ASN LEADING THE FIGHT AGAINST KIDNEY DISEASE

Abstract Supplement

October 2017 | Volume 28, Abstract Edition | www.asn-online.org

KIDNEYWEEK 2017

New Orleans, LA • Oct 31 - Nov 5

Abstract Supplement

Abstract Publication
More than 4,400 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 28, 2017: Page(s).

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

Abstract Disclaimer and Copyright

ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week 2017 program, which can be found on the ASN website and in the Kidney Week mobile app, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Comorbid Disease Trends in Hemodialysis and Peritoneal Dialysis Patients Rita L. McGill,[3] Jennifer L. Bragg-Gresham,[2] Kevin He,[2] Eduardo K. Lacson,[1] Dana Miskulin,[1] Rajiv Saran.[2] *[1]Tufts University School of Medicine, Boston, MA; [2]University of Michigan, Ann Arbor, MI; [3]University of Chicago, Chicago, IL.*

Background: The US Renal Data System has collected comorbid conditions data on incident hemodialysis (HD) and peritoneal dialysis (PD) patients since 1995. We evaluated the prevalence of several comorbid conditions over 20 years, and compared trends in both groups.

Methods: All first-time HD and PD patients 1996-2015 were included, and analyzed by year of initiation. Diabetes (DM) and cardiovascular disease (CVD) were condensed into single variables, to align data obtained from the 1995 and 2005 Medical Evidence forms. The proportions of co-morbid conditions were evaluated with logistic regression, treating year of initiation as a continuous variable, stratifying by dialysis type, and adjusting for age, sex, and race. Five year prevalence trends were expressed as odds ratios (OR) and 95% confidence intervals, with OR > 1 representing increasing prevalence.

Results: Among 1,864,386 HD and 157,395 PD patients, the mean age increased by 3 years; PD patients were consistently 5-6 years younger than HD patients. CVD decreased in PD but remained flat in HD. In HD patients, hypertension (HTN), DM and lung disease (COPD) increased and peripheral vascular disease (PVD) decreased. PD patients had a smaller increase in DM, and COPD and PVD decreased, but HTN increased. Stroke and cancer did not change significantly over time. Five-year OR's are shown below.

Conclusions: While HD and PD patients in the United States are both becoming older, and increasingly hypertensive and diabetic, the comorbid disease burdens have been diverging over the past 20 years, resulting in PD patients having less DM, CVD, and COPD than their counterparts receiving HD.

Time trends in Comorbid Diseases over 20 years, for HD and PD Patients

TH-OR002

Racial Disparities in Coronary Artery Bypass Graft Surgery in Maintenance Dialysis Patients Robert Nee,[3,4] Keith C. Norris,[2] Christina M. Yuan,[3,4] Lawrence Agodoa,[1] Kevin C. Abbott.[1] *[1]NIDDK, National Institutes of Health, Bethesda, MD; [2]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [4]Medicine, Uniformed Services University, Bethesda, MD.*

Background: Racial disparities in invasive cardiac procedures such as coronary artery bypass graft (CABG) in the general population are well documented. However, contemporary national-level data on such disparities in the end-stage renal disease (ESRD) population are lacking. Herein we assessed racial differences in the receipt of CABG between Blacks and Whites with ESRD, after the start of maintenance dialysis.

Methods: Using the US Renal Data System database, we identified 281,464 Medicare primary patients initiated on maintenance dialysis from 1 January 2009 through 1 June 2013, and followed until 31 December 2013. We abstracted Medicare hospital claims for CABG among patients who had primary diagnoses of either native coronary atherosclerosis (NCA) or acute myocardial infarction (AMI). We conducted logistic regression analyses, adjusted for demographic characteristics, Hispanic ethnicity, cause of ESRD, comorbidities, socioeconomic factors (insurance type to include Medicare-Medicaid dual eligibility as a proxy measure of individual-level poverty, employment status, and ZIP code-level median household income [MHI] obtained from the 2010 US Census).

Results: 8,004 patients underwent CABG surgery during the study period, of whom 19.4% were Blacks and 74.6% were Whites. Fully adjusted models demonstrated that, among patients with primary diagnoses of NCA or AMI, Blacks were significantly less likely to undergo CABG compared to Whites (odds ratio [OR] 0.76, 95% CI 0.64-0.90, p=0.002). The odds were similar in non-Hispanic Blacks vs. non-Hispanic Whites (OR 0.74, 95% CI 0.62-0.88, p=0.001). There were no significant interactions between race and ZIP code-level MHI (p=0.31), or dual-eligibility status (p=0.60).

Conclusions: Similar to the general population, there exists a racial gap among incident dialysis patients undergoing CABG surgery despite having comprehensive coverage with Medicare. These findings persisted despite accounting for demographic, clinical and socioeconomic factors. *Disclaimer: The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, National Institutes of Health, or the United States government.*

Clinical Effects of Molecular Hydrogen (H2) Delivery during Hemodialysis in Chronic Dialysis Patients: Five Years Prospective Observational Study Masaaki Nakayama,[4] Wan-Jun Zhu,[4] Tae Yamamoto,[2] Mariko Miyazaki,[3] Sadayoshi Ito.[1] *[1]Tohoku Graduate School of Medicine, Sendai Miyagi, Japan; [2]Tohoku University, Sendai, Japan; [3]Tohoku University Hospital, Sendai, Japan; [4]Tohoku University, Tohoku University Hospital, Sendai City, Japan.*

Background: Enhanced oxidative stress and inflammation are supposed to play a crucial role for poor clinical outcomes in patients on chronic hemodialysis (HD) treatment. Recent studies have revealed unique biological characteristics of molecular hydrogen (H_2) as an anti-inflammatory agent. Thus, we developed a novel hemodialysis (E-HD) system which delivers H_2 (30 to 80 ppb)-enriched dialysis solution by water electrolysis technique, and conducted a prospective study (UMIN000004857) to study the clinical impact of E-HD as compared to the conventional-HD (C-HD).

Methods: Prevalent chronic HD patients (n=309, mean HD vintage, 7.8 years; age, 66 years old; male, 57%; history of cardio- and cerebro-vascular disease (CVD), 29%) were registered from 7 HD centers in Japan (from Mar 2011 to Dec 2012), and allocated to either E-HD (n= 161), orC-HD (n=148). They had been treated by the respective HD treatments during the study. Primary end-point was composite of all-cause of mortality, and development of non-lethal CVDs (apoplexy, cardiac diseases, and peripheral artery disease).

Results: During the five-year observation periods (end of Oct 2016), no differences were found in dialysis parameters between the two groups. However, there were uniquechanges in clinical profiles in patients on E-HD, i.e. significant reduction in post-HD systolic BP in those who had remained hypertensive state after HD at baseline, which was accompanied by significant reductions ofprescriptions of anti-hypertensive agents. There were 91 events during the mean observation periods of 3.28 years. The number of primary events were 50 cases in C-HD (17 in death and 29 in CVD: Event Rate; 107.1 /1000 patients-year:95%CI:81.2-141.1), and 41 cases in E-HD (20 in death and 20 in CVD:Event Rate;75.4:55.6-102.2), respectively. Multivariate analysis of Cox proportional hazard model revealed that E-HD was an independent significant factor for the primary event (HR 0.59, 95%CI:0.38-0.92) after adjusting for confounding factors (age, history of CVD, serum albumin, and CRP).

Conclusions: The data indicates E-HD could improve prognosis of chronic HD patients, through the unique BP control effect during HD treatment.

Increased Risk of Premature Cerebral Small Vessel Diseases in Dialysis Patients: A Cross-Sectional Controlled Study Ke Zheng, Haiyun Wang. *Peking Union Medical College Hospital, Beijing, China.*

Background: Growing evidence suggests a higher prevalence of cerebrovascular diseases in patients with end-stage renal disease and undergoing dialysis. As an important cause of stroke, dementia or disability, cerebral small vessel disease (CSVD) has been recognized recently. However, discovery of CVSD needs brain resonance imaging (MRI) scan. There were only small sample size non-controlled study in this field. These limited us to get a further understanding of CSVD in dialysis population. By now, a comprehensive controlled assessment of CSVD in a dialysis cohort of large sample size is lacking.

Methods: In this cross-sectional controlled study, we enrolled a total of 179 dialysis patients (116 in hemodialysis (HD) and 63 in peritoneal dialysis (PD)) and 351 matched non-chronic kidney disease (CKD) controls. We collected detailed clinical characteristics and all participants underwent brain MRI. We assessed and compared the presence and location of CSVD in the dialysis patients and controls, including lacunes, microbleeds, and white matter hyperintensities (WMH). We used univariable and multivariable logistic regression to investigate the risk factors.

Results: Prevalence of the CSVD lesions were significantly higher in the dialysis patients compared with non-CKD controls (OR: 1.86 (95% CI 1.23–2.81) in lacunes; 3.61 (95% CI2.32–5.61) in microbleeds; 1.92 (95% CI 1.31–2.82) in WMH). In dialysis patients, the majority of lacunes were detected in the subcortical white matter and basal ganglia, while the majority of the microbleeds were found in the lobes and basal ganglia. After adjusting age, dialysis vintage, hypertension, diabetes mellitus (DM), hyperlipidemia, smoking and drinking habits, significantly increased risk was observed in the dialysis patients for microbleeds (OR 2.82, 95% CI1.70-4.65) and WMH with total Fazekas larger than two (OR 2.04,95% CI1.25-3.34). Finally, the age of lesion detection was significantly smaller in dialysis patients ((p=0.017, 0.004 and 0.020 for lacunes, microbleeds and WMH). In our dialysis cohort, these was no significant differences in all three types of CSVD lesions between HD and PD modality.

Conclusions: Patients on dialysis were associated with significantly increased risk of CSVD comparing with controls, they also demonstrated a tendency premature CSVD.

Intradialytic Hypertension Frequency and Short-Term Clinical Outcomes among Hemodialysis Patients Magdalene M. Assimon, Jennifer E. Flythe. *University of North Carolina, Chapel Hill, NC.*

Background: Intradialytic hypertension (ID-HTN) occurs in 5-20% of hemodialysis treatments. Observational data support an association between ID-HTN and increased long-term mortality. However, the short-term cardiovascular (CV) consequences of recurrent ID-HTN are unknown.

Methods: Data were taken from a cohort of prevalent hemodialysis patients receiving treatment at a large U.S. dialysis organization on 01/01/2010. Using a retrospective cohort design with a 180-day baseline, 30-day exposure assessment and 30-day follow-up period, we estimated the association between ID-HTN frequency and: 1) 30-day mortality and 2) 30-day hospitalizations. We defined ID-HTN frequency during the 30-day exposure period as the proportion of hemodialysis treatments with a pre- to post-dialysis systolic blood pressure (BP) rise >0 mmHg. Multivariable Cox proportional hazards models, adjusting for numerous clinical, laboratory and dialysis treatment covariates, were used to estimate adjusted hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Of 37,094 study patients, 5,242 (14%), 17,965 (48%), 10,821 (29%), 3,066 (8%) had ID-HTN in 0%, 1-32%, 33-66% and ≥67% of exposure period treatments, respectively. More frequent ID-HTN was associated with incremental increases in 30-day mortality and volume overload hospitalizations (**Figure**). Patients with ID-HTN in ≥67% (vs. 0%) of exposure period treatments had the highest risk of all-cause death, adjusted HR [95% CI]: 2.6 [1.7-3.9]; CV death, 3.7 [1.9-7.1]; and volume overload hospitalizations, 2.3 [1.3-4.2]. Analogous incremental associations were observed for all-cause and CV hospitalizations. In sensitivity analyses, use of alternative BP thresholds (≥5 and ≥10 mmHg) to define ID-HTN yielded similar results (data not shown).

Conclusions: Among prevalent hemodialysis patients, ID-HTN frequency is incrementally associated with short-term morbidity and mortality. Randomized trials are needed to determine if ID-HTN frequency mitigation improves patient outcomes.

Pre ESRD Coronary Artery Revascularization and Post ESRD Mortality Abduzhappar Gaipov,[4] Miklos Z. Molnar,[4] Praveen Kumar Potukuchi,[4] Keiichi Sumida,[2] Robert B. Canada,[4] Oguz Akbilgic,[4] Kairat Kabulbayev,[1] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[4] *[1]Kazakh national medical university, Almaty, Kazakhstan; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]University of California Irvine, School of Medicine, Orange, CA; [4]University of Tennessee Health Science Center, Memphis, TN.*

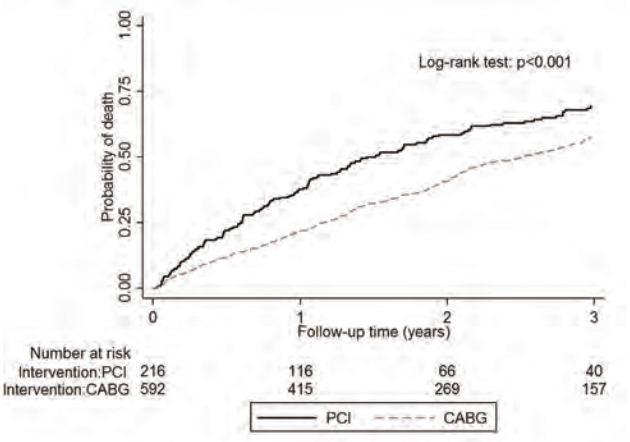
Background: Coronary artery bypass grafting (CABG) is associated with better survival than percutaneous coronary intervention (PCI) in patients with mild-to-moderate CKD and ESRD. However, the optimal strategy for coronary artery revascularization in advanced CKD patients who transition to ESRD is unclear.

Methods: We examined a contemporary national cohort of 815 US veterans with incident ESRD, who underwent first CABG or PCI up to 5 years prior to dialysis initiation. We examined the association of CABG versus PCI with all-cause mortality following transition to dialysis, using Cox proportional hazards models adjusted for time to dialysis start, sociodemographics, comorbidities and medications.

Results: 596 patients underwent CABG and 219 patients underwent PCI. The mean age was 66±8 years, 99% of patients were male, 78% were white, 20% were African Americans, and 84% were diabetic. The all-cause post-dialysis mortality rates after CABG and PCI were 301/1000 patient-years (PY) [95% CI=271–333] and 436/1000PY [95% CI=371–512], respectively. Mortality was lower after CABG (Figure). The multivariable adjusted hazard ratio of all-cause mortality in patients who underwent CABG compared to PCI was 0.72 (95% CI=0.58–0.89, p=0.003).

Conclusions: In patients with advanced CKD CABG is associated with lower risk of post-ESRD death compared to PCI.

Funding: NIDDK Support



TH-OR007

Association of Peridialytic Systolic Blood Pressure Change and Pre-Dialysis Systolic Blood Pressures on Mortality among Hemodialysis Patients Hanjie Zhang,[6] Priscila Preciado,[7] Yuedong Wang,[2] Anna Meyring-Wosten,[6] Alice Topping,[6] Jochen G. Raimann,[6] Jeroen Kooman,[4] Frank van der Sande,[5] Len A. Usvyat,[3] Dugan Maddux,[3] Franklin W. Maddux,[1] Peter Kotanko.[6] *[1]Fresenius Medical Care, Waltham, MA; [2]University of California - Santa Barbara, Santa Barbara, CA; [3]Fresenius Medical Care North America, Melrose, MA; [4]Maastricht University Medical Centre, Maastricht, Netherlands; [5]Maastricht University Medical Centre, Maastricht, Netherlands; [6]Renal Research Institute, New York, NY; [7]Renal Research Institute, New York, NY.*

Background: Pre-dialysis systolic blood pressure (pre-SBP) and peridialytic SBP change (ΔSBP) had been associated with mortality in former studies, but the nature of this interaction is still not fully explained.

Methods: Pre-SBP and ΔSBP (post-HD – pre-HD) were analyzed between 1/2001 and 12/2012 in HD patients treated in Fresenius Medical Care (FMC) facilities. Baseline was defined as months 4-6 in the first year of HD, the primary outcome was all-cause mortality. Censoring events were renal transplantation, modality change, or study end. Only patients who survived the baseline and had no missing covariates were included. We fitted Cox proportional hazard model with a bivariate spline for the primary predictors, pre-SBP and ΔSBP, with adjustment for age, gender, race, diabetes, access-type, relative interdialytic weight gain (IDWG), body mass index (BMI) and albumin, enPCR, and ultrafiltration rate (≥13 or <13 mL/kg body weight/hour).

Results: A total of 191 491 patients were included. We found that a peridialytic SBP increase in the presence of high pre-SBP was associated with an increased mortality, while in patients with low pre-SBP a peridialytic SBP increase was associated with better survival **(Fig. 1)**.

Conclusions: We showed association of pre-SBP and peridialytic SBP changes with all-cause mortality in a large and diverse HD population. Patients with low pre-SBP may benefit from an increase in peridialytic SBP, while an increase in SBP may be detrimental in patients with a high pre-SBP.

Funding: Commercial Support - Fresenius Medical Care

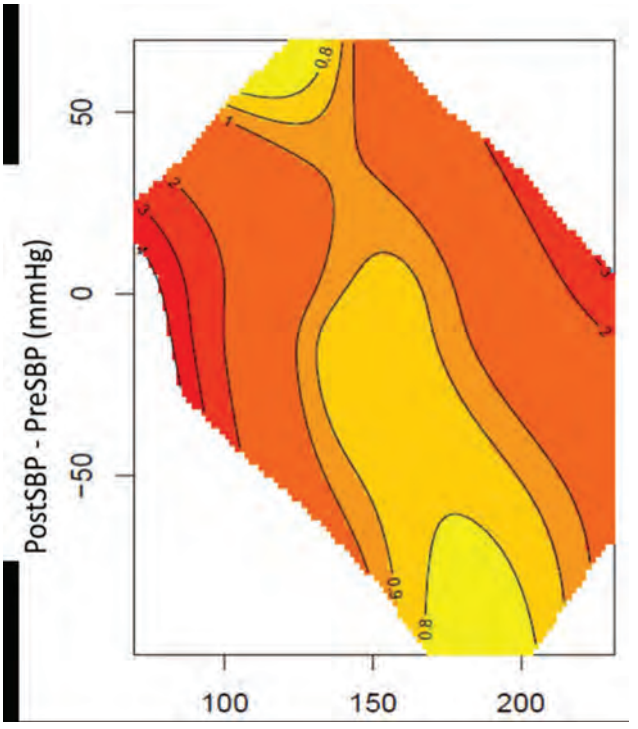


Figure 1: Contour plot showing the relationship between pre-SBP, ΔSBP and hazard ratios (HR) for all-cause mortality. Contour lines indicate discrete HR levels.

TH-OR008

Individualized Cool Dialysate as an Effective Therapy for Intradialytic Hypotension Alexander Bullen,[2,1] Dena E. Rifkin,[2,1] Danuta Trzebinska.[3] *[1]La Jolla, CA; [2]UCSD, San Diego, CA; [3]UCSD Medical Center, SAN DIEGO, CA.*

Background: Intradialytic hypotension (IDH) is the most common dialytic complication identified in 15-20% of all dialysis encounters. Cool dialysate by promoting peripheral vasocontriction leads to decreased IDH and may be an effective approach to reduce IDH. However, only small studies have been done to date using a cool dialysate and they have not typically used an individualized cool dialysate temperature. Therefore, we designed a study to determine if cool dialysate would decrease the number of episodes of IDH in a high-comorbidity dialysis population served within our hospital.

Methods: We conducted a single center study at the UCSD dialysis unit. Baseline characteristics were obtained from the electronic medical record including age, race, and co-morbidities. The study consisted of baseline and intervention phases, with patients serving as their own controls. In the first phase, core baseline temperature (CBT) was determined as an average of oral temperature prior to three sessions of hemodialysis. During this phase hemodynamic parameters during dialysis were recorded for 6 HD sessions. In the second phase, the CBT was then decreased by 0.5 degrees Celsius and hemodynamic parameters were then collected again for 6 more HD sessions. Parameters during the control phase and cool phase were compared.

Results: 93 participants with mean age was 56.7±1.5 were included. 53% were women, and 53.8% were Hispanic. The average years on HD were 4.7±0.5 years. The number of IDH episodes between the control and the cool phase, decreased significantly (P<0.001) from 3.27±0.29 per patient to 1.96±0.23. The lowest recorded intradialytic MAP increased from 78.22±1.60 mmHg to 85.60±1.20 mmHg, the mean increase was of 4.75±2.12 (P=0.028). No correlation was found between a change in UF and improved hemodynamics (P=0.22). Adequacy of HD (Kt/v) did not change significantly (P=0.75).

Conclusions: Individualized cool dialysate is an effective and easy to implement method to decrease intradialytic hypotension and it may ameliorate clinical symptoms and ease nursing burden in patients with frequent IDH.

Ratio of Early Mitral Inflow Velocity to Global Diastolic Strain Rate and Global Left Ventricular Longitudinal Systolic Strain Predicts Overall Mortality and Cardiovascular Events in Hemodialysis Jiun-Chi Huang,[1,2] Szu-Chia Chen,[1,2] Jer-Ming Chang.[2,3] *[1]Department of Internal Medicine, Kaohsiung Municipal Hsiao-Kang Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Department of Internal Medicine, Kaohsiung Municipal Cijin Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, Kaohsiung, Taiwan.*

Background: The associations between the ratio of early mitral inflow velocity (E) to global diastolic strain rate (E'sr) and global left ventricular longitudinal systolic strain (GLS) obtained from two-dimensional speckle-tracking echocardiography with cardiovascular (CV) outcomes remain unclear in patients undergoing hemodialysis (HD). This study aimed to examine the ability of E/E'sr ratio and GLS to predict overall mortality and CV events in maintenance HD patients.

Methods: Echocardiography was performed in 190 HD patients. E'sr and GLS were measured from three standard apical views using the index beat method. CV events were defined as CV death, non-fatal stroke, coronary artery disease, peripheral artery disease and heart failure.

Results: During the mean follow-up period of 2.7 years, 28 patients died and 28 CV events were recorded. After multivariate adjustment, the E/E'sr ratio (hazard ratio [HR]: 1.561; 95% confidence interval [CI], 1.221–1.995) and GLS (HR: 1.229; 95% CI, 1.061–1.423) were associated with overall mortality. Furthermore, the E/E'sr ratio (HR: 1.233; 95% CI, 1.001–1.518) and GLS (HR: 1.299; 95% CI, 1.104–1.529) were both associated with CV events in multivariate analysis. The E/E'sr ratio and GLS had a better predictive ability of overall mortality and CV events than the ratio of E to early diastolic mitral annular velocity (E') and left ventricular ejection fraction (LVEF). Moreover, adding the E/E'sr ratio and GLS to a clinical model with conventional echocardiographic parameters improved the prediction of both mortality ($p = 0.002$) and CV events ($p < 0.001$).

Conclusions: The E/E'sr ratio and GLS are stronger than the E/E' ratio and LVEF in predicting unfavorable outcomes, and may provide additional prognostic value to conventional clinical and echocardiographic parameters in maintenance HD patients.

Predictive values of echocardiographic parameters in relation to overall and cardiovascular events

Parameters	Overall mortality		Cardiovascular events	
	difference in likelihood ratio	p	difference in likelihood ratio	p
Basic model + ABI < 0.9, baPWV, CTR, AoAC	17.667	0.001	21.900	<0.001
Basic model + ABI < 0.9, baPWV, CTR, AoAC + LAVI, LVMI, LVEF, E/E'	16.212	0.003	31.541	<0.001
Basic model + ABI < 0.9, baPWV, CTR, AoAC + LAVI, LVMI, LVEF, E/E' + E/E'sr, GLS	12.195	0.002	97.735	<0.001

p value was based on the incremental value compared with the basic model which was adjusted for demographic, clinical, and biochemical risk factors

TH-OR010

Hemodialysis Induces Decline in Cerebral Blood Flow in Elderly Patients: A Quantitative [15O]H2O-PET-CT Study Harmke A. Polinder-Bos,[3] David Vállez,[3] Johanna J. Kuipers,[4] Jan willem Elting,[3] Marcel Aries,[5] Henk Groen,[3] Wim Krijnen,[2] Antoon Willemsen,[3] Peter Jan van Laar,[3] Fijanne Strijkert,[3] Gert Luurtsema,[3] Riemer hja Slart,[3] Ralf Westerhuis,[1] Ron T. Gansevoort,[3] Carlo A. Gaillard,[3] Casper F. Franssen.[3] *[1]Dialyses Center Groningen, Groningen, Netherlands; [2]Hanze University of Applied Sciences, Groningen, Netherlands; [3]University Medical Center Groningen, Groningen, Netherlands; [4]Dialyse Centrum Groningen, Groningen, Netherlands; [5]Maastricht University Medical Center, Maastricht, Netherlands.*

Background: The transition to hemodialysis (HD) is associated with a decline of cognitive function and an increased incidence of cerebrovascular accidents and white matter lesions. It has been hypothesized that the repetitive circulatory stress of

HD induces ischemic injury to the brain, but the mechanism is unclear. Despite the sophisticated regulation of the brain to keep the cerebral blood flow (CBF) steady, HD might induce a fall in CBF. We evaluated whether a change in CBF occurred during a HD session, measured by [^{15}O]H_2O-PET-CT, which is considered the gold standard for measuring CBF.

Methods: Twelve maintenance HD patients aged ≥65 years, (5 females, 7 males) with a median dialysis vintage of 3.8 years, participated in this observational study. During a single HD session three [^{15}O]H_2O-PET-CT scans were performed: before, early after the start, and at the end of HD. For each PET-CT scan a bolus injection of [^{15}O]H_2O was administered intravenously in the non-dialysis access arm, and arterial blood was continuously sampled from the arteriovenous fistula. Dialysate temperature was 36.5°C. Mixed linear models were used to study global and regional CBF change during HD.

Results: Mean arterial pressure declined non-significantly from 101±11 before HD to 93±17mmHg at the end of HD, whereas pCO_2 remained stable. The PET-CT scan at the end of the HD session showed a significant 10 (±15)% decline in global CBF from a mean of 34.5 to 30.5 ml/100g/min (difference: -4.0 ml/100g/min [-7.3; -0.7], P=0.01). CBF fell significantly in all regions of interest: the frontal, parietal, temporal, and occipital lobes, cerebellum and thalamus. The largest CBF reductions were observed in the thalamus (-5.2 ml/100g/min [-8.8; -1.6], P=0.001) and frontal lobe (-5.1 ml/100g/min [-7.7; -2.5], P<0.0001).

Conclusions: Conventional HD induces a significant reduction in CBF in elderly patients. This finding fits well into the hypothesis that HD induces ischemic injury to the brain, which in the long-term might contribute to cognitive function decline, especially in elderly HD patients.

TH-OR011

New Intravital Imaging Technique Visualizes Renal ATP Dynamics during AKI Predicting Renal Prognosis Shinya Yamamoto,[1] Masamichi Yamamoto,[1,2] Motoko Yanagita.[1] *[1]Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Japan Science and Technology Agency, PRESTO, Tokyo, Japan.*

Background: The kidney constantly produces and consumes adenosin 5' triphosphate (ATP), and mitochondrial dysfunction, which leads to ATP depletion, plays an important role in the pathogenesis of renal diseases. In spite of importance of ATP dynamics, however, lack of technology has hindered further analysis. Here we established a novel ATP intravital imaging technique and analyzed whether the ATP dynamics during acute kidney injury (AKI) could predict the renal prognosis.

Methods: To enable intravital imaging of ATP dynamics, we generated a novel mouse line, which expressed the FRET-based ATP biosensor in all tissues. We visualized renal ATP dynamics at a single cell level in the physiological condition as well as in ischemic reperfusion (IR) model with two-photon microscope. Furthermore, we performed the quantification of fibrosis two weeks after IR, and assessed the correlation between the ATP recovery and fibrosis.

Results: The ATP levels in proximal tubules (PTs) rapidly decreased to the basal level in only 2 minutes after induction of ischemia, whereas the ATP levels in distal tubules (DTs) were maintained even after 30 minutes. The ATP dynamics in PTs after reperfusion was variable depending on the duration of ischemic time. The ATP recovery in PTs after 15, 30, and 60 minute-IR took 2, 5, and 30 minutes to reach a peak plateau, and the % ATP recovery (recovery ATP/ initial ATP levels) were 90%, 83%, and 69%, respectively. The longer ischemic time led to slower and more insufficient ATP recovery in PTs. Interestingly, ATP recovery time and the % ATP recovery in DTs were 4 minutes and 90% even after 60 minute-IR, indicating the tolerance of DTs to ischemia. The longer ischemic led to more significant renal fibrosis in chronic phase, and the fibrosis was inversely well correlated with the ATP recovery slopes in PTs in acute phase.

Conclusions: We, for the first time, succeeded in visualizing the spatiotemporal ATP dynamics in the kidney by generating a novel FRET-based ATP biosensor mice. We demonstrated the rapid reduction of ATP in PTs and the slow reduction in DTs after ischemia. After reperfusion, the rate and sufficiency of ATP recovery were dependent on the severity of injury, and the ATP dynamics in the acute phase might determine the outcome in chronic phase. We also confirmed the tolerance of DTs to ishemia from the point of ATP dynamics.

TH-OR012

Activated CD47 Promotes AKI by Limiting Autophagy Natasha M. Rogers, Barkha Sanganeria, Maryam El-Rashid. *Westmead Institute for Medical Research, Sydney, NSW, Australia.*

Background: Renal ischemia reperfusion injury (IRI) initiates a complex pathophysiological cascade leading to epithelial cell death manifesting as acute kidney injury. Recent studies identify autophagy, the mechanism of intracellular degradation of cytoplasmic constituents, as important in protection against injury. We have reported that the protein thrombospondin-1 (TSP1), and its receptor CD47, are induced in renal IRI, however the mechanism underlying the regulation of renal injury is unknown.

Methods: Age and gender-matched wild-type (WT) and CD47$^{-/-}$ mice were challenged with bilateral renal IRI. All animals underwent analysis of renal function and biomolecular phenotyping. Human and murine WT and CD47$^{-/-}$ renal tubular epithelial cells (rTEC) were studied *in vitro*.

Results: CD47$^{-/-}$ mice were resistant to renal IRI at multiple time-points following reperfusion (24 h, 72 h, 168 h), with significantly decreased urea and creatinine (2.1±0.5 *vs* 0.9±0.3 mg/dl at 24 h, p<0.001), and ameliorated histological changes compared to WT animals. CD47$^{-/-}$ mice demonstrated concurrent upregulation of key autophagy genes, including Atg5, Atg7, Beclin-1, and LC3 at baseline and at all reperfusion time-points. WT mice consistently demonstrated negligible autophagy expression in the kidney. However, p62 expression was not significantly different between WT and CD47$^{-/-}$ mice. rTEC from CD47$^{-/-}$ mice displayed basal upregulation of autophagy genes that was preserved under exogenous stress (hypoxia, FiO_2 1%, or treatment with TSP1, 2.2nM for 24 h), and this correlated with enhanced viability when compared to WT cells. Treatment of WT rTEC with an oligonucleotide to block TSP1-CD47 signalling increased autophagy. Human rTEC similarly demonstrated downregulated autophagy in response to exogenous TSP1, which was mitigated in conjunction with a CD47-blocking antibody. Finally, in a syngeneic mouse kidney transplantation model, treatment with a CD47-blocking antibody improved renal function and decreased histologic damage compared to control mice, and this was associated with increased autophagy.

Conclusions: These data suggest activated CD47 is a proximate promoter of renal IRI through inhibition of autophagy and cell viability, and point to CD47 as a target to restore renal function following injury.

JNK1 Promotes Renal Ischaemia-Reperfusion Injury Keren Grynberg,[1] Elyce Ozols,[1] William R. Mulley,[1] Kate Blease,[2] David J. Nikolic-Paterson,[1] Frank Y. Ma.[1] *[1]Department of Nephrology, Monash Medical Centre, Monash, Victoria, Austria; [2]Celgene, San Diego, CA.*

Background: Tubular activation of the c-Jun amino-terminal kinase (JNK) pathway is prominent in most forms of acute and progressive tubulointerstitial damage, including renal ischaemia/reperfusion (I/R) injury. Both *Jnk1* and *Jnk2* genes are expressed in most cells of the kidney resulting in considerable redundancy. Combined blockade of JNK1/2 is known to be protective in renal I/R injury; however, the relative contribution of each isoform is unknown. The aim of this study is to determine the relative contribution of JNK1 versus JNK2 in renal I/R injury.

Methods: Preferential pharmacological inhibition of JNK1 (CC90001) was compared to mice with global deletion of *Jnk1* or *Jnk2* and mice with combined global Jnk2 deletion plus Jnk1 deletion in proximal tubular cells (*Jnk-PT* mice). Bilateral warm renal ischaemia injury was induced with vascular clamps and animals killed 24hr after reperfusion. Controls were sham operated. Sprague-Dawley rats (n=8-10/group) were treated 3 times with CC-90001 (10mg/kg) or vehicle starting 1 hour prior to surgery. Renal I/R injury studies were also performed in *Jnk1-/-* (n=10), *Jnk2-/-* (n=8), *Jnk PT* (n=8) and wild type (WT) mice (n=10).

Results: Treatment with CC-90001 provided significant protection in rat I/R injury (8±0.5 vs 20±2 fold increase in serum creatinine (sCR), drug versus vehicle, respectively; P<0.001). In a separate study, *Jnk1-/-* mice also showed significant protection from I/R injury compared to WT mice (4±0.5 vs 8±1 fold increase in sCr respectively; p=0.01); however, this was not replicated in *Jnk2-/-* mice (16±0.5 vs 15±2 fold increase in sCr, *Jnk2-/-* versus WT, respectively; p=NS). *Jnk-PT* mice exposed to renal I/R injury showed significant protection from injury compared to WT mice (5.5±0.7 vs 15±2 fold increase in sCr respectively p<0.01). CC-90001 treatment reduced tubular damage and macrophage infiltration. This protection was replicated in *Jnk1-/-* and *Jnk-PT* mice.

Conclusions: Using complementary approaches, we have established that JNK1 in the proximal tubule is crucial for renal IR injury. Prophylactic JNK1 inhibition may have clinical utility in anticipated renal IR injury.

TH-OR014

A Snapshot of RNA Expression in a Single Segment of the Kidney Reveals Stimulus Specific Responses Katherine Xu,[3] Jacob Stauber,[2] Jonathan M. Barasch.[1] *[1]Columbia Presbyterian, New York, NY; [2]Columbia University, New York, NY; [3]None, East Elmhurst, NY.*

Background: The identification of acute kidney disease at the time of patient encounter remains a central problem in clinical medicine. A single analyte, the serum creatinine (sCr) is currently in use as a surrogate for tubular, vascular, or interstitial cellular damage. Nonetheless the sCr test is not specific to kidney injury, but rather might reflect physiological responses to a the primary disease in a distant organ. In addition, while cellular events occur over minutes or hours, sCr requires 24 hours or more to reach a worrisome clinical threshold or demonstrate further deterioration of tissue function and architecture.

Methods: To examine the cell and stimulus specific responses, we have adapted the method of Gay et al, (2013) to allow cell specific labelling of RNA at the time of our choosing after injury. The technique involves cre driven, cell specific expression of a uracil phosphoribosyltransferase (Uprt) and the subsequent purification of 4-thio-uracil labelled nascent RNAs. We used this technique with Atp6b1v1-Cre and Hoxb7-Cre to perform transcriptional profiling of the new newly synthesized RNA in the cell types in mouse models of iAKI (intrinsic-AKI) and vAKI volume (volume depleted-AKI).

Results: We found hundreds of genes responding in each cell specific and stimulus specific RNA pool. There was almost no overlap between vAKI and iAKI, although they both raise sCr, and limited overlap between Atp6b1v1-Cre and Hoxb7-Cre RNA pools. To validate this technique, we show that collecting duct marker genes are enriched and genes from the other segments of the kidney are deenriched in the tagged RNA. In addition, we validated the technique by independently using a GFP-Hoxb7 mouse and FAC-sorting out the collecting duct cells for gene expression.

Conclusions: Hence, a snapshot of newly synthesized RNA reveals the complexity subsumed by diagnostic classifications dependent on sCr. We suggest that the Uprt technique will allow characterization of each cell type in the nephron at multiple time

points after the onset of injury. These data will replace our current diagnostic strategies with Precision Medicine approach to AKI.

Parabiosis Reveals Renal Resident Leukocytes in Quiescence and AKI Jeremie M. Lever,[1] Ravindra Boddu,[1] Oreoluwa O. Adedoyin,[1] Zhengqin Yang,[1] Lingling Guo,[1] Amie Traylor,[1] Reny Joseph,[1] James F. George,[1] Anupam Agarwal.[1,2] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]VA Medical Center, Birmingham, AL.*

Background: Inflammation drives damage and promotes tissue regeneration in AKI, but the origin of inflammatory cells found in renal tissue (infiltrative versus tissue-resident) has remained elusive. In this study, we developed a novel model of AKI in parabiosis chimeras to study exchange of inflammatory cells with the circulation. Our goal was to discern which renal leukocyte populations are tissue-resident and how this may change in the setting of injury-induced inflammation.

Methods: Parabiosis was established between C57BL/6J adult congenic mice with differing CD45 allotypes, allowing identification of cells from each individual. After 28d, chimeras were subject to 30m of renal ischemia-reperfusion injury (IRI) or sham surgery and harvested at 24 and 72h. Kidney, peripheral blood, and spleen were analyzed by multicolor flow cytometry.

Results: After 28d of parabiosis, chimerism for intrarenal neutrophils was 24.2% (95% CI, 14.2 to 34.2). In contrast, F4/80^{Hi}CD11b^{Low}CX3CR1^{Hi}CD11c^{+} macrophages, CD3^{+}CD4^{-}CD8^{-} T lymphocytes, and NK1.1^{+}CD3^{+} NKT cells in the kidney demonstrated low exchange with the blood, with chimerism equal to 2.4% (95% CI, 1.0 to 3.8%; p = 0.002 compared with blood), 2.3% (95% CI, 0.6 to 4.1%; p = 0.02), and 2.3% (95% CI, 0.7 to 3.9%; p = 0.002), respectively in uninjured kidneys. In injured kidneys, a trend toward chimeric CD45.1^{+} leukocyte infiltration was observed relative to sham control ($6.6 \times 10^5 \pm 1.1 \times 10^4$ vs $1.8 \times 10^5 \pm 8.4 \times 10^4$ cells/g tissue, p = 0.10, n = 3 pairs, 24h after injury). However, absolute numbers of chimeric F4/80^{Hi}CD11b^{Low}CX3CR1^{Hi}CD11c^{+} macrophages were not different, indicating bone marrow precursors from the peripheral blood do not supplement expansion of this population, *even* in the setting of acute inflammation.

Conclusions: Certain renal leukocyte populations exhibit low or no exchange with the peripheral blood, indicating they are long-lived or undergo self-renewal *in situ*. Kidney resident macrophages do not appear to be supplemented by infiltrating cells during acute inflammation. These findings may be important in targeting inflammation after AKI with small molecule drugs or development of cell-based therapeutics.

Endothelial Marker Expressing Stromal Cells Are Important Regulators of Recovery from AKI Katherine V. Maringer,[3] Elina Mukherjee,[2] Sunder Sims-Lucas.[1] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]None, Pittsburgh, PA; [3]Pediatric Nephrology, University of Pittsburgh, Pittsburgh, PA.*

Background: Acute Kidney Injury (AKI) is characterized by an abrupt decrease in renal function that can lead to renal failure, contributing to morbidity and mortality. We have identified a subset of endothelial marker expressing stromal (EMES) cells that contribute to peritubular capillary endothelium. The peritubular capillaries are the primary sites of damage during AKI. We have previously shown that EMES cells are important during the injury phase of AKI. Subsequently, we hypothesize that EMES cells are important contributors to recovery after AKI.

Methods: To determine the importance of EMES following ischemia reperfusion injury (IRI) we utilized lineage tracing, using a TdTomato reporter (labeling all EMES cells) and interrogated the percentage of EMES cells present in IRI and contralateral kidneys. We then interrogated re-expression of stromal genes using RT-PCR. Furthermore, we generated mice with a conditional deletion of Flk1 (Vegfr2, essential for vascular development) in Foxd1cre positive renal stroma (*Flk1*$^{ST-/-}$), and evaluated tissue after blood flow dependent AKI, utilizing (IRI), and blood flow independent/nephrotoxic AKI utilizing cisplatin and focused on the recovery phase (7, or 28 days) post injury.

Results: We determined that EMES cells were upregulated 7 days after IRI contributing to vascular recovery. We next determined following both AKI models that developmental stromal genes were re-expressed, suggestive of stromal de-differentiation, which may drive EMES proliferation. To interrogate the importance of EMES cells after AKI, we used *Flk1*$^{ST-/-}$ animals subjected to IRI or cisplatin, and found mutants had less perfusion and increased HIF1a expression at 7 days in IRI models while cisplatin treatment had no change in perfusion but increased HIF1a. In both models, persistent proximal tubule de-differentiation was observed in mutants. Furthermore, 28 days after injury mutants contained significant fibrosis, and damage compared to controls.

Conclusions: Following AKI the renal stroma requires de-differentiation and re-expression of developmental stromal genes prior to proliferation and re-differentiation. This coupled with EMES cell proliferation, reestablishes normal oxygen concentrations and regulates HIF signaling to modulate repair and recovery from AKI.

Kidney PANX1 Releases ATP to Mediate Ischemia-Reperfusion Injury Jakub Jankowski,[1] Heather M. Perry,[1] Liping Huang,[1] Diane L. Rosin,[2] Christopher B. Medina,[3] Brant Isakson,[4] Kodi S. Ravichandran,[3] Mark D. Okusa.[1] *[1]Department of Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA; [3]Department of Microbiology, Immunology, and Cancer Biology, Center for Cell Clearance, University of Virginia, Charlottesville, VA; [4]Robert M. Berne Cardiovascular Research Center, Department of Molecular Physiology and Biological Physics, University of Virginia, Charlotesville, VA.*

Background: Extracellular ATP, a DAMP molecule, is deleterious in a number of kidney disease models. There is little data on its source and impact in AKI. We hypothesize that ATP is released from injured kidney cells by transmembrane pannexin1 (PANX1) channels and mediates ischemia-reperfusion injury (IRI). Earlier we reported that global PANX1 KO mice are protected against kidney IRI. We hypothesize that PANX1 expression on specific cell types in the kidney can contribute to injury by different mechanisms.

Methods: Proximal tubule (PT) and endothelial cell (EC) specific PANX1 KO mice (*PepckCrePanx1*$^{f/f}$ and *VECadCrePanx1*$^{f/f}$, n=7 and 9 respectively) and appropriate controls were subjected to 26m bilateral kidney IRI or sham operation and 24h of reperfusion. To generate bone marrow chimeras global PANX1 KO and control mice (n=18 and 20) were lethally irradiated and $1x10^7$ donor bone marrow cells were administered i.v. and after 9 weeks mice were subjected to IRI. Kidney function and injury were assessed by plasma creatinine (PCr) and stereological quantification of acute tubular necrosis (ATN). Markers of kidney injury were quantified by real-time PCR of whole kidney lysates. Murine proximal tubule cell line (TKPTS) was transfected using CRISPR/Cas9 to create stable PANX1 deficiency. Injury after in vitro hypoxia/reoxygenation (H/R) was assessed by fluorescent ATP release assay and qPCR.

Results: PANX1 KO mice receiving PANX1 KO bone marrow (KO→KO) had lower PCr levels compared to WT→WT group after injury (0.57 vs.1.67; p<0.0001). KO→WT chimeras had increased level of plasma creatinine compared to WT→KO (1.67 vs. 0.38; p<0.0001), suggesting importance of parenchymal PANX1 deficiency in mediating tissue protection. The increase in PCr in WT mice subjected to IRI was attenuated in both PT (1.73 vs. 0.28; p<0.0001) and EC specific PANX1KO (1.3 vs. 0.16; p<0.0001). Histological injury scores were also lower in both PT (28.7% vs 87.8%; p<0.01) and EC PANX1KO (22.5% vs. 89.3%; p<0.001) compared to their respective controls. In TKPTS cells subjected to H/R medium ATP content and *TNFa* expression correlated positively with *Panx1* expression.

Conclusions: These results show that loss of PANX1 from both PT and endothelium protects mouse kidneys from IRI. Targeting parenchymal PANX1 may lead to new therapeutic agents in the treatment of AKI.

TH-OR018

Towards Single Cell RNA-Sequencing of Tubular Epithelium in AKI Haojia Wu,[1] Erinn L. Donnelly,[1] Samantha A. Morris,[2] Benjamin D. Humphreys.[1] *[1]Division of Nephrology, Washington University in St. Louis, Saint Louis, MO; [2]Department of Developmental Biology, Washington University in St Louis, Saint Louis, MO.*

Background: A complete transcriptional atlas of epithelial states and dynamics during AKI and repair is a goal of the Kidney Precision Medicine Project. Here, we apply DropSeq, a microfluidic single cell RNA sequencing (scRNA-seq) technique, to characterize kidney tubule single cell transcriptional signatures. We additionally asked if MeOH fixation allows storage of single cells for subsequent scRNA-seq.

Methods: Mouse kidney was dissociated with Liberase TL and DNase I. Single cells were fixed by methanol and stored in -80°C for 4 days. Rehydrated cells were purified by FACS and DropSeq performed according to Macosko et al. Unsupervised clustering was performed to group the kidney cells into separate clusters based on the biological variations on gene expression. Cell types were annotated with known markers or by comparing to a published tubular cell transcriptional profiling dataset.

Results: High quality DropSeq cDNA libraries (average insert size of 1284bp) was generated from MeOH fixed kidney cells. We sequenced 3130 fixed cells at a depth of 7795 reads/cell, detecting an average of 2283 transcripts and 961 genes per cell. Unbiased clustering revealed 12 separate cell types in kidney. This included six tubular cell types, including proximal tubule (PT), Loop of Henle (LOH), distal tubule, connecting tubule and collecting duct. A majority of the cells (67.7%) expressed proximal tubular markers (Slc34a1 and Lrp2), highlighting the preference of PT cell type dissociation with the current protocol. Reclustering analysis of Slc34a1 expressing cells further revealed 5 separate subtypes within the PT cluster. These included three distinct PT subtypes that correspond to S1, S2 and S3 segments. Interestingly, we identified two distinct PT subtypes co-expressing LOH markers (e.g. Wfdc2 and Jun).

Conclusions: DropSeq can be performed on MeOH fixed mouse kidney cells. This will facilitate future analysis of human kidney, whose availability is unpredictable, and allow generation of biobanks for downstream scRNA-seq analysis. Our approach enriches for tubular cell types, including S1, S2 and S3 segments of the proximal tubule, making it well suited for analysis of acute tubular injury and repair at cellular resolution.

Inhibition of Endothelial PHD2 Protects against Ischemic Kidney Injury through HIF-1 Dependent Suppression of Neutrophilic Inflammation Ganeshkumar Rajendran,[1] Michael P. Schonfeld,[2] Rafael Torosyan,[3] Pinelopi P. Kapitsinou.[3] *[1]KANSAS UNIVERSITY MEDICAL CENTER, KANSAS CITY, KS; [2]KUMC - University of Kansas Medical Center, Kansas City, KS; [3]University of Kansas Medical Center, Kansas City, KS.*

Background: Peritubular endothelial cells (ECs) are major determinants in renal ischemia reperfusion injury (IRI) but the molecular mechanisms remain undefined. Key regulators of hypoxic vascular responses are Hypoxia-Inducible-Factors (HIF)-1 and -2, transcription factors whose activity is inhibited by prolyl-hydroxylase domain proteins 1 to 3 (PHD1 to PHD3), PHD2 being the main oxygen sensor. We previously reported that deficiency of endothelial HIF-2 exacerbated renal IRI, while inactivation of endothelial PHD2 provided renoprotection. Here, we investigated the contribution of HIF1/HIF2 in renoprotection induced by endothelial PHD2 loss.

Methods: EC-specific HIF activation was achieved by crossing Vecadherin (Cdh5)-Cre transgenics to Phd2 floxed mice (*ePHD2*), while the contribution of each HIF isoform was assessed by generating double mutants lacking PHD2 and HIF-2 (*ePHD2HIF2*) or PHD2 and HIF-1 (*ePHD2HIF1*) in ECs. IRI was induced by unilateral renal artery clamping.

Results: Deletion of HIF-1 in endothelial PHD2 deficient background completely reversed the renoprotection conferred by endothelial PHD2 loss as indicated by histological injury scores and *Kim1* mRNA levels in kidney homogenates (Day 3 post IRI, n=8 mice). In contrast, double ePHD2HIF2 mutants had attenuated kidney injury with ~1.7 fold down-regulation in *Kim1* transcript levels compared to controls. CD45 staining showed comparable inflammatory cell infiltration in ePHD2HIF1 injured kidneys with Cre-, while ePHD2HIF2 kidneys had significantly less $CD45^{+ve}$ area than their corresponding controls. Consistently, FACs analysis indicated significant reduction in neutrophils in ePHD2HIF2 kidneys while no difference was detected in ePHD2HIF1 compared to controls. To assess how endothelial PHD2/HIF-1 suppressed post-ischemic inflammation, we examined the expression of EC-adhesion molecules and chemokines known to regulate neutrophil recruitment. We found that *Icam1*, *Tnfa*, *Cxcl1* and *Cxcl2* mRNA levels were significantly reduced in *ePHD2HIF2* post-ischemic kidneys compared to controls, while no differences were noted for ePHD2HIF1 kidneys.

Conclusions: Our data establish that endothelial HIF-1 mediates the renoprotective effects generated by endothelial PHD2 deficiency through suppression of leukocyte recruitment and adhesion to endothelium.

MicroRNA-709 Mediates Acute Tubular Injury by Negatively Regulating the TFAM/Mitochondria Axis Aihua Zhang,[1] Yan Guo,[2] Yue Zhang,[1] Songming Huang,[1] Zhanjun Jia.[1] *[1]Nephrology Departement, Children's Hospital of Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Mitochondrial dysfunction (MtD) plays important roles in the pathogenesis of acute kidney injury (AKI), whereas therapeutic approaches to improve mitochondrial function are still limited. In the present study, we investigated the pathogenic role of miR-709 in mediating mitochondrial impairment and tubular cell death in AKI.

Methods: We used cisplatin-induced AKI mouse model and renal tubular cells to investigate the role of miR-709 in AKI, as well as the mechanisms. The mitochondrial function was determined by the examination of mitochondrial DNA copy number, mitochondrial membrane potential, mitochondrial ROS production, oxygen consumption and the expressions of mitochondrial proteins.

Results: In cisplatin-treated mice, renal miR-709 was significantly upregulated by more than 2 folds. In proximal tubular cells (PTCs), cisplatin led to 6-fold increase of miR-709. Notably, overexpression of miR-709 in mouse PTCs significantly induced MtD and cell apoptosis (>50%), whereas inhibition of miR-709 ameliorated cisplatin-induced MtD and cell apoptosis (about 50%). Further analyses showed that TFAM (mitochondrial transcriptional factor A) is a target gene of miR-709 and that genetic restoration of TFAM blocked the MtD and cell injury induced by cisplatin or miR-709 overexpression. More importantly, miR-709 antagonism with a miR-709 antagomir dramatically attenuated cisplatin-induced kidney injury and MtD in mice. Finally, we verified the overexpression of miR-709 in renal PTCs of 21 patients with AKI of various etiologies (ischemia, nephrotoxins et al), and found a close correlation between the expression of miR-709 and the severity of kidney injury.

Conclusions: These results suggest that miR-709 plays an important role in mediating cisplatin-induced AKI via negative regulation of TFAM and subsequent MtD.

TH-OR021

DNAJ Homolog Subfamily B Member 9 Is a Putative Autoantigen in Fibrillary Glomerulonephritis Nicole K. Andeen, Han-Yin Yang, Dao-Fu Dai, Michael Maccoss, Kelly D. Smith. *University of Washington, Seattle, WA.*

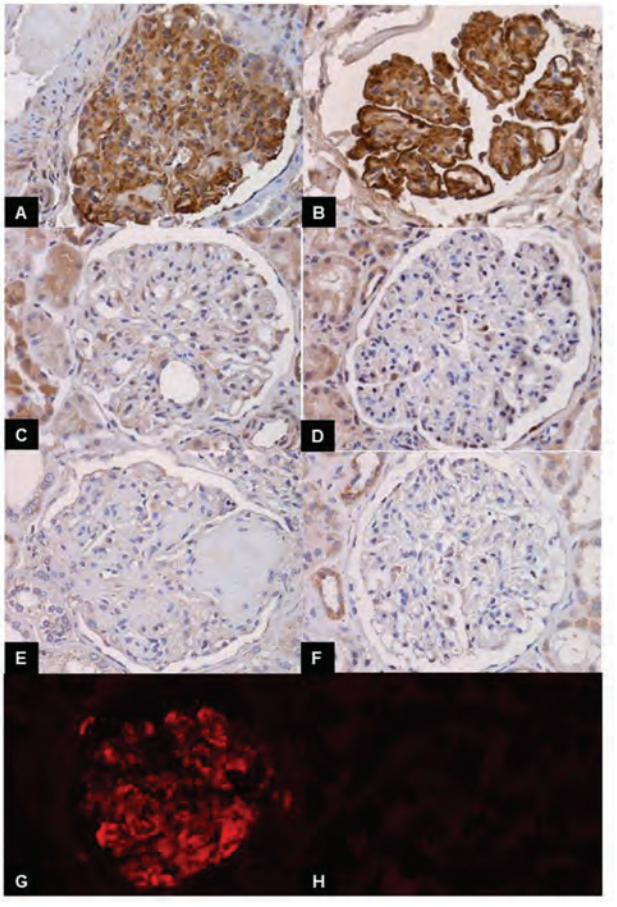
Background: Fibrillary glomerulonephritis (FGN) is a rare form of glomerulonephritis of uncertain pathogenesis, which is characterized by the glomerular accumulations of non-branching, randomly arranged fibrils composed of immunoglobulin and complement proteins. In this study, we utilized mass spectrometry to comprehensively define the glomerular proteome in FGN compared to controls and non-FGN renal diseases.

Methods: Glomeruli from formalin-fixed and paraffin-embedded biopsies were isolated using laser capture microdissection (LCM) and analyzed with liquid chromatography and data-dependent tandem mass spectrometry (LC MS/MS). Findings were correlated with immunohistochemistry (IHC).

Results: These studies identified DNAJ homolog subfamily B member 9 (DNAJB9) as a frequently sampled protein by mass spectrometry in FGN cases that was not detected in other samples. The glomerular proteome of FGN cases also contained IgG1 as the dominant immunoglobulin and proteins of the classical complement pathway. Immunostaining with anti-DNAJB9 demonstrated strong and specific staining of the glomerular tufts in a distribution that mimicked the immune deposits of FGN cases.

Conclusions: Our results identify DNAJB9 as a putative autoantigen in FGN and IgG1 effector pathways as likely mediators for the destructive glomerular injury in FGN.

Funding: Other NIH Support - This work was supported by NIH grants: R21 CA192983, P41 GM103533, and P30 AG013280 (MM), and the University of Washington Department of Pathology (KS, NA).



Anti-DNAJB9 shows strong, discrete peripheral capillary wall and mesangial staining in fibrillary glomerulonephritis (A, B), but not in membranous nephropathy (C), immunotactoid glomerulopathy (D), diabetic glomerulopathy (E), or normal controls (F, H) (IHC). By immunofluorescence microscopy, anti-DNAJB9 shows bright peripheral capillary wall and mesangial staining in fibrillary glomerulonephritis (G), but is negative in normal controls (H).

TH-OR022

Antibody Guided Therapy with Cyclophosphamide and Prednisone in Patients with Membranous Nephropathy Anne-Els van de Logt,[2] Coralien Vink- van Setten,[2] Julia M. Hofstra,[1] Jack F. Wetzels.[2] *[1]Hospital Gelderse Vallei, Ede, Netherlands; [2]Radboud University Medical Center, Nijmegen, Netherlands.*

Background: The discovery of anti-PLA2R antibodies provides options for individualized therapy in patients with membranous nephropathy (MN). We previously showed that monitoring of aPLA2R allowed shortening of the overall duration of cyclophosphamide (Cyc) treatment (van de Logt, Kidney week 2015). Here we present longer-term follow-up data.

Methods: Cyc-therapy (combined with steroids) is started in patients with aPLA2R positive MN and high risk of progression. In our antibody guided cohort aPLA2R are repeatedly monitored (IFT test) at 8, 16, and 24 weeks after start of treatment. If

antibodies become negative, Cyc is stopped and prednisone is tapered. Otherwise, therapy is continued after 24 weeks with MMF and prednisone.

Results: Thus far 46 patients (30 males) are included; mean age was 57 ± 13 years, median creatinine 122 μmol/l (IQR 96-159), mean albumin 21.6 ± 6.8 g/l and protein-creatinine ratio 8.6 ±4.3 g/10 mmol. Follow-up duration was 22 ± 11 months. Time to disappearance of aPLA2R was on average short (median 2.1 month), however ranged from 1.4 to 14.6 months. As a consequence the median duration of treatment was 3.2 (range 1.4 to 16.6) months. Cumulative remission rates (PCR <3.0 g/10 mmol) were 52% and 76% respectively 6 and 12 months after start of therapy, not significantly different from historical controls (40% and 60%). The cumulative incidence of relapses at 12 months after onset of remission was 21% and after 24 months 30% in our cohort (respectively 16 % at 24 months in historical controls, van den Brand JASN 2014).

Conclusions: Overall, this strategy shortens the duration of Cyc therapy, maintaining remission rates. The relapse rate however is increased. Still, 70 % of patients remain in remission beyond two years after start of therapy (Figure 1).

Funding: Government Support - Non-U.S.

TH-OR023

Immunological Remission in PLA2R-Antibody Associated Membranous Nephropathy (MN): Cyclophosphamide versus Rituximab Anne-Els van de Logt,[4] Karine Dahan,[2] Alexandra Rousseau,[1] Hanna Debiec,[3] Pierre M. Ronco,[2] Jack F. Wetzels.[4] *[1]AP-HP, Paris, France; [2]Hospital Tenon, Paris, France; [3]INSERM UMR S702, Paris, France; [4]Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Rituximab (cumulative dose 750 mg/m2) induces remissions in patients with MN (Kahan JASN2017). However, efficacy is limited in patients with high anti-PLA2R (aPLA2R) levels. Cyclophosphamide therapy is effective independent of aPLA2R levels (van de Logt SA-PO 631, kidneyweek 2016). Incidence of partial remissions was higher with Cyclophosphamide vs Rituximab (van de Brand JASN2017). We questioned if differences in the immunological (aPLA2R) response could explain these observations. We therefore evaluated the change in aPLA2R levels during treatment with Cyclophosphamide (1.5mg/kg/day, duration 8-24 weeks; Nijmegen cohort) and Rituximab (the GEMRITUX cohort (rituximab 375 mg/m2 at day 1 and 8).

Methods: We included 30 anti-PLA2R positive patients treated with Cyclophosphamide and 27 patients treated with Rituximab. In stored samples (baseline, and at the end of therapy or after 6 months) aPLA2R were measured with ELISA (Euroimmun®).

Results: In the Cyclophosphamide cohort 19 patients were male, mean age was 56 ± 13 years, median serum creatinine level was 1.3 g/dl (IQR 1.1-1.6) and median protein creatinine ratio 7.7 g/g (IQR 5.5-11.3). In the Rituximab cohort, 21 patients were male, mean age was 51 ± 14 years, median serum creatinine level was 1.1 g/dl (IQR 0.93-1.3) and median protein creatinine ratio 8.4 g/g (IQR 4.4-11.0). aPLA2R disappeared in all but one patient treated with Cyclophosphamide, and in 13 of 27 patients treated with Rituximab. The reponse was associated with baseline titers (table 1). Rituximab did not induce immunological remission in patients in the highest tertile of aPLA2R levels.

Conclusions: Rituximab in a dose of 750mg/m2 is less effective than Cyclophosphamide in inducing an immunological remission in patients with MN and high antibody levels. Our study highlights the potential role of PLA2R antibody measurements in predicting outcome to therapy. Higher doses of Rituximab must be evaluated.

Cumulative percentage samples negative after 24 wk	89 %	56 %	0 %

TH-OR024

Presence of Cellular or Fibrocellular Crescent Is Important for a Long-Term Renal Prognosis in Patients with IgA Nephropathy Followed for 10 Years or Longer on Average Takayuki Fujii, Satoshi Suzuki, Noriko Terasaki, Kaiji Saito, Mizuki Shinozaki, Mayu Morimoto, Tanaka Hiroaki. *Seirei Sakura Citizen Hospital, Sakura-shi Chiba, Japan.*

Background: Regarding the prognosis of patients with IgA nephropathy, the addition of the crescent score: C0 (no crescent), C1 (crescents in more than zero but less than one fourth of glomeurli), and C2 (crescents in one fourth or more of glomeruli), to the conventional factors of the Oxford classification: M, E, S, T score has been proposed (J Am Soc Nephrol 2017). However, the observation period in the above study was relatively short (mean: 4.7 years) and it is unclear whether the C score, which may be modified by treatment, serves as a factor associated with the long-term prognosis of patients followed for more than 10 years on average. We investigated the influence of the C score on the long-term prognosis.

Methods: The subjects were 658 patients with biopsy-proven IgA nephropathy who could be followed up for one year or longer, or reached end stage kidney disease and required renal replacement therapy within one year. A single-center retrospective cohort study was performed involving these patients. Setting the outcome at 50% reduction of eGFR, the influence of the C score on the prognosis was investigated using the Kaplan-Meier method and Cox proportional hazard model. Model A was adjusted with the clinicopathological data including time average proteinuria (TAP) and time average mean blood pressure (TAMAP) during the course, and the M, E, S, and T scores, and model B was adjusted with model A + treatment with or without steroid and RAS inhibitors for analysis.

Results: The mean observation period was 10.9±8.8 years, eGFR at the time of kidney biopsy was 75.8±26.4 mL/min/1.73 m^2, TAP was 0.8±1.2 g/day, C1 and C2 accounted for 18.2% and 1.5%, respectively, and the outcome was reached in 18.0%. On analysis using the Kaplan-Meier method, the outcome was significantly more favorable in the order of C0, C1, and C2 (log-rank $p<0.0001$). Regarding C0 as the reference, HR of C1 or higher was 1.68 (95% CI: 1.04-2.64) in model A and 1.81 (95% CI: 1.11-2.87) in model B, showing that the score was applicable as a prognostic predictor in addition to the Oxford T score, TAP and TAMAP, and eGFR at the time of kidney biopsy.

Conclusions: The C score was important for a long-term renal prognosis even when treatment was included in the analysis.

Prognosis of Henoch-Schönlein Purpura Nephritis among Adult and Elderly Patients: Nationwide Cohort Study Based on the Japan Renal Biopsy Registry Hiroyuki Komatsu,[4] Shouichi Fujimoto,[5] Hitoshi Sugiyama,[2] Hiroshi Sato,[3] Hitoshi Yokoyama.[1] *[1]Kanazawa Medical University, Ishikawa, Japan; [2]Okayama University Graduate School, Okayama, Japan; [3]Tohoku University, Sendai, Japan; [4]University of Miyazaki, Miyazaki, Japan; [5]University of Miyazaki, Miyazaki, Japan. Group/Team: HSPN study group of J-RBR in Japan.*

Background: The clinical presentation and prognosis of adult and elderly patients with Henoch-Schönlein purpura nephritis (HSPN) has not been investigated in detail. We therefore surveyed the features and outcomes of HSPN based on nationwide data from the Japan Renal Biopsy Registry (J-RBR).

Methods: This multi-center cohort study compared the clinico-pathological parameters at diagnosis, initial therapies and outcomes between 106 adult (age 19 - 64 years), and 46 elderly (age ≥ 65 years) patients with HSPN who were registered in the J-RBR between 2007 and 2012. The primary end-points comprised a 50% increase in serum creatinine (sCr) values or end-stage kidney disease. Factors affecting a decrease in renal function were assessed using a Cox proportional hazards model.

Results: The rates of hypertension, impaired renal function, hypoalbuminemia, and crescentic glomerulonephritis were significantly higher among the elderly, compared with the adult patients. About 80% and 60% of the patients in both groups were respectively treated with corticosteroid and renin-angiotensin system (RAS) inhibitors. Both groups had favorable renal survival rates for nine years (93.6% and 91.4% of the adult and elderly patients, respectively). Significantly more elderly than adult patients developed a 50% increase in sCr during a mean observation period of 3.9 years (21.7% vs. 4.7%, $p = 0.012$). In addition, significantly fewer elderly than adult patients achieved clinical remission (24% vs. 46%, $p = 0.016$). Multivariate analysis revealed that advanced age (≥ 65 years) was an independent prognostic factor for a decline in renal function (HR, 6.08; $p = 0.018$).

Conclusions: The renal prognosis of adult and elderly patients with HSPN was favorable when treated aggressively with corticosteroid and RAS inhibitors. However, the course of renal function should be carefully monitored in patients aged over 65 years.

Renal Complications during Pregnancy Before and After Glomerulonephropathy Diagnosis Andrea L. Oliverio,[3,6] Monica L. Reynolds,[5,6] Laura H. Mariani,[3,6] Michelle M. O'Shaughnessy,[2,6] Jarcy Zee,[1,6] Michelle A. Hladunewich.[4,6] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Stanford University Medical Center, Palo Alto, CA; [3]University of Michigan, Ann Arbor, MI; [4]University of Toronto, Toronto, ON, Canada; [5]University of North Carolina, Chapel Hill, NC; [6]CureGN Women's Health Working Group, Bethesda, MD.*

Background: Pregnancy studies in women with glomerulonephropathy (GN) are limited to single centers and small samples. Delineating pregnancy-associated risks would better inform counseling and determine safe management strategies.

Methods: CureGN is an ongoing 64-center prospective cohort study of children and adults with biopsy-proven MCD, FSGS, MN, or IgAN/IgAV. Patient-reported pregnancy outcomes and maternal/fetal complications are collected at each study visit. Descriptive statistics were used to assess complications of pregnancies before and after GN diagnosis. Among pregnancies prior to diagnosis, a generalized estimating equation model was fit to compare time to diagnosis for those with and without pregnancy complications.

Results: As of May 2017, 273 out of 427 adult women enrolled in CureGN reported 585 pregnancies prior to GN diagnosis and 30 after diagnosis, excluding elective terminations. Of pregnancies after GN diagnosis, 13.3% were in women with MCD, 40% FSGS, 13.3% MN, 33.3% IgAN. Of those with pregnancies prior to GN diagnosis, 12.5% reported increasing proteinuria, 5.8% worsening kidney function, 11.7% worsening blood pressure and 88.5% full term delivery compared to 48.1%, 35.7%, 25.9 % and 57.1%, respectively among pregnancies after diagnosis. Women with pregnancy complications prior to diagnosis had a significantly shorter time between pregnancy and subsequent GN diagnosis than those with uncomplicated pregnancies (Figure).

Conclusions: Pregnancies in women with GN diagnosis had high rates of maternal/fetal complications, necessitating high-risk care. Decreased latency between complicated pregnancies and subsequent GN diagnosis suggests that diagnosis may have been missed during pregnancy or that the physiologic stress of pregnancy may have unmasked a smoldering glomerular disease. While currently at 73% of target enrollment, CureGN is projected to be the largest multi-center international cohort poised to study pregnancy outcomes in women with GN.

Similarities between THSD7A and PLA2R Antigens in Autoimmune Membranous Nephropathy (AMN) Samuel Rhoden,[3] Maryline Fresquet,[3] Thomas A. Jowitt,[3] Jennet O. Gummadova,[3] Ian Roberts,[1] Rachel Lennon,[3] Paul E. Brenchley.[2] *[1]John Radcliff Hospital, Headington, United Kingdom; [2]Manchester Royal Infirmary, Manchester, United Kingdom; [3]University of Manchester, Manchester, United Kingdom.*

Background: Patients with AMN either have autoantibodies against PLA2R (75%) or THSD7A (2%). PLA2R and THSD7A proteins share similar structural and biochemical properties. Both proteins are large transmembrane receptors expressed on podocytes with multiple disulfide-bonded and N-glycosylated extracellular domains. We previously described the major epitope within PLA2R but the dominant epitope in THSD7A is still unknown. **Hypothesis:** The major epitope in THSD7A may share shape homology with PLA2R.

Methods: Recombinant full length extracellular domains of THSD7A (FL 180kDa) and a fragment (NT 120kDa) were expressed, purified and used to screen 1400 AMN sera by ELISA for anti-THSD7A. Clinical phenotype on 10 cases was collected. Biopsies were stained for THSD7A and PLA2R. Sera were characterised by western blotting, ELISA and slot blotting on various THSD7A fragments and peptides. The homology model of the PLA2R CysR domain was used to thread the THSD7A epitope peptide.

Results: 22 cases negative for anti-PLA2R were found anti-THSD7A positive (2%). We selected the 10 highest titre sera from the MN group (6F/4M mean age= 64yr). All 10 sera could be inhibited by the THSD7A NT fragment indicating an epitope(s) within this region. Interestingly a short sequence within the NT fragment shares homology with the PLA2R epitope. This short sequence peptide bound antibodies by slot blotting and inhibited binding to the antibodies by ELISA in all patients' sera suggesting a potential epitope in THSD7A. Homology modelling of these two epitopes in PLA2R and THSD7A revealed two regions important for antibody binding.

Conclusions: We describe the first ELISA for anti-THSD7A and report an incidence of 2% positivity in a large cohort of anti-PLA2R negative AMN patients. We identified a specific region on THSD7A with structural homology to the major epitope in PLA2R and show this sequence to be a potential epitope in THSD7A. These results suggest a pathological epitope structure common to autoantigens involved in MN.

TH-OR028

The Microbiota Is a Central Determinant in IgA Nephropathy as Its Modulation Prevents Disease Development Jonathan M. Chemouny,[2,1] Patricia Lepage,[3] Patrick J. Gleeson,[1] Lilia Abbad,[1] Agnes Jamin,[1] Eric Daugas,[2,1] Francois Vrtovsnik,[2,1] Sanae Ben mkaddem,[1] Laureline Berthelot,[1] Marion Leclerc,[3] Renato C. Monteiro.[2,1] *[1]INSERM U1149 & ELR8252 CNRS, Paris, France; [2]AP-HP, Hopital Bichat, Paris, France; [3]INRA, Jouy-en-Josas, France.*

Background: IgA nephropathy (IgAN) is associated with microbiota dysbiosis when compared to healthy individuals (De Angelis et al. PLoS One 2014). Here, we studied the composition of fecal microbiota of IgAN patients compared with non-IgAN glomerular disease (non IgAN-GD). An IgAN mouse model (α1KI-CD89Tg) was used to study the effect of gut microbiota modulation in disease development.

Methods: We collected feces from patients with IgAN and non-IgAN-GD. Fecal microbiota compositions were studied through 16S rRNA pyrosequencing. For the experimental part of the study, 31 four-week old male α1KI-CD89Tg mice were fed an antibiotic mix (ATB) or vehicle twice a week for 8 weeks. Urine samples were collected before the first administration. At the end of experiments, urine, blood samples and kidneys were collected. Proteinuria and creatininuria were measured.

Results: IgAN and non-IgA-GN patients showed significant differences in proportions of the main phylum Firmicutes (p=0.020) and in Lentispherae (p=0.019). As the data suggest an IgAN-linked dysbiosis, we targeted the gut microbiota in a mouse model of IgAN to modulate disease expression. As expected total bacterial load was significantly lesser in the ATB group (p<0.001). Protein/creatinine ratio (PCR) did not rise over the course of 12 weeks in the ATB group (p=0.436) whereas there was a significant increase (p<0.001) in the PCR in the vehicle control group. Markedly less mesangial IgA1 deposits was seen in the ATB group. While no differences were seen in serum human IgA1 levels in the mice, there were significantly fewer lymphoid follicles in Peyer's patches (PP) among ATB treated as compared to vehicle group.

Conclusions: Our data suggest the gut dysbiosis in IgAN patients may be independent of the effect of CKD. Moreover, gut commensal bacteria may have a pathogenic role in IgAN as gut microbiota modulation through the administration of antibiotics prevented disease development in mice. Finally, nephrotoxic IgA1 may originates from the gut mucosa, as despite the presence of PP alterations in ATB group, serum IgA1 levels remained unaffected.

TH-OR029

Ubiquitin Carboxyl-Terminal Hydrolase L1 Is a Podocyte Target of IgG Antibodies in Idiopathic Nephrotic Syndrome (INS) Georges Deschênes,[2] Agnes Jamin,[3] Laureline Berthelot,[4] Renato C. Monteiro.[1] *[1]Bichat Medical School, Paris, France; [2]Hospital Robert Debre, Paris, France; [3]INSERM U1149 & ELR8252 CNRS, 75018 Paris, France; [4]INSERM U699, Paris, France.*

Background: The efficiency of B cell-depleting treatments highlights the involvement of B cells in INS. This study searched for identifying antibodies (Abs) directed against podocytes in patients with INS.

Methods: The study was performed using a biobank including 86 patients sampled at various stages of INS and 76 controls. Fractions of plasma obtained by size exclusion chromatography and tested on cultured podocyte adhesion; specificities of IgG Abs contained in the plasma fraction of interest were studied through immunoprecipitation of a podocyte lysate then identification of cognate antigens by liquid chromatography-mass spectrometry.

Results: Cultured podocyte detachment was observed with one specific plasma fraction in 16/34 INS relapsing patients, 1/11 INS patients in remission and 0/25 controls. IgG were isolated from this specific plasma fraction in 3 INS relapsing patients (all detaching cultured podocytes), 3 from the same INS patients in remission (all not detaching cultured podocytes) and in 3 controls, then used to immunoprecipitate a podocyte lysate. Comparative proteomic analysis allowed selecting 5 proteins according to statistical and biological criteria. Specific Abs were tested and only anti-Ubiquitin Carboxyl-Terminal Hydrolase L1 (UCHL1) IgG led to podocyte detachment. Pre-incubation of either anti-UCHL1 IgG Abs or plasma fractions with recombinant UCHL1 prevented podocyte detachment. Plasma levels of anti-UCHL1 IgG Abs were increased in 18/42 relapsing INS patients over the highest level of 38 controls (median=0.20 AU/*g of total IgG;IQ0.15-0.29;range0.07-0.85). For those 18 patients, the level of anti-UCHL1 IgG Abs in 43 samples available at various stage of INS was confirmed to be significantly higher in relapse (n=23;median=1.22AU/µg of total IgG; IQ 0.92-1.90) compared to remission (n=20;median=0.51;IQ 0.33-0.77;p<0.001). In those 18 INS patients, proteinuria correlated with anti-UCHL1 IgG Abs level (n=43,r=0.57,p<0.001).

Conclusions: UCHL1 is involved in the adhesion of cultured podocytes. UCHL1 is a target of circulating IgG Abs in a subset of relapsing INS patients.

Circulating Serum miR-148b and let-7b Are Inherited in IgA Nephropathy (IgAN) Trios Grazia Serino,[7] Sharon N. Cox,[5,9] Massimiliano Copetti,[3] Luigi Bisceglia,[8] Gianluigi Zaza,[6] Isabella Squarzoni,[1] Martina Ferraresi,[4] Luigi Biancone,[2] Francesco P. Schena.[5,9] *[1]Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy; [2]Department of Medical Science, Turin, Italy; [3]IRCCS, San Giovanni Rotondo, Italy; [4]Nephrology, Dialysis and Transplantation, Turin, Italy; [5]University of Bari, Bari, Italy; [6]University of Verona, Verona, Italy; [7]IRCCS "S. de Bellis", Castellana Grotte (BA), Italy; [8]IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy; [9]Schena Foundation, Valenzano (BA), Italy.*

Background: IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide characterized by aberrant O-glycosylation in the hinge region of IgA1. Our recent work demonstrates that serum levels of the combined miRNA biomarker, let-7b and miR-148b, appears to be a novel, reliable, and non-invasive test to predict the probability of having IgAN (Kidney International, 89, 683-692; 2016). In this study our aim was to evaluate if the serum levels of the combined biomarker are heritable.

Methods: Serum miRNA was extracted using QIAzol Lysis Reagent and miRNeasy Mini Kit (Qiagen) according to the manufacturer's protocol. Using quantitative real-time PCR, we detected the expression of circulating miRNAs (let-7b and miR-148b) in 90 trios that consists of one IgAN patient and their two parents. Heritability was estimated using the approach proposed in Rabe-Hesketh et al. (Biometrics, 64, 280-288, 2008) implemented in R package "gap".

Results: We found that serum levels of the combined biomarker (let-7b and miR-148b) were elevated in the first-degree relatives of IgAN patients compared with healthy blood donors (IgAN 0.31±0.23; IgAN relatives 0.29±0.18; HBD -1.04±0.09). In addition, serum level of the combined biomarker did not differ between IgAN patients and their relatives (p=0.93). The estimated heritability (h2) of the serum biomarkers was 37,54% (95%CI: 13.57%-61,51%; p= 0.001) in crude (unudjasted) model. Age- and gender-adjusted heritability improved at 52.94% (95%CI=22.28%-83.59%, p=0.000356).

Conclusions: These results suggest that serum levels of the combined biomarker are, in part, genetically determined and may constitute a helpful tool for screening of relative at risk for IgAN development.

EXPEDITION-4: Efficacy and Safety of Glecaprevir/Pibrentasvir in Patients with Chronic Hepatitis C Genotype 1-6 Infection by Dialysis Status Csaba P. Kovesdy,[1] Emily Dumas,[9] Alexander Thompson,[2] Yves Horsmans,[3] Hendrik Reynaert,[4] Peter Ghali,[5] Laurent Alric,[6] Dominique Larrey,[7] Giuliano Rizzardini,[8] Caroline Park,[9] Yang Lei,[9] David Pugatch,[9] Federico Mensa,[9] Magdy Elkhashab,[10] Meghan E. Sise.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]St. Vincent's Hospital Melbourne and the University of Melbourne, Fitzroy, NSW, Australia; [3]Université Catholique De Louvain, Louvain-la-Neuve, Brussels, Belgium; [4]University Hospital UZBrussel, Brussels, Belgium; [5]McGill University, Montreal, QC, Canada; [6]CHU Toulouse, Toulouse, France; [7]Hôpital Saint Eloi CHRU Montpellier, Montpellier, France; [8]Ospedale Luigi Sacco, Milan, Italy; [9]AbbVie, Chicago, IL; [10]Toronto Liver Centre, Toronto, ON, Canada.*

Background: Hepatitis C (HCV)-infected patients with late-stage kidney disease have limited treatment options. The ribavirin-free regimen of glecaprevir/pibrentasvir (coformulated as G/P; glecaprevir identified by AbbVie and Enanta) has a renal excretion <1% and has yielded sustained virologic response (SVR) >97% in clinical trials. Here we report efficacy and safety by dialysis status from a Phase 3 study of G/P in HCV genotype (GT) 1-6-infected patients.

Methods: HCV GT1-6 patients with an eGFR <30 mL/min/1.73 m^2, without cirrhosis or with compensated cirrhosis, received G/P (300 mg/120 mg) once daily for 12 weeks. Outcomes were analyzed by predialysis (CKD stages 4-5) and dialysis status.

Results: The trial enrolled 104 patients (predialysis, 19; dialysis, 85): 76% were men, 58% treatment-naïve, 19% cirrhotic, and 52% GT1-infected. The overall SVR12 and SVR24 rates were 98% and 96%, respectively, without virologic failures. The rates of serious AEs were 26% (predialysis) and 24% (dialysis); none was considered G/P-related. In predialysis patients, mean ± SD change in creatinine clearance from baseline to Week 12 was -1.4 ± 3.6 mL/min (median: -1.0 mL/min).

Conclusions: G/P is an all-oral pangenotypic anti-HCV treatment with high efficacy and a favorable safety profile, regardless of patients' dialysis status. AbbVie sponsored the studies, contributed to their design, collection, analysis, and interpretation of the data, and participated in the writing, review, and approval of the abstract. All authors had access to relevant data. This abstract contains information on the investigational products glecaprevir (ABT-493) and pibrentasvir (ABT-530). Medical writing support, was provided by Vojislav Pejovic of Medical Expressions, Chicago, IL, funded by AbbVie.

Intensive Systolic Blood Pressure (SBP) Control and Incident CKD in Persons with and without Diabetes Mellitus (DM) Srini Beddhu,[1] Alfred K. Cheung,[1] Glenn M. Chertow,[2] Paul K. Whelton,[3] R. E. Boucher,[1] Guo Wei,[1] Paul L. Kimmel,[4] William C. Cushman,[5] Tom Greene.[1] *[1]Univ of Utah, SLC, UT; [2]Stanford Univ, Palo Alto, CA; [3]Tulane Univ, New Orleans, LA; [4]NIDDK, Bethesda, MD; [5]VAMC, Memphis, TN.*

Background: In Systolic Blood Pressure Intervention Trial (SPRINT), higher incidence of CKD with intensive SBP control in persons without DM was reported. It is unclear whether intensive SBP control has similar effects in DM.

Methods: SPRINT tested the effects of SBP goal < 120 vs. < 140 mm Hg on CV outcomes in persons without DM whereas Action to Control Cardiovascular Risk in Diabetes (ACCORD) BP trial tested the same in type 2 DM. In separate Cox models, we related the interventions to incident CKD (defined as a >30% decrease in eGFR to a value <60 ml/min/1.73 m^2) in participants without CKD at baseline (N = 6677 in SPRINT; N = 4305 in ACCORD).

Results: Baseline characteristics are summarized. (table) The absolute risks of incident CKD estimated by Kaplan Meier (KM) curves at 3 years of follow-up in standard vs. intensive arms were 1.0 vs. 3.5% in SPRINT and 4.6 vs. 11.5% in ACCORD with an absolute risk increase % (95% CI) at 3-years of 2.5 (1.8 to 3.2) in SPRINT and 6.9 (5.2 to 8.5) in ACCORD. KM failure curves and hazard ratios are presented in the figure.

Conclusions: Intensive SBP control increased the risk of incident CKD in persons with and without DM, however, absolute risk increase is higher in DM. The long-term implications of these findings need to be established.

Funding: NIDDK Support, Other NIH Support - NHLBI

Autologous Hematopoietic Stem Cell Transplantation for Refractory Lupus Nephritis Xiang-hua Huang, Wencui Chen, Weixin Hu, Zhi-Hong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing China, Nanjing, China.*

Background: To evaluate the efficiency and safety of the treatment of autologous hematopoietic stem cell transplantation (ASCT) for patients with refractory lupus nephritis (LN).

Methods: From Jul 2011 to Jan 2015,a total of twenty-two patients with refractory LN relapse or had no response to standard immunosuppressive therapies were enrolled in this study. Peripheral blood stem cells were mobilized with cyclophosphamide (CTX) and granulocyte colony-stimulating factor (G-CSF),and reinfused after treatment with CTX and antithymocyte globulin(ATG). The primary end point was remission rate,and secondary end points included the survival and relapse rate, changes in proteinuria, renal function and serology immunologic test. All the complications were recorded for safety access.

Results: Twenty-two patients were enrolled and underwent stem cell mobilization. They were 9 males and 13 females with a median LN duration of 45.5(33-71) months. The mean number of $CD34^+$ cells was $(7.3 \pm 3.8) \times 10^6$ /kg. All patients had successful engraftment,and the median time of granulocyte and platelet engraftment was 8 and 9 days, respectively. The major complications of ASCT were fever and symptom of gastrointestinal tract. The treatment-related mortality was 4.5% (1/22). After a median follow-up of 53 months,eighteen patients (81.8%) achieved completed remission,one patient (4.5%) achieved partial remission,and one had no response and received peritoneal dialysis at 12 months after ASCT. One patient died for sepsis at 5 month after ASCT. The median time of renal response was 3 months. The 5-years overall survival was 90%. The probability of disease-free survival at 5 years following ASCT was 52.9%. Six patients had relapse during the follow-up and the relapse rate was 27.3%.

Conclusions: Our preliminary data shows that ASCT is a safe and effective treatment of refractory LN, the completed response rate was high and the complications was manageable. Infection is still an important cause of treatment failure, the long-term efficacy still need further observation.

TH-OR034

Influence of Baseline Diastolic Blood Pressure (DBP) Level on the Effects of Intensive Blood Pressure Lowering on Incident CKD in SPRINT Srini Beddhu,[1] Glenn M. Chertow,[2] Alfred K. Cheung,[1] Mahboob Rahman,[3] Tom Greene,[1] Guo Wei,[1] William E. Haley,[4] William C. Cushman,[5] Paul K. Whelton.[6] *[1]Univ Utah, SLC, UT; ; [2]Stanford, Palo Alto, CA; [3]CWRU, Cleveland, OH; [4]Mayo Clinic, Jacksonville, FL; [5]Memphis VA Medical Center, Memphis, TN; [6]Tulane Univ, New Orleans, LA. Group/Team: For SPRINT Research Group.*

Background: Lowering systolic blood pressure (SBP) in persons with low DBP might affect kidney perfusion and thereby, ↑ risk for incident CKD.

Methods: SPRINT tested the effects of SBP goal < 120 vs. < 140 mm Hg on CV outcomes. We tested for effect modification by baseline DBP of the intervention on incident CKD (defined as a >30% decrease in eGFR to a value <60 ml/min/1.73 m^2) in participants without CKD at baseline (N = 6677).

Results: Participants with lower baseline DBP were older, had ↑ prevalence of CV disease and ↓ eGFR (table). There was a U-shaped relation between baseline DBP and incident CKD (Fig Panel A). Within each baseline DBP quintile, participants randomized to the intensive arm had a higher hazard ratio of incident CKD (Fig Panel B). P-value for comparison of hazard ratios in the lowest quintile to the upper 4 quintiles was non-significant (p = 0.79). P-value for the linear treatment by baseline DBP interaction was also non-significant (p = 0.94).

Conclusions: Lower baseline DBP was associated with ↑ risk of incident CKD, but there was no evidence that the effects of intensive SBP lowering on incident CKD differed by baseline DBP.

Funding: NIDDK Support, Other NIH Support - NHLBI

Baseline characteristics by baseline quintiles of DBP in non-CKD subgroup in SPRINT (N=6677)

Variable name	1st quintile <71 (N=1460)	2nd quintile 71-76 (N=1283)	3rd quintile 77-82 (N=1365)	4th quintile 83-89 (N=1356)	5th quintile >89 (N=1251)	P value

Empagliflozin (EMPA) and Incidence of Rapid Decline in eGFR in Patients with Type 2 Diabetes (T2D) and Established Cardiovascular Disease (CVD): An Exploratory Analysis from the EMPA-REG OUTCOME Trial Samy Hadjadj,[1] Merlin C. Thomas,[2] Mark E. Cooper,[2] Audrey Koitka-Weber,[4] Stefan Hantel,[4] Maximilian von Eynatten,[5] Christoph Wanner.[6] *[1]University Hospital Centre, Poitiers, France; [2]Department of Diabetes, Monash University, Melbourne, VIC, Australia; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [6]Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany.*

Background: The eGFR progressively declines in most patients with T2D. In some patients a more rapid decline in eGFR is observed, putting them at risk for the consequences of uremia and ultimately end-stage renal disease. In the EMPA-REG OUTCOME® trial, EMPA was associated with slower progression of kidney disease. In this *post-hoc* analysis, we evaluated the effect of EMPA on the incidence of patients experiencing a more rapid decline in eGFR.

Methods: 7020 patients with T2D and established CVD were randomized (1:1:1) to EMPA 10 mg, 25 mg or placebo (PBO) in addition to standard of care. Change in eGFR decline over the study period (from baseline to follow-up) was calculated by utilizing linear regression models. A rapid decline in eGFR was defined by an annual decline in eGFR ≥5 ml/min/1.73m^2. Logistic regression analysis was used to investigate differences between EMPA vs PBO groups.

Results: At baseline, mean (SD) eGFR was 74.0 (21.4) ml/min/1.73m^2. Over the study period, 354 participants (5.1%) experienced a rapid decline in eGFR, including 8.9% in the PBO group and 3.2% in participants receiving EMPA. After adjusting for other risk factors, this equated to two-thirds reduction in risk (Figure, odds ratio 0.33 [95% CI 0.26, 0.41]; $p<0.0001$) among participants receiving EMPA. A similar reduction among EMPA-treated participants in the incidence of patients experiencing a rapid decline in eGFR was also observed using a lower threshold (Figure).

Conclusions: Patients treated with EMPA were significantly less likely to experience a rapid decline in eGFR over approximately 3 years of treatment. This finding suggests that EMPA may have the potential to reduce the incidence of chronic renal failure in T2D in the long term.

Diffusion MRI for Assessment of Kidney Fibrosis Lena Berchtold,[2] Iris Friedli,[2] Karine Hadaya,[3] Pierre-Yves F. Martin,[1] Jean-Paul Vallée,[2] Sophie M. De Seigneux.[2] *[1]Hospital Universitaire de Geneve, Geneva City, Switzerland; [2]Hôpitaux Universitaire de Genève, Geneva, Switzerland; [3]University Hospital of Geneva, Geneva, Switzerland.*

Background: Renal interstitial fibrosis (IF) is a process common to all kidney diseases and is predictive of renal prognosis. IF can currently only be assessed by biopsy, an invasive procedure associated with complications and focal sampling. There is currently no clinically available noninvasive method to assess IF. Diffusion Magnetic Resonance Imaging (MRI) is emerging as a promising tool to evaluate kidney fibrosis non invasively. The aim of this study was to validate in a mixed CKD population a novel renal MRI diffusion sequence that we recently developed and to create a new non-invasive score for assessment of IF.

Methods: In this prospective study, we included 124 CKD patients having undergone a kidney biopsy (native or transplant). Optimized Diffusion-Weighted Imaging (DWI) and T1 sequences were compared to histological assessment of IF. Differences between cortical and medullary Apparent Diffusion Coefficient (ΔADC) and T1(ΔT1) values were assessed and compared to gold standard histopathology. We then combined routinely measured serum markers and ΔADC to create a new score for assessment of IF.

Results: In CKD patients, ΔADC correlated well with IF ($r=-0.55$, $p<0.001$). This good correlation was observed in both CKD and kidney transplant patients. ΔADC showed a better discrimination to IF than cortical ADC values, T1 values and ΔT1. To optimize fibrosis prediction, we combined ΔADC values to routinely obtained markers

known to correlate to fibrosis (phosphate, hemoglobin, eGFR) to obtain a score of predicted fibrosis. We observed a strong correlation between our score and histological IF($r=0.8$, $p<0.001$). We further built receiver operating characteristic curves and reported area under the curve (AUC) to discriminate between patients with high levels of fibrosis (≥40%). Analysis revealed that the new score was predictive of fibrosis ≥40% with an AUC was 0.99. The sensitivity and specificity to detect IF of more than 40% were 76.2% and 100% respectively, implying that our scoring system is able to identify patients with more than 40% without false positive.

Conclusions: In summary, we validated the use of the ΔADC to predict IF non invasively in CKD and kidney transplant patients. We further derive a scoring system from ΔADC and commonly obtained laboratory values and showed a high specificity to identify non invasively patient harboring extensive fibrosis (≥40%).

A Pilot Pragmatic Randomized Trial of CKD Screening to Improve Care Among Hypertensive Veterans Carmen A. Peralta,[7] Martin J. Frigaard,[1] Anna Rubinsky,[8] Leticia Rolon,[6] Lowell J. Lo,[2] Santhi Voora,[5] Delphine S. Tuot,[8] Neil R. Powe,[3] Michael Shlipak.[4] *[1]Kidney Health Research Collaborative, Oakland, CA; [2]None, San Francisco, CA; [3]Priscilla Chan and Mark Zuckerberg San Francisco General Hospital & University of California SF, San Francisco, CA; [4]San Francisco VA Medical Center, San Francisco, CA; [5]UC San Francisco, San Francisco, CA; [6]UCSF Medical Center, San Francisco, CA; [7]University of California San Francisco/SFVAMC, San Francisco, CA; [8]University of California, San Francisco, San Francisco, CA.*

Background: It is uncertain whether screening for chronic kidney disease (CKD) can improve care of persons at high risk for complications.

Methods: We conducted a 3-arm randomized controlled trial within an integrated primary care clinic at the San Francisco VA (SFVA). The electronic health record (EHR) was used to identify eligible participants (from administrative codes), deliver interventions and ascertain outcomes. Non-diabetic hypertensive veterans without known CKD who receive primary care at SFVA were enrolled and cluster-randomized (41 clusters by provider) to Usual Care (UC), CKD Screening with patient-provider Education (SE) or CKD Screen-Educate plus clinical Pharmacist management (SEP). CKD screening included creatinine, cystatin C and albuminuria and CKD was defined as $eGFR_{creat\text{-}cys}$ <60 ml/min/1.73m^2 or albumin to creatinine ratio ≥30mg/g. Consent was written for providers and opt-out by mail for veterans.

Results: We mailed 2,012 consent letters and 133 veterans opted out. After exclusions, we randomized 1,819 veterans. Of 1,142 veterans randomized to intervention, 525 were identified with an upcoming appointment and had CKD screening ordered, among whom 371 (71%) completed testing. The yield of new CKD cases was 73 (20%, 95% CI 16-24%). Overall, proportions of participants who initiated ACE/ARB by end of study were 4.3% for UC, 6.0% for SE and 6.3%, for SEP. Proportions who initiated diuretics were 3.6% (UC), 4.8% (SE) and 6.0% (SEP). Among participants with screen-detected CKD, proportions who initiated ACE/ARB were 14.6% (SE) and 12.5% (SEP), and proportions who initiated diuretics were 7.3% (SE) and 9.4% (SEP). Differences were not statistically significant (all $p>0.2$). No adverse events were reported by providers.

Conclusions: We successfully implemented an EHR-based pragmatic trial of CKD screening with high rates of participation, and a 20% yield of undetected CKD among those screened. A larger study is required to test whether CKD screening would impact process of care and clinical outcomes.

Ferric Citrate Reduced FGF23 in Patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) and Iron Deficiency Anemia (IDA) Irrespective of the Change in Serum Phosphate (P) Geoffrey A. Block,[3] Pablo E. Pergola,[2] Katrin Uhlig,[1] John F. Neylan,[1] Steven Fishbane,[4] Glenn M. Chertow.[5] *[1]Keryx Biopharmaceuticals, Boston, MA; [2]Renal Associates PA, San Antonio, TX; [3]Denver Nephrology, Denver, CO; [4]Hofstra Northwell Health, Commack, NY; [5]Stanford University School of Medicine, Palo Alto, CA.*

Background: Ferric citrate (FC), an oral iron-based P binder approved for control of serum P in patients (pts) with CKD on dialysis, has also been shown to improve hemoglobin (Hb) and iron parameters in pts with NDD-CKD with IDA. FGF23 is a key phosphate-regulating hormone and known to be elevated in patients with iron deficiency. Here, in a post hoc analysis of a phase 3 study, we examine effects of FC on FGF23 in pts stratified by baseline (BL) P and transferrin saturation (TSAT).

Methods: 233 pts with NDD-CKD and IDA were randomized 1:1 to receive FC (n=117) or placebo (n=116) for 16 wks. FC was initiated at 3 1-g tablets/day and titrated to achieve an increase in Hb ≥1 g/dL from BL (max 12 g/day). The effect of FC on both intact (i) and c-terminal (c)-FGF23 are reported by BL strata of P and TSAT, and the effect of FC on serum P are shown stratified by BL P.

Results: BL levels of iFGF23 and cFGF23 were positively related to BL P. After 16 wks of FC treatment, iFGF23 concentrations significantly decreased in both TSAT strata and across all strata of BL P except in pts with BL P <3.5 mg/dL. cFGF23 significantly decreased in both TSAT strata, and in all BL P strata except the highest (≥5.5 mg/dL). Changes in FGF23 did not consistently track with P changes [Table].

Conclusions: In pts with NDD-CKD and IDA, 16 wks of treatment with FC significantly reduced iFGF23 except in pts with the lowest BL P, while cFGF23 was significantly reduced except in pts with the highest BL P. iFGF23 and cFGF23 reductions occurred irrespective of BL TSAT, BL P and P change. These data suggest that FC reduces FGF23 via several, potentially independent pathways in pts with CKD and IDA.

Subclinical Coronary Artery Calcification Predicts Future Risk of Acute Coronary Syndrome Among Non-Dialysis CKD: A 5-Year Prospective Analysis Angela Y. Wang,[1] Henry H. Wu,[1] Sharon Yui Ling Cheung,[1] Sharon S. Wong,[1] Yat Y. Yau,[2] Sharbat Ryskaliyeva.[1] *[1]Medicine, University of Hong Kong, Queen Mary Hospital, HONG KONG, China; [2]Radiology, Biomedical Imaging Center, Hong Kong, Hong Kong.*

Background: Vascular calcification is highly prevalent in chronic kidney disease (CKD) and is considered to be largely a medial type of arterial calcification, secondary to deranged mineral metabolism as a result of impaired kidney function. This is in contrast to studies in the general population suggesting that vascular calcification is a marker of atherosclerotic burden. The current study aims to determine if subclinical coronary artery calcification may predict future risk of acute coronary syndrome (ACS) in non-dialysis CKD.

Methods: Two hundred and seventy-two asymptomatic CKD 3-5 subjects with no known history of coronary artery disease (age: 60 ± 10 years, 56% men) were recruited from a University Teaching Hospital. All subjects underwent plain multi-slice computed tomography to estimate coronary artery calcium score (CACS) and blood collection.

Results: All subjects were followed up prospectively for a median duration of 69 months, during which 18% of subjects developed ACS or died from other causes. Having a CACS ≥ 400 was independently associated with an increased risk of ACS and mortality [adjusted hazard ratio (HR), 4.66, 95% confidence intervals (CI), 1.37 - 15.83] controlling for Framingham risk factors. Further adjusting for eGFR, proteinuria, hemoglobin, serum albumin, phosphate, low density lipoprotein-cholesterol, and C-reactive protein did not alter the independent association between CACS ≥ 400 with ACS and death [adjusted HR, 4.31, 95% CI, 1.22 – 15.27]. The area under the receiver-operator characteristics curve for CACS in predicting a composite outcome of ACS and mortality in CKD was 0.74 (95% CI, 0.67 - 0.82). Having a CACS ≥ 400 showed a specificity of 86% in predicting a future risk of ACS and mortality.

Conclusions: This study for the first time demonstrates the importance of subclinical coronary artery calcification in predicting future risk of ACS and mortality among asymptomatic non-dialysis CKD subjects. These novel findings suggest that coronary artery calcification reflects atherosclerotic disease burden other than 'mineral stress' among CKD subjects. The potential value of CACS as a screening tool to early identify CKD subjects at future risk of ACS warrant further large scale evaluation.

Comparative Performance of Longitudinal Measures of Change in Kidney Function in Predicting ESRD and Death Benjamin C. Bowe,[2] Yan Yan,[2,4] Yan Xie,[2] Hong Xian,[2,1] Tingting Li,[2,3] Ziyad Al-Aly.[2,3] *[1]Department of Biostatistics, Saint Louis University College for Public Health & Social Justice, St. Louis, MO; [2]Clinical Epidemiology Center, Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [3]Department of Medicine, Washington University School of Medicine, St. Louis, MO; [4]Department of Surgery, Washington University School of Medicine, St. Louis, MO.*

Background: Four different methods are commonly used in the evaluation of longitudinal changes of eGFR: ordinary least square (OLS), annualized change (AC), group-based trajectory models (GBT), and empirical Bayes slopes (EBS). Their comparative predictive performance for ESRD and death is unknown.

Methods: We built a development (N=274,277) and five validation cohorts (N~54,857 each) of US Veterans with stage 3a CKD and aimed to comparatively evaluate risk discrimination and reclassification of Cox proportional hazard regression models using the various longitudinal eGFR change measurement methods.

Results: For the outcome of death, when eGFR change was captured over a 5-year period, risk discrimination improved gradually from base model, OLS, AC, GBT, and EBS with a corresponding c-statistic of 0.698 (0.696-0.700), 0.702 (0.700-0.704), 0.703

(0.701-0.705), 0.706 (0.704-0.708), and 0.707 (0.705-0.709), respectively. Similarly, for the outcome of ESRD, the base, OLS, AC, GBT, and EBS models had a c-statistic of 0.699 (0.693-0.705), 0.710 (0.704-0.716), 0.711 (0.705-0.717), 0.716 (0.710-0.722), and 0.718 (0.712-0.724), respectively. EBS models offered the largest net reclassification improvement of 4% and 5% for death and ESRD, respectively, and they offered the largest integrated discrimination improvement of 0.56%, and 1.27% for death and ESRD, respectively. Results were reproduced in 5 validation cohorts, and were consistent when change in eGFR was captured over 1-year period.

Conclusions: Longitudinal eGFR change contributed to risk discrimination; measuring change using empirical Bayes slopes offered the most risk discrimination, and the largest improvement in net reclassification, and integrated discrimination for the outcomes of death as well as ESRD.

TH-OR041

NPHP1 Gene Deletions Cause ESRD in 0.9% of Adult-Onset Cases Rozemarijn Snoek,[2] Jessica Van setten,[2] Bert Van der zwaag,[2] Brendan Keating,[3] Nine V. Knoers,[2] Martin H. De Borst,[1] Albertien M. van Eerde.[2] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands; [3]University of Pennsylvania, Philadelphia, PA. Group/Team: International Genetics & Translational Research in Transplantation Network* .

Background: Nephronophthisis (NPH) is the most prevalent (15%) genetic cause for end-stage renal disease (ESRD) in children. ~16% is caused by homozygous full gene deletions of the autosomal recessive *NPHP1* gene. However, little is known about the prevalence of these mutations in adult-onset ESRD. With data generated to perform genome-wide association studies in adult-onset ESRD patients, we aimed to determine the prevalence of homozygous *NPHP1* full gene deletions.

Methods: Renal transplant recipients were genotyped using the Affymetrix *Axiom Tx GWAS Array*, containing ~780,000 markers accross the genome with probes to cover *a priori* copy number variant (CNV) regions. CNVs (e.g. deletions and duplications) were determined based on median log2 ratios and B-allele frequency patterns. All findings were independently validated. In this abstract we report on 1272 cases, all Caucasian, from the TransplantLines-Genetics cohort. As we are currently analyzing ~4300 additional samples of various ethnicities, from the DeKAF Genomics, GoCAR, Dublin and Vienna cohorts (part of iGeneTRAiN), we will soon be able to report on ~5500 cases. Cases are included in the analysis when they had adult-onset ESRD, defined as start of renal replacement therapy (RRT) at any age ≧18 years.

Results: 1250 cases in the TransplantLines-Genetics cohort met the age criteria, of whom 11 (0.9%) showed a homozygous deletion of the *NPHP1* gene. Median age at start of RRT was 35 years (range 18-42), with eight cases aged ≧30. Notably only three out of 11 cases (27%) were diagnosed as having NPH. The other cases (8/11, 73%) were noted as chronic kidney disease with unknown etiology (n=5), glomerulonephritis (n=1), sporadic primary reflux nephropathy (n=1) and autosomal dominant polycystic kidney disease (n=1).

Conclusions: NPH is a classical pediatric kidney disease. However, we show that homozygous *NPHP1* full gene deletions alone cause 0.9% of all adult-onset ESRD in our dataset, with the majority of *NPHP1* cases ≧30 years of age. Considering that other types of mutations in *NPHP1* were not analyzed, and the other 19 known NPH genes were not even investigated, NPH is a relatively frequent cause of adult-onset ESRD. As only 27% of *NPHP1* cases were registered clinically as NPH, these results warrant wider application of genetic testing in adult-onset ESRD.

TH-OR042

Mutations of DNAJB11 Cause Autosomal Dominant Polycystic Kidney Disease Emilie Cornec-Le Gall,[1,2] Vladimir Gainullin,[1] Binu Porath,[1] Christina M. Heyer,[1] Marie-Pierre Audrezet,[2] Yannick Le Meur,[2] Francois Jouret,[3] Dominique A. Joly,[4] Claude Ferec,[2] Alan S. Yu,[5] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Mayo Clinic, Rochester, AL; [2]University Hospital, Brest, France; [3]University of Liege Hospital (ULg CHU), Liege, Belgium; [4]Assistance Publique Hôpitaux de Paris, Paris, France; [5]University of Kansas Medical Center, Kansas City, KS.*

Background: Seven to 10% of ADPKD patients remain genetically unresolved (GUR). Mutations of *GANAB*, *ALG8* and *SEC61B* impair polycystin-1 (PC1) maturation and were recently identified in ADPKD or Autosomal Dominant Polycystic Liver Disease families (ADPLD). We hypothesized that other genes processing PC1 may cause ADPKD.

Methods: We performed whole exome sequencing (WES) in a multiplex pedigree and analyzed 600 other GUR families (508 PKD, 92 PLD) by targeted NGS sequencing (TNGS; 55 candidate genes involved in N-linked glycosylation and/or identified by WES). TNGS enrichment was performed using the Agilent SureSelect Target Enrichment Kit and sequenced on the Illumina HiSeq4000.

Results: WES identified a missense variant (p.P54R) in *DNAJB11* in a 78y mother and her 47y daughter, both presenting with unenlarged polycystic kidneys; and CKD4 in the mother (eGFR=28ml/min/1.73m^2). *DNAJB11* is a protein of the endoplasmic reticulum (ER) functioning as a co-chaperone of BiP, a key player in the control of the protein folding and the regulation of ER stress. p.P54R occurs in the hallmark HPD motif of the highly conserved J domain of the protein, likely disrupting its interaction with BiP. TNGS led to the identification of 3 other *DNAJB11* mutations (p.R206*(3), c.479delC(1), p.L77P(1)) in 5 additional families. Ages at diagnosis ranged from 35 to 84y. Clinical presentation was consistent in the 12 affected members (35-92y, 3 males), with normal-sized polycystic kidneys and evolution to kidney atrophy; 5 patients (3 families) reaching ESRD (60y to 92y). Only 5 patients were hypertensive, all after age 50; PLD was mild or absent. Analysis of *DNAJB11-/-* cells showed a disruption of maturation of polycystin-1 (PC1), while reduced mature PC1 was seen in *DNAJB11+/–* cells.

Conclusions: Our findings extend the spectrum of genetic causes of ADPKD. DNAJB11 differs from typical ADPKD, with no renal enlargement but progressive tubulointerstitial fibrosis leading to ESRD. In addition to inhibiting PC1 maturation and leading to cystogenesis, mutations of *DNAJB11* may inhibit responding appropriately to ER stress in the kidney. Recognizing this further genetic heterogeneity is important since these patients may not benefit from the same therapeutic strategies.

Highly Efficient Organoid Cystogenesis Reveals a Critical Role for Physical Microenvironment in Human Polycystic Kidney Disease Nelly M. Cruz,[1] Xuewen Song,[2] York P. Pei,[2] Benjamin S. Freedman.[1] *[1]University of Washington, Seattle, WA; [2]University Health Network and University of Toronto, Toronto, ON, Canada*.

Background: Polycystic kidney disease (PKD) is a life-threatening disorder in which tubular epithelia form fluid-filled cysts, disrupting organ architecture. A major barrier to understanding the pathophysiology of PKD is the absence of human cellular models that accurately and efficiently recapitulate cystogenesis. Previously, a genetic model of PKD has been generated using human pluripotent stem cells (hPSCs) and derived kidney organoids. Here we show that systematic substitution of physical components in this system can be used to dramatically increase or decrease cyst formation, unveiling a critical role for microenvironment in PKD.

Methods: Genome-modified *PKD1$^{-/-}$*, *PKD2$^{-/-}$*, or isogenic control hPSCs were differentiated *in vitro* into kidney organoids and subsequently cultured in the presence or absence of extracellular matrix and stroma. To directly test the effect of PKD mutations on the matrix microenvironment, individual organoids were embedded into larger collagen droplets. Structure and composition of organoid cysts were analyzed by immunofluorescence, microarray and immunoblot, and compared histologically to disease tissue from PKD patients.

Results: Removal of adherent cues increased cystogenesis 10-fold, producing cysts that phenotypically resembled human PKD cysts and expanded massively to 1-centimeter diameters. Non-PKD control organoids of identical genetic background did not form cysts. Cysts derived from hyperproliferative kidney tubular epithelial cells and showed upregulation of known PKD signaling pathways. Removal of stroma enabled proliferation and outgrowth of PKD cell lines, which revealed PC1 deficiency as a common molecular endpoint. Collagen droplets implanted with organoids furthermore contracted dramatically over a period of 2 weeks in a PKD-dependent manner.

Conclusions: Culture conditions have a significant impact on rates of cystogenesis in PKD organoids, enabling us to establish a highly efficient model of PKD cystogenesis. Collagen contraction could not be explained by differences in proliferation alone. Our findings directly implicate the microenvironment as a critical component at the earliest stages of PKD, with PC1 likely functioning as an adhesive or signaling molecule to control tissue contractility.

Loss of Cep120 Disrupts Centriole Maturation and Ciliary Assembly and Function and Causes Cystic Kidney Disease Ewelina Betleja, Tao Cheng, Moe Mahjoub. *Washington University, St Louis, MO*.

Background: Jeune asphyxiating thoracic dystrophy (JATD) is a skeletal dysplasia characterized by a small thoracic cage, shortened bones in the limbs, and polydactyly. Infants develop difficulties with breathing due to abnormal development of their thoracic cage, but may survive into early childhood following surgery to correct these defects. However, these children develop life-threatening renal abnormalities, namely cystic kidneys. Whole-exome sequencing of JATD patients recently identified mutations in CEP120, which we previously showed to be important for centriole duplication. What remains unknown is the functional *in vivo* role of Cep120 during embryonic kidney development and adult kidney homeostasis.

Methods: Two complementary approaches were used to characterize the loss-of-function of Cep120. First, siRNA-mediated depletion of Cep120 was performed in mouse embryonic fibroblasts and epithelia to analyze its role *in vitro*. Next, we utilized a transgenic mouse model harboring a conditional allele (Cep120$^{f/f}$) to delete Cep120 in the developing kidney. Cep120$^{f/f}$ mice were crossed with Six2-Cre animals to delete the gene in the metanephric mesenchyme, and with Hoxb7-Cre animals to knock out Cep120 in the ureteric bud epithelium.

Results: Here we show that Cep120 plays a critical inhibitory role at the daughter centriole. Depletion of Cep120 in quiescent cells causes accumulation of pericentriolar material (PCM) components at the daughter centriole including pericentrin, Cdk5Rap2, ninein and Cep170. The elevated PCM levels result in an overall increase in microtubule-nucleating capacity at the centrosome. Consequently, loss of Cep120 leads to aberrant dynein-dependent trafficking of centrosomal proteins, dispersal of centriolar satellites, and defective ciliary assembly and function. Finally, we show that deletion of Cep120 in the developing mouse kidney recapitulates the *in vitro* cellular phenotypes, and results in rapid renal cystogenesis that is evident at birth.

Conclusions: Our results indicate that Cep120 inhibits untimely maturation of the daughter centriole, and defines a novel mechanism that regulates the asymmetric properties of the two centrioles in quiescent cells. These data provide the first detailed

characterization of the role of Cep120 (and potentially other daughter centriolar proteins) in renal cystogenesis of patients with JATD.

Defective Mitochondrial Structure and Function Might Explain the Metabolic Derangement in Polycystic Kidney Disease Laura Cassina, Marco Chiaravalli, Christine Podrini, Isaline Rowe, Gianfranco Distefano, Alessandra Boletta. *San Raffaele Scientific Institute, Milan, Italy. Group/Team: Molecular basis of Polycystic Kidney Disease Unit*.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disorder characterized by bilateral renal cyst formation. By metabolomic profiling, we showed that *Pkd1* mutations result in enhanced glycolysis in cells and murine models of PKD. Moreover, inhibition of mitochondrial ATP synthase only mildly decreased ATP content in $Pkd1^{-/-}$ cells, indicating a weak mitochondrial contribution to total ATP production (Rowe et al, *Nat Med* 2013). Interestingly a recent study implicated a role for the Polycystins in mitochondrial function (Padovano et al, *Mol Cell Biol* 2017). We are investigating the role of mitochondria in the metabolic alterations in PKD.

Methods: Mitochondrial size, shape, and structural organization were analyzed by transmission electron microscopy (TEM). Mitochondrial oxygen consumption rate (OCR) was measured using Seahorse XFe96 Analyzer, and mitochondrial network morphology by live imaging of mitochondria-targeted EYFP.

Results: TEM images of the cystic epithelia showed evidence of grossly altered mitochondrial structure in kidneys of $Pkd1^{flox/-}$:Ksp-Cre mice at P4, as compared to control littermates. We have also observed mitochondria with altered cristae and decreased matrix electron density scattered among apparently normal mitochondria. Morphometric analysis of TEM images from $Pkd1^{flox/-}$:Ksp-Cre indicated decreased mitochondrial area and length. Time course analysis of mitochondrial shaping-proteins by western blot showed that the structural alterations seem to precede the biochemical ones. In parallel, we are assessing mitochondrial morphology in $Pkd1^{-/-}$ MEFs and CRISPR/Cas9-mediated *Pkd1* knockout IMCD cells and preliminary findings indicate that the absence of PC-1 affects mitochondrial network morphology. In line with this, functional analysis indicated that both basal and maximal OCRs are severely affected in cells lacking *Pkd1*.

Conclusions: Our data indicate that alteration in mitochondrial structure might explain the severe metabolic alterations in PKD models. Alternatively, the mitochondrial structural impairment might be secondary to metabolic defects. Our investigations along with ongoing genetic interaction studies will clarify whether mitochondria are players or modifiers in the pathophysiology of ADPKD.

TH-OR046

The Long Noncoding RNA Hoxb3os Is Dysregulated in Autosomal Dominant Polycystic Kidney Disease and Regulates mTOR Signaling Karam S. Aboudehen,[1] Mohammed S. Kanchwala,[3] Shayan A. Farahani,[1] Sophia M. Vrba,[1] Siu Chiu Chan,[1] Svetlana Avdulov,[1] Alan Mickelson,[1] Vishal Patel,[2] Chao Xing,[2] Peter Igarashi.[1] *[1]University of Minnesota, Minneapolis, MN; [2]University of Texas Southwestern Medical Center, Dallas, TX; [3]UT Southwestern Medical Center, Dallas, TX*.

Background: Polycystic kidney disease (PKD) is a debilitating disease that is characterized by the accumulation of numerous fluid-filled cysts in the kidney. Autosomal dominant polycystic kidney disease (ADPKD), is primarily caused by mutations in two genes, *PKD1* and *PKD2*. The pathophysiology of PKD is incompletely understood, and no FDA-approved treatment currently exists. Long noncoding RNAs (lncRNAs) are single-stranded RNA molecules that are >200 nucleotides in length, lack a long open-reading-frame, and have recently emerged as epigenetic regulators of development and disease; however, their involvement in PKD has not been explored previously.

Methods:

Results: Here, we performed deep RNA sequencing to identify lncRNAs that are deregulated in two orthologous mouse models of ADPKD (kidney-specific *Pkd1* and *Pkd2* mutant mice). We identified a kidney-specific and highly conserved lncRNA, called *Hoxb3os*, that was down-regulated in cystic kidneys from *Pkd1* and *Pkd2* mutant mice as well as in a *Pkd2* mutant renal cell line. Its human ortholog *HOXB3-AS* was down-regulated in kidneys from PKD patients. *Hoxb3os* was normally highly expressed in renal tubules in adult wild-type mice, whereas its expression was lost in the cyst epithelium of mutant mice. To investigate the function of *Hoxb3os*, we performed RNA-seq analysis on *Hoxb3os* knockdown mIMCD3 cells. Knockdown of *Hoxb3os* resulted in >2-fold dysregulation of 77 genes, 40 of which were similarly dysregulated in PKD mouse models. Pathway analysis suggested that *Hoxb3os* activated mTOR signaling, a pathway that has been implicated in PKD. Consistent with this result, ablation of *Hoxb3os* in mIMCD3 cells with CRISPR/Cas9 resulted in hyperactivation of mTOR signaling, as evidenced by enhanced phosphorylation of mTOR and ribosomal protein S6. Compared to wild-type cells, *Hoxb3os* knockout cells had increased rates of cell proliferation. Conversely, overexpression of *Hoxb3os* in wild-type mIMCD3 cells decreased phosphorylation of mTOR and S6. Collectively, these findings identify *Hoxb3os* as a novel lncRNA that is dysregulated in human and mouse PKD.

Conclusions: Down-regulation of Hoxb3os may underlie transcriptional abnormalities and hyperactivation of mTOR signaling in PKD.

A Ketogenic Diet Slows Disease Progression in a Rat Model of Polycystic Kidney Disease Jacob A. Torres, Caroline M. Broderick, Samantha Kruger, Margaret F. Schimmel, Thomas Weimbs. *University of California, Santa Barbara, Goleta, CA*.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a slowly progressing, life-threatening disease wherein normal healthy kidney tissue is replaced with fluid-filled cysts, decreasing renal function and leading to eventual renal failure. Cyst-lining cells have been shown to exhibit a metabolic shift towards aerobic glycolysis which may be exploited as a therapeutic approach. We have recently demonstrated that a reduction of food intake leads to a decrease in disease progression in a mouse model of ADPKD but the exact mechanism remained to be elucidated.

Methods: Here we show that the reduced food intake regimen leads to a partial state of ketosis and increased levels of beta-hydroxybutyrate (BHB). To test whether ketosis, rather than caloric reduction per se, leads to inhibition of renal cyst growth we treated the Han:SPRD rat model of PKD with a ketogenic diet regimen fed ad libitum.

Results: The high-fat, ketogenic diet leads to strong ketosis, elevation of BHB and concomitant reduction in blood glucose levels. Remarkably, Han:SPRD rats on the ketogenic diet exhibit strongly reduced disease progression with marked reduction in their cystic phenotype including significant reductions in kidney/body weight ratio, cystic index, proliferation and fibrosis.

Conclusions: These results suggest that cyst-lining cells may be dependent on glucose as their main energy source and are unable to switch to the use of ketone bodies and fatty acids under conditions of ketosis. These findings raise the exciting possibility that ketogenic diets may be a viable therapy for ADPKD.

Canonical Wnt Inhibitors Ameliorate Cystogenesis in a Mouse Orthologue of Human ADPKD Ao Li, Yuchen Xu, Song Fan, Jialin Meng, Xufeng Shen, Dongyue Ma, Li Zhang, Xiansheng Zhang, Guanqing Wu, Chaozhao Liang. *Anhui Province PKD Center, Institute/Department of Urology, The First Affiliated Hospital of Anhui Medical University, Hefei, China*.

Background: ADPKD is a heterogeneous disease which is caused by mutations in the *PKD1* or *PKD2* genes. Our previous study indicated that lack of *Pkd2* causes elevated β-catenin signaling in mouse tissues and cells (Kim et al. *JASN* 2009;20:2556). However, it remains unclear if β-catenin signaling plays a role in PKD phenotypes and if Wnt inhibitor halts the cyst formation in the disease models.

Methods: In this study, we crossed a newly generated standardized ADPKD mouse model for *Pkd2* (*Vil*-Cre;$Pkd2^{f3/f3}$) (Li et al *J. Cell Mol. Med.* 2017) with $Ctnnb1^{+/-}$ mice to generate the mouse model that haploinsufficiency of *Ctnnb1* (*Vil*-Cre;$Pkd2^{f3/f3}$;$Ctnnb1^{+/-}$). In addition, we also explored the effects of canonical Wnt signaling inhibitors (XAV939 and LGK974) on amelioration of disease phenotypes. XAV939-treated group and its solvent DMSO control group (n≥5/group) were intraperitoneally treated by 50 mg/kg/d and the same amount of DMSO from postnatal days 10 (P10) to 60 (P60); while LGK974-treated group and its solvent control group were intragastrically treated by 3mg/kg/d from postnatal days 30 (P30) to 90 (P90). The XAV939 and LGK974 treated animals were sacrificed at P65 and P95, respectively.

