD Patients

	Plasma Levels a				Clearance b		Excretion/Removal c	
Solute	UN d (mg/dl)	Cr (mg/dl)	MG (μM)	Urea (ml/min)	Cr	MG	Urea (g/day)	MG (μmoles/day)
Normal (n=6)	14.89 ± 3.23	0.83 ± 0.18	0.047 ± 0.013	55.19 ± 13.75	119.07 ± 22.03	68.09 ± 62.07	24.89 ± 6.24	4.6 ± 4.2
ESRD (n=7)	44.05 ± 23.06	10.8 ± 3.1	5.17 ± 2.61	238.83 ± 69.4	173.04 ± 51.1	122.53 ± 26.5	12.65 ± 6.62	47.12 ± 18.35

FR-PO828

Capturing and Reporting Performance Measures for Chronic Hemodialysis Care: The Veterans Health Administration (VHA) Dialysis Dashboard Experience Michael J. Fischer,[2,4] Karen Sovern,[1] Susan T. Crowley.[3] *[1]Department of Veterans Affairs, Cincinnati, OH; [2]University of Illinois Hospital and Health Sciences Center, Chicago, IL; [3]Veterans Health Administration, West Haven, CT; [4]Jesse Brown VAMC and Hines VA Hospital, Chicago, IL.*

Background: End-stage renal disease (ESRD) is a common, burdensome, and costly chronic condition among Veterans. Assessment and improvement of the quality of Veteran chronic hemodialysis (HD) care is a VHA goal. However, VHA has historically been reliant on external vendors to provide assessments of chronic VHA HD facility-level performance and to meet stakeholder requests for quality reports.

Methods: The VHA National Kidney Program began a process of leveraging multiple kidney disease and dialysis informatics initiatives to build an internal kidney disease surveillance system in 2012. A four step process was used to develop and implement a national VHA Dialysis Dashboard for capturing and reporting of clinical performance measures (PMs) for approximately 3000 Veterans at 71 VHA HD facilities. This electronic dashboard is accessible by VA operations and clinical dialysis staff for quality assurance and improvement activities.

Results: First, the assembly of a diverse stakeholder committee was required to achieve broad consensus for PMs and ensure acceptance in the field. Second, a process for conducting an environmental scan of existing ESRD/HD PMs and vetting was developed. Through teleconference discussions and web-based voting on 78 PMs from recognized

reference organizations, 11 mature facility-level PMs were selected that encompass dialysis adequacy, vascular access, anemia, mineral metabolism, and infection. Third, collaboration across different VHA service lines proved essential to create this dashboard, which leveraged the VA electronic medical record and data warehouses, and created a web-based application for field reporting. Fourth, a coordinated series of national rollout calls, pilot testing, and user acceptance testing was essential for final implementation. The Dashboard was fully implemented in 2013, and by 2016 there was 100% VA dialysis facility participation and 96% usable records for PMs.

Conclusions: The VHA Dialysis Dashboard is a versatile surveillance and reporting tool to provide national and facility level assessment of the quality of chronic dialysis care, to guide and motivate high quality care, to target quality improvement efforts at a facility level, and to provide an atmosphere for promoting a cohesive approach to process improvement efforts at a national level.

FR-PO829

Protein-Bound and Large Toxin Removals between Hemodialysis Using High Cut-off Dialyzers with Adsorptive Cartridge and High-Efficiency Online Hemodiafiltration: A Crossover Randomized Controlled Trial Nutchaya Khemnark,[1,2] Khajohn Tiranathanagul,[1,2] Maneerut Limjariyakul,[1] Supeecha Wittayalertpanya,[1] Paweena Susantitaphong,[1,2] Somchai Eiam-Ong,[1,2] Kearkiat Praditpornsilpa.[1,2] *[1]Chulalongkorn University, Bangkok, Thailand; [2]King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Protein-bound toxins especially indoxyl sulfate (IS) which could not be removed by standard hemodialysis (HD) using high-flux dialyzer are obviously correlated with high mortality in HD patients. High-efficiency online hemodiafiltration using high-flux dialyzer (OL-HDF) has been reported to enhance IS removal and improve patient survival. At present, there are certain limitations of OL-HDF including necessity for special machine and high investment cost. Therefore, we proposed a new HD modality which can be performed in any HD centers with standard HD machine by using high cut-off (HCO) dialyzer, PES-17Dα (Nipro, Japan) in combination with hemoperfusion (HP) using HA130 adsorptive cartridge (Jafron, China) and compared with OL-HDF.

Methods: This was a cross-over randomized control trial. Ten chronic hemodialysis patients were randomized to consecutively undergo dialysis with either new HD modality (HCO HD with HP) or OL-HDF before cross-over to the other modality for 8-week each period. The efficacy including percentage reduction after dialysis of IS, β2 microglobulin (β2m) and urea were assessed. Patient safety and dialysate albumin loss were monitored. IS was measured by high performance liquid chromatography.

Results: The plasma IS levels significantly decreased in both treatment modalities. The percentage reduction of IS were comparable between HCO HD with HP and OL-HDF (52.0±11.7 vs. 56.3±7.5 %, p=0.28). The percentage reduction of β2m did not differ (83.7±4.9 vs. 84.0±4.3 %, p=0.75). Two techniques provided adequate small solute removal. Although the dialysate albumin loss was significantly higher in HCO HD with HP than OL-HDF (4.2±2.4 vs. 0.5±0.8 g/session; P=0.008), there were no significant long-term changes in serum albumin levels of both modalities.

Conclusions: Standard HD using HCO dialyzer with HP using adsorptive cartridge, which could be performed in any HD centers, can effectively remove IS, β2m, and small toxin in comparable with high cost OL-HDF and could replace OL HDF where it is unavailable.

FR-PO830

Renal AA-Amyloidosis in Dialysis-Dependent Drug Addicts Camilla Madsen, Ingjerd W. Manner, Helga Gudmundsdottir. *Oslo University Hospital, Ulleval, Oslo, Norway.*

Background: A substantial increase of dialysis-dependent injecting drug abusers has been observed in Oslo, Norway. The incidence in other parts of the country is low. Longstanding chronic skin infections caused by subcutaneous administration ("skin popping") of illicit drugs, when the intravenous route is exhausted may induce AA-amyloidosis. The kidneys are the organs most frequently affected. Renal AA-amyloidosis is characterized by nephrotic syndrome and progression to end stage renal disease and the prognosis is poor. The diagnosis can only be confirmed by tissue biopsy. The prevalence of hepatitis B, C and HIV in this population of patients tends to high.

Methods: Retrospective investigation including all patients with past or present injecting drug abuse who started dialysis between January 2005 and June 2017 in the city of Oslo, Norway.

Results: A total of 46 injecting drug addicts were included in the study. All patients were Caucasian, 70% males, mean age was 50.2 ± 8.3 years and they had been injecting drug addicts for 27.3 ± 9.2 (range 9-47) years). A total of 54.3% were crash landers (i.e. referred within 4 months of requiring dialysis). Renal biopsy was performed in 34 patients (74%), and AA-amyloidosis was confirmed in all but one patient. All patients were positive for anti-hepatitis C virus antibodies, and 4.3% were HIV infected. All had a history of repeated chronic suppurative skin infections. All had ongoing drug abuse and all had been offered medication-assisted therapy. No patients fulfilled criteria for renal transplantation due to chronic infections and ongoing drug abuse. The prognosis after starting dialysis was poor with 34% mortality in 1 year. As of today, 16% of our dialysis population are past or present injecting drug addicts with renal failure caused by renal amyloidosis.

Conclusions: Renal AA-amyloidosis is the most common cause of end stage renal disease in injecting drug addicts in Oslo. Morbidity and mortality is high. It is a challenging and complex population without the option of transplantation. More focus is needed on prevention and early intervention.

FR-PO831

Effect of Different Dialysis Procedures on Mid-Term Protein-Bound Toxins Plasma Levels Detlef H. Krieter,[1] Simon Kerwagen,[1] Marieke Rueth,[2] Horst-Dieter Lemke,[2] Christoph Wanner.[1] *[1]University Hospital, Wuerzburg, Germany; [2]eXcorLab GmbH, Obernburg, Germany.*

Background: Protein bound uremic toxins (PBT) are involved in dialysis associated morbidity. If dialysis procedures differ in their effect on PBT plasma levels over longer periods has barely been studied. Purpose of the present trial was to monitor PBT plasma levels over a 6-week period in patients on different extracorporeal dialysis forms.

Methods: In a prospective, randomized, controlled, cross-over trial enrolling 15 maintenance dialysis patients (*DRKS00010788*), low-flux and high-flux hemodialysis (HD) were compared to high convective volume (≥25 L) postdilution hemodiafiltration (HDF). Each patient was subjected thrice weekly to each treatment mode for 6 consecutive weeks. Dialysis membrane material was always identical (PUREMA® L and H, resp.). Dialysate flow rates differed in HD and HDF (500 vs. 700 mL/min). Blood flow rates and treatment time were kept identical for individual patients. Plasma levels of free and total para-cresyl sulfate (pCS) and indoxyl sulfate (IS) were determined at baseline (t0), after 3 (t3) and 6 weeks (t6) of each treatment period. Reduction ratios were measured at t0 and t3. Serum CRP and albumin were also monitored.

Results: During HDF, plasma concentrations of total IS decreased from t0 (18.9±13.0 mg/L) to t3 (16.6±12.1 mg/L, P=0.027). Total IS levels at t0 and t3 during HDF were lower compared to low-flux HD (20.8±14.4 mg/L, P=0.046, and 20.0±12.7 mg/L, P=0.021, resp.), but did not differ from high-flux HD (20.1±12.6 and 19.3±11.6 mg/L). Total IS reduction ratio in HDF (t0, 48.1±9.6; t3, 46.0±18.3%) were much higher (P<0.001) compared to low-flux (36.5±10.7; 34.3±8.2%) and high-flux HD (35.9±8.7; 37.0±10.5%). Although, reduction ratios for free IS and pCS as well as for total pCS were also significantly higher in HDF, no differences in these PBT plasma levels were determined. Interestingly, free and total IS concentrations highly correlated with CRP (r 0.378 and 0.520, resp.; each P<0.001), but not with albumin.

Conclusions: Differences in instantaneous removal by dialysis therapies have only limited impact on mid-term plasma levels of PBT. The association of inflammation and IS further indicates that other factors are more important determinants of PBT concentrations.

FR-PO832

Plasma Total Matrix Gla Protein, Vitamin K Levels, and Vascular Calcification in Prevalent Hemodialysis Patients Sonoo Mizuiri,[3] Yoshiko Nishizawa,[3] Kazuomi Yamashita,[3] Kohji Usui,[1] Chie Tanji,[1] Shigehiro Doi,[2] Takao Masaki,[2] Kenichiro Shigemoto.[3] *[1]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [2]Hiroshima University Hospital, Hiroshima, Japan; [3]Ichiyokai Harada Hospital, Hiroshima, Japan.*

Background: Hemodialysis (HD) patients suffer from accelerated vascular calcification. Vitamin K-dependent matrix Gla protein (MGP) is a potent inhibitor of vascular calcification but published data on plasma MGP levels of HD patients are inconsistent. This study investigated the associations between the plasma total MGP level and the vitamin K level or vascular calcification in HD patients.

Methods: Subjects were 73 prevalent HD patients aged≤60 years and 40 healthy controls. Plasma total (including inactive) MGP levels were assessed using an ELISA kit (Cloud-Clone Corp). Predictors of the plasma MGP level in patients were identified by regression analyses [variables: age, presence of diabetes, presence of cardiovascular disease, dialysis vintage, Agatston (coronary artery calcification) score, serum phosphate, calcium, intact parathyroid hormone, vitamin K1, and vitamin K2 levels, Kt/Vurea, and geriatric nutritional risk index (GNRI)]. The variables that displayed significance in the univariate analyses were subjected to multiple regression analysis.

Results: The healthy subjects' mean estimated glomerular filtration rate was 78±13 ml/min/1.73m^2. The HD patients' (including 25 patients with diabetes) median dialysis vintage was 78 (36-152) months. The age (50±6 vs.48±6 years), sex distribution, and body mass index and vitamin K2 levels were not significantly different, but the vitamin K1 levels were significantly lower (0.56±0.37 vs. 0.98±0.61 ng/ml, P<0.0001), and the MGP levels were significantly higher (290±50 vs.160±41 ng/ml, P<0.0001) in HD patients as compared to controls. Regression analyses indicated that age, dialysis vintage, presence of cardiovascular disease, vitamin K1 level, and GNRI were significantly associated with the MGP level [β (95% CI): 0.35 (2.11-6.52), P<0.001, 0.25 (0.01-0.23), P<0.05, 0.28 (2.79-27.15), P<0.05, -0.28 (-70.01--14.56), P<0.05, -0.25 (-4.36--0.18), P<0.05, respectively]. In the multiple regression analysis, only presence of cardiovascular disease was found to be significantly associated with the MGP level [β (95% CI): 0.24 (0.58-24.77), P<0.05].

Conclusions: HD patients had lower vitamin K1 levels than healthy subjects, and the plasma total MGP level is significantly associated with cardiovascular disease, but not the Agatston score, in HD patients.

FR-PO833

Trends in Emergency Hospitalization for Cardiovascular and Infectious Diseases between Hemodialysis and Peritoneal Dialysis over 20 Years Masataka Banshodani, Hideki Kawanishi, Misaki Moriishi, Sadanori Shintaku, Shinichiro Tsuchiya. *Tsuchiya General Hospital, Hiroshima, Japan.*

Background: In hemodialysis (HD), volume and electrolyte status drastically change, whereas peritoneal dialysis (PD) is a continuous dialysis and thus maintain a stable volume and electrolyte status. However, no studies have evaluated trends of hospitalization for cardiovascular diseases (CVDs) and infectious diseases (IDs) according to dialysis modality over time.

Methods: This is a retrospective observational cohort study that evaluated 13,078 hospitalizations (1,955 HD and 497 PD patients with end-stage renal disease) to clarify associations between dialysis modality and emergency hospitalization for CVDs (HD, 1,704; PD, 261 times) and IDs (excluding PD-related infections; HD, 970; PD, 132 times) at a single institution over 20 years (1995–2014).

Results: The CVD hospitalization rate (per 100 person-years) in PD remained at the same level over 20 years (1995–1999, 2000–2004, 2005–2009, 2010–2014; 9.7, 6.5, 10.5, and 7.2, respectively), while in HD, the rate decreased (15.4, 8.3, 5.7, and 6.3; every $P < 0.001$, v.s. 1995–1999). The ID hospitalization rate in PD decreased in the last 5 years (5.0, 5.0, 5.4, and 2.5, respectively; $P = 0.001$, 2005–2009 v.s. 2010–2014). In HD, the rate increased (5.9, 3.9, 3.8, and 5.4; $P < 0.001$, 2005–2009 v.s. 2010–2014). In the logistic regression analyses, the odds of dialysis vintage (odds ratio [OR], 3.58; confidence interval [CI], 2.25–5.77; $P < 0.001$) and HD (OR, 2.04; CI, 1.57–2.68, $P < 0.001$) were significantly higher for CVD hospitalization in the first 10 years, but the significances disappeared in the last 10 years. Although no significance was found in first 10 years, the odds of male sex (OR, 1.27; CI, 1.08–1.51, $P = 0.004$) and HD (OR, 1.52; CI, 1.19–1.96, $P < 0.001$) were significantly higher for ID hospitalization in the last 10 years.

Conclusions: The risk of CVD hospitalization was significantly higher in HD than in PD in the first 10 years, but the risk disappeared in the last 10 years. However, the increased risk of ID hospitalization in HD should be solved. Further multicenter studies are needed to compare hospitalization rates among dialysis modalities.

FR-PO834

The Impact of Early Hospitalizations after Initiation of Dialysis on All-Cause Mortality in Incident Hemodialysis Patients Yu ah Hong,[1] Su Hyun Kim,[3] Yong-Lim Kim,[4] Yon Su Kim,[5] Shin-Wook Kang,[6] Seong il Jo,[1] Yoon-Kyung Chang,[2] Suk young Kim,[2] Yong Kyun Kim.[2] *[1]The Catholic University of Korea, Daejeon, Republic of Korea; [2]The Catholic University of Korea, Daejeon, Republic of Korea; [3]Chung-Ang University Hospital, Seoul, Republic of Korea; [4]Kyungpook National University Hospital, Daegu, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea; [6]College of Medicine, BK21, Yonsei Univ., Seoul, Republic of Korea.*

Background: Background/Aims: Hospitalization and mortality rates are relatively high within first several months after initiation of dialysis in end-stage renal disease (ESRD). Limited data are available about the association between early hospitalization after initiation of dialysis and clinical outcomes in ESRD patients. We investigate the association between early hospitalization and all-cause mortality in incident hemodialysis (HD) patients.

Methods: Methods: Incident dialysis patients were selected from the Clinical Research Center registry a prospective Cohort study on dialysis patients in Korea. Early hospitalization was defined as all-cause hospitalization within 90 days after initiation of HD. The primary outcome was all cause mortality and the secondary outcome was cardiovascular and infection-related mortality.

Results: Results: A total of 1,584 hemodialysis patients were included. The median follow-up period was 24.5 months. During follow up period, 150/1,584 (9.5 %) was died. 43/1,584 (2.7%) and 33/1,584 (2.1 %) was died of cardiovascular and infection-related cause. Kaplan-Meier analysis showed that the all-cause mortality rates ($P < 0.001$, Log-rank) as well as cardiovascular infection-related mortality rates ($P < 0.001$ and $P < 0.001$, respectively, Log-rank) were significantly higher in patients with early hospitalization than in patients with no hospitalization. The multivariate Cox regression analysis showed that patients with early hospitalization remained at higher risk for all-cause mortality than those without early hospitalization after adjusting for confounding variables (HR 2.888 [1.806-4.616], $P < 0.001$). In addition, cardiovascular and infection-related mortality were significantly higher in patients with early hospitalization than in patients with no hospitalization after adjusting for confounding variables (HR 7.547 [2.893-19.690], $P < 0.001$ and HR 2.900 [1.157-7.27], $P < 0.001$, respectively).

Conclusions: Conclusion: Early hospitalization within 90 days after initiation of dialysis was an independent predictor marker of all-cause mortality in incident HD patients, which suggest that careful attention for HD patients with early hospitalization is needed.

FR-PO835

Association of Waist-to-Hip Ratio with Sudden Cardiac Death and Cardiovascular Mortality in Incident Hemodialysis Patients Jessica Fitzpatrick,[1] Stephen M. Sozio,[2] Bernard G. Jaar,[2] Michelle M. Estrella,[4] Jose M. Monroy-Trujillo,[2] Larisa G. Tereshchenko,[3] Rulan S. Parekh.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]Johns Hopkins University, Baltimore, MD; [3]Oregon Health and Science University, Portland, OR; [4]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA.*

Background: Waist-to-hip ratio (WHR) is a predictor of cardiovascular disease (CVD) and mortality in the general population. Few studies, however, have examined the association of WHR and risk of CVD mortality, particularly sudden cardiac death (SCD), among end-stage renal disease (ESRD) patients undergoing hemodialysis.

Methods: This study included 379 incident hemodialysis patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) Study. WHR was calculated as the ratio of waist-to-hip circumference. CV death was defined as deaths arising from arrhythmias, ischemic CVD, and ischemic cerebrovascular disease, as well as SCD. Cox proportional hazards regression was used to estimate the association of baseline WHR with risk of CVD death, SCD, and non-CVD death.

Results: At baseline, the mean age was 54.9 years, 41% were female, 73% were African American, 57% had diabetes, the mean comorbidity index was 5.2, the mean body mass index (BMI) was 29.3 kg/m^2, the mean WHR was 0.95, and 85% were above the World Health Organization WHR threshold for metabolic complications. WHR and BMI were weakly correlated (r=0.21). During a median follow-up time of 2.5 years, there were 35 CVD deaths, 15 SCD, and 48 deaths from non-CVD causes. An increase in WHR was associated with higher hazard of CVD mortality and SCD, but not non-CVD mortality. In adjusted models, WHR was strongly associated with SCD. There was no evidence of interaction between WHR and race or BMI in any of the models.[Table]

Conclusions: WHR is associated with SCD and CVD death in incident hemodialysis patients. The easily measured WHR may be a useful metric to risk stratify ESRD patients for CVD mortality.

A Scoring System to Guide Systemic Oral Anticoagulation Among Incident Dialysis Patients with a Preexisting Diagnosis of Atrial Fibrillation/Flutter Robert C. Albright,[2] John J. Dillon,[2] Dena E. Cohen,[1] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Mayo Clinic, Rochester, MN.*

Background: Among the general population, patients with atrial fibrillation/flutter (Afib) and a CHA_2DS_2-VASc score ≥2 have high stroke risk and may receive systemic oral anticoagulation (SOA). Utility of CHA_2DS_2-VASc in patients initiating hemodialysis (HD) with pre-existing Afib is unclear.

Methods: We considered adult Medicare enrollees who initiated HD at a large US dialysis organization in 2010-2011 with pre-existing Afib, determined from claims. Exposures were risk scores and SOA, based on a prescription fill during the first 3 months of HD. Outcome (stroke/transient ischemic attack [TIA]) was considered from HD start until censoring or study end (Dec 2012), and compared using intention-to-treat principles and Cox proportional hazard models. An HD-specific risk score was developed using a logistic model fit by stepwise elimination of non-contributing variables ($p>0.1$). Positive outcomes were SOA and no stroke/TIA, and no SOA and stroke/TIA; negative outcomes were the converse.

Results: Among 2742 patients initiating HD with Afib, no association was observed between SOA and risk of stroke/TIA across CHA_2DS_2-VASc categories. Female sex, Hispanic race, use of a central venous catheter, congestive heart failure, and diabetes defined an HD-specific risk score. In the top quartile of this score, SOA (vs. no SOA) was associated, at near statistical significance, with a lower point estimate for risk of stroke/TIA.

Conclusions: We developed a risk score that, unlike CHA_2DS_2-VASc, may identify incident HD patients with Afib who will benefit from SOA. Further work is needed to refine and validate this HD-specific score.

Dialysis Modality and Incident Atrial Fibrillation in Older Patients with ESRD Initiating Dialysis Jingbo Niu, Maulin Shah, Jose J. Perez, Medha Airy, Sankar D. Navaneethan, Wolfgang C. Winkelmayer. *Baylor College of Medicine, Houston, TX.*

Background: The incidence of atrial fibrillation (AF) in older patients with ESRD initiating hemodialysis (HD) is high, at 14.8 per 100 person-years, and AF is associated with increased morbidity and mortality. It has been posited that peritoneal dialysis (PD) may confer lower AF risk owing to lesser fluctuations of fluid and electrolyte status. We tested whether the incidence of AF differed between patients using PD versus HD for the initiation of dialysis in a national U.S. cohort.

Methods: Patients 67+ years who initiated dialysis for ESRD in the continental US were eligible if they had been continuously enrolled in Medicare A&B during the 2 years pre- and 90 days post-ESRD. Those with any diagnosis of AF prior to initiation of dialysis (=index date) were excluded. Patients were further required to have exclusively used a single modality for these first 90 days (or until they died or received a transplant during that period). Patients were then followed for AF incidence, which was ascertained from 1 inpatient or 2 outpatient diagnoses (ICD-9 code: 427.3x). Follow-up was terminated 3 years after index date or at loss of Medicare A&B coverage. Death and kidney transplantation were handled as either censoring or competing events in separate analyses. Multivariable Cox proportional hazards regression models were used to estimate the cause-specific and sub-distribution hazard ratios [HR (95% confidence interval)] for PD vs HD.

Results: We identified 251,092 patients with ESRD initiating dialysis between 1996 and 2011; 93.2% used HD and 6.8% used PD. During 447,253 years of follow up, 69,656 patients were newly diagnosed with AF; 3,324 received a kidney transplant and 102,202 died. The unadjusted AF incidence rates per 100 person-years were 15.7 for HD and 14.5 for PD, respectively. The unadjusted cause-specific HR for AF comparing PD to HD (referent) was 0.93 (0.91-0.96) and the sub-distribution HR was 0.97 (0.95-1.00). Multivariable adjustment yielded a cause-specific HR of 1.03 (1.00-1.06) and a sub-distribution HR of 1.00 (0.97-1.03).

Conclusions: In older individuals with ESRD initiating dialysis in the U.S., patients using PD had very similar adjusted rates of AF compared with otherwise similar patients using HD.

Oral Anticoagulation Among Patients Initiating Dialysis with Existing Atrial Fibrillation/Flutter: Association with Outcomes and Risk Score Robert C. Albright,[2] John J. Dillon,[2] Dena E. Cohen,[1] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Mayo Clinic, Rochester, MN.*

Background: In the general population, systemic oral anticoagulation (SOA) may reduce stroke risk among patients with atrial fibrillation/flutter (Afib). Patients who develop Afib after starting hemodialysis (HD) do not typically benefit from SOA. Guidance for use of SOA among patients who initiate HD with pre-existing Afib is scant.

Methods: This study considered adult Medicare A, B, and D beneficiaries who initiated in-center HD at a large US dialysis organization in 2010 or 2011 with a pre-existing diagnosis of Afib, ascertained from claims data. SOA (exposure) was based on a Medicare D claim for a prescription fill during the first 3 months of HD. Outcomes were considered from HD start until death, loss to follow-up, or study end (31 Dec 2012). Comparisons were made using intention-to-treat principles and negative binomial (hospitalization) or Cox proportional hazard (death, stroke, ischemic stroke, and stroke/transient ischemic attack [TIA]) models adjusted for imbalanced characteristics.

Results: Among 2742 patients initiating HD with Afib, 835 had a fill for SOA, and 1907 did not. No independent association was observed between SOA and any outcome considered. No protective association of SOA was observed in patients with high (or low) CHA_2DS_2-VASc risk score (*p*-interaction > 0.1 for each). No association was observed between SOA use and risk of gastrointestinal bleed.

Conclusions: Among patients who initiate HD with pre-exisiting Afib, traditionally accepted stroke risk scores cannot adequately guide clinicians with respect to possible benefit of SOA. Alternate methods are needed to guide use of SOA in such patients.

FR-PO839

Relationship between History of Stroke before Dialysis Initiation and All-Cause Mortality in Dialysis Patients Masayasu Kojima,[1] Daijo Inaguma,[2] Hideaki Shimizu,[1] Shigehisa Koide,[2] Kazuo Takahashi,[2] Hiroki Hayashi,[2] Midori Hasegawa,[2] Yukio Yuzawa.[2] *[1]Nephrology, Daido Hospital, Nagoya, Japan; [2]Nephrology, Fujita Health University School of Medicine, Toyoake, Japan.*

Background: Some reports have shown a relationship between stroke and all-cause mortality in pre-dialysis or maintenance dialysis patients. However, there are few previous studies describing the prognosis of dialysis patients whose baseline was set at the time dialysis was initiated. Therefore, we examined whether all-cause mortality differed between dialysis patients with and without a history of stroke before dialysis initiation.

Methods: The subjects were patients in the 17 centers participating in the Aichi Cohort Study of Prognosis in Patients Newly Initiated into Dialysis (AICOPP) from October 2011 to September 2013. We determined by a survey conducted at the end of March 2015. Thus, we enrolled 1,520 subjects into the study. We classified patients into 2 groups according to the history of stroke (i.e., a stroke group and a non-stroke group). Propensity scores (PS) represented the probability of being assigned to a group with or without a history of stroke. All-cause mortality was compared in PS-matched patients by using the log-rank test for Kaplan-Meier curves. Factors contributing to all-cause mortality were examined using stepwise multivariate Cox proportional hazards analysis.

Results: There were 236 patients in each group after PS-matching. The median of follow up period was 1,318 days (interquartile range: 1,109-1,509 days). During observation, all-cause death occurred in 84 patients (35.6%) in the stroke group and 28 (11.9%) patients in the non-stroke group. Cardiovascular related death occurred in 32 patients (13.6%) in the stroke group and 10 (4.2%) patients in the non-stroke group. The all-cause mortality was significantly higher in the stroke group compared to the non-stroke group after PS-matching (Logrank test: $p < 0.001$). The all-cause mortality was significantly higher in the stroke group compared to the non-stroke group (hazard ratio = 5.00, 95% confidence interval = 2.81-8.90) in multivariate analysis adjusted for age, gender, comorbidity of diabetes, history of coronary artery disease, body mass index, blood pressure, hemoglobin, eGFR, use of loop diuretics, CRP, and bicarbonate.

Conclusions: History of stroke before dialysis initiation was associated with a higher all-cause mortality.

FR-PO840

Hemoglobin Concentrations and the Risk of Hemorrhagic and Ischemic Stroke in Patients Undergoing Hemodialysis: The Q-Cohort Study Ryusuke Yotsueda,[3] Shigeru Tanaka,[1] Masatomo Taniguchi,[2] Hideki N. Hirakata,[2] Kazuhiko Tsuruya,[3] Takanari Kitazono.[3] *[1]Fukuoka Dental College, Fukuoka, Japan; [2]Fukuoka Renal Clinic, Fukuoka City, Japan; [3]Kyushu University, Graduate School of Medical Sciences, Fukuoka City, Japan.*

Background: Several lines of evidence have suggested an association between low hemoglobin concentrations and hemorrhagic stroke, and an association between high hemoglobin concentrations and ischemic stroke. However, the contribution of hemoglobin concentrations to the separate incidence of hemorrhagic or ischemic stroke in patients undergoing hemodialysis remains unclear.

Methods: A total of 3,436 participants undergoing maintenance hemodialysis were followed up for 4 years. The primary outcome was incidence of first development of hemorrhagic or ischemic stroke. Hemoglobin concentrations were divided into quartiles based on baseline data (hemoglobin [g/dL]: Q1, ≤9.7; Q2, 9.8–10.5; Q3, 10.6–11.1; Q4, ≥11.2). The associations between hemoglobin concentrations with each types of stroke were examined using Kaplan–Meier method and Cox proportional hazards model.

Results: During the follow-up period, 77 (2.2%) patients experienced hemorrhagic stroke and 141 (4.1%) experienced ischemic stroke. The 4-year incidence rate of hemorrhagic stroke was significantly higher with lower hemoglobin concentrations. Compared with the quartile of the highest hemoglobin concentrations (Q4), the multivariable-adjusted hazard ratios for hemorrhagic stroke were 1.18 (95% confidence interval, 0.56–2.51), 1.65 (0.85–3.30), and 2.16 (1.14–4.64) in patients with Q3, Q2, and

Q1, respectively. There did not appear to be an association between the 4-year incidence rate of ischemic stroke and hemoglobin concentrations. Compared with the quartile of the lowest hemoglobin concentrations (Q1), the multivariable-adjusted hazard ratios for ischemic stroke were 1.19 (95% confidence interval, 0.75–1.92), 0.87 (0.50–1.49), and 1.11 (0.68–1.85) in patients with Q2, Q3, and Q4, respectively.

Conclusions: Low hemoglobin concentrations are associated with high risk of hemorrhagic stroke in patients undergoing hemodialysis. However, hemoglobin concentrations are not associated with the risk of ischemic stroke.

FR-PO841

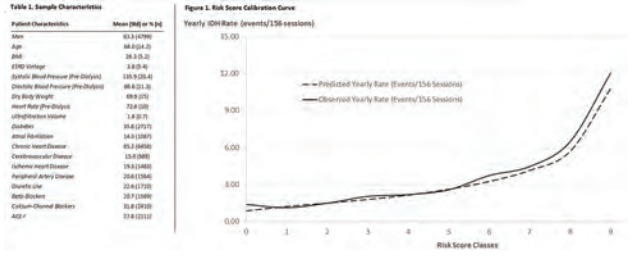
Identifying Patients at Risk for Intradialytic Hypotension Luca Neri, Milena Chermisi, Carlo Barbieri, Flavio Mari, Stefano Stuard. *Fresenius Medical Care, Bad Homburg, Germany.*

Background: Despite Intradialytic Hypotension is a prominent clinical problem for patients on dialysis, there currently is no valid risk prediction tool

Methods: All FME patients registered in Spain (2013 - 2015) have been enrolled in a historical cohort. We extracted medical data from de-identified electronic clinical charts (EuClid database). We partitioned the initial dataset in a training (90%) and validation (10%) sample. We implemented a two-part regression to evaluate correlates of Intradialytic Hypotension (IDH) and derived a risk score. Stage 1 identified patients at high risk of experiencing at least 1 IDH. Stage 2 predicted IDH rate in patients identified in stage 1 as the IDH cluster. AIC minimization was used for model selection

Results: Among 7582 patients (Validation set: 758), 4346 had at least one IDH during follow up time (mean=1.58 ±1.03 years). On average there were 5.1±9.5 events per patient during the follow up (incidence: 0.023±0.036 IDH/person-treatment). Factors associated with increased IDH risk: ESRD vintage, previous IDH, variability of intradialytic body weight drop, intradialytic blood pressure drop, ultrafiltration volume, pre-dialysis blood pressure, serum potassium, extracellular water volume, calcium, ferritin, body fat, female sex, use of diuretics, diabetes, CRP, history of stroke, dialysate bicarbonate and sodium, dementia, over-hydration. Factors associated with reduced IDH risk: intradialytic blood pressure variability, dry body weight, lower intracellular water volume, intradialytic heart rate variability, urea distribution volume, hematocrit, serum potassium. The risk score had excellent calibration and accurately discriminated across different risk classes (fig1)

Conclusions: We identified potentially modifiable risk factors for IDH. Additionally, our prediction algorithm provides a reliable tool for risk stratification



FR-PO842

Effects of Blood Pressure Variability on Mortality in Chronic Hemodialysis Patients: OCTOPUS Study Takayuki Adachi,[2] Kentaro Kohagura,[3] Hisatomi Arima,[1] Kunitoshi Iseki.[2] *[1]Fukuoka Uniuversity, Fukuoka, Japan; [2]Tomishiro Central Hospital, Tomigusuku city, Japan; [3]University of the Ryukyus, Nishihara-cho, Japan.*

Background: We examined the relationship between blood pressure variability and survival among chronic HD patients.

Methods: We previously reported the results of the multi-center prospective, open trial of the Olmesartan Clinical Trial in Okinawa Patients Under Okinawa Dialysis Study (OCTOPUS). In a multicenter, prospective, randomized, open label, blinded-endpoint trial, 469 patients with chronic HD and elevated BP (140–199/90–99 mmHg) were assigned to receive the angiotensin receptor blockade (ARB) olmesartan (at a dose of 10–40 mg daily; n = 235) or another treatment that does not include angiotensin receptor blockers and angiotensin-converting enzyme (ACE) inhibitors (n = 234). For this study, we examined of 435 patients after excluding those who died within 1 year after registration (N=28) and lack of blood pressure data for more than 2 time (N=6). We adopted the coefficient of variation (CV), which was obtained using 6 pre-HD blood pressure within the first year after registration, as a marker of blood pressure variability. Cox proportional hazard analysis was used to examine the relationship between blood pressure variability and mortality after the 1-year visit with adjustment for age, sex, smoking, DM, HD vintage, and use of angiotensin receptor blockade.

Results: During the mean follow-up of 2.5 years after the 1-year visit, we observed 58 deaths. We used five quintile groups of CV pre-HD systolic blood pressure (Q1 to Q5). The mortality rate was 9.2% (Q1), 12.8% (Q2), 9.1% (Q3), 16.1% (Q4), and 19.5% (Q5), respectively. The adjusted hazard ratio (95% confidence interval) was 1.83 (0.73-4.63) in Q1, 1.83 (0.73-4.63) in Q2, 1.84 (0.77-4.40) in Q4, and 2.42 (1.04-5.62) in Q5 when the Q3 was taken as reference.

Conclusions: Mortality rate was higher among patients with higher pre-HD variability of blood pressure.

FR-PO843

Association of Intradialytic Hypotension and Vascular Calcification in Hemodialysis Patients Ajin Cho,[3] Jung-woo Noh,[2] Dong Ho Shin.[1] *[1]College of Medicine, Hallym University, Seoul, Republic of Korea; [2]Hallym University, Seoul, Republic of Korea; [3]Hallym university Kangnam Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: Intradialytic hypotension (IDH) is a common complication during hemodialysis (HD). IDH not only causes discomfort, but also increases patient mortality and cardiovascular events (CVEs). Vascular calcification is associated with structural and functional abnormality of the heart and blood vessels. It induces a reduction in vascular compliance and diastolic LV dysfunction. Therefore, IDH may be associated with vascular calcification in HD patients. We investigated the relationship between IDH and vascular calcification in HD patients, and their impacts on CVEs.

Methods: We enrolled 191 maintenance HD patients who underwent plain abdomen radiography for abdominal aortic calcification score (AACS). A nadir systolic blood pressure (BP) < 90 mm Hg or the requirement of bolus fluid administration was required to quantify the hypotension diagnosis. IDH was defined as > 2 hypotension episodes during 10 HD treatments.

Results: Among the 191 patients, IDH occurred in 32. AACS was higher in the IDH group compared with the no-IDH group (8.4 ± 6.0 vs. 4.9 ± 5.2, respectively; P = 0.001). High AACS was an independent risk factor after adjustment for age, diabetes mellitus, ultrafiltration, diastolic BP, and calcium level (odds ratio (OR) = 1.08, 95% CI = 1.002–1.16; P = 0.04). Patients with both IDH and AACS > 4 had the highest cumulative CVE rate (27.9%, P=0.008) compared with 11.2%, 12.5%, and 6% for those with AACS > 4 only, with IDH only, and neither, respectively. In multivariate analysis, the presence of both IDH and AACS > 4 was a significant predictor of CVE (hazard ratio (HR) = 2.84, 95% CI = 1.04–7.74, P = 0.04).

Conclusions: IDH is associated with abdominal aortic calcification and is an independent risk factor for IDH. Both IDH and high AACS were significant predictors of CVE.

FR-PO844

Peridialysis BP Levels and Risk of All-Cause Mortality: A Meta-Analysis Yu-Chen Han. *Zhongda Hospital, Southeast University School of Medicine, Nanjing, China.*

Background: Blood pressure (BP) management posed great challenge in hemodialysis (HD) population. The optimal peridialysis BP for HD population was unknown. We conducted a dose-response meta-analysis to investigate the quantitative features and the potential threshold effect of the associations between peridialysis BP levels and all-cause mortality risk in HD population.

Methods: We searched all of the prospective cohort studies (published before March 18, 2017) on the associations between peridialysis BP levels and all-cause mortality risk.

Results: A total of 229,688 prevalent HD patients from 8 studies were included. The non-linear associations were noted between peridialytic BP levels and all-cause mortality risk. Significant increased risk of death was found in four peridialysis BP ranges, that is, low levels of predialysis SBP (<135mmHg, 140mmHg as the reference), two extremes of predialysis DBP (<55 and >95mmHg, 90mmHg as the reference), high levels of postdialysis SBP (>180mmHg, 130mmHg as the reference), and low levels of postdialysis DBP (<75mmHg, 80mmHg as the reference). The peridialysis BP ranges with the peak survival were 160-165mmHg for predialysis SBP, 80-85mmHg for predialysis DBP, 135-140mmHg for postdialysis SBP and 80-85mmHg for postdialysis DBP. Threshold effect was determined in the associations between peridialysis BP and all-cause mortality risk, and potential BP thresholds were identified (149mmHg for predialysis SBP, 79mmHg for predialysis DBP, 147mmHg for postdialysis SBP and 76mmHg for postdialysis DBP).

Conclusions: The optimal peridialysis BP for HD population was unknown. By incorporating major hemodialysis databases in the world, major quantitative features of the peridialysis mortality associations were explicitly identified in our study. The proposed peridialysis BP ranges and the threshold values could help clinicians identify high risk patients and give guidance to BP-lowering therapy (dry weight probing and antihypertensive drugs) in HD population.

Comparison between 44-Hours Ambulatory Blood Pressure Monitoring (ABPM) and 24-Hours Non-Dialysis Day ABPM in Indian Dialysis Subjects Rajesh B. Kumar, Rachana H. Jasani, SHRIRANG BICHU, Viswanath Billa, Paras Dedhia. *Apex Kidney Foundation, Mumbai, India.*

Background: ABPM is considered as a gold standard method to assess hypertension in dialysis population. However, 44 hours ABPM is cumbersome and usually enocunters reluctance from patients. 24 hours ABPM is more practical and convenient for patients.

Methods: Ambulatory BP monitoring (ABPM) performed for 44 hours in between 2 dialysis sessions. ABPM recorded every 20 min during the day (7 am to 11 pm) and every 30 min during the night (11 pm to 7 am) in non-fistula arm. Hourly means were averaged to obtain interdialytic systolic and diastolic blood pressure readings. 24 hours ABPM data were extracted from hourly means on non-dialysis day from 6am to 6am. ABPM data with less than 70% readings were excluded from the study. 24 hours mean systolic blood pressure (SBP) and diastolic blood pressure (DBP) were compared with 44 hours measurement using paired t-test.

Results: 35 patients were included in the analysis. Mean age was 54.5 ± 12.7 years and 66% were males and 34% were females. Mean dialysis vintage was 2.7 ± 2.8 years. 49% were diabetic, 97% were hypertensive and 23% had IHD. Mean 44 hour BP was 151.9 ± 15.8/ 83.2±13.4 mm Hg and mean 24 hour BP was 151.5 ± 15.9/82.6± 13.7 mm Hg. There was no statistical difference between 44 hour and 24 hour mean SBP (*p* value: 0.45) and mean DBP (*p* value: 0.77).

Conclusions: Mean SBP and DBP of 44-hours ambulatory blood pressure monitoring and 24-hours non-dialysis ABPM were comparable in study subjects. We conclude that 24 hours ABPM on non-dialysis day is an alternate feasible option in assessing BP in dialysis patients.

FR-PO846

Use of Beta-Blockers Associated with Lower Orthostatic Response in Dialysis Patients Gustavo Laham.[1,2] *[1]Internal Medicine, Nephrology section, CEMIC, Ciudad de Buenos Aires, Argentina; [2]FME CEMIC Saavedra, Ciudad de Buenos Aires, Argentina.*

Background: Beta Blockers (BB) are widely used in dialysis patients (pts). However, the evidence supporting their utility in improving cardiovascular (CV) outcomes in this population is conflicting.

Methods: Within a CV evaluation program for pts with ESRD in our Hospital. We evaluated 102 pts attended the interdialysis day. BP and hemodynamics was determined with impedance cardiography in supine position and after the third minute of standing. Following variables: SBP, DBP, heart rate (HR), stroke volume (SV), systemic vascular resistance index (SVRI) and thoracic fluid content (TFC). At the same time, the variability of the frequency was evaluated during 3 minutes at rest and in standing position. Patients were classified into 2 groups according to the presence of Hypotension (HYPOT) or not (EST). Orthostatic hypotension was defined as a drop of 20mmHg or more of SBP and/ or 10mmHg or more of DBP when standing. Hemodynamic variables were analyzed : 1-baseline conditions and 2-differences (delta standing-lying) between the two groups (t-test and Mann-Whitney U test). Independent predictors of orthostatic hypotension were determined adjusting for age, sex, BP, anthropometric variables, time on dialysis and medication through a logistic regression.

Results: We included 81 patients: age: 59,8 ± 14 years, female 55,5%: SBP: 137,7± 27,2 mmHg, DBP: 83,5 ± 19,7 mmHg. Twenty nine pts (35,8%) had orthostatic hypotension. No significant differences were found in age, sex, BMI, time on dialysis, DM and CV events between both groups. 86.21% of the pts in the HYPO group received BB and 28.8 of the pts in the EST group with a significant difference (p<0, 0004). At rest position there were no hemodynamic or autonomic differences between both groups, but in Standing position, HYPO group, showed delta of SVRI (p < 0.037) lower, as well as lower delta DBP, delta Median Blood Pressure and delta SBP (p< 0,0001) compared to de EST group. There were no significant differences in the delta TFC as well as between autonomic variables. In logistic regression the use of BB was an independent variable for orthostatic hypotension.

Conclusions: In this group of dialysis pts the use of BB was a determining factor to attenuate or nullify the compensatory increase of the vascular resistance against the bipedestation. Therefore BB could collaborate with the development of hypotension when standing independently of the autonomic response.

FR-PO847

Association of Betaine with Blood Pressure in Dialysis Patients Lulu Wang,[2] Mingming Zhao,[3] Wenjin Liu,[1] Lemin Zheng,[3] Junwei Yang.[4] *[1]2nd Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Center for Kidney Disease, Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; [3]Peking University, Beijing, China; [4]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Patients with chronic kidney disease have an increased risk of cardiovascular morbidity and mortality. Hypertension has been considered as one of the most important contributor to the increased risk. Betaine is a zwitterionic quaternary ammonium compound and distributed widely in rich dietary sources. Previous studies suggest a possible link between alteration of circulating betaine and hypertension. However, there is a paucity of data regarding patients on maintenance hemodialysis. We aimed to explore the association of betaine with blood pressure in this disease population.

Methods: Between July 2015 to July 2016, 368 patients on maintenance hemodialysis (4h / thrice weekly over 3 months) from six tertiary hospitals were recruited to participate an ongoing cohort study. Interdialytic blood pressure was evaluated by ambulatory blood pressure monitoring. Plasma betaine level was measured by high performance liquid chromatography–mass spectrometry for 327 subjects. The association between betaine and blood pressure was evaluated by multiple linear regression analysis.

Results: The mean age of the patients was 52.6±11.9 years, and 58.4% were male. Average interdialytic ambulatory systolic and diastolic blood pressure were 138.4±22.7 mm Hg and 84.4±12.5 mm Hg, respectively. Mean plasma betaine level was 37.6 umol/L. There was no significant difference of plasma betaine level across certain subgroups, including age (>60 vs. ≤60), gender (male vs. female), BMI (≥25 vs. <25), diabetes (yes vs no) and previous history of cardiovascular disease (yes vs no). Multiple linear regression analysis revealed significant associations of betaine with both systolic blood pressure (β=-3.66,P=0.003) and diastolic blood pressure (β=-2,P=0.004). The associations persisted even after extensive adjustment for cardiovascular covariates.

Conclusions: In conclusion, we demonstrated, for the first time, significant association between betaine and blood pressure level in a group of hemodialysis patients. Our data suggests that alteration of circulating betaine possibly contributes to blood pressure regulation in these patients.

FR-PO848

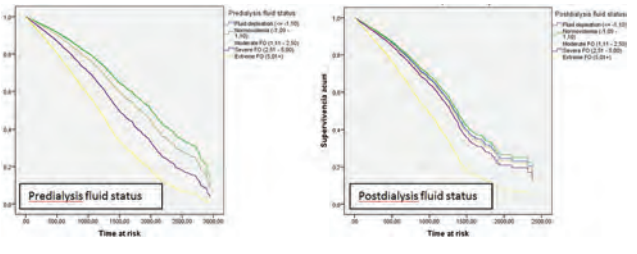
Fluid Status (FS) as Predictor of Long Term Survival in Hemodialysis (HD) Patients Adrian M. Guinsburg, Marcelo D. Ferder, Cristina Marelli. *Fresenius Medical Care, Moron, Argentina.*

Background: Extracellular fluid overload (FO) has been typically described as predictor of all-cause mortality in HD patients. A recent publication [Dekker et al, KI (2017), 91, 1214-1223] also demonstrated a beneficial effect of pre and postdialysis fluid depletion on survival. In this study we aim to analyze the relationship between FS and survival in a large cohort of patients from Fresenius Medical Care LatinAmerica (FMCLA)

Methods: Patients on HD at FMCLA between 09/2008 and 12/2016 were included. Body composition after 90 days of dialysis was assessed by multifrequency bioimpedance spectroscopy (BCM©, Fresenius Medical Care). Pre and postdialysis fluid status (FS) groups were defined according to overhydration (OH) as follow: fluid depletion (FD, <= -1.1 lts), normovolemia (NV, -1.1 to 1.1 lts), moderate FO (MFO, 1.1 to 2.5 lts), severe FO (SFO, 2.5 to 5 lts) and extreme FO (EFO, +5 lts). A Cox regression model was constructed to analyze independent relationship between FS and survival accounting for age, gender, vintage, diabetes, CVD, cancer, predialysis systolic blood pressure (preSBP), BMI, lean and fat tissue index, albumin, CRP, cholesterol, Hgb, Ca, P, Na and eKt/V. Values are expressed as mean±SD or [CI]

Results: 43,786 patients were included into initial dataset but only 9,501 had available data on all variables. Age 57.9±16.1 yrs, vintage 3.1 [3.06-3.14] yrs, male 58.2%, OH 1.76 [1.74-1.78] lts, preSBP 140.4±23.4 mmHg, alb 3.8±0.5 (g/dl), hgb 10.8±1.9 g/dl, Ca 8.8±0.9 mg/dl, P 4.7±1.4 mg/dl, Na 137.8±4.0 mEq/l, eKt/V 1.36±0.30. DBT 30.9%, CVD 8.0%, cancer 1.0%. Mean follow-up time was 4.45 years and 2,978 death events were observed. After controlling, RR of death for each group as compared to NV (ref) was a) for predialysis FS: FD 1.19 [NS], MFO 1.18 [1.08-1.30], SFO 1.61 [1.45-1.79], EFO 2.50 [2.09-2.98]; b) for postdialysis FS: FD 1.06 [NS], MFO 1.1 [NS], SFO 1.18 [NS], EFO 1.94 [1.36-2.76]

Conclusions: In our cohort and after multivariate adjustments predialysis MFO, SFO and EFO increased risk of death while there was no impact of FD. Postdialysis FS had no independent impact on survival except for EFO patients.



FR-PO849

Assessment of Pulmonary Congestion by thoracic Fluid Content Predicts Mortality in Hemodialysis Patients Jining Wu, Hong Ye, Junwei Yang. *Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Pulmonary congestion is prevalent and usually asymotomatic in patients with end-stage renal disease (ESRD). Thoracic fluid content (TFC) measured by thoracic electrical bioimpedance (TEB) is suggested to serve as a non-invasive measure of pulmonary congestion. We explored the clinical and echocadiographic correlates of thoracic fluid content as well as its prognostic value in hemodialysis patients.

Methods: In this prospective observational study, we enrolled 114 patients from a single hemodialysis unit. We used different methods of evaluation: thoracic bioimopedance (pre- and post-dialysis) and echocardiography (pre-dialysis). Our aim was to test the prognostic value of TFC in this population. Mortality was analysed after a median of 560.5-day follow-up. The primary outcome was all-cause death.

Results: TEB examination were successfully completed in 114 patients. Patients were divided into two categories based on the TFC measured before dialysis. TFC was strongly associated with left atrial diameter(LAD)(r=0.454,P=0.001), left ventricular posterior wall thickness (LVPW) (r=0.473,P=0.001)and ejection fraction (EF) (r=-0.527,P=0.001). After a median follow-up of 520-day, compaired with those patients having lower TFC, patients with higher TFC had 4.95–fold risk of death.

Conclusions: TEB is a technique that could detect pulmonary congestion at a pre-clinical stage in hemodialysis patients, and TFC emerged as a predictor for the mortality in this population.

Changes in Blood Pressure Following a Fluid Management Quality Improvement Project (QIP) during In-Center Hemodialysis (HD)

Paul Balter,[2] Ludmila Anderson,[1] Lisa A. Pacelli,[2] Patrice B. Taylor,[1] Claudy Mullon,[1] Robert J. Kossmann,[1] Linda H. Ficociello.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Institute, New Haven, CT.*

Background: Fluid and sodium retention are leading causes of hypertension (HT) among HD patients. A QIP with a goal to improve fluid management among patients on thrice weekly HD was conducted. This analysis aimed to determine whether QIP initiation was associated with BP changes among HT patients.

Methods: The QIP utilized Crit-Line® Monitors (CLM III) that non-invasively assess intra-dialytic relative blood volume (RBV) and provide real-time data to allow for ongoing fluid monitoring and management. De-identified data from electronic medical records of active patients at QIP initiation were analyzed. Average values for parameters at baseline (BL; 1 mo. prior to QIP initiation) and during first 3 mos. of the QIP were assessed. Changes in RBV, ultrafiltration volume (UFV), treatment (TX) time, and BP were analyzed. Stratified analyses by BL hypertension (HT) status (HT defined as pre-HD SBP > 140 or pre-HD DBP > 90 mmHg) were conducted. T-test and α=.05 were used to compare the BL and the 3rd month of the QIP.

Results: In total, 54 out of 83 (65%) patients had HT at BL. Although UFV and TX time did not change between BL and mo.3 of the QIP, the majority of measured parameters of BP (Table) improved. On average, pre-HD SBP decreased from 163.3 to 157.8 mmHg (p=.01) and pre-HD DBP decreased from 88.0 to 85.1 mmHg (p=.05). Among normotensive patients (n=29), all BP parameters remained unchanged. The % of RBV removed during HD changed from 8.9% during mo.1 to 9.4% during mo.3 of the QIP among HT patients (p=0.7), and from 9.8% to 10.0% among normotensive patients (p=0.8).

Conclusions: QIP initiation was associated with a decrease in BP parameters among HT patients. Neither TX time nor UFV changed over 4 mos. of observation.

FR-PO851

Defining the Extent of Replacement Myocardial Fibrosis in Hemodialysis Patients with Non-Contrast Cardiac Magnetic Resonance

Matthew P. Graham-Brown,[2,3] Daniel S. March,[1] James Burton.[1] *[1]University of Leicester, Leicester, United Kingdom; [2]John Walls Renal Unit, University Hospitals Leicester, Leicester, United Kingdom; [3]National Centre for Sport and Exercise Medicine, Loughborough University, Loughborough, United Kingdom. Group/Team: CYCLE-HD.*

Background: Extent of replacement myocardial fibrosis predicts patient mortality in advanced renal disease. Gadolinium enhanced cardiac MRI (CMR) defines myocardial fibrosis in disease groups with normal renal function, but is not possible in patients with advanced renal disease due to the risk of nephrogenic systemic fibrosis. In this study we describe and assess a non-contrast native T1 CMR signal thresholding technique (T11SD) that may be used for the detection and quantification of myocardial scar burden in haemodialysis (HD) patients.

Methods: The T11SD technique defines the mean native T1 and standard deviation (SD) in regions of discretely increased signal on native T1 parametric maps. The mean +/- SD of the region of interest are then applied as a threshold to the entire myocardium to give a threshold percentage. We assessed the agreement between T11SD and late gadolinium enhanced CMR (LGE-CMR) defined myocardial scarring (using full width half maximum analysis) in patients with aortic stenosis (AS) (n=25). We then compared T11SD between patients with AS (n=25) and patients on HD (n=25) and assessed inter- and intra-observer variability of T11SD in HD patients (n=10).

Results: Myocardial scar assessed by LGE-CMR correlated with T11SD in AS patients (r=0.913) with moderate agreement (ICC=0.55). Bland-Altman showed T11SD systematically overestimated scar burden by 4.3% compared to LGE-CMR. Extent of myocardial scarring defined by T11SD was higher in HD patients compared to AS patients (21.92%±1.0 vs 18.24%±1.4). Global native T1 time was higher in HD patients compared to AS patients (1279ms±5.8 vs 1143ms±12.49) as was the region of interest defined as scar (1390±8.7 vs 1276ms±20.5). The difference between remote myocardium and regions defined as scar were no different between groups (111.4ms±7.6 vs 133.2ms±17.5) representing a 9.6% and 10.4% increase from background myocardium. Inter-and intra-observer variability of T11SD were excellent (ICC=0.87, and 0.96).

Conclusions: This study suggests that extent of replacement myocardial fibrosis can be defined quantitatively with the native T1 signal intensity thresholding technique T11SD in HD patients, which we describe for the first time. This has important implications for the assessment and risk stratification in future research and clinical practice.

FR-PO852

The Impact of Left Ventricular Hypertrophy and Left Ventricular Geometry at Dialysis Initiation on Cardiovascular Events on Chronic Dialysis in Japanese CKD Patients

Taisuke Takatsuka, Daisuke Yoshimura, Yukimasa Iwata, Hiroki Okushima, Rei Iio, Tatsuya Shoji, Terumasa Hayashi. *Osaka General Medical Center, Osaka-Shi, Japan.*

Background: Although, left ventricular hypertrophy (LVH) is common and worsens as CKD stage progresses and is an independent predictor of mortality and cardiovascular events (CVE) in CKD patients on dialysis, there are conflicting reports on the association between left ventricular geometry (LVG) and clinical outcomes. Thus, we conducted retrospective cohort study in incident dialysis patients at two major tertiary referral hospitals in Japan to investigate the impact of LVH and LVG at dialysis initiation on CVE on chronic dialysis.

Methods: Study population comprised 371 and 400 consecutive patients who started maintenance dialysis from 2006 to 2015 at our hospital and from 2001 to 2009 at Rinku General Medical Center, respectively. Echocardiogram was basically performed just before dialysis initiation. We categorized into four groups using LVH [left ventricular mass index (LVMI) >49g/m$^{2.7}$ for men and >45g/m$^{2.7}$ for women] and relative wall thickness [≥0.42 or <0.42]; normal geometry (NG), concentric remodeling (CR), eccentric hypertrophy (EH), concentric hypertrophy (CH). We compared patients' status at dialysis initiation among four groups and Cox proportional hazard model was used to investigate the association of LVH and LVG with CVE on chronic dialysis.

Results: Median age was 69 (male, 60.4%) and eGFR was 4.9ml/min/1.73m^2. Median ejection fraction (EF) and LVMI were 64.1% and 60.8g/m$^{2.7}$, respectively. Among 771 patients, 81 (10.5%), 56 (7.3%), 322 (41.7%) and 312 (40.5%) were classified into NG, CR, EH and CH, respectively. Multivariate Cox model showed that male gender, history of heart failure, Hemoglobin and EF were independently associated with CVE, whereas LVMI and LVG were not. Subgroup analysis revealed that EF (P 0.004) and history of heart failure (P <0.001) had significant interactions on the association of LVMI with CVE.

Conclusions: LVG at dialysis initiation was not associated with CVE on chronic dialysis. On the other hand, LVMI may be predictive for CVE in patients with preserved cardiac function or without history of heart failure.

FR-PO853

Significant Improvement of Left Ventricular Mass Index (LVMI) in Pediatric Patients within 6-12 Months of Initiation of Chronic Dialysis

Poyyapakkam Srivaths,[4,2] Jessica Geer,[4] Sarah J. Swartz,[2] Alisa A. Acosta,[3] Shweta S. Shah,[4] Eileen D. Brewer.[1] *[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [2]Baylor College of Medicine, Texas Children's Hospital, Houston, TX; [3]None, Houston, TX; [4]Texas Children's Hospital, Houston, TX.*

Background: : Left ventricular hypertrophy (LVH) determined by increased left ventricular mass indexed for index allometric height^ 2.7 (LVMI) is highly prevalent in children receiving chronic dialysis (CD). Natural history of LVH in pediatric (ped) CD patients (pts) has not been well studied; only one study showed no change in LVMI observed after 6 months of starting CD. We sought to investigate changes in LVMI from the start of CD to 6-12 months after, and its association with hypertension (HTN).

Methods: Retrospective chart review for prevalent pts at a single center treated from 2014-2017. Pts with baseline echocardiogram (ECHO) within 3 months of starting CD, who had repeat within 6-12 months while continuing CD were included. Pts were excluded if follow up ECHOs was not available or pts initiated CD at another center. Charts were reviewed for demographics and hypertension (HTN) defined by ICD diagnosis and receiving antihypertensive meds. LVH by LVMI was defined using known age and gender norms

Results: 58 pts (32 male, 55%; 32 chronic HD, 55%), mean age 13.9 (range 5-19.7 years). Mean LVMI from initiation decreased significantly on follow up ECHO (initiation 56.7 ±23.7 g/m^2.7 vs. 43.7 ± 15.9 g/m^2.7, p= 0.00001), independent of CD modality or gender. 50/58 pts had HTN at CD initiation; 53/58 pts had LVH by elevated LVMI. 49/50 pts with HTN at initiation had LVH, while 4/8 normotensive pts also had LVH (exact test p=0.001). On follow up at 6-12 mon, 21/53 pts with LVH at CD initiation normalized LVMI. Only 1 pt developed new onset LVH. Uncontrolled HTN (persistent HTN and/or increased meds) was significantly associated with persistent LVH on follow up in the group who had LVH at initiation of dialysis (table).

Conclusions: Nearly all ped CD pts with HTN at initiation had LVH by LVMI. LVMI improved significantly within 6-12 mon of CD initiation. Persistent LVH was associated with uncontrolled hypertension in ped CD pts.

FR-PO854

Increased Stroke Volume Variability during Hemodialysis Is Associated with High Cardiac Output State and Enhanced Mortality Dan Sapoznikov, Rebecca Backenroth, Michal Dranitzki Elhalel, Dvora Rubinger. *Hadassah University Medical Center, Jerusalem, Israel.*

Background: Stroke volume (SV) variability (sdSV) is a measure of the consistency of myocardial responsiveness during hemodynamic alterations, but its significance and predictive value in hemodialysis (HD) patients (pts.) are not well defined. The present study was undertaken to assess:1. the relationship of intradialytic sdSV with clinical data and other hemodynamic measurements and, 2. its effect on survival in chronic HD pts.

Methods: Continuous beat-to-beat intervals (IBI) and systolic (SBP) blood pressure were monitored using Finometer recordings in 119 HD pts. and in 34 age-matched control (C) individuals. Cardiac output (CO), SV and total peripheral resistance (TPR) were assessed using Beatscope software and the ModelFlow simulation method. The standard deviations (sd) of the above indices were considered to represent their variabilities. Kaplan Meier analysis was performrd to assess survival. A cutoff point of sdSV of 6.9 ml was chosen for best Log Rank significance.

Results: Table 1 lists hemodynamic data in C, in pts. with lower sdSV (≦6.9 ml, n=72) and in those with higher sdSV (>6.9 ml, n=47) (see Table 1 below). Clinical data were similar in both HD groups with the exception of more prevalent peripheral vascular disease and use of antihypertensive drugs in pts. with higher sdSV. Kaplan-Meier analysis of 5y survival showed a significantly increased mortality in HD pts. with higher as compared with those with lower sdSV (p=0.01).

Conclusions: Our data show that a special group of HD pts are characterized by high CO, SV and sdSV and decreased TPR. Increased sdSV in HD pts. was associated with decreased survival, as previously reported in pts with high output cardiac failure and preserved renal function. The causes of this syndrome may include inadequate vascular compliance, excessive vasodilatation or the type of vascular access and deserve further investigation.

Table 1.

	C	HD Lower sdSV	p (vs. C)	HD Higher sdSV	p (vs.C)	p (Higher vs. Lower sd SV)

Changes in QT Interval in Long-Term Hemodialysis Patients Yoshihiro Matsumoto,[2] Yasuo Mori,[3] Shinji Kageyama,[1] Kazuo Arihara,[4] Hidemaro Sato,[5] Kijun Nagata,[5] Yasushi Shimada,[2] Youichi Nojima,[2] Koichiro Iguchi,[2] Sugiyama Toshikazu.[6] *[1]Kageyama Urological Clinic, Shziuoka city, Japan; [2]Shizuoka City Hospital, Shizuoka, Japan; [3]Shibukawa Clinic, Shizuoka, Japan; [4]Ohtemachi Clinic, Shizuoka, Japan; [5]Sawada Hospital, GIFU, Japan; [6]Sugiyama Clinic, Shizuoka, Japan.*

Background: Cardiovascular diseases, including sudden cardiac death (SCD), are the leading cause of death in hemodialysis (HD) patients. A prolonged QT interval on the electrocardiogram (ECG) is a risk factor for SCD in HD patients as well as in the general population. This study sought to investigate whether the heart rate-corrected QT (QTc) interval increases with dialysis vintage.

Methods: A total of 102 patients from 7 outpatient HD clinics were retrospectively studied. They had been undergoing HD for more than 7 years, and had ECG data at 1, 4, and 7 years after HD initiation. The control group comprised 68 age-matched individuals without chronic kidney disease who had two available ECG reports at an interval of more than 4 years. Patients with ECGs showing heart rates of <57 or >103, extrasystoles, or any rhythm other than sinus were excluded. QTc was measured according to the Bazett formula. The association between a prolonged QTc interval and dialysis vintage was estimated using Dunnett's multiple comparison test.

Results: Average QTc intervals at 1, 4, and 7 years after HD treatment were 437, 443, and 445 ms, respectively. Those at 4 and 7 years after HD treatment were longer than those at 1 year after HD treatment; the difference was statistically significant (p<0.05). On the other hand, QTc intervals in the control group were 392 in the first year and 394 ms after an average of 6 years, which were much shorter than those in our HD patients and did not show an increase during the 6 years.

Conclusions: The QTc interval at 1 year after HD initiation was longer than in control subjects and increased over several years of HD treatment. Larger-scale studies are recommended to evaluate the association between SCD and QTc prolongation in HD patients.

FR-PO856

Hemodiafiltration Is Associated with Reduced Inflammation and Oxidative Stress and Improved Endothelial Risk Profile Compared to High-Flux Hemodialysis in Children Ayse Agbas,[1] Nur Canpolat,[1] Salim Caliskan,[1] Alev Yilmaz,[2] Hakan Ekmekçi,[3] Mark Mayes,[4] Helen Aitkenhead,[5] Lale Sever,[1] Rukshana Shroff.[6] *[1]Department of Pediatric Nephrology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey; [2]Department of Pediatric Nephrology, Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey; [3]Department of Biochemistry, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey; [4]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [5]Department of Chemical Pathology, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [6]Department of Pediatric Nephrology, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom.*

Background: Randomised trials in adults have shown reduced all-cause and cardiovascular (CV) mortality on hemodiafiltration (HDF) compared to conventional hemodialysis (HD), but the mechanisms for improved outcome are not clear and pediatric data is scarce.

Methods: We studied CV risk factors for inflammation, oxidative stress, antioxidant capacity and endothelial function in 22 children (13 female, age 8.9 - 15.5 years) in two dialysis units. All children received HD for at least 3 months, and were then switched to HDF. Biochemical measures were performed after 3 months on HD followed by 3 months on HDF.

Results: After 3-months on HDF there was a significant improvement in ß2 microglobulin, IL-10, hsCRP, ADMA, SDMA, AGE, ox-LDL and TAC compared to levels on HD (Table). HDF was associated with a significant reduction in ADMA, SDMA, hs-CRP and AGE even in children with residual renal function. Clearance was not associated with the type of vascular access, but children with a lower blood flow had higher inflammatory status (higher IL-6/IL-10 ratio; p=0.045, r=-0.431). Children with a higher convective volume (≥median 12.8L/m2) had lower Ox-LDL (p=0.024). None of the measures, except IL-10 levels, correlated with time on dialysis, suggesting that even a short dialysis vintage of 3 months on HD increases inflammatory and endothelial markers.

Conclusions: A significant improvement in inflammation, antioxidant capacity and endothelial risk profile is seen even within a short time (3 months) of HDF compared to HD treatment.

Mediterranean and Dietary Approaches to Stop Hypertension (DASH) Diets and Cardiovascular and All-Cause Mortality in Adults on Hemodialysis: The DIET-HD Multinational Cohort Study Valeria M. Saglimbene,[1,3] Germaine Wong,[1] Jonathan C. Craig,[2] Jorgen B. Hegbrant,[3] Giovanni F. Strippoli.[4,3] *[1]University of Sydney, Sydney, NSW, Australia; [2]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [3]Diaverum Medical Scientific Office, Lund, Sweden; [4]University of Bari, Bari, Italy. Group/Team: For DIET-HD investigators.*

Background: Mediterranean and DASH diets are associated with reduced cardiovascular and all-cause mortality in the general population, but these benefits may not be transferable in patients on hemodialysis due to the high content of potassium and phosphate in these diets.

Methods: Mediterranean and DASH diet scores were measured from the GA²LEN food frequency questionnaire within the DIET-HD study, a prospective cohort study (January 2014-January 2016) of 9757 adults treated with hemodialysis in Europe and South America. Adjusted cox regression analyses clustered by country were conducted to evaluate the association between Mediterranean or DASH scores and cardiovascular and all-cause mortality.

Results: During a median follow up of 1.5 years (8108 person-years), there were 1214 deaths of which 515 were attributable to cardiovascular causes. The mean (standard deviation) Mediterranean and DASH scores were 4.0 (1.5) (scale 0 to 8) and 20.4 (3.7) (scale 0 to 34), respectively. Compared with the lowest Mediterranean score quartile (0-3), the adjusted hazard ratios (95% confidence intervals) for cardiovascular mortality in the second (3-4), third (4-5) and fourth (>5) quartile were 0.92 (0.72-1.17), 1.12 (0.87-1.43) and 1.05 (0.78-1.41), respectively; the adjusted hazard ratios for all-cause mortality were 1.05 (0.90-1.23), 1.16 (0.99-1.37) and 1.15 (0.95-1.40), respectively. Compared with the

lowest DASH score quartile (0-18), the adjusted hazard ratios for cardiovascular mortality in the second (18-20), third (20-23) and fourth (>23) quartile were 0.95 (0.72-1.24), 1.28 (1.00-1.64) and 1.14 (0.85-1.52), respectively; the adjusted hazard ratios for all-cause mortality were 0.98 (0.83-1.16), 1.04 (0.89-1.23) and 0.95 (0.78-1.14), respectively.

Conclusions: Mediterranean or DASH dietary patterns were not associated with cardiovascular and all-cause mortality for patients on hemodialysis.

FR-PO858

Long-Term Trends in the Co-Morbid Disease Burden of Incident Hemodialysis Patients Rita L. McGill,[3] Jennifer L. Bragg-Gresham,[2] Kevin He,[2] Eduardo K. Lacson,[1] Dana Miskulin,[1] Rajiv Saran.[2] *[1]Tufts University School of Medicine, Boston, MA; [2]University of Michigan, Ann Arbor, MI; [3]University of Chicago, Chicago, IL.*

Background: Since April 1995, dialysis facilities and kidney transplant centers in the United States have been required to report the comorbid conditions of all new kidney failure patients to the US Renal Data System (USRDS). We examined the prevalence of several relevant comorbid diagnoses of all new hemodialysis (HD) patients reported to USRDS from 1996-2015.

Methods: All first-time HD patients initiating treatment between January 1996 and December 2015 were included, and analyzed by year of HD initiation. Diabetes and cardiac diagnoses were condensed into single variables, to align data obtained from the 1995 and 2005 versions of the Medical Evidence form. Five year prevalence trends in the proportions of each co-morbid condition were evaluated with logistic regression, treating year of HD initiation as a continuous variable and adjusting for age, sex, and race. Five year prevalence trends were expressed as odds ratios (OR) and 95% confidence intervals (CI), with OR > 1 representing increasing prevalence.

Results: 1,864,386 incident HD patients were assessed. Mean age increased gradually over time from 60.9 to 63.8 years. Time trends revealed linear increases in the prevalence of hypertension (OR=1.34, 95% CI=1.34-1.35) and diabetes (OR=1.16, 95% CI= 1.16-1.17). From 2006 onwards there was decreased prevalence of peripheral vascular disease (OR=0.91, 95% CI=0.91-0.91) and cardiovascular disease (OR=0.92, 95% CI=0.91-0.93). Prevalences of stroke, cancer, and lung disease showed no clinically significant changes.

Conclusions: The HD population in the United States is becoming older, with more hypertension and diabetes, but the prevalences of cardiovascular and peripheral vascular disease have decreased over the past ten years.

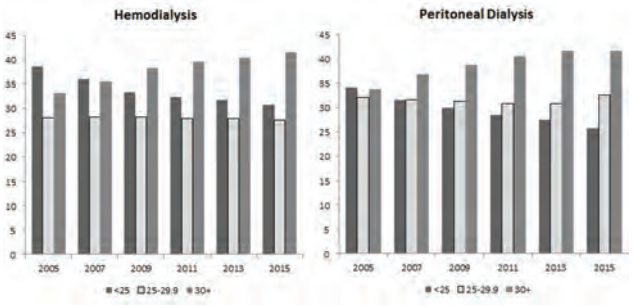
Impact of the Obesity Epidemic on Dialysis Patients Rita L. McGill,[3] Varun Gupta,[1] Klemens B. Meyer.[2] *[1]Creighton University, Northbrook, IL; [2]Tufts Medical Center, Boston, MA; [3]University of Chicago, Chicago, IL.*

Background: Obesity promotes chronic kidney disease directly via glomerular hyperfiltration, indirectly via increased diabetes and cardiovascular disease, and may reduce the likelihood of dying prior to kidney failure. We examined the impact of the US obesity epidemic on body mass index (BMI) of incident dialysis patients.

Methods: Cohorts of all incident adult USRDS patients between 2005 and 2015 with values recorded for BMI were examined, with stratification for hemodialysis (HD) and peritoneal dialysis (PD). BMI in kg/m^2 was categorized as <25, 25-29.9, 30-34.9, 35-39.9, and >=40. Age, race, sex, and end-stage renal disease (ESRD) network were also recorded. Multivariable linear regression was used to estimate the change in BMI over time separately for HD and PD patients.

Results: Among 1,007,774 incident HD patients and 78,745 incident PD patients, the proportions of patients with BMI<25 decreased, the proportions of patients with BMI 25-29.99 were stable, and the proportions of all groups with BMI≥30 increased between 2005 and 2015. After adjustment for age, sex, ESRD network, and race, BMI at dialysis initiation increased 0.147 kg/m^2 per year in HD patients and 0.126 kg/m^2 in PD patients (P<0.0001 for both).

Conclusions: Obesity and morbid obesity have been slowly increasing in the US dialysis population. Depending upon transplantation center criteria, 10-20% of patients enter dialysis with a BMI too high to be considered for kidney transplantation. Despite the paradoxical effects on survival, increasing obesity threatens the health of the dialysis patients, who face increased co-morbid disease burdens, reduced opportunities for optimal vascular access, and lower likelihoods that PD clearance will be adequate.



Distribution of BMI in Patients on HD and PD over Time

FR-PO860

A New, "Lighter" Operational Definition of Frailty in ESKD Ranjani N. Moorthi,[1] Keith Avin,[1] Ravi I. Thadhani,[2] Sharon M. Moe.[1] *[1]Indiana University-Indianapolis, Indianapolis, IN; [2]Massachusetts General Hospital, Boston, MA.*

Background: Frailty detection in incident patients on hemodialysis enables prevention strategies for disability, falls, hospitalizations and death. Traditional operational definitions of frailty developed with community-dwelling older adults includes self-report of "involuntary weight loss of >4.5 kg in the past year". Weight loss in ESKD is difficult to ascertain given volumetric flux during dialysis. We hypothesize that omitting weight criteria from the operational definition of frailty will reclassify incident dialysis patients to capture comorbidities, physical function and disability.

Methods: This is a cross-sectional analysis of subjects in the Indiana cohort in LUCID, a longitudinal study of incident dialysis patients. The 5 traditional frailty criteria are weight loss, exhaustion, low physical activity, slowness and weakness, with a sum score of ≥3 termed "frail". Our "Light" (weight free) definition excludes weight loss and categorizes a sum > 2 as "new-frail". SF36 scores, physical function (gait speed and grip strength), demographics as well as co-morbidities were compared between those "frail" and "new-frail". We also determined the % of subjects of identified as "disabled" in the frail and new-frail groups, using published FiND criteria (which are all self-report).

Results: Mean (SD) age of the 146 subjects was 54 (13) years; 54% male, 71% black, 53% had DM, and median (IQR) dialysis vintage was 90(65) days. New-frail criteria (4 elements) increased the number of participants identified as frail using the traditional 5 element definition from 43 to 90. The new frail compared to the traditional definition increased the odds of being identified as frail 1) in diabetics, (OR 1.56 to 2.31) and 2) for those with inability to walk several blocks (OR 3.032 to 7.792) (both p<0.001). (OR 1.381 to 3.047, p=0.003). The new definition also identified more subjects who are frail, but not yet disabled (n=37% vs traditional criteria 16.5% p<0.001).

Conclusions: Use of weight loss in traditional frailty definitions is complicated by its fluctuations during dialysis. The omission of weight and thus changing to a 4 element index demonstrated higher ORs for disease and function. This tool may be better at identifying frailty risk in women and those frail but not yet disabled. Longitudinal outcomes associated with this definition are currently being studied.

FR-PO861

Low Gait Speed and Difficulty with ADLs in Incident ESKD Patients Ranjani N. Moorthi,[1] Keith Avin,[1] Ravi I. Thadhani,[2] Sharon M. Moe.[1,3] *[1]Indiana University-Indianapolis, Indianapolis, IN; [2]Massachusetts General Hospital, Boston, MA; [3]VAMC, Indpls, IN.*

Background: A gait speed less than 0.8 m/s is associated with poor muscle strength and lower life expectancy in community dwelling elderly. In dialysis patients, low gait speed is associated with poor outcomes but this has not been robustly shown in incident patients. We hypothesized that a gait speed < 0.8 m/s is associated with poor muscle strength and difficulty with activities of daily living (ADL) in those new to dialysis.

Methods: "LUCID" is a longitudinal study of subjects incident to dialysis. This analysis was limited to Indiana University cohort who underwent measures of physical function; we examined the cross-sectional relationship between gait speed < 0.8 m/s and hand grip strength, demographics and ADLs collected on the SF36 by multivariate regression analyses. Data is presented as mean (SD) or median (IQR).

Results: Mean (SD) age of the 146 subjects was 54 (13) years; 54% were men, 71% were black, 53% had diabetes, and median dialysis vintage was 90(65) days. Median gait speed was 0.77(0.25) m/s. Hand grip strength was significantly lower in those with gait speed < 0.8 m/s: left hand 16 (10) vs 22 (16) kg, p<0.001; right gave similar results. Presence of diabetes significantly increased odds of lower gait speed by 2.9 fold (p=0.004), and a lower pre-dialysis diastolic BP, but not systolic, was associated with low gait speed (p=0.02). In a multiple logistic regression model, increased age, presence of DM and female gender were significantly associated with risk of gait speed less than 0.8 m/s. We then determined the association for a low gait speed of < 0.8 m/s to the SF36 questions: No difficulty climbing a flight of stairs decreased the risk by 0.11 times (P = 0.001); Inability to walk several blocks increased the risk by 3.4 times (p=0.008). Median gait speed was significantly lower in those subjects "who never exercised" compared to those were less sedentary: 0.68 (0.32) versus 0.79 (0.30), p=0.046. In a multiple linear

regression model, higher age, female sex, poor grip strength and the inability to walk several blocks were associated with lower average gait speed (adjusted R^2 0.38).

Conclusions: Lower skeletal muscle strength is associated with impaired mobility in patients new to dialysis. Older females with diabetes remain at greatest risk for mobility impairment. Poor gait speed is associated with decreased ability to perform ADLs in an incident dialysis population.

Does Hemodialysis Impact Motor Performance beyond Diabetes and Peripheral Neuropathy? Objective Assessment of Gait and Balance Using Wearable Technology in a Hemodialysis Clinic

Noreen Siddiqi,[1] He Zhou,[1] Fadwa S. Al-Ali,[2] Abdullah Hamad,[2] Rania A. Ibrahim,[2] Talal Talal,[2] Sergio N. Sardon melo,[2] Bijan Najafi.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Hamad Medical Corporation, Doha, Qatar.*

Background: Poor motor-performance is a serious problem for older adults undergoing hemodialysis (HD) treatment. HD process often leaves these patients too fatigued to engage in any physical activity or daily exercise; further deteriorating their gait and balance. In particular, little is known about how HD impacts gait and balance mainly due to difficulty of bringing these highly vulnerable population to a gait lab. In this study, we used wearable sensors to objectively examine the impact of HD on gait and balance.

Methods: 33 eligible subjects (age=66+6years, body mass index=31+7kg/m^2, male=58%) in 3 age-matched groups were recruited: 11 undergoing HD treatment, 11 with diabetes peripheral neuropathy (DPN) not requiring HD and 11 healthy controls (HC). Gait and balance performances were assessed using wearable sensors. Single task walking (ST), dual task waking (DT), and double stance balance under eyes open (EO) and eyes closed (EC) conditions were measured.

Results: The HD group had the worst gait performance compared to other groups, which reached statistical significant level after adjusting for demographic information. The highest effect size to discriminate between HD and DPN as well as between HD and HC, was ST stride velocity (d=4.825, p<0.001 and d=7.361, p<0.001). The HD group had the worst balance performance of all groups. Between-group differences of ankle sway and hip sway under both EO and EC conditions, reached statistical significance. The largest effect size to discriminate between the HD and DPN groups as well as between the HD and HC, occurred at EO hip sway (d=1.692, p<0.001) and EC hip sway (d=1.868, p<0.001).

Conclusions: To our knowledge this is the first study that utilize wearable technology to objectively characterize gait and balance in HD patients during clinic visit. Results demonstrated HD patients have significantly poorer gait and balance, even when compared to DPN patients. Poor balance and gait reduce the ability of HD patients to be active, which in turn may impact the outcomes and associated risk including poor lower extremities perfusion, foot problems, falls and early frailty.

FR-PO863

Low Serum Uric Acid-Mortality Association in Incident Hemodialysis Patients

Yoshiko Nishizawa,[1] Sonoo Mizuiri,[1] Mariko Asai,[1] Kyoka Ono,[1] Kenichiro Shigemoto,[1] Kohji Usui,[3] Kazuomi Yamashita,[2] Michiko Arita,[4] Takao Masaki.[5] *[1]Division of Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Ichiyokai Yokogawa Clinic, Hiroshima, Japan; [3]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [4]Ichiyokai East Clinic, Hiroshima, Japan; [5]Nephrology, Hiroshima University Hospital, Hiroshima, Japan.*

Background: The association between serum uric acid (SUA) and mortality is contradictory in studies of hemodialysis (HD) patients. We hypothesized that nutritional status modifies the SUA-mortality association in the HD population.

Methods: We identified 462 patients who had HD treatment over 12 years (2004–2016) and had SUA measurements at HD initiation. Patients were followed-up until death. Kaplan-Meier survival analysis was assessed in each baseline SUA quartile (Q). Univariate Cox regression analyses of 1-year death were performed using data from HD initiation [variables: age, sex, presence of diabetes, hemoglobin, SUA (<5.0 mg/dl or Q4), creatinine, potassium, phosphate, C-reactive protein, geriatric nutritional risk index (GNRI), normalized protein catabolic rate (nPCR), and beta-2 microglobulin]. Multivariate Cox models were performed using significant variables from the univariate analyses. Regression analyses (RA) and multiple RA for SUA were performed using the same independent variables as univariate Cox models.

Results: The cumulative 1-year survival rate of patients belonging to the lowest UA Q1 (<6.2 mg/dl) was 81.1%, and was significantly lower (P<0.05) than patients in Q2 (92.7%, 6.2–7.2 mg/dl), Q3 (94.8%, 7.3–8.3 mg/dl), and Q4 (90.6%, ≥8.4 mg/dl). The cumulative 3 and 5 year survival rates of UA Q1 group were significantly (P<0.05) lower than those of the UA Q4 group (81.4% vs. 93.4%, and 80.7% vs. 89.6%, respectively). One-year all-cause mortality was found to be significantly associated with sex [hazard ratio (HR) 22.3, 95% confidence interval (CI) 2.56–338.6, P<0.01], serum creatinine (HR 0.26, 95% CI 0.10–0.52, P<0.01), serum phosphate (HR 3.22, 95% CI 1.40–8.20, P<0.01), SUA<5.0 mg/dl (HR 8.42, 95% CI, P<0.01), but not UA Q1. The HR of patients with SUA<5.0 mg/dl was 8.4 (P<0.05). In RA, SUA level was significantly associated with age, sex, hemoglobin, creatinine, potassium, phosphate, C-reactive protein, GNRI and nPCR (P<0.05). In multiple RA, SUA level was only associated with serum phosphate (β 0.20, P<0.01), creatinine(β 0.14, P<0.05), and GNRI (β 0.19, P<0.01).

Conclusions: Low SUA level but not high SUA level is associated with 1, 3, and 5-year mortality in incident HD patients, and a link between low SUA concentration and malnutrition status was present in this population.

FR-PO864

Pre-ESRD Uric Acid Levels and 1-Year Post-ESRD Hospital Admissions: A Transition of Care in CKD Study

Christina Park,[1] Melissa Soohoo,[1] Elani Streja,[1] Yoshitsugu Obi,[1] Hamid Moradi,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Elevated serum uric acid (SUA) levels are associated with higher risk of mortality in patients with chronic kidney disease, yet are paradoxically associated with lower risk of mortality in hemodialysis patients. Though the relationship of SUA and mortality has been studied, the relationship of pre-ESRD (end-stage renal disease) SUA levels and early post-ESRD hospitalization rates is relatively unknown.

Methods: Among US veterans who transitioned to ESRD in 2007-2014, we identified 10,715 patients with SUA measurements within 6 months prior to the start of dialysis treatment (prelude). Using Poisson regression, we calculated incidence rate ratios (IRR) for hospitalizations during the first year after initiation according to prelude SUA strata, hierarchically adjusting for case-mix and laboratory covariates.

Results: Patients were 67 ± 11 years old, 2% female, 34% African-American and 69% diabetic. The 6-month prelude SUA was 8.1 ± 2.2 mg/dL. The median [IQR] number of hospital admissions during the first year on dialysis was 1 [0-3] with an incidence rate of 2 per 100 patient-years. A U-shaped association was observed between SUA and 1-year post-ESRD hospitalizations. In the fully adjusted model, compared with the reference group (7-<8 mg/dL), the IRR were higher among the low and high (IRR [95%CI]: 1.06 [1.00, 1.11] and 1.10 [1.05, 1.14], respectively), but not intermediate 6-month pre-ESRD SUA strata, for hospitalization within the first year of dialysis [Figure]

Conclusions: High and low prelude SUA levels were associated with a higher rate of hospitalization following the first year of dialysis initiation. Further investigation is needed to examine the mechanism behind pre-ESRD SUA levels and post-ESRD hospitalizations in this population.

FR-PO865

Depression Is Associated with Mortality Independent of Previous Screenings

John Sy,[1] Kirsten L. Johansen.[2] *[1]UCSF Medical Center, San Francisco, CA; [2]University of California, San Franicsco, San Francisco, CA.*

Background: Depression affects up to 40% of dialysis patients and is associated with 50% higher risk of mortality, but it is not known whether changes in depressive symptoms mitigate the risk. We used a longitudinal cohort to analyze the association between depressive symptoms and changes in symptoms with mortality.

Methods: We examined the association between depression screening (at baseline and 12 months) and mortality using Cox models among 762 prevalent dialysis patients enrolled from 6/2009 to 8/2011 in the ACTIVE/ADIPOSE prospective cohort. The CES-D Scale was used as a screening tool for depression. Death was ascertained through linkage with the USRDS as of 3/31/2014. Among 687 patients with paired baseline and 12m data, differences in mortality risk were assessed in 4 groups defined according to depression screening at baseline and 12 m (neg to neg; neg to pos; pos to pos; pos to neg). Models were adjusted for age, sex, race, frailty, comorbidities, and inflammatory makers.

Results: 30.0% screened positive for depression at baseline. After adjustment, screening positive at baseline (HR 1.73, 95% CI 1.28 – 2.34) or 12m (HR 3.50, 95% CI 2.59 – 4.74) was associated with higher mortality risk. Compared to those who never screened positive for depression, those who screened positive at 12m were at statistically significantly higher risk of mortality regardless of baseline depression status (figure). To formally test whether trajectory predicted mortality independently of depression at follow-up, we adjusted for CES-D scores at 12m. Screening positive for depression at 12m was associated with higher mortality, but trajectory was not.

Conclusions: Positive depression screening was associated with higher mortality risk at any time point regardless of changes over the preceding 12 months. Results suggest that effective treatment of depression has the potential to improve outcomes.

FR-PO866

Adverse Outcomes of Subsequent Depression in ESKD Patients Undergoing Peritoneal Dialysis: A Longitudinal Prospective Study surapon nochaiwong,[3,4] Chidchanok Ruengorn,[2,4] Kiatkriangkrai Koyratkoson,[3,4] Chayutthaphong Chaisai,[3,4] Kajohnsak Noppakun,[5] Ratanaporn -. Awiphan,[2,4] Wilaiwan -. Chongruksut,[6,4] Sirisak Nanta.[1,4] *[1]Maesai District Hospital, Chiang Rai, Thailand, Chiang Rai, Thailand; [2]Facultty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; [3]Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; [4]Pharmacoepidemiology and Statistics Research Center (PESC), Chiang Mai University, Chiang Mai, Thailand; [5]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand; [6]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand. Group/Team: Thai Renal Outcomes Research (THOR) Investigators.*

Background: Existing epidemiological studies demonstrated that depression subsequently predicts adverse outcomes in various populations. Nevertheless, evidences were inconclusive and limited with regard to dialysis patients, particularly in patients on peritoneal dialysis (PD).

Methods: We conducted a prospective single cohort study from the Kidney Center, general hospital, Chiang Mai, Thailand from May 2012 to December 2014, involving adults treated with long-term PD. Participants were followed up until December 2016. Depression was defined by the Beck Depression Inventory (BDI) II score ≥ 14 at baseline. Adverse outcomes of interest included all-cause mortality, cardiovascular (CV) mortality, CV hospitalization, and health-related quality of life (HRQOL). Multivariable Cox regression analyses were used to estimate mortality and hospitalization risk. HRQOL scores using the Kidney Disease Quality of Life (KDQOL-36) instrument were also compared by linear regression. Baseline sociodemographics and known risk factors were adjusted in the models.

Results: Our cohort consisted of 409 PD patients with mean age of 59.3 ± 12.4 years and 44.0% were female. Depression presented in 28.6% at recruitment. After a median follow-up of 1.73 years (835.2 person-year), 139 (34%) participants had died, of which 50 (36%) were attributable to CV death.

Conclusions: Depression is common in PD patients and is strongly associated with increased risk of death, CV hospitalization, and worse HRQOL scores. Further investigation is warranted to establish whether recognition and treatment of depression can improve patient outcomes.

Funding: Government Support - Non-U.S.

Adverse outcomes for depressive disorder (BDI-II ≥ 14) versus non-depressive disorders (BDI-II < 14)

Clinical Adverse Outcomes	No. of Events	Unadjusted HR (95% CI)	Adjusted HR (95% CI)
• All-cause mortality	139	2.61 (1.87 – 3.64)	2.54 (1.61 – 4.02)
• CV mortality	50	3.42 (1.96 – 5.97)	3.36 (1.43 – 7.87)
• CV hospitalization	86	2.78 (1.82 – 4.25)	2.96 (1.67 – 5.26)
Patient-Reported HRQOL	**Outcome Mean**	**Unadjusted Difference (95% CI)**	**Adjusted Difference (95% CI)**
• KDQOL-36 physical component	49.9	-5.1 (-8.9 to -1.2)	-5.4 (-9.6 to -1.1)
• KDQOL-36 mental component	64.3	-4.2 (-7.8 to -0.5)	-4.7 (-8.6 to -0.8)
• KDQOL-36 kidney disease burden	74.2	-4.5 (-7.5 to -1.4)	-5.3 (-8.6 to -2.1)
• Summary KDQOL-36 scores	62.8	-4.6 (-7.8 to -1.3)	-5.1 (-8.6 to -1.7)

Temporal Variations in Hemoglobin before and after Transition to ESRD among Veterans: A Transition of Care in CKD Study Omesh N. Ranasinghe,[1] Melissa Soohoo,[2] Christina Park,[2] Connie Rhee,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[2] Elani Streja.[2] *[1]UCLA, Los Angeles, CA; [2]UC Irvine, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Hemoglobin (Hgb) levels decrease as renal function deteriorates and higher Hgb variability is associated with poorer outcomes in patients transitioning to end-stage renal disease (ESRD). However, the relationship of pre- and post-transition Hgb trajectories as well as its association with post-ESRD outcomes is unclear.

Methods: We used a mixed-effects regression model to evaluate the trajectories of Hgb over the 1-year pre- and post-ESRD initiation periods in 31,472 US veterans who transitioned to ESRD in 2007-2014. Trajectories were stratified by baseline 6-month pre-ESRD (prelude) Hgb concentrations. With hierarchically adjusted Cox models, we examined the association of 1-year prelude Hgb slope with early post-ESRD mortality.

Results: The mean±SD age of the cohort was 68±11 years, with a median[IQR] 1-year prelude Hgb slope of -1.6[-2.6, -0.7] g/dL/year. In the prelude period, all Hgb groups showed a gradual decreasing trend and patients with a lower baseline Hgb (<10 g/dL) had the steepest drop before transition. Hgb levels were then corrected towards a normal range with reduced variation across groups in the post-ESRD period. Those with the steepest Hgb decline in the 1-year prelude (≤-3 g/dL/year) had the highest risk of early post-ESRD mortality (HR[95%CI]: 1.16[1.07, 1.26] ref: slope -2< to ≤ -1 g/dL/year) after demographics adjustment, yet the relationship was attenuated after further laboratory and medication adjustments (HR[95%CI]: 1.03[0.95, 1.12]).

Conclusions: Hemoglobin levels rapidly decrease before dialysis initiation and then quickly normalize after initiation and steep pre-ESRD Hgb decline is associated with higher early post-ESRD mortality risk. Further studies are needed to examine the impact of anemia management during the pre- and post-ESRD period on post-transition dialysis outcomes.

Does Experience Matter? Nephrology Provider Experience and Patient Outcomes Scott Reule,[2] Robert N. Foley,[2] Paul E. Drawz,[2] Areef Ishani,[1] Mark E. Rosenberg.[2] *[1]None, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Provider experience is associated with patient outcomes in select surgical settings. Similar associations have not demonstrated in other fields including nephrology, a field tasked with the care of patients with multimorbidity.

Methods: Using physician data within the AMA Masterfile combined with patient and Medicare claims data from the USRDS limited to the years 2010-2012, we determined associations between experience and survival after initiation of renal replacement therapy.

Results: We identified 360,787 patients on renal replacement therapy cared for by 7,535 providers. A total of 38,889 patients received care from 1,412 providers with 0-8 years of experience; 178,802 patients received care from 3,615 providers with 9-21 years of experience; and 129,855 patients received care from 2,508 providers with > 21 years of experience. Compared to both those with 9-21 and > 21 years of experience, providers with 0-8 years were more likely to be female (34.1% vs. 27.1% with 9-21 yrs.; 34.1% vs. 16.1% with > 21 yrs.) practice in the Midwest region of the US (20.8% vs. 18.9% with 9-21yrs.; 20.8% vs. 17.9%, with > 21 yrs.), and have graduated from an osteopathic training program (6.6% vs. 4.8%; with 9-21 yrs.; 6.6% vs. 2.2%, > 21 yrs.). No significant patient level characteristics were associated with provider experience. Overall, 31.4% of the cohort died at a mean of 5.8 years. Increased provider experience was associated with lower HR of death (AHR 0.95, 9-21 years; AHR 0.96, > 21 yrs. vs. 0-8 yrs.) adjusted for provider and patient level variables. One-year survival after initiation of renal replacement therapy was lowest for those receiving care from those with 0-8 years of experience (Log rank, P < 0.001).

Conclusions: In our limited sample, increasing provider experience is associated with decreased patient mortality on renal replacement therapy providing evidence that experience does matter.

FR-PO869

Screening for Peripheral Vascular Disease in Hemodialysis Patients by Measurement of Skin Perfusion Pressure Saad Mohammed Shariff, Alian Albalas, Ammar Almehmi, Vinay Narasimha Krishna, Timmy C. Lee, Ahmed K. Abdel Aal, Michael Allon. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Peripheral vascular disease (PVD) is common in hemodialysis patients, but the optimal noninvasive screening test is unclear. Ankle Brachial Index (ABI) is the most commonly used test, but its accuracy in ESRD patients is limited by medial calcific sclerosis. Skin perfusion pressure (SPP) in the feet may be a more accurate measure of the severity of PAD, but its use in hemodialysis patients has not been evaluated. An SPP less than 50 mm Hg indicates significant PVD. We analyzed the association of SPP with clinical characteristics of these patients.

Methods: We studied 78 chronic hemodialysis patients. After administration of a brief screening questionnaire and physical examination of the lower extremities, SPP was measured in both lower extremities immediately before a dialysis session. We analyzed the association of SPP (the lower value between the 2 extremities) and individual clinical characteristics.

Results: Among the 78 study patients, 51% had diabetes, and 10% had a history of a lower extremity amputation. Seven patients (9%) had an SPP < 50 mm Hg. Among patients with a history of lower extremity amputation, the SPP in the remaining lower extremity was significantly lower than that measured in patients without prior amputation (p=0.01). There was no significant association of SPP with patient age, gender, diabetes, smoking history, history of stroke, claudication or LDL cholesterol (Table).

Conclusions: Of all the clinical risk factors evaluated, only a history of lower extremity amputation was significantly associated with a lower SPP. We are currently following these patients prospectively to determine the predictive value of SPP for future lower extremity ischemia.

Skin perfusion Pressure measurement in Hemodialysis patients (N=78)

	Skin Perfusion Pressure (mm Hg), Mean ± SE		p- Value
Patient Variable	Yes	No	
Age >= 65 yr (n=25)	78 ± 5	83 ± 4	0.44

Understanding Early Mortality after Dialysis Initiation: The Role of Severity of Illness, AKI, and ESRD Certification Diane Steffick,[2] Kevin He,[1] Maggie Yin,[2] Jennifer L. Bragg-Gresham,[2] Vahakn B. Shahinian,[2] Michael Heung,[2] Rajiv Saran.[2] *[1]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Analysis of CMS-certified ESRD patient mortality has consistently shown an increase in the first weeks after dialysis initiation, peaking at 6-8 weeks and then declining. The factors underlying this mortality pattern are unclear. To explore this, we examined mortality rates from the first dialysis session, which often occurs prior to ESRD certification for many patients, for those patients on Medicare prior to ESRD.

Methods: This retrospective cohort study used the Medicare 5% sample of patients with a dialysis claim, merged with the USRDS ESRD database. Patients had no dialysis in 2005 and their first claim in 2006-2014 was selected. Patients with an ESRD first service date before the first dialysis claim were excluded. Poisson regression was used to calculate weekly mortality rates, standardized to the sample mean age, sex and race.

Results: N=55,478 patients had a first dialysis claim. 69% began as inpatients (39% ICU), 72% had a diagnosis of AKI, and 41% were eventually certified as ESRD. Most AKI patients who were never certified as ESRD started as inpatients (88%, 60% ICU) with high week 1 mortality that increased further in week 2 and then declined. ESRD-certified patients without AKI at first dialysis showed more gradual increase in mortality rates, peaking around week 11 and again at week 24. Only 29% started as inpatients (6% ICU). Non-AKI patients never certified as ESRD were more likely to start as inpatients (48%, 14% ICU) than the ESRD-certified. 69% of AKI patients that were ESRD certified started as inpatients, with 34% in the ICU [Figure].

Conclusions: Severity of illness at the time of dialysis initiation (with or without AKI) seems to drive the high early mortality seen following dialysis initiation. Low mortality rates at the time of ESRD certification are likely an artifact of clinical decision making that channels early survivors into the ESRD program.

Comparative Effectiveness of Dialysis for Veterans in VA and Non-VA Settings Virginia Wang,[1,2] Cynthia Coffman,[1,2] Karen M. Stechuchak,[1] Paul L. Hebert,[3] Ann M. O'Hare,[3] David Edelman,[1,2] Hollis J. Weidenbacher,[1] Matthew L. Maciejewski.[1,2] *[1]Durham VAMC, Durham, NC; [2]Duke Univ, Durham, NC; [3]VA Puget Sound Health Care System, Seattle, WA.*

Background: Veterans with ESRD have different options for obtaining dialysis including: Medicare-funded community dialysis; VA in-house; and VA-purchased community dialysis (VA-PC). Differences in outcomes across these settings may reflect differences in patient characteristics or quality of care and care coordination, or both. This study compares hospitalization rates and days of care between Veterans receiving outpatient dialysis in VA, VA-PC, and Medicare settings.

Methods: We used VA and Medicare administrative data to construct a national cohort of VA-enrolled Veterans who initiated maintenance dialysis in 2008-2011. Cohort members were classified based on dialysis setting during the 2-year period immediately following dialysis initiation: 1) VA dialysis (VA); 2) VA-PC in non-VA dialysis units; 3) Medicare-financed dialysis in non-VA units (Medicare); or 4) "Mixed". We used logistic and negative binomial regression models to examine the associations between dialysis setting and hospitalization and hospital days (respectively) within 2-years after dialysis initiation (censoring at renal transplant or death), adjusting for patient demographic and clinical characteristics.

Results: Of the 27,301 cohort members, 67% received dialysis outside the VA under Medicare, 11% received dialysis outside the VA through VA-PC, 4% were treated in VA facilities, and 18% were treated in two or more of these settings (Table 1). Most Veterans were hospitalized (83%) and spent an average of 22.7 days in the hospital (median=14, IQR=8) during follow-up. Only Veterans receiving dialysis in two or more settings had higher rates of hospitalization versus those receiving dialysis under Medicare (OR= 1.3; 95% CI= 1.1, 1.5). There were no differences between groups in length of stay (p=0.26).

Conclusions: Veterans who received dialysis in more than one setting were at increased risk for hospitalization during the first two years after dialysis initiation.

Impact of Social Capital and Other Environmental Factors on Hemodialysis Patients' Health Outcomes Marta Reviriego-Mendoza, John W. Larkin, Dugan Maddux, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: While it is documented that environmental and societal factors impact general population's health outcomes, most focus of dialysis research is on traditional biomarkers. Social capital, which has been defined as "connections among individuals – social networks and the norms of reciprocity and trustworthiness that arise from them" (Putnam, 2000), has been shown to significantly affect patient's health (Kawachi et al., 1997; Yang et al., 2011). We thus aimed to investigate if social capital and other social determinants such as rurality and income have an effect on dialysis patients' hospitalization rates.

Methods: We included all patients who initiated dialysis treatment in the Fresenius Kidney Care clinics from Jan-2013 to Dec-2016. Patient's data was collected during the first 120 days on dialysis and included laboratory values and demographic data. Household income, educational level and rurality data was extracted from the United States Census Bureau at the zip code level. Data of county level measure of social capital was obtained from Rupasingha, et al., 2006. We calculated the impact of these variables on patients' hospital admissions for the reminder of the first year on dialysis using Poisson model with log of exposure days as offset variable.

Results: A total of 49,195 patients were included in the study. From the analysis, it was estimated that both household income (beta=-0.001, p=0.1052) and education (beta=0.0000, p=0.8255) had only a small, non-significant impact on patients' hospitalization rates. We also observed that patients who are married (-0.05, p less than 0.0001), living in a rural setting (-0.062, p=0.0017) and, to a lesser extent, in areas with more social capital (-0.020, p=0.1558), have a favorable impact on hospital admissions.

Conclusions: Rural settings and the existence of social networks may encourage neighbors' awareness. Our analysis suggests that, in addition to the health status and access of care, dialysis patients' clinical outcomes may be affected by their environmental and social surroundings. Deeper analyses are warranted to better understand the effects of social determinants on patients, outcomes.

Serum Levels of Resistin-Like Molecule Beta Is Associated with Gastrointestinal Complications in Patients with ESRD on Hemodialysis Kentaro Tanaka,[4,1] Akifumi Kushiyama,[1] Yoshihide Tanaka,[3] Shigeko Hara,[2] Takashi Ozawa.[3] *[1]Division of Diabetes and Metabolism, The Institute for Adult Diseases, Asahi Life Foundation, Tokyo, Japan; [2]Okinaka Memorial Institute for Medical Research, Toranomon Hospital, Tokyo, Japan; [3]Higashiyamato Nangai Clinic, Tokyo, Japan; [4]Higashikurume Ekimae Clinic, Tokyo, Japan.*

Background: Resistin-like molecule (RELM) β is a secretory protein homologous to resistin and reportedly contributes to local immune response regulation in gut and bronchial epithelial cells. RELMβ is experimentally associated with chronic inflammation such as metabolic syndrome, diabetes, dyslipidemia, colon cancer, IBD and atherosclerosis. However, there are no reports in patients with end-stage renal disease (ESRD). To investigate the roles of RELMβ in ESRD, we analyzed the serum levels of RELMβ in ESRD patients before and after hemodialysis and the association between serum RELMβ and gastrointestinal complications (GIC).

Methods: 69 patients with ESRD on hemodialysis provided written informed consent at our dialysis clinic in October 2015. We newly developed RELMβ ELISA and evaluated serum RELMβ from ESRD patients, compared with values from health check group as reference. Patients with severe bronchial asthma, abdominal operation just before measurement, and one failure measurement with non-specific signal were excluded. Then the remaining 66 patients (38 men, 28 women) were investigated for GIC in ESRD patients after serum RELMβ measurement. Onset date of complications were the day patients admitted to hospital for treatment. Statistical analysis was used by cox regression models.

Results: Serum RELMβ levels before dialysis which were markedly elevated as compared with those of control subjects (median 152 vs.60pg/ml, p=0.0008). Serum RELMβ was not eliminated after dialysis (p=0.54). Over median 14-month follow-up, 13 patients (19.6%) developed GIC (enteritis 2; bleeding 6; cancer 4; perforation 1). The patients in the lowest tertile of serum RELMβ (<90pg/ml) had no GIC. In a Cox univariate analysis, 10pg/mL increase of serum RELMβ was associated with GIC (hazard ratio 1.08, [95% CI 1.01-1.15], p=0.01). In Cox multivariate analysis, 10pg/mL increase of serum RELMβ was an independent predictor of GIC after adjusted by age, sex, diabetes, dialysis vintage, BMI, alb, CRP, Kt/V(1.12 [1.04-1.22], p=0.001).

Conclusions: Serum RELMβ is high in patients with ESRD, and high serum level of RELMβ is associated with the onset of GIC. These results suggest that the RELMβ plays a causal role in pathophysiology of GIC in ESRD and might be a useful marker.

Association of Dialysis-Related Amyloidosis with Lower Quality of Life in Patients on Hemodialysis More Than 10 Years: The Kyushu Dialysis-Related Amyloidosis Study Kazuhiko Tsuruya,[5] Masayoshi Tsuji,[1] Hisatomi Arima,[2] Kunitoshi Iseki,[4] Hideki N. Hirakata.[3] *[1]Department of Preventive Medicine and Public Health, Fukuoka University, Fukuoka, Japan; [2]Preventive Medicine and Public Health, Fukuoka Uniuversity, Fukuoka, Japan; [3]Fukuoka Renal Clinic, Fukuoka City, Japan; [4]Tomishiro Central Hospital, Tomigusuku, Japan; [5]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan. Group/Team: Kyushu Dialysis-Related Amyloidosis Study.*

Background: Dialysis-related amyloidosis (DRA) is one of the important critical issues in patients with long-term dialysis therapy. However, it remains unknown whether DRA is independently associated with patients' quality of life (QOL) and outcomes. Thus, we conducted a multicenter prospective cohort study to examine the association between DRA and QOL using cross-sectional and longitudinal study designs.

Methods: The major inclusion criteria were patients on dialysis for more than 10 years. Diagnosis of DRA was based on the clinical diagnostic criteria of DRA in Japan. Briefly, patients having two or more of five DRA-related findings (polyarthralgia, carpal tunnel syndrome, trigger finger, dialysis-related spondyloarthropathy, or bone cysts) were diagnosed with DRA. QOL was evaluated using EQ-5D health state utility scores. Decline in QOL was defined as an absolute change in EQ-5D scores from baseline to two years of follow-up (ΔEQ-5D scores) less than 0.

Results: A total of 1,314 patients from 72 dialysis facilities were enrolled in this study. Among them, 277 (21%) were diagnosed with DRA. EQ-5D scores were significantly lower in patients with DRA compared to those without DRA [median (interquartile range): 0.649 (0.533–0.768) vs. 0.768 (0.693–1.000); P<0.001]. Among the all patients, 931 (71%) could be followed for two years and were divided into three groups according to baseline and follow-up DRA status: patients with DRA at baseline (G1, n=190), those who had not DRA at baseline, but developed DRA during the follow-up period (G2, n=44), and those without DRA both at baseline and after two years (G3, n=697). Although G3 had shorter dialysis vintage (15 years) compared to G1 (27 years) and G2 (23 years), age, sex, and previous history of cardiovascular diseases were comparable among three groups. Decline in QOL was observed in significantly greater proportion in G1 (45%, P<0.05) and G2 (66%, P<0.01) compared to G3 (35%). Multivariable-adjusted odds ratios (95% confidence intervals) for the decline in QOL in G1, G2, and G3 were 1.40 (0.84–2.31) and 2.26 (1.01–5.09), and 1.00 (reference), respectively. The ΔEQ-5D scores were significantly lower in G2 than G3.

Conclusions: DRA was associated with lower QOL in hemodialysis patients with long-term dialysis therapy.

FR-PO875

Randomized, Placebo-Controlled Study on the Efficacy of CR845 in Reducing CKD-Associated Pruritus in Hemodialysis Patients Robert H. Spencer, Catherine Munera, Maria S. Oberdick, Joseph W. Stauffer, Frederique Menzaghi. *Cara Therapeutics, Inc., Stamford, CT.*

Background: With no treatment approved in the US, patients with chronic kidney disease-associated pruritus continue to be afflicted by this debilitating condition. The present study evaluated the anti-pruritic efficacy of the novel potent and selective peripherally-acting kappa-opioid receptor agonist CR845 in hemodialysis (HD) patients with moderate-to-severe pruritus.

Methods: 174 HD patients experiencing pruritus for ~4.4 years with a mean baseline numerical rating score (NRS) >4 for worst itching intensity (0 [no itching] to 10 [worst itching imaginable]) were enrolled across 33 dialysis centers. Patients were randomized to receive one of 3 intravenous doses of CR845 (0.5 mcg/kg, n=44; 1 mcg/kg, n=41 and 1.5 mcg/kg, n=44) or placebo (n=45) at the end of each dialysis session over an 8-week treatment period. The primary efficacy endpoint was the change in the weekly mean of the daily 24-hour worst itching intensity NRS score from baseline (one week mean prior to randomization) to Week 8.

Results: Demographics and baseline features were well balanced across treatment groups, and CR845 was well tolerated at all doses. Average reduction in itch NRS scores from baseline (LS Mean ± SE) ranged from -2.8 (±0.38) in the 1.0 mcg/kg group (95% CI: -3.5 to -2.0) to -3.8 (±0.38) in the 0.5 mcg/kg group (95% CI: -4.5 to -3.1), with no significant differences between doses. The reduction in itch NRS scores was significantly different from placebo at the 0.5 and 1.5 mcg/kg dose (p≤ 0.019) with 64% (p=0.016) of patients in the 0.5 mcg/kg dose group reporting ≥ 30% reduction in worst itch NRS scores by Week 8, compared to 38% of the placebo patients. These results were supported by a significantly higher proportion of CR845 patients reporting that their itch was "very much improved" or "much improved" at the end of the study compared to placebo (66% CR845 vs 42% placebo; p=0.007) as measured by the Patient Global Impression of Change, along with a significant improvement in quality of life, including quality of sleep.

Conclusions: CR845 effectively and safely reduced itch intensity in HD patients with moderate-to-severe pruritus over 2 months of treatment.

FR-PO876

The Moisturizer Improves Pruritus of Dialysis Patients by Increasing Water Content in the Stratum Corneum Yukie Yoshida,[2,1] Kazumasa Hashimoto,[2] Hidehisa Saeki,[3] Seiki Fujimoto,[4] Shuichi Tsuruoka.[1] *[1]Department of Nephrology, Nippon Medical School, Tokyo, Japan; [2]Kidney Clinic, Nippon Medical School, Tokyo, Japan; [3]Department of Dermatorogy, Nippon Medical School, Tokyo, Japan; [4]Maruho Co., Ltd., Osaka, Japan.*

Background: In dialysis patients, skin disorder (dryness, itching, etc.) is frequently observed and treated with moisturizers without sufficient evidence. We therefore evaluated the usefulness of a moisturizer in the treatment of dry skin in dialysis patients in an exploratory manner.

Methods: This study was an open-label, randomized, before-after, parallel group comparison study conducted after approval by the Institutional Review Board of Nippon Medical School. The study was funded by Maruho Co., Ltd. (Osaka, Japan), and registered at the University Hospital Medical Information Network (UMIN) Clinical Trials Registry as UMIN000017016. Included were 12 maintenance hemodialysis outpatients in stable condition in our hospital, randomized to receive treatment with a lotion containing heparinoid (Maruho) for 2 weeks followed by 2-week washout (Group A: 6 subjects) or another 2-week treatment (Group B: 6 subjects). The primary efficacy measure was water content in the stratum corneum in the hypochondrium (flank). Secondary measures included visual analogue scale (VAS) itching score. Safety was evaluated based on adverse events. Efficacy data were collected on Day 1 and after 1, 2, 3, and 4 weeks of treatment, on which the water content was measured using a Corneometer (Courage-Khazaka) at 1 to 2 hours after the start of dialysis. Subjects additionally assessed their itching at the application site on a 100-mm VAS before dialysis.

Results: The moisture in the stratum corneum significantly increased at Weeks 1 and 2, then significantly decreased in Group A, in which study treatment was discontinued, but was almost maintained in Group B, in which treatment was continued. Itching VAS score significantly decreased at Weeks 1 and 2, indicating reduction of itching, then increased in Group A, suggesting that itching returned to the baseline condition. The score decreased in Group B, indicating further reduction of itching. At Week 4, the score was significantly different between Groups A and B. As for safety, mild upper respiratory tract infection was reported in 1 subject during treatment, but was not related to study treatment.

Conclusions: Continuous moisture retention with a preparation containing heparinoid may be effective and safe to reduce dry skin and maintain good skin condition in dialysis patients.

Funding: Commercial Support - Maruho Co., Ltd. (Osaka, Japan),

FR-PO877

The Present Status of Fatigue in Maintenance Hemodialysis Patients and Its Influencing Factors Bing Zhuang,[2] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]The second affiliated hospital of nanjing medical university, Nanjing, China.*

Background: Fatigue is a common and complex phenomenon in maintenance hemodialysis patients that significantly decreases the health-related quality of life, especially after hemodialysis treatment, frequently requiremore time to recover. The aim of this study was to analysis the fatigue status of hemodialysis patients in our dialysis center, explore the influencing factors of fatigue in these patients and proposeeffective intervention measures.

Methods: This study is a observational study. From June 2016 to February 2017,120 maintenance hemodialysis patients were enrolled the research in our center. The patients completed the questionnaires, including the Fatigue Assessment Scale(FAS) and the time of recovery from a dialysis session. The serum concentration of hemoglobin, albumin, electrolyte and the levels of PH, bicarbonate, lactic acidwere examined to statistics and analysis.

Results: 120 questionnaires were distributed and 111 were taken back, and 109 (90.8%) were effective among the questionnaires. The incidence of fatigue in maintenance hemodialysis patients was high, 63 of 109 (57.8%) patients enrolled in the study assessed of fatigue, 9.2% of patients had a severe fatigue. The time of recovery from hemodialysis (TIRD) is differently from 30 minutes to 24 hours. 66.1% of patients' recovery time was shorter than 2 hours, 29.3% was 2-12 hours, 4.6% of patients taked longer time to recover from a dialysis session. Most of them required more rest or sleep immediately after dialysis. The result of analysis is that the fatigue of patients was correlated with comorbidities (OR=0.202),the levels of lactic acid (OR=3.933) and the bicarbonate (OR=0.643) after dialysis. The rate of ultrafiltration,the levels of serum sodium and the levels of lactic acid after dialysis are different to the TIRD, the raised of lactic acid (OR=4.21) is associated of longer recovery time.

Conclusions: The incidence of fatigue patients in our dialysis center is more than a half,a few number of patients had a heavy fatigue,required more rest or sleep immediately after dialysis. The levels of lactic acid was the significant influencing factor of the fatigue in hemodialysis patients,TIRD was correlated with the raised of lactic acid during the dialysis process.

The Cataract Surgery Related Complications in Patients with ESRD Chia-Chun Wu. *Chi Mei Medical Center, Tainan, Taiwan.*

Background: Higher surgery risk in end stage renal disease (ESRD) patients is well known, but most reports focus on major surgeries. Cataract is the most common cause of visual loss worldwide. Although catarct surgery is a minor surgery, surgery related complications still happen. Herein, we want to know if ESRD patients have higher risk of cataract surgery related complications.

Methods: The National Health Insurance Research Database in Taiwan was used to identify patients who received cataract surgery. Patients with regular hemodialysis(HD) or peritoneal dialysis longer than 3 months were selected as study group. Control group is patients without chronic kidney disease and matched on age, gender and surgery year. Other exclusion criteria is any eye surgery within 3 years prior cataract surgery. The main outcome measures are cataract surgery–related complications within 3 months after surgery. Conditional logistic regression was used for the risk of complications.

Results: Patients with ESRD have higher percentage of hypertension, diabetes mellitus and more likely to have a cataract surgery in medical centers. Patients with ESRD have a 6.81 times higher risk to have vitreous hemorrhage within 3 months after cataract surgery. The odds ratios of vitreous hemorrage are 4.20, 4.86, 9.8 in the 1st, 2nd and 3rd month individually.

Conclusions: Patients with ESRD have a higher risk of vitreous hemorrhage after cataract surgery. Heparin is frequently used during HD to prevent clot formation in blood circuit, this analysis result might afford a reference to adjust the heparin dose in HD patients after receiving cataract surgery.

The multiple complications after cataract surgery within 3 months in ESRD patients and Control group

	ESRD patients (N=439)	Controls (N=1317)	Adjusted OR(95% CI)	P-value

Sex-Based Immunological Disparity in ESRD Patients Feng-Jung Yang,[1,2] Yen-Ling Chiu.[1,3] *[1]Graduate Institute of Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan; [2]Internal Medicine Department, National Taiwan University Hospital Yunlin Branch, Douliu, Taiwan; [3]Internal Medicine Department, Far Eastern Memorial Hospital, Banciao, New Taipei City, Taiwan.*

Background: Sex differences in the immune response and in infectious disease susceptibility have been well described, although the mechanisms underlying these differences remain incompletely understood. Patients with end-stage renal disease may face higher risk of infection. The activity and distribution of T cell and monocyte subsets between the sexes is still unknown.

Methods: The immunity in ESRD study (iESRD) recruited 412 hemodialysis patients from both northern and southern Taiwan. Peripheral blood were sampled before hemodialysis session and processed immediately for mononuclear cell isolation and staining. Using multicolor flow cytometry, lymphocytes were separated into subpopulations including naive Tn cells, central memory TCM, effector memory TEM, and terminally differentiated TEMRA. Monocytes were separated into three groups M1 M2 M3. Plasma levels of high-sensitivity C reactive protein was determined.

Results: Among CD4+/CD8+ T cell subsets, male patients showed decreased percentage of naïve CD4+/CD8+ Tn cell and increased percentage of effector memory CD4+/CD8+ TEM. Among monocytes subset, female patients showed increased percentage of classical monocytes and decreased percentage of nonclassical monocytes CD14+CD16+ monocytes. The M1 percentage of ESRD was lower than general population ~80%. Low M1 and high M3 indicating more inflammatory response in the this group. Besides, female patients have more numbers of naïve CD4+/CD8+ Tn cell and central memory CD8 TCM but less numbers of nonclassical monocytes M3.

Conclusions: Males and females differ in innate and adaptive immune responses. These sex-based immunological disparities contribute to variations in the incidence of autoimmune diseases and malignancies, susceptibility to infection. Our study showed the immune age of female was younger than male in ESRD. Male have more 'Non-classical' subtype monocytes which display more 'inflammatory' characteristics Sex associated immune response should be further investigated in the pathogenesis of infection and aging in ESRD.

FR-PO880

A Comparison between Hemodialysis and Peritoneal Dialysis on the Risk of Hip Fractures in Diabetics with Chronic Renal Disease Ammar Qureshi,[2] Fernando R. Aguilar,[1] Nesreen Benhamed.[3] *[1]Georgetown University Hospital, Washington, DC; [2]Internal Medicine, Marshall University, Huntington, WV; [3]Internal Medicine, MUSOM, Barboursville, WV.*

Background: It is well established that bone fragility and fractures are common complications of patients on dialysis, notably if they are diabetics. It remains uncertain if the risk of fractures changes depending on the dialysis modality either hemodialysis (HD) or peritoneal dialysis (PD). We aim in this study to set the risk of bone fractures between those two modalities in patients with DM2.

Methods: Data was extracted from the 2005 to 2012 Nationwide Inpatient Sample (NIS). Using propensity score matching, ESRD-DM patients on PD were matched with patients on HD at a 1:1 ratio. Analyses were performed using SAS version 9.3 (SAS Institute, Cary, NC, USA).

Results: Among 586,238 patients with incident ESRD, 568,469(96.97%) and 17,769(3.03%) were initiated on HD and PD, respectively, during the hospitalization. After matching both groups, we find no difference in the rate of ulnar (0.1 vs 0.1; p=1) and hip fractures (0.3 vs 0.31; p=0.78) while spine (0.32 vs 0.21; p<0.0001) and humeral fractures (0.21 vs 0.15; p= 0.01) occur significantly more in the HD group.

Conclusions: Diabetic patients with ESRD on HD have higher risk for spine and humeral fractures. Further studies are needed to evaluate the different bone pathogenesis of both dialysis modalities to explain our findings.

FR-PO881

Association of Pre-ESRD Serum Bicarbonate with Post-ESRD Mortality among Incident Dialysis Patients: A Transition of Care in CKD Study Yoshitsugu Obi,[1] Christina J. Catabay,[1] Melissa Soohoo,[1] Christina Park,[1] Elani Streja,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Serum bicarbonate ($S\text{-}CO_2$) levels decline as CKD progresses and rise after dialysis initiation. While the current clinical guidelines suggest maintaining $S\text{-}CO_2$ > 22 mEq/L among pre-ESRD patients with CKD, there are scarce data on the impact of pre-ESRD $S\text{-}CO_2$ levels on post-ESRD mortality.

Methods: Among 32,655 US veterans who transitioned to dialysis between October 2007 and March 2014, we calculated 6-month averaged levels and annual decline rate of $S\text{-}CO_2$ during the last pre-ESRD period, and then estimated their risk for all-cause mortality with Cox regression adjusting for demographics, comorbidities, BMI, and eGFR.

Results: Mean baseline concentrations and rates of decline of $S\text{-}CO_2$ were 23±4 mEq/L and -1.8±2.4 mEq/L/year, respectively. Higher $S\text{-}CO_2$ >20 mEq/L showed higher adjusted mortality risk while there was no clear trend in the lower range. Compared to $S\text{-}CO_2$ of 22 mEq/L, adjusted HRs (95%CIs) were 0.96 (0.94–0.97), 1.09 (1.07–1.12), and 1.22 (1.18–1.27) at 20, 24, and 26 mEq/L, respectively. Consistent associations were observed irrespective of sodium bicarbonate use. There was a U-shaped association between the rate of decline in $S\text{-}CO_2$ and mortality with the lowest risk being approximately -2.0 mEq/L/year. Both faster decline and rise in $S\text{-}CO_2$ were more strongly associated with mortality among sodium bicarbonate users vs. non-users.

Conclusions: Pre-ESRD $S\text{-}CO_2$ levels above 20 mEq/L exhibited an incrementaly higher post-ESRD mortality risk. Further studies are needed to elucidate whether high S-CO2 is a surrogate of low protein intake, comorbid states, or other mechanisms.

FR-PO882

Phosphate Binder Use and Cost Trends in US Dialysis Patients Wendy L. St. Peter,[3] Lori Wazny,[1] Eric D. Weinhandl.[3,2] *[1]Manitoba Renal Program, Winnipeg, MB, Canada; [2]NxStage Medical, Inc., Victoria, MN; [3]University of MInnesota, Minneapolis, MN.*

Background: Phosphate binder costs for US dialysis patients having Medicare Part D was almost $1 billion in 2014. Our objectives were to examine current trends in use and cost data for phosphate binders and to determine gross Medicare Part D costs per equivalent phosphate binding dose.

Methods: Using data from United States Renal Data System, we report trends in phosphate binder use and costs for Medicare-covered dialysis patients with Medicare Part D prescription drug coverage from 2006-2013. We identified all medication fills for phosphate binders (calcium acetate, lanthanum carbonate, sevelamer carbonate, and sevelamer hydrochloride) and all Part D-covered drugs. For each year, we calculated percent of patients using phosphate binders (overall and by binder), weighted by cumulative follow-up time per patient, cumulative gross costs, gross costs per patient-year and gross costs per user-year. For each phosphate binder, we estimated gross costs per calcium carbonate-equivalent gram by applying relative phosphate binding capacities equal to 1.00 for calcium acetate, 2.00 for lanthanum, and 0.75 for sevelamer products.

Results: Number of dialysis patients with Medicare Part D coverage filling phosphate binder prescriptions steadily increased from 174,974 in 2006 to 263,404 in 2013 (50% cumulative increase), while percentages filling phosphate binder prescriptions remained stable at around 75% while gross costs per user-year for phosphate binders increased from $1433 to $3716 (159% cumulative increase, or 15% year-over-year increase). Gross costs per user-year for all other Part D-covered prescription medications in dialysis patients cumulatively increased by 44% (5.4% year-over-year growth). Between 2006 and 2013, gross costs per user-year for calcium acetate, sevelamer carbonate, and lanthanum carbonate increased by 153%, 284%, and 307%, respectively. Adjusted for relative phosphate binding capacity, gross costs of calcium acetate, lanthanum carbonate, and sevelamer carbonate were $0.79, $4.67, and $4.85, respectively, per one calcium carbonate-equivalent gram in 2013.

Conclusions: Growth in cost of phosphate binders outpaced growth in costs of other Medicare Part D medications in dialysis patients. To achieve an equal degree of phosphorus control in an average patient, Medicare expended roughly 6 times as much on sevelamer carbonate and lanthanum carbonate as on calcium acetate in 2013.

FR-PO883

Differential Effects of Hemodialysis and Transplantation on Cognitive Function in ESRD Mark D. Findlay,[1,2] Patrick B. Mark,[1,2] Jesse Dawson.[1,2] *[1]University of Glasgow, Glasgow, United Kingdom; [2]Queen Elizabeth University Hospital, Glasgow, United Kingdom.*

Background: Cognitive impairment (CI) is common in people receiving hemodialysis (HD). We examined for changes in cognitive function during the HD session and the effect of continued HD or renal transplantation on cognitive function at 12 months

Methods: Prospective observational study in adult patients on chronic HD. A neurocognitive battery was performed during a routine dialysis session and on a non-dialysis day. Cognitive tests included the Montreal Cognitive Assessment and additional tests of language, memory, processing speed and executive function. Mean flow velocity (MFV) was measured in the middle cerebral artery before, during and after dialysis using transcranial Doppler ultrasound. We compared cognitive function and MFV on and off dialysis and assessed the relationship between any changes using Spearman's rank correlation. Cognitive function was reassessed in a similar fashion 12 months later.

Results: 97 participants were enrolled (median age 59yr [IQR 51, 67], 40% female, median duration of end stage renal disease 1.76 years [IQR 0.6, 4.0]). 88 participants attended both intradialytic and non-dialysis day assessments. CI was present in 44(50%). Those with CI were more likely to have hypertension (95.5 v 81.8%, p<0.05). MFV declined during dialysis (mean; 49.8 to 43.2cm/s, p<0.001) correlating with UF volume, r=0.49 p<0.001. Participants scored lower on tests of processing speed and executive function during dialysis when compared to their non-dialysis day scores, p<0.001. Decline in test scores for language and executive function correlated with the dialysis-related fall in MFV, r=-0.27 p=0.02 and r=0.44 p<0.001 respectively. At 12 months, 59 remained on dialysis; 15 transplanted, 5 withdrew and 5 died. Improvements in language and attention tests were observed in those continuing HD, whereas those who received a transplant demonstrated improvements in executive function and processing speed, p<0.05.

Conclusions: Occult CI is common and cognitive function demonstrably worse during dialysis. Cerebral blood flow is reduced during HD, relating to UF volume and a measurable decline in cognitive function. The transient decline in executive function during dialysis does not appear to exert a progressive effect at 12 months, however its significant improvement following transplant highlights an aspect of cognitive function vulnerable to continued HD.

FR-PO884

Implications of Variation in Cognitive Performance on Dialysis: A Pilot Study of an Electronic Cognitive Battery Meera N. Harhay,[2] Lucy Robinson,[1] Hasan Arif,[2] Karthik M. Ranganna,[2] Maria T. Schultheis.[1] *[1]Drexel University, Philadelphia, PA; [2]Medicine, Drexel University College of Medicine, Philadelphia, PA.*

Background: Cognitive impairment (CI) is common among dialysis patients, and some patients may exhibit transient CI during dialysis therapy. However, traditional neurocognitive testing has limited feasibility for use in clinical settings, and no studies have examined whether a decline in cognition during dialysis predicts health outcomes. We examined the association of variation in performance on the electronic Cogstate Brief Battery, consisting of four card-based cognitive tasks called Detection (processing speed), Identification (attention), One Card Learning (visual memory) and One Back (working memory), on the risk of subsequent hospitalization in a cohort of hemodialysis patients.

Methods: We enrolled 28 participants from a single dialysis unit in Philadelphia, PA. Participants completed the 10-minute Cogstate battery twice, once prior to dialysis and again during the last hour of dialysis therapy. For both sessions, participants were defined as "low" scorers on individual tasks if they scored below the cohort median score. We estimated age-adjusted Poisson regression models for the association of pre-dialysis and intradialytic cognitive performance and the number of hospitalizations participants experienced during six months of follow-up.

Results: The average age of the cohort was 58 years (SD 13), 97% were black, 60% were female. Mean dialysis duration was 6 years (range 2-20). After six months of follow-up, 35% of the cohort had at least 1 hospitalization, and 18% of participants (n=5) had >1 hospitalization. In age adjusted Poisson regression models, compared to participants who scored higher than the median both times for the Identification task, those who scored 1) higher pre-dialysis and lower during dialysis and 2) those that scored lower both times had a 9-fold and 7.5-fold increase in the expected number of hospitalizations in six months, respectively (p=0.03 for both). Reasons for hospitalization in low scorers included syncope and mechanical fall.

Conclusions: In this pilot study, we found that consistently low performance on a self-administered electronic cognitive task, or poorer performance during dialysis, signaled hospitalization risk among prevalent hemodialysis patients. Given limitations

due to low sample size, future studies should confirm and expand on these findings in larger cohorts.

Fall Injury Prediction Using Quadriceps Thickness by Ultrasound Measurement of Patients with ESRD on Hemodialysis: A Prospective Study

Yoshihide Tanaka,[2,3] Kentaro Tanaka,[2,1] Akifumi Kushiyama,[1] Atsumi Kuki,[2] Ken Sakai,[3] Shigeko Hara,[4] Yui Izumi,[2] Takashi Ozawa.[2] *[1]Division of Diabetes and Metabolism, The Institute for Adult Diseases, Asahi Life Foundation, Tokyo, Japan; [2]Higashiyamato Nangai Clinic, Tokyo, Japan; [3]Toho University School of Medicine, Ohta-ku, Japan; [4]Okinaka Memorial Institute for Medical Research, Toranomon Hospital, Tokyo, Japan.*

Background: Patients with end stage renal disease (ESRD) have an increased risk of fall injury. Recently, quadriceps muscle thickness (QT) by ultrasound (US) measurement has been reported as valid assessment of muscle wasting and physical function and easily applicable at the bedside. The aim of this study is to investigate if QT by US can prospectively predict fall injury in patients with ESRD on hemodialysis.

Methods: Within 732 patients with ESRD on hemodialysis at our 4 dialysis Clinics in April 2015, 182 patients provided written informed consent. The QT by US is indicated as the sum of both legs. The relative reliability of QT by US measurement was confirmed using intraclass correlation coefficient(ICC);right QT ICC(1,2)=0.99 and left QT ICC(1,2)=0.98. Patients with unstable condition such as discharge or initiation of oral steroid administration, or drop out before the first measurement were excluded. 179 patients (men127, women52) were studied. A fall was defined as an event in which a person was inadvertently located on the ground or other low position. Fall injury was defined as any injury with a fall, based on patient's self-report including bone fracture, crack, bleeding, bruise, and abrasion.

Results: Over median 12-month follow-up period, 42 patients (23.4%) developed the fall injury in 179 patients. When subjects were stratified by QT level into sex-specific tertiles, the patients in the lowest tertile (men<3.66cm, women<3.52cm) indicated a significantly higher risk of fall injury than the middle and highest tertiles by using Kaplan Meier estimate (logrank test, p<0.05). In a univariate analysis using Cox regression model, 1cm decrease of the QT by US indicated significant risk increase (hazard ratio 1.85, [95% CI 1.33-2.70], p=0.0002). In multivariate analysis, the hazard ration between the QT by US remained significant after adjusting various confounding factors such as sex, age, dialysis vintage, BMI, diabetes mellitus, nutritional state, grip strength (1.64, 1.04-2.63,0.03).

Conclusions: QT by US is an independent and useful predictor of fall injury in patients with ESRD on hemodialysis.

Evaluating the Real-World Safety and Effectiveness of Sucroferric Oxyhydroxide in Dialysis Patients: An Interim Analysis of the VERIFIE Study

Marc G. Vervloet,[9] John N. Boletis,[12] Angel Luis M. De Francisco,[5] Denis Fouque,[11] Philip A. Kalra,[7] Markus Ketteler,[6] Piergiorgio Messa,[13] Manuela Stauss-Grabo,[3] Viatcheslav Rakov,[10] Sebastian Walpen,[10] Linda H. Ficociello,[1] Jacques B. Rottembourg,[4] Christoph Wanner,[8] Jorge B. Cannata-Andia.[2] *[1]Fresenius Medical Care - North America, Waltham, MA; [2]Hospital Universitario Central de Asturias, Oviedo, Spain; [3]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [4]Groupe Hospitalier Pitié-Salpêtrière, Paris, France; [5]Marques de Valdecilla University Hospital, Santander, Spain; [6]Coburg Clinic and KfH-Dialysis Center, Coburg, Germany; [7]Salford Royal Hospital NHS Trust, Salford, United Kingdom; [8]University Hospital of Würzburg, Wuerzburg, Germany; [9]VU University Medical Centre, 2051 JN Overveen, Netherlands; [10]Vifor Fresenius Medical Care Renal Pharma, Glattbrugg, Switzerland; [11]University Claude Bernard, Pierre Benite, France; [12]Laiko University Hospital, Athens, Greece; [13]Maggiore Hospital, Milan, Italy.*

Background: Sucroferric oxyhydroxide (SFOH) is a non-calcium-, iron-based phosphate binder. The VERIFIE study aims to investigate the real-life safety and effectiveness of SFOH in prevalent dialysis patients with hyperphosphatemia.

Methods: This is a non-interventional, prospective, multicenter, European cohort study (scheduled observation period per patient: 12–36 months; planned enrollment: 1000 patients). The non-interventional design allows the observation of patients in a broad range of settings reflecting routine clinical practice. SFOH initiation was based on the physician's decision and was not influenced by study inclusion.

Results: This interim analysis presents data from 244 patients (mean age: 63.8 [standard deviation: 14.7] years; 64.0% male) included in the safety analysis set, of whom 219 were included in the full analysis set for the evaluation of laboratory parameters (serum ferritin and serum phosphorus). The mean observation period was 129 days. Phosphate binder use at baseline was reported in 64% of patients, mostly sevelamer (55%), calcium-based (39%) or lanthanum (34%). Mean initial dose of SFOH was 1175.4 mg (2.4 pills/day), rising to 1299.4 mg (2.6 pills/day) at the time of this analysis. The large majority of adverse drug reactions reported were gastrointestinal (Table). Serum phosphorus decreased from baseline to last visit by a mean of 0.8 mg/dL (p<0.0001). Serum ferritin levels were not significantly different from baseline by the last visit (p=0.23).

Conclusions: These interim real-world data show that SFOH is well tolerated, and no new safety risks were identified. In addition, SFOH was effective at reducing serum phosphorus in real-world practice.

Funding: Veterans Affairs Support

Table: Key safety and effectiveness measures

Parameter	Time point (N=244)
ADRs, n (%)	90 (36.9)
Serious ADRs, n (%)	8 (3.3)
Treatment discontinuation, n (%)	38 (15.6)
Gastrointestinal ADRs, n (%)	83 (34.0)
Discolored feces	43 (17.6)
Diarrhea	25 (10.3)
Serum ferritin, mean ng/mL (SD)	
Baseline (n=198)	431.1 (373.93)
Last visit (n=110)	444.1 (348.39)
Serum phosphorus, mean mg/dL (SD)	
Baseline (n=209)	6.5 (1.61)
Last visit (n=182)	5.7 (1.72)

ADR, adverse drug reaction; SD, standard deviation

Mineral Bone Disorder Management in Hemodialysis Patients: Comparing PTH Control Practices in Japan with Europe and North America: The Dialysis Outcomes and Practice Patterns Study (DOPPS)

Suguru Yamamoto,[1] Angelo Karaboyas,[2] Hirotaka Komaba,[3] Masatomo Taniguchi,[4] Takanobu Nomura,[5] Brian Bieber,[2] Patricia De Sequera,[6] Anders Christensson,[7] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] Masafumi Fukagawa.[3] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [4]Fukuoka Renal Clinic, Fukukoka, Japan; [5]Medical Affairs Department, Kyowa Hakko Kirin Co Ltd, Tokyo, Japan; [6]University Hospital Infanta Leonor, Madrid, Spain; [7]Department of Nephrology, Skåne University Hospital, Malmö, Sweden.*

Background: High circulating level of parathyroid hormone (PTH) is associated with elevated mortality. While the Japanese Society for Dialysis Therapy suggests a low/narrow PTH target, other international guidelines suggest much higher PTH targets. This discrepancy may help explain better survival in Japanese hemodialysis patients, and we analyzed PTH control practices in Japan compared with other regions.

Methods: We analyzed data from hemodialysis patients with ≥3 measurements of PTH during the first 9 months in DOPPS phase 4 and 5 (2009-2015). PTH control was defined by slope of log (PTH), parameterized as % change per month, and PTH mean was defined by the geometric mean of all measurements over the 9 month run-in period. Distribution of PTH slopes and means were assessed by regions [Europe/Australia/New Zealand (Eur-ANZ), Japan and North America] and dialysis vintage (<90 days, 90 days-1 year and >1 year). Mortality rates were compared across PTH slope and mean using Cox regression models.

Results: Our sample included 6035 patients in Eur-ANZ, 2644 in Japan and 18485 in North America. Mean PTH was much lower in Japan than in other regions across dialysis vintage categories. In patients with dialysis vintage <90 days, PTH level was more likely to decline >5% per month in Japan (49% of patients) vs. Eur-ANZ (34%) and North America(32%). In patients with dialysis vintage >1 year, Japanese patients were most likely to maintain steady PTH (ΔPTH within +/-5% per month: 47% in Japan vs 41% in Eur-ANZ and 41% in North America), with patients in Eur-ANZ and North America more likely to experience increase in PTH. During 13.5 (IQR, 5.9-22.9) months follow-up, prevalent patients with the highest mean PTH (>600 pg/mL) had the highest mortality rate [HR=1.22 (95% CI 1.02-1.47) vs. PTH 200-400 pg/mL]. PTH slope was not clearly associated with all-cause mortality.

Conclusions: PTH control, as measured by keeping a stable PTH level over 9 months, is better in Japan vs. other regions. No additional survival benefit for PTH control was observed, further study is needed to understand the reasons of keeping low PTH levels and its impact on survival advantage in Japan.

FR-PO888

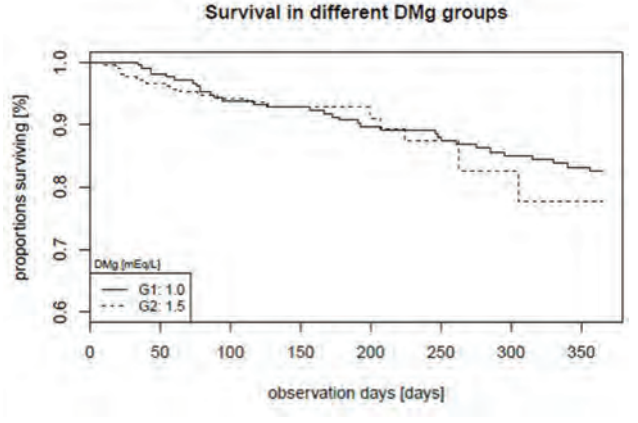
Associations between Dialysate Magnesium, Serum Magnesium, and Mortality: A Retrospective Cohort Study of the Monitoring Dialysis Outcomes (MONDO) Initiative Xiaoling Ye,[7] Adrian M. Guinsburg,[2] Cristina Marelli,[3] Bernard J. Canaud,[1] Stefano Stuard,[2] Xiaoqi Xu,[4] Jeroen Kooman,[6] Frank van der Sande,[6] Albert J. Power,[8] Len A. Usvyat,[5] Yuedong Wang,[9] John T. Daugirdas,[10] Peter Kotanko,[7] Jochen G. Raimann.[7] *[1]FMC Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care, Moron, Argentina; [3]Fresenius Medical Care Argentina, buenos Aires, Argentina; [4]Fresenius Medical Care Asia Pacific, Hong Kong, China; [5]Fresenius Medical Care North America, Melrose, MA; [6]Maastricht University Medical Centre, Maastricht, Netherlands; [7]Renal Research Institute, New York, NY; [8]Richard Bright Renal Unit, Bristol, United Kingdom; [9]University of California - Santa Barbara, Santa Barbara, CA; [10]University of Illinois College of Medicine, Burr Ridge, IL. Group/Team: MONDO initiative.*

Background: Serum magnesium (SMg) associated with mortality and particularly its deficiency substantially increases the risk of adverse outcomes. We studied the relationship between dialysate magnesium (DMg) and SMg and the effects DMg on all-cause mortality in a large global cohort.

Methods: All the patients(pts) started in-center hemodialysis(HD) between 2000 and 2012 were included. Following the first available DMg data point we established a 3 months baseline. All the value were average during baseline. Follow-up defined as 1 year after that. A multivariable regression model was applied to study the association of 1.0 versus 0.75 mEq/L DMg on SMg. Then we used 1:1 propensity score matching (age, gender, catheter, and vintage) to create two cohorts with DMg of 1.0 and 1.5 mEq/L, respectively. We compared survival times between these 2 cohorts using KM analysis, log rank-test and Cox regression analysis adjusted for age, gender, and catheter.

Results: We studied 15,211 pts (57.4 yrs, 58% males, 41% DM, 24% catheter; DMg 0.75: 2481 (16%), 1.0: 12,508 (82%) and 1.5: 222 (1%)]. In multivariate regression accounting for age, nPCR, NLR and albumin, a DMg increase by 0.25 mEq/L (from 0.75 to 1.0 mEq/L) was associated with a SMg increase by 0.09 (95%CI 0.03 to 0.14) mEq/L. Propensity score-matching created 2 well balanced cohorts with DMg of 1.5 and 1.0. Uni- and multivariate survival analysis did not show significant differences between the two DMg groups [**Figure 1**; adjusted HR of DMg 1.5: 1.1 (95% CI 0.6 to 2.0)].

Conclusions: Our results indicate a direct association between DMg and SMg. This finding is of importance, since higher SMg are associated with better outcomes in observational studies. Prospective studies are warranted to further delineate the complex interaction between DMg, SMg, and patient outcomes.



FR-PO889

Effect of Bioelectrical Impedance Analysis-Guided Comparing with Standard Clinical-Guided Dry Weight Assessment on Sleep Quality in Chronic Hemodialysis Patients Sethanant Sethakarun, Pariya Phanachet, Chagriya Kitiyakara, Sirimon Reutrakul, Arkom Nongnuch. *Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Background: Sleep disturbances are common among chronic hemodialysis patients, leading to poor quality of life, increased morbidity and mortality. Hypervolemia has been linked to sleep problems in chronic hemodialysis patients, thus optimizing fluid status might improve sleep quality in such patients. This study aim to compare subjective and objectively measured sleep parameters, using Pittsburgh Sleep Quality Index (PSQI) questionnaire and actigraphy recordings, between bioelectrical impedance analysis (BIA)-guided and standard clinical-guided dry weight assessment during 6 months period.

Methods: We randomly assigned 19 chronic hemodialysis patients with subclinical hypervolemia; defined as clinically euvolemic status despite the ratio of extracellular water to total body water more than 0.4 on BIA, who were poor sleeper (PSQI>5) to either BIA-guided (BIA group) or standard clinical-guided dry weight group (clinical group). The outcomes were changes in PSQI score, and sleep parameters by actigraphy at 1, 3 and 6 months.

Results: Mean age was 63.53 ± 11.12 years and 42.11% were male. The baseline characteristic and sleep quality were comparable. At 3 and 6 months, subjective sleep quality in the BIA group significantly improved as reflected by a greater decline in PSQI score compared to the clinical group [3 months: mean difference -1.8 (-2.98 to -0.63), p= 0.003; 6 months: mean difference -3.11 (-4.31 to -1.92), p<0.01](figure 1). However, sleep parameters by actigraphy were not significantly different between groups.

Conclusions: Better optimization of fluid status using BIA significantly improves subjective sleep quality in chronic hemodialysis patients. This should be further explored in larger clinical trial.

Ultrafiltration Profiling: Association with Clinical Outcomes among Incident Dialysis Patients Scott Sibbel, Adam G. Walker, Steven M. Brunelli. *DaVita Clinical Research, Minneapolis, MN.*

Background: Ultrafiltration (UF) profiling is the practice of varying the UF rate during dialysis in order to mitigate the consequences of decreased effective circulating volume. In practice, UF profiling may be used on a standing basis, a PRN basis, or not at all. We conducted parallel matched analyses comparing standing UF profiling to PRN UF profiling and to no profiling.

Methods: We considered all incident hemodialysis patients at a large dialysis organization (Jan 2010-Jun 2015). We identified all patients who received a first-ever order for standing UF profiling. We considered eligible controls of two types: PRN profile patients, who initiated a first-ever order for UF profiling on a PRN basis in the same vintage month; and patients who had not used UF profiling through the same vintage month. Each standing UF profile patient was matched (separately) to an eligible control of each type based on race and Charlson comorbidity index score using intention-to-treat methods. Rates of death, all-cause hospitalizations, missed dialysis treatments, and episodes of intradialytic hypotension (IDH) were assessed over the subsequent 12 months on an intention-to-treat basis.

Results: No UF profiling (vs standing UF profiling) was associated with lower rates of IDH and hospitalization, but indistinguishable rates of death and missed treatments. PRN UF profiling (vs standing UF profiling) was associated with lower rates of IDH, but higher rates of hospitalization and missed treatments; no difference in death rate was observed.

Conclusions: We did not detect a benefit of standing vs no UF profiling, nor evidence to suggest that PRN UF profiling is superior to standing UF profiling. These data call into question the rationale underlying commonplace use of UF profiling in clinical practice.

FR-PO891

Effects of Hemodialysis, Isolated Ultrafiltration, and Isolated Diffusion on Oxygen Extraction Ratio (OER) Silverio Rotondi,[5] Lida Tartaglione,[4] Luciano Carbone,[6] Maria luisa Muci,[1] Marzia Pasquali,[2] Sandro Mazzaferro.[3] *[1]Policlinico Umberto I Roma, Roma, Italy; [2]Policlinico Umberto I, Rome, Rome, Italy; [3]Sapienza University of Rome, Rome, Italy; [4]sapienza university of rome, Rome, Italy; [5]Nephrology and Dialysis Unit, ICOT Hospital, Polo Pontino, Sapienza University of Rome, Latina, Italy; [6]ICOT, Latina, Italy.*

Background: Hemodialysis sessions cause tissue hypoxia whis is not routinely measured. OER (n.v. 25-30%), obtained as the ratio between SaO_2 and Central Venous Oxygen Saturation ($SvcO_2$), is employed in ICU to quantify tissue hypoxic stress. We aimed to evaluate if the OER : a. Increases during dialysis session; b. is different after long (HD_{long}) or short (HD_{short}) dialysis intervals ; c. is differently affected by isolated ultrafiltration (iUf) or isolated diffusion (iD).

Methods: We enrolled 20 clinically stable patients on HD since >6 months, with Central Venous Catheter. We measured SaO_2 (by capillary oxymeter) and $ScvO_2$ (by blood gas analysis) to calculate the OER basally, 15', 30', 60', 120' and end of HD_{Long}. In 10 of them, OER was re-measured in the following two HD_{Short} sessions. Further in all patients, OER was re-measured during the first hour of the first and second HD_{Short} performed by applying, alternatively, iUF or iD. During each HD, UF rate was kept at<10 ml/kg/h and symptoms were recorded.

Results: In the HD_{Long} session, OER increased within 30' (post hoc test p<.05) and then progressively up to the end of HD, by 38%. Mean basal OER of HD_{Long} (34,4±7), HD_{Short1} (33,8±7) and HD_{Short2} (36,2±6) were not different (Tab.1). In the two HD_{Short} sessions, OER changes overlapped with those in HD_{Long}. During the first hour of the HD_{Short} session with iUF, the increment of OER was not significant, at variance with the significant increase recorded during the HD_{Short} with iD (Tab. 1). All HD sessions were asymptomatic with no change in blood pressure (systolic or diastolic) or heart rate. During sessions, no significant change was evident for capillary SaO_2 (98±1 %), while $ScvO_2$ progressively decreased.

Conclusions: a. OER increases significantly during HD sessions; b. HD intervals do not modify the adaptive process to hypoxia; c. iD affects this adaptive response possibly more than iUF. OER might be a marker of HD stress, potentially useful in fragile patients.

Extended Weekly Hemodialysis Hours Selectively Improves Kidney Disease-Specific Quality of Life: A Secondary Analysis of the ACTIVE Dialysis Trial Brendan Smyth,[1,2] Oliver van den Broek-Best,[2] Li Zuo,[3] Nicholas A. Gray,[4] Christopher T. Chan,[5] Janak R. de Zoysa,[6] Kirsten Howard,[2] Kris Rogers,[1] Meg J. Jardine,[1] Vlado Perkovic.[1] *[1]The George Institute for Global Health, UNSW, Sydney, NSW, Australia; [2]University of Sydney, Sydney, NSW, Australia; [3]Peking University People's Hospital, Beijing, China; [4]Sunshine Coast University Hospital, Birtinya, NSW, Australia; [5]Toronto General Hospital, Toronto, ON, Canada; [6]Waitemata District Health Board, AUCKLAND, New Zealand.*

Background: End-stage kidney disease is associated with high symptom burden and poor quality of life (QOL). The ACTIVE Dialysis trial randomized 200 hemodialysis (HD) patients to standard (median 12) or extended (median 24) weekly HD hours for 12 months. Extended hours HD did not affect EQ-5D utility-based QOL but had a small but significant effect on generic health-related QOL, measured by the SF-36. We aimed to determine the impact of extended hours HD on kidney disease-specific QOL.

Methods: QOL assessments were administered by blinded interviewers at 3-monthly intervals during the trial. The Kidney Disease Component Summary (KDCS) is a disease-specific summary measure ranging from 0-100 including disease-specific dimensions such as disease impact, dialysis delivery and symptoms. The average intervention effect on KDCS was determined using mixed linear regression adjusted for time and baseline score. Pre-specified subgroups were defined by residence in China or other, dialysis in an institution or at home and dialysing for more or less than 6 months.

Results: Mean baseline KDCS scores were similar in participants randomised to standard and extended weekly dialysis hours (66.6 [95% CI 64.1-69.1] and 66.0 [95%CI 63.2-68.7] respectively). Extended weekly HD hours improved mean KDCS by 3.48 points (95%CI 1.44-5.51, p=0.0009). Subgroup analysis demonstrated the improvement in KDCS was individually significant in those from China, dialysing in an institution or of dialysis vintage >6 months (4.54 [95%CI 2.04-7.05], 4.05 [95%CI 1.83-6.27] and 4.20 [95%CI 1.92-6.48] respectively, all p<0.001).

Conclusions: Extended hours HD is associated with improvement in kidney disease-specific QOL despite having no effect on overall EQ-5D measured QOL. The impact in defined patient populations warrants further investigation. NCT00649298

Evaluation of Sex Difference in Fluid and Nutritional Statuses at the Initiation of Hemodialysis Using a New Bio-Impedance Spectroscopy Device Tatsunori Toida,[3,1] Shin Fukunaga,[1] Reiko Toida,[2] Shigehiro Uezono,[2] Hideto Nakagawa,[3] Yuji Sato,[3] Shouichi Fujimoto.[3] *[1]Nobeoka Prefectural Hospital, Nobeoka, Japan; [2]Chiyoda Hospital, Hyuga, Japan; [3]University of Miyazaki, Miyazaki, Japan.*

Background: Recently, the sex differences in health outcomes among patients undergoing maintenance dialysis were reported (JASN, 2017). The maintenance of an appropriate body fluid volume and nutritional status in hemodialysis patients is important for improving their prognoses. We herein cross-sectionally evaluated sex difference in over-hydration (OH) and the nutritional status (lean tissue index; LTI and skeletal muscle index; SMI) at the initiation of hemodialysis (HD) using a bio-impedance spectroscopy device (Body Composition Monitor, BCM).

Methods: 119 patients at the initiation of hemodialysis (female vs. male, 49 vs. 70; mean age, 69.7 ± 11.2 years; mean BMI, 23.9 ± 4.5 kg/m2, 59 diabetic patients) were enrolled between February 2015 and December 2016 at Nobeoka Prefectural Hospital and Chiyoda Hospital. Measurements were performed before HD in the early phase after the initiation of HD by BCM and relationships between clinical data were also assessed. Furthermore, the nutritional statuses of HD patients in the present study were compared with our previous findings obtained in healthy Japanese volunteers (Biomed Mater Eng, 2015).

Results: Patients with diabetes or pleural effusion showed significantly higher OH levels compared to those without diabetes or pleural effusion. Serum NT-proBNP values and BMI were positively correlated with OH levels, respectively. OH level was not different between male and female. LTI and SMI were negatively correlated with age in males, respectively, but not in females. LTI and SMI were not correlated with the levels of serum albumin or C-reactive protein. These indexes were not different between patients with or without diabetes. In males, LTI and SMI were lower in HD patients than in healthy volunteers, but not in females.

Conclusions: Present study suggests that BCM is a useful tool for evaluating the body fluid and nutritional status in patients at the initiation of HD. Furthermore, malnutrition is a concern in males at the initiation of HD. Follow-up observations using BCM may be useful for managing HD patients.

HEMO Study Results Suggest that "Clinically Negligible" Residual Kidney Function (RKF) Is a Significant Contributor to Uremic Solute Clearance Stephanie M. Toth-Manikowski,[2] Tammy L. Sirich,[4] Thomas H. Hostetter,[1] Seungyoung Hwang,[2] Josef Coresh,[5] Neil R. Powe,[3] Tariq Shafi.[2] *[1]Case Western Reserve University, Cleveland, OH; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Priscilla Chan and Mark Zuckerberg San Francisco General Hospital & University of California SF, San Francisco, CA; [4]Stanford University, Palo Alto, CA; [5]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD.*

Background: RKF is thought to exert its beneficial effects through improved clearance of uremic toxins but the level of native kidney function where this clearance becomes negligible is not known. The HEMO study excluded patients with RKF >1.5 mL/min, as a level below was regarded as "clinically negligible." We aimed to assess whether the levels of non-urea solutes associated with clinical outcomes differed among patients with this "clinically negligible" RKF compared to those with no RKF.

Methods: We measured 8 non-urea solutes in plasma from 1,280 patients of the HEMO Study 3-6 months post-randomization. We calculated the relative difference in solute levels among patients with and without RKF and compared it to the relative difference achieved by high vs standard hemodialysis (HD) dose (mean Kt/Urea 1.7 vs 1.3, respectively).

Results: At baseline, 34% of patients had "clinically negligible" RKF (mean 0.7±0.4 mL/min); 66% had no RKF. Those with RKF were older, had more recent onset of dialysis, and had lower UF requirements than those without RKF. Patients with RKF had significantly lower non-urea solute levels than patients without RKF. The differences were comparable or more pronounced than in those randomized to high HD dose (Table).

Conclusions: Even at a very low level, RKF is not "negligible" as it continues to provide clearance of solutes associated with clinical outcomes.

Post-Hospitalization Dialysis Facility Processes of Care and Pulmonary Edema-Related Hospital Readmissions among Hemodialysis Patients Laura Plantinga,[1] Janice P. Lea,[1] Tahsin Masud,[1] John M. Burkart,[3] Bernard G. Jaar.[2] *[1]Emory University, Atlanta, GA; [2]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [3]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Both dialysis facilities and hospitals are accountable for 30-day readmissions among U.S. hemodialysis (HD) patients. Steps taken at the dialysis facility post-hospitalization may prevent pulmonary edema-related (PER) readmissions. We examined the association of post-hospitalization HD processes of care with PER readmissions.

Methods: Using electronic health record (EHR) data from 23 Southeastern dialysis facilities, starting in 2010 and linked with national registry data for complete follow-up through 2014, we identified 1454 in-center HD patients who had ≥1 hospitalization (first=index), survived ≥30 days, and had ≥3 contiguous dialysis sessions following the index discharge. Readmissions were defined as admissions that occurred within 30 days of the index discharge; PER readmissions were further defined by the presence of discharge codes for pulmonary edema, fluid overload, and/or congestive heart failure (CHF). Indicators of processes of care were defined by EHR data as present vs. absent in the first 3 sessions post-index discharge.

Results: Overall, 19.9% of patients were readmitted, and 8.3% had PER readmissions (38.7% of all readmissions). Compared to patients who did not, patients who had PER readmissions were slightly older (63.9 vs. 61.6 years; *P*=0.09), less likely to be black (54.6% vs. 63.4%; *P*=0.09) and more likely to have history of CHF (76.0% vs. 39.7%; *P*<0.001) or index admissions also related to pulmonary edema (72.7% vs. 35.1%; *P*<0.001). New dialysis orders, particularly with target weight changes, were more common among those with PER readmissions. Higher epoetin dose was less common in readmitted patients; drawing of labs was not different by readmission status (Table).

Conclusions: Patients who had PER readmissions were more, not less, likely to have target weight changes in dialysis orders and medication reductions within 3 sessions of index admission discharge. In general, these results suggest that usual post-hospitalization care at the dialysis facility may not prevent PER or all-cause readmissions.

Factors Associated with Higher Risk of Emergency Department Use within 30 days of Hospital Discharge Jonathan H. Segal, John Stephen, Tempie H. Shearon, Bin Nan, Caitlin Hanna, Claudia Dahlerus. *University of Michigan, Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

Background: Chronic dialysis patients visit the emergency department (ED) at 4-fould higher rates than Medicare beneficiaries in the general population yet little is known about outpatient ED use after hospital discharge. We examined clinical and sociodemographic/socioeconomic (SDS/SES) factors associated with increased ED use within 30 days after hospital discharge in the US Medicare dialysis population.

Methods: Data on ED visits (outpatient or observation stays) for dialysis patients in 2014 were obtained from Medicare Outpatient Claims. Adjustment was made for patient and area level clinical and SDS/SES characteristics. A two stage multivariate logistic regression model determined odds of an outpatient ED encounter within 30 days of an index hospital discharge adjusted for these SDS/SES and clinical factors.

Results: 14.5 % of the 423,165 index discharges among 201,674 unique patients in 2014 were followed by an outpatient ED visits within 30 days. Females, younger age, longer ESRD vintage and black race were associated with higher odds of an ED encounter within 30 days. Dually-eligible (DE) patients (Medicare and Medicaid) had 13% higher odds compared to Medicare Primary; Medicare secondary patients/Medicare HMO had 54% lower odds of an ED encounter.

Conclusions: Outpatient ED encounters within 30 days after a hospital discharge occur frequently for chronic dialysis patients. Patient characteristics of SDS/SES (DE status, younger age, female sex) are associated with a higher risk of ED use following a hospital discharge. These ED visits represent an opportunity for greater coordination to reduce potentially preventable acute care.

Effects of Predictive Modeling Assisted Care Interventions on Hospitalization Rates in Hemodialysis Patients David F. Sweet, Sheetal Chaudhuri, Hao Han, Anthony Chamberas, Dugan Maddux, Marta Reviriego-Mendoza, John W. Larkin, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Hemodialysis (HD) patients continue to have high hospitalization rates regardless of advances in the treatment of end stage renal disease. We have developed and deployed a predictive model including more than 200 variables to identify in-center Hemodialysis (HD) patients at an increased risk for a hospitalization. In the pilot Dialysis Hospitalization Reduction Program (DHRP), we perform early identification of patients at risk for a critical event which may aid clinicians to intervene in a timely manner. We thus investigated the impact of DHRP on hospitalization rates in HD patients.

Methods: A total of 72 Fresenius Kidney Care clinics were included in the pilot; 141 clinics in neighboring regions to DHRP clinics were used as controls. We implemented the pilot in South Alabama/Florida Panhandle Region since Jan of 2015. For patients identified at high risk of hospitalization, Social Workers assessed and placed them on an intensive program employing community resources and integrated care. The dietitians utilized a high risk assessment looking at weight, nutrition, and access to food and supplements. The resident nurses assessed current care for anemia, adequacy, access, prior hospitalizations, and blood pressures. We compared mean quarterly hospital admission and readmission rates per patient year between groups.

Results: We analyzed the results 24 months after the start of the program and we found that DHRP patients exhibited: 1) 23% reduction in average yearly hospital admission rate compared to controls, and 2) 3.6% lower average yearly hospital readmission rate compared to controls. When fitting a linear regression model, both the quarterly hospital admission rate and quarterly readmission rate for the control group indicated an increasing trend with time, while the DHRP group indicated a small decreasing trend. Quarterly differences between groups for both admission rate and readmission rate increased over time ($p < 0.003$).

Conclusions: These findings suggest that care coordination based on predictive risk assessment in the DHRP is associated with lower hospitalization rates in HD patients, compared to controls. Further studies are needed to confirm these results.

FR-PO898

In-Patient Hospitalization of Dialysis Patients in Canada: Opportunities to Decrease the Burden on Patients Juliana Wu,[1] Michael Terner,[1] Kelvin Lam,[1] Frank Ivis,[1] Greg Webster,[1] Scott Klarenbach.[2] *[1]Canadian Institute for Health Information, Toronto, ON, Canada; [2]University of Alberta, Edmonton, AB, Canada.*

Background: All cause hospitalization rates for dialysis patients is high, with 1.7 hospitalizations per patient-year reported in the United States. In Canada, the Canadian Organ Replacement Register program at the Canadian Institute for Health Information examined hospitalization in Canada for both all-cause, and infections related to dialysis treatment.

Methods: A cohort of 38,369 incident dialysis patients between 2005 and 2014 were included in the study. Crude rates for hospitalization (all cause and infection) and in-hospital mortality were calculated. A frailty model was used to calculate hazard ratios for covariates including age, sex, race, income, comorbidity, primary diagnosis, year of dialysis start, care type, modality and pre-dialysis hospitalization.

Results: The all-cause hospitalization rate for dialysis patients was 1.1 hospitalizations per patient-year. Pediatric patients (HR = 2.73; p<0.001) and Indigenous patients (HR = 1.20; p<0.001) had higher risk than peers for hospitalization, and patients on home hemodialysis and peritoneal dialysis (HR = 0.84; p<0.001) had a lower risk of being hospitalized than in-centre patients. Similar results were observed for hospitalization for infections related to dialysis. All-cause hospitalizations were more frequent at dialysis initiation and decreased over time for both patients receiving peritoneal or hemodialysis.

Conclusions: Targeted national interventions such as promoting greater arteriovenous fistula use to reduce catheter infections, earlier transplantation for pediatric patients and expanding programs designed to improve care to Indigenous patients could be used to reduce the rate of hospitalization for higher-risk dialysis patients in Canada.

FR-PO899

Impact of Extended Weekly Hemodialysis Hours on Diverse Health-Related Quality of Life Domains: A Secondary Analysis of the ACTIVE Dialysis Trial Oliver van den Broek-Best,[1] Brendan Smyth,[2,1] Li Zuo,[3] Nicholas A. Gray,[4] Christopher T. Chan,[5] Janak R. de Zoysa,[6] Kirsten Howard,[1] Kris Rogers,[2] Vlado Perkovic,[2] Meg J. Jardine.[2] *[1]University of Sydney, Lewisham, NSW, Australia; [2]The George Institute for Global Health, UNSW, Sydney, NSW, Australia; [3]Peking University People's Hospital, Beijing, China; [4]Sunshine Coast University Hospital, Birtinya, NSW, Australia; [5]Toronto General Hospital, Toronto, ON, Canada; [6]Waitemata District Health Board, AUCKLAND, New Zealand.*

Background: The SF-36 quality of life (QOL) tool has been validated in multiple populations and conditions. The ACTIVE Dialysis trial randomised 200 haemodialysis (HD) recipients to standard (median 12) or extended (median 24) weekly HD hours for 12 months with no impact on overall EQ-5D utility-based QOL. Extended hours led to small but significant improvements in both SF-36 physical (PCS) and mental (MCS) composite scores (PCS 2.30, 95%CI 0.52-4.07; MCS 2.54, 95%CI 0.42-4.65). We aimed to examine the impact of extended weekly dialysis hours on individual SF-36 domains.

Methods: Generic health-related QOL was assessed by blinded interviewers every 3 months with SF-36 which includes PCS, MCS and 8 domains. The average intervention effect was calculated using mixed linear regression adjusted for baseline score and time.

Results: ACTIVE dialysis participants had a mean age of 51.6±11.5 years, with 62% recruited from China and 75% dialysing in-center. Extended dialysis had a significant, positive effect on 4 of the 8 domains: General Health Perceptions (7.33, 95%CI 2.85-11.81, p=0.002), Social Functioning (6.70, 95%CI 1.14-12.25, p=0.02), Role Emotional (8.17, 95%CI 0.03-16.30, p=0.05) and Mental Health (3.30, 95%CI 0.15-6.45, p=0.04). Although not reaching statistical significance, point estimates in other domains were also in a consistent positive direction: Physical Functioning (3.54, 95%CI -0.67-7.74, p=0.1), Role Physical (6.67, 95%CI -0.95-14.28, p=0.1), Bodily Pain (4.92, 95%CI -0.24-10.08, p=0.06) and Vitality (3.46, 95%CI -0.93-7.84, p=0.12).

Conclusions: Predominantly in-center extended weekly HD hours may have a positive effect on SF-36 measures beyond purely physical domains. Dialysis delivery involves multiple dimensions including biochemical, haemodynamic, social and health service access. Better understandings of the mechanisms for its impact on QOL are needed. FR-PO900

Hemodiafiltration and Mortality: Data from the Real World Ana Fernandes. *Centro Hospitalar Setubal, Setubal, Portugal.*

Background: Mortality remains high for hemodialysis (HD) patients and no single intervention has shown to decrease mortality. Online hemodiafiltration (HDF) is a promising technique, but randomized trials have shown inconsistent results.

Methods: We conducted a cohort study including all incident patients that started dialysis in 40 randomly selected units over a two-year period, and these patients were followed for at least 5 years, or until death or loss to follow up whichever occurred first. A descriptive statistic was used to characterize the population. To analyse time to mortality we used the Cox's Proportional Hazard model to evaluate the covariates that may modify the outcome. Covariates included in the model were comorbidities and vascular access type.

Results: 1,229 patients were included. Mean age was 65.2±15.5 years, 40.4% were male. Diabetes was the most frequent cause of CKD. At baseline, 23% had coronary artery disease (CAD), 43.7% had diabetes (DM), 31.3% had cerebrovascular disease (CBD) and 2.4% peripheral artery disease (PAD). Vascular access at the beginning of dialysis was a catheter in 45.9% of the patients, an arteriovenous fistula in 49.7% and a graft in 4.4%. Eight per cent of the patients were undergoing low flux HD, 66.5% high flux HD and 22% HDF. Three per cent of the patients were taking a calcimimetic, 37,9% were receiving a vitamin D analogue and the most common phosphate binding utilized was calcium carbonate. Median time of follow up was 48 months (Interquartile range 22-64) Univariate analysis showed that CAD (hazard ratio [HR] 1.89; 95%CI 1.54-2.32), DM (HR 1.32; 95%CI; 1.09-1.60), and PAD (HR 2.05; 95%CI 1.22-3.44) were associated with increased mortality. In multivariate analysis only CAD was associated with an increased risk of death (HR 2.00; 95%CI 1.61-2.46). Hemodiafiltration, as compared with low flux dialysis, was associated with a decreased mortality (HR 0.34, 95%CI 0.49-0.89). There was no difference in the risk of death between low-flux and high-flux hemodialysis (HR 1.19; 95%CI 0.92-1.55). Median survival time was not yet reached but it was longer in the hemodiafiltration group. (p< 0,0001)

Conclusions: This study suggests that HDF, as compared with low-flux dialysis, may reduce the risk of mortality. The magnitude of the effect size is possibly overestimated by the observational nature of study.

FR-PO901

Opioid Overdose Hospitalizations with Patients with ESRD – Nationwide Trends and Outcomes Swati Sakhuja,[2] Ankit Sakhuja,[1] Kianoush Banaei-Kashani.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Opioid overdose is responsible for more deaths than firearms or motor vehicle crashes in the United States. Recent studies have shown opioid use to be widely prevalent in end stage renal disease (ESRD) patients, however, epidemiology and outcomes of opioid overdose in this population are unclear.

Methods: Using data from National/Natiowide Inpatient Sample database from year 2000-2013, we identified patients 20 years or older with opioid overdose admissions and those with ESRD using ICD-9-CM codes. Using data from US Census and USRDS render, we assessed the trend of incidence of opioid overdoses in ESRD and general population. We also examined the associated mortality and if ESRD is an independent predictor of mortality in these patients in a model adjusted for age, sex, race, primary payer, Charlson's score, hospital bed size, volume, region, location & teaching status, use of mechanical ventilation, classification of poisoning as suicidal, homicidal, accidental or unknown and year of admission.

Results: Of total 558,737 opioid overdose admissions, 7496 (1.3%) had ESRD. The incidence of opioid overdose (per 100,000 population) increased from 92 to 183 in ESRD and 19 to 31 in general population (Fig 1). Patients with ESRD were more often in 45-79 yr age-group, blacks or Hispanic and with higher co-morbidities. Inpatient mortality was higher in patients with ESRD (4.0% vs 2.5%; p<0.001). In addition, having ESRD was an independent predictor for mortality in these patients (OR 1.42; 95% CI 1.02-1.98).

Conclusions: The incidence of opioid overdose is higher in ESRD patients and is rising at a rapid pace. ESRD patients with overdose have higher mortality and ESRD is an independent predictor for mortality in patients with opioid overdose.

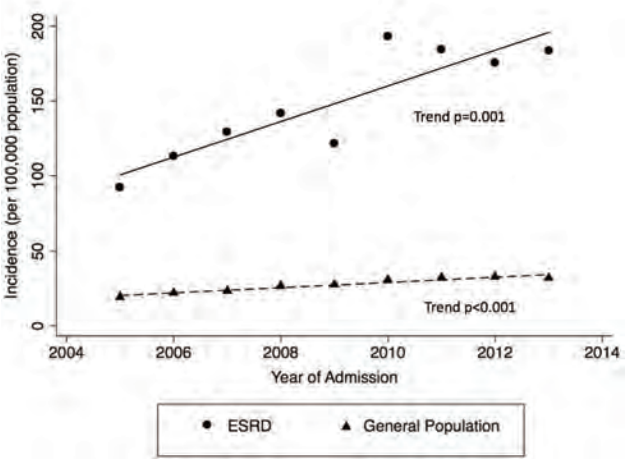

Fig 1: Trends of incidence of opioid overdose in ESRD and general population

FR-PO902

Novel Prediction Score for Early Death upon Transition to Dialysis: A Veterans Affairs (VA) and Kaiser Permanente Southern California (KPSC) Big Data Approach Yoshitsugu Obi,[1] Danh V. Nguyen,[1] Hui Zhou,[2] Elani Streja,[1] Melissa Soohoo,[1] Lishi Zhang,[1] Yanjun Chen,[1] Miklos Z. Molnar,[3] John J. Sim,[2] Steven J. Jacobsen,[2] Connie Rhee,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]Kaiser Permanente Southern California, Pasadena, CA; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Mortality is exceptionally high during the first year among incident dialysis patients. We aimed to establish a risk prediction tool for early mortality based on pre-ESRD conditions.

Methods: Among 35,853 US veterans who transitioned to dialysis over 6.5 years (10/2007–03/2014), we developed new risk scores based on demographics, primary ESRD causes, comorbid conditions, and pre-ESRD laboratory data. We stratified patients by low and high eGFR (i.e., <15 and ≥15 mL/min/1.73m^2, respectively), and then applied a Cox model with AIC-based backward variable selection to 14-month survival data. The final model was validated among 4,284 KPSC patients over 8.75 years (01/2007–09/2015).

Results: Observed 1-year mortality was 27% in the VA cohort, and was not significantly different from predicted mortality. C-index values in the VA cohort were 0.71 and 0.67 among patients with low vs. high eGFR, respectively. The external validation using the KPSC cohort showed C-index values of 0.77 and 0.74 among men vs. women with low eGFR, respectively, and 0.71 and 0.67 among men vs. women with high eGFR, respectively.

Conclusions: New risk scores for early mortality have been developed and externally validated among a cohort of racially, ethnically, and gender diverse ESRD patients transitioning to dialysis. It would help with the identification of a high risk population and provide information that may contribute to dialysis initiation planning.

First-Year Mortality among Patients Initiating Hemodialysis with a Functional Arteriovenous Fistula Compared with Peritoneal Dialysis Purna Mukhopadhyay,[1] Kenneth J. Woodside,[2] Keith McCullough,[1] Kaitlyn Ratkowiak,[1] Douglas E. Schaubel,[2] Ronald L. Pisoni,[1] Vahakn B. Shahinian,[2] Rajiv Saran.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Comparison of initial outcomes between in-center HD and PD are subject to bias, as typically PD patients (pts) are younger, healthier, & may have received longer pre-ESRD care. Restricting comparisons to better prepared pts who initiate HD with a functional arteriovenous fistula at start of renal replacement (HDAVF) may minimize this bias.

Methods: Five annual cohorts (USRDS 2010-2014, CMS Form 2728) of incident HDAVF pts (N=81,850) & PD pts (N=47,830) were followed up to 1 year for the outcome of death. Death & time at risk for cohorts were determined in each of 12 consecutive 30-day segments, censoring for transplantation, switch to PD (or HD), recovery of renal function, loss to follow-up, or end of study. Death rates are expressed per 100 patient years (PY). Unadjusted and adjusted hazard ratios for death averaged over 2010-2014 were calculated for four 90-day risk periods.

Results: HD pts were on average older (64 vs 57 years), male (63.4% vs 56.8%), had received pre-ESRD care (89% vs 85.8%), & had greater comorbid burden at start of ESRD. The average unadjusted mortality rate for the HD cohort was higher, with 9.9 PY deaths in the first 30-days vs 5.6 PY deaths for PD. The hazard ratio of HD vs. PD in the unadjusted model was 1.6 ($p < 0.001$) in the 0-90 day period, declining to 1.2 ($p < 0.001$) post-180 days. In the adjusted model, the HR for first 30 days was 1.05 ($p = 0.34$), & decreased to 0.88-8.82 ($p < 0.01$) in the post-90 day period (Figure).

Conclusions: After accounting for pt characteristics, those who start renal replacement therapy on HDAVF appear to have a survival advantage over those that initiate with PD, particularly after 90 days. These findings could guide providers in advising the patients on modality & vascular access choice at dialysis start, have policy implications, & provide impetus for future research.

Options Education before Initiation of Dialysis Is Associated to Improved Hospitalization and Mortality Rates Marta Reviriego-Mendoza, Yue Jiao, John W. Larkin, Rob Lynch, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: KDOQI guidelines recommend that chronic kidney disease patients receive options education to learn optimal ways to prepare for dialysis. Little is known about the impacts of options education on patient outcomes after the progression to end stage renal disease (ESRD). We investigated if options education is associated with improved hospitalization and mortality outcomes in incident dialysis patients.

Methods: We studied data from incident Fresenius Kidney Care (FKC) patients who initiated dialysis between 2009 and 2016. Patients were grouped by enrollment in FKC options education prior to initiating dialysis or not, as well as whether patients started dialysis as an outpatient or inpatient. In these groups, we calculated and compared the mean annual hospital admission and mortality rate during the first 120 days of dialysis.

Results: We analyzed data from a total of 300,818 patients; of these, 68,721 patients received options education prior to initiating dialysis. Throughout 2009-2016, patients who received options education generally exhibited lower rates of hospital admissions and mortality during the first 120 days of dialysis, as compared to those who did not receive education. Similar findings were observed, yet less pronounced, for admission and mortality rates in patients starting dialysis as an inpatient versus outpatient. Specifically, in 2016 outpatients without education had 1.74 admissions per patient year (ppy) and 0.19 deaths per 100 patient years (p100py). When compared to those with education, we observed a 23.6% decrease in admissions (1.33 admissions ppy) and a 52.6% decrease in death rate (0.09 deaths p100py). Inpatients without education had 2.1 admissions ppy and 0.27 deaths p100py, while patients with options education were observed to have a 7.14% decrease in admissions (1.95 admissions ppy) and a 37% decrease in death rate (0.17 deaths p100py).

Conclusions: The analysis herein indicates that receiving options education before progression to ESRD is associated with lower rates of hospital admissions and mortality in the incident dialysis period. More analyses are needed to confirm these observations.

Race, Ethnicity, and End-of-Life Care in US Dialysis Patients, 2000 to 2011 Robert N. Foley,[2] Paul E. Drawz,[2] Donal J. Sexton,[1] Scott Reule.[2] *[1]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland; [2]University of Minnesota, Minneapolis, MN.*

Background: End-of-life care is an increasingly prominent consideration, especially in situations where death appears imminent and quality of life is poor. As little is known regarding potential racial and ethnic disparities, we performed a national study to determine whether end-of-life care in US dialysis patients was subject to racial or ethnic disparity.

Methods: Retrospective United States Renal Data System files were used to examine the primary outcome, a composite of withdrawal of dialysis and death in a non-hospital or hospice setting (2000 to 2011, N=910,559). The following racial-ethnic groups were examined: (non-Hispanic) white, African American, Native American, Asian; Hispanic. Logistic regression was used to calculate odds ratios for end-of-life care outcomes per race-ethnicity.

Results: The primary outcome was less likely in patients from any minority group (10.1%) than in the non-Hispanic white population (21.5%, *P*-Value < 0.001). Corresponding values for dialysis withdrawal, hospice and non-hospital death were 16.3% Vs. 30.8%, 8.8% Vs. 15.7% and 33.1% Vs. 45.0%, respectively (*P*-Value < 0.001 for each comparison). After extensive covariate adjustment, the primary outcome was less likely in the combined minority group than in the white population (adjusted odds ratio [AOR] 0.53, 95% confidence interval [CI] 0.53-0.53, *P*-Value < 0.001); within individual minority groups, AOR values arrayed as follows (Vs. white, *P*-Value < 0.001 for each):

non-Hispanic Asian, AOR 0.43 (95% CI 0.41,0.46); non-Hispanic African American, AOR 0.48 (95% CI 0.47,0.49); non-Hispanic Native American, AOR 0.64 (95% CI 0.60, 0.68); Hispanic AOR 0.71 (95% CI 0.69,0.73). Minority-associated AORs for the primary outcome were < 1 in all 44 subgroups examined.

Conclusions: Compared to their non-Hispanic white counterparts, substantial, graded, unexplained disparities in end-of-life care practices appear to be present in all racial and ethnic minority groups.

FR-PO906

Challenges to Conducting Kidney Palliative Care Research Dana Assis,[1] Rebeca Wright,[2] Jennifer S. Scherer.[3] *[1]Nephrology, NYU School of Medicine, New York, NY; [2]Johns Hopkins University, Baltimore, MD; [3]NYU School of Medicine, New York, NY.*

Background: Despite having significant symptom burden and decreased quality of life, patients with advanced kidney disease have limited exposure to palliative care. This is partly explained by lack of research and evidence for the field. We report on challenges to conducting research in an outpatient kidney palliative care clinic (KPCC).

Methods: Patients with ESRD or CKD stage IV/V and their caregivers were approached to participate in a interview study on their experience in a KPCC. Consent was obtained in person during clinic visits from Jan - June 2017.

Results: Thirty three patients were referred to KPCC, with a no show rate of 18%. Fifteen patients met inclusion criteria; ten patients and three caregivers were consented. Cognitive impairment or psychiatric diagnosis led to patient exclusion. Hospitalization, fatigue, or pain led to attrition after consent and the potential bias towards a healthier population being interviewed. Some patients were confused by palliative care or became emotionally distressed during the interview. Patients could stop interviews and supportive conversations took place, however, maintaining a focus on the research question rather than immediately addressing clinical needs was complex. Logistically the consent process was difficult given patients had to stay past their already 60 minute long appointment. Patient physical and cognitive vulnerability, the emotional nature of palliative care topics, and provider-researcher conflict were observed challenges.

Conclusions: We uncovered barriers to palliative care research that are unique to patients living with advanced kidney disease. Future kidney palliative care research will need to consider the patient's emotional and physical state as well as the provider-researcher challenge when crafting study design to encourage patient participation and ongoing study of this essential field. *Funding: ASN Small Grants Program for Scholarly Work in Geriatric Nephrology and Renal Palliative Care*

Advanced Care Planning (ACP) among CKD and ESRD Patients: Kaiser Permanente Northern California (KPNC) Experience Sharina Belani,[1] Joanna Mroz.[2] *[1]Nephrology, Kaiser Permanente, San Rafael, CA; [2]The Permanente Medical Group, Oakland, CA.*

Background: Patients with advanced CKD and ESRD face difficult choices around extending life and managing quality of life with treatment burden. Yet, ACP choices related to dialysis therapy are rarely addressed. Nephrologists identify multiple barriers including lack of time, communication skills, and supportive tools. KPNC is an integrated health care delivery system providing care to more than 35,000 advanced CKD and 4,000 ESRD patients. KPNC Nephrology operationalized a structured ACP program called Life Care Planning (LCP) based on Respecting Choices® that follows the trajectory of CKD patients.

Methods: The KPNC LCP Nephrology program is an organized process to discuss future health care decisions and to create a written plan based on patient values and current health status. The program is operationalized with a three step staged approach using standardized communication including scripted conversations delivered by trained facilitators. First Steps is targeted to CKD 3 and 4 patients. Next Steps is targeted to prevalent ESRD patients on dialysis focusing on critical functions and trade-offs with dialysis therapy. Advanced Steps is targeted to ESRD patients with a predicted survival of less than 12 months based on clinical indicators. Registries in our EMR are used to identify at risk nephrology patients and identify the appropriate LCP step.

Results: Currently, 30% of our prevalent advaned CKD patients were able to both identify a decision maker for health care and provide verbal or written documentation in our EMR. Among our prevalent ESRD patients on dialysis, more than 30% of these patients have been invited to a Next Steps facilitated discussion and 16% of patients completed the discussion. Finally, 20% of highest risk ESRD patients have completed the Advanced Steps.

Conclusions: As an integrated health care system, KPNC is well suited to provide ongoing ACP and serious illness conversations for Nephrology patients. Future research is needed to identify effect of our LCP model at end of life including concordance with patient's identified wishes.

FR-PO908

External Validation of a Short-Term Prognostic Model for Patients Who Are on Maintenance Hemodialysis Wonngarm Kittanamongkolchai,[2] M. Lourdes Gonzalez Suarez,[1] James R. Gregoire.[1] *[1]Mayo Clinic, Rochester, MN; [2]Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Simple and accurate instruments for prognostication are needed to enable nephrologists to identify dialysis patients who have a poor prognosis and benefit from palliative care and advance care planning. Prognostic models have been developed but external validation studies are scarce. We aimed to externally validate a short-term prognostic model among our dialysis patients.

Methods: Between October 1 to October 31 2015, all of the adult HD patients (n =89) at a single dialysis facility in Rochester, MN were screened. Patient charts were reviewed for actuarial predictors (age, serum albumin, dementia and peripheral vascular disease) and nephrologists answered the "surprise" question, "Would I be surprised if this patient died within the next 6 months?". One-year survival was calculated using the prognostic calculator tool derived from a study by Cohen et al[1] (H:\QI palliative\ Prospective study\Prognosis calculator.htm) with each patient's individual covariates. Survival was monitored for 12 months. We assessed the predictive accuracy of the short-term prognostic model by calculating c-index based on the receiver operating characteristic curve.

Results: The mean predicted 1-year mortality was 19% compared with the observed mortality of 12%. The model had a C-index of 0.82 (p = 0.0001). Thirty eight percent of patients with 1-y predicted survival rate in the lowest quartile (equal or less than 66%) died compared to 3% of those with 1-Y predicted survival rate more than 66%. As seen in Figure 1, the model successfully predicted which patients had worse and better survival over time.

Conclusions: The short-term prognostic tool for dialysis patients may be of value for clinicians to improve end-of-life care by providing more accurate prognostic information. Reference: 1. Cohen LM, et al. Clin J Am Soc Nephrol. 2010 Jan;5(1):72-9

Single Questions for the Diagnoses of Restless Legs Syndrome, Anxiety, and Depression in Hemodialysis (SQUIRREL) David T. Collister,[1,2] Jennifer C. Rodrigues,[1,2] Andrea E. Mazzetti,[2] Kelsi Salisbury,[2] Laura M. Morosin,[2] K. S. Brimble,[1,2] Michael Walsh.[1,2] *[1]McMaster University, Hamilton, ON, Canada; [2]St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

Background: Symptoms in patients with kidney disease, such as restless leg syndrome (RLS), depression and anxiety, are common, reduce quality of life and are potentially treatable. Simple, accurate screening tools are needed. We examined the operating characteristics of the single questions for RLS, depression and anxiety from the revised Edmonton Symptom Assessment System (ESAS-r) in hemodialysis patients.

Methods: We conducted a cohort study of adults receiving chronic hemodialysis in Hamilton, Canada. Diagnoses of RLS, anxiety and depression were made using the 2012 IRLSSG criteria and the Hospital Anxiety and Depression Scale. Participants were asked to the degree to which they experienced restless legs, anxiety and depression using the ESAS-r 11-point scales anchored at 0 (no symptoms) and 10 (worst possible symptoms). ESAS-r single questions were compared to their reference standards using cutoffs greater than 0 indicating the presence of symptoms using logistic regression from which receiver operating characteristics (ROC) curves were generated.

Results: We recruited 50 participants with a mean age of 64 (12.4) years, of whom 52% were male and 92% were on 3x weekly hemodialysis. Using the reference standards, 14 (28%) had a diagnosis of RLS, 27 (54%) had depression and 28 (56%) had anxiety. 27 (54%), 36 (72%) and 25 (50%) expressed symptoms of RLS, anxiety and depression. Areas under the ROC curves were 0.65, 0.81, 0.82 for RLS, anxiety and depression respectively (Figure 1). As a screening tool, an IRLS cutoff of 19 had the highest area under the ROC curve at 0.76 with a sensitivity of 71% and specificity of 81%.

Conclusions: The ESAS-r single question for RLS has poor discrimination for the diagnosis of RLS in a hemodialysis population although the ESAS-r single questions for anxiety, depression and the IRLS demonstrate reasonable discrimination.

Funding: Government Support - Non-U.S.

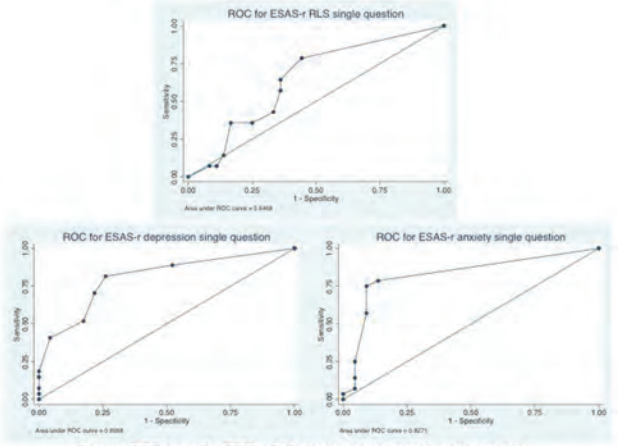

Figure 1: ROC curves for ESAS-r RLS, depression and anxiety single questions
Note: ROC = receiver operatoring characteristics,
ESAS-r = revised Edmonton Symptom Assessment System, RLS = restless legs syndrome

FR-PO910

Geographic Income Inequality and End-of-Life Care in US Dialysis Patients, 2000 to 2011 Robert N. Foley, Scott Reule. *University of Minnesota, Minneapolis, MN.*

Background: End-of-life care is increasingly considered in dialysis patients when death is imminent and quality of life is poor. Although end-of-life care can add financial and other burdens to dialysis patients and their families, associations with regional income dispersion have not been examined. As little is known regarding geographic income inequality, we performed a national study to examine potential associations with end-of-life care in US dialysis patients.

Methods: Retrospective United States Renal Data System files were used to end-of-life care parameters (all deaths from 2000 to 2011, N=910,559). The main exposure variable was county-level Gini index of income dispersion (range: 0 [perfect equality] to 1 [perfect inequality]; observed quartile thresholds 0.430, 0.453 and 0.481).

Results: The primary outcome-a composite of withdrawal of dialysis and death in a non-hospital or hospice setting-decreased monotonically with increasing income dispersion (20.9%, 18.6%, 17.0% and 10.2%, respectively, for Quartiles 1 to 4 of Gini index, *P*-Value < 0.001). Similarly, monotonic patterns (*P*-Value < 0.001 throughout) were seen for dialysis withdrawal (30.0%, 27.3%, 25.2% and 16.0%), hospice (15.1%, 14.1%, 13.3% and 9.0%) and non-hospital death (44.5%, 41.9%, 40.1% and 33.3%). After adjustment for age, sex, race-ethnicity, region, urban or rural domicile, kidney disease, mode of dialysis, previous transplant, insurance and dialysis facility characteristics, the primary outcome was similarly less likely in Quartiles 2 (adjusted odds ratio [AOR] 0.91 [95% CI 0.89-0.92], [Vs. Quartile 1]) and 3 (AOR 0.90 [0.88-0.91]) and even less likely in Quartile 4 (AOR 0.61 [0.61-0.62]), a pattern that was repeated when dialysis withdrawal, hospice and non-hospital death were examined (*P*-Value < 0.001 for each AOR). Multivariate associations between income dispersion and end-of-life care were present in all 45 subgroups examined.

Conclusions: End-of-life care in dialysis patients varies meaningfully by geographic income inequality.

FR-PO911

Improving Advanced Care Planning in Maintenance HD Patients with ESRD Bashir El-Khoury, Chandandeep Takkar. *University of Texas Health Science Center San Antonio, San Antonio, TX.*

Background: More than 80,000 Americans die every year while receiving maintenance dialysis therapy for ESRD. The adjusted mortality rate of maintenance dialysis patients is nearly twice that of adults with cancer and more than twice that of adults with CHF or stroke. Rates of hospitalization and ICU admission during last month of life are also higher in ESRD patients. Although studies have shown that dialysis patients with a treatment-limiting advance directive were less likely to be hospitalized, receive intensive procedures, and die in the hospital, advanced care planning (ACP) or completion of Advance Directives (AD)/Medical Power of Attorneys (MPOA) is lacking in the ESRD population compared to other chronic illnesses.

Methods: We conducted a pilot quality improvement project aimed at improving ACP in the maintenance HD community. Our goal was to increase the percentage of MWF second shift hemodialysis patients at University Dialysis Northwest (one of four dialysis units affiliated with us) with AD/MPOAs on file by 25% between November 2016 and February 2017. An inter-disciplinary team was convened. We surveyed our patients to obtain baseline information on current rates of AD/MPOA completion, knowledge of ACP, desire to participate in ACP, and identify barriers to completion. We collaborated with the Department of Palliative Medicine and implemented a series of interventions aimed towards facilitating the completion of ADs/MPOAs in our patients.

Results: We were able to increase the percentage of completed ADs/MPOAs to 29.2% from a baseline of 4.2% during our timeline. We are currently implementing measures including dedicated training in ACP for dialysis staff at all our outpatient dialysis facilities, incorporating ACP into interdisciplinary team meetings, establishing on-site notaries, and providing patient education in order to sustain results and expand the program to all UHS outpatient HD units.

Conclusions: Advance care planning is a vital aspect of patient-centered care at the end of life. Unfortunately it is lacking in the maintenance dialysis patient population due to a variety of cultural, provider and institutional barriers. We demonstrated that a comprehensive multidisciplinary approach to advance care planning improves AD/MPOA completion rates in our patient population.

FR-PO912

CKD Measures and Physical Function in Older Adults: The Atherosclerosis Risk in Communities (ARIC) Study Yugo Shibagaki,[1,5] Shoshana Ballew,[5] Priya Palta,[3] B G. Windham,[2] Josef Coresh,[4] Kunihiro Matsushita.[5] *[1]Division of Nephrology and Hypertension, St Marianna University Hospital, Kawasaki, Japan; [2]UMMC, Jackson, MS; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Reduced estimated glomerular filtration rate (eGFR) has been shown to be related to impaired physical function. However, data on the other chronic kidney disease (CKD) measure, albuminuria, in this context are sparse. Furthermore, whether cognitive function modifies these associations is unknown.

Methods: Among 4,608 community-dwelling older adults at ARIC visit 5 (2011-2013), we studied cross-sectional associations of eGFR with cystatin C (eGFRcys) and urine albumin-creatinine ratio (ACR) with physical function based on the Short Physical Performance Battery (SPPB). Cognitive function was classified as no cognitive impairment, mild cognitive impairment (MCI), or dementia according to a diagnostic review of neuropsychiatric, neurologic, and brain imaging assessments.

Results: Mean age of participants was 75.7 (SD 5.1) years, and median SPPB was 10 (IQR 8-11), with 13.8% (n=636) having impaired physical function (defined as SPPB score <6). Adjusted for potential confounders, the odds ratio of having impaired physical function was 1.98 (95%CI 1.21-3.24) in GFR <45 ml/min/1.73m^2, 1.42 (0.88-2.30) in GFR 45-59, and 0.98 (0.61-1.57) in GFR 60-89, compared to GFR ≥90 (Table). Similarly, the odds ratio was 1.92 (95%CI 1.20-3.05) in ACR ≥300 mg/g and 1.71 (1.38-2.14) in ACR 30-299, compared to ACR <30. When stratified by cognitive function (n=3,449 with normal and 1,159 with MCI/dementia), of the associations of eGFF and ACR with impaired physical function were stronger in normal cognition than in MCI/dementia (Table).

Conclusions: Both high albuminuria and low eGFR were independently associated with impaired physical function, with more evident results when cognition was preserved.

Adjusted odds ratios (95% CIs) of impaired physical function according to CKD measures.

	eGFRcys				UACR		
	>= 90 N=353	60 – 90 N=1,963	45 – 60 N=1,286	< 45 N=1,006	< 30 N=3,700	30 – 300 N=792	>= 300 N=116

FR-PO913

Kidney Function Is Not Associated with an Accelerated Decline in Objective Tests of Physical Performance in Older Adults Mark Canney,[1,2] Daniel Carey,[1] Rose Anne M. Kenny,[1] Mark A. Little,[2] Conall M. O'Seaghdha.[3] *[1]The Irish Longitudinal Study on Ageing, Trinity College Dublin, Dublin, Ireland; [2]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [3]Department of Nephrology and Transplantation, Beaumont Hospital, Dublin, Ireland.*

Background: Cross-sectional studies in older adults have identified an association between diminished estimated glomerular filtration rate (eGFR) and frailty. Whether kidney function is driving frailty, or both conditions have shared risk factors, is not well understood. Longitudinal studies could inform this question. We sought to examine whether baseline eGFR predicted an accelerated decline in gait speed or timed-up-and-go (TUG) in a large representative sample of older adults.

Methods: Prospective analysis from the first 3 waves (2009-2015) of The Irish Longitudinal Study on Ageing, a nationally representative cohort of community-based adults aged ≥50 years. Gait speed was measured at waves 1 and 3 in 3140 participants (mean age 60.9 years). TUG was measured at all 3 waves in 4930 participants (mean age 62.6 years). We calculated eGFR at wave 1 from cystatin C using the Chronic Kidney Disease Epidemiology equation. We used mixed effects linear regression to examine the association between categorical eGFR (>90, 60-89, <60mL/min/1.73m^2) and each outcome. Models were adjusted for age, sex, height, waist circumference, smoking, diabetes, pulse pressure, cardiovascular disease, polypharmacy, chronic health conditions. Each covariate was included as a main effect and its interaction with time (wave). The parameter of interest was the time*eGFR interaction. Analyses were weighted to account for differential non-response and attrition across waves.

Results: For gait speed the unadjusted time*eGFR interaction was strongly statistically significant (p<0.001) but did not retain significance after adjustment for age, sex and comorbidites (p=0.22). A similar pattern was observed for TUG: p<0.001 for unadjusted interaction, p=0.43 for multivariable-adjusted interaction. In a subgroup analysis, participants with eGFR<50mL/min/1.73m^2 (the median eGFR in the <60mL/min/1.73m^2 category) had some evidence of worse TUG over time compared to those with eGFR>60mL/min/1.73m^2, however the effect size was modest (0.3 seconds longer).

Conclusions: In this large cohort of older adults, a diminished eGFR did not predict an accelerated decline in objectively measured tests of physical performance. The strong association between eGFR and markers of frailty may be best explained by comorbidity rather than reduced kidney function per se.

FR-PO914

Impact of Poor Functional Status on Outcomes among Elderly Dialysis Patients Silvi Shah, Anthony C. Leonard, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: One-in-four incident end stage renal disease (ESRD) patients are > 75 years of age; and in prevalent trends for ESRD, the highest growth has occurred in those above 75 years. Hospitalizations and comorbidities are common in pre-ESRD patients, and along with age, can contribute to poor functional status at dialysis initiation.

Methods: We evaluated 49,645 adult incident dialysis patients (1/1/2008 to 12/31/2008) from the United States Renal Data System (USRDS) with linked Medicare data for at least 2 years prior to dialysis initiation. Poor functional status was defined by any of the three comorbidities listed in form 2728 – inability to ambulate, inability to transfer or need of assistance with daily activities. Using case-mix logistic regression adjusted models (16 variables including pre-ESRD hospitalizations), we examined the impact of poor functional status on type of dialysis modality (hemodialysis [HD] vs. peritoneal dialysis [PD]) and one-year all cause mortality. In a separate model among HD patients, we studied the effect of functional status on type of vascular access (arteriovenous [AV] access vs. catheter).

Results: Of the study cohort, 55% were male. Mean age was 72 ±11 years. At dialysis initiation, 26% were octogenarian, 20% reported poor functional status and 10% had reported nursing home stay. Patients with poor functional status were 10 times more likely have a nursing home stay than those without poor functional status. Only 4% of patients initiated PD. Of those who started HD, 82% initiated with a catheter. Overall, one-year mortality was 31%; it was 48% in patients with poor functional status and 57% in octogenarians with poor functional status. In adjusted analyses, patients with poor functional status were more likely to be started on HD (odds ratio [OR], 1.42; 95% confidence interval [CI], 1.18-1.69); and among those on HD, the odds for starting HD with AV access were lower (OR, 0.78; CI, 0.72-0.85). One-year adjusted mortality was higher in patients with poor functional status (OR, 1.5; CI, 1.42-1.59).