Results: *Vil*-Cre;$Pkd2^{f3/f3}$ mice with $Ctnnb1^{+/-}$ allele and the mice treated with XAV939 or LGK974 exhibit significantly prolonged lifespan, decreased cyst index, kidney/body ratio and improved renal function (BUN and Cr). All treated mice also showed significantly decreased proliferation, but no change for apoptosis, in renal cyst-lining epithelial cells. Canonical Wnt signaling targeted genes, including *Axin2*, *Ccnd1* and *c-Myc*, were also significantly downregulated in the treated ADPKD mouse kidney.

Conclusions: Our study provides clear evidence for the importance of β-catenin signaling in *Pkd2*-associated ADPKD phenotypes and develops new Wnt inhibitors XAV939 and LGK974, which affects at different targets of Wnt signaling, as a potential therapeutic modality for ADPKD that currently lacks effective therapy.

A Novel Strategy to Identify an Effective Treatment for Juvenile Nephronophthisis Hugo Garcia,[1] Flora Silbermann,[1] Esther Porée,[1] Clementine Mahaut,[2] Berangere M. Deleglise,[2] Pamela C. Rodriguez,[2] Soraya Sin-Monnot,[2] Luis Briseno-Roa,[2] Jean-Philippe M. Annereau,[2] Corinne Antignac,[1] Remi Salomon,[1,3] Marion H. Delous,[1] Sophie Saunier.[1] *[1]Imagine Inst, INSERM UMR1163, Paris, France; [2]Alexion R&D France, Paris, France; [3]Pediatric Nephrology, Necker Hospital, Paris, France*.

Background: Nephronophthisis (NPH) is an autosomal recessive tubulointerstitial nephropathy and the most common cause of hereditary end-stage renal disease in children and young adults. No specific treatment is currently available. Almost all the 21 identified *NPHP* genes encode proteins localized in the primary cilium.

Methods: We designed an *in vitro* high-throughput drug-screen strategy based on the Prestwick Chemical Library that includes more than 1120 compounds (mostly FDA-approved). We first evaluated migration and ciliogenesis in mammalian renal epithelial cells invalidated for either *Nphp1* or *Nphp4*, the two main genes involved in juvenile NPH, and identified 78 modulating drugs in these models. Then we selected 30 molecules

based on pharmacodynamics and assessed their effect on ciliogenesis of immortalized renal tubular cells derived from urine samples of *NPHP1*-deleted patients (URECs).

Results: We validated the positive effects of one compound (ARDF006) that increases the percentage of ciliated cell from and normalizes cilia length distribution. A similar rescue was observed when using specific agonists and antagonists targeting ARDF006 receptors. These G protein–coupled receptors partially localize at primary cilia. We could confirm *in vivo* effects of ARDF006 and a structural analog by using the *nphp4*-ATG morphant zebrafish model, which present a classical ciliopathy-related phenotype: body curvature and pronephric cysts. By using semi-automated imaging and analysis tools, we observed that ARDF006 treatment of morphant embryos does not have a significative impact on body curvature; however, it leads to a 27% relative reduction of pronephric cysts formation and an increase of ciliated cells percentage and cilia length in the distal part of the pronephros.

Conclusions: URECs and zebrafish represent useful and fast models to recapitulate patients' ciliogenesis defects and implement a pharmacologic approach for genetic deletion-related disease such as NPH.

TH-OR050

Fenofibrate, a PPARA Agonist, Enhances Mitochondrial Metabolism and Slows Kidney and Liver Cyst Progression in a 6 Month Pre-Clinical Trial Ronak Lakhia, Matanel Yheskel, Andrea N. Flaten, Ezekiel Quittner-Strom, Vishal Patel. *University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Impaired fatty acid oxidation (FAO) and oxidative phosphorylation (OXPHOS) are thought to underlie ADPKD progression. Peroxisome proliferator activated receptor alpha (PPARA) is a key regulator of FAO and OXPHOS. PPARA is downregulated in mouse and human ADPKD kidney cysts. We recently showed that deletion of *Ppara* aggravates cyst formation in an ADPKD model. The goal of this study was to determine if augmentation of FAO using the PPARA agonist fenofibrate can slow cyst growth.

Methods: Q-PCR, Western blot, and immunofluorescence staining confirmed downregulation of Ppara and its FAO-related target genes in 200-day-old *Pkd1*$^{RC/RC}$ mice. Sixteen 50-day-old *Pkd1*$^{RC/RC}$ mice were randomized to receive either standard chow diet or standard chow diet supplemented with fenofibrate. All mice underwent MRI to determine total kidney volume and total cyst volume at 180 days of age and were subsequently sacrificed at 200 days of age for molecular and histological analysis. An additional cohort of mice underwent *in-vivo* FAO assessment by ^{3}H-triolein assay.

Results: Fenofibrate treatment upregulated PPARA and enhanced FAO and OXPHOS in the kidneys of *Pkd1*$^{RC/RC}$ mice as evidenced by upregulation of FAO/OXPHOS genes, improved mitochondrial biogenesis, and increased oxidation of ^{3}H-triolein. MRI-assessed total kidney volume and total cyst volume was reduced by 30% and 60%, respectively, in fenofibrate-treated *Pkd1*$^{RC/RC}$ mice compared to *Pkd1*$^{RC/RC}$ mice on control diet. Moreover, kidney-weight-to-body-weight ratio, cyst index and serum creatinine were also reduced in the fenofibrate-treated *Pkd1*$^{RC/RC}$ mice. Fenofibrate treatment was associated with reduced kidney cyst proliferation and M2-like macrophages infiltration in *Pkd1*$^{RC/RC}$ mice treated with fenofibrate compared to *Pkd1*$^{RC/RC}$ mice on control diet. Fenofibrate treatment also reduced liver cyst burden, cyst proliferation, and liver inflammation and fibrosis.

Conclusions: Fenofibrate augments Ppara expression, improves FAO, and slows kidney and liver cyst growth, in *Pkd1*$^{RC/RC}$ mice. Our studies suggest that normalizing Ppara activity may be a useful therapeutic strategy for ADPKD.

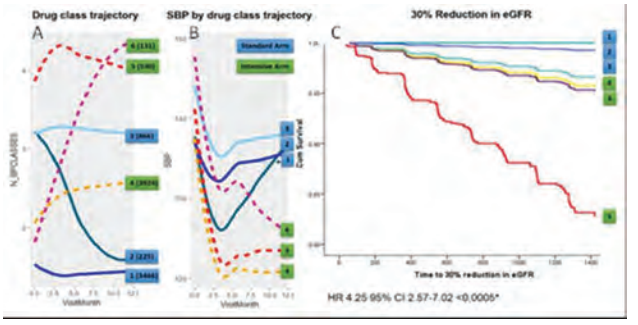
The Use of Four or More Drugs for Intensive Control of Blood Pressure Is Associated with Detrimental Renal Effects in the SPRINT Indranil Dasgupta,[1,2] Linsay Mccallum,[3] Alan G. Jardine,[4] Sandosh Padmanabhan.[4] *[1]Renal Medicine, Heartlands Hospital, Birmingham, United Kingdom; [2]University of Birmingham, Birmingham, United Kingdom; [3]Univeristy of Glasgow, Glasgow, United Kingdom; [4]University of Glasgow, Glasgow, United Kingdom.*

Background: In the SPRINT trial, A Randomized Trial of Intensive versus Standard Blood-Pressure Control, achievement of target SBP in the intensive arm required a higher number of drugs. Intensive treatment was associated with lower CV events and death but an increased incidence of adverse events. In this analysis we assessed the relationship between number of antihypertensive drugs classes used to achieve blood pressure target and renal adverse events.

Methods: Number of drug classes prescribed at randomisation and at 1,2,3,6,9,12 months were used to identify distinct trajectory groups in the standard and intensive arm using Latent Class Mixed Modelling, in 8,449 participants. Cox-PH models, adjusted for age, sex, SBP (AUC 0-12 months), prevalent CVD, prevalent CKD and number of drug classes at randomisation, were used to assess the association between drug class trajectories and renal adverse events.

Results: The 6 groups based on the trajectories of drug classes prescribed over the first year are shown in the panel A with corresponding SBP by drug class groups in panel B. Cox-PH model (reference category: Int-4, SBP <125 on 2.5 drug classes) showed that, in those without CKD at baseline, in Int-5 (125 on 4 drug classes) there was a higher risk of 30% reduction in eGFR (HR 4.25 [2.57-7.02]; p <0.0005) whilst those in Std-1 (SBP 133 on 1.5 drugs) had a lower risk (HR 0.17[0.10-0.29]; p <0.0005) (panel C. Those in Int-5 had a higher risk of hyperkalaemia (HR 1.64 [1.03-2.61]; p 0.036) with trend towards higher risk of AKI (HR 1.42 [0.95-2.12]; p 0.09).

Conclusions: Within the intensive arm of the SPRINT, treatment with ≥4 antihypertensive drug classes was associated with adverse renal events, independent of BP achieved in the first year.



Trajectories of number of antihypertensive drug classes used and GFR decline

TH-OR052

Dietary Sodium Restriction versus Diuretics for Salt-Sensitive Hypertension in CKD Dominique M. Bovee, Alexander H. Danser, Robert Zietse, Ewout J. Hoorn. *Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Fluid overload and salt-sensitive hypertension are hallmarks of advanced chronic kidney disease (CKD) and associated with worse outcomes. Dietary sodium (Na^+) restriction is an accepted intervention, but longterm adherence remains a challenge. Distal diuretics could provide an alternative approach but they are considered less effective in advanced CKD because of reduced tubular secretion. Here, we compared both approaches head-to-head.

Methods: Twenty-two patients with CKD stage 3 or 4 and hypertension were included in this single-center, open-label, randomized cross-over trial (baseline eGFR 38 ± 13 ml/min/1.73 m2). Renin-angiotensin inhibitors and diuretics were discontinued (2 weeks prior to interventions and during study period). Subsequently, we compared dietary Na^+ restriction (60 mmol/day) versus amiloride/hydrochlorothiazide (5/50 mg once daily). Both interventions lasted for two weeks and were separated by a 2-week wash-out period. The primary endpoint was 24h systolic blood pressure (SBP).

Results: Urinary Na^+ excretion was successfully lowered with dietary Na^+ restriction (156 ± 66 to 60 ± 26 mmol/day, p<0.001), and remained similar with diuretics (147 ± 46 to 135 ± 39 mmol/day, p=0.3). Dietary Na^+ restriction lowered 24-hour SBP moderately (134 ± 13 to 131 ± 14 mmHg, p=0.08), whereas diuretics had a strong effect (137 ± 12 to 124 ± 13 mmHg, p<0.01 both for within intervention and between interventions). Both maneuvers significantly lowered indices of fluid overload, including body weight (-1.4 ± 1.1 kg with dietary Na^+ restriction and -1.8 ± 1.5 kg with diuretics), NT-pro-BNP (median -13 and -5 pmol/L), and overhydration as assessed by bioimpedance (-0.5 ± 0.6 and -1.4 ± 0.7 L). Finally, both interventions lowered eGFR (-3 ± 4 and -5 ± 4 ml/min/1.73 m2, p<0.05 for both) and showed a trend towards albuminuria reduction (median -25 mg/day for both interventions).

Conclusions: Distal diuretics but not dietary Na^+ restriction effectively lowers blood pressure in CKD 3 or 4 in the absence of renin-angiotensin inhibitors. Both interventions are equally effective in lowering indices of fluid overload, including body weight, NT-pro-BNP, and overhydration. These beneficial effects may outweigh the (hemodynamic) reduction in eGFR.

TH-OR053

Bilateral Renal Cryo-Denervation Decreases Blood Pressure and Improves Insulin Sensitivity in Fructose-Fed Sprague Dawley Rats Tyler Soncrant,[1] William H. Beierwaltes,[1] Haiping Chen,[1] Min Wu,[1] Noreen F. Rossi.[1,2] *[1]Wayne State University, Detroit, MI; [2]John D. Dingell VAMC, Detroit, MI.*

Background: Consumption of foods with fructose content is highly prevalent in modern diets with the average western intake at 17% of total calories. In combination with high salt intake, an elevated fructose diet leads to increased blood pressure and renal sympathetic nerve activity even prior to development of frank metabolic syndrome. Renal denervation reportedly improves glycemic control. We tested the hypothesis that bilateral cryo-denervation of the renal nerves will decrease mean arterial pressure (MAP) and improve insulin sensitivity in prediabetic fructose-fed rats on high salt diet.

Methods: Male Sprague Dawley rats were equipped with radiotransmitters to measure hemodynamics. They were given 20% fructose in their drinking water and 0.4% NaCl diet. After 7 days, they were either kept on 0.4% (LS) or switched to 4% NaCl (HS) diet for an additional 10-12 days. Control rats (C) were given plain water and 0.4% NaCl diet throughout. Rats were then subjected either to sham denervation (shamDNX) or bilateral denervation by alternately freezing (-150°C) and thawing the nerve 3 times (cryoDNX).

Results: One week later, MAP was unchanged in C or fructose-fed LS rats but had risen significantly in the fructose-fed HS rats from 110 ± 1 to 117± 2 mmHg; $P < 0.05$). Norepinephrine content decreased by 85% in cryoDNX vs shamDNX kidneys ($P < 0.01$).

MAP did not change in shamDNX but returned to pre-diet levels cryoDNX fructose-fed HS rats ($P < 0.05$). Blood glucose (BG) was 100 ± 9 mg/dL in C rats vs 131 ± 8 mg/dL in conscious fructose-fed rats ($P < 0.02$). Glucose:insulin ratio in shamDNX rats was lower (47 ± 8) than in cryoDNX rats (105 ±18; $P < 0.05$) regardless of sodium intake, consistent with improved insulin sensitivity in the cryoDNX rats.

Conclusions: We conclude that bilateral renal denervation normalizes MAP in prediabetic fructose-fed rats on high salt diet and also improves insulin sensitivity in fructose-fed rats regardless of sodium intake. Further studies are needed to identify whether afferent inputs from or efferent sympathetic inputs to the kidney are involved. Thus, the renal nerves likely play important role in glucose disposal.

TH-OR054

In Two-Kidney One-Clip Hypertensive Sheep Cardiac and Contralateral Renal Sympathetic Nerve Activity Are Differentially Controlled

Tycho R. Tromp,[2,1] Jaap A. Joles,[2] Rohit Ramchandra.[1] *[1]The University of Aucklad, Auckland, New Zealand; [2]University Medical Center Utrecht, Utrecht, Netherlands.*

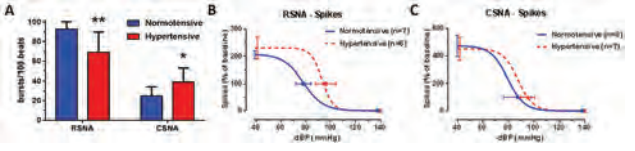
Background: Hypertension is often initiated and maintained by elevated sympathetic tone. We investigated changes in directly recorded sympathetic nerve activity (SNA) to the heart and nonclipped kidney in two-kidney one-clip (2K-1C) hypertensive sheep.

Methods: Adult ewes either underwent unilateral renal artery clipping (n=12) or sham surgery (n=15). Two weeks later, the carotid artery was cannulated and electrodes were placed in the (nonclipped) renal and/or cardiac nerve. Blood pressure (BP), heart rate (HR) and baseline and baroreflex control of SNA were recorded in the conscious sheep one week later.

Results: Unilateral renal artery clipping induced hypertension (systolic blood pressure 130±3 vs 111±4 mmHg in shams, p<0.001) after 21±5 days, and shifted the heart rate baroreflex curve rightwards (BP_{50} 120±13 vs 104±16 mmHg, p<0.01). HR was unchanged. The renal SNA (RSNA) baroreflex curve was also shifted rightwards (BP_{50} 93±3 vs 78±2, p<0.01) and showed increased gain (p<0.05). In the hypertensive group, cardiac SNA (CSNA) burst incidence (bursts/100 beats) was increased (39±14 vs 25±9 in normotensives, p<0.05), whereas RSNA burst incidence was decreased (69±20 vs 93±8 in normotensives, p<0.01).

Conclusions: In this ovine model of 2K-1C renovascular hypertension we show that cardiac and contraleteral renal sympathetic nerve activity were differentially controlled three weeks after clipping: baseline CSNA was increased whilst RNSA to the nonclipped kidney was decreased. We speculate that the observed contralateral RSNA decrease is a homeostatic response to increased blood pressure and the sodium avid state of the clipped kidney.

Funding: Private Foundation Support, Government Support - Non-U.S.



Differential control of contralateral renal and cardiac sympathetic nerve activity (SNA). Baseline contralateral renal SNA was decreased whereas cardiac SNA was increased (A). Baroreflex control of contralateral renal (B) and cardiac SNA (C) was differentially regulated.

Sodium-Sensitive Blood Pressure Response in Type 1 Diabetes Is Accompanied by Impeded Skin Lymphangiogenesis

Eliane F. Wenstedt, Nienke M. Rorije, Rik H. Olde Engberink, Bert-jan Van den born, Jan Aten, Liffert Vogt. *Academic Medical Center, Amsterdam, Netherlands.*

Background: Studies showed that sodium can be non-osmotically stored within the skin. In response to high sodium diet (HSD), skin sodium content increases and macrophages are attracted, inducing lymphangiogenesis. Disruption of this system has been shown to lead to sodium-sensitive hypertension. This study investigates the effects of HSD on skin lymphatic and blood capillaries as well as blood pressure (BP) in type 1 diabetic patients (DM1).

Methods: We performed a randomized crossover study in males with DM1 and healthy controls. All subjects pursued an 8-day low sodium diet (LSD: <50 mmol Na^+/day) and HSD (>200 mmol Na^+/day). Diet order was randomized and time in-between diets was 1-2 weeks. After each diet, BP measurements and skin biopsies were obtained. Macrophages (CD68), vascular endothelium (CD31) and lymphatic endothelium (D2-40) were identified through immunohistochemistry.

Results: This study included 8 patients with DM1 and 12 controls who were similar regarding age, BMI and eGFR. In DM1 patients, mean arterial pressure was higher after HSD as compared to LSD (mean (SE) 85(2) vs. 80(1) mmHg, p=0.03) whereas in controls no differences were observed (78(1) vs. 78(2) mmHg, p=0.66). HSD increased lymphatic cross sectional surface area in controls (p=0.01) but not in DM1 patients (fig 1a). Less $CD68^+$ macrophages were present in DM1 patients compared to controls (p<0.001) (fig 1b). In both groups, there was a strong association between lymphatic capillary density and macrophage density (DM1 r=0.57 p=0.02; controls r=0.71 p=0.02).

Conclusions: The sodium-sensitive BP increase in DM1 patients is accompanied by impeded skin lymphangiogenesis and reduced skin macrophage content. Lymphangiogenesis may help to prevent sodium-sensitive hypertension.

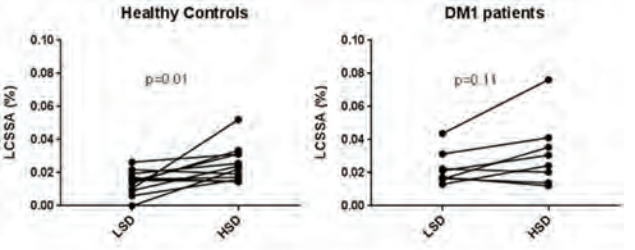

Fig 1A. Lymphatic cross sectional surface area (LCSSA) expressed as a percentage of the histological slice. LSD = low sodium diet, HSD = high sodium diet.

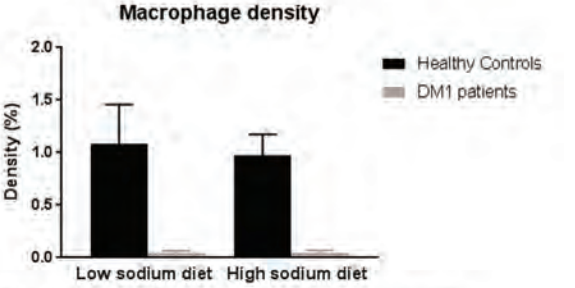

Fig 1B. Macrophage density in healthy controls and DM1 patients after low and high sodium diet, expressed as the percentage of the histological slice that is positively stained with CD68. Data are presented as median with interquartile range.

TH-OR056

Renal Medullary Interstitial Cell COX-2 Protects against Salt-Sensitive Hypertension and Papillary Necrosis

Ming-Zhi Zhang,[2] Aolei Niu,[2] Yinqiu Wang,[2] Suwan Wang,[2] Chuan-Ming Hao,[2,1] Raymond C. Harris.[2] *[1]Huashan Hosp., Shanghai, China; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Cycloxygenase 2 (COX-2)-derived prostaglandins regulate renal hemodynamics and salt and water homeostasis. COX-2 is highly expressed in renal medullary interstitial cell (RMICs). COX-2 inhibition causes blood pressure elevation and papillary necrosis and COX-2 sustains RMIC survival in response to hypertonicity in vitro. However, the role or RMIC COX-2 *in vivo* in response to stimuli has not yet been definitively studied. We investigated the effect of COX-2 deletion in RMICs on blood pressure and papillary integrity in response to high salt intake.

Methods: We used inducible COX-2 deletion in RMICs in adult mice to avoid any potential developmental abnormalities of the inner medulla/papilla. Male $COX\text{-}2^{f/f}$ (WT) and Tenascin-C-CreER2;$COX\text{-}2^{f/f}$ (RMIC COX-2-/-) mice were fed a high salt diet, and blood pressure was monitored with tail cuff plethysmography. Mice were sacrificed at 2, 4, 9 weeks. For acute salt loading, mice were IP injected with isotonic saline equivalent to 10% of body weight, placed in metabolic cages, and 4-h urine was collected.

Results: Tamoxifen efficiently induced COX-2 deletion in inner medulla/papilla of the Tenascin-C-CreER2; $COX\text{-}2^{f/f}$ mice. Blood pressure was similar between RMIC COX-2-/- mice and WT mice on a normal salt diet. Although blood pressure was not altered in WT mice on a high salt diet, it increased gradually in RMIC COX-2-/- mice, peaked at 4-5 weeks (131 ± 5 vs. 121 ± 4 mmHg, $P < 0.05$, n = 7), and then progressively decreased to levels significantly lower than corresponding WT. After return to a normal salt diet for 3 weeks, RMIC COX-2-/- mice still had lower blood pressure (101 ± 4 vs. 116 ± 3 mmHg, $P < 0.05$, n = 4) and a urine concentrating defect (2535 ± 97 vs. 3080 ± 120 mOsm/kg H_2O of WT, $P < 0.01$, n = 6), in association with striking loss of papillae. Increased apoptotic cells in papillae of high salt treated RMIC COX-2-/- mice were seen 2 weeks after high salt intake. In addition, RMIC COX-2-/- mice had impaired pressure natriuresis one week after high salt diet (% of sodium excretion: 69.6 ± 8.9 vs. 98.4 ± 4.7 of WT, $P < 0.05$, n = 4).

Conclusions: These studies indicate that RMIC COX-2 plays an important role in salt and water homeostasis and provides cytoprotection for papillary structures in response to chronic high salt intake.

Loss of Salt Sensing Kinase, SGK1, in T Cells Abrogates Memory Cell Formation, Hypertension, and End-Organ Damage Hana A. Itani, Arvind K. Pandey, David G. Harrison. *Clinical Pharmacology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Accumulating evidence indicates that NaCl can be concentrated in tissues with high salt-intake, age and in the setting of hypertension. Elevated NaCl has been shown to promote T_H17 cell formation in an SGK1-dependent fashion. We have previously shown that Memory T cells play a major role in the genesis of hypertension. These long-lived cells remain responsive to repeated hypertensive stimuli, such as salt feeding, and can be mobilized to enter the kidney where they release cytokines that promote renal dysfunction. To examine mechanisms by which T cells sense salt and contribute to salt-sensitivity, we tested the hypothesis that SGK1 in T cells is necessary for formation of memory T cells and their activation in salt-sensitive hypertension.

Methods: To study the role of SKG1 in hypertension, we produced mice with T cell specific deletion of SGK1, $SGK1^{fl/fl}$ x tg^{CD4cre} mice and used $SGK1^{fl/fl}$ mice as controls. To impose repeated episodes of hypertension, we treated these mice with L-NAME (0.5mg/ml) in drinking water for two weeks, allowed a two-week normotensive interval and a then fed high salt (4% NaCl) for three weeks.

Results: L-NAME followed by high salt increased memory T cells in the kidney, aorta and bone marrow of $SGK1^{fl/fl}$ control mice but not in $SGK1^{fl/fl}$ x tg^{CD4cre} mice, as identified by the surface marker $CD44^{hi}$. To assess markers of renal injury, we measured albumin in 24-hour urine samples collected at the end of the L-NAME/high salt. L-NAME/high salt caused striking albuminuria in $SGK1^{fl/fl}$ mice and was absent in $SGK1^{fl/fl}$ x tg^{CD4cre} mice. In additional studies, we found that loss of SGK1 in T cells abrogates renal and vascular inflammation and protects against hypertensive renal and vascular injury in the L-NAME/high salt model.

Conclusions: Thus, our data provide a potential mechanism by which SGK1 in T cells promotes their development of salt sensitivity and their mediation of renal and vascular dysfunction in hypertension.

TH-OR058

Angiotensin II Type 2 Receptor Contributes to Hypertension in Elastin Insufficiency Carmen M. Halabi. *Washington University School of Medicine, Saint Louis, MO.*

Background: Hypertension and vascular stiffness are major consequences of elastin insufficiency, as seen in patients with Williams syndrome and animals models of elastin insufficiency. Altered reactivity of resistance vessels was recently proposed to contribute to hypertension in elastin insufficiency. Specifically, mesenteric arteries of elastin insufficient mice were shown to be hypercontractile to angiotensin II (AngII) *ex vivo*. Interestingly, this hypercontractile response to AngII was partially mediated by AngII type 2 receptors (AT2R) as blockade of AT2R by PD123319 abrogated the hypercontractile response to AngII. The purpose of this study was to determine whether AT2R contributes to the hypertension seen with elastin insufficiency *in vivo*.

Methods: Elastin haploinsufficient (Eln^{het}) mice were bred to AT2R knock-out ($Agtr2^{KO}$) mice. Arterial blood pressure measurement and large artery compliance studies were performed on three month-old male littermate progeny with the following genotypes ($Agtr2^{WT}/Eln^{WT}$; $Agtr2^{KO}/Eln^{WT}$; $Agtr2^{WT}/Eln^{het}$; *and* $Agtr2^{KO}/Eln^{het}$). Structural examination of ascending aorta and mesenteric arteries was done via Alexa-633 hydrazide staining and transmission electron microscopy, respectively.

Results: As expected, compared to wild type (WT) mice, loss of AT2R had no effect on blood pressure or large vessel compliance in the presence of WT elastin ($Agtr2^{KO}/Eln^{WT}$), while elastin insufficiency resulted in elevated systolic blood pressure, pulse pressure, and reduced large vessel compliance in the presence of AT2R ($Agtr2^{WT}/Eln^{het}$). Loss of AT2R in elastin insufficient mice ($Agtr2^{KO}/Eln^{het}$) resulted in significant reduction of systolic and diastolic blood pressures, but no change in pulse pressure or large artery compliance. There were no structural changes in either the ascending aortae or mesenteric arteries of $Agtr2^{KO}/Eln^{het}$ compared to $Agtr2^{WT}/Eln^{het}$.

Conclusions: These results provide *in vivo* evidence for a role of AT2R in mediating elastin insufficiency-associated hypertension. Furthermore, these data suggest distinct mechanisms for the development of hypertension and vascular stiffness in elastin insufficiency, as loss of AT2R reduced blood pressure, but had no effect on large artery stiffness in this mouse model. Studies are underway to determine the effect of AT2R loss on resistance artery reactivity.

TH-OR059

Interference with COP9 Signalosome Mimics FHHt Effects on WNK/NCC Signaling Ryan J. Cornelius, Chao-Ling Yang, David H. Ellison. *Oregon Health and Science University, Portland, OR.*

Background: The Familial Hyperkalemic Hypertension (FHHt) cullin 3 (CUL3) mutant is unable to degrade WNK kinases normally, activating the thiazide-sensitive NaCl cotransporter (NCC). Previous work showed that the CUL3 mutant does not bind to the COP9 signalosome (CSN), a deneddylase involved in regulating cullin-RING ligases. We sought to determine whether this impaired binding was the cause of the increased WNK protein abundance in FHHt by inhibiting the CSN *in vivo*.

Methods: The Pax8 mouse system was used to generate mice in which the catalytically active CSN subunit, JAB1, was deleted only along the nephron, after full development (KS-$JAB1^{-/-}$).

Results: JAB1 protein abundance was 62% lower in KS-$JAB1^{-/-}$ kidney vs WT. Western blot analysis demonstrated that loss of JAB1 caused enhanced neddylation of CUL3. Moreover, total CUL3 expression was reduced by 37%, indicating decreased CUL3 stability, as reported by other groups for the FHHt CUL3 mutant. As expected, KLHL3 protein abundance was lower and total WNK1 and WNK4 protein abundance were higher. Phosphorylated WNK4 levels and the ratio of pNCC to total NCC were also higher, but, surprisingly, total NCC protein abundance was dramatically reduced. Consistent with the low total NCC, KS-$JAB1^{-/-}$ mice did not develop an FHHt phenotype. KS-$JAB1^{-/-}$ mice were hypokalemic ($[K^+]$: 3.20 ± 0.07 vs 3.55 ± 0.06 mM, $P < 0.01$), hyperchloremic ($[Cl^-]$: 117.5 ± 1.7 vs 112.7 ± 1.3 mM; $P < 0.05$), and acidemic ([TCO]: 11.83 ± 0.87 vs 18.00 ± 0.57 mM, $P < 0.001$). Urine output was approximately twice as high in KS-$JAB1^{-/-}$ (9.4 ± 1.6 vs 4.7 ± 0.50 ml/day, $P < 0.05$) and there was Na^+ and K^+ wasting (Na^+ clearance: 0.135 ± 0.013 vs 0.088 ± 0.006 ml/day/g, $P < 0.01$; K^+ clearance: 4.90 ± 0.40 vs 3.68 ± 0.28 ml/day/g, $P < 0.05$). As we reported with CUL3 deletion, chronic JAB1 deletion also led to kidney tubule damage, as determined by H&E staining.

Conclusions: CUL3 in KS-$JAB1^{-/-}$ mice was highly neddylated, with increased WNK protein abundance, consistent with impaired degradation; Na^+ and K^+ wasting was observed, however, due to decreased levels of total NCC. In conclusion, KS-$JAB1^{-/-}$ mice mimic many, but not all, aspects of the FHHt phenotype.

Pannexin 1 Channels in Renin Expressing Cells Regulate RAAS and Blood Pressure Leon DeLalio,[2,4] Ester Masati,[4] Thu H. Le,[3] Paula Q. Barrett,[2] Roberto Ariel Gomez,[2] Brant Isakson.[5,4] *[2]Child Health Research Center, University of Virginia, Charlottesville, VA; [3]University of Virginia School of Medicine, Charlottesville, VA; [4]Robert M. Berne Cardiovascular Research Center, University of Virginia, Charlottesville, VA; [5]Molecular Physiology and Biological Physics, University of Virginia, Charlottesville, VA.*

Background: The homeostatic regulation of blood pressure (BP) by renin lineage-cell differentiation in the renal vasculature and the adrenal zona glomerulosa (ZG) is crucial for controlling renin expression and aldosterone synthesis. In the renal vasculature, renin lineage cells respond to changes in blood pressure by differentiating and re-expressing a fetal renin gene program, termed recruitment. In the adrenal cortex, ZG cells of the renin lineage centripetally turnover, differentiating from an aldosterone synthetic program to a glucocorticoid synthetic one, thus maintaining steady state aldosterone production. The cellular signals coordinating these responses is unclear, but evidence from our lab posits a potential role for purinergic signaling mediated by Pannexin 1 channels. **We hypothesized that Pannexin 1 (Px1) channels regulate purinergic communication and cell differentiation in the renal vasculature and adrenal ZG cells to maintain blood pressure homeostasis.**

Methods: Blood pressure radiotelemtry, hormone specific RIA and ELISA, immunohistological staining, qPCR, and pressure myography.

Results: To test this hypothesis, we generated a novel renin cell Panx1 knockout mouse (Ren1-Px1 KO). At baseline, mice exhibit no differences in kidney size, morphology, or plasma renin concentration. However, KO mice have enhanced vasoconstriction responses and a significant elevation in aldosterone levels (1737 compared to 1172 pg/mL; $p<0.5$), which corresponded with aberrant ZG cell differentiation in the adrenal cortex. By radiotelemetry, Ren1-Px1 KO mice displayed increased baseline BP (110 compared to 100 mmHg; $p<0.5$). Lastly, we assessed renal renin dynamics in response to BP lowering with captopril. Ren1-Px1 KO mice retain adequate capacity to secrete renin at baseline, but fail to adequately upregulate renin expression in the juxtaglomerular afferent arteriole, determined by quantitative immunostaining, after BP lowering.

Conclusions: We conclude that loss of Panx1 from renin lineage cells causes activation of RAAS primarily by influencing differentiation responses in ZG cells, despite changes in renal renin dynamics. Thus, Pannxin 1 channels may regulate complex adrenal cell differentiation events important for long term BP control.

Single-Cell Transcriptome Profiling of Glomeruli from Healthy and Nephritic Mice Jun-Jae Chung,[1] Jasmine Chen,[2] Leonard Goldstein,[2] Zora Modrusan,[2] Andrey S. Shaw.[1] *[1]Research Biology, Genentech, South San Francisco, CA; [2]Molecular Biology, Genentech, South San Francisco, CA.*

Background: Disruption of glomerular homeostasis leads to filtration barrier damage and kidney disease. Determining the gene expression profiles of cells that comprise the glomerulus will facilitate understanding of the processes involved in kidney diseases. Single-cell RNA-seq analysis can provide information not attainable using bulk RNA-seq, such as cell subpopulations and heterogeneity of cellular responses to injury.

Methods: Single cell suspensions of glomerular cells were prepared via magnetic bead isolation followed by enzymatic digestion from healthy C57BL/6J mice or mice with anti-GBM glomerulonephritis. The individual transcriptome of thousands of cells in the mouse glomeruli were obtained using the droplet-based 10x Genomics Chromium™ technology and Next-Generation Sequencing.

Results: Principle component analysis (PCA) of cells from healthy glomeruli clearly distinguished the three major cell types in the glomerulus (podocytes, mesangial cells, endothelial cells). Analysis of differentially expressed genes identified novel candidates for mesangial cell markers. After induction of anti-GBM glomerulonephritis, we detected

accumulation of immune cells and significant changes in the gene expression patterns of glomerular cells. After resolution of the heterologous phase, global gene expression pattern of podocytes largely reverted back to its original state, whereas the transcriptome profile of mesangial cells and endothelial cells remained altered. We observed heterogeneous expression of CCL2 in the mesangium of a CCL2-reporter mouse, which was increased after induction of glomerulonephritis. CCL2 expression was enriched in mesangial cells that had higher levels of immediate early genes, suggesting these cells may act as sentinels during glomerular injury. Comparing the transcriptomes of each cell type from healthy and nephritic glomeruli reveal candidate genes for further functional studies.

Conclusions: Single-cell RNA-seq reveals previously undetected heterogeneity in the injury response of glomerular cells.

Human iPSC-Derived Glomeruli Facilitate Accurate Modeling of Podocytopathy Lorna J. Hale,[2] Sara E. Howden,[2] Belinda Phipson,[2] Irene Ghobrial,[2] Pei Xuan Er,[1] Santhosh V Kumar,[3] Alicia Oshlack,[2] Melissa H. Little.[2] *[1]Murdoch Children's Research Institute, Parkville, NSW, Australia; [2]Murdoch Childrens Research Institute, MELBOURNE, NSW, Australia; [3]Murdoch childrens research institute, Melbourne, NSW, Australia*.

Background: Numerous kidney diseases leading to proteinuria result from alterations to the podocyte which leads to foot process effacement and loss of slit diaphragms. Immortalised cell lines have been the gold standard in podocyte biology, however, this model has inherent limitations. Consequently, validation of novel disease-associated mutations is most often performed in animal models which may not replicate the human condition. The advent of iPSC organoids now provides a new avenue for the study of human podocyte disease *ex utero*.

Methods: Sieved glomeruli isolated from human iPSC kidney organoids were characterised and compared to conditionally immortalised human podocytes by RNA-sequencing. The capacity of organoid-derived glomeruli to recapitulated podocytopathy through introduction of clinically relevant mutations into iPSC was assessed using CRISPR-Cas9 technology.

Results: Organoid-derived glomeruli showed superior podocyte-specific gene expression when compared to conditionally immortalised podocytes, with an upregulation of 2187 genes. GO terms associated with slit diaphragm development, and glomerular epithelial cell differentiation and development were significantly enriched. Glomeruli isolated from homozygous MAFB mutant organoids accurately recapitulated anticipated disease related transcriptional changes.

Conclusions: We provide the first evidence that human iPSC kidney organoids can accurately model podocytopathy. Organoid podocytes which are allowed to form in 3D via the patterning and segmentation seen during normal nephrogenesis are superior to the current gold standard conditionally immortalised podocyte cell system. The capacity to readily generate such an accurate model of the human glomerulus from iPSC will facilitate patient-specific functional genomics to validate novel podocytopathy genes and further interrogate the pathogenic mechanisms of existing podocytopathies *in vitro*.

Calcium/Calmodulin-Dependent Kinase IV Compromises Podocyte Function in Autoimmune and Non-Autoimmune Kidney Diseases Kayaho Maeda,[1] Kotaro Otomo,[3] Nobuya Yoshida,[1] Sean D. Bickerton,[4] Tarek Fahmy,[4] Maria Tsokos,[2] George C. Tsokos.[1] *[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Keio University School of Medicine, Tokyo, Japan; [4]Yale School of Medicine, New Haven, CT*.

Background: Podocyte dysfunction is a common feature of renal injury in autoimmune or non-autoimmune renal diseases and the good target of proteinuric kidney diseases. We previously reported that calcium/calmodulin-dependent kinase IV (CaMK4) was upregulated as a result of exposure to IgG from the patients with lupus nephritis (LN). Since podocytes from patients and mice with lupus have increased levels of CaMK4 linked to decreased nephrin expression, we considered that targeted delivery of a CaMK4 inhibitor (KN93) to podocytes should preserve podocyte function.

Methods: We treated lupus-prone MRL.*lpr* mice starting at 8 weeks age, mice injected lipopolysaccharide (LPS) or adriamycin with anti-podocin or nephrin tagged nanolipogels (nlg) loaded with KN93 intraperitonealy (i.p.). We also used immortalized differentiated human podocytes to examine the actin structure and function under LPS or lupus IgG treatment.

Results: Podocytes from lupus-prone or LPS-or adriamycin-treated mice and patients with LN or focal segmental glomerulosclerosis (FSGS) displayed increased expression of CaMK4. Targeted delivery of KN93 to podocytes suppressed proteinuria, immune complex deposition and crescent formation in lupus-prone mice and proteinuria in mice with LPS-or adriamycin-induced podocyte injury by preserving podocyte structure, nephrin and synaptopodin expression. In animals exposed to adriamycin, podocyte-specific delivery of KN93 prevented and reversed renal disease. Similarly, CaMK4 deficiency also protected from those podocyte injuries. Inhibition or silencing of CaMK4 protected from LPS-induced the actin cytoskeleton injury and synaptopodin degradation in human podocytes. Activated CaMK4 interacted with 14-3-3β and disrupted the binding of synaptopodin with 14-3-3β leading to actin cytoskeleton rearrangement of podocytes.

Conclusions: We conclude that inhibition of CaMK4 preserves podocyte structure and function and targeted delivery of a CaMK4 inhibitor to podocytes should have therapeutic value in lupus nephritis and podocytopathies including FSGS.

Ex Vivo Induced Neutrophil Extracellular Traps Are Intrinsically Different in ANCA-Associated Vasculitis- and Systemic Lupus Erythematosus Laura S. van Dam,[1] Tineke Kraaij,[1] Sylvia Kamerling,[1] Hans Ulrich Scherer,[1] Charles D. Pusey,[2] Ton J. Rabelink,[1] Cees van Kooten,[1] Yoe Kie Onno Teng.[1] *[1]LUMC, Leiden, Netherlands; [2]Imperial College London, London, United Kingdom*.

Background: Neutrophil extracellular traps (NETs) are immunogenic, extracellular DNA structures that harness important autoantigens to be recognized by the adaptive immune system. NETs are thought to play a pivotal role in the pathogenesis of AAV and SLE. However it is still unclear how and if NETs act as a common pathway in the pathophysiology of these clinically divergent autoimmune diseases. The aim of the present study is to characterize AAV- and SLE-induced NETs.

Methods: Healthy neutrophils were stimulated with 10% serum of AAV (n=101) and SLE (n=59) patients to induce NETs. Ex vivo NET induction by serum and IgG-depleted serum was measured by a novel, highly-sensitive NET quantification assay using 3D-confocal microscopy. Qualitative characteristics of NETs were studied by immunofluorescence to detect NET-related auto-antigens. Additionally, the morphology and kinetics of AAV- and SLE-induced NETs were visualized by live cell imaging and electron microscopy.

Results: Ex vivo NET induction by AAV sera was 20.74 [9.56 – 74.14], (median [Q1 - Q3]) fold higher than sera of healthy controls (n=10) and also significantly higher than NET induction by SLE sera 5.02 [1.88 – 14.33]). Depletion of IgG from serum did not reduce NET induction in AAV, whereas it was significantly decreased in SLE. Colocalisation of NET-related auto-antigens was different: citrullinated histon-3 (CitH3) was predominantly found on AAV-induced NETs, whereas high mobility group box protein-1 (HMGB1) was exclusively found on SLE-induced NETs. Live cell imaging demonstrated that the kinetics of SLE-induced NETs peaked at 30 minutes, while AAV-induced NETs peaked at 4 hours. Intriguingly, SLE sera induced immediate clustering of neutrophils surrounding NETs whereas AAV sera induced NETs composed of long, thin DNA-fibres through lytic expulsion.

Conclusions: We demonstrate distinct features of ex vivo AAV- and SLE-induced NETs, indicating that NET formation in AAV and SLE is based on different mechanisms. Future studies should be directed at unravelling how different NETs are involved in causing SLE- or AAV-associated glomerulonephritis.

TH-OR065

The Co-Inhibitory Molecule PD-L1 Contributes to Regulatory T Cell-Mediated Protection in Murine Crescentic Glomerulonephritis Katrin Neumann, Annett Ostmann, Philippe C. Breda, Hans-Joachim Paust, Ulf Panzer, Gisa Tiegs. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*.

Background: Glomerular diseases such as crescentic glomerulonephritis (cGN) are mediated by inappropriate cellular and humoral immune responses towards autoantigens subsequently leading to the development of end-stage renal failure. Previously, we demonstrated a crucial role for regulatory T cells (Tregs) in suppressing pro-inflammatory Th1 and Th17 cell-mediated immune responses during nephrotoxic nephritis (NTN), the murine model of cGN. However, mechanisms of immune regulation in cGN are insufficiently understood. Here, we aim at investigating the role of the co-inhibitory molecule PD-L1 in Treg-mediated protection from NTN.

Methods: NTN was induced in PD-L1$^{-/-}$ mice by injection of the nephritogenic serum. Disease severity was investigated at day 8 after NTN induction and compared to C57BL/6 wild type (WT) mice. Kidney damage was quantified by crescent formation in PAS-stained tissue sections and determination of albumin-to-creatinine ratio by ELISA. PD-L1 was blocked in WT mice by injection of an anti-PD-L1 antibody. To neutralize IFNγ, PD-L1$^{-/-}$ mice were treated with an anti-IFNγ antibody. Tregs from nephritic PD-L1$^{-/-}$ or WT mice were adoptively transferred into Rag1$^{-/-}$ mice one day before NTN induction. Gene and protein expression analysis was done by quantitative RT-PCR and flow cytometry.

Results: PD-L1$^{-/-}$ mice developed more severe NTN compared to WT mice. Histological analysis revealed increased numbers of T cells, macrophages/DCs but also Foxp3^{+} Tregs in the kidneys of nephritic PD-L1$^{-/-}$ mice. Moreover, renal and systemic IFNγ-mediated Th1 immune response as well as systemic humoral immune response were strongly enhanced in nephritic PD-L1$^{-/-}$ mice. Blockage of PD-L1 in WT mice amplified renal Th1 response and aggravated disease pathogenesis. Furthermore, neutralization of IFNγ ameliorated NTN in PD-L1$^{-/-}$ mice. In co-culture, renal DCs from nephritic PD-L1$^{-/-}$ mice strengthened expression of IFNγ in CD4^{+} T cells. Interestingly, PD-L1$^{-/-}$ Tregs were not able to suppress activation and proliferation of responder CD4^{+} T cells *in vitro* and they also failed to protect from NTN *in vivo*.

Conclusions: PD-L1 displays a protective role in NTN, which is related to Treg- and DC-dependent suppression of the Th1 immune response. Thus, targeting PD-L1 may represent a novel therapeutic option in cGN.

TH-OR066

DNA-Aptamer Raised against RAGE Improves the Development of Lupus Nephritis in MRL/lpr Mice Kensei Taguchi,[1,5] Akito Maeshima,[2] Sho-ichi Yamagishi,[3] Yosuke Nakayama,[1] Yusuke Kaida,[1] Yuichiro Higashimoto,[4] Craig R. Brooks,[5] Kei Fukami.[1] *[1]Division of Nephrology, Department of Medicine, Kurume University, Kurume, Japan; [2]Gunma University Graduate School of Medicine, Maebashi, Japan; [3]Kurume University, Kurume, Japan; [4]Kurume University School of Medicine, Kurume, Japan; [5]Vanderbilt University Medical Center, Nashville, TN.*

Background: Lupus nephritis (LN) affects 60% of patients with systemic lupus erythematosus (SLE). Although immunosuppressive drugs are used as a first-line therapy, LN still negatively impacts the survival and quality of life in SLE patients. The Receptor for advanced glycation endproducts (RAGE), which belongs to the immunoglobulin superfamily, is strongly associated with innate immune responses. In this study, we examined whether RAGE could be involved in LN development in lupus prone MRL/lpr mice. Further, we explored the therapeutic impact of RAGE DNA-aptamer on renal damages on these mice.

Methods: Renal expression levels and urinary RAGE excretion (uRAGE) were determined in female mice at 8, 12, 16, 18, 20 weeks of age by IHC and ELISA, respectively. A DNA-aptamer raised against RAGE (RAGE-apt) or Control-aptamer (Ctrl-apt) was subcutaneously administered to MRL/lpr mice for 10weeks. Histological and serological analyses were performed.

Results: uRAGE levels, but not urinary protein excretion, were significantly increased in 8-week-old MRL/lpr mice compared with control MRL/MPJ mice. In addition, glomerular RAGE expression was markedly increased starting at 12 weeks and was associated with the increased glomerular extracellular matrix accumulation and cellular crescents. RAGE expression was dramatically increased in endothelium and infiltrating macrophages of the glomeruli. Administration of RAGE-apt significantly ameliorated mesangial expansion, wire-loop and crescent formation, and macrophage infiltration into the glomeruli in MRL/lpr mice. In addition, RAGE-apt, but not Ctrl-apt, significantly reduced the levels of pro-inflammatory cytokines gene expression such as IL-6, TNF-a, and MCP-1 in renal cortex of MRL/lpr mice.

Conclusions: RAGE is involved in the pathogenesis of LN, and the treatment with RAGE-apt represents a promising therapeutic strategy for preventing the development of LN.

Funding: Government Support - Non-U.S.

TH-OR067

Urine Neutrophil Gelatinase-Associated Lipocalin to Predict Renal Response after Induction Therapy in Active Lupus Nephritis Bancha Satirapoj,[2] Chagriya Kitiyakara,[3] Yingyos Avihingsanon,[1] Ouppatham Supasyndh.[2] *[1]King Chulalongkorn Memorial hospital, Chulalongkorn University, Bangkok, Thailand; [2]Phramongkutklao hospital, Bangkok, Thailand; [3]Ramathibodi Hospital, Bangkok, Thailand.*

Background: Tubulointerstitial injury is important to predict the progression of lupus nephritis (LN). Urine neutrophil gelatinase-associated lipocalin (NGAL) has been reported to detect worsening LN disease activity. Thus, urine NGAL may predict renal outcomes among lupus patients.

Methods: We conducted a prospective multi-center study among active LN patients with biopsy-proven. All patients provided urine samples for NGAL measurement by ELISA collected from all patients at baseline and at 6-month follow-up after induction therapy.

Results: In all, 75 active LN patients were enrolled (mean age 31.8±9.9 years, median UPCR 4.8 g/g creatinine level with interquartile range (IQR) 2.5 to 8.4 and mean estimated glomerular filtration rate (GFR) 89.1±36.3 mL/min/1.73 m2). At baseline measurement, median urinary NGAL in complete response, partial response and nonresponse groups was 11.8 (IQR; 6.2, 23.5), 18.9 (IQR; 8.9, 43.1), and 78.9 (IQR; 23.2, 118.4) ng/mL, respectively (P=0.004). Urinary NGAL (ng/mL) correlated positively with proteinuria and correlated negatively with serum complement C3 level. Based on ROC analysis, urinary NGAL (AUC; 0.769, 95%CI 0.603-0.935) outperformed conventional biomarkers (serum creatinine, urine protein, and GFR) in differentiating complete and partial response groups from the nonresponse group. The urine NGAL cutoff value in the ROC curve, 28.07 ng/mL, discriminated nonresponse with 75% sensitivity and 66.7% specificity.

Conclusions: Urine NGAL at baseline performed better than conventional markers in predicting a clinical response to treatment of active LN except serum complement C3 level. It may have the potential to predict poor response after induction therapy.

Funding: Other NIH Support - This study was supported by a grant from the National Science and Technology Development Agency (NSTDA, P-13-00505), Bangkok, Thailand.

Molecular Profiling of Renal Compartments from Serial Lupus Nephritis Kidney Biopsies to Identify Markers of Response Samir V. Parikh,[4] Ana Malvar,[1] Huijuan Song,[4] John P. Shapiro,[4] Valeria G. Alberton,[5] Juan M. Mejia-Vilet,[4] Isabelle Ayoub,[4] Anjali A. Satoskar,[4] Jianying Zhang,[4] Lianbo Yu,[4] Paolo Fadda,[4] Michael T. Eadon,[2] Daniel J. Birmingham,[3] Brad H. Rovin.[4] *[1]HOSPITAL FERNANDEZ, Buenos Aires, Argentina; [2]Indiana University Division of Nephrology, Indianapolis, IN; [3]Ohio State University Medical Center, Columbus, OH; [4]Ohio State University Wexner Medical Center, Columbus, OH; [5]hospital Fernandez, Buenos Aires, Argentina.*

Background: Molecular profiling of kidney compartments from serial renal biopsies of proliferative lupus nephritis (LN) may provide novel information to improve treatment. Here we present results of molecular profiling of the glomeruli and tubulointerstitum (TI).

Methods: A kidney biopsy was done at flare (Bx1) and after induction therapy (Bx2) in 56 LN patients. Controls were living donor transplant biopsies (n=7). Glomeruli and TI were isolated using laser capture microdissection, RNA was extracted and analyzed by Nanostring. Transcript expression of LN flares was compared to controls, and complete renal responders (CR, n=28) were compared to non-responders (NR, n=9).

Results: The top upregulated glomerular transcripts were *TGFBI(*fold-change (FC): 10.6, P=6x10^{-9}*), FCER1G (FC:8.2, P=2x10^{-7}), CCL2(FC:3.5, P=0.001), FN1(FC:3.5, P=2x10^{-7}), ICAM1(FC:3.2, P=0.0001)* and *VCAM1 (FC:2.7, P=6x10^{-13}).* The top upregulated TI transcripts were *CCR10*(FC:2.8, P=5x10^{-9}), *STAT1*(FC:2.8, P=6x10^{-8}), *HLA-DRB3(FC:2.6, P=2x10^{-12}), CCL19*(FC:2.8, P=2x10^{-7}), *CD74*(FC:2.3, P=1x10^{-15}) and *CFD*(FC:2.2, P=0.00001). At Bx1 26 glomerular and 39 TI transcripts differentiated CR from NR. After treatment several glomerular and TI transcripts differentially-expressed in Bx1 trended toward control levels in Bx2, but 15 transcripts significantly increased in expression, suggesting increased infiltration of T cells (*CD5, CD7, ICOS, CD45*), NK cells (*CD2, KLRB1*), and neutrophils (*CSF3RB*) in NR TI.

Conclusions: The inflammatory profiles of glomeruli and TI at LN flare and after treatment are different. CR and NR also have unique profiles at flare that may be helpful in predicting response to therapy. After treatment NR are characterized by increased infiltration of T cells, NK Cells and neutrophils in the TI compared to CR. These transcripts may be used to refine subsequent treatment of NR and convert these patients to CR.

Effects of Blisibimod, a Selective Inhibitor of B-Cell Activating Factor, on Urinary Protein:Creatinine Ratio (UPCR) in Subjects with Renal Manifestations of Systemic Lupus Erythematosus (SLE) Joan T. Merrill,[1] Renee Martin,[2] William Shanahan,[2] Kenneth Kalunian,[3] David Wofsy.[4] *[1]Oklahoma Medical Research Foundation, Oklahoma City, OK; [2]Anthera Pharmaceuticals, Inc., Hayward, CA; [3]UCSD, La Jolla, CA; [4]University of California, San Francisco, CA.*

Background: The CHABLIS-SC1 trial (NCT01395745) was a Phase 3 trial of blisibimod in 442 patients with active systemic lupus, 135 of whom had UPCR≥0.5 mg/mg at study entry.

Methods: Subjects in the CHABLIS-SC1 trial were randomized to receive weekly subcutaneous blisibimod (200 mg) or placebo. All subjects had anti-nuclear or anti-dsDNA antibodies and SLEDAI score ≥10 on standard of care medications. Patients with renal manifestations were eligible unless proteinuria exceeded 6 g/24hour or disease severity was likely to require escalation of immunosuppressive therapy. This report evaluates the effects of blisibimod in the subgroup of subjects with baseline UPCR≥0.5 mg/mg.

Results: In the renal subgroup, greater decreases in UPCR from baseline were observed in the blisibimod arm (Figure). Significantly more subjects who received blisibimod achieved >50% reduction in UPCR from baseline (59.7% vs 30.8%, p=0.006). A higher proportion also achieved UPCR<0.5 (53.2% and 30.8%, p=0.021). No treatment effects were noted on eGFR and serum creatinine, which typically were within normal ranges throughout the trial. Across all 442 enrolled subjects, adverse events were balanced between treatment arms excepting mild or moderate injection site erythema and injection site reaction which occurred more frequently with blisibimod.

Conclusions: The reduction in proteinuria in SLE subjects with clinical evidence of nephritis suggests that blisibimod may have therapeutic potential in lupus nephritis and, perhaps, other B-cell-associated renal diseases.

Treatment and Outcomes of the ANCA Associated Vasculitis in the Very Elderly – A Single Centre Experience Turren tarun S. Chaggar. *Epsom and St Helier NHS Trust, London, United Kingdom.*

Background: ANCA-associated vasculitis has a peal incidence between 65-74 years of age, and not uncommonly presents in the very elderly (>80yrs). Decisions regarding immunosuppression in the very elderly can be challenging, given likely co-morbidities and general frailty, and on treatment and outcomes in this age group is lacking.

Methods: Patients were identified retrospectively from the local renal database. A total of 231 patients presented with ANCA associated vasculitis between 2006 and 2015. Data from patients >= 80 years during the study period were collected. Follow-up was until May 2017. The collected data were analysed with respect to age, sex, renal function at diagnosis, patient and renal survival, induction and maintenance treatment and disease relapse

Results: We identified 32 patients from this cohort, mean age of 83.5 yrs (range 80- 90 years), mean follow-up period of 35.5 months (range 0.2 – 106). Of these, 14 were PR3 positive and 18 were MPO positive. Overall survival to completion of induction therapy at 3 months was 91% (29/32) and 1 year survival was 90% (26/29). Mean creatinine at presentation was 406 µmol/L and 38% (12/32) required renal replacement therapy (RRT) within 72 hours of presentation. Induction of remission was achieved using corticosteroids with either cyclophosphamide (25/32), MMF (1/32) or rituximab (1/32). In two patients azathioprine was used with corticosteroids as first line therapy. N=6 had Plasma Exchange in addition to RRT. Of these, 4 were RRT independent at 3 months. Renal survival was 79% (23/29) at 3 months and 85% (22/26) at 1 year. No patients progressed to ESRD after 3 months. Disease relapse occurred in 2 patients, with a mean time to relapse of 21.5 months.

Conclusions: AAV is a disease with substantial mortality and morbidity among elderly patients. The results of this retrospective study showed that very elderly patients can benefit from immunosuppressive therapy with good outcomes to 3 month and 1 year survival. Relapse rates are low. Dialysis independence can be achieved in those patients requiring RRT on admission and this treatment ensures that patients are maintained off RRT upto a median of 35.5 months follow-up.

TH-OR071

Single-Cell RNA-Seq Reveals Distribution of Na, K, and Cl Transporters among the Major Cell Types of the Collecting Duct Lihe Chen,[3] Chung-Lin Chou,[3] Maurice B. Burg,[3] Jill W. Verlander,[2] Susan M. Wall,[1] Mark A. Knepper.[3] *[1]Emory University School of Medicine, Atlanta, GA; [2]University of Florida, Gainesville, FL; [3]National Heart Lung and Blood Institute, Bethesda, MD.*

Background: Fine control of water, ion, and acid-base homeostasis is maintained by transport processes in the collecting duct. Collecting ducts are made up of at least 3 cell types: type A intercalated cells (A-ICs), type B intercalated cells (B-ICs) and principal cells (PCs). To identify transcriptomes for A-ICs, B-ICs and PCs, it is necessary to carry out RNA-Seq at a single-cell level.

Methods: We used cell-surface markers for A-ICs (c-Kit), B-ICs (PNA) and PCs (DBA), allowing these cell types to be enriched from kidney cell suspensions from untreated mice using fluorescence-activated cell sorting (FACS). The enriched fractions were used for microfluidic-based single-cell RNA-Seq. We performed a t-distributed stochastic neighbor embedding (t-SNE) analysis and resolved cell clusters. Based on the gene expression patterns, three major clusters are identified as A-ICs, B-ICs and PCs.

Results: In the table below, we present transcript abundances in TPM values for major Na, K and Cl transporters and associated regulators in the three major cell types of the collecting duct (largest value in bold). Our data confirm the selective expression of *Hsd11b2, Scnn1b* and *Scnn1g*, and major potassium channels (*Kcnj1, Kcne1, Kcnj10, Kcnj16*) in PCs. We also found AE1 (*Slc4a1*) and pendrin (*Slc26a4*) are mutually exclusive in A-IC and B-IC, respectively. Interestingly, we found that ENaC alpha (*Scnn1a*) and Na-K-ATPase (*Atp1a1*) transcripts are more abundant in B-ICs than in PCs or A-ICs. In addition, the mineralocorticoid receptor is predominantly expressed in B-ICs, while glucocorticoid receptor is expressed in all three cell types. AE4 (*Slc4a9*) was expressed in both IC cell types (confirmed by immunohistochemistry).

Conclusions: In conclusion, the single-cell RNA-Seq profiling results revealed a distinct distribution pattern of transporters and their regulators in A-ICs, B-ICs and PCs. The identification of transcripts related to Na^+ transport and its regulation in B-ICs is consistent with a direct role of B-ICs in regulated Na reabsorption.

Interleukin 6 Regulates the Epithelial Sodium Channel Brandi M. Wynne,[1] Qiang Yue,[1] Gillian G. Hecht,[1] Henrieke J. van Elst,[1] Hayley C. Moyer,[1] Douglas C. Eaton,[1] Robert S. Hoover.[1,2] *[1]Emory University, Atlanta, GA; [2]Veteran's Administration, Decatur, GA.*

Background: Hypertension is characterized by increased sodium (Na^+) reabsorption along the aldosterone-sensitive distal nephron (ASDN), as well as a chronic systemic inflammation. Interleukin-6 (IL-6) is a mediator of this inflammatory process. We have previously demonstrated that IL-6 activates the mineralocorticoid receptor (MR), and increases sodium chloride cotransporter expression and activity. We hypothesized that IL-6 will increase ENaC activity and/or expression.

Methods: We used mpkCCD cells to determine amiloride-sensitive transepithelial voltage and resistance (EVOM) with IL-6 (100ng/mL, 18hrs). C57Bl6 (Wt) mice were perfused with IL-6 (16ng/min, intrarenal, 3d) or vehicle, and/or treated with spironolactone. Kidney cortex homogenates were used to determine ENaC (α, γ) expression. SGK1 immunofluorescence was determined in tissue slices. ENaC channel density (N) and activity (NP_o) was obtained using split open tubules (cortical collecting duct, CCD) from IL-6 KO and Wt mice. Data are expressed as mean±SEM.

Results: Using EVOM, IL-6-mediated amiloride-sensitive current (7.4±0.7 *vs.* 6.2±0.7µAmp/cm², n=6, p<0.0001) was increased. IL-6 perfusion increased ENaCα (≈1.49, n=3, p<0.05) and γ (≈3.14, n=8, p<0.05) protein expression, as compared to vehicle. SGK1 pixel intensity (PI) was increased following IL-6 perfusion (306±4.7 *vs.* 263±4.4PI, n=6, p<0.0001); spironolactone reduced this response (224.3±4.5PI *vs.* vehicle, n=6, p<0.0001). Baseline ENaC activity (NP_o) was less than half in split open tubules from IL-6 KO mice, as compared to Wt (0.337±0.01 *vs.* 0.151±0.04, n=3, p<0.001).

Conclusions: Here, we show that IL-6 infusion increases ENaCα and γ protein expression, as well as SGK1 levels in an MR-dependent manner. Amiloride-sensitive current was also increased, corroborating the increased ENaC expression found following IL-6 perfusion. With whole animal IL-6 depletion, there was a significant reduction in ENaC activity. Together, our data suggest that a basal level of IL-6 is necessary to for adequate ENaC activity and that increased IL-6 levels may contribute to increased ENaC protein expression. Our data reveal a possible role for IL-6 mediated increases in ENaC expression and/or activity, which is especially important during hypertension.

TH-OR073

Potassium Acts through mTORC2 to Regulate SGK1 and ENaC Directly in Collecting Duct Cells Bidisha Saha,[2] Prasanna K. Allu,[2] Peng Wu,[1] WenHui Wang,[1] David Pearce.[2] *[1]New York Medical College, Valhalla, NY; [2]University of California San Francisco, San Francisco, CA.*

Background: The control of K+ excretion is critical to the maintenance of blood [K+]. Aldosterone controls renal tubule K+ secretion substantially by increasing SGK1 expression, which in turn stimulates ENaC. In addition to expression, SGK1 must be activated by the kinase, mTORC2. The key physiological inputs that control this phosphorylation are poorly characterized. We postulated that [K+] itself might directly regulate SGK1 activity through effects on mTORC2-dependent phosphorylation.

Methods: mpkCCD cortical collecting duct (CCD) cells were grown on Transwell filters, and treated for 4 h with aldosterone to stimulate SGK1 expression and adapted to either 1 mM or 5 mM [K+]. At t = 0, basolateral [K+] was changed from 1 to 5 mM or from 5 mM to 1 mM, followed by a return to 5 mM in the presence or absence of either an SGK1 or mTOR inhibitor. Additional experiments were performed using patch clamp to detect ENaC currents in mice subjected to low sodium diet for 7 days, followed by acute change in bath [K+] from 5 mM to 1 mM.

Results: In mpkCCD cells, raising basolateral [K+] from 1 to 5 mM increased SGK1 phosphorylation approximately 3-fold, while lowering [K+] from 5 mM to 1 mM decreased SGK1 phosphorylation approximately 4.5-fold ($p < 0.01$). The stimulatory effects were dependent on mTORC2 in that they were inhibited by a global mTOR inhibitor (AZD 8055) but not by the mTORC1-specific inhibitor, rapamycin. Changing apical [K+] had no significant effect. Further, shifting basolateral [K+] from 5 mM to 1 mM markedly reduced ENaC-dependent Na+ current, and returning [K+] to 5 mM

induced a rapid increase in Na+ current. This latter effect was blocked by SGK1 or mTOR inhibitor. Finally, in mice subjected to patch clamp, ENaC currents were significantly greater in the presence of 5 mM (330 +/-25 pA, N=5) than in the presence of 1 mM (250 +/- 20 pA, N=5) [K+] ($p < 0.05$).

Conclusions: Changes in extracellular [K+] rapidly modulate mTORC2-dependent SGK1 phosphorylation resulting in altered ENaC-mediated Na+ transport. In light of recent evidence that Na-Cl cotransporter (NCC) phosphorylation and activity are regulated in distal convoluted cells directly by extracellular fluid [K+], these data support a new model of coordinated regulation of Na+ transport between distal convoluted tubule and CCD, which is directly modulated by local renal [K+].

TH-OR074

Aldosterone Is Essential for Angiotensin II-Induced Upregulation of Pendrin Daigoro Hirohama,[1] Nobuhiro Ayuzawa,[1] Kohei Ueda,[1] Mitsuhiro Nishimoto,[1] Wakako Kawarazaki,[1] Atsushi Watanabe,[1,2] Tatsuo Shimosawa,[3] Takeshi Marumo,[1] Shigeru Shibata,[1,4] Toshiro Fujita.[1] *[1]Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo, Japan; [2]Department of Nephrology and Endocrinology, National Defense Medical College, Tokorozawa, Saitama, Japan; [3]Department of Clinical Laboratory, School of Medicine, International University of Health and Welfare, Narita, Chiba, Japan; [4]Division of Nephrology, Department of Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan.*

Background: The renin-angiotensin-aldosterone system (RAAS) is known to play an important role in the control of fluid homeostasis and blood pressure during volume depletion. Dietary salt restriction elevates circulating angiotensin II (AngII) and aldosterone levels, which increase levels of the Cl^-/HCO_3^- exchanger (pendrin) in β-intercalated cells and Na^+-Cl^- cotransporter (NCC) in distal convoluted tubules; however, the independent roles of AngII and aldosterone in regulating these levels remain unclear.

Methods: In both C57BL/6J mice receiving a low-salt diet or AngII infusion and adrenalectomized mice receiving either AngII or co-administration of AngII and aldosterone, we evaluated membrane-protein abundance of pendrin, NCC and mineralocorticoid receptor (MR) phosphorylation, which selectively inhibits aldosterone binding in intercalated cells. We also measured blood pressure (BP) by radiotelemetry in pendrin-knockout and wild-type mice.

Results: A low-salt diet as well as AngII infusion upregulated NCC and pendrin levels, associated with decreased MR phosphorylation. Notably, a low-salt diet did not alter BP in wild-type mice, but significantly decreased BP in pendrin-knockout mice, suggesting the important role of pendrin in the regulation of BP. In adrenalectomized mice, AngII infusion again upregulated NCC, but did not affect pendrin expression despite the decreased MR phosphorylation. By contrast, AngII and aldosterone co-administration markedly elevated pendrin levels in adrenalectomized mice. AngII and aldosterone co-administration induced enhanced translocation of the MR to the nucleus in β-intercalated cells, whereas AngII alone did not.

Conclusions: Our results indicate that aldosterone is necessary for AngII-induced pendrin upregulation, and suggest that pendrin contributes to maintaining normal BP in cooperation with NCC during activation of the RAAS by dietary salt restriction.

TH-OR075

The Cystic Fibrosis Transmembrane Regulator (CFTR) and the Na+/H+ Exchanger NHE-2 Play Important Roles in Compensatory Salt Absorption in Kidneys of Na-Cl Cotransport (NCC) Deficient Mice Manoocher Soleimani,[1,2] Sharon L. Barone,[1,2] Jie Xu,[1] Marybeth Brooks,[1] Kamyar A. Zahedi.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Administration, Cincinnati, OH.*

Background: Background: The ablation of the Na-Cl cotransporter NCC (Slc12a3) does not cause any significant salt wasting in mice, in part due to activation of the Cl^-/HCO_3^- exchanger pendrin and the epithelial sodium channel ENaC. However, whether other transporters/channels contribute to compensatory salt absorption in NCC null mice remains speculative.

Methods: To better identify the compensatory salt absorptive mechanisms in NCC deficient mice RNA-Seq analysis was performed on kidney cortices of wild type, NCC KO and pendrin KO mice. Results were verified by expression studies in kidneys and complemented by functional studies in live animals.

Results: One notable transporter/channel, which was significantly upregulated in NCC KO but downregulated in pendrin KO mice was CFTR. Another transporter, which was upregulated in NCC KO mice was NHE-2. Northern hybridizations verified enhanced expression of CFTR and NHE-2 in the kidney cortex of NCC KO mice and immunofluorescence labeling studies indicated the upregulation of CFTR and NHE-2 in the CCD and DCT, respectively. To ascertain the role of CFTR in compensatory salt absorption in NCC KO mice, WT and NCC KO mice were placed in metabolic cages and injected twice/ day with the CFTR inhibitor GlyH-101 for 4 days. Urine volume increased by ~60% and urine sodium increased by 35% vs. baseline in response to GlyH-101 treatment ($p<0.05$ for both parameters). Wild type mice showed no significant increase in urine output or sodium excretion in response to GlyH. NCC KO, but not WT mice showed enhanced salt excretion in response to amiloride injection which was likely resulting from combined inhibition of NHE-2 and ENaC.

Conclusions: CFTR is upregulated in the distal nephron and plays an important role in compensatory salt absorption in NCC deficient mice. In addition, NHE-2 is activated in the distal nephron and facilitates the absorption of sodium. We propose that CFTR may facilitate the activity of the Cl^-/HCO_3^- exchanger pendrin and ENaC in B intercalated cells and principal cells, respectively, leading to enhanced salt absorption in NCC KO mice. We further propose that NHE-2 is activated and works in tandem with pendrin to facilitate the electroneutral absorption of sodium and chloride.

TH-OR076

Role of ClC-K and Barttin in Low-Potassium Induced Sodium-Chloride Cotransporter Activation and Hypertension in Mouse Kidney Naohiro Nomura, Wakana Shoda, Yuanlong Wang, Daiei Takahashi, Moko Zeniya, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Tokyo Medical and Dental University, Tokyo, Japan.*

Background: The sodium-chloride cotransporter (NCC) was identified as a key molecule regulating potassium balance. The mechanisms of NCC regulation during low extracellular potassium concentrations have been investigated *in vitro* showing that the hyperpolarization induced by low potassium concentrations increased chloride efflux through the ClC-K chloride channels, leading to the activation of chloride-sensitive WNK kinases and their downstream molecules including SPAK and NCC. However, this mechanism was not investigated *in vivo*.

Methods: We used the barttin hypomorphic mouse (*Bsnd*$^{neo/neo}$ mice), expressing very low levels of barttin and ClC-K channels since barttin is an essential ß-subunit of ClC-K. Mice were fed a normal diet or a low-potassium diet *in vivo*. Kidney slices were incubated in different potassium concentration buffer *ex vivo*. Then, SPAK and NCC phosphorylation was evaluated by Western blotting.

Results: In contrast to *Bsnd*$^{-/-}$ mice, *Bsnd*$^{neo/neo}$ mice survived to adulthood, which enabled us to investigate the role of ClC-K in NCC activation. When mice were fed a normal diet, there was no significant difference in total and phosphorylated NCC between wild-type mice and *Bsnd*$^{neo/neo}$ mice. In *Bsnd*$^{neo/neo}$ mice, SPAK and NCC activation (phosphorylation) after consuming a high-salt and low-potassium (HSLK) diet was clearly impaired compared to that in wild-type mice. In *ex vivo* kidney slice experiment, the increase in phosphorylated NCC in low-potassium medium was also blunted in *Bsnd*$^{neo/neo}$ mice. Furthermore, the increase in blood pressure was observed in wild-type mice fed a HSLK diet, which was not evident in the *Bsnd*$^{neo/neo}$ mice.

Conclusions: Our study provides *in vivo* evidence that ClC-K and barttin play important roles in the activation of the WNK4-SPAK-NCC cascade and the blood pressure regulation, in response to a low-potassium diet.

TH-OR077

Paracellular Properties of the Cortical Collecting Duct Nina Himmerkus,[2] Julian Isermann,[2] Lieske Jarck,[2] Yongfeng Gong,[1] Susanne Milatz,[2] Jianghui Hou,[1] Markus Bleich.[2] *[1]Washington University School of Medicine, Saint Louis, MO; [2]Christian-Albrechts-University Kiel, Kiel, Germany.*

Background: Collecting duct salt and water transport is involved in the regulation of extracellular volume and blood pressure. Ions are transported either transcellularly or through the paracellular pathway following electrochemical driving forces. Claudins are the major determinants of tight junction permeability. They form the paracellular pathway and claudin-4 and -8 have been discussed to be involved in paracellular chloride transport.

Methods: Cortical collecting ducts (CCD) from principal cell-specific claudin-4 knockout animals (KO) and their respective controls (Ctrl) were investigated under normal diet and low salt diet. CCD were isolated by manual dissection, perfused *in vitro* and investigated for their basic trans- and paracellular transport properties. Transepithelial voltage (V_{te}), transepithelial resistance (R_{te}) and equivalent short circuit current (I'_{sc}) were measured before and after luminal application of 50 μM amiloride and 100 μM hydrochlorothiazide to inhibit transcellular ion transport. A diffusion potential was generated by changing the basolateral solution from 145 to 30 mM NaCl (isotonic) to test for paracellular ion selectivity and the permeability ratio P_{Cl}/P_{Na} was calculated. Immunofluorescence was used to localize and quantify claudin-4 expression along the nephron and particularly in the collecting duct.

Results: Under normal diet CCDs of Ctrl as well as of KO showed similar transcellular amiloride dependent lumen negative V_{te}. Under inhibition of transcellular transport, however, R_{te} was lower in KO CCD (111±8 Ωcm²) vs. Ctrl CCD (151±11 Ωcm²), respectively. P_{Cl}/P_{Na} values showed chloride selectivity in Ctrl CCD (1.36±0.08) but hardly any selectivity in KO CCD (1.07±0.03). Low salt diet increased amiloride dependent V_{te} in both genotypes to a similar extend, however, with increased R_{te} in KO CCD (192±16 Ωcm²) vs. in Ctrl CCD (147±11 Ωcm²), under inhibition of transcellular transport, respectively. P_{Cl}/P_{Na} did neither change in Ctrl CCD (1.24±0.05) nor in KO CCD (1.04±0.03). Immunofluorescence confirmed claudin-4 knockout with residual low expression of claudin-4 in intercalated cells.

Conclusions: In summary, claudin-4 is expressed in both, principal and intercalated cells of CCD and claudin-4 deficiency leads to the loss of Cl^- selectivity.

HIF Regulation of Nephron Progenitor Metabolic State Mediates Cell Fate Decisions Anjana Murali,[3] Kasey Cargill,[3] Elina Mukherjee,[3] Zubaida R. Saifudeen,[2] Sunder Sims-Lucas.[1] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Tulane University School of Medicine, New Orleans, LA; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Hypoxia inducible factors (HIFs) are transcription factors involved in the differentiation of nephron progenitors (NP) into functional nephrons. Alterations in nephron differentiation lead to renal abnormalities. As renal oxygen increases, von Hippel-Lindau (VHL) marks HIF-1α for degradation and facilitates normal nephron differentiation. Alternatively, pathological hypoxia results in HIF-1α accumulation and initiation of processes including cellular survival and metabolism. Previous *in vitro* studies have also linked HIF-1α stabilization to mitochondrial pathologies suggesting that HIF-1α plays a role in cellular and mitochondrial respiration. Therefore, we hypothesize that HIF-1α alters mitochondrial function, mediating a metabolic switch to determine NP fate.

Methods: To determine the role of HIFs in the NPs we utilized VHL floxed mice bred with the *Six2EGFPcre* line, to generate Six2creVHL$^{lox/lox}$ mutant mice. RNA sequencing was conducted on E14 whole kidneys to look at differential gene expression, and validated via RT-PCR. We also performed a metabolic assessment using seahorse extracellular flux analysis, and coupled this with immunofluorescence (IF) and western blot analysis to analyze metabolic markers.

Results: RNA sequencing of Six2creVHL$^{lox/lox}$ mutant mice revealed metabolic gene dysregulation. Furthermore, seahorse extracellular flux analysis suggested that mutants with HIF-1α stabilization in the NPs remained in a glycolytic state, and were subsequently unable to switch to oxidative phosphorylation, which drives NP differentiation. IF staining and western blot analysis supported these results revealing fewer mature nephron structures and decreased mitochondrial content in mutant kidneys.

Conclusions: HIFs are critical in determining the metabolic state of the NPs. In the absence of VHL, HIF1α is stabilized. This stabilization maintains NPs in a state of glycolysis and in turn blocks the switch to oxidative phosphorylation causing NP differentiation defects and kidney malformations.

TH-OR079

Cadherin-11 Is Induced by BMP7 and Stimulates Cap Mesenchyme Formation Midori Awazu,[1] Michio Nagata,[2] Mariko Hida.[1] *[1]Keio University School of Medicine, Tokyo, Japan; [2]Renal Vascular Pathology, University of Tsukuba, Tsukuba, Japan.*

Background: Cadherin-11 (CDH11) is an adhesion molecule specific to mesenchymal cells, which has been shown to promote cell migration and compaction and be involved in the differentiation of progenitor cells. In the developing kidney, CDH11 is expressed in cap mesenchyme and the interstitium. We investigated the role of CDH11 in kidney development and its relationship to BMP7, a growth factor necessary for maintaining and priming nephron progenitors.

Methods: Mice embryonic day 12 (E12) and E13 kidneys were transfected with two different siRNA against CDH11 (a or b) or irrelevant siRNA and cultured. Ureteric bud and cap mesenchyme were stained with pancytokeratin and Six2, respectively. An immortalized metanephric mesenchymal cell line MS7 was generated from the metanephroi of E11.5 homozygous mouse transgenic for H-2Kb-tsA (*J Am Soc Nephrol* 12:964, 2001). The effect of different concentrations of BMP7 (0.25, 1, and 10 nM) on CDH11 expression in MS7 was assessed by quantitative real-time PCR and immunoblot.

Results: Cap mesenchyme, marked by Six2, was well observed around ureteric tips in control metanephroi and those transfected with irrelevant siRNA. In metanephroi transfected with siRNA a or b, on the other hand, Six2-positive cells were diffusely distributed and condensation around the ureteric tips was faint. CDH11 expression, assessed by whole mount staining, was distinctly observed in cap mesenchyme in controls, but was diffuse and reduced in metanephroi transfected with siRNAs. Ureteric bud tip number was significantly reduced by siRNAs (a 6.3±1.5, b 5.8±0.2) compared with controls (7.3±2.4/kidney). Kidney size cultured with siRNAs also tended to be smaller (a 6.3±1.5, b 5.8±0.2, control 7.3±2.4). Incubation of MS7 with BMP7 for 24 h dose-dependently increased mRNA and protein expression of CDH11 with the maximal effect at 1 nM. Cadherin 6 and E-cadherin were not expressed by MS7 nor induced by BMP7. As previously reported by us, BMP7 1 nM stimulated both ERK and p38 at 24 h. While BMP7-stimulated proliferation of MS7 was suppressed by a MEK inhibitor PD98059 5 μM or a p38 inhibitor SB203580, BMP7-induced CDH11 expression was not inhibited by PD98059 or SB203580 alone but by combination of both.

Conclusions: CDH11 is induced by BMP7 *via* ERK and p38, and stimulates cap mesenchyme formation.

Single-Cell Analysis of Progenitor Cell Dynamics and Lineage Specification of the Human Fetal Kidney Cristina Cebrian Ligero,[1] Rajasree Menon,[1] Edgar A. Otto,[1] Austin Kokoruda,[1] Jian Zhou,[2] Zidong Zhang,[2] Olga Troyanskaya,[2] Jason R. Spence,[1] Matthias Kretzler.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]Princeton University, Princeton, NJ.*

Background: The study of animal models has identified a plethora of genes and pathways driving the repetitive and reciprocal interactions between the Ureteric Bud (UB) and the Metanephric Mesenchyme (MM) that give rise to the collecting system and the nephron pool. However, these expression patterns and how they drive differentiation have not been systematically characterized in the human kidney. We have used single-cell transcriptomics to study individual cell dynamics and characterize the expression profile of the human kidney.

Methods: Fetal kidneys (105 to 115 days of gestation) were dissociated to single cells and processed for DropSeq workflow as described by the McCarroll lab. Individual cells were identified by barcodes, and transcripts were tagged with Unique Molecular Identifiers. Paired-end RNASeq was performed on a HiSeq2500 platform. Bioinformatics analysis employed the Picard tools developed by the Broad Institute and unsupervised clustering algorithms were executed with the R package toolkit "Seurat". RNA profiles were mapped into trajectories derived using a nonparametric ridge estimation statistical framework. Gene expression was confirmed by immunofluorescence on fetal kidneys.

Results: Single cell transcriptome analyses of 3,865 cells (fig.A) enabled the distinction of UB-4 and MM-1 progenitors as well as their intermediate and differentiated lineages including the mature collecting ducts-18, the renal vesicle and comma- and s-shaped bodies-2, immature-9 and mature podocytes-13, proximal tubules-6, Henle's loop and distal tubules-8, as well as mesangium-5 and cortical-5 and medullary interstitium-10. Importantly, known as well as novel markers for these cell types were revealed in the analysis.

Conclusions: We have generated an accurate map of gene expression and lineage relationships (fig.B) in the human fetal kidney. These results confirm the expression of genes identified by studying animal models. New gene-expression patterns have also been identified that may help understand human renal development.

Profiling and Mathematically Modelling Cell and Tissue Morphogenesis during Renal Development Ian Smyth,[3] Kieran M. Short,[3] James Lefevre,[1] Timothy Lamberton,[5] Alexander N. Combes,[6] Andrew P. McMahon,[2] Melissa H. Little,[4] Nicholas A. Hamilton.[5] *[1]Institute for Molecular Bioscience, The University of Queensland, Highgate Hill, NSW, Australia; [2]Keck School of Medicine of the University of Southern California, Los Angeles, CA; [3]Monash University, Melbourne, NSW, Australia; [4]Murdoch Childrens Research Institute, Melbourne, VIC, Australia; [5]The University of Queensland, Brisbane, NSW, Australia; [6]University of Melbourne, Parkville, NSW, Australia.*

Background: While cell, tissue and even organism level analyses of morphogenesis are feasible in invertebrates, the size, opacity and complexity of mammalian organs has impeded systematic analyses of developmental processes critical to organ function.

Methods: Here, we integrate optical projection tomography, single-cell resolution confocal microscopy and quantitative image analysis to comprehensively document mouse kidney organogenesis across time. Using mathematical modeling, we develop a framework for generating and comparing modes of branching morphogenesis and compare these models with datasets derived from fetal mouse kidneys.

Results: Our tissue and cell based analysis reveals a previously unappreciated structurally stereotypic organ architecture undergoing a temporally non-uniform process of development with respect to rates of cellular proliferation, dominant morphogenetic processes and spatial relationships between key cellular compartments. Mathematical modelling was able to determine base patterning programs operant in driving branching of the ureteric epithelium, facilitating the analysis of different genetic and morphological impacts on the development of the organ.

Conclusions: Integrating cell, tissue and organ level datasets facilitates quantitative analysis of even subtle perturbations to kidney development and is also applicable to other organ systems. Our data describes a mechanism of branching morphogenesis which is highly patterned when comparing one organ to the next, and across developmental time. The existence of such distinct phases of development and patterning of branching morphogenesis predicts temporal sensitivity to genetic and environmental insults, potentially enhancing our understanding of the mechanism by which developmental anomalies and normal variation in renal anatomy arise.

TH-OR082

Polycomb Repressive Complex-2 (PRC2) Fine-Tunes Timing of the Final Wave of Nephrogenesis Samir S. El-Dahr,[2] Zubaida R. Saifudeen,[2] Hongbing Liu.[1] *[1]Tulane, New Orleans, LA; [2]Tulane University School of Medicine, New Orleans, LA.*

Background: The mechanisms that control cessation of nephrogenesis are not well understood. Heterochronic transplantation and epigenome profiling suggest that old nephron progenitor cells (NPC) are poised for differentiation limiting their lifespan. In stem cells, Enhancers of Zeste, Ezh1 and Ezh2, the catalytic components of PRC2, mediate H3K27 methylation to maintain lineage-specific genes in a silent yet poised state. We hypothesized that PRC2 activity restrains NPC aging and is essential for timely cessation of nephrogenesis.

Methods: We generated conditional Six2$^{Ezh2-/-}$; ROSA26^{Tomato} and compound Six2$^{Ezh2-/-}$;Ezh1$^{-/-}$;ROSA26^{Tomato} mice. Molecular and phenotypic analyses were accomplished by section IF and ISH at E15.5, E17.5, and P0, and transcriptome profiling of Six2-GFP^{+} cells at E17.5. Results were integrated with genome-wide maps of accessible chromatin, Six2 and histone mark occupancy, and scRNA-seq databases.

Results: Six2$^{Ezh2-/-}$ and germline Ezh1$^{-/-}$ kidneys are morphologically normal. In contrast, **E17.5** Six2$^{Ezh2-/-}$;Ezh1$^{-/-}$ and Six2$^{Ezh2-/-}$;Ezh1$^{+/-}$ NPC fail to form the cap mesenchyme and display a unique gene expression signature consisting of the cell cycle inhibitor Cdkn2a/p16, Lin28B (inhibitor of Let-7 miRNA upregulated in Wilm's tumor), Six1 (normally expressed in early metanephric mesenchyme but absent in mouse cap mesenchyme), Hoxd13 and Wnt5A/10A genes. In wild-type NPC, these aberrantly expressed genes are silent and heavily methylated on H3K27, yet display small peaks of accessible chromatin suggesting a state of epigenetic poising. At **P0**, Six2$^{Ezh2-/-}$;Ezh1$^{+/-}$ NPC undergo en mass differentiation into ectopic Tomato^{+}/Wnt4^{+}/Pax2^{+}/Lef1^{+}/Lhx1^{+} renal vesicles located dorsal to the UB tips, akin to the final wave of nephrogenesis that normally occurs at P2-P4. There was complete loss of H3K27me3 in double Ezh1/Ezh2 mutant NPC and their derived epithelial tubules.

Conclusions: We conclude that H3K27 methylation fine-tunes timing of the last wave of nephrogenesis by restraining Cdkn2a/p16 and unscheduled activation of canonical Wnts in NPC. Ectopic induction of Lin28B, Hox and Six1 in mutant progenitors suggests a state of arrested differentiation of metanephric mesenchyme. Interventions targeting PRC2 function may be beneficial for nephron progenitor maintenance and regeneration.

DNA Methylation Changes in Human Kidney Development and Disease Revealed by Whole Genome Bisulfite Sequencing of Tissue Samples Jihwan Park, Szu-Yuan Li, Matthew J. Seasock, Joshua S. Bryer, Rojesh Shrestha, Katalin Susztak. *Renal-Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA.*

Background: Numerous epidemiologic studies have confirmed the associations between "fetal programming" and development of chronic kidney disease (CKD) and hypertension. The epigenetic system is not only heritable but also under the influence of the environment, therefore proposed to mediate the environmental "programming effect". Cytosine methylation is important epigenetic signal, however limited data is available in kidneys of different conditions. In addition, most prior reports have examined epigenetic changes in only < 1% of about 1 billion cytosines in the genome.

Methods: Here, we generated base pair resolution methylome maps of early (11.5 weeks) and late (18.5 weeks) human fetal kidneys and microdissected tubules from healthy and CKD adult subjects (n=12). Our whole genome bisulfite sequencing (WGBS) data cover 96~98% of all CpGs with 15x mean genome coverage. Computational analysis included WGBS alignment and methylation extract followed by differential methylation analysis and PCA. Functional regions were mapped using histone modification ChIP-Seq datasets.

Results: In fetal kidneys we identified low methylated regions (LMRs) and unmethylated regions (UMRs) which are enriched in enhancers and promoters, respectively inferring their functional activity. Transcription factor motif analysis indicates enrichment for CTCF in early and SIX1 in late fetal kidneys in the LMRs. We also identified differentially methylation regions (DMRs) in adult CKD tubule samples when compared to the controls. DMR-genes were associated with immune and Notch signaling (VEGFA, TNF, STAT5A and NOTCH1). We finally compared fetal and adult kidneys, and found that (1) PC1 separates fetal from adult kidneys and (2) PC2 separates early fetal and adult fibrosis from late fetal and normal kidneys. The DMRs between the groups separated by PC2 are associated with developmental genes such as HNF1B, MTSS1, NOTCH1, PAX2 and SIX1. HNF1 binding motif is highly enriched in the DMRs and expression of HNF1B and its potential target, MTSS1, are reduced in fibrosis samples of human and mouse CKD models.

Conclusions: Our study provides a novel comprehensive epigenome map of human fetal kidneys and identified common DNA methylome changes in normal development and fibrosis, which offers new insight into injury repair processes in CKD.

TH-OR084

TFAP2A Is a Novel Regulator of Renal Progenitor Fate during Kidney Ontogeny Brooke E. Chambers, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

Background: Occurring in 1 in 500 births, Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) are the primary cause of pediatric end-stage renal disease. The central etiology of these conditions involves aberrant development of nephrons, which are the functional units of the kidney.

Methods: Zebrafish have emerged as a powerful genetic system to study the molecular coordination of cell fate decisions during vertebrate nephron formation. Here, through a forward ENU screen, we isolated a nephron mutant with abrogated distal tubules. Whole genome sequencing revealed a lesion that disrupts splicing of *transcription factor AP-2 alpha* (*tfap2a)*, thereby truncating essential transcriptional activation and DNA binding domains. Until now, *tfap2a* has been known as essential for neural crest and epidermis differentiation but was not appreciated to act during renal ontogeny.

Results: We found that *tfap2a* was dynamically expressed in zebrafish renal progenitors, eventually restricting to the distal tubules. During mouse embryogenesis, *tfap2a* expression was abundant within the developing urogenital tract encompassing structures such as the ureteric tip and distal tubules. Human *tfap2a* mutations result in branchio-oculo-facial syndrome (BOFS), which primarily affects craniofacial tissue, though case reports have linked *tfap2a* lesions to multicystic dysplastic kidney. Complementation tests between our mutant line and *tfap2a*^{m819}, which encodes a nonsense allele, as well as knockdown studies similarly abolished the distal tubule. Conversely, overexpression of *tfap2a* caused a striking expansion of distal cells. Through a subsequent suite of functional studies, we have determined that *tfap2a* acts upstream of several key lineage factors necessary for distal tubule formation, like the T-box transcription factor *tbx2b*. In addition, our data suggests *tfap2a* interplays with Iroquois homeobox genes *irx1a* and *irx3b* to pattern distal nephron structures.

Conclusions: Taken together, our studies have revealed novel mechanisms by which *tfap2a* directs cell fate during nephrogenesis. Examining the molecular activities of this conserved transcription factor in renal progenitors will shed light on the regulatory role of the mammalian homologue, *AP-2α*, in congenital diseases.

TH-OR085

Transcription Factor 21 (TCF21) Controls Branching Morphogenesis via GDNF Signaling and Has Pleiotropic Roles in Kidney Development Gal Finer,[4] Shintaro Ide,[1] Tomokazu Souma,[2] Minghao Ye,[3] Jing Jin,[3] Yoshiro Maezawa,[1] Susan E. Quaggin.[3] *[1]Chiba University Graduate School of Medicine, Chiba, Japan; [2]None, Chicago, IL; [3]Northwestern University, Chicago, IL; [4]Kidney Diseases, Northwestern University, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the leading cause of chronic kidney disease in children. Although the pathogenesis of CAKUT is incompletely understood and heterogeneous, many cases arise from alterations in genes critical for kidney development. We previously showed that absence of *Tcf21* causes CAKUT in the mouse but the mechanisms remain obscure.

Methods: We utilized systemic and conditional *Tcf21* knockout mouse models and employed immunohistochemistry, in-situ hybridization, RT qPCR and kidney explant studies.

Results: Global deletion of *Tcf21* showed abnormal UB branching and arrested mesenchymal to epithelial transition with resultant severe renal dysplasia. These kidneys had markedly reduced expression of *Gdnf*, *Wnt11* and *Ret* mRNA to 16%, 29% and 52% of normal levels respectively. When *Tcf21* was specifically deleted from the cap mesenchyme and its progenitors (Tcf21$^{fl/fl}$;Six2-Cre), mutant kidneys showed abnormal UB branching at early developmental stages (E11.5-13.5) but normal appearing collecting ducts subsequently. Importantly however, when *Tcf21* was selectively deleted from kidney stromal cells (Tcf21$^{fl/fl}$;FoxD1-Cre), the mice developed diabetes insipidus-like phenotype suggestive of functional defect in the collecting ducts. This was also supported by findings of severe defect in UB branching at early stages of kidney development and by the absence of collecting ducts at P0 in Tcf21$^{fl/fl}$;FoxD1-Cre mice. Mechanistically, deletion of *Tcf21* from renal stromal cells was again associated with down-regulation of *Gdnf* and *Wnt11* supporting impaired branching signaling. Moreover, the stromal factor BMP4, a known inhibitor of GDNF, was up-regulated in *Tcf21* null kidneys both at the mRNA and protein levels. This suggested that TCF21 controls UB branching by regulating BMP4.

Conclusions: Taken together, these results suggest that TCF21 is essential for normal branching morphogenesis via regulation of *Gdnf-Wnt11-Ret* axis, likely via control of BMP4 in the renal stroma. Further study is required to identify direct gene targets for TCF21.

Identification of GREB1L as a Novel Causative Gene for Bilateral Kidney Agenesis Lara De tomasi,[1] Pierre David,[2] Flora Silbermann,[1] Christelle Arrondel,[1] Olivier Alibeu,[3] Cecile Fourrage,[4] Brigitte Lelongt,[5] Joëlle Roume,[6] Christine Pietrement,[7] Bertrand Isidor,[8] Philippe Khau van kien,[9] Robert Novo,[10] Jelena Martinovic,[11] Marie Gonzales,[12] Laurence Heidet,[13] Sophie Saunier,[1] Cecile Jeanpierre.[1] *[1]Inserm UMR1163 - Imagine Institute, Paris, France; [2]Transgenesis Platform, Imagine Institute, Paris, France; [3]Genomic Platform, Imagine Institute, Paris, France; [4]Bioinformatics Platform, Imagine Institute, Paris, France; [5]UMR_S1155 - Tenon Hospital, Paris, France; [6]Department of Genetics, CHI POISSY ST GERMAIN EN LAYE, POISSY, France; [7]Pediatric Nephrology Department, American Memorial Hospital, Reims, France; [8]Department of Genetics, CHU Nantes, Nantes, France; [9]Department of Genetics, University Hospital Nîmes, Nîmes, France; [10]Department of Pediatric Nephrology, CHRU, Lille, France; [11]Unit of Fetal Pathology, Antoine Béclère University Hospital, Clamart, France; [12]Department of fetal pathology, AP-HP A Trousseau Hospital, Paris, France; [13]Pediatric Nephrology Department, Reference Center MARHEA, APHP - Necker Hospital, Paris, France.*

Background: Renal hypodysplasia (RHD) is a heterogeneous condition encompassing a spectrum of developmental kidney defects, i.e. renal agenesis, hypoplasia, and cystic and non-cystic dysplasia. Many studies have identified genes involved in kidney development. Heterozygous mutations in several of these genes have been shown to lead to various forms of RHD. However, the pathophysiological mechanisms leading to bilateral renal agenesis (BKA) remain largely elusive.

Methods: In order to identify novel RHD genes, we used whole exome/targeted exome sequencing and analysed familial and severe cases including 68 families/cases with BKA. *Greb1l* knock-out mice were generated using CRISPR/Cas9 and immunostaining analysis was performed in cleared kidneys.

Results: Through whole exome sequencing we identified heterozygous loss-of-function variants in *GREB1L* (Growth Regulation By Estrogen In Breast Cancer 1-Like) in two families with BKA fetuses. Targeted exome sequencing revealed *GREB1L* variations in 14 additional families, including 10 with BKA fetuses. Altogether, two nonsense, one frameshift, one splice and twelve damaging missense variants were identified. All these variants were absent from the ExAC database. *GREB1L* encodes an uncharacterised target of retinoic acid, never yet associated with kidney abnormalities. Embryonic lethality was observed in *Greb1l* knock-out mice in the homozygous state. Analysis at E13.5 revealed that all *Greb1l*$^{-/-}$ embryos were smaller and presented with exencephaly and lack of kidneys. Light-sheet imaging of cleared kidneys did not reveal any differences in size or branching in *Greb1l*$^{+/-}$ embryos compared to wild-type. We also showed that the fetal kidney was the major site of GREB1L expression. Analyses are in progress to more precisely characterize the pattern of expression within fetal kidney. In parallel, we generated *Greb1l* KO IMCD3 cells that are currently being used to analyse the role of Greb1l in epithelialization and branching. These cells will also be useful to validate the pathogenicity of the missense variations.

Conclusions: These data demonstrate that *GREB1L* represents a novel RHD gene with a crucial role in kidney development.

TH-OR087

Protein Kinase 2b (PTK2b): A Novel Marker That Controls Urinary Pacemaker Cell Function Norman D. Rosenblum,[1,2] Samir M. Iskander.[1,2] *[1]Paediatrics, The Hospital for Sick Children, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: Congenital non-obstructive hydronephrosis occurs in 0.5-1% of pregnancies. Previously, we demonstrated that murine congenital non-obstructive hydronephrosis is associated with absent expression of HCN3 and cKIT, which mark distinct populations of urinary tract pacemaker cells (utPMCs) located in the pelvis-kidney junction and ureter, respectively (*JCI*, 2011). Further, we showed that utPMCs are derived from the *Wnt1*+ neural crest (NC) cell lineage (Feeney M, ASN, 2015). Elucidation of the ontogeny and function of utPMCs in health and disease are limited by the lack of known cellular markers expressed earlier than the onset of expression of cKIT/HCN3 (E15.5). The goal of these studies is to identify novel utPMC proteins that control their function.

Methods: HCN3+ and cKIT+ cells were isolated and purified using FACS. RNAs differentially expressed in HCN3+ and HCN- cells were identified by RNA sequencing (Seq) and validated by quantitative (q) PCR. Protein expression was analyzed by immunoflouresence in situ. Contractile function was analyzed in murine pyeloureteric explants with time-lapse imaging. NC derived-cells were identified by TOMATO expression in *Wnt1-Cre;ROSA*$^{tdTomato+}$ mice.

Results: RNASeq of FACS-isolated murine E18.5 HCN3+ utPMCs versus adjacent HCN3- cells, identified *Ptk2b*, a regulator of Ca2+ signaling and ion channel activity, among seven other novel gene transcripts enriched in HCN3+ cells (P<0.0001, n=3/group). Validation of RNASeq results by qPCR revealed 11.5- and 2.5-fold higher *Ptk2b* mRNA in FACS-isolated HCN3+ and cKIT+ utPMCs, respectively, compared to their adjacent HCN3- and cKIT- cells (P<0.05, n=3). Co-localization with TOMATO in *Wnt1-Cre;ROSA*$^{tdTomato+}$ mice demonstrated PTK2B expression in NC cells as early as E12.5. Immunofluorescence in situ showed colocalization of PTK2b with HCN3 and cKIT as early as E15.5 with sustained PTK2B expression in cKIT+ and HCN3+ cells until P8 and adulthood, respectively. Treatment of murine pyeloureteric explants with the PTK2b inhibitors, PF431396 and Leflunomide (associated with human fetal non-obstructive hydronephrosis), decreased contraction frequency by 50% compared to vehicle-treated controls (P<0.01, n=3).

Conclusions: PTK2b is a novel marker of utPMCs that: (i) is expressed in neural crest cells before the onset of and coincident with HCN3 and cKIT expression, and (ii) controls pelvic-ureteric contraction.

TH-OR088

Survival and Kidney Transplant Incidence on Home versus In-Center Hemodialysis, Following Peritoneal Dialysis Technique Failure Sheru Kansal,[1] Jose A. Morfin,[3] Eric D. Weinhandl.[2,4] *[1]None, Cleveland, OH; [2]NxStage Medical, Inc., Victoria, MN; [3]University of California Davis, El Dorado Hills, CA; [4]University of Minnesota, Minneapolis, MN.*

Background: Peritoneal dialysis (PD) technique failure is often accompanied by complications that increase risks of hospitalization and death. Planned transition to hemodialysis may improve outcomes. Transitioning patients from PD to home hemodialysis (HHD) may improve continuity of lifestyle and facilitate delivery of more frequent treatment. However, data about transfer from PD to HHD are sparse.

Methods: We analyzed United States Renal Data System (USRDS) data from to compare incidence of death and kidney transplant in patients that transferred from PD to HHD in 2006-2012 and matched patients that transferred from PD to in-center hemodialysis (IHD). We used propensity score matching, with scores as a function of demographics and comorbidity; for each patient that transferred from PD to HHD, we selected 3 matched patients that transferred from PD to IHD. We used Fine-Gray regression to estimate intention-to-treat hazard ratios (HRs) of death and transplant for HHD versus IHD, in aggregate and stratified by insurance status (non-Medicare, Medicare).

Results: We identified 521 patients who transferred to HHD and 32,871 patients who transferred to IHD. Before matching, mean hospitalized days during the 6-month interval surrounding PD technique failure were 9.1 in Medicare patients who transferred to HHD and 18.5 in Medicare patients who transferred to IHD. Survival in HHD patients was 89.1% at 1 year and 80.5% at 2 years. The HR of death for HHD versus matched IHD patients was 0.76 (95% confidence interval, 0.65-0.90). In subsets of non-Medicare and Medicare patients, corresponding HRs were 0.57 (0.43-0.75) and 0.92 (0.75-1.13), respectively. In Medicare patients, lower hazard of death with HHD was evident only after 2 years of follow-up. Kidney transplant incidence in HHD patients was 10.6% at 1 year and 21.0% at 2 years. The HR of transplant for HHD versus matched IHD patients was 1.36 (1.14-1.61).

Conclusions: Transfer to HHD after PD technique failure was rare, but associated with lower risk of death and higher incidence of transplant than transfer to IHD. Heterogeneity in relative risks by insurance status suggests uncertainty about the magnitude of benefit. Still, the high hospitalization rate that typifies the transfer from PD to IHD suggests that clinical outcomes after PD technique failure can be improved.

TH-OR089

Contemporary Anemia Management in Peritoneal Dialysis Patients: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) Rachel Perlman,[1,2] Junhui Zhao,[2] Douglas S. Fuller,[2] Brian Bieber,[2] Yun Li,[3] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] David W. Johnson,[4] Hideki Kawanishi,[5] Simon J. Davies,[6] Martin J. Schreiber,[7] Jeffrey Perl.[8] *[1]University of Michigan Health Center, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI; [4]Princess Alexandra Hospital, Brisbane, QLD, Australia; [5]Tsuchiya General Hospital, Hiroshima, Japan; [6]University Hospital of North Midlands, Stoke-on-Trent, United Kingdom; [7]DaVita HealthCare Partners Inc., Denver, CO; [8]St. Michael's Hospital, Toronto, ON, Canada.*

Background: Gaps in knowledge exist regarding anemia management among peritoneal dialysis (PD) patients. We sought to understand international variation in anemia management among patients receiving PD.

Methods: PDOPPS is an international prospective cohort study based on randomly selected national samples of PD patients. Hemoglobin (Hgb), TSAT, and ferritin levels, as well as erythropoiesis stimulating agent (ESA) and iron use collected between 2014-16 were compared in cross-sections of PD patients at study enrolment. Results were analysed by country: Australia and New Zealand (A/NZ), Canada, Japan, United Kingdom (UK), and United States (US).

Results: Mean Hgb ranged from 10.9-11.2 g/dL across countries (table). ESA use was higher in Japan (93%) vs. 65-71% elsewhere, with ESA type varying by country. Median epoetin dose ranged from 2500-7250 units/week. In US and Japan, 87-88% of patients had a TSAT≥20%, compared to 72-76% of patients in other countries. Ferritin >500 ng/mL was most common in US, at 60% compared to 7-35% in other countries. IV iron use was higher in US (53%) than elsewhere (5-18%).

Conclusions: In the largest international study to date of anemia and iron management in PD patients, we have demonstrated comparable Hgb levels across countries but significant variations in markers of iron adequacy and ESA and iron use. Notably, US PD patients have higher ferritin levels, iron saturation and IV iron use than other countries. Future analyses will investigate whether these differences persist after patient- and facility-level adjustments, and will evaluate associations between anemia management practices and clinical and patient-reported outcomes.

Randomized Trial on Adjunctive Lavage for Severe Peritonitis Steve Siu-Man Wong,[1] Yuk L. Cheng,[1] Alex W. Yu.[2] *[1]Alice Ho Miu Ling Nethersole Hospital, N.T., Hong Kong; [2]Hong Kong Baptist Hospital, Kowloon, Hong Kong.*

Background: No adjunctive therapy has been shown to improve the antibiotic response in peritoneal dialysis (PD)-related peritonitis. This study was conducted to assess if adjunctive lavage is useful for severe cases, as it may enhance the removal of bacteria and inflammatory cells from the peritoneal cavity.

Methods: Intraperitoneal (IP) cefazolin/ ceftazidime were the empirical treatment for PD peritonitis. Severe cases were defined as persistent symptoms with PD effluent (PDE) leukocyte count >1090/mm^3 on day 3. We excluded patients with concurrent exit site infection (ESI), or known fungal/ mycobacterial growth from the PDE. Recruited patients with severe peritonitis were randomized into the lavage or control group. While both groups involved empirical antibiotics escalation (vancomycin/ gentamicin) before the microbiology report became available, continuous lavage by a cycler PD machine was applied in the lavage group for 2-3 days, during which the antibiotics were given intravenously. Usual PD regimen and IP administration of antibiotics were resumed after lavage completed. Primary endpoint was the treatment outcome: success (cleared PDE) or failure (catheter removed).

Results: Between March 2014 and May 2017, there were 399 peritonitis episodes in our center. A total of 39 episodes, involving 36 patients, were recruited. The other 360 episodes were not recruited mostly because of their mild severity or treatment initiated in other units. Among the recruited patients, 5 were excluded due to later development of ESI (n=1), fungal (n=3) or mycobacterial growth (n=1) from the PDE. The peritonitis details and outcome are shown in the Table.

Conclusions: Adjunctive lavage did not bring additional merit. Yet, the high treatment success rates in both groups indicated that an early antibiotic escalation could be beneficial in severe PD peritonitis with poor clinical response.

Patients' characteristics & peritonitis details

	Lavage group (n=17)	Control group (n=17)	P values
Age, years	64.1 ± 9.2	58.8 ± 10.2	0.12
Male gender, n (%)	12 (70.6)	5 (29.4)	0.04
Peritoneal dialysis vintage, years	4.2 ± 2.7	4.7 ± 3.6	0.57
Dialysate leukocyte count on day 3, /mm^3	6804 ± 5164	5297 ± 3876	0.34
Gram-positive peritonitis, n (%)	6 (35.3)	10 (58.8)	0.30
Gram-negative peritonitis, n (%)	8 (47.1)	4 (23.5)	0.28

Retroperitoneal Leakage as an Important Cause of Acute Ultrafiltration Failure in Peritoneal Dialysis Patients Min Zhang,[4] Qionghong Xie,[3] Da Shang,[1] Chuan-Ming Hao,[2] Tongying Zhu.[1] *[1]Division of Nephrology, Huashan Hospital, Fudan University, Shanghai, China; [2]Huashan Hosp., Shanghai, China; [3]Huashan Hospital of Fudan University, Shanghai, China; [4]Huashan Hospital, Fudan University, SHANGHAI, China.*

Background: Acute ultrafiltration failure (AUFF), characterized by a sudden reduction in ultrafiltration, is one of the causes of technique failure in peritoneal dialysis (PD). AUFF can lead to fluid overload, which is a high risk factor for mortality in PD patients. Retroperitoneal leakage (RPL) is one of the causes of AUFF. In this study, we aimed to analyze the risk factors of RPL in PD patients and observe the outcomes.

Methods: RPL was determined by magnetic resonance (MR) peritoneography in the patients with AUFF. Non-AUFF patients were chosen as controls. Demographic and PD related characteristics were analyzed between these two groups and treatment outcome was observed in RPL patients.

Results: During a 6-year observational period, 142 out of 421 PD patients developed AUFF, and 49 (34.5% in AUFF) of them were diagnosed as RPL by MR Peritoneography. None of RPL patients had hernia, pleural fistula or PD tube exit fistula, while one patient had scrotal fistula. Twenty-one (42.9%) of the RPL cases occurred in the first 3 months, while 16 (32.7%) occurred after 2 years' PD therapy. The percentage of male patients was significantly higher in the RPL group than in the controls (75% vs. 51%, P=0.003). RPL patients were younger than non-RPL patients (48.42±14.64 vs. 55.86±16.99, P<0.001). No child-bearing experience was a risk factor for RPL in female PD patients (3/12 vs. 10/119, P=0.002). While multi-variants analysis showed that only younger age was a risk factor (P=0.017). After 8 weeks' intermittent peritoneal dialysis (IPD) or hemodialysis, four patients turned to hemodialysis permanently because of severe and persistent leakage, while others improved remarkably confirmed by MR peritoneography and resumed CAPD.

Conclusions: RPL is common in PD patients and an important cause of AUFF. MR peritoneography is an ideal diagnostic method to detect RPL. Risk factors for RPL include younger age and probably no child-bearing experience in females. RPL is reversible after transitional therapy of IPD or hemodialysis.

Bio Impedance Measurements Taken Over a Period of Time May Be Better Predictors of Survival Than Baseline Measurements in Peritoneal Dialysis Patients Hari Dukka,[3] Mark Lambie,[1] Simon J. Davies.[2] *[1]Keele University, Crewe, United Kingdom; [2]University Hospital of North Midlands, Stoke-on-Trent, United Kingdom; [3]Nephrology, University Hospital North Midlands, Stoke on Trent, United Kingdom.*

Background: Numerous recent studies have shown that a single measure of body composition estimated from bioimpedance (BI) in dialysis patients is predictive of survival. However, fluid status varies with time and it is not known whether repeated measures improve predictions when compared to a single measure.

Methods: We analysed the long-term predictive value of baseline and longitudinal (5 measures over 12 months). BI measurements obtained from 289 patients enrolled into the UK and Shanghai BI trial (4 centres, 2009-2010). Patients were followed up until a censor date of 30 April 2016 and events such as death, Haemodialysis and transplantation were recorded. Analysis was performed using Cox model stratified for centre.

Results: On univariate analysis, increased extracellular water to total body water ratio (ECW/TBW) and lower phase angle (PA) predicted worse survival with HR's of 1.063 (95% CI 1.030-1.097) and 0.792 (95% CI 0.671-0.933) respectively. In an analysis adjusted for age, co-morbid score, albumin and urine volume, baseline values of both ECW/TBW and PA provided estimated hazard ratios closer to 1 (HR 1.023, 95% CI 0.984-1.063, and HR 0.913, 95% CI 0.761-1.095 respectively). When time varying rather than baseline values were used in the same adjusted analysis, the goodness of fit statistics improved significantly (ECW/TBW Δ-2LL 7.7, PA Δ-2LL 6.2) and estimated HR's were further from 1 (ECW/TBW HR 1.063, 95%CI 1.023-1.106, PA HR 0.726, 95%CI 0.577-0.913).

Conclusions: Our analysis demonstrates that repeated BI measurements over a period of time increases the predictive value compared to baseline measurements.

Effects of Long-Term Treatment with Low GDP, pH Neutral Solution on the Peritoneal Functions and Morphological Changes in PD Patients Mitsuhiro Tawada,[1,2] Yasuhiko Ito,[3,2] Chieko Hamada,[4] Masashi Mizuno,[2] Yasuhiro Suzuki,[2] Fumiko Sakata,[2] Shoichi Maruyama.[2] *[1]Koujyukai Kasugai Hospital, Kasugai, Japan; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Aichi Medical University, Nagakute, Japan; [4]Juntendo University, Tokyo, Japan.*

Background: Effects of long-term treatment with acidic solution on the peritoneal membrane are well known. However, the peritoneal membrane damage induced by long-term peritoneal dialysis low GDP, pH neutral solution (neutral solution) has not been

reported in detail. The aim of this study was to investigate the effects of neutral solutions on peritoneal functions and morphological changes.

Methods: This study used pathological and immunopathological techniques to assess peritoneal membrane biopsy samples from peritoneal dialysis patients treated with acidic solution or neutral solution. And we investigate the D/P Cr changes by long-term neutral solution treatments.

Results: The morphological changes were compared between the acidic solution group (n=54) and neutral solution group (n=67). According to the analyses, the ratio of lumen diameter to vessel diameter (L/V ratio) was significantly smaller ($p<0.01$), peritoneal membrane was thicker ($p<0.01$) and accumulation of advanced glycation end-products (AGEs) was higher in the acidic solution group than in the neutral solution group ($p<0.01$). In addition, acidic solution group (n=33) and neutral solution group (n=31) who were treated for 4 to 10 years were compared. In this study, the L/V ratio was significantly smaller ($p<0.01$) and peritoneal membrane was thicker ($p=0.034$), and there were no significant differences in number of CD31 positive vessels and CD68 positive cells between the two groups. Furthermore, the L/V ratio in the acidic solution group significantly decreased over time ($p<0.01$), no such change was seen in the neutral solution group. According to the results of peritoneal equilibration tests for long term neutral solution treatments, D/P Cr also did not change over time.

Conclusions: These findings suggest that neutral peritoneal dialysis solutions prevent morphological changes and keep peritoneal functions with no changes in D/P Cr after long term PD treatment.

TH-OR094

Socioeconomic Factors and Racial/Ethnic Disparities in PD Initiation Jenny I. Shen,[1] Holly Wilhalme,[3] Sitaram Vangala,[3] Anjali B. Saxena,[2] Keith C. Norris.[3] *[1]LaBiomed at Harbor-UCLA, Torrance, CA; [2]Stanford University / Santa Clara Valley Med Ctr, Los Altos, CA; [3]UCLA, Los Angeles, CA.*

Background: Peritoneal dialysis (PD) has been underutilized in the US. The discrepancy is most pronounced in black and Hispanic patients who, despite having a higher prevalence of chronic kidney disease than non-Hispanic White and Asian patients, are less likely to use PD. We investigated the association of socioeconomic factors with racial and ethnic disparities in the initiation of dialysis with PD in the US.

Methods: We identified from the USRDS all adult patients who initiated dialysis on Day 1 with either hemodialysis (HD) or PD from 2005-13 and categorized them as either non-Hispanic White, Hispanic White, non-Hispanic Black, or non-Hispanic Asian. We then used logistic regression to estimate the odds ratio (OR) of initiating dialysis with PD vs. HD for each of the minority groups compared to non-Hispanic White patients.

Results: Of 522,767 patients, 55% were non-Hispanic White, 28% black, 13% Hispanic white, and 4% Asian; 8% started dialysis on PD. In unadjusted analyses, Blacks and Hispanics were 30% and 21% less likely and Asians were 32% more likely to start on PD than whites (Table). The gap for Blacks and Hispanics widened and for Asians lessened when adjusted for age, sex, and calendar year of dialysis initiation. However, the disparities narrowed when adjusted for individual and neighborhood level socioeconomic factors.

Conclusions: Black and Hispanic patients are less likely to start on PD than White patients, especially given their age, sex, and era of dialysis initiation. This disparity is reduced, but still statistically significant when adjusted for socioeconomic factors. More research is needed to determine whether these variables are associated with potentially modifiable factors such as physician or patient bias against starting PD in patients of a certain socioeconomic background.

TH-OR095

Quasi-Continuous Monitoring of intraperitoneal Volume Using Segmental Bioimpedance in Peritoneal Dialysis Patients Fansan Zhu,[1] Samer R. Abbas,[1] Roxana M. Bologa,[2] Nathan W. Levin,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]The Rogosin Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Ultrafiltration failure (UFF) is a frequent complication in peritoneal dialysis (PD) patients. The peritoneal equilibration test (PET) is the standard method for assessing peritoneal transport characteristics. However, dynamic changes in intraperitoneal volume (IPV) during the dwell cannot be determined by PET. The aim of this pilot study was to explore the feasibility of segmental bioimpedance analysis (SBIA) to quasi-continuously monitor IPV during dwell periods.

Methods: 10 PD patients (7 females, age 59±8.8 years, weight 71.9±12 kg) with standard 4 hours PET using 2 L of 2.5 % dextrose PD solution were studied. Eight electrodes were placed as shown in Figure 1. At 5 kHz resistance (R_5, Ohm) was measured from each pair of electrodes minute-by-minute with the Hydra 4200 device. During the PET IPV was calculated from the average R_5 of the left and right sides of the abdomen (Zhu et al., *Am J Kidney Dis*, 42:167-172, 2003). This setting allowed us to follow the IPV time course and determine the maximum IPV from visual inspection of the recordings.

Results: In 9 patients the IPV measurements were technically successful; in 1 patient signal quality was poor. Figure 2 shows a typical IPV measurement. Average (SD) drain volume at 4 hours was 0.5±0.3 L by SBIA compared to weight loss (ΔWt) of 0.54±0.27 kg. Maximal IPV indicated by SBIA was 1.0±0.4 L. The difference between maximal IPV and drain volume was 0.5±0.4 L (95% confidence interval: 0.2 to 1.2; $P<0.01$ in a paired t-test) L. Maximal IPV was reached after a dwell time of 157±57 minutes (range 113 to 200 min).

Conclusions: This pilot study demonstrates the feasability of segmental bioimpedance to quasi-continuoously monitor IPV and to identify the time point of maximum IPV. These insights may help to optimize individual PD treatments and improve ultrafiltration efficiency. While these results are encouraging, additional validation studies, to automatically detect maximum IPV, and efforts to improve measurement convenience are required.

Low Serum Potassium Is Associated with Indicators of Under-Nutrition and Reduced Residual Kidney Function: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) Simon J. Davies,[1] Junhui Zhao,[2] Brian Bieber,[2] Douglas S. Fuller,[2] James A. Sloand,[3] Andreas Vychytil,[4] Hideki Kawanishi,[5] David W. Johnson,[6] Angela Y. Wang,[7] Sarinya Boongird,[8] Thyago P. Moraes,[9] Sunil V. Badve,[10] Jeffrey Perl.[11] *[1]University Hospital of North Midlands, Stoke-on-Trent, United Kingdom; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Baxter Healthcare Corporation, Deerfield, IL; [4]Medical University of Vienna, Vienna, Austria; [5]Tsuchiya General Hospital, Hiroshima, Japan; [6]Princess Alexandra Hospital, Brisbane, QLD, Australia; [7]University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [8]Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [9]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [10]St. George Hospital, Kogarah, NSW, Australia; [11]St. Michael's Hospital, Toronto, ON, Canada. Group/Team: On behalf of PDOPPS dialysis prescriptiOn and fluid management working group.*

Background: Serum potassium <4mmol/L is associated with increased all-cause mortality risk and possibly increased risk of peritonitis in PD patients. We evaluated the relationship between serum potassium (K) and patient characteristics and clinical practices in PDOPPS.

Methods: PDOPPS is a prospective cohort study of PD treatment and outcomes in Australia, Canada, Japan, New Zealand, Thailand, the UK, and the US. Using the most recent value within 8 months of study enrollment, we defined low K as <4 mEq/L. We assessed demographic and clinical associations with low K using logistic regression generalized estimating equations.

Results: Among 2486 incident and prevalent patients analyzed, 69% had K <4 mEq/L. Demographic variables were similar in patients with or without low K. Low K was associated with several indicators of poorer nutritional status, including lower levels of serum phosphorus, creatinine, and albumin, but higher levels of serum bicarbonate. Patients with greater residual kidney function were less likely to have low K. Low K was associated with higher prescribed glucose concentrations and systolic blood pressure.

Conclusions: Low K is associated with indicators of reduced muscle mass and/or protein intake and reduced residual kidney function rather than increased dialytic clearance. Increased blood pressure and prescription of glucose in patients with K≥4 mEq/L group likely reflects their higher oral salt and fluid intake but could reflect increased calorie contribution from dialysate. Clinicians should recognize that lower K levels, even within the normal range, may reflect under-nutrition particularly when associated with reduced residual function and that could contribute to increased mortality risk.

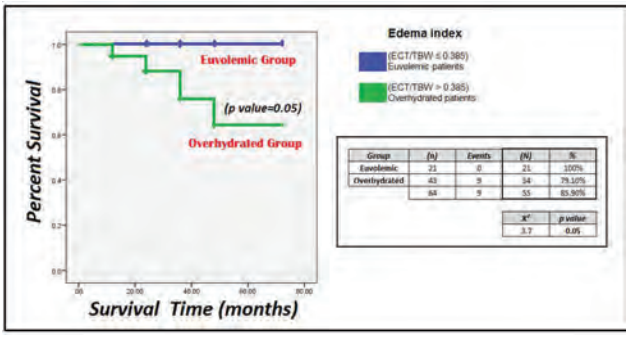
New Overhydration Definition and Mortality Risk Assessment in Automated Peritoneal Dialysis Mexican Patients Julio C. Arriaga,[2] Gabriela Leal,[3] Bernardo Moguel.[1] [1]*Instituto Nacional de Cardiologia, Mexico City, Mexico;* [2]*Instituto Nacional de Cardiologia Ignacio Chavez, Tlalpan, Mexico;* [3]*Instituto Nacional de Cardiología, México, Mexico.*

Background: CKD prevalence in Mexico is about 33% and peritoneal dialysis (PD) represents 66% of renal replacement therapy. Overhydration assessment with bioimpedance in APD patients may be a key point predictor for mortality.

Methods: We analyze an APD cohort of 64 Mexican patients. Anthropometric, blood and nutritional profiles, time in APD, dialysis prescription, use of medication and bioimpedance analysis was assessed and reported as the average of 3 repeated samples during the last 6 months. Inclusion criteria were age ≧18 years, clinical and biochemical stability and adherence to dialytic therapy. Patients with other systemic comorbidities were excluded. Edema index *(Ei)* was defined as ECW/TBW (extracellular water/ total body water) ≧0.385 and phase angle (*Pa*)⟨4.8. Euvolemic and overhydrated groups were compared in mortality, regression, correlation and risk factor analysis.

Results: Mean age was 38.9 ±15 years. BMI was normal in half of the patients; 43 patients were overhydrated and 21 euvolemic, we observed significant differences between groups (p⟨0.05) for *Ei*, *Pa*, albumin, residual urine volume and RDW. Survival analysis at 48 months was 100% for euvolemic arm and 79.1% for overhydrated patients (*p=0.05*). Regression model showed an *r2= 0.6*. Correlation coefficient analysis for overhydration was 0.85 for *Pa* and 0.52 for low albumin both with p⟨0.05. Risk factors for mortality were *Ei* OR=1.26 (IC 1.08-1.47), *Pa*⟨4.8 OR=6.13 (IC 1.16-32.3), albumin ⟨3.5 OR=5.8 (IC 1.29-26.5), Age ≧50 years OR=5.0 (IC 1.15-21.7) and RDW ≧14.5% OR=1.38 (1.12-1.69).

Conclusions: Bioimpedance analysis is a practical, useful, cheap, easy and relevant evaluation that impacts on mortality. Cut point values for Mexican PD population *(Ei*=0.385 and *Pa*=4.8*)* are proposed as a new overhydration definition in stable normotensive and non-clinical edema patients. Overhydration, albumin and RDW model predicts 60% of mortality risk in this population.



TH-OR098

Development of an AKI Prediction Model Using Machine Learning Jay L. Koyner, Kyle Carey, Matthew M. Churpek. *University of Chicago, Chicago, IL.*

Background: Early identification of hospitalized patients at risk for the development of AKI prior to changes in serum creatinine(SCr) may improve patient outcomes. We aimed to develop an AKI risk prediction algorithm using electronic health record(EHR) data across ward and ICU patients

Methods: All hospitalized patients at the University of Chicago who had SCr measured from 11/2008 to 1/2016 were eligible. Patients with a first SCr>3.0mg/dl, those who had an ICD9 code for CKD Stage 4 or higher, or received renal replacement therapy(RRT) within 48 hours (hrs) of admission were excluded. Demographics, vital signs, lab results, interventions, medications, blood transfusion & diagnostic testing were utilized in a gradient boosted machine learning algorithm to predict SCr-based KDIGO stage 2 AKI, with 60% of the data used for derivation and 40% for validation. Area under the curve (AUC) was calculated in the validation cohort, and subgroup analyses were conducted across admission SCr, AKI severity, and hospital location

Results: Among the 121,158 included patients, 17,481(14.4%) developed KDIGO AKI, with 4,251(3.5%) developing Stage 2 and 1,997(1.6%) Stage 3. The AUC(95%CI) of the model in the validation cohort was 0.90(0.90-0.90) for predicting Stage 2 AKI within 24 hrs and 0.87(0.87-0.87) within 48 hours. The AUC was 0.95(0.95-0.95) for Stage 3 in 24 hrs and 0.92(0.92-0.93) for 48 hrs. Accuracy was excellent for predicting RRT(n=821) in the next 72 hrs 0.94(0.94-0.94). AUCs for the subgroups can be found in the table. At a threshold with a sensitivity of 85% and a specificity of 85%, the median time from first reaching the threshold to stage 2 AKI was 42(IQR 12,140) hrs

Conclusions: Readily available EHR data can be used to predict impending AKI prior to changes in SCr with excellent accuracy across different patient locations and admission SCr. Real-time use of this model would allow early diagnostic and therapeutic interventions for those at high risk of AKI and may improve cost and outcomes

	AUC(95%CI) for Predicting Stage 2 AKI within 24 hrs

The Effect of Early Initiation of Renal Replacement Therapy Guided by Furosemide Stress Test on Clinical Outcomes: A Multicenter Randomized Controlled Trial (FST Trial) Nuttha Lumlertgul,[1] Sadudee Peerapornratana,[1] Karjbundid -. Surasit,[2] Thananda Trakarnvanich,[3] Wanjak Pongsittisak,[3] Pleumjit Tankee,[4] Kriang Tungsanga,[1] Somchai Eiam-Ong,[1] Kearkiat Praditpornsilpa,[1] Nattachai Srisawat.[1] [1]*Chulalongkorn University, Bangkok, Thailand;* [2]*Nakornping hospital, Chiangmai, Thailand;* [3]*Vajira Hospital, Bangkok, Thailand;* [4]*Vachira Phuket Hospital, Phuket, Thailand.*

Background: Recently, furosemide stress test (FST) has been introduced as a novel acute kidney injury(AKI) test. Furosemide-nonresponsive AKI patients have poor outcomes. There are unavailable data whether early initiation of renal replacement therapy (RRT) in furosemide non-responsive AKI patients could provide better outcomes than standard RRT. This FST trial **(NCT02730117)** was conducted to determine whether early initiation of RRT in furosemide-nonresponsive patients could improve 28-day mortality.

Methods: AKI patients were recruited from 5 tertiary care hospitals. FST was performed by giving intravenous furosemide (1 mg/kg in furosemide-naïve or 1.5 mg/kg in previous furosemide use). Furosemide non-responsive patients (urine output less than 200 mL in 2 hours) were randomized into early or standard RRT group. With the early strategy, RRT was initiated within 12 hours after randomization. With the standard strategy, RRT was started when standard criteria were met. We also collected blood samples for testing plasma NGAL, NT-proBNP and angiopoietin-2 on day 0, 3, and 7.

Results: Among 87 furosemide-nonresponsive patients, 97.7% in the early RRT group and 70.5% in the standard RRT group received RRT. The 28-day mortality in the early RRT and the standard RRT were comparable (65.1 VS 56.8%, P=0.33). There was no difference in the dialysis dependence rate (35.3 VS 45%, P=0.55). Interestingly, urine output on day 7 in the early RRT group was lower than the standard RRT group (498.5 VS 1,560 mL, P=0.035). There was a trend of more hemodynamic instability related to RRT in the early RRT group than the standard group (32.6 VS 15.9%, P = 0.07). Of interest, time to renal recovery occurred significantly earlier in the standard than the early RRT group (2 VS 7 days; P=0.018). There were no differences in plasma NGAL, NT-proBNP, and angiopoietin-2 levels between 2 groups.

Conclusions: This was the first study to test the role of FST in guiding RRT initiation. Early RRT in furosemide-nonresponsive patients is not recommended since it could not improve 28-day mortality and might prolong time to renal recovery.

Urinary Matrix Metalloproteinase-7 Predicts Severe AKI and Poor Outcomes after Cardiac Surgery Xiaobing Yang,[2] Fan Fan Hou.[1] [1]*Nanfang Hospital, Guangzhou, China;* [2]*Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Urinary matrix metalloproteinase (uMMP)-7 levels faithfully reflect the activity of intrarenal Wnt/β-catenin which is activated in AKI models. uMMP-7 level might be used as a noninvasive biomarker for early predicting AKI after cardiac surgeries.

Methods: we performed a prospective, multicenter, two-stage cohort study in 721 patients undergoing cardiac surgery. In stage 1, 323 children were recruited from 3 academic medical centers. In stage 2, 398 adults were enrolled at 6 centers. The levels

of uMMP-7 and other injury biomarkers were analyzed during the perioperative period. Severe AKI was defined as Kidney Disease Improving Global Outcomes stage 2 or 3.

Results: uMMP-7 peaked within 6 hours after surgery in patients who subsequently developed severe AKI. After multivariate adjustment, the highest quintile of uMMP-7 was associated with 17-fold (in adults) and 36-fold (in children) higher odds of severe AKI compared with the lowest quintile. Elevated uMMP-7 associated with increased risk of composite events (severe AKI, acute dialysis, and in-hospital death) and longer stay in intensive care unit and hospital. For predicting severe AKI, uMMP-7 had an area under the receiver-operating characteristic curve (AUC) of 0.81 (in children) and 0.76 (in adults), outperforming urinary interleukin-18, urinary angiotensinogen, urinary neutrophil gelatinase-associated lipocalin, urinary albumin to creatinine ratio, urinary tissue inhibitor metalloproteinase-2×IGF-binding protein-7, and the clinical model. uMMP-7 significantly improved risk reclassification over the clinical model alone as measured by net reclassification improvement and integrated discrimination improvement.

Conclusions: uMMP-7 is a promising predictor for severe AKI and poor in-hospital outcomes in patients after cardiac surgery.

Urine Insulin like Growth Factor Binding Protein1 (IGFBP1): Novel Prognostic Biomarker in AKI Nithin Karakala,[1,2] Ricky Edmondson,[1] Christian Herzog,[1] John M. Arthur.[1,2] *[1]Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR; [2]Nephrology, Central Arkansas VA, Little Rock, AR.*

Background: Serum creatinine (Cr) is a poor prognostic marker in early AKI. Prognostic urine biomarkers could be valuable tools to detect high risk patients in early AKI. We identified urine IGFBP1 as a potential biomarker using discovery proteomics and validated it in a larger cohort.

Methods: We performed liquid chromatography/ tandem mass spectrometry on urine from patients who developed stage 1 AKI within 48 hours after cardiac surgery. 10 patients that required renal replacement therapy within 7 days after surgery were matched to 20 patients with similar comorbities, baseline Cr, surgical type, bypass status and change in Cr at urine collection. The biomarker concentration was subsequently measured in 213 patients by ELISA to validate the prognostic ability. The primary outcome in the validation set was the composite of death, renal replacement therapy (RRT) and KDIGO stage 3.

Results: In the discovery phase we identified 2065 high confidence proteins of which 126 had p values of less than 0.01 between groups. IGFBP1 had the largest fold increase in RRT (14.8-fold). Median amino acid coverage of IGFBP1 in controls was 0% (range 0-15%) and 26% (0-38%) in RRT. Based on these data, we performed validation with ELISA in a larger cohort. Of the 213 patients included in the validation set, 27 met the primary outcome. The median time to urine collection from cardiac surgery was 22 hours (range:19-43). There were no significant differences between the outcome groups with respect to demographics, underlying medical conditions, type of surgery or pre-op Cr. The median concentration of IGFBP1 was significantly higher in the primary outcome group at 40 (95%CI:10-244) vs 3 (1-11) ng/ml; p<0.05. Median concentration of IGFBP1 was significantly higher in those that met secondary outcomes of mortality (40, 95%CI: 10-333 vs 3: 1-16 ng/ml; p<0.05) and RRT (81: 13-353 vs 4: 1-17 ng/ml; p<0.05) compared those who did not meet these outcomes. Urine IGFBP1 levels were highly discriminative for identifying the primary outcome (ROC AUC: 0.85) and the secondary outcomes death (0.82) and dialysis (0.85). The results did not significantly change when urine IGFBP1 concentrations were normalized to urine Cr.

Conclusions: Urinary IGFBP1 is a prognostic biomarker of AKI after cardiac surgery and can predict adverse outcomes early in the course of disease.

Polymyxin-B Induces Fas-Mediated Apoptosis in a Human Kidney Proximal Tubule Microphysiological System (Organ-on-a-Chip) Pavan K. Bhatraju,[2] Elijah Weber,[2] Jonathan Himmelfarb,[1] Edward J. Kelly.[2] *[1]Kidney Research Institute, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: In response to the emergence of multi-drug resistant gram negative infections, polymyxin-B (PMB) use has increased despite the clinical observations of severe nephrotoxicity. Our lab is modeling PMB-induced nephrotoxicity in 2D proximal tubule epithelial cells (PTECs) and in a 3D microphysiological system (MPS) to identify biological pathways in the development of renal epithelial cell injury.

Methods: PTECs were treated in 2D with escalating doses of PMB (0 uM to 800 uM). Cellular viability (cell cytotoxicity assay) and caspase 3, 7 activation (fluorescent caspase detection) were measured. The minimal concentration that led to cell death in 2D cultured PTECs was used in the MPS. The MPS system was treated with 50 uM for 48 hours. Effluent was collected at 24 hours and analyzed for caspase cleaved cytokeratin 18 (CK-18). Additionally, transcriptional response was analyzed via RNA-sequencing (RNA-seq) of PMB treated MPS.

Results: In two separate donors, PMB-induced toxicity was observed in 2D in a concentration dependent manner with decreasing cellular viability with increasing PMB concentrations. The EC50 for PMB was 130 uM (SD +/- 12.3) and the minimal concentration that led to cell death was 50 uM. Additionally, we observed increasing caspase activation with decreasing cellular viability (one way ANOVA p-value <0.0015). In the 3D MPS, PMB significantly increased CK-18 effluent levels (control 70 +/- 11 U/l versus PMB 207 +/- 24 U/l, p < 0.001). RNA-seq demonstrated increased transcription of Fas/FasL related genes including Fas cell surface receptor (*FAS*), Fas associated death domain (*FADD*) as well as others. The RNA seq response was distinct compared to MPS treated with cadmium, another known nephrotoxicant.

Conclusions: We have demonstrated that in 2D and in 3D, PMB induced injury is mediated through apoptosis. Furthermore, transcriptional response data demonstrates upregulation of Fas pathways in human PTECs after PMB exposure. This study supports continued study of apoptosis and the Fas-pathway to potentially develop therapies that ameliorate PMB induced nephrotoxicity. Clinically, CK-18 may be useful as a biomarker of PMB induced-AKI. This research was supported by an unrestricted gift from the Northwest Kidney Centers to the Kidney Research Institute, F32DK112532, UH3TR000504.

Precision Medicine in Renal Failure: Role of Lanosterol Synthase Gene and Endogenous Ouabain in AKI Marco Simonini,[4] Chiara Lanzani,[4] Elena Bignami,[4] Nunzia Casamassima,[4] Lorena Citterio,[8] Rossella Iatrino,[9] Roberta Meroni,[2] Laura Zagato,[2] Simone Fontana,[7] Simona Delli carpini,[3] Elisabetta Messaggio,[6] Elena Brioni,[10] John Hamlyn,[5] Paolo Manunta.[1] *[1]HSR-Nefrologia, Milano, Italy; [2]Ospedale San Raffaele, Milano, Italy; [3]San Raffaele Hospital, Milano, Italy; [4]San Raffaele Scientific Institute, Milan, Italy; [5]University of Maryland, Baltimore, Baltimore, MD; [6]Università San Raffaele, Milano, Italy; [7]Università Vita Salute San Raffaele, Milan, Italy; [8]Università Vita-Salute - Ospedale San Raffaele, Milano, Italy; [9]Vita-Salute San Raffaele University, Milan, Italy; [10]ospedale San Raffaele, Milan, Italy.*

Background: A key question in renal failure concerns the mechanism(s) that underlie the decline in renal function. Endogenous Ouabain (EO) has been proposed as predictive biomarker for acute kidney injury (AKI), and effector of glomerular damage in salt-sensitive hypertensive rats. Lanosterol Synthase (LSS) is a key enzyme in the EO biosynthesis. This work explores the association of LSS genotypes and kidney EO with renal damage and its progression.

Methods: Three different conditions were investigated: 1. Renal EO: we analyzed EO contents of the cortex and medulla of healthy kidneys derived from nephrectomised patients genotyped for LSS genetic variants. 2. Essential Hypertension: 338 naïve hypertensive (f 162, m 176, age 44.5±0.42 years) were enrolled for a prospective follow-up study, in which BP was maintained in similar range and changes in renal function were followed. 3. AKI: 1097 individuals undergoing elective cardiovascular surgery were enrolled for a prospective, observational study, investigating the genetic predisposition to AKI.

Results: Among LSS genotypes, individuals with LSS AA variant had higher renal cortical content of EO (2.14±0.29 ng/g), than their LSS CC (1.25±0.08 ng/g; p=0.0009) counterparts. The follow-up study revealed a genotype-dependent decline in renal function over time. LSS AA exhibited greater eGFR decay than LSS CC (AA -2.02±1.22 vs CC 2.24±0.76 ml/1.73m2/yr; p=0.027), despite similar blood pressure values. Likewise, the incidence of AKI following cardiovascular surgery was greater among LSS AA individuals, and proportional to the number of A alleles (AA 30.7% vs AC 26.0% vs CC 17.4%; p=0.001).

Conclusions: Our findings support the view that LSS drives a common mechanism of renal damage in hypertension and AKI and this appears to be mediated in part by EO. LSS-based risk stratification can be used for the timely preoperative recognition and improved management of acute kidney failure.

TH-OR104

Cell-Cycle Arrest Biomarkers TIMP2*IGFBP7 Predict Worse Outcomes in Septic Patients without Clinical Evidence of AKI Marco Fiorentino,[1,2] Christopher M. Keener,[1] Ali Smith,[1] John A. Kellum.[1] *[1]Center for Critical Care Nephrology, CRISMA, Department of Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Department of Emergency and Organ Transplantation, Nephrology, Dialysis and Transplantation Unit, University of Bari, Bari, Italy.*

Background: Acute kidney injury (AKI) is associated with both short and long-term adverse outcomes in patients with sepsis. Standard criteria for AKI, like serum creatinine (sCr) and urine output (UO), are poor, late and non-specific diagnostic tools. The aim of this study is to analyze the performance of several biomarkers in addition to standard criteria for early prediction of sepsis-associated AKI.

Methods: We analyzed data from 1243 patients with septic shock enrolled in the ProCESS trial of early goal-directed therapy, for which biomarkers at admission were available. TIMP2*IGFBP7, uNGAL and uKIM1 at the time of admission were independently combined with clinical parameters for AKI (sCr and UO). Our primary endpoint was the development of severe AKI (KDIGO stage 3), renal replacement therapy (RRT) or death in the first 7 days of enrollment. We analyzed the frequency of the outcome and the odds ratios (ORs) for each combination, compared to a reference (normal sCr, UO and negative biomarkers). We also examined the effect of different resuscitation strategies on the endpoint.

Results: Excluding patients with stage 3 AKI at admission and those with missing data, we analyzed 493 patients with availability of biomarkers at time 0. No significant differences in the outcome were found when uNGAL and uKIM1 were added to sCr and UO. By contrast, in patients with normal sCr and UO, the proportion of patients who developed the endpoint was significantly higher in those with positive (>0.3 ng/ml^2/1000) urine TIMP2*IGFBP-7 (16.2% vs 5.7%, p=0.02) and the odds ratio for developing the

endpoint was 3 times greater (OR 3.03, 95%CI 1.27-7.22). Similar results were found in sensitivity analyses using the highest cut-off for TIMP2*IGFBP7 (>2 ng/ml²/1000; OR 2.8, 95%CI 1.14-6.84) and using different outcomes (death/dialysis at 30 days OR 3, 95%CI 1.26-7.15, p=0.005; death/dialysis at 1 year OR 3.32, 95%CI 1.41-7.85, p=0.002). Moreover, the effect of the protocolized resuscitation vs usual care on the endpoint was negative and not different across TIMP2*IGFBP7 strata.

Conclusions: Early assessment of TIMP2*IGFBP7 at the time of admission in ICUs may significantly improve the ability to predict hard outcomes (severe AKI, RRT and death within 7 days) in apparently "asymptomatic" septic patients (normal sCr and UO).

AKI Severity and Risk of Adverse Pregnancy Outcomes in Women with Recovered AKI Jessica S. Tangren,[1] Wan Ahmad Hafiz Wan Md Adnan,[2] Elizabeth D. Ankers,[1] Ravi I. Thadhani.[1] [1]*Massachusetts General Hospital, Boston, MA;* [2]*University Malaya, Kuala Lumpur, Malaysia.*

Background: We previously reported that an episode of clinically recovered AKI (rAKI) before pregnancy was associated with increased rates of pregnancy complications including preeclampsia. Our initial study was not powered to determine if stage of AKI was associated with adverse outcomes. Using an expanded cohort of women with recovered AKI with 8 years of additional data, we aimed to identify if AKI severity prior to pregnancy was associated with adverse pregnancy outcomes.

Methods: We conducted a retrospective cohort study of women who delivered infants from 1998 to 2016 at the Massachusetts General Hospital. Pregnancy outcomes in women with a history of Stage 1 (S1, n=98), Stage 2 (S2, n=99) and Stage 3 (S3, n=49) AKI were compared to women without a history of AKI (controls, n=24,460).

Results: Pre-pregnancy serum creatinine measurements were similar between women with rAKI and controls (0.63 ± 0.1 vs 0.69 ± 0.1 mg/dl). Women with rAKI had an increased rate of preeclampsia (22% versus 4%, p<0.01). Infants of women with r-AKI were born earlier (38.2±3.1 vs. 39.2±2.2 weeks, p<0.01). Increasing AKI stage was associated with higher rates preterm delivery and preeclampsia (Table 1). Rates of IUGR were higher in women with rAKI but did not show a dose-response effect (p for trend = 0.40). After multivariate adjustment women with S3 AKI were at increased risk for preeclampsia compared to women with S1 AKI (OR 3.7 95%CI 1.5-9.1) Longer duration (years) from AKI to pregnancy was associated with decreased risk for preeclampsia (OR 0.7 95% CI 0.6-0.9).

Conclusions: Severity of AKI demonstrated a dose-response relationship with many adverse pregnancy outcomes. Longer duration between AKI episode and pregnancy was protective against adverse outcomes. Further research is needed to determine how best to counsel young women with AKI planning pregnancy.

Potential Impact of CMS Payment Policy on Misclassification of Dialysis-Requiring AKI (AKI-D) as ESRD: A National Temporal Trend Analysis Benjamin J. Lee,[1] Kirsten L. Johansen,[1,2] Charles E. McCulloch,[1] Chi-yuan Hsu.[1] [1]*University of California, San Francisco, San Francisco, CA;* [2]*San Francisco VA Medical Center, San Francisco, CA.*

Background: Difficulty in predicting which patients with AKI-D will recover to discontinue dialysis may result in misclassification of such patients as having ESRD, which may be detrimental to patient well-being and may falsely inflate estimates of national ESRD incidence. External factors such as reimbursement policies may influence misclassification.

Methods: Using US Renal Data System (USRDS) Standard Analytic Files, we studied all patients registered as having incident ESRD from 1995 to 2014 (n=2,049,212). Patients subsequently reported to be alive ≥90 days without continued dialysis treatments or kidney transplant were considered misclassified AKI-D and not true ESRD cases. We used linear regression and interrupted time-series (ITS) regression to estimate temporal trends in AKI-D misclassification, with particular attention to mid-2012 when the Centers for Medicare & Medicaid Services (CMS) changed reimbursement policy to forbid ESRD facilities from providing dialysis to AKI-D outpatients.

Results: The overall AKI-D misclassification rate was 6.2%, but with a distinct temporal trend (**Figure**). AKI-D misclassification increased on average 0.36% (95% CI 0.33-0.38%) per year from 2000 to 2010. It then abruptly changed in July 2012, when our univariate ITS model estimated that misclassification incidence decreased 2.14% (1.11-3.18%).

Conclusions: Approximately 1 in every 16 patients in the ESRD registry is actually misclassified AKI-D, a much higher proportion than reported previously. The incidence of misclassification increased throughout the first decade of the 21st century but subsequently decreased around the time of a key Medicare reimbursement policy change.

Funding: NIDDK Support

Mitochondria Homing Drug MA-5 Protects against Contrast Induced AKI Takehiro Suzuki, Tetsuro Matsuhashi, Akihiro Matsuo, Koichi Kikuchi, Eikan Mishima, Chitose Suzuki, Sadayoshi Ito, Takaaki Abe. *Tohoku university, Sendai, Japan.*

Background: Contrast induced acute kidney injury (CI-AKI) is the common cause of the iatrogenic and drug-induced kidney injury, but the therapeutic procedures have not been established. The renal hypoxia and the toxic effects on renal tubular cells are postulated as the pathophysiologic mechanisms of CI-AKI. Recently we reported mitochondria homing drug, mitochonic acid-5 (MA-5) increased intracellular ATP, decreased mitochondrial ROS and improved cell survivals of fibroblasts form mitochondrial disease patients by binding mitochondrial protein Mitofilin and promoting oligomelization of ATP synthases (Suzuki T. *Tohoku J Exp Med* 2015, Matushashi T. *EBioMedicine* 2017). MA-5 improved the renal function and tubular cell injuries in murine renal ischemia reperfusion and cisplatin induced nephropathy models (Suzuki T. *JASN* 2016). The aim of this study is to examine the protective effects of MA-5 on CI-AKI.

Methods: Human proximal tubular cell line HK-2 cells were cultured to 80% confluent and MA-5 at 10uM final concentration for 24hr without serum and then added radiocontrasts sodium ditrizoate, Iopamidol and iohexol at 75mg iodine /ml for another 1hr. Cell viability and cytotoxicity were accessed by WST-8 assay and LDH assay respectively. Male CD-1 and C57/BL6 mice, 10-12 week old were left-nephrectomized (Nx) and MA-5 was administrated, at 50mg/kg body weight by gavage, to mice 2hr before they injected with an inhibitor of prostaglandin synthesis (indomethacin, 10 mg/kg) intraperitoneally and iohexol (300 mg iodine/ml, 2 g iodine/kg) intravenously. 24hr after iohexol injection, mice were sacrificed, serum creatinine (Cr), urinary Neutrophil gelatinase-associated lipocalin (NGAL) and renal pathology were examined.

Results: MA-5 improved cell viabilities and reduced injured cell derived LDH activity in culture medium in Sodium ditrizoate, Iopamidol and iohexol treated HK2 cell culture. Serum Cr at 24hr after iohexol injection showed tendency to improve but not significant in MA-5 treated mice comapred to control group. Urinary NGAL was significantly decreased in MA-5 treated animals compared to vehicle gavaged mice.

Conclusions: MA-5 exhibited improved viability in contrast medium treated HK-2 cells as well as decrease renal injury marker NGAL in CI-AKI model mice. MA-5 might have the therapeutic potency on CI-AKI.

ADAM17 Induces Sustained Pro-Fibrotic EGFR Activation via a Positive Feedback Loop Involving YAP1-Dependent Transcription of Pro-AREG Eirini Kefalogianni, Andreas Herrlich. *Washington University in St. Louis, St. Louis, MO.*

Background: We recently showed that the cell-surface metalloprotease ADAM17 and its substrates, including in particular the epidermal growth factor receptor (EGFR) ligand pro-amphiregulin (pro-AREG) are highly upregulated after kidney injury and that inducible proximal tubule (PT)-specific knockout of ADAM17 confers protection against fibrosis in ischemic and obstructive kidney injury mouse models. To clarify the role and function of ADAM17 and its substrate AREG in PT cells *in vivo*, we have now genetically labeled (tdTomato) PT cells in ADAM17 *wt* or ADAM17 PT-KO mice and studied them after kidney ischemia-reperfusion injury (IRI). We have also examined the transcriptional regulation and function of pro-AREG in PT cells *in vitro*. Finally, we investigated the activation of these pathways in acute kidney injury (AKI) and chronic kidney disease (CKD) in human samples.

Methods: We used SLC34a1-Cre-ERt2;R26tdTomato;ADAM17fl/fl (PT-KO) and respective littermates and subjected them to unilateral IRI. tdTomato positive cells were isolated by FACS. ADAM17 and downstream pathways were studied in human and mouse PT cells *in vitro* and in human AKI and CKD samples.

Results: IRI induces the transcriptional upregulation of ADAM17 and pro-AREG in PT cells (tdTomato+ cells). This upregulation is diminished in PT cells lacking ADAM17, suggesting that a positive feedback loop exists in which ADAM17 activity drives not only the release of soluble active AREG but also the upregulation of pro-AREG. This positive feedback is also observed *in vitro*; soluble AREG causes sustained (profibrotic) activation of EGFR that requires Yap1-dependent upregulation of pro-AREG expression, followed by ADAM17-mediated release of soluble AREG. AREG is unique among other EGFR ligands in inducing a panel of proinflammatory and profibrotic cytokines *in vitro*. PT cells isolated from injured mice and lacking ADAM17 show diminished production of these factors as compared to controls. Finally, levels of urinary and serum soluble AREG are upregulated in human AKI and CKD samples, suggesting that this pathway is also active in human kidney disease.

Conclusions: Injury-induced ADAM17-dependent release of soluble AREG drives a profibrotic positive feedback loop of further AREG release via Yap1-dependent transcriptional upregulation of pro-AREG.

Macrophage Mitophagy Modulates Pro-Fibrotic Response in Renal Fibrosis Divya Bhatia, Mary E. Choi. *Division of Nephrology and Hypertension, Weill Cornell Medicine, New York, NY.*

Background: Kidney injury involves infiltration of pro-inflammatory macrophages and oxidative stress induced mitochondrial dysfunction, and pro-fibrotic macrophages driving progression of renal fibrosis. Mitophagy, the selective autophagy of dysfunctional mitochondria, is important for cellular homeostasis. We examined the role of PTEN-induced kinase1 (PINK1), major mediator of mitophagy, in regulating macrophage derived fibrotic response.

Methods: Wild type (WT) and PINK1-KO mice, subjected to unilateral ureteral obstruction (UUO), a model of progressive renal fibrosis, were sacrificed at day 3. Peritoneal and bone marrow-derived macrophages were isolated. The expression levels of CD11b, Ly6C, F4.80, CD206 and CX3CR1 were detected by flow cytometry. Arginase1 (Arg1), TGFβ type I receptor (TGFβRI), fibronectin and α-smooth muscle actin (α-SMA) expression was determined by western blot. MitoSox staining was used to assess mitochondrial derived superoxide production. Mitophagy was suppressed in RAW264.7 cells through transfection of PINK1 small interfering RNA (siRNA).

Results: UUO-induced increase in the expression of circulating Ly6C++ CD11b+ pro-inflammatory monocytes was higher in PINK1-KO mice compared to WT. PINK1-KO mice displayed higher expression of F4.80+ CD206+ pro-fibrotic macrophages and chemokine receptor CX3CR1 in obstructed kidneys compared to WT and contralateral kidneys. Flow cytometric data revealed increase in the Ly6C++ pro-inflammatory cells in kidney post-UUO at day 3. However, their expression was comparable in kidneys from KO and WT mice. The expression of Arg1 and fibronectin was higher in kidneys of KO mice after UUO. Furthermore, PINK1 deficient macrophages (both primary PINK1-KO and siRNA knockdown RAW264.7) exhibited enhanced polarization towards pro-fibrotic phenotype. Primary PINK1-KO macrophages also showed higher expression of Arg1, TGFβRI, fibronectin and α-SMA. The expression levels of Arg1, fibronectin and α-SMA were further increased after stimulation with TGFβ. In addition, PINK1 deficient macrophages displayed higher mitochondrial superoxide levels upon TGFβ stimulation compared to WT.

Conclusions: PINK1-mediated mitophagy deficiency results in increased oxidative stress and enhanced pro-fibrotic response by macrophages. Macrophage mitochondrial superoxide production might play critical role in activation of their pro-fibrotic phenotype and progression of renal fibrosis.

TH-OR110

Therapeutic Angiogenesis in CKD Alejandro R. Chade, Gene L. Bidwell. *University of Mississippi, Jackson, MS.*

Background: Renal microvascular (MV) loss in CKD correlates with progressive loss of renal function. However, whether this is an association or a cause-effect relation is unclear. We developed a drug-delivery construct of an elastin-like polypeptide (ELP) fused to VEGF-A and showed that intra-renal infusion of ELP-VEGF in CKD improved renal function. We tested the hypothesis that ELP-VEGF therapy may induce long-term recovery in CKD by stimulation of MV proliferation and repair.

Methods: CKD was induced in 8 pigs by bilateral renal artery stenosis and diet-induced dyslipidemia. Blood pressure was continuously measured (telemetry). Bilateral RBF and GFR were quantified *in vivo* using multi-detector CT after 6 weeks of CKD, and then pigs randomly treated with a single intra-renal administration of ELP-VEGF (100 μg/kg) or placebo (n=4 each). *In vivo* studies were repeated 4 and 8 weeks after treatment, pigs were then euthanized, and *ex vivo* studies performed to quantify renal MV density (micro-CT), MV remodeling, and angiogenic signaling

Results: RBF and GFR were reduced in CKD, accompanied by hypertension, cortical and medullary MV remodeling and loss, and blunted expression of VEGF, HGF, specific VEGF/HGF receptors, and markers of cell progenitors (Oct-4 and CD-34). However, CKD+ELP-VEGF pigs showed 28% and 53% improvement in RBF and GFR 4 weeks after treatment, and 46% and 74% recovery after 8 weeks, respectively (compared to pre-treatment), followed by increased expression of angiogenic and progenitor cell markers, reduced MV loss and remodeling [Figure]

Conclusions: Therapeutic angiogenesis via single-dose ELP-VEGF therapy stimulates renal neovascularization and MV repair, which likely drove recovery of renal function and improved CKD stage from 2 to 1. CKD recovery was progressive, and our data imply that underlying mechanisms of the long-term effects may involve sustained stimulation of cell progenitors to and within the kidney.

TH-OR111

The Impact of a Young Circulation on Renal Injury and Fibrosis in Aged Mice David A. Ferenbach,[1,2] Cuiyan Xin,[1] Julia Wilflingseder,[1] Jeremy Hughes,[2] Joseph V. Bonventre.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom.*

Background: Aging is associated with an increased risk of acute kidney injury (AKI) and higher rates of subsequent fibrotic chronic kidney disease (CKD). The mechanisms accounting for these changes in injury and fibrosis susceptibility remain poorly understood. We conducted studies using heterochronic parabiosis to test whether the young circulation can influence injury imposed on an older mouse.

Methods: Parabiotic pairs were established between young (Y, 8 weeks old) and old (O, 14 months old) female C57BL6 mice to generate YY, OO, OY and YO pairings, and a shared microcirculation was allowed to develop for 28 days. Baseline and post-injury renal characteristics were assessed by immunofluorescence, western blotting, microarray analysis and Somascan measurement of circulating protein levels. AKI was induced via 20 minutes bilateral renal ischaemia/reperfusion injury (IRI), and chronic fibrosis via unilateral ureteric obstruction. Animals were followed for 24hrs for peak IRI severity, and for up to 14 days for UUO-induced fibrosis

Results: Baseline renal function was equivalent in all groups. At d28 of parabiosis, old animals in both OO and OY pairings had increased levels of baseline fibrosis ($p<0.05$) compared to the young in YO and YY pairs. In the acute injury model on the Old mice, OY animals demonstrated significantly lower 24 hr serum creatinine compared with OO animals ($p<0.05$). In the UUO model of chronic renal fibrosis, Old animals in OY pairs showed reduced scarring, macrophage infiltration and inflammatory gene transcription compared to Old paired with Old mice (OO) (all $p<0.05$). Microarray studies revealed multiple transcriptional processes which alter with aging and injury and revert to 'young' patterns after OY pairing. Bulk proteomics on >1000 circulating proteins identified 11 compounds which track with the protected phenotype.

Conclusions: Our data show that normal aged kidneys exhibit differences from the young kidney at a transcriptomic and proteomic level even with well maintained renal function. Furthermore, connection to a young circulation modifies the transcriptional signature in the aged kidney at baseline and protects against subsequent AKI and progressive renal scarring, indicating the presence of a circulating factor which modifies renal aging. Therapeutic targeting of these compounds is ongoing.

5-Lipoxygenase Promotes Renal Interstitial Injury and Fibrosis John R. Montford,[1] Colin D. Bauer,[1] Evgenia Dobrinskikh,[1] Katharina Hopp,[1] Moshe Levi,[1] Raphael A. Nemenoff,[1] Seth B. Furgeson.[1,2] *[1]University of Colorado Denver, AMC, Aurora, CO; [2]Denver Health, Denver, CO.*

Background: Although macrophages promote renal fibrosis, the mechanism is incompletely understood. Macrophages may exert tissue damage through activation of 5-lipoxygenase (5-LO). 5-LO and 5-LO associated protein (FLAP) initiate leukotriene synthesis; the downstream enzymes LTA_4 hydrolase (Lta4h) and LTC_4 synthase (Ltc4s) catalyze the production of LTB_4 and cysteinyl leukotrienes, respectively. We hypothesized that leukotriene inhibition would decrease renal fibrosis after unilateral ureteral obstruction (UUO).

Methods: C57Bl/6 mice undergoing UUO were treated with zileuton (5-LO antagonist) or vehicle. UUO was also done in wild type, Flap knockout (ko), Lta4h ko and Ltc4s ko mice. Renal fibrosis was measured using both a biochemical assay (hydroxyproline) and microscopy to detect second harmonic generation (SHG) signal from collagen. To measure metabolic changes in renal tubular epithelial cells, fluorescent lifetime imaging microscopy (FLIM) was performed to determine alterations in free and bound NADH levels.

Results: We found a large induction in 5-LO-expressing interstitial leukocytes in kidneys of UUO mice. Treatment of mice with zileuton before UUO significantly decreased hydroxyproline content at 7 days (37% reduction vs. vehicle). SHG microscopy also confirmed a significant decrease in renal fibrosis in zileuton-treated mice (40% reduction). Compared to littermate controls, Flap ko mice had less interstitial fibrosis as measured by hydroxyproline assay (33% reduction). Ltc4s ko mice, but not Lta4h ko mice, were significantly protected from UUO-induced fibrosis (44% reduction in hydroxyproline content and 41% reduction in fibrotic area by SHG). We then performed FLIM for NADH to determine if 5-LO inhibition led to metabolic changes in renal tubular epithelial cells. We found that there was significant shift to glycolytic metabolism after UUO in control mice; this was partially abrogated in zileuton-treated mice. To validate these findings, we tested whether 5-LO is induced in other models of chronic kidney disease and found increased numbers of 5-LO expressing leukocytes in mice with polycystic kidney disease.

Conclusions: 5-lipoxygenase and LTC_4 synthase are potent inducers of renal fibrosis after UUO. The pathologic effects of leukotrienes may be partially mediated through changes in renal tubular epithelial metabolism.

MicroRNA-214 Confers the Pathogenesis of CKD by Disrupting the Mitochondrial OXPHOS Aihua Zhang, Mi Bai, Yue Zhang, Songming Huang, Zhanjun Jia. *Nephrology Department, Children's Hospital of Nanjing Medical University, Nanjing, China.*

Background: Mitochondria are critical in determining the energy hemostasis and cell fate. Mitochondrial dysfunction (MtD) presenting with aberrant mitochondrial oxidative phosphorylation (OXPHOS) and other abnormalities is involved in the chronic kidney disease (CKD). Here we investigated the role of miR-214 in mediating the MtD and kidney injury in CKD.

Methods: The CKD patients' renal biopsy tissues, three CKD animal models (UUO, albumin-overload, and post-AKI), and tubular cells challenged with several insults were used to define the role of miR-214 in CKD, as well as the potential mechanisms.

Results: In CKD patients, the renal tubules presented more abundant miR-214 expression compared with the healthy controls, which was accompanied by a positive correlation with the severity of proteinuria and renal fibrosis. Meanwhile, several lines of CKD animal model of UUO, albumin-overload, and post-AKI and renal tubular cell models induced by IL-1β, hypoxia, albumin, or TGF-β displayed similar enhancement of miR-214. Importantly, systemic inhibition or specific tubular deletion of miR-214 strikingly attenuated CKD pathology in line with the ameliorated responses of apoptosis, inflammation, and fibrosis in CKD models mentioned above. In contrast, overexpressing miR-214 induced tubular cell apoptosis. Moreover, in the mechanistic study, we proved that cytoplasm miR-214 could be translocated into the mitochondria to target mitochondrial gene ND4L and ND6 to disrupt mitochondrial OXPHOS, leading to mitochondrial dysfunction and subsequent tubular injury and fibrosis in CKDs.

Conclusions: These results not only demonstrated a pathogenic role of miR-214 in CKDs by targeting mitochondrial gene ND4L and ND6 to disrupt mitochondrial OXPHOS but also suggested the potential of this microRNA as the therapeutic target and diagnostic biomarker of CKDs.

Biopsy Transcriptome Expression Identifies Loss of FRMD3 as a Mediator of Declining Renal Function in CKD Eoin P. Brennan,[2] Caitriona M. McEvoy,[2] Oisín Gough,[2] Susan M. McAnallen,[2] Mohd R. Rodzlan Akib,[1] Anthony M. Dorman,[1,3] Peter J. Conlon,[1] Denise M. Sadlier,[2,4] Catherine Godson.[2] *[1]Department of Nephrology and Pathology, Beaumont Hospital, Dublin, Ireland; [2]Diabetes Complications Research Centre, UCD Conway Institute & School of Medicine UCD, University College Dublin, Dublin, Ireland; [3]Royal College of Surgeons Ireland, Dublin, Ireland; [4]Mater Misericordiae University Hospital, Dublin, Ireland. Group/Team: GENIE Consortium.*

Background: We have generated global transcriptome profiles of renal biopsies from patients with chronic kidney disease (CKD). Here, we investigated the relationship between renal gene expression and clinical parameters of kidney function, and identify an association between loss of Ferm domain-containing protein 3 (FRMD3) and a decline in renal function.

Methods: We performed RNA-Seq gene expression profiling on material obtained from patients undergoing clinically indicated biopsy (n=44). Using this phenotypically heterogenous cohort of patients, the association of gene expression with clinical parameters [tubulointerstitial fibrosis (TIF) score, eGFR, serum creatinine, glomerular basement membrane thickness] was investigated. Follow-up clinical data (serum creatinine measurements 3-6 years post-biopsy) was used to identify gene expression profiles predictive of disease progression. Subsets of genes were identified that were significantly associated (FDR $P<0.05$) with these parameters of kidney disease.

Results: Pathway analyses identified enrichment for pro-inflammatory signalling (e.g. T-cell infiltration, TNF-α, NF-κB, IFN-γ, CD3) in patients with severe CKD. 1,590 genes were significantly associated with renal decline in these patients during a 3-6 year follow-up period (FDR $P<0.05$), including loss of FRMD3 expression (FDR $P=0.006$). Interestingly, large scale genome-wide association studies have recently implicated FRMD3 as a genetic candidate in kidney disease. Using functional studies we investigated the role of FRMD3 in renal cells using *in vitro* models of renal fibrosis. Here, FRMD3 knockdown caused exaggerated fibrotic responses to TGF-β1 in renal tubule epithelial cells. Finally, mass spectrometry analysis of FRMD3 binding partners indicated interactions with mitochondrial respiratory chain components (complex I, III and V).

Conclusions: Taken together, these data implicate FRMD3 as a novel regulator of renal function in CKD.

TH-OR115

Rescue of Reno-Protective BMP7 by Low-Dose Hydralazine Protects Functional Parenchyma with Restoration of Solute and Solvent Transporters Bjoern Tampe, Desiree Tampe, Gerhard A. Mueller, Michael Zeisberg. *University Medical Center Goettingen, Goettingen, Germany.*

Background: CKD progression remains an unsolved problem in clinical Nephrology since approaches to reverse or repair chronic renal injury are not yet available. BMP7 and its agonists are among leading compounds currently under clinical testing and widely accepted to facilitate regeneration of the injured kidney, ultimatively associated with attenuation of disease progression. The impact of restoring intrarenal BMP7 with regard of renal excretory function on a molecular level remains elusive.

Methods: In multiple mouse models of acute (moderate IRI), acute-on-chronic (severe IRI) and chronic kidney disease (UUO, 5/6 Nx, FAN, NTN), dynamic regulation of BMP7 and signaling (pSmad1/5/8) were analyzed by qRT-PCR, Western blotting and immunostaining. Furthermore, *BMP7* promoter methylation was assessed by MeDIP in cohorts of mice treated with low-dose Hydralazine and corresponding cell culture models of EMT program in TECs. Finally, impact on expression of solute and solvent transporters was analyzed by qRT-PCR, immunostaining and functional monitoring of transporter function.

Results: Based on a genome-wide transcriptional expression dataset for bioactive small molecules, transcriptional induction of *BMP7* was among top induced candidate genes in response to Hydralazine. Low-dose Hydralazine mediates TET3-dependent normalization of *BMP7* promoter methylation in multiple rodent CKD models and human cell lines. On a mechanistic level, transcriptional induction of reno-protective BMP7 attenuates intratubular EMT program commonly observed during CKD progression, ultimatively associated with protection from G2/M arrest of TECs and attenuation of renal fibrogenesis. We provide evidence that protection of functional parenchyma restores solute and solvent transporter function, including AQP1, AQP3 and Na^+/K^+-ATPase, supporting a protective role also for renal excretory function on a molecular level. Based on existing transciptional profiling datasets, decline of renal excretory function is commonly associated with loss of intrarenal BMP7 expression, suggesting that reno-protection mediated by Hydralazine may also have promise among CKD patients.

Conclusions: In summary, low-dose Hydralazine induces reno-protective BMP7 and protects functional parenchyma with restoration of solute and solvent transporters.

TH-OR116

SIRT6-Knockout Mice Exhibit Marked Type IV Collagen Deposition, Causing Phenotypes Similar to Those of Diabetic Tubulopathy Hirokazu Muraoka, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio University, Tokyo, Japan.*

Background: The class of NAD-dependent deacetylase and longevity genes called sirtuins comprises seven isoforms (SIRT1 to SIRT7). Here we investigated the role of SIRT6 in the kidneys.

Methods:

Results: We investigated the intrarenal distribution of SIRT6 expression in different physiological conditions using wild-type mice and human renal biopsy specimens. High Sirt6 levels were detected in the nucleus of proximal tubules (PTs), whereas low levels were observed in glomeruli and other tubules. To assess the temporal changes in SIRT6 expression in different physiological conditions, we modeled several kidney injuries. Among these, diabetic nephropathy models demonstrated marked alterations. We next evaluated the temporal changes in SIRT6 expression every 8 weeks (8W, 16W, 24W, and 32W) in STZ and db/db models. At 8W and 16W, SIRT6 expression exhibited no difference. However, SIRT6 expression was conspicuously downregulated at 24W and was further augmented at 32W in both STZ and db/db models. To delineate the endogenous role of SIRT6 in the kidneys, we newly created PT-specific SIRT6-conditional knockout (CKO) mice by crossbreeding SIRT6 flox/flox[Editor1] mice with g-GT Cre mice. PT-SIRT6-CKO mice exhibited marked proximal tubular basement membrane (TBM) thickening and widespread peri-proximal tubular fibrosis. We next tested the molecular mechanisms underlying tubulopathy augmentation caused by SIRT6 knockdown. By performing DNA microarray and confirmatory real-time PCR analyses after microdissecting PT-injured regions together with immunostaining and immunogold electron microscopy, we could demonstrate that tissue inhibitor metalloproteinase 1 (TIMP-1) mRNA levels were elevated, leading to decreased MMP-9 activity and upregulated type IV collagen protein levels. These changes were consistent with the phenotypes of PT-SIRT6-CKO mice. Lastly, we analyzed in detail the mechanisms whereby SIRT6 knockdown directly elevated TIMP-1 mRNA levels and revealed that SIRT6 deficiency in PTs directly hyperacetylated histone H3 lysine K9 and RELA at these target regions within the TIMP-1 promoter.

Conclusions: PT Sirt6 is suggested to be involved in type IV collagen-related TBM thickening and peritubular fibrosis, which directly regulates TIMP-1 expression and plays a crucial role in tissue fibrosis, especially in diabetic nephropathy.

Aging Phenotype(s) in Kidneys of Diabetic Mice Are p66ShcA Dependent Himanshu Vashistha,[1] Allyson E. Bradley,[1] Bronwyn Leblanc,[1] Frank C. Abbruscato,[1] Ashwani Malhotra,[2] Pravin C. Singhal,[2] Leonard G. Meggs.[1] *[1]Ochsner Health System, New Orleans, LA; [2]Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Hyperglycemia constitutively activates the p66ShcA protein, which controls cellular responses to oxidative stress, aging and apoptosis. Here, we test the hypothesis aging phenotype(s) in kidneys of diabetic mice, that are commonly associated with the broad category of chronic kidney disease (glomerulosclerosis, interstitial fibrosis, tubular atrophy), are linked to the p66ShcA locus.

Methods: Stem cell antigen-1^{+} (Sca-1+) mesenchymal stem cells (MSCs) were isolated from kidneys of WT and p66 KO mouse, and plated in media containing normal or high glucose. Parameters evaluated were ROS metabolism, apoptosis, cellular and molecular markers of senescence and DNA microarray gene profiles. p66 KO diabetic mice, were generated by crossing Akita (Ins2+) with p66 KO mouse. Kidneys were examined at 12 mo of age by light microscopy and deconvolution microscopy.

Results: WT-MSCs exhibit an exponential increase in ROS metabolism, upregulation of senescence associated proteins (p21; p16^{INK4a}; p53) and enter apoptotic or senescent phenotypes. DNA microarray detected downregulation of Wnt regulatory genes, implicated in self renewal and differentiation. By contrast, p66KO-MSCs are resistant to HG-stress signals, apoptosis/cell senescence and express increase levels of intracellular b-catenin, mimicking canonical Wnt signaling. Small clusters of Sca-1+MSCs in kidneys of p66 KO Akita were captured by deconvolution microscopy scattered in the interstitium adjacent to tubules, but were only rarely seen in kidneys of WT and Akita. Furthermore, the senescent biomarker p16^{INK4a} was upregulated in proximal tubular epithelial cells of Akita, whereas expression levels did not differ between p66 KO-Akita and WT (non-diabetic); indicative p66ShcA participates in activation of p16^{INK4a} in diabetic kidneys. Histologic markers of aging were prominent in Akita kidneys, whereas these aging phenotypes were barely detectable in kidneys of p66 KO-Akita. Taken together, p66 ShcA is necessary and sufficient for the expression of aging phenotypes in kidneys of diabetic mice.

Conclusions: Our results establish a genetic link between diabetes, constitutive p66ShcA expression and accelerated aging phenotype(s) in the kidney, that may serve as precursors to diabetic nephropathy.

Kidney Allografts with High Risk APOL1 Genotypes Have Worse Outcomes: Association with Decreased Podocyte Density Dhruti P. Chen,[5] Ziad S. Zaky,[1] Jesse D. Schold,[1] Leal C. Herlitz,[1] Rasha El-Rifai,[3] Paul E. Drawz,[4] Leslie A. Bruggeman,[3] John R. Sedor,[2] Emilio D. Poggio,[1] John F. O'Toole.[5] *[1]Cleveland Clinic, Cleveland, OH; [2]MetroHealth Medical Center, Cleveland, OH; [3]None, Cleveland, OH; [4]University of Minnesota, Minneapolis, MN; [5]Case Western Reserve University, Cleveland, OH.*

Background: Variants in *APOL1 gene* (G1 or G2), which encodes apolipoprotein L1(APOL1), associate with non-diabetic kidney diseases in African Americans (AA) but the mechanisms driving this association remain unclear. Kidney diseases only develop in a subset of individuals with high risk *APOL1* genotypes, consistent with a need for a "second hit" or stress to initiate disease. Mice transgenic for G2 have a podocyte depletion phenotype compared to wild-type mice or mice expressing the reference allele (G0). We hypothesized that variant APOL1 generates subclinical, prodromal podocyte injury that is a "first hit."

Methods: A cohort of 107 AA kidney donors, living (LD) and deceased (DD), with available implant biopsy tissue and DNA were genotyped for *APOL1* risk variants and evaluated for baseline kidney phenotypes, histology, and podocyte density in implant biopsies. Recipients were genotyped for APOL1 and outcomes collected, including graft loss and rate of eGFR decline.

Results: Donor demographic data and clinical phenotypes at graft implant were similar between high risk (HR, 2 risk variants, n=16) and low risk groups (LR, <2 risk variants, n=91). Glomerular volume was lower in HR group (2.58 um^{3}X10^6 vs. 3.13 um^{3}X10^6, p=0.03) of implant biopsies. Podocyte density was significantly less in HR compared to LR (108 ± 26 vs 127±40 podocytes/10^{6}um^3, p=0.03). Similarly, podocyte coverage of glomerular area was reduced in HR vs. LR donors (30% vs. 39%, p=0.05). Recipients were 64% AA and 36% White or not specified;38% of AA recipients had HR *APOL1*. Recipients were followed for 48 months, and increased graft loss of HR donor was noted using a multivariate model (Hazard Ratio = 2.7; 95% CI, 0.9-7.8) and Kaplan Meier graft survival (HR 61% vs. LR 91%, log rank p-value=0.049). eGFR decline was also greater in recipients of HR APOL1 allografts with slope of overall decline statistically significant (p<0.001), eGFR(mL/min) at 60 months was 27 in HR vs. 51 in LR.

Conclusions: In living and deceased donors, outcomes of *APOL1* HR allografts were significantly worse. Importantly, variant APOL1 generates subclinical, prodromal podocyte depletion, which only becomes clinically evident when subsequent stress supervenes and initiates progressive CKD in African Americans with *APOL1* HR.

Funding: Other NIH Support - T32

TH-OR119

Interaction of SHROOM3 with FYN Impacts Phosphorylation of Nephrin Causing Proteinuria with Foot Process Effacement Madhav C. Menon,[4] Nimrod Philippe,[2] Chengguo Wei,[1] Ruijie Liu,[3] Jenny Wong,[4] Zhengzi Yi,[1] Weijia Zhang,[4] John C. He,[4] Barbara T. Murphy.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai Hospital, New York, NY; [3]Mount Sinai Medical School, New York, NY; [4]Mount Sinai School of Medicine, Forest Hills, NY.*

Background: In the GoCAR study, we identified that a CKD-associated SHROOM3-SNP, and tubular *Shroom3* expression correlated with the development of renal fibrosis post-transplant. We showed that SHROOM3 facilitated TGF-B signaling suggesting its potential role as a therapeutic target. However, recent data suggest a *protective* role for SHROOM3 in glomerular development.

Methods: To study the role of SHROOM3 in adult glomeruli, we used doxycycline-inducible (DOX), shRNA-mediated SHROOM3 knockdown, Podocin- and tubular-specific (PAX8)-RTTA mice, comparing these to non-transgenic DOX-fed littermates.

Results: Adult Podo-RTTA mice, but not PAX8-RTTA, developed significant albuminuria compared to littermates with DOX. Albuminuria was reversible on DOX-withdrawal, and reappeared on re-initiation. EM revealed diffuse foot process effacement (Fig1). Glomerular RNA-seq identifed downregulated intracellular signaling/actin-cytoskeleton among Gene-ontology terms in knockdown mice. We performed mass spectrometry on protein lysates of 293-T cells overexpressing SHROOM3 immunoprecipitated (IP) with either anti-V5, -SHROOM3 or IgG. Among 491 unique interactions, we identified FYN – a src-kinase – as a top ranking candidate. Podocyte FYN is crucial for NPHS1-phosphorylation, and FYN-deficient mice show a proteinuria phenotype. In human podocytes, we confirmed the interaction of endogenous SHROOM3 and FYN by IP. Glomerular protein extracts of Shroom3-knockdown mice showed decreased phosphorylation of FYN, and NPHS1. In human allografts from GoCAR, we identifed a corresponding reduced albuminuria (>1year post-transplant) associated with homozygosity of the risk allele in the donor.

Conclusions: In summary, Podocyte-specific SHROOM3 knockdown causes a reversible proteinuria phenotype in adult mice, by interacting with FYN, a mechanism distinct from its effect on renal fibrosis in allografts.

Polygenic Risk Score as a Determinant of Risk of Non-Melanoma Skin Cancer Post-Renal Transplantation Caragh P. Stapleton,[9] Kelly A. Birdwell,[8] Patrick B. Mark,[6] M. Lee Sanders,[7] Paul J. Phelan,[10] Alexander P. Maxwell,[5] A.J. McKnight,[5] Claire Kennedy,[1] Alan G. Jardine,[6] Jamie P. Traynor,[3] Fiona A. Chapman,[4] Brendan Keating,[2] Peter J. Conlon,[1] Gianpiero Cavalleri.[9] *[1]Beaumont Hospital, Dublin 9, Dublin, Ireland; [2]University of Pennsylvania, Philadelphia, PA; [3]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [4]NHS Scotland, Glasgow, United Kingdom; [5]Queen's University Belfast, Belfast, United Kingdom; [6]University of Glasgow, Glasgow, United Kingdom; [7]University of Iowa Hospitals and Clinics, Iowa City, IA; [8]Vanderbilt University, Nashville, TN; [9]Department of Molecular and Cellular Therapeutics, Royal College of Surgeons, Dublin, Ireland; [10]Royal Infirmary of Edinburgh, NHS Lothian, Edinburgh, United Kingdom. Group/Team: International Genetics & Translational Research in Transplantation Network.*

Background: Multiple genetic loci have been identified for non-melanoma skin cancer (NMSC) in the general population. Polygenic risk score (PRS) was defined as the sum of all alleles associated with a trait weighted by the effect size of that allele as determined by a previous genome-wide association study (GWAS). We tested whether PRS, calculated using a GWAS of NMSC in a non-transplant population, can be used to determine risk of developing and time to NMSC post-kidney transplant.

Methods: Post-kidney transplant NMSC cases (n=155) and controls (n=442) were collected from Tennessee, Ireland and Scotland. Genetic variants that reached pre-defined levels of significance were chosen from a squamous cell carcinoma (SCC), and a basal cell carcinoma (BCC) GWAS, both conducted in non-transplant populations. Using these GWAS results, BCC and SCC PRSs were calculated at each p-value threshold (pT) for each sample in the renal transplant cohorts. PRSs were normalized so mean = 0 and standard deviation = 1. PRSs were tested as a predictor of case: control status in a logistic regression model and time to NMSC post-transplant in a survival model. Age of recipient at transplant, recruitment centre, azathioprine exposure and the first four principal components were included as covariates in both models.

Results: SCC PRS calculated at pT of $1x10^{-6}$ was the most significant predictor of case: control status of NMSC post-transplant (OR per 1 standard deviation increase in PRS = 2.3; corrected P (P_c) =0.04). When we subdivided NMSC into SCC and BCC, SCC PRS pT $1x10^{-6}$ was a significant predictor of case:control SCC (OR = 2.5, P_c = 0.02) and BCC status (OR = 7.6, P_c = 0.02). SCC PRS pT $1x10^{-5}$ was also a significant predictor of time to post-transplant BCC (P_c = 0.007, HR = 1.8) and SCC (P_c = 0.05, HR = 1.4).

Conclusions: PRS of non-transplant NMSC can be used to predict case:control status of post-transplant NMSC, SCC and BCC as well as time to developing BCC and SCC post-transplant.

Effect of Conversion to Belatacept on Tacrolimus-Induced Diabetes Mellitus Chul Woo Yang,[1,2] Sun Woo Lim,[2] Kang Luo,[2] Yoo-Jin Shin.[2] *[1]Department of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea; [2]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: The effect of belatacept conversion on tacrolimus (TAC)-induced diabetes mellitus (DM) is still undetermined. In the present study, we first tested the dose-dependent effect of belatacept on pancreatic islet function and viability in rats. Second, in an experimental model of TAC induced DM, TAC was switched to belatacept and parameters of glucose control were measured. In addition, the direct effect of belatacept on TAC-induced pancreatic islet cell injury was evaluated in vitro.

Methods: The first study was designed to evaluate whether belatacept has a diabetogenic effect in rats. We tested the dose-dependency of belatacept (0.25, 0.5, 1, 2, and 4 mg/kg) on pancreatic islet function and viability. The second study aimed to evaluate the effect of conversion from TAC to belatacept on pancreatic islet function in established TAC-induced DM. After the establishment of TAC-induced DM (three weeks), TAC was continued, withdrawn, or replaced by belatacept treatment (1 or 2 mg/kg). Rats were treated with vehicle or subcutaneous TAC daily, and belatacept was injected weekly via the tail vein. The effect of belatacept on TAC-induced diabetes was evaluated by assessing pancreatic islet function, histopathology. The protective effect of belatacept was evaluated by measuring markers of oxidtive stress, apoptosis, and infiltrating macrophage. Reactive oxygen species production using MitoSOX red and cell death using Annexin V were also evaluated in INS-1 cells.

Results: Pancreatic islet function and islet cell death were not affected by any of the tested doses of belatacept. TAC withdrawal ameliorated pancreatic islet dysfunction compared with that in the group in which TAC treatment was continued, and conversion to belatacept further improved pancreatic islet function compared with that in the TAC withdrawal group. TAC-induced oxidative stress, apoptotic cell death, and infiltration of macrophages decreased with TAC withdrawal, and belatacept conversion further reduced those values. In an in vitro study, belatacept decreased TAC-induced pancreatic islet cell death and reactive oxygen species production.

Conclusions: The results of these studies suggest that conversion to belatacept is an effective approach to reduce TAC-induced DM. Moreover, belatacept has a protective effect against TAC-induced pancreatic islet injury.

TH-OR122

Tacrolimus Prevents Von Willebrand Factor Exocytosis from Human Glomerular Endothelial Cells Treated with Anti-HLA Antibodies Stephanie Beland, Olivier Desy, Patrice Vallin, Sacha A. De Serres. *University Health Center (CHU) of Quebec, Laval University, Quebec, QC, Canada.*

Background: Mechanistic knowledge about the direct effect of DSA on the endothelium is lacking. Von Willebrand factor (vWF) is a glycoprotein involved in endothelial hemostasis. Previous studies reported that anti-HLA-I antibodies promote vWF exocytosis. It is known that higher CNI levels associates with better outcomes in patients with DSA. We hypothesized that TAC prevents endothelial damage by inhibiting vWF exocytosis from cells exposed to anti-HLA antibodies.

Methods: We measured *in vitro* the vWF expression of human glomerular endothelial cells treated with anti-HLA-I or II, in the presence and absence of TAC. Cell viability was confirmed in all experiments. vWF was quantified by immunofluorescence and ELISA. Platelet adhesion on the endothelial cells was assessed by immunofluorescence. We next measured the association between vWF and TAC blood levels in 71 samples from 69 kidney recipients.

Results: Anti-HLAs antibodies increased surface expression of vWF as well as vWF levels in cell supernatants (anti-HLA I 36±4, anti-HLA-II 40±5 vs. NS 22±4%, both $p<0.05$). vWF release in the supernatant following anti-HLA-II stimulation was higher than with anti-HLA-I (3.4±2.5 vs. 5.6±3.2 ng/mL; p=0.03). Treatment with TAC (5, 10 ng/mL) abrogated the percentage of vWF-positive cells after anti-HLA stimulation (for anti-HLA-I, TAC0 vs. TAC5 vs. TAC10 : 32±5 vs. 5±3 vs. 5±3% respectively; for anti-HLA-II, TAC0 vs. TAC5 vs. TAC10 36±7 vs. 7±3 vs. 2±1% respectively; all $p<0.01$) and led to a decrease in platelet adhesion (all $p<0.01$). In patients, TAC was a significant negative predictor of vWF blood levels (-768±239 ng/mL per 1ng/mL increase in TAC); this association was robust to adjustment for clinical and histological predictors.

Conclusions: Direct disruption of endothelial hemostasis through vWF exocytosis is a potential mechanism for the higher occurrence of transplant glomerulopathy in patients with DSA. Mechanistic studies are underway to better understand these observations, given that TAC is seldom associated with thrombotic microangiopathy.

TH-OR123

B Cell Deficiency Inhibits Chronic Antibody Mediated Rejection in a Th1 and IL-10 Dependent Pathway in a Rat Kidney Transplant Model Sarah E. Panzer, Shannon Reese, Nancy A. Wilson, Lucille D. Ptak, Isabelle S. Renteria, Arjang Djamali. *University of Wisconsin Madison, Madison, WI.*

Background: The pathologic role of B cells in chronic antibody mediated rejection (cAMR) remains unclear.

Methods: We generated B cell deficient Lewis rats ($B^{-/-}$) via CRISPR technology. Kidney transplantation was performed in 4 groups: syngeneic (Lewis to Lewis), allogeneic (Fisher to Lewis), sensitized (Fisher to Lewis 3 weeks following donor-specific blood transfusion), and allogeneic B cell deficient recipients (Fisher to $B^{-/-}$ Lewis). All animals were harvested at 6 months.

Results: cAMR was reduced in $B^{-/-}$ recipients compared to allogeneic and sensitized recipients based on Banff scores for microvascular inflammation (allogeneic: 3.0±1.7, sensitized: 4.6±0.5, $B^{-/-}$: 1.5±0.6; P=0.001) and C4d staining (allogeneic: 1.5±0.6, sensitized: 2.2±0.8, $B^{-/-}$: 0.5±0.6; P=0.05). Allograft deposition of IgM was significantly reduced in $B^{-/-}$ compared to allogeneic recipients (Fig1A). Intragraft macrophages and fibrosis by Picrosirius red stain demonstrated no differences among allogeneic, sensitized, and $B^{-/-}$ recipients (Fig1B). Th1 (IL-2 and IFN-gamma) and IL-10 cytokines by RT PCR were significantly reduced in $B^{-/-}$ compared to allogeneic recipients, but not Th2 (IL-4 and IL-6) or Th17 (Fig1C). Chronicity scores (Banff chronicity score = cg + ct + ci + cv)

were elevated in allogeneic, sensitized, and $B^{-/-}$ recipients (3.0±1.7, 4.6±0.5, and 1.5±0.6, respectively).

Conclusions: B cell deficiency inhibits cAMR in a Th1 and IL-10 dependent pathway. Further studies are needed to determine the contributions from non-B cell mediated factors, such as innate immunity, to the development of fibrosis in chronic rejection.

Funding: Other NIH Support - This project was supported by the Clinical and Translational Science Award (CTSA) program, through the NIH National Center for Advancing Translational Sciences (NCATS), grant UL1TR000427, and the KL2 training Award (KL2TR000428).

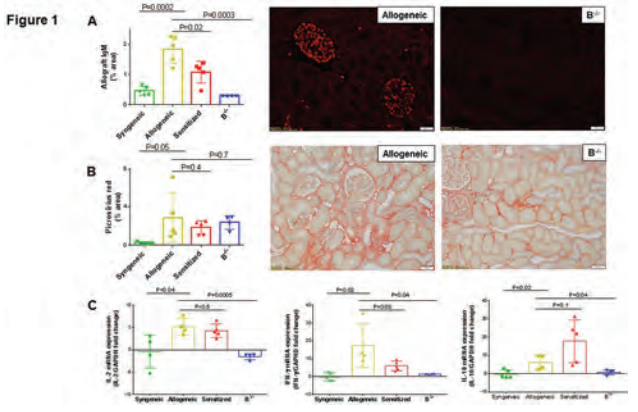

Figure 1. B cell deficient recipients demonstrated reduced allograft inflammation. (A) Immunoflourescence showed absent antibody deposition in the allografts of $B^{-/-}$ recipients. (B) Fibrosis, as determined by Picorsirius red stain, was unchanged among allogeneic, sensitized, and $B^{-/-}$ recipients. (C) RT PCR of allografts demonstrated a reduction in Th1 cytokines (IL-2, IFN-gamma) and IL-10.

Absence of MFGE8 Promotes Rejection in a Murine Model of Transplant Vasculopathy

Benoit Brilland,[1,2] Pamela Thebault,[2] Michaël Chassé,[2] Shijie Qi,[2] Patrick Laplante,[2] Jean-Francois Cailhier.[2] *[1]CHU d'Angers, Angers, France; [2]CHUM Research Center, Centre Hospitalier de l'Universite de Montreal, Montreal, ON, Canada.*

Background: Transplant vasculopathy (TV) is the major cause of long-term allograft dysfunction in renal and heart transplantation. TV is characterized by persistent endothelial and epithelial apoptosis, leading to neointima formation and release of mediators in the microenvironment. Amongst them, we found that Milk Fat Globule Epidermal growth factor-8 (MFG-E8) can reprogram macrophages from a pro-inflammatory to a pro-repair phenotype. We hypothesize that MFG-E8 from the allograft is crucial to dampen local and systemic inflammation; attenuating the initial pro-inflammatory macrophage program resulting in better transplant outcomes.

Methods: We used a filly mismatched murine aortic transplant model. Abdominal aorta from MFG-E8 KO and WT mice (C57BL/6J background) were transplanted into Balb/C recipients. Following transplantation, each group received MFG-E8 or vehicle (PBS) twice a week. 4 groups (8-10 mice in each) were constituted (KO+PBS, KO+MFG-E8, WT+PBS, WT+MFG-E8). Isografts were performed between Balb/C mice as control. Intimal proliferation of the transplant was evaluated at week 9. Leukocyte phenotypes and activation status were assessed by flow cytometry, weekly in blood and at week nine in spleen. Variation overtime was evaluated using mixed linear models to account for repeated measurement and time effect when appropriate.

Results: At week nine, intimal proliferation was higher in the KO+PBS group than in all the others groups. CD8+ T cell activation in spleen was higher in the KO+PBS group compared with the KO+MFG-E8 and with the WT+PBS. In circulating blood, the variations over time of activated CD4+ T cells, regulatory T cells, B cells and plasmablasts were significantly different between groups.

Conclusions: The absence of MFG-E8 is associated with increased intimal proliferation in the transplant, increased activation of T cells in spleen and significant variation of T and B cells subpopulation in circulating blood. The addition of recombinant MFG-E8 dampened this proliferation and activation.

A Proteomic Analysis of Kidneys Subjected to Normothermic Ex-Vivo Kidney Perfusion Demonstrates Metabolism and Energy Production Are Important Determinants of Kidney Function Following Warm Ischemia

Shelby Reid,[1] Peter Urbanellis,[7] Matyas Hamar,[4] Moritz Kaths,[6] Lisa Robinson,[2] Markus Selzner,[3] James W. Scholey,[7] Ana Konvalinka.[5] *[1]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada; [4]UHN/TGH/SickKids, Toronto, ON, Canada; [5]University Health Network, University of Toronto, Toronto, ON, Canada; [6]University Hospital Essen, Essen, Germany; [7]University of Toronto, Toronto, ON, Canada.*

Background: Organ shortage remains a problem for kidney transplantation, leading to an increased use of marginal grafts. These grafts tolerate cold storage poorly, resulting in more severe ischemia-reperfusion injury (IRI) and a higher rate of delayed graft function (DGF). This has led to the development of alternative preservation techniques that aim to reduce IRI and the rate of DGF. Normothermic ex-vivo kidney perfusion (NEVKP) is a storage method that may result in improved kidney function and limit IRI compared to traditional static-cold-storage (SCS).

Methods: Porcine kidneys were explanted, subjected to 30-minutes of warm ischemia, and stored via NEVKP or SCS for 8 hours, followed by re-implantation. Creatinine and BUN were measured in serum samples daily, until post-operative day (POD) 10. Kidney biopsies were taken at time of explant, 30 minutes following anastomosis and on POD3. Biopsy tissue was subjected to proteomic analysis on Q-Exactive mass spectrometer. Cytoscape software was used for enrichment analysis of differentially expressed proteins.

Results: Serum creatinine and BUN measurements demonstrated lower values in NEVKP grafts compared with SCS kidneys with POD10 levels in the NEVKP group comparable to their baseline values. Proteomic analysis allowed for quantification of 6179 proteins in total. Eighty proteins were differentially expressed ($p<0.05$; paired t-test) between NEVKP and SCS biopsies at 30 minutes following anastomosis with top enriched pathways relating to regulation of metabolism in NEVKP and energy production in SCS ($p<0.05$; Cytoscape pathway analysis). Analysis of samples from POD3 revealed 112 differentially expressed proteins with top enriched pathways relating to metabolism and catabolism in both groups.

Conclusions: NEVKP leads to improved kidney function compared to traditional SCS. Metabolism, energy production and catabolism represent key biological processes differentiating NEVKP from SCS proteome. Better understanding and manipulation of metabolism in kidney grafts may lead to amelioration of IRI and prevention of DGF.

TH-OR126

Normothermic Ex-Vivo Kidney Perfusion Improves Function of Marginal Renal Grafts That Were Subjected to Prolonged Ischemia prior to Preservation

Peter Urbanellis,[2,3] Matyas Hamar,[2] Ivan Linares,[2,3] Dagmar Kollmann,[2] Sujani Ganesh,[2] Paul M. Yip,[2] Rohan John,[2] Istvan Mucsi,[2] Ana Konvalinka,[2] Darius Bagli,[1] David Grant,[2] Lisa Robinson,[1] Markus Selzner.[2] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; [3]Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada.*

Background: Normothermic ex-vivo kidney perfusion (NEVKP) is an emerging technique for renal graft preservation. We investigated whether NEVKP could promote improved marginal graft function compared to cold storage in a model of donation after cardiac death.

Methods: Kidneys from 30kg Yorkshire pigs were removed following 30, 60, 90, or 120 minutes of warm ischemia (WI). These grafts were then preserved in either cold histidine-tryptophan-ketoglutarate solution (CS) or subjected to pressure-controlled NEVKP for 8 hours prior to heterotopic autotransplantation.

Results: Prolonging WI time prior to kidney retrieval and subsequent storage in CS resulted in grafts that demonstrated incremental posttransplant increases in serum creatinine with grafts subjected to 120min of WI having persistent elevation (POD7: 13.45±3.50mg/dl vs baseline: 1.1±0.33mg/dl $p<0.01$, n=4). During NEVKP perfusion, 120min WI grafts cleared lactate from perfusion solution (0hr: 10.48±0.93mmol/L vs 7hr: 1.48±0.85mmol/L, $p<0.01$, n=5), had decreasing intra-renal resistance (0hr: 2.26±0.9mmHg/mL/min vs 7hr: 0.37±0.6mmHg/mL/min, $p<0.01$), and continuous urine production. Posttransplantation, 120min WI grafts with NEVKP, compared to CS, demonstrated significantly decreased serum creatinine peak values (POD4: 12.62±2.34mg/dl vs POD5: 18.95±1.11mg/dL, p=0.001) and higher creatinine clearance (POD4: 6.61±4.03mL/min vs 0.35±0.30mL/min, p=0.02 and POD7: 26.31±11.54mL/min vs 9.78±4.6mL/min, p=0.03). On POD7, serum creatinine returned to baseline values in the NEVKP group (POD7: 4.88±5.57mg/dL vs baseline: 1.02±0.16mg/dL, p=0.16) but not the CS group (POD7: 13.45±3.50mg/dl vs baseline: 1.1±0.33mg/dl $p<0.01$, n=4). Histology from 120min WI NEVKP grafts at POD7 demonstrated decreased tubular injury scores compared to cold CS grafts (1.8+/-0.8 vs. 3.0+/-0.0, p=0.03) as assessed by a blinded pathologist.

Conclusions: Kidney grafts subjected to 120min of WI before retrieval showed significant improvement in function following 8hrs of continuous pressure-controlled NEVKP compared to CS. This suggests NEVKP could be utilized to expand the donor pool through the consideration of extreme marginal grafts for transplantation.

Bioengineering a Kidney in Secondary Lymphoid Tissues: A LTβR Dependent Pathway for Ectopic Organogenesis Maria G. Francipane,[1] Bing Han,[1] Leif Oxburgh,[2] Sunder Sims-Lucas,[3] Carlton M. Bates,[3] Eric Lagasse.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Maine Medical Center Research Institute, Scarborough, ME; [3]Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Kidney diseases are rising rapidly worldwide. While further work needs to be done before induced pluripotent stem cells (iPSCs) technology can be used to generate transplantable kidneys, disease modeling using iPSCs can facilitate the development of targeted therapies benefiting kidney patients. Unfortunately, while organoids expressing markers of kidney cells have been generated in vitro from mouse nephron progenitors and human iPSCs, there is little evidence that these cells exhibit phenotypic and functional aspects in vivo. Paradoxically, orthotopic engraftment of kidney tissue in the adult does not provide an environment conducive to vascularization and functional differentiation. Among potential endogenous bioreactors, the lymph node (LN) stands out, having permissive properties for kidney rudiments. Understanding LN remodeling and adaptation upon tissue transplantation could prove valuable in future endeavors to create a niche for human kidney cells. We hypothesize that LTβR signaling in LN fibroblastic reticular cells (FRCs) drives ectopic organogenesis.

Methods: Human fetal kidneys, mouse nephron progenitor- or human iPSC-derived kidney organoids were transplanted into mouse LNs. The maturation of transplanted cells and tissues was investigated through immunofluorescence. Three-dimensional reconstructions and Dextran uptake assay were used to test graft architecture and glomerular filtration, respectively. To investigate the molecular mechanism contributing to ectopic organogenesis, mice bearing grafts were treated with LTβR-Fc fusion protein. $LT\beta R^{-/-}$ mice were also used to confirm that LTβR ablation negatively affects ectopic kidney organogenesis (as $LT\beta R^{-/-}$ mice do not have LNs, omentum was used as an alternative secondary lymphoid organ for transplantation).

Results: Our preliminary data show engraftment of human fetal kidneys as well as efficient maturation of mouse nephron progenitor- and iPSC-derived kidney organoids in LN. Importantly, in the absence of an active LTβR pathway grafts exhibited impaired vascularization and structure.

Conclusions: The LN act as an innovative bioreactor to organize kidney progenitors into vascularized and functional renal structures. Our study has a wide-ranging impact for tissue engineering approaches for the rebuilding of functional kidneys in vivo.

Single Cell Transcriptome Atlas of the Mouse Kidney Reveals Important Cell Diversity Jihwan Park, Rojesh Shrestha, Chengxiang Qiu, Ayano Kondo, Szu-Yuan Li, Katalin Susztak. *Renal Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA.*

Background: A revolution in cellular measurement technology is under way: For the first time, we have the ability to monitor global gene regulation in thousands of individual cells in a single experiment. They overcome fundamental limitations inherent in measurements of bulk cell population that have frustrated efforts to resolve precise cellular states. These methods also provide a stunningly high-resolution view of transitions between states. Single-cell transcriptomics will allow us to identify cell type specific expression changes, discover novel disease associated cell types and trace cell composition changes in complex disease such as diabetic kidney disease (DKD).

Methods: Using droplet-based single-cell barcoding and sequencing methods we cataloged mouse kidney cell types in an unbiased manner. We have developed a novel cell isolation method and individually profiled over 30,000 cells from the kidneys. Computational analysis included normalization, quality control, dimension reduction and clustering followed by identification of cell types using known markers and bulk RNAsequencing data of kidney segments.

Results: Main clustering analysis identified 15 major cell populations in normal mouse kidneys; three distinct ureteric bud- and 7 metanephric mesenchyme-derived epithelial clusters, in addition to endothelial cells, fibroblasts, different immune cell types and two novel epithelial cell populations that have not been described before. Cell trajectory analysis highlighted cell type conversion in the collecting duct and discovered novel transient cell type. Furthermore we have developed methods for single cell marker based in silico deconvolution of bulk RNAsequencing datasets. We found that most transcript level changes previously reported in kidney disease are resulted from cell type proportion changes in kidney samples, such as accumulation of immune cells and fibroblasts and decrease of tubule epithelial cells in disease development. Finally, we identified key transcription factors, mapped GWAS candidates, known drug targets, and nephrotic syndrome genes in the clusters showing their cell type-specific expression patterns.

Conclusions: In conclusion, our first single cell transcriptome of the entire mouse kidney could have a transformative impact to understand transcriptional networks maintaining cell identity and development of DKD.

SH3D21 Dysregulation May Cause Disruption of the Actin Cytoskeleton in Diabetic Nephropathy Heiko J. Schenk, Irini Schaefer, Patricia Bolanos-Palmieri, Beina Teng, Janina Müller-Deile, Hermann G. Haller, Mario Schiffer. *Department of Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Diabetes is the most common cause of end-stage renal disease. The onset of albuminuria and podocyte damage is associated with disruption of the actin cytoskeleton. We identified SH3D21 as a potential key regulator of the actin cytoskeleton in podocytes which changes its expression in diabetes.

Methods: Cultured murine and human podocytes under glucose- and VEGF-stimulation were used to mimic diabetic conditions and compared to osmolality controls with mannitol. To model type I diabetes, C57BL/6J mice were treated for 5 days either with intraperitoneal injections of streptozotocin (STZ) or sodium citrate buffer as control while blood glucose levels were determined for 16 weeks. WB analysis of STZ-injected mice and buffer-injected mice was carried out. Immunofluorescence (IF) staining on cryosections of STZ- or buffer-injected mice was performed. IF of SH3D21 was performed on kidney cryosections of STZ- or buffer-injected mice as well as human and murine cultured podocytes. To identify protein interaction partners of SH3D21, we performed co-affinity purification mass spectrometry (MS) of murine whole kidneys as well as human cultured podocytes. Knockdown of sh3d21 was performed in zebrafish and proteinuria was measured using transgenic zebrafish line Tg*(l-fabp*:eGFP-DBP).

Results: Reduction of SH3D21 protein expression was detected in murine kidney and cultured podocytes under diabetic conditions. IF of diabetic murine kidney cryosections showed reduced Sh3d21 expression associated with the absence of Sh3d21-Nephrin co-expression. In murine and human podocytes we could document a shift from a membrane to a perinuclear or cytosolic speckled expression pattern which paralleled actin disruption under glucose- or VEGF-treatment. In murine and human podocytes SH3D21 primarily interacts with cytoskeletal proteins. Knockdown of sh3d21 in zebrafish caused proteinuria and foot process effacement.

Conclusions: SH3D21 is a novel interaction partner of nephrin which appears to be an important regulator of the actin cytoskeleton impacting slit diaphragm functions in diabetes.

Amelioration of Diabetic Nephropathy in miR-379 Knockout Mice Mitsuo Kato,[3] Maryam Abdollahi,[3] Linda L. Lanting,[2] Mei P. Wang,[4] Rama Natarajan.[1] *[1]Diabetes Complications and Metabolism, Beckman Research Institute of City of Hope, Duarte, CA; [2]Diabetes Complications and Metabolism, Beckman Research Institute of City of Hope, Duarte, CA; [3]Diabetes Complications and Metabolism, Beckman Research Institute of City of Hope, Duarte, CA; [4]Diabetes Complications and Metabolism, Beckman Research Institute of City of Hope, Duarte, CA.*

Background: Major features of diabetic nephropathy (DN) include extracellular matrix (ECM) accumulation, glomerular hypertrophy and fibrosis. Evidence shows that key microRNAs (miRNAs) and long noncoding RNAs (lncRNAs) are involved in DN development. Recently we found that miR-379 megacluster of miRNAs and its host transcript lncRNA are regulated by endoplasmic reticulum (ER) stress, increased in glomeruli of diabetic mice and mediate early DN. Therefore, here we developed miR-379-knockout (KO) mice using CRISPR-Cas9 system to examine the hypothesis that miR-379, the first miRNA in the cluster, has an in vivo role in DN progression.

Methods: miR-379KO mice were generated by CRISPR-Cas9 nickase and dual guideRNA strategy. Diabetes was induced with streptozotocin (STZ) in 10 wk old wild type (WT-STZ) and miR379-KO (miR379-KO-STZ) C57BL/6 mice (n=6). Non-diabetic age/gender matched mice acted as control (WT-Con and miR379-KO-Con; n=6). Urine albumin excretion and urinary albumin/creatinine ratio (ACR) were measured before euthanization at 24 wks post diabetes induction. Renal glomeruli were isolated for measuring miRNAs, profibrotic and miR379 target genes. Cortical sections were stained for histopathology. Expression of TGFß1 and ER stress regulator EDEM3, a target of miR-379, were examined by immunohistochemical staining.

Results: miR-379KO mice did not depict any abnormalities, and developed diabetes to the same extent as WT mice. On the other hand, miR379-KO-STZ mice did not lose body weight like WT-STZ mice. Increased urine albumin and ACR in WT-STZ mice were attenuated in miR-379KO-STZ mice. Glomerular hypertrophy, ECM accumulation and fibrosis observed in WT-STZ mice were all significantly reduced in miR-379KO-STZ mice. Other candidate miRNAs in the miR-379 cluster (miR-495 and miR-377) were increased in glomeruli of WT-STZ, but not miR-379KO-STZ mice. Furthermore, increases in expression of profibrotic genes Col4α1, Col1α2, and TGF-ß1 seen in WT-STZ mice were significantly attenuated in miR-379KO-STZ mice. Conversely, decreased expression of EDEM3 in WT-STZ mice was not observed in miR-379KO-STZ mice.

Conclusions: Genetic deletion of miR-379 in mice by CRISPR-Cas9 system prevents glomerular hypertrophy and ECM accumulation associated with early DN. miR-379 and its target EDEM3 may play key roles in inducing ER stress and TGFß1 in diabetes to increase glomerular damage.

TH-OR131

Comprehensive Renoprotective Mechanisms of Ipragliflozin against Diabetic Nephropathy Michitsugu Kamezaki,[1,2] Tetsuro Kusaba,[2] Noriyuki Yamashita,[2] Masahiro Uehara,[2] Keiichi Tamagaki.[2] *[1]Kyoto Chubu Medical Center, Nantan, Japan; [2]Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Clinical and experimental investigations showed that sodium glucose co-transporter 2 inhibitors (SGLT2i) potentiate glucose-lowering and natriuretic effects and contribute to the prevention of diabetic kidney disease progression. Amelioration of glomerular hyperfiltration is one of the candidate, but the other molecular mechanisms are not fully understood.

Methods: To distinguish these different pharmacological effects on the molecular mechanisms underlying the development of diabetic kidney disease, we administered different doses of SGLT2i, ipragliflozin, (low dose: Ipra-LD, high dose: ipra-HD or vehicle) into type 2 diabetic, *db/db* mice for 8weeks through oral gavage.

Results: Though body fluid volume was depleted in both Ipra-LD and Ipra-HD, only high dose Ipra significantly lowered blood glucose and reduced urinary albumin excretion. 3-nitrotyrosine (3-NT) immunostaining demonstrated that oxidative stress in the kidney was ameliorated by Ipra at dose-dependent manner. qPCR showed that expressions of tubular injury marker and NADPH oxidase 4 (Nox4) was improved in both Ipra-LD and Ipra-HD. Electron microscopy showed that Ipra improved the diabetes induced-abnormal mitochondrial cristae formation. Regarding kidney hypoxia, pimonidazole immunostaining showed that both high and low dose Ipra ameliorated the tubular hypoxia in the renal cortex where SGLT2i act. Regarding glomerulus, increased glomerular area in diabetic kidney reflecting hyperfiltration was ameliorated by both Ipra-LD and -HD. 3-NT immunostaining in glomerulus demonstrated the dose-dependent amelioration of oxidative stress in podocyte by Ipra. We further assessed the molecular mechanisms by using a glomeruli isolation technique, and found that high dose ipra preserved podocyte markers and reduced Nox4 expressions.

Conclusions: We verified the dose-dependent difference in the effect of ipra on diabetic nephropathy *in vivo*. Especially even low dose ipra improved the renal cortical hypoxia and abnormal hemodynamics in early diabetic nephropathy. In addition to these effects, high dose ipra exhibited renoprotective effects through the reduction of oxidative stress in both tubular epithelia and glomerular podocytes.

TH-OR132

Transcriptome of Urinary Extracellular Vesicles in Diabetic Kidney Disease Karina A. Barreiro,[3] Om Dwivedi,[7] Maija Puhka,[2] Carol Forsblom,[1] Per-Henrik Groop,[6] Leif Groop,[4] Tobias B. Huber,[5] Harry B. Holthofer.[7,8] *[1]Helsinki University Central Hospital, Helsinki, Finland; [2]Institute for Molecular Medicine Finland FIMM, Helsinki, Finland; [3]Institute for Molecular Medicine Finland FIMM, University of Helsinki, Helsinki, Finland; [4]Lund University, Maimo, Sweden; [5]University Medical Center Hamburg, Hamburg, Germany; [6]University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [7]Finnish Institute of Molecular Medicine, University of Helsinki, Helsinki, Finland; [8]III Dept of Medicine, University Clinic Hamburg-Eppendorf, Hamburg, Germany.*

Background: We compared methods for the urinary extracellular vesicle (uEV) harvest and respective transcriptomes in diabetic kidney disease (DKD). This also included study of storage conditions, in -20°C vs. -80°C, to find out whether existing large sample collections stored at -20°C can be successfully used.

Methods: Patients: Type 1 diabetic patients (T1D) and normoalbuminuric controls were included. **Main Measurables**: EVs were isolated from 40ml of 24h urines by differential centrifugation, Hydrostatic Filtration Dialysis (HFD) or kit-based isolation. Quality of the EV yield was analyzed with EM and Western blotting. Isolated RNAs were profiled with Bioanalyzer Pico kit and subjected to RNAseq after cDNA library preparation using ultra-low amount protocols. RNAseq was performed using HiSeq 2000 (Illumina) pair-end (2X100) protocol. Output reads were aligned to human reference genome and counted using GENCODE gene annotations. We used gene length normalized values FKPM (Fragments Per Kilobase Of Exon Per Million) as expression measurement for genes.

Results: Results: The isolated EVs appeared typical at EM. All samples had >15 million RNA eads. On average, expression (FKPM >1) of 13,161 genes and a high expression (FPKM≥5) of key kidney specific genes (e.g. *SLC12A3, SLC12A1, LGALS1, ATP6V1B1, NPHS2, AQP3, AQP2, SLC22A12*). A comprehensive analysis of 182 kidney specific genes revealed >70% (total 132) of the genes in urine EVs. Principal component analysis of these discriminated macro-albuminuric from normoalbuminuric T1D patients. Six genes were differentially expressed in DKD ($P_{uncorrected}$ <0.001 and fold change >1.5 or <0.66). The highest expressed genes were enriched ($P>10^{-11}$) in pathways of cellular metabolism (oxidative phosphorylation and TCA cycle), mitochondrial, ribosomal and vesicle trafficking functions. Pathway and gene enrichment analyses implicate (P<0.002) TGF-beta signaling, PI3K-Akt signaling and immune pathway in DKD.

Conclusions: uEV transcriptome captures a significant kidney specific transcriptome which differentiates macroalbuminuric from normoalbuminuric T1D patients. Technically, samples stored at different temperatures cannot be directly compared with each other. Our results show high value of urinary EV transcriptome for biomarker search and call for meticulous standardization of protocols used.

TH-OR133

Deletion of Adaptor Protein p66Shc Decreases Afferent Arteriolar KATP Channel Activity and Decreases Renal Damage in Diabetic Dahl SS Rats Andrey Sorokin,[1] Bradley S. Miller,[1] Shoshana R. Blumenthal,[1] John D. Imig.[2] *[1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Pharmacology & Toxicology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Increased expression of adaptor protein p66Shc has been associated with progression of diabetic nephropathy. Afferent arteriolar dilation and glomerular hyperfiltration in diabetes are due to increased K_{ATP} channel availability and activity.

Methods: This study tested the hypothesis that p66Shc KO Dahl SS rats with STZ-induced diabetes are protected from glomerular injury because afferent arterioles do not exhibit enhanced K_{ATP} channel activity. Afferent arteriolar responses to the K_{ATP} channel opener pinacidil and the K_{ATP} channel blocker glibenclamide were assessed in Dahl SS, Dahl SS p66Shc KO, Dahl SS with STZ-induced diabetes, and Dahl SS p66Shc KO with STZ-induced diabetes rats. Afferent arteriolar diameter responses were determined using the juxtamedullary nephron technique six weeks following induction of STZ diabetes. Hyperglycemia, excessive urination, body weight, albuminuria and glomerular injury was evaluated in all rat groups to monitor the progression of diabetic nephropathy.

Results: Afferent arteriolar diameters at 100 mmHg averaged 22.9 ± 0.9 μm (n=8) in Dahl SS rats, 21.1 ± 0.8 μm (n=6) Dahl SS p66Shc KO. Dahl SS with STZ-induced diabetes rats had a significant increase in the afferent arteriolar diameter (24.7 ± 1.3 μm; n=6). Inversely, Dahl SS p66Shc KO with STZ-induced diabetes rats did not have increased afferent arteriolar diameters (22.1 ± 1.2 μm; n=6). Afferent arteriolar dilator responses to pinacidil were not different between Dahl SS rats and Dahl SS p66Shc KO. However; Dahl SS with STZ-induced diabetes but not Dahl SS p66Shc KO with STZ-induced diabetes rats had an increased vasodilator response to pinacidil. Likewise, the K_{ATP} inhibitor gibenclamide (30 μM) resulted in a greater decrease in afferent arteriolar diameter in Dahl SS & STZ-induced diabetes (23 ± 4%, n =6) compared to Dahl SS p66Shc KO & STZ-induced diabetes (13 ± 2%, n =6). The glomerular injury was mitigated in Dahl SS p66Shc KO with STZ-induced diabetes.

Conclusions: Taken together, these results indicate that increased afferent arteriolar K_{ATP} channel activity contributes to increased diameters and renal injury in Dahl SS & STZ-induced diabetes. Moreover, deletion of the adaptor protein p66Shc decreases afferent arteriolar K_{ATP} channel activity and decreases renal damage in diabetic Dahl SS rats.

Funding: NIDDK Support

Genetic Ablation of Vasohibin-2 Prevents the Progression of Diabetic Nephropathy in an Experimental Mouse Model Kana Masuda, Katsuyuki Tanabe, Haruyo Ujike, Norikazu Hinamoto, Hiromasa Miyake, Hitoshi Sugiyama, Yohei Maeshima, Jun Wada. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Science, Okayama, Japan.*

Background: Diabetic nephropathy has been reported to be associated with abnormal angiogenesis and increased glomerular VEGF, which could represent potential therapeutic targets. Vasohibin-2 (VASH2) is a novel pro-angiogenic factor and has shown to be involved in tumor enlargement. In the present study, we investigated whether VASH2 was involved in the progression of diabetic nephropathy in vivo and in vitro experiments.

Methods: Eight to ten weeks old male C57BL/6 wild type (WT) or VASH2-knockout ($VASH2^{LacZ/LacZ}$) mice received intraperitoneal injections of 50mg/kg STZ or vehicle on five consecutive days. The experimental subgroups included 1) non-diabetic WT, 2) non-diabetic $VASH2^{LacZ/LacZ}$, 3) diabetic WT and 4) diabetic $VASH2^{LacZ/LacZ}$. Blood glucose (BG) and urine albumin excretion (UAE) were evaluated every other week, and 16 weeks after the injections, blood pressure (BP) was measured and blood and kidney samples were obtained. Conditionally immortalized human mesangial cells were stimulated by high glucose (25mM) or TGF-β1 (10 ng/ml) under the presence of control or VASH2 siRNA.

Results: There were no differences in BP, BG and serum creatinine between diabetic WT and $VASH2^{LacZ/LacZ}$ group. However, increased UAE and creatinine clearance observed in diabetic WT mice were significantly decreased in diabetic $VASH2^{LacZ/LacZ}$ mice. In addition, increased glomerular CD31 positive area induced by diabetes was also suppressed in $VASH2^{LacZ/LacZ}$ group. VASH2 deficiency did not affect renal level of VEGF but suppressed diabetes-induced elevation of renal VEGFR2 expression. Increased glomerular type IV collagen accumulation and renal TGF-β1 mRNA in diabetic WT mice were prevented in diabetic $VASH2^{LacZ/LacZ}$ mice. Endogenous VASH2 level was increased by diabetes, and immunostaining suggested that VASH2 was localized in mesangial cells in glomeruli. Knockdown of VASH2 using siRNA suppressed the increased mRNA level of type IV collagen and α-SMA in cultured mesangial cells treated with high glucose or TGF-β1 stimulation.

Conclusions: Deletion of VASH2 had protective effects in diabetic nephropathy through the suppression of excessive VEGF action on endothelial cells and extracellular matrix production in mesangial cells.

TH-OR135

Soluble Nogo-B Overexpression Ameliorates Diabetic Glomerulopathy Ivan Hernandez,[1] Carlo alberto Ricciardi,[1] Kathryn E. White,[3] Anthea E. Hayward,[1] Xiaoyan Bai,[2] Fan Fan Hou,[2] David A. Long,[4] Luigi Gnudi.[1] *[1]King's College London, London, United Kingdom; [2]Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]Newcastle University, Newcastle upon Tyne, United Kingdom; [4]University College London, London, United Kingdom.*

Background: Diabetic glomerulopathy (DG) is characterized by altered vascular remodelling, increased vascular permeability. Neurite Outgrowth Inhibitor (Nogo)-B and its soluble form (sNogo-B) bind to NgBR and have been implicated in vascular remodelling. Full-length Nogo-B is expressed in glomerular endothelial cells and podocytes and is downregulated in experimental model of diabetic nephropathy and in patients with diabetic nephropathy (DN). Our aims were to investigate whether overexpression of sNogo-B could ameliorate DG in an experimental animal model of diabetes.

Methods: 8-10 weeks-old male DBA/2J mice were made diabetic (streptozotocin), and administered (12-14 week-old) an adeno-associated viral vector (AAV) expressing sNogoB or GFP (control). Animals were divided into four groups: non-diabetic (ND) and diabetic (D) mice treated with either GFP-AAV or sNogo-B-AAV followed by 12-14 weeks of diabetes. Blood pressure was assessed with tail-cuff methodology, plasma sNogo-B levels by ELISA, full-length Nogo-B and AKT phosphorylation with immunoblotting, creatinine by mass spectrometry, albuminuria by fluorescence, and glomerular ultrastructure by electron microscopy.

Results: sNogo-B-AAV allowed a sustained expression of sNogoB in the circulation ($p<0.05$). Diabetes-mediated albuminuria ($p<0.01$) was ameliorated by sNogo-B upregulation ($p=0.04$). Similarly, increase in creatinine clearance was corrected by sNogo-B overexpression to control ND mice levels ($P<0.006$). Blood pressure was similar in all groups. sNogo-B overexpression ameliorated diabetes-mediated mesangial expansion ($p<0.05$), full-length Nogo-B downregulation ($p=0.02$), and blunted Akt-Serine phosphorylation ($p=0.01$) in diabetic mice in kidney cortex lysate.

Conclusions: Overexpression of sNogo-B ameliorates DG via prevention of diabetes-mediated Nogo-B downregulation. Ongoing work is dissecting the major molecular mechanisms involved. sNogo-B could represent a potential novel future treatment for DG.

TH-OR136

A Small Molecule Inhibitor of ASK1 Modulates Biomarkers and Pathways Associated with Diabetic Kidney Disease (DKD) Shawn S. Badal,[1] Haichun Yang,[2] Li Li,[1] Henry Liu,[1] Agnes B. Fogo,[2] David G. Breckenridge,[1] John T. Liles.[1] *[1]Gilead Sciences, Foster City, CA; [2]Vanderbilt University, Nashville, TN.*

Background: Apoptosis signal-regulating kinase 1 (ASK1) promotes inflammation, apoptosis, and fibrosis via activation of MAPK kinases p38 and c-Jun N terminal kinase (JNK). ASK1 pathway activation has been demonstrated in human DKD biopsies and in kidneys of db/db eNOS$^{-/-}$ mice. Clinically relevant urinary biomarkers associated with kidney damage and GFR decline in DKD patients have not been investigated in this animal model. This study evaluated effects of a selective, small molecule ASK1 inhibitor on urinary biomarkers and expression of DKD-related genes in db/db eNOS$^{-/-}$ mice.

Methods: db/db eNOS$^{-/-}$ mice were treated with a structural analog of the ASK1 inhibitor, Selonsertib, (GS-444217, 0.3% in chow) or vehicle for 8 weeks, starting at 10 weeks of age (baseline) (n=8-10 mice/group). At 18 weeks of age EGF, KIM-1 and TIMP1 levels in urine were quantified at end of study by ELISA and values normalized to urine creatinine levels. GFR was measured by FITC-inulin clearance. Kidney cortex mRNA was isolated and gene expression analyzed by qPCR and RNA-Seq.

Results: At 18 weeks, vehicle-treated mice had significant reductions in GFR (212± 21 vs 296±27 ml/min, $p=0.0265$) and uEGF levels (1.38 ± 0.11 vs 2.17± 0.27 μg/mg, $p=0.0067$) compared to baseline. ASK1 inhibition halted GFR decline (365± 31 vs 212± 21 ml/min, $p=0.0007$), prevented decreases in uEGF (2.51± 0.23 μg/mg vs 1.38±0.11, $p=0.0003$) and preserved kidney *Egf* mRNA levels. ASK1 inhibition reduced urinary TIMP1 (481.5± 96.3 vs 903.4± 158.8 pg/mg, $p=0.0473$) and *Timp1* mRNA, compared to vehicle. Additionally, urinary KIM-1 as well as *Havcr1* (KIM-1), *Lcn2* (NGAL), *Mcp1*, and *Tnf* mRNA were all significantly reduced by ASK1 inhibition. Gene set enrichment analysis (GSEA) of RNA-Seq data revealed that TNFα signaling and inflammatory response pathways were enriched in db/db eNOS$^{-/-}$ mice and down-regulated by treatment with an ASK1 inhibitor.

Conclusions: Biomarkers related to kidney injury, inflammation, fibrosis and GFR decline in DKD patients are dysregulated in db/db eNOS$^{-/-}$ mice. The administration of an ASK1 inhibitor improved these biomarker levels and kidney function. These data establish db/db eNOS$^{-/-}$ mice as a relevant model to evaluate drug effects on biomarkers associated with GFR decline.

Increased Podocyte SIRT1 Function Attenuates Diabetic Kidney Injury Quan Hong,[1,4] Lu Zhang,[3,4] Bhaskar Das,[4] Guangyan Cai,[1] Xiangmei Chen,[1] Peter Y. Chuang,[2,4] John C. He,[4] Kyung Lee.[4] *[1]Chinese PLA General Hospital, Bei Jing, China; [2]Connecticut Kidney Center, LLC, Orange, CT; [3]Xiamen University Affiliated The First Hospital, Amoy, China; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We previously found that the glomerular expression of Sirtuin-1 (SIRT1) was reduced in human diabetic kidneys and the loss of SIRT1 aggravated albuminuria and worsened kidney disease progression in diabetic mice. SIRT1 encodes an NAD-dependent deacetylase that modifies the activity of key transcriptional regulators affected in diabetic kidneys, including NF-κB and STAT3. Consistent with reduced SIRT1, acetylation of NF-κB and STAT3 was reduced in diabetic kidneys, resulting in their increased activities. In this study we employed genetic and pharmacological means to interrogate whether the increased SIRT1 function is sufficient to attenuate diabetic kidney injury.

Methods: For the genetic approach, we generated doxycline-inducible podocyte-specific overexpression of SIRT1 (Pod-SIRT1^{OV}) mice, which were further crossed with diabetic OVE26 mice to generate OVE26;Pod-SIRT1^{OV}. Littermates without SIRT1 transgene (OVE26;WT) and age-matched nondiabetic mice were used as controls. Healthy control, OVE26;WT and OVE26;Pod-SIRT1^{OV} mice were given dox-supplemented chow starting at 16 weeks of age, at which time the OVE26 mice exhibit pronounced hyperglycemia and proteinuria. For the pharmacological approach, OVE26 mice at 16 weeks of age were treated with either vehicle or novel SIRT1 inhibitor, BF175 (0.4mg/kg daily). All mice were sacrificed at 22 weeks of age for analysis.

Results: 6 weeks of Dox administration led to significant reduciton in kidney-to-body weight ratio and urinary albumin excretion in OVE26;Pod-SIRT1^{OV} in comparison to OVE26;WT mice. Glomerular hypertrophy, mesangial matrix expansion, and podocyte foot process effacement were also markedly reduced in OVE26;Pod-SIRT1^{OV} mice. Administration of SIRT1 agonist BF175 for 6 weeks similarly led to significant reductions in albuminuria, mesangial matrix expansion, and podocyte foot process effacement in OVE26 mice compared to vehicle treatment. Both OVE26;Pod-SIRT1^{OV} and OVE26 mice treated with BF175 showed increased podocyte number compared to control OVE26, suggesting that increased SIRT1 function protected against podocyte loss in OVE26 glomeruli.

Conclusions: Our data demonstrates that increased podocyte SIRT1 expression is sufficient to significantly mitigate early diabetic injury and that BF175 is a novel SIRT1 agonist that can be further developed as a potential therapy for early DKD.

Mentorship in the Digital Age: Nephrology Social Media Collective Internship – 2 Year Experience Silvi Shah,[8] Matthew A. Sparks,[2] Scherly Leon,[6] Hector M. Madariaga,[4] Kenar D. Jhaveri,[5] Edgar V. Lerma,[1] Timothy Yau,[7] Paul J. Phelan,[6] Nikhil A. Shah,[6] Ali Poyan-Mehr,[6] Michelle N. Rheault,[3] Swapnil Hiremath,[9] Joel M. Topf.[6] *[1]Associates in Nephrology, Berwyn, IL; [2]Duke University and Durham VA Medical Centers, Durham, NC; [3]University of Minnesota, Minneapolis, MN; [4]Good Samaritan Medical Center, Brockton, MA; [5]Hofstra Northwell School of Medicine-Northwell health system, Great neck, NY; [6]Detroit, MI; [7]Washington University School of Medicine, Saint Louis, MO; [8]University of Cincinnati, Cincinnati, OH; [9]University of Ottawa, Ottawa, ON, Canada. Group/Team: Nephrology Social Media Collective Internship Group.*

Background: Although social media use by healthcare professionals is increasing, formal education is lacking. The Nephrology Social Media Collective (NSMC) internship is a worldwide collaboration among nephrologists to cultivate leaders in the use of social media in medicine by instilling knowledge, competence, and professionalism.

Methods: he NSMC internship was established in 2015. The NSMC faculty consists of 21 individuals who are clinicians, educators, and scientists. The internship is 1 year. Interns are selected on the basis of their curriculum vitae, personal statement, and interest. There is an entrance discussion with each intern to discuss goals followed by quarterly online meetings. Interns are paired with 2 faculty mentors and are expected to contribute 3-4 hours/month. Interns attend NephJC (online nephrology journal club) and participate in NephJC administrative activities (curating a Twitter chat, constructing a visual abstract, writing blog posts or moderating a session). Interns participate in the two required projects - the annual NephMadness contest and the Renal Fellow Network blog. Assessment are based on participation in NephJC, timely completion and quality of projects.

Results: The initial class of 2015 class enrolled 4 interns. The subsequent class of 2016 included 7 interns. The classes were near gender balanced with 6/11 male. There were 6 fellows, 2 medical students, 1 practising physician and 1 nurse. 8 were from USA, 2 from the United Kingdom and 1 from Canada. NSMC internship increased exposure and opportunities for engagement in other social media activities. Following completion, interns became part of NephJC team (N=5) and NephMadness editorial team (N=2). Interns were invited to join International Society of Nephrology's Social Media Task force (N=2), Women in Nephrology's communications' committee (N=2) and ASN's media and communication committee (N=1). The current class of 2017 has enrolled 9 interns.

Conclusions: NSMC internship provides modern communication skills and opportunities to improve skills in social media. It resulted in successful recruitment of the graduated interns in various social media forums. NSMC internship can be included as a part of nephrology fellowship training curriculum.

FR-OR002

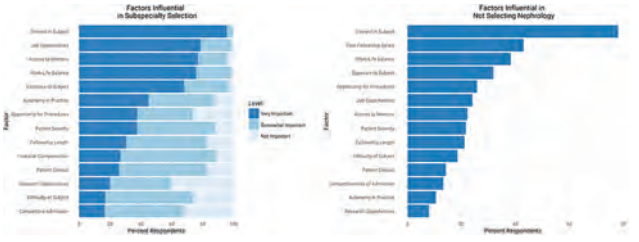
Specialty Choice and Nephrology: Perceptions Among Medical Students and Internal Medicine Residents Devika Nair,[1] Kurtis Pivert.[2] [1]*Vanderbilt University, Nashville, TN;* [2]*American Society of Nephrology, Washington, DC.*

Background: Fewer medical trainees are choosing to pursue nephrology. Only 60.8% of nephrology fellowship positions filled in the AY 2017 nephrology Match, especially concerning in the setting of a growing number of patients with kidney disease.

Methods: To understand perceptions about nephrology and assess factors influencing specialty choice among trainees, an anonymous survey was distributed to medical students and internal medicine residents at 30 US medical schools and residencies. Of 4199 recipients, 648 (15.4%) trainees responded, including 333 upper-level medical students, 304 residents, and three chief residents.

Results: Interest in the subject matter was the most critical factor in choosing to pursue a specialty (92% of participants). Other key considerations included a suitable post-fellowship work-life balance (73%), access to mentors (70%), and adequate exposure to the subject (66%). Lack of interest was the most common reason to forgo a nephrology fellowship (79% of responses). Concerns about remuneration (43%), perceptions of an unsatisfactory work-life balance (39%), and inadequate exposure to nephrology during earlier training (32%) were frequently cited dissuading factors. Several respondents expressed a desire for a combined nephrology-critical care or nephrology-interventional radiology fellowship. Interest in renal physiology and access to mentors were noted as highly influential to those who considered a nephrology career at any point.

Conclusions: Lack of interest in nephrology was the leading factor in respondents' decision to not pursue the specialty. Innovative ways to expose trainees to the meaningful rewards and worthwhile challenges of kidney care are needed to continue to attract qualified applicants.



FR-OR003

Best Practices to Increase Resident Interest in Nephrology: A Mixed Methods Study Stephen M. Sozio,[3,7] Kurtis Pivert,[6] Hitesh H. Shah,[1] Abdo Asmar,[4] Benjamin D. Morrow,[2] Nancy D. Adams.[5] [1]*Hofstra Northwell School of Medicine, Great Neck, NY;* [2]*Uniformed Services University of the Health Sciences (USUHS), San Antonio, TX;* [3]*Medicine, Johns Hopkins University School of Medicine, Baltimore, MD;* [4]*University of Central Florida Shool of Medicine, Orlando, FL;* [5]*University of Connecticut Health Center, Hartford, CT;* [6]*American Society of Nephrology, Washington, DC;* [7]*Welch Center for Prevention, Epidemiology, and Clinical Research, Baltimore, MD.*

Background: Interest in nephrology careers has declined. Understanding practices of internal medicine (IM) residency programs that successfully generate nephrology interest is sorely needed.

Methods: The *Best Practices Project* is an ASN Workforce and Training Committee project to increase nephrology interest. Residents graduating 2002-2012 were identified with the AMA Masterfile; programs were ranked by number of residents ultimately choosing nephrology. Nephrology training program directors (TPDs) from the top 30 institutions were sent a survey about their renal elective and educational experience for IM residents. Directed focus groups were conducted among IM-PDs (top 15 programs) probing key factors in each program's success. Survey results were analyzed across program ranking and compared to a previously-reported national survey. Transcripts from focus groups were analyzed using thematic content analysis.

Results: 19 nephrology TPDs (68%) responded to our survey and 4 IM-PDs (27%) directed focus group sessions were conducted. Most programs were in large tertiary centers. Nephrology TPDs noted faculty mentoring (78%), elective experience (72%), research opportunities (56%), and exposure to nephrology fellows (56%) were most effective in fostering interest. All programs offered renal electives; 33% were mandatory. 53% of programs' typical electives incorporate outpatient experiences, higher than the national average (42%). Programs with more IM residents choosing nephrology were significantly more likely to offer ambulatory experiences in general nephrology in their elective (p=0.042) and have residents mentored in more impactful research projects (p=0.025). IM-PDs noted faculty exposure, quality of nephrology teaching, and demonstrating nephrology as a viable field were keys to success. One exemplar quote: *[Faculty] work hard and play hard. This group of faculty always hosts dinners at the end of the rotation. They actually make their own t-shirts. They kind of have their own branding of what they are*

Conclusions: Integrating outpatient experiences in nephrology electives and mentoring residents in high quality research projects likely increase interest in nephrology. Faculty contact and teaching in both electives and core resident areas also contribute to generating nephrology interest. Interventions to enhance these activities are needed.

FR-OR004

Breaking Bad News: An Objective Structured Clinical Examination (OSCE) of Renal Replacement Therapy (RRT) and Kidney Biopsy Communication Skills Lisa K. Prince, Anna M. Howle, Christina M. Yuan. *Walter Reed National Military Medical Center, Silver Spring, MD. Group/ Team: NERDC.*

Background: There are few reported simulation-based assessments for nephrology-specific interpersonal communication skills (ICS) and professionalism (PROF). We developed a "Breaking Bad News" OSCE that assesses fellow competence in counseling a surrogate decision maker for acute RRT, a patient with advanced chronic kidney disease for RRT, and a patient for kidney biopsy.

Methods: The OSCE was designed for the 2-year nephrology fellowship cycle, with 2 sets of scenarios. Fellows are provided with a brief clinical summary before counseling a simulated patient (SP). SP are trained to portray a nephrology patient with a specific condition, to provide feedback and rate fellows. SPs receive a medical and social history designed to stimulate fellows to demonstrate ICS. After each encounter SPs rate ICS and PROF using the Essential Elements of Communication-Global Rating Scale 2005 (EEC-GRS). Faculty assess performance using a 5-point Likert Mini-Clinical Examination Exercise (Mini-CEX). The two scenario sets were beta-tested in Spring 2015 (3 second year fellows and 2 first year fellows) and 2016 (2 second year fellows and 1 first year fellow).

Results: The OSCE is being evaluated prospectively at 5 training programs (16 first-year; 10 second-year fellows) over a two year period. There are 3 faculty per training site. Primary outcome is overall score on the EEC-GRS for each scenario (first vs. second year fellow performance for each scenario, and individual fellow scores between first and second year). Secondary outcomes include score < 3 (Satisfactory for level of training) on any subsection of the mini-CEX and overall score < 3 on the EEC-GRS. Preliminary satisfaction survey data indicate that 100% of faculty (6/6) and fellows (7/7) rated the OSCE as having met objectives, and 86% (6/7) fellows rated the experience as being "good" or better.

Conclusions: The Breaking Bad News OSCE, designed for a 2-year fellowship cycle, uses previously validated instruments (EEC-GRS; MiniCEX) to assess nephrology-specific ICS and PROF skills. Fellows and faculty report satisfaction with the OSCE, and indicate that it meets objectives. *The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, the Department of the Navy, the Department of Defense or the United States Government.*

FR-OR005

Renal Fellows' Point-of-Care Lung Ultrasound Curriculum Nathaniel C. Reisinger,[2] Anubhav Kumar,[2,1] Vishnu S. Potluri,[2] Jehan Z. Bahrainwala,[2] Jeffrey S. Berns.[2] [1]*None, Philadelphia, PA;* [2]*Penn, Philadelphia, PA.*

Background: Fluid overload (FO) is a prevalent risk factor for death in patients on hemodialysis (HD) and is underdiagnosed. Lung ultrasound (US) B-line score is a tool to quantify extravascular lung water and measure FO. B-lines are reverberation artifacts that correlate with lung congestion and disappear with ultrafiltration during HD. B-line score is superior to physical exam in detection of asymptomatic pulmonary congestion. B-line score correlates with cardiovascular outcomes, death, and readmissions for patients on HD. A prospective clinical trial is ongoing which uses a web-based tutorial to ensure interobserver agreement among attending physicians. Competency among nephrology fellows is not known.

Methods: To assess and improve the current state of knowledge and ability of nephrology fellows in obtaining and interpreting lung US we employed a mobile-optimized, app-supported curriculum for didactic learning as well as pre- and post-course surveys (using a 5-point Likert Scale) and knowledge assessments. Trainees had a hands-on, one-on-one teaching session with a peer-user to hone psychomotor skills in point-of-care lung US. Images were obtained using a commercially available curvilinear US probe and a tablet computer. A panel of expert trainers reviewed representative images remotely, provided feedback on image acquisition, and adjudicated B-line scores. Scores were compared using a paired two sample means t-Test with a one-tailed p value. Interclass correlation coefficients were calculated in Stata.

Results: Surveys demonstrated statistically significant increases in confidence in five domains critical to point-of-care US. Mean knowledge assessment score was 4% before the course and 92% after the course. Interclass correlation coefficients averaged 0.90 with no scores below 0.7 demonstrating excellent agreement in interpreting B-line scores which was confirmed on regression analysis. Bland-Altman plot showed good agreement and low bias. User images were well-reviewed by the expert trainers.

Conclusions: Point-of-care US to quantify lung water by B-line score can be taught to nephrology fellows quickly and reliably combining a web-based curriculum and hands-on training.

FR-OR006

Point of Care Echocardiography and Ultrasound-Guided Volume Assessment Training for Nephrologists and Trainees to Teach Point of Care ECHO Skills Nithin Karakala,[1,2] Gerren Hobby,[1] Kelly W. Bulloch,[1] Krishna siva sai Kakkera,[1] John T. Huggins.[1] *[1]Medicine, University of Arkansas for Medical Sciences, Little Rock, AR; [2]Medicine, Central Arkansas VA, Little Rock, AR.*

Background: Intravascular volume assessment is an extremely important in the care of patients with acute kidney injury (AKI), chronic kidney disease, and patients needing intermittent and continuous renal replacement therapy. The current volume assessment tools like, MAP, heart rate, clinical examination are unreliable in assessing intravascular (IV) volume. The accuracy of invasive methods like central venous pressure, and pulmonary artery pressure measurements in assessing responsive to volume have been questioned in recent years. Nephrologists play a pivotal role in volume assessment and management. Point of care (echocardiogram) ECHO is a very valuable non-invasive tool for volume assessment.