Conclusions: Poor functional status is associated with higher odds of initiating HD than PD; increases the risk of catheter use in those with HD, and is an independent predictor of one-year mortality. Patients with poor functional status, independent of age, should be counseled for shared decision-making and assessed for conservative treatment options.

FR-PO915

Racial and Gender Disparities in Long-Term Clinical Outcomes among Elderly Dialysis Patients Silvi Shah, Anthony C. Leonard, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: Mortality in end stage renal disease (ESRD) patients is highest during the first year of dialysis. However, after considering the influence of pre-dialysis health status (defined as nephrology care and acute care hospitalizations) and dialysis access; the effects of race and gender on long-term mortality among incident Medicare dialysis patients are not known.

Methods: We evaluated 49,645 adult incident dialysis patients (1/1/2008 to 12/31/2008) from the United States Renal Data System (USRDS) with linked Medicare data for at least 2 years prior to dialysis initiation. Information on pre-dialysis health status was obtained from form 2728 and linked Medicare claims. Using case-mix adjusted logistic regression models (16 variables), we examined the effect of race and gender on one-year all cause mortality after dialysis initiation.

Results: Mean age of study population was 72±11 years. Of the study cohort, 26% were octogenarian; 55% were male; and 63% were White. Of those who started hemodialysis (HD), 82% initiated with a catheter. One-year mortality was 31%. Pre-dialysis nephrology care was associated with lower mortality in dialysis patients than those without nephrology care (26% vs. 39%, p<0.001). Pre-dialysis acute hospitalization was associated with higher mortality than those without pre-dialysis hospitalization (33% vs. 19%, p<0.001). As compared to patients with catheter, incident AV access was associated with lower mortality (35% vs. 16%; p<0.001). In adjusted analyses, as compared to Whites, one-year mortality was lower among Blacks (odds ratio [OR], 0.7; 95% confidence interval [CI], 0.66-0.74]), Hispanics (OR, 0.65; CI, 0.60-0.70) and Asians (OR, 0.65; CI, 0.57-0.74). Females were less likely to die within one year after initiating dialysis than males (OR, 0.95; CI, 0.91-0.99).

Conclusions: Among elderly dialysis patients; Blacks, Hispanics and Asians have a lower mortality than Whites; and females have lower mortality than males. These differences across race and gender exist independent of pre-dialysis health status and dialysis access type. Biological factors associated with these disparities need to be explored further to understand the reasons behind the survival advantage among minorities and women.

FR-PO916

Extracellular Volume Expansion and Inflammation Are Independently Associated with Malnutrition, Determined by Geriatric Nutritional Risk Index in Hemodialysis Patients Dong Ho Yang,[2] So-young Lee,[3] Mi Jung Lee,[2] Hye yun Jeong.[1] *[1]CHA Bundang Medical Center, Seongnam-si, Republic of Korea; [2]Internal Medicine, CHA Bundang Medical Center, CHA Univ., Seongnam-si, Not Applicable, Republic of Korea; [3]Internal Medicine, CHA Bundang Medical Center, CHA Univ., Seongnam-si, Not Applicable, Republic of Korea.*

Background: It is well known that malnutrition is implicated with increased morbidity and mortality in end-stage renal disease (ESRD) patients. Therefore, exploring risk factors for malnutrition has clinical relevance in these patients. In the present study, we aimed to investigate the significant association between fluid overload, inflammation, and malnutrition in ESRD patients on hemodialysis (HD).

Methods: A cross-sectional study was undertaken in 76 prevalent HD patients in South Korea. Geriatric nutritional risk index (GNRI) was calculated to determine nutritional status. Ratio of extracellular water (ECW) to total body water (TBW) was measured to determine fluid overload using multi-frequency bioimpedance (Inbody S20, Biospace, Seoul, Korea). Independent association between variables and GNRI were tested by linear regression analyses.

Results: The mean age was 59.1 ± 13.4 years, and 44 patients (57.9%) were mean. The mean GNRI value was 97.2 ± 6.6 (median 97.8, interquartile range 94.4 to 101.8). The mean ratio of ECW to TBW (ECW/TBW) was 0.38 ± 0.02. In univariate analysis, age (per 1 year, ß=-0.13, 95% confidence interval [CI]=-0.24 to -0.02), ECW/TBW (per 0.01, ß=-1.89, 95% CI=-2.58 to -1.19), and C-reactive protein concentrations (per 1 mg/l, ß=-4.73, 95% CI=-7.19 to -2.28) were negatively associated with GNRI, while serum potassium (per 1 mEq/l, ß=2.46, 95% CI=0.36 to 4.55) and calcium-phosphorous products (per 1 mg^2/dl^2, ß=0.18, 95% CI=0.06 to 0.29) were positively associated with GNRI. Moreover, men and patients with previous cardiovascular disease history had lower GNRI values. Multivariate analysis demonstrated that higher values of ECW/TBW (per 0.01, ß=-1.33, 95% CI=-2.06 to -0.59) and C-reactive protein (per 1 mg/l, ß=-2.88, 95% CI=-5.07 to -0.68) were independently associated with lower GNRI values after adjustment of confounding variables.

Conclusions: Extracellular volume expansion and inflammation showed an independent association with lower GNRI values in HD patients. This result suggest that avoiding fluid overload and inflammation could be helpful to mitigate malnutrition in these patients.

FR-PO917

Effect of Lower BMI on Mortality Risk in Older Patients Starting Dialysis Is Time-Dependent Harmke A. Polinder-Bos,[2] Ron T. Gansevoort,[2] Merel Van diepen,[1] Friedo W. Dekker,[1] Ellen K. Hoogeveen,[3,1] Casper F. Franssen,[2] Carlo A. Gaillard.[2] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands; [3]Jeroen Bosch Hospital, Den Bosch, Netherlands.*

Background: Lower body mass index (BMI) has consistently been associated with worse survival in older individuals in the general population and in chronic disease populations. Remarkably, in older dialysis patients no association of BMI with mortality was found. Therefore, we performed an in-depth analysis on this association in the NECOSAD cohort.

Methods: 908 patients aged ≥65 years were followed from start of dialysis until death or kidney transplantation, and were divided into tertiles by baseline BMI (BMI <23 (lower), 23-26 (reference), >26 (higher) kg/m^2). Because the hazards changed significantly during follow-up, the effect of BMI was modeled for the short-term (<1 year after dialysis initiation) and longer-term (≥1 years after dialysis initiation) using time-dependent Cox-regression models. Furthermore, differences between lower BMI patients who survived versus died during the first year of dialysis therapy were evaluated.

Results: During a median follow-up period of 3.8 year, 567 deaths occurred. Cumulative survival proportions at end of follow-up were 30%, 28% and 31% for the lower, middle and higher BMI groups, respectively. Lower BMI was associated with a higher short-term mortality risk (HR 1.57 [1.10-2.23] *P*=0.01), and a lower longer-term mortality risk (HR 0.77 [0.60-0.99] *P*=0.04), adjusted for age, sex, race, and smoking. Patients with a lower BMI who died during the first year of dialysis therapy had significantly more comorbidity, less physical mobility and ability to perform usual activities, and had lower albumin levels compared with those who survived the first year.

Conclusions: In older patients who start dialysis therapy lower BMI is associated with increased 1-year mortality. Remarkably, when surviving the first year of dialysis, patients with lower baseline BMI had a similar or even lower mortality risk compared with patients who had a normal or higher baseline BMI. Especially those older patients with lower BMI that have limited comorbidity and mildly or non-impaired physical function may benefit from having started dialysis.

FR-PO918

Importance of Skeletal Muscle Mass on the Long Term Patient Survival in the Elderly AKI Patients Who Underwent Continuous Renal Replacement Therapy Harin Rhee,[4] Sang Heon Song,[3] Miyeun Han,[7] Eun Young Seong,[3] Il Young Kim,[6] Dong Won Lee,[5] Soo Bong Lee,[2] Ihm Soo Kwak.[1] *[1]Busan National University Hospital, Busan, Republic of Korea; [2]None, Yangsan-si, Gyeongsangnam-do, Republic of Korea; [3]Pusan National University Hospital, Busan, Busan, Republic of Korea; [4]Internal medicine, Pusan National University Hospital, Busan, Republic of Korea; [5]Pusan National University School of Medicine, Yangsan, Republic of Korea; [6]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [7]SEOUL NATIONAL UNIVERSITY HOSPITAL, SEOUL, Republic of Korea.*

Background: In patients with chronic kidney disease, survival has been shown to be better with increasing body mass index. Recently, it is also reported to be true in patients with acute kidney injury (AKI). However, few studies were conducted to reveal which of the two body components, muscle or fat, was beneficial to the patient survival. The aim of this study is to evaluate the impacts of skeletal mass and fat mass on the long term patient survival in elderly AKI patients who underwent CRRT.

Methods: This study was a single center retrospective study of elderly patients who survived from AKI needed CRRT from January 2013 to December 2015. Patient's long term survival was verified in March 2016 by individual phone call. Skeletal muscle mass (SMM) and fat mass (FM) were measured using bioimpedance analysis method at the time of CRRT initiation. SMM and FM were adjusted with height squared. Multivariable cox regression analysis was adjusted to evaluate the significant factors associated with long term patient survival.

Results: A total of 170 patients were included in this study. The mean patient age was 73.77±5.68 years old, and 57.1% of the patients were male. The mean BMI was 22.94±3.27 kg/m^2. During the median follow up period of 287.0 days, 40.0% (68/170) of the patients were dead. When we performed multivariable analysis to define factors associated with long term patient survival, lower SMM was associated with higher long term mortality (HR 0.830(0.697-0.988), p=0.036) along with older age (HR 1.062(1.105-1.110), p=0.009), history of sepsis (HR1.994(HR1.174-3.387), p=0.011) and prolonged prothrombin time (1.396, HR(1.155-1.688), P=0.001). However, lower FM was not associated with long term patient survival in this group.

Conclusions: In the elderly patients with AKI treated with CRRT, lower skeletal muscle mass rather than lower fat mass was associated with long term patient mortality.

FR-PO919

A Frailty Screening Tool for Use in CKD by Medical and Nursing Staff Andrew Nixon,[1,2] Theodoros M. Bampouras,[3] Alastair R. Petrie,[3] Atinuke J. Afolabi,[3] Neil Pendleton,[1] Sandip Mitra,[4] Ajay P. Dhaygude.[2] *[1]University of Manchester, Manchester, United Kingdom; [2]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [3]University of Cumbria, Lancaster, United Kingdom; [4]Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.*

Background: Frailty is associated with adverse clinical outcomes in chronic kidney disease (CKD) including an increased risk of hospitalisation and mortality. Nephrologists need a well-validated frailty screening tool.

Methods: Fifty-eight dialysis-dependent CKD and pre-dialysis stage 4 and 5 CKD patients were recruited. Patients were assessed by a doctor and nurses using the Clinical Frailty Scale (CFS). Frailty was also assessed using two operationalised frailty definitions: the frailty phenotype (FP) and the frailty index (FI). CFS scores were compared with FP and FI scores and ROC curves were calculated.

Results: Median age was 70 years old (IQR: 58.75-77.00) with 28 male patients. Half were receiving haemodialysis. Mean Charlson Comorbidity Index was 3.12 (SD: 1.29). Using the CFS, 29% were idenitified as frail by a doctor and 31% by nurses. Using the FP, frailty prevalance was 24%. Mean FI was 0.32 (SD: 0.13). Doctor and nurse CFS scores correlated well with each other (r=0.81, 95% CI: 0.70-0.89). Doctor CFS scores correlated well with FP (r=0.80, 95% CI: 0.70- 0.87) and FI (r=0.85, 95% CI: 0.75-0.92) scores. Nurse CFS scores correlated moderately well with FP (r=0.66, 95% CI: 0.51-0.77) and FI (r=0.67, 95% CI: 0.52-0.79) scores. The ROC AUC was 0.90 (95% CI: 0.82-0.98) for the doctor CFS and 0.81 (95% CI: 0.70-0.93) for the nurse CFS (figure 1). A CFS score ≥4 gave a sensitivity of 1.00 and 1.00 with a specificity of 0.41 and 0.43 for identifying frailty (as defined by the FP) by a doctor and nurse, respectively.

Conclusions: The CFS is a useful frailty screening tool in those with CKD and can be effectively used by medical and nursing staff. Further study is needed to evaluate its ability to risk stratify patients prior to the commencement of renal replacement therapy.

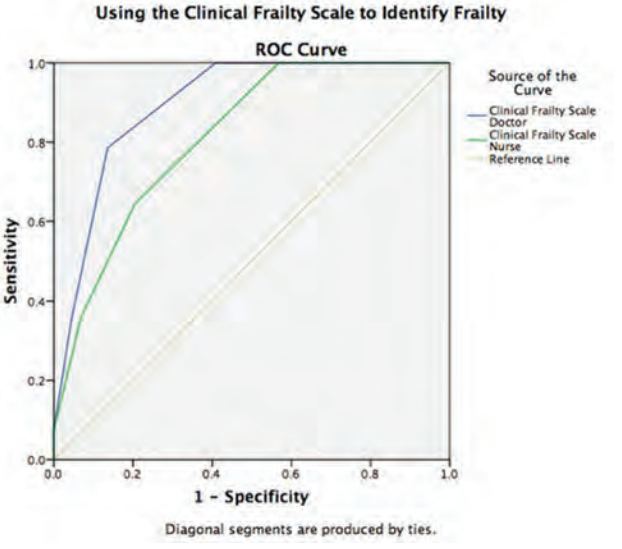

Figure 1. Using the CFS to Identify Frailty.

FR-PO920

Evaluation of a Patient-Directed Frailty Screening Tool for Use in CKD Andrew Nixon,[1,2] Theodoros M. Bampouras,[3] Alastair R. Petrie,[3] Atinuke J. Afolabi,[3] Neil Pendleton,[2] Sandip Mitra,[4] Ajay P. Dhaygude.[1] *[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]University of Manchester, Manchester, United Kingdom; [3]University of Cumbria, Lancaster, United Kingdom; [4]Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.*

Background: Frailty is associated with adverse outcomes in Chronic Kidney Disease (CKD). There is a need for a frailty screening tool that is well-validated in CKD. The British Geriatric Society (BGS) has suggested that the PRISMA 7 questionnaire is a useful self-assessment screening method for frailty in the general population. However, it has not yet been validated in those with CKD.

Methods: Fifty-eight dialysis-dependent CKD and pre-dialysis stage 4 and 5 CKD patients were recruited. Patients were asked to complete the PRISMA 7 questionnaire. As suggested by the BGS, a score of ≥3 was considered to identify frailty. Frailty was also assessed using two operationalised frailty definitions: the frailty phenotype (FP) and the frailty index (FI). The correlation between PRISMA 7 scores and FP and FI scores was assessed. ROC curves were calculated to assess the PRISMA 7 questionnaire's sensitivity and specificity.

Results: Median age was 70 years old (IQR: 58.75-77.00) with 28 male patients. Half were receiving haemodialysis. Mean Charlson Comorbidity Index was 3.12 (SD: 1.29). The PRISMA 7 identified 48% as frail. Using the FP, frailty prevalance was 24%. Mean FI was 0.32 (SD: 0.13). The PRISMA 7 scores correlated moderately well with FP (r=0.66, 95% CI 0.52-0.78) and FI (r=0.76, 95% CI 0.66-0.84) scores. Figure 1 demonstrates the ROC curve for the PRISMA 7. The ROC AUC was 0.87 (95% CI 0.77-0.97) for the PRISMA 7. A PRISMA 7 score ≥3 had a sensitivity of 0.93 and specificity of 0.66 for identifying frailty, as defined by the FP.

Conclusions: The PRISMA 7 questionnaire is an effective patient-directed frailty screening tool with excellent sensitivity for identifying frailty. It can be easily incorporated into routine clinical care. Further research is needed to evaluate its prognostic accuracy.

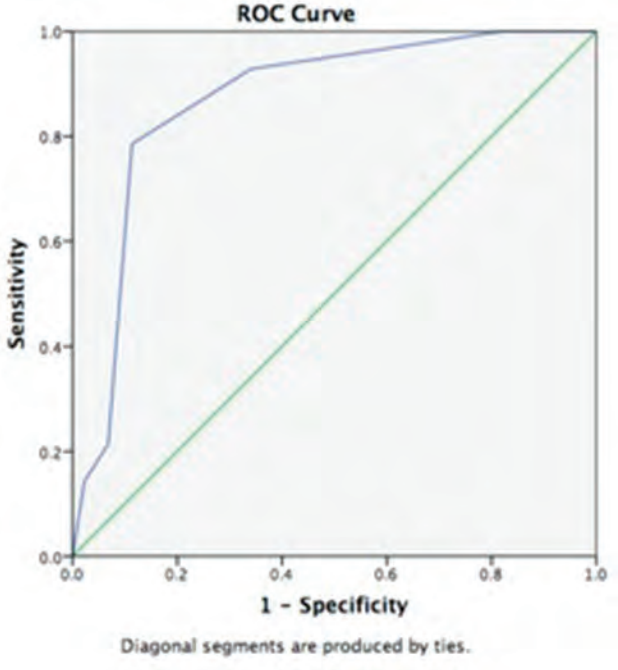

Figure 1. ROC Curve Assessing the PRISMA 7 Questionnaire's Ability to Identify Frailty

FR-PO921

Step Length as a Novel Predictor of Physical Function in Patients with CKD Rima N. Pai,[1] Rupinder singh Buttar,[8] William Paredes,[2] Matthew Custodio,[1] Hina Farooq,[4] BUSHRA ZAIDI,[6] Nabin R. Karki,[5] Aagat Sharma khatiwada,[7] Stephen Ansah-Addo,[1] Ashley Tran,[3] Meredith Hawkins,[1] Matthew K. Abramowitz.[1] *[1]Albert Einstein College of Medicine, New York, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Ambra Health, Holmdel, NJ; [4]Louis A. Weiss Memorial Hospital, Chicago, IL; [5]Medstar Harbor Hospital, Baltimore, MD; [6]ALBERT EINSTEIN COLLEGE OF MEDICINE, Bronx, NY; [7]University of Leicester, Leicester, United Kingdom; [8]Jacobi medical center, Bronx, NY.*

Background: Impaired mobility and disability are common in patients with CKD and contribute to morbidity and mortality. Novel predictors of functional decline could facilitate earlier identification of at-risk patients.

Methods: We measured average step length (SL) in 32 patients with CKD stages 4 and 5 who had physical function assessments performed every 3 months (median, 4 assessments). SL was calculated based on the number of steps needed to complete a 4m walk at usual pace. We also assessed lower extremity performance (Short Physical Performance Battery), muscle strength, endurance capacity (2 minute walk distance), self-reported physical function (SF-36 Physical Component Score (PCS)), and symptom burden (Renal Palliative Care Outcome Scale (POS)). Age and sex-adjusted linear regression and mixed effects models were used to test the association of SL with baseline characteristics and with physical function parameters over time, respectively.

Results: The mean age was 64±13 years, 44% were women, mean eGFR 20±10 mL/min/1.73m^2, mean BMI 32±7 kg/m^2, 59% had diabetes, and 16% had peripheral vascular disease. Lower PCS and higher POS associated with shorter SL (4.7cm (1.8-7.7) and 6.3cm (2.7-9.9) per 10 point difference, respectively), as did 2 SPPB domains (2.3cm (1.7-2.9) per 0.1m/s slower gait speed and 7.3cm (1.1-13.5) shorter SL with impaired balance). Over time, each 10cm shorter SL was associated with 1.4kg (0.2-2.7) weaker handgrip strength and 26.5ft (8.6-44.5) shorter 2-minute walk distance, and with 0.4 point (0.02-0.7) decrease in SPPB during follow-up. Furthermore, SL was shorter in patients experiencing a fall (46±11 vs. 56±8 cm, p=0.008).

Conclusions: In a cohort of patients with advanced CKD, shorter SL associated with poorer subjective and objective measures of physical function and with the likelihood of falling. SL may be a useful predictor of fall risk and functional decline in CKD patients.

FR-PO922

Serious Fall Injury History and Adverse Health Outcomes after Initiating Hemodialysis among Older US Adults C. Barrett Bowling,[1,3] Rasheeda K. Hall,[3,1] Anjali Khakharia,[2] Harold A. Franch,[2,4] Laura Plantinga.[2] *[1]Durham VA Medical Center, Decatur, GA; [2]Emory University, Atlanta, GA; [3]Duke University, Durham, NC; [4]Atlanta VAMC, Decatur, GA.*

Background: Although older adults with pre-dialysis CKD are at increased risk for falls, the prognostic significance of a serious fall injury prior to dialysis initiation has not been well described in the end-stage renal disease population.

Methods: We examined the association between a serious fall injury in the year prior to starting hemodialysis and adverse health outcomes in the year following dialysis initiation using a retrospective cohort study of U.S. Medicare claims data from the 2 years spanning dialysis start, among patients initiating dialysis in 2010-2012. Participants included Medicare beneficiaries aged ≥67 years. Serious fall injuries were defined using diagnostic codes for falls in combination with an injury code for a fracture, joint dislocation, or head injury. Outcomes were defined as time-to-event variables within the first year of dialysis for four outcomes: subsequent serious fall injury, hospital admission, post-acute skilled nursing facility (SNF) utilization, and mortality.

Results: Among this cohort of 81,653 initiating hemodialysis, 2,958 (3.6%) patients had a serious fall injury in the year prior to hemodialysis initiation. Compared to those without serious fall injuries, those with a serious fall injury in the prior year were older (mean age 78.1 vs 76.7), more likely to be female (57.7% vs. 46.8%) and white (73.5% vs. 65.2%), and more likely to need assistance with daily activities (27.2% vs. 17.8%). In the first year of dialysis, 7.6%, 67.6%, 30.7%, and 26.1% had a serious injury fall, hospitalization, SNF claim, or died. Multivariable adjusted hazard ratios (95% confidence intervals) for a serious fall injury, hospitalization, SNF claim, or death for those with vs. without a history of serious fall injury in the year prior to hemodialysis initiation were 2.94 (2.71-3.20), 1.20 (1.15-1.26), 1.62 (1.52-1.73), and 1.28 (1.20-1.43), respectively.

Conclusions: A serious fall injury in the year prior to dialysis was associated with an increased risk for adverse health outcomes. For older adults initiating dialysis, a history of a serious fall injury may be novel marker for frailty and provide prognostic information to support decision-making and establish expectations for life after dialysis initiation.

FR-PO923

Kidney Function Is Not an Independent Predictor of Falls among Community-Dwelling Older Adults Mark Canney,[1,2] Daniel Carey,[1] Rose Anne M. Kenny,[1] Mark A. Little,[2] Conall M. O'Seaghdha.[3] *[1]The Irish Longitudinal Study on Ageing, Trinity College Dublin, Dublin, Ireland; [2]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [3]Department of Nephrology and Transplantation, Beaumont Hospital, Dublin, Ireland.*

Background: While several studies have identified a link between chronic kidney disease and markers of frailty in older age, it is largely unknown if this association translates into meaningful outcomes such as a greater risk of falls. We sought to examine the relationship between kidney function and falls in a large representative cohort of older adults.

Methods: Prospective analysis of 5060 participants from the first 3 waves (2009-2015) of The Irish Longitudinal Study on Ageing, a nationally representative sample of community-dwelling adults aged ≥50 years. All participants had estimated glomerular filtration rate (eGFR) calculated from cystatin C at wave 1. Data regarding falls (any fall in the last year or between waves) were captured via a computer-assisted personal interview at each wave. We used mixed effects logistic regression to examine the association between eGFR (≥90 [reference], 60-89, <60mL/min/1.73m^2) and reporting a fall. Models were adjusted for age, sex, frailty (pre-frail/frail versus robust), diabetes, cardiovascular disease, pulse pressure, polypharmacy and chronic health conditions. Each covariate was modelled as a main effect and as a time*covariate interaction. An inverse probability weight was applied to all estimates to account for differential non-response and attrition.

Results: Mean (standard deviation) age of participants was 62.8 (9.1) years, 46% were male and median (interquartile range) eGFR was 80 (67-93) mL/min/1.73m^2. After adjusting for age and sex, participants with eGFR <60mL/min/1.73m^2 had a 5.0% (95% confidence interval 1.3 to 8.6%) increased probability of a fall versus the reference group (eGFR ≥90mL/min/1.73m^2). This association was attenuated in the extended model (2.6% increased probability [-1.1 to 6.2%]). Results did not vary by age (over or under 65) or sex. The time*eGFR interaction was not statistically significant after adjusting for age and sex (p=0.65). Frailty and the number of chronic conditions were both independent predictors of falls in the multivariable model.

Conclusions: In this large prospective study of older community-based adults, kidney function was not found to be an independent predictor of falls. Our data suggest that, in the general population of older individuals, frailty status and comorbidity burden are more important predictors of falls than kidney function alone.

Improving Physical Function and Social Networks of Older Adults with ESRD: Development and Testing of Seniors Optimizing Community Integration to Advance Better Living with ESRD (SOCIABLE) Deidra C. Crews,[5] Alice M. Delaney,[7] Janiece L. Walker,[2] Thomas K. Cudjoe,[1] Allyson Evelyn-Gustave,[3] Jill Roth,[6] David L. Roth,[4] Sarah Szanton.[3] *[1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins School of Nursing, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]Johns hopkins School of Nursing, Baltimore, MD; [7]University of Maryland, Essex, MD.*

Background: Older adults with ESRD have increased morbidity, life constraining fatigue and decreased physical function. These conditions can inhibit self-care and social engagement while restricting ability to leave home. We developed a home-based program to improve physical and social functioning of low income, older adults on hemodialysis (HD).

Methods: We 1) identified daily functional needs and home environmental barriers to engaging social networks among low income older patients on HD through focus groups (n=7 patients); 2) mapped focus group findings onto aspects of an established program for low income older adults with physical limitations (which includes home visits with an occupational therapist, nurse and handyman to provide ≦$1300 worth of repairs, modifications and devices) tailoring the newly developed program (SOCIABLE) to the needs of HD patients; and 3) piloted the program among 12 patients. We used a randomized wait list design to deliver the services in a staggered fashion that allowed a control comparison.

Results: Focus group themes included those in the **Table**. We adapted the original program using these themes to produce SOCIABLE, which we tested. All participants were African American (50% male), mean age was 68 (SD= 5.9). From baseline to 6 month follow up, participants improved on average from 2.3 in Activities of Daily Living (ADL) difficulties (scale of 8) and improved 2.5 (scale of 8) Instrumental ADL difficulties. Participants' mean social network scores increased from 18.4 to 23.1 (out of a possible 40). Satisfaction with social support improved less.

Conclusions: Our results show that it is possible to improve physical and social function of low income older adults with ESRD via a home based intervention. As people with ESRD have low quality of life and account for substantial costs to the U.S. health system ($33 Billion), it is important to better understand how to improve life and decrease costs for this population with a full-scale efficacy trial.

Funding: Other NIH Support - National Institute on Aging

Representative Focus Group Quotes

Theme	Quote
Desire to live Independently	In reference to Nursing Home: "Where you have no independence. It's, you're at their beck and call for everything. Even when you don't want to eat, for an example, you're stuck."
Fatigue	"So after dialysis I am, I feel like I'm not tired until I actually leave. That's when it starts... That's my main thing, I have to rest."
Lack of Social Support	"They kind of like, they distance themselves, and they do it, they try to do it in different ways. And I can tell, because you don't hear from them as often as you did at first."

FR-PO925

Association of Kidney Disease Quality of Life (KDQOL-36) Subscale Scores with Mortality and Hospitalization in Older Dialysis Patients Rasheeda K. Hall, Alison Luciano, Carl F. Pieper, Cathleen Colon-emeric. *Duke University, Durham, NC.*

Background: The Kidney Disease Quality of Life (KDQOL-36) instrument is routinely administered to dialysis patients. Subscale scores may be useful for prognostication but their association with clinical outcomes has not been reported in older adults.

Methods: We conducted a longitudinal study of 3500 adults aged ≥ 75 years receiving dialysis through a large dialysis organization in 2012 and 2013. We used Cox and Fine and Gray models to evaluate the association of KDQOL-36 subscales (1- Burden of kidney disease, 2- Effects of kidney disease, 3- Symptoms of kidney disease, 4- SF-12 physical component score (PCS), and 5- SF-12 mental component score (MCS)) with risks of death and hospitalization, respectively. All models were adjusted for sociodemographic variables, hemodialysis access type, laboratory values, and Charlson index. We compared models with and without the KDQOL-36 subscales using likelihood ratio (LR) statistics.

Results: Among members of this cohort, 3,267 patients completed the KDQOL-36. From the date of KDQOL-36 completion, 929 (25.6%) patients died and 2,005 (61.4%) had at least one hospitalization over a median follow-up of 511 and 204 days, respectively. In unadjusted analyses, cohort members with KDQOL-36 scores in the lowest quintile (relative to the highest quintile) for all subscales had a higher probability of death. Cohort members with a SF-12 PCS in the lowest quintile had an increased adjusted risk of death [hazard ratio (HR), 1.53, 95% confidence interval (CI) 1.18-1.99] and hospitalization (HR, 1.33, 95% CI 1.12-1.58) compared with those with scores in the highest quintile. Cohort members with SF-12 MCS scores in the lowest quintile had an increased adjusted risk of hospitalization (HR, 1.41, 95% CI 1.19-1.68) compared with those in the highest quintile and those with Effects of kidney disease subscale scores in the lowest quintile had a lower risk of hospitalization (HR, 0.78, 95% CI 0.63-0.95). The magnitude of these associations was similar in competing risk models. Inclusion of KDQOL-36 subscales improved model fit both for death (LR 41.04; p-value = 0.004) and hospitalization (LR 68.14; p-value < 0.001).

Conclusions: Routinely administered KDQOL-36 subscales may improve risk stratification of older adults receiving dialysis for death and future hospitalizations.

An Integrated Prognostic Model for Shared Decision-Making with Patients with Stage 4-5 CKD Daniel L. Landry,[1] Lewis Cohen,[2] Rebecca J. Schmidt,[3] Alvin H. Moss,[4] Brian H. Nathanson,[5] Michael J. Germain.[6] *[1]Department of Medicine, Section of Nephrology, Baystate Medical Center, Springfield, MA; [2]Department of Psychiatry, Baystate Medical Center, Springfield, MA; [3]Department of Medicine, Section of Nephrology, West Virginia University School of Medicine, Morgantown, WV; [4]Department of Medicine, Section of Nephrology, West Virginia University School of Medicine, Morgantown, WV; [5]OptiStatim, LLC, Longmeadow, MA; [6]Department of Medicine, Section of Nephrology, Baystate Medical Center, Springfield, MA.*

Background: Patients with advanced chronic kidney disease (CKD) have high mortality and often die before needing dialysis. Studies show that prognostic information is important to patients facing the decision to pursue or forgo dialysis. A model that integrates clinical intuition with objective measures to predict 12-month mortality in patients with advanced CKD could help inform decisions.

Methods: In this prospective, observational study, 749 patients with CKD stage 4 or 5 were followed for 2 years. Demographics and laboratory data were collected while providers assessed functional status by the Karnofsky Performance Scale Index (KPSI) and answered a "surprise" question (SQ), "Would you be surprised if your patient died within the next 6 months?" upon each clinic visit.

Results: Mean (SD) age of the cohort was 69.3 (14.6), 50.9% were male, and 83.6% were Caucasian. Mean (SD) Charlson Comorbidity Index score was 5.9 (2.1) and 136 patients (18.2%) had a KPSI score of 50 ("requires considerable assistance and frequent medical care") or worse. By 12 months, 101 (13.5%) died and 99 (13.2%) initiated dialysis. A logistic regression model was constructed with 3 predictors of mortality. Area under the ROC curve was 0.81 indicating good discrimination.

Conclusions: In this model, advanced age, poor functional status, and the SQ predicted 12-month mortality in advanced CKD patients. The model is being validated and may assist nephrologists in shared decision-making with CKD patients who are choosing between dialysis versus conservative management.

Funding: Private Foundation Support

Logistic Regression Model of 12-Month Mortality (n = 736 patients with complete data)

Covariate	Odds Ratio; 95% CI	P-Value
Surprise Question (SQ) = No; Baseline Category = Yes	6.63; (3.68, 11.96)	<0.001
Age per 10 year increase	1.49; (1.21, 1.83)	<0.001
Karnofsky Performance Scale Index (KPSI); Baseline Category = 80 to 100	1	
• KPSI = 50 to 70	2.22; (1.24, 3.98)	0.008
• KPSI = 10 to 40	3.15; (1.02, 9.68)	0.046

Accelerated Brain Aging in ESRD Patients Yi-Fang Chuang,[4,2] Kai-Hsiang Shu,[1] Yu-sen Peng,[1] Yen-Ling Chiu.[1,3] *[1]Nephrology, Far Eastern Memorial Hospital, Banciao, New Taipei City, Taiwan; [2]School of Public Health, National Yang Ming University, Taipei, Taiwan; [3]Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, Taiwan; [4]Psychiatry, Far Eastern Memorial Hospital, Taipei, Taiwan.*

Background: Patients with end-stage renal disease (ESRD) suffer from higher risk of cognition impairment and dementia compared to the general population. It is known that brain structure changes appear years before the development of cognitive impairments and dementia. However, the relationship between brain structure changes and cognitive functions in ESRD patients has never been studied.

Methods: Twenty-six patients on maintenance hemodialysis without dementia and fifty-two age-matched non-renal failure control individuals were recruited from the Far Eastern Memorial Hospital (For ESRD patients, average age: 59.9 years and 31% had diabetes). All patients lives an independent life and can attend hemodialysis treatment independently. Brain structure was measured by 3T-MRI and analyzed using Freesurfer. A battery of neuropsychological tests were also performed.

Results: Mini Mental State Examination (MMSE) scores were comparable between ESRD patients and control subjects (28.5 vs 28.6). However, ESRD patients showed poorer performance in psychomoter speed and executive function, measured by symbol search, sympbol substitution, trail making task and Stroop test after adjusting for age, gender, diabetes and education level (all $P < 0.05$). Neverthelss, there was no difference in both immediate recall or delayed recall memory tests. In addition, ESRD patients showed decreased volume in total gray matter and numerous brain structures, especially decreased volume of hippocampus (-0.98 mm^3), amygdala (-0.34 mm^3), and putamen (-1.61mm^3, all $P < 0.001$).

Conclusions: As the overall ESRD population grow older, how to prevent cognitive function decline and dementia is a pressing issue. Our study indicates that ESRD patients exhibit numerous accelerated brain aging represented by decreased brain volume in specific areas pertinent to the development of mild cogntive impairment (MCI) and dementia. Whether these changes are predicitive of further cognitive decline requires further study.

Octogenarians in the Emergency Room: AKI, Risk Factors, and Outcomes Mohsen Abu Alfeilat,[1] Itzchak N. Slotki,[1] Linda Shavit.[2] *[1]Share Zedek Medical Center, Jerusalem, Israel; [2]Shaare Zedek Medical Center, Jerusalem, Israel.*

Background: The prevalence of acute kidney injury (AKI) in the elderly is growing and the prognosis is dismal. The structural and functional changes of the aging kidney, multiple comorbidities and exposure to medications explain this susceptibility to AKI in elderly. The aim of this study was to evaluate the incidence, risk factors, clinical characteristics and outcomes of AKI in octogenarians admitted to the emergency room (ER) and to compare these parameters with those in a younger group of patients admitted in the same period.

Methods: This is a prospective, observational, single center study that enrolled adult patients admitted to the ER of Shaare Zedek Medical Center, Jerusalem, Israel. Patients were stratified by age (> or < 80 years) and followed up prospectively until discharge. Incidence of AKI, in hospital mortality and duration of hospital stay were recorded.

Results: Of 319 patients, 128 were octogenarians (mean age 86.7, range 80 to 105) and 191 were younger (mean age 60.6, range 18 to 79). The incidence of AKI and in hospital mortality was significantly higher in octogenarians (16.4 % vs 12.6 %, p= 0.039 and 15.6% vs 3.1 %, p= 0.001, respectively). In univariate analyses, sepsis and low blood pressure were associated with AKI in octogenarians, whereas history of CVA or CKD, hypoalbuminemia and anemia were associated with AKI in the younger group. In multivariate analysis, only low systolic blood pressure (SBP) at admission in octogenarians (p=0.002) and history of CKD and hypoalbuminemia in the younger patients (p<0.001; p=0.001) were independent risk factors for AKI.

Conclusions: Our results confirm the observation that AKI is common in octogenarians and is associated with significantly higher mortality. We identified SBP as the only independent variable associated with AKI. However, the role of therapeutic strategies aimed to increase SBP and diminish complications in octogenarians remains to be elucidated.

FR-PO929

Geriatric Nephrology: AKI in Elderly Patients; Differences in Etiology, Morbidity, and Mortality; Age Is Not a Prognostic Factor Francisco javier Lavilla, Pedro Errasti, Christian I. Alfaro Sanchez. *Clinica Universidad de Navarra, Pamplona, Spain.*

Background: Age is considered an acute kidney injury (AKI) prognostic factor. But can be more important than biologic age, the" clinical age" that include morbidity, acute and chronic health status. The objective is evaluate acute kidney injury (AKI) in elderly and very patient, and the influence of age as a prognostic factor.

Methods: In a cohort with 2714 hospitalizated patients (medium age 62 years, SD 0.3; 66.3 % males) with AKI (KDIGO), we made three groups (group A with age lower than 65 years, group B between 65 to 85 years and group C with more than 85 years). We evaluate AKI etiology, treatment and index prognosis (ISI –individual severity index-), chronic morbidity (cancer, chronic renal and cardiac failure, diabetes), health chronic status (Karnofsky) and acute morbidity (inflammatory status, lower hemoglobin level). We use SPSS 20.0.

Results: Exitus (%): (A: 19.5, B: 14.6, C: 14) (p=0.003) Etiology: AKI functional (%) (A: 33.1, B: 48, C: 64) (p=0.001). ATN (%) (A: 22, B: 18.7, C: 14) (p=0.001). Complex AKI (%) (functional and ATN) (A: 39.1, B: 27.6, C 20.9) (p=0.001). Renal replacement therapy (%) (A: 28.4, B: 24.4, C: 14) (p=0.001). Acute disease: Acute inflammatory disease (%) (A: 46.8, B: 35.6, C 29.1) (p=0.001). Surgical procedure (%) (A: 16.8, B: 25.3, C: 28.4) (p=0.001). Chronic disease: Diabetes (%) (A: 6.7, B: 12.3, C 16.3) (p=0.001). Previous chronic kidney disease (%) (A: 34.4, B: 55.1, C: 66.3) (p=0.001). Chronic Heart disease Previous chronic kidney disease (%) (A: 2.9, B: 4.9, C: 12.8) (p=0.001). Cancer (%) (A: 62.9, B: 41, C: 14) (p=0.001). Analytical parameters: C reactive protein peak (mg/dL) (A: 15.1 SD 0.4, B: 15.4 SD 0.42, C: 11.3 SD 1.39) (p=0.038). Lowe Hb level (g/L) (A: 8.5 SD 0.07, B: 9.2 SD 0.15, C: 9.82 SD 0.3) (p=0.001). Acute anc chronic health status: ISI (A: 0.2818, B: 0.3272, C: 0.3651) (p=0.001). Karnofsky (A: 69.5 SD 0.4, B: 68.28 SD 0.4, C: 61.3 SD 2.02) (p=0.001)

Conclusions: The AKI in very elderly patients were more functional and less complex, with lower mortality and acute disease, but more chronic disease. Age is not the more important prognostic factor in AKI. Is more important others (some acute diseases –inflammatory-, chronic diseases –cancer-, health chronic and acute status and AKI etiology–complexity related with previous factors-).

FR-PO930

Polypharmacy and Outcomes in Older Dialysis Patients Sashika Samaranayaka,[2] Robert J. Walker,[2] Ari Samaranayaka,[2] Sarah Derrett,[2] John B. Schollum.[1] *[1]Dunedin Hospital, Dunedin, New Zealand; [2]University of Otago, Dunedin, New Zealand.*

Background: The impact of polypharmacy on patients with end stage kidney disease (ESKD) and associated comorbidities is uncertain since a direct causation cannot be determined. More medications could be an indicator of more complex patients with a higher risk of poor health outcomes, regardless of polypharmacy. This study investigated the association between polypharmacy, comorbidities and patients' health outcomes as measured by hospital admissions and mortality in a cohort of ESKD patients ≥65 years

Methods: 225 participants aged ≥ 65 years, either already on dialysis or eligible for dialysis (eGFR<15 ml/mn/1.73m^2) were recruited and followed for 3 years[1]. Individual medications and the number of 'medication groups' (by therapeutic indication) per person were recorded at baseline. Hospitalisation, irrespective of cause, was measured as the number of days per person per 12 month follow up. Comorbidities were dichotomised to 0-2 and ≥3. Negative Binomial (NB) regression and Modified Poisson regression were used to assess associations medication had with hospitalisation rate and mortality respectively, first at univariate level, then after adjusting for confounders including comorbidities.

Results: Individual medications ranged from 2 to 20 (IQR 8 to 12) while the medication groups ranged from 2 to 15 (IQR 6 to 10). Most participants (83.5%) took between 3-8 'medication groups'. The most common 'medication groups' were metabolic bone disease related (87%), haemotenics (76%), cholesterol management (66%) and antithrombotics (65%). There was a significant increase in hospitalisation rates for each increase in medication group (RR 1.12, 95% CI: 1.02-1.23). Univariate analysis showed an 8% increase in the risk of mortality with each medication (RR 1.08, 95th CI 1.05-1.11) and an 11% increase in risk of mortality with each increase in 'medication group' (RR 1.11, 95% CI 1.09-1.13). Similarly, multivariate analysis showed an increase in individual medications increased the risk of death by 8% (RR= 1.08, 95% CI: 1.07-1.09) and each individual 'medication group' by 11% (RR= 1.11, 95% CI: 1.09-1.12)

Conclusions: In this high risk population, who may require polypharmacy, polypharmacy is also an indicator of increased risk of hospitalisation and mortality in those with ESKD ≥65 years. 1. Walker et al. BMC Nephrology 2013, 14:175

FR-PO931

Impact of Age and Glomerular Filtration Rate on Cardiovascular Drug Use in CKD Patients Cédric Villain,[7,8] Sophie Liabeuf,[6,8] Marie Metzger,[8] Christian Combe,[5] Denis Fouque,[4] Luc Frimat,[3] Christian Jacquelinet,[1,8] Maurice Laville,[4] Ronald L. Pisoni,[2] Benedicte Stengel,[8] Ziad Massy.[7,8] *[1]Agence de la biomedecine, Saint-Denis La Plaine, France; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]CHRU Nancy-Brabois, Vandoeuvre les Nancy, France; [4]CHU Lyon Sud, Pierre Benite, France; [5]CHU de Bordeaux, Bordeaux, France; [6]Service de Pharmacologie Clinique, CHU Amiens, Amiens, France; [7]CHU Ambroise Paré, APHP, Boulogne-Billancourt, France; [8]CESP, INSERM U1018, Univ. Paris-Sud, UVSQ, Univ Paris-Saclay, Villejuif, France.*

Background: Evidence for prescribing cardiovascular drugs is low in elderly patients (pts) with chronic kidney disease (CKD). We analyzed the impact of age and glomerular filtration rate (GFR) on use of drugs recommended for several cardiovascular diseases (CVD) among pts with CKD.

Methods: We used baseline data from the CKD REIN cohort including 3033 adult pts with CKD stage 3-4. We studied use of several CVD-specific drugs according cardiovascular antecedents: antiplatelet agents, renin-angiotensin-aldosterone system (RAAS) blockers, beta-blockers, and statins or ezetimibe in coronary heart disease; antiplatelet agents or oral anticoagulant drugs (vitamin K antagonist or oral direct anticoagulant) in stroke or transient ischemic attack; oral anticoagulant drugs in atrial fibrillation with CHADS2-VASc2 score ≥2. Odds-ratios (OR) of drug use according to age and estimated GFR were adjusted for sex, educational, activities of daily living, and other CVD specific relevant confounders.

Results: Mean age was 66.8 yr, and mean CKD-EPI GFR 32.9 ml/min/1.73m^2. Prevalence of coronary heart disease was 24.5% (81.3% of these pts were receiving antiplatelet agents, 75.7% RAAS blockers, 66.1% beta blockers, and 82.9% statins or ezetimibe), that of stroke or transient ischemic attack was 10.1% (88.3% pts receiving antiplatelet agents or oral anticoagulant drugs), and that of atrial fibrillation and CHADS2-VASc≥2 11.2% (69.0% receiving oral anticoagulant drugs). Results of logistic regression are shown in Table 1.

Conclusions: Although the management of CVD was appropriate in the majority of CKD patients, old age and to a lesser extend low eGFR were associated with underuse of certain recommended drugs. The cross-sectional design of our study, however, does not enable to show whether these drugs were never used or were discontinued due to side effect.

Funding: Commercial Support - Amgen, Baxter, GSK, Fresenius Medical Care, Lilly, MSD, Otsuka supported the CKD REIN cohort.

Table 1 – Adjusted odds-ratios (95% confidence interval) of CVD drug use according to age and GFR

History of CVD	Drugs	Age (years)				eGFR (ml/min)	
		<65	[65-75[	[75-85[	≥85	≥30	<30
Coronary heart disease	Antiplatelet agents[a]	1	1.31 (0.69-2.53)	1.31 (0.66-2.60)	0.81 (0.26-2.48)	0.67	1	0.84 (0.52-1.34)

ANCA Associated Vasculitis and Treatment Associated Morbidity in the Very Elderly – A Single Centre Experience Turren tarun S. Chaggar,[1] Marie B. Condon,[2] David Makanjuola.[2] *[1]Epsom and St Helier NHS Trust, London, United Kingdom; [2]St. Helier Hospital, Surrey, United Kingdom.*

Background: ANCA-associated vasculitis presents in later life and is not uncommon in the very elderly (>80 years) patients, but published data concerning the safety and

tolerability is lacking. Concerns about treatment toxicity and tolerability may be a barrier to starting appropriate immunosuppression.

Methods: Retrospective review of our local database identified all patients presenting between 2006 and 2015 with ANCA associated vasculitis, and data from those aged >=80 at presentation were analysed for the purposes of this study. Follow-up was until May 2017 or death. The incidence of treatment related complications; leucopaenia and infections was recorded. Survival data were analysed with respect to age, sex, renal function at diagnosis as well as treatment regime used. Cause of death was reviewed where available.

Results: We identified 32 cases with a mean age of 83.5 yrs (range 80-90), mean follow-up period of 35.5 months (range 0.2 – 106). Of these, 14 were PR3 positive and 18 were MPO positive. Mean admission creatinine was 406 μmol/L and 38% (12/32) required RRT within 72 hours. Induction therapy was combined with steroids and 78% received cyclophosphamide (25/32), 6% azathioprine (2/32), 3% MMF (1/32) and 3% rituximab. Maintenance therapy was with Azathioprine in 55% (16/29), MMF 17% (5/29) and steroid alone 21% (6/29). Leucopaenia was recorded in N = 5. Of these, cyclophosphamide induction therapy was associated with two episodes of leucopaenia. Azathioprine therapy was associated with 2 cases. The 5th case identified was following Rituximab induction therapy. There were 10 documented cases of infection. Three patients died during the induction therapy. Induction of remission was achieved in 24/25 patients with cyclophosphamide and steroid therapy. Renal survival was 79% (23/29) at 3 months and 85% (22/26) at 1 year. Patient survival was 91% (29/32) at 3 months and 90% (26/29) at 1 year. Overall 50% (16/32) patients died during the period up period with a mean time to death of 25.2 months.

Conclusions: The results of the retrospective study show that induction therapy with cyclophosphamide was generally well tolerated with low rates of leucopenia and infections occurring during the maintenance phase. Mean survival of 25.2 months was comparable in this cohort of patients when compared to elderly patients (aged > 80) with CKD 5.

FR-PO933

Progression of CKD4 to CKD5/ESRD versus Death in the Very Elderly and Factors Associated with Survival Hui Xue, Shayna L. Henry, Qiaoling Chen, Mark P. Rutkowski, Nichole Mihara, Mi Chang. *Kaiser Permanente Southern California, San Diego, CA.*

Background: Geriatrics is the fastest growing population with End Stage Renal Disease (ESRD), and there is limited knowledge of transition from CKD4 to CKD5/ESRD vs death in this group. This study aims to shed light on the rate of progression from CKD stage 4 to CKD stage 5 or ESRD vs death, and the factors associated with survival in patients with eGFR≤20 and >75yrs old.

Methods: From 2003 to 2008, 1,431 adults, mean age 81.1±4.7yrs (range 75-99), with 15< eGFR ≤ 20 for at least 3 consecutive months RRT, were followed for 5 years with censoring at Dec 31, 2013. Subjects were followed until death vs eGFR≤15/dialysis, and those who maintained eGFR> 15 were censored at 5yrs. Survival of those who transitioned to CKD5/ESRD were separated into conservative care vs. Renal Replacement Therapy (RRT) groups and followed until death vs censoring at 5yrs. Multivariable hazard ratios were calculated for survival for the study population.

Results: Among older adults with CKD4, 930 (65%) reached CKD5/ESRD first, while 432 (30.2%) reached death first, and 69 (4.8%) maintained CKD4 and were censored at 5yrs. Most individuals reached CKD5/ESRD before death up till age 90. Among the 930 individuals who transitioned to CKD5/ESRD, 214 received conservative care and 716 received RRT. In the conservative management group, 140/214 (65.4%) died, vs in the RRT group 467/716 (65.2%) died. Median survival was 46 and 37 months for RRT and no RRT groups, respectively, and not statistically different (p=0.314). Age was the greatest factor associated with death, followed by medical comorbidities except hyperlipidemia. Asian race, statin, phosphate binder, and ACEi/ARB use offered survival advantages.

Conclusions: Among >75yrs old CKD4 patients, the risk of progression CKD5/ESRD is still higher than death up to age 90. Factors associated with improved survival, statin, phosphorous binders, ACEi/ARB, use, hyperlipidemia, and Asian race, warrant closer evaluation in future studies.

FR-PO934

Predicting Long-Term Renal and Patient Survival by Histological Diagnosis in Elderly Patients Undergoing a Renal Biopsy Arunraj Navaratnarajah, Candice A. Roufosse, H. Terence Cook, Michelle Willicombe. *Imperial College NHS Healthcare Trust, London, United Kingdom.*

Background: Evidence on long-term outcomes following renal biopsies in the elderly are lacking. This study aims to describe renal and patient outcomes in the elderly according to indication for biopsy, clinical parameters and histological diagnosis.

Methods: An analysis of 445 patients >70yrs old who had a renal biopsy between 2005 and 2015 was performed. Median age was 75.1yrs (70.1-91.0) and follow-up 5.8yrs.

Results: 180/445 patients progressed to ESRD or died. 83/445 died without renal replacement therapy (RRT), 97/445 required RRT and 49/97 died after requiring RRT. This equates to 1, 3 and 5yr renal survival of 86.1, 80.1 and 76.9% and patient survival of 92.6, 82.8 and 72.3% respectively. Patients who progressed to ESRD were at higher risk of dying compared with those who remained dialysis independent, HR 2.54(1.64-2.93), p<0.0001. Variables associated with risk of ESRD included higher serum creatinine (Cr) at time of biopsy [HR 1.005(1.004-1.007), p<0.0001] and biopsy for the indication of nephrotic syndrome (NS) with renal dysfunction [3.08(1.50-6.32), p=0.002]. Whilst having either histological features of GN [0.49(0.26-0.95, p=0.033] or TIN [0.075(0.01-0.55), p=0.01] were associated with dialysis independence. Variables associated with reduced patient survival included increasing age [1.09(1.04-1.15), p=0.0004], Cr at time of biopsy [HR 1.0018(1.008-1.0028), p=0.0003], biopsy for NS with renal dysfunction [2.80(1.69-4.63), p=0.000] and histological diagnosis of MGRS [2.81(1.47-5.37), p=0.0017]. Those with tubulointerstitial scarring without a definite cause [HR 2.19(1.33-3.62), p=0.0011], GN [HR 2.07(1.16-3.70), p=0.006] and vasculitis [HR 3.56(1.68-7.50), p<0.0001] were at risk of progressing to ESRD before dying. There was no difference in risk of ESRD or death in patients with TIN, who had a good prognosis. Patients with MGRS also had no increased risk of ESRD over death, 1.36(0.52-3.60), p=0.52, however prognosis was poor with median time to death or dialysis 0.91yrs.

Conclusions: Renal biopsies in the elderly not only provide a histological diagnosis but also prognostic information on renal and patient survival. Data from this study may be useful for informed decision making by patients and nephrologists.

Histological Feature	Glomerulonephritis excluding vasculitis (GN)	Vasculitis	Tubulointerstitial nephritis (TIN)	Monoclonal Gammopathy of Renal Significance (MGRS)	Tubulointerstitial scarring without a definite cause
No. of patients (%)	113 (25.4)	56 (12.6)	53 (11.9)	29 (6.5)	194 (43.6)

FR-PO935

Deletion of the Gene for Adiponectin Accelerates Age-Related Kidney Injury Eun Hui Bae,[1] Hong sang Choi,[3] Ha yeon Kim,[2] Chang Seong Kim,[1] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Dongku, Republic of Korea; [3]Chonnam national university hospital, Gwangju, Republic of Korea.*

Background: Aging causes renal fibrosis, and aging related renal changes are characterized by oxidative stress. However, the role of adiponectin in aging process has not been elucidated. The present study was aimed to investigate the role of adiponectin in renal fibrosis in aging.

Methods: We used male 2 and 12 months old C57BL/6 (wild type, WT) mice and adiponectin knock out ($APN^{-/-}$) mice. The protein expression of transforming growth factor β (TGF- β), Smad-2/3, Smad-4, Smad-6, α smooth muscle actin (α-SMA), collagen IV, pro-apoptoic Bax and anti-apoptotic protein Bcl-2, phosphorylated AMP-activated protein kinase (p-AMPK) was determined by semiquantitative immunoblotting. For the in vitro experiments, human proximal tubular epithelial (HK2) cells were treated with TGF- β with or without pretreatment of adiponectin.

Results: 12 month old $APN^{-/-}$ mice exhibited decreased body weight, increased albuminuria and kidney to body weight ratio compared to 12 months WT mice. Fibrosis markers such as α smooth muscle actin and collagen IV were increased. The protein expression of TGFβ, Smad-2/3, and Smad-4 was increased, while inhibitory Smad-6 decreased in 12 months $APN^{-/-}$ mice compared to WT mice. ROS generation was also increased. Apoptosis marker such as Bax expression was increased while Bcl-2 expression was decreased in 12 months $APN^{-/-}$ mice compared WT mice. Phosphorylation of AMP-activated protein kinase (AMPK) was decreased in 12 months $APN^{-/-}$ mice compared to WT mice. TGFβ treatment showed decreased AMPK phosphorylation in HK2 cells. Pre-treatment of adiponectin attenuated fibrosis markers, apoptosis marker expression and ROS generation.

Conclusions: Our results suggest that adiponectin plays a role in the pathogenesis of progressive kidney injury associated with aging process.

FR-PO936

Impact of Aging on the Risk of Platinum-Related Renal Toxicity, Clinical Response, and Prognosis: A Systematic Review and Meta Analysis Guangyan Cai.[1,2] *[1]Nephrology, Chinese PLA Genaral Hospital, Beijing, China; [2]State Key Laboratory of Kidney Diseases, National Clinical Research Center of Kidney Diseases, Beijing, China.*

Background: Renal toxicity limits clinical use of platinum-based theray in the elderly. In order to clarify the impact of aging on (1) the risk of platinum-related nephrotoxicity; (2) clinical efficiency and prognosis of platinum therapy, the following meta analysis were carried out.

Methods: We searched multiple databases for the studies published before January 2017. The inclusion criteria were case-control, cohort studies published in any language.

Results: 34 studies with a total of 10,637 patients were included. The risk of platinum nephrotoxicity in the elderly group was 1.43 times higher than in the non elderly group (Risk Rate). The risk of grade I/II renal toxicity in the elderly group was 1.64 times higher than that in the non elderly group. There was no significant difference in the incidence of grade III/IV renal toxicity. Subgroup analysis of different platinum drugs confirmed carboplatin had less risk of nephrotoxicity than cisplatin. The risk of renal toxicity in the elderly patients from Asia is 2.63 times higher than that in young patients, which was significantly higher than those from Europe and North america. Although treatment with hydration, the risk in the elderly group was still 2.07 times higher than that in the control group. Presumably, the protective effect of hydration is more pronounced in non elderly patients who have better reserve of renal function. The risk of nephrotoxicities in the 60-70 year and more than 70 year group were 1.77 and 1.35 times greater than that in the non elderly group, respectively. There were no significant differences in the response rate, median survival time and 1-years survival rate between the elderly and the young patients with IIIB or IV grade of non-small cell lung cancer. The 1-year survival rate in the renal toxicity group is 44.8%, which is significantly higher than that in the non renal toxicity group (33.2%) (P=0.035).

Conclusions: Aging increases the risk of platinum nephrotoxicity by 43%, in which mild renal toxicity is dominant. There are no significant effects of aging on clinical efficiency and prognosis of platinum therapy. The 1-year survival rate of renal toxicity group is significantly higher than that without renal toxicity group.

Kidney Size in Relation to Aging, Gender, Function, and CKD Risk Factors Antonello Pani,[5] Doloretta Piras,[5] Marco Masala,[6] Alessandro Delitala,[7] Silvana A. Urru,[1] Lenuta Balaci,[7] Liana Ferreli,[7] Francesco Loi,[7] Alice Atzeni,[5] Walter Racugno,[3] Laura Ventura,[4] Magdalena Zoledziewska,[6] Maristella Steri,[7] Edoardo Fiorillo,[7] David Schlessinger,[2] Francesco Cucca.[6,7] *[1]CRS4, Pula, Italy; [2]National Institute on Aging, Baltimore, MD; [3]University of Cagliari, Cagliari, Italy; [4]Università di Padova, Padova, Italy; [5]Nefrologia e Dialisi, Azienda Ospedaliera G. Brotzu, Cagliari, Italy; [6]Istituto di Ricerca Genetica e Biomedica (IRGB), CNR, Cagliari, Italy; [7]Center ProgeNIA, Istituto di Ricerca Genetica e Biomedica (IRGB), CNR, Cagliari, Italy.*

Background: Renal function is known to decrease progressively with age even in healthy individuals, in a process known as nephrosenescence. However, the relation of aging to renal volume is less clear. In our study we examined the relationship between renal function and kidney size, with a focus on the progressive effect of aging and the effect of several variables (heritability, CKD risk factors) on renal volumes.

Methods: Ultrasound kidney size parameters (total kidney volume, parenchymal kidney volume, and kidney length) were systematically determined using cross-sectional data from a general population cohort encompassing an age range 18-100. Among them, we separately analyzed 2,421 "healthy" and 1,539 "comorbid" individuals carrying CKD risk factors. Kidney volumes were adjusted for BSA.

Results: Gender and age effects on kidney size parameters were observed. In healthy volunteers, an early increase in kidney size was followed by progressive decrease in males, whereas in females the decline began earlier and continued throughout the lifespan. As a result, after the 3-4th decade, men had higher kidney volumes than women throughout life ($p< 0.001$). In comorbid individuals, a more evident early increase and a faster subsequent decrease in kidney sizes were seen ($p < 0.001$). The decline in kidney size parameters in the elderly was accompanied by a parallel decrease in eGFR. Heritability estimates for kidney size parameters ranged from 12% to 27%; the predominant influence of non-genetic parameters included effects of smoking and other CDK risk factors.

Conclusions: Our cross-sectional analysis showed dynamic changes in kidney size throughout life, which were influenced by both gender, age, and CKD risk factors. Heritability was overall relatively modest, while substantial effects of metabolic comorbidities and modifiable risk factors (e.g., smoking and lipid levels) were seen.

How Do Creatinine Based GFR Equations Perform in Chinese Nonagenarians Mengjing Wang,[1] Xinyu Dong,[2] Minmin Zhang,[3] Li Ni,[2] Zuyun Liu,[5] Xiaofeng Wang,[4] Jing Chen.[2] *[1]Huashan Hosopital, Fudan Univeristy, Shanghai, China; [2]Huashan Hospital affiliated to Fudan University, Shanghai, China; [3]Huashan Hospital, Fudan Univerisy, Shanghai, China; [4]State Key Laboratory of Genetic Engineering and Ministry of Education Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan University, Shanghai, China; [5]State Key Laboratory of Genetic Engineering and Ministry of Education Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan University, Shanghai, China.*

Background: The clinical and prognostic meaning of evaluating Glomerular filtration rate (GFR) may be different in the very old population. This study aimed to elucidate the performance and predictive value of 4 GFR estimation equations in Chinese nonagenarians.

Methods: We calculated baseline eGFR from serum creatinine using the CKD epidemiology collaboration (CKD-EPI) equation, the Modification of Diet in Renal Disease Study (MDRD) equation, Berlin Initiative Study-1 (BIS1) equation, and modified MDRD equation from Chinese population in 278 nonagenarians from the Rugao longevity cohort over the period of 2007 to 2014. We compared the association of GFR estimated from 4 equations with risk of all-cause mortality using fully-adjusted Cox model. Overall improvement in reclassification based on clinical eGFR categories was assessed applying net reclassification improvement (NRI).

Results: Mean age of participants was 97±2 years old with 77% of women. Follow-up time was 2.8±1.8 years. Median (IQR) eGFR by CKD-EPI, MDRD, BIS, and modified MDRD equations were 73.9 (62.2–77.6), 87.5 (71.7–104.8), 56.4 (47.9–63.9), and 107.9 (88.4–129.2) ml/min per 1.73m², respectively. Higher $eGFR_{EPI}$ was associated with lower mortality after multivariate adjustment which includes frailty (for continuous $eGFR_{EPI}$: HR 0.987, 95%CI 0.976-0.998; for categorical $eGFR_{EPI}$: HR 0.782, 95%CI 0.628-0.945), while GFR estimated from other equations didn't show any associations with mortality. NRI for death by the CKD-EPI equation compared to MDRD, BIS1 and modified MDRD equations was 0.06, 0.06, and 0.03 (P>0.05 for all), respectively.

Conclusions: The CKD-EPI equation showed more appropriate estimation of GFR in long-lived individuals with respect to GFR distribution and risk of long-term mortality as compared to the other equations, suggesting improved clinical usefulness in Chinese nonagenarians.

Value-Based Evaluation of Dialysis versus Conservative Care in Older Patients with Advanced CKD Wouter Verberne,[1] Janneke Dijkers,[1] Johannes C. Kelder,[1] Tom B. Geers,[1] Wilbert Jellema,[1] Hieronymus H. Vincent,[1] Johannes Van delden,[2] Willem Jan W. Bos.[1] *[1]St Antonius Hospital, Nieuwegein, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Older patients approaching end-stage renal disease face the decision whether or not to start dialysis. Conservative care is argued to be a reasonable alternative as dialysis is not always associated with a survival benefit, as shown in our previous survival analysis. To truly foster decision-making, we analyzed more patient-relevant outcomes and treatment costs in an extended cohort.

Methods: We conducted a single-center cohort study in 366 patients ≥70 years old with stage 4/5 chronic kidney disease, who chose either dialysis (n=240) or conservative care (n=126) after careful counselling. Using a value-based health care approach (value = outcomes/cost), survival, quality of life, assessed with KDQOL-SF™ questionnaire in 98 patients, and treatment burden, determined as hospital free days, were evaluated, together with treatment costs.

Results: The survival advantage in patients choosing dialysis over patients choosing conservative care diminished or disappeared in patients ≥80 years or with severe comorbidity. There were no differences between patients managed conservatively (n=23) and patients started on dialysis (n=34) on physical and mental health summary scores (all P>0.1). Patients choosing conservative care had 353 versus 283 hospital free days per year, measured from date of treatment decision (incidence rate ratio: 1.15, 95% confidence interval 1.09 to 1.21, P<0.001). Annual hospital costs were significantly lower in the conservative care group (cost ratio: 0.43, 95% CI 0.28 to 0.67, P<0.001).

Conclusions: Choosing dialysis was associated with little or no survival benefit in patients with the highest ages or with severe comorbidity. In all patients, choosing conservative care was associated with similar quality of life, lower treatment burden, and lower treatment costs in comparison to choosing dialysis. By achieving similar outcomes against lower treatment burden and costs, value was created for older patients with advanced chronic kidney disease choosing conservative care.

FR-PO940

Outcomes in Dialysis versus Conservative Care for Older Patients: A Prospective Cohort Analysis of Stage 5 CKD Maharajan Raman, Philip A. Kalra, Darren Green. *Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom.*

Background: The benefits of dialysis in older people with ESKD are not clear. We aimed to establish whether dialysis has survival advantage compared to conservative care (CC) in older people who were medically suitable for dialysis therapy.

Methods: This was a prospective observational study of CKD patients aged ≥75 years when eGFR first reached ≤15ml/min/1.73m². Estimates of median survival and hazard ratios (HR) for death were compared between patients who chose dialysis versus those who chose conservative care from two time points: when first seen in pre-dialysis clinic (eGFR ≤15ml/min/1.73m²) and when initiation of dialysis first considered (eGFR ≤10ml/min/1.73m²). Patients with co-morbidities likely to significantly reduce life expectancy were excluded (NYHA class 3 or 4 heart failure, malignancy, dementia). Comparative data on number of days spent in hospital during follow up were also collected.

Results: There were 204 patient (123 dialysis, 81 CC) with eGFR was ≤15ml/min/1.73m². Of these, 115 went on to record an eGFR of ≤10ml/min/1.73m² (73 dialysis, 42 CC). The median survival from eGFR first ≤15ml/min/1.73m² for the dialysis and CC group were 42 (95% CI =33–50) and 31 (21-41) months respectively. The co-morbities adjusted HR for death in the dialysis group compared to CC was 0.61(0.41-0.61, p= 0.01). When eGFR first ≤10ml/min/1.73m², the respective median survival times were 36 (25–47) and 12 (0-5) months. The co-morbidities adjusted HR for death in dialysis group compared to CC was 0.36 (0.21-0.62, p <0.001). The median annualized number of hospital days (in-patient and outpatient) from eGFR ≤15mL/min/1.73m² was 23 (IQR 10-86) for dialysis patients, and 10 (5-25) for CC. The median annualized number of hospital days (in-patient and outpatient) from eGFR ≤10mL/min/1.73m² was 78 (IQR 18-125) for dialysis patients, and 21 (8-80) for CC.

Conclusions: This study is novel in being both prospective and in excluding patients with co-morbidly, which may limit suitability for dialysis. It indicates that dialysis increases survival in older patients, as the statistically significant difference in survival only appeared when eGFR was ≤10mL/min/1.73m². This advantage may be offset by the increase in time spent at hospital. Hence, a future focus on quality of life is needed to establish the true benefits of dialysis in older people.

FR-PO941

Hydrogen Sulfide Ameliorates Aging Associated Kidney Changes in Mice Hak Joo Lee,[1] Denis Feliers,[1] Jeffrey L. Barnes,[1] Sae Byeol Oh,[1] Goutam Ghosh-Choudhury,[1] Veronica Galvan,[1] Randy Strong,[1] James F. Nelson,[1] Adam Salmon,[1] Christopher G. Kevil,[2] Balakuntalam S. Kasinath.[1] *[1]University of Texas Health Science Center, San Antonio, TX; [2]Louisiana State University Health Science Center, Shreveport, Shreveport, LA.*

Background: Hydrogen sulfide (H2S) ameliorates renal fibrosis and proteinuria in chronic kidney disease. We examined the status of H2S in kidney aging.

Methods: First study: The status of H2S metabolism and signaling pathways related to synthesis of proteins including matrix proteins were studied in renal cortical extracts from C57BL/6 male young (5 months old, n=10) vs. old mice (30 months old, n=10). Second study: We randomized 18-19 month-old male mice to receive NaHS in drinking water (30 μmoles/L) (NaHS group, n=20 mice) vs. water alone (Control group, n=14 mice) for 5 months.

Results: First study: Compared to young mice, increase in renal cortical laminin and type 1-collagen content in old mice was associated with decreased generation of H2S, increase in tyrosine phosphorylation of insulin receptor (IR) and IRS2, decrease in AMPK activity and activation of Akt-mTORC1-mRNA translation signaling axis. Second study: Administration of NaHS to 18-19 month-old mice increased plasma free sulfide levels. Food, water intake and body weights were similar and blood glucose normal in the two groups throughout the study duration. Systolic, diastolic, and mean blood pressures (BPs) were high at baseline and continued to rise in the Control group; NaHS reduced the BPs. NaHS abolished the progressive increase in urinary albumin to creatinine ratio seen in control mice and reduced serum cystatin C levels. NaHS inhibited the increase in renal cortical content of laminin and type 1-collagen and ameliorated the increase in glomerular fractional mesangial matrix volume. NaHS inhibited tyrosine phosphorylation of renal cortical IR and IRS-2. NaHS restored decreased AMPK activity to normal and inhibited the Akt-mTORC1-mRNA translation axis that leads to increase in protein synthesis. Aging mice showed increase in renal cortical monocyte infiltration and content of p21, IL-1β, IL-6, components of Senescence Associated Secretory Phenotype, SASP, which contribute to tissue injury; NaHS inhibited these changes.

Conclusions: Aging-induced kidney changes are associated with H2S deficiency. Administration of H2S ameliorates aging-induced kidney changes; the mechanisms appear to involve reduced hypertension, inhibition of signaling pathways leading to matrix protein synthesis, and SASP.

FR-PO942

Age-Related Changes in Nuclear Reduced Glutathione Levels in Rat Kidney Cortex and Medulla Marianna J. Zamlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN.*

Background: Aging is associated with changes in the cell related to oxidative stress caused by free radicals produced in aerobic metabolism. Maintenance of reduced glutathione (GSH), the major antioxidant inside cells, provides protection against cell damage caused by free radicals. Although age-related changes in GSH levels in cell organelles, such as the mitochondria, have been reported in previous studies, there is limited information on GSH levels in the cell nucleus and age. The present study was undertaken to investigate the effect of age on changes in nuclear GSH levels in rat kidney cortex and medulla.

Methods: Young (3 months of age) and Old (22 months of age) female Lewis rats were used. The kidneys were harvested from anesthetized rats after being perfused with isotonic saline via a catheter in the abdominal aorta. The kidneys were separated into cortical and medullary sections and homogenized in isotonic saline. Differential centrifugation was used to isolate the nuclear fractions. GSH and oxidized glutathione (GSSG) levels were measured in the fractions using a spectrophotometric assay, and expressed as nmol/g kidney wet weight. Total GSH was determined from the sum of GSH and GSSG expressed in GSH equivalents. The redox ratio (i.e., GSH/GSSG) was also determined. Differences were evaluated using a a Student's t Test.

Results: There was a significant decrease in GSH, GSSG and TOTAL GSH levels with age in the nucleus from rat kidney cortex. There was not a significant decrease in the aforementioned variables with age in the nucleus from rat kidney medulla. The redox ratio was not changed with age in either the kidney cortex or medulla.

Conclusions: The findings indicate that nuclei from the rat kidney cortex do undergo a significant decrease in the antioxidant glutathione with age. This indicates the nucleus from rat kidney cortex is experiencing increased oxidative stress and thus, damage with age.

Age-Related Changes in Nuclear Glutathione Levels in Rat Kidney Cortex and Medulla

		GSH nmol/g kidney wet wt	GSSG nmol/g kidney wet wt	TOTAL GSH nmol/g kidney wet wt	GSH/GSSG (Redox Ratio)
Young rats (n = 6)	Cortex	310 ± 22	272 ± 49	811 ± 127	1.3 ± 0.2
	Medulla	213 ± 31	312 ± 83	837 ± 167	1.0 ± 0.3
Old rats (n = 6)	Cortex	203 ± 22 *	126 ± 40 *	455 ± 40 *	2.5 ± 0.6
	Medulla	158 ± 22	130 ± 43	419 ± 103	2.1 ± 0.6

All data expressed as X +/- SEM. * Significantly different ($p<0.05$) from Young rats.

FR-PO943

Outcomes of Peritoneal Dialysis Associated Peritonitis in the Elderly Population: A Single Centre Experience Htay Htay,[1] Suh C. Pang,[1] Mui hian Sim,[2] Jun Jie Benjamin Seng,[2] Sin yan Wu,[1] Marjorie W. Foo.[1] *[1]Department of Renal Medicine, Singapore General Hospital, Singapore, Singapore; [2]Department of Pharmacy, Singapore General Hospital, Singapore, Singapore.*

Background: The clinical outcomes of peritonitis in the elderly peritoneal dialysis (PD) patients have not been well studied before. The study aimed to determine the outcomes of peritonitis in elderly patients.

Methods: This was a single centre retrospective cohort study, including all peritonitis episodes between 2011 and 2014. The primary outcome was medical cure (defined as peritonitis episode cured by antibiotics without complicated by catheter removal, haemodialysis (HD) transfer, relapsed/recurrent peritonitis and/or death) in elderly patients, defined as ≥ 65 years old. The secondary outcomes were complications of peritonitis. These outcomes were compared between elderly and younger patients using multivariable logistic regression.

Results: Total 377 episodes of peritonitis occurred in 247 patients during the study period. Of these, 169 episodes occurred in 105 elderly patients. Of 105 elderly, 51% were male, 79% were Chinese, 65% had diabetes mellitus, 95% had hypertension and 54% had cardiovascular disease. Diabetes nephropathy (52%) was the commonest cause of renal failure. The causative organisms were Gram-positive (32%), Gram-negative (29%), culture negative (22%), polymicrobial (12%), fungal (4%) and mycobacterial (1%) organisms. Elderly patients were less likely to present with fever (17% versus 30%) and cloudy effluent (85% versus 92%) than younger patients. Total 112 episodes (66%) of peritonitis in elderly patients achieved medical cure. The remaining 57 episodes were not cured because of one or more of the following complications: catheter removal (n=29), haemodialysis transfer (n=20), relapsed/recurrent peritonitis (n=19), and/or death (n=11). There was no significant difference in the odds of medical cure (Odds ratio (OR) 0.93, 95% confidence interval (CI) 0.56 - 1.54; p=0.78) between the elderly and the younger patients after adjusting for cardiovascular disease, primary renal disease and causative organisms. Similar results were observed for complications of peritonitis (catheter removal, transfer HD, relapse/recurrence) except that the odds of peritonitis-related death was significantly higher in the elderly patients (adjusted OR 2.59, 95% CI 1.07-6.29; p=0.04).

Conclusions: Elderly PD patients achieved comparable medical cure but had higher peritonitis-related mortality than younger patients.

FR-PO944

Peritoneal Dialysis-Related Peritonitis in the Era of the Elderly Dialysis Population: A Retrospective, Multicenter Study in Thailand Kiatkriangkrai Koyratkoson,[4,5] surapon nochaiwong,[4,5] Chidchanok Ruengorn,[3,5] Chayutthaphong Chaisai,[4,5] Kajohnsak Noppakun,[6] Ratanaporn -. Awiphan,[2,5] Wilaiwan -. Chongruksut,[7,5] Sirisak Nanta.[1,5] *[1]Maesai District Hospital, Chiang Rai, Thailand, Chiang Rai, Thailand; [2]Chiangmai University, Chiangmai, Thailand; [3]Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; [4]Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; [5]Pharmacoepidemiology and Statistics Research Center (PESC), Chiang Mai University, Chiang Mai, Thailand; [6]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand; [7]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand. Group/Team: Thai Renal Outcomes Research (THOR) Investigators.*

Background: Peritonitis, a major complication of peritoneal dialysis (PD), contributes to treatment failure, hospitalization, and mortality, particularly in elderly PD cases. Regardless of technical problems, social difficulties, and burden of comorbidities, it remains debated whether elderly patients have a significantly amplified risk of peritonitis than younger patients. Thus, we aimed to evaluate the impact of advanced age on the risk of PD-related peritonitis.

Methods: We conducted a retrospective cohort study using the PD registry database of an incident PD patients with aged ≥ 18 years. At PD initiation, subjects were categorized into <55, 55-65, and >65 years of age groups. Clinical characteristics regarding age groups were compared among participants from three large PD centers in Thailand between January 2006 and December 2016, and followed through April 2017. Time-to-first PD-related peritonitis and longitudinal rates were analyzed by multivariable Cox's proportional hazards model and Poisson regression, respectively.

Results: Among 1,023 PD patients included, 401 (39.2%), 312 (30.5%), and 310 (30.3%) patients aged <55, 55-65, and >65 years, respectively. After a total follow-up of 19,463.4 person-months, 519 (50.7%) were recognized as having PD-related peritonitis. There was no significant difference in spectra of causative microorganisms among patient age groups.

Conclusions: The risk of first episode peritonitis is not increased in elderly PD patients, however, compared with younger patients, the higher peritonitis rate was observed in elderly PD patients. Large prospective trials are needed to validate these findings.

Funding: Government Support - Non-U.S.

Safety Profile of Outpatient Percutaneous Native Renal Biopsy: A Large Monocentric Single Operator Cohort Dario Roccatello,[2] Savino Sciascia,[3] Roberta Fenoglio.[1] *[1]None, TORINO, Italy; [2]Ospedale San GIovanni Bosco, Torino, Italy; [3]Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Torino, Italy.*

Background: In the study we aim to evaluate the safety of performing percutaneous renal biopsy as an outpatient procedure compared to the traditional inpatient policy. Additionally, the rate and risk factors of complications after a procedure were investigated.

Methods: We ambispectively studied native kidney biopsies performed in our Institution between January 2000 and November 2015. Since January 2012, we began performing renal biopsies as outpatient procedures. Two groups of patients were considered: group I, in whom kidney biopsy was performed and followed by at least 1-day hospital admission; and group II, in whom renal biopsy was performed in the outpatient department and followed by 6 hours' observation period and then by regular outpatient visits. All biopsies were performed by a single nephrologist with the use of real-time ultrasound and automated biopsy needle (18 gauge), following a structured protocol.

Results: 462 biopsies were reviewed, 210 (45.5%) of patients were female and the mean age was 54.7 ± 17.9 years. One-hundred and twenty-nine (27.9%) of these biopsies were performed in outpatients. A total of 36 (7.8%) of patients developed a complication, and of those 9 (1.9%) suffered for a major complication [arteriovenous fistula (6 cases, 1.2%), ischaemic stroke (2, 0.4%), thromboembolic pulmonary embolism (1, 0,2%)] and 27 (5.8%) for minor [macroscopic haematuria (12 cases, 2,6%), haematomas on sonography not requiring intervention (15 cases, 3,2%)]. When comparing the complication rate between group I and II, no statically difference were observed [overall 24 (7,2%) complications in group 1 and 12 (9,3%) in group II; 5 (1,5%) and 4 (3,1%) major, 19 (5,5%) and 8 (6.2%) minor complications, respectively in group I and II]. When analysing together both groups, after multivariate analysis, serum creatinine >3 mg/dl (OR 2.03 95%CI 1.18-6.81) and known severe hypertension (OR 2.01 95%CI 1.2-4.7) were found to be independent risk factors for minor and major complications, respectively. Conversely, we found no association of risk with the number of biopsy passes, gender, age, diagnosis, presence of haematuria before the kidney biopsy nor the degree of proteinuria.

Conclusions: Outpatient biopsy could be a valuable, safe, and perhaps cost-effective method of obtaining diagnostic renal tissue in the majority of patients.

FR-PO946

Should Kidney Biopsies Be Done via CT-Guidance? Comparison of Percutaneous Native Kidney Biopsy Complications and Glomerular Yield between Interventional Radiologists and Nephrologists Brigani G. Amante,[1] Alkesh Jani.[2] *[1]UNIVERSITY OF COLORADO, HOUSTON, TX; [2]University of Denver Colorado, Aurora, CO.*

Background: Percutaneous native kidney biopsy (PNKB) is performed as an outpatient procedure by interventional radiologists (IR) & nephrologists. However, data on tissue yield & complication rates comparing IR performed (IRP) & nephrology performed (NP) PNKB are lacking. Also, there is no published study that directly compares outcomes of PNKBs performed via computed tomography (CT) vs. ultrasound (US) guidance.

Methods: 131 PNKBs performed at the University of Colorado Health System from 1/2014-12/2016 were included. Biopsies were performed by nephrologists using real-time US guidance or IR using CT guidance.

Results: 72 biopsies were done by nephrologists & 59 by IR. The NP group had a significantly longer duration of patient observation post-biopsy (20.7 vs 5.0 hrs, $p < 0.05$), used a larger biopsy needle (16G in 93% vs 18G in 100% of patients, $p < 0.05$), had lower number of needle passes (2.8 vs 3.5, $p < 0.05$), & had higher glomerular yield/needle pass (8.9 vs 6.4, $p = 0.05$) with lower rate of inadequate tissue (6.9% vs 18.6%, $p = 0.05$) than the IRP group. No differences in post-biopsy complications such as hematoma, hematuria, need for transfusion or intervention, analgesic use, emergency room visits, infection/sepsis, or patient death were observed between the groups.

Conclusions: Out-patient PNKB done via CT guidance had similar complication rates vs. real-time US guidance, and required a significantly shorter period of patient observation post-biopsy. Tissue yield was significantly better with real-time US guidance than with CT guidance, likely due to use of a larger-gauge needle. CT guided biopsy by IR offers similar complication rates for significantly less observation time vs US by Nephrology.

Table 1. Baseline Characteristics of Study Population.

Performance of Diagnostic and Interventional Nephrology (DIN) in Spain Haridian Sosa Barrios,[3] Jose Ibeas,[7] Angels Betriu,[6] Vicente Paraiso,[4] Pedro Quiros,[5] Ramon Roca-Tey,[1] Jose I. Cornago,[2] Maite Rivera.[3] *[1]Hospital De Mollet, Bancelona, Spain; [2]Hospital Galdakao, Bilbao, Spain; [3]Hospital Ramon y Cajal, Madrid, Spain; [4]Hospital U del Henares, Coslada, Spain; [5]Servicio Andaluz de Salud (Spain), El Puerto de Santa María, Spain; [6]IRB LLEIDA, LLEIDA, Spain; [7]LONDON, United Kingdom. Group/Team: GNDI.*

Background: Diagnostic and Interventional Nephrology (DIN) has gained drive in the last few years. Line insertion (whether ultrasound guided or not), renal biopsy (native and transplanted), renal ultrasound and peritoneal dialysis (PD) catheters or permanent dialysis lines insertion are vital to our specialty. Some of these procedures are delegated in other specialties. In our view, nephrologists should resume DIN as risk-benefit balance is better assessed, providing complete care for patients and reducing waiting times.

Methods: An online survey was sent by email to all Spanish Renal Departments in June 2015. The survey could be completed by any consultant and only one response per centre was allowed. Questions are listed in table 1. The survey was written, supervised and approved by the DIN Nefrology Group (GNDI, Spanish Society of Nephrology).

Results: Of 195 Nephrology Departments in Spain, 70 responded (35.8%). All centres had HD, 81.4% PD and 34.3% had a transplant program. 72.3% (52) had ultrasound equipment. Regarding catheter placement, 77.1% insert temporary jugular ones and 92.8% femoral. 75.7% perform native renal biopsies, of which 35.8% (19) are real-time ultrasound guided by nephrologists in full. Graft kidney biopsies are done in 26 centres, of which 46.1% are done by nephrologists. Tunnelled haemodialysis catheters are done in 38.5%, peritoneal catheter insertion in 25.7% and only 2 centres (2.8%) perform arteriovenous fistulae (AVF) angioplasty. In terms of ultrasound imaging, 28.5% do native kidneys ultrasound and 22.8% grafts. 71.4% of all centres offer carotid ultrasound assessment to evaluate cardiovascular risk, only 21% done by nephrologists. AVF's ultrasound scanning is done in 55.7% (39 centres).

Conclusions: DIN has spread in Spain, although there's still a long way ahead. It includes basic techniques to our specialty and allows more independency and efficiency. Therefore, appropriate training on different techniques should be warranted to nephrologists, implementing programs to do so aiming to minimize complication rates.

FR-PO948

Preventing Unnecessary Renal Replacement Therapy for AKI: A Quality Improvement Project Adrianna Douvris,[3] Khalid Zeid,[3] Swapnil Hiremath,[3] Manish M. Sood,[1] Edward G. Clark.[2] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]The Ottawa Hospital and Kidney Research Centre - Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [3]University of Ottawa, Ottawa, ON, Canada.*

Background: AKI is a frequent complication in hospital with the highest mortality observed in patients requiring renal replacement therapy (RRT). Also, RRT for AKI may be harmful for renal recovery. There are no effective pharmacological interventions to treat established AKI. Treatment focuses on limiting further renal damage, and reducing the risk of requiring RRT. Our objective is to characterize events that contribute to potentially avoidable RRT for AKI patients at the Ottawa Hospital. Ultimately, our results will serve as a guide to create a clinical pathway for AKI to limit iatrogenic harm in this population.

Methods: This is a retrospective cohort study of 100 consecutive patients who required acute RRT for AKI while hospitalized at TOH between July 1, 2015-August 31, 2016. Inclusion criteria: age 18 or over, and all dialysis modalities except peritoneal dialysis. Exclusion criteria: end stage kidney disease (ESKD), and RRT within 72 hours of admission. The main outcome is the frequency of iatrogenic events in the period after AKI but prior to RRT that may cause harm.

Results: We screened 344 charts to include 100 patients. Admission diagnoses were sepsis (26%), cardiac (31%), surgical (18%) and renal (15%). 36% of patients required ICU, CCU, or cardiac surgery ICU (CSICU) care at one point. Possible AKI etiologies cited: pre-renal (51%), ATN (68%), AIN (16%), and post-renal (6%). Contrast-induced nephropathy was suggested in 27%. Volume overload was the most common indication for initiating RRT; hyperkalemia was cited as an indication in 32%. Relative hypotension from anti-hypertensives was cited as an AKI contributor in 7%. With regards to nephrotoxins post-AKI, NSAIDs were continued in 3%, ACEi/ARB in 16%, and spironolactone in 13%. Of the 32 patients dialyzed with hyperkalemia, only 43.7% were placed on a low K+ diet, and 7% received a form of additional K+ after AKI and with a serum K+≥5.

Conclusions: Our study includes many seriously ill patients with AKI where RRT is likely unavoidable. However, we have identified potentially harmful events. These include nephrotoxic medications, iodinated contrast dye, potassium supplementation, and hypertension management. Upon completion, we plan to use our data to create solutions that will hopefully reduce the risk of iatrogenic harm for hospitalized AKI patients.

FR-PO949

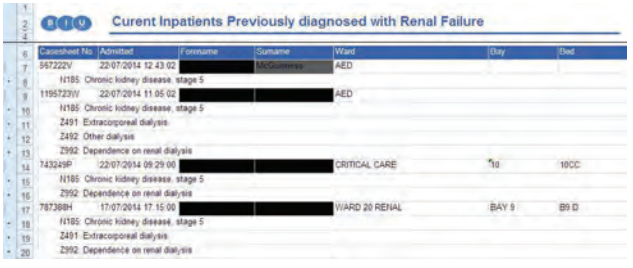
Patient Attendance Alert to Specialty System (PAASS): An Automatic Alert as a Novel Approach to Identify Patients with Advanced Kidney Disease for Early Specialty Input on Admission Bhavna Pandya, Samantha Dolan. *University of Liverpool, UK, LIVERPOOL, United Kingdom. Group/Team: Aintree Nephrology Dept; Aintree Business Intelligence System.*

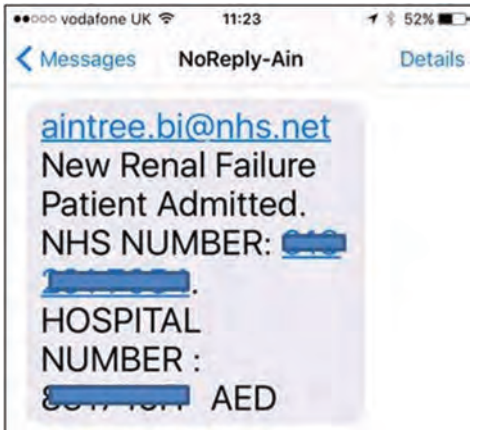
Background: Patients with pre-existing advanced renal disease admitted in emergency to hospital are managed by the admitting team. Renal specialists are involved at a late stage depending upon the mode of communication and rely on admitting team for notification. Delays in specialist input contribute to increased morbidity, length of stay, untoward incidences and even mortality. To avoid this delay, we designed an automatic, secure Patient Attendance Alert to Speciality System (PAASS) which alerts the renal team via e-mail and SMS message to notify the attendance of these patients to the appropriate specialist.

Methods: We carried out a retrospective analysis of patients admitted within several weeks between July-August 2016 with advanced renal disease. Comparison was made between PAASS alerted and manually referred patients. Length of stay, 30 day/ 6 month/ 12- month readmission rate and patient mortality rate were measured to compare with data prior to the implementation of PAASS alert. Trust's business intelligence system was used for alert details.

Results: The PAASS alert had acceptable sensitivity (95.2%) and specificity (100%). There was no difference in 6-month mortality and readmission rate between groups; however alerted patients had a significantly reduced 'length of stay' in hospital (p=0.0002, 95% CI -12.9,-7.6, SE 0.95), compared to those patients who were referred manually.

Conclusions: Our findings indicate that early notification of patient attendance to hospital using the PAASS alert contributed to reducing length of stay significantly.





FR-PO950

Disaster Preparation in Kidney Transplant Patients: A Survey-Based Assessment Shimi Sharief, Daniel J. Freitas, Deborah B. Adey, James A. Wiley. *University of California, San Francisco, San Francisco, CA.*

Background: Few quantitative assessments have been undertaken to assess the disaster preparedness of kidney transplant patients, a population at risk due to their dependence on immunosuppression. This is a survey-based assessment of the disaster preparedness of a cohort of 200 patients recruited from the UCSF Kidney Transplant clinic.

Methods: We recruited 200 kidney transplant recipients from the waiting room of the transplant clinic. They answered short pencil and paper questionnaires assessing their level of preparedness as well as what barriers they faced in becoming adequately prepared. Preparedness was scored based on the response to 7 different items and an index created. Medical and demographic data was extracted from the clinical chart. We analyzed the data using univariate analyses of different participant characteristics against three tertiles of preparedness – low (scores between 0-2), medium (scores of 3 or 4) and high (scores of 5-7). We created average scores of preparedness for various counties in California and geocoded them on maps created with Google Fusion Tables.

Results: Only 30 percent of patients were highly prepared for disasters. Participants were most prepared in stockpiling medications (78.5%) and least prepared in having a medical ID bracelet that identifies them as transplant patients (13%). A significant minority of patients (at least 40% of patients or more) were unprepared with lists of medications, important phone numbers and disaster kits. There were no major associations between preparedness and different participant characteristics such as age, race, gender, number of years since transplant or various clinical variables including type of immunosuppression or other comorbid conditions. Thirty-one of the 34 counties sampled were from California, of which Monterey County was the most prepared with an average preparedness score of 4.25 (out of 7).

Conclusions: Patients of all demographic and clinical backgrounds should be educated on the importance of disaster preparation. Since most deficiencies in preparedness are in general items, there should be a concerted effort on the part of city and medical services to address specialized populations in general preparedness planning.

Development and Usability Testing of a Patient Safety Educational Program in CKD Clarissa J. Diamantidis,[1] Jennifer St. clair russell,[1] Joseph Lunyera,[2] Janell R. Wylie,[1] Nikita Shah,[1] Jeffrey C. Fink.[3] *[1]Duke University School of Medicine, Durham, NC; [2]Duke University----, Durham, NC; [3]University of Maryland, Baltimore, MD.*

Background: Chronic kidney disease (CKD) threatens patient safety, yet few interventions educate patients about kidney-specific safety hazards. We sought to develop and usability test an educational program designed to promote patient awareness of relevant safety topics in CKD.

Methods: We included 4 patient safety objectives in a tablet-based educational program: 1) avoidance of non-steroidal anti-inflammatory drugs (NSAIDs); 2) hypoglycemia awareness (only for individuals with diabetes); 3) temporary cessation of certain medications while acutely volume deplete (i.e. "sick day protocol"); and 4) contrast dye risk awareness. Content was developed for each objective using plain language principles. Teaching strategies optimized human-computer interaction and content retention; audio, animation, and clinical vignettes reinforced themes. For example, using a vignette of a CKD patient with pain and pictures of common NSAIDs, participants are asked, "which of the following pain medicines are safe for Mr. Smith to take for his belly pain?" Assessment methods consisted of pre- and post- knowledge surveys, with provision of correct responses and explanations. Usability testing was performed among patients with CKD, and program tasks completion were rated as 1) no error, 2) non-critical error (self-corrected), or 3) critical error (not completed).

Results: All usability participants owned a mobile device and used it daily. Of 318 total tasks there were 3 non-critical errors (1%) and 6 critical errors (2%). One participant accounted for 7 of all total errors. All participants rated use of the tablet as 'very easy,' activity length as 'just right' (vs too long/short), the use of clinical vignettes as helpful, and would recommend this activity to others; the majority felt the program was 'very' or 'somewhat easy' to use (80%) and use of the audio was helpful (60%). All rated the activity between 8 (60%) and 10 (20%) on a scale of 1 to 10 (best). All usability testing recommendations were incorporated into the final version of the educational program.

Conclusions: A tablet-based patient safety educational program is acceptable and usable among individuals with CKD. Future studies will explore its impact on health outcomes in this high-risk population.

Quality Improvement Pilot: A Novel, Personalised, Nurse Led Pathway for Patients Commencing Haemodialysis Shows Improved Outcomes Vicky Ashworth, Alexandra C. Mccrudden, Peter J. Cole, Asheesh Sharma. *Royal Liverpool & Broadgreen University Hospitals Trust, Liverpool, United Kingdom.*

Background: Commencing haemodialysis (HD) is a time of physical and psychological distress, with a high incidence of hospitalization. Despite good pre dialysis care many patients experience a suboptimal start to HD. Mortality is at its highest within

the first 90 days of commencing dialysis. **Aim:** To develop, test and evaluate the impact of a novel, personalised nurse led pathway for patients commencing HD on a range of patient centred process and outcome measures.

Methods: Sequential PDSA cycles were used to develop a personalised nurse led pathway for the first 6 sessions of HD (see fig). Patient distress was recorded at week 2, 4 and 8 using the validated Patient Distress Thermometer (Renal). Baseline control data were retrospectively collected for patients commencing HD from July 2015-June 2016. Our prospective pilot recruits patients from July 2016-June 2017, and we report 90 day follow-up data.

Results: There were 78 patients in the historic control cohort (mean age 58.4y, 62% male, 45% diabetic). 90 day follow up data are available for 37 patients who started HD using the new pathway (mean age 56.2y, 51% male, 27% diabetic). All outcome measures have improved (see table). Patient distress score has dropped from 4.3 (week 2) to 2.4 (week 8). Patient and staff feedback has been strongly positive.

Conclusions: These data suggest improvements in patient experience and outcomes using this novel intervention.

Funding: Private Foundation Support

Improvements in Patient Outcome Measures

	Historic control group	New patient pathway
% listed for transplant or in work up at 90d	21%	31%
% definitive vascular access at 90d	40%	56%
% with home therapy plan at 90d	8.5%	20%
Days in hospital in first 90d	12.2 days	8.6 days
Unadjusted 90d mortality	5.1%	2.7%

Novel Nurse Led Pathway	
Mandatory Interventions	**Personalised Interventions**
Early review of dialysis prescription	Patient experience questionnaire
Access plan	Priority of home therapies if appropriate
Early review of dry weight	Transplantation plan
Medication and dietary advice	Supportive approach for frailer patients
Anaemia and blood biochemistry	Individualised education support for both patients and families
Distress score & early psychology review	Support for both patients and families
Early consultant review	
Production of update letter for patient consultant and GP	

Components of nurse led pathway

FR-PO953

Prevalence of Depression in Patients with ESRD on Hemodialysis and Peritoneal Dialysis in the West Area of Puerto Rico Sherryl D. Mitchell. *Baylor College of Medicine, Houston, TX.*

Background: Depressive symptoms and depression are major public health problems and the most frequent psychological problems reported among ESRD patients being treated by hemodialysis. We assessed the prevalence of depressive symptoms among hemodialysis and peritoneal dialysis patients at West area of Puerto Rico. Despite these findings, depression may remain under recognized and undertreated, particularly among ESRD patients. A systematic assessment of depression in hemodialysis patients would supply information about patient feelings of well being. Existing data suggest that screening for depression may help identify patients at higher risk for death and hospitalization.

Methods: This cross-sectional study was represented with a sample of 146 hemodialysis patients selected from 3 dialysis centers of West Area at Puerto Rico. We provided written informed consent before filling questionnaires to patients. The Beck Depression Inventory (BDI-II) is considered to be the standard instrument for assessing symptoms of depression and screening for clinical depression. We used this scale of 21 short answer question for assess degree of depression in studied patients.

Results: The prevalence of depression in peritoneal dialysis patients is 36% in our study when we compare the depression between HD and PD patients we noted that there is more prevalence of depression in Hemodialysis patients with a 53% than in the peritoneal group. There is significant effect between these groups (DF= 1, Value= 2.9849 and P-Value= 0.084) with a significance level at 10%. For age ranges no significant effect was observed in depressive symptomatology (DF=1, P-value= 0.8453, Value=0.0381). In relation to the variable weather time in PD treatment and prevalence of depression there is not found significant differences (DF=2, P-value=0.8474, Value=0.3311). More results to discuss further.

Conclusions: Based on our investigation the prevalence of depression is present in ESRD on PD and HD patients at West area of Puerto Rico. This supports the recommendations of early implementation psychological measures and medical treatment in an effort to influence the prognosis associated with the progression related morbidity/ mortality and decrease hospitalization in ESRD on HD patients and improve quality of life!

FR-PO955

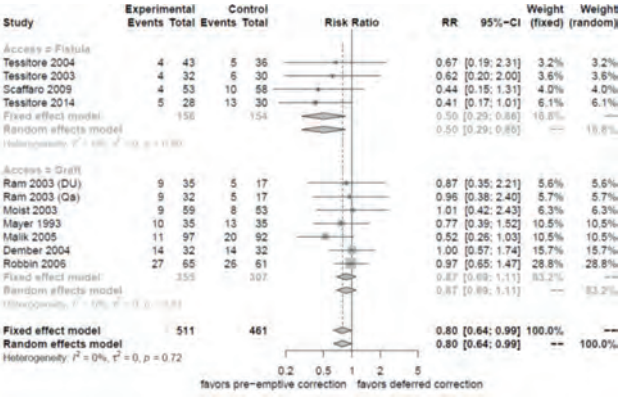
Meta-Analysis and Commentary: Preemptive Correction of Arteriovenous Access Stenosis Jochen G. Raimann,[2,1] Levi D. Waldron,[1] Elsie Koh,[3] Gregg Miller,[3] Murat Sor,[3] Richard J. Gray,[3] Peter Kotanko.[2,4] *[1]CUNY School of Public Health, New York, NY; [2]Research Division, Renal Research Institute, New York, NY; [3]Fresenius Vascular Care, Woodland Park, NJ; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: A recent meta-analysis (Ravani et al., Am J Kidney Dis 2016) studied the effect of pre-emptive correction of arterio-venous (AV) vascular access versus deferred care, based on data from 10 trials. It reported a non-significant protective treatment effect of pre-emptive correction on access loss and a significant protective effect on thrombosis rates conferred by pre-emptive correction. We revisit this analysis, including data extraction and effects of heterogeneous study populations.

Methods: We repeated data extraction from referenced publications, and corrected event counts where applicable. As a next step we repeated the meta-analyses for studies that recruited patients with AV fistulae (AVF) and grafts (AVG), using a random effects model with VA access loss as the outcome.

Results: Our conclusions differ from the original findings: After amendment of the extracted event counts we find a significant overall positive effect of pre-emptive correction on AV access loss in the overall study population [RR 0.80 (95% CI 0.64 to 0.99), RD -0.07 (95% CI -0.12 to -0.02); Figure 1]. Whereas the data do not conclusively show a benefit of pre-emptive correction for AVG (RR = 0.87, 95% CI: 0.69 – 1.11), they show a strong protective effect for AVF (RR = 0.5, 95% CI: 0.29 to 0.86).

Conclusions: These findings corroborate clinical arguments such as superior long-term patency of AVF and the nature of AVG failure that often involve infectious causes. The available data indicate mild or no benefit of pre-emptive correction for AVG, but support tight monitoring of AV dialysis accesses and preemptive intervention and correction upon the detection of access stenosis for AVF. **Figure 1:** Meta-analysis of AV access loss, overall and by access type.



FR-PO956

Calculating Maximum Allowable Contrast Dose to Minimize Contrast Induced Nephropathy Following Coronary Angiography: Comparison of Validated Methods with Implications for Practice Habib Mawad,[4] Kelly M. Zerr,[4] Anurag Singh,[5] Simon Robinson,[3,1] Sean C. Hardiman,[1,3] Adeera Levin.[4,5] *[1]Cardiac Services BC, Vancouver, BC, Canada; [3]Department of Cardiology, Univ of British Columbia, Vancouver, BC, Canada; [4]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [5]BC Renal Agency, Vancouver, BC, Canada.*

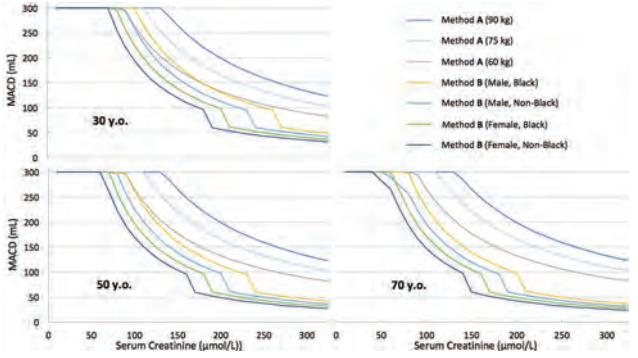
Background: The contrast volume used during angiographic procedures represents an important modifiable risk factor for contrast-induced nephropathy (CIN). As a result, attempts have been made to limit contrast exposure by determining maximum allowable contrast dose (MACD), using specific equations. Two published methods exist, but they use different components to derive the MACD: Method A uses weight and creatinine, Method B uses the estimated GFR (eGFR) multiplied by a specific ratio. Our study analyzed and compared the 2 methods with respect to concordance, and implications for incorporating into clinical practice. The goal was to find a simple equation to implement which would be safe (i.e. give the lowest MACD).

Methods: We calculated the MACD for a wide range of serum creatinine levels, weights and demographic variables (i.e. age, sex and race), using the 2 methods. Method A: MACD (mL) = (5* Body Weight (kg) * 88.42)/ Serum Creatinine (umol/L); and Method B: MACD (mL) = Ratio* eGFR (ml/min per 1.73m^2). A ratio of 3 was used if

eGFR >30 and a ratio of 2 if eGFR ≤30 ml/min per 1.73m^2. Irrespective of methodology, recommendations suggest that MACD should not exceed 300 mL.

Results: The results show a marked discordance in calculation of MACD depending on the equation used (see Figures). In the majority of cases method B gives a more conservative estimate of MACD. The difference is most marked for those who are heavier, older and are female, particularly non-black females.

Conclusions: Discrepancies in allowable contrast doses based on published formulae may lead to different and higher contrast exposure for some patients. We propose an alternative method which suggests lower contrast doses in those at highest risk of CIN. The impact of implementation of these methods on MACD used, subsequent incidence of CIN and dialysis as well as cardiovascular outcomes remains to be studied.



FR-PO957

Provider versus Pharmacy Led Initiation of ACEI or ARB Kelly Mazurek, Margaret E. Fleet, Bessie A. Young. *Uniiversity of Washington, Seattle, WA.*

Background: Guideline attainment in diabetes and early diabetic nephropathy is difficult. Primary care provider (PCP) directed recommendations can either be from a specialist or from a pharmacist. Studies looking at the efficacy of either approach have been mixed. The purpose of this study was to determine whether a provider (Nephrologist) versus pharmacy led invention, consisting of initiation of an ACEI or an ARB (Ac/Ar), was more effective.

Methods: Data were collected from the Diabetes Registry at the Veterans Affairs (VA) Puget Sound Health Care System. Search criteria were: diabetes mellitus, hypertension or blood pressure >140/90 mmHg, albuminuria >30 mg/g, and not being on an Ac/Ar. Exclusion criteria were taking an Ac/Ar, previously enrolled in pharmacy clinic, anaphylaxis or angioedema to an Ac/Ar, ESRD or no longer being a VA patient. Patients were followed over 7 months. Nephrology recommendations and guidelines were given to PCPs for starting an Ac/Ar. PCPs had the option to place an electronic nephrology consult to manage the intervention. On the other hand, the pharmacy team identified patients and placed referrals to a pharmacy clinic. The primary pharmacist made decisions on drug initiation, monitoring, titration and laboratory tests based on the same recommendations. The primary outcome was the rate of Ac/Ar initiation.

Results: A total of 34 patients were found in the provider group and 19 patients in the pharmacy group. There was a trend towards increased efficacy in the pharmacy led team (58%) over the provider led team (41%). However, there was no statistical difference (p 0.56). A post study survey showed that majority of participants favored that pharmacists identify, start and manage recommendations.

Conclusions: A pharmacy led intervention was no more effective than a provider led intervention in implementing current standards of care for diabetic patients. On the pharmacy arm, patients were more likely to have follow-up appointments if they were by telephone rather than in person. Telephone intervention is less burdensome and may lead to more successful interventions and continuity of care. PCPs are often overwhelmed with their patient panel and correct medication management can go overlooked. Pharmacists are just as effective, are more accessible health care practitioners and are well positioned to implement appropriate medication use.

FR-PO958

Renal Safety of Cisplatin-Based Chemotherapy in Urothelial Carcinoma Patients with a Solitary Kidney Masahiro Kondo,[1] Yuji Hotta,[2] Ryosuke Ando,[3] Takahiro Yasui,[3] Kazunori Kimura.[1,2] *[1]Pharmacy, Nagoya City University Hospital, Nagoya, Japan; [2]Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [3]Nephro-urology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.*

Background: There is little information on renal safety to cisplatin-based chemotherapies in patients with a solitary kidney after nephroureterectomy. We evaluated the nephrotoxicity and hematologic toxicities of gemcitabine plus cisplatin (GC) in urothelial carcinoma patients with a solitary kidney.

Methods: We retrospectively reviewed patients treated between August 2007 and December 2016. Eligible patients received GC as first-line chemotherapy, including as neo-adjuvant and adjuvant treatment. Patients with one kidney comprised the solitary kidney (SK) group; those with both kidneys comprised the BK group. Incidences of renal insufficiency and hematologic toxicities were examined and compared between the groups.

Results: There were 18 and 43 patients in the SK and BK groups, respectively. Mean serum creatinine [SCre] levels at baseline were significantly higher in the SK group than in the BK group (P<0.001). There were no significant differences in median numbers of administered cycles and doses of GC between the groups. No significant differences were observed between the groups in the incidence of acute kidney injury (SK: 11.1%, BK: 7.0%, P=0.627). SCre levels in both groups did not significantly increase during treatment (Fig.1); mean differences in SCre levels between baseline and each post-chemotherapy cycle were similar between the groups. The incidence of hematologic toxicity (grade 3/4) was not significantly different between the groups. Multivariate analysis revealed no statistically significant association between having a solitary kidney and severe hematologic toxicities.

Conclusions: Renal safety and treatment tolerability to GC chemotherapy is not inferior in patients with a solitary kidney.

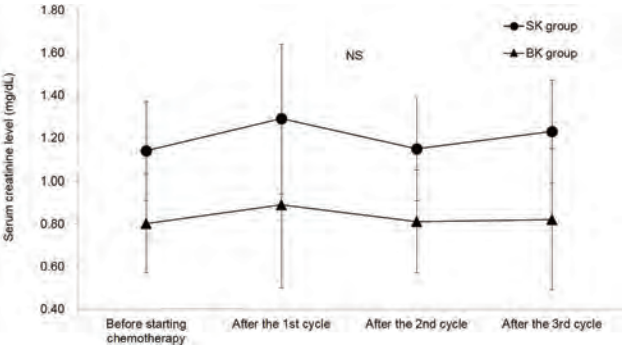


Fig.1: Change in serum creatinine levels between baseline and after each chemotherapy cycle of gemcitabine plus cisplatin in the solitary kidney (SK) and both kidneys (BK) groups. Repeated-measures analysis of variance: NS, not significant.

FR-PO959

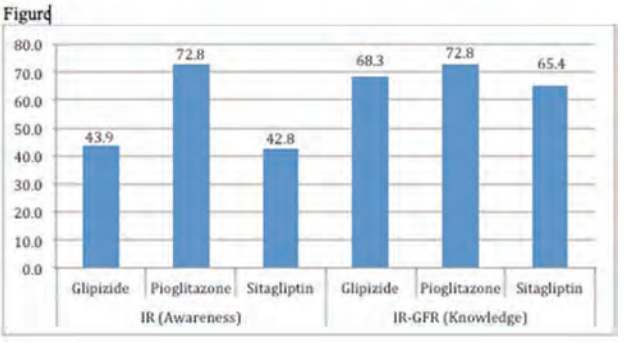
Awareness and Knowledge among Internal Medicine House-Staff for Dose Adjustment of Diabetes Medications in CKD Matthew S. Snyder,[1] Joshua Fogel,[2] Sofia Rubinstein.[1] *[1]Nephrology and Hypertension, Nassau University Medical Center, East Meadow, NY; [2]Brooklyn College, Brooklyn, NY.*

Background: Drug dosing errors result in adverse patient outcomes and are more common in patients with diabetes mellitus (DM) and chronic kidney disease (CKD). As internists treat the majority of patients with DM and CKD, we study if Internal Medicine house-staff (IMHS) have awareness and knowledge about the correct dosage of commonly used diabetes medications in those with CKD.

Methods: We surveyed 353 IMHS to evaluate incorrect awareness of whether a medication needs dose adjustment in patients with CKD (IR) and incorrect knowledge at what level of glomerular filtration rate a medication needs to be adjusted (IR-GFR) for Glipizide (GLI), Pioglitazone (PIO), and Sitagliptin (SIT).

Results: There were high percentages for lack of awareness and knowledge, with the highest for PIO at 72.8% (Figure). Multivariate logistic regression analyses showed that PGY1 had higher odds than PGY3 for GLI and SIT for both IR and IR-GFR and PGY2 had higher odds than PGY3 for PIO for both IR and IR-GFR. More Nephrology training and exposure in medical school or residency were each associated with lower odds for both IR and IR-GFR.

Conclusions: There is poor awareness and knowledge among IMHS for dose adjustment of diabetes medications in patients with DM and CKD. IMHS should receive more nephrology exposure and formal didactic educational training during medical school and residency to better manage complex treatment regimens and prevent medication dosing errors in those with DM and CKD.



Percentages for Incorrect Response to Medication Dose Needs Adjustment and Incorrect Response to Medication Dose Needs Adjustment at Appropriate GFR Level for Diabetic Medications

Prevention of Medication Reconciliation Errors: Results of a QI Study Manisha Singh,[5] Temekis D. Hampton,[4] Sherida R. O'neal-wright,[3] Shree G. Sharma,[1] Michelle W. Krause.[2] *[1]Arkana Laboratories, Little Rock, AR; [2]University of Arkansas for Medical Sciences, Little Rock, AR; [3]DCI, Little Rock, AR; [4]UAMS, Little Rock, AR; [5]Nephrology/Internal medicine, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Medication errors are one of the leading preventable causes of adverse patient outcomes. Accurate reconciliation can greatly decrease this risk. Dialysis patients have increased risk with polypharmacy of up to 5-10 medications/patient. We attempt to enable the patient himself to carry the information for their own care in a quality-improvement project using medication wallets.

Methods: Wallet design: Wallet contains contact information, care-buddy details, dialysis unit information, Physician and APN contacts, immunization record, current dialysis prescription with medications, known medical history and allergy information. The wallet has space to keep a driver's license, credit cards and cash. Method: Project consisted of 3 phases: Phase 1: Identify patients for participation.12/15 home dialysis patients consented for study. Phase 2: Review and compare medications in patient's record from available admission/discharge lists. Phase 3: Introduce intervention (Dialysis Wallet) and monitor its effectiveness through a questionnaire-based survey at each clinic visit.

Results: 67% of the patients had a medical visit since previous clinic visit. 17% of patients were hospitalized. Their dialysis prescription was unchanged during that hospitalization.100% of patients feel that their dialysis prescription were continued as prescribed.33% of patients felt that, after discharge from medical visit, their medication lists were not updated. They felt that the wallet contributed positively to their care. They reported that other providers appreciated this input at all physician and APN visits. Their immunization records helped expedite care. After the use of this wallet, participants report they would prefer continued use of wallet/hard copy. 67% of patient brought the wallet to clinic visits.

Conclusions: Our results indicate that the medication wallet may be a very effective way to minimize medication errors during transitions and an effective way to enable better patient care. The limitations are failure to update the wallet by some treating teams and patients forgetting to bring the wallet during some treatment visits. We hope that over time, this will get corrected as the importance of this step will be more apparent to providers as well as the patients.

FR-PO961

Medication Dosing in Dialysis Dependent ESKD Patients: A Retrospective Single Center Review Daryl U. Nnani,[3] Timothy V. Nguyen,[2] Archna Jariwala,[3] Vijay Lapsia.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Long Island University - AMS College of Pharmacy and Health Sciences, Little Ferry, NJ; [3]Mount Sinai Hospital, New York, NY.*

Background: Patients with hemodialysis (HD) dependent end stage kidney disease (ESKD) are more prone adverse events and poor outcomes due to inappropriate medication dosing. A significant number of medications are converted into active metabolites and failure to adjust doses may result in toxicity. Medication errors account for a majority of adverse events within the inpatient setting. The purpose of this study was to assess the appropriateness of medication dosing in hospitalized HD dependent ESKD patients.

Methods: This was an IRB-approved, single-center, retrospective medication chart review of adult HD-dependent patients diagnosed with ESKD admitted between 1/2016 – 8/2016. Patients were excluded if they were on peritoneal dialysis, admitted for kidney transplantation, or had missing pertinent information. The appropriateness of medication dosing was assessed by evaluating inpatient medication orders on day one of admission and was compared to drug manufacturer and tertiary reference renal dose adjustment recommendations.

Results: A total of 509 patients were included in this study and 6,964 medication orders were reviewed for a mean of 13.7±8.32 medications per patient. A total of 221 inappropriate medications orders were identified and 32.4% (165 of 509) of patients included in this study had an inappropriate medication order on admission. A total of 20 medication classes were ordered inappropriately on day one of admission. The most frequently inappropriately ordered medication classes were anticonvulsants 26.1% (58 of 221), opioids 25.6% (57 of 221), antibiotics 16.2% (36 of 221), histamine-2 receptor antagonists 8.1% (18 of 221) and HMG-CoA reductase inhibitors 6.3% (14 of 221). Morphine sulfate accounted for 83% (47 of 57) of inappropriate opioid medication orders. Gabapentin accounted for 66% (38 of 58) and levetircetam accounted for 28% (16 of 58) of inappropriate anticonvulsants medication orders in this study.

Conclusions: Anticonvulsants and opioids accounted for greater than 50% of inappropriate medications orders. Mandatory pharmacist medication reconciliation in this patient population and implementation of a best practice alert integrated into the computerized physician order entry system may result in a reduction of inappropriate medication orders in this patient population.

FR-PO962

Hydralazine-Associated Death and CKD Roman Zuckerman,[1] Mayurkumar P. Patel,[1] Rany Al haj,[1] Harry J. Dounis,[1] Seyedehsara Seyedali,[1] Ali Nayer,[2] Arif Asif.[1] *[1]Jersey Shore University Medical Center, Neptune, NJ; [2]Miami Renal Institute, North Miami Beach, FL.*

Background: Despite the widespread availability of effective anti-hypertensive agents (calcium channel blockers, ACE-Inhibitors/ARBs, diuretics, aldosterone receptor, and beta-blockers), hydralazine continues to be used as one of the first line agents in the management of hypertension. Hydralazine is known to cause drug-induced lupus (DIL) as well drug-induced anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (DIV).

Methods: Herein we describe three male and one female patients (age: 53, 83, 57, 87) treated with hydralazine therapy, who presented with acute kidney injury, proteinuria, and hematuria. All demonstrated positive anti-histone antibodies. The two patents with DIV demonstrated pauci-immune, necrotizing crescentic glomerulonephritis on renal biopsy. The other two were found to have features consistent with drug-induced lupus (DIL) and immune complex deposition in the sub-endothelial, subepithelial and mesangial areas. Both patients with DIV were initiated on hemodialysis. One of them recovered successfully, whereas the other patient's condition deteriorated and hospice care was initiated. Of the two patients with DIL neither one required dialysis. One patient developed severe sepsis with subsequent withdrawal of care, while the other one was discharged home with renal function at baseline.

Results:

Conclusions: Our report calls for heightened awareness and prompt diagnosis of DIL and DIV associated with hydralazine therapy to minimize its morbidity and mortality associated with this agent. Given an extremely unfavorable side effect profile and multiple alternatives available on the market, hydralazine should generally be avoided. In situations where its use is necessary either due to other agents' unavailability, intolerance, or inefficiency, we find that it is imperative for a clinician to monitor closely the patients on a long-term/high dose hydralazine regimen.

FR-PO963

Tramadol Induced Severe Hypoglycemia in a Non Diabetic ESRD Patient Ameen Taleb,[1] Michael E. O'Brien,[4] Brianna D. Jewell,[2] Yuvaraj Thangaraj.[3] *[1]Mercy Medical Center-North Iowa, Mason City, IA; [2]Mercy North Iowa, Mason City, IA; [3]None, Mason City, IA; [4]University of Iowa, West Union, IA.*

Background: Tramadol is a generally well-tolerated medicine in ESRD patients on hemodialysis. We present a case of severe hypoglycemia in an ESRD patient within days of initiating tramadol for pain at appropriate dose and timing interval.

Methods: A 54 y/o man with a history of ESRD on hemodialysis, hypertension and chronic back pain presented with hypoglycemia on the day of dialysis after receiving dialysis treatment. He reported taking100 mg of tramadol after dialysis. He was noted to have severe symptomatic hypoglycemia with a blood sugar of 33 mg/dl. The patient required multiple ampules of IV dextrose 25g and subsequently received 50% dextrose infusion in the critical care unit for persistent hypoglycemia. Lab findings including drug screen and acid base status were unremarkable aside from hypoglycemia. Insulin levels, c-peptide level and IGF1 level were within normal limits. Screen for meglitinides and sulfonylureas were negative. CT abdomen and pelvis with contrast showed small hypodensities within the pancreas. The CT findings were not radiographically consistent with insulinoma and represented small cysts that appeared to be unchanged from the previous CT. Patient's clinical condition and hypoglycemia significantly improved within 48 to 72 hours after discontinuation of tramadol and receiving dialysis treatment. The patient did not have any further episodes of hypoglycemia in post hospitalization follow up.

Results: Tramadol's hypoglycemia effect appears to be due to a synergistic effect between mu opioid receptor stimulation and decreased serotonin and epinephrine reuptake in nerve endings, which subsequently promotes higher levels of intracerebral serotonin and epinephrine. Tramadol depends on a cytochrome P450 enzyme, the expression of which is highly variable for activation into its active metabolites. Those metabolites are renally cleared and dialyzable. Henceforth, the pain modulating effect and the hypoglycemic side effect of tramadol are not dose dependent.

Conclusions: This case illustrates the importance of early recognition and appropriate management of tramadol induced life threatening hypoglycemia in ESRD patients including the need for heightened vigilance and slow up-titration of dose to prevent severe hypoglycemia.

FR-PO964

Influence of Communication of Hyponatremia on Outcomes Kirsten Salline,[2] Jeffrey I. Silberzweig,[1,3] Stephanie Tsai,[2] Clara Oromendia,[2] Vesh Srivatana,[1,3] Gordon Hildick-Smith.[2] *[1]The Rogosin Institute, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Medicine, Weill Cornell Medical College, New York, NY.*

Background: Despite the growing body of literature documenting the prognostic importance of hyponatremia, it is commonly treated as a peripheral issue during hospital admissions. We seek to quantify the degree to which hyponatremia is reported to outpatient providers and to evaluate factors associated with communication and associations between communication and standard outcome measures.

Methods: With IRB approval, we designed a retrospective cohort study of patients admitted to the Weill Cornell Campus of the New York-Presbyterian Hospital in January 2014 with corrected serum sodium <130 mEq/L who survived the hospitalization. Discharge summaries were manually reviewed for mention of hyponatremia; charts were reviewed for pertinent information. Patients who did and did not have hyponatremia mentioned in the discharge summary were compared using chi-square (or Fisher's Exact) and Kruskal-Wallis tests for categorical and continuous variables, respectively. Statistical significance was determined be at the 0.05 alpha level.

Results: Of 101 patients, hyponatremia was mentioned in discharge summaries in 37%. Patients with communicated hyponatremia were older (mean 77 vs. 66; p=0.004), and there was a non-significant trend towards Caucasian race (57% vs. 38% p=0.095), other demographic features did not differ. Nadir sodium (125.3 vs 127.3 mEq/L; p=0.001), and discharge sodium (132.2 vs. 134.7 mEq/L mEq/L, p=0.10) were lower for the group with communication. Mean duration of hospitalization was shorter (12 vs. 21 days, p=0.008). Communication of hyponatremia was not associated with one-year mortality, readmissions or readmissions with hyponatremia. Differences in subsequent outpatient providers' assessment of sodium levels were not significant (60% vs. 49%; n=50, p=0.665). Only 2 patients had hyponatremia labeled as a problem in the encounter note; in just one of these was it also mentioned in the discharge summary.

Conclusions: Despite its prognostic significance, our results suggest that hyponatremia is infrequently communicated to outpatient providers. Higher rates of communication were associated with severity of hyponatremia and shorter hospital stay. A lack of specific outpatient provider response to hyponatremia may explain the lack of association between communication of hyponatremia and outcome measures.

FR-PO965

An Integrated Analysis of Safety and Tolerability of Etelcalcetide in Adult Patients on Hemodialysis (HD) with Secondary Hyperparathyroidism (SHPT) Geoffrey A. Block,[4] Glenn M. Chertow,[5] John T. Sullivan,[1] Hongjie Deng,[3] Omar Mather,[2] Holly Tomlin,[3] Michael Serenko.[1] *[1]Amgen, Thousand Oaks, CA; [2]Amgen Inc, Thousand Oaks, CA; [3]Amgen Inc., Thousand Oaks, CA; [4]Denver Nephrology, Denver, CO; [5]Stanford University School of Medicine, Palo Alto, CA.*

Background: Etelcalcetide (ETL) is a novel, IV calcimimetic for the treatment of SHPT in patients on HD. Here, the safety profile of ETL is summarized.

Methods: Safety was assessed by the nature, frequency, and severity of treatment-emergent adverse events (AEs) and changes in lab parameters in the integrated datasets of two 26-week randomized, placebo (PBO)-controlled (PC) studies, a 26-week randomized active-controlled (AC with cinacalcet [CIN]) study, and 2 single-arm open-label extension (OLE) studies. The ETL starting dose was 5 mg 3 times/week (TIW) at the end of HD. Depending on serum PTH and Ca values, the dose could be increased by 2.5 or 5 mg at 4-week intervals to a maximum dose of 15 mg TIW.

Results: 841 patients received ETL in the PC (n=503) and AC (n=338) studies and 1289 in the OLE studies for up to 3.4 yr. In the combined dataset of PC studies, common (≥5%) AEs occurring in the ETL group with a ≥1% greater frequency than PBO were blood Ca decrease (63.8% vs 10.1%), muscle spasms (11.5% vs 6.6%), diarrhea (10.7% vs 8.6%), nausea (10.7% vs 6.2%), vomiting (8.9% vs 5.1%), headache (7.6% vs 6.0%), and symptomatic hypocalcaemia (7.0 vs 0.2%). Rates of AEs of interest were similar between ETL and PBO for convulsions (0.8% vs 1.0%), fractures (1.6% vs 2.9%), hypersensitivity (4.4% vs 3.7%), infusion reaction (5.8% vs 5.7%), ventricular tachyarrhythmia (0.4% vs 0.8%), and GI bleeding (2.0% and 2.1%); a small numerical difference was noted in the rate of adjudicated cardiac failure (2.2% vs 1.2%). More patients in the ETL vs PBO groups experienced hypophosphatemia (1.4% vs 0.4%). ETL had no clinically significant effects on blood pressure, heart rate, weight, or hematology lab parameters. No clinically significant differences were observed in the safety profiles of ETL and CIN in the AC study. No new safety signals were identified with long-term ETL exposure in the OLE studies.

Conclusions: Consistent with its mechanism of action, the most important risks associated with ETL were serum Ca reductions and hypocalcemia-related AEs. Integrated safety assessment of ETL across both controlled clinical trials and OLE studies showed an overall favorable risk/benefit profile with no unexpected safety signals.

FR-PO966

Detection of Chlorite in Dialysis Water, an Unrecognized Safety Issue Edward T. Casey,[3] Susan T. Crowley,[2] Jeffrey Birdsong,[1] Paul M. Palevsky.[4] *[1]Orlando VAMC, Orlando, FL; [2]Veterans Health Administration, West Haven, CT; [3]Nephrology, Orlando VAMC, Orlando, FL; [4]University of Pittsburgh, Pittsburgh, PA.*

Background: Chlorine dioxide (ClO_2) is increasing used by medical facilities as a water disinfectant to mitigate risk of environmental Legionella infection. When exposed to water, ClO_2 generates chlorite (ClO_2^-), which may produce similar toxicity for dialysis patients as chlorine exposure. Although dialysis water is routinely tested for total residual chlorine that will detect chlorine, chloramines and ClO_2, these methods will not detect residual chlorite. No specific safe level for residual chlorite has been established.

Methods: Our medical center injects ClO_2 into the water supply due to Legionella concerns. Measurements of ClO_2 and ClO_2^- were taken throughout the medical center, including dialysis water, on a weekly basis using a Nelco ChlordioX Plus instrument. Feed water ClO_2 target level was 0.3-0.8 ppm, ClO_2^- maximum was 1 ppm. Water for dialysis is provided using portable RO with two pre-treatment granulated activated charcoal (GAC) filters. ClO_2 and ClO_2^- testing was performed from the sampling port between the two GAC filters. After 8 months of undetectable levels, we detected 0.04 mg/L ClO_2^- from 1 of 4 portable RO units, with undetectable levels of ClO_2. The GAC filters are replaced quarterly and had been replaced 7 weeks prior detection of ClO_2^-. Following replacement of the GAC, repeat testing showed undetectable levels of ClO_2^- and ClO_2.

Results:

Conclusions: When ClO_2 is used as a disinfectant for Legionella mitigation, it breaks down to yield chlorite, chlorate and chloride ions. While chlorate and chloride are effectively removed by GAC in dialysis water pretreatment, chlorite removal is not complete. We detected residual chlorite despite the GAC replacement 7 weeks earlier. After replacing the GAC filters, repeat sampling did not detect residual chlorite. Thus, the GAC appeared to remove ClO_2 appropriately, but became saturated with chlorite well before the scheduled GAC replacement date. Although ClO_2 is detected using the standard testing for total chlorine, chlorite is not. The effects of chronic low level exposure to chlorite are unknown, but potentially could lead to erythropoietin stimulating agent resistance and/or increased red blood cell destruction. Dialysis providers should be aware of this hazard, and recognize that more intensive monitoring and more frequent replacement of GAC may be required when ClO_2 is present in municipal or hospital water.

FR-PO967

Changes in Creatinine and Potassium after Initiating Renin Aldosterone Inhibitor and Diuretic Therapy in CKD: A Cohort Study from Outpatient Practices Katherine Garlo,[1] Diane Seger,[3] Julie Fiskio,[3] David W. Bates,[2] David M. Charytan.[1] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA; [3]Partners Healthcare System, Somerville, MA.*

Background: Clinical trials of renin aldosterone system inhibitors (RASi) have demonstrated major cardiovascular and renal benefits to patients with chronic kidney disease (CKD), but these benefits must be weighed against the risks of a decline in estimated glomerular filtration rate (eGFR) and hyperkalemia. Since randomized controlled trials do not include the breadth of patients in real world clinical settings, we assessed changes in creatinine (Cr), estimated glomerular filtration rate (eGFR), and potassium in a large cohort of CKD patients prescribed a new RASi or diuretic.

Methods: Retrospective cohort study of adults with pre-dialysis CKD stage 3-5 who received a new outpatient RASi or diuretic prescription during 2009-2011. Lab data was collected electronically and analyzed for changes in Cr, eGFR, and potassium.

Results: A total of 8,272 individuals (mean age 72 yrs ±13.5, 44% male, 86% white) with CKD (90% stage 3, 7% stage 4, 2% stage 5) were included; 52% received a RASi and 48% received a diuretic. Follow up labs were done within 2 weeks in 28% (RASi: 24%, diuretic: 31%). The mean percent change within 2 weeks of drug prescription in Cr was lower in the RASi group compared to the diuretic group (3.8%±19.6 and 5.6%±21.8 ml/min/1.732m^2, p<0.01). Over half of the subjects had <30% increase in Cr (RASi: 51.0%, diuretic: 52.2%) and over one third had an improvement in Cr (RASi: 37.5%, diuretic: 34.1%). Very few patients had a rise in Cr >50% (RASi: 2.2%, diuretic: 2.4%). The mean change in potassium was 0.07±0.5 in the RASi group and -0.03±0.6 in the diuretic group p <0.01. At follow up, the majority had a potassium <5.0 mmol/L (RASi: 80.4%, diuretic: 84.4%). Significant hyperkalemia (potassium >5.5) was rare (RASi: 1.9%, diuretic: 2.0%).

Conclusions: The low rate of meaningful changes in Cr and potassium following new prescriptions supports use in patients with moderate to advanced CKD. Further study is needed to determine lab monitoring strategies that improve safety and are cost-effective.

FR-PO968

Conversion of Single Glomerular and Tubule Segments into Proteomic Data for Discovery of Pathomechanisms in Proteinuric Kidney Diseases Markus M. Rinschen,[1] Tobias B. Huber,[2] Thomas Benzing,[1] Martin Höhne.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]University Medical Center Hamburg, Hamburg, Germany.*

Background: Diseases of the kidney often originate in the glomerulus. Proteinuria, the leakage of the renal filter, is a hallmark and accelerator of renal disease. Virtually all glomerular diseases are histologically heterogeneous at early stages and affect a certain percentage of glomeruli to different extents. Our understanding of physiological kidney function is largely derived from the functional analysis of single nephron segments.

Methods: Here, we developed a nano-scale sample preparation protocol combined with targeted proteomics and single-unit bioinformatics analysis for the discovery of pathogenetic mechanisms in both single glomeruli and single tubuli. The method was applied to clinical samples, as well as different rodent models of glomerular disease.

Results: We analyzed the proteome of single glomeruli from mice and humans in different podocyte injury models. We could identify up to 2000 proteins (~10000 peptides) per single glomerulus. Analysis of 7 single glomeruli from patients with **congenital nephrotic syndrome and proven** *NPHS1* **mutations** discovered decreased amounts of nephrin but unchanged podocin amounts. A targeted podocyte sentinel assay was designed to acquire reproducible proteomic data across 24 glomeruli from two different podocyte damage models. The assay monitors podocyte actin cytoskeletal function, slit diaphragm function, glomerular basement membrane abundance and podocyte stress response. Bioinformatic analysis using hierarchical clustering and correlational approaches delineated common responses in glomerular damage across glomerular populations and across models. The method was also able to clearly discriminate microdissected tubular segments (e.g. S1 proximal tubule, mTAL and cortical collecting ducts), with potential applications in renal physiology.

Conclusions: These data demonstrate the potential of single segment proteomics for both basic research and translational medicine.

Funding: Government Support - Non-U.S.

FR-PO969

Metagenomic Analysis of Microbial Nanovesicle in Blood of Maintenance Hemodialysis Patients Un Sil Jeon,[1,2] Jinho Yang,[3] Seung Hee Yang,[4] Yoon-Keun Kim.[3] *[1]Nephrology, Sheikh Khalifa Specialty Hospital, Ras Al Khaimah, United Arab Emirates; [2]Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [3]MD Healthcare Inc., Seoul, Republic of Korea; [4]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea.*

Background: Gut dysbiosis in uremic patients is known to contribute to progression and complications of chronic kidney disease (CKD). Extracellular vesicles (EVs) excreted from bacteria contain not only bacterial DNA and RNA, but also endotoxins and other virulent proteins. EVs can enter systemic circulation through intestinal mucosal membrane freely and be key communication messengers in host-microbe communication in human diseases.

Methods: We performed metagenomic analysis of bacteria-derived EVs in blood of 20 maintenance hemodialysis (HD) patients (10 diabetic and 10 non-diabetic) and 20 healthy controls. EVs in human serum were isolated using the differential centrifugation method as described previously (*Proteomics 2007;7:3143–3153*). DNA was extracted from 1 ug of serum EVs, and 16S ribosomal RNA (16S rRNA) gene sequencing was performed using high-throughput 454 pyrosequencing after amplification of the V1–V3 region of the 16S rDNA. Taxonomy assignment was carried out by using UCLUST and QIIME against the 16sRNA sequence database in GreenGenes.

Results: The value of alpha-diversity was lower in HD patients than in healthy controls, which means HD patients had a lower diversity of microbiome than healthy controls. The value of beta-diversity was significantly different between HD patients and controls. At the level of Phylum, HD patients had a significant higher level of *Acidobacteria EVs* than controls, but a lower level of *Proteobacteria* EVs. At the level of Genus, we found 37 biomarkers which revealed different levels between HD patients and controls (29 elevated and 18 decreased EVs in HD patients). *Streptococcus., Koribacteraceae(f), Ellin6513(o), and Burkholderia spp.* EVs were higher in HD patients than in controls, and *Enterobacteriaceae(f), Acinetobacter, Pseudomonas, Akkermansia, Proteus and Lactobacillus spp.* EVs were lower in HD patients. However, there were no differences between diabetic and non-diabetic HD patients.

Conclusions: In conclusion, we observed significant differences in the composition and amounts of bacteria-derived EVs in blood between HD patients and healthy controls using metagenomic analysis. Metagenomic analysis of bacteria-derived EVs could be a useful tool to investigate microbial dysbiosis and biomarkers in CKD patients.

FR-PO970

Comparing Raman Spectroscopy-Derived Metabolomic Signatures of Urine from Patients with CKD to Those with Normal Kidney Function James L. Pirkle,[2] John L. Robertson,[1] Mitchell Warren,[2] Ryan S. Senger.[1] *[1]Virginia Tech, Blacksburg, VA; [2]Wake Forest School of Medicine, Winston Salem, NC.*

Background: The field of metabolomics is being used increasingly in clinical research to improve aspects of clinical care ranging from early diagnosis to monitoring treatment progress and prognosis. It would be useful to have an affordable metabolomic test for urine that could identify patients with chronic kidney disease in the absence of albuminuria. Raman spectroscopy is an analytic tool used chiefly in solid state chemistry that has shown increasing application in analyzing molecular compositions of biological samples. We performed a pilot study to assess the ability of Raman spectroscopy analysis of urine samples to differentiate between patients with CKD and those with normal kidney function.

Methods: Free-catch urine samples were collected from 93 patients with CKD (on peritoneal dialysis) and from 25 generally healthy volunteers with normal kidney function. Raman spectra were analyzed using an Agiltron PeakSeeker Pro spectrometer with 785 nm laser excitation at 5 mW. A 1 s integration time was used, spectra were collected between 200-2000 cm^{-1}, and each sample was scanned 10 times. Spectra were analyzed by a multivariate statistical pipeline involving (i) principal component analysis and (ii) discriminate analysis of principal components following baseline correction and vector normalization of raw spectra.

Results: The individual raw spectra show that only the urea band at 1003 cm^{-1} is distinguishable. The multivariate statistical pipeline was used to determine whether differing molecular signatures existed elsewhere for urine from patients with CKD and those with normal kidney function. Results are shown in a canonical plot, where every data point represents an entire Raman spectrum. Distinct clusters of data points are observed between the urine of CKD patients (receiving PD) and those with normal kidney function, indicating recognizably different Raman signals and molecular compositions for each group.

Conclusions: Raman spectroscopy provides a rapid, cost-effective way to assess differences in the molecular composition of urine between patients with CKD and those with normal kidney function. Future research will focus on quantifying these differences and testing of unknown populations. Potential applications for this technology would include community screening for CKD using rapid urine testing.

FR-PO971

The Differential Expression of Circular RNAs in Exosomes from Serum and Urine in Patients with IMN Hualin Ma,[1,2] Xin-zhou Zhang.[1,2] *[1]Department of Nephrology, Shenzhen People's Hospital, Shenzhen, China; [2]Key Renal Laboratory of Shenzhen, Shenzhen, China.*

Background: To further explore the pathogenesis of idiopathic membranous nephropathy (IMN), the technique of gene-sequencing was used to analyze the differentially expressed circRNAs in exosomes from both the serum and urine of patients with IMN, which may lay the foundation for the research of circRNAs as a new class of exosome-based idiopathic membranous nephropathy diagnosis biomarkers.

Methods: Ten patients with idiopathic membranous nephropathy (IMN group) and ten normal controls (NC group) were recruited as experimental subjects in our study. The exosomes were extracted from the collected serum and urine by the ExoQuick Exosome Precipitation Solution and ultracentrifugation. Then, the pure circRNAs were extracted from the exosomes with a series of enzymatic reactions. Afterwards, the significantly differentially expressed circRNAs were chosen by the method of gene-sequencing to analyze the function of corresponding target genes.

Results: Compared with normal controls, the circRNAs were reduced in the exosomes from serum of patients with IMN, which mostly originated from intron gene regions. Meanwhile, a total of 89 circRNAs were significantly differentially expressed, which were also mostly derived from intron gene regions, including 49 up-regulated and 40 down-regulated genes. However, the species were increased in the exosomes from the urine of patients with IMN compared to normal controls, and they mainly originated from exon gene regions. Simultaneously, a total of 60 circRNAs were significantly differentially expressed, which primarily belonged to intron gene regions, including 54 up-regulated and 6 down-regulated regions. Compared with the circRNAs detected from urinary exosomes, a total of 59 circRNAs were significantly differentially expressed in the exosomes from the serum of patients with IMN, which also mostly originated from intron gene regions, including 32 up-regulated and 27 down-regulated regions.

Conclusions: The significant differential and specific expression of circRNAs in the exosomes from the serum and urine of patients with IMN were observed. For example, MUC3A, which originated from chr7:100550808|100551062, could be considered a potential diagnostic biomarker of IMN. Furthermore, these figures suggested that the significantly differentially expressed circRNAs can be used as a reference or supplement in the research of the pathogenesis of IMN.

FR-PO972

Integrity and Expression of Low-Input, Degraded Renal mRNA for Precision Medicine Applications Michael T. Eadon,[2] Tarek M. El-Achkar,[1] Yinghua Cheng,[3] Ken Dunn,[1] Samir V. Parikh,[4] Brad H. Rovin,[5] Seth Winfree,[3] Katherine J. Kelly,[1] Timothy A. Sutton,[3] Pierre C. Dagher.[1] *[1]Indiana University, Indianapolis, IN; [2]Indiana University Division of Nephrology, Indianapolis, IN; [3]Indiana University School of Medicine, Greenwood, IN; [4]Ohio State University Medical Center, Columbus, OH; [5]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Personalized medicine initiatives may entail the performance of molecular diagnostics on existing pathology samples from biological repositories. Technologies continue to evolve to define molecular signatures from low amounts of highly degraded RNA. We sought to understand the effect of differential tissue preservation and RNA degradation on renal expression using two different transcript expression platforms.

Methods: Kidneys from c57Bl/6 mice were subjected to one of five preservation conditions and RNA integrity was measured: frozen immediately (RIN 7.4 ± 0.2), stored 6 h in Michels solution (6.8 ± 0.6), stored 24 h in Michels solution (6.6 ± 0.3), stored 6 h in BE70 solution (3.3 ± 0.2), or formalin fixed (2.63 ± 0.2). In preparation for laser microdissection, tissue was subjected to immunofluorescence for the frozen (RIN 3.4 ± 0.2 post-stain) and formalin fixed (RIN 2.2 ± 0.1) conditions. Gene expression was measured using RNA sequencing and a microarray.

Results: Both platforms revealed a strong correlation between RNA from fresh frozen samples and highly degraded RNA from frozen stained (RNAseq: R = 0.922, Microarray: 0.964) or stained formalin fixed samples (RNAseq: R = 0.920, Microarray: 0.916). The inter-platform correlation ranged from R of 0.700 to 0.821. As compared to the microarray, both the dynamic range and coefficient of variation for RNAseq expression was larger.

Conclusions: Both the RNA sequencing and microarray platforms appear adequate to measure renal gene expression in highly degraded low-input RNA.

FR-PO973

Home Kidney Screening Device Ragwa Elsayed. *San Jose State University, Daly City, CA.*

Background: Kidney filters blood from wastes. As per USRDS, most CKD patients are between stage 1 to 3 and only 10% aware about their disease. The objective of this project is to design a new technique using mobile App to monitor the creatinine level in blood at home or at screening events and facilitate user at home to send the results to his physician.

Methods: Experiment based on Jaffe's reactions between picric acid and creatinine. Different concentrations of creatinine were prepared in 0.1 M Hcl solution. Picric acid was prepared 1.6% solution in an alkaline 0.75 M NaOH. Test Strip design: PVC or

Opaque plastic sheets (10 cm * 0.5 cm) Absorbable sheets (1 cm * 0.5 cm) immersed in picric alkaline solution for an hour then glued to test strip. 200 ul of creatinine solutions have been applied on test strips Using Matlab to measure creatinine color intensity from a mobile image of test strip

Results: A standard curve is established from results by using Matlab software image 1. A mobile app will be used to detect creatinine level from color intensity of test strip when apply a blood drop. We observed when applying higher creatinine concentration, test strip color become darker image 2

Conclusions: By using the chemical property of picric acid when react with creatinine, a relation is established as a standard curve between creatinine concentration and color intensity. Using the mobile phone cameras, anyone at home can measure creatinine level by taking an image of test strip.

Automatic Detection of Global Sclerosis in Pathological Glomerular Images with Deep Neural Networks Eiichiro Uchino,[1] Kei Taneishi,[2] Noriaki Sato,[1] Hideki Yokoi,[1] Yasushi Okuno,[1] Motoko Yanagita.[1] *[1]Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]RIKEN Advanced Institute for Computational Science, Kobe, Japan.*

Background: Renal pathology is essential for diagnosis and treatment planning for patients with renal disease, and the application of digital pathology, which is a recent active field of automated histology analysis, to renal field is an important challenge. In recent literature, several studies have developed algorithm for detecting glomeruli from a whole slide image of kidney, but few studies have focused on detecting pathological features such as global sclerosis from those glomerular images.

Methods: We developed deep convolutional neural network (CNN) models which can automatically classify glomerular images as global sclerosis or not. Total 12422 glomerular images of periodic acid-Schiff (PAS) stain (n=3180), periodic acid methenamine silver (PAM) stain (n=3311), hematoxylin and eosin (HE) stain (n=2979), and Masson's trichrome (MT) or elastica-Masson (EM) stain (n=2952) were cropped from whole slide images of 133 patients who underwent renal biopsy in our hospital in 2013 and 2014, and were manually annotated based on clinical pathology reports. By each staining, CNNs were trained and validated by 5-fold cross validation with five patient groups assigned randomly. We evaluated area under the curve (AUC) of receiver operating characteristic (ROC), sensitivity, and specificity at optimal cut-point estimated from Youden's index.

Results: Out of 12422 glomeruli, 1743 (14.0%) were manually annotated as global sclerosis. For detecting global sclerosis, our CNN models for PAS stain had the best AUC in all staining (AUC, 0.977 ± 0.006 (mean ± SD); sensitivity, 95.8 ± 2.6%; specificity, 92.1 ± 2.3%). The models for the other staining showed similar performances for PAM (AUC, 0.971 ± 0.010; sensitivity, 90.3 ± 2.5%; specificity, 95.9 ± 2.4%), HE (AUC, 0.965 ± 0.010; sensitivity, 87.6 ± 2.3%; specificity, 95.4 ± 1.8%), and, MT or EM (AUC, 0.976 ± 0.010; sensitivity, 91.2 ± 3.2%; specificity, 95.2 ± 4.1%).

Conclusions: Our CNN models achieved good performance in detecting global sclerosis from glomerular images, which suggests that this approach is applicable for detecting other pathological features in future studies.

FR-PO975

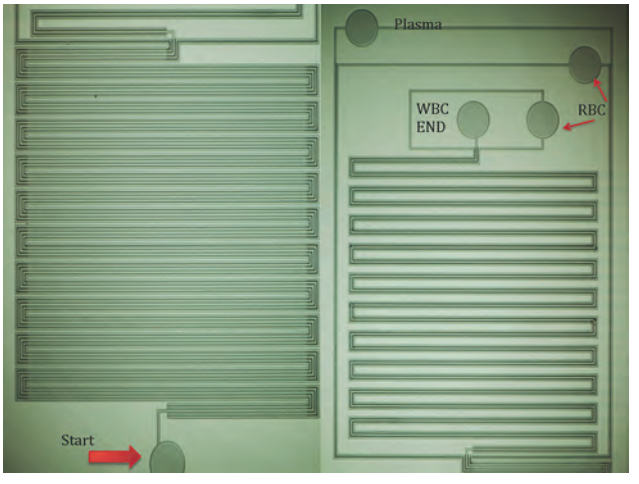
Parallel Cross-Flow Filtration Microfluidic Device for Renal Micro-Environment Emulation Zach Odeh. *Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: Whole human blood, a non-Newtonian fluid, can effectively be filtered on a microfluidic device. Past microfluidic design approaches utilized dead-end filtration concepts that lead to clogging since the cells are trapped in the direction of flow. This limitation also precludes the filtration of plasma, an important component to investigate renal inflammation. There is a need for a novel design that can mimic capillary action and fenestrations gaps akin to the renal micro-environment. The primary aim of this study was to design, fabricate, and test a novel microfluidic device for separating whole human blood (plasma, white blood cells, and red blood cells).

Methods: Development of the microfluidic device utilizes photolithography and micro-molding techniques that involve the following basic components: silicon wafer (1 1 1), chrome masks, glass, and polydimethysiloxane (PDMS). Design assumptions called for human blood as the testing fluid. The design utilized a five-row filtration system in the first modular section with varying gap sizes (between pillar edges) from 6.5 microns to 2.5microns. The second modular design included three channels with the main channel flanked by weir micro filtration barriers of consistent gap slits of 3.5 micons.

Results: The combined (pillar and weir) cross-flow design was shown to rapidly separate different categories of blood cells simultaneously based on size-exclusion principles despite spacing anomalies. The pillar filtration segment appears to show gradient changes, especially in the last two filtration tunnels. The other weir filtration segment does not show as drastic a color gradient change.

Conclusions: This microfluidic chip, based on a multi-level parallel cross-flow design, offers enhanced features over prior microfluidic approaches. It effectively addressed dead-end filtration limitations with no visible clogging obstacles. It demonstrates a successful integration of modular micro-feature units (pillar and weir).



Modular Micro-Feature Systems

Bioengineering an Organotypic Normal and Diseased Kidney Tubule Array Balaji karthick Subramanian,[1,2] Oguzhan Kaya,[1] Jing Zhou.[1] *[1]Medicine - Nephrology, Brigham and Womens Hospital /Harvard Medical School, Boston, MA; [2]Medicine - Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Maintenance of homogenous kidney tubular structures is critical to retain kidney shape and function, and in accordance aberrations in their structures are manifested in disease conditions. Lack of *in vitro* kidney tubule models that are homogeneous in tissue geometry structures and also emulating aberrations in disease conditions have limited the understanding of their pathology and the therapeutics development.

Methods: Homogenous tubular tissue geometry micropatterns were imprinted in different extracellular matrix combinations as an array using a combination of photolithography and soft lithography techniques. Tubular kidney epithelial cells were then cultured in the3D micro-molded extracellular matrix array and were evaluated for

the morphogenic outcomes. Cystic kidney disease emulation was achieved by treatments with cAMP-elevating agents, while for acute kidney injury emulation cisplatin drug treatment was used.

Results: Both mouse and human kidney epithelial cells formed homogeneous tubular structures as defined by the tissue geometry yielding kidney tubular arrays. The tubule features in the array were validated based on the characteristic distributionof actin (f-actin), cilia (acetylated tubulin), tight junction (ZO-1), and Na+K+-ATPasepump. Further, the disease emulations of cystic kidney disease and acute kidney injury were confirmed for tubule to cyst transformation and Kidney injury molecule (Kim-1) expression respectively.

Conclusions: The tubule array yielded organotypic homogenous tubules with *in vivo*-scale dimensions, which can be utilized for assessing nephrotoxicity of drugs and the mechanistic studies of various tubular kidney disease, making it an alternative to animal studies.

FR-PO977

Development of Functional Vasculature in Decellularized Whole Porcine Kidneys with Human Endothelial Cells Pablo D. Cabral,[2,4] Dominique Seetapun,[2] Senthuran Atputhanathan,[2] Jeff Ross,[1] Morgan D. Black.[3] *[1]Miromatrix Medical, Eden Prairie, MN; [2]Miromatrix Medical Inc., Eden Prairie, MN; [3]Miromatrix Medical, Inc., Eden Prairie, MN; [4]Case Western Reserve University, CLEVELAND, OH.*

Background: End stage renal disease (ESRD) represents a major epidemic both in the US and worldwide. Patients with ESRD have two options: kidney transplantation or hemodialysis. Due to the organ donor shortage, only a few patients receive transplants. The alternative, hemodialysis, has a 5-year mortality rate of 35% compared to only 3% for transplantation. With ~500,000 hemodialysis patients in the US, a new therapy is needed. The ultimate solution would be a bioengineered kidney to solve the chronic shortage. A critical first step is the demonstration of a functional vasculature to continuously perfuse blood. We demonstrate that a functional vasculature can be achieved by repopulating decellularized kidneys with human primary cells.

Methods: Whole porcine kidneys were perfusion decellularized without compromising the native microarchitecture of both the vascular and tubular compartments. Human umbilical vein endothelial cells (HUVEC) and primary human epithelial cells (HRE) were perfused into the vascular and tubular compartments respectively. Whole organ culture was performed under continous perfusion and key metabolic parameters were monitored daily to assess cell proliferation and viability. Functional vasculature assessment was performed with blood loops using whole porcine blood to model in-vivo performance.

Results: Cellular engraftment and viability were measured by metabolic parameters including glucose consumption over 3 to 4 weeks (n=12) to achieve the desired level. These data were further corroborated by histological analysis of formalin fixed kidney sections demonstrating the presence of a single layer of engrafted cells on vascular and tubular compartments. Furthermore, cells positive for the endothelial cell marker CD31 were confined to the vascular compartment and cells positive for the epithelial cell marker e-cadherin were confined to the tubular compartment. Vascular functionality was characterized by blood loops and demonstrated long-term continuous perfusion of whole blood compared at physiological pressures compared to non-recellularized kidneys that demonstrated the lack of flow after a few minutes.

Conclusions: These results demonstrate the ability to generate a functional vasculature in recellularized kidney grafts, a critical first step in the engineering of a fully bioengineered kidney.

The Role of Endothelial Nitric Oxide Synthase Expression in Arteriovenous Fistula Remodeling and Hemodynamic Adaptation Timmy C. Lee,[1] Daniel Pike,[2] Tatyana Isayeva Waldrop,[1] Lingling Guo,[1] Maheshika S. Somarathna,[1] Yan-Ting Shiu.[2] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Utah, SALT LAKE CITY, UT.*

Background: Endothelial nitric oxide synthase (NOS3), via its role of producing nitric oxide (NO), plays an important role in arteriovenous fistula (AVF) maturation following AVF creation. NOS3 dysfunction may play an important role in AVF development.

Methods: Carotid (side)-jugular (end) AVFs were created in NOS3-/- (knockout), NOS3+/+ (wildtype), and NOS3 overexpression (OE) mice on C57/BL6 background. Serial AVF lumen and hemodynamic changes were characterized using non-contrast MRI-imaging and computation fluid dynamic imaging (Fig. 1). Mice were sacrificed at 21 days for histologic and biochemical studies.

Results: At day 21, NOS3 OE AVFs have large venous lumen at and near the anastomosis, smooth velocity streamlines, low vorticity, as well as relatively uniform and low wall shear stress (WSS), suggesting desired vascular remodeling and restoration of WSS. In contrast, both NOS3+/+ and NOS3-/- AVFs have small lumen, disturbed velocity streamlines, high vorticity, and high venous WSS. AVF vein MMP9 protein expression was reduced at 21 days in NOS3 OE mice compared to NOS3+/+ and NOS3-/- mice (p=0.09). AVF vein average intima/media thickness ratio was significantly lower in NOS3 OE mice compared to NOS3+/+ and NOS3-/- mice ($p<0.0001$) at 21 days. cGMP levels were significantly higher in NOS3 OE AVFs vs NOS3-/- and NOS3+/+ AVFs (p=0.05)

Conclusions: Increased NOS3 expression improves AVF hemodynamics and remodeling and reduces neointimal hyperplasia development. Future interventions that target increasing NOS3 expression and NO delivery may be beneficial to improving AVF development.

Funding: Clinical Revenue Support

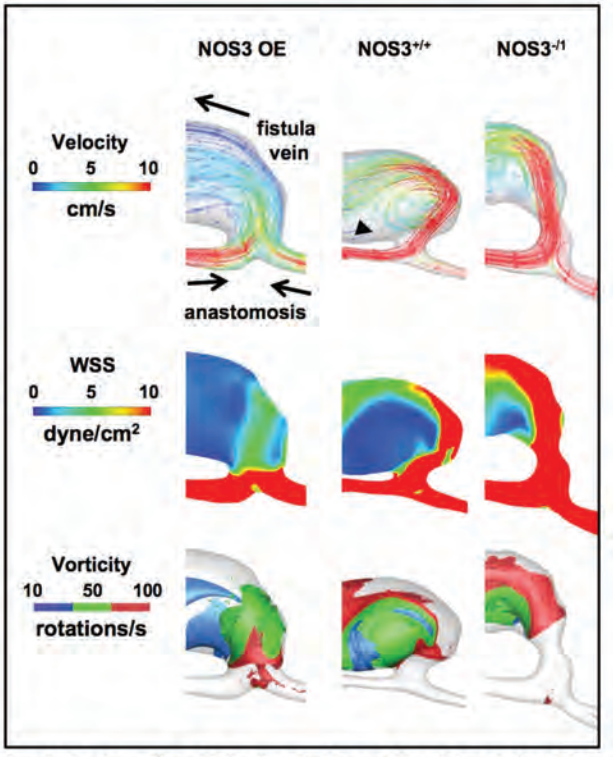

Fig. 1: 21 Day Flow Velocity, WSS and Vorticity Color Maps in Murine AVF. Note the different hemodynamic profiles in NOS3 OE, NOS3$^{+/+}$, and NOS3$^{-/-}$ mice at vein anastomoses and AVF veins. NOS3 OE mice had smoother velocity streamlines and lower WSS and vorticity (good adaptation) when compared to the NOS3$^{+/+}$ and NOS3$^{-/-}$ mice.

FR-PO979

Renal Protection during Cardiopulmonary Bypass (CPB) with a Leukocyte Modulatory Device (L-MOD) H. David Humes,[1] A. Westover,[3] D. Buffington,[3] K. Johnston.[2] *[1]Internal Medicine, University of Michigan Medical School, Ann Arbor, MI; [2]Innovative BioTherapies, Ann Arbor, MI; [3]Innovative BioTherapies, Inc., Ann Arbor, MI.*

Background: Leukocyte activation during cardiopulmonary bypass (CPB) contributes to a systemic inflammatory response that can cause organ injury and dysfunction, including the kidney. The therapeutic value of incorporating an extracorporeal leukocyte modulatory device (L-MOD) during and after CPB was investigated. Assessment of leukocyte mediated organ injury in a pre-clinical animal model was the primary outcome criteria.

Methods: Twenty-two pigs underwent a simulated cardiothoracic surgical procedure with 180 minutes of CPB and 5 hours post-operative observation. Pigs received CPB with no intervention (Group 1, n= 9), 3 hours of L-MOD therapy by incorporation of L-MOD into the CPB circuit (Group 2, n=6) or 8 hours of L-MOD therapy using a femoral veno-venous extracorporeal circuit during and after CPB (Group 3, n=7). Leukocyte counts and activation were serially measured. Hemodynamics, pulmonary parameters and urine output were monitored as indices of organ function. Serum troponin-I and urine neutrophil gelatinase-associated lipocalin (NGAL) served as biomarkers of organ injury for heart and kidney, respectively.

Results: Leukocyte activation at the end of CPB was significantly increased in Groups 1 and 2 but not Group 3. Leukocyte counts, namely neutrophils, significantly increased post-operatively in Groups 1 and 2 but not in Group 3. Systemic vascular resistance was not as reduced post CPB for the L-MOD treated pigs and at 5 hours post CPB, organ injury markers, troponin-I and NGAL, were lowest in Group 3.

Conclusions: 8 hours of L-MOD therapy limited leukocyte activation and the inflammatory response to CPB which resulted in less organ injury and dysfunction, including the kidney. Continuation of L-MOD therapy into the post-operative period was required for therapeutic impact.

A Comparison of Electronic Health Record (EHR) Phenotype Definitions for CKD C. Blake Cameron, John W. Stanifer, Rachel Richesson. *Duke University, Durham, NC.*

Background: Multiple methods for identifying patients with CKD using EHR-based phenotypes have been proposed. Few studies have systematically compared or prospectively validated these phenotype definitions.

Methods: In a rural, community-based healthcare system, we applied five distinct CKD phenotype definitions (A-E) to the EHR. Phenotype A defined CKD as ≥2 eGFR values <60mL/min/1.73m^2 separated by 90-730 days. Phenotype B was the same but also included individuals with albuminuria ≥30mg/g. Phenotypes C and D defined CKD by a single eGFR result <60 and <45 mL/min/1.73m^2 respectively. Phenotype E defined CKD as having ≥2 ambulatory encounters associated with an eligible ICD-9-CM or ICD-10-CM diagnosis code. We evaluated inter-rater agreement between each phenotype pair by calculating Chamberlain's percent positive agreement and Cohen's Kappa statistic.

Results: We identified 59,848 unique adults with at least one ambulatory encounter over a two-year period, of whom 6,620 (11%) were classified as having CKD by any one of the phenotypes. Only 666 (1%) were classified as having CKD by all five phenotypes. Phenotype C classified the most patients as having CKD (n=5,596; 9%), followed by phenotype B (n=3,837; 6%); phenotype A (n=3,268; 5%); phenotype D (n=2,552; 4%) and phenotype E (n=1,615; 3%). Phenotypes A and B showed the greatest agreement (Kappa=0.915), followed by phenotypes A and C (Kappa=0.718) and phenotypes B and C (Kappa=0.693). Phenotype E showed low agreement with any of the phenotypes.

Conclusions: In a rural, community-based healthcare system, several commonly used phenotype definitions showed poor agreement in classifying CKD. Additional studies using external reference standards that include prospective laboratory assessment of kidney function and albuminuria are required in order to validate performance characteristics of CKD phenotypes. Once validated, one or more CKD phenotypes could be promoted as a standard to define similar populations for clinical research and population health management.

VA MobileKidney App – A Mobile Educational and Clinical Engagement Tool for Veterans with CKD and Their Providers R. Brooks Robey,[1,2] Susan T. Crowley,[3,4] Devasmita Choudhury.[5,6] *[1]White River Junction VA Medical Center, White River Junction, VT; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]VA Connecticut Health Care System, West Haven, CT; [4]Yale School of Medicine, New Haven, CT; [5]Salem VA Medical Center, Salem, VA; [6]Virginia Tech Carilion School of Medicine, Roanoke, VA.*

Background: Patient health illiteracy and lack of accurate, reliable, and efficient mechanisms for evaluating self-care between clinic visits represent major barriers to optimal CKD management that are potentially amenable to digital telehealth solutions.

Methods: To address these barriers, we designed a secure digital application with 1) broad mobile device compatibility, 2) real time access to the CKD education and information resources housed in the cloud-based virtual VA *e*Kidney Clinic (*http://ckd.vacloud.us/*), and 3) novel electronic self-care journaling capabilities viewable remotely via a VA provider-facing interface.

Results: In addition to providing unrestricted mobile access to pertinent healthcare information and educational resources, the VA Mobile*e*Kidney app will allow Veterans with CKD to enter, annotate, and track self-gathered clinical information on personal mobile devices and securely share these data with their providers for asynchronous review, curation, and direct incorporation into the electronic health record (EHR). Graphical display of selected serial measures (e.g. weight, blood pressure, heart rate, and glucometer readings) permits both visual identification and monitoring of trends between visits. The corresponding ability to organize, curate, and import this information into the EHR in tabular form will also reduce associated transcription burdens and errors. In addition, free text annotations provide a vehicle for recording associated interval health questions and observations – and for recording special provider instructions during clinic visits.

Conclusions: Mobile*e*Kidney is scheduled for field testing and launch by Kidney Week 2017. It will provide accessible education resources to Veterans with CKD and their providers, as well as a mobile digital platform for sharing detailed self-gathered interval health information for joint review at regularly scheduled clinic visits. Free text journaling capabilities also afford flexibility to tailor application use to specific clinical needs. This novel digital tool for interval healthcare data acquisition, delivery, and review also provides a structured replacement for traditional hardcopy health diaries and promises to enhance patient buy-in and engagement in self-monitoring activities, as well as improve patient-provider communication, documentation, and coordination of care.

FR-PO982

Engineering Design of Robust Ultrafiltration Profiles in Hemodialysis Rammah M. Abohtyra,[2] Christopher V. Hollot,[1] Joseph Horowitz,[3] Yossi Chait.[3] *[1]Department of Electrical and Computer Enginering, University of Massachusetts Amherst, Amherst, MA; [2]UMass, Florence, MA; [3]University of Massachusetts, Amherst, MA.*

Background: Fluid removal during hemodialysis (HD) by ultrafiltration can lead to intradialytic hypotension, which is associated with an increase in morbidity and mortality. We design a robust, individualized ultrafiltration rate (UFR) profile to achieve a target volume removal under constraints on maximal UFR and maximal hematocrit (HCT) levels.

Methods: The fluid volume dynamics during HD was described by a validated nonlinear model comprising intravascular and interstitial pools, microvascular refilling/filtration, and lymphatic flow. Model parameters, red blood cells volume (V_{rbc}), plasma protein mass (m_p), and filtration coefficient (K_f), were estimated using 30 minutes of UFR and HCT clinical data and validated using remaining data. Anticipated parameter changes during HD and estimation errors were accounted for by allowing parameter uncertainty ranges of +/- 5%. The profile was designed using an optimization algorithm to remove 2.8 L in 4 hrs, with UFR not exceeding 10 ml/hr/kg, and HCT not exceeding 110% of initial HCT, and to guarantee performance over the entire range of parameter uncertainty.

Results: Model parameters (V_{rbc} =2.24 L, K_f =0.006 L/min/mmHg, and m_p=179.58 gr) of a 75 kg patient were estimated based on the initial 30 minutes of the HD session (Figure, top left) and validated over an additional 170 minutes of the session (Figure, bottom left). Simulation of the designed UFR profile (Figure, top right) over the range of model parameter uncertainty confirmed that all specifications were achieved (worst case HCT shown in Figure, bottom right); the worst case of HCT is simulated for a particular set of parameters within the parameter uncertainty range of the model.

Conclusions: The divergence of the validated response later in the HD period demonstrates that the underlying patient's response can deviate from model prediction due to, for example, autonomous adaption not captured in the model. This motivated the use of robust design of UFR profiles. Our UFR profile is designed to satisfy HCT and UFR constraints, and to guarantee that performance criteria are met over the entire model parameter uncertainty range.

FR-PO983

Machine Learning Model versus SOFA, APSIII, and OASIS in Prediction of Renal Replacement Therapy (RRT) within First 8 Days after ICU Admission in MIMIC-III (Medical Information Mart for Intensive Care III) Lukasz Kiljanek, Sandeep Aggarwal. *Drexel University College of Medicine, Philadelphia, PA.*

Background: There is a paucity of prediction tools for new onset RRT in ICU population. Computer based Machine learning models are being employed to create risk prediction tools using large databases. In this study we attempted the use of Gradient Boosting Machine (GBM) - Machine learning algorithm to create a RRT prediction tool using MIMIC 3 database

Methods: GBM algorithm from H2O.ai R project library was used to model 2008-2012 MIMIC 3 database. We defined 750 clinical and laboratory variables from first 24 hours after ICU admission. Patients with history of dialysis or RRT related events charted within first 24 hours of ICU stay were excluded. 17045 patients were divided 30 times randomly into training (90% of patients) and testing (10% of patients) datasets. **RRT within 8 days of ICU stay was defined as any RRT related event charted between 24 hours and 8 days mark**. Incidence of RRT was 27.8 [95% CI 25.9-29.6] for 30 testing sets. Each training dataset was used to build GBM for predicting need for RRT, which was validated on testing dataset. Area under curve (AUC) of receiver-operator characteristics curve (ROC) was recorded. For each of 30 testing datasets, AUC for prediction of RRT by SOFA, OASIS and APS III was also recorded.

Results: For 30 testing datasets, AUC of ROC for; GBM was 0.87 [95% CI 0.85-0.89], and SOFA was 0.83 [95% CI 0.82-0.84], APSIII was 0.82 [95% CI 0.81-0.83] and OASIS was 0.71 [95% CI 0.70 0.72], in predicting RRT within 8 days. GBM vs SOFA, GBM vs APSIII and GBM vs OASIS revealed statistically significant higher AUC of GBM (p<0.05 Wilcoxon signed-rank test). Most important predictors**,** seen within first 24 hours of ICU stay, from 1 of 30 runs, with their scaled importances were : last serum creatinine recorded (1), maximal serum creatinine recorded (0.94)

Conclusions: In our analysis GBM model showed statistically superior accuracy compared to conventional ICU severity scores to predict patients who survive until and require RRT after ICU admission. Additionally, we discovered applicability of conventional ICU severity scores to predict RRT in this setting. This can be employed to EMRs in hospitals for as an RRT event prediction too, but more research is warranted to assess clinical aplicability and robustness of our methods.

Engineering-Based Individualized Anemia Management in Hemodialysis Patients Biro Alexander,[6] Sara Blumberg Benyamini,[7] Michael J. Germain,[2] Joseph Horowitz,[5] Zvi Barnea,[4] Relu Cernes,[3] Yossi Chait,[5] Eliezer Rachmilewitz,[7] Ze'ev Katzir.[1] *[1]Institute of Nephrology, Holon, Israel; [2]Renal and Transplant Assoc of New England, Hampden, MA; [3]WOLFSON MEDICAL CENTER, HOLON, ISRAEL, HOLON, Israel; [4]Wolfson Medical Center, Holon, Israel, Holon, Israel; [5]University of Massachusetts, Amherst, MA; [6]WOLFSON MEDICAL CENTER, HOLON, Israel; [7]Wolfson Medical Center, Holon, Israel.*

Background: Management of erythropoietin stimulating agents and parenteral iron in hemodialysis (HD) patients is performed according to protocols derived from population response data. This pilot study examined whether individualized dosing can reduce hemoglobin (Hb) variability and increase the proportion of Hb levels within range compared with standard protocol results, while transferrin saturation (TSAT) and Ferritin levels would remain similar, and that the use of medications could be reduced.

Methods: We enrolled 25 maintenance HD patients treated using a bi-weekly titration and dosing protocol. We switched into a computerized, individualized protocol based on feedback principles and a mathematical model [1]; The ESA protocol has been validated in prior studies while the IV Iron protocol was newly derived. In the individualized protocol dosing schedule was switched to weekly. Target and range Hb were 11.5 and (11,12) g/dl, respectively. Results are reported from the first 9 months of the year-long, crossover study with 3-month washout period; Hb variability measure was the standard deviation (sd). Baseline refers to the 6-month period prior to the study, and Study refers to the most recent 6-month. For normal data we used the t-test to compare means and Pitman's test for sds; medians of nonnormal data were compared by the signed rank test; and McNemar's test was used for binary data. and statistical significance is defined as P-value < 0.05.

Results: (Table)

Conclusions: The individualized anemia protocol has improved %Hb in range and reduced Hb variability compared with standard protocol, while Aranesp and Venofer doses were reduced. However, TSAT and Ferritin levels decreased suggesting that our Iron IV algorithm may require modification. 1. Chait Y, Horowitz J, Nichols B, Shrestha RP, Hollot CV, Germain MJ. Sodium MRI Identifies Differences of Sodium Concentration with Age, Gender, and Race in Muscle and Skin of Healthy Subjects from the US Jonathan Dyke,[3] Anna Meyring-Wosten,[1] Yize Zhao,[3] Stephan Thijssen,[1] Peter Linz,[2] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]University Hospital Erlangen, Erlangen, Germany; [3]Weill Cornell Medical College, NY, NY.*

Background: Sodium (Na+) balance is important in managing hemodialysis patients; however, its assessment is difficult and incomplete. Experimental studies show that Na+ is stored without commensurate water accumulation in muscle and skin and may exceed levels measured in the serum. Our study implemented quantitative ^{23}Na MRI imaging of the calf muscle and skin of healthy subjects compared with ex-vivo reference standards. Contributions from age, gender and race were examined.

Methods: A total of 30 subjects were enrolled for the study [(15M/15F), 46.4±14.8 yrs, (10 White/20 African-American)]. Studies were performed on a 3.0 Tesla Siemens MRI using a ^{23}Na coil (Helmut Stark;Germany)[Fig 1]. Scan-rescan reproducibility was assessed the same day and 1 week later for a total of 4 time points/subject. Regions of interest were defined in the skin and following muscles: lateral gastrocnemius (LGM), medial gastrocnemius (MGM), soleus, tibialis anterior and peroneus. A mixed effects model was used based on repeated measures to determine the marginal multivariate effects of age, gender and race versus sodium MRI concentrations. A Bland-Altman plot assessed scan-rescan variability with the smallest real difference (SRD) calculated as 2.77*SEM.

Results: The Bland-Altman plots indicated high agreement between runs in all regions. The SRD was 9.7% and 4.1% within the same day and 10.9% and 12.2% comparing runs a week apart. Sodium increased in all muscles and skin with age. An association in muscle sodium was seen in the LGM (p=0.03), anterior (p=0.04) and peroneus (p=0.01) muscles with gender. No significant association was seen between sodium levels and race.

Conclusions: Tissue Na+ content was confirmed to increase with age in both muscle and skin of healthy controls. Differences in muscle sodium levels were also found with gender but not race. Reproducibility of ^{23}Na MRI in the muscle and skin resulted in an SRD that shows promise to assess serial changes in patients with renal insufficiency.

Computational Volume-Analysis of Compensatory Hypertrophy of the Kidney after Contralateral Nephrectomy Jun Nagayma. *Urology, Japanese Red Cross Nagoya First Hospital, Nagoya, Japan.*

Background: Kidney volume usually increases after contralateral nephrectomy according to the preoperative disease-affected kidney function. We preliminarily assessed post-nephrectomy-parenchymal volume divided into two regions (cortex and medulla) to examine compensatory hypertrophy in each using computational volume analyzer on new computational imaging technologies.

Methods: The arterial-phased enhanced imaging data (DICOM formatted) of 11 patients (age ranged between 51 and 86) were obtained from the institutional database. Nephrectomy was underwent in all patients in which 7 renal cell carcinoma, 3 pelvic and ureteral cancer and 1 pyonephrosis were included. Pre- and postoperative (after completion of compensatory hypertrophy) parenchymal volumes were calculated using Synapse Vincent, Fujifilm and compared regional increasing ratio in each area (total parenchyma, cortex and medulla).

Results: Mean preoperative volume of total kidney, cortex and medulla were 181.95 (31.38) ml, 112.53 (25.57) ml and 67.40 (16.85) ml and mean postoperative one were 200.81 (41.65) ml, 126.66 (34.94) ml and 74.15 (16.81) ml, respectively. Cortex volume increases significantly comparing to the preoperative status (p=0.04); however, medulla volume and cortex-medulla volume ratio did not change significantly. Body mass index, gender and preoperative estimated glomerular filtration ratio (eGFR) did not affect the cortex hypertrophy. When comparing the cortex increasing ratio to the change in eGFR, cortex hypertrophy indicated fewer decline in eGFR (fig: p=0.2, R=0.41).

Conclusions: Within the small preliminary experience, computational volume-analysis indicated kidney volume increase after nephrectomy in the cortex region superiority to the medulla. Cortex hypertrophy might correlate with better preservation of renal function in eGFR.

Contrast Enhanced Ultrasound (CEUS): A Novel Marker of Kidney Disease Mona Shaban,[3] Emily H. Chang,[2] Anush Sridharan,[4] Paul Dayton.[1] *[1]UNC Chapel Hill and NC State University Raleigh, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]Nephrology, University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]University of North Carolina, Chapel Hill, NC.*

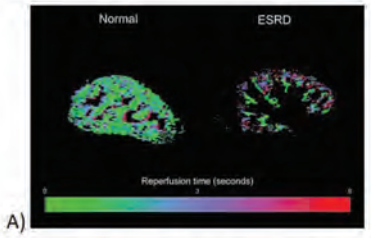
Background: The number of patients with chronic kidney disease (CKD) is on the rise and non-invasive methods of detecting early stages of kidney insufficiency are limited. Rise in creatinine often lags behind loss of kidney function and current ultrasound technology to evaluate severity of CKD hinges on kidney size and echogenicity, which is a subjective marker. Contrast enhanced ultrasound (CEUS) provides qualitative and quantitative measurements of perfusion, which may lead to earlier diagnosis of CKD and provide a better marker of kidney disease progression.

Methods: Patients with various stages of CKD were subjected to CEUS of the kidney. Contrast agent (Definity) was infused at a constant rate based on BMI. High mechanical index flash perfusion imaging was captured. Baseline serum creatinine and urinalysis was collected. Time-intensity curves (TICs) were generated for regions of interest (ROI) from the kidney parenchyma, as well as maximum intensity projections and reperfusion maps. TICs are used to generate a wash-in rate, area under the curve, and time-to-peak intensity.

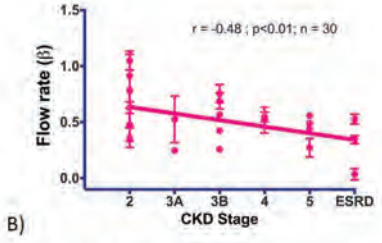
Results: A total of 30 patients with CKD and 3 healthy controls participated in this study. We have found that the enhancement of kidney parenchyma was markedly reduced in patients with lower glomerular filtration rate (GFR) (image 1A). Additionally, we have demonstrated a linear inverse correlation between reperfusion rate and stage of CKD (image 1B). These values will be compared to multiple metrics including GFR and proteinuria in hopes of establishing a novel technique that detects degree of CKD, particularly early stages.

Conclusions: CEUS is a novel, non-invasive imaging modality measuring kidney perfusion, which may be an earlier marker of kidney injury. The generation of wash-in rate, area under the curve, and time-to-peak intensity values will lead to quantitative measurements of kidney function. We are currently working to determine the diagnostic accuracy of these metrics.

Figure 1



Reperfusion maps of renal parenchyma comparing healthy volunteer (left) to ESRD patient (right)



The rate of kidney perfusion as measured by CEUS inversely correlates with stage of CKD

Effect of Hemodialysis on T2 Relaxation Times in Body Tissues Kristin M. Corapi,[2] Lina A. Colucci,[4] Xavier F. Parada,[2] Herbert Y. Lin,[3] Michael J. Cima.[1] *[1]MIT, Cambridge, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [4]Massachusetts Institute of Technology, Cambridge, MA.*

Background: Quantitative magnetic resonance (qMRI) can inform about the water content of different tissues. In this study we performed qMRI of the calf, pre and post-HD, to detect fluid changes in muscle and subcutaneous (SC) tissues.

Methods: Adult, male HD patients and healthy controls were enrolled. HD patients underwent qMRI before and after HD while controls underwent qMRI before and after 4 hours of bedrest. MRI scans were done on a 1.5T Siemens MRI Scanner using a knee coil. Quantitative T2 relaxation maps of the upper calf were generated using a spin echo sequences with 32 echoes, TR 3,300ms, TE 8ms, and 4 slices of 5mm thickness. Regions of interest (ROIs) enclosing SC tissue and muscle were manually drawn. Histograms of the T2 relaxation values in those ROIs were generated from the pre and post scans of all participants. The mean, median, and standard deviation of the T2 relaxation time distributions were calculated.

Results: Demographics are shown in table 1. HD patients have longer T2 relaxation times in both the muscle and SC tissue (figure 1a and 1b). We also observed a statistically significant (p=0.01) change in the T2 relaxation time for muscle, but not SC tissue (p=0.45), after treatment with hemodialysis (figure 1c and 1d).

Conclusions: Our results suggest that there is a larger change in relaxation time in muscle than in SC tissue during hemodialysis. This suggests more water movement from the muscle compartment than the SC tissue. Devices to better understand the kinetics of fluid shifts during HD may help alter prescriptions and mitigate symptoms.

Portable Magnetic Resonance Sensor to Detect Volume Changes Lina A. Colucci,[4] Kristin M. Corapi,[2] Xavier F. Parada,[2] Herbert Y. Lin,[3] Michael J. Cima.[1] *[1]MIT, Cambridge, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [4]Massachusetts Institute of Technology, Cambridge, MA.*

Background: Magnetic resonance technology provides information about the quantity, volume, and motion of water. In this study, we used portable, non-invasive MR sensors to monitor water movement in healthy controls and hemodialysis (HD) patients.

Methods: Adult, male HD patients and controls were enrolled. A custom, single-sided MR sensor developed by the Cima Lab at MIT was used to collect data from the upper calf of HD patients before and after dialysis. Controls had data collected before and after 4 hours of bedrest. The MR sensor collected T2 relaxation time measurements of a cubic centimeter voxel that included subcutaneous tissue and muscle. The T2 relaxation time measurements were analyzed with an inverse Laplace transformation to generate a relaxogram. The individual relaxograms were averaged together in each group.

Results: Demographics are shown in table 1. Free fluids are associated with long T2 relaxation times whereas bound hydrogen in connective tissues are associated with short T2 relaxation times. We observe that controls have nearly identical relaxograms at 0 and 4 hrs. Dialysis patients before treatment display an added peak in their relaxogram at higher relaxation times, representing excess free fluid. We demonstrate that this peak shifts to the left after dialysis and that the relaxogram of the HD patients becomes comparable to controls (Figure 1a-d).

Conclusions: Portable MR sensors may quantify fluid overload in HD patients non-invasively. Further study is necessary to understand the sensitivity of these sensors to fluid shifts during HD and develop an absolute scale that relates relaxation time measurements to fluid overload.

FR-PO990

Evaluation of the Utility of [18F]DiFA as a Novel Kidney Hypoxia Imaging Tracer Norihito Nakata,[1] Masato Kiriu,[1] Yuki Okumura,[1] Hiroki Matsumoto,[1] Yuji Kuge.[2] *[1]Nihon Medi-Physics Co., Ltd., Sodegaura, Japan; [2]Hokkaido University, Sapporo, Japan.*

Background: It is reported that hypoxia is important as a final common pathway in which chronic kidney disease progresses to end-stage renal failure. Therefore, evaluation of hypoxic condition in the kidney is considered to be useful as a surrogate marker of drug treatment. However, it is difficult to evaluate the hypoxic condition in the kidney with the current in vitro diagnosis. We have investigated the basic properties of a new intratumoral hypoxic imaging agent 1- (2,2-Dihydroxymethyl-3- [^{18}F] Fluoropropyl) Azomycin ([^{18}F] DiFA) and have already reported its usefulness. In this study, we investigated whether [^{18}F]DiFA can evaluate the hypoxic condition in the kidney using a drug-induced renal impairment model. Furthermore, comparison with existing hypoxic imaging tracer, [^{18}F] FMISO, was also conducted.

Methods: [^{18}F]DiFA or [^{18}F]FMISO was administered to adriamycin-induced renal injury model rats and a PET imaging experiment was performed. Autoradiography was performed using [^{18}F]DiFA[S1] and compared with the results of immunohistochemistry using HIF-1α as a hypoxic marker.

Results: As a result of PET imaging of [^{18}F]DiFA, the uptake in the kidney cortex was observed at 80 minutes after administration, and an image visualized with high contrast was presented hypoxia of the renal cortex portion (Figure.1). These analysis results were shown in the following table. Since the localization of [^{18}F]DiFA in kidney and localization of HIF-1α were in good agreement, it was confirmed that [^{18}F]DiFA selectively accumulated in the hypoxic region in the kidney.

Conclusions: These results suggested that [^{18}F]DiFA may be useful as a hypoxia imaging tracer in the kidney compared to [^{18}F]FMISO.

Mesoscale Nanoparticles Selectively and Safely Target Renal Proximal Tubules Ryan M. Williams,[1] Janki Shah,[1] Xi Chen,[2,1] Edgar A. Jaimes,[1,2] Daniel A. Heller.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medical College, New York, NY.*

Background: Acute kidney injury accounts for 1% of hospital admissions in the US and over 20 million US adults (~11%) have chronic kidney disease. To address this problem, we developed mesoscale nanoparticles (MNPs) to selectively deliver therapies to the renal proximal tubules.

Methods: We synthesized MNPs from a biocompatible polymer (PLGA-PEG) to encapsulate a fluorescent dye for biodistribution and toxicology studies. Particles exhibited a size of approximately 400 nm and a negative surface charge. In vivo fluorescence imaging of mice determined the extent of renal localization via varying administration routes and doses. We used intravital and ex vivo fluorescence confocal microscopy to determine tissue-level distribution of MNPs. Finally, we performed toxicology experiments in mice via histology, blood counts, and renal biochemical panels to ascertain the safety of the particles up to one month in mice.

Results: We found that via intravenous administration, MNPs selectively localize to the kidneys up to 25-fold more than any other organ, uniquely selective among drug carrier systems. Within the kidneys, the localization was primarily to the proximal tubular epithelial cells, which is also novel to this system. Further, we found that these particles degrade and release their payload over weeks while they cause no renal or systemic toxicity.

Conclusions: Together, these results portend the pre-clinical development of therapeutic nanoparticles that are highly selective, safe, and provide long-term drug release with a single intravenous dose to treat renal diseases such as AKI and CKD.

3-D Kidney-on-Chip Platform for Quantitative Screening of Podocyte Structural Integrity Smiti Bhattacharya,[2,5] Amit Ron,[1] Rhodora C. Calizo,[3] Robert Wiener,[3] John C. He,[4] Ravi Iyengar,[3] James C. Hone,[2] Evren U. Azeloglu.[3] *[1]Columbia University, New York, NY; [2]Columbia University, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Mount Sinai School of Medicine, New York, NY; [5]Department of Pharmacological Sciences, Ichan School Of Medicine at Mount Sinai, New York, NY.*

Background: Podocytes have an intricate *in vivo* morphology that is critical for their physiological function. Under disease conditions or upon isolation and culture, podocytes dedifferentiate and lose their specialized morphology, which prevents the use of primary or immortalized podocyte lines as translatable *in vitro* models of chronic kidney disease. In order to systematically study podocyte mechanobiology and drug response, we developed an *in vitro* culture system that utilizes microfabricated 3-D biochips to mechanically induce formation of fine peripheral processes in podocytes.

Methods: We microfabricated 3-D biochips using photolithography. We developed biochips of varying size formats from standard 96-well plates to 25-mm coverslips. Immortalized human podocytes were plated on 3-D biochips and differentiated for five days at 37 degrees Centigrade. Transcriptomic expression of differentiation markers was quantified using RT-PCR. Spatial localization and protein expression were quantified using immunofluorescence. Spatial biomechanics were quantified using atomic force microscope elastography.

Results: Podocytes in 3-D biochips displayed significant upregulation of a wide range of genes associated with the differentiated phenotype. The peripheral processes were selectively enriched for slit diaphragm components nephrin, podocin and neph1 as well as crosslinked actin bundles. Micropatterned podocytes exhibited heterogeneous biomechanical properties with significantly increased elastic modulus in peripheral processes. This spatial phenotype was lost when cells were treated with known nephrotoxic drugs or inhibitors of cytoskeletal integrity. When we looked at phenotypic signatures of protein localization, focal adhesion maturation and cytoskeletal integrity,

podocytes in biochips showed reduced cell-to-cell variability and high reproducibility compared to those on unpatterned glass surfaces.

Conclusions: We developed a 3-D kidney-on-chip system that provides a quantitative, high-throughput *in vitro* platform for studying podocyte morphology, biomechanics and drug response with high reproducibility.

Biomimetic Microenvironment Promotes In Vivo-Like Phenotype of Conditionally Immortalized Podocytes Matthew Ishahak, Ellery Jones, Alessia Fornoni, Ashutosh Agarwal. *University of Miami, Miami, FL.*

Background: Microenvironmental cues are integral in providing signals that modulate podocyte development and function. However, standard culture conditions fail to recapitulate the chemical, physical, and architectural cues presented by the glomerular basement membrane (GBM). We report the effect of an engineered GBM-mimic hydrogel on conditionally immortalized human podocyte cultures.

Methods: A hydrogel was developed through the enzymatic crosslinking of denatured collagen to serve as a GBM-mimic. 3D grooves were micromolded into the surface of the biomimetic hydrogel. Mechanical properties of the GBM-mimic hydrogel were characterized using a rheometer fitted with a metal parallel plate in oscillation mode. Conditionally immortalized human podocytes were cultured on various substrates in permissive conditions. Once cells reached ~90% confluence, they were moved to non-permissive conditions and cultured for 14 days to allow for differentiation. Phenotypic features were assessed by fluorescent imaging and scanning electron microscopy (SEM).

Results: A GBM-mimic hydrogel that recapitulates the protein composition, mechanical properties, and 3D surface topography of the GBM was successfully fabricated. The stiffness of the hydrogel (E=5.43±0.69 kPa) was much closer to the physiological stiffness of the glomerulus than that of other cell culture substrates (Fig 1A). SEM revealed the formation of processes branching from the main cell body of podocytes grown on the GBM-mimic hydrogels (Fig 1B).

Conclusions: These results demonstrate that microenvironmental cues induce in-vivo like podocyte morphology. Current studies are focused on incorporating additional GBM components (e.g. laminin) and dynamic physiological phenomenon (e.g. fluid flow, pressure differential, and protein gradient). Ultimately, an integrated platform that maintains and measures long term glomerular filtration will be developed to serve as a powerful addition to the toolkit for studying kidney disease and developing therapeutics.

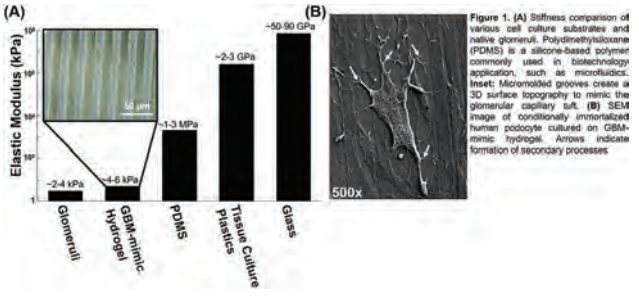

Figure 1. (A) Stiffness comparison of various cell culture substrates and native glomeruli. Polydimethylsiloxane (PDMS) is a silicone-based polymer commonly used in biotechnology application, such as microfluidics. Inset: Micromolded grooves create a 3D surface topography to mimic the glomerular capillary tuft. (B) SEM image of conditionally immortalized human podocyte cultured on GBM-mimic hydrogel. Multiscale Mechanical Properties of Glycated Kidney Extracellular Matrix Nicholas J. Ferrell,[1] Sarah Dillender,[1] Rishabh Agarwal,[1,2] Minhal H. Abidi,[1] Gwyneth D. Walker.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Illinois at Chicago, Lisle, IL.*

Background: Non-enzymatic glycation of the extracellular matrix (ECM) contributes to diabetic nephropathy. A subset of advanced glycation end-products (AGEs) crosslink the ECM and may increase ECM stiffness. Matrix stiffening is recognized as a contributor to progression of fibrotic diseases, but the role of non-enzymatic stiffening of kidney ECM in the progression of diabetic nephropathy is not well understood and may provide new targets for intervention. The aim of this work was to evaluate the degree to which ex vivo glycation increased the stiffness of cortical, glomerular, and tubular ECM using multiple biomechanical characterization techniques.

Methods: Cortical and glomerular ECM were isolated from porcine kidney cortex by gross dissection and differential sieving, respectively. Mouse tubules were isolated from wild type mouse kidneys by microdissection. ECM was decellularized and evaluated by histology and immunostaining to evaluate the effects of decellularization on ECM structure. ECM was glycated by incubation in glucose or ribose (0-500 mM) for 30 days. Following glycation, ECM was subjected to either compressive or tensile mechanical testing using custom microscale measurement techniques (for tubules and glomeruli) or commercial testing techniques (for cortical matrix).

Results: Histological examination and immunostaining for ECM proteins (collagen IV and laminin) showed that structural proteins were retained in the ECM and the matrix largely retained its three dimensional structure following decellularization. Biomechanical testing showed that glycation increased ECM elastic modulus (stiffness) following exposure to both glucose and ribose at concentrations >5 mM. This effect was more pronounced for ribose given its higher reactivity relative to glucose. The origin of the ECM (cortical, glomerular, or tubular) and the method of applied stress (tension or compression) had a significant effect on the measured stiffness. This variability is likely due structural differences between the matrix components and anisotropy in the tensile versus compressive mechanical properties.

Conclusions: These data suggest a potential role for ECM stiffening in progression of diabetic kidney disease. Care should be taken in interpretation of the measured elastic modulus depending on the origin of the matrix and the method of characterizing the ECM stiffness.

Genomic Analysis of Primary Human Kidney Podocytes Reveals Numerous Differences from Widely Used Podocyte Cell Lines Karsten B. Sieber,[1] Shreeram Akilesh.[2] *[1]GlaxoSmithKline, King of Prussia, PA; [2]University of Washington, Seattle, WA.*

Background: Kidney disease is a major and increasing burden on society, affecting ~10% of adults worldwide and causing increased risk of all-cause mortality. The glomerular podocyte is an important cell type with limited proliferative/regenerative potential that is the target of many proteinuric kidney diseases. Despite extensive cell biological characterization, very few studies have focused on characterizing the podocyte-specific epigenetic architecture and transcriptome. Such studies promise to shed light on the mechanisms of genome regulation in this important cell type and to calibrate and improve commonly used and emerging (e.g. iPSC-derived) podocyte cell culture systems.

Methods: We generated high resolution chromatin accessibility (DNase-seq) and gene expression (RNA-seq) data for primary cultures of human podocytes (n=4), and compared them to similar datasets generated from a widely used conditionally immortalized human podocyte cell line cultured under growth-permissive and differentiation-inducing conditions.

Results: Initial transcriptomic analyses revealed that nearly 2000 genes are differentially expressed between the primary podocytes and a widely-used podocyte cell line. Of these genes, more than 100 transcription factors are differentially expressed; notably, primary podocytes retain strong expression of the lineage-defining transcription factor WT1, in contrast to the podocyte cell line which has weak expression of this gene. Many of the other differentially expressed transcription factors have not been specifically studied in podocytes. To understand their functional consequence, we are analyzing recently generated chromatin accessibility data to elucidate the transcription factor regulatory networks that drive the unique podocyte phenotype.

Conclusions: Compared to primary podocytes, these findings indicate widespread genome regulatory differences in the conditionally immortalized podocyte cell lines and suggest caution in their use. Ongoing studies are focusing on the impact of these differentially expressed transcription factors on the unique chromatin accessibility landscape of primary podocytes.

Targeting Renal Fibrosis Using Self-Assembled Nanoparticles Joan Li,[1] Justin Cooper-White.[1,2] *[1]The University of Queensland, Brisbane, QLD, Australia; [2]Biomedical Manufacturing, Manufacturing Flagship, CSIRO, Melbourne, VIC, Australia.*

Background: MicroRNAs (miRNAs) are emerging as potential therapeutics for Chronic Kidney Disease (CKD) to reduce fibrosis, and myofibroblast proliferation. However, the lack of targeted delivery of miRNAs with sustained expression or suppression are major challenges in translating microRNA therapy to treat CKD. We have developed a novel self-assembled nanoparticle (*SAnP*) delivery system that, when functionalised with a specific cell-targeting ligand, is recognised by both interstitial fibroblasts and injured epithelial cells within the kidney, enabling cell-specific delivery of miRNA via receptor-mediated uptake.

Methods: *In vitro* Epithelial-to-mesenchymal transition (EMT) model was induced in cultured MDCK cells with TGF-β (10ng/ml) and treated with or without miR-29 (1nM) for 72 hours. Renal fibrosis model was created using *Postn*-Cre;Rosa26R-Zsgreen mice (~ 20 weeks), subjected to Unilateral Ureteral Obstruction (UUO). The miR-29 mimic (0.1mg/kg), either packaged into the *SAnP* system targeting receptor "X" or as "naked" microRNA, was directly delivered into the renal parenchyma of the UUO model, at the time of the obstruction. Mice were euthanized 7 days after UUO. Kidneys were collected and processed for histology analysis.

Results: To test the specificity of our *SAnP* delivery system, we packaged Cy3-labelled miR into the SAnP and infected cells expressing receptor "X": MDCK cells. Uptake of Cy-3 was only detected in cells transfected with *SAnP-Cy3-miR* (97% vs 0.4% for Cy3-miR only), confirming receptor-mediated uptake. In cultured MDCK cells, TGF-β induced EMT was partially blocked by administration of the miR-29 mimic, as treated cells maintained the *cobblestone*-like morphology and preserved E-cadherin expression on the cell membrane. At 7 days post-UUO, our *SAnP*-delivered miR-29 mimic was able to reduce tubular dilatation and perivascular infiltration. Quantification of Picrosirius red staining indicated a 24% decrease in collage deposition. Delivery of "naked" miR-29 mimic did not show any beneficial effect in the UUO model.

Conclusions: Our preliminary data demonstrate that whilst miR-29 alone can inhibit the EMT transition *in vitro*, "naked" miR-29 had no effect *in vivo*. Our *SAnP* system however could affect cell-specific targeted delivery of miR29, significantly reducing tubular dilatation, interstitial infiltration and collagen deposition in the UUO model.

FR-PO997

Transcriptome Signatures for Dietary Fructose Induced Changes in the Proximal Tubule Ulrich Hopfer, Agustin Gonzalez-Vicente, Jeffrey L. Garvin. *Case Western Reserve University, Cleveland, OH.*

Background: Fructose consumption has been associated with renal dysfunction and salt-sensitive hypertension. Proximal tubules reabsorb and metabolize fructose.

Methods: To study the effect of fructose on genetic programs in proximal tubules, rats were given a 20% fructose (FRU) or water for 7 days. We used 4 groups of rats fed either chow 1 (normal salt) or 2 (high salt) +/- FRU. Each group contained 4 rats. The exposure time to FRU was short enough so that the rats showed no signs of metabolic syndrome. Total RNA from the superficial kidney cortex was analyzed using the Affymetrix microarray *RaGene*-2_0-st. Differential expression (DE) analysis of FRU vs. water on chow 1 or 2, was carried out using 3 different statistical methods: 1) Univariate ANOVA (Affymetrix TAC software), 2) Bayesian (BAMarray), and 3) Multivariate Characteristic Direction (CD). CD analysis of DE includes also information from the co-variance matrix between pairs of groups and calculates a vector of co-regulated genes ranked on a quantitative relative scale.

Results: Cosine similarity comparison of the FRU/water vectors from the 2 different chows showed greater similarity than FRU/water vector under either chow versus chow-alone vector. Intersection of the high ranking genes from the two FRU/water vectors (under diet 1 or 2) yielded 139 FRU-specific genes. Only 6 of these genes were also identified as DE genes by both univariate methods. They include the 2 most highly ranked CD genes as well as some lower ranked ones, suggesting that the univariate methods miss many DE genes because of high FRU-unrelated variance. DE genes identified by CD include G6pc, Slc5a8, Tkfc, Slc2a5, Khk, which directly transport or metabolize fructose in proximal tubules. Enrichment for GO:Biological Processes identified "response to nutrient" (GO:0007584), "cellular response to fructose stimulus" (GO:0071332) and "response to fructose" (GO:0009750). Enrichment for GO:Cellular Constituents identified 11 mitochondrial enzymes, suggesting amino acid catabolism, cataplerosis, ketogenesis, and fatty acid synthesis. DE of the cytosolic enzymes Pck1 and G6pc in FRU regardless of chow, suggest increases in gluconeogenesis and glyceroneogenesis.

Conclusions: In summary, the CD method outperforms commonly used univariate methods and provides a meaningful transcriptome signature of FRU in proximal tubules.

Development of Method for Assessing Chemical-Induced Toxicity against Kidney Cells by In Vivo Live Imaging Technique Using Nephron-Visualized-Transparent-Zebrafish Shin'ichi Akiyama, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Zebrafish is a well-established vertebrate model for studying genetically higher levels of biological phenomena and it is suitable for the identification of toxic- or therapeutic-compounds on a larger scale. Larva of zebrafish are transparent, so they are often used for in vivo phenotype-based toxicological assay, but because the body of juvenile or adult fish body is not transparent, it is not suitable for that. In this study, we tried to develop a new platform for assessing chemicals safety and toxicity against kidney by using a nephron-visualized-transparent-zebrafish.

Methods: We generated nephron-visualized-transparent zebrafish, which expressing green fluorescent protein (GFP) in glomeruli and proximal-mid tubule, by bioengineering technique using a promoter region of slc20a1a gene, a Gal4-UAS system, GFP cDNA and transparent zebrafish (Casper line). The larvae, juvenile and young adult of this fish were administrated a gentamicin, as positive control of nephrotoxicin, or several compounds by microinjection or exposure. Further, when evaluating protein leakage from the glomeruli, the dye-labeled dextran (MW, 70k) was administered by microinjection. At 24 or 48 hours post administration, we evaluated the survival, edema formation, form and number of nephron, and leakage of dextran.

Results: Live nephrons of the nephron visualized transparent zebrafish, could be clearly observed through the skin from outside the body from larva to young adult fish (2 months post-fertilization). In the fish treated with nephrotoxicin, edema increase, nephron loss, and dextran leakage were observed in a dose-dependent manner.

Conclusions: These results suggest that our in vivo assessing technique using the nephron-visualized-transparent-zebrafish have the potential to provide more easy and advanced platforms for assessing kidney health impacts of chemicals.