Methods: During an intense 8 hour workshop, participants were trained by an experienced intensivist and a trained nephrologist. There were 2 stations which utilized live standardized patients and a preceptor. Station 1 covered basics of ECHO, cardiac para-sternal short and long axis views, and measurement of Inferior VenaCava (IVC) diameter and variability; second 2 station was cardiac apical 4 and 5 chamber views and lung parenchymal exam. The preceptors initially demonstrated the techniques, and then the participants were allowed to practice under supervision. We conducted a 20 multiple choice question (5 basics of ECHO, 9 cardiac ECHO, and 6 IVC and lung parenchymal volume assessment) per and post-test. There were 5 five-scale questions assessing procedural confidence.

Results: Twenty two participants (5 nephrologists, 16 trainees) attended and completed the test. There was a significant improvement in mean percentage of correct answers for the post compared to pre-test 78% (SD:17) vs 46% (SD:11); $p<0.0001$. The improvement during post compared to pre-test was observed in all 3 categories: basics of ECHO (79%, SD:22 vs 53%, SD:21; $p<.001$), cardiac ECHO (77%: 19 vs 40%: 19; $p<0.0001$) and IVC and lung (77%: 12 vs 46: 28; $p<0.001$). After attending the workshop the participants answered that they were either confident or extremely confident in acquiring or interpreting basic images 62% (SD: 17) vas 4% (SD:8) pre workshop.

Conclusions: Point of care ECHO training can help nephrologists learn and improve bedside volume assessment skill and reignite passion for nephrology among residents.

Funding: Clinical Revenue Support

FR-OR007

Project Nephron: Teaching Medical Students Physiology and Histology Lena Vaynberg. *FAU Charles E Schmidt College of Medicine, Highland Beach, FL, FL.*

Background: The objective of PBL in the FAU COM curriculum is to foster self-directed learning, communication skills, and teamwork among the students as well as linking these skills to basic sciences and patient problems. Students have a difficult time with the physiology of the nephron with regard to channels, transporters, pumps and diuretics. Since 2014, at the start of the renal course, each of eight case inquiry groups received a poster of a nephron with the objective of understanding he functions of the cells in different portions of the nephron.

Methods: Each group of students received a poster of a nephron with the cells of different parts of the glomerulus and tubule drawn in. The pathways for anion and cation transfer were left blank. They were directed to search through the 8th edition of *Vander's Renal Physiology* and fill in the functions of the different cells. They did so and following the final session, they were given a nephron with the labeled pathways (Fig. 1)

Results: Following the end of the renal course, the students were surveyed as to whether or not the poster was useful to them in learning the physiology and histology of the nephron. Sixty three of the 65 students responded to the survey. The questions were phrased for a yes or no response as well as a degree of helpfulness that ranged from 1 (not helpful) to 5 (extremely helpful). There was also a section for comments. To the question "did the nephron help you learn the histology of the nephron"? The students gave it an average helpfulness of 4. To the question "did the nephron help you learn the physiology of the nephron"? The students gave it an average helpfulness of 3.5. To the question "did you continue to use nephron in subsequent cases"? The students gave it an average helpfulness of 4.1. As for the comments, the students found it a useful learning tool which they reviewed in subsequent IQ cases.

Conclusions: The students found the poster helpful in understanding renal (nephron) physiology and histology. Once the poster was complete, it was helpful in understanding the pathophysiologic and the pathologic anatomy of the nephron. Coming before the lectures and the IQ cases, it gave them a frame of reference for understanding the function of the nephron and the mechanisms of action of the diuretics.

FR-OR008

NephMadness: 5 Years' Experience Joel M. Topf,[5] Anna M. Burgner,[3] Timothy Yau,[4] Swapnil Hiremath,[2] Matthew A. Sparks.[1] *[1]Duke University and Durham VA Medical Centers, Durham, NC; [2]University of Ottawa, Ottawa, ON, Canada; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Washington University School of Medicine, Saint Louis, MO; [5]Medicine, Oakland University William Beaumont School of Medicine, Rochester, MI.*

Background: NephMadness (NM) is an educational game that takes place entirely on the internet through blog-based review articles, participatory interactive website, and Twitter-based discussion. NM leverages social media and Free Open Access Medical Education (FOAMed) to highlight advances and neglected issues in nephrology. NM began in 2013 and has completed 5 iterations. NM has evolved as the organizers have experimented with the medium. This review of the evolution of NM provides lessons to organizers of other online educational campaigns.

Methods: The NM curriculum takes the form of an online game that mimics the March Madness basketball tournament. The field consists of 32 nephrology concepts in 8 topics. The concepts and topics change every year. The field initially consisted of 64 concepts but this was reduced to 32 to encourage participation. Each concept is reviewed in a blog post providing the core educational content of the game. Independent content experts help select the concepts and fact check the blog posts. During the 3-week contest, additional commentaries are published from other experts. In 5 years NM has covered 256 nephrology concepts and posted 185 reviews and commentaries.

Results: Participants attempt to predict the winners of all 31 matchups. Initially the winners of each single elimination contest was scripted by the organizers. After significant push back by the users, winners were selected by participant voting. NM now uses a panel of experts to determine the winners. The NM team encourages training programs to participate using a flipped classroom model. In 2017, 32 training programs participated. NM encourages participation from all levels, ranging from lay people, to medical students, to attendings. Prizes are awarded for the most accurate predictions and for programs with the greatest participation. 1481 individuals from 55 countries, two thirds from the US, have played NM in the last 4 years.

Conclusions: NM is a unique forum to present medical education that takes nephrology education out of the classrooms and textbooks and transforms it into a gamified, interactive campaign that populates social media channels. The mixture of free, evidence-based, expert content with twitter and blogs is a novel method of delivering high quality continuing medical education that could serve as a template for future projects.

FR-OR009

GlomCon – International Web-Based Glomerular Disease Case Conferences: Connecting Peers to Enhance Clinical Experience Nikhil Agrawal,[14,15] Rhea Bhargava,[9] Roger A. Rodby,[11] Mihran V. Naljayan,[7] Kenar D. Jhaveri,[5] Stewart H. Lecker,[2] Johannes S. Schlondorff,[3] Meghan E. Sise,[8] Timothy Yau,[13] Isaac E. Stillman,[3] Franco H. Cabeza Rivera,[12] Jorge L. Castaneda,[9] Arley F. Diaz,[6] Michael J. Germain,[10] Francesco Iannuzzella,[9] Olufunmilola A. Olubukola,[1] Adam M. Segal,[9] Jonathan Slater,[9] Joseph Kupferman,[3] David J. Friedman,[9] John Danziger,[15] Jeffrey H. William,[3] Bradley M. Denker,[9] Martin R. Pollak,[4] Ali Poyan-Mehr.[9] *[1]BIDMC, CONCORD, NH; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [5]Hofstra Northwell School of Medicine- Northwell health system, Great neck, NY; [6]Kidney Care and Transplant Associates of New England, Springfield, MA; [7]LSUHSC School of Medicine, New Orleans, LA; [8]Massachusetts General Hospital, Boston, MA; [9]None, Boston, MA; [10]Renal and Transplant Assoc of New England, Hampden, MA; [11]Rush University Medical Center, Chicago, IL; [12]University of Mississippi Medical Center, Ridgeland, MS; [13]Washington University School of Medicine, Saint Louis, MO; [14]Nephrology, Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [15]Harvard Medical School, Boston, MA.*

Background: Gaining enough exposure to glomerular diseases is a challenge and may lead to uncertainties in the management of these patients. The aim of our Glomerular Disease Case Conferences (GlomCon) is to increase nephrologist's/nephropathologist's exposure to patients with glomerular disorders and to create a forum to discuss diagnosis and management of individual cases in detail with colleagues.

Methods: We have created a web-based, secure video platform at Glomcon.org where nephrologists/nephropathologists can connect worldwide and participate in live "peer-to-peer" clinical exchange. Participants submit challenging cases from their daily practice. Cases are reviewed by a volunteering nephropathologist/nephrologist and clinico-pathological correlation and therapeutic options discussed in bi-monthly live web sessions. All participants were surveyed in April 2017 for feedback.

Results: Since inception in July 2016, the conferences have seen a steady increase in worldwide participation. As of April 2017, GlomCon includes over 100 participants from 27 countries. A survey of 113 participants yielded the following results: 54% responded. Of these, 100% were "Very satisfied" or "Satisfied", 86% noted that participation impacted their care, for 31% knowledge about glomerular kidney disorders improved "extremely" and for 54% "very". 100% believe that the conferences improve the care of patients with glomerular kidney disease.

Conclusions: GlomCon is a new platform which enables nephrologists/ nephropathologists to share their experience and solicit peer-to-peer opinion and expertise. The majority of participants feel it has improved their clinical knowledge and with this impacted and improved patient care. Through this inclusive and open-access initiative, new opportunities for raising awareness and enhancing education in glomerular kidney disease has been created.

FR-OR010

The Use of a Medical Application Improves the Identification and Classification of AKI Rolando Claure-Del Granado,[2,4] Maria F. Iturricha caceres,[4] Etienne Macedo,[1] Ravindra L. Mehta.[3] *[1]UCSD, San Diego, CA; [2]Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [3]University of California San Diego Medical Center, San Diego, CA; [4]Hospital Obrero #2 - C.N.S., Cochabamba, Bolivia, Plurinational State of.*

Background: The use of mobile devices by health care professionals (HCPs) has transformed many aspects of clinical practice. Mobile devices and apps provide many benefits for HCPs, perhaps most significantly they increase the access to point-of-care tools, which has been shown to support better clinical decision-making and improved patient outcomes. In this study we tested the hypothesis that the use of an app specifically designed for recognition and management of AKI will help HCPs to better identify and classify AKI.

Methods: We included 20 AKI cases from our center that were part of the 0by25 Global Snapshot study report. Twenty clinical vignettes of these patients (including baseline serum creatinine (sCr) and a second sCr that was measure in a 7 day period) were presented to 50 last year medical students and ask two simple questions: 1) Did the patient develop AKI? and 2) To classify the stage of AKI; before and after providing them with an app that was developed for early identification, classification and management of AKI (IRA SLANH app, Island of the Moon® V.1, 2014; Cochabamba-Bolivia). We analyzed if the use of a medical app could improve correct identification and stage classification of AKI.

Results: Before the IRA SLANH app was introduce to the 50 medical students, the mean number of correct answers were 14.7±4.7 with a minimum of 3 correct answers and a maximum of 20 correct answers; and only in 6.7±4.4 of the cases the correct stage of AKI was identified. After the app was presented to the medical students the number of correct answers improved to 20 and in all cases AKI stage was correctly classified. Before the medical app was presented to the medical students, only 22% of them were able to correctly identify all AKI cases, and 0% of them could correctly classify all cases of AKI.

Conclusions: Medical applications are useful tools in the practice of evidence-based medicine at the point of care. The use of a medical application specifically developed for the identification and staging of AKI could play a very important role in early identification and correct classification of AKI potentially allowing earlier intervention with preventive and treatment strategies to reverse kidney injury and improve recovery.

FR-OR011

The Risk of Stroke with Atrial Fibrillation in CKD Patients Manish M. Sood,[4] Ngan Lam,[5] Megan K. Mccallum,[1] Amit X. Garg,[2] Amber O. Molnar.[3] *[1]Institute for Clinical Evaluative Sciences, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]McMaster University, Hamilton, ON, Canada; [4]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [5]University of Alberta, Edmonton, AB, Canada.*

Background: Both atrial fibrillation (AF) and chronic kidney disease (CKD) are known to increase the risk of ischemic and hemorrhagic stroke. However the relative contribution of albuminuria and eGFR level on stroke risk in patients with and without AF remains unknown.

Methods: From a total cohort of 736,666 patients from Ontario, Canada from 2002-2015, 35024 patients developed incident AF with an ACR and eGFR measure within 12 months prior. AF and stroke were determined by hospital diagnostic codes at admission. We used propensity-score matched Cox proportional and Fine and Grey sub-distribution hazards ratio models to determine the time to first event of ischemic, hemorrhagic or any stroke.

Results: After matching to examine exposure to incident AF, 35,024 matched pairs were identified. There were a total of 1781 (5.1%) strokes (85% ischemic) with an average time to stroke for patients with CKD + AF of 2.7 years (+/- 2.4) compared to 3.4 years (+/- 2.4) in patients with no AF. Among the entire cohort the presence of AF was associated with an increased risk of stroke with a HR of 2.93 (95%CI 2.67, 3.2). The crude rate of ischemic, hemorrhagic and any stroke were 16.24 (95%CI 15.43-17.08), 2.79 (95%CI 2.46-3.15) and 19.03 (95%CI 18.15-19.93) with AF and 4.38 (95%CI 4.01-4.78), 0.94 (95%CI 0.78-1.14) and 5.32 (95%CI 4.92-5.76) with no AF per 1000 person-years of follow up, respectively. Higher ACR and lower eGFR were associated with ischemic, hemorrhagic and any stroke compared to those with no AF, eGFR > 90 and ACR < 3 ($p<0.0001$ for all). The adjusted HR of stroke was higher across all categories of ACR and eGFR with the presence of AF compared to those without AF (ACR X stroke interaction $p <0.0001$, eGFR X stroke interaction $p <0.0001$).

Conclusions: CKD patients with atrial fibrillation are at a high risk of total, ischemic and hemorrhagic stroke and this risk is higher with lower eGFR and higher ACR.

FR-OR012

The Association of Beta-Blockers and All-Cause Mortality by eGFR in Patients with Heart Failure Amber O. Molnar,[2] Amit X. Garg,[1] Manish M. Sood.[3] *[1]London Health Sciences Centre, London, ON, Canada; [2]McMaster University, Hamilton, ON, Canada; [3]Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Congestive heart failure (CHF) and CKD are strongly interrelated and when occurring concurrently, are associated with very high mortality, especially in the elderly. Whether the mortality benefit of beta-blockers (BB) extends to patients with CHF and lower levels of eGFR remains unknown.

Methods: A population-level administrative database study using linked datasets in Ontario, Canada. Incident CHF cases age > 66 years from April 2002 to March 2014 were included. The date of the first prescription for a BB was the date of inclusion (index date). Patients without evidence of a BB prescription were randomly assigned an index date based on the distribution of index dates for those prescribed a BB. Individuals without an eGFR measure within 1 year prior to the index date, or a prior history of kidney or heart transplant or chronic dialysis were excluded. We matched BB users to non-users (1:1) based on age, sex, eGFR grouping, and a high dimensional propensity score. We examined all-cause mortality using Cox proportional hazards models with BB prescription at baseline and as a time-varying covariate.

Results: Results: After matching, a total of 3,574 pairs were identified. By eGFR category, the number of all-cause mortality events in the BB versus the no beta-blocker (NBB) groups were eGFR > 90: BB 44 (12.7%) vs. NBB 188 (38.6%), eGFR 60-90, BB 357 (14.0%) vs. NBB 1352 (22.2%), eGFR 30-60, BB 274 (19.0%) vs NBB 917 (47.7%), eGFR < 30 BB 47 (20.4%) vs. NBB 166 (53%). Examining baseline BB use, there was no mortality benefit with BB usage in lower eGFR categories [eGFR >90: HR 0.67 (0.48-0.94), eGFR 60-90: HR 0.96 (0.85-1.08), eGFR 30-60: HR 0.96 (0.88-1.05), eGFR <30: HR 0.87 (0.68-1.13), eGFR category X BB interaction p=0.225]. When examining time-varying BB use, it was associated with a similar reduction in all-cause mortality across all eGFR categories [eGFR 90: HR 0.56 (0.39-0.79), eGFR 60-90: HR 0.63 (0.55-0.73), eGFR 30-60: HR 0.59 (0.52-0.66), eGFR <30: HR 0.47 (0.33-0.66), eGFR category X beta-blocker interaction p=0.458].

Conclusions: In elderly patients with CHF, BB use was associated with a similar reduction in mortality across all eGFR categories. Our findings suggest that mortality benefits of BB's observed in CHF patients included in randomized trials could be extended to patients with eGFR < 30 not on dialysis.

FR-OR013

Assessing the Impact of CKD Progression on Cardiovascular Disease in a Contemporary UK Cohort of 30,222 Diabetics Claudia S. Cabrera. *AstraZeneca R&D, Mölndal, Sweden.*

Background: We evaluated the association between Chronic Kidney Disease (CKD) progression, based on glomerular filtration (eGFR) slope estimates and the risk of cardiovascular disease (CVD) in a contemporary cohort of persons with Type 2 diabetes mellitus (T2DM).

Methods: Incident CKD subjects were selected from a prevalent population of T2DM between Jan 1, 2005 and Dec 31, 2015. Subjects were retrieved from the Clinical Practice Research Data Link (CPRD) in England and followed from CKD diagnosis until event of heart failure (HF), myocardial infarction (MI), ischemic stroke (IS), a composite endpoint including all three event types (MACE plus), mortality, drop out from the database, or end of study. The association between CKD and CVD was estimated using adjusted proportional hazard models (HR 95% CI) in this cohort (n=30,222). The main variables of interest were the updated eGFR slope calculated over multiple overlapping 2 year periods throughout the follow-up time and the updated mean eGFR during these periods with ~ 5 over-lapping slopes/subject and a mean of 11 eGFR values per patient.

Results: The updated eGFR slope predicted CVD outcomes independently of current renal risk (updated mean eGFR) and key risk factors: CVD treatment, smoking, comorbidity, and metabolic risk factors. Both updated mean eGFR (ref ≥60, >30 to 60, ≤30) and the updated eGFR slope (ref ≥3, ≥0 to <3, ≥-3 to <0, ≤ -3) were monotonically associated with MACE plus and HF. Updated eGFR slope decline of ≤- 3 significantly increased the risk of MACE plus (HR 1.45; 95% CI 1.26 - 1.67), HF (HR 1.49; 95% CI 1.27 - 1.76), and MI (HR 1.39; 95% 1.01 - 1.91).

Conclusions: These results indicate that CKD is an independent risk factor for CVD and that rate of progression and cumulative status of CKD elucidate important but distinct aspects of this risk independently of underlying disease such as hypertension and obesity.

Continuation of Statin Therapy Initiated in Pre-ESRD Period and All-Cause and Cardiovascular Mortality after Transition to Dialysis Elvira Gosmanova,[3] Miklos Z. Molnar,[5] Praveen Kumar Potukuchi,[5] Elani Streja,[1] Keiichi Sumida,[2] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[5] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]Stratton VA Medical Center, Albany, NY; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of Tennessee Health Science Center, Memphis, TN.*

Background: *De novo* statin therapy in ESRD patients failed to demonstrate significant cardiovascular (CV) protection in randomized clinical trials and, therefore, it is not recommended. However, whether continuation of statins from late-stages of non-dialysis dependent CKD to the post-ESRD period is associated with improved all-cause and CV mortality in dialysis patients is unknown.

Methods: We identified 14,939 US veterans transitioning to dialysis between 2007-2011 who were receiving statins during the 1 year prior to dialysis initiation and had adequate adherence, defined as proportion of days covered (PDC) of ≥80%. Subsequently, dialysis patients were characterized as statin continuers (N=5,066) if statin therapy was continued with PDC ≥80% during up to 1 year following dialysis initiation, and statin discontinuers (N=9,874) if statins were stopped or adherence to statins was inadequate (PDC <80%). Associations of statin continuation with all-cause and CV mortality following dialysis initiation was examined using Cox regressions adjusted for demographics, comorbidities, medications, and laboratory parameters.

Results: All-cause and CV mortality rates were 285 [95% CI 279-291]/1000 patient-years and 116 [95% CI 112-121]/1000 patient-years, respectively, during a mean ± SD 2.01±1.38 years of follow-up. Statin continuation after ESRD onset was associated with lower all-cause and CV mortality in unadjusted and various adjusted analyses (figure).

Conclusions: Extension of statin therapy following dialysis transition was associated with reduced all-cause and CV mortality. This data support experts' opinion in the current lipid guidelines that statins started prior to dialysis should be continued after dialysis initiation.

Incident Atrial Fibrillation and Risk of Subsequent Cardiovascular Events and Mortality: The CRIC Study Nisha Bansal,[5] Dawei Xie,[11] Daohang Sha,[11] Lawrence J. Appel,[3] Rajat Deo,[11] Harold I. Feldman,[11] Jiang He,[7] Kenneth A. Jamerson,[10] John W. Kusek,[6] Steven R. Messe,[11] Sankar D. Navaneethan,[1] Mahboob Rahman,[2] Ana C. Ricardo,[9] Elsayed Z. Soliman,[14] Raymond R. Townsend,[11] Alan S. Go.[4] *[1]Baylor College of Medicine, Houston, TX; [2]Case Western Reserve University, Cleveland, OH; [3]Johns Hopkins Medical Institutions, Baltimore, MD; [4]Kaiser Permanente Northern California, Oakland, CA; [5]Kidney Research Institute, Seattle, WA; [6]NIDDK, Bethesda, MD; [7]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [9]University of Illinois at Chicago, Chicago, IL; [10]University of Michigan Health System, Ann Arbor, MI; [11]University of Pennsylvania, Philadelphia, PA; [14]Wake Forest University School of Medicine, Winston Salem, NC.*

Background: Atrial fibrillation (AF) is the most common sustained arrhythmia in patients with chronic kidney disease (CKD) and may be associated with poor clinical outcomes. We examined the association of incident AF with the risk of subsequent incident cardiovascular (CVD) events and mortality.

Methods: We studied participants enrolled in the prospective Chronic Renal Insufficiency Cohort (CRIC) Study without AF at baseline. Incident AF was identified by ECGs and physician-adjudicated hospitalizations. Outcomes included: incident heart failure (HF), myocardial infarction (MI), stroke and death after diagnosis of AF. Cox regression models (with time-updated AF) and marginal structural models (MSM, to account for time-dependent confounding) were used to examine the association of incident AF with outcomes, adjusting for demographics, clinical characteristics and ECG measures.

Results: Among 2,814 participants, 288 (9.2%) developed incident AF. During a mean (SD) follow-up of 7.0 (2.1) years, rates of HF, MI, stroke and death were higher in those who developed AF versus those who did not (**Table**). Cox and MSM models demonstrated that incident AF was associated with greater than 4-fold increased risk of subsequent incident HF, MI and death. Cox models also showed a significant association of incident AF with stroke (**Table**). These associations remained robust with additional adjustment for biomarkers of inflammation, cardiac stress and mineral metabolism as well as left ventricular mass, ejection fraction and left atrial diameter.

Conclusions: Incident AF is associated with increased risk of developing subsequent CVD and death in adults with CKD. Further study is needed to determine whether treatment of AF mitigates this risk.

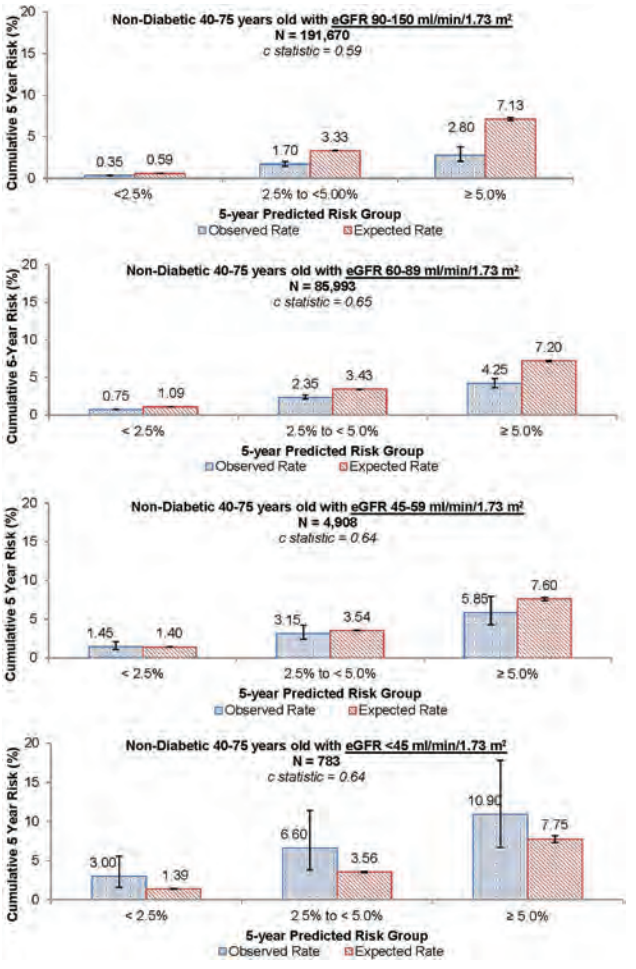
Accuracy of ACC/AHA ASCVD Risk Estimator by eGFR in a Large, Multiethnic Non-Diabetic Population Alan S. Go, Grace H. Tabada, Tracy Y. Jonelis, Sue hee Sung, Jamal S. Rana. *Kaiser Permanente Northern California, Oakland, CA.*

Background: Earlier atherosclerotic cardiovascular disease (ASCVD) prediction equations have limited utility in adults with kidney disease. The ACC/AHA ASCVD Risk Estimator has been recommended to assist with primary prevention planning, but its accuracy varies in contemporary populations and little is known about its performance by level of kidney function. We evaluated its accuracy and discrimination in a large community-based population across the range of eGFR.

Methods: Within Kaiser Permanente Northern California, we identified members age 40-75 years in 2008 who had LDL-C 70-189 mg/dL, no prior ASCVD or lipid-lowering therapy, no diabetes, available eGFR, and full 5-year follow-up. Non-fatal and fatal ASCVD events through 2013 were ascertained from electronic health records using validated algorithms. We compared observed vs. ACC/AHA Risk Estimator-based 5-year risk of ASCVD events by baseline eGFR (90-150, 60-89, 45-59 and <45 ml/min/1.73m^2) with associated c statistics.

Results: In 283,354 non-diabetic adults, mean age was 55 years, 61% women and 32% minorities. Overall, the distribution of 5-year predicted ASCVD risk was <2.5% (55%), 2.5% to <5.0% (21%) and ≧5.0% (24%), with higher proportions of patients at high predicted ASCVD risk with lower eGFR. Going from eGFR 90-150 to 45-59, there was progressively less overestimation of actual 5-year ASCVD risk using the ACC/AHA ASVD Risk Estimator, with underestimation of risk for eGFR <45 (Figure). Discrimination was only modest across eGFR levels (c=0.59-0.65).

Conclusions: Accuracy of the ACC/AHA ASCVD Risk Estimator varies by eGFR level, and recalibration in contemporary, ethnically diverse populations would increase its utility to assist with primary prevention strategy decision-making.



Utility of ACC/AHA ASCVD Risk Estimator by Category of eGFR

FR-OR017

Incident Atrial Fibrillation and the Risk of Subsequent Adverse Outcomes in Patients with a Decreased eGFR David Massicotte-Azarniouch,[7] John Paul Kuwornu,[1] Juan J. Carrero,[2] Ngan Lam,[8] Amber O. Molnar,[4] Deborah Lynn Zimmerman,[5] Megan K. Mccallum,[1] Ron Wald,[6] Amit X. Garg,[3] Manish M. Sood.[5] *[1]Institute for Clinical Evaluative Sciences, London, ON, Canada; [2]Karolinska Institutet, Stockholm, Sweden; [3]London Health Sciences Centre, London, ON, Canada; [4]McMaster University, Hamilton, ON, Canada; [5]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [6]St. Michael's Hospital, Toronto, ON, Canada; [7]Medicine, University of Ottawa, Ottawa, ON, Canada; [8]University of Alberta, Edmonton, AB, Canada.*

Background: The effect of atrial fibrillation (AF) among patients with decreases in eGFR and its subsequent effect on adverse outcomes remain unknown.

Methods: In this population-based retrospective cohort study, we determined the association of AF with congestive heart failure (CHF), myocardial infarction (MI), end stage kidney disease (ESKD) and all-cause mortality in patients with reduced renal function. Among 1,422,978 million adult residents with an eGFR measure < 90 ml/min/1.73m², we identified 93,414 with AF. We used propensity-score matched, competing risk models to determine the risk of CHF, MI and ESKD accounting for the competing risk of mortality. The eGFR level was examined using interaction terms for each adverse outcome.

Results: All adverse events were more frequent in individuals with atrial fibrillation compared to no atrial fibrillation [CHF: AF 9.9% vs. No AF 3.1%, HR 3.88 (95% confidence interval, CI 3.69-4.07)], [ESKD: AF 0.7% vs. No AF 0.4%, HR 2.10 (95%CI 1.89-2.32)], [MI: AF 3.2% vs. No AF 2.0%, HR 1.60(95% CI 1.54-1.67)], [all-cause mortality: AF 21.7% vs. No AF 17.6%, HR 1.32 (95%CI 1.29-1.35)]. The eGFR level was an effect modifier for all outcomes (p<0.05 for eGFR X outcome interaction). The risk of CHF, MI and ESKD were highest within the first 6 months of AF onset.

Conclusions: Incident AF is associated with a high risk of adverse outcomes in patients with an eGFR < 90ml/min/1.73m² and the risk differs by eGFR level. As the risk is highest within the first 6 months after AF diagnosis, therapeutic interventions and monitoring may improve outcomes.

FR-OR018

Are RAASi Underused in Moderate to Advanced CKD? Early Findings from CKDopps Roberto Pecoits-Filho,[1] Charlotte Tu,[2] Jarcy Zee,[2] Lindsay Zepel,[2] Brian Bieber,[2] Michelle M. Wong,[2] Friedrich K. Port,[2] Christian Combe,[3,4] Danilo Fliser,[5] Ricardo Sesso,[6] Ichiei Narita,[7] Bruce M. Robinson,[2] Ziad Massy.[8] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]CHU de Bordeaux, Bordeaux, France; [4]Université de Bordeaux, Bordeaux, France; [5]Saarland University Medical Centre, Homburg/Saar, Germany; [6]Escola Paulista De Medicina, Unifesp, Sao Paulo, Brazil; [7]Niigata University, Niigata, Japan; [8]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France. Group/Team: On behalf of CKDopps and CKD REIN investigators.*

Background: Current guidelines support prescription of RAASi for CKD patients (pts) with comorbidities such as diabetes and heart failure (HF). These drugs may be underused, particularly due to hyperkalemia as a side effect of RAASi. We hypothesize that the use of RAASi in advanced CKD is influenced by the presence of hyperkalemia and the use of potassium (K) binders, diuretics, and bicarbonate.

Methods: We used data from CKDopps (2013-2017), a multinational cohort study of pts with eGFR <60 ml/min/1.73m² to describe RAASi prescription patterns by country and patient subgroups. Brazil (BR), Germany (GER), and the US are shown; data from France and Japan are forthcoming.

Results: Among 2,817 pts, ranges by country were: mean age 66-74 years; eGFR <30 69%-74%; HF 17%-19%; diabetes 41-58%; serum potassium ≥5 21-35%; albuminuria 50-69%. RAASi prescription was more common in GER (80%) than BR (66%) and US (54%); less common in CKD stage 5 in all countries; less common with higher serum K in US; and lower with albuminuria in GER and US (Table 1). RAASi use was higher among pts with (vs. without) CHF/diabetes in BR, but only for diabetes in US. Among pts prescribed RAASi, prescriptions of loop or thiazide diuretics were 68-74%; resins were 6% in GER, almost absent in BR and US; and bicarbonate was 6-8%.

Conclusions: RAASi prescription patterns in CKD vary by country, demographic, and clinical characteristics. RAASi may be underused**,** especially in the US where only half were prescribed a RAASi even among pts with strong class-specific recommendations including albuminuria, diabetes, or heart failure. Antihyperkalemia measures, such as dietary restriction, loop diuretics, bicarbonate and K binders may raise RAASi use.

Electronic Health Records-Based Computable Phenotype for CKD Diagnosis and Staging Ning Shang,[1] Paul E. Drawz,[2] Robert J. Carroll,[3] Adelaide M. Arruda-Olson,[4] Sumit Mohan,[5] Iuliana Ionita-Laza,[6] Ali G. Gharavi,[5] Chunhua Weng,[1] George Hripcsak,[1] Krzysztof Kiryluk.[5]
[1]Department of Biomedical Informatics, Columbia University, New York, NY; [2]Department of Medicine, University of Minnesota, Minneapolis, MN; [3]Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN; [4]Department of Cardiovascular Diseases, Mayo Clinic, Rochester, MN; [5]Department of Medicine, Columbia University, New York, NY; [6]Department of Biostatistics, Columbia University, New York, NY.

Background: Chronic Kidney Disease (CKD) diagnosis can be made by blood, urine, or imaging tests. This study is to design and evaluate a portable electronic phenotype for automated detection and staging of CKD based on electronic health records (EHR).

Methods: With urine tests data of 68,617 patients from three major health care systems (Columbia, Minnesota, and Vanderbilt), we used machine learning to design a universal albuminuria (A-stage) classifier that accommodates five common methods for quantification of urinary protein excretion, including two urine dipstick scales in combination with urine specific gravity. The performance of the classifier for each type of urine test was assessed by a 10-fold cross-validation procedure against matched UACR data. By integrating our A-stage classification with kidney-related diagnostic codes and serum Cr-based eGFR, a rule-based method, each individual is automatically assigned as CKD case or control. Each CKD case is additionally placed on a "staging grid" of albuminuria (A-stage) by eGFR (G-stage).

Results: The CKD algorithm has been designed, implemented and tested at Columbia University, achieving 100% and 83% PPVs for cases and controls respectively by manual chart review. We then performed external validation at Vanderbilt University and Mayo Clinic; where our electronic phenotype had PPVs of 85% and 98% for cases and controls, respectively. Based on expert review of 265 charts across all three sites, the PPVs to diagnose CKD Stage 1, 2, 3a, 3b, 4, and 5 were 75%, 98%, 95%, 93%, 89%, and 79%, respectively.

Conclusions: Using machine learning and rule-based methods, we developed and validated a portable CKD diagnosis and staging algorithm in a large multi-center effort. The electronic phenotype follows the latest guidelines and can be applied to both pediatric and adult patients. This algorithm can be implemented within any EHR to enable real-time automated detection and staging of CKD, enabling the implementation of stage-specific clinical decision support tools.

FR-OR020

Comparison of Estimated versus Measured GFR Decline in the Association with ESRD and Mortality Marieke van Rijn,[4] Karen Leffondre,[7] Marie Metzger,[2] Martin Flamant,[1] Jean-philippe Haymann,[6] Benedicte Stengel,[3] Jan A. van den Brand.[5] *[1]APHP, Paris, France; [2]CESP U1018, INSERM, Villejuif, France; [3]Inserm – DRPA11, Le Kremlin-Bicêtre Cedex, France; [4]Radboud Univ Medical Centre, The Netherlands; Inserm U1018, France, Nijmegen, Netherlands; [5]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [6]UPMC, INSERM UMRS 702, AH-HP, Paris, France; [7]University of Bordeaux, Bordeaux, France. Group/Team: On behalf of NephroTest study group.*

Background: There is growing interest for GFR decline as an alternative endpoint for end-stage renal disease (ESRD), but whether using estimated GFR (eGFR) instead of measured GFR (mGFR) is appropriate has not been evaluated. We compared the association of eGFR and mGFR decline with risk for ESRD and mortality in patients with CKD.

Methods: We included 1734 adult patients with CKD stage 1 to 4 who had a total of 4790 simultaneous eGFR and mGFR measurements, over a median 3.3-year follow-up (IQR: 2.0-5.4). mGFR was measured with 51Cr-EDTA renal clearance and CKD-EPI eGFR was based on IDMS-traceable creatinine. We used shared parameter joint models to estimate the association between current value and slope of eGFR or mGFR and ESRD or death, adjusted for baseline age, gender, and albumin to creatinine ratio (ACR).

Results: Patients (mean age 59±15 yrs, 31% women) had a median of 2.0 (IQR 1.0-4.0) visits, a mean mGFR of 43.5 mL/min/1.73m², and a median ACR of 8.0 mg/mmol (IQR: 1.5-46.2). eGFR and mGFR decline was comparable, 1.87 (2.02-1.73) *versus* 1.88 (2.04-1.73) mL/min/1.73m2/year, respectively. HRs for death were similar for both current value and slope of mGFR or eGFR. In contrast, HRs for ESRD were lower when using current value and slope of mGFR than eGFR.

Conclusions: This study shows that the association of GFR slope with mortality is similar whether using eGFR or mGFR, but not that with ESRD. The hazard ratio of ESRD is lower with mGFR than eGFR. Therefore, mGFR decline may be considered as an alternative endpoint for ESRD rather than eGFR in clinical trials.

	HR for death (95% CI)		HR for ESRD (95%CI)	
	mGFR	CKD-EPI eGFR	mGFR	CKD-EPI eGFR
Current GFR (ml/min/1.73m2)	0,98 (0,97 – 0,99)	0,98 (0,97 – 0,99)	0,84 (0,81- 0,87)	0,86 (0,83 – 0,88)
Current GFR slope (ml/min/1.73m2 per year)	0,89 (0,78 – 1,02)	0,89 (0,79 – 0,99)	0,80 (0,66 – 0,97)	0,85 (0,73 – 0,99)

Plasma Zonulin Levels in Childhood Nephrotic Syndrome (NS) Howard Trachtman,[3] Debbie S. Gipson,[7] Kevin V. Lemley,[1] Jonathan P. Troost,[7] Christian Faul,[6] Debra J. Morrison,[4] Suzanne M. Vento,[2] Judith D. Goldberg,[5] Dong-hyun Ahn.[5] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]NYU Langone Medical Center, New York, NY; [3]NYU Langone Med Ctr, New York City, NY; [4]NYU Medical Center, New York, NY; [5]New York University School of Medicine, New York, NY; [6]The University of Alabama at Birmingham, Birmingham, AL; [7]University of Michigan, Ann Arbor, MI.*

Background: Case reports suggest that NS is responsive to dietary modifications including a gluten-free diet (GFD). In celiac disease, zonulin is released from enterocytes after exposure to gliadin, activates protease activated receptor 2 (PAR2), and perturbs the actin cytoskeleton and cell-cell junctions in the gut. PAR2 is present on podocytes and, therefore, zonulin may increase glomerular permeability in NS. We conducted this study to test the hypothesis that plasma zonulin levels are elevated in pediatric patients with NS.

Methods: Plasma specimens collected from patients ≤18 yr old with minimal change disease or FSGS enrolled in the NEPTUNE study, were tested. Clinical and laboratory data were retrieved coincident with the visit when the zonulin level was measured. Samples were available for testing from the 4 or 8 month visit. Plasma zonulin levels were measured by ELISA. Results (mean±SD or median (IQR)) were analyzed by t-test, Wilcoxon, Kruskal-Wallis, or linear regression and considered significant if $P<0.05$

Results: There were 113 patients, 9.5±4.9 yr, 53% male, 42% white, 40% black and 18% other. Disease classification was infrequent relapser in 27%, frequent relapser/steroid dependent 42% and steroid resistant 30%. The mean BP, eGFR, and serum albumin were normal. Urine protein:creatinine (UPC) ratio was 3.9±6.9 (g:g). The plasma zonulin level in NS children was 14.2±6.0 vs 10±2.5 ng/ml in healthy adults ($P<0.01$) and was >3 standard deviations above the mean in 27%. There was a trend toward lower zonulin levels in children with UPC ≥2 vs <2, 12.9(7.4) vs 16.7(8.0) ($P=0.051$). Plasma zonulin levels did not differ by eGFR, disease classification, or BP. Plasma zonulin and serum albumin concentrations were directly correlated, $r=0.24$, $P=0.04$.

Conclusions: The plasma zonulin level was significantly elevated in more than a quarter of children with NS and was unrelated to BP or eGFR. We observed a significant relationship between zonulin values and serum albumin but not proteinuria. There was a trend to lower zonulin levels in children with nephrotic-range proteinuria. Further study is needed to determine the relationship between plasma zonulin levels and proteinuria and to test whether the plasma zonulin level can be used to predict response to a GFD in children with NS.

Rhinovirus-Induced Defect of CTLA-4 Expression Plays a Critical Role in Relapse of Childhood Idiopathic Nephrotic Syndrome Ching-Yuang Lin.
China Medical University Children's Hospital, Taichung, Taiwan.

Background: The onset of minimal change disease (MCD) in idiopathic nephrotic syndrome(INS) is often preceded by an upper respiratory tract infection(URI) such as human rhinoviruses (HRVs). Transient spontaneous remission of nephrotic syndrome after intercurrent measles infection has also been reported. Upregulation of CD80 with an altered podocyte shape has been reported to result in proteinuria. CTLA-4 is the natural inhibitor of CD80, and the suppressive function of Tregs is dependent on CTLA-4. The aim of this study was to investigate whether an increase in systemic $CD4^+$ $CD80^+/CD4^+$ $CTLA\text{-}4^+$, Th17/Treg ratio and podocyte CD80/CTLA-4 ratio after HRV infection would result in a higher urinary CD80/CTLA-4 ratio and proteinuria.

Methods: Of the 123 URI were proven to be caused by HRV, Thirty-two patients with relapsing INS and biopsy-proven MCD were enrolled. Peripheral blood mononuclear cells (PBMCs) from the INS patients and six age-matched normal controls were exposed to either one infectious unit/cell of HRV or measles virus for 48 h. The surface expressions of CD80, CTLA-4, IL-17 and FoxP3 in the PBMCs and cultured podocytes were evaluated by flow cytometry.

Results: Systemic $CD4^+$ $CD80^+/CD4^+$ $CTLA\text{-}4^+$ T cell and Th17/Treg ratios significantly increased during the nephrotic phase and returned to normal during remission. The urinary CD80/CTLA-4 ratio increased significantly during relapse and decreased in remission. Histologically, strongly positive staining of CD80 and weak staining of CTLA-4 were found in all renal biopsy specimens of the patients with MCD. In vitro HRV infection on PBMCs of relapsing INS patients induced a significantly higher CD80/CTLA-4 expression than in the controls. In contrast, in vitro measles infection caused an slightly increase in CD80 and a 6-fold increase in CTLA-4 on $CD4^+$ T cells and significantly down-regulated the $CD4^+$ $CD80^+/CD4^+$ $CTLA\text{-}4^+$ T cell ratio in the PBMCs of the normal controls. It was also upregulated CD80 and down regulated CTLA-4 in cultured podocyte treated with HRV.

Conclusions: Systemically high levels of the $CD4^+$ $CD80/CD4^+$ CTLA-4 ratio in PBMCs induced by HRV infection in patients with MCD may result in an enhanced Th17/Treg ratio, thereby leading to altered endogenous podocyte autoregulation of the CD80/CTLA-4 ratio and the development of proteinuria.

Tissue Transcriptomic Profiles Perform Similarly to Clinical and Pathology Features for Nephrotic Syndrome Outcome Prediction Laura H. Mariani, Huateng Huang, Brad A. Godfrey, Matthias Kretzler, Yuanfang Guan. *University of Michigan, Ann Arbor, MI.*

Background: Clinical parameters do not accurately predict outcomes in nephrotic syndrome (NS). Traditional statistics are not well equipped to identify predictors from many potential parameters across the genotype-phenotype continuum. Machine learning techniques have been developed to address this, but have not been widely applied to NS.

Methods: NEPTUNE is a cohort study of NS patients enrolled at the time of biopsy. Clinical data, pathologic features and kidney tissue genome wide mRNA expression levels are collected. Elastic net regularization was used to build Cox proportional hazards models for time to (1)composite of ESRD/40% eGFR decline and (2)complete remission (UPCR <0.3mg/mg) using different sets of predictors: clinical+pathology data, gene expression modules, all variables. In 200 bootstrap replicates, models were built in training sets and time-dependent area under the curve (tAUC) was computed in test sets. Paired t-test of mean tAUCs across replicates was used to compare prediction accuracy between models.

Results: 432 patients were in clinical/pathology models [mean age 33(21), eGFR 83(36), UPCR 3.7(5.5), 41% male, 27% black, 18% MN, 31% MCD, 13% IgA, 38% FSGS]. 198 patients in gene expression models had similar characteristics. Elastic net models had higher tAUC than simple cox models(Table). Signifcant predictors are shown(Fig).

Conclusions: Machine learning elastic net models had highest accuracy and identified novel predictors. Tissue mRNA expression modules were more accurate predictors of composite outcome than routine clinical parameters and may better capture the underlying biologic heterogeneity of NS.

Funding: NIDDK Support, Other NIH Support - NCATS, CTSA-KL2

Model Comparison of Prediction Accuracy

Cohort	Model (p-value comparison is default model)	tAUC Composite	tAUC Complete Remission
Clinical Cohort	Simple Cox Model (Default: demographics, eGFR, UPCR)	0.68	0.71
	Elastic Net Clinical and Pathology	0.76 (p=0.02)	0.73 (p<0.01)

Response to Second-Line Immunosuppressive Treatments in Genetically Stratified Steroid-Resistant Nephrotic Syndrome Ethan S. Sen,[1,2] Agnieszka Bierzynska,[1] Gavin I. Welsh,[1] Moin Saleem.[1,2] *[1]University of Bristol, Bristol, United Kingdom; [2]Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is a heterogeneous condition with significant numbers of patients progressing to end-stage renal failure. Response to second-line immunosuppression is variable. This study aimed to evaluate effectiveness of second-line treatment according to genetic aetiology and pattern of steroid resistance.

Methods: Paediatric patients with SRNS were recruited into the United Kingdom Renal Registry. We have previously reported whole exome sequencing of these patients (Bierzynska et al. *KI* 2017;91:937-947). The current study included subjects from this group with available data on response to immunosuppression. Complete response (CR) was defined as urine protein:creatinine ratio (PCR) < 20mg/mmol or negative/trace dipstick proteinuria within 6 months of starting therapy. Partial response (PR) was PCR > 20mg/mmol or dipstick ≥ 1+ but plasma albumin > 25g/L.

Results: Of 177 genetically-sequenced patients, 140 (72 male, median age at onset 4.4 years, 80 FSGS on first biopsy) received 298 second-line medications. These included ciclosporin in 64%, tacrolimus 51%, cyclophosphamide 33%, mycophenolate mofetil 29% and rituximab 27%. In 21 monogenic patients (33 treatments), overall CR was 9.1% and PR was 36.4% compared with 31.4% and 25.2% respectively in 119 non-genetic patients (242 treatments). Within the non-genetic group, among 92 patients with presumed or primary steroid resistance (SR) (178 treatments), overall CR was 27.0% and PR was 26.4% compared with 43.3% and 21.7% respectively in 25 patients with secondary SR (60 treatments). Fifteen patients suffered post-transplant disease recurrence among whom pre-transplant CR and PR were both 5.9% (34 treatments). When considering only first immunosuppressive treatments in non-genetic patients, there was CR to ciclosporin in 36.5% (19/52), to tacrolimus in 33.3% (9/27) and to cyclophosphamide in 11.5% (3/26).

Conclusions: CR occurred most frequently in patients with secondary SR, followed by non-genetic primary SR and then patients with genetic disease. Subjects retrospectively identified as having circulating factor disease based on post-transplant recurrence had a particularly poor response to immunosuppression.

The Effectiveness of a Short-Term Steroid Regimen for Adult Steroid Sensitive Nephrotic Syndrome Takaya Ozeki, Takayuki Katsuno, Sawako Kato, Yoshinari Yasuda, Tomoki Kosugi, Naotake Tsuboi, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: In pediatric patients with steroid sensitive nephrotic syndrome, recent trials have revealed that 2 months short-term steroid regimen (STSR) is not inferior to the extending steroid course. However, the optimal duration of the initial steroid therapy for adult patients remains unclear.

Methods: Adult MCD or FSGS cases (n=35) who had started STSR from Jan. 2015 through Jun. 2016 were included in this study. Control MCD patients (n=140) who were treated with conventional regimen were also enrolled from our retrospective cohort. All patients fulfilled the criteria below: biopsy proven MCD or FSGS, over 20 years old, first time episode of nephrotic syndrome, and complete remission achieved within 4 weeks. The detail of STSR was as below; (1) prednisolone started 0.8-1.0 mg/kg/day as initial dose and continued for 4-6 weeks. (2) reduced to 0.5-0.6 mg/kg/alternative day and continued for 4 weeks. STSR cases were compared with the control patients who were treated with conventional regimen.

Results: Throughout the observation period (median, 469 days), 23 (65.7%) of 35 STSR patients developed at least one relapse. In survival analysis, STSR associated with earlier first relapse (p<0.001, logrank test) but not with frequent relapse (p=0.21, logrank test). Among STSR group, none had symptom of adrenal insufficiency. The cumulative steroid doses during observational period were significantly smaller in patients with STSR than those with conventional regimen (Figure).

Conclusions: Although the timing of the first relapse in STSR group was earlier compared with conventional group, there was no difference in the occurrence of frequent relapse. Furthermore, STSR achieved lower steroid exposure. The present study suggest that STSR could be an effective treatment option for adult steroid sensitive MCD or FSGS.

Long-Term Effect of Sparsentan (SPAR), a Dual Angiotensin and Endothelin Receptor Antagonist, on Proteinuria in Patients with Primary FSGS: Interim Analysis of the DUET Trial Howard Trachtman,[3] Ivan Rychlik,[1] Robert M. Haws,[2] Carla M. Nester,[5] Alessia Fornoni,[6] Radko Komers.[4] *[1]Charles University, 3rd Faculty of Medicine, Prague 10, Czech Republic; [2]Marshfield Clinic, Marshfield, WI; [3]NYU Langone Med Ctr, New York City, NY; [4]Retrophin, Inc., Portland, OR; [5]University of Iowa, Iowa City, IA; [6]University of Miami, Miami, FL.*

Background: In the ongoing DUET trial, SPAR (200, 400, 800 mg/day) resulted in greater reduction in proteinuria vs. irbesartan (IRB, 300 mg/day) over the 8-week double-blind (DB) period. Generally, SPAR was safe and well tolerated. After DB, patients

were treated in an open-label extension (OLE). We present interim results of OLE for sustainability of the antiproteinuric effect of SPAR.

Methods: In the OLE, patients [biopsy-proven FSGS, baseline (BL) urine protein/creatinine ratios (Up/C)>1g/g, age 8-75 y (U.S.), eGFR>30 ml/min] randomized to SPAR continued (SPAR:SPAR), and those randomized to IRB received SPAR (IRB:SPAR). Up/C, eGFR and blood pressure (BP) were measured every 12 weeks to Week 48 and compared to BL (Week 0 for SPAR:SPAR; Week 8 for IRB:SPAR).

Results: Results of patients with available Up/C are below. In SPAR:SPAR, SPAR resulted in rapid reduction of Up/C and BP which remained sustained over 48 weeks, while eGFR remained stable. In IRB:SPAR group, transition to SPAR resulted in a significant reduction in Up/C (Week 16), which was sustained until the end of follow-up. In contrast to SPAR:SPAR, IRB:SPAR was associated with mild, temporary, but significant reduction in eGFR, while SPAR-induced BP reduction was less apparent.

Conclusions: SPAR was well tolerated and achieved a sustained antiproteinuric effect in primary FSGS with early BP reduction and stable eGFR over 48 weeks. Transition to SPAR from IRB led to significant, sustained reduction of proteinuria and a temporary, mild reduction in eGFR without long-term impact on BP.

Diagnosing Recurrent FSGS Using a Novel Cell-Based Assay Pankaj Srivastava,[1] Ehtesham Arif,[2] Ashish K. Solanki,[2] Kenneth Kwon,[2] Michael G. Janech,[2] Deepak Nihalani.[2] *[1]MEDICAL UNIVERSITY OF SOUTH CAROLINA, CHARLESTON, SC; [2]Medical University of South Carolina, Charleston, SC.*

Background: Here we report a novel human podocyte cell-based assay that will serve as a non-invasive diagnostic clinical tool to detect rFSGS (recurrent focal and segmental glomerulosclerosis), which provides rapid and accurate identification of rFSGS patients. The concepts and approaches demonstrated in this proposal are widely applicable in designing assays for other forms of FSGS (or ESRD) whose diagnosis and treatment options remains inadequate. This assay is aimed at specifically diagnosing rFSGS to avert the ineffective renal transplant in FSGS patients.

Methods: As a first step, we identified rFSGS responsive genes by mRNA profiling of human podocytes treated with plasma derived from human rFSGS and control patients, which also induced significant alterations to podocyte actin cytoskeleton partially mimicking the disease processes. Two unique candidate genes (**proprietary information**) based on profiling data from control, non-FSGS and rFSGS patients were selected. In second step, the promoter regions for these genes were cloned into a promoterless reporter vector and transduced into podocytes to generate two stable podocyte cell lines, where expression of reporter was under the control of these promoters. This assay allowed us to measure plasma-induced increase in luminescence in these cells.

Results: Remarkably, both cell lines showed similar results, where only rFSGS patient plasma showed ~2-fold induction, whereas no induction was observed with plasma from other nephropathies including minimal change disease (MCD), membranous glomerulonephritis (MGN) and FSGS (Fig1).

Conclusions: Multiple centers within the country including CureGN and NEPTUNE have been solicited to analyze many rFSGS and non-rFSGS patient plasma using this assay and studies are being planned for conducting clinical trials to utilize its full diagnostic potential.

IgM Bound to the Surface of T Cells: A Novel Prognostic Marker of Steroid Dependence in Idiopathic Nephrotic Syndrome Manuela Colucci, Francesco Emma, Marina Vivarelli. *Bambino Gesù Children's Hospital - IRCCS, Rome, Italy.*

Background: The pathogenesis of non-genetic forms of idiopathic nephrotic syndrome (INS) is unknown, but the therapeutic success of rituximab suggests a role of B cells and possibly immunoglobulins. During the characterization of the T and B cell phenotype of INS patients pre-rituximab, we observed an unexpected presence of IgM on the surface of T lymphocytes of some patients. Therefore, we investigated the role of IgM on the T cell surface of patients with INS.

Methods: We evaluated by FACS analysis the presence of IgM on the surface of T lymphocytes (T-cell IgM intensity) in 103 healthy donors (HD, 78 adults and 25 children) and 113 INS pediatric patients at onset (44 patients) or subdivided between steroid-sensitive (SSNS, 28) and steroid-dependent (SDNS, 41) patients, in relapse or in remission. We compared T-cell IgM intensity with other predictive parameters of response to steroid treatment and explored *in vitro* the mechanism responsible for this unexpected finding and its potential pathogenic role.

Results: At disease onset (before treatment) 34% patients showed an intense presence of IgM on the surface of T cells as compared to HD, and individuals with higher T-cell IgM intensity showed a significantly increased risk of relapse by Log Rank test ($p<0.03$). Furthermore, T-cell IgM intensity discriminated between SDNS and SSNS patients by ROC analysis (AUC, 0.85; $p<0.001$). *In vitro*, serum IgM from INS patients bound healthy T cells more than serum IgM from HD ($p<0.001$) and showed a reduced sialylation of their N-linked glycan residues, more evident in the steroid-dependent group. Commercially available desialylated IgM bind to T cell surface and fail to be internalized, causing elevated T-cell IgM intensity. Interestingly, whereas commercially available sialylated IgM inhibit the induction of T-cell activation and proliferation, desialylated IgM fail to exert this immunomodulatory effect, reduce the T-cell response to steroid inhibition and allow production of T-cell-derived podocyte damaging factors.

Conclusions: The presence of IgM on T cells may be a prognostic marker of steroid dependence in INS at disease onset. Desialylated IgM in some INS patients may bind to T cell surface and contribute to T cell dysregulation, possibly playing a role in INS pathogenesis.

Development and Validation of an EHR-Based Computable Phenotype to Rapidly Identify Glomerular Disease in Large Populations Michelle Denburg,[2] Charles Bailey,[2] Hanieh Razzaghi,[2] Danielle Soranno,[3] Ari Pollack,[4] Donna J. Claes,[5] Vikas R. Dharnidharka,[6] William E. Smoyer,[7] Michael J. Somers,[8] Joshua Zaritsky,[9] Joseph T. Flynn,[4] Mark Mitsnefes,[5] Maryjane Benton,[2] Laura H. Mariani,[10] Christopher B. Forrest,[2] Susan L. Furth.[2] *[2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Children's Hospital Colorado, Aurora, CO; [4]Seattle Children's Hospital, Seattle, WA; [5]Cincinnati Children's Hospital, Cincinnati, OH; [6]Washington University School of Medicine, St Louis, MO; [7]Nationwide Children's Hospital, Columbus, OH; [8]Children's Hospital, Boston, MA; [9]Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE; [10]University of Michigan, Ann Arbor, MI.*

Background: The objective of this study was to develop and validate a computable phenotype algorithm to identify all patients with glomerular disease (GD) using PEDSnet, a pediatric clinical research network (CDRN) that aggregates and standardizes electronic health record (EHR) data on >5 million children from multiple pediatric health systems.

Methods: A systematic review of EHR data from 231 patients with GD seen at the Children's Hospital of Philadelphia (CHOP) from April-December 2013 was used to develop, iterate, and validate a computerized algorithm comprised of Systematized

Nomenclature of Medicine (SNOMED) diagnosis codes, kidney biopsy and transplant procedure codes, and pediatric nephrologist encounters. The algorithm identified 6138 cases of GD from 7 PEDSnet institutions. For validation, non-cases were defined as patients with ≥3 pediatric nephrologist encounters (n=42,186). Random samples of cases (n=694) and non-cases (n=697) were evaluated at each site using a standardized chart review form, and with the reviewer blinded to case status.

Results: When first implemented at CHOP, the computable phenotype identified GD with a sensitivity (SENS) of 100%, specificity (SPEC) of 93%, positive predictive value (PPV) of 92%, and negative predictive value (NPV) of 100%. When implemented across 7 health systems in PEDSnet, the performance characteristics were: SENS 97%, SPEC 80%, PPV 76%, and NPV 97%. One SNOMED code contributed considerably to the false positives, and refining the algorithm to exclude it as a qualifying code improved performance: SENS 96%, SPEC 87%, PPV 83%, and NPV 97%. The most common biopsy-based diagnoses were focal segmental glomerulosclerosis (18%), minimal change disease (17%), lupus nephritis (16%), and IgA nephropathy (13%). The most common non-biopsy diagnosis was nephrotic syndrome (41%).

Conclusions: We developed and validated an EHR-based computerized algorithm that identifies virtually all patients with GD within the PEDSnet CDRN. This method for rapid cohort identification is critcal for population-based comparative effectiveness and outcomes research in GD and other rare diseases across large health system populations.

Mobile Text Messaging for Disease Activity, Stressors, and Treatment Adherence Monitoring in Pediatric Nephrotic Syndrome

Chia-Shi Wang,[1] Jonathan P. Troost,[2] Larry A. Greenbaum,[1] Tarak Srivastava,[3] Keisha L. Gibson,[4] Howard Trachtman,[5] Emily G. Herreshoff,[2] Debbie S. Gipson.[2] *[1]Emory University, Atlanta, GA; [2]University of Michigan, Ann Arbor, MI; [3]Childrens's Mercy Hospital, Kansas City, MO; [4]University of North Carolina Kidney Center, Chapel Hill, NC; [5]NYU Langone Med Ctr, New York City, NY. Group/Team: cNEPTUNE Working Group*.

Background: There is limited information on the role of medication adherence or infectious/other stressors on the response to corticosteroids (IST) or risk of relapse in childhood nephrotic syndrome (NS). Mobile text messaging (SMS) technology may capture the impact of these factors on childhood NS disease course.

Methods: SMS data were collected on incident pediatric NS patients enrolled in the Nephrotic Syndrome Study Network (NEPTUNE) within 30 days of IST initiation. Parents or patients ≥12 years old responded to daily messages on the results of their urine protein testing and weekly messages on the presence of stressors (infections, allergies, or other) and adherence to NS medications. Non-adherence was defined as self-/parent-report of not taking prescribed NS medications in the first week of SMS. Time to remission was described using Kaplan-Meier method, stratified by adherent/non-adherent groups. Stressors were examined for relationship to disease relapses within a 7 day window via Chi-squared test.

Results: 69 pediatric NS patients were included in this analysis. Response rate to messages was 95%. Median follow-up was 364 days. 52 (76%) patients reached complete remission during follow-up. Among those who remitted, 25 (48%) later relapsed, with 47 relapse events. Median time to remission was 7 days among adherent patients and 34 days among non-adherent patients (Figure; p=0.01). The frequency of stressor occurrence in the week prior to relapse did not differ from other weeks while a patient was in remission (6/47 (13%) vs. 171/1,641 (10%) *p*=0.63).

Conclusions: Mobile text messaging was an effective method to monitor disease activity and adherence in childhood NS. Non-adherence to medications was associated with a longer time to remission. Allergies, infections, or other stressors were not found to be associated with disease relapse.

Funding: NIDDK Support

Conserved Transcriptional Changes in Drosophila and Mouse Models of APOL1 Nephropathy

Zhe Han,[1,2] Yulong Fu,[1] Peng Zhang,[1] Jun-yi Zhu.[1] *[1]Children's National Health System, Washington, DC; [2]Dept. of Pediatrics, George Washington University, Washington, DC*.

Background: African Americans are at higher risk for developing chronic kidney diseases due to APOL1 risk alleles (RA), but the mechanism remains unclear. Expression of APOL1-RA in both the fly nephrocytes (a cell type similar to human podocytes) and the mouse podocytes led to cellular toxicity and renal disease phenotypes, but whether APOL1-RA induces similar transcriptional changes in kidney cells across different species is unknown.

Methods: We performed RNA-seq analysis for Drosophila nephrocytes with APOL1-G0, G1 or G2 expression, and compared the results with the recently published RNA-seq data from mouse kidney with induced expression of APOL1-G0, G1 or G2 in podocytes. Significant number of common target genes were identified. We characterized these genes into different groups based on molecular function and biological processes. Using the fly APOL1 model together with nephrocyte-specific gene knock down, we tested these common target genes of APOL1-RA for genetic interaction. We also examined the expression level changes of some common target genes in human patient samples.

Results: We found strikingly similar transcriptional profile changes in the genes that are dramatically up- or down-regulated from the RNA-seq analysis of the fly and mouse APOL1 nephropathy models. Among the significantly up-regulated genes in both fly nephrocytes and mouse podocytes are genes involved in gluconeogenesis, oxidation-reduction process, proton transport and cell adhesion. The most down-regulated common target genes are involved in glycogen biosynthesis, fatty acid metabolic process, cell trafficking, and mitochondria coenzymes. Genetic interaction assays demonstrated that knocking down of many common down-regulated genes in APOL1-RA expressing nephrocytes made the phenotype worse, whereas knocking down some of the up-regulated common target genes could partially rescue the nephrocyte phenotype caused by APOL1-RA. We found similar transcriptional changes for some common target genes in human APOL1 nephropathy patient samples.

Conclusions: Our findings suggest that the fly and mouse APOL1 nephropathy models share highly similar transcriptional profile changes, and some of these changes can be found in human patients, indicating conserved APOL1 toxicity mechanism in flies, mice and humans. We also showed that some common target genes of APOL1-RA could be used as potential therapeutic targets.

Rare Exonic Variants in Idiopathic Nephrotic Syndrome

Adele Mitrotti,[1] Priya Krithivasan,[1] Emily Groopman,[1] David Fasel,[1] Rik Westland,[1] Hila Milo Rasouly,[1] Maddalena Marasa,[1] Junying Zhang,[1] Yifu Li,[1] Monica Bodria,[2] Paola Pontrelli,[3] Maddalena Gigante,[5] Vivette D. D'Agati,[1] Andrew S. Bomback,[1] Gerald B. Appel,[1] Loreto Gesualdo,[3] Isabella Pisani,[6] Francesco Scolari,[4] Gian Marco Ghiggeri,[2] Ali G. Gharavi,[1] David B. Goldstein,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University Medical Center, New York, NY; [2]G. Gaslini Children Hospital, Genoa, Italy; [3]University of Bari, Altamura, Italy; [4]University of Brescia, Montichiari (Brescia), Italy; [5]University of Foggia, Foggia, Italy; [6]University of Parma, Bozzolo (Mantova), Italy*.

Background: Idiopathic nephrotic syndrome (NS) is a major cause of end stage renal disease and the molecular diagnosis in the majority of drug-resistant and hereditary forms remains unknown.

Methods: We performed whole exome sequencing in 310 patients with idiopathic NS from 259 independent families. 116 (44%) of these cases were familial and 143 (56%) were sporadic. A case-control exome-wide collapsing analysis for rare functional variants (i.e. burden tests) was performed, comparing 259 index affected by familial or sporadic idiopathic NS with 6,905 controls.

Results: We identified diagnostic or likely pathogenic mutations in 28 cases (10.8%; 15.5% of familial 7.0% of sporadic NS): these included variants in *INF2*, *WT1*, *LMX1B*, and *TRPC6*. To identify novel susceptibility genes for NS we conducted a rare variant collapsing analysis comparing 259 cases and 6,905 controls. The analysis yielded 25 genes at a p-value $<2.5\times10^{-3}$ with minimal genomic inflation. Among these top-ranking signals, we identified 6 genes implicated in Mendelian forms of NS or structural kidney disease: *TRPC6* (rank 3; $p=2.01\times10^{-4}$; OR 12.1); *COL4A3* (rank 7; $p=5.39\times10^{-4}$; OR 6.98); *UMOD* (rank 17; $p=1.53\times10^{-3}$; OR 19.9); ACE (rank 18; $p=1.53\times10^{-3}$; OR 7.0); *LMX1B* (rank 19; $p=1.53\times10^{-3}$; OR 19.9); and *WT1* (rank 24; $p=2.39\times10^{-3}$; OR 15.9). Aggregate analysis of 12 known genes involved in adult-onset NS identified qualifying variants in 30 (11.6%) cases and 152 (2.2%) controls (OR 5.8, $p=1.6\times10^{-12}$). The estimated fraction of disease explained by variants at these genes was 9.4%, similar to that explained by variants identified by prioritization, expert inspection, and segregation tests.

Conclusions: Rare variants collapsing analysis represent a powerful approach to identify known and novel monogenic forms of NS in absence of large pedigrees or segregation data, and holds promises to help dissecting the complex genetic architecture of NS.

Connectivity Mapping in Experimental Alport Syndrome Identifies Lysine Deacetylase Inhibition as a Potential Therapy Vanessa R. Williams,[2] Ana Konvalinka,[1,2] Xuewen Song,[1] Rohan John,[1,2] York P. Pei,[1,2] James W. Scholey.[2,1] *[1]University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: Alport syndrome (AS) is a hereditary progressive nephropathy caused by mutations in type IV collagen genes. Currently there are few effective therapies for AS. We applied a drug repurposing strategy based on gene expression to identify a novel treatment.

Methods: Wild-type (WT) and *Col4a3*$^{-/-}$ (KO) mice on a 129/SvJ background were studied. Global RNA expression profiling was performed on whole kidney cortex at 4 and 7 weeks of age. Differential gene expression was determined with Significance Analysis of Microarrays (SAM). A disease progression signature was generated and then subsequently used to query the Connectivity Map (CMAP). CMAP identified vorinostat, a lysine deacetylase inhibitor, as a potential treatment. KO mice were treated with vorinostat at a dose of 50 mg/kg/day in DMSO by oral gavage from 4 to 7 weeks of age. DMSO-treated KO mice served as the control group. Mice were sacrificed at 7 weeks of age for analysis of kidney structure, function, inflammation, and fibrosis. Separate groups were followed out to 12 weeks of age.

Results: Pilot studies showed that vorinostat increased the acetylation of lysine in the kidney. Vorinostat led to a significant increase in survival (n = 19/group). This effect was associated with a trend toward decreased mean values in serum creatinine and urinary protein excretion rates that did not reach statistical significance (n = 6-10/group). There was no effect of vorinostat treatment on glomerulosclerosis scores. mRNA for the cytokines *Ccl2*, *Il6*, *Cxcl2* were reduced in cortical tissue from treated animals (n = 6/group). Western blot analysis showed that vorinostat lowered α-SMA expression in kidney cortex. This was associated with a trend toward decreased urinary excretion rates of TGF-β1. The urinary excretion rate of NGAL, a marker of tubular injury, was significantly reduced by vorinostat treatment.

Conclusions: CMAP can be used to identify new treatments for kidney disease based on expression profiling. Vorinostat was identified by CMAP analysis. We found that it extended the lifespan of KO mice but had modest effects on kidney function. It did not impact on glomerular injury but reduced kidney inflammation and excretion of a tubular injury marker. Future studies will provide more insight into the role of lysine acetylation in the progression of AS nephropathy.

Glomerular and Tubulointerstitial eQTLs of Patients with Nephrotic Syndrome R Putler, Xiaoquan Wen, Matt G. Sampson. *University of Michigan, Ann Arbor, MI. Group/Team: NEPTUNE.*

Background: Using intrarenal mRNA expression as a molecular phenotype in expression quantitative trait loci (eQTL) studies of nephrotic syndrome (NS) can lead to discovery of transcripts under significant genetic control, reveal novel NS-related biology, and identify loci associated with clinically meaningful outcomes. To describe the intrarenal eQTL landscape of NS, we paired whole genome sequencing with glomerular (GLOM) & tubulointerstitial (TI) transcriptomes from patients in the Nephrotic Syndrome Study Network (NEPTUNE).

Methods: NEPTUNE is a prospective, longitudinal study of NS enrolling affected adults and children receiving a clinically indicated biopsy. Rich demographic, clinical, and genomic data is collected and GLOM & TI transcriptomes are derived from a microdissected research biopsy core. We performed a cis-eQTL study to identify GLOM & TI transcripts under genetic regulation by SNPs within 1Mb of the gene. We used the Bayesian "Deterministic Approximation of Posteriors" (DAP), which uses linkage disequilibrium and annotation information, to discover & fine-map eQTL signals within each locus while controlling for multiple testing. We included appropriate covariates for each dataset. We utilized MatrixEQTL for the same data to gain insight into direction of effect for these signals.

Results: At genome-wide significance, we discovered 340 independent eQTL signals in 313 unique genes in GLOM and 862 independent signals in 772 unique genes in TI. *PLCG2*, previously implicated in steroid sensitive NS via burden testing, was one of the strongest GLOM eQTLs. Five of 30 Mendelian NS genes had both a GLOM eQTL and a significant association with eGFR. This suggests that non-coding variants regulating Mendelian NS gene expression can impact clinical outcomes. 14% and 28% of significant eQTLs were GLOM- and TUB-specific, respectively. 58% of eQTLs were shared between GLOM & TI. When we compared the significance of GLOM- & TI-eQTLs with blood-derived eQTLs (from GTeX), 19% of eQTLs had more significant minimum p-value in GLOM & TI vs blood, despite smaller sample size.

Conclusions: In our glomerular & tubulointerstitial eQTL study of NS patients, we discovered 100s of genes under significant genetic control. We can now pursue their biologic & clinical correlates. Making this NS eQTL database publicly available should be a useful resource to inform future molecular & epidemiologic studies of NS.

FR-OR035

Clinical Utility of Whole-Exome Sequencing for CKD Emily Groopman, Maddalena Marasa, Hila Milo Rasouly, Adele Mitrotti, Krzysztof Kiryluk, Simone Sanna-Cherchi, David B. Goldstein, Ali G. Gharavi. *Columbia University, New York, NY.*

Background: Whole-exome sequencing (WES) has recently been introduced into clinical diagnostics, but its value for adult constitutional disorders requires further evaluation. We are assessing the diagnostic yield of WES in a large cohort of adults with all-cause CKD or ESRD recruited at Columbia University (N=1920).

Methods: WES was performed in 1920 patients evaluated at Columbia University for various forms of CKD. To date, the exomes of 765 patients have been analyzed using American College of Medical Genetics (ACMG) guidelines for clinical sequence interpretation.

Results: 97.4% of 765 patients were adults and 51.0% were non-Caucasian; 54% had glomerulopathy, 7% had congenital defects, and 17.5% had CKD of unknown etiology. In total, 82 (10.7%) patients had a diagnostic variant for a genetic form of nephropathy. Among these diagnosed cases, 19.5% had presented with "CKD of unknown origin" and 41.5% noted no family history of nephropathy. In 47.6% of diagnosed cases, the molecular diagnosis confirmed the clinical diagnosis (e.g., Alport syndrome); in 52.4% it clarified the diagnosis (e.g., UMOD mutation in a patient with tubulointerstitial nephropathy) or provided an alternative diagnosis (e.g., Dent disease in a case of suspected glomerulopathy). Diagnostic variants were mainly found in genes for glomerulopathies (65.9%), followed by those for cystic disease (11.0%), tubulointerstitial disease (9.8%), other nephropathies (9.8%), and congenital anomalies (3.7%). In addition, 6 patients (0.8%) had a secondary, pathogenic variant in one of the 59 ACMG actionable genes. In the majority of cases, the results impacted clinical decision-making, through aspects such as initiation of targeted surveillance, family counseling, selection of transplant donors, and changes in therapy.

Conclusions: In a large all-cause CKD cohort, WES gave a molecular diagnosis for 1 in 10 patients, and in 52.4% of positive cases, pinpointed an etiology not detected using traditional diagnostics, impacting clinical care. The completion of this study will inform the utility of genetic testing for nephropathy across broad demographic subgroups and etiologic subtypes.

Effect Modification Detected in a Genome-Wide Comparison of Kidney Function Variants between Over 270,000 Diabetic and Non-Diabetic Participants: The Million Veterans Program Adriana Hung,[5,3] Ayush Giri,[3] Digna R. Velez edwards,[3] Jacklyn N. Hellwege,[3] Otis D. Wilson,[3] Eric S. Torstenson,[3] Csaba P. Kovesdy,[2] Kelly A. Birdwell,[3,5] Edward D. Siew,[3,5] Christianne Roumie,[5,3] Christopher J. O'Donnell,[1] Todd L. Edwards.[4] *[1]Boston Veterans Administration, Boston, MA; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Vanderbilt University, Nashville, TN; [4]Vanderbilt University Medical Center, Nashville, TN; [5]VA TVHS Nashville, Nashville, TN. Group/Team: On behalf of VA Million Veteran Program.*

Background: Diabetes is the number one cause of end stage kidney disease worldwide and diabetic kidney disease is often thought to be distinct from non-diabetic kidney disease. To investigate the extent of shared genetic etiology between these two subgroups in relation to kidney function

Methods: We conducted two genome-wide association studies (GWAS) in the Million Veteran Program (MVP) cohort to detect associations with eGFR: in self-reported black and white, non-diabetic veterans (N = 181,315) and diabetic veterans (N = 91,523).

Results: In total, 1,991 SNPs at 36 loci reached genome-wide significance (p-value $<5x10^{-8}$) in the diabetic subgroup, of which 15 were novel loci. *UMOD* represented the most striking signal in diabetics (p-value = $2.43x10^{-82}$). In the non-diabetic group, 7,357 SNPs at 101 loci, of which 52 were novel loci, reached genome-wide significance, with *SPATA5L1* having the strongest association (p-value = $6.39x10^{-106}$). Notably, 24 genome-wide significant loci were shared between diabetics and non-diabetics, including 5 novel loci: *TPPP*, *NRIP1*, *MAS1L*, *HFE*, and *C15orf54*. Comparison of effect estimates for significant loci showed a positive correlation between estimates across diabetics and nondiabetics (R^2 = 0.69). Correlations were strongest for known loci *SPATA5L1* and *UMOD* (r^2=0.93 and 0.98, respectively). Differences in effect sizes between diabetics and non-diabetics were also observed at two distinct loci: *MAF* and *C2*. Index SNP rs11644758 near *MAF* was associated with eGFR in non-diabetics (beta: 0.018; p-value = $1.1x10^{-9}$), but not in diabetics (beta = -0.003; p-value = 0.54), while index SNP rs644045 in *C2* was only associated in diabetics

Conclusions: In the largest comparative investigation of GWAS loci for eGFR between diabetics and non-diabetics known to date, this study reports numerous known and novel loci for eGFR, with mostly shared, and a few distinct loci across the two groups.

FR-OR037

Analysis of Humans and Mice with DSTYK Mutations Reveals Complex Association with Urinary Tract Malformations and Neurological Phenotypes Jeremiah Martino,[3] Shouhong Xuan,[3] Alejandra Perez,[2] Katarina Vukojevic,[5] Qingxue Liu,[3] Rik Westland,[4] Adele Mitrotti,[3] Cathy Mendelsohn,[3] David B. Goldstein,[1] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]Columbia University College of Physicians & Surgeons, New York, NY; [3]Columbia University Medical Center, New York, NY; [4]VU University Medical Center, Amsterdam, Netherlands; [5]Department of Anatomy, Histology and Embryology, University of Split School of Medicine, Split, Croatia.*

Background: Our previous work has shown that dominant splice-site or premature termination mutations in DSTYK produce urinary tract malformations associated with epilepsy/ataxia in humans.

Methods: We queried exome sequencing data from large datasets of epilepsy patients and controls. We analyzed Dstyk null mice and human DSTYK null 293T cells generated using CRISPR technology.

Results: We queried exome sequencing data for 11,081 epilepsy patients, and 36,952 in house controls. The disease-implicated splice variant c.654+1G>A is present in ~1 in 3,300 European individuals from ExAC, and in 12/36,952 house controls and 3/11,081 epilepsy patients, suggesting it may be an incompletely penetrant allele. Healthy controls were completely depleted of any *DSTYK* loss-of-function (LOF) mutations. We also identified a new splice mutation, absent in ExAC and all our controls, in monozygotic twins with bilateral congenital hydronephrosis, and two premature termination mutations in two epilepsy patients for whom renal history is not yet available. Inactivation of *Dstyk* in the mouse showed perinatal lethality at P0/P1 and CAKUT. We observed unilateral renal agenesis and hypoplasia, shortened ureters and pelvic kidneys, and bladder diverticuli. Age-dependent obstructive uropathy was observed in ~70% of *Dstyk*$^{-/-}$ embryos. Hydronephrosis, papillary septation and maldevelopment increased in severity with age. To gain more insight into molecular pathogenesis, we generated two compound heterozygous *DSTYK*-null clones in 293T cells. Analysis of RNA-seq data of WT and *DSTYK* null cells show alterations in cell adhesion and neurogenesis pathways, including altered signaling by BMP, FGF, NOTCH, and WNT pathways. Genes associated to monogenic forms of epilepsy (*GABRB3*, *PCDH19,* and *PRRT2)* and CAKUT (*GDNF*, *ITGA8, GPC3)* were also downregulated. Finally, DOK6, an adaptor protein that interacts with RET was also downregulated in the *DSTYK* null cells.

Conclusions: In summary, we identified novel LOF mutations in patients with epilepsy confirming a new potential clinical association, provide evidence for genetic causality for CAKUT based on gene inactivation in the mouse, and identified cellular pathways perturbed by *DSTYK* inactivation.

FR-OR038

The Multi-Phenotype Derived Nephrotic Syndrome Severity (NS2) Score Empowers Genomic Discovery C. Gillies,[1] K Yasutake,[2] Xiaoquan Wen,[2] Matt G. Sampson.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI. Group/Team: NEPTUNE.*

Background: Among patients with nephrotic syndrome (NS), we are interested in discovering genomic factors associated with disease severity over time. This requires creating accurate models of NS biology and a statistical strategy that takes advantage of deep phenotypic data while accounting for modest sample sizes and multiple testing. Thus, we developed a Nephrotic Syndrome Severity ("NS2") score for patients in the Nephrotic Syndrome Study Network (NEPTUNE).

Methods: NEPTUNE is a prospective, longitudinal study of NS enrolling affected adults and children receiving a clinically indicated biopsy. Rich demographic and clinical data are collected at baseline and over time. Genomic and histologic data are collected at baseline. We used the following parameters to create the multi-phenotype NS2 score: interstitial fibrosis, eGFR, protein/creatinine ratio, eGFR slope, time to complete remission, and time to a composite endpoint. We modeled the relationships between these variables and meaningful covariates using a Bayesian network (BN). The NS2 score represents a latent factor explaining the correlations in the observed data. The BN's parameters were inferred from 616 patients NEPTUNE participants using Markov chain Monte Carlo.

Results: Compared to existing multi-phenotype methods, NS2 score increased power for discovery without inflating Type I error. With regards to known biomarkers of NS severity, a worse NS2 score was significantly associated with the *APOL1* high-risk genotype in black patients ($p< 2.2$ e-5) and lower tubulointerstitial expression of *EGF* ($p< 5.7$ e-10). After FDR control, 1,040 glomerular transcripts were significantly associated with NS2 score. Using geneset enrichment analysis, kidney development genes were among the most enriched NS2-associated glomerular transcripts in adults ($p<5.3$ e-9), including 15 known Mendelian SRNS genes. In children, TNF alpha induced protein 3's glomerular expression was most associated with NS2 score.

Conclusions: The NS2 score is a robust metric created by capitalizing on extensive clinical data and NS-specific knowledge. As a robust multi-phenotype method, it improved statistical power for discovery without inflating false positives and replicates known genomic associations. Ultimately, using NS2 score as an outcome measure in analyses ranging from gene expression correlation to GWAS may empower genomic discoveries.

Novel Loci for Renal Decline in Type 1 Diabetes (T1D) Marcus G. Pezzolesi,[9,6] Jan Skupien,[6,8] Chunyi Wu,[2] Adam Smiles,[6] Tarunveer S. Ahluwalia,[1] Niina Sandholm,[4,5] Erkka A. Valo,[4,5] Beáta György,[7] Suna Onengut-Gumuscu,[3] Wei-Min Chen,[3] Carol Forsblom,[4,5] Josyf Mychaleckyj,[3] Michel Marre,[7] Stephen Rich,[3] Andrzej Galecki,[2] Samy Hadjadj,[7] Peter Rossing,[1] Per-Henrik Groop,[4,5] Andrzej S. Krolewski.[6,10] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Michigan, Ann Arbor, MI; [3]University of Virginia School of Medicine, Charlottesville, VA; [4]Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, Finland; [5]University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [6]Joslin Diabetes Center, Boston, MA; [7]INSERM, Poitiers, France; [8]Jagiellonian Univiversity Medical College, Krakow, Poland; [9]University of Utah, Salt Lake City, UT; [10]Harvard School of Medicine, Boston, MA.*

Background: Progressive renal decline is the predominant clinical feature of diabetic kidney disease (DKD) that leads to end-stage renal disease. Although genetic factors are known to contribute to DKD's susceptibility, despite intense effort, the identification of variants that underlie its risk has proven challenging. To advance this area of research, as part of the JDRF-sponsored Diabetic Nephropathy Collaborative Research Initiative, we recently performed the first genome-wide association study (GWAS) aimed at identifying variants associated with progressive renal decline in T1D.

Methods: We performed a linear mixed-effects model (LMM) meta-GWAS using serial measures of estimated glomerular filtration rate (eGFR) to estimate the effects of genetic variants on eGFR slope in 1,614 T1D patients with proteinuria assembled from 4 cohorts of European ancestry (Boston, Finland, Denmark and France). In total, more than 38,000 longitudinal eGFR measures collected over 5-20 years of follow-up were used to establish eGFR slopes in these patients.

Results: Our LMM meta-GWAS identified several novel loci that were strongly associated with eGFR decline. Our top finding was a variant in *LRP1B* that approached genome-wide significance (P=7.3x10^{-8}). In total, 37 variants across 20 distinct loci achieved P<1x10^{-4}, including 6 variants with P<1x10^{-6} in genes not previously associated with DKD. In addition to novel loci for progressive renal function decline, our LMM meta-GWAS replicated an association at *FRMD3*, a gene that we initially identified as part of our GWAS in the GoKinD collection.

Conclusions: Using a LMM meta-GWAS approach and longitudinal measures of renal function, we discovered several novel loci that contribute to progressive renal decline in patients with T1D and, thereby, further our understanding of the biology underlying DKD.

GSTM1 Deficiency Exaggerates Hypertension, Oxidative Stress, and Kidney Injury in Experimental Mouse Models of Hypertension and CKD Thu H. Le,[4] Gabor Bodonyi-Kovacs,[1] Phillip Ruiz,[2] Sylvia Cechova.[3] *[1]Renal Division, George Washington University, Washington, DC; [2]University Of Miami, Miami, FL; [3]University of Virginia, Charlottesville, VA; [4]Medicine, University of Virginia, Charlottesville, VA.*

Background: *GSTM1* encodes the glutathione S-transferase m-1 (GSTM1) enzyme that belongs to a superfamily of phase II antioxidant enzymes. In humans, a common deletion mutation, the null allele *GSTM1(0)*, results in decreased GSTM1 enzymatic activity and is associated with higher levels of oxidative stress. We reported that *GSTM1(0)* is associated with accelerated kidney disease progression in the African Americans Study of Kidney Disease (AASK). This has been confirmed in the Atherosclerosis Risk in Communities (ARIC) Study, in which *GSTM1(0)* is associated with incident kidney failure in both European Americans and African Americans.

Methods: To directly determine the impact of loss of GSTM1 enzyme on kidney disease development, we deleted *Gstm1* in the mouse to determine its consequence in the angiotensin II model of hypertension (Ang II-HTN) and the surgical remnant model of chronic kidney disease (Nx-CKD).

Results: Compared to wild-type mice, *Gstm1-/-* mice display higher levels of urinary 8-isoprostane and a modest but significantly higher BP at baseline. In both Ang II-HTN and Nx-CKD models, *Gstm1-/-* mice have exaggerated HTN, increased superoxide levels and worse kidney injury, independent of activation of Nox2 and Nox4 NADPH oxidases. In AngII-HTN, *Gstm1-/-* mice display increased renal expression of genes involved in inflammation - CXCL-1, MCP-1, IL-1b and IL-6 – and increased renal macrophage infiltration. In the Nx-CKD model, deletion of *Gstm1* resulted in early mortality, and significantly higher plasma creatinine and increased albuminuria. Isolated primary podocytes from *Gstm1 KO* mice also displayed a higher rate of migration in wound-healing assay.

Conclusions: In hypertension and CKD, GSTM1 enzyme may be protective by modulating oxidative stress and inflammation. Therapy directed at *GSTM1* pathway in those genetically most susceptible may ameliorate kidney disease progression.

Early Transcriptional Changes Associated with the Altered Flow Environment and Intimal Hyperplasia Following AVF Creation Kyle M. Staton,[1] Jared Rozowsky,[2] Qiongyao Hu,[1] Sarah Barbey.[1] *[1]The University of Florida, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: While recent clinical studies have provided insights into factors that dictate success or failure in arteriovenous fistula (AVF) maturation, advances in our understanding of the fundamental biology within the fistula vein wall that controls these events has been limited to animal models. Two-stage basilic vein transposition (BVT) fistula offer the unique opportunity for collection of vein wall sample at initial placement and 4-6 weeks following AVF creation. This study utilizes high-throughput genomics to evaluate the transcriptional changes associated with the independent effects of vein wall pathology versus the altered flow environment on mRNA expression.

Methods: Vein samples were collected from patients at Stage 1 and Stage 2 of BVT creation (n=14). mRNA was isolated and analyzed for 44,699 genes using the HTA 2.0 microarray. BRB ArrayTools and Ingenity Pathway Analysis was used to identify genome changes, relevant ontologies, and upstream regulators. Histomorphometry was evaluated using Movat's stain.

Results: Substantial heterogeneity was identified at the time of AVF creation (intimal thickness: range =42-260 µm; mean = 133 µm). 86% of the Stage 2 samples demonstrated an increase in intimal thickness from baseline, with 50% of these veins exhibiting a greater than 2-fold increase in intima. A linear mixed model demonstrated 150 genes associated with the stage of fistula creation and 51 genes associated with extent of intimal disease (>1.5-fold change, p<0.01; Figure). Genes regulating AVF creation/local flow environment were associated with cell cycle progression, metabolism, and inflammation (with IL1, IL12, and CCL4 as extracellular regulators). Genes related to the extent of intimal disease were related to cell migration, cell cycle progression, and cell death (with ADAMTS1, PDGF, and TGFβ as regulators).

Conclusions: Within the vein wall of patients undergoing AVF creation, independent genomic signatures related to alterations in flow and intimal hyperplasia can be identified. These differences offer the opportunity for development of target interventional strategies to improve AVF maturation and durability.

FR-OR042

A Randomised Controlled Trial of Early Cannulation Grafts (ecAVGs) versus Tunneled Central Venous Catheters in Patients Requiring Urgent Vascular Access for Haemodialysis: One Year Follow-Up Data Emma L. Aitken, Peter C. Thomson, David Kingsmore. *NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Early cannulation arteriovenous grafts (ecAVGs) are proposed as an alternative to tunnelled central venous catheters (TCVCs) in patients requiring immediate vascular access for haemodialysis (HD). We compare bacteraemia rates in patients treated with ecAVG and TCVC. Early follow-up data was recently published in *The Journal of Vascular Surgery*. One-year follow-up is now presented.

Methods: 121 adult patients requiring "urgent" vascular access for HD were randomised in a 1:1 fashion to receive either ecAVG+/-AVF (n=60) or TCVC+/-AVF (n=61). Patients were excluded if they had active systemic sepsis, no anatomically suitable vessels or anticipated life expectancy <3months. The primary end-point was culture-proven bacteraemia rate at 6 months, with the trial powered to detect a reduction in bacteraemia from 24% to 5% (alpha=0.05, beta=0.8). Secondary end points included thrombosis, re-intervention and mortality rates at 6 months and bacteraemia and mortality rates at 12 months (ISRCTN 8058854).

Results: Ten patients in the TCVC+/-AVF arm (16.4%) developed culture-proven bacteraemia within 6 months compared to two (3.3%) in the ecAVG+/-AVF arm (risk ratio 0.2 95% CI 0.12, 0.56; P=0.02). Six-month mortality was also higher in the TCVC+/-AVF cohort (16.4% [n=10] vs. 5% [n=3]; risk ratio 0.3 95% CI 0.08, 0.45; P=0.04). At 1-year follow-up 14 patients (23.3%) in the ecAVG+/-AVF arm and 16 patients (26.2%) in the TCVC+/-AVF arm were dialysing via AVF. Fewer patients in the ecAVG+/-AVF cohort were dialysing via TCVC (18.3% [n=11] vs. 41.0% [n=25]. Eleven patients in the TCVC arm (18.0%) had developed culture-proven bacteraemia at 12 months compared to six (10.0%) in the ecAVG+/-AVF arm (risk ratio 0.55 95% CI 0.24, 0.77; P<0.001). 12-month mortality was also higher in the TCVC+/-AVF cohort (18.0% [n=11] vs. 10.0% [n=6]; risk ratio 0.55 95% CI 0.24, 0.77; P<0.001.

Conclusions: Compared to TCVC+/-AVF, a strategy of ecAVG+/-AVF reduced the rate of culture-proven bacteraemia and mortality in patients requiring urgent vascular access for HD. The previously described early benefits of a strategy of ecAVG+/-AVF have now been demonstrated to persist to at least a year following "urgent" access creation.

FR-OR043

Procedural Burden Following Successful Arteriovenous Fistula Maturation in the United States Kenneth J. Woodside,[1] Kaitlyn Ratkowiak,[2] Purna Mukhopadhyay,[2] Douglas E. Schaubel,[1] Vahakn B. Shahinian,[1] Rajiv Saran,[1] Ronald L. Pisoni.[2] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Over the last decade, the number of arteriovenous fistula (AVF) in the prevalent US hemodialysis (HD) population has increased. We have previously reported that just under half of patients required interventional procedures for successful maturation of AVF. Herein, we sought to determine the procedural burden following successful AVF maturation (defined as first-use) among newly placed AVF in United States.

Methods: Using the United States Renal Data System (USRDS), Medicare claims and CROWNWeb data, we analyzed patients new to HD from 7/1/12 to 6/30/13 who had first-time AVF placements (after HD start) between 7/1/12 and 6/30/2014. Successful maturation was defined as documentation of first AVF use in the CROWNWeb monthly reporting of vascular access in use. Patients were followed until 12/31/2015.

Results: Among the 102,703 incident HD patients, there were 24,416 first-time AVF placements of which 72.6% were successfully utilized, 24.0% had no recorded use, and 3.4% were lost to follow-up. Of those AVF that successfully matured, 30.0% required interventions during the maturation phase ("assisted maturation"), with about half (55.1%) of these interventions requiring angioplasty. Rates of interventions during the maintenance phase, expressed as a rate per patient per year (ppy), are summarized in the Table. AVF that required interventional assistance to mature also had higher procedural burden for AVF maintenance.

Conclusions: While there have been improvements in AVF prevalence in the HD population, interventions on these AVF were exceedingly common. Future work will examine factors predisposing to greater requirements for intervention, cost effectiveness, patient outcomes, and comparisons with alternative vascular access types.

Intermittent Pneumatic Compression Increases Forearm AV Fistula Dilation: The First Medical Wearable for the Renal Community Tej M. Singh.[1,2] *[1]Vascular Surgery, El Camino Hospital, Mountain View, CA; [2]Fist Assist Devices, LLC, Los Altos Hills, CA.*

Background: Delays in AV fistula (AVF) maturation cause increased catheter dependency and costs. Forearm fistulas have very poor maturation rates compared to upper arm AVF. Increased distention pressure, nitric oxide release, and intermittent wall shear stress may help dilate forearm veins after AVF creation. Early use of non-invasive devices may help assist clinical AVF maturation and dilation.

Methods: One week after AVF creation, a novel, intermittent pneumatic compression device [Fist Assist (FA)] was applied 15 cm proximal to the AVF in order to apply intermittent, cyclic compression for 60 mm Hg for six hours daily for 30 days. Fourty (n=46) AVF patients were enrolled in an IRB approved study to test vein maturation at baseline and with the FA. Controls (n=17) used a sham device. Vein size was measured and recorded at baseline and after 30 days by duplex measurement. Clinical results (percentage increase) were recorded and tested for significance using standard t-tests.

Results: No patients experienced immediate thrombosis or adverse effects. Patient compliance and satisfaction was high. After one month, the mean percentage increase in vein diameter in the FA treatment group for all fistulas was significantly larger (p=0.05) than controls in the first 5 mm segment of the AVF vein. Forearm AVF veins dilated in all segments of the veins compared to upper arm veins. In the midportion alone, veins dilated compared to upper arms (39±35% vs. 94±44%) (p<.05). No fistulas had complications on dialysis or after needle placement.

Conclusions: Early application of an intermittent pneumatic compression device may assist in AVF maturation and success. Novel, non-invasive devices like Fist Assist may have clinical utility to create functional fistulae development and decrease costs as they may assist in maturation. FA may assist in forearm vein dilation and may provide the first wearable for the renal community to assist in AVF dilation especially at the forearm vein region.

VasQ™ External Support Device Improves Functionality of Arteriovenous Fistulas: Randomized Controlled Study Results Nikolaos Karydis,[1] Paul Bevis,[2] Gary Maytham,[3] Moshe Halak,[4] Noam Zilberman.[5] *[1]Guy's Hospital, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]Bristol, Bath and Weston Vascular Network, Bristol, United Kingdom; [3]Vascular Institute, St Georges University Hospital NHS Foundation Trust, London, United Kingdom; [4]Vascular Surgery, Sheba Medical Center, Ramat - Gan, Israel; [5]Laminate Medical Technologies, Tel-Aviv, Israel.*

Background: Inadequate maturation is a major drawback of the Arteriovenous Fistula (AVF). Non-laminar flow at the peri-anastomotic area and venous exposure to arterial circulation are associated with development of neo-intimal hyperplasia, impairing venous remodeling. VasQ™ is a novel external support device designed to optimize anastomosis geometry, regulate flow patterns and support the venous wall, thus improving AVF outcomes. Interim results of a randomized controlled study designed to evaluate VasQ™ usability, safety and efficacy are presented here.

Methods: Sixty patients referred for a Brachiocephalic AVF (BCAVF) in 4 different hospitals were recruited and randomized to the 'Device' group (End-to-side BCAVF + VasQ™, n=40), or the 'Control' group (End-to-side BCAVF, n=20). Patients were followed up 1, 3, and 6 months post AVF creation.

Results: Device implantation easily integrated with the BCAVF procedure. All patients were free from device related complications. Of patients with patent AVFs undergoing hemodialysis, significantly higher rates of AVF use, larger diameter veins, and less stenosis were seen in the 'Device' group 3 months post AVF creation (Table 1) Primary patency rates 6 months post AVF creation were 79% vs. 67%, and the secondary patency rates were 88% vs. 79% in the 'Device' and 'Control' groups respectively. Average blood flow rates (mL/min) were 1214 vs. 1208 at 1 month, 1426 vs. 1173 at 3 months, and 1269 vs. 1175 at 6 months post AVF creation, for the 'Device' and 'Control' groups respectively.

Conclusions: A significant increase in functionality 3 months post AVF creation was observed in the Device group. This may be associated with an increase in laminar flow and a decrease in venous wall tension promoted by VasQ™.

Funding: Commercial Support - Laminate Medical Technologies

FR-OR046

Does Regional Compared to Local Anaesthesia Influence Outcome after Arteriovenous Fistula Creation? One Year Follow-Up of a Randomised Controlled Trial Emma L. Aitken,[2] Andrew J. Jackson,[3] Rachel J. Kearns,[3] John Kinsella,[4] Alan J. Macfarlane,[1] Marc J. Clancy.[2] *[1]Glasgow Royal Infirmary, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [3]NHS Greater Glasgow & Clyde, Glasgow, United Kingdom; [4]University of Glasgow, Glasgow, United Kingdom.*

Background: AVF are the optimal form of vascular access but have a high early failure rate. Although regional compared to local anaesthesia produces vasodilation and increases short-term blood flow there is no evidence that anaesthesia modality influences long-term fistula patency. This study investigated whether regional compared to local anaesthesia improved long-term AVF patency. The early (3 month) patency rates were recently published in *The Lancet.* 1 year follow-up data is now presented.

Methods: An observer-blinded randomised controlled trial was performed at three university hospitals in Glasgow, UK. Adults undergoing primary radiocephalic (RCF) or brachiocephalic (BCF) AVF creation were randomly assigned (1:1; in blocks of eight) using a computer-generated allocation system to receive either local anaesthesia (LA) or regional (brachial plexus block (BPB)) anaesthesia. Patients were excluded if they were coagulopathic, had no suitable vessels or had a previous failed ipsilateral fistula. The primary end point was AVF patency at 3 months. Secondary end points included functional patency at 3 months and 1 year, vessel diameters and brachial artery blood flow before and after anaesthesia (NCT01706354).

Results: 163 patients were assessed for eligibility and 126 patients were randomly assigned to LA (n=63) or BPB (n=63). All patients completed follow-up on an intention-to-treat basis. Primary patency at 3 months was higher in the BPB group than the LA group (53 [84%] vs 39 patients [62%]; odds ratio [OR] 3.3, p=0.005) and was greater in RCF (20 [77%] vs 12 patients [48%]; OR 3.6, p=0.03). In the subsequent year, 18 revisional procedures aimed at improving functional patency were performed on 10 patients. Functional patency at 1 year was higher in the BPB group than the LA group (51 [81%] vs 35 patients [56%]; OR 3.4, p<0.001). This difference remained more marked for RCF than BCF.

Conclusions: BPB significantly improved 3 month primary and functional patency and 12 month functional patency rates. This difference was more marked in RCF. The low early functional patency rates observed in our previously published data are not reproduced in 1 year follow-up data.

FR-OR047

Locking Solutions Impact on Biofilm Formation in Tunneled Hemodialysis Catheters (T-HDC) and Activation of the Inflammatory Response Mario Jimenez Hernandez. *Nephrology, Hospital Clinic of Barcelona, BARCELONA, Spain.*

Background: The surface of the T-HDC proves an optimal environment for the development of bacterial biofilm. The presence of these biofilms facilitates the generation of catheter-related infections (CRI) and possibly thrombosis, which can significantly reduce catheter life as well as its relationship with higher inflammatory state. Use locking solutions into catheter with antibacterial and anticoagulant activity seems reduced those complications. To date, there are no studies comparing locking solutions and biofilm formation on catheter surface and their possible relation with inflammatory response.

Methods: Objetive: To analyze biofilm formation into THDC locked with heparin solution 10%, citrate 4% or taurolidine + heparin 500UI + citrate al 4% mix solution through confocal microscopy and activation of the inflammatory response Prospective study, 35 patients in HD were included in whom the catheter was removed for non–infection-related reasons, according to the lock solution used in T-HDC were divided in three groups: 1) heparin 1:1000, 2) citrate 4% and 3) taurolidine+citrate 4%+heparin 500UI. Microbiological growth were determined in each catheter. C- reactive protein, IL-6, IL-10 and Tumoral Necrosis Factor alfa were determined. We use confocal microscopy to determine the characteristics of biofilm.

Results: 35 patients were included, mean age was 67.06±4.41 y.o, 80% were male sex; no significant differences were found related with clinical and demographical variables. Both catheters and blood cultures were negative. Catheter locking with taurolidine had lower thickness of biofilm compared with citrate 4% and heparin (28.85±6.86 *vs* 49.99 ±16.56 vs 56.2 ±15.67*mm*; p<0.001) respectively, as well as volume of biofilm (1013967.2 ±1184812.3 vs 3706378,3 ±2152223,8 vs 5553246,791 ±2448121,8 mm^3; *p<0.001).* No significant differences were found in the inflammatory markers studied among the 3 locking solutions

Conclusions: The presence of biofilm was found in all catheters, even in the absence of bacteremia and regardless of the type of locking solution used, however, biofilm was thiner in those catheters locked with the taurolodine-based solution which could be related with better outcome and lower bacteremia rates. No statistical differences were found in inflammatory response between citrate 4% años taurolidine based solution.

Changes in Biomarker Profile a nd L eft Ventricular Hypertrophy Regression: Results from the Frequent Hemodialysis Network Trials Christopher T. Chan,[6] George A. Kaysen,[3] Gerald J. Beck,[1] Minwei Li,[1] Joan C. Lo,[2] Michael V. Rocco,[5] Alan S. Kliger,[7] The FHN Trial Group.[4] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Kaiser Permanente Northern California, Oakland, CA; [3]UC Davis, Davis, CA; [4]NIDDK, NIH, Bethesda, MD; [5]Wake Forest School of Medicine, Winston-Salem, NC; [6]Toronto General Hospital, Toronto, ON, Canada; [7]Yale New Haven Health System, New Haven, CT. Group/Team: FHN Trials Group.*

Background: Regression of left ventricular hypertrophy (LVH) has been shown to be feasible with more frequent hemodialysis. We aimed to ascertain potential biological pathways associated with regression of left ventricular mass (LVM) in patients enrolled in the Frequent Hemodialysis Network (FHN) Trials.

Methods: FHN participants were stratified according to LVM response. Regressors were defined as patients who achieved a reduction of more than 10% in LVM at 12 months. Progressors were defined as patients who had a minimum of 10% increase in LVM at 12 months.

Results: Among 332 randomized patients, there were 77 regressors and 45 progressors. LVM change differed between the 2 groups by -65.6(-74.0, -57.2) g, p < 0.001). Regressors had a median increase in dialysis frequency (from 3 (3,3) to 4.9 (3, 5.7) per week, p = 0.001) and median reductions in pre-dialysis systolic (from 149 (136, 162) to 136 (123, 152) mmHg, p <0.001) and diastolic (from 83 (71, 91) to 76 (68,

84) mmHg, p<0.001) BP. Amongst the various pre-defined cardiac biomarkers, Klotho levels increased significantly in patients with LVM regression versus those who had LVM progression (76.9 (10.5; 143.3) pg/ml, p = 0.024). Similarly, tissue inhibitors of metalloproteinase - 2 (TIMP – 2) levels fell in patients who had LVM regression than in the progressors (-7853 (-14653; -1052) pg/ml, p = 0.024). TIMP – 1 and LogBNP levels also tended to fall in patients with LVM regression. Changes in LVM correlated inversely with changes in Klotho (r = -0.24, p = 0.014). Amongst patients with LVH at baseline, copeptin tended to differ between progressors and regressors (-87.2 (-178.8; 4.4) pmol/L, p =0.06).

Conclusions: Our results demonstrated that markers of collagen turnover and changes in klotho levels are novel pathways, which may provide mechanistic insights into the regression of LVH in dialysis patients.

A Light Dialysis Session Makes a Heavy Heart: Extended Haemodialysis Offers Cardio-Protection Darren R. Churchward,[3,2] Katherine L. Hull,[2] Daniel S. March,[3,2] Matthew P. Graham-Brown,[2,1] James Burton.[3,2] *[1]None, Leicestershire, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Coventry, United Kingdom; [3]University of Leicester, Leicester, United Kingdom.*

Background: Internationally, there is a growing body of observational data that extended hours haemodialysis (HD) improves morbidity, mortality and quality of life. Limited experimental data are available comparing conventional HD (CD) to in-centre programmes of extended HD. This study examined the effects of extended in-centre nocturnal HD (INHD) on left ventricular geometry and circulating markers of cardiac injury, compared to CD.

Methods: : The MIDNIGHT trial (ISCTRN16672784) is a non-randomised controlled trial of INHD (3x5-8hours, n=10) vs CD (3x4hours, n=12), with patients matched for age, gender and HD vintage. Left ventricular mass index (LVMI) was assessed by cardiac magnetic resonance imaging; levels of heat shock protein 70 (HSP70), fibroblast growth factor-23 (FGF-23) and troponin-I (Trop-I) were analysed from blood samples taken prior to HD. All measures were completed at baseline and 6-months. LVMI results are shown as mean with standard deviation (*Mean*±*SD*); blood markers are presented as median with lower and upper quartiles (*Mdn*[LQ,UQ]).

Results: LVMI significantly reduced in the INHD group (63.6±20.7 vs 55.0±17.3, *p*=0.02) and tended to increase in the CD group (51.4±8.6 vs 54.6±11.1, *p*=0.46). No change to HSP70 was seen in either group. Reductions in FGF-23 were seen in the INHD group (489.7[156.3, 1515.0] vs 88.3[49.7,400.6], *p*=0.043) but not the CD group (399.24[174.1,4670] vs 657.3[158.9,1099.7], *p*=0.735). Similarly, no change to Trop-I in the INHD group (15[5.3,20.5] vs 6.5[0.0,25.0], *p*=0.917) but a trend to increase in the CD group (11.0[6.3,20.3] vs 15.0[8.8,38.8], *p*=0.066).

Conclusions: In this study, INHD patients demonstrated favourable changes in circulating biomarkers of cardiovascular disease as well as regression of left ventricular hypertrophy, compared to controls. These results provide further evidence that extended HD regimens may improve cardiovascular outcomes and therefore warrant further investigation.

FR-OR050

Reduction in Post-Dialysis Recovery Time in the FREEDOM Study of Frequent Home Hemodialysis Bertrand L. Jaber,[2] Eric D. Weinhandl,[1,4] Allan J. Collins,[1,4] Fredric O. Finkelstein.[3] *[1]NxStage Medical, Inc., Victoria, MN; [2]St. Elizabeth's Medical Center, Boston, MA; [3]Yale University, New Haven, CT; [4]University of Minnesota, Minneapolis, MN.*

Background: Long post-dialysis recovery time (RT) is associated with higher risk of death and lower quality of life. Increasing treatment frequency reduced RT in the Frequent Hemodialysis Network trials. The FREEDOM (Following Rehabilitation, Economics and Everyday-Dialysis Outcome Measurements) Study was a 12-month prospective cohort study of short daily home hemodialysis (SDHHD). Interim analysis of the FREEDOM Study indicated that SDHHD led to decreased RT. We sought to confirm these findings in a final analysis.

Methods: We analyzed RT, as elicited by the question, "How long does it take you to recover from a dialysis session and resume your normal, usual activities?", in intention-to-treat (ITT), conditional ITT (cITT), and as-treated (AT) cohorts. The ITT, cITT, and AT cohorts comprised all patients who initiated SDHHD, those who completed 2 months of follow-up, and those who completed 12 months of follow-up, respectively. RT was measured at baseline, 4 months (if the patient remained on SDHHD), and 12 months (if the patient remained on SDHHD). Patients were censored at death or kidney transplantation. We used mixed models to analyze changes in RT, with adjustments for demographics and comorbidity.

Results: The ITT, cITT, and AT cohorts included 487, 407, and 247 patients, respectively. In the ITT cohort, mean RT decreased from 494 minutes (min) at baseline to 227 and 198 min at 4 and 12 months, respectively, while median RT decreased from 180 min at baseline to 60 and 45 min at 4 and 12 months. In the AT cohort, mean RT decreased from 512 min at baseline to 132 and 96 min at 4 and 12 months, while median RT decreased from 180 min at baseline to 30 min at both 4 and 12 months. Adjusted differences in mean RT between baseline and 4 months were -263 min, -306 min, and -380 min in the ITT, cITT, and AT cohorts, respectively, and corresponding adjusted differences between baseline and 12 months were -287 min, -339 min, and -416 minutes ($P < 0.001$ for all differences).

Conclusions: In a 12-month prospective cohort study, SDHHD was associated with large reductions in mean and median post-dialysis recovery time. Reductions were evident after 4 months on SDHHD and sustained after 12 months. Increasing treatment frequency likely reduces recovery time, but the physiologic mechanisms underlying this effect remain uncertain and merit further research.

FR-OR051

Determinants of Interdialytic Volume Overload During More Frequent Hemodialysis: Time-Integrated Estimate of Fluid Load (TIFL) J. Ken Leypoldt,[3] Allan J. Collins,[1] Eric D. Weinhandl.[2] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]NxStage Medical, Inc., Victoria, MN; [3]None, San Clemente, CA.*

Background: The Frequent Hemodialysis Network has recently demonstrated that a novel measure of interdialytic volume overload, the time-integrated estimate of fluid load (TIFL), is inversely associated with left ventricular mass reduction and could therefore be used to evaluate the effect of volume overload on cardiac stress (Raimann et al, Blood Purif 2016). The relative importance of clinical factors, such as dietary sodium intake (NaI), interdialytic weight gain (IDWG) and dialysate sodium concentration (dialNa), on TIFL during conventional and more frequent hemodialysis (HD) are incompletely understood.

Methods: We compared the effect of clinical factors on the mean interdialytic excess of extracellular fluid volume (eECV) and TIFL using mathematical model simulations. A conventional model of sodium and fluid kinetics was used to simulate intradialytic and interdialytic changes in serum sodium and extracellular fluid volume (Kimura & Gotch, Int J Artif Organs 1984). TIFL was calculated using the approach of Raimann et al (Blood Purif 2016) that assumes rapid post-dialysis fluid intake to maintain the sodium set-point and accounts for the length of the interdialytic interval. Residual kidney urine volume was assumed negligible. We compared eECV and TIFL for conventional HD, daily HD and nocturnal HD.

Results: As expected, eECV and TIFL were strongly and positively associated with IDWG. In contrast, eECV and TIFL were inversely associated with NaI when not accompanied by increased IDWG. The effects of treatment modality and dialNa are tabulated.

Conclusions: More frequent (daily and nocturnal) HD result in substantial reductions in eECV and TIFL. Similar reductions in these measures cannot be achieved with reductions in dietary Na intake or dialysate Na concentrations. The use of increased HD frequency for reduction of interdialytic fluid overload should be preferred over stringent dietary Na restriction or reductions in dialysate Na concentration.

Funding: Commercial Support - NxStage Medical

HD	Treatments/wk	Treatment Time (min)	dialNa (meq/L)	eECV (L)	TIFL (L-days)
Conventional	3	220	136	1.27	12.4
			140	1.25	12.8
Daily	6	180	136	0.76	8.5
			140	0.75	8.7
Nocturnal	6	480	136	0.61	5.4

FR-OR052

Preservation of Residual Renal Function in a European Cohort of Frequent Home Hemodialysis Patients Sunita Nair,[2] Maria Fernanda Slon.[1] *[1]Complejo Hospitalario de Navarra, Pamplona, Spain; [2]Shrewsbury and Telford Hospital NHS Trust, Shrewsbury, United Kingdom. Group/Team: KIHDNEy Investigators.*

Background: Residual renal function (RRF) in dialysis patients promotes clearance of phosphate and middle molecules, permits more liberal fluid intake, and associates with improved survival. Intensive hemodialysis (HD) may accelerate loss of RRF, but whether all intensive HD schedules are similarly associated with deterioration of RRF is uncertain. We assessed the trajectory of 24-hour urine volume (UVol) in a European cohort of frequent home hemodialysis (HHD) patients.

Methods: We analyzed data from the KIHDNEy (Knowledge to Improve Home Hemodialysis Network in Europe) cohort, which comprises HHD patients at 9 centers in 5 Western European countries. All patients used the NxStage System One. Data about the HD prescription and 24-hour urine volume were collected at HHD initiation, 6 months, and 12 months. We retained patients with 24-hour UVol ≥500 mL at baseline and ≥4 sessions/week. We used generalized estimating equations to model changes in UVol between HHD initiation and 12 months.

Results: Baseline UVol was recorded in 98 (54%) of 182 patients, 44 (45%) of 98 had UVol ≥500 mL, and 43 (98%) of 44 dialyzed ≥4 sessions/week. Mean age was 51 years, 49% were female, median dialysis duration before HHD was 11.5 months, 9% had diabetes, and 19% had glomerulonephritis. Treatment frequencies were 5 and 6 sessions/week in 70% and 30% of patients, respectively, and mean treatment time was 12.2 hours/week. Mean UVol decreased (P = 0.001) from 1310 mL at baseline to 1080 mL at 6 months and 910 mL at 12 months. Cumulative incidence of anuria (UVol ≤50 mL) was 6% at 6 months and 18% at 12 months. Concurrently, mean ultrafiltration volume increased from 0.69 L at baseline to 0.85 L at 6 months and 0.96 L at 12 months. Antihypertensive medication use declined from 1.62 agents/day at baseline to 1.35 agents/day at 12 months. Concurrently, use of ACE inhibitors or ARBs declined from 28% to 16% of patients, while use of loop diuretics in non-anuric patients remained between 30% and 40%.

Conclusions: RRF decreased during 12 months of frequent HHD, with treatment time per week comparable to conventional HD. However, cumulative incidence of anuria was lower than with nocturnal HD in FHN (Daurgidas, Kidney Int, 2013), as well as lower than with peritoneal dialysis in NECOSAD (Michels, CJASN, 2011). Further research should assess whether specific approaches to intensive HD better preserve RRF.

FR-OR053

A Comparison of Patient and Technique Survival on Peritoneal Dialysis and Home Hemodialysis in Canada

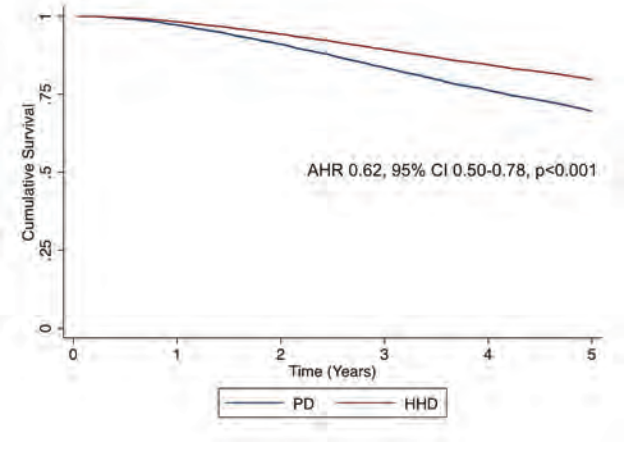
Annie-Claire Nadeau-Fredette,[3] David W. Johnson,[2] Jeffrey Perl,[4] Karthik K. Tennankore,[1] Joanne M. Bargman,[5] Christopher T. Chan.[5] *[1]Dalhousie/Nova Scotia Health, Halifax, NS, Canada; [2]Princess Alexandra Hospital, Brisbane, QLD, Australia; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]St. Michael's Hospital, Toronto, ON, Canada; [5]Toronto General Hospital, Toronto, ON, Canada.*

Background: Improved outcomes and superior cost effectiveness among home dialysis patients compared to conventional hemodialysis has led to greater utilization of home dialysis in Canada. Little is known about survival comparisons among home dialysis modalities. This study aimed to compare the survival and technique failure of patients treated with either peritoneal dialysis (PD) or home hemodialysis (HHD).

Methods: All incident dialysis patient treated with PD or HHD within 180 days of renal replacement therapy start in Canada between January 2000 and December 2013 were analyzed. The primary outcome of death was assessed in a Cox proportional hazards model adjusting for baseline demographics, comorbidities, dialysis vintage, era and geographic region, and censored at time of transplantation or loss to follow-up. A sensitivity analysis was performed using a 2:1 propensity score matched (PSM) model. Secondary outcomes included the composite of home dialysis technique failure and death.

Results: The study included 14 589 PD patients and 721 HHD patients. Unadjusted 5-year survival was 77% for HHD patients and 52% for PD patients. In the adjusted analysis, patient mortality was lower with HHD compared to PD (adjusted hazard ratio [AHR] 0.62, 95% confidence interval [CI] 0.50-0.78, p<0.001) and the association was consistent in the PSM model (HR 0.73, 95% CI 0.56-0.95, p=0.02). The composite of on-treatment mortality and technique failure was also lower with HHD compared to PD (AHR 0.48, 95% CI 0.42-0.72, p<0.001).

Conclusions: In Canada, incident HHD was associated with a lower mortality compared to PD. Whether or not this association is related to the impact of dialysis modality or due to differences in patient selection remains uncertain and should be evaluated in further prospective studies.



Adjusted survival

Vascular Audit Checklist in Home Hemodialysis: A Prospective Cohort Study

Miten Dhruve,[2] Christopher T. Chan.[1] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada.*

Background: Vascular access related infections lead to increased morbidity and mortality in the home hemodialysis (HHD) population. We had previously reported that errors made on nurse – administered vascular access audit were associated with higher rate of access-related infection. In the present study, we hypothesize that repeat administration of vascular audit, will result in a decrease in the number of errors performed. Furthermore, increase in errors will augment the future risk of vascular related infection.

Methods: We conducted a prospective cohort study of all HHD patients from 2013 to 2016. Vascular access audits errors were obtained from checklists that were nurse administered and occurred on average every six and a half (0 – 32) months.

Results: 370 audits were performed on 122 patients with an average HHD vintage of 6.7 (0.8 – 19.5) years. At baseline the mean number of errors was 1.24 ± 1.75. This decreased significantly to mean of 0.33± 0.49 by 8th audit. Patients with multiple audits demonstrated a significant decrease in median number of errors (baseline median 1, (0-2) end of study median 0, (0-1) p= 0.01). There was a significant relation between ≥ 2 errors and future risk of infection, p<0.001 (**Table 1**). The overall infection rate was 0.57 infections per patient year.

Conclusions: Vascular access audits have a significant role to play in identification of errors in HHD population with repeat audits leading to a decrease in the number of errors. There exists a strong relation between 2 or more errors and increased risk of future infection. Vascular audit tool should be utilized in HHD programs to identify patient errors in aspiration of decreasing infection rates.

TABLE 1: Chi Square analysis to assess relation between 2 or more errors and future risk of infection.

Therapy Attrition on Nocturnal versus Diurnal Home Hemodialysis

Eric D. Weinhandl,[1,2] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Nocturnal hemodialysis offers several clinical advantages over diurnal hemodialysis, including slower ultrafiltration rate and increased cumulative phosphorus clearance. In addition, because nocturnal hemodialysis transfers treatment time to overnights, patients may gain daytime hours for activity unrelated to health care. Recently, the NxStage System One (NSO) was cleared by the US Food and Drug Administration for nocturnal home hemodialysis (NHHD). We aimed to identify the relative risk of all-cause and cause-specific therapy attrition in NHHD patients and diurnal HHD patients using the NSO.