FR-PO999

Effects of Nitric Oxide Releasing Bionanomatrix Gel on Reducing Neointimal Hyperplasia and Inflammation Maheshika S. Somarathna,[1] Patrick Hwang,[2] Tatyana Isayeva Waldrop,[1] Grant Alexander,[1] Lingling Guo,[1] HO-WOOK JUN,[1,2] Timmy C. Lee.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Endomimetics LLC, Birmingham, AL.*

Background: Vascular access is the lifeline for hemodialysis patients. An arteriovenous fistula (AVF) is the preferred type of vascular access. However, nearly 60% of the time, AVF maturation failure occurs due to early venous neointimal hyperplasia (NIH) formation and poor vascular remodeling. We hypothesize that local nitric oxide (NO) therapy administered at the time of AVF creation can inhibit venous NIH development and reduce local AVF inflammation. The aims of this study are to evaluate in a rat AVF model the effects of a NO-releasing bionanomatrix gel on: 1) NIH formation and 2) expression of inflammatory biomarkers such as MCP-1, IL-1, IL-6 and TNF-α in AVF vein.

Methods: Femoral vein to artery AVFs were created. After AVF creation, the NO-releasing gel was applied on the AVF anastomosis in 16 week old Sprague-Dawley rats (Figure 1). Rats were sacrificed at 7 days to perform: 1) Morphometric analysis of the AVF vein to access the changes in NIH development and 2) Western blot analysis from the vein segments to evaluate changes in expression levels of inflammatory biomarkers.

Results: The NO-releasing gel treatment group showed a significant reduction in NIH development at 7 days after AVF creation (Figure 1) when compared to the control group. MCP-1, IL-1, IL-6 and TNF-α protein expression in AVF vein was significantly lower in the NO-releasing gel treated group.

Conclusions: NO-releasing gel therapy applied locally on the AVF has great potential to promote AVF maturation by reducing NIH and mitigating local inflammation following AVF creation.

Funding: NIDDK Support

Autonomic Nervous System Dysfunction Status Post Solid Organ Transplant Nina Tazi,[2] Mira T. Keddis.[1] *[1]Mayo Clinic, Phoenix, AZ; [2]Internal Medicine, Mayo Clinic, Scottsdale, AZ.*

Background: Introduction: Autonomic nervous system (ANS) dysfunction has been reported to stabilize or improve following solid organ transplantation. This paper describes the phenomenon of ANS dysfunction, that happens within 30 days of solid organ transplant (kidney, kidney-pancreas or liver), requiring multiple medications, and ultimately resolves over several months.

Methods: Materials and methods: All patients who underwent solid organ transplant from 2012-2016 and were evaluated by neurology after transplant were included (n=8). Data gathered included pre transplant autonomic dysfunction, post-transplant BP, laboratory variables and paraneoplastic antibodies.

Results: Results: A total of 8 patients were identified who suffered severe symptoms of ANS dysfunction including symptoms of orthostatic intolerance and syncope in all, and significant gastrointestinal symptoms in 7 that began concurrently with adrenergic failure. Symptoms of ANS dysfunction occurred 1 - 3 weeks post-transplant. Symptoms present post-transplant included lower blood pressure, hypoalbuminemia, anemia requiring transfusion in 5 of 8 patients. Paraneoplastic autoantibody panel was drawn in 4 patients and abnormal in 3. Complications of autonomic failure in these patients resulted in prolonged and recurrent hospitalizations.

Conclusions: Conclusion: Autonomic testing confirmed the presence of significant autonomic neuropathy in those tested, and autoantibodies associated with autoimmune autonomic neuropathy were present in 3 of 4 patients tested, suggesting a potential autoimmune cause. Ultimately, the autonomic failure resolved in all patients with established long-term follow-up.

FR-PO1001

Organ-Specific Immunosuppression in Kidney Transplantation Dominik R. Kentrup,[3] Katharina Schütte-Nütgen,[3] Helga Pawlski,[3] Hermann Pavenstädt,[3] Sven Hermann,[1] Michael Schaefers,[1] Gregor Larbig,[2] Armin Kuebelbeck,[2] Stefan Reuter.[3] *[1]European Institute for Molecular Imaging - EIMI, Muenster, Germany; [2]Merck KGaA, Darmstadt, Germany; [3]University Hospital Münster, Münster, Germany.*

Background: Severe side effects attributable to immunosuppressive therapy are a major obstacle in organ transplantation. In this study we assessed a kidney-specific drug delivery mechanism and show that prednisolone, coupled to a specific polypeptide is selectively taken up by the kidney in rats which underwent renal transplantation, avoiding adverse systemic effects.

Methods: All experiments were performed using male rats, ten groups of animals were assessed (N=5-6): Syngeneically (Lewis Brown Norway F1 to Lewis Brown Norway F1) and allogeneically (Lewis Brown Norway F1 to Lewis) transplanted rats without immunosuppression, as well as allogeneically transplanted rats receiving either normal or modified prednisolone at two different concentrations (4mg/kg/12h or 16mg/kg/12h, i.p). Immunosuppressive treatment was either preventive (continuous treatment until the end of the experiment 4 days post surgery; six groups) or therapeutic (started 4 days after surgery and maintained for 3 days until day 7 post surgery; 4 groups, no low dose treatment). Treatment efficiency was evaluated by ^{18}F-FDG positron emission tomography in the preventive experimental setting 4 days post surgery, as well as on day 4 (baseline), day 5 and day 7 post surgery in the therapeutic setting. Moreover, histological analyses were performed and blood glucose levels were measured to assess systemic effects.

Results: High dosage treatment with normal prednisolone significantly reduced renal ^{18}F-FDG accumulation and histological signs of rejection both in the preventive and the

therapeutic setting, low dose treatment had no effect. In comparison, animals treated with modified prednisolone showed significantly reduced signs of renal graft rejection even under low dose treatment in the preventive setting, high dose treatment was at least as effective as conventional treatment in both the preventive and therapeutic setting. Moreover, treatment with modified prednisolone did not result in elevated blood glucose levels, contrary to normal prednisolone.

Conclusions: Immunosuppressive treatment with the modified, kidney specific prednisolone proved to be as least as effective as normal prednisolone and may even outperform the latter. In the case of renal transplantations, organ-specific immunosuppression is possible.

FR-PO1002

In Proximal Tubular Cells, Cyclosporine Triggers Actin Reorganization and MRTF-SRF Inhibition through Changes in Cofilin Oligomerization and Activity Bastien Burat,[2] Pierre Marquet,[2] Marie Essig.[2,1] *[1]CHU Limoges, Limoges, France; [2]INSERM UMR U850, Limoges University, Limoges, France.*

Background: Calcineurin Inhibitors, Cyclosporine A (CsA) and Tacrolimus, are the keystones of immunosuppressive regimens in solid organ transplantation. However, they induce a nephrotoxicity whose mechanisms remain widely elusive. We have previously shown that CsA affect actin organization in proximal tubular cells. Here, we explored the intracellular pathways leading to this actin reorganization and its downstream consequences.

Methods: Porcine proximal tubular LLC PK-1 cells were exposed for 24 hours to CsA (5μM), and S3R (10μM) a specific inhbibitor of cofilin phosphorylation. LLC PK-1 proteome was analyzed with iTRAQ shotgun proteomics by nano-LC-QTOF tandem mass spectrometry. Actin cytoskeleton was analyzed by TRITC-phalloidin labeling of F-actin. Cofilin oligomerization state was investigated by Western blot in non-reducing conditions after formaldehyde cross-linking Na/K-ATPase activity was quantified by colorimetric assay of inorganic phosphate. Serum response factor (SRF) activity was assessed by luciferase gene reporter assay.

Results: CsA induced a decrease in perimembranous branched F-actin meshwork with a significant decrease in Factin fluorescence positive area, (-3.3%, $p < 0.0001$). iTRAQ analysis showed that CsA induced a decrease in F-Actin/G-Actin ratio and a decrease in cofilin/actin ratio resulting from a global actin overexpression. Furthermore, CsA induced a 20% shift from tetramer to dimer's forms of cofilin. These modifications of F-actin/G-actin ratio and cofilin oligomerization were associated with an inhibition of SRF activity (-56% of control activity). CsA induced a 21% inhibition of the Na/K-ATPase activity. Such inhibition has been previously demonstrated to activate cofilin. The cofilin inhibitor S3-R, which has no significant impact on F-Actin/G-Actin ratio or SRF, blocked CsA effects on actin organization and SRF activity.

Conclusions: Our results suggest that CsA deeply affects the actin cytoskeleton of proximal tubular cells through the decrease in the tetrameric, polymerizing form of cofilin. This effect favored the depolymerization activit of cofilin leading to a decrease in branched actin microfilament. This reorganization of actin cytoskeleton leads to G-Actin increase and SRF inhibition, which may trigger tubular atrophy, one of the typical lesions of CsA toxicity.

FR-PO1003

Ginseng Extract Reduces Tacrolimus-Induced Oxidative Stress by Modulating Autophagy in Pancreatic Beta Cell Sun Woo Lim,[2] Yoo-Jin Shin,[2] Kang Luo,[2] Chul Woo Yang.[1,2] *[1]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [2]The Catholic University of Korea, Seoul, Korea., Seoul, Republic of Korea.*

Background: Growing evidence suggests that regulation of autophagy may be an effective approach to protect beta cells against various extra-/intracellular stimuli. We previously demonstrated that long-term treatment of calcineurin inhibitor causes excessive autophagosome burden and impaired autophagy clearance in pancreatic beta cells. This study investigated the effect of Korean red ginseng extract on autophagy modulation focused on oxidative stress.

Methods: The rat insulinoma cell line INS-1 was treated with Tac (40 ug/mL) and KRGE (100 pg/mL) with or without 3-methyladenine (3-MA, 10 mM) or bafilomycine A1 (BA, 2nM) for 6h. Mice were treated with Tac (1.5 mg/kg, subcutaneous) and KRGE (0.4 g/kg, orgal gavage) for 4 weeks. The effect of KRGE on Tac-induced diabetes was evaluated by assessing intraperitoneal glucose tolerance test, plasma insulin level, beta cell area, and 8-hydroxy-2'deoxyguanosin in serum and islet. Autophagy and mitochondria functions were examined by measuring either microtubule-associated protein 1 light chain 3 beta expression, the number of autophagic vacuoles, and lysosome function or oxygen consumption and mitochondrial membrane potential.

Results: In mice with Tac-induced diabetes mellitus, KRGE improved islet dysfunction, and decreased oxidative stress and autophagic vacuoles. In vitro study, KRGE decreased autophagosome formation and improved lysosomal degradation, accompanied by improved beta cell viability and insulin secretion. Addition 3-methyladenine (3-MA), an inhibitor of autophagosome, to KRGE further improved cell viability and insulin secretion, and bafilomycin A (BA), an inhibitor of lysosomal function, reduced those effects of KRGE. At subcellular level, Tac caused mitochondrial dysfunction (impaired mitochondrial oxygen consumption, ATP production, and increased reactive oxygen species production). But, KRGE improved these parameters. The effect of KRGE on the mitochondrial function enhanced by 3-MA but decreased by BA, suggesting causal relationship between KRGE effect and autophagy modulation in Tac-induced mitochondrial dysfunction.

Conclusions: These findings indicate that KRGE modulates autophagy favorably by reducing Tac-induced oxidative stress, and this effect is closely associated with improvement of mitochondrial function.

FR-PO1004

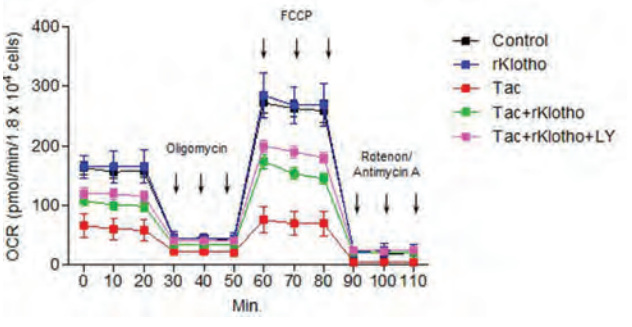
Klotho Enhances FoxO3-Mediated Manganese Superoxide Dismutase Expression by Negative Regulation of PI3K/AKT Pathway in Tacrolimus-Induced Oxidative Stress Sun Woo Lim,[1] Yoo-Jin Shin,[1] Kang Luo,[1] Chul Woo Yang.[2,1] *[1]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea; [2]Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: Mammalian forkhead members of the class O (FoxO) transcription factor are implicated in the regulation of oxidative stress, and FoxO proteins are negatively regulated by the phosphatidylinositol 3-kinase (PI3K)–AKT signaling pathway. We examined the effect of Klotho on PI3K/AKT pathway and manganese superoxide dismutase (MnSOD) in tacrolimus (Tac)-induced oxidative stress.

Methods: Mice were treated with Tac (1.5 mg/kg, subcutaneously) and recombinant Klotho (rKlotho, shedding form, 10 ug/kg once every 2 days, IP injection) for 4 weeks. For in vitro study, HK-2 cells were seeded in culture plates and treated with Tac (60 ug/mL) and rKlotho (1 ug/mL) with or without LY294003 (25 uM) for 12 h. We examined whether the oxidative stress and signaling pathway are involved in the protection by Klotho using immunoblot, immunostaining, RT-PCR, ChIP assay, oxygen consumption, ect.

Results: Klotho-treated mice showed decreased Tac-induced oxidative stress accompanied by functional and histological improvement. Klotho inhibited the PI3K/AKT-mediated phosphorylation of FoxO3a and enhanced FoxO3a binding to the MnSOD promoter. Klotho increased MnSOD mRNA and protein in mitochondria, and overexpressed MnSOD reduced Tac-induced toxicity in HK-2 cells. In mitochondria, Klotho improved Tac-induced mitochondrial dysfunction and decreased mitochondrial ROS, and this effect was enhanced by blocking PI3K activity with LY294002.

Conclusions: Collectively, Klotho protects Tac-induced oxidative stress by negative regulation of PI3K/AKT pathway, and subsequently enhances FoxO3a-mediated MnSOD expression. Through this mechanism, Klotho may protect against Tac-induced oxidative damage and apoptotic cell death. Finally, our results suggested that Klotho protein or Klotho-enhancing compounds may provide treatment options for nephrotoxicity in the future.



Klotho preserves Tac-induced mitochondrial dysfunction in HK-2 cells.

FR-PO1005

Dehydropeptidase-I Inhibitor Reduces Tacrolimus-Induced Kidney Injury by Anti-Oxidative and Anti-Apoptotic Effect Kang Luo,[3,1] Sun Woo Lim,[2,1] Chul Woo Yang.[3,1] *[1]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [2]The Catholic University of Korea, Seoul, Republic of Korea; [3]The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Cilastatin is an inhibitor of dehydropeptidase-I which enhances the antibacterial activity of imipenem. Dehydropeptidase I is associated with not only the metabolism of the enzyme but also the formation of possible renal toxic products. At present, role of cilastatin in chronic Tacrolimus (TAC) nephropathy still unclear.

Methods: Chronic TAC nephropathy was induced by administering TAC (1.5 mg/kg/day, subcutaneously) to rats on a low-salt diet (0.05%) with cilastatin (75 or 150 mg/kg/day, intraperitoneal injection) for 4 weeks. The effects of cilastatin on TAC-induced renal injury were evaluated in terms of renal function, tubulointerstitial inflammation and fibrosis. As a possible mechanism, we evaluated the effect of cilastatin on TAC-induced oxidative stress and apoptosis.

Results: Chronic TAC nephropathy was confirmed with impaired renal function and typical striped interstitial fibrosis. Combined treatment of TAC and cilastatin attenuated TAC-induced kidney dysfunction (serum creatinine, blood urea nitrogen, creatinine clearance, urine microalbumin) and interstitial fibrosis and maker of profibrotic cytokine (α-smooth muscle actin, transforming growth factor β1). Also, cilastation treatment decreased TAC-induced interstitial inflammation, demonstrated by decreased the ED-1-positive cells and pro-inflammatory cytokine (osteopontin) expression. Oxidative stress, a common mechanism of calcinurin inhibitor nephrotoxicity, was decreased with cilastatin treatment, demonstrated by decreased 8-OHdG and increased manganese superoxide dismutase. The increased number of TUNEL-positive cells and pro-apopptic

active caspase-3 and decreased antiapoptotic Bcl-2 expression by TAC was reversed with cilastatin treatment.

Conclusions: Cilastatin has anti-oxidative and anti-apoptotic properties and this may be responsible for protection of TAC-induced nephrotoxicity.

FR-PO1006

Effect of Conversion to Belatacept on Tacrolimus-Induced Diabetes Mellitus in Rats Long Jin. *The First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: Belatacept is a promising immunosuppressant for replacing calcineurin inhibitors (CNIs). However, its effect on CNIs-induced diabetes mellitus (DM) is not adequately studied. Therefore, we tested the effect of conversion to belatacept on tacrolimus-induced DM.

Methods: Two separate experiments performed. The first experiment was conducted to determine diabetogenicity of belatacept. We administered five doses of belatacept via tail vein injection at the weekly basis for four weeks. The second experiment was conversion study. After inducing tacrolimus-induced DM with three weeks treatment with tacrolimus (TAC), TAC was converted to belatacept for three additional weeks. The effect of belatacept on TAC-induced pancreatic islet dysfunction was evaluated. The influence of oxidative stress was evaluated by measuring markers of oxidative stress 8-OHdG and antioxidant enzyme maker of MnSOD in pancreas tissues. The effect of conversion to belatacept on macrophage infiltration and apoptosis were detected by ED-1 and caspase-3. We also measured cell viability AO/PI staining in isolated rat islets. Finally, the direct effect of belatacept on TAC-induced ROS production and cell viability in vitro were investigated.

Results: The first experiment showed that treatment with belatacept showed similar blood glucose level compares with VH group. However, there was no difference between the other groups and time course. From the first study, we found that 1 and 2 mg/kg of belatacept have a clinically relevant therapeutic level. As expected, conversion from TAC to belatacept groups improved TAC-induced pancreatic beta-cell dysfunction compared with the TAC and TAC withdrawal groups. TAC treatment increased the level of 8-OHdG and reduced the level of MnSOD, and conversion could recover this effect. Conversion to belatacept significantly decreased the level of ED-1 and caspase-3 compared with that in the TAC and TAC withdrawal groups. AO/PI staining showed that conversion to belatacept effectively decreased TAC-induced islet cell death. In vitro study revealed that belatacept treatment significantly decreased ROS production and cell viability compared with that reported with TAC alone

Conclusions: Our study indicated that conversion from TAC to belatacept is effective in improving TAC-induced DM, and belatacept has a protective effect against TAC-induced pancreatic islet injury.

FR-PO1007

Insuline Resistance Promoting the Progression of Chronic Renal Allograft Dysfunction via the ERK1/2-GSK3β-NF-κB Signaling Pathway Qin Zhou,[1] Zhihong Zhao,[1] Hequn Zou.[2] *[1]The Third Affiliated Hospital of Southern Medical University, Guangzhou, China; [2]The 3rd Affiliated Hospital of Southern Medical University, Guangzhou, China.*

Background: Several studies had reported that insuline resistance (IR) was an important nonimmunological risk factors for chronic renal allograft dysfunction (CRAD). However, the pathogenesis of IR-mediated CRAD is still unclear. The aim of this study is to investigate the effect of rosiglitazone on ERK1/2-GSK3β-NF-κB signaling pathway in renal transplantation rats with insulin resistance.

Methods: The rats in CRAD group received classical orthotopic F344-Lewis kidney transplantation and then fed with normal diet. The rats in CRAD+IR group administrated with high fat diet for 8 weeks after kidney transplantation. The rats in CRAD+IR+ERK1/2 Inhibitor group and those in CRAD+IR+GSK-3β Inhibitor group were respectively treated with rosiglitazone (ERK1/2 inhibitor, 5mg/kg/d, gavage) and TDZD8 (GSK-3β inhibitor, 1mg/kg/week, tail vein injection) based on above CRAD+IR model. The controls were F344 and Lewis uninephrectomized rats fed with normal diet. Renal tissue was stained with HE and PAS. The expression of ERK1/2-GSK3β-NF-κB signaling proteins and its downstream inflammation factors were evaluated by means of immunohistochemical and western blot assays.

Results: (1) Function and histology: Compared with CRAD group, serum creatinine and 24-hour urinary protein output were significantly increased in CRAD+IR group. Compared with CRAD+IR group, the above indexes were significantly decreased and the infiltration of inflammation cell in transplanted kidney was significantly alleviated in CRAD+IR+ERK1/2 Inhibitor group. (2) Signaling pathway: Compared with CRAD group, the expression of P-ERK1/2, P-GSK3β and P-NF-κB P65 were significantly increased in CRAD+IR group, and the expression of the downstream inflammation proteins MCP-1 and ICAM-1 were increased in CRAD+IR group; Compared with CRAD+IR group, the expression of P-ERK1/2, P-GSK3β, P-NFκB P65, MCP-1 and ICAM-1 were significantly down-regulated in CRAD+IR+ERK1/2 Inhibitor group. The expression of P-NFκB, MCP-1 and ICAM-1 were inhibited by GSK-3β inhibitor.

Conclusions: It is shown that IR promoted CRAD in our rat model and ERK1/2 inhibitor and GSK-3β inhibitor improved the infiltration of inflammation cells in renal allograft tissue at the early stage of CRAD promoted by IR.ERK1/2-GSK3β-NF-κB signaling pathway participant in the pathogenesis of the early stage of CRAD promoted by IR.

Everolimus Has Effect on the Tacrolimus Concentration within the Renal Proximal Tubular Cells in Dose Dependent Manners Haewon Lee,[1] Yang Wook Kim,[1] Bongsoo Park,[1] Sihyung Park,[1] Yoo jin Lee,[1] Seok ju Park,[2] Sang Youb Han.[2] *[1]Haeundae Paik Hospital, inje university, Pusan, Republic of Korea; [2]Inje University, Busan, Republic of Korea.*

Background: It was reported that everolimus in combination with varying levels of Tacrolimus is efficacious and associated with good kidney function. We aimed to investigate the effect of everolimus on the tacrolimus intracelluar concentration in the kidney cells when it is used concomitantly.

Methods: HK-2 Cells(immortalized Human Renal Proximal Tubule Cells) were treated with tacrolimus at the dose of 5 ng/ml, 10 ng/ml and 15 ng/ml. After 30 minutes, we treated with everolimus at the dose of 3 ng/ml, 9 ng/ml and 15 ng/ml, additionally, in the absence or presence of tacrolimus for 1 hour. We measured the intracelluar tacrolimus concentrations using LC/MSMS.

Results: Tacrolimus intracellular accumulation was significantly decreased by everolimus in a concentration dependent manner. At the concomitant treatment with 5 ng/ml of tacrolimus and everolimus (3 ng/ml, 9 ng/ml, 15 ng/ml), the intracellular tacrolimus concentrations was significantly decreased compared with abscence of everolimus. The intracellular tacrololimus was decreased by everolimus showing 0.348± 0.025 ng/ml/1x10^{6}cells, 0.279± 0.034 ng/ml/1x10^{6}cells, 0.232± 0.025 ng/ml/1x10^{6}cells vs 0.643± 0.087 ng/ml/1x10^{6}cells (P=0.01), respectively. At the concomitant treatment with 10 ng/ml of tacrolimus and everolimus (3 ng/ml, 9 ng/ml, 15 ng/ml), the intracellular tacrolimus concentrations was significantly decreased compared with abscence of everolimus, The intracellular tacrololimus was decreased by everolimus showing 0.544± 0.103 ng/ml/1x10^{6}cells, 0.393± 0.042 ng/ml/1x10^{6}cells, 0.376± 0.06 ng/ml/1x10^{6}cells vs 0.71± 0.177 ng/ml/1x10^{6}cells,(P=0.042), respectively. The effect of everolimus on intracelluar tacrolimus concentration decreased as the dose of tacrolimus increased. At the concomitant treatment with 15 ng/ml of tacrolimus and everolimus (3 ng/ml, 9 ng/ml, 15 ng/ml), the intracellular tacrolimus concentrations was significantly decreased compared with abscence of everolimus. The intracellular tacrololimus was decreased by everolimus showing 0.654± 0.043 ng/ml/1x10^{6}cells, 0.635± 0.096 ng/ml/1x10^{6}cells, 0.579± 0.251 ng/ml/1x10^{6}cells, vs 0.822± 0.168 ng/ml/1x10^{6}cells,(P=0.038), respectively.

Conclusions: We suggest that everolimus has effect on the tacrolimus concentration within the kidney proximal tubular cells in dose dependent manners.

FR-PO1009

Non-Invasive Proteomics to Detect Biomarkers for Kidney Allograft Dysfunction Maura A. Watson,[6] Meera Srivastava,[2] Dustin J. Little,[1] Ofer Eidelman,[5] Robert Nee,[6] Alakesh Bera,[3] David K. Oliver,[6] Harvey Pollard,[5] Rahul M. Jindal.[4] *[1]AstraZeneca, Gaithersburg, MD; [2]USU School of Medicine, Bethesda, MD; [3]Uniformed Services University, Bethesda, MD; [4]Uniformed Services University of Health Sciences, SILVER SPRING, MD; [5]Uniformed Services University of the Health Sciences, Bethesda, MD, MD; [6]Walter Reed National Military Medical Center, Vienna, VA.*

Background: Non-invasive biomarkers are needed for monitoring patients with transplant-associated renal injury to predict early acute rejection (AR). Currently, invasive allograft biopsy is required to make a definitive diagnosis of AR. We hypothesized that protein biomarkers released from rejecting allograft tissues can be detected early in the systemic circulation.

Methods: Serum from healthy individuals, transplant patients with either stable allograft function or chronic kidney disease (CKD), transplant patients requiring kidney biopsy, and CKD patients awaiting transplant (25 patients per category) were labeled with the fluorescent dye Cy3, and assayed on 1275 feature phosphoprotein microarray platform from Fullmoon biosystems. We validated these biomarkers associated with disease severity using a quantitative Reverse Capture Protein Microarray (RCPM) platform. Serum samples were spotted individually in serial dilutions and probed with a specific antibody predicted by the antibody microarray platform.

Results: Bioinformatic analysis compared healthy individuals, pre and post-transplant CKD patients and identified proteins that were present in higher serum concentrations in pre-transplant CKD and transplant allograft rejected patients. These included ATM, p38MAPK, HDAC8, SAPK/JNK, GSK3a-b, NFkappa B and RelB which pointed to an affected p53 signaling pathway. Among the tested phosphorylated proteins, phospho-species of SAPK/JNK and RelB were elevated in stable allograft function compared with CKD pre-transplant and graft rejected serum.

Conclusions: These novel serum analytes, together or independently, may constitute a robust and quantitative serum proteomic signature for AR in renal allografts. Detection of kidney allograft AR by affinity proteomics offers a promising non-invasive tool for surveillance of transplant recipients and for guiding treatment of graft rejection. The views expressed are the authors and do not reflect official policy of the Department of Army/Navy/Air Force, Department of Defense, or U.S. Government.

FR-PO1010

A Role for IgE-Mediated Immune Response in the Pathogenesis of Chronic Antibody-Mediated Rejection (CAMR) F. Rascio,[1] Paola Pontrelli,[4] Elisabetta Manno,[1] Giuseppe S. Netti,[1] Barbara Infante,[1] Giulia Cocina,[1] Simona Simone,[3] Giuseppe Castellano,[3] Loreto Gesualdo,[3] Giovanni Stallone,[1] Giuseppe Grandaliano.[2] *[1]University of Foggia, Foggia, Italy; [2]Nefrologia/ Dialisi/Trapianto, Foggia, Italy; [3]University of Bari, Altamura, Italy; [4]University of Bari-Dept. of Emergency and Organ Transplantation, Bari, Italy*.

Background: CAMR is the main cause of graft loss and share with systemic lupus erythematosus (SLE), an autoimmune disease, the antibody-mediated kidney damage, the development of autoantibodies, and the activation of the interferon-alpha (IFN-alpha) pathway. IgE-mediated immune response play a key role in the development of SLE nephritis and is associated with IFN-alpha secretion. The aim of our study was to investigate IgE-mediated immune response in CAMR grafts.

Methods: We enrolled 40 biopsy-proven CAMR patients (pts), 15 transplant pts with normal graft function/histology (CTRL), 15 pts with interstitial fibrosis/tubular atrophy (IFTA) and 6 SLE pts. IgE deposition as well as recruitment of basophil and mast cells, the two main cell types activated by IgE, were studied by confocal microscopy. The IFN-alpha response was assessed measuring serum MxA, an IFN-alpha-induced protein, by ELISA.

Results: We observed a significant increase in tubular and glomerular deposition of IgE in CAMR patients (1876±197 pixels/area) and SLE (1678±178 pixels/area) compared with IFTA (379±87 pixels/area) and CTRL (355±93 pixels/area) (p<.001). Interestingly, the stainings for triptase, a marker of mast cells, and CD203c, a specific marker of basophil activation, revealed a significant infiltration of both cell types IgE in CAMR grafts (triptase+cells/field: CAMR 15±5 vs. LES 3.0±.4 and CTRL 0.2±0.4, p=.02. Cd203c+cells: CAMR 21±5 vs. LES 2.0±.4 and CTRL .2±.4, p=.02). We also observed that the absolute number of circulating basophils was significantly increased in CAMR (48±3/ul) compared to CTRL (20±1/ul) and IFTA (15±.5/ul, p=.02). MxA serum levels were significantly higher in CAMR compared to CTRL (123.3±22.6 vs 42.9±37.9 ng/ml, p=.002) and directly associated with the extent of IgE deposits (r=.347, p=.01).

Conclusions: Our data suggest that IgE deposition and the subsequent recruitment of basophils and mast cells within the graft may play a key pathogenic role in CAMR. The genesis of these events appears to be linked, as in SLE, to the systemic activation of the IFN-alpha pathway.

Development of De Novo Donor-Specific Antibodies, Intra-Graft B Cell Populations, and Allograft Function and Morphology in a Rat Model of Non-Adherence to Therapy after Renal Transplantation Louisa Kühne. *University Hospital Regensburg, Regensburg, Germany*.

Background: Introduction: Non-adherence to immunosuppressive therapy has been associated with *de novo* donor-specific antibodies (dnDSA) and antibody-mediated rejection (ABMR). The aim of this study was to investigate the development of *dnDSA,* intra-graft leukocyte and specifically B cell subpopulations, as well as allograft function and morphology in a model of renal transplant simulating non-adherence.

Methods: Methods: We used a rat model of renal transplantation (Brown Norway -> Lewis) with intermittent cyclosporine A administration (CyA 5mg/KG) on every other day (daily application until d7), to simulate non-adherence. Transplanted rats were sacrificed after 6, 28, and 56 days. *DnDSA* were measured by flow crossmatch and complement-dependent cytotoxicity (CDC) assay. DSA IgG subclasses were also assessed. Flow cytometry was used to assess changes in leukocyte (CD11b/c, CD3, CD45R) and B cell subsets (CD45R, CD38, CD27, IgM) in renal allografts. The intra-graft distribution of leukocyte and B cell subsets was assessed by immunohistochemistry and immunofluorescence. Intra-graft transcription of chemokines and cytokines was analyzed by qPCR. Allograft fibrosis was stained using trichrome method. Functional parameters, including urinary protein excretion and serum creatinine concentration were measured by ELISA.

Results: Results: Simulation of non-adherence to immunosuppressive therapy led to development of *dnDSA*, predominantly of the complement-fixing IgG subclass IgG1 and IgG2b. Flow cytometric analysis of leukocyte populations showed a reduction in the absolute number of intra-graft leukocyte subsets (CD11b/c, CD3, CD45R) and specific B cell subsets (CD38, CD27, IgM) over time. Intra-graft mRNA expression of specific chemokines (lymphotoxin-ß) and IgG were increased over time. Functional and morphological changes indicating chronic allograft injury, such as fibrosis, proteinuria and serum creatinine were detected and increased over time in this model of non-adherence.

Conclusions: Conclusion: Using a rat model of non-adherence to immunosuppressive therapy in renal transplantation, we found an induction of dnDSA. Although intra-graft leukocyte and B cell numbers were reduced over time, a mild increase in functional and morphological indicators of chronic allograft injury was noted after non-adherence.

Podocyte Injury Is a Feature of Transplant Glomerulopathy Sara Moradi,[2] Hui Chen,[1] Jean M. Francis,[3] Joel M. Henderson.[3] *[1]BMC, Boston, MA; [2]Boston University, Worcesterr, MA; [3]Boston University Medical Center, Boston, MA.*

Background: Transplant Glomerulopathy (TG) is a chronic progressive glomerular lesion seen in about 20% of human renal allografts at five years post-transplant. TG is primarily a result of endothelial injury and is analogous to the glomerular lesion of thrombotic microangiopathy. Diagnosis of TG is strongly associated with poor long-term graft survival; however there is no effective treatment to prevent the development or progression of TG. Since proteinuria is a key feature of TG, we hypothesize that podocyte injury is associated with its development and progression.

Methods: We examined diagnostic electron micrographs from 21 kidney allograft biopsies (range 1 month to 15 years post-transplant), and scored these images for ultrastructural features of podocyte and endothelial injury. Podocyte injury in the form of foot process (FP) effacement, and endothelial injury in the form of cell swelling and loss of fenestrations, were scored on a 0 to 3 scale corresponding to percentage of capillary loop surface involved by the lesion throughout the biopsy (0=0-10%, 1=10-25%, 2=25-50%, 3=50%+). We also immunostained formalin-fixed, paraffin-embedded sections with primary antibodies against a panel of podocyte-specific proteins, and molecular markers of podocyte injury. Features of podocyte injury were correlated with severity of TG (Banff "cg" score for the biopsy) and endothelial injury.

Results: We found a significant correlation between podocyte injury severity and both "cg" score and endothelial injury severity. FP effacement score increases with increasing cg score; Kruskal-Wallis test reveals that median vary significantly (P<0.05). FP effacement also correlates with endothelial injury; linear regression of these data reveals a significantly non-zero slope (P<0.0001) and R-squared = 0.5673. Immunohistochemical staining suggests loss of differentiating features in podocytes in association with transplant glomerulopathy and endothelial injury.

Conclusions: These findings support the contention that podocyte injury is a common feature of TG, and its severity (and potentially its pathogenesis) is closely tied to extent and severity of the endothelial injury.

Novel Approaches to Modulate T Cell Responses Based on Insights from Tumor Metabolism: Lactate and Pyruvate Control T Cell Function through NAD Redox Metabolism Ulf H. Beier,[2] Jing Jiao,[2] Zhonglin Wang,[1] William J. Quinn,[1] Joseph A. Baur,[1] Wayne W. Hancock,[2] Matthew H. Levine.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Solid tumors can evade host immunity due to their distinctive metabolic properties; e.g. the tumor microenvironment can be glucose-depleted but rich in lactic acid, thereby weakening anti-tumor immunity, since cytotoxic and effector T cells require glycolysis to function. We questioned if such insights might suggest novel approaches for T cell suppression in transplant recipients.

Methods: We co-stimulated human and murine CD8+ and CD4+ T cells and exposed them to pH-neutral 5-40 mM sodium L-lactate, D-lactate, or pyruvate, using equimolar NaCl as a control, and measuring T cell proliferation and cytokine production (IL-2, IFN-g, IL-17), and bioenergetics profiles by Seahorse. We measured nicotinamide adenine dinucleotide both in oxidized (NAD+) and reduced (NADH) form, and tested the effects of drugs that oxidize NAD (alpha-ketobutyrate, beta-lapachone, pyrroloquinoline quinone), or impair NAD recycling (FK 866) or NAD oxidation/reduction via lactate dehydrogenase (LDH) inhibition (GSK 2837808A). We induced a tumor-like glycolytic metabolism in MHC-mismatched cardiac allografts by perfusing BALB/c hearts with UW solution containing 1 mM phenformin, 1-2 μM oligomycin, 2 μM nicolsamide, or 2.5 μM UK5099 for 1 hour prior to their engraftment in untreated C57BL/6 recipients.

Results: Sodium L- (& D-) lactate reduced NAD+ to NADH in an LDH(D)-dependent manner, impaired T cell proliferation, and increased induced Foxp3+ Treg formation. Sodium pyruvate achieved the opposite, oxidized NADH to NAD+, reduced iTreg formation, and increased effector T cell proliferation. Bioenergetic measurements showed that in activated effector T cells, NAD+ oxidation increased, while NADH reduction impaired glycolysis, showing that T cell function depends on the NAD:NADH redox status, and less on the absolute amount of NAD. Interestingly, transiently inducing a glycolytic metabolism in MHC-mismatched cardiac allografts prolonged allograft survival for several days.

Conclusions: NAD redox metabolism controls T cell function through aerobic glycolysis, and inducing glycolytic metabolism in cardiac allografts can promote allograft survival. These data provide a rationale for testing further approaches to modulate NAD redox metabolism in allograft recipients.

Adenosine Pathway Implication in M2 Macrophage Phenotype Switch in Deceased Renal Donors Montserrat M. Diaz Encarnacion,[2,5] Elena Guillen-gomez,[3] L. Guirado,[1] Jose Ballarin.[4] *[1]Fundació Puigvert, Barcelona, Spain; [2]Fundación Pugvert, Barcelona, Spain; [3]Fundación Puigvert, Barcelona, Spain; [4]None, Barcelona, Spain; [5]Medicine, Autonoma de Barcelona University, Barcelona, Spain.*

Background: A recent publication from our group shows that before kidney transplantation there is an activation and infiltration of immune cells in grafts from deceased donors. Adenosine levels increase during inflammation and hypoxia, principally through the hydrolysis of ATP, which is released after cell damage/death. This adenosine increment could initiate a macrophage phenotype shift from an ATP-driven pro-inflammatory environment to an anti-inflammatory and even pro-fibrotic milieu.

Methods: The aim of this study is to address the implication of purinome membrane elements in inflammation and fibrosis driven by macrophages in renal grafts. Purinergic markers from pre-implantational renal allograft biopsies from living (LD) and deceased donors (DD) were quantified by qPCR and western-blot.

Results: Kidney samples from DD showed activation of both macrophage M1 inflammatory and M2 anti-inflammatory pathways evidenced by an increased expression of M1 and M2 markers. This result point to an early inflammatory response followed by activation of mechanisms for inflammation resolution. We found that expression of CNT2, a high-affinity Na^+-dependent adenosine transporter, is decreased. This is consistent with the need to increase extracellular adenosine concentration by inhibiting its uptake, since the extracellular conversion to adenosine is also limited by the ecto-5'-nucleotidase CD73 inhibition. In addition, CNT2 correlated with the adenosine receptor A2a ($A_{2A}R$), which suggests that extracellular adenosine would activate $A_{2A}R$ to trigger anti-inflammatory processes through cAMP increase. Western-blot results indicate an activation of $A_{2A}R$-PKA-CREB pathway as well as an increase of the M2 macrophage marker CD163, in DD biopsies. Moreover $A_{2A}R$ expression correlates with pro-fibrotic markers such as α-SMA, fibronectin, vimentin and collagen.

Conclusions: Persistent inflammation in DD and M2 macrophage activation by extracellular adenosine even before implantation would contribute to the induction of pro-fibrotic processes in grafts from DD.

FR-PO1015

Role of Ubiquitin Proteasome System during Renal Cold Storage and Transplantation Nirmala Parajuli, Sorena B. Lo, Lee Ann MacMillan-Crow. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: We previously reported that renal cold storage (**CS**) leads to increased mitochondrial injury and renal damage following transplantation (**Tx**). However, CS induced molecular pathways responsible for worsening mitochondrial and renal damage following Tx are poorly understood. Alteration of Ubiquitin Proteasome System (**UPS**) has been reported in numerous diseases. The goal of this study was to evaluate if UPS was altered, and if this contributes to mitochondrial and renal damage after CS plus Tx (CS/Tx).

Methods: Rat kidneys exposed to **CS** (18hr) followed by Tx (**CS/Tx**) were used. Sham, autotransplant (ATx, a Tx without CS), and CS alone kidneys were used as control. The proteasome function in the renal extracts was measured using fluorogenic peptide substrates and spectrofluorometer. Mitochondrial function was assessed via high resolution respirometry.

Results: Proteasome function (chymotrypsin-like) was compromised after CS/Tx, but not in sham, ATx, or CS alone kidneys. A selective reduction of β5 (catalytic) subunit of the proteasome was observed only after CS/Tx. None of the groups showed change in expression of the predicted molecular weight of Rpt6 subunits of the proteasome. However, only CS/Tx kidneys showed an intense Rpt6 reactive bands of high and low molecular weights. Co-immunoprecipitation of renal extracts with Rpt6 antibody showed an association of Rpt6 subunit with heat shock proteins, which was significantly altered after CS/Tx. Similarly, compromised mitochondrial function was evident after CS, which was exacerbated after CS/Tx. Proteasome inhibition of NRK cells with Bortezomib showed reduced activity for mitochondrial complexes I, II and III. Similarly, antimycin A, a mitochondrial complex III inhibitor, treatment of NRK cells showed compromised proteasome function.

Conclusions: These data suggest, for the first time, that renal CS/Tx leads to altered expression/function of the UPS as well as its compromised association with heat shock proteins. Similarly, *in vivo* data suggest that the mitochondrial dysfunction precedes proteasome inactivation during CS/Tx. *In vitro* studies confirmed that a functional interaction exists between renal mitochondria and the UPS. New studies designed to preserve the UPS/mitochondrial function may have promising therapeutic implications for better outcomes after renal transplantation.

Caspase Inhibition during Cold Storage Improves Graft Function and Histology of Transplanted Kidneys Swati Jain,[1] Trevor L. Nydam,[2] Robert J. Plenter,[2] Alkesh Jani.[3] *[1]UC Denver, Aurora, CO; [2]University of Colorado Denver, Aurora, CO; [3]University of Denver Colorado, Aurora, CO.*

Background: Prolonged cold ischemia is a risk factor for delayed graft function (DGF) of kidney transplants, and is associated with caspase-3 mediated apoptotic tubular cell death. We hypothesized that treatment of a donor organ with the caspase inhibitor, QVD-OPh, prior to kidney transplantation would be associated with significantly reduced renal tubular epithelial cell (RTEC) apoptosis, histology and improved renal function post-transplant in a mouse kidney transplant model of DGF.

Methods: For in vitro studies, mouse RTECs were incubated with either DMSO or QVD-OPh during cold storage in saline followed by rewarming in RPMI media. For in vivo studies, donor kidneys from C57BL/6 mice were perfused with either cold saline, DMSO (vehicle), or QVD-OPh, recovered, stored in the same solution at 4°C for 60 minutes, and transplanted into syngeneic C57BL/6 recipients. RTEC apoptosis, histological changes and sCr were quantitated

Results: Tubular cells treated with the caspase inhibitor QVD-OPh had significantly reduced capsase-3 protein expression, caspase-3 activity, and apoptotic cell death vs saline or DMSO (vehicle) in a dose dependent manner. Treatment of donor kidneys with QVD-OPh significantly reduced sCr, and resulted in significantly less tubular cell apoptosis, brush border injury, tubular injury, cast formation, and tubule lumen dilation vs. DMSO and saline treated kidneys (Table 1).

Conclusions: Treatment of RTECs and donor kidneys with Q-VD-OPh significantly reduces apoptosis, histological injury and improves renal function in a mouse model of kidney transplantation. Caspase inhibition may be a useful strategy to prevent DGF and increase the donor pool.

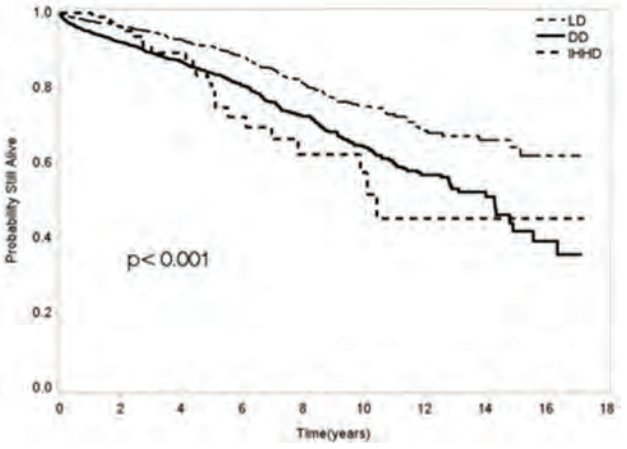
Intensive Home Hemodialysis Survival Is Comparable to Deceased Donor Kidney Transplant Angie G. Nishio-Lucar,[1] Genevieve R. Lyons,[1] Subhasish Bose,[2] Robert S. Lockridge.[1,2] *[1]University of Virginia HS, Charlottesville, VA; [2]Lynchburg Nephrology Physicians, Lynchburg, VA.*

Background: Kidney transplant (KT) is the treatment of choice for end-stage renal disease (ESRD) but, unfortunately, kidney donors are scarce. A prior Canadian study suggested intensive home hemodialysis (IHHD) had similar survival to deceased donor (DD) KT. Herein; we compare the survival of a large cohort of IHHD patients with kidney transplant recipients (KTR) in the same U.S. region.

Methods: We included all consecutive adult patients who received a first KT or started IHHD in the same Virginia region between October 1997 and June 2014. We obtained data on KTR from the Scientific Registry of Transplant Recipients and data on IHHD patients from Lynchburg Nephrology Physicians practice in Lynchburg, Virginia. We excluded recipients of en-bloc kidneys, multi-organ transplants and subsequent KT. Those receiving other home dialysis therapies, in-center hemodialysis (HD) or home HD getting < 20hrs/week or <4 sessions/week were also excluded. Kaplan-Meier method was used to estimate the overall survival (OS) among different modalities: IHHD versus living donor (LD) and DD KT. Adjusted hazard ratios (HR) were estimated using multivariate Cox proportional hazards regression.

Results: We identified 3097 KTR and 116 IHHD patients. Both cohorts had similar proportion of females (40.5% KTR vs 41.4% IHHD), African Americans (48.9% vs 50.9%) and diabetics (36.51% vs 37.1%). Compared to KTR, IHHD patients were more likely to be obese and have history of malignancy. LD KTR had the highest patient survival (Figure 1). At 5 years, the survival probability in IHHD patients was 79% (CI 0.69-0.90) compared to 84% (CI 0.82-0.86) in DD KTR, however the HRs did not significantly differ (HR 1.05, CI 0.68-1.62, p=0.837) after adjusting for ESRD cause, sex, age, and peripheral vascular disease.

Conclusions: In this study, survival of IHHD patients was not statistically different from DD KTR suggesting IHHD could be a reasonable alternative to DD KT. .



FR-PO1018

The Effect of Donor-Recipient Size Mismatch on Graft Survival Is Modified by Kidney Transplant Recipient and Donor Age Fanny Lepeytre,[5] Catherine Delmas-Frenette,[4] Xun Zhang,[3] Ruth Sapir-Pichhadze,[1] Bethany J. Foster,[2] Heloise Cardinal.[5] *[1]McGill University, Montreal, QC, Canada; [2]McGill University Health Center, Montreal, QC, Canada; [3]McGill University Health Centre, Montreal, QC, Canada; [4]None, Westmount, QC, Canada; [5]Centre de Recherche du CHUM, Montreal, QC, Canada.*

Background: Advanced donor age, recipient age and donor-recipient size mismatch are all independent risk factors for poorer kidney graft survival, but how these variables interact is unknown.

Methods: We performed a retrospective cohort study using the Scientific Registry of Transplant Recipient (SRTR). All first deceased donor kidney transplantations performed between Jan 1st 2000 and Jan 1st 2015 in recipients aged ≥18 years were included. We used multivariable Cox proportional hazards models to assess the association between donor-recipient body surface area (BSA) ratio (≤ 0.9 vs. >0.9) and overall graft survival, defined as death with function, return to dialysis or retransplantation. We considered interactions between BSA ratio and each of recipient age (≤54 vs. >54 years; the median age) and donor age (≤60 vs. >60 years), as well as a 3-way interaction term of BSA ratio by recipient age and donor age.

Results: From a total of 118,101 patients, 39,330 (33.3%) experienced graft loss over a median follow-up of 4.8 years. The 3-way donor-recipient BSA ratio by donor age by recipient age interaction was statistically significant (p=0.02). Among recipients ≤54 years, a donor-recipient BSA ratio ≤ 0.9 was associated with a higher risk of graft failure when donors were younger than 60 (hazard ratio (HR): 1.11, 95% confidence interval (CI) 1.07-1.14); when the donor was older than 60, donor-recipient BSA ratio ≤ 0.9 was not associated with graft survival (HR: 0.92, 95% CI 0.81-1.04). In recipients >54 years, donor-recipient BSA ratio ≤ 0.9 was significantly associated with graft failure regardless of donor age (HR: 1.07, 95% CI 1.03-1.10 for donors ≤60 and HR: 1.09, 95% CI 1.02-1.16) for donors >60.

Conclusions: We find donor-recipient size mismatch to have a small but significant impact on graft survival in all but younger recipients of older deceased donors. We hypothesize that in the latter group, the adverse impact of donor age superscedes the effect of donor-recipient size mismatch, and a size mismatch should not be considered as adversely affect graft survival in this patient population.

FR-PO1019

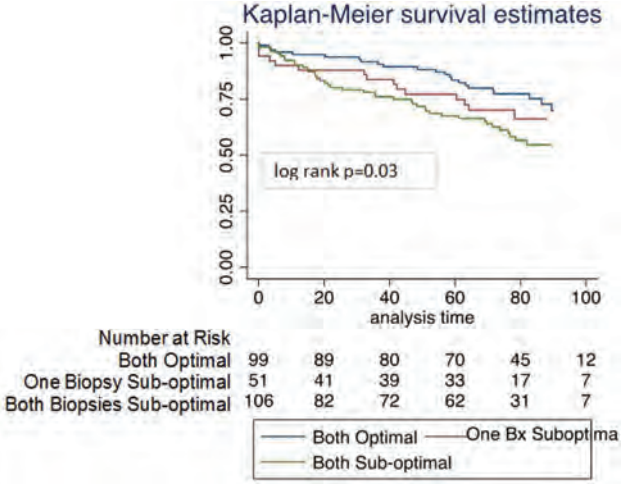
Contralateral Deceased Donor Kidney Procurement Biopsy Predicts Allograft Outcomes Syed A. Husain,[2] Dustin Carpenter,[1] Raphael Rosen,[3] Dominick Santoriello,[2] Mariana C. Chiles,[2] Leigh-Anne Dale,[4] Lloyd E. Ratner,[1] Sumit Mohan.[1] *[1]Columbia University, New York City, NY; [2]Columbia University Medical Center, New York, NY; [3]New York Presbyterian - Columbia, New York, NY; [4]New York Presbyterian Columbia, New York, NY.*

Background: Deceased donor kidney (DDK) procurement biopsies are often used to assess organ quality but have limited ability to predict outcomes, likely due to sampling error. We studied whether combining bilateral kidney biopsy results improves the prediction of allograft survival.

Methods: We identified all DDKs transplanted at our center from 2005-2009 that had procurement biopsies performed. Biopsy results from these kidneys and their contralateral partners (if available) were obtained from donor charts. Histology was classified as optimal if glomerulosclerosis (GS)≤10%, interstitial fibrosis/tubular atrophy (IFTA)≤10%, and vascular disease was none/mild. We compared death-censored graft failure for kidneys based on histologic category.

Results: 256 donors had a procurement biopsy on both kidneys, among whom 80.1% had concordant bilateral histologic categorization (99 both optimal, 106 both suboptimal) (κ=0.60, p<0.001). Agreement was higher for IFTA and vascular disease (both 75.8%) than GS (58.6%). When bilateral kidney biopsy results were combined, death-censored graft failure was highest for suboptimal kidneys with suboptimal partners, lower if only one kidney in the pair had optimal histology, and lowest for optimal kidneys with optimal partners (p=0.03) (Figure1). 43 kidneys (16.8%) had contralateral partners that were discarded. Discarded contralateral kidneys were more likely to have GS>5% (58.1% v 38.0%, p=0.02), as were their transplanted partners (60.5% v 41.3%, p=0.02). IFTA and vascular disease were not associated with discard. Partner discard did not predict transplanted kidney outcomes beyond biopsy results.

Conclusions: Adding contralateral kidney biopsy findings to DDK procurement biopsy appears to improve predictive power. When available, contralateral kidney biopsy findings should be provided to clinicians as part of the organ offer.



FR-PO1020

Outcomes of HLA-Incompatible Living Donor Kidney Transplantation Compared to Deceased Donor Kidney Transplantation or Dialysis and HLA-Compatible Living Donor Kidney Transplantation Tai yeon Koo, Jung-hwa Ryu, Ji-Jing Yan, Kyungok Min, Jaeseok Yang. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: HLA-incompatible(HLAi) living donor(LD) kidney transplantation(KT) is one of efforts to increase opportunity for sensitized end-stage renal disease patients due to organ shortage. Recently there are controversies for outcomes of HLAi KT. US data showed better outcomes of HLAi LDKT compared to HLA-compatible(HLAc) deceased donor(DD) KT or dialysis, whereas UK data demonstrated that waiting for DDKT or HLAc LDKT has good outcomes comparable to HLAi LDKT. Therefore, we tried to compare outcomes of HLAi LDKT with those of DDKT or dialysius, and HLAc LDKT in Korea

Methods: Forty-eight patients underwent HLAi LDKT after desensitization between 2006 and 2017. Indications of desensitization were positive complement-dependent cytotoxicity cross-match, positive flow-cytometric cross-match, high panel-reactive antibody tests, and positive donor-specific antibodies. We compared outcomes among HLAi LDKT patients, wait-listed patients who had continued to undergo dialysis(n=2047), patients who underwent either dialysis or DDKT(dialysis-or-transplantation group; n=2610), DDKT patients(n=563) and HLAc LDKT patients(n=654).

Results: In the HLAi LDKT group, patient survival rates were 97.8% at 1 year, 97.8% at 5 years and 97.8% at 8 years, as compared with rates of 98.4%, 96.4%, and 94.8% respectively in dialysis-group, rates of 98.3%, 97.2%, and 95.2% repectively in dialysis-or-transplantation group, rates of 99.7%, 99.4% and 98.6% respectively in LDKT group. There was no significant difference in patients survival rate among the groups. Although 6-month graft survival rate in HLAi LDKT was worse than that in HLAc LDKT, there was no significant difference in graft survival rates after 6 months between HLAi LDKT and any other group. Patient and graft survival rate of HLAc LDKT were better than dialysis or DDKT. In safety aspects, incidence of either antibody-mediated rejection or infectious complication did not differ among the groups.

Conclusions: In conclusion, outcomes of HLAi LDKT were comparable with those of dialysis or DDKT, dialysis alone, and HLAc LDKT. Therefore, we should consider many factors such as outcomes of dialysis, mean waiting time for HLAc DDKT, donor exchange program and experience of desensitization before decision of HLAi LDKT in sensitized candidates.

FR-PO1021

Predicting Expanded Criteria Donor Transplant Outcomes Ruth Sapir-Pichhadze,[1] Jean Tchervenkov,[2] Carly Rabin,[3] Dana Baran,[4,1] Justin Morein,[1] Paramita Saha chaudhuri.[1] *[1]McGill University, Montreal, QC, Canada; [2]McGill Unversity Health Center, Montreal, AB, Canada; [3]Royal College of Surgeons in Ireland (RCSI), Montreal, QC, Canada; [4]Royal Victoria Hospital, Montreal, QC, Canada.*

Background: Decisions on expanded criteria donor (ECD) organ utilization or discard rely primarily on selected clinical and histological features of ECD grafts. We

sought to identify which of the donor, recipient, and transplant characteristics are most predictive of long-term ECD transplant outcomes.

Methods: We conducted a retrospective cohort study in first time ECD kidney transplant recipients (KTR) transplanted between January 1, 2008 and December 31, 2014 at a Canadian Centre. The value of baseline donor (kidney donor risk index (KDRI), eGFR, and histology on frozen sections of procurement biopsies), recipient (age, sex, and cause of ESRD) and transplant (HLA mismatch, pulsatile perfusion, cold ischemia time, induction therapy, maintenance immunosuppression, and delayed graft function (DGF)) characteristics in predicting all-cause graft failure, defined as return to dialysis, re-transplantation, and death with function, was evaluated in univariate Cox proportional hazards models. Given the small sample size, variables that were statistically significant at level = 0.1 in the univariate analysis were considered for inclusion in multivariable models. In addition to baseline characteristics, a multivariable model including time-varying post-transplant eGFR measured at 3-months intervals was also fit. For the multivariable Cox proportional hazards models, p-value <0.05 was considered statistically significant.

Results: A total of 163 first-time ECD KTR with a median post-transplant follow-up of 3 years were included. Of the baseline donor, recipient and transplant characteristics, recipient age, cause of ESRD, and DGF were statistically significantly associated with all-cause graft loss in univariate analyses (p-value of likelihood ratio test 0.04, 0.07, and 0.01, respectively). In the time-fixed and time-varying multivariable Cox proportional hazards models, only recipient age (hazard ratio (HR) 1.04 [95% confidence interval (CI): 1.00, 1.09]; p-value=0.06) and time-varying eGFR (HR 0.96 [95%CI: 0.94, 0.98]; p-value=0.001), respectively, were independently associated with all-cause graft loss. C-indeces were 0.62 and 0.696 (SE=0.05), respectively.

Conclusions: In our study, recipient age and post-transplant eGFR were most predictive of ECD transplant outcomes. Caution should be exercised when considering organ discard based on ECD donor characteristics alone.

FR-PO1022

Inter-Correlations between Psychosocial Pre Transplant Determinant of Post-Transplant Kidney Allograft Function Sujan P. Shah, Brittany L. Schreiber, Flor Espinoza, Ann Kathleen N. Gamilla-Crudo, Rohan Patankar, Omar A. Aleter, Wayne G. Fischer, Muhammad A. Mujtaba. *University of Texas Medical Branch, Galveston, TX.*

Background: Psychosocial factors are common in patients with advanced and end stage kidney disease and they may be associated with post kidney transplant outcomes. When these patients are referred for transplant evaluation psychosocial and nutrition history is an important component of evaluation however there is lack of data on post-transplant implication of these factors. The aim of this study was to determine the correlations between pretransplant, nonclinical and psychosocial factors to post-transplant clinical outcomes.

Methods: We selected the following pre-transplant factors: gender, food stamp, marital relationship, insurer, education, Karnofsky score, history of depression, exercise, albumin level history of substance abuse, distance from transplant center. The posttransplant clinical outcomes selected were quality of kidney allograft at 6 months expressed as serum creatinine. The study involved retrospective analysis of 136 kidney transplant patients. There were 56 female patients and 75 male patients. We had 72 Hispanics (53%), 33 African Americans (24%), 22 Whites (16%), 9 Asians (7%). Patients age ranged from 25 years to 77 years. We used nominal logistic regression analysis and multinominal logistic regression analysis to identify the significant relationship between one dependent nominal variable and one or more continuous-level independent variables. A p-value of ≤ 0.05 was considered significant.

Results: Factors associated with significantly better serum creatinine at 6 months included: Female gender (p 0.014), active pre listing clinic follow up (0.0001), compliance with dialysis (0.06), and serum albumin >3.5 gm/dl (0.007). Patient primary insurer, family support, mariatal status, exercise, food stamp status, history of depression, history of substance abuse, education level, race, distance from transplant center, and retransplant status was not found to be associated with 6 months serum creatinine.

Conclusions: Pretransplant psychosocial factors are associated with the post transplant kidney allograft function. This also shows the pre transplant psychosocial history is an integral but often ignored part of evaluation and should be stressed upon. More prospective trials are required to confirm our findings.

FR-PO1023

The Reproducibility and Prognostic Capability of Procurement Frozen Section Renal Allograft Biopsies Dustin Carpenter,[2] Syed A. Husain,[3] Raphael Rosen,[4] Dominick Santoriello,[3] Mariana C. Chiles,[3] Lloyd E. Ratner,[2] Sumit Mohan.[1] *[1]Columbia University, New York, NY; [2]Columbia University, New York City, NY; [3]Columbia University Medical Center, New York, NY; [4]New York Presbyterian - Columbia, New York, NY.*

Background: Biopsies taken at the time of deceased donor kidney procurement are frequently used to assess organ quality and are cited as a leading reason for discard. However, the reproducibility and prognostic capability of these biopsies are controversial.

Methods: We compiled a retrospective, single institution, continuous cohort of deceased donor kidney transplants with complete biopsy reads from 2006-2009 (n=301). Histology was classified as optimal if glomerulosclerosis and interstitial fibrosis/tubular atrophy were each ≤10%, and vascular disease was mild or none. Cox proportional hazards and Kaplan-Meier methods were used for time to event analysis.

Results: The reproducibility of procurement biopsies was poor: in the 119 kidneys that were biopsied twice, 44.5% had histologic category (optimal vs. suboptimal) discrepancies comparing the first and second biopsies (κ=0.11, p=0.11). Using the frozen section biopsy nearest the time of procurement, graft survival was worse for kidneys with suboptimal vs.optimal histology (HR 1.91, p=0.004) (figure 1). This discriminatory ability of procurement biopsies to predict graft failure was stronger when they were obtained and read in our local OPO (p=0.04) compared to the donor OPO (p=0.18). Regardless of histologic category, transplantation was associated with a significant survival advantage compared to remaining on dialysis (5-year overall patient survival 87.1% [optimal] vs. 83.4% [suboptimal] vs. 35% [dialysis]).

Conclusions: Frozen section procurement kidney biopsies are poorly reproducible, but may help determine long term allograft function. However, even DDRT kidneys with suboptimal histology will result in a significant survival advantage compared to dialysis suggesting that biopsy findings alone should not be used to discard an organ.

FR-PO1024

The Deceased Donor Implantation Biopsy and Histopathological Characteristics for Predicting Graft Outcomes in Kidney Transplant Recipients Diping Wang,[2] Cindy S. Yip,[2] Christopher Dodoo,[1] Aijaz A. Gundroo,[2] Alok K. Dwivedi,[1] Lin Liu,[2] Shirley S. Chang,[3] Mareena S. Zachariah,[3] John E. Tomaszewski.[2] *[1]Texas Tech University Health Sciences Center El Paso, El Paso, TX; [2]University at Buffalo, Buffalo, NY; [3]Nephrology, Erie County Medical Center, Buffalo, NY.*

Background: The allocation of deceased donor kidneys has become more complex because of the increasing spectrum of donor and recipient co-morbidities. The kidney donor risk index (KDRI) was designed to capture the donor factors known at the time of organ procurement, but donor gender, cigarette use, polysubstance abuse, glomerulonephritides, and interstitial disease are not included in the KDRI and can influence graft outcomes. In this study, we evaluted the prognostic value of pre-implantation histopathological parameters in predicting the graft function after transplantation.

Methods: Deceased donor recipients transplanted between January 2012 and March 2016 were followed up to four years were included in this study. Pre-implantation biopsies were re-evaluated per the Banff 97 classification and chronic allograft damage index (CADI) and graft function was monitored. Glomerular filtration rate (GFR) at the last visit was categorized into a staging variable (Stage) after which multinomial logistic regression was used to assess the association between stage and the cofactors. Ordinary linear regression was also used to assess the association between GFR at last visit and the cofactors. Logistic and linear regressions were used to assess the association between Banff and CADI scores and the cofactors.

Results: Inter-observer correlation between the two pathologists for total Banff score (ICC = 97%) and CADI score (ICC = 92%) were excellent. The presence of glomerulosclerosis (GS, -10.15) and tubular atrophy (TA, -10.39) in CADI score were found to be associated with final GFR. In addition to GS, glomerular mesangial matrix (GM) in CADI was also associated with stages of GFR. Only presence of glomerular mesangial matrix (CM) parameter in Banff score was found to be associated with stage and graft function. In separate multivariable analyses after adjusting for other significant variables, GM present and CM present were associated with chronic kidney disease stage.

Conclusions: A multiparametric approach may be developed by incorporating pre-implantation biopsy information along with important clinical variables to predict outcome.

FR-PO1025

Is There a Role for Implantation Biopsies in the Era of Kidney Donor Profile Index (KDPI)? Luis C. Francalacci, Ling-Xin Chen, Richard V. Perez, Angelo M. De Mattos. *University of California, Davis, Sacramento, CA.*

Background: Implantation biopsies (**IBx**) are commonly performed after deceased donor kidney transplantation (**DD**). However, its role in the management of these grafts and the impact on outcomes are not fully described. We evaluated the role of IBx on short and long term graft outcomes and their relationships with KDPI.

Methods: We analyzed all the DD performed at our center between 2007 and 2013. Grafts not eligible for IBx (en-bloc pediatric) were excluded. Multivariable analysis was used to adjusted for confounding variables.

Results: Out of 885 DD performed, 477 had a IBx and 411 had not. The two groups were not different in terms of gender, age, race (donors and recipients), re-transplant, diabetes, PRA, or HLA mismatches, proportions of ECD, DCD, deaths from CVA, local procurement, pulsatile perfusion, terminal creatinine, and distribution of KDPI. There was a lower proportion of DCD in the IBx group (15 vs 21%, p=.02) and lower mean cold ischemic time - **CIT** (23 vs 25h, p=.006). The IBx group had a significantly better one year graft survival (96 vs 91%, p=.001). By multivariable analysis IBx was associated with 60% (CI 21.9 – 72.1%, p=.002) decreased risk of graft loss within the first year when adjusted by DCD, KDPI, and cold ischemia time. Long term graft survival was worse across strata of KDPI (p=.006). However, there were no difference in graft survival between the IBx and no-IBx groups (p=.16), even within the strata of KDPI: <35% (p=.7), 35 – 85% (p=.1), and >85% (p=.7). The composite chronicity score: (glomerulosclerosis-**GS** plus interstitial fibrosis-**IF**) was different across strata of KDPI (14, 44, and 66%, p<.001). However, there were no differences in graft survival by the percentage of GS (p=.4), IF (p=.4), or GS+IF (p=.08) on IBx. There was a lower incidence of delayed graft function on the IBx group (19 vs 31%, p<.001) that persisted even after adjustment for CIT and DCD. There were differences in e-GFR at 1, 3, and 5 years across strata of KDPI. However, no differences in e-GFR were found between the IBx and no IBx groups at the same time points.

Conclusions: Implantation biopsy is independently associated with better one year graft survival. However, KDPI becomes the most important factor associated with long term graft survival. The specific management modifications based on the results of IBx should be the focus of future investigation.

Histologic Findings on Time-Zero Allograft Biopsies Correlate with Kidney Donor Profile Index (KDPI) and 30-Day Serum Creatinine Kuang-Yu Jen, Ling-Xin Chen, Luis C. Francalacci, Richard V. Perez, Angelo M. De Mattos. *University of California, Davis, Sacramento, CA.*

Background: KDPI is used as a numerical measure of deceased donor kidney quality relative to other recovered kidneys. It uses 10 donor factors but does not consider histologic findings. Correlation of KDPI to histologic findings is lacking. In this study, we examined the correlation between KDPI and chronic changes seen in time zero biopsies. We also assess whether such histologic findings add to the predictive ability of KDPI for 30-day serum creatinine and delayed graft function.

Methods: All deceased donor kidney transplants at our institution from 07/01/2016 to 03/15/2017 that had a time-zero biopsy were included. The biopsies were graded according to Banff 2015 guidelines. Distribution of KDPI was compared by Banff scores for chronicity (ci and ct) as well as chronic vascular disease (ah and cv). Linear regression was used to assess: 1) correlation between Banff scores and donor KDPI and 2) the ability of KDPI and Banff scores (either individually or together) to predict 30-day serum creatinine. Logistic regression was used to assess the ability of KDPI and/or Banff scores to predict delayed graft function.

Results: 134 recipients had a time-zero biopsy performed. There was correlation between the following Banff scores and KDPI: ci, ct, ah and cv (Table 1). ah score of greater or equal to 2 most closely correlated with KDPI. 30-day serum creatinine was predicted by KDPI, as well as ci, ct and ah scores. Using KDPI with ci + ct scores resulted in the best prediction of 30-day serum creatinine, with a correlation coefficient of 0.27. There was no correlation between Banff scores and the occurrence of delayed graft function. A KDPI score of 20-85% predicted delayed graft function at an OR of 8.18 (95% CI 1.80-37.2, p-value 0.007).

Conclusions: Chronic changes seen in time zero allograft biopsies correlate with KDPI and may be useful for predicting early graft outcomes.

Histologic variables, mean 30-day SCr and DGF by KDPI categories

KDPI	N	ci + ct ≥ 2	ah ≥ 2	cv ≥ 2	Mean 30-day SCr (mg/dL)	DGF, n (%)

FR-PO1027

Clinical Outcome of Kidney Transplantation from Deceased Donors with Marginal Kidney Function Seong Sik Kang,[1,2] Hayeon Park,[1] Sang Mok Yeo,[1] Woo Yeong Park,[1,2] Kyubok Jin,[1,2] Sung Bae Park,[1,2] Seungyeup Han.[1,2] *[1]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: Deceased donor kidney transplantation (DDKT) in Korea has been activated recently. However, organ shortage for transplantation is getting worse, and DDKT using acute kidney injury (AKI), expanded criteria donor (ECD), or high kidney donor profile index (KDPI) kidney is increasing. Herein, we evaluated the clinical outcome of KT recipients (KTRs) who received marginal kidneys.

Methods: We retrospectively reviewed DDKT performed at Keimyung university hospital between January 2010 and December 2014. Ninety four DD and their corresponding 95 KTRs were included. We analyzed the clinical outcomes of DDKT according to AKI, ECD, and high KDPI (> 85%).

Results: KTRs belonging to the AKI group were 42 (44.2%), ECD group were 23 (24.2%), and high KDPI group were 16 (16.8%). The mean follow-up period was 42.6 ± 17.4 months (range 2-81). The incidence of delayed graft function (DGF) was significantly higher in the AKI group than in the non-AKI group ($P = 0.011$), but not in the ECD group and the high KDPI group. The estimated glomerular filtration rate (eGFR) of the AKI group was significantly lower at 1 week, 2 weeks and 1 month after KT compared to the non-AKI group. After 3 months of KT, there was no significant difference in eGFR between the AKI group and non-AKI group, the ECD group and standard criteria donor group, and the high KDPI group and low KDPI group. Patient survival rate showed no significant difference, according to AKI, ECD, or high KDPI. Allograft survival rate showed no significant difference in the AKI, ECD, and high KDPI groups compared with the control groups. However, allograft survival rate was significantly lower only in the group with acute rejection (AR) than in the group without AR ($P < 0.001$). In a multivariate analysis, AR was an independent risk factor for graft failure (hazard ratio 85.75, 95% confidence interval, 7.02-1047.77, $P < 0.001$), but AKI, ECD, or high KDPI were not.

Conclusions: AKI of DD kidney showed significant association with increased incidence of DGF. However, KT using AKI, ECD, or high KDPI donor kidney performed similarly to the control group in terms of graft function, graft survival, and patient survival. More detailed criteria for selecting a proper DD will be needed.

FR-PO1028

Impact of the Kidney Allocation System (KAS) in Highly Sensitized Patients Vineeta Kumar, Jayme E. Locke, Robert S. Gaston. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Highly sensitized (HS) patients, defined as a PRA of 99-100% are awarded additional priority points in the new KAS instituted December 2014. We evaluated the impact of these changes at our institution at 1 and 2 year post transplantation

Methods: HS candidates who received a transplant on or after 12/4/2014 were prospectively monitored. Treatment included induction with anti-thymocyte globulin & IV corticosteroids, maintenance with tacrolimus, mycophenolate & prednisone. Designated care providers followed the HS recipients with more intensive frequency, donor specific anti HLA antibody (DSA) & viral monitoring, implantation & 6 month surveillance biopsies. Outcomes of interest were rate of transplantation, patient & allograft survival and function, acute cellular or antibody mediated rejection (AbMR). and were compared in a matched control population in a 1:2 fashion for age, race, and time of transplant.

Results: There were 15 HS patients transplanted between 12/8/14-10/5/15. The rate of transplant has risen from 1.6% in 2012 to 12.6% in 2015.60% of these were from national offers in contrast to 37.5% in the past. All 15 recipients have >1 year follow up time with 100% patient & graft survival. 12 out of 15 have 2 year follow up time with 2 graft losses (for recurrent FSGS) and 1 death for sepsis in this group. Rate of patient and graft survial in the matched cohort was 100% at 1 & 2 years post transplant. Graft function was equivalent in the two groups with serum creatinine (1.4vs.1.6mg/dl, Pvalue 0.7), eGFR (52vs.48ml/min/m2, pvalue 0.9), random urine protein/creatinine ratio (1.1vs.2.3). Rate of denovo DSA formation at 2 years was similar in the two groups at 23vs.26%, p value 0.1. All the high PRA patients in this study were followed by a specialized team with an average of 16 clinic visits per patient vs. 9 in the control population

Conclusions: There has been a shift to increased national offers under the new KAS within the HS candidates at our institution as was intended by the new KAS. All of them have had acceptable early patient and allograft survival and function with intensive and individualized monitoring and follow up. However care of these patients is very resource itensive and needs a dedicated and specialized group of care givers for post transplant care for a successful outcome that benefits a very specific subset of patients.

FR-PO1029

Recipient Age Is Significantly Associated with Immunological and Infective Complications Post Kidney Transplantation Rachel Hung,[3] Sumoyee Basu,[2] Gabrielle Goldet,[1] Raymond Fernando,[5] Sacha A. De Serres,[6] Paul Bass,[2] Mark Harber,[4] Alan D. Salama,[5] Ciara N. Magee.[1] *[1]None, Boston, MA; [2]Royal Free Hospital, London, United Kingdom; [3]Royal Free Hospital, London, London, United Kingdom; [4]UCL centre for Nephrology, London, United Kingdom; [5]University College London, London, United Kingdom; [6]University Health Center (CHU) of Quebec, Laval University, Quebec, QC, Canada*.

Background: In recent years, there has been a marked increase in the number of older patients (> 65) undergoing kidney transplantation. While there is increasing evidence that the ageing immune system is characterised by immunosenescence, many centres do not have age-specific protocols for immunosuppression. In this study, we sought to examine the effect of recipient age on the development of complications of over- and under-immunosuppression post-transplantation.

Methods: We investigated the outcomes of 90 patients aged > 65 who underwent kidney transplantation in our centre between April 2009-March 2016, 42 of whom were aged >70; these patients were compared to 57 controls aged 18 – 64, who were matched for number of HLA mismatches. Recorded variables included % cRF pre-transplant, rejection, development of *de novo* donor-specific anti-HLA antibodies (DSA) and development of CMV viraemia post-transplantation.

Results: Interestingly, there were significant differences in the mean %cRF pre-transplant across the groups:18-34, 17.75%; 35-49, 29.65%; 50-64, 36.29%; 65-69, 17.1%; and >70, 8.4%; p=0.008. The rate of rejection was markedly increased in the control group compared to those aged > 65 years (19.3% vs. 11.1%), although this did not reach statistical significance. Conversely, rates of CMV viraemia were significantly elevated in recipients >65 when compared to recipients <65 (75.6% vs 50.9%, p=0.03). Rates of *de novo* Class I DSA were also significantly higher in the younger age groups (18.8%, 0% & 23.8% in patients aged 18-34, 35-49 & 50-64, compared to 4.2% & 7.1% in recipients aged 65-69 & >70, respectively; p=0.025), while the development of *de novo* Class II DSA followed a similar trend (6.3%, 20% & 14.3% in patients aged 18-34, 35-49 & 50-64, versus 2.1% & 4.8% in recipients aged 65-69 & >70, respectively; p=0.077).

Conclusions: These data indicate that older recipient age is associated with reduced rates of rejection and *de novo* DSA but significantly increased infectious complications post-transplantation. Given the significant morbidity consequent to over-immunosuppression, consideration should be given to the development of age-specific protocols for immunosuppression.

FR-PO1030

Impact of Modifiable and Non-Modifiable Factors on Patient and Kidney Allograft Outcomes: A Twin Kidney Analysis of Left/Right Deceased Donor Kidney Pairs Natalie M. Otto,[1] Thomas Schachtner,[1] Petra Reinke.[2] *[1]Charite Campus Virchow Clinic, Berlin, Germany; [2]Charité, Campus Virchow Klinikum, Berlin, Germany*.

Background: The impact of donor factors on kidney allograft outcomes and infectious complications has been suggested in many previous studies. However, analysis of left or right donor kidney pairs are rarely performed, although individual recipients risk factors may be analyzed in a paired difference test and significantly reduce donor cofounders.

Methods: Here, we studied all transplanted left/right deceased donor kidney pairs at our center between 2003 and 2015. A total of 174 paired kidney transplantations were performed from 87 donors. To account for identical donor characteristics among left/right donor kidney pairs a paired difference testing was performed.

Results: Patient survival, allograft survival and allograft function were not correlated among left/right donor kidney pairs (p>0.05). In a paired analysis recipient age, gender, BMI, preformed diabetes, cold ischemia time, HLA-match did not impact allograft outcomes among left/right kidney pairs (p<0.05). Delayed allograft function was more likely detected in both kidney pairs than one pair only (p<0.05). Male gender was associated with delayed allograft function among kidney pairs (p=0.021). Primary nonfunction, acute cellular rejection, BK viremia, EBV viremia, sepsis, and cancer were more likely detected in one pair only (p<0.05). All 20 cases of BK viremia were detected in one pair only (p<0.001). A higher number of HLA-mismatches was associated with BK viremia among kidney pairs (p=0.006). Re-transplantation in one pair was associated with a higher incidence of acute cellular rejection.

Conclusions: Despite an increased incidence of delayed allograft function in left/right kidney pairs, our results suggest low impact of donor factors on patient and allograft outcomes. In contrast, our data suggest a strong impact of individual recipient characteristics as common infectious complications as CMV or BKV don't appear solely attributable to donor origin, but to impaired immunity of the recipient.

FR-PO1031

Factors Impacting Racial Disparity in Kidney Transplant Wait-Listing Yue-Harn Ng,[1] V. Shane Pankratz,[1] Kellee Bornemann,[2] Emilee J. Croswell,[2] John R. Pleis,[2] Ron Shapiro,[3] Mark L. Unruh,[1] Larissa Myaskovsky.[2] *[1]University of New Mexico, Albuquerque, NM; [2]University of Pittsburgh, Pittsburgh, PA; [3]RECANATI/MILLER TRANSPLANTATION INSTITUTE, New York, NY*.

Background: African Americans (AA) have a higher incidence of end-stage renal disease but lower rates of kidney transplantation (KT) compared to whites (WH). Disparities persist after adjusting for medical factors. We assessed the relationship of non-medical (eg. cultural, psychosocial, knowledge) factors with KT wait-listing (WL) within the context of racial differences.

Methods: We conducted a longitudinal cohort study with 1057 patients who were referred for KT evaluation. We used Kruskal-Wallis and chi-square test to examine race differences in non-medical factors. We assessed differences in time to KT WL with propensity weight adjustments. We then identified variables associated with early(<100d) vs late WL(>100d).

Results: We found significant racial differences in baseline characteristics[Tab1]. Both with and without propensity weight adjustment, AAs were less likely to be wait-listed compared to WH. This disparity was evident in the late wait-listers[Fig1]. KT knowledge, income and having live donors were positively associated with WL. Age, comorbidities, low SES, and being on dialysis were negatively associated with early WL. Among the late wait-listers, trust in physicians, family loyalty, and social support were positively associated but being AA was negatively associated with WL.

Conclusions: Non-medical factors affect racial disparities in KT WL. Developing interventions targeting cultural and psychosocial factors that put patients at greater risk for later WL may promote equal access to KT.

Long-Term Outcomes of Kidney Transplantation Using Non Conventional Donors Luis C. Francalacci, Ling-Xin Chen, Richard V. Perez, Angelo M. De Mattos. *University of California, Davis, Sacramento, CA.*

Background: With the donor-recipient gap widening the pressure to utilize more non-conventional deceased donors (NCD) has increased. However, analysis of long term outcomes of such transplants is lacking. We described our experience with NCD over the past decade.

Methods: We included all deceased donor transplants performed at our center between 2005 and 2013 using donors with cardiac death, dual grafts, extended criteria, and with acute kidney injury: the **NCD** group. We compared their graft survival (Kaplan-Meier and Cox-regression) and renal function (MDRD eGFR) with our standard criteria donor (**SCD**) cohort.

Results: Of all 996 adult deceased donors transplants 459 were NCD and 537 were SCD. The groups were not different in terms of gender, race, dialysis or HCV exposure, type of insurance, and BMI at transplant, The NCD group was older and had more diabetics, PRA was lower and less re-transplants. More often their kidneys came from older donors, were non-local, had a longer cold ischemic time, placed on pulsatile perfusion, and donor death by CVA (p<.001, all comparisons). Death censored graft survival was not different between groups (fig 1). After adjusting for all significant variables only age of recipients (p=.02) and donors with CVA (p=.002) were significant factors for graft failure. Renal function was lower on the NCD group at all time points. However, the eGFR was stable (and above 50 ml/min) within the groups for up to 7 years (table 1).

Conclusions: The use of NCD kidneys resulted in similar long term outcomes in terms of graft survival and function, as compared to SCD. The nephrology community and their patients should be aware of the benefits of accepting these grafts.

FR-PO1033

Factors Affecting Kidney Transplant Outcome in Very Old Recipients of Grafts from Very Old Donors Hernando Trujillo Cuellar,[1] Amado Andres,[1] Garcia A. Santiago,[1] Teresa Cavero escribano,[1] Candela Moliz,[1] Beatriz Redondo navarro,[2] Teresa Bada bosch,[2] Manuel Praga,[1] Esther Gonzalez monte.[1] *[1]Hospital 12 de Octubre, Madrid, Spain; [2]Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Kidney transplantation is the best option for elderly patients with end stage renal disease. The major limitation in this group of patients is shortage of donors since kidneys from young donors are assigned to younger recipients. Spain had 43,4 donors pmp in 2016, 30% of them were aged over 70 years. Kidneys from these donors can be assigned to older patients without detriment to young recipients.

Methods: We performed a retrospective analysis of pretransplant clinical factors associated with graft and recipient survival in elderly patients (≥70 years) that received a kidney transplant from a very old donor (≥70 years) at our institution from October 2004 to December 2013 (and followed through April 25, 2017) (n = 155).

Results: Median age of donors and recipients was 77 (74-79) and 75 (73-78) years, respectively. The 3-year and 5-year patient survival was 73.1% and 67.1%. Mortality in the first year was 15.9%. Death censored graft survival was 83.4% at year 3 and 80.8% at year 5. History of cerebrovascular disease in the recipient was the only factor associated with patient survival (HR 5.12, p=0.027), while history of diabetes mellitus in the recipient was the only factor associated with the risk of graft loss (HR 4.40, p=0.0001).

Conclusions: Kidney transplantation from very old donors in patients over 70 years offers a survival advantage over staying on dialysis. History of cerebrovascular disease in the recipient was associated with an increased risk of recipient mortality, while history of diabetes in the recipient was associated with increased risk of graft loss. Further studies are needed to identify pretransplant clinical factors associated with increased risk of graft failure and recipient mortality in this population in order to improve allocation of these old allografts in the elderly patients.

Referral Rates for Renal Transplant in Dialysis Clinic, Inc. Antonia Harford,[1] S. Paine,[2] R. Schrader,[2] Ambreen Gul,[2] Philip Zager.[1,2] *[1]UNM, Albuquerque, NM; [2]DCI, Albuquerque, NM.*

Background: Kidney transplantation (TXP) is the treatment of choice for medically appropriate End-Stage Renal Disease (ESRD) patients. Dialysis facilities play pivotal roles in (1) referring ESRD patients for the initial TXP evaluation; (2) assisting in the evaluation process; and (3) listing. Renal transplantation rates reflect significant racial disparity. Among ESRD patients incident in the US in 2011, overall the percent waitlisted or transplanted (WL/TXP) within 3 years was 13.7% but varied greatly by race, highest among Asians (32.7%) & lowest among Native Americans/Alaskan Native (11.1%). Dialysis Clinic, Inc. (DCI), a large not-for-profit provider, founded by a transplant nephrologist, is developing an innovative education program to enhance referral, WL/TXP & reduce health disparities.

Methods: The present study was conducted to obtain baseline data that will facilitate future annual assessments of the impact of this program. We studied 2,677 dialysis patients under age 70 who began dialysis in 2015, in 230 facilities operated by DCI. We used DCI's MIS to calculate referral, WL/TXP, & refusal rates, stratified by race, sex & diabetes status within the first year of dialysis.

Results: Overall, the referral rate was 62.6; 19.0% were WL/TXP, 43.6% were referred but not yet WL/TXP, 18.4% refused referral, & 28.3% were not referred. The rates, expressed per 100 patient years (95% CI), for referrals, not referred, WL/TXP & refusals, stratified by race, diabetes status, & sex are shown. There were no significant differences in referral or refusal rates across racial groups. Referral & refusal rates, respectively, did not differ significantly by race, sex or diabetes status. However, the point estimates for WL/TXP were lower in Blacks & Native Americans vs. Whites & in diabetics vs. non-diabetics.

Conclusions: Excellence in patient & staff education is essential to maximize transplant referral, WL/TXP, and minimize TXP related disparities. To accomplish these objectives innovative educational programs need to be developed & implemented for both dialysis facility staff & patients across the full-range of providers.

Rates, expressed as per 100 patient years (95% CI), for patients incident in 2015

	Total Referred	WL/TXP	Not Referred	Refused
Black	61.7 (56.3 – 67.0)	16.2 (13.4 – 18.9)	29.5 (25.8 – 33.2)	16.3 (13.5 – 19.0)
Native American	60.1 (39.3 – 80.9)	7.5 (0.2 – 14.9)	28.2 (13.9 – 42.4)	22.5 (9.8 – 35.3)

Discrepancy in the Documented Causes of Death among Kidney Transplant Recipients between USRDS and UNOS Databases Jingbo Niu,[1] Sankar D. Navaneethan,[1] Sreedhar A. Mandayam,[2] Jenny S. Pan,[1] Kevin F. Erickson,[1] Wolfgang C. Winkelmayer,[1] Venkat Ramanathan.[1] *[1]Baylor College of Medicine, Houston, TX; [2]None, Bellaire, TX.*

Background: Accurate reporting of cause of death is critical towards identifying specific interventions to improve survival. For U.S. kidney transplant recipients (KTR) cause of death is reported in the United Network for Organ Sharing (UNOS) and United States Renal Data System (USRDS) registries. Herein, we compared the causes of death reported in these two national databases.

Methods: We identified all adult first-time KTRs (1996-2012) with functioning graft when died and separately ascertained their reported causes of death from the USRDS and UNOS databases. Deaths were classified into: a) cardiovascular, b) infectious, c) malignancy, d) others, and e) unknown.

Results: Of 196,748 KTRs, for whom USRDS reported causes of death for 40,742 and UNOS reported causes of death for 40,424 patients, we included 30,721 patients with cause of death information available in both databases. As shown in Table 1, cause of death was coded as unknown for 28% in UNOS and for 57% in USRDS among KTRs. Among 12424 (40%) KRTs with exact cause of death documented in both databases, the agreement between the two databases on the cause of death was 76%.

Conclusions: In both national registries, the exact cause of death is unknown for a sizable proportion of patients who die with a functioning graft. There is considerable discrepancy between the two national registries for causes of death that are reported. Documenting the correct diagnosis is pivotal to design future clinical studies to extend survival of KTR.

Table 1. Cause of death among kidney transplant recipients from two national databases

Cause of death (USRDS data)	Cause of death (UNOS data)					
N (%)	Cardiovascular	Infectious	Malignant	Others	Unknown	Total
Cardiovascular	3526 (11.5)	98 (0.3)	25 (0.1)	841 (2.7)	395 (1.3)	4885 (15.9)
Infectious	110 (0.4)	1564 (5.1)	17 (0.1)	938 (3.0)	163 (0.5)	2792 (9.1)
Malignant	22 (0.1)	25 (0.1)	1658 (5.4)	156 (0.5)	88 (0.3)	1949 (6.3)
Others	414 (1.3)	202 (0.7)	191 (0.6)	2635 (8.6)	272 (0.9)	3714 (12.1)

Impact of Donor Ethnicity on Long-Term Kidney Transplant Outcomes Bhavna Chopra, Kalathil K. Sureshkumar. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: African American (AA) ethnicity increases the risk for developing chronic kidney disease (CKD). There is limited data on graft outcomes based on donor ethnicity. Donor ethicity is a variable in the kidney donor profile index (KDPI) designed to aid in organ allocation and in predicting long-term transplant outcomes. We aimed to evaluate long-term kidney transplant outcomes based on donor ethnicity under different KDPI groups.

Methods: Using the OPTN/UNOS database, adult deceased donor kidney (DDK) transplant recipients from 2000 to 2015 who received induction therapy and were discharged on calcineurin inhibitor/ mycophenolate mofetil-based maintenance were identified. Patients were further divided into 4 KDPI categories (0-20%,21-50%,51-85% and >85%). Long term graft and patient outcomes were compared for recipients of AA vs. non-AA donor kidneys under each KDPI group in a multivariate Cox model.

Results: There were 59,648 participants in the study cohort with a median follow up of 48 months. Adjusted graft and patient outcomes among recipients of AA vs.non-AA donor kidneys by KDPI groups are shown in Table 1 and Figure 1. Overall and death-censored graft failure risks were higher for recipeints of AA donor kidneys among higher KDPI (51-85% and >85%) groups but similar among lower KDPI (0-20 and 21-50%) groups. Patient survivals were similar.

Conclusions: Our study showed inferior graft outcomes among recipients of AA donor kidneys in higher KDPI groups despite ethnicity being a variable in deriving KDPI. One could speculate that higher prevalence of risk factors for CKD progression such as APOL1 and sickle cell trait gene mutations among other factors in AA population as contributing to inferior graft outcomes. Prospective studies are needed to further elucidate these findings.

Table 1	KDPI 0-20% AA donor; n=560 Non-AA donor; n=14690		KDPI 21-50% AA donor; n=2807 Non-AA donor; n=16548		KDPI 51-85% AA donor; n=2774 Non-AA donor; n=16638		KDPI >85% AA donor; n=1670 Non-AA donor; n=3961

Living Kidney Donor Evaluation Time and Pre-emptive Kidney Transplantation Steven Habbous,[1] Amit X. Garg.[2] *[1]Western University, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada.*

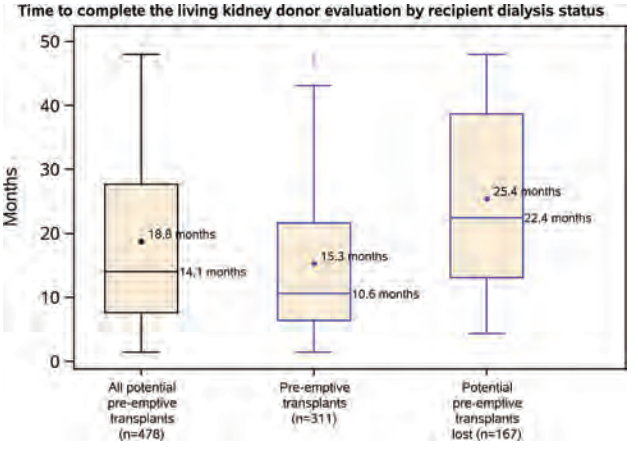
Background: A pre-emptive kidney transplant avoids the risks of initiating dialysis and may result in better outcomes than other treatment options available to patients with kidney failure.

Methods: Using healthcare databases in Ontario, Canada, we retrospectively studied 478 living donor kidney transplants from 2004-2014 where the recipients were not receiving dialysis when their donors' evaluation was underway (for at least three months). We assessed how often dialysis was initiated before transplantation, and explored factors associated with a higher likelihood of dialysis initiation prior to transplant. Results are presented as median (25th, 75th percentile).

Results: A total of 167/478 (35%) of patients with kidney failure initiated dialysis 9.7 (5.4, 18.7) months after their donor candidate began their evaluation, and received dialysis for 8.8 (3.6, 16.9) months before transplantation. The total cost of initiating and receiving dialysis was CAD $8.1 million and 44/167 (26%) patients initiated their dialysis urgently in hospital. The median total donor evaluation time (time from evaluation start to donation) was 10.6 (6.4, 21.6) months for pre-emptive transplants and 22.4 (13.1, 38.7) months for donors whose recipients started dialysis prior to transplant. Characteristics associated with a higher likelihood of the recipient initiating dialysis prior to transplantation included donor female sex, non-white donors, lower donor and recipient neighbourhood income quintile, and a longer time until the transplant program received the recipient referral. Results varied across transplant centres.

Conclusions: One-third of living donor kidney transplant recipients start dialysis prior to transplantation with significant costs to the healthcare system.

Funding: Government Support - Non-U.S.



Distribution of living donor evaluation times by recipient dialysis status when the living donor started the evaluation. Recipients who started dialysis before transplant were potential pre-emptive transplants lost.

Limitation of Terminal Serum Creatinine as a KDPI Variable in Predicting Long-term Kidney Transplant Outcomes Bhavna Chopra, Richard J. Marcus, Kalathil K. Sureshkumar. *Allegheny General Hospital, Pittsburgh, PA.*

Background: Terminal serum creatinine (Cr) is a varible in deriving kidney donor profile index (KDPI) which is used for deceased donor kidney (DDK) allocation and predicting transplant outcomes. Terminal Cr is a dynamic variable and can increase from reversible causes. We hypothesize that transplantation of DDKs with higher terminal

Cr within a KDPI group results in better long-term outcomes since these kidneys likely undergo procurement biopsy and transplant centers generally accept these kidneys only if the biopsy shows predominantly acute tubular injury with minimal chronicity.

Methods: Using the UNOS database, we identified adult DDK transplant recipients from 2000 to 2015 who received induction and were discharged on calcineurin inhibitor and mycophenolate mofetil maintenance. Patients were divided into 4 KDPI categories (0-20%, 21-50%, 51-85% and >85%). Using a Cox model, adjusted long-term graft and patient outcomes were compared between recipients of kidneys with terminal Cr >2.0 vs. ≤2.0 mg/dL under each KDPI category.

Results: Study comprised of 59,645 patients with a median follow up of 48 months. Adjusted graft and patient outcome comparisons based on terminal Cr for different KDPI groups are shown in the table. Adjusted overall graft failure and patient death risks were lower in patients who received DDKs with termial Cr >2 vs. ≤ 2 mg/dL in KDPI 21-50% and 51-85% groups but not in best quality (KDPI 0-20%) and marginal kidney (KDPI >85%) recipients. There were no differences in death-censored graft failure risks. Lower overall graft failure and similar death-censored graft failure in recipients of DDK with terminal Cr >2.0 mg/dL indicated reduced death with functioning graft.

Conclusions: The finding of reduced risk for death with functioning graft in patients who recieved DDK with termial Cr >2 mg/dL in the mid KDPI ranges likely reflects the selective use of these kidneys when procurment biopsy findings are favorable resulting in better long-term allograft function. Our study highlights limitations of using elevated terminal Cr in derivng KDPI.

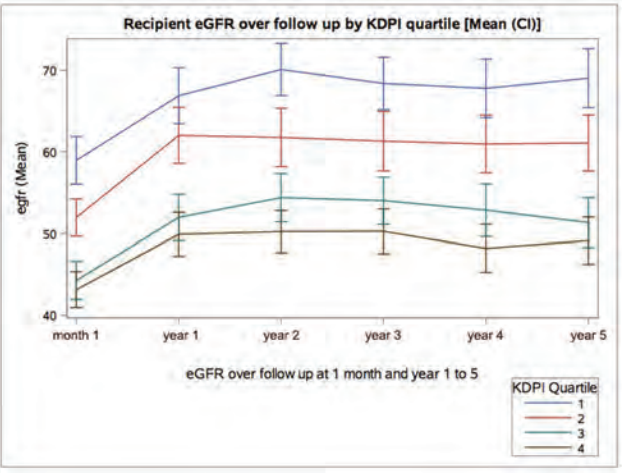
KDPI and Allograft eGFR in Deceased Donor Kidney Transplant Recipients over Follow Up: 1995-2013 Donal J. Sexton,[2,1] Patrick O'kelly,[1] Claire Kennedy,[1] Declan G. de Freitas,[1] Conall M. O'Seaghdha,[1] Peter J. Conlon.[1] *[1]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [2]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland.*

Background: The KDPI has been validated for prediction of deceased donor graft outcomes and popularized in organ allocation in the United States. Whether KDPI predicts eGFR over long-term follow up has not been extensively characterised.

Methods: We performed a retrospective analysis of eGFR (CKD EPI equation) and graft outcomes over follow up in the National Kidney Transplant Service of Ireland database for the years 2006–2013. Associations of the composite KDPI score with eGFR at various time points over follow up were modeled using linear regression, linear mixed effects models and time to event strategies respectively.

Results: N=877 patients had complete data regarding KDPI calculation, N=148 allografts failed. Median (IQR) KDPI score was 52 (49). *At year 1* eGFR ml/min/1.73m^2 were*:* 69.2 (57.6-82.5) (N=172) quartile 1 of KDPI, 59.4 (50.2-74.5) (N=171) in quartile 2 KDPI, 51.9 (42.2-62.2) (N=176) in quartile 3 KDPI, 48.3 (38.5-58.5) (N=162) in quartile 4 KDPI, P<0.001. *At year 5* eGFR in these quartiles were 74.5 (60.5-88.2) (N=110), 64.6 (51.7-83.2) (N=104), 48.8 (34.4-61.6) (N=85), and 43.6 (37.5-58.1) (N=69), P<0.001. On repeated measures analysis with linear mixed effects models with a random participant specific intercept and a random time effect, KDPI (fixed effect covariate) associated with eGFR over follow up (see Fig 1): estimate (se) -0.25 (0.02) P<0.001 for KDPI. The variability in eGFR over 5 years alligned with KDPI score was 21% after adjusting for recipient age (time-varying covariate).

Conclusions: KDPI score predicted eGFR at multiple time points over long term follow up in this study. However, taking the KDPI as a composite of non-modifiable donor factors, a considerable portion of eGFR variability is likely attributable non-donor factors.



A plot of mean eGFR by quartile of KDPI score in deceased donor transplants in Ireland over 5 years follow up.

SCD ≠ KDPI <0.85 Shan Shan Chen, V. Shane Pankratz, Rawan T. Al-Odat, Mark L. Unruh, Yue-Harn Ng. *University of New Mexico, Albuquerque, NM.*

Background: The new kidney allocation system (KAS) assigns a kidney with Kidney Donor Profile Index (KDPI) > 0.85 [K>85] as high risk for allograft failure. Differences exist between the previous and current KAS: previous study showed that 8.3% of Expanded Criteria Donor (ECD) kidneys have a KDPI of < 0.85 (K<85). Outcomes following transplant of "discordant kidneys" (DK) is unclear. In this study, we compared the outcomes of DKs vs "concordant kidneys" (CK) using data from the Scientific Registry of Transplant Recipients.

Methods: We retrospectively calculated the KDPI of all kidneys transplanted from 2003 to 2016 and divided them into standard CK (Standard Criteria Donor [SCD] + K<85), expanded CK (ECD+K>85), standard DK (SCD+K>85) or expanded DK (ECD + K<85). We compared the characteristics of recipients who received different kidneys and assessed the rates of allograft failure for these kidneys.

Results: From 2003 to 2016, 148,887 kidney transplants were performed in the US with 16,222 (10.9%) DK transplanted. Significant differences were noted among the recipients of different donor kidney types [Table1]. Recipients of K>85 kidneys had poorer allograft survival compared to recipient of K<85 kidneys. Standard DK recipients had higher risk of allograft loss compared to expanded CK recipients. Recipients of expanded DK had higher risk of allograft failure compared to standard CK recipients [Fig1].

Conclusions: The new KAS is superior to the old KAS at predicting allograft failure. However, recipient of expanded DKs need to be counseled about the higher risk of graft loss compared to standard CKs.

Kidney Donor Profile Index (KDPI) Predicts Outcome of Deceased Donor Kidney Transplant in a Brazilian Center Carlos rafael A. Felipe,[3] Andre S. Alvarenga,[3] Silvana Maria C. Miranda,[1] Ana elisa S. Jorge,[3] Pedro Augusto M. Souza,[2] Izabela L. Piana.[4] *[1]Hospital Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [2]None, Belo Horizonte, Brazil; [3]Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [4]Faculdade de Minas Faminas BH, Belo Horizonte, Brazil.*

Background: Kidney Donor Profile Index (KDPI) is a well-established index to predict the outcome of deceased donor renal transplant (DDRT), but it has not been established for brazillian population.

Methods: We retrospectively calculated the KDPI and analyzed the outcomes of 45 consecutives DDRT from November/2014 to March/2016: mean cold ischemia time (CIT) was 13.9 hours; the incidence of delayed graft function (DGF). The median of KDPI was 53%.

Results: Patients who died had higher KDPI (median 82.0% vs 50.5%; p 0.018), as well as those with allograft failure (median 77.0% vs 50.5%; p 0.021). The area under the KDPI ROC curve for the composite outcome of death or graft loss was 0.80 (Figure1), similar to donor serum creatinine. One year graft survival was 40% for kidneys with KDPI ≥ 70% versus 84.5% for kidneys with KDPI < 70% (relative risk = 4.81; p 0.003). There was no association between KPDI > 70% and cytomegalovirus (CMV) infection. Donor age, final donor creatinine and expanded criteria donor were also associated with death and allograft failure (Table 1).

Conclusions: KDPI accurately predicted graft survival after DDRT and may be helpful in selecting and allocating a deceased kidney in Brazilian population.

Table 1: Study population data and outcomes

FR-PO1042

Can Kidneys from Deceased Donors with AKI and Circulatory Death Be Transplanted? Swati Rao, Iris J. Lee, Avrum Gillespie, Serban Constantinescu. *Temple University School of Medicine, Philadelphia, PA.*

Background: Kidneys from deceased donors with acute kidney injury (AKI) are often not transplanted despite similar 1 year outcomes as donors without AKI. Our center utilizes a high percentage of AKI donors (15%), including donors with severe AKI requiring renal replacement therapy. We compared the 3 year outcomes of AKI donors after brain death (DBD) and circulatory death (DCD), with non-AKI donors.

Methods: We conducted a retrospective chart review of deceased donor kidney transplant (DDKT) recipients from 1/2011 to 6/2016. AKI was defined as terminal serum creatinine (SCr) of ≥ 1.5mg/dl.

Results: 138 eligible DDKT recipients were divided into 4 groups based on donor characteristics: Group 1 [DBD non-AKI, n=73(53%)], Group 2 [DCD non-AKI, n=44 (32%)], Group 3 [DBD-AKI, n=14(10%)], and Group 4 [DCD-AKI, n=7(5%)]. The terminal SCr was significantly higher in DBD-AKI (2.8mg/dl) and DCD-AKI (2.1mg/dl) compared to DBD non-AKI (0.9mg/dl) and DCD non-AKI (0.8mg/dl) (p <0.01). Recipients were 60% male, 65% Caucasian, and mean age of 57±12yrs, with no significant differences among groups. Donors in DCD-AKI group were younger than other groups (24yr vs 35-40yr p=0.02), but all had similar KDPI (43%, p=0.6). Although delayed graft function (DGF) was not different between the groups, the duration of DGF was longer in the DCD non-AKI group than other groups (16d vs 7.5-9d, p=0.04). Patient survival at 1yr, 2yr, and 3yr was 97%, 94% and 97% in group 1, 98%, 93% and 84% in group 2 respectively, and 100% for all years for group 3 and group 4 (p= 0.76, 0.91, and 0.62). Death censored allograft survival at 1yr, 2yr and 3yr was similar between the groups, 98%, 96% and 93% in group 1, 98%, 88%, and 87% in group 2 respectively, and 100% for all years in group 3 and group 4 (p=0.53, 0.70, and 0.93). The SCr was higher and eGFR was lower at 1 month post-KT in the DCD non-AKI group compared to other groups (p <0.01), but both became similar to other groups at 1 yr and remained comparable at 3yr post-transplant. At 3yr, 92% of DBD non-AKI, 86% of DCD non-AKI and 100% of DBD-AKI and DCD-AKI donors had eGFR of more than 30ml/min (p=0.9).

Conclusions: Judicious use of AKI donors had excellent 1yr and 3yr patient and allograft outcomes with no difference between DCD and DBD donors. Selected AKI donors, especially young donors, can be safely utilized to expand the donor pool.

FR-PO1043

Effect of Spontaneous Donor Hypothermia on Graft Outcome in Organ Transplantation Bernhard K. Krämer,[1] Urs Benck,[2] Peter Schnuelle.[2,3] *[1]Vth Department of Medicine, University Hospital Mannheim, Mannheim, Germany; [2]University Medicine Mannheim, Mannheim, Germany; [3]Nierenzentrum, Weinheim, Germany. Group/Team: Randomized Dopamine Trial Study Group.*

Background: A previous controlled donor intervention trial found that therapeutic hypothermia reduced delayed graft function (DGF) after kidney transplantation.

Methods: This retrospective cohort study nested in the randomized dopamine trial (ClinicalTrials.gov identifier: NCT000115115) investigates the effects of spontaneous donor hypothermia on initial kidney graft function, and evaluates graft survival including heart and liver transplants. All 264 donors who met the eligibility criteria for enrollment in the randomized dopamine trial were grouped by occurrence of spontaneous hypothermia. Hypothermia was defined by a core body temperature of less than 36.0°C before organ procurement. Accordingly, we assigned 54 donors to the hypothermia group and the remaining 210 donors served as controls.

Results: Hypothermia was associated with less DGF after kidney transplantation (OR 0.56, 95%CI 0.34 – 0.91). The benefit was greater when need for more than a single post-transplant dialysis session was analyzed (OR 0.48, 95%CI 0.28 – 0.82). Donor dopamine ameliorated dialysis requirement independently from hypothermia in a time-relationship with exposure (OR 0.93; 95%CI 0.87 – 0.98, per hour). Hypothermia did not alter kidney graft survival (HR 0.83, 95%CI 0.54 – 1.27), while dopamine treatment was associated with improved long-term outcome (HR 0.95, 95%CI 0.91 – 0.99 per hour). Stratified

analyses of non-renal organs in tertiles of the donor's core body temperature disclosed negative effects on heart allograft survival (HR 1.89, 95%CI 1.09 – 3.27).

Conclusions: Spontaneous donor hypothermia is associated with less DGF but does not appear to affect long-term outcome of the kidney graft. Our data raise safety concerns against therapeutic hypothermia in multi-organ donors when a thoracic transplantation is considered.

FR-PO1044

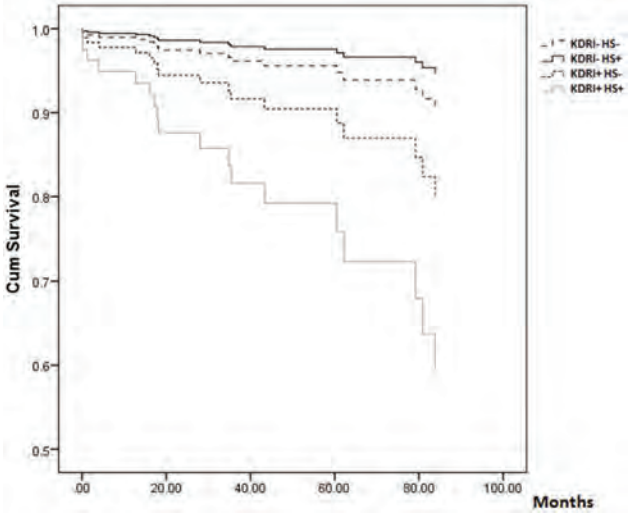
The Combination of KDRI and the Histological Score Improves the Risk Stratification of Marginal Organs in Kidney Transplantation Marco Fiorentino,[1] Francesco Pesce,[1] Giuseppe Castellano,[1] Simona Simone,[1] Pasquale Gallo,[1] Giuseppe Grandaliano,[2] Michele Battaglia,[3] Loreto Gesualdo.[1] *[1]Department of Emergency and Organ Transplantation, Nephrology, Dialysis and Transplantation Unit, University of Bari, Bari, Italy; [2]Nephrology, Dialysis and Transplantation Unit, Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy; [3]Department of Emergency and Organ Transplantation, Urology, Andrology and Kidney Transplantation Unit, University of Bari, Bari, Italy*.

Background: The organ shortage has led to increase the procurement of kidneys from marginal donors, but the risk of graft failure is still object of debate. The aim of the study is to assess whether using both clinical and histological scores can better assess the risk for worse outcome for marginal organs.

Methods: We analyzed 210 kidney transplant recipients from donors aged >50 years. We retrospectively calculated the Kidney Donor Risk Index (KDRI) for each donor and we divided the population according to the KDRI (-, if KDRI ≤ median; +, if KDRI > median) and the histological score (HS, -, if HS ≤ 3; +, if HS > 3) in 4 groups: KDRI-HS- (low KDRI and HS), KDRI-HS+ (low KDRI and high HS), KDRI+HS-(high KDRI and low HS) and KDRI+HS+ (high KDRI and HS). We compared graft function between groups at 2 years and Cox regression analysis was performed to assess the risk for end stage renal disease (ESRD) between groups.

Results: Overall, median KDRI was 1.44 (1.25-1.65), while mean total HS was 3.04±1.62. Median follow-up was 51.9 (26.4 – 99.4) months. Graft function at 2 years was significantly worse in groups with high KDRI (KDRI+HS- and KDRI+HS+) compared to those with low KDRI (p<0.001), while no differences were found according to the HS. By contrast, the best ROC curve in predicting the development of ESRD is for the model that included both KDRI and histological score (AUC 0.81, 95%CI 0.708-0.914, p<0.001). A Cox model adjusted for recipient age, gender, acute rejection, DGF and chronic allograft dysfunction, patients with high KDRI and high HS are more likely to develop ESRD compared to the other groups (OR 5.6, 95%CI 1.3 to 24.5, p=0.02).

Conclusions: Patients with high KDRI and HS have worse outcome compared to patients with high KDRI but better histology. The integration of histology to clinical score may improve the assessment of the risk for graft failure in patients receiving organs from marginal donors.



FR-PO1045

Practice Variation in PHS-IR Kidney Transplants Corey Brennan,[1] Syed A. Husain,[2] Sumit Mohan,[1] Mariana C. Chiles.[2] *[1]Columbia University, New York, NY; [2]Columbia University Medical Center, New York, NY*.

Background: There is significant center level practice variation for accepting deceased donor organs in the U.S. We hypothesized that this variation occurs even for kidneys with good outcomes such as those from PHS-IR donors.

Methods: Using data from the Scientific Registry of Transplant Recipients (SRTR) from 2010-2016, we identified 78,087 kidney-alone deceased donor transplant recipients to evaluate transplant center use of PHS-IR organs in the U.S. Additionally, Cox regression analysis was used to assess the difference in allograft outcomes between PHS-IR and non-PHS-IR kidneys.

Results: 12,751 (16.3%) of kidneys were procured from PHS-IR donors who were younger (33.1±12.2 vs 38.9±16.5 years), with less hypertension (17.5 vs 29.3%), diabetes (4.1 vs 7.8%), marginally higher terminal SCr (1.31±1.15 vs 1.13±1.06) and lower KDPI (36.7 vs 49.2%) than non-PHS-IR donors (all p<0.001). PHS-IR kidneys demonstrated lower all-cause (12.2 vs 16.7%) and death-censored (5.5 vs 8.2%) graft failure (p<0.001). Despite the objectively higher quality, nearly a third (32.9%) of all PHS-IR kidneys were transplanted by just 10 transplant centers while 20 centers performed no PHS-IR transplants over the 7 year study period (**Figure 1**). PHS-IR kidneys were also significantly more likely to be shared between OPOs (30.6% vs 23.9%, p<0.001), underscoring the reluctance by some centers to use PHS-IR kidneys. PHS-IR kidneys experienced a reduced risk of graft failure (HR=0.787, p<0.001), persisting even after adjusting for KDPI and EPTS (HR=0.921, p=0.046).

Conclusions: Considerable variation in acceptance of PHS-IR donor kidneys exists despite evidence of the low risk of disease transmission and excellent outcomes. Although the number of potential donors who meet PHS-IR criteria is likely to rise during the opioid epidemic, the reluctance to use these organs is likely to adversely impact organ procurement and kidney discard in the U.S and reaffirms that deceased donors are often declined for factors other than organ quality.

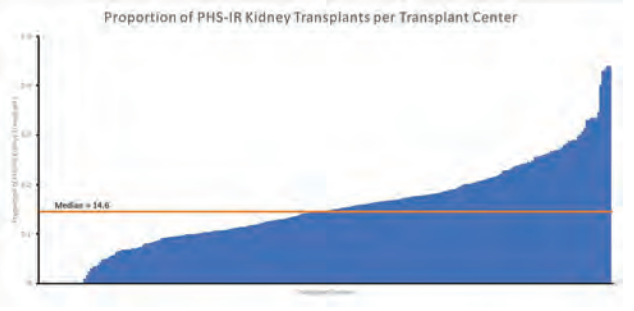


Figure 1.

FR-PO1046

Impact of Cold Ischemia Time, Independent of DGF, on Allograft Outcomes Mariana C. Chiles, Jordan G. Nestor, Syed A. Husain, Russell J. Crew, Heather K. Morris, Geoffrey K. Dube, Rachel E. Patzer, Stephen O. Pastan, Sumit Mohan. *Columbia University, New York, NY*.

Background: The rate of deceased donor kidney (DDK) discard is rising in the U.S., and prolonged cold ischemia time (CIT) is a frequently cited reason for discard. Although long CIT is associated with delayed graft function (DGF), the impact of both CIT and DGF on long-term survival is unclear.

Methods: To assess the risks associated with transplanting DDKs that have accrued long CIT, we used Scientific Registry of Transplant Recipients data to perform a paired kidney analysis and evaluated post-transplant death-censored graft failure. From 2000-2015, we identified 5,773 pairs (11,546 kidneys) that had a difference in CIT ≥5 hours, where 1 kidney developed DGF. The kidney from each pair with shorter CIT was included in the "short CIT" group and the kidney with longer CIT was included in the "long CIT" group.

Results: CIT for the long CIT kidneys was 24.8±8.9 hours versus 13.9±7.2 hours for the short CIT group (p<0.001). Long CIT kidneys were more likely to develop DGF (26.0% vs 22.4%, p<0.001). When examining pairs in which at least 1 kidney developed DGF and using the kidneys with short CIT and no DGF as the reference, kidneys that developed DGF had a higher probability of graft failure over the study period regardless of CIT (long CIT with DGF OR=1.87, p<0.001; short CIT with DGF OR=1.81, p<0.001; Figure 1), but kidneys with long CIT had no difference in graft failure (OR 0.98, p=0.71). In multivariable analysis, only recipients who developed DGF (whether with short or long CIT) had a higher risk of allograft failure compared to recipients of short CIT kidneys that did not experience DGF (long CIT with DGF OR=2.07, p<0.001; short CIT with DGF OR=1.98, p<0.001).

Conclusions: Kidneys with longer CIT had a marginally increased incidence of DGF, but long CIT was not associated with increased graft failure after stratifying recipients by DGF development. DGF describes a clinically heterogeneous entity resulting from multiple factors beyond prolonged CIT.

FR-PO1047

Perceptions of Patients with ESRD about Reasons for Transplant Non-Referral and Non-Listing Mary Morrow-Sutton, Hafiz Z. Mahmood, Umar Farooq, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Kidney transplant (KT) is the treatment of choice for most patients with end stage renal disease (ESRD). We explored patients' understanding of reasons for non-referral for transplant and reasons for not having been placed on the transplant waiting list.

Methods: We sent flyers to 1,283 dialysis units. Of 2536 interested participants who fulfilled inclusion criteria, we randomly selected and invited 1400 to complete a survey which included questions regarding referral, evaluation and listing for KT.

Results: Of 673 participants, 401 had been referred, 361 had been evaluated and 201 were listed for transplant. A total of 272 patients (40%) indicated that they had not been referred for evaluation. The most common reasons cited by patients for not being referred for evaluation included: patient choice (24%), age (10%), weight (10%), and being too sick (9%). In 10% of cases, the patients indicated that their nephrologist had not mentioned KT as an option. The reason for non-referral was unknown to 16% of the patients. Forty patients indicated that they had been referred but never evaluated for listing. Patient choice was the most common cause for not being evaluated (26%), followed by being overweight (10%) and being too sick (8%). The reason for not being evaluated was unknown to 17% of referred patients. Of the patients who had undergone the evaluation process, 160 (44%) were not listed. Patient choice was the most common reason for not pursuing the listing process (33%), being too sick (13%), and being overweight (10%). The reason for not being listed was unknown to 12% of the evaluated patients.

Conclusions: Patient choice is the most commonly cited reason for not being referred, evaluated or listed for KT. A significant proportion of patients are not aware of the reason they have not been referred, evaluated or listed for KT.

FR-PO1048

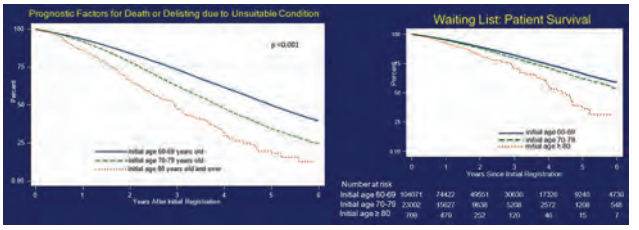
Removal Rates and Reasons from Waitlist in Elderly Kidney Transplant Candidates in the United States Korntip Phonphok,[2] Yong W. Cho,[1] Suphamai Bunnapradist.[2] *[1]Mendez National Institution of Transplantation, Los Angeles, CA; [2]UCLA, Los Angeles, CA.*

Background: The number of kidney transplant candidates on waiting list has been increasing over year, as well as the median age at initial registration. Since now there are 97,621 candidates on waitlist, among these 22,290 (22. 8%) are 65 years old and older (Data of June 1, 2017). Over 30,000 patients were removed from waiting list by year due to various reasons. We hypothesized that elderly candidates would have higher waitlist removal rates and less likely to achieve successful transplantation.

Methods: We used data from the Organ Procurement Transplant Network (OPTN/UNOS) as of December 8, 2016. We examined rates and reasons of waitlist removal in 137,553 kidney transplant candidates registered between January 1, 2000, and September 30, 2015. To allow for a sufficient follow-up period, candidates registered for transplantation up to September 31, 2015 (1 year before the date of last follow-up in the database) were included. Those candidates who were put on waitlists for organs other than kidney or multiple organs were excluded. We divided patients into 3 groups based on age at initial registration; 1) aged 60-69 years, 2)aged 70-79 years, and 3)aged ≥ 80 years. Reasons for waitlist removal were defined as being transplanted, delisted, and death.

Results: A total of 56,544 (48.3%) candidates were removed from waitlist over the study period due to reasons other than being transplanted. Delisting rate was increased by age group and was highest in aged ≥ 80 group. Among these, 22,908 (19.6%) were removed due to death during on waiting list. Candidates aged ≥ 80 years had the highest number of delisting due to condition unsuitable for transplant and also demonstrated worst patient survival while waiting for a transplant. ($p<0.01$) (graph)

Conclusions: Elderly kidney transplant candidates had high delisting rates due to death and condition unsuitable for transplant especially in those aged ≥ 80 years at initial registration, with decreased patient survival. Only half of them received successful transplantation. These results imply that patient selection before waitlist registration could avoid high rate of delisting.



FR-PO1049

The Impact of Donor Chemical Urine Toxicology on Outcomes of Kidney Transplantation Blaithin A. McMahon, Christopher A. Molini, Tessa K. Novick, Steven Menez, Edward S. Kraus. *Medicine, Johns Hopkins University, Baltimore, MD.*

Background: Most transplant centers now accept kidney grafts from victims who have acute chemical intoxications. Despite the widely acceptance of many of these donors the effect of the acute intoxication on kidney graft outcome is poorly understood.

Methods: This is a single center retrospective cohort analysis of 500 patients undergoing deceased donor kidney transplantation (DDKT). Urine toxicology agents tested from donor urine included: alcohol, heroin, cocaine, opioids/methadone, cannabinoids, benzodiazepines and methamphetamine. Delayed graft function (DGF) was defined as the need for dialysis within 1 week of kidney transplantation (KT). Graft failure was defined as the need to return to dialysis. Multiple logistical regression (MLR) analysis was used to assess the odds ratio for DGF and graft failure. MLR models were adjusted for donor age, donor race, donor terminal creatinine, recipient race, cold ischemic time, donation after cardiac death, and preemptive KT.

Results: Of 500 random DDKTs performed at our institution between January 2010 and October 2015, 230 deceased kidney donors (46%) were current drug users. The main chemical toxins detectable in donor urine were: alcohol (n=132, 26 %), heroin (n=80, 16%), opioid/methadone (n=40, 8%), cocaine (n=57, 11%), cannabinoids (n=90, 18%), benzodiazepines (n=15, 3%), methamphetamine (n=19, 4%). 23% of donors had more than one urine toxicology test positive, 13% had more than two tests positive and 5% more than two tests positive. The urine chemical toxicology of kidney donors did not have a significant effect on KT outcomes of DGF and graft failure on adjusted MLR analysis (median follow up of 24 months) (P for odds ratios > 0.05). There was also no association between donors with multiple positive urine chemical toxicology results (greater than 1 or 2 or 3 or 4 agent's positive in urine) and DGF or graft survival on MLR ($p > 0.05$).

Conclusions: The use of deceased donor kidney grafts from donors with positive urine chemical toxicology may be a worthwhile method of increasing the availability of scarce donor kidney organs as urine chemical toxicology is not associated with major transplant outcomes.

FR-PO1050

A Donor and Recipient Genome-Wide Association Study of Renal Allograft Function Caragh P. Stapleton,[3] Graham M. Lord,[6] Martin H. De Borst,[9] Harold Snieder,[9] Claire Kennedy,[4] Maria P. Hernandez-Fuentes,[6] Michael Weale,[6] Florence R. Delaney,[5] Patrick B. Mark,[10] Paul J. Phelan,[2] Fiona A. Chapman,[7] Alexander P. Maxwell,[1] A.J. McKnight,[1] Donal J. Sexton,[8] Kelly A. Birdwell,[12] Brendan Keating,[11] Gianpiero Cavalleri,[3] Peter J. Conlon.[4] *[1]Queen's University Belfast, Belfast, United Kingdom; [2]Royal Infirmary of Edinburgh, NHS Lothian, Edinburgh, United Kingdom; [3]Dept of Molecular and Cellular Therapeutics, Royal College of Surgeons, Dublin, Ireland; [4]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [5]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [6]King's College London, London, United Kingdom; [7]NHS Scotland, Glasgow, United Kingdom; [8]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland; [9]University Medical Center Groningen, Groningen, Netherlands; [10]University of Glasgow, Glasgow, United Kingdom; [11]University of Pennsylvania, Philadelphia, PA; [12]Vanderbilt University, Nashville, TN. Group/Team: UK and Ireland Renal Transplant Consortium; International Genetics and Translational Research in Transplantation Network.*

Background: Previous studies have suggested the influence of common genetic variation on renal transplant outcome. Our aim was to expand on these studies and examine single variant effects of both donor and recipient genotypes on graft function (using estimated glomerular filtration rate (eGFR) as a proxy) taking a genome-wide association study (GWAS) approach.

Methods: We meta-analysed donor and recipient genetic variants across two cohorts (Netherlands cohort and UK/Ireland cohort). We carried out both donor and recipient GWAS of eGFR at 1 year (n donors=2,344; n recipients=2,840) and 5 years (n donors=2,190; n recipients=2,606) post-kidney transplant and examined change in eGFR between 1 and 5 years (Δ eGFR; n donors=1,678; n recipients=2,002). For the 1 year and 5 year analysis, where eGFR was missing due to death/failure the last known eGFR was used and death/failure was included as a covariate in the analysis. Samples with death/failure before 5 years were excluded in the Δ eGFR GWAS. Other covariates included the first eight principle components, donor and recipient age, donor type (living/deceased) and donor gender.

Results: No genome-wide significant associations were found in the three donor GWAS. In the recipient 5 year eGFR GWAS a significant association was observed with a locus on chromosome 19 (combined $p=2.59x10^{-8}$). The presence of the minor allele correlated with a decrease in eGFR (beta= -0.15). This region contains the gene *ZSCAN18* which may play a role in transcriptional regulation.

Conclusions: No single common genetic variant was associated with 1 year, 5 year or Δ eGFR in the donor GWAS. We detected a locus on chromosome 19 that associated with 5 year eGFR in the recipient GWAS suggesting that recipient genotype may be used to predict medium-term renal allograft outcome. Further work is required to assess the robustness of this signal and to replicate these findings.

FR-PO1051

Genome-Wide Donor-Recipient Genetic Differences Influence Renal Allograft Survival Independent of HLA Madhav C. Menon,[2] Zhongyang Zhang,[1] Weijia Zhang,[2] Eli A. Stahl,[1] Ke Hao,[1] Barbara T. Murphy.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai School of Medicine, Forest Hills, NY.*

Background: Renal interstitial fibrosis (IF-TA) is a non-specific histologic entity identified in 30-40% of all allografts that fail. Transcriptomic studies of human allograft biopsies show that gene-signatures of ongoing alloimmune activity persist in these IF-TA lesions. Conventionally, anti-donor alloimmunity is attributed to HLA-mismatching. However, non-HLA loci have recently been shown to determine allo-recognition & responses.

Methods: We utilized unique genome-wide SNP array data encompassing Donor-Recipient pairs (D-R) from our recently completed multicenter GoCAR study [PI- Barbara Murphy] to study the role of D-R differences on death-censored allograft survival (DCGS) after excluding HLA-regions (n=385). We used ADMIXTURE analysis on genome-wide genotype data to plot the actual genomic race (AGR) of D-Rs using 1000-genome data (Fig-1). Long term survival data were obtained from UNOS/ANZDATA.

Results: AGR was more accurate than self-reported race (reclassifying 2.7-54% D-Rs among different races). Recipient AGR impacted DCGS in adjusted cox survival models (aHR-2.25 for African-American AGR), while donor AGR had minimal effect. Euclidean D-R genetic distance calculated from AGR significantly associated with DCGS. HLA-matching did not impact DCGS in adjusted analysis. In D-R pairs of similar ancestry, proportion of genome-shared identity-by-descent (pIBD), was predictive of allograft survival (n=224; Log rank P<0.01; pIBD<0.1 vs > 0.1). Notably, pIBD and AGR were not significantly associated with clinical/subclinical rejection at any time post-transplant. In multivariate analysis, lower pIBD scores strongly associated with histologic vascular intimal fibrosis and IF-TA in biopsies obtained less than 1-year (n=199; P<0.01). External validation of these results is ongoing.

Conclusions: Together our novel data show that non-HLA D-R differences determine vascular intimal fibrosis, IF-TA and impact allograft survival.

FR-PO1052

Circulating Fibrocytes Predict eGFR Slope Post Transplant and Are Associated with Chronic Tubular Changes Michael H. Lee, Christine M. Ribic, Azim S. Gangji, Peter Margetts. *McMaster University, Hamilton, ON, Canada.*

Background: Interstitial fibrosis and tubular atrophy predicts renal transplant outcomes. Circulating fibrocytes are associated with fibrogenic disease in other organs. We aim to evaluate the role of fibrocytes in predicting long-term renal function and the extent of graft fibrosis.

Methods: A single center observational study was conducted in patients undergoing a first kidney transplant. Blood was drawn pre-transplant, 1, 3, 6, and 12-months post-transplant. Circulating fibrocyte levels were identified by flow cytometry using cell surface CD45 and intracellular collagen I. Biopsy samples were stained for a-smooth muscle actin (SMA) and tissue fibrocytes were identified using dual labeling of CXCR4 and Prolyl-4-hydroxylase. The Banff classification was used to evaluate chronic biopsy changes.

Results: Eighty enrolled patients were followed to 12-months post-transplant. One-month circulating fibrocyte levels correlated inversely with the slope of the eGFR from 3 to 12 months (R=-0.257, p=0.03). Thirteen patients had a clinically indicated biopsy. The number of tissue fibrocytes correlated with a-SMA staining (R=0.637, p=0.026). Increased chronic tubular changes were associated with elevated 1-month circulating fibrocyte levels (p<0.001). Increased chronic interstitial changes were associated with increased numbers of tissue fibrocytes (p=0.028).

Conclusions: Elevated circulating fibrocytes at 1-month post-transplant may be prognostic of transplant outcome. Also, increased circulating fibrocytes at 1-month is predictive of chronic tubular changes on biopsy. The number of tissue fibrocytes correlates with interstitial fibrosis and a-SMA staining. Circulating fibrocytes at 1-month can be a biomarker for graft dysfunction and may predict the severity of graft fibrosis.

AKI Following Coronary Angiography: Survival and Development of CKD Dadi Helgason,[3,2] Thorir E. Long,[3,2] Sólveig Helgadóttir,[1] Runolfur Palsson,[2,3] Gisli H. Sigurdsson,[2,3] Tomas Gudbjartsson,[2,3] Ingibjorg J. Gudmundsdottir,[2] Martin I. Sigurdsson,[4] Olafur S. Indridason.[2] *[1]Akademiska Hospital Uppsala University, Uppsala, Sweden; [2]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [3]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [4]Duke Univeristy Medical Center, Durham, NC.*

Background: Acute kidney injury (AKI) is a recognized complication following coronary angiography (CA) and has been associated with adverse short-term outcomes. We studied the association of AKI following CA with survival and the development and/or progression of chronic kidney disease (CKD).

Methods: This was a retrospective study of patients undergoing CA in Iceland in 2008-2015. Excluded were patients on chronic dialysis, those without baseline serum creatinine (SCr) and patients who underwent open heart surgery in the first 3 days following CA. AKI was defined according to the KDIGO SCr criteria, CKD was defined as eGFR <60 mL/min/1.73 m^2 for at least 3 months, and progression of CKD as worsening of at least one stage sustained over 90 days. Clinical information was obtained from hospital medical records and a prospective CA registry (SCAAR-Swedeheart) and mortality data from Statistics Iceland. Survival was estimated with Kaplan-Meier method and compared to non AKI patients for the whole group (log rank test) and after 1:1 propensity score matching (Klein test). Cox proportional hazards model was used to determine predictors of CKD development/progression.

Results: AKI was diagnosed in 251 out of 13465 cases (1.9%). The 30-day mortality was 23.1% vs. 1.1%, and 1-year survival was 68.6% vs. 97.1%, in the AKI and non-AKI group, respectively (p<0.0001). After excluding patients who died within 30 days, the AKI patients had worse 1-year survival compared with a propensity score-matched control group, or 89.2% vs. 96.2% (p=0.03). While 2343 patients (17.4%) had CKD at baseline, 1935 of the 13465 cases (14.4%) developed incident CKD or progression of pre-existing CKD following CA, with a median time of follow-up of 3.5 (range 0.2-8.0) years. In multivariate analysis, AKI was a predictor of development/progression of CKD (HR 2.5; 95%-CI: 2.0-3.1).

Conclusions: Short-term mortality of patients with AKI following CA is high. However, even after excluding early deaths, AKI appears associated with less favorable long-term survival and the development and/or progression of CKD.

SA-PO002

Temporal Trends in the Incidence of AKI after Coronary Revascularization in a Nationwide Study Wen Shen,[3] Siddartha Bhandary,[2] Jaeil Ahn.[1] *[1]Georgeotown University, Washington, DC; [2]Providence Hospital, Derwood, MD; [3]Georgetown University Hospital, DC, WA.*

Background: The major modalities of coronary revascularization - coronary artery bypass grafting (CABG) and percutaneous coronary intervention (PCI) both carry high risk of acute kidney injury (AKI). Our previous study has shown that CABG was associated with higher incidence of post-procedural AKI compared with PCI. Since the temporal trends of AKI incidence in the general population have been changing, it is important to study the temporal changes of AKI incidence in CABG and PCI which could help us better understand the risk profile migration over the years in the coronary revascularization modalities.

Methods: We generated a propensity-matched cohort of 274,464 hospitalizations that had first time CABG or PCI for multivessel coronary disease in 2004 to 2012 from the National Inpatient Sample. Patients received concomitant valvular repair or both CABG and PCI on the same admission, history of organ transplant, CKD stage V or ESRD on dialysis were excluded. Both groups were propensity score matched for age, gender, race, payer, prior MI, unstable angina, heart failure, CVA, peripheral arterial disease,

valvular disease, atrial flutter or fibrillation, CKD, diabetes, HTN, dyslipidemia, smoking, cirrhosis, COPD, systemic cancer, obesity, and anemia. The odds ratios were estimated by the random intercept logistic regression model.

Results: The temporal trends of AKI incidence in both CABG and PCI groups had been increasing over the years from 5.9% in 2004 up to 14.2% in 2012 for CABG, 2.7% in 2004 up to 8.8% in 2012 for PCI. Compared with PCI, CABG was associated with higher incidence of post-procedural AKI in each individual year from 2004 to 2012 (Time effect: OR 1.138, 95% CI: 1.113-1.164, P <0.01). Interestingly, although CABG had higher likelihood to develop AKI throughout the study period than PCI, the odds had been decreasing gradually (OR 3.29, 95% CI 3.08-3.54, P<0.01 in 2006; OR 1.73, 95% CI 1.58-1.88, P<0.01 in 2012).

Conclusions: Both CABG and PCI were associated with increasing temporal trends in AKI incidence over the years. Although CABG was associated with higher likelihood of developing post-procedural AKI in each individual year compared to PCI, the odds had been decreasing yearly.

Epidemiology of AKI in Cancer Patients Young Lee Jung,[1] Eunjeong Kang,[1] Minsu Park,[2] Namyong Park,[3] Hajeong Lee.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Biomedical Engineering, Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Computer Science and Engineering, Seoul National University College of Engineering, Seoul, Republic of Korea.*

Background: Acute kidney injury (AKI) is common in patients with cancer because of malignancy itself, treatment regimen, contrast exposure and coexisting morbidities. However, epidemiologic data for AKI in cancer patients are still lacking.

Methods: We retrospectively assembled newly diagnosed cancer patients at Seoul National University Hospital between January 2004 and December 2013. Among a total of 106,004 cancer patients, we excluded patients with dual primary cancer, age under 18 years-old, advanced renal dysfunction with eGFR less than 15 ml/min/1.73m^2. Patients who could not define AKI due to lack of data were also excluded. AKI was defined as the KDIGO guideline. We categorized patients according to involved organs. We collected demographic information, comorbidities such as diabetes and hypertension, laboratory tests, contrast exposures represented by CT count, and treatment regimen including surgery and chemotherapeutic agents use. AKI incidence was showed as incidence rate estimated by the person-years at risk.

Results: After exclusion, we finally included 68,036 patients. Among them, 23,024 (33.8%) patients developed AKI after cancer diagnosis. More than half of AKI patients experienced recurrent AKI events and 15.9% went through more than 5 times of AKI events. Interestingly, AKI in cancer patients tend to be increasing over time continuously. When compared AKI incidence rate according to cancer type, respiratory tract cancer revealed the highest incidence rate (289.5 cases/1,000 person-year), followed by genitourinary tract cancer (260.8 cases/1,000 person-year) and hematologic malignancies (217.1 cases/1,000 person-year). Patients with AKI experience were older, more men, and had more coexisting diseases such as diabetes and hypertension. They had lower initial renal function, lower serum albumin, and serum hemoglobin. In addition, they exposure more frequent contrast CT scan and chemotherapeutic agents.

Conclusions: In this study, we find that AKI events are increasing, and develop quite frequently and repetitively. Notably, respiratory tract cancer is proved to be the highest risk of AKI incidence. Not only demographic and co-existing factors but also treatment related factors may contribute to the AKI development.

SA-PO004

AKI in Cancer Patients: Risk Factors and Impact on Mortality Eunjeong Kang,[1,2] Minsu Park,[3] Namyong Park,[4] Peong gang Park,[5] U Kang,[4] Hee Gyung Kang,[1,5] Hyung-Jin Yoon,[3] Hajeong Lee.[1,2] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [3]Biomedical Engineering, Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Computer Science and Engineering, Seoul National University College of Engineering, Seoul, Republic of Korea; [5]Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea.*

Background: Burden of acute kidney injury (AKI) has been demonstrated in a variety of clinical settings including surgery, intensive care unit, and exposures of nephrotoxic agents, although it remains unclear the impact of AKI on mortality in cancer patients.

Methods: We enrolled all patients who were diagnosed any type of cancer in a tertiary hospital during 10 years. Patients with double primary cancer, age less than 18 years, advanced renal dysfunction with estimated glomerular filtration rate (eGFR) <15mL/min/1.73m^2 were excluded. Initial serum creatinine (sCr) level was defined as first measured sCr within 2 months before and after cancer diagnosis, and baseline sCr was defined as minimum value of sCr from the previous 3 weeks by shifting the reference point every 3 weeks based on cancer diagnosis. AKI was defined according to KDIGO-AKI guideline. Demographic factors, co-morbidities, cancer type, eGFR, count of enhanced computed tomography (CT), and treatment options such as surgery and chemotherapy were included as covariates.

Results: Total 67,986 patients were included. Mean age was 56.9±13.0 years and 50.6% were male. AKI occurred in 22,990 (33.8%) of cancer patients during the follow-up period. More than half of patients (n=5,442, 23.7%) experienced 3 or more AKI events per year. Patients who developed AKI had lower eGFR at cancer diagnosis and was experienced more contrast CT exam. In multivariate logistic regression analysis, AKI developed in patients with older age, male, underlying hypertension, diabetes, lower serum albumin and hemoglobin levels, lower initial eGFR, genitourinary cancer type and receiving chemotherapy. A total of 23,140 (34.0%) deaths occurred during 48.5±40.3 months of follow-up. AKI development was demonstrated as an independent risk factor for mortality with graded response (AKI >0-3/year, hazard ratio [HR] 1.07, 95% CI 1.04-1.11, *P*<0.001; AKI ≥3/year, HR 2.31, 95% CI 2.20-2.43, *P*<0.001; reference, no AKI).

Conclusions: AKI development was common in cancer patients, especially in those with co-morbidities, impaired renal function, exposure of nephrotoxic agents such as radiocontrast and chemotherapy. Notably, AKI was an important and independent risk factors for mortality in cancer patients with dose-responsive manner.

SA-PO005

Obesity and Recovery from AKI: An Observational Feasibility Study Helen L. MacLaughlin,[1,4] Gerda K. Pot,[4] Iain C. Macdougall,[1] Christopher W. McIntyre,[3] Nicholas M. Selby.[2] *[1]King's College Hospital, London, United Kingdom; [2]University of Nottingham, Derby, United Kingdom; [3]London Health Sciences Centre, London, ON, Canada; [4]Diabetes and Nutritional Sciences Division, King's College London, London, United Kingdom.*

Background: Acute kidney injury (AKI) occurs in ⟩5% of hospital admission in the UK, and is associated with an increased risk of developing or worsening chronic kidney disease (CKD). The effect of obesity on recovery of kidney function after AKI, and the combined risk of obesity and AKI on subsequent development of CKD is not known.

Methods: A study was conducted to determine the feasibility of recruitment, retention and data collection procedures for the planned Ob-AKI cohort study in a sample of 100 patients hospitalised with an episode of AKI. Feasibility outcomes for recruitment, retention and trends in exploratory measures of recovery from AKI (⟩75% of preAKI eGFR) and development/progression of CKD (decrease in eGFR of ≥25% + rise in CKD category) were examined by BMI (⟨25, 25-29.9, 30+) over 12 months. Potential participants were identified by referral and electronic detection of episodes of AKI during hospital admissions. Inclusion criteria were 18-85 years, episode of AKI (KDIGO 2012), and pre AKI creatinine measured within the previous 12 months.

Results: 41% of eligible patients consented to participate in the study, exceeding the feasibility target of 15%. 101 patients were recruited to the study (67M, 34F, mean age 63.5 (±12.6) years and mean BMI 29.9kg/m^2, range 18.1 to 54.3kg/m^2); 28.3% with stage 1, 21.2% stage 2 and 50.5% stage 3 AKI. Retention was 86% at 6 months and 80% at 12 months; there were 10 deaths and 3 patients commenced dialysis during the study. There may be an interaction between obesity, pre-existing CKD and renal function after AKI. In obese patients with pre-existing CKD, recovery of kidney function at 6 months may be higher with subsequently greater progression at 12 months, compared to patients with normal BMI with CKD (71% (10/14) vs 61% (8/13)) and (31% (5/16) vs 27% (3/11)) respectively. Conversely, obese patients without CKD at baseline may have lower renal recovery at 6 months (35% (8/17) vs 47% (6/17)), yet develop less CKD at 12 months (37% (6/16) vs 69% (9/13)), compared to patients with normal BMI.

Conclusions: We have demonstrated that it is feasible to perform long term observational studies addressing AKI outcomes associated with obesity. A fully powered prospective cohort study to examine the relationships between obesity and outcomes afrer AKI is warranted.

Funding: Government Support - Non-U.S.

SA-PO006

Survival after Initiation of Renal Replacement Therapy for AKI in Cirrhosis Andrew S. Allegretti,[2] Xavier F. Parada,[2] Nwamaka D. Eneanya,[2] Raymond T. Chung,[1] Ravi I. Thadhani,[2] Hannah M. Gilligan.[2] *[1]MGH, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Mortality is high after initiation of renal replacement therapy for acute kidney injury in cirrhosis. Literature on the appropriateness of dialysis in hepatorenal syndrome is sparse and is confounded by liver transplant eligibility. An update on outcomes in the non-listed subgroup is needed. Our objective is to compare survival after initiation of renal replacement therapy in cirrhosis between hepatorenal syndrome and acute tubular necrosis, stratifying by liver transplant listing status.

Methods: Retrospective cohort study of patients with cirrhosis acutely initiated on hemodialysis or continuous renal replacement therapy at five hospitals, including one liver transplant center. Multivariable regression and survival analysis were performed.

Results: 472 subjects were analyzed, 131 listed and 341 not listed for transplant. 24% (114/472) were alive at six months. Among those who did not receive a transplant, 14% (59/409) were alive at six months. Using stepwise regression, significant predictors of mortality were: non-listed transplant status, MELD score, age, admission to the intensive care unit, serum ALT, mechanical ventilation, and initiation with continuous renal replacement therapy. When stratified by transplant listing, adjusted Cox models showed similar survival between hepatorenal syndrome and acute tubular necrosis (HR 0.81 [95% CI 0.59, 1.11]; p = 0.19 among those not listed; HR 0.73 [95% CI 0.44, 1.19]; p = 0.21 among those listed).

Conclusions: After initiation of renal replacement therapy in cirrhosis, mortality is high at six months. Transplant listing status, MELD score, and indicators of critical illness best predicted mortality. Etiology of acute kidney injury (hepatorenal syndrome versus acute tubular necrosis) was not significantly associated with mortality.

Inflammation and Malnutrition Are Predictors of Long-Term Outcomes after Postoperative AKI in Non-Cardiac Surgery Masatoshi Nishimoto,[1] Miho Tagawa,[1] Takayuki Hamano,[3] Kokubu Maiko,[1] Masaru Matsui,[2] Kenichi Samejima,[1] Yasuhiro Akai,[1] Yoshihiko Saito.[1] *[1]Nara Medical University, Kashihara, Japan; [2]First Department of Internal Medicine, Nara Medical University, KASHIHARA, Japan; [3]Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Previous studies showed that AKI is an independent predictor of long-term mortality after adjustment for comorbidities. However, these studies did not account for inflammation and malnutrition, which is associated with increased mortality in CKD.

Methods: This is a retrospective cohort study. Inclusion criteria were adult patients who underwent non-cardiac surgery under general anesthesia from 2007 to 2010. Exclusion criteria were urological or obstetric surgery, missing creatinine values, and preoperative dialysis. The exposure of interest was AKI, defined by KDIGO criteria, within 1 week postoperatively. Outcome variable was all-cause mortality. Statistical analyses were performed using Kaplan-Meier curve and Cox regression model.

Results: Among 1,704 patients, 129 developed AKI. During median follow-up of 3.9 years, the mortality of patients with AKI and without AKI were 27.9%, and 14.7%, respectively. AKI was independently associated with all-cause mortality after adjustment for comorbidities. After further adjustment for C-reactive protein (CRP) and albumin, the association between AKI and mortality was not significant (Table). Among non-users of statin and users of statin, adjusted HR of mortality (AKI vs no-AKI) was 1.92 (1.32-2.81) and 0.57 (0.15-2.23), respectively.

Conclusions: Attenuation of the association between AKI and all-cause mortality by adjustment for albumin and CRP suggested that inflammation and malnutrition, which predisposing patients to AKI, are predictors of increased all-cause mortality after AKI. Anti-inflammatory agents, such as statins, may improve long-term outcome after AKI.

The association between postoperative AKI and all-cause mortality

	HR(95%C.I)
Model 1	1.72(1.19-2.46)
Model 1 + CRP	1.59(1.10-2.31)
Model 1 + CRP + Alb	1.17(0.77-1.76)

Model 1 was adjusted for age, sex, eGFR, and history of DM, hypertension, malignancy, and cardiovascular diseases.

Renal Recovery after Dialysis-Requiring AKI Is Associated with Decreased Short-Term Mortality Benjamin J. Lee,[2] Chi-yuan Hsu,[2] Rishi V. Parikh,[1] Thomas Leong,[1] Thida C. Tan,[1] Sophia Walia,[1] Raymond K. Hsu,[2] Kathleen D. Liu,[2] Alan S. Go.[1,2] *[1]Kaiser Permanente Northern California, Oakland, CA; [2]University of California, San Francisco, San Francisco, CA.*

Background: Dialysis-requiring acute kidney injury (AKI-D) is associated with increased risk of death even after hospital discharge and higher subsequent rates of cardiovascular disease. We examined whether renal recovery after AKI-D mitigates these risks in a diverse, community-based cohort.

Methods: We evaluated all adult members of Kaiser Permanente Northern California who experienced AKI-D between January 2009 and September 2015. We compared AKI-D patients who recovered adequate kidney function to come off dialysis to AKI-D patients who did not. The primary outcomes were all-cause death, heart failure hospitalization, acute coronary syndrome (ACS), and acute ischemic stroke or transient ischemic attack (TIA) within 1 year of acute renal replacement therapy initiation. Baseline demographics, eGFR, dipstick proteinuria, other labs, comorbidities, and medication use were identified from electronic health records and used for multivariable adjustment.

Results: Compared to AKI-D patients who did not recover (n=1,865), AKI-D patients who recovered (n=1,347) were younger, had higher baseline eGFR and less proteinuria, and were less likely to have pre-existing cardiovascular disease, hypertension, or diabetes. In multivariable Cox regression, recovery after AKI-D was independently associated with a 30% lower relative risk of all-cause death (adjusted hazard ratio [aHR] 0.70, 95% CI 0.55-0.88). Recovery after AKI-D was not statistically significantly associated with adjusted differences in heart failure hospitalization, ACS, or acute ischemic stroke/TIA events (**Table**).

Conclusions: Recovery after AKI-D was independently associated with lower short-term mortality. Interventions to promote early recovery of renal function after AKI-D should be evaluated.

SA-PO009

AKI and Associated Risk Factors for Mortality in Influenza Patients Raymundo A. Sánchez, Luis I. Bonilla, Raymundo Vera, Israel A. Villegas-Gasson, Alan L. Reyes, Jesus Cruz Valdez, Lilia M. Rizo Topete. *Hospital Universitario Dr. José Eleuterio González, Monterrey, Nuevo León, Mexico.*

Background: In 2009, a pandemia of influenza A(H1N1) virus severely affected Mexico. Several reports described the presentation of this disease in critically ill patients. Acute kidney injury (AKI) and mortality showed high prevalence in these studies. AKI incidence has been reported between 33.6%and 51% in A(H1N1) patients, with mortality rates between 36.3 and 51%.

Methods: We conducted a retrospective, observational study in patients admitted to the ICU during the 2016-2017 influenza season. All patients were diagnosed as ARDS and had suspicion of influenza infection. We obtained demographic, clinical and laboratory data. AKI was defined according to Acute Kidney Injury Network criteria. Patients were divided into two groups, survivors and non survivors.

Results: 30 patients were included in the study;20(66.6%) were male, median age was 46.4(±11.91). Mortality in the ICU was 60% and AKI was present in 66.6% of the patients. The mean APACHE II score was 24.2 ± 7.97, mean stay in ICU was 10 days(IQR: 6-15). Use of double vasopressor in 14(46.6%). All patients required invasive mechanical ventilation with PEEP 10.13(± 5.68), PaO2/FIO2 126.42(IQR: 75.9-171.25), tidal volume of 185(IQR:150-205). The diagnosis of influenza was confirmed in 12(40%), 3(16.7%) with influenza rapid diagnostic test (RIDTs) and 9(83.3%) with reverse transcriptase PCR(RT-PCR);of these 5(41.6%) confirmed influenza A(H1N1). The main comorbidities recorded were obesity(n=14, 46.7%), smoking(n=12, 40%), and diabetes mellitus type 2(n=11, 36.7%). The risk factors associated with mortality were obesity OR=2.62(IC=0.881-7.824, p=0.82), A(H1N1)influenza infection confirmed by PCR OR=3.824(IC=1.006-14.536, p=0.016), presence of AKI OR=2.8(IC=1.184-6.622, p=0.18), specially KDIGO 3 OR 10 (p=0.007), and renal replacement therapy(RRT) OR=11 (IC=1.164-103.94, p=0.018).

Conclusions: Influenza A(H1N1) is still a cause of great morbidity and mortality in the young Mexican population. In our cohort we found consistent data that can help the treatment of these patients in the setting of the ICU. The presence of acute kidney injury, obesity, and the need for RRT were strong risk factors for mortality in this study. Modifiable factors should be early identified to improve outcomes in critically ill.

SA-PO010

Differential Trends in Incident Rates of AKI by Severity Stage in the Irish Health System Leonard Browne,[5,1] Alaa Mohamed Alamin Abdelrahim Mohamed ALi,[3] Arunkumar Aruna udayakumar,[4,1] Wael F. Hussein,[2] Rajiv Saran,[6] Austin G. Stack.[1,7] *[1]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [2]Limerick University Hospital, Limerick, Ireland; [3]University Hospital Limerick, Limerick, Ireland; [4]University Of Limerick, Limerick, Ireland; [5]University of Limerick, Limerick, Ireland; [6]University of Michigan, Ann Arbor, MI; [7]Health Research Institute, Limerick, Ireland. Group/Team: UL Kidney Consortium.*

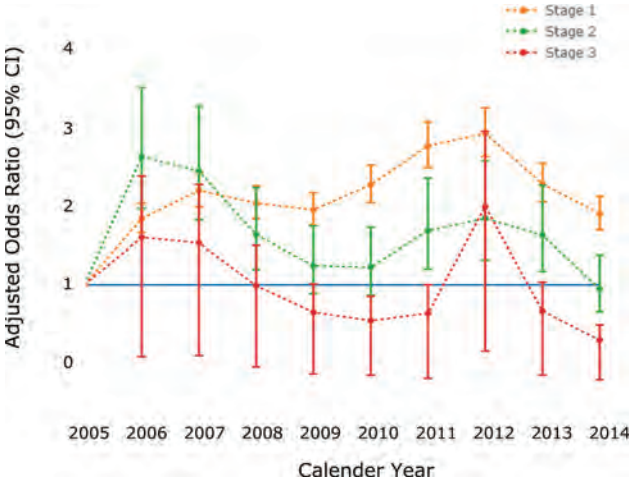
Background: Surveillance of Acute Kidney Injury (AKI) is a fundamental component of prevention strategies in health systems in order to reduce adverse outcomes. Recent studies have shown rising incident trends for dialysis-requiring AKI. We determined incident rates of first AKI by stage from 2005-2014 in the Irish Health System

Methods: We utilised data from the National Kidney Disease Surveillance System in Ireland to explore trends in incident AKI within the health system from 2005 to 2014 (n= 453, 509). AKI events were identified per KDIGO guidelines and classified by stage (1 to 3) and incidence rates per 100 patients were calculated for each year. Multivariable logistic models explored the relationship of calendar year with AKI incidence expressed

as odds ratio (OR) and 95% Confidence Intervals (CI) with adjustment for age, sex, county of residence, location of medical supervision and laboratory indicators of health.

Results: From 2005 to 2014, incidence rates of AKI per 100 patients increased from 5.5 % (5.4, 5.7) to 11.8 % (11.4, 12.1) in Stage 1; 0.58 % (0.53, 0.63) to 1.32 % (1.19, 1.45) in Stage 2, and from 0.46 % (0.41, 0.51) to 0.71 % (0.61, 0.81) in Stage 3. With adjustment for age, sex and baseline eGFR, a pattern of increasing odds of AKI was observed across all 3 stages (P<0.001 for trend). With further adjustment for county of residence, hospital, location of medical supervision and laboratory health indicators, a rising trend in incidence was observed only AKI Stage 1, while the reverse was seen for AKI Stage 2 and 3 (Figure 1), all P<0.001.

Conclusions: Increasing incidence of Stage 1 AKI is primarily responsible for overall growth of AKI in the Irish Health System. Accounting for changing demographic, clinical and geographic profiles, incident rates of Stage 2 and Stage 3 AKI have fallen in recent years and suggest improved preventive strategies.



SA-PO011

Prediction Model for AKI after Non-Cardiac Surgery Kokubu Maiko,[3] Miho Tagawa,[3] Takayuki Hamano,[1] Masatoshi Nishimoto,[4] Masaru Matsui,[2] Ken-ichi Samejima,[2] Yasuhiro Akai,[4] Yoshihiko Saito.[4] *[1]Osaka University, Suita, Japan; [2]Nara Medical University, Kashihara, Japan; [3]nara medical university, NARA, Japan; [4]Nara Medical University, Nara, Japan.*

Background: There are many prediction models for AKI after cardiac surgery, but few reports exist for non-cardiac surgery.

Methods: This is a retrospective cohort study in adults who underwent non-cardiac surgery under general anesthesia from 2007-2010. We exclude patients who had preoperative dialysis, urologic, and obstetric surgery or did not have creatinine level preoperatively. Predictive variables were patients' demographics and characteristics of surgeries. Outcome variable was AKI within 1 week postoperatively according to the KDIGO criteria. The cohort was divided into derivation and validation cohorts (2:1). In derivation cohort, predictors of AKI were analyzed by multivariate logistic regression analysis and prediction model was created using regression coefficients. Validity of the model was tested in validation cohort using ROC curve and calibration slope.

Results: Among 2,912 patients in the derivation cohort, 172 (5.9%) patients developed AKI. Variables independently associated with AKI and points according to the model are shown (Table). In the validation cohort, AUC was 0.72 (0.67-0.77) and there was no significant difference in predicted and observed incidence (p=0.12) (Fig).

Conclusions: Our prediction model for AKI after non-cardiac surgery was well calibrated. The model needs to be validated in other cohorts.

SA-PO012

Prevalence and Variation of Best Practices in AKI: A Multi-Center Study Francis P. Wilson,[3] Aditya Biswas,[2] Dennis G. Moledina,[3] Sherry Mansour,[1] Chirag R. Parikh.[4] *[1]None, New Haven, CT; [2]Yale University, New Haven, CT; [3]Yale School of Medicine, New Haven, CT; [4]Yale University and VAMC, New Haven, CT.*

Background: AKI is common in hospitalized settings and is associated with increased morbidity, mortality, and length of stay. While there is no specific therapy for AKI, guidelines recommend certain best practice measures that could potentially form the basis of a standardized set of responses to AKI and the development of an AKI "report card". Adherence to such metrics in real-world settings is unknown.

Methods: Using guidelines published by the Kidney Disease: Improving Global Outcomes and National Institute for Health and Care Excellence, we identified four potential universal best practice metrics for hospitalized patients post-AKI including: subsequent creatinine measurement, urinalysis, urine output monitoring and avoidance of certain nephrotoxins (including aminoglycosides, non-steroidal anti-inflammatory drugs, and contrast media). We examined patients with AKI at three Connecticut hospitals to determine the rates of performance of these best practices within 24 hours of AKI onset. Patients discharged within 24 hours of AKI onset were excluded.

Results: Over three years, we identified 26,333 individuals (49.8% male, 18% black) with AKI based upon KDIGO-Creatinine criteria. The Table documents the rates of best practices across the three study hospitals and demonstrates significant variation. A multivariable model demonstrated that surgical patients, male patients, those with private insurance, and those with electrolyte abnormalities at AKI onset had more best practices performed. Of those *without* a creatinine measurement within 24 hours of AKI, 13.8% had progression to a higher stage of AKI, 1.5% went on to inpatient dialysis, and 6.2% died during the hospitalization.

Conclusions: Adherence to AKI best practice varies by hospital, ward, and patient factors. Standardization of best practice guidelines may help to reduce variation and improve outcomes.

Funding: NIDDK Support

Evaluation of the Accuracy of Estimated Baseline Serum Creatinine for Diagnosis of AKI in the Japanese Population Taro Horino, Yutaka Hatakeyama, Tatsuki Matsumoto, Keitaro Nagata, Kosuke Inoue, Yoshio Terada, Yoshiyasu Okuhara. *Kochi Medical School, Nankoku, Japan.*

Background: Modern epidemiologic studies of acute kidney injury (AKI) have been facilitated by the increasing availability of electronic medical records. However, pre-morbid reference serum creatinine (SCr) data are often unavailable in such records. Investigators substitute estimated baseline SCr with the eGFR 75 approach, instead of using actually measured baseline SCr. Here, we evaluated the accuracy of estimated baseline SCr for AKI diagnosis in the Japanese population.

Methods: Inpatients and outpatients aged 18-80 years were retrospectively enrolled. AKI was diagnosed according to the Kidney Disease Improving Global Outcomes criteria, using SCr levels. The non-AKI and AKI groups were selected using the following criteria: increase 1.5 times greater than baseline SCr, "baseline SCr" or increase 0.3 mg/dL greater than baseline SCr in 48 h, "increase in 48 h". AKI accuracy defined by the estimated reference SCr, the average SCr value of the non-AKI population, eb-GFR-A approach, or the back-calculated SCr from fixed eGFR = 75 mL/min/1.73 m^2, eGFR 75 approach, or, eb-GFR-B approach in this study, was evaluated.

Results: We analyzed data from 131,358 Japanese patients. The number of patients with reference baseline SCr in the non-AKI and AKI patients were 29,834 and 8,952, respectively. For AKI patients diagnosed using "baseline SCr", the AKI diagnostic accuracy

rates as defined by eb-GFR-A and eb-GFR-B were 63.5% and 57.7%, respectively, while in AKI diagnosed using "increase in 48 h", the AKI diagnostic accuracy rates as defined by eb-GFR-A and eb-GFR-B were 78.7% and 75.1%, respectively. In non-AKI patients, false positive rates of AKI misdiagnosed via eb-GFR-A and eb-GFR-B were 7.4% and 6.8%, respectively.

Conclusions: AKI diagnosis using the average SCr value of the general population may yield more accurate results than diagnosis using the eGFR 75 approach when the reference SCr is unavailable.

SA-PO014

Racial Differences in the Risk for AKI after Cardiac Surgery James F. George,[1] Rongbing Xie,[1] Margaret Tresler,[1] James K. Kirklin,[1] Anupam Agarwal.[2,3] *[1]Surgery, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine, University of Alabama at Birmingham, Birmingham, AL; [3]Department of Veterans Affairs, Birmingham, AL.*

Background: The effects of race on developing AKI following cardiac surgery are unknown. To determine the extent of this disparity, we studied risk factors for AKI after cardiac surgery at a tertiary referral center.

Methods: AKI was defined using the KDIGO working group definition. Pre-op or baseline creatinine (CRE) was defined as the minimum value within 30 days before surgery. Post-op CRE was defined as the maximum value within 48 hours after surgery. Post-operative risk factors for AKI were determined using multivariable logistic analysis to predict the probability of AKI KDIGO stage >1.

Results: Among 5347 patients (pts) who underwent cardiac surgery between July 1, 2010 and December 31, 2015, the study included 2175 pts who had coronary artery bypass grafts (CABG, 1309, 60%), valve procedure (585, 27%), or combined CABG and valve procedures (279, 13%). The remaining 3172 pts were excluded due to concomitant other surgeries, assist devices, a prior dialysis, race other than black or white, death or discharge within 48 hours, or missing CRE values. 1791 of included pts were white (82%) and 382 were black (18%). 1589 pts were KDIGO=0, 522 were KDIGO=1, and 62 were KDIGO>=2. By multivariable analysis, factors predictive ($p<0.001$) of KDIGO stage >1 included black race (OR 1.57, $p=0.0005$), increased BMI at time of surgery (OR 1.02, $p<0.0001$), older age (OR 1.02, $p<0.0001$), higher number of diseased vessels (OR 1.21, $p=0.0002$), and mitral valve procedure (OR 2.05, $p=0.0007$). Mean pre-op CRE among blacks was 1.21 (0.9-1.3, 25th to 75th percentile) and 1.07 (0.8-1.2) in whites, a difference of 0.14 ($p<0.0001$). Mean post-op CRE among blacks was 1.45 (1.0-1.6) and 1.22 (0.9-1.4) in whites. Notably, the mean difference between post-op and pre-op CRE was significantly larger in blacks at 0.24 (0.0-0.3) versus 0.15 (0.0-0.3) in whites ($p=0.0011$). Review of Medicare billing data showed 53 (3%) whites and 20 (5%) blacks received a Nephrology consult during hospitalization ($p=0.03$). Only 16 (1%) of white and 9 (2%) of blacks required dialysis ($p=0.02$).

Conclusions: Black race was a significant risk factor for AKI after cardiac surgery, with blacks exhibiting larger increases in CRE after surgery. These results indicate that a larger, multicenter study examining race and AKI post-cardiac surgery is clearly warranted and tailored interventions to prevent AKI in blacks are needed.

SA-PO015

Risk Factors for Community-Acquired AKI in Patients with and without CKD and Impact of Its Initial Management on Prognosis: A Prospective Observational Study Patrick Saudan,[3] Fabien Stucker,[1] Thomas Perneger,[2] Cyrielle Alves,[3] Pierre-Yves F. Martin.[3] *[1]Nephrology Unit, Hôpital de la Providence, Neuchatel, Switzerland; [2]Department of Clinical Epidemiology, Geneva University Hospitals, Geneva, Switzerland; [3]Department of Nephrology, Geneva University Hospitals, Geneva, Switzerland.*

Background: We aimed to describe clinical characteristics of patients with community-acquired acute kidney injury (CA-AKI), the effectiveness of initial management of CA-AKI, its prognosis and the impact of medication on its occurrence in patients with previous chronic kidney disease (CKD).

Methods: We conducted a prospective observational study within the Emergency Department (ED) of a University Hospital including any patient > 16 years admitted with an eGFR < 60 ml/mn/1.73m^2. With the help of a computer-based database, we identified daily the patients admitted with an eGFR < 60ml/mn/1.73m2 and a panel of nephrologists reviewed the files to assess the presence of AKI. We then analysed the clinical and demographic characteristics of the patients, the use of medications, and the adequate management of CA-AKI within the ED. The files were reviewed in the subsequent days and at one and three-years and mortality, renal recovery and renal function decline were analyzed.

Results: From May 1st to June 21st 2013, there were 8464 admissions in the ED, of which 653 had an eGFR < 60 ml/mn/1.73m^2. Of these, 352 had previous CKD, 341 had CA-AKI, and 104 had superimposed CA-AKI on CKD. Occurrence of superimposed CA-AKI in CKD patients was associated with male gender and with use of diuretics, but not with use of ARBs or ACEIs. Adequate management of CA-AKI defined as identification, diagnostic procedures and therapeutic intervention within 24 hours, was recorded in 45% of the cases and was not associated with improved outcomes. Three-year mortality was 21 and 48 % in CKD patients, respectively, without or with CA-AKI, and 40 % in patients with only CA-AKI ($p<0.001$). Mortality was significantly associated with age, hypertension, ischemic heart disease and CA-AKI. Progression of renal insufficiency was associated with male gender and age.

Conclusions: CA-AKI is more frequently encountered in male patients and those treated with diuretics and is an independent risk factor for long-term mortality. Its initial adequate management failed to improve outcomes.

SA-PO016

Furosemide Stress Test and Renal Angina Index for the Prediction of AKI Rolando Claure-Del Granado,[1,2] Yamile Serrano-Pinto,[2] Daniela Torrico-Guillen.[2] *[1]Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [2]Hospital Obrero #2 - C.N.S., Cochabamba, Bolivia, Plurinational State of.*

Background: In recent years several approaches for identifying patients at risk of acute kidney injury (AKI) were used; among them two have been of increasing interest: the Furosemide Stress Test (FST) and the Renal Angina Index (RAI). These two different approaches aim to identify patients at risk for subsequent AKI, and also have been used for the prediction of AKI severity. We assessed the performance of these two different approaches to identify patients at risk of AKI in an ongoing cohort of adult critically ill patients.

Methods: We analyzed data from 58 hospitalized patients admitted to a Medical ICU. We measured serum creatinine (sCr) every 24 hours for 7 consecutive days following ICU admission, and urinary volume was assessed hourly each 24 hours. At admission (day 0), **RAI (1-40)** was calculated using the following formula: **Risk level** (presence of sepsis = 1 point, presence of diabetes = 3 points, and vasopressors and use of invasive mechanical ventilation = 5 points) *x* **Injury level** (changes in eGFR: no change = 1 point, 0-24.9% = 2 points, 25-50% = 4 points, ≥ 50% = 8 points); and we applied the **FST** at day 0 (as describe by Chawla et. al. in Crit Care 2013 Sep 20; 17(5): R207). We assessed the performance of the FST and the RAI to predict the subsequent development of AKI using KDIGO sCr and urinary volume criteria.

Results: Of the 58 patients included in this study, 5 (8.6%) patients met the primary end point of AKI (sCr KDIGO criteria) and 4 (6.8%) using urinary volume KDIGO criteria. The performance of **Furosemide Stress Test** and the **Renal Angina Index** are shown on figure 1. Of note, we consider a cut-off point of <725 cc of urine at 2 hours for **Furosemide Stress Test** since none of the patients who developed AKI had <200 cc of urine at 2 hours as the original cut-off proposed value.

Conclusions: The Furosemide Stress Test and the Renal Angina Index have robust predictive capacity to identify critically ill patients at high risk of developing AKI before a rise in sCr occurs. These preliminary data of our ongoing study warrants future studies to validate these findings.

Performance	Furosemide Stress Test	Renal Angina Index
Sensitivity (%)	100	100
Specificity (%)	79.2	96.2
PPV (%)	31.2	71.4
NPV (%)	100	100
ROC-AUC (*p* value)	0.909 (0.003)	1.00 (< 0.001)

Incidence and Costs of AKI in Hospitalized Patients with Infective Endocarditis Katherine M. Donaldson,[1] Mark Rudy,[1] Daniel E. Cleland,[1] Gaixin Du,[4] Moises A. Huaman,[3] Alice Thornton,[1] Laura Fanucchi,[1] Javier A. Neyra.[2] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY; [3]University of Cincinnati, Cincinnati, OH; [4]UKY, Lexington, KY.*

Background: Acute kidney injury (AKI) is a frequent complication of hospitalized patients with infective endocarditis (IE) and carries adverse outcome. We examined the incidence, costs and characteristics associated with AKI in hospitalized patients with IE.

Methods: Retrospective cohort study of patients with IE admitted to UK hospital from 1/2013 to 12/2015. IE was defined by the modified Duke criteria. AKI was defined by the serum creatinine-KDIGO criteria. Patients with end-stage renal disease, kidney transplant, or baseline eGFR<15 were excluded. Multivariable logistic regression analysis of AKI as the dependent variable was used.

Results: 297 patients were included in the analysis. Of these, 40.4% were women and 94.9% were white. Mean age (SD) was 45.2 (16.3) years. AKI occurred in 186 (66.0%) patients: 54 (29.0%) developed AKI within the first 72 h and 132 (71.0%) after 72 h of admission. AKI was more common in women than in men (70.8% vs 57.0%, $p=0.016$). Hospital mortality in patients with AKI was 18.8% vs 14.4% in those without AKI, $p=0.33$. Patients who developed AKI had a longer hospital stay: median (IQR) 30 (15–47) vs 9 (5–18) days, $p<0.001$. AKI occurred more often in patients of poor socioeconomic status, with a diagnosis of hepatitis B and C or bacteremia, with exposure to aminoglycosides or diuretics and with a history of recurrent IE (all $p<0.01$). The median total direct cost of hospitalization in those with AKI vs without AKI was $51,488 (23,325–73,985) vs $14,801 (6,722–31,910), $p<0.001$. Female gender (OR 1.77, 95% CI 1.03–3.07), hepatitis C diagnosis (OR 1.98, 1.15–3.41) and comorbidity risk of mortality score=4 (OR 4.51, 2.64-7.69) were independently associated with incident AKI.

Conclusions: Two out of three hospitalized patients with IE develop AKI. Most episodes of AKI occurred after 72 h of hospital admission. Patients with AKI had a longer

hospital stay, incurring higher total direct costs. Female gender, hepatitis C diagnosis and risk of mortality score=4 were independently associated with the occurrence of AKI in this susceptible population.

SA-PO018

AKI Associated with Antibiotic Exposure in Critically Ill Children Emily L. Joyce,[1,2] Priyanka Priyanka,[1] John A. Kellum.[1] *[1]The University of Pittsburgh, Pittsburgh, PA; [2]Children's Hospital of Pittsburgh, Pittsburgh, PA. Group/Team: Critical Care Nephrology, CRISMA.*

Background: Acute kidney injury (AKI) is associated with adverse outcomes including prolonged hospital stay, increased healthcare costs, and delay in other organ recovery as well as development of chronic kidney disease. It is unclear which medications are associated with increased risk of AKI in pediatric critically ill patients.

Methods: Data was obtained from a convenience sample taken from the Pediatric HiDenIC database which contains > 12,000 critically ill patient records from the Children's Hospital of Pittsburgh between 2010 and 2014. Patients were categorized regarding exposure to any antibiotic within the first 24 hours of ICU admission with subsequent development of AKI using KDIGO staging.

Results: Out of 2890 critically ill pediatric patient encounters, 18% developed stage 2 or 3 AKI within the first week of admission to the ICU. Those who developed AKI had a longer ICU length of stay (p<0.001), longer hospital length of stay (p<0.01) and higher mortality rate (p<0.001). Within the cohort, 2254 patient encounters (78%) were exposed to any antibiotic within the first 24 hours of ICU admission. On univariate analysis, exposure to antibiotics including cefepime (OR 1.59, n=225, p<0.01), linezolid (OR 3.99, n=28, p<0.001), piperacillin/tazobactam (OR 2.04, n=546, p<0.001), and vancomycin (OR 1.45, n=1028, p<0.001) was associated with increased odds of developing AKI.

Conclusions: AKI is prevalent in critically ill children and associated with poor outcomes. Antibiotic use in this population is common and is associated with increased risk for development of AKI.

Funding: NIDDK Support

Direct-Acting Oral Antiviral Therapy in the Treatment of Chronic Hepatitis C Is Associated with an Interim Increase in Serum Creatinine Levels Avinash G. Adiga,[2] Praveen Ratanasrimetha.[1] *[1]Texas Tech University, Lubbock, TX; [2]Texas Tech University Health Sciences Center, LUBBOCK, TX.*

Background: The introduction of newer all-oral, direct-acting antiviral therapy in place of traditional interferon-based therapy has revolutionized the management of CHC infection. The aims of our study are to evaluate i) Renal adverse effects related to all oral direct- acting, antiviral therapy for hepatitis C ii) relationship between changes in viral load and renal function tests in chronic hepatitis C patients.

Methods: A retrospective study involving 164 patients with chronic hepatitis C infection followed up in outpatient clinics between October 1, 2014, and September 30, 2015. Ninety- five patients who received antiviral therapy were included as cases and sixty-nine patients who did not receive treatment were included as controls. Creatinine levels of cases were noted at four- time points: pre-treatment, at four weeks, at the end of treatment (3 months), and at 12-week post-treatment (6 months) and at the similar time frame for controls. Patients with CKD stage 3 or more and patients with missing values were excluded.

Results: The rate of kidney disease in our study population is 8.7%. Baseline creatinine in the studied population was 0.92mg/dl. Viral clearance was seen in 98.9% of patients, who received the treatment. At the end of treatment, higher creatinine levels were seen in the treatment group than the control group. However, no significant differences in creatinine levels were seen at 6 months. When compared to baseline statistically significant increase in creatinine levels were seen at 3 months and 6 months were seen in both groups.

Conclusions: Serum creatinine levels are higher at the end of treatment in patients receiving anti-viral therapy when compared to controls. This difference tends to cease with further time duration. A decrease in the hepatitis C viral load is not associated with a concurrent decrease in creatinine levels.

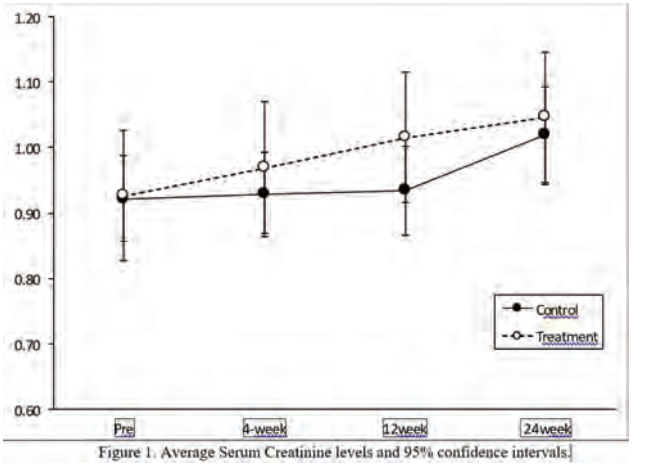

Figure 1. Average Serum Creatinine levels and 95% confidence intervals.

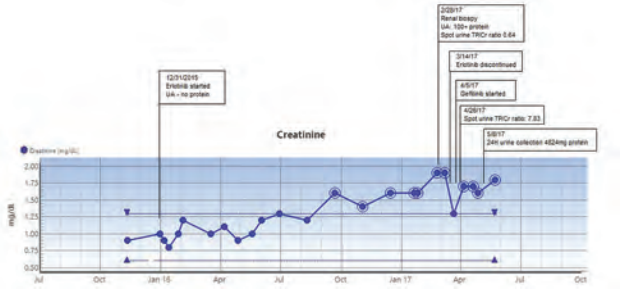
Reversible AKI from Erlotinib Due to Glomerular Endotheliosis Sheron Latcha,[1,3] Victoria Gutgarts,[3] Surya V. Seshan.[2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medical Center, New York, NY; [3]Medical College, Weill Cornell, New York, NY.*

Background: Erlotinib is an oral epidermal growth factor receptor associated tyrosine kinase inhibitor approved for the treatment of metastatic non small cell lung (NSCLC) with exon 19 deletions or L858R substitution mutations. Renal toxicity is rare with one report of crescenteric glomerulonephritis.

Methods: A 67 year old female with metastatic lung adenocarcinoma (+EGFR L858R) was sent for renal evaluation for AKI. At start of erlotinib, creatinine (SCr) was 0.9mg/dl and UA showed no proteinuria. Thereafter, the SCr increased. At evaluation, blood pressure (BP) was 146/72 (no change from baseline), no edema was present, UA showed 100+ protein and spot urine total protein creatinine ratio was 0.64. Renal biopsy showed diffuse glomerular endothelial injury, global glomerulosclerosis (16/44 glomeruli), mild to moderate acute tubular injury, moderate widespread tubular atrophy, severe arterio and arteriolosclerosis and extensive arteriolar intimal hyalinosis. No proliferative or immune complex glomerular lesions were seen. The foot processes were partially effaced. Her disease had been well controlled on erlotinib so it was continued at a reduced dose. Subsequently it stopped for increases in SCr. After stopping erlotinib, the SCr decreased to 1.3mg/dl. Because of previously good response to an EGFR TKI, gefitinib was started. Subsequently, an increased SCr, proteinuria and BP were noted. At last followup on gefitinib, the BP was 167/83, no edema was present, SCr was 1.8mg/dl, a 24H urine collection showed 4.8gms of protein and there was no progression of disease on CAT scan.

Results:

Conclusions: Erlotinib treatment was associated with mild proteinuria and reversible AKI. The renal biopsy was consistent with glomerular endothelial injury which may be consistent with a mild form of thrombotic microangiopathy. The presence of significant arteriolar intimal hyalinosis may represent healed endothelial injury. The recurrence of AKI and worsening proteinuria with gefitinib may indicate that this is a "class effect" of EGFR TKIs.



SA-PO021

Carfilzomib Treatment and AKI in Patients with Multiple Myeloma Marianne Camargo,[2] Kinsuk Chauhan,[1] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Nephrology, Mount Sinai Hospital, New York, NY.*

Background: Carfilzomib is a selective proteasome inhibitor approved for the treatment of relapsed and refractory multiple myeloma in patients who have been previously treated with at least two other agents. Initial clinical studies reported renal injury in 25-33% of patients treated, yet clinical trials reported the incidence of acute

kidney injury (AKI) between 4-8% when compared to other anti-myeloma agents. Our objective was to evaluate the real-world incidence and severity of AKI that is presumed due to carfilzomib treatment.

Methods: Electronic medical record (EMR) data was extracted from patients who received carfilzomib between 1/2012 and 12/2016 at a major academic medical center. Data included baseline demographics, medical history, and laboratory results including baseline creatinine and follow-up values during the course of treatment. AKI was defined as rise in creatinine by 0.3mg/dl or by 1.5 times increase from baseline. To estimate the incidence of AKI, a Poisson regression was used, adjusting for age, gender, kappa-lambda ratio, adjusted serum calcium, and history of hypertension, heart failure, and chronic kidney disease.

Results: Out of 429 patients identified between 1/2012-12/2017, 86 patients had received more than one dose of carfilzomib and had complete data. The average age was 65 years old, 42% women, 51% White. Forty-one percent of patients had at least one event of AKI. AKI was more common in women (IRR 2.2, 95% CI 1.7-2.8, p<0.01), older age (IRR 1.02 for each year of age, 95% CI 1.01-1.03 p<0.01), and African Americans (IRR 4.75, 95% CI 3.05-7.39, p<0.01).

Conclusions: Carfilzomib is a third line therapeutic agent for patients with refractory/relapsed multiple myeloma. Our analysis showed higher incidence of AKI events when compared to previous trials. Further studies are needed to clarify the epidemiology and risk factors for AKI in this population.

SA-PO022

Weighting the AKI Risk of Individual Nephrotoxins Karyn Yonekawa,[1] Chuan Zhou.[2] [1]*Seattle Children's Hospital/UW, Seattle, WA;* [2]*Seattle Children's Research Institute, Seattle, WA.*

Background: Seattle Children's Hospital's AKI surveillance system monitors the use of medications suspected to be nephrotoxic and for nephrotoxin-related AKI. An alert to the prescriber is triggered when ≥3 nephrotoxins are ordered. Our current system's sensitivity is 32% in detecting nephrotoxin-related AKI. To improve surveillance, we aimed to determine an individual risk weight for each nephrotoxin and develop a new alert system based on a scoring rule rather than on the number of nephrotoxins prescribed.

Methods: Nephrotoxin orders and AKI alert information (n=23,744) for 2 years (2013-2015) from a large tertiary-care children's hospital were analyzed. A risk weight was constructed for each nephrotoxin using the estimated probability of AKI when the nephrotoxin was present (either alone or in combination with other nephrotoxins). Nephrotoxic medication orders were scored by totaling the constructed risk weights of the individual nephrotoxins. We conducted ROC analysis on the final scores to determine alert thresholds and assess sensitivity and specificity.

Results: Using a total score threshold of 16 to trigger an alert, our model system's sensitivity and specificity was 70% and 80%, respectively. A total score threshold of 14 delivered a sensitivity of 83% and a specificity of 75%.

Conclusions: A surveillance system using individual risk weights for nephrotoxins and a scoring rule delivers improved nephrotoxin-related AKI detection. Additional work is needed to expand our analysis beyond the original list of suspected nephrotoxins to include other medications frequently prescribed in patients who are at risk for AKI.

Association between Statin Therapy and Occurrence of AKI in Patients with Peripheral Artery Diseases Daisuke Kanai,[1,2] Kentaro Nakai,[2,3] Hideki Fujii,[3] Shinichi Nishi.[3] [1]*Department of Internal Medicine, Nishiwaki Municipal Hospital, Nishiwaki, Japan;* [2]*Division of Nephrology, Kakogawa Central City Hospital, Kakogawa, Japan;* [3]*Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Acute kidney injury (AKI) is an important clinical problem in diagnosis and treatment of cardiovascular diseases. Though may studies have reported that statin therapy before coronary angiography and/or intervention significantly decreased the occurrence of AKI, the association between pretreatment by statin and occurrence of AKI in patients with peripheral arterial diseases (PAD) remains unclear. Therefore, we researched the association between statin therapy and occurrence of AKI in patients with PAD.

Methods: We retrospectively analyzed data from the endovascular treatment (EVT) database in our hospital. The angiography and/or intervention for PAD were performed for 377 patients between October 2011 and March 2016. Sixty nine hemodialysis patients and 13 patients without sufficient data were excluded from a present study. Remaining 295 patients were enrolled and divided into the two groups; those without statin (control group; N=157) and those with statin (statin group; N=138) for at least one months before admission. AKI was defined by absolute increase in serum creatinine (SCr) of ≥0.5 mg/dl or a relative increase of ≥25% measured 1week after procedure.

Results: Before procedure, sex, SCr, amount of contrast medium, use of renin angiotensin system inhibitor, smoking and blood pressure were similar in both group. The statin group has significantly younger patients, more diabetes patients, higher body mass index (BMI) and lower low density lipoprotein-cholesterol (LDL-C) (100±32 mg/dL vs 108±31 mg/dL) than the control group. As for occurrence of AKI, there was significantly lower incidence in the statin group compared to the control group (5% vs 16%, p<0.05). We performed a multivariate analysis adjusted for age, BMI, diabetes mellitus, LDL-C, SCr and statin therapy. The result of multivariate analysis showed that statin therapy was significantly correlated with the lower occurrence of AKI (p<0.05).

Conclusions: The results of our study suggested that statin therapy may prevent the occurrence of AKI after angiography and/or intervention for PAD.

SA-PO024

Hydration Protocols with Cisplatin: Need for Consensus and Cost Curtailment Sandhya Manohar, Wonngarm Kittanamongkolchai, Jennifer Mcdonald, Jeffrey A. Betcher, Heidi D. Finnes, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Background: Platinum based drugs use is often restricted due to the high risk of nephrotoxicity. The incidence of nephrotoxicity for Cisplatin is reported to be 25-30%. Many nephroprotective measures have been studied with hydration being the most commonly used. We sought to compare the incidence of Acute Kidney injury (AKI) at two large tertiary referral centers that use different nephroprotective protocols

Methods: We retrospectively reviewed all adult patients that received first dose of Cisplatin at Mayo Clinic Rochester (MCR) and Arizona (MCA) from 2010-2015 and had at least one creatinine value 7 days before and 72 hours after the drug administration. MCR utilizes a limited dose dependent hydration fluid with mannitol in the bag containing Cisplatin whereas MCA uses a liberal 1 liter pre- and post-hydration without mannitol.

Results: Out of the 2188 patients that had received Cisplatin at the 2 centers, only 191 patients met the inclusion criteria. Among them the overall incidence of AKI was 9.4% (18/191) with MCR having 10% (11/110) and MCA 8.6% (7/81) and the difference was not statistically significant. Only one patient had AKIN Stage 2 AKI and the rest were AKIN Stage 1. The average dose of Cisplatin received was higher in MCA (85.5 mg vs 74.9 mg) which was statistically significant (p 0.05). The average dose of fluids was 1316.7 ml (SD 615) in the 2 cohorts. There was no significant difference in the age, gender, history of chronic kidney disease, diabetes, hypertension, baseline creatinine, 30 day hospitalization and time to death after initiating chemotherapy among the two cohorts.

Conclusions: Our study showed that despite the marked differences in the nephroprotective protocols used at each of the center there was no difference in the AKI rate. In this time when the need for cost effective medicine is paramount we must try to be judicious in the drugs we use. We have since converged our Cisplatin hydration protocol, to be dose directed and without routine mannitol use, across the Mayo Clinic enterprise.

SA-PO025

The Risk of Contrast Induced AKI Is Still Present Despite Normal Renal Function Jasarat Chowdhury, Seema Jain, Masud Khan, Jasmine B. Lee. *Acute Medicine, Lewisham and Greenwich NHS Trust, London, United Kingdom.*

Background: Iodinated contrast CT studies are a common investigation for patients admitted to hospital. Contrast induced AKI (CI-AKI) is quoted to be the third most common contributor to in hospital AKI with patients with pre-existing CKD, cardiac dysfunction, diabetes and hypertension most at risk. However these studies were done before newer, low osmolality contrast media was common practise. This study investigates the incidence of contrast induced AKI (CI-AKI) in patients admitted to a UK district general hospital who underwent contrast CT studies.

Methods: All patients who had contrast CT studies over a 2 week period in November 2016 were included in the study. For these studies, 50-100ml of non-ionic, low osmolar contrast agent was injected. CI-AKI was defined using the KDIGO classification for AKI.

Results: 92 patients had contrast CT studies over the time period. Of these patients, 13% had pre-existing CKD, 11% had cardiac dysfunction, 15% had Diabetes and 36% had Hypertension. 5% of patient developed CI-AKI. 4% had stage 1 and 1% had stage 2, no patients had stage 3. However of the 5 patients who developed CI-AKI, none had pre-existing CKD or cardiac dysfunction, 1 had diabetes and 2 had hypertension.

Conclusions: The incidence of CI-AKI in our cohort was lower and less severe than quoted in previous studies which may be due to the lower osmolality contrast agent used. However, despite risk factors being present in this cohort, none of the patients who developed CI-AKI had pre-existing CKD which is thought to be the most significant risk factor and therefore features most highly in CI-AKI prevention guidelines. This study suggests that guidance given to prevent CI-AKI should be followed in all patients irrespective of pre-existing risk factors and that having existing CKD should not preclude a contrast study if necessary.

SA-PO026

Risk Factors for Polymyxin-Induced AKI in Critically Ill Patients Cassiane D. da Fonseca,[4,6] Mirian Watanabe,[6] Maria De Fatima Vattimo,[1] Sheila M. Fernandes,[4] Luciana soares C. Santos,[5] Filipe U. Coelho,[3] Natalia A. Oliveira.[2] *[1]Sao Paulo, Brazil; [2]Organization University of São Paulo, São Paulo, Brazil; [3]University of São Paulo, São paulo, Brazil; [4]School of Nursing, University of São Paulo, Carapicuíba, Brazil; [5]Universidade de São Paulo, SÃO PAULO, Brazil; [6]University of Sao Paulo, Sao Paulo, Brazil. Group/Team: Research Group on Acute Kidney Injury-GERA.*

Background: Critically ill patients with infections and sepsis frequently need robust antimicrobial agents, such as polymyxins (Pmxs), for efficacy against multi-resistant gram-negative bacteria. However, acute kidney injury (AKI) may be the most important limiting adverse effect of Pmxs. This study evaluated the incidence and identified the risk factors for the development of AKI in critically patients receiving Pmxs.

Methods: A multicenter retrospective cohort study enrolling 1009 intensive care patients Wwas performed. AKI was defined by KDIGO criteria. Primary outcome was patients who received Pmxs and developed AKI. The main secundary outcomes were clinical risk factors for Pmxs-induced AKI. Multivariate analyses with logistic regression were performed.

Results: A total of 936 patients were included. AKI was detected in 404 (43%) patients. Mean age was 59.1 ± 17.0 years, 63% were male. Systemic arterial hypertension (45%), Diabetes Mellitus (26%), sepsis (22%) and shock state (57%) were observed in AKI individuals. The mortality was 37% for AKI patients (P<0.001). Among 75 patients treated with Pmxs, rate of AKI was 88%. The risk factor of AKI associated with Pmxs were prolonged hospital stay, mechanical ventilation and shock state (P<0.001).

Conclusions: This data highligted that the rate of Pmx-induced AKI was greather than other studies. Critically ill patients are at higher risk due to the presence of prolonged hospital stay, mechanical ventilation and shock state.

Funding: Government Support - Non-U.S.

Risk factor of AKI associated polymyxins use

Variable	OR (IC 95%)	p value
Age	0.05 (0.9-1.0)	0.059
Shock	4.91 (1.6-14.8)	0.005
Vasoactive drug	0.59 (0.2-1.3)	0.212
Mechanical ventilation	1.07 (1.0-1.1)	<0.001
Clinical hospitalization	1.39 (0.7-2.7)	0.337
ICU hospital stay	1.09 (1.0-1.1)	<0.001

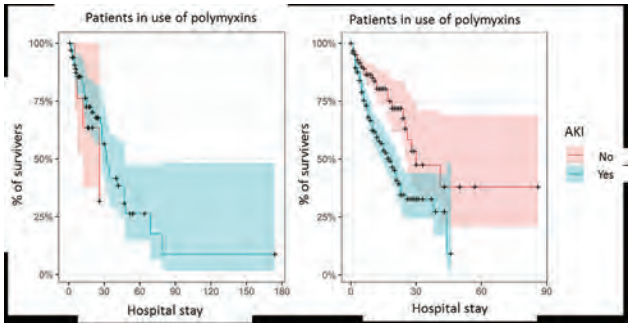

Figure 1. Survivel curve of patients in use of polymyxins.

Vancomycin-Associated AKI with a Steep Rise in Serum Creatinine Juan Carlos Q. Velez,[4] Ndidiamaka O. Obadan,[2] Mohammed Alzubaidi,[2] Bhavna Bhasin,[1] John M. Arthur,[5] Gautam M. Phadke.[3] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Medical University of South Carolina, Charleston, SC; [3]University of North Dakota School of Medicine, Fargo, ND; [4]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [5]University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: The incidence of vancomycin-associated (VA) acute kidney injury (AKI) has increased after the Infectious Diseases Society of America updated their recommendations for higher therapeutic trough levels for methicillin-resistant *Staphylococcus aureus* infections. However, distinct laboratorial features of VA-AKI have not been described.

Methods: We defined precipitous AKI as a case with an increase in serum creatinine (sCr) ≥ 1.5 mg/dL/day. After encountering 2 cases of adults with VA-AKI presenting with an unusually steep rise in sCr, we probed for similar cases by surveying nephrologists at the American Society of Nephrology Communities online forum and by searching for published cases of VA-AKI via PubMed or Google to extract those with criterion for precipitous AKI. We also collected daily sCr values of consecutive AKI cases not associated with vancomycin exposure as a control group (non-VA-AKI).

Results: Seven original cases of VA-AKI characterized by an abrupt and exceedingly large rise in sCr shortly after a cumulative dose of vancomycin of ≥ 5 g given over 1 - 4 days were compiled from 4 different medical centers (mean age 41.6 years, 43% women, 57% black, mean body mass index 32 kg/m^2). In 3 cases, simultaneously obtained serum cystatin C (sCy) values did not reveal relative steep increments from the upper limit of normal (mean: 2.6 vs. 0.5 mg/dL, for sCr and sCy, respectively), suggesting that the reductions in glomerular filtration rate were overestimated by the sCr increase. In addition, we extracted 4 published cases of precipitous AKI due to vancomycin. The median initial 24-hour rise in sCr in all 11 VA-AKI cases compiled was 2.5 mg/dL (range 1.4 – 3.5 mg/dL). The slope of the initial 48-hour sCr rise of the VA-AKI (n = 11) cases was greater than that of non-VA-AKI (n = 44) cases [2.01 (CI: 1.6-2.4) vs 0.61 (CI: 0.5-0.7) mg/dL/day; p<0.0001]. A concomitant steep rise in blood urea nitrogen was not observed in these VA-AKI cases.

Conclusions: VA-AKI can occasionally manifest with a precipitous rise in sCr after a high cumulative dose of vancomycin. True toxic tubular injury overrepresented by the sCr rise is possibly present in these cases. Whether interference of vancomycin with tubular secretion of creatinine explains the phenomenon requires further study.

SA-PO028

Colistimethate Sodium and AKI: Incidence, Evolution, Risk Factors, and Prognosis Saul Pampa-Saico. *Hospital Ramon y Cajal, MADRID, Spain.*

Background: Colistimethate sodium (CMS) treatment has increased in the last years due to exponential increase in multidrug-resistant bacterial infections with the risk of CMS nephrotoxicity. The aim of this study was to determine the incidence and risk factors of AKI attributable to CMS based on KDIGO criteria. To identify prognostic factors which conditioning kidney function outcome at six months of follow-up.

Methods: Retrospective observational study, including patients >18 years old admitted from January 2007 to December 2013 who received CMS for > 48hours. Demographic, clinical and biochemical parameters of prognostic interest were collected. A multivariate logistic regression analysis was used to identify the risk factors associated with the development of AKI. To evaluate the renal function outcomes at 6 months after discharge (by eGFR (MDRD-4)) were analyzed by multivariate lineal regression. Unfavorable kidney evolution at six months was defined as residual impairment of kidney function indicated by a eGFR less than 60 ml/min/m2 or a reduction of creatinine clearance >25% at 3 months in comparison with baseline

Results: 126 patients (mean age 64.4±14 years) were included in the study; 61 patients developed AKI (48%). Independent predictors of AKI were the infection grade: severe sepsis (OR 3.1; p=0.026); septic shock (OR 11.9; p=0.0004), intravenous iodinated contrast media (OR 2.9; p=0.024) and serum creatinine at hospital admission (OR 2.9, p=0.031). Eighty-four patients (67%) survived at discharge. Independent predictors of decline in renal function after 6 months were eGFR at hospital admission (p=0.016) and hospital discharge (p=0.0004) (R^2_c = 0.823). 56% (34/61) patients who developed AKI during admission survived, 32% of them (11/34) had an unfavorable kidney outcome at 6 months, the main determinants were eGFR at hospital admission (p=0.023), at the start CMS (p=0.002) and at hospital discharge (p=0.0003).

Conclusions: The development of AKI associated with CMS treatment was correlated with the infection grade, intravenous iodinated contrast and serum creatinine at hospital admission. Neither doses nor length of therapy with CMS were associated with AKI. The eGFR levels at hospital admission and hospital discharge were independently factors associated with renal function outcome at six months. These predictors may assist in clinical decision making for this patient population.

SA-PO029

Angiotensin 2 Receptor Blocker (ARB) and Angiotensin Converting Enzyme-Inhibitor (ACE) Therapy Indications and Risks in Patients Who Develop an AKI During Hospital Admission Toby Humphrey, Oshini Shivakumar, Kate Berresford, Clare Morlidge, Andrew Findlay, Suresh Mathavakkannan. *East and North Hertfordshire NHS Trust, Stevenage, United Kingdom.*

Background: ACE/ARB are the second most prescribed medicine from primary care in England. Despite an aged and co-morbid population prescription of ACE/ARB is increasing. There are defined benefits for patients on ACE/ARB in certain clinical situations but there is concern in frail, elderly patients at risk of AKI. We sought to review the indications and risk factors for ACE/ARB use in patients (prescribed ACE/ARB in the community) who developed AKI during admission to a 700 bed secondary care hospital.

Methods: Adult elective and non-elective patients who developed AKI during an admission episode in February to April 2016 were identified by electronic AKI alert. 311 AKI events were reviewed by an AKI specialist nurse over this time period. Demographic details and medications including ACE/ARB were documented. All AKI patients admitted on ACE/ARB therapy had retrospective searches of their co-morbidities and indications for ACE/ARB therapy on electronic patient record and pathology database.

Results: 311 AKI events were reviewed by the AKI nurse between February - April 2016. 102 /311 (32.8%) of those patients had been prescribed ACE/ARB therapy up until admission. Of those 102 patients (M:F, 52:50), the mean age was 81.44 years, median age adjusted Charlson Co-Morbidity score was 6. 65 patients (63.73%) had a prior history of AKI whilst only 38 patients (37.25%) had a diagnosis of type 2 Diabetes, 24 (23.53%) had heart failure diagnosed by echocardiogram, 17 patients (16.67%) had documented proteinuria prior to admisison, 34 (33.33%) had a prior history of ischaemic heart disease. 13 patients (12.75%) had a diagnosis of cancer and 24 (23.53%) had a diagnosis of dementia.

Conclusions: Our data indicates patients on ACE/ARB therapy who develop an AKI during hospital episode are frequently elderly and co-morbid with a high likelihood of previous AKI. They frequently do not have good indications for ACE/ARB therapy with few diabetics, few diagnoses of cardiac failure, ischaemic heart disease and proteinuria. This data should be used to support further studies to identify elderly patient populations in the community prescribed ACE/ARB therapy who may benefit from rationalisation of their medication.

SA-PO030

Statins Can Offer Renal Protection in Patients with CKD or DM Afflicted with AKI Rabia Akhtar, Ghada Elshimy, Seme Tabassum, Chandra B. Chandran. *St Joseph Regional Medical Center/New York Medical College, Paterson, NJ.*

Background: Statins are some of the most commonly prescribed medications in the United States. Aside from the lipid-lowering effects, this class of medications may offer benefits to other organ systems and may play a role in preventing AKI through these pleiotropic effects. This has been studied most specifically in patients undergoing cardiac catheterization or cardiac surgery. Our study is unique in that it seeks to analyze whether the general population with CKD or diabetes not undergoing any cardiac surgery could also stand to benefit from statin therapy.

Methods: We conducted a chart review of 339 patients admitted to a major teaching hospital in New Jersey during the time period between 2000-2010 and had the diagnosis of AKI and then stratified patients as statin users and non-statin users. We aimed to study whether these groups had differences in their rates of recovery. A series of logistic regressions were conducted to investigate predictors of patients recovery. The predictors that were included in this analysis were race, HTN, DM, CKD, rhabdomyolysis, statin intensity, stage of CKD and mean HbA1c value.

Results: We found that in patients with normal kidney function, those who were on statins were not more likely to recover than patients not on statins ($p > .05$). However, among patients with chronic kidney disease, statins increased the odds that they would recover by a factor of 3.56 ($p < .05$). In addition, for patients with Diabetes Mellitus, statins increased the odds that a patient would recover by a factor of 3.81 ($p < .05$).

Conclusions: The results of our study show that statins may offer renal protection to patients with chronic kidney disease or diabetes and not just those undergoing cardiac catheterization or cardiac surgery. The results of our study also emphasize the need for further studies looking at statin use and outcomes in AKI. Further matched-analyses would be helpful to look at whether our results are reproducible.

SA-PO031

Oral Hydration to Prevent Contrast Induced Nephropathy Corinne E. Balemans,[1] Yvonne R. de Waal,[1] Marc A. Ten Dam,[2] Jack F. Wetzels.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Canisius Wilhelmina Hospital, Nijmegen, Netherlands.*

Background: Contrast Induced Nephropathy (CIN) complicates the use of iodinated contrast media. Guidelines advise intravenous hydration as preventive measure in high risk patients. However, i.v. hydration requires complicated logistics and is associated with high costs and adverse events (de Waal, ASN 2015). We showed in a small sized study that oral hydration might be as effective as i.v. hydration (Balemans, ASN 2015). We now report the efficacy of oral hydration in a large prospective cohort.

Methods: Two hospitals participated in the study. Between January 2015 and May 2017 high risk patients were screened and if eligible hydrated with sodiumchloride tablets 1g/10kg of body weight/day on day -2 and -1 before contrast exposure. Patients with eGFR <30ml/min/1.73m2, overt heart failure, Multiple Myeloma or an emergency procedure were excluded and hydrated intravenously with sodiumbicarbonate. We evaluated the incidence of CIN (defined as a rise in serum creatinine ≥25% or ≥44umol/L 48-96hrs after contrast injection) and adverse events.

Results: In the study period 927 radiological procedures were planned in high risk patients. 393 patients gave informed consent, 20 were lost to follow up, 10 CT scans were cancelled. We eventually evaluated 363 procedures, 99 patients were treated with iv hydration mainly because of heartfailure and eGFR < 30ml/min/1.73m2. 264 patients (30.7% female) received oral hydration, mean age 70.6±8.3 yrs, mean eGFR 44.1±7.1 ml/min/1.73m2. The incidence of CIN after oral hydration was 3.0% (95%CI 1.44-5.97). In a historical control group, treated with iv hydration the incidence of CIN was 2.4% (95%CI 1.61-3.65) (Balemans, Radiology 2012). The main adverse event in the oral hydration group was nausea, in one case leading to conversion to iv hydration. One case of overhydration was reported (0.4%) compared to 12/490 (2.4%) after i.v. hydration (de Waal, ASN 2015)

Conclusions: Oral hydration is as effective as intravenous hydration in preventing CIN and can be used safely. Oral hydration obviates the need for hospital admission, and thus reduces costs.

SA-PO032

Contrast-Nephropathy Following Intra-Arterial and Intravenous Contrast Administration in CKD Patients Pulkit Chaudhury,[3] Stacey Jolly,[2] Serge Harb,[3] Jesse D. Schold,[2] Susana Arrigain,[2] Victoria Konig,[2] Joseph V. Nally,[2] Sankar D. Navaneethan,[1] Georges Nakhoul.[3] *[1]Baylor College of Medicine, Houston, TX; [2]Cleveland Clinic, Cleveland, OH; [3]Cleveland Clinic Foundation, Cleveland Heights, OH.*

Background: Contrast-induced nephropathy (CIN) refers to acute kidney injury (AKI) that develops after administration of iodinated radiocontrast agents. It has been described following coronary intraarterial (IA) contrast administration. However, true risk of CIN after intravenous (IV) contrast administration is debated. Recent retrospective analyses have questioned any assocation between iodinated contrast and nephrotoxicity following IV administration. Here, we measure the risk of AKI and specifically CIN after IA and IV contrast administration in a high-risk population of hospitalized patients with CKD.

Methods: Pre-existing Cleveland Clinic CKD registry was used to conduct a propensity-matched analysis of patients getting inpatient left heart catheterization (LHC), contrast CT (CCT) and noncontrast CT (NCCT) scans between 2010 and 2015, with adequate creatinine measurements before and after scans. Propensity scores were developed using several variables including: age, gender, race, CKD stage, cardiovascular comorbidities, malignancy, hemoglobin and medications. One-to-one greedy matching with 0.1 caliper was used to match LHC patients to CCT and then to NCCT patients. Charts were independently reviewed to determine the etiology of the AKI. Chi-square tests were used to compare the proportion of AKI and CIN across matched groups.

Results: A total of 163 of 244 (67%) patients with LHC were matched to CCT and NCCT patietns. Patients had a mean age of 74 years with 55% males. The incidence of AKI was 25.8% in LHC, 21.5% in CCT and 22.7% in NCCT (P=0.64). The incidence of CIN was 20.2% LHC and 12.3% in CCT (P=0.05).

Conclusions: CIN can be observed following administration of both IA and IV contrast but is more frequently associated with administration of IA contrast. Although, the incidence of AKI was similar in the three groups, the distribution of AKI etiologies were significantly different as expected. Extrapolating the risk of CIN by comparing the incidence AKI in these fundamentally different populations, as has been recently published, should be done with caution.

Incidence of AKI and CIN after Contrast Media Administration

	Coronary Angiogram (n=163)	Contrast CT (n=163)	Non-Contrast CT (n=163)
All AKI	42 (25.8%)	35 (21.5%)	37 (22.7%)
CIN	33 (20.2%)	20 (12.3%)	0 (0%)

SA-PO033

Antithrombin III Is a Novel Predictor for Contrast Induced Nephropathy after Coronary Angiography: An Observational, Cross-Sectional Study Jianyong Yin, Feng Wang, Niansong Wang. *Department of Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Antithrombin III (AT-III) functions as an important endogenous anticoagulant and has powerful anti-inflammatory effects. Low AT-III activity is considered to be a predictor of poor outcomes in several conditions, including acute kidney injury after cardiac surgery. However, whether the AT-III levels are related to the incidence of contrast induced nephropathy(CIN) has not been identified yet.

Methods: A cross-sectional study on CIN after CAG was conducted to identify the potential predictive value of AT-III for CIN. A total of 460 patients who underwent coronary angiography(CAG) from January 2015 to December 2016 in coronary care units(CCU) were enrolled. CIN was diagnosed according to the KDIGO guideline. Plasma AT-III activity was measured before CAG and <75% was recognized as low activity according to reference values.

Results: Of 460 patients undergoing CAG, 125(27.17%) developed CIN. The incidence of CIN was significantly higher in patients with low AT-III activities than that in normal group (Pearson's chi-squared test P=0.002). Besides, with the decline of AT-III activity, the prevalence of CIN progressively rise, with the highest value(58.8%) in patients with AT-III activity<60%. Moreover, the AT-III activity was significantly lower in CIN patients than that in non-CIN ones(84.43±16.3% vs. 92.14±13.94%, P<0.001). After multivariable analysis, low AT-III activity remained a significant independent predictor of CIN(OR 2.207,95%CI[1.29-3.777];P=0.004) as well as baseline serum creatinine(OR 1.009,95%CI[1.001-1.016];P=0.026).

Conclusions: Patients with low AT-III activities presented a higher risk of developing CIN after CAG. And the initial AT-III activity may be an independent predictor for CIN.

SA-PO034

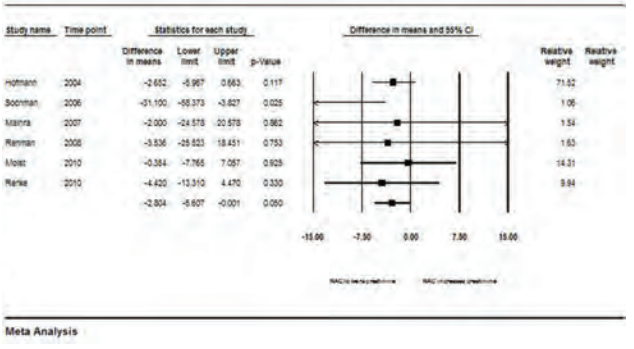
The Effect of N-Acetylcysteine on Serum Creatinine: A Systematic Review of the Evidence Johnny Huang, Ayub Akbari, Swapnil Hiremath. *University of Ottawa, Ottawa, ON, Canada.*

Background: Contrast-induced acute kidney injury (CI-AKI) is a major iatrogenic concern with contrast imaging procedures. N-acetylcysteine (NAC) has been tested in prevention of CI-AKI with conflicting reports of efficacy, and there has not been a good scientific explanation for this heterogeneity reported in the literature. Interference of NAC with serum creatinine measurement has been proposed to be one explanation, but the research on this topic has been discrepant. One possibility is that the interference may vary with the type of assay used to measure creatinine. **Objective:** What is the effect of NAC on serum creatinine, administered in the absence of any other confounding events (eg contrast administration, surgery)?

Methods: A systematic search was performed in MEDLINE, EMBASE, and Cochrane Library to identify studies with participants receiving NAC and before/after serum creatinine measurements, without confounding factors. Two authors independently screened the citations, and data of relevant articles was extracted for meta-analysis.

Results: The literature search produced 503 citations, of which 6 were eligible and included in the review. There is clinical heterogeneity in the studies in terms of study population (healthy volunteers, patients with normal and decreased kidney function), dose of NAC used and method of creatinine estimation. Overall, all studies did show a numerically lower creatinine after NAC administration, ranging from 0.35 to 31.1 µmol/L. The summary weighted mean difference was -2.8 µmol/L (95% CI -0.001, -5.6, p = 0.05). There was no statistical heterogeneity in the results.

Conclusions: Conclusion: There is a small decrease in serum creatinine with NAC administration, but, given the small sample sizes and clinical heterogeneity, a definitive study should be done to establish the true magnitude and nature of the effect.



SA-PO035

Effects of Fluid Resuscitation on Macro and Microcirculatory Perturbations in Ovine Septic Shock Yugeesh R. Lankadeva,[2] Junko Kosaka,[2] Naoya Iguchi,[2] Roger G. Evans,[3] Lindsea C. Booth,[2] Rinaldo Bellomo,[1] Clive N. May.[2] *[1]Austin Health, Melbourne, NSW, Australia; [2]Florey Institute of Neuroscience and Mental Health, Parkville, Victoria, NSW, Australia; [3]Monash University, Melbourne, NSW, Australia.*

Background: Aggressive fluid resuscitation, with multiple boluses of crystalloids remains the first-line intervention to maintain systemic hemodynamics in septic shock, but its effects on the renal microcirculation are unknown. We therefore examined the effects of three successive boluses of sodium lactate on intra-renal and urinary oxygenation (pO_2) in conscious sheep with established septic acute kidney injury (AKI).

Methods: Sheep were instrumented with fiber-optic probes in the renal cortex, medulla and within a bladder catheter. Sheep received an infusion of *Escherichia coli* or vehicle-saline for 30 hours. A 500-mL bolus of sodium lactate was infused intravenously every hour at 24, 25 and 26 h of sepsis (N=8) over 15 min time-intervals.

Results: Septic AKI was characterized by hypotension (80±2 to 68±2 mmHg) and reduced creatinine clearance (82±8 to 40±6 mL/min)) (both P<0.01). Medullary tissue pO_2 (43±4 to 19±4 mmHg) and urinary pO_2 (44±4 to 20±3 mmHg) were simultaneously reduced (both P<0.001). Infusion of crystalloids briefly increased blood pressure (to 74±6 mmHg), creatinine clearance (to 71±16 mL/min) and improved medullary pO_2 (to 35±4 mmHg) and urinary pO_2 (to 28±6 mmHg). These effects were short-lived and rapidly diminished within the 3-h recovery period. Sheep with septic AKI retained 70% of the total volume of crystalloids infused.

Conclusions: Infusion of three successive boluses of crystalloids briefly reversed renal medullary hypoxia and improved kidney function in septic AKI. However, the transient nature of these effects challenges the long-term benefits of aggressive volume resuscitation in septic shock. In septic AKI, excessive fluid retention may lead to increased cardiac filling pressures and tissue oedema. Urinary pO_2 may be a real-time surrogate marker of medullary tissue pO_2 during fluid resuscitation in septic AKI.

Funding: Government Support - Non-U.S.

SA-PO036

Long-Term Survival in Patients with Septic AKI Is Strongly Influenced by Renal Recovery Marco Fiorentino,[1,2] Fadi Tohme,[1,3] Shu Wang,[1,4] John A. Kellum.[1,3] *[1]Center for Critical Care Nephrology, CRISMA, Department of Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Department of Emergency and Organ Transplantation, Nephrology, Dialysis and Transplantation Unit, University of Bari, Bari, Italy; [3]Renal & Electrolyte Division, Department of Medicine, University of Pittsburgh, Pittsburgh, PA; [4]Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA.*

Background: Prior studies have found that long-term survival after critical illness is influenced by acute kidney injury (AKI) even in patients who appear to recover renal function. In the current report, we sought to examine the effects of septic AKI on longer-term survival as a function of recovery by discharge.

Methods: We analyzed patients with community-acquired pneumonia from a large multicenter cohort. Patients who developed AKI (KDIGO stages 2- 3) were included and renal recovery was defined as being alive at hospital discharge with return of SCr to within 150% of baseline without dialysis. Our primary outcome was survival up to 3 years analyzed using Kaplan-Meier and Gray's models.

Results: Stage 2-3 AKI occurred in 262/1742 (15%) patients of which 111 (42.4%) recovered. Patients without recovery were older (75±14 vs 69±15 years, p=0.001), and were more likely to have at least stage 1 AKI on day 1 (83% vs 52%, p<0.001). 11/262 (4%) patients developed ESRD by 1 year of follow-up. Mortality rates were 23.4% (347/1480) for no AKI, 28% (31/111) for AKI with recovery and 44.3% (67/151) for AKI without recovery. Non-recovery at hospital discharge was associated with lower survival compared to no AKI (p<0.001), while patients with recovery had similar survival compared to no AKI (p=0.2)(**Figure 1**). In a covariate-adjusted Gray's model, patients who did not recover had a greater hazard for mortality compared to no AKI (HR range 1.05–2.46, overall p=0.001), while recovering patients had similar risk for mortality compared to no AKI (HR range 0.6-0.28, overall p=0.43). Absence of AKI on day 1, no in-hospital RRT, higher Apache III score and higher baseline SCr were associated with recovery after AKI.

Conclusions: Recovery by hospital discharge is associated with improved long-term survival in patients with sepsis-associated AKI. Measures to enhance renal recovery by discharge might reverse the long-term adverse consequences of sepsis-associated AKI

SA-PO037

The Clinical Significance of Alkaline Phosphatase Activity in Patients with Septic AKI Seung don Baek. *Mediplex Sejong Hospital, Gyeyang-gu, INCHEON, Republic of Korea.*

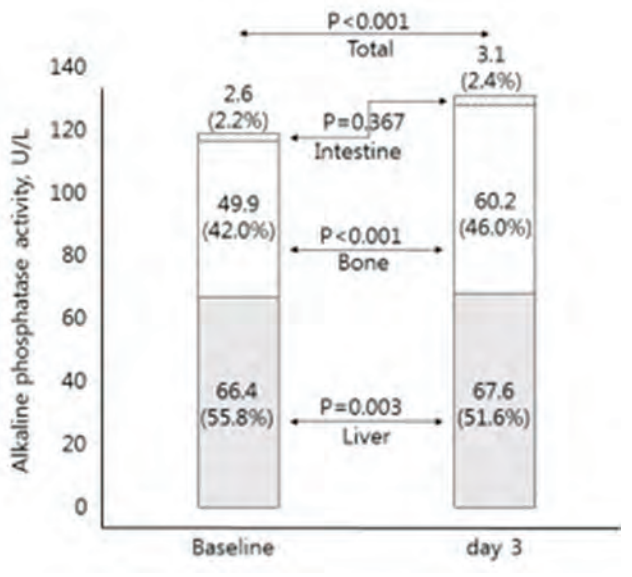
Background: Evidences suggested that alkaline phosphatase attenuate inflammatory response in sepsis by lipopolysaccharide detoxification and adenosine triphosphate dephosphorylation. We sought to determine alkaline phosphatase (AP) activity change during septic acute kidney injury (AKI) and clinical parameters associated with AP activity.

Methods: In a retrospective study of the patients who underwent continuous renal replacement therapy (CRRT) due to septic AKI, we investigated the baseline, follow-up AP activity on day 3 and the associated outcomes.

Results: We analyzed baseline AP activity of 155 patients and day 3 AP activity of 123 patients. Baseline AP activity of 90 (59–133) U/L increased to 105 (79–156) U/L on day 3, of which liver and bone isoforms increased significantly, but intestine isoforms did not reach statistical significance. Baseline AP activity did not show an association with renal and inflammatory biomarkers, or outcomes. Also, it did not differ significantly

between 75 survivors and 80 non-survivors (p=0.155). Day 3 AP activity increased in 70.6% of patients with mean difference of 19 (-3 to 53) U/L. Day 3 AP activity showed weak correlation with length of ICU stay (r=0.205, p=0.023) and length of hospital stay (r=0.190, p=0.036), however, not with survival (r=-0.035, p=0.698).

Conclusions: Endogenous AP activity modestly, but significantly increased in 70.6% of patients with septic AKI. However, neither baseline nor follow-up AP activity was associated with survival.



SA-PO038

Spanish Experience of Pregnancy-Associated Atypical Hemolytic Uremic Syndrome Ana Huerta,[5] Santiago Rodriguez de Cordoba,[4] Emilia Arjona,[1] Manuel Praga,[2] Jose M. Portoles.[3] *[1]Centro de Investigaciones Biologicas-CSIC, Madrid, Spain; [2]Hospital 12 de Octubre, Pozuelo De Alarcon, Spain; [3]Hospital Universitario Puerta de Hierro, Majadahonda, Spain; [4]Consejo Superior de Investigaciones Cientificas, Madrid, Spain; [5]Puerta de Hierro Hospital-Nephrology Department., Madrid, Spain. Group/Team: Spanish Group for Study of Complement and Renal Disease.*

Background: Pregnancy-associated atypical hemolytic uremic syndrome (P-aHUS) refers to the thrombotic microangiopathy that result from uncontrolled complement activation during pregnancy or the postpartum period. P-aHUS is a devastating disease for which we still have a limited clinical understanding and treatment experience. Here we report a retrospective study to analyze the clinical and prognostic data under different treatments of the cohort of P-aHUS patients from the Spanish aHUS Registry.

Methods: In the Spanish aHUS Registry we identified 242 adult female patients, of whom 22 fulfilled P-aHUS criteria. We performed a functional and genetic study of the complement system in all of them. We retrospectively collected the clinical, analytical, treatment and evolution characteristics of these patients. We present the data as median and interquartile range.

Results: The age of presentation was 34 years. It was the first pregnancy in 16 patients (73%). 73% of the cases occurred postpartum. Of these, 81% required cesarean section. 41% required acute hemodialysis. 19 patients associated hypertension, 7 neurological disorders, 4 gastrointestinal problems and 3 cardiac symtoms. A renal biopsy was performed in 11 patients: 10 presented MAT lesions and 3 an associated glomerulonephritis. Abnormalities in the complement system related genes were detected in only 41% of the cohort. 16 patients underwent plasma replacement, achieving haematologic response in 5 and renal response in 2. 3 patients received infusion treatment of fresh frozen plasma, with haematological response in 3 but renal response in 2. 10 of the 22 patients (45%) received treatment with Eculizumab, achieving haematological and renal response in 100% of them. 3 of the patients treated with Eculizumab required acute hemodialysis, but none of them required renal replacement therapy during follow-up.

Conclusions: P-aHUS seems to have similar characteristics than other types of aHUS. It seems to be an association between cesarean delivery and the development of P-aHUS. Treatment with Eculizumab was effective in 100% of our cohort. More studies are needed to confirm our findings.

SA-PO039

Obstetric AKI and Renal Outcomes Secondary to Pre-Eclampsia Frances I. Conti-Ramsden,[1] Hannah L. Nathan,[1] Annemarie De greeff,[2] Daniel W. Steyn,[3] David Hall,[4] Lucy C. Chappell,[1] Andrew H. Shennan,[1] Kate Bramham.[1] *[1]Kings College London, London, United Kingdom; [2]Accuracy Assessed Medical Devices CC, Diamond, South Africa; [3]Stellenbosch University, Parow, South Africa; [4]Stellenbosh University and Tygerberg Hospital, Cape Town, South Africa.*

Background: Introduction: Pre-eclampsia (PET) is a common cause of acute kidney injury (AKI) but AKI incidence, risk factors, maternal and renal outcomes in a middle-income setting are unknown. Objectives: To define the incidence of obstetric AKI in the CRADLE-II pre-eclampsia cohort, explore the association between maximal creatinine and maternal outcomes, and to identify the proportion of women with persistently elevated serum creatinine (Cr) before and after discharge.

Methods: A prospective observational study of women with PET at 3 centres in South Africa was conducted (Jan 2015-May 2016). Pre-specified outcomes were eclampsia, stroke, maximal Cr during admission ≥90 μmol/L (MaxCr90), maternal and perinatal death. Serial Cr (pre-pregnancy to May 2017) were subsequently extracted from national databases in all women with MaxCr90.

Results: 272/1547 (17.6%) of women had MaxCr90 (median 114, range 90-1097). Relative risk of death in women with MaxCr90 was 6.2 (95% CI 2.2,17.8). 236 (15.2%) women had AKI (KDIGO criteria; 123 (52.1%) Stage 1; 63 (26.7%) Stage 2; 50 (21.2%) Stage 3) with 188/236 (79.7%) cases occurring within 48hrs of admission. 138 women (58.5%) had AKI recovery at discharge (Cr returned to <1.5x baseline or <90 μmol/L if no baseline), 92 women (39.0%) did not have AKI recovery at discharge (Cr >1.5x baseline or >90 μmol/L if no baseline) and 6 (2.5%) women died. Serum Cr was repeated post discharge in 25 (27.1%) women without AKI recovery: 19 (76%) had AKI recovery; 6 (24%) no recovery. Overall, 96.3% (157/163) of women with repeat Cr assessment had AKI recovery but 3.7% (6/162) did not. Repeat Cr was not assessed in 67/92 (72.8%) women without AKI recovery at discharge.

Conclusions: Obstetric AKI was common in women with PET in this middle-income cohort. Maximal Cr ≥90 μmol/L was associated with a significantly increased risk of maternal death. Approximately two in five women had persistently raised serum Cr at discharge, which was not subsequently repeated in almost three quarters of these women. However, recovery from obstetric AKI in those assessed was high. Few women had persistently raised Cr reflecting new or pre-existing chronic kidney disease (CKD). The long term impact of recovered obstetric AKI on future CKD development requires further study.

NephroCheck AKIScore for AKI Prediction in Pregnancy Jennifer R. Joslin,[2] Sittiga Hassan-reshat,[1] Maria Ostermann,[1] Frances I. Conti-Ramsden,[2] Carolyn Gill,[2] Lucy C. Chappell,[2] Kate Bramham.[2] *[1]Guy's & St Thomas' Hospital, London, United Kingdom; [2]King's College London, London, United Kingdom.*

Background: NephroCheck AKIScore is a urinary assay of G1 cell cycle arrest markers: Tissue Inhibitor of Metalloproteinase-2 (TIMP-2) and Insulin-like Growth Factor Binding Protein-7 (IGFBP-7). Numerous studies have demonstrated incremental risk Acute Kidney Injury (AKI) with AKIScores >0.3 and 2.0 $(ng/ml)^2/10^3$ but its predictive role in pregnancy is unknown Aims: To determine AKIScore predictive value for AKI in pregnancy; to explore relationships between AKIScore and gestation, protein-creatinine ratio (uPCR) and pre-eclampsia diagnosis (PE).

Methods: Women recruited to the Pre-EclampsiA, Chronic Hypertension, rEnal and SLE (PEACHES) study with suspected or confirmed PE without pre-existing maternal disease with ≥1 creatinine concentration after baseline urine sampling were included. Urinary AKIScore (TIMP-2*IGFBP-7) was assessed. AKI was defined according to KDIGO criteria.

Results: 116 women were included with Median creatinine 58μmol/L (IQR 52-66) at baseline. Proportion of women according to AKIScore thresholds are shown in Table 1. AKIScore >2.0 had high specificity (94.7%; 95% CI: 85.4-98.9) and NPV (92.9%; 84.8-96.8) but low sensitivity (33.3%; 0.8-90.7) and PPV (25.0%; 4.6-70.0) for prediction of AKI within 48 hours; AKIScore >0.3 had low sensitivity and specificity (<50%). 31 (54%) of women without AKI had AKIScore >0.3 (25-31% risk of AKI in non-pregnant populations). 86 women had a repeat creatinine within 7 days. There was no relationship between AKIScore and baseline or peak creatinine within 7 days. There was no difference in AKIScore between women with (Median 0.4; Range 0-8.4) and without PE (0.3; 0.1-1.5) and no correlations between AKIScore and uPCR or gestation.

Conclusions: The majority of women with suspected or confirmed PE had high AKIScores without developing AKI which were independent of gestation or PE diagnosis. Further study to determine if different AKIScore thresholds are required for prediction of pregnancy AKI is needed, and if pregnancy and/or PE are associated with subclinical renal tubular stress.

Table 1: AKIScore and development of AKI within 48 hours

AKIScore (ng/ml)^2/10^3	AKI	No AKI
≤0.3	2 (66.6%)	26 (45.6%)
0.3-2.0	0	28 (49.1%)
>2.0	1 (33.3%)	3 (5.3%)
Median AKIScore (range)	0.23 (0.22-3.64)	0.32 (0-8.44)

SA-PO041

Clinical Profile of Pregnancy Related AKI (PRAKI): A Single Center Experience Mayur V. Patil. *Department of Nephrology and Clinical Transplantation, Institute of Kidney Disease and Research Centre and Institute of Transplantation Sciences, Ahmedabad, India.*

Background: Acute renal failure (ARF) of obstetric origin is one of the most common complication of pregnancy and leads to poor maternal and fetal outcome. The incidence of PRAKI in developed country is 1 in 20,000 pregnancies, where as in developing country like India is 1 in 50. Septic abortion, poor follow up of pregnancy, limited screening of pregnant patients with hypertensive complications and late referrals to tertiary center are responsible for high incidence of ARF in developing countries.

Methods: The study was conducted at government aided tertiary care hospital between April 2016 to March 2017. A total 1021 patients of ARF were admitted out of which 96 were PRAKI. ARF was defined according to KIDIGO guidelines. Renal biopsy was performed if the patient was oliguric or creatinine still >2mg/dl at the end of three weeks.

Results: The incidence of PRAKI was 9.4%. Most common age group was 24-29 years(53.13%). 45.83% patients presented in late pregnancy while 36.46% presented in postpartum period. Antenatal care was recieved by only 30.21% patients. 25% patients required termination of pregnancy. Most common cause for PRAKI was puerperal sepsis followed by pre eclampsia. 18.75% patients were managed conservatively while 69.79% were kept on intermittent hemodialysis and 11.46% required SLED/CRRT. Acute patchy cortical necrosis was most common histological finding, others were thrombotic microangiopathy and glomerulonephritis. Complete recovery occured in 43.75%, whereas 16.67% had partial recovery (became dialysis independent but with persistent renal impairment), 19.79% were kept on renal replacement therapy. Maternal mortality was seen in 19.79% of cases.

Conclusions: In our study, puerperal sepsis was the most common etiological factor for pregnancy-related AKI. Sepsis, thrombocytopenia, disseminated intra-vascular coagulation were associated with increased mortality.

SA-PO042

Pregnancy Related AKI: A Single Center Experience Umesh L. *Nephrology, Institute of nephrourology, Bangalore, India.*

Background: The incidence of pregnancy-related acute renal failure (PRAKI) in the developed countries is 1–2.8%, About 25% referrals to dialysis centres in the developing world comprise of pregnancy related acute kidney injury (PRAKI). It is associated with siginificant maternal and fetal mortality.

Methods: A prospective longitudinal observational study between February 2012 to april 2017. To evaluate the clinical, etiological and final outcome of AKI with special reference to pregnancy related acute kidney injury. AKI was diagnosed as per AKIN criterion with or without requiring hemodialysis.

Results: A total of 712 patients were studied. Among them 152 (21.34%) patients had PRAKI. The mean age among PRAKI was 21±5 years. The mean duration of hospital stay was 10.17± 6.7 days. Etiological factors include puerperal sepsis in 77 (50.65%), pregnancy induced hypertension in 37(24.34%), 17(11.18%) patients had post partum hemorrhage, 9 (5.92%) ante partum hemorrhage, postpartum hemolytic uremic syndrome in 3 patients (1.97%) and miscellaneous causes was seen 9 (5.92%). Biopsy was done on 34 patients who found to be oliguric or who needed dialysis support at the end of three weeks. seventeen showed acute tubular necrosis. eleven of them had patchy cortical necrosis .three with features of acute interstitial nephritis Three patients had thrombotic microangiopathy. Out of 152, 113 (74.34%) patients recovered from acute kidney injury, 10 patient remained on dialysis and seven patients had partial recovery from renal failure. 22 patients died with mortality rate of 14.47%. Out of these 11 patients died within 48 hours of admission. Sepsis, multiorgan dysfunction, coagulation abnormalities and retained products of conception were factors associated with mortality.

Conclusions: PRAKI is a significant cause of AKI in developing countries. Puerperal sepsis is the most frequent etiological factor and accounted for a majority of maternal mortality

SA-PO043

Preeclampsia: Long-Term Effects on Pediatric Social Disability Carmen Mercurio,[4] Patrocinio Rodriguez benitez,[2] Maria rosa Elero,[3] Alberto Tejedor jorge.[1] *[1]Fundación para la Investigación Biomédica del Hospital General Universitario Gregorio Marañón, Madrid, Spain; [2]Hospital General Universitario "Gregorio Marañón", Madrid, Spain; [3]Hospital Genral "Gregorio Marañón", Madrid, Spain; [4]Universidad Complutense Madrid, Madrid, Spain.*

Background: Preclampsia affects up to 10% of pregnancies worldwide and is one of the main causes of fetal morbi-mortality. Although its effects on maternal renal function are well established and have been attempted to relate to delayed pediatric development, its long-term effects on the child have not yet been quantified. **Objectives.** Our aim is to evaluate whether the preclampsia's severity and its obstetric management correlate to fetal morbidity and the degree of developmental delay in these infants.

Methods: This is an observational and descriptive study performed on a population of 96 women who were diagnosed with severe preclampsia at Hospital General Universitario Gregorio Marañón between 2007 and 2014, and their 111 children. To assess the mother, we gathered data from her medical history, blood analytics, medical management of the preeclampsia, evolution of renal function at 12 weeks and discharge from nephrology. To assess the children, we collected information of the pregnancy and delivery, as well as main diagnoses at birth. We used the Pediatric Evaluation of Disability Inventory in its computerized adaptive test version (PEDI-CAT) to study neurodevelopment, the TNO-AZL Preschool children Quality of Life (TAPQOL) to estimate quality of life, and M-CHAT (Modified Checklist for Autism in Toddlers) for Autism screening.

Results: Preclampsias with greater impact on maternal fidney function correlated with higher periventricular-intraventricular hemorrhage rates in the newborn. In terms of functional activity, PEDI-CAT percentiles were consistently lower in the Social/Cognitive domain, and these were associated to both lower maternal IgG levels, to low maternal platelet levels and maternal high urinary osmolality. High rates of maternal proteinuria were associated to greater risk of perinatal death. The presence of neonatal necrotizing enterocolitis was also associated with lower Social/Cognitive percentiles.

Conclusions: A connection between preclampsia and poor social/cognitive outcomes exists. This association is stronger when the mother has thrombocytopenia and increased ADH. Renal involvement and proteinuria are associated with higher morbi-mortality attributable to prematurity but not with alterations in subsequent social-cognitive development. ADH deficit in the newborn could have implications or could be responsible for a behavior of social retraction.

SA-PO044

The Effect of a Hourly Urine Output on the Clinical Outcomes in Nontraumatic Exercise-Induced Rhabdomyolysis Won jae Shin, Young kyung Ko, Young-Il Jo. *Nephrology, Konkuk University Medical Center, Seoul, Republic of Korea.*

Background: Rhabdomyolysis-induced renal failure is a relatively rare condition, but its clinical consequences are occasionally serious and dramatic. Early and aggressive fluid resuscitation is commonly used to prevent renal failure in rhabdomyolysis. However, the optimal fluid and rate of repletion are unclear. The purpose of this study is to evaluate the effect of the degree of urine output following fluid repletion on the clinical outcomes in nontraumatic exercise-induced rhabdomyolysis (EIR).

Methods: The medical records of all nontraumatic EIR patients admitted to Konkuk University Medical Center between 2011 and 2015 were reviewed. After establishing a definitive diagnosis of nontraumatic EIR, fluid infusion was promptly initiated, with the goal of maintaining a urinary flow of 150-300 mL/h according to existing protocol.

Results: Total 45 cases were analyzed. Patients were categorized according to the hourly urine output during initial 48 hours following fluid resuscitation: the high urine output (≥200 mL/hr) and the low urine output (<200 mL/hr) group. No significant differences were noted between two groups in initial levels of CPK, serum myoglobin, and creatinine. The fluid rate of initial repletion was significantly higher in the high urine output group (4.6±1.5 vs. 2.5±0.7 mL/kg/hr, p<0.001). The hourly urine output was also significantly high in the high urine output group (307.5±116.6 vs. 138.7±42.8 mL/hr, p<0.001). There was no differences in the clinical outcomes including maximal level of CPK, incidence of AKI and mean hospital stay between two groups (Table).

Conclusions: Our results indicated early fluid resuscitation, even though a urine output was less than 200 mL/hour, was effective for prevention of acute kidney injury in nontraumatic exercise-induced rhabdomyolysis. A prospective, controlled, multicenter trial is necessary to determine optimal fluid therapy to prevent acute kidney injury in nontraumatic EIR.

Table 1. Clinical Parameters of the low urine output and the high urine output group.

	Low urine output group (<200ml/hr) (n=17)	High urine output group (≥200ml/hr) (n=28)	P-value
Baseline Characteristics			
Age (years)	34.2 ± 0.7	27.7 ± 0.5	NS
Male gender (%)	52.9%	64.2%	NS
CPK, initial (U/L)	45097.0 ± 44495.1	59969.7 ± 41900.8	NS
Creatinine, initial (mg/dL)	1.2 ± 1.3	1.0 ± 0.9	NS
Treatment			
Hourly urine output (ml/hr)	138.7 ± 42.8	307.5 ± 116.6	<0.0001
Rate of fluid repletion (ml/kg/hr)	2.5 ± 0.7	4.6 ± 1.5	<0.0001
Use of bicarbonate (%)	23.0%	37.0%	NS
Clinical Outcomes			
Peak CPK (U/L)	46853.1 ± 44439.9	56263.8 ± 38803.1	NS
Development of AKI, (number [%])	1 (7.6%)	0 (0.0%)	NS

Renal Fibrosis and Tubular Transport Adaptation Caused by Cardiac Arrest and Cardiopulmonary Resuscitation (CA/CPR) in Mice Michael Hutchens,[1] Rumie Wakasaki,[3] Ian P. Coe,[3] Mohammed Z. Ferdaus,[2] James A. McCormick,[2] Sharon Anderson.[3] *[1]Oregon Health & Science, Portland, OR; [2]Oregon Health & Science University, Portland, OR; [3]Oregon Health and Science University, Portland, OR.*

Background: Studies of of cardiorenal AKI-to-CKD transition report higher incidence of CKD than studies of all-cause AKI-to-CKD transition. The mechanism is unknown because animal models of AKI-CKD transition exclude cardiac disease. We have reported that murine cardiac arrest and cardiopulmonary resuscitation (CA/CPR) is an experimental model of acute cardiorenal syndrome (Ikeda, AJPR 2017). Here, we show that CA/CPR causes essential findings of CKD.

Methods: CA was induced in mice with potassium chloride and confirmed as described. Mice were resuscitated 8 min later with CPR and epinephrine. 28 days later GFR was measured and the right kidney stained for alpha-smooth muscle actin and picrosirius red, which were quantified in unbiased fashon. Immunoblotting was performed for the tubular transporters NKCC2, pNKCC2, NCC, and pNCC.

Results: 28d after CA/CPR, mice demonstrate reduced GFR and elevated serum urea nitrogen (sham 33±4, CA/CPR 49±3 mg/dL, p=0.01). Tubulointerstitial collagen deposition is markedly increased 1 month after CA/CPR compared with sham. Quantification of αSMA revealed a CA/CPR-induced 20-fold increase in tubulointerstitial fibrosis compared with sham (figure 1). pNKCC2 was markedly reduced by CA/CPR compared with sham (49.7%, p=0.001, n=9).

Conclusions: Renal fibrosis and loss of renal function follows resolution of acute kidney injury in experimental acute cardiorenal syndrome. Because CKD damages tubular structure and leads to hypertension, we determined whether tubular sodium transporters critical to blood pressure regulation were altered by CA/CPR. Our findings are consistent with reduced tubular sodium reabsorption, which may reflect a compensatory response to sodium retention. Overall these findings suggest that experimental acute cardiorenal syndrome models AKI-CKD transition.

Funding: NIDDK Support

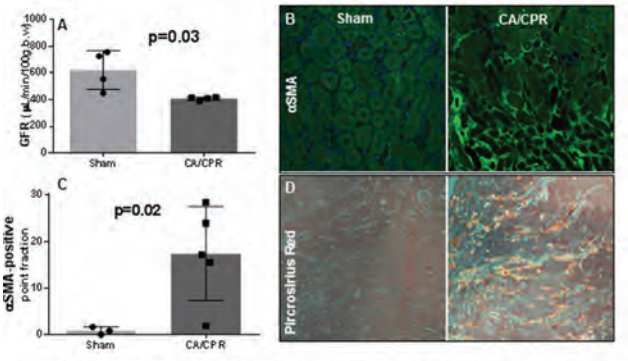

Figure 1: Renal failure and fibrosis 1 month after CA/CPR. A. GFR is reduced by 30% compared with sham. B. Renal αSMA (green) IHC in sham and CA/CPR. Tubulointerstitial αSMA is markedly enhanced in 1 month CA/CPR mice. C. Quantification of αSMA signal, n=8. D. Collagen stained with picrosirius red demonstrated with polarized light.

SA-PO046

Clinical Determinants of Complicated Hyperkalemia in Hospitalized Patients Etienne Macedo,[1] Linda Awdishu,[2] Ravindra L. Mehta.[1] *[1]Medicine, University of California San Diego, San Diego, CA; [2]UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA.*

Background: Hyperkalemia (HighK) is common in hospitalized patients and can be life-threatening. Preventive and management strategies differ based on patient presentation, underlying co-morbidities, concurrent medications and availability of health care resources. In this study we evaluated risk factors for complicated hyperkalemia and its association with patient course and outcomes during hospitalization.

Methods: Adult patients with at least 2 consecutive K>5mmol/L during a hospital stay were identified from electronic medical records (EMR). Data regarding patient location, comorbidities, medications in use prior to and after HighK detection and outcomes were extracted from the EMR. Complicated hyperkalemia(CK) was defined as reaching max K>6.5mmol/L, time to normalization of K levels>200 hours, death with K>5, more than 3 drugs prescribed for HighK treatment, need for ICU level care after HighK diagnosis and need for dialysis.

Results: Of 91,709 patients hospitalized over 24 months, 9,391 (8%) had two K>5mmol/l, and in 1,203 (1.3%) these were consecutive. 47% of the HighK episodes were present at hospital admission; in ER (67%). CK occurred in 577 (47%) of patients and was more frequent in males 51% vs. 32% of females. 711 patients had acute kidney injury (AKI) and CK was more commonly seen in AKI 227 (39%) than in AKI in CKD patients 117 (20%), no AKI/CKD 106 (18%) or ESRD 97 (16%) patients. Most AKI patients, 63%, were using at least one drug associated with hyperkalemia development before AKI diagnosis. The most common diagnoses associated with CK were heart diseases, sepsis, hepatic failure/hepatorenal syndrome, and fluid overload. Most frequent drugs used to treat CK were calcium 58%, insulin/dextrose 49%, albuterol 17% and sodium bicarbonate 28%. Recurrence of HighK during hospitalization ocurred in 720 (60%), of whom 250 (21%) were discharged and 75 (6.2%) died with K>5mmol/l. Length of hospital stay (CK vs HighK 16 (7—32) vs 7 (3-12) days; p<0.001) and mortality (CK 123 (21.3%) vs HighK 39 (6.2%); p<0.001) were significantly higher in patients with CK.

Conclusions: HighK is common in hospitalized patients and associated with high mortality. Clinical and process of care factors can help determine patients with HighK who are at highest risk for complications. These data can be utilized to identify high-risk patients in order to improve patient care and reduce complications.

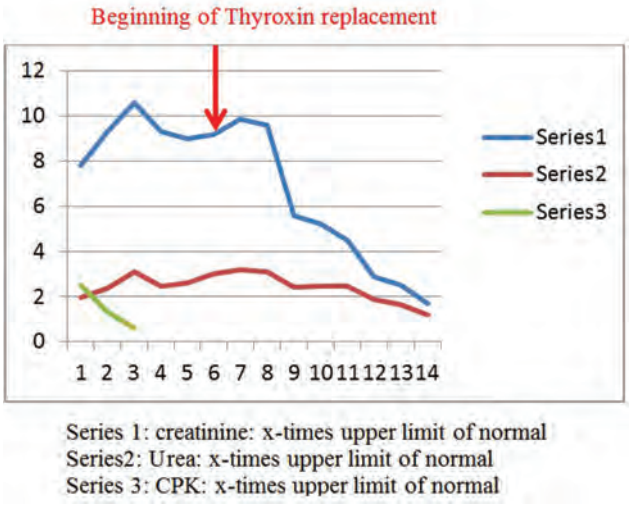
Hypothyroidism: A Known but Neglected Cause of AKI Chandra M. Jha,[1] Hormaz D. Dastoor,[2] Yassin El shahat,[3] Sarah H. Khan,[4] Ammar M. Jabar.[3] *[1]Gulf Diagnostic Center Hospital, Abu Dhabi, United Arab Emirates; [2]Rahba Hospital, ABU DHABI, United Arab Emirates; [3]Burjeel Hospital, Abu Dhabi, United Arab Emirates; [4]Mafraq Hospital, Abu Dhabi, United Arab Emirates. Group/Team: ADHARR.*

Background: Acute Kidney injury (AKI) of variable severity is common. Its recovery rests upon early diagnosis & specific intervention. We report a case of severe AKI due to hypothyroidism which recovered completely with the treatment of hypothyroidism. Literature review revealed that association of AKI with hypothyroidism has been recognized but standard textbooks on medicine, Endocrinology & Nephrology have failed to mention either AKI caused by hypothyroidism or hypothyroidism due to AKI.

Methods: A 26 year old Bangladeshi male electrician, smoker and occasional alcohol user, had symptoms of "not being well" & low back pain of one week duration. He had nonoligouric severe AKI (urea 6.3 mmol/L, creatinine 860 μmol/L, Creatinine clearance 5.02 ml/minute) without significant proteinuria (244 mg/day), normal electrolytes & normal ultrasonological study of Kidney, ureter and bladder. Moderately high CPK (1078 IU/L) without myoglobuniuria normalized within 72 hours but creatinine continued to rise. A history of weight gain & constipation of two months duration prompted us to check for thyroid function test. TSH was 590 miU/L, more than 140 times upper limit of normal. T3 & T4 were low. Thyroglobulin antibody & TSH receptor antibody were normal while microsomal antibody was elevated (326.8 KIU/L).

Results: Institution of levothyroxine therapy resulted in rapid decline of creatinine and symptomatic improvement of patient. His Creatinine clearance increased from 5.02 ml/minute to 49 ml/minute over two weeks and his creatinine level normalized over 4 weeks period. It saved the patient from kidney biopsy and dialysis.

Conclusions: We suggest that thyroid function test should *always* be part of investigation of AKI and renal function test should be part of investigation of hypothyroidism. Hypothyroidism should be included in the table of causes of AKI in standard textbooks.



High Creatinine and its response to Thyroxine treatment

SA-PO048

Clinical Aspects of IgG4-Related Retroperitoneal Fibrosis in a Single Center Study Yoon kyung Choi, Sang-Kyung Jo, Won-Yong Cho, Myung-gyu Kim, Jihyun Yang, Taeyeon Hwang, Woori C. Cho. *Korea University Hospital, Seoul, Republic of Korea.*

Background: Retroperitoneal fibrosis (RF) is a rare condition characterized by the proliferation of fibrous tissue in the periaortic and periiliac retroperitoneum. Along with increasing awareness of IgG4 related disease, we try to find the prevalence of IgG4-related retroperitoneal fibrosis (IgG4-related RF) and compare its clinical feature with non IgG4-related RF.

Methods: The material of this retrospective single center study included 21 patients with retroperitoneal fibrosis between January 2006 to December 2016. We entered all clinical and laboratory information for statistical analysis to determine the prevalence, clinical feature and outcomes of IgG-related RF.

Results: In total 21 patients with retroperitoneal fibrosis, 18 (85.7%) were idiopathic, and remaining 3 (14.3%) had secondary causes for retroperitoneal fibrosis. Among 18 idiopathic RF patients, 10 (55.5%) were diagnosed with IgG4-related RF (2 patients classified as 'definite' IgG4-related RF, 2 as 'probable', and 6 as 'possible'). The average age was 62.2 years (range, 41-79) and 6 (60%) were male. All lesions were detected around the infrarenal portion of the abdominal aorta and 7 cases simultaneously affected the iliac arteries. Hydronephrosis was present in 8 cases (80%) and acute kidney injury was observed in 6 patients. The median serum IgG4 at diagnosis was 641 (range, 24.8-3660). The elevation of serum IgG4 level was not observed in 2 patients. Eight patients were initially treated with steroid therapy. Seven of them (87%) showed radiological response, which showed poor correlation with serum IgG4 level. Comparing with 11 patients of non IgG4 related retroperitoneal fibrosis (52.4%), there were no statistically significant difference between the groups in age, gender distribution, incidence of hypertension, diabetes mellitus, heart failure, malignancy, acute kidney injury, proteinuria, or hematuria, concentration of hemoglobin, white cell counts, inflammatory markers, and complements.

Conclusions: This is a pilot study to evaluate the clinical and laboratory features of IgG related retroperitoneal fibrosis. Larger studies are needed for prevalence and prognosis of IgG4 related or non related RF.

SA-PO049

Not Such a Fun-gi Rebecca Blonsky, Leal C. Herlitz, Evamaria Anvari. *Cleveland Clinic, Cleveland, OH.*

Background: *Amanita Phalloides* is a poisonous mushroom known as death cap, found in central Europe and the northeastern United States. Its toxicity arises from amatoxins, which when ingested can lead to severe gastrointestinal (GI) malady, renal and liver failure and in some cases, death.

Methods: A 55-year-old Nepali male presented with nausea and vomiting for four days. He and his family were in a park and they saw mushrooms similar to those in Nepal which they collected and consumed. They then developed abdominal pain, nausea, vomiting and diarrhea. As their symptoms persisted, they sought care and it was found they had ingested *amanita phalloides*. Initial labs showed a creatinine (Cr) of 4.67 mg/dL, AST 1551 U/L, ALT 1103 U/L and total bilirubin 1.8 mg/dL. The patient was admitted to intensive care and nephrology was called for acute kidney injury (AKI). Urinalysis and renal ultrasound were normal but urine microscopy showed many unusual crystals, but no signs of acute tubular necrosis (ATN). The patient was treated with intravenous fluids, N-acetyl cysteine, octreotide and was enrolled in a trial using silibinin derived from *Silybum marianum* (milk thistle) being studied in amatoxin ingestion. With treatment, liver function improved and renal function normalized and was discharged after three days with a Cr of 0.8 mg/dL. Ten days later he returned complaining of edema, shortness of breath, anorexia and bitter taste. Labs showed BUN of 45 mg/dL and Cr of 8.69 mg/dL. Renal biopsy was done and showed ATN. After a total of two sessions of intermittent hemodialysis, he regained renal function and was discharged with a Cr of 3.95 mg/dL. On three month follow up, he achieved partial renal recovery to a stable Cr of 1.7 mg/dL.

Results:

Conclusions: AKI frequently occurs in amatoxin ingestion. It causes pre-renal azotemia as well as direct tubular toxicity through the amatoxins' inhibition of RNA polyermase II causing ATN. Though not well described, renal injury could be as a result of crystal deposition. Renal failure has also been reported following normalization of liver function. This pathophysiology is not well defined and has been hypothesized to be a result of the formation of free radicals causing ATN as the toxin is cleared after treatment. Patients who have ingested *amanita phalloides* require close follow up even with normalization of hepatic and renal function.

SA-PO050

Interim Analysis of Randomised Controlled Trial Comparing Effects of Intravenous versus Oral Hydration on Subclinical AKI in Laparoscopic Live Kidney Donors Ryan Ghita,[1] David Bruce,[2] Shona Mackinnon,[2] Emma L. Aitken,[1] Marc J. Clancy.[1] *[1]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [2]University of Glasgow, Brighton, United Kingdom.*

Background: Laparoscopic donor nephrectomy is the gold standard for kidney donation due to improved donor convalescence. Pneumoperitoneum required for this procedure exposes patients to increased risk of renal injury. Intensive pre-operative intravenous hydration has shown to improve intraoperative haemodynamics but shows no improvement to creatinine clearance. This is potentially due to the reduced sensitivity of creatinine as a marker for renal injury in the acute setting. Neutrophil gelatinase-associated lipocalin (NGAL) is a biomarker with high sensitivity for acute kidney injury.

Methods: Patients were randomised 1:1 to receive 3L of preoperative intravenous fluids or ad-libitum oral hydration. NGAL samples were taken prior to intervention on day -1, day 0 pre- and post-operatively and on day+1. During the procedure, intraoperative urine output and haemodynamics were recorded. Data for baseline characteristics, eGFR from day -1 to 1 year and peri-operative outcomes were collected.

Results: 49 patients consented to take part. After removing withdrawals, 19 participants in the control group and 22 participants in the intravenous fluid group were analysed. All baseline characteristics were balanced between groups. On day 1 post-operatively 29.4% of patients in the intravenous fluids group had acute kidney injury compared to 40% of patients in the control group (p=0.529). Mean NGAL level was lower in the intravenous fluid group at every time point however with current numbers this was not found to be statistically significant. Percentage change in eGFR from baseline was also less pronounced in the intravenous fluid group at every time point but again was not statistically significant. Statistical analysis for all other outcomes showed that significant differences between groups were only found for intraoperative urine output and post-pneumoperitoneum stroke volume.

Conclusions: At this midpoint analysis the study was unable to fully establish a definitive effect of pre-operative hydration upon renal function in laparoscopic donor nephrectomy patients. There is a potential reduction in postoperative AKI and improvement of eGFR however a fully powered clinical trial should give definitive findings with relevant clinical applications.

SA-PO051

Nephrology Follow-Up Post AKI: Effects on Outcomes and Re-Hospitalization Arpita Basu,[2] Edward J. Horwitz,[1] Yasir Tarabichi.[1] *[1]MetroHealth, Cleveland, OH; [2]University Hospitals- Case Medical Center, Cleveland, OH.*

Background: AKI complicates 20% of all hospitalizations resulting in higher mortality, readmissions and costs. Mortality across all AKI stages is estimated at 21%. In a retrospective study, those with AKI were more likely to be rehospitalized within 30 days of discharge with cardiovascular events, mainly heart failure and acute myocardial infarction. Despite this, less than 20% of patients see a nephrologist within 3 months of discharge.

Methods: We retrospectively collected data on patients 18 years or older discharged after a hospitalization with AKI diagnosis during 1/1/14 to 12/31/16. Data on age, sex, length of stay and discharge diagnoses by ICD-9 or 10 codes was collected and categorized into Elixhauser comorbidity classification. Data also included time to outpatient provider visit, provider specialty and time to next admission. Cox proportional survival analysis was used to model time to readmission and death. Censoring was at 180 days post discharge or 12/31/2016. Hypothesis was tested with NephroOPTF registered as TRUE for patients having seen Nephrology versus FALSE for those seen by another specialty.

Results: 4563 discharges were included, with 1534 events (readmissions or death) documented. The cox-proportional hazards model showed that of patients who saw an outpatient provider, those that saw a Nephrologist had a significant reduction in time to readmission or death compared to those that did not (adjusted hazard ratio of 0.79 [95% CI 0.65 to 0.94, p<0.001].

Conclusions: Patients with AKI if seen by a nephrologist on discharge have lower risks of death or readmission in the acute setting when compared to those evaluated by non-Nephrologists. This study is limited in its retrospective nature, but provides a model for randomized studies to better evaluate and optimize outpatient care post discharge after AKI.

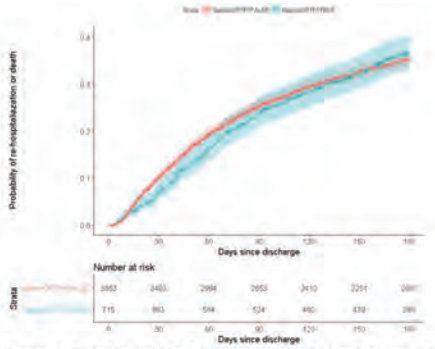


Figure 1: Unadjusted Kaplan Meir Curves for each group. NephroOPTF = TRUE represents patients that did see Nephrology in the outpatient setting. Shaded areas represent the confidence intervals for each group.

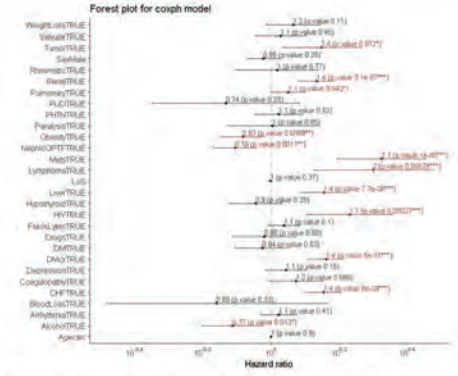

Figure 2: Forest Plots for coefficients tested. Age, LOS were continuous while the rest are categorical variables. The coefficient is listed above the curve with standard errors represented by the horizontal lines. * = p < 0.05, ** = p<0.01 and *** = p<0.001.

SA-PO052

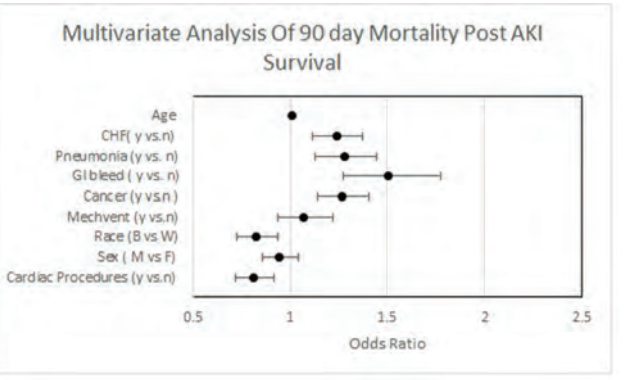
Race and Post-Hospitalization Mortality in AKI Itunu O. Owoyemi, Wenjun Xin, Emaad M. Abdel-Rahman, Rasheed A. Balogun. *University of Virginia, Charlottesville, VA.*

Background: Acute Kidney Injury (AKI), like ESRD, is known to be associated with increased mortality. Racial differences in outcomes exist in patients with multiple medical conditions and "access to care" is one of the linked variables. This study aims to determine if racial differences in mortality exists after hospital discharge for AKI when access to care may be inconsistent.

Methods: Retrospective cohort study of adults admitted to the University of Virginia Medical Center between January 1, 2001 and December 31, 2015 who had AKI during hospitalization. AKI definition of ≥ 0.3 mg/dl rise in serum creatinine, SCr, within 48 hours was used (Kidney Disease Improving Global Outcomes, KDIGO). Patients' characteristics or risk factors were summarized as frequencies and percentages for categorical variables and as mean ± standard deviation for continuous variables. The associations of these factors with the outcome of 90-day mortality post hospitalization were evaluated in logistic regression, measured by odds ratios (ORs) for the likelihood of post-hospitalization mortality. The 95% confidence intervals (CIs) for ORs and the corresponding p-values are reported. A p-value < 0.05 was considered to be statistically significant.

Results: We had a total of 11, 837 patients in our cohort with 79.7% whites and 17.8% blacks. Mean age was 62.41±15.52. Mean baseline SCr was 1.33±0.78 and mean Charlson index score of 4.13 ± 3.21. A total of 9808 were followed post hospital discharge while 1914 patients died in hospital and 88 patients did not have a last follow up date. A multivariate assessment adjusting for several co-morbidities showed a lower mortality rate at 90 days in black patients versus Caucasians.

Conclusions: Black patients with AKI had lower post-hospitalization 90-day mortality. This outcome is similar to that seen in black patients treated for ESRD in USA. A better understanding of mechanisms underlying a possible survival advantage in black Americans with AKI needs further investigation.



SA-PO053

Association of Kidney Function Decline with Survival in Primary Myelofibrosis Umut Selamet, Shouhao Zhou, Juhee Song, Srdan Verstovsek, Ala Abudayyeh. *MD Anderson Cancer Center, Houston, TX.*

Background: Primarymyelofibrosis (PMF) is a type of myeloproliferative neoplasm which causes megakaryocyte and granulocyte proliferation in bone marrow leading to fibrous tissue deposition and extramedullary hematopoiesis. Renal involment in PMF is rare however acute kidney injury may develop during the disease course due to thrombosis of the renal vessels, occlusion of the urinary tract by blood clots or megacaryocyte infiltration of the kidney interstitium. PMF is a rare disease, and the impact of kidney function on survival has not been studied well.

Methods: We retrospectively evaluated 107 patients with PMF treated with Ruxolitinib between 2007 and 2015. The mean follow-up was 51.2 months (95% CI: 43.4, 66.7). Patient characteristics are summarized in Table 1. Seventy-six percent (n=81) of patients were dead at the time of analysis. Multivariate logistic regression model was used to assess predictors of treatment response, and dynamic prediction model was used for modeling associations with survival.

Results: We observed that estimated glomerular filtration rate (eGFR) was strongly associated with the risk of overall survival. Halving of eGFR levels resulted in 1.4-fold (95% CI: 1.06-1.78, p=0.042) increase of risk. No significant associations were observed between eGFR and clinical response including spleen response.

Conclusions: We have shown that kidney function decline is a risk factor for survival in PMF. Larger prospective studies are needed to evaluate the impact of kidney function both on clinical response and survival in this rare condition.

Effect of Community Acquired AKI on Long Term Outcomes in Patients Presenting with an Acute Myocardial Infarction Roy Mathew,[4] Mandeep S. Sidhu,[5] Jennifer Othersen,[3] Robert R. Moran,[6] Arif Asif,[1] Sripal Bangalore.[2] *[1]Jersey Shore University Medical Center, Neptune, NJ; [2]New York University School of Medicine, New York, NY; [3]WJB Dorn VA Medical Center, Columbia, SC; [4]William Jennings Bryan Dorn VAMC, Blythewood, SC; [5]Albany Medical College, Stratton VAMC, Albany Medical Center, Albany, NY; [6]Epidemiology, USC, Columbia, SC.*

Background: We sought to examine long-term outcomes in patients admitted for a myocardial infarction (MI) based on whether they experienced community acquired acute kidney injury (CAAKI), hospital acquired acute kidney injury (HAAKI), or no acute kidney injury (no AKI).

Methods: Methods: Retrospective parallel cohort analysis of Veterans admitted for acute MI between 2005 and 2008. Data was obtained from the corporate data warehouse (CDW) using the VA Informatics and Computing Infrastructure (VINCI) computing environment. AKI was determined by assessing for changes in serum creatinine according to the KDIGO AKI classification system. Outcomes were death, hospitalization for cardiovascular (CV) events (MI, congestive heart failure, or stroke).

Results: Results: 11,580 patients with an MI were identified. Of these patients 15.1% had CAAKI, 14.5% had HAAKI and 70.4% had no AKI. Patients who developed AKI (CAAKI or HAAKI) were older, and had greater number of comorbidities as well as severity of initial admission (ICU stay, ventilation requirement or dialysis requirement) than no AKI. Patients with CAAKI were less likely to get cardiac catheterization during admission than those with HAAKI or no AKI (44.7%, 57.9%, 67.3%, respectively, p<0.001). Mortality was higher in both AKI groups as compared to the no AKI group at 5 year follow-up (adjusted HR and 95%CI: CAAKI 1.96, 1.83-2.09; HAAKI 1.60, 1.50-1.72). Patients with AKI (CA or HA) were more likely to have a repeat CV hospitalization than patients with no AKI (CAAKI adjusted HR 1.14 p=0.004; HAAKI adjusted HR 1.11, p=0.02; no difference between AKI groups).

Conclusions: Conclusions: In patients admitted with an acute MI, the presence of CAAKI was associated with long term outcomes as poor as HAAKI. Further research is needed to understand these associations.

SA-PO055

Risk Factors and Long-Term Prognosis of Post-Operative AKI under Non-General Anesthesia Soojin Lee,[4] Sehoon Park,[3] Anna Lee,[1] Ho Jun Chin,[2] Ki Young Na,[2] Sejoong Kim.[2] *[1]SNUBH, Gyeonggi-do, Democratic People's Republic of Korea; [2]Seoul National University Bundang Hospital, Seong nam, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, SEoul, Republic of Korea; [4]Seoul national university hospital, Seoul, Republic of Korea.*

Background: The patients who receive surgeries under non-general anesthesia are less likely to be evaluated for their post-operative acute kidney injury (AKI) risks in detail than patients who undergo major operation. Risk factors and long-term prognosis data of these patients are scarce.

Methods: We conducted a retrospective cohort study on all adult patients who underwent surgeries under non-general anesthesia during the year 2013. Patients who had other surgeries within 1 month from their index operation, those with kidney injury prior to the surgery and those who lacked information of baseline or follow-up serum creatinine (sCr) measurement were excluded. Postoperative AKI was defined as 0.3 mg/dL or 1.5 times elevation of the patients' sCr from the baseline within 2 weeks from the surgery. Long-term outcomes were a composition of doubling of sCr and eGFR decrement for 30%, at 3 months or 6 months after operation. Risk factors for AKI were evaluated by multivariable logistic regression analyses.

Results: As a result, a number of 1,737 patients were included in our study cohort. Among them, 158 cases experienced post-operative AKI. Most of the AKI cases occurred after pulmonary or orthopedic surgeries with non-general anesthesia. Presence of baseline diabetes mellitus (adjusted OR 1.87, 95% CI 1.27-2.75, P < 0.001) and anemia (hemoglobin < 11 g/dL, adjusted OR 1.76, 95% CI 1.14-2.72, P=0.01) were significant risk factors for the AI events. When the long-term prognosis was evaluated, those who experienced AKI after non-general anesthesia surgeries significantly had worse renal outcomes at 3 month (adjusted OR 5.57, 95% CI 3.28-9.39, P < 0.001) or 6 month (adjusted OR 5.29, 95% CI 2.72-10.19, P < 0.001).

Conclusions: Therefore, postoperative AKI occurs in non-negligible portion of patients who underwent surgeries under non-general anesthesia, and their long-term renal prognoses were worse than of those without the event. Robust evaluation of underlying risk factors for post-operative AKI and careful follow-up for those who developed AKI should be warranted, regardless of anesthesia method used for the surgery.

SA-PO056

Risk of Hypoglycemia after Hospital Discharge Following AKI Adriana Hung,[1,3] Edward D. Siew,[3,1] Otis D. Wilson,[2] Amy Perkins,[2] Robert Greevy,[2,1] Khaled Abdel-Kader,[3,1] Sharidan Parr,[1,3] Talat Alp Ikizler,[3,1] Theodore Speroff,[2,1] Michael E. Matheny.[1,2] *[1]TVHS Veterans Administration, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt Division of Nephrology and Hypertension, Nashville, TN.*

Background: Hypoglycemia remains a common life-threatening complication in patients with diabetes. The risk of hypoglycemia after acute kidney injury (AKI) is not well defined. In this study we evaluate the risk of hypoglycemia in patients with diabetes within 90 days post-discharge between hospitalizations with and without AKI.

Methods: We performed a propensity-matched analysis of patients with and without AKI using a retrospective national cohort of Veterans with diabetes hospitalized between 2004 and 2012. AKI was defined as a 0.3 mg/dl or 50% increase in serum creatinine from baseline to peak serum creatinine during hospitalization. Hypoglycemia was defined as hospital admission or an emergency department visit for hypoglycemia, or an outpatient blood glucose < 60 mg/dL. Time to incident hypoglycemia within 90 days was examined using Cox proportional hazards models. Pre-specified subgroup analyses by renal recovery and baseline CKD and HbA1c status were performed

Results: We identified 65,206 propensity score matched pairs with and without AKI. The incidence per 100 person-years for hypoglycemia was 29.7 (95% confidence interval [CI]: 28.9-30.4) for patients with AKI and 23.7 (95% CI: 23.0-24.4) for patients without AKI, hazard ratio (HR): 1.25 (95% CI: 1.19-1.30). After adjustment, AKI was associated with 26% increased risk of incident hypoglycemia HR: 1.26 (95%CI: 1.21-1.32). The risk of hypoglycemia varied by degree of renal recovery. For patients with full recovery, the HR was 1.17 (95% CI: 1.11-1.24), for partial recovery, the HR was 1.29 (95% CI: 1.22-1.37), and for no recovery, the HR was 1.45 (95% CI: 1.34-1.57) compared to those with no AKI.

Conclusions: AKI is a risk factor for developing hypoglycemia in the 90 days following discharge from a hospitalization, and the risk is modified by the degree of renal recovery. Guidelines for increased monitoring and treatment modification post-AKI need to be developed

SA-PO057

Incidence and Outcomes of AKI in Octogenarians in Northern Jordan Ashraf O. Oweis,[1] Sameeha A. Alshelleh.[2] *[1]Medicine, Jordan University Of Science and Technology, Irbid, Jordan; [2]Medicine, University Of Jordan, Amman, Jordan.*

Background: Due to improvements in the health care system worldwide, human life expectancy has increased, resulting in a greater number of geriatric patients diagnosed

with acute kidney injury (AKI). We evaluated the incidence and outcome of AKI in octogenarians, as studies in this age group are few.

Methods: Design: Retrospective chart review. **Setting**: The medical ward of our tertiary-care hospital in northern Jordan. **Participants**: All patients aged 80-89 admitted to our medical ward between January 2010 and December 2013. Patients with stage IV and V chronic kidney disease were excluded. **Measurements**: The incidence of AKI determined by the Acute Kidney Injury Network classification, mortality, and hospital length of stay.

Results: There were 850 patients admitted during the study period. Of these, 135 were excluded from our analysis. The most common admission diagnoses were uncontrolled diabetes mellitus and acute coronary syndrome. AKI occurred in 216 patients (30.2%). In these cases, Stage 1, Stage 2, and Stage 3 disease were present in 59%, 17.5%, and 23.5%, respectively. Of the 115 patients who died before discharge (16.1%), 87 (75.6%) had developed AKI. Hypertension, the use of angiotensin receptor blockers and non-steroidal anti-inflammatory drugs, heart failure, and exposure to radiologic contrast media were significant risk factors for AKI.

Conclusions: Appropriate management of diabetes and hypertension in octogenarians will likely decrease the incidence of AKI in this age group leading to reduced hospital length of stay and mortality.

Funding: Government Support - Non-U.S.

SA-PO058

Nutritional Assessment of Patients in the Recovery Phase of Moderate to Severe AKI Etienne Macedo,[1] Vivek Kumar,[4] Nancy Sahni,[2] Krishan Lal L. Gupta,[3] Ravindra L. Mehta.[1] *[1]Medicine, University of California San Diego, San Diego, CA; [2]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [3]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [4]Postgraduate Institute of Medical Education and Research, Chandigarh, India.*

Background: The role of nutritional status has not been studied in the recovery phase of AKI. Although protein restriction could reduce the tubular workload in the recovering kidney, malnutrition is common and may affect overall patient outcome. In order to further our understanding of the role of nutrition, we evaluated parameters of nutrition status in patients during the recovery phase of AKI.

Methods: This is an analysis of preliminary data from a pilot single center, open-label, randomized controlled, trial of patients who have an episode of Stage 2/3 AKI. Baseline CKD Stage 4 or higher, need of RRT for>2weeks or dialysis dependency at hospital discharge were exclusion criteria. A screening and comprehensive nutritional assessment was performed by a dietitian and quality of well-being, along with bioelectrical impedance measurments, blood and urine tests.

Results: Of 32 enrolled patient, mean age was 41yo, 43% were male, 38% had hypertension and 13% DM. Of 26 patients with complete nutritional assessment, 23% were classified as normal nutritional status, 46% at risk of malnutrition and 30% as malnourished. Only 3 patients were admitted to an ICU and 23 were dialyzed during hospital stay. Most patients lost weight at discharge, mean difference from admission was 5.5 kgs, with a trend to be higher in patients at risk of malnutrition (7kg) and malnourished (6kg), as compared to normal nutritional status (4.5kg). At hospital discharge charlson comorbidity index, EQ-5D-5L, albumin (3.8±0.7g/dl) and sCR (3.3±1.7mg/dl) values were not different by nutritional category status. Evaluation of body composition showed that all patients had decreased muscle mass according to normal age/gender composition. Fat mass was increased in 41% of patients at risk for malnutrition, as compared to 17% in normal and 24% in malnourished patients. The mini nutritional assessment (MNA) screening had a good correlation with the complete nutritional assessment; r=.842 (p<0.001).

Conclusions: Patients recovering from an AKI episode are at increased risk for malnutrition, particularly those undergoing dialysis during hospital stay. Nutritional screening is a simple, rapid and sensitive process that can detect all or nearly all of the patients at nutritional risk. Further evaluation including body composition may help to determine patients in need of nutritional follow up.

SA-PO059

Incident Trends in Hyperkalaemia among Patients with AKI in the Irish Health System Leonard Browne,[3,5] Arunkumar Aruna udayakumar,[6,1] Natalie Hsiao-Fang-Yen,[2,1] Rajiv Saran,[4,7] Austin G. Stack.[1,5] *[1]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [2]University Hospital Limerick, Limerick, Ireland; [3]University of Limerick, Limerick, Ireland; [4]University of Michigan, Ann Arbor, MI; [5]Health Research Institute, Limerick, Ireland; [6]Nephrology, University Of Limerick, Limerick, Ireland; [7]Kidney Epidemiology and Cost Centre, Ann Arbor, MI.*

Background: Acute Kidney Injury (AKI) is increasingly common and associated with adverse clinical outcomes in the health system. Hyperkalaemia is an equally dangerous electrolyte disorder that frequently develops in the setting of AKI but little is known regarding its occurrence in this setting.

Methods: We utilised data from the National Kidney Disease Surveillance System in Ireland to explore trends in incident hyperkalaemia occurring in the setting of AKI from 2005 to 2014 (n= 47,259). AKI was identified from laboratory system per KDIGO guidelines and serum potassium recorded concurrently were graded as mild> 5.0, moderate 5-5-6.0, and severe > 6.0 mmol/L. Incidence rates per 100 patients were computed and multivariable logistic models explored the relationship of calendar year with incidence of hyperkalaemia expressed as odds ratio (OR) and 95% Confidence Intervals (CI) with adjustment for age, sex, county of residence, location of medical supervision and laboratory variables.

Results: From 2005 to 2014, incident rates of hyperkalaemia increased from 12.6% (11.7, 13.5) to 17.3 % (16.1, 18.4), P<0.001. Rates of mild hyperkalaemia remained relatively overall stable during period [from 8.2% ((7.5, 9.0) to 9.0% (8.1, 9.8) respectively], while rates of moderate and severe hyperkalaemia increased significantly [from 2.5% (2.05, 2.9) to 4.3% (3.7, 4.9) and from 1.9% (1.6, 2.3) to 4.0 % (3.4, 4.6) respectively, P<0.001. With adjustment for age, sex and baseline eGFR, the OR of hyperkalaemia > 5.0 mmol/L increased with calendar year from 2005 (OR, 1.00) to 2014 (OR,1.55, 95% CI 1.38-1.75). With additional adjustment for location of medical supervision, county of residence, laboratory indicators of health, the likelihood decreased

Conclusions: The incidence of hyperkalaemia has increased in the Irish Health system in well-defined demographic and clinical settings. The increasing trend is largely explained by changes in health status and practices in location of supervision.

SA-PO060

A Predictive Model for CKD Development after Severe AKI in Children: A Single Center Prospective Study Stuart Goldstein,[1] Donna J. Claes,[1] Jacob R. Englert,[2] Parker J. Kain,[2] Rachel M. Driehaus,[2] Dhanuja Kasturiratna.[2] *[1]Cincinnati Children's Hospital, Cincinnati, OH; [2]Northern Kentucky University, Highland Heights, KY.*

Background: The association between hospital acquired AKI and CKD development in children has only been studied in either select cohorts comprised of convenience samples of available patients (pts) or from administrative data.

Methods: We conducted a prospective study of all non-BMT pts who developed severe AKI (sAKI, Pediatric Modified RIFLE-I or F) for at least 2 days to assess for CKD development after sAKI. Risk factors included standard of care lab data, AKI severity and duration, solid organ transplant status and nephrotoxic medication burden. The primary outcome was eGFR <90 ml/min/1.73m2 (CKiD Schwartz formula) at 6 months after sAKI. Significant predictors were identified based on a series of bivariate analyses (p<0.3), which were used to build several logistic regression models. The models were then compared and validated by Receiver Operator Characteristic (ROC) and Leave One Out Cross Validation (LOOCV).

Results: 193 pts who developed Stage 2 AKI were enrolled in this study (99M, 94F, mean age 10.5±6.2yrs, mean weight 43.7±31.0 kg). The median [IQR] AKI duration was 12 days [7, 21]. 45 pts required RRT. 79 pts had an eGFR assessment at 6 months, 24 of whom had an eGFR <90. On bivariate analysis, age, AKI duration, number of nephrotoxic medications, history of transplantation, lower eGFR, and lower serum albumin at AKI diagnosis was associated with CKD development at 6 months. Interestingly, RRT provision was not associated with CKD development. Seven candidate models were developed with AUCs that ranged from 0.81 to 0.82 and LOOCV that ranged from 0.67 to 0.76. The best candidate model (see table) based on a combination of AUC, LOOCV

and simplicity (5 variables vs. 7) had an AUC 0.81 [95%CI 70.2-92.6] and LOOCV value of 0.76.

Conclusions: A simple 5 variable model was developed to predict presence of CKD at 6 months in children who developed pRIFLE-I/F AKI from any cause. Further prospective work will need to be conducted to validate and calibrate this model.

Best Predictive Model for AKI to CKD Development

Variable	Coefficients	p-values	Odds Ratios	(95% CI)
Age	0.0904	0.12	1.09	(0.98,1.24)
AKI Days	0.0383	0.09	1.04	(1.0,1.1)
RRT (yes)	-1.6967	0.13	0.18	(0.013,1.3)
eGFR (nadir)	-0.0284	0.004	0.97	(0.95,0.98)
Transplant (yes)	1.8916	0.03	6.63	(1.27,43.4)

SA-PO061

AKI by KDIGO and AKIN Criteria in Patients with Non-ST Elevation Myocardial Infarction: Association with Risk Scores Avantee V. Gokhale,[3] Samuel Mon-Wei Yu,[2] Hector Alvarado verduzco,[1] Pitchaphon Nissaisorakarn,[2] Poonam Mahato,[2] Anjali Acharya.[3] *[1]JACOBI MEDICAL CENTER, BRONX, NY; [2]Jacobi Medical Center, Bronx, NY; [3]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: Acute kidney injury (AKI) is commonly associated with the acute coronary syndrome, both STEMI and NSTEMI. We aimed to assess the incidence of AKI, as defined by AKIN and KDIGO criteria, in patients with NSTEMI at a safety net hospital catering to minority populations, and examined the association between the scores used for risk stratification in NSTEMI and AKI.

Methods: 170 out of 296 consecutively admitted patients between 1.1.2015 and 7.1.2016 with a primary diagnosis of NSTEMI were included in this study. 126 were excluded, mainly due to primary diagnosis of STEMI, and transfer to outside hospital. Their data were collected by retrospective chart reviews. GRACE and Killip scores were calculated for NSTEMI characterization. AKI was assessed as present/absent by 2 different criteria viz. AKIN and KDIGO. Statistical analyses included descriptive statistics and multivariable logistic regression.

Results: Out of 170 patients (mean age=69, 56% males), 39% were Hispanic. 28% had CKD, while, hypertension prevalence was 84%. Median baseline serum creatinine in the study group was 0.9. Median GRACE score was 119 and majority patients fell under Killip class 1 (78%). KDIGO and AKIN scores diagnosed AKI in equal number of NSTEMI patients (45%). While Killip class failed to predict AKI, GRACE score significantly associated with AKI by both AKI criteria [OR 1.03, 95% CI 1.01-1.04; p<0.001 for both]. Finally, when adjusted for age, sex, ACE-inhibitor, aspirin, statin, beta-blocker, diuretic use, history of diabetes and contrast exposure, GRACE score remained significantly associated with AKI by both criteria [1.03 (1.01-1.05), p=0.001 for both].

Conclusions: In a single-center, inner-city safety net hospital cohort of NSTEMI patients with predominantly Hispanic population, GRACE score, which incorporates initial creatinine into the score, was associated with AKI after adjustment for traditional risk factors for AKI. Furthermore, contrary to observations in STEMI, both AKIN and KDIGO predicted AKI to a similar extent in NSTEMI patients. However, larger population-based prospective studies are needed to confirm our findings and further assess the association with mortality.

SA-PO062

AKI in Hospitalized Dermatology Patients: An Epidemiology Study in Two Chinese Centers Yuanhan Chen,[2] Xinling Liang.[1] *[1]Guangdong general hospital (Guangdong Academy of Medical Sciences), Guangzhoou, China; [2]Guangdong General Hosiptial (Guangdong Academy of Medical Sciences), Guangzhou, China. Group/Team: China collaborative study on AKI.*

Background: Acute kidney injury (AKI) has become a worldwide public health problem, but little information is available in patients with skin diseases.

Methods: This study comes from the China collaborative study on AKI (ClinicalTrails.gov: NCT03054142; Ethical approval: GDREC.2016327H). The electronic medical information were collected retrospectively and the results of creatinine tests were analyzed by data mining. Total 4,710 hospitalized patients in the Department of Dermatology with at least two creatinine tests within 7 days were screened out from Sichuan Provincial People's Hospital (n=3,978) and Guangdong General Hospital (n=732). AKI was defined and staged according to Kidney Disease Improving Global Outcomes criteria on the basis of changes in serum creatinine.

Results: Two-hundred and ninety-five (6.3%) patients were classified into AKI, including 121(41.0%) hospital-adquired and 174 (59.0%) community-adquired AKI. In the top 15 general skin diseases (more than 1% in hospitalized dermatology patients), the AKI incidences of psoriasis with systemic reaction (14.8%), erythroderma (12.8%), drug eruption (12.6%) and systemic lupus erythematosus (12.5%) were significant higher than the total incidence (Figure 1). In multivariate logistic regression model, these 4 skin diseases were associated with AKI after adjusted by chronic kidney disease and diabetes mellitus. The Odds ratio were 2.970, 1.932, 2.446 and 2.254, respectively. The mean lenth of hospital stay was 2 days longer and the median hospital cost was about $500 higher in patients with AKI than those without. In addition, the mortality was much higher in patients with AKI than those without (3.1% *vs* 0.1%, $P < 0.001$). After adjusted by age and comorbidities, the AKI was related to in-hospital death (Odds ratio 24.630).

Conclusions: AKI was common in the hospitalized dermatology patients. It is associated with significantly higher in-hospital mortality and resource utilization.

Funding: Government Support - Non-U.S.

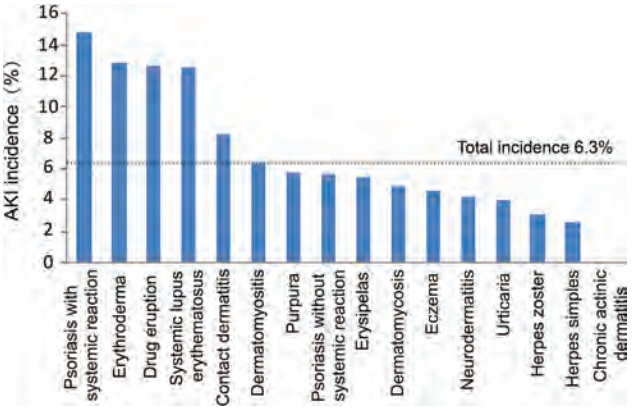

Figure 1. AKI incidence in the top 15 general skin diseases

SA-PO063

Patient Perspectives on Participation in Biopsy-Based AKI Research Dennis G. Moledina,[2] Bettina Cheung,[2] Randy L. Luciano,[3] Aldo J. Peixoto,[3] Francis P. Wilson,[1] Sandra L. Alfano,[2] Chirag R. Parikh.[4] *[1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT; [3]Yale University School of Medicine, New Haven, CT; [4]Yale University and VAMC, New Haven, CT.*

Background: As part of its new precision medicine initiative, the NIH/NIDDK has proposed collecting human kidney tissue to discover novel therapeutic targets in patients with acute kidney injury(AKI). Patient perspectives on participating in kidney biopsy-based AKI research are unknown

Methods: We surveyed participants enrolled in the Yale Acute Interstitial Nephritis(AIN) study who underwent a clinically-indicated kidney biopsy for AKI evaluation between 1/2015-10/2016, asked open-ended questions, and classified their answers into pre-defined categories

Results: Out of the 177 participants alive at contact, 117(66%) agreed to participate in the survey. Our survey included 59(50%) female, 34(29%) African-American, and 14(12%) Hispanic participants. 85(73%) reported that, if they hypothetically needed another clinically-indicated kidney biopsy, they would allow additional needle passes to donate kidney tissue for research. The major reasons described by participants for their choice are shown in **Figure**. Older [64(51-72) vs. 54(43-65) years, P=0.02] and African-American [16(50%) vs. 18(21%), P=0.002] participants were less likely to allow an extra pass with kidney biopsy; however, participants did not differ on self-reported biopsy complications such as pain, anxiety, and hematuria. 23(20%) participants agreed to participate in a study that obtained kidney tissue for research purposes even if another clinically-indicated biopsy was not needed

Conclusions: Among patients who had experienced a kidney biopsy, a majority were amenable to additional needle passes to donate kidney tissue for research at the time of a hypothetical, future, clinically-indicated biopsy

Funding: NIDDK Support, Private Foundation Support

Is Reduced Telomere Length Associated with an Increased Risk of AKI Following Cardiac Surgery? Damian C. Balmforth,[2] Vasantha M. Muthuppalaniappan,[2] Sai Krishna Duraisingham,[2] Steven M. Harwood,[2] Julius E. Kieswich,[2] Rakesh Uppal,[1] Muhammad M. Yaqoob.[2] *[1]Barts and the London NHS Trust, London, United Kingdom; [2]William Harvey Research Institute, London, United Kingdom.*

Background: Patients undergoing cardiopulmonary bypass are at risk of post-operative acute kidney injury (AKI) due to renal ischemia. Several studies have demonstrated an association between cardiac surgery associated-AKI (CSA-AKI) and reduced long-term survival which persists even when the degree of AKI is mild and where there is complete resolution of the injury prior to discharge. The mechanism by which CSA-AKI is associated with increased mortality is not currently understood. Telomere length has been proposed as a biomarker for cellular senescence and aging and shortened telomeres have been shown to delay recovery after ischemia induced renal injury in animal models. We hypothesised that patients with reduced telomere length undergoing cardiac surgery may have increased long-term mortality and be more susceptible to ischemia-induced AKI.

Methods: Blood samples were taken immediately prior to surgery and mean leukocyte telomere length (TL) measured by quantitative real time polymerase chain reaction (rt-PCR). The primary outcome was the development of AKI in the first 7 days post-operatively, defined by the Adult Kidney Injury Network (AKIN) criteria. All patients were entered into a study database that recorded a range of pre-operative, intra-operative, and post-operative variables. Univariate statistical analysis was performed.

Results: Between January 2016 and March 2017, 243 patients at a single institution were recruited. Of these, 51 developed post-operative AKI (21%) as defined by the AKIN criteria (stage 1 = 45; stage 2 = 6; stage 3 = 4). No differences were found between the AKI and non-AKI groups in terms of male gender (79.4% Vs 79.4%; p = 1), mean age (67.0 Vs 63.1 years; p = 0.061), or ethnicity (p = 0.223). As expected, mean length of stay was significantly longer in the AKI group at 14.8 days compared to 9.3 days in the non-AKI group (p <0.0001). No difference in mean telomere length was found between the groups with a mean relative TL of 0.73 and 0.76 in the AKI and non-AKI groups respectively (p = 0.334).

Conclusions: No association was found between mean telomere length and the development of AKI following cardiac surgery.

Renal Oximetry Measured by Near-Infrared Spectroscopy before Cardiopulmonary Bypass Predicts Cardiac Surgery-Associated AKI Rachel Joffe,[2] Mohammed M. Al aklabi,[1] Sudeshna Bhattacharya,[3] Dominic A. Cave,[1] Daniel Garros,[1] Lindsay Ryerson,[3] Catherine Morgan.[3] *[1]Stollery Children's Hospital, Edmonton, AB, Canada; [2]Stollery Children's Hospital, University of Alberta, Edmonton, AB, Canada; [3]University of Alberta, Edmonton, AB, Canada.*

Background: Cardiac surgery-associated acute kidney injury (CS-AKI) is common in children and associates with negative outcomes. Novel interventions to reduce CS-AKI require knowledge of its pathophysiology. States of altered perfusion, oxygen delivery and energy consumption occur during cardiopulmonary bypass (CPB) and could protect against or contribute to renal cellular injury and recovery. NIRS (near-infrared spectroscopy) is noninvasive technology for monitoring regional blood flow and tissue oxygenation. This study evaluated the relationship between renal regional oxygen saturation (rSO_2) and CS-AKI, using NIRS monitoring before, during, and after CPB in children.

Methods: Design, setting, and patients: We conducted a prospective cohort study evaluating children ≤10 kg who underwent CPB (Stollery Children's Hospital, Edmonton, Alberta, Canada). Heart transplant, preoperative dialysis, sepsis, extracorporeal life support, congenital renal disease, and preoperative nephrotoxins were exclusions. **Measurements:** Outcome measure was development of AKI after cardiac surgery (defined according to Kidney Disease: Improving Global Outcomes criteria). rSO_2 was measured continuously using NIRS (INVOS™ 5100C Cerebral/Somatic Oximeter, Troy, MI, USA) from time of anesthesia to time of transfer to intensive care.

Results: Main Results: CS-AKI occurred in 65%. Lower baseline (preoperative) rSO_2 associated with decreased risk of CS-AKI (p=0.01); children with baseline rSO_2 in the highest tertile were 7.14 times more likely to get CS-AKI (vs lowest tertile). Area under the curve for ability of baseline rSO_2 to predict CS-AKI was 0.73 (95%CI 0.60 to 0.85). Children with lower baseline glomerular filtration rate had lower mean renal rSO_2.

Conclusions: Conclusions: Findings demonstrate that preoperative oxygen supply/demand balance is an important predictor of CS-AKI, suggesting lower preoperative (and intraoperative) renal blood flow may be protective. There is not yet a definite link between remote ischemic preconditioning and prevention of CS-AKI, however renal protective effects of sublethal ischemia should continue to be explored.

Funding: Private Foundation Support

SA-PO066

Impact of Standard Mean Arterial Pressure on AKI in Patients with Shock According to Age Groups Sarah Y. Atallah,[1] Mazen Zaarour,[4] Chanudi Weerasinghe,[3] Julie Zaidan,[1] Bader Kfoury,[1] Elias Moussaly,[1] Ahmed Mahgoub,[1] Elie El-Charabaty,[2] Suzanne E. El Sayegh.[2] *[1]Internal Medicine, Staten Island University Hospital, Staten Island, NY; [2]Nephrology, Staten Island University Hospital, Staten Island, NY; [3]Hematology and Oncology, Staten Island University Hospital, Staten Island, NY; [4]Hematology and Oncology, Tulane University, New Orleans, LA.*

Background: Management of mean arterial pressure (MAP) to a target value is crucial in shock. Recent studies advocate the use of higher MAP target in patients in shock who are at risk acute kidney injury (AKI). However, there is limited clinical data to support this approach. Our objective was to compare the AKI outcome in patients with shock according to age and the achieved MAP.

Methods: We performed a retrospective chart review of patients admitted to the Intensive Care Unit (ICU) of one tertiary care center from Jan 2012 to May 2015. We obtained 3 MAP readings per day for the first 3 ICU days (D 0,1,2), with one mean value per day. Patients were stratified into 3 MAP groups (65-70,70-75 and 75-80mmHg). Patients were also grouped according to age (<60 year of agr and ≥60 year of age). The study's primary outcome was the incidence of AKI according to both age and MAP.

Results: Our sample size included 255 patients (104 <60 y.o, 151 ≥60 y.o). The incidence of AKI was higher in older patients (75.5%) compared to younger ones (69.2%). The incidence of AKI was similar regardless of the achieved MAP (Table 1). Within each age group, MAP did not have an impact on the incidence of AKI (incience of AKI in age <60 on D0: 86.6% in MAP 65-70 mmHg, 73.9% in MAP 70-75 mmHg, 78.9% in MAP 75-80 mmHg, p=0.65; incience of AKI in age≥60 on D0: 67.8% in MAP 65-70 mmHg, 76% in MAP 70-75 mmHg, 75% in MAP 75-80 mmHg, p=0.81). Furthermore, there were no statistically significant differences in the incidence of AKI for all age and MAP groups on all studied days (D0, D1, D2).

Conclusions: Older adults with shock have a higher incidence of AKI compared to younger patients, with no associated reduction in AKI incidence with higher MAP. Larger studies are needed to confirm whether a more conservative MAP target achieves the similar AKI outcomes compared to a higher, more aggressive one.

Table 1: Incidence of AKI across the three mean MAP groups in the total population

	Day 0	Day 1	Day 2
MAP 65-70	74.4%	70.0%	73.5%
MAP 70-75	75%	40.4%	80%
MAP 75-80	76.6%	30.1%	69.5%
	p=1	p=0.97	p=0.49

SA-PO067

Admission Hyperphosphatemia Increases Risk of AKI in Hospitalized Patients Wisit Cheungpasitporn,[2] Charat Thongprayoon,[1] Michael A. Mao,[2] Wonngarm Kittanamongkolchai,[2] Ankit Sakhuja,[2] Stephen B. Erickson.[2] *[1]Bassett Medical Center, Cooperstown, NY; [2]Mayo Clinic, Rochester, MN.*

Background: The association between elevated admission serum phosphate and risk of in-hospital acute kidney injury (AKI) is limited. The aim of this study was to assess the risk of AKI in hospitalized patients stratified by various admission serum phosphate levels.

Methods: This is a single-center retrospective study conducted at a tertiary referral hospital. All hospitalized adult patients who had admission phosphate levels available between January and December 2013 were enrolled. Admission phosphate was categorized based on its distribution into six groups (<2.4, 2.4 to 2.9, 2.9 to 3.4, 3.4 to 3.9, 3.9 to 4.4, and ≥4.4 mg/dL). The primary outcome was in-hospital AKI occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of AKI for various admission phosphate strata using the phosphate 2.4 to 2.9 mg/dL level (lowest incidence of AKI) as the reference group.

Results: After excluding patients with ESRD, without serum creatinine measurement, and those who presented with AKI at the time of admission, a total of 5,036 patients were studied. Phosphate levels of <2.4 mg/dL and ≥4.4 mg/dL were found in 458 (9.1%) and 585 (11.6%) patients, respectively. In-hospital AKI occurred in 595 (11.8%) patients. The incidence of AKI was 10.5%, 9.5%, 11.8%, 10.0%, 12.8%, and 17.9% in patients with admission phosphate <2.4, 2.4-2.9, 2.9-3.4, 3.4-3.9, 3.9-4.4, and ≥4.4 mg/dL, respectively. After adjusting for potential confounders, admission serum phosphate levels >4.4 mg/dL was associated with an increased risk of developing AKI with an odds ratios of 1.72 (95% CI 1.20-2.47), whereas admission serum phosphate level <4.4 mg/dL was not associated with development of AKI during hospitalization.

Conclusions: Elevated admission phosphate was associated with an increased risk for in-hospital AKI.

SA-PO068

Complex Relationship Among Obesity, AKI, and Long-Term Mortality in Coronary Artery Bypass Grafting Hongran Moon,[2] Yeonhee Lee,[2] Sejoong Kim,[1] Dong Ki Kim,[2] Ho Jun Chin,[1] Yon Su Kim,[2] Ki Young Na,[1] Seung Seok Han.[2] *[1]Seoul National University Bundang Hospital, Seongnam, GYEONGGI-DO, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Obesity is an important health concern and related with several comorbidities and mortality. However, its relationship with acute kidney injury (AKI) and long-term mortality remains unresolved, particularly in Korean patients undergoing coronary artery bypass grafting (CABG).

Methods: A total of 3018 patients (aged ≥18 years) were retrospectively reviewed from two tertiary referral centers between 2004 and 2017. Obesity was defined using body mass index (BMI), according to the World Health Organization recommendation. The odds ratios (ORs) and hazard ratios (HRs) for post-surgical AKI and all-cause mortality were calculated after adjusting for multiple covariates. Patients were followed for 90 ± 40.9 months (maximum 13 years).

Results: The proportions of normal weight, underweight, overweight at risk, obese I, and obese II status were 31.7%, 2.4%, 27.8%, 35.1%, and 4.0%, respectively. Post-surgical AKI developed in 799 patients (26.5%). The obese group had a higher OR of AKI [1.72 (1.149-2.560)] than the normal weight group (P=0.008), whereas other groups with abnormal weight status did not confer the higher risk of AKI than the normal weight group. This result suggest that obesity was an indicator of the AKI risk in the CABG subset. However, the relationship trend with mortality was different from the above one. During the follow-up period, 787 patients (26.1%) died. The group with underweight status had a higher HR of mortality [2.69 (1.957-3.687)] than the normal weight group, whereas the groups with overweight at risk, obese I, and obese II status had lower HRs than the normal weight group, as follows: 0.59 (0.486-0.706), 0.61 (0.512-0.720) and 0.62 (0.410-0.926), respectively. These results suggest that normal weight status did not guarantee the lowest mortality in the CABG subset.

Conclusions: Obesity is related with the high risk of AKI, but not with the high mortality in Korean patients undergoing CABG. Rather, the patients with overweight at risk, obese I status showed better survival rates than the patients with normal weight. These results should be monitored in clinical practice, based on the consideration for several confounding factors, such as inflammation and malnutrition.

SA-PO069

Extracellular and Cardiothoracic Hypervolemia Evaluated with Bioimpedance Analysis as a Prognostic Marker in AKI Francisco javier Lavilla, Pedro Errasti, Christian I. Alfaro Sanchez, Nuria Garcia-Fernandez, Pelayo M. Fdez-Felechosa, Jose maria Mora gutierrez. *Clinica Universidad de Navarra, Pamplona, Spain.*

Background: The bioelectrical impedance analysis (BIA) can offer information about volemia. We evaluate corporal, hemodynamic BIA, and volemic parameters (Extracelular/intracelular watter ratio –ECW/ICW-, Extracelular/Total body watter ratio –ECW/TBW-, and Fluid thoracic volumen –FTV-) in acute kidney injury (AKI).

Methods: We include a cohort of 159 patients (médium age 66 years SD 1.3, and male 73 %) with AKI and corporal BIA (Study A), and another cohort of 50 patients (mean age 71.2 years SD 1.6, 79.6% males) with AKI and hemodynamic BIA (Study B). We evaluate clinical prognostic index (individual severity index –ISI-), analytical inflammatory parameter (C-reactive protein) and chronic health index (Karnofsky –K-). We evaluate mortality and renal replacement therapy requeriment. We use SPSS 20.0.

Results: Study A: Exitus 27%. ECW/ICW and ECW/TBW was associated with prognosis index, clinical and analytical parametes in AKI. ECW/ICW was associated with ISI (r=-0.240, p=0.002) and CRP (r=0.224, p=0.006) and Karnosky(r=-0.253 p<0.002). ECW/TBW was associated with ISI (r=-0.115 p=0.148) and CRP (r=0.116 p=0.158) and Karnosky(r=-0.242 p=0.002). ECW/ICW was associated with risk mortality (OR 2.313 p=0.004 CI 95% 1.308-4.092), and ECW/TBW also (OR 5.539 p=0.018 CI 95% 1.333-23.007). The AUC with ECW/ICW was 0.773 (p=0.001, CI 95% 0.672- 0.874) and with ECW/TBW was 0.734 (p=0.003, CI 95% 0.625- 0.844) respect to survive. Extracelular corporal volumen not was associated with renal replacement therapy requeriment. **Study B:** Renal replacement therapy was associated with higher FVT (p= 0.005 37/49.2 l/kOhm), and ventilatory support also (p=0.005 37 vs 49.2 l/kOhm). FVT was associated with C reactive protein (r=-0.310, p= 0.046). FVT not was associated with mortality.

Conclusions: Higher ECW/ICW or ECW/TBW are associated with poor prognosis in AKI. Extracelular hypervolemia are related with inflammatory, proteín metabolism, and health status prior to the event. Thoracic hypervolemia was associated with respiratory failure and renal replacement therapy requeriment. Both BIAs can used to made a better AKI patient management (use of diuretic, intravenous solutions) and triage (mortality, respiratory failure with renal replacement theraphy risk).

SA-PO070

The Incidence and Risk Factors of AKI in Patients with Pulmonary Infection-Associated Acute Respiratory Distress Syndrome Xin Wan,[1] Changchun Cao.[2] *[1]Nanjing Hospital Affiliated to Nanjing Medical University (Nanjing First Hospital), Nanjing, China; [2]Sir Run Run Hospital Affiliated to Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) is a common complication in critically ill patients and is a major risk factor for death. Among critically ill patients, AKI occurred in 31.3% of patients and was more common in patients with ARDS (44.3% versus 27.4% in patients without ARDS. Infection (44.1%) was the most common risk factor for the development of ARDS. Lung was the most common infection site in infection-related ARDS, and also the only infection site significantly associated with increased risk of developing ARDS.there is no a study pay a attention to AKI in patients with pulmonary infection -associated ARDS (PI-ARDS). Therefore, we aimed to explore the incidence and risk factors of acute kidney injury in patients with PI-ARDS.

Methods: This retrospective cohort study included patients aged 18 or more who was admitted to hospital for pulmonary infection combined with or secondary to ARDS at Nanjing First Hospital in Nanjing, China, between January 2014 and March 2017. Univariate and multiple logistic regression models were used for determining the association between the development of AKI and risk factors. Multiple Cox-proportional hazards modeling was performed to evaluate the impact of AKI on the in-hospital mortality and hospital length of stay (LOS).

Results: Of 846 patients with ARDS result from pulmonary infection, the incidence of patients with PI-ARDS developed AKI was 53.1% (449/846). A total of 36(8.0%) PI-ARDS patients required renal replacement therapy. In the multivariate analysis, factors independently associated with AKI were male, age, white blood cell, platelets, several nephrotoxic drugs (diuretic, vancomycin, Aminoglycosides), proteinuria and invasive ventilation. The model was well calibrated and an area under the receiver operator curve (AUC) was 0.766. Furthermore, subjects with proteinuria of trace to 1+, 2+, 3+, had a 1.45(P = 0.037, 1.02 to 2.06), 3.36(P <0.001, 1.78 to 6.35), 11.26(P < 0.001, 3.11 to 40.80) fold increase in adjusted odds ratio of AKI compared with subjects with negative, respectively. AKI was also significantly associated with in-hospital mortality, especially in patients needing RRT, and prolonged hospital length of stay.

Conclusions: Proteinuria is an independent risk factor for AKI in PI-ARDS patients, and patients with PI-ARDS develop AKI would have a grave prognosis.

SA-PO071

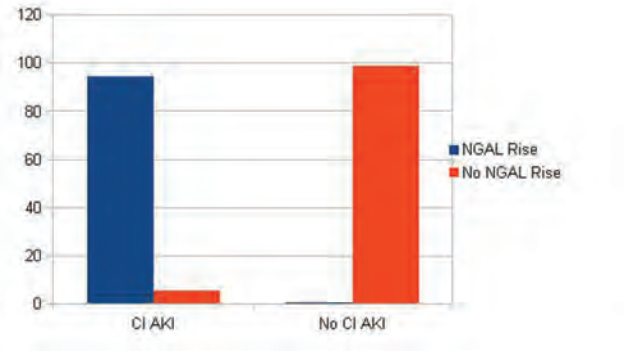
Role of Urinary NGAL at 4 Hours Post Coronary Angiogram in Detecting Contrast Induced AKI Madhav Venkatesan. *Amrita Institute of Medical Sciences, Trichy, India.*

Background: Serum creatinine is an unreliable biomarker of acute kidney injury(AKI). Newer biomarkers can diagnose AKI earlier. We attempted to determine the sensitivity, specificity, positive and negative predictive values of urine NGAL in detecting CI-AKI post a coronary angiogram, and to study the risk factors of CI-AKI.

Methods: 240 patients undergoing coronary angiogram were prospectively studied. Patients with a starting serum creatinine of more than 1.4mg/dl were excluded from the study. Serum creatinine and urine NGAL were measured before the procedure. Urine NGAL was measured 4 hours post procedure and serum creatinine was measured at 48 hours post procedure.

Results: The incidence of CI AKI in patients who underwent coronary angiogram was 8%. There was a rise in urinary NGAL in 95% of these patients (n=18). The sensitivity and specificity of urine NGAL at 4 hours were 94.7% and 99.1% respectively. The positive and negative predicitve values were 90% and 99.5% respectively. Age more than 75 years, presence of diabetes mellitus, congestive heart failure, prior history of CI-AKI and anemia had significant association with CI-AKI. Multivariate analysis showed that CHF and anemia were significantly associated with increased risk of CI-AKI.

Conclusions: Urine NGAL has a high sensitivity and specificity in the diagnosis of contrast induced acute kidney injury post coronary angiogram. Age above 75 years, diabetes mellitus, congestive heart failure, anemia and previous history of contrast induced AKI were significant risk factors for CI-AKI. Congestive heart failure and anemia were the risk factors with highest association with CI AKI. Based on our study we suggest that urine NGAL may be used for early detection of contrast induced acute kidney injury post a coronary angiogram with sensitivity and specificity of 94.7% and 99.1% respectively and with positive and negative predicitve values of 90%. and 99.5% respectively.



Association of rise in urine NGAL with CI-AKI

SA-PO072

Identification of Urine Apolipoprotein A-I as a Biomarker for Early Diagnosis of AKI Following Percutaneous Coronary Intervention by ITRAQ-Based Quantitative Proteomics Fangfang Zhou,[1,2] Qun Luo,[1,2] Gen Shen,[3,2] Honghua Ye,[3,2] Lina Han,[1,2] Lulu Huang,[1,2] Yumei Li,[1,2] Zemin Wang.[1,2] *[1]Department of Nephrology, Ningbo NO.2 Hospital, Ningbo City, China; [2]School of Medicine, Ningbo University, Ningbo, China; [3]Department of Cardiology, Ningbo NO.2 Hospital, Ningbo, China.*

Background: Acute kidney injury(AKI) has been recognized as a common complication of percutaneous coronary intervention(PCI). Our study aimed to discover and validate novel diagnostic biomarkers of acute kidney injury(AKI) following PCI by Isobaric Tags for Relative and Absolute Quantitation(ITRAQ) technology dynamically, and to explore potential mechanisms of AKI.

Methods: We performed a prospective nested case-control study. 14 older patients(>60yr) were identified with PCI-AKI. 12 patients were selected as controls, matched by age and gender. Urine were collected at different time points of pre-PCI, 6hrs, 24hrs, and 48hrs post-PCI. A training set of 56 urine samples(AKI group, n=6 and control group, n=6) were subjected to ITRAQ technology. Proteins were considered to be differentially expressed if the difference was statistically significant($p<0.05$) and the fold change was >1.2 or <0.83. Differentially expressed proteins, also analyzed by bioinformatics analysis, were then investigated in a validation set of 48 urine samples (AKI group, n=8 and control group, n=6) via parallel reaction monitoring(PRM) based targeted proteomics.

Results: A total of 14 overlapped proteins at all the different time points post-PCI showed an abundance change in AKI group as compared to those before PCI and controls. Among them, the accumulation of apolipoproteins A-I(apoA-I) were 14.86-, 18.88-, and 7.44-fold higher at 6h, 24h, and 48h post-PCI in AKI group, as compared to pre-PCI value respectively ($p=0.0409$, =0.0338, $p=0.1009$). Using the PRM approach, we successfully confirmed the differential accumulation of apoA-I at different time points post-PCI in the validation set. We also confirmed that serum level of high density lipoprotein (HDL) and apoA-I were significantly lower in AKI patients ($p=0.023$, $p=0.047$) as compared with controls. Bioinformatics analysis described that apoA-I may involved in Peroxisome Proliferator Activated Receptor(PPAR) signaling pathway.

Conclusions: The presence of urine apoA-I demonstrated in our study a potential diagnostic biomarker for PCI-AKI, suggesting lipid abnormalities in AKI, which may be related to HDL deficiency. Comparatively little is known regarding the role of lipids in pathogenic mechanisms of AKI, which deserve further study.

SA-PO073

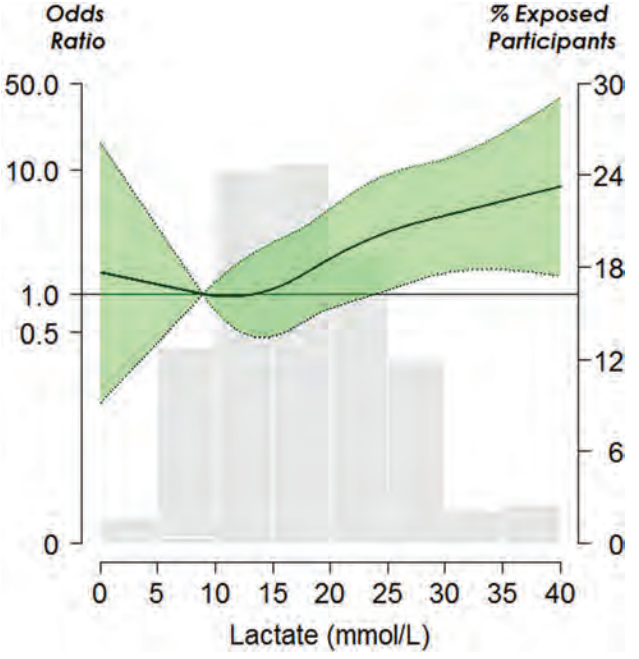
Serum Lactate Level Predicts Mortality among Patients with Metformin-Associated Lactic Acidosis Requiring Renal Replacement Therapy Chin-Chi Kuo,[2] Ching-Wei Tsai.[1] *[1]Internal Medicine and Big Data Center, China Medical University Hospital, Taichung City, Taiwan; [2]Internal Medicine and Big Data Center, China Medical University Hospital, Taichung City, Taiwan. Group/Team: CHMU Kidney Research Group.*

Background: The risk factor for mortality and the best practice concerning timing, mode, and dose of renal replacement therapy (RRT) for patients with metformin-associated lactic acidosis (MALA) with renal failure remain undetermined.

Methods: We searched case reports and case series published in PubMed/Medline and EMBASE from inception to Sep 2014 and applied predetermined exclusion criteria. Case-level data including case's demographics and clinical information related to MALA were abstracted. Multiple logistic regression modeling was used to examine the predictors of mortality.

Results: A total of 253 unique cases were identified with cumulative mortality of 17.2%. Eighty-seven percent of patients had acute kidney injury. Serum lactate level was significantly higher in non-survivors (median 22.5 mmol/L) than in survivors (17.0 mmol/L, *p*-value <0.01) and so did the median blood metformin concentrations (58.5 vs. 43.9 mg/L, *p*-value=0.05). The survival advantage was not significantly different between the modalities of RRT. The adjusted odds ratio of mortality for every one mmol/L increase in serum lactate level was 1.09 (95% CI 1.02-1.17, *p*-value=0.01). The dose-response curve indicated a lactate threshold greater than 20 mmol/L was significantly associated with mortality.

Conclusions: Our study suggests that predialysis level of serum lactate level is an important marker of mortality in MALA patients requiring RRT with a linear dose-response relationship. To better evaluate the optimal prescription of RRT in MALA, we recommend fostering an international consortium to support prospective research and large-scale standardized case collection.



Odds ratio for MALA mortality by serum lactate level. Solid lines: adjusted odds ratios based on restricted quadratic splines for the serum lactate level, with knots at the 10th, 50th, and 90th percentiles. The shaded green region: upper and lower 95% CIs.

SA-PO074

Preoperative Risk Assessment Improves Biomarker Detection for Predicting AKI After Cardiac Surgery Cheng chia Lee,[1,2] Chih-Hsiang Chang,[1,2] Chih-Wei Yang.[1,2] *[1]Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan.*

Background: The major challenge in managing acute kidney injury (AKI) lies in making an early diagnosis. Although urinary neutrophil gelatinase-associated lipocalin (NGAL) has emerged as a promising biomarker for the early detection of kidney injury, previous studies of adult patients have reported only moderate discrimination. The age, creatinine, and ejection fraction (ACEF) score is a preoperative validated risk model for predicting AKI following cardiac surgery. It remains unknown whether combined preoperative risk assessment through ACEF scores followed by urinary NGAL is an optimal approach with improved predictive performance.

Methods: This prospective study was performed in a tertiary referral center in Taiwan between July 2014 and February 2015. A total of 177 consecutive patients who underwent cardiac surgery were enrolled. Clinical characteristics, prognostic model scores, and outcomes were assessed. The ACEF scores were calculated as age (years)/ejection fraction (%) + 1 (if creatinine > 2.0 mg/dL). NGAL were examined within 6 hours after cardiac surgery. Patients were stratified according to preoperative ACEF scores, and comparisons were made using the area under the receiver operator characteristic (AUROC) curve for the prediction of AKI.

Results: A total of 45.8% (81/177) of the patients had AKI. Patients with ACEF scores ≥ 1.1 were older and more likely to have diabetes mellitus, myocardial infarction, peripheral arterial disease, and class III or IV heart failure. Urinary NGAL alone moderately predicted AKI, with an AUROC of 0.732. Risk stratification by ACEF scores ≥ 1.1 substantially improved the AUROC of urinary NGAL to 0.873 (95% confidence interval, 0.784–0.961; $P < .001$).

Conclusions: Risk stratification by preoperative ACEF scores ≥ 1.1, followed by postoperative urinary NGAL, provides more satisfactory risk discrimination than does urinary NGAL alone for the early detection of AKI after cardiac surgery. Future studies should investigate whether this strategy could improve the outcomes and cost-effectiveness of care in patients undergoing cardiac surgery.

Funding: Government Support - Non-U.S.

Performance of NGAL in discriminating AKI, stratified by ACEF scores

Population	AUROC (95% CI)	P value	Optimal cut-off (ng/mL)	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
ACEF < 1.1	0.606 (0.492–0.720)	0.071	>45.1	61.5	61.5	50.5	68.5
ACEF ≥ 1.1	0.873 (0.784–0.961)	<0.001	>77.5	83.3	87.2	81.2	88.7

AKI Biomarkers and Cystic Fibrosis (CF): Does Having CF or Being a Girl Make a Difference? Courtney B. Munro.[1,2] *[1]Murdoch Childrens Research Institute, Melbourne, Victoria, NSW, Australia; [2]Paediatrics, University of Melbourne, Melbourne, VIC, Australia.*

Background: Novel urinary biomarkers are useful for prediction of acute kidney injury (AKI). Cystic fibrosis (CF) is a life limiting disease, caused by a gene defect in Cystic Fibrosis Transmembrane Regulator (CFTR), that predisposes the individual to recurrent respiratory infections which are often treated with nephrotoxic antibiotics. CFTR is highly expressed in the kidney, yet its effects in the human kidney in CF have not been closely examined. Previous studies have demonstrated renal glomerular hyperfiltration in children with CF. We set out to determine if novel urinary biomarkers could be used in children with CF, by determining reference levels in a paediatric CF population, and if this differed to healthy age-matched controls.

Methods: Urine was collected and analysed for kidney injury molecule-1 (KIM-1), neutrophil gelatinase associated lipocalin (NGAL) and fibroblast growth factor-23 (FGF-23) using ELISA and normalised to urinary creatinine (UCr). Analysis of biomarkers by cohort (CF vs. healthy controls), age and sex was performed.

Results: Urine was collected on 448 occasions (CF *n*=229; healthy controls *n*=219) from children aged 1 to 6-years, median 4-years. Median values were: KIM-1 205.44 pg/mL (Interquartile range (IQR) 107.11 to 427.93), NGAL 1.03 ng/mL (IQR 0.01 to 3.65), FGF-23 45.25 pg/mL (IQR 17.05 to 96.21) and UCr 4.21 mmol/L (IQR 2.56 to 6.26). KIM-1, NGAL and UCr were higher in healthy controls than in CF (p=0.0000), suggesting a concentrating defect. FGF-23 was higher in CF (p=0.0101) which may reflect inflammation and infection. In healthy controls KIM-1 and UCr increased with age (p=0.0000), whereas NGAL decreased with age (p=0.0141). In CF, only UCr increased with age (p=0.0166). In healthy controls there were significant sex differences with KIM-1 and UCr higher for boys (p=0.0002 and p=0.0006), whereas NGAL was approximately 5 times higher for girls (p=0.0003). Sex differences were not observed in CF.

Conclusions: This is the first reference range study for urinary KIM-1, NGAL and FGF-23 in young children with CF and highlights significant differences in AKI biomarkers in CF, and for age and sex in healthy children. This information is essential for interpreting AKI biomarkers in the context of CF. Further research is required as to the role of CFTR in the kidney and why children with CF express not only lower biomarker levels, but the absence of sex differences.

Worsening Renal Function During Aggressive Diuresis Is Not Due to Kidney Injury in Acute Heart Failure Patients Joshua L. Rein,[1] Keyanna Jackson,[2] Veena Rao,[2] Steven G. Coca,[1] Jeffrey M. Testani.[2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale University, New Haven, CT.*

Background: The mechanisms underlying worsening renal function (WRF) in the setting of aggressive diuresis for acute heart failure (AHF) treatment may reflect renal tubular injury or simply indicate a hemodynamic or functional change in glomerular filtration. Well-validated tubular injury biomarkers—NAG, NGAL, and KIM-1— are now available that can quantify the degree of renal tubular injury. The ROSE trial provides an ideal experimental platform for the study of mechanisms of WRF during aggressive diuresis for AHF as the ROSE protocol dictated high dose loop diuretic therapy in all patients. We sought to determine whether kidney injury is a predominant mechanism for WRF in the setting of aggressive diuresis and its impact on prognosis.

Methods: Patients in the multicenter ROSE trial with baseline and 72-hour urine injury biomarkers were analyzed (*N*=277). WRF was defined as a ≥20% decrease in glomerular filtration rate estimated using cystatin C.

Results: Levels of NAG and KIM-1 did not change with aggressive diuresis (*P*>0.49, both), whereas levels of NGAL decreased slightly [-8.0 ng/mg (-169, 35 ng/mg), *P*<0.001]. WRF occurred in 21.7% of the population and was not associated with an increase in any marker of renal injury: NGAL (*P*=0.23), NAG (*P*=0.49), or KIM-1 (*P*=0.22). WRF was not associated with reduced survival (*P*=0.51). However, increases in NGAL, NAG, and KIM-1 were paradoxically associated with improved survival (adjusted HR: 0.78 per 10 percentile increase, 95% CI: 0.69-0.91; *P*=0.001). Change in injury biomarkers could not differentiate high versus low risk forms of WRF ($P_{interaction}$=0.35).

Conclusions: Renal injury was not a dominant mechanism for WRF in the context of aggressive diuresis of ADHF patients. Moreover, neither WRF nor renal injury was associated with an increased risk of death. These findings reinforce the notion that small to moderate "bumps" in creatinine commonly encountered with aggressive diuresis are mechanistically and prognostically different from traditional causes of acute kidney injury.

SA-PO077

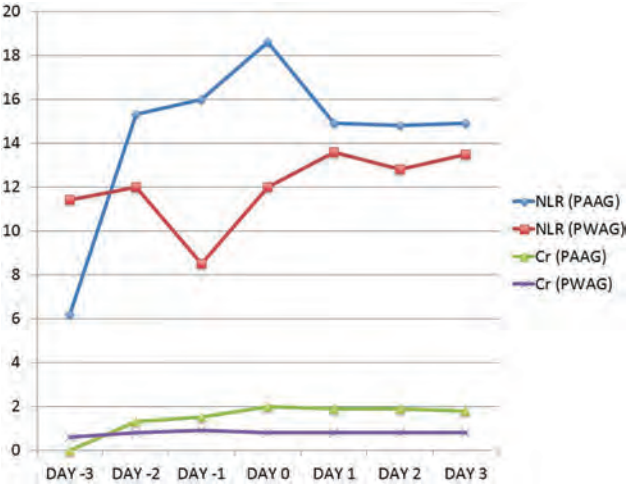
Utilizing CBC to Predict AKI and Its Recovery Asif Khan,[2] Anna S. Gutman,[1] Elie El-Charabaty,[2] Suzanne E. El Sayegh.[2] *[1]Northwell Health, Brooklyn, NY; [2]Staten Island University Hospital, Brooklyn, NY.*

Background: The difficulty in diagnosing acute kidney injury (AKI) prior to an elevation of serum creatinine, or a decrease in urine output, continues to pose challenges for nephrologists. Multiple new biomarkers of kidney damage have been evaluated, but their clinical value remains limited. The value of the neutrophil to lymphocyte ratio (NLR) is an indicator of systemic inflammation, which is easily calculated from a CBC. We investigated the hypothesis that a high NLR may predict the development of AKI.

Methods: This retrospective study identified patients of 18 years and older. We compared the NLR trends between patients with pneumonia and AKI as the experimental group (PAAG), to patients with pneumonia without AKI as the control group (PWAG). Day 0 was labeled as the day of AKI diagnosis, and the day of pneumonia diagnosis in the PAAG and the PWAG respectively. We documented trends of NLR and kidney function from 3 days before Day 0 until 3 days after Day 0.

Results: Of the 222 patients enrolled, 115 were in the PAAG, and 107 in the PWAG. Both groups had similar percentages of sexes, ethnicities, underlying hypertension, coronary artery disease, heart failure, and a similar median age. The PAAG had a significantly higher number of patients with chronic kidney disease and diabetes mellitus compared to the PWAG (47.9% vs. 4.8% (P<0.001) for CKD, and 40.4% vs. 24.1% (p=0.02) for DM). There was an increase in the mean NLR from day -3 to day 0 of 12.4 in the PAAG, and only a 0.6 in the PWAG group. These results suggest a positive correlation between a certain net change in NLR and the development of AKI.

Conclusions: The potential of NLR as an indicator of systemic inflammation is well established. A timely use of NLR within twenty-four hours of admission may predict an impending AKI. Further studies are necessary to establish the trends in NLR prior to the diagnosis of AKI.



Graph showing the trends in NLR in the PAAG compared to the PWAG, and trends in the serum creatinine of both groups.

SA-PO078

Efficacy of Urinary Output for the Early Diagnosis and Urinary NGAL for the Prognosis of AKI after Major Elective Non-Vascular Abdominal Surgeries Graziela R. Souza,[1] Emmanuel A. Burdmann,[4] Lia J. Marçal,[2] Luis Yu,[3] Dirce M. Zanetta.[5] *[1]São Paulo University, São Paulo, Brazil; [2]UNIVERSIDADE DE SAO PAULO, Sao Paulo - SP, Brazil; [3]University of Sao Paolo School of Medicine, Sao Paulo, Brazil; [4]University of Sao Paulo Medical School, Sao Paulo, Brazil; [5]University of São Paulo, S Paulo, Brazil.*

Background: Data comparing the efficacy of urinary output (UO) and serum creatinine (SCr) changes using RIFLE and KDIGO AKI definitions after major elective non-vascular abdominal surgeries (MENVAS) are scarce. The role of urinary NGAL as an outcome predictor in these patients is unknown. The aims of this study are to compare the efficacy of RIFLE and KDIGO SCr and UO criteria for AKI diagnosis and the role

of NGAL changes in the outcome of patients (pts) submitted to MENVAS admitted to the ICU.

Methods: One hundred and seventy one pts were prospectively evaluated, peri-operatively and from the ICU admission up to 7 days. SCr (mg/dl) was assessed before surgery and once a day up to 7 d or until ICU discharge. Hourly UO (ml/kg/h) was measured daily. AKI was diagnosed using either SCr or UO according RIFLE and KDIGO definitions. Urine samples were collected at the pre-operatory, at ICU admission, and 12 and 24 hours after ICU admission for NGAL (ng/mg urinary Cr) analysis. Data are presented as mean ± SD, median (minimal and maximum value) or frequency. Statistical significance was $p<0.05$.

Results: According to RIFLE criteria 101 pts (59.1%) developed AKI: 5 by SCr, 76 by UO and 20 by SCr+UO. Using KDIGO criteria 102 pts (60%) developed AKI: 6 by SCr, 67 by UO and 29 by SCr+UO. Pts with AKI diagnosed by UO, SCr and SCr+UO had, respectively, hospital length of stay (LoS) 19±19, 14±10 and 24±22 d (NS), ICU LoS of 3±1, 4±3 and 5±3 d ($p<0.001$ UO vs. SCr+UO) and mortality 4.5, 33.3 and 17.2%, respectively ($p=0.0211$). If the SCr criteria alone was utilized for AKI diagnosis, 25 pts in RIFLE group and 35 in the KDIGO group would be overlooked. Pts who died had higher NGAL values in the immediate post-surgery [108 (24-31642) vs. 45 (4–3763) no death, $p=0.0085$] and 24 h post-surgery [222 (59-8482) vs. 54 (3–6579) no death, $p=0.0026$] periods.

Conclusions: UO measurement seems to be pivotal for early AKI recognition, since the use of SCr criteria alone would miss a high number of AKI diagnoses, using either RIFLE or KDIGO definitions. Early NGAL increase after major elective non-vascular abdominal surgeries was associated with higher mortality in this group of patients.

SA-PO079

Interval Change Plasma Neutrophil Gelatinase-Associated Lipocalin Level and Urine Output as a Predictor for Survival in Critically Ill Patients Undergoing Continuous Renal Replacement Therapy

Ha yeon Kim,[2] Eun Hui Bae,[1] Soo Wan Kim,[2] Seong Kwon Ma.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: Continuous renal replacement therapy (CRRT) is increasingly modality of treatment in hemodynamic unstable ICU patients with AKI. Several biomarker have been attempted an early detection or assisted predicting prognosis. The neutrophil gelatinase-associated lipocalin (NGAL) is a one of them used early kidney injury marker. The aim of this study was to determine the outcome and identify the predictors of mortality of critically ill patients treated with CRRT for AKI in the ICU.

Methods: Protocol 1: In the single tertiary medical center retrospective study of 1,527 patients admitted ICU and undergoing CRRT from January 2011 to December 2013 was performed. Univariate and multivariate regression analyses were conducted to examine the independent predictor of patients' survival. **Protocol 2**: This retrospective observational study included 404 AKI patients treated with CRRT. The levels of serum creatinine (Cr), plasma NGAL obtained at baseline and at 48 hour after starting CRRT were analyzed.

Results: In total, 1,527 patients with AKI treated with CRRT, the overall in-hospital mortality rate of the CRRT treated AKI patients was 50.6%. Multivariate cox proportional hazards analysis identified that a urine output less 30 ml for initial first hour at the initiation of CRRT was independent predictor (HR; 1.73, CI; 1.45-2.07, p value; <0.001) besides APACHE II score and older age per 10 years and congestive heart failure also showed the significant predictors. Plasma NGAL was not different between survivor and non-survivor, whereas the difference of plasma NGAL between at baseline and at 48 hour after starting CRRT was significant different. However, univariate analysis revealed that delta plasma NGAL was not significant factor for the survival.

Conclusions: Plasma NGAL have limitation of early biomarker of predictor of survival. At initiation of CRRT, a urine output less 30 ml for initial first hour is a predictor of survival. Urine output is still a robust prognostic biomarker in these patients with AKI treated with CRRT.

Development and Validation of 7-Plex Assay Panels to Measure Urine and Plasma Biomarkers Implicated in Prediction of CKD

Venkata Sabbisetti,[1,2] Emily Christie,[1,2] Sushrut S. Waikar,[1,2] Joseph V. Bonventre.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Biomarkers including TNFR1, TNFR2, suPAR, KIM-1, YKL 40, MCP-1 and BMP 7 have been shown to be associated with progression of kidney disease. We have developed and validated multiplex assays on the Meso Scale Discovery (MSD) platform to measure these 7 analytes simultaneously in both urine and plasma matrix.

Methods: We have developed a 7-Plex assay using MSD U-PLEX technology. Capture antibodies were biotinylated and conjugated to unique U-PLEX linkers and coupled to MSD 7-spot U-PLEX plates by incubating overnight at 4°C. Plates were coated with specific antibodies and then incubated with recombinant proteins, plasma or urine specimens from CKD patients for 1h followed by incubation with GOLD SULFO-TAGGED secondary antibodies for 1h. The amount of chemiluminescence in each well was measured using MSD SQ120 instrument.

Results: The MSD 7-plex assay demonstrated excellent linearity of dilution and spike recovery with no interference of various substances including glucose, bilirubin and albumin in both urine and plasma matrix. The intra and inter-assay coefficient of variation was below 15%.

Conclusions: We have developed a robust and reliable 7-plex assay on MSD platform to measure biomarkers implicated as potentially predictive of progression of kidney disease in plasma and urine specimens.

Funding: NIDDK Support

Establishment of a Tubule-Specific Renal Panel in AKI

Brent J. Portz, Michael A. Moore. *Danville Regional Medical Center, Danville, VA.*

Background: Early recognition to allow prevention of Acute Kidney Injury (AKI) is an ongoing inpatient challenge due to AKI's high morbidity and mortality. The traditional use of changes in serum creatinine and urinary output only define AKI after it is well established and kidney injury has begun. Better biomarkers of early acute renal injury are needed. Developments in systems biology techniques and advancements of genomic and proteomic technologies have provided an emerging list of novel glomerular and renal tubular cell biomarkers.

Methods: A comprehensive literature review was completed utilizing PubMed and MEDLINE databases from inception to January 2017 searching for 'AKI Biomarkers and Systems Biology'. Validated and Non-Validated novel AKI biomarkers discovered at tubule-specific sites via genomic, proteomic and systems biology techniques were identified. Unique biomarkers at distinct nephron segments were composited in a Tubule-Specific Renal Injury Panel.

Results: Amongst other identified markers, KIM-1 (Proximal Tubule), CNTF (Loop of Henle), bcl-2 (Distal Tubule), and NGAL (Collecting Tubule) suggested the highest potential for clinically applicable AKI biomarkers (Table 1).

Conclusions: The establishment of a tubule-specific renal panel is proposed to provide increased sensitivity/specificity to enable diagnosis earlier in acute renal injury.

Early Detection of Urine Neutrophil Gelatinase-Associated Lipocalin for 90-Day Mortality Prediction in Cirrhotic Patients with AKI

Zemin Wang, Fangfang Zhou. *Ningbo NO.2 Hospital, Ningbo City, China.*

Background: Our study was to investigate the prediction role of early detection of urine neutrophil gelatinase-associated lipocalin (uNGAL) after risk factors for 90-day mortality in cirrhotic patients with acute kidney injury (AKI).

Methods: We conducted a prospective nested case-control study of 90 cirrhotic patients with risk factors (bacterial infections, bleeding from oesophageal varices, large volume paracentesis (>3L/d), increased dosage of diuretics, and receiving contrast medium). Urine samples were collected at the time of risk factors occurred and 1d, 2d and 3d after the risk factors. Among these patients, 11 patients diagnosed as AKI(KDIGO AKI criteria, 2012). 9 patients were selected as controls, matched by age and gender. uNGAL was measured by ELISA. All the patients were followed up for 90 days.

Results: There were no significant differences in terms of baseline characteristics between AKI and control group. In the AKI group, the levels of uNGAL of 1-day, 2-day and 3-day after risk factors were significantly higher than those at the time of risk factors happened($P=0.013$, $P=0.009$, $P=0.012$). Totally 6 patients (30%) died during the 90-day follow-up period. The rate of mortality was much higher in patients with AKI compared with control group patients ($P < 0.05$). uNGAL level of 1d and 2d after risk factors was significantly higher in deceased patients compared with those in surviving patients (189.43(108.88,368.27) vs. 66.03(20.55,115.42), $P=0.049$; 148.31(70.06,326.68) vs.45.42(20.43,97.33), $P=0.039$). The serum Na, albumin, total bilirubin, levels of

uNGAL, and scores of Child-Pugh and MELD were signficantly associated with prognosis. Multivariate Cox regression analysis showed that uNGAL value of 2d after risk factors and MELD score independently predict 90-d mortality. ROC curve analysis showed that the plot of the uNGAL of 1-day and 2-day after risk factors could predict the risk of 90-day mortality in cirrhotic patients (AUC=0.792 (95%CI: 0.526-1.000), P=0.049; AUC=0.806 (95%CI: 0.584-1.000), P=0.039, respectively).

Conclusions: Early detection (1-2 days) of uNGAL after risk factors could predict 90-day mortality in cirrhotic patients with AKI, independent of other commonly used risk factors.

SA-PO083

Usefulness of L-FABP as a Predictive Biomarker of AKI in Children with Cancer Sohsaku Yamanouchi, Takahisa Kimata, Shoji Tsuji, Kazunari Kaneko. *Kansai Medical University, Hirakata-shi, Japan.*

Background: Acute kidney injury (AKI) is one of severe complications during the course of administration of anti-cancer chemotherapy. Lahoti et al. have reported that 36% of adults with acute myelogenous leukemia or high-risk myelodysplastic syndrome developed AKI associated with chemotherapy, and 8-week mortality rates were approximately 15% in patients with AKI compared to 3% in non-AKI patients (Lahoti A, Cancer, 2010). Therefore, early and accurate diagnosis of AKI is essential even in children though the available information is scarce. Purpose: To identify predictive biomarkers of AKI in children with pediatric cancers.

Methods: We enrolled 16 children with cancer (acute leukemia in 11, and brain tumor in 5). Pediatric-modified RIFLE criteria modified by AKI Network were used to evaluate AKI. Urine samples were evaluated for: TP, Alb, NAG, BMG, and L-FABP. We obtained laboratory data thrice a week in 16 children with cancers who received 58 courses of chemotherapy consisting of Vincristine, Cisplatin, Cyclophosphamide, Carboplatin, Etoposide, Daunorubicin, L-asparaginase and Methotrexate. A course was between 4 and 8 weeks. AKI was noted in 14 out of 16 patients (87.5%) and 31 (53.4%) of 58 courses. Values of urinary biomarkers such as TP, Alb, NAG, BMG, and L-FABP were corrected using creatinine and compared between the courses with regard to patients showing AKI (n=31) and those without AKI (n=27). To assess the usefulness of these biomarkers in predicting AKI during chemotherapy, the receiver operating characteristic (ROC) curve was analyzed using the maximum value before developing AKI.

Results: Among urinary biomarkers, L-FABP and BMG (median value 15.5 μg/gCr and 320 μg/mgCr), demonstrated significantly higher levels in children who developed AKI than values in children without AKI (median value 6.8 μg/gCr and 201 μg/mgCr, P = 0.0007 and 0.003). Among the area under the curve in receiver operating characteristic curve calculated for each urinary biomarker, urinary L-FABP yielded the highest value: L-FABP (0.75) > BMG (0.72) > TP (0.64) > Alb (0.61) > NAG (0.53). Using the point on the curve closest to the (0, 1) point, cut-off for urinary L-FABP was 8.53 μg/gCr. Test sensitivity was 77.4 %, and specificity was 63.3 %.

Conclusions: We conclude that L-FABP is a possible predictive biomarker of AKI in children with cancer undergoing chemotherapy.

SA-PO084

Assessment the Utility of Finger-Nail Creatinine to Differentiate between AKI and CKD Nilesh Shinde,[1] Atul Sajgure,[1] Atul Mulay,[1] Charan B. Bale,[1] Ashwini Sharma,[1] Abhishek Goel,[1] Vajed Mogal,[1] Pratik Shete,[1] Shirin Telang,[2] Tushar A. Dighe.[1] *[1]Nephrology, Dr. D Y Patil Medical College, Pune, India, Pune, India; [2]shayadri hospital, kothrud, pune, Pune, India.*

Background: It is necessary to establish if azotemia is acute or chronic as it plays vital role in initiating treatment and in preventing its progression. When a patient presents with renal failure, it is often difficult to ascertain whether the individual is suffering from acute or chronic renal failure. Efforts were made to use fingernail creatinine to differentiate between the two. While some studies found this useful, there are studies which were inconclusive. OBJECTIVE: - To determine usefulness of finger-nail creatinine to differentiate between Acute Kidney Injury and Chronic Kidney Disease.

Methods: In this prospective observational cohort study conducted at tertiary health care centre, 20 patients were selected for the study. Out of which 10 patients were diagnosed as Acute Kidney Disease (AKI) and 10 patients were diagnosed as chronic Kidney disease (CKD) with 30 days of dialysis vintage. 10 healthy volunteers were also included in the study as controls. For estimating finger-nail creatinine concentrations, fingernails of all participating subjects were clipped and collected separately in plain tubes. The nails were cleaned under tap water, dried & the weight was recorded. The Nail creatinine was extracted in water first by pulverization, followed by mechanical powdering. Sample powder incubated at 45°C for 2 hrs, centrifuged and then assayed by Alkaline Picrate-method on semi Auto Biochemistry Analyzer (Robonik).

Results: We found that when nail creatinine level in AKI (30.41 +/- 4.32 micrograms/g of nails) was significantly low compared with nail creatinine in CKD (91.59 +/- 47.76 micrograms/g of nails) [p-value (Two-tailed unpaired T test) 0.0013]. However, when nail creatinine level in AKI compared with nail creatinine in healthy volunteer (33.99 +/- 4.54 micrograms/g of nails), there was no significant difference [p-value (Two-tailed unpaired T test) 0.088].

Conclusions: The finger-nail creatinine level in AKI was significantly low than finger-nail creatinine in CKD. Hence nail creatinine can be used as a one of the diagnostic tool to differentiate between AKI & CKD in patients presenting with renal failure.

SA-PO085

Use of Biomarkers in the Early Diagnosis of AKI in Critically Ill Patients: Systematic Review Luana A. Pedroso,[1] Vandack Nobre,[4] Claudmeire D. De almeida,[2] Nathalia S. De,[4] Rafael Souza,[4] Ana cristina Simões e silva,[3] Maria auxiliadora P. Martins.[4] *[1]Federal University of Minas Gerais, Ouro Preto, Brazil; [2]UFMG, Belo Horizonte, Brazil; [3]UFMG, Brazil, Belo Horizonte, Brazil; [4]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*

Background: Acute kidney injury (AKI) is a recognized condition among hospitalized patients and it is more common in intensive care units (ICU). AKI can be assessed by measuring serum creatinine; however, is considered a poor and delayed marker. New circulating and urinary biomarkers emerged in recent decades as promising in the early diagnosis of AKI, with better sensitivity (s) and specificity (sp) profile. Given its potential benefits in the diagnosis and prognosis of AKI, the need of using these new biomarkers in clinical practice is consensual. This study aims to perform a systematic review of literature, that evaluated the performance of biomarkers for the early diagnosis of AKI.

Methods: A systematic review of the medical literature, including experimental and observational studies published in MEDLINE, BVS, CINAHL and EMBASE, published between 2006-2016. The review will include experimental and observational studies, involving patients with 18 years or older more admitted to an ICU. The systematic review protocol was submitted and approved by the International Prospective Register of Systematic Reviews (PROSPERO), under the code CRD42016037325.

Results: Eight studies were selected. The main biomarkers investigated were neutrophil gelatinase-associated lipocalin (NGAL), L-type fatty acid binding protein (L-FABP), *N-acetyl glucosamine* (NAG) and cystatin C. In 16 out of 23 (66.7%) tests performed by the studies, analyzes have used urine samples. The biomarkers that presented the highest s and sp profile were the heat shock protein-72 (s=100%, sp=90%) and Interleukin 18 (s=92%, sp=100%). Cystatin C showed poor performance in two studies. Overall, two studies presented unfavorable results for the use of biomarker because their levels were significantly affected by comorbidities even in the absence of AKI.

Conclusions: All biomarkers have suffered some influence of other factors, such as comorbidities or etiology of AKI. An understanding of a single biomarker is unable to help identifying the etiology and mechanisms of AKI. Thus, the use of a diagnostic kit combining different biomarkers could be suggested for early diagnosis of AKI. Besides, the identification of AKI etiology may be helpful to guide the implementation strategies.

SA-PO086

A Study of Cell Therapy for Subjects With AKI Who Are Receiving Continuous Renal Replacement Therapy Brian Miller. *Sentien Biotechnologies, Inc., Medford, MA.*

Background: Sentien Biotechnologies, Inc. is developing SBI-101, a combination product containing allogeneic human mesenchymal stromal cells (MSCs) inoculated into a hollow-fiber unit for the treatment of patients with acute kidney injury (AKI) and the need for continuous renal replacement therapy (CRRT). MSCs are a unique source of therapeutic secreted factors that modulate the immune-mediated inflammatory response to acute organ injury and can enhance the repair of injured tissue. SBI-101 therapy is a novel approach designed to overcome the limitations of infusion of MSCs via the utilization of an extracorporeal, blood-contacting device. By immobilizing the MSCs outside of the patient, SBI-101 therapy is designed to facilitate dynamic, continuous blood conditioning in patients undergoing severe organ injury, including AKI requiring CRRT, combining an active therapy with standard of care for these patients.

Methods: The study is a prospective, multi-center, randomized, double-blind, sham-controlled, study of subjects with a clinical diagnosis of AKI due to various etiologies who are receiving CRRT. Subjects must have tolerated CRRT for at least 12 hours after commencement of CRRT and at the time of randomization and treatment with SBI-101. Up to 32 subjects may be enrolled to provide 24 subjects evaluable (as a per protocol population). -Low dose: (250 x106 MSCs) SBI-101 device -High dose: (750 x 106 MSCs) SBI-101 device -Control: Sham SBI-101 (no MSCs) For the low and high dose cohorts, 8 subjects will receive active treatment and 4 subjects will receive sham control.

Results: This study is actively recruiting patients with results expected in 2018.

Conclusions: This first-in-human clinical trial will evalute the safety and tolerability of SBI-101 in patients with AKI requiring CRRT. The study will also measure renal efficacy parameters as well as exploratory biomarkers chosen to characterize the pharmacodynamic effect of SBI-101 in treated subjects.

Renal Recovery among Patients with AKI Who Require Outpatient Dialysis: Impact of ESRD Certification Michael Heung,[3] Maggie Yin,[3] Diane Steffick,[3] Kevin He,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh,[2] Vahakn B. Shahinian,[3] Rajiv Saran.[3] *[1]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [2]University of California Irvine, School of Medicine, Orange, CA; [3]Internal Medicine - Nephrology, University of Michigan, Ann Arbor, MI; [4]University of Tennessee Health Science Center, Memphis, TN.*

Background: AKI patients requiring outpatient dialysis are a vulnerable and growing population. We examined factors associated with ESRD certification and its impact on subsequent renal recovery.

Methods: Using a national Medicare 5% sample from 2004-2014, we identified a cohort of hospitalized patients with AKI-D who survived to discharge and required outpatient dialysis (n=5861). We compared patient characteristics between those declared ESRD (CMS Form 2728) within 10 days of hospital discharge (ESRD group) to those who were not (AKI group). We also examined renal recovery (dialysis independence for ≥30 days) at 90 and 365 days post-discharge, and time trends.

Results: Among the AKI-D outpatient cohort, 76% were declared ESRD while 24% remained AKI. There were no differences between the ESRD and AKI groups in sex or age distribution. Blacks were more likely to be ESRD than whites. The ESRD group had greater proportions of DM, CHF and pre-existing CKD. By 90 days 9.3% of ESRD and 41.2% of AKI patients recovered renal function. At 365 days these rates rose to 15.5% and 44.9%. In a multivariate model, lower odds of 90 day renal recovery were associated with ESRD declaration (OR 0.14, 0.12-0.17), CKD, CHF and black race. During the study period, a decreasing proportion of AKI-D patients were declared ESRD; 90 day recovery rates also decreased slightly, while 365 day rates remained stable (Figure). A significant proportion of AKI-D patients recovered renal function after hospital discharge, including those declared ESRD. After adjusting for clinical factors, ESRD certification remained the strongest independent predictor of renal non-recovery.

Conclusions: Further study is needed to determine the impact of ESRD versus AKI dialysis protocols on renal recovery.

Post-hospitalization outcomes for Medicare AKI-D patients, 2004-2014

SA-PO088

Risk Factors Associated with Early Mortality in Continuous Renal Replacement Therapy for AKI Haewon Lee,[1] Yang Wook Kim,[1] Bongsoo Park,[1] Sihyung Park,[1] Seok ju Park,[2] Yoo jin Lee.[1] *[1]Haeundae Paik Hospital, inje university, Pusan, Republic of Korea; [2]Inje University, Busan, Republic of Korea.*

Background: Continuous renal replacement therapy (CRRT) is a modality favored in hemodynamically unstable acute kidney injury (AKI) patients. However, the mortality of AKI is high despite the use of CRRT in intensive care units. In this study, we aimed to identify factors associated with an increased risk for 72-hour mortality in CRRT.

Methods: We conducted a retrospective observational study among 154 patients who received CRRT from March 2010 to December 2016. Laboratory parameters, demographic characteristics, administration of vasopressors, ventilator use, comorbidities, presence of anuria and fluid overload before starting CRRT were analyzed for any association with mortality.

Results: A total of 154 patients were enrolled in this study. Among them, 137 (89%) died in the ICU while on CRRT. Survivors and non-survivors showed significant differences in total bilirubin (1.61 ± 1.6 vs. 6.06 ± 7.73 mg/dl, p=0.01), mean BP (77.7 ±16.69 vs 66.91 ± 13.98 mmHg, p=0.01), systolic BP (108.53 ± 22.07 vs. 90.12 ± 19.63 mmHg, p=0.01), and amount of fluid overload for 3 days before initiating CRRT (5.02 ± 5.73 vs. 8.21 ± 5.44 L, p=0.01). Univariate analysis revealed parameters associated with mortality included ventilator use (OR 10.75, 95% CI 0.031~0.283), vasopressors (OR 4.16, 95% CI 0.085~1.71), malignancies (OR 4.76, 95% CI 0.04~0.9), and pre-CRRT fluid overload more than 2.5L (OR 3.91, 95% CI 1.06~14.3). Cox multivariate regression analysis was performed to exclude confounding factors. Use of vasopressors (HR 0.32, p=0.01), malignancy (HR 0.55, p=0.02), and pre-CRRT fluid overload (HR 0.63, p=0.03) were independent factors for death within 72 hours after initiating CRRT.

Conclusions: In conclusion, comorbidities such as malignancies, systolic blood pressure, and pre-CRRT fluid overload were closely related with 72-hour mortality in CRRT which may require close attention during ICU care. We emphasize the need to identify clinical or laboratory factors, especially those that are correctable, in the management of critical acute kidney injury.

SA-PO089

AKI Requiring Dialysis in ECMO Cristina E. Pinal,[1,2] Maaz Syed Ahmed,[1,2] Luis A. Concepcion.[1,2] *[1]Medicine, Baylor Scott&White, Temple, TX; [2]Texas A&M Health Science center, Temple, TX.*

Background: ECMO is used in critically ill patients with life threatening acute respiratory or circulatory failure. AKI requiring dialysis (RRT) is a frequent complication. Purpose: single center retrospective study to determine the incidence of AKI requiring dialysis, the outcome and survival in patients requiring ECMO.

Methods: Adult patients requiring ECMO (2012-1015) included. Demographic, laboratory and dialysis data obtained from the EMR. ECMO in VA/VV configuration by standard methods. Dialysis performed placing a dialyzer(Sorin SH14) in line w/ ECMO circuit and running dialysate (Nxstage[tm] bicarbonate based), using IV pumps 2 L per hour x 24 h a day, Ultrafiltation controlled with IV pump. No heparin used other than for the ECMO circuit. Results as mean and standard deviation, statistical analysis done w/ SPSS version 13.

Results: 169 patients, age 53(15) y, weight 92.7 (22) kg, BMI 31(6)EF 49(15)%. 77% white, 10%AA,28%DM,61%HTN 13%CKD, 41%CHD, 39% sepsis, 82% anemia(Hb<13). ECMO type:52% VA 48%VV. AKI requiring dialysis occur in 89(52.4%). Overall mortality 53%(64%VA 42%VV ECMO). The patients that required RRT had 51.7%mortality vs 54.4% not requiring RRT. Indications for RRT:75%fluid overload, 7.7%hyperkalemia, 3.6%acidosis. Within 4 days of admission 69.3%were on ECMO. Within 4 days in ECMO 60.7%of the patient with AKI required RRT.53%of the dialysis treatments done w/ 3K bath, 31% 2K, 11% 4K. The mean time on dialysis was 15.7 days(23).52.1% required 8 d of RRT and 75% required 22days of RRT. The patients had 6.7(7)liters of positive fluid balance at the start of RRT. The UF per day was 1.1(1.7)L with 75% of the patients the average daily UF was 2.3L. Serum creatinine at the start of ECMO was 1.57(1.1), at the start of RRT 2.94(1.3)mg/dl. BUN at the start of RRT was 67(37) mg/dl. The number of pressors in RRT 2.9 (1.2) vs 2.6(1.1) in non RRT patients($p<0.05$). By Kaplan-Meier analysis the median survival was 31 days(all population), No difference between VA and VV ECMO. For RRT the median survival was 41.6days, not RRT 45 days (NS) by log rank. No difference by diabetic status in survival.

Conclusions: AKI requiring dialysis is a frequent event in patients requiring ECMO. On line dialysis can be performed without the need of a dialysis machine. The mortality was not influence by the need of dialysis support in this critically ill patients. More pressors were needed in the patients that required dialysis support.

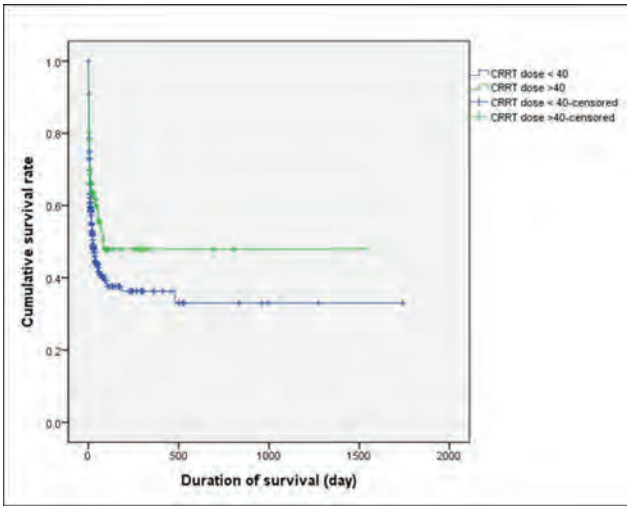
The Influence of Hypophosphatemia on Outcomes during CRRT in AKI Patients Yeonsoon Jung, Weon hyung Lee, Ho Sik Shin, Hark Rim, Hyo jong Kim, Ye na Kim. *Kosin University College of Medicine, Gospel Hospital, Busan, Republic of Korea.*

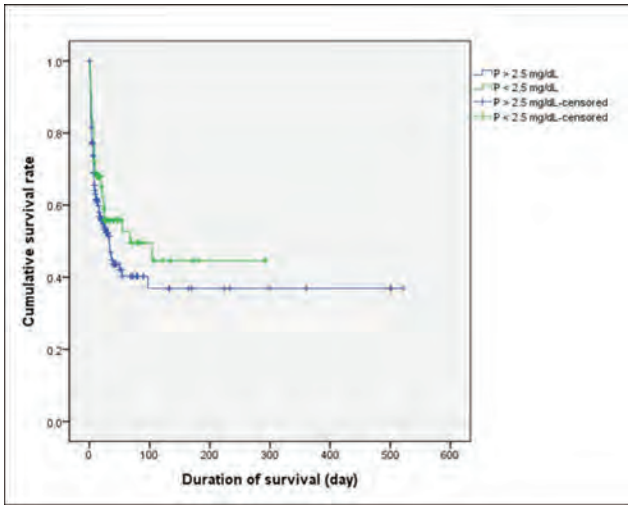
Background: To assess the role of hypophosphatemia in major clinical outcomes in patients treated with low-or high-intensity continuous renal replacement therapy(CRRT).

Methods: We performed a retrospective analysis of data collected from 620 patients. We divided the patients into two different groups of CRRT intensity (more than or less than 40 mL/kg/hour of effluent generation) and measured serum phosphate level daily.

Results: We obtained a total of 1800 phosphate measurements on days 0,1 and 2 and identified 49 patients (8%), 93 patients (15%), and 142 patients (23%) with hypophosphatemia on each of these respective days. In patients treated with lower-intensity CRRT, 23 episodes of hypophosphatemia/1000 patinet days were identified, compared with 83 episodes/1000 patient days in patients receiving higher-intensity CRRT ($P < 0.01$). Multiple Cox proportional hazards analyses showed that APACHE score, utilization of vasoactive drugs, and arterial pH on the third CRRT day were significant predictors of mortality; however, serum phosphate level was not a sinificant contributor.

Conclusions: The APACHE score, use of vasoactive drugs, and arterial pH on the 2nd CRRT day were significant predictors of mortality. Hypophosphatemia might not eb a major risk factor of increased motality in patients treate with CRRT.





SA-PO091

Effect of Low Dialysate Temperature on Blood Pressure During SLED in Patients with AKI Fahad Y. Edrees, Anitha Vijayan. *Washington University in St. Louis, St. Louis, MO.*

Background: AKI requiring RRT is associated with high mortality and morbidity. Intradialytic hypotension (IDH) may delay renal recovery by perpetuating ischemic injury. Studies have shown that lowering dialysate temperature to 35.5-36°C in ESRD patients is associated with decrease in the incidence of IDH. However, data in AKI patients undergoing CRRT or sustained low-efficiency dialysis (SLED) are scarce. We conducted a prospective, randomized, cross-over study to evaluate the effect of lower dialysate temperature on the hemodynamic status of critically ill patients with AKI during SLED.

Methods: We obtained approval from Washington University IRB. Patients were randomized to start SLED on either high (37°C) (Group A) or low (35°C) dialysate temperature (Group B) and then alternate treatments. Patients who had a single treatment, required antihypertensive medication after enrollment, or were on 3 pressers before starting treatment were excluded. SLED was performed using the NxStage System One®, with blood flow at 300ml/min and dialysate flow of 33 -126ml/min. Hypotensive event was defined by any of the following: ↓SBP ≥ 20mmHg, ↓MAP ≥ 10mmHg, decrease in ultrafiltration or change in vasopressors requirement. The number of events was analyzed by Poisson regression and other outcomes with repeated-measures ANOVA.

Results: We enrolled 21 patients who underwent a total of 78 SLED sessions, 39 in each arm. The mean age was 56.1 and mean SOFA score at time of enrollment 9.4 ± 2.6. There was doubling of hypotensive events in high temperature (1.4±1.0) compared to low temperature (0.7±0.6) sessions (P=0.007).(Table1)

Conclusions: AKI patients undergoing SLED with low dialysate temperature, experience significantly less intradialytic HoTN. Prevention of IDH may help to achieve UF targets, thereby preventing volume overload and may also help to promote renal recovery. A larger study is required to confirm our findings.

Primary and Secondary Outcomes

Outcome	Estimate ± SEM	Mean ± SEM		IRR	95% CI	p-value
		High Temp	Low Temp			
Events	0.75 ± 0.14	1.4 ± 1.0	0.7 ± 0.6	2.11	1.59 - 2.79	0.007
Ultrafiltration Difference	238 ± 104	421 ± 78	182 ± 79		21 - 456	0.03
Ultrafiltration % Achieved	-8.0 ± 4.1	84.0 ± 32.3	93.0 ± 3.3		-17 - -0.26	0.04
Lowest temp during SLED	0.02 ± 0.10	36.6 ± 0.1	36.5 ± 0.1		-0.20 - 0.23	0.88
Temp at end of SLED	0.10 ± 0.14	36.9 ± 0.1	36.8 ± 0.1		-0.19 - 0.38	0.48

Improving CRRT Lifespan: A QI Initiative Nathaniel C. Reisinger, Behdad Besharatian, Akash N. Sethi, Margaret Duffy, Ramnika I. Gumber, Joseph A. Messana, Jordana B. Cohen, Alan G. Wasserstein, Michael Chaknos, Dan Negoianu. *Penn, Philadelphia, PA.*

Background: Unplanned interruptions of continuous renal replacement therapy (CRRT) can impact patient care, nursing workflow, and value of care. At our center, a rapid blood flow rate (Qb) of 300 mL/min is used to minimize the need for anticoagulation. At this Qb, circuit lifespan should be 48 hours. Retrospective review of 4 weeks of data showed that over 50% of treatments last less than 24 hours. The optimal Qb to maximize filter life is not known. Furthermore, short catheter length is associated with decreased CRRT filter life in a randomized trial. We wished to explore whether increased blood flow and/or catheter position would be associated with improved filter life.

Methods: CRRT treatments were tracked prospectively for one month before and one month after our standard Qb was increased from 300 mL/min to 350 mL/min. The duration of treatment, reason for circuit discontinuation, and position of the tip of the catheter was noted. Kruskall-Wallis rank sum test was used to compare median circuit life as categorized by catheter position for the pre-intervention data set.

Results: Pre-intervention versus post-intervention, respectively, 23% versus 22% of CRRT circuits failed within 24 hours, 13% versus 13% failed between 24 and 48 hours, and 64% versus 65% expired having met their approved lifespan. Catheters in the upper 1/3 superior vena cava (SVC) had median lifespan of 36.5 hours (interquartile range 21-47). Catheters in the mid 1/3 SVC had median lifespan of 21 hours (interquartile range 14-27). Catheters in the lower 1/3 SVC had median lifespan of 48 hours (interquartile range 46.5-48). Catheters in the right atrium (RA) had median lifespan of 47 hours (interquartile range 40.5-48). p=0.0013 for the overall comparison.

Conclusions: Increasing blood flow rate to 350 mL/min did not decrease the percentage of treatments which clogged or clotted before 24 hours. However, more central catheter position was significantly associated with improved filter life. We intend to explore methods to improve catheter placement in the future.

SA-PO093

Inferior Vena Cava Diameter Correlates with Ultrafiltrate Removal in Septic Patients with AKI Jung Hee Chae,[1] Jennifer L. Waller,[1] Azeem Mohammed,[1] John J. White,[1] Matthew J. Diamond,[1] Muhammad O. Saleem,[1] N. Stanley Nahman.[1,2] *[1]Augusta University, Augusta, GA; [2]Norwood VAMC, Augusta, GA.*

Background: The physical examination in septic patients with acute kidney injury (AKI) may over or under estimate effective circulating blood volume. As a result, target ultrafiltration goals (UF) are frequently empiric, often defined in retrospect by hypotension or cardiac instability. We previously showed pre-dialysis inferior vena cava diameter (IVCD) correlated with volume removal in volume-expanded hemodialysis (HD) patients (Mohammed JASN 27:573A). In the present study, we theorized that pre-dialysis IVCD would better estimate and correlate with safe UF removal from septic AKI patients.

Methods: Septic AKI patients were studied before and during the first session of dialysis. Prior to dialysis, systolic blood pressure (SBP), the presence of rales or edema was recorded, and a UF goal was empirically assigned. Two trained operators (JC and AM) assessed IVCD using a GE Sonosite machine prior to the institution of dialysis. Linear regression (LR) was used to examine the association between pre-IVCD and volume removal.

Results: 20 septic AKI consented patients (see table) were studied: 60% black, 55% male, 70% hypervolemic (based on the presence of edema or rales), 40% on vasopressors, 55% intubated. Dialysis modalities included HD (n=16) and CRRT (n=4). Pre-dialysis parameters (mean±SD) included: age 59.7±12 yrs, SBP 128.3±22.2 mmHg, IVCD 2.65±0.7 cm. The average volume removed with dialysis was 2.50±1.9L. In the final multiple LR model, only IVCD predicted UF removal controlling for age, edema, volume status, intubation and pre-SBP, where for every one cm increase in pre-IVCD, 2.14 kg of volume was removed ($R^2 = 0.5182$, $p < 0.0003$). Neither edema nor rales was statistically predictive.

Conclusions: In septic AKI patients, the physical examination is not predictive of UF removal with dialysis, but the pre-dialysis IVCD correlates strongly with the ability to remove excess fluid. Measuring IVCD may improve UF removal estimates in septic patients with AKI, and reduce hypotensive and cardiac events associated with dialysis.

Dialysis modality	Age (yrs)	Black race (%)	SBP (mmHg)	IVCD (cm)	Volume removed (L)
HD	61.7±9.8	62.5	129.3±23.4	2.71±0.68	2.72±1.78
CRRT	52±16.5	50	124.2±11.1	2.46±0.7	1.63±1.71
Total	59.7±12	60	128.3±22.2	2.65±0.7	2.50±1.9

SA-PO094

Comparison of Measured versus Online Urea Kinetics in Patients with AKI Undergoing Hemodialysis Owais Bhatti, Yifei F. Zhang, Anitha Vijayan. *Washington University St Louis, Saint Louis, MO.*

Background: In patients with acute kidney injury (AKI) on intermittent hemodialysis (HD), KDIGO guidelines recommend a target single pool Kt/V (spKt/V) of 1.3, three times per week. Currently, the standard method of monitoring dialysis adequacy is by calculating spKt/V using pre and post serum BUN. This requires additional blood draws which are associated with nursing labor and laboratory costs. Online urea kinetic monitor systems, such as continuous dialysate UV-adsorbance monitoring, can potentially measure real time spKt/V without added cost. Unlike ESRD, AKI patients have fluctuating volume of distribution of urea and data on online urea monitoring in AKI are scarce.

Methods: We instituted a QI project to compare online monitoring to measured Kt/Vurea. After approval from the Washington University IRB we conducted a retrospective analysis of this data. For a single dialysis session per patient, spKt/V was calculated via Daugirdas equation, and compared to Kt/V measured by dialysate online urea monitoring. All patients underwent HD using B.Braun Dialog$^{+(R)}$ machines. Data were analyzed using Bland-Altman analysis.

Results: We reviewed 43 dialysis treatments of 20 patients with AKI. The mean age was 53 years, 60 % (12) were men and 65 % (13) had ATN. Bland- Altman analyses of the data showed that both methods were in agreement (Fig 1).

Conclusions: In this pilot study, data suggest that spKt/V calculated via pre and post serum BUN is comparable to the Kt/Vurea measured by continuous dialysate monitoring using UV-adsorbance. This has major implications regarding cost savings while ensuring that AKI patients are receiving adequate dialysis. A larger prospective study is needed to

determine whether online urea kinetics monitoring can be substituted for measured Kt/Vurea in patients with AKI.

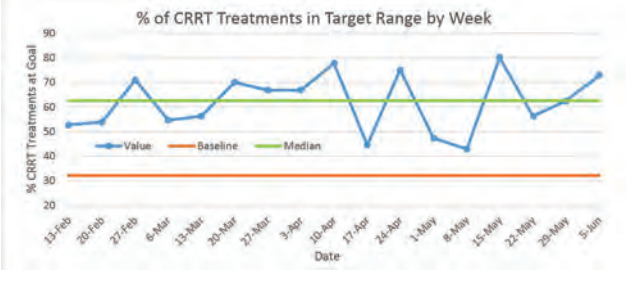
Continuous Renal Replacement Therapy Dosing in Critically Ill Patients Benjamin Griffin,[4] Amanda Thomson,[7] Mark Yoder,[2] Shannon J. Bortolotto,[3] Deb G. Bonnes,[2] Lisa M. Dufficy,[7] Adam P. Bregman,[1] Sarah Faubel,[5] Diana I. Jalal.[6] *[1]None, Denver, CO; [2]UCHealth, Aurora, CO; [3]Univeristy of Colorado Hospital/UCHealth, Aurora, CO; [4]University of Colorado, Aurora, CO; [5]University of Colorado Denver, Denver, CO; [6]University of Colorado Denver Health Science Center, Aurora, CO; [7]University of Colorado Hospital, Aurora, CO.*

Background: Continuous Renal Replacement Therapy (CRRT) is a commonly performed procedure in critically ill patients with acute kidney injury (AKI) in the intensive care unit (ICU). National guidelines from Kidney Disease Improving Global Outcomes (KDIGO) give a level 1A recommendation that CRRT should be prescribed to achieve a daily dose of 20-25 ml/kg/hr. Unfortunately, nationwide prescribing practices are quite variable, including among renal staff at the University of Colorado Hospital (UCH).

Methods: Our aim was to deliver a 20-25 mL/kg/hr average daily dose of CRRT in >80% of daily sessions. All patients at UCH who received CRRT were included. Key interventions included modifications to the CRRT flowsheet in EPIC to display actual delivered dose in terms of mL/kg/hr, development of a "CRRT Provider Protocol" to standardize CRRT delivery across the division, implementation of a CRRT didactic session within the clinical fellows' core curriculum, and an update of the standard CRRT procedure note to include the 24-hour average delivered dose. The outcome variable was % of patients with CRRT dosing in the range of 20-25 mL/kg/hr. Process variables included % of CRRT hours charted correctly by the nursing staff, and % of nephrology notes that record the dose. Balancing measures included nursing satisfaction and time spent charting.

Results: The above implementations were employed starting in February 2017. Prior to then only 32% of patients had an average daily delivered CRRT dose in the range of 20-25 mL/kg/hr. The median value since implementation in 62% (Figure 1). Nurses accurately charted the dosing variables 87% of the time when the new flowsheet was implemented, which has since risen to 96% charting accuracy. 100% of nurses surveyed feel their workload is the same or less with the new flowsheet.

Conclusions: Achieving the KDIGO recommended guidelines of delivering CRRT at 20-25 mL/kg/hr is achievable using EMR tools, and does not significantly increase the workload for nephrologists or nursing staff.



SA-PO096

Performance of Immunoglobulin E, Immunoglobulin G, and Combined Both in Predicting Minimal Change Disease before Renal Biopsy Kun-Hua Tu,[2] Cheng chia Lee.[1] *[1]Chang Gung memorial hospital, Taipei, Taiwan; [2]Chang gung memorial hospital, Taoyuan, Taiwan.*

Background: The diagnosis of minimal change disease (MCD) in adults rely mainly on renal biopsy. Procedure of renal biopsy brings not only the diagnostic benefit but also risk of complications. Although advance in image modality of percutaneous renal biopsy, biopsy-related complication still occurs. Bleeding is one of the major complications that may lead to hemodynamic instability and even death in few cases. Thus, development of model to predict MCD for high risk patients unsuitable for renal biopsy is necessary.

Methods: 142 patients with nephrotic syndrome who received renal biopsy between October 2007 and April 2011 at one tertiary medical center were enrolled in this study. Demographic, clinical, and pre-biopsy laboratory variables were retrospectively recorded and analyzed.

Results: The overall prevalence of MCD in this study was 26.8%. Age, hemoglobin levels, 24hrs urine protein, IgG, IgE differ significantly between MCD and non-MCD group. Further analyses demonstrated combined above clinical model and this two Ig risk factors (IgG < 450 and IgE > 110) exhibited best discrimination power in predicting the diagnosis of MCD, with the AUROC of 0.91 (95% CI 0.85-0.97, p<0.001).

Conclusions: The current study demonstrated that age, hemoglobin, 24-hours urinary protein are significant predictors of minimal change disease before renal biopsy. Combined above clinical model and this two Ig risk factors provide medical physician simple and valuable clinical markers to diagnose MCD. Further studies are warranted to examine the role of Ig as diagnostic, pathogenic, and prognostic marker in MCD

SA-PO097

Clinical Consequences of Different Albumin Measurement Methods in Patients with Membranous Nephropathy Coralien Vink- van Setten,[1] Anne-Els van de Logt,[1] Jack F. Wetzels.[2,1] *[1]Radboud UMC, Nijmegen, Netherlands; [2]Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Albumin levels are often used to define disease or predict risk. Cut off values are used to define nephrotic syndrome or advise toward the use of prophylactic anticoagulant therapy in patients with membranous nephropathy (MN). However, differences between albumin assays, although recognized (Bachmann 2016) are often unnoticed. In this study we aimed at quantifying differences between different albumin assays (immunonephelometry (reference), bromcresol green (BCG) and bromcresol purple (BCP)) in nephrotic patients with MN.

Methods: Plasma samples were collected from nephrotic patients with MN. Samples were stored at -80 °C. Albumin was measured with BCG, BCP and immunonephelometry in plasma in our hospital. A round robin was organized to compare the results of the BCG assay used in three regional hospitals.

Results: We included 23 MN patients (83% male), mean age was 60 ± 13 years, median serum creatinine level was 107 µmol/l (IQR 83-152) and median protein creatinine ratio 6.3 g/10 mmol (IQR 3.9-8.9). Mean serum albumin in nephelometric assay was 21.1±4.5 g/l. Whereas bias with the BCP was limited (0.3±1.8 g/l), BCG reported higher bias (5.1±1.9 g/l). Three regional hospitals, that used BCG, also reported higher serum albumin values. Variation between centers was large (Figure 1). Bias in hospital 1 and 3 was very high; respectively 6.7±2.1 g/l and 7.7±2.3 g/l. In hospital 2 a bias comparable with our assay (4.8±1.9 g/l) was noticed. Calculated accuracy of prophylactic anticoagulant therapy using a cut-off value of 25 g/l ranged between 53 % and 83 %, indicating that up to 47 % of patients might not receive appropriate therapy.

Conclusions: A large bias and impression was noticed between different albumin assays in patients with MN. The BCG assay overestimates serum albumin values. There were large between-centers differences. Inaccuracy of serum albumin assays will contribute to incorrect treatment decision. Clinicians should be aware of these variations. More attention to calibration and standardization is urgently needed.

Urinary Metabolomic Study in Patients with Membranous Nephropathy Hyung Ah Jo,[2] Seung Hee Yang,[1] Dong Ki Kim.[2] *[1]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jong ro Gu, SEOUL, Republic of Korea.*

Background: Membranous nephropathy (MN) is a leading cause of adult-onset nephrotic syndrome. Primary MN is an autoimmune disease caused by autoantibodies such as phospholipase A2 receptor antibody (PLA2RAb) and thrombospondin type 1 domain-containing 7A antibody against the podocyte antigen. Many previous studies showed that the prognosis of patients with MN can be predicted by measuring the levels of these autoantibodies. However, the treatment response varies among individuals, and adverse reaction to immunosuppressive agent (ISA) is significant. The treatment response should be optimized and the adverse reaction to ISA should be minimized. Thus, we performed a urine metabolomic study to identify the predictive biomarker of the prognosis and treatment response in patients with MN.

Methods: We used urine samples from patients with biopsy-proven primary MN that were stored at the time of kidney biopsy in Seoul National University Hospital Biobank to find differences in urine metabolites between the MN (n = 79), minimal-change-disease (n = 74), and control groups (n=82). The 800-MHz nuclear magnetic resonance-based metabolomic method was used. We investigated the urine metabolites specific to MN after excluding outliers and matching factors such as age, sex, and presence of diabetes mellitus. Serum PLA2RAb level was examined using an enzyme-linked immunosorbent assay. Hard outcome was defined as initiation of dialysis, a 50% decrease in the estimated glomerular filtration rates, and doubling of serum creatinine levels. We reviewed the association of urine metabolites with each patient's ISA response and the presence of hard outcome.

Results: After excluding outliers and matching for age, sex, and presence of diabetes mellitus, the levels of urine metabolites such as tyrosine, alanine, fumarate were higher than those measured in the control urine samples. The urinary fumarate level was significantly higher in the patients with steroid-resistant MN than that measured in the urine sample from the steroid-responsive patients. In this study, the patients with a hard outcome during the follow-up period showed urine fumarate levels 2.53-fold higher than those of the patients with a non-hard outcome.

Conclusions: Fumarate is a reliable biomarker for predicting the prognosis and treatment response of patients with MN. We have a plan to validate this metabolomic study.

Dysbiosis of Gut Microbiota in Children with Relapsing Idiopathic Nephrotic Syndrome Chikushi Suruda,[1] Takahisa Kimata,[2] Sohsaku Yamanouchi,[2] Shoji Tsuji,[2] Kazunari Kaneko.[2] *[1]Department of Pediatrics, Kansai Medical University, Osaka, Japan; [2]Kansai Medical University, Hirakata-shi, Japan.*

Background: Background and Aims: Although the etiology of idiopathic nephrotic syndrome (INS) remains unknown, it is suggested that an abnormality in regulatory T cells (Treg), which have a central role in the suppression of inflammatory and allergic responses is involved. We also reported that the Treg is suppressed in number at the onset or relapse of INS in childhood (Pediatr Int., 2017). It was recently reported that *Clostridium* species, particularly clusters IV and XIVa of the genus *Clostridium* composing gut microbiota enhance the frequency of Treg in the colon. Taken together, we wonder whether a dysbiosis of gut microbiota leads to insufficient induction of Treg resulting in the relapse of INS. This study was conducted to clarify the dysbiosis in patients with INS and its association with their relapse.

Methods: Subjects and Methods: We collected naturally excreted feces (at onset of INS) from eight INS patients who relapsed (group R; median age: 3.0 years, 5 males and 3 females), four INS patients who did not relapse (group NR; median age: 4.3 years, 2 males and 2 females), and seven healthy children (group C; median age: 3.7 years, 4 males and 3 females). We conducted metagenome analysis using bacterial DNA that was extracted from the feces, The composition of colonizing bacteria was assessed by 16S ribosomal RNA gene sequencing of fecal samples using the Ion 16S Metagenomics Kit and the Ion Torrent Personal Genome Machine platform and compared the proportion of *Clostridium* species, clusters IV and XIVa of gut microbiota among 3 groups. Kruskal-Wallis test was used for statistical analysis.

Results: The proportion of *Clostridium* species, clusters IV and XIVa was significantly lower in the group R (median 0.8%) than those in the group C (14.3%) (P = 0.002, respectively). In contrast, there was no significant difference in the proportion between the group NR(11.4%) and group C (P = 0.83).

Conclusions: Discussion and Conclusion: Gut dysbiosis characterized by the lower proportion of clusters IV and XIVa of the genus *Clostridium* might be contributed to relapse of INS.

Lupus Nephritis Is Linked to Immunity to an Intestinal Commensal Lachnospiracaea Species Brad H. Rovin,[1] Doua F. Azzouz,[2] Jill P. Buyon,[2] Alexander Alekseyenko,[3] Gregg Silverman.[2] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]NYU School of Medicine, New York, NY; [3]Medical University of South Carolina, Charleston, SC.*

Background: A transmissible agent has long been suspected in the pathogenesis of SLE. We therefore investigated the potential contribution of the intestinal microbiome to LN.

Methods: Blood and fecal samples from SLE patients were obtained, unless a patient had selective IgA deficiency, prior cytotoxic drugs, or antibiotics within four months. Fecal 16S rRNA NGS was performed. Sera samples were profiled for autoantibodies. Sera from two independent lupus cohorts were studied for validation.

Results: Compared to controls, the intestinal microbiome from SLE patients (N=61) showed decreased species richness diversity. The microbiomes of patients in clinical remission (based on SLEDAI) were most similar to healthy controls, while reductions in taxonomic complexity were most pronounced in those with high disease activity. Notably, SLE patients had an overall 5-fold greater representation of a particular species in the Blautia genus of the Lachnospiracaea family of obligate anaerobic Gram-positive cocci. Abundance of this species significantly correlated with serum IgG to a cell wall moiety from a strain of this species (P=0.002, N=61, Spearman) but not with 7 other strains. There was also a significant correlation between the distribution of SLEDAI scores and levels of these circulating anti-strain IgG antibodies (P=0.02, N=48). Using antigen treated with DNAse/proteinase K, levels of IgG anti-strain antibodies were significantly higher in those with active nephritis at time of sampling compared to SLE without renal activity (Cohort 1 P=0.01 N=48; Cohort 2 P=0.001, N=53, Mann-Whitney). Levels of anti- strain antibodies also significantly correlated with high-titer serum IgG to native DNA (P<0.0001, N=27), and inversely correlated with C3 and C4 (each P<0.01, N=61). High titers of these anti-bacterial antibodies were found in active Class III, IV and V LN.

Conclusions: These findings suggest a novel paradigm for the pathogenesis of LN: Specific strains of common intestinal commensal bacteria affect IgG-autoantibody responses in patients with LN. This is reminiscent of post-streptococcal GN, although the postulated intestinal bacterial bloom occurs without clinical infection.

Molecular Profiling of the Kidney Biopsy in Class V Lupus Nephritis: Implications for Therapy Juan M. Mejia-Vilet,[1,2] Samir V. Parikh,[1] Huijuan Song,[1] Paolo Fadda,[1] Norma O. Uribe-uribe,[2] John P. Shapiro,[1] Lianbo Yu,[1] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: Class V lupus nephritis (LN) is often grouped with proliferative LN in clinical trials of experimental therapeutics. Given its distinctly different histology there is concern that class V patients may confound trial results of proliferative LN. We used molecular profiling of the kidney biopsy to identify potential differences in the immune pathogenesis of class V LN and proliferative LN.

Methods: Kidney biopsies from 21 patients having their first episode of LN were used. The glomeruli and tubulointerstitium (TI) were isolated by laser capture microdissection. RNA was extracted from each compartment and a panel of 578 immune-response genes was measured by Nanostring. Transcript expression was compared between proliferative (PF; classes III/IV) LN (n=7), membranous (MLN, class V) LN (n=5) and mixed (MT, classes III/IV+V) LN (n=9). Living transplant donor kidneys (n=10) were used as normal controls (NC).

Results: Principal component analysis showed clustering of patients by LN class in both renal compartments, but this was particularly striking for MLN and NC groups. A total of 42, 29 and 8 genes were differentially expressed in the glomeruli between MLN and MT, MLN and PF and MT and PF groups, respectively. Interferon-α2 (IFNA2)-regulated genes had higher expression in MLN glomeruli compared to MT and PF glomeruli. In contrast, 20 transcripts regulated by TGF-b1 had lower expression in MLN glomeruli compared to MT. In the TI, a total of 108, 21 and 25 genes were differentially expressed between MLN and MT, MLN and PF and MT and PF. In par ticular, transcripts regulated by IL-3 and IL-18 had higher expression in MLN than MT.

Conclusions: MLN has a distinctive gene expression pattern when compared to MT and PF LN which likely reflects a different pathogenesis. This has implications for treatment and for inclusion in clinical trials of experimental therapeutics.

Characterizing the Glomerular Immune Response to Induction Therapy in Lupus Nephritis (LN) through Molecular Imaging of Serial Kidney Biopsies Samir V. Parikh,[3] Ana Malvar,[1] Huijuan Song,[3] John P. Shapiro,[3] Valeria G. Alberton,[4] Juan M. Mejia-Vilet,[3] Isabelle Ayoub,[3] Anjali A. Satoskar,[3] Jianying Zhang,[3] Paolo Fadda,[3] Michael T. Eadon,[2] Daniel J. Birmingham,[3] Brad H. Rovin.[3] *[1]HOSPITAL FERNANDEZ, Buenos Aires, Argentina; [2]Indiana University Division of Nephrology, Indianapolis, IN; [3]Ohio State University Wexner Medical Center, Columbus, OH; [4]hospital Fernandez, Buenos Aires, Argentina.*

Background: The effects of LN therapy on the molecular profile of kidney is unknown. To address this question we examined the glomerular transcriptomes before and after induction therapy.

Methods: Patients with proliferative LN (n=56) were diagnosed by kidney biopsy (Bx1), treated with steroids plus cyclophosphamide (CYC) or mycophenolate (MMF) and re-biopsied after induction (Bx2). At Bx2 14 CYC and 13 MMF patients achieved a complete renal response (CR) and 6 CYC and 3 MMF patients had no response (NR). Glomeruli were isolated by laser capture microdissection and RNA was analyzed by Nanostring technology. Transcript expression was compared between Bx1 and Bx2 for each group. Only transcripts with at least 2-fold change (FC) and p<0.01 were considered differentially-expressed.

Results: After treatment, transcripts that were differentially overexpressed at Bx1 decreased in expression at Bx2 in CR treated with CYC or MMF. This included significant downregulation of pro-inflammatory, complement and fibrosis genes including *FCER1G, C1QB, CCL2, FN1, and TGFBI.* Conversely, NR after CYC showed persistent overexpression of transcripts upregulated at Bx1 and increased expression of additional transcripts including *CR1* (FC: 2.0, P=0.001), *C8G* (P=2.1, FC=0.002), *MIF* (FC-2.0, P=0.009), *STAT6* (FC: 1.9, P=0.0009) and *LGALS3* (FC: 1.9, P=0.005). NR after MMF also showed persistent overexpression of transcripts upregulated at Bx1 but also increased expression of over 20 additional transcripts, including dendritic cell, neutrophil, and NK cell signatures, such as *IL3 (FC: 2.5, P=0.0004), CSF2RB* (FC: 3.1, P=0.0001), *KLRF1* (FC: 3.4, P=0.0003), *TNFSF12* (FC: 2.7, P=0.001), *IL21R* (FC: 3.5, P=0.0003), *FN1* (FC:3.9, P=0.001), and *LAMP3* (FC:2.2, P=0.0003).

Conclusions: The glomerular immune signature in NR after MMF therapy is different than after CYC. These data suggest that different approaches may be needed to rescue NR depending on choice of induction treatment.

SA-PO103

Elevated BAFF Following Rituximab for Lupus Nephritis (LN) Is Associated with Higher Anti-dsDNA Titers in Patients with B Cell Recovery Liliana M. Gomez Mendez,[3] Matthew Cascino,[1] Brad H. Rovin,[2] Paul R. Brakeman,[3] Jay P. Garg,[1] Paul Brunetta,[1] Leonard L. Dragone.[1] *[1]Genentech, South San Francisco, CA; [2]Ohio State University, Columbus, OH; [3]UCSF, San Francisco, CA.*

Background: B-cell activating factor (BAFF) increases following B cell depletion by rituximab (RTX) in lupus. This has been associated with increased anti-dsDNA titers and may contribute to lupus relapses. The relationship between treatment with RTX, changes in BAFF, and anti-dsDNA titers at time of B cell recovery has not been previously assessed using clinical trial data.

Methods: We analyzed data from LUNAR (NCT00282347), a randomized trial that compared the addition of RTX or placebo (PBO) to background therapy of mycophenolate mofetil and steroids for the treatment of LN. At 78 weeks (12 months after final RTX infusion), linear regression was used to estimate the association between treatment, change in BAFF, B cell recovery, and anti-dsDNA titers. B cell recovery was defined as CD19 counts ≥ 50 cells/μL.

Results: Complete data was available for 99 patients. At baseline, median BAFF did not differ by treatment arm (3145 vs 3150 pg/mL) but was higher in patients who were anti-dsDNA positive (3540 vs 2380 pg/mL, p=0.002). BAFF increased in both arms at week 28 vs baseline (PBO 1674 pg/mL, p<0.001; RTX 4940 pg/ml, p<0.001). Between weeks 28 and 78, BAFF fell in both treatment arms but did not return to baseline. At week 78, 25 RTX patients had B cell recovery. In this subgroup, every increment of 1000 pg/mL in BAFF predicted a 9% higher anti-dsDNA at week 78 (p=0.019). This association was not seen among patients without B cell recovery or in PBO arm. However, absolute anti-dsDNA levels at week 78 were similar in the B cell recovery group vs patients without recovery (42 vs 24 IU/mL, p=0.8). Furthermore, anti-dsDNA levels were significantly lower in RTX-treated patients than PBO patients at week 78 (37 vs 66 IU/mL p=0.03).

Conclusions: BAFF increased in both treatment arms of the LUNAR trial, but with a larger increase in the RTX arm. In patients with B cell recovery at week 78, increased BAFF levels correlated with increased anti-dsDNA levels. Despite higher BAFF, anti-dsDNA levels remained significantly lower in the RTX group compared to the PBO group throughout 78 weeks. Therefore, the overall effect RTX has on lowering antibody titers may offset the effects of RTX-induced increases in BAFF.

Molecular Heterogeneity of the Kidney in Lupus Nephritis (LN) in Patients of Different Races and Ethnicities Isabelle Ayoub,[1] Juan M. Mejia-Vilet,[2] Daniel J. Birmingham,[1] Samir V. Parikh,[1] Huijuan Song,[1] John P. Shapiro,[1] Paolo Fadda,[1] Anjali A. Satoskar,[1] Lianbo Yu,[1] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico. Group/ Team: CKD Biomarker Consortium.*

Background: Black and Hispanic LN patients often have a more severe course and worse renal outcomes than white patients. This has been attributed to several factors, including socioeconomic status. We postulated that activation of different pathogenic pathways during LN may account, in part, for these racial/ethnic differences. To test this hypothesis the kidney transcriptomes of black, Hispanic and white patients were examined at LN flare.

Methods: Kidney biopsy was done at the first episode of LN in black (n=5), white (n=2) and Hispanic (n=3) SLE patients. All showed class III or IV LN. Glomeruli were isolated using laser capture microdissection. RNA was extracted and transcript expression analyzed by Nanostring technology. The expression of 358 immune/inflammatory genes was compared in blacks, whites and Hispanics

Results: As shown in the table, 3 transcripts were significantly upregulated and 3 transcripts were significantly decreased in glomeruli from black and Hispanic patients compared to glomeruli from white patients. Two transcripts were significantly upregulated in glomeruli from black and white patients compared to Hispanic patients (table)

Conclusions: Intra-renal molecular signatures appear to be different for the same histologic classes of LN among different races and ethnicities. The data suggest, for example, that interferonγ may be higher in black and Hispanic patients given the upregulation of SPP1 and CD276. In contrast, downregulation of the protective HLA-DRB1and HLA-DQA1 in black and Hispanic patients may predispose to more severe injury. Such differences may help explain why standard treatments appear to be less effective in black and Hispanic than white patients. Understanding these pathways may allow more targeted therapies for specific groups of patients and improve long-term kidney outcomes.

Anti-CRP Antibodies in Patients with Lupus Nephritis: Extended Follow-Up Satu S. Pesickova,[3,1] Martin Lenicek,[2] Romana Rysava,[3] Zdenka Hruskova,[3] Vladimir Tesar.[3] *[1]Hemodialysis unit, Dialcorp, s.r.o., Prague, Czech Republic; [2]Department of Clinical Biochemistry and Laboratory Diagnostics, First Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic; [3]Department of Nephrology, General University Hospital and First Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic.*

Background: Antibodies against monomeric CRP (anti-CRP-Ab) in patients with lupus nephritis (LN) seemed to be strong risk factor for poor outcome: non response to therapy, renal flare, end stage renal disease (ESRD) after two years of standard therapy, as it was shown in our previous study. The aim of this retrospective study is to verify the utility of anti-CRP- Ab in longer term follow-up.

Methods: Twenty three patients (1 male) with new diagnosis of LN proven by renal biopsy were followed-up for median (25-75%) of 8.9 (7.8-9.35) years. At the end of follow up (May 2017) renal and mortality data were collected. Unfavorable outcome was defined as ESRD, renal flare and non response to therapy. Baseline anti-CRP-Ab levels were measured by an in-house ELISA and compared regarding to the outcome (Mann Whitney test). ROC curve was constructed to define anti-CRP- Ab threshold level. Predictive value of anti-CRP-Ab positivity was tested by Fisher exact test.

Results: During the long term follow-up 1 patient (without response to therapy) died (anti-CRP-Ab positive), 6 patients experienced at least one renal flare (4 were anti-CRP-Ab positive), 3 patients progressed to ESRD (2 were anti-CRP-Ab positive). Baseline levels of anti-CRP-Ab were higher in patients with unfavorable outcome (53.9 vs 31.6 AU) p=0.023. Area under ROC curve was 0.81, sensitivity and specificity for given threshold (44 AU) was 81% and 70%, respectively. Anti-CRP-Ab positive patients seemed to have higher risk of unfavorable outcome when compared to those anti-CRP-Ab negative: OR=6.00 (0.67-75.61), p=0.089.

Conclusions: Anti-CRP- Ab seem to be promising prognostic marker of theraputic outcome. Further studies on larger groups should be performed.

SA-PO106

AKI Biomarker Expression in Glomeruli of Lupus Nephritis Biopsies Kelly V. Liang,[1] David R. Emlet,[2] Sheldon Bastacky,[1] Paul M. Palevsky,[1] John A. Kellum.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) biomarkers urine insulin-like growth factor-binding protein 7 (IGFBP7), tissue inhibitor of metalloproteinases-2 (TIMP-2), and kidney injury molecule 1 (KIM-1) have been validated in critically ill as markers of tubular injury and cell-cycle arrest, but they have not been studied extensively in lupus nephritis (LN). Studies in animal models of LN suggest they may play a pathophysiologic role. Therefore, we sought to determine if IGFBP7, TIMP-2, and KIM-1 are expressed in human LN tissues.

Methods: Five frozen renal biopsies with LN class IV were identified from the Renal Pathology Department. Controls were human tissue from kidneys rejected for transplant. The samples were subjected to standard double-label indirect immunofluorescence with antibodies to IGFBP7, TIMP-2, and KIM-1 and appropriate fluorochrome-conjugated secondary antibodies. In vivo expression of biomarkers were determined semi-quantitatively using confocal microscopy.

Results: While the level of expression was variable from sample to sample, in every case, the levels of expression of IGFBP7, TIMP2, and KIM-1 were greater in glomeruli of LN biopsies compared to control kidney tissues. Figure 1 shows sample immunofluorescence images from a LN sample, a non-LN control tissue sample, and a negative control for each biomarker.

Conclusions: This is the first study to evaluate glomerular expression of TIMP-2 and IGFPB7 in glomeruli of patients with LN. IGFBP7, TIMP2, and KIM-1 expression was greater in glomeruli of LN biopsies compared to control kidney tissues. Therefore, further studies are warranted to determine if they may be useful biomarkers in LN and other glomerular disorders.

SA-PO107

Characterization of the Molecular Profile of the Kidney at the Initial Episode of Lupus Nephritis and at Renal Flare in the Same Patients Juan M. Mejia-Vilet,[1,2] Samir V. Parikh,[1] John P. Shapiro,[1] Paolo Fadda,[1] Norma O. Uribe-uribe,[2] Huijuan Song,[1] Lianbo Yu,[1] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: Renal flares are common in lupus nephritis (LN), and are generally treated in the same way as previous episodes of active LN. It is conceivable however, that after long-term immunosuppression the immune pathogenesis of a flare is different than the first episode of LN. We tested this hypothesis.

Methods: A cohort of 14 patients had kidney biopsies done at their first episode of LN, were successfully treated but subsequently flared and were biopsied again. These 28 pairs of renal biopsies were studied. LN class was the same between first and repeat biopsy. Glomeruli and tubulointerstitium (TI) were isolated by laser capture microdissection, RNA was extracted from each compartment and the expression of 578 immune-response genes was measured by Nanostring technology. Intra-renal transcript expression was compared between the first biopsy and the flare biopsy for each patient. Living transplant donor kidney biopsies at implantation (n=10) were used as normal controls.

Results: All patients were female and naïve to LN induction treatment at the time of the first biopsy. A principal component analysis did not show broad differences in gene expression between first and recurrent episodes of LN. However, glomeruli from flare biopsies demonstrated a significantly higher expression of complement pathway genes (CFH, C3, C1R, C1QB), TNF-regulated genes, and FN1, ITGA5, VCAM1 and IGF2R transcripts Conversely, in the TI there was lower expression of genes regulated by interferon-alpha 2 (CCL3, CXCL9, MX1, PML).

Conclusions: Although the expression of most immune genes was similar in the glomeruli and TI from initial and flare kidney biopsies, there were several differentially-expressed transcripts at flare. Knowledge of these differences may allow optimization of LN flare treatment, especially as targeted therapies become available.

Interferon-Inducible Protein 10 and Disease Activity in Patients with Systemic Lupus Erythematous and Lupus Nephritis: A Systematic Review and Meta-Analysis Pongpratch Puapatanakul,[2] Sonchai Chansritrakul,[1] Paweena Susantitaphong,[2] Somchai Eiam-Ong,[2] Kearkiat Praditpornsilpa.[2] *[1]Chonburi Hospital, Chonburi, Thailand; [2]Chulalongkorn University, Bangkok, Thailand.*

Background: There has been increasing evidence regarding correlation between serum as well as urine interferon-inducible protein 10 (IP-10) and disease activity of systemic lupus erythematous (SLE) patients.

Methods: We conducted a comprehensive search on PubMed, Scopus, and Cochrane electronic database through the end of December 2016. All studies that measured serum or urine IP-10 using enzyme immunoassay (EIA) in SLE patients with or without lupus nephritis (LN) were retrieved. Meta-analysis of correlation between each test and disease activity was performed using a random-effects model.

Results: Thirteen studies measured either serum or urine IP-10 levels in SLE/LN patients. However, only 9 and 4 studies provided adequate data of serum and urine IP-10 levels, respectively in 396 active SLE,175 active LN, 442 inactive SLE patients, and 310 non-SLE controls. Serum IP-10 levels were significantly higher in active SLE than in non-active SLE patients (mean difference [MD] 365.8 pg/mL, 95% CI 262.8 to 468.7, $p < 0.001$) but were indifferent between patients with active and non-active LN (MD 18.8 pg/mL, 95% CI -136.7 to 174.3, $p = 0.813$). Serum IP-10 also showed positive correlation with disease activity in SLE and LN patients (pooled r = 0.28, 95% CI 0.20 to 0.37, $p < 0.001$; pooled r = 0.26, 95% CI 0.08 to 0.43, $p = 0.006$; respectively). Urine IP-10 levels were comparable between active and non-active SLE patients (MD 2.44 pg/mgCr, 95% CI -0.50 to 5.38, $p = 0.10$) but were significantly higher in active LN patients compared to non-active LN patients (MD 4.57 pg/mgCr, 95% CI 1.68 to 7.47, $p = 0.002$). Urine IP-10 also had positive correlation with disease activity in SLE and LN patients (pooled r = 0.21, 95% CI 0.05 to 0.36, $p = 0.011$; pooled r = 0.40, 95% CI 0.13 to 0.62, $p = 0.005$; respectively).

Conclusions: Serum and urine IP-10 levels demonstrate positive correlation with disease activity in both SLE and LN patients. However, an increase in serum IP-10 is more pronounced in active SLE while urine IP-10 showed a significant increase mainly in active LN.

SA-PO109

The Ability of Serial Spot Urine Protein/Creatinine Ratios to Correctly Identify Proteinuria Trend in Lupus Nephritis Varies Greatly from Patient to Patient Isabelle Ayoub,[4] Ganesh B. Shidham,[1] Daniel J. Birmingham,[1] Brad H. Rovin,[3] Lee A. Hebert.[2] *[1]Ohio State University, Columbus, AL; [2]Ohio State University Medical Center, Columbus, OH; [3]Ohio State University Wexner Medical Center, Columbus, OH; [4]Medicine, The Ohio State Wexner Medical Center, Columbus, OH.*

Background: In most clinical laboratories the vast majority of testing for proteinuria in adult patients is based on spot protein/creatinine ratio (PCR). This follows KDIGO recommendations. It is widely recognized that spot PCR is more variable than 24h PCR testing. This is assumed to be a random property of spot PCR. In research, spot PCR variability is mitigated when data sets are averaged. However, in individual patient management, spot PCR's variability could confound management. Here we show for the first time that spot PCR in many patients are highly unreliable estimates of proteinuria trend.

Methods: We analyzed the variability of longitudinal testing of spot PCR and 24h PCR in 103patients with stage III or IV lupus nephritis (LN) participating in the ACCESS multicenter randomized trial. The gold standard estimate of proteinuria trend is that described by the line joining the serial 24h PCR values. To assess spot PCR reliability we compared in each patient the trend in serial spot PCR values to that of their 24h PCR trend line. Using semi-quantitative technique we stratified the patients according to whether the sequential spot PCR were deemed to be reliable, problematic or unreliable in identifying proteinuria trends based on the gold standard, the 24h PCR trend line.

Results: Of the 103 patients who had follow up testing of concurrent spot PCR and 24h PCR, 41% (42/103) had reliable, 24% (25/103) had problematic, and 35%(36/103) had unreliable spot PCR. No baseline predictors were significantly associated with any of the three categories. Patients with unreliable spot PCR were more likely to have unfavorable outcomes of their LN.

Conclusions: Clinical decision making in LN management should not be based on spot PCR testing. Instead, a reliable estimate of proteinuria magnitude can be obtained with the PCR of intended 24 hour urines that are at least 50% complete based on their creatinine content.

Circulating Cell Free DNA Is Associated with Dynamics in FOXP3 Expression in Peripheral CD4+CD25+CD127+ T Cells in Patients with Lupus Nephritis

Bartosz Foroncewicz,[1] Krzysztof Mucha,[1,2] Katarzyna Bocian,[3] Radoslaw Zagozdzon,[4,1] Agnieszka Wirkowska,[1] Anna Truszewska,[1,5] Joanna Kaminska,[6] Barbara Moszczuk,[1] Gra?yna Korczak-Kowalska,[3,4] Leszek Paczek.[1,2] *[1]Department of Immunology, Transplantology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland; [2]Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland; [3]Department of Immunology, University of Warsaw, Faculty of Biology, Warsaw, Poland; [4]Department of Clinical Immunology, Medical University of Warsaw, Warsaw, Poland; [5]Postgraduate School of Molecular Medicine, Medical University of Warsaw, Warsaw, Poland; [6]Department of Internal Diseases and Dialysis Unit, West Hospital of Saint Paul II, Grodzisk Mazowiecki, Poland.*

Background: Lupus nephritis (LN) is a manifestation of systemic lupus erythematosus (SLE) associated with poor outcome. The pathophysiology of LN is multifactorial and the search continues for a set of suitable biomarkers to assess the status of the disease. Recently, attention has been drawn to abnormally elevated circulating cell free DNA (cfDNA) as a potential biomarker of SLE progression towards LN. However, it is unclear how concentrations of cfDNA correlate with the pattern and changes within functional subpopulations of T cells in LN patients. We carried our such an assessment in our study.

Methods: Forty eight LN patients were enrolled. Their blood was collected twice: at baseline and after six months for biochemical tests and biomarker evaluation. Flow cytometry was used for analysis of T cells populations for the expression of CD4, CD25, CD127 and intracellular FOXP3. cfDNA was isolated by use of QIAamp Circulating Nucleic Acid Kit (QIAGEN, Hilden, Germany).

Results: We found significant associations between cfDNA concentrations at baseline and also cfDNA change over six months with the changes in intracellular FOXP3 content in subpopulation of CD4(+)CD25(+)CD127(+) T cells.

Conclusions: CD4(+)CD25(+)CD127(+)FoxP3(+) subpopulation of T cells has been proposed to act as a suppressor of autoimmunity. The exact biomarker potential of this subpopulation of T cells in autoimmune diseases, including LN, has not been fully explored. Our study suggests that this particular subpopulation of T cells may become useful as an attractive indicator of disease activity in LN, which warrants further investigation.

Urine VCAM-1 and ICAM-1 as Biomarkers for Active and Chronic Kidney Injury in Lupus Nephritis

Shikha Wadhwani,[1] Xiaolan Zhang,[1] Juan M. Mejia-Vilet,[2] Anthony S. Alvarado,[1] Tibor Nadasdy,[1] Brad H. Rovin.[1,3] *[1]The Ohio State University, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [3]for the CKD Biomarkers Consortium, Bethesda, MD.*

Background: Urine levels of the adhesion molecules VCAM-1 and ICAM-1 may reflect active kidney disease in patients with lupus nephritis (LN), but it is unknown if these analytes are biomarkers of kidney pathology. This study investigated the relationship of urine (u)VCAM-1 and uICAM-1 to renal histology in LN.

Methods: uVCAM-1 and uICAM-1 were measured by ELISA at the time of kidney biopsy in 129 LN patients. SLE patients without kidney involvement (non-renal (nr) SLE, n=35) served as controls. Urine analyte levels were normalized to urine creatinine concentration, log-transformed and then examined in relation to ISN/RPS histologic class and specific histologic lesions using ANOVA, nonparametric Wilcoxon ranked-sum testing and linear regression as appropriate.

Results: uVCAM (R=0.57; p<0.0001) and uICAM (R=0.52; p<0.0001) correlated with proteinuria. Mean uVCAM and uICAM levels from LN patients were 5.4 and 2.2-fold higher, respectively than levels from nrSLE (p<0.0001). Significance was maintained when classes II-V LN were compared individually to nrSLE. In proliferative LN, uVCAM and uICAM levels positively correlated with biopsy activity index (R=0.32; p= 0.0037 and R=0.26; p=0.0143 respectively). uVCAM and uICAM levels were elevated in patients whose biopsies had karyorrhexis/fibrinoid necrosis (p<0.006; p<0.02, uVCAM; uICAM), hyaline deposits (p<0.006; p<0.02, uVCAM; uICAM) and PMN infiltrates (p < 0.003; p<0.03, uVCAM; uICAM). Only uVCAM was elevated in the presence of cellular crescents (p=0.002), and neither analyte reflected interstitial inflammation. Conversely, uICAM was negatively associated with biopsy chronicity index (R=0.32; p=0.0026), and was significantly lower in patients whose biopsies showed glomerular sclerosis and fibrous crescents (p=0.03; p=0.002). uICAM did not reflect interstitial fibrosis or tubular atrophy.

Conclusions: uVCAM-1 and uICAM-1 are biomarkers for glomerular injury in LN. uVCAM-1 levels reflect glomerular inflammation while uICAM-1 levels indicate chronic glomerular damage.

Early Renal Response Biomarkers in Lupus Nephritis: Data from the AURION and AURA Trials

Robert B. Huizinga,[1] Brad H. Rovin,[3] James A. Tumlin,[4] Matt Truman,[1] Neil Solomons.[1] *[1]Aurinia Pharmaceuticals, Victoria, BC, Canada; [3]Ohio State University Wexner Medical Center, Columbus, OH; [4]University of Tennessee College of Medicine, Chattanooga, TN.*

Background: During treatment of lupus nephritis (LN) early biomarkers of complete, partial and no renal response (CR, PR, NR) would allow changing therapy in patients destined to not respond to their current treatment. Changes in complement and proteinuria after 8 weeks of therapy were shown to predict renal response at 6 months in the ALMS LN trial. To validate these biomarkers their performance was tested in the recently completed AURION and AURA LN trials.

Methods: Data was taken from the AURION 10 patient open-label study of voclosporin (VCS) 23.7 mg po BID, MMF and steroids in active LN, and from the AURA 265 patient randomized double-blind study of voclosporin in active LN. In AURA patients were dosed with voclosporin 23.7 mg po BID, 39.5 mg po BID or placebo, MMF and steroids. First morning voids (FMVs), 24 hour urine collections C3, C4 and anti-dsDNA were collected throughout. Normalization of C3 or C4 at week 12 and 25% reduction in Week 8 UPCR (25%UPCR) were used as predictors of CR at 24 and 48 weeks.

Results: In AURION, a 25%UPCR was 71% and 75% sensitive in predicting CR at weeks 24 and 48, but specificities were 33% and 25% respectively. Similar sensitivities (99% and 90%) for predicting 24 and 48 week CR were seen for a 25%UPCR, specificity remaining low (33% and 33%). In AURION C3 or C4 normalization at week 12 was not sensitive (29 and 25%), but specific (100% and 75%) for predicting 24 and 48 week CR. Similarly in AURA, C3 or C4 were not sensitive, but C3 was 80% and 81% specific while C4 was 77% and 76% specific for predicting 24 and 48 week CR. Change in anti-dsDNA has similar specificities as C3 or C4 but lower sensitivity for predicting CR at 24 and 48 weeks.

Conclusions: As active lupus nephritis flares cause damage within the renal matrix, a more rapid way of predicting CR at 24 or 48 weeks is needed. A rapid predictor should demonstrate both high sensitivity and specificity providing clinicians confidence for changing therapy earlier rather than waiting for 24 or 48 weeks. Use of a 25% reduction in Week 8 UPCR plus C3 normalization at week 12 provides clinicians a sensitive (99%) and specific (80%) method of predicting CR at 24 weeks. This same combination also provides clinicians a sensitive (90%) and specific (81%) method of predicting CR at 48 weeks. Future clinical trials should consider the use of this methodology.