Methods: We analyzed data in prescription records maintained by NxStage Medical (Lawrence, MA). We identified all US patients who initiated NHHD between April 1, 2015, and December 31, 2016. We also identified all US patients who initiated HHD between April 1, 2006, and December 31, 2016. For all patients, we collected age, race, sex, and year of HHD initiation with the NSO. We followed NHHD patients from the date of NHHD initiation, followed diurnal HHD patients from HHD initiation with the NSO, and followed all patients until the earlier of HHD cessation or January 15, 2015. We used stratified Cox regression to estimate hazard ratios of all-cause and cause-specific (transplant, technique failure, death) attrition for nocturnal versus diurnal HHD, with adjustment for age, race, and sex, and stratification by year of HHD initiation; in models, follow-up time was enumerated in days from HHD initiation with the NSO, in order to address HHD vintage.

Results: We identified 406 patients who initiated NHHD. Mean age was 53.3 years, 72% with known race were white, and 68% were male. During follow-up, there were 21 transplants, 43 technique failures, and 21 deaths. Cumulative incidence of HHD attrition at 12 months after NHHD initiation was 24.9% (95% confidence interval [CI], 20.0-30.0%). Compared to diurnal HHD, hazards ratios of HHD attrition for NHHD were 0.63 (95% CI, 0.52-0.78) for all causes, 0.70 (0.45-1.08) for transplant, 0.54 (0.40-0.73) for technique failure, and 0.77 (0.54-1.12) for death.

Conclusions: Nocturnal HHD with the NSO was associated with lower risk of HHD attrition, with significantly lower risk of technique failure, compared to diurnal HHD. Lower risks of both transplant and death on NHHD merit further analysis, including adjustment for the comorbidity profile of NHHD patients.

FR-OR056

Improvement in Health-Related Quality of Life in the FREEDOM Study of Frequent Home Hemodialysis

Fredric O. Finkelstein,[3] Eric D. Weinhandl,[1,4] Allan J. Collins,[1,4] Bertrand L. Jaber.[2] *[1]NxStage Medical, Inc., Victoria, MN; [2]St. Elizabeth's Medical Center, Boston, MA; [3]Yale University, New Haven, CT; [4]University of Minnesota, Minneapolis, MN.*

Background: Poor health-related quality of life (HRQOL) is common in dialysis patients. Increasing treatment frequency improved physical HRQOL in the Frequent Hemodialysis Network trials. The FREEDOM (Following Rehabilitation, Economics and

Everyday-Dialysis Outcome Measurements) Study was a 12-month prospective cohort study of short daily home hemodialysis (SDHHD). Interim analysis of the FREEDOM Study indicated that SDHHD led to improvements in HRQOL. We sought to confirm these findings in a final analysis.

Methods: We analyzed HRQOL in intention-to-treat (ITT), conditional ITT (cITT), and as-treated (AT) cohorts. The ITT, cITT, and AT cohorts comprised all patients who initiated SDHHD, those who completed 2 months of follow-up, and those who completed 12 months of follow-up, respectively. HRQOL was measured with the Short Form-36 health survey at baseline, 4 months (if the patient remained on SDHHD), and 12 months (if the patient remained on SDHHD). Patients were censored at death or kidney transplantation. We used adjusted mixed models to analyze changes in HRQOL domains, the physical-composite summary (PCS), and the mental-composite summary (MCS).

Results: The ITT, cITT, and AT cohorts included 487, 408, and 247 patients, respectively. In the ITT cohort, mean PCS increased from 34.8 at baseline to 37.1 at 12 months, while mean MCS increased from 45.8 to 48.0. In the AT cohort, mean PCS increased from 35.5 to 38.6, while mean MCS increased from 48.4 to 50.4. Modeled changes in HRQOL domains between baseline, 4 months, and 12 months are displayed in the table. Changes were uniformly positive.

Conclusions: In a 12-month prospective cohort study, SDHHD was associated with widespread improvements across domains of both physical and mental HRQOL.

HRQOL domain	ITT cohort		cITT cohort		AT cohort	
	4 months	12 months	4 months	12 months	4 months	12 months

FR-OR057

Comparing Mortality between Incident Peritoneal Dialysis and Home Hemodialysis Patients Soo Jeong Choi,[1] Yoshitsugu Obi,[1] Miklos Z. Molnar,[2] Connie Rhee,[1] Elani Streja,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: The use of home dialysis modalities, including peritoneal dialysis (PD) and home hemodialysis (HHD), has recently increased. Although HHD differs from PD in terms of setting, frequency and patient preference, prior studies have shown that HHD patients have lower mortality risk than PD, in which we sought to examine using propensity scores in a large contemporary cohort of home dialysis patients.

Methods: We retrospectively examined a cohort of 1,993 HHD and 16,515 PD patients who initiated home dialysis from 2007-2011. HHD patients were matched with 2 PD patients using propensity score (PS) matching. Demographics, comorbidities, vintage and body mass index were included in logistic regression model for PS matching. We matched 1,988 HHD with 3,876 PD patients. Patients were stratified by vintage at the time of home modality initiation (<3 months (M), 3-<12M, and >12M).

Results: In the matched cohort, 244 and 699 deaths occurred in HHD and PD patients, respectively (cumulative incidence rate: 9.4 vs 12.0/100 patient year, p = 0.002). But, PD patients who transitioned within 12M of vintage had similar mortality risk. Only PD patients who transitioned after 12M of vintage had higher risk for mortality (HR, 1.62; 95% CI, 1.18-2.20).

Conclusions: Whereas there appears to be no survival difference among those who started home dialysis in the first 12 M, patients who transitioned to PD after 12 M of vintage had worse survival than those who transitioned to HHD after 12 M of vintage. Additional studies are warranted to further investigate these differences.

A Novel Nephrotic Syndrome Circulating Factor Disease Model Based on PAR-1 Activation Carl J. May, Sarah Higgins, Fern Barrington, Richard Coward, Gavin I. Welsh, Moin Saleem. *University of Bristol, Bristol, United Kingdom.*

Background: There is strong evidence for the role of a circulating factor in the pathogenesis of idiopathic nephrotic syndrome (iNS). Several candidates have been put forward over the years, however, none have been definitively proved. Work previously published by this group has suggested a role for Protease Activated Receptor 1 (PAR-1). Cultured podocytes respond to treatment with nephrotic syndrome relapse plasma (and not paired remission plasma) by phosphorylating VASP and increasing motility. Furthermore, the response can be blocked by knocking down the PAR-1 receptor with siRNA. A transgenic mouse was developed that expressed a podocyte specific constitutively active form of PAR-1. We hypothesise that this replicates over exposure to a circulating protease and hence causes idiopathic nephrotic syndrome.

Methods: Transgenic mice were generated by Genoway (Lyon, France). The transgene was inserted at the Rosa 26 locus. These mice were crossed with Pod- Cre mice for the developmental line and Pod- rtTA Tet- O- Cre mice for the inducible line. Kidneys were harvested and processed for histological staining and EM as indicated.

Results: The developmental PAR-1_{active} mice were born normal, and died consistently between the ages of 39 and 45 days. They demonstrate proteinuria from the age of 14 days. The level of proteinuria increases considerably over time. By day 40 they have significantly higher blood urea and creatinine (mean 70mMol/L, 60μMol/L respectively), suggesting the mice die of renal failure. EM analysis showed a significantly thickened GBM and foot process effacement. PAS and Masson's Trichrome staining over a time-course ranging from 8 to 40 days demonstrated an initial hypercellualrity within the Bowman's capsule at 8 days that appear to reduce by 14 days. By 30 days there is clear evidence of fibrosis and by 40 days there is both fibrosis and sclerosis. The inducible PAR-1 Active mice show a similar phenotype although less severe. These mice die around 6 months old. We have also seen increased staining for activated PAR-1 in human iNS, compared to IgAN control biopsies.

Conclusions: This work demonstrates a clear role for the PAR-1 receptor in proteinuria, and strengthens the hypothesis that circulating factor(s) may act via this receptor. Additionally, this is a novel model for circulating factor NS, to test therapies *in vivo*.

Angiomotin Knockout in Rats Causes Proteinuria Yaochun Zhang,[2] Jerrold m. Ward,[3] Zakir Hossain,[2] Sik Yin Foo,[2] Isaac Liu,[2] Chang-Yien Chan,[2] Zi Jin Sun,[2] Hui Kim Yap,[1] Kar Hui Ng.[2] *[1]National University Hospital, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]Global VetPathology, Montgomery Village, MD.*

Background: Angiomotins were originally identified as angiostatin binding proteins and implicated in the regulation of endothelial cell migration and tube formation. Recent studies have shown that Angiomotion plays a central role in tight junction maintenance via the complex formed with ARHGAP17, which acts by regulating the uptake of polarity proteins at tight junctions. This study aimed to investigate the renal functions of *Angiomotin* with an *Angiomotin* knockout (Amot KO) rat model.

Methods: Using CRISPR/Cas9 system, we created an Amot KO founder rat with a 5 bp insertion in the coding region, which produced a premature stop codon, resulting in a truncated protein of 63 amino acids. The founder was crossed with wild type rats to establish Amot KO rat line. The phenotypes of Amot KO (n = 11) male rats were studied and compared with wild type control (n = 11). Body weight, serum and urine albumin:creatinine ratios were monitored monthly. Total RNA were extracted from peripheral blood mononuclear cells and sent for RNA-Seq. The rats were euthanized at different time points. Kidney cortex samples were obtained for pathological examinations.

Results: Increased urine albumin:creatinine ratio was found as early as 4 month age in the Amot KO rats. The ratio increased progressively with age and reached 547.7 ± 254.6 μg/mg in the 6 month old Amot KO rats, while the ratio is 150.4 ± 117.4 μg/mg for the wild type control (p < 0.01). Pathological changes in the rat kidneys were systemically examined with H&E and PAS staining. While wild type control rats showed normal renal glomeruli and proximal tubules, prominent thickened GBMs, thickened Bowman's capsule, casts or crystal in distal tubule, thicker tubular basement membrane and hyperplastic epithelium as well as podocyte atypia can be seen in the 6 and 10 month old Amot KO rats. RNA-Seq results showed more than 300 differentially expressed genes including Smad7, Rac1 and pdlim1. Analysis using IPA revealed altered effector pathways in glomerular injury, renal necrosis, and nephritis.

Conclusions: AMOT appears to play important roles in regulating renal functions. AMOT may exert its function through Rich1/Gap complex affecting activation status of Rho GTPases or via interactions with slit diaphragm and actin cytoskeleton proteins.

CCR2 Inhibitor Improves Renal Function and Structure in Murine Models of Focal Segmental Glomerulosclerosis (FSGS) Zhenhua Miao, Linda Ertl, Jeffrey P. Mcmahon, Bin N. Zhao, James J. Campbell, Xiaoli Liu, Ton H. Dang, Shichang Miao, Thomas J. Schall, Rajinder Singh. *ChemoCentryx, Mt View, CA.*

Background: FSGS is the most common primary glomerular disorder causing in at least 4% of patients with ESRD. The current SOC includes renin-angiotensin-aldosterone (RAAS) inhibitors, steroids and/or immunosuppresants. Several lines of evidence support a role for chemokine receptor 2 (CCR2) positive monocyte/macrophages in the pathogenesis of FSGS, and inhibition of CCR2 presents a potential therapeutic treatment of FSGS.

Methods: Two murine models of FSGS, 5/6 nephrectomy and Adriamycin nephropathy were used to investigate the efficacy of either CCR2 antagonist alone or in combination with RAAS inhibitor candesartan (CST). Kidney injury was assessed by proteinuria (UAER), UACR, BUN, serum creatinine and histopathology.

Results: In the 5/6 nephrectomy model, mice had a rapid reduction in UAER when treated with either the CCR2 antagonist (42% reduction by week 1) or RAAS inhibitor (69% reduction). Addition of the CCR2 antagonist to RAAS inhibitor further reduced the UAER (92% reduction; $p < .005$ versus RAAS inhibitor alone). The same renal protective effects of CCR2 blockade were seen in the Adriamycin nephropathy model. UAER was significantly reduced by administration of CCR2 antagonist (66% reduction; $p = .05$ versus vehicle), but not by RAAS inhibitor alone. Furthermore, the combination of the CCR2 antagonist and RAAS inhibition resulted in an additive effect (74% reduction; $p = .027$ versus vehicle) in Adriamycin nephropathy model. The combination of the CCR2 antagonist and RAAS inhibitor significantly reduced serum creatinine and BUN. Histological parameters also improved with CCR2 antagonist treatment and/or RAAS inhibitor. The combination of the CCR2 antagonist and RAAS inhibition reduced tubulointerstitial injury (including inflammation, fibrosis, tubular casts and dilatation) and glomerular injury (including glomerular hypertrophy, mesangial expansion and glomerular sclerosis).

Conclusions: CCR2 inhibition provides significant and rapid renal protection in two models of FSGS, as measured by renal functions and histological parameters, and thus represents a novel and mechanistically distinct approach for the treatment of FSGS. We are moving forward to initiate a clinical trial in the treatment of FSGS with our late stage drug candidate CCR2 antagonist CCX140.

FR-OR061

A New Mouse Model of Chronic Proteinuria Due to a Glomerular Basement Membrane Laminin-521 Polymerization Defect Steven D. Funk, Raymond H. Bayer, Jeffrey H. Miner. *Washington University School of Medicine, St. Louis, MO.*

Background: The glomerular basement membrane (GBM) is a dense extracellular matrix that separates endothelium from podocytes. The GBM is thought to stabilize foot processes and slit diaphragms and, together with podocytes and endothelium, forms the glomerular filtration barrier. GBM integrity is maintained by: 1) polymerization of laminin $\alpha5\beta2\gamma1$ (LM-521) via tripartite α-β-γ chain NH2-terminal LN domain interactions; 2) attachment of the LMα5 C-terminal LG domain to podocyte & endothelial cell integrins; and 3) linkage of the laminin network to the type IV collagen network by nidogen. Null and missense mutations in the LMβ2 chain of LM-521 cause nephrotic syndrome. In previous studies of *Lamb2-/-* mice proteinuria preceded both foot process effacement and loss of slit diaphragms. Thus, LAMB2 LN domain missense mutations found in nephrotic patients may cause disease by impairing laminin polymerization.

Methods: In vivo CRISPR gene editing was used to generate a point mutation in the LN domain of mouse LAMB2, but DNA analysis of 1 founder showed an unexpected in-frame, 44 amino acid deletion within the LN domain. Homozygous LAMB2-d44 mice were observed for up to 8 months. Urine, blood, and tissues were taken at select time points to evaluate albuminuria, BUN, histopathology, and GBM composition and ultrastructure.

Results: The unexpected LAMB2-d44 mutation is analogous to the dy-2J mutation in mouse LMα2 that causes severe muscular dystrophy due to defective LM-211 polymerization. The GBM of LAMB2-d44 mice contained a normal level of LAMB2, but the mice exhibited modest proteinuria between 4-6 wks of age and nephrotic range by 8 wks. Foot process swelling was observed at 6 wks of age, with effacement at 8 wks. LAMB2-d44 mice died spontaneously from 4 months onward, but some lived over 8 months. Moderate glomerulosclerosis, tubular dilations, protein casts, and occasional immune infiltrates were commonly observed features.

Conclusions: LAMB2-d44 mice exhibit modest proteinuria early but have intact foot processes. Chronic nephrotic range proteinuria is accompanied by effacement. This mutant will serve as a tool to test innovative protein-based methods for strengthening the GBM's laminin network and reducing proteinuria. More generally, this new genetic model of nephrotic syndrome will useful for investigating disease progression.

FR-OR062

The miRNA-29a to Claudin-1 Pathway Is an important Regulator of Glomerular Albumin Permeation in Diabetic Nephropathy Yongfeng Gong,[3] George Jarad,[4] Ming-Zhi Zhang,[2] Raymond C. Harris,[1] Jianghui Hou.[4] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical School, Nashville, TN; [3]Washington University Renal Division, Saint Louis, MO; [4]Washington University School of Medicine, St. Louis, MO.*

Background: Diabetic nephropathy (DN) is characterized by alteration in glomerular filtration barrier, which include thickening of the the glomerular basement membrane (GBM), podocyte foot process effacement, reduced slit width and loss of slit diaphragm (SD). The disappearance of the SD is associated with the appearance of the tight junction (TJ) and re-expression of claudin-1 in podocytes, suggesting a previously unknown role for TJ in DN. Hyperglycemia has been shown to suppress the expression of miRNA-29 family in podocytes, which is known to modulate the expression of claudin-1 and extracellular matrix (ECM). These data suggest that miRNA-29a family might play roles in the development of podocyte dysfunction and glomerular phenotype of DN.

Methods: We have generated a series of transgenic mouse models to study the role of claudins and microRNAs in DN. Using a nephrin-rtTA mouse model, we have generated podocyte specific overexpression of claudin-1 in tetracycline inducible manner. Using gene targeting approach, we have generated a miRNA-29a knockout mouse model in the kidney.

Results: 1. Expression of miRNA-29a is downregulated in the podocytes from the *db/db-eNOS* mouse model of DN. 2. Knockout of miRNA-29a, the innate regulator of claudin-1 and ECM in podocytes, resulted in progressive proteinuria, accompanied by destabilization of podocyte SD and thickening of the GBM, which are the hallmarks of DN. Mechanistically, such pathologic changes are derived from increased expression of cell junction gene - claudin-1, and in GBM genes - collagen IV alpha3,4,5 and laminin beta2, all of which are direct targets of miRNA-29a. 3. Induction of claudin-1 gene expression in mature podocytes caused albuminuria. Using freeze fracture techniques, we confirmed the cell junction induced by claudin-1 overexpression, which culminate in the transformation of podocyte SD into TJ. Immunolabeling of SD proteins revealed that claudin-1 overexpression destabilized the SD protein complex, with significant reduction and altered localization of nephrin and podocin.

Conclusions: Our data attest to a novel concept that a central signaling pathway from microRNA to claudin-1 may coordinately regulate a wide spectrum of podocyte lesions important to DN. Such a pathway may lead to a new therapeutic aproach to treat DN by manipulating mircoRNA expression.

FR-OR063

The Potential Significance of Complement Factor D Bypass in fD-Targeted Treatment for C3G Yuzhou Zhang,[1] Adam C. Keenan,[1] Margaret A. Lindorfer,[3] Carla M. Nester,[1] Ronald P. Taylor,[3] John Lambris,[2] Richard J. Smith.[1] *[1]University of Iowa, Iowa City, IA; [2]University of Pennsylvania School of Medicine, Philadelphia, PA; [3]University of Virginia School of Medicine, Charlottesville, VA.*

Background: C3 glomerulopathy (C3G) is characterized by predominant deposition of complement C3 in the glomerulus in the absence or sparse presence of immunoglobulins. The underlying disease mechanism is uncontrolled activity of the C3 convertase of the alternative pathway (AP). Convertase activity is normally tightly controlled by the fluid-phase AP regulator factor H (fH). Mice with a targeted deletion of fH (*Cfh-/-*) develop features of C3G, with intense C3 deposition along glomerular capillary walls accompanied by subendothelial electron-dense deposits. The rate-limiting protease, fD, is the only enzyme known to cleave fB. Several AP inhibiting small-molecule antagonists against fD have been developed.

Methods: To assess fD-targeted therapy, we backcrossed *Cfh-/-* mice with *Cfd-/-* mice for >10 generations and evaluated complement dysregulation and renal pathology in *Cfh-/-* mice, *Cfd-/-* mice and *Cfh-/-*;*Cfd-/-* mice. We developed an *in vitro* fB-cleavage assay using a recombinant protein that contains the active catalytic domain of mannose-binding lectin-associated serine protease 3 (MASP-3).

Results: *Cfh-/-*;*Cfd-/-* mice have abundant mesangial and capillary deposition of C3 and C5b-9 with scant densities on electron microscopy consistent with ongoing complement dysregulation even in the absence of fD. Serum from *Cfh-/- mice* was devoid of complement activity due to depletion of complement proteins. Circulating C3 levels in *Cfd-/-* mice were 40% higher than in wild type mice however serum from *Cfd-/-* mice could not initiate AP activity without the addition of human fD. C3 levels in *Cfh-/-*;*Cfd-/-* and wild-type mice were comparable however even without fD serum from *Cfh-/-*;*Cfd-/-* mice was able to initiate AP activity based on hemolysis of rabbit erythrocytes and a positive C3-deposition assay. In the absence of fD, we found that the MASP-3 catalytic domain was capable of cleaving fB in the presence of C3b.

Conclusions: In the absence of fD, AP convertase assembly and activation can be initiated by the fB-cleavage activity of the lectin pathway serine protease MASP-3. This *in vivo* fD-bypass activation mechanism is always present but only becomes operational when the complement system is 'pushed' by the absence of both fH and fD. The implications of this bypass mechanism should be considered in fD-targeted treatment for C3G.

FR-OR064

Ex Vivo Formation of C5b9 on Endothelial Cells Differentiates Complement-Mediated Renal Failure from Hypertensive Nephrosclerosis in Severely Hypertensive Patients Sjoerd Timmermans,[2] Chris Reutelingsperger,[1] Pieter V. Paassen.[2] *[1]Maastricht University, Maastricht, Netherlands; [2]Maastricht University Medical Center, Maastricht, Netherlands. Group/Team: Limburg Renal Registry.*

Background: Severe hypertension (HTN) can induce renal failure due to hypertensive nephrosclerosis, a diagnosis rarely confirmed by biopsy assuming that the kidney is the victim rather than culprit of HTN. Underlying acute thrombotic microangiopathy (TMA) can therefore be missed, particularly in patients not presenting with microangiopathic hemolysis and thrombocytopenia. Moreover, it is critical to distinguish TMA due to shear stress from TMA dominantly caused by complement dysregulation, having major impact on treatment and prognosis.

Methods: To differentiate complement-mediated from shear stress-induced kidney injury in patients with severe HTN (blood pressure >180/120 mmHg) and renal failure, we analyzed serum-induced C5b9 formation on resting and ADP activated human microvascular endothelial cells (HMEC) by using samples from patients with severe HTN either with active TMA or hypertensive nephrosclerosis on kidney biopsy. Serum from patients with atypical hemolytic uremic syndrome (aHUS) and dense deposits disease (DDD) were used as positive and negative controls; all samples were compared with normal human serum run in parallel.

Results: Serum from 12 patients with HTN-associated TMA induced extensive C5b9 formation on resting (293%, $P<0.001$) and activated HMEC (318%, $P<0.001$), identical to aHUS samples ($n=3$; 344% and 394%, respectively). In contrast, samples from 5 patients with hypertensive nephrosclerosis induced scanty C5b9 formation on both resting (98%, $P=1.0$) and activated HMEC (108%, $P=0.7$), identical to DDD ($n=5$; 89% and 90%, respectively). C3c and C5b9 staining on kidney sections linked complement activation to TMA but not to nephrosclerosis. Moreover, genetic analysis confirmed complement defects in 6 (50%) out of 12 patients with HTN-associated TMA.

Conclusions: In conclusion, intrarenal solid phase complement dysregulation and ongoing TMA appears the dominant cause of renal failure in a subset of patients with severe HTN. The HMEC test differentiates complement-mediated TMA from other causes of HTN associated kidney injury, such as shear stress.

FR-OR065

Stem Cell-Derived Extracellular Vesicles Protect from VEGF-Induced Endothelial Damage in the Kidney Sargis Sedrakyan,[1] Valentina Villani,[1] Stefano Da Sacco,[1] Nikita Tripuraneni,[1] Stefano Porta,[2] Andrea Achena,[1] Maria J. Lavarreda-Pearce,[1] Astgik Petrosyan,[1] Hasmik Soloyan,[1] Roger E. De Filippo,[1] Benedetta Bussolati,[2] Laura Perin.[1] *[1]Children's hospital Los Angeles, Los Angeles, CA; [2]University of Torino, Torino, Italy.*

Background: Tight regulation of paracrine VEGF signaling between podocytes and glomerular endothelial cells (GEC) is required for maintenance of the glomerular filtration barrier structure and function. Disruption of VEGF signaling has been implicated in various types of glomerular diseases. However, current therapies neither specifically target the glomerulus nor the local VEGF but in addition, present multiple side effects. Therefore, identification of new approaches that will restore local VEGF signaling remains a potential therapeutic target to treat glomerular disease. We previously showed that amniotic fluid stem cells (AFSC) are renoprotective in Alport Syndrome (AS), a model of CKD. They home within the diseased glomeruli and secrete extracellular vesicles (EVs). EVs play a key role in stem cell-mediated paracrine function, including the kidney. Herein, we demonstrate that AFSC derived EVs regulate VEGF/VEGFRs signaling balance in AS GEC via a trapping mechanism involving VEGFR1 expressed on the surface of EVs.

Methods: We measured VEGF activity in AS glomeruli by WB. We also assessed VEGF/VEGFRs activity in GEC. We characterized AFSC-EVs cargo by FACS and by miRs arrays and evaluated their potential to affect VEGF biology in GEC and kidney function. EVs silenced for VEGFR1 were used to confirm VEGF trapping by VEGFR1.

Results: Glomeruli from AS mice at 3-months showed increased VEGF activity that was associated with GEC damage and subsequent onset of proteinuria. Treatment with EVs ameliorated the damage and improved kidney function by trapping and sequestration of VEGF. We found VEGFR1, present on the surface of EVs, responsible for this mechanism of action. EVs lacking both the full and soluble VEGFR-1 failed to rescue GEC from VEGF inflicted damage.

Conclusions: We demonstrated for the first time the aberration of VEGF signaling within AS glomeruli. We further showed that AFSC derived EVs play important role in maintaining glomerular homeostasis of VEGF signaling, presenting with a potential for new targeted therapies in CKD.

NG2 Lineage Cells Migrate onto the Glomerular Tuft and Bowman's Capsule with Expression of PEC Markers in Experimental FSGS Taihei Suzuki,[2] Jeffrey W. Pippin,[1] Diana G. Eng,[1] Stuart J. Shankland.[2] *[1]University of Washington, Seattle, WA; [2]Nephrology, University of Washington, Seattle, WA.*

Background: Glomerular regeneration typically relies on local stem/progenitor cells. After podocyte loss, parietal epithelial cells (PECs) and cells of renin lineage serve as adult podocyte progenitors. Although Neural/glial antigen 2 (NG2) cells are considered to have progenitor potency, their ability to participate in regeneration following podocyte loss is not fully understood. We sought to determine if NG2 lineage cells serve as adult glomerular stem/progenitors in disease.

Methods: We generated *NG2CreER tdTomato* reporter mice (n=11). Tamoxifen was given to 8 week-old mice to permanently label cells of NG2 lineage with the red fluorescent protein (RFP) tdTomato. After a washout period, podocytes were depleted with a cytopathic anti-podocyte antibody. Serial biopsies were taken at baseline, D14, and D28, to assess and fate map the behavior of NG2 lineage cells in individual mice.

Results: Podocyte number decreased by ~35% on D14 from baseline, and partially recovered on D28 ($p<0.05$ vs D14). Following podocyte loss, the percentage of glomeruli with RFP^+ cells increased two-fold on D14 and D28 ($p<0.05$ vs baseline). RFP^+ cells in glomeruli did not co-express podocyte proteins (synaptopodin, nephrin, podocin). Glomeruli with RFP^+ cells along Bowman's capsule increased significantly accompanied by increased PEC density, (PAX8 staining), at D14 and D28. Co-staining for PAX8 and src-suppressed C-kinase substrate to determine if the RFP+ cells along Bowman's capsule transdifferentiated to adult PECs showed that within individual mice, the percentage of glomeruli with $RFP^+/PAX8^+$, and $RFP^+/SSeCKS^+$ on Bowman's capsule increased significantly from baseline at both D14 and D28 following podocyte loss. Double-staining for RFP and BrdU for cell proliferation revealed that RFP^+ cells in glomerular tuft and capsule did not co-express BrdU.

Conclusions: We showed that after an abrupt loss of podocytes in an inducible reporter mouse, NG2 lineage cells migrated onto the glomerular tuft, but did not express podocyte proteins. However, a majority of NG2 labeled cells that migrated to Bowman's capsule co-expressed the PEC markers PAX8 and SSeCKS, which was accompanied by a higher PEC density. These results suggest that a subset of cells of NG2 lineage might serve as adult PEC stem/progenitors in glomerular disease.

Krüppel-Like Factor 4 Is a Negative Regulator of Aberrant Glomerular Epithelial Cell Proliferation Chelsea C. Estrada,[4] Yiqing Guo,[4] Praharshasai Paladugu,[4] Stephanie Cardona,[4] Monica P. Revelo Penafiel,[3] David J. Salant,[1] John C. He,[2] Sandeep K. Mallipattu.[4] *[1]Boston University Medical Center, Boston, MA; [2]Mount Sinai School of Medicine, New York, NY; [3]University of Utah, Murray, UT; [4]Stony Brook Medicine, Stony Brook, NY.*

Background: Pathologic glomerular epithelial cell (GEC) proliferation is characteristic of both RPGN and subtypes of FSGS. Although initial podocyte injury resulting in activation of signal transducer and activator of transcription (STAT) 3 signals GEC proliferation in both diseases, mechanism(s) regulating this process are largely unknown. Krüppel-Like Factor 4 (KLF4), a zinc finger transcription factor, is a negative regulator of proliferation and has recently been shown to inhibit STAT3 activation in neurons. Furthermore, KLF4 was previously shown to be renoprotective in proteinuric kidney disease. Based on these data, we hypothesize that podocyte-specific *Klf4* deletion exacerbates pathologic GEC proliferation by activation of STAT3 signaling.

Methods: Podocyte-specific *Klf4* knockout mice ($Klf4^{\Delta Pod}$) were generated on *C57BL/6* background by crossing $Klf4^{fl/fl}$ mice with *Podocin-Cre* mice. Nephrotoxic serum (NTS) nephritis was used to induce RPGN. $Klf4^{\Delta Pod}$ mice were backcrossed to a background susceptible to FSGS (*FVB/n*). Finally, human podocytes with stable knockdown of *KLF4* (*KLF4-shRNA*) and overexpression of *KLF4* (*lentiORF-KLF4*), with appropriate controls, were generated.

Results: Glomerular KLF4 expression was increased 7 days after NTS treatment. NTS-treated $Klf4^{\Delta Pod}$ (*C57BL/6*) mice exhibited increased crescent formation, parietal epithelial cell (PEC) proliferation (Claudin1, Ki67), serum creatinine, and STAT3 signaling (phospho-STAT3, *Il-6, Socs3* expression) as compared to NTS-treated wildtype mice. Untreated backcrossed $Klf4^{\Delta Pod}$ (*FVB/n*) mice exhibited STAT3 activation, cellular FSGS with PEC proliferation, renal failure, and a 50% increase in mortality as compared to wildtype mice at 12 weeks of age. Furthermore, basal STAT3 activation was significantly increased in wild-type *FVB/n* as compared to the *C57BL/6* strain. Differentiated *KLF4-shRNA* podocytes also exhibited increased STAT3 activation with mitotic catastrophe (re-entry into cell cycle, actin destabilization) leading to reduced survival as compared with *EV-shRNA* podocytes. Conversely, these changes were rescued with re-induction of *KLF4* (*lentiORF-KLF4)* in cultured podocytes.

Conclusions: Collectively these data suggest that KLF4 is a key regulator of STAT3-mediated aberrant GEC proliferation in RPGN and FSGS.

Effects of the Potassium Binding Polymer Patiromer on Markers of Mineral Metabolism David A. Bushinsky,[2] David M. Spiegel,[3] Jinwei Yuan,[3] Suzette Warren,[3] Pablo E. Pergola.[4] *[2]Division of Nephrology, University of Rochester Medical Center, Rochester, NY; [3]Relypsa, Inc., a Vifor Pharma Company, Redwood City, CA; [4]Renal Associates, PA, San Antonio, TX.*

Background: Patiromer is a non-absorbed potassium (K)-binding polymer approved for treatment of hyperkalemia (HK), which uses calcium (Ca) as the counter-exchange ion. The 4-week TOURMALINE study in patients with HK demonstrated that patiromer once-daily (QD) reduces serum K when given without food similarly to when given with food. Here we report data from TOURMALINE on markers of mineral metabolism.

Methods: Initial patiromer dose was 8.4 g QD and was adjusted to achieve and maintain serum K between 3.8-5.0 mEq/L. In this prespecified analysis, baseline and week 4 (wk 4) serum and 24-hour urine (u) markers of mineral metabolism normalized for u-creatinine (Cr) excretion, to correct for collection errors, are reported for the overall population of 112 patients. All values are mean ± SE; p values are for change from baseline by paired t-test.

Results: Baseline serum Ca and phosphate (P) were 9.31 ± 0.06 and 4.10 ± 0.07 mg/dL, respectively, and were not different at wk 4 (9.34 ± 0.06 and 3.99 ± 0.07 mg/dL, respectively). In the 16 patients with elevated serum P (> 4.8 mg/dL) at baseline, patiromer decreased P from 5.32 ± 0.11 to 4.68 ± 0.26 mg/dL at wk 4 ($p<0.02$). In the overall population, Cr-normalized uP decreased from 628.2 ± 28.2 at baseline to 573.6 ± 29.4 mg/24 hr at wk 4 ($p<0.01$). Cr-normalized uCa was 50.8 ± 6.4 at baseline and did not change at wk 4 (58.5 ± 6.7 mg/24 hr; $p=0.1$). Serum $1,25(OH)_2D$ levels decreased from 37.3 ± 1.6 at baseline to 34.1 ± 1.7 pg/mL at wk 4 ($p<0.05$), while PTH decreased from 85.1 ± 5.6 at baseline to 65.2 ± 4.5 pg/mL at wk 4 ($p<0.0001$). There were no changes in mean levels of FGF-23 or 25(OH)D.

Conclusions: In addition to lowering serum K, patiromer decreased mean uP excretion in the overall population and mean serum P in patients with hyperphosphatemia, while not changing mean uCa or mean serum Ca. PTH and $1,25(OH)_2D$ both decreased. These findings suggest that when patiromer exchanges intestinal K for Ca, some of the released Ca binds to intestinal P lowering uP and serum P in hyperphosphatemic patients and some of the Ca is absorbed, lowering PTH and $1,25(OH)_2D$ without changing serum Ca.

Erythropoietin Is Associated with Total FGF23 Levels in Mice and Humans with CKD Mark R. Hanudel,[1] Maxime Rappaport,[1] Victoria R. Gabayan,[2] Tomas Ganz,[2] Elizabeta Nemeth,[2] Isidro B. Salusky.[1] *[1]Department of Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Department of Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: We have previously demonstrated that exogenous erythropoietin (EPO) acutely increases bone and circulating FGF23 levels in mice and humans with normal kidney function. It is unknown if EPO has similar effects on FGF23 in the setting of CKD.

Methods: We administered a single dose of EPO to wild type mice with adenine diet-induced CKD. We evaluated associations between serum EPO levels and circulating FGF23 in adult and pediatric non-dialysis CKD patients, and between recombinant human EPO (rhEPO) doses and circulating FGF23 in adult and pediatric dialysis patients.

Results: At six hours post-injection, compared to CKD mice injected with saline, CKD mice intraperitoneally injected with 70 U/g rhEPO demonstrated a 10-fold increase in bone *Fgf23* mRNA expression and a 5-fold increase in plasma C-terminal (total) FGF23 (cFGF23) levels, but only a 3-fold increase in plasma intact FGF23 (iFGF23) levels, with a 40% decrease in percentage iFGF23 (iFGF23/total FGF23 x 100%). These data suggest that EPO-induced increases in *Fgf23* mRNA expression are coupled with increased FGF23 proteolytic cleavage. In 70 adult and pediatric non-dialysis CKD patients, after adjustment for eGFR ($p<0.001$) and phosphate ($p<0.001$), serum EPO levels positively associated with Log cFGF23 (std. coeff. 0.25, $p=0.010$; model adjusted $R^2=0.44$). The association remained significant ($p=0.023$; model adjusted $R^2=0.42$) after further adjustment for age, calcium, Log PTH, TSAT, Log ferritin, Hgb, and Log CRP, none of which were independently associated with Log cFGF23. Unlike cFGF23, Log iFGF23 was not significantly associated with EPO levels. In 79 adult and pediatric dialysis patients, after adjustment for age ($p<0.001$), phosphate ($p<0.001$), calcium ($p=0.013$), Log CRP ($p=0.015$), and Log ferritin ($p=0.018$), Log rhEPO dose positively associated with Log cFGF23 (std. coeff. 0.23, $p=0.013$; model adjusted $R^2=0.44$). The association remained significant ($p=0.016$; model adjusted $R^2=0.43$) after further adjustment for Log PTH, TSAT, and Hgb, none of which were independently associated with Log cFGF23. Similar to the non-dialysis CKD patients, Log rhEPO dose was not significantly associated with Log iFGF23.

Conclusions: In CKD patients, erythropoietin has stronger associations with total FGF23 than intact FGF23, suggesting coupling of increased production with increased cleavage.

FR-OR070

Ferric Citrate Administration Reduces FGF23 Production and Improves Renal Function in a Mouse Model of CKD Connor Francis,[2] Guillaume Courbon,[2] Samantha Neuburg,[2] Claire Gerber,[2] Xueyan Wang,[2] Corey Dussold,[2] Lixin Qi,[2] Aline Martin,[2] Myles S. Wolf,[1] Valentin David.[2] *[1]Duke University, Durham, NC; [2]Northwestern University - Feinberg School of Medicine, Chicago, IL.*

Background: Elevated levels of fibroblast growth factor 23 (FGF23) are strongly associated with cardiovascular disease, mortality, and progression of chronic kidney disease (CKD). Hyperphosphatemia and iron deficiency are powerful stimuli of FGF23 production. This suggests that reducing dietary phosphate intake or absorption and increasing serum iron may lower FGF23 levels and improve clinical outcomes in CKD.

Methods: We tested the hypotheses that ferric citrate treatment will simultaneously correct iron deficiency and also bind to dietary phosphate in the $Col4a_3^{ko}$ mouse model of progressive CKD. We fed 4 week-old wild-type (WT) and $Col4a_3^{ko}$ (CKD) mice, a control (Ctr) or a 5% Ferric Citrate enriched (FC) diet for 6 weeks and performed biochemical, molecular and histological analyses.

Results: At ten weeks, Ctr-CKD animals displayed a decline in renal function, as shown by a 8 fold increase in Blood Urea Nitrogen (BUN) and urinary albumin, signs of iron deficiency anemia, evidenced by low serum iron (99±12 vs 128±5 mg/dL) and hemoglobin (15±1 vs 19±1 g/dL), as well as a 2 fold increase in serum phosphate ($p<0.05$ vs WT). This was concomitant with a marked increase in both total (tFGF23, which includes intact and cleaved proteins) and intact FGF23 (iFGF23) serum levels, compared to WT (11426±2623 vs. 433±32 and 7312±1749 vs. 207±57 pg/mL respectively, $p<0.05$). In addition, serum 1,25 Vitamin D levels were low (34±7 vs 143±45 pg/mL) in Ctr-CKD animal ($p<0.05$, vs. Ctr-WT). Ferric citrate increased serum iron levels by 1.6 fold in CKD mice and resulted in a 1.5 fold serum phosphate reduction ($p<0.05$, vs. Ctr-CKD). In addition, tFGF23 and iFGF23 were reduced by 4 and 3 fold respectively and serum 1,25 Vitamin D levels increased by 2 fold in FC-CKD mice ($p<0.05$ vs. Ctr-CKD). Interestingly, the FC diet also decreased BUN (127±21 vs. 218±24 mg/dL) and 24h urine albumin (101±69 vs. 586±91 µg) ($p<0.05$ vs. Ctr-CKD). Reductions in interstitial fibrosis and tubular dystrophy were also evident by histology in FC-CKD animals compared to Ctr-CKD group.

Conclusions: Our data show that ferric citrate administration in CKD mice reduces the magnitude of FGF23 increase and slows disease progression. This suggests that ferric citrate might mitigate renal injury.

Occurrence of Hypophosphatemia Following IV Iron Treatment: Results from a Randomized Controlled Trial Myles S. Wolf,[2] William Strauss,[1] Kristine Bernard,[1] Naomi V. Dahl,[1] Robert F. Kaper,[1] Julie S. Krop.[1] *[1]AMAG Pharmaceuticals, Inc., Waltham, MA; [2]Duke University, Durham, NC.*

Background: Hypophosphatemia is a common complication of administration of certain IV irons. For example, 32.1% of patients with gastrointestinal disorders who received treatment with ferric carboxymaltose (FCM) developed hypophosphatemia, <0.6 mmol/L (1.9 mg/dl) (Schaefer et al., PLoS ONE 2016). Acute increases in circulating levels of intact fibroblast growth factor 23 (FGF23) mediate hypophosphatemia due to renal phosphate wasting in response to FCM, but not iron dextran, suggesting that the specific carbohydrate moieties might be involved in the differential FGF23 response to IV iron (Wolf et al., Bone Min Res, 2013). While initially considered a transient and benign laboratory finding, reports are accumulating of significant clinical sequelae associated with chronic FCM-associated hypophosphatemia.

Methods: In a large RCT (NCT02694978) that compared the safety and efficacy of standard courses of ferumoxytol (FER, 510mg x 2 doses; N=997), vs. FCM (750mg x 2 doses; N=1000) in patients with iron deficiency anemia of any etiology except dialysis-dependent CKD, we measured serum phosphate and fractional excretion of phosphate (FEPi) at baseline, day 8 (prior to dose 2), week 2 and week 5.

Results: Mean baseline serum phosphate was 1.22 mmol/L (3.8 mg/dl) and FEPi was 15.7% in both groups. Among patients receiving FCM, serum phosphate decreased significantly, and FEPi increased significantly at all time points compared to ferumoxytol-treated patients ($P<0.0001$; Figure). Serum phosphate <0.6 mmol/L (1.9 mg/dl) occurred in 38.7% of FCM patients, and only 0.4% of FER patients.

Conclusions: FCM induced a marked drop in blood phosphorus occurring as soon as 8 days following 750mg of FCM secondary to a significant increase in FEPi. Almost 40% of patients developed at least moderate hypophosphatemia. These changes did not occur following FER.

FR-OR072

Cardiac Hypertrophy Elevates Serum FGF23 Karin Shimada, Isao Matsui, Tatsufumi Oka, Daisuke Mori, Nobuhiro Hashimoto, Ayumi Matsumoto, Satoshi Yamaguchi, Keiichi Kubota, Sayoko Yonemoto, Yusuke Sakaguchi, Takayuki Hamano, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita, Japan.*

Background: FGF23 is a potent phosphaturic hormone predominantly produced by the bone. Although several studies have revealed FGF23 induces left ventricular hypertrophy (LVH), effect of LVH on FGF23 remains uncertain.

Methods: The activation of calcineurin/NFAT pathway plays pivotal roles in the development of pathological LVH. Therefore, we performed experiments using cardiomyocyte-specific calcineurin A transgenic (TG) mice.

Results: The TG mice at 6-week-old showed severe LVH. Body weight, systolic blood pressure, food intake, water intake, urinary volume, and creatinine clearance were not different between wild type (WT) and the TG mice. We found that serum intact FGF23 (iFGF23) in the TG mice were elevated (TG 125.6 ± 16.1 vs. WT 87.5 ± 10.1 pg/mL, $P=0.0107$). Both real time PCR and immunohistochemistry revealed that the elevation of iFGF23 in the TG mice was derived from hypertrophic cardiomyocytes but not from the bone. The promoter region of the FGF23 gene contained two putative NFAT-biding sites. Luciferase assay showed that NFAT1 activates the promoter in a proximal NFAT-binding site dependent manner. Although serum level of iFGF23 was elevated in the TG mice, all parameters — serum, urinary, and fractional excretion of calcium/phosphate, and serum $1,25(OH)_2$ vitamin D — were not different between the WT and the TG mice. Renal levels of α-klotho were also at comparable levels between the two groups. We found that plasma ADH levels of the TG mice were higher than those of the WT mice (TG 1.01 ± 0.68 vs. WT 0.40 ± 0.46 pg/mL, $P=0.0306$). To investigate the effects of ADH on the function of FGF23, we injected ADH and/or FGF23 into WT mice. As previously reported, FGF23 suppressed renal mRNA levels of CYP27B1. The suppression of CYP27B1 was restored by ADH. In addition, FGF23-dependent elevation of CYP24 was suppressed by ADH. Both FGF23 and ADH did not affect expression levels of α-klotho in the kidney.

Conclusions: Hypertrophic cardiomyocyte produces FGF23. Proximal NFAT-binding site in the FGF23 gene promoter was important for the transcriptional regulation of FGF23. ADH causes FGF23-resistance in the kidney.

Funding: Private Foundation Support

FR-OR073

Different Outcome of Cardiac Remodeling in Two Mouse Models with FGF23 Excess and Klotho Deficiency Beatrice Richter,[5] Melis Basaran,[6] Ioana Alesutan,[7] Jakob Voelkl,[4] Florian C. Lang,[1] Dieter Haffner,[3] Maren Leifheit-Nestler.[2] *[1]Department of Cardiology, Vascular Medicine and Physiology, University of Tuebingen, Tuebingen, Germany; [2]Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [3]Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [4]Department of Internal Medicine and Cardiology, Center for Cardiovascular Research, Charité University Medicine, Berlin, Germany; [5]Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [6]Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [7]Department of Internal Medicine and Cardiology, Center for Cardiovascular Research, Charité University Medicine, Berlin, Germany.*

Background: High levels of fibroblast growth factor-23 (FGF23), phosphate and parathyroid hormone (PTH) as well as deficiency in active vitamin D (1,25D) and klotho are strongly associated with the development of cardiovascular disease, including left ventricular hypertrophy and myocardial fibrosis. *In vivo*, klotho and 1,25D improve cardiac hypertrophy and *in vitro*, klotho inhibits fibroblast activation and collagen synthesis in the heart and protects against FGF23-induced oxidative stress.

Methods: Heart tissue from two mouse models with high FGF23 serum levels and klotho deficiency was analyzed: 1) klotho hypomorphic ($KL^{-/-}$) mice displaying both high phosphate and 1,25D levels, but low PTH; 2) *Hyp* mouse presenting high PTH, but low plasma levels of phosphate and 1,25D.

Results: For both mouse models an enhanced relative heart weight and raised cross-sectional area of cardiomyocytes were detected when compared to respective wild type controls. In $KL^{-/-}$ mice, a clear increase of cardiac Fgf23, Fgfr4, activation of calcineurin/NFAT signaling and induction of pro-hypertrophic genes *Rcan1, BNP, ANP* and *bMHC* was seen. Furthermore, $KL^{-/-}$ mice showed an enhanced expression of transcription factors (Cebpb, Gata4) and fibrosis-related factors (*Tgfb1, collagen 1, Mmp2*) that are involved in cardiac remodeling events. In contrast, *Hyp* mice presented a strong increase of cardiac *Fgf23* mRNA and intact cardiac Fgf23 protein as well, but missed the induction of the Fgfr4/calcineurin/NFAT pathway. Moreover, the expression of the pro-hypertrophic markers *BNP, ANP, bMHC* and pro-fibrotic factors was absent in *Hyp* mice.

Conclusions: Despite the FGF23 excess, high PTH, low 1,25D and reduced klotho, it seems that *Hyp* mice are protected from the development of pathological heart changes may be due to hypophosphatemia. Contrary, $KL^{-/-}$ mice show induced cardiac hypertrophy and fibrosis though high 1,25D plasma levels.

FR-OR074

Fibroblast Growth Factor 23 (FGF23) Regulates PTH Levels through FGF Receptor Signaling In Vivo at Normal, but Not at Low, Plasma Calcium Maria L. Mace,[2] Eva Gravesen,[3] Anders Nordholm,[2] Jacob Hofman-Bang,[3] Klaus Olgaard,[1] Ewa Lewin.[2] *[1]Copenhagen University, Copenhagen, Denmark; [2]Herlev Hospital, Herlev, Denmark; [3]Rigshospitalet, Copenhagen, Denmark.*

Background: The regulation of PTH secretion is primarily mediated by calcium. FGF23 is a bone derived phosphatonin that requires klotho as a co-receptor for binding to the FGF receptors (FGFR). Parathyroid cells express both Klotho and FGFRs, however, the physiological function of FGF23 in the parathyroid gland is not fully clarified. Parathyroid cells lose rapidly their calcium-sensing responsiveness *ex vivo*, and no functional parathyroid cell line has been established. Therefore the aim of the present investigation was to study FGF23's regulation of PTH levels *in vivo*.

Methods: Wistar rats were randomized to FGFR inhibition by PD173074 (20-40mg) or vehicle. Acute hypocalcemia was induced by a continuous intravenuous EGTA infusion (40mM, 3ml/h) in normal rats and rats after prior FGFR inhibition. Increasing doses (0.1, 1, and 10 μg) of recombinant FGF23 were given to normal rats and rats after prior FGFR inhibition. Plasma Ca^{++}, phosphate, FGF23 and PTH were measured.

Results: Acute inhibition of FGFR resulted in a decrease in p-FGF23 (364±22 to 154±18 pg/ml, $p<0.05$) and a concomitant increase in p-PTH levels (134±34 to 685±285 pg/ml, $p<0.01$). The PTH secretory response was challenged by acute severe hypocalcemia (p-Ca^{++} decreased from 1.37±0.01 to 0.98±0.03 mmol/l, $p<0.01$). Again at normocalcemia PTH increased in FGFR inhibited rats (85±13 to 182±10 pg/ml), while the maximal PTH secretion at low p-Ca^{++} was not different in FGFR inhibited rats compared to vehicle treated rats (347±61 vs. 316±22 pg/ml). Exogenous rFGF23 0.1 μg inhibited rapidly, at 20 min, PTH levels in normal rats (137±71 to 10±4 pg/ml, $p<0.05$). In FGFR inhibited rats 0.1 μg rFGF23 did not suppress PTH levels (270±50 vs. 347±62 pg/ml). Higher doses of rFGF23 resulted in very high levels of p-FGF23 (12,000 & 120,000 pg/ml), still these high levels had no effect on PTH levels when the FGFR was inhibited.

Conclusions: FGF23 regulates PTH tonus in vivo via the FGF receptor. The inhibitory effect of FGF23 on PTH is present at normal range of plasma Ca^{++}, but not at low Ca^{++} levels, when increased PTH secretion is needed.

FR-OR075

Acute and Mid-Term Mineral Disturbances Following Kidney Donation Kenneth Lim,[1,4] Jane C. Smith,[4] Carmel M. McEniery,[4] Laurie A. Tomlinson,[2] Ian Wilkinson,[4] Thomas F. Hiemstra.[3,4] *[1]Division of Nephrology, Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]London School of Hygiene and Tropical Medicine, London, United Kingdom; [3]University of Cambridge, Cambridge, United Kingdom; [4]School of Clinical Medicine, University of Cambridge, Cambridge, United Kingdom.*

Background: Unilateral nephrectomy performed for live transplant donation is increasing due to a greater demand for available organs. To counteract the growing transplant waiting list, the opportunity to donate organs has been extended to a broader population. However, these expanded criteria donors (ECDs) maybe at greater risk from a fall in GFR following unilateral nephrectomy. While emerging studies have demonstrated profound mineral disturbances that occur following kidney donation, whether acute disturbances in mineral homeostasis occur following unilateral nephrectomy is currently unknown.

Methods: We conducted the KARMA (Effect of Kidney Donation on Bone and Mineral Metabolism) study, a prospective controlled observational cohort study. Biochemical parameters were determined before and acutely after kidney donation on days 1-3 with mid-term follow-up at 6 weeks and 12 months in the donor group and at baseline, 6 weeks and 12 months in the control group.

Results: We enrolled 34 donors (59% male) and 34 healthy controls (47% male). Both groups had similar characteristics: mean (±SD) age (53±10 vs 50±14 years, p=0.33), BMI (26±2.8 vs 25.9±3.7, p=0.59), systolic BP (128±13 vs 130±6, p=0.59), diastolic BP (80±9 vs 81±9, p=0.68) and baseline GFR (84.4±20.2 vs 83.6±25.2 ml/min/1.73m^2, p=0.89). Kidney donation reduced eGFR significantly from 84.4±20.2 to 52.3±17.5 ($p<0.001$) acutely by day 1 and remained lower than baseline by 6 weeks (60.0±20.0; $p<0.001$) and 12 months (88.6±24.3; $p<0.001$). Phosphate levels increased from baseline by day 1 (1.1[0.9,1.2] to 1.3[1.1, 1.4], $p<0.001$) and then declined to 0.8[0.8, 1.0] by day 2 ($p<0.001$) before normalizing by 6 weeks. Albumin-corrected calcium declined on day 1 (p=0.003) but did not differ at 6 weeks or 12 months after donation. PTH levels did not rise significantly from baseline until 1 year (4.77[3.39, 5.8] vs 5.8[4.56, 8.7]; p=0.018). FGF-23 levels were statistically unchanged at all time points. However, soluble α-Klotho levels were significantly reduced by day 1 (p=0.001) and remained low at 6 weeks (p=0.02) and 1 year (p=0.04).

Conclusions: Profound mineral disturbances occur acutely after kidney donation. Acute mineral disturbances in phosphate and calcium occur independently of changes in the phosphaturic hormones, PTH and FGF-23. Serum α-Klotho levels decline acutely following unilateral nephrectomy.

FR-OR076

Quantitative Systems Pharmacology (QSP) Model of Metabolic Bone Disease in ESRD Michael E. Brier,[1] Matthew J. Graves,[1] Eleanor D. Lederer,[2] Adam E. Gaweda.[1] *[1]University of Louisville, Louisville, KY; [2]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

Background: Metabolic bone disorder (MBD), a universal complication of chronic kidney disease (CKD), is a recognized contributor to the accelerated mortality of CKD patients but achieving established goals for therapy is challenging. We tested the hypothesis that a QSP model of MBD-CKD could provide a precision medicine tool to guide pharmacologic interventions for MBD.

Methods: We modified the Peterson-Riggs (Bone 2010) model of phosphate (PO4), calcium (Ca), PTH, and Calcitriol (CTL) in CKD to apply to end-stage renal disease patients. The model consists of a set of nonlinear differential equations describing the regulation of serum PO4, Ca, PTH, and CTL, implemented in Matlab, and includes the effect of intermittent hemodialysis and the administration of phosphate binders, cinacalcet, and vitamin D analogs. We tested the model by simulating the administration of different agents and performed a Sensitivity Analysis to identify key model components. Data were obtained from in-center dialysis patients at the University of Louisville.

Results: The QSP model accurately predicts the concentration time profile of PTH following repeated administration of cinacalcet and CTL and the impact of intermittent hemodialysis on the serum concentrations of Ca and PO4. Sensitivity Analysis results for the top 5/100 parameters along with the contribution of each of the individual components are shown. The table entries represent the correlation between the model parameters and goodness of fit for an individual patient. The model is most sensitive to flux of PO4, kidney PO4 excretion, and Ca absorption and hydroxyapatite conversion.

Conclusions: We conclude that a QSP model of MBD-CKD accurately predicts the serum concentrations of PO4, Ca, PTH, and CTL and that these predictions are heavily influenced by PO4 flux, PO4 excretion sensitivity, and availability of Ca.

Parameter	PTH	Ca	PO4	CTL	Total
k85	0.01	-0.06	0.11	-0.39	0.57
d59	-0.04	-0.01	-0.08	0.42	0.55
T13	-0.34	-0.08	-0.06	-0.06	0.54
k58	-0.05	-0.02	-0.08	0.38	0.54
T15	0.33	0.03	0.08	0.05	0.49

k85 and k58 PO4 transfer rate between serum and intracellular compartment; d59 kidney phosphate excretion sensitivity; T13 normalized calcium absorption rate; and T15 hydroxyapatite conversion rate

FGF23 Trajectories Among Patients Undergoing Chronic Hemodialysis in the HEMO Study Anna J. Jovanovich,[2] Zhiying You,[5] Kristen L. Nowak,[8] Lilia Cervantes,[1] Tamara Isakova,[4] Myles S. Wolf,[3] Michel Chonchol,[6] Jessica B. Kendrick.[7] *[1]Denver Health, Denver, CO; [2]Denver VA / University of Colorado, Denver, CO; [3]Duke University, Durham, NC; [4]Feinberg School of Medicine, Northwestern University, Chicago, IL; [5]UC Denver, Aurora, CO; [6]University of Colorado, Aurora, CO; [7]University of Colorado Denver and Denver Health Medical Center, Denver, CO; [8]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO.*

Background: Single measurements of elevated circulating levels of fibroblast growth factor 23 (FGF23) are associated with all-cause mortality in patients with end stage kidney disease (ESKD); however, long-term patterns in FGF23 levels have been poorly characterized. The objective of this study was to identify common FGF23 trajectories in patients with ESKD, and to evaluate predictors and outcomes among trajectories.

Methods: The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum intact FGF23 (iFGF23) levels were measured in stored serum samples obtained at baseline and annually in this cohort. Among 919 HEMO participants with at least two measurements of iFGF23, latent mixture modeling was used to identify trajectories of iFGF23 over time. Logistics regression models were employed to identify demographics, cardiovascular risk factors, markers of mineral metabolism and other variables associated with trajectory group membership. Cox regression models were used to examine the association between trajectory group and all-cause mortality.

Results: We identified 5 distinct FGF23 trajectories during the initial 2 years of the HEMO study: low-stable (16.8%; n=154), moderate-increasing (17.3%; n=159), elevated-increasing (27.5%; n=253); elevated-stable (25.4%; 233) and moderate-decreasing (13.1%; n=120). The only predictors of the moderate decreasing trajectory versus the low-stable trajectory were lower serum calcium (OR: 0.50; 95% CI 0.35-0.71; p <0.0001), lower serum phosphorus (OR: 0.64; 95% CI 0.53-0.78; p=0.0001), and lower serum interleukin-6 (0.58; 95% CI 0.39-0.87; p=0.009). In fully adjusted analyses, participants with elevated-stable FGF23 trajectory were at higher risk of death (HR: 1.61 95% CI 1.10-2.40; p=0.01) compared with the low-stable group trajectory.

Conclusions: FGF23 trajectories in patients undergoing hemodialysis vary and higher FGF23 trajectories are associated with an increased risk of death. Lower serum calcium and interleukin-6 appear to be important predictors of decreasing FGF23 levels.

Athena Study Outcomes on Allograft Function after 12 Months with Everolimus-Based versus Tacrolimus-MPA Regimen in De Novo Renal Transplant Recipients Friedrich Thaiss,[9] Barbara M. Suwelack,[3] Claudia Sommerer,[11] Duska Dragun,[10] Ingeborg A. Hauser,[2] Peter Schenker,[6] Oliver Witzke,[8] Christian Hugo,[12] Nassim Kamar,[7] Pierre Merville,[5] Martina Junge,[4] Björn Nashan.[1] *[1]Bundesärztekammer, Hamburg, Germany; [2]University Clinic Frankfurt (UKF), Frankfurt Main, Germany; [3]Muenster, Germany; [4]Novartis Pharma GmbH Germany, Nuremberg, Germany; [5]PELLEGRIN HOSPITAL, Bordeaux, France; [6]Ruhr-University Bochum, Bochum, Germany; [7]Toulouse University Hospital, Toulouse, France; [8]University Duisburg-Essen, Essen, Germany; [9]University Hospital, Hamburg, Germany; [10]University Hospital Charite, Campus Virchow, Berlin, Germany; [11]University Hospital of Heidelberg, HEIDELBERG, Germany; [12]University of Dresden, Dresden, Germany, Dresden, Germany. Group/Team: Athena Study Group.*

Background: The ATHENA study was designed to compare efficacy, safety and outcomes on renal function [GFR] of everolimus [EVR] combined with tacrolimus [TAC] or cyclosporine A [CyA] vs. a standard regimen of mycophenolic acid [MPA] +TAC in de novo kidney transplant [KTx] recipients.

Methods: In this 12 months [M], prospective, randomized study with 15 German and 12 French sites, 612 patients [pts] were randomized 1:1:1 at time of Tx to either EVR (3-8ng/ml M1-M12) +TAC (4-8ng/ml M1-M3; 3-5ng/ml M3-M12), or EVR (3-8ng/ml M1-M12) + CyA (75-125ng/ml M1-M3; 50-100ng/ml M3-M12) or control TAC (4-8ng/ml M1-M3; 3-5ng/ml M3-M12) +MPA. Steroids were to be continued. Here we report M12 outcomes on allograft function from ITT full analysis set with 208 EVR+TAC vs 199 EVR+CyA vs 205 TAC+MPA pts.

Results: From rdz to M12 allograft recovery was good in all 3 treatment groups with increase in GFR (Nankivell) as ΔeGFR M1-M12: a) EVR+TAC +6.6ml/min, b) EVR +CyA +9.6ml/min, c) TAC+MPA +7.6 ml/min (not significantly different). Analysis of donor age categories [<35; 35-49; 50-64; >65 years] showed that donor age >65years had worst renal allograft outcomes, regardless of treatment. Urinary protein excretion at M12 was not different between groups with a category analysis showing only 3.7% of TAC+MPA vs 1.3% of TAC+EVR vs 0.7% of CyA+EVR pts had proteinuria in nephrotic range [>339mg/mmol] at M12.

Conclusions: ATHENA, the largest European KTx study, showed comparable improvement in renal allograft function between all treatment groups with no difference in measured urinary protein excretion after 12 Mo drug exposure. Strongest impact on post Tx GFR appears to be determined by donor age, which is shown here for the first time in a large prospective study.

HLA-DQ Mismatching and Kidney Transplant Outcomes: A UNOS/OPTN Analysis Napat Leeaphorn, J. ryan Pena, Natanong Thamcharoen, Eliyahu V. Khankin, Martha Pavlakis, Francesca Cardarelli. *Beth Israel Deaconess Medical Center, Brookline, MA.*

Background: Recent evidence suggests that HLA epitope-mismatching at HLA-DQ loci is strongly associated with the development of anti-DQ donor-specific antibodies (DSA) and adverse graft outcomes. However, the clinical significance of broad antigen HLA-DQ mismatching (MM) in predicting graft outcomes is not well examined. Using UNOS/OPTN data, we analyzed the effect of HLA-DQ MM on graft outcomes.

Methods: Patients with primary kidney transplants performed between 2007 and 2015 were included. Patients were classified as having either zero HLA-DQ MM, one or two HLA-DQ MM. Primary outcomes were death-censored graft survival (DCGS), and incidence of acute rejection.

Results: 95,664 patients were included in the analysis, with median follow-up time of 3.45 years. Of these, 22,379 (23.39%) and 73,294 (76.61%) received zero and one or two HLA-DQ MM kidneys, respectively. After adjusting for HLA-ABDR, various recipient and donor variables and initial immunosuppression, HLA-DQ MM was associated with an increased risk of graft loss in living donor kidney transplant (LDKT) recipients with an adjusted hazard ratio (HR) of 1.12 (95% CI, 1.01-1.26; p=0.042), but not in deceased donor kidney transplant (DDKT) recipients (HR 1.07, 95% CI, 0.99-1.53; p=0.066). When taking cold ischemic time (CIT) into account, HLA-DQ MM was an independent factor for an increased risk of graft loss in DDKT recipients with CIT ≤ 17 hours (HR 1.15, 95% CI 1.03-1.27; p=0.010), but not in DDKT recipients with CIT > 17 hours (HR 1.00, 95% CI, 0.90-1.11; p=0.971). Compared with recipients who received zero HLA-DQ MM kidneys, those who received one or two HLA-DQ MM kidneys had a higher incidence of acute rejection at 1-year with adjusted odd ratios of 1.12 (95% CI, 1.02-1.22; p=0.012) in DDKT and 1.14 (95% CI, 1.03-1.28; p=0.016) in LDKT, respectively.

Conclusions: HLA-DQ mismatching is a predictor for graft survival and acute rejection independent of mismatching of HLA-ABDR and initial immunosuppression. Cold ischemic times of longer than 17 hours appear to obviate the benefit of zero HLA-DQ MM.

FR-OR080

Donor-Derived Cell-Free DNA Improves DSA-Informed Diagnosis of ABMR in Kidney Transplant Patients Stanley C. Jordan,[1] Arthur J. Matas,[2] Suphamai Bunnapradist,[3] Anthony J. Langone,[4] David Hiller,[5] Robert Woodward,[5] Marica Grskovic,[5] John J. Sninsky,[5] Jim Yee.[5] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]University of Minnesota, Minneapolis, MN; [3]UCLA, Los Angeles, CA; [4]Vanderbilt University Medical Center, Nashville, TN; [5]CareDx, Brisbane, CA.*

Background: Donor-derived cell-free DNA (dd-cfDNA) discriminates active T cell mediated (TCMR) and antibody mediated rejection (ABMR) in kidney transplant patients. Many transplant patients are monitored with donor-specific antibodies (DSA), which is a risk factor for ABMR. This study assesses the combined use of dd-cfDNA and DSA to diagnose active rejection and subtypes of rejection.

Methods: dd-cfDNA (AlloSure) was assayed in 107 blood samples with paired clinically indicated biopsies from 102 kidney transplant patients from the DART multicenter study (NCT02424227). Patients were divided into those who had prior or current positive DSA (DSA+, n=33 samples) and those who did not (DSA-, n=74 samples). DSA+ cutoffs were determined by center. Prevalence of biopsy-based diagnosis of rejection was computed. Mixed rejections were included in the ABMR group. Samples were further divided into dd-cfDNA > 1% (dd-cfDNA+) and dd-cfDNA ≤ 1% (dd-cfDNA-), and PPV of dd-cfDNA to predict ABMR and TCMR within DSA+ and DSA- patients were computed.

Results: DSA+ patients were 47 ± 14 years old, 48% Caucasian, and 58% male. DSA- patients were 53 ± 13 years old, 51% Caucasian, 62% male. 40% of DSA+ and no DSA- patients had ABMR. PPV of dd-cfDNA+ to detect ABMR in DSA+ patients is 76% (95% CI, 63%-100%). 14% of DSA+ and 13% of DSA- patients had TCMR. PPV of dd-cfDNA to detect TCMR in DSA+ patients is 25% (95% CI, 0%-54%) and in DSA- patients is 22% (95% CI 0%-44%). 13/16 DSA+, dd-cfDNA+ patients had ABMR and 1/16 had TCMR. 3/17 DSA+, dd-cfDNA- patients had ABMR and 3/17 had TCMR. 2/12 DSA-, dd-cfDNA+ patients had TCMR. 5/62 DSA-, dd-cfDNA- patients had TCMR.

Conclusions: Donor-derived cell free DNA may be used in conjunction with DSA status to improve the diagnosis of rejection in kidney transplant patients. Patients with dd-cfDNA+/ DSA+ have highest probability of rejection, most likely ABMR. Patients with dd-cfDNA-/DSA+ have a medium probability of rejection, either TCMR or ABMR. Since DSA is required to diagnose ABMR (Banff 2013), DSA- patients can only have TCMR. Patients with dd-cfDNA+/DSA- have a medium probability of TCMR and patients with dd-cfDNA-/DSA- have a low probability of TCMR.

A Substantial Fraction of Standard-of-Care Transplant Biopsies Have Clinically Actionable Findings Evan A. Farkash, Ali K. Shammout. *University of Michigan, Ann Arbor, MI.*

Background: Standard-of-care (SOC) or "protocol" biopsies may detect subclinical disease impacting renal allograft longevity. Transplant recipients at our center have SOC biopsies at 3, 6, and 12 months after implantation. Indication biopsies are also performed in the setting of graft dysfunction or *de novo* DSA. We hypothesize that a substantial percentage of SOC biopsies identify pathologic processes that trigger patient management changes.

Methods: An Access database was populated with pathology reports on all renal biopsies over a 40 month period, obtained from a pathology laboratory information system (Soft) and a transplantation clinical database (Otis). Biopsies were categorized by type (native vs. allograft, indication vs. SOC) and time after transplantation. Natural language diagnoses were standardized. Rejection (antibody and cellular), infection (bacterial and viral), recurrent disease, calcineurin inhibitor toxicity, and obstruction were identified as clinically actionable diagnoses.

Results: 2410 of the 3724 biopsies over this time period were allograft biopsies. At 3, 6, and 12 months after transplant, 15.1%, 17.8%, and 17.8% of SOC biopsies had clinically actionable diagnoses, respectively. 47.9% of indication biopsies had clinically actionable diagnoses ($p<0.0001$ compared to SOC, chi-squared). Cellular rejection tended to be diagnosed earlier than antibody mediated rejection diagnoses in this population (Figure 1). About 1 in 20 biopsies at or before 6 months had evidence of viral or bacterial infection, many of which were SOC biopsies.

Conclusions: The SOC biopsy program frequently identified findings affecting patient management and is a valuable addition to post-transplant patient care. The temporal spectrum of rejection related diagnoses in all biopsies over this time period is consistent with the literature. Infectious diagnoses, particularly subclinical infections, are frequent and can occur early after transplantation.

Notch Receptor Expression Is Significantly Increased during Human Kidney Transplant Rejection Amy Bowes,[5] Kirsten Morris,[5] Naoka Murakami,[1] Paul Bass,[4] Alan D. Salama,[4,2] Hans J. Stauss,[3] Leonardo V. Riella,[1] Ciara N. Magee.[4] *[1]Brigham and Women's Hospital, Harvard Medical School, Brookline, MA; [2]None, Boston, MA; [3]UCL, London, United Kingdom; [4]UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom; [5]Royal Free London NHS Foundation Trust, London, United Kingdom.*

Background: Despite significant advances in transplantation, our ability to appropriately modify the immune response therein remains limited. Development of therapies that promote regulation while suppressing effector immunity is imperative to improve graft survival and minimize immunosuppression. Notch receptor signaling is crucial to cell development and plays a key role in T cell activation and differentiation, though limited data exist on its importance in immune regulation. In this study, we investigated the pattern of Notch receptor expression in human renal transplantation.

Methods: Transplant kidney biopsy samples obtained from patients enrolled in an immune monitoring study in our institution were evaluated. All patients had a routine time zero biopsy; a subset of patients underwent further biopsy post-transplant due to episodes of graft dysfunction, and were classified as acute rejection (n=12), or non-rejection (n=15). Immunohistochemical analysis was performed to identify intact and activated (cleaved) Notch receptor expression (measured as % threshold area using ImageJ) on paraffin-embedded sections. Cellular samples were collected from another cohort of renal transplant patients during times of clinical quiescence or acute rejection and analyzed for T cell subset expression of Notch using flow cytometry.

Results: Renal expression of cleaved Notch1, cleaved and intact Notch2 was significantly increased in patients with acute rejection when compared to their baseline biopsies and post-transplant patients without rejection ($p<0.0001$, $p<0.0001$ & $p<0.0001$, respectively). Next, we investigated the expression of Notch1 in T conventional cells (T_{conv}: $CD4^+Foxp3^-$) and T_{regs} ($CD4^+Foxp3^+$) in transplant recipients. During clinical quiescence, a significantly higher proportion of T_{regs} expressed Notch1 compared to T_{conv} cells. However, there was a 100-fold increase in the proportion of T_{conv} expressing Notch1 during a rejection episode, with a slight reduction in the proportion of T_{regs} expressing Notch1.

Conclusions: We found that there is significant upregulation of both celluar and tissue Notch receptor expression during immune activation. Given the importance of Notch signaling in T cell activation, treatment with Notch inhibition may provide a novel means of attenuating cellular responses in transplantation.

FR-OR083

GWAS of Time to Renal Allograft Failure after Transplantation of African American Deceased-Donor Kidneys Jasmin Divers,[5] Lijun Ma,[5] William M. Brown,[5] Nicholette D. Palmer,[5] Ajay K. Israni,[3] Stephen O. Pastan,[1] Bruce A. Julian,[4] Robert S. Gaston,[4] Pamela J. Hicks,[2] Amber M. Reeves-Daniel,[5] Barry I. Freedman.[5] *[1]Emory University School of Medicine, Atlanta, GA; [2]Wake Forest Baptist Health, Winston Salem, NC; [3]Hennepin County Medical Center, Minneapolis, MN; [4]University of Alabama at Birmingham, Birmingham, AL; [5]Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Two apolipoprotein L1 gene (*APOL1*) renal-risk variants in African American (AA) deceased donors (DD) associate with shorter renal allograft survival after transplantation. Modifying factors are likely involved because not all deceased donor kidney transplants (DDKT) from AA donors with *APOL1* risk genotypes fail early.

Methods: To identify genes contributing to allograft failure in addition to *APOL1*, a genome-wide association study (GWAS) was performed using the Illumina 5M chip in 477 AA DD, yielding 880 DDKTs. Association tests were performed using Cox proportional hazard on the genotyped and 1000 Genomes-imputed markers, using death-censored allograft survival as the outcome with each single nucleotide polymorphism (SNP), and accounting for donor African ancestry proportion, sex and age, and recipient sex, age, HLA match, cold ischemia time and peak panel reactive antibodies, using data collected from the Scientific Registry of Transplant Recipients (SRTR). SNP-by-*APOL1* interaction effects on allograft survival were also assessed.

Results: Seven SNPs near the Nudix Hydrolase 7*(NUDT7)* gene, a coenzyme A diphosphatase, were among the top hits showing independent effects after accounting for *APOL1* ($p=1.6x10^{-8}$ -$3.8x10^{-8}$). *NUDT7* is expressed in human renal tubule cells. Two SNPs in the *SEC63* gene modified the effect of *APOL1* on allograft survival (interaction $p=2x10^{-9}$ - $3.7x10^{-8}$). *SEC63* encodes a protein translocation regulator, which appears at the endoplasmic reticulum (ER) and ER-mitochondria contact sites, and is expressed in human renal tubules and glomeruli.

Conclusions: Genetic associations were detected with 41 SNPs ($p= 2x10^{-9}$ - $5x10^{-8}$) contributing independently or interacting with *APOL1* to impact renal allograft survival after DDKT from AA deceased donors. Replication and functional validation efforts are needed to elucidate these associations.

FR-OR084

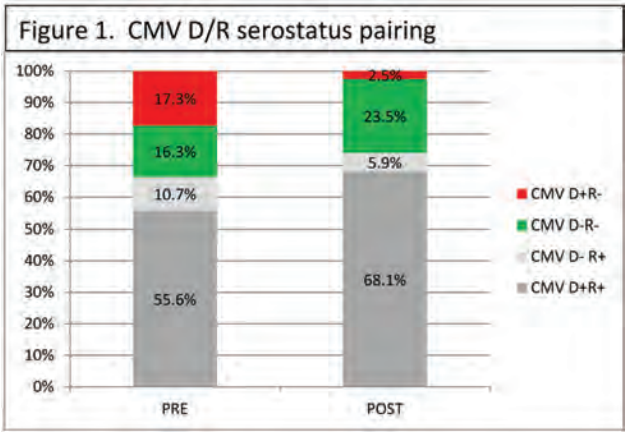
Kidney Transplant Allocation with CMV Seromatching Reduces CMV Infection Douglas J. Norman,[2] Eric D. Langewisch,[3] Joseph B. Lockridge.[1] *[1]None, Tualatin, OR; [2]Oregon Health and Science University, Portland, OR; [3]University of Nebraska Medical Center, Omaha, NE.*

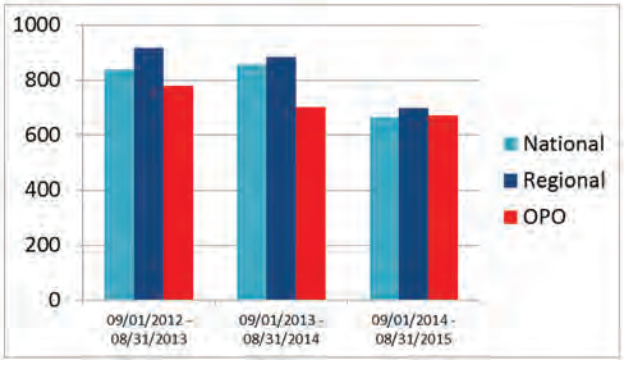
Background: Cytomegalovirus (CMV) infection is a major cause of morbidity in kidney transplant recipients. A pre-transplant allocation strategy by matching deceased kidney donors and recipients by CMV serostatus may reduce CMV infection. .

Methods: We adopted a CMV seromatching allocation policy within our Organ Procurement Organization (OPO) beginning 09/01/2012. In this retrospective analysis of 400 consecutive deceased donor kidney transplant recipients, we compared rates of CMV syndrome between a historical control (PRE: 1/1/2010 – 8/31/2012) versus after the CMV matching protocol (POST: 9/1/2012 – 12/3/2014). Wait times in the OPO were reviewed after the protocol was implemented.

Results: CMV matching decreased the number of high CMV risk (donor seropositive / recipient seronegative) transplants from 17.3% to 2.5% ($p<0.001$) and increased the number of low CMV risk (donor seronegative / recipient seronegative) transplants from 16.3% to 23.5% ($p=0.072$) (Figure 1). CMV viremia was reduced from 13.3% to 5.9% ($p=0.0118$) while CMV syndrome or disease decreased from 9.2% to 2.9% ($p=0.008$). After the allocation change, median waiting times for all deceased donor recipients in the OPO did not increase and appeared to be consistent with national and regional trends (Figure 2).

Conclusions: CMV seromatching optimizes high and low risk CMV profiles and significantly reduces the rate of CMV infection without appearing to disadvantage wait times for recipients





Median Wait Times For Deceased Donor Kidney Recipients(days) after CMV Allocation Change

FR-OR085

Increased Expression of the Co-Inhibitors PD-1 and BTLA on CMV-Specific T-Cells Is Associated with Symptomatic CMV Infection in Renal Transplant Patients Benjamin Wilde,[2] Sebastian Dolff,[3] Oliver Witzke.[1] *[1]Department of Infectious Diseases, University Duisburg-Essen, Essen, Germany; [2]Department of Nephrology, University Duisburg-Essen, University Hospital Essen, Essen, Germany; [3]Department of Infectious Diseases, University Duisburg-Essen, University Hospital Essen, Essen, Germany.*

Background: Cytomegalovirus (CMV) infections occur frequently in renal transplant patients due to immunosuppressive therapy inhibiting CMV-specific T-cell immunity. Prophylaxis with antiviral agents or pre-emptive strategies to monitor viral load and then treat do not prevent infections sufficiently. It was the aim of this study to investigate if the expression of inhibitory molecules on CMV specific T-cells is associated with the clinical course of renal transplant patients.

Methods: 30 renal transplant patients were recruited. Peripheral blood was sampled and stimulated with CMV lysate, SEB or control serum. The coinhibitors PD-1 and BTLA were determined on CMV-specific T-cells. Clinical data was collected retrospectively from patient files. Symptomatic CMV infection was defined as CMV syndrome or tissue invasive disease. Asymptomatic CMV infection was defined as detectable CMV replication in peripheral blood and absence of signs indicating CMV syndrome/tissue invasive disease.

Results: Two renal transplant patients were at low risk for CMV infection according to donor /recipient CMV IgG sero-status at the time of transplantation (D neg / R neg). Seven patients had a high risk according to sero-status (D pos /R neg) and the remaining 21 patients were confined to the intermediate risk group (D pos /R pos or D neg / R pos). Patients with low risk were excluded for further analysis. PD-1 expression was significantly enhanced on CMV-specific CD3+ T-cells in patients with a history of symptomatic CMV infection (n=6) as compared to patients with asymptomatic CMV (n=14) infection ($CD3^+CD154^+$: % of $PD\text{-}1^+$ 63.8 ±16.0% vs. 37.2 ±19.4%, p=0.006). Likewise, expression of BTLA on CMV-specific T-cells was significantly increased in patients with symptomatic versus asymptomatic CMV infection ($CD3^+CD154^+$: % of $BTLA^+$ 89.3 ±9.5% vs. 66.0 ±22.0%, p=0.003).

Conclusions: Patients with symptomatic CMV infection had enhanced expression of PD-1/BTLA on virus-specific T-cells. The coinhibitors PD-1/BTLA usually promote T-cell suppression. Therefore, increased expression of PD-1/BTLA on CMV-specific T-cells may compromise viral control and could serve as biomarker to stratify patients at risk.

FR-OR086

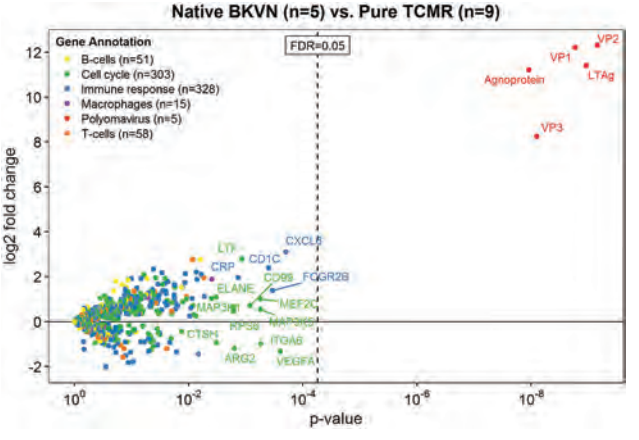
The Molecular Phenotype of Polyomavirus Nephropathy and Its Discrimination from T-Cell Mediated Rejection Benjamin A. Adam,[8] Siegfried Wagner,[8] Jan H. Braesen,[5] Verena Broecker,[2] Vivette D. D'Agati,[1] Cinthia Drachenberg,[9] Evan A. Farkash,[10] Alton B. Farris,[3] Laurette Geldenhuys,[6] Volker Nickeleit,[7] Parmjeet S. Randhawa,[11] Heinz Regele,[4] Michael Mengel.[8] *[1]Columbia University College of Physicians and Surgeons, New York, NY; [2]Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Emory University, Atlanta, GA; [4]Medical University of Vienna, Vienna, Austria; [5]Medizinische Hochschule Hannover, Hannover, Germany; [6]Queen Elizabeth II Health Sciences Centre, Halifax, NS, Canada; [7]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [8]University of Alberta, Edmonton, AB, Canada; [9]University of Maryland School of Medicine, Baltimore, MD; [10]University of Michigan, Ann Arbor, MI; [11]University of Pittsburgh, Pittsburgh, PA.*

Background: Improved immunosuppression protocols have reduced the incidence of T-cell mediated rejection (TCMR) but still carry a significant risk of BK polyomavirus nephropathy (BKVN). Despite requiring opposite treatments, BKVN and TCMR often have overlapping clinical and histological presentations. Molecular testing may allow for more precise diagnosis.

Methods: NanoString® was used to measure the expression of 800 genes in 40 formalin-fixed paraffin-embedded human samples. The genes included 795 human immune-related genes and 5 polyomavirus (PV) genes (Agnoprotein, LTAg, VP1, VP2, VP3). The samples included native kidney BKVN (n=5), pure TCMR (n=9), SV40 immunohistochemistry-positive carcinoma (tumor BK, n=9), and normal implant kidney biopsies (n=8). Using six additional nephrectomies with mixed BKVN and TCMR, regions showing histologic features of only BKVN (mixed BKVN, n=6) and only TCMR (mixed TCMR, n=3) were isolated with laser capture microdissection. Differential gene expression and diagnostic performance were assessed.

Results: All five PV genes were significantly increased (FDR<0.05) in native BKVN versus pure TMCR but no human genes were differentially expressed (Figure 1). PV gene expression was also significantly higher (versus pure TCMR) in tumor BK (p<0.01), mixed BKVN (p<0.001), and mixed TCMR (p<0.05, except VP1). ROC analysis revealed excellent discrimination between BK-positive (including mixed TCMR) and BK-negative cases (AUC=0.96-1.00). As a 5-gene set, the PV genes demonstrated near-perfect diagnostic performance (AUC=0.99) with improved sensitivity (0.96) over histology (0.87).

Conclusions: These data suggest that PV gene expression is more sensitive than histology and can more precisely discriminate BKVN and TCMR. However, at the molecular level, no significant difference in immune response was identified.



FR-OR087

Comparison of Outcomes after DAA Therapy among HCV Infected Kidney Transplant Recipients Who Received Grafts from Either HCV Positive or Negative Donors Mai Sedki,[4] Camilo Cortesi,[4] Paul Martin,[2] David Roth,[3] Kalyan R. Bhamidimarri.[1] *[1]University of Maimi, Miami, FL; [2]University of Miami, Miami, FL; [3]University of Miami Miller School of Medicine, Miami, FL; [4]University of Miami/Jackson Memorial Hospital, Miami, FL.*

Background: Direct acting antivirals (DAA) have transformed hepatitis C virus (HCV) treatment. In the kidney transplant (KT) setting, HCV-infected patients (R+) can now receive deceased donor KT (DDKT) from HCV positive donors (D+) and undergo treatment in the post-transplant period. However, a few cases of rejection have been reported in this HCV D+R+ cohort. We sought to compare outcomes among R+ receiving grafts from HCV negative donors (D-) versus D+.

Methods: This is a case series of 39 KT recipients of which 14 R+ have been transplanted with a kidney from D- and the rest from D+. All patients completed a full course of DAA. Time to transplantation, efficacy of DAA therapy, rejection episodes, tacrolimus dose adjustments, and renal function were assessed in both groups.

Results: The average age of our cohort was 56.7±8.8 and 59.1±10.5 years with 64% and 77% male in D-R+ and D+R+, respectively. In both groups the predominant genotype was 1A. The median METAVIR fibrosis stage was 2.0 in D-R+ and 1.0 in D+R+. The SVR at 12 weeks was 100% in D-R+ and 96% in D+R+. The median waiting time to transplantation was 802 days for D-R+ and 58 days in D+R+. Additionally, the median time between transplantation and start of DAA therapy was 405 days and 124 days in D-R+ and D+R+, respectively. There were 4 antibody mediated rejection episodes in D+R+ and 1 mixed rejection in D-R+. Tacrolimus dose adjustments were required in 64% of D-R+ and 52% of D+R+. When comparing kidney function before and after treatment with DAA, 42% of D-R+ and 28% of D+R+ had a significant change, defined as a change in creatinine by ≥ 0.3mg/dL.

Conclusions: Acceptance of a D+ kidney resulted in a significant decrease in transplant waiting time in R+ candidates without marked compromise. The response to DAA therapy was excellent and the SVR rates were similar to those reported in the general population. In both groups, tacrolimus dose adjustments were necessary. Our data suggests that KT recipients should be closely monitored during and immediately following HCV therapy with DAAs.

Dulaglutide Treatment Is Associated with Less eGFR Decline and Greater Reduction in Albuminuria in Type 2 Diabetes and CKD Stages 3-4 (AWARD-7) Katherine R. Tuttle,[2] Mark C. Lakshmanan,[4] Jorge L. Gross,[5] Brian Rayner,[3] Robert S. Busch,[1] Brad Woodward,[4] Alan G. Zimmermann,[4] Fady T. Botros.[4] *[1]Albany Medical Center Division of Community Endocrinology, Albany, NY; [2]Providence Health Care, University of Washington School of Medicine, Spokane, WA; [3]Division of Nephrology and Hypertension, Groote Schuur Hospital and University of Cape Town, Cape Town, South Africa; [4]Eli Lilly and Company, Indianapolis, IN; [5]Centro de Pesquisas em Diabetes, Porto Alegre, Rio Grande do Sul, Brazil.*

Background: The AWARD-7 phase 3 trial compared weekly dulaglutide (DU 1.5 or 0.75 mg) to daily insulin glargine (IG), both with insulin lispro, in participants with type 2 diabetes (T2D) and chronic kidney disease (CKD) stages 3-4.

Methods: Baseline (BL) characteristics (N=576) were: estimated glomerular filtration rate (eGFR CKD-EPI): 38±13 mL/min/1.73m^2 [mean±SD], urine albumin/creatinine ratio (UACR, mean [median]): 847.2 (209.3), age: 65±9 years, A1c: 8.6±1.0%, duration of T2D: 18±9 years.

Results: After 52 weeks, mean eGFR was not statistically different from BL with DU 1.5 mg, while it decreased with DU 0.75 mg and IG; UACR decreased from BL with both DU doses (table). DU 1.5 mg vs IG differences were statistically significant in participants with UACR >300 mg/g. Both doses of DU were noninferior to IG for the change in A1c.

Conclusions: In participants with T2D and CKD stages 3-4, overall effects on eGFR and UACR were mainly driven by lesser eGFR decline and greater UACR reduction in the DU 1.5 mg group vs IG in participants with UACR >300 mg/g.

Funding: Commercial Support - Eli Lilly and Company

Table. Effects of DU and IG on eGFR and albuminuria after 52 weeks

FR-OR089

Effect of SGLT-2 Inhibitors on Proximal Tubular Function and Injury in Patients with Type 2 Diabetes: A Randomized Controlled Trial Pattharamon Korkiatpitak,[2] Bancha Satirapoj,[2] Naowanit Nata,[2] Amnart Chaiprasert,[1] Pamila Tasanavipas,[1] Theerasak Tangwonglert,[2] Ouppatham Supasyndh.[1] *[1]Phramongkutklao Hospital, Pathumthani, Thailand; [2]Phramongkutklao hospital, Bangkok, Thailand. Group/Team: phramongkutklao.*

Background: Intensive glucose control reduces the risk for microvascular complications in type 2 diabetes (T2DM). Recently, sodium glucose cotransporter 2 (SGLT2) inhibitors have the potential to exert renoprotection beyond glycemic control, the effects of SGLT2 inhibitors on the organs are not well known. There is limited data of SGLT2 inhibitors on biomarkers of kidney injury in T2DM patients.

Methods: T2DM patients with persistent HbA1c > 7% randomly assigned to add dapagliflozin 10 mg/day or standard treatment for 12 weeks. Proximal tubular injury biomarkers including urine kidney injury molecule-1 (KIM-1), urine cystatin-C, urine albumin to creatinine ratio (UACR), fraction excretion of phosphate (FEPO4) and uric acid (FEUric) were measured at baseline and the end of study.

Results: Patients were randomized to receive dapagliflozin (N=28) and control (N=29). Baseline characteristics were comparable across treatment groups. After 12 weeks, dapagliflozin-treated versus standard-treated patients showed reductions in HbA1c (-0.75 ± 0.21 vs -0.07 ± 0.25 %, p-value=0.882), fasting plasma glucose (-19.59 ± 8.26 vs -11.07 ± 8.71 mg/dL, p-value=0.481) and serum uric acid -0.06 ±0.18 vs 0.18 ± 0.12 mg/dL). There were significant between-group differences in the reduction of UACR (-23.31 ± 10 vs 19.88 ± 11.54 mcg/mgCr., p-value=0.010) and urine KIM-1 to creatinine ratio (-26.70 ± 98.2 vs 422.19 ± 181.05 mcg/mgCr, p-value=0.036), but no significant in changes of urine cystatin-C to creatinine ratio between two groups. There was no significant change of glomerular filtration rate, serum phosphorus, FEUric and FEPO4 in the dapagliflozin. No serious renal-related adverse events were observed in any group.

Conclusions: This study indicates that dapagliflozin in T2DM patients can decrease urinary proximal tubular injury biomarkers which refer to renoprotective effects. SGLT2-Inhibitors may be useful in treating T2DM for protect renal tubular injury and may lead to a reduced long-term renal outcome.

FR-OR090

Effect of the SGLT-2 Inhibitor Dapagliflozin on Glomerular and Tubular Injury Markers Claire Dekkers,[4] Sergei Petrykiv,[1] Gozewijn D. Laverman,[2] Ron T. Gansevoort,[3] Hiddo J. Lambers Heerspink.[4] *[1]None, Groningen, Netherlands; [2]ZGT Almelo, Almelo, Netherlands; [3]UMC Groningen, Groningen, Netherlands; [4]University Medical Center Groningen, Groningen, Netherlands.*

Background: Sodium-glucose co-transporter 2 (SGLT2) inhibitors have been shown to delay progression of kidney function decline in type 2 diabetes. However, an FDA communication reported potential risk of acute kidney injury (AKI) particular during the first weeks of treatment, potentially due to tubular injury. Here we assessed effects of the SGLT2 inhibitor dapagliflozin (DAPA) on markers of subclinical tubular injury.

Methods: Data was used from a randomized controlled cross-over trial in 33 patients with type 2 diabetes and albuminuria ≥100 mg/g designed to assess the albuminuria lowering effect of 6-weeks treatment with DAPA 10 mg/d. IgG and IgG4 were measured as markers of glomerular damage and fractional excretion of the IgG to IgG4 ratio was used as proxy of charge selectivity. Urinary KIM-1, NGAL and LFABP were assessed as tubular damage markers, whereas urinary MCP-1 and urinary IL-6 were measured as inflammation markers.

Results: Compared to placebo, DAPA decreased IgG and IgG4 excretion, but did not change the glomerular charge selectivity index (table 1). Compared to placebo, DAPA decreased urinary KIM-1 excretion, whereas no change in NGAL and LFABP was observed. The inflammatory marker IL-6 significantly decreased during DAPA therapy. DAPA also decreased albuminuria (36.2% [95%CI 22.9, 47.2]) and eGFR (5.3 ml/min/1.73m^2 [8.0, 2.7]). Albuminuria change tended to correlate with eGFR change during DAPA (r=0.34; p=0.06). Tubular injury markers did not correlate with change in eGFR. Changes in IgG, MCP-1 and IL-6 significantly correlated with change in albuminuria (all p<0.02).

Conclusions: DAPA lowers urinary excretion of glomerular and tubular injury markers as well as inflammation markers. These data indicate that the fall in eGFR after start of dapagliflozin reflects a hemodynamic response and not (subclinical) tubular injury.

Table 1

Injury markers	Mean change % from baseline compared to placebo (95% CI)	P-value
IgG	-28.4 (-7.2, -44.7)	0.01
IgG4	-34.6 (-3.0, -55.9)	0.04
IgG/IgG4	17.8 (-25.2, 85.4)	0.46
KIM-1	-22.6 (-0.3, -39.8)	0.05
NGAL	-13.4 (-35.6, 16.6)	0.33
LFABP	0.9 (-13.2, 17.2)	0.91
IL-6	-23.5 (-1.4, -40.6)	0.04
MCP-1	-14.1 (-32.2, 8.8)	0.20

FR-OR091

Effect of the SGLT2 Inhibitor Dapagliflozin in Patients with Type 2 Diabetes and Stages 3b-4 CKD David C. Wheeler,[3] Claire Dekkers,[4] David Sjostrom,[2] Bergur V. Stefansson,[1] Valerie Cain,[5] Hiddo J. Lambers Heerspink.[4] *[1]AstraZeneca, Molndal, Sweden; [2]AstraZeneca LP, Molndal, Sweden; [3]University College London, London, United Kingdom; [4]University Medical Center Groningen, Groningen, Netherlands; [5]Bogier Clinical and IT Solutions, Inc, Haddonfield, NJ.*

Background: Dapagliflozin, an anti-diabetic drug targeting the sodium-glucose co-transporter 2, decreases HbA1c, body weight, blood pressure (BP), and albuminuria (UACR) in patients with type 2 diabetes. Although the glucose lowering capacity of dapagliflozin is diminished in patients with reduced kidney function, the effects of this drug on body weight, BP, and UACR as well as its safety have not been properly defined in patients with type 2 diabetes and stages 3b-4 chronic kidney disease (CKD).

Methods: In a pooled analysis of 11 phase 3 randomized controlled clinical trials, we determined changes in HbA1c, body weight, BP, hematocrit, eGFR, and UACR over 24 weeks in patients with type 2 diabetes and an eGFR <45 ml/min/1.73m^2 receiving placebo (n=70) or dapagliflozin 5 mg or 10 mg (n=151). Effects on UACR were determined in a subgroup of patients with baseline UACR ≥ 30 mg/g (n=137).

Results: Placebo-corrected changes in HbA1c with dapagliflozin 5 and 10 mg were -0.02 (95% CI: -0.36, 0.33) and -0.03 (95% CI: -0.34, 0.28). Dapagliflozin 5 and 10 mg compared to placebo changed eGFR after 24 weeks by -1.5 (95% CI: -4.6, 1.5) and -2.6 (95% CI: -5.3, 0.2) and UACR by -48.3% (95% CI: -67.4, -17.8), and -32.7% (95% CI: -56.2, 3.5), respectively. Additionally, dapagliflozin at both 5 and 10 mg compared to placebo increased hematocrit and decreased body weight and BP. The overall frequency of adverse events was similar among treatment groups. Adverse events associated with renal function occurred more frequently in the dapagliflozin 10 mg group. These events included many asymptomatic increases in serum creatinine of which none qualified as a serious adverse event.

Conclusions: Dapagliflozin does not decrease HbA1c in patients with type 2 diabetes and stages 3b-4 CKD. However, the drug decreases UACR, BP, and body weight to a clinically meaningful extent without major side effects. These actions of dapagliflozin support a large outcomes trial in this population to confirm long-term safety and efficacy in reducing adverse clinical end points.

Are the Renal Effects of Empagliflozin Consistent in Patients Already Using Medications That Alter Renal Hemodynamics? An Exploratory Analysis from EMPA-REG OUTCOME Gert J. Mayer,[1] Christoph Wanner,[2] Matthew R. Weir,[3] Silvio E. Inzucchi,[4] Audrey Koitka-Weber,[5] Stefan Hantel,[5] Maximilian von Eynatten,[6] Bernard Zinman,[7] David Cherney.[8] *[1]Dept of Internal Medicine IV (Nephrology and Hypertension), Medical University Innsbruck, Innsbruck, Austria; [2]Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; [3]Dept of Nephrology, University of Maryland School of Medicine, Baltimore, MD; [4]Yale University School of Medicine, New Haven, CT; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [6]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [7]Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, ON, Canada; [8]Toronto General Hospital, Univ of Toronto, Toronto, ON, Canada.*

Background: Among patients with type 2 diabetes (T2D) at high cardiovascular (CV) risk, the SGLT2 inhibitor empagliflozin (EMPA) decreases progression of kidney disease, likely via reduction in intraglomerular pressure. These patients often receive other agents to prevent development or progression of both CV disease (CVD) and chronic kidney disease (CKD). Some of these agents may also alter renal hemodynamics, such as RAS inhibitors, diuretics, NSAIDs and CCBs. We investigated whether the renal effects of EMPA are consistent in those already using these background medications.

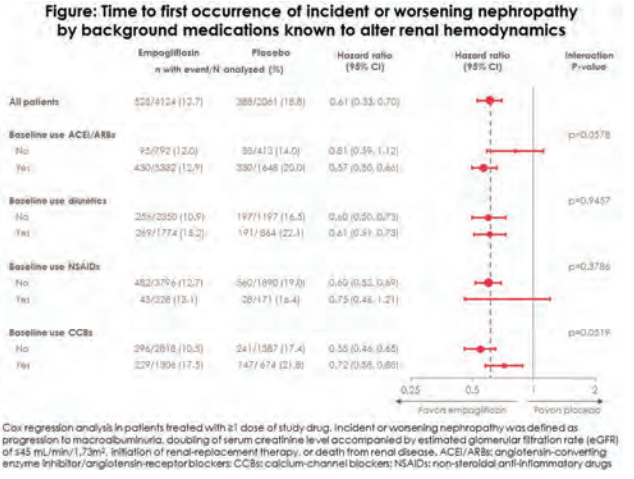
Methods: 7020 patients with T2D and established CVD were randomized (1:1:1) to EMPA 10 mg, 25 mg or placebo (PBO) in addition to standard of care. Differences in risk of incident or worsening nephropathy for EMPA vs PBO across subgroups by baseline background medications were assessed using a Cox proportional hazards model. Acute renal failure (ARF) events were assessed based on the MedDRA narrow standardized query.

Results: Risk reductions in incident or worsening nephropathy seen with EMPA were consistent across background medication subgroups, with no heterogeneity of treatment effect (Figure). RAS inhibitors were the most commonly used background medication group and there was an overall increased risk for ARF with ACEi/ARBs in the PBO group (ACEi/ARB yes: 7% vs ACEi/ARB no: 5.2%) but no imbalance was seen with EMPA 10 mg and 25 mg, respectively (ACEi/ARB yes: 5.3% and 5.9%; ACEi/ARB no: 4.5%, 2.7%).

Conclusions: Addition of EMPA resulted in a consistent reduction in CKD progression in T2D patients at high CV risk, irrespective of commonly used background medications that also alter renal hemodynamics.

Funding: Commercial Support - Boehringer Ingelheim & Eli Lilly and Company Diabetes Alliance

Figure: Time to first occurrence of incident or worsening nephropathy by background medications known to alter renal hemodynamics



Cox regression analysis in patients treated with ≥1 dose of study drug. Incident or worsening nephropathy was defined as progression to macroalbuminuria, doubling of serum creatinine level accompanied by estimated glomerular filtration rate (eGFR) of ≤45 mL/min/1.73m^2, initiation of renal-replacement therapy, or death from renal disease. ACEi/ARBs: angiotensin-converting enzyme inhibitor/angiotensin-receptor blockers; CCBs: calcium-channel blockers; NSAIDs: non-steroidal anti-inflammatory drugs

FR-OR093

Effects of SGLT2 Inhibition on Fibroblast Growth Factor 23 and 25(OH) Vitamin D Maarten A. de Jong,[1] Sergei Petrykiv,[1] Gozewijn D. Laverman,[2] Dick de Zeeuw,[1] Stephan J. Bakker,[1] Hiddo J. Lambers Heerspink,[1] Martin H. De Borst.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]ZGT Almelo, Almelo, Netherlands.*

Background: Sodium glucose co-transporter 2 (SGLT2) inhibitors like dapagliflozin are novel drugs for the treatment of diabetes mellitus, which also promise to slow the progression of kidney disease. Previous studies found that SGLT2 inhibition increases serum phosphate and PTH. However, the effects on fibroblast growth factor 23 (FGF23) and vitamin D are less well studied.

Methods: This is a post-hoc analysis of a double-blind, randomized, cross-over trial, enrolling patients on stable RAAS blockade, albumin:creatinine ratio between 100 and 3500 mg/g, eGFR ≥ 45 ml/min/1.73m^2 and HbA1c ≥ 55 and <100 mmol/mol. Patients were treated with dapagliflozin 10 mg/d (DAPA) or placebo during 2 consecutive periods of 6 weeks each, with a 6-week wash-out in between. Plasma C-terminal FGF23 was measured with ELISA (Immutopics Inc), 25(OH) vitamin D with LC-MS/MS. Data are shown as mean (95%CI). Endpoints were assessed with linear mixed models.

Results: Thirty-three patients (age 61±9 yrs; 24% female; median 24h UAE 470 mg/24hr) completed the study. Baseline characteristics and results are shown in table 1. DAPA increased serum phosphate, PTH and FGF23 compared to both baseline and placebo. Serum calcium and 25(OH)D did not change (p=0.9, p=0.8). DAPA reduced eGFR, but change in eGFR and change in bone and mineral parameters were not correlated (all P>0.5). All effects of DAPA were reversed 6 weeks after discontinuation.

Conclusions: Dapagliflozin treatment induced a significant rise in serum phosphate, PTH and FGF23 levels, independent of concomitant effects on eGFR. Serum calcium and 25(OH)D levels remained unchanged. In light of the high prevalence of bone and mineral disorders in patients with diabetes and kidney disease, future studies should assess the clinical significance of these alterations.

AKI in Patients on SGLT2 inhibitors: A Propensity Matched Analysis Girish N. Nadkarni,[2] Rocco Ferrandino,[3] Alex R. Chang,[1] Aditya L. Surapaneni,[5] Kinsuk Chauhan,[3] Priti Poojary,[6] Aparna Saha,[4] Bart Ferket,[3] Morgan Grams,[5] Steven G. Coca.[3] *[1]Geisinger Medical Center, Danville, PA; [2]Icahn School of Medicine, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Icahn school of medicine at Mount Sinai, NEW YORK, NY; [5]Johns Hopkins University, Baltimore, India; [6]Icahn School of Medicine at Sinai, New York, NY.*

Background: Sodium-glucose co-transporter-2 inhibitors (SGLT2i) improve both renal and cardiovascular outcomes in type 2 diabetes (T2D) patients. However, the FDA has issued alerts regarding increased acute kidney injury (AKI) with canagliflozin/dapagliflozin. We aimed to assess real world AKI risk with SGLT2i separately in two health-care cohorts.

Methods: We utilized the Mount Sinai chronic kidney disease (MSCKD) registry and Geisinger Health System (GHS) cohort. We selected SGLT2i users/non-users and determined AKI by KDIGO definition (AKI_{KDIGO}). We used nearest neighbor 1: 1 propensity matching and calculated unadjusted and adjusted (accounting for covariates poorly balanced in the propensity match) hazard ratios (HRs).

Results: We analyzed 377 SGLT-2i users: non-user pairs in MSCKD, and 1242 SGLTi users: non-user pairs in GHS. During median follow-up time of 14 months, 4% in Mount Sinai and 3% of SGLTi users experienced an AKI_{KDIGO} event, vs. 10% and 7% of non-users, respectively. Unadjusted HRs for AKI_{KDIGO} were 0.46 (95% CI 0.26-0.82) and 0.43 (95% CI 0.29-0.63) in MSCKD and GHS, respectively. After adjustment, decreased risk persisted (aHR 0.48; 95% CI: 0.25-0.91, and aHR 0.63, 95% CI: 0.39-1.00, respectively). These estimates did not qualitatively change across sensitivity analyses, including by SGLTi type. (Table 1)

Conclusions: These pharmacoepidemiologic findings suggest there may not be increased AKI risk in SGLT2i users vs. comparable T2D patients. In fact, all three SGLTi were associated with lower AKI risk, similar to empagliflozin trial results. Our results suggest that perceived AKI risk with canagliflozin/dapagliflozin may be attributable to the high-risk population taking these medications and not to inherent nephrotoxicity.

Funding: NIDDK Support

Organelles in Organoids: Live Imaging of Human Mini-Kidneys Using Targeted Tracers Reveals Dynamic Intracellular Responses to Kidney Injury Angela J. Churchill,[2] Jonathan Himmelfarb,[1] Benjamin S. Freedman.[2] *[1]Kidney Research Institute, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: Cellular subcompartments, known as organelles, play critical roles in cell biology, but little is known about the dynamics of organelles in complex tissues and organs. Mini-kidney organoids derived from human pluripotent stem cells (hPSCs) are complex structures *in vitro* that resemble nephrons and can be genetically modified to study regeneration and disease. We used human mini-kidneys to model organelle dynamics in complex tissues and acute kidney injury.

Methods: CRISPR-modified hPSC lines encoding fluorescently-tagged microtubules, nuclear envelopes, mitochondria, or desmosomes were differentiated into kidney organoids. Whole organoids were imaged every 5 minutes with a spinning disk confocal microscope over the course of 16 hours, and organelle dynamics were quantified. Organoids were physically disrupted or chemically treated to simulate kidney injury. Organelle distributions in tubule and podocyte populations were compared to fixed organoids and kidney tissue *in vivo* by fluorescence and electron microscopy.

Results: Live movies of human kidney organoids captured tubule movements, cell rearrangements, and mitotic events at high temporal and spatial resolution. Organelle distribution in diverse nephron segments closely resembled kidney tissue *in vivo*. Organelles exhibited a range of behaviors, from highly dynamic microtubules and nuclear envelopes, to relatively static desmosomes forming regularly-spaced foci. Quantitative time-lapse analysis revealed extended cell division duration and fragmented mitochondrial morphology under acute kidney injury conditions.

Conclusions: Live imaging of fluorescently-labeled kidney organoids reveals that organelle distributions and dynamics depend on nephron segment identity and environmental cues, approximating tissues *in vivo*. Furthermore, kidney injury induces changes in cell cycle length and mitochondrial structure, recapitulating and revealing aspects of the tubular injury/repair process. The study of organelles in organoids provides a new framework for elucidating the intracellular mechanisms underlying kidney injury, disease, and regeneration.

Dissecting Lineage Relationships in Kidney Organoids Sara E. Howden, Jessica M. Vanslambrouck, Sean Wilson, Melissa H. Little. *Murdoch Childrens Research Institute, Parkville, NSW, Australia.*

Background: The capacity to create a model of the developing human kidney in vitro provides a unique opportunity to better understand nephrogenesis at the molecular level in human cells. Here we begin to characterise lineage relationships during human nephrogenesis through the generation of complex 3D kidney organoid cultures from human pluripotent stem cells (PSCs) that have been genetically modified to permit fate-mapping of specific cell lineages in real-time.

Methods: Human PSCs lines suitable for fate-mapping studies were generated by inserting a dual fluorescence cassette (loxP-flanked EGFP and adjacent mCherry reporter genes) within the "safe-harbor" GAPDH locus (GAPDHdual). Upon expression of Cre recombinase, cells switch from constitutive EGFP (green) expression to constitutive mCherry (red) expression. To interrogate the nephron lineage within human kidney organoids and validate the utility of GAPDHdual PSCs for fate-mapping studies, we used CRISPR/Cas9 to insert the Cre recombinase gene within the endogenous SIX2 locus of GAPDHdual PSCs (GAPDHdual:SIX2Cre). Kidney organoids were generated from GAPDHdual:SIX2Cre PSCs and monitored for mCherry expression.

Results: Following the derivation of kidney organoids from GAPDHdual:SIX2Cre PSCs, mCherry-expressing cells arise from day 10 of differentiation, coinciding with endogenous SIX2 expression. The proportion of mCherry+ cells increased steadily thereafter with a corresponding loss of EGFP-expressing cells. Importantly, subsequent analysis by immunofluorescence revealed that mCherry+ cells predominantly contributed to ECAD+ epithelial structures characteristic of the developing nephron. In constrast, mCherry+ cells were excluded from GATA3+ collecting duct. This is consistent with the lineage relationships previously demonstrated in murine kidney development.

Conclusions: Our findings validate lineage relationships of nephrons during human development and demonstrate the feasibility of using reporter/Cre-driver PSCs for fate-mapping studies in developing kidney organoids. We are currently using CRISPR/Cas9 mediated knock-out of specific genes in these GAPDHdual:SIX2Cre PSCs to interrogate the requirement for specific genes in the formation of human nephrons. We also propose to generate several other Cre-drivers to interrogate lineage relationships of other cellular compartments within the developing kidney that remain largely unknown.

Ureteric Bud Organoids Derived from Human Pluripotent Stem Cells Facilitate Self-Organization of Nephron Organoids Navin R. Gupta,[1,2] Joseph V. Bonventre,[1,2] Ryuji Morizane.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA.*

Background: Renal epithelia arise from the reciprocal induction between two populations of cells, the ureteric bud (UB) of the anterior intermediate mesoderm (aIM) and nephron progenitor cells (NPCs) of the posterior intermediate mesoderm (pIM). We previously generated nephron organoids through the efficient induction of SIX2+ NPCs from human pluripotent stem cells (hPSCs). By design the nephron organoids were optimized for formation from pIM and hence lacked the organized collecting duct system derived from the UB, an outpouching of the Wolffian duct (WD).

Methods: A 4-step directed differentiation protocol over 7 days was designed to mimic mammalian UB development *in vivo*. Differentiation efficiency was evaluated by immunostaining at key intermediate cell stages. Quantification of aIM induction efficiency was performed using quantitative morphometric analysis of protein expression. hPSC-GFP lines, generated from the transduction with a CMV-GFP lentiviral construct, permitted lineage tracing in co-culture experiments with distinction between UB and nephron organoids.

Results: Following induction of mesendoderm, addition of retinoic acid, FGF2, and BMP4 induced aIM expressing up to 95% GATA3, 88% HOXB4, 78% PAX2, 74% WT1, and 71% LHX1 in both human embryonic stem cells and induced pluripotent stem cells. Subsequent treatment of aIM with noggin generated $CDH1^+PAX2^+GATA3^+$ tubular epithelia consistent with putative Wolffian Duct (WD). Ensuing treatment of WD with GDNF and retinoic acid to induce ret signaling upregulated SALL4 in tubular epithelial structures, consistent with ureteric bud (UB) induction. Using an hESC-GFP line, 3D culture of aIM-GFP cells treated with noggin and FGFs (2, 7,10) generated presumptive WD organoids. Co-culture of WD-GFP and nephron organoids induced $GFP^+CDH1^+GATA3^+$ tubular epithelial structures connected in series with $CDH1^+GFP^-$ distal segments of MM organoids, consistent with the addition of an in-series distal tubule-collecting duct structural linkage. Moreover, UB organoids provided Wnt signaling to the nephron organoids, negating the need for a transient CHIR pulse.

Conclusions: hPSC-derived UB organoids, whether alone or in co-culture with nephron organoids, will provide a human tissue tool for the study of kidney development and human disease modeling with implications for drug discovery and regenerative medicine.

Fluidic Shear Stress Induces Vascular and Glomerular Development in Kidney Organoids Kimberly Homan,[4] Navin R. Gupta,[1] Katharina T. Kroll,[4] David Kolesky,[4] Mark A. Skylar-Scott,[4] Tomoya Miyoshi,[2] M. Todd Valerius,[2] Joseph V. Bonventre,[2] Jennifer A. Lewis,[3] Ryuji Morizane.[2] *[1]Brigham & Women's Hospital/Massachusetts General Hospital, Brighton, MA; [2]Brigham and Women's Hospital, Brookline, MA; [3]Harvard School of Engineering and Applied Sciences, Cambridge, MA; [4]Harvard University, Cambridge, MA.*

Background: Kidney organoids, derived from human pluripotent stem cells (hPSCs), provide a novel platform to study basic kidney development, drug toxicity, and disease modeling. The cellular heterogeneity and tubular architectures recapitulated in these systems are noteworthy, and recent studies demonstrated that vascularized glomeruli can be formed with host endothelial cells upon transplantation of organoid-derived podocytes to SCID mice. However, in current organoid systems *in vitro*, glomerular development is

imperfect and vasculature is neither perfusable nor remains viable longitudinally, limiting both the degree of relevant applications and potential extent of translatability to human physiology *in vivo*.

Methods: Early nephron organoids (renal vesicle stage) derived from both human embryonic stem cells (hESCs) and induced pluripotent stem cells (hiPSCs) were embedded on extracellular matrix (ECM) in 3D perfusable chips. The degree, distribution, and maturation of vascular networks were evaluated by immunostaining, RT-qPCR, and flow cytometry for FLK1, CD146, and CD31 at regular intervals when subject to variable degrees of fluidic shear stress as well as of growth factors including VEGF, as compared to controls in static chips.

Results: By subjecting renal organoids to the right combination of underlying ECM, medium components, and fluidic shear stress, the abundance of vasculature, the incidence of capillary invasion of glomerular clefts, and the number of vascularized glomerular structures as well as peritubular vasculature are significantly enhanced. We also demonstrate that the vasculature contains open lumens which can be visualized with fluorescent beads, indicating that vasculature in the organoids is perfusable.

Conclusions: Culturing renal organoids under fluidic shear stress has the potential to unlock new opportunities for glomerular disease modeling, podocyte/vascular maturation, and development of a glomerular filtration barrier *in vitro*.

A Microfluidic Kidney Organoid System Reveals Real-Time Dynamics of Nutrient Absorption Ramila E. Gulieva,[2] Jonathan Himmelfarb,[1] Benjamin S. Freedman.[2] *[1]Kidney Research Institute, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: Human mini-kidney organoids derived from pluripotent stem cells have great potential for kidney disease modeling and regeneration. Microfluidic flow is an essential component of the nephron for reabsorption and filtration, but is absent from existing organoid cultures. To more accurately model nephron functions *in vivo,* we tested whether introduction of fluid flow into kidney organoids could be used to visualize absorption of transport cargoes and nutrients in real time.

Methods: Human mini-kidneys were either differentiated *de novo* from hPSCs or transferred into chambers from cryopreserved stocks in microfluidic flow chambers. Fluorescence-labeled glucose, albumin and dextran were introduced and monitored live every 15 minutes over the course of 24 hours, under constant perfusion conditions. Absorption was quantified using image intensity analysis with background subtraction, compared to static conditions without flow, or in the presence of glucose transport inhibitors. Transporter expression was determined by immunofluorescence.

Results: Organoid proximal tubules, distal tubules, and podocytes differentiated normally, expressed SGLT2 and LRP2 transporters, and remained stable under flow for as long as two weeks. Accumulation of glucose occurred very rapidly, while absorption of albumin and dextran increased gradually in a linear fashion and eventually reached a plateau over 24 hours. The magnitude of absorption was significantly increased and featured increased signal to noise under flow conditions, compared to static conditions where absorption was minimal. Inhibition of SGLT transporters blocked glucose absorption in a dose-dependent manner.

Conclusions: The combination of kidney organoids with microfluidics enables visualization of nutrient and transport cargo absorption in nephron-like structures with high spatial and temporal resolution. Organoids under flow exhibit increased ability to absorb nutrients, relative to other cells in these cultures or organoids without flow. Our results indicate that this system can be utilized to accurately model absorption dynamics of specific substrates and to test the effects of therapeutic compounds, such as SGLT2 inhibitors. As flow is an essential component of the nephron, these experiments also build towards more sophisticated organoid microphysiological systems and artificial kidney devices.

Multi-Segmented Kidney Organoids Derived from Human ES Cells by Stepwise Transcription Factor Administration Ken Hiratsuka,[2] Toshiaki Monkawa,[2] Shintaro Yamaguchi,[2] Ryuji Morizane,[1] Shigeru B. Ko,[2] Hiroshi Itoh,[2] Minoru S. Ko.[2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Keio University School of Medicine, Tokyo, Japan.*

Background: We have recently reported a method to differentiate renal tubule-like cells from human Embryonic Stem Cells(hESCs) by a combinatorial administration of defined transcription factor(TF) mRNAs. However, a critical problem of this protocol, referred as direct reprogramming, is that it generates only proximal and distal tubular cells, but not other cell types. Here, we identified TFs that can induce the formation of SIX2+ metanephric mesenchyme/renal vesicles, which can be further differentiated into all other renal linages.

Methods: We utilized the human ES lines with doxycycline-inducible transcription factors (~700 genes), analyzed correlation of gene expression response to the induction of human TFs with tissue-specific gene expression in silico, and identified candidate TFs for differentiating towards renal lineages. Modified mRNAs for TFs were synthesized by in vitro transcription. hESCs were transfected with several combinations of synthetic mRNAs for four days by lipofection and cultured for up to 14 days to form kidney organoids, mimicking renal developmental stage. hESCs-derived kidney organoids were used for RNA sequencing analysis(RNA-Seq) and were tested functional assays to model kidney injury.

Results: Based on in-silico analysis, we identified a set of four TFs that induce SIX2+ metanephric mesenchyme and another set of four TFs that help differentiate toward renal vesicles. Two days after the transfection of the first set of four TFs together into hESCs, metanephric mesenchyme cell populations ($SIX2^+$, $SALL1^+$) were induced efficiently (~95%). Subsequent administration of the second set of four TFs transfection induced differentiation into renal vesicles($PAX8^+LHX1^+$). On day 14, epithelial characteristic changes and multi-segmented kidney structures containing podocyte(PNA+PODXL+), proximal tubules(AQP1+KSP+), and distal tubules(CDH1+BRN1+) were observed in both 2D and 3D cultures. RNA-Seq analysis also showed the global expression profile closely resembled kidney profile in renal developmental stages. Moreover, treatment with gentamicin, nephrotoxic agent, induced KIM-1 expression.

Conclusions: We have identified specific TFs for the differentiation of hESCs toward renal lineage via SIX2+ metanephric mesenchyme, and generated multi-segmented functional kidney organoids.

FR-OR101

Nephron Organoids Derived from Patients with ARPKD Model Polycystic Kidney Disease Respond to a cAMP Inducer and an Src Inhibitor and Provide a Platform for Drug Screening In Vitro Ryuji Morizane,[1,3] Tomoya Miyoshi,[1] Navin R. Gupta,[1,3] Koichiro Susa,[1] Edgar Garcia,[2] Albert Q. Lam,[1] Jing Zhou,[1,3] M. Todd Valerius,[1,3] Joseph V. Bonventre.[1,3] *[1]Brigham & Women's Hospital/Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Stem Cell Institute, Cambridge, MA.*

Background: Nephron organoids, derived from human pluripotent stem cells (hPSCs), represent a method to study inherited kidney diseases and perform drug screening *in vitro*. Previously, we established proof of concept by modeling autosomal dominant PKD (ADPKD), an adult-onset form, using PKD1 or PKD2 CRISPR-mutant hPSC lines that generated 6% cystic organoids. Here, we sought to model autosomal recessive PKD (ARPKD), an early-onset form, using patient derived induced pluripotent stem cell lines (hiPSCs) to generate cystic organoids with greater efficiency, establishing a suitable platform for studying cystogenic mechanisms and therapeutic screens *in vitro*.

Methods: Nephron organoids were generated in 96-well culture plates from a human embryonic stem cell (hESC) line and a hiPSC line derived from subjects without cystic kidney disease (controls), and 2 ARPKD patient-derived hiPSC lines using our established protocol. Cyst formation was evaluated by bright field imaging and staining for LTL and CDH1. Organoids were treated with forskolin, a cAMP inducer, and tubular cell proliferation assessed by Ki67 staining. Abnormal polarization of cystic epithelia was determined by NaK-ATPase staining. The effect of Src inhibition on cystogenesis was assessed by organoid size.

Results: Patient-derived ARPKD nephron organoids spontaneously formed cysts and demonstrated enhanced cystogenesis with forskolin treatment. Bright field imaging detected cysts in >90% of ARPKD organoids, while control hESC and hiPSC organoids formed very few cysts. Forskolin increased the number of $Ki67^+$ tubular epithelial cells in ARPKD organoids, but not in controls. Mislocalization of the NaK-ATPase to the apical membrane was observed in ARPKD organoids, while control organoids demonstrated NaK-ATPase basolateral restriction. Src inhibition decreased the size of ARPKD organoids.

Conclusions: Patient-derived ARPKD organoids efficiently demonstrated cystic phenotypes that retain known pathophysiology: proliferative response to cAMP and loss of tubular epithelial cell polarity. Src treatment suppressed cystogenesis in a 96-well format, indicating the feasibility of drug screening *in vitro*.

Defining Cellular Ontologies in Inducible Pluripotent Stem Cell (iPSC)-Derived Kidney Organoids by Mapping into Human Nephrogenesis via ssRNAseq Jennifer L. Harder,[1] Edgar A. Otto,[1] Rajasree Menon,[1] Cristina Cebrian Ligero,[1] Jizhong Zou,[2] Benjamin S. Freedman,[4] Robert G. Nelson,[3] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]NHLBI, NIH, Bethesda, MD; [3]National Institutes of Health, Phoenix, AZ; [4]University of Washington, Seattle, WA.*

Background: Generation of kidney organoids from iPSCs offers a novel method to study genetic effects on kidney cell phenotypes, and may provide useful models of kidney development and disease. Techniques to address the variable cell heterogeneity of these organoids will enhance their value as model systems.

Methods: iPSCs were derived from peripheral blood mononuclear cells from individuals with diabetic kidney disease and kidney organoids were generated using a Matrigel sandwiching technique. Droplet-based single cell RNA-Seq (ssRNAseq) was performed on dissociated cells and sequencing data were aligned to the human genome. Downstream clustering and further analyses were performed using various R statistical packages (Seurat, SC3, Limma). Organoid single cell gene expression was compared to human fetal kidney ssRNAseq data and to publically available expression datasets.

Results: SsRNAseq signatures of cells from iPSC-derived organoids separated into 3 clusters with distinct patterns of differential gene expression reflecting differentiated kidney cell lineages: podocyte (PODXL, NPHS1, NPHS2, CLIC5), tubular (IGFBP7, SLC3A1, VILLIN1, CUBN, CLDN16), and stromal/mesangial (COL3A1, TAGLN, ACTA2). Gene expression of these clusters mapped to cell clusters from ssRNAseq analysis of early second trimester human fetal kidney. When compared to bulk RNA expression patterns of human fetal and adult tissues, iPSC-derived kidney organoid

clusters overlapped prominently with microdissected developing and adult murine kidney tissues and showed kidney specificity.

Conclusions: Human iPSC-derived kidney organoid cultures contain subsets of cells with unique gene expression patterns that recapitulate distinct tissue states of developing and adult human kidney. Identification of individual cells with specific markers of interest provides both the ability to analyze co-expression of genes within an individual cell in a heterogeneous environment and a method to isolate cells of interest within organoid experiments. These results highlight the benefits of modeling human kidney disease with human iPSCs in a kidney organoid culture system and provide strategies to address the system's inherent cellular heterogeneity.

FR-OR103

Defining the Cellular Composition of Human Kidney Organoids Using High Throughput Single Cell Sequencing Alexander N. Combes,[2,1] Luke Zappia,[1] Belinda Phipson,[1] Pei Xuan Er,[1] Alicia Oshlack,[1] Melissa H. Little.[1,3] *[1]Murdoch Children's Research Institute, Melbourne, VIC, Australia; [2]Anatomy and Neuroscience, University of Melbourne, Parkville, VIC, Australia; [3]Peadiatrics, University of Melbourne, Parkville, VIC, Australia.*

Background: Single cell sequencing is a rapidly developing method for transcriptional analysis that has resulted in new insight into the cellular composition of complex tissues. Our lab and others have recently established protocols to direct the differentiation of human pluripotent cells to a kidney fate. This resulted in the formation of self-organizing structures that contain the basic components of the developing kidney. Understanding the cellular composition of these organoids is important to clarify the extent of tissue-specific diseases that may be modelled in this system, and to determine whether all known renal progenitors have been generated.

Methods: Kidney organoids were generated as previously described and harvested after 18 days of culture. We used the 10x Genomics Single Cell platform to profile ~7000 cells from three independent organoids.

Results: Clustering the single cell data identified multiple cell types enriched for markers of early proximal tubule, podocyte, pre-podocyte, collecting duct, ureter, vasculature, neural cells, and multiple interstitial populations. Cell types such as the vasculature and podocytes expressed multiple markers that enable unequivocal identification and give an insight into the state of maturity and fidelity of those cell types. Two distinct populations were identified which were enriched for podocyte markers such as PODXL, NPHS1, NPHS2, PTPRO, and SYNPO. While these both suggest podocyte identity, this may infer distinctions between early visceral and parietal epithelial cell types. Nephron segments such as the loop of Henle and distal tubule were not clearly identified. However, remaining epithelial clusters may represent progenitors of mature nephron segments. This is consistent with organoid morphology, which suggests nephron segmentation equivalent to Stage III/capillary-loop formation.

Conclusions: The analysis of organoid cellular composition using single cell transcriptional profiling has enabled a rapid survey of cellular diversity and fidelity of the cell types generated. The major cell types previously identified in kidney organoids were confirmed and extended with gene expression profiles for each. This data suggests that our kidney organoids will be useful for modelling development and disease of the early proximal tubule, collecting duct, and podocytes.

Defining Kidney Organoid Cell Diversity by scRNA-Seq Haojia Wu,[1] Kohei Uchimura,[1] Erinn L. Donnelly,[1] Samantha A. Morris,[2] Benjamin D. Humphreys.[1] *[1]Division of Nephrology, Washington University in St. Louis, Saint Louis, MO; [2]Department of Developmental Biology, Washington University in St. Louis, Saint Louis, MO.*

Background: Kidney organoids differentiated from pluripotent stem cells hold great promise for understanding organogenesis, disease modeling and ultimately as a source of replacement tissue. Realizing this potential requires a comprehensive evaluation of organoid cell diversity and differentiation state.

Methods: We generated kidney organoids from human BJFF iPS cells (Little protocol). Proper organoid differentiation was confirmed by histology and immunofluorescence. Day 26 organoids were processed for single cell RNA-Sequencing (scRNA-Seq) using DropSeq. We sequenced 4958 cells to a final read depth of 9086 mapped reads/cell with 2137 transcripts and 1185 unique genes detected per cell. Single cell data was visualized by an unsupervised approach combining dimension reduction and graph-based clustering embedded in Seurat. Clusters were annotated by examining known markers and gene ontology analysis. Gene correlation was visualized after data transformation by diffusion based imputation.

Results: Unsupervised clustering revealed 12 separate cell types present in d26 organoids. Kidney cell types made up 61% of all cells: podocytes, proximal tubule (PT), Loop of Henle (LOH), distal convoluted tubule, myofibroblasts and fibroblasts. The epithelial cell types were immature. For example, PT cells expressed terminal differentiation markers SLC3A1, SLC34A1 but coexpressed anterior intermediate mesoderm markers LHX1 and EMX2. LOH also expressed differentiation markers (SLC12A1) and developmental markers (ID1, ID2, and ID4). Surprisingly, many known neural markers (e.g. CRABP1, MAP2, PCP4 and CNTNAP2) were uniquely expressed in four cell clusters and were absent from all kidney cell clusters, indicating distinct neuronal populations. In fact neuronal cell types made up 20.5% of the cell total. Re-analysis of the bulk RNA-seq data in Takasato *et al* confirmed the presence of these neuron-specific genes suggesting that neural differentiation may be a common outcome using this differentiation protocol.

Conclusions: We provide the first comprehensive scRNA-Seq analysis of 4958 kidney organoid cells. We reveal diverse kidney cell types that are immature and the unexpected emergence of neuronal identity with the kidney organoid.

Transcription Factor Meis1 Is Upregulated in Kidney Stroma after Injury and in Aging and Regulates Tubulointerstitial Cross-Talk Monica Chang Panesso,[4] Farid F. Kadyrov,[2] Flavia G. Machado,[3] Benjamin D. Humphreys.[1] *[1]Washington University School of Medicine, Clayton, MO; [2]Washington University in St Louis, St Louis, MO; [3]Washington University in St Louis, School of Medicine, St Louis, MO; [4]Washington University in St. Louis, St Louis, MO.*

Background: $P16^{INK4a}$, a cell cycle regulator and mediator of cellular senescence, accumulates during aging including in kidney. Meis1 is a transcription factor known to regulate $p16^{INK4a}$ and other cyclin-dependent kinases. We hypothesized that Meis1 may mediate cell senescence in kidney and investigated the expression and function of Meis1 in kidney injury and aging.

Methods: We used Meis1ECFP reporter mice and antibody-based detection of endogenous Meis1. We also deleted Meis1 from kidney stroma by crossing a FoxD1-GFPCre with the Meis1-floxed allele.

Results: Meis1 was strongly expressed in PDGFRβ+ pericytes and fibroblasts based on both immunofluorescence and Meis1ECFP reporter mice. Meis1 mRNA and protein was upregulated after bilateral ischemia-reperfusion injury (IRI). It was also strongly upregulated in myofibroblasts of aged (23 mo) mice. To examine the functional role of Meis1 in kidney stroma, we generated bigenic $Meis1^{f/f}$;$FoxD1GC^{+/-}$. Examination by qPCR and IF staining showed efficient Meis1 deletion of approximately ~90% compared to controls. There was no gross histological abnormality at either P0 or P30 in the $Meis1^{f/f}$;$FoxD1GC^{+/-}$ compared to littermate controls. However by P30, kidneys of $Meis1^{f/f}$;$FoxD1GC^{+/-}$ mice weighed less compared to controls and had a higher BUN. Further histological evaluation at P30, revealed unexpected expression of Kidney Injury Molecule-1 (Kim1) protein expression in the outer medulla, indicating tubular injury. Kim1 upregulation was confirmed by qPCR. There was no NGAL expression indicating that the injury pattern was restricted to the S3 proximal tubular segment. Meis1 knockout mice had normal peritubular capillary density, normal numbers of glomeruli and no albuminuria.

Conclusions: Meis1 is upregulated in myofibroblasts during kidney fibrosis and in aging. Surprisingly, conditional deletion of Meis1 in the stromal lineage led to focal injury of the S3 segment of the proximal tubule in the absence of structural kidney abnormalities. These findings suggest that Meis1 expression in kidney stroma regulates proximal tubule health by a non cell-autonomous mechanism.

FR-OR106

Renal Tubular-Specific Jagged1 Deletion Ameliorates Kidney Fibrosis via Mitochondrial Transcription Factor A (TFAM) Regulation and Metabolic Reprogramming Shizheng Huang, Jihwan Park, Chengxiang Qiu, Szu-Yuan Li, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Notch is a basic cell-cell communication pathway where expression of the ligand, Jagged1,2 or Delta1,3,4 on signal-sending cells, Notch1-4 on the signal-receiving cell. Our group previously established that tubular epithelial cell (TEC) Notch signaling plays a key role in kidney fibrosis development. However, the precise ligand and receptor pairs that contribute to kidney fibrosis still remain unknown. Here we performed a systematic analysis to define the specific ligands and molecular pathways of Notch-induced fibrosis development in TEC.

Methods: To examine Notch ligands and receptors expression profiles, we used genome wide gene expression arrays from well phenotyped microdissected human kidney tubule samples (n=94). Mechanistic studies were performed by generating mice with tubule-specific deletion of Jagged1 (Ksp^{cre}/$Jagged1^{flox/flox}$). Kidney injury was induced by administering folic acid (FA) intraperitoneally. In vitro studies were performed using a co-culture system of rat tubule epithelial cells (NRK52E) and mouse stromal cells that express Jagged1. Direct targets of Notch signaling were identified by ChIP-Seq with co-transcription factor Rbpj.

Results: In microdissected human kidney tissue samples, of the ligands, Jagged1 showed the best correlation with the degree of interstitial fibrosis. Increased Jagged1 expression was recapitulated in the FA-induced kidney fibrosis model and in primary cultured TEC treated with TGFB1. Mice with tubule specific deletion of Jagged1 mice showed no kidney specific alterations at baseline, but were protected from FA-induced kidney fibrosis. There was marked reduction in inflammatory and profibrotic gene expression and improvement of histology in the Jagged1 knock-out mice following FA injection. In vitro co-culture studies indicated that Jagged1 expression induces proliferation and dedifferentiation of TEC. We found that mitochondrial transcription factor A (TFAM) is a direct target gene for Notch signaling by ChIP-seq. Expression of TFAM could rescue the metabolic defect and protect from Jagged1-induced fibrosis development in co-culture system.

Conclusions: The effect of Notch in TEC induced fibrosis development is mediated by Jagged1. Jagged1 induces epithelial dedifferentiation and fibrosis via TFAM mediated metabolic reprogramming.

Myokines Mediate Muscle-Kidney Crosstalk Suppressing Metabolic Reprogramming and Fibrosis in Damaged Kidneys Hui Peng,[3,1] Yanlin Wang,[1] William E. Mitch,[1] Sandhya S. Thomas,[2] Zhaoyong Hu.[1] *[1]Baylor College of Medicine, Houston, TX; [2]None, Houston, TX; [3]The third affiliated hospital of Sun Yat-sen University, Guangzhou, China*.

Background: Kidney injury initiates metabolic reprogramming in tubule cells that contributes to the development of chronic kidney disease (CKD). Because exercise might benefit the outcomes of CKD, we hypothesized that the induction of myokines will improve kidney energy metabolism and suppress kidney damage.

Methods: we investigated how a substitute for exercise, overexpression of PGC-1α only in skeletal muscles (mPGC-1a), affects recovery from kidney tubule cell damage in three mouse models including folic acid nephropathy (FAN); unilateral ureteral obstruction (UUO); or subtotal nephrectomy (CKD).

Results: Despite injury from folic acid, unilateral ureteral ligation or subtotal nephrectomy, kidney tubules from mPGC-1α mice resisted progressive cellular damage and subsequent fibrogenesis. Metabolomics analysis revealed improved energy metabolism and ATP production in injured kidneys from mPGC-1α mice. A myokine-enriched serum fraction from mPGC-1α mice (<50 kDa but > 10 kDa) improved energy metabolism in primary cultures of tubule cells. Specifically, the myokine, irisin, protected kidney cells from injury by suppressing metabolic reprogramming. A neutralizing anti-irisin antibody blocked improvements in kidney cell metabolism engendered by serum from mPGC-1a mice. Recombinant irisin administration to mice with kidney injury attenuated kidney damage and fibrosis. The mechanism underlying irisin-initiated improvements is that irisin competes with TGF-β1 for binding to the TGF-b type 2 receptor, thereby impeding activation of the TGF-β type 1 receptor and Smad2/3 signaling, as result, suppression of metabolic reprogramming and fibrogenesis.

Conclusions: myokine-mediated crosstalk between muscle and kidney can protect kidney tubule cell from damage. Myokine, irisin counteracts metabolic reprogramming in injured kidney cells with improvement in kidney function and suppression of kidney fibrosis.

RNA of APOL1 Risk Alleles Causes Cellular Toxicity through the PKR Pathway Zhe Han,[1,2] Yulong Fu,[1] Jun-yi Zhu.[1] *[1]Children's National Health System, Washington, DC; [2]Dept. of Pediatrics, George Washington University, Washington, DC.*

Background: African Americans are at higher risk for developing chronic kidney diseases due to APOL1 risk alleles (RA), but the mechanism of the cellular toxicity remains unclear. We generated *Drosophila* models of APOL1 nephropathy by expressing APOL1-RA in nephrocytes, which shares striking similarities with podocytes. Using fly genetic screen, we identified genes that interact with APOL1-RA. One of these genes is Pyk, homolog of human protein kinase R (PKR). PKR was suggested to interact with APOL1-RA RNA. Here we test the hypothesis that the APOL1-RA RNA induce toxicity through activating the PKR pathway.

Methods: A series of transgenic flies carrying APOL1-RA with different mutations were generated. Some carry an early stop codon so that these APOL1 proteins are gone but RNA remains same (STOP mutations), some carry synonymous mutations so that the APOL1 RNA no longer interacts with the Pyk protein, but proteins are same (Synonymous mutations). These transgenic lines, together with controls, were tested in different cell types. We also tested how Pyk knocking down affect the phenotype of these transgenes in different cell types, and whether the PKR inhibitor is beneficial for fly models of APOL1 nephropathy.

Results: We found that expression of either STOP or Synonymous mutations of APOL1-RA lead to cellular toxicity. In the fly wing, phenotypes caused by APOL1 RNA and protein appear different, suggesting that APOL1 RNA and protein have different molecular mechanism of cellular toxicity. In the nephrocytes, however, APOL1 STOP and Synonymous mutations cause similar phenotype, characterized as nephrocyte hypertrophy followed by functional decline and cell death. Knocking down of Pyk could rescue the toxicity caused by APOL1-RA with STOP mutations but not by APOL1-RA with Synonymous mutations, suggesting that PKR interaction is uniquely required for the APOL1 RNA toxicity. Feeding with PKR inhibitor reduced the overall toxicity of APOL1-G1 and G2, suggesting that inhibiting the PKR pathway is beneficial for reducing the cellular toxicity caused by the RNA of APOL1-RA.

Conclusions: Our findings demonstrated that both the RNA and the protein of APOL1-RA contribute to the overall cellular toxicity. We provided the *in vivo* evidence for the mechanism of APOL1 RNA toxicity through the PKR pathway, and showed that PKR inhibitor could be used as a potential therapeutic treatment to reduce APOL1 RNA toxicity.

Potential Therapeutic Targets for CKD by Comparative Analysis of Conserved Transcriptional Changes in Human and Mouse Kidney Fibrosis Rojesh Shrestha,[1] Jihwan Park,[1] Chengxiang Qiu,[1] Shizheng Huang,[1] Szu-Yuan Li,[1] Yi-An Ko,[1] Thomas Bell,[2] Aaron Donner,[2] Emily Brand,[2] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Ionis Pharmaceuticals, Carlsbad, CA.*

Background: Kidney fibrosis is the histological manifestation of chronic kidney disease (CKD). Kidney fibrosis is associated with global gene expression changes and while some of them might be causally related to disease development, others could be a consequence of the disease. While not all aspect of CKD is recapitulated in mouse models, changes that consistent in a different species could have a higher likelihood to be causal. Furthermore, genetic modification of mouse models can be used to understand causality.

Methods: We performed expression profiling for a large cohort (n=95) of human microdissected normal and CKD tubule samples. Using an adjusted linear regression model, we identified genes whose expression levels were significantly associated with phenotypic changes including GFR and tubulointerstitial fibrosis. By using RNA sequencing, we examined gene expression changes in four mouse fibrosis models; folate induced fibrosis (FA), unilateral ureteral obstruction (UUO), tubule specific Notch transgenic and podocyte specific risk allele APOL1 transgenic mice.

Results: We identified 761 conserved expression changes and 10 transcription factors between mouse and human kidney disease. Here, we focused on E74-like factor 4 (Elf4), which is mainly expressed in immune cells and fibroblasts. It is also an important transcription factor that mediates the effect of interferon response. Then, we developed and tested the effectiveness of antisense oligonucleotide (ASO) both in vitro and in vivo for Elf4 knock-down. ASO mediated knockdown of ELF4 in kidney prevented interstitial fibrosis in FA model. Mice injected with Elf4 ASO showed lower expression of fibrosis markers (vimentin, fibronectin, collagen) compared to control FA injected mice. In addition, Elf4 ASO mice also showed marked histological improvement in fibrosis.

Conclusions: Thus, comparative analysis of human and mouse kidney fibrosis have identified conserved genes and pathways in kidney fibrosis. These genes can serve as potential new biomarkers or therapeutic targets for kidney disease development.

Smad Anchor for Receptor Activation (SARA) Overexpression in Pericytes Prevents Renal Fibrosis Tomoko Hayashida,[2,3] Zhe Han,[1] Constance Runyan,[2] H. William Schnaper,[2,3] Xiaoyan Liang.[2] *[1]Children's National Medical Center, Washington, DC; [2]Northwestern University, Chicago, IL; [3]Lurie Children's Hospital, Chicago, IL.*

Background: We previously reported that overexpressing SARA in cultured proximal tubular epithelial cells prevents transforming growth factor (TGF)-β-induced mesenchymal phenotypic transition, and SARA knockdown alone is sufficient to induce such changes, suggesting that SARA is critical for maintenance of cellular phenotype. Here we tested whether maintaining SARA levels could ameliorate mouse and fly models of kidney fibrosis.

Methods: A SARA-overexpressing (SARA-Tg) mouse was generated by inserting full-length human cDNA for SARA1 preceded by a lox-stop-lox cassette at the ROSA26 locus, and was crossed with either PDGFRβ-Cre or tamoxifen-inducible Cre-ERT2 mice to induce ectopic SARA expression specifically in pericytes or systemically, respectively. Aristolochic acid (AA), 5 mg/kg, was given intraperitoneally 3x week for 4 weeks beginning at 8 weeks old, to SARA Tg-Cre mice and their Cre-negative littermates. The mice were sacrificed for analysis one week after AA treatment was stopped. Drosophila heart tube/nephrocyte fibrosis model was generated using a 4xHand-Gal4 driver and iRNA for Wds or Ada2b.

Results: Severe interstitial fibrosis was observed in wild-type mice subjected to AA and whole-kidney SARA expression was significantly lower than in non-AA control mice. On the other hand, SARA levels remained similar even after AA administration to SARA-Tg Cre-ERT2 mice treated with tamoxifen. Cre expression in PDGFRβ-Cre mice starts approximately at E12.5, but SARA-Tg PDGFRβ-Cre mice developed normally and were fertile. PDGFRβ-Cre expression was detected in pericytes and in some mesangial cells as expected. AA-induced fibrosis as detected by COL1A2 and α-smooth-muscle actin staining and mRNA levels were significantly less in PDGFRβ-Cre+ SARA-Tg mice compared to their Cre-negative littermates. In Drosophila, cardioblast/nephrocyte-specific knockdown of Wds or Ada2b caused fibrosis around the heart tube as shown by increased pericardin expression. SARA knockdown significantly enhanced, and SARA overexpression virtually prevented, pericardin expression.

Conclusions: SARA maintains renal cell phenotype in murine kidney disease and decreases the collagen-producing response in mice and flies. Our data support the recent findings by others that pericytes are essential for renal fibrosis, and suggest a role for SARA in ameliorating fibrogenesis.

Erythrocyte Adenosine A2B Receptor (ADORA2B) Promotes Oxygen Release to Counteract Renal Tissue Damage Zhangzhe Peng,[3,5] Renna Luo,[1] Lijian Tao,[4] Yang Xia.[2] *[1]The First Affiliated Hospital of Dalian Medical University, Dalian, China; [2]Universith of Texas-Medical School, Houston, TX; [3]Xiangya Hospital, Central South University, Changsha, China; [4]Xiangya hospital, Central South University, Changsha, China; [5]Departments of Biochemistry and Molecular Biology, McGovern Medical School, the University of Texas Health Science Center, Houston, TX.*

Background: Hypoxia, defined as inadequate oxygen supply to the whole body or a region of the body, is commonly seen in patients with chronic kidney disease(CKD), and frequently promotes renal failure. As the only cell type responsible for delivering oxygen, erythrocytes quickly respond to hypoxia by increasing their oxygen delivery ability. However, there is an enormous gap in our understanding of the role of erythrocytes in renal tissue damage.

Methods: Non-biased metabolomics screening was conducted in the whole blood of Angiotensin II(Ang II) treated WT mice. Subsequently, we infused Ang II to mice with specific deletion of ADORA2B in erythrocytes (ADORA2B$^{f/f}$/EpoR-Cre^{+}), and examined tissue hypoxia, damage, and erythrocyte function. Human studies were conducted on CKD patient samples.

Results: First, metabolomics profiling revealed that 2,3-BPG, an erythrocyte-specific metabolite regulating oxygen release, was highly elevated in the whole blood of Ang II treated mice. Erythrocyte-specific ADORA2B deficiency suppressed Ang II-induced 2,3-BPG production and 2,3-BPG mutase activity. After Ang II infusion, erythrocyte oxygen release ability (P50) was significantly elevated in EpoR-Cre^{+} mice but not in ADORA2B$^{f/f}$/EpoR-Cre^{+}. Moreover, renal and cardiac hypoxia was more severe in ADORA2B$^{f/f}$/EpoR-Cre^{+} mice. Ang II also significantly increased proteinuria in ADORA2B$^{f/f}$/EpoR-Cre^{+} mice. In addition, both the protein and mRNA levels of HIF-1α in heart and kidney were further increased in kidneys and hearts of ADORA2B$^{f/f}$/EpoR-Cre^{+} mice infused with Ang II, together with the mRNA levels of collagen I, fibronectin, indicating significantly more severe tissue damages. Mechanistically, we revealed that AMPK is an intracellular signaling molecular which functions downstream of ADORA2B underlying elevated 2,3-BPG production by inducing BPG mutase activity. Subsequently, we translate our mouse study to human and confirmed that the levels of 2,3-BPG, P50 and p-AMPK were elevated in erythrocytes of mild CKD patients and further increased in severe CKD patients, indicating a compensation mechanism in response to hypoxia.

Conclusions: Our findings reveal a previously unrecognized beneficial role of erythrocyte ADORA2B signaling in Ang II-induced systemic hypoxia and renal tissue damage and thereby identify novel and important therapeutic possibilities for hypoxia-induced tissue damage.

Pik3c3-Dependent mTORC1 Signaling Mediates Compensatory Nephron Hypertrophy Ting Liu,[1] Jinxian Xu,[1] Benjamin D. Humphreys,[2] Caihong Dai,[1] Jian-Kang Chen.[1] *[1]Augusta University, Augusta, GA; [2]Washington University School of Medicine, Clayton, MO.*

Background: Nephron loss stimulates the residual nephrons to undergo compensatory nephron hypertrophy (CNH), which is implicated in progressive nephron damage. Activation of the mechanistic (formerly mammalian) target of rapamycin complex 1 (mTORC1) mediates uninephrectomy (UNX)-induced CNH. We recently observed class 3 phosphatidylinositol 3-kinase (Pik3c3) activation in the remaining kidney after UNX. However, whether Pik3c3 activation is essential for mTORC1 activation and CNH remains undefined.

Methods: We created homozygous *Pik3c3*-hypomorphic (*Hypo*) mice to compare with gender-matched heterozygous (*Het*) and wild type *(WT)* littermates. We also created tamoxifen-inducible proximal tubule-specific *Pik3c3* knockout (*KO*) mice, which have a genotype of *Pik3c3*$^{flox/flox}$;*SLC34a1.CreER*^{T2}(+). Gender-matched *Pik3c3*$^{flox/flox}$;*CreER*^{T2}(-) littermates were used as controls (*Ctrl*) mice.

Results: *Hypo* mice express markedly less Pik3c3 than *Het* littermates, which already express a lower level of Pik3c3 than *WT* littermates. Interestingly, when subjected to UNX, *Hypo* mice developed less CNH than both *WT* and *Het* mice, revealed by UNX-induced increases in kidney-to-body weight ratio (*WT*: 31.78±1.89 vs. *Hypo*: 18.10±1.31%, p<0.0001; *Het*: 27.14±1.04 vs. *Hypo*: 18.10±1.31%, p<0.001; n=5-7). Consistently, UNX induced significantly less CNH in *KO* mice than in *Ctrl* mice, indicated by UNX-induced increases in kidney-to-body weight ratio (*Ctrl*: 33.15±1.97 vs. *KO*: 15.81±2.82%, p<0.001; n=7) as well as protein-to-DNA ratio (*Ctrl*: 25.00±4.01 vs. *KO*: 9.78±2.88%, p<0.05; n=7). Signaling studies with immunoblotting and immunostaining unveiled that UNX-induced mTORC1 activation in the remaining kidney was markedly inhibited in both *Pik3c3*-hypomorphic and *Pik3c3-KO* models.

Conclusions: The present study using two genetically engineered mouse models provides unequivocal evidence that Pik3c3-dependent mTORC1 activation is a major mechanism underlying nephron loss-induced residual nephron hypertrophy.

Dysfunction of Proteasome in Podocytes Results in CKD Shinichi Makino,[2] Naritoshi Shirata,[4] Kanae Nonaka,[3] Motoko Yanagita,[3] Katsuhiko Asanuma.[1] *[1]Chiba University Graduate School of Medicine, Chiba, Japan; [2]Kyoto University Graduate School, Kyoto, Japan; [3]Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]Mitsubishi Tanabe Pharma Corporation, Toda, Japan.*

Background: Ubiquitin-proteasome(UP) and autophagy had been known as major intracellular degradation systems. The importance of autophagy in podocyte has already been reported, however, the role of UP has not well been understood.

Methods: To investigate the role of UP in podocyte, we generated podocyte-specific proteasome knockout mice (Rpt3^{pdKO}) by deletion of Rpt3, which is essential for construction of 26S proteasome, using Cre-loxP system under the regulation of the podocyte specific podocin promoter. To evaluate autophagy activity, LC3 was visualized by crossing with GFP-LC3 transgenic mice.

Results: Rpt3^{pdKO} mice developed albuminuria starting at 4 weeks of age and increased significantly higher levels compared with their Rpt3^{Ctrl} littermates on 8weeks of age. The ratio of sclerotic glomeruli and serum creatinine levels were significantly increased. The KO mice exhibited a significantly lower survival ratio than the littermates due to severe renal failure. Ubiquitinated proteins were accumulated and the oxidative stress marker 8OHdG intensity was increased in podocytes of Rpt3^{pdKO} mice. Expressions of p53 and cleaved caspase3 to regulate apoptosis were increased in podocytes of the KO mice. On the other hand, LC3 positive dots in the KO podocytes were not increased, and accumulation of p62 which is detected in autophagy failure, was seen in the KO podocytes.

Conclusions: Ubiquitin-proteasome plays an important role in podocytes, resulting in severe renal failure.

Keap1/Nrf2 Signaling Reveals Homeostatic Function in Renal and Cardiovascular Physiology Soma Jobbagy,[1] Dario A. Vitturi,[1] Sonia R. Salvatore,[1] Scott Hahn,[1] Adam Straub,[1] Arohan R. Subramanya,[2] Bruce Freeman,[1] Francisco J. Schopfer.[1] *[1]Pharmacology & Chemical Biology, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Keap1/Nrf2 signaling is well-established as a master regulator of cellular responses to oxidative stress; however, recent findings suggest that this pathway additionally performs key functions in renal solute and water homeostasis. Herein we study the functional consequences of constitutive graded Nrf2 activation on renal salt and water handling and integrate renal and cardiovascular endpoints.

Methods: Wild-type, Keap1 hypomorphic (Keap1$^{f/f}$), and Nrf2$^{-/-}$ mice were studied under control conditions or in response to dietary sodium maneuvers, and renal and plasma biomarkers were assayed by IF, PCR, immunoblot, and HPLC-MS/MS. Cardiovascular function was assessed by radiotelemetry and wire myography.

Results: Keap1$^{f/f}$ mice exhibited 5-fold upregulation of Nrf2 target gene NQO1 in the kidney and were polyuric. Consistent with a urine concentrating defect and volume depletion, hematocrits were higher in the Keap1$^{f/f}$ cohort (45.5% vs 37.2% WT). The latter was not attributable to upregulation of renal EPO expression or increased RBC antioxidant enzyme production, and resolved after salt loading. 2-fold down-regulated expression of total NKCC2 and NCC by western blot implicated a distal nephron defect. Compensatory activation of WNK signaling was consistent with 2-fold elevation in plasma renin activity and led to 3-fold increase in phospho-to-total NCC ratio in Keap1$^{f/f}$ mice after sodium depletion. Finally, 2-fold reduction in renal cycolooxygenase-1 and -2 in Keap1$^{f/f}$ mice suggests crosstalk between Nrf2 and prostaglandin signaling, and resulted in reduction in vasodilatory PGI_2. Blood pressure was unchanged between WT and Keap1$^{f/f}$ mice, however heart rate was significantly depressed in the Keap1$^{f/f}$ cohort. Wire myography revealed impaired vasodilation of resistance arteries in response to ACh.

Conclusions: Mice with genetic Keap1 hypomorphism were studied as a pharmacomimetic model of chemical Nrf2 inducers to delineate physiologic effects of this pathway. Keap1$^{f/f}$ mice display distal nephron defect with reduced urine concentrating function and volume depletion. Compensatory activation of RAS- and WNK-signaling likely serves to mitigate solute and water loss in this model. Differences in prostanoid biosynthesis suggest a mechanism underlying renal and vascular effects of constitutive Nrf2 activity.

FR-OR115

The Prevalence of Mesoamerican Nephropathy in Larreynaga-Malpaisillo, Leon, Nicaragua Stefano Bianchi,[1] Elba M. Jimenez penado,[2] Andrea Grillo,[1] Francesca Nistri,[1] Giada G. Santini,[1] Elisa Poderelli,[1] Eva D'Aurizio,[1] Sara Samoni,[1] Filippo Cellai,[1] Roberto Bigazzi.[1] *[1]ASL NO, Livorno, Italy; [2]Blood bank - Health MInister, León, Nicaragua.*

Background: An unrelenting epidemic of unexplained chronic kidney disease (CKD) affecting primarily young individuals has been observed throughout Central America. This condition has been called Mesoamerican Nephropathy (MeN). This disease is characterized by elevated serum creatinine, hyperuricemia, leukocyturia, and minimal

proteinuria and hematuria. Kidney biopsies are consistent with chronic tubulointerstitial nephritis. The causes of this epidemic remain obscure and systematic epidemiological data are scarse.

Methods: In the context of a joint effort between Regione Toscana and the Department of Leon we performed a screening of the population in the city of Malpaisillo-Larreynaga, in the Department of León, Nicaragua *. Out of a general population of 23885 inhabitants we selected 18510 subjects, age ≥ 12 years, (mean age (± SD) 36.3 ± 18 years, 8771 M, 9739 F), and extracted a sample of 2768 subjects (1310 M, 1458 F), of these 1915 subjects (723 M and 1192 F; mean age 38.9 ± 18) were enrolled. All participants filled a questionnaire and in all of them we collected blood and urine samples to estimate glomerular filtration rate (eGFR) (CKD-EPI mL/min/1.73m^2), and urine albumin excretion (UAE= albumin, mg / creatinine, g).

Results: Among participants, 1410 (73.6%; 483 M and 927 F) had normal eGFR, and 505 (26.4%; 240 M and 265 F) manifested CKD (Stage 1=21.6%; Stage 2=14.8%; Stage 3a= 25.5%; Stage 3b=15.8%; Stage 4=16%; Stage 5=6.3%). Males (33.2%) were more affected than females (22.2%). Among participants with CKD Stage 3-5, 160 (~50%) had UAE < 30 and 162 (~50%) had UAE > 30. Among the latter, only 40 (25%) of subjects manifested UAE > 300. No patient manifested nephrotic syndrome.

Conclusions: For the first time a systematic epidemiological approach to estimate the prevalence of MeN has been used. We report an alarming prevalence of CKD affecting a relatively young population in Malpaisillo-Larreynaga, Leon, Nicaragua. The disease is in large part asymptomatic and characterized by minimal proteinura in keeping with a diagnosis of tubulointerstitial disease. The cause(s) of this disease remain to be determined. *Perfil epidemiologico de la enfermedad renal cronica y sus principales factores de riesco en el municipio Larreynaga-Malpaisillo, Leon, Nicaragua.

CKDu in Mexico: The Case of Poncitlán, Jalisco Guillermo Garcia-Garcia, Evelyn F. Morraz Mej?a, José M. Montalban, Jonathan Chavez, Luz E. Vazquez martinez, Eduardo N. Pacheco, Karina Renoirte. *Hospital Civil De Guadalajara, University of Guadalajara, Guadalajara, Mexico.*

Background: An elevated prevalence of CKD of unspecified cause (CKDu) has been documented in various developing countries. It has been reported by the media a high prevalence of CKDu in towns located by Chapala Lake, Mexico, particularly in the communities of San Pedro Itzican, Agua Caliente, and Mezcala, in Poncitlan, Mexico. Environmental factors have been blamed as the probable cause of the pandemia.

Methods: Since 2006, we pioneered screening people at risk for the presence of CKD using mobile units that travel to rural and urban communities of Jalisco. Trained personnel collected demographic and clinical data, and obtained blood and urine for serum chemistry and dipstick urinalysis. Those individuals who were aware they had kidney disease were not assessed; all others were eligible to participate. GFR was estimated with the MDRD formula. CKD was defined as an eGFR < 60 ml/min/1.73m2.

Results: Between 2007-2016, 50,909 adults were screened with the mobile units. Findings in individuals residing in Poncitlan were compared with those living in other Jalisco municipalities (Table)

Conclusions: CKD and proteinuria were highly prevalent among individuals living in communities of Poncitlan, Mexico. CKD prevalence was two-fold higher among the adult population in comparison with other Jalisco municipalities. Prevalence of proteinuria was three-fold higher than in other communities of Jalisco. Undergoing studies will provide information on the causes of this epidemic

SPRINT Trial: Intensive Hypertension Treatment and CKD Incidence Rita Magriço,[1] Miguel Bigotte Vieira,[2] Catarina Viegas dias,[3] Lia Leitão,[4] João Sérgio Neves.[5] *[1]Nephrology Department, Hospital Garcia de Orta, Almada, Portugal; [2]Nephrology and Renal Transplantation Department, Centro Hospitalar Lisboa Norte, Lisboa, Portugal; [3]Dafundo Family Health Unit, Agrupamento de Centros de Saúde Lisboa Ocidental e Oeiras, Lisboa, Portugal; [4]Neurology Department, Hospital Prof. Doutor Fernando Fonseca, Amadora, Portugal; [5]Department of Endocrinology, Diabetes and Metabolism, Hospital de São João, Faculdade de Medicina, Universidade do Porto, Porto, Portugal.*

Background: The Systolic Blood Pressure Intervention Trial (SPRINT) showed that in non-diabetic patients with high cardiovascular risk, intensive systolic blood pressure treatment (<120 mmHg) was associated with lower rates of major cardiovascular events and mortality. However, intensive treatment was associated with increased CKD incidence. We evaluated the association between mean arterial pressure (MAP) reduction and CKD incidence in the intensive-treatment group.

Methods: We performed a secondary analysis of the SPRINT trial. We categorized patients in the intensive-treatment group according to MAP reduction: <20 mmHg; 20 to <40 mmHg; ≥40 mmHg. We defined the primary outcome as ≥30% reduction in eGFR to <60 ml/min/1.73m2, and the secondary outcome as cardiovascular events or death. We also performed a propensity score analysis, matching patients in each MAP reduction category from the intensive-treatment group with patients from the standard-treatment group, in order to calculate the number needed to treat (NNT) regarding cardiovascular events or mortality and the number needed to harm (NNH) regarding CKD incidence.

Results: 1138 (34.4%) patients presented MAP reduction <20 mmHg, 1857 (56.3%) presented 20 to <40 mmHg and 309 (9.4%) ≥40 mmHg. Adjusted hazard ratios for CKD incidence were 2.14 (95% CI, 1.25-3.66) for MAP reduction between 20 and 40 mmHg and 6.35 (95% CI, 2.82-14.29) for MAP reduction ≥40 mmHg. In the propensity score analysis, MAP reduction <20 mmHg presented a NNT of 43.5 and a NNH of 65.4; MAP reduction between 20 and <40 mmHg presented a NNT of 41.7 and a NNH of 35.1 and MAP reduction ≥40 mmHg presented a NNT of 95.2 and a NNH of 15.9.

Conclusions: Higher categories of MAP reduction were associated with increased risk of CKD incidence. The benefit-risk balance of intensive treatment was less favourable as MAP reduction increased.

FR-OR118

The Effect of Intensive Blood Pressure Lowering on Kidney Tubule Injury among Participants with CKD in the SPRINT Trial Rakesh Malhotra,[9] Timothy Craven,[10] Walter T. Ambrosius,[2] Anthony A. Killeen,[4] William E. Haley,[1] Alfred K. Cheung,[8] Michel Chonchol,[7] Mark J. Sarnak,[6] Chirag R. Parikh,[5] Joachim H. Ix,[9] Michael Shlipak.[3] *[1]Mayo Clinic, Jacksonville, FL; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]San Francisco VA Medical Center, San Francisco, CA; [4]University of Minnesota, Minneapolis, MN; [5]Yale University, New Haven, CT; [6]Tufts Medical Center, Boston, MA; [7]University of Colorado, Aurora, CO; [8]University of Utah, Salt Lake City, UT; [9]UCSD, San Diego, CA; [10]Wake Forest, Winston-Salem, NC.*

Background: Randomization to the intensive (SBP<120 mm Hg) arm in SPRINT resulted in more rapid decline in estimated glomerular filtration rate (eGFR) than in the standard arm (SBP <140 mm Hg). Whether this change reflects hemodynamic effects or accelerated intrinsic kidney damage is unknown.

Methods: In a subset of SPRINT with CKD (eGFR<60 ml/min/1.73m^2), we compared changes in kidney tubule biomarkers over 4 years between the intensive and standard arms. Among these 978 participants (519 in intensive and 459 in the standard arm), we measured urine biomarkers of tubule cell injury (KIM-1, IL-18), repair (YKL-40) and inflammation (MCP-1) at baseline, year 1 and year 4. Biomarkers were assayed *en bloc* in multiplex panels. Biomarker changes were evaluated using linear mixed-effects models in an intention-to-treat design.

Results: Mean age was 72± 8.6 and eGFR 46.1 ± 9.4. Clinical characteristics, eGFR, urinary albumin-to-creatinine ratio (ACR), and all 4 biomarkers were similar between arms at baseline. Compared to the standard arm, eGFR was 2.9 and 3.3 ml/min/1.73m^2 lower in the intensive arm at year 1 and year 4, and ACR was also lower in the intensive arm. All urinary biomarkers, except YKL-40, were significantly lower at year 1 in the intensive arm, and none differed between arms at year 4 (**Figure 1**).

Conclusions: Among CKD participants in SPRINT, intensive BP control reduced eGFR but did not increase urine markers of tubule cell injury. These findings may support the hypothesis that eGFR decline in the intensive arm of SPRINT reflects hemodynamic changes.

Funding: NIDDK Support

Longitudinal Changes in Plasma Biomarkers Strongly Associate with Risk for DKD Progression in the VA NEPHRON-D Trial Steven G. Coca,[1] Yuan Huang,[2] Dennis G. Moledina,[3] Veena Rao,[3] Divya A. Verghese,[1] Wassim Obeid,[3] Girish N. Nadkarni,[1] Bart Ferket,[1] Linda F. Fried,[4] Chirag R. Parikh.[5] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]VA Cooperative Studies Program, West Haven, CT; [3]Yale School of Medicine, New Haven, CT; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]Yale University and VAMC, New Haven, CT.*

Background: While baseline levels of plasma TNFR-1, TNFR-2, and KIM-1 are independently associated with risk for renal function decline in diabetic kidney disease (DKD), the prognostic value of longitudinal changes in these biomarkers is unknown.

Methods: In this ancillary study of the Veterans Affairs Nephropathy in Diabetes Trial (VA NEPHRON-D) that included 759 participants with plasma samples at both baseline and 1 year, we measured plasma TNFR1, TNFR2 and KIM-1 *via* MesoScale Discovery multiplex assay. We assessed the association between the change in plasma biomarker concentrations at 12 months from baseline with the renal endpoint (decline in eGFR or ESRD as defined in the trial) using Cox Proportional Hazards Models with adjustment for study arm, biomarker, eGFR and albuminuria at baseline and change in eGFR and albuminuria by 12 months.

Results: In the 123 (16%) participants who experienced the renal endpoint after 12 months, plasma TNFR1, TNFR2 and KIM-1 increased by 34%, 17%, and 6%, respectively by 12 months (**TABLE**). In the 636 participants that did not reach the renal endpoint, plasma TNFR1 and TNFR2 increased by 11% and 3%, respectively, whereas KIM-1 decreased by 6%. After multivariable adjustment, including baseline biomarker concentration eGFR, urine albumin at baseline and change in eGFR and albuminuria at 12 months, increases in TNFR1, TNFR2 and KIM-1 over time were associated with increased hazards of developing the renal end point (**TABLE**). There were no statistically significant differences in the change in the three biomarkers or interactions on the outcomes between the combination-therapy group vs. the monotherapy arms.

Conclusions: Longitudinal changes in plasma TNFR1, TNFR2 and KIM-1 add additional prognostic information to baseline concentrations of these markers, even after accounting for clinical variables, including changes in eGFR and albuminuria.

suPAR Serum Levels Predict Progression of Kidney Disease in Children Franz S. Schaefer,[7] Howard Trachtman,[3] Marietta Kirchner,[6] Salim Hayek,[1] David C. Wei,[5] Sanja Sever,[2] William E. Smoyer,[4] Jochen Reiser.[5] *[1]Emory University School of Medicine, Atlanta, GA; [2]Massachusetts General Hospital, Charlestown, MA; [3]NYU Langone Med Ctr, New York City, NY; [4]Nationwide Children's Hospital, Columbus, OH; [5]Rush University Medical Center, Chicago, IL; [6]University Heidelberg, Heidelberg, Germany; [7]University of Heidelberg, Heidelberg, Germany. Group/Team: ESCAPE Trial Consortium and the 4C Study Group.*

Background: Renal disease progression rate in chronic kidney disease (CKD) children is highly variable, and no serum markers exist today that aid with prediction of renal function decline. Even within individual age and disease groups, progression rate varies widely, defining a need for informative prognostic biomarkers predicting disease progression and the need for early intervention in an individual patient. Recently, soluble urokinase receptor (suPAR) has been shown to be a strong predictor of CKD incidence and progression. Here we determine whether elevated suPAR levels are associated with renal disease progression in children with CKD.

Methods: *Post-hoc* analysis of two prospectively followed pediatric CKD cohorts (ESCAPE trial and 4C Study) including 898 children (mean age 11.9±3.5 years) with serum suPAR level measured at enrollment and longitudinal eGFR measured prospectively. Renal diagnoses included CAKUT (70%), tubulointerstitial nephropathies (10.2%), glomerulopathies (7.7%), post-ischemic (4.7%), and other CKD (6.5%). Mean eGFR was 34±16 ml/min/1.73m^2, median follow-up 3.1 (0 to 7.9) years. The primary renal endpoint was a composite of 50% eGFR loss, eGFR<10 ml/min/1.73 m^2 or start of renal replacement therapy.

Results: 5-year endpoint-free renal survival was 64.5% (95%CI 57.4-71.7%) in children with suPAR in the lowest quartile as compared to 35.9% (95%CI 28.7-43.0%) in those with levels in the highest quartile (P<0.0001). In multivariable analysis, the risk of attaining the endpoint was higher in children with glomerulopathies and increased with age, blood pressure, proteinuria and lower eGFR at baseline. In patients with baseline eGFR>40 ml/min/1.73 m^2, higher log-transformed suPAR levels were independently associated with a higher risk of CKD progression (HR 5.12, 95% CI 1.56-16.7, P=0.007).

Conclusions: Elevated suPAR levels are independently associated with disease progression in children with mild to moderate CKD.

Funding: NIDDK Support

Soluble Urokinase Plasminogen Activation Receptor and Cardiovascular Mortality in Persons Undergoing Coronary Angiography Claudia Sommerer,[5] Marcus E. Kleber,[1] Christian Morath,[6] Jochen Reiser,[3] Martin G. Zeier,[2] Winfried März.[4] *[1]Heidelberg University, Mannheim, Germany; [2]None, Heidelberg, Germany; [3]Rush University Medical Center, Chicago, IL; [4]Synlab Services GmbH, Mannheim, Germany; [5]Nephrology, University Hospital of Heidelberg, HEIDELBERG, Germany; [6]University of Heidelberg, Heidelberg, Germany.*

Background: Soluble urokinase plasminogen activation receptor (suPAR) is an emerging biomarker for prediction and progression of kidney disease and cardiovascular outcomes. To further validate the value of suPAR as a cardiorenal biomarker we studied German persons undergoing coronary angiography having a follow-up of ten years.

Methods: suPAR was measured in baseline samples of participants of the Ludwigshafen Risk and Cardiovascular Health (LURIC) study. We estimated overall risk of cardiovascular death by Cox proportional hazards regression according to quartiles of suPAR, including age, sex, use of lipid-lowering drugs, body mass index, diabetes mellitus, hypertension, smoking, LDL cholesterol, HDL cholesterol, triglycerides, as well as eGFR (CKD-EPI), NT-proBNP, IL-6 and CRP as covariates.

Results: A total of 2922 participants (69 % males, mean age 62.7 ± 10.5) having a median GFR of 81ml/min/1.73 m^2 were included. 393 patients had a GFR<60ml/min /1.73 m^2. Median suPAR levels 3000 pg/ml (interquartile range, 2250-3980 pg/ml). Using the lowest quartile of suPAR as the reference, crude HRs for cardiovascular mortality were 1.58 (95% CI 1.16-2.16), 1.85 (95% CI 1.37-2.52) and 2.75 (95% CI 2.03-3.71) in the second, third and fourth quartile, respectively. Adjusting for eGFR or inflammation (IL-6 and CRP) did not materially alter this relationship. In a fully adjusted model HRs for cardiovascular death were 1.52 (95% CI 1.11-2.09), 1.56 (95% CI 1.14-2.15), and 1.78 (95% CI 1.28-2.46) in quartiles two to four.

Conclusions: suPAR predicts cardiovascular death over a period of ten years in persons undergoing coronary angiography, independent of kidney function and markers of systemic inflammation. su-PAR has the potential to stratify the risk in patients with cardiovascular disease and kidney disease. su-PAR could be a useful and additional biomarker in cardiovascular and renal medicine.

Treatment of Metabolic Acidosis in CKD with Fruits and Vegetables Yields Better Overall Health Outcomes Than Oral NaHCO3 Nimrit Goraya,[4,5] Jan Simoni,[3] Yolanda Munoz Maldonado,[1] Donald E. Wesson.[2,4] *[1]Biostatistics, Baylor Scott & White Health, Temple, TX; [2]Diabetes Health and Wellness Institute, Dallas, TX; [3]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX; [4]Internal Medicine, Baylor Scott and White Health, Temple, TX; [5]Internal Medicine, Texas A and M School of Medicine, Temple, TX.*

Background: Dietary acid reduction added to pharmacologic anti-angiotensin II therapy appears to provide adjunctive kidney protection and KDIGO guidelines recommend Na^+-based alkali for treatment of metabolic acidosis in chronic kidney disease (CKD). Nevertheless, base-producing fruits and vegetables (F+V) also improve metabolic acidosis and might yield better overall health outcomes in patients with CKD than Na^+-based alkali. We tested the hypothesis that F+V compared to oral $NaHCO_3$ (HCO_3) treatment of metabolic acidosis in CKD yielded better long-term (five years) health outcomes.

Methods: One hundred eight macroalbuminuric, non-diabetic CKD 3 subjects with metabolic acidosis but with serum [HCO_3] between 22-24 meq/L were randomized to receive F+V (n=36) in amounts to reduce dietary potential renal acid load by half, oral $NaHCO_3$ (HCO_3, n=36) 0.3 meq/Kg bw/day, or to Usual Care (UC, n=36). All had a systolic blood pressure (SBP) goal < 130 mm Hg using drug regimens including ACE inhibition and were followed with annual assessments for five years. A score of 1 for improved, 0 for no change, and -1 for worsened at 5 years was assigned to the following 4 parameters: plasma total CO_2 ($PTCO_2$), LDL, HDL, and change in medication dose (a decrease in dose among the 7 possible medications was considered improved; an increase in dose was considered worsened). A score of 1 for met goal and 0 for not meeting goal was assigned to eGFR (goal > 30 ml/min/m^2) and SBP (goal < 130 mm Hg) at five years.

Results: All three groups showed improved health outcomes during follow up ($p<0.05$) but the health score was greater than UC (1.17 ± 1.44) for both HCO_3 and F+V (2.89 ± 1.70 and 7.39 ± 1.61, respectively, $p<0.01$). Additionally, the F+V health score was greater than HCO_3 ($p<0.01$) due mostly to greater F+V than HCO_3 reductions in medication (predominately anti-hypertensive) dosage, lower LDL, and a greater proportion of patients achieving SBP goal.

Conclusions: Treatment of metabolic acidosis in CKD with F+V and $NaHCO_3$ yielded better overall health outcomes in CKD 3 patients than Usual Care but health outcomes were dramatically better in F+V than HCO_3. The data support an overall long-term health advantage of F+V compared to HCO_3 as a dietary acid reduction strategy for the treatment of metabolic acidosis in CKD 3.

Blood Pressure Lowering and Risk of Mortality in CKD: A Meta-Analysis of Randomized Controlled Trials Rakesh Malhotra,[10] Hoang Anh Nguyen,[5] Oscar Benavente,[6] Mihriye Mete,[2] Jonathan Mant,[8] Michelle Odden,[3] Carmen A. Peralta,[7] Alfred K. Cheung,[9] Girish N. Nadkarni,[1] Ruth L. Coleman,[11] Holman Rury,[11] Alberto Zanchetti,[12] Ruth Peters,[13] Nigel Beckett,[14] Jan A. Staessen,[4] Joachim H. Ix.[10] *[1]Ichan School of Medicine, New York, NY; [2]Medstar Health Research Institute, Hyattsville, MD; [3]Oregon State University, Corvallis, OR; [4]Studies Coordinating Centre, Division of Hypertension and Cardiovascular Rehabilitation, Department of Cardiovascular Diseases, University of Leuven, Leuven, Belgium; [5]UCSD Department of Nephrology and Hypertension, San Diego, CA; [6]University of British Columbia, Vancouver, BC, Canada; [7]University of California San Francisco/SFVAMC, San Francisco, CA; [8]University of Cambridge, Cambridge, United Kingdom; [9]University of Utah, Salt Lake City, UT; [10]UCSD, San Diego, CA; [11]University of Oxford, Oxford, United Kingdom; [12]Istituto Auxologico Italiano, University of Milan, Milan, Italy; [13]Imperial College London, London, United Kingdom; [14]Guys and St Thomas' NHS Foundation Trust, London, United Kingdom.*

Background: Trials in hypertensive patients demonstrate that intensive blood pressure (BP) lowering reduces CVD and mortality risk, but may increase risk of chronic kidney disease (CKD) progression. Whether intensive BP lowering is associated with a lower mortality in patients with prevalent CKD remains uncertain.

Methods: We conducted a meta-analysis of randomized controlled trials (RCTs) that enrolled patients with CKD stage 3-5 and determined whether randomization to more vs. less intensive BP control was associated with mortality. Ovid Medline, Cochrane Library, Embase, Pubmed, and ClinicalTrials.gov electronic databases were searched. All RCTs that compared two defined BP targets (either active treatment vs. placebo or no treatment, or intensive vs. less intensive BP control) and enrolled persons with CKD stages 3-5 exclusively or as CKD subgroup between January 1950 and June 2016 were included. The main outcome was mortality during the active phase of each trial.

Results: We identified 31 RCTs, among which we were able to extract the CKD subset mortality data in 19 trials. There were 1300 deaths among 15,861 participants with CKD. More vs. less-intensive BP control resulted in 14% lower risk of all-cause mortality (Odds Ratio (OR) 0.86; 95% CI 0.76- 0.96, p = 0.009) (**Figure 1**); a finding that was without significant heterogeneity (p=non-sig) across subgroups including type of treatment in the comparator arm (placebo vs. less intensive BP target), length of follow-up, presence of diabetes, baseline SBP, achieved SBP during the trial and degree of SBP differences across the treatment arms.

Conclusions: Randomization to more intensive BP control is associated with lower mortality risk among CKD trial participants.

Influence of Altitude of Residence on the Prevalence of Anemia of CKD Christos Argyropoulos,[4] V. Shane Pankratz,[3] Orrin Myers,[4] Mark L. Unruh,[4] Keith C. Norris,[2] Joseph A. Vassalotti.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]UCLA, Marina Del Rey, CA; [3]UNM Health Sciences Center, Albuquerque, NM; [4]University of New Mexico, Albuquerque, NM.*

Background: Hypoxia is the major regulator of erythropoietin production in the kidney. There are currently minimal data about the prevalence of anemia in patients with varying degrees of CKD who reside in high altitudes.

Methods: We undertook an exploratory analysis of the National Kidney Education Kidney Early Evaluation Program. Participant's address were geocoded to geographic coordinates using National Elevation US Database and the altitude of the residence of each participant in KEEP was determined. We examined prevalence of anemia (Hemoglobin, Hgb < 10g/dL) against the severity of CKD (eGFR) and other predictors after weighting the KEEP participants to the US census, in order to account for the self-selection bias in KEEP.

Results: In multivariate analyses, race, ACR, personal history of anemia (Table), age (a relationship that differed between women Figure A and men Figure B), eGFR and altitude were significant predictors of the odds of anemia (p<0.001). Predicted prevalence of anemia was half at 2.0 km elevation vs. sea level for all eGFR values (Figures C,D). There was no interaction between altitude and eGFR.

Conclusions: The odds of anemia differ for individuals residing at different altitudes. This relationship likely contributes to geographic disparities of CKD complications. Further studies should examine the response to iron and ESA according to altitude.

FR-OR125

The A-Splice Variant of NBCe1 (NBCe1-A) Is Necessary for the Renal Ammonia and K Response to Hypokalemia Hyun-Wook Lee,[1] Gunars Osis,[1] Autumn N. Harris,[1] Kierstin L. Webster,[1] Heather L. Holmes,[2] Adam J. Rossano,[2] Michael F. Romero,[2] Jill W. Verlander,[1] I. D. Weiner.[1,3] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Mayo Clinic College of Medicine, Rochester, MN; [3]Nephrology, NF/SGVHS, Gainesville, FL.*

Background: Hypokalemia is associated with increased ammonia excretion, but neither the specific proteins that signal this response nor the functional role of increased ammonia excretion are known. This study's purpose was to determine NBCe1-A's role in the effect of hypokalemia on renal ammonia metabolism and potassium homeostasis.

Methods: We used mice with NBCe1-A deletion generated using TALEN techniques. We compared mice with homozygous deletion (KO) to wild-type (WT) littermates. Hypokalemia was induced by feeding a K-free diet for 7 days.

Results: A K-free diet caused persistently increased urinary ammonia excretion in WT mice, whereas in KO mice urinary ammonia increased only on day 1 and 2, and then returned to baseline. In proximal convoluted tubule (PCT), NBCe1-A KO had significantly lower expression, compared to WT, of key ammoniagenic proteins, phosphoenolpyruvate carboxykinase (PEPCK) and phosphate-dependent glutaminase (PDG), and greater expression of the ammonia-recycling protein, glutamine synthetase (GS). In contrast, in the proximal straight tubule (PST) in the outer medulla, where relatively little NBCe1-A expression is found compared to the PCT, hypokalemic KO mice exhibited PEPCK and PDG expression that was greater and GS expression that was less than in hypokalemic WT. NBCe1-A deletion also altered renal K handling during hypokalemia. Serum K did not differ on normal diet, but was lower in KO mice on K-free diet (KO 1.8±0.1; WT 3.2±0.1 mM, P<0.01). Despite more severe hypokalemia, urinary K was significantly higher, 75%±16% greater in KO than WT during days 3-7, when maximal K conservation occurred in both WT and KO. Total NCC expression was unchanged, but phospho-NCC, which decreases renal K excretion, was significantly less in hypokalemic KO than WT mice.

Conclusions: 1) NBCe1-A is essential to the signaling pathway that increases ammonia excretion in response to hypokalemia; 2) KO mice partially compensate to NBCe1-A deletion with supranormal responses in PST; and, 3) NBCe1-A is critical for PT signaling to distal sites to conserve K through a mechanism that may involve NCC phosphorylation. Thus, hypokalemia's induction of ammonia metabolism via NBCe1 may be a critical signaling mechanism regulating distal epithelial K transport.

Expression, Localization, and Role of Slc4a8 (NDCBE) in Acid Base Transport in Kidney Tubules Jie Xu,[1,2] Sharon L. Barone,[1,2] Marybeth Brooks,[1] Manoocher Soleimani.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Administration, Cincinnati, OH.*

Background: The sodium-dependent bicarbonate transporter Slc4a8, also known as NDCBE, mediates the cotransport of sodium and bicarbonate in exchange for chloride (Na-dependent Cl^-/HCO_3^- exchanger). NDCBE is abundantly detected in the brain, with very low expression levels in the kidney. The cell distribution, subcellular localization and role of NDCBE in acid/base and electrolyte homeostasis in the kidney have been the subject of conflicting reports. There are no localization studies (such as immunolabeling and/or in situ hybridization) and no functional studies to pinpoint the location and demonstrate the function of NDCBE in the kidney.

Methods: Molecular techniques including RT-PCR, Northern Hybridization and in situ hybridization were employed in kidney sections and tagged epitopes were used to examine the membrane localization of NDCBE in transfected polarized kidney epithelium. Crispr/Cas9 approach was used to generate and examine NDCBE KO mice.

Results: Zonal distribution (cortex, outer medulla and inner medulla) studies by northern hybridization and RT-PCR and in situ hybridization experiments using FISH (Fluorescence *In Situ* Hybridization) showed very little to no expression for NDCBE in the cortex or in cortical collecting ducts (CCD). NDCBE was predominantly detected in the kidney medulla with significant expression in medullary collecting ducts. NDCBE was targeted to the basolateral membrane of MDCK cells when grown in hypertonic medium, a physiologic environment for cells in medullary collecting duct. NDCBE deficient mice show no salt, bicarbonate or fluid wasting phenotype under baseline condition, and their urine pH remained comparable to wild type mice in response to bicarbonate loading or salt restriction. Expression levels of pendrin and NCC were comparable in kidney cortices of NDCBE KO and wild type mice.

Conclusions: Slc4a8 (NDCBE) is predominantly detected in mouse medullary collecting duct, is targeted to the basolateral membrane, shows increased activity in hypertonic environment and its deletion does not cause any noticeable acid base perturbation either under baseline conditions or in response to bicarbonate loading or salt restriction.

Robust Circadian Clock Oscillation and Osmotic Rhythms in the Inner Medulla Reflecting Cortico-Medullary Osmotic Gradient Rhythm in Rodent Kidney Masayuki Hara,[1,2] Yoichi Minami,[1] Nobuya Koike,[1] Tetsuro Kusaba,[2] Keiichi Tamagaki,[2] Kazuhiro Yagita.[1] *[1]Physiology and Systems Bioscience, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Nephrology, Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Circadian clocks in mammals function in most organs and tissues throughout the body. Various renal functions such as the glomerular filtration and excretion of electrolytes exhibit circadian rhythms. Although it has been reported that the expression of the clock genes composing molecular oscillators show apparent daily rhythms in rodent kidneys, functional variations of regional clocks are not yet fully understood.

Methods: 1. To monitor the molecular clock work and localization, we applied the macroscopic bioluminescence imaging method of the PER2::Luciferase knock-in mouse kidney. 2. We analyzed the circadian fluctuation of the cortico-medullary osmotic pressure gradient. 3. We analyzed diurnal expression patterns of genes contributing to high osmotic pressure and reabsorption of water in mice kidneys. 4. To analyze the effect of molecular clock on diurnal variations of osmotic pressure gradient, we measured osmotic pressure gradient in systemic *Bmal1* deficient mice which completely lack a functional clock.

Results: 1. PER2::Luciferase knock-in mice exhibited strong and robust circadian clock oscillation in the medulla. 2. Significant diurnal rhythm of the tissue osmolality with peaking at night (active phase) was found in the medulla but not in the cortex. This suggests that cortico-medullary osmotic pressure gradient changes diurnally depending on osmotic pressure rhythm in the inner medulla. 3. Vasopressin receptors (*V1aR, V2R*), urea transporter (*UT-A2*) and water channel (*Aqp2*) show diurnal variations in the inner medulla. 4. Systemic *Bmal1* deficient mice impaired circadian rhythm of osmotic pressure gradient and of expression of genes (*V1aR, V2R, UT-A2, and Aqp2*) in the inner medulla.

Conclusions: The circadian clocks in the medulla of the kidney regulate the circadian rhythm of gene expressions related to the water reabsorption and subsequent cortico-medullary osmotic pressure gradient, resulting in the physiological day-night rhythm of urination.

FR-OR128

Global Identification of Protein Phosphorylation Changes Following CRISPR/Cas9-Deletion of cAMP-Dependent Protein Kinase (PKA) in Collecting Duct Cells Kiyoshi Isobe, Hyun Jun Jung, Chin-Rang Yang, Maurice B. Burg, Viswanathan Raghuram, Mark A. Knepper. *NHLBI/NIH, Bethesda, MD.*

Background: Vasopressin regulates water and sodium transport in collecting duct principal cells by binding to the V2 receptor and increasing cAMP, thereby activating cAMP-regulated protein kinase PKA catalytic subunits PKA-Cα and/or PKA-Cβ. Signaling downstream from PKA is poorly understood.

Methods: To identify PKA-dependent phosphorylation changes, we deleted both PKA catalytic subunits using CRISPR-Cas9 in vasopressin-sensitive mpkCCD cells. Indel mutations were confirmed by Sanger sequencing. We carried out large-scale quantitative phosphoproteomic analysis using protein mass spectrometry in three pairs of PKA-knockout (KO) vs. control clones. The cells were grown on permeable supports in the presence of 0.1 nM dDAVP.

Results: The PKA-KO cells maintained viability and polarity. Phosphoproteomics identified 229 PKA substrate sites. These sites contained the motif R-(R/K)-X-pS and were significantly decreased in PKA-KO. Most of these PKA targets are not annotated in public databases. Surprisingly, a large number of phosphorylation sites with the motif X-(pS/pT)-P showed increased phospho-occupancy, pointing to increased activity of one or more MAP kinases in PKA-KO cells. Indeed, a marked increase in phosphorylation of ERK2 at T183 and Y185 (which activates ERK2) was seen in PKA-KO cells. The ERK2 site is downstream from a direct PKA site in Sipa1l1, which indirectly inhibits Raf1 through Rap1 inactivation. Aquaporin-2 phosphorylation at S256 was **not** decreased in PKA-KO cells. The datasets were integrated to identify a causal network describing PKA signaling that explains vasopressin's actions to regulate membrane trafficking and gene transcription. The model predicts that, through PKA activation and inhibition of MAP kinase signaling, vasopressin stimulates AQP2 exocytosis (confirmed by immunofluorescence microscopy), induces nuclear translocation of the transcriptional co-activator/acetyltransferase EP300 (confirmed by immunoblotting of nuclear fractions) and increases histone H3K27 acetylation of vasopressin-responsive genes (confirmed by ChIP-Seq).

Conclusions: We conclude that PKA-dependent signaling is more complex than previously believed with both primary and secondary effects on phosphorylation that explain vasopressin responses.

FR-OR129

Proteomics and Water Channel Function of AQP2-Rich Extracellular Vesicles in Human Urine Yuko Miyazawa,[1] Saki Mikami,[1] Masaki Sakai,[1] Tatsuya Saito,[1] Kenichi Ishibashi,[1] Sei Sasaki.[1,2] *[1]Meiji Pharmaceutical University, Kiyose-shi, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan.*

Background: AQP2 water channel is a key membrane protein which determines urine concentrating ability. AQP2 is excreted in urine in a form of extracellular vesicles (EVs), mostly in exosomes and urine AQP2 is now measured as a useful biomarker for diagnosis and treatment of water-balance disorders. However, proteomic and functional analysis of AQP2-bearing EVs have not been performed.

Methods: Urine EVs were obtained from heathy volunteers by the differential centrifugation. Membrane-disrupted (freeze-thaw) AQP2-bearing EVs were obtained by immunoprecipitation with an AQP2-specific antibody and the proteins were digested with trypsin and applied to LC-MS/MS proteomic analysis. The proteins were also analyzed by Western blots. Osmotic water permeability (Pf) of the AQP2-enriched EVs was measured by a stopped flow method monitoring 90 degree scattered light intensity in response to outwardly directed osmotic gradient created by glycerol.

Results: 1) The MS analysis of the EVs co-immunoprecipitated with the AQP2 antibody identified 137 proteins, surprisingly, 103 of these 137 proteins have been shown to express in collecting duct cells, suggesting that our co-immunoprecipitation successfully gather AQP2-bearing EVs membranes. Pathway analysis show the presence of late endosome and multiple vesicular body-related proteins such as TSG101, ALIX, CHMP1-6, VPS4,7,9,25. MS analysis of urine EVs showed the phosphorylation of AQP2 at Ser256 and Ser261. Western blot analysis confirmed the presence of these proteins and S256, S261, and S269 phosphorylated AQP2. 2) Pf of 160,000 xg EVs was $4.75 \pm 0.38 \times 10^{-4}$ cm/s which was inhibited by 63% by 0.3 mM HgCl2 pretreatment. The activation energy was 3.51 kcal/mol which is consistent with a water channel activity. Pf was not detectable when EVs membranes were disrupted by extensive sonication. The measured Pf values of EVs samples were proportional to the protein amounts of AQP2 ($r=0.95$, $p<0.014$). A positive correlation was also observed between the EVs Pf and osmolality of the urine from which urine EVs were prepared ($r=0.879$, $p<0.049$).

Conclusions: Urine AQP2 excretion is mediated by late endosome-multiple vesicular body pathway, and AQP2 at EVs preserve the original water channel function.

RNA-Seq in Microdissected Rat Cortical Collecting Ducts during Development of Lithium-Induced Nephrogenic Diabetes Insipidus Chih-chien Sung,[1,2] Chung-Lin Chou,[1] Lihe Chen,[1] Hyun Jun Jung,[1] Mark A. Knepper.[1] *[1]NHLBI/NIH, Bethesda, MD; [2]Tri-Service General Hospital, Taipei, Taiwan.*

Background: Lithium has been widely used to treat bipolar disorder, but many patients develop nephrogenic diabetes insipidus (NDI). Our previous studies in rats have demonstrated rapid activation of ERK1/ERK2 in collecting ducts after oral lithium administration (Trepiccione et al., KI, 2014). Associated gene expression changes early in the development of lithium-induced NDI have been incompletely explored.

Methods: Cortical collecting ducts (CCDs) were microdissected from rats 72 hrs after beginning treatment with lithium (lithium chloride, 40 mmol/kg of dry food) versus time controls. Single-tubule RNA-Seq was carried out independently in 3-5 CCD samples per rat (4 lithium-treated rats versus 4 controls) using the methods of Lee et al. (JASN, 2015). Cortical thick ascending limbs (cTALs) were also microdissected for RNA-Seq at 72 hrs.

Results: Lithium-treated rats showed increased water intake within 24 hrs, concomitant with a fall in AQP2 protein abundance (western blotting). RNA-Seq data at 72 hr revealed moderate decreases in AQP2, AQP3, and AQP4 mRNA. The three subunits of ENaC showed more profound decreases. A large number of transcripts coding for other transporters and receptors were decreased with lithium treatment including the vasopressin V2 receptor and the chloride channel ClC-Kb. Several known aldosterone-regulated genes showed decreases in mRNA including Sgk1, αENaC, and Gadd45g. Immediate early genes (typical of MAP kinase activation) and transcriptional targets of NF-κB were significantly more frequent among transcripts increased with lithium than among all expressed genes (Chi-square). Similar over-representation among lithium-affected transcripts were seen for two other pathways, e.g. cell cycle signaling, and Wnt signaling. No association with lithium treatment was found for several pathways including cyclic AMP signaling, estrogen receptor signaling and insulin signaling. In contrast to the CCD, no significant changes were found in mRNA levels in cTALs in response to lithium, indicating the effect of lithium was selective for CCD.

Conclusions: Cellular signaling during development of lithium-induced NDI is consistent with known responses to increased MAP kinase activation and includes major gene expression changes characteristic of NF-κB-dependent inflammatory signaling.

FR-OR131

Identification of miRNAs Regulating the Water Transport in the Collecting Duct Federica Petrillo,[5] Anna Iervolino,[3] Alfonso De Falco,[4] Federica Prosperi,[3] Luigi R. De la motte,[5] Sabina K. Jelen,[1] Robert A. Fenton,[2] Giovambattista Capasso,[5] Francesco Trepiccione.[6] *[1]Biogem S.C.R.L, Ariano Irpino, Italy; [2]University of Aarhus, Aarhus, Denmark; [3]Biogem scarl, Ariano Irpino, Italy; [4]Laboratoire National de Santè, Dudelange, Luxembourg; [5]University of Campania Luigi Vanvitelli, Napoli, Italy; [6]Dpt of Cardio-Thoracic and Respiratory Science, University of Campania, Naples, Italy*.

Background: Principal cells (PC) contribute to water reabsorption in the collecting duct (CD). In response to vasopressin, they express on their apical membrane the AQP2, and so increase water permeability of the CD. Finally, an interstitium driven osmotic gradient leads the water to be reabsorbed. Although several molecular mechanisms have been identified as master regulators of this process, both dependent and independent by vasopressin stimulation, no miRNAs involved in the water reabsorption are known. miRNas are post-trascriptional regulators of gene expression and, thus, they are appealing targets for new therapy. We aim to identify the miRNAs involved in urinary concentrating mechanism to fill this gap.

Methods: To identify whether the miRNAs are crucial for the water reabsorption in the CD, we generate a mouse model deficient of dicer selectively in the AQP2 expressing cells. By microarray analysis we compared the miRNAs expressing profile of the inner medulla from Dicer cKO and their littermate control mice. miRNAs target prediction and IPA analysis was used to build a network of interaction between miRNAs and target proteins and to select candidate miRNAs, master regulators of the AQP2 expression. In vitro assay of miRNAs activity has been performed to validate bio-informatic data.

Results: Single segment evaluation of Dicer expression confirmed its ablation only in the CD. Dicer-AQP2 cKO mice present with a severe water concentrating defect that is resistant to dDAVP administration. Loss of expression of AQP2 all along the PC made these mice consistent with an experimental model of neprhogenic diabetes insipidus. Since principal cells keep expressing other cellular markers such as AQP4 and ENaC, our hypothesis was that Dicer suppression targets mostly AQP2 expression. Microarray screening of the miRNas profile reveals potential candidate miRNA, able to directly interfere with the V2R-AQP2 axis. In vitro validation in mpkCCD cells confirms the role of 3 miRNAs in regulating the expression of target mRNA crucial for the water reabsorption.

Conclusions: We identify for the first time miRNAs able to regulate the AQP2 expression in the PC. This is the first step to build a miRNA-based therpy to potentially approach the nephrogenic diabetes insipidus.

FR-OR132

ILDR1 Expression in the Tricellular Junction Regulates Epithelial Water Impermeability Nina Himmerkus,[1] Yongfeng Gong,[2] Susanne Milatz,[1] Cosima Merkel,[1] Jianghui Hou,[2] Markus Bleich.[1] *[1]Christian Albrechts University Kiel, Kiel, Germany; [2]Washington University School of Medicine, Saint Louis, MO*.

Background: The ability to produce a wide range of urine osmolality depends on epithelial water tightness of the thick ascending limb (TAL). The collecting duct (CD) uses the corticomedullary concentration gradient for controlled transcellular water absorption under control of anti-diuretic hormone (AVP). Water tightness of the space in between epithelial cells is determined by the properties of bicellular and tricellular tight junctions. ILDR1 is expressed in the tricellular junction and ILDR1 knockout mice (KO) show high urine production with nearly plasma isotonic urine osmolality.

Methods: ILDR1 expression was investigated in isolated tubular segments along the nephron by qPCR and immunofluorescence. Transepithelial water permeability was assessed in isolated perfused tubules of KO and control mice (CTRL). Tubules were freshly isolated and microperfused with FITC-dextran as indicator of luminal concentration. Transepithelial water flux was measured as changes in fluorescence intensity of the luminal perfusate after application of a transepithelial osmotic gradient and closure of the open tubular end. In addition, CD transcellular water permeability was measured under unstimulated conditions and after stimulation by basolateral application of AVP. Relative fluorescence intensity increment per time was calculated as correlate of transepithelial water transport.

Results: ILDR1 was localized in the tricellular junctions of TAL and CD but was absent in proximal tubules. TAL of KO showed a water leak in comparison to the watertight TAL of Ctrl. Also CD of KO showed a significant water permeability already under unstimulated conditions whereas CD of Ctrl were water tight in the absence of AVP. The effect of basolateral AVP on CD water permeability was additive in ILDR1 knockout animals and not different to controls.

Conclusions: In summary, ILDR1 is part of the tricellular junction in the nephron segments TAL and CD and it confers paracellular water tightness. Impaired water tightness in the TAL by ILDR1 knockout impedes the dilution of the luminal fluid as well as the concentration of the medullary interstitium. ILDR1 might therefore be a new target to regulate renal concentrating ability.

Renal Phenotype of P2Y12 Receptor Knockout Mice Bellamkonda K. Kishore,[5] Kenny M. Hansson,[1] Tao Liu,[4] Kerstin Magnell,[2] Noel G. Carlson,[6] Yue Zhang.[3] *[1]AstraZeneca, Cardiovascular and Metabolic Diseases iMED, Mölndal, Sweden; [2]AstraZenecaR&D, Mölndal, Sweden; [3]Univ. of Utah & VA Medical Center, Salt Lake City, UT; [4]Internal Medicine, Univ. of Utah & VA Med Ctr, Salt Lake City, UT; [5]Univ. of Utah and VA Medical Center, Salt Lake City, UT; [6]VA Salt Lake City Health Care System, Salt Lake City, UT*.

Background: Previously we reported that pharmacological blockade of P2Y12 receptor (R) potentiates the action of arginine vasopressin (AVP) on renal medullary collecting duct (mCD). To establish that the observed effect is mediated through P2Y12-R, we evaluated the renal phenotype of P2Y12-R global knockout (KO) mice.

Methods: The P2ry12 gene was disrupted by targeted homologous recombination in ES cells. Urinary excretion of AVP, cAMP, PGE2, Na and K was assayed in adult homozygous KO and syngeneic C57/Bl6 wild type (WT) mice under basal conditions. Primary cultures of mCD cells from KO and WT mice were stimulated with 0.1 nM of dDAVP for 24 h, and assayed for cAMP generation, and mRNA expression of AQP2.

Results: The urine from KO mice showed significant increases in cAMP, PGE2 and K compared to WT mice (see Table). Comparisons between mCD cells derived from KO and WT mice showed significantly higher production of cAMP in response to stimulation with dDAVP (16-fold vs. 4-fold, $P < 0.006$, $N = 6$). Significantly higher level of mRNA expression of AQP2 was observed in mCD from KO vs. WT mice after dDAVP stimulation (2.43-fold, $P < 0.04$).

Conclusions: These findings are consistent with our previous observations and show that loss of P2Y12-R by either pharmacological blockade or genetic deletion potentiates the action of AVP/dDAVP on mCD. These data also reveal that P2Y12-R may play a role in renal handling of sodium and potassium.

Novel Imaging Techniques Reveal Axial Differences in Endo-Lysosomal Uptake Capacity along the Kidney Proximal Tubule Claus D. Schuh,[1] Marcello Polesel,[1] Dominik Haenni,[1] Evgenia Platonova,[1] Urs Ziegler,[2] Olivier Devuyst,[1] Andrew Hall.[1] *[1]University of Zurich, Zurich, Switzerland; [2]University of Zurich, Center for Microscopy and Image Analysis, Zurich, Switzerland*.

Background: The kidney filters low-molecular weight proteins (LMWPs) and albumin, which are reclaimed by the proximal convoluted tubule (PCT) to prevent wasting in urine. PCT cells take up proteins across the apical membrane by receptor-mediated endocytosis, which involves binding to megalin/cubilin, internalization into early endosomes (EE), and subsequent trafficking to late endosomes (LE) and lysosomes. Early (S1) and late (S2) PCT segments show ultrastructural differences in the endo-lysosomal system by EM, but how these might relate to differences in uptake capacity is unclear.

Methods: Confocal microscopy of immuno-stained mouse kidney. Multiphoton intravital imaging and 3-D analysis of cleared post-mortem tissue.

Results: Using established antibody markers for EEs (Rab5), LEs (Rab 7), recycling endosomes (Rab11) and lysosomes (LAMP1), we found that expression levels of these 4 markers were far higher in S1 than in S2 segments. In contrast, expression of megalin was similar in both. Intravital imaging revealed that uptake of dye-labeled albumin and

LMWP lysozyme occurred exclusively in S1, whereas uptake of 10 kDa dextran – a substrate for fluid phase endocytosis - was observed in S1 and S2. Experiments were repeated using two different fluorescent labels for each ligand to exclude a confounding effect on substrate handling. Real-time imaging of lysozyme uptake revealed the expected dynamic progression from brush border to EEs, and then LEs/lysosomes. Following saturation of S1 uptake capacity with a high concentration of injected lysozyme, some uptake was observed in S2 segments, but it remained far lower than in S1. Antibody staining in tissue fixed post-lysozyme injection revealed that the uptake pattern closely matched the expression of endo-lysosomal proteins, but not megalin. A major constraint of intravital kidney microscopy is limited depth of imaging. We therefore treated fixed kidneys chemically with a modified CLARITY protocol to increase transparency. Using this approach, we were able to image through the entire cortex and confirm that lysozyme uptake was confined to early segments in all PCTs, whereas dextran uptake was more diffuse.

Conclusions: We have found evidence for major axial differences in endo-lysosomal uptake capacity along the PCT, independent of megalin expression.

Novel Imaging Technique Reveals Changes in the Podocyte Actin Network after Injury Hani Suleiman,[2] Andrey S. Shaw,[1] Jeffrey H. Miner.[3] *[1]Genentech, South San Francisco, CA; [2]Washington University, Saint Louis, MO; [3]Washington University School of Medicine, St. Louis, MO.*

Background: Actin stress fibers are abundant structures in cultured cells, including podocytes, yet no clearly equivalent structures have been observed *in vivo.* This discrepancy has been thought to be the result of current tissue preparation methods that do not preserve actin structures in their intact forms. Here we developed a new method that allows us to view actin stress fibers in their native state in the whole kidney glomerulus using focused ion beam scanning electron microscopy (FIB-SEM).

Methods: Kidney glomeruli from wild-type and *Col4a3-/-* (Alport) mice were isolated, the cytoskeleton was stabilized, and at the same time all cell membranes were extracted with detergent. Samples were processed and imaged using FIB-SEM using the serial block-face imaging mode.

Results: Block-face imaging of membrane-extracted healthy glomeruli showed all nuclei and basement membranes as electron dense material, similar to their appearance by transmission electron microscopy. In contrast, the cellular edges were completely gone, leaving behind only the contours of the cytoskeleton. This method allowed us to view the cytoskeleton of the foot processes (FPs), which formed a continuous electron dense sheet incorporating the slit diaphragms (SDs) and covering the glomerular basement membrance (GBM). Tracking this dense material across serial sections in the FPs revealed continuity with the central actin cables in individual FPs that fuse together to form thick actin bundles in the podocyte's major processes (MP). These bundles, in turn, appear to anchor at the periphery of podocyte cell bodies. In contrast, analysis of Alport glomeruli revealed thick actin bundles running in different directions juxtaposed to the GBM as part of the cytoskeletal transformation that accompanies podocyte injury.

Conclusions: Here, we imaged the complete cytoskeleton of the podocytes in both health and disease. Our data indicate that in the normal podocyte, actin filaments in the FPs are connected to the SDs to form one continuous network enclosing the capillary wall, like a wire mesh, suggesting that podocyte FPs and the SDs work as one unit to form the outer structure of the glomerular filtration barrier. Our data also indicate that in injured podocytes, foot process effacement changes the orientation of the actin cables and affects the SDs, thus disrupting the integrity of the wire mesh, leading to proteinuria.

Deep Mapping of the Podocyte Proteome Unravels Altered Protein Dynamics during Differentiation Christina B. Schroeter,[2] Thomas Benzing,[3] Markus M. Rinschen,[1] Paul T. Brinkkoetter.[2] *[1]CECAD, Cologne, Germany; [2]University Hospital Cologne, Cologne, Germany; [3]University of Cologne, Köln, Germany.*

Background: Podocytes are epithelial postmitotic cells which maintain the renal filtration barrier. Immortalized podocyte cell lines are widely utilized tools to estimate podocyte injury and cytoskeletal rearrangement processes *in vitro*. We intended to generate a comprehensive map of proteins expressed in proliferating and differentiated cultured human podocytes *in vitro* thereby providing a thorough database and useful tool for researchers in the podocyte field.

Methods: We analysed 7637 proteins in depth and quantified 7230 of them. We performed additional in-depth analyses of the cultured human podocyte proteome in order to characterize changes regarding protein expression, protein synthesis and proteostatic mechanisms during differentiation of the cells. We included a detailed analysis on the expression of podocyte-specific proteins that govern the function and dysfunction of the slit diaphragm, and of gene products mutated in hereditary nephrotic syndrome. Finally, we compared the resulting proteomic dataset to data obtained from the previously published murine cultured podocyte proteome. We also performed comparative analysis with transcriptomic data from cultured human podocytes.

Results: Cultured podocytes express abundant copy numbers of endogenous receptors. Some protein classes associated with podocyte disease, such as slit-diaphragm associated proteins and ion channels, were hardly detected. Differentiation-induced changes were comparable in mouse and human podocytes, but slight differences, e.g. in proteins associated with lipid metabolism were detected. Also, there were distinct differences in expression of genes commonly thought to be associated with podocyte function. Notably, this data set detected general perturbations in proteostatic mechanisms as a dominant alteration during podocyte differentiation irrespectively of the species: Proteasome activity and kinetics were high in the undifferentiated state and lysosomal activity was high in the differentiated state.

Conclusions: In conclusion, podocyte differentiation *in vitro* is largely associated with a proteostatic shift, and the deep proteomic mapping approach utilized here may demonstrate the limitations, but also the potential of podocyte cell culture.

SA-OR003

Super Resolution Microscopy and Automatized Digital Image Processing as a Novel and Rapid Diagnostic Tool for Podocyte Foot Process Effacement Nicole Endlich,[1] Florian Siegerist,[1] Silvia Ribback,[2] Frank Dombrowski,[2] Kerstin U. Amann,[3] Karlhans Endlich.[1] *[1]Anatomy and Cell Biology, University Medicine Greifswald, Greifswald, Germany; [2]Pathology, University Medicine Greifswald, Greifswald, Germany; [3]Nephropathology, University Medicine Erlangen, Erlangen, Germany.*

Background: Podocyte foot process morphology plays an essential role for proper glomerular filtration. In glomerular diseases like *minimal change disease*, interdigitating foot processes are replaced by flattened cellular protrusions. Since foot processes are around 200-300nm in width, morphometrics could only be performed by time consuming electron microscopy. Recently, super resolution microscopy techniques have been developed which allow lightmicroscopic imaging beyond *Abbe's* optical resolution limit of ~200nm. Using one of those techniques, structured illumination microscopy (SIM), it is now possible to double the optical resolution limit. We hypothesized that SIM would allow the analysis of podocyte morphology and to diagnose foot process effacement.

Methods: 4µm sections were obtained from formalin fixed and paraffin embedded renal tissue of human and murine origin and stained with an antibody against the slit diaphragm protein nephrin. Morphometrics of SIM-reconstructed podocyte foot processes were manually measured using ImageJ. For automatic evaluation of the slit diaphragm density, meaning slit diaphragm length / glomerular capillary area, we programmed a specific ImageJ plugin. The plugin automatically segments the nephrin positive slit diaphragm and measures the total length and the glomerular capilarry area.

Results: In human samples, we measured a mean foot process width of 0.249±0.68µm in healthy, and 0.675±0.246µm in MCD patients. By the use of our custom made software we measured a slit diaphragm density of 3.099±0.268µm/µm² in healthy compared to 1.825±0.493µm/µm² in MCD patients. Using both methods we found statistically significant differences between the MCD patients in comparison to the healthy control subjects. As we found out that the both results highly correlate (R^2=0.91) we show that the techniques can be used equivalently. Furthermore, we show that we can image and measure foot process morphology in murine kidneys.

Conclusions: Taken together, we have established a novel method which allows quick analysis of kidney sections for foot process effacement in an automated fashion. Including this technique into the diagnostic routine could effectively shorten the time until diagnosis of podocyte foot process effacement in patients and in animal models.

SA-OR004

Intravital Imaging Reveals the Important Role of A-Synuclein in Podocytes Georgina Gyarmati, Anne Riquier-brison, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA 90033, CA.*

Background: Podocytes are known to functionally express a number of neuron-specific proteins. Recent studies predicted the Parkinson's and Alzheimer's disease amyloid a-synuclein (SNCA) to be among 136 top podocyte genes (PMID23950145), and top 5 phosphoproteins with increased expression in Fabry disease podocytes (PMID27681560). SNCA was also recently linked to disruption of the autophagy-lysosome pathway and neuropathology in Fabry disease (PMID24529306). The present study aimed to establish the functional importance of SNCA in podocytes.

Methods: Constitutive or tamoxifen-inducible podocyte-specific SNCA knockout mice (i/Pod-SNCA KO) were generated that also expressed the intensely green calcium indicator GCaMP5/Tomato or the green/red mTmG reporter only in podocytes. Serial high resolution intravital multiphoton microscopy (MPM) of the same glomeruli in the same intact living kidney consecutively for three weeks was performed non-invasively via a dorsal abdominal imaging window to directly visualize and track the changes in glomerular and podocyte function including cell [Ca^{2+}] after SNCA deletion.

Results: Immunohistochemistry of human and mouse kidney tissue sections confirmed the podocyte-specific expression of SNCA. Intact podocyte and glomerular functions were found at baseline in iPod-SNCA mice. However, within one week of tamoxifen-induced SNCA KO, podocytes developed an enlarged cell body with balled-up appearance, which gradually progressed within two additional weeks to the appearance of focally increased cell [Ca^{2+}], podocyte detachment and shedding into the tubular fluid and migration to the parietal Bowman's capsule, leakage of plasma albumin-Alexa594 into the filtrate and tubular fluid, and glomerular capillary microthrombi blocking blood flow. High magnification MPM found widened podocyte primary and secondary processes and foot process effacement. Histology of constitutive Pod-SNCA kidney sections found numerous tuft adhesions and detached podocytes.

Conclusions: This study visually demonstrated the development and progression of glomerular pathology after SNCA knockout, suggesting the important role of SNCA in maintaining normal podocyte and glomerular functions.

aPKC Independent Signaling Events of Par3 at the Glomerular Slit Diaphragm Sybille Köhler,[4] Carien M. Niessen,[1] Sandra Iden,[5] Wilhelm Bloch,[3] Bernhard Schermer,[4] Thomas Benzing,[5] Barry Denholm,[2] Paul T. Brinkkoetter.[4] *[1]CECAD University clinic of Cologne, Cologne, Germany; [2]Edinburgh University, Edinburgh, United Kingdom; [3]German Sport University, Cologne, Germany; [4]University Hospital Cologne, Cologne, Germany; [5]University of Cologne, Köln, Germany*.

Background: Polarity signaling through the aPKC-Par polarity complex is essential for the development and maintenance of the podocyte architecture and the function of the glomerular filtration barrier of the kidney. Despite its well-established role in aPKC-mediated signaling, Par3A appears to be dispensable for the function of the glomerular filtration barrier.

Methods:

Results: mRNA seq data from primary podocytes revealed high levels of Par3B in podocytes, which were much higher in comparison to Par3A levels. Interestingly, loss of Par3B also did not cause glomerulosclerosis or albuminuria. To study a potential compensatory mechanism between Par3A and Par3B, we generated podocyte-specific Par3A/B double knockout mice. Par3A/B double knockout mice were born following Mendelian rules. Within 8 weeks of age Par3A/B DKO mice developed severe proteinuria in comparison to control mice. To further study the interplay between the different Par3 proteins, we utilized *Drosophila* nephrocytes. Here, we show co-localization of the Par3A/B homolog bazooka and the nephrocyte diaphragm proteins Sns (nephrin) and Duf (NEPH1) in different developmental stages at the nephrocyte diaphragm. Second, we analyzed the role of bazooka on nephrocyte function. Silencing bazooka expression resulted in a disturbed nephrocyte diaphragm morphology and severe filtration defects. To study the mammalian Par3 proteins in greater detail, we used the UAS-GAL4 system to re-express different murine Par3 variants in a *bazooka* knockdown background. Although the rescue capacity differed between the different mammalian Par3A isoforms, none of the isoforms resulted in a complete rescue. Even the 100kDa isoform, lacking the aPKC-binding domain, resulted in partial rescue, suggesting an aPKC-independent function for Par3A in nephrocyte filtration. In line with these findings, an aPKCiota interactome from immortalized mouse podocytes, revealed Lgl2 and Par6 as predominant interactors of aPKCiota.

Conclusions: Taken together, the data establish an important role for Par3 function in podocytes and reveal this function is, at least partially, independent from aPKC.

SA-OR006

The Interaction between MAGI2 and RapGEF2 Sustains Podocyte Rap1GTPase Signaling and Is Critical for Glomerular Filter Function Bingbing Zhu,[1,2] Jianhua Li,[1] Jenny Wong,[1] Kirk N. Campbell,[1] Shazia Ashraf,[3] Agnieszka Bierzynska,[4] Moin Saleem,[4] Charles Sawyers,[5] John C. He,[1] Friedhelm Hildebrandt,[3] Vivette D. D'Agati,[6] Wen Peng,[2] Lewis Kaufman.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Putuo Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China; [3]Boston Childrens Hospital, Harvard Medical School, Boston, MA; [4]University of Bristol, Bristol, United Kingdom; [5]MSKCC, New York, NY; [6]Columbia University College of Physicians and Surgeons, New York, NY*.

Background: The essential role of MAGI2 in proper podocyte function is reflected by the severe FSGS phenotypes of both MAGI2 knockout mice and of humans with congenital nephrotic syndrome (CNS) caused by mutations in MAGI2.

Methods:

Results: In the current work, we perform co-immunoprecipitation experiments that show MAGI2 directly binds the Rap1 guanine nucleotide exchange factor, RapGEF2, and that this interaction is lost when expressing MAGI2 variants that cause CNS. In cultured cells, co-expression of RapGEF2 with wild-type MAGI2, but not MAGI2 variants known to cause CNS, dramatically enhanced activation of the small GTPase Rap1, a pathway we previously demonstrated to be essential for normal podocyte function. Furthermore, in mice, podocyte specific deletion of RapGEF2 resulted in spontaneous proteinuria with FSGS, substantiating the critical importance of RapGEF2 to sustain normal podocyte function. Although the FSGS phenotype of MAGI2 knockout mice is considerably more severe than that of RapGEF2, both models show comparable qualitative glomerular features including mesangial expansion, focal segmental and global sclerosis, podocyte loss, and glomerular epithelial cell proliferation, suggesting mechanistic similarities. Indeed, knockdown of either RapGEF2 or MAGI2 in cultured podocytes caused nearly identical reductions in levels of Rap1GTPase activation, dramatic reductions in many Rap1 downstream signaling targets, and similarly high rates of podocyte apoptosis. Finally, immunostaining of kidney sections from CNS patients with MAGI2 mutations also suggested reduced glomerular Rap1GTPase mediated signaling.

Conclusions: We conclude that Rap1 activation induced by the complex of MAGI2 and RapGEF2 is indispensable for normal podocyte homeostasis.

SA-OR007

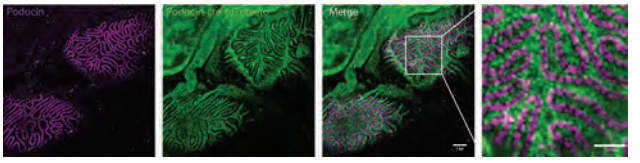
Confocal Imaging of the Glomerular Filtration Barrier in Expanded Kidney Tissue Samples David Unnersjö-Jess,[2] Lena Scott,[1] Sonia Zambrano Sevilla,[1] Jaakko Patrakka,[1] Hans Blom,[2] Hjalmar Brismar.[2] *[1]Karolinska Institutet, Solna, Sweden; [2]Royal Institute of Technology, Solna, Sweden*.

Background: When studying the glomerular filtration barrier (GFB), one is normally restricted to electron microscopy (EM). However, using EM, it is not trivial to perform volumetric imaging and multiple labelling of different epitopes. We have recently demonstrated an optical clearing protocol that in combination with super-resolution STED microscopy enables epitope-specific nanoscale imaging of the GFB. STED microscopy is presently an expensive and complex technique, and thus it would be highly relevant to develop more conventional bioimaging methods which resolve the GFB.

Methods: We apply a sample preparation protocol which isotropically expands kidney tissue samples approximately 5 times, while making them optically transparent. We then use immunofluorescence and confocal microscopy to image components of the GFB.

Results: Kidney samples were sufficiently expanded to allow for nanoscale localizations of different parts of the GFB (e.g. glomerular basement membrane, podocyte foot processes and the slit diaphragm), at an effective resolution below 70 nm. 2-color z-stacks of glomeruli were acquired, giving the unique possibility to study the 3D localizations of GFB proteins in intact tissue samples, including the detection of foot process effacement in mice with induced glomerulonephritis. Additionally, by applying super-resolution STED microscopy on expanded kidney samples, a resolution below 20 nm could be obtained.

Conclusions: We show that an expansion protocol in combination with confocal microscopy can be used to perform sub-70 nm resolution imaging of the GFB using standard lab equipment and reagents. This finding has an impact for researchers and clinical pathologists, since conventional light microscopy can for the first time be used to study kidney fine-morphology and protein topology on the effective nanometer-scale.



Expanded kidney sample stained for podocin (magenta) and cytosolic podocyte-specific tdTomato (pod-cre-tdTomato, green), showing podocyte foot processes and the filtration slit. The sample was imaged using confocal microscopy.

SA-OR008

APOL1 Risk Variant Induced Kidney Injury in Podocytes Is Mediated by Caspase-1 Dorottya Laczko, Pazit Beckerman, Jing Bi Karchin, Frank S. Chinga, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA*.

Background: Coding variants of APOL1 (termed as G1 and G2) are associated with increased risk of kidney disease in African Americans. Recently, we developed a new mouse model that recapitulates APOL1 associated renal disease by conditional inducible expression of G1 and G2 APOL1 variants in podocytes. While these animals develop albuminuria, glomerulosclerosis and azotemia, the exact pathomechanism of APOL1 variant induced kidney disease remains poorly understood. Here, we tested whether caspase-1 (Cas1) / IL-1β mediated pyroptotic cell death play a role in disease development.

Methods: Podocyte specific G2 APOL1 transgenic mice was generated by crossing TRE-G2 APOL1 animals with mice carrying the nephrin rtTA. Transgene expression was controled by doxycycline. To test the role of Cas1, we crossed nephrin rtTA/TRE-G2 APOL1 with Cas1 knock-out (KO) mice. To test the role of IL-1β we treated mice with IL-1β neutralizing antibody Anakinra. Histological changes were evaluated by PAS staining and the level of proteinuria was determined by albumin specific ELISA. The mRNA levels of kidney injury markers (KIM1, Col4a1, SMA) were analyzed by qPCR. For in vitro testing cells with inducible G2 APOL1 expression were generated, and the effect of pan-caspase, Cas1 and -3 were tested.

Results: In vitro expression of G2 APOL1 resulted in increased cleaved Cas1 and IL-1β levels. Pan-caspase and Cas1 inhibitors ameliorated cell death induced by G2 APOL1. In vivo, Anakinra injection for 21 days failed to significantly reduce albuminuria or glomerulosclerosis of G2 APOL1 mice. In line with these findings, no change in the transcript level of kidney injury markers was observed after neutralization of IL-1β compared to their control saline injected littermates. In contrast, renal disease was ameliorated in G2 APOL1 Cas1 KO mice as evidenced by decreasing level of proteinuria over the 21 days doxycycline treatment period as opposed to their Cas1 wild type littermates. In addition to this, Cas1 KO mice displayed marked reduction of kidney fibrosis confirmed by PAS staining.

Conclusions: Our initial data suggest that Cas1 plays a crucial role in the development of G2 APOL1 induced kidney damage, albeit the mechanism still needs to be elucidated. We propose that inhibition of Cas1 can offer a potential therapeutic target for APOL1 associated kidney damage.

SA-OR009

COSMC, the Molecular Chaperone of O-Linked Glycosylation, Is Essential for Podocyte Function Brian R. Stotter,[1,2] Brianna Talbot,[1] Johannes S. Schlondorff.[1] *[1]Div of Nephrology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [2]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA.*

Background: Proper podocyte function is required to maintain the glomerular filtration barrier. Many podocyte proteins undergo post-translational O-linked glycosylation (OLG), which requires T-synthase and its molecular chaperone Cosmc. Prior studies have shown that global *COSMC* knockout produces immature glycoproteins that express Tn antigen. We hypothesize that podocyte-specific *COSMC* deletion causes albuminuria, renal failure, and glomerulosclerosis due to aberrant OLG.

Methods: Male podocin-Cre mice were bred with female *COSMC*$^{fl/fl}$ mice to produce males devoid of *COSMC* in podocytes (Podo-*COSMC*$^{Y/fl}$) and females with mosaic *COSMC* loss in podocytes (Podo-*COSMC*$^{+/fl}$). Serum creatinine (SCr) and urine albuminuria were measured at 1 and 2 months of life for experimental and control mice. Kidneys were harvested for histology, immunofluorescence (IF), electron microscopy (EM), and biochemical analysis. Immature OLG was detected by staining for Tn antigen with lectin HPA.

Results: Podo-*COSMC*$^{Y/fl}$ males have heavy albuminuria by 1 month, with mesangial expansion and glomerulomegaly on histology and diffuse foot process effacement by EM. By 2 months, SCr is elevated compared to controls and histology shows extensive glomerulosclerosis, interstitial fibrosis, and tubular atrophy. Podo-*COSMC*$^{+/fl}$ females have mosaic glomerular Tn antigen expression, mild albuminuria, and normal SCr by 1 and 2 months. Podo-*COSMC*$^{+/fl}$ females have normal histology at 1 month but both rare segmental sclerosis and foot process effacement by 2 months. IF shows diffuse lectin HPA staining in Podo-*COSMC*$^{Y/fl}$ male podocytes and mosaic staining in Podo-*COSMC*$^{+/fl}$ female podocytes. Podocalyxin, an O-linked podocyte glycoprotein, is normally expressed in 1 month Podo-*COSMC*$^{Y/fl}$ males and 1 and 2 month Podo-*COSMC*$^{+/fl}$ females, but is lost in 2 month Podo-*COSMC*$^{Y/fl}$ males. In contrast, staining of O-linked glycoprotein podoplanin is reduced in *COSMC*-deficient podocytes by 1 month, confirmed by Western blot of glomerular lysates.

Conclusions: Loss of *COSMC* in podocytes causes albuminuria and renal failure with glomerulosclerosis, interstitial fibrosis, and tubular atrophy. This phenotype is most severe in male mice that have complete *COSMC* excision, and less severe in mosaic females. The mechanism of podocyte injury may be due to aberrant function of podocalyxin, podoplanin, and other O-linked glycoproteins.

SA-OR010

Dissociation-Induced Maff and Egr1 Upregulation Triggers Dedifferentiation of Podocytes Masahiro Okabe,[1,2] Masaru Motojima,[1] Yoichi Miyazaki,[2] Takashi Yokoo,[2] Taiji Matsusaka.[1] *[1]Tokai University School of Medicine, Isehara, Japan; [2]Jikei University School of Medicine, Tokyo, Japan.*

Background: Podocytes quickly lose their characteristics when they are cultured *in vitro*, suggesting that detachment from the glomerular basement membrane (GBM) may trigger dedifferentiation. We aimed to explore gene expression changes induced by podocyte dissociation from the GBM.

Methods: We obtained podocyte-specific RNAs by two methods. One method was to dissociate glomerular cells and purify RNAs from FACS-sorted podocytes that are transgenically labeled with fluorescent protein. The other was to utilize RiboTag transgenic mice, in which podocyte ribosomes are tagged with HA epitope, and podocyte RNAs were obtained by immunoprecipitation without dissociating glomerular cells. We then analyzed them (each n=4) with Agilent 8X66K array and compared the two profiles.

Results: Array and qRT-PCR analyses confirmed that known podocyte-specific mRNAs were similarly concentrated in both samples. Among 39,430 probes, 554 were downregulated (<0.125-fold) in dissociated podocytes, including *Itga8* and *Icam2* (0.019 and 0.12-fold, respectively). 1,013 probes were upregulated (>8-fold), including *Fos* and *Fosb* (720 and 2,000-fold, respectively). We next searched for mRNAs that were commonly upregulated by both dissociation and injury. For this, we analyzed mRNA profiles of injured podocytes in NEP25 mice (n=4) 7 days after injection with podocyte-targeted immunotoxin. Expression of 55 genes was increased more than 16-fold by both dissociation and injury. Among them, we focused on transcription factors, *Maff* and *Egr1*. MafF and MafB, as well as EGR-1 and WT-1, share the same DNA binding sequence, but not transcriptional activation domain. MafB and WT-1 are indispensable for maintaining podocyte differentiation state. In baseline primary cultured podocytes, *Maff* and *Egr1* mRNAs were increased 15 and 4.2-fold compared to *in vivo* podocytes of RiboTag mice, respectively. *Maff* knockdown increased MafB target- *Nphs2* mRNA (2.4-fold) without change of *Mafb* mRNA. *Egr1* knockdown increased Wt-1 target- *Ptpro* mRNA (2.2-fold) without change of *Wt1* mRNA.

Conclusions: These findings indicate that detachment from the GBM activates MafF and EGR-1 in podocytes, which actively facilitate dedifferentiation by competing with MafB and WT-1, respectively. These molecules may be novel drug targets for preventing progressive podocyte deterioration.

Impact on Blood Pressure of Mobile-Based Application (eKidneyCare) in Patients with CKD: A Randomized Controlled Trial Stephanie W. Ong,[2] Sarbjit V. Jassal,[2] Kelly Min,[2] Akib Uddin,[2] Eveline C. Porter,[2] George Tomlinson,[2] Alexander G. Logan.[1,2] *[1]Mount Sinai Hospital, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada.*

Background: We have previously demonstrated feasibility and acceptability of an integrated app (eKidneyCare) used for CKD management (CJASN 2016). It allows patients to monitor blood pressure (BP), manage medication, assess symptoms and track laboratory results. Customizable algorithms provide real-time personalized patient feedback and alerts to providers. Currently we are performing a one-year randomized controlled trial comparing eKidneyCare (intervention) to MyMedRec (control). The latter is a commercially available app that records medical information without providing feedback. Study midpoint results are presented.

Methods: Consenting patients with CKD 3b-5 or 5D were recruited from 6 out-patient renal clinics or dialysis units at University Health Network (UHN) and randomized to eKidneyCare or MyMedRec monitoring. Outcome assessments include BP at 6 and 12 months and medication reconciliation, questionnaires on self-management and, at study end, in-person interviews.

Results: A total of 182 patients were enrolled and randomly allocated to the intervention (n=89) or the control (n=93) group. A total of 157 patients completed the 6 month BP assessment using the automated oscillometric device, BpTRU. Premature withdrawals included 11 transferred or incomplete data, 8 who withdrew consent and 6 withdrawn after medical complications. At 6m, the fall in BP of patients with uncontrolled hypertension at baseline was greater in the active (eKidneyCare) group (median reduction in systolic BP mmHg -18 vs 13 mmHg respectively, p =0.05; diastolic BP 9 vs 5.5 mmHg p=0.03). There was no between group difference in normotensive patients.

Conclusions: Hypertensive patients allocated to the eKidneyCare app had a significantly lower BP than those using the commercially available app. This preliminary analysis suggests that real time patient feedback and integrated mobile apps are critical components for success with mHealth monitoring.

Reducing Health Disparity – PCORI Supported Home Based Kidney Care Approach in Zuni Indians Vallabh O. Shah,[2] Robert G. Nelson,[1] V. Shane Pankratz,[2] Donica M. Ghahate,[2] Jeanette Bobelu.[2] *[1]National Institutes of Health, Phoenix, AZ; [2]University of New Mexico Health Science Center, Albuquerque, NM.*

Background: To conduct a randomized trial of home based kidney care (HBKC) of patient activation measure (PAM) with lifestyle intervention to reduce risk factors for chronic kidney disease (CKD) in Zuni Indians.

Methods: Randomized families with more than one individual with CKD (1:1) to a usual care (UC) or an HBKC intervention group. After initial lifestyle coaching in both groups, the HBKC received reinforcement of healthy behaviors through alternate weekly home visits by the community health representatives, and with quarterly group sessions. The primary outcome was change in PAM. The secondary outcomes were changes in measures of T2D, CKD, BP, lipid profiles, BMI, Morisky score), KDQOL and diet. Tests for significance were performed using mixed models analysis of variance with a per-household random effect and while adjusting for baseline levels of the variables being examined.

Results: Patients in the HBKC group increased PAM total score by 9.5±26.1 points, compared to a decrease of 0.7±14.0 points in the UC (p=0.04). Similarly, 16.7% more of the HBKC group were in the PAM "activated" group (PAM level >3) at the study's end, while 12.5% fewer of the UC group were in the PAM "activated" group at the study's end. In our secondary analyses, progression of multiple risk factors for kidney disease, especially BMI, A1C, and hsCRP, slowed by the HBKC intervention. We also observed greater improvements in QOL in the HBKC group; SF12 mental scores significantly increased in the HBKC compared to the UC (p=0.02), with an average±S.D. point change in the HBKC group of 7.5±11.0 compared to a -0.2±9.0 point change in the control group

Conclusions: A HBKC intervention of continuous patient engagement, a potentially scalable approach to providing care to patients with CKD, was effective in improving PAM levels and in reducing risk factors for CKD.

SA-OR013

Loss of Renal Function and Benefits of Measured GFR among Lung Transplant Patients Nans Florens,[1,2] Laurence Dubourg,[1,2] Agathe Senechal,[1] François Philit,[1] Laurent Juillard,[1,2] Sandrine Lemoine.[1,2] *[1]Hospices Civils de Lyon, Lyon, France; [2]University of Lyon, Lyon, France.*

Background: There are about 4000 lung transplant patients over the world. Renal dysfunction and chronic kidney disease among this population are underestimated. The aim of our study was to evaluate the loss of glomerular filtration rate (GFR) after a lung transplantation.

Methods: All the lung transplant patients in the university hospital of Lyon between January 2012 and April 2016 were studied retrospectively. Patients had a pre- and/or post-transplantation measurement of their GFR (mGFR) either by the inulin gold standard

method or by iohexol clearance. Estimation of the GFR was achieved with CKD-EPI equation.

Results: 111 lung transplantations were performed between January 2012 and April 2016. 91 patients had a pre-transplantation mGFR. Among those patients, 13 deceased during the follow-up period, 28 had a mGFR after 1 or 2 years of their transplantation and 6 patients underwent maintenance hemodialysis after their transplantation. Mean pre-transplantation mGFR was 106 mL/min/1.73m^2 and 58 mL/min/1.73m^2 after transplantation ($p<0.05$) with a mean loss per patient of 48 mL/min/1.73m^2. 6 % of the patients had a CKD stage 3 or more before the transplantation while 66% after. In pre-transplantation patients, eGFR and mGFR were significantly different (16 ± 6 mL/min/1.73m^2, $p<0.05$) while not in post-transplantation. The risk of developing a CKD stage 3 after the transplantation was higher for patients with a pre-transplantation mGFR under 90 mL/min/1.73m^2 (RR = 2,1; IC 95% 1,2 – 3,6). Patients undergoing a maintenance hemodialysis had a lower pre-transplantation mGFR than all the other patients with a post-transplantation CKD (74 ± 7 mL/min/1.73m^2 *vs* 108 ± 5, $p<0.05$).

Conclusions: The prevalence of CKD among lung transplant patients is important as the loss of kidney function is about 50 mL/min/1.73m^2 per patient. Lung transplant candidates with a mGFR under 90 mL/min/1.73m^2 need an increased monitoring of their renal function and patients with an initial GFR< 50 mL/min/1.73m^2 had to be discussed for a double-lung and kidney transplant.

SA-OR014

Racial and Ethnic Disparities in Access to Predialysis Nephrology Care in the US: Have We Made Any Progress over the Last Decade? Tanjala S. Purnell, Xun Luo, Sunjae Bae, Deidra C. Crews, Lisa A. Cooper, Dorry L. Segev. *Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Over the past decade, there has been increased attention and efforts to improve overall access and redress racial and ethnic disparities in access to predialysis nephrology care in the US. The goal of this study was to investigate whether these efforts have been successful.

Methods: Using USRDS patient data, we performed multivariable logistic regression models to quantify temporal changes in racial and ethnic disparities in receipt of predialysis nephrology care among 934,599 adults who initiated chronic dialysis treatment between 2005 and 2015. We adjusted regression models for differences in patient sociodemographic factors.

Results: Over the last decade, racial and ethnic disparities in access to predialysis nephrology care slightly worsened. In 2005-2007, Blacks were 14% (aOR: 0.86, 95% CI: 0.85-0.88) and Hispanics were 22% (aOR: 0.78, 95% CI: 0.76-0.80) less likely to receive predialysis nephrology care than Whites. In 2008-2010, Blacks were 14% (aOR: 0.86, 95% CI: 0.84-0.87) and Hispanics were 29% (aOR: 0.71, 95% CI: 0.70-0.73) less likely than Whites. In 2011-2013, Blacks were 18% (aOR: 0.82, 95% CI: 0.81-0.84) and Hispanics were 30% (aOR: 0.70, 95% CI: 0.69-0.72) less likely than Whites. In 2014-2015, Blacks were 19% (aOR: 0.81, 95% CI: 0.79-0.83) and Hispanics were 29% (aOR: 0.71, 95% CI: 0.69-0.73) less likely than Whites. **(Figure 1)**

Conclusions: Disparities in access to predialysis nephrology care worsened (versus narrowed) over the past decade. Targeted interventions to effectively reduce these disparities should be identified and adopted widespread to improve outcomes for patients with ESRD in the US.

SA-OR015

Disease-Specific Stress Experienced by Patients with CKD Julie A. Wright Nunes,[3] Eve Kerr,[2] Emily P. Chen,[1] Gunjan Garg,[2] Angela Fagerlin.[4] *[1]University of Michgan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]University of Michigan Health System, Ann Arbor, MI; [4]University of Utah, Salt Lake City, UT.*

Background: Increased psychological stress is independently associated with decreased social functioning, poor quality of life and morbidity. We developed a new scale to assess patient psychological stress about a chronic kidney disease (CKD) diagnosis and examined whether stress varies across different patient demographics.

Methods: Adults with CKD Stages 1-5 were enrolled to take a cross-sectional survey from April 2015-May 2016. Eight questions (stress scale) assessed how often patients thought about their CKD, had trouble sleeping because of it, and felt fearful and worried (scale 0="not at all" to 3="often"). We also asked patients to rank CKD importance compared to other conditions. An *a priori* model was used to examine for validity. Reliability was calculated using Cronbach's alpha. Associations were examined using linear regression.

Results: 203 patients were enrolled with a mean (SD) age 59 (16) years; 49% were men, 78% Caucasian, 16% African American (AA), 5% other races, 73% had CKD Stage 3-5, 48% had an annual income < $50K, and 95% had ≥ H.S. education. Cronbach's alpha was 0.89 (excellent reliability). The mean (SD) of the 8-item scale was 1.1 (0.6), range 0.0 – 2.8. Sixty-seven percent ranked CKD as either very important or their top health priority. Age was negatively associated [β = -0.01 (CI -0.02, -0.005); $p<0.01$] and AA race positively associated [β=0.4 (0.1, 0.6); $p<0.01$] with CKD stress scores. In adjusted analysis, age remained independently and negatively associated with stress scores [β = -0.01 (-0.02, -0.001); p=0.03], while AA race and CKD stage trended towards a positive association [β=0.33 (-0.004, 0.7); p=0.05] and [β=0.2 (-0.02, 0.5); p=0.08], respectively.

Conclusions: Our scale exhibits excellent internal reliability and evidence of validity assessing disease-specific stress in patients with CKD. Despite the majority of patients ranking CKD as very important/top health priority, overall patients reported low stress about their diagnosis. African American race conferred more perceived stress related to CKD. Future education and awareness interventions must consider the impact that disease knowledge has on patient stress, in particular for African American patients--and integrate individualized psychosocial support for all patients into education programs.

SA-OR016

Reported Kidney Disease Awareness and Medical Subspecialty Use before and after the Affordable Care Act Implementation among National Health Interview Survey Participants Anna J. Jovanovich,[1] Michel Chonchol,[3] Zhiying You.[2] *[1]Denver VA / University of Colorado, Denver, CO; [2]UC Denver, Aurora, CO; [3]University of Colorado, Aurora, CO.*

Background: In the U.S., individual awareness of chronic kidney disease (CKD) is low. Nephrology referral improves CKD awareness and clinical outcomes. The Affordable Care Act (ACA) implementation on January 1, 2014 increased insurance coverage and access to health care for people with chronic disease. It is unknown if the ACA has impacted people with CKD.

Methods: Utilizing National Health Interview Survey (NHIS) data, we compared kidney disease awareness and medical subspecialty use during 2012, a full year before the ACA implementation, and 2015, a full year after. The sample included 66,624 non-institutionalized U.S. citizens ages 19-64. In this quasi-experimental analysis, we used logistic regression to examine whether kidney disease awareness and medical subspecialty use increased after the ACA implementation, using weights as appropriate.

Results: Baseline characteristics among NHIS participants in the years 2012 and 2015 were similar: age 47 years, 52% female, and 80% white. The percentage of participants reporting no health insurance coverage decreased from 17% in 2012 to 10% in 2012 ($p<0.0001$). Kidney disease awareness, medical subspecialty use, and a combination of both increased from 2012 to 2015: 1.6% to 2.0% (p = 0.002), 26% to 28% (p = 0.002), and 1.0% to 1.3% (p = 0.006), respectively. After adjustment for age, sex, race, ethnicity, marital status, education, income, and region, 2015 NHIS participants were 27% (odds ratio [OR] 1.27 [95% CI, 1.10-1.46]) more likely to report kidney disease awareness, 6% (OR 1.06, [95% CI, 1.00 to 1.11]) more likely to report medical subspecialty use, and 27% (OR 1.27 [95% CI, 1.07 to 1.50]) more likely to report both. When insurance status was added to the models, the magnitude of all the odds ratios was attenuated suggesting that insurance status influences reported kidney disease awareness and medical subspecialty use.