Accurately Representing the Heterogeneity of IgA1 O-Glycosylation in Patients with IgA Nephropathy

Matthew B. Renfrow,[2] Audra A. Hargett,[2] Stacy D. Hall,[1] Bruce A. Julian,[3] Jan Novak.[3] *[1]UAB, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients with several autoimmune disorders, chronic inflammatory diseases, and some infectious diseases exhibit abnormal glycosylation of serum immunoglobulins and other glycoproteins. The biological functions of these modifications in health and disease continue to be a significant area of interest in biomedical research. Specifically, the task of defining site-specific glycoprotein heterogeneity is recognized as an area that still needs a considerable amount of effort to fully understand the role of glycan heterogeneity in biological processes and disease pathogenesis.

Methods: We have developed robust workflows for the analysis of the IgA1 clustered *O*-glycan heterogeneity in clinical samples from patients with IgA nephropathy (IGAN).

Results: IgAN is the leading cause of glomerulonephritis in the world with as many as 20-40% of patients progressing to end stage renal disease. Patients with IgA nephropathy have increased levels of nephritogenic circulating immune complexes that contain the immunoglobulin, IgA1. We and others have shown that IgA1 in patients with IgAN have altered *O*-glycan heterogeneity. This work demonstrates the progress we have made in characterizing the differing patterns of IgA1 O-glycan heterogeneity in patients with IGAN. IgA1 was isolated from serum of healthy controls and patients with IGAN, in order to determine each samples' specific *O*-glycosylation profile. Each patient's monomeric, polymeric, and circulating immune complex IgA1 were analyzed separately to determine if there was a difference in the glycan signature of the specific type of IgA1. The HR-MS profile of both the IGAN patients and healthy controls was also tested using existing lectin ELISA test for Gd-IgA1.

Conclusions: The detailed characterization of glycoprotein site occupancy and glycan heterogeneity is required for a better understanding of the biological roles of induvial glycoproteins and to determine the impact of the glycosylation on the proteins functionality. Our current results will demonstrate our ability to reliably provide quantitative comparison of individual sites of glycosylation across a range of *O*-linked glycosylation sites in order to determine a protein's Glycan Signature and how that signature relates to the proteins function. This work is supported by the NIH (GM098539).

Assessment of the Impact of Serum Levels of Gd-IgA1-Specific IgG Autoantibodies on the Prediction of the Course of Disease in Czech Patients with IgA Nephropathy Dita Maixnerova,[4] Stacy D. Hall,[1] Colin Reily,[1] Michaela Neprasova,[4] Jelena Skibova,[3] Miloslav Suchanek,[2] Eva Honsova,[3] Rhubell T. Brown,[1] Jan Novak,[1] Vladimir Tesar.[4] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Chemical Technology Prague, Prague, Czech Republic; [3]Institute of Clinical and Experimental Medicine, Prague, Czech Republic; [4]Dept. of Nephrology, General Teaching Hospital, 1st Faculty of Medicine, Charles University, Prague, Czech Republic.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis, often leading to end-stage renal disease. The diagnosis and assessment of disease severity requires renal biopsy. Due to its inherent risks, non-invasive approaches would be very helpful.

Methods: We examined 94 patients with biopsy-proven IgAN who were assessed at the time of diagnosis for renal function, proteinuria, microscopic hematuria, and hypertension, and followed-up clinically since then. Using serum samples collected the time of diagnosis, we determined levels of galactose-deficient IgA1 (Gd-IgA1) and IgG autoantibodies specific for Gd-IgA1 (IgGAb) using lectin and immunodetection methods. Discriminant analysis and logistic regression model were used for statistical analyses.

Results: Clinical data (serum creatinine and eGFR), serum biochemical markers (Gd-IgA1, IgGAb) and histological scoring (Oxford MEST system) were used to develop a formula predicting the risk of disease progression at the time of biopsy. We observed higher levels of IgG autoantibodies in IgAN patients with progressive renal insufficiency at diagnosis compared to IgAN patients with stable renal function at the onset. We confirmed the association of IgG autoantibodies with the progression of Czech patients with IgAN.

Conclusions: Elevated serum levels of IgGAb may serve as marker of disease activity and/or decline of renal function and, thus, unfavorable predictor of disease progression in patients with IgAN. Longer clinical follow-up of this group and further evaluation of these results in larger cohorts are needed. Proteomics of Glomeruli with IgA Nephropathy Reveals the Concomitant Abnormalities of Cytoskeleton in the Podocytes Hiroki Yamaguchi,[1] Shin Goto,[1] Yoshitoshi Hirao,[2] Bo Xu,[2] Keiko Yamamoto,[2] Suguru Yamamoto,[1] Yoshikatsu Kaneko,[1] Tadashi Yamamoto,[2] Ichiei Narita.[1] *[1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Biofluid Biomarker Center, Institute for Research Collaboration and Promotion, Niigata University, Niigata, Japan.*

Background: Previously, extensive molecular research had been carried out to disclose the mechanism of glomerular injuries in IgAN, however, comprehensive analysis targeted to human glomeruli have been rarely reported. To investigate the molecular network of IgAN, we conducted quantitative proteomic analysis of dissected glomeruli of patients with IgAN.

Methods: We enrolled 12 IgAN patients (mean eGFR, 90.9 ml/min/1.73m^2; mean urinary protein, 0.61 g/day; crescentic lesion in kidney biopsy < 10%), and 4 nephrectomized patients due to urological cancers as normal samples (Nor). The glomerular samples were collected by laser microdissection and digested peptides were subjected to LC–MS/MS analysis. Their MS/MS spectral data were searched against Swiss-Prot database. Finally, we performed label-free quantitation using Normalized Spectral Index and extracted proteins which were significantly and distinctively expressed in glomeruli of IgAN or Nor. These proteins were assigned to web-accessible program, DAVID to discover enriched functional related-protein groups.

Results: A total of 3143 proteins were identified with peptide FDR < 1%, and 394 and 563 proteins were selected as expressed differentially in IgAN and Nor respectively. Functional annotation clustering on the glomerular proteins in IgAN ranked several metabolic and biosynthesis pathways as top categories, while that on the glomerular proteins in Nor gave higher enrichment scores to cytoskeletal proteins rich in the podocytes. Especially, the abundance of Actinin-alfa-4, synaptopodin, and RhoA-specific GEF were significantly lower in IgAN. Between the IgAN groups divided by the level of urinary protein (0.5 g/day), the expression of synaptopodin was significantly lower in the group with higher proteinuria.

Conclusions: These results suggest that mesangial inflammation in IgAN could cause the cytoskeletal abnormalities in podocytes, resulting to significant proteinuria and glomerular injury.

SA-PO116

Renal Immune Deposits of Patients with IgA Nephropathy Are Enriched for IgG Autoantibody Specific for Galactose-Deficient IgA1 Manish K. Saha,[3] Dana Rizk,[2] Stacy D. Hall,[1] Rhubell T. Brown,[3] Lea Novak,[3] Bruce A. Julian,[3] Jan Novak.[3] *[1]UAB, Birmingham, AL; [2]University of Alabama, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients with IgA nephropathy (IgAN) have circulating immune complexes (ICs) consisting of galactose-deficient IgA1 (Gd-IgA1) bound by Gd-IgA1-specific IgG autoantibodies. Some ICs deposit in the kidney, inciting injury. Renal biopsy examination by routine immunofluorescence reveals IgA, usually with C3 and variably with IgG. We assessed whether patients with IgAN have Gd-IgA1-specific IgG autoantibodies in renal biopsy tissue.

Methods: Frozen remnant renal biopsy specimens from patients with IgAN with (n=5) or without (n=10) IgG glomerular co-deposits (determined by routine immunofluorescence) and a patient with membranous nephropathy (MN; disease control) were used. Tissues were washed with PBS to remove interstitial and blood IgG. IgG from immunodeposits was then extracted by acidic buffer (*N Engl J Med* 361:11,2009). IgG concentrations were determined by ELISA. IgG molecular integrity was assessed by SDS-PAGE western blots. IgG autoantibodies were determined by their binding to Gd-IgA1 (*J Clin Invest* 119:1668,2009). Confocal microscopic evaluation was performed using frozen tissue specimens stained with fluorochrome-labeled antibodies specific for IgA, IgG, and C3.

Results: IgG was isolated from washes and extracts of all biopsy specimens, as determined by ELISA and confirmed by western blotting. This finding, suggesting that routine immunofluorescence has low sensitivity and underestimates IgG in immunodeposits, was confirmed by high-resolution confocal microscopy. Line intensity analysis confirmed co-localization of IgA and IgG. Moreover, IgG autoantibodies specific for Gd-IgA1 were detected in extracts of all biopsy specimens from patients with IgAN, but not MN control. Washes had no or very low amounts of IgG autoantibodies.

Conclusions: IgG autoantibodies specific for Gd-IgA1 were detected in renal immunodeposits of patients with IgAN, even in those without IgG by routine immunofluorescence. These findings support the pathogenic significance of IgG autoantibodies in IgAN.

Gut Microbiota in IgA Nephropathy: What Is the Possible Association with Clinical Manifestations? Wen Tang. *Peking University Third Hospital, Beijing, China.*

Background: Few study have investigated the microbiota in IgA nephropathy (IgAN) and their association with clinical disease progression factors. In the present study, we investigated the microbiota in IgAN patients with relative normal renal function and further examed the association between clinical risk parameters of IgAN and microbial groups.

Methods: Fecal microbiota was studied in nineteen new diagnosed IgAN and fifteen matched healthy control. Microbiota composition and functional capacity were characterized using sequencing of the 16S rRNA gene on Illumina MiSeq platform Patients' clinic parameters were also collected to investigate their association with the microbiota.

Results: The proportion of *Bifidobacterium* was higher but Bacteroidetes was lower in the patients with IgAN as compared to healthy control. Additionally, CCA (canonical correlation analysis) analyse (Figure 1) revealed that Bifidobacterium was positively associated with serum IgA level and 24 hour proteinuria. Lachnoclostridium was positively associated with present of hypertension. Bacteroides and Prevotella were negative with them. Escherichia-Shigella was positive with urinary red blood cell account.

Conclusions: This study has for the first time revealed the association between microbiota and the factors associated with IgAN progression, which found that Bifidobacterium was positive associated with disease progressive factors. Further research are need to understand the potential role of the Bifidobacterim in the IgAN

Plasma CX3CL1: A Biomarker Predicts Renal Inflammation and Progression of IgA Nephropathy Ran Luo, Shuiming Guo, Gang Xu, Shuwang Ge. *Dept of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: Plasma biomakers of IgA nephropathy (IGAN) are still relatively unknown to date. This study was to investigate whether CX3CL1 was associated with pathology and renal outcome in IGAN.

Methods: 229 patients with IGAN diagnosed by renal biopsy between 2012 and 2014 at Huazhong University of Science and Technology Tongji hospital, were included in the study. Follow-up time was up to 42.5 months. Renal outcome was defined as composite endpoints, including ESRD and doubling of plasma creatinine. Plasma CX3CL1 level was measured by ELISA. Inflammatory cells including CD4+, CD8+, CD20+ and CD68+ cells in renal biopsy tissues were detected by immunohistochemistry. The two single nucleotide polymorphisms (SNPs) of CX3CR1, rs3732378 and rs3732379, were assessed with IGAN leukocyte.

Results: Plasma CX3CL1 levels correlated with serum creatinine (p<0.0001, r=0.344), estimated glomerular filtration rate (eGFR) (p<0.0001, r=-0.370), albumin (p=0.0002, r=-0.249). In renal biopsy specimens, the density of CD68+ (p<0.0270, r=0.461) and CD20+ (p<0.0014, r=0.363) cells was significantly associated with plasma CX3CL1. The study showed that mesangial hypercellularity (M1), endocapillary hypercellularity (E1), tubular atrophy/interstitial fibrosis (T2) according to the Oxford classification were associated with the levels of CX3CL1. ROC curve showed that plasma CX3CL1 had a predictive value for composite endpoints (cut-off CX3CL1=0.511ng/ml, AUC=0.780, sensitivity=0.818, specificity=0.693). Higher CX3CL1 predicted worse renal outcome during follow-up (Log rank, p=0.0016) by Kaplan-Meier analysis. In multivariate Cox proportional hazard analysis, CX3CL1 levels at the time of renal biopsy was found to be an independent predictor of composite endpoints after adjustment for age, gender, mean arterial blood pressure, prior tonsillectomy (per 1% increase, hazard ratio=27.94, 95% confidence interval=2.06-374.74, p=0.012). The haplotype frequency of rs3732378 and rs3732379 was 5.43% and 5.88%. There was no association of plasma CX3CL1 with these genotypes. Neither of the SNPs was associated with composite endpoints.

Conclusions: Plasma CX3CL1 correlates with IGAN pathology and prognosis. CX3CL1 may be a risk factor for progression of IGAN.

SA-PO119

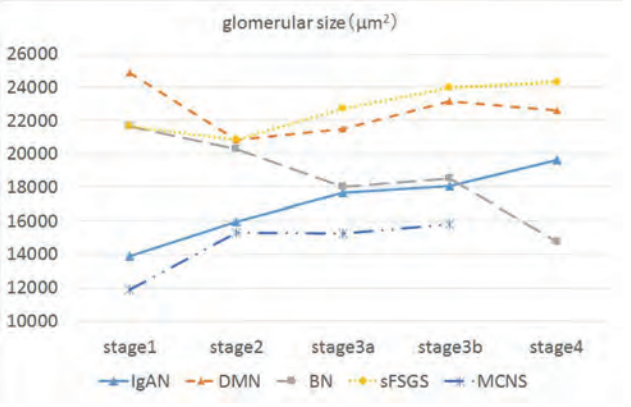
The Change in the Glomerular Size According to the Type of Glomerular Disease and the Renal Function Toshiyuki Imasawa, Masaki Uehara, Takafumi Yamakawa, Takehiko Kawaguchi. *Department of Nephrology, National Hospital Organization, Chiba-East Hospital, Chiba, Japan.*

Background: The glomerular size differs in each patient. Although it is assumed that the glomerular size should change according to the type of kidney disease and the hemodynamic state of the glomeruli, no clinical studies have investigated the impact of these factors on the glomerular size.

Methods: PAM-stained images of paraffin-embedded kidney sections were imported into a vertical slide system. The glomerular size was automatically calculated by manually outlining the glomerular tuft area on the display. We measured a total 18,673 glomeruli (with the exception of for globally sclerosed glomeruli) from 677 patients who underwent kidney biopsy in our hospital. All measurements were performed by a technical assistant in a blinded manner. In the present study, we especially focused on the glomerular sizes of patients with IgA nephropathy (IgAN) (n=212), diabetic nephropathy (DMN) (n=107), benign nephrosclerosis (BN) (n=78), and secondary focal segmental glomerulosclerosis (sFSGS) (n=53), and minimal change nephrotic syndrome (MCNS) (n=28). We also analyzed the glomerular sizes in patients with each stage of CKD.

Results: As shown in Figure, in CKD stages 1 and 2, the glomerular sizes of patients with diabetic nephropathy, benign nephrosclerosis, and secondary FSGS were significantly larger in comparison to patients with IgAN or MCNS ($p < 0.05$). In DMN and sFSGS, the sizes are similar in all CKD stages, while those in BN gradually decreased with the progression of the CKD stage. Conversely, the glomerular sizes of patients with IgAN gradually increased with the progression of the CKD stage.

Conclusions: The changes in glomerular size depend on the individual kidney disease. The pattern of the changes that occur with the progression of CKD should also differ according to the kidney disease.



SA-PO120

Transcriptomic Profiling of BTBRob/ob and eNOS-/-db/db Kidneys Sheds Light on Contrasting Morphological Phenotypes Anette E. Ericsson,[4] Anna Reznichenko,[4] Haichun Yang,[1] José Sanchez,[3] Lena William-Olsson,[4] Magnus Soderberg,[2] Agnes B. Fogo,[1] Anna Granqvist.[4] *[1]Department of Pathology, Microbiology and Immunology, Vanderbilt University School of Medicine, Nashville, TN; [2]Drug, Safety and Metabolism, AstraZeneca, Gothenburg, Sweden; [3]Discovery Sciences, AstraZeneca, Gothenburg, Sweden; [4]Innovative Medicines and Early Development, Cardiovascular and Metabolic Diseases, AstraZeneca, Gothenburg, Sweden.*

Background: There is a need for robust and translatable pre-clinical models for diabetic nephropathy (DN). The BTBRob/ob and eNOS-/-db/db mouse models develop progressive albuminuria and morphological lesions resembling early to moderate human disease. Mesangial expansion was evident in both models, however, podocyte foot process effacement was only local and minor in BTBRob/ob but widespread in eNOS-/-db/db.

Methods: This prompted us to perform RNA sequencing of kidney cortex and isolated glomeruli with parallel analysis of blood glucose, UACR and histology. To test whether transcriptional differences underlie the histologically disparate phenotypes, we performed an unbiased as well as targeted analysis of the RNA-seq data comparing expression profiles of a panel of known glomerular cell-specific markers that included genes for podocytes (n=50), mesangial (n=53) and glomerular endothelial cells (n=19).

Results: Obesity and hyperglycemia were present (BTBRob/ob, 16.5±2.0 mM; eNOS-/-db/db 16.1±2.5 mM blood glucose) as well as significant albuminuria in both models (BTBRob/ob, 10-fold vs lean; eNOS-/-db/db, 14-fold vs lean) at 20 (BTBRob/ob) and 18 (eNOS-/-db/db) weeks age. Transcriptomic analysis revealed a set of podocyte markers exclusively modulated in eNOS-/-db/db but not BTBRob/ob (Cd80, Kirrel, Nes, Podxl, Efnb1, Actn4, Utrn), while endothelial genes Eng, Pecam1, Kdr, Ehd3, Flt1, Tek, and Emcn were modulated in BTBRob/ob only. A number of these genes were also changed in glomeruli from human DN biopsies.

Conclusions: In summary, the two models share features of DN, however the eNOS-/-db/db mouse present more pronounced glomerular injury and podocyte effacement. Identified gene signatures suggest that the phenotype in eNOS-/-db/db has a stronger component of podocyte changes whereas BTBRob/ob has a stronger endothelial component, which may explain in part some of the differences in morphology and will be the subject for further studies.

SA-PO121

High Protein Diet Accelerates Development of Diabetic Nephropathy in db/db Mice Sisse A. Nørgaard,[2,3] Dorte B. Sørensen,[3] Elisabeth D. Galsgaard,[1] Fredrik Wolfhagen Sand,[2] Henrik Søndergaard.[4] *[1]Liver Disease Pharmacology, Novo Nordisk A/S, Maaloev, Denmark; [2]Diabetes & Cardiovascular Pharmacology, Novo Nordisk A/S, Måløv, Denmark; [3]Veterinary Disease Biology, University of Copenhagen, Copenhagen, Denmark; [4]Diabetes Complications Pharmacology, Novo Nordisk A/S, Måløv, Denmark.*

Background: Diabetic and obese db/db mice are widely used in diabetic nephropathy (DN) research. However, this model only mimics the early changes in human DN with mild albuminuria and mesangial expansion (ME) as primary readouts. Both in humans and in diabetic models, a high protein diet (HPD) has been reported to affect the progression of nephropathy. Here, the objective was to explore if a HPD could accelerate nephropathy in db/db mice with the perspectives to study more advanced aspects of DN (e.g. interstitial fibrosis) and improve the therapeutic window.

Methods: 32 diabetic (C57BLKS-Lepr$^{db/db}$) and 20 non-diabetic (C57BLKS-Lepr$^{db/+}$) were fed either regular chow diet (21 kcal% protein) or HPD (60 kcal% protein) from 6 weeks of age (WoA) until termination at 21 WoA. In-life readouts were: body weight, blood glucose (BG), %HbA1c and albuminuria. At termination the kidneys were weighed and processed for histology and qPCR analysis. ME was scored on a scale from 0 to 3, on blinded PAS stained sections.

Results: Feeding db/db mice HPD was well tolerated and all db/db mice were diabetic throughout the study (BG >16.6mM) although mildly reduced compared to db/db mice fed regular chow. HPD increased albuminuria more than 10-fold at 21 WoA and kidney size at termination compared to db/db mice fed regular chow. The ME score revealed a significant increase in db/db mice on HPD compared to regular chow ($p<0.0001$). Further histopathological assessment of renal lesions (e.g. fibrosis) and gene expression profiling of the kidney by qPCR will be performed to extend these findings. No changes were found in db/+ mice given HPD for either of the readouts.

Conclusions: Feeding db/db mice HPD instead of regular chow seems to accelerate the development of diabetic nephropathy without affecting lean non-diabetic mice. Thereby, HPD could potentially improve the overall quality of this model through an accelerated disease progression and an increased therapeutic window. Further histopathological assessment of the kidney will reveal if HPD additionally enhances other readouts associated with advanced nephropathy e.g. fibrosis.

SA-PO122

Linagliptin Treatment versus RAAS Inhibition Alone Improves Murine Diabetic Nephropathy Anna Batorsky,[2] Monica Sanchez avila,[2] Kelly L. Hudkins,[1] Charles E. Alpers.[3] *[1]University of WA, Seattle, WA; [2]University of Washington, Seattle, WA; [3]University of Washington Medical Center, Seattle, WA.*

Background: Linagliptin (LIN) and other DPP4 inhibitors have proven effects as treatments for diabetes (DM), but the renal benefit is not well understood. We explore effects of LIN, and LIN in combination with the ARB, losartan (LOS), on diabetic nephropathy (DN). The leptin-deficient BTBR *ob/ob* (OB) mouse is shown to mimic morphologically advanced human DN and type II DM. Administration of leptin (LEP) is shown to reduce body weight by 20-40%, return mice to normoglycemic levels, and improve functional and structural characteristics of DN.

Methods: Cohorts of female mice (n=12) were treated with LIN (83mg/kg in chow), LOS (100mg/mL in drinking water), combined LIN/LOS or LEP for 6 weeks starting at 18 weeks of age. We collected 6-hour fasting glucose and protein excretion measurements for all mice at 18 and 24 weeks. Baseline structural characteristics for WT and OB mice were determined by sacrificing untreated mice at 18 weeks. Glomerular abnormalities assessed at 24 weeks include expansion of silver stained mesangial matrix by computer morphometry, and podocyte density using the p57 marker of mature podocytes. Renal function was assessed by measurement of urine albumin/creatinine ratio (UACR) and measurement of 8-OHdG in urine as a marker of DNA/RNA damage.

Results: LIN-treated mice exhibit reduced mesangial expansion (13.6% silver positive matrix per glomerular cross section) compared to untreated mice (18.4%) at 24 weeks ($p=0.02$). Treatment with LOS, or LIN/LOS resulted in statistically significant reduction in UACR when paired 18 and 24 week urine samples were analyzed ($p=0.032$, 0.035 respectively). An ELISA assay for 8-OHdG in urine showed all treatment groups have significantly lower levels of oxidative damage compared to untreated controls at 24 weeks (WT 28.2, 24wk OB 93.1, 24wk OB LIN 35.4, 24wk OB LIN/LOS 30.5, 24wk OB LOS 41.4, 24wk OB LEP 39.6 ng 8-OHdG/mg Cre, $p<0.001$). LEP-treated mice had restored podocyte density, but no significant difference was detected between other treatment groups and untreated controls.

Conclusions: Our results suggest that DPP4- and RAAS-inhibition may ameliorate features of DN via mechanisms independent of restored podocyte density.

Omentin1 Ameliorates Hyperglycemia or Hypoxia-Induced Podocyte Dysfunction by Activating AMP-Activating Protein Kinase Hidetoshi Kobayashi, Fumihiko Furuya, Toshihisa Ishii, Kenichiro Kitamura. *University of Yamanashi, Chuo, Japan.*

Background: Increased albuminuria is associated with the loss of capillary wall permselectivity in podocytes and is one of the risk factors for end stage kidney disease (ESKD). Omentin1 is an adipocytokine and has anti-inflammatory and anti-atherogenic properties. The aim of this study is to elucidate whether serum omentin1 levels are associated with the progression of diabetic kidney disease (DKD) and to explore the molecular mechanisms by which omentin1 induces anti-diabetic properties.

Methods: One hundred twenty-five diabetes patients were followed up for 7 years. Logistic regression models were used to evaluate the association with progression of DKD. To explore the protective function of omentin1, we focused on the AMPK pathway in podocytes. We exposed cultured podocytes to hyperglycemia or hypoxia and analyzed the kinase activities and the expression of downstream pathway in the presence or absence of omentin1.

Results: During the observation, progression either to the next albuminuria level in 16 patients or to ESKD occurred in 5 patients. In these progressors of DKD, baseline of serum omentin1 was significantly low compared with non-progressors. Multiple regression analysis revealed that a significant inverse association between serum omentin1 levels and the progression of DKD. In cultured podocytes, omentin1 administration was associated with increased activity of AMPK, and AMPK activation reduced podocyte permeability to albumin and podocyte dysfunction under hyperglycemia or hypoxia, as evidenced by zona occludens1 translocation to the membrane. These omentin1-induced activation of AMPK pathways are mediated through the adiponectin receptor1 (AdipoR1) in podocyte since it was diminished by siRNA-mediated knockdown of AdipoR1. These effects seemed to be caused by reduction of oxidative stress, as AdipoR1 and AMPK activation both reduced protein levels of NADPH oxidative Nox4 in podocytes.

Conclusions: Decreased serum omentin1 levels predict the progression of DKD in diabetes patients. Our in vitro findings demonstrated that omentin1-bound AdipoR1 is one of the key regulator of albuminuria and progression of DKD, likely acting through the AMPK pathway to modulate oxidative stress in podocytes.

Inappropriate Expression of Angiopoietin-Like 2 Promotes Podocytes Dysfunction by Activating Focal Adhesion Kinase in Diabetic Kidney Disease Toshihisa Ishii, Fumihiko Furuya, Hidetoshi Kobayashi, Kenichiro Kitamura. *University of Yamanashi, Chuo, Japan.*

Background: Angiopoietin-like protein 2 (Angptl2) is an adiopokine which was secreted by adipose tissue or macrophages and that its circulating level was closely related to systemic insulin resistance, and inflammation in both mice and humans. We assessed the relationship between Angptl2 and the prevalence of the progression of diabetic kidney disease (DKD) and clarified the molecular mechanism of Angptl2-associated dysfunctions of podocytes.

Methods: One hundred forty eight diabetes patients were followed up for 7 years. Logistic regression models for the progression at every stage of DKD were used to evaluate the predictive value of Angptl2. The potential benefit of using Angptl2 alone or together with albumin excretion rate (AER) and eGFR was assessed by receiver operating characteristic (ROC) curve analysis. Furthermore, we investigated the expression of Angptl2 in macrophages and the effects of recombinant Angptl2 on podocyte *in vitro*.

Results: Progression of DKD was defined as the passage from one stage to the next based on AER or eGFR. The odds ratio for the prevalence of the presence diabetes, fatty changes of liver, and chronic kidney disease increased with higher serum Angptl2 levels. Cohort study indicated that baseline of Anptl2 was an independent predictor of progression at all stages of DKD. Reduced leukocyte DNA methylation in the promoter region of Angptl2 is associated with the pro-inflammatory environment that characterized with diabetic patients with ESKD from controls. In murine podocytes, Angptl2 induced the activation of focal adhesion kinase (FAK) via integrin α5β1-integrin-linked kinase and translocation of zona occludens-1 in the membrane and alubumin permeability.

Conclusions: Increased serum Angptl2 levels predict the progression of DKD in diabetes patients. Our in vitro findings suggest that Angptl2 is a key regulator of albuminuria, likely acting through the FAK pathway.

SA-PO125

Role of Wnt-β Catenin Pathway in Mediating Salutary Effects of Paricalcitol in Experimental Diabetic Nephropathy Sharma S. Prabhakar, Madhura Bose. *Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Diabetic nephropathy (DN) remains the most frequent cause of end stage renal disease but its pathogenesis remains unclear and consequently the treatment is not optimal. Many investigations including ours have shown renoprotective effects of paricalcitol (PAR) in DN. The aim of the current studies is to examine the role of Wnt- β catenin signaling in the beneficial effects of PAR in DN.

Methods: Obese ZSF rats, an established model of DN (type 2 diabetes), were treated with PAR (0.2 μg sc. twice a week) for 10 weeks from 21 weeks of age while control rats received none. Urine and blood samples were collected at the start and end of study. At 31 weeks rats were sacrificed, kidneys harvested and homogenates of one kidney in each rat were used to study expression of Wnt proteins and other pathogenic mediators by immunoblotting while the other kidney was used for RNA isolation and Next Gen

Sequencing (NGS) analysis. Kidney RNA seq data from ZSF obese and PAR treated rats were compared. Genes that were significantly altered based on 95% confidence and Log 2 fold change were filtered and mapped to canonical pathways in the IPA Knowledge Base. The dataset was filtered and a student t test was used to identify the genes most significantly altered following PAR treatment.

Results: PAR decreased proteinuria (970 mg/dl vs.1750 mg/dl in control) and slowed the decline of GFR (Ccr 3.6 L/Kg/BW vs.2.7 L/Kg/BW in control) in obese ZSF rats. NGS analysis of kidneys revealed that Wnt-β catenin signaling (which was differentially expressed compared to non-diabetic lean ZSF rats, per previous studies) is significantly altered in treated rats suggesting that changes in these pathways could account for the salutary effects of PAR. Western blot data confirmed that PAR inhibited the expression of many proteins in the Wnt signaling pathways specifically Wnt-3, Wnt-11 and c-myc. Other significant changes included Nitric Oxide, and OX-40 pathways in NGS and upregulation of phospho-eNOS, and inhibition of CTGF and NFkB protein expression.

Conclusions: We conclude that Wnt- β catenin is one of the important canonical pathways differentially modified by PAR and inhibition of Wnt proteins, along with changes in eNOS and CTGF may significantly contribute to renoprotective effects of PAR. These observations could potentially aid the development of novel therapies for DN.

Effective Therapy of Type 2 Diabetic Nephropathy by Protecting Pancreatic and Glomerular Endothelium with AAV10.COMP-Ang1 Yufeng Huang, Mi Tian, Li Tang, Christof Westenfelder. *Division of Nephrology, University of Utah Health, Salt Lake City, UT.*

Background: Diabetic hyperglycemia causes progressive and generalized damage to the microvasculature. In the kidney, this results in the loss of podocytes and thereby constitutive angiopoietin (Ang)-1 signaling required for maintenance and stabilization of the glomerular endothelium. As a consequence, glomerular endothelial cells are damaged, leading to leakage, glomerulosclerosis, and renal failure, i.e., diabetic nephropathy (DN). Therefore, we hypothesized that replacing Ang1 by constitutively expressing it with the plasmid AAVrh10.COMP-Ang1 would improve glomerular architecture and function thereby reducing glomerulosclerosis in db/db mice, a model of T2DM.

Methods: Uninephrectomy was performed on all experimental mice at 8 wks of age. Three groups included non-diabetic db/m, untreated diabetic db/db control and diabetic db/db mice treated with a single dose of AAVrh10.COMP-Ang1 ($2x10^{11}$ particles) injected via left carotid artery at 10 wks of age.

Results: The overexpression of COMP-Ang1 was confirmed not only in glomeruli but also in pancreatic and hepatic capillaries, which corrected the diabetes-induced dysregulation of tissue Ang2/Ang1 balance. Untreated db/db mice had substantial hyperglycemia (BG, 576±31mg/dl; Hb1Ac, 11.3±1.3%) and developed progressive increases in albuminuria and glomerular mesangial matrix expansion, associated with increased renal PAI-1, a1(IV) collagen and fibronectin expression compared with db/m mice at 18wks of age. Treatment with COMP-Ang1 yielded a significant reduction of glycemia (BG, 241±193mg/dl; Hb1Ac, 7.2±1.5%) and slowed the progression of albuminuria and glomerulosclerosis in db/db mice by 70% and 61%, respectively. Furthermore, renal expression of NF-kBp65, Nox2 and p47phox and pancreatic production of myeloperoxidase were increased while tissue SirT1 levels were decreased in untreated db/db mice, which were ameliorated by COMP-Ang1 overexpression.

Conclusions: These observations confirm our hypothesis and suggest that overexpression of COMP-Ang1 locally not only improves pancreatic function but also slows the progression of diabetes-associated glomerulosclerosis by improving both pancreatic and glomerular endothelial function via potently stimulating Ang1-Tie2 signaling. We conclude that upregulation of Ang1 expression locally has promise in improving glucose control and DN in T2DM.

SA-PO127

Intraperitoneal Administration of Human "Neo-Islets" Composed of Equal Numbers of Mesenchymal Stem and Pancreatic Islet Cells Durably Corrects Hyperglycemia in Diabetic NOD/SCID Mice Christof Westenfelder, Anna Gooch, Zhuma Hu, Ping Zhang. *University of Utah and VA Medical Centers, Salt Lake City, UT.*

Background: Globally, individuals with autoimmune Type 1 Diabetes mellitus (T1DM) continue to depend for survival on insulin injections. While pancreas and intrahepatic pancreatic islet transplants can produce insulin-independence and ameliorate serious complications, both therapies depend on potentially toxic anti-rejection drugs. Furthermore, the scarcity of pancreas donors, islet transplant failures, and the inability to adequately culture expand insulin-producing β-cells significantly limit the general availability of such and other cell-based interventions. Encapsulation of islets to protect them from allo- and auto-immune destruction has shown both promise and failures. We reported recently [STEM CELLS Translational Medicine, 7, 2017] that allogeneic "Neo-Islets" (NI) are immune protected and correct autoimmune diabetes in NOD mice. Furthermore, we are conducting an FDA-approved Pilot Study with canine NIs in insulin-dependent dogs using identical technology. As there remains a critical need for curative therapies of T1DM, we engineered human NIs and tested their ability, after i.p. administration, to reestablish euglycemia in streptozotocin (STZ)-diabetic NOD/SCID mice.

Methods: We generated *ex vivo* islet-sized NIs in which culture-expanded islet cells were aggregated in cell clusters with equal numbers of MSCs. NIs (5x10e6/kg b.wt.) or vehicle were administered i.p. to groups (n=6 each) of STZ-diabetic NOD/SCID mice.

Results: This minimally invasive i.p. administration of NIs durably normalized blood glucose levels in diabetic NOD/SCID mice. This was achieved by the spontaneous engraftment of NIs in the animals' omenta, and spontaneous redifferentiation of NI-intrinsic islet cells that physiologically secrete insulin into the hepatic portal vein.

Conclusions: Human NIs, as engineered here, show promise as a novel therapy that, we posit, has significant translational relevance to clinical T1DM. Specifically, this technology addresses the need for anti-rejection drugs and overcomes the scarcity of suitable donors.

A Novel SHIP2 Inhibitor Reduces the Catalytic Activity of SHIP2 in Kidney, Muscle, and Liver and Enhances Insulin Sensitivity Sanna H. Lehtonen,[2] Zydrune Polianskyte-prause,[2] Tuomas A. Tolvanen,[2] Sonja Lindfors,[2] Kanta Kon,[3] Hong Wang,[2] Vincent Dumont,[2] Per-Henrik Groop,[1,5] Tsutomu Wada,[3] Hiroshi Tsuneki,[4] Toshiyasu Sasaoka.[3] *[1]Folkhälsan Institute of Genetics, Folkhälsan Research Center, University of Helsinki, Helsinki, Finland; [2]Department of Pathology, University of Helsinki, 00290 Helsinki, Finland; [3]University of Toyama, Toyama, Japan; [4]University of Toyama, Toyama, Japan; [5]Division of Nephrology, Helsinki University Hospital, Helsinki, Finland.*

Background: The expression of lipid phosphatase SHIP2 is elevated in kidney, muscle and adipose tissues in experimental models of diabetes. Thus, SHIP2 is a potential therapeutic target to treat diabetic kidney injury and insulin resistance. To date, only few chemical compounds possessing an inhibitory effect on SHIP2 are known. All of them have poor bioavailability and none have reached clinical use.

Methods: To identify novel small molecules that inhibit SHIP2 we performed virtual screening of chemical libraries. The most potent SHIP2 inhibitors were validated by using recombinant SHIP2 fusion protein, cultured cells and diabetic db/db and SHIP2 overexpressing (SHIP2-Tg) mice.

Results: Virtual screening of chemical libraries containing 88680 molecules revealed compound II as a potential SHIP2 inhibitor. Compound II inhibits the catalytic activity of the recombinant SHIP2 phosphatase domain with an IC_{50} value of 0.75 μM. It also inhibits the activity of SHIP2 in cultured podocytes, myocytes and hepatocytes. Compound II increases glucose uptake in myocytes, and SHIP2 overexpression abrogates its insulin-mimetic properties. Treatment of SHIP2-Tg mice for 12 days with compound II reduces SHIP2 activity in kidney, skeletal muscle and liver and enhances insulin sensitivity. Treatment of db/db mice with compound II for 10 weeks enhances insulin sensitivity, decreases SHIP2 activity in the kidney and tends to reduce urinary albumin excretion.

Conclusions: Compound II inhibits the activity of SHIP2, enhances glucose uptake, and increases insulin sensitivity of both SHIP2-Tg and db/db mice. The db/db mice also show a trend of reduced albuminuria. This highlights the potential of SHIP2 as a drug target to treat diabetic kidney injury and insulin resistance. The data also propose that compound II and its derivatives have potential to be used for developing new insulin sensitizers.

Phenotype Agglomeration Analysis of Clinical and Histological End Points of Diabetic Kidney Disease Defines Modules with Improved Transcriptional Associations Paolo Guarnieri,[1] Jonathan Hill,[1] Viji Nair,[2] Jennifer L. Harder,[2] Junke Wang,[1] Julie Hawkins,[1] Steven S. Pullen,[1] Robert G. Nelson,[3] Carine Boustany,[1] Behzad Najafian,[4] Michael Mauer,[5] Matthias Kretzler.[2] *[1]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT; [2]University of Michigan, Ann Arbor, MI; [3]National Institutes of Health, Phoenix, AZ; [4]University of Washington, Seattle, WA; [5]University of Minnesota, Minneapolis, MN.*

Background: Diabetic kidney disease (DKD) is the primary cause of end stage renal disease worldwide. While the structural and functional determinants of DKD have been studied extensively in various populations, comprehensive aggregation of longitudinal phenotypic measures with molecular mechanisms is lacking.

Methods: We collected an extensive set of clinical and histological endpoints from a cohort of 70 Pima Indians with type 2 diabetes and DKD. Patients underwent annual research examinations that included measurement of glomerular filtration rate (GFR, iothalamate) and had 2 research kidney biopsies performed 10 years apart. We developed a method in which missing values were interpolated with the mean, normalized and log transformed, if applicable. For inter-related traits only the most representative measurement was selected. The remaining traits were then clustered across samples balancing silhouette coefficients with minimum cluster size. A single composite trait – eigentrait – was then generated by averaging its components. Weighted gene co-expression network analysis was used to generate modules of genes with highly correlated expression, associated with either measured traits or eigentraits. Enriched biological functions were determined using Ingenuity Pathway Analysis on composite genes of significantly associated modules.

Results: We identified 7 eigentraits defining modules of mixed clinical and histological endpoints. A highly robust module included the slope of GFR, glomerular basement membrane thickening and mesangial expansion, and was associated in the first biopsy with immune cell migration while in the second biopsy with extracellular matrix synthesis, thereby supporting a role for inflammation in the initiation of DKD.

Conclusions: Phenotype agglomeration analysis provided a means of distilling biologically meaningful signals from a complex collection of traits in Pima Indians with DKD.

Adiposity and Renal Hemodynamic Function in Adults with Longstanding Type 1 Diabetes with and without Diabetic Kidney Disease Petter Bjornstad,[1] Julie A. Lovshin,[9] Yuliya Lytvyn,[9] Genevieve Boulet,[4] Leif E. Lovblom,[3] Omar N. Alhuzaim,[9] Mohammed A. Farooqi,[5] Vesta S. Lai,[8] Josephine Tse,[8] Leslie Cham,[7] Andrej Orszag,[6] Alanna Weisman,[9] Hillary A. Keenan,[2] Michael Brent,[9] Narinder Paul,[8] Vera Bril,[9] Bruce A. Perkins,[9] David Cherney.[9] *[1]Children's Hospital Colorado, Aurora, CO; [2]Joslin Diabetes Center, Boston, MA; [3]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [4]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital. Toronto, Ontario, Canada, Quebec City, QC, Canada; [5]None, Oakville, ON, Canada; [6]Sinai Health System, Toronto, ON, Canada; [7]Universal Health Network, Toronto, ON, Canada; [8]University Health Network, Toronto, ON, Canada; [9]University of Toronto, Toronto, ON, Canada.*

Background: Central adiposity is considered an important cardio-renal risk factor in the general population and in type 1 diabetes (T1D). We sought to determine the relationship between central adiposity and renal hemodynamic function in adults with longstanding T1D with and without diabetic nephropathy (DN).

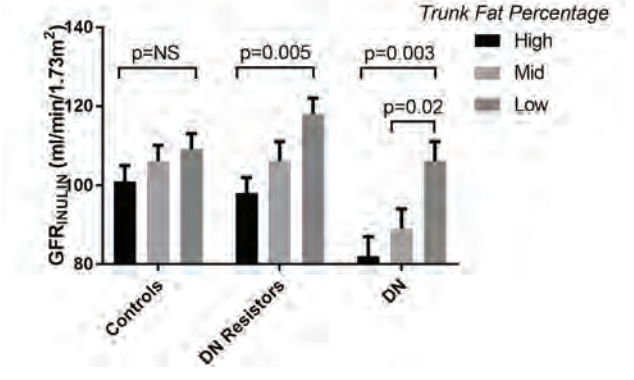
Methods: Patients with longstanding T1D (n=75, duration >50 yrs) and age/sex-matched healthy controls (HC, n=75) were studied. The T1D cohort was stratified into 50 DN Resistors (eGFR >60mL/min/1.73m^2 and <30 mg/day urine albumin) and 25 with DN. Renal hemodynamic function (glomerular filtration rate [GFR_{INULIN}], effective renal plasma flow [$ERPF_{PAH}$] was measured. Afferent arteriolar resistance (R_A), efferent arteriolar resistance (R_E), renal blood flow [RBF], renal vascular resistance [RVR], filtration fraction [FF], glomerular pressure (P_{GLO}) derived from Gomez' equations. Fat and lean mass were quantified by DXA.

Results: In healthy controls, measures of adiposity did not associate with GFR_{INULIN} or $ERPF_{PAH}$. In T1D, trunk fat mass inversely correlated with GFR_{INULIN} (r: -0.46, p<0.0001), $ERPF_{PAH}$ (r: -0.31, p=0.01) and positively with RVR (r: 0.53, p=0.0003). In analyses stratified by DN status, greater central adiposity related to lower GFR_{INULIN} in both DN and DN resistors, but the relationships between central adiposity, $ERPF_{PAH}$ and RVR were attenuated and/or reversed in DN compared to DN resistors. GFR_{INULIN} across tertiles of trunk fat percentage are shown in Fig 1.

Conclusions: The adiposity-renal hemodynamic function relationship may be modified by the presence of T1D and of DN, requiring further study of the mechanisms by which adiposity influences renal hemodynamic function in health and disease.

Funding: NIDDK Support

Fig 1. Sex-adjusted means of GFR across tertiles of trunk fat percentage



SA-PO131

Policy Impact on Diabetes Detection in Vulnerable Populations Kate Cartwright, David N. van der Goes. *University of New Mexico, Albuquerque, NM.*

Background: Earlier detection of type 2 diabetes is associated with improved management of diabetes. Populations with barriers to care are more likely to have type 2 diabetes and are more likely to be diagnosed at an advanced stage of the disease. US residing Hispanics are not only more likely to be diagnosed with diabetes than their non-Hispanic counterparts, but they are also more likely to die of a diabetes-related cause. Before the ACA, Hispanics were the most likely to be uninsured or underinsured in all states. After the ACA, in states which expanded Medicaid, the uninsured rate for Latinos was reduced to 9% compared to 7% for non-Hispanic whites. However, in states which did not adopt Medicaid expansion, 24% of Latinos are uninsured compared to 10% of non-Hispanic whites. California went further by expanding coverage to non-citizens, which increased the number of non-citizens covered by about 31%. In this project, we analyze the change in self-reported diabetes among non-citizen Hispanic women in expansion and non-expansion states.

Methods: In a multivariate regression framework, we use the 2011-2015 NHIS to analyze the change in self-reported diagnosis of diabetes among Hispanic non-citizen women before and after the ACA Medicaid expansion. Less than 5% of Hispanic women in the South lived in states that expanded Medicaid, while approximately 97% of Hispanic women in the West lived in states that expanded Medicaid under the ACA. We use a difference-in-difference model with our second difference comparing the Southern US to the Western US.

Results: Non-citizen Hispanic women living in Medicaid expansion states saw an 80% (1.81 OR; CI 1.11-2.93) relative increase in self-reported diabetes (compared to non-citizen Hispanic women in non-expansion states). Comparing the same group's changes in self-assessed health and BMI showed no change. This indicates the change in self-reported diabetes in unlikely due to changes in health status, but instead due to improved detection of diabetes.

Conclusions: This investigation supports the argument that expanding health coverage is associated with improved health knowledge. One of the most vulnerable groups in the US, non-citizen Hispanic women, seems to have benefited from Medicaid coverage expansion. Improved detection of diabetes in this population creates an opportunity to better manage this condition and improve health outcomes, survival odds, and heatlh equity.

SA-PO132

Systems Biology Identified Molecular Pathways and Biomarkers Associated with Diabetic Kidney Disease Progression Skander Mulder,[1] Viji Nair,[2] Wenjun Ju,[2] Kelli M. Sas,[2] Hiddo J. Lambers Heerspink,[1] Matthias Kretzler.[2] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]University of Michigan, Ann Arbor, MI.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage kidney disease (ESKD). Understanding of molecular pathways involved in the initiation and progression of DKD facilitates biomarker development and drug target identification. We aim to identify molecular pathways associated with progressive loss of kidney function in both early and advanced stages of DKD.

Methods: We included 810 patients with early DKD from the DIRECT-2 trial (eGFR 69 ±11ml/min/1.73m^2 and normoalbuminuria) and 911 patients with advanced DKD from SUN-Macro (eGFR 33 ±10 and macroalbuminuria). Baseline urine proteomics, serum metabolomics and proteins were mapped to intra-renal transcriptional profiles of DKD biopsies from the European Renal cDNA Biobank (ERCB, n=19). All molecular features were associated with the primary end point of 30% eGFR decline or ESKD (n= 288), and subsequently with the secondary endpoint of eGFR slope < -3ml/year (n=704). Ingenuity pathway analysis identified significantly enriched canonical pathways and disease networks in associated features.

Results: The systems biology integration identified canonical pathways significantly enriched in molecular features associated with renal end points in early (3 pathways), advanced (1) and both stages (5) of DKD, respectively (Figure 1). These pathways include novel (Intrinsic Prothrombin Activation) and known DKD associated pathways (NAD biosynthesis and LXR/RXR activation). Antibody based assay results confirmed 11 (10 serum, 1 urine) biomarkers to be predictive for endpoints, including MMP7, TNFR1 and Endostatin representing the 5 enriched pathways in both early and late DKD.

Conclusions: By integrating intra-renal transcriptomic data with unbiased proteomics and metabolomics we identified stage-specific and shared molecular pathways, as well as their representing biomarkers, that are associated with DKD progression in early and late stages of DKD. Our work sets the stage for investigations of these biomarkers and molecular pathways for prognostic and interventional purposes.

Funding: Government Support - Non-U.S.

Identification of Novel Genetic Factors Linked to Diabetic Nephropathy Paolo Guarnieri,[1] Chengxiang Qiu,[2] Julie Hawkins,[1] Jonathan Hill,[1] Weiling Niu,[1] Matthew Palmer,[2] Yong G. Yue,[1] Steven S. Pullen,[1] Carine Boustany,[1] Katalin Susztak.[2] *[1]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Diabetic nephropathy (DN) is serious kidney condition and the leading cause of chronic kidney disease in the USA contributing to 30-40 % of all end-stage renal disease cases. In order to provide a better insight into its molecular mechanism, genetic determinants and finally identify novel targets, we first generated a novel dataset from a cohort of 250 patients undergoing nephrectomy and then we analytically integrated the results with public domain data from genome-wide association studies (GWAS).

Methods: Patients in the study were genotyped using high density Axiom arrays and phenotyped using collected clinical records. Each matched kidney specimen was histologically assessed and RNA-seq transcriptionally profiled separating tubules from glomeruli.

Results: Our analysis identified several genes associated with kidney function decline (estimated glomerular filtration rate), many also responsible for the progressive increase in interstitial fibrosis and/or associated with lymphocytic infiltration. Cell type specific gene signatures used with deconvolution algorithms revealed that several immune cells, mostly T lymphocytes, are active since the early stages of the disease. Our distinctive study design enabled the first human kidney specific eQTL analysis and helped focus on genes for which expression in kidney is genetically determined either in tubules, in glomeruli or both. We completed the expression to genotype to trait associations by performing a Bayesian co-localization analysis between our results with those available from GWAS and then matched the direction of the expression change with the effect on the trait.

Conclusions: In this study we generated a high resolution tissue and disease specific transcriptome database which allowed the study of genes and processes implicated in DN.

Fluorescence Lifetime Imaging Microscopy Reveals Gradual Accumulation of Collagens and NADH Lifetime Decrease in Human Kidney Glomeruli with Diabetic Disease Progression Evgenia Dobrinskikh,[3] Kammi J. Henriksen,[1] Moshe Levi.[2] *[1]The University of Chicago, Chicago, IL; [2]University of Colorado Denver, Aurora, CO; [3]University of Colorado, Denver, Aurora, CO.*

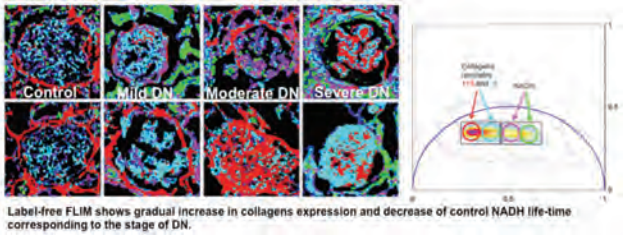
Background: Diabetes mellitus is a heterogeneous group of diseases which is a leading cause of renal cell and tissue damage, fibrosis and eventual renal failure. In view of recent therapies aimed at the pathogenesis of fibrosis generation and progression, sensitive and quantitative techniques for recording fibrosis becomes necessary.

Methods: We have applied Two Photon Excitation (TPE), Second Harmonic Generation (SHG) and Fluorescence Lifetime Imaging Microscopy (FLIM) for label-free imaging of kidney sections from kidney biopsies from human diabetic subjects. We have applied the phasor approach for FLIM analysis, which allows for the visual determination of collagens and other extracellular matrix components localization, and metabolic state of the kidney (free to bound NADH ratio) taking advantage of the specific autofluorescence characteristics of these molecules.

Results: In kidney biopsies obtained from diabetic humans, compared to biopsies obtained from nondiabetic subjects, we have determined that there is a strong SHG signal around the glomerulus and tubulointerstitial areas, which indicates presence of fibrosis. FLIM shows graduate increase of different types of collagens in the glomerulus and tubulointerstitial areas with the diabetes progression, which suggests different organization of extracellular matrix. NADH signal decreases and its lifetime shifts to the shorter lifetime in diabetic's kidneys that corresponds to different metabolic state of the tissue. FLIM also might determine relative degree of the disease progression based on the ratio of NADH lifetimes in different regions in diabetic compared to nondiabetic control kidneys.

Conclusions: TPE-SHG and FLIM imaging is a sensitive technique for label-free imaging, which can show metabolic state and ECM accumulation with the disease progression of the kidney based on the autofluorescence of the ECM components and NADH.

Funding: NIDDK Support



Label-free FLIM shows gradual increase in collagens expression and decrease of control NADH life-time corresponding to the stage of DN.

Alternative Splice Isoforms in Human Diabetic Kidney Disease (DKD) Rajasree Menon,[1] Viji Nair,[1] Brad A. Godfrey,[1] Felix H. Eichinger,[1] Yuanfang Guan,[1] Maria Luiza A. Caramori,[2] Michael Mauer,[2] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Minnesota, Minneapolis, MN.*

Background: mRNA transcript splice isoforms add a substantial complexity to gene regulation, but their expression and differentiated function have not been explored in renal disease. The goal of this study was to identify whether or not alternative splice isoforms were expressed in biopsy tissues from patients with diabetes.

Methods: TruSeq RNA Access based mRNA-Sequencing was performed on research kidney biopsy samples from 10 living kidney donors and 18 research volunteers with Type 1 diabetes (T1D) followed by weighted correlation network analysis (WGCNA) of the top 5,000 highly expressed variable transcripts. T1D patients were classified as fast-(n=10) and slow-progressors (n=8) for DKD. Alternative splice isoforms, defined by UniProt annotation, had to be differentially expressed (FDR< 0.3) between T1D and controls and to be contained in modules associated with disease progression. As alternative splice isoforms are poorly annotated, an integrated analysis using structure, function and motif predictions was performed and non-canonical isoforms with differential regulation and function from their canonical isoforms were further studied.

Results: 39 protein coding transcripts contained in three WGCNA modules were differentially expressed. EGF signaling, extra-cellular matrix and epithelial differentiation were among the top enriched processes. The protein products of 9 of these 39 transcripts are annotated as alternative /non-canonical isoforms. Analysis of the non-canonical isoform 3 of ATF3 was predicted to be involved in type I interferon and cell-substrate junction assembly compared to the canonical isoform. Consistent with this prediction, expression of the non-canonical, but not of the canonical ATF3 isoform, correlated highly with DUSP1 and EGR1 transcripts, known to be regulated by type I interferon. Structure predictions of the ATF3 isoform showed structural differences with RMSD of 3.5 from that of the canonical form with part of the basic leucine zipper domain missing in isoform 3 of ATF3.

Conclusions: We have identified alternative splice isoforms with substantial differential regulation and function prediction associated with key progression pathways in DKD, opening an analytical window to address the complexity of the transcriptome in renal disease.

Funding: NIDDK Support

SA-PO136

Type 1 Interferon Is Associated with Kidney Dysfunction in Type 2 Diabetes James Conway,[1] Felix H. Eichinger,[3] Brad A. Godfrey,[3] Viji Nair,[3] Anna Reznichenko,[2] Tim Slidel,[1] Clemens D. Cohen,[4] Brandon W. Higgs,[1] Carol P. Moreno Quinn,[1] Matthias Kretzler.[3] *[1]MedImmune, Gaithersburg, MD; [2]AstraZeneca, Molndal, Sweden; [3]University of Michigan, Ann Arbor, MI; [4]Klinikum Munchen, Munchen, Germany.*

Background: Type I interferon (IFN) is linked to the pathogenesis of autoimmune and inflammatory diseases known as interferonopathies. A portion of patients show aberrant type I IFN signaling, which can be measured by a gene expression signature composed of IFN-inducible genes (IFNGS). Chronic kidney disease (CKD) is characterized by chronic inflammation and interstitial fibrosis, yet little is known regarding type I IFN signaling in type 2 diabetics (T2D) with diabetic nephropathy (DN). Here we evaluated a type I IFNGS in these patients and identified an association with immune response and kidney dysfunction.

Methods: Tissue from human glomeruli (DN, n_1=12), tubulointerstitium from two independent patient sets (DN; n_1=17, n_2=31), and living donors (n_1=46) were obtained from the European Renal cDNA Bank and profiled by Affymetrix array. Gene-set variation analysis (GSVA) quantified a 21-gene type I IFNGS identified by Yao Y *et al* (PMID: 20948567) and other function-specific signatures. Patients were assigned to type I IFN-low or IFN-high groups based on median GSVA score. Gene signatures for which IFN-high patients differed from IFN-low were identified. P-values were adjusted for sex and age. A Fisher's combined probability was applied to summarize both studies (p_{chi}).

Results: Type I IFNGS was elevated in the tubulointerstitium (p_{chi}=1.3x10^{-4}), but not the glomeruli of DN patients compared to living donors. IFN-high patients associated with lower glomerular filtration rate (GFR) compared to IFN-low patients (p_{chi}=0.02). Although a high collagen signature associated with decreased GFR (p_{chi}=0.001), it did not correlate with type I IFNGS, suggesting an independent mechanism. IFN-high patients displayed increased T cell activation (p_{chi}=6.6x10^{-6}), TLR4 signaling (p_{chi}=5.7x10^{-5}) and innate immune response (p_{chi}=1.9x10^{-5}).

Conclusions: A significant decrease in GFR was observed in T2D patients with elevated Type I IFN signaling, which was also linked to increases in immune response signatures. This link between type I IFN signaling and kidney dysfunction may inform on patient selection for therapies targeting immune response pathways. This hypothesis should be confirmed in an independent study.

Integrated Score from Glomerular Structure and Molecular Profiles Predicts ESRD in Diabetic Kidney Disease (DKD) Viji Nair,[1] Jennifer L. Harder,[1] Paolo Guarnieri,[2] Jonathan Hill,[2] Brad A. Godfrey,[1] Carine Boustany,[2] Behzad Najafian,[3] Michael Mauer,[4] Robert G. Nelson,[5] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Boehringer Ingelheim, Ridgefield, CT; [3]University of Washington, Seattle, WA; [4]University of Minnesota, Minneapolis, MN; [5]National Institutes of Health, Phoenix, AZ.*

Background: DKD progression is the major cause of ESRD and increased mortality risk globally. We used systems biology tools to identify predictors of DKD progression through the integration of kidney structural changes with transcriptional profiling.

Methods: Glomerular specific gene expression profiling and quantitative morphometric analyses were performed on protocol kidney biopsies from 70 Pima Indians with type 2 diabetes [iothalamate (iGFR) 145 ± 52 ml/min and ACR 25.9[139.5]) mg/g]. Transcriptional co-expression modules were associated with glomerular morphometric traits using Weighted Gene Coexpression Network Analysis (WGCNA). Traits included glomerular basement membrane width (GBMW), mesangial fractional volume per glomerulus [Vv(Mes)], foot process width (FPW) and % peripheral capillary endothelial surface which is fenestrated (%EF), all associated with clinical expression of DKD. A z-score was computed from the gene set that correlated with these traits and associated

with the ESRD outcome. The prediction ability of this score for ESRD over a median of 15 years of follow up was evaluated using the Area Under the Curve Statistic (AUC).

Results: WGCNA analysis identified 14 modules of coexpressed genes. Glomerular structural traits of DKD showed strong associations with molecular signatures. Inflammatory responses and cellular signaling and proliferation pathways were the prominent functions enriched within these shared structural traits. The glomerular lesions gene score discriminated patients with and without progression to ESRD (AUC 0.85[0.75 - 0.96], p <0.001) where cross sectional iGFR performed poorly 0.43[0.27-0.56]. The score also correlated significantly with iGFR slope (r= -0.55, p <0.001).

Conclusions: Early glomerular lesions of DKD and the gene expression pathways associated with these lesions strongly predicted progressive DKD in type 2 diabetes. Further evaluation of these pathways could provide early intervention targets and novel noninvasive biomarkers with predictive clinical utility.

SA-PO138

Reduction of H3K27Me3 and Metabolic Memory Associated Inflammation in Podocytes Brad Dieter,[1] Rick L. Meek,[1] Robert J. Anderberg,[1] Sheryl K. Cooney,[1] Katherine R. Tuttle.[1,2] *[1]Providence Sacred Heart, Spokane, WA; [2]University of Washington School of Medicine, Spokane, WA.*

Background: Poor glycemic control, even with subsequent periods of well-controlled glycemia, increases risk for diabetic complications. This phenomenon, known as metabolic memory, may cause epigenetic changes such as reduction of histone 3 lysine 27 trimethylation (H3K27Me3), which increases expression of inflammatory mediators including serum amyloid A (SAA) in the diabetic kidney. The aim of this study was to determine if a sustained inflammatory response to metabolic memory may be mediated by increased SAA expression due to H3K27Me3 demethylation near the SAA promoter in podocytes, a cell centrally involved in diabetic kidney disease.

Methods: SAA knockout podocytes were generated using CRISPR-Cas9. In experiments to model metabolic memory, wild type and SAA knockout mouse podocytes were differentiated for 8-10 days, then exposed to advanced glycation end products (AGE, 300 μg/ml) for 7 days, followed by AGE removal and ongoing culture in control conditions for 7 more days. Chromatin immunoprecipitation measured H3K27Me3 near the SAA promoter. qRT-PCR was used to measure mRNA expression of inflammatory mediators: SAA, CXCL5, CCL2, and CCL5. Podocytes were exposed to AGE (300 μg/ml) for 1 day while H3K27Me3 demethylation was prevented by inhibiting the H3K27me3 specific demethylase, jmjd3, with GSK-J1 (20 μM).

Results: In metabolic memory experiments conducted in podocytes (n=6), histone H3K27Me3 near the SAA promoter was markedly reduced (95%) at day 14, while SAA mRNA increased (17±6-fold, p=0.025), as were SAA-dependent inflammatory mediators: CXCL5 (18.5±12-fold, p=0.004), CCL2 (2.0±0.7-fold, p=0.001), and CCL5 (1.6±0.6-fold, p=0.026). SAA knockout in podocytes reduced expression of CXCL5, CCL2, and CCL5 by ≥60% (p<0.05 for all) in metabolic memory experiments. jmjd3 inhibition reduced AGE-induced expression of SAA and each of the SAA-dependent inflammatory mediators by ≥60% (p<0.05 for all) in podocytes.

Conclusions: Short term exposure of podocytes to hyperglycemia-related perturbations causes sustained H3K27Me3 demethylation and increased SAA expression, leading to a sustained SAA-dependent inflammatory response.

SA-PO139

Atrasentan Treatment Combined with RAAS Inhibition Increases Parietal Epithelial Cell Activation and Restores Podocyte Number Kelly L. Hudkins,[1] Tomasz A. Wietecha,[3] Floortje Steegh,[2] Charles E. Alpers.[4] *[1]University of Washington, Seattle, WA; [2]Academic Hospital Maastricht, Maastricht, Netherlands; [3]University of Washington, Seattle, WA; [4]University of Washington Medical Center, Seattle, WA.*

Background: BTBR *ob/ob* (OB) mice develop robust type 2 diabetes and nephropathy that resembles human DN, with mesangial expansion, podocyte loss and proteinuria. This study tested the treatment effect of atrasentan (A), an endothelin-1 receptor antagonist, with or without concurrent RAAS inhibition by losartan (L) in mice with established DN.

Methods: Groups of 18 week old OB and WT littermates were treated via drinking water with A (5 mg/kg/day), A plus L (25 mg/kg/day) or normal drinking water for 6 weeks. Mice were analyzed for renal function and morphologic manifestations of DN, including proteinuria, podocyte number, mesangial matrix expansion, glomerular inflammatory infiltration, ultrastructural morphology and parietal epithelial cell (PEC) activation.

Results: Mice treated with A or A plus L had a 3 fold decrease in average albumin creatinine ratio (ACR) after 6 weeks of treatment. Analysis of paired urine samples at 18w and 24w showed significant ACR reduction in 5 of 6 OB mice (p=0.017) treated with A. Serum creatinine levels also decreased in OB mice treated with A and A plus L (p< 0.05). Renal function improvement was accompanied by decreased glomerular mesangial matrix, increased macrophage infiltration, restoration of podocyte foot processes and an increase in podocyte number. Expression of CD44 and pERK 1/2, both markers of PEC activation, were significantly increased in OB vs. WT (p<0.05). Treatment with A alone increased CD44 and pERK 1/2 PEC expression, while A plus L treatment showed a further increase in CD44 expression but a decrease of pERK1/2. Glomerular expression of pS6, a surrogate of mTOR activation, is increased in OB vs. WT mice (p<0.05), and treatment with A and A plus L resulted in a significant decrease.

Conclusions: Atrasentan treatment resulted in improvement of renal function, matrix accumulation and podocyte number in BTBR *ob/ob* mice with established DN. Combined treatment with A plus L resulted in increased restoration of podocyte number compared to A alone. PEC activation was also increased in treated mice, while activation of the mTOR pathway was reduced by treatment. The benefit of combined A plus L treatment in patients with DN may occur through restoration of podocyte number, potentially via PEC cell activation and migration, and foot process integrity.

Exogenous miRNA-23a/27a Attenuates Diabetes-Related Muscle Atrophy and Renal Fibrotic Lesions Bin Wang,[1,2] Aiqing Zhang,[1,3] Faten Hasounah,[1] Xiaonan H. Wang.[1] *[1]Emory University, Atlanta, GA; [2]Institute of Nephrology, Zhong Da Hospital, Southeast University, Nanjing, China; [3]Department of Pediatric Nephrology, The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Muscle atrophy is a frequent complication of diabetes mellitus. The microRNA-23a, -27a and 24-2, are located together in a gene cluster on chromosome 8. MiR-23a and miR-27a are known to regulate proteins that are involved in the atrophy and fibrosis process. We hypothesized that treatment with miR-23a/27a would reduce both diabetes-induced muscle wasting and renal fibrosis through exosome-mediated muscle-kidney crosstalk.

Methods: We generated an adeno-associated virus (AAV) that overexpresses miR-23a~27a~24-2 precursor RNA (and an AAV-GFP control) and injected it into the tibialis anterior (TA) muscle of STZ-induced diabetic mice. After 3 months, mice were killed and muscles and kidneys were analyzed for protein markers of atrophy and fibrosis. In-Vivo Xtreme camera system was used to track GFP migration to kidney in vivo.

Results: Injection of AAV-miRs into muscle increased miR-23a and miR-27a. The insulin/IGF signaling pathway was upregulated in skeletal muscle; e.g., increased phosphorylated Akt, attenuated FoxO1 and PTEN, reduced TRIM63/MuRF1 and FBXO32/atrogin-1. Myostatin signaling was downregulated; e.g., decreased myostatin and phosphorylated SMAD2/3 protein levels. Curiously, the serum BUN of diabetic animals was reduced in mice undergoing the miR-23a/27a intervention in muscle. Renal fibrosis, evaluated by Masson trichrome, was decreased as were pSMAD2/3, alpha smooth muscle actin, fibronectin and collagens. When diabetic mice were injected intramuscularly with AAV-GFP, the kidneys showed GFP fluorescence at levels that correlated with the levels in injected muscle, examined by linear regression. The abundance of GFP protein in skeletal muscle, serum exosomes and kidney increased over time after injection. Serum exosomes and kidneys of mice that received intramuscular injections of miR-23a/27a showed levels of those miRs that were higher than the un-injected control mice. No viral DNA was detected in the kidney.

Conclusions: Overexpression of miR-23a/27a in muscle prevents diabetes-induced muscle loss and attenuates renal fibrosis lesions via exosome-mediated muscle-kidney crosstalk.

Dietary Acid Reduction with Either Fruits and Vegetables or Oral NaHCO3 Reduces Oxidative Stress and Slows Progression of Kidney Injury in Stage 1 CKD Nimrit Goraya,[2,5] Lauren N. Sager,[1] Jan Simoni,[3] Donald E. Wesson.[4,3] *[1]Biostatistics, Baylor Scott & White, Temple, TX; [2]Internal Medicine, Baylor Scott and White Health, Temple, TX; [3]Internal Medicine, Baylor Scott & White Health, Temple, TX; [4]Diabetes Health and Wellness Institute, Dallas, TX; [5]Internal Medicine, Texas A and M School of Medicine, Temple, TX.*

Background: Chronic kidney disease stage 1 (eGFR > 90 ml/min/m^2, CKD 1) patients with macroalbuminuria (urine albumin-to-creatinine ratio > 200 mg/g creatinine) are at increased risk for CKD progression with higher morbidity, mortality, and costs. Dietary acid (H^+) induces nephropathy progression in animal models of CKD, mediated in part though angiotensin II (AII)-induced oxidative stress. We tested the hypothesis that dietary H^+ reduction with base-producing fruits and vegetables (F+V) or oral $NaHCO_3$ (HCO_3) prevents further kidney injury in CKD 1.

Methods: Seventy-one macroalbuminuric, non-diabetic CKD 1 subjects had systolic blood pressure (SBP) reduced to < 150 mm Hg with regimens including ACE inhibition and were then randomized to receive F+V (n=23) in amounts to reduce dietary potential renal acid load by half, oral $NaHCO_3$ (HCO_3, n=23) 0.4 meq/Kg bw/day, or no additional intervention (Usual Care, n=25). Creatinine-based eGFR and spot urine levels of the following, factored per g creatinine, were measured at baseline and yearly for five years: albumin (Ualb), an index of kidney injury, angiotensinogen (UAGT), an index of kidney angiotensin II, and isoprostane 8-isoprostaglandin F_{2a} (8-iso), an index of oxidative stress.

Results: Baseline eGFR, Ualb, UAGT, and U8-iso were not different among the groups. The five-year course (mean, 95% confidence limit or CI) of Ualb was lower than Usual Care (406 mg/g, CI=376-435) in both F+V (332 mg/g, CI=312-352) and HCO_3 (324 mg/g, CI=299-349), consistent with less kidney injury in each dietary acid reduction group. Combining F+V and HCO_3 into one dietary acid reduction group, UAGT course was lower than Usual Care (p<0.02), consistent with lower kidney AII. The five-year course of U8-iso was lower than Usual Care (1.24 ug/g, CI=1.19-1.29) in both F+V (1.10 ug/g, CI=1.06-1.15) and HCO_3 (1.11 ug/g, CI=1.07-1.14), consistent with less oxidative stress in both dietary reduction groups. There was no significant change in eGFR over the five years in any of the three groups.

Conclusions: Dietary acid reduction in CKD 1 with either F+V or $NaHCO_3$ yielded less kidney injury and less oxidative stress than Usual Care, possibly mediated though reduced kidney AII, supporting that dietary acid reduction reduces the risk for progression to advanced CKD stages.

SA-PO142

Changes in Protein Intake among Adults with and without CKD: NHANES 2003-2014 Karen R. Siegel, Meda E. Pavkov. *Centers for Disease Control, Atlanta, GA.*

Background: Consuming a diet with moderate amounts of protein is recommended for all individuals, including those with Chronic Kidney Disease (CKD).

Methods: Using the National Health and Nutrition Examination Surveys (NHANES) 2003-2008 (T1) and 2009-2014 (T2), we estimated changes in protein intake over time and the percentage of adults consuming above the RDA average recommended amount of protein (56 gram[g]/day for men, 46 g/day for women), overall and by CKD status. We included adults ≥19 years old, excluded those pregnant or lactating, those with missing data on CKD status, diabetes status, or protein intake. The final analytic sample yielded 12,302 adults for T1 and 13,293 adults for T2. An average of 2 days of 24-hour dietary recalls were used to estimate protein intake. Protein intake was converted to kcal by multiplying each g by 4 kcal; to calculate protein intake as percentage of dietary intake, we divided by total daily kcal. CKD status was defined by albuminuria and/or eGFR <60 ml/min/1.73 m^2.

Results: Overall, protein intake was 98.8 g (Standard Error: 0.7), or 395 kcal, for men and 68.8 g (0.5), or 275 kcal, for women in T1; 97.3 g (0.6), or 389 kcal, for men and 69.3 g (0.4), or 277 kcal, for women in T2. This translates into 84.3% (0.7) of men and 77.8% (0.8) of women consuming above the recommended amount in T1, and 84.5% (0.5) of men and 78.2% (0.5) of women exceeding recommended protein intake in T2. In both time periods adults with CKD were less likely than those without CKD to consume above the recommended protein intake (83.1% vs 90.5% among men and 77.2% vs 83.7% among women in T1, and 82.7% vs 90.8% among men and 76.5% vs 84.1% among women in T2).

Conclusions: The percentage of the population exceeding protein intake recommendations remained high in 2003-2008 and 2009-2014. There is much room for improvement in reducing protein intake and potentially slowing disease progression in those with CKD. In ongoing work we also examine types of protein (e.g., animal, dairy, plant) and how their intake varies by CKD status.

SA-PO143

Osteoprotegerin Is a Strong Independent Marker of Cardiovascular Mortality in Patients with CKD Stage 3 to 5 Marcelo M. Nascimento,[1,4] Gustavo L. Marques,[1] Shirley Hayashi,[2] Anna Bjällmark,[2] Matilda Larsson,[2] Miguel C. Riella,[3] Bengt Lindholm.[4] *[1]UFPR, Hospital de Clinicas, Curitiba, Brazil; [2]Royal Institute of Technology (KTH), Huddinge, Sweden; [3]Evangelic School of Medicine of Parana, Curitiba, Brazil, Curitiba, Brazil; [4]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Osteoprotegerin (OPG) regulates bone mass by inhibiting osteoclast differentiation and activation, and might play a role in vascular calcification. Increased levels of circulating OPG in patients with chronic kidney disease (CKD) have been reported to be associated with both aortic calcification and increased mortality. Here we assessed the mortality predictive role of OPG in CKD stage 3-5 patients followed for up to 5 years.

Methods: We evaluated the relationship between OPG and mortality (general and due to cardiovascular cause) in 143 CKD patients including 36 patients on hemodialysis, 55 patients on peritoneal dialysis, and 52 conservatively treated patients with CKD stages 3-5. Clinical characteristics, markers of mineral metabolism (including fibroblast growth factor-23 [FGF-23]), inflammation (high-sensitivity C-reactive protein [hsCRP] and interleukin-6 [IL-6]), intima-media thickness (IMT) in the common carotid arteries as assessed by ultrasound, and cardiac status by color tissue Doppler echocardiography, were measured at baseline, and correlations with OPG levels were analyzed.

Results: OPG levels were positively associated with IL-6 ($r = 0.44$, $P<0.01$), FGF-23 ($r = 0.26$, $P<0.01$) and hsCRP ($r = 0.27$, $P<0.01$), troponin I ($r = 0.55$, $P<0.01$) and IMT ($r = 0.39$, $P<0.01$), as well as with higher left ventricular mass. After 60 months follow-up, the survival rate by Kaplan-Meier analysis was significantly worse in those with higher baseline OPG levels for all cause as well as cardiovascular mortality (both Chi-Square: 15.60 $p<0.0001$). The Cox model for all cause and cardiovascular mortality demonstrated that only OPG (per pg/mL; HR=1.07, 95%CI=1.02-1.13, and HR=4.46, 95%CI=1.4-13.5, respectively) and hsCRP (per mg/dL; HR=1.02, 95%CI=1.01-1.04, and HR=5.71, 95%CI=1.17-27.9, respectively) were independently associated with increased all-cause and cardiovascular risk of death, respectively.

Conclusions: Elevated levels of serum OPG associate with markers of inflammation and mineral metabolism, signs of atherosclerosis and cardiovascular deaths in patients with CKD stage 3-5. OPG is a strong independent predictor of cardiovascular mortality in this patient population.

SA-PO144

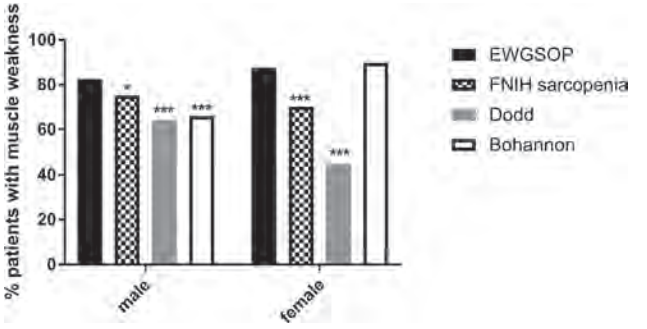
Differences in Prevalence of Muscle Weakness (Sarcopenia) in Haemodialysis Patients Determined by Hand Grip Strength According to Variation in Sarcopenia Guidelines Rachel Hung,[2] Kamonwan Tangvoraphonkchai,[1] Omid sadeghi-alavijeh,[3] Andrew Davenport.[3] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Royal Free Hospital, London, London, United Kingdom; [3]Royal Free Hospital, London, United Kingdom.*

Background: Muscle weakness is associated with increased mortality, and patients on haemodialysis (HD) are at increased risk of muscle loss. There is no universal agreed definition for muscle weakness, so we wished to determine whether using different cut off criteria recommended by clinical guideline groups altered the prevalence in HD patients.

Methods: We measured hand grip strength (HGS) in HD outpatients comparing HGS with clinical guideline cut offs (European Working Group on Sarcopenia in Older People (EWGSOP), National Institutes of Health Sarcopenia Project (FNIH)) used to define muscle wasting (sarcopenia), as well as age and gender matched normative data.

Results: We studied 459 patients, 61.4% male, 47.3% diabetic. The prevalence of muscle weakness was significantly different when measuring HGS; 84.5% using the EWGSOP cut off, 73.2% with FNIH criteria and 75.2% using North American and 56.6% UK normative data ($p<0.01$). On logistic regression, muscle weakness was associated with age (odds ratio (OR) 1.05, $p<0.001$), weight (OR 0.96, $p<0.001$), serum albumin (OR 0.89, $p=0.007$)and being a non-diabetic (OR 0.31, $p=0.001$) whereas gender is not a significant factor. In addition, 66.7% of patients with no-comorbidities were weak, compared to 93.8% with highest co-morbidity score, $p<0.001$.

Conclusions: There is currently no agreed universal definition for muscle wasting (sarcopenia), but the EWGSOP and FNIH advocate HGS cut offs as part of their definition of sarcopenia. The prevalence of muscle weakness varies according to cut off, and whether age and gender matched normative data is used. In addition, patient characteristics in terms of age and co-morbidity also determine the prevalence of muscle weakness.



Male and female cut off points for different sarcopenia guidelines.* $p<0.5$, ** $p<0.01$, *** $p<0.001$ for EWSOP vs others

SA-PO145

Effect of Statin Therapy on Markers of Thrombosis and Inflammation in ESRD Daniel Chang,[2] Carlos H. Moreno Castaneda,[2] Farhanah Yousaf,[2] Hafiz Hussain,[2] Chaim Charytan,[2] Bruce S. Spinowitz.[1] *[1]New York Hospital Medical Center of Queens, New Rochelle, NY; [2]New York Presbyterian / Queens, Fresh Meadows, NY.*

Background: Large platelets have more granules, aggregate more rapidly with collagen, have higher thromboxane A2 levels and express more glycoprotein Ib and IIb/IIIa receptors. Upper quintile limit of mean platelet volume (MPV) predicts coronary artery disease in the hemodialysis population. Evidence suggests that statins may reduce MPV.

Methods: Medical records of prevalent hemodialysis patients as of 30Jun2016 were reviewed. Statins group included patients taking statins ≥6 months prior to 1Jan2016 and continued statins until 30Jun2016. No statins group included patients never taking statins or who stopped taking statins >6 months prior to 1Jan2016. Basic demographic, comorbidity, and laboratory data was tabulated. Independent t-test was used to compare 6-month (1Jan–30Jun2016) average MPV, WBC to MPV ratio, and ferritin levels in no statins versus statins groups.

Results: 224 patients were prevalent as of 30Jun2016. Exclusion consisted of 20 new patients, 98 with active infection or hospitalization, 5 on omega-3, 6 on steroid, 9 on statins <6 months, 7 started statins after 31Dec2015, 3 stopped statins between 1Jan-30Jun2016, and 5 received blood transfusion. In remaining 71 patients, 36 patients (24 males, 11 diabetics) aged 61±17 years never used or discontinued statins >6 months prior to 1Jan2016 while 35 patients (22 males, 22 diabetics) aged 70±13 years ($p=0.018$) taking statins ≥6 months prior to 1Jan2016 and continued statins until 30Jun2016. In statins group, 2 were on low intensity, 26 were on moderate intensity, and 7 were on high intensity statins. No statins group had higher mean cholesterol (159±34 vs 134±40 mg/dL) and LDL level (94±28 vs 73±34mg/dL) compared to statins group. After controlling for age and diabetes ($r^2=0.2$), mean MPV was significantly higher in statins group (11.2±1fL) versus no statins group (10.4±1fL) [$p=0.013$] while WBC to MPV ratio and ferritin levels were similar.

Conclusions: Our findings suggest that statin therapy in hemodialysis population is not associated with lower but rather higher MPV. Moreover, WBC to MPV ratio and

ferritin levels are unaffected by the use of statins. Lack of statins impact on markers of thrombosis and inflammation in end stage renal disease may explain lack of mortality benefit observed in previous literature.

SA-PO146

Exercise Capacity Predicts Mortality and Morbidity in Patients across the CKD Trajectory Sharlene A. Greenwood,[1,2] Ellen M. O'Connor,[1] Helen L. MacLaughlin,[1] Iain C. Macdougall.[1] *[1]King's College Hospital, London, United Kingdom; [2]King's College London, London, United Kingdom.*

Background: Exercise capacity is reduced in patients with chronic kidney disease (CKD). Low exercise capacity has been shown to be an independent predictor of mortality in patients with end-stage renal disease. We analysed the value of exercise capacity, characterised as the incremental shuttle walk test (ISWT) for predicting mortality and morbidity in a cohort of 438 patients (male 54%) from across the CKD trajectory (124 haemodialysis patients, 126 kidney transplant recipients, 31 peritoneal dialysis patients, 157 non-dialysis patients) over a 12-year period from 2005 to 2017 (median follow-up of 34 months).

Methods: Survival status was determined for 438 patients with CKD who were referred to an outpatient renal rehabilitation programme for which the ISWT and other clinical data had been determined. Chi-square and Kaplan-Meier survival analyses were performed. Risk of mortality was investigated independent of modality, BMI, diabetic status, age, gender, ethnicity, and smoking status using Cox proportional hazards model.

Results: There were a total of 108 combined events (death, cerebrovascular accident and hospitalisation for chronic heart failure) during the follow-up period. ISWT (>270m; p<0.0001 by Kaplan-Meier) was a strong predictor of mortality and morbidity. Determinants of functional ability, Sit to Stand 60 test (>18 complete transfers; p<0.0001 by Kaplan-Meier), Timed Up and Go 3m test (>8.05s; p=0.0001 by Kaplan-Meier), the Duke's Activity Status Index (>23.45; 0.003 by Kaplan-Meier) were also strong predictors of survival. On multivariate analysis, ISWT contributed significantly to the minimal explanatory model relating clinical variables to mortality and morbidity (overall x2 37.4, p=0.001). Patients who were able to walk >270m had a 2.3-fold (Hazard Ratio = 2.3; 95% confidence interval: 1.1 to 4.7) independent greater risk of a combined event (P = 0.02).

Conclusions: Exercise capacity is strongly predictive of mortality and morbidity in patients across the CKD trajectory. Exercise training interventions to improve clinical outcome in patients with CKD should be explored.

SA-PO147

Randomized Controlled Clinical Study to Prevent Decline in Renal Function and Nutritional Status in Predialysis Patients Using Ketoanalogue Supplementation Anita Saxena,[2] Amit Gupta,[1] Trisha Sachan,[4] Chandra M. Pandey.[3] *[1]Department of Nephrology, Lucknow, India; [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India; [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [4]department of nephrology, sanjay gandhi post graduate institute of medical sciences, Lucknow, India.*

Background: Low protein diet is a means to protect residual renal function and to slow down progression of CKD to end stage renal disease. Study was conducted to evaluate effect of combined therapy of very low protein diet (vLPD) and ketoanalogues on renal function of predialysis patients and compliance to very low protein diet.

Methods: Prospective randomized controlled study. **Forty patients** divided into two groups of 20 each. CKD patients with GFR <60 but >30 ml/minute were included. Group I was supplemented with 300 mg/d of ketoanalogues combined with 0.4 gram /kg day protein (vLPD) and 35 kcal/kg/d of energy for 10 months. Group 2, control, was kept on low protein diet 0.6 g/kg /day and 35 kcal/kg /day energy. Biochemical investigations, included serum albumin, hemoglobin, sodium, potassium, calcium, phosphorus, and blood glucose were done at baseline (visit 1) and at 10 months (Visit 2). Dietary intake was taken by dietician. Nutritional status was assessed using SGA.

Results: At baseline, the GFR was higher in controls (51.14±15.1 ml/min). compared to ketoanalogue group (47.79±13.2 ml/min). GFR declined in the control group from 51.14 ml/min at baseline to 35.5±7.94 ml/min over a period of 10 months. In ketoanalogue group the GFR remained stable after 10 months 47.65±13.26.ml/min (47.79±13.2 at baseline). Serum albumin was preserved at 4.03 ±0.52 g/dL after10 months (4.11±0.43 g/dL at visit 1) in ketoanalogue group. In control group serum albumin decreased from 3.8±0.90 g/dL at visit 1 to 3.09±0.38 after 10 months (visit 2). GFR (p = 0.023) and serum albumin (p =0.000) were significantly higher in ketoanalogue vLPD group compared to controls at visit 2. Group 1 patients were noncompliant to vLPD as protein intake was 0.62±0.24 g/kg/d instead of 0.4 g/kg/d but GFR remained stable at 47.7 ml/min over 10 months. Energy intake was low 19.48±6.84 kcal/kg/d and 16.15±5.85 kcal/kg/d in group 1 and 2 respectively compared to RDA.

Conclusions: Ketoanalogue supplementation preserves nutritional status and prevents decline renal function.

SA-PO148

The Effect of a Renal Specific Oral Nutritional Supplement on Nutritional Status in Non-Dialytic CKD Wen-Yi Cheng,[2] Shang-Jyh Hwang,[3] Chih-Ching Lin,[4] Meng-Chuan Huang,[3] Owen J. Kelly.[1] *[1]Abbott Laboratories, Columbus, AL; [2]Abbott Laboratories Services Corp., Taipei, Taiwan; [3]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [4]Taipei Veterans General Hospital, Taipei City, Taiwan.*

Background: The purpose of this study was to determine if 1-2 servings/d of a renal specific ONS (oral nutrition supplement) aids in maintaining nutritional status and avoids potential deleterious consequences in non-dialyzed stage 3b-5 CKD patients due to low dietary protein intake.

Methods: This is a prospective, multicenter, single arm, and open label study. Non-dialyzed stage 3b-5 CKD patients, with or without type 2 diabetes mellitus, with serum albumin ≥ 3.0 g/dl, and currently receiving standard medical care but not scheduled for dialysis treatment within 18 months were recruited. Subjects were requested to consume 1-2 servings per day (475 kcal, 10.6 g protein per serving), renal specific ONS for 6 months based on individual needs under dietitian's assessment. The change of serum albumin, body weight, and BMI were assessed for nutritional status. Protein and energy intakes were estimated from the dietary records. The outcomes on handgrip strength, blood biochemistries, appetite change, and quality of life were also examined.

Results: Totally 45 patients completed the intervention trial. Daily protein and energy intakes were elevated significantly 6 months later (+9.42 g/day, p<0.02; +175.37 kcal/day, p<0.001). Mean body weight and BMI increased significantly (+1.18 kg, p<0.001; +0.47 kg/m^2 p<0.001) but there was no significant difference in serum albumin (4.09 g/dl to 4.13 g/dl) after intervention for 6 months. However, handgrip strength and appetite improved significantly (+1.28 kg, p<0.001; +0.20 scores, p=0.03). There was no significant difference in the parameters of quality of life and the profiles of blood biochemistries.

Conclusions: The addition of renal specific ONS can maintain albumin level and improve anthropometry, handgrip strength, and appetite in non-dialyzed stage 3b-5 CKD patients compared to those who received standard diet counseling.

Effects of Resistant Starch Supplementation on Inflammatory and Oxidative Stress Status in Hemodialysis Patients: A Pilot Randomized, Double-Blind, Placebo-Controlled Clinical Trial Denise Mafra, Marta Esgalhado, Milena B. Stockler-Pinto, Natalia A. Borges, Ludmila F. Cardozo, Bruna Paiva, Mariana Z. Jardim, Julie ann Kemp. *Federal Fluminense University, Niterói, Brazil.*

Background: In recent years, researchers have suggested that gut microbiota imbalance may be considered as a new cardiovascular risk factor in chronic kidney disease (CKD) patients, once it is associated with inflammatory and oxidative stress state. In this context, prebiotics use has been pointed out as a promising non-pharmacological therapeutic strategy by reestablishing the gut microbiota balance. The aim of this study was to determine the effect of resistant starch (RS) (as prebiotic source) supplementation on inflammatory and oxidative stress status on hemodialysis (HD) patients.

Methods: This randomized, double-blind, placebo-controlled clinical trial evaluated 20 CKD patients on HD (55% male, 55.6 ± 10.7 years, 30.5 (14.2 – 62) months HD vintage, BMI, 26.5 ± 4.8 kg/m^2). Patients were randomized to receive prebiotic (10 patients received 9 cookies/d in the dialysis days and 1 sachet/d in non-dialysis days, containing 16g of RS- Hi-Maize 260, Ingredion®) or placebo (10 patients received cookies and sachets - containing manioc flour) for 4 weeks. High sensitive C-reactive protein (hs-CRP) was analyzed using Bioclin® kit by automatic biochemical analyzer, interleukin (IL)-6 plasma levels were performed by ELISA and, malonaldehyde (MDA) plasma levels, a common marker of lipid peroxidation, were measured by thiobarbituric acid reaction. Routine biochemical parameters and nutritional status were also obtained.

Results: There was no significant difference between baseline values for any variable in both groups. After 4 weeks of RS supplementation, there was a significant reduction in IL-6 (from 3.47 ± 0.004 to 3.46 ± 0.001 pg/mL, p= 0.001) and MDA (from 4.64 ± 2.47 to 2.33 ± 1.57 nmol/mL, p=0.04) plasma levels. *No change was observed* in *placebo group.*

Conclusions: Data from this randomized study suggest that RS supplementation may modulate inflammation and oxidative stress in HD patients. These findings support the need for more studies with prebiotics in CKD patients to confirm the hypothesis that they could be a new non-pharmacological therapeutic strategy to modulate gut microbiota in these patients and reduce complications related to its imbalance.

Optical Analysis of Mitochondrial Dynamics and Function in Renal Physiology and Pathology In Vivo Using Metabolic Biosensor Transgenic Zebrafish Yuya Sugano,[2,3] Jacob P. Keller,[4,5] Ritu Tomar,[2,3] Hugo L. Siegfried,[2,3] Loren Looger,[4,5] Iain A. Drummond.[1,3] *[1]Massachusetts General Hospital, Charlestown, MA; [2]Massachusetts General Hospital, Charlestown, MA; [3]Harvard Medical School, Boston, MA; [4]Janelia Research Campus, Ashburn, VA; [5]Howard Hughes Medical Institute, Ashburn, VA.*

Background: Accumulating amounts of evidence suggest that mitochondria play a major role in maintenance of renal function and pathogenesis of kidney diseases. Despite

the apparent importance, however, little is known about mechanisms by which altered mitochondrial function leads to development of renal disease due to lack of appropriate tools. Mitochondria are a dynamic organelle that actively changes its shape, number and site of residence, thereby making it critical to analyze them *in vivo*. In order to establish *in vivo* tools to study mitochondria, we applied the genetically encoded biosensor technology to the zebrafish, an optically accessible and genetically tractable model system.

Methods: A transgenic zebrafish line incorporating a mitochondria targeted redox sensor (mitoGrx1-roGFP2) under the UAS effector element was generated. By crossing this UAS effector line into Gal4 driver lines with *podocin* and *cdh17* promoter [Tg(podo:Gal4) and Tg(cdh17:Gal4)], mitoGrx1-roGFP2 was expressed in glomerular podocytes and tubular epithelial cells, respectively, in the pronephros. Live imaging of the transgenic zebrafish was performed by sequential excitation at 405 nm and 488 nm for ratiometric measurements.

Results: We found that mitochondrial structure and dynamics in podocytes can be imaged in living zebrafish by two-photon microscopy. Time lapse imaging of Tg(podo:Gal4, UAS:mitoGrx1-roGFP2) demonstrated that mitochondria are stationary in pronephric podocytes. Upon exposure to a nephrotoxic antibiotic, puromycin aminonucleoside, mitochondria appeared to relocalize to primary and secondary processes from the cell body. Furthermore, ratiometric measurements of mitoGrx1-roGFP2 reported changes in oxidative stress levels in mitochondria in renal tubular epithelia in response to tert butyl hydroperoxide.

Conclusions: These transgenic zebrafish represent a novel tool to investigate mitochondrial structure and function *in vivo*. In addition, transgenic zebrafish with biosensors for other metabolic parameters, such as glucose, are also being validated. These transgenic zebrafish offer a versatile and accessible *in vivo* system to study mitochondrial dynamics and activity as well as their associated metabolism in the kidney in health and disease.

Low Density Lipoprotein Cholesterol Is Associated with Decreased Infectious Death and Hospitalization in Hemodialysis Patients

Xiaoling Ye,[2] Jochen G. Raimann,[2] Alice Topping,[2] Len A. Usvyat,[1] Peter Kotanko,[2,4] George A. Kaysen.[3,2] *[1]Fresenius Medical Care North America, Melrose, MA; [2]Renal Research Institute, New York, NY; [3]Medicine and Biochemistry and Molecular Medicine, UC Davis, Davis, CA; [4]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Reduction in low density lipoprotein (LDL) does not decrease mortality in hemodialysis (HD) patients. The second leading cause of death in HD after cardiovascular (CV) diseases is infectious. LDL absorbs and inactivates bacterial toxins. Injected human LDL prevents endotoxin induced lethality in mice. We examined the effect of LDL, High Density Lipoprotein (HDL) and triglycerides (TG) on infectious, CV events and all cause mortality.

Methods: We explored relationships between blood lipids and outcomes in databases from Renal Research Institute (RRI) clinics in US and Fresenius Medical Care (FMC) clinics in Europe, and west Asia (14,650 patients, 60.2% male). All incident and prevalent patients starting in-center HD between Jan 1, 2000 and Dec 31, 2012 with at least one lipid measurements and inflammatory measures (C reactive protein (CRP)) or neutrophil lymphocyte ratio (NLR) measured were selected. Time to bacterial infectious, CV hospitalization or death or all cause death during up to 4 years of following the last lipid measurement were analyzed by Cox time varying proportional hazards.

Results: LDL reduced risk of infectious death and hospitalizations, and all-cause mortality (HR 0.98 0.971-0.989, (P< 0.001). HDL was associated with a reduction in CV death and hospitilization (HR 0.901 0.847-0.958 P = 0.0009) and all-cause mortality (HR 0.919 0.897-0943 P <0.001) and TG was associated with a reduction in all cause mortality (HR 0.683 0.642-0.726 P <0.001).

Conclusions: Higher LDL is associated with decreased all cause death and infectious death and hospitalizations, but not with increased CV risk, possibly accounting for the observation that reducing LDL cholesterol has a limited effect on outcomes in patients undergoing hemodialysis.

Low Plasma Insulin-Like Growth Factor-1 Associates with Increased Mortality in CKD Patients with Reduced Muscle Strength

Chen Zhimin,[1,2] Bengt Lindholm,[1] Olof Heimburger,[1] Peter F. Barany,[1] Peter Stenvinkel,[1] Jianghua Chen,[2] Abdul Rashid T. Qureshi.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]1st Affiliated Hospital College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Chronic kidney disease (CKD) leads to metabolic and nutritional abnormalities including resistance to insulin-like growth factor-1 (IGF-1) action. Low plasma IGF-1 concentration as well as low handgrip strength (HGS), a reliable and easy-to-perform nutritional parameter, are independent predictors of increased mortality in CKD patients (pts). We hypothesized that low muscle strength enhances the negative impact of low IGF-1 on survival in CKD.

Methods: We included 685 CKD pts (62% males; median age 58 years) including 75 CKD 3-4 pts, 361 incident dialysis pts, 70 prevalent peritoneal dialysis pts and 179 prevalent hemodialysis pts. Baseline measurements of IGF-1, HGS, nutritional status (by subjective global assessment, SGA), lean body mass index (LBMI), and metabolic and inflammatory biomarkers potentially linked to IGF-1 were analysed in relation to mortality during follow up period of up to 5 years during which 208 pts (30.4%) died. We compared survival in four groups with high or low (cut-offs defined by ROC curve analysis) levels of IGF-1 and HGS.

Results: Pts with low IGF-1 were older, had lower body mass index (BMI), HGS and LBMI, more likely to have diabetes, CVD and malnutrition (SGA >1), and had sensitivity C-reactive protein (hsCRP) levels. During 5 years of follow-up, 208 pts (30.4%) died. Pts with Low IGF-1 + Low HGS had markedly increased mortality rate: In competing-risks regression analysis, sub-hazard ratio (SHR) of pts with Low HGS + Low IGF-1 was 2.3 times higher than for pts with High HGS + Low IGF-1. Low IGF-1 + Low HGS was independently associated with all-cause mortality after adjustments for age, sex, diabetes, CVD, SGA, smoking, hsCRP, albumin and LBMI.

Conclusions: Low IGF-1 together with low HGS - but not low IGF-1 together with high HGS - was independently associated with increased all-cause mortality suggesting that the effect of IGF-1 on mortality in CKD patients depends on nutritional status.

SA-PO153

Influence of Diabetes on Sarcopenia in Hemodialysis Patients

Senji Okuno,[1] Jiro Miyawaki,[1] Hisanori Okazaki,[1] Kyoko Norimine,[1] Shigeichi Shoji,[1] Tomoyuki Yamakawa,[1] Eiji Ishimura,[2] Masaaki Inaba.[2] *[1]Shirasagi Hospital, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Recently, the associations between sarcopania and diabetes and between sarcopenia and chronic kidney disease, including hemodialysis (HD) condition, have been reported. However, there have been few reports that examine the relationship between sarcopenia and diabetes in HD patients. Little is known how far diabetes affects sarcopenia in HD patients. Moreover, definition of sarcopenia was made only in considering the low muscle mass in most of the previous studies. The purpose of this study was to assess sarcopenia which was strictly assessed by both muscle mass and muscle strength, and was to examine the association of diabetes with sarcopenia in HD patients.

Methods: A total of 308 patients on maintenance HD (age 58.1 ± 11.9 years, HD duration 6.5 ± 6.0 years, 60 % males, and 33 % diabetics) were examined. Appendicular

skeletal muscle mass was measured by dual energy X-ray absorptiometry (DXA). Low muscle mass was defined as skeletal muscle mass index (SMI) of < 6.87 kg/m² for males and < 5.46 kg/m² for females. Low muscle strength was defined as hand grip strength of < 26 kg for males and < 18 kg for females. Sarcopenia was defined as decline in both SMI hand grip strength.

Results: There were no significant differences in HD duration or in hemoglobin between patients with and without sarcopenia. Age was significantly higher, and body mass index and serum albumin were significantly lower in patients with sarcopenia than in those without sarcopenia (63.5 ± 11.0 *vs.* 54.1 ± 11.0 years, p < 0.0001; 19.4 ± 2.5 *vs.* 21.2 ± 2.3 kg/m², p < 0.0001 and 3.9 ± 0.3 *vs.* 4.1 ± 0.3 g/dL, p < 0.0001, respectively). Prevalence of sarcopenia in diabetic patients was significantly higher than that in non-diabetic patients (51 % *vs.* 36 %, p = 0.0151). In a multiple logistic regression analysis, presence of diabetes (OR = 3.02, p = 0.0008) was significantly, independenly associated with sarcopenia after adjustment with age, gender, HD duration, body mass index, hemoglobin, serum albumin, and C-reactive protein levels (R^2 = 0.273, p < 0.0001).

Conclusions: Present study clearly demonstrates, for the first time, that, in HD patients who are considered to be at higher prevalence of sarcopenia, diabetes is further an additional, strong risk factor for sarcopenia, which was strictly assessed by both muscle mass and muscle strength.

SA-PO154

Severe Vitamin D Deficiency Is a Risk Factor for Renal Hyperfiltration Jong Hyun Jhee,[1] Tae-Hyun Yoo,[1] Sukyung Kang,[2] Arum Choi.[2] *[1]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea.*

Background: Recent studies suggested that renal hyperfiltration (RHF) is significantly associated with increased risk of all-cause and cardiovascular mortality in relatively healthy adult population as well as diabetic patients. On the other hand, vitamin D deficiency is well known risk factor for renal progression in various diseases. This study aimed to investigate the association between RHF and vitamin D deficiency among relatively healthy adult population.

Methods: The data from subjects participated in the Korean National Health and Nutrition Examination Survey (KNHANES) from 2008 to 2015 were collected. A total of 33,210 subjects with normal renal function were included in the final analysis. Estimated GFR (eGFR) was calculated with the Chronic Kidney Disease Epidemiology Collaboration creatinine equation, and RHF was defined as eGFR > 95th percentile after adjustment for age, sex, and history of diabetes and/or hypertension. Severe vitamin D deficiency was defined as serum 25(OH)D < 10 ng/mL.

Results: The mean ages of the subjects were 48.1 years and the numbers of female subjects were 18,779 (56.5%). 1,637 (4.9%) subjects were categorized into RHF group. The proportions of hypertension and diabetes were significantly higher in RHF group than those in patients without RHF. According to serum 25(OH) level, the prevalence of renal hyperfiltration was significantly higher in the lowest 25(OH)D group (5.7%, P<0.001). Furthermore, multivariate linear regression analysis showed that 25(OH)D level was negatively associated with eGFR (β=-0.04, P < 0.001), systolic blood pressure (β=-0.01, P < 0.001), and fasting plasma glucose (β=-0.01, P < 0.001). In multivariate logistic regression model, severe vitamin D deficient group showed significantly high odds ratio (OR) for renal hyperfiltration than that in group with 25(OH)D ≥ 30 ng/mL (OR, 2.23; 95% confidence interval, 1.65-2.99; P <0.001).

Conclusions: Severe vitamin D deficiency is significantly associated with increasing prevalence of renal hyperfiltration in a relatively healthy population.

SA-PO155

Thiamine Deficiency in End-Stage CKD Patients Yosuke Saka, Tomohiko Naruse. *Nephrology, Kasugai Municipal Hospital, Kasugai, Japan.*

Background: Thiamine deficiency presents with several clinical manifestations such as heart failure, peripheral neuropathy and encephalopathy. Thiamine deficiency is observed also in patients with chronic kidney disease (CKD), resulting from malnutrition and long-term diuretic therapy. The risk of thiamine deficiency might be enhanced, especially in end-stage CKD patients. Thereby, we assessed thiamine status on incident dialysis patients.

Methods: This study included 188 consecutive patients initiated into dialysis between April 2013 and March 2016 in our hospital. Of 188 patients, 14 patients taking thiamine supplements were excluded. Thiamine status was evaluated by high-performance liquid chromatography (HPLC) measurement of thiamine in whole blood. We evaluated the association between blood thiamine concentration and other clinical parameters.

Results: The median value of blood thiamine concentration was 29.7 ng/mL [IQR:24.4–38.8]. In 21 patients (12.1%), blood thiamine concentration was lower than the normal lower limit (21.3 ng/ml). In Spearman univariate correlation analysis, blood thiamine concentration was correlated with age, Barthel index (BI) score and body mass index (BMI). Serum albumin concentration and loop diuretics therapy had no correlation with blood thiamine concentration. Multivariate regression analysis indicated that age (β-coefficient = –0.24, p = 0.043) and BI score (β-coefficient = 0.14, p = 0.025) were independent risk factors of thiamine deficiency.

Conclusions: This study shows that the proportion of end-stage CKD patients with low blood thiamine concentration was high. In addition, this study suggest that age and low physical activity (low score on BI) are independent risk factors of thiamine deficiency. Clinicians should be aware of thiamine deficiency when end-stage CKD patients, especially elderly patients with low physical activity, present unexplained cardiac or neurologic symptoms.

SA-PO156

Thyroid Status and Body Composition in a Prospective Hemodialysis Cohort Connie Rhee,[3] Yanjun Chen,[3] Amy S. You,[5] Csaba P. Kovesdy,[6] Matthew J. Budoff,[2] Tracy Nakata,[1] Alejandra Novoa,[5] Gregory Brent,[7] Kamyar Kalantar-Zadeh,[4] Danh V. Nguyen.[5] *[1]UC Irvine, Orange, CA; [2]UCLA School of Medicine, Torrance, CA; [3]University of California Irvine, Huntington Beach, CA; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of California, Irvine, Orange, CA; [6]University of Tennessee Health Science Center, Memphis, TN; [7]VA Greater Los Angeles Healthcare, Los Angeles, CA.*

Background: Thyroid status is known to control metabolism, with subsequent effect upon body composition. In addition to causing excess adiposity, hypothyroidism also increases development and growth of skeletal muscle. Whereas hypothyroidism is highly prevalent in hemodialysis (HD) patients, there has not been prior study of thyroid status and trajectory of body composition parameters in this population.

Methods: Among 590 HD patients from the prospective *Malnutrition, Diet, and Racial Disparities in Kidney Disease* study, we examined the association of thyroid status, defined by baseline serum TSH, with body composition parameters over time using case-mix+laboratory linear mixed effects models. Over 2013-17, patients were recruited from 17 outpatient HD facilities and underwent protocolized TSH testing and body anthropometry testing: subcutaneous fat (biceps and triceps skinfold [SF]); skeletal muscle (mid-arm circumference [MAC], mid-arm muscle circumference [MAMC]; total body fat (near infra-red [NIR] body fat); and visceral fat (waist circumference).

Results: Higher TSH levels were incrementally associated with greater biceps SF (ref: TSH <1mIU/L): β=+0.8mm (p=0.03) and β=+1.2mm (p=0.02) for TSH levels 1-3 and >3mIU/L, respectively (Figure). Similarly, incrementally higher TSH levels were associated with greater NIR body fat: β=+0.4% (p=0.13) and β=+0.8% (p=0.04) for TSH levels 1-3 and >3mIU/L, respectively. There was a trend between higher TSH levels and higher MAC: β=+0.3cm (p=0.15) and β=+0.5cm (p=0.06) for TSH levels 1-3 and >3mIU/L, respectively.

Conclusions: In HD patients higher TSH levels are associated with greater markers of subcutaneous and total body fat, and may potentially be associated with greater muscle mass. Future studies are needed to determine if thyroid-modulating therapy alters the body composition of hypothyroid HD patients.

The Best Cut-Off Value of Malnutrition-Inflammation Score (MIS) for Predicting Death in Maintenance Hemodialysis Patients Yanet Parodis Lopez,[6,2] Nery N. Sablón gonzalez,[1] Francisco Javier Rodriguez-Esparragon,[1,5] Noel Lorenzo villalba,[7] Gloria Anton,[2] Fayna Gonzalez cabrera,[3,1] Elena Oliva-Damaso,[4,3] Eduardo Baamonde,[3] Jose carlos Rodriguez perez.[1,3] *[1]Nephrology, Hospital Dr. Negrin, Las Palmas de GC, Spain; [2]Avericum, Telde, Spain; [3]Hospital Dr. Negrin, SANTA BRIGIDA, Spain; [4]Hospital General Universitario de Gran Canaria Dr Negrin, Las Palmas, Spain; [5]Unidad de Investigación, Hptal Dr. Negrín, Gran Canaria, Spain; [6]Nephrology, Centro de Hemodiálisis AVERICUM, Las Palmas de Gran Canaria, Spain; [7]Néphrologie, Centre Hospitalier Saint Cyr, France, France.*

Background: Mis score is associated with morbidity and mortality; however, there are few studies about cut-off value of MIS to categorize patients into high or low risk patients.

Methods: A total of 221 patients from the peripheral hemodialysis center of Dr Negrín University Hospital of Las Palmas de Gran Canaria were included. Demographic and biochemical data were obtained as well as MIS score. A three-year follow-up was carried out to evaluate the best cut-off value of MIS score for predicting death as the primary outcome.

Results: The MIS mean was 7,33 ± 4,57 and was higher in deceased patients (8,34 ± 4,56) than in the non-deceased patients (6,5 ± 4,26) (p = 0,002). In the ROC analysis, the optimal cut-off value of MIS for predicting death was 5 with 81,5 percent sensitivity and 42,6 percent specificity (Figure 1). MIS ≥ 5 was found in 67,3% of patients. 81,5% of the deceased patients had a MIS ≥ 5 compared to only 57,4% of the non-deceased patients (p <0,001) High MIS and Charlson index, advanced age and low lymphocytes were found to be predictors of mortality in the multivariate logistic regression analysis. As the MIS increases, overall survival is lower according to the Kaplan Meier's statistical analysis (p = 0,003) (Figure 2).

Conclusions: MIS was a practical, simple and independent predictor of mortality in hemodialysis patients, being 5 the best cut-off point to predict mortality. Additional risk factors associated with mortality were high Charlson Index, advanced age as well as lymphopenia.

Figure 1 :"The optimal cut-off value of MIS for predicting death in maintenance hemodialys patients"

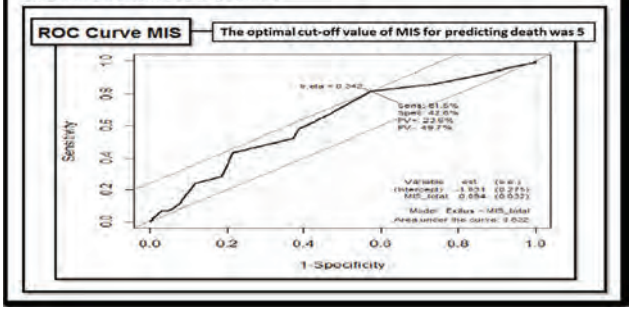

Figure 2: "Overall survival according MIS score (Kaplan Meier's statistical analysis)".

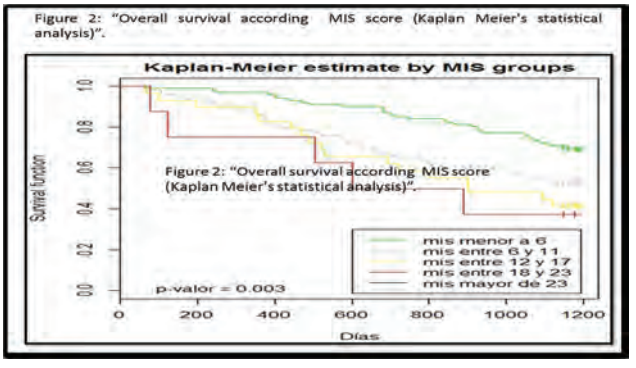

SA-PO158

Effects of Intravenous Iron Therapy on the Mortality and Hospitalization in Hemodialysis Patients Chun Soo Lim, Yun Kyu Oh. *Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Iron replacement therapy is inevitable to correct iron deficiency anemia in advanced chronic kidney disease patients. Intravenous (IV) iron therapy has been known as an efficient method to replace iron, especially in patients who are intolerant to oral iron. However, there have been concerns of considerable side effects with IV iron usage including increased risks of infection or cardiovascular disease (CVD). In this study, we compared IV iron usage with oral iron to assess the adverse effects in the prospective cohort of Korean patients.

Methods: We conducted multicenter prospective cohort study using Clinical Research Center for end stage renal disease. We enrolled 1,721 adult patients who were on hemodialysis between 2008 and 2013. Basic patient characteristics, laboratory data, dose of erythropoiesis stimulating agents (ESA) and 3-month iron dose were collected after enrollment. All-cause mortality, death and hospitalization due to infection or CVD were compared and propensity score matching were conducted to exclude the effects of other factors in outcome.

Results: In total 1,721 patients, 505 patients received IV iron therapy and 658 patients received oral iron only. Median IV iron dose during 3 months was 600mg (100 – 9,000 mg). In IV iron usage group, hemoglobin, ferritin, serum iron and transferrin saturation were significantly lower and total iron-binding capacity, ESA dose and erythropoietin resistance index were higher compared to oral iron group. During mean follow-up duration of 743.6±578.4 days, all-cause mortality, death due to infection or CVD and both death and hospitalization due to infection or CVD did not differ between two groups. Even in subgroup analysis of patients with higher IV iron usage (>600 mg/3 months), there were no significant differences in adverse outcomes. However, in subgroup analysis of prevalent patients, IV iron usage group tend to show higher hospitalization and death due to infection and CVD. After propensity score matching, similar trends were observed.

Conclusions: The current clinical usage of IV iron in hemodialysis patients did not increase all-cause mortality or death and hospitalization due to infection or CVD compared to oral iron therapy. A well-designed randomized controlled trial is needed to clarify both short-term and long-term effects of IV iron therapy.

Association of Adiposity with Hemoglobin Levels in Patients with CKD Not on Dialysis Hirokazu Honda,[1] Kota Ono,[5] Tadao Akizawa,[2] Kosaku Nitta,[3] Akira Hishida.[4] *[1]Showa University Koto Toyosu Hospital, Tokyo, Japan; [2]Showa University School of Medicine, Tokyo, Japan; [3]Tokyo Women's Medical University, Shinjuku-ku, Japan; [4]Yaizu City Hospital, Yaizu, Japan; [5]Hokkaido University Hospital, Sapporo, Japan.*

Background: Adiposity influences erythropoiesis and iron metabolism in the general population. We therefore hypothesized that adiposity could be associated with erythropoiesis or impaired iron metabolism in patients with CKD; however, and that these associations would be influenced by the severity of CKD. The present study aimed to assess the relationship between adiposity—as estimated by body mass index (BMI) and abdominal circumference (AC)—and biomarkers of erythropoiesis in patients with chronic kidney disease (CKD) not on dialysis.

Methods: A total of 2,322 patients from the Chronic Kidney Disease Japan Cohort study were analyzed. Patients were grouped according to BMI category (low: BMI <18.5, normal: BMI 18.5-24.5, and high: BMI ≥25) and AC category (large: AC ≥90 cm for males and AC ≥80 cm for females, and; small: AC measurements below the large values<90 cm and <80 cm). Body composition and laboratory data were measured at baseline, 1 year, and 2 years.

Results: Multivariate regression analysis at 3 time points showed that a high BMI and large AC in male patients were significantly associated with higher hemoglobin levels. Hemoglobin levels in female patients with BMI<18.5 and small AC were lower than with 18.5≤BMI<25 and large AC, respectively (Fig. 1). However, hemoglobin levels were plateaued above threshold of 25 of BMI and 80cm of AC, respectively (Fig. 1). While BMI and AC were positively associated with C-reactive protein levels, they were not associated with levels of transferrin saturation, ferritin, and erythropoietin in multivariate models.

Conclusions: In conclusion, body composition may be associated with erythropoiesis;, however, adiposity may be only associated with increased erythropoiesis in male patients. It does not appear to hamper iron metabolism in CKD patients not on dialysis.

Falls and Fall-Related Injuries in Older Americans with CKD Brandon Kistler,[1] Jagdish Khubchandani,[1] Gina Jakubowicz,[1] Ken Wilund,[2] Jacob J. Sosnoff.[3] *[1]Ball State University, Muncie, IN; [2]University of Illinois, Urbana, IL; [3]University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Falls are among the leading causes of morbidity and mortality in older adults (age ≥65 years). Within older adult populations, few studies have identified the risk factors for falls in chronic kidney disease (CKD) patients. Previous studies have primarily been based on small convenience samples from healthcare facilities, emphasized severely ill patients, and explored only a few predictors of falls. This has led to conflicting data on risk factors for falling. Therefore, our objective was to examine the prevalence and predictors of falls in older adults with CKD from a large non-hospitalized population-based sample.

Methods: Using complex sample data analysis procedures, we analyzed the US Behavioral Risk Factor Surveillance System (BRFSS) to assess the prevalence and predictors of falls and fall-related injuries among older adults with CKD.

Results: The sample contained 157,753 older adults (56% female, 77% White, 57% in the age range of 65-75 years) with a fall prevalence of 28.7% within the last year. Within the sample, 9,116 (6.1%) had a diagnosis of CKD and 32,669 (23.5%) had diabetes. In multiple logistic regression models, individuals with CKD were more likely than those without CKD to report falls (OR 1.81 [95% CI] (1.63-2.01)) and fall-related injuries (OR 1.49 (1.26-1.77)) even after adjusting for demographic characteristics and chronic conditions. Within the CKD group, females (OR=1.71, p<0.01), non-whites (OR=1.17, p<0.05), diabetics (OR=1.21, p<0.05), those who used any special equipment, such as cane/wheelchair (OR=2.79, p<0.001), and those who had limited activity due to physical or mental problems (OR=2.23, p<0.001) had the highest odds of reporting falls. Furthermore, there was a trend for increased falls with increasing age category (p=0.06).

Conclusions: Falls and fall-related injuries are highly prevalent in elderly individuals with CKD, particularly in women, special equipment users, and those with limited activity. Multifactorial fall prevention strategies should be designed to target these at-risk populations.

Effect of Fructooligosaccharide on Microbiota-Derived Uremic Toxins in Predialysis Patients: A Randomized Controlled Trial

Christiane I. Ramos,[1,3] Rachel G. Armani,[1] Lia S. Nakao,[4] Maria Eugenia F. Canziani,[1] Katrina L. Campbell,[2,3] Lilian Cuppari.[1] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Princess Alexandra Hospital, Brisbane, NSW, Australia; [3]Bond University, Robina, QLD, Australia; [4]Federal University of Parana, Curitiba, Brazil.*

Background: Microbiota-derived uremic toxins, p-cresyl sulfate (PCS) and indoxyl sulfate (IS), have been associated with poor outcomes in chronic kidney disease (CKD). This has encouraged the investigation of alternative approaches to modulate gut environment and to attenuate toxin production. The present trial aimed to evaluate the effect of the prebiotic fructooligosaccharide (FOS) on changes in PCS, IS, indole 3-acetic acid (IAA), kidney damage (eGFR and proteinuria) and insulin resistance in predialysis patients (stages 3b, 4 and 5).

Methods: The 3-month double-blind randomized controlled trial included 46 non-diabetic CKD patients [52% men; 57.6±14.4 years; eGFR: 21.3±7.3 mL/min/1.73m^2]. Intervention and placebo consisted in 12g/day of FOS or maltodextrin, respectively. PCS, IS and IAA were determined by high performance liquid chromatography. Dietary intake was assessed by 3-day food records; supplement adherence (sachet count) and gastrointestinal events by the Gastrointestinal Symptom Rating Scale.

Results: Aside for the intervention group being older (53.4±16.0 vs 61.9±11.4 years, p=0.04) the groups were homogeneous. Overall sachet adherence was excellent (mean consumption: 93.1±8.1%). No changes in the ratio of dietary protein/fibre intake or gastrointestinal symptoms were observed during the follow-up. Changes in the outcomes are depicted in the table.

Conclusions: FOS was well tolerated and resulted in a trend for reduced PCS. No effect of FOS on IS, IAA, kidney damage or insulin resistance was observed.

The Effects of More Frequent Hemodialysis (HD) on Plasma Vitamin C Concentration: An Ancillary Study of the Frequent Hemodialysis Network (FHN) Daily Trial

Jochen G. Raimann,[5] Samer R. Abbas,[5] Li Liu,[4] Brett Larive,[1] Yuguan Liu,[6] Gerald J. Beck,[2] Peter Kotanko,[5,7] Nathan W. Levin,[5] Garry J. Handelman,[6] The FHN Trial Group.[3] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Foundation, Shaker Heights, OH; [3]NIDDK, NIH, Bethesda, MD; [4]Peking University First Hospital, Beijing, China; [5]Renal Research Institute, New York, NY; [6]University of Massachusetts, Lowell, MA; [7]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Reports on vitamin C in HD patients have shown effects of vitamin C deficiency (Raimann, Semin Dial 2013) in association with scurvy symptoms. Dialyzability of water soluble vitamins is high and substantial losses in those who are dialyzed more frequently were hypothesized. The randomized FHN Daily Trial compared the effects of in-center HD six versus three times per week. We studied baseline correlations between vitamin C and potentially associated parameters, and the effect of more frequent HD on circulating vitamin C.

Methods: We studied vitamin C levels at baseline, and at months, 3, 5 and 11. Patients enrolled between 2007 and 2009 into the main trial in the East Coast consortium were approached for participation, and informed consent was obtained. Pre HD samples were processed with metaphosphoric acid and frozen at -70 C for measurement with HPLC. Regression models between baseline log-transformed vitamin C and hemoglobin, CRP, eKt/V, ePCR and PTH, and a linear mixed-effects model to estimate the effect size of more frequent HD on plasma vitamin C, were constructed.

Results: We studied 44 subjects enrolled in the FHN Daily trial (50±12 years, 36% female, 29% Hispanics and 64% blacks, 60% anuric). Vitamin C correlated significantly with pre HD hemoglobin (r=0.3; P=0.03) and PTH (r=-0.3, P=0.04), respectively. Vitamin C did not significantly differ at baseline (6x/week: 25.8 ± 25.9 versus 3x/week: 32.6 ±39.4 µmol/L) and no significant treatment effect on vitamin C concentrations was found [-26.2 (95%CI -57.5 to 5.1) µmol/L at Month 4 and -2.5 (95%CI -15.6 to 10.6) µmol/L at Month 12.

Conclusions: Based on data from this randomized-controlled trial no significant effect of the intervention on circulating plasma vitamin C concentrations was found. While admittedly no information on supplements were available, these data allays the concerns that more frequent HD would affect the concentrations of water-soluble vitamins and adversely affect patient's well-being. Correlations between vitamin C and hemoglobin and PTH support the importance of vitamin C for normal bone and mineral metabolism and anemia management.

Pyridoxine Lowers Urine Oxalate in Kidney Stone Formers with Enteric Hyperoxaluria

Jennifer Scott, Mitchell Humphreys, Sean Mcadams, Mira T. Keddis. *Mayo Clinic, Phoenix, AZ.*

Background: Pyridoxine is commonly deficient in patients with enteric hyperoxaluria. We hypothesize that pyridoxine replacement may reduce urine oxalate in stone formers with enteric hyperoxaluria.

Methods: All patients with nephrolithiasis and urine metabolic analysis between 2008-2016 at Mayo Clinic Arizona were identified. Patients with 24-hour urine oxalate >40 mg and prescribed pyridoxine were included in the study (n=13). Patients with primary hyperoxaluria were excluded.

Results: 13 patients with risk factors for enteric hyperoxaluria were prescribed pyridoxine for treatment of nephrolithiasis. 10 (77%) patients had urine metabolic studies performed post-treatment. 5 were male, with mean age of 57.7± 10.7 years. 5 had <2 L/24hr of urine volume, 3 had hypocitraturia (<440mg/24hr), and 3 had hypercalcuria (>200mg/24hr). The mean baseline 24-hour urine oxalate was 70.67 ± 39.40 mg/d. Pyridoxine dose ranged from 25-100mg/d. Repeat urine was performed after median of 10 months (1.5-21). Mean 24-hour urine oxalate was 57.86 ± 33.09 mg/d after treatment (mean difference 12.8 ± 29 mg/d). Urine oxalate level improved in 7 and normalized in 4 patients post-treatment. There was no statistically significant difference between urine oxalate levels pre- and post- pyridoxine treatment (p 0.31). 7 patients had stone analysis performed, 6 of whom had predominately calcium oxalate stones. Only 3 of 10 patients treated had recurrent kidney stones after pyridoxine treatment.

Conclusions: In our cohort, pyridoxine improved hyperoxaluria and decreased risk of recurrent nephrolithiasis in 70% of patients. Future studies are required to evaluate the dose of pyridoxine and validate our findings in a larger cohort of patients with malabsorptive enteric hyperoxaluria.

Patient	Pyridoxine dose(mg)	Urine volume(L) 24hr baseline	Oxalate(mg)	Citrate(mg)	Calcium(mg)	Urine volume(L) 24hr post-treatment	Oxalate(mg)	Citrate(mg)	Calcium(mg)

SA-PO164

Low Leptin Level Is Associated with Poor Nutritional Status in ESRD

Jun young Lee,[3] Jae seok Kim,[5] Jae Won Yang,[2] Seung-Ok Choi,[4] Byoung Geun Han.[1] *[1]None, Wonju, Republic of Korea; [2]Wonju Christian Hospital, Wonju, GangWon-Do, Republic of Korea; [3]Wonju christian severance hospital, Wonju, Kangwon do, Republic of Korea; [4]Yonsei University Wonju College of Medicine, Wonju, Kangwon, Republic of Korea; [5]Yonsei wonju college of medicine, Won-ju, Republic of Korea.*

Background: Poor nutritional status is associated with poor prognosis in end stage renal disease (ESRD) patients. Bio-impedance spectroscopy (BIS) is a useful method to estimate body fluid and nutritional status. Particularly, phase angle (PhA, °) is a parameter that represents nutritional status well. In the study, we aim to identify factors related to nutritional status in ESRD patients not undergoing dialysis.

Methods: We enrolled total 91 ESRD patients not undergoing dialysis. We measured routine serum markers including albumin and NT-proBNP, and appetite regulating hormones, leptin and ghrelin. With BIS, we measured OH (overhydration, liter) and OH/ECW (OH/extracellular water ratio) values to estimate body fluid amounts, and PhA to determine nutritional status. We defined poor nutritional status as a PhA <4.5°, and proper nutritional status as a PhA ≥4.5°. Lastly, we evaluated patient's nutritional status by assessing geriatric nutritional risk index (GNRI).

Results: Forty-one patients (45%) had poor nutritional status. The patients with poor nutrition, compared to proper nutrition, had significantly higher levels of NT-proBNP (14,477.8±12,712 vs. 4,965.2±8,824 pg/mL, p<0.001) and OH/ECW (29.6±12.7 vs. 6.2±10.3 %, p<0.001), and lower levels of albumin (3.0±0.5 vs. 3.7±0.5 g/dL, p<0.001), leptin (3.8±3.1 VS. 7.0±6.2 ng/mL, p=0.004) and GNRI (85.1±7.1 vs. 96.5±7.7, p<0.001). In Pearson's correlation test, leptin had negative correlations with NT-proBNP (r= -0.237, p=0.026) and OH/ECW (r= -0.288, p=0.006). On the contrary, leptin had positive correlations with BMI (r=0.351, p=0.001), PhA (r=0.263, p=0.012) and GNRI (r=0.281, p=0.007). In multivariate logistic regression test, high level of leptin (OR 6.12, 95% CI 1.01-37.13) and albumin (OR 10.14, 95% CI 1.51-68.20) predicted proper nutrition well, while increased level of NT-proBNP (OR 0.07, 95% CI 0.01-0.84) and OH/ECW (OR 0.04, 95% CI 0.01-0.19) were related to poor nutrition.

Conclusions: Our study demonstrates that ESRD patients with poor nutrition generally have a problem of excessive body fluid as well. Leptin is well correlated positively with nutritional status. Low leptin level suggests poor nutrition in ESRD patients. We believe that these relationships may be due to a counter-regulatory mechanism of leptin to nutritional status as an appetite suppressing hormone.

SA-PO165

Oral Alkali Supplementation to Reduce Uremic Toxin in Early Stage CKD Patients Michiaki Abe,[4] Tomokazu Souma,[3] Hiroshi Sato,[1] Sadayoshi Ito.[2] *[1]Clinical Pharamacology and Therapeutics, Graduate School of pharmaceutical Sciences, Tohoku University, Sendai, Japan; [2]Tohoku Graduate School of Medicine, Sendai Miyagi, Japan; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Tohoku University Hospital, Sendai, Japan. Group/Team: CKOALA study group.*

Background: Patients with chronic kidney disease (CKD) has increased plasma uremic toxins (UTxs) and they develop metabolic acidosis and aciduria. These metaboic dsysregulations affects CKD progression and cardiovascular and bone complicaitons. Recently, oral alkali therapy has been suggested to slow the progression of CKD pathologies. To investigate the effects of alkali supplementation on UTx accumulation, we have initiated a double-blinded randomized control cohort study of "Estimating the efficacy of the Oral ALkALizers in patients with CKD; CKOALA study." Two types of alkalizers, Na/K citrate and Na bicarbonate, were used.

Methods: Total 47 CKD patients (CKD stage G2, G3a, G3b) were randomized to divide into 3 groups, control (n=15), Na bicarbonate (n=16) and Na/K citrate (n=16). The urine and plasma samples at 0, 6, 12 and 24 weeks after the intervention were collected and anonymized. Five UTxs including (Indoxyl sulfate (IS), p-cresyl sulfate (PCS), phenylacetyl L-glutamine (PAG), and argininosuccinate (ASA) and hippuric acid) were quantified by a quantitative-target LC-MS/MS. Individual change of UTx abundance were compared and Mann-Whitney test was used for statistical analysis. This research was approved as a secondary use of CKOALA study by Tohoku University Hospital Ethics Committee.

Results: %change of urinary concentrations of IS, PCS, PAG and ASA from was compared among groups. Urinary UTx levels in the Na/K citrate-treated group were significantly increased compared to the other two groups [IS; 93% (control) vs. 145% (bicarbonate), p=0.017; PCS, 116% (control) or 181% (bicarbonate) vs. 351% (citrate), p=0.001 or p=0.015; PAG, 94% (control) or 100% (bicarbonate) vs. 160% (citrate), p=0.016 or p=0.019; ASA, 87% (control) vs. 126 (citrate), p=0.003]. Furtheremore, plasma concentrations for IS was significantly reduced by Na/K citrate-treatment (control 1.2 μg/mL or bicarbonate 1.4 μg/mL vs. citrate 1.1 μg/mL, p=0.029 or p=0.035).

Conclusions: Our feasiblity study shows that an alkali therapy reduces some kinds of UTxs abundance in CKD patients and may represent a mechanism whereby oral alkali supplementation prevents CKD progression.

SA-PO166

Leptin Levels Are Not Reduced by High-Flux Compared with Low-Flux Haemodialysis: Results of a Randomized Trial Andreas Schneider,[1] Markus P. Schneider,[5] Detlef H. Krieter,[4] Hubert Scharnagl,[2] Christoph Wanner,[3] Christiane Drechsler.[3] *[1]University of Wuerzburg, Wuerzburg, Germany; [2]Medical University of Graz, Graz, Austria; [3]University Hospital Wuerzburg, Wuerzburg, Germany; [4]University Hospital Würzburg, Würzburg, Germany; [5]University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Leptin, in addition to its well described effects on glucose homeostasis, might be directly involved in the progression of atherosclerosis, as it promotes chronic inflammation and vascular smooth muscle cell proliferation. Interestingly, leptin levels are significantly increased in haemodialysis (HD) patients compared with healthy controls. Interventional strategies able to reduce levels of leptin in HD patients are of particular interest. The low molecular weight of leptin (16 kD) suggests that its elimination might depend on the specific HD modality.

Methods: We performed a randomized controlled trial on the effects of high-flux versus low-flux HD. 127 maintenance HD patients were randomized to low-flux (n=62) or high-flux (n=65) HD for 52 weeks. The primary endpoint of the study was the effect on parameters of anaemia, which has been published previously. The secondary endpoint included the effect on leptin levels. Leptin levels were measured by ELISA at baseline and after 52 weeks of treatment.

Results: Patients in both groups were 66 years (mean age). Underlying kidney disease was diabetic nephropathy in most cases (28% in the low-flux group and 38% in the high-flux group). Compared to baseline, a significant increase in leptin levels after one year of low-flux HD was observed (Delta leptin 41.7 ng/ml; p=0.032). In contrast, leptin levels remained more stable in the high flux group (Delta leptin 32.8 ng/ml; p=0.062). However, there was no difference in absolute change of leptin levels over time between the two randomization groups (p=0.743).

Conclusions: In this randomized controlled trial, we found that leptin levels increased after one year in patients allocated to low-flux HD, but remained more stable in those allocated to high-flux HD. However, the lack of a significant treatment difference suggests that high-flux HD is not more effective than low-flux HD. Future studies should investigate whether enhanced convective solute transport (e.g. by haemodiafiltration) would be able to improve leptin removal and patient outcome.

SA-PO167

The Discrepancy in the Predictability of Subjective Global Assessment for Mortality According to Dialysis Vintage in Hemodialysis Patients Ye Eun Ko,[1] Taeyoung Yun,[2] Dong-Ryeol Ryu.[1] *[1]Ewha Womans University, Seoul, Republic of Korea; [2]Ewha womans university, Seoul, Republic of Korea.*

Background: Subjective Global Assessment (SGA) is used to gauge nutritional status in dialysis patients. Still, SGA is not reliable for predicting mortality. There is no study on the predictability of SGA regarding mortality between incident and prevalent hemodialysis (HD) patients.

Methods: *A total of 2,798 dialysis patients were enrolled from CRC for end-stage renal disease between May 2009 and December 2015. The cohort was divided into two groups: incident (n=1,481) and prevalent HD (n=1,317). Each was stratified into two groups based on SGA: 'Good nutrition (G1)' and 'Mild to severe malnutrition (G2).' Kaplan-Meier (KM) and multivariate Cox analyses were performed to evaluate the relation between SGA and mortality in each HD group. Prevalent HD patients were divided into 'short-term' and 'long-term' groups based on median dialysis duration (36.7months), and multivariate Cox analyses were conducted. Incident HD patients were divided based on the presence of diabetes mellitus, age of 65 years or older, and obesity (BMI≥25 kg/m²). The relationship between SGA and mortality was further examined in sub-analyses.*

Results: During a median 3.1 years of follow-up period, 590 (21.1%) patients died. The KM survival curve showed that the cumulative survival rate in G1 was significantly higher than that in G2 among all patients (P<0.001) as well as in each group stratified based on dialysis vintage (P<0.001). Multivariate Cox analyses revealed that G2 was significantly associated with an increase in mortality (HR; 1.27, 95%CI; 1.10-1.47, P=0.002) compared with G1 among all patients. G2 was also significantly related to an increase in mortality in prevalent HD patients, but not incident HD patients (HR; 1.33, 95%CI; 1.01-1.75, P=0.04). Yet, in short-term, not long-term prevalent patients, G2 was significantly associated with an increase in mortality compared to G1 (HR; 1.52, 95%CI; 1.04-2.24, P=0.03). There were no significant relations between the SGA and mortality in the sub-analysis among incident HD patients.

Conclusions: Nutrition status according to SGA might be helpful for predicting mortality especially in prevalent HD patients, whereas SGA alone do not reflect the adverse clinical outcomes in incident HD patients. Further evaluation is needed to determine the discrepancy in association with mortality between two HD populations.

SA-PO168

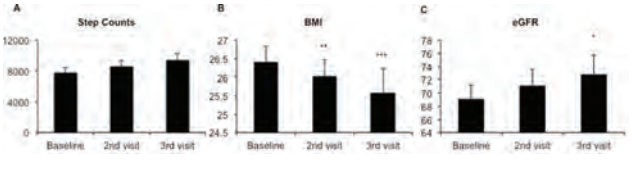
Exercise Favorably Affects Renal Function in Metabolic Syndrome without CKD: A Prospective Single-Center Study Atsushi Ueda,[1] Kei Nagai,[3] Aki Hirayama,[4] Chie Saito,[2] Kunihiro Yamagata.[2] *[1]Tsukuba University Hospital Hitachi Medical Education and Research Center, Hitachi, Ibaraki, Japan; [2]University of Tsukuba, Tsukuba, Japan; [3]University of Tsukuba hospital, Tsukuba-city Ibaraki, Japan; [4]Tsukuba University of Technology, Tsukuba, Japan.*

Background: A high body mass index (BMI) predicts an onset of CKD in population with normal renal function (Kidney Int. 2017; 91:1224-1235). It is expected that lifestyle-modification in obese individuals without CKD has favorable effects on renal function through the normalization of body weight and BMI. However, whether exercise can improve the renal function in obese individuals without drug-medications has not been fully resolved.

Methods: We studied 29 patients with high BMI (>25 kg/m²) and/or hypertensive (>grade 1 hypertension) and/or high LDL-C (>140 mg/dL) and/or moderately high HbA1c (6.5–7.5%), with no abnormality of urinalysis and no drug-medications. We provided education regarding resistance-exercise and aerobic exercise to the subjects for one hour at the first (baseline) visit. We measured their weight, waist circumference, blood pressure, and laboratory data at every visit. In addition, step-counts per day were calculated from cumulative records for every day by the pedometer during visits.

Results: Compared to first (baseline, visit 1), one month (visit 2), and two month later (visit 3), the mean step-counts of the subjects tend to increase (P=0.07, **Fig 1A**). The mean body weight and BMI were 71.9, 70.8 and 69.3 kg (P<0.01), and 26.4, 26.0, and 25.6 kg/m² (P<0.01, **Fig 1B**), respectively. Changes in step-counts and that in body weight were negatively correlated (r=-0.51, P=0.01). While serum LDL-C and HbA1c were not significantly declined, serum creatinine (P=0.01) and eGFR (P=0.01, **Fig 1C**) were improved during the follow-up.

Conclusions: Though the changes in most of parameters (blood pressure, lipid status and glycemic status) were not significant in this limited follow-up time, significant changes in renal function (serum creatinine and eGFR) were identified. It is suggested that exercise among obese individuals has a potential to improve their renal function independent of drug-medications.



SA-PO169

Protein Energy Wasting Is Correlated with Irisin and Over Load Fluid in Peritoneal Dialysis Patients Sijia Zhou, Ai Hua Zhang. *Peking University Third Hospital, Beijing, China.*

Background: Protein energy wasting (PEW) is a common phenomenon in maintenance dialysis patients and increased morbidity and mortality. The mechanisms are unclear. Over load fluid may also induce PEW in peritoneal dialysis patients. Irisin is a newly discovered myokine which can alleviate insulin risistance, is one kind of regulators of energy homeostasis and metabolism in humans. The aim of this study is to assess the relationships between irisin, over load fluid and PEW in PD patients.

Methods: This study is a cross-sectional study with 160 patients on maintenance peritoneal dialysis in peritoneal dialysis center of Peking University Third Hospital involved and 35 healthy people in a control group. PD patients were divided into two groups: protein energy waste group (PEW group) and non-protein energy waste group (non-PEW group) according to PEW diagnosis criteria. Serum irisin concentrations were measured by ELISA methods. The body composition consisting of over load fluid status [over hydration (OH) value >=2)] was analyzed by bioelectrical impedance.

Results: The serum irisin levels were significantly lower in PD patients compared with controls [113.2±11.8ng/ml vs. 464.2±37.4ng/ml, P<0.01]. The serum irisin levels were lower in PD patients with protein energy wasting than those of the patients without protein energy wasting[107.8±9.6ng/ml vs. 119.0±11.3ng/ml, P<0.01]. Existing over load fluid patients with higher prevalence of PEW (59.8%Vs.40.2%, x2=6.223, P=0.013). But there was no direct relationship between irisin level and over load fluid. The independent determinants of PEW were serum irisin and serum albumin.

Conclusions: Our results provide clinical evidence of the association between irisin, over load fluid and protein energy wasting in PD patients. Low irisin and over load fluid may aggravate protein energy wasting.

Bariatric Surgery Reduces Proteinuria in Severely Obese Patients with Normal Kidney Function by Reducing Systemic Inflammation Nam-Jun Cho, Hyo-Wook Gil, Chi-Young Choi. *Soon Chun Hyang University College of Medicine, Cheonan Hospital, Cheonan, Republic of Korea.*

Background: Obesity are associated with renal disease, including proteinuria, chronic kidney disease (CKD) and progression to end-stage renal disease. Bariatric surgery (BS) reduce proteinuria and improve renal function. The mechanism include improved blood pressure, improved glucose homeostasis, and reduced systemic inflammation associated with weight loss. However, it is unclear whether the mechanism by which BS reduces albuminuria is due to weight loss per se or by improved systemic inflammation induced by weight loss. To elucidate whether weight loss directly reduces albuminuria or via improvement of systemic inflammation induced by weight loss, a prospective cohort study was performed.

Methods: Patients older than 18 years who received BS in Soonchunhyang University Hospital from 1 January 2011 to 31 December 2011 were included. Other including criteria were followed: body mass index (BMI) ≥ 30, serum creatinine level ≤ 1.0, and without over proteinuria (dip stick ≤ trace). The patients were followed at 1, 6 months after BS.

Results: Forty-three patients were included. Three patients were men, 10 patients had diabetes, 12 patients had hypertension. eGFR estimated by CKD-EPI equation were 115.7 ± 16.5. There were significant reduction in body weight (98.9 ± 17.6 to 78.1 ± 14.8 kg), BMI (36.9 [34.0 – 42.8] to 29.5 [26.6 – 32.2] kg/m^2), high-sensitivity C-reactive protein (hs-CRP, 0.39 [0.24 – 0.69] to 0.09 [0.05 – 0.23] mg/L), and urine albumin-to-creatinine ratio (17.95 [6.81 – 72.89] to 8.11 [4.67 – 15.92] mg/g). There were positive correlations between delta hs-CRP and delta body weight (r = 0.349, p = 0.043) or delta BMI (r = 0.362, p 0.035); between hs-CRP and body weight (r = 0.374, p = 0.001) or BMI (r = 0.431, p < 0.001). In a multivariate analysis using linear mixed model demonstrated that hs-CRP (β = 0.5451, p = 0.022) is independent risk factors to affect ACR.

Conclusions: Our results suggests that weight loss by BS directly improve systemic inflammation, which subsequently leads to reduce albuminuria.

SA-PO171

The Additional Benefit of Weighted Subjective Global Assessment (SGA) for the Predictability of Mortality in Incident Peritoneal Dialysis Patients Taeyoung Yun, Dong-Ryeol Ryu. *Ewha Womans University, Seoul, Republic of Korea.*

Background: Although Subjective Global Assessment (SGA) is a widely-used tool for the nutritional investigation, it has limitation to assess nutritional status for the dependence on inspectors' subjective opinion. Moreover, there is no study for the usefulness of SGA and modified SGA in incident peritoneal dialysis (PD) patients.

Methods: A total of 365 incident PD patients between May 2009 and December 2015 at the 36 centers of the Clinical Research Center for end-stage renal disease in Korea were initially recruited, and we measured SGA and calculated weighted SGA using serum albumin and total iron binding capacity (TIBC) levels based on the normal values. Cox proportional regression analyses were performed and receiver operating curve was also conducted.

Results: During median 3.2 years of follow-up period, 61 patients (16.7%) were dead. Kaplan-Meier curve showed that the cumulative survival rate in 'Good nutrition (G1)' was significantly higher compared to that in 'Mild to severe malnutrition (G2)' (*P* < 0.001). G2 was also significantly associated with increase of all-cause mortality even after adjusting for age, gender, several comorbidities and TIBC (HR; 1.78, *P* = 0.038) compared with G1. Moreover, 1 unit increase of weighted SGA was still significantly correlated with the development of the mortality after adjustment of the same covariates (HR; 1.65, *P* = 0.013). However, G2 was significantly associated with increase of all-cause mortality in non-DM, DM, and old-aged group (in non-DM; HR; 2.86, *P* = 0.049, in DM; HR; 2.04, *P* = 0.021, and in old-aged; HR; 2.96, *P* = 0.026, respectively) except for young-aged group after adjusting for several covariates, whereas 1 unit increase of weighted SGA was revealed to be significantly related to increase of the mortality in all the subgroup analyses. Furthermore, the AUC of SGA and weighted SGA for all-cause mortality was 0.616 (*P* = 0.004) and 0.708 (*P* < 0.001). In addition, the AUCs of weighted SGAs in all the groups were significantly increased compared with those of SGA alone.

Conclusions: The evaluation of nutritional status based on SGA in incident PD patients may be useful for predicting mortality. However, weighted SGA with objective parameters including serum albumin and TIBC can provide an additionally predictable power for all-cause mortality compared with SGA alone.

SA-PO172

Serum Albumin Concentration, Estimated Glomerular Filtration Rate, and Cardiovascular Mortality among 1999-2010 NHANES Participants Amanda R. Tortorici,[1] Elani Streja,[1] Melissa Soohoo,[1] Daniel L. Gillen,[1] Connie Rhee,[1] Keith C. Norris,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]UCLA, Los Angeles, CA.*

Background: As a potential strong predictor of longevity in persons with chronic kidney disease, we sought to examine whether higher serum albumin (Alb) levels are associated with reduced cardiovascular mortality in a nationally representative cohort of NHANES participants.

Methods: We identified 31,274 participants from the 1999-2010 continuous NHANES survey who had available Alb measurements and laboratory values for calculation of eGFR, as well as cardiovascular mortality data. Follow up time began the day after Alb measurement until December 31, 2011. We analyzed the association of Alb (<4.2, 4.2-<4.4 and ≥4.4 g/dL) with cardiovascular mortality across strata of eGFR (<60, 60-<90, and ≥90 ml/min/1.73m^2) using Cox proportional hazards models adjusted for age, sex, race, smoking, diabetes and education.

Results: The mean±SD age of the cohort was 48±20 years, among whom 52% were female, 20% were African-American, 22% were Mexican-American, and 7% were other Hispanic American. Across all eGFR strata, participants with Alb levels <4.2 g/dL (n=11,384 people) trended towards higher cardiovascular mortality risks compared to the reference group (Alb 4.2-<4.4 g/dL, n=10,793 people). When stratified by eGFR, participants with Alb levels >4.4 g/dL (n=9,097 overall) trended toward better cardiovascular survival among those with eGFR >60 ml/min/1.73m^2 (n=8,779), but worse cardiovascular mortality among those with eGFR <60 ml/min/1.73m^2 (n=318). [Figure]

Conclusions: Among 1999-2010 continuous NHANES participants, lower Alb levels trended toward 30% to 50% higher cardiovascular mortality risk irrespective of the eGFR level. Mortality predictability of Alb and the implications of its screening across the population at large warrants comparison to a lipid panel screening.

The Effect of Selenium Deficiency on Thyroid Function and Cardiovascular Diseases in Peritoneal Dialysis Patients Jong tae Cho, So Mi Kim, Eun kyoung Lee, Chang hyun Park, Jihyen Jeon. *Division of Nephrology, Department of Internal Medicine, Dankook University Hospital, Dankook University, College of Medicine, Cheonan, Chungnam, Republic of Korea*.

Background: Trace element, selenium deficiency is known to be associated with impairment of thyroid hormone, and it can cause cardiovascular diseases, such as ischemic heart disease (IHD), heart failure (HF) or cardiomyopathy. In peritoneal dialysis (PD) patients, various causes may contribute to selenium deficiency, including dietary restriction, malabsorption, alteration of metabolism, and removal through dialysis itself. Therefore, we tried to investigate the effect of selenium deficiency on thyroid hormone and cardiovascular diseases in PD patients

Methods: This cross-sectional study enrolled 86 end-stage renal disease patients who underwent PD. The patients were divided into 2 groups based on serum seleium levels : 62 patients were normal level and 22 patients were selenium deficient. Thyroid hormones, including TSH, free T4 were measured. And presence of cardiovascular diseases, using echocardiography, coronary computed tomography or coronary angiography were evaluated.

Results: There were no significant differences in baseline characteristics, including age, sex, presence of diabetes mellitus, duration of PD and weekly Kt/V between the two groups. Although there was no significant difference, thyroid hormone impairment showed higher tendency in selenium deficient group than that in non- selenium deficient group (25 % vs 10 % p=0.06). The prevalence of IHD was significantly higher in selenium deficient group than that in the non-selenium deficient group (55 % vs 21 %, p=0.04). But, there was no difference in HF defined as ejection fraction with below 40 %, and cardiomyopathy between the two groups. All patients with thyroid hormone impairment showed high prevalence of IHD and the coincidence of thyroid impairment and IHD was significantly higher than that in selenium deficient group than that in non-selenium deficient group (63 % vs 31 %, p=0.01).

Conclusions: This study showed higher prevalence of thyroid hormone impairment and IHD in PD patients with selenium deficiency. Selenium deficiency may be related to thyroid hormone impairment, leading to cardiovascular diseases.

SA-PO174

A Pilot Study Characterizing Dysgeusia in Hemodialysis Patients Ciara Fitzgerald,[3,2] Ranjani N. Moorthi,[1] Sharon M. Moe,[1] Kathleen M. Hill Gallant,[2,1] Cordelia A. Running.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Purdue University, West Lafayette, IN; [3]The Dublin Institute of Technology, West Lafayette, IN*.

Background: Dysgeusia is common in dialysis patients and contributes to poor nutritional intake. But, its underlying mechanisms are poorly understood. Studies have shown that taste improves after dialysis sessions, which implicates abnormal serum and salivary parameters as playing a possible role in how dialysis patients perceive taste stimuli. The goal of this pilot study was to characterize altered taste perceptions in dialysis patients compared to healthy adults, and to evaluate relationships between serum levels of potassium, sodium, phosphate, and urea with taste perceptions of these compounds. Our hypotheses were that dialysis patients would have blunted taste compared to controls, and that related serum levels would be inversely related to taste perception of compounds.

Methods: Using a cross-sectional design, we performed suprathreshold taste tests of stimuli (NaCl, KCl, $CaCl_2$, $NaPO_4$, $FeSO_4$, H_3PO_4, MSG, & urea solutions) in hemodialysis patients at a single center(n=16, 10 60±18 y) and healthy adults (n=27, 32±12 y). Participants rated a number of solutions on a 100mm visual analog scale to determine flavor and liking perception and scores were adjusted for each individual's perception of water. In the dialysis cohort, flavor scores were correlated against serum biochemistries drawn pre-dialysis.

Results: No significant differences were observed between how dialysis patients and controls rated each stimuli for flavor and liking (P=0.9). However, when flavor and liking were adjusted for each individual's perception of water, significant differences emerged, especially for compounds containing sodium ions (MSG, NaCl & $NaPO_4$) p<0.05. These differences all showed that dialysis patients experience a larger increase in flavor from the stimuli compared to water than the controls. No significant relationships were observed between serum ion levels and taste perceptions in the dialysis patients.

Conclusions: Our results did not support our original hypotheses. Interestingly, dialysis patients appeared to have stronger taste perception of sodium solutions compared with controls. These results should be considered preliminary due to the limited sample size and lack of age-matched controls. Larger, longer term studies are needed to fully evaluate how dysguesia is experienced by CKD patients pre- and post-dialysis using whole foods in addition to isolated compounds.

Risk Factors for the Decreased Upper Limb Muscle Strength in MHD Patients Qian Zhang,[1] Jiaying Zhang,[2] Minmin Zhang,[3] Jing Chen.[4] *[1]Huashan Hospital, Fudan University, Shanghai, China; [2]Fudan University, Shanghai, China; [3]Huashan Hospital, Fudan Univerisy, Shanghai, China; [4]Huashan Hospital affiliated to Fudan University, Shanghai, China*.

Background: To assess the risk factors for the decreased biceps muscle strength in young (<65 years) and old (≥65years) MHD patients

Methods: This is a cross-sectional analysis with prospective follow-up from MHD patients. All patients underwent assessment of strength of the biceps, body composition, anthropometry, dietary intake, nutritional status and the daily steps. Blood samples were obtained on the midweek dialysis day. Univariate and multivariate regression analysis was used to analyze the predictors of the decreased upper limb muscle strength. Survival analysis was made with the Kaplan–Meier survival curve and the Cox proportional hazard model.

Results: 174 patients were selected, 93 were male and 81 were female patients. The mean age was 63.05±12.29 ys, and the dialysis vintage was 9.19±6.66 ys. Patients were divided into young MHD group (n=97) and elderly MHD group (n=77). In young MHD group, gender (β = -2.01, P = 0.003), modified SGA score (β = -0.29, P = 0.03), muscle mass (β = 0.09, P = 0.03), 25(OH)D level (β = 0.04, P = 0.03) and IL-6 (β = -0.09, P = 0.002) were associated with the decreased biceps muscle strength. In the elderly MHD group, age(β=-0.25, P<0.001), muscle mass(β=0.08, P=0.03), 25(OH)D(β=0.08, P=0.001)and Log NT-proBNP(β=-1.62, P=0.008) were associated with the decreased biceps muscle strength. Patients were further divided into four groups according to 25(OH)D<25,25-50,50-75 and ≥75 nmol/L. Comparing the biceps muscle strength between the groups, it was found that the biceps muscle strength gradually increased with the gradual increase of 25(OH)D levels. During the follow-up of 52 weeks, 16 patients died. 14 of whom died of cardiovascular and cerebrovascular diseases and 2 died of tumor. Kaplan-Merier showed that the survival rate was significantly high in the high muscle strength group than that in low muscle strength group (P=0.002). Cox multivariate analysis showed that the association between low muscle strength and higher mortality risk remained strong in fully adjusted models.

Conclusions: In young MHD group, gender, modified SGA score, muscle mass, 25(OH)D and IL-6 were associated with the decreased biceps muscle strength. In the elderly MHD group, age, muscle mass, 25(OH)D and NT-proBNP were associated with the decreased biceps muscle strength. The biceps muscle strength was an independent risk factor for the survival of MHD patients.

SA-PO176

Tissue Content of Advanced Glycation End-Products and Augmentation Index, a Marker of Vascular Stiffness, Are Linked to Cardiovascular Disease and Mortality in CKD Patients Hideyuki Mukai,[1] Bengt Lindholm,[1] Dai Lu,[1] Jonaz Ripsweden,[2] Torkel Brismar,[2] Olof Heimburger,[1] Peter F. Barany,[1] Peter Stenvinkel,[1] Abdul Rashid T. Qureshi.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]Medical Imaging and Technology, Karolinska Institutet, Stockholm, Sweden*.

Background: Accumulation of advanced glycation end-products (AGEs) may contribute to cardiovascular disease (CVD) and increased mortality in chronic kidney disease (CKD) patients. Skin autofluorescence (SAF), a noninvasive measurement of tissue AGE accumulation, and augmentation index (Aix) by applanation tonometry, may be markers of vascular damage and arterial stiffness respectively. We investigated associations of SAF, AIx and Framingham's CVD risk score with mortality in CKD patients.

Methods: SAF (AGE Reader) and Aix (SphygmoCor; adjusted for 75 heart beats per minute) were measured in 261 CKD patients (median age 56 years, 66% male, 20% diabetes; 130 non-dialyzed, 93 on peritoneal dialysis and 38 on hemodialysis). In 201 patients, coronary artery calcium score was assessed by computed tomography. Associations of SAF, AIx, and Framingham's CVD risk score (FRS) with all-cause mortality was evaluated by multivariate Cox models. During follow-up for median 25 months, there were 46 deaths.

Results: SAF associated with FRS (rho=0.51), hsCRP (rho=0.31), handgrip strength, HGS (rho=-0.30), fat body mass index, FBMI (rho=0.24), and bone mineral density, BMD (rho=-0.22). AIx associated with HGS (rho=-0.43), FRS (rho=0.41), albumin (rho=-0.26), hsCRP (rho=0.25), BMD (rho=-0.23) and lean body mass index, LBMI (rho=-0.20). ROC curve analysis of classifiers of CVD and predictors all-cause mortality showed as expected high values for FRS (AUC=0.75 and 0.77), however closely followed by SAF (AUC=0.71 and 0.75) and AIx (AUC=0.64 and 0.70). The highest tertile of Aix associated with all-cause mortality, HR 2.52 (95% CI 0.98-6.46; p=0.05), after adjusting for FRS.

Conclusions: SAF and AIx were associated with presence of CVD and mortality in ROC curve analysis; however, only AIx - and not SAF associated (p=0.05) with increased mortality risk after adjusting for Framingham's CVD risk score in CKD patients.

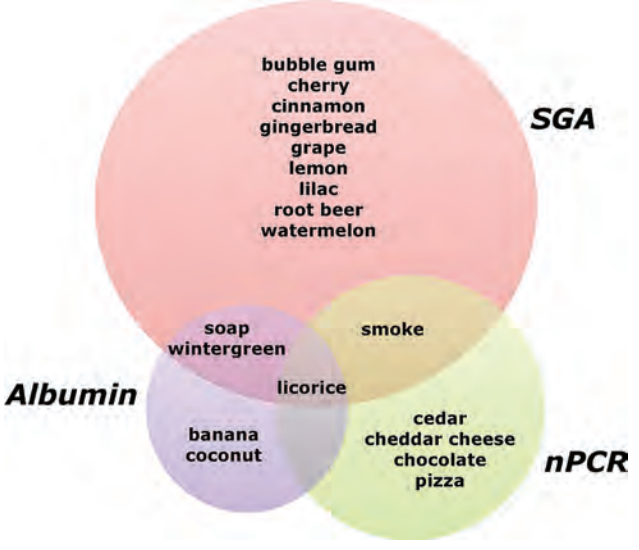
Olfaction–Nutrition Association in Patients with Kidney Disease: Odorant Specificity Teodor G. Paunescu, Dihua Xu, Sahir Kalim, Ravi I. Thadhani, Sagar U. Nigwekar. *Massachusetts General Hospital, Boston, MA.*

Background: Malnutrition is common in patients with chronic kidney disease (CKD) and especially end-stage renal disease (ESRD). Most of these patients have odor identification deficits, and a reduction in odor identification score is associated with higher subjective global assessment (SGA) score and lower total cholesterol, LDL cholesterol, and albumin. We investigated whether the identification of specific odorants is linked to abnormalities in nutritional markers.

Methods: We quantified odor identification in CKD (n=36) and ESRD patients (n=100) and healthy volunteers (HV, n=25) using the University of Pennsylvania Smell Identification Test (UPSIT). We assessed the correlation between the percentage of correct answers for each of the 40 odorants on the UPSIT test and nutritional markers.

Results: Correct identification of multiple odorants significantly correlates with levels of albumin (14 odorants), LDL (15 odorants) and total cholesterol (20 odorants). In analyses restricted to ESRD patients, lower SGA scores correlate with the correct identification of 13 odorants, while higher nPCR and albumin levels correlate with the correct identification of 6 and 5 odorants, respectively. Odorant-based analysis reveals that correct identification of certain odorants correlates more closely with nutritional markers: *licorice* correlates with albumin, nPCR, SGA, and triglycerides; *banana* correlates with albumin, pre-albumin, total and LDL cholesterol, and triglycerides; *watermelon* correlates with albumin, pre-albumin, SGA, and triglycerides. Some odorants, such as *gasoline, lime,* and *natural gas,* show no correlation with any of the nutritional markers we assessed.

Conclusions: Patients with kidney disease have odor identification defects that correlate with nutritional markers. Correct identification of specific odorants by ESRD patients is linked with levels of nutritional markers. These odorants should be followed to assess occurrence of malnutrition.



SA-PO178

Could a Low Protein Diet Exert Influence on Uremic Toxin Levels in Non-Dialysis CKD Patients? Denise Mafra,[1] Ana paula B. Dreux,[1] Juliana S. Anjos,[1] Milena B. Stockler-Pinto,[1] Ludmila F. Cardozo,[1] Carla J. Dolenga,[2] Lia S. Nakao,[2] Dennis C. Ferreira,[4] Flavia L. Carmo,[3] Alexandre S. Rosado,[3] José C. Carraro-Eduardo,[1] Natalia A. Borges.[1] *[1]Federal Fluminense University, Niteroi / Rj, Brazil; [2]Federal University of Parana, Curitiba, Brazil; [3]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [4]UNESA-UVA, Rio de Janeiro, Brazil.*

Background: Among many benefits for non-dialysis CKD patients, low protein diet (LPD) can be effective to modulate the gut dysbiosis reducing the influx into plasma of uremic toxins such as indoxyl-sulfate (IS), p-Cresyl Sulfate (p-CS) and Indole-3-Acetic Acid (IAA). The aim of this study was to evaluate the effects of LPD on uremic toxins serum levels and gut microbiota profile in non-dialysis CKD patients.

Methods: In this longitudinal study, LPD was prescribed for 30 non-dialysis CKD patients and anthropometric and biochemical parameters were evaluated at baseline and after 6 mo. Adherence to the diet was evaluated based on nPNA. Total concentrations serum of uremic toxins (IS, p-CS, IAA) were obtained by RP-HPLC. Fecal samples were collected to evaluate the gut microbiota profile by Polymerase Chain Reaction (PCR) and Denaturing Gradient Gel Electrophoresis analysis (DGGE). Patients were divided into 2 groups: patients who adhered to the LPD (N=14, 52.0 ±12.2yrs, eGFR, 35.2 ± 10.8 mL/min, BMI, 28.0 ± 5.0 Kg/m^2) and patients who not adhered to the diet (N=16, 59.6 ±16.1 yrs, eGFR, 36.0 ± 13.7 mL/min, BMI, 30.1 ± 6.6 Kg/m^2).

Results: Patients who adhered to the diet, presented a significant improvement in renal function and reduction in total and LDL cholesterol. After 6 months, the p-CS serum levels were reduced from 19.3 (9.6-24.7) to 15.5 (9.8-24.1) mg/L (p=0.03) in patients who adhered and, in contrast, levels were increased significantly in patients who not adhered to the LPD. There was no change in the average number of bands according DGGE. However, the average number of bands was positively associated with protein intake (r=0.44, p= 0.04).

Conclusions: Additionally to the improvement of renal function, LPD may be a good strategy to reduce the uremic toxins production by the gut microbiota in non-dialysis CKD patients.

Funding: Government Support - Non-U.S.

SA-PO179

Diagnostic Discordance between Body Mass Index and Body Fat Percentage for Obesity among Patients with CKD Ting-yun Lin, Szu-Chun Hung. *Teipai Tzu Chi Hospital, Taipei City, Taiwan.*

Background: In contrast to the general population, a higher body mass index (BMI) appears to be associated with a greater survival among patients with CKD, referred to as "obesity paradox". This may be explained by limitation of BMI as a measure of adiposity in CKD. Both BMI and body fat percentage (BF%) are used to classify obesity but outcomes may vary.

Methods: We investigated the two different cutoffs for diagnosing obesity (BMI ≥28 kg/m^2 or BF% >25% for male or >35% for female) and the impact on all-cause mortality in 326 nondialysis-dependent CKD patients with a median follow-up of 4.6 years. Body fat mass was determined using the Body Composition Monitor, a novel multifrequency bioimpedance spectroscopy device.

Results: Using BMI, 27.9% of patients were obese. However, 48.8% of patients were obese according to BF%. Although obesity defined by BMI was associated with a significantly lower risk of death, the result tended to be reverse when obesity was defined by BF%. When patients were classified into four distinct groups based on both BMI and BF% cutoffs for obesity, a considerable proportion of patients (29.4%) had excess body fat in the context of a normal BMI. These patients were more likely to have lower lean body mass and had higher mortality as compared to patients with obesity defined by both BMI and BF%.

Conclusions: Thus, diagnostic discordance between BMI and BF% may explain the "obesity paradox" because using BMI to detect obesity among those with CKD may miss a large number of patients with excess body fat. Proper diagnosis of obesity in patients with CKD is required for both risk prediction and treatment.

Cox models for relative risk of all-cause mortality calculated for obesity or not defined by BMI or BF%

Characteristics	Unadjusted		Model 1		Model 2

SA-PO180

The Use of Phase Angle to Evaluate Fluid Status in Dialysis Patients Laura Rosales,[1] Fansan Zhu,[1] Priscila Preciado,[1] Ohnmar Thwin,[1] Xia Tao,[1,2] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Phase angle (PA) has been suggested as an indicator for assessing body composition and fluid status in hemodialysis (HD) patients. PA is calculated by the ratio of reactance and resistance. Resistance represents body water content and reactance relates to body cell mass. The primary aim of this study was to evaluate the relationship between peridialytic fluid and phase angle changes in different fluid status in HD patients and healthy subjects (HS).

Methods: Ten HD patients (8 males, age 58.1±12 years, height 167±11 cm) and 12 healthy subjects (HS; 7 females, age 33±6 years, height 169±10 cm) were studied with the Seca mBCA 514 bioimpedance device (Seca North America, Chino, CA USA). Resistance (R, Ohm), reactance (Xc, Ohm), impedance (Imp, Ohm), and phase angle (PA, degrees) were measured pre- and post-HD treatment. HS were measured once. R, Xc, Imp and PA were compared between pre- and post-HD. In addition, we compared the post-HD levels with HS using 1-way ANOVA. Pre- and post-HD weights and body mass index (BMI) were recorded.

Results: Peridialytic body weight reduction was 2.63±0.54 kg. This weight change was accompanied by increased in PA and decreased in Xc. Average PA and Xc differed significantly from various hydration groups (pre-, post-HD and HS) by a nonparametric test (Fig. 1 A and C). Of note, pre- and post-HD R and Imp did not differ significantly in

HD patients (Fig. 1 B and D). BMI and PA were not correlated. Coefficient of variation of PA is 12.7% in HS group.

Conclusions: PA reflects peridialytic fluid status changes and thus is useful for evaluating relative changes in a given patient. However, PA may not be used to identify normal fluid status due to its large variability in HS (Fig 1 A). This variability is possibly due to the fact that PA is computed as the ratio of two variables, resistance and reactance, which represent different body components.

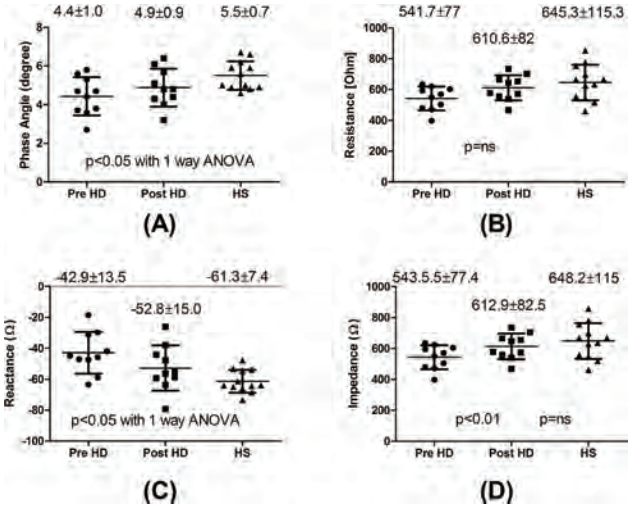

Fig. 1

SA-PO181

Is Zinc-Alpha2-Glycoprotein (ZAG) a Predictor of Mortality in Patients on Hemodialysis? Anaïs Bouchara,[2] Dan Yi,[5] Myriam Pastural,[3] Maurice Laville,[2] Solenne Pelletier,[1] Denis Fouque,[2] Christophe O. Soulage,[4] Laetitia Koppe.[2] *[1]Centre hospitalier Lyon Sud, Pierre-Bénite, France; [2]Hôpital Lyon Sud, LYON, France; [3]AURAL, LYON, France; [4]CarMeN, INSERM u1060, INSA LYON, VILLEURBANNE, France; [5]INSA-Lyon, VILLEURBANE, France.*

Background: Zinc alpha 2 glycoproteine (ZAG) is a new adipokine involved in cachexia due to its potent lipolytic effects. It has been shown that plasma ZAG concentration was increased in chronic kidney disease (CKD) and patients on hemodialysis treatment (HD). However, the impact of ZAG accumulation on mortality and cardio-vascular risks has never been studied.

Methods: Plasma ZAG concentration was measured by enzyme immuno-assays (EIA ZAG, Raybiotech, USA) in 253 patients on HD for at least 3 months, without progressive cancer. Mortality and cardio-vascular events have been registered during 4 years.

Results: During the follow-up period (31.3 ± 17.1 months), a total of 49 patients died (among which 16 from cardio-vascular events). Plasma ZAG concentration was inversely correlated with serum albumin (p=0.008), creatinine (p=0.007) and triglycerides (p=0.04). By contrast, it was positively correlated with age (p=0.002). Plasma ZAG concentration was independent of serum CRP, parathyroid hormone, LDL cholesterol and glycated hemoglobin. Kaplan-Meier analysis showed a significant correlation between plasma ZAG concentration and overall mortality (log rank, p<0.05) and cardio-vascular events (log rank, p<0.01). After Cox multivariate analysis, the association between plasma ZAG concentration and cardio-vascular events persisted after adjustment for demographic factors (age, sex, dialysis vintage), metabolic parameters (serum albumin, prealbumin, triglycerides, nPCR, BMI) and cardio-vascular risks (diabetes, dyslipidemia, hypertension, tobacco). Plasma ZAG concentration was however not associated with protein energy wasting.

Conclusions: Plasma ZAG accumulation does not correlate with protein energy wasting by contrast with patients having a cancer. ZAG does not seem to be involved in metabolic disturbances (type 2 diabetes, dyslipidemia) as observed in obese patien. ZAG accumulation seems to be associated with an excess overall mortality and cardiovascular mortality risk in HD patients. Complementary studies will be necessary to define the role of ZAG and the pathophysiological mechanisms in cardiovascular events in patients with CKD.

Different Measures of Dietary Protein Intake and Correlations with Laboratory Markers across Race in Hemodialysis Patients Jui-Ting Hsiung, Elani Streja, Melissa Soohoo, Connie Rhee, Kamyar Kalantar-Zadeh. *UC Irvine, Orange, CA.*

Background: Clinical practice guidelines recommend higher protein intake in hemodialysis (HD) patients, given their heightened risk of protein catabolism and protein energy wasting. Little is known how different components of protein intake correlate with laboratory markers, and whether this differs by race/ethnicity.

Methods: We examined HD patients from three prospective studies, the Anti-Inflammatory and Anti-Oxidative Nutrition in Hypoalbuminemic Dialysis Patients (AIONID), Nutritional and Inflammatory Evaluation in Dialysis (NIED), and Fosrenal for Enhancing Dietary Protein Intake in Hypoalbuminemic Dialysis Patients (FrEDI). We analyzed the correlations of dietary protein (total, animal, and vegetable) ascertained by three-day dietary record with laboratory measures including normalized protein catabolic rate (nPCR), serum albumin, and serum bicarbonate (CO2) stratified by race/ethnicity.

Results: The cohort was comprised of 336 HD patients, among whom 46% and 37% of patients were Hispanic White and African-American, respectively, 48% of patients were female and the mean±SD age was 55±14 years. In the overall cohort, nPCR strongly correlated with total protein (r=0.25, p<0.001) and animal protein (r=0.25, p<0.001), as well as within strata of African American, Caucasian, and Hispanic patients. However, there was no correlation between nPCR and vegetable protein (r=0.07, p=0.22) in any of the racial/ethnic groups. Serum albumin and CO2 showed weaker correlations with total protein, animal protein, and vegetable protein across all patients.

Conclusions: These findings suggest that nPCR has a stronger correlation with total and animal protein intake than with serum albumin and CO2 across all racial/ethnic groups. Further studies are needed to determine whether nPCR may be a more accurate tool for monitoring dietary protein among HD patients in the clinical setting.

Does Thyroid Hormone (TH) Substitution Alter Hormonal Metabolism in Patients with Hypothyroidism and Renal Failure (RF)? Longin Niemczyk,[1] Ivanna Dubchak,[3] Malgorzata Gomolka,[3] Katarzyna Szamotulska,[2] Stanislaw Niemczyk.[3] *[1]Medical University of Warsaw, Warszawa, Poland; [2]National Research Institute of Mother and Child, Warsaw, Poland; [3]Military Institute of Medicine, Warsaw, Poland.*

Background: RF disrupts the metabolism of TH, and disorders are exacerbated by concomitant hypothyroidism. TH replacement therapy should equalize hormone levels but lack comprehensive research in this area. In patients with ESRD there is a tendency for higher TSH and lower triiodothyronine (T3) and thyroxine (T4) levels probably due to reduced TH conversion (T4 to T3). **The aim of the study** was to evaluate the effect of TH substitution on conversion factors and rT3 concentration in patients with coexisting RF and hypothyroidism.

Methods: The study involved 2 groups of patients with hypothyroidism and TH replacement therapy: Group A - 13 pts. without RF (12 F, 1 M) 48,4±10,67y.o., Group B - 26 pts. with ESRD treated with HD (16 F, 10 M) 58,8±15,52y.o. Pts. with ESRD, treated with HD, were studied during planned dialysis. CRP, creatinine, urea, PTH, TSH and TH: total - (TT4), (TT3), free fractions - (fT4), (fT3), and rT3 were measured and conversion factors (rT3/TT4, rT3/TT3) were calculated. Basic descriptive statistics, Pearson's linear correlation, the Mann-Whitney nonparametric test and Fisher's test were used. Adopted significance level was 0,05.

Results: Results were shown in table.

Conclusions: There is a tendency for a higher rT3 levels during thyroid hormone substitution in hypothyroid patients without renal failure. The inhibitory effect of renal failure on rT3 production in hypothyroid patients is still present during thyroid hormones substitution.

Association between Decrease in Skeletal Muscle Mass Index and Renal Atrophy in Patients with Non-Dialysis CKD Rei Iio, Rika Kumamoto, Taisuke Takatsuka, Daisuke Yoshimura, Hiroki Okushima, Yukimasa Iwata, Mitsumoto Kensuke, Tatsuya Shoji, Terumasa Hayashi. *Osaka General Medical Center, Osaka, Japan.*

Background: The frequency of sarcopenia increases as chronic kidney disease (CKD) progresses. CKD patients should be screened for sarcopenia and presarcopenia in order to detect them during an earlier stage of CKD and improve prognosis. Kidney size is associated with aging, inflammation, and decreased renal function, as seen with sarcopenia. We investigated the association of kidney size with muscle mass and muscle mass change in CKD patients.

Methods: We performed a single-center retrospective cohort study of 180 non-dialysis dependent CKD patients (age 66.4±12.5 years; male 66.1%; eGFR 31.4±17.5 mL/min/1.73m^2; etiology glomerulonephritis 22.2%, diabetic nephropathy 23.9%). We measured kidney size by ultrasonography and calculated total kidney volume (TKV) using an ellipsoid equation. Skeletal muscle mass index (SMI) were estimated using bioelectrical impedance analysis, and presarcopenia was defined as SMI ≤7.0 kg/m^2 for men and ≤5.7 kg/m^2 for women. The rate of change in SMI over a 6-month period was evaluated.

Results: The mean rate of change in SMI in six months was -1.5±7.1%. Multivariate logistic regression analysis showed that TKV was associated with presarcopenia (OR: 0.98, 95% confidential interval: 0.97-1.00, p=0.041). Multivariate regression analysis showed that SMI (β: -3.95, SE: 0.92, p<0.001) and TKV (β: 0.037, SE: 0.015, p=0.016) were associated with the rate of change of SMI in six months adjusted for age, sex, BMI, diabetes mellitus, history of cardiovascular disease, serum albumin, and proteinuria.

Conclusions: Among patients with CKD, presarcopenia is significantly associated with TKV, and patients with a small TKV are more prone to developing a decrease in skeletal muscle mass.

8-Hydroxy-2-Deoxyguanosine (8-OHdG), a Marker of Oxidative DNA Damage, Is Associated with Mortality Independent of Inflammation in CKD Patients Dai Lu, Abdul Rashid T. Qureshi, Hideyuki Mukai, Anna Machowska, Olof Heimburger, Peter F. Barany, Peter Stenvinkel, Bengt Lindholm. *Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Oxidative stress and inflammation are two common interlinked features of CKD that associate with poor outcomes. We tested the hypothesis that inflammation modifies the mortality predictive capacity of serum 8-OHdG in CKD patients.

Methods: In 376 clinically stable CKD stage 1-5 patients (63% male; median age 57 years) including 53 CKD stage 1-2, 60 CKD stage 3-4 and 263 CKD stage 5 non-dialysis patients, 8-OHdG, and high-sensitivity C-reactive protein (hsCRP), interleukin-6 (IL-6) and tumor necrosis factor alpha (TNF), were measured at recruitment. The effect of inflammatory markers on the association between baseline 8-OHdG and 5-year mortality risk was investigated using multivariable modeling strategies using cut-off levels of each marker as determined by ROC curve analysis.

Results: The crude mortality rate was markedly increased in patients with high 8-OHdG especially when combined with high hsCRP and IL-6 **(Figure 1)**. In multivariable analysis, adjusting for age, sex, comorbidity, calendar year and eGFR, high 8-OHdG associated with increased relative risk ratio of death, 1.15 (1.07-1.25), 1.16 (1.07-1.25) and 1.17 (1.08-1.26) respectively, when adjusted also for hsCRP, IL-6 and TNF-α, respectively **(Table 1)**.

Conclusions: All-cause mortality risk was increased - independent of inflammation - in CKD patients with elevated 8-OHdG.

Low Dose Aspirin Increases 15-Epi-Lipoxin A4 Levels in CKD Patients Marian Goicoechea,[1] Maria Dolores Sanchez-Nino,[2] Alberto Ortiz,[2] Maria soledad Garcia de vinuesa,[3] Borja Quiroga,[4] Enrique Morales,[5] Gema Fernandez Juarez,[6] Patricia De Sequera,[7] Ursula Verdalles,[1] Eduardo Verde,[3] Jose Luno.[1] *[1]Hospital General Universitario Gregorio Marañón, Madrid, Spain; [2]Fundacion Jimenez Diaz, Madrid, Spain; [3]Hospital General Universitario Gregorio Marañon, Madrid, Spain; [4]Hospital de La Princesa, Madrid, Spain; [5]HOSPITAL 12 DE OCTUBRE, MADRID, Spain; [6]HOSPITAL DE ALCORCON, ALCORCON, Spain; [7]University Hospital Infanta Leonor, Madrid, Spain.*

Background: Resolution of inflammation is regulated by endogenous lipid mediators, such as lipoxins and their epimers, including 15-epi-lipoxin A4 (15-epi-LXA4). However, there is no information on 15-epi-LXA4 and its in vivo regulation in chronic kidney disease (CKD) patients.

Methods: Study Design: Open label randomized clinical trial. **Setting & Participants:** 50 participants with chronic kidney disease (CKD) stage 3 and 4 without prior cardiovascular disease (25 in the aspirin group and 25 in the standard group) followed for 46 months. **Intervention:** Aspirin (100 mg/day) or standard treatment. **Aim:** To analyze the effect of aspirin on plasma 15-epi-LXA4 levels and inflammatory markers in CKD patients.

Results: Baseline plasma15-epi-LXA4 levels were lower in diabetic (1.22±0.99 ng/ml) than in non-diabetic CKD patients (2.05±1.06 ng/ml, p<0.001) and inversely correlated with glycosylated hemoglobin levels (r=-0.303, p=0.006). In multivariate analysis, diabetes was associated with lower 15-epi-LXA4 levels, adjusted for age, inflammatory markers and renal function (p=0.005). In the whole study population, 15-epi-LXA4 levels tended to increase after twelve months on aspirin (from mean±SD 1.84±1.06 to 2.04±0.75 ng/ml) and decreased in the standard care group (1.60±1.15 to 1.52±0.68 ng/ml, p=0.04). The aspirin effect on 15-epi-LXA4 levels was more striking in diabetic patients, increasing from 0.94±0.70 to 1.93±0.74 ng/ml, p=0.017.

Conclusions: Diabetic patients with CKD have lower circulating 15-epi-LXA4 levels than non-diabetic CKD patients. Low dose aspirin for 12 months increased 15-epi-LXA4 levels, especially in diabetic patients. Given its anti-inflammatory properties, this increase in 15-epi-LXA4 levels may contribute to the beneficial effects of low dose aspirin.

AGE Content of a Protein Load Is Responsible for Renal Hemodynamical Modifications Gabrielle L. Normand,[5] Sandrine Lemoine,[4] Marjorie Villien,[3] Didier Le bars,[1] Ines Merida,[1] Zacharie Irace,[8] Thomas Troalen,[6] Nicolas Costes,[2] Laurent Juillard.[7] *[1]CERMEP, BRON, France; [2]CERMEP - Imagerie du vivant, Lyon, France; [3]CERMEP imagerie du vivant, Tassin la demi lune, France; [4]Edouard Herriot Hospital, Lyon, France; [5]Hospices Civils de Lyon, Lyon----, France; [6]Siemens Healthcare S.A.S., Lyon, France; [7]University of Lyon, Lyon, France; [8]cermep, BRON, France.*

Background: Low-protein diet is recommended to slow down chronic kidney disease progression because each protein load leads to a detrimental glomerular hyperfiltration. Protein preparations used to demonstrate protein-mediated renal hemodynamic effects were rich in AGE. The aim of our study was to evaluate if the AGE content of a protein load is responsible for protein-induced renal hemodynamic modifications.

Methods: Ten healthy subjects were assigned to a high-protein (1g/kg) low-AGE (3.000 kU AGE) versus high-AGE (30.000 kU AGE) meal, during imaging sessions performed on two different days. Renal perfusion assessed by PET using [^{15}O] H2O, and renal oxidative metabolism measured by PET using [^{11}C] labeled acetate, were measured before and 120- minutes after each meal.

Results: Renal perfusion increased significantly (3.16 ± 0.55 to 3.80 ± 0.42 mL/ min/g, p=0.0002) after the high-AGE meal whereas it was not modified after the low-AGE meal (3.35±0.65 to 3.38±0.53 ml/min/g, p=0.88) (Table 1 and Figure 1). Oxidative metabolism increased significantly after the high-AGE meal (0.3 ± 0.04 vs 0.36 ± 0.08 min-1, p=0.005) compared to the low-AGE meal (0.30 ± 0.02 vs 0.31 ± 0.06 min-1, p=0.76) for both cortices.

Conclusions: This is not the high protein content of a meal that increases renal perfusion and oxidative metabolism but its high-AGE content. This study suggests that prevention of CKD progression should aim predominantly at reducing food AGE content.

Nocturnal Intermittent Hypoxia Is Associated with Elevated Circulating Fibroblast Growth Factor 21 in ESRD Takuya Murakami,[1] Takahiro Masuda,[1] Marina Kohara,[1,2] Kazuhiro Shiizaki,[2] Tetsu Akimoto,[1] Sumiko Honma,[3] Yuko Watanabe,[1] Osamu Saito,[1] Eiji Kusano,[4] Yasushi Asano,[3] Makoto Kuro-o,[2] Daisuke Nagata.[1] *[1]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan; [2]Division of Anti-aging Medicine, Center for Molecular Medicine, Jichi Medical University, Shimotsuke, Japan; [3]Department of Nephrology, Japanese Red Cross Koga Hospital, Koga, Japan; [4]JCHO Utsunomiya Hospital, Shimotsuke, Japan.*

Background: Fibroblast growth factor (FGF) 21 is an endocrine factor mainly produced in the liver in response to various stress including inflammation and oxidative stress. We recently reported that higher circulating FGF21 predicts all-cause mortality in end-stage renal disease (ESRD) (Kohara M et al. PLoS One 2017), but the regulator to increase circulating FGF21 remains unclear. We therefore examined the association between circulating FGF21 and sleep-disordered breathing (SDB), characterized by nocturnal intermittent hypoxia and a mediator for chronic inflammation in ESRD.

Methods: Sixty-three ESRD patients receiving maintenance hemodialysis (age 64.2 ± 13.0 years, male 50.8%) were enrolled in this study. Overnight pulse oximetry was performed on a dialysis day, and numbers of over 3% desaturation per hour were defined as the 3% oxygen desaturation index (3%ODI). Patients were categorized into low- and high-FGF21 groups by the median value. Multivariable logistic regression analysis was used to examine the association between serum FGF21 levels and 3%ODI.

Results: The median value of serum FGF21 was 2021 pg/mL. The 3%ODI (6.8 ± 0.9 vs. 3.8 ± 1.0 times/hour, p=0.023) and the percentage of male (63.6 vs. 36.7 %, p=0.031) were significantly higher in the high-FGF21 group than in the low-FGF21 group. On the other hand, the mean oxygen saturation at night did not differ between the two groups (96.2 ± 1.6 vs. 96.4 ± 1.6 %, p=0.34). The 3%ODI was an independent risk factor for higher serum FGF21 levels (odds ratio 1.16: 95% confidence interval: 1.01-1.36, p=0.028) even after adjustment for age, gender, duration of dialysis and presence of diabetes.

Conclusions: Nocturnal intermittent hypoxia, but not mean oxygen saturation, is associated with elevated circulating FGF21 in ESRD. This result suggests that SDB is a novel therapeutic target for regulating circulating FGF21 levels.

Body Fat Mass Is Predictive of Coronary Artery Calcification in Non-Dialysis CKD Patients: A Cross-Sectional Study Denise Mafra, Greicielle S. Da silva, Mariana Z. Jardim, Juliana S. Anjos, Ana paula B. Dreux, Daniel G. Neves, Natalia A. Borges, Milena B. Stockler-Pinto, Marcelo Nacif. *Federal Fluminense University, Niteroi / Rj, Brazil.*

Background: The most common cardiovascular disease (CVD) is coronary artery disease (CAD), which is an important cause of death in patients with chronic kidney disease (CKD). Several CVD risk factors are present in these patients since the early CKD stages, including obesity that is the cause of a variety of metabolic disorders which can increase the risk of CVD in CKD patients. The aim of this study was to evaluate the presence of atherosclerosis and possible association with body composition in non-dialysis CKD patients.

Methods: Twenty-eight patients [53.6% of men, 59.0 ± 13.4 years, creatinine clearance of 32.3 ± 16.6 mL/min, Body Mass Index (BMI) 26.6 ± 5.2kg/m^2] were evaluated in this cross-sectional study. Coronary atherosclerosis was assessed by coronary artery calcium (CAC) scoring done with non-contrast computed tomography. CAC scores as 0 Agatston units was classified without risk, and higher than 100 Agatston were considered representative of significant atherosclerotic disease. Routine biochemical tests, such as lipid profile and C-reactive protein (CRP), were evaluated using standard laboratory methods. Nutritional status was evaluated by BMI, % body fat and waist circumference.

Results: The median of calcium score was 323.7 (125.4- 700) Agatston, 18 patients had no risk for atherosclerosis (calcium score = 0), and 10 patients had risk for atherosclerosis (Ca Score > 100). The median of number of atherosclerosis lesions was 14 (9.2-44). There was correlation between Ca score and BMI (r= 0.37; p= 0.047), % fat body (r= 0.43; p= 0.03) and waist circumference (r= 0.53; p= 0.003). Multivariable logistic regression analysis revealed that % body fat mass and waist circumference were predictors for atherosclerosis risk, regardless of age, creatinine clearance, BMI, sex and CRP (R^2adjusted model = 0.76).

Conclusions: The present study suggests that non-dialysis CKD patients with high body fat mass showed the highest risk for CAC. In this sense, more longitudinal studies are required to confirm this association.

HDL Subclasses Alter with CKD Progression and Are Associated with ABI and Klotho Level in CKD-Stage-Specific Manner Eiichiro Kanda,[1] Yoshitaka Maeda.[2] *[1]Tokyo Kyosai Hospital, Meguro, Japan; [2]JA Toride Medical Center, Ibaraki, Japan.*

Background: Atherosclerosis is a complication of chronic kidney disease (CKD). Lipoprotein subclasses consist of a continuous spectrum of particles of different sizes and densities, and high-density lipoproteins (HDLs) are grouped into various subclasses (Table 1). We investigated the roles of lipoprotein subclasses in atherosclerosis and CKD-mineral and bone disorder.

Methods: Seventy one CKD patients (male, 70.4%; diabetic nephropathy, 23.9%) were enrolled in this prospective cohort study in Japan. The proportion of cholesterol level to total cholesterol level and the lipoprotein particle number in 20 lipoprotein fractions were measured by a newly developed method of high-performance gel permeation chromatography (HGPC).

Results: The average age (SD) was 75.0 (11.1) years and the estimated glomerular filtration rate (eGFR) was 17.2 (8.3) ml/min/1.73m^2. Although no statistically significant difference in cholesterol levels in lipoproteins or triglyceride levels between CKD stages 4 and 5 was shown by HGPC, the method showed that the lipoprotein particle number in small HDLs was higher in Stage 4 than in Stage 5 (p=0.002). Multivariate regression analysis adjusted for baseline characteristics showed that the cholesterol proportion in very small HDLs was negatively associated with eGFR change rate [fraction (F) 19 β=-17.63, p=0.036] and was associated with ABI [F19 β= 0.047, p=0.047] in Stage 4. Moreover, serum soluble α-Klotho level was associated with the number of very small HDL particles [F19 β=0.00026, p=0.012; F20 β=0.00041, p=0.036] in Stage 5.

Conclusions: This study showed that HDL subclasses alter with CKD progression and are associated with ABI and Klotho level in a CKD-stage-specific manner.

Diagnostic Biomarkers of Endoplasmic Reticulum Stress in Glomerular Disease Nihad T. Abouelazm,[3] Joan Papillon,[4] Julie Guillemette,[1] Andrey V. Cybulsky.[2] *[1]Medicine, McGill University, Montreal, QC, Canada; [2]Medicine, McGill University, Montreal, QC, Canada; [3]Medicine, McGill University, Montreal, QC, Canada; [4]Medicine, McGill University, Montreal, QC, Canada.*

Background: Endoplasmic reticulum (ER) stress has been implicated in the pathogenesis of various glomerular and tubular diseases. ER chaperones lacking the KDEL motif, e.g. ERdj3 and mesencephalic astrocyte-derived neurotrophic factor (MANF), can be secreted extracellularly. We propose that induction of ER stress in glomerular diseases may lead to accumulation of secreted ER chaperones in the urine. Such chaperones may potentially serve as biomarkers for diagnosis and therapy.

Methods: ER stress was induced in cultured glomerular epithelial cells (GECs) and in vivo with tunicamycin (TM). In addition, complement-induced ER stress in podocytes was studied in passive Heymann nephritis (PHN), a rat model of human membranous nephropathy. Intracellular expression and secretion of ER chaperones was monitored by immunoblotting. The protective effect of the chemical chaperone, 4-phenyl butyric acid (4-PBA), on complement-mediated podocyte injury was examined by adding 4-PBA to the drinking water of rats with PHN.

Results: In cultured GECs, TM upregulated ER chaperones, ERdj3 and MANF, intracellularly and in culture medium, whereas GRP94 (KDEL chaperone) increased only intracellularly. ERdj3 and MANF extracellular secretion was blocked by the secretory trafficking inhibitor, brefeldin A. ERdj3 and MANF immunoreactivity was stimulated in urines and glomerular lysates of TM-injected rats after 24 h and was independent of proteinuria. Compared to control, ERdj3 and MANF were increased significantly in the urine of PHN rats on days 7-14 after injection of nephritogenic antibody, and coincided with the onset of proteinuria on day 7. Moreover, in PHN, there were concomitant

increases in glomerular ER chaperones, GRP94, ERP57, and MANF, compared to control. Rats with PHN were treated with 4-PBA starting at the time of disease induction, or on day 7, until day 14. In both protocols, 4-PBA reduced proteinuria (on days 7-14), as well as urinary ER chaperone secretion, compared to PHN rats treated with saline.

Conclusions: ERdj3 and MANF secreted into the urine reflect glomerular ER stress. 4-PBA protected against complement-mediated podocyte injury and the therapeutic response could be monitored by ERdj3 and MANF secretion. Urinary ER chaperones may potentially serve as diagnostic biomarkers for identifying patients with glomerular ER dysfunction.

Whole Glomerular Transcriptome Analysis from CKD Biopsies Predicts Cell Lineage-Specific Transcripts Sean Eddy,[1] Viji Nair,[1] Tao Wei,[2] Anna Reznichenko,[3] Rajasree Menon,[1] John R. Hartman,[1] Edgar A. Otto,[1] Mark Tomilo,[1] Wenjun Ju,[1] Felix H. Eichinger,[1] Brad A. Godfrey,[1] Yu Chen,[2] James Conway,[4] Maja Lindenmeyer,[5] Clemens D. Cohen,[5] Shawn S. Badal,[6] Johnna D. Wesley,[7] Uptal D. Patel,[6] Matthew D. Breyer,[2] Kevin L. Duffin,[2] Maria chiara Magnone,[3] Carol P. Moreno Quinn,[4] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Eli Lilly and Company, Indianapolis, IN; [3]AstraZeneca, Mölndal, Sweden; [4]MedImmune, Gaithersburg, NJ; [5]Ludwig-Maximilians-Universität München, München, Germany; [6]Gilead Sciences, Inc., Foster City, CA; [7]Novo Nordisk Research Center, Seattle, Seattle, WA.*

Background: Single cell transcriptome analysis yields a wealth of information on cell type specific transcripts but is not feasible on a large scale, while tissue-level transcriptomic analysis yields a wealth of information on gene regulation but lacks cell type specificity. Coupling whole tissue transcriptome analysis with single cell transcriptome analysis can yield insights into cell type markers and expression profiles.

Methods: Transcriptomic profiles of microdissected glomeruli from clinically indicated renal biopsies were generated from 170 CKD patients in the European Renal cDNA Bank cohort. Gene expression modules were generated using weighted gene co-expression network analysis. Cell lineage signatures curated from published literature were used to compare with modules.

Results: Across the glomerular transcriptome, 22 co-expression modules were identified ranging in size from 76 to 2012 genes. Limiting the analysis to the most variant transcripts yielded 16 co-expression modules ranging in size from 99 to 1046 genes. Re-sampling analysis indicated that modules were stable. From the most variant transcript analysis, eigengenes were compared to cell type specific signatures and two modules (698 genes) were strongly correlated ($r>0.75$, $p<10E-30$) with a podocyte signature generated from podocyte gene set (Ju et al., 2013). Functional enrichment of these modules identified biology associated with podocyte dysfunction, fibrosis, and glomerular toxicity. These two modules contained 62% (21/34) of the podocyte genes expressed in the variant filtered dataset including NPHS1 and WT1, and 69% (93/134) of previously predicted podocyte genes; 11-33% of the remaining genes in the podocyte signature-associated modules were expressed in podocytes from single cell RNA-seq analysis of human kidney tissue (based on different thresholding criteria for defining single cell expression).

Conclusions: This approach allows for the identification of cell-lineage specific transcripts in whole tissue transcriptome datasets and offers the opportunity to identify novel cell lineage transcripts.

Transcriptional Reprogramming by Wilms' Tumor 1 and FoxC2 Mediates a Repair Response during Podocyte Injury Sandrine S. Ettou,[1] Youngsook L. Jung,[2] Martin Kann,[3] Peter Park,[2] Jordan A. Kreidberg.[1] *[1]Boston Childrens Hospital- Harvard Medical School, Boston, MA; [2]Center for Biomedical Informatics, Harvard Medical School, Boston, MA; [3]Nephrolab Cologne, Kidney Research Center Cologne, Cologne, Germany.*

Background: Foot process effacement and proteinuria, representing a breakdown of the glomerular filtration barrier (GFB), may be caused by decreased expression of key podocyte proteins. We previously reported a Wilms' tumor-1 (WT1) ChIP-Seq study that identified components of the GFB and many other important podocyte genes as WT1 target genes. Many WT1 target genes in podocytes also appear to be bound by FoxC2, including *Nphs2*, and *Synpo*. In the present study we demonstrate that WT1 and FoxC2 transcriptionally program a repair response after podocyte injury induced by Adriamycin.

Methods: We used ChIP-Seq to study the DNA binding of WT1 and Foxc2 to target genes in normal podocytes. We used Adriamycin-induced podocyte injury as a model for human FSGS. WT1 and FoxC2 binding was determined by direct ChIP-qPCR at time points after injury using isolated glomeruli from 3, 5 and 7 days post-injection or control Balb/C mice.

Results: Our ChIP-Seq results demonstrate that WT1 and FoxC2 have multiple binding sites at target genes including *Nphs2* and *Synpo*. We previously observed that after the onset of heavy proteinuria, *Nphs2* and *Synpo* expression decreases, as does WT1 and FoxC2 binding to their respective target sites. However, in examining mice prior to, or during the early phase of proteinuria, WT1 and FoxC2 binding to target genes actually undergoes a transient increase at specific enhancer and promoter sites, and *Nphs2* and *Synpo* expression dramatically increases. Using immortalized podocytes, we also demonstrate that WT1 and FoxC2 binding to target genes is interdependent and that knockdown of WT1 or Adriamycin treatment results in epigenetic silencing of the *Nphs2* and *Synpo* genes.

Conclusions: Thus, our results reveal a previously unrecognized repair attempt in podocytes immediately after Adriamycin injury mediated by WT1 and FoxC2 to transcriptionally activate target genes required to maintain the GFB. In the Adriamycin model this repair attempt is ultimately unsuccessful, but transcriptional reprogramming may represent a therapeutic modality to maintain the GFB after podocyte injury.

Acute Kidney Slices as a Tool to Dissect Calcium Signals in Podocytes Julia Binz,[1] Hadiseh Khalili,[2] Bernhard Schermer,[1] Thomas Benzing,[3] Matthias Hackl.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]University Hospital of Cologne, Köln, Germany; [3]University of Cologne, Köln, Germany.*

Background: Calcium signaling in the kidney has been a focus of research for many years. Especially calcium handling in podocytes has been of great interest since it is implicated to play a role in podocyte injury. As isolated podocytes in cell culture are lacking their physiologic microenviroment and isolated glomeruli are prepared with several treatment steps, acute kidney slices (AKS) represent an ex vivo model where the structural complexity of the glomerulus is preserved and which can be prepared within minutes after sacrificing the animal.

Methods: Prior to the preparation of AKS 8-week old C57BL6 mice expressing GCaMP3 under the Pod:Cre promoter were treated with Adriamycin (25mg/kg) for five days. Untreated mice were used as control group. For AKS preparation mice were sacrificed, the kidneys were removed and cut into 500 µm thick slices. During imaging a multiphoton laser was used at 940nm and AKS were treated with an angiotensin-II containing solution to induce calcium signaling in podocytes. As control experiments we used laser-induced calcium signaling and propidium iodide to show that podocytes remain viable and able to produce calcium signals.

Results: The podocytes with genetically encoded calcium indicator are viable and able to produce a calcium wave after laser injury as published in vivo. High doses of angiotensin-II elicit calcium signals in podocytes of untreated animals. Furthermore, there is an increase in calcium response after induction of Adriamycin nephropathy.

Conclusions: Acute slices of the kidney are a great tool to study podocytes, retaining the complex microarchitecture of the glomerulus, and provide results comparable to in vivo imaging. They allow testing of different dosages and compounds on individual kidney slices as the two kidneys provide enough material for at least 5 slices each. The technical setup needed for preparation is limited and the technique can be quickly taught. A confocal imaging setup is sufficient to image AKS. Therefore, AKS have the potential to become a widely used tool in glomerular research.

Podocyte De-Differentiation Repatterns Energy Metabolism and Promotes Cellular Crescent Formation Jiao Miao,[1] Qi Sun,[2] Junwei Yang.[2] *[1]Center for Kidney Disease, Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: The role of podocytes in human crescentic glomerulonephritis (GN) has been underestimated. This may be due to the confounding fact that "dysregulated" podocytes are able to proliferate, lose their markers, and undergo de-differentiation. Specific deletion of *Tsc1* in podocytes led to spontaneous cellular or mixed cellular and fibrous crescents at 12 wk of age. These cellular crescents were immunostaining positive for WT-1 and Ki-67, suggesting that podocytes proceed profound phenotype changing in this model. This study is to investigate the mechanism that governs podocyte de-differentiation. Here we demonstrated that a switch of metabolism from oxidative phosphorylation to aerobic glycolysis was the primary feature during podocyte de-differentiation and also might be the initial step to promote proliferating.

Methods: Renal biopsies from patients with anti-GBM disease, lupus GN and IgA nephropathy were studied by immunofluorescence for WT-1 for podocyte identification and Ki-67 for cell cycle assessment. The de-differentiated podocyte undergoing proliferation was assessed by flow cytometry and fluorescent. Western blot and quantitative real-time PCR were performed to examine the expression level of glycolysis related enzymes. Meanwhile, podocyte-specific *Tsc1* knockout mice were generated as a model for crescentic GN.

Results: Both gene and protein assay showed that the expression of glycolysis enzymes were upregulated in *Tsc1KO* mouse kidneys or in TGFβ1-treated podocytes. Aerobic glycolysis flux, indicated by glucose uptake and lactate production, was increased in TGFβ1-treated podocyte and positively correlated with cell de-differentiation and proliferation. Furthermore, continuously administrating 2-DG starting at 4 wk of age for 8 wk alleviateed crescents formation as well as the induction of p-S6, HIF1a, and PFK in the glomeruli from the *Tsc1*-knockouts.

Conclusions: Our findings demonstrate the critical role of aerobic glycolysis in podocyte de-differentation and proliferation and provide the treatment with aerobic glycolysis inhibitors as a potential anti-crescentic GN strategy.