Conclusions: Kidney disease awareness and medical subspecialty use reported by NHIS participants significantly increased from 2012 to 2015, after the ACA implementation, while participants reporting no health insurance significantly decreased. These data suggest that the ACA improves access to care among people with CKD, and thus, may be key to improving clinical outcomes.

The Association between Participation in a Specialized Renal Disease Management Program and Economic Outcomes Changhung A. Chien, Kael Haig, Matt Ruyter, Ana R. Stankovic. *OptumHealth, Minneapolis, MN.*

Background: A 2016 meta-analysis of efficacy of chronic kidney-focused disease management (DM) programs demonstrated improved quality of life among chronic kidney disease (CKD) patients. However, published evaluations of DM program impact on medical spend, utilization, and transplantation have been inconsistent. We measured the association between participation in a specialized renal disease management (DM) program and all-cause medical spend, utilization outcomes, and transplantation among patients with Stage 4 or 5 CKD or ESRD.

Methods: The study included commercially insured members 18 years or older identified as having Stage 4 or 5 CKD or ESRD during January 2013 – December 2016. All members included in the study were eligible for the DM program. We compared members who participated in a nurse-based telephonic DM program (CKD = 1,428 and

ESRD = 4,144) to members who did not participate in the DM program (CKD = 8,179 and ESRD = 5,825). Kaplan-Meier curves were used to estimate the probability of kidney transplant evaluation and transplant among CKD and ESRD patients. Chi-square and t-tests were used to compare differences in average inpatient admission rate, inpatient length of stay, and all-cause medical spend between DM program participants and non-participants.

Results: CKD patients who participated in the DM program were more likely to be evaluated for transplant than non-participants (25.8% vs. 7.1%) and to receive a preemptive transplant (4.8% vs. 1.5%). Similarly, ESRD patients who participated in the DM program were more likely to be evaluated for transplant than non-participants (32.5% vs. 4.5%) and also to receive a transplant (5.6% vs. 0.7%). ESRD program participants had fewer annual inpatient admissions (1.2 vs. 1.4) and fewer inpatient days per year (10.5 vs. 14.4) than non-participants. All reported differences were significant with $p < 0.05$. There were no significant differences in inpatient length of stay and all-cause medical expenditures between the study groups.

Conclusions: Participation in a specialized DM program was associated with higher transplant evaluation rate, higher preemptive and non-preemptive transplant rate, fewer inpatient admissions, and fewer inpatient days per year among patients with Stage 4 or 5 CKD or ESRD.

Interaction of Socioeconomic Status with Genetic Factors in Kidney Function Outcomes Chris H. Thio,[2] Harold Snieder,[1] Ute Bültmann,[3] Ron T. Gansevoort.[4] *[1]Epidemiology, UMCG, Groningen, Netherlands; [2]Epidemiology, UMCG, Groningen, Netherlands; [3]Health Sciences, UMCG, Groningen, Netherlands; [4]Nephrology, UMCG, Groningen, Netherlands.*

Background: Chronic kidney disease (CKD) is potentially caused by genetic and environmental factors. Previous studies suggested joint effects of socio-economic status (SES) and genetic risk in obesity and diabetes, but this issue has not been investigated in CKD. We therefore tested whether SES and genetic risk interact in their association with eGFR decline and incident CKD (CKDi).

Methods: In the community-based PREVEND cohort, we calculated eGFR from creatinine and cystatin C at five examinations. We defined CKDi as eGFR<60 mL/min/1.73m^2 during follow-up in those without baseline CKD. SES was measured by educational level and categorized into low, medium, and high (<secondary; secondary/equivalent; >secondary school). To quantify genetic risk, we used a genetic risk score (GRS) comprising 53 eGFR SNPs, weighted for published effects. In longitudinal analyses, we tested main effects of SES and GRS, as well as their interaction. Covariates were age, sex, smoking, BMI, urinary albumin, diabetes, hypertension, high cholesterol, and cardiovascular disease.

Results: We included 3,393 subjects (Caucasian, 52% male, median age 49 yrs [IQR 40-60], median follow-up duration 11 yrs [IQR 4.7-12], N=109 baseline CKD, N=190 CKDi). Mean GRS did not differ between SES levels. In univariate analyses, both high GRS and low SES were associated with lower eGFR levels. Low SES was associated with steeper eGFR decline, but higher GRS was not. However, their interaction was significant (SES*GRS*time, p=0.01). A higher GRS was associated with steeper decline only in those with low SES (see Figure). Covariate adjustment did not affect these conclusions. Both SES and GRS were univariately associated with CKDi, but their interaction was not significant.

Conclusions: Our data suggest that in subjects with low SES the effects of genetic risk for kidney function decline are stronger, independent of CKD risk factors. Future studies need to corroborate these findings in larger samples and focus on aspects of SES that mediate this relation.

Qualitative Assessment of an Online Peer Mentoring Platform for Patients with CKD Awais Ammar,[1] Mary Morrow-Sutton,[1] Tabitha Semancik,[2] Tara Liaghat,[1] Umar Farooq,[1] Nasrollah Ghahramani.[1] *[1]Penn State College of Medicine, Hershey, PA; [2]Kidney Foundation of Central Pennsylvania, Harrisburg, PA.*

Background: Peer mentoring (PM) is an effective model for patients with the same chronic disease to share knowledge and experience to which others often cannot relate. PM occurs in various settings, including face-to-face, via telephone or online. This study is a qualitative assessment of the communications in an online PM platform designed for patients with chronic kidney disease (CKD).

Methods: Twenty-one patients were assigned to trained peer mentors with whom they had regular online communication in a PM relationship. The interactive online platform allowed patients to post their concerns and questions about specific symptoms or treatment decisions through a private network. Patients used an intuitive user interface, utilizing mood and symptom icons, to indicate their current status. The program coordinator monitored the patients' and mentors' updated posts. Stress Score (SS: 1-10), as subjectively indicated by the patients, were used to quantitatively assess the severity of their concerns.

Results: A total of 213 posts, initiated by 21 patients, were included in the analysis. The posts were categorized into 15 general topic areas. The largest number of posts (n=34) related to family relationship concerns, followed by posts regarding weakness and lack of energy (n=25), weight change (n=19), overall prognosis (n=18) and financial stressors (n=16). Quantitatively, the most stressful concerns related to financial matters (SS: 7/10) and family relationships (SS: 6.5/10).

Conclusions: Patients communicate with their peers via an online platform regarding a variety of concerns and questions. Concerns about finances and family relationships form a significant aspect of the communication. These findings underscore the patients' concern about the impact of their disease on their families. Trajectories of HRQOL in Children with CKD Arlene C. Gerson,[1] Matthew Matheson,[2] Rebecca J. Johnson,[3] Stephen R. Hooper,[4] S. Shinnar,[5] Bradley A. Warady,[6] Susan L. Furth,[7] Cynthia Wong,[8] Amy Kogon,[9] Marc Lande,[10] Lyndsay Harshman,[11] Susan R. Mendley.[12] *[1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Children's Mercy Kansas City, Kansas City, MO; [4]University of North Carolina School of Medicine, Chapel Hill, NC; [5]Montefiore Medical Center, Albert EInstein College of MEdicine, Bronx, NY; [6]The Children's Mercy Hospital, Kansas City, MO; [7]The Children's Hospital of Philadelphia, Philadelphia, PA; [8]Stanford University, Stanford, CA; [9]Nationwide Children's Hospital, Columbus, OH; [10]University of Rochester, Rochester, NY; [11]University of Iowa Children's Hospital, Iowa City, IA; [12]University of Maryland, Baltimore, MD.*

Background: Trajectories of health related quality of life (HRQOL) may offer valuable insights into psychosocial aspects of disease progression in children with chronic kidney disease (CKD). Few longitudinal studies have evaluated the impact of CKD duration on HRQOL. The aim of this study was to determine how HRQOL changes over the time course of CKD.

Methods: The subjects in this study were participants in the Chronic Kidney Disease in Children (CKiD) cohort who completed the Pediatric Quality of Life Inventory (PedsQL) on three or more occasions over the course of two or more years. Generalized gamma (GG) mixed effects models were applied to assess the effect of CKD duration on HRQOL while controlling for confirmed covariates from previous cross-sectional analyses.

Results: 660 children (median age: 11.3) with a median of 8.5 years duration of CKD were evaluated. GG models with child self-report PedsQL data indicated that longer CKD duration was associated with improved Overall, Physical, Emotional, Social and School HRQOL. GG models with parent-proxy PedsQL data indicated that longer duration was associated with worse School HRQOL. Increasing trajectories of child self-report HRQOL were observed in the majority of subjects (ranging from 64% to 96% depending on subscale and baseline HRQOL level), while lower percentages of increasing trajectories were observed on parent-proxy scales. In the overall group there was no significant relationship between HRQOL and time varying GFR.

Conclusions: Longer duration of disease is associated with improved HRQOL on all child self-report scales. This finding may be a function of changes in internal standards, values or conceptualization of illness.

Funding: NIDDK Support, Other NIH Support - NICHD, NHLBI

Protective Role of Type III Sodium-Dependent Phosphate Transporter, PiT-2, in Uremic Vascular Calcification Shunsuke Yamada, Elizabeth M. Soberg, Timothy C. Cox, Mei Y. Speer, Cecilia M. Giachelli. *University of Washington, Seattle, WA.*

Background: Vascular calcification (VC) is prevalent in patients with chronic kidney disease (CKD) and increases the risk of cardiovascular deaths. PiT-2 is a type III sodium-dependent phosphate (Pi) transporter expressed in various tissues and a causative gene for familial basal ganglion arterial calcification. However, it is unknown whether PiT-2 plays a role in the pathogenesis of VC related to CKD.

Methods: To determine the role of PiT-2 in VC, wild-type (WT) and global PiT-2 heterozygous (HET) knockout mice were challenged with CKD. At two weeks after the two-step 5/6th nephrectomy, mice were fed a normal (0.5%) or high (1.5%) Pi diet for 11 days and terminated. At termination, blood, aorta, kidney, and femur were collected. Serum chemistry, histology, and micro CT analyses were performed. Primary vascular smooth muscle cells (VSMCs) isolated from the aortas of WT and PiT-2 HET mice were used for *in vitro* Pi-induced calcification and P-uptake assays. WT-derived VSMCs were also treated with scramble or PiT-2 small interfering RNA (siRNA) and used for gene and protein expression analysis.

Results: Uremic mice fed a high Pi diet developed VC in the medial layer of the aorta, which was exemplified by Alizarin red staining and calcium quantification of the blood vessel. PIT-2 haploinsufficiency greatly enhanced VC in the setting of CKD and high Pi diet. No differences were observed in the serum levels of calcium, Pi, and FGF23, kidney function, and renal mRNA expression of SLC34A1 and SLC34A3 between the WT and PiT-2 HET mice with CKD. MicroCT analyses showed that haploinsufficiency of PiT-2 decreased trabecular bone mineral density and thickness in CKD. *In vitro*, Pi uptake activity was decreased in the cultured VSMCs isolated from the PiT-2 HET mice compared with those from the WT mice. Under high Pi medium condition, PiT-2 haploinsufficiency increased calcification of the cultured VSMCs. Similar results were also found in WT VSMCs treated with PiT-2 siRNA. Finally, mRNA expression and protein levels of osteoprotegerin, an inhibitor of VC, were decreased in VSMCs treated with PiT-2 siRNA compared to scramble controls.

Conclusions: PiT-2 plays a protective role in the pathogenesis of VC and bone disorders in CKD mice, and can be a promising therapeutic target in the CKD population.

Large Secondary Calciprotein Particles Are Associated with Vascular Calcification Wei Chen,[1] Viktoriya Anokhina,[1] Benjamin L. Miller,[1] Gregory Dieudonne,[1] Matthew K. Abramowitz,[2] Randeep Kashyap,[1] Chen Yan,[1] Tong tong Wu,[1] David A. Bushinsky.[1] *[1]University of Rochester School of Medicine, Rochester, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Vascular calcification (VC) is common and contributes to cardiovascular mortality in patients with CKD. Calcification propensity as measured by the serum assay of Pasch et al. using nephelometry is associated with cardiovascular events; however, whether it is a biomarker for VC is unknown. We modified this assay through the use of microplate-based dynamic light scattering, which allowed us to measure both time for half-maximal transformation (T_{50}) of 1° to 2° calciprotein particles (CPPs) and size of 2°CPPs (CPP2) (instead of only T_{50} with nephelometry). A fast T_{50} and/or a large CPP2 appears to reflect a procalcific milieu. Here we tested the hypothesis that a fast T_{50} and/or a large CPP2 would be associated with VC.

Methods: We measured T_{50} and CPP2 in 46 subjects with stage 4-5 CKD and 17 healthy volunteers. T_{50} and CPP2 were examined as continuous and categorical variables (dichotomized at the median). VC was measured on plain radiographs and defined as a Kauppila score >6 (lumbar aorta) or Adragao score ≥3 (iliac, femoral, radial and digital arteries). Logistic regression was used to examine the association of T_{50} and CPP2 size with VC, adjusting for age, gender, eGFR and diabetes.

Results: Compared to healthy volunteers (age 24±5 yr, eGFR 114±13ml/min/1.73m^2), CKD patients (age 65±12 yr, eGFR 19±8ml/min/1.73m^2) had lower mean T_{50} (191±40 vs. 221±31 min, p=0.008) and higher median CPP2 [305 (187-477) vs. 168 (145-352) nm, p=0.02]. T_{50} was correlated inversely with CPP2 (r=-0.50, p<0.001). No healthy volunteers had VC, while 51% of CKD patients did. In all subjects, compared to those without VC, those with VC had a higher median CPP2 [370 (272-566) vs. 195 (153-327) nm, p=0.001] with no difference in mean T_{50} (191±39 vs. 203±41 min, p=0.27). Compared to those with CPP2 in the lower half (median=305nm), those with CPP2 in the upper half had 10.7 times higher odds of having VC (95% CI 1.4, 79.1, p=0.02). Similar results were obtained when analysis was limited to CKD patients.

Conclusions: CKD patients had larger CPP2 and faster T_{50} indicating greater calcification propensity compared with healthy volunteers. While a faster T_{50} was associated with larger CPP2, only a large CPP2 was associated with VC suggesting that CPP2 may be a useful biomarker for VC.

The Effect of Increasing Dialysate Magnesium on Serum Calcification Propensity in Subjects with ESRD: A Randomised Double-Blind Controlled Trial Iain B. Bressendorff,[2,5] Ditte Hansen,[2] Morten Schou,[1] Andreas Pasch,[4] Lisbet Brandi.[3] *[1]Department of Cardiology, Herlev Hospital, Herlev, Denmark; [2]Department of Nephrology, Herlev Hospital, Copenhagen, Denmark; [3]Department of Cardiology, Nephrology and Endocrinology, Nordsjællands Hospital, Hillerød, Denmark; [4]University Hospital Bern, Bern, Switzerland; [5]Department of Cardiology, Nephrology and Endocrinology, Nordsjællands Hospital, Hillerød, Denmark.*

Background: Patients undergoing haemodialysis (HD) for end-stage renal disease (ESRD) have an enormously high risk of cardiovascular disease. Serum calcification propensity (T_{50}) is a novel functional test, which quantifies the functionality of the humoral system of calcification control. Low T_{50} values are associated with increased risk of cardiovascular events and death in patients with ESRD. Increasing magnesium (Mg) in serum increases (i.e. improves) T_{50} *in vitro*, but so far no clinical trials have investigated whether increasing serum Mg increases T_{50} in subjects with ESRD.

Methods: We conducted a single-centre, randomised, double-blinded, controlled clinical trial, in which we examined the effect of increasing dialysate Mg from 0.5 mmol/L to 1.0 mmol/L compared to maintaining dialysate Mg at 0.5 mmol/L on T_{50} in subjects undergoing HD for ESRD. Fifty-nine subjects underwent 28 days of intervention followed by 14 days of observation.

Results: After increasing dialysate Mg from 0.5 mmol/L to 1.0 mmol/L for 28 days the difference in serum Mg between the two groups was 0.351 mmol/L (between-group difference, 95% confidence interval 0.263 - 0.440, p < 0.001). In parallel to the increase in serum Mg, the difference in T_{50} between the two groups was 72 min (between-group difference, 95% confidence interval 29 - 114, p < 0.001). One subject withdrew consent (high dialysate Mg group) and two subjects died (one in each treatment group). There were no adverse events considered to be related to the intervention.

Conclusions: Increasing dialysate Mg increased T_{50} in subjects undergoing maintenance HD. Improving T_{50} might lead to reductions in cardiovascular events and death in subjects with ESRD.

Monocyte Chemoattractant Protein-1 (MCP-1) Is Associated with Atherosclerotic (ASCV) Events and Death in CKD Maria Clarissa Tio,[1] Lucile Parker Gregg,[3,2] Xilong Li,[4] Beverley Adams-Huet,[4] James Delemos,[5] Susan Hedayati.[3,2] *[1]Department of Medicine, University of Texas Southwestern Medical Center, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX; [3]Division of Nephrology, University of Texas Southwestern Medical Center, Dallas, TX; [4]Department of Clinical Sciences, University of Texas Southwestern Medical Center, Dallas, TX; [5]Division of Cardiology, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: MCP-1, an inflammatory chemokine involved in atherogenesis, is associated with CV events in individuals with known coronary artery disease. Few data exist regarding its association with hard outcomes in CKD.

Methods: We studied 3,257 participants of the Dallas Heart Study, 285 (8.8%) of whom had CKD (eGFR <60 mL/min/1.73m^2 or albuminuria), followed for a median of 12.5 years for all-cause death, global CV events (CV death, MI, stroke, CV revascularization, hospitalization for heart failure or atrial fibrillation), and ASCV events (CV death, MI, stroke, CV revascularization). Cox proportional hazards regression assessed associations between log MCP-1 levels and outcomes, unadjusted and adjusted for traditional CV risk factors (age, sex, race, hypertension, diabetes, current smoking, total and HDL cholesterol) and eGFR.

Results: There were 327 deaths, 287 global CV and 228 ASCV events in the entire cohort. In the CKD group, there were 97 (34%) deaths, 76 (34.5%) global CV and 62 (27.9%) ASCV events. Median (IQR) MCP-1 was 164.7 (120.3, 220.9) pg/mL in non-CKD vs. 192.2 (143.6, 269.8) in CKD individuals, P<0.001, and negatively correlated with eGFR, r=-0.23, P<0.0001. In the CKD group, MCP-1 was associated with death (HR 1.96, 95% CI 1.35-2.85) and ASCV events (HR 1.72, 95% CI 1.04-2.87) but not global CV events in unadjusted models (**Figure**). Adjustment for CV risk factors attenuated the association between MCP-1 and ASCV events, but the association with death remained significant in non-CKD (aHR=1.65, 95% CI 1.32-2.07) and CKD (aHR=1.49, 95% CI 1.01-2.19) groups. There were no significant CKDxMCP-1 interactions on outcomes.

Conclusions: While MCP-1 does not predict global CV and ASCV events after adjusting for CV risk factors, it is an independent predictor of all-cause death in both CKD and non-CKD individuals. Future directions include exploring its inclusion in outcome prediction models in the CKD population.

Metabolic and Hypertensive Complications of Pregnancy in Women with Nephrolithiasis Jessica S. Tangren, Elizabeth D. Ankers, Ravi I. Thadhani. *Massachusetts General Hospital, Boston, MA.*

Background: Kidney stones are associated with future development of hypertension, diabetes and the metabolic syndrome. The relationship between nephrolithiasis and pregnancy complications, including gestational dysglycemia and gestational hypertension has not previously been evaluated. We assessed whether stone formation *prior to pregnancy* was associated with metabolic and hypertensive complications in pregnancy. We hypothesized that stone formation is a marker of metabolic disease and associated with increased risk for maternal complications in pregnancy.

Methods: We conducted a retrospective cohort study of women who delivered infants at the Massachusetts General Hospital from 2006 to 2016. Women with abdominal imaging (CT or ultrasound) prior to pregnancy were included in the analysis. Pregnancy outcomes in women with documented stones on imaging (stone formers, n=174) were compared to women without stones on imaging (controls, n=1,330). Women with pre-existing CKD, hypertension and diabetes were excluded.

Results: Maximum systolic blood pressure (mSBP) in pregnancy was increased in stone formers versus controls despite similar first trimester blood pressure. Gestational diabetes and gestational hypertension were more common in stone formers (18% vs. 6%, p<0.01 and 19% vs. 13%, p=0.04). After multivariate adjustment, stones were associated with increased risk of preterm delivery, gestational diabetes and preeclampsia (1A). Stone formation was an effect modifier of the relationship between mSBP and BMI (1B).

Conclusions: In women without preexisting diabetes and hypertension, a history of nephrolithiasis was associated with gestational dysglycemia and hypertension. Nephrolithiasis may be a marker of increased metabolic risk in women without traditional risk factors for pregnancy complications.

SA-OR026

Antibiotic Use and Risk of Incident Kidney Stones Eric N. Taylor,[3] Gary C. Curhan,[1] Pietro Manuel Ferraro.[2] *[1]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [2]Fondazione Policlinico Universitario A. Gemelli, Rome, Italy; [3]Maine Medical Center, Portland, ME.*

Background: Intestinal microbiota may play a role in the formation of kidney stones. Antibiotics alter the gut microbiome and therefore represent a potential risk factor for kidney stones.

Methods: We prospectively examined the independent associations between antibiotic use at age 20 to 39 and age 40 to 59 with risk of a subsequent symptomatic, incident kidney stone in the Nurses' Health Study I (NHS I; N=67,051 women). We also examined antibiotic use at age 20 to 39 and age 40 to 49 in the Nurses' Health Study II (NHS II; N=74,467 women). Medical record review of a subset of cases confirmed ≥ 95% of self-reported incident kidney stones in each cohort, and the majority of stones (≥ 77%) were predominantly calcium oxalate. Validated food frequency questionnaires were used to update dietary intakes every four years. Cox proportional hazards regression was used to adjust for age, body mass index, thiazide use, family history of kidney stones, hypertension, diabetes, fluid intake, supplemental calcium, and dietary factors.

Results: We documented 1,318 incident kidney stones over a combined 14 years of follow-up. At baseline, mean age was 68 in NHS I and 50 in NHS II. Compared with non-users, women who used antibiotics for ≥ 2 months between age 20 to 39 had a multivariable relative risk (MVRR) for kidney stones of 1.41 (95% CI 0.95 to 2.09) in NHS I and 1.28 (95% CI 0.87 to 1.89) in NHS II. Compared with non-users, women who used antibiotics for ≥ 2 months between age 40 to 59 in NHS I and between age 40 to 49 in NHS II had MVRRs for kidney stones of 1.62 (95% CI 1.01 to 2.60) and 1.35 (95% CI 1.00 to 1.84), respectively. Excluding women with self-reported urinary tract infections before the symptomatic kidney stone event did not change the results. There was no statistically significant interaction between dietary oxalate, antibiotic use, and kidney stone risk.

Conclusions: Long-term antibiotic use in early and middle adulthood may be independently associated with a higher risk of kidney stones later in life.

SA-OR027

Effect of Dietary Phosphate Intake on Blood Pressure in Healthy Humans Reto Krapf,[2] Lukas Bestmann,[1] Roberto Scanni,[4] Henry N. Hulter.[3] *[1]Bioanalytica Labs, Lucerne, Switzerland; [2]Medicine, University of Basel, Lucern, Switzerland; [3]University of California San Francisco, San Rafael, CA; [4]Istituto Oncologico Veneto, Padova, Italy.*

Background: Despite strong epidemiologic evidence for CV toxicity of high dietary phosphate (Pi) in humans with normal renal function, controlled Pi intervention effects on systemic human hemodynamics have not been reported. Vitamin D is known to increase intestinal Pi absorption, thereby increasing Pi load. Conversely, vitamin D supply has been associated with better CV outcome.

Methods: Prospective outpatient study with blinded assessment in 20 young healthy humans with normal renal function randomly assigned to high (HP, regular diet, RD, + 1 mmol/kg bw/d of Pi as neutral NaPO4) or to low Pi (LP, RD + lanthanum 750 mg p.o. TID plus 0.7 mmols/kg bw/d NaCl to correct for excess Na intake in HP group) for 11 weeks (w). At end of w6, each subject received 600 000 U of vitamin D3 (i.m.) and continued on HP and LP for another 5w. Recovery visits on RD were performed 2 months after w11. Plasma and 24h urinary assays were performed at BL, w6 and w11. CV endpoints: 24h ABPM. endothelial function (reactive hypoxia index), arterial elasticity (pulse wave velocity). Data are means of 3 consecutive daily measurements/period.

Results: Mean fasting [Pi]p increased significantly by 0.23±0.11 (SEM) mmol/l in HP group as did 24h SBP and DBP, both in comparison to own baseline and to the LP group: + 4.1 (range 2.1-6.1) and 3.2 (1.2-5.2) mmHg, respectively. 24h U Pi was 14.6 ± 1.8, 21.9 ± 2.4 and 41.5 ± 4.1 mmol/24h in LP, RD and HP. Mean 24h pulse rate increased significantly by + 4.0 (2.0-6.0) bpm. Plasma renin/aldosterone concentrations and 24h urinary excretion rates of Na, aldosterone and free cortisol did not differ among the 2 groups. 24h urinary excretion of metanephrin increased significantly (intra- and intergp) in the HP group by + 60 (50-70) ugr/24h. Vitamin D had no effect on the HP-induced increases in BP, pulse rate, metanephrin or renin/aldosterone values and increased U Pi/24h only in the LP group. Serum FGF23, PTH, a-Klotho and urinary Klotho increased significantly in HP vs. LP. Recovery RD visits showed reversal of the elevated 24h ABPM and pulse rates in the HP group. Neither modulation of Pi intake nor vitamin D affected endothelial and arterial function tests significantly.

Conclusions: Increased Pi intake (controlled for sodium intake) significantly increases SBP, DBP and pulse rate in normal humans, an effect explained at least in part by increased sympathoadrenergic activity.

Understanding the Metatranscriptome and Metagenome Regulating Oxalate Metabolism in the Human Gut Lama Nazzal,[2] Tom W. Battaglia,[2] Menghan Liu,[2] David S. Goldfarb,[1] Kelly Ruggles,[2] Martin J. Blaser.[2] *[1]New York Harbor VAMC, Hastings on Hudson, NY; [2]New York University School Of Medicine, New York, NY.*

Background: Multiple bacterial species are capable of degrading oxalate in vitro. Certain taxa degrade oxalate as their sole source of energy and carbon (e.g. *Oxalobacter formigenes*), whereas others use oxalate as an auxiliary carbon source. For oxalate metabolism, it is not yet well-understood how genomic potential relates to transcriptional regulation. We asked whether the human gut could have a community of oxalate-degrading taxa working synergistically to diminish the effects of this toxic metabolite. Our hypothesis is that oxalate metabolism is regulated by a multi-organism oxalate-degrading community (oxalobiome) that is dominated by specialist oxalate degraders.

Methods: We used data from 2 public databases: (i)8 healthy subjects in the USA; and (ii)471 healthy subjects in the Netherlands as part of the Human Functional Genomic Project (HFGP). Both collected fecal samples for metagenomic and/or metatranscriptomic high throughput sequencing. Using HUMAnN2 with customized settings, we profiled the metabolic activity of oxalate-degrading bacterial species. Output from these analyses was expressed as Reads per Kilobase per Million mapped reads (RPKM).

Results: We identified the oxalate degradation pathway (ODP) in the metagenome and metatranscriptome of all 8 subjects. Mean ODP is 35.3±28.1 and 90.1±43.5 RPKM in the metagenome and the metatranscriptome, respectively, indicating active expression. *O. formigenes, E. coli,* and unclassified bacteria were present in metagenomic and metatranscriptomic reads. *B. dentium* had detectable ODP in its genome but was not transcribing it. In the HFGP database, we identified ODP in 328 subjects of the 471 tested (70%) (Mean=18.1±2.1 RPKM). ODP was detected in *B. animalis, B. dentium, B. pseudocatenulatum, E.coli/Shigella, L. acidophilus, L. gasseri, L. mucosae, O. formigenes* and unclassified bacteria. ODP was examined in the metagenome of 265 females (Mean ODP= 21.7±3.3) and 200 males (Mean ODP=13.3±1.9 RPKM; p=0.04 by unpaired t test).

Conclusions: We have identified a community of bacteria with the potential to degrade oxalate in healthy humans and species actively transcribing ODP. These include *E.coli*, which might be a common contributor of oxalate degradation in humans. The sex differences in ODP is consistent with the ~ 2:1 male/female incidence and prevalence of calcium oxalate stones.

The L530R Variation Found in Kidney Stone Patients Impacts the Structure and Function of TRPV5 Lingyun Wang, Ji-Bin Peng. *Div of Nephrology, Dept of Medicine, Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL.*

Background: TRPV5 is a Ca^{2+}-selective channel that plays a key role in the reabsorption of Ca^{2+} ions in the kidney. Recently, a L530R variation in TRPV5 was found in some kidney stone formers. This variation introduces a positive charged residue into a hydrophobic region of the pore helix and may alter the Ca^{2+} transport activity of TRPV5. However, it is unclear to what extent this variation alters the structure and function of TRPV5.

Methods: To evaluate the function and expression of the TRPV5 variant, Ca^{2+} uptake in *Xenopus* oocytes and western blot analysis were performed. To assess the structural effects of L530R, TRPV5 was modeled using MODELLER based on the core structure of TRPV6 containing all the six transmembrane (TM) helices and the TRP domain. The L530R variation was introduced into TRPV5 using PyMOL. The modeled TRPV5 was embedded in a lipid bilayer composed of 299 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) lipids using CHARMM-GUI, and water molecules were added on both sides of the bilayer. Two 400 ns molecular dynamics simulations were performed using AMBER14.

Results: The L530R variation abolished the Ca^{2+} uptake activity of TRPV5 in *Xenopus* oocytes. The variant protein was expressed with abnormal complex glycosylation. Simulation results show that the L530R variation breaks the hydrophobic interaction between L530 and L502, damaging the secondary structure of TM5. The variation also alters its interaction with membrane lipid molecules. Compared to the electroneutral L530, the positively charged R530 residue shifts the surface electrostatic potential towards positive. R530 is attracted to the negatively charged phosphorus atoms rather than the hydrophobic carbon atoms of membrane lipids. This shifts the pore helix where R530 is located and the D542 residue in the Ca^{2+}-selective filter towards the surface of membrane where phosphorus atoms are located.

Conclusions: Our results indicate that the L530R variation damages the secondary structure of TM5 of TRPV5 and alters the interaction between TRPV5 and membrane lipids. This may lead to misfolding of TRPV5 or impaired translocation of the channel to the plasma membrane, and ultimately disrupt TRPV5-mediated Ca^{2+} reabsorption.

Chlorthalidone Is Superior to Potassium Citrate in Reducing Calcium Phosphate Stone Formation in Genetic Hypercalciuric Stone-Forming Rats Nancy S. Krieger,[2] John R. Asplin,[1] Ignacio Granja,[1] Felix M. Ramos,[2] Courtney A. Flotteron,[2] Luojing Chen,[2] David A. Bushinsky.[2] *[1]Litholink Corp, Chicago, IL; [2]Univ. of Rochester, Rochester, NY.*

Background: To study human idiopathic hypercalciuria (IH) we developed an animal model, genetic hypercalciuric stone-forming (GHS) rats, whose pathophysiology parallels that found in human IH. All GHS rats form calcium phosphate (CaP) kidney stones while there is no stone formation in the founder Sprague-Dawley (SD) rats. Previously, in GHS rats, we have shown that potassium citrate (KCit) increases urine supersaturation (ss) with respect to CaP but does not alter stone formation. In this study we tested the hypothesis that chlorthalidone (CTD) and KCit combined would reduce CaP stone formation in the GHS rats.

Methods: 111th generation GHS rats were fed a fixed amount of a normal Ca (1.2%) and P (0.65%) diet, housed in metabolic cages and divided into four groups. Diets were supplemented with KCit (4 mmol/d) or CTD (4-5mg/kg/d), alone, or combined. Rats not receiving KCit were given KCl (4 mmol/d). Urine (u) was collected at 6, 12, and 18 wks for electrolyte analyses and kidney stone formation was determined by X-ray at 18 weeks.

Results: Compared to KCl, KCit reduced uCa (KCl=17.2±0.6 mg/d, KCit=14.9±0.3), CTD reduced it further (CTD= 12.4±0.5) and KCit+CTD reduced it even further (KCit+CTD=10.5±0.4). CTD raised uCit (KCl=112.1±3.6 mg/d, CTD=133.9±2.5) KCit raised it further (KCit=182.2±2.5) while KCit+CTD did not increase it further (KCit+CTD=171.7±3.2). KCit alone increased uP (KCl=20.4±0.6 mg/d, KCit=26.7±1.0). CTD did not change uCaP ss (KCl= 4.1±0.2 vs CTD=3.2±0.3), while KCit alone, or in combination with CTD, increased it (KCit=8.0±0.5, KCit+CTD=9.5±0.8). Compared to KCl (stone formation range of 0-4: KCl=2.6±0.3), KCit did not alter stone formation (3.3±0.3), while there was no stone formation in the GHS rats fed with CTD alone (CTD=0). The combination of KCit+CTD (2.0±0.3) resulted in more stones than CTD alone. All changes were significant to $p<0.05$.

Conclusions: Thus in GHS rats, who universally spontaneously form CaP stones, CTD alone is superior to KCit alone or in combination with CTD, in reducing stone formation.

SA-OR031

Dementia and Alzheimer's Disease Among Older Adults Initiating Hemodialysis Mara McAdams-DeMarco,[1] Matthew Daubresse,[4] Sunjae Bae,[2] Dorry L. Segev.[3] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Older end-stage renal disease (ESRD) patients experience rapid declines in executive function after initiating hemodialysis; these impairments might lead to high rates of dementia and Alzheimer's disease (AD) in this population. We estimated incidence, risk factors, and sequelae of dementia and AD among older ESRD patients initiating hemodialysis.

Methods: We studied 356,668 older (age≥66) hemodialysis patients (1/1/2001-12/31/2013) from national registry data [United States Renal Data System] linked to Medicare. We estimated dementia and AD risk (cumulative incidence), studied factors associated with these disorders using competing risks models, and estimated the risk of subsequent mortality using Cox proportional hazards models.

Results: The 1-year, 10-year, and lifetime dementia risks were 4.6%, 22.1%, 25.1% for women and 3.7%, 18.9%, and 21.3% for men. The corresponding AD risks were 0.6%, 4.3%, and 5.4% for women and 0.4%, 3.4%, and 4.2% for men. The strongest independent risk factors for dementia and AD were age≥86 years (dementia: HR=2.11, 95%CI:1.99-2.23; AD: HR=2.33, 95%CI:2.06-2.63), African American race (dementia: HR=1.70, 95%CI:1.64-1.75; AD: HR=1.92, 95%CI:1.79-2.06), and institutionalization (dementia: HR=1.50, 95%CI:1.41-1.59; AD: HR=1.49, 95%CI:1.31-1.69). Older HD patients with dementia were at 2.17-fold (95%CI:2.15-2.19) increased risk of subsequent mortality; those with AD were at 1.92-fold (95%CI:1.88-1.95) increased mortality risk.

Conclusions: Older hemodialysis patients are at substantial risk of dementia and AD, and these disorders increase subsequent mortality risk 2-fold. Hemodialysis may be inadequate to treat ESRD patients; the role of renal replacement therapy, particularly in older adults, should be expanded to protect cognitive function.

Cumulative Incidence of Dementia After Hemodialysis Initiation

SA-OR032

Randomized, Placebo-Controlled Study on the Efficacy of CR845 in Improving the Quality of Life of Hemodialysis Patients with CKD-Associated Pruritus Frederique Menzaghi, Catherine Munera, Maria S. Oberdick, Joseph W. Stauffer, Robert H. Spencer. *Cara Therapeutics, Inc., Stamford, CT.*

Background: Chronic kidney disease-associated pruritus is a serious itching disorder associated with poor quality of life (QOL), linked to sleep disturbance, depressed mood and increased mortality. The present trial evaluated the anti-pruritic efficacy of the novel kappa-opioid receptor agonist CR845 and its impact on QOL in hemodialysis (HD) patients suffering from moderate-to-severe pruritus.

Methods: 174 HD patients with a mean baseline numerical rating score (NRS) for worst itching intensity >4 were enrolled [0=no itching up to 10=worst itching imaginable]. Patients were randomized to receive one of 3 intravenous doses of CR845 (0.5 mcg/kg, n=44; 1 mcg/kg, n=41 and 1.5 mcg/kg, n=44) or placebo (n=45) at the end of each dialysis over an 8-week treatment period. Worst itching intensity (NRS, primary endpoint) and QOL measures due to itching (secondary/exploratory endpoints) were recorded, with efficacy being defined as the change from baseline to the last week of the treatment (i.e. Week 8). Changes in QOL was assessed using multidimensional questionnaires including the Skindex-10 (with measures of emotional distress and social functioning), 5-D itch scale (with measures of sleep and social functioning) and the MOS sleep disturbance subscale.

Results: CR845 was well tolerated and reduction in itch NRS scores over placebo was observed at all doses, with a change from baseline ≥3 NRS points by end of Week 8 for 64% of the patients treated with CR845 0.5 mcg/kg vs 29% of the placebo patients (p<0.001). Improvement in QOL measures was significantly different from placebo for all doses of CR845 with respect to the Skindex-10 and the 5-D itch scale (p values ranging from <0.001 to <0.026), along with a significant improvement in sleep at doses of 0.5 and 1 mcg/kg (p=0.006). The mean change in QOL measures correlated with the change in itch intensity (Pearson's correlation ranging from r=0.67 to 0.74, p<0.0001).

Conclusions: CR845 produced a substantial improvement in multiple measures of itch-related QOL associated with a clinically important reduction in itch intensity in HD patients with moderate-to-severe pruritus that was sustained over 2 months of treatment.

SA-OR033

Conservative Kidney Profile Prior to Transitioning to Dialysis and Early Dialysis Outcomes in US Veterans: A Transition of Care in CKD Study Melissa Soohoo,[1] Elani Streja,[1] Yoshitsugu Obi,[1] Connie Rhee,[1] Daniel L. Gillen,[1] Keiichi Sumida,[2] Danh V. Nguyen,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: National data has shown that more patients transition to end-stage renal disease (ESRD) at a higher estimated glomerular filtration rate (eGFR), yet mortality is high in the first months upon ESRD transition and studies have questioned the contribution of aggressive dialysis initiation to this outcome. We hypothesized that among US veterans transitioning to ESRD, a more conservative kidney profile in the pre-ESRD (prelude) period, including lower kidney function level and slower eGFR slope, is associated with better outcomes.

Methods: In 19,985 veterans transitioning to ESRD in 2007-2014, we examined the association of eGFR at transition and its slope over the final 12 months of the prelude period with 12-month post-ESRD mortality and hospitalization rates, using Cox and Poisson regression models, respectively. Two groups of low vs. high eGFR (dichotomized at 10 mL/min/1.73m^2) and slow vs. fast slope (dichotomized at -10 mL/min/1.73m^2/year) were combined into four groups.

Results: Patients had a median[IQR] of eGFR at transition and slope of 9.7[7.1,13.3] mL/min/1.73m^2 and -10.5[-18.8,-5.9] mL/min/1.73m^2/year, respectively. Patients with a conservative kidney profile (low eGFR and slow slope), had the lowest 12-month all-cause and cardiovascular (CV) mortality risks (Figure), and hospitalization rate. Conversely, patients with a high eGFR and fast slope had the highest adjusted all-cause (HR [95% CI]: 1.80 [1.62, 1.99]) and CV mortality risks (1.57 [1.32,1.88]) and hospitalization rate (IRR [95% CI] 1.39 [1.34, 1.44]) compared to conservative kidney profile patients.

Conclusions: A kidney profile characterized by slower chronic kidney disease progression and a later transition to ESRD is associated with more favorable early dialysis outcomes. Trials to examine a more conservative approach to dialysis are warranted.

SA-OR034

Residual Kidney Function and Ultrafiltration Rate: Their Association with Mortality Jason A. Chou,[1] Yoshitsugu Obi,[1] Connie Rhee,[1] Elani Streja,[1] Danh V. Nguyen,[1] Melissa Soohoo,[1] Csaba P. Kovesdy,[2] John J. Sim,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Kaiser Permanente Southern California, Pasadena, CA.*

Background: Residual kidney function (RKF) among both peritoneal dialysis and hemodialysis (HD) patients has been associated with improved survival. Although faster ultrafiltration rates (UFR) with HD have been observed to have greater mortality risk among incident HD patients with RKF, the ideal UFR goals are unknown. We hypothesize that in incident HD patients with RKF, a lower UFR will have improved survival.

Methods: We examined the association of RKF measured as Kru (mL/min/1.73m^2) and UFR (mL/kg/hr) in combined groups with 1- and 5-year all-cause mortality in a cohort of 34,546 incident HD patients with Cox regression models adjusted for case-mix, comorbidities and selected lab covariates. A total of 9 groups were analyzed, composed of the following groups: Kru <1.5, 1.5-<3.0 and ≥3.0 mL/min/1.73m^2 and UFR <6, 6-<10, and ≥10 mL/kg/hr with reference group of Kru ≥3.0 and UFR 6-<10.

Results: We found that Kru-UFR groups with a higher Kru and lower UFR demonstrated a graded association with survival where the Kru ≥3.0 mL/min/1.73m^2 and UFR <6 ml/kg/hr group had a 1 year mortality HR (CI 95%) of 0.83 (0.74-0.93) (p-for-interaction 0.002) in the fully adjusted model. All associations were robust to all levels of adjustment on both 1- and 5- year mortality outcomes.

Conclusions: Among incident HD patients with RKF, lower UFR rates were associated with improved survival. Targeting different UFR goals may be a focus of intervention given its potential impact on RKF and mortality.

Renal Function Recovery in Incident US Dialysis Patients
Paul L. Kimmel,[1] Chyng-Wen Fwu,[3] Kevin C. Abbott,[4] Paul Eggers.[2] *[1]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [2]Retired, Olney, MD; [3]Social & Scientific Systems, Inc., Silver Spring, MD; [4]The National Institutes of Health, NIDDK, Bethesda, MD.*

Background: Recovery of renal function (RRF) in ESRD patients is thought to be uncommon, but there are few recent descriptive data. Factors associated with RRF as well as outcomes after RRF are unknown.

Methods: Using USRDS data, we included incident dialysis patients between 2006 and 2015, followed until 6/30/2016. RRF was physician-determined and reported by dialysis facility. Logistic regression examined associations of RRF 6m after dialysis initiation with demographic characteristics and diagnoses causing ESRD. Percent of RRF patients who died, returned to ESRD, and alive and not on ESRD therapy 3y after RRF were determined.

Results: 1,087,954 incident dialysis patients from 2006 through 2015 were included. 68,711 patients (6%) recovered renal function during the study. The incidence of RRF within 6m, accounting for 77% of all RRF, was 9.0 cases/1,000 person-months (95% CI, 8.9-9.1). Mean patient age with RRF was 62±15 y compared with 63±15 y for those without RRF (p<0.001). Males, non-Hispanic Whites, younger patients, those receiving hemodialysis as first modality, patients with higher eGFR, and patients with central catheters had greater likelihood of RRF, compared with their counterparts (all p<0.001). Acute interstitial nephritis (AIN; percent with RRF, odds ratio and 95% CI: 40%, 12.8, 11.7-14.0), acute tubular necrosis (ATN; 35%, 8.8, 8.6-9.1), nephrotoxins (18%, 5.1, 4.7-5.5), traumatic or surgical loss of kidney (19%, 4.8, 4.1-5.6), and multiple myeloma (16%, 3.5, 3.3-3.7) had higher odds of RRF, while patients with cystic kidney (1%, 0.4, 0.3-0.4) had lower odds of RRF, compared with patients with diabetes (4%) as primary cause of ESRD. AIN and ATN patients together account for 3% of incident patients, but comprised 18% of all recoveries. At 3y, 53% of recovered patients were still alive and not on ESRD therapy, 32% had died, and 15% were living on ESRD therapy.

Conclusions: RRF is not uncommon, occurs later than previously reported, and is associated with acute kidney injury diagnoses. A majority of patients survive after RRF, but more than 45% of patients with RRF return to ESRD and/or die within the following 3y. To better detect RRF earlier, for the benefit of patients, practitioners and dialysis providers, patients with acute diagnoses and abrupt presentations should receive more intensive monitoring after initiation of dialysis than is currently practiced.

Impact of Transition of Care Visits on Readmission Rates in Dialysis Patients
Terry L. Ketchersid,[1] Michael P. Martin,[2] Daniel E. Geary,[2] Greg S. Garza,[2] Maria Radonova,[2] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Chris Richmond,[2] Anna Alanis,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Health Partners, Austin, TX.*

Background: End stage renal disease (ESRD) patients discharged from an acute care facility have 30-day readmission rates that approach 30% (USDS, 2015). In a fee for service environment, the Centers for Medicare & Medicaid Services (CMS) Transitional Care Management Services cannot be submitted by a physician billing for ESRD Monthly Capitation Payment services. Through the Comprehensive ESRD Care (CEC) Model, FMCNA has partnered with CMS to identify, test, and evaluate new ways to improve care for Medicare beneficiaries with ESRD. Utilizing the ESRD Seamless Care Organization (ESCO) care coordination waiver, we hypothesized that nephrology providers could feasibly conduct ESRD specific Transition of Care (TOC) visits that would lower readmission rates. We are obligated to disclose that the statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Methods: We established an ESRD specific TOC template. Nephrology providers were paid a care coordination fee for completing the TOC within 14 days of discharge. We analyzed claims data from May-2016 to Dec-2016 using a 3 month claims run out for 6 ESCOs representing 7,248 discharges. We determined the frequency of TOC visits conducted by the nephrology practice within 14 days of discharge. We measured 30-day readmission rates for each ESCO for the patients who had a TOC visit within 14 days of discharge.

Results: Completion of the TOC visits varied among the 6 ESCOs from a low of 11% to a high of 36%; TOC completion rates were inversely correlated with the ESCOs number of discharges (correlation coefficient -0.95). Among 5 ESCOs, 30-day readmission rates were 0.6% to 4.2% lower in patients who received a TOC visit; at one ESCO there was 0.9% increase.

Conclusions: Conducting a formal TOC visit within 14 days of discharge is associated with reductions in 30-day readmission rates. Smaller ESCOs completed TOC visits at a higher rate as compared to larger ESCOs.

Pre-ESRD Nephrology Care Associated with Larger Survival Benefit for Black Compared to White Patients on Hemodialysis (HD)
Jennifer L. Bragg-Gresham,[3] Shervin Assari,[3] Kevin He,[2] Austin G. Stack,[1] Rajiv Saran.[3] *[1]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [2]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI.*

Background: Recent literature suggests that psychosocial resources, medical risk factors, and treatments may have differential effects across racial groups. We sought to compare the potential impact of pre-ESRD Nephrology care on all-cause mortality by race (Black versus White) among patients newly enrolled in the United States Renal Data System (USRDS) over the last decade.

Methods: Using data on 791,248 incident HD patients initiating treatment from 2006-2015, we examined the association between pre-ERSD Nephrology care (defined as 'no care' versus 'any pre-ESRD nephrology care') on long-term survival, adjusting for age, sex, and comorbidities for both Black and White race groups. Cox regression was used to test the multiplicative effect of race and pre-ESRD care, by interaction. Patients were followed for mortality through 2015 (average follow-up was 2.8 years).

Results: Overall, fewer Black patients had pre-ESRD Nephrology care compared to White patients (53.1% vs. 60.1%). Although pre-ESRD care was associated with lower hazard of mortality in both race groups (p<0.0001), a significant interaction was found, i.e., lower hazard for mortality was associated with Pre-ESRD care for Black (HR=0.73) versus White patients (HR=0.81; p for interaction <0.0001). Survival curves are shown in the Figure.

Conclusions: This finding advocates for promotion of Pre-ESRD care for Black patients, particularly given their lower chance of getting such services, compared to Whites. Future work will expand this to study other race categories and Hispanic ethnicity to gain insight into differential health gain across sub-populations to guide public health priorities toward reducing disparities.

Scheduled versus Emergency Dialysis in ESRD Saves Lives and Lowers Utilization: A Quasi-Randomized Study Oanh K. Nguyen,[1] Miguel A. Vazquez,[1] Lakeesha Charles,[2] Joseph R. Berger,[1] Henry Quinones,[1] Richard C. Fuquay,[3] Ethan Halm,[1] Anil N. Makam.[1] *[1]UT Southwestern Medical Center, Dallas, TX; [2]Parkland Health & Hospital System, Dallas, TX; [3]Dallas Nephrology Associates, Dallas, TX.*

Background: In many states across the U.S., individuals with end-stage renal disease (ESRD) lacking federal funding for scheduled dialysis instead receive intermittent emergency dialysis only for life-threatening indications. The effects on health outcomes and utilization compared to scheduled dialysis are unknown. We sought to compare these strategies through a natural experiment among individuals with ESRD on emergency dialysis who were newly eligible and applied for private insurance coverage for scheduled dialysis, with nearly half receiving coverage in a quasi-randomized fashion.

Methods: Retrospective cohort study of 193 adults on emergency dialysis in Dallas, Texas who applied for private insurance in February 2015. Patient characteristics and outcomes were ascertained using medical record and all-payer regional claims data. Overall, 112 were enrolled in scheduled dialysis; 81 were declined for non-patient-related reasons (i.e., their dialysis center declined to participate) and remained on emergency dialysis (control). We compared emergency department (ED) visits and hospitalizations in a 6-month baseline and a 12-month follow-up period after enrollment with a 1-month washout, using intention-to-treat negative binomial difference-in-differences (DiD) regression analyses.

Results: At baseline, the scheduled group was younger (45 vs. 52 yrs., p<0.001), had more frequent dialysis (1.0 vs 0.6 sessions/week, p=0.04), more ED visits (7.6 vs. 4.3 median visits/month, p<0.001), and similar hospitalizations (median 2.5 vs. 3.2 per 6 months, NS) vs. controls. After enrollment, the scheduled group had fewer deaths (6% vs. 16%, p<0.01). In adjusted analyses, compared to baseline, the scheduled group had a larger net decrease in ED visits (-6.7 vs. -0.1 visits/month, p<0.001; DiD of 6.6 fewer visits/month, 95% CI 5.5-7.7) and similar net decrease in hospitalizations (-1.7 vs. -1.4 per 6 months, p=0.46) during follow-up vs. controls.

Conclusions: In this quasi-randomized controlled study, individuals enrolled in a scheduled dialysis program had far lower rates of death and ED utilization in the year after enrollment compared to those remaining on emergency dialysis, despite being sicker at baseline. Universal scheduled dialysis improves health outcomes and may also be more cost-effective.

SA-OR039

Opiate Analgesics and Adverse Outcomes in Hemodialysis Patients Julie H. Ishida, Charles E. McCulloch, Michael Steinman, Barbara A. Grimes, Kirsten L. Johansen. *UCSF, San Francisco, CA.*

Background: Pain is a highly prevalent symptom in hemodialysis patients and has been associated with worse quality of life and survival. Hemodialysis patients may be particularly vulnerable to adverse events from the use of opiate analgesics, but studies evaluating their risk are scare and have not examined associations with dose or specific agents.

Methods: From the USRDS, we identified 140,899 Medicare-covered adults on in-center hemodialysis with Part D coverage in 2011. Using Cox regression models in which we adjusted for demographics, comorbidities, number of medications, and use of potentially confounding concomitant medications (e.g., sedatives/hypnotics), we investigated the association between receipt of opiate analgesics, modeled as a time-varying exposure, and time to first emergency room visit or hospitalization for altered mental status (AMS), fall, and fracture defined by ICD-9 and CPT codes. We evaluated risk according to average daily dose (high >60 mg, low <=60 mg, and per 10 mg) and specific agents (hydrocodone, oxycodone, tramadol, codeine, hydromorphone, fentanyl, morphine, methadone per 10 mg). Doses are expressed in standardized oral morphine equivalents (OME), and exposure was time-lagged (i.e., ascertained from the prior day) for fall and fracture to account for the possibility of effect/cause.

Results: There were 90,124 (64%) patients who received opiate analgesics and 39,173 (28%) who had an episode of AMS, fall, or fracture in 2011. Opiate use was associated with risk of AMS, fall, and fracture in a dose-dependent manner (Table). Agents were associated with significantly higher rates of adverse outcomes (hazards per 10 mg OME): all agents for AMS (2-22% higher hazard); hydromorphone, hydrocodone, oxycodone, tramadol, and morphine for fall (2-7% higher hazard); and hydrocodone, oxycodone, and tramadol for fracture (3-10% higher hazard).

Conclusions: Opiate analgesics are associated with a high risk of adverse outcomes in hemodialysis patients, even at lower doses and for agents recommended by guidelines. Future research intended to predict and mitigate risks of opiate use in this population is warranted.

Funding: NIDDK Support

Adverse Outcomes by Opiate Dose

	Hazard Ratio (95% Confidence Interval)		
	AMS	Fall	Fracture
<=60 mg vs. none	1.30 (1.24-1.35)	1.30 (1.22-1.38)	1.50 (1.38-1.62)
>60 mg vs. none	1.79 (1.68-1.90)	1.51 (1.37-1.65)	1.75 (1.54-1.99)

Utilizing Symptom Targeted Intervention to Help Dialysis Patients Remain Vocationally Active Deborah S. Evans, Duane V. Dunn, Kathryn M. Aebel-Groesch, Jay Gervens, Deborah A. Benner. *DaVita, Inc, Denver, CO.*

Background: Ongoing vocational activity among patients with end-stage renal disease receiving dialysis is associated with considerable benefits, including better financial/insurance status, higher quality of life, and greater likelihood of receiving a kidney transplant. In spite of these benefits, most dialysis patients are not vocationally active. Perceived barriers to vocational activity include lack of access to transportation, depression, and lack of motivation. Here, we tested the utility of social workers applying Symptom Targeted Intervention (STI) to mediate psychosocial challenges and support ongoing vocational activity among dialysis patients.

Methods: In this pilot study (2016-2017), 85 specifically trained social workers at a large US dialysis organization provided 6 or more STI counseling sessions, delivered over a period of ~10 weeks, to dialysis patients who were either vocationally active (employed, student/trainee, volunteer) or interested in becoming vocationally active. Following completion of STI, each patient was matched to a control subject (no STI) based on geographic area, vocational status, and dialysis vintage. Subjects were followed until the earliest of transplant, death, loss to follow-up, or 6 months post-enrollment.

Results: Of 246 patients who received STI in the pilot study, 210 were matched to eligible controls (15 were withheld from matching due to enrollment in additional intervention programs; appropriate controls could not be identified for the remainder). A larger proportion of pilot patients were vocationally active during follow-up as compared to controls.

Conclusions: Previous work has shown that STI benefits patients who display difficulty with adjustment to dialysis. Here, we demonstrate that proactive incorporation of STI by social workers may support ongoing vocational activity among patients on dialysis.

Haemodiafiltration (HDF) Improves the Cardiovascular Risk Profile Compared to Conventional Haemodialysis (HD) in Children – The HDF, Heart, and Height (3H) Trial Rukshana Shroff,[1] Colette J. Smith,[2] Karolis Azukaitis,[3] Constantinos J. Stefanidis,[4] Nur Canpolat,[5] Saoussen Krid,[6] Mieczys?aw P. Litwin,[7] Franz S. Schaefer.[8] *[1]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [2]University College London, London, United Kingdom; [3]Vilnius University, Lithuania, Vilnius, Lithuania; [4]A. and P. Kyriakou Childrens Hospital Athens, Greece, Athens, Greece; [5]Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey; [6]Hôpital, Paris, France; [7]The Children's Memorial Health Institute, Warsaw, Warsaw, Poland; [8]University of Heidelberg, Heidelberg, Germany. Group/Team: On behalf of International Pediatric Hemodialysis Network and 4C study investigators.*

Background: Fluid overload, hypertension and cardiovascular disease are common in children on dialysis. In adults, HDF is shown to reduce cardiovascular mortality, but causes for this are not clear and data in children are scarce.

Methods: We performed a non-randomized parallel-arm clinical trial within the International Pediatric Hemodialysis Network registry to assess changes in fluid status, BP, biochemistry and cardiovascular measures in children on HDF compared with conventional HD. The primary outcome measure was change in carotid intima media thickness standard deviation score (cIMT SDS) at 1-year. (ClinicalTrials.gov NCT02063776)

Results: 190 children (from 28 centres across Europe and North America) were recruited, and 179 fulfilled inclusion criteria. 134 children (78 on HD and 56 on HDF) completed one-year follow-up. There was no difference between HD and HDF groups in age, gender, underlying renal disease, dialysis vintage, access type, blood flow or residual renal function. There were 45 drop-outs, mainly (75%) due to transplantation; there were no deaths. The median convective volume achieved in the HDF group was 13.3 (inter-quartile range 12.4 to 14.5) ml/m^2/session. At 1-year, children on HDF had lower cIMT SDS and lower pulse wave velocity-SDS compared to those on conventional HD (1.88 vs 2.64; p=0.007 and 0.77 vs 1.99, p<0.001 respectively). Annualised change in cIMT SDS was 10-fold lower in HDF compared to HD (0.013 vs 0.48; p=0.002). 24-hour mean arterial pressure, left ventricular mass index and parathyroid hormone level were also significantly lower on HDF (p<0.01 for all). On univariable analysis the HDF vs HD group, serum phosphate and PTH and dialysate water quality significantly associated with cIMT SDS. On multivariable linear regression analysis, the annualised change in cIMT SDS was 0.3 higher (95%CI -0.01 to 0.61) and PWV SDS was 0.26 higher (95%CI -0.4 to 0.9) in children on HD compared to those on HDF. All data were adjusted for centre and baseline cIMT-SDS.

Conclusions: In children, HDF attenuates the progression of vascular disease compared to conventional HD. This may be due to improved fluid and BP control as well as normalisation of phosphate and PTH levels.

SA-OR042

Using KDIGO Criteria, Beta-2 Microglobulin Predicts the Development of AKI Kevin T. Barton, Hongjie Gu, Charles Goss, Dennis Dietzen, Aadil K. Kakajiwala, Vikas R. Dharnidharka. *Washington University School of Medicine, St Louis, MO.*

Background: Beta-2-microglobulin (B2M) is a functional marker of proximal tubular injury and glomerular filtration. Analyses using older/non-standardized definitions have shown low efficacy of B2M as a predictor of AKI. We assessed if elevated levels of B2M would predict the diagnosis of or recovery from AKI.

Methods: We performed a retrospective study including children >1 year, between 01/2011 and 12/2015, who had urine (UB2M) and/or serum B2M (SB2M) measured by immunoturbidometry. We defined AKI using changes in serum creatinine (sCr) based on KDIGO criteria and urine output <0.5 mL/kg/hr for 24 hours. We defined recovery from AKI as return to baseline serum creatinine within six months of AKI. We gathered data on baseline, maximum and recovery sCr, SB2M, and UB2M. We calculated receiver-operating-characteristic (ROC) area under curves (AUC).

Results: 245/529 patients developed AKI. SB2M and UB2M predicted AKI development with an ROC-AUC of 0.84 and 0.73 respectively (Figure 1). Patients had a graded higher median SB2M and UB2M with each higher AKI Stage. SB2M and UB2M differentiated between Stage I and Stage III AKI (both p-value <0.0001). Serum B2M also differentiated between Stage II and Stage III AKI (p-value <0.0001). However, neither UB2M nor SB2M levels predicted recovery from AKI. Only older age and need for dialysis predicted less than complete recovery after AKI (HR: 0.97 (CI 0.94, 0.99) and 0.39 (CI 0.23, 0.61) respectively).

Conclusions: Using the latest AKI definition, serum B2M performs well to predict AKI. Given the relative ease and lower cost of B2M we suggest more widespread use of B2M for the detection of AKI.

Variable	AKI (Median [IQR])	No AKI (Median [IQR])	p-value
Serum B2M (mg/L)	4.3 (2.8,9.6)	1.7 (1.3,2.5)	< 0.0001
Urine B2M (mg/L)	3.2 (0.4, 16.8)	0.2 (0.2, 0.9)	< 0.0001

The Effect of Prenatal Lead Exposure and Gestational Age on Blood Pressure among Children Alison P. Sanders,[2] Katherine Svensson,[2] Chris Gennings,[2] Chitra Amarasiriwardena,[2] Priyanka Basnet,[2] Maria L. Pizano,[5] Lourdes Schnaas,[5] Marcela Tamayo y ortiz,[4] Lisa M. Satlin,[2] Andrea A. Baccarelli,[3] Martha M. Tellez-Rojo,[1] Robert O. Wright.[2] *[1]National Institute of Public Health, Cuernavaca, Mexico; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Columbia University, New York, NY; [4]National Council of Science and Technology (CONACYT) - National Institute of Public Health (INSP), Cuernavaca, Mexico; [5]National Institute of Perinatology, Mexico City, Mexico.*

Background: Prenatal metal exposure occurs during a susceptible period of renal development and may program later life cardiovascular and renal disease. Our objective was to evaluate the association between prenatal lead exposure and gestational age on childhood blood pressure measured at 4 years of age.

Methods: Maternal blood lead levels (BLLs) collected in the second trimester were analyzed via inductively coupled plasma-mass spectrometry. Resting blood pressure was obtained using a Dinamap automated oscillometer from 565 children between 4 and 6 years of age in the PROGRESS cohort located in Mexico City, Mexico. We performed nonlinear piecewise regression to examine the association between prenatal lead levels and gestational age on children's systolic blood pressure (SBP) adjusting for child's age, sex, and height.

Results: Maternal second trimester BLLs ranged from 0.7 to 17.8 μg/dL with 112 (20%) above the CDC guideline level of 5 μg/dL. We identified a threshold lead level of concern of 2.5 μg/dL. When data were stratified at this lead level, shorter gestations were associated with increased SBP for subjects with BLLs ≥ 2.5 μg/dL, whereas shorter gestations were not associated with SBP for BLLs < 2.5 μg/dL. Specifically, for BLLs ≥ 2.5 μg/dL, SBP was 1.6 (95%CI: 0.4, 2.9) mmHg higher per each week shorter gestation among gestations shorter than 36.9 weeks; and among gestations longer than 36.9 weeks, this relationship was attenuated yet remained significant [β: 0.9, 95%CI (0.2, 1.6)].

Conclusions: Prenatal lead exposure may contribute to subclinical changes in the developing kidney or cardiovascular system leading to elevated SBP in childhood. We found that higher prenatal blood lead modified the association between shorter gestation and higher blood pressure. Ongoing studies will assess renal molecular changes due to early life lead exposure.

Long-Term Renal Outcomes in Children Who Had Surgical Repair of Congenital Heart Disease Chirag R. Parikh,[7] Jason H. Greenberg,[6] Eric McArthur,[1] Heather Thiessen Philbrook,[6] Ron Wald,[5] Michael Zappitelli,[3] Rahul Chanchlani,[4] Amit X. Garg.[2] *[1]Institute for Clinical Evaluative Sciences, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]McGill University Health Centre, Montreal Children's Hospital, Montreal, QC, Canada; [4]None, Hamilton, ON, Canada; [5]St. Michael's Hospital, Toronto, ON, Canada; [6]Yale University, New Haven, CT; [7]Yale University and VAMC, New Haven, CT.*

Background: The risk of mortality in children who require surgery for congenital heart disease (S-CHD) has markedly reduced in recent years due to advances in pediatric and surgical care. However, there are limited data on long-term kidney outcomes in children after S-CHD compared with the general population of children.

Methods: A registry-based, matched-cohort study was conducted across 7 administrative Canadian databases. Children were included if they were born between April 1, 2002 and March 31, 2015 and underwent surgery for CHD. Follow-up and comorbidity data were collected until March 2015. Children serving as controls (10 controls for each patient with S-CHD), were matched for age, sex, neighborhood income quintile, and county, and were randomly selected from the general population. Survival analyses were performed with Cox proportional hazards models.

Results: Of the 3600 patients with a diagnosis of S-CHD, 1595 were female (44.3%). Median age at first surgery was 150 (IQR, 40-252) days and 21.8% of the children were low birthweight (<2500 grams). The median (IQR) follow-up time was 5.9 (2.9-9.0) years. 52 (1.4%) children reached ESRD in follow-up. The 10-year cumulative incidences of hypertension and CKD were 12.9% and 2.1%, respectively. The hazard ratios for renal outcomes and mortality in children with S-CHD compared with controls were significantly higher (Table). According to RACHS-1 severity classifications, the group of patients with the most severe complex defects (RACHS-1 category 4) had the highest risk for death and renal outcomes. Trends in relative increase in risk of renal outcomes and mortality were also seen associated with younger age at surgery (<150 days), but not with income quintile or preterm status at birth.

Conclusions: Despite dramatic recent improvements in outcomes after S-CHD, the incidence of long-term hypertension, CKD, ESRD and mortality remains high in these patients compared to matched controls. Further interventions aimed at improving renal outcomes in this vulnerable group are required.

Funding: NIDDK Support, Veterans Affairs Support

Table: Long-Term Outcomes following Surgical Repair of Congenital Heart Disease

Outcome	Status	N	No. of events	%	Incidence rate per 10000 person-years	Hazard Ratio (95% CI)	P Value

Amniotic Fluid Peptide Biomarkers for In Utero Prediction of Postnatal Renal Function in CAKUT Julie Klein,[1] Benedicte Buffin-Meyer,[1] Franck Boizard,[1] Pedro Magalhães,[2] Petra Zürbig,[2] Benjamin Breuil,[1] Elena N. Levtchenko,[3] An Hindryckx,[3] Lounis Nadia,[4] Francoise Auriol,[4] Jean-loup Bascands,[1] Stéphane Decramer,[4] Joost Schanstra.[1] *[1]Inserm U1048, Toulouse, France; [2]Mosaiques Diagnostics GmbH, Hannover, Germany; [3]University Hospitals Leuven, Herent, Belgium; [4]Hopital des Enfants, Toulouse, France. Group/Team: Bioman-consortium.*

Background: Clinical management of fetuses with bilateral CAKUT is hampered by the lack of methods able to predict evolution towards kidney failure. Here we explored the amniotic fluid (AF) peptidome of 152 bilateral CAKUT pregnancies in order to identify biomarkers predictive of disease progression.

Methods: Using capillary electrophoresis coupled to mass spectrometry, comparison of the AF peptidome from 32 fetuses with normal postnatal renal function at 2 years and 18 fetuses with early renal failure allowed the identification of 59 differentially abundant peptides, including fragments from extracellular matrix proteins, osteopontin, proSAAS or thymosin beta-4.

Results: Modelling the 59 peptides into a random forest classifier combined with clinical features (AF volume and the age of the fetus at the time of sampling) predicted the renal outcome at 2 years in a separate validation cohort of 68 CAKUT fetuses with 89% sensitivity, 98% specificity and a positive likelihood ratio of 44. Next, we used the classifier to discriminate 34 CAKUT fetuses subjected to termination of pregnancy (TOP) but where fetopathology analysis either failed to demonstrate severe renal damage or was absent or inconclusive. The classifier scores suggested that TOP without severe renal damage could have been avoided in 80% of the cases. In addition, the classifier predicted 55% of absent/inconclusive fetopathology as having severe postnatal outcome and 45% with normal function. Taking into account likelihood ratio and sensitivity, we can speculate that approximately 40% of these fetuses with non-interpretable fetopathology were subjected to TOP while most likely evolving to normal postnatal renal function.

Conclusions: We believe that identification of the 59 AF peptide biomarkers is a significant step forward for antenatal prediction of the postnatal renal function outcome in CAKUT fetuses and should be of great help for early prenatal counsellingand improved clinical management of CAKUT pregnancies, hence alleviating the psychological burden imposed on the parents. [Equal contribution JK and BBM].

Survival and Morbidity of Children with Posterior Ureteral Valves Gina Lockwood,[1,2] Katherine W. Herbst,[1] Cynthia J. D'Alessandri-Silva.[1,3] *[1]Connecticut Children's Medical Center, Hartford, CT; [2]Urology, University of Connecticut Health Center, Farmington, CT; [3]Pediatrics, University of Connecticut Health Center, Farmington, CT.*

Background: Posterior urethral valves (PUV) is a severe urologic condition causing a spectrum of sequelae. PUV can lead to end-stage renal disease, dialysis, renal transplantation, and premature death. Predicting outcomes is challenging as prognostic measures remain imprecise. We aimed to describe outcomes for children with PUV in United States children's hospitals.

Methods: The Pediatric Health Information System (PHIS) database was searched for children diagnosed with PUV (ICD-9 code 753.6; congenital urethral stenosis) with initial hospitalization between 1992 and 2006 in their first year of life. Valve ablation or mortality following urinary drain placement was used to confirm diagnosis of PUV. Primary outcomes of dialysis catheter placement, renal transplant and mortality were determined by disposition and ICD-9/ICD-10 codes found in subsequent hospitalizations through 12/31/2016. Dialysis catheter insertion was used as a proxy for dialysis treatments, as these are not generally captured in the PHIS dataset. Subjects from hospitals without a transplant program were excluded from transplant analysis.

Results: Our cohort included 754 males with median age upon hospitalization of 7 days (IQR 1-38 days). Over 90% were discharged at one month of age or less. The majority (621; 82%) did not experience any of the outcomes described, and 232 (37%) did not have a subsequent PHIS hospitalization. Of 60 (7.9%) subjects who underwent dialysis catheter placement, 34 (57%) did so during their initial hospitalization. Only 10 (16.7%) underwent placement at >5 years. Thirty-six (6.5%) subjects underwent renal transplant at a median age of 3.2 years (IQR 2.0-8.1 years), with 26 (43%) of those who underwent dialysis catheter placement undergoing transplantation. Twelve (33%) subjects underwent transplant after five years of age. Of 33 (4.4%) patients who died, 32 (97%) did so at <5 years, with 19 (58%) expiring during their initial hospitalization.

Conclusions: Relatively small but significant proportions of children with PUV at PHIS hospitals undergo dialysis, renal transplantation and/or premature death. Most outcomes occur at <5 years of age, as expected in those born with severe nephropathy. As risk factors for renal deterioration are studied, these statistics from a large cohort can help to counsel parents and guide physician management.

IL-6/Stat3 Signaling Promotes Antimicrobial Peptide Expression and Limits Epithelial Invasion and Ascending Infection by Uropathogenic Escherichia coli Sudipti Gupta,[6] Christina B. Ching,[4] Birong Li,[1] Hanna H. Cortado,[2] Ashley R. Jackson,[3] Kirk M. McHugh,[5] Brian Becknell.[5] *[1]Nephrology, Nationwide Children's Hospital, Columbus, OH; [2]Nephrology, Nationwide Children's Hospital, Columbus, OH; [3]Nephrology, Nationwide Children's Hospital, Columbus, OH; [4]Urology, Nationwide Children's Hospital, Columbus, OH; [5]Anatomy, Ohio State University, Columbus, OH; [6]Urology, Nationwide Children's Hospital, Columbus, OH.*

Background: The signaling networks regulating host antimicrobial activity during UTI are incompletely understood. Bacterial virulence varies inversely with IL-6 production during UTI, suggesting IL-6 signaling plays an important role in bacterial containment in infection. The specific contributions of IL-6 to host immunity against uropathogens, however, are unknown. We hypothesized that IL-6 activates the Stat3 transcription factor in infected urothelium, driving an antimicrobial program of gene expression with consequences on bacterial colonization of the urinary tract.

Methods: C57BL/6J, IL-6 deficient, or Stat3 conditional knockout mice were transurethrally inoculated with uropathogenic *E. coli* (UPEC). IL-6 production, Stat3 phosphorylation (pStat3), and antimicrobial peptide (AMP) mRNA expression were analyzed by ELISA, Western blotting, and qRT-PCR, respectively. Intracellular bacterial communities (IBC) were enumerated by beta-galactosidase staining. Bacterial invasion assays were performed in IL-6 or carrier treated human urothelial cells. The role of Tlr4 signaling in IL-6 signaling was established using C3H/HeJ mice (Lps-hyporesponsive) and C3H/HeOuJ (Lps-sensitive) controls. Chronic IL-6 depletion was evaluated by systemic administration of IL-6 neutralizing or isotype control antibody.

Results: Transurethral inoculation of UPEC leads to IL-6 secretion, urothelial pStat3, and activation of AMP transcription, in a Tlr4-dependent manner. Recombinant IL-6 elicits pStat3 and suppresses UPEC invasion in human urothelial cells. Systemic IL-6 administration promotes urothelial pStat3 and AMP expression in vivo. IL-6 deficiency leads to decreased urothelial pStat3 and AMP mRNA expression following UTI, accompanied by increased IBC formation and persistent bacteriuria. Moreover, chronic IL-6 depletion leads to increased renal bacterial burden and severe pyelonephritis in C3H/HeOuJ mice. Conditional Stat3 deletion results in reduced AMP mRNA levels and increased IBC formation following experimental UTI.

Conclusions: IL-6/Stat3 signaling drives a transcriptional program of antimicrobial gene expression in infected urothelium, with key roles in limiting epithelial invasion and ascending infection.

Furth,[11] Craig S. Wong,[2] Anna Materna-Kiryluk,[19] Krzysztof Kiryluk,[8] Hakon Hakonarson,[3] Gian Marco Ghiggeri,[6] Feng Zhang,[5] Virginia Papaioannou,[8] Cathy Mendelsohn,[8] Ali G. Gharavi,[8] Simone Sanna-Cherchi.[8] *[1]Boston Children's Hospital, Boston, MA; [2]UNM, Albuquerque, NM; [3]Children's Hospital of Philadelphia, Philadelphia, PA; [5]Fudan University, Shanghai, China; [6]G. Gaslini Children Hospital, Genoa, Italy; [7]UFMG, Brazil, Belo Horizonte, Brazil; [8]Columbia University, New York, NY; [10]Inserm UMR1163/Imagine Institute, Paris, France; [11]The Children's Hospital of Philadelphia, Philadelphia, PA; [12]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [13]University Hospital in Split, Split, Croatia; [14]University of Bari, Altamura, Italy; [15]University of Brescia, Montichiari (Brescia), Italy; [16]University of Michigan, Ann Arbor, MI; [18]Vrije Universiteit University Hospital Amsterdam, Amsterdam, Netherlands; [19]Poznan University of Medical Sciences, Poznan, Poland.*

Background: Copy number variations (CNVs) play an important role in the pathogenesis of human birth defects.

Methods: We performed a genome-wide CNV study in 2,824 cases compared to 21,498 controls to elucidate the genomic landscape of disease across the whole phenotypic spectrum of CAKUT.

Results: CAKUT cases carried a significant increased burden of rare CNVs and were highly enriched for known genomic disorders (GD) compared to controls (OR 6.6, P=7.5x10^{-41}). Renal hypodysplasia (RHD) showed the highest enrichment (OR 12.7, P=8.5x10^{-50}), followed by obstructive uropathy (OU; OR 3.5, P=6.0x10^{-4}), and posterior urethral valves (PUV; OR 5.9, P=2.2x10^{-3}). The most frequent GD loci in cases were 17q12 (n=26), 22q11.2 (n=17), the 1q21 (n=10), and 16p11.2 (n=9). While the 17q12, 22q11.2, and 1q21 were specific for RHD, the 16p11.2 showed high pleiotropy. At the loci where deletions were associated to RHD, duplications were associated to PUV or duplicated collecting system. Deletion mapping and *in silico* annotation identified *TBX6* as a candidate driver gene for CAKUT in the 16p11.2 deletion syndrome. We identified a *de novo* frameshift mutation in *TBX6* in a case with scoliosis and CAKUT. Analysis of mouse models for two different *Tbx6* alleles identified highly penetrant CAKUT recapitulating the high pleiotropic effect observed in humans with 16p11.2 deletions.

Conclusions: Our study describes the genomic landscape across the phenotypic spectrum of CAKUT, identifies recurrent CNVs for urinary tract developmental phenotypes and identifies *TBX6* as a genetic driver of CAKUT in the 16p11.2 deletion syndrome.

Loss of Dicer Activity in the Peri-Wolffian Duct Stroma Leads to Increased Rates of Vesicoureteral Reflux Melissa J. Anslow,[3] Jacqueline Ho,[1] Carlton M. Bates,[2] Andrew J. Bodnar,[1] Sunder Sims-Lucas.[2] *[1]Children's Hosp of Pittsburgh of UPMC, Pittsburgh, PA; [2]Children's Hospital of Pittsburgh, Pittsburgh, PA; [3]Pediatric Nephrology, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: Vesicoureteral reflux (VUR) is associated with urinary tract infections, hypertension, and reflux nephropathy, which is the 4th most frequent cause of end-stage renal disease in children. The formation of the vesicoureteral junction occurs during development through induction of the ureteric bud from the Wolffian duct, which requires signaling factors from both the Wolffian duct and surrounding stroma. VUR is known to be heritable, but very little is known about which specific genes are involved. miRNAs are small, noncoding RNAs that regulate gene expression post-transcriptionally. We hypothesize that miRNAs are also important in vesicoureteral junction development and play a role in VUR.

Methods: We generated a transgenic mouse model with loss of Dicer in the peri-Wolffian duct stroma. Dicer is a key component in the production of mature, functional miRNAs. Euthanized cystograms and 3D reconstructions of the ureters and bladder were performed on mutants (Tbx18Cre+:Dicerflx/flx) and controls (Tbx18Cre negative littermates).

Results: Euthanized cystograms demonstrated significantly higher rates of VUR in the mutant mice compared to control, ~42% (5/12) of Dicer mutants as opposed to ~5% (2/37) of controls ($p < 0.01$). Of the mutant mice, two had bilateral VUR and three had unilateral VUR. Preliminary 3D reconstruction data suggests lower ureteral insertion into the bladder in mutants compared to control mice.

Conclusions: Together, these data suggest for the first time that miRNAs play a role in VUR, and that this may be due to lower ureteral insertion into the bladder in mutant mice. Future work will further assess for ureteric bud induction abnormalities and explore other potential etiologies of increased VUR in the mutant mice.

Conditional Ablation of the Prorenin Receptor (PRR) in Nephron Progenitor Cells (NPCs) Results in Developmental Programming of Hypertension Renfang Song, Adam T. Janssen, Laura R. Kidd, Ihor V. Yosypiv. *Tulane University, New Orleans, LA.*

Background: The PRR is a receptor for renin and prorenin, and an accessory subunit of the vacuolar proton pump V-ATPase. Previously, we demonstrated that conditional ablation of the *PRR* in *Six2*$^{+}$ NPCs in mice (cKO) causes reduced congenital nephron endowment and early neonatal death (Song et al., 2016).

Methods: Here, we: 1) Investigated PRR-regulated genes and pathways in *Six2*$^{+}$ NPCs FACS-isolated from cKO and control (Co) kidneys on embryonic day E15.5 (n=3 pooled samples/genotype) using whole-genome-based analysis of gene expression; 2) Tested whether reduced *PRR* gene dosage in heterozygous *Six2*$^{PRR+/-}$ mice (Het) is associated with development of hypertension during later life; and 3) Tested the hypothesis that soluble PRR (sPRR), PRR cleavage product generated subcellularly and secreted into the urine by renal tubular cells, can contribute to BP programming in Het mice.

Results: Top 10 genes downregulated in cKO included *Hoxb8*, *Mspt*, *Mdfi* and *Gpc2*. The functional groups of differentially expressed genes within the altered gene set in cKO mice included genes involved in embryonic development, tissue/cell morphology, cellular assembly and organization, cell death and survival. While the number of glomeruli per kidney section was reduced at 2 months of age (69±4.0 vs. 178±4.9, $p<0.001$), conscious tail-cuff mean (95.5±2.8 vs. 70.4±3.8, $p<0.01$), systolic (143±5.3 vs. 113±6.5, $p<0.01$) and diastolic (67±4.5 vs. 51±4.0, $p<0.05$) arterial blood pressure was increased in Het compared with Co mice. Electron microscopy showed segmental thickening of the GBM with focal podocyte foot process effacement in Het mice. Urine sPRR levels measured by ELISA at 2 months of age were increased in Het compared to Co mice (262±28 vs. 146±13 pg/ml, $p<0.01$).

Conclusions: These data demonstrate that NPC PRR performs essential functions during nephrogenesis *via* control of hierarchy of genes that regulate critical cellular processes. Reduced nephron endowment, glomerular injury and augmented urine sPRR likely contribute to programming of hypertension in Het mice.

Circulating miRNAs Profile and Risk of ESRD in Type 1 Diabetes Eiichiro Satake,[1] Marcus G. Pezzolesi,[2] Adam Smiles,[1] Monika A. Niewczas,[1] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]University of Utah, Salt Lake City, UT.*

Background: MicroRNAs (miRNAs) are short endogenous, non-coding RNA molecules which are expressed in a variety of human biofluids. These molecules are involved in gene regulation and play important roles in the pathogenesis of various renal diseases including diabetic nephropathy. However, miRNA signatures associated with diabetic nephropathy in Type 1 diabetes (T1D) has not been fully established. The objective of this study was to determine the circulating miRNA signature that is associated with risk of end- stage renal disease (ESRD) in T1D patients with chronic kidney disease (CKD).

Methods: The expression levels of 2,083 miRNAs from the human miRNA genome were measured in baseline plasma samples from 196 T1D patients with CKD3. We applied a new technology, High Throughput Genomics (HTG) Edge Sequence platform for miRNA sequencing and quantitation. Data were normalized by quantile normalization with sample weights.

Results: Among 196 patients, there were 90 patients who progressed to ESRD within 10 years follow- up. After filtering out miRNAs with low expression level, a total of 988 miRNAs were detectable in plasma samples from these study participants. To identify miRNAs associated with risk of ESRD, we performed fold change analysis and Cox model analysis. In total, there were 28 miRNAs significantly correlated to risk of ESRD (p-value <10^{-4}). For these candidate miRNAs, we divided them into 5 groups according to the Cox model analysis, and selected 5 representative miRNAs (exemplars) from each group. Multivariate Cox analysis showed that 4 of them were still associated with risk of ESRD after adjusting for baseline ACR and eGFR. Pathway analysis revealed that 3 exemplars were associated with insulin signaling pathway and/or the TGF-β pathway.

Conclusions: We discovered a profile of circulating miRNAs that is a very strong predictor/determinant of progression to ESRD in patients with T1D. This profile is represented by exemplar miRNAs which can be used to develop a multi-miRNA prognostic biomarker to predict time to onset of ESRD. Furthermore, some of these miRNAs can be used as therapeutic targets to prevent or treat progressive renal decline that leads to ESRD in diabetes.

Immunolocalization of Apolipoprotein L1 with Specific Antibodies Suzie J. Scales, Nidhi Gupta, Kathy J. Hotzel, Andrew A. Pierce, Georgios Koukos, Paul Moran, Michael T. Lipari, Xinhua Wang, Daniel Kirchhofer, Randall J. Brezski, Oded Foreman, Andrew S. Peterson. *Genentech, Inc., South San Francisco, CA.*

Background: Human Apolipoprotein (ApoL1) is the only secreted member of the apolipoprotein (ApoL) family (ApoL1-ApoL6), with 53% amino acid identity (63% similarity) to its closest relative, ApoL2. ApoL1 has been widely studied because of its protective role against *Trypanosoma* infections and the association of its variants G1 and

G2 with chronic kidney disease. To better understand the role of ApoL1 in kidney disease, it is important to identify its localization within the kidney. By immunohistochemistry, ApoL1 is reportedly strongest in proximal tubules but only just detectable in podocytes, the susceptible kidney cell type in ApoL1 nephropathies. There are conflicting reports of immunofluorescent ApoL1 subcellular localization using different commercially available antibodies: in the endoplasmic reticulum, on the plasma membrane, endosomes and even mitochondria. However, these antibodies have not been well characterized for cross-reactivity with other members of the ApoL family, giving rise to misleading results.

Methods: We generated monoclonal antibodies to ApoL1 and characterized their cross-reactivity with all members of the ApoL family in parallel with the commercially available polyclonal antibodies. ApoL family expression in podocytes was determined by Taqman analysis. ApoL1-specific antibodies were used to determine the true localization of ApoL1 in kidney and liver by immunohistochemistry, and in cultured podocytes by dual immunofluorescence labeling.

Results: All the commercially available antibodies previously published for localization studies cross-react with ApoL2, as did half of our monoclonals. Human podocytes express ApoL1, 2 and 6 mRNAs. In tissues, ApoL1 was specifically and robustly detected in serum, liver hepatocytes and kidney podocytes, but not in most proximal tubules. In cells, overexpressed ApoL1 and ApoL2 were found on opposite faces of the endoplasmic reticulum. Endogenous ApoL1 was also detected inside the endoplasmic reticulum (but not endosomes or mitochondria) of wild type podocytes and was enhanced by gamma interferon. The specificity of the staining was proven by its absence from ApoL1 knockout (CRISPR) podocytes.

Conclusions: Non-ApoL2 cross-reactive antibodies are essential for determining the true localization of endogenous ApoL1.

Metabolomic Profiling of APOL1 Risk Alleles Adrienne Tin,[10] Girish N. Nadkarni,[3] Cheryl A. Winkler,[7] Erwin P. Bottinger,[1] Lesley Inker,[8] Andrew S. Levey,[8] Michael S. Lipkowitz,[2] Lawrence J. Appel,[4] Dan Arking,[6] Josef Coresh,[9] Morgan Grams.[5] *[1]Berlin Institute of Health, Berlin, Germany; [2]Georgetown University Medical Center, Washington, DC; [3]Ichan School of Medicine, New York, NY; [4]Johns Hopkins Medical Institutions, Baltimore, MD; [5]Johns Hopkins University, Baltimore, MD; [6]Johns Hopkins University School of Medicine, Baltimore, MD; [7]NCI, NIH, Frederick National Laboratory, Frederick, MD; [8]Tufts Medical Center, Boston, MA; [9]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [10]Epidemiology, Johns Hopkins University, Baltimore, MD.*

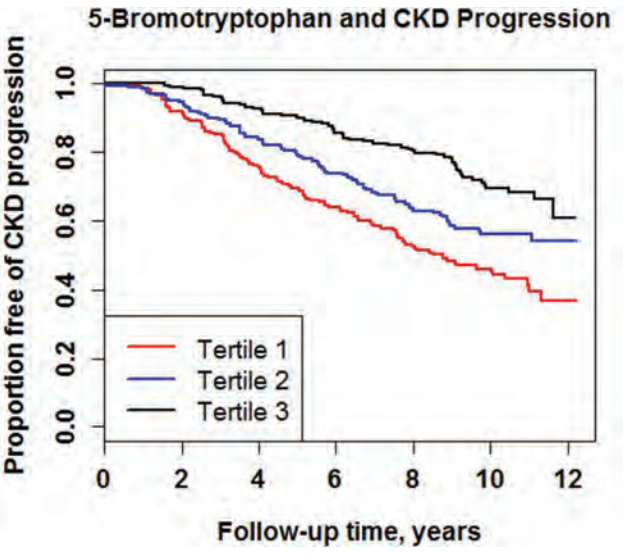
Background: Apoliprotein L1 (*APOL1*) risk alleles have been associated with chronic kidney disease (CKD) progression. Metabolomic profiling by *APOL1* risk allele status may inform our understanding of the pathogenesis of *APOL1*-associated kidney disease.

Methods: We evaluated the association between 1,133 serum metabolites identified via an untargeted approach at Metabolon and the number of *APOL1* high risk alleles (0,1, or 2) in the African American Study of Kidney Disease (AASK) (N=609). The significance threshold was set at 2.4e-4 based on principal component analysis. Significantly associated metabolites were then tested in a second cohort of African American patients with CKD (BioMe; N=680). Metabolites that replicated were evaluated as risk factors for CKD progression, defined as ESRD or at least doubling of serum creatinine.

Results: Of the six metabolites significantly associated with *APOL1* in AASK, one, 5-bromotryptophan, was also significant in BioMe, with lower levels associated with higher number of risk alleles (beta per *APOL1* risk allele, AASK: -0.23, p=2.5e-5; BioMe: -0.14, p=4.1e-3). In further analysis in AASK, lower levels of 5-bromotryptophan, a product of tryptophan metabolism, were associated with CKD progression adjusting for demographics, study assignments, baseline GFR, proteinuria, and *APOL1* high-risk status (adjusted HR by tertile [T]: T2 vs T1 (lowest): 0.86 (95% CI: 0.64, 1.16); T3 (highest) vs T1: 0.63, 95% CI: 0.45, 0.88, p for trend: 0.008, figure).

Conclusions: Metabolomic profiling identified an association of *APOL1* high risk alleles with lower 5-bromotryptophan levels, which was also associated with CKD progression, a finding which was consistent in two cohorts.

Funding: NIDDK Support



Kaplan-Meier estimates of proportion free of CKD progression by tertile of 5-bromotryptophan

Apolipoprotein L1 Risk Variants and Soluble Urokinase Plasminogen Activator Receptor Synergistically Mediate CKD in African Americans Salim Hayek,[1] Kwi Hye Koh,[12] Morgan Grams,[4] David C. Wei,[11] Hyun Lee,[2] Ranadheer Dande,[12] Ha Won Lee,[12] Eunsil Hahm,[12] Vasil Peev,[12] Nicholas J. Tardi,[12] Vineet Gupta,[12] Mehmet M. Altintas,[11] Nikolina Stojanovic,[5] Cheryl A. Winkler,[7] Michael S. Lipkowitz,[3] Adrienne Tin,[9] Lesley Inker,[13] Andrew S. Levey,[13] Martin G. Zeier,[16] Barry I. Freedman,[14] Jeffrey B. Kopp,[8] Karl Skorecki,[10] Josef Coresh,[15] Sanja Sever,[6] Jochen Reiser.[12] *[1]Emory University School of Medicine, Atlanta, GA; [2]Univ. of Illinois at Chicago, Chicago, IL; [3]Georgetown University Medical Center, Washington, DC; [4]Johns Hopkins University, Baltimore, MD; [5]MGH, Charlestown, MA; [6]Massachusetts General Hospital, Charlestown, MA; [7]NCI, NIH, Frederick National Laboratory, Frederick, MD; [8]NIDDK, NIH, Bethesda, MD; [9]None, Baltimore, MD; [10]Rambam Health Care Campus, Haifa, Israel; [11]Rush University, Chicago, IL; [12]Rush University Medical Center, Chicago, IL; [13]Tufts Medical Center, Boston, MA; [14]Wake Forest University School of Medicine, Winston-Salem, NC; [15]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [16]Division of Nephrology, Ruprecht Karls University, Heidelberg, Germany.*

Background: Apolipoprotein L1 (APOL1) gene variants G1 and G2 but not the reference allele G0 are associated with an increased risk for chronic kidney disease (CKD) in African Americans, but the mechanisms are unknown. Soluble urokinase plasminogen activator receptor (suPAR) strongly predicts CKD.

Methods: We characterized *APOL1* genetic variants and plasma suPAR levels in two separate cohorts of African-American patients, the Emory Cardiovascular Biobank (EmCAB; $n = 487$) and the African American Study of Kidney Disease and Hypertension (AASK; $n = 607$). We studied the biochemical interaction between ApoL1, suPAR, and integrin β3 by immunoprecipitation and surface plasmon resonance (SPR).

Results: Here we show that individuals carrying the high-risk APOL1 genotype, i.e. 2 copies of risk variants, manifest a steeper decline in kidney function with increasing suPAR levels compared to individuals harboring low-risk genotypes. SPR identified high affinity interactions between ApoL1, suPAR and αvβ3 integrin. ApoL1 protein variants G1 and G2 exhibited higher affinity for suPAR-activated αvβ3 integrin than ApoL1 G0, and activated podocyte αvβ3 integrin. APOL1 G1 or G2 expression causes proteinuria in mice in a suPAR dependent manner.

Conclusions: The synergistic activation of αvβ3 integrin by circulating factor suPAR and ApoL1 G1 or G2 is a mechanism for CKD in patients of recent African ancestry.

Metabolites Associated to Mortality and ESRD in a Brazilian CKD Cohort: The Progredir Study Silvia M. Titan,[3] Gabriela Venturini,[2] Kallyandra Padilha,[2] Paulo Lotufo,[4] Isabela M. Bensenor,[4] Ravi I. Thadhani,[1] Eugene P. Rhee,[1] Alexandre C. Pereira.[5] *[1]Nephrology Division, Massachusetts General Hospital, Boston, MA; [2]Laboratório de Cardiologia Molecular, Incor, Hospital das Clínicas, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil; [3]Nephrology Division, Faculty of Medicine, Sao Paulo University, Sao Paulo, Brazil; [4]Clinical Research Center, Universitary Hospital, Sao Paulo University, Sao Paulo, Brazil; [5]Laboratorio de Cardiologia Molecular, Incor, Hospital das Clínicas, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil.*

Background: Recent studies have evaluated metabolomics in relation to eGFR and to incident CKD. However, very few studies have evaluated metabolomics biomarkers in the setting of prevalent CKD and hard outcomes. **Objective**: To evaluate metabolites related to death, ESRD and a composite outcome of both in a CKD population (n=454).

Methods: Metabolomics was performed by GC and Mass Spectrometry. Metabolites were identified using Agilent Fiehn GC/MS Metabolomics and NIST libraries (Agilent MassHunter Work-station Quantitative Analysis, version B.06.00). From initial 10940 metabolites, we excluded those present <50% of the samples, leaving 293. We selected candidate metabolites by applying a FDR q value <0.05 in a Cox model on the composite outcome adjusted only for batch. Among the 34 selected metabolites, Cox regression models were built on death (n=93), ESRD (n=36) and composite outcome (n=126). Competing risk analysis was also performed for ESRD.

Results: Mean age was 68(±12)y, mean eGFR-CKDEPI was 38.4 (±14.6) ml/min/1.73m^2 and 57% were diabetic. After adjustment for batch, sex, age, DM and eGFR, 18 metabolites remained significantly related to the composite outcome, with lactose, D-threitol, docosahexaenoic acid (DHA), butanoic acid and mannitol among the top. For mortality only, 9 metabolites remained significantly associated with death, with D-malic acid (TCA cycle, OR 1.84, 95%CI1.32 – 2.56, p=0.0003), butanoic acid (colon microbiota; 1.59, 95%CI1.17 – 2.15, p=0.003), and DHA (omega3 fatty acid, OR 0.58, 95%CI0.39 – 0.88, p=0.009) among the top 3. For ESRD, 4 metabolites remained significantly associated to its risk: lactose, 2-O-glycerol-α-D-galactopyranoside, D-threitol and tyrosine (Table1), findings confirmed by the competing analysis except for D-threitol.

Conclusions: Our results identify specific metabolites related to hard outcomes in a CKD population. These results require confirmation.

Funding: Government Support - Non-U.S.

Table1. Cox proportional hazard models on the risk of ESRD after adjustment for batch, sex, age, eGFR and DM.

Metabolite (log2)	HR	95%CI HR		p
Lactose	1.68	1.21	2.34	.002
2-O-Glycerol-α-d-galactopyranoside	1.77	1.11	2.84	.02
D-threitol	2.74	1.04	7.20	.04
Tyrosine	0.59	0.35	0.98	.04

SA-OR056

The Global Burden of Kidney Disease Attributable to Air Pollution Benjamin C. Bowe,[1] Yan Xie,[1] Hong Xian,[1,2] Tingting Li,[3,4] Ziyad Al-Aly.[1,4] *[1]Clinical Epidemiology Center, Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [2]Department of Biostatistics, Saint Louis University College for Public Health & Social Justice, St. Louis, MO; [3]Washington University in St. Louis, Saint Louis, MO; [4]Department of Medicine, Washington University School of Medicine, St. Louis, MO.*

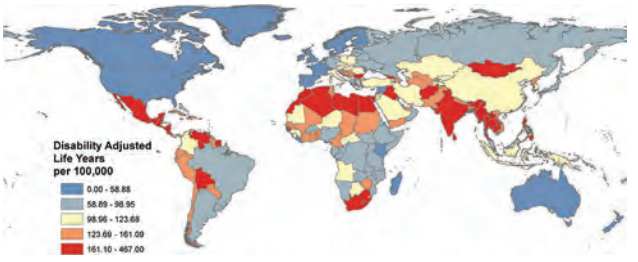
Background: We previously described an association between increased levels of fine particulate matter of <2.5 μm in aerodynamic diameter ($PM_{2.5}$) and risk of incident chronic kidney disease (CKD). This work aims to provide a quantitative assessment of the global burden of CKD attributable to elevated levels of $PM_{2.5}$.

Methods: We used the Global Burden of Disease (GBD) study methodologies to estimate the burden of CKD attributable to air pollution using the following measures: attributable burden of disease (ABD), years living with disability (YLD), years of life lost (YLL), and disability-adjusted life years (DALY). Relative risk was derived from our prior work. Population weighted $PM_{2.5}$ levels and incident rates of CKD for each country were curated from the GBD study publicly available data sources.

Results: Our estimate for the global annual burden of incident CKD attributable to elevated $PM_{2.5}$ was 10,784,514 (95% Uncertainty Interval: 7,821,109-13,857,623). YLD, YLL, and DALYs of CKD attributable to elevated $PM_{2.5}$ were 2,185,317 (1,418,442-3,061,477), 7,897,941 (5,471,081-10,514,433), and 10,083,258 (7,064,399-13,323,685), respectively. Standardized ABD in the 10 most populated countries showed Nigeria, Bangladesh, Pakistan, and India having high ABDs, exceeding 200 incident cases of CKD per 100,000 population. Populations in Mexico, Central America, Southeast Asia, India, and Northern Africa were amongst those with highest DALYs. For example, DALYs per 100,000 were 366.71 (251.05, 498.01) in Nicaragua and 353.93 (260.05-449.24) in Mexico, compared to 44.59 (24.07-65.74) in the United States.

Conclusions: The global toll of CKD attributable to air pollution is significant. The burden varies substantially by geography. Air pollution might at least partially explain the rise in incidence of CKD of unknown cause in many geographies around the world, and the rise in Mesoamerican nephropathy in Mexico, and Central America.

Funding: Veterans Affairs Support



The global burden of chronic kidney disease attributable to elevated $PM_{2.5.}$ expressed in disability adjusted life years (DALY) per 100,000 population.

SA-OR057

A Machine Learning Approach to Predicting ESRD Girish N. Nadkarni,[1] Edward Lee,[2] Oliver L. Fielding,[2] Teddy Cha,[2] Hai po Sun,[2] Chris Kipers,[2] William D. Paiva,[3] Elvena Fong,[3] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]pulseData, Inc., New York, NY; [3]Center for Health Systems Innovation (Oklahoma State University), Stillwater, OK.*

Background: Risk prediction of end stage renal disease (ESRD) for population management and care intervention is both a research priority and unmet public health need. The use of electronic medical records (EMR) can be leveraged for improved assessment of ESRD onset. However, traditional risk scoring may not provide accurate risk prediction or complete population coverage if EMR data is incomplete. To handle missing data we developed a machine learning (ML) approach and compared it to traditional risk scoring in two EMR cohorts.

Methods: We utilized longitudinal data from the Mount Sinai Chronic Kidney Disease registry and a data set from the Center for Health Systems Innovation at Oklahoma State University provided by the Cerner Corporation. Using a random forest ML technique and imputation we can predict risk of ESRD (defined as administrative codes for dialysis or transplant). We then compared it to the Tangri 4-Variable kidney failure risk equation (KFRE) by comparing area under curve (AUC) measures and the percent of the population on which each metric can be calculated.

Results: We analyzed data from 318,292 patients. The median age was 65 years, 54% were female and 20% were African American. 60% of the cohort had at least one estimated glomerular filtration rate (eGFR) measurement before ESRD onset, however, only 6% had both an eGFR measurement and a urine albumin creatinine ratio (UACR) value before failure. The AUC of the 4-Variable KFRE was 0.89 (95% CI [0.88, 0.91]), while the ML approach had an AUC of 0.94 (95% CI [0.94, 0.95]). Importantly, the improvement in AUC was achieved while risk-scoring 10 times more of the population.

Conclusions: The ML approach outperformed traditional risk scoring such as the 4-Variable KFRE both in risk discrimination and in population coverage. Therefore, future efforts to risk stratify for population management and care intervention will benefit from utilizing ML approaches.

Table. Comparison of 4-Variable KFRE and ML approach

	4 Variable KFRE	Machine Learning Approach
Population coverage, n (%)	19,880 (6.3)	191,435 (60.1)
ESRD events, n(%)	846 (4.3)	12,870 (6.7)
eGFR, Mean (SD)	67.6 [49.6, 88.4]	65.3 [47.2, 86.9]
Follow Up in Years, Mean (SD)	3 [1.3, 5.3]	3.4 [1.4, 6.0]
AUC (95% Confidence Interval)	0.89 (0.88-0.90)	0.94 (0.93-0.95)

Association between Pre-ESRD RAAS Blockade and Post-ESRD Mortality Miklos Z. Molnar,[4] Adnan Naseer,[6] Keiichi Sumida,[2] Ariel R. Riezenman,[5] Praveen Kumar Potukuchi,[4] Abduzhappar Gaipov,[4] Elani Streja,[1] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[4] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]University of California Irvine, School of Medicine, Orange, CA; [4]University of Tennessee Health Science Center, Memphis, TN; [5]University of Tennessee Health Science Center - Memphis, Memphis, TN; [6]VAMC, Germantown, TN.*

Background: Renin-Angiotensin-Aldosterone system inhibitor (RAASi) use is associated with slower progression of chronic kidney disease (CKD) and lower mortality in patients with CKD. However, the association between pre-end stage renal disease (ESRD) RAASi use and post-ESRD mortality is unclear.

Methods: We examined 15,966 US veterans initiating dialysis during 2007-2014. We divided patients into three groups of RAASi use pattern in the last 3 pre-dialysis years: never exposed (n=7,294), exposed but discontinued in the last pre-dialysis year (n=6,833) and uninterrupted use (n=1,839). Associations of RAASi use patterns with all-cause mortality were examined in multivariable adjusted Cox models.

Results: Patients were 72±11 years old, 98% male, 23% African-American, and 65% diabetic. The all-cause mortality rates were 303 [95% CI 294-311]/1000 patient-years (PY) in patients never exposed to RAASi, 276 [95% CI 268-284]/1000PY in patients who discontinued RAASi and 240 [95% CI 227-254]/1000PY in patients on uninterrupted

RAASi, respectively, during a median of 2.2 years of follow-up. Uninterrupted RAASi use was associated with lower risk of death after dialysis start in unadjusted and various adjusted analyses (Figure).

Conclusions: Uninterrupted RAASi use prior to dialysis is associated with lower risk of death after dialysis start. There was no post-ESRD survival benefit observed in patients who discontinued RAASi in the final year before MHD initiation.

High FGF-23 Is Associated with Coronary Calcification Only in Patients with High Adiponectin: From the KNOW-CKD Study Young Youl Hyun,[6] Kook-Hwan Oh,[4] Curie Ahn,[4] Yong-Soo Kim,[3] Tae-Hyun Yoo,[5] Soo Wan Kim,[1] Yeong Hoon Kim.[2] *[1]Chonnam National University Medical School, Dongku, Republic of Korea; [2]Inje University Medical School, Busan, Republic of Korea; [3]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea; [5]Yonsei University College of Medicine, Seoul, Republic of Korea; [6]Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea. Group/Team: KNOW-CKD Study Group.*

Background: Both FGF-23 and coronary artery calcification (CAC) are known as predictors of high cardiovascular and all-cause mortality. However, previous studies on the association between FGF-23 and CAC were inconclusive. Recently, it has been shown that adiponectin modulates renal handling of phosphate and calcium, important factors in vascular calcification. We hypothesized that adiponectin play a role in the effect of FGF-23 on CAC, and explored whether this association between FGF-23 and CAC is modified by serum adiponectin level in CKD patients.

Methods: This cross-sectional study analyzed 1,153 predialysis CKD patients from the KNOW-CKD cohort who measured coronary artery calcium scores (CACS), serum FGF-23 and serum adiponectin. Participants were divided into three groups according to their FGF-23 levels as follows: low <5.0 RU/ml, middle =5.0-29.9 RU/ml, and high ≥30.0 RU/ml. We evaluated the association between FGF-23 and CACS by multivariate Tobit regression and multivariate logistic regression in each group with lower half and upper half of adiponectin.

Results: Median [interquartile range] CACS were not different between low and high adiponectin group (2.0 [0.0-91.8] vs 0.4 [0.0-103.5], P=0.536). The CACS ratio comparing the high FGF-23 to the low FGF-23 was significantly increased in high adiponectin group, but not in low adiponectin group [3.25 (1.53-6.91) vs 1.07 (0.50-2.29), P for interaction=0.029). Similarly, the ORs for CAC in the high FGF-23 group compared to the low group were significantly increased only in the high adiponectin group (Table).

Conclusions: High serum FGF-23 was associated with CAC only in CKD patients with high adiponectin, but not in those with low adiponectin. Further studies are warranted to verify the role of adiponectin in FGF-23-related coronary calcification.

Funding: Government Support - Non-U.S.

HDL Cholesterol and Its Associations with Cause-Specific Mortality in Patients with CKD Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Susana Arrigain,[2] Stacey Jolly,[2] Carl P. Walther,[1] Wolfgang C. Winkelmayer,[1] Joseph V. Nally.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Cleveland Clinic, Cleveland, OH.*

Background: Recent data suggest a U-shaped association between HDL cholesterol (HDL-c) and death in CKD. However, whether the increased mortality in patients with extreme levels is driven by specific causes of death remains unclear. Herein, we examined the associations between HDL-c and cause-specific mortality in a large CKD population.

Methods: We included 38,377 patients with eGFR 15-59 ml/min/1.73 m² who had lipid levels measured within 1 year of CKD diagnosis. We ascertained overall and cause-specific deaths from the State mortality data and classified deaths into 3 major categories: a) cardiovascular; b) malignancy; and c) non-cardiovascular/non-malignancy causes. We fitted Cox regression models for overall mortality and separate competing risk models for each major cause of death category to evaluate their respective associations with categories of HDL-c (≤30, 31-40, 41-50 [referent], 51-60, >60 mg/dl). Separate analyses were conducted for men and women.

Results: During a median follow-up of 4.5 years, 9,665 patients died. HDL-c ≤30 mg/dl was associated with higher risk of all-cause and cardiovascular mortality in both sexes and higher risk of malignancy-related deaths in women (Table 1). HDL-c >60 mg/dl was associated with lower all-cause mortality in women only. HDL-c >60 mg/dl was associated with higher risk of non-cardiovascular/non-malignancy related deaths in men but not women. Exclusion of those with malignancy yielded results similar to primary analyses.

Conclusions: In a non-dialysis dependent CKD population, HDL-c ≤30 mg/dl was associated with higher all-cause and cardiovascular mortality, but not with non-cardiovascular mortality. HDL-c >60 mg/dl was associated with higher risk of non-cardiovascular/non-malignancy related deaths in men only. Additional studies examining the reasons for these different associations between HDL-c and cause-specific mortality, and potential effect modification by sex, are needed.

Funding: Commercial Support - Development of CCF CKD registry was suppoerted by an unrestricted educational fund to the Department of Nephrology and Hypertension from Amgen, Inc

Differential Effects of STCH and HSP70 on the Stability and Maturation of NKCC2 Elie Seaayfan,[2] Sylvie Demaretz,[2] Martin Kömhoff,[1] Kamel Laghmani.[2] *[1]Philipps Univ Marburg, Marburg, Germany; [2]Centre de Recherche des Cordeliers, INSERM-U1138, UPMC, CNRS-ERL8228, Paris, France.*

Background: Mutations in the apically located Na-K-2Cl cotransporter, NKCC2, lead to type I Bartter syndrome, a life-threatening kidney disorder associated with salt wasting, hypokalemia, and metabolic alkalosis. Conversely, increased expression of NKCC2 promotes hypertension. We previously showed that export from the ER constitutes the limiting step in the maturation and cell surface expression of NKCC2 and its disease causing mutants. Yet the molecular mechanisms involved in this process remain obscure.

Methods: To identify the protein partners involved in ER associated degradation of NKCC2, we screened a kidney cDNA library through yeast two-hybrid using NKCC2 C-terminus as bait. NKCC2 protein expression was monitored in transiently transfected HEK cells, using immunoblot and confocal imaging. NKCC2 stability was assessed by cycloheximide chase assay.

Results: We identified STCH, a *constitutively* expressed member of the heat shock protein 70 family, as a specific binding partner of NKCC2. STCH is known to be a microsome-associated chaperone. Co-immunoprecipitation and co-immunolocalization experiments confirmed NKCC2-STCH interaction in HEK cells. Interestingly, they also identified the cytoplasmic and *stress-inducible* heat shock protein 70 (HSP70) as an interactor with NKCC2. STCH and HSP70 binding to NKCC2 involve mainly the immature form of the co-transporter and takes place at the ER. STCH co-expression heavily decreased total cellular WT NKCC2 protein and its disease associated folding mutants, in a dose dependent fashion, whereas HSP70 co-expression had the opposite effect. Cycloheximide chase assay showed that in cells over-expressing STCH, NKCC2 stability and maturation are heavily impaired. In contrast to STCH, HSP70 co-expression increased strikingly NKCC2 expression and maturation.

Conclusions: Our results are consistent with STCH and HSP70 having differential and antagonistic effects with regard to NKCC2 biogenesis, in particular under ER stress conditions. Most importantly, they may have an impact on our understanding and potential treatment of diseases related to aberrant NKCC2 trafficking and expression.

Modeling the Structural and Dynamical Changes of TRPV5 Caused by the A563T Variation Based on the Structure of TRPV6 Lingyun Wang, Ji-Bin Peng. *Div of Nephrology, Dept of Medicine, Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL.*

Background: TRPV5 is an epithelial Ca^{2+} channel that plays a key role in the active Ca^{2+} reabsorption process in the kidney. The single nucleotide polymorphism (SNP) rs4252499 in TRPV5 gene has a minor allele frequency of around 0.17 in African descendants. This SNP results in an A563T variation in the sixth transmembrane (TM) domain of TRPV5. Our previous study indicates that the variation increases Ca^{2+} uptake and alters Mg^{2+} sensitivity of TRPV5. To understand the molecular mechanism, molecular simulations have been performed based on the structure of TRPV1. Recently, the structure of TRPV6 was determined. Since TRPV5 is much more similar to TRPV6 than TRPV1, new molecular simulation based on TRPV6 structure would provide more accurate information on the A563T variation in TRPV5.

Methods: Using MODELLER, TRPV5 model was set up based on a newly deposited structure of TRPV6 which shares 75% amino acid identity with TRPV5. This model contains all the six TM helices and the TRP domain of TRPV5. The A563T variation was introduced into TRPV5 using PyMOL. To mimic the membrane environment, the modeled TRPV5 was embedded in a lipid bilayer composed of 299 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) lipids using CHARMM-GUI, and then water molecules were added on both sides of the bilayer. Two 400 ns molecular dynamic simulations were performed using AMBER14.

Results: Consistent with TRPV1-based simulation, the current simulation indicates that the A563T variation results in increased contacts between residues 563 and V540, enhanced stability for the secondary structure of TM helix 6, and reduced correlated motion among monomers. The stable secondary structure of the variant mainly results from the stabilized hydrogen bond between T563 and T567. In contrast to TRPV1-based simulation, no significant changes in the pore size or in the electrostatic potential for the pore region were observed between the two forms of TRPV5 in this study.

Conclusions: Simulations based on the newly determined TRPV6 structure confirm that the A563T variation affects the structure and dynamics of TRPV5 through increased interactions with V540, which is one residue away from the key residue D542 in the Ca^{2+} filter.

Transcriptional Activation of Kir5.1 by HNF1B – Implications for Autosomal Dominant Tubulo-Interstitial Kidney Disease Joost Hoenderop,[1] Andreas Kompatscher,[1] Karam S. Aboudehen,[2] Peter Igarashi,[2] Jeroen H. De Baaij,[1] René J. Bindels.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]University of Minnesota, Minneapolis, MN.*

Background: Hepatocyte nuclear factor 1 homeobox B (*HNF1B)* is an essential transcription factor for the development and functioning of the kidney. Mutations in HNF1b cause autosomal dominant tubulointerstitial kidney disease (ADTKD-HNF1B). Patients often suffer from a severe electrolyte phenotype consisting of hypomagnesemia and hypokalemia. Until now, known genes regulated by HNF1B do not fully explain the phenotype of the patients.

Methods: Therefore, a chromatin immunoprecipitation and sequencing (chIP-seq) was conducted in immortalized mouse kidney cells (mpkDCT) to identify HNF1B binding sites at a genome-wide scale. Luciferase-promoter assays, siRNA-mediated knockdown of *Hnf1b* in DCT cells and RT-qPCR on HNF1B mutant mouse kidneys were performed to assess the transcriptional regulation of *Hnf1b* on candidate genes *in vitro* and *in vivo*.

Results: In total 7,421 HNF1B binding sites were identified, including several genes involved in electrolyte transport and diabetes. A highly conserved HNF1B site was identified in the promoter of *Kcnj16*, encoding the potassium channel Kir5.1. Luciferase-promoter assays showed a 2.2 fold increase in *Kcnj16* expression when HNF1B was present. Expression of the *Hnf1b* p.Lys156Glu mutant that was identified in a ADTKD-HNF1B patient, did not activate *Kcnj16* expression. Knockdown of *Hnf1b* in mpkDCT cells significantly reduced the expression of *Kcnj16* (Kir5.1) and *Kcnj10* (Kir4.1) by 38% and 37%. These results were confirmed in a HNF1B renal knockout mouse, exhibiting downregulation of *Kcnj16, Kcnj10* and *Slc12a3* transcripts in the kidney by 78%, 83% and 76%, respectively, compared to HNF1B wild-type mice.

Conclusions: HNF1B has been identified as a transcriptional activator of *Kcnj16*. Consequently patients with *HNF1B* mutations may have reduced Kir5.1 activity in the kidney, resulting in hypokalemia and hypomagnesemia.

CLDN10 Mutations Cause a Novel Autosomal Recessive Hypokalemic-Alkalotic Salt-Losing Tubulopathy Tom Nijenhuis,[2] Ernie M. Bongers,[2] Luke M. Shelton,[2] Susanne Milatz,[1] Sjoerd Verkaart,[2] Anneke Bech,[2] Jeroen Schoots,[2] Elisabeth A. Cornelissen,[2] Markus Bleich,[1] Joost Hoenderop,[2] Jack F. Wetzels,[2] Dorien Lugtenberg.[2] *[1]Christian Albrechts University Kiel, Kiel, Germany; [2]Radboud university medical center, Lent, Netherlands.*

Background: Hypokalemic alkalosis result from acquired causes or rare (genetic) tubular disorders. Salt-losing nephropathies, due to mutations affecting transcellular sodium reabsorption, induce hypokalemic alkalosis by increasing distal tubular flow and sodium delivery. However, the importance of paracellular transport across tight junctions, involving the claudin protein family, is increasingly acknowledged.

Methods: We phenotyped two unrelated patients with hypokalemic alkalosis, including tubular function testing, performed whole exome sequencing and characterized the identified *CLDN10* sequence variations *in vitro*.

Results: The first patient was diagnosed with Bartter syndrome (BS) over 30 years ago. Re-evaluation demonstrated hypocalciuria and hypercalcemia, suggesting Gitelman syndrome (GS). However, serum magnesium was in the upper-normal to hypermagnesemic range, thiazide responsiveness was not blunted, and genetic analyses did not show mutations in genes associated with either GS or BS. A reduced urinary concentrating ability with a preserved aquaporin-2 response to desmopressin was demonstrated, with an intact to exaggerated response to furosemide. These findings are not in line with any known salt-losing nephropathy. Whole exome sequencing revealed compound heterozygous *CLDN10* sequence variants. A second unrelated patient was thereafter identified demonstrating a similar phenotype and compound heterozygous *CLND10* sequence variants. Both patients' phenotypes resemble a mouse model lacking distal tubular Claudin-10, that demonstrates a reduced TAL paracellular sodium permeability leading to a urine concentrating defect, and enhanced paracellular magnesium and calcium permeability. Cell surface biotinylation and immunofluorescence experiments in cells expressing the Claudin-10 mutants showed that the phenotype is not explained by mere lack of Claudin-10 membrane localization or tight junction strand formation.

Conclusions: Pathogenic *CLDN10* mutations cause a novel tight junction disease, possibly affecting TAL paracellular ion transport, characterized by a non-Bartter non-Gitelman hypokalemic-alkalotic salt-losing phenotype and a renal concentration defect, with hypocalciuria and unexpectedly normal to high serum magnesium levels.

SA-OR065

Effect of Sodium-Glucose Cotransporter 2 Inhibitor on Fluid Distribution: Comparison with Furosemide and Tolvaptan Ken Ohara, Takahiro Masuda, Takuya Murakami, Toshimi Imai, Saki Nakagawa, Mari Okada, Hiromichi Yoshizawa, Atsushi Miki, Kentaro Oka, Maki Asakura, Taro Sugase, Akira Onishi, Tetsu Akimoto, Osamu Saito, Shigeaki Muto, Daisuke Nagata. *Divison of Nephrology, Department of Internal Medicine, Jichi Medical University, Oyama, Japan.*

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitor is a new antihyperglycemic drug that increases urinary glucose excretion. Recently, the diuretic property of SGLT2 inhibitors has been reported, but the effect on fluid distribution remains unclear. We therefore examined the change of fluid distribution after the administration of SGLT2 inhibitor dapagliflozin (DAPA), and compared with loop diuretic furosemide (FR) and vasopressin V2 receptor antagonist tolvaptan (TLV).

Methods: Forty chronic kidney disease (CKD) patients with fluid retention (average eGFR 29.0±3.3 mL/min/1.73 m^2) were enrolled in this study. The patients were divided into the three groups: DAPA (n=15, dose 5 mg/day), FR (n=15, dose 55.7±12.4 mg/day) and TLV (n=10, dose 7.5 mg/day). The fluid volume was measured using a bioimpedance

analysis (BIA) device day 0 and 1 week after the administration. One-way ANOVA was performed to measure differences between the groups.

Results: After 1 week, changes in body weight (DAPA -3.1±0.8, FR -4.6±0.8, TLV -2.6±1.0 kg, p=0.22) and urine volume (+81±220, +451±243, +187±230 mL/day, p=0.52) were not significantly different among the groups. BIA showed changes in intracellular water (-6.2±1.3, -7.3±1.2, -7.1±1.4 %, p=0.82) were similar among the groups, and changes in extracellular water (ECW) tended to increase in FR (-8.5±1.6, -12.6±1.6, -7.9±1.8 %, p=0.10). Changes in the ratio of ECW to total body water (ECW/TBW) were significantly different (-1.3±0.5, -3.4±0.5, -0.3±0.6 %, p<0.001). Changes in estimated glomerular filtration ratio were not significantly different during the treatment (-2.0±3.3, 3.9±3.3, 0.4±4.1 %, p=0.46).

Conclusions: SGLT2 inhibitor dapagliflozin predominantly decreases ECW, but the reduction rate of ECW/TBW differs from furosemide and tolvaptan. These results indicate that SGLT2 inhibitor has a novel property on fluid distribution not found in conventional diuretics.