Role of Exocyst Complex in Podocytes Ashish K. Solanki,[5] Deepak Nihalani,[5] Ehtesham Arif,[5] Pankaj Srivastava,[1] Joshua H. Lipschutz,[5] Xiaofeng Zuo,[1] Yanhui Su,[4] Yujing Dang,[5] Habeeb Alsudani,[2] Soumitra Ghoshroy.[3] *[1]MEDICAL UNIVERSITY OF SOUTH CAROLINA, CHARLESTON, SC; [2]USC, Columbia, SC; [3]University of South Carolina, Columbia, SC; [4]MUSC, Charleston, SC; [5]Medical University of South Carolina, Charleston, SC.*

Background: Exocytosis is mediated through the exocyst complex, which is critical for protein transport and its disruption causes defects in various cellular processes including cell polarity, migration, ciliogenesis and autophagy. Since various glomerular injuries disrupt these processes, we hypothesized that disruption of exocytosis in podocytes will lead to a disease phenotype. In this study, we generated podocyte-specific Exoc5 (a central component of the octameric exocyst complex) knockout mice that showed massive proteinuria and died within 4 weeks of birth.

Methods: Exoc5 was genetically deleted in podocytes by crossing Exoc5f/f with pod-CreTg/+ mice. Mice were analyzed using biochemical, histological, morphological and immunofluorescence approaches. Exoc5 knocked down stable cultured podocyte cells were created using Exoc5-specific shRNA and stained with acetylated tubulin and ciliary phenotype was evaluated by superresolution microscopy.

Results: The Exoc5f/f;PodCreTg/+ mice were proteinuric and died between 21-27 days after birth. Kidney section analysis showed severe glomerular defects with increased fibrosis and proteinaceous casts. Ultrastructural analysis showed effaced podocytes with loss of slit diaphragm. Immunofluorescence analysis showed significant mislocalization of junctional proteins Neph1 and ZO-1, and decreased Nephrin protein expression. To study ciliogenesis defects, we stained isolated mice glomeruli with tubulin antibody, which showed numerous cilia on wild type (WT) glomeruli (Fig1), while cilia in Exoc5 KO glomeruli were absent. In contrast, cultured podocytes showed reduced cilia number with shortened length.

Conclusions: This is the first report that highlights role of exocyst complex in podocytes and shows that loss of Exoc5 results in massive glomerular damage, loss of cilia and death in mice.

Beclin 1 Regulates Podocyte Secretory Pathways Tillmann Bork,[1] Wei Liang,[2] Kosuke Yamahara,[1] Tobias B. Huber.[3] *[1]University Hospital Freiburg, Freiburg, Germany; [2]Renmin Hospital of Wuhan University, Wuhan, China; [3]University Medical Center Hamburg, Hamburg, Germany.*

Background: Podocyte crosstalk with other glomerular cells might be a common theme of glomerular health and disease. However, very little is known how podocyte secretory pathways are being regulated. The complex molecular structure of the autophagy initiating protein Beclin 1 (ATG6) suggested an additional involvement in membrane dynamics. Using podocyte-specific knock-out of Beclin 1 we aimed to further elucidate the specific role of Beclin 1 in podocytes.

Methods: Mice with podocyte-specific loss of Beclin 1 were generated by using cre-loxp technique and analyzed. For autophagy assessment and primary cell culture these mice were crossed to Tomato/eGFP and GFP-LC3 reporter strains, respectively.

Results: Podocyte-specific knock-out of Beclin 1 results in proteinuria and decreased life span. Strikingly, podocytes show massively enlarged Golgi apparatus promoted by increased PI4P production leading to aberrant vesicle formation and vesicle accumulation indicating a functional disruption of the secretory pathway. In fact, VEGF secretion was massively decreased in of Beclin 1-deficient podocytes resulting in severe endothelial damage.

Conclusions: Here we identify a key regulatory protein of the secretory pathway by unravelling a novel function of Beclin 1 in podocytes. Promoting the delivery of secreted factors such as VEGF Beclin 1 is required for glomerular maintenance and might represent a novel pathway being affected in glomerular diseases.

SA-PO198

Deiodinase 3 Downregulation: A Thyroid Hormone Associated Renoprotective Mechanism Nicholas J. Tardi,[2] Chuang Chen,[1] Ranadheer Dande,[2] Jochen Reiser.[2] *[1]Rush University, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.*

Background: Deiodinase 3 (D3) is a membrane-bound, catabolic enzyme that regulates cellular metabolism by deactivating tri-iodothyronine (T3), the metabolically active thyroid hormone. As evident by the embryonic lethality of D3 knockout animals, proper regulation of thyroid hormone activity is vital in nearly all cell types. In the kidney, hyperthyroidism increases renal filtration pressure and absorption capacity, while hypothyroidism thickens the glomerular basement membrane and reduces filtration rate. Despite the prevalence of overlapping complications of thyroid hormone disorders and kidney disease, a unifying mechanism regulating T3 homeostasis in the kidney is absent. Though well studied in endocrine tissues, the role of D3 in local regulation of thyroid hormone in renal tissue has not been addressed. To fill this void, we initially assayed for deiodinase expression in podocytes, as they have a significant role in energy metabolism; having mechanisms that respond to both glomeruli derived and circulating changes in hormone levels. After discovering D3 was highly expressed in podocytes and downregulated in injury models, we aimed to determine the significance of D3 dysfunction in glomerular kidney disease.

Methods: The T3 regulatory capacity of D3 was analyzed via cleavage assay using a radioisotope labeled substrate in cultured podocytes treated with puromycin aminonucleoside (PAN). The role of D3 in proteinuric kidney disease was evaluated using podocyte specific D3 KO mice. Glomerular D3 expression was measured in renal biopsies from kidney disease patients by immunofluorescence.

Results: D3 expression and activity was downregulated in response to PAN induced podocyte injury *in vitro*. D3 expression was prominently diminished at the cell membrane, yet remained concentrated in the golgi and perinuclear region where metabolically active T3 resides. Podocyte specific D3 KO mice responded poorly to LPS-induced acute kidney injury, resulting in heavy proteinuria compared to control. D3 expression in glomeruli of kidney disease patients suffering from minimal change disease, diabetic nephropathy, or focal segmental glomerulosclerosis showed unique profiles amongst diseases.

Conclusions: Our data shows D3 downregulation in podocytes as a response to injury, and suggests D3 may have a renoprotective role in thyroid hormone associated kidney disease.

DDR1 Inhibition Preserves Renal Function in a Mouse Model of Alport Syndrome Judith T. Molina David,[1,2] Jin Ju Kim,[1,2] Javier T. Varona Santos,[1,2] Anja Harmeier,[3] Hans Richter,[3] Rodolfo Gasser,[3] Christian Faul,[1,2] Marco Prunotto,[3] Alessia Fornoni.[1,2] *[1]Katz Family Division of Nephrology and Hypertension, University of Miami Miller School of Medicine, Miami, FL; [2]Katz Family Drug Discovery Center, University of Miami Miller School of Medicine, Miami, FL; [3]Hoffmann-La Roche, AG, Basel, Switzerland.*

Background: Alport Syndrome (AS) is a hereditary disease condition caused by mutations in the type IV collagen genes, leading to progressive renal fibrosis, hearing loss and ocular changes. Discoidin domain receptor 1 (DDR1) is a receptor tyrosine kinase that is activated by collagen and that promotes fibrosis, whereas genetic deletion of DDR1 in mice protects from renal failure in AS. Our study was aimed at identifying a selective DDR1 inhibitor to prevent kidney disease in Col4a3 knockout (KO) mice.

Methods: Approximately 56.000 compounds were screened in *in vitro* binding assay and a fraction of those (circa 1000) were further evaluated in a cell based assay aimed at evaluating DDR1 phosphorylation in dose response. Five compounds were finally selected based on their selectivity, potency and pharmacokinetic and pharmacodynamics profile for further *in vivo* testing and a unique lead compound (cpd) was identified for further in depth *in vivo* analysis. Four-week-old Col4a3 KO and wildtype (WT) mice were injected intraperitoneally with cpd (90 mg/kg) or vehicle on a daily basis. Experimental groups included: WT+vehicle (n=10), WT+cpd (n=11), KO+vehicle (n=11), and KO+cpd (n=14). At 8-weeks of age, mice were sacrificed and kidney tissue, blood and urine were collected for further analysis. Histological analysis was performed by H&E, PAS, Picrosirius Red and immunofluorescence staining (IF). Serum and urine samples were used to determine BUN, albumin, creatinine. Total and pDDR1 levels were measured in kidney cortex by immunoprecipitation.

Results: Fibrosis was assessed by IF for smooth muscle actin (αSMA), Collagen type 1 and laminin. Cpd treatment significantly improved serum BUN, urine albumin/creatinine ratio and fibrosis in KO mice in association with reduced levels of total and phosphorylated DDR1.

Conclusions: These results indicate that drugs targeting DDR1 may represent a novel strategy to treat kidney disease in patients with AS.

SA-PO200

The Role of DDR1 in Podocyte Lipotoxicity and Progression of Alport Syndrome Jin Ju Kim,[1,2] Judith T. Molina David,[1,2] Javier T. Varona Santos,[1,2] Marco Prunotto,[3] Sandra M. Merscher,[1,2] Jeffrey H. Miner,[4] Alessia Fornoni.[1,2] *[1]Katz Family Division of Nephrology and Hypertension, University of Miami Miller School of Medicine, Miami, FL; [2]Katz Family Drug Discovery Center, University of Miami Miller School of Medicine, Miami, FL; [3]F. Hoffmann-La Roche Ltd., Basel, Switzerland; [4]Washington University School of Medicine, St. Louis, MO.*

Background: The GBM is primarily composed by laminin and Collagen type IV. *De novo* production of collagen type I (Col I) has been observed in a mouse models of Alport Syndrome (AS-Col4a3KO). Discoidin-domain-receptor1 (DDR1) is a unique receptor tyrosine kinase that is activated by collagens. Deletion of the DDR1 in Col4a3KO mice improves survival and renal function. However, how DDR1 activation by aberrant collagen production contributes to podocyte injury and proteinuria is poorly understood.

Methods: Differentiated human podocytes were serum starved, followed by 18hrs treatment with 50ug/mL Col I (Corning). Podocyte lipid content was determined by BODIPY 493/503 and Cell Mask Blue staining. Free Fatty acid (FFA) uptake assessed using the fluorometric free fatty acid uptake kit (abcam). Col4a3KO mice (Jackson Laboratory) were utilized for the determination of kidney cortex DDR1 phosphorylation. HEK293 transfected with Dominant active (DA) and dominant negative (DN) constructs were utilized in selected experiments.

Results: DDR1 phosphorylation was increased in kidney cortex from Col4a3KO mice ($p<0.05$), whereas the expression of podocin and synaptopodin was decreased. pDDR1 correlated with blood urine nitrogen (BUN, $R^2=0.7$, $p<0.01$). *In vitro*, podocyte DDR1 was phosphorylated by Col I at 18 hours. Increased intracellular lipid accumulation ($p<0.05$) and FFA uptake ($p<0.001$) were also observed in Col I treated podocytes. DDR1 DA transfected HEK293 cells showed increased expression of CD36, a protein involved in FA uptake, and FFA uptake compared to cells transfected with DDR1 WT and DN ($p<0.05$). Glomeruli isolated from Col4a3KO mice showed increased lipid deposition and expression of CD36.

Conclusions: Our data suggest that col I-induced/DDR1-mediated lipotoxicity may represent a novel mechanism leading to podocyte injury in AS.

SA-PO201

Inducible Podocyte-Specific Deletion of CTCF Leads to Progressive CKD with Severe Bone and Mineral Disease in the Absence of Renal Fibrosis Marta Christov,[6,5] Abbe R. Clark,[4] Eugene P. Rhee,[5] Hiroaki Saito,[7] Eric Hesse,[7] Mary L. Bouxsein,[3] Astrid Weins,[1] Peter H. Mundel,[2] Harald Jüppner,[5,3] Anna Greka.[1,3] *[1]Brigham & Women's Hospital, Boston, MA; [2]Goldfinch Bio, Cambridge, MA; [3]Harvard Medical School, Boston, MA; [4]Harvard University, Boston, MA; [5]Massachusetts General Hospital, Boston, MA; [6]New York Medical College, Valhalla, NY; [7]University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Progressive chronic kidney disease (CKD) is on the rise worldwide with more than 500 million people affected. However, the sequence of events resulting in onset and progression of CKD remain poorly understood. Likewise, while FGF23 elevations are associated with increased mortality, its utility as a biomarker of early CKD remains uncertain, and whether it can be manipulated through dietary or pharmacologic interventions is controversial. Animal CKD models exploring these issues are confounded by systemic toxicities or artificial surgical interventions.

Methods: Floxed CTCF mice ($CTCF^{fl/fl}$) were mated with doxycycline-inducible, podocyte-specific CRE transgenic mice ($iCre^{pod}$). Treatment of Cre^{pod}-$CTCF^{fl/fl}$ mice with doxycycline started at 6 weeks of age to generate $iCTCF^{pod-/-}$ mice, and treated wild-type (WT) mice served as controls. We assessed kidney histology for podocyte loss and interstitial fibrosis, as well as mineral metabolism parameters at 2, 4, 6 and 8 weeks. We determined bone parameters by microCT and histomorphometry in $iCTCF^{pod-/-}$ and WT mice at 8 weeks.

Results: We generated a novel CKD mouse model through the selective and inducible podocyte-specific deletion of an essential endogenous molecule, the chromatin structure regulator CCCTC-binding factor (CTCF), which leads to rapid podocyte loss ($iCTCF^{pod-/-}$). As a consequence, $iCTCF^{pod-/-}$ mice develop severe progressive albuminuria, hyperlipidemia and hypoalbuminemia, the hallmarks of the nephrotic syndrome, and die within 8-10 weeks. Progressive CKD in $iCTCF^{pod-/-}$ mice leads to high serum phosphate and low ionized blood calcium levels, and consequently to profound elevations in FGF23 and PTH levels that rapidly cause bone mineralization defects, increased bone resorption and bone loss.

Conclusions: Dissection of the timeline leading to glomerular pathology in this new CKD model led us to the surprising observation that podocyte ablation and the resulting glomerular filter destruction is sufficient to drive progressive CKD in the absence of interstitial fibrosis. This work highlights podocyte-protective strategies rather than the prevention of renal fibrosis as the most promising therapeutic approach for CKD.

Funding: NIDDK Support

SA-PO202

Loss of Function of Rhpn1 Leads to Proteinuria through Downregulation of Wt1 via Wtip Kan Katayama.[1,2] *[1]Cardiology and Nephrology, Mie university graduate school of medicine, Tsu, Japan; [2]Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.*

Background: Rhophilin-1, Rhpn1 was identified as one of podocyte-enriched proteins and Rhpn1 inactivation in mice showed proteinuria at an early stage. Although the onset of proteinuria was suggested by a mechanism due to the altered actin cytoskeleton structure, the underlying pathogenesis is not fully clarified. Moreover, there is no report in human so far.

Methods: Therefore, we investigated the function of rhpn1 in zebrafish to evaluate whether the phenotypic change was conserved in zebrafish.

Results: Knockdown of rhpn1 in zebrafish caused proteinuria, which was confirmed by the uptake of 500 kDa Fluorescein isothiocyanate-conjugated dextran in proximal tubules. To further analyze the function of Rhpn1, yeast two hybrid screening was performed and Wilms tumor protein 1-interacting protein, Wtip, was identified as an interaction partner of Rhpn1. rhpn1 knockdown in zebrafish or Rhpn1 knockout in mouse resulted in downregulation of mRNA of Wilms tumor protein 1, WT1. In kidneys from Rhpn1 knockout mouse, nuclear translocation of Wtip protein was observed more commonly compared to wild-type mouse kidneys.

Conclusions: Taken together, loss of interaction between Rhpn1 and Wtip might be involved in the development of proteinuria through downregulation of Wt1.

SA-PO203

Ezrin Plays Important Roles in the Regulation of Foot Process Morphology in the Glomerular Podocytes Ryo Hatano. *Ritsumeikan University, Kusatsu, Japan.*

Background: Ezrin is highly expressed in the glomerular podocytes, and is reported to form multi-protein complex with a scaffold protein Na^+/H^+ exchanger regulatory factor 2 (NHERF2), and podocalyxin, a major sialoprotein. Podocalyxin deficient mice died within 24 hrs after birth with anuric renal failure, whereas NHERF2 knockout mice did not show apparent renal phenotype. On the other hand, physiological roles of ezrin in glomerular podocytes still remain unclear.

Methods: To investigate the physiological roles of ezrin in the regulation of glomerular podocyte function, ezrin knockdown mice ($Vil2^{kd/kd}$) were used in this study. Histological analysis of glomerulus was performed by H&E staining and electron microscopy. Western blotting and immunofluorescent analysis were performed the expression and localization of related proteins in the podocytes. Rho activities were investigated by ELISA-based pull down assay using isolated mouse glomeruli from WT and $Vil2^{kd/kd}$ mice and glomerula podocyte cell line, E11.

Results: $Vil2^{kd/kd}$ mice did not exhibit apparent glomerular dysfunction, morphological defects, and disturbance in the localizations of podocalyxin and NHERF2 in podocytes. In $Vil2^{kd/kd}$ glomeruli, Rac1 activity was significantly decreased in $Vil2^{kd/kd}$ glomeruli compared to WT glomeruli although RhoA activity was increased. Then, we examined Rho-activities in E11 cells, in which ezrin expression was downregulated by siRNA. Rac1 activity was significantly decreased in ezrin knockdown E11 cells, whereas significant change in the RhoA activity was not observed. On the other hand, transfection of constitutively active ezrin (T567D) increased the activity of Rac1. Furthermore, increased lamellipodia formation was observed in the T567D-transfected E11 cells.

Conclusions: Our results suggest that ezrin regulates the foot process formation via the Rac1 activity in the podocytes. Ezrin is known to interact with Rho-GDP dissociation inhibitor (RhoGDI). Since ezrin promotes the activation of Rho via the striping RhoGDI from GDP-bound Rho, activation of ezrin might be involved with Rac1 activation in the glomerular podocytes.

SA-PO204

The Protective Role of Podocyte Hypertrophy via mTOR Signalling after Mild Podocyte Depletion Victor G. Puelles,[1,2] James W. Van der wolde,[1] Luise A. Cullen-McEwen,[1] Luc Furic,[1] Kate M. Denton,[3] Marcus J. Moeller,[2] David J. Nikolic-Paterson,[4] John F. Bertram.[1] *[1]Anatomy and Developmental Biology, Monash University, Melbourne, VIC, Australia; [2]Nephrology and Clinical Immunology, University Hospital RWTH Aachen, Aachen, Germany; [3]Physiology, Monash University, Melbourne, VIC, Australia; [4]Nephrology, Monash Medical Centre, Melbourne, VIC, Australia.*

Background: Marked podocyte depletion is an established key feature of glomerulosclerosis (FSGS). However, little is known about the consequences of mild podocyte loss. In addition, activation of parietal epithelial cells (PECs) has been proposed as a major effector in FSGS. This study investigates the consequences of graded podocyte depletion, the hypertrophic response of podocytes and associations with PEC activation and thereby glomerulosclerosis.

Methods: We induced selective podocyte depletion in Pod^{Cre}iDTR mice by injection of diphtheria toxin (DT) at different doses. L-NAME induced hypertension was used as a second hit challenge after mild podocyte loss. The mammalian target of rapamycin (mTOR) signalling pathway was manipulated using mTOR inhibitors (RAD001 and INK128). Podocyte depletion and hypertrophy were examined by 3D analysis of whole glomeruli in optically-cleared kidney slices.

Results: Pod^{Cre}iDTR mice injected with a low dose of DT presented mild podocyte depletion, compensatory podocyte hypertrophy and reversible albuminuria without PEC

activation or glomerulosclerosis, even following a second hit challenge (high blood pressure), suggesting a protective role of podocyte hypertrophy. Injection of a higher dose of DT in Pod^{Cre}iDTR mice led to greater podocyte loss and hypertrophy. However, these mice showed PEC activation, glomerulosclerosis and persistent albuminuria, suggesting there is a limit for the protective role of podocyte hypertrophy. Pharmacological inhibition of mTOR during the induction of mild podocyte depletion led to persistent and exacerbated albuminuria, impairment of podocyte hypertrophy, PEC activation and glomerulosclerosis.

Conclusions: Podocyte hypertrophy via mTOR signalling is required for the adaptive hypertrophic response of remaining podocytes after mild podocyte depletion. These results are relevant for the use of mTOR inhibitors in the context of FSGS and CKD.

SA-PO205

HMGA1-Driven Long Non-Coding RNAs Mediate Endothelial-to-Mesenchymal Transition in Kidney Fibrosis Roel Bijkerk,[1] Atefeh Lafzi,[2] Wendy Stam,[1] Angela Koudijs,[1] Ellen Lievers,[1] Ton J. Rabelink,[1] Hilal Kazan,[3] Anton J. Van Zonneveld.[1] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]CNAG-CRG, Barcelona, Spain; [3]Antalya International University, Antalya, Turkey*.

Background: Chronic kidney disease associates with the development of interstitial fibrosis characterized by a loss of the microvasculature and myofibroblast formation. Endothelial cells (ECs) are important for maintaining a healthy microvasculature while ECs also provide a potential source for myofibroblasts through endothelial-to-mesenchymal transition (EndoMT). Here, we aimed to identify a role for long non-coding RNAs (lncRNAs), novel central post-transcriptional regulators, in ECs in the development of kidney fibrosis.

Methods: We used VE-cadherin-ERT2;tdTomato mice to label and trace endothelial cells. We applied both the ischemia-reperfusion injury (IRI) and unilateral urethral obstruction (UUO) models followed by FACS sorting of the tomato-positive cells from healthy and diseased kidneys. Subsequently, we isolated RNA from these cells and profiled for lncRNAs, as well as gene expression, using comprehensive genome-wide transcript arrays.

Results: Upon kidney injury, we observed substantial co-localization of VE-cadherin-derived tomato positive signal with a-SMA staining, indicating that a significant portion (~15-20%) of myofibroblasts originated from ECs. We confirmed that ECs acquired a myofibroblast phenotype by using qPCR on FACS sorted tomato-positive cells showing reduced expression of EC markers CD31 and VE-cadherin while myofibroblast markers α-SMA and col1α1 increased. In UUO and IRI, we found 586 and 416 lncRNAs to be differentially expressed (>2-fold, $p<0.05$) in the VE-cadherin-derived tomato-positive cells, respectively. Using bioinformatic analyses to determine transcription factor motif-enrichment amongst differentially expressed lncRNAs we found strong enrichment for HMGA1 binding sites, a transcription factor previously described to be essential in EndoMT. Using ChIP-seq, we validated binding of HMGA1 to lncRNA promoters, including that of MALAT1, one of the differentially expressed and conserved lncRNAs, and subsequently demonstrated in an in vitro model for EndoMT that blocking MALAT1 with gapmers enhanced TGF-β induced EndoMT.

Conclusions: We demonstrated that HMGA1-induced lncRNAs mediate EndoMT which may provide novel strategies to counteract the development of kidney fibrosis.

SA-PO206

Rap1 and Its Guanine Nucleotide Exchange Factor C3G Are Critical for Drosophila Nephrocyte Filter Function Christopher P. Dlugos,[1] Cara Picciotto,[2] Astrid Jeibmann,[4] Michael P. Krahn,[3] Roland Wedlich-Söldner,[3] Hermann Pavenstädt,[5] Christian Klämbt,[3] Britta George.[1] *[1]Medizinische Klinik D, Universitiy Hospital Münster, Münster, Germany; [2]University Hospital Münster, Münster, Germany; [3]University of Muenster, Muenster, Germany; [4]Institute of Neuropathology, Münster, Germany; [5]UKM Münster, Münster, Germany*.

Background: Podocytes are crucial for kidney filter function. Podocyte damage is associated with a broad range of glomerular diseases with defective filter function based on aberrant intercellular junctions (slit diaphragms) and actin cytoskeletal dynamics resulting in renal failure and over time to end stage renal disease. Patients with mutations in the human gene encoding the slit diaphragm protein Nephrin do not develop functional slit diaphragms leading to a severe proteinuria. *Drosophila* nephrocytes form a slit diaphragm-like filtration barrier and express the Nephrin orthologue sticks-and-stones (sns). Nephrocytes represent a genetically tractable model to study Nephrin signaling *in vivo*. This study aims to elucidate Nephrin signal transduction to the actin cytoskeleton and focal adhesions.

Methods: To characterize the role of genes of interest in *Drosophila* nephrocyte filter function the secreted protein Atrial Natriuretic Factor (ANF-GFP-GFP) which is taken up by nephrocytes with functional filtration slits was ectopically expressed by the *ubiquitin* promoter (*ubi::ANF-GFP-GFP*). The *sns::Gal4* transgene allowed nephrocyte-specific expression of *UAS-dsRNA* by crossing the respective strains. Standard immunofluorescence and transmission electron microscopy were employed to analyze nephrocyte phenotypes.

Results: Co-immunoprecipitation experiments revealed an interaction of Nephrin and guanine nucleotide exchange factor C3G in HEK lysates. Engagement of a chimeric Nephrin molecule which results in downstream signaling events led to activation of integrin beta1 in podocytes. *In vivo*, nephrocyte-specific knockdown of the Nephrin orthologue *sns* as well as *C3G* or *roughened* (mammalian Rap1) compromised filtration, shown by impaired ANF-GFP-GFP uptake into *Drosophila* nephrocytes. Altered localization of integrin and the integrin-associated protein talin was observed following knockdown of *sns*. Ultrastructurally, knockdown of either *sns*, *C3G* or *roughened* resulted in loss of nephrocyte filtration slits.

Conclusions: *Drosophila melanogaster* is an effective model system to study nephrocyte function and Nephrin signaling. C3G interacts with Nephrin and is necessary for nephrocyte function.

KAT5-Mediated DNA Damage Repair Is Essential for the Maintenance of Podocytes Akihito Hishikawa,[1] Kaori Hayashi,[1] Toshiaki Monkawa,[2] Hiroshi Itoh.[1] *[1]Internal Medicine, Keio University School of Medicine, Tokyo, Japan; [2]Medical Education Center, Keio University School of Medicine, Tokyo, Japan*.

Background: We have recently reported the gene-selective epigenetic control in podocytes via KLF4 (Hayashi et al, JCI 2014. KI 2015). However, the precise formation process of epigenetic changes involved in diseases states remains unclear. Here we focused on KAT5, a histone acetyltransferase which has been reported as a KLF4 interacting protein and an important factor in repairing DNA, to investigate the possible role of DNA damage repair process in formation of epigenetic changes.

Methods: Expression of KAT5 was examined in streptozotocin (STZ)-induced diabetic mice model and the effect of KAT5 gene transfer was evaluated. To analyze the physiological role of KAT5, we generated podocyte-specific KAT5 knockout (KO) mice, and investigated the epigenetic changes and DNA damage status. We performed in vitro studies using cultured human podocytes to examine the mechanism of KAT5-associated epigenetic changes.

Results: KAT5 expression was significantly decreased in isolated podocytes in STZ mice and a marker of DNA double strand breaks γH2AX was increased in glomeruli of STZ mice. Restoration of KAT5 expression in STZ mice using a hydrodynamic-based gene transfer method ameliorated albuminuria, γH2AX and nephrin expression. KAT5 KO mice developed massive proteinuria (6 week-old, WT 33±16 mg/gCr, KO 3326±1023 mg/gCr, $p<0.05$) with segmental glomerurosclerosis and diffuse effacement of podocyte foot process. In KO mice, nephrin expression in isolated podocytes was decreased, and WT1-positive podocyte number was reduced with an increase in TUNEL positive cells. Epigenetic changes and an increase in γH2AX expression were observed in glomeruli of KO mice. In cultured human podocytes, high-glucose treatment (30mM) induced KAT5 reduction and overexpression of KAT5 increased nephrin expression. It was revealed that overexpression of KAT5 induced a decreased methylation and a decreased binding of DNMT1 in the nephrin promoter region by methylation-specific PCR method and ChIP analysis.

Conclusions: DNA damage repair through KAT5 is essential for the maintenance of podocytes and has relation to the changes in podocyte epigenome. Increased KAT5 in podocytes ameliorates diabetic nephropathy with promoted DNA damage repair and elevated nephrin expression.

Isoform Specific Phosphorylation of Dynamin1 in Regulating the Cortical Actin Cytoskeleton in Podocytes Changkyu Gu,[2] Nikolina Stojanovic,[2] Mario Schiffer,[1] Sanja Sever.[3] *[1]Hannover Medical School, Hannover, Germany; [2]Massachusetts General Hospital, Charlestown, MA; [3]Massachusetts General Hospital, Charlestown, MA*.

Background: Dynamin is an essential actin regulatory protein in podocyte, and loss of its function is closely connected to podocyte injury and proteinuria. Recently, our studies have shown that dynamin directly regulates actin cytoskeleton via its oligomerization state. Importantly, dynamin specific small drug (Bis-T-23) that induces its oligomerization ameliorates proteinuria in diverse proteinuric animal models through recovering functional actin structures in injured podocytes. Threrfore, it is important to maintain balance between dynamin assembly and disassembly. This dynamin oligomerization can be regulated through interaction with diverse cellular proteins, and it was reported that dynamin1 can differentially alter the affinity for its protein binding partners via phosphorylation by two different serine/thronine kinases, GSK3β and CDK5, in neurons. Based on these data, we hypothesize that phosphorylation-dependent dynamin1 oligomerization is an important molecular mechanism that regulates actin dynamics in podocytes.

Methods: Dynamin1 phosphorylation in podocytes was detected by western blot using phospho-dynamin1 specific antibodies in the presence of GSK3β or CDK5 inhibitor. Actin and paxillin in podocytes were stained to observe actin structures and focal adhesions. Cell migration and spreading assays were performed with podocytes expressing phosphor-dynamin1 mutants. For zebrafish experiments, each phosphor-dynamin1 mutant was expressed in dynamin2^{KD} zebrafish.

Results: 1. Dynamin1 is phosphorylated by GSK3β and CDK5 in podocytes. 2. Expression of phosphor-dynamin1 mutants alters cortical actin networks during cell spreading. 3. Expression of phosphor-dynamin1 mutants attects cell migration. 4. Expression of phosphor-dynamin1 mutants fails to rescue proteinuria in dynamin2^{KD} zebrafish.

Conclusions: The role of dynamin in actin cytoskeleton in podocytes is essential to maintain the glomerular filtration barrier. Dynamin directly regulates actin structures via its oligomerization state. Our data suggest that dynamin1 phosphorylation is implicated

in cortical actin dynamics in podocytes, and its balanced phosphorylation by GSK3β and CDK5 is crucial to podocyte's function in glomerular filtration.

Flotillin-2 Is Required to Recruit Slit Diaphragm Protein into Rafts and Mediates Podocyte Injury and Proteinuric Glomerular Disease Li Zhang, Hong Zhang, Wei Shi, Xinling Liang. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China*.

Background: Podocytes are critical in the maintenance of the normal glomerular filtration barrier and is believed to be the target of numerous glomerular diseases leading to proteinuria. Lipid microdomains in podocytes play important roles in the normal cell morphology and glomerular barrier function. Raft proteins are thought to mediate diverse cellular processes. Flotillin-2/reggie-1(Flot-2) is a ubiquitously expressed and highly conserved raft protein. However, the biologic function in podocyte and proteinuric glomerular disease remains unknown.

Methods:

Results: Here, we identify and describe the functional role of Flot-2 as a novel podocyte-protein of the kidney glomerulus. Our novel studies demonstrate that flot2 expression is significantly reduced in glomerular podocytes of subjects with proteinuric glomerular diseases, and is also markedly reduced in response to podocyte injury induced by Lipopolysaccharide (LPS)/Adriamycin (ADR) in vitro and in vivo. We further find by immunoelectron microscopy that flot2 localizes to the insertion site of the slit diaphragm (SD) of podocytes. Reduced flot2 expression in vitro and in vivo using small interfering RNA and podocyte- specific flot2 knockout causes cytoskeleton disruptions and fails to recruit podocin, nephrin and CD2AP into rafts. Podocyte-specific flot2-deletion develops worse albuminuria, podocyte injury and glomerular pathology in LPS or ADR-induced nephropathy mice. Conversely, overexpression of flot2 in vitro and in vivo podocytes attenuates cytoskeleton disruptions and inhibits the reduction of SD-associated protein podocin, nephrin and CD2AP in lipid rafts. Meanwhile, podocyte injury, albuminuria and pathologic aberrance are prevented in podocyte-specific flot2 overexpression of transgenic mice when challenged with LPS or ADR. Mechanistically, we show that Flot2 and podocin directly interacts with each other via their SPFH domain. Further studies reveal that Krüppel-like factor 15(KLF15) directly bound to the flot2 promoter region, and regulate the expression of flot2 protein.

Conclusions: Thus, our results first indicate that flot-2 is required to recruit slit diaphragm protein into rafts and mediates podocyte injury and proteinuric glomerular disease. Maintaining necessary flot2 would be one potent way to prevent proteinuria kidney diseases.

In Vivo Investigation of Calcium Dynamics in Developing Podocytes during Glomerular Morphogenesis Lydia Djenoune,[1,2] Ritu Tomar,[1,2] Erin Merkel,[1,2] Iain A. Drummond.[1,2] *[1]Massachusetts General Hospital, Charlestown, MA; [2]Harvard Medical School, Boston, MA.*

Background: Podocytes are highly specialized epithelial cells in the kidney glomerulus that play critical roles in maintaining the glomerular filtration barrier. Nephrotic syndrome genes, including TrpC6 and PLCe1, affect podocyte calcium signaling. However, the role of calcium signaling during podocyte development *in vivo* remains unknown.

Methods: Here we aim at understanding the role of calcium signaling during glomerular development using live imaging of zebrafish.

Results: Live imaging showed that immature podocytes (48 hours post fertilization) are dynamic and interact with the dorsal aorta to form glomerular capillaries. By 4 days post fertilization (dpf) podocytes stabilize and the filtration barrier is functionally mature. Using the calcium biosensor GCaMP3, we observed spontaneous intracellular calcium transients in podocytes at early stages (2-3 dpf) of development in the zebrafish larva which were silenced by 4 dpf suggesting a role for calcium signaling in podocyte maturation. To determine the source of calcium, larvae were treated with calcium inhibitors and we observed that calcium transients were blocked by cyclopiazonic acid, thapsigargin and 2APB but not by cilnidipine or nifedipine, indicating calcium release from intracellular stores. *plce1* knockdown resulted in podocyte defects, disorganized capillaries, and loss of podocin expression suggesting a requirement for calcium signaling in podocyte differentiation. Using an unbiased whole glomeruli RNAseq transcriptome approach we identified multiple candidate signaling receptors potentially responsible for developmental podocyte calcium signaling.

Conclusions: These studies will help to identify new targets for intervention in glomerular diseases and establish zebrafish as a model for glomerular diseases caused by impaired calcium signaling.

Loss of DUSP4 Promotes Insulin Resistance in Podocytes through JNK Activation Benoit Denhez,[3] Marina Rousseau,[3] Farah Lizotte,[3] Mannix Auger-Messier,[4] Anne-Marie Cote,[1] Pedro M. Geraldes.[2] *[1]CHUS - Hopital Fleurimont, Sherbrooke, QC, Canada; [2]University of Sherbooke, Sherbrooke, AB, Canada; [3]University of Sherbrooke, Sherbrooke, QC, Canada; [4]Université de Sherbrooke, Sherbrooke, QC, Canada*.

Background: Diabetic nephropathy is characterized by early damages to podocytes which lead to their dysfunction and loss. Insulin action in podocytes has been shown to be essential for their integrity. Multiple evidences suggested that the activation of JNK can lead to insulin resistance in various cell types. Data from our laboratory showed that the expression of DUSP4, a protein known to inhibit JNK, is reduced in the renal cortex of type 1 diabetic mice and cultured podocytes exposed to high glucose levels. Deletion of DUSP4 in diabetic mice resulted in significant increase of albuminuria, podocyte apoptosis and activation of JNK. The objective is to evaluate the effect of JNK activation induced by the loss of DUSP4 expression on insulin signaling pathway in cultured podocytes exposed to high glucose and diabetic mice.

Methods: Non-diabetic (NDM) and diabetic (DM) mice with the deletion of DUSP4 (D4KO) were stimulated with insulin to evaluate its downstream signaling pathway on the activation of IRS1 and Akt in the renal cortex. Mouse podocytes were exposed to normal (NG; 5.6 mM) or high (HG; 25 mM) glucose levels for 72 hours with or without the overexpression of DUSP4 adenoviral vector to evaluate the phosphorylation of JNK and the insulin signaling pathway.

Results: Insulin-stimulated Akt and ERK phosphorylation in the renal cortex of DM mice was decreased compared to NDM mice, and was further reduced in DM D4KO mice. Loss of insulin effects in DM D4KO mice was associated with increased phospho-serine 307 of IRS-1, which is known to inhibit IRS1 activity. In cultured podocytes, HG exposure inhibited insulin-induced activation of Akt, which was associated with a reduction in DUSP4 expression and a 2.8 fold increase in phospho-serine 307 of IRS-1. Overexpression of DUSP4 prevented both the HG-induced increased phosphorylation of JNK and phospho-serine 307 of IRS-1, and restored insulin-stimulated Akt activation in podocytes.

Conclusions: In conlusion, the reduction of DUSP4 expression by hyperglycemia in podocytes contributed to insulin resistance by promoting JNK activation.

The Role of the Atypical Cyclin-Dependent Kinase Cdk5 on Development and Function of Podocytes Nicole C. Mangold,[3] Henning Hagmann,[2] Stuart J. Shankland,[4] Markus M. Rinschen,[1] Thomas Benzing,[3] Paul T. Brinkkoetter.[2] *[1]CECAD, Cologne, Germany; [2]University Hospital Cologne, Cologne, Germany; [3]University of Cologne, Köln, Germany; [4]University of Washington, Seattle, WA.*

Background: The atypical Cyclin-dependent kinase 5 (Cdk5) controls migration, cell adhesion and synaptic plasticity in neurons. In the kidney Cdk5 expression is restricted to the podocytes. In these visceral epithelial cells Cdk5 is activated by three known activators, p35, p25 and Cyclin I and mediates anti-apoptotic function via MEK/ERK and BCL-2. This led to the hypothesis, that Cdk5 is a master regulator of podocyte apoptosis or detachment from the glomerular basement membrane. In the mouse model of nephrotoxic nephritis the conventional knockout of Cyclin I and p35 as well as the conventional double knockout of these alleles were shown to cause increase susceptibility to glomerular damage. Prolonged and mislocalized activity of Cdk5 by increased levels of p25 in neurons leads to neurodegeneration phenotypes and dementia.

Methods:

Results: To evaluate the role of the Cdk5 effector kinase in podocytes, podocyte specific Cdk5 knockout mice were generated by crossing Cdk5 floxed mice to a podocyte-specific Podocin:Cre line. Mice were born according to Mendelian rules and did not develop a phenotype until the age of 72 weeks as documented in urine and serum analyses as well as immunohistochemical stainings. In the nephrotoxic nephritis model Cdk5-deficiency resulted in increased susceptibility to glomerular injury, aggravated proteinuria and glomerular sclerosis and a decreased number of podocytes per glomerulum. In addition, a transgenic podocyte cell line expressing MYC-tagged p25 was generated by lentiviral gene transfer to investigate Cdk5 hyperactivity in podocytes. As compared to control podocytes, p25-transgenic cells showed an enhanced migratory phenotype, survival was not affected. Proteomic using MS/MS analysis revealed enhanced expression of proteins modulating cytoskeletal remodeling.

Conclusions: Whereas Cdk5 deficient mice develop no phenotype at baseline, this study highlights the anti-apoptotic effect of Cdk5 in the model of nephrotoxic nephritis. Whether activity of Cdk5 is protective in disease most likely depends on the balance of specific Cdk5-activators in the cell.

SA-PO213

The Essential Role of Cofilin1 in Podocytes under Diabetic Conditions Beina Teng, Irini Schaefer, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hannover, Hannover, Germany*.

Background: Cofilin1 is known as actin filament severing protein and thus a key regulator of actin dynamics. Its deficiency results in the loss of a precisely organized actin

cytoskeletal architecture and can reduce cell migration and motility. In podocytes, Cofilin1 dysregulation leads to loss of secondary foot processes and FP effacement. Cofilin1 is also described as a part of a complex with actin and phosphorylated RNA polymerase (Pol) II, playing a major role in the regulation of gene transcription. In mammalian cells, Cofilin1 is inactivated via phosphorylation and translocated to the nucleus

Methods: To study the role of Cofilin1 in diabetes, sections of Type I diabetic mice induced by STZ, Type II diabetic db/db mice and Type II diabetic patients were evaluated by IF stainings against Cofilin1 and p-Cofilin1. Human and murine podocytes stimulated with glucose or TGF-β were analyzed for Cofilin1, its colocalization with Pol II and the distribution of F-actin. We also analyzed the phosphorylation profile of Cofilin1 at different time points using westernblot. After glucose treatment, migration assays were perfomed to compare the capability of podocytes to migrate into to the scratched wound with or without addition of p-Cofilin1 blocking peptide.

Results: Phosphorylated Cofilin1 is strongly detected in the nucleus of podocytes in diabetic mice and patients. Stimulation of cultured podocytes with glucose or TGF-β induced the translocation of Cofilin1 into the nucleus and led to a dysregulation of actin filaments, and Cofilin1 phosphorylated on Ser3 is mainly localized to the nucleus. Westernblots indicated an increased phosphoylation of Cofilin1 30 minutes after glucose treatment. Comparing the location of p-Cofilin1 with phosphorylated Pol II indicated a redistribution of Pol II away from areas with p-Cofilin1/actin, which most likely impacts transcriptional elongation. Podocytes remained static after glucose treatment in culture, but their migration ability was restored when p-Cofilin blocking peptide was added.

Conclusions: Localization of p-Cofilin1 to the nucleus is a strong indicator of diabetes induced dysfunction of podocytes; impacting the reorganization of the actin cytoskeleton as well as transcription. The phospho-inhibitor of Cofilin1 is a novel potential candidate to prevent p-Cofilin1 mediated progression of podocyte dysfunction and podocyte damage in diabetes.

SA-PO214

Paricalcitol Prevents PAN-Induced Podocyte Morphological Change via Direct Regulation of Nestin Transcription through the Interaction of VDR/VDRE Yuling Zhang,[1] Xinxin Jiang,[1] Xinyu Dong,[2] Jing Chen.[2] *[1]Huashan Hospital, Shanghai, China; [2]Huashan Hospital affiliated to Fudan University, Shanghai, China.*

Background: Podocyte morphological change is a pathologic feature of a variety of chronic kidney disease. Several lines of evidence suggested a potential protecting role of vitamin D in podocytes, but the underlying mechanism remained unclear. We hypothesized that vitamin D analogue paricalcitol restored podocytes morphology in puromycin aminonucleoside (PAN) induced nephrosis by modulating nestin gene expression

Methods: A rat model of podocyte injury was created by a single intraperitoneal injection of PAN and subjected to either saline or paricalcitol. Proteinuria, podocyte foot process effacement (FPE), expression of nestin and vitamin D receptor (VDR) in glomeruli was evaluated. The influence of PAN or paricalcitol on cultured mouse podoctyes were also observed. VDR expression was silenced by VDR siRNA or plasmids containing VDR shRNA transfection. Chromatin immunoprecipitation (ChIP) and luciferase reporter assays were performed to study the connection between VDR and nestin gene expression.

Results: Paricalcitol significantly alleviated PAN-induced proteinuria and podocyte FPE. This protective effect was accompanied by an increased expression of VDR in the glomeruli. Paricalcitol also inhibited PAN-induced glomeruli nestin overexpression. In vitro study showed that PAN significantly inhibited VDR protein expression and stimulated nestin protein expression which resulted in nestin filament derangement. Paricalcitol treatment abolished the effect. Downregulation of VDR in cultured podocytes also resulted in overexpression and derangement of nestin. ChIP assays revealed a VDR response element (VDRE) in nestin promoter and paricalcitol enhanced the binding of VDR and VDRE. Luciferase reporter assays of the nestin promoter fragment showed paricalcitol effectively repressed nestin reporter gene expression after PAN treatment. However, paricalcitol treatment alone showed no influence on luciferase activity. Mutation of VDRE abolished the effect.

Conclusions: Paricalcitol prevents morphological change of podocytes in PAN nephrosis via direct regulation of nestin trascription through the interaction of VDR/VDRE.

The Melanocortin-1 Receptor Protects Podocytes by Downregulating the Epidermal Growth Factor Receptor Lovisa Bergwall,[2,3] Johannes Elvin,[2,4] Roberto Boi,[2,3] Hanna I. Wallentin,[2,3] Borje Haraldsson,[1] Jenny C. Nystrom,[2,3] Lisa Buvall.[2,3] *[1]Novartis, Gothenburg, Switzerland; [2]University of Gothenburg, Gothenburg, Sweden; [3]Institution of Neuroscience and Physiology, Sahlgrenska Academy, Gothenburg, Sweden; [4]Institution of Medicine, Sahlgrenska Academy, Gothenburg, Sweden.*

Background: The Melanocortin-1 receptor in podocytes has been suggested as the mediator of the renoprotective effects seen in ACTH treatment of nephrotic syndrome. The protective effect has been proposed to be through stabilization of the actin cytoskeleton in podocytes.

Methods: Using phosphoproteomic mass spectrometry, actin regulatory pathways were identified downstream of the MC1R in podocytes over-expressing the MC1R and treated with the MC1R specific agonist BMS. Confirmation of regulated proteins and pathways was done using western blot. Actin dynamics was studied using phalloidin labeling. To evaluate the protective effect of MC1R-induced ERK phosphorylation and EGFR signaling, protamine sulfate was used on cultured podocytes in the presence or absence of the ERK-inhibitor PD98059.

Results: Actin cytoskeleton signaling was the toped ranked regulated pathway in podocytes identified in the phosphoproteomic data following BMS treatment. The activity of MAP-kinases, ERK and the EGFR was found to be significantly regulated. To confirm the proteomics data, western blot analysis was performed. Increased phosphorylation of ERK1/2 following BMS treatment was observed already after 5 minutes. This was followed by an increase in phosphorylation on EGFR T669, a site commonly phosphorylated by ERK and known to inactivate the receptor. Perturbed EGFR signaling was observed in MC1R activated podocytes shown by increased downregulation of the EGFR following EGF treatment in BMS exposed cells. MC1R was shown to protect podocytes from protamine sulfate induced EGFR activation and actin cytoskeleton rearrangement in podocytes. The rescue effect was shown to be attenuated by inhibiting ERK.

Conclusions: In this study, we show that MC1R activation leads to the ERK-dependent phosphorylation of EGFR T669, with ensuing downregulation of the receptor. Activation of the EGFR has previously been shown to be a negative regulator of actin cytoskeleton dynamics in podocytes. These data thereby suggest that the MC1R protective effect on the actin cytoskeleton in podocytes is due to its inhibitory role on EGFR signaling.

SA-PO216

Dynamin: A Potential Regulator of Actin-Microtubule Interplay in Podocytes Kamalika Mukherjee,[1] Changkyu Gu,[2] Sanja Sever.[1] *[1]Massachusetts General Hospital, Charlestown, MA; [2]Massachusetts General Hospital, Charlestown, MA.*

Background: Podocytes are a critical component of the glomerular filtration unit. Structural and functional anomalies in podocytes have been implicated in renal diseases such as focal segmental glomerulosclerosis and diabetic nephropathy. Podocyte injury, dysfunction and loss are correlated with aberrations in cytoskeletal organization of these specialized cells. Microtubules and actin are the prevalent cytoskeletal components of major processes and foot processes in podocytes. We therefore sought to decipher the interplay between microtubules and actin in podocytes and identify regulatory proteins that may facilitate this interaction.

Methods: Immunocytochemistry was performed to detect changes in the cytoskeleton. Spin-down- and GTP hydrolysis- assays were used to assess dynamin and microtubule interaction. Microtubule polymerization and depolymerization were studied in an isolated system using fluorescence based assays.

Results: 1. Microtubule-regulating drugs alter actin cytoskeleton in podocytes. 2. Actin active drugs reorganize microtubule network. 3. Dynamin-modulating small molecules alter both microtubules and actin organization in podocytes. 4. Microtubule depolymerization is initiated in the presence of dynamin. 5. Tubulin polymerization is inhibited by dynamin. 6. Dynamin-regulating small molecules, in the presence of dynamin, alter polymerization state of microtubules.

Conclusions: Small molecule mediated alteration of actin cytoskeleton culminates in reorganization of microtubule network and *vice versa*. These observations demonstrate that the two cytoskeletal proteins are involved in constant communication with each other in podocytes. Moreover, altering the oligomerization state of dynamin affects both microtubule- and actin- cytoskeleton, which indicates that dynamin may qualify as one of the regulators of actin-microtubule crosstalk. Dynamin's ability to promote actin polymerization has already been documented. Our current findings show that dynamin oligomerizes on microtubule templates and induces its depolymerization. Additionally, tubulin polymerization into microtubules is inhibited by dynamin. Therefore, dynamin oligomerization affects the polymerization state of both actin and microtubules. Taken together, we provide evidence that dynamin may regulate the interplay between microtubules and actin in podocytes.

SA-PO217

Podocyte Expressed miR-146a Protects against Diabetic Glomerulopathy via Suppression of ErbB4 and Notch-1 Terese D. Geraghty,[3] Samia Khan,[2] Shehryar J. Khaliqdina,[4] Ha Won Lee,[4] Mehmet M. Altintas,[3] Pierre-Louis Tharaux,[1] Tobias B. Huber,[5] Markus Bitzer,[6] Jochen Reiser,[4] Vineet Gupta.[4] *[1]INSERM, Paris, France; [2]None, Chicago, IL; [3]Rush University, Chicago, IL; [4]Rush University Medical Center, Chicago, IL; [5]University Medical Center Hamburg, Hamburg, Germany; [6]University of Michigan, Ann Arbor, MI.*

Background: Diabetic glomerulopathy is a major complication of Diabetes Mellitus (DM) and is the leading cause of end stage renal disease (ESRD). MicroRNA-146a (miR-146a) is a negative regulator of inflammation and is highly expressed in myeloid cells and in podocytes. We have previously shown that miR-146a levels are significantly reduced in the glomeruli of diabetic nephropathy (DN) patients. To study its role in podocyte function, we have generated mice with selective deletion of miR-146a in podocytes. Here we will present our results from studies in these animals.

Methods: We generated and characterized podocyte-specific miR-146a deficient mice. To investigate the role of miR-146a in glomerular function in vivo, we induced hyperglycemia in C57BL/6 wildtype mice (WT), global miR-146a knockout mice (miR-

146a-/-) and podocyte-specific miR-146a knockout (KO) animals using streptozotocin (STZ).

Results: We further confirmed that podocytic miR-146a expression decreased in the glomeruli of type 2 diabetes (T2D) patients and correlated with increased albuminuria and glomerular damage. Mice lacking miR-146a globally or selectively in podocytes showed accelerated development of glomerulopathy upon STZ-induced hyperglycemia. miR-146a targets, Notch-1 and ErbB4, were significantly upregulated in the diseased glomeruli and TGFβ signaling was induced. Treatment of podocytes in vitro with TGFβ resulted in increased levels of Notch-1 and ErbB4, increased ErbB4 phosphorylation, and increased expression of inflammatory chemokine MCP-1, which suppresses miR-146a via an autocrine loop. Similarly, administration of low-dose LPS to podocyte-specific miR-146a KO mice resulted in increased albuminuria as compared to the WT mice, further suggesting that podocyte-expressed miR-146a protects from glomerular damage.

Conclusions: We suggest a novel role for miR-146a in protecting against glomerular injury via protecting podocytes from injury and cell death. This indicates that miR-146a might have a therapeutic potential in DN.

SA-PO218

Cell Adhesion Function of β-Catenin in Podocytes Is Crucial for Glomerular Filtration Barrier Michelle Duong,[1] Beina Teng,[3] Hermann G. Haller,[2] Mario Schiffer.[2] *[1]Hanover Medical School, Hannover, Germany; [2]Hannover Medical School, Hannover, Germany; [3]Medical School Hannover, Hannover, Germany.*

Background: β-Catenin has two functions: it mediates cell adhesion and Wnt signaling. Its function depends on its subcellular localization, as membranous β-catenin locates at cell adhesion complexes with cadherin and α-Catenin. On the other hand, β-catenin transcriptional activity is regulated by a nuclear β-catenin localization. We have shown β-catenin interacts with PKCε and PKCε deficiency leads to a nuclear localization of β-catenin. PKCε -/- podocytes show a increased cell detachment, apoptosis and reduced differentiation. P-cadherin and IQGAP1 are proteins involved in membranous β-catenin stability. We therefore investigated the relationship of this complex in podocytes.

Methods: We performed time course Western blot of cell lysates of murine PKCε -/- podocytes and tested the IQGAP and P-cadherin expression. We used adenoviral PKCε and β-catenin constructs to overexpress these proteins in PKCε deficient podocytes. Immunofluorescent staining was performed on murine kidney sections and podocytes to examine the P-cadherin and vinculin expression. Zebrafish larvae were injected with β-catenin1 morpholino and localization mutant β-catenin RNAs to investigate their function *in vivo*.

Results: During the differentiation of PKCε -/- podocytes, IQGAP1 and p-cadherin expression was reduced compared to WT cells. Overexpression of not only PKCε, but also ß-catenin, could reverse this effect and led to an normal IQGAP1 expression. We saw in immunofluorescence and western blot analysis a downregulated vinculin expression in PKCε -/- podocytes, which could be reversed by β-catenin overexpression. β-Catenin1 knockdown in zebrafish led to with proteinuria and edema. This could be partially rescued with overexpression of a β-catenin mutant expressed in the membrane, while a β-catenin mutant expressed in the nucleus could not reverse proteinuria.

Conclusions: We show β-catenin as a upstream mediator of cell-adhesion by its regulation of the adherens junction proteins P-cadherin, IQGAP1 and focal adhesion molecules such as vinculin. This complex is disturbed in functionally disabled podocytes. ß-catenin is translocated to the nucleus in unhealthy podocytes and the cell-adhesion function of β-catenin plays a more important role in the maintenance of the glomerular filtration barrier in zebrafish. The Wnt signaling function of β-catenin alone seems not to promote kidney health.

SA-PO219

Podocytes from 129S1 Mouse Glomerular Outgrowths Can Be Used for Functional Studies Hong Wang,[3] Kathleen A. Lincoln,[4] Christina S. Bartlett,[1] Jay Kuo,[2] Steven S. Pullen.[3] *[1]Boehringer Ingelheim, Ridgefield, CT; [2]Boehringer Ingelheim Pharmaceutical, Inc., Ridgefield, CT; [3]Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT; [4]Boehringer-Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: Podocytes are specialized, terminally differentiated epithelial cells which are essential for integrity of the glomerular filtration barrier. Efforts to develop podocyte-directed therapies have been hampered by lack of *in vitro* systems for studying podocyte functions. Immortalized podocyte cell lines fail to represent native gene expression profiles, while the anatomic location of podocytes makes it difficult to study cell behaviors *ex vivo*. The 129S mouse strain is susceptible to and commonly used for models of renal disease, while currently primary mouse podocyte culture has been limited to use of the resistant C57BL/J strain. Therefore, we sought to isolate and characterize podocytes from glomerular outgrowths from 129S1 mice, a strain for which podocyte glomerular outgrowths have not been evaluated.

Methods: Glomeruli were isolated from 129S1/Svlm mice using Dynabead perfusion and magnetic isolation. We modified our protocol to include a brief collagenase incubation and MACS cell dissociation step to reduce handling time and increase viability. Purified glomeruli were resuspended in culture media and seeded on collagen IV coated plates. Intact glomeruli were removed after 4 days in culture. After 6 days, cells were treated with puromycin aminonucleoside (PAN) for 24 hours. Podocyte markers were measured using Taqman gene expression, and F-actin was visualized using fluorescent phalloidin.

Results: Expression of podocyte specific markers (nephrin, podocin, podocalyxin, synaptopodin, WT1, Glepp-1) was observed at 6 days of culture from 129S1 glomerular outgrowths. Nephrin gene expression was lost by 10 days of culture, although expression of other podocyte markers persisted. PAN treatment dose dependently up-regulated apoptotic genes, Caspase-3 and BAD, while podocyte markers and integrin gene expression were significantly reduced. Phallodin staining showed highly organized actin fibers present within the cytoplasm of cultured cells and was reduced by PAN treatment.

Conclusions: We successfully cultured primary mouse podocytes from the 129S1 mouse strain, modified the standard protocol to reduce glomerular isolation time, and identified the useful window of utility. This method will be valuable for rapid evaluation of genetic mouse models of podocytopathy and development of assays for podocyte functional assessment.

SA-PO220

Yap Dependent Mechanotransduction Determines the Podocyte's Response to Injury Markus M. Rinschen,[1] Tobias B. Huber,[2] Thomas Benzing,[1] Bernhard Schermer.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]University Medical Center Hamburg, Hamburg, Germany.*

Background: Podocytes, terminally differentiated cells of the kidney filtration barrier, are subjected to considerable mechanical strain by physiological filtration pressure, which can even be increased by severe hypertension. When injury causes cytoskeletal reorganization and morphological alterations of these cells, the filtration barrier may become compromised and allow proteins to leak into the urine (proteinuria). The activities of the transcriptional co-activators YAP and TAZ are tightly controlled by the Hippo signaling pathway and are sensitive to mechanical cues.

Methods: We used time-resolved quantitative proteomics in the in vivo and in vitro PAN model of podocyte injury.

Results: We show that podocyte injury stimulates YAP activity and the expression of YAP-dependent target genes in a rat model of glomerular disease prior to the development of proteinuria. In contrast, injury of cultured human and mouse podocyte cell lines reduced YAP and TAZ activity when the cells were grown on stiff substrates. However, culturing these cells on soft matrix or inhibiting stress fiber formation recapitulated the damage-induced YAP upregulation observed in vivo, indicating a mechanotransduction-dependent mechanism of YAP activation in podocytes. YAP overexpression in cultured podocytes enhanced the abundance of extracellular matrix–related proteins. YAP activity was increased in mouse models of diabetic nephropathy, and expression of the YAP target *CTGF* was observed in renal biopsies from patients with glomerular disease. Whereas overexpression of human YAP in mice induced mild proteinuria, pharmacological inhibition of the interaction between YAP and its partner TEAD in rats ameliorated glomerular disease and reduced damage-induced mechanosignaling in glomeruli.

Conclusions: We conclude that perturbation of the mechanosensitive Hippo signaling pathway is a potential therapeutic target for treating some glomerular diseases.

Loss of OMA1 Activates the mTOR Pathway but Fails to Rescue PHB2 Deficient Podocytes Independent of Stress-Induced OPA1 Processing Paul T. Brinkkoetter,[1] Alexander Kuczkowski,[1] Kristina Schoenfelder,[2] Bernhard Schermer,[1] Thomas Benzing.[3] *[1]University Hospital Cologne, Cologne, Germany; [2]University Hospital of Cologne, Cologne, Germany; [3]University of Cologne, Köln, Germany.*

Background: The dynamin-like GTPase OPA1 is conceived as a central regulatory hub that controls mitochondrial dynamics, fusion and fission respectively, under stress and in states of disease. Stress-induced OPA1 processing by the metalloendopeptidase OMA1 triggers mitochondrial fission as seen in podocyte-specific knock-out mice lacking prohibitin membrane scaffolds as a model of impaired mitochondrial function.

Methods:

Results: As reported previously, loss of prohibitins resulted in increased insulin and mTOR signaling and, subsequently, renal failure and premature death after 4-5 weeks after birth. Here, we studied the interplay between the peptidase OMA1 and prohibitins and their effect on mitochondrial function and the activation of the mTOR signaling cascade in glomerular podocytes. In contrast to neurons, genetic depletion of OMA1 failed to rescue renal function in PHB2 deficient podocytes and did not prolong animal survival despite stabilizing mitochondrial morphology. OMA1 single knock-out animals showed increased mTOR signaling activity at baseline without compromising renal function or animal survival. This activating effect on mTOR was additive to the PHB2 effect as OMA1/PHB2 double knock-out animals showed even stronger levels of mTOR activation.

Conclusions: Taken together, impairment of mitochondrial dynamics results in activation of mTOR, which is not sufficient to cause podocyte disease at baseline. Additional insults, such as increased cellular stress or a destabilized slit-diaphragm as shown for PHB2 are required to induce podocyte disease. These findings not only emphasize the central role of mitochondria to control insulin and mTOR signaling in podocytes but also provide additional evidence for an additional function of prohibitins in podocytes beyond their established role as protein scaffolds at the inner mitochondrial membrane to control mitochondrial fusion and fission.

Dlg1 Is a Novel Regulator of Slit Diaphragm Formation in the Drosophila Nephrocyte John S. Poulton. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Proper glomerular filtration requires the formation and maintenance of slit diaphragms (SDs) between podocyte foot processes. Mutations affecting SD formation/function result in nephrotic syndrome. SD formation is coupled to podocyte maturation, which involves changes in cell polarity. Previous work in mammals has revealed that apical polarity proteins play important roles in SD formation, however the basolateral polarity complex appears dispensable.

Methods: To further explore the role of polarity proteins in SD formation, I took advantage of the Drosophila nephrocyte, which form SDs analogous to vertebrate podocytes. The facile genetics of Drosophila allowed efficient screening of multiple RNAi lines targeting components of the basolateral polarity complex.

Results: Consistent with previous findings in mouse podocytes, I found no obvious role for the basolateral protein Scrib in SD formation. In addition, knockdown of Lgl, another key component of the basolateral complex also produced no defects in SD formation. Surprisingly, loss of Discs Large1 (Dlg1) led to dramatic mislocalization of core SD components, including the fly homologues of Nephrin, Neph1, and ZO-1. Transmission electron microscopy of Dlg1 knockdown nephrocytes revealed significant reduction in the number of SDs, though some small patches of nephrocyte surface did retain SDs. Intriguingly, numerous ectopic SDs were observed internal to the cell surface, lining the labyrinthine channels—a phenotype not observed in wildtype nephrocytes.

Conclusions: These data identify Dlg1 as a novel and vital regulator of SD formation and localization. Dlg1 is a highly conserved PDZ protein best known for its role as a scaffold in the basolateral polarity complex, where it helps define apicobasal polarity in polarized epithelia. However, our findings indicate that Dlg's function in SD formation is independent of its role in cell polarity. I am currently working to determine Dlg's mechanism of action in this new context and also test Dlg's potential role in SD formation in vertebrate podocytes.

SA-PO223

Novel Genetic Modeling of Podocyte Diseases and Early Mesodermal Development Bridgette Drummond, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

Background: Specialized renal epithelial cells known as podocytes create an essential filter that when comprimised is causitive of numerous kidney diseases. Podocyte morphology and genetic regulatory systems are conserved in zebrafish, making them a simplified and accessible model to study podocyte development and disease states.

Methods: To systematically elucidate the network of podocyte development genes, we have developed a haploid ethylnitrosurea (ENU) screen to identify novel podocyte regulators.

Results: In the emerging panel of these new congenital models of podocyte genesis, we have isolated classes of defects including podocyte abrogation, reduction of podocyte number suggesting alterations in proliferation or survival of the lineage, and delayed differentiation. Of these, one mutant that has been identified has a complete loss or significant reduction of several established podocyte markers. In conjunction with this, the pronephros is proximally abrogated and has a dramatic decrease in several solute-transporter cells that distinguish both proximal and distal tubule segments. Interestingly, several known renal progenitors that demarcate the intermediate mesoderm also reduced in these mutants.

Conclusions: Elucidation of the genetic lesions in these mutants will provide valuable insights into the molecular components that are involved in podocyte development, and possibly provide models for congenital defects and other kidney diseases.

TRPC5 Overexpression and Activation Do Not Per Se Cause Nor Augment Kidney Disease Xuexiang Wang, Ranadheer Dande, Hao Yu, Mehmet M. Altintas, Jochen Reiser. *Rush University Medical Center, Chicago, IL.*

Background: The transient receptor potential canonical cation channel, subfamily C, member 5 (TRPC5) is broadly expressed in brain and kidney with the capability to mediate the calcium (Ca^{2+}) influx as well as cell migration. It was reported that TRPC5 is vital for Ca^{2+} homeostasis in podocytes due to its location in podocyte foot processes. It is believed to regulate podocyte cytoskeletal remodeling through its association with active Rac1 GTPase. Genetic knockout or pharmacological inhibition of TRPC5 protects mice from albuminuria. However, the gain in function role of TRPC5 *in vivo* has not been explored.

Methods: Two novel transgenic mouse models (C57BL/6, B/6) were developed by overexpressing either wild-type TRPC5 (TG) or the dominant negative TRPC5 (DN, pore mutant), respectively. Highly expressed TRPC5 was validated by mRNA expression, Western blot and glomerular immunofluorescence (IF). The natural progression of proteinuria was quantified over time and histology was examined by the end at 8 months old mice. LPS-induced albuminuria was measured at 24 and 48 hours after two experiments with separate injection regimens and TEM of podocytes was analyzed. Treatment with TRPC5 agonist Englerin A and antagonist ML204 were performed and proteinuria was compared.

Results: TRPC5 mRNA and protein level were significantly higher in TG and DN compared with B/6. Glomerular IF exhibited stronger TRPC5 staining in two transgenic mice than B/6 mice. Neither TG nor DN developed increased proteinuria at 8 months old. Histology analysis showed no noticeable abnormalities at this age. Both single high dose LPS challenge and two lower doses LPS challenge demonstrated substantially augmented proteinuria. However, no difference in proteinuria was found among TG, DN and B/6. TEM analysis revealed a similar level of foot process effacement among three groups of animals. TRPC5 activator Englerin A injection induced no change in proteinuria. TRPC5 inhibitor ML204 treatment did not rescue kidney filtration barrier injury from LPS challenge.

Conclusions: Overexpression of TRPC5 does not cause kidney injury over time per se or more podocyte damage to LPS challenge. Neither agonizing nor antagonizing TRPC5 by drug affects the podocytes function and proteinuria level. TRPC5 appears not as a mediator of glomerular kidney disease. Its role in other renal diseases requires further study.

SA-PO225

Ephrin-B1 Bound to Nephrin at the Slit Diaphragm Controls Podocyte Function through the JNK Pathway Independently with Nephrin Phosphorylation Yoshiyasu Fukusumi, Ying Zhang, Hiroshi Kawachi. *Dept. Cell Biology, Kidney Research Center, Niigata University, Niigata, Japan.*

Background: We have reported ephrin-B1 is a novel component of the slit diaphragm (SD), and interacts with nephrin via their extracellular domains in cis form. We also reported that the podocyte-specific ephrin-B1 conditional knockout (CKO) mice showed proteinuria and disarrangement of the SD molecules. However, the precise function of the ephrin-B1 and nephrin at the SD is not well elucidated yet.

Methods: The mechanisms of the phosphorylations of ephrin-B1 and nephrin, and their downstreams were analyzed with HEK293 cell system, the rat nephrotic model and the ephrin-B1 CKO mice. The role of the nephrin-binding ephrin-B1 in regulating cell function was analyzed.

Results: Analyses with the HEK cells showed that not only nephrin but also the nephrin-binding ephrin-B1 was phosphorylated by the anti-nephrin antibody stimulation, and that the phosphorylation was Src kinase dependent. By contrast, the nephrin bound to ephrin-B1 was not phosphorylated by the stimulation to ephrin-B1. The ephrin-B1 co-transfected with the truncated nephrin lacking phosphorylation sites was phosphorylated more evidently, indicating the nephrin phosphorylation lowered the phosphorylation of the nephrin-binding ephrin-B1. Although the phosphorylation of nephrin was enhanced by the co-expression with ephrin-B1, the co-expression of the ephrin-B1 lacking tyrosine residues did not enhance, indicating the phosphorylation of ephrin-B1 is necessary for the enhancement of nephrin phosphorylation. Ephrin-B1 phosphorylation was also detected in glomeruli of the nephrotic model caused by anti-nephrin antibody. The phosphorylated ephrin-B1 phosphorylated JNK evidently. By contrast, nephrin signaling did not phosphorylate JNK. JNK phosphorylation was not detected in glomeruli of the ephrin-B1 CKO mice. The wound-healing assay with the HEK cells showed that the phosphorylation of ephrin-B1 promoted the cell motility, while nephrin did not promote it.

Conclusions: The phosphorylations of nephrin and the nephrin-binding ephrin-B1 were causally regulated, and the phosphorylation of the ephrin-B1 transferred the signals to downstream via another route of the nephrin signaling. Ephrin-B1 controls podocyte function through JNK pathway. The ephrin-B1 resided together with nephrin at the SD plays an essential role in maintaining the podocyte function.

Nephrin Is Necessary for Podocyte Recovery Following Injury in an Adult Mature Glomerulus Rakesh Verma, Madhusudan M. Venkatareddy, Theodore Z. Li, Sanjeevkumar R. Patel, Puneet Garg. *University of Michigan, Ann Arbor, MI.*

Background: Nephrin (*Nphs1*) is an adhesion protein and is expressed at the podocyte intercellular junction in the glomerulus. *Nphs1* mutations in humans or deletion in animal genetic models results in a developmental failure of foot process formation. Though nephrin is essential for foot process (FP) development, its role following development is not well defined. In order to understand the role of nephrin following developent we initially generated a nephrin flox mouse. Using this mouse we were able to delete nephrin in an inducible manner using tamoxifen (*Nphs1*$^{Tam\text{-}Cre}$).

Methods: Mice with podocyte specific deletion of nephrin were generated by breeding *Nphs1*$^{fl/fl}$ mice with *NPHS2*-Cre and tamoxifen-inducible (*NPHS2-Cre)* mice. We used biochemical and cell biology techniques to assess nephrin expression in the glomeurlus. Protamine sulfate (PS) and nephrotoxic serum (NTS) were used to study the role of nephrin following injury and in recovery.

Results: Deletion of nephrin using *Nphs2-Cre* resulted in FP spreading and proteinuria by 10-12 d following birth. Nephrin expression decreased by 85% at 10 days post-induction with tamoxifen. The *Nphs1*$^{Tam\text{-}Cre}$ mice had normal FP ultrastructure and intact filtration barrier upto 4-6 weeks post-induction. Interestingly, nephrin expression persisted at the slit diaphragm upto 16-20 wks post-tamoxifen. *Nphs1*$^{Tam\text{-}Cre}$ mice developed proteinuria 8 wks following induction along with FP structural changes. Nphs1$^{Tam\text{-}Cre}$ mice 2 wks post induction subjected to PS model of podocyte injury, demonstrated failure of recovery following heparin sulfate. Similarly, Nphs1$^{Tam\text{-}Cre}$ mice failed to recover following NTS with persistence of proteinuria and FP effacement.

Conclusions: As in development nephrin is necessary for maintenance of a healthy glomerular filter. Interestingly, nephrin expression persists for several months following

deletion. The small fraction of nephrin that remains is relatively stable and is sufficient to maintain the junction for 4-6 wks. It is likely that some nephrin is either recycled continously at the membrane or is stably linked to actin. Following injury, recovery requires larger amount of nephrin as evident by failure of recovery following PS and NTS injury. This would suggest that induction or maintanence of nephrin expression would be benefical to prevent proteinuric kidney diseases.

Novel Methods to Analyze Mechanisms of TRPC6 Activation

Asim B. Dey,[1] Fang Li,[1] Simon J. Atkinson,[2] Mark Kowala,[1] Mark Rekhter.[1] *[1]Eli Lilly and Company, Indianapolis, IN; [2]Indiana University - Purdue University Indianapolis, Indianapolis, IN.*

Background: TRPC6 is a calcium channel activated by diacylglycerol (DAG) and reactive oxygen species (ROS). TRPC6 mutations are associated with proteinuria in human focal segmental glomerulosclerosis. New data suggest that circulating factors in diabetes induce kidney injury via TRPC6-mediated calcium flux. It is unknown how different factors activate TRPC6. The goal of this study was to develop a platform for analysis of DAG and ROS in TRPC6 activation.

Methods: Full length human TRPC6 cDNA was cloned into pcDNA5/TO (Thermo Fischer) under CMV promoter and transfected into HEK293 cells. Stable clones were selected based on the TRPC6 expression. Calcium signaling was analyzed using FLIPR membrane potential assay. DAG synthesis was monitored using recombinant circularly permutated probe, Downward DAG (Montana Molecular). Cells were infected with baculovirus carrying the biosensor construct. Fluorescent signal was captured using FLIPR. For ROS detection, cells were stained with Cell-ROX dye and analyzed using confocal microscope.

Results: The stable cell line, C11, showed >7000x increase in hTRPC6 gene expression. Calcium signaling was stimulated in a dose-dependent manner by angiotensin II (AngII), 1-oleoyl-2-acetyl-sn-glycerol (OAG), endothelin 1 and hyperforin 9 (Hyp9), specific activator of TRPC6. DAG signal was increased by Hyp9 and endothelin 1, but not by AngII. However, AngII but neither Hyp9 nor endothelin 1 induced ROS formation.

Conclusions: We generated novel tools to investigate mechanisms of TRPC6 activation and demonstrated differential involvement of DAG and ROS in TRPC-induced calcium flux.

The Role of APOL1 and Cholesterol Dependent Podocyte Injury in Focal Segmental Glomerulosclerosis

Mengyuan Ge,[1,2] Alexis J. Sloan,[1,2] Javier T. Varona Santos,[1,2] Christopher E. Pedigo,[1,2] Armando Mendez,[3] Jeffrey B. Kopp,[4] Sandra M. Merscher,[1,2] Alessia Fornoni.[1,2] *[1]Katz Family Division of Nephrology and Hypertension, University of Miami Miller School of Medicine, Miami, FL; [2]Katz Family Drug Discovery Center, University of Miami Miller School of Medicine, Miami, FL; [3]Diabetes Research Institute, University of Miami Miller School of Medicine, Miami, FL; [4]Kidney Disease Section, National Institute of Diabetes and Digestive and Kidney Diseases, National Institute of Health, Bethesda, MD.*

Background: Focal segmental glomerulosclerosis (FSGS) is the most common primary glomerular disorder causing chronic kidney disease (CKD). Susceptibility to FSGS in African Americans is associated with the presence of genetic variants of the Apolipoprotein L 1 gene (APOL1) named G1 and G2. APOL1 is an integral component of high-density lipoprotein (HDL) particles suggesting it might be involved in cholesterol efflux from cells. We recently established that the pathogenesis of FSGS is linked to tumor necrosis factor (TNF)-mediated, ATP-binding cassette transporters A1 (ABCA1) dependent impairment of cholesterol efflux from podocytes, which are key cells of the glomerular filtration barrier preventing the development of proteinuria in kidney disease. In addition to ABCA1, ABCG1 was shown in other cells to play an important role in cholesterol efflux from cells.

Methods: HeLa cells were stably transfected with lentivirus carrying the APOL1 risk variants under the CMV promoter. Immortalized human urine derived epithelial cells (HUPECs) were established from patients with FSGS carrying different APOL1 genetic variants.

Results: Here we tested the hypothesis that APOL1 confers susceptibility to proteinuric kidney disease by modulating cholesterol efflux from podocytes. We show that APOL1 risk variant expression in HeLa cells leads to decreased cholesterol efflux. The expression of APOL1 risk alleles in HUPECs was not associated with significantly decreased cholesterol efflux from podocytes. However, we observed decreased ABCG1 and APOL1 expression ($p<0.01$) in the absence of ABCA1 repression. TNF and Interferon (IFN) treatment increased the expression of APOL1 ($p<0.001$) in urinary podocytes.

Conclusions: Our data reveal that APOL1 risk variant expression may play a role in modulating cholesterol efflux from podocytes, which may contribute to APOL1 mediated genetic susceptibility to FSGS.

SA-PO229

Vangl2 Is Associated with Ephrin-B1, a Novel Critical Component of the Slit Diaphragm, and Its Downregulation Is Involved in the Initiation Event of the Podocyte Injury

Yoshiyasu Fukusumi, Ying Zhang, Hiroshi Kawachi. *Dept. Cell Biology, Kidney Research Center, Niigata University, Niigata, Japan.*

Background: Podocyte-specific ephrin-B1 conditional knockout (CKO) mice showed proteinuria and disarrangement of the slit diaphragm (SD) molecules. However, the interaction of ephrin-B1 with other podocyte molecules is not well analyzed. To identify the molecules related with ephrin-B1, the gene expression profile in glomeruli of the CKO mice was analyzed by RNA-seq. The profile showed 260 molecules were downregulated to less than 50% in glomeruli of the CKO mice. We found a planar cell polarity protein vangl2 was evidently downregulated. It is reported that vangl2 plays an important role in podocyte maturation. However, the interaction of vangl2 with ephrin-B1 and the role of vangl2 in the development of nephrotic syndrome were not investigated.

Methods: The expression of vangl2 and its interaction with ephrin-B1 and other SD molecules were analyzed in glomeruli of the ephrin-B1 CKO mice and three types of rat nephrotic models, the SD specific injury caused by the anti-nephrin antibody (ANA), puromycin aminonucleoside (PAN) nephropathy, a mimic of MCNS, and adriamycin (ADR) nephropathy, a mimic of FSGS.

Results: The decrease of vangl2 mRNA expression in glomeruli of the ephrin-B1 CKO mice was confirmed by the qRT-PCR ($33 \pm 21\%$ to control, $p < 0.01$). The immunostaining of vangl2 was evidently decreased in the CKO mice. In ANA nephropathy, mRNA expression of vangl2 was already decreased at 1 h (1h, 27%, $p < 0.05$; day 1, 13%, $p < 0.01$; day 5, 34%, $p < 0.05$). The intensity of the vangl2 staining clearly decreased at 1 h when the nephrin staining was not decreased yet. The staining of vangl2 decreased also in PAN nephropathy, although the mRNA expression was not altered. In ADR nephropathy, the intensity of the vangl2 staining was clearly decreased on day 7 and 28. By contrast, the mRNA expression of vangl2 was upregulated.

Conclusions: Vangl2 was clearly downregulated in the ephrin-B1 CKO mice. The decrease of the vangl2 staining in the nephrotic models advances the decrease of the expressions of ephrin-B1, nephrin and other SD molecules. It is plausible that the alteration of vangl2 expression is involved in the initiation event of the nephrotic syndrome. Vangl2 could be an early marker to detect podocyte injury.

Studying the Role of Tcf21 In Vitro and In Vivo

Felix Kliewe,[1] Andreas W. Kuß,[3] Maja Lindenmeyer,[5] Marcus J. Moeller,[2] Kerstin U. Amann,[4] Karlhans Endlich,[1] Nicole Endlich.[1] *[1]University Medicine Greifswald, Greifswald, Germany; [2]University of Aachen, RWTH, Aachen, Germany; [3]Universitätsmedizin Greifswald, Greifswald, Germany; [4]Department of Nephropathology, Erlangen, Germany; [5]Nephrological Center, Munich, Germany.*

Background: Dedifferentiation and loss of podocytes are the major causes of chronic kidney disease. The basic helix-loop-helix (bHLH) transcription factor Tcf21 plays an important role for the differentiation of podocytes and is strongly expressed in mature podocytes *in vivo*. Tcf21 -/- mice die in the perinatal period due to the failure in the development of the lung and the kidney glomeruli.

Methods: Since parietal epithelial cells (PECs) are still under debate to be a type of progenitor cell for podocytes, we performed comparative gene expression analysis between freshly isolated podocytes, cultured primary PECs and cultured primary podocytes of mice. Furthermore, we performed ChIP-Seq analysis to identify new putative interaction partners and target genes of Tcf21.

Results: We identified 644 differentially regulated genes in freshly isolated podocytes in comparison to PECs and podocytes in culture. Tcf21 was identified as one of the most upregulated genes in freshly isolated podocytes (24- and 15-fold, respectively) as compared to PECs and podocytes, respectively, in culture. Interestingly, the expression of Tcf21 in PECs induced **m**ultilobulation and **b**udding of the nuclei, and the formation of **mi**cronuclei (MBM). Furthermore, we found an increased number of tetraploid cells. The multilobulation of nuclei was reversible after the addition of nocodazole and taxol indicating an involvement of microtubules. By qRT-PCR and Western blot analysis we found that Tcf21 downregulates the transcription factor YY1. Co-expression of YY1 and Tcf21 rescued the formation of MBM. Moreover, we observed that Tcf21 levels regulate the expression of cyclins like cyclin D1 and cyclin D2, suggesting a role of Tcf21 in cell cycle control. Additionally, by ChIP-Seq analysis we identified a genome-wide Tcf21-binding site (CAGCTG), which matched the CANNTG sequence that is the common E-box binding motif used by bHLH factors. Interestingly, many of the Tcf21 targets genes are involved in the regulation of the cell cycle, cell division, microtubule-based processes and chromosome segregation.

Conclusions: Taken together, Tcf21 is a transcription factor that appears to be importantly involved in the cell cycle regulation and function of podocytes.

SA-PO231

Loss of Glomerular Endothelial Surface Layer and Cell Integrity Is Mediated by Increased Ednra and Crosstalk with Podocyte Derived Edn1 Kerstin Ebefors,[3] Robert Wiener,[1] Evren U. Azeloglu,[1] Borje Haraldsson,[3,2] Ilse S. Daehn.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Novartis, Gothenburg, Switzerland; [3]University of Gothenburg, Gothenburg, Sweden.*

Background: Chronic kidney disease is increasing in prevalence worldwide with the majority of cases caused by glomerular diseases, including diabetic and hypertensive nephropathy and glomerulonephritis. There is emerging evidence that the specialized fenestrated glomerular endothelial cells (ECs) maintain the charge selective barrier to proteinuria via the endothelial surface layer (ESL) or glycocalyx. The ESL is a polysaccharide gel that lines the luminal surface composed of glycosaminoglycans (GAGs). We have previously demonstrated that activated podocytes can release endothelin-1 (Edn1) causing stress and dysfunction of ECs via increased Edn receptor A (Ednra) and consequently, podocyte loss in mice. We hypothesize that podocyte-EC crosstalk results in loss of early glomerular endothelial integrity.

Methods: Ultrastructural assessment of glomerular ECs by scanning EM at different time points of Dox induced TGF-β type I receptor signaling specifically in podocytes (PodTbrI mice). We measured ESL thickness by intralipid infusion EM and IsolectinB4 (IB4). Atomic force microscopy (AFM) measured the nanomechanical properties of the ESL in murine glomerular ECs (mGEC), we measured IB4, heparan sulfate (HS) by FACS, Heparanase (Hpse) and Hyaluronidase (Hyal) expression by RT-PCR.

Results: Compared to ECs of control mice showing extensive fenestration, we detected a striking loss of fenestrae and significant cellular blebbing after 4d of Dox in the absence of foot process effacement and significant microalbuminuria. After 4d of Dox, there was a robust reduction of ESL thickness, decreased further over time, and the ESL loss was prevented by Ednra inhibitor BQ-123. We examined whether loss of ESL is mediated by podocyte released Edn1. mGEC were treated with Edn1, or co-incubated with supernatant from Control (CtrlSN) or Dox (DoxSN) treated PodTbrI podocytes. AFM measurements showed a significant reduction in ESL by Edn1 and DoxSN, concomitant with decreased IB4 and HS, and prevented by BQ123. Upregulation of Hpse and Hyal expression denoted increased GAG degradation and remodeling by ECs in response to podocyte Edn1.

Conclusions: We show evidence of early crosstalk between podocytes and glomerular ECs that results in loss of EC integrity preceding podocyte foot process effacement in glomerular disease.

SA-PO232

CLIC5A Protects Renal Glomeruli from Diabetes-Induced Damage Xin Wang, Laiji Li, Barbara J. Ballermann. *University of Alberta, Edmonton, AB, Canada.*

Background: Podocyte injury, including foot process (FP) effacement, is a critical early step in the development of diabetic nephropathy. Activated ezrin, podocalyxin and CLIC5A form a complex at the apical plasma membrane of FPs, coupling podocalyxin to actin. Disruption of this complex leads to FP effacement. We have shown that CLIC5A stimulates ezrin activation through Rac1-dependent $PI(4,5)P_2$ accumulation (*J Cell Sci 127:5164; 2014 & Kidney Int 89:833; 2016*). Here, we studied the role of CLIC5A in FP formation and diabetic nephropathy.

Methods: Conditionally immortalized mouse podocytes were differentiated for 14 days and infected with adenovirus-CLIC5A or vector. Cdc42 and Rac1 activity were determined by GTPase pull-down. Podocyte morphology was assessed by scanning electron microscopy (SEM) and confocal actin immunofluorescence (IF). Diabetes was induced with streptozotocin (50 mg/kg, IP X 5 days) in wild-type (WT) or CLIC5A deficient (KO) mice. Controls were given buffer IP. Histology was evaluated on Masson-Trichrome stained sections (n= 3-6 mice/group).

Results: In differentiated podocytes, CLIC5A raised active GTP-Cdc42 and Rac1 levels, it activated ezrin, and induced FP-like projections, observed by SEM and actin IF. In glomerular lysates of WT diabetic mice, CLIC5A, active ezrin and podocalyxin levels were reduced compared to nondiabetic WT mice. GTP-Cdc42/Rac1 complexes from renal cortex lysates of WT mice contained both, CLIC5A and the $PI(4,5)P_2$ generating enzyme PI4P5Kα (n=6). Notably, PI4P5Kα was absent from GTP-Cdc42/Rac1 pulldowns of KO mice (n=6). Diabetes strongly activated Cdc42 and Rac1 in WT and KO mice (n=3 each), but active ezrin was profoundly reduced in lysates and GTP-Cdc42/Rac1 complexes from KO compared to WT diabetic mice. Albuminuria, segmental glomerular sclerosis and interstitial fibrosis were significantly greater in CLIC5A KO diabetic mice than in WT diabetic mice.

Conclusions: In podocytes, CLIC5A activates Rac1 and Cdc42 and stimulates FP formation. The findings in mice that CLIC5A is necessary for the association of PI4P5Kα with GTP-Rac1/Cdc42, and that ezrin activation is profoundly reduced in diabetic CLIC5A deficient mice despite Rac1/Cdc42 activation, indicate that CLIC5A forms the critical link between the active GTPase(s) and PI4P5Kα which leads to $PI(4,5)P_2$-dependent ezrin activation. Inhibition of this novel mechanism contributes to diabetic nephropathy.

A Syndrome of IgA-Related Polycythemia Camille Cohen,[8,15] Séverine Coulon,[14] Kanit Bhukhai,[10] Michaël Dussiot,[9] Antoine Neuraz,[4] Martin Flamant,[1] Francois Vrtovsnik,[12] Aurelie Hummel,[16] Bertrand Knebelmann,[15] Laurent Mesnard,[13] Eric Rondeau,[2] Marc Benhamou,[7] Christophe M. Legendre,[3] Olivier Hermine,[11] Khalil El Karoui,[6] Ivan C. Moura.[5] *[1]APHP, Paris, France; [2]APHP; University Paris 6, PARIS, France; [3]Hôpital Necker, Paris, France; [4]Hopital Necker-Enfants Malades, APHP, Paris, France; [5]IMAGINE INSTITUTE, Paris, France; [6]IMRB, U955 Inserm Universite Paris Est Creteil, UPEC, CRETEIL, France; [7]INSERM, Paris, France; [8]U1151, INSERM, Paris, France; [9]INSERM U 1163 / CNRS ERL 8254, Paris, France; [10]Institut Imagine, Paris, France; [11]NECKER HOSPITAL, PARIS, France; [12]Hopital Bichat, AP-HP, Paris, France; [13]INSERM U702, PARIS, France; [14]Pharmacie, Grand Hôpital de l'Est Francilien, Meaux, France; [15]Nephrology, Hôpital Necker, Paris, France; [16]Nephrology, Necker hospital, Paris, France.*

Background: IgA nephropathy (IgAN) is associated with elevated levels of polymeric IgA (pIgA1) and circulating IgA1 complexes. We previously reported that pIgA1 controls erythropoiesis through activation of transferrin receptor (Coulon et al, Nat Med 2011), but data in patients are still lacking to involve pIgA1 in normal or pathologic erythropoiesis. In patients with IgAN and unexplained polycythemia, we hypothesized that pIgA1 could also be involved in the increased red blood cell production.

Methods: Sera from patients with IgAN and unexplained polycythemia (IgAN-Pcy, persistent hematocrit (Ht) >54%) were collected after written consent. Human progenitor $CD34^+$ cells with addition of IgAN-Pcy or control serum were plated in semi-solid methycellulose medium and quantified, and IgA1 depletion was performed as previously described (Coulon et al, Nat Med 2011). We performed a multivariate linear regression to analyze Hb levels among various groups of a CKD cohort (696 patients with glomerulonephritis but no ESRD, IgAN n=171), and in a post-transplant cohort (2600 patients, IgAN n=271).

Results: We report 6 patients with IgAN-Pcy who developed polycythemia (median Ht55%). No JAK2 mutations were found. All patients had normal blood oxygen level, as well as EPO levels (median 7.6 mUI/L, range 5.8-9.9) and abdominal ultrasound. In contrast, *in vitro* at low dose of Epo, we found that the number of erythroid burst forming unit (BFU-E)-derived colonies was increased in the presence of IgAN-Pcy serum compared to control (73 vs 52, $p<0.05$). Removal of IgA1 from IgAN-Pcy patients normalized the number of colonies while add-back of these IgA1 increased it to initial values. Emphasizing our finding, among glomerulonephritis, Hb level was significantly higher in patients with IgAN by multivariate analysis (13.1g/dL vs 12.2 g/dL, p=0.01). In the post-transplant cohort, the mean elevation of Hb at M3 and M12 compared to M0 was higher in IgAN compared to other patients (Δhb M0-M3 0.87 and 0.22g/dL; ΔM0-M12 1.36 and 0.71g/dL respectively), suggesting that Hb recovery is faster after acute anemia following renal transplantation.

Conclusions: These data suggest a role of pIgA1 in erythropoiesis regulation and describe a new etiology of polycythemia.

SA-PO234

The Loss of Heparin Sulphate Editing Enzyme Sulf1 Reduces VEGF Signaling and Enhances Endothelial Glomerular Injury and Albuminuria Anna K. Masseli,[1] Patricia A. Schroder,[4] Laura L. Beverly-Staggs,[3] Mario Schiffer,[1] Janina Müller-Deile,[2] Heiko J. Schenk,[1] Joon-Keun Park,[1] Hermann G. Haller.[1] *[1]Hannover Medical School, Hannover, Germany; [2]MHH, Hanover, Germany; [3]Mount Desert Island Biological Lab, Salisbury Harbor, ME; [4]Mount Desert Island Biological Laboratory, Salisbury Cove, ME.*

Background: The endothelial cell surface is covered by the heparin sulphate proteoglycans (HSPG). Alterations in the level of 6-*O*-sulfation of the HS chains modulate the binding and release of signaling molecules and affect vascular function. The regulation of the glycocalyx is not well understood. Heparan sulfate 6-*O*-endosulfatases (sulf1 and -2) regulate the binding properties of the glycocalyx. We tested the hypothesis that 6-*O*-sulfation is important for glomerular stability and that changes in 6-*O*-sulfation lead to glomerular damage and albuminuria.

Methods: To assess sulf-1 and -2 function *in vivo* we used a transgenic zebrafish model (Tg(*I-fabp*:eGFP-DBP) and measured edema formation and loss of fluorescent protein from the circulation after knock-down of sulf-1 and -2. We further tested whether loss of sulf enhanced glomerular injury in zebrafish using PAN injury. In addition, mice deficient for Sulf-1 and -2 were analyzed. Urinary albumin was measured by ELISA. Immunohistochemistry was performed on cryostat or on paraffin sections.

Results: Loss of Sulf-1 and -2A/B led to a dose-dependent increase in edema formation and albuminuria in zebrafish. Vascular permeability was enhanced after sulf-2 knock down. Reduction of sulfatases enhanced the PAN-induced albuminuria significantly. Vascular patterning was slightly affected by Sulf-2, indicating a role in vascular development of the isoform. In Sulf-2 deficient mice albuminuria occurred after week 4. The glomerular mesangium showed increased proliferation. Glomerular VEGF165 as well as p38 and pERK immunoreactivity were increased.

Conclusions: The level of 6-*O*-sulfation of HS chains of the glycocalyx is an important determinator of glomerular health and pathophysiology. Our results suggest that Sulf-1 and -2 regulate the signaling properties of VEGF and other growth factors in the renal microcirculation.

Endothelial Epas1 Deficiency Is Sufficient to Promote PEC Activation and FSGS in Experimental Hypertension Olivia Lenoir,[3] Yosu Luque,[4] Veronique Baudrie,[5] Placier Sandrine,[4] Laurent Mesnard,[4] Eric Rondeau,[1] Pierre-Louis Tharaux.[2] *[1]APHP; University Paris 6, PARIS, France; [2]INSERM, Paris, France; [3]U970, INSERM, Paris, France; [4]INSERM U702, PARIS, France; [5]inserm U970, Paris, France.*

Background: Focal segmental glomerulosclerosis (FSGS) is the most common primary glomerular disorder causing end-stage renal disease. It is still a complex, only partially understood disease. Progressive sclerosis represents a hallmark of focal segmental glomerulosclerosis. Genetic tracing studies showed that parietal epithelial cells participate in the formation of sclerotic lesions. The loss of podocytes triggers a focal activation of parietal epithelial cells, which subsequently form cellular adhesions with the capillary tuft. Meanwhile, in the absence of intrinsic podocyte alteration, the origin of the pathogenic signal that could trigger parietal epithelial cells recruitment is elusive. We studied the role of the endothelial PAS domain protein 1, a regulatory α subunit of the Hypoxia Inducible Factor complex, during angiotensin II-induced hypertensive nephropathy. Here, we hypothesized that endothelial EPAS1 could drive protection against Ang II-induced hypertension and glomerular injury leading to CKD.

Methods: To understand the role of endothelial EPAS1 during hypertensive nephropathy, we used a genetic approach to abrogate EPAS1 from endothelial cells in Ang II-induced hypertension in mice.

Results: We found that endothelial EPAS1 protects from glomerular injury induced by chronic hypertension. We also observed that endothelial EPAS1 abrogation aggravates podocyte and parietal epithelial cell (PEC) injury in a blood pressure-independent manner and impairs renal local vasoreactivity to Ang II.

Conclusions: The murine Ang II-induced hypertension developed in this study revealed a protective role of endothelial EPAS1 maintaining glomerular integrity during the hypertensive chronic insult. Interestingly, endothelial *Epas1* gene deficiency promoted podocyte damage and parietal epithelial cells activation and segmental sclerosis, supporting proof of principle that endothelial-derived signal can trigger FSGS. This also suggests that endothelial EPAS1 dysfunction could be a susceptibility factor for hypertension-associated FSGS lesions and CKD progression with endothelial *Epas1* functional variants or interacting pathways being potential key modifiers to understand secondary FSGS-lesions.

SA-PO236

Sphingosine 1-Phosphate (S1P) as a Novel Paracrine Mediator of Classic and Regenerative Functions of Macula Densa Cells Ina M. Schiessl, Anne Riquier-brison, Dorinne Desposito, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: Macula densa (MD) cells play a key role in the regulation of renal hemodynamics. Newly emerging non-classic MD functions include the release of tissue remodeling factors and the recruitment of renal progenitor cells. S1P-signaling contributes to cell migration and proliferation and regulates renal vascular development. Also, in vitro studies demonstrated that S1P-signalling acutely regulates glomerular hemodynamics. Hence, we hypothesized that S1P may be synthesized locally in the MD, and that MD-derived S1P may contribute to classic and regenerative cell functions.

Methods: To investigate if S1P signaling regulates glomerular hemodynamics in vivo, we evaluated the acute effects of the S1P analogue FTY720 [1 mg/kg] on single nephron GFR (snGFR) using intravital multiphoton microscopy (MPM) of C57BL6 mice. Cell proliferation was determined using Ki67 staining of frozen kidney sections from mice treated with L-NAME [500mg/L, per os] for one week with or without daily FTY720 injections [3 mg/kg]. The expression and regulation of known S1P synthesizing or activating enzymes in MD cells was studied using MD gene profiling with the translating ribosome affinity purification (TRAP) technique. To isolate translated mRNA from MD cells, adult nNOS-eGFR-L10a mice were used, which were either treated with low salt/enalapril [100 mg/L] or a normal diet for 2 weeks.

Results: FTY720 administration reduced afferent arteriole diameter by 10 % (n=7, p=.0232) and snGFR by 24% (n=11, p=.0013). In the L-NAME injury model, we found significantly more Ki67+ proliferating cells in FTY720-treated kidneys compared to control (8.3±1.3 vs. 5.1±0.7 cells/area, n=12, p<.05). Screening the MD gene profile for S1P-relevant enzymes revealed the expression of sphingosine kinase 1, ceramide synthases (CS) 1, 2, 4 and 6, and a 2-fold upregulation in response to MD-stimulating treatment for CS 4 and 6 (p<.05) as well as a 2.5-fold reduction of sphingosine-1-phosphate phosphatase 2 mRNA abundance (p<0.01).

Conclusions: Our data show that S1P acutely decreases glomerular blood flow and snGFR in vivo, enhances kidney cell proliferation, and that MD cells express and regulate several S1P synthesizing or activating enzymes. This suggests that MD cell-derived S1P may act as a paracrine regulator of classic and new tissue regenerative MD cell functions.

Tripartite Motif-Containing 55 (TRIM55) Participates in the Immune Response in Experimental Anti-Thy1 Glomerulonephritis Lei Chen,[2] Hongli Jiang.[1] *[1]Dialysis Center of First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi'an, Shaanxi, China; [2]Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: Mesangial proliferative glomerulonephritis (MsPGN) is considered as an immune-related disease. Its pathogenesis is involved with activation of mesangial cells and the subsequent immune inflammatory response. However, the mechanism underlying the regulation of immune response remains largely elusive. Tripartite motif family was reported to be closely related to immune regulation. In this study, we performed a series of experiments in vivo and vitro to investigate the role of tripartite motif-containing 55 (TRIM55), a member of tripartite motif family, in the progression of MsPGN.

Methods: 36 male SD rats were randomly divided into 6 groups, 5 of which were received tail vein injection of anti Thy-1 antibody (2.5 mg/kg body weight), and the remaining group was received PBS injection as negative control(NC). Specimens of the NC group were collected at 0d after the injection, while those of other groups were collected at 1d, 2d, 3d, 4d, and 5d, respectively. Immunohistochemical stainig of CD68 was performed to evaluate the level of macrophages infiltration. qPCR analysis of glomerulus was performed to examine the expression of TRIM55. Primary RMCs with overexpression of TRIM55 were obtained through plasmid transfection. In addition, si-RNA tranfection was used to knock down the expression of TRIM55 in primary RMCs. qPCR analysis was conducted to detect the level of cytokines, such as TNF-α, CCL2, CXCL6, CXCL10, and IL-6.

Results: PAS staining results indicated mesangial dissolution occurred since 1d, followed by inflammatory cell infiltration. CD68 immunohistochemical staining results showed that macrophages infiltration peaked at 1d and then decreased gradually. The expression of TRIM55 mRNA also peaked at 1d and decreased gradually, which was consistent with the trend of macrophages infiltration. In primary RMCs, knockdown of DBP led to down-regulation of the expression of cytokines (TNF-α, CCL2, CXCL6, CXCL10 and IL-6). On the other hand, the expression of those cytokines(TNF-α, CCL2, CXCL6, CXCL10 and IL-6) significantly increased in TRIM55-overexpressed primary RMCs.

Conclusions: The above results indicate that TRIM55 participates in the immune response in anti-Thy1 nephritis by regulating the production of cytokines. We duce TRIM55 may be a promising therapeutic intervention to ameliorate leukocyte infiltration in MsPGN.

SA-PO238

Nephronectin Is a Component of Novel Glomerular Adhesions That Regulate Mesangial Adhesion and Behavior Chitkale Hiremath, Denise K. Marciano. *University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Defects in the glomerular basement membrane (GBM) cause heritable glomerular disease and are associated with the majority of acquired glomerular diseases, although their role in pathogenesis of the latter is unclear. The GBM contacts all cells of the glomerular tuft, namely podocytes, endothelia, and mesangial cells, whose function is coordinated to form an integrated filtration unit. Much of the GBM is deposited between podocytes and endothelia, where it is well known to form a critical part of the permeability barrier. However, the GBM also interacts directly with mesangial cells. Currently, little is known of specific GBM-mesangial interactions and their role in glomerular development, maintenance, and disease.

Methods: We utilize several mouse models in this study including conditional deletion of *Npnt*, the gene encoding nephronectin, using the *Six2-cre* line and *Podocin-cre* line.

Results: We find nephronectin, a GBM component and known ligand of α8β1 integrin, is produced by podocytes and deposited into the GBM, where it is required for formation of a novel GBM-mesangial cell adhesion structure. These specialized adhesions occur at sites of mesangial cell protrusion that are highly enriched in α8β1 integrin and appear to anchor capillary loops. Absence of nephronectin disrupts these adhesion structures, leading to mislocalization of α8β1, a pronounced increase in mesangial cell number, and mesangial sclerosis.

Conclusions: These results demonstrate a novel role for nephronectin-α8β1 integrin in a newly described adhesion complex.

Impact of Tryptophan Metabolism Alteration by Kynurenine 3-Monooxygenase Inhibition on Renal Cells and Its Role in Diabetic Kidney Disease Patricia Bolanos-Palmieri,[1] Patricia A. Schroder,[2] Heiko J. Schenk,[1] Janina Müller-Deile,[1] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Mount Desert Island Biological Laboratory, Salisbury Cove, ME.*

Background: The kynurenine pathway (KP) is the major route for tryptophan catabolism, and changes in KP metabolites correlate with renal complications in a diverse range of pathologies. Previous work from our group identified the enzyme kynurenine 3-monooxygenase (KMO) as a factor underlying the onset of proteinuria in diabetes by

contributing to morphological changes in podocyte foot processes. However, in spite of the correlational evidence for kynurenine involvement in the worsening of renal function, the pathological and functional significance of the increase in KP metabolites on renal cells remains unkown.

Methods: To assess if the enzymes of the KP are altered in diabetic kidney disease we performed IF staining of mouse kidney sections after Streptozotocin (STZ) injections, as a model for type I diabetes. Alongside this, cultured murine and human podocytes were analyzed upon inhibition of KMO to define the impact of KP dysregulation. Cell shape, size and substrate adherence were monitored. Finally, since KMO is an integral part of the mitochondrial membrane and the KP plays a role in the production of NAD^+, we assessed mitochondrial function of podocytes after KMO inhibition by measuring bioenergetics parameters in a microplate-based live-cell metabolic assay.

Results: In line with our previous results, STZ-injected mice show reduced KMO expression in the renal cortex. Similarly, the expression of Arylformamidase, that catalyzes the production of kynurenine, is altered in diabetes. This change is more prominent in the glomeruli, where a reduction in the nuclear localization of AFMID was observed. Furthermore, KMO inhibition in cultured podocytes resulted in a substantial reduction in average cell size, and changes in Paxillin staining show alterations in the focal adhesions, which correlate with an increase in cellular detachment. Moreover, the changes in spare respiratory capacity observed after KMO inhibition are consistent with mitochondrial dysfunction which could affect the cells' ability to respond to variations in energy demand.

Conclusions: Taken together, these results highlight the prominent role of the KP in the maintenance of podocyte function as its dysregulation has an impact on cell morphology, substrate adherence and metabolic profile.

Funding: Government Support - Non-U.S.

Macrophage Activation Syndrome (MAS) and Systemic Lupus Erythematosus (SLE): Early Diagnosis Improves Outcomes – Case Series from a Tertiary Centre Iolanda Godinho, Liliana Cunha, Allyson C. Egan, Tom Cairns, Matthew C. Pickering, Liz Lightstone. *Imperial College Lupus Centre, Hammersmith Hospital, London, United Kingdom.*

Background: MAS is a life-threatening complication of SLE, characterised by fevers, hyperferritinaemia, paenias, high triglycerides, abnormal liver, neurological & renal function. We report our case series & growing experience which led to improved recognition & outcomes

Methods: From clinical records & identifying all those patients in our lupus nephritis biopsy database (1997-2016, 475 patients, 806 biopsies) aged >18yrs with serum ferritin >2000ng/ml not explained by other causes, we report clinical & laboratory features & outcomes of 17 patients with 18 episodes of MAS.

Results: Of the 17 patients, 82% were female, median age 45 yrs (29-62). At time of acute MAS, 59% had new-onset SLE & 41% were flaring. Clinical & biochemical features summarised in table 1(image). Aggressive therapy with a combination of IV cyclophosphamide, plasma exchange, IV & oral steroids, IVIg & anti CD20 mAb was used. Where tolerated, tacrolimus given for 2 wks at presentation. Compared to dismal outcomes in the literature (as low as 34%), majority of patients responded to therapy (83%) though 3 (17.6%) died: 1 refractory to therapy & 2 in whom immunosuppression limited by infections.

Conclusions: This case series likely underestimates incidence: a) only a minority of patients with features of MAS have renal biopsies; b) until recently, few patients with severe SLE had ferritin measured acutely. MAS develops in context of a highly active SLE & should be screened for using serum ferritin, LDH, blood film, amylase & triglycerides to ensure early diagnosis. Our relatively low mortality & very high response rates reflect rapid diagnosis allowing early aggressive therapy aimed at quenching the inflammatory storm & treating the underlying SLE.

TABLE 1. CLINICAL and LABORATORY FEATURES	Number (%) of episodes
Fever	18 (100)
Splenomegaly (n=11)	2 (18)

Urinary AlphaM Subunit of Integrin Mac-1 Associates With Glomerular Inflammation in Lupus Nephritis Akimitsu Kitagawa, Naotake Tsuboi, Yutaka Kamimura, Takayuki Katsuno, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya-shi, Aichi, Japan.*

Background: One of the pathogenesis of glomerulonephritis is glomerular accumulation of leukocytes. Integrin Mac-1 is composed of a unique α (α_m; CD11b) complexed to a common β2 subunit (CD18) on neutrophils and monocytes/macrophages. Mac-1 has been demonstrated to support various immunological functions on glomerular endothelium including leukocyte recruitment and immune-complex clearance. Interestingly, leukocytes have been shown to release Mac-1 from the surface upon cell activation under inflammatory conditions. In the current study, we evaluated the association of urine levels of CD11b (U-CD11b) with histological disease activity in experimental animals with glomerulonephritis and patients with various glomerular diseases, in particular lupus nephritis (LN).

Methods: Antibody-mediated glomerulonephritis was induced by rabbit anti-mouse nephrotoxic serum in male C57BL/6J mice (NTS-GN). Urine and kidney samples from NTS-GN mice and from 272 patients with glomerular diseases including LN between 2008 and 2014 in Nagoya University were subjected to the study. Urinary concentrations of CD11b, hemoglobin scavenger receptor CD163 (U-CD163), and MCP-1 (U-MCP-1) were measured by ELISA. Glomerular $CD11b^+$ cells for neutrophils and monocytes/macrophages were also immunohistologically analyzed. In 118 LN patients, histological disease activity was evaluated semiquantitatively using the biopsy activity index (BAI).

Results: U-CD11b was evident on day 14 and elevated until day 21 in NTS-GN mice. In human patients, U-CD11b levels were significantly increased in ANCA-associated vasculitis and LN group, particularly in the ISN/RPS class IV. In LN, the number of

glomerular CD11b$^+$ cells was correlated with U-CD11b concentration (r=0.547) and BAI (r=0.643). It is of note that corticosteroid treatment significantly reduced U-CD11b excretion associated with the disease amelioration both in experimental animals with NTS-GN and human LN patients. In the ROC curve generated to predict ISN/RPS class III and IV subpopulations, area under the curve of U-CD11b (0.904, sensitivity: 89.7%, specificity:84.7%) was greater than that of U-CD163 and U-MCP-1.

Conclusions: These data collectively suggest that U-CD11b can be a useful biomarker for prediction of histological disease activity in LN.

SA-PO242

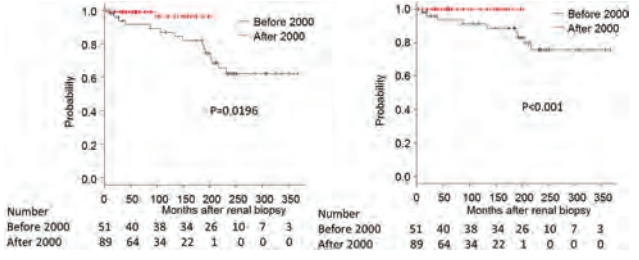
Improvement of Prognosis of Lupus Nephritis in Recent Years: A Single Center Retrospective Study Junya Suwa,[1] Hidekazu Ikeuchi,[1] Masao Nakasatomi,[2] Toru Sakairi,[1] Yoriaki Kaneko,[1] Akito Maeshima,[1] Yoshihisa Nojima,[2] Keiju Hiromura.[1] *[1]Department of Nephrology and Rheumatology, Gunma University Graduate School of Medicine, Maebashi, Japan; [2]Department of Rheumatology and Nephrology, Japan Red Cross Maebashi Hospital, Maebashi, Japan.*

Background: The treatment of SLE has been changing year by year, but it is not clear how the change actually relates to the improvement of the prognosis.

Methods: The treatment of lupus nephritis (LN) has been changing. In the present study, we examined the change of prognosis of LN in our facility.

Results: Median age was 34 years (IQR 28-47), median observation period was 105 months (IQR 47-189). ISN/RPS Class was follows: III(±V), 35 pts; IV(±V) 82 pts; pure V, 23 pts. The prognosis was significantly better in patients after 2000 in both renal events + patient death or renal events alone (P=0.0196 and P<0.001, respectively, Figure). In addition, frequency of proteinuric remission was significantly better in patients after 2000 at both of 6 months and 12 months after treatment (43.1% vs 68.9%, P<0.001; 60.7% vs. 78.7%, P= 0.031; respectively). There was no significant difference in levels of SCr and complements, and frequency of anti-DNA antibodies at baseline. Regarding the treatments, frequencies of steroid pulse therapy and dose of prednisolone were not different between the 2 groups, However, frequencies of immunosuppressants for the first induction therapy were different between before and after 2000: p.o. cyclophosphamide, 45.0% vs 3.3%, P<0.01; tacrolimus, 0.0% vs 11.2%, P=0.014; mycophenolate mofetil + tacrolimus, 0.0% vs 23.5%, P<0.01.

Conclusions: In our facility, the prognosis of active LN has been improved in recent years. The changes of immunosuppressants might contribute to better proteinuric remission rate at 6 and 12 months after induction therapy and lead to better long-term prognosis of LN.



Left: Renal events + Patient death, Right: Renal events

Acute Tubular Necrosis in Lupus Nephritis Shikha Wadhwani, Joshua Leisring, Anjali A. Satoskar, Samir V. Parikh, Brad H. Rovin. *Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Glomerular pathology drives management of lupus nephritis (LN) although acute tubular necrosis (ATN) is frequently seen on biopsy. The prevalence and significance of ATN in LN is unknown. To address these questions, we queried our native kidney biopsy data base.

Methods: 309 patients who underwent kidney biopsy from 2004 to 2011 were found to have LN. Pathology reports were reviewed for ISN/RPS class, glomerular histology, and tubulointerstitial damage, including presence of ATN. The relationship of ATN to patient demographics, pathology findings, and long-term outcomes were examined using Fischer's exact or Mann-Whitney tests, as appropriate.

Results: ATN was found in 78 (25%) LN patients. Patients with ATN had significantly higher serum Cr (2.18 ± 29 vs 1.55 ± 1.37 mg/dL; p<0.001) and proteinuria (4.66 ± 4.33 vs 3.22 ± 3.05 g/g; p=0.032) at time of biopsy than those without ATN. The presence of ATN was not affected by race or gender. Patients with active crescents (p = 0.006), glomerular capillary necrosis (p=0.035), or interstitial inflammation (p<0.001) were significantly more likely to have ATN than patients without these lesions. The degree of interstitial fibrosis and tubular atrophy was not increased in patients with ATN. Of the patients with at least 3 years of follow-up (mean 7.3 ± 2.2 years in ATN group, 8.4 ± 2.3 years in no ATN group), serum Cr at follow-up was not significantly different in those with ATN (n=20) and those without (n=62).

Conclusions: ATN commonly accompanies severe glomerular injury in LN, and is associated with impaired kidney function and high levels of proteinuria. However patients with ATN do not seem to have more long-term renal damage than patients without ATN.

Male Pediatric Lupus Nephritis Patients Experience Greater Mortality but Less Progression to ESKD Halei Benefield,[4] Meghan A. Jobson,[4] Anna L. Baldwin,[3] Eve Wu,[1] William F. Pendergraft,[2] Keisha L. Gibson.[2] *[1]The University of North Carolina, Chapel Hill, NC; [2]University of North Carolina Kidney Center, Chapel Hill, NC; [3]University of North Carolina School of Medicine, Chapel Hill, NC; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Epidemiological data on pediatric lupus nephritis are lacking. Here we present characteristics and outcomes of a racially diverse cohort of pediatric lupus nephritis patients.

Methods: We evaluated disease history and outcomes of patients age ≤ 19 years with tissue read by the UNC Nephropathology department as biopsy-proven lupus nephritis. Primary outcomes were end-stage kidney disease (ESKD) and death. Secondary outcomes included kidney transplant and adverse events per years of follow-up. Univariate logistic regression was used to calculate odds ratios and 95% confidence intervals with race (black or white) and sex coded as dichotomous categorical variables.

Results: Of 87 patients identified, 52 (60%) were female, 54 (62%) were black, 21 (24%) were white, and 12 (14%) were other. The mean follow-up duration was 11.6 years (SD 8.0). At diagnosis, 80% of patients presented with renal involvement, 59% with cutaneous symptoms, and 43% with hematological manifestations. The median age at biopsy was 14.6 years (IQR: 12.4, 17.2). 17 patients (20%) died with a median age at death of 20.8 years (18.9, 24.7). 18 patients (21%) progressed to ESKD with a median time to ESKD from first biopsy of 5.1 years (1.9, 7.4). Four patients (5%) underwent kidney transplant. Black patients experienced a median of 1.1 (0.4, 3.4) adverse events per 5 years of follow-up versus 0.6 (0.4, 1.2) in white patients; male patients experienced 0.6 (0.4, 1.7) events versus 1.6 (0.5, 4.0) in female patients. Black patients had 1.7 times the odds of death (95% CI: 0.4, 6.8) and 3.0 times the odds of ESKD (0.6, 14.7) compared to white patients. Male patients had 1.4 times the odds of death (0.5, 4.1) but 0.2 times the odds of ESKD (0.06, 0.9) as compared to female patients.

Conclusions: Our findings suggest that black pediatric patients with lupus nephritis have higher morbidity and mortality than white patients and that male patients have higher mortality but less renal morbidity than female patients. Longer follow-up and continued cohort enrollment will be important to broaden our knowledge of pediatric lupus nephritis.

SA-PO245

Evaluation of the slope of Change in eGFR as a Treatment Response Variable in Lupus Nephritis Ingrid R. Bispo, Evandro Klumb, Jose H. Suassuna. *Rio de Janeiro State University, Rio De Janeiro, Brazil.*

Background: In spite of treatment advances, up to 60% of lupus nephritis (LN) patients may eventually develop CKD. The commonest manifestations of LN include an active urinary sediment, proteinuria, and a loss of GFR. They are also the main tools determine treatment response, usually in a static fashion. We are not aware of any study that examined the predictive value of the slope of changes in renal function over time.

Methods: Out of 660 patients with SLE that attended our institution, between August of 2014 and June of 2016, we found and analyzed 227 patients with established LN. Estimated GFR by the CKD-EPI equation was evaluated longitudinally by linear regression and slopes calculated as ΔGFR in mL/min/month. Patients were grouped in tertiles of ΔGFR. Each tertile was analyzed by social-demographic, clinical, laboratorial and histopathologic features. Results were compared to treatment response variables as established in the literature. CKD and time to ESRD were analyzed as secondary outcomes.

Results: Women comprised 87% of the patients and mean age was 30 years. Proliferative GN predominated (77%) and mean of proteinuria at presentation was 3,6g/24h. The lowest tertile (worst response) was independently associated with race (Afro-Brazilians, p=0,05), lower levels of education (p=0,002) and with proliferative nephritides (p=0,03). Patients in this tertile also had more flares (p=0,003) but less active urinary sediment (p=0,03). On the other hand, the upper tertile (better response) was associated with higher education (p< 0,001), lower number of flares (p< 0,001), higher creatinine in the acute phase (p< 0,001). Subjects in low tertile and those that did not achieve complete response were more like to present CKD and ESRD.

Conclusions: The combination of traditional response variables along with slopes of change in GFR may provide an added discriminatory predictive value for evaluation of the treatment response in lupus nephritis.

SA-PO246

Impact of Extraglomerular Involvement on Clinical Presentation and Outcomes in Patients with Lupus Nephritis Krishan Lal L. Gupta, Hari A. Prasad, Manish Rathi, Aman Sharma, Ritambhra Nada. *Post Graduate Institute of Medical Education & Research, Chandigarh, India.*

Background: In patients with lupus nephritis, treatment and prognosis is characterized by its class which is based on glomerular pathology. Extra glomerular involvement, seen frequently was not considered in classification of lupus nephritis. Aim of this study was to analyze the incidence of tubulointerstitial and vascular involvement in lupus nephritis and their correlation with clinical presentation and outcomes.

Methods: This was a prospective retrospective cohort study including patients with biopsy proven lupus nephritis. A total of 241 patients were included in the study period between January2010 - June2016.

Results: The mean age of study population was 29 years. Among 241 patients in the study group, male: female ratio was 1:7. Although the clinical parameters at presentation were similar between the two groups, male patients had poor outcomes when compared with females (response rates 58.6%vs79.7%, P-0.04; resistant disease 34.5%vs15.7%, P-0.01). Interstitial involvement including interstitial inflammation, interstitial fibrosis and tubular atrophy was seen in 60.1% and vascular involvement was seen in 32.3% of biopsies (**Table1**). Patients with interstitial involvement had worse clinical parameters at presentation and poor outcomes at the end of 6 months of therapy (response rates 65.5%vs82.7%, P<0.01; resistant disease - 21.3%vs10.7%, P-0.03). Similarly in those with vascular involvement also had worse clinical parameters at presentation and poor outcomes (complete remission 38.2%vs61.9%, P<0.01; resistant disease - 26.3%vs14.3%, P=0.02). This trend of poor outcomes was especially seen in those with vascular TMA (response rates - 60%vs79.1%, P-0.04)(Table1).

Conclusions: The involvement of extraglomerular compartment in lupus nephritis patients is common and they play an important role in determining the outcomes along with glomerular lesions.

Distribution of Extra glomerular lesions on renal biopsy

TUBULOINTERSTITIAL INVOLVEMENT	145 (60.1%)	VASCULAR INVOLVEMENT	78 (32.3%)
Interstitial inflammation	93 (38.5%)	Asymptomatic vascular immune deposits	13 (5.3%)
Interstitial fibrosis/ Tubular atrophy	115 (47.7%)	Vasculopathy	5 (2%)
		Vasculitis	2 (0.8%)
		Vascular TMA	27 (11.2%)
		Arteriosclerosis	55 (22.8%)

Eculizumab in Refractory Lupus Nephritis with Thrombotic Microangiopathy Jessica M. Nelson,[1] Daniel J. Birmingham,[1] Huijuan Song,[1] James A. Tumlin,[2] Brad H. Rovin.[1] *[1]Ohio State University, Columbus, OH; [2]University of Tennessee College of Medicine, Chattanooga, TN.*

Background: A patient with refractory lupus nephritis (LN) developed thrombotic microangiopathy (TMA) and was treated with the anti-C5 monoclonal antibody eculizumab (ECU). The response to ECU was minimal, so we characterized C5 cleavage during ECU therapy.

Methods: Complement component C5 and the membrane attack complex (C5b-9) were measured by the complement laboratory at the University of Iowa. Urine C5a were measured by sandwich ELISA. The C5 cDNA was directly sequenced by Sanger methodology.

Results: A 38 year old Asian woman with SLE had an LN flare (class IV+V) and was treated with 6 months of pulse cyclophosphamide + methylprednisolone. Proteinuria and hematuria persisted and serum complement levels remained depressed. The patient developed Coomb's negative hemolytic anemia and thrombocytopenia with elevated LDH, prothrombin fragments, and fibrin split products, and was diagnosed with TMA. ECU was started. Complement levels after 3 months of ECU are shown (Table). Although the patient's platelets improved hemolysis continued, circulating C5b-9 was not suppressed and C5a levels were elevated in the urine. Paradoxically concurrent serum C5 levels were above normal. The C5 exons were sequenced but the single nucleotide polymorphisms (SNP) that alter arginine 885 and block ECU binding were not found. However 2 SNPs that affected the amino acid sequence (V802I and E1437D) were found.

Conclusions: ECU did not effectively block C5 cleavage in this patient, and may have caused elevated circulating C5. These findings may be due to genetic variants in the patient's C5 gene.

Funding: Clinical Revenue Support

Test	Pre-ECU	During ECU	Reference Range
Serum Creatinine (mg/dL)	0.7	0.5	0.5-1.2
Urine Protein:Creatinine	7.3	11	<0.2
Hemoglobin (g/dL)	6.8	11 (transfused)	11.7-15.5
Platelets (k/uL)	132	196	150-400
Haptoglobin (mg/dL)	-	<30	44-215
C3 (mg/dL)	26	52	87-200
C4 (mg/dL)	2	undetc	18-53
C5 (mg/dL)	-	36	10-21
Urine C5a (ng/mg creatinine)	-	20	<1
Soluble C5b-9 (mg/L)	-	0.4	<0.3

Clinical Parameters after Induction Treatment Are Better Predictors of 36-Month Renal Survival Than the Baseline Biopsy Histopathological Scores in Lupus Nephritis Sonia Rodriguez,[3] Luis E. Morales-Buenrostro,[1] Norma O. Uribe-uribe,[2] Juan M. Mejia-Vilet.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion, "Salvador Zubiran", Mexico City, Mexico; [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.*

Background: Baseline clinical parameters and histopathological scores have been associated with lupus nephritis (LN) outcomes. Recently, it was suggested that adding intimal hyperplasia findings to the NIH chronicity score (CS) may enhance its predictive value. We evaluated the capacity of before and after-treatment clinical and histopathological parameters to predict 36-month renal survival.

Methods: We included a cohort of 255 patients with class III, IV or V LN and a minimum 36-month follow-up. We registered clinical and histopathological parameters and determined their predictive value for 36-month renal survival by means of logistic regression and ROC curves. A new chronicity score (CS+vasc) was created by adding 0 or 1 point to the NIH chronicity score based on vascular intimal thickening findings.

Results: The cohort comprised 89% female patients, median age 28 years (IQR 23-37). Median baseline eGFR and proteinuria were 81ml/min (IQR 45-117) and 3.2g/g (IQR 1.9-5.3) respectively. Forty patients (15.7%) developed end-stage renal disease by 36 months. The ROC curves area under the curve were 0.732 for baseline eGFR, 0.602 for baseline proteinuria, 0.620 for the NIH activity score, 0.739 for the chronicity score, 0.760 for CS+vasc 0.760, 0.857 for 12-month eGFR, 0.835 for 12-month proteinuria (figure). A 12-month proteinuria <0.8 had 71% sensitivity and 88% specificity for 36-month survival (LR 5.70) The activity score was associated with lower renal survival exclusively at a cutoff over 10 points.

Conclusions: Post-treatment 12-month proteinuria is an individual good renal survival predictor. At baseline, the best predictor is the histopathological NIH CS, which improves little with the addition of points for intimal thickening evaluation.

Comparison of Tacrolimus and Mycophenolate Mofetil for Induction of Remission in Lupus Nephritis in Thailand: A Multicenter Randomized Controlled Trial Vuddhidej Ophascharoensuk,[1] Atiporn Ingsathit,[2] Sirirat Anutrakulchai,[3] Yingyos Avihingsanon,[4] Ratana Chawanasuntorapoj,[8] Pornpen Sangthawan,[5] Nuntana Kasitanon,[1] Warangkana Pichaiwong,[6] Pintip Ngamjanyaporn,[7] Vasant Sumethkul.[7] *[1]Chiang Mai University, Chiang Mai, Thailand; [2]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [3]Khon Kaen University, Khon Kaen, Thailand; [4]King Chulalongkorn Memorial hospital, Chulalongkorn University, Bangkok, Thailand; [5]Prince of Songkla University Hospital, Songkhla, Thailand; [6]RAJAVITHI HOSPITAL, Bangkok, Thailand; [7]Ramathibodi Hospital, Bangkok, Thailand; [8]Siriraj Hospital, Bangkok, Thailand. Group/Team: warangkana.*

Background: We conducted a prospective multi-center, opened-label, parallel, randomized, controlled trial to compare tacrolimus (TAC) and mycophenolate mofetil (MMF) for induction of remission in lupus nephritis (LN).

Methods: Adult patients with biopsy-proven LN ISN/RPS Class III-V and active nephritis were receive prednisolone (0.7-1.0 mg/kg/day for 4 weeks of run in period and tapered) and randomly assigned to receive TAC (0.1 mg/kg/day) or MMF (1.5–2 g/day) for 6 months. All patients who had remission received AZA 1-2 mg/kg/day as standard treatment in the maintenance phase. The primary outcome was the probability of complete remission (CR) at 6 and 12 months and the secondary outcomes included CR or partial remission (PR), renal parameter (UPCR, serum creatinine, and GFR), adverse events (infection, leukopenia, GI symptoms, new onset DM/hyperglycemia, and alopecia) and health related quality of life scores (EQ5D).

Results: 84 patients were randomized. One patient who was randomized to TAC group withdrew from the study immediately after randomization. Therefore, 42 patients were received MMF and 41 patients were received TAC. Median times to complete remission were 6.1 months and 5.1 months in MMF and TAC groups (P= 0.82). The probability of CR was similar between 2 groups (HR=0.99; 95%CI 0.53 to 1.85; P=0.97). The reduction in UPCR were similar between 2 groups during induction period but there were significantly increasing UPCR in TAC group at 12 months (P=0.03). There were worsening serum creatinine and GFR in TAC group compared with MMF group during induction period but both serum creatinine and GFR were similar after maintenance therapy. Infection occurred more frequently in MMF group. Other adverse events and EQ5D scores were similar between 2 groups.

Conclusions: TAC is effective as MMF for induction therapy of active LN class III-IV. It have less infections than MMF but transiently increased serum creatinine and decreased GFR compared with MMF. ClinicalTrials.gov ID: NCT01580865

The Long Term Outcome and Histological Transformation of ISN/RPS Class II Lupus Nephritis Abdulkareem Alsuwaida,[4] Amaar A. Bakhit,[5] Sufia Husain,[3] Feras A. Alsuwaida,[4] Junaid Wadera,[1] Hala M. KFoury.[2] *[1]KING KHALID UNIVERSITY HOSPITAL, RIYADH, Saudi Arabia; [2]KSU-KKUH, Riyadh, Saudi Arabia; [3]King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia; [4]King Saud University, Riyadh, Saudi Arabia; [5]King Saud University Medical City, Riyadh, Saudi Arabia.*

Background: There are discrepancies on the guidelines of the treatment of Class II LN due to the lack of scientific evidence. The role of immunosuppression, however, is less clear. The primary objective of this study is to assess the response of immunosuppressive therapy, the long-term prognosis and the histological transformation to other ISN/RPS classes among those who underwent a repeated biopsy.

Methods: A retrospective study was carried out that included patients who had received a diagnosis of LN class II on their first renal biopsy, between the years 1996 till 2016. The rate of complete remission, defined as Proteinuria less than 0.3 gm per day, with normal creatinine 6 month after biopsy were also evaluated. We also compared the histological transformation among those who underwent a repeated biopsy during the follow up.

Results: The study included 32 female patients with SLE and class II LN with the mean age of 31.2 years. The most frequent presentation (72%) was asymptomatic hematuria and/or subnephrotic range Proteinuria. The median serum creatinine and proteinuria at presentation were 78 umol/l and 0.8 gm per day, respectively. Acute kidney injury was noted in 7 patients (22%) and 3 patients (9.4%) had a nephrotic range proteinuria. The management was steroid alone in 25 patients (78%), Mycophenolate Mofetil in 6 patients (18.8%) and cyclophosphamide in 1 patient. Among the 25 patients treated with prednisolone alone (0.5-1 mg/kg), complete remission was seen in 23 patients (92%). After a median follow up of 8 years, two patients doubled their serum creatinine. The repeated biopsy was done in 17 patients (53%) and the detail of transformation to other classes is shown in table 1. The repeated biopsy showed transformation to other classes in 11 patients (65%).

Conclusions: Daily steroid monotherapy may be an appropriate first-line treatment for class II LN. Larger, prospective, trials are needed to validate this strategy and identify those patients who are less likely to obtain remission.

Funding: Government Support - Non-U.S.

Table 1. ISN/RPS classifications on repeat biopsy among 17 patients with baseline ISN/RPS Class II Lupus Nephritis

ISN/RPS II	ISN/RPS III	ISN/RPS IV	ISN/RPS VI
6 patients (35.3%)	5 patients (29.4%)	4 patients (23.5%)	2 patients (11.8%)

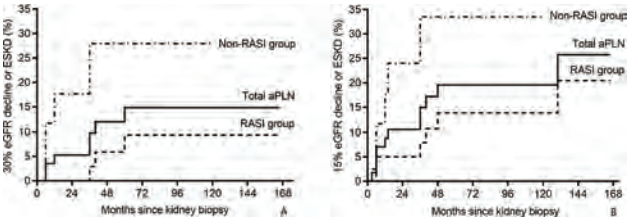
Early Renin-Angiotensin System Blockade Improved the Short-Term and Long-Term Renal Outcomes of Lupus Patients with Antiphospholipid-Associated Nephropathy Cai Yue, Guanhong Li, Xuemei Li, Ruitong Gao. *Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China.*

Background: Antiphospholipid-associated nephropathy (aPLN) represents a constellation of renal vasculopathies associated with antiphospholipid antibodies. Coexisting aPLN is associated with more severe renal involvement and worsened renal outcome in patients with lupus nephritis. Our aim with this research was to investigate the renal protective effects of early renin-angiotensin-aldosterone system (RAAS) blockade in lupus patients with aPLN.

Methods: Medical data of 57 lupus patients with biopsy proven aPLN were analyzed. Early RAAS blockade was defined as administration of renin-angiotensin system inhibitors (RASI) within 3 months after kidney biopsy and continued for at least 12 months.

Results: Patients were comparable in demographic data, laboratory findings, and renal histology by the time of kidney biopsy, except that the RASI group had higher proteinuria level (5.2 [2.8-8.8] vs 1.9 [0.6-2.8]g/d, p=0.005) and higher prevalence of hypertension (75 vs 29%, p=0.001). The two groups were comparable in estimated glomerular filtration rate (eGFR), mean arterial pressure (MAP), and proteinuria level at 12 months after kidney biopsy. The improvement ratio of eGFR at 12 months was significantly higher in the RASI group (26 [-5, 86] vs -2 [-20, 20]%, p=0.028), and the rate of change in eGFR after 12 months were comparable between groups. During a mean 80-months follow-up, 4 (23%) patients in the non-RASI group and 3 (8%) patients in the RASI group developed kidney disease progression. Early RAAS blockade significantly decreased the risk of kidney disease progression (HR 0.11 [0.02-0.59]; p=0.009). Proteinuria and hypertension controls were comparable between groups.

Conclusions: Early RAAS blockade improved the short-term and long-term renal outcomes in lupus patients with aPLN. The renal protective effect of RASI was independent of its antihypertensive and antiproteinuric effects.



Cumulative incidence of kidney disease progression in lupus patients with aPLN. A, kidney disease progression defined as 30% decline of eGFR or ESKD. 2B, kidney disease progression defined as 15% decline of eGFR or ESKD.

Successful Multitarget Therapy in Refractory Lupus Nephritis: A Retrospective Cohort Camila B. Oliveira,[1,2] Denise M. Costa,[1,2] Gisele Vajgel,[1] Carolina A. Vasconcelos,[2] Maria Alina G. Cavalcante,[1] Lucila Maria Valente.[1] *[1]Hospital das Clínicas - UFPE, Recife, Brazil; [2]IMIP, Recife, Brazil.*

Background: Multitarget therapy (MT) with mycophenolate mofetil (MMF), calcineurin inhibitor and steroids has been studied for induction treatment of lupus nephritis (LN). Nevertheless, its use in refractory LN is still being evaluated.

Methods: Retrospective cohort study of adult patients with refractory LN (EULAR/ERA-EDTA recommendations) treated with MT. Clinical characteristics, serological data and long-term follow-up were analyzed. Complete response (CR) and partial response (PR) were defined by KDIGO Clinical Practice Guideline for Glomerulonephritis.

Results: Data from 8 patients with refractory LN are shown in Table 1. The mean age was 34.6 ± 6 years and 87.5% were female. Mean sCr was 0.8 ± 0.2 mg/dl and median proteinuria was 3.7 (3.1 – 4.1) g/24h. All patients were treated with MMF (1 – 2g/day) plus cyclosporine A 2.5 – 4.0 mg/Kg/day (7 patients) or tacrolimus 0.06 mg/Kg/day (1 patient) plus steroids. After a follow-up of 18 (7.5 – 29.8) months, 7 patients had CR or PR, mean sCr was 1.0 ± 0.3mg/dl and median proteinuria was 1.4 (0.8 – 2.0) g/24h. There were no major adverse events (severe infections or drug nephrotoxicity).

Conclusions: MT successfully induced CR or PR in most patients with refractory LN with no major adverse events.

Table 1. Patients characteristics and long-term follow-up of Multitarget Therapy in refractory lupus nephritis

Predictors of Renal Outcomes in Sclerotic Class ANCA GN Steven Menez,[5] Sami Alasfar,[3] Zdenka Hruskova,[1] Jennifer O. Scott,[3] Min Chen,[6] Mark A. Little,[4] Vladimir Tesar,[3] Duvuru Geetha.[2] *[1]Department of Nephrology, General University Hospital and First Faculty of Medicine, Charles University, Prague 2, Czech Republic; [2]John Hopkins Bayview Medical Center, Baltimore, MD; [3]None, Rosedale, MD; [4]Trinity College Dublin, Dublin, Ireland; [5]Medicine, Div. of Nephrology, Johns Hopkins Medicine, Baltimore, MD; [6]Peking University First Hospital, Peking, China.*

Background: The ANCA GN classification has been shown to have prognostic value in ANCA associated glomerulonephritis (GN) with sclerotic class portending poor renal outcomes. Relevant published data on factors predicting outcomes in sclerotic ANCA GN is limited and these patients are not well covered in published guidelines.

Methods: Patients were recruited from 1998-2016 from 4 centers worldwide (N= 45) for this retrospective cohort study. All patients had biopsy proven sclerotic ANGN with > 50% of sampled glomeruli showing global sclerosis. We describe the clinical characteristics of this cohort and evaluate predictors of one year GFR and ESRD.

Descriptive data are described as mean (SD). Logistic and linear regression models were used as appropriate.

Results: Of the 45 patients, 91% were Caucasian and 58% male with a mean age of 60 years. 80% had new diagnosis, 71% had renal limited disease and 84% were MPO ANCA positive. Kidney biopsies contained a mean (SD) 25 (18) glomeruli, mean (SD) % sclerosed glomeruli was 69(12) with 96% showing moderate to severe interstitial fibrosis (IF). 43 patients received immunosuppressive therapy: 69% pulse solumedrol, 71% cyclophosphamide, 24% rituximab and 18% received plasmapheresis. Disease remission was achieved in all. The mean (SD) eGFR at entry was 15 (18) and at 1 year was 17(13) ml/min/1.73m^2. Entry GFR, rituximab use and IF but not % normal glomeruli were predictive of 1 year GFR (Table1). Over a mean (SD) follow up of 60 (58) months, 25 patients reached ESRD and baseline GFR predicted risk of ESRD (p=0.04).

Conclusions: Entry GFR, use of RTX and lesser degree of IF predicted better GFR at 1 year in sclerotic ANCA GN. Further studies are needed to validate these findings.

Predictors of GFR at 12 Months

	Correlation coefficient or mean difference	Confidence interval	P-value
Age	0.15	(-0.15 - 0.45)	0.31
Gender (Female)	0.67	(-8.33 - 9.68)	0.88
ANCA type (PR3)	3.6	(-9.29- 16.59)	0.57
GFR at Entry	1.27	(.90 - 1.63)	<0.0005
Use of RTX versus CYC	19.285	(10.65 - 27.91)	<0.0005
Glomerular Sclerosis >75%	6.15	(-4.016 - 16.31)	0.23
Percentage of normal glomeruli >2%	-1.69	(-10.80 - 7.4)	0.75
Degree of Interstitial Fibrosis	-8.56	(-15.88 -- -1.23)	0.0001

Pulmonary and Renal Outcomes in Patients with Pulmonary Renal Syndromes Treated with Plasmapheresis at VCU Christen Vagts, Catherine Grossman, Jason M. Kidd. *VCUHS, Richmond, VA.*

Background: Pulmonary renal syndromes (PRS) are a group of vasculitis syndromes characterized by pulmonary capillaritis, often resulting in diffuse alveolar hemorrhage, and glomerulonephritis. This includes anti-GBM disease and ANCA-associated vasculitis. The indications for plasmapheresis vary based upon the type of pulmonary renal syndrome and their presenting kidney function. The purpose of this study was to characterize patients with PRS treated with plasmapheresis at VCU, identify outcomes of pulmonary and renal functions of these patients, and to correlate estimated 30 day mortality with use of APACHE-II scoring with actual 30 day mortality.

Methods: A retrospective review of patients with PRS treated with plasmapheresis between 2006 and 2014 at VCU was conducted from a pre-existing database. Data regarding presentation, clinical course, follow up, and mortality were collected and evaluated.

Results: A total of 17 patients treated with plasmapheresis for a PRS were identified; eight had anti-GBM disease and nine had ANCA-associated vasculitis (AAV). 66% of patients with AAV were African American and 37.5% of patients with anti-GBM disease were African American. More patients with anti-GBM disease were tobacco users. Patients with AAV had a higher incidence of diffuse alveolar hemorrhage (78% vs. 25% patients with anti-GBM disease) and higher rates of intubation (78% vs. 11% patients with anti-GBM disease). More patients with anti-GBM disease presented with high degree renal failure, defined as Cr >5.7 (50% vs. 22% of patients with AAV). All patients with anti-GBM disease required hemodialysis (HD) during the plasmapheresis treatment period and all required chronic dialysis. In-hospital mortality was higher in patients with AAV (55% vs. 0% of patients with anti-GBM disease). APACHE-II scores appeared similar between the two groups, while both 30 day and 1 year mortality was higher in AAV (44% 30-day and 55% 1-yr mortality vs. 0% and 12.5% in anti-GBM disease respectively).

Conclusions: Patients with PRS requiring treatment with plasmapheresis had varying outcomes, with anti-GBM disease having overall worse renal-related morbidity but improved mortality when compared to ANCA associated disease.

SA-PO255

The Steroid Tapering in ANCA Vasculitis Evaluation Study (STAVE) 2: A Systematic Review and Meta-Analysis Jennifer C. Rodrigues,[1] David T. Collister,[1] Amy Archer,[3] Kim P. Cheema,[6] Christian Pagnoux,[2] Lehana Thabane,[7] Peter A. Merkel,[5] David R. Jayne,[4] Michael Walsh.[1] *[1]Nephrology, McMaster University, Toronto, ON, Canada; [2]Rheumatology, Mount Sinai Hospital, Toronto, ON, Canada; [3]Rheumatology, Northwestern University, Chicago, IL; [4]Rheumatology, University of Cambridge, Cambridge, United Kingdom; [5]Rheumatology, University of Pennsylvania, Philadelphia, PA; [6]Nephrology, University of Calgary, Calgary, AB, Canada; [7]Health Research Methods, Evidence, and Impact, McMaster University, Hamilton, ON, Canada.*

Background: Relapses of ANCA-associated vasculitis (AAV) are associated with death, decreased renal function, and ESRD. The role of glucocorticoids (GC) in relapse prevention is unclear.

Methods: MEDLINE, EMBASE, Cochrane Clinical Trials, and Grey Literature were searched from January 1, 2008 until May 26, 2016 without language restriction for studies with patients with AAV. GC use was specified *a priori* with minimum follow up of 18 months. Randomized controlled trials (RCT) and prospective cohort studies were included. Quality of evidence was assessed using modified Newcastle-Ottawa criteria. Meta-analysis was completed using a random-effects model of DerSimonian and Laird.

Results: 24 studies met criteria with 2272 patients. 13 (54%) discontinued GC in < 1 year. The pooled relapse rate was 14.3 per 100 patient years (95% CI 4.5,24.0). Relapse was more frequent when discontinuation was compared to long-term, low-dose GC (20.7 per 100 patient years, 95% CI 6.8,34.5 vs. 8.0 per 100 patient years, 95% CI 5.7,21.7 Figure 1). Multivariable linear meta-regression confirmed that long-term, low-dose GC was associated with lower relapse rates (β = -0.16, 95% CI -0.26,0.07, P = 0.001) and follow up time was associated with increased relapse rates (β = 0.003, 95% CI 0.001,0.006, P = 0.002). Multivariable linear meta-regression did not demonstrate any association of GC dosing with infections.

Conclusions: Long-term, low-dose GC was associated with decreased relapse rates in patients with AAV. Characterization and reporting of adverse events limited analysis. RCT are needed to determine optimal GC administration.

Outcome Predictors in Childhood-Onset Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis: Clinicopathological Analysis in a Nationwide Japanese Survey Daishi Hirano,[3] Kazumoto Iijima,[2] Shuichi Ito.[1] *[1]Department of Pediatrics, Graduate School of Medicine, Yokohama City University, Yokohama, Japan; [2]Dept. of Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Japan; [3]The Jikei university school of medicine, Tokyo, Japan.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) occurs mainly in adults (estimated annual incidence ~ 10–20 per million, peak age at onset 60 years). Little is known about the disease in children. Here, we examined clinicopathological predictors of patient and renal outcomes in childhood-onset AAV.

Methods: This was a retrospective nationwide multicenter survey of patients with AAV diagnosed before age 16. Eligibility criteria were: (1) fulfilled the Chapel Hill Consensus Conference criteria for microscopic polyangiitis (MPA) or granulomatosis with polyangiitis (GPA), and (2) kidney biopsy showing histology consistent with AAV.

Results: The cohort consisted of 46 children; 35 (76%) were female, 38 (83%) had MPA, 9 (17%) had GPA, 83% were MPO-ANCA-positive, 13% were PR3-ANCA-positive. Median age at onset was 10.7 years, and median time to diagnosis was 2.0 months. Initial symptoms included fever and fatigue (43%), renal (74%), pulmonary (30%), ocular (20%), and mucocutaneous involvement (22%). Clinical features differed between MPA and GPA. Remission was achieved after induction therapy in 27 (55%) cases. After a median follow-up of 3.6 years, 14 (30%) patients had chronic kidney disease stages 2–3. Seven (15%) patients progressed to end-stage renal disease (ESRD). Renal outcome was better in GPA than MPA. In univariate analysis, although sex, age at onset, and diagnosis delay were not associated with risk of progression to ESRD, type of AAV, nephrotic-range proteinuria, and histological chronicity indices predicted renal outcome. Nephrotic-range proteinuria was significantly correlated with histological chronicity ($r = 0.50$, $P < 0.01$) and was an independent predictor of ESRD on logistic regression ($P < 0.01$).

Conclusions: There were significant differences between two types of AAV in terms of clinical features and outcomes. Nephrotic-range proteinuria was an independent

predictor of ESRD. Nearly 90% of the cohort did not need renal replacement therapy at a median follow-up of 3.6 years, indicating that renal survival in childhood-onset AAV has improved with the development of modern therapies.

Design of the Maintenance of ANCA Vasculitis Remission by Intermittent Rituximab Dosing Based on B Cell Reconstitution versus a Serologic ANCA Flare (MAINTANCAVAS) Trial Frank B. Cortazar,[2] William F. Pendergraft,[1] Colleen B. Dunbar,[2] Karen A. Laliberte,[2] John Niles.[2] *[1]University of North Carolina Kidney Center, Chapel Hill, NC; [2]Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: B cell depletion with rituximab (RTX) is an effective strategy for maintenance of remission in ANCA vasculitis. Unfortunately, cessation of therapy is associated with a high rate of relapse, while indefinite continuation of fixed-dose treatment is associated with significant complications. No clinical trial data exists to guide the optimal use of RTX after two years of maintenance therapy. To address this unmet need, we designed the MAINTANCAVAS Trial.

Methods: The MAINTANCAVAS Trial is an open-label, randomized, and two-arm controlled trial to evaluate the efficacy of two RTX dosing strategies to prevent disease relapse: 1) RTX dosing upon B cell reconstitution (B cell arm), and 2) RTX dosing upon a significant rise in ANCA titer (ANCA arm). Eligible patients have a history of ANCA vasculitis and have completed at least 24 months of fixed-interval (i.e., every 4-6 months) RTX maintenance therapy in remission (BVAS-WG=0 and prednisone ≤ 7.5 mg/day). Upon randomization, patients discontinue fixed-interval RTX and are followed with clinical assessment and laboratory monitoring every three months. Patients assigned to the B cell arm are re-dosed with RTX 1 gm x 1 when the CD20 count rises above 10 cells/mm^3, while patients in the ANCA arm are re-dosed with RTX 1 gm x 2 (separated by 2 weeks) when the ANCA titer rises by pre-specified level. The primary outcome is disease relapse at 36 months. Secondary outcomes include significant adverse events, vasculitis damage, and RTX utilization. At an alpha level of 0.05 and power of 0.80, 180 patients are required to detect a 15% difference in relapse between the strategies.

Results: Enrollment commenced 6/7/2016. To date, a total of 43 patients have been enrolled. No relapses have occurred. Six patients in the B cell arm (n=22) have been re-dosed with RTX at the following times: 6 months (n=2), 9 months (n=3), and 1 year (n=1). No patients in the ANCA arm have been re-dosed. There have been no serious adverse events.

Conclusions: The optimal long-term RTX dosing strategy for maintenance of remission in ANCA vasculitis remains unknown. The MAINTANCAVAS trial should provide useful information to address this important question.

SA-PO258

Associated Clinical Characteristics in Anti-Neutrophil Cytoplasmic Antibody Negative, Pauci-Immune Crescentic Glomerulonephritis: Results of a Case Series at a Tertiary Care Center Prince Amaechi,[1] Evelyn Bruner,[3] Milos N. Budisavljevic.[2] *[1]Medical University of South Carolina, Charleston, SC; [2]Medical University of South Carolina----, Charleston, SC; [3]Medical university of south carolina, Charleston, SC.*

Background: Pauci-immune crescentic glomerulonephritis (PCGN) is the most common cause of rapidly progressive glomerulonephritis in adults and elderly patients. Approximately 10-30% of patients with PCGN have anti-neutrophil cytoplasmic antibody (ANCA) negativity. However the etiology of idiopathic ANCA-negative PCGN has never been clearly characterized besides a few case reports. We therefore conducted a case series of patients in our tertiary care center diagnosed with pauci-immune crescentic glomerulonephritis in the last 33 years to see if there was any specific associated factors.

Methods: We looked at all the patients in our hospital that had a diagnosis of pauci-immune crescentic glomerulonephritis from November 1994- June 2017. Those with additional diagnosis such as glomerular basement membrane disease or other autoimmune disorders were excluded. We identified 59 patients however, some had incomplete records and they were further excluded. The final number was 14 patients, of which 10 were ANCA- positive and 4 were ANCA-negative. Their medical records were evaluated for any associated medical conditions.

Results: Out of the 4 patients who were ANCA-negative, all of them had an infection that preceded their illness and that was clearly present at the time of renal failure diagnosis (100%); whereas, only 2 out of the 10 who were ANCA-positive had an associated infection with their illness (20%). In this small series of patients, the two categories of patients had a similar severity of illness as estimated by their Sequential Organ Failure (SOFA) Assessment Scores (averaging 3.6 and 3 respectively).

Conclusions: 100% of our patients with a diagnosis of ANCA-negative PCGN had associated infections preceding their illness, whereas this was true of only 20% of the ANCA-positive ones. The infections involved included BK virus, Parvovirus, Staph aureus pneumonia and streptococcal pneumonia. Our results suggest that there is a positive link between otherwise idiopathic ANCA-negative crescentic pauci-immune glomerulonephritis and a preceding episode of infection.

Relationship between ANCA positive vs negative with infection

ANCA- positive (+) infection = 2	ANCA- negative (+) infection= 4
ANCA-positive (-) infection = 8	ANCA- negative (-) infection = 0

ANCA- positive total n= 10, ANCA-negative total n= 4

SA-PO259

Relapse Free Survival after Steroid Withdrawal in ANCA Vasculitis Eirini LIOUDAKI,[5] Marie B. Condon,[4] Lubna Rashid,[3] Fiona E. Harris,[1] David Makanjuola,[4] Bhrigu Raj Sood.[2] *[1]Epsom and St Helier NHS Trust, Surrey, United Kingdom; [2]South West Thames Renal Unit, Carshalton, United Kingdom; [3]St Helier Hospital, London, United Kingdom; [4]St. Helier Hospital, Surrey, United Kingdom; [5]ST HELIER HOSPITAL, London, United Kingdom.*

Background: Current immunosuppressive regimens have made a marked difference to patient and organ survival; toxicity associated with long term treatment is recognised. Withdrawal of treatment is associated with disease relapse. It is unclear if there are cohorts of patients in whom immunosuppression can be withdrawn and if so when. We report, from our centre on the long term outcomes on 93 patients(pts) in whom steroid maintenance treatment was withdrawn after a stable remission was achieved.

Methods: 93 pts identified from a long term cohort of 219 pts presenting over a 13 year period. Data collected from medical records. Follow up ranged from 6 - 168 mths (median 60mths). Remission was achieved with standard induction (Plasma Exchange, Cyclophosphamide (cyclo) (oral or intravenous), mycophenolate mofetil (MMF) or Rituximab; all in combination with corticosteroid) and maintained with Azathioprine or MMF in combination with corticosteroid. In patients in whom a stable remission was achieved, withdrawal of corticosteroid would begin at 18 to 24 mths. We have looked at steroid withdrawal and subsequent disease activity.

Results: 38 female; 87 white ethinicity; median age at diagnosis of 69 yrs (range 18-89). Median creatinine (creat) at presentation was 309umol/L; 22 pts with a serum creat >500. Induction: 86 pts cyclo (6 oral, 80 IV); 1 Rituximab, 1 Azathioprine, 5 MMF. 30 pts received plasma exchange. Median time to cessation of prednisolone from induction was 25mths (4-93). 72 pts (77%) remain relapse free at a median of 39 months since steroid withdrawal (3-126). Antibody class or induction treatment did not predict relapse free status; neither did presentation renal function (median creat 309 in non relapse pts / creat 330 in relapse). Follow up of patients who had relapsed was longer than for those who are disease free; 110 (53-163) versus 66 (14-165) mths, however 62 patients have remained disease free for over 18mths off steroid. (median 24 (range 4-93)).

Conclusions: In this cohort we have so far not identified a clear predictor of steroid withdrawal without relapse, however 77% of our patients remain relapse free off steroid with significant follow up period. We would suggest that withdrawal of steroid should be the aim when patients have achieved a stable remission, and that this can be achieved safely with close monitoring.

SA-PO260

Combination Therapy with Rituximab and Cyclophosphamide for Remission Induction in ANCA Vasculitis Frank B. Cortazar,[3] Saif A. Muhsin,[3] William F. Pendergraft,[2] Zachary S. Wallace,[1] Colleen B. Dunbar,[3] Karen A. Laliberte,[3] John Niles.[3] *[1]Massachusetts General Hospital, Boston, MA; [2]University of North Carolina Kidney Center, Chapel Hill, NC; [3]Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Remission induction in ANCA vasculitis may be complicated by slow response to treatment and toxicity from glucocorticoids. More effective and less toxic regimens are needed.

Methods: Patients were included if they had ANCA vasculitis and were treated with a standardized remission induction regimen (SIR): Rituximab 1000 mg Q 2 weeks x 2 doses, oral cyclophosphamide 2.5 mg/kg x 1 week and 1.5 mg/Kg x 7 weeks (adjusted for eGFR), and a rapid prednisone taper that lowers the dose to ≤ 15mg/d by 1 month. Complete remission (CR) was defined as a BVAS-WG of 0 and a prednisone dose ≤ 7.5 mg/d.

Results: We identified 129 patients treated with the SIR, 31% of whom also received PLEX for RPGN or pulmonary hemorrhage (PH). Seventy percent of patients had MPO-ANCA and 30% had PR3-ANCA. Median time to CR was 4 months (IQR, 3.9 to 4.4), and by 5 months 84% of patients were in CR. Prednisone was tapered to discontinuation as tolerated, such that the median prednisone dose at 8 months was 0 mg/day (IQR, 0 to 2.5). In patients with RPGN (n=75), PR3-ANCA was associated with a greater increase in eGFR at 6 months compared with MPO-ANCA (16.1 [IQR 0.0 to 22.5] versus 5.6 [IQR, -0.4 to 15.6] ml/min/1.73m2; p=0.028). During the first year following CR, 1 major relapse occurred over 122 patient-years. Serious infections occurred more frequently in patients receiving PLEX and were associated with increasing age and PH. Four deaths occurred, 3 of which were associated with serious infections.

Conclusions: Combination therapy with rituximab and cyclophosphamide was efficacious, allowed for rapid tapering of high-dose glucocorticoids and was well tolerated.

SA-PO261

Plasmapheresis, Rituximab, and Low-Dose Cyclophosphamide for Remission Induction Therapy in Severe ANCA-Associated Vasculitis Kavita Gulati, Stephen P. McAdoo, Jack W. Galliford, Megan Griffith, Tom Cairns, Charles D. Pusey. *Imperial College London, London, United Kingdom.*

Background: Rituximab (RTX) is an established treatment for remission-induction in ANCA-associated vasculitis (AAV), though data regarding its use in immediately organ- or life-threatening disease are limited. We have studied the use of RTX as adjuctive therapy to plasmapheresis (PEX), cyclophosphamide (CYC) and oral steroids in patients presenting with diffuse alveolar haemorrhage (DAH) or severe renal failure (presenting requirement for dialysis or serum creatinine >500μ/L).

Methods: This is a cohort study of patients treated for severe AAV between 2011-15 with a combination of PEX, low dose pulsed i.v. CYC (6x500-750mg) and RTX (2x1g after completion of PEX) and tapered oral corticosteroids (initial dose 1mg/kg, maximum 60mg od) without intravenous steroids. Maintenance therapy was commenced at 3 months with azathioprine (MMF if intolerant) and patients received prophylactic treatment for PCP, peptic ulcer disease and osteoporosis. Data are reported as median & IQR.

Results: Thirty patients have been treated with this regimen, with median follow-up 2.1 yrs. Median age was 62 yrs (IQR 55-75); 50% were PR3-ANCA+ve, 50% MPO-ANCA+ve. Presenting BVAS was 21 (16-25), creatinine 452 μmol/L (338-590), and 43% required dialysis. DAH was present in 43%. Patients received 7 (7-10) plasma exchanges, and cumulative RTX and CYC doses were 2g (all patients) and 3g (2.5-3.5), respectively. At 6 months, 90% of patients were in remission (BVAS=0). All patients achieved B cell depletion (<1 cell/μL) and 83% became ANCA negative at median 5.1 months. The median time to B cell repopulation (>10 cell/μL) was 35 months. Sustained B cell depletion was associated with low rates of relapse during long-term follow up: at 1, 3 and 5 years, 96%, 84% and 75%, of patients, respectively, were in sustained remission. The serious infection rate was 0.4/yr and 6 patients developed hypoIgG. Renal survival was 72%, 64%, 64% at 1, 3 and 5 years. Overall patient surival was 93%, 79% 79% at the same respective time points.

Conclusions: This combination regimen was an effective remission-induction strategy in severe AAV. Long-term relapse rates and renal and patient survival were favourable in a cohort of patients presenting with life-threatening disease manifestations. Combination regimens warrant further investigation in severe AAV.

SA-PO262

ATwo-CentreCohortExperienceofAnti-GBMDisease MarilinaAntonelou,[2] Benjamin A. Oliveira,[2] Astrid Baumann,[1] Mark Blunden,[3] Mark Harber.[2] *[1]Royal Free Hospital, London, United Kingdom; [2]UCL centre for Nephrology, London, United Kingdom; [3]Royal London Hospital, London, United Kingdom.*

Background: The important determinant for the response of therapy and long term prognosis in anti-glomerular basement membrane (GBM) disease is early diagnosis. The aim of this study is to identify possible delays in the recognition and treatment of the disease and determine renal outcomes.

Methods: Retrospective review of cases of all patients identified as anti-GBM positive presenting in two tertiary referral centres and associated district hospitals between 1978 and 2016. Case notes, pathology archives and laboratory results were reviewed to collect demographic and clinical data at presentation and last follow-up.

Results: Forty nine patients presented across both sites with anti-GBM disease (28 at the Royal Free and 21 at the Royal London Hospital), 17 (34.7%) of which initially presented to a district hospital prior to transfer. Twenty five (51%) were male. Their median age was 58 (10-82) years and GBM titre 134(31-779) U/ml. Thirty (61%) had a renal biopsy. Seven (14%) had pulmonary haemorrhage at presentation. Figure1 shows different time interval points where delays can occur from presentation to treatment. The median follow up was 4 (0.5-37.9) years. 70% became dialysis dependent within a month of presentation. At last follow-up (n=41), 12(29.3%) were renal replacement therapy (RRT) dependent, 12(29.3%) had received a renal transplant and three (7.3%) were RRT independent. Fourteen (34,1%) patients died.

Conclusions: Patients with (GBM) disease are at increased risk of morbidity and mortality. Local review of clinical practice is crucial to avoid delays in establishing a diagnosis and initiating treatment.

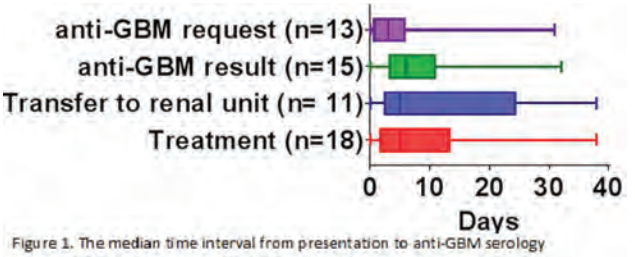

Figure 1. The median time interval from presentation to anti-GBM serology request 3(0.5-6) days, result 6(3-11)days, transfer to a tertiary unit 5(2-24) days and treatment 5(1.5-13.5) days.

SA-PO263

Describing the Natural History of C3 Glomerulopathy Chloe E. Gumpert,[1,2] Richard J. Smith,[2,3] Carla M. Nester.[2,3] *[1]University of Iowa Carver College of Medicine, Iowa City, IA; [2]Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; [3]Rare Renal Disease Clinic, Department of Pediatrics and Internal Medicine, University of Iowa, Iowa City, IA.*

Background: C3 glomerulopathy (C3G) is a rare, aggressive form of complement-mediated glomerular disease that carries the highest risk for irreversible renal failure of the known glomerular diseases. This dismal outlook results not only from a poor understanding of the natural history of disease (i.e. both what marks disease activity and what constitutes treatable disease), but also from the lack of disease-directed therapeutics. We have recently expanded the clinical data capture for our research subjects, and now include all patients with C3G seen in the University of Iowa's Rare Renal Disease Clinic. The following is the initial clinical cohort.

Methods: Data are derived from the clinic records of a contemporary cohort of 36 patients with a biopsy-proven diagnosis of C3G who have at least 1 year of clinical follow-up. Data are reported (without censoring for broader pathology characteristics) from time of presentation and at last follow-up.

Results: 29 C3GN and 7 DDD patients met criteria for evaluation. There was no difference in C3 at presentation or follow-up between the two disease types. No statistically significant difference was noted in eGFR at presentation. At last follow-up, 38% and 57% of C3GN and DDD patients respectively were at CKD Stage 3 or greater. DDD patients were more likely to progress to transplant.

Conclusions: C3GN and DDD are clinically similar, aggressive diseases with high risk for progression to late stage CKD. Routine clinical parameters and biomarkers of disease do not distinguish the two groups. Expansion of the cohort size and longitudinal re-evaluation is ongoing. Analyses of pathology and expanded biomarkers are ongoing. We expect this data will be critical for devising effective treatments for this group of patients.

Funding: NIDDK Support

Table 1. Clinical and biological data according to histological type

	C3GN (n=29)	DDD (n=7)	p value (α=0.05)
At Time of Disease Onset			
Serum Cr (mg/dL)	1.5	1.6	0.80
eGFR (mL/min/1.73m^2)	54.3	52.0	0.76
Serum C3 (mg/dL)	50.3	66.7	0.62
At Time of Last Follow-Up			
Mean Follow-Up (yrs)	4.6	3.8	0.97
Serum Cr (mg/dL)	2.7	3.7	0.61
eGFR (mL/min/1.73m^2)	53.4	46.5	0.91
≥ Stage 3 CKD	11 (38%)	4 (57%)	0.48
Serum C3 (mg/dL)	75.9	79.6	0.92

Overlap of C3 Glomerulonephritis and Thrombotic Microangiopathy Aishwarya Ravindran, Fernando C. Fervenza, Sanjeev Sethi. *Mayo Clinic, Rochester, MN.*

Background: Dysregulation of the alternate pathway (AP) of complement underlies the pathogenesis of both C3 glomerulonephritis (C3GN) and thrombotic microangiopathies (aHUS/TMA). In this study, we describe both the disease entities occurring in a series of 5 patients.

Methods: We identified 114 patients seen at the Mayo Clinic from 2007-2016 with a diagnosis of C3 glomerulopathy (C3GN or DDD) in native kidney biopsies. Patients with tissue diagnosis of thrombotic microangiopathy along with C3G were included.

Results: The median age at diagnosis was 58 years (range: 28-69), all were male. The median serum creatinine and proteinuria at presentation were 2.2 mg/dL (range: 1.7-3.2) and 2089 mg/24 hours (range: 250-5220). Monoclonal protein was present in 1 of the 3 patients tested. None of the patients had a history of infection or autoimmune disease. Light microscopy showed a membranoproliferative GN in 3 patients and a mesangioproliferative GN in 2 patients. Immunofluorescence showed bright C3 staining in the mesangium and/or capillary walls. On electron microscopy, capillary loops showed marked subendothelial expansion by fluffy material (and absence of deposits in these loops). However, capillary wall deposits were present in other loops in 4 (80%) of 5 biopsies. Mesangial deposits were present in all the biopsies. Ultrastructural features of DDD were not present; thus all biopsies were consistent with C3GN and aHUS/TMA. Complement studies showed low C3 in 4 (80%) patients, low C4 in 2 (40%) patients. Genetic evaluation of the AP showed positive CFH mutation and polymorphisms of CFB/CFH/CFHR5 genes in 1 patient tested. One patient had normal ADAMTS13, others were not tested. Of the 5 patients, 1 recieved steroid only; 1 received steroid and mycophenolate mofetil; 1 received therapeutic plasma exchange, steroid, eculizumab, cyclophosphamide; 1 was managed conservatively, and 1 was recommended therapeutic plasma exchange but lost to follow-up. At a median final follow-up of 18.3 months (range: 4-47.2), 1 progressed to ESRD, and for the remaining, the median creatinine and proteinuria were 2.5 mg/dL (range:1.4-3.6) and 1169 mg/24 hours (range: 947-2172), respectively.

Conclusions: We describe the clinicopathological features and renal outcomes of patients with features of both C3GN and aHUS/TMA. Dysregulation of the AP of complement can result in either C3GN, aHUS/TMA, or overlapping C3GN/aHUS.

SA-PO265

Triggering Factors and Associated Conditions in C3 Glomerulopathy Aishwarya Ravindran, Fernando C. Fervenza, Sanjeev Sethi. *Mayo Clinic, Rochester, MN.*

Background: C3 glomerulopathy (C3G), comprising C3 glomerulonephritis (C3GN) and dense deposit disease (DDD), is characterized by glomerular accumulation of complement proteins due to over activation of the alternative pathway of complement. Most of the reports on C3G are based on individual cases or small series of C3GN/DDD patients. There are no large scale studies describing the triggers/acquired conditions associated with C3G.

Methods: We identified 114 patients seen at the Mayo Clinic from 2007-2016 with a diagnosis of C3G, of which 102 (89.5%) had C3GN and 12 (10.5%) had DDD.

Results: Our study revealed 3 main triggers/acquired conditions associated with C3G: monoclonal Ig, infections and autoimmune diseases (figure 1). 1) Ninety five (83.3%) of the 114 patients were evaluated for a monoclonal Ig. Overall, 36 (37.9%) had a monoclonal Ig; furthermore 28 (65.1%) patient's ≥ 50 years had a monoclonal Ig. Twenty-six patients were classified as MGUS/MGRS, 5 as multiple myeloma, 2 as smoldering myeloma, 1 as CLL, 2 with cryoglobulins of which one was associated with lymphoma of the stomach. 2) Thirty-three (28.9%) patients had a history of infection at the time of diagnosis, with upper respiratory tract infection as the most common infection associated with C3G. Post-infectious GN was ruled out as these patients continued to have persistent hematuria long after resolution of the infection. 3). Twenty-seven (23.7%) patients had history of autoimmune diseases. The most common findings of autoimmunity was a positive ANA in 12 (12.2%), positive dsDNA in 6 (8.2%) and positive antiphospholipid antibody in 3 (4.1%) patients.

Conclusions: Triggering factors and acquired conditions are commonly present and can be the principal drivers of C3G. Each case should be evaluated for these conditions as these disorders can be important therapeutic targets in the management of C3G.

The Cure Glomerulonephropathy (CureGN) IgA Nephropathy and IgA Vasculitis Cohort David T. Selewski,[13] Josephine M. Ambruzs,[2] Gerald B. Appel,[5] Andrew S. Bomback,[4] Daniel C. Cattran,[10] Melissa Fava,[1] Brenda W. Gillespie,[13] Margaret Helmuth,[1] Jonathan J. Hogan,[6] Bruce A. Julian,[12] Richard A. Lafayette,[8] Patrick H. Nachman,[14] Cynthia C. Nast,[3] Jan Novak,[12] Michelle M. O'Shaughnessy,[9] Matthew Palmer,[15] Heather N. Reich,[10] Dana Rizk,[11] Bruce M. Robinson,[1] Neil S. Sanghani,[16] Melissa Sexton,[1] John Sperati,[7] Jarcy Zee,[1] Krzysztof Kiryluk.[4] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Arkana Laboratories, Little Rock, AR; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]Columbia University, New York, NY; [5]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [6]Hospital of the University of Pennsylvania, Philadelphia, PA; [7]Johns Hopkins University School of Medicine, Baltimore, MD; [8]Stanford University, Stanford, CA; [9]Stanford University Medical Center, Palo Alto, CA; [10]Toronto General Hospital, Toronto, ON, Canada; [11]University of Alabama, Birmingham, AL; [12]University of Alabama at Birmingham, Birmingham, AL; [13]University of Michigan, Ann Arbor, MI; [14]University of North Carolina School of Medicine, Chapel Hill, NC; [15]University of Pennsylvania, Philadelphia, PA; [16]Vanderbilt Nephrology, Nashville, TN. Group/Team: On behalf of the CureGN IgA writing group.*

Background: Cure Glomerulonephropathy (CureGN) is a multi-center(66 sites), NIDDK-funded longitudinal observational cohort study of 2400 prevalent (biopsy within 5 years) patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, and IgA nephropathy (IgAN), including IgA vasculitis (IgAV, previously referred to as Henoch-Schonlein Purpura). We present enrollment data for the fully enrolled IgAN/IgAV cohort comparing children and adults.

Methods: Study data of 590 patients with biopsy confirmed IgAN or IgAV were reviewed. Lab and treatment data up to the time of enrollment are shown using descriptive statistics and univariate tests. We analyzed data to compare adults and children with IgAN and IgAV. Data are presented as median(IQR) and N(%).

Results: A total of 590 patients (355 adult and 235 pediatric) are in the IgAN/IgAV cohort. A comparison of adult to pediatric patients with IgAN and IgAV is in Table 1. Adults had lower eGFR at both time-points and lower enrollment albumin. For IgAN, adults had more proteinuria at both time-points. Patients with IgAV received more immunosuppression (83%v53%, p<0.001) and corticosteroids (81%v50%, p<0.001). 30% of children and 28% of adults with IgAV received either cyclophosphamide or mycophenolate mofetil.

Conclusions: This study reveals significant differences in the disease presentation and early disease course between children and adults with IgAV and IgAN. Furthermore, there were significant differences in treatments between IgAV and IgAN. This is the largest North American prospective IgAN/IgAV cohort initiated to date and will serve as an important resource to answer pathobiology questions in the future.

Routine Urinalysis Does Not Correlate with Kidney Pathology in IgA Nephropathy after Steroid Therapy Hyaejin Yun,[3] Byoung-Soo Cho,[2] Sung min Jung,[2] Wang kwang Hong,[4] Daeyoung Kim,[5] Sung-gyu Ha,[1] Haengil Ko.[1] *[1]MIRAE ING Kidney Center, Seoul, Republic of Korea; [2]Mirae Kidney Center, Seoul, Republic of Korea; [3]MIRAE ING kidney center, Seoul, Republic of Korea; [4]ByulE plastic surgery, Seoul, Republic of Korea; [5]n-biotek, Seoul, Republic of Korea.*

Background: Routine urinalysis, especially hematuria and proteinuria, has long been used as the most important laboratory tools in the diagnosis of glomerulonephritis and also widely adopted as a screening tool for kidney problems at school screening or health checking program. Recently other newly developed markers for kidney injury, such as cystatin-c, KIM-1, L-FABP, NGAL etc., were developed but not routinely used because lack of accumulated convincing data as yet.

Methods: We performed follow up kidney biopsy who showed normal urinalysis and serum cystatin-c for more than 3 months after steroid therapy to check the kidney status in 25 patients with IgA nephropathy. All 25 patients took longterm steroid therapy more than 6 months. Mean age was 28.1 years old. Mean follow up biopsy interval was 13.3 months. All kidney biopsy were performed at the OPD level without admission. We used ACE-Cut disposable biopsy needle under the ultrasound guide(LOGIQ E9).

Results: All 25cases showed abnormal urinalysis such as persistent hematuria, persistent proteinuria or associated with hematuria and proteinuria at initial kidney biopsy, and showed persistent normal urinalysis findings include hematuria and proteinuria more than 3 months at the time of follow up renal biopsy. Twenty cases showed persistent original diseases although slight to moderate degree pathological improvement. However only 5 cases progressed renal pathologies at the time of follow up biopsy. Among five pathologically progressed cases, 3 cases showed improvement of urinalysis findings and urine protein to creatinine ratio.

Conclusions: Although further studies are needed, anyone who showed segmental or global sclerosis, when associated with moderate to severe tubular atrophy and interstitial fibrosis at initial kidney biopsy, follow up kidney biopsy is mandatory even showed persistent normal urinalysis and lab findings before finishing steroid therapy.

Group/Team: On behalf of the CureGN IgA writing group.*

Background: Cure Glomerulonephropathy (CureGN) is a multi-center(66 sites), NIDDK-funded longitudinal observational cohort study of 2400 prevalent (biopsy within 5 years) patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, and IgA nephropathy (IgAN), including IgA vasculitis (IgAV, previously referred to as Henoch-Schonlein Purpura). The IgAN/IgAV cohort has recently filled and we present the enrollment data for pediatric IgAN and IgAV.

Methods: Data for all pediatric patients (<18 years) with biopsy confirmed IgAN or IgAV were reviewed. This analysis compares those with IgAN and IgAV. Data (lab, treatment) up to the time of enrollment are shown using descriptive statistics and univariate tests with results as median(IQR) or N(%).

Results: 590 patients are enrolled in the IgAN/IgAV cohort including 235 pediatric patients (143 (61%) IgAN and 92 (39%) IgAV). A comparison of IgAN and IgAV is presented in Table 1. Those with IgAV differed significantly in age at diagnosis, disease duration, proteinuria at biopsy, and serum albumin at biopsy. Those with IgAV were significantly more likely than those with IgAN to receive immunosuppression and corticosteroids (Table 1).

Conclusions: This study reveals significant differences in the demographics, disease presentation and treatments in children with IgAV and IgAN. Participants will now be followed longitudinally as part of CureGN to further define disease characteristics such as disease progression, pathophysiology and response to therapy.

Occurrence of IgA Nephropathy with Lupus Nephritis Ana Malvar,[3] Valeria G. Alberton,[4] Bruno J. Lococo,[5] Renzo Tais,[1] Matias Ferrari,[1] Pamela Delgado,[1] Angelica Sarabia,[1] Brad H. Rovin.[2] *[1]Fernandez Hospital, Buenos Aires, Argentina; [2]Ohio State University Wexner Medical Center, Columbus, OH; [3]HOSPITAL FERNANDEZ, Buenos Aires, Argentina; [4]hospital Fernandez, Buenos Aires, Argentina; [5]DIAVERUN, Buenos Aires, Argentina.*

Background: IgA nephropathy (IgAN) without lupus nephritis (LN) has been seen in a small number of patients with SLE who developed proteinuria. The coincident occurrence of IgAN and LN has not been previously reported. We describe 5 patients with LN who had prominent mesangial IgA deposits that persisted after induction therapy for LN resulted in resolution of the other immune complexes.

Methods: A cohort of 131 proliferative LN patients had a kidney biopsy for diagnosis (Bx1) and again after induction with steroids plus MMF or cyclophosphamide (Bx2). Mean follow up was 42 ±7 months.

Results: Five patients (4 females; average age 38) were found to have dominant IgA deposits before and after induction therapy for LN. LN class, immunofluorescence pattern, serum creatinine (Scr), and 24-hour proteinuria (prot) are described in the table. At Bx2 20% of IgA-dominant patients achieved a complete renal remission (prot ≤ 0.5g/d; normal SCr mg/dl) compared to 41% of the whole cohort. CKD developed in 60% of the IgA-dominant patients and 20% of the whole cohort after 4 years of follow-up.

Conclusions: We identified a small subset of patients with proliferative LN who simultaneously appeared to have IgAN. This subset of patients did not appear to do as well as with induction therapy or during long-term follow-up of a contemporaneous cohort of proliferative LN patients

Chronic HBV Infection Was Associated with Failure to Complete Remission of IgA Nephropathy Haiting Wu,[2] Zhen Wu,[1] Yubing Wen,[2] Jianfang Cai,[2] Hang Li,[2] Xuemei Li,[2] Xuewang Li.[2] *[1]Beijing Frendship Hospital, Capital Medical University, Beijing, China; [2]Peking Union Medical College Hospital, Chinese Academy of Medicine Sciences & Peking Union Medical College, Beijing, China.*

Background: Chronic HBV infection is associated with Glomerulopathies including IgA nephropathy. We conducted a retrospective study to investigate the association between chronic HBV infection and remission of IgA nephropathy.

Methods: In this retrospective cohort, 715 patients with biopsy-proved IgA nephropathy were included, of whom 95 were diagnosed as chronic hepatitis B virus (HBV) infection defined as persistent positivity of hepatitis B virus surface antigen. Data on age, sex, body mass index, presence of hypertension and diabetes mellitus, laboratory tests prior to treatment, and therapeutic regimens were retrospectively retrieved from medical records. Complete remission (CR) was defined as a 24-hour urinary protein <0.3g with a stable estimated glomerular filtration rate (eGFR). Multiple logistic regression analysis was used to estimate the association of HBV infection with CR and a 30% decline in eGFR.

Results: Patients with chronic HBV infection were younger (27.31±35.64 vs 35.64±11.51, P=0.005) and more likely to present heavier proteinuria (3.02±3.44, 2.02±2.18g P < 0.001) and avoid using immunosuppressive agents (10.52%, 58.57%, P < 0.001) as compared with those free of chronic HBV infection. However, the two groups did not differ in baseline eGFR, presence of hypertension and diabetes, administration of RAAS inhibitors and glucocorticoids. In one-year follow-up, HBV infection was associated with failure to CR in proteinuria (OR [95% CI], 2.10 [1.173-3.758], P=0.013),

but not with a 30% decline in eGFR(OR [95% CI], OR 1.192 [0.438-3.249], P=0.731), independently of gender, age, diabetes, hypertension, baseline eGFR, 24-hour urinary protein, use of glucocorticoids, immunosuppressive agents and RAAS inhibitors.

Conclusions: Chronic HBV infection may be associatited with failure to complete remission of IgA nephropathy.

SA-PO271

The Derivation and Validation of an International Multi-Ethnic Risk Prediction Model in IgA Nephropathy Sean Barbour,[6] Rosanna Coppo,[2] Yusuke Suzuki,[3] Zhi-Hong Liu,[4] Gabriela Espino-Hernandez,[1] Heather N. Reich,[5] Daniel C. Cattran.[5] *[1]BC Renal Agency, Vancouver, BC, Canada; [2]Torino, Italy; [3]Juntendo University, Tokyo, Japan; [4]Nanjing University, Nanjing, China; [5]University of Toronto, Toronto, ON, Canada; [6]University of BC, Vancouver, BC, Canada. Group/Team: International IgAN Collaboration.*

Background: Predicting renal outcome in IgA nephropathy (IgAN) is challenging. A prediction model is needed to improve risk stratification that is properly validated in multiple ethnic groups worldwide and can be used in clinical practice. To overcome these obstacles, we used large datasets from international collaborators to generate an accurate prediction model in IgAN.

Methods: The derivation dataset was from European, Japanese and Chinese adult cohorts; the validation dataset was from separate North/South American, European, Chinese and Japanese cohorts. Time from biopsy to the composite outcome (50% decline in eGFR or ESRD) was analyzed using Cox survival models.

Results: The validation dataset (N=2784) is 42% Caucasian, 21% Japanese and 37% Chinese; 18% (N=495) experienced the composite outcome over a median 4.8 years of follow-up. Two models were considered: a reduced model containing eGFR, blood pressure, proteinuria at biopsy, and MEST score; and a full model that also contained age, sex, race, use of RAS blockade/immunosuppression, and crescents. Compared to the reduced model, the full model had improved prediction with better AIC (5679 vs 5648), R^2 (19 vs 21%), ΔC-statistic (0.01, 95%CI 0.008-0.03), continuous NRI (0.17, 95%CI 0.11-0.27) and IDI (0.03, 95%CI 0.01-0.05), with similar calibration curves. We will next externally validate the full model in the validation dataset (N=1401), and convert the model into web and mobile app calculators for implementation in clinical practice.

Conclusions: Using the largest and most diverse datasets to date in IgAN, we will generate the first risk prediction tool that is externally validated in multiple ethnic groups worldwide and can be easily implemented in clinical practice using web/app-based calculators. We expect the prediction model will become the international standard for risk stratification in IgAN, and will facilitate both clinical trial recruitment of high-risk patients and testing the added prediction benefit of novel biomarkers.

SA-PO272

Short-Term Anti-Proteinuric Effect of Tacrolimus Is Not Related to Preservation of Glomerular Filtration Rate during 5 Year-Follow Up Period in IgA Nephropathy Mi-yeon Yu,[1] Yong Chul Kim,[1] Ho Jun Chin.[2] *[1]Seoul national university hospital, Seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: It has been known that tacrolimus reduced proteinuria in IgA nephropathy for a short period of time. We investigate persistent effects of proteinuria reduction and improvement of kidney function after discontinuation of the tacrolimus administration.

Methods: Patients with biopsy-proven IgA nephropathy were randomly selected for two treatment groups and control groups for each group; 1) patients treated with tacrolimus (Tac group) and 2) a placebo group (placebo group) with stratification by using a renin angiotensin system blocker. The Tac group was treated up to 16 weeks and then stopped administration of tacrolimus at the final visit (trial phase). We tracked patients at 12-, 24-, 52-, and 240-week (observational phase). The primary outcome was the percentage change of time-averaged proteinuria (TA-proteinuria; g/g cr) and estimated glomerular filtration rate (eGFR) between the trial and observational phases. The TA-proteinuria was defined as the average of urine protein to creatinine ratio (UPCR) measured every three month during the two phases.

Results: Significant reduction of UPCR was observed in the Tac group compared to its control group at 4-week and 8-week visits during the trial phase (p=0.023 and p=0.003, respectively). The difference between Tac and its control group was not evident at the other periods, estimated by repeated measured ANOVA. The percent change of TA-proteinuria in the Tac group was more than the control group (116 ± 96 % vs. 63 ± 239 %, p=0.004). Therefore the TA-proteinuria during the observational phase was not significantly different between the Tac and control groups (1.150 ± 0.733 g/g cr vs. 1.455 ± 2.017 g/g cr, p=0.775). The levels of eGFR throughout the observational phase were not significantly different between the two groups. Furthermore, the mean rate of eGFR change during the whole phase was -6.4 ml/min/1.73 m2/year in the control group and -5.4 ml/min/1.73 m2/year in the Tac group (p=0.988).

Conclusions: The anti-proteinuric effect of tacrolimus was promptly reversed 3 months after discontinuing the drug. The use of tacrolimus for a short period of time for the patients with IgA nephropathy temporarily reduces proteinuria, but ultimately, there is no long-term efficacy such as reduction of proteinuria and improvement of renal function.

SA-PO273

The Effects of Renin Angiotensin Aldosterone System Inhibitors (RASI) for IgA Nephropathy (IgAN) Patients with Oxford T1/2 Lesions Takahiro Kamiyama,[2] Takahito Moriyama,[3] Marie Nakano,[4] Kazunori Karasawa,[1] Kosaku Nitta.[3] *[1]Department medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [2]Tokyo Women's Medical University, Tokyo-to, Japan; [3]Tokyo Women's Medical University, Tokyo, Japan; [4]Tokyo Women's Medical University Hospital, Tokyo, Japan.*

Background: IgAN has been recognized as a not a benign disease and 40% of patients developed to end-stage renal disease (ESRD) within 20 years. Severe histological findings have been reported as risk factors of IgAN. Global sclerosis was one of the risk factors, and in Oxford classification, it was recognized as same as tubulointerstitial (T) lesions according to their correlation. Therefore, in IgAN patients with T lesions, the glomerular hyperfiltration and hypertension were seemed to be occurred, and, RASI might be effective to decrease them and prevent progressing to ESRD. However, these beneficial effects of RASI on patients with T lesions haven't been previously reported.

Methods: In this retrospective cohort study, from 697 biopsy proven IgAN patients in our institution between 1990 and 2010, we divided 87 patients withT1/2 lesions into two groups: RASI group (n=47, treated with RASI) and control groups treated with antiplatelet agents (APA group, n=40). We analyzed the clinical and histological background, the serial change of blood pressure and the amount of urinary protein (U-Prot), progression to ESRD, and the risk factors for progression after adjusting by propensity score matching.

Results: After adjusting clinical findings with significant difference at base line, 22 cases from each group were selected, and clinical and histological characteristics were similar between both groups The mean eGFR 58.5 vs.57.1 ml/min/1.73^2, and median U-Prot 1.14 vs. 0.95 g/day in RASI and APA group, respectively. Serial change of blood pressure during two years after treatment was significantly decreased in RASI group (p=0.0029), but not in APA group. The serial change of U-prot was tended to decrease in RASI group, though it was not significant (1.14 to 0.47 g/gCre), but it was similar in APA group (0.95 to 0.85 g/gCre). The renal survival rate in Kaplan Meyer Analysis was 60%/20 years in RASI group and 20%/20 years in APA group (p=0.0119). In multivariate Cox regression analysis, RASI was an independent factor to prevent from progression to ESRD (HR 5.91, 95% CI: 1.53-22.8).

Conclusions: RASI has shown significant beneficial effect on histologically advanced IgAN patients with Oxford T1/2 lesions, who were suspected to have glomerular hypertension and hyperfiltration according to severe global sclerosis.

SA-PO274

Efficacy of Steroid Therapy for IgA Nephropathy Yasuyuki Nagasawa,[1] Ryohei Yamamoto,[6] Maki Shinzawa,[6] Tatsuya Shoji,[4] Katsuyuki Nagatoya,[5] Terumasa Hayashi,[4] Yukiko Hasuike,[1] Takahiro Kuragano,[3] Atsushi Yamauchi,[5] Toshiki Moriyama,[7] Yoshitaka Isaka,[6] Takeshi Nakanishi.[2] *[1]Hyogo College of Medicine, Nishinomiya, Japan; [2]Hyogo College of Mediicne, Nishinomiya, Japan; [3]Internal Medicine Division of Kidney and Dialysis, Nishinomiya, Japan; [4]Osaka General Medical Center, Osaka, Japan; [5]Osaka Rosai Hospital, Sakai-city, Japan; [6]Osaka University Graduate School of Medicine, Suita, Japan; [7]Osaka University Health Care Center, Toyonaka, Japan.*

Background: IgA Nephropathy is most common primary glomerular nephritis not only in Asian, but also in Caucasians. Steroid therapy had been established as standard therapy for IgA nephropathy. But, IgA nephropathy patients with low proteinuria and with normal kidney function were known to have good prognosis. In this point, it is not clear that how much proteinuria and how worse eGFR in IgA nephropathy patients required for the steroid therapy. The aim in this study is to evaluate the relationship between eGFR, proteinuria and efficacy of steroid therapy for IgA nephropathy

Methods: Study design. Retrospective cohort study, 882. IgA nephropathy patients at the age more than 18, whose eGFR was more than 15mL/min/1.73m2, who were diagnosed by renal biopsy. Ethical committee in these three hospitals approved for this study. Exposures were eGFR at the renal biopsy, steroid therapy within one year after renal biops. 1.5 time increase of serum creatinine was treated as outcome.

Results: Multiple Poisson model analysis revealed proteinuria (per 1g/day, IRR 1.40 [95%CI 1.26-1.56]), eGFR (per 10 mL/min/1.73m2, 0.72 [0.63-0.83]), steroid therapy(0.15 [0.03-0.66]) were identified as renal progression factors, and there was significant interaction between steroid therapy*eGFR (interaction P=0.035). There was stronger suppression effect upon renal progression by steroid therapy in the IgA patients whose eGFR were less than 60mL/min/1.73m2, than in the IgA patients whose eGFR were more than 60(mL/min/1.73m2 (Figure 1). There was favorable effect by steroid upon renal progression in the IgA patient whose proteinuria was more than 60mL/min/1.73m2 (Figure 2)

Conclusions: There was no significant effect of steroid therapy in IgA nephropathy patients with less than 60 eGFR and more than 0.5g/day proteinuria at least during observation periods (5.6 years). Steroid therapy is effective for IgA nephropathy patients whose eGFR were less than 60 and proteinuria were more than 0.5g/day.

Renal CD141+ Dendritic Cell Infiltration in IgA Nephropathy Titi Chen,[6,7] Qi Cao,[1] Padmashree Rao,[5,3] Guoping Zheng,[4,1] Yiping Wang,[2] David C. Harris.[3,7] *[1]Centre for Transplant and Renal Research, Westmead Millennium Institute, University of Sydney, Sydney, NSW, Australia; [2]Centre for Transplantation and Renal Research, Westmead Millennium Institute, The University of Sydney, Westmead, NSW, NSW, Australia; [3]Sydney Medical School - University of Sydney, Terrey Hills, NSW, Australia; [4]The University of Sydney, Sydney, NSW, Australia; [5]Westmead Millenium Institute for Medical Research, Parramatta, NSW, Australia; [6]School of Medicine, University of Sydney, Westmead, NSW, Australia; [7]Centre for Transplant and Renal Research, The Westmead Institute for Medical Research, Westmead, NSW, Australia.*

Background: Previous studies have shown that the severity of interstitial inflammatory infiltrates, which include myeloid dendritic cells (DCs), correlates with progression of IgA nephropathy. CD141+ DCs have recently been identified as a unique myeloid DC subset that plays a significant role in the induction and regulation of immunity. This DC subset has been studied in mouse models, but studies in humans are lacking. We aim to investigate the relationship between CD141+ DC infiltration and clinicopathologic features in IgA nephropathy.

Methods: Thirty adult patients with a sole diagnosis of IgA nephropathy were included in this study. Patients were excluded if they had received glucocorticoids or immunosuppressant therapy before renal biopsy. The histological classification was scored according to the Oxford classification. CD141+ DCs were identified through immunofluorescence staining and visualised using confocal microscopy.

Results: In normal human kidney, CD141+DCs were rarely present. Patients with IgA nephropathy had significantly higher number of CD141+ DCs than normal control (P=0.021) and CD141+DCs were mainly present in the interstitium. Higher CD141+ DC density was significantly associated with worse serum creatinine (r=0.81, P=0.015) and proteinuria (r=0.75, P=0.049). Higher CD141+ DC density was also associated with increased severity of tubular atrophy/interstitial fibrosis (P=0.025), but not with mesangial hypercellularity, endocapillary hypercellularity, segmental glomerulosclerosis, or number of crescents.

Conclusions: Our data highlight the close correlation between the density of CD141+ DCs and clinicopathologic features of IgA nephropathy progression. Further studies will be conducted in human samples and murine models to investigate whether CD141+ DCs mediate kidney injury, and the possible mechanisms involved.

Improvement of Clinical Outcome in Kidney Diseases via the On-line Thai Glomerular Disease Registry: IgA Nephropathy Warangkana Pichaiwong,[3] Ratana Chawanasuntorapoj,[5] Ngoentra Tantranont,[6] Veerapatr Nimkietkajorn,[1] Suchin Worawichawong,[4] Chagriya Kitiyakara.[2] *[1]Buddhachinaraj hospital, Phitsanulok, Thailand; [2]Bangkok, Thailand; [3]RAJAVITHI HOSPITAL, Bangkok, Thailand; [4]Ramathibodi Hospital, Bangkok, Thailand; [5]Medicine, Siriraj Hospital, Bangkok, Thailand; [6]Siriraj Hospital, Mahidol University, Bangkok, Thailand. Group/Team: Thai Glomerular Disease Collaborative Network (TGCN).*

Background: IgA nephroathy (IgAN) is the most common primary glomerular disease leading the end stage renal disease in Thailand. The data on epidemiology of IgA nephropathy (IgAN) in Thailand are limited. The available data came from few medical schools, which might not represent the entire Thai population. The Thai Glomerular Disease Collaborative Network (TGCN) was established to determine the prevalence, clinical characteristics, outcomes and prognosis in Thai glomerular disease patients.

Methods: The data collected prospectively from TGCN included adult patients with biopsy-proven glomerular disease from institutes in Thailand participating in TGCN from July 2014 to March 2017. The clinical and renal pathology characteristics, treatment regimens at the time of renal biopsy were obtained via online data collection forms.

Results: Among 1,556 patients, the most common renal pathology finding in primary glomerular disease was IgAN with prevalence of 13.5%. At baseline, 44.3% of IgAN patients were male, the mean age was 39.4±13 years, median serum creatinine (sCr) was 1.76 mg/dL (0.56-13.2), median urine protein creatinine ratio (UPCR) was 2.63 g/g. Cr (0.02-21.56), and mean serum albumin (sAlb) was 3.6±0.7 g/dL. Nephritis was the most common presentation account for 48.1%. Most of the patients had high initial sCr at the time of biopsy (sCr ≥ 1.2 mg/dL, 77.5%). Clinically, both systolic and diastolic blood pressure at time of biopsy had the significantly high in patients who had serum creatinine ≥ 3 mg/dL compare to < 3 mg/dL (147±18/88±14 *vs*. 136±16/84±12 mmHg, p = 0.001 and p= 0.048). Histologically, an analysis of The Oxford Classification of IgAN, interstitial fibrosis/tubular atrophy (T) > 50% had significantly high in patients who had serum creatinine ≥ 3 mg/dL.

Conclusions: Conclusions: The prevalence of IgAN in our study was 13.5%. Two independent factors of severe manifestation at the time of biopsy were high blood pressure and high score of tubulointerstitial involvement. Further follow-up of clinical outcomes is being investigated.

Funding: Private Foundation Support

SA-PO277

The Beneficial Effect of Tonsillectomy Combined with Steroid Pulse Therapy on IgA Nephropathy Patients with Impaired Renal Function Saeko Kumon,[3] Takahito Moriyama,[2] Takahiro Kamiyama,[1] Marie Nakano,[3] Kosaku Nitta.[2] *[1]Tokyo Women's Medical University, Tokyo-to, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan; [3]Tokyo Women's Medical University Hospital, Tokyo, Japan.*

Background: Tonsilectomy combined with steroid pulse therapy (TSP) has been reported to have beneficial effects on IgA nephropathy (IgAN), and has become a major treatment in Japan. However, it is still controversial whether TSP is effective for IgAN with impaired renal function or not, though the impaired renal function at the time of renal biopsy is still recognized as one of the severe risk factor of IgAN. Therefore, we analyzed the efficacy of TSP in IgAN with impaired renal function.

Methods: In this retrospective analysis, IgAN patients who was diagnosed from January 2006 to May 2015 in our institution, age≧16, >0.5g/day proteinuria and estimated glomerular filtration rate(eGFR) < 60 ml/min/1.73m^2 were divided into the two groups : the patients treated with TSP (TSP group; n=25) and the patients treated with oral prednisolone (oPSL group; n=41). We compared the clinical and histological findings at base line, renal survival rate until 25 % decline of eGFR from base line and progression to end stage renal disease (ESRD), and clinical remission(CR) rate defined as <0.3 g/day proteinuria and <5 urinary red blood cells per high-powered field (HPF) between both groups.

Results: There was no significant difference in clinical and histological findings between both groups (mean eGFR: 44.6 vs. 44.3 mL/min/1.73m^2; p=0.875, median proteinuria: 1.78 vs. 1.37 g/g creatinine; p=0.247, distribution of the amount of hematuria: 2, 11, 1, 13 vs. 3, 13, 5, 4 (<5, 5-20, 21-50, >51/HPF; p=0.097). The renal survival rate, until 25 % reduction from baseline eGFR, and until progression to ESRD was significantly higher in TSP than oPSL group (79.7% vs. 40.4%/9 years; p=0.009, 100.0% vs. 65.4%/9years; p=0.0495, respectively). The remission rate of hematuria was significantly higher in TSP than oPSL group (92.9% vs. 47.1%/4.5years; p<0.0001), though the remission rate of proteinuria was similar between both groups. TSP was the only independent factor to decrease hematuria according to the multivariate Cox regression analysis (OR: 3.10, 95% CI: 1.40-6.77, p=0.006).

Conclusions: TSP was effective for remission of hematuria and long term renal prognosis in IgAN patients with impaired renal function.

SA-PO278

Maintenance of Remission Following Completion of OMS721 Treatment in Patients with IgA Nephropathy (IGAN) Geoffrey A. Block,[1] Steve Whitaker.[2] *[1]Denver Nephrology, Denver, CO; [2]Omeros Corporation, SEATTLE, WA.*

Background: The lectin pathway of complement has been implicated in the pathogenesis of several glomerulopathies including IgAN. OMS721 is a fully human monoclonal antibody that inhibits mannan-associated lectin-binding serine protease-2 (MASP-2), the effector enzyme of the lectin pathway. In a clinical trial, all OMS721-treated patients with IgAN achieved partial remission. These patients were followed after the trial. The duration of remission after OMS721 treatment was assessed.

Methods: The 4 IgAN patients are from an ongoing OMS721 Phase 2 clinical trial. All completed the trial. For inclusion, patients demonstrated 1) biopsy-diagnosed IgAN, 2) uACR > 0.6 g/g, 3) eGFR ≥ 30 mL/min/1.73 m^2, 4) controlled BP on stable ACEI/ARB treatment, and 5) a stable steroid dose ≥ 10 mg prednisone. All patients received OMS721 IV once weekly for 12 weeks. After OMS721 treatment, patients were followed for 6 more weeks in the trial. After trial completion patients have been followed by the investigator. In the trial endpoints were uACR and 24-hour proteinuria. In post-trial follow-up, uPCR was measured. Each uPCR value was converted to uACR by multiplying by 0.64. (Zhao, Clin J Am Soc Nephrol 2016;11:947-55)

Results: All patients achieved partial remission following OMS721 treatment. The mean age of the 3 females and 1 male was 42 years, 3 are Caucasian and one is Asian, the mean eGFR was 41 mL/min/1.73 m^2, and the mean entry steroid dose was 55 mg. Follow-up ranged from 2-9 months after the last OMS721 dose. During the trial the mean uACR decreased 77% (p = 0.026). Three patients maintained partial remission during available follow-up (54%, 79%, and 88% uACR decreases at 12, 12, and 5 months, respectively). One patient had 90% of baseline uACR at 7 months. Three patients also demonstrated improved eGFR by 7, 13, and 7 ml/min/1.73 m^2 during follow-up. The fourth patient's eGFR was stable. All patients discontinued steroids. OMS721 was well tolerated. All adverse events were mild with headache and sinus congestion considered possibly related by the investigator.

Conclusions: Proteinuria significantly decreased in patients with IgAN during the 12-week treatment with OMS721. This reduction in proteinuria was maintained for up to

9 months after treatment completion. These data suggest that OMS721 may be efficacious in the treatment of IgAN and further study is warranted.

SA-PO279

Natural History of IgA Nephropathy and Henoch-Schönlein Purpura Nephritis Benjamin L. Spector, Jason Misurac. *University of Iowa, Iowa City, IA.*

Background: Though histopathologically identical, Henoch-Schönlein purpura nephritis (HSPN) and IgA nephropathy (IgAN) are thought to follow markedly different courses. Despite their relatively high prevalence, limited data exist describing their natural histories.

Methods: This retrospective analysis examines all biopsy-confirmed cases of HSPN (n=22) and IgAN (n=19) at our institution from January 1989 to May 2016 through 1-year of follow-up. Inclusion criteria were diagnosis before age 18 years, minimum 1-year of follow-up, and absence of pre-existing renal disease. We compared demographics, clinical biomarkers, and treatments.

Results: Both cohorts show male predominance. In HSPN, age at diagnosis was younger and renal biopsies showed higher rates of glomerular crescents and endocapillary proliferation. The IgAN cohort presented more often with gross hematuria (31.8% vs 63.2%, p= 0.06), hypertension (HTN), and lower estimated glomerular filtration rate (eGFR). Urine protein/creatinine ratio (UPC) and overall hematuria rates were equivalent between groups. At 1-year follow-up, there were no differences in clinical features or immunosuppressant use.

Conclusions: In HSPN, patients had younger presentation and higher prevalence of crescents and endocapillary proliferation on biopsy. IgAN was more likely to present with HTN, gross hematuria, and lower eGFR. There were no significant differences in clinical biomarkers at 1-year follow-up.

Demographics and clinical features

Item	HSPN	IgAN	P
Median			
Age at diagnosis (years)	8.4	12.4	0.09
eGFR at diagnosis (mL/min)	106	82	0.01
eGFR at 1 year (mL/min)	95	101	0.61
UPC at diagnosis	1.8	1.1	0.58
UPC at 1 year	0.2	0.2	0.75
Proportion (%)			
Male	68.1	89.4	0.14
Hypertension at diagnosis	45.5	26.3	0.33
Hypertension at 1 year	9.1	10.5	1.00
Hematuria at diagnosis	86.4	94.7	0.61
Hematuria at 1 year	36.4	36.8	1.00
Biopsy results (%)			
Mesangial proliferation	81.0	94.7	0.35
Endocapillary proliferation	36.3	5.3	0.02
Segmental sclerosis	52.4	68.4	0.35
Interstitial fibrosis/tubular atrophy	33.3	26.3	0.74
Glomerular crescents	45.5	15.8	0.05

SA-PO280

Is MEST Score a Risk Predictor in Pediatric Henoch-Schönlein Purpura Nephritis? Ashton Chen,[2,1] Dan P. Goldstein,[2] Marcia Voigt,[2] Andrew M. South,[2] Jen-Jar Lin.[3] *[1]Wake Forest Baptist Health, Winston Salem, NC; [2]Wake Forest School of Medicine, Winston Salem, NC; [3]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Oxford Classification of IgA nephropathy (IgAN) includes the histologic components: mesangial (M) and endocapillary (E) hypercellularity, segmental sclerosis (S) and interstitial fibrosis or tubular atrophy (T). These have been utilized as the MEST score to predict renal outcome in IgAN. Pathological findings on renal biopsy in IgAN are identical to Henoch-Schönlein purpura nephritis (HSPN), but MEST score has not been validated in HSPN.

Methods: A retrospective chart review was performed from April 1, 2004 to May 31, 2017 at our center, identifying all children referred for HSPN who underwent renal biopsy. Blood pressure (BP), glomerular filtration rate (GFR), and degree of proteinuria were recorded at time of biopsy and compared at last follow-up. Biopsy reports were reviewed and assessed for crescents and MEST score. Treatment with steroids, immunosuppression, and ACEI/ARB was assessed.

Results: Of 49 patients referred for HSPN, n=29 underwent renal biopsy. Of 29 patients, all had spot urine protein/creatinine (u p/c) >0.2, 15 of whom had nephrotic-level proteinuria (u p/c>2.0). All had normal GFR at time of biopsy and 9/29 (31%) had hypertension (HTN). Overall biopsy results showed: crescents (69%), MEST M1 (66%), E1 (69%), S1 (28%), T1 (23%), and T2 (0%). Of patients with HTN: crescents (78%), M1 (78%), E1 (78%), S1 (11%), and T1 (22%). Those with nephrotic-level proteinuria had crescents (73%), M1 (73%), E1 (86%), S1 (13%), and T1 (13%). Patients with 10% or more crescents had higher rate of HTN at presentation (37% vs 20%, p=NS) and nephrotic proteinuria (58% vs 50%, p=NS). Median follow-up was 3.1 years. Patients with M1 vs M0 were more likely to have higher urine p/c at follow-up (p=0.14). Of patients with >10% crescents, 92% received steroids and 79% received immunosuppression. At last follow-up 1 patient had GFR <100mL/min/1.73m2, 2 had pre-HTN, and 5 had proteinuria.

Conclusions: After treatment, renal outcome in pediatric HSPN is favorable even with significant proteinuria and hypertension at presentation. Crescents and MEST score of M1 may be associated with HTN and nephrotic proteinuria at presentation in children. Further studies are needed to validate use of MEST score in pediatric HSPN.

SA-PO281

Long-Term Outcome of Pneumococcal Haemolytic Uraemic Syndrome Aoife Waters.[1,2] *[1]UCL Great Ormond Street Institute of Child Health, LONDON, United Kingdom; [2]Nephrology, Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom. Group/Team: UK P-HUS Study Group.*

Background: Haemolytic uraemic syndrome [HUS] is defined by microangiopathic haemolytic anaemia [MAHA], thrombocytopaenia and oliguria/elevated creatinine for age clinically manifesting from endothelial cell injury and microvascular thrombosis. Occurring as a rare complication of pneumococcal infection, P-HUS accounts for 5-15% of HUS cases in young children and is characterised by a more severe disease course compared to Shiga-toxin associated HUS[1]. We determined the long-term renal outcome of P-HUS[1] and serotype profile of P-HUS following the introduction of the pneumococcal conjugate vaccines (PCV7 and PCV13) in the UK.

Methods: A case note review of P-HUS was undertaken in 5 participating UK centres. P-HUS was defined as reported [1] and cases were included if followed for at least 5 years' duration. Data pertaining to duration of dialysis at presentation, duration of follow up, estimated GFR at follow up, proteinuria, blood pressure percentile, dialysis requirement and transplantation was collected. Additional information pertaining to mortality and co-morbidties were also collected. Information on pneumococcal serotype in post 2007 cases [following PCV vaccine introduction in UK] was also collected. Research protocols were approved by regional governance teams.

Results: Long-term outcome data was available for 16 of 38 patients who were previously reported[1]. All patients presented with P-HUS between April 1999 and February 2010: Median age at presentation: 10 months (IQR: 8,17), M:F 6:10, (0.6). Median duration of hospitalisation: 37 days (IQR: 23,75 days). Median eGFR 54 mls/min/1.73m^2 (IQR: 25,81) with median duration of follow-up: 10 years (IQR: 8,12). At time of follow up, none were on dialysis but three patients [18%] had received renal transplants without recurrence. Nine patients [56%] patients were on anti-hypertensive treatment at follow up, 7 of whom are on monotherapy [ACEI(5)] and 2 on dual therapy [ACEI with other]. Three patients had persistent proteinuria. Individual data will be presented. Following PCV7 introduction in 2010, the predominant serotype was 3 [previously 19A] and after PCV13 introduction, no cases of P-HUS have been observed since 2012.

Conclusions: Over 60% of P-HUS patients under follow up have chronic kidney disease. Ongoing analysis involving more UK centres is underway including those discharged from care. Reference: 1. Waters et al, J Pediatr. 2007 Aug;151(2):140-4

SA-PO282

Renal Outcomes in Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits Ramnika I. Gumber,[3] Jordana B. Cohen,[3] Matthew Palmer,[2] Laura M. Dember,[3] Brendan M. Weiss,[1] Jonathan J. Hogan.[3] *[1]Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA; [2]Pathology, University of Pennsylvania, Philadelphia, PA; [3]Nephrology, University of Pennsylvania, Philadelphia, PA.*

Background: The natural history and response to therapy of proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is poorly characterized.

Methods: We retrospectively analyzed renal responses of 20 patients with PGNMID evaluated at our center from 2011 though 2016. Patients were stratified by treatment approach: targeted to detected clonal cell type or non-targeted. Renal response was defined as: 1. complete response (CR) if proteinuria decreased to <0.5 grams (per 24h urine collection or urine protein:creatinine ratio<0.5) with return to baseline of serum creatinine (SCr) 2. partial response (PR) if there was ≥50% decrease in proteinuria (and at least <3 grams) with stabilization of SCr.

Results: Median eGFR at presentation was 37 (interquartile range (IQR) 22-56) ml/min/1.73m^2, median proteinuria was 3.7 (IQR 2.5-8.1) grams. A paraprotein was detected in serum or urine in 8 patients and an underlying clone was detected in 7 patients (B cell n=2, plasma cell n=3, lymphoplasmacytic cell n=2); 5 of these patients received clone-directed therapy. All patients with clone-directed therapy had a renal response (CR in 60%); 54% of patients not receiving clone directed therapy had a renal response (CR in 27%). All patients receiving bortezomib-based therapy (n=4) had renal response (CR in 75%); 67% of patients not receiving bortezomib-based therapy (n=12) had renal response (CR in 25%). Among those who responded, median time to any renal response was 98 days in bortezomib-treated patients vs. 190 days in non-bortezomib-treated patients.

Conclusions: All patients with PGNMID who received clone-directed therapy had a renal response. Future studies should explore more sensitive methods for detecting an underlying pathogenic clone to direct treatment. Bortezomib appears promising for these conditions and should be explored further.

Renal response stratified by treatment approach

	Clone-Directed Therapy (N=5)	Non-Clone Directed Therapy (N=11)	No Therapy (N=4)
Complete Response	3 (60%)	3 (27%)	0 (0%)
Partial Response	2 (40%)	3 (27%)	0 (0%)
No Response	0 (0%)	5 (45%)	4 (100%)

SA-PO283

Diversity of Biopsy-Proven Kidney Diseases in Thai Diabetic Patients: Analysis of Thai Glomerular Disease Collaborative Network (TGCN) Veerapatr Nimkietkajorn,[3] Ratana Chawanasuntorapoj,[4] Ngoentra Tantranont,[5] Pornpen Sangthawan,[2] Warangkana Pichaiwong.[1] *[1]Medicine, RAJAVITHI HOSPITAL, Bangkok, Thailand; [2]Medicine, Prince of Songkla University Hospital, Songkhla, Thailand; [3]Medicine, Buddhachinaraj hospital, Phitsanulok, Thailand; [4]Medicine, Siriraj Hospital, Bangkok, Thailand; [5]Pathology, Siriraj Hospital, Mahidol University, Bangkok, Thailand. Group/ Team: Thai Glomerular Disease Collaborative Network (TGCN).*

Background: Diabetic nephropathy (DN) is the leading cause of chronic kidney disease worldwide including Thailand. However, there is also increasing recognized diagnosis of non-diabetic renal diseases (NDRD) in diabetic patients, which may influence in the different treatments and outcomes. This study reported the spectrum and clinical characteristics of NDRD and NDRD superimposed DN in Thai diabetic population.

Methods: Clinical data of the diabetic patients with aged > 18 years undergone kidney biopsy were collected via the nationwide web-based Thai glomerular diseases registry from TGCN during 2014-2017. These data including the demographic data and laboratory data together with kidney biopsy pathological findings.

Results: The 276 from 1,556 patients were recruited in this study; 123 cases were male (44.6%). The mean age was 51.8±years, and the median serum creatinine was 1.99 mg/dL (0.42-13.2). The 114 cases (41.3%) were diagnosed NDRD, while 23 cases (8.3%) were diagnosed NDRD superimposed DN. The rest of the patients were diagnosed isolated diabetic nephropathy; DN (50.4%). FSGS was either the most prevalent glomerular disease in both NDRD (23.7%) and NDRD superimposed DN (34.8%). The second and third kidney biopsy findings in NDRD were lupus nephritis (21.9%), IgA nephropathy (13.2%), respectively. In NDRD superimposed DN, membranous nephropathy (26.1%), and post-infectious glomerulonephritis (21.7%) were the second and third pathological findings. Nephritis was the clinical presentation of NDRD and NDRD superimposed DN approximately 15.8% and 13%, whereas it was not found in DN. Nephrotic syndrome was more common in DN and NDRD superimposed DN than in NDRD (80.6%, 73.9%, and 37.7%, respectively, $p<0.05$). Moreover, the quantity of proteinuria was found to be higher in DN and NDRD superimposed DN than in NDRD (6.4, 6.5, and 3.7 g/day, respectively, $p<0.05$).

Conclusions: This report disclosed the diversity and prevalence of NDRD that was diagnosed in more than one-third of Thai diabetic patients. Presence of nephritis was the more suggestive diagnosis of NDRD or NDRD superimposed DN. However, kidney biopsy is still the important means for the definite diagnosis of glomerular disease in diabetic patients.

Distribution of Glomerular Diseases in Taiwan: Preliminary Report of National Renal Biopsy Registry – Report on Behalf of Taiwan Society of Nephrology Hsien-Fu Chiu,[1] Kuo-cheng Lu,[2] Hung-Chun Chen,[3] Kuo-hsiung Shu.[4] *[1]Taichung Veteran General Hospital, Taichung, Taiwan; [2]Division of Nephrology, Department of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic University, New Taipei City, Taiwan; [3]Kaohsiung Medical Univ, Taiwan, Taiwan; [4]Lin Shin Hospital, Taichung, Taiwan.*

Background: Despite the development of biomarkers and noninvasive imaging tools, biopsy remains the only method for correctly diagnosing patients with unexplained hematuria, proteinuria and renal failure. Renal biopsy has been performed for several decades in Taiwan; however, a national data registry is still lacking until 2013.

Methods: The Renal Biopsy Registry Committee was established within the Taiwan Society of Nephrology in January 2013. A biopsy registry format, including basic demographic data, baseline clinical features, laboratory data, and clinical and pathological diagnosis was developed. Approval from the local institutional review board was obtained in each participating medical center.

Results: From January 2014 to September 2016, 1445 renal biopsies were identified from 17 medical centers. 53.8% cases were reported in men. The mean age at biopsy was 48.4±16.6 years. The median serum creatinine was 1.6 (IQR 0.9–3.3) mg/dL. The median daily urine protein was 2.7 (IQR 0.7–6.8) g/day, whereas 57.3% patients had hematuria. Primary glomerulonephritis (GN), secondary GN, tubulointerstitial diseases, and post-renal transplantation accounted for 40.7%, 33.6%, 10.3%, and 15.3%, respectively. Among primary GN, IgA nephropathy (26.0%), focal segmental glomerulosclerosis (FSGS) (21.6%), and membranous nephropathy (MGN) (20.6%) were most frequently diagnosed. Diabetic nephropathy (22.4%) and lupus nephritis (21.8%) were the most common among secondary GN. Patients with minimal change disease (MCD) and MGN had heavier proteinuria than those with FSGS and IgA nephropathy. The most common cause of nephrotic syndrome in primary glomerular disease was MGN (28.8%), followed by MCD (28.2%). IgA nephropathy was the leading cause of chronic nephritic syndrome, acute nephritic syndrome, and persistent hematuria. The incidence was 0.55, 0.47, 0.45, and 0.41 in 100,000/year for IgA nephropathy, FSGS, MGN, and MCD, respectively. The incidence of primary GN was 2.19 in 100,000/year.

Conclusions: This is the first report of the National Renal Biopsy Registry in Taiwan. IgA nephropathy is the most common primary GN, while MGN is the most common cause of nephrotic syndrome. Primary GN distribution in Taiwan is slightly different from that in other Asian countries.

SA-PO285

The Spectrum of Biopsy Proven Glomerular Disease among Children in China Sheng Nie. *National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Children with glomerular disease comprise an important part of pediatric patients worldwide, especially in developing countries. Nationwide epidemiological data on the spectrum of biopsy-proven glomerular diseases in children is currently limited in China.

Methods: We previously conducted a nationwide renal biopsy survey including 71,151 patients from 938 hospitals spanning 282 cities across China, over an 11-year period from January 2004 to December 2014. A total of 8547 pediatric patients (≤ 18 years old) were selected from the survey for current analysis. The demographic and clinical variables were extracted from referral records and pathological reports.

Results: We found nephrotic syndrome (49.5%) and proteinuria coexisted with hematuria (26.1%) were frequent indications of renal biopsy in children. Minimal change disease (MCD) was the most common primary glomerular disease (27.9%), followed by IgA nephropathy (IgAN) (17.0%) and mesangial proliferative glomerulonephritis (10.1%). Henoch-Schonlein purpura nephritis (13.2%) and lupus nephritis (LN) (8.8%) were two most common secondary glomerular diseases. Compare with male patients, female tended to be less frequently diagnosed as MCD (Odds Ratio [OR] 0.26, 95% CI 0.23-0.30) and Alport nephropathy (OR 0.38, 95% CI 0.21-0.69), while membraneous nephropathy (MN) (OR 2.91, 95% CI 2.41-3.51) and LN (OR 10.91, 95% CI 8.92-13.33) were more frequent in female patients, adjusting for age, region, indications of biopsy and hospital levels. Moreover, MCD (30.7%) was the most common glomerulopathy in adolescent (11-18 years old), while purpura nephritis (22.7%) was the major pathological diagnosis in younger children (0-10 years old). The frequency of MN and LN were varied greatly among different geographic regions of China.

Conclusions: In conclusion, we provided comprehensive information on the composition of pediatric glomerular diseases in China. The spectrum and clinicopathological correlations of pediatric glomerular diseases varied greatly across genders and age groups.

Diabetic and Non-Diabetic Kidney Disease in Patients with Diabetes Mellitus (DM) Youngho Kim, Caroline J. Poulton, Yichun Hu, Susan L. Hogan, Amy K. Mottl, Ronald J. Falk, J. Charles Jennette, Patrick H. Nachman. *UNC Kidney Center, University of North Carolina, Chapel Hill, NC.*

Background: Glomerular and interstitial diseases occur in patients with DM, with or without concurrent diabetic nephropathy (DN). Limited data exists on the impact of DM and DN on the treatment and outcomes of patients with non-diabetic kidney disease (NDKD). We explored the characteristics, treatments and outcomes in a large cohort of patients with DM.

Methods: We reviewed medical records and kidney biopsy reports of patients with DM from the Glomerular Disease Collaborative Network and University of North Carolina. We grouped the patients into 3 categories based on pathologic diagnosis: DN alone, NDKD alone and concurrent DN+NDKD.

Results: 382 patients with DM and kidney biopsy were identified: 53% male, 47% White, 40% Black, median age 55 years [IQR 46-64], BMI 30.9 kg/m² [26.8-36], eGFR 28 ml/min/1.73m² [16-49] and urine protein-creatinine ratio (UPCR) 5.5g/g [2.8-10.0]. Of these, 112 had DN, 180 had NDKD, and 90 DN+NDKD. Table 1 summarizes significant differences between these 3 groups. The DN+NDKD and NDKD groups differed significantly with respect to the distribution of glomerular and interstitial diseases (P=0.002). Lesions of FSGS were the most common in both groups (44% of DN+NDKD and 30% of NDKD). Interstitial nephritis was significantly more common in DN+NDKD (12% vs. 3%; P=0.007) and ANCA-GN more common in NDKD (7% vs 1%; P=0.04). Patients with NDKD received immunosuppressive therapy more frequently (64% vs 43%) and had more frequent remission (69% vs 33%) compared to DN+NDKD.

Conclusions: The concurrence of NDKD and DN affect the likelihood of immunosuppressive therapy and of remission. Given the high prevalence of DM in the general U.S. population, an in-depth analysis of treatment, adverse effects and outcomes of patients with DM and NDKD is warranted.

Very Low Levels of Microscopic Hematuria in Potential Living Kidney Donors Is Associated with Pathology That Precludes Donation Vineeta Kumar,[3] Manish K. Saha,[1] Bruce A. Julian,[2] Jayme E. Locke,[2] Robert S. Gaston.[2] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: A threshold of ≥3 rbc/hpf (red blood cells/high power field) or higher prompts additional testing when evaluating potential living kidney donors at most centers in the United States. In our experience, a lower degree of hematuria has yielded pathology that precluded kidney donation and here in we present the results of a single center experience.

Methods: We prospectively identified isolated asymptomatic microscopic hematuria in 19 out of 1124 potential living kidney donors. Microscopic hematuria was defined as presence of ≥1 rbc/hpf and persistent by presence on ≥2 separate urinalysis. Isolated was defined as presence of microscopic hematuria and with preserved GFR, absence of proteinuria, microalbuminuria or hypertension and no identifiable anatomical cause on native kidney imaging. Donors expressing continued interest had an evaluation with a cystoscopy. If unrevealing, they underwent a native kidney biopsy analyzed by a single pathologist using light, immunofluorescence and electron microscopy.

Results: There were no biopsy related complications. Degree of hematuria was modest ranging from 0-2 upto 3-10 rbc/hpf. Higher degree of hematuria was not isolated. 3/19 had IgA nephropathy and were not approved for kidney donation. All of these donors were related to their recipients. 1/19 had arteriosclerosis. Thin basement membrane disease (GBM) diagnosed after ruling out Alports was the most common finding in 11/19 patients and 4/19 had possible thin GBM based on segemental thinning only. These 15/19 were given a choice to donate after extensive counseling. One and two year follow up data have no worsening of hematuria or any of the renal parameters since donation.

Conclusions: Persistent asymptomatic microscopic hematuria of very minor degree in potential kidney donors with a biologically related recipient can be associated with pathologic findings that preclude kidney donation. A higher threshold of rbc/hpf on urine analysis as currently used can lead to a missed diagnosis and alter long term prognosis. At our center we have lowered our definition to ≥1 rbc/hpf after the results of this analysis.

SA-PO288

IgA Nephropathy with Positive Anti-Neutrophil Cytoplasm Antibody – A Case Series Amy Kang,[2] H. Terence Cook,[3] Charles D. Pusey.[1] *[1]Imperial College London, London, United Kingdom; [2]Imperial College Renal and Transplant Centre, London, United Kingdom; [3]Imperial College of London, London, United Kingdom.*

Background: IgA nephropathy (IgAN) with positive anti-neutrophil cytoplasm antibody (ANCA) is rare and may have different clinical characteristics from isolated IgAN.

Methods: We describe seven biopsy-proven IgAN patients (3% of our cohort) with positive ANCA (age 25 -66 years, 5 male and 2 female, median Cr 57mmol/L, eGFR 51mL/min/1.73m^2). Two initially ANCA negative patients developed worsening renal function and ANCA seropositivity. One recovered renal function with immunosuppression; the other was not immunosuppressed and progressed to dialysis. Five patients were ANCA positive from presentation. Two patients, with features of systemic vasculitis, received immunosuppression; one recovered renal function and the other progressed to dialysis. Two out of three patients with renal-limited disease had stable renal function on mycophenolate mofetil, and one was lost to follow-up. On biopsy, three out of the seven patients had segmental necrosis and crescents on a background of IgAN. Of the remaining four patients, one had features of endocapillary proliferation and the other three did not. IgAN can be associated with both PR3 and MPO – ANCA, but MPO-ANCA was more frequent in our cases (5 out of 7).

Results:

Conclusions: ANCA status can change in patients with IgAN and should be considered as a cause of rapid deterioration in renal function, as shown here. The patients in this series received a variety of treatment regimens. Four out of five patients who were selected to receive immunosuppressive therapy had improved or stable renal function at the end of follow up. IgAN with positive ANCA may represent an overlap syndrome between IgAN and ANCA vasculitis, and hence be more responsive to immunosuppressive treatment. We suggest that ANCA are tested in patients with IgAN, especially if renal function deteriorates rapidly, and that immunosuppressive treatment is considered if ANCA is detected.

SA-PO289

Anti-Ro Antibodies: A Novel Scleroderma Renal Crisis Biomarker Sarah M. Gordon, Stephen W. Olson. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Autoimmunity is thought to play a significant role in the pathogenesis of scleroderma renal crisis (SRC). Anti- RNA polymerase III (RNAPOL3-Ab) is associated with SRC but only present in 20—50% of cases. Therefore, additional autoimmune risk factors for SRC are likely. Anti-Ro antibodies (Ro-Ab) are known to be associated with systemic sclerosis (SSc), but have not been studied at or before SRC diagnosis.

Methods: We queried the military electronic medical record for ICD9 code 701.1 (SSc) between 2005 and 2016. By individual chart review we identified 54 SRC cases and 407 SSc without SRC disease controls. Background data was collected to include presence of Ro-Ab. Department of Defense Serum Repository (DoDSR) provided up to 3 longitudinal prediagnostic serum samples for 16 SRC cases and 30 age, sex, race, and age of serum matched SSc without SRC disease controls. Ro-Ab levels were measured at the NIH using an established luciferase technique. We first compared presence of Ro-Ab among the 54 SRC cases to the 407 SSc without SRC controls at SSc diagnosis. We then compared longitudinal pre-diagnostic Ro-Ab levels in 16 SRC cases to that of 30 SSc matched disease controls. The non-white group was predominantly Black or 'Other.'

Results: More SRC cases had Ro-Ab at diagnosis than SSc without SRC disease controls (27% vs.13%, p=0.03). Ro-Ab were only associated with SRC in the non-White subgroup (38% vs.17%, p=0.04) versus the White subgroup (15% vs. 10%, p=0.69). More non-White SRC cases had persistent significantly elevated prediagnostic Ro-Ab than non-White SSc without SRC controls (40% vs.6%, p=0.01). In each SRC case, the Ro-Ab was greater than 30 times normal in the earliest available index sample up to 26.1 years before clinical presentation. No White cases had an elevated prediagnostic Ro-Ab level. Prediagnostic Ro-Ab and RNAPOL3-Ab were not present in the same cases.

Conclusions: We report for the first time that Ro-Ab are elevated both at and before SRC diagnosis, making it a potential predictive biomarker in non-Whites. Elevated serial prediagnostic Ro-Ab levels found decades before clinical SRC suggest a 'multi-hit' mechanism of disease that requires a second insult to manifest clinical disease. Our results also suggest that the subclinical pathophysiology of SRC may vary by race, similar to known clinical and serologic heterogeneity in SSc.

Activated Farnesoid X Receptor by GW4064 Protects against Renal Fibrosis through Regulation of Hippo Pathway Donghyun Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: Renal fibrosis is the common pathway of chronic kidney disease progression. transforming growth factor-β(TGF-β) induced SMAD2/3 is a critical event in progressive chronic kidney disease. However, the role of non-SMAD signaling in fibrotic progress and its underlying molecular mechanisms remain unexplored. The nuclear receptor farnesoid X receptor (FXR), a ligand-activated transcriptional factor, may play a pivotal role in renal fibrosis.

Methods: We tested whether activated-FXR by GW4064 protects against renal fibrosis through non-SMAD signaling. To explore anti-fibrotic effects of FXR, we investigated the effects of GW4064 in TGF-β induced renal fibrosis in human proximal tubular epithelial (HK-2) cells. We also examined the phosphorylation level of epidermal growth factor receptor (EGFR), Src kinase and Hippo pathway to identify the anti-fibrotic signals. To explore the anti-fibrotic effects of FXR agonist in the kidney of unilateral ureteral obstruction (UUO) mouse model, we treated with vehicle or GW4064 (30mg/kg) for 5 days, and checked the fibrosis markers.

Results: TGF-β-induced Src kinase and EGFR phosphorylations were decreased by the treatment of FXR synthetic agonist GW4064, while those phosphorylations were not altered by the treatment of chenodoxycholic acid (CDCA), FXR agonist. TGF-β-induced fibronectin, connective tissue growth factor and α-smooth muscle actin expressions were markedly decreased by GW4064 treatment. Phosphorylations of yes-associated protein (YAP), Mst1/2, and Lats1 were increased by GW4064 treatment, which facilitates blocked YAP nuclear accumulation and protects against renal fibrosis. The in vivo experiments showed that FXR agonist GW4064 protected against renal fibrosis in UUO mice.

Conclusions: These results suggested that activated nuclear receptor FXR by GW4064 has anti-fibrotic effects through regulation of Hippo pathway by inhibition of Src kinase phosphorylation. FXR-Src-Hippo pathway may be a novel target for the treatment of renal fibrosis.

Inability to Increase Fatty Acid Oxidation Following Renal Injury Worsens Renal Fibrosis Mardiana Lee,[1,2] Peter F. Mount,[1] Marina Katerelos,[1] Kurt Gleich,[1] David A. Power.[1,2] *[1]Austin Health, Melbourne, VIC, Australia; [2]Medicine, University of Melbourne, Melbourne, VIC, Australia.*

Background: Recent studies have reported reduced expression of genes regulating fatty acid metabolism in fibrotic kidneys. However, the exact role of fatty acid metabolism in renal fibrosis is still unclear. To answer this question, we used mice with knock-in mutations of the regulatory S79 and S212 phosphorylation sites in acetyl CoA carboxylase 1 and 2 (ACC 1/2 KI) which have reduced ability to increase fatty acid oxidation when stressed. We aimed to determine whether reduced fatty acid oxidation contributes to renal fibrosis.

Methods: The folic acid nephropathy (FAN) and unilateral ureteric obstruction (UUO) models were induced in male ACC1/2KI mice and wild type (WT) controls. Mice were sacrificed at 14 and 7 days, respectively. Samples were studied by histomorphometry, Western blot and qRT-PCR.

Results: There was no difference in the appearance or function of ACC1/2KI kidneys at 8-10 weeks of age compared with WT. Reduced expression of genes controlling fatty acid oxidation was confirmed in the FAN model. In both FAN and UUO models there was increased accumulation of lipid by Oil Red O staining in ACC1/2KI mice ($p<0.05$ and $p<0.01$, respectively). Sirius red staining demonstrated increased fibrosis in ACC1/2KI mice in both models ($p<0.05$ and $p<0.001$)(Fig. 1). This was associated with increased expression of α-smooth muscle actin by Western blot ($p<0.05$) and qRT-PCR ($p<0.01$). In the FAN model, ACC1/2KI mice also had increased mRNA transcripts for Collagen I ($P<0.05$) by qRT-PCR compared with WT.

Conclusions: These data indicate that a reduced ability to regulate fatty acid oxidation in response to renal injury contributes to the development of renal fibrosis, and is not simply a consequence of injury. Regulation of fatty acid oxidation may be a potential therapeutic target in renal fibrosis.

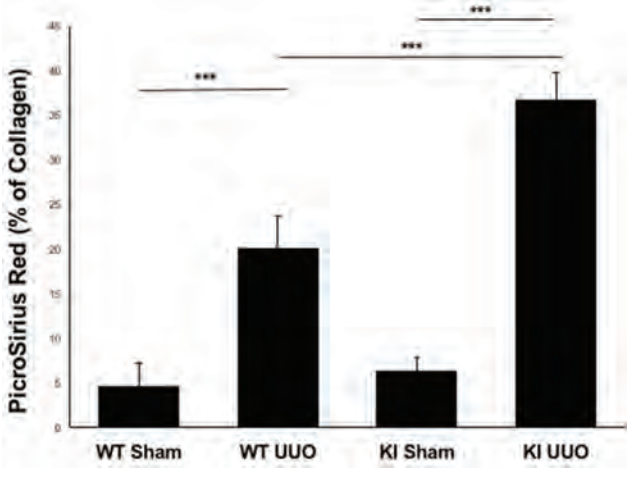

Figure 1. Quantification of PicroSirius Red stained kidney sections analysis showing increased Collagen in KI UUO compared to WT UUO (***P<0.001).

Lipoxins Attenuate Diabetic Complications in the ApoE-/- Mouse Eoin P. Brennan,[2] Muthukumar Mohan,[1] Monica De gaetano,[2] Chris Tikellis,[1] Mariam Marai,[2] Mark Ziemann,[1] Orina Belton,[3] Assam El-Osta,[1] Karin Jandeleit-Dahm,[1] Mark E. Cooper,[1] Phillip Kantharidis,[1] Catherine Godson.[2] *[1]Department of Diabetes, and Central Clinical School, Monash University, Melbourne, VIC, Australia; [2]Diabetes Complications Research Centre, UCD Conway Institute & School of Medicine UCD, University College Dublin, Dublin, Ireland; [3]School of Biomolecular and Biomedical Science, University College Dublin, Belfield, Dublin, Ireland.*

Background: Targeting both inflammation and fibrosis in diabetes-related complications has proven elusive. Endogenous lipid mediators including Lipoxins (LXs) actively promote the resolution of inflammatory responses. We investigated the potential of Lipoxin A4 (LXA_4), an endogenously produced mediator that promotes the resolution of inflammation, and a synthetic lipoxin 15(R)-Benzo-LXA_4 as experimental therapeutics in the streptozotocin-induced diabetic $ApoE^{-/-}$ mouse, a model of diabetic complications.

Methods: Diabetes was induced with low-dose streptozotocin (55mg/kg). Following 10 weeks of diabetes progression, mice were administered either vehicle (0.1% ethanol), LXA_4 (5ug/kg), or Benzo-LXA_4 analogue (1.7ug/kg) for 6 additional weeks.

Results: LXs attenuated kidney disease, with evidence of reduced albuminuria (Diabetes+Vehicle: 25.1±2.1 μg/24h vs Diabetic+LXA_4: 17.3±2.4 μg/24h), glomerular expansion, and collagen deposition. RNA-Seq transcriptome profiling identified the diabetic renal gene signature (725 genes) and subsets regulated by LXs. Pathway analysis identified established (TGF-β1, PDGF, TNF-α, NF-κB) and novel (EGR-1) networks regulated by LXs. LXs also reduced aortic atherosclerotic plaque development and pro-inflammatory signaling pathways in vascular tissue. LXs attenuated vascular smooth muscle cell proliferation and migration, and inhibited monocyte-endothelial cell adhesion. Treatment of human carotid plaques *ex vivo* with LXA_4 attenuated secretion of pro-inflammatory cytokines including IFN-γ, IL-1β and TNF-α, thereby highlighting the potential clinical relevance of LX-based therapeutics. Finally, we have previously identified the let-7 miRNA family as important mediators of renal fibrosis, and here we demonstrate that restoration of let-7 levels in aortic vascular tissues could provide a new target for an anti-inflammatory approach in diabetic vascular disease.

Conclusions: In conclusion, these data support a novel pro-resolution therapeutic approach for treating and preventing concomitantly multiple vascular complications of diabetes.

TGF-β1 Promotes Fibrotic Gene Expression through Induction of Histone Variant H3.3 and Histone Chaperone HIRA Toshihiro Shindo, Shigehiro Doi, Kensuke Sasaki, Ayumu Nakashima, Takao Masaki. *Hiroshima university, Hiroshima city, Japan.*

Background: Recent studies show that histone variants and their chaperones serve as epigenetic marks that regulate transcriptional activity. In this study, we investigated transforming growth factor (TGF)-β1-induced histone variant H3.3 and its histone chaperone, HIRA, on fibrotic genes *in vivo* and *in vitro*.

Methods: Male C57BL/6J mice underwent unilateral ureteral obstruction (UUO) and were sacrificed on day 7. In UUO mice, expression of H3.3, HIRA, and α-smooth muscle actin (αSMA) were evaluated by western blotting (WB) and immunohistochemistry (IHC) with or without administration of a TGF-β1-neutralizing antibody. For *in vitro* experiments, rat renal tubular cells (NRK52E) and rat kidney fibroblasts (NRK49F) were used. TGF-β1-iduced expression of H3.3, HIRA and αSMA was assessed by WB with pretreatment of Smad3 or HIRA siRNAs. Furthermore, chromatin immunoprecipitation (ChIP) assays were carried out using primers for fibrotic genes, which were designed to include in a Smad-binding element, in TGF-β1-stimulated NRK52E cells.

Results: Expression of H3.3 and HIRA was increased in UUO mice, and the TGF-β1 -neutralizing antibody suppressed their expression. Smad3 siRNA treatment inhibited expression of H3.3 and HIRA in TGF-β1-stimulated NRK52E cells. HIRA siRNA treatment attenuated expression of H3.3 and αSMA in TGF-β1-stimulated NRK52E cells. In ChIP assays, TGF-β1 increased promoter activities of collagen 1 (Col1a1), connective tissue growth factor (CTGF), and plasminogen activator inhibitor-1 (PAI-1) in NRK-52E cells, which were colocalized with H3.3 and suppressed by the TGF-β1 neutralizing antibody.

Conclusions: TGF-β1-induced H3.3 and HIRA play an important role in expression of fibrotic genes.

SA-PO294

Galectin-1 Is a New Renal Fibrosis Gene Upregulated in Type I and Type II Diabetes Samy L. Habib. *UTHSCSA, San Antonio, TX.*

Background: Chronic exposure of tubular renal cells to elevated blood glucose contributes to tubulointerstitial changes seen in diabetic nephropathy. Tubular cells are primary targets of hyperglycemia, and chronic exposure to elevated blood glucose levels contributes to the tubulointerstitial changes seen in overt diabetic nephropathy.

Methods: Kidney tissues from wild type and diabetic mice from both type 1 DM (Akita) and type 2 (db/db) groups at age of 4, 6, 8 months old were used. RNA sequence and analysis of Gal-mRNA were performed in RNA extracted from kidney tissues. Proximal tubular epithelial renal cells treated with high glucose and/or HG+Insulin for different time points were used to measure promoter activity and protein expression of Gal-1. Gal-1 was cloned and transcription factor AP4 was i immunoprecipitated to identify the binding of Ap4 to Gal-1 promoter. siRNA of Gal-1, AP4 and tuberin as well as Gal-1 inhibitor and Akt inhibitor were used to test the effect of its downregulation on Gal-1 expression and promoter activity.

Results: In the present study, we identified a new fibrosis gene called Galectin-1 (Gal-1) that highly expressed in tubular cells in kidney of type I and type II mouse models of diabetes. Gal-1 protein and RNA expression showed significant Increased in kidney cortex of Akita and db/db mice compared to wild type mice. Mouse proximal tubular exposed to high glucose (HG) and HG+Insulin showed significant increase in phosphorylation of Akt that associated with significant increase in expression of Gal-1. We identified that AP4 binds to Gal-1 promoter to upregulates its function. The mutated binding sites of Ap4 to Gal-1 promoter showed decease in protein and function activity of Gal-1. Inhibition of Gal-1 by OTX-008 showed significant decrease in phosphorylation of Akt and expression of AP4 and Gal-1 protein/promoter activity. In addition, downregulation of Ap4 by siRNA resulted in significant decrease in protein expression and promoter activity of Gal-1.

Conclusions: In summery, our data showed that Gal-1 is highly expressed in kidney of type 1 and II diabetic mouse and Ap4 is a major transcription factor that activates Gal-1 under hyperglycemia through activation of Akt. Inhibition of Gal-1 by OTX-008 blocks activation of Akt and prevent accumulation of Gal-1 suggest a novel role of Gal-1 inhibitor as possible therapeutic target to treat renal fibrosis in diabetes.

SA-PO295

Knockdown of Peroxiredoxin V (Prdx V) Exacerbates Unilateral Ureteral Obstruction-Induced Renal Fibrosis Hoon In Choi,[2] Tae-Hoon Lee,[1] Jung Sun Park,[2] Donghyun Kim,[2] Eun Hui Bae,[2] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]School of Dentistry, Chonnam National University, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: Renal fibrosis is closely associated with chronic inflammation. Peroxiredoxin V (Prdx V), an atypical 2-Cys member of the Prdxs family, functions as anti-inflammatory effector as well as a thiol-dependent peroxidase in its catalytic cysteine-dependent manner. Recently, we demonstrated that overexpression of Prdx V attenuate TGF-β induced fibrosis in NRK49F cells. However, the relevance of Prdx V to renal pathobiology has not been fully characterized and the underlying mechanism remains poorly understood.

Methods: To investigate the role of Prdx V in renal fibrosis, we used a transgenic mouse model with PrdxV siRNA expression controlled by U6 promoter (C57BL/6J-Tg(U6-PrdxVsi)1Thlee/Krb; Prdx V^{si} mice). For in vivo experiments, both Prdx V^{wt} and Prdx V^{si} mice were divided to each two groups (Control vs UUO group, each n = 8). The UUO groups were subjected to unilateral ureteral obstruction (UUO) by ligation of the left ureter for seven days. The control groups were performed to the same treatment for seven days, with the exception of the ligature.

Results: Consistent with our previous data, the protein expression of Prdx V was less in UUO group kidney than the control group kidney. Compared with UUO-induced Prdx V^{wt} mouse kidney, UUO-induced Prdx V^{si} mouse kidney had more stained by TGF-β and α-SMA which is gradually increased by fibrosis progression. Knockdown of Prdx V in kidney exacerbated the UUO-induced increase in fibrotic marker expression, such as TGF-β, α-SMA, and vimentin, and also, augmented the reduction of E-cadherin, an epithelial marker as well as the increase in oxidative stress, such as nitrotyrosine and lipid peroxidation. Furthermore, we observed the activation of canonical and non-canonical TGF- β signal pathway, resulting in renal fibrosis progression. In canonical TGF- β signals, the increase of Smad4 that plays a critical role in nucleocytoplasmic shuttling of Smad2/3 is remarkable in UUO-induced Prdx V^{si} mouse kidney. In non-canonical TGF-β signals, phosphorylation of Stat3 is accentuated in UUO-induced Prdx V^{si} mouse kidney consistent with our earlier in vitro data.

Conclusions: Prdx V is an anti-fibrotic effector that sustains renal physiology. Negative regulation mechanism of TGF-β signaling by Prdx V could be a therapeutic target to protect renal fibrosis.

SA-PO296

The Kidneys and the Lungs in the Rat Show Different Vascular and Fibrotic Changes in an Acute Model of Fat Embolism in the Presence or Absence of the Renin Inhibitor Aliskiren Hisham Elsherbiny,[4] Farnaz Khalafi,[1] Vaishnavi L. Vaidyanathan,[3] Alan Poisner,[2] Dauod Arif,[3] Ahsan Siddiqi,[3] Agostino Molteni.[1] *[1]University of Missouri at Kansas City, Kansas City, MO; [2]Univ of Kansas Medical Center, Overland Park, KS; [3]University of Missouri-Kansas City, Kansas City, MO; [4]Internal Medicine, University of Missouri at Kansas CIty, Kansas City, MO.*

Background: In a rat model of fat embolism (FE) induced by injection of triolein (T), a severe inflammatory reaction leads to vasculitis and pulmonary fibrosis that was mitigated by drugs interfering with the renin angiotensin system (RAS): a renin inhibitor aliskiren (ALI). We extended the study to the kidneys by evaluating the renal arterial response to T treatment in this FE model and the effect of ALI.

Methods: 22 Sprague Dawley rats received T (0.2 ml IV, n=18) or saline (n=4). The T-treated rats were divided into three groups of 6 rats each and injected IP one hour later, with saline, ALI 50mg/kg or ALI 100mg/kg. Four controls received saline. Rats were killed 48 hours later; the organs fixed and stained with H&E, trichrome and smooth muscle actin (SMA). The vascular evaluation included lumen patency (LP) and media adventitia ratio (MAR), a marker of edema. Photos at 400 X and 100 X were taken on each slide by two pathologists unaware of the slide identity. Alpha SMA and trichrome-stained slides were digitally analyzed by image J software (NIH) to quantify the amount of myofibroblasts and collagen present in each slide.

Results: Rats injected with T + saline showed the expected severe pulmonary vascular inflammation markedly reduced by both ALI doses but no significant inflammatory response was observed in the kidneys. T + ALI 50 showed a significant ($p<0.01$) increase in pulmonary lumen patency vs the T + saline group which revealed only a trend in reduction vs the controls. No differences in lumen patency were seen for renal arteries. The pulmonary MAR measurements were similar in the four groups whereas there was a significant effect in the kidneys ($p<0.0007$) with a slightly larger ratio for the T +saline and T + ALI groups. Image J determination revealed other organ differences with ALI reducing alpha SMA and trichrome in lungs but not in kidneys. An opposite trend was seen in the MAR where T +ALI showed a return toward control values vs the T + saline induced increase while no difference among treatments were observed in lungs.

Conclusions: MAR differences suggest that FE has some renal vascular effects in this acute model mediated by the RAS, albeit different from that in the lungs.

Reduced Proteoglycans in the Kidney Causes Both Tubule and Glomerular Abnormalities Nabin Poudel,[1] Maria C. Munteanu,[1] Robert Silasi-Mansat,[2] Florea Lupu,[2] Myron Hinsdale.[1,3] *[1]Physiological Sciences, Oklahoma State University, Stillwater, OK; [2]Program of Cardiovascular Biology Research, Oklahoma Medical Research Foundation, Oklahoma City, OK; [3]Department of Cell Biology, University of Oklahoma, Oklahoma City, OK.*

Background: Most cells produce some form of proteoglycan(s). The initial assembly of glycosaminoglycan (GAG) on the core protein of proteoglycans(PG) requires the transfer of a xylose to a designated serine. The enzyme responsible for this is xylosyltransferase and it exists in two isoforms as xylosyltransferase 1(XylT1) and 2 (XylT2). The latter is ubiquitously expressed in many organs suggesting a significant biochemical role of XylT2 dependent proteoglycans in these organs. In our XylT2 knock-out mice (*Xylt2-/-* mice), substantial XylT activity remains in the kidney due to the remaining XylT1 activity. However, considerable renal abnormalities still occur including glomerular basement membrane changes, fibrosis, and tubule dilation. Our previous findings in *Xylt2-/-* mice established that proteoglycans are important in cyst development in the liver. Considering our findings in the *Xylt2-/-* mice and that reduced proteoglycans occurs in many different diseases affecting the kidney (e.g. polycystic kidney disease, PKD), we hypothesize that GAG levels have a modifying role in kidney function. Notably, PKD patients can develop proteinuria indicating a much poorer long-term prognosis.

Methods: Blood Urea Nitrogen (BUN) was measured from *Xylt2-/-* mice. Western blotting was performed on urine of *Xylt2-/-* mice to detect proteinuria. Transmission Electron Microscopy (TEM) was used to evaluate the structural changes in glomerular basement membrane and kidney tubule. In addition, TEM was performed on kidneys from mice injected with polyethylenemine (PEI) to measure anionic sites in the GBM.

Results: *Xylt2-/-* mice have increased BUN, proteinuria, and, in aged mice, renal failure. Investigations also show that additional changes occur ultrastructurally in the glomerular basement membrane including decreases in anionic charge. Furthermore, tubule structure is also impacted indicating tubule dysfunction.

Conclusions: The findings in the XylT2 deficient kidneys indicates that XylT2-dependent glycosaminoglycan (GAG) assembly onto core proteins is important in nephron homeostasis. Our analyses suggest that one source of the proteinuria could be reduced renal proteoglycans.

Serelaxin Improves Cardiac and Renal Function in a DOCA-Salt Model of Cardiorenal Syndrome in Rats Dong Wang,[5] Yuhuan Luo,[1] Komuraiah Myakala,[1] Xiaoxin Wang,[3] David J. Orlicky,[2] Evgenia Dobrinskikh,[4] Moshe Levi.[3] *[1]University of Colorado, Aurora, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]University of Colorado Denver, Aurora, CO; [4]University of Colorado, Denver, Aurora, CO; [5]medicine, Uc denver, Aurora, CO.*

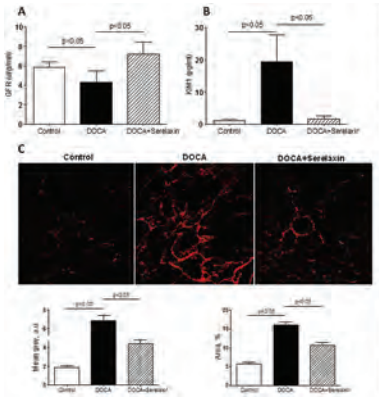
Background: Serelaxin, a recombinant form of the naturally occurring peptide hormone relaxin-2, is a pleiotropic vasodilating hormone that has been studied in patients with acute heart failure. In this study, the effects of serelaxin on cardiac and renal function, fibrosis, inflammation and lipid accumulation were studied in DOCA-salt treated rats.

Methods: Uninephrectomized rats were assigned to two groups: controls provided with normal drinking water and DOCA provided with DOCA pellets and sodium chloride drinking water. After 4 weeks, the DOCA-salt rats were randomly selected and implanted with osmotic minipumps delivering vehicle or serelaxin for another 4 weeks.

Results: Treatment with serelaxin prevented cardiac and renal dysfunction in DOCA-salt rats. Serelaxin prevented cardiac and renal fibrosis, as determined by Picrosirius Red staining and Second Harmonic Generation (SHG) Microscopy. Treatment of DOCA-salt rats with serelaxin decreased renal inflammation, including the expression of TGF-β, NFκB, MCP-1, interleukin-1, interleukin-6, intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1) and CD68 macrophages. Serelaxin also decreased lipid accumulation in kidney in part by decreasing SREBP-1c, SREBP-2, ChREBP, FATP1, HMGCoAR, and LDL receptor, that mediate fatty acid and cholesterol synthesis and uptake, and increasing Acox1 and ABCA1, that mediate fatty acid oxidation and cholesterol efflux.

Conclusions: In conclusion, serelaxin reversed DOCA-salt induced cardiac and renal dysfunction by modulating inflammation, lipid metabolism, and fibrosis.

Funding: NIDDK Support, Commercial Support - Novartis



Serelaxin improves renal function of DOCA-salt rats. (A) DOCA induced a decrease in glomerular filtration rate and treatment with serelaxin reversed the decrease in glomerular filtration rate. **(B)** DOCA induced a marked increase in urinary KIM1 excretion and treatment with serelaxin significantly decreased and normalized KIM1 excretion. **(C)** Second Harmonic Generation Microscopy shows DOCA induces a marked increase in tubulointerstitial fibrosis and treatment with serelaxin markedly decreased the fibrosis.

The RNA Binding Protein Staufen2 Is Required to Maintain Integrity of the Golgi Apparatus and Podocyte Cell-Matrix Adhesion Jessica J. Harris,[1] Valerie A. Schumacher.[2] [1]*Boston Childrens Hospital, Boston, MA;* [2]*Childrens Hospital Boston, Boston, MA.*

Background: Proper adhesion of podocytes to the glomerular basement membrane is necessary to withstand high transcapillary filtration pressure and to prevent glomerulosclerosis. Our preliminary data shows that the RNA binding protein Staufen2, known to mediate mRNA transport and local translation in neurons, is required for podocyte-matrix adhesion. In addition, we demonstrate that mice deficient in Staufen1 and 2 are more susceptible to glomerular disease, suggesting a role for local translation in the maintenance of the glomerular filtration barrier. The present study aims at determining the molecular mechanisms by which Staufen2 regulates cell-matrix adhesion.

Methods: A cell biological and biochemical approach was used to study the role of Staufen2 in the maintenance of cell-matrix adhesion.

Results: The most critical cell-matrix adhesion receptor in podocytes is a3b1 integrin, which bridges laminin 521 in the GBM to the intracellular actin cytoskeleton. We show that glycosylation of integrin β1 is altered in Staufen2 knockdown immortalized podocytes and that there is decreased phosphorylation of the b1 integrin effectors Src tyrosine kinase and focal adhesion kinase (FAK). Specifically, complex-type *N*-glycans added to b1 integrin in the Golgi apparatus by glucosaminyltransferases Gnt-III and V were decreased in Staufen2 knockdown cells. Both corresponding mRNAs were found to be bound and stabilized by Staufen2, suggesting a role for Staufen2 in regulating complex-type glycosylation. In addition, the Golgi apparatus was severely fragmented in Staufen2 knockdown podocytes, especially following mechanical stretch. This coincided with an increase in F-actin, known to cause Golgi fragmentation.

Conclusions: Staufen2 mediated morphological and functional integrity of the Golgi apparatus may represent a novel mechanism by which podocyte-matrix adhesion is maintained.

The Role of Plekha7 in Renal Fibrosis Michael M. Yeboah,[1] Marla A. Chesnik.[2] [1]*Medicine, Medical College of Wisconsin, Milwaukee, WI;* [2]*Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: Chronic kidney disease (CKD) affects about 12% of all adults in the United States and is associated with significant morbidity, including but not limited to progression to end-stage kidney failure, and increased cardiovascular death. The associated healthcare costs are enormous and continues to increase. Progressive tubule-interstitial fibrosis (TIF) is the hallmark of CKD irrespective of the underlying kidney disease. TIF results from excessive deposition and accumulation of extracellular matrix in the renal interstitium by myofibroblasts which may originate from tubular epithelial cells through a process called epithelial-mesenchymal transition (EMT). The pleckstrin homology domain containing family A member 7 (Plekha7) is a novel protein that is localized at the adherens junction of epithelial cells in association with E-cadherin which is involved with intercellular contacts. Plekha7 is also linked to signaling molecules (including β-catenin) and the cellular cytoskeleton. A SNP in Plekha7 has been associated with hypertension in multiple genome-wide association studies, and mutation of Plekha7 in rats leads to a reduction in salt-sensitive hypertension. In this study, we examined a possible role of Plekha7 in modulating EMT and development of renal fibrosis.

Methods: In vivo, plekha7 mutant and wild type rats underwent unilateral ureteral obstruction (UUO), an established model of kidney fibrosis. The animals were euthanized after 2 weeks and the kidneys were retrieved for analysis of fibrosis markers. In vitro, plekha7 was stably knocked down or overexpressed in HK-2 cells via lentiviral transduction.

Results: Plekha7 mutation resulted in increased TGF-beta expression, macrophage recruitment, and fibrosis in rat kidneys after UUO. In HK-2 cells, plekha7 knockdown reduced E-cadherin and increased alpha-smooth muscle actin and collagen 1A1 expression, while plekha7 overexpression in the cells was associated with increased E-cadherin and reduced fibronectin and collagen 1A1 expression.

Conclusions: Mutation of Plekha7 results in increased renal fibrosis in rats. Knockdown of plekha7 promotes EMT in HK-2 cells, while plekha7 overexpression restores the epithelial phenotype and reduces TGF-β-induced EMT.

Characterization of a Synthetic Adeno-Associated Virus (AAV-2/Anc80) That Targets Kidney Stroma and Validation through Gli2 Deletion in Fibrosis Yoichiro Ikeda,[4] Ru Xiao,[1] Luk Vandenberghe,[1] Zhao Sun,[3] Benjamin D. Humphreys.[2] [1]*Schepens Eye Research Institute, Harvard Medical School, Boston, MA;* [2]*Washington University School of Medicine, Clayton, MO;* [3]*Washington University in St Louis, Saint Louis, MO;* [4]*Washington University, School of Medicine, St. Louis, MO.*

Background: AAV is a non-integrating virus currently in human clinical trials for gene therapy. There are no reports of AAV with tropism to kidney, limiting our ability to deliver genetic material to that organ. We characterized the kidney tropism for a panel of AAV serotypes to set the stage for future use in human clinical trials.

Methods: Pseudotyped AAV with various capsid proteins and promoters were prepared and tested to validate the efficacy of transduction in mouse kidney. Initial studies utilized GFP reporters and later studies used AAV viruses that express Cre recombinase. To establish whether an AAV-based approach could efficiently delete floxed genes in kidney pericytes, we injected AAV-2/Anc80-CASI-Cre (3x10^11 GC/mouse) into Gli2(f/f);R26(tdTomato) mice or control. After three weeks, we performed UUO surgery, then kidneys were analyzed. Human iPSC kidney organoids and primary human kidney fibroblasts from patients were exposed to AAV-GFP and analyzed with fluorescent microscopy.

Results: Of all serotypes of AAV analyzed, AAV-2/Anc80-CASI most efficiently transduced kidney cell types. When AAV-2/Anc80-CASI-Cre was injected into R26(tdTomato) reporter mice, 58.9±3.5% (mean±SEM) of all pericytes became TdTomato positive. Other reporter positive cells were mesangial cells and juxtaglomerular cells. AAV-Cre injected Gli2(f/f); R26(tdTomato) mice had reduced fibrosis including 30 – 60% reduction in aSMA, fibronectin, collagen1a1, collagen3a1 mRNA and protein levels after UUO compared to control, which is consistent to immunofluorescent stainings of aSMA and collagen1. There were 40% fewer myofibroblasts in the Gli2flox compared to control kidneys after UUO. There was no toxicity to extrarenal organs with this dose, though higher dose (10^12 GC/mouse) of AAV-2/8-CASI did cause hepatitis. AAV-2/Anc80-CASI-GFP drove GFP specifically in stromal cells of human iPSC kidney organoids (30% of total Meis1 positive cells) and primary human kidney fibroblasts.

Conclusions: We demonstrate that AAV-Cre targets kidney pericytes and efficiently deleted Gli2 leading to an antifibrotic effect. AAV strategies will be useful both in preclinical models but also in human clinical trials.

Adult Renal Stem/Progenitor Cells Can Revert LPS-Induced Endothelial-to-Mesenchymal Transition of Endothelial Cells Fabio Sallustio, Alessandra Stasi, Claudia Curci, Rossana Franzin, Chiara Divella, Paola Laghetti, Giuseppe De Palma, Angela Picerno, Monica Rutigliano, G. Lucarelli, Michele Battaglia, Giuseppe Castellano, Loreto Gesualdo. *DETO, University of Bari, Bari, Italy*.

Background: Acute Kidney Injury (AKI) is the major complication encountered in sepsis. Lipopolysaccharides (LPS) are frequently involved in the pathogenesis of AKI, that is mainly characterized by endothelial cell (EC) dysfunction. EC acquire a myo-fibroblast phenotype, by endothelial-to-mesenchymal transition (EndMT), contributing to the renal fibrosis. Resident adult renal stem/progenitor cells (ARPCs) enhance tubular regenerative mechanism during AKI, but little is known about their effects on endothelial compartment. The aim of this study is to investigate the effects of ARPCs on endothelial dysfunction.

Methods: Endothelial cells were stimulated in vitro with LPS for 48h and co-cultured with ARPCs for 24h. MTT cell viability assay was used to analyze the EC proliferation rate following LPS stimulation and in co-culture with ARPCs. FACs analysis was used to study the expression of myofibroblast markers. Gene expression profiles of ARPCs and EC were generated using Agilent Microarrays.

Results: We observed a significant increase of EC proliferation after stimulation with LPS. ARPCs in co-culture with EC normalized their proliferation rate and decrease the cell growth rate, even in presence of LPS. Moreover, LPS induced a significant decrease of EC markers, CD31 and VE-cadherin and a significant increase of EC dysfunction markers, Collagen I and Vimentin. ARPCs in co-culture with EC abrogated the LPS-induced EndMT by restoring the high expression of CD31 (95% vs 66%) and VE-cadherin (96% vs 31%) and limiting Collagen I (18% vs 73%) and Vimentin (35 % vs 50.86%) expression. Microarray analysis showed that LPS induced the upregulation of 305 genes and the down regulation of 694 genes in ARPCs (Q value < 0,05 and Fold change >2). Gene Set Enrichement Analysis and pathway analysis identified 27 genes specifically involved in prevention and recovery from infections caused by external agents.

Conclusions: Our data demonstrate that ARPCs could preserve EC phenotype by regulating LPS-induced EndMT. Interestingly, LPS induces the expression of a specific gene set in ARPCs able to prevent EC dysfunction.

SA-PO303

Alpha-Actinin-4 Is Required for Shp2 Activation in Podocytes Hsiao-Hui Lee. *Department of Life Sciences and Institute of Genome Sciences, National Yang-Ming University, Taipei, Taiwan.*

Background: Integrins mediate cell-matrix interaction and form focal adhesion (FA) to connect with cytoskeleton in adherent cells. Previously, we found that Shp2 promotes ROCKII activation that facilitates FA maturation and stress fibers orientation to optimize cellular tension in response to the increase of matrix rigidity.

Methods:

Results: In this study, we identified that α-actinin-4 interacts with Shp2 at FAs in mouse embryonic fibroblasts by an in vitro pull-down assay with recombinant Shp2 N-SH2 domain. This interaction between endogenous Shp2 and α-actinin-4 at FAs was confirmed by co-immunoprecipitation and proximity ligation assay. Since α-actinin-4 plays an important role in podocytes adhesion, we then used a mouse temperature-inducible podocyte line and found that differentiated podocytes exhibited distinct FAs and stress fibers with the hyperactivation of Shp2 and ROCKII. Knockout of ACTN4, which encodes α-actinin-4, by CRISPR/Cas9 reduced Shp2 activation significantly in podocytes. Furthermore, inhibition of Shp2 reduced ROCKII activation, FAs, stress fibers, and BSA-filtration ability of podocytes.

Conclusions: Taken together, our results suggest the essential role of α-actinin-4 in Shp2 activation that is crucial for the cell adhesion and filtration function in podocytes.

Expression of APOL1 Risk Alleles (G1 and G2) Compromises Spreading of Podocytes by Down Regulation of β3 Integrin Ali Hussain,[2] Rukhsana Aslam,[1] Vinod Kumar,[5] Ashwani Malhotra,[5] Karl Skorecki,[4] Pravin C. Singhal.[3] *[1]Feinstein Institute for medical research, Glenoaks, NY; [2]Feinstein Institute of Medical Research, New York, NY; [3]North Shore LIJ Health System, Great Neck, NY; [4]Rambam Health Care Campus, Haifa, Israel; [5]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Genetic epidemiology indicated that Africans Americans are at four fold higher risk for the development of focal segmental glomerulosclerosis when compared to European Americans. This disparity amongst African American has been attributed to carrying APOL1 risk alleles (G1 and G2). Expression of APOL1 G1 and G2 by podocytes has been reported to promote cell death both *in vitro* and *in vivo* studies. However, the role of APOL1G0 (wild- type) in podocytes is far from clear. Podocytes are normally detached and excreted in the urine in a normal physiological state. However, adjacent podocytes are able to maintain the integrity of the glomerular filtration barrier by spreading over the naked basement membrane caused by detachment of podocytes. We hypothesize that APOL1 risk alleles (G1 and G2) could be affecting the spread of podocytes compromising integrity of glomerular filtration barrier.

Methods: Cultured immortalized human podocytes proliferate at 33°C and differentiate at 37°C. Podocytes stably expressing vector, APOL1G0, APOL1G1, and APOL1G2 grown on coverslips (collagen coated) were incubated in media for 12 and 24 hours at 37°C (n=4). Subsequently, podocytes were labeled with α-actinin antibody and examined under a confocal microscope. Average size of podocytes determined at 8 random fields using J Image program. Proteins extracted from the cells treated under similar conditions, were probed for β3 integrin and α-actinin expession and reprobed for actin.

Results: Podocytes expressing APOL1 G1 and G2 displayed decreased ($P<0.01$) spreading when compared to podocytes expressing vector (V) or APOLO1G0 (Mean podocyte size at 12 hours: V, 74.3 ± 18.6; APOLO1G0, 87.8 ± 15.3; APOL1G1, 42.5 ± 12.2; APOL1G2, 35.2 ± 9.7 μM and at 24 hours: V, 118.1 ± 15.7; APOL1G0, 130.6 ± 17.5; APOL1G1, 65.1 ± 18.0; APOL1G2, 79.7 ± 16.4 μM) both at 12 h and 24 h. Podocytes expressing APOL1G0 displayed increased ($P<0.05$) spreading when compared to Vector. Western blot analysis demonstrated 2- 5 fold decreased expression of β3 integrin and α-actinin in podoctyes expressing APOL1G1 and G2 when compared to podocytes expressing vector and APOL1G0.

Conclusions: Expression of APOL1 risk alleles (G1 and G2) compromised podocyte spreading by down regulation of β3 intergrin α-actinin expressions.

Inhibiting Post-Translational Core Fucosylation Protects against Albumin-Induced Proximal Tubular Epithelial Cell Injury Wang Dapeng. *The First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: Albuminuria is an independent risk factor for renal interstitial fibrosis (RIF). Glomerular-filtered albumin may cause injury to proximal tubular epithelial cells (PTECs) in endocytic and non-endocytic pathways via megalin and TGFβRII respectively. As megalin and TGFβRII are both modified by post-translational core fucosylation which plays a critical role in RIF, we identified whether or not core fucosylation is a potential target for reducing albumin-induced injury to PTECs.

Methods: We constructed a human PTEC-derived cell line of HK-2 cells and a bovine serum albumin (BSA) injury model *in vitro*. RNAi was used to inhibit expression of megalin, TGFβRII and FUT8. Western blotting, immunostaining, enzyme-linked immunosorbent assay, lectin blotting and fluorescence-activated cell sorting were used to determine BSA-induced endocytic and non-endocytic damages in HK-2 cells. FUT8 is a core fucosylation-related gene, the expression of FUT8 was significantly increased after incubation with BSA in HK-2 cells.

Results: FUT8siRNA significantly reduced core fucosyaltion of megalin and TGFβRII. Meanwhile, it could also inhibit activation of the TGFβ/TGFβRII/Smad2/3 signaling pathway. Furthermore, FUT8siRNA could reduce monocyte chemotactic protein-1; reactive oxygen species and apoptosis; and significantly decrease fibronectin and collagen I levels in BSA-overloaded HK-2 cells. Notably, inhibiting core fucosylation is more effective than either inhibiting megalin or inhibiting TGFβRII in the prevention of albumin-induced injury to PTECs.

Conclusions: Inhibition of core fucosylation could effectively alleviate albumin-induced endocytic and non-endocytic injury to PTECs, our study provides a potential therapeutic target in albuminuria-induced injury.

Funding: Government Support - Non-U.S.

SA-PO306

Binding of Anti-dsDNA Antibodies to Major Vault Protein of Proximal Renal Tubular Epithelial Cells Resulted in Increased Fibronectin Expression and MCP-1 Secretion Susan Yung, Shirli S. Ho, Abel Chun, Kin Yi Au, Kwok Fan Cheung, Mel Chau, Daniel Tak Mao Chan. *Department of Medicine, The University of Hong Kong, Hong Kong SAR, Hong Kong.*

Background: Anti-dsDNA antibodies deposit in the kidney parenchyma in lupus nephritis. In addition to complement activation by immune complexes and activation of downstream pro-inflammatory mechanisms, whether these antibodies could directly induce organ damage remains controversial. We investigated the binding of human anti-dsDNA antibodies to proximal renal tubular epithelial cells (PTEC) and the downstream impact on cell functions.

Methods: Human polyclonal anti-dsDNA antibodies were isolated from the sera of lupus nephritis patients using affinity chromatography and those with high binding affinity to PTEC were selected for further studies. PTEC membrane, cytosolic and nuclear proteins were isolated and immunoprecipitated with anti-dsDNA antibodies to identify cross-reactive antigens using liquid chromatography-mass spectrometry (*LC-MS*).

Results: Anti-dsDNA antibodies bound to a 100 kDa protein, identified as major vault protein (MVP), which was present in the cytosolic and nuclear fractions, but not in the plasma membrane fraction. Incubation of PTEC with anti-dsDNA antibodies increased MVP expression, as determined by Western blot analysis, in a time-dependent manner ($P<0.001$, for 24h), and accompanied by increased fibronectin expression ($P<0.01$) and MCP-1 secretion ($P<0.05$) compared to cells incubated with IgG from healthy controls. Immunohistochemical studies showed predominantly perinuclear localization of MVP and weak intracellular expression of fibronectin under basal conditions. MVP overexpression in PTEC, by transfection with MVP plasmid, resulted in clustering of MVP in the cytoplasm, which was accompanied by fibronectin accumulation in the extracellular matrix and increased MCP-1 secretion ($P<0.01$). MVP gene silencing using RNAi resulted in 40% reduction in fibronectin expression and 53% reduction in MCP-1 secretion. Kidney biopsies from lupus nephritis patients showed markedly increased MVP expression, predominantly on proximal tubular epithelial cells.

Conclusions: Our data showed that anti-dsDNA antibody binding to MVP in PTEC was associated with downstream inflammatory and fibrogenic processes.

SA-PO307

Module IV-Defected Mutant CCN2 Knock-In Transgenic Mice Grow and Develop Normally, but Fibrotic Properties Are Attenuated in a Number of Kidney Diseases Tsutomu Inoue, Ono Atsushi, Hirokazu Okada. *Saitama Medical University, Iruma-gun, Saitama, Japan.*

Background: CCN2 has been considered as important therapeutic target for CKD. It also plays a part in wound healing and metabolism in hard tissues, thus inhibition of the overall function of CCN2 is not practical as a treatment. Therefore, we are focusing on the modules that are responsible for fibrosis in the kidney.

Methods: As previously reported, we found that module IV-defective CCN2 expressed in tubular epithelial cells did not induce fibronectin synthesis in other cells. A CCN2 knockout mouse is potentially lethal. We next generated exon 5-deleted CCN2 gene knock-in mice (CCN2Ex5-/-), in which mutant CCN2 was expressed under the same control as the wild type. This experimental strategy allows us to investigate the fibrotic properties of CCN2 in detail. Unilateral ureter obstruction (UUO), subtotal nephrectomy (5/6Nx) and ischemic reperfusion (IRI) models were employed.

Results: In the UUO model, interstitial fibrosis was progressed at 8 and 24 hours, and 7 days in a time-dependent manner. The fibrotic area detected by Masson trichrome staining was significantly reduced in CCN2Ex5-/- mice. Expression of mutant CCN2 was elevated in CCN2Ex5-/- mice in comparison to CCN2Ex5+/+ mice. On the other hand, the expression of type I collagen (0.86 ± 0.28 vs. 0.52 ± 0.18), TGF-β1 (0.35 ± 0.07 vs. 0.23 ± 0.06), PAI-1 (0.13 ± 0.05 vs. 0.06 ± 0.04) were significantly decreased in CCN2Ex5-/- mice ($p<0.05$, Mann-Whitney U test). In the IRI model, although there was no significant difference in fibrosis or cytokine expression in the acute phase (at 3 days), both the progression of fibrosis and expression of related cytokines were significantly suppressed in CCN2Ex5-/- mice in the chronic phase (2 weeks). The same results were obtained with the 5/6Nx model. Western blot analysis using UUO 24-hour whole kidney samples revealed that there were no significant differences in signaling alterations in previously-reported cascades, including MAPK (ERK, p38, JNK) and Wnt/β-cat, between CCN2Ex5+/+ and CCN2Ex5-/-.

Conclusions: As module IV-defective CCN2 probably acts in a dominant-negative manner, the progression of interstitial fibrosis was suppressed in our transgenic mice. Also, this study indicates that module IV specifically contributes to the progression of CKD regardless of the type of primary disease process.

Sexual Dimorphism in the AKI to CKD Transition in the Rat Ixchel Q. Lima Posada,[3] Cinthya giovanna Portas cortés,[3] Rosalba Pérez-villalva,[2] Francesco Fontana,[4] Andrea Sanchez-Navarro,[3] Roxana Rodríguez Romo,[3] Gerardo Gamba,[1] Elena Zambrano,[1] Norma Bobadilla.[2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion SZ, Mexico City, Mexico; [2]Molecular Physiology Unit, México, Mexico; [3]UNAM, Ciudad de México, Mexico; [4]Università degli studi di Modena e Reggio Emilia, Modena, Italy.*

Background: Recent epidemiological and experimental evidence has shown that after an episode of AKI, patients are at risk for developing CKD. In addition, it has been shown that the progression of chronic kidney disease is greater in men than in women before menopause, suggesting the involvement of sex hormones. This study evaluated if there is sexual dimorphism in the acute kidney injury to CKD transition, as well as the time course of the mechanisms involved in this potential dimorphic response.

Methods: Thirty nine female (F) and 39 male (M) rats were included. The rats were divided into two groups: sham operated and rats underwent 45 min bilateral renal ischemia (F+IR, and M+IR). All groups were studied and sacrificed at: 24 h, 1, 2, 4, and 4-months post-ischemia. Also, 41 oophorectomized rats were included and divided into sham or IR groups (Op and Op+IR). At the end of each experimental period, physiological, histopathological, and molecular studies were performed.

Results: We found a sexual dimorphic response in the AKI to CKD transition. After 24 h, I/R induced a similar functional and structural extent of renal injury in females and males, but female rats exhibited less oxidative stress and increased renal GSH content. After 4 months and despite similar renal injuries, the M+IR group developed CKD characterized by progressive proteinuria, renal dysfunction, tubulo-interstitial fibrosis and glomerular hypertrophy. Most of these alterations were observed since the 3rd month after IR and were associated with increased oxidative stress and a significant reduction in HIF1α, VEGF and endothelin receptor B mRNA levels since the 1st month. Interestingly, F+IR group did not develop CKD. Moreover, this group exhibited a significant increase in eNOS, TGFβ and Hif1α mRNA levels, since the 1st month after IR. Supporting this sexual dimorphism, Of+IR rats developed CKD similar to that observed in M+IR group.

Conclusions: We found a sexual dimorphic response in the AKI to CKD transition. Early antioxidant defense and higher TGFβ, HIF1α and eNOS mRNA levels were among the renoprotective mechanisms that the F+IR group demonstrated.

Funding: Government Support - Non-U.S.

Kidney-Resident Macrophages (KRM) Upregulate Pro-Angiogenic Response in Chronic Ischemic Kidney Injury Amrutesh Puranik,[2] Irina A. Leaf,[1] Ahmed Saad,[2] Joseph P. Grande,[2] Stephen C. Textor,[2] Amir Lerman,[2] Jeremy S. Duffield,[3] Lilach O. Lerman.[2] *[1]Biogen, Cambridge, MA; [2]Mayo Clinic, Rochester, MN; [3]Vertex Pharmaceuticals, Boston, MA.*

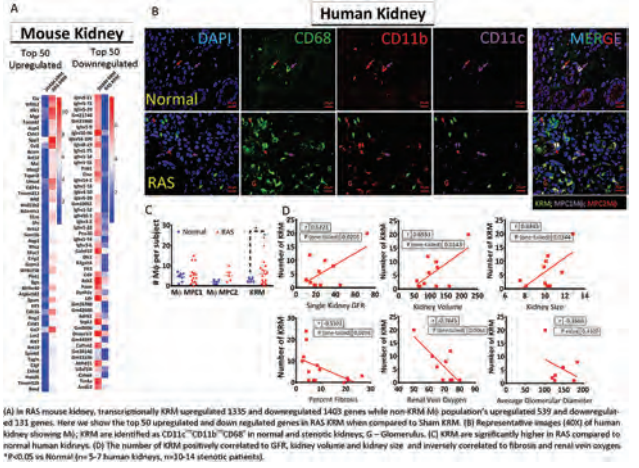
Background: Macrophages (Mϕ) play important roles in regulating progression & resolution of renal injury in renal artery stenosis (RAS). We have recently found that murine kidney Mϕ expressing $CD64^+F4/80^+FCRIV^+CD11b^{int}CD11c^{int}$ are anti-fibrotic and reparative. We hypothesized that these are KRM & expand in mouse and human renal ischemic disease

Methods: Using $CX3CR1^{creER}$:$Rosa26^{tdTomato}$ mice we fate-mapped the KRM and studied their kinetics in RAS. To dissect molecular mechanisms potentially underlying their protective properties in RAS, we compared KRM transcriptional profiles to non-KRM Mϕ by RNA Sequencing (Fig A). Furthermore, we identified $CD11b^{int}CD11c^{int}CD68^+$ KRM in human kidney biopsies of normal and RAS patient kidneys and correlated their number with kidney function (Fig B).

Results: Fate-mapping studies identified $CD64^+F4/80^+CD11b^{int}CD11c^{int}$ as KRM. BrdU labeling show KRM expand in RAS. KRM showed a more robust response to RAS compared to Sham KRM and non-KRM Mϕ (Fig A). RAS KRM were transcriptionally heterogeneous, containing both pro- and anti-inflammatory pathways. Angiogenic Pathway was the greatest functionally enriched in RAS-KRM. Further, while both KRM and non-KRM upregulated immune pathways, only KRM downregulated immune genes including Irf5, a molecular switch to pro-inflammatory states. Finally, KRM number significantly (Fig C) increased in human stenotic kidney biopsies compared to normal and correlated with better kidney function and lower fibrosis (Fig D).

Conclusions: Thus, murine $CD64^+F4/80^+FCRIV^+CD11b^{int}CD11c^{int}$ Mϕ are KRM, and can also be identified in human kidneys. KRM show a more robust response to chronic ischemic kidney injury compared to non-KRM Mϕ, upregulating a pro-angiogenic and reparative gene profile. These observations may have important prognostic and therapeutic implications in chronic kidney injury.

Funding: NIDDK Support



(A) In RAS mouse kidney, transcriptionally KRM upregulated 1335 and downregulated 1403 genes while non-KRM Mϕ population's upregulated 539 and downregulated 131 genes. Here we show the top 50 upregulated and down regulated genes in RAS KRM when compared to Sham KRM. (B) Representative images (40X) of human kidney showing Mϕ; KRM are identified as $CD11c^{+}CD11b^{int}CD68^{+}$ in normal and stenotic kidneys; G – Glomerulus. (C) KRM are significantly higher in RAS compared to normal human kidneys. (D) The number of KRM positively correlated to GFR, kidney volume and kidney size and inversely correlated to fibrosis and renal vein oxygen. *P<0.05 vs Normal (n= 5-7 human kidneys, n=10-14 stenotic patients).

SA-PO310

Hypoxia-Induced Proteins as Novel Biomarkers of Early Stage Kidney Disease Leah M. Ewart,[1] Karen A. Creevey,[1] Caitriona M. McEvoy,[1] Debra F. Higgins.[1,2] *[1]UCD Conway Institute, Dublin, Ireland; [2]School of Medicine, University College Dublin, Dublin, Ireland.*

Background: In the kidney, hypoxia (low oxygen) promotes fibrogenesis through stabilisation of hypoxia inducible transcription factors (HIFs), induction of pro-fibrogenic and pro-inflammatory gene expression, and modulation of the extracellular matrix. Inhibiting HIF-1 function attenuates renal fibrosis in vivo. As hypoxia is an early pathological feature of kidney injury, hypoxia-induced proteins may represent novel urinary biomarkers for detection of early stage renal injury.

Methods: Hypoxia-induced gene and protein expression was analysed in two pre-clinical models of kidney injury; reverse-unilateral ureteral obstruction (R-UUO) and gentamicin-sulphate-induced (GS) renal disease (40 or 120 mg/kg/day for 9 days), and in two independent kidney transplant biopsy collections from the GoCAR (Genomics of Chronic Allograft Nephropathy, United States) and the North Dublin Renal Biobank (Ireland) studies.

Results: A number of hypoxia-responsive genes were significantly increased in UUO and down-regulated with resolution of injury. Expression analysis of these genes revealed positive correlation with degree of injury and negative correlation with eGFR in the two independent renal transplant collections. Furthermore, urinary levels of the encoded hypoxia-responsive proteins correlated with injury in the gentamicin model and inhibition of their function protected the kidney from disease.

Conclusions: We conclude that hypoxia-responsive proteins are up-regulated during kidney injury, can be exploited as urinary biomarkers for early stage kidney disease and have potential as novel therapeutic targets for CKD.

Hypoxia-Inducible Factors-1α Driving a Metabolic Shift in Tubular Epithelial Cells Promotes Renal Fibrosis Qi Yuan,[1] Junwei Yang.[2] *[1]Nanjing Medical University, Jiangsu Nanjing, China; [2]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Hypoxia promotes fibrosis in various renal disease models. Hypoxia-inducible factor 1 (HIF-1), a transcriptional factor, is a master regulator of gene expressions under hypoxic conditions. Fatty acids are used to fuel oxidative phosphorylation (OXPHOS) to produce ATP in normal tubular epithelial cells. Hypoxia can drive glycolysis, as an oxygen deficit results in limited OXPHOS. Recent studies have established that besides glycolysis, several aspects of lipid metabolism including lipid droplets and β-oxidation play key roles in adaptation to low oxygen conditions. Therefore, we hypothesize that the HIF pathway may provide a switch through which metabolic phenotypes can be amended during the process of renal fibrosis.

Methods: Western blot and qPCR analysis were performed to examine the levels of lipid catabolism enzymes, glycolytic enzymes and HIF-1α in folic acid (FA) induced renal fibrotic mice. Then, FA mice were administered with control or dinitrophenol (DNP), which causes kidney hypoxia and activates HIF-1α, to determine whether HIF-1α affects metabolic switch. Further mechanism was searched in tubular epithelial cells in vitro.

Results: We identified significant lipid accumulation and higher expression of glycolytic enzymes accompanied with up-regulated HIF-1α in renal tissues of FA mice. DNP treatment decreased fatty acid oxidation and increased glycolysis, which served to maintain sustained ATP and promote fibroblast proliferation and ECM production in mice kidney. In tubular epithelial cells, TGF-βaccumulated higher amount of lipids through a combination of metabolic alterations including fatty acid uptake, decreased fatty acid oxidation, and activated glycolysis enzymes, while increased the markers of collagen fibrils. Transfection with siRNA to HIF-1α reversed the effect in vitro.

Conclusions: It can be concluded that HIF-1α plays a major role in the metabolic reprogramming of renal fibrosis. Targeting the HIF pathway may provide novel therapeutic approach of kidney fibrosis.

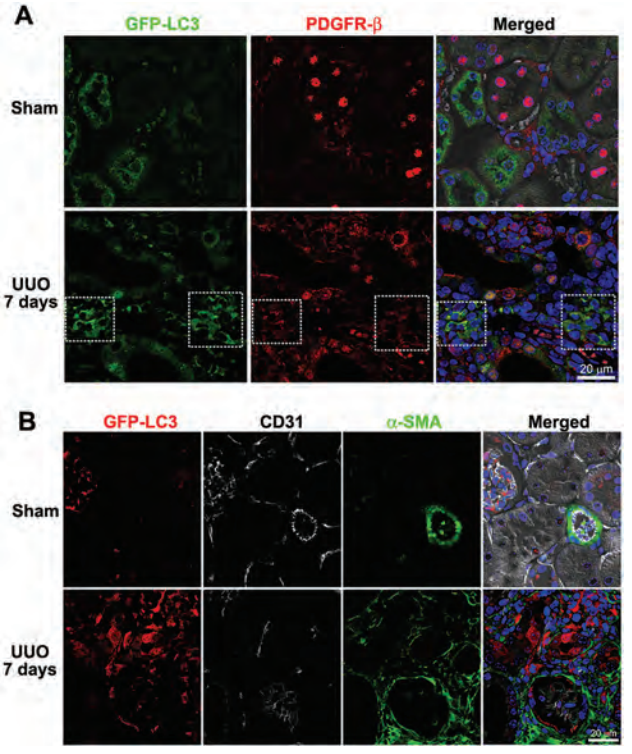
Autophagy in FOXD1 Stroma-Derived Cells Plays a Critical Role in Renal Tubulointerstitial Fibrosis Yong Kyun Kim,[3,4] Sun-ah Nam,[2] Chul Woo Yang,[1] Jin Kim.[2] *[1]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [2]The Catholic University of Korea, Seoul, Republic of Korea; [3]Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [4]Cell Death Disease Research Center, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Autophagy is a cellular process of degradation of damaged cytoplasmic components and regulates cell death and proliferation. It remians unclear whether the induction of autophagy has positive impact or negative impact in renal tubulointerstitial fibrosis (TIF). FOXD1 lineage pericyte has been recognized to plays a critical role in renal TIF. Here, we hypothesized that autophagy in FOXD1 lineage stromal cell may have pivotal role in renal TIF.

Methods: To examine the distribution of cells where autophagy was induced, we used GFP-LC3 transgenic mice. We also generated conditional knockout mice in which Atg7 is genetically ablated specifically in FOXD1-cells ($Atg7^{f/f}$;FOXD1-Cre^{+}).

Results: Punctate distribution of GFP-LC3 was was highly expressed in not only renal tubular epithelial cells but interstitial cells after UUO, which were colocalized with PDGFR-β positive cells. Tubulointerstitial fibrosis was enhanced in $Atg7^{f/f}$;FOXD1-Cre^{+} after UUO through Smad dependent TGF-β signaling compared with wild type (WT) mice. In $Atg7^{f/f}$;FOXD1-Cre^{+}, the accumulation of interstitial myofibroblasts was increased and the differentiation of pericyte into myofibroblasts was enhanced compared with WT mice after UUO. The peritubular capillary rarefaction and the apoptosis of interstitial cells were accelerated in $Atg7^{f/f}$;FOXD1-Cre^{+} after UUO.

Conclusions: Our data showed that autophagy in FOXD1 stroma-derived cells play a protective role in development of renal TIF, which may be a new therapeutic target for renal TIF.



A. After UUO, GFP-LC3 puncta was highly expressed in not only renal tubular epithelial cells but also interstitial cells, which were colocalized with PDGFR-β positive cells.B. GFP-LC3 puncta were rarely colocalized with a-SMA–positive interstitial cells or CD31-positive cells.

SA-PO313

Autophagy Is Induced via HIF-1 to Facilitate Renal Interstitial Fibrosis during Unilateral Ureteral Obstruction in Mice and Hypoxia in Tubular Cells Jing Liu,[1,2] Man J. Livingston,[2] Qingqing Wei,[2] Zheng Dong.[2,1] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; [2]Augusta University Medical College of Georgia, Augusta, GA.*

Background: Autophagy, a fundamental cellular catabolic process, has recently been implicated in renal fibrosis. However, it is unclear how autophagy is activated under this condition. Hypoxia-inducible factors (HIF) are master regulators of hypoxia responsive genes and may contribute to renal fibrosis. Whether HIF is involved in autophagy activation during renal fibrosis is largely unknown.

Methods: In vivo, renal fibrosis was induced by unilateral urethral obstruction in mice. In vitro, renal proximal tubular cells were exposed to hypoxia to induce fibrotic changes. YC-1 was used to inhibit HIF pharmacologically. Kidney proximal tubule-specific HIF-1 knockout (PT-HIF-1 KO) mice were also examined.

Results: UUO induced HIF-1 and autophagy, which was accompanied by renal interstitial fibrosis. Pharmacological inhibition of HIF with YC-1 attenuated autophagy activation and renal interstitial fibrosis during UUO. Moreover, compared with wild-type mice, PT-HIF-1 KO mice showed significantly lower autophagy during UUO. These mice also had lower levels of renal fibrosis as shown by the decreased expression of fibronectin, collagen I, α-SMA and vimentin. In cultured proximal tubular cells, hypoxia induced HIF-1, autophagy, and the accumulation of fibronectin, which were suppressed by the HIF inhibitor YC-1. In addition, knockdown HIF-1 in these cells attenuated autophagy activation and fibronectin accumulation during hypoxia exposure.

Conclusions: The results suggest that in renal fibrosis, HIF-1 may activate autophagy in renal tubular cells to facilitate the development of renal interstitial fibrosis.

Screening Fibroblasts for Novel Therapeutic Targets in CKD Ian Logan,[3] Neil S. Sheerin,[1] Victoria G. Shuttleworth.[2] *[1]Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Newcastle University, UK, Newcastle Upon Tyne, United Kingdom; [3]newcastle hospitals, Newcastle----, United Kingdom.*

Background: The most significant problem in nephrology is the progression of Chronic Kidney Disease (CKD) to End Stage Renal Disease (ESRD), which requires either dialysis or transplantation to sustain life. Despite an our knowledge that ESRD is caused by accumulation of fibrotic scar tissue leading to organ failure, no treatments are

available to treat fibrosis. Targeting disease-causing renal fibroblasts may hold the key to new drugs to treat CKD.

Methods: Drug screening: Human renal fibroblasts were isolated under ethical approval from the normal poles of 3 nephrectomy specimens and expanded by outgrowth. They were cultured in the presence of TGF B-1 and 181 drugs targetting human epigenetic enzymes prior to WST-1 proliferation assays. Flow cytometry: Cell cycle profiles were evaluated by propidium iodide staining fixed cells, whereas apoptosis was analysed using Annexin V staining in live cells. Animal studies: Black 6 mice underwent unilateral ureteric obstruction (UUO) by ligation, under ethical approval and licencing, then treated with Aurora kinase inhibitors from day zero. Animals were sacrificed on day 10. Immunohistochemistry for alpha-SMA was performed on kidney tissue and analysed by automated microscopy. Values were subject to T-test statistical analysis.

Results: 1. Drug screening revealed that 15 Aurora kinase inhibitors were effective at inhibiting proliferation of primary renal fibroblasts to more than 85%. Counterscreening showed these had no such impact on primary tubular cells. 2. Flow cytometry demonstrated that fibroblast cell cycle profiles were relatively unchanged upon Aurora kinase inhibitor treatment, but we observed a large enrichment in apoptosis to > 85% upon drug treatment. 3. We observed a 75% reduction in alpha-SMA staining upon treatment with Aurora kinase A inhibitor in injured kidneys compared to vehicle-treated animals.

Conclusions: 1. Primary renal fibroblasts can be propagated and used as a model of CKD in target identification studies. 2. Targeting Aurora kinases with small molecule inhibitors causes selective apoptosis in fibroblasts but not tubular cells. 3. UUO mice demonstrate reduced fibroblast accumulation, by alpha-SMA expression, upon Aurora kinase A inhibition. Overall, our data suggest that Aurora kinase inhibitors may have therapeutic utility in slowing progression of CKD to ESRD.

SA-PO315

Mechanisms of GLP-1 Receptor Independent Renoprotective and Anti-Fibrotic Effects of DPP-4 Inhibitor Linagliptin in GLP-1 Receptor Knockout Mice with 5/6 Nephrectomy Berthold Hocher,[3] Ahmed A. Hasan,[3] Karoline von Websky,[3] Christoph Reichetzeder,[3] Oleg Tsuprykov,[3] Jingli Guo,[2] Denis Delic,[1] Thomas Klein.[1] *[1]Boehringer Ingelheim, Biberach, Germany; [2]Charité-Universitätsmedizin, Berlin, Germany; [3]University of Potsdam, Potsdam, Germany*.

Background: Dipeptidyl peptidase (DPP)-4 inhibitors were reported to have beneficial effects in experimental chronic kidney disease models. The underlying mechanisms are not clearly understood. Many studies suggested that these renoprotective effects are mediated via the glucagon like peptide-1 (GLP-1)/GLP-1 receptor pathway. To challenge this hypothesis we investigated the renal effects of the DPP-4 inhibitor linagliptin (LIN) in GLP-1r$^{-/-}$ mice with 5/6 nephrectomy (5/6 Nx)

Methods: The mice were allocated to the following groups: sham + wild-type + placebo (PBO); 5/6 Nx + wild-type + PBO; 5/6 Nx + wild-type + LIN; sham + GLP-1r$^{-/-}$ + PBO; 5/6 Nx + GLP-1r$^{-/-}$ + PBO and 5/6 Nx + GLP-1r$^{-/-}$ + LIN and the treatment period was 12 weeks

Results: 5/6 Nx led to the development of renal interstitial fibrosis and glomerulosclerosis, increased plasma cystatin C levels and suppressed renal gelatinase/collagenase activity and these effects were counteracted by LIN treatment. In addition, proteins were separated from kidney tissues and subjected to LC-MALDI mass spectrometry. LIN treatment significantly up-regulated 4 peptides derived from collagen Iα1, thymosin β4, α-enolase and heterogeneous nuclear ribonucleoprotein A1 (HNRNPA1) and significantly down-regulated one peptide derived from Yb-1 (Nuclease-sensitive element-binding protein 1)

Conclusions: HNRNPA1 phosphorylation plays a major role in the downstream nuclear signaling of atrial natriuretic peptide (ANP) through cGMP and cGMP-dependent protein kinase. In the kidney, a disturbance of ANP-mediated cGMP synthesis is known to be a trigger of fibrosis. Also, Yb-1, α-enolase and thymosin β4 were reported to be involved in renal fibrosis through controlling TGFβ-1, PAI-1, and extracellular matrix degradation. In conclusion, the beneficial renal effects of LIN in mice with 5/6 nephrectomy cannot solely be attributed to the GLP-1/GLP-1 receptor pathway, highlighting the importance of other novel signaling pathways influenced by DPP-4 inhibition such as collagen I homeostasis, the ANP/cGMP/HNRNPA1 pathway, Yb-1, α-enolase and thymosin β4

The Atypical Chemokine Receptor 2 Limits Fibrotic Remodelling after Ischemia-Reperfusion Injury of the Kidney Moritz X. Lux, Andrei Bideak, Alexander Blaut, Nuru Eltrich, Volker Vielhauer. *Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-University Munich, Munich, Germany*.

Background: Acute kidney injury (AKI) is a risk factor for the development of chronic kidney disease (CKD). After ischemia-reperfusion-injury (IRI), a major aetiology of human AKI, resolution of renal inflammation allows tubular regeneration, whereas ongoing inflammatory injury mediated by infiltrating leukocytes leads to nephron loss and renal fibrosis, typical hallmarks of CKD. The atypical chemokine receptor 2 (ACKR2) is a chemokine decoy receptor, which scavenges inflammatory CC-chemokines and reduces local leukocyte accumulation and inflammation.

Methods: Here, we hypothesized that ACKR2 limits leukocyte infiltration, inflammation and fibrotic tissue remodelling after renal IRI, thus preventing progression to CKD after AKI. We tested this hypothesis by subjecting wild-type (WT) and Ackr2-deficient mice to IRI induced by transient renal pedicle clamping. In addition, in vitro experiments were performed with tubulointerstitial tissue isolated form wild-type and Ackr2-/- mice.

Results: Compared to WT control Ackr2 deficiency lead to significantly increased CCL2 levels in TNF-stimulated tubulointerstitial tissue in vitro. In vivo, Ackr2 deficiency did not affect renal dysfunction and tubular injury in early IRI one day after bilateral or 5 days after unilateral pedicle clamping, although accumulation of mononuclear phagocytes increased in postischemic Ackr2-/- kidneys. Regarding long-term outcomes, postischemic Ackr2-/- kidneys displayed significantly more tubular injury 5 weeks after unilateral IRI, which was associated with persistent increases in mononuclear phagocyte and T cell infiltrates compared to WT. Moreover, Ackr2 deficiency resulted in more severe inflammation in postischemic kidneys, with increased expression of proinflammatory chemokines and M1 macrophage markers, and enhanced accumulation of Ly6C^{high} inflammatory macrophages. This was associated with aggravated renal fibrosis in Ackr2-/- kidneys 5 weeks after IRI, as revealed by increased expression of matrix molecules, renal accumulation of αSMA+ myofibroblasts and enhanced renal infiltration of bone marrow-derived fibrocytes.

Conclusions: These data suggest that the chemokine decoy receptor ACKR2 plays an important role in limiting persistent inflammation, tubular loss, and renal fibrosis after ischemic AKI, and thus prevents subsequent progression to CKD.

Loss of the Protein Cystathionine β-Synthase during Kidney Injury Promotes Renal Tubulointerstitial Fibrosis Qiongjing Yuan. *Xiangya Hospital, Central South University, Changsha, China*.

Background: Renal tubulointerstitial fibrosis (TIF) is the common pathway of progressive chronic kidney disease. Inflammation has been widely accepted as the major driving force of TIF. Cystathionine β-synthase (CBS) is the first and rate-limiting enzyme in the transsulfuration pathway. The purpose of this study was to investigate the potential role and mechanism of CBS in renal inflammation and TIF.

Methods: Renal function, tubulointerstitium damage index score, extracellular matrix (ECM) deposition, and the expressions of CD3, CD68, IL-1β, TNF-α were measured in sham operation and UUO rats. Proteomics and gene array analysis were performed to screen differentially expressed molecules in the development of renal inflammation and TIF in UUO rats. The expression of CBS was detected in patients with obstructive nephropathy and UUO rats. We confirmed the expression of CBS using western blot and real-time PCR in HK-2 cells. Overexpression plasmid and siRNA were transfected specifically to study the possible function of CBS in HK-2 cells.

Results: Abundant expression of CBS, localized in renal tubular epithelial cells, was revealed in human and rat renal tissue, which correlated negatively with the progression of fibrotic disease. Expression of CBS was dramatically decreased in the obstructed kidney from UUO rats as compared with the sham group. In addition, knocking down CBS exacerbated ECM deposition, whereas CBS overexpression attenuated TGF-β1-induced ECM deposition in vitro. Inflammatory and chemotactic factors were also increased in CBS knockdown HK-2 cells stimulated by IL-1β.

Conclusions: These findings establish CBS as a novel inhibitor in renal fibrosis and as a new therapeutic target in patients with chronic kidney disease.

Funding: Government Support - Non-U.S.

Paraquat-Induced CKD in Experimental Animals: Relevance to CKD of Unknown Origin (CKDu) Fan Lei,[3] Qingtian Li,[1] Yi Tang,[4,1] Luping Huang,[1] Luan D. Truong,[2] David Sheikh-Hamad.[1] *[1]Baylor College of Medicine, Houston, TX; [2]The Methodist Hospital, Houston, TX; [3]Baylor College of Medcine, Houston, TX; [4]West China Hospital of Sichuan University, Chengdu, China*.

Background: CKDu is typically encountered in farm workers from different regions of the world, and kidney biopsies from representative patients display tubulointerstitial injury and inflammation. Survey of patients with chronic kidney disease of unknown etiology (CKDu) encountered at a safety net hospital in Houston, identified the herbicide Gramoxone (paraquat-based) as a possible etiologic factor for CKDu in migrant workers originally engaged in agricultural/farm work before their immigration to the US. These subjects described repeated and chronic (years) skin exposure to Gramoxone, as protective gear is not ordinarily used during preparation and spray work. We tested the hypothesis that repetitive exposure of mice to paraquat will lead to chronic kidney disease; as such, repetitive exposure to Gramoxone might produce CKD in humans.

Methods: Mice were given 10 i.p. injections of 20 mg/kg paraquat, given weekly, and allowed free access to food and water. This dose was based on titration experiments where a single dose produces no functional or histological changes in the kidney. At the end of week 10, 24h urine was collected and blood samples were obtained for measurement of creatinine clearance. Mice were euthanized and kidneys were subjected to PAS and Trichome stains and immunostain for T cells (CD3) and macrophages (F4/80); parallel examination of lung, liver and spleen was carried out to determine the effects on other organs.

Results: Paraquat-treated mice displayed doubling of serum creatinine, 50% reduction in creatinine clearance, three-fold increase in T-cells and macrophage infiltration, and increased trichrome staining. There were no changes in the morphology or macrophage infiltration in the liver and lung; however, the spleen showed increased macrophage infiltration.

Conclusions: Repetitive exposure of mice to paraquat given i.p. to simulate exposure of farm workers to paraquat (Gramoxone), produced CKD characterized by tubulointerstitial injury and inflammation, reminiscent of the pathological picture observed in patients with CKDu. Our data suggest that chronic exposure to the herbicide Gramoxone by farm workers in different regions of the world should be considered as a possible etiologic factor for CKDu.

SA-PO319

Development of a Refined Subtotal Nephrectomy Mouse Model to Study Progressive Renal Disease James O'Sullivan, Sarah L. Finnie, Laura Denby. *University of Edinburgh, Edinburgh, United Kingdom*.

Background: Chronic Kidney Disease (CKD) is characterised as the decline of renal function over time. Metabolomics data has elucidated new metabolites, including citrulline, to be associated with human CKD indicating alterations in metabolic pathways being involved in CKD [Rhee EP et al, 2013]. Furthermore, defective fatty acid oxidation has been found to be involved in tubulointerstitial fibrosis [Kang HM et al, 2015]. The rat subtotal nephrectomy (STNx) model is a commonly used model of progressive renal disease and replicates many aspects of human CKD. However, a consistent mouse model of STNx which mimics most of the typical features of CKD would be advantageous to elucidate the pathophysiology.

Methods: Inbred 129S2/SvHsd mice were randomised to sham or one-step subtotal nephrectomy (STNx) surgery and sacrificed after 6 (n=6/gp) or 10-weeks (n=8-9/group). The one-step STNx involves flank incision nephrectomy followed by flank incision removal of upper and lower poles of the remaining kidney. At sacrifice, tissue was taken for RNA, protein and histological analyses. At baseline, 6 weeks and 9 weeks animals had urine collected and echocardiography performed. Blood pressure (BP) was measured by tail cuff plethysmography (baseline and 9 weeks). Gene expression was determined via qRT-PCR and normalised to 18S/PPIA. Fibrosis scoring was conducted using picrosirius red staining for total collagen, quantified in ImageJ.

Results: This refined STNx model had a survival rate of 95%. At 10 weeks post surgery STNx animals had significantly increased systolic BP (Sham: 110+/7.8 vs STNx: 153.1+/-13.8 mmHg), significantly increased urinary albumin:creatinine ratio ($p<0.01$; 16.37 vs 2028.5 mg/g; sham vs STNx) and developed left ventricular hypertrophy (LVH) (1.4-fold increase STNX vs SHAM). Histological analysis revealed a significant increase in renal and cardiac fibrosis in STNx mice vs sham which was reflected by 2-fold increase in collagen gene expression ($p<0.01$ vs sham). Additionally, gene expression of metabolic pathways was downregulated in STNx kidneys and heart ($p<0.05$ vs sham).

Conclusions: Our refined STNx model is a robust model of progressive renal disease that develops significant hypertension, proteinuria, renal and cardiac fibrosis, LVH and alterations in cellular metabolism indicating this model reflects the cardio-renal dysfunction observed in human CKD.

SA-PO321

Elucidation of the Gene Regulatory Networks That Control Diabetes-Induced Kidney Damage Bo Wang,[2] Haroon Naeem,[2] Guanyu Ji,[1] Phillip Kantharidis,[2] Sharon D. Ricardo.[2] *[1]E-gene co.ltd, ShenZhen, China; [2]Monash University, Melbourne, NSW, Australia*.

Background: Diabetes mellitus is an epidemic of the 21st century and is now the leading cause of chronic kidney disease (CKD) that results in the development of fibrosis. TGF-b1 is of the major drivers in the progression of diabetic nephropathy We use advanced next-generation sequencing (NGS) technology to identify genomic sequences and signatures unique to TGF-b1 to provide a global approach for interrogating TGF-β1-induced kidney damage. The discovery of new therapeutic targets was coupled with complementary functional analyses to identify and validate novel regulators of kidney injury and fibrosis.

Methods: Mesangial cells were treated with TGF-β1 at 10ng/ml for 72 hours, followed by NGS to determine miRNA, mRNA, DNA methylation and H3K27me3 levels. Integrative and complementary functional analyses were employed to identify potential regulators and qPCR and luciferase assay used for validation.

Results: A genetic and epigenetic library as established and includes miRNA, RNA, DNA methylation and histone (H3K27me3) modification. Our data showed that the hyper-methylation of DNA methylation was induced by TGF-β1. H3K27me3 expression was inhibited by TGF-β1 treatment together with the regulation of NRARP and TnxB identified as new targets in the development of fibrosis. The negative and positive expression pattern of miRNA and mRNA were quantified in response to TGF-β1. A novel regulator, miR-378, was also found to be a pivotal regulator of the TGF-β/Smad pathway, confirmed using NRK52E cells co-transfected with the SMAD3 CAGA reporter and miR-378 in the presence of TGF-β1 for 3 days of culture and STZ-induced diabetic kidney samples. Moreover, miR-378 was found to regulate MAPK signalling through repression of the MAPK1 pathway.

Conclusions: TGF-b1 mediates genetic and epigenetic interactions in kidney mesangial cells within a complicated network of gene expression and DNA modification. DNA methylation and H3K27me3 modification were found to be involved in TGF-β1 regulated pathogenesis of mesangial cells. We established a multi-omics library to demonstrate the gene expression regulated by miRNA and epigenetic changes. We report a protective regulator of miR-378 through mediating MAPK pathway, in the downstream induction of kidney cell fibrosis and mesangial hypertrophy. Moreover, H3K27me3 was indicated as a novel regulator using NGS technology.

SA-PO322

Modulation of Upregulated Transcriptional Signaling Pathways in Rodent Diabetic Nephropathy after Treatment with a Novel Anti-Fibrotic Agent FT011: Correlates with Human Diabetic Kidney Disease Robyn G. Langham,[3] Sebastian Martini,[1] Felix H. Eichinger,[2] Viji Nair,[2] Matthias Kretzler,[2] Darren J. Kelly.[1] *[1]Ludwig Maximilian University Munich, Munich, Germany; [2]University of Michigan, Ann Arbor, MI; [3]Monash University, Melbourne, VIC, Australia*.

Background: Transcriptomic analysis of diabetic nephropathy (DN) biopsy tissue has provided valuable insights into the regulatory networks that may drive progressive disease. In this study, we undertook a transcriptomic analysis associated with demonstrated improved histological and clinical effects of a new anti-fibrotic, FT011, in a rodent model of DN. We also aimed to compare the animal findings with that already understood to be involved in human DN, a means of predicting utility of FT011 in humans.

Methods: Control and diabetic Ren(2) rats were treated with either FT-011(200mg/kg/day) or vehicle for 16 weeks(Early), or for the last 2 days of the study(Late). Total RNA was isolated from renal cortex, reverse transcribed, linearly amplified, and hybridized on Affymetrix microarrays. The Ingenuity® Pathway Analysis Software Suite was used for gene analysis.

Results: Gene expression data in diabetic rats showed early findings in keeping with Type 1 diabetes, early suppression of lymphocyte genes, and an increase in known diabetes-related genes. Short term FT011-treatment of rats with established DN showed acute up-regulation of Fatty acid oxidation pathways, while the longer term treatment showed a suppression of activated inflammatory pathways, and suppression of drivers of fibrosis (*TGFß*) and of transcriptional regulators known to be involved in progressive forms of DN (*STAT1*). Short-term late treatment with FT011 showed a reduced inhibitory effect on inflammatory pathways. Comparison with the transcriptome from human DN demonstrated several overlapping key features and pathways of the human disease to be recapitulated in the animal model used, with a significant z-score of 6.4.

Conclusions: Analysis of transcriptional changes mediated by treatment with FT011 has shown an early up-regulation of fatty acid oxidation, and a later, more sustained anti-inflammatory and anti-fibrotic action. Similarity of the changes seen in the animal model to the human transcriptional data set highlights the close alignment of this model to the human disease. As well, the ability of FT011 to modulate key signaling pathways identified as important in the pathogenesis of human DN further supports its potential utility as a new therapy for DN.

SA-PO323

Melatonin Ameliorates Intrarenal Renin-Angiotensin System in a 5/6 Nephrectomy Rat Model Sayaka Ishigaki, Naro Ohashi, Takashi Matsuyama, Shinsuke Isobe, Naoko Tsuji, Tomoyuki Fujikura, Takayuki Tsuji, Akihiko Kato, Hideo Yasuda. *Hamamatsu University School of Medicine, Hamamatsu, Japan.*

Background: Activation of the intrarenal renin-angiotensin system (RAS) plays a critical role in the pathophysiology of chronic kidney disease (CKD) and hypertension. Reactive oxygen species (ROS) are important components of intrarenal RAS activation and there has been great interest in developing strategies that target the ROS-RAS axis in the treatment of CKD. Melatonin is recognized as a powerful antioxidant, and we recently reported that impaired nighttime melatonin secretion correlates negatively with urinary angiotensinogen excretion, the surrogate marker of intrarenal RAS activity in patients with CKD. However, whether melatonin supplementation ameliorates the augmentation of intrarenal RAS in CKD has remained unknown. We aimed to clarify whether exogenous melatonin ameliorates intrarenal RAS activation via the reduction of ROS production.

Methods: 5/6 nephrectomized (Nx) rats were used as a chronic progressive CKD model and compared with sham-operated control rats. The Nx rats were divided into untreated Nx rats and melatonin-treated Nx rats. The levels of intrarenal RAS, ROS components, and renal injury were evaluated after 4 weeks of treatment.

Results: Compared with the control rats, the untreated Nx rats exhibited significant increases in intrarenal RAS (angiotensinogen, angiotensin II type 1 receptors, and angiotensin II), accompanied by elevated blood pressure, higher oxidative stress (8-hydroxy-2'–deoxyguanosine), lower antioxidant (superoxide dismutase) activity, and increased markers of interstitial fibrosis (α-smooth muscle actin and type I collagen) in the remnant kidneys. Treatment with melatonin significantly reversed intrarenal RAS and ROS activation (angiotensin II positive area (%); Nx: 5.54 ± 0.44 vs. Nx+MEL: 2.99 ± 0.33, p<0.01 and superoxide dismutase (U/g tissue); Nx: 27.4 ± 3.0 vs. Nx+MEL: 42.4 ± 3.2, p=0.011), decreased blood pressure (systolic blood pressure (mmHg); Nx: 203.5±8.7 vs. Nx+MEL: 173.0 ± 8.7, p=0.049), and ameliorated interstitial fibrosis (α-smooth muscle actin (%); Nx: 2.76 ± 0.37 vs. Nx+MEL: 1.51 ± 0.21, p=0.033).

Conclusions: Antioxidant treatment with melatonin was shown to ameliorate intrarenal RAS and ROS activation and renal injury in a 5/6 Nx rat model.

SA-PO324

Targeting Src Attenuates Peritoneal Fibrosis and Inhibits Epithelial to Mesenchymal Transition of Peritoneal Mesothelial Cells Jun Wang,[2] Liuqing Xu,[3] Na Liu,[2] Shougang Zhuang.[1] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Department of Nephrology, Shanghai East Hospital, Tongji University, Shanghai, China; [3]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: Src mediates tissue fibrosis in several organs, but its role in peritoneal fibrosis remains unknown.

Methods: We evaluated the therapeutic effect of a highly selective Src inhibitor KX2-391, on development of chlorhexidine gluconate (CG)-induced peritoneal fibrosis in a rat model.

Results: Daily intraperitoneal CG injections induced peritoneal fibrosis, indicated by submesothelial collagen fibril accumulation and myofibroblast activation, accompanied by time-dependent Src phosphorylation at tyrosine 416. KX2-391 attenuated peritoneal fibrosis, abrogating increased phosphorylation of Src and multiple signaling molecules associated with tissue fibrosis, including epidermal growth factor receptor, Akt, Signal transducer and activator of transcription 3 and nuclear factor-κ*B* in the injured peritoneum. KX2-391 inhibited proinflammatory cytokine production and macrophage infiltration of injured peritoneum. Src inhibition by KX2-391 or siRNA in cultured human peritoneal mesothelial cells led to decreased expression of α-smooth muscle actin, fibronectin and collagen I, markers of epithelial to mesenchymal transition.

Conclusions: Src may be a critical mediator of epithelial to mesenchymal transition, fibroblast activation and peritoneal fibrosis. Src could be a potential therapeutic target for treating peritoneal fibrosis.

SA-PO325

Renal Iron Trafficking – Potential Role for Endothelin System Malgorzata Kasztan, Kelly A. Hyndman, David M. Pollock. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Elevated endothelin-1 (ET-1) levels reported in sickle cell disease correlate with microalbuminuria, linking ET-1, renal iron deposition and early sickle nephropathy. In humanized sickle cell mice (HbSS), long-term ET_A receptor antagonism provides robust protection from diverse renal pathologies, including significant attenuation of renal tubular iron deposition in proximal tubules (PT). We hypothesize that ET-1 regulates renal iron trafficking in iron overload-associated sickle nephropathy.

Methods: We first determined the time and concentration-dependent effect of ET-1 on the expression of iron trafficking mediators in mouse primary PT epithelial cells.

Results: Expression of the iron import transporter transferrin receptor 1, TfR-1, and the iron storage protein, H-ferritin, were increased in concentration-dependent manner by ET-1. The ET-1-induced decrease in iron exporter ferroportin-1, FPN-1 (65% reduction), was associated with a doubling in expression of hepcidin, HAMP, a key regulator of FPN-1 and iron removal from the cell. Exposure of PT cell to plasma from HbSS mice, increased cellular iron uptake compared to plasma from control HbAA mice (0.098±0.017 vs. 0.004±0.001 ng/μl). The ET_A antagonist, BQ123, completely prevented ET-1-induced alterations in all iron mediators, suggesting involvement of ET_A receptor in iron trafficking mechanisms. Neither selective ET_B nor combined (ET_A+ET_B) antagonism affected ET-1-induced changes in iron trafficking mediators. Cortical tissues of HbSS mice showed increased expression of TfR-1, H-ferritin and decreased expression of FPN-1 compared to HbAA mice.

Conclusions: These results reveal a novel role for ET-1 in PT iron trafficking and provide rational for the use of selective ET_A receptor blockade as a potential therapeutic approach in iron overload-associated sickle nephropathy.

Enteral Iron Therapy and Renal Autophagy in Juvenile Mice with Adenine-Induced CKD Oleh M. Akchurin,[3] Edwin A. Patino,[3] Divya Bhatia,[3] Vidhi Dalal,[4] Sureshbabu Angara,[2] Stefano Rivella,[1] Mary E. Choi.[3] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]Weill Cornell Medicine, New York City, NY; [3]Weill Cornell Medical College, NEW YORK, NY; [4]NYP Cornell, Cornell, NY.*

Background: Autophagy has been implicated in the pathophysiology of chronic renal injury and fibrosis. Iron therapy is common in patients with chronic kidney disease (CKD) and non-hematologic effects of iron therapy in CKD are of great interest. Iron-induced oxidative stress can damage cellular proteins and organells, which then need to be recycled by autophagy. However, the effect of iron on renal autophagy has not been elucidated.

Methods: Autophagy proteins Beclin 1 and LC3b were evaluated by western blot in the whole kidney lysates of juvenile C57Bl/6 male mice fed the following four diets from age 3 to 11 weeks: (1) physiologic diet, (2) 0.2% adenine diet (CKD), (3) 0.5% carbonyl iron diet (iron therapy), (4) 0.2% adenine + 0.5% carbonyl iron diet. Mice were euthanized after 8 weeks of experimental diet. Data were analyzed with ANOVA followed by Tukey post-hoc test.

Results: Adenine-induced CKD, as expected, was characterized by elevated serum hepcidin, low serum iron, and low hemoglobin. Iron therapy normalized serum iron and improved anemia in mice with CKD, while further elevating serum hepcidin. Iron therapy led to elevated non-heme iron content in the kidneys of mice with and without CKD. mRNA expression of iron exporter ferroportin was induced by high iron diet in control mice but not in mice with CKD, while kidney ferroportin protein expression was reduced in CKD, irrespective of iron therapy. Iron therapy led to higher expression of autophagy proteins Beclin 1 and LC3b in the kidneys of mice with CKD, as compared to mice with CKD not treated with iron. In contrast, expression of NCOA4, a marker of ferritinophagy, was reduced in mice with CKD, without significant influence of systemic iron status.

Conclusions: To our knowledge, this is the first study that demonstrated induction of renal autophagy by iron therapy in CKD. This effect was not specific to ferritinophagy, as ferritin cargo receptor NCOA4, which mediates its autophagy, was not induced by iron therapy in this model. In our ongoing experiments, we are evaluating mechanistic relationship between iron-mediated autophagy and renal fibrosis in CKD.

Role of Hepcidin and Iron Homeostasis in the Progression of AKI to CKD Ewa U. Mandziak,[3] Yogesh M. Scindia,[2] Valentina Loi,[1] Saleh Mohammad,[3] Sundararaman Swaminathan.[3] *[1]AO Brotzu Cagliari, Cagliari, Italy; [2]Univerisity of Virginia, Charlottesville, VA; [3]University of Virginia, Charlottesville, VA.*

Background: Maladaptive repair and fibrosis after acute kidney injury (AKI) contributes to progressive loss of kidney function. Systemic iron depletion strategies using iron chelators or diet-induced iron deficiency are known to reduce renal fibrosis. Splenic red pulp macrophages are one of the primary storage sites for iron. Hepcidin (*Hamp*), the master regulator of iron homeostasis, plays an important role in anemia of chronic kidney disease (CKD) through its effects on hepatic and splenic macrophages. We hypothesized that hepcidin dependent changes in systemic iron homeostasis may modulate renal fibrosis.

Methods: To induce CKD, Folic Acid (FA) 250 mg/kg (i.p.) was administered to WT, *Hamp KO* and *Hamp Het* mice (all on C57BL/6J background). BUN was measured to monitor AKI on day 2. In some experiments *Hamp Het* mice were reconstituted with exogenous hepcidin (50 μg, i.p) after the onset of AKI. Renal function and fibrosis related parameters were examined 19 days later.

Results: Compared to WT mice, AKI and mortality were reduced in *Hamp het* and *Hamp KO* mice. This initial worse AKI translated to more severe fibrosis on day 19 in WT, as indicated by collagen and α smooth muscle actin content. Both these parameters were significantly lower in *Hamp* deficient mice. There was a large infiltration of F4/80$^+$ macrophages in the fibrotic kidneys of the WT and *Hamp KO* mice, that was not seen in *Hamp* Het mice. Compared to WT kidneys, there was a significant reduction in both NOS-2 and Arginase-1 gene expression in *Hamp* Het kidneys. Arginase-1 showed a downward trend in *Hamp KO* kidneys also. Hepcidin reconstitution exacerbated renal fibrosis in *Hamp Het* mice.

Conclusions: Our studies reveal a novel protective role of hepcidin deficiency in progression of AKI to CKD. This protection was associated with reduction in splenic iron content and renal M2 macrophage infiltration.

Copper and Copper Transporter 1 Promote Renal Interstitial Fibrosis by Regulating Intracellular and Extracellular Transport of Copper Ions Niu Yangyang, Chen Yu. *Shanghai Tongji Hospital, SHANGHAI, China.*

Background: Copper is an essential trace element required for many biological processes. Some studies have demonstrated that copper accumulating was related to liver fibrosis, but the underlying mechanism is not very clear. Copper is the essential unit of lysyl oxidase (LOXs), which are the key enzymes of crosslinking of extracellular matrix. Copper transporter 1 (CTR1) is the most important factor responding to copper transport.

Methods: Sprague-Dawley rats were divided into the sham group, unilateral ureteral obstruction (UUO) operated group and UUO treated with copper chelating agents tetrathiomolybdate (TM). Rat kidney fibroblast cells (NRK-49F) were used in vitro. The concentration of copper, the LOXs activity and the degree of cross-linking of extracellular collagen were detected in vivo and vitro.

Results: (1) The copper concentration in serum, urine and kidney of rats increased significantly at 7 days after UUO surgery; After treatment of TGF-β1, the intracellular copper concentration was increased significantly in cells; (2) The expression of CTR1 was upregulated in the kidneys of UUO rats; The level of CTR1 was increased significantly by TGF-β1 in vitro; (3) Blockage of Smad2/3 suppresses TGF-β1-induced expression of CTR1; (4) Downregulation of CTR1 significantly inhibited the intracellular copper concentration; (5) The activity of LOXs was increased significantly after TGF-β1 treatment; (6) Downregulation of CTR1 significantly inhibited the activity of LOXs and the cross-linking of extracellular collagen induced by TGF-β1 in vitro; (7) The concentration of copper, the degree of collagen cross-linking and the deposition of collagen were decreased in the kidney tissue of UUO rats after treatment with TM. The concentration of intracellular copper, the activity of LOXs and the degree of collagen cross-linking were attenuated with treatment of TM in vitro.

Conclusions: We firstly found that the intracellular copper accumulating was closely to renal fibrosis. The underlying mechanism was related with the increasing expression of CTR1 and activity of LOXs. Treatment with TM ameliorated the renal fibrosis. This study presented a novel treatment target.

NLRP3 Inflammasome Inhibition Ameliorates Tubulointerstitial Injury in the Remnant Kidney Model Orestes Foresto-Neto, Victor F. Avila, Simone C. Arias, Fernanda F. Zambom, Lisienny C. Rempel, Flavia G. Machado, Camilla Fanelli, Claudia R. Sena, Vivian L. Viana, Denise M. Malheiros, Hugo Abensur, Niels O. Camara, Roberto Zatz, Clarice K. Fujihara. *University of Sao Paulo, Sao Paulo, Brazil.*

Background: We showed previously that NF-κB signaling inhibition attenuates renal injury and inflammation in the 5/6 renal ablation (Nx) model (AJPRenal, 2007). We subsequently showed that the NLRP3 inflammasome, another innate immunity pathway, is also activated in Nx (SciRep, 2017). There is evidence that the xanthine oxidase (XO) inhibitor allopurinol (ALLO) inhibits NLRP3 activation. We investigated whether NLRP3 inhibition by ALLO exerts renoprotection in Nx.

Methods: Munich-Wistar rats (N=33) underwent Nx or sham operation (**S**, N=16). Nx rats were divided in: **Nx**, untreated, and **Nx+ALLO**, given ALLO 36 mg/kg/day vo. On day 60, tail-cuff pressure (TCP, mmHg), urinary NGAL (uNGAL, mg/24h), interstitial collagen 1 (COL, %) and macrophages (MΦ, cells/mm^2), renal XO activity (rXO, μU/mg), renal uric acid (rUA, mg/g) and renal content of heme oxygenase 1 (HO-1), superoxide dismutase 2 (SOD2), caspase 1 (CASP1) and nuclear p65 (NF-κB) (fold increase x C), IL-1β (pg/mg), and interstitial NLRP3 (cells/ mm^2) were assessed.

Results: ALLO normalized rXO activity and prevented rUA and oxidative stress enhancement in Nx. ALLO also attenuated hypertension and promoted selective tubulointerstitial protection, reducing uNGAL, COL and MΦ. ALLO reduced the renal content of the inflammasome components (NLRP3, CASP1 and IL-1β), but not the NF-κB activation.

Conclusions: In view of its antiinflammatory, antioxidant and renoprotective effects, ALLO may help to prevent the progression of CKD. FAPESP/CNPq

Protective Effect of DNA Methyltransferase Inhibitor against Progressive Renal Tubulointerstitial Inflammation and Fibrosis Eun Sil Koh,[1] Soojeong Kim,[2] Seok Joon Shin,[1] Cheol Whee Park,[1] Chul Woo Yang,[1] Yong-Soo Kim,[1] Sungjin Chung.[1,3] *[1]Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [2]Department of Biochemistry, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [3]Division of Nephrology and Hypertension, Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN.*

Background: Renal fibrosis is the final common pathway of virtually all progressive kidney diseases and correlates with the aggravation of renal function. However, the contributon of DNA methylation to the process of renal fibrosis is not clarified. The current study examined the impact of DNA methyltransferase inhibitor on the progression of inflammation and fibrosis in kidneys of mice with unilateral ureteral obstruction (UUO).

Methods: Zebularine (225 mg/kg/day), a DNA methytrasferase inhibitor, or vehicle was administred to male C57BL/6 mice intraperitoneally for 3 or 7 days after UUO operation.

Results: Administration of zebularine significantly attenuated renal tubulointerstitial fibrosis and inflammation as assessed by trichrome, α-smooth muscle actin, collgen IV, transforming growth factor-β1 staining both at 3 and 7 days after UUO. Zebularine downregulated mRNA expression levels of matric metalloproteinase (MMP) 2, MMP9 and fibronectin, and it also suppressed nuclear factor-κB (NF-κB) and pro-finlammatory cytokines such as tumor necrosis factor-α, interleukin (IL) – 1β and IL-6 in obstructed kidneys. Furthermore, zebularine treatment upregulated the nuclear expression of nuclear factor erythroid-derived 2 like factors 2 (Nrf2) and its subsequent antioxidant downstreams such as heme oxygenase-1, catalase, superoxide dismutase 1 and NAD(P) H: quinone oxidoreduates-1 in UUO kidneys.

Conclusions: Our findings suggest that inhibition of DNA methylation could restore the disrupted balance in pro-inflammatory pathway and antioxidant defence mechanism and alleviate renal fibrosis.

SA-PO331

Renal Release of Ac-SDKP Is Part of an Antifibrotic Peptidergic System in the Kidney Cesar A. Romero,[3] Nitin Kumar,[1] Oscar A. Carretero.[2] *[1]Henry Ford Health System, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI; [3]Hypertension and Vascular research Division, Henry Ford Hospital, Detroit, MI.*

Background: Ac-SDKP is a natural peptide with anti-fibrotic and anti-inflammatory properties in vascular, myocardial and kidney diseases. Ac-SDKP is present in urine and increases under angiotensin converting enzyme inhibitors (ACEi). Ac-SDKP is released from Thymosin B4 (Tβ4) by two step enzymatic reactions by meprin-α and the prolyl oligopeptidase enzymes (POP) and degraded by angiotensin converting enzyme (ACE). Tβ4, Meprin-α and POP enzymes has been reported in kidney. *We hypothesized that Ac-SDKP is produced in the kidney.*

Methods: We evaluated the presence of Tβ4, Meprin-α and POP mRNA by analyzing the trascriptome in each segment of the nephron using the public access NHI database ESBL. We confirmed kidney expression of Meprin-α and POP by immunofluorescence and enzyme activity measurements. The *Stop Flow Pressure* technique was used to evaluate the Ac-SDKP formation in different segments of the nephron, in normal condition, under POP inhibition (POPi) and ACEi. All experiments were performed in Sprague-Dawley rats.

Results: Tβ4 mRNA was present in all the nephron segments, however Meprin-α mRNA was only expressed in proximal tubule (s3 region), and POP mRNA was present in proximal tubule, loop of Henle (inner medulla) and distal nephron (distal, connecting and collecting tubules). We confirmed the expression of Meprin-α by immunofluorescence in proximal tubules and the POP was found in the distal convoluted tubule in cortex and in higher amounts in the medullary region. POP activity was also high in kidney medulla (Cortex 613.8±352.1 vs. Medulla 1162.2±408.5 pmol/min/mg prot; P<0.01). The Stop flow technique showed the high Ac-SDKP/Inulin ratio in the distal nephron: 10.5±0.8 vs. 4.2±0.1 in the proximal segments (p<0.01). POPi infusion into the kidney decreased Ac-SDKP/Inulin in comparison to the vehicle group in distal (10.5±0.8 vs 5.6±0.8, p<0.01) and proximal nephron segments (4.22±0.1 vs. 2.1±0.2, p<0.01). ACEi increased the Ac-SDKP content in all nephron segments, mainly in the distal part. Chronic infusion of POP inhibitor increase kidney medullary interstitial fibrosis and that was prevented by Ac-SDKP (Fibrotic area in %: Vehicle 1.84±0.8, POPi 3.3±1*, POPi+Ac-SDKP 1.37±0.58; **p<0.001POPi vs. Vehicle and POPi+Ac-SDKP*).

Conclusions: We conclude that Ac-SDKP is released by the nephron and has an important antifibrotic effect in the kidney.

Epstein-Barr Virus Induced Epithelial Mesenchymal Transition in HK2 Cells Sang Youb Han,[1] Seok ju Park,[1] Daeyoung Hur.[2] *[1]Inje University, GoYang, Republic of Korea; [2]Inje University College of medicine, Busan, Republic of Korea.*

Background: Epithelial mesenchymal transition (EMT) represents conversion of epithelial cells into mesenchymal phenotype. It is an important mechanism in tissue

fibrosis including kidney. Epstein-Barr virus (EBV), which is well known cause of acute febrile illness and lymphoproliferative diseases, is reported to induce tissue fibrosis such as lung, skin, and liver. However, it is not reported its association with renal fibrosis. We tested whether EBV could induce EMT in renal epithelial cells.

Methods: HK2 cells were incubated with EBV. HK2 cells changed their shape from cobble stone appearance into spindle shape. After confirmation of mesenchymal changes of HK2 cells, we evaluated E-cadherin, ZO-1, and beta-catenin for epithelial marker, N-cadherin, vimentin, TGF-beta for mesenchymal marker, MCP-1, IL8, TNF-alpha, IL18 for inflammatory changes, and Slug, Snail, V-Set And Immunoglobulin Domain Containing 4 (VSIG4) and pSTAT3 for EMT marker. All markers were tested using real-time PCR for mRNA or western blotting for protein expression.

Results: The expressions of E-cadherin, ZO-1, and beta-catenin were decreased and N-cadherin, vimentin, TGF-beta mesenchymal markers were increased after EBV exposure. And expressions of Slug, Snail, and pSTAT3 were also increased. And inflammatory markers such as MCP-1, IL8, TNF-alpha, IL18 were increased. To confirm whether these changes were due to EBV transfection or secretory proteins from EBV, the HK2 cells were stimulated with latent membrane protein 1 (LMP-1), which is representative EBV-related protein. LMP-1 downregulated the expression of E-cadherin, and upregulated those of vimentin and VSIG4. These findings suggested that EMT was induced by LMP-1 alone. To test VSIG4 involvement in LMP1-induced EMT, VSIG4 siRNA were treated in LMP1-stimulated HK2. The expression of E-cadherin and vimentin were reversed. The expression of E-cadherin was increased and that of vimentin was decreased.

Conclusions: In conclusion, EMT was induced by EBV-associated protein, LMP1, not by EBV in itself. The LMP1-induced EMT was related with VSIG4 changes. This result provided the possibility of EBV-related EMT in renal fibrosis.

SA-PO333

Novel Role of IL-20 Subfamily in the Pathogenesis of CKD Domonkos Pap,[1,2] Rita Lippai,[1] Apor Veres-Székely,[1] Réka Rokonay,[1] István M. Takács,[1] Erna Sziksz,[1,2] Beáta Szebeni,[1,2] Andrea Fekete,[1,3] Attila J. Szabo,[1,2] Ádám Vannay.[1,2] *[1]Semmelweis University, 1st Department of Pediatrics, Budapest, Hungary; [2]MTA-SE, Pediatrics and Nephrology Research Group, Budapest, Hungary; [3]MTA-SE, Lendület Diabetes Research Group, Budapest, Hungary.*

Background: Regardless of the etiology kidney fibrosis is a common outcome of progressive kidney diseases. Our recent study showed that levels of interleukin (IL)-20 subfamily members, including IL-19 and IL-24 significantly increased in newborn rat kidneys underwent unilateral ureteral obstruction (UUO). However, their precise role in the pathomechanism of renal fibrosis has not been investigated.

Methods: To study the role of IL-20 cytokine subfamily we applied a mouse model of UUO induced kidney fibrosis on wild type and IL-20 receptor beta gene knockout (IL-20Rβ KO) mice. Masson's trichrome and Picro-Sirius Red staining, real-time RT-PCR and western blot method were used to investigate the expression of fibrosis associated genes at mRNA and protein level between the two strains. We also investigated the *in vitro* effect of IL-24 treatment on transforming growth factor beta (TGF-β) and platelet derived growth factor B (PDGF-B) expression of human proximal tubular epithelial (HK-2) cells by real-time RT-PCR and flow cytometry.

Results: We found elevated level of IL-19, IL-24 and IL-20Rβ in the fibrotic kidneys. Lack of IL-20Rβ in KO mice was associated with decreased level of the pro-fibrotic marker alpha smooth muscle actin, TGF-β and PDGF-B expression and also with reduced amount of extracellular matrix deposition in the obstructed kidneys. Treatment of renal epithelial cells with IL-24 increased their TGF-β and PDGF-B production.

Conclusions: Increased expression of IL-19, IL-24 and IL-20Rβ in the fibrotic kidney suggest their role in the pathomechanism of obstructive nephropathy. IL-24 may promote tissue remodeling shifted toward an excessive deposition of extracellular matrix components via increased production of pro-fibrotic factors. Our data suggest that inhibition of IL-24 may have significant anti-fibrotic effect.

SA-PO334

Noninvasive Evaluation of Microcirculation Disorder, Tubular Injury, and Kidney Fibrosis Using Functional Magnetic Resonance Imaging Jiong Zhang,[1] Xiong Tang,[1] Ming-chao Zhang,[1] Long jiang Zhang,[2] Zhi-Hong Liu.[1] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing China, Nanjing, China; [2]Medical Imaging, Department of Medical Imaging, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: The key contributors to the progression of nearly all forms of CKD are reduced microvascular blood flow, tubular injury and fibrosis. Despite theirs importance, clinicians currently have no means of noninvasively assessing these factors, except historically relied on percutaneous renal biopsy. Recent advances in imaging technology have raised the exciting possibility of MRI. The aim of this study was to evaluate the feasibility of functional MRI for functional assessment of renal morphology and diffusion, tubular injury, also fibrosis burden in CKD.

Methods: Seventy CKD patients were studied. The feasibility of three fRMI sequences, which were diffusion-wighted-imageing (DWI), aquaporins (AQP), and magnetic resonance elastography (MRE) were evaluated to assess kindey microcirculation disorder, tubular injury and scarring burden. Capillary situation was assessed by peritubular capillaries number, which was showed by CD34 staining. Tubular injury was measured by AQP1 staining. Cortex fibrosis was measured by kidney sections stainded with Masson's trichrome, which were scanned with an Aperio ScanScope system and analyzed using ImageScope.

Results: Functional MRI sequence DWI-ADC showed negative correlation with glomerulosclerosis and cortex fibrosis burden, R^2=0.128 and 0.167 respectively, P<0.01. Apparent DWI-ADC cortex values were significantly increased in CKD stage 3 and 4, which were higher than CKD stage 1 (P=0.02). There were no significant relationships with PTCs number per x400 image. AQP1 staining, which stands for AQP in tubular cells, was significantly decreased in later stages (P<0.01). Although, the fMRI-AQP value did not show statistical correlation with renal AQP staining changings in cortex (P=0.796), AQP sequence showed positive correlation with cortex fibrosis burden (R^2=0.071, P=0.028). Apparently, MRE60e Hz had negative correlation with glomerulosclerosis and cortex scarring burden in these patients (R^2=0.115 and 0.026 respectively, P=0.040 and 0.052). Interestingly, it was showed that MRE values were significantly lower in serious renal fibrosis subgroup than mild group or normal.

Conclusions: In this pioneer study, DWI, AQP and MRE sequence from functional MRI appear to serve as noninvasive evaluation method for evaluating renal microcirculation, tubular injury and fibrosis.

SA-PO335

A Broad-Spectrum Protein-Tyrosine-Kinase Inhibitor Prevents Upregulation of Inflammation/Fibrosis-Related Genes Induced by IgA1-Containing Immune Complexes in a Passive Mouse Model of IgA Nephropathy Zhi qiang Huang,[6] Colin Reily,[1] Nuo Xu,[7] Zina Moldoveanu,[4] Lea Novak,[5] Stacy D. Hall,[3] Rhubell T. Brown,[6] Terry L. Lewis,[6] Casey T. Weaver,[5] Bruce A. Julian,[6] Christopher D. Willey,[2] Jan Novak.[6] *[1]None, Birmingham, AL; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]UAB, Birmingham, AL; [4]Univ of Alabama at Birmingham, Birmingham, AL; [5]University of Alabama at Birmingham, Birmingham, AL; [6]University of Alabama at Birmingham, Birmingham, AL; [7]university of alabama at birmingham, Birmingham, AL.*

Background: To identify potential therapeutic targets in IgA nephropathy (IgAN), we developed two systems: cultured primary human mesangial cells (MC) and a passive mouse model. Both systems use engineered immune complexes (EIC) consisting of galactose-deficient IgA1 bound by IgG autoantibody. EIC activate MC through multiple signaling pathways, leading to cellular proliferation. These events are blocked by dasatinib, a broad-spectrum protein-tyrosine-kinase inhibitor. These findings have been validated in a passive mouse model of IgAN and dasatinib prevented pathologic changes induced by EIC. To further study the effects of dasatinib, we assessed the kidney transcriptome in this IgAN mouse model.

Methods: SCID mice were injected every other day for three doses of EIC, EIC+dasatinib, or only IgA1. Kidneys were removed 1 day after last injection and snap-frozen in liquid nitrogen for RNAseq studies or fixed and processed for histopathology.

Results: Mice injected with EIC exhibited mesangial hypercellularity compared to control (51.6±8.0 *vs.* 39.4±6.5 nuclei x10^{-5}/um^2). This effect was blocked by dasatinib (39.0±5.3 nuclei x10^{-5}/um^2). RNAseq data revealed that most genes with expression altered by EIC were expressed at normal levels when dasatinib was used. Moreover, several genes that were upregulated by EICs are upregulated in human IgAN biopsy specimens (data from public databases). Among those genes, 10 were upregulated in glomeruli and 5 in tubuli. Among these genes, 7 are associated with inflammation, 4 with tissue fibrosis, and 2 with glycogen-storage disease. In mice treated with EIC and dasatinib, no upregulation of these genes was observed. SDS-PAGE-Western blotting and tissue staining for selected targets indicated that protein expression followed the pattern of mRNA expression.

Conclusions: Pathogenic EIC upregulated expression of inflammation/fibrosis-related genes. These changes were prevented by dasatinib. Use of signaling inhibitors may thus represent a rational therapeutic approach for IgAN.

Previous Resistance Training Impact in CKD Leading to Improvements in Proteinuria, Creatinine Clearance, and Mortality Rate Reduction in Rats Alexandre Saud,[2] Rafael Luiz,[2] Natalia Reinecke,[2] Wesley Silva,[4] Samuel T. Filho,[4] Rodolfo R. Rampaso,[1] Nestor Schor.[3] *[1]None, São Paulo, Brazil; [2]UNIFESP, São Paulo, Brazil; [3]Universidade Federal de Sao Paulo/ Escola Paulista de Medicina, Sao Paulo, Brazil; [4]Universidade Federal de São Paulo, Sao Paulo [SP], Brazil.*

Background: The resistance training is applied to improve and increase muscle mass, however, how resistance exercise improves renal function is not fully understood. The aim of this study was to evaluate the EXE effects on renal function and mortality rate in rats with 5/6Nx

Methods: Adult Wistar rats were divided in four groups (n=8): Previous Exercise + Nx 5/6 + post surgery Exercise (ENE), Previous Exercise + Nx 5/6 + post surgery Sedentary (ENS), Sedentary + Nx 5/6 + post surgery Exercise (SNE) and Sedentary + Nx5/6 + post surgery Sedentary (SNS). We evaluated mean arterial pressure (MAP), creatinine clearance (CrCl), proteinuria (uProt), blood urea nitrogen (BUN), maximal load test (MLT), well as mortality rate. EXE was performed as follows: 6 to 12 climbs/day, 5 days a week, during 8 weeks, 40 to 60% of maximal load test

Results: Exercise in ENE group prevented the increase in proteinuria rate (45,7±3,6 mg/24h, p<0.05) vs SNS, Creatinine Clearance(1,3±0,1ml/min p<0,05) vs all and mean BUN(33,3±2,7 mg/dL p<0,05) was lower compared with the SNS and ENS groups. A

gain of strength was observed in ENE vs all (556±35 g p<0,05). A lower mortality rate was observed in ENE(0%) vs SNS(62%). Results suggested that the EXE minimize the impact of 5/6Nx, with lower proteinuria(35%), Clearance of creatinine(40%), lower increase in BUN(35%) and gain of strength(30%)

Conclusions: Results suggested that the EXE minimize the impact of 5/6Nx, with lower proteinuria (35%), Clearance of creatinine (40%), lower increase in BUN (35%) and gain of strength (30%). These parameters indicate that exercise could have a protective effect, especially under this experimental protocol. Thus, this study suggests that the exercise plays a preventive role in mortality and could be an additional strategy to be employed in CKD.

Four Weeks of Resistance Training (RT) Improves Physical Capacity, Creatinine Clearance, and Glomerulosclerosis and Decreases Mortality Rate in Rats with CKD Rafael Luiz, Alexandre Saud, Wesley Silva, Maria A. Gloria, Rodolfo R. Rampaso, Edson A. Pessoa, Nestor Schor. *NEPHROLOGY, UNIFESP, SAO PAULO, Brazil*.

Background: The aim of this study was to evaluate if 4 weeks of RT improves physical capacity (strength gain and VO_{2peak}), renal function, glomerulosclerosis and mortality in rats with CKD by nephrectomy 5/6 (Nx5/6).

Methods: Adult Wistar rats were divided in four groups (n=8): Sedentary (S) Exercise (E), Nx 5/6 + Sedentary (NSR), Nx 5/6 + Exercise (NER). We evaluated creatinine clearance (CrCl), proteinuria (uProt), blood urea nitrogen (BUN), glomerulosclerosis, mean arterial pressure (MAP) as well mortality rate. EXE periods were as follows: 6 to 12 climbs/day, 5 days a week, during 4 weeks, 40 to 60% of maximal load test (MLT). The physical capacity was performed with maximal load test (MLT), ergoespirometry test (Vo_{2peak}) and maximal exercise test (MEtest).

Results: The CrCl was improve in NER (43%) vs NS group, (p<0.05). Proteinuria was different in NSR and NER vs S and R groups but not in NSR vs NER. BUN was higher in NSR and NER vs S and R. Glomerulosclerosis was different in NSR vs NER (p<0.05). The MAP was lower in NER vs NSR group (p<0.05). Physical Capacity (MLT, VO_{2peak} and Mtest) was increased in NER vs NSR. A higher mortality rate was observed in NS (30%).

Conclusions: Results suggested that the 4 weeks of RT minimize the impact of 5/6Nx by increase in physical capacity (MLT, VO_{2peak} and Mtest), reduce the impact on CrCl (43%) and improve in glomerulosclerosis (44%). These parameters indicate that exercise could have a protective effect, especially under this experimental protocol. Thus, this study suggests that the exercise plays a preventive role in mortality and could be an additional strategy to be employed in CKD.

Kidney Injury Induces HER3 Pathway Activation Bruno Seva Pessoa,[2] Eirini Kefalogianni,[1] Andreas Herrlich.[3] *[1]Washington University School of Medicine, St. Louis, MO; [2]Washington University St Louis, St. Louis, MO; [3]Washington University in St. Louis, St. Louis, MO*.

Background: Activation of epidermal growth factor receptor (EGFR or HER1) by specific soluble HER1 ligands drives injury-induced kidney fibrosis, and HER1 inhibition or deletion significantly protects against these effects. Another member of the HER family, HER3 has also been linked to fibrosis in lung and liver. HER1 function requires dimerization either with itself or with other HER receptors (HER2, HER3 or HER4). Whether HER3 and its ligands, soluble NRG1 and NRG2, are involved in injury-induced fibrosis and whether it acts in concert with HER1 or independently is unknown.

Methods: We performed bilateral ischemia-reperfusion injury (IRI) (30min of ischemia) or unilateral-ureteral-obstruction (UUO) (7 days) in wild-type mice. HER2, HER3, HER4 activation and their respective ligands were analyzed in mouse kidney samples by qPCR, Western blot and Immunofluorescence. Human biopsies were analyzed by Immunofluorescence.

Results: We show that kidney injury by IRI or UUO induces very significant transcriptional upregulation of HER3 and its ligands pro-NRG1 and pro-NRG2. Moreover, production of soluble active NRG1 was induced by IRI and HER3 phosphorylation could be detected in tubular cells and glomeruli. Similarly, fibrotic chronic kidney disease (CKD) biopsies also showed strong HER3 phosphorylation in tubular and glomerular compartments, suggesting that HER3 has an important function in these cellular compartments in mice and humans. To further study the HER3 pathway, we generated and validated proximal tubular- or podocyte-specific HER3 KO mice to test the role of HER3 in mouse models of kidney disease.

Conclusions: NRG1/HER3 pathway is activated by severe pro-fibrotic kidney injury, suggesting a potential role for NRG1/HER3 in this process.

RIPK3 Blockade Ameliorates Renal Fibrosis in Diabetic Model of eNOS Knockout Mice Ying Shi,[2] Yongli Zhao,[2,1] Chunling Huang,[2] Xinming Chen,[2] Carol A. Pollock.[2] *[1]The Second Hospital of Dalian Medical University, Dalian, China; [2]kolling institute, the University of Sydney, Sydney, NSW, Australia*.

Background: Current therapies for renal fibrosis are largely ineffective. Therefore, identification of novel therapeutic targets is essential. RIPK3 is identified as a crucial regulator of necrosis, apoptosis and inflammation, which have been well recognised to be involved in renal fibrogenesis. To date, the role of RIPK3 in renal fibrosis has not been reported.

Methods: Endothelial nitric oxide synthase (eNOS) knockout mice were used in the study. STZ (55 mg/kg/day) was administrated to induce diabetic model by i.p. for 5 consecutive days. Dabrafenib (RIPK3 inhibitor) or vehicle were used as treatment on diabetic mice. After 24 weeks treatment, mice were sacrificed and kidney function was measured by 24 hour of urinary albumin excretion and urinary albumin creatinine ratio (UACR) by ELISAs. Kidney histological change and ECM deposition was assessed by PAS, Masson's trichrome, picrosirius red staining and immunohistochemistry. TGF-β expression level was detected by quantitative RT-PCR analysis.

Results: RIPK3 inhibition reduced 24 hours urinary albumin excretion and UACR compared to the increased level of vehicle diabetic group. Histological detections demonstrated the vehicle diabetic group had more renal fibrosis and ECM deposition compared to Dabrafenib treated mice. Immunohistochemistry showed consistent results on type III and type IV collagen expression on above groups. Moreover, quantitative RT-PCR exhibited Dabrafenib treated mice had lower expression level of TGF-β.

Conclusions: These results suggest that RIPK3 blockade may be a potential novel target in renal fibrosis.

BET Bromodomains Regulate Tubular EMT Program during Renal Fibrogenesis Bjoern Tampe, Desiree Tampe, Gerhard A. Mueller, Michael Zeisberg. *University Medical Center Goettingen, Goettingen, Germany*.

Background: Kidney fibrosis is associated with loss of functional parenchyma, directly linked to compromised kidney function. Intratubular EMT program of TECs has been shown to contribute to impaired tubular function and correlates with disease progression. In this context, TWIST is considered as a master regulator of EMT. Transcriptional activation is associated with local N-ε-acetylation of lysine side chains towards amino-terminal tails of histone proteins. Members of the bromodomain and dextraterminal (BET) family of bromodomain-containing epigenetic readers associate with acetylated chromatin structures promoting chromatin remodeling, recruitment of proteins involved in transcriptional initiation and activation. It has recently been shown that BRD4 interacts with di-acetylated TWIST to faciliate its recruitment to target gene promoters, initiating EMT program. Because genetically inhibition of TWIST-mediated EMT program in TECs has been shown to faciliate protection of functional parenchyma, we hypothesized that phamacological BET inhibition equally blocks TEC-EMT program.

Methods: In an *in vitro* system of TEC-EMT, BET inhibition was performed using specific siRNAs and small compounds i-BET151, RVX-208, PFI-1 and (+)-JQ1. Using mice challenged with UUO, the impact of (+)-JQ-1 administration was analyzed by immunostaining and qRT-PCR with regard of renal fibrosis and solute/solvent transporters of functional parenchyma.

Results: Here, we provide evidence that TWIST-induced EMT in TECs requires BRD4. EMT inhibition by targeting BET bromodomains with (+)-JQ1 blocks BRD4/TWIST-mediated transcriptional EMT program, restores altered solute and solvent transporter expression, ultimately associated with attenuation of experimental kidney fibrogenesis. This mechanism is not limited to rodents, we provide evidence that EMT program is also driven by BRD4/TWIST in human cells. Based on existing transcriptional profiling datasets among CKD patients, induction of BRD4/TWIST is associated with intrarenal EMT program (reflected by *TWIST1*, *SNAI1*, *SNAI2*) and kidney fibrosis (reflected by *COL1A2* and *ACTA2*), suggesting that pre-requisits for therapeutical intervention by targeting BRD4/TWIST (e.g. through administration of (+)-JQ1) are also present in humans in principle.

Conclusions: In summary, inhibition of BET bromodomains in the context of EMT represents a potential anti-fibrotic therapy.

Wnt/β-Catenin-Promoted Macrophage Proliferation, Migration, and Alternative Activation Contribute to Kidney Fibrosis Ye Feng, Chunsun Dai. *Nanjing medical university, Nanjing, China.*

Background: The Wnt/β-catenin pathway initiates a signaling cascade that is crucial in both normal development and throughout life. However, the role and mechanisms for Wnt/β-catenin in regulating macrophage activation and its contribution to kidney fibrosis remain to be determined.

Methods: A mouse model with with tamoxifen-inducible deletion of β-catenin in macrophages was created.

Results: Here we found that in addition to promoting macrophage proliferation and migration, Wnt/β-catenin could exacerbate IL4 or TGFβ1-induced macrophage M2 polarization via activating STAT3 molecule. This observation was further confirmed in a mouse model with inducible deletion of β-catenin in macrophages. In that model, kidney fibrosis, macrophage accumulation, proliferation and M2 polarization were all diminished in the fibrotic kidneys compared to their control littermates.

Conclusions: This study demonstrated that Wntb-catenin signaling activation promotes kidney fibrosis may be ascribed to stimulating macrophage proliferation, migration, and M2 polarization.

Therapeutic Activity of the Novel Kinase Inhibitor ANG3070 in Models of Renal Scarring Accompanied by Co-Morbidities Prakash Narayan,[1] Bin Duan,[1] Ping Zhou,[1] Latha Paka,[1] Michael A. Yamin,[2] Itzhak D. Goldberg.[2] *[1]Angion Biomedica Corp, Uniondale, NY; [2]Angion Biomedica Corp., Uniondale, NY.*

Background: Chronic kidney disease (CKD), characterized by extracellular matrix deposition in the renal interstitium, is driven, in part by aberrant receptor tyrosine kinase signaling. We investigated the effects of a novel small molecule receptor tyrosine kinase inhibitor, ANG3070, in clinically relevant models of CKD accompanied by co-morbidities.

Methods: Approximately 18 month old male Fischer 344 rats were subjected to 5/6 nephrectomy (or sham surgery) to model CKD in middle-aged patients. Following onset of renal disease, animals were randomized to vehicle or ANG3070 (various doses, PO, BID). In order to model CKD in the setting of metabolic syndrome, ~8 week old, obese, male, ZSF1 rats were subjected to 5/6 nephrectomy, and following onset of renal disease, randomized to vehicle or ANG3070 (various doses, PO, BID). In both models, after 8 weeks of drug treatment, a comprehensive panel of renal functional and histological endpoints was evaluated to assess the effects of ANG3070.

Results: Intervention with ANG3070 in aged rats with CKD, reduced albuminuria and attenuated several indices of renal scarring including kidney hydroxyproline content, α-smooth muscle actin expression and collagen (picosirius red staining). Intervention with ANG3070 in the rat model of metabolic syndrome and CKD was associated with reduced kidney hydroxyproline content, α-smooth muscle actin expression and collagen (Masson's trichrome and picosirius red staining).

Conclusions: In clinically relevant models of renal scarring, intervention with the novel receptor tyrosine kinase inhibitor ANG3070 is beneficial.

SA-PO345

Inhibition of NF-κB Signaling in Neural Crest-Derived Fibroblasts Attenuates Renal Fibrosis Tadashi Yoshida,[3] Maho Yamashita,[1] Matsuhiko Hayashi.[2] *[1]Apheresis and Dialysis Center, Keio University School of Medicine, Tokyo, Japan; [2]Apheresis and Dialysis Center, Keio University School of Medicine, Tokyo, Japan; [3]Apheresis and Dialysis Center, Keio University School of Medicine, Tokyo, Japan.*

Background: It has been recently reported that renal fibroblasts are derived from neural crest and phenotypic conversion of fibroblasts into myofibroblasts contributes to renal fibrosis in chronic kidney disease. The aim of the present study was to determine whether the NF-κB signaling in neural crest-derived fibroblasts was involved in renal fibrosis in a mouse unilateral ureteral obstruction (UUO) model.

Methods: Transgenic (P0-Cre/IκBΔN) mice, in which truncated IκB was expressed and the NF-κB signaling was inhibited selectively in neural crest-derived cells, were generated. Renal fibrosis and infiltration of inflammatory cells were examined in P0-Cre/IκBΔN and control mice following UUO.

Results: In response to UUO, renal fibrosis was developed in P0-Cre/IκBΔN and control mice, as determined by Masson trichrome staining and SM α-actin staining. However, of importance, renal fibrosis was significantly attenuated in P0-Cre/IκBΔN mice, as compared to control mice 14 days after UUO. By contrast, renal infiltration of inflammatory cells, including neutrophils, F4/80-positive macrophages, and CD3-positive lymphocytes, was not different between P0-Cre/IκBΔN and control mice.

Conclusions: Results suggest that the NF-κB signaling in fibroblasts originated from neural crest plays an important role in renal fibrosis in chronic kidney disease.

Potential Impact of Adenine (P0) Receptors on Urinary Albumin/Creatinine Ratio in CKD Yue Zhang,[2] Christa E. Müller,[4] Tao Liu,[5] Anna U. Brandes,[1] Bellamkonda K. Kishore.[3] *[1]Univ. of Utah & VA Medical Center, Salt Lake City, UT; [2]Univ. of Utah & VA Medical Center, Salt Lake City, UT; [3]Univ. of Utah and VA Medical Center, Salt Lake City, UT; [4]University of Bonn, Bonn, Germany; [5]Univ. of Utah & VA Medical Center, Salt Lake City, UT.*

Background: P0 is a G protein-coupled receptor (R), which binds adenine with high affinity, but not adenosine, AMP/ADP/ATP. Blood levels of adenine are markedly elevated in chronic kidney disease (CKD), and positively correlate with the duration or severity of CKD. We observed that P0-R is expressed in all regions of the mouse kidney, and hypothesized that blocking it in CKD will have significant effects.

Methods: 5/6[th] nephrectomized (Nx) CD-1 mice were divided into 2 groups. One group was infused with PSB-08162, a selective antagonist of P0-R, through osmotic minipumps to attain steady state plasma concentration ~30 μM. Controls were sham-operated. After 4 weeks of infusion, urine and blood samples were collected, and the mice were euthanized.

Results: The results of analysis (mean ± se) of terminal urine and serum samples are shown in the Table. Despite no significant differences in serum creatinine (CR) between Nx and Nx+PSB groups, the latter showed marked increase in urinary albumin/CR ratio (UACR), apparently due to low urinary CR excretion. In parallel the serum levels of 3-hydroxybutyrate, a ketone body, were significantly elevated.

Conclusions: Our results suggest that blocking the P0-R in CKD may elevate UACR by reducing urinary excretion of CR, probably by decreasing its secretion by the kidney. The elevated keto acid may also contribute to reduction in CR secretion in the kidney. Conversely, the elevated adenine levels in CKD may increase CR secretion in the kidney, and thus may decrease UACR values.

Omega 3 Fatty Acid Attenuates Kidney Fibrosis in Ureteral Obstructed Mice via Enhancement of Autophagy Flux Dae Eun Choi,[1] Yoon-Kyung Chang,[2] Hyunsu Choi,[3] Chang hun Song,[1] Jiwon M. Lee,[4] Kiryang Na,[1] Kang Wook Lee,[1] Hong jin Bae,[1] Youngrok Ham.[1] *[1]Nephrology, School of Medicine, Chungnam National University, Daejeon, Republic of Korea; [2]Nephrology, School of Medicine, The Catholic University of Korea, Daejeon, Republic of Korea; [3]Clinical Institute of Medicine, Daejeon St. Mary's Hospital, Daejeon, Republic of Korea; [4]Pediatrics, School of Medicine, Chungnam National University, Daejeon, Republic of Korea.*

Background: It has been known that unilateral ureteral obstruction (UUO) induces autophagic activation in obstructed kidney. Inhibition of autophagy aggravates renal injury in UUO mice. Recently, it is reported that Omega 3 fatty acid regulate the autophagy. we evaluated whether ω3-PUFA may attenuate renal fbrosis in UUO mice, and evaluated associating mechanism.

Methods: 10-week-old male C57Bl/6 mice were divided into 4 groups; sham, Omega 3 + sham, vehicle (normal saline, same volume to Omega 3 + UUO, Omega 3 + UUO. Omega 3 and vehicle were administered orally using an NG tube (Omega 3 100mg/kg/day) from pre-operation day to 7 days after operation. Mice were sacrifced at 7 days after surgery and kidney tissue were collected. Real time RT-PCR, western blot and immunohistochemistry for molecular study and H&E stain and PAS stain for histologic examination were performed.

Results: Omega 3 treated UUO mice showed improvement of renal cell survival, renal function, and pathologic damage compared to vehicle treated UUO mice. Also omega-3 treatment reduced the renal expression of MCP-1, collagen IV, and TGF-ß in UUO kidney. UUO mice kidney showed that higher amounts of LC3, Beclin-1, Atg7 and p62 compared to sham mice. Omega 3 treated UUO kidney showed higher amounts of LC3, Beclin-1 and Atg7 and lower amounts of p62 compared to vehicle treated UUO kidney. Moreover, renal cathepsin D and ATP6E were also increased in Omega 3 treated UUO mice compared to vehicle treated UUO mice mice.

Conclusions: Omega 3 fatty acid ameliorate renal fbrosis in UUO kidney via enhancement of autophagy fux.

Funding: Government Support - Non-U.S.

The Effect of Hirudin on PAR-1, TGF-β1, α-SMA of Renal Interstitial Tissue in Rats with Unilateral Ureteral Obstruction Dai Lu,[2] Yang Kang,[1] Pei Ming,[2] Ren Tong,[2] Shouci Hu,[1] Lijuan Wei,[1] Bo Yang,[2] Lin Yan,[2] Hongtao Yang.[2] *[1]Tianjin University of Chinese Traditional Medicine, Tianjin, China; [2]Division of Nephrology, First Teaching Hospital of Tianjin University of Traditional Chinese Medicine, Tianjin, China.*

Background: In the process of renal interstitial fibrosis, hirudin may reduce the expression of proteins and genes of PAR-1, TGF-β1 and α-SMA in the renal interstitial, We explored the intervention effect of hirudin by establishing a unilateral ureteral obstruction model.

Methods: The 90 healthy Sprague-Dawley (SD) male rats, with the average weight of 180±20g, were randomly divided into Sham-operation group(SOR, n=18), unilateral ureteral obstruction model group(UUO, n=18), UUO with high dose Hirudin treatment group(UUO+HI, n=18), UUO with low dose Hirudin treatment group(UUO+LI, n=18), UUO with Lotensin treatment group(UUO+LOT, n=18). On 3rd, 7th, 14th days after the operation, 6 rats from each group were randomly sacrificed, the obstructive side of kidneys were storaged for RT-PCR and Western Blot tests to detected the expression of proteins and genes of PAR-1, TGF-β1, α-SMA with drug intervention.

Results: 1 Western Blot test: Compared with UUO group, the expression of PAR-1, TGF-β1 and α-SMA at each time point in UUO+LOT and UUO+HI groups were significantly reduced (P<0.05). **2 RT-PCR test:** Compared with UUO group, the expression of PAR-1 and α-SMA at each time points in each intervention groups were reduced (P<0.05). Compared with UUO group, the expression of TGF-β1 at different time points in UUO+HI group, on the 14th day in UUO+LI and UUO+LOT groups were decreased(P<0.05).

Conclusions: High dose of hirudin can significantly reduce the protein expression of PAR-1, TGF-β1 and α-SMA in renal interstitial of UUO rat model. Both high dose and low dose of hirudin can reduce the mRNA expression of PAR-1, TGF-β1, α-SMA in different degrees. Compared with UUO+LI group, UUO+HI group has a better effect on the down-regulation of the protein and mRNA expression of PAR-1, TGF-β1, α-SMA, the difference between two groups may be related to the mechanism of the best drug effective dose.

Impact of Intrarenal and Circulating APOL1 Expression Levels on Phenotypes in Nephrotic Syndrome K Yasutake,[4] Anders H. Berg,[3] Khuloud Shukha,[1] Martin R. Pollak,[2] Matt G. Sampson.[4] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [3]Boston, MA; [4]University of Michigan, Ann Arbor, MI. Group/Team: NEPTUNE.*

Background: Although high-risk (HR) *APOL1* genotypes are associated with FSGS development & worse outcomes in patients with nephrotic syndrome (NS), less is known about the relationship between *APOL1* expression & clinical parameters. While in population & CKD cohorts, circulating *APOL1* levels are not CKD-associated, this relationship has not been studied in NS. Intrarenal *APOL1* expression level is not associated with HR genotype in NS patients. But higher *APOL1* expression, even the wildtype form, is associated with cytotoxicity & FSGS in model systems. Does increased *APOL1* expression contribute to poor outcomes in NS across races? To assess this, we characterized associations of intrarenal & circulating *APOL1* expression levels with clinical & histological phenotypes in black & non-black patients in the Nephrotic Syndrome Study Network (NEPTUNE).

Methods: NEPTUNE is a prospective study of NS patients of all ages receiving a clinically indicated biopsy. We identified *APOL1* genotyped patients with baseline & longitudinal clinical data and intrarenal mRNA expression profiling of microdissected glomeruli (GLOM) (n=160) or tubulointerstitium (TI) (n=193). 95 also had circulating *APOL1* protein levels measured with ELISA. Non-blacks made up 29% of patients with intrarenal & 68% with circulating expression. As a function of baseline GLOM, TI, or circulating *APOL1* expression, we modeled baseline eGFR, interstitial fibrosis (IF) on biopsy, complete remission (CR), & a composite endpoint. We also did analyses stratified by race & risk genotype.

Results: In multivariable analyses of black patients, higher TI expression of *APOL1* was significantly associated with lower eGFR (-9.8ml/min per doubling of *APOL1* expression; p=0.02) and increased IF(p=0.01), independent of *APOL1* risk genotype. These associations were not observed with TI *APOL1* expression in non-black or GLOM in black & non-black patients. There were no significant association of circulating *APOL1* levels with clinical or histologic parameters, across races & risk genotypes.

Conclusions: In black patients with NS, elevated TI *APOL1* expression, independent of risk genotype, was associated with lower eGFR & more fibrosis. It may be worth investigating whether decreasing intrarenal *APOL1* level is beneficial in any black NS patient. Further inquiry in larger cohorts of non-blacks with NS is also warranted.

SA-PO350

Apolipoprotein L1 Variants and the Prevalence of JC Polyoma Virus in Black South Africans with Hypertensive CKD Nolubabalo U. Nqebelele, Caroline Dickens, Therese Dix-peek, Raquel Duarte, Saraladevi Naicker. *University of the Witwatersrand, Gardenview, South Africa.*

Background: Variants in the apolipoprotein 1 (*APOL1*) gene associate with higher rates of nondiabetic nephropathy in black patients. First-degree relatives of African Americans with nondiabetic nephropathy with two *APOL1* risk variants had lower rates of kidney disease if they also had JC viruria. We aimed to determine the association of *APOL1* risk variants with renal traits and the prevalence of polyomavirus infection in black South Africans with hypertensive chronic kidney disease (CKD).

Methods: Black South Africans with hypertensive CKD (CKD patients) and their first-degree relatives were recruited. Controls were healthy black South Africans. Informed consent was obtained in 166 participants. Using restriction fragment length polymorphism, custom designed primers were used to genotype G1: rs60910145 and rs73885319 and G2: rs71785313 *APOL1* risk variants. Viral DNA was extracted from urine using Maxwell® system protocols. Viral-loads were determined by quantitative qPCR using genesig® JCV and BKV standard kits.

Results: CKD patients had advanced kidney disease with a median eGFR of 7 IQR (4-13), both controls and relatives had normal renal function; median eGFR of 121 (98-130) and 124 (93-144) respectively, with eGFR measured in mL/min/1.73m^2. *APOL1* high-risk alleles were absent in 50% of CKD patients, 41% of controls and 52% of relatives. Two *APOL1* risk alleles were present in 10% of CKD patients, 8.6% of controls and in 6**%** of relatives. In CKD patients, there was no difference in blood pressure, eGFR, proteinuria based on any allele combination. The overall prevalence of JCV was 21% compared to 6% for BKV, with coinfection present in four participants. JCV was present in only 3% CKD patients compared to 39% of controls and 21% of relatives; P < 0.0001, Fisher's exact test. None of the CKD patients had evidence of BKV. There was no difference in mean $\log_{10}$ viral load JCV between CKD patients and controls (P = 0.2644), between CKD patients and their relatives (P = 0.3074) or between controls and relatives (P= 0.7073), *t* test.

Conclusions: Apolipoproprotein L1 risk variants are infrequent in black South Africans with hypertensive CKD. There was a higher prevalence of JCV infection in black South Africans with normal renal function. JC virus seems to protect against development of kidney disease.

SA-PO351

Distribution of APOL1 Renal Risk Variants in General Population from Central Africa (Democratic Republic of Congo) Pepe M. Ekulu,[1,3] Michel N. Aloni,[1] François B. Lepira,[2] Elena N. Levtchenko.[3] *[1]Pediatrics, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); [2]Nephrology Internal Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); [3]Pediatric Nephrology, KU Leuven, Leuven, Belgium.*

Background: The susceptibility in chronic kidney disease among sub-Saharan African descent has been attributed to apolipoprotein-L1 (*APOL1*) genetic variants G1 and G2. However, in Africa, data related to the geographical distribution of *APOL1* risk variants are limited, and there is no reliable data from Democratic Republic of Congo (DRC). We aimed to describe the frequencies of *APOL1* risk variants in a large population from Central Africa and to assess the association with the early kidney damage in children.

Methods: A total of 465 participants from four large districts in Kinshasa were enrolled. *APOL1* high-risk genotype was defined by the presence of 2 high-risk variants (G1/G1, G2/G2, G1/G2) and low risk genotype if 0 or 1 risk variants were present. Albumin-to-creatinine ratio (ACR) was assessed in a fresh morning urine sample in children only, and elevated ACR was defined as ACR>30mg/g.

Results: From 465 subjects enrolled, 453 were successfully genotyped, of whom 388 children and 65 adults. APOL1 sequence analysis revealed 201 (44%) participants carrying at least one APOL1 risk variant, 36 (8%) 2 risk variants. Concerning the frequency of *APOL1* risk alleles, 14 % of all chromosomes carried G1 whilst 13% carried G2. Thus, the burden of *APOL1* risk allele was 27%. Of 388 children, 39 (10%) had elevated ACR. Compared to those carrying low-risk genotype, children with *APOL1* high-risk genotype had a higher prevalence of microalbuminuria (OR 1.48, 95% CI 0.41-4.84).

Conclusions: The burden of *APOL1* renal risk variants is high in DRC. However, no strong statistical association has been found between the high-risk genotype and the early kidney damage in general population of children

SA-PO352

Houston Encounters of CKD of Uncertain Origin (CKDu): Lack of Major Etiologic Factor, except for Exposure to Herbicide Ilse M. Espina,[1] Edlyn G. Bustamante,[2] Maria E. Maldonado,[1] Joniqua N. Ceasar,[1] Jose R. Dominguez,[1] David Sheikh-Hamad.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Harris Health, Houston, TX.*

Background: CKDu (aka MesoAmerican Nephropathy) is encountered globally. Proposed etiologies for CKDu include dehydration, toxic exposure and infection. To identify possible etiology for CKDu among patients encountered at a safety net hospital in Houston, we carried out chart review of CKD5 patients matching the inclusion criteria for the study.

Methods: Thirty patients were identified based on history consistent with CKDu – young, migrant worker, otherwise healthy who presents in renal failure. Patients were included in the study if 1) laboratory studies are consistent with CKD5 (BUN, serum creatinine, Ca/PO4, iPTH and anemia), 2) kidney ultrasound showing small kidneys, 3) urine studies without significant proteinuria or urine sediment, and 4) negative studies for viral hepatitis, syphilis, HIV, ANA, ANCA, SPEP, UPEP. Exclusion criteria: history of diabetes, known primary or secondary renal disease.

Results: 10 patients were available for interview. 9/10 male, 1/10 female; 6/10 from Mexico, 3/10 from El Salvador, 1/10 from Honduras. Only one had knowledge of kidney disease upon presentation, 3 had family history of CKD, 4/10 had occasional intake of Tylenol. Mean age at presentation 32.8 years (median: 33, range 25-43). Mean stay in the US before CKD5 diagnosis 9.2 years (median 8, range 1-15). Before immigrating to the US, 7/10 lived in a village/farm, 3/10 lived a city. 8/10 lived in hot climate zones (6/10 mountains, 2 valleys, 2 close to ocean); 4/10 worked in agriculture/farming (8-15 years). While in the US, 6/10 worked in construction, 3/10 in landscaping, 0/10 in farming. Of the 4 farm workers, 2/10 cultivated cane, 2/10 cotton, 3/10 corn, and 2/10 had exposure to animal stock; 3 had chronic intermittent exposure to Gramaxone (paraquat-based herbicide), while 1/10 had exposure to bug killer and fertilizers. 4/10 drank well water, the rest consumed bottled water, and only 2/10 consumed sweetened drinks; uric acid levels were normal (available on 3/10).

Conclusions: Patients with CKDu encountered are migrant workers, male, young, originally from a farm/village, living in hot mountainous regions. Hydration solution consisted of water. We found no clear identifiable risk factors for CKDu except for chronic exposure to Gramaxone/paraquat in farm workers.

CKDu in Mexican Children: The Case of Poncitlan, Jalisco Guillermo Garcia-Garcia, Ricardo Rubio, Melina D. Amador, Margarita Ibarra-Hernández, Librado De la Torre-Campos, Alexia C. Romero, Guillermo Navarro blackaller, Francisco gonzalo Rodríguez garcía. *Hospital Civil De Guadalajara, University of Guadalajara, Guadalajara, Mexico.*

Background: An elevated prevalence of CKD of unspecified cause (CKDu) has been documented in various developing countries. It has been reported by the media a high prevalence of CKDu among children in towns located by Chapala Lake, particularly within the municipality of Poncitlan, Jalisco. Environmental facros have been blamed as the probable cause of the pandemia.

Methods: Since 2006, we pioneered screening people at risk for the presence of CKD using mobile units that travel to rural and urban communities of Jalisco. Trained personnel collected demographic and clinical data, and obtained blood and urine for serum chemistry and dipstick urinalysis. Those individuals who were aware they had kidney disease were not assessed; all others were eligible to participate. GFR was estimated with the Schwartz equation. CKD was defined as an eGFR < 60 ml/min/1.73m^2. HTN, malnutrition, and obesity were defined by gender, age, and height specific normative values.

Results: Between 2007-2016, 659 children were screened in the mobile units, 144 of them in the municipality of Poncitlan. Results were compared with those of all other Jalisco municipalities (Table 1)

Conclusions: The prevalence of proteinuria and malnutrition was higher in Poncitlan as compared to other Jalisco municipalities. Undergoing studies will provide information on the posible causes of this high prevalence. Screening programs should be linked to community- and individual-level interventions to reduce the risk of chronic kidney disease in adulthood.

Funding: Private Foundation Support

Prevalence and Risk Factors of CKD among Workers in the Brick Making Industry of La Paz Centro, Nicaragua Lyanne E. Gallo,[6] Komal Basra,[2] Mauricio E. Sánchez-Delgado,[6] Tania M. Gamez,[3] Caryn M. Sennett,[1] Rebecca L. Laws,[2] Juan J. Amador,[1] Damaris A. Lopez pilarte,[1] Yorghos Tripodis,[2] Michael Mcclean,[2] Joseph Kupferman,[1] David J. Friedman,[4] Marvin A. Gonzalez,[5] Madeleine K. Scammell,[2] Ana G. García,[1] Daniel R. Brooks,[2] Aurora Aragon.[1] *[1]Boston University, Boston, MA; [2]Boston University School of Public Health, Boston, AL; [3]MINSA, Chinandega, Nicaragua; [4]None, Brookline, MA; [5]Research Center on Health, Work and Environment at National Autonomous University of Nicaragua, Leon, León, Nicaragua; [6]UNAN.León, León, Nicaragua.*

Background: Western Nicaragua is a hotspot for Chronic Kidney Disease (CKD) of non-traditional etiology, also called Mesoamerican Nephropathy. This disease has killed tens of thousands of economically active individuals; primarily agricultural workers at sea level. The aim of this study is to establish the prevalence of CKD among workers in the artisanal brick and tile industry, and explore associations between risk factors of interest and changes in kidney function over time.

Methods: In 2016, 257 workers in small brick and tile making industries in the La Paz Centro region of Nicaragua were recruited for a prospective cohort study. Of those, 224 (93.5%) participated in follow-up four months later. At both baseline and follow-up, serum creatinine was measured using the Jaffe methods at the biochemical laboratory at the Medical Faculty of UNAN-León and used to estimate glomerular filtration rate (eGFR) using the CKD-EPI equation. CKD was defined as two measurements of eGFR<60 ml/min/1.73m^2 at least 3 months apart.

Results: 14.8% of participants had eGFR<60 at baseline. Virtually all were confirmed at follow-up for a prevalence of CKD of 14.3%; 97% of cases were male, 25% were less than 35 years of age, and 28% had stage 5 CKD (eGFR<15.) The mean difference in eGFR measured between baseline and follow-up was -4.1 (standard deviation=20.4), suggesting a decrease in mean kidney function in this brickmaking population over the study period. Linear mixed effects models indicate predictors include a job task that entails loading or operating the oven, age, sex, education, smoking status, water intake and having an immediate family member with CKD.

Conclusions: CKD prevalence among the workers in La Paz Centro was similar to prevalence reported in cross sectional studies conducted in the sugarcane growing region of Nicaragua, and slightly slower than prevalence among low-land agricultural workers in El Salvador.

Funding: Commercial Support - Funding was provided by Los Azucareros Del Istmo Centroamericano (AICA), and was managed by the CDC Foundation. Donors had no prior review of these results nor influence on content of abstract.

SA-PO355

Association between Obesity and Prevalence of CKD in Patients with Type 2 Diabetes Mellitus and/or Arterial Hypertension Laura Cortes-Sanabria,[2] Rafael A. Ayala cortes,[5] Clementina E. Calderon Garcia,[3] Enrique Rojas-Campos,[1] Alfonso M. Cueto-Manzano.[4] *[1]INSTITUTO MEXICANO DEL SEGURO SOCIAL, GUADALAJARA, Mexico; [2]Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; [3]Mexican Social Security Institute, Guadalajara, Mexico; [4]None, Zapopan, Jalisco, Mexico; [5]Unidad de Investigación Médica en Enfermedades Renales, Guadalajara, Jalisco, Mexico.*

Background: Obesity, directly or through several comorbidities such as diabetes mellitus, high blood pressure, metabolic syndrome or cardiovascular disease, increase the risk for development and progression of CKD. It is noteworthy, however, the lack of information in this regard in settings with high prevalence of risk factors for CKD, such as Latin America, and particularly Mexico. *Aim*: To determine the association between obesity and CKD in patients recently diagnosed with only type 2 diabetes mellitus (DM2), arterial hypertension (AHT) without DM2, and DM2+AHT.

Methods: Cross-sectional study. Patients with transient causes of albuminuria were excluded. All patients had a medical history and clinical examination; glomerular filtration rate was estimated (eGFR) by the CKD-EPI formula and albuminuria/creatininuria was determined by nephelometry. Obesity was classified according with WHO criteria and CKD according with KDIGO guidelines.

Results: 2123 patients (DM2 = n 676; DM2+AHT = n 877, and AHT = n 570) were studied. Mean age was 60±12 yrs, 62% women, DM2 vintage 9 (4-15) yrs and AHT vintage 7 (3-14) yrs. Prevalence of obesity was lower in DM2 (35%) compared to DM2+AHT (45%) and AHT (46%) (p<0.0001). Comparing patients with obesity *vs* normal weight, prevalence of CKD were lower in DM2 (31% *vs* 42%, respectively, p= 0.01), but it was higher in DM2+AHT (38% *vs* 20%, p=0.02) and AHT (40% *vs* 16%, p= 0.01) patients. Results of multivariate analysis are shown in the Table

Conclusions: Frequency of obesity was significantly higher in patients with DM2+AHT. The risk to present CKD is higher in DM2+AHT than in isolated DM2 or AHT. It is necessary to advice for modification of negative lifestyle habits, especially in patients with diabetes and hypertension in order to prevent development and progression of kidney damage.

Logistic regression model of variables predicting CKD

	DM2			DM2+AHT			AHT		
Variable	OR	CI 95%	p	OR	CI 95%	p	OR	CI 95%	p

Progression of CKD and Outcomes in Thailand: Thai-SEEK Project Amnart Chaiprasert,[4] Kraiwiporn Kiattisunthorn,[2] Warangkana Pichaiwong,[1] Vuddhidej Ophascharoensuk,[3] Thananda Trakarnvanich,[5] Dhawee Sirivong,[7] Atiporn Ingsathit.[6] *[1]RAJAVITHI HOSPITAL, Bangkok, Thailand; [2]Siriraj Medical School, Mahidol University, Bangkok, Thailand; [3]Chiang Mai University, Chiang Mai, Thailand; [4]Phramongkutklao Hospital, Pathumthani, Thailand; [5]Vajira Hospital, Bangkok, Thailand; [6]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [7]Faculty of Medicine Khon Kaen University, Khon Kaen, Thailand. Group/Team: Thai-SEEK Steering Committee, Nephrology Society of Thailand.*

Background: Chronic kidney disease (CKD) is one of the major public health problems, however, the data of CKD in Thai population including prevalence and progression, also its outcomes are limited. In 2008, Thai-SEEK (Screening and Early Evaluation of Kidney Disease) study, a community-based cross-sectional study using stratified-cluster sampling method, was initiated which found prevalence of CKD for 17.5%. Therefore, the study was conducted to evaluate the progression and outcomes as well as predicting factors of CKD in Thailand.

Methods: A prospective cohort study was run from June 16, 2015 to December 15, 2016 by using subjects of the first survey. Data from history taking and physical examination, serum creatinine, urinalysis, and urine albumin creatinine ratio were done in 2,396 subjects (70%) who gave responses for participating follow up program, and death certificates were used to identify causes of death. Four hundred and eight subjects (68% of those diagnosed CKD in the first survey) were analyzed for CKD progression and outcomes. Serum creatinine standardized with SRM967a (National Institute of Standards and Technology, MD, USA) was put in GFR calculation using CKD-EPI formula. Staging of CKD was based on KDIGO 2012 criteria, and rapid CKD progression was defined as a change in CKD staging plus a decline in GFR >25% or >5 ml/min/1.73m^2/year or renal replacement therapy was initiated.

Results: Mean age was 54.6±13.7 years and 41% was male. Median follow-up time was 7.9 years (min, max 7.7, 9.1). Incidence of CKD progression was 0.23 (95% CI: 0.19, 0.28) with a decline in GFR 1.40±1.13, 1.95±1.66, 1.59±1.25, 1.66±1.18 and 1.60 ±0.77 ml./min/1.73 m^2/year in CKD stage G1, G2, G3a, G3b and G4, respectively. Predictors of progression were diabetes mellitus (RR 1.39; 95% CI: 0.09, 2.14) and hyperuricemia (RR 1.70; 95% CI: 1.17, 2.47). Mortality rate was 6% per year and associated severity of CKD staging at diagnosis. The most common cause of death was cancer (22%), following by cardiovascular disease (19.8%) and infection (12.8%).

Conclusions: During 8-year follow up, risk of CKD progression was 23%. Diabetes mellitus and hyperuricemia were the strong predictors of progression. The population based cohort would be a significant contributor in national policy making for slow CKD progression in Thailand.

Vascular Access Creation Decelerates Renal Function Decline and Its Determinant Factors Ming-Tso Yan,[2] Shih-Hua P. Lin.[1] *[1]Tri-Service General Hospital, Neihu, Taiwan; [2]Cathay General Hospital, Taipei, Taiwan.*

Background: Vascular access (VA) creation before hemodialysis (HD) initiation has been suggested to decelerate estimated glomerular filtration rate (eGFR) decline but it remains uncertain which factors contributing to the renal benefit of VA creation.

Methods: One hundred and nine patientswith chronic kidney disease (CKD) (aged 65.3 years, Male:Female=58:51) transitioning to hemodialysis during January 2009 to December 2015 were recruited in this retrospectively single-center study and all had at least 3 estimated glomerular filtration rate (eGFR) measurements either before or after VA creation. The correlation between ratio of pre-/post-VA creation eGFR declined rate and other factors was examined through logistic regression.

Results: VA was created at mean age of 67.7 ± 11.8 and HD was initiated at 68.1 ± 11.8 years, respectively. Fifty one (46.8%) patients had decelerated eGFR declined rate after VA creation and were characterized by faster eGFR declined rate before VA creation (1.00 ± 1.41 vs 0.29 ± 0.23 ml/min per month, P < 0.001), regardless of age, gender and history of diabetes mellitus (DM) and hypertension. Biochemical surveys at the time of VA creation showed that lower serum creatinine level (3.57 ± 1.50 vs 4.49 ± 1.68 mg/dl, p = 0.003), lower serum albumin (3.50 ± 0.46 vs 3.72 ± 0.62 g/L, p = 0.02) and higher eGFR (19.04 ± 11.08 vs 14.57 ± 8.51 ml/min, p = 0.02) in patients with decelerated eGFR declined rate. Serum albumin level at VA creation showed reversely linear correlation with ratio of pre-/post-VA creation eGFR declined rate. A positive correlation between ratio of pre-/post-VA creation eGFR declined rate and HbA1c level at VA creation was disclosed in patients with DM.

Conclusions: It may be better to create VA earlier to postpone initiation of dialysis especially in patients with poor baseline conditions such as faster eGFR declined rate, low serum albumin level and, if patients with DM, higher HbA1c level.

SA-PO358

Renal Biopsy Results from Patients with Multiple Myeloma – Data from a Comprehensive National Cancer Institute: A 10 Year MD Anderson Experience Laila S. Lakhani,[3] Umut Selamet,[1] Ali Ziaolhagh,[4] William F. Glass,[6] Amanda Tchakarov,[5] Ala Abudayyeh.[2] *[1]MD Anderson Cancer Center, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX; [3]UT Houston, Houston, TX; [4]University of Texas, Housotn, TX; [5]University of Texas Medical School at Houston, Houston, TX; [6]University of Texas – Houston Medical School, Houston, TX.*

Background: Around 50% of patients with Multiple Myeloma (MM) have renal involvement at presentation. Renal lesions in MM is both heterogeneous and multifactorial. We set out to study the spectrum of these deposits and electron micrographic lesions, to determine their extent and correlation with biochemical paraproteinemia, clinically significant proteinuria and the other systemic findings in this population.

Methods: Data is extracted from the retrospective chart review of all patients at MD Anderson Cancer Center who received a renal biopsy between Jan 2008 – June 2017

Results: Out of 193 patients who underwent renal biopsy during this period, 39 had the diagnosis of Multiple Myeloma at the time of biopsy, with 14/39 (36%) on active chemotherapy and 11/39 s/p stem cell transplant. An equal gender distribution was noted (19 females, 20 males) with an average age of 62.5 years. The co-existing medical conditions included HTN (69%), DM (31%), and rarely other malignancies (8%). The most common indication for renal biopsy was AKI -85%, followed by proteinuria in 67% patients - (28% had nephrotic range proteinuria). 2/39 were inadequate biopsy samples. From the remaining 37 biopsies, 13/37 (35%) had glomerulopathy and tubulopathy from cast deposition, 4/37 (11%) had AL Amyloidosis and 1 patient had granulomatous TIN (AFB/fungal stains negative). Interestingly 19/37 (51%) had no evidence of 'myeloma kidney'; the most common findings in these patients were focal global glomerulosclerosis, hypertensive arterial and arteriolar glomerulosclerosis and diabetic nodular glomerulosclerosis.

Conclusions: The severity of renal involvement confers worse prognosis in patients with Multiple Myeloma. The biopsy findings helps us to predict outcomes and tailor our clinical approach and treatment regimens to minimize morbidity and mortality in patients with Multiple Myeloma.

TGF Beta Pathway Enriched as Candidate Plasma Severity Biomarkers in CKD Jennifer E. Van eyk,[1] Lesley Inker,[4] Josef Coresh,[5] Paul L. Kimmel,[2] Adrienne Tin.[3] *[1]Cedars Sinai Medical Center, Los Angeles, CA; [2]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [3]Baltimore, MD; [4]Tufts Medical Center, Boston, MA; [5]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD. Group/Team: Biocon 1.*

Background: Our hypothesis is that in-depth proteomics discovery could identify novel plasma biomarkers that could be useful for the prognosis for development of chronic kidney disease (CKD) and to monitor progression (severity) of CKD. Furthermore, that as subset of markers would be related to key signaling pathways underlying the disease.

Methods: A four group design in which 64 plasma samples collected at two time points (T0 and T1) for 16 cases and 16 controls were analyzed. Cases were individuals with GFR slope >5ml/min/year and a total decline of at least 30 ml/min/year follow-up of at least 3 years while the controls had <1 ml/min/year for at least 3 years matched by age, sex, race, diabetes, hypertension, GR at T0, ACR. Each sample was depleted of the top 14 abundant plasma proteins, fractionated using reversed phase HPLC, digested, analyzed by mass spectrometry and batched searched. Proteins were ranked based on *p* values for prognosis (protein differences between cases and controls at T=0) and severity (cases between T0 &T1 / controls between T0 & T1) and deteremined pathways between the various candidate markers.

Results: Across all plasma samples, 1151 nonredundant protiens were identified with a protein and peptide probability of <0.1% (with >625,000 spectral counts). There were 3 and 43 candidate prognostic markers that were found to have p<0.01 and p<0.05, respectively. Within in this top group of severity markers were APO II, APO CIII, Haptoglobin and APOL1 which were ranked 4th (p=0.0058), #6 (p=0.011),13th (p=0.018) and 19th (p=0.021), respectively for prognosis. There were 2 and 66 candidate severity markers with p<0.01 and p<0.05, respectively. Of these CRP, Cystatin C and beta trace protein were ranked 6th (p=0.004), 7th (p=0.006) and 18th (P=0.04), respectively, as severity markers. Interestingly, the TGF beta pathway proteins was enriched in the candidate severity proteins (p<0.05) based on over 15 protein linkages. Although TGF beta 1 was identified in this data set, 90% of the data was missing.

Conclusions: This study indicates that *de novo* proteomic analysis of plasma can confirm changes of known biomarkers and identify potential new biomarkers. That different plasma proteins are aligned with prognosis versus severity. Proteins in the TGF beta pathway are particularly enriched as candidate severity biomarkers.

SA-PO360

The Role of Renal Vascular Endothelial-Mesenchymal Transition in Systemic Lupus Erythematosus Associated Thrombotic Microangiopathy Weixin Hu, Ying Zhou, Ying-hua Chen, Ming-chao Zhang, Shao-shan Liang, Fan Yang, Zheng-zhao Liu, Zhi-Hong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing China, Nanjing, China.*

Background: To investigate the phenotypic changes of renal vascular endothelial cells and its relationship with the vascular injury and renal interstitial fibrosis in patients with SLE associated thrombotic microangiopathy (SLE-TMA).

Methods: Biopsies from 30 SLE patients which showed lupus nephritis and renal vascular TMA were included in this study. TMA was divided into acute and chronic TMA groups according to the histology. The expression of vascular endothelial CD31, vessel endothelial cadherin (VE-cadherin), α-smooth muscle actin (α-SMA) and transforming growth factor-β (TGF-β) were stained with immunofluorescence and immune histochemical assays, the intensity of endothelial marker expression recorded as the mean density (integral optical density/ area of vascular endothelial layer) and the extent of renal interstitial fibrosis were quantitatively analyzed with Image-Pro-Plus 6.0 and ImageScope (Aperio) respectively.

Results: Confocal immunofluorescence microscopy demonstrated no α-SMA expression in endothelial cells in normal renal vessels but markedly higher endothelial α-SMA expression in renal vessels showing TMA. Compared with the normal group, the intensity of endothelial CD31 and VE-cadherin expression was significantly lower ($P<0.05$), and α-SMA expression was much higher ($P<0.001$) in acute TMA group. The endothelial CD31, VE-cadherin and TGF-β expression were significantly lower, while the α-SMA expression significantly higher in chronic TMA group than that in acute TMA group and normal group ($P<0.001$). The intensity of endothelial α-SMA expression was positively correlated with the extent of renal interstitial fibrosis ($r=0.439$, $P<0.05$), while the endothelial CD31 expression was negatively correlated with renal interstitial fibrosis ($r=-0.458$,$P<0.05$). Furthermore, endothelial α-SMA expression was also an independent risk factor for the poor treatment response in patients with SLE-TMA.

Conclusions: In SLE-TMA, the lower expression of normal endothelial cell markers and higher α-SMA expression indicated a pathogenetic process of vascular endothelial to mesenchymal transition, which was related with renal interstitial fibrosis and poor treatment response.

SA-PO361

Cystinosis Is Associated with Abnormal Bone Microarchitecture and Sarcopenia in Children and Adults Candice Sheldon,[1] Paul C. Grimm,[4] Jessica R. Whalen,[3] Kyla Kent,[2] Jin Long,[3] Maira Simas,[3] Mary B. Leonard.[2] *[1]Stanford, Palo Alto, CA; [2]Stanford School of Medicine, Palo Alto, CA; [3]Stanford University, Palo Alto, CA; [4]Stanford University Medical Center, Stanford, CA.*

Background: Cystinosis is associated with multiple risk factors for abnormal bone metabolism, including phosphate wasting, metabolic acidosis, malnutrition, chronic kidney disease, hypothyroidism, myopathy, delayed puberty and male hypogonadism. Prior bone studies are limited to case reports and a case series. Muscle mass has not been quantified.

Methods: Regional and whole body DXA scans were obtained in 37 cystinosis patients, age 6-49 yr. High-resolution quantitative CT (QCT) tibia scans were obtained in cystinosis patients and 61 matched controls. DXA results were converted to sex, race and age-specific Z-scores using robust population-based reference data in children and adults. Linear regression was used to assess group differences in QCT results, adjusted for age, sex and tibia length.

Results: Total Hip (mean ± SD: -0.96 ± 1.22), femoral neck (-1.23 ± 1.14), and 1/3rd radius (-1.02 ± 1.48) bone mineral density (BMD) Z-scores were reduced compared with reference data (all $p<0.001$) and were comparable in children and adults. Appendicular lean mass Z-scores were reduced in children (-0.93 ± 1.27, $p<0.01$) and adults (-1.80 ± 1.32, $p<0.0001$), and were positively associated with DXA BMD Z-scores at all sites (R 0.46-0.50, $p<0.01$). Median (interquartile range) eGFR was 58 (32-76) ml/min/1.73m^2. DXA Z-scores were not associated with eGFR. Tibia diaphysis cortical thickness and BMD ($p<0.02$), metaphysis trabecular bone volume fraction, thickness and number ($p<0.01$) and finite element estimates of failure load in the diaphysis and distal tibia ($p<0.0001$) were lower in cystinosis vs. controls in multivariate analyses. Appendicular mass was highly associated with failure load ($p<0.001$) independent of age, sex and tibia length. Adjustment for lean mass eliminated group differences in cortical thickness and failure load in the diaphysis ($p>0.20$) and attenuated differences in failure load in the distal tibia ($p=0.06$). In contrast, trabecular deficits persisted.

Conclusions: Cystinosis is associated with severe musculoskeletal deficits in children and adults. Bone deficits were correlated with sarcopenia suggesting a role of decreased biomechanical loading. Studies are needed to identify interventions to improve bone strength and muscle mass in cystinosis.

Plasma 25-Hydroxyvitamin D Levels and Renal Function Decline in African Americans Joseph Lunyera,[1] Clemontina A. Davenport,[1] Clarissa J. Diamantidis,[1] Nrupen A. Bhavsar,[1] Mario Sims,[2] Myles S. Wolf,[1] Jane F. Pendergast,[1] L. Ebony Boulware,[1] Julia J. Scialla.[1] *[1]Duke University School of Medicine, Durham, NC; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: 25-hydroxyvitamin D [25(OH)D] deficiency is highly prevalent among African Americans and may contribute to their disproportionate risk of adverse chronic kidney disease (CKD) outcomes. We examined the association between plasma 25(OH)D levels and adverse CKD outcomes in the Jackson Heart Study (JHS).

Methods: We adjusted plasma 25(OH)D3 levels measured at baseline for monthly variation in sunlight exposure by using the residuals from the regression of 25(OH)D3 on the month of blood draw plus the overall mean. We examined the associations between baseline adjusted 25(OH)D3 and (a) annual estimated glomerular filtration rate (eGFR) decline and (b) incident CKD during follow-up using generalized linear models adjusted for demographics, behavioral factors, and comorbidity. Incident CKD was defined as either eGFR <60 mL/min/1.73m^{2}and a 25% decline in eGFR between baseline and follow-up, or albumin-to-creatinine ratio ≥30 mg/g at follow up among those without CKD at baseline.

Results: Among 5164 participants with non-missing 25(OH)D3 (97% of JHS cohort), the median [IQR] adjusted 25(OH)D3 was 12.0 [8.71-16.56] ng/mL, and mean ±SD eGFR was 94.11 ±21.98 mL/min/1.73m^2 at baseline. Over a median of 8 years, the mean ±SD annual eGFR decline was 1.27 ±1.96 mL/min/1.73m^2 per year, and 249 participants (12% of those whose CKD status could be determined) developed incident CKD. After adjusting for demographics, behavioral factors and comorbidity, each 10 ng/mL lower adjusted 25(OH)D3 was associated with 0.19 (95% CI 0.05-0.33) mL/min/1.73m^2 per year faster eGFR decline. However, the association did not persist after additional adjustment for baseline eGFR ($p=0.146$). 25(OH)D3 was not associated with incident CKD (OR [95% CI] per 10 ng/mL lower 25(OH)D3 1.12 [0.85,1.47]).

Conclusions: Plasma 25(OH)D3 was not associated with risk of kidney function decline in African Americans after adjustment for baseline eGFR and other covariates. Despite low levels at baseline, our data do not support a role of supplementation in preventing or slowing CKD in African Americans

Soluble Urokinase Plasminogen Activation Receptor (suPAR) in the German Chronic Kidney Disease (GCKD) Study Claudia Sommerer,[3] Nicole G. Metzendorf,[1] Matthias Schmid,[5] Kai-Uwe Eckardt,[4] Jochen Reiser,[2] Martin G. Zeier.[3] *[1]Kidney Center Heidelberg, Heidelberg, Germany; [2]Rush University Medical Center, Chicago, IL; [3]University Hospital of Heidelberg, HEIDELBERG, Germany; [4]University of Erlangen-Nuremberg, Erlangen, Germany; [5]Institute of Biometry, University of Bonn, Bonn, Germany. Group/ Team: On behalf of GCKD investigators.*

Background: Soluble urokinase plasminogen activation receptor (suPAR) is an emerging biomarker for prediction and progression of kidney disease and cardiovascular events. The value of suPAR as a biomarker was evaluated in the large prospective observational German Chronic Kidney Disease (GCKD) study.

Methods: Chronic kidney disease (CKD) patients aged 18-76 years with an estimated glomerular filtration rate (eGFR) of 30 - <60 mL/min/1.73 m^2 or eGFR≥60 and overt proteinuria were enrolled in the GCKD study. suPAR was measured in baseline samples of participants and categorized in quintiles for investigation of the underlying disease, age and renal function.

Results: A total of 4994 CKD patients were studied (60.09 % males, mean age 60.08 ±11.98 years). Mean eGFR was 49.47 ± 18.29 mL/min/1.73 m^2 and median (IQR) albumin/creatinine ratio was 50.85 (25% quantile: 9.61, 75% quantile 387.17) mg/g. Mean suPAR level was 2184±1952 pg/mL with a range from 221 to 45433 (median 1771, 25% quantile: 1446.9, 75% quantile: 2254.1). Prevalence of patients with cardiovascular diseases, diabetic nephropathy, systemic diseases and smoking showed an upwards trend from suPAR quintile 1 to quintile 5. Median suPAR concentration increased with worsening renal function (CKD stage 1 to CKD stage 4, $p<0.0001$) and age ($p<0.0001$). Within CKD categories, suPAR rised with increase of albuminuria.

Conclusions: suPAR was evaluated in one of the worldwide largest CKD cohorts. In this study cohort, suPAR was associated with underlying cardiovascular disease, diabetic nephropathy as well as systemic disease involving the kidney. suPAR depended on renal function, proteinuria and age. The predictive value of suPAR on development of renal function and cardiovascular disease will be evaluated in this prospective study.

SA-PO364

The Relationship between Intrarenal Dopamine and Intrarenal Renin-Angiotensin System in CKD Patients Is Dependent on Renal Function Takashi Matsuyama,[4] Naro Ohashi,[4] Sayaka Ishigaki,[4] Shinsuke Isobe,[4] Naoko Tsuji,[2] Tomoyuki Fujikura,[3] Takayuki Tsuji,[4] Akihiko Kato,[1] Hideo Yasuda.[4] *[1]Hamamatsu University Hospital, Hamamatsu, Japan; [2]Hamamatsu University School of Medicine, Hamamatsu, Japan; [3]Hamamatsu university school of medicine, Munich, Germany; [4]Hamamatsu University School of Medicine, Numazu, Japan.*

Background: The mechanisms to activate intrarenal renin-angiotensin system (RAS) depend on the conditions of kidney diseases. In the angiotensin II (AngII) infusion models, the circulating AngII is filtered into renal tubular lumens and activates intrarenal RAS. Intrarenal dopamine system activation was shown to reduce angiotensinogen (AGT) expression in the proximal tubules and suppress intrarenal RAS activity. In the chronic kidney disease (CKD) models where filtered plasma AGT into the tubular lumens due to glomerular injury activates intrarenal RAS, the relationship between intrarenal dopamine system and intrarenal RAS in CKD models has not been clarified. Therefore, we performed this study to determine the mutual relationship in CKD patients.

Methods: We recruited 46 CKD patients (age: 51.1 ± 20.0 years old, 16 males, causes of CKD: chronic glomerulonephritis; 34, diabetic nephropathy; 2, nephrosclerosis; 4, or others; 6) without undergoing dialysis or taking RAS blockers. The urinary dopamine (U-DOPA) excretion as an indicator of intrarenal dopamine activity and the urinary AGT (U-AGT) excretion as a surrogate marker of intrarenal RAS activity were measured, and the relationships were investigated.

Results: U-DOPA excretion levels in patients with CKD stage 5 were significantly lower than those in patients with other CKD stages, and U-DOPA excretion levels tended to decrease as the CKD stages progressed. Conversely, U-AGT excretion levels in patients with CKD stage 5 were significantly higher than those in patients with CKD stages 1 to 3, and tended to increase as the CKD stages progressed. U-DOPA excretion levels were significantly and negatively correlated with U-AGT excretion levels ($r=-0.42$, $p<0.01$) and significantly and positively correlated with estimated glomerular filtration rate (eGFR) ($r=0.64$, $p<0.01$). Multiple regression analysis revealed that U-DOPA excretion levels were associated with U-AGT excretion levels after adjustment of age, sex, and body mass index ($\beta=-0.34$, $p=0.025$). However, the correlation disappeared when eGFR was additionally adjusted ($\beta=-0.057$, $p=0.70$).

Conclusions: The negative correlation between intrarenal dopamine system and intrarenal RAS system in CKD patients is affected by renal function.

Impact of Bariatric Surgery on Prognosis of CKD Allon N. Friedman,[1] Abdus S. Wahed,[7] Junyao Wang,[7] Anita Courcoulas,[8] Gregory Dakin,[10] Paul L. Kimmel,[3] James E. Mitchell,[2] Jonathan Q. Purnell,[5] Carel W. Le roux,[6] Richard C. Thirlby,[9] Bruce M. Wolfe.[4] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]NRI, CHASKA, MN; [3]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [4]Oregon Health & Science University, Portland, OR; [5]Oregon Health and Science University, Portland, OR; [6]University College Dublin, University College Dublin, Ireland; [7]University of Pittsburgh, Pittsburgh, PA; [8]University of Pittsburgh Medical Center, Pittsburgh, PA; [9]Virginia Mason, Seattle, WA; [10]Weill Cornell Medical College, New York, NY.*

Background: Obesity is linked to the development and progression of chronic kidney disease (CKD) but whether weight reduction through bariatric surgery protects against CKD is poorly understood. Our goal was to assess if bariatric surgery influences the prognostic risk for CKD.

Methods: We studied the patient cohort from Longitudinal Assessment of Bariatric Surgery 2 (LABS-2), which included 2458 adults who underwent bariatric surgery from March 2006 to April 2009 at 10 US hospitals in 6 geographically diverse clinical centers. Participants underwent Roux-en-Y gastric bypass (n=1530), laparoscopic adjustable band (n=523), sleeve gastrectomy (n=52), banded gastric bypass (n=22), or biliopancreatic diversion with duodenal switch (n=17). The primary outcome was prognostic risk for CKD as measured by the Kidney Disease Improving Global Outcomes (KDIG) consortium criteria.

Results: Patients were 79% female and 87% white with a median age of 46 years. Using the KDIGO criteria 41% and 22% of the group classified at moderate prognostic risk for CKD before surgery (n=254, 11.9% of total cohort) had improvement in their risk category at 1 year and 7 years, respectively. In patients with high prognostic risk at baseline (n=73, 3.4% of total cohort) 56% and 29% improved their risk category at 1 and 7 years, respectively. In patients with very high prognostic risk at baseline (n=29, 1.4% of total cohort) 35% and 7% improved their risk category at 1 and 7 years, respectively. The proportion of patients whose prognostic risk category for CKD worsened was minimal (<5%) and only 5 patients developed end stage renal disease during the follow-up period. When year 1 was used as baseline in order to minimize the effect of weight loss on serum creatinine (and thereby influencing CKD prognostic risk), the magnitude of the benefits was reduced though results were qualitatively similar.

Conclusions: Treatment with bariatric surgery was associated with a reduction in the prognostic risk for CKD in a large proportion of patients for up to 7 years, especially in those with high risk at baseline. These findings support the consideration and further study of bariatric surgery as a treatment for CKD in obese patients.

Proton Pump Inhibitors and Risk of CKD: A Meta-analysis Karn Wijarnpreecha,[2] Wisit Cheungpasitporn,[5] Supavit Chesdachai,[4] Panadeekarn Panjawatanan,[3] Charat Thongprayoon.[1] *[1]Bassett Medical Center, Cooperstown, NY; [2]Medicine, Bassett Medical Center, Cooperstown, NY; [3]Chiang Mai University, Chiangmai, Thailand; [4]Mahidol University, Bangkok, Thailand; [5]Mayo Clinic, Rochester, MN.*

Background: Proton pump inhibitors (PPIs) are one of the most commonly prescribed medications worldwide. Recent studies have raised a concern over increased risk of chronic kidney disease (CKD) or end-stage renal disease (ESRD) among PPIs users but the results of those studies were inconsistent. This meta-analysis was conducted to summarize all available data and to estimate this potential association.

Methods: A comprehensive literature review was conducted using MEDLINE and EMBASE database through March 2017 to identify all studies that reported the risk of CKD or ESRD among PPIs users compared with non-PPI users were included. Adjusted point estimates from each study were combined by the generic inverse variance method of DerSimonian and Laird.

Results: Of 8,950 studies, five studies (three cohort studies and two case-control studies) with 536,902 participants met the eligibility criteria and were included in the meta-analysis. We found that individuals with PPIs use had significantly increased the risk of CKD or ESRD when compared with non-PPIs users (pooled RR of 1.33, 95% CI, 1.18-1.51). There was no publication bias of overall included studies assessed by the funnel plots.

Conclusions: This study demonstrated an increased risk of CKD or ESRD among PPIs users. Whether this association is causal requires further investigations.

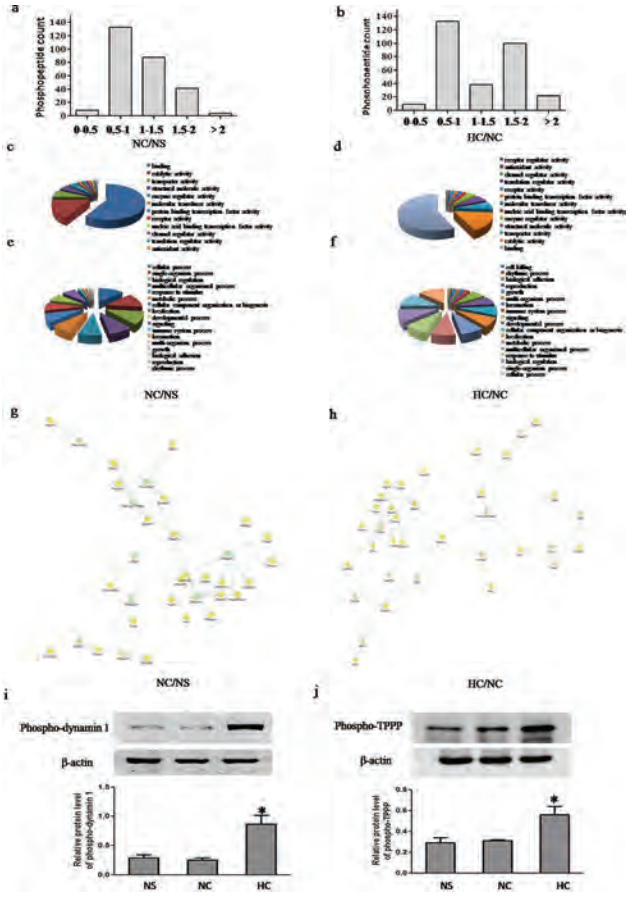
Salt-Induced Phosphoproteomic Changes in the Hypothalamic Paraventricular Nucleus in Rats with Chronic Renal Failure Aiqing Li, Lanying Li, Jiawen Li, Lishan Tan, Minzi Qiu. *Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Hypothalamic paraventricular nucleus (PVN) is a cardiovascular regulating center within the brain,which plays a critical role in high salt-induced progression of chronic renal failure (CRF). However, the phosphoproteomic changes in the PVN caused by CRF remain unclear. This study aimed to perform large-scale phosphoproteomic analysis of PVN induced by CRF and high salt intake.

Methods: Eight weeks post 5/6 nephrectomy (CRF model) or sham operation, Sprague–Dawley rats were fed a high-salt (4%) or normal-salt (0.4%) diet for 3 weeks. TiO_2 enrichment, iTRAQ labeling, and liquid chromatography tandem mass spectrometry were applied for phosphoproteomic profiling of PVN.

Results: A total of 3723 unique phosphopeptides corresponding to 1530 phosphoproteins were identified. Compared with sham group, 133 upregulated and 141 downregulated phosphopeptides were identified in CRF group during normal-salt feeding. However, with a high-salt diet, 160 phosphopeptides were upregulated and 142 downregulated in the CRF group. Gene Ontology analysis revealed that these phosphoproteins were involved in binding, catalytic, transporter, and other molecular functions. Search Tool for the Retrieval of Interacting Genes protein–protein analysis showed direct or indirect functional links among 25 differentially expressed phosphoproteins in CRF rats compared with sham group. However, 24 differentially phosphorylated proteins induced by high salt intake were functionally linked in CRF animals. The altered phosphorylation levels of dynamin 1 and TPPP were validated.

Conclusions: Phosphoproteomic changes of PVN triggered by CRF and high salt-load have been investigated. It will provide new insight into pathogenetic mechanisms of development of chronic kidney disease and salt sensitivity.



SA-PO368

Allopurinol and/or Bicarbonate Therapy Improves the Renal Damage Induced by Recurrent Thermal Dehydration (TD) and Cyclic Episodes of Rhabdomyolysis (CR) in Rats Fernando E. García-arroyo,[1] Guillermo Gonzaga,[1] Monica G. Blas-Marron,[1] Octaviano Silverio,[1] Edilia Tapia,[1] Ilana Weiss,[2] Jason R. Glaser,[4] Richard J. Johnson,[5] L. Gabriela Sanchez-Lozada.[3] *[1]INC Ignacio Chavez, Mexico City, Mexico; [2]La Isla Network, Ada, MI; [3]Nephrology, INCICh, Mexico City, DF, Mexico; [4]La Isla Foundation, INC., Ada, MI; [5]University of Colorado Denver, Aurora, CO.*

Background: Mesoamerican nephropathy (MeN) pathophysiology is poorly understood, but ↓CrCl, mild Uprot and hyperuricemia are observed. The aims of this study were to develop an experimental model and to test therapeutic alternatives.

Methods: TD was induced by exposure to 37°C, 1 h. CR was induced by IM glycerol dosed at day 1, 9, 18, 25 and 32. Hepatic uricase was also inhibited with oxonic acid (OA, 750 mg/K/d). The following groups were included: TD-CR, TD-CR-Allopurinol (AP, 150 mg/L), TD-CR+Bicarbonate (BC, 160 mM), and TD-CR+AP+BC. We also included Normal and OA groups as references. Cr, uric acid, osmolality, creatine kinase (CK), copeptin, NAG, and pH were measured in plasma and/or urine. In renal tissue, markers for oxidative stress, and the expression of the enzymes of polyo-fructokinase pathway were evaluated.

Results: The rodent model for MeN reproduced some of the characteristics of the disease (Table). Also, increased plasma CK, copeptin and NAG in urine, as well as increased oxidative stress and the overexpression of polyol-fructokinase enzymes in renal tissue, were found. BC raised urine pH. AP and BC treatments partially prevented muscle damage, hyperuricemia, overexpression of polyol-fructokinase pathway and renal damage, but only AP significantly prevented the fall in CrCl. Co-treatment with AP+BC did not provide further benefit.

Conclusions: In conclusion, a model for MeN was developed in rats. As AP and BC provided similar benefit and the cotreatment did not have a synergistic effect, those data suggest that both treatments might act by blocking pathophysiological pathways that converge in similar outcomes.

Kidney Produces Fibroblast Growth Factor 23 in Rat CKD Model Hidekazu Sugiura,[3] Nobuo Nagano,[1] Kosaku Nitta,[2] Ken Tsuchiya.[2] *[1]Hidaka-kai, Takasaki-shi, Japan; [2]Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]Department of Nephrology, Division of Medicine, Saiseikai Kurihashi Hospital, Saitama, Japan.*

Background: Fibroblast growth factor 23 (FGF23) is a hormone secreted from the bone, and involved in phosphorus metabolism. FGF23 mainly bounds to the fibroblast growth factor receptor, which is accompanied by αKlotho expressed in the kidney or parathyroid, and regulates the expression of phosphate co-transporter, production of 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$), and secretion of parathyroid hormone (PTH). In chronic kidney disease (CKD), blood FGF23 level rises, which is believed to associated with cardiac hypertrophy and mortality.

Methods: In this study, we chose unilateral nephrectomy rat fed with high-phosphorus diet, 5/6 nephrectomy rat and doxorubicin renal failure rat as CKD model animals, and analyzed expression of renal FGF23 in each CKD model animal by real-time PCR and Western blot analysis.

Results: All model rats showed renal dysfunction and increased level of blood phosphorus. In both unilateral nephrectomy rat fed with high-phosphorus diet and 5/6 nephrectomy rat, blood FGF23 and PTH level were increased. However, level of $1,25(OH)_2D_3$ was increased in unilateral nephrectomy rat fed with high-phosphorus diet and decreased in 5/6 nephrectomy rat. In all three model animals, mRNA expression *of αKlotho, Na-dependent phosphate co-transporter type IIa and type IIc* were decreased in kidneys. *FGF23* mRNA was also measured in kidney. While *FGF23* mRNA expression in kidney was barely detectable in control groups, it was detectable in CKD model groups. The difference between two groups was statistically significant. In unilateral nephrectomy rat fed with high-phosphorus diet and 5/6nephrectomy rat, Western blot showed the level of renal FGF23 protein was increased.

Conclusions: This result suggests that FGF23 is expressed in kidney of the CKD model rat. FGF23 produced in kidney is suggested to affect the phosphorus metabolism in the kidney. We demonstrated in this study that FGF23 is produced in the kidney in CKD model rats.

Phosphorus Is an Exacerbation Factor in the Progression of CKD Model by the Accumulation of Small Kidney Injury in Klotho Deficit Mice Ken Tsuchiya,[1] Hidekazu Sugiura,[2] Norio Hanafusa,[1] Kosaku Nitta.[3] *[1]Department of Blood Purification, Tokyo Women's Medical University, Shinjuku-ku, Japan; [2]Department of Nephrology, Saiseikai Kurihashi Hospital, Kuki, Japan; [3]Department of Medicine IV, Tokyo Women's Medical University, Shinjuku-ku, Japan.*

Background: It has been established that klotho protein is a key molecule in the axis of Ca/P metabolism in CKD-MBD, on the other hand, klotho is speculated to be implicated in the mechanism of preceding the CKD, in which klotho suppression is likely to be a result and a cause of CKD. Previously, we reported that repeated minor kidney injury results in more reduction of klotho and cause of CKD in klotho deficit mice. In this study with this model, we investigated several factors which may be involved in making worse or improving the progression of CKD.

Methods: Short time clamping of renal artery for 20 minutes was performed and repeated once a week for 3 weeks in the klotho gene heterozygous mice (*kl(-/+)*). Renal function, the score of tissue damage and altered expression factors were monitored with immunohistochemistry and RT-PCR for mRNA expression. Then, klotho expression was modified by erythropoietin treatment or diet therapy assuming clinical matter. Practically, 200 μ/kg BW of recombinant erythropoietin (ESA) was injected subcutaneously 3 times per week. Since phosphorus is an old and new aggravating factor for CKD which has been drawing attention, stepwise dose of phosphorus was fed in diet in whole experimental period for dietary modification.

Results: Repeated ischemia reduced the renal function and worsen tissue score in *kl (-/+)* mice than in wild type mice. These changes were attenuated by ESA treatment. Klotho mRNA slightly recovered and the expression of fibrotic factors were reduced. Phosphorus is an aggravating factor that stands out than the other factors. Klotho deficit mice treated with repeated minor kidney injury were more sensitive to high phosphorus (2%) loading than control, resulting in more severely reducing the expression of klotho and accelerating renal damage (ATN scores 2.4 folds vs. control).

Conclusions: Repetitions of mild kidney injury possibly initiate or accelerate CKD in reduced klotho expression. Phosphorus loading damaged the kidney much more in these *kl(-/+)* mice, which may suggest that phosphorus restriction (reflecting low protein diet) is likely to be meaningful for the attenuation of the progression of CKD, indicating the importance of re-estimating of the significance of low protein diet (namely, low phosphorus) in clinical practice.

SA-PO371

Vitamin D Deficiency Impairs the Renal Expression of M2 Macrophages in Rats Submitted to 5/6 Nephrectomy Rildo A. Volpini, Daniele Canale, Janaina G. Gonçalves, Maria H. Shimizu, Antonio C. Seguro, Ana Carolina de Braganca. *Faculty of Medicine - University of Sao Paulo, São Paulo, Brazil.*

Background: 5/6 nephrectomy (Nx) is a classical experimental model of chronic kidney disease (CKD). Many studies have shown a pivotal role of macrophages (MØ) in the progression of CKD. Broadly, two main groups of MØ are designated: M1 (proinflammatory MØ) and M2 (tissue repair MØ). Moreover, recent investigations have been linking Vitamin D Deficiency (VDD) to inflammatory process and predisposition to fibrosis formation.

Methods: For 90 days, male Wistar rats were fed a standard [Sham and Nx groups] or a vitamin D-free (VDD and VDD+Nx) diets. On day 30, Nx and VDD+Nx rats were submitted to Nx surgery. On day 90, we measured serum levels of 25(OH)D and PTH by ELISA, inulin clearance (Cin), mean arterial pressure (MAP), immunoblotted for TGF-β and performed IHC for MØ type 1 (ED1) and 2 (Mannose Receptor). Also, we estimated the interstitium enlargement by fraction interstitial area (FIA).

Results: As described in Table 1, VDD were associated with MAP elevation and decreased Cin in VDD+Nx group. Moreover, we observed higher expression of M1 macrophages and TGF-β as well as larger FIA in the renal cortex of those animals. Interestingly, we found a lower expression of M2 macrophages in VDD+Nx rats, indicating an important role of Vitamin D in the tissue repair and maintenance of inflammatory process.

Conclusions: Our study suggests that VDD is involved in tissue repair and fibrosis formation after Nx, reinforcing the role of VDD as an aggravating factor for CKD progression. (Financial Support: FAPESP 2015/05513-1)

Tubular Matrix Gla Protein Expression Increases Progressively with CKD Kana N. Miyata,[1] Pei Zhang,[1,2] Tiane Dai,[1] Cynthia C. Nast,[3] Ramanath B. Dukkipati,[1] Janine A. La page,[1] Jonathan P. Troost,[4] Leon J. Schurgers,[5] Sharon G. Adler.[1] *[1]LA Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [2]The First Affiliated Hospital of Anhui Medical University, He Fei, China; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]University of Michigan, Ann Arbor, MI; [5]Maastricht University, Maastricht, Netherlands.*

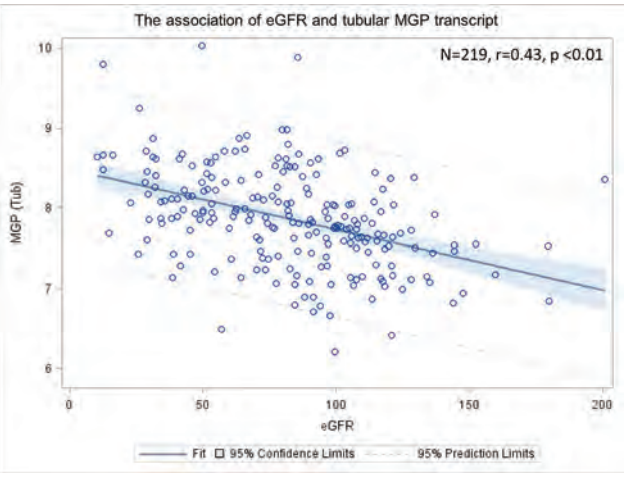
Background: Experimental data indicate that renal tubule dedifferentiation may contribute to CKD progression. A vitamin K–dependent protein, Matrix Gla Protein (MGP), is a potent in vivo inhibitor of arterial calcification. Little is known about de novo MGP expression and function in kidney.

Methods: We performed 5/6 nephrectomy (Nx) in rats, sacrificed them at 2 days, 2 weeks, and 4 weeks, and measured gene expression by microarray. Altered expression was noted for many proteins involved in vascular calcification. We focused on MGP and localized carboxylated MGP (cMGP) in kidneys from patients with CKD. Then, we analyzed the association between eGFR at biopsy and the MGP transcript levels of patients in the Nephrotic Syndrome Study Network (NEPTUNE) cohort.

Results: Renal MGP expression was significantly increased in 5/6Nx rats: 2.16-fold (2 days, p=0.002), 3.27-fold (2 weeks, p=0.0002), and 3.31-fold (4 weeks, p=0.0002). There was a trend for patients with advanced CKD (n=8) to have greater tubulointerstitial (TI) cMGP staining vs controls (NS). In NEPTUNE samples, there was an inverse relationship between eGFR and the TI MGP transcript. The TI MGP transcript correlated positively with interstitial fibrosis (r=0.47, p<0.01) and tubular atrophy (r=0.45, p<0.01), even after adjustment for eGFR, and was significantly higher in kidneys with acute tubular injury(p<0.01).

Conclusions: Our experiments demonstrate increased TI MGP expression in CKD in experimental animals and patients. TI MGP transcript levels increased progressively with CKD progression and was associated with interstitial fibrosis, tubular atrophy, and acute tubular injury. In published microarrays, TI MGP expression is also increased in patients with diabetic kidney disease and in ageing rats. Additional studies are needed to determine if the de novo expression of MGP represents tubular dedifferentiation or an adaptation to injury.

Funding: Other NIH Support - The Nephrotic Syndrome Study Network Consortium (NEPTUNE), U54-DK-083912, is a part of the National Institutes of Health (NIH) Rare Disease Clinical Research Network (RDCRN), supported through a collaboration between the Office of Rare Diseases Research (ORDR), NCATS, and the National Institute of Diabetes, Digestive, and Kidney Diseases. Additional funding and/or programmatic support for this project has also been provided by the University of Michigan, the NephCure Kidney International and the Halpin Foundation.



SA-PO373

Heat-Induced Renal Damage (HRD) Is Dose-Dependently Worsened by Fructose (F) Concentration in Rehydration Fluid L. Gabriela Sanchez-Lozada,[2] Fernando E. García-arroyo,[2] Guillermo Gonzaga,[2] Monica G. Blas-Marron,[2] Octaviano Silverio,[2] Itzel Muñoz,[1] Edilia Tapia,[2] Richard J. Johnson.[3] *[1]Government, México City, Mexico; [2]INC Ignacio Chavez, Mexico City, Mexico; [3]University of Colorado Denver, Aurora, CO.*

Background: Recurrent episodes of heat exposure result in HRD that is aggravated when F containing beverages are provided as rehydration fluid. The purpose of this study was to explore the effect of different concentrations of F in the rehydration fluid and correlate them with parameters of kidney damage.

Methods: Male Wistar rats were exposed to heat from Monday to Friday at 37°C, 1 h. Rats were allowed to rehydrate only at night with fluids containing the following F concentrations: 0, 2.5, 5, 7.5 and 10%. A group of the normal non-dehydrated rats was included as a reference. At 4 weeks, blood samples and urine were collected. Cr, uric acid (UA), osmolality (plasma and urine), vasopressin (plasma copeptin), and NAG were measured. Proximal and distal nephron segments were isolated, and the expression of aquaporin-2 (Aqp2) and cAMP concentrations were evaluated.

Results: Aqp2 expression and cAMP concentrations in distal segments were increased by repeated heat exposure and further by F rehydration, but there were no differences among the increasing F concentrations.

Conclusions: F rehydration aggravated the HRD in a dose-dependent fashion. F further increased UOsm and Aqp2 expression, despite there was not an additive effect caused by the increased F concentrations. These data suggest that the higher concentrations of vasopressin and hyperuricemia may contribute to exacerbating renal alterations in HDR. The fact that UOsm, Aqp2 expression and [cAMP] reached a threshold after the lower F concentration suggests that F might damage distal portions of the nephron affecting the urinary concentration capacity.

A Recessive K572Q Mutation in Gamma-Adducin Plays a Causal Role in Impaired Renal Vascular Reactivity in FHH and MNS Rats Chao Zhang,[1,2] Ying Ge,[1] Tongyu Zhu,[2] Paige N. Mims,[1] Fan Fan,[1] Richard J. Roman.[1] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: The Fawn-Hooded hypertensive (FHH) rat is a genetic model for studying hypertension induced renal disease, however the causal genes involved are

unclear. We previously reported that the transfer of a small region in Chr. 1 of Brown-Norway (BN) rats which contains 15 genes, including gamma-Adducin (Add3), into the FHH background could restore the impaired renal microvascular function in FHH rats. Our further work identified a K572Q mutation in Add3 in FHH rats as a potential candidate variant in the pathogenesis of renal disease.

Methods: The present study examined the role of the K572Q mutation of Add3 in the autoregulation of renal blood flow (RBF) and the myogenic response of renal afferent arteriole (af-art) by using Add3 transgenic and knockout (KO) rats.

Results: RBF increased by 21.5 ± 3.0% in SD. Add3 KO rats (n=7) when mean arterial pressure (MAP) was increased from 100 to 150 mmHg. In contrast, RBF only increased by 3.5 ± 0.9% in wildtype (wt) SD rats (n=13). The diameter of the renal af-art decreased by 13 ± 0.8% in SD rats when perfusion pressure was increased from 60 to 120 mmHg, but it increased in by 5.0 ± 0.6% in the SD.Add3 KO rats. The myogenic response of af-arts in FHH rats was markedly impaired and increased by 8 ± 1.2% when the pressure was increased by from 60 to 120 mmHg. The myogenic response was restored, and the diameter of Af-art decreased by 12 ± 0.7% and 7 ± 1.0% in FHH. 1^{BN} congenic rats (n=27) and Add3 transgenic FHH rats that express wt-Add3. RBF increased by 35.1 ± 3.0% when MAP was increased from 100 to 150 mmHg in FHH rats (n=15) versus only 7.5 ± 1.7% and 6.0+ 1.3% in FHH.1^{BN} or a F1 cross of FHH and FHH.1^{BN} rats (n=8) and in Add3 transgenic FHH rats that express the wt-Add3 gene. The myogenic response of Af-art and autoregulation of RBF were also impaired in MNS rats (n=6) that carry the same K572Q mutation in Add3 as FHH rats. These phenotypes were complemented in an F1 of cross of FHH and MNS rats (n=7), but the myogenic response and autoregulation of RBF were restored in an F1 cross of FHH and FHH.1^{BN} rats with one copy of wt-Add3.

Conclusions: There results suggest that the recessive K572Q mutation of Add3 in FHH and MNS rats plays a causal role in renal microvascular dysfunction that may contribute to the development of proteinuria and chronic kidney disease in these models.

MDM2 Subcellular Trafficking Is Involved in the AKD to CKD Progression Induced by Repeated Cisplatin Exposure Hua Su. *Huazhong Science and Technology University, Wuhan, China.*

Background: Repeated cisplatin (CP) administration frequently leads to the development from acute kidney disease (AKD) to chronic kidney disease (CKD). During above pathogenic process the tubular epithelial cell (TEC) damage is the cardinal event. MDM2 is an E3 ligase and participates in multiple pathophysiologic responses. Previously our studies revealed that MDM2 not only involves in AKD but also accounts for CKD by promoting fibroblast activation. However, the role of MDM2 in repeated CP exposure induced AKD to CKD transition is unclear.

Methods: AKD to CKD mice model was established by intraperitoneal injection of CP (8mg/Kg) once a week. The mice were grouped into 1CP, 2CP, 3CP and 4CP according to the times of CP administration. 7 days after the final injection the mice were sacrificed and kidney cortex was collected. Immunostaining and sucrose gradient ultracentrifugation were utilized to label or isolate subcellular organelles. Immunoprecipitation was employed to examine the interaction between MDM2 with p53 or NHERF1, as well as the ubiquitination of p53 and NHERF1.

Results: We successfully established the CP-induced AKD to CKD mice model which was proved by the increased NAGL and KIM-1 expression in 2 CP group with later upregulated α-SMA, Collagen 3 and serum creatinine in 3CP and 4CP groups. Our data shown in physiological state MDM2 predominantly distributes in nuclei and binds with p53, however after first time of CP administration MDM2 moves from nuclei to cytoplasm along with decreased interaction of p53 and upregulated p53 expression. Furthermore, after 3 and 4 times of CP injection, we found cytoplasmic MDM2 further transports to cell membrane and interacts with NHERF1, a negative regulator of PDGF-BB/PDGFR-β axis, and which leads to the enhanced ubiquitination of NHERF1. Consequently, the abundance of NHERF1 minimized with the activation of PDGF-BB/PDGFR-β signaling, a well-known cytokine pathway involved in CKD development via autocrine as well as paracrine manner.

Conclusions: Repeated CP administration initiates the MDM2 trafficking form nuclei to cytoplasm, and eventually move to the cell membrane where MDM2 binds with and ubiquitinates NHERF1. Consequently, NHERF1 is degraded and PDGF-BB/PDGFR-β signaling is activated.

Adaptive and Pathologic Mechanisms in Diabetic Kidney Disease: A Modeling Analysis Hari shankar Mahato,[3] Christine Ahlström,[2] Rasmus Jansson-Lofmark,[2] Gabriel Helmlinger,[1] Melissa Hallow.[3] *[1]AstraZeneca Pharmaceuticals, Waltham, MA; [2]AstraZeneca R&D, Mölndal, Sweden; [3]University of Georgia, Athens, GA.*

Background: Translation from preclinical animal models to human diabetic kidney disease is challenging due to species differences in disease processes and timecourses. Quantitative systems models are helpful in understanding disease mechanisms and interspecies differences. We aimed to adapt a physiological model of human renal function to mice, to incorporate adaptive and pathologic mechanisms of diabetes and nephrectomy observed in the db/db uninephrectomized (UNX) mouse model, and to explore the response to clinically renoprotective drugs.

Methods: Some renal structural/functional characteristics are preserved across species (e.g. pressures, single nephron flow rates), while others differ markedly (e.g. nephron number, tubular lengths). We reparameterized a systems model of human renal hemodynamics to represent mice, and ensured appropriate phenotypic behavior (e.g. glomerular filtration rate [GFR], blood pressure). To model the adaptive and pathologic renal effects in kidney disease, we assumed that elevated glomerular capillary pressure causes 1) glomerular capillary hypertrophy, up to a limit, 2) podocyte damage and increased protein filtration, and 3) glomerulosclerosis. The renal consequences of 1) UNX, 2) increased blood glucose (and associated increased proximal reabsorption via SGLT) and sodium intake in db/db mice, and 3) the combination, was then simulated using experimental data to inform the model.

Results: The model implicitly reproduced the GFR rise (hyperfiltration) observed in db/db mice when glucose and Na+ intake increased, as well as the compensatory increase in single nephron GFR to keep total GFR stableafter UNX. In both cases, glomerular hypertrophy normalized glomerular pressure, so that proteinuria was minimal, as observed experimentally. However, combining UNX with diabetes increased glomerular pressure beyond the adaptive capacity and caused overt progressive proteinuria. The model also reproduced the proteinuria reduction observed in with enalapril, eplerenone and dapagliflozin.

Conclusions: The systems model provides insight into adaptive and pathologic renal processes in db/db UNX mice. By simulating responses to therapies for which preclinical and clinical data is available, it may aid benchmarking for clinical translation.

Experimental Heat Stress Nephropathy Is Improved by Allopurinol Carlos A. Roncal-jimenez,[4] Tamara Milagres,[4] Miguel A. Lanaspa,[4] Ana Andres-hernando,[4] Masanari Kuwabara,[4] Yuka Sato,[4] Thomas Jensen,[4] Gabriela E. Garcia,[4] L. Gabriela Sanchez-Lozada,[3] Ramon Garcia-Trabanino,[1] Emmanuel Jarquin,[1] Jason R. Glaser,[2] Richard J. Johnson.[4] *[1]Hospital Nacional Rosales, San Salvador, El Salvador; [2]La Isla Foundation, INC., Ada, MI; [3]NoneInst. Nal Cardiol. Ignacio Chavez, Mexico City, DF, Mexico; [4]University of Colorado Denver, Aurora, CO.*

Background: Mesoamerican nephropathy (MN) is a disease of unknown cause observed primarily in sugarcane workers with recurrent dehydration that affect to the kidney chronically (CKD). Some evidence suggests hyperuricemia may be involved; to test that hypothesis we evaluated the role of uric acid (UA) in an animal model of heat stress and dehydration.

Methods: Mice exposed to heat 39.5 °C x 30 min, 8x daily for 5 weeks, with water provided at night with allopurinol 32mg/Kg/d in drinking water, Group 4 (**Heat +AP**) or without allopurinol Group 3 (**Heat**), as well as **contro**l groups that were normal mice receiving water or water with allopurinol Groups 1 (**Control**) and 2 (**AP**), respectively n=7 per group

Results:

Conclusions: Allopurinol lowered serum uric acid in animals with heat stress and this was associated with less fibrosis, less proximal tubular injury (preserved ACE staining) and improved renal function. Interestingly, lowering serum uric acid was also associated with an increase in serum vasopressin and lower serum osmolarity in Heat animals; and with higher copeptin, lower urine osmolarity in normal mice. *p value** shows the value by Bonferroni's post hoc analysis between Heat and Heat+AP.

Domain-Specific Antibodies Reveal the Membrane Topology of ApoL1 Nidhi Gupta,[1] Xinhua Wang,[1] Ann De Maziere,[2] George Posthuma,[2] Paul Moran,[1] Michael T. Lipari,[1] Daniel Kirchhofer,[1] Judith Klumperman,[2] Randall J. Brezski,[1] Andrew S. Peterson,[1] Suzie J. Scales.[1] *[1]Genentech, Inc., South San Francisco, CA; [2]UMC Utrecht, Utrecht, Netherlands.*

Background: ApoL1 (Apolipoprotein L1) is a component of the trypanolytic factor that circulates on HDL3b particles and protects against *Trypanosoma brucei brucei* infection. Two common African variants in ApoL1 (G1 and G2) additionally protect against *Trypanosoma brucei rhodesiense*, but also confer a greater risk of chronic kidney disease in homozygotes. ApoL1 contains three domains named for their roles in trypanolysis – a pore forming domain that forms ion channels leading to lysis; a membrane addressing domain responsible for HDL binding and lysosomal membrane insertion; and an SRA-interacting domain that binds to the serum resistance factor of *T.b. rhodesiense*. However, little is known about ApoL1 topology i.e. which domains are exposed on HDL particles and kidney podocytes, the susceptible cell type in chronic kidney disease.

Methods: We generated >100 monoclonal antibodies to ApoL1 to better understand its topology, localization and roles in kidney disease and trypanolysis. We probed ApoL1 membrane topology in cell lines using immunofluorescence on differentially permeabilized cells, electron microscopy and flow cytometry. ApoL1 domain accessibility in human serum was mapped by the ability of the antibodies to block trypanolysis.

Results: We obtained specific (non ApoL2 cross-reactive) antibodies to all three domains of ApoL1. ApoL1 localized to the endoplasmic reticulum in overexpressing kidney cells, with all three domains sequestered within the lumen, topologically equivalent to the cell surface. By contrast, ApoL2 (which lacks a signal sequence) localized to the cytoplasmic face of the endoplasmic reticulum. We found portions of all three domains of ApoL1 are exposed in serum, as judged by pull-down and inhibition of trypanolysis assays. However, on the podocyte cell surface, the membrane addressing domain of ApoL1 is not exposed.

Conclusions: ApoL1 topology differs between serum and kidney cells.

Modulation of Podocyte (PD) Homeostasis by Mesenchymal Stromal Bone Marrow Cells (MS-BMC) in the Adriamycin Two and Single Kidney Injury Models Rukhsana Aslam,[1] Ali Hussain,[2] Seyedeh Shadafarin Marashi Shoshtari,[5] Abheepsa Mishra,[3] Vinod Kumar,[6] Ashwani Malhotra,[7] Pravin C. Singhal.[4] *[1]Feinstein Institute for medical research, Glenoaks, NY; [2]Feinstein Institute of Medical Research, New York, NY; [3]Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY; [4]North Shore LIJ Health System, Great Neck, NY; [5]The Feinstein Institute for Medical Research, Manhasset, NY; [6]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [7]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Adriamycin has been demonstrated to induce focal segmental glomerulosclerosis (FSGS). Mesenchymal stromal bone marrow cells (MS-BMCs) have been demonstrated to provide cytoprotection by the modulation of cytokine production in several nephrotoxic models. Recently, parietal epithelial cells (PECS) have been considered as progenitor cells to manage podocyte homeostasis; however, PECs may also act as profibrotic cells in adverse milieus. In the present study, we evaluated the effect of MS-BMCs on modulation of the role of parietal epithelial cells in mananging the podocyte homeostasis in adriamycin-induced podocyte injury in two and single kidney injury models.

Methods: MS-BMCs were harvested from bone marrows of mice and their profile was characterized. Mice in groups of six were administered either buffer (group A), intracapsular instillation of MS-BMCs in left kidney (group B), or intraperitoneal MS-BMCs administration (Group C) 24 hours prior to Adriamycin (150 mg/Kg, subcutaneously) administration. Additional six mice administered normal saline were used as controls. All mice were euthanized after 4 weeks; urine and blood samples were collected for BUN and albumin: creatinine ratio. Kidneys were harvested for histology, immuno-staining for p57 and co-labeling for CD44 and phospho-ERK. Immunoblots were prepared and probed for podocin and WT1 and reprobed for actin.

Results: Group B and C mice displayed a decrease ($P<0.05$) in albumin: creatinine ratio vs. Group A mice. Immunoblotting studies revealed decreased ($P<0.01$) podocin, WT1, and p57 expressions in renal tissues of group C when compared to renal tissues of group A. On the other hand, renal tissues of the left kidneys from Group B displayed increased ($P<0.01$) protein expression of podocin, WT1, and p57 when compared to contralateral kidneys. Kidneys from the group C and right kidneys from the group B displayed increased ($P<0.05$) number of profibrotic cells (colabeled for phos-ERK and CD44) but a decreased ($P<0.05$) number of p57 +ve cells.

Conclusions: These findings indicate that MS-BMCs provide protection from injurious effect of adriamycin by decreasing the number of pro-fibrotic PECs and increasin the number of progentor cells.

The Impact of Canagliflozin on the Gut Microbiota of Non-Diabetic CKD Rats and Its Effect on Cardiovascular System Ayumi Matsui,[4] Ayumi Yoshifuji,[1] Junichiro Irie,[3] Takaya Tajima,[4] Kiyotaka Uchiyama,[5] Tomoaki Ito,[2] Shu Wakino,[2] Hiroshi Itoh.[3] *[1]KEIO UNIVERSITY, Tokyo, Japan; [2]Keio University, Tokyo-to, Japan; [3]Keio University School of Medicine, Tokyo, Japan; [4]Keio University school of medicine, Tokyo, Japan; [5]Keio University, School of Medicine, Tokyo, Japan.*

Background: The gut is responsible for the production of some uremic toxins by microbiota which induces the tissue damages in chronic kidney disease (CKD). Gut microbiota population was reported to be aberrated in CKD. Novel anti-diabetic reagent sodium glucose cotransporter (SGLT)2 inhibitor, canagliflozin(Cana) harbors a marginal inhibitory potential to gut-type SGLT1, which is hypothesized to affect the dysbiosis in CKD. We investigated the impact of Cana on the microbiota and on cardiovascular and renal tissues in non-diabetic CKD rats.

Methods: 6-week-old male spontaneously-hypertensive rats (SHRs) were randomly assigned to three experimental groups; sham operated SHR (Sham), 5/6 nephrectomized SHR (Nx), and 5/6 nephrectomized SHR treated with Cana (0.024% mixed in standard chow) (Nx+C). After 12weeks, microbiota population was examined by T-RFLP and following PCR. The tissue findings and molecular changes of kidney, cardiovascular systems and intestine were also investigated.

Results: Proteinuria, serum creatinine and BUN levels were significantly elevated in Nx group, although Cana failed to improve the impaired renal function. Serum concentrations of gut-derived uremic toxins such as indoxyl sulfate and hippuric acid were significantly elevated in Nx rats, which were lowered by Cana. The population of gut microbiota was changed in Nx rats, which were restored by Cana. Quantitative analysis of *Lactobacillus* species confirmed a significant decrease of *Lactobacillus* by Nx, which was also reversed by Cana. Immunoblotting analysis of the tight junction proteins of colonic tissue confirmed that Cana restored claudin-1, occludin, and Zo1 expression which were downregulated in Nx rats. Nx rats showed significantly increased wall thickness of the thoracic aorta and cardiac intestinal fibrosis. CTGF and TGFβ1 mRNA expression in cardiac tissues were significantly increased by Nx. These changes were ameliorated by Cana.

Conclusions: Cana successfully reduced serum indoxyl sulfate and hippuric acid levels by restoring dysbiosis in non-diabetic CKD rats, which might have favorable effects on cardiovascular systems in CKD condition.

DESI-MSI Based Spatial Metabolomics Reveals Altered Metabolome and Increased Pseudouridine in Renal Proximal Tubules of Mice with Diabetic Kidney Disease Guanshi Zhang,[1] Jialing Zhang,[2] Rachel J. Dehoog,[2] Manjula Darshi,[1,3] Benjamin F. Van espen,[1,3] Subramaniam Pennathur,[4] Vighnesh Walavalkar,[5] Theodore Alexandrov,[6,7] Livia S. Eberlin,[2] Kumar Sharma.[1,3] *[1]Center for Renal Translational Medicine, Division of Nephrology-Hypertension, Institute of Metabolomic Medicine, University of California San Diego, La Jolla, CA; [2]Department of Chemistry, The University of Texas at Austin, Austin, TX; [3]Division of Nephrology-Hypertension, Veterans Affairs San Diego Healthcare System, La Jolla, CA; [4]Division of Nephrology Department of Internal Medicine, University of Michigan, Ann Arbor, MI; [5]Department of Pathology, University of California San Diego, La Jolla, CA; [6]Structural and Computational Biology Unit, European Molecular Biology Laboratory, Heidelberg, Germany; [7]Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California San Diego, La Jolla, CA.*

Background: Diabetic kidney disease (DKD) is the most prevalent complication in diabetic patients, which contributes to high morbidity and mortality. Urine and plasma metabolomics studies have reported that both blood and urinary metabolites to provide valuable insights for DKD. Spatial distributions of metabolites in kidney tissues would link circulating metabolites to actual kidney compartments but the techniques are challenging. We employed an ambient desorption electrospray ionization – mass spectrometry imaging (DESI-MSI) approach to characterize the metabolome in a mouse model of DKD coupled to a novel bioinformatics platform (METASPACE).

Methods: DESI-MSI was performed for spatial untargeted metabolomics analysis in kidneys of mouse models (F1 C57BL/6J-*Ins2*^{Akita} male mice at 17 weeks of age) of type 1 diabetes (T1D, n = 5) and heathy controls (n = 6). Metabolite annotations from MSI were conducted using METASPACE and further validated by collision induced dissociation or higher-energy collisional dissociation tandem MS analysis. MetaboAnalyst 3.0 was employed for statistical analyses.

Results: Multivariate analyses (i.e., PCA and PLS-DA (a 2000 permutation test: $P < 0.001$)) showed clearly separated clusters for the two groups of mice on the basis of 878 measured *m/z*'s in kidney cortical tissues. Specifically, mice with T1D had increased relative abundances of pseudouridine (*m/z* 279.039), fatty acids (FA) (e.g., FA (18:2), *m/z* 279.233), and glycerophosphoglycerols (PG) (e.g., PG (36:1), *m/z* 775.548) in cortical proximal tubules when compared with healthy controls.

Conclusions: Results from the current study further support a role for pseudouridine in DKD and the data suggests that pseudouridine accumulation might originate from cortical proximal tubules. Lipid data indicate disordered fatty acid metabolism (e.g., enhanced FA synthesis and altered FA oxidation) and glycerophospholipid metabolism in DKD mice. DESI-MSI technology is a powerful approach to shed new light on fundamental pathways in disease states.

SA-PO382

Investigating Endoplasmic Reticulum Stress in the Development of Lupus Nephritis Mathilde L. Bonnemaison, Erika I. Boesen. *University of Nebraska Medical Center, Omaha, NE.*

Background: Lupus nephritis is a common complication of the autoimmune disease systemic lupus erythematosus (SLE) and is associated with glomerular and tubular injury. Although albumin uptake has been shown to induce endoplasmic reticulum (ER) stress in proximal tubule cells *in vitro*, it is unknown whether ER stress occurs in and contributes to the development of renal injury in SLE.

Methods:

Results: To investigate this, the current study used a well-established model of lupus nephritis, the NZBWF1 mouse (female only). Mice were randomized to receive either vehicle (normal drinking water) or the ER stress blocker 4-phenylbutyric acid (4-PBA, 20 mM) in drinking water starting from 12 weeks of age until 34 weeks of age or the onset of albuminuria, whichever came first. In a pilot study, this treatment protocol significantly reduced mRNA expression of the ER stress marker CHOP in both 20 and 34 week old NZBWF1 mice ($P_{treatment}=0.02$). Mice were sacrificed at the onset of albuminuria (≥100mg/dL by dipstick) or at 34 weeks of age, whichever came first. The relative risk of the 4-PBA mice progressing to albuminuria before 34 weeks of age was 0.83 (95% confidence interval of 0.56-1.3, P=0.2 by Chi-square test). Blood urea

nitrogen was significantly elevated in mice that developed albuminuria before 34 weeks of age (P<0.0001), but was not different between vehicle and 4-PBA groups. Plasma creatinine levels were unchanged over time in both groups. CHOP mRNA expression in the renal cortex was compared between untreated 20 week old mice (prior to SLE development) and vehicle-treated albuminuric and non-albuminuric 34 week old mice. Surprisingly, mRNA levels of the ER stress marker CHOP were significantly reduced in the renal cortex of albuminuric mice compared to the 20 week old mice (P<0.05), which had similar CHOP expression to 34 week old non-albuminuric mice. A similar trend was observed for GRP94, but this did not reach statistical significance.

Conclusions: Together, these findings do not support a major role for ER stress in the early stages of the development of renal injury in SLE, as defined by onset of albuminuria. Whether ER stress contributes to the further progression of renal injury in lupus nephritis once albuminuria has developed remains to be investigated.

Effect of Pioglitazone on the Shedding of Urinary Angiotensin Converting Enzyme (ACE) 2 and Neprilysin (NEP) in db/db Mice and Their Role as Urinary Biomarkers for Diabetic Kidney Disease

Meenasri Kumbaji,[2] Rucha Fadnavis,[2] Salim El-Amouri,[2] Mohammad G. Saklayen,[1] Khalid M. Elased,[2] Nadja Grobe.[2] *[1]VA Medical Center, Dayton, OH; [2]Wright State University, Dayton, OH.*

Background: Diabetic kidney disease (DKD) is one of the major causes of end-stage renal disease. Angiotensin (Ang) II is the major biological active peptide of the renin angiotensin system. Elevated levels of Ang II contribute to initiation and progression of DKD. The actions of Ang II could be antagonized by its conversion to the vasodilator Ang (1-7), partly generated by the action of ACE2 and NEP. Although there is an emergence of some urinary biomarkers such as angiotensinogen, kidney injury molecule-1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL), there is still a need for new early biomarkers for DKD. The aim is to investigate the effect of hyperglycemia on urinary albuminuria, ACE2, NEP and KIM-1 and to test the hypothesis that ACE2 and NEP can be used as early biomarkers for DKD.

Methods: 8 weeks old control and *db/db* diabetic mice were subjected to pioglitazone treatment (20 mg/kg/day) for 10 weeks. Metabolic and renal parameters were measured. Urine was collected for the evaluation of ACE2, NEP, KIM-1 protein expression and RAS activity.

Results: At 7 weeks old, there was no significant difference in urinary albumin, NEP and KIM-1 between *db*/*db* and control mice. However, western blot showed a significant increased shedding of urinary ACE2 fragment (60KDa and 70kDa immunoreactive bands) in *db*/*db* mice compared to controls. Although there was a prominent immunoreactive band for NEP in control mice at 9 weeks, there was no detectable immunoreactive band for ACE2. After the development of albuminuria in older *db*/*db* mice (9-17week), there was a significant increase of full length (95KDa) and fragment of ACE2, NEP (90kDa) and KIM-1 (75KDa) compared to control mice. Urinary NEP and ACE2 activities significantly increased in 17 weeks *db*/*db* mice compared to controls. Pioglitazone normalized hyperglycemia and attenuated urinary albumin, glucose and ACE2 shedding. However, it has no effect on urinary NEP and KIM-1.

Conclusions: In *db*/*db* diabetic mice, increased shedding of enzymatically active ACE2 precedes albuminuria. Depletion of tubular renal ACE2, NEP, could lead to accumulation of Ang II, with concomitant development of microalbuminuria. Urinary ACE2 and NEP could be used as biomarkers for DKD.

SA-PO384

Angiotensin II Induces Cholesterol Accumulation and Injury in Podocytes

Yingjie Yang. *Renmin Hospital of Wuhan University, Wuhan, China.*

Background: Angiotensin Ⅱ (AngⅡ) is a risk factor for the initiation and progression of chronic kidney disease (CKD), elevated AngⅡ levels can lead to podocyte injury. Cholesterol is major component of lipid droplet (LD), cholesterol homeostasis exerts an important role in podocyte physiology. However, there are no studies on the role of AngⅡ in cholesterol metabolism or on the podocyte injury caused by cholesterol metabolism disorder.

Methods: In *vivo*, Oil red O and Nile red staining were evaluated LD deposition in glomeruli of AngⅡ-infused rats. The expression of LD marker ADRP and WT-1 by double immunolabeling was evaluated LD distribution in podocytes. In *vitro*, human podocytes were exposed to AngⅡ (10^{-7}M) for 24 h. LD was observed by Oil red O and Nile red staining. The expression of ADRP was determined by immunofluorescence and Western blot. Cholesterol content was tested by cholesterol quantitation kit. The expression of cholesterol metabolism-related molecules was determined by Real-time PCR and Western blot. Cholesterol efflux inducer methyl-β-cyclodextrin (CD) and cholesterol synthesis enzyme antagonist simvastatin were respectively pretreated to podocytes. Podocyte apoptosis was assessed by flow cytometry.

Results: In vivo, Oil red O and Nile red staining indicated that LD accumulated in glomeruli of AngⅡ-infused rats. Double immunolabeling of ADRP and WT-1 showed that LD deposited in podocytes. In *vitro*, LD was detected in podocyte exposed to AngⅡ but little in controls. The expression of ADRP was upregulated by AngⅡ. Cholesterol content was also increased, which was accompanied by decreased expression of cholesterol efflux-related molecule ABCA1 and increased expression of the cholesterol uptake-related molecule LDLR and cholesterol synthesis-related molecules SREBP-1, SREBP-2 and HMGCR. Treatment of AngⅡ-stimulated podocytes with CD showed that CD could decrease AngⅡ-induced cholesterol accumulation and reduce AngⅡ-induced podocyte apoptosis. Treatment of AngⅡ-treated podocytes with simvastatin indicated that simvastatin did not improve AngⅡ-induced cholesterol accumulation and podocyte apoptosis.

Conclusions: The present study suggests that AngⅡ induces podocyte cholesterol accumulation by regulating the expression of cholesterol metabolism related-molecules. Excess cholesterol induces podocyte injury.

SA-PO385

Phosphate Niclosamide Mitigates Renal Fibrosis through Inhibiting HIPK2 Expression

Xin Zhen, Xiaoyan Chang. *Nanfang Hospital Southern Medical University, Guangzhou, China.*

Background: Renal fibrosis is the final common pathway of all kinds of progressive chronic kidney disease (CKD). However, there are no effective therapies to prevent or slow the progression of renal fibrosis. Recently, homeodomain interacting protein kinase 2 (HIPK2) has been identified as a key regulator in kidney fibrosis and idiopathic pulmonary fibrosis (IPF) that acts upstream of several major pro-fibrotic and pro-inflammatory pathways including TGF-β/Smad, Wnt/β-catenin, Notch pathway and NF-κB pathway, indicating that HIPK2 might be a potential target for anti-fibrosis therapy. Niclosamide is a Food and Drug Administration (FDA) approved oral antihelminthic drug used for treating most tapeworm infections. It has been shown that P-NICLO exerts antitumor function by targeting multiple signaling pathways including NF-κB, Wnt/β-catenin, and Notch pathway. Given the critical role of the above pathways in the pathogenesis of renal fibrosis, the aim of the present study is to explore the potential therapeutic effect of P-NICLO on renal fibrosis.

Methods: In vivo, male BALB/C mice were injected with ADR(12mg/kg). P-NICLO (30mg/kg/d) was injected 2 weeks after ADR for 3 weeks. UUO mice received intraperitoneal injection of P-NICLO (30mg/kg/d) from day 7 after operation for 7 days. In vitro, NRK-52E or HK-2 cells reached approximately 60% confluence, pre-incubated with indicated amount of P-NICLO for 1 h followed by con-incubation with recombinant TGF-β1. WT-HIPK2 construct was transfected into HK-2 cells by using Lipofectamin 2000 Reagent 24 h after TGF-β1 (10ng/ml) and P-NICLO (0.4 μM) treatment.

Results: 1.P-NICLO attenuates glomerular injury and interstitial fibrosis induced by ADR. 2.P-NICLO ameliorates established renal fibrosis and interstitial inflammation induced by UUO 3.P-NICLO inhibits multiple profibrotic signaling pathways include TGF-β/Smads, Wnt/β-catenin, NF-κB and Notch pathways in vitro and in vivo 4.P-NICLO inhibits HIPK2 transcription through interfering the binding of Smad3 to the promoter region of HIPK2 gene to inhibit the expression of pro-fibrosis markers

Conclusions: In summary, we have shown here that P-NICLO is effective in slowing the progression of renal fibrosis. Mechanistically, P-NICLO directly attenuated the activation of multiple pro-inflammatory and profibrotic signalings through suppressing TGF-β1-induced HIPK2 expression

SA-PO386

FGF23 Promotes Progression of CKD by Directly Activating Pro-Inflammatory Signaling in Renal Epithelial Cells

Olena Andrukhova,[2] Lukas Endler,[1] Birgit Strobl,[2] Reinhold Erben.[2] *[1]University of Veterinary Medicine, Vienna, Austria; [2]University of Veterinary Medicine of Vienna, Vienna, Austria.*

Background: There is solid evidence from several clinical and epidemiological studies that fibroblast growth factor 23 (FGF23) is a strong predictor of disease progression and adverse outcomes in patients with chronic kidney disease (CKD). However, the mechanisms underlying the association between FGF23 and CKD progression are unclear.

Methods: To gain more insight into the signaling mechanisms induced by FGF23 in renal epithelial cells, we treated 3-month-old wild-type (WT) mice, $Fgf23^{-/-}$/VDR (Fgf23/VDR; VDR, vitamin D receptor), and $Klotho^{-/-}$/VDR (Klotho/VDR) compound mutant mice with recombinant FGF23 (rFGF23), harvested proximal and distal renal tubules by laser capture microdissection 2 and 8 hours after treatment, and performed mRNA expression profiling by next generation sequencing (RNA-Seq).

Results: RNA-Seq analysis revealed that rFGF23 treatment led to strong activation of the Janus kinase/signal transducer and activator of transcription (Jak/STAT) pathway in proximal and distal renal epithelium in a Klotho independent fashion. This unexpected and striking finding was confirmed by qRT-PCR and immunohistochemical analysis of the Jak/STAT pathway. *In vitro* experiments using murine primary renal epithelial cells revealed that rFGF23 rapidly and Klotho-independently activates Jak/STAT signaling in a largely FGF receptor-3 dependent fashion. To analyze the role of FGF23-induced pro-inflammatory signaling in CKD pathology, we used 5/6-nephrectomized (5/6-Nx) mice as a disease model. CKD mice were characterized by high circulating concentrations of intact Fgf23, activation of renal Jak/STAT signaling, and renal interstitial fibrosis, 8 weeks after 5/6-Nx. Treatment of CKD mice with low doses of neutralizing anti-Fgf23 antibody (50 μg per mouse, two times per week) over 8 weeks largely prevented CKD progression, and profoundly reduced the Jak/STAT-mediated pro-inflammatory and pro-fibrotic pathways in a Klotho independent manner.

Conclusions: In conclusion, our study identified excessive FGF23 signaling as a pro-inflammatory factor, directly acting on renal epithelial cells to promote inflammation and fibrosis in the diseased kidney.

The Effects of Sevelamer on Renal Klotho Expression and Serum Levels of Klotho, FGF23, and sTWEAK in Adenine Induced CKD Rats Hassan Argani. *Modares Hospital, Tehran, Islamic Republic of Iran.*

Background: Klotho down-regulation may be induced by specific cytokines such as tumour necrosis factor-α or TWEAK through the canonical activation of the inflammatory transcription factor nuclear factor kappa B (NFκB) and, specifically RelA. Klotho itself has antioxidant and anti-inflammatory properties and the canonical NFκB component RelA is one of its targets. Klotho is a key regulator of phosphate balance and phosphate play a role in ageing. Recent studies demonstrate soluble tumor necrosis factor (TNF) weak inducer of apoptosis (sTWEAK) levels follow declining of renal function, as a marker of cardiovascular events in nondialyzed chronic kidney disease patients were reduced, On the other hand high FGF23and low Klotho were reported in CKD patients. Over last few years, several studies have noted a direct correlation of inflammatory markers such as Tumor Necrosis Factor-α (TNF) with circulating FGF23 in patients with CKD. The present study is aim at evaluating the sevelamer (phosphate binder) effect in renal Klotho expression and Serum levels of FGF23, s TWEAK, Klotho in rat model of adenine induced renal failure.

Methods: Adenine 3mg/kg was used to induce CKD in 60 male wistar rats. These divided into 6 groups based on the dose administration of sevelamer for 4 weeks. Group 1 (n = 10) control group was given 0% adenine, 0% Sev, Group2 (n = 10) 0% Sev in Aenine group, Adeine contol group, Group 3(n = 10) 1% Sev in Aenine group, Group 4(n = 10) 2% Sev in Aenine group, Group 5 (n = 10) 3% Sev in Aenine group and group 6 (n = 10) 2% Sev in the normal diet. Serum stweak, Klotho levels were measured by enzyme-linked immunosorbent assay. Real-time polymerase chain reaction and Western blotting were used to evaluate Renal Klotho expression in each group.

Results: Induced renal failure was induced by adenin, FGF23 levels could be manipulated through the control of serum phosphorus levels by sevelamer treatment. Treatment with sevelamer controlled sTWEAK and KLotho downregulated in CKD rats. Sevelamer treatment also improved reduced renal expression and serum levels of Klotho and deteriorated renal function and could alleviate adenine -induced renal histological changes.

Conclusions: Treatment with sevelamer might lead to ameliorat renal Klotho and downregulation sTWEAK in CKD and suppressed FGF23 increases through the control of serum phosphorus levels in CKD patients.

suPAR Induces Proteinuria in Solitary Functioning Kidney Models Xuexiang Wang,[1] Michael R. Garrett,[2] David C. Wei,[1] Jochen Reiser.[1] *[1]Rush University Medical Center, Chicago, IL; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: Single functioning kidney (SFK) is expected in one out of 1500 births, and it causes renal injury before adulthood in over 50% of those affected. Similarly, kidney donors may have increased risk for future CKD. The underlying mechanisms and related biomarkers are still lacking. The soluble urokinase receptor (suPAR) is a circulating factor implicated in FSGS and is also a potent biomarker for predicting CKD incidence and progression. In this study, we explore the effect of elevated circulating suPAR on proteinuria development in three different rodent models of SFK.

Methods: Uninephrectomy and sham surgeries were performed on C57B/6 (B/6) mice, suPAR transgenic models or littermate controls. Minipumps with three different concentrations of LPS were implanted subcutaneously in B/6 mice only. Proteinuria and/or suPAR were followed weekly for 4 weeks. In the HSRA spontaneous one-kidney rat model, the recombinant human suPAR protein was injected intravenously into HSRA single kidney rats (HSRA-S) and two-kidney controls (HSRA-C). Proteinuria was measured 24 hours after. The activity of beta3 integrin in podocytes was determined by AP5 immunostaining.

Results: In B/6 mice, all three concentrations of LPS infusion resulted in increased level of serum and urine suPAR. Interestingly, nephrectomy resulted in higher serum suPAR and proteinuria, compared to the sham two-kidney groups. In contrast, uPAR deficient SFK mice are protected from LPS induced proteinuria. Nephrectomized suPAR transgenic mice demonstrated slowly increased proteinuria over 4 weeks of time, while the littermate control mice with nephrectomy showed no change in the urinary protein. HSRA-S rats revealed an increase of proteinuria compared to HSRA-C after the recombinant human suPAR injection. Moreover, the activity of the suPAR receptor beta3 integrin was significantly increased in the kidney of HSRA-S rats following administration of suPAR.

Conclusions: Increased circulating suPAR levels, either induced by LPS, or from suPAR transgenic models or extrinsically injected, induce proteinuria in uninephrectomized mice or rats with unilateral kidney agenesis, when compared to their two-kidney controls. These findings suggest an important role of suPAR in SFK kidney, possibly in kidney donors. Monitoring circulating suPAR levels might be important in understanding the pathogenesis and risk-control for patients with SFK.

Essential Role of Endothelial HIF-1a in Light-Induced Hypertensive CKD Renna Luo. *The First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: Hypertensive chronic kidney disease (CKD) is one of the most prevalent medical conditions with high morbidity and mortality in the United States and worldwide. Emerging evidence indicates that increased inflammatory response is involved in hypertensive CKD. Supporting this notion, recent study show that infusion of cytokine to mice leads to chronic hypertension, such as LIGHT, a TNF-a superfamily member. To determine the general significance of persistently elevated endothelial HIF-1 in hypertensive CKD, we used LIGHT-infused hypertensive CKD mouse model.

Methods: We obtained *VE-cadherin cre*$^{+}$ mice and *Hif-1α*$^{f/f}$*VE-cadherin cre*$^{+}$ mice from Dr. Holger Eltzchig's laboratory in University of Colorado at Denver. Six to twelve mice for each group were infused with LIGHT by minipump(4ng/day). Control mice were infused with PBS. We collected urine and measured blood pressure at 0,3,7,10,14 day. After treatment for 14-days, mice were sacrificed.

Results: We first found that LIGHT infusion induced persistently elevated HIF-1a protein levels in endothelial cells of capillary lumen of glomeruli in the control HIF-1a$^{f/f}$ mice. Then we identified that LIGHT-induced HIF-1a gene expression is crucial for prolonged accumulation of HIF-1a in the endothelial cells in hypertensive CKD by inducing a series of potent vasoactive components. As such, we further found that LIGHT-induced hypertension, proteinuria, decreased urinary osmotic pressure and renal fibrosis. Next, we found that endothelial HIF-1a gene expression was induced by LIGHT in a NF-kB-dependent manner. Finally, we discovered reciprocal positive transcriptional regulation of endothelial *Hif-1α* and *Nf-κb* genes is a key driving force for their persistent activation and disease progression. Overall, our findings revealed that the stimulation of HIF-1α in endothelial cells is detrimental to induce kidney injury, hypertension and disease progression.

Conclusions: Our findings highlight early diagnostic opportunities and therapeutic approaches for hypertensive CKD.

Blocking the Phosphorylation of Ribosomal Protein S6 Inhibits Focal Segmental Glomerulosclerosis Fang Li,[6,1] Caihong Dai,[2] Qiyuan Zhuang,[5] Jian-Kang Chen,[4] Huijuan Wu.[3] *[1]2. Departments of Cellular Biology & Anatomy and Medicine, AUGUSTA UNIVERSITY, AUGUSTA, GA; [2]Augusta University, Augusta, GA; [3]Department of Pathology, School of Basic Medical Sciences, Fudan University, Shanghai, China; [4]None, Evans, GA; [5]Shanghai Medical College, Fudan University, Shanghai, China; [6]Department of pathology, Fudan University, Shanghai, China.*

Background: The pathogenic mechanism of focal segmental glomerulosclerosis (FSGS) remains poorly understood. Renal hypertrophy is largely mediated by phosphorylated rpS6 (p-rpS6), a downstream effector of the mTORC1-S6K1 pathway.

Methods: We detected p-rpS6 levels in kidney biopsy specimens from patients with FSGS. By crossing *Tsc1*-floxed mice with podocin-Cre mice, we generated podocyte-specific Tsc1 knockout (TSC1^{pdKO}) mice with or without rapamycin treatment. We also compared Adriamycin (ADR)-induced FSGS, a widely used mouse model of FSGS, in *rpS6* knockin mice expressing nonphosphorylatable rpS6 (rpS6$^{P-/-}$) and in gender-matched wild type littermates.

Results: p-rpS6 was markedly increased in the renal glomeruli of both FSGS patients and ADR-induced FSGS mice. Podocyte specific rpS6 hyper-phosphorylation induced by genetic deletion of Tsc1, an upstream negative regulator of mTORC1, induced striking hypertrophy of surviving podocytes and recapitulated many features of human FSGS, including podocyte loss and segmental glomerulosclerosis, which were blunted by low-dose rapamycin treatment (0.5 or 1 mg/kg). Similarly, treatment with the phosphatase inhibitor, Tautomycin, also increased p-rpS6 and significantly promoted podocyte hypertrophy, leading to exacerbated FSGS. Conversely, completely blocking rpS6 phosphorylation by generating congenic rpS6 knockin mice expressing non-phosphorylatable rpS6 significantly blunted podocyte hypertrophy and podocyte loss (20% podocytes were lost in rpS6 knockin mice vs. 46% podocytes loss seen in wild type mice) in the ADR-induced mouse model of FSGS. Moreover, pharmacologic inhibition of S6K1 signaling to rpS6 phosphorylation using the S6K1 inhibitor, PF- 4708671, markedly blunted podocyte hypertrophy and attenuated FSGS.

Conclusions: rpS6 hyperphosphorylation plays a key role in adaptive podocyte hypertrophy and progressive podocyte loss in response to initial podocyte injury during the development and progression of FSGS.

Acute Renal Venous Pressure-Induced Renal Vasoconstriction Is Not Mediated by Increased Renal Sympathetic Nerve Activity and Is Abolished by High Salt Diet in Rats Shereen M. Hamza,[1,2] Xiaohua Huang,[1] Wenqing Zhuang,[1] William A. Cupples,[3] Branko Braam.[1,2] *[1]Medicine, University of Alberta, Edmonton, AB, Canada; [2]Physiology, University of Alberta, Edmonton, AB, Canada; [3]Simon Fraser University, Burnaby, BC, Canada.*

Background: Combined cardiac/renal dysfunction may be perpetuated by elevated renal venous pressure (RVP). We demonstrated that renal nerves modulate the increase

in renal vascular resistance (RVR) in response to mild but not severe RVP elevation. This suggests additional non-neural mechanisms. We hypothesized that mild RVP elevation would increase renal sympathetic nerve activity (RSNA) and that severe RVP elevation leads to vasoconstriction and diminished GFR via activation of the RAS. **Objectives:** (1) Measure renal sympathetic nerve activity in response to RVP elevation. (2) Evaluate RVP-induced modulation of renal hemodynamics following RAS suppression by high salt diet.

Methods: Blood pressure, RVP and RSNA were measured in anesthetized rats (300-400g, n=25). Separately, renal arterial blood flow (RBF) and GFR were assessed in rats (n=11) supplemented with 6% NaCl (2 weeks). In all rats, following baseline, RVP was increased to 10 or 20 mmHg by partial occlusion of the left renal vein for 120 min.

Results: RSNA was maintained in response to RVP 10 mmHg (frequency: 12.3±12.4%; amplitude: 0.06±0.2μV). RVP 20 mmHg induced a significant and sustained reduction in RSNA (-50.3±11.3%, $p<0.05$) and spike amplitude (-0.68±0.2μV, $p<0.05$). After high salt diet, RVP 10 or 20 mmHg did not elicit a change in RBF (RVP 10: -0.8±0.4ml/min; RVP 20: -1.0±0.4ml/min) and completely abolished the increase in RVR (RVP 10: -1.3±1.3mmHg.ml^{-1}.min; RVP 20: -1.7±2.0mmHg.ml^{-1}.min). High salt did not alter GFR response to RVP increase (RVP 10 GFR: -0.09±0.26ml/min; RVP 20 GFR: -1.11±0.28ml/min).

Conclusions: Mild RVP elevation sustains RSNA while severe RVP elevation supresses RSNA and reduces recruitment of nerve fibres. High salt-suppression of the RAS abolishes RVP-induced modulation of renal hemodynamics, indicating that the RAS, rather than RSNA mediates the renal response to acute RVP elevation.

RNA-Sequencing Based Approach to Identify Novel Pathways Regulating Atrophic and Hypertrophic Renal Remodeling Mark Paterson,[1] Alison J. Kriegel.[1,2] *[1]Department of Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Center of Systems Molecular Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: There is a great need to understand the mechanisms that regulate renal survival to preserve tubular function in patients with various forms of renal disease. In previous studies in Sprague Dawley rats we observed that excision of 2/3 of the left kidney resulted in atrophy of the remnant kidney, while excisions of both 2/3 of the left kidney and the entire right kidney resulted a robust hypertrophy of the remnant kidney from 5 to 7 weeks after surgery. The sole difference between these models is the presence or absence of the right kidney, providing a well-controlled opportunity to explore mechanisms that promote survival and senescence. The goal of this study was to identify molecular pathways that regulate renal hypertrophy and atrophy by the contrasting mRNA expression changes within each model. We hypothesized that transcript analysis would reveal unique expression profiles, highlighting the distinct stress response in each state.

Methods: We collected remnant kidneys from the atrophic and hypertrophic models (n=6/group), as well as the left kidney in sham operated controls 6 weeks after respective surgery (n=5). Next-generation RNA sequencing of these samples was performed, and subsequent statistical and Ingenuity Pathway Analysis (IPA) was completed.

Results: Comparison of RNA expression in atrophic and hypertrophic remnant kidneys against sham control kidneys identified 1112 and 867 differentially expressed transcripts (DET; adjusted p-value <0.05), respectively. In the atrophic kidney nearly 1/3 of the DET were downregulated (32.4%). IPA revealed an enrichment of numerous downregulated transcripts encoding proteins within electron transport chain and amino acid synthesis pathways, among others, consistent with changes expected in senescent tissue. The transcripts altered in the hypertrophic kidney were overwhelmingly upregulated (98.5%), enriched in pathways related to hypertrophic growth and many others. This analysis also revealed novel upstream pathways enriched with differentially expressed transcripts that will be explored to nominate therapeutic targets for functional evaluation in these models.

Conclusions: Together our data suggest that these remnant kidney models will allow us to appropriately model processes relevant to renal hypertrophy and renal atrophy and indentify molecular pathways involved with morphological and functional changes.

SA-PO393

MicroRNA-451 as an Early Predictor of and Protector against Diabetic Nephropathy (DN) Maurice Fluitt, Narayan Shivapurkar, Lijun Li, Carolyn M. Ecelbarger. *Georgetown University, Washington, DC.*

Background: MicroRNAs (MiRs) play a role in affecting transcription of a number of genes involved in DN progression, and are an attractive target as biomarkers and therapeutics. Recent studies report an early elevation in urine exosomal (UE) miR-451 with developing DN, but that overall higher renal expression was relatively protective. The current study aimed to determine whether UE miR-451 is an early predictor of albuminuria and the effect of miR-451 antagonism on DN progression in mice prone to type 2 diabetes.

Methods: Male TALLYHO/Jng mice were divided into 2 treatment groups. Mice received weekly intraperitoneal injections of locked nucleic acid (LNA)-miR-451-inhibitor or LNA-scrambled compound (2mg/kg bw; n = 8/ treatment) for 8 weeks. All mice were fed a high-fat diet (60% kCal). Urine (24-hr) was collected every 2 weeks. Mice were humanely euthanized after 8 weeks and kidneys, livers, abdominal adipose tissue, and pancreas were collected for analysis. UE were prepared by high-speed centrifugation (200,000xg). MiR-451 was quantified by qRT-PCR.

Results: UE miR451 levels were reduced 97% in antagonist-treated mice by week 2. Urine albumin levels at week 8 were positively correlated to UE miR-451 at week 2 showing potential predictive power (r=0.45). MiR-451 antagonist did not significantly affect final body or kidney weights. Fasting blood glucose (18-hr) did increase in in the inhibitor treated group at week 3, but decreased at 6 weeks. Inhibitor treated mice also presented with greater variability in blood glucose, with some mice becoming hypoglycemic at 6 weeks (blood glucose <65 mg/dl). Blood collected at euthanasia was analyzed by iSTAT. Serum sodium was significantly higher (2.4%) in the LNA-inhibitor treated group (when compared to the scramble-treated group). In addition, BUN and base excess (extracellular fluid) were 16% and 67% lower, respectively, in the LNA-inhibitor treated group. No other blood chemistry parameters were significantly different. Masson's trichrome-stained were scored for collagen deposition and showed an increase in increased glomerular injury and collagen deposition in the LNA-inhibitor treated group (scores 2.00 versus 2.95, $p < 0.001$).

Conclusions: Overall, we find that miR-451 may hold promise as an early biomarker for DN in mice, and that therapy to enhance renal expression may be beneficial.

SA-PO394

Alterations in Notch Signaling Pathway Activity and Its Potential Role in Kidney Damage in Carriers of APOL1 Risk Alleles Marianinha Joanes,[1] Shi Yang,[3] Chris Andry,[1] Adam Gower,[2] Joel M. Henderson.[3] *[1]Boston Medical Center, Boston, MA; [2]Boston University, Boston, MA; [3]Boston University Medical Center, Boston, MA.*

Background: The association between apolipoprotein L1 (*APOL1*) gene variations and the increased incidence of chronic kidney disease (CKD) in individuals of African ancestry has been well established. Despite their importance, little is known about how these variants contribute to renal dysfunction, and better understanding of this mechanism could yield new diagnostic and treatment options.

Methods: To address this shortcoming, we studied kidney tissue obtained before the development of parenchymal damage in order to identify any pathway alterations that create a milieu that promotes the later development of kidney injury. We focused on glomerular changes, given the association of *APOL1* variations with several glomerular disease phenotypes. Kidney samples were stratified according to *APOL1* genotype, including zero risk alleles (G0G0), one risk allele (G0G1, G0G2) and two risk alleles (G1G2). Gene expression profiling was performed using Affymetrix microarrays with RNA extracted from laser capture micro-dissected glomeruli, and biological pathways that are coordinately regulated between the G0G0 and G1G2 groups were identified using Gene Set Enrichment Analysis (GSEA).

Results: Our data shows that gene sets related to the Notch signaling pathway (NSP) are significantly coordinately upregulated in the G1G2 group compared to the G0G0 group (FDR $q < 0.25$).

Conclusions: Given that the NSP is already implicated in other glomerular diseases, the altered NSP activity in carriers of *APOL1* risk alleles may be a precursor to future disease before overt kidney injury is apparent. This also suggests that genetic variation in *APOL1* may have indirect effects on other genes relevant to glomerular function.

SA-PO395

Albuminuria and Podocytopathy Induced by Podocyte-Specific Deletion of Acid Ceramidase α Subunit Guangbi Li,[1] Krishna M. Boini,[1] Todd W. Gehr,[4] Pin-lan Li.[1] *[1]Department of Pharmacology and Toxicology, School of Medicine, Virginia Commonwealth University, Richmond, VA; [4]Devision of Nephrology, School of Medicine, Virginia Commonwealth University, Richmond, VA.*

Background: Acid ceramidase (AC) as a lysosomal enzyme has been shown to be critical for the metabolism of sphingolipid, ceramide, which regulate lysosome function and related cellular activities such as autophagy and vesicle or molecular trafficking. It remains unknown whether AC is involved in the control of podocyte function and in the development of glomerular disease. In the present study, we generated a mouse line with podocyte-specific deletion of α subunit in Asah1 gene (AC gene code in mouse), a main subunit for its activity in lysosomes using Cre-Lox recombination technology. This AC flox/podocyte Cre (Asah1fl/fl/podoCre) mouse colony was characterized by several genetic, molecular and biochemical approaches. By PCR genotyping, detection of both homozygous floxed gene Asah1 and Cre recombinase gene was considered as homozygous mice with Cre expression. If neither floxed Asah1 gene nor Cre recombinase gene was detected, mice are wild type (WT/WT). If only floxed Asah1 gene was detected without Cre recombinase gene, the mice were Asah1 flox control without podocyte specific deletion (Asah1fl/fl/WT). Immunofluorescent staining and immunohistochemistry showed that ACα was not detactable in podocytes in glomeruli of Asah1fl/fl/podoCre mice, compared to Asah1fl/fl/WT and WT/WT mice. Although Periodic acid-Schiff staining showed no significant increase in glomerular damage index in Asah1fl/fl/podoCre mice compared with other two types of mice, there were severe proteinuria and albuminuria found in Asah1fl/fl/podoCre mice even started at 6 weeks old. Correspondingly, compared Asah1fl/fl/WT and WT/WT mice at the same ages, hypoalbuminemia and edema were observed in Asah1fl/fl/podoCre mice when they grew to 12 weeks old. Under electron microscope, Asah1fl/fl/podoCre mice were found to have foot process effacement, vacuolation, and microvillus formation in podocytes. In cultured mouse podocytes, we also found that inhibition of AC activity by carmofur, a selective AC inhibitor, remarkably decreased the expression of podocin. These results suggest that AC and associated metabolism of ceramide are essential for the maintenance of podocyte structural and functional integrity and that the defect or deficiency of AC expression and function may result in podocytopathy and related glomerular disease such as minimal change disease.

Sex Differences in the Exacerbating Effects of Chronic Nicotine on Angiotensin II-Induced Renal Injury Rodrigo Maranon,[2] Kiran B. Chandrashekar,[1] Luis A. Juncos.[2] *[1]UMMC, Brandon, MS; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: Chronic Nicotine (Ch-Nic) worsens angiotensin II (AngII)-induced renal injury in male rodents via various mechanisms that alter heme oxygenase and oxidant stress. Because females may regulate these factors differently, and also metabolize nicotine than males, we tested whether Ch-Nic exacerbates AngII-induced renal injury in females to the same extent as in males. For this, we tested male and female Sprague Dawley rats for 60 days with Ch-Nic (12.5µg/ml) or vehicle in water, and then randomized into 4 groups each, which received either AngII (200ng/kg/min) or vehicle via SQ osmotic minipumps for an additional 28 days. Systolic blood pressure (SBP) was measured by tail-cuff plethysmography twice weekly and parameters of renal function and injury were assessed at the end of the experiments. See Table below.

Methods:

Results:

Conclusions: Cotinine excretion rates were 5 times higher in females than males, suggesting that females metabolize nicotine much faster and thus may be protected against the deleterious effects of Ch-Nic. Despite this, Ch-Nic exacerbated AngII-induced renal injury in both males and females, albeit with some differences. Males developed proteinuria earlier than females, and sustained higher levels of proteinuria throughout the study. Despite less proteinuria, NGAl and inflammation (TNF), females appeared to lose more GFR, as suggested by the more pronounced increase in serum creatinine levels. Our data indicate that despite the rapid metabolism of nicotine in females, Ch-Nic still induces renal injury in them. The differences in the pattern of injury and lack of inflammation, raise the possibility that the mechanisms of renal injury are different between the sexes.

Heterogeneity and Clinical Relevance of Tertiary Lymphoid Tissue in Murine and Human Kidneys Yuki Sato,[1,2] Peter Boor,[3] Jürgen Floege,[4] Motoko Yanagita.[2] *[1]Medical Innovation Center TMKP, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Institute of Pathology, RWTH University of Aachen, Aachen, Germany; [4]Department of Nephrology, RWTH University of Aachen, Aachen, Germany*.

Background: Unlike reversible AKI in the young, AKI in the elderly often leads to end-stage renal disease. We previously demonstrated that after AKI aged but not young mice developed multiple renal tertiary lymphoid tissues (TLTs), which comprised mainly lymphocytes and fibroblasts. These promoted aberrant inflammation and underlied the "AKI to CKD sequence". We also showed that aged (> 60 yrs old) but not young (40 yrs old >) humans exhibited renal TLTs (*Sato Y et al. JCI insight 2016*). Although TLTs are closely involved in the pathophysiology of various chronic inflammatory diseases in human, the developmental stages and clinical relevance remain ill defined.

Methods: Utilizing surgically removed human kidney samples as well as the mouse TLT model, which we have recently established, we investigated the developmental stages and potential clinical relevance of renal TLTs. Human kidney samples were derived from 2 independent patient groups: Japanese aged patients and German pyelonephritis patients.

Results: Kidneys from patients with chronic pyelonephritis exhibited multiple heterogeneous TLTs, which appeared to represent various developmental stage of TLTs. The same cellular and molecular components such as CXCL13 and p75NTR in fibroblasts were detectable both in pyelonephritis-induced TLTs and age-dependent TLTs and proved indistinguishable, suggesting that TLT formation is a uniform response to injury irrespective of the etiology in human kidney. Furthermore, we classified TLTs into 3 groups based on their presumed developmental stages and found that the TLT-stage was closely associated with the severity of kidney injury in mice, raising the possibility that the presence and developmental stage of TLTs can be a predictor of kidney disease progression. In humans, the kidneys of aged patients with CKD exhibited more frequent and advanced TLT-stages than those without CKD, whereas in chronic pyelonephritic kidneys TLTs in advanced stages clustered in destroyed areas.

Conclusions: TLT-formation in murine and human kidneys appears to be a relatively uniform process that proceeds through several stages. Stratification using the TLT-stages may offer a novel strategy to evaluate the CKD patients and potentially improve their therapeutic approaches.

Chronic Nicotine Mediated Accentuation of Angiotensin-II-Induced Renal Injury Is Prevented but Not Readily Reversed by Sildenafil Kiran B. Chandrashekar,[3] Rodrigo Maranon,[4] Arnaldo F. Lopez-Ruiz,[2] Istvan Arany,[1] Luis A. Juncos.[4] *[1]Dept. Pediatrics, Dv. Pediatric Nephrology, UMC, Jackson, MS; [2]None, Rochester, MN; [3]UMMC, Brandon, MS; [4]University of Mississippi Medical Center, Jackson, MS.*

Background: Chronic Nicotine (Ch-Nic) exacerbates angiotensin II (AngII)-induced renal dysfunction. Because sildenafil can preserve cGMP levels and increase heme oxygenase 1, both of which are protective against renal injury, we tested whether early administration of sildenafil prevents Ch-Nic-mediated exacerbation of AngII-induced renal injury. We also tested whether late administration sildenafil, after there is established renal injury, halts or reverses the progression of renal dysfunction

Methods: Sprague Dawley rats received nicotine (12 g/ml in their drinking water) with or without SP-AngII (200ng/kg/min via SQ infusion for 22 days). Separate groups were also concomitantly treated with sildenafil from either day 0 (Early sildenafil) or day 14 (Late sildenafil). Systolic blood pressure (SBP) was measured throughout and renal vascular resistance (OM-RVR) calculated. Renal function (plasma creatinine), pro-inflammatory (TNF-alfa), renal injury (NGAL), pro-apoptotic (cyt-c) and pro-fibrotic (TGF-beta) markers were assessed by ELISA. HO activity was evaluated based on the amount of bilirubin generated.

Results: p≤ 0.05: * vs. Control; # vs. Ang-II; Ω vs. AngII+ NIC. Early sildenafil treatment was very effective at decreasing Ch-Nic mediated exacerbation of AngII-induced renal dysfunction, inflammation, injury, and pro-apoptotic and pro-fibrotic signaling while increasing HO activity. In contrast, late sildenafil decreased blood pressure, but was much less effective at improving renal parameters of injury

Conclusions: Our data indicates early SIL therapy may ameliorate the exacerbating effects of NIC in a SP-AngII hypertensive model, but longer term studies are necessary to determine whether it can prevent progression or cause reversal of injury.

SA-PO399

Fludrocortisone Time-Dependently Up-Regulates Erythropoietin (Epo) mRNA Expression via HIF2α Pathway in Rat Kidney Hiroshi Nonoguchi,[4] Yukiko Yasuoka,[1] Yuichiro Izumi,[5] Yushi Nakayama,[5] Hideki Inoue,[5] Takanori Nagai,[2] Masayoshi Nanami,[2] Takeshi Nakanishi,[2] Masashi Mukoyama,[5] Yuichi Sato,[3] Katsumasa Kawahara.[1] *[1]Dept of Physiol, Kitasato Univ School of Med, Sagamihara, Japan; [2]Hyogo College of Medicine, Nishinomiya, Japan; [3]Kitasato University, Sagamihara, Japan; [4]Kitasato University Medical Center, Kitamoto, Japan; [5]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan*.

Background: Epo is produced by the kidney in response to hypoxia and anemia via stimulation of hypoxia-inducible factor 2α (HIF2α). Although renin-angiotensin-aldosterone system (RAS) blocker-induced renal anemia strongly suggests the participation of RAS on Epo production, no hormonal studies of Epo production have been conducted. Therefore, we investigated the effects of fludrocortisone, an analogue of aldosterone, on Epo mRNA expression in the rat kidney.

Methods: Male SD rats were given intraperitoneal injection of fludrocortisone 2.5 mg/100 g BW/day. At 2, 4, 6 and 72 hr, the kidney was removed and RNA was extracted for real time PCR. We also used tubule suspensions of renal cortex to test the direct effects of aldosterone (10^{-9} and 10^{-6} M) on Epo mRNA expression. Tubule suspensions were incubated w/ or w/o aldosterone in 2 hr. Plasma Epo concentration was also measured using CLEIA.

Results: In kidney cortex, the Epo mRNA expression was increased by 3-fold at 4 hr and decreased to very low level at 72 hr after the injection of fludrocortisone. The levels of HIF2α, HIF1α and PHD2 mRNA expressions also changed in the same time course. In tubule suspension, the Epo and HIF2α mRNA expression levels became nearly zero after 3 hr-incubation. It was restored by 2-hr incubation with aldosterone, together with the increase of HIF2 α, HIF1α, mineralocorticoid receptor, GATA2 and GATA3 mRNA expressions. Plasma Epo concentrations were increased from 1.10 ± 0.4 to 2.22 ± 0.17

mIU/ml (n=5, p<0.05) at 6 hr after the injection of fludrocortisone, but was decreased to 1.62 ± 0.43 U/ml (n=10, p>0.05) at 72 hr.

Conclusions: Aldosterone may regulate Epo production by the nephron via stimulation of a HIF2α pathway. HIF2α is regulated not only by hypoxia but also by RAS.

Current Nephrology Practices for Slowing CKD Progression – The Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) Benedicte Stengel,[1,2] Charlotte Tu,[3] Celine Lange,[4] Lindsay Zepel,[3] Danilo Fliser,[6] Roberto Pecoits-Filho,[5] Ziad Massy,[7,1] Bruce M. Robinson.[3] *[1]Inserm-CESP, Villejuif, France; [2]Univ Paris-Saclay, Villejuif, France; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Biomedicine Agency, La Plaine Saint-Denis, France; [5]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [6]Saarland University Medical Centre, Homburg/Saar, Germany; [7]Ambroise Pare University Hospital, Boulogne Billancourt/ Paris cedex, France. Group/Team: CKD-REIN and CKDopps.*

Background: The 2012 KDIGO guideline for the management of CKD recommends several measures for preventing CKD progression, including blood pressure (BP) control, use of renin-angiotensin system inhibitors (RASi), and dietary advice. Whether these recommendations are followed in current nephrology practice is unknown.

Methods: We used baseline data from CKDopps (2013-17), a prospective cohort study of adult patients (pts) with eGFR < 60 ml/min/1.73m^2 from national samples of nephrology clinics in Brazil (BR), France (FR), Germany (GER), and the United States (US) to describe success rates in achieving recommended measures by albuminuria category (using either spot or 24-hour urinary albumin or protein equivalent) or eGFR, and by country

Results: Median age ranged from 67 yrs in BR to 77 yrs in GE. Albuminuria or proteinuria was routinely measured in 42%, 44%, 43% of pts in BR, GER, and the US, respectively, and 89% in FR (where this was requested per study protocol). Proteinuria was more commonly measured than albuminuria in all countries. Percentages of pts with BP <140/90 were lower at higher UAP, and higher in the US and GER than in BR and FR. RASi use did not vary by albuminuria level, but was lower at lower eGFR in BR, GER, and the US. Receiving dietary advices was slightly more common in pts with low eGFR, and better for salt than protein intake, but dietician visit was not common practice.

Conclusions: Monitoring albuminuria as recommended is not a standard practice in nephrology. BP control and RASi use vary substantially by country, and expert dietary advice remains poor across participating countries. The effects on clinical outcomes, and reported variation in incidence of kidney failure by country, will be evaluated during follow-up.

Nomograms for Evaluating the Long-Term Prognostic Risk of IgA Nephropathy Xiangmei Chen. *Chinese PLA General Hospital, Beijing, China.*

Background: IgA nephropathy(IgAN) shows strong heterogeneity between individuals. The prognosis of IgAN is associated with lesions of Oxford classification and many clinical indicators. However, simple tools for evaluating the prognosis for clinician remains limited. Our objective was to develop an intuitive estimation tool for predicting the prognosis of IgAN.

Methods: Patients with IgAN diagnosed by renal biopsy at Chinese PLA General Hospital were retrospectively analyzed. The endpoint was a decrease in estimate Glomerular filtration rate (eGFR)≥50% or progression to end-stage renal disease(ESRD). Multivariate COX proportional hazards model with backward stepwise were performed. Using COX regression coefficients, nomograms was developed to predict the risk of endpoint events.

Results: In the modeling cohort, 48 among 274 patients developed into endpoints during 81 months followed- up. Nomograms was established, of which mesangial lesions, tubulointerstitial lesions as well as baseline 24h urinary protein content>1g, baseline eGFR<90ml/min/1.73m^2 and baseline mean arterial pressure were included. Additional 117 IgAN patients were retrospectively followed as validation cohort at a mean of 79 months.[s1] The nomograms showed good discrimination and goodness of fit in the modeling cohort (C-index=0.86,r^2=0.75) and in the validation cohort (C-index=0.89,r^2=0.72) respectively.

Conclusions: The nomograms involving clinical and pathological parameters can predict the prognosis of IgAN effectively and intuitively

Impact of Inter-Laboratory Variability of Serum Creatinine Assays on KFRE Risk Scores Divyanshi Jalan,[1] Elizabeth S. Lee,[2] Christine P. Collier,[3] Ayub Akbari,[4] Christine A. White.[3] *[1]Queen's University School of Medicine, Kingston, ON, Canada; [2]University of British Columbia, Vancouver, BC, Canada; [3]Queen's University, Kingston, ON, Canada; [4]University of Ottawa, Ottawa, ON, Canada.*

Background: Inter-laboratory variation in creatinine (Cr) measurement exist and result in inter-laboratory variability in eGFR-EPI and chronic kidney disease (CKD) diagnosis. We aim to examine the impact of inter-laboratory variability in Cr measurement on the Kidney Function Risk Equation (KFRE).

Methods: Split serum samples from 33 patients with eGFR-EPI between 10 and 60 ml/min/1.73m^2 were sent to 12 laboratories for Cr measurement. For each patient and laboratory we calculated the 5 year risk of ESKD using the KFRE equation (KFRE-5) assuming 65 year old non-African American woman and three ACR levels (27, 266, 885 mg/g). For each patient and ACR value we calculated the KFRE-5 all method mean (AMM), coefficient of variation (CV_a) and range. For the cohort, we determined the mean KFRE-5 range, CV_a and the mean ratio of minimum and maximum KFRE-5 scores.

Results: Figure 1 shows individual patients' mean, minimum and maximum KFRE-5 scores (ACR 266 mg/g). There is substantial variability in KFRE scores which are more pronounced with higher albuminuria and when KFRE values are between 5% and 80% [Table 1, Figure 1].

Conclusions: Inter-laboratory variability of serum Cr measurement results in variability in KFRE scores which is more pronounced when eGFR is moderately-severely reduced and ACR is high. This needs to be considered when using KFRE cut-offs for referrals, clinic discharge, vascular access placement and suitability for CKD funding. Manufacturers need to improve assay specificity in order to reduce KFRE variability between laboratories.

Funding: Private Foundation Support

Table 1: Mean ± SD KFRE-5 range and max/min ratios

	ACR 27 mg/g	ACR 266 mg/g	ACR 885 mg/g
KFRE-5 range (mean ± SD) (%)	2.9 ± 2.4	6.3 ± 4.5	8.4 ± 5.7
KFRE-5 CVa (mean ± SD) (%)	20.8 ± 11.3	19.9 ± 11.6	19.0 ± 12.0
KFRE-5 max/min (mean ± SD)	2.4 ± 1.2	2.3 ± 1.2	2.3 ± 1.2

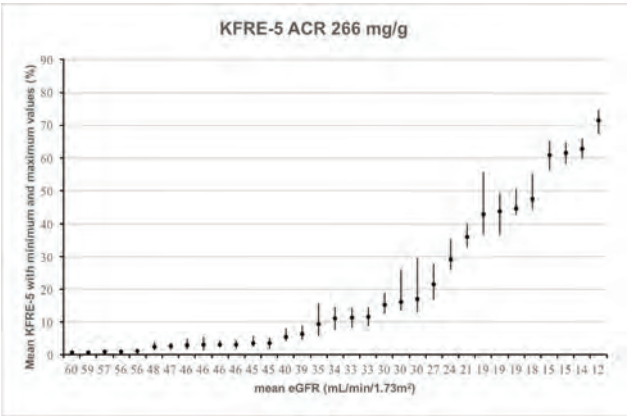

Figure 1: Individual patients' mean, minimum and maximum KFRE-5 scores (ACR 266 mg/g)

SA-PO403

GFR Measurement Method: A Critical Determinant in Estimation Equation Assessment Céline M. Allen,[1] Ayub Akbari,[2] Greg A. Knoll,[2] Christine P. Collier,[1] Christine A. White.[1] *[1]Queen's University, Kingston, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada.*

Background: Multiple equations exist to translate various serum analyte concentrations into estimates of the glomerular filtration rate (eGFR). Validation studies of these estimates often yield differing results. This is likely the result of differing patient populations and characteristics, analyte assay manufacturer biases, and GFR measurement protocols. This study was designed to examine the impact of GFR measurement methodology on the performance of the creatinine CKD-EPI equation (eGFRCr-EPI).

Methods: Cr was measured and eGFRCr-EPI calculated in 85 research subjects. GFR was measured (mGFR) simultaneously using different methodologies: renal inulin clearance, plasma ^{99m}Tc-DTPA clearance (2-4 hour sampling), plasma iohexol clearance (2-4 hour sampling) and plasma iohexol clearance (2-10 hour sampling). For each method, bias (eGFR - mGFR), precision (standard deviation of mean bias) and accuracy (P30-the percent of all eGFRCr-EPI within 30% of the mGFR) were determined. Bias and accuracies were compared using paired t-tests and McNemar's test respectively.

Results: Mean age 60 ± 14 yrs, mean BSA 1.98 ± 0.30 m^2, 95% non-black and 40% female sex. Mean inulin GFR 39.3 ± 28.8 ml/min/1.73m^2 while mean eGFRCr-EPI was 38.7 ± 28.5 ml/min/1.73m^2. Performance results are shown in Table 1.

Conclusions: eGFRCr-EPI performance results differ significantly depending on how GFR is measured (tracer, clearance strategy and sample timing). Short plasma-based strategies yield the highest biases and worse accuracies for the eGFRcr-EPI equation. These discrepancies need to be considered when interpreting validation data and designing validation studies.

Funding: Government Support - Non-U.S.

Table 1: eGFRCr-EPI performance by GFR methodology

	Mean Bias (ml/min/1.73m^2)	Precision (IQR) (ml/min/1.73m^2)	Accuracy: P30 (%)
mGFR-renal inulin	-0.5	8.8	79
mGFR-plasma DTPA (2-4 hour)	-8.3 *	13.6	57 $^{\beta}$
mGFR-plasma iohexol (2-4 hour)	-5.5 *	11.8	59 $^{\delta}$
mGFR-plasma iohexol (2-10 hour)	-2.1 **	9.6	79

* p = 0.0001 compared to inulin, ** p = 0.08 (NS) compared to inulin, $^{\beta}$ p = 0.0012 compared to inulin, $^{\delta}$ p = 0.006 compared to inulin

SA-PO404

The Spectrum of CKD in China: A National Study Based on 64.7 Million Hospitalized Patients from 2010 to 2015 Yu-ming Huang,[3] Damin Xu,[3] Jianyan Long,[1] Ying Shi,[1] Luxia Zhang,[3] Haibo Wang,[1] Adeera Levin,[2] Ming Hui Zhao.[3] *[1]China Standard Medical Information Research Center, Shenzhen, China; [2]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [3]Renal Division, Peking University First Hospital, Beijing, China.*

Background: Chronic kidney disease (CKD) is a significant public health burden worldwide. Previous studies demonstrate that diabetes exceeded glomerulonephritis and became the leading cause of CKD in China, but the transition of other causes was still unclear.

Methods: We utilized a national in-patients database covering 878 class 3 hospitals (which provide primary, secondary and tertiary care to nationwide patients) and involving 64.7 million adult patients from 2010 to 2015. The specific causes of CKD were extracted from International Classification of Diseases-10 codes of discharge diagnoses.

Results: Altogether 4.5% of hospitalized patients (1.8 million) were identified as having CKD, with an increased percentage from 2010 (3.7%) to 2015 (4.7%). Increasing trends of diabetic kidney disease and hypertensive kidney damage were observed from 2010 to 2015, especially for northern urban areas. The percentage of obstructive nephropathy also increased gradually and constituted an important cause of CKD for southern rural residents.

Conclusions: The spectrum of etiologies of CKD is changing in China, and varies over time and geographic regions.

Funding: Other NIH Support - the World Health Organization (WHO Reference 2014/435380-0); the National Key Technology R&D Program of the Ministry of Science and Technology (2011BAI10B01); the Beijing Science and Technology Committee (D131100004713007); and the University of Michigan Health System-Peking University Health Science Center Joint Institute for Translational and Clinical Research (BMU20140479), Government Support - Non-U.S.

SA-PO405

Regional Differences in Prevalence and Determinants of CKD among Individuals with Hypertension in Rural Communities in South Asia Liang Feng, Tazeen H. Jafar. *Duke-NUS Medical School, Singapore, Singapore.*

Background: The objectives of the study were to determine the regional burden and differences in prevalence and determinants of chronic kidney disease (CKD) in rural Bangladesh, Pakistan, and Sri Lanka.

Methods: We conducted a cross-sectional study on 2349 participants aged ≥ 40 years with hypertension in 30 randomly selected rural communities, 10 each in Bangladesh, Pakistan, and Sri Lanka. The primary outcome was CKD defined as estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 estimated by CKD Epidemiology Collaboration (CKD-EPI) or urinary albumin to creatinine ratio ≥ 30 mg/g

Results: The mean (SD) age of participants was 58.8 (11.3) years, and 36% were men, 27% had diabetes, and 10% were current smokers. The age-standardized prevalence (95% CI) of primary outcome of CKD was 38.4% (34.1 to 42.8%) in Bangladesh, 19.1% (15.7 to 22.5%) in Pakistan, and 49.8% (45.1 to 54.6%) in Sri Lanka. The factors independently associated with CKD were older age (OR=1.06,95%CI(1.05,1.07) for every 1 year increase), diabetes (OR=2.03,95%CI(1.63,2.52)), elevated systolic blood pressure (OR=1.06,95%CI(1.04,1.09), per 5 mm Hg increase), current vs non-smoker

(OR=1.42,95%CI(1.01,2.00)), and country (OR=0.57,95%CI(0.40,0.80) for Bangladesh vs Sri Lanka, and OR=0.18,95%CI(0.12,0.26) for Pakistan vs Sri Lanka). A significant interaction with p<0.001 was detected between age and country indicating that the association between older age and higher prevalence of CKD was stronger in Sri Lanka compared to the other two countries.

Conclusions: CKD is common among individuals with hypertension in rural South Asia with alarmingly high rates of reduced kidney function in Sri Lanka. Our findings underscore the urgency of addressing the key determinants of CKD, and establishing CKD detection and management programs as a public health priority in the South Asian region.

Funding: Government Support - Non-U.S.

Table 1. Crude prevalence of CKD (n=2349)

CKD n (%, 95% CI)	Total N=2349	Bangladesh N=818	Pakistan N=685	Sri Lanka N=796
CKD (eGFR <60 ml/min/1.73m2 or UACR≥30mg/g)	908 (38.6. (36.7,40.7))	316(36.4 (33.2,39.7))	127 (18.5 (15.6,21.5))	465 (58.4(54.9,61.9))
eGFR <60 ml/min/1.73m2 only	519 (22.1,(20.4,23.8))	102 (11.8 (9.6,14.0)	34 (5.0 (3.3,6.7))	383 (48.1 (44.6,51.7))
UACR≥30 mg/g only	573 (24.4,(22.6,26.2)	257 (29.6 (26.5,32.7))	110 (16.1 (13.2,18.9))	206 (25.9 (22.8,29.0))

Prevalence of CKD in the Healthy Elderly Using the Aspirin in Reducing Events in the Elderly (ASPREE) Study Cohort Kevan Polkinghorne,[4] Rory Wolfe,[1] Robyn L. Woods,[1] John J. Mcneil,[1] Mark Nelson,[3] Christopher M. Reid,[1] Anne M. Murray.[2] *[1]Monash University, Melbourne, VIC, Australia; [2]Hennepin County Medical Center, Minneapolis, MN; [3]University Of Tasmania, Hobart, NSW, Australia; [4]Monash Medical Centre and Monash University, Melbourne, VIC, Australia. Group/Team: ASPREE investigators.*

Background: The diagnosis & definition of CKD in the elderly is controversial. GFR declines with age such that reduced eGFR is common in the elderly but may not reflect true underlying kidney related disease. The ASPREE study is an international (Australia, US) RCT designed to assess whether daily treatment with aspirin extends the duration of life free of dementia & physical disability in healthy elderly participants who are free of diagnosed cardiovascular disease or disability. Subjects with diabetes &/or hypertension (unless poorly controlled) were included. We assessed prevalence & predictors of CKD in this cohort using the MDRD and CKD-Epi eGFR equations as well as the elderly specific Berlin Initiative Study equation 1 (BIS1).

Methods: A cross sectional analysis of the ASPREE cohort at randomisation was performed. eGFR was estimated using all 3 equations. CKD was defined as eGFR<60 ml/min with or without albuminuria. CKD prevalence was calculated using each equation and compared. Predictors of CKD were assessed by logistic regression.

Results: 17,931 subjects (15,588 Australia, 2,343 USA) had complete data from urine and blood testing. Mean age was 75 years (SD 4.6), 56% were female, 76% had hypertension and 9% diabetes mellitus. Median UACR was 0.8 (IQR 0.5, 1.6) mg/mmol. Mean eGFR by CKD-Epi was 72.8 (SD 14.3) ml/min. CKD prevalence was similar by the MDRD and CKD-Epi equations (19 and 18% respectively) but substantially higher by the BIS1 equation (41%). This difference was predominantly driven by reclassification of individuals from stage 2 CKD to stage 3a without albuminuria. 69% of those with CKD by CKD-Epi had stage 3a without albuminuria compared to 75% of those using the BIS1 equation. An increased risk of CKD was related to participants being older, female, diabetic, or having higher BMI.

Conclusions: The prevalence of CKD in this healthy elderly population was 19% (CKD-Epi) and lower than previously described in the US (47% by CKD-Epi). The elderly-specific GFR equation BIS1 doubled the prevalence of CKD with the majority reclassified from stage 2 to stage 3a CKD.

SA-PO407

A Comparison of Different Equations for Estimating GFR in 29 US Health Care Organizations Nikita Stempniewicz,[1,2] Shoshana Ballew,[2,3] Elizabeth Ciemins,[1] Morgan Grams,[3,4] Kunihiro Matsushita,[2,3] Jerry Penso,[1] Josef Coresh.[2,3] *[1]AMGA, Alexandria, VA; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: The KDIGO 2012 guidelines recommend reporting eGFRcreat in adults using the 2009 CKD-EPI creatinine equation to diagnose and stages CKD with known risk relationships. Some health care organizations use different equations, with common alternatives being the MDRD and Mayo Clinic Quadratic (MCQ). Electronic heath record (EHR) data provide the opportunity to estimate the impact of using these three common equations to estimate GFR to a health care organization and its patient population.

Methods: This study uses EHR data from 29 AMGA member organizations who are using the Optum One population health analytics platform. Data from 2.3 million patients age 18-99, with a history of hyperglycemia, at least 1 ambulatory office visit, and a serum creatinine recorded between 01/01/2013 and 12/31/2016 were included. Estimated GFR was calculated for each patient using the CKD-EPI, MDRD, and MCQ equations.

Results: The 2.3 million patients had mean age 62.3 years, were 52.8% female, 10.7% black race, and 51.1% had a diagnosis of type 2 diabetes (on a claim or the patients problem list in the EHR). The average (standard deviation) eGFR from the CKD-EPI, MDRD, and MCQ equations were 77.4 (25.4), 76.3 (28.9), and 88.8 (25.4) mL/min/1.73 m^2, respectively. Distributions of eGFR for the three equations differed markedly (Figure 1). In the CKD G3+ range (<60 ml/min/1.73m^2) the MCQ estimates gave a much lower prevalence compared to the CKD-EPI and MDRD equations (23.2 and 24.8 vs. 12.7%, summing the prevalence in range below 60 in Figure 1). Only 48.7% of patients were classified in the same CKD GFR categories with all three equations.

Conclusions: Compared to the CKD-EPI equation which is currently recommended and stages CKD with a known relationship to risk, the MDRD equation produces similar results at low eGFR, while the MCQ equation yields a dramatically lower prevalence of CKD.

Creatinine versus Cystatin C: Is There Any Benefit in Using a Cystatin C Based Equation for Assessment of CKD in Older Adults? Shahrzad Zonoozi,[2] Sheena E. Ramsay,[1] Olia Papacosta,[2] Peter Whincup,[3] Sasiwarang G. Wannamethee.[2] *[1]Newcastle University, Newcastle Upon Tyne, United Kingdom; [2]University College London, London, United Kingdom; [3]SGUL, London, United Kingdom.*

Background: Chronic kidney disease (CKD) is associated with excess cardiovascular disease (CVD) mortality and morbidity. CKD diagnosis relies on calculation of the estimated glomerular filtration rate (eGFR) commonly based on serum creatinine which may lead to inaccurate estimations of GFR in the older population. Cystatin C is an alternative GFR marker less influenced by exogenous factors and the CKD Epidemiology Collaboration (CKD-EPI) has developed an equation for estimating GFR using this marker (CKD-EPI$_{Cys}$). Whether this is a better indicator of CVD risk and mortality in older adults than the CKD-EPI creatinine-based equation (CKD-EPI$_{Cr}$) is unclear. We have investigated the association between CKD classification, using CKD-EPI$_{Cr}$ and CKD-EPI$_{Cys}$, and cardiovascular risk markers and CVD mortality in older adults.

Methods: Prospective and cross-sectional analysis of 1722 men aged 71-92 examined in 2010-2012 across 24 British towns, from the British Regional Heart Study initiated in 1978-1980, followed up for a median of 5 years for CVD and all-cause mortality. Participants completed a questionnaire, underwent a physical examination and had blood samples taken.

Results: The prevalence of CKD stages 1, 4 and 5 was increased in our population using CKD-EPI$_{Cys}$ versus CKD-EPI$_{Cr}$ to calculate eGFR. Both CKD equations were significantly associated with markers of inflammation (C-reactive protein), endothelial function (von Willebrand factor) and cardiac function (N-terminal pro brain natriuretic peptide). The hazard ratio (HR) for all CVD mortality in those with CKD stages 4 and 5 versus those with CKD stages 1 and 2 was 3.05 (95% CI, 1.63-5.70) and 3.62 (95% CI, 2.08-6.30) using CKD-EPI$_{Cr}$ and CKD-EPI$_{Cys}$ respectively. For all-cause mortality the HR was 2.30 (95% CI, 1.60-3.32) and 2.57 (95% CI, 1.87-3.54) using CKD-EPI$_{Cr}$ and CKD-EPI$_{Cys}$ respectively.

Conclusions: Estimating GFR using CKD-EPI$_{Cys}$ leads to reclassification of CKD staging and increased prevalence of CKD stages 1, 4 and 5 compared to CKD-EPI$_{Cr}$. Our study shows that compared to CKD-EPI$_{Cr}$, CKD-EPI$_{Cys}$ shows no improvement in the prediction of all-cause and CVD mortality in older British men. In view of the drive to use cystatin-c based equations in clinical practice, this may have important cost implications.

Comparison of eGFR with Creatinine and Cystatin C by eCKD-EPI in CKD Patients with and without Hypoalbuminemia Carlos Federico Varela,[1] Graciela Jimenez,[1] Griselda Bratti,[1] Maria L. Ocampo,[2] Gustavo Greloni,[1] Guillermo Rosa Diez.[1] *[1]Nephrology, Hospital Italiano de Buenos Aires, CABA, Argentina; [2]Nephrology, Hospital Italiano Buenos Aires, CABA, Argentina.*

Background: Serum cystatine C (CysC) could be a better predictor than serum creatinine (Crea) in comorbid patients with CKD. Differences between CysC and Crea eGFR in patients with and without hypoalbuminemia (hypoA) were poorly understood/studied. We compare average differences between eGFR based on CysC and Crea in patients with and without hypoalbuminemia.

Methods: We estimated GFR by the new CKD-EPI equations based on CysC and Crea The CKD stage was determined by the Crea-based eGFR. HypoA was defining by serum albumin ≤ 3.5 gr/L. In each CKD stage, differences between average of CysC and Crea-based equation and concordance to assign to the same CKD stage were calculated. We performed the same analysis in patients with and without hypoA.

Results: We included 1954 patients, (46.5% female) aging 63±18 years. 50.9% were elderly. Mean Crea, CysC and serum albumin in total group were 1.6 ± 1.2 mg/dl, 2.1±1.1 mg/dl and 3.5±0.6 gr/L respectively. Mean of eGFR of Crea was 54.8± 28 and CysC was 38.9±25 ml/min/1.73. Mean differences between eGFR of Crea and CysC were 34.9, 21.5, 14.2, 10.1, 5.5, -0.9 ml/min/1.73 for stage 1 to 5 respectively in total group. Serum albumin was 2.8±0.4 and 3.9±0.3 gr/L in patients with and without hypoA. Patients with hypoA had significantly differences between mean eGFR of Crea and CysC compared with those without hypoA, showing 48 vs 17 in stage1, 31 vs 15 in stage 2, 19 vs 11 in stage 3A, 13 vs 8 in stage 3B, 6 vs 4 in stage 4 and -0.9 vs -0.8 in stage 5. All differences except stage 5 were significant.

Conclusions: Differences between eGFR in CysC and Crea-based equation could be affected in the setting of low serum albumin values. Patients with hypoA show highest differences.

Table: 1. Characteristics of the study population.

CKD stage	1	2	3A	3B	4	5
Serum Creatinine	0.72 (0.17)	0.96 (0.20)	1.26 (0.21)	1.66 (0.33)	2.62 (0.66)	5.46 (1.73)
Serum Cystatine C	1.23 (0.46)	1.45 (0.48)	1.82 (0.61)	2.29 (0.72)	3.29 (0.95)	4.48 (1.01)
CKD-EPI-Crea	105.2 (14.1)	73.1 (8.8)	51.8 (4.3)	37.5 (4.2)	22.5 (4.5)	10.1 (2.8)
CKD-EPI-CysC	70.3 (28.8)	51.6 (21.3)	37.6 (14.8)	27.4 (10.7)	16.9 (6.1)	11.1 (3.5)
Concordance Crea vs CysC	38.8 %	46.7 %	68.9 %	80.1 %	49.1 %	44.8 %
Diff hypoalbuminemia	48 (±23)	31 (±16)	19 (±12)	13 (1±0)	6 (±6)	-0.9 (±3)
Diff without hypoalbuminemia	17 (±23) °°	15 (±20) °°	11 (±14) °°	8 (±9) °°	4 (±5) °	-0.8 (±3)

References:. °°; p value < 0.001 and °; p value < 0.05 between patients with and without hypoA.

SA-PO410

Estimated Glomerular Filtration Rate by Serum Creatinine Lacks Accuracy and Precision in Older Adults with and without Type 1 Diabetes: Results from the Canadian Study of Longevity in Type 1 Diabetes Daniel Scarr,[3] Leif E. Lovblom,[3] Petter Bjornstad,[1] Julie A. Lovshin,[4] Mohammed A. Farooqi,[3] Genevieve Boulet,[3] Andrej Orszag,[3] Yuliya Lytvyn,[4] Alanna Weisman,[3] Hillary A. Keenan,[2] Michael Brent,[4] Narinder Paul,[4] Vera Bril,[4] David Cherney,[4] Bruce A. Perkins.[4] *[1]Children's Hospital Colorado, Aurora, CO; [2]Joslin Diabetes Center, Boston, MA; [3]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [4]University of Toronto, Toronto, ON, Canada.*

Background: Estimates of glomerular filtration rate (eGFR) by serum creatinine are routinely used for clinical assessment of kidney function, however eGFR is considered inaccurate until GFR <60mL/min/1.73m². Accurate ascertainment of eGFR is important to identify kidney disease. We aimed to evaluate the performance of creatinine-based equations compared to GFR by inulin clearance in older adults with and without type 1 diabetes (T1D).

Methods: Sixty-six adults with ≥50yr T1D duration and 73 non-diabetic controls from age/sex-matched subgroups (65±8yr and 77[55%] were female) underwent measurement of GFR by inulin clearance (mGFR) and eGFR was calculated by serum creatinine using the MDRD ($eGFR_{MDRD}$) and CKD-EPI ($eGFR_{CKD-EPI}$) equations. In T1D, eGFR and mGFR were measured under clamped euglycemia (4-6mmol/L). Equation performance was evaluated using bias (mean difference), precision (SD), and accuracy (inaccuracy defined as the proportion of eGFR that differed by >20% of mGFR) metrics.

Results: In the 139 participants mean mGFR was 104±18mL/min/1.73m² (range: 70-154mL/min/1.73m²) and was not different between T1D (103±17mL/min/1.73m²) and controls (105±19mL/min/1.73m², p=0.39). Both equations significantly underestimated mGFR with bias –14.9mL/min/1.73m² (p<0.001) for $eGFR_{MDRD}$ and –15.9mL/min/1.73m² for $eGFR_{CKD-EPI}$ (p<0.001); bias was similar between equations (p=0.15). Precision was similar between $eGFR_{MDRD}$ (SD 17.2mL/min/1.73m²) and $eGFR_{CKD-EPI}$ (SD 16.5mL/min/1.73m², p=0.63). Inaccuracy was similar between $eGFR_{MDRD}$ (32.4%) and $eGFR_{CKD-EPI}$ (37.4%, p=0.13). Both equations demonstrated greater bias and were less accurate across higher ranges of mGFR (60-89, 90-119, and ≥120mL/min/1.73m², p<0.001 for all comparisons). Results were similar between T1D and controls.

Conclusions: Creatinine-based eGFR substantially underestimated mGFR, lacked precision and accuracy, and had lower performance at higher ranges of mGFR. Better measures of kidney function in older adults are needed for research and clinical practice.

SA-PO411

Prediction of Mortality in Elderly Patients with CKD – The Role of Cystatin C and Other GFR Markers Sebastjan Bevc,[1,3] Nina Hojs,[1,3] Masa Knehtl,[1,3] Robert Ekart,[2,3] Radovan Hojs.[1,3] *[1]Department of Nephrology, University Clinical Centre Maribor, Maribor, Slovenia; [2]Department of Dialysis, UKC Maribor, Maribor, Slovenia; [3]Faculty of Medicine, University of Maribor, Maribor, Slovenia.*

Background: The prevalence of chronic kidney disease (CKD) in the elderly is high. Serum cystatin C is accurate marker of kidney function and has also prognostic utility in CKD patients. The aim of our study was to determine the prediction of cystatin C and other markers of kidney function on long-term survival in elderly CKD patients.

Methods: 58 adult Caucasian patients, older than 65 years (50% women; mean age 73 years; range from 65 to 85 years), were included. Patients with known malignancy, on steroid therapy and/or thyroid disease were not enrolled in the study. In each patient ^{51}CrEDTA clearance, serum creatinine (IDMS traceable method), serum cystatin C (immunonephelometric method) and eGFR using three formulas (CKD-EPI creatinine, BIS2 and FAS) were determined on the same day and patients were then followed for 11 years or until their death.

Results: The means: ^{51}CrEDTA clearance 53.3±17.4 ml/min/1.73m², serum creatinine 143.4±44 μmol/l, serum cystatin C 1.79±0.5 mg/l, CKD-EPI creatinine 40.3±14.2, BIS2 39.3±10.9, FAS 31±10.4 ml/min/1.73m², respectively. In the follow up period of 11 years 47 (81%) of our elderly CKD patients (23 women and 24 men) died. Cox regression analysis showed different hazard ratios (HR) for death: for ^{51}CrEDTA clearance HR 0.978 (95% CI 0.960-0.996; P=0.015), serum creatinine HR 1.013 (95% CI 1.006-1.019; P<0.001), serum cystatin C HR 2.028 (95% CI 1.269-3.241; P=0.003), CKD-EPI creatinine HR 0.953 (95% CI 0.928-0.980; P=0.001), BIS2 HR 0.947 (95% CI 0.918-0.977; P=0.001), FAS HR 0.946 (95% CI 0.914-0.979; P=0.002).

Conclusions: Our results showed the highest hazard ratio for serum cystatin C values among the markers of kidney function for prediction of the outcome in elderly CKD patients.

Metabolites Associated to Renal Function in the CKD and General Population Silvia M. Titan,[1] Gabriela Venturini,[4] Kallyandra Padilha,[4] Gesiane F. Tavares,[1] Isabela M. Bensenor,[3] Paulo Lotufo,[3] Eugene P. Rhee,[2] Ravi I. Thadhani,[2] Alexandre C. Pereira.[4] *[1]Nephrology Division, Faculty of Medicine, Sao Paulo University, Sao Paulo, Brazil; [2]Nephrology Division, Massachusetts General Hospital, Boston, MA; [3]Clinical Research Center, Universitary Hospital, Sao Paulo University, Sao Paulo, Brazil; [4]Laboratório de Cardiologia Molecular, Incor, Hospital das Clínicas, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil.*

Background: Metabolomics is a novel tool to identify biomarkers and pathways involved in diseases. In CKD, there is a growing interest in metabolites that are related to renal function that could be used for assessing GFR. However, data is scarce and diverse. **Objective:** To evaluate metabolites related to eGFR in a CKD Study. Replication was tested in 2 other studies using the same metabolomics platform.

Methods: Derivation study was the Progredir Study (PS; n=454 class 3 and 4 CKD). Validation studies were Diabetic Nephropathy Study (DNS; n=56 macroalbuminuric DN) and the Baependi Study (BS; n=1145p from the general population). Metabolomics was performed by GC and Mass Spectrometry. Metabolites were identified using Agilent Fiehn GC/MS Metabolomics and NIST libraries (Agilent MassHunter Work-station Quantitative Analysis, version B.06.00). Adjusted linear regression models on eGFR-CKDEPI were built. FDR<0,05 was used in the derivation study.

Results: In the PS, 135 metabolites where related to eGFR, after adjustments for batch, sex, age, DM, smoking and SBP. Of those, 24 were also related to eGFR in the BS and 17 in the DNS. However, only 6 metabolites were significantly related to eGFR in all 3 studies: D-threitol, myo-inositol, ribitol, 4-deoxierythronic acid, galactonic acid and galacturonic acid. While correlation to eGFR was high in the 2 CKD studies, it was moderate in the general population (Table 1).

Conclusions: Our results demonstrate that metabolites are potential markers of renal function. Further investigation is needed to determine their performance against otherwise gold-standard methods, most notably among those with normal eGFR.

Funding: Government Support - Non-U.S.

Table 1. Spearman's correlation coefficients and p values for metabolites and eGFR in the 3 studies.

Metabolite (log2)	PS	DNS	BS
Replicated in the 3 studies			
D-threitol	-0.71 / 8.7E-70	-0.80 / 9.6E-14	-0.28 / 1.6E-21
Myo-inositol	-0.70 / 4.9E-66	-0.81 / 5.4E-14	-0.19 / 2.0E-11
Galactonic acid	-0.61 / 5.7E-19	-0.47 / 2.8E-04	-0.23 / 2.8E-05
Galacturonic acid	-0.47 / 6.1E-15	-0.58 / 9.3E-06	-0.23 / 9.0E-11
4-Deoxyerythronic acid	-0.38 / 7.9E-17	-0.56 / 2.5E-05	-0.02 / 0.51
Ribitol	-0.36 / 3.0E-8	-0.81 / 7.7E-13	-0.28 / 8.0E-22
Replicated only in the CKD studies			
Pseudo uridine	-0.71 / 1.26E-65	-0.86 / 3.8E-17	-0.08 / 0.01
Butyric acid	-0.67 / 8.26E-53	-0.60 / 1.6E-05	-

A Novel Equation Using Low-Invasive Test Items to Estimate the Severity of Interstitial Fibrosis in IgA Nephropathy Keita Inui,[1] Kosuke Yamaka,[1] Yosuke Yamada,[1] Yuji Kamijo.[2] *[1]Shinshu University, Matsumoto, Japan; [2]Shinshu University School of Medicine, Matsumoto, Japan.*

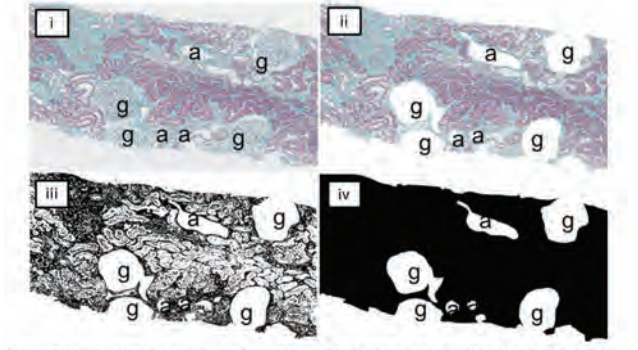
Background: In IgA nephropathy, tubulointerstitial fibrosis is said to be very important in predicting whether or not renal dysfunction is progressive. Until now, however, invasive renal biopsy has been the primary means of determining the severity of fibrosis in IgA nephropathy. A formula to estimate tubulointerstitial fibrosis severity using such low-invasive parameters as physical findings, serology, and urinalysis is therefore needed.

Methods: Masson Trichrome-stained renal biopsy specimens of 51 patients diagnosed as having IgA nephropathy at Shinshu University Hospital were collected. The severity of interstitial fibrosis as calculated by the percentage of area stained blue in the cortex tubulointerstitium (Fib%) was quantitatively measured by ImageJ analysis software (Figure) and its correlation with various factors was examined. A formula for estimating interstitial fibrosis was then derived by multiple regression analysis using parameters whose correlation with Fib% was strong.

Results: Fib% increased proportionally to Oxford classification T-score ($P<0.001$) and accurately reflected the severity of interstitial fibrosis. Fib% also correlated strongly with serum creatinine (sCre) (mg/dL) (correlation coefficient [R]: 0.61; $P<0.01$), urinary N-acetyl-β-D-glucosaminidase (uNAG) (U/gCre) (R: 0.44; $P<0.01$), and body mass index (BMI) (kg/m^2) (R: 0.44; $P<0.01$). The estimation formula of Fib% from these 3 parameters was determined as: Fib% = 16.84 + 17.71(sCre) + 0.51(BMI) + 0.59(uNAG) (coefficient of determination: 0.53; $P<0.01$).

Conclusions: Interstitial fibrosis in IgA nephropathy can be estimated using data obtained from low-invasive tests. A prospective study is being planned to validate our novel formula.

Figure



i) a, artery; g, glomerulus. ii) Parts containing arteries and glomeruli are removed. iii) Parts of blue-stained areas were detected and area was calculated. iv) The area of all tubulointerstitial parts was calculated. Fib% = area iii/area iv × 100%

SA-PO414

Prediction of Urinary Creatinine Excretion and of Renal Function in CKD Patients from Body Composition Analysis Carlo Donadio. *University of Pisa, Pisa, Italy.*

Background: The utility of creatinine clearance (CCr) to measure renal function is greatly reduced by its low accuracy and by the need for a timed collection of urine. Different formulas have been proposed to predict CCr or GFR from serum creatinine (PCr) and anthropometric data. However, the inaccuracy in the estimate of urinary creatinine excretion (UCr) is probably the major cause of error of prediction formulas. The aim of this study was to evaluate the possibility to obtain a more accurate prediction of UCr, and hence of CCr from the measure of body cell mass (BCM). BCM is the body compartment which contains muscle mass, where creatinine is generated.

Methods: Two-hundred and eleven CKD patients (115 women), aged 17-81 years, PCr 0.5-14.4 mg/dL. Glomerular filtration rate (GFR) was measured in all patients as the renal clearance of 99mTc-DTPA. The other examined parameters were: PCr; UCr (urine collection 24 hrs); CCr measured as UCr x V / PCr (m-CCr); CCr predicted by Cockcroft and Gault formula (C&G-CCr). BCM was measured using a single frequency tetrapolar impedance analyzer.

Results: GFR was 1.3-147 mL/min (mean 55.1), mCCr 3.7-135 mL/min (mean 61.2), 24h-UCr 416-2102 mg (mean 1075), BCM 12.2-45.2 kg (mean 23.7). A strict linear correlation was found between 24h-UCr and BCM (r=0.780), which was closer than that between 24h-UCr and BW (r=0.626). Multiple linear regression (MR) modeling for urinary creatinine excretion indicated that UCr was determined positively by BCM, body weight, male gender and height, and negatively by age and PCr. The most relevant determinants of UCr were BCM, age, and PCr. UCr predicted from MR equation (MR-UCr) ranged 378-1856 mg (mean 1075) quite similar to measured 24h-UCr. MR-BCM-CCr, that is CCr predicted from MR-UCr and PCr, was very similar to measured CCr (61.5±32.0 VS 61.2±32.1 mL/min, NS), with a closer correlation than C&G CCr (r= 0.940 VS 0.857) and a lower prediction error (11.1 VS 13.0 mL/min). The concordance between MR-BCM-CCr and mCCr was better than that of C&G CCr.

Conclusions: In CKD patients at the different stages of GFR impairment, urinary creatinine excretion can be more accurately estimated, and creatinine clearance can be predicted from the value of body cell mass combined with other anthropometric data and with serum creatinine.

Funding: Government Support - Non-U.S.

SA-PO415

Usefulness of Repeated Measurement of Casual Urine Sodium-to-Potassium Ratio in Patients with CKD Yuka Okuyama,[2] Haruhito A. Uchida,[1] Toshiyuki Iwahori,[4] Hidemi Takeuchi,[2] Nozomu Otaka,[2] Masashi Kitagawa,[3] Hitoshi Sugiyama,[3] Katsuyuki Miura,[4] Hirotsugu Ueshima and EPOCH-JAPAN Group,[4] Jun Wada.[1] *[1]Okayama Univeristy, Okayama, Japan; [2]Okayama University, Okayama, Japan; [3]Okayama University Graduate School, Okayama, Japan; [4]Shiga University of Medical Science, Otsu, Shiga, Japan.*

Background: Lowering sodium-to-potassium ratio has been reported to benefit people for hypertension prevention and control in epidemiological studies. Four to seven repeated measurements of casual urine sodium-to-potassium ratio is known to provide high correlation and good agreement quality with less bias to estimate 7-day 24-hour urinary Na/K ratio in normotensive and hypertensive individuals. However, little is known about urinary Na/K ratio in patients with chronic kidney disease (CKD). The aim of this study was to clarify the relationship of the repeated measurement of casual and 24-hour urinary sodium-to-potassium ratio in patients with CKD.

Methods: A total of 61 inpatients with CKD, 31 in stage 1-3 (eGFR ≥ 30 ml/min/1.73m^2) and 30 in stage 4-5 (eGFR < 30 ml/min/1.73m^2), aged 20 to 85 under low-sodium diet (NaCl 6 g/day) were recruited in Okayama University hospital. Na/K ratio in casual urine at 4 points/day (first void after rising, each urine after breakfast, lunch or dinner) for 2 days and 2-day 24-hr urine at the same day were measured. Correlation and the quality of agreement by Bland and Altman between casual urine and 24-hour urine samples were analyzed.

Results: Mean 24-hour Na and K excretion was lower in participants in stage 4-5 (Na: 87.5 mmol/24h, K: 18.8 mmol/24h) than in participants in stage 1-3 (Na: 99.0 mmol/24h, K: 26.1 mmol/24h), whereas mean 24-hour urine Na/K ratio was higher in participants in stage 4-5 (5.1) than in participants in stage 1-3 (4.1). Casual urine Na/K ratio was strongly correlated with 2-day 24-hour urinary Na/K ratio by sampling 2 casual urine specimens per day for 2 days in participants in stage 1-3 (r = 0.69-0.78), but not in stage 4-5 (r = 0.12-0.19). The bias for mean Na/K ratio between 2-day 24-hour urine and sampling 2 casual urine per day for 2 days in participants in stage 1-3 ranged from -0.86 to 0.16, and the quality of agreement for the mean of this casual urine sampling was similar to that of all 8 points of casual urine samples for estimating 2-day 24-hour values.

Conclusions: Repeated casual urine Na/K ratio measurement is useful to estimate 24-hour urine Na/K ratio in stage 1-3 CKD patients as well as normotensive and hypertensive people; however, not in stage 4-5 CKD patients.

SA-PO416

Metabolic Syndrome, Inflammation, and Risk of Developing CKD in Rheumatoid Arthritis Masako Kochi, Kentaro Kohagura, Yusuke Ohya. *University of the Ryukyus, Nishihara-cho, Japan.*

Background: Inflammation is a risk factor for progression of CKD in patients with rheumatoid arthritis (RA) as well as general population. High incidence of metabolic syndrome (MetS) has been reported in RA. MetS is associated with both inflammation and developing CKD. However, the combined effects of MetS and inflammation on the risk of developing CKD are not known in RA. This study aims to examine the relationship between MetS, C-reactive protein (CRP; a marker of inflammation), and the incidence of CKD in RA patients.

Methods: We retrospectively examined a total of 345 RA patients. The outcome of interest was incidence of CKD which was defined as an eGFR<60 mL/min/1.73 m^2 and/or positive dipstick testing for proteinuria for ≥3 months. MetS was defined as the presence of ≥3 of the following criteria: obesity, hypertriglyceridemia, low high-density lipoprotein cholesterol, high blood pressure, and high fasting glucose level. CRP was used as an inflammation marker, and a high CRP was defined as persistently CRP value of >3 mg/L during the first 6 months of follow-up. Patients were categorized into four subgroups by the presence of MetS and high CRP at baseline: non-MetS with low CRP, non-MetS with high CRP, MetS with low CRP, and MetS with high CRP.

Results: Mean baseline patient age was 57 years, and mean eGFR was 87 ml/minute/1.73 m^2. Over a median follow-up of 8 years, 47 (14%) patients developed CKD. MetS and high CRP were independently associated with the incidence of CKD,respectively. Subgroup analysis showed that the cumulative incidence of CKD was the highest in patients with MetS / high CRP group compared with all other groups ($P < 0.0001$, log-rank test). In a multivariate analysis, MetS / high CRP group was significantly associated with increased risk for incident CKD (adjusted HR, 5.35; 95% confidence interval, 2.27–12.71; $P = 0.0002$) independent of age, eGFR, and anti-RA drug uses.

Conclusions: Independent of confounding risk factors, MetS had an inflammation-augmented association with increased risk of incident CKD in patients with RA.

SA-PO417

Association of Estimated Glomerular Filtration Rate and Gestational Complications Sehoon Park,[2] Ho Jun Chin,[1] Ki Young Na,[1] Dong Ki Kim,[2] Yon Su Kim,[2] Hajeong Lee.[2] *[1]Seoul National University Bundang Hospital, Seong nam, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, SEOUL, Republic of Korea.*

Background: Glomerular filtration rate elevation represents the intrarenal hemodynamic changes in pregnant women, yet, estimated glomerular filtration rate (eGFR) during gestation and its association with pregnancy outcomes remains to be investigated.

Methods: We collected pregnancy cases in two tertiary teaching hospitals in Korea from 2001 to 2015. With eGFR during pregnancy, estimated by CKD-EPI method, we calculated time-averaged eGFR considering the value as a time-dependent variable. Adverse pregnancy outcome was composition of preterm birth, low birth weight and preeclampsia.

Results: Among total of 12,900 mothers, a number of 4,028 (31.2%) mothers experienced composite adverse pregnancy outcomes. Gestational eGFR showed a non-linear U-shaped association with the risk of gestational complication, which was most prominent with the midterm eGFR values. The adjusted odds ratio (aOR) and associated 95% confidence interval of an adverse pregnancy outcome for eGFR levels below and above the reference level of 120–150 mL/min/1.73 m^2 were as follows: ≥150 mL/min/1.73 m^2, aOR 1.86 (1.56-2.22), *P*<0.001; 90–120 mL/min/1.73 m^2, aOR 1.18 (1.06-1.31), *P*=0.003; and 60–90 mL/min/1.73 m^2, aOR 1.72 (1.12-2.65), *P*=0.014. Moreover, gestational eGFR additively elevated power to predict gestational complications [AUROC with eGFR 0.733 (0.717-0.740). vs AUROC without eGFR 0.728 (0.722-0.744), *P* for AUROC comparison = 0.006].

Conclusions: We demonstrated a non-linear, U-shaped relationship between eGFR during gestation and the risk of adverse pregnancy outcome. Appropriate interpretation of eGFR values in pregnancy might be helpful for risk prediction of gestational complications.

The Prevalence of Sleep Apnea in Non-Dialysis CKD Patients: A Systematic Review and Meta-Analysis Zhuo Huang, Xi Tang, Ping Fu. *Kidney Research Institute, Division of Nephrology, West China Hospital, Sichuan University, Chengdu 610041, China.*

Background: The prevalence of sleep apnea (SA) is diverse across preceding studies in chronic kidney disease (CKD) patients.

Methods: A systematic review and meta-analysis was conducted to estimate the aggregated prevalence of SA in adults with non-dialysis CKD. We searched Medline and Embase (up to April 2017) for relevant studies. The pooled prevalence of SA was calculated. Subgroup analyses based on varied means of identifying SA, different stages of CKD and gender were conducted as well. Random-effects model was employed in our meta-analysis.

Results: 20 out of 2553 studies involving 2,790 participants were included. The pooled prevalence of SA positive varied between different tools. The prevalence of SA positive screened by sleep rating scales was 25%, while the prevalence of SA diagnosed by sleep monitoring like polysomnography was 54%, which was significantly higher than that in sleep questionnaires subgroup (P for subgroup analysis=0.018; Figure 1). Besides, in studies utilizing polysomnography patients with advanced CKD may have a greater chance of suffering from severe SA (P for subgroup difference=0.082; Figure 2). In addition, subgroup analysis based on gender showed that male participants were more likely to be affected by moderate to severe SA than female participants (50% vs. 29%, P for subgroup difference =0.02: Figure 3).

Conclusions: SA is a common comorbidity in about half of non-dialysis CKD patients. Sleep rating scales underestimates the presence of SA compared with sleep monitoring. The risk of SA increases with the stages of CKD. Moreover, Male CKD patients have a higher risk for SA than female patients. It is necessary to routinely screen SA in non-dialysis CKD patients, and randomized trials using standard diagnostic criteria to identify SA are needed. More studies about effects of interventions against SA on the progression of CKD are required.

Oral Iron Therapy and Serum Hepcidin in Children with CKD Ameneh Amini,[2] Richa Gautam,[2] Eduardo M. Perelstein,[2] Stefano Rivella,[1] Mary E. Choi,[2] Juhi Kumar,[2] Oleh M. Akchurin.[2] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]Weill Cornell College of Medicine, New York, NY.*

Background: Hepatic peptide hepcidin, a major regulator of iron homeostasis, is up-regulated in adults and children with chronic kidney disease (CKD). Hepcidin blockade ameliorates renal anemia in experimental CKD. Iron and inflammation contribute to hepcidin over-production in animal models and in adult patients with CKD. However, the relationship between oral iron therapy and hepcidin in children with CKD has not been characterized.

Methods: Cross-sectional single center study. Serum hepcidin was measured by ELISA (Intrinsic Lifesciences, USA). Clinical data were abstracted from medical records of children with stages 2-5 CKD. Platelet-to-lymphocyte ratio (PLR) was used as a marker of inflammation. Glomerular filtration rate (GFR) was estimated using bedside Schwartz formula. Normally distributed data are shown as mean±SD. T-test and linear regression were used for data analysis.

Results: Hepcidin was measured in 36 childern (60% males, median age 12.5). Hepcidin strongly correlated with serum ferritin (r=0.64, p<0.005) and modestly with total iron binding capacity (TIBC; r=-0.43, p=0.02), and GFR (r=-0.34, p=0.04). There was a trend toward correlation between hepcidin and hemoglobin (r=-0.29, nondirectional p=0.09, directional p=0.04). No significant correlation was observed between serum hepcidin and PLR (r=0.1). Oral iron therapy was prescribed to 14 children (Fe+ group) and not prescribed to 22 (Fe-). GFR was 34.6 and 47.4 mL/min/1.73m^2 in the Fe+ and Fe- groups, respectively (p=0.03). Fe+ group had lower hemoglobin compared to Fe- group (11.7±1.5 vs. 13.0±2.0, p=0.04), but similar serum iron, ferritin, TIBC, and transferrin saturation. Serum hepcidin was higher in the Fe+ group than in Fe- group (94.6±41 ng/mL vs. 44±78, p=0.015). This difference remained significant after adjusting for age, sex, CKD etiology (glomerular vs. non-glomerular) and PLR (adjusted p=0.017), and was attenuated after additional adjustment for GFR (adjusted p=0.05).

Conclusions: In this pediatric CKD cohort, serum hepcidin was associated with iron therapy status, independently of PLR. Additional analyses of inflammatory markers in this cohort are ongoing. Further investigations of the impact of iron-mediated hepcidin elevation on clinically relevant outcomes in childern with CKD are warranted.

SA-PO420

Assessment of Renal Impairment on the Prognosis of Newly Diagnosed Multiple Myeloma Veronica T. Costa e Silva,[7] Elerson Costalonga,[3] Marcella M. Frediani,[1] Renato A. Caires,[7] Fernanda O. Coelho,[2] Emmanuel A. Burdmann,[6] Antonio A. Portela Neto,[5] Adriel G. Silva.[4] *[1]HC-FMUSP, Sao Paulo, Brazil; [2]None, São Paulo, Brazil; [3]School of Medicine, University of Sao Paulo, São Paulo, Brazil; [4]USP, São Paulo, Brazil; [5]University State of São Paulo, São Paulo, Brazil; [6]University of Sao Paulo Medical School, Sao Paulo, Brazil; [7]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Severe Renal Impairment (RI) is associated with early death in patients (pts) with multiple myeloma (MM). The new criteria from the International Myeloma Working Group (IMWG) defined RI as serum creatinine (SCr) > 2.0 mg/dL or estimated glomerular filtration rate (eGFR) < 40 ml/min/1.73 m^2. If these definitions are associated to overall survival (OS) is still debatable.

Methods: All pts with newly diagnosed MM (up to three months) admitted for treatment at the Hematology Outpatient Service from the Sao Paulo State Cancer Institute, between February 2012 and January 2014, were prospectively followed. Exclusion criteria were: age < 18 years; pts on maintenance dialysis; follow up < 3 months. Chronic Kidney Disease (CKD) was diagnosed as eGFR < 60 ml/min/1.73 m^2. GFR was estimated by the CKD Epidemiology Collaboration formula. International Staging System (ISS) relyed on serum albumin (Alb) and ß$_2$ microglobulin (B2M).

Results: One hundred twenty pts were enrolled. Pts characteristics were age 62.02 ± 11.2 years, 56.2% male. MM type was IgG Kappa in 59% of cases and 21% of pts had light chain MM. The clinical stages included Durie-Salmon stage III (DS-III) in 81% and ISS stage III (ISS-III) in 30% of pts. Serum exams were: 43% hemoglobin (Hb) < 10 g/dL; 14.3% total calcium (CaT) > 11 mg/dL; 39.2% SAlb < 3.5 g/dL; 54.5% B2M > 3.5 mg/L; 18.3% lactate dehydrogenase (LDH) > normal value. At the moment of enrollment, SCr was 1.05 (0.74 – 1.43) mg/dL and eGFR was 69.8 (42.7 – 97.1) ml/min/1.73 m^2. Thirteen percent of pts had RI with SCr > 2.0 mg/dL; CKD stage 3 was detected in 43% pts. Overall survival (OS) was 3.70 (1.97 – 4.44) years. No pts characteristics, CaT, Hb or DS-III were related to reduced OS. Neither was SCr > 2.0 mg/dL (P=0.425) or eGFR < 40 ml/min/1.73 m^2(P=0.189). Conversely, CKD stage 3 was associated to reduced OS (3.26 [1.56 – 4.41] vs 3.72 (2.69 – 4.96) years, P=0.032) as well as ISS-III (P=0.022). On Cox regression model, only B2M > 3.5 mg/L (Hazard Ratio : 2.14 [1.03 – 4.42]) and LDH > normal value (Hazard Ratio: 2.74 [1.45 – 5.18]) were associated with lower OS.

Conclusions: Currently used KDIGO CKD definitions seem to be superior than the new IMWG criteria to assess the impact of RI on the prognosis of newly diagnosed MM pts.

SA-PO421

Results from the Cross-Sectional Evaluation of Clinical Symptoms and Epidemiologic Parameters in Patients with TMA, Differentiated by Laboratory Parameters Study (CESAR) Ulf Schoenermarck,[3] Wolfgang Ries,[2] Bernd Schroppel,[4] Michael Jeglitsch.[1] *[1]Alexion, Munich, Germany; [2]Diako Flensburg, Flensburg, Germany; [3]University Hospital Munich-Grosshadern, D-81377 Muenchen, Germany; [4]University of Ulm, Ulm, Germany.*

Background: Atypical hemolytic uremic syndrome (aHUS), thrombotic thrombocytopenic purpura (TTP) and HUS caused by Shiga toxin-producing *Escherichia coli* (STEC-HUS) are diseases with thrombotic microangiopathy (TMA) and similar clinical presentations. Epidemiological data on TTP and aHUS in Germany are lacking.

Methods: CESAR is a German prospective, multicenter, cross-sectional, epidemiological study of the relative incidences (RI) of aHUS, TTP and STEC-HUS in patients (pts) presenting with TMA. ADAMTS13 activity and presence of STEC were tested. Treating clinicians diagnosed pts as either aHUS, TTP, STEC-HUS or "other".

Results: From 04/2014 to 03/2017, 232 pts were enrolled in 22 German centers. RIs and clinical data are shown in the table. 104 (74%) pts with aHUS had at least one complement-amplifying condition.

Conclusions: aHUS was the most common diagnosis in pts with clinical TMA. Less frequent differential diagnoses including TTP should be rapidly ruled out through specific diagnostic tests. Pts with aHUS or STEC-HUS were less thrombocytopenic and experienced more severe acute kidney injury than pts with TTP.

Funding: Commercial Support - Alexion Pharma Germany GmbH

Table 1. Relative incidences, demographic and clinical characteristics of patients presenting with TMA

Characteristic	aHUS (n=141)	TTP (n=31)	STEC-HUS (n=14)	Other (n=46)
Relative incidence	61%	13%	6%	20%
Age at enrolment (years), mean (SD)	55.4 (20.3)	50.5 (16.7)	24.3 (29.9)	57.5 (20.7)
Gender, female, n (%)	79 (56)	21 (68)	8 (57)	17 (37)
Presenting symptoms, n (%)				
Renal	131 (93)	22 (71)	14 (100)	43 (93)
Gastrointestinal	71 (50)	11 (35)	12 (86)	23 (50)
Neurological	57 (40)	18 (58)	4 (29)	10 (22)
Cardiovascular	51 (36)	7 (23)	2 (14)	4 (9)

Nephrologist-Reported Symptoms and Their Impacts on Patients with Anemia Associated with CKD Tony Okoro,[1] Kirsten L. Johansen,[3] Susan Mathias,[2] Hilary H. Colwell,[2] Steven I. Blum,[1] Vanja Sikirica.[1] *[1]GlaxoSmithKline, Collegeville, PA; [2]Health Outcomes Solutions, Winter Park, FL; [3]University of California, San Franicsco, San Francisco, CA.*

Background: To explore the relevant symptoms and their impacts on patients with anemia associated with chronic kidney disease (aCKD) as reported by nephrologists.

Methods: Double-blind (sponsor and nephrologist) qualitative telephone interviews using a semi-structured interview guide were conducted with a random sample of practicing nephrologists in the United States. Nephrologists were asked about symptoms and their impacts reported by their patients, as well as which symptoms they ask their patients about during clinic visits. Symptoms and impacts reported both spontaneously and with probing were included. Interviews were audio-recorded, transcribed, and analyzed using MAXQDA software. Verbal consent was obtained.

Results: Nephrologists (n=29) had been in practice for ~19 years; most were in freestanding (66%), for-profit (69%), and nonacademic (69%) institutions. Nephrologists reported (spontaneously or after being probed) a range of symptoms that their patients with aCKD experience (**Table**). Nephrologists reported that 48% of their patients are negatively affected by aCKD symptoms in the area of physical functioning, 50% in their ability to carry out daily activities, and 37% in emotional functioning. Symptoms that bother patients the most are fatigue (93%), dyspnea (41%), and difficulty sleeping (22%). The symptoms that clinicians most commonly ask their patients about are fatigue (83%), dyspnea (57%), and loss of appetite (43%).

Conclusions: In general, clinicians reported that their patients with aCKD experience a variety of symptoms and related impacts. Fatigue and dyspnea are frequently and spontaneously reported by clinicians and routinely assessed. Nephrologists may not commonly ask about other symptoms such as difficulty remembering things or concentrating, which may be relevant to their patients.

Funding: Commercial Support - GlaxoSmithKline

Symptom	Any Mention, n (%) (n=29)	Spontaneous, n	Probed, n
Fatigue	29 (100)	29	None
Dyspnea	28 (97)	24	4
Gastrointestinal symptoms	26 (90)	2	24
Difficulty sleeping	26 (90)	9	17
Difficulty remembering	22 (76)	5	17
Difficulty concentrating	23 (79)	5	18

SA-PO423

Evolution of HIV-Associated Glomerulopathy with Treatment and Time: A Study of Serial Biopsies Rachel Hung,[2] Viyaasan Mahalingasivam,[1] John Connolly,[2] John W. Booth.[2] *[1]Mid Essex Hospitals NHS Trust, Harrow, United Kingdom; [2]Royal Free Hospital, London, London, United Kingdom.*

Background: While the spectrum of HIV-associated glomerular disease is well described, the impact of treatment on evolution of these diseases, both clinically and histologically, is less clear. In the era of widespread antiretroviral therapy (ART) use, many patients with renal disease will be identified and investigated after a period of suppressed viral replication, potentially complicating interpretation of the renal biopsy. Serial biopsies are rarely performed so histological progression is as yet not well understood. Our aim was to examine the histologic evolution of HIV-associated glomerular disease with time and/or treatment through study of patients who had undergone serial kidney biopsies.

Methods: Patients with HIV and serial biopsies were identified through local database searches in two UK renal units. Patients whose first biopsy was considered non-diagnostic (n=2) were excluded. Histology data was obtained from structured departmental reports; all repeat biopsies had been reported with reference to the initial biopsy. Clinical data and drug treatments were obtained by review of notes and pathology databases.

Results: 13 patients with glomerular disease and serial biopsies were identified (n; HIV-associated nephropathy (HIVAN)=3, immune complex kidney disease (ICKD)=6, IgA nephropathy=4). Typical collapsing glomerulopathy was not identified on the second biopsy of any patient with HIVAN, all of whom had received ART in the intervening period. 3 patients with ICKD had cellular segmental lesions with crescents in their index biopsy; all had resolved on serial biopsy leaving segmental scleroses (n=2, both received ART) or mesangial hyperplasia (n=1, received steroids). Glomerular appearances showed no improvement on serial biopsy in IgA patients; 1 patient with crescentic IgA showed no improvement on 2 serial biopsies despite robust control of viral replication

Conclusions: In this small and unique study, it was demonstrated that the morphology of established HIV-associated glomerular disease can change with treatment and time. 'Healed' segmental proliferative lesions in ICKD may simulate 'primary' FSGS, while typical collapsing glomerulopathy in HIVAN may be reversed, or obscured by glomerular obsolescence. On the other hand, viral control did not impact on histological activity of HIV-associated IgA.

SA-PO424

Performance of a Pure Metabolite Panel Estimate of GFR (accuGFR) Josef Coresh,[1] Lesley Inker,[2] Jingsha Chen,[1] Gudny Eiriksdottir,[3] Vilmundur Gudnason,[3] Vicente E. Torres,[4] Lisa Ford,[5] Maria Oyaski,[5] Regis Perichon,[5] Andrew S. Levey.[2] *[1]Johns Hopkins Medical Institutions, Baltimore, MD; [2]Tufts Medical Center, Boston, MA; [3]Icelandic Heart Association, Kopavogur, Iceland; [4]Mayo Clinic, Rochester, MN; [5]Metabolon, Inc., RTP, NC.*

Background: We showed that panels of metabolites can provide an accurate estimate of glomerular filtration rate (GFR) without creatinine and demographic characteristics. We present a Laboratory Developed Test (LDT) to estimate GFR (accuGFR) and estimate its performance in subgroups where eGFRcr is less accurate. **Study Population:** GFR measurements (mGFR) on 3,236 individuals in the AASK, MDRD, AGES and the CRISP studies were divided randomly into a development sample (50%) and validation samples (25% complete, 25% unused backup).

Methods: Laboratory Methods: Stored (-70°C) serum specimens were subjected to targeted UPLC-mass spectrometry assays for 4 metabolites and serum creatinine (CV <5%). **Data Analysis:** accuGFR estimated using linear regression of log mGFR on log metabolites in the development sample. Performance measured using large errors (1-P30

and 1-P20, the percentage of estimates deviating from the mGFR by >30% and >20%). We compared the accuGFR to eGFR by CKD-EPI equations.

Results: mGFR spanned a wide range (mean 55, SD 26 ml/min/1.73m^2). accuGFR based on 4 metabolites without demographics had substantially better accuracy than eGFRcr and eGFRcys but similar performance to eGFRcr-cys in the accuGFR development and validation samples. In subgroups where there is concern that eGFRcr may be inaccurate, accuGFR often outperformed even eGFRcr-cys, particularly for 1-P20.

Conclusions: accuGFR based on four metabolites without serum creatinine or demographics nearly halved the rate of large errors compared to eGFRcr and appears to be robust across a range of relevant subgroups. The utility of the accuGFR test based on a single blood draw should be tested in diverse clinical and research populations.

Table 1. Improved performance by accuGFR vs. CKD-EPI eGFRcr, eGFRcys and eGFRcr-cys

1-P30	accuGFR Development (n=1612)	accuGFR Validation (n=806)	All accuGFR Age ≥75 (n=526)	All accuGFR BMI ≥35 (n=333)	All accuGFR Poor eGFRcr (n=380)

accuGFR sample: MDRD, AASK, AGES and CRISP (sampled 50% for development and 25% for validation); "all accuGFR" samples include 2/3 used for algorithm development, plus 1/3 validation samples not used in algorithm development

* p<0.05, ** p<0.01, ***p<0.001 vs. accuGFR, Poor eGFRcr performance defined as errors from mGFR > 30%

SA-PO425

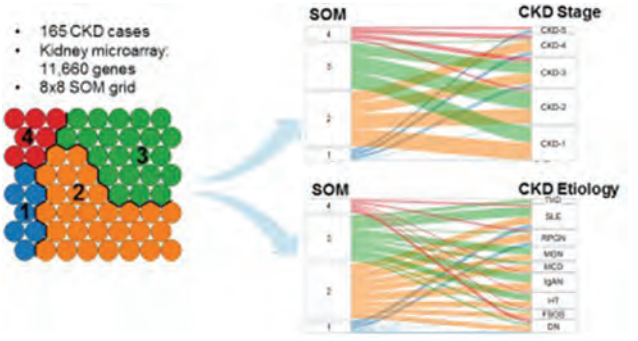
Molecular Re-Classification of CKD Based on Kidney Transcriptomics Profiles Anna Reznichenko,[1] Viji Nair,[5] Sean Eddy,[5] Tao Wei,[2] Tim Slidel,[6] Wenjun Ju,[5] James Conway,[7] Shawn S. Badal,[3] Johnna D. Wesley,[4] John T. Liles,[3] Uptal D. Patel,[3] Matthew D. Breyer,[2] Kevin L. Duffin,[2] Carol P. Moreno Quinn,[6] Maria chiara Magnone,[1] Matthias Kretzler.[5] *[1]AstraZeneca, Gothenburg, Sweden; [2]Eli Lilly and Company, Indianapolis, IN; [3]Gilead Sciences, Inc., Foster City, CA; [4]Novo Nordisk Research Center, Seattle, Seattle, WA; [5]University of Michigan, Ann Arbor, MI; [6]MedImmune, Cambridge, United Kingdom; [7]MedImmune, Gaithersburg, MD. Group/Team: Renal Precompetitive Consortium (RPC2).*

Background: The CKD population is highly heterogeneous and includes a wide range of etiologies with a multitude of underlying molecular processes in the kidney. Current clinical classification of CKD into five stages based on GFR and albuminuria is agnostic to the disease heterogeneity and intrarenal biology, and thus is antithetical to the personalized medicine (PM) concept. We re-classified a CKD patient population based on the kidney molecular profiles, consistent with PM initiatives.

Methods: From clinically indicated renal biopsies in 165 ERCB cohort participants, transcriptomics profiles were generated using Affymetrix U133 platforms. Self-Organizing Maps (SOM), an unsupervised neural network machine learning algorithm, was used to stratify CKD population by clustering cases with similar transcriptomics profiles. Gene Ontology, pathway, and Gene Set Enrichment analyses were performed to identify key molecular mechanisms per SOM cluster.

Results: Using SOM, we identified four distinct patient clusters within the topological map of renal transcriptomics data structure. Relating these molecular clusters back to the current classification revealed the lack of overlap with CKD stages, thus demonstrating that SOM clusters represent a novel characterization beyond clinical classification. The SOM clusters were also not explained by CKD etiology, confirming the hypothesis of disease heterogeneity at the molecular level. Enrichment analyses showed that the SOM clusters differed in terms of biological pathways in the kidney including inflammation, metabolism, cell signaling and apoptosis.

Conclusions: Molecular re-classification may help realize the potential of PM for CKD. Elucidation of the molecular drivers of population clustering can lead to new biological hypotheses, therapeutic targets, and cluster-specific biomarkers that would enable PM-based regimens.



CKD molecular re-classification

SA-PO426

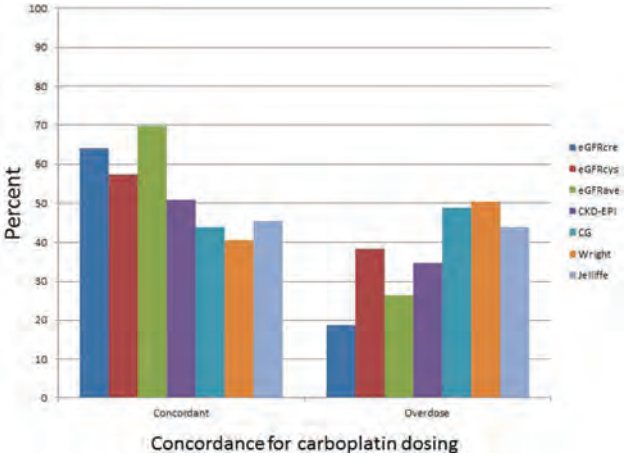
Quest for Simple and Accurate Estimate of Kidney Function for Chemotherapy Dosing: A Comparison of Commonly Used GFR Estimates and Inulin Clearance Fumiaki Tanemoto,[1] Taisuke Ishii,[1] Eriko Nakano,[2] Yasuhiro Komatsu.[1] *[1]Nephrology, St.Luke's International Hospital, Tokyo, Japan; [2]Medical oncology, St.Luke's International Hospital, Tokyo, Japan.*

Background: The increase in the number of oncology patients with renal impairment demands the accurate estimate of kidney function to avoid unnecessary adverse effects caused by overdose of chemotherapy. However, dose accuracy after renal function assessment calculated using eGFR equations based on creatinine measured by enzymatic assay and/or cystatin C remains unclear.

Methods: In this single-center study, we collected data from all adult patients whose inulin clearance was measured between January 2009 and March 2017. Renal function and consequent dose of renally-excreted chemotherapy, including carboplatin, were calculated by estimated creatinine-based GFR (eGFRcre) developed by the Japanese Society of Nephrology (JSN), estimated cystatin C-based GFR (eGFRcys) developed by JSN, averaged value of eGFRcre and eGFRcys (eGFRave), Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI), Cockcroft-Gault (CG), Wright, and Jelliffe formulae. Logistic regression analysis was conducted to determine factors associated with overdose.

Results: The concordance of renal function estimates according to the CKD classification with measured inulin clearance (67±32 ml/min/1.73m^2) in 187 adults (age 52±16, 58.3% men) for eGFRcre, eGFRcys, eGFRave, CKD-EPI, CG, Wright, and Jelliffe formulae was 53.5%, 56.6%, 58.5%, 52.9%, 49.2%, 52.4%, and 52.9%, respectively. Concordance for recommended dosage of chemotherapy using each respective formulae was 71.1%, 64.8%, 74.8%, 68.9%, 65.2%, 67.9%, and 67.4%. Especially concordance for carboplatin was 64.2%, 57.2%, 69.8%, 57.2%, 43.9%, 40.6%, and 47.6%, respectively. Hypoalbuminemia was an independent factor for overdose (OR 3.14, 95% CI 1.75-5.61).

Conclusions: For accurate chemotherapy dosing, eGFRave appears to be the most appropriate estimate of renal function. Patients with hypoalbuminemia may need actual measurement of inulin clearance.



SA-PO427

Serum Creatinine from 29 US Health Care Organizations: The Case of Imprecise Measurement Nikita Stempniewicz,[1,2] Shoshana Ballew,[2,3] Elizabeth Ciemins,[1] Morgan Grams,[3,4] Kunihiro Matsushita,[2,3] Jerry Penso,[1] Josef Coresh.[2,3] *[1]AMGA, Alexandria, VA; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD.*

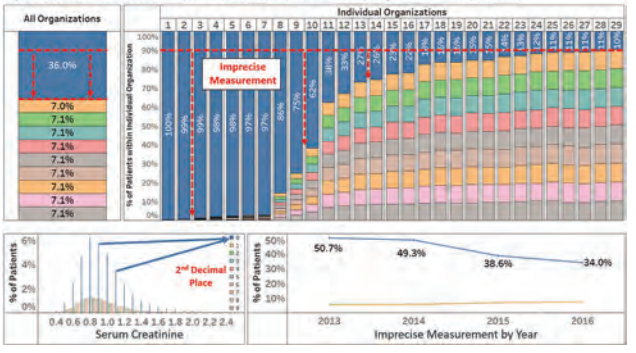
Background: For precise measurement of estimated GFR (eGFR), KDIGO 2012 guidelines recommend clinical laboratories report serum creatinine to the nearest 0.01 mg/dl. Rounding serum creatinine measurements to 0.1 mg/dl reduces the precision of eGFR, e.g., a female with a serum creatinine of 1.0 mg/dl, and ages of 60, 70, or 80 would represent eGFR (CKD-EPI) in the ranges of 58-64, 54-60, and 51-56 mL/min/1.73 m^2, respectively. However, many laboratories still round to 0.1 mg/dl.

Methods: We analyzed 2.3 million patients with serum creatinine measurements from the electronic health record (EHR) data of 29 AMGA member organizations who use the Optum One population health analytics platform. We used the most recent serum creatinine recorded between 01/01/2013 and 12/31/2016 for patients age 18-99, with a history of hyperglycemia, and at least one ambulatory office visit. Imprecision in serum creatinine reporting was quantified using the proportion of values with a 0 in the second place after the decimal (e.g., 0.90, 1.00). With precise measurement we expect ~10% of patients to end in each digit including 0.

Results: Overall, 36% of serum creatinine measurements had 0 for the second decimal place (e.g. X.X0, blue in Figure 1). This proportion varied among organizations, ranging from 10%-100%. Over the last 4 years the proportion with 0 in the second place after the decimal decreased from 51% (2013) to 34% (2016).

Conclusions: Imprecise measurement of serum creatinine by clinical laboratories in the US is improving but is still a prevalent practice which should be eliminated to meet with guidelines and improve the quality of health care.

Figure 1: Differences in Precise Serum Creatinine Measurement, by Organization and Over Time



SA-PO428

Existing Creatinine Based Estimating Equations Overestimate GFR in Indian Subjects Vivek Kumar,[5] Ashok K. Yadav,[5] Yoshinari Yasuda,[3] Vinod Kumar,[6] Krishan Lal L. Gupta,[4] Masaru Horio,[2] Vivekanand Jha.[1] *[1]George Institute for Global Health, New Delhi, India; [2]Osaka University Graduate School of Medicine, Ashiya, Japan; [3]Nagoya University Post Graduate School of Medicine, Nagoya, Japan; [4]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [5]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [6]Fienstine Institute for Medical Research, New York, NY.*

Background: Ethnic differences, predominantly vegetarian diet and poor representation in derivation and validation cohorts for eGFR equations call for assessment of accuracy of current eGFR equations in Indian population.

Methods: This study was done at PGIMER, Chandigarh, India. Stable adult prospective living renal donors or subjects with CKD were eligible for enrolment. GFR was measured (mGFR) by urinary clearance of inulin. eGFR were calculated using CKD-EPI$_{Cr}$, Japanese coefficient-modified CKD-EPI, MDRD and CKD-EPI Pakistan equation. Bias (mGFR-eGFR), 95% limits of agreement, precision (95% CI of mGFR-eGFR) and accuracy (RMSE of mGFR-eGFR, and % of subjects with eGFR within ±30% of mGFR i.e. P_{30}] were calculated.

Results: After excluding 5 subjects with incomplete data, 130 subjects were included for final analyses (63 prospective donors and 67 subjects with previously diagnosed CKD). 50% were strict vegetarian and average meat intake among meat eaters was only 3.8 times/month. The average creatinine (Cr) excretion was 14.7 mg/kg/day (95% CI: 13.5 to 15.9 mg/kg/day) and 12.4 mg/kg/day (95% CI: 11.2 to 13.6 mg/kg/day) in males and females, respectively. The average daily protein intake based on 24-hour urea nitrogen excretion was 46.1 g/day (95% CI: 43.2 to 48.8 g/day), respectively. Bias, precision and accuracy of eGFR equations are shown in table 1. All Cr based eGFR equations overestimated GFR with CKD-EPI$_{Cr}$ and MDRD being the poorest.

Conclusions: Cr based eGFR equations significantly overestimate GFR in the predominantly vegetarian Indian population. Lower Cr excretion suggest that this overestimation is likely linked to lower muscle mass. There is need of an appropriately powered study to develop either a correction factor or a new equation for accurate assessment of kidney function in Indian population.

Funding: Private Foundation Support

Table 1: Performance of GFR estimating equations as compared to measured GFR by urinary inulin clearance

eGFR equation	Bias (mGFR-eGFR) (ml/min/1.73m2)	95% Limits of agreement (ml/min/1.73m2)	Precision (95% CI) (ml/min/1.73m2)	Accuracy RMSE (ml/min/1.73m2)	Accuracy P30 (%)
CKD-EPICr	-24.92±17.17	-58.57 to 8.73	-27.90 to -21.95	30.22	22.3

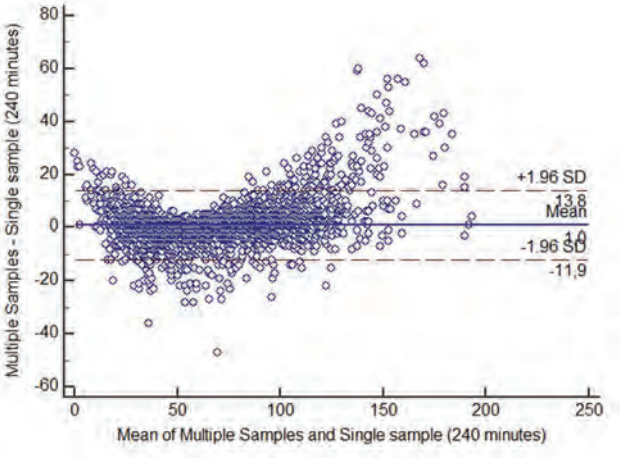
Measuring Plasma Clearance for Exact Assessment of GFR: Multi versus Single Sampling Natalie Ebert,[3] Elke Schaeffner,[2] Hans Pottel,[4] Etienne Cavalier,[5] Laurence Dubourg,[7] Martin Flamant,[1] Pierre Delanaye.[6] *[1]APHP, Paris, France; [2]Charite, Berlin, Germany; [3]Charite University Hospital, Belgrade, Serbia; [4]KULeuven, Kortrijk, Belgium; [5]University of Liege, CHU Sart-Tilman, Liege, Belgium; [6]University of Liège, Liège, Belgium; [7]hospices civils de Lyon -Université Claude Bernard Lyon 1-INSERM U 820, LYON, France.*

Background: Measurement of plasma clearance (PC) of iohexol or 51Cr-EDTA are both recognized as gold standard for exact GFR assessment. However, there are different protocols for PC measurement in terms of a varying number of plasma samples. We compare GFR results obtained from multi sample (MS) versus single sample (SS) PC measurement.

Methods: We used data from 4 European cohorts including indiv. with PC of iohexol (Liège, Lyon, Berlin) or 51Cr-EDTA (Paris). MS clearance was calculated using a one compartment model with 3 or 4 samples at 120, 180, 240 and 300 min (or longer) after injection and Bröchner-Mortensen correction. The SS PC was calculated using the Jacobsson method based on the preexisting estimated GFR. We studied concordance between both methods within ±10%.

Results: N=5,106 were included into the analysis with PC results based on 3 sampling points (120, 180 and 240 min) for slope calculation. Out of 5,106 indiv 657 had GFR results based on a 300 min (or longer) sampling period. In total 43% were females, mean age (SD) was 54 (±17) yrs, BMI 25.9 (±5.5) kg/sqm, mean GFR 65±26 mL/min (4-195 mL/min). Overall GFR results with SS at 120, 180 and 240 min had a concordance of ±10% with MS of 67, 84 and 91%, respectively. In the 657 individuals, highest concordance was observed with the 300 min sample if GFR <50 ml/min and with 240 min sample if GFR ≥50 ml/min (concordance within 10% was 96%, within 5% was 85%). Smallest concordance was found in individuals with very low GFR, at old age and with extreme BMI.

Conclusions: GFR results obtained from PC measurement with SS showed a high concordance with values from MS technique. This applies all the more if the timing for SS method was adjusted to estimated GFR. In conclusion, we found that in certain circumstances, i.e. epidemiological studies, SS iohexol PC measurement is an acceptable alternative to MS method.



SA-PO430

Prevalence of Hyperkalemia in Medicare Patients Keith Betts,[1] J. Michael Woolley,[2] Fan Mu,[1] Wenxi Tang,[1] Yao Wang,[1] Eric Wu.[1] *[1]Analysis Group, Inc., Los Angeles, CA; [2]ZS Pharma Inc., San Mateo, CA.*

Background: The objective of this study was to estimate the prevalence of hyperkalemia in the Medicare patient population.

Methods: Adults with at least one medical service were selected from the 5% random Medicare sample (01/01/2010-12/31/2014). Patients with at least one calendar year of data with continuous enrollment throughout the year were included. Hyperkalemia was

defined as having at least one diagnosis code of hyperkalemia (ICD-9, 276.7). Prevalence of hyperkalemia for each calendar year (2010-2014) was calculated as the number of patients with hyperkalemia divided by the total number of eligible patients within the year. Additionally, prevalence of hyperkalemia was also estimated among comorbidity subgroups defined by chronic kidney disease (CKD), CKD stage, heart failure (HF) and dialysis. CKD, CKD stage, and HF were identified via ICD-9 codes, and dialysis was identified via procedure codes. Hyperkalemia prevalence standardized to the US elderly population was calculated using hyperkalemia prevalence stratified by age and gender among patients aged 65 and above in the 5% Medicare sample and the corresponding US census population distribution.

Results: A total of 1,964,905 patients were included in the analysis (2010-2014). The prevalence of hyperkalemia in the overall population ranged from 2.6%-2.7% across calendar years. The prevalence of hyperkalemia was 10.8%-12.4% among CKD patients, 8.6%-9.4% among HF patients, 8.9%-9.3% among patients with CKD and/or HF, and 50.2%-52.8% among patients that underwent dialysis. The prevalence of hyperkalemia was 9.4%-11.1% for CKD stage 3 patients, 19.5%-20.7% for CKD stage 4 patients, and 17.8%-20.2% for CKD stage 5 patients. The standardized prevalence of hyperkalemia ranged between 1.0 and 1.1 million (2.5%-2.6%) from 2010-2014 in the US elderly population.

Conclusions: This study estimated that the prevalence of hyperkalemia among Medicare beneficiaries is 2.6%-2.7%. The prevalence of hyperkalemia is much higher among CKD patients, HF patients, CKD and/or HF patients, and patients that underwent dialysis, as compared to the general Medicare population. Annually, approximately 1 million of US population aged 65 and above are estimated to have hyperkalemia.

SA-PO431

Economic Burden of Hyperkalemia in the Medicare System Keith Betts,[1] J. Michael Woolley,[2] Fan Mu,[1] Cheryl Q. Xiang,[1] Akanksha Dua,[1] Eric Wu.[1] *[1]Analysis Group, Inc., Boston, MA; [2]ZS Pharma Inc., San Mateo, CA.*

Background: The objective of this study was to estimate the economic burden associated with hyperkalemia in the Medicare population.

Methods: Adult patients with and without hyperkalemia (cases vs. controls), were selected from the Medicare Claims Database (5% random sample) (1/1/2010-12/31/2014). Hyperkalemia was defined as having at least one diagnosis code of hyperkalemia (ICD-9-CM 276.7). The index date was a randomly selected claim date with hyperkalemia diagnosis for cases and a randomly selected claim date for controls. Continuous enrollment for at least 6 months before the index date (baseline period) and 12 months after the index date (study period) was required. Controls were exactly matched one-to-one to cases on age group, chronic kidney disease (CKD) stage, dialysis and heart failure (HF). 30-day and 1-year resource utilization and total costs (2016 USD) were compared between cases and controls.

Results: A total of 90,814 patients with hyperkalemia were matched to 90,814 patients without hyperkalemia. Cases had higher rates of inpatient admissions (30-day: 0.48 vs. 0.06; 1 year: 1.28 vs. 0.44), outpatient visits (30-day: 3.11 vs. 3.04; 1-year: 30.48 vs. 23.88), emergency department (ED) visits (30-day: 0.27 vs. 0.14; 1-year: 2.01 vs. 1.17) and skilled nursing facility (NF) admissions (30-day: 0.15 vs. 0.02; 1-year: 0.36 vs. 0.11) (all p<0.001). Cases also had more inpatient days (30-day: 3.79 vs. 0.34; 1-year: 10.54 vs. 3.04) and skilled NF days (30-day: 2.46 vs. 0.39; 1-year: 14.78 vs. 4.84) compared to controls (all p<0.001). Cases incurred $7,208 higher 30-day costs ($8,894 vs. $1,685) and $19,348 higher 1-year costs ($34,362 vs. $15,013) than controls (both p<0.001). Among the 41,271 matched pairs of patients with CKD and/or HF, the 30-day and 1-year total cost differences were $7,726 ($9,906 vs. $2,180) and $21,577 ($41,416 vs. $19,839), respectively (both p<0.001).

Conclusions: Patients with hyperkalemia were more likely to have inpatient, ED and skilled NF admissions, and had longer stays in inpatient and skilled NF compared to their matched patients without hyperkalemia. These data indicate that hyperkalemia is associated with a significant economic burden to Medicare.

SA-PO432

Post-Discharge Economic Burden of Hyperkalemia-Related Hospitalizations Keith Betts,[1] J. Michael Woolley,[2] Fan Mu,[1] Sneha S. Kelkar,[1] Cheryl Q. Xiang,[1] Yao Wang,[1] Eric Wu.[1] *[1]Analysis Group, Inc., Boston, MA; [2]ZS Pharma Inc., San Mateo, CA.*

Background: The objective of this study was to estimate healthcare resource use and costs post hyperkalemia-related hospitalization discharge.

Methods: Adults with potassium lab results available were selected from a large US commercial claims database (1/1/2010-12/31/2014). Patients with at least one hospitalization with a hyperkalemia diagnosis (ICD-9 276.7) during the inpatient stay were selected as cases. Patients with at least one hospitalization and with normal potassium lab results (≤5.0 mEq/L), no hyperkalemia diagnoses, and no sodium polystyrene sulfonate prescriptions were selected as controls. The first hyperkalemia-related hospitalization was defined as the index hospitalization for cases and a randomly selected eligible hospitalization was identified as the index hospitalization for controls. Continuous enrollment from 6 months prior to index hospitalization admission (baseline period) to 12 months post discharge (study period) was required. The day after index hospitalization discharge was defined as the index date. Controls were matched 1:1 to cases exactly on age group, chronic kidney disease (CKD) stage, receiving dialysis, heart failure, Renin-Angiotensin-Aldosterone-System inhibitor use, major diagnostic categories, and selected diagnosis-related groups. Resource use and total costs (2016 USD) were compared between cases and controls.

Results: A total of 4,418 matched cases and controls were included in the analysis. Cases had higher rates of inpatient admissions (1.00 vs. 0.41), emergency department visits (1.98 vs. 1.13), and outpatient visits (49.60 vs. 38.93) compared to controls in the 1-year study period (all p<0.001). Cases incurred $33,120 higher 1-year total all-cause costs ($71,322 vs. $38,203), and higher costs within each quarter (Q1: $23,615 vs. $12,041; Q2: $16,466 vs. $9,241; Q3: $16,630 vs. $8,560; Q4: $14,611 vs. $8,361) compared to controls (all p<0.001). Among patients with CKD and/or heart failure, cases had $33,827 higher 1-year total costs than controls ($76,971 vs. $43,143; p<0.001).

Conclusions: The results indicate that hyperkalemia-related hospitalizations are associated with significant economic burden during the 1-year post-discharge period.

SA-PO433

Development of a Predictive Model for Hyperkalemia Keith Betts,[1] J. Michael Woolley,[2] Fan Mu,[1] Iryna Bocharova,[1] Arielle G. Bensimon,[1] Eric Wu.[1] *[1]Analysis Group, Inc., Boston, MA; [2]ZS Pharma Inc., San Mateo, CA.*

Background: The objective of this study was to develop and validate a predictive model for the risk of hyperkalemia (HK) in US adults.

Methods: Adults were selected from a large US commercial claims database (2013-2014) if they were continuously enrolled from 7/1/13-12/31/13 (baseline) and 1/1/14-12/31/14 (follow-up) and had at least one serum potassium (K+) lab result during follow-up. The resulting sample was partitioned into two subsamples to train (60%) and validate (40%) the model. HK was defined as having in 2014: two elevated K+ values (>5.0 mEq/L); or one diagnosis for HK (ICD-9=276.7); or one prescription fill of sodium polystyrene sulfonate. In the training sample, multivariate logistic regression was used to develop a model estimating the 1-year probability of HK as a function of baseline covariates. Receiver operating characteristic (ROC) curve analysis of the validation sample was used to assess the predictive performance of the model.

Results: HK was identified in 4,815 (1.6%) of 295,511 adult patients in the training sample. Some important baseline predictors of HK included: CKD stages 3-5 (e.g., odds ratio [OR] for stage 5 without dialysis= 8.11; 95% CI: 6.51-10.11); each additional year in age (OR=1.028; 1.025-1.030); history of HK (e.g., number of HK-related hospitalizations OR=1.65; 1.20-2.26); type II diabetes (OR=1.65; 1.53-1.77); and use of renin-angiotensin-aldosterone system inhibitors (RAASi, OR=1.38; 1.29-1.47). ROC curve analysis in the validation sample showed good predictive accuracy (area under the curve=0.78). The figure shows the probability of HK for a RAASi patient as a function of CKD stage, age, and history of hyperkalemia.

Conclusions: This study developed a HK prediction model with the most important predictors being CKD stage, age, and history of HK. More frequent K+ monitoring may be warranted for patients at elevated risk.

Probability of Hyperkalemia in RAASi Patient

No History of Hyperkalemia				History of Hyperkalemia		
Age				Age		
50	65	80	CKD	50	65	80
1%	2%	3%	None	6%	8%	12%
3%	4%	6%	Stage 3	14%	19%	26%
7%	10%	14%	Stage 4	27%	36%	46%
9%	12%	18%	Stage 5	33%	43%	53%

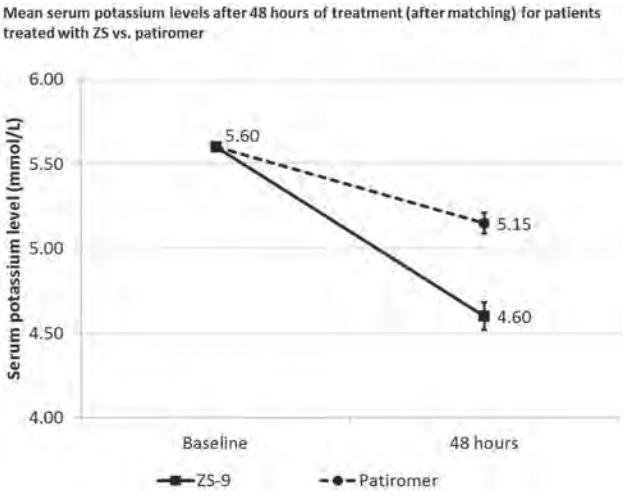
Indirect Comparison of Sodium Zirconium Cyclosilicate versus Patiromer in the Treatment of Hyperkalemia through 48 Hours Keith Betts,[1] J. Michael Woolley,[2] Yan Song,[1] Wei Gao,[1] Eric Wu.[1] *[1]Analysis Group, Inc., Boston, MA; [2]ZS Pharma Inc., San Mateo, CA.*

Background: Two agents have completed phase 3 trials for treatment of hyperkalemia; patiromer which was approved by US FDA in 2015 and sodium zirconium cyclosilicate (ZS) which is an investigational medication. An indirect treatment comparison was conducted to compare efficacy of ZS and patiromer in lowering serum potassium [K^+] after 48 hours of treatment.

Methods: To compare mean [K^+] after 48 hours of treatment, a matching-adjusted indirect comparison (MAIC) was conducted using patient-level data for patients treated with 10g ZS from the ZS-003 and ZS-004 trials and published aggregate data of patiromer from the OPAL-HK trial. Inclusion/exclusion criteria of the OPAL-HK trial were applied to ZS trials to derive a subset of patients comparable to those in the OPAL-HK trial. To adjust for cross-trial differences, patients from ZS trials were reweighted using the method of moments to exactly match baseline characteristics reported in OPAL-HK.

Results: Applying inclusion/exclusion criteria of OPAL-HK, 253 ZS treated and 243 patiromer treated patients were included in the analysis. After matching, all baseline characteristics were balanced between the two treatments. The mean baseline [K^+]of both sets of patients was 5.60 mmol/L, and, after 48 hours of treatment, the mean [K^+] achieved by ZS treated patients was significantly lower than those treated with patiromer (4.60 vs. 5.15 mmol/L; difference = –0.55 mmol/L; p-value <0.01; Figure 1). As a sensitivity analyses, the exclusion criteria were varied and the results remained consistent.

Conclusions: After adjusting for baseline differences, at 48 hours after the initiation of treatment, patients treated with ZS had a statistically significantly lower mean [K^+] than those treated with patiromer.



SA-PO435

Management of Hyperkalemia in Veterans with Advanced CKD Enrica Fung,[1] I-Chun Thomas,[1] Manjula Kurella Tamura.[1,2] *[1]Stanford University, Palo Alto, CA; [2]Veteran Affairs Palo Alto Health Care System, Palo Alto, CA.*

Background: Hyperkalemia is a serious complication among patients with advanced chronic kidney disease. The frequency and success of hyperkalemia management strategies are not well described.

Methods: We assembled a national cohort of veterans with advanced CKD not on dialysis, defined by an outpatient eGFR ≤30 ml/min/1.73m^2 and at least one episode of hyperkalemia (potassium ≥5.5meq/L), using administrative, laboratory and medication data from the Department of Veterans Health Affairs.

Results: Among 76,021 veterans with advanced CKD, 25,227 (33.2%) had at least one episode of hyperkalemia during 5 years of follow-up. The majority of patients (57.3%) were on at least one medication that can potentiate hyperkalemia, and 18.1% were on two or more potentiating medications. Of these patients, 74.1% had drug discontinuation after the hyperkalemic episode, including 59.0% on RAAS blockade. Initiation of potassium lowering medications occurred in 30.6% of patients, with diuretic initiation being most common (23.7%), while 3% of patients received acute dialysis. Recurrence of hyperkalemia within 90 days occurred in 5.5% of the cohort, with those prescribed fludrocortisone, sodium polystyrene sulfonate, and those who discontinued NSAIDs having the highest frequency of recurrence (**Table**).

Conclusions: Among patients with advanced CKD and hyperkalemia, discontinuation of RAAS blockers and initiation of diuretics are the most common strategies employed to manage hyperkalemia. Recurrence of hyperkalemia is infrequent, but may occur more commonly with certain management strategies.

Funding: NIDDK Support, Veterans Affairs Support

SA-PO436

Beta Blockers as the Cause of Hyperkalemia in Near-End Stage Renal Disease Patients: A Cross-Sectional Study Kazuhiro Okamura,[1] Sho Sasaki,[1,2] Masahide Furusho,[1] Makoto Hirakawa.[1] *[1]Iizuka Hospital, Iizuka-city, Japan; [2]Department of Healthcare Epidemiology, Kyoto University Graduate School of Public Health, Kyoto city, Japan. Group/Team: JOINT-KD.*

Background: Although there are several case reports on hyperkalemia caused by beta blockers so far, few studies have verified its causal relationship based on epidemiological methods. The objectives of this study were to assess the association between beta blocker use and risk of hyperkalemia among patients with near end-stage renal failure (ESRD).

Methods: Design and participants: We performed a cross-sectional study at seven Japanese teaching hospitals. Consecutive adult patients with eGFR <15 ml/min/1.73m2 that visited outpatient departments from April 1 to June 30, 2013, were enrolled. Patients with dialysis, post-transplantation, or hospitalization within 30 days were excluded. **Exposure**: We set the usage of beta blockers as the exposure to be tested. **Outcomes**: Serum K^+ concentration was taken as the outcome. **Statistical analysis**: Descriptive analysis was done. Next, multivariate analysis adjusted for age, sex, eGFR, presence of diabetes mellitus, RAAS inhibitor use, K-sparing diuretics use, loop diuretics use, and K absorption drugs use was conducted. In addition, analysis stratified by age (cut off: 75 yo) and RAAS inhibitor use was performed.

Results: Of 517 patients (56.9% male) who were at a median age of 72 (interquartile range, 63 to 80), with median eGFR 11.1 ml/min/1.73m2 (interquartile range, 9.2 to 13.1) included, 239 (46.2%) had diabetes mellitus, 305 (59%) used RAAS inhibitors, and 148 (28.6%) used beta blockers. In the results of the multivariate analysis adjusted for possible confounders, there was no significant difference in the serum K^+ value between the group using the beta blockers and the group not using the beta blockers (+0.07mEq/L, 95% Confidence Interval [CI] -0.067 to - 0.211, p=0.3). An additional analysis stratified for age showed that beta blocker use in participants with an age of 75 yo or older results in significantly higher serum K^+ levels (+0.24 mEq/L, 95%CI 0.012 to 0.470, p= 0.04) compared with participants without beta blockers. Further, the combined use of RAAS inhibitors and beta blockers resulted in higher serum K^+ levels (+0.42mEq/L, 95% CI 0.14 - 0.71, p<0.01) compared with participants who used neither in the subgroup of 75 yo or older.

Conclusions: In patients with near ESRD who were 75 years of age or older, it was suggested that the use of beta blockers may raise the serum K^+ value.

SA-PO437

Medication Discrepancies in Late Stage CKD Jamil Ibrahim,[1] Azzour Hazzan,[1] Vipulbhai Sakhiya,[1] Meng Zhang,[2] Candice Halinski,[1] Steven Fishbane.[1] *[1]Nephrology, Hofstra Northwell Health School of Medicine, Great Neck, NY; [2]Biostatistics, Northwell Health, Manhasset, NY.*

Background: Late stage chronic kidney disease (LS-CKD) is defined by glomerular filtration rate (GFR) 0- 30 ml/min in patients not yet on dialysis. It is a period at high risk for medication discrepancies for multiple reasons. In this study we sought to characterize medication discrepancies in LS-CKD.

Methods: We analyzed patients enrolled in Northwell Health's Healthy Transitions in Late Stage CKD program from its inception in 2011. All patients had eGFR 0-30 ml/min. Medications were reviewed by a nurse care manager at a home visit, at the first program contact with the patient. The patient presented their medication bottles, with careful review for which medications were actually being used and how they were being taken. The patient's medication usage and practice were compared to the nephrologist's electronic health record medication list. We defined high risk discrepancies (HRD) as mismatches in dose or frequency or medications not being taken, excluding laxatives, vitamins and herbals.

Results: All 716 patients were reviewed. The mean age was 67.5±16.5 years, 56% were men, 25% were black, 54% were white, 9% were Hispanic, 51% were diabetic, 93% had hypertension. There were 395 (55.1%) patients with medication discrepancies, 3.2±2.8 (range 1-18) per patient. HRD occurred in 285 patients (39.8% of all patients) *with a total of 553 HRD*. The most common medications for HRD were antibiotics, cardiovascular medications, analgesics and treatments for renal mineral and bone disorder. By univariate analysis, male gender (p=0.02), hypertension (p=0.047) and CHF (p<0.0001) were predictors of HRD. By multivariable logistic regression only CHF remained a significant predictor of HRD, (odds ratio=1.83, 95% CI 1.28 to 2.59, p= 0.0008).

Conclusions: Medication discrepancies are common in LS-CKD. The presence of CHF is a key predictor of high risk discrepancies. Further research should be directed at systems of care to improve medication safety in LS-CKD.

Funding: Other U.S. Government Support

Effect	Odds Ratio Point Estimates	95% Confidence Intervals		P Value
Age	1.003	0.99	1.01	0.58

End-of-Life Care in Advanced Kidney Disease Treated and Not Treated with Maintenance Dialysis Susan P. Wong,[2] Margaret K. Yu,[3] Chuan-fen Liu,[2] Paul L. Hebert,[1] Ann M. O'Hare.[2] *[1]VA HSR&D Puget Sound Healthcare System, Seattle, WA; [2]VA Puget Sound Health Care System, HSR&D, Seattle, WA; [3]Stanford Univerity, Stanford, CA.*

Background: Little is known about the clinical course of patients with chronic kidney disease (CKD) who do not receive maintenance dialysis.

Methods: We followed a national cohort of 28,568 patients receiving care in the US Department of Veterans Affairs (VA) from the date of their second estimated glomerular filtration rate <15 ml/min per 1.73m^2 occurring between 2000-2009 through October 1, 2011. We used a combination of national registry data on dialysis, VA and Medicare files, and medical record review to identify a subset of 18,051 patients who were treated with dialysis, 851 patients in whom there was a decision not to pursue dialysis, and 640 patients

who were preparing for but had not started dialysis during follow-up. We compared survival, hospitalization and receipt of an intensive procedure during the final month of life, in-hospital death, palliative care consultation and hospice enrollment during follow-up across treatment groups.

Results: Median survival was 47.4 months for patients who received dialysis, 6.3 months for those who did not pursue dialysis (HR 2.17, 95% CI 2.94-3.42) and 10.7 months for those who were preparing for dialysis (HR 2.39, 95% CI 2.19-2.62). Hospitalization (57.3% vs. 76.8%; OR 0.40, 95% CI 0.34-0.46), receipt of an intensive procedure (3.5% vs. 24.6%; OR 0.15, 95% CI 0.10-0.22) and in-hospital death (41.4% vs. 57.3%; OR 0.78, 95% CI 0.74-0.82) were less common and palliative care consultation (52.6% vs. 21.6%; OR 4.19, 95% CI 3.58-4.90) and hospice enrollment (38.7% vs. 18.2%; OR 3.32, 95% CI 2.83-3.89) more common among patients who did not pursue dialysis than in those who received dialysis. For patients who were preparing for dialysis, hospitalization, receipt of an intensive procedure, and in-hospital death were less common but palliative care consultation and hospice referral similar as compared with patients treated with dialysis.

Conclusions: Patients with advanced CKD not treated with dialysis had more limited survival and received less intensive end-of-life care than those treated with dialysis.

Ethnic Differences in Mortality among Veterans with Kidney Disease: A 13-Year National Longitudinal Cohort Study Mukoso N. Ozieh,[2,4] Mulugeta Gebregziabher,[1,6] Ralph Ward,[6] David J. Taber,[1,6] Leonard Egede.[3,5]
[1]Medical University of South Carolina, Charleston, SC; [2]Nephrology, Medical College of Wisconsin, Milwaukee, WI; [3]Internal Medicine, Medical College of Wisconsin, Milwaukee, WI; [4]Nephrology, Zablocki VAMC, Milwaukee, WI; [5]Center for Patient Care and Outcomes Research (PCOR), Medical College of Wisconsin, Milwaukee, WI; [6]Health Equity and Rural Outreach Innovation Center, Ralph H. Johnson VAMC, Charleston, WI.

Background: To assess the association between ethnic differences and mortality among Veterans with chronic kidney disease (CKD) over a 13-year period.

Methods: We examined all-cause mortality among Veterans with CKD from Jan 2000 to Dec 2012, including 3,015,318 Veterans using a unique algorithm to identify CKD; which was defined as estimated glomerular filtration rate (eGFR) of >60ml/min/1.73m^2 and presence of proteinuria for >3 months for stage 1 and 2 CKD or eGFR <60 ml/min/1.73m^2 for >3 months for stage 3 CKD or higher. Cox proportional hazards models were used to assess the relationship between mortality and racial/ethnic groups, and the models were developed in a sequential fashion. Hazard ratios (HR) and corresponding 95% CI were reported overall. All analyses were performed in SAS 9.4.

Results: The mean age for the cohort was 76.7 ± 11 years, which varied by ethnicity: 70.8 ± 12 years in Non-Hispanic blacks (NHB); 74.5 ± 11.7 years in Hispanics and 78.0 ± 10.3 years in non-Hispanic whites (NHW)]. The unadjusted all-cause mortality rate was 52.0% in NHW, 42.7% in NHB and 41.3% in Hispanics. After adjusting for demographic variables, NHBs and Hispanics had statistically significant lower CKD mortality risk relative to NHW (HR 0.92; 95% CI, 0.91 - 0.92) and (HR: 0.73, 95% CI, 0.72 - 0.74) respectively. In the fully adjusted model (adjusting for CKD stage and comorbidities in addition to other relevant covariates), NHB and Hispanics maintained this survival advantage compared to NHW, [NHB (HR: 0.85, 95% CI, 0.84 - 0.85) and Hispanic (HR: 0.74, 95% CI, 0.73 - 0.74)].

Conclusions: This is the first national longitudinal cohort study among Veterans which uses a robust algorithm to identify CKD. Non-Hispanic blacks and Hispanic Veterans with CKD have a survival advantage relative to NHW after adjusting for demographics, CKD stage and comorbidities.

Treatment of Depression Symptoms Is Associated with Attenuated Risk of All-Cause Mortality among Patients with CKD Delphine S. Tuot,[3] Keith C. Norris,[2] Jennifer J. Gassman,[1] Elaine Ku.[3] *[1]Cleveland Clinic, Cleveland, OH; [2]UCLA, Marina Del Rey, CA; [3]University of California, San Francisco, San Francisco, CA.*

Background: Depression is common, under-recognized, and undertreated among patients with CKD, especially among racial/ethnic minorities. We examined whether the relationship between depressive affect and mortality differs by antidepressant use or race/ethnicity among patients with CKD.

Methods: We assessed the presence of depressive symptoms among Chronic Renal Insufficient Cohort (CRIC) participants, defined by a Beck Depression Inventory II (BDI) score of ≥14 at baseline enrollment. Cox regression was used to associate baseline depressive symptoms with risk of all-cause mortality (before or after ESRD) adjusted for socioeconomic factors, baseline CKD severity, time-updated comorbid conditions including ESRD status, and baseline anti-depressant use. We tested for the presence of interaction between race/ethnicity and depressive symptoms. Confirmatory analyses were performed using long-term follow-up data from the African American Study of Kidney Disease and Hypertension Cohort (AASK).

Results: Among 3725 CRIC participants, 23.3% had a baseline BDI of ≥14 with 17.0% prevalence of anti-depressant use. Crude mortality rate was 3.37/100-person years (PY) during 6.7 years of median follow-up. Baseline BDI ≥14 was associated with higher risk of all-cause mortality, attenuated by antidepressant use (Table). Differences in the relationship between BDI score and mortality were noted by race/ethnicity ($P_{interaction}$= 0.04, Table). Results were consistent among 652 AASK study participants, among whom 30.3% had BDI ≥14 with a crude mortality rate of 6.8/100-PY. Baseline BDI ≥14 in AASK was not associated with greater risk of mortality during 5.1 years of median follow-up (aHR=0.84; 0.61-1.18).

Conclusions: Treatment of depressive symptoms was associated with attenuated risk of mortality among individuals with CKD. Further investigation is needed to better understand differences in mortality risk by depressive symptoms among racial/ethnic subgroups.

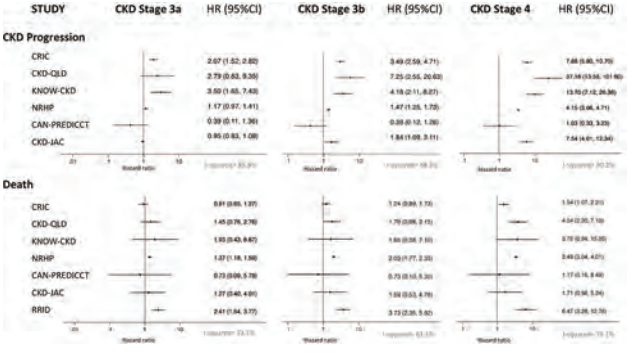
Global Variation in Rates of ESRD and Death among the ISN's International Network of CKD Cohort Studies (iNET-CKD) Paula F. Orlandi,[2] Adam Shardlow,[6] Adeera Levin,[8] Curie Ahn,[7] Helen G. Healy,[5] Kook-Hwan Oh,[7] Laura Sola,[3] Lisa C. Nessel,[11] Maarten W. Taal,[5] Masafumi Fukagawa,[10] Naohiko Fujii,[4] Ognjenka Djurdjev,[1] Pablo Rios,[12] Wei Yang,[11] Wendy E. Hoy,[9] Harold I. Feldman.[11] *[1]BC Renal Agency, Vancouver, AB, Canada; [2]University of Pennsylvania, Philadelphia, PA; [3]CASMU-IAMPP, Montevideo, Uruguay; [4]Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan; [5]None, Philadelphia, PA; [6]Royal Derby Hospital, Derby, United Kingdom; [7]Seoul National University Hospital, Seoul, Republic of Korea; [8]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [9]The University of Queensland, Brisbane, QLD, Australia; [10]Tokai University School of Medicine, Isehara, Japan; [11]University of Pennsylvania, Philadelphia, PA; [12]National Fund of Resources, Montevideo, Uruguay.*

Background: Little is known about the variability in rates of CKD progression and death among CKD populations across the globe. The aim of this study was to assess this variability among cohorts that are members of iNET-CKD.

Methods: Group-level analysis comparing rates of CKD progression and death among 7 iNET-CKD cohorts. A total of 34,466 participants with eGFR < 90 ml/min/1.73m2 were included. Crude incidence rates were calculated overall and stratified by CKD stage. Cox regression models were performed to compare relative rates of CKD progression and death adjusted for age, sex, education, history of diabetes, cardiovascular disease, systolic blood pressure, BMI, smoking status, and proteinuria.

Results: Overall, crude rates (100 p-y) varied from 3.1 (95%CI: 3.0-3.3) to 9.2 (95%CI: 8.6-10.0) (100 p-y) for CKD progression and from 0.8 (95%CI: 0.6-1.1) to 6.0 (95%CI: 5.6-6.6) for death. Rates of CKD progression among participants with CKD stage 4 varied from 0 to 19.2 (95%CI: 17.7-20.8) and for death varied from 1.0 (95%CI:0.7-1.4) to 11.2 (95%CI: 9.9-12.7). The contrast among study rates remained significant after adjustment for baseline characteristics **(figure).**

Conclusions: Crude rates and adjusted relative rates of CKD progression and death vary extensively among iNET-CKD cohorts. Both findings suggest that factors that mediate CKD progression and death vary across countries and represent opportunities for future research.



Adjusted hazard ratios for CKD progression and death across CKD stages for each cohort study (reference group: CKD stage 2)

Body Mass Index, Waist Circumference, and Risk of Kidney Function Decline in a Global Consortium Alex R. Chang. *CKD Prognosis Consortium, Baltimore, MD.*

Background: Limited data exist on the association between body mass index (BMI) or waist circumference (WC) with kidney function decline.

Methods: We performed collaborative meta-analyses to examine the association between BMI and WC with kidney function decline (ESKD or eGFR decline ≥40%) in 26 general population (GP) (n=712748) cohorts, of which 17 (n=238210) cohorts had WC data. Secondary meta-analyses were done in 12 CKD cohorts (n=22587), and in 6 high-risk population cohorts (n=135054). References were set at BMI 25 kg/m^2 and sex-specific WC values of 92 cm (men) and 78 cm (women).

Results: In GP cohorts, mean values for BMI, eGFR, and sex-specific WC were 27.8 (6.3) kg/m^2, 90.1 (22.5) ml/min/1.73m^2, and 92.2 (11.5) cm for men and 84.3 (13.2) cm for women, respectively. Within the 26 cohorts, 26,424 individuals developed kidney function decline over a mean follow-up of 6.9 (4.2) years. In analyses adjusted for age, sex, race, and current smoking, a BMI of 30 kg/m^2 vs. 25 kg/m^2 was associated with a hazard ratio (HR) of 1.20 (95% CI: 1.14-1.26) for kidney function decline **(Figure).** For the same outcome, WHO-recommended cut-points of waist circumference of 102 cm (men) and 88 cm (women) were associated with an HR of 1.15 (95% CI: 0.99-1.34) relative to the sex-specific references. The relationship between BMI and kidney function decline did not significantly differ by age, gender, diabetes, or baseline eGFR category. Associations were attenuated in high-risk and CKD cohorts, and when models were additionally adjusted for baseline diabetes, cardiovascular disease, hypertension, and eGFR.

Conclusions: Elevated BMI and WC are risk factors for ESKD and eGFR decline ≥40% in individuals with normal and reduced eGFR.

Why Select Conservative Management? A Qualitative Study of Patient-Identified Factors and Influences Contributing to Advanced Kidney Disease Patients' Decisions to Choose Non-Dialysis Care Emily Lu,[1] Jeffrey I. Silberzweig,[2] Anna M. Hennon,[3] Nathaniel E. Berman,[2] Ronald D. Adelman,[3] Megan J. Shen,[3] Katherine Lampa,[3] Manney C. Reid.[3] *[1]Nephrology and Hypertension, Weill Cornell Medicine/New York Presbyterian Hospital, New York, NY; [2]The Rogosin Institute, New York, NY; [3]Geriatrics and Palliative Medicine, Weill Cornell Medicine/New York Presbyterian Hospital, New York, NY.*

Background: Conservative management (CM) of advanced chronic kidney disease (CKD) continues to be an area of growing interest. However, in the United States, little is known about why and how patients decide to pursue CM. The purpose of this study is to

better understand why American patients with advanced CKD select CM and to identify factors or influences important to them in this decision-making process.

Methods: Patients with estimated glomerular filtration rate (eGFR) <30 ml/min who had previously made the decision to select CM—non-dialysis care—for their CKD were recruited. Semi-structured interviews of 15 patients were conducted, audiotaped, and transcribed. Data were analyzed inductively using grounded theory to identify common themes in patients' narratives.

Results: Four emerging themes were identified: 1) Choice of CM remains ultimately fluid, provisional, or circumstance-dependent (patients would consider dialysis if specific situation(s) developed, e.g. imminent danger/death, nephrologist recommendation, no longer felt well); 2) Importance of quality of life (negative impact of time required for dialysis, wish to live without restriction/limitation); 3) Currently feeling well (selected CM because does not feel sick); 4) Gaps in knowledge of and/or discussion with nephrologist regarding CKD care options (lack of recollection of discussion or content, difficulty describing anticipated symptoms of CKD progression).

Conclusions: Understanding how advanced CKD patients select CM as a treatment option for their CKD provides insight regarding the values/beliefs, motivations, and concerns they take into account during the decision-making process. Further interviews will be conducted to reach thematic saturation. The identified themes will inform a future longitudinal study of treatment decision-making in advanced CKD.

Polycystic Kidney Disease Is Significantly Associated with Alzheimer Dementia RiskPropensity Score Matched Analysis of a Nationwide, Population-Base Cohort Tung-Min Yu, Ya-Wen Chuang, Misaki Moriishi, Shinichiro Tsuchiya. *Taichung Veterans General Hospital, Taichung ---, Taiwan.*

Background: Data on the risk of neurodegenerative diseases, including Alzheimer disease and Parkinson disease, in patients with polycystic kidney disease (PKD) are lacking.

Methods: A total of 4229 patients who were aged ≥20 years and had received a diagnosis of PKD were included in the PKD cohort. For each PKD case identified, 1 participant aged ≥20 years without a history of PKD, dementia, or PD was selected from the comparison cohort. For each patient with PKD, the corresponding controls were selected 1:1 on the basis of the nearest propensity score calculated using logistic regression.

Results: The incidence density rates of dementia were 4.31 and 2.50 per 1000 person-years in the PKD and control cohorts, respectively. A 2.04-fold higher risk of dementia was observed in patients with PKD than in controls (adjusted hazard ratio [aHR] = 2.04; 95% confidence interval [CI] = 1.46–2.85). Regarding the risk of different dementia subtypes including AD and vascular dementia (VD), the aHR for AD and pre-senile dementia was 2.71 (95% CI = 1.08–6.75) and that for VD was 0.90 (95% CI = 0.43–1.87) in patients with PKD compared with controls, after adjustment for age, sex, and comorbidities. Compared with controls, the risk of PD increased by 1.78-fold (95% CI = 1.14–2.79) in patients with PKD.

Conclusions: In clinical practice, health care professions should be aware of the risk of these neurodegenerative diseases in patients with PKD.