SA-OR066

Mobilization of Nonosmotically Stored Sodium after Water Loading in Healthy Individuals Rosa D. Wouda,[4] Shosha Dekker,[2] Joelle Reijm,[3] Rik H. Olde Engberink,[1] Liffert Vogt.[1] *[1]Academic Medical Center, Amsterdam, Netherlands; [2]AMC Amsterdam, Amsterdam, Netherlands; [3]Academic medical center, Amsterdam, Netherlands; [4]Academic Medical Center, Amsterdam, Amsterdam, Netherlands.*

Background: Recently it was discovered that significant amounts of sodium (Na^+) can be stored without concurrent water retention. These observations indicate the presence of a third compartment for Na^+ distribution. The role of this compartment under hypotonic conditions is not known. In this study we investigated whether Na^+ can be released from its nonosmotic stores after a hypotonic fluid load.

Methods: Twelve healthy male subjects had a water loading test (WL; 20 ml water/kg in 20 min). During a 240 min follow-up, we compared the observed plasma [Na^+], fluid and cation excretion with values predicted by the Barsoum-Levine and Nguyen-Kurtz formula. These formulas are used for guidance of fluid therapy during dysnatraemia and do not account for nonosmotic Na^+ stores.

Results: 30 min after WL plasma [Na^+] was decreased with -3.2±0.5 mmol/L (mean (SE)), after which plasma [Na^+] increased gradually. The observed maximal decrease in plasma [Na^+] after WL was significantly overestimated by the Barsoum-Levine (-4.4±0.3 mmol/L) and Nguyen-Kurtz formula (-5.2±0.4 mmol/L)(p<0.05). In addition, 120 min after WL the Barsoum-Levine and Nguyen-Kurtz formula overestimated urine volume, while cation excretion was significantly underestimated with a cation gap of 51±18 mmol and 60±19 mmol, respectively (p<0.05). At 240 min, this gap was 29±18 mmol and 5±23 mmol, respectively (p=NS).

Conclusions: These data demonstrate that healthy individuals are able to mobilize osmotically inactivated Na^+ after a hypotonic fluid load. Further research is needed to expand knowledge on the Na^+ buffer and asses its impact on therapy of dysnatremia.

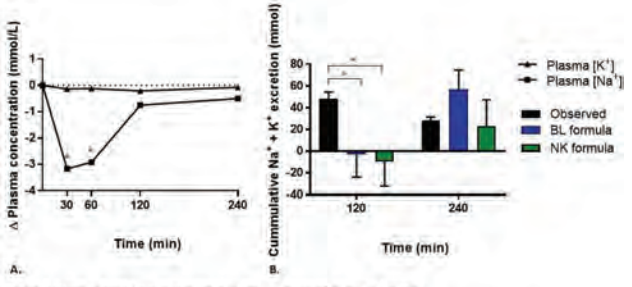

Figure 1. Expected and observed urinary cation excretion after water loading
A. In healthy subjects plasma [Na^+] reached nadir only 30 min after initiation of WL, while plasma [K^+] remained stable. **B.** 120 min after WL the corresponding changes in urinary cation excretion were largely underestimated compared to the observed values by both the Barsoum-Levine and Nguyen-Kurtz formula. Data are presented as mean ± SE. *p<0.05

SA-OR067

Expression Pattern of Renal Transporters in Urinary Exosomes from Patients with Edematous States Silvana Bazua-Valenti,[1,2] Lorena L. Rojas,[1] Fabiola Gallardo,[1] Diego L. Carrillo Perez,[1] Braulio A. Marfil,[1] Pablo E. Galindo,[1] Gerardo Gamba.[1,2] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Tlalpan, Mexico City, Mexico; [2]Instituto de Investigaciones Biomédicas, UNAM, Mexico City, Mexico.*

Background: The use of urinary exosomes (UE) is a non-invasive powerful tool to study the pathophysiology of renal diseases and also as a diagnostic tool for assessment of human samples. For instance, we have shown that in renal transplant patients, tacrolimus increases expression and phosphorylation of NCC in UE. Here we analyzed UE from patients with liver cirrhosis or chronic kidney disease (CKD) with and without edema to assess the expression of a variety of renal transporters.

Methods: We conducted a prospective and observational study. We obtained clinical and biochemical data, and urinary samples from adult patients with liver cirrhosis (Child B) (N=6 with, N=6 no-edema), with CKD (KDIGO G3-G5) (N=6 with, N=6 no-edema) and healthy subjects (N=5), as controls. UE from 8 ml of urine were obtained by ultracentrifugation for western blot analysis of SGLT2, NHE3, NKCC2, NCC and CaSR. The amount of UE used per patient was adjusted to urinary creatinine.

Results: We found no significant differences in laboratory findings of cirrhotic patients with or without edema, except for higher serum Na^+ in the edema group (133.9±4.9 vs. 140.1±2.1 p<0.05). In CKD patients, however, we found differences in the BMI (31±6.9 vs. 25±3 p<0.01), serum K^+ (5.2±0.39 vs. 4.6±0.55 p<0.01) and serum Ca^{2+} (8.6±0.47 vs. 9.3±0.75 p<0.05) in the edema vs. no-edema group, respectively. Analysis of UE showed a significant increase in NCC phosphorylation, SGLT2, NHE3 and CaSR expression in both cirrhotic and CKD patients when compared to healthy controls. In the cirrhotic patients, those with edema showed increased expression of SGLT2, NHE3 and CaSR vs. the non-edema group. In CKD patients, although the expression of these transporters looks higher in the edema group, the difference did not reach significance. Interestingly, NKCC2 expression showed no changes in any group.

Conclusions: We observed different expression patterns for five proteins in UE of cirrhotic and CKD patients. Moreover, in cirrhotic patients the expression of the transporters was higher in the edema group. These results suggest that the analysis of renal transporters using UE can give insights into the molecular mechanisms of salt retention in patients with edematous states and may contribute to the design of early therapeutic strategies.

Low Dietary Acid Intake May Help the Kidneys Improve Exercise Capacity Enni-Maria Hietavala,[2] Lynda A. Frassetto.[1] *[1]University of California San Francisco, San Francisco, CA; [2]University of Jyväskylä, Jyväskylä, Finland.*

Background: Diet composition influences the acid-base status of the body. The effects of differing acid balances may become more relevant as renal functional capacity declines with aging. We examined the effects of low (LD) versus high dietary acid load (HD) on blood bicarbonate and exercise performance.

Methods: The 88 healthy volunteers who participated - 22 adolescents (AD), 33 young adults (YA) and 33 elderly (EL) - followed a 7-day LD and HD in a randomized order. At the end of both diet periods the subjects performed a cycle ergometer test (3x10 min at 35%, 55%, 75%, and (except EL) until exhaustion at 100% of VO_2peak). At the beginning of, and after the diet periods, blood samples were collected at rest and after all workloads. Oxygen consumption, respiratory exchange ratio and heart rate were monitored during cycling. Glomerular filtration rate (GFR) was calculated with CKD-EPI equation. Two-way repeated measure ANOVA and Pearson correlation analyses were done on SPSS Statistics 22.0.

Results: Bicarbonate (HCO_3^-) decreased over the HD period in YA women (p<0.001), YA men (p=0.027), EL women (p<0.001) and EL men (p<0.001). HCO3- increased over the LD period in AD girls (p=0.005) and EL men (p=0.039). HCO_3^- was lower at rest after HD compared to LD in YA women (p<0.001), YA men (p=0.042) and in both EL groups (p<0.001). HCO_3^- was lower at submaximal workloads after HD compared to LD in YA women (p≤0.022) and EL women (p≤0.020). In young women, the maximal workload was 19 % shorter (p=0.001) and maximal cardiorespiratory measures (p≤0.029) lower after HD compared to LD.

Conclusions: Our data uniquely suggests that better renal function is associated with higher availability of bases, which may diminish exercise-induced acidosis and improve performance. Glomerular filtration rate decreased with aging and was higher in men compared to women, likely explaining the larger effects of dietary acid load on acid-base status in the elderly compared to younger subjects and in women compared to men. The diet composition along with renal functional capacity affects acid-base status of the body at rest and in exercise.

SA-OR069

Impact of Fluid Balance on One-Year Mortality of Patients with Septic Shock Tsering Dhondup,[1] Jong-Chie Claudia Tien,[1] Hon Liang Tan,[2] Alberto E. Marquez,[1] Kianoush Banaei-Kashani.[1] *[1]Mayo Clinic, Rochester, MN; [2]Singapore General Hospital, Singapore, Singapore.*

Background: Septic shock patients require early and aggressive volume resuscitation. However, current evidence shows higher risk with the intensity and duration of fluid overload in critically ill patients. In this report, we outline the impact of fluid balance and timing of volume de-resuscitation on outcomes in septic shock patients.

Methods: We retrospectively identified adult septic shock/ severe sepsis patients admitted to the ICU of Mayo Clinic Hospital from January 1st, 2007 to December 31st, 2009. Data was abstracted electronically and validated manually. We collected basic demographic, clinical, laboratory and outcome variables. Social security death index was used for missing mortality information. De-resuscitation day was defined as the 1st day with the negative fluid balance, and KDIGO criteria were used for AKI definition.

Results: A total of 633 patients were included with mean age of 68 years, with 348(55%) being males. Median ICU length of stay was 2.4 (IQR of 1.3-5.5) days, and median daily fluid balance in ICU was 2352 (IQR of 990-4323) ml. The median day-1 SOFA score was 7, and 57 (9%) patients had pre-existing ESRD. In ICU, de-resuscitation was achieved in 443 (70%) patients within [median (IQR)] 2 (1-3) days of ICU admission. Among those starting de-resuscitation in ICU, the average cumulative fluid balance was -1.4 (±5.7) liters. 371 of 576 non-ESRD (64%) patients developed AKI of which 291 patients were admitted with AKI. Eighty (22%) of those with AKI required initiation of dialysis with 63 patients being initiated on CVVH and 17 on intermittent hemodialysis.

Adjusted for age, Charlson Comorbidity Index, APACHE III score and day 1 SOFA score, every 1 liter positive cumulative fluid balance was associated with increased hospital mortality (OR of 1.10; 95% CI: 1.06-1.16) in patients who achieved de- resuscitation phase. More interestingly, every 1 liter positive cumulative fluid balance was also associated with increased 1-year mortality (OR of 1.07; 95% CI: 1.03-1.12). Association of positive cumulative fluid balance with increased risk of Hospital and 1-year death remained significant irrespective of pre-existing ESRD or AKI development.

Conclusions: In our cohort of patients with septic shock who achieved de-resuscitation, positive cumulative fluid balance was associated with increased hospital and 1-year mortality.

SA-OR070

TRC101, a Novel Hydrochloric Acid Binder, Increases Serum Bicarbonate in Acidemic Patients with CKD David A. Bushinsky,[5] Thomas H. Hostetter,[1] Robert J. Alpern,[4] Gerrit Klaerner,[3] Yuri Stasiv,[3] Claire Lockey,[3] Sarah McNulty,[3] Angela A. Lee,[3] Dawn Parsell,[6] Vandana S. Mathur,[2] Jerry M. Buysse.[3] *[1]Case Western Reserve Univ., Cleveland, OH; [2]Mathur Consulting, Woodside, CA; [3]Tricida, Inc., South San Francisco, CA; [4]Yale School of Medicine, New Haven, CT; [5]Univ. of Rochester, Rochester, NY; [6]Parsell Associates, Cedar Park, TX.*

Background: Metabolic acidosis is common in patients with chronic kidney disease (CKD) and has significant adverse effects on renal function, muscle, and bone. TRC101 is a novel, orally-administered, non-absorbed, metal and counterion-free polymer that selectively binds hydrochloric acid. In this study of acidemic CKD patients we evaluated the safety and tolerability of TRC101, and its effectiveness in increasing serum bicarbonate.

Methods: In this randomized, double-blind, placebo-controlled study, 135 acidemic CKD patients (eGFR 20 to <60 mL/min/1.73m^2) were admitted to an in-patient unit and treated for 14 days with placebo (BID or QD) or one of four TRC101 dosing regimens (1.5, 3.0, or 4.5 g BID; 6.0 g QD), while on a controlled diet. After completion of treatment, patients were discharged and followed for up to 14 days.

Results: Patients had a mean baseline eGFR of 34.8 mL/min/1.73m^2 and a mean baseline serum bicarbonate of 17.7 mEq/L. Comorbidities included hypertension (93%), diabetes (70%), and heart failure (22%). Within 72 hours of the first TRC101 dose, mean serum bicarbonate increased in each of the four TRC101 treatment groups by >1.4 mEq/L and was significantly increased ($p<0.0001$) by 3.1 - 3.8 mEq/L at the end of treatment compared to placebo. Mean serum bicarbonate continued to increase in all treatment groups over the course of the study while the mean bicarbonate in the placebo group remained stable. In the combined TRC101 treatment groups, serum bicarbonate was in the normal range (22 - 29 mEq/L) at the end of treatment in 34.6% of patients and increased by >4 mEq/L in 38.5% of patients. After discontinuation of TRC101, serum bicarbonate decreased nearly to baseline levels within 2 weeks. All adverse events were mild or moderate in intensity and there were no serious or severe adverse events. All patients completed the study.

Conclusions: In this 14-day study of acidemic CKD patients TRC101 was safe and well-tolerated and led to a significant increase in the level of serum bicarbonate.

Economic Evaluation of Contemporary Kidney Transplant Practice David A. Axelrod,[2] William Irish,[1] Mark Schnitzler,[3] Janet E. Tuttle-newhall,[5] Krista L. Lentine.[4] *[1]CTI, Raleigh, NC; [2]Lahey Hospital and Clinic, Burlington, MA; [3]Saint Louis Univ, St Louis, MO; [4]Saint Louis University, St. Louis, MO; [5]St Louis University Center for Outcomes Research, St Louis, AL.*

Background: Kidney transplantation (KT) has been established as the optimal therapy for medically suitable patients with end-stage renal disease, prolonging survival and reducing health care spending. However, KT economics using Markov models have assumed compatible donors of average or better quality. The economic implication of KT in contemporary practice including the use of high kidney donor profile index (KPDI) and public health service high risk (PHS) deceased donors, as well transplantation from ABO or HLA incompatible living donors, has not been assessed.

Methods: Using contemporary modeling techniques including Discrete Event Simulation (DES) over a 10-year time horizon, we compared the cost effectiveness of KT from varying donor types and dialysis for patients with kidney failure. DES models were constructed using data drawn from the United States Renal Data System, the national transplant registry, University HealthSystem Consortium, and literature review. Graft failure rates, transplant cost, and disease transmission events were adjusted for donor characteristics.

Results: All KT options resulted in improved patient survival compared to long term dialysis; however, the relative benefits and costs differed substantially (**Table**). Over a 10 year period, living donor KT with 0-3 HLA mismatches (mm) yielded 77.3 Quality Adjusted Life Months (QALM) at a cost of $53,982 per quality adjusted life year (QALY). By comparison, dialysis provided only 56.4 QALMs at a cost of $110,580 per QALY. HLA incompatible living donor KT was more expensive than dialysis, but resulted in an additional 12 QALM of survival over 10 years. Sensitivity analysis suggests that these results are robust over a clinically relevant range of inputs

Conclusions: KT is cost effective over across a spectrum of donor characteristics, despite higher costs for marginal organs and innovative living donor KT practices.

Funding: Private Foundation Support

COSTS, SURVIVAL & COST-EFFECTIVENESS BY RENAL REPLACEMENT MODALITY

Modality	Total Cost	Quality Adjusted Life Months	Cost per Quality Adjusted Life Year
Dialysis	$519,748	56.4	$110,589
KDPI > 85%	$452,772	64.2	$84,669
KDPI <= 85%	$394,690	72.3	$65,502
PHS High Risk Deceased Donor	$425,604	72.8	$70,206
HLA Incompatible Living Donor	$622,436	68.4	$109,132
ABOi Living Donor	$513,487	75.0	$82,158
HLA mm 4-6 Living Donor	$363,481	77.3	$56,467
HLA mm 0-3 Living Donor	$348,193	77.4	$53,983

SA-OR072

Association of Dialysis Facility Ownership on Access to Kidney Transplant Waitlist or Living Donor Transplant Jennifer C. Gander,[3] Katherine Ross,[3] Sumit Mohan,[1] Stephen O. Pastan,[4] Rachel E. Patzer.[2] *[1]Columbia University, New York, NY; [2]Emory Transplant Center, Atlanta, GA; [3]Emory University, Atlanta, GA; [4]Emory University School of Medicine, Atlanta, GA.*

Background: Past studies have shown for-profit facilities have lower rates of kidney transplantation (KT), but used older data that did not account for differences in facility ownership. Our aim was to examine the relationship between dialysis facility ownership and access to KT.

Methods: We linked adult, incident ESRD, United States Renal Data System (2000-2014) patient data with facility ownership (Dialysis Facility Compare) and facility-level characteristics (Dialysis Facility Report). Access to KT was defined as incident waitlisting or receipt of living donor KT. Facility ownership was categorized into one of five groups as either for-profit, large company (Groups A and B), for-profit small clinics(Group C), for-profit independent clinics (Group D), or non-for profit clinics (Group E). Hierarchical survival analysis assessed the association between access to KT and dialysis facility ownership while controlling for patient- and facility-level characteristics and patient-level clustering.

Results: Among 1,137,113 patients in our study cohort, 166,240 (14.6%) were waitlisted or received a living donor KT and among 6,263 U.S. facilities. In adjusted survival analysis, patients waitlisted or receiving a living donor KT were more likely to be Hispanic (HR=1.45; 95% CI 1.40, 1.51) and male (HR=1.39; 95% CI 1.33, 1.46), and less likely to have heart disease (HR=0.46; 95% CI 0.46, 0.47), and Medicaid insurance (HR=0.44; 95% CI 0.43, 0.45). ESRD patients receiving treatment from Group A and Group B facilities were less likely (HR=0.59; 95% CI 0.53, 0.66 and HR=0.57; 95% CI 0.51, 0.64; respectively) to be waitlisted or receive a living donor KT compared to non-profit facilities (Figure 1).

Conclusions: Dialysis facility ownership was found to be significantly associated with a patient's access to KT. Facilities can influence their patients' access to the KT waitlist and living donor KT. We urge CMS to adopt quality measures that hold dialysis facilities accountable for patient access to KT.

Funding: NIDDK Support

Figure 1. Adjusted* hierarchical survival analysis to determine the association between dialysis facility chain ownership and access to kidney transplantation, measured by a patient's placement on the waitlist or receipt of living donor kidney transplantation. (Reference group was Non-profit dialysis facilities)

Significantly Lower Rates of Transplantation and Increased Wait List Mortality among Kidney Transplant Candidates with VA Insurance Joshua J. Augustine,[1,2] Susana Arrigain,[1] Krishna P. Balabhadrapatruni,[2] Niraj Desai,[2] Jesse D. Schold.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland VAMC, Case Western Reserve University, Cleveland, OH.*

Background: Military veterans do not incur cost for kidney transplantation within the VA system, but transplant availability has historically been limited to just four VA

centers nationwide. Recent SRTR reports show a lower observed vs. expected rate of transplant in VA centers. Because VA centers are affiliated with non-VA academic centers within the same donor service area (DSA), we sought to compare transplantation rates nationally and also between the four VA centers and their non-VA (NVA) affiliates.

Methods: SRTR data was used to identify adult patients listed for a primary kidney transplant from 2004 through 2016. Patients with VA insurance (n=3663) were compared to those with private insurance (PI) (n=141,523), Medicaid (n=25,245) and Medicare (n=132,026). Analyses were conducted using multivariable Cox and competing risks regression models for time to transplantation, and unadjusted cumulative incidence functions of death with transplant as a competing risk.

Results: Compared to PI, VA patients were older and mostly male, with more black patients, diabetes, and vascular disease. VA patients lived much further from the transplant center compared to other groups (med. 282 vs. 23 miles). VA patients had a lower likelihood of transplantation compared to PI nationally (HR: 0.72(95% CI:0.69,0.76)), and compared to PI patients within the four NVA programs (HR: 0.78(95% CI:0.71,0.85). This difference with NVA centers persisted after excluding living donors (HR of 0.84(95% CI:0.76,0.93)), and in a model with death as a competing risk. VA patients also had a lower rate of transplantation vs. Medicare nationally (HR of 0.86(95% CI:0.82,0.91)) but did not differ from Medicare in the NVA centers. The HR of VA vs. Medicaid was not different nationally (HR 1.01(0.95,1.06)). The unadjusted cumulative incidence of waitlist mortality at 2 years was 7.0(95% CI:6.1,7.9) in VA patients, 5.8(5.6,5.9) in PI nationally, and 4.6(3.9,5.3) in PI within NVA centers.

Conclusions: VA patients had a lower rate of transplantation and greater waitlist mortality compared to PI patients both nationally and within four paired NVA academic centers that shared DSAs. The reasons for this discrepancy require further study, but may include differences in patient availability and organ acceptance between VA and non-VA centers.

SA-OR074

Hospitalizations for AKI in Kidney Transplant Recipients in the United States, 2004–2014 Tripti Singh, Nilay Kumar, Sana Waheed, Arjang Djamali, Neetika Garg. *School of Medicine and Public Health, University of Wisconsin, Madison, WI.*

Background: There is little information on the incidence of acute kidney injury (AKI) and mortality associated with AKI in hospitalized kidney transplant recipients.

Methods: We used the National Inpatient Sample 2004 – 2014 to identify hospitalizations with a primary or secondary diagnosis of AKI in the setting of known history of kidney transplantation. Survey analysis techniques were used to generate national estimates. Linear and logistic regression were used to test trends in outcomes.

Results: There were 36,457 hospitalizations for AKI representative of 176,128 hospitalizations nationally in renal transplant recipients during the study period. Mean age of kidney transplant recipients admitted for AKI was 55.5 years and 43.4% were females. There was a significant increase in the comorbidity burden during the period of study (Charlson comorbidity index 1.3 in 2004 to 2.8 in 2014, p<0.001). There was a nearly threefold increase in hospitalization rate for AKI (52 to 135/1000 transplant recipients, p<0.001) over 10 years. We found a concomitant decline in in-hospital mortality, dialysis requirement and length of stay (LOS) along with a modest but significant negative trend in cost. Utilization for intubation and mechanical ventilation increased during the study period.

Conclusions: Hospitalizations for AKI have increased in the kidney transplant recipients but in-hospital outcomes and resource utilization have improved significantly. Further study is warranted to understand the reasons for increasing rate of hospitalizations for AKI in renal transplant patients.

Hospitalizations in kidney transplant recipients for AKI

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	P-trend
Hospitalization rate (per 1000 renal transplant recipients)	51.6	58.6	69.4	81.3	91.6	105.1	111.2	109.0	114.2	122.6	134.8	<0.001
In-hospital mortality (%)	5.2	4.9	4.4	3.8	4.3	4.2	3.0	3.6	3.7	3.4	3.6	0.001

SA-OR075

Consequences of Declining a Public Health Service Increased Risk (PHS-IR) Donor Kidney Hilda E. Fernandez, Mariana C. Chiles, Marcus Pereira, Syed A. Husain, Sumit Mohan. *NYP-CUMC, NYC, NY.*

Background: The risk of disease transmission from PHS-IR kidney donors is extremely low but the perception increased risk by patients may adversely impact their willingness to accept these organs.

Methods: We performed a retrospective, single-center study of all PHS-IR kidney offers made to patients at Columbia University Medical Center (CUMC) from 6/2004 to 5/2015 to 1) identify who was likely to accept these organs and 2) assess the potential consequences of declining such offer.

Results: Among 2423 candidates who received a PHS-IR kidney offer, 358 accepted and 2065 declined. On multivariate analysis, higher estimated post-transplant survival (EPTS) score (OR=1.005, p=0.025), male sex (OR=1.345, p=0.035), and higher educational achievement (OR=0.693, p=0.025) appear to influence organ offer acceptance. Among those who declined, 57.5% subsequently received a non-PHS-IR transplant while 16.5% remained on the waitlist. Acceptance of a PHS-IR offer was associated with a lower mortality (3.63% vs 11.6%; adjusted HR 0.467, p=0.0008) and PHS-IR allografts were associated with lower death censored allograft failure rates (HR = 0.677, p=0.041).

Conclusions: Declining a PHS-IR kidney offer appears to be associated with a survival disadvantage at our center. This underscores the importance of patient education regarding the risks and benefits of PHS-IR organs. Efforts must be made to increase acceptance of PHS-IR organs in order to improve outcomes for those on the waitlist.

Abstract Withdrawn

SA-OR077

Obesity Is a Risk Factor for New-Onset Diabetes Mellitus after Living Kidney Donation Krista L. Lentine,[8] Farrukh M. Koraishy,[8] Abhijit S. Naik,[4] Ngan Lam,[9] David A. Axelrod,[3] Mark Schnitzler,[5] Zidong Zhang,[8] Gregory P. Hess,[2] Amit X. Garg,[7] Bertram L. Kasiske,[1] Daniel C. Brennan,[10] Dorry L. Segev.[6] *[1]Hennepin County Medical Center, Minneapolis, MN; [2]LDI University of Pennsylvania/IMS, Plymouth Meeting, PA; [3]Lahey Hospital and Clinic, Burlington, MA; [4]None, Ann Arbor, MI; [5]Saint Louis Univ, St Louis, MO; [6]Johns Hopkins University, Baltimore, MD; [7]London Health Sciences Centre, London, ON, Canada; [8]Saint Louis University, St. Louis, MO; [9]University of Alberta, Edmonton, AB, Canada; [10]Washington University in St. Louis, St. Louis, MO.*

Background: End-stage renal disease is uncommon in living kidney donors (LKD), but most kidney failure developing late after donation appears to be due to diabetes or hypertension. To improve understanding of the relationship of obesity and post-donation diabetes mellitus (PDDM), we examined a novel linkage of national transplant registry data with records from a pharmacy claims clearinghouse that identifies diabetes treatments.

Methods: Among 20,238 LKD with at least 1 year of pre-donation pharmacy records, fills for insulin and non-insulin diabetes agents were examined as measures of new-onset PDDM. Time to first fill of insulin or other diabetes agents in relation to body mass index (BMI), age, sex, race, and other clinical factors in the registry was examined by Kaplan-Meier analysis and Cox regression (adjusted hazard ratio, $_{LCL}$ aHR $_{UCL}$).

Results: Mean age at donation was 42.7 years. Of LKD, 67.5% were women; 75% white, 10.5% black, and 10.9% Hispanic; 40.8% were overweight (BMI 25-<30 m2) and 22.8% were obese (BMI ≥30 kg/m2). The 5-year risk of non-insulin PDDM treatments rose in a graded manner with higher BMI, from 0.6% in normal weight to 3-fold increased risk in overweight (1.5%, aHR, $_{1.76}3.05_{5.27}$) and 3.4% in obese (3.4%, aHR, $_{3.70}6.45_{11.03}$) LKDs. Adjusted 5-year risk of insulin use after donation was 5 times higher in obese than in normal weight LKDs (1.1% vs 0.04%, aHR, $_{1.09}5.24_{25.3}$). **[Fig1].** Once PDDM treatments were started, use of non-insulin agents and insulin continued over 99% and 30% of remaining observation.

Conclusions: Obesity is a strong correlate of PDDM treatments in LKD. Future research should define relationships of obesity and PDDM with outcomes including kidney failure after donation.

Early Post-Donation eGFR and ESRD in Living Kidney Donors <u>Allan Massie</u>,[3] Lara Fahmy,[2] Macey L. Henderson,[1] Jon J. Snyder,[5] Courtenay M. Holscher,[4] Sandra R. Dibrito,[1] Dorry L. Segev.[4] *[1]Johns Hopkins, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Detroit, MI; [3]Johns Hopkins School of Medicine, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD; [5]Minneapolis Medical Research Foundation, Minneapolis, MN.*

Background: Several studies have shown higher ESRD risk in living kidney donors (LKDs) compared to healthy nondonors. All LKDs may not equally tolerate nephrectomy. Identifying post-donation risk factors for ESRD would improve post-donation counseling and care. We studied the association between early post-donation eGFR and subsequent ESRD risk.

Methods: Using SRTR data, we studied 64,989 LKDs 1999-2015 who were ESRD-free 9 months post-donation and who had at least one valid post-donation SCr value reported to OPTN between 3-30 months post-donation. When eGFR measured between 3-9 months post-donation (6-month eGFR) was missing, we multiply imputed based on pre-donation eGFR and other post-donation eGFR values. We studied the association between 6-month eGFR and post-donation ESRD (via CMS linkage) using Cox regression, adjusting for age, sex, race (black vs nonblack), pre-donation eGFR, BMI, and 1st-degree biological relationship to recipient.

Results: Median (IQR) 6-month eGFR was 63.2 (54.2-74.3) mL/min/1.73 m^2. Out of 64,989 donors, 50 progressed to ESRD during the study period. Donors with lower 6-month eGFR had greater incidence of ESRD (Figure). There was no evidence of association between pre-donation eGFR and post-donation ESRD risk (p=0.3, Table). A 10-unit difference in 6-month eGFR was associated with 32% decreased risk of ESRD (aHR=$_{0.53}$ 0.68 $_{0.87}$, p<0.01, Table).

Conclusions: Lower eGFR in the first 6 months post-donation is associated with higher subsequent risk of post-donation ESRD in living kidney donors. Careful monitoring of early post-donation eGFR is essential to provide adequate post-donation care and counseling.

Estimated GFR before Living Kidney Donation as a Predictor of Postdonation Measured GFR <u>Marco van Londen</u>, Jessica V. Weijden, Robert Pol, Jan-Stephan Sanders, Stefan P. Berger, Stephan J. Bakker, Gerjan Navis, Martin H. De Borst. *University Medical Center Groningen, Groningen, Netherlands.*

Background: In living kidney donor screening, precise renal function measurement is vital to ensure adequate postdonation renal function. Measured GFR (mGFR) is the gold standard, but costly and laborious. We tested the capacity of predonation estimated GFR (eGFR) equations to predict postdonation mGFR.

Methods: In a single-center prospective cohort study in 750 living kidney donors, we determined predonation mGFR (continuous iothalamate) including dopamine stimulation, and creatinine-based eGFR (CKD-EPI, Cockcroft-Gault and MDRD equations), as well as mGFR at 3 months postdonation. We used linear regression, Receiver Operating Characteristic curves, and Bayesian statistics to test the performance of eGFR equations.

Results: Mean donor age was 51±11 years, 48% of donors were male. Predonation mGFR was 102±16 ml/min/1.73 m^2, stimulated mGFR was 110±18 ml/min/1.73 m^2, $eGFR_{CKD\text{-}EPI}$ was 88±14 ml/min/1.73 m^2, $eGFR_{CG}$ was 93±19 ml/min/1.73 m^2, and $eGFR_{MDRD}$ was 86±16 ml/min/1.73 m^2. Postdonation mGFR was 65±11 ml/min/1.73 m^2. Predonation mGFR and the results of the three eGFR formulas were positively associated with postdonation mGFR (mGFR R^2=0.49, dopamine stimulated mGFR R^2=0.34, $eGFR_{CKD\text{-}EPI}$ R^2=0.21, $eGFR_{CG}$ R^2=0.22, $eGFR_{MDRD}$ R^2=0.14). A predonation $eGFR_{CKD\text{-}EPI}$ >102 ml/min/1.73 m^2 (present in 16% of donors) excludes a postdonation mGFR <60 ml/min/1.73 m^2 with a specificity of 100% (AUC 0.74), for predonation $eGFR_{CG}$ this threshold is 114 ml/min/1.73 m^2 (AUC 0.78) and for $eGFR_{MDRD}$ 114 ml/min/1.73 m^2 (AUC 0.70). A predonation $eGFR_{CKD\text{-}EPI}$ of 95 ml/min/1.73 m^2 (present in 30% of donors) excludes a postdonation mGFR of <50 ml/min/1.73 m^2 with 100% specificity (AUC 0.78), for predonation $eGFR_{CG}$ this threshold is 105 ml/min/1.73 m^2 (AUC 0.82) and for $eGFR_{MDRD}$ 97 ml/min/1.73 m^2 (AUC 0.74).

Conclusions: We provide cut-off values for predonation donor eGFR to select donors with a high probability of good renal function postdonation without requiring mGFR measurement. In order to avoid incorrect exclusion of a large proportion of donors, additional renal function tests such as measured GFR are warranted in donors with an $eGFR_{CKD\text{-}EPI}$ <95 ml/min/1.73 m^2.

SA-OR080

Predonation Recruitment of Renal Functional Reserve Capacity Is Associated with Early Renal Adaptation after Living Kidney Donation <u>Marco van Londen</u>, Jessica V. Weijden, Jan-Stephan Sanders, Stefan P. Berger, Stephan J. Bakker, Martin H. De Borst, Gerjan Navis. *University Medical Center Groningen, Groningen, Netherlands.*

Background: Early renal adaptation after kidney donation results in a GFR above 50% of the predonation value. This is probably due to early hemodynamic changes, whereas long-term renal adaptation, which may further increase GFR in the months thereafter is likely more structural in nature. Recruitment of Renal Reserve Capacity assessed by the renal response to dopamine infusion (RRC) is considered to reflect functional reserve capacity, but it is unknown whether it predicts short- or long-term renal adaptation or both. In this study we investigate the association between pre-donation RRC and GFR changes after donation.

Methods: In 750 living kidney donors between 1984 and 2017, we prospectively measured mGFR (^{125}-Iothalamate clearance) and RRC. We performed multivariable linear regression analysis with short-term postdonation mGFR as dependent variable. In a subgroup with 5 year follow-up after donation we assessed the association with long-term mGFR.

Results: Mean donor age was 52±11 years, 48% were male. Mean predonation mGFR was 107±28 ml/min, $mGFR_{Dopamine}$ was 115±30 ml/min, resulting in a RRC of 9 ±10 ml/min. Three months postdonation, mGFR was 73±15 ml/min and $mGFR_{Dopamine}$ was 76±15 ml/min, indicating that donors still had RRC (2.7±5.8 ml/min, p<0.001). Predonation RRC was associated with mGFR preservation, independent of age, mGFR, blood pressure and BMI (st. β 0.12, p<0.001, final model R^2=0.63). In the subgroup of donors of whom 5-year follow-up data was available, RRC was neither associated with absolute mGFR at 5 years postdonation (st. β 0.02, p=0.78), nor with compensatory mGFR increase between 3 months and 5 year after donation (st. β 0.03, p=0.67).

Conclusions: Dopamine-recruited renal reserve capacity is independently associated with preservation of mGFR early after donation, but not with long-term mGFR. This indicates that $RC_{Dopamine}$ is a marker of early, hemodynamic-driven, adaptation to kidney donation rather than long-term mGFR changes. More long-term follow-up data are needed to provide conclusive results about the use of dopamine in living kidney donors.

Role of COUP-TFII in Pericyte Activation and Kidney Fibrosis Li Li, Xiaoyan Xiao, Takaharu Ichimura, Julia Wilflingseder, Joseph V. Bonventre. *Brigham & Women's Hospital/Harvard Medical School, Boston, MA.*

Background: Genetic fate mapping studies suggest that pericytes are the main source of myofibroblasts enriched in injury-induce kidney fibrosis. The transcriptional network that controls the pericyte-myofibroblast transdifferentiation is poorly understood. Chicken Ovalbumin Upstream Promoter-Transcription Factor II (COUP-TFII) is a transcription factor critical to the kidney development. It is broadly detected in the mesenchyme of developing organs and has a profound impact on organogenesis and cell fate determination.

Methods: We measured COUP-TFII mRNA by quantitative real-time PCR (qRT-PCR) and protein by Western Blot from normal C57BL/6 mouse kidneys and at different times after unilateral ureter obstruction (UUO). To assess the origin of COUP-TFII+ cells, we crossed Forkhead Box D1 (Foxd1)-Cre driver mice to tdTomato reporter mice to genetically label the Foxd1-derived stromal cells. In vitro, knockdown of COUP-TFII was attained by transfecting a small interfering RNA (siRNA) into CH310T1/2 (pericyte-like cells). COUP-TFII and αSMA expression was evaluated in tissue by immunostaining and in siRNA-transfected CH310T1/2 by RT-PCR.

Results: In non-injured kidney, expression of COUP-TFII is sparsely distributed in interstitial cells, Bowman's capsule and to a lesser extent in tubules. Cells expressing COUP-TFII are PDGFRβ+ (pericytes/fibroblasts) and are adjacent to CD31+ (endothelial) cells. Most COUP-TFII+ cells are localized in the region of Foxd1-derived stromal cells. Upon injury, COUP-TFII expression is significantly increased in αSMA+ cells (myofibroblasts) localized within the fibrotic region. COUP-TFII expression did not overlap with F4/80 (macrophages) staining. Both mRNA and protein levels of COUP-TFII increased at 5, 7 and 10 days after UUO and are associated with increased levels of αSMA at the same time point. In vitro, knockdown of COUP-TFII by siRNA results in decreased αSMA expression in pericyte-like cells.

Conclusions: COUP-TFII is expressed at basal levels in non-injured kidney in Foxd1-derived stromal cells. Upon injury, COUP-TFII expression increased in αSMA+ cells localized within the fibrotic region. Attenuation of COUP-TFII expression is associated with reduced expression of αSMA in pericyte-like cells. These data suggest that COUP-TFII may play a role in the regulation of pericyte-myofibroblast transdifferentiation in injury-induce kidney fibrosis.

The Breast Cancer Type 1 Susceptibility Protein (BRCA1) Mediates Fibrotic Kidney Disease Akinwande A. Akinfolarin, Amrendra K. Ajay, Venkata Sabbisetti, Joseph V. Bonventre. *Brigham and Women's Hospital, Boston, MA.*

Background: Repetitive tubular injury leads to chronic fibrotic kidney disease (CKD). Chemical, ischemic and obstructive kidney injuries lead to replication fork arrest (RFA) and double strand DNA breaks (DSB), triggering the DNA damage response. *BRCA1* is a breast tumor suppressor gene with a role in homologous recombination (HR) and maintenance of genome integrity by DNA repair. Here we deplete BRCA1 in the adult mouse proximal tubule (PT) to examine its effect on the development of interstitial fibrosis

Methods: *SLC34A1 Cre* mice were crossed to mice with floxed *BRCA1 exon 11* allele yielding models of inducible PT *BRCA1* gene deletion. After Tamoxifen-induced *Cre* activation, we subjected mice to bilateral ischemia/reperfusion (I/R), unilateral ureteric obstruction (UUO), or aristolochic acid (AA)-induced injury. Kidney extracts were evaluated by western blot, real time PCR and Masson's trichrome (MT) and Picrosirius Red (PS) staining for markers of interstitial fibrosis. Markers of DNA damage, cell cycle arrest and senescence were examined by immunofluorescence. BRCA1 was also down regulated in PT cells using short-hairpin RNA against *BRCA1* and cells were treated with AA and cisplatin to explore the relationship between injury and cell cycle stage, apoptosis and secretory senescence

Results: There was reduced kidney fibrosis in mice heterozygous ($BRCA1^{WT/\Delta11}$) and homozygous ($BRCA1^{\Delta11/\Delta11}$) for PT *BRCA1* deletion compared to wild type ($BRCA1^{WT/WT+}$) littermate controls by MT and PS staining after I/R, UUO or AA. There was a corresponding decrease in fibrogenic factors including CTGF, COL4A1, fibronectin and ACTA2 in the $BRCA1^{WT/\Delta11}$ and $BRCA1^{\Delta11/\Delta11}$ mice. There was a decrease in the markers of cell cycle arrest and senescence ($p16^{ink4a}$ and GATA4) and an increase in apoptosis among $BRCA1^{WT/\Delta11}$ or $BRCA1^{\Delta11/\Delta11}$ mice when compared to WT mice. These murine data were supported by in vitro experiments with AA and Cisplatin after depleting BRCA1 in PT cells which caused less G2 cell cycle arrest and secretion of fewer fibrogenic factors

Conclusions: BRCA1 facilitates interstitial fibrosis following kidney tubular injury in mice through its role in DNA damage response and induction of senescence. We have thus identified a novel role of BRCA1 in non malignant pathobiology.

Bone Marrow Stromal Cell Antigen-1 Identified by RNA-Seq and ChIP-Seq Is important for Inducing Renal Ischemia-Reperfusion Injury and Fibrosis Tsuyoshi Inoue,[2] Liping Huang,[2] Diane L. Rosin,[2] Katsuhiko Ishihara,[3] Youichiro Wada,[1] Mark D. Okusa.[2] *[1]University of Tokyo, Tokyo, Japan; [2]University of Virginia, Charlottesville, VA; [3]Kawasaki Medical School, Kurashiki, Japan.*

Background: Sphingosine kinase 2-deficient mice (SphK2KO) develop less fibrosis after unilateral kidney ischemia-reperfusion injury (IRI). Sphingosine 1-phosphate (S1P) produced by SphK2 inhibits histone deacetylase (HDAC) and changes in histone acetylation status, which can lead to an altered target gene expression. The aim of this study is to elucidate new mechanisms of kidney fibrosis through epigenetic changes.

Methods: RNA-seq and ChIP-seq of H3K9ac and H3K27ac using primary renal fibroblasts from WT, Sphk1KO and Sphk2KO mice were performed. Flow cytometry was used to identify bone marrow stromal cell antigen-1 (BST-1/CD157) expression in hematopoietic cells. In addition, bone marrow chimeric mice were created to evaluate the role of BST-1 in bone marrow-derived cells. Unilateral IRI was used as a renal fibrosis model and bilateral IRI was used as an acute kidney injury (AKI) model.

Results: The combination of RNA-seq and ChIP-seq analysis yielded 30 candidate genes that might be regulated by SphK2 through epigenetic change. We applied SphK2 knock down to WT fibroblasts and overexpression to fibroblasts from SphK2KO to determine if the selected genes are regulated by SphK2. Gene expression was also evaluated using an in vivo fibrosis model. *Bst1* was identified as a gene that is regulated by SphK2 through a change in histone acetylation level. *Bst1*-deficient mice (*Bst1*KO) developed less fibrosis after renal unilateral IRI and were protected against renal bilateral IRI in the AKI model. Bone marrow chimera experiments further revealed that BST-1 expression on hematopoietic, but not parenchymal cells, is responsible for inducing renal IRI and fibrosis. BST-1 was found mainly in B cells and neutrophils by flow cytometry of spleen and bone marrow. The migration of neutrophils from *Bst1*KO was suppressed, and adoptive transfer of neutrophils from *Bst1*WT mice abolished the renal protective effect in *Bst1*KO mice.

Conclusions: *Bst1* is a gene that is regulated by SphK2 through epigenetic change and is critical in kidney injury and fibrosis. *Bst1*KO mice are protected against renal IRI and develop less fibrosis. Furthermore *Bst1* expression in neutrophils plays an important role in inducing renal ischemia-reperfusion injury and fibrosis.

BET Protein Family Member BRD4 Promotes Transcription through Super-Enhancer Activation in Kidney Repair and Progression of Fibrosis Julia Wilflingseder,[1,2] Michaela Willi,[2] Chaochen Wang,[2] Hannes Olauson,[1,3] Takaharu Ichimura,[1] M. Todd Valerius,[1] Lothar Hennighausen,[2] Joseph V. Bonventre.[1] *[1]Renal Division, Brigham & Women's Hospital/Harvard Medical School, Boston, MA; [2]Laboratory of Genetics and Physiology, NIDDK/NIH, Bethesda, MD; [3]Division of Renal Medicine, Karolinska Institutet, Stockholm, Sweden.*

Background: The mammalian kidney can repair after acute kidney injury (AKI) through robust proliferation of tubular epithelial cells. Maladaptive repair can however lead to kidney fibrosis and chronic kidney disease (CKD). There is currently limited understanding of which transcriptional regulators activate these repair programs and how transcriptional deregulation leads to CKD. Here we investigate the existence of enhancer regulatory elements occupied by BRD4 that are activated in regenerating mouse kidney.

Methods: RNA-Seq and CHIP-Seq (H3K27ac, H3K4m3, BRD4, MED1, POL2) were performed on samples from repairing kidney cortex day 2 after ischemia reperfusion injury (IRI) to identify activated genes, transcription factors, enhancer and super-enhancers associated with kidney repair. Further we investigated the role of super-enhancer activation in kidney repair through pharmacological BET inhibition via the small chemical compound JQ1 in vitro and in three kidney injury models in vivo.

Results: Here we establish the enhancer and super-enhancer landscape associated with kidney injury and repair. Furthermore, we identify key transcription factors, which cooperate with BRD4 and MED1 at enhancer sites, likely activating repair programs in tubular epithelial cells. Loss of BRD4 function by systemic administration of the

BET inhibitor JQ1 (50mg/kg/d) before IRI leads to impaired recovery after AKI and increased mortality between day 2 and 3 after injury. By contrast, inhibition of prolonged transcriptional responses during repair, through blockade of BRD4 at enhancer sites via JQ1 starting at day 2 and day 7 after injury, ameliorates interstitial fibrosis in UUO, unilateral IRI and aristolochic acid (AA) kidney injury models at day 10 and day 21, respectively.

Conclusions: These results are the first demonstration of BRD4 enhancer and super-enhancer function in the repairing kidney, providing a critical link between AKI and CKD. In addition, our data call attention to potential caveats for use of small molecule inhibitors of BET proteins that are already being tested in clinical trials in patient at risk for AKI. Our comprehensive analysis of epigenetic changes after kidney injury in vivo has the potential to identify new targets for therapeutic intervention.

Endocycle-Mediated Hypertrophy and Progenitor Proliferation as Central Mechanisms of Response to AKI Elena Lazzeri, Maria Lucia Angelotti, Anna J. Peired, Carolina Conte, Laura Lasagni, Paola Romagnani. *Center of Excellence DENOthe, Department of Biomedical Experimental and Clinical Sciences, University of Florence, Florence, Italy.*

Background: Acute kidney injury (AKI) is considered a reversible disease because of the capacity of all tubular cells to proliferate as demonstrated by proliferation markers. As AKI can be followed by chronic kidney disease (CKD), we questioned the high intrinsic regenerative capacity of tubules.

Methods: To investigate the proliferative capacity of tubules after AKI, we developed 2 conditional transgenic mouse models: 1. *Pax8.rtTA;TetO.Cre;R26.FUCCI2aR* (Pax8/FUCCI2aR) to track all tubular cells; 2. *Pax2.rtTA;TetO.Cre;R26.FUCCI2aR* (Pax2/FUCCI2aR) to track a putative scattered tubular progenitor population. After doxycycline administration, we investigated the reporter expression in Pax8 and Pax2 cells (cells in G1 phase are mCherry+, in S/G2/M phase are mVenus+) in healthy and at 30 days after unilateral ischemia reperfusion injury (IRI).

Results: Confocal analysis of Pax8/FUCCI2aR mice demonstrated that immunostaining for proliferation markers (KI-67, PCNA and p-H3) didn't mirror exactly cell-cycle phase as indicated by FUCCI2aR reporter. This suggests that cell-cycle markers indicate cell-cycle activation but not cell division after IRI. We, therefore, explored aberrant cell-cycles such as endocycle, where G1 and S proceed repeatedly wihout mitosis, generating cells arrested in G1 phase with a doubled DNA content and an increased size. To detect these cells, we combined FUCCI2aR expression and DNA content assessment by flow-cytometry. This analysis revealed that 11.5±0.8% of Pax8+tubular cells underwent endocycles at day 30 after IRI. Most of endocycling cells were in S1-S2 segments of the cortex with a higher cell surface area in comparison to cells in G1 phase. Accordingly, tubular cell hypertrophy *via* endocycle is the dominant feature in the cortex of human biopsies with CKD after AKI. By contrast, Pax2+tubular cells didn't undergo endocycle but rather complete mitosis at day 30 after IRI. Automatic quantification analysis by flow-cytometry demonstrated that while Pax8+tubular cells are irreversibly lost, Pax2+tubular cells are the only proliferating cells, generating new tubular cells after AKI.

Conclusions: These results demonstrate that, although limited regeneration occurs *via* Pax2 cell proliferation, persistent tubular cell loss and tubular cell hypertrophy *via* endocycle are the dominant features after AKI.

SA-OR086

YAP, Not TAZ, Mediates EGF Receptor Dependent Renal Recovery from AKI Jianchun Chen, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Both EGFR and the Hippo signaling pathway are implicated in cell proliferation and differentiation. Our previous studies have shown that activation of EGFR in renal proximal tubule epithelial cells (RPTC) plays a critical role in functional and structural recovery from Ischemia-reperfusion injury (IRI). YAP and TAZ, two key downstream effectors of Hippo pathway, are activators for multiple gene transcriptional factors in the nucleus. The goal of these studies was to determine whether YAP and/or TAZ play a role in mediating EGFR's effects in AKI.

Methods: Mice with EGF receptor deletion ($Egfr^{ptKO}$), inducible $SLC34a1^{GCE}$-Cre mediated Yap/Taz double deletion ($Yap/Taz^{l\text{-}ptDKO}$) or Taz single deletion ($Taz^{l\text{-}ptKO}$) specifically in renal proximal tubule epithelial cells (RPTC) or their wild type littermates (WT) were subjected to ischemia-reperfusion injury (IRI). We also determined the effects of silencing EGFR, AKT1 and YAP gene expression by specific siRNAs in a human renal proximal tubule epithelial cell line (hRPTC) on cellular responses to hypoxia exposure for 3 h followed by reoxygenation for either 3 h or 8 h.

Results: Deletion of EGFR specifically in RPTC or administration of an EGFR tyrosine kinase inhibitor, Erlotinib, markedly inhibited YAP expression and nuclear translocation and the YAP downstream target gene, amphiregulin, in response to IRI. Deletion in renal proximal tubule of both *Yap* and *Taz* but not *Taz* alone delayed renal recovery from IRI. BUN remained elevated in $Yap/Taz^{l\text{-}ptDKO}$ mice at day 7 (64 ± 2.5 mg/dl, n=3, P<0.05), while decreasing to 39 ± 3.8 mg/dl or 32 ± 2.5 mg/dl in the $Taz^{l\text{-}ptKO}$ mice or the WT mice after IRI. Upregulation of amphiregulin and cyclin D and phosphorylation of retinoblastoma protein (Rb) in response to IRI were inhibited in $Egfr^{ptKO}$ and the $Yap/Taz^{l\text{-}ptDKO}$ mice. Exposure of the hRPTC to hypoxia followed by reoxygenation increased YAP nuclear translocation, amphiregulin expression, cyclin D expression and Rb phosphorylation, which were inhibited by an EGFR tyrosine kinase or PI3K inhibitor treatments or transfection of EGFR, AKT1 or YAP specific siRNAs.

Conclusions: This study demonstrates that EGFR-PI3K-Akt dependent YAP activation plays an essential role in mediating epithelial cell regeneration during kidney recovery from AKI.

SA-OR087

Gli1+ Pericytes Are Required for AKI Recovery and Regulate Renal Function Flavia G. Machado,[3] Eoghainín O hAinmhire,[1] Benjamin D. Humphreys.[2] *[1]Washington University, Lake St. Louis, MO; [2]Washington University School of Medicine, Clayton, MO; [3]Washington University in St Louis, School of Medicine, St Louis, MO.*

Background: Gli1+ pericytes support the peritubular vasculature, and their ablation causes transient tubular injury and permanent, subclinical, capillary rarefaction. Whether Gli1+ pericytes are required for renal repair after AKI is unknown.

Methods: We evaluated distribution and density of Gli1+ pericytes after bilateral IRI (bIRI) using Gli1-nLacZ reporter mice. We tested whether the Gli1+ population is fixed or dynamic using Gli1-nLacZ;Gli1CreERT2;R26-tdTomato triple transgenic mice. We asked whether Gli1+ pericytes are required for AKI repair by ablating them and measuring GFR by FITC-sinistrin, then performing biIRI. We also tested the effect of pharmacologic blockade of hedgehog signaling on biIRI recovery with the smoothened inhibitor LDE225.

Results: Gli1+ cells expand in the cortex and outer medulla during AKI recovery. There is substantial de novo Gli1+ expression, as well as loss of Gli1 expression in previously Gli1+ cells, as assessed with Gli1-nLacZ; Gli1CreERT2; R26-tdTomato mice. tdTom single positive and tdTom/nLacZ double positive cell populations increased 3-fold by two weeks after IRI. By contrast, nLacZ single positive cells increased 7-fold. Genetic ablation of Gli1+ cells spontaneously reduced GFR of 242±108ml/min/100gBW (delta baseline vs. after DTX). Mice with ablated Gli1+ pericytes had substantially increased mortality after biIRI (50% 7d after injury, p<0.05 vs. PBS injected mice with 100% survival). Surviving mice 7 days after bIRI had poorer renal recovery compared to controls (434±69 ml/min/100gBW) with 35% of their baseline renal function (vs. 62% on PBS group, p<0.05). Inhibition of hedgehog signaling had a similar effect: 3 days after bIRI mice that received LDE225 exhibited 60 – 80% mortality whether drug was given before or after IRI. Mice receiving vehicle had no mortality.

Conclusions: The Gli1+ pericyte population is not fixed but expands after AKI through both recruitment and proliferation. These cells are required for repair from AKI since their ablation increases mortality and reduces GFR during repair. We suggest that the mechanism is via the hedgehog-Gli signaling pathway itself, since inhibition of smoothened had the same effect after biIRI as Gli1+ cell ablation.

SA-OR088

Myeloid Mineralocorticoid Receptor Controls Inflammatory and Fibrotic Responses after Renal Ischemic Injury via Macrophage Interleukin-4 Receptor Jonatan Barrera-Chimal,[3] Sebastian M. Lechner,[1] Soumaya El moghrabi,[1] Peter Kolkhof,[2] Frederic Jaisser.[1] *[1]INSERM U1130, Centre de Recherche des Cordeliers, Paris, France; [2]BAYER AG, Wuppertal, Germany; [3]Instituto de Investigaciones Biomédicas, UNAM, ----Mexico City, Mexico.*

Background: Pharmacological mineralocorticoid receptor (MR) antagonism is useful to prevent chronic kidney disease (CKD) after an episode of ischemic acute kidney injury (AKI) in the rat. We aimed to test the involvement of myeloid MR in the development of kidney fibrosis after an ischemic AKI episode.

Methods: We included 18 male C57/B6 mice that were divided in: sham, renal ischemia for 22.5 min and IR plus treatment with the non-steroidal MR antagonist finerenone (10 mg/kg) at -48, -24 and -1 h before IR. MR inactivation in myeloid cells (MR^{MyKO}) was achieved by crossing mice with the MR alleles flanked by loxP sites ($MR^{f/f}$) with mice expressing the Cre recombinase under the LysM promoter activity. In $MR^{f/f}$ and MR^{MyKO} mice we induced renal IR of 22.5 min or sham surgery. The mice were followed-up during 4 weeks to test for AKI to CKD transition. In another set of mice, the macrophages were sorted from kidneys after 24 h of reperfusion for flow cytometry analysis or mRNA extraction. Thyoglycolate elicited peritoneal macrophages were used for *in vitro* studies.

Results: The progression of AKI to CKD after 4 weeks of renal ischemia in the untreated C57/B6 and $MR^{f/f}$ mice was characterized by a 50% increase in plasma creatinine, a 2-fold increase in the mRNA levels of TGF-b and fibronectin as well as by severe tubule-interstitial fibrosis. The mice that received finerenone or MR^{MyKO} mice were protected against these alterations. Increased expression of M2-anti-inflamatory markers in kidney-isolated macrophages from finerenone-treated or MR^{MyKO} mice was observed. The inflammatory population of $Ly6C^{high}$ macrophages was reduced by 50%. In peritoneal macrophages in culture, MR inhibition promoted increased IL-4 receptor expression and activation, facilitating macrophage polarization to an M2 phenotype.

Conclusions: MR antagonism or myeloid MR deficiency facilitates macrophage polarization to an M2, anti-inflammatory phenotype after kidney IR, preventing maladaptive repair and chronic kidney fibrosis. MR inhibition acts through the modulation of IL-4 receptor signaling to facilitate macrophage phenotype switching.

SA-OR089

Biodistribution and Homing of Human Endothelial Colony Forming Cell-Derived Exosomes in Ischemia-Reperfusion AKI Jose L. Vinas,[1] Matthew Spence,[4] William A. Knoll,[1] Alex Gutsol,[4] Dylan Burger,[1] David Allan,[2] Kevin D. Burns.[3] *[1]Kidney Research Centre, Ottawa, ON, Canada; [2]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [3]Medicine, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [4]University of Ottawa, Ottawa, ON, Canada.*

Background: Infusion of human cord blood endothelial colony forming cell (ECFC)-derived exosomes prevents ischemia/reperfusion acute kidney injury (AKI) in mice, via the transfer of microRNA-(miR)-486-5p, which is highly enriched within these exosomes. Whether exosomes selectively home to the kidneys, and possible targeting mechanisms, are unclear.

Methods: Exosomes were isolated from ECFC conditioned media by serial centrifugation. Ischemia-reperfusion injury was induced in mice by bilateral renal vascular clamp (30 min), with i.v. infusion of DiR-labeled ECFC exosomes at the time of reperfusion, followed by optical imaging. miR-486-5p levels were measured by qPCR in various tissues. Cy3-labeled-pre miR-486-5p was used to study the transfer of exosomal miR-486-5p from ECFCs to cultured human umbilical vein endothelial cells (HUVECs). The potential role of the chemokine SDF1-α and its receptor CXCR4 in exosome homing was studied in HUVECs using a blocking antibody to SDF1-α.

Results: In mice, i.v. infusion of exosomes at the time of reperfusion increased kidney miR-486-5p levels after 30 min ($p<0.01$ vs AKI alone, n=3), with no significant change in miR-486-5p levels in liver, spleen, heart or lungs. After 24 hrs, a further significant increase in miR-486-5p levels was observed only within kidneys ($p<0.01$, n=3). Optical imaging revealed selective homing of exosomes to the kidneys 30 min after reperfusion ($p<0.01$, n=4). Conditioned media from ECFCs transfected with Cy3-pre-miR-486-5p induced an increase in cytoplasmic fluorescence within HUVECs, which was blocked when ECFCs were first treated with the exosome release inhibitor GW4869 or when HUVECs were incubated with the inhibitor of pinocytosis, ethylisopropyl amiloride ($p<0.001$, n=3). By immunoblot, ECFC exosomes expressed CXCR4, and incubation of HUVECs with blocking antibody to SDF1-α prevented exosome uptake (n=3).

Conclusions: ECFC exosomes selectively home to the kidneys after infusion in mice with ischemia-reperfusion AKI, associated with early and sustained increases in kidney levels of miR-486-5p. Endothelial cells are targeted by exosomes, possibly via interaction of CXCR4 with SDF1-α, leading to transfer of miR-486-5p. The results suggest that ECFC exosomes may have therapeutic potential in human AKI due to selective kidney targeting.

SA-OR090

Role of Cyclin G1 in Maladaptive Repair and Kidney Fibrosis Adam W. Scott,[1,3] Craig R. Brooks,[2] Takaharu Ichimura,[3] Joseph V. Bonventre.[3] *[1]Boston Children's Hospital, Boston, MA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Brigham & Women's Hospital/ Harvard Medical School, Boston, MA.*

Background: Survivors of acute kidney injury (AKI) have an increased risk for the development of chronic kidney disease (CKD). Previous work from our lab has demonstrated that G2/M cell cycle arrest is an important driver for the maladaptive repair process that leads to renal fibrosis. Using unbiased gene expression profiling, one of the major pathways upregulated following injury is the p53 pathway, and within this pathway cyclin G1 expression was increased. While the exact function of cyclin G1 is not well known, it is known to interact with p53 and is involved in cell cycle arrest at G2/M. We hypothesize that cyclin G1 plays a critical role in the maladaptive repair process following AKI that leads to progressive fibrosis and CKD.

Methods: We transfected HK-2 cells with the mouse (mCG1) or human form of cyclin G1 (hCG1), and analyzed cell cycle markers as well as inflammatory cytokines. Using a global knockout murine model of cyclin G1 compared with wild-type mice, we performed bilateral IRI to evaluate the effect of cyclin G1 on AKI. Animals were sacrificed at 48 hours and 7 days. We then analyzed markers of renal dysfunction and routine histology. We also performed immunofluorescence experiments staining for KIM-1 to compare proximal tubule injury between the two groups.

Results: Transfection with either mCG1 or hCG1 in vitro induced a higher percentage of cells into G2/M phase. These cells also demonstrated increased production of TGF-beta and CTGF. At 48 hours after ischemic kidney injury, there was a tendency towards increased KIM-1 staining by immunofluorescence in the wild-type animals compared to cyclin G1 knockout animals. At 7 days, KIM-1 staining by immunofluorescence was decreased in the knockout animals compared to wild-type mice. Histologically, there was a decreased amount of tubular injury, including reduced inflammatory response and tubular vacuolization, in the knockout animals compared to the wild-type animals.

Conclusions: Cyclin G1 overexpression leads to an increase in the number of cells in the G2/M phase of the cell cycle, and is associated with a pro-inflammatory phenotype. In vivo, cyclin G1 is associated with a more severe injury phenotype in an animal model of AKI. In vivo knockout of cyclin G1 expression led to decreased proximal tubular injury and suggests a role for cyclin G1 in promoting maladaptive repair following AKI that leads to renal fibrosis.

Neutrophils Induce Endothelial Cell Injury through the Release of Extracellular Vesicles Containing miRNA in ANCA-Associated Renal Vasculitis Alexandre Glemain,[1,2] Mélanie Néel,[1,2] Rozenn Le Bloas,[1,2] Fadi Fakhouri,[1,2] Sarah Bruneau.[1,2] *[1]Centre de Recherche en Transplantation et Immunologie UMR1064, INSERM, Université de Nantes, Nantes, France; [2]Institut de Transplantation Urologie Néphrologie (ITUN), CHU Nantes, Nantes, France.*

Background: To date, the pathophysiological mechanisms by which neutrophils cause endothelial damage in anti-neutrophil cytoplasm antibodies (ANCA)-associated renal vasculitis (AARV) are not fully elucidated. Some data suggest that neutrophil-derived extracellular vesicles (EV) may contribute to endothelial cell (EC) activation, but the mechanisms by which these EV can induce EC damage in the context of AARV, and the role of miRNA they may contain have not been studied.

Methods: In these studies, we used TaqMan Low Density Arrays to identify miRNA released in EV by ANCA-activated neutrophils that are internalized by microvascular EC in vitro. The consequences of this miRNA transfer were analyzed using an overexpression approach in microvascular EC.

Results: We identified three particular miRNA transferred from ANCA-activated neutrophils to microvascular EC in vitro: miR-223, miR-142-3p and miR-451. The overexpression of miR-142-3p and/or of miR-451 in EC led to profound cell damage, especially in inflammatory conditions (TNFα). This was characterized by the induction of EC apoptosis by miR-142-3p (n=8, $P<0.01$), the inhibition of EC proliferation by miR-451 (n=8, $P<0.05$) and as a result, impairment of EC repair and angiogenesis by these two miRNA as observed in wound-healing (n=6, $P<0.05$) and tube formation (n=7, $P<0.05$) assays. Using phosphokinase protein arrays, we found that miR-142-3p inhibits the mTORC1, ERK1/2 and eNOS signaling pathways in EC, which may explain its strong effect on EC injury. Moreover, miR-142-3p and miR-451 overexpression in EC resulted in marked activation responses, characterized by induced expression of the leukocyte chemoattractant chemokines CXCL10 (2- to 5-fold), CXCL11 (2- to 3-fold) and IL8 (6-fold), as well as the proinflammatory cytokine IL6 (4-fold), as assessed by mRNA expression arrays. In contrast, miR-223 overexpression had no significant impact on EC responses in our studies.

Conclusions: Collectively, these findings identify miR-142-3p and miR-451 as critical mediators of neutrophil-induced endothelial damage in the course of AARV, and suggest that specific targeting of these miRNA in EC may have implications for the prevention of microvascular injury in AARV patients.

CKD-induced Hedgehog/PDGFRα Signaling Activates Mesenchymal Stem Cells, Accelerating Arteriovenous Fistula Failure Ke Song, William E. Mitch, Jizhong Cheng. *Baylor College of Medicine, Houston, TX.*

Background: we find that ~50% of neointima cells in failing arteriovenous fistulas (AVF), originate from vascular smooth muscle cells (VSMCs) of the arterial anastomosis. Other sources of VSMCs are unclear. One contributor is the adventitial $Gli1^+$-mesenchymal stem cells (MSCs) that transdifferentiate into fibroblasts or VSMCs. How MSCs contribute to AVF neointimal formation in CKD mice is unknown.

Methods: in mice, we created CKD and then, AVFs in order to study how Hedgehog/PDGFRα signaling stimulates activation and differentiation of MSCs. We also examined crosstalk between MSCs and VSMCs assessed both *in vivo* and *in vitro*. This was possible because we labelled VSMCs and MSCs by using SMMHC-ERCre and Gi1-ERCre reporter mice, respectively.

Results: in AVFs, created in Gli1-CreER uremic mice, few GFP-labelled MSCs were in the neointima. Most of these MSCs were in the adventitia and they expressed fibroblast markers. Using VSMC reporter mice (SMMHC-ERCre mice), we found that VSMCs migrated into the AVF adventitia. Consequently, adventitial MSCs were able to interact with VSMCs, promoting activation and proliferation of VSMCs. What accounts for these interactions? First, we found that CKD stimulates MSCs to differentiate into either myofibroblasts or VSMCs via TGF-β1. MSCs isolated from CKD showed increased potential for differentiation into myofibroblasts with the expense of adipogenesis. Secondly, there was increased hedgehog signaling in MSCs that increased the expression of PDGFRα which is required for activation of TGF-b1 signaling. Notably, an inducible-specific KO of PDGFRα in MSCs led to reduced MSCs differentiation into adventitial fibroblasts. This process impairs VSMC activation resulting in reduced neointima area with increased AVF patency despite CKD.

Conclusions: CKD activates hedgehog/PDGFRα signaling in adventitial MSCs, promoting their differentiation into myofibroblasts or VSMCs. Interfering with the Hedgehog/PDGFRα signaling pathway in MSCs could suppress neointima formation with improvement in AFV maturation.

SA-OR093

Genetic Risk for Scleroderma Renal Crisis in RNA-Polymerase III Antibody Positive Patients Edward Stern,[1,2] Sandra G. Guerra,[2] Mark Harber,[1] Aine Burns,[1] Carmen Fonseca,[2] Christopher P. Denton.[2] *[1]Centre for Nephrology, UCL, London, United Kingdom; [2]Centre for Rheumatology and Connective Tissue Diseases, UCL, London, United Kingdom.*

Background: Scleroderma renal crisis (SRC), characterised by accelerated hypertension and AKI, is a life-threatening complication of systemic sclerosis (SSc). Most SSc cases have a disease-specific circulating antibody, including the anti Scl-70, anti-centromere or anti RNA polymerase III (ARA) antibodies. Previous studies confirm ARA as a powerful serological predictor of SRC, and cases of SRC more than 5 years after the diagnosis of SSc are rare. We developed an innovative approach to identify genetic susceptibility loci for SRC, comparing ARA positive patients with and without the occurrence of SRC.

Methods: From a well-characterised SSc cohort (n=415), we selected 100 ARA+ patients with more than 5 years of follow-up data. 50 had a history of SRC and 50 had not developed SRC. Cases were genotyped using the Illumina Human Omni-express chip. Quality control checks were performed in PLINK (Hardy-Weinberg equilibrium p < 0.001; genotyping rate >90%). Based on the results of logistic regression analysis, ten SNPs were put forward for validation in a separate US cohort of 256 ARA+ patients (40 SRC+), using ThermoFisher TaqMan genotyping probes. Immunohistochemistry (IHC) was performed on SRC biopsy samples to identify proteins associated with our genes of interest.

Results: After quality control checks, 641,489 SNPs were analysed in the first cohort. In logistic regression analysis of our initial cohort, the SNPs within genes and gene regions most strongly associated with SRC were for POU2F1 ($p=4.12 \times 10^{-5}$), CTNND2 ($p=2.92 \times 10^{-5}$), HECW2 ($p=2.71 \times 10^{-5}$), GRIA3 ($p=2.16 \times 10^{-5}$) and GPATCH2L ($p=2.06 \times 10^{-5}$). The SNP within the GPATCH2L region was also significantly associated with SRC in our validation cohort (p=0.025). GPATCH2L polymorphisms have been associated with arterial hypertension in previous GWAS analyses. Polymorphisms in the CTNND2 gene have been demonstrated to be associated with pulmonary arterial hypertension, another vasculopathic complication of SSc, in previous studies. We performed IHC for this protein, and confirmed altered staining of mesangial cells in SRC biopsy samples compared with controls.

Conclusions: A novel autoantibody-based extreme phenotype method identifies risk alleles for SRC within a rare disease cohort. In particular we identify CTNND2 and GPATCH2L as candidates for investigation of SRC aetiopathogenesis.

Upregulation of Lysyl Oxidase Activity in Vascular Smooth Muscle Underlies Increased Vascular Stiffness in CKD Rajesh Mohandas,[2,3] Brandon To,[1] William W. Hahn,[1] Philip Ferns,[1] Cody Kilar,[1] Mark S. Segal.[2,3] *[1]University of Florida, Melbourne, FL; [2]University of Florida, Gainesville, FL; [3]Renal Section, North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Background: Introduction: Individuals with chronic kidney disease (CKD) have increased vascular stiffness which correlates with adverse cardiovascular outcomes and mortality. This increase in stiffness is thought to be a consequence of the metabolic derangements of CKD. However, our data shows that vascular smooth muscle dysfunction occurs early in CKD and is not completely explained by endothelial dysfunction. Lysyl oxidase is an amine oxidase that crosslinks collagen and elastin and contributes to stiffness of extracellular matrix. LOX is upregulated by reactive oxygen species, which is increased in CKD. **Hypothesis:** We hypothesized that increased vascular stiffness in CKD is due to upregulation lysyl oxidase and increases in collagen and elastin cross linking.

Methods: Method: In vitro: Aortic smooth muscle cells were treated with serum from uremic patients or healthy controls. Lysyl oxidase mRNA and activity was measured by a colorimetricassay. In vivo: 6-8 week old C57BL6 mice were subject to a 5/6 nephrectomy model of CKD or sham surgery. 6 weeks later mice were sacrificed. Serum levels of lysyl oxidase were assayed. Mesenteric arteries were mounted in an arteriograph chamber and denuded of endothelium. Passive compliance was determined by measuring changes in luminal diameter to step wise increments in luminal pressure. Aortic smooth muscle lysates were assayed for lysyl oxidaseactivity.

Results: Results: Treatment with uremic serum resulted in an upregulation of lysyl oxidase in cell culture supernatant 22.5 vs 15.58 (n=6 p=0.001). Mice subjected to the CKD model demonstrated increased vascular stiffness. Aortic smooth muscle lysates demonstrated increased lysyl oxidase activity in CKD mice as compared to sham surgical controls [15.67 vs. 12.75 (n=5, p=0.02)]. There was no change in serum lysyl oxidase activity.

Conclusions: Conclusion: Upregulation of lysyl oxidase in vascular smooth muscle cells occurs early in CKD and may be a key mediator of increased vascular stiffness. Lysyl oxidase is a potential novel therapeutic target for CV disease in CKD.

Mitoprotection Preserves the Renal Microvasculature in Porcine Metabolic Syndrome Alfonso Eirin, Ahmad F. Hedayat, Christopher M. Ferguson, Kyra L. Jordan, Stephen C. Textor, Amir Lerman, Lilach O. Lerman. *Mayo Clinic, Rochester, MN.*

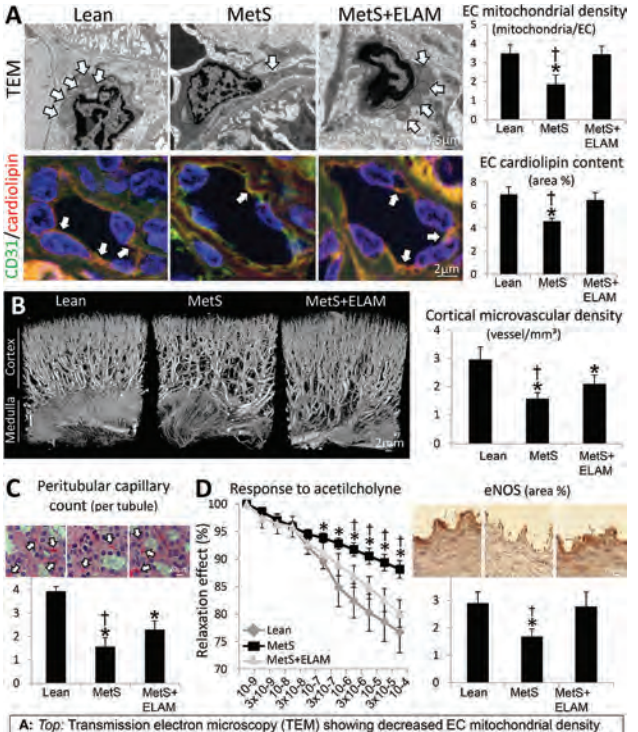
Background: The metabolic syndrome (MetS) induces intra-renal microvascular disease, which may involve mitochondrial injury. The mitochondrial cardiolipin-targeting peptide elamipretide (ELAM) improves the microcirculation in post-stenotic kidneys, but its potential for attenuating MetS-induced microvascular dysfunction is unknown. We hypothesized that chronic treatment with ELAM would decrease vascular remodeling and dysfunction in swine MetS.

Methods: Pigs were studied after 16 weeks of diet-induced MetS, MetS after 4 weeks of ELAM treatment (0.1mg/kg SC q.d), and Lean controls (n=6 each). Vascular endothelial cell (EC) mitochondrial density (electron microscopy) and cardiolipin content (10N-nonyl acridine orange staining) were assessed in situ. The density of peritubular capillaries (PTC, H&E staining) and renal microvessels (20-500μm, 3D micro-CT), and the function of renal artery segments (organ bath, endothelial nitric oxide (eNOS) expression) were characterized.

Results: MetS pigs developed obesity, hypertension, hyperlipidemia, and insulin resistance. Mitochondrial density and cardiolipin content in EC were diminished in MetS, but improved in ELAM-treated pigs. Furthermore, ELAM improved PTC and microvascular density, and restored eNOS expression and endothelial-dependent relaxation of renal artery segments.

Conclusions: MetS-induced mitochondrial alterations might contribute to renal PTC and microvascular loss, and impair renal artery endothelial function in pigs. These observations suggest a potential role for mitoprotection in preserving the renal microvasculature in MetS.

Funding: NIDDK Support, Commercial Support - Stealth BioTherapeutics, Inc.



A: *Top:* Transmission electron microscopy (TEM) showing decreased EC mitochondrial density (arrows) in MetS that improved in MetS+ELAM. *Bottom:* Double immunofluorescence staining of CD31 and cardiolipin (arrows). **B:** Representative 3D micro-CT images of the pig kidney, showing decreased number of cortical microvessels in MetS that improved in MetS+ELAM. **C:** Peritubular capillary density (arrows) decreased in MetS, but improved in ELAM-treated pigs. **D:** ELAM restored endothelial-dependent relaxation and eNOS expression in renal artery segments. *p<0.05 vs. Lean; †p<0.05 vs. MetS+ELAM.

Targeting STUB1-Tissue Factor Axis Normalizes the Hyperthrombotic Uremic Phenotype without Increasing Bleeding Risk Moshe Shashar,[3] Mostafa Belghasem,[3] Shinobu Matsuura,[3] Faisal F. Alousi,[3] Keshab Rijal,[3] Vijaya B. Kolachalama,[4] Joel M. Henderson,[3] Amitabh Gautam,[1] Jean M. Francis,[3] Katya Ravid,[2] Vipul C. Chitalia.[4] *[1]Boston Medical Center, Boston, MA; [2]Boston University, Boston, MA; [3]Boston University Medical Center, West Roxbury, MA; [4]Boston University School of Medicine, Boston, MA.*

Background: Atherothrombosis remains one of the major complications in CKD patients despite their treatment with antithrombotic/antiplatelet therapies. Though associations of uremic solutes (e.g. indolic solutes) and vascular wall protein, such as

tissue factor (TF) and Aryl Hydrocarbon Receptor (AHR) have been defined, the specific mechanisms that drive the thrombotic and bleeding risks have not been fully understood, nor means by which they might be therapeutically manipulated. We further probed the uremic solute-AHR-TF axis for it's role in uremic hyperthrombogenicity.

Methods: TF expression and activity and half-life were examined. Indoxyl sulfate was detected in animals using LC/MS approach. Adenine-induced CKD model and a novel uremic-solute injected mice were generated. Customized object-level intensity estimation algorithms were developed to quantify TF and carboxy terminus Hsc70 interacting protein (CHIP/STUB1) expressions in human arteriovenous fistulae (AVF) explants.

Results: We demonstrate that indolic solutes mediate the hyperthrombotic phenotype across all CKD stages in AHR- and TF-dependent manners in a mouse model *in vivo*. We demonstrate further that AHR regulates TF through STUB1, by interacting and degrading TF through ubiquitination, dependent on the uremic status. TF regulation by STUB1 is substantiated in humans by an inverse relationship between STUB1 and TF expression, and reduced STUB1-TF interaction in AVF explants. AHR and STUB1 modulations normalized the uremic hyperthrombotic phenotype to non-CKD range in both the animal models of CKD without prolonging the bleeding time. This finding is in stark contrast to Heparin, the standard-of-care antithrombotic in CKD patients

Conclusions: Our data implicate indolic solutes as bonafide mediators of the hyperthrombotic uremic *milieu*. Importantly, targeting the STUB1-TF axis reverses the thrombosis risk to the non-CKD range, importantly, without altering the hemostatic balance. Overall, we have significantly expanded the understanding of the interconnected relationships of thrombosis and hemostasis that drive the fragile thrombotic state in CKD.

SA-OR097

Renin Cell Precursors Require B1 Integrin for Normal Vascular Development and Renal Function Tahagod Mohamed, Rajwinderjit Kaur, Roberto Ariel Gomez, Maria Luisa S. Sequeira Lopez. *University of Virginia, Charlottesville, VA.*

Background: Integrins are the largest family of cell adhesion molecules that mediate cell-to-cell and cell-to-matrix interactions. β1-Integrin (Itgb1) is the most abundantly expressed β subunit and is present in almost every cell type. Previous studies showed that Itgb1 is required for normal development of the ureteric bud and podocytes and for the function of the proximal tubule. However, its role in the kidney vasculature has not been explored. Renin cells are crucial for blood pressure homeostasis and for normal nephrovascular development. The mechanisms involved in their morphogenetic functions are not well understood. We found that Itgb1 is highly expressed in renin expressing cells throughout development.

Methods: To study the role of Itgb1 in renin cells we generated a conditional deletion (cKO) of Itgb1 in cells of the renin lineage by crossing floxed Itgb1 mice with mice expressing *cre recombinase* driven by the *renin* locus

Results: Itgb1 cKO mice were smaller in size (20.32 ± 4.35 g *vs* 29.55 ± 7.39 g, *p=0.016*), had smaller kidney to body weight ratio (0.92 ± 0.30 *vs* 1.31 ± 0.30, *p=0.017*), hypotension (MABP 82.33 ± 4.00 mmHg *vs* 92.55 ± 7.72 mmHg, *p=0.02*), anemia (hemoglobin 11.26 ± 1.48 g/dL *vs* 15.07 ± 1.31 d/dL, *p=0.003*; hematocrit 40.39 ± 5.48% *vs* 53.8 ± 4.21%, *p=0.002*), renal failure (BUN 71.44 ± 32.81 mg/dL *vs* 29.4 ± 7.67mg/dL, *p=0.004),* and lower plasma renin levels (6664.58 ± 3251.92 *vs* 43357.09 ± 17032.63 pg/ml, *p*=0.001*).* Mutants also developed hyposthenuria (urine osmolality 452 ± 138.98 mOsm/kg *vs* 1460.5 ± 482.09 mOsm/kg, *p<0.02*). Histological analysis revealed excessive collagen deposition in the interstitium and peri-glomerular areas; fibrocystic glomeruli; tubular dilatation and protein casts in the tubules. Immunostaining for renin and α-smooth muscle actin showed a marked decrease in renin protein expression and abundant α-smooth muscle actin expression in the interstitium. Microdissection of the renal arterial tree combined with renin immunostaining confirmed the marked decrease in renin and evidenced the overall vascular abnormalities including fewer and shorter arterial and arteriolar branches.

Conclusions: Overall, this study shows that β1-Integrin in cells of the renin lineage is crucial for renin expression, morphogenesis of the renal vasculature and maintenance of the normal kidney architecture and function.

SA-OR098

Liraglutide Treatment Improves Renal Vascular Function in Zucker Rats as Visualized by Microangiography Vijayakumar Sukumaran,[2,3] Takashi Sonobe,[3] Hirotsugu Tsuchimochi,[3] Eisuke Tatsumi,[2] Mikiyasu Shirai,[1] James T. Pearson.[3,4] *[1]Department of Advanced Medical Research for Pulmonary Hypertension, National Cerebral and Cardiovascular Center, Suita, Japan; [2]Department of Artificial Organ, National Cerebral and Cardiovascular Center, Suita, Japan; [3]Department of Cardiac Physiology, National Cerebral and Cardiovascular Centre, Osaka, Japan; [4]Department of Physiology, Monash Biomedicine Discovery Institute, Monash University, Clayton 3800, ACT, Australia.*

Background: Metabolic syndrome is a cluster of conditions that synergistically increase the risk of cardiovascular disease, type 2 diabetes, and premature mortality. In this present study, we investigated whether chronic liraglutide (LIRA) treatment affects the metabolic profile and renal vascular function in Zucker rats on a high-salt diet (6%NaCl).

Methods: Eight-week old Zucker lean and Zucker obese (fa/fa) rats were treated with vehicle or LIRA (0.1mg/kg/day) for 8 weeks. Glomerular filtration rate (GFR) was measured at 0 and 8 weeks by using fluorescein isothiocyanate (FITC)-sinistrin method in conscious rats. Further, we used X-ray microangiography to measure the renal arterial diameter (70-350 μm) and vessel number in the anaesthetised rats. Renal protein expression levels of nitrotyrosine and transforming growth factor (TGF)-beta 1 were detected by Western blotting.

Results: After 8 weeks of high-salt diet, systolic blood pressure was significantly increased, renal function and structure were impaired, and collagen deposition was abundant in renal tissues of vehicle-treated Zucker fa/fa rats. We found that in comparison to the untreated Zucker fa/fa rats, rats treated chronically with LIRA showed improved GFR and nitric oxide-mediated vasodilation in response to acetylcholine in small artery and arterioles (<200 μm diameter). Further, vessel internal diameter and visible vessel number (%) were greater in LIRA treated fa/fa rats compared to vehicle-treated rats (Figure 1). Moreover, LIRA treatment decreased the protein expression of nitrotyrosine and TGF-β1 compared to those of vehicle-treated rats.

Conclusions: These results suggest that LIRA treatment improved renal vascular function through dilation of small intrarenal arteries and arterioles.

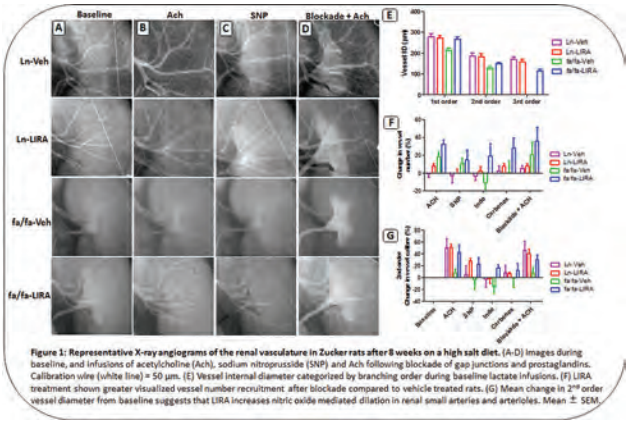

Figure 1: Representative X-ray angiograms of the renal vasculature in Zucker rats after 8 weeks on a high salt diet. (A-D) Images during baseline, and infusions of acetylcholine (Ach), sodium nitroprusside (SNP) and Ach following blockade of gap junctions and prostaglandins. Calibration wire (white line) = 50 μm. (E) Vessel internal diameter categorized by branching order during baseline lactate infusions. (F) LIRA treatment shown greater visualized vessel number recruitment after blockade compared to vehicle treated rats. (G) Mean change in 2nd order vessel diameter from baseline suggests that LIRA increases nitric oxide mediated dilation in renal small arteries and arterioles. Mean ± SEM.

SA-OR099

Indoxyl sulfate Promotes Macrophage Activation via Novel Crosstalk between OATP2B1 and Dll4-Notch Signaling Toshiaki Nakano,[2] Julius L. Decano,[2] Shunsuke Katsuki,[2] Mario S. Boff,[2] Whitney S. Irvin,[2] Hideyuki Higashi,[2] Sasha Singh,[2] Elena Aikawa,[1] Masanori Aikawa.[2] *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: CKD increases cardiovascular risk, however, its underlying mechanisms remain obscure. We previously reported the role of the Notch signaling ligand Delta-like 4 (Dll4) in macrophages. We tested the novel hypothesis that Dll4-Notch mediates macrophage activation stimulated by indoxyl sulfate.

Methods: We examined the effects of indoxyl sulfate (0.25–1.0 mM) on pro-inflammatory responses and Notch signaling in macrophages and the roles of organic anion transporters / polypeptides (OATs/OATPs). To determine the contribution of OATP2B1 to pro-inflammatory activation of macrophages *in vivo*, we used macrophage-targeted lipid nanoparticles to deliver siRNA to mice. To address the role of Dll4 in atherogenesis in CKD, we used 5/6 nephrectomy and Dll4 neutralizing antibody in mice.

Results: [In vitro] In human primary macrophages, indoxyl sulfate induced pro-inflammatory molecules IL-1β, TNFα, and MCP-1 and Notch signaling components Dll4, Notch1 and Hes1. Decreased degradation by ubiquitin-proteasome pathway appears to promote rapid induction of Dll4 < 1 hour by indoxyl sulfate (FACS, Western blotting, immunofuorescence), which in turn triggers Notch signaling. Notch inhibition with the γ-Secretase inhibitor, Dll4 siRNA or Dll4 antibody indeed suppressed indoxyl sulfate-induced macrophage activation. We identified previously unreported 9 OATs/OATPs in macrophages, among which human and mouse commonly expressed OATP2B1. Suppression of OATP2B1 suppressed macrophage uptake of indoxyl sulfate (HPLC), Notch signal components Dll4 and Hes1, and pro-inflammatory genes. [In vivo] Indoxyl sulfate administration in mice promoted expression of IL-1β and MCP-1 in peritoneal macrophages. Co-administration of Dll4 antibody or OATP2B1 siRNA encapsulated in macrophage-targeted nanoparticles suppressed these responses ($p<0.05$, n=6-8). In LDL receptor-deficient mice, 5/6 nephrectomy enhanced Notch signaling and the development of atherosclerosis, macrophage burden, calcification, and pro-inflammatory responses, which were abrogated by Dll4 antibody ($p<0.01$ vs. IgG; n=20/group).

Conclusions: These lines of in vitro and in vivo evidence suggest that crosstalk between OATP2B1 and Dll4-Notch signaling mediates indoxyl sulfate-induced macrophage activation and vascular disease.

Autologous Mesenchymal Stem Cells Decrease Blood Pressure and Kidney Injury in Human Renovascular Disease Ahmed Saad, Sandra Herrmann, LaTonya J. Hickson, James Glockner, Allan B. Dietz, Lilach O. Lerman, Stephen C. Textor. *Mayo Clinic, Rochester, MN.*

Background: Atherosclerotic renovascular disease (RVD) reduces blood flow (RBF), glomerular filtration rate (GFR) and accelerates both systemic hypertension and post-stenotic kidney (SK) tissue injury. Preclinical studies indicate that MSCs stimulate angiogenesis and modify immune function in experimental RVD. We assessed the safety and clinical effects of intrarenal autologous MSCs in a phase 1/2A study of human subjects with RVD.

Methods: Adipose tissue-derived MSCs were collected from 21 RVD patients (age 73.7 ± 4.3; 13 male and 8 females). Inpatient studies were performed during fixed Na+ intake and ACE/ARB Rx before and 3 months after unilateral intra-arterial single infusion of MSC of either 1.0, 2.5 or 5 x 10^5 cells/kg into the SK (n=7 each). SK cortical/medullary perfusion and RBF were measured using multidetector CT, GFR by iothalamate clearance, Injury markers including NGAL and VEGF-C were measured in the renal veins and renal tissue oxygenation was assessed by BOLD-MRI at 3T.

Results: Intra-arterial MSC infusions were tolerated without adverse effects. Tissue perfusion and RBF increased after 3 months ($p<0.05$ vs. baseline), and fractional hypoxia (%R2*>30 sec-1) decreased in the treated kidneys. Renal vein levels of NGAL and VEGF-C decreased (Table). Systolic blood pressure fell ($P<0.05$) and iothalamate-GFR marginally increased ($P=0.053$) 3 months after MSC (Table). These changes were of similar magnitude among the 3 doses.

Conclusions: In this "first-in-human" dose escalation study in 21 patients with atherosclerotic RVD, a single intraarterial infusion of autologous adipose tissue-derived MSCs into the SK decreased systolic blood pressure and increased RBF after three months. These were associated with a reduction in tissue hypoxia and renal injury cytokines, while GFR tended to improve. Our results demonstrate the capability of intrarenal MSC to increase tissue oxygenation and RBF in the human kidney, and support a potential role for MSC in the management of ischemic renal disease.

Funding: NIDDK Support

Causes of Death in Patients Who Survive a Hospitalization with AKI Samuel A. Silver,[6] Ziv Harel,[4] Eric McArthur,[1] Danielle M. Nash,[3] Rey R. Acedillo,[2] Abhijat Kitchlu,[7] Amit X. Garg,[3] Glenn M. Chertow,[5] Ron Wald.[4] *[1]Institute for Clinical Evaluative Sciences, London, ON, Canada; [2]Kingston Health Sciences Centre, Kingston, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]St. Michael's Hospital, Toronto, ON, Canada; [5]Stanford University School of Medicine, Palo Alto, CA; [6]Queen's University, Kingston, ON, Canada; [7]University of Toronto, Toronto, ON, Canada.*

Background: Mortality after an acute kidney injury (AKI) episode is high, but the causes of death are not well described. We sought to better understand causes of death in patients who survive a hospitalization with AKI, and hypothesized that cardiovascular disease would account for most deaths after hospital discharge.

Methods: We conducted a population-based study of residents in Ontario, Canada, who survived a hospitalization with AKI from 2003-2013. We defined AKI with validated ICD-10 diagnosis codes. Using linked administrative databases, we categorized cause of death in the year following hospital discharge as cardiovascular, cancer, infection-related, or other. We calculated standardized mortality ratios (SMR) to compare the cause of death in survivors of AKI to the general adult population, and used Cox proportional hazards modeling to estimate determinants of death.

Results: Of the 156,690 patients discharged after an AKI episode, 43,422 (28%) died in the subsequent year. The most common causes of death were cardiovascular disease (28%) and cancer (28%), with respective SMRs nearly six-fold (5.81, 95% CI 5.70-5.92) and nearly eight-fold (7.87, 95% CI 7.72-8.02) higher relative to the general population. The highest SMRs were for cancer-related mortality, specifically bladder cancer (18.24, 95% CI 17.10-19.41), gynecologic cancer (16.83, 95% CI 15.63-18.07), and leukemia (14.99, 95% CI 14.16-15.85). In addition to older age and nursing home residence, factors most strongly associated with one-year mortality were cancer (hazard ratio [HR] 1.62, 95% CI 1.58-1.65) and inpatient chemotherapy (2.03, 95% CI 1.90-2.17).

Conclusions: Among survivors of a hospitalization with AKI, cancer-related death was as common as cardiovascular death; moreover, cancer-related deaths occurred at the highest rates relative to the general adult population. In addition to modifying the risk of subsequent cardiovascular disease, strategies are needed to care for and counsel patients with cancer who experience AKI.

SA-OR102

Ultrasonography-Based Volume Status Assessment Unveils Misclassification of AKI in Cirrhotics as Hepatorenal Syndrome Juan Carlos Q. Velez,[3] Nithin Karakala,[2] John T. Huggins.[1] *[1]Division of Pulmonary and Critical Care, Medical University of South Carolina, Charleston, SC; [2]Division of Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR; [3]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: The International Ascites Club criteria for the diagnosis of hepatorenal syndrome (HRS) requires documentation of failure to respond to 2 days of intravenous (IV) volume expansion and/or diuretic withdrawal. We hypothesized that ultrasonography (US)-based bedside techniques to assess volume status may provide clinically significant information to ascertain or disprove the clinical diagnosis of HRS.

Methods: A pilot prospective study was conducted to determine the feasibility and clinical utility of US examination of inferior vena cava (IVC) diameter and collapsibility and echocardiographic measurement of velocity time integral (VTI) to assess intravascular volume status in hospitalized adult patients with cirrhosis and acute kidney injury (AKI) who had been deemed adequately volume resuscitated and assigned a clinical diagnosis of HRS.

Results: A total of 52 patients completed the study (mean age 56.2 years, 48% women, 88% white). Mean serum creatinine (sCr) at the time of volume status assessment was 2.9 ± 1.4 mg/dL, and mean Model for End-Stage Liver Disease (MELD) score was 29.8. Twenty-two (42%) patients had an IVC diameter < 1.3 cm and were reclassified as volume depleted, 13 (25%) had an IVC diameter between 1.3 to 2 cm and 17 (33%) had an IVC > 2 cm and were reclassified as volume overloaded. Twenty-four hours later, 12 (55%) of patients reclassified as volume depleted exhibited ≥ 20% decrease in sCr along with improvement in VTI following additional IV volume expansion with ≥ 25 g/day of albumin, whereas 11 (65%) of those reclassified as volume overloaded had ≥ 20% decrease in sCr and improvement in VTI following loop diuretic therapy and/or large volume paracentesis (≥ 5 L). Altogether, 21 (40%) of patients labeled *a priori* as having HRS partially improved kidney function as a result of a therapeutic intervention guided by US-based volume status assessment.

Conclusions: Utilization of bedside US-based assessment of volume status in cirrhotic individuals with AKI may reduce the likelihood of incorrectly assigning a diagnosis of HRS. Further exploration of the clinical applicability of this approach is warranted.

SA-OR103

Prospective Evaluation of AKI and Risk of Heart Failure: The ASSESS-AKI Study Alan S. Go,[2] Talat Alp Ikizler,[6] Vernon M. Chinchilli,[3] Jonathan Himmelfarb,[4] Paul L. Kimmel,[1] James S. Kaufman,[5] Chirag R. Parikh.[7] *[1]NIDDK, Bethesda, MD; [2]Kaiser Permanente Northern California, Oakland, CA; [3]Penn State University, Hershey, PA; [4]Kidney Research Institute, Seattle, WA; [5]VA New York, New York, NY; [6]Vanderbilt University, Nashville, TN; [7]Yale University, New Haven, CT. Group/Team: ASSESS-AKI Study Investigators.*

Background: Several retrospective studies suggest that acute kidney injury (AKI) is associated with excess risk of heart failure (HF), but have important methodological limitations. We prospectively evaluated whether AKI impacts subsequent risk of HF.

Methods: Individually-matched hospitalized adults with and without AKI were enrolled in a parallel cohort study from 4 centers between 2009-2015 and completed an outpatient baseline visit within 3 months of discharge. Potential hospitalized HF events were adjudicated through Feb 2017 using medical records and standardized criteria. Demographics, clinical characteristics and kidney function were obtained at baseline. Multivariable Cox proportional hazards regression was used to examine the association of AKI with HF events, overall and stratified by AKI severity and by pre-existing chronic kidney disease (CKD) status.

Results: Among 769 AKI and 769 matched non-AKI adults, baseline characteristics were similar except for higher prevalence of prior cardiovascular disease, diabetes mellitus and diagnosed sepsis during the index admission in AKI patients. During follow-up, the rate (per 100 person-years) of HF was 3.90 in AKI compared with 1.83 in matched non-AKI adults ($P<0.0001$). In multivariable analyses, AKI was associated with a nearly 2-fold higher rate of HF (adjusted hazard ratio [aHR] 1.85, 95% CI:1.34-2.56), with stronger associations with greater AKI severity and in those without pre-existing CKD (aHR 2.44, 1.41-4.22) vs. with pre-existing CKD (aHR 1.48, 1.00-2.21) (Figure).

Conclusions: AKI independently increases the risk of being hospitalized for HF in the presence or absence of pre-existing CKD. Studies should evaluate underlying mechanisms and whether early surveillance and intervention can prevent HF after an episode of AKI.

AKI and CKD Incidence and Progression: The ASSESS-AKI Study Talat Alp Ikizler,[6] Alan S. Go,[1] Vernon M. Chinchilli,[4] Jonathan Himmelfarb,[2] Paul L. Kimmel,[3] James S. Kaufman,[5] Chirag R. Parikh.[7] *[1]Kaiser Permanente Northern California, Oakland, CA; [2]Kidney Research Institute, Seattle, WA; [3]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [4]Penn State College of Medicine, Hershey, PA; [5]VA New York Harbor Healthcare System, New York, NY; [6]Vanderbilt University Medical Center, Nashville, TN; [7]Yale University and VAMC, New Haven, CT. Group/ Team: ASSESS-AKI.*

Background: Retrospective studies suggest AKI associates with risk of CKD and faster CKD progression, but there are few prospective data. We prospectively evaluated whether AKI independently increases risks of incident and progressive CKD.

Methods: Hospitalized adults with and without AKI were enrolled in a parallel matched cohort from 4 centers between 2009-2015 and had an outpatient baseline visit within 3 months post-discharge. AKI (≥50% relative or absolute increase ≥ 0.3mg/dL in peak inpatient SCr compared to baseline outpatient SCr) was identified during the index hospitalization. AKI and non-AKI participants were matched on center and baseline CKD status (using eGFR<60ml/min/1.73m^2). CKD incidence was defined as ≥25% decrease in baseline eGFR and eGFR <60 ml/min/1.73m^2. In patients with CKD at index hospitalization, CKD progression was defined as ≥50% decrease in eGFR from baseline, reaching eGFR <15 ml/min/1.73m^2 or receiving renal replacement therapy. Multivariable Cox regression was used to examine association of AKI with CKD.

Results: A total of 769 AKI and 769 well-matched non-AKI adults were enrolled. During follow-up, CKD incidence rate was 66 per 1000 p-y in AKI group compared with 26 per 1000 p-y in matched non-AKI adults (P<0.0001). In patients with underlying CKD, CKD progression rate was 35 per 1000 p-y in AKI group compared with 14 per 1000 p-y in matched non-AKI adults (P<0.0001). In multivariable analyses, AKI was associated with an over threefold higher adjusted rate of CKD incidence (adjusted hazard ratio [aHR] 3.17, 95% CI: 2.25-4.46), and an over twofold higher adjusted rate of CKD progression (aHR 2.03, 1.11-3.74).

Conclusions: AKI independently increases the post-discharge risks of incident CKD and CKD progression. Future studies should assess if early surveillance of and intervention in AKI patients with or without underlying CKD can prevent CKD incidence and progression post-AKI.

SA-OR105

Defining Renal Recovery Following Postoperative AKI Thorir E. Long,[2,1] Sólveig Helgadóttir,[4] Dadi Helgason,[2,1] Runolfur Palsson,[1,2] Tomas Gudbjartsson,[1,2] Gisli H. Sigurdsson,[1,2] Martin I. Sigurdsson,[3] Olafur S. Indridason.[1] *[1]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [2]Faculty of Medicine, Univeristy of Iceland, Reykjavik, Iceland; [3]Duke Univeristy, Durham, NC; [4]Akademiska Hospital Uppsala Univeristy, Uppsala, Sweden.*

Background: Consensus on the definition of renal recovery after acute kidney injury (AKI) is lacking. The aim of this study was to examine the association of different definitions of renal recovery with survival among individuals with AKI following surgical procedures.

Methods: This was a retrospective study of all adult patients who underwent abdominal, cardiothoracic, vascular or orthopedic surgery at the University Hospital in Reykjavik in 1998-2015. Clinical data was extracted from electronic medical records. AKI was diagnosed according to the serum creatinine (SCr) part of the KDIGO criteria. Association between 1-year survival and renal recovery of varying degree (SCr reduction to less than 1.5, 1.25 and 1.1 x baseline SCr) and at various time points (10, 20 and 30 days following AKI) was examined by logistic regression. We excluded patients with baseline eGFR <15 mL/min/1.73 m^2, those who died during the index admission, and recurrent AKI episodes

Results: A total of 2,410 patients had AKI. All recovery definitions, namely SCr <1.5, 1.25 or 1.10 x baseline SCr at 10, 20 or 30 days after surgery, were significantly associated with 1-year survival. Reaching SCr <1.5 x baseline within 30 days had the strongest relationship with 1-year survival (OR 0.37; 95% CI, 0.29-0.48, p<0.001) in a multivariable logistic model adjusting for age, AKI stage, year of the AKI episode, previous diagnoses of congestive heart failure, chronic pulmonary disease or neoplasm, preoperative eGFR<60 mL/min/1.73 m^2 and type of surgery. Increased odds of 1-year mortality was observed for those who had persistent SCr 1.5 x baseline following AKI compared with patients whose SCr returned to <1.1 x baseline (Table).

Conclusions: Among patients with postoperative AKI surviving to hospital discharge, achieving SCr <1.5 x baseline within 30 days had the strongest association with 1-year survival. This might therefore be a useful definition of renal recovery after AKI

Funding: Government Support - Non-U.S.

Odds ratio for one-year mortality according to renal recovery at 30 days

Recovery at 30 days, (SCr compared to baseline SCr)	Unadjusted	p-value	Adjusted	p-value

Intensity of Ultrafiltration and Mortality in Critically Ill Patients with AKI and Fluid Overload Vikram Balakumar,[1] Raghavan M. Murugan,[3] Paul M. Palevsky,[2] John A. Kellum.[2] *[1]Department of Critical Care Medicine, , University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]Department of Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA.*

Background: We examined the association between ultrafiltration intensity and risk-adjusted one-year mortality among critically ill patients with fluid overload and receiving renal replacement therapy (RRT).

Methods: We analyzed a large intensive care unit (ICU) dataset involving adults admitted to a tertiary academic medical center over 8-year period. Acute kidney injury (AKI) was defined according to KDIGO criteria and only patients with AKI and fluid overload ≥ 5% of body weight prior to initiation of RRT were included. UF intensity was calculated as volume removed per day from initiation of either continuous or intermittent RRT until end of ICU stay adjusted for patient hospital admission body weight as follows: high >25ml/kg/day; moderate ≤25 - >20ml/kg/day, and low ≤20ml/kg/day. We constructed a propensity score to account for indication bias for UF intensity using age, sex, body mass index, race, surgery, baseline estimated GFR, first RRT modality, pre-RRT fluid balance, duration of RRT, time to RRT initiation as well as risk factors measured in the first 24 hours of ICU admission such as APACHE-III score, vasopressor use, mechanical ventilation use, suspected sepsis and severity of hypotension. We examined Kaplan-Meir failure plots in the propensity-matched cohort and fitted multivariable logistic regression for mortality.

Results: Of 1,075 patients with ≥5% fluid overload and receiving RRT, the distribution of high, moderate and low intensity UF were 40.4%(n=434), 15.2%(n=166) and 44.2%(n=475), respectively. The crude mortality was 59.4%, 60.2% and 69.7%, respectively. After combining low and moderate intensity groups (n=322) and propensity matching with high intensity group (n=322) in a 1:1 ratio, the high intensity UF groups had lower mortality compared with moderate and low intensity UF (56.5% vs. 70.2%, P<0.001). In the overall cohort, mortality was lower in high intensity UF group compared with low intensity UF (adjusted OR, 0.51, 95% CI, 0.35 - 0.73; P<0.001), whereas, there was no difference in mortality between moderate, compared with low intensity UF group (adjusted OR, 0.67; 95% CI, 0.42-1.05; P=0.08).

Conclusions: Higher intensity ultrafiltration of >25mls/kg/day compared with low intensity ultrafiltration of <20mls/kg/day is associated with lower one-year mortality in critically ill patients with fluid overload.

The Epidemiology and Impact of Fluid Balance on Outcomes in Critically Ill Preterm Neonates: A Report from the AWAKEN Study

David T. Selewski,[14] Ayse Akcan Arikan,[1] Elizabeth Bonachea,[8] Katja M. Gist,[12] Stuart Goldstein,[5] Mina Hanna,[13] Catherine Joseph,[15] John D. Mahan,[9] Arwa Nada,[6] Amy Nathan,[4] Kimberly J. Reidy,[3] Amy Staples,[15] Pia Wintermark,[7] Louis J. Boohaker,[2] Russell Griffin,[11] David J. Askenazi,[10] Ronnie Guillet.[16] *[1]Baylor College of Medicine, Houston, TX; [2]Children's of Alabama, Hoover, AL; [3]Children's Hospital at Monte iore/ Albert Einstein College of Medicine, Bronxville, NY; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [6]LeBonheur Children's Hospital, Memphis, TN; [7]McGill University, Montreal, QC, Canada; [8]Nationwide Children's hospital, Columbus, OH; [9]Nationwide Children's Hospital, Columbus, OH; [10]University of Alabama at Birmingham, Birmingham, AL; [11]University of Alabama at Birmingham, Birmingham, AL; [12]University of Colorado, Children's Hospital Colorado, Aurora, CO; [13]University of Kentucky, Lexington, KY; [14]University of Michigan, Ann Arbor, MI; [15]University of New Mexico, Albuquerque, NM; [16]University of Rochester, Rochester, NY.*

Background: Critically ill preterm neonates are at risk of AKI and disorders of fluid balance(FB). Very little data exist on the association between FB and outcomes in this population. We aim to evaluate the epidemiology of FB over the first week of life and impact on outcomes in a multi-center cohort of premature neonates.

Methods: The Assessment of Worldwide Acute Kidney injury Epidemiology in Neonates (AWAKEN) study included neonatal ICU admissions at 24 institutions from 01/14-03/14. Inclusion criteria: intravenous fluids for ≥48 hrs. Exclusion criteria: congenital heart disease repair at ≤7 days of life (DOL), lethal chromosomal anomaly or death ≤48 hrs. This analysis includes infants <36 weeks gestational age admitted by DOL 7. FB during the first week of life was defined by percent change in weight from birthweight. Outcomes: Mechanical ventilation(MV) at DOL 7, mortality

Results: 1136 preterm neonates were enrolled. Median peak FB was 0%(IQR -2.9, 1.9) at median DOL 2 (IQR 1,5). The pattern of peak FB over the first week included: < birthweight in 510(44.8%), 0-5% in 458(40.2%), 5-10% in 83(7.3%), 10-15% in 34(3.0%) and >15% in 51(4.9%). 155(13.6%) were on MV at DOL 7 and 46(4%) died. Table 1 describes the association of variables, including FB, with MV at DOL 7. Peak FB was higher in non-survivors (0%(IQR -2.9,1.7) v 0%(IQR-1.2, 9.3), p=0.002).

Conclusions: The AWAKEN study describes the impact of FB in the first week of life on outcomes in preterm infants. Over half of the cohort had a positive peak FB in the first week of life. Peak FB was associated with MV at DOL 7 and mortality in this cohort.

Conclusions: The AWAKEN study describes the impact of FB in the first week of life on outcomes in preterm infants. Over half of the cohort had a positive peak FB in the first week of life. Peak FB was associated with MV at DOL 7 and mortality in this cohort.

Development and Validation of a Risk Prediction Model for AKI Following the First Course of Cisplatin

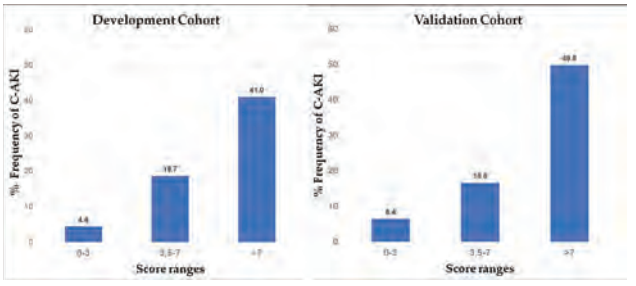
Shveta S. Motwani,[2] Gearoid M. McMahon,[1] Benjamin D. Humphreys,[4] Sushrut S. Waikar,[2] Gary C. Curhan.[3] *[1]Brigham and Women's Hospital, Brookline, MA; [2]Brigham and Women's Hospital and Massachusetts General Hospital, Chelsea, MA; [3]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [4]Washington University School of Medicine, Clayton, MO.*

Background: Cisplatin-associated acute kidney injury (C-AKI) remains a frequent problem occurring in up to 30% of patients who have received cisplatin (Cis). Candidacy for Cis has largely been determined by renal function alone. We sought to develop and validate a predictive model for C-AKI for patients who received Cis.

Methods: Clinical and demographic data were collected on patients who received Cis between 2000-2016 at two large independent cancer centers in Boston. C-AKI was defined as a 0.3mg/dl rise in creatinine from baseline to peak measurement within 14 days of the first course of Cis. Multivariable (MV) logistic regression models using C-AKI as the primary outcome were created and a scoring model was developed using one cohort (Ct). The score-based model was then tested in the validation Ct.

Results: C-AKI occurred in 13.2% of 2049 patients and 11.6% of 2362 patients after the first course of Cis in the development and validation Cts respectively. The following factors were associated with C-AKI in the development Ct: age 61-70 years (OR=1.72, 95% CI 1.26, 2.35, p=0.0007) and age 71-90 years (OR=3.21, 95% CI 2.21, 4.66, p<0.0001) when compared with age ≤60 years; Cis dose 101-150mg (OR= 1.62, 95% CI 1.16, 2.27; p=0.005) and >150mg (OR=3.77; 95% CI 2.69, 5.30; p<0.0001) when compared with ≤100mg; history of hypertension (OR= 2.24; 95% CI 1.67, 3.01; p<0.0001) when compared with no hypertension; serum albumin 2.0-3.5 g/dl (OR=1.95; 95% CI 1.39, 2.73; p=0.0001) when compared with serum albumin >3.5 g/dl; and low blood pressure within 14 days of Cis (OR=1.47; 95% CI 1.07, 2.05; p=0.02) when compared with those without low blood pressure during that interval. The c-statistics of the score-based model in the development Ct and validation Ct were 0.73 and 0.70, respectively.

Conclusions: A score-based model using the patient's age, Cis dose, history of hypertension, serum albumin, and low blood pressure after infusion is predictive of cisplatin-associated acute kidney injury.



Frequency of C-AKI across various score ranges.

AKI Precipitating Initiation of Chronic Maintenance Hemodialysis

Csaba P. Kovesdy,[6] Adnan Naseer,[7] Keiichi Sumida,[2] Miklos Z. Molnar,[6] Praveen Kumar Potukuchi,[6] Fridtjof Thomas,[6] Elani Streja,[1] Michael Heung,[5] Kevin C. Abbott,[3] Rajiv Saran,[5] Kamyar Kalantar-Zadeh.[4] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]The National Institutes of Health, NIDDK, Bethesda, MD; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of Michigan, Ann Arbor, MI; [6]University of Tennessee Health Science Center, Memphis, TN; [7]VAMC, Germantown, TN.*

Background: Acute kidney injury (AKI) often occurs in patients with advanced chronic kidney disease (CKD) and may hasten the need to initiate maintenance hemodialysis (MHD) treatment. It is unclear how frequently AKI occurs in patients transitioning to MHD, and what outcomes it leads to.

Methods: We examined a national cohort of 23,349 US veterans initiating MHD during 2007-2014. We defined AKI as a 50% decrease in eGFR at the time of MHD start, compared to the expected eGFR estimated from the disease trajectory recorded in the last year before dialysis. Associations of AKI with all-cause mortality and with recovery of kidney function (per USRDS records) in the first 6 months after MHD start were examined in multivariable adjusted Cox models and competing risk regression models.

Results: Patients were 67±11 years old, 98% male, 33% African-American, and 72% diabetic. 4,804 (21%) of all patients had AKI. Renal recovery occurred in 12.2% of patients with AKI vs. 1.6% of those without AKI (adjusted subhazard ratio, 95%CI: 4.42, 3.72-5.27, p<0.001) (Fig A). AKI was associated with 45% higher multivariable adjusted mortality (hazard ratio and 95% CI: 1.45, 1.33-1.57) (Fig B).

Conclusions: Nearly 1 in 8 patients experienced AKI during transition to MHD, and this was associated with higher mortality in the immediate post-transition period. Patients with AKI also experience a much higher rate of renal recovery, hence careful attention to residual kidney function is warranted in these patients.

Kidney Tubular Dysfunction among HIV-Negative Persons Receiving Tenofovir-Based Pre-Exposure Prophylaxis Vasantha Jotwani,[4] Rebecca Scherzer,[4] David V. Glidden,[4] Steven G. Coca,[1] Chirag R. Parikh,[2] Robert M. Grant,[4] Michael Shlipak.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale University and VAMC, New Haven, CT; [3]San Francisco VA Medical Center, San Francisco, CA; [4]UCSF, San Francisco, CA.*

Background: Pre-exposure prophylaxis (PrEP) with once-daily tenofovir disoproxil fumarate (TDF) and emtricitabine (FTC) has been adopted by the World Health Organization and the United States Centers for Disease Control as a global strategy for HIV prevention. Tenofovir can cause proximal tubular damage and chronic kidney disease in HIV-infected persons, but little is known regarding its nephrotoxicity in persons without HIV. We evaluated the effects of PrEP on kidney health using a panel of urinary biomarkers.

Methods: Biomarker levels were measured in urine specimens collected before and after PrEP initiation in 109 HIV seronegative participants of the iPrEx-OLE study, a longitudinal cohort of former PrEP trial participants who received open-label TDF/FTC. Cross-sectional correlations of hair drug concentrations with post-TDF urine biomarker levels were evaluated.

Results: After 24 weeks on PrEP, we observed statistically significant increases in proteinuria and α1-microglobulin, a marker of proximal tubule dysfunction, whereas monocyte chemoattractant protein-1 (MCP-1), a marker of renal repair, and eGFR declined (112 ml/min/1.73m2 pre-TDF vs 108 ml/min/1.73m2 post-TDF). Higher tenofovir concentrations, measured in hair, were associated with lower concentrations of uromodulin (r=-0.404; p<0.001), a protein secreted by healthy tubular cells.

Conclusions: PrEP with TDF/FTC was associated with changes in renal tubular health, captured by urine biomarker levels. Urine biomarkers may be useful indicators of nephrotoxicity in PrEP users.

Complement System and Rapid Renal Function Decline in Type 1 (T1D) and Type 2 Diabetes (T2D) – Application of Novel SOMAscan-Based Proteomic Technology John J. Tsay,[2,3] Adam Smiles,[2] Stephanie E. Croall,[2] Joseph V. Bonventre,[1,4] Andrzej S. Krolewski,[2,4] Monika A. Niewczas.[2,4] *[1]Brigham and Women's Hospital, Boston, MA; [2]Joslin Diabetes Center, Boston, MA; [3]Veterans Administration, West Roxbury, MA; [4]Harvard Medical School, Boston, MA.*

Background: We aimed to investigate inflammatory protein signatures in the urine associated with rapid renal function loss in subjects with diabetes.

Methods: In a case-control study of 60 subjects nested within the Joslin Kidney Study cohort of subjects with T1D, proteinuria and CKD 3 (discovery panel), we performed urinary baseline measurements of 194 inflammatory proteins using the SOMAscan platform. Subjects with a Rapid Renal Function Decline (eGFR loss >40% within 5 years) were defined as cases (n=29). Eighteen out of 29 subjects developed ESRD within this time period. Further, we performed urinary proteomic measurements in the validation panel of T2D patients. The 2nd nested case-control study group consisted of 26 T2D subjects with eGFR loss >40% within 5 years (cases); 11 of these progressed to ESRD, and 26 controls remained alive with preserved renal function during the follow-up.

Results: Six major inflammatory classes of proteins were measured within the array. We identified 26 proteins that were concordantly associated with rapid eGFR loss in the discovery panel (Bonferroni corrected nominal *p* value) and in the validation panel (nominal *p* value < 10^{-2}). Candidate inflammatory proteins were particularly enriched for proteins from the complement system ($\chi^2 = 21.5$; p<0.0001). Complements C3a, C5a and factor H were among the top proteins associated with an increased renal risk.

Conclusions: In our study we identified a robust inflammatory signature enriched for proteins of the complement system that are associated with rapid renal function decline in both types of diabetes. Our findings suggest that local kidney disturbances of the complement pathway are etiologically linked to the development of kidney complications in diabetes.

Systems Methylome Analysis Identifies CTCF Regulated Pathways in Disease Progression to Diabetic Nephropathy Ishant Khurana,[1] Mark E. Cooper,[1] Per-Henrik Groop,[2] Assam El-Osta.[1] *[1]Department of Diabetes, Central Clinical School, Monash University, Melbourne, VIC, Australia; [2]University of Helsinki and Helsinki University Hospital, Helsinki, Finland. Group/Team: Finnish Diabetic Nephropathy study.*

Background: Despite extensive GWAS by multiple groups and consortia, including the The Finnish Diabetic Nephropathy Study (FinnDiane), only a few genes that explain <5% of susceptibility to nephropathy in type 1 diabetes (T1D) have been identified. With increased awareness of epigenetics as it pertains to human disease, there remains scepticism whether the signalling pathways in diabetes are an association or represent a direct pathogenic state. Therefore, we used a global approach to characterize methylation-mediated function in clinical samples combined with integrative molecular studies to define mechanisms implicated in hyperglycemia and diabetes.

Methods: Leukocyte DNA isolated from case and control groups were fragmented and DNA precipitated using methyl-CpG capture followed by massive parallel sequencing (methyl-seq). We have mapped the methylome of (FinnDiane) participants selected based on the presence or absence diabetic nephropathy. The case group included 25 participants with T1D characterized into three groups, normoalbuminuria (Normo), macroalbuminuria (Macro) and end stage renal disease (ESRD). The control group consisted of 14 non-diabetic participants with no proteinuria.

Results: We show for the first time DNA methylation sequence changes derived from leukocytes for genes important in insulin signaling, integrin interactions and lipid metabolism. Methylation sequencing identified mechanistic target of rapamycin (mTOR) gene regulation was subject to differential CpG methylation in the genebody at CTCF binding sites. *Ex vivo* cell experiments confirm transition from normal to high glucose conditions reduced DNA methylation and increased mTOR gene expression. The significance of DNA methylation on mTOR was also validated using the DNA methylation inhibitor, 5-aza-2'-deoxycytidine (5adC). We show exon-specific mTOR expression is DNA methylation dependent and hypothesize alternative splicing of mTOR is mediated by Pol II pausing conferred by DNA methylation. CTCF binding is dependent on DNA methylation and regulates mTOR in primary cells stimulated by hyperglycemia and, 5adC.

Conclusions: These results highlight glucose-derived changes to CTCF binding sites are sensitive to loss-of-methylation with gain-of-function of mTOR in diabetes with strengthens the evidence base against DNA methylation changes just being an epiphenomenon.

Fasting Plasma Trimethylamine-N-Oxide as a Risk Marker of Poor Renal Outcomes, Cardiovascular Disease, and Mortality in Patients with Type 1 Diabetes with Diabetic Nephropathy Signe Abitz Winther,[4,6] Jens C. Øllgaard,[2] Hans-Henrik Parving,[5] Stanley L. Hazen,[1] Oluf Pedersen,[3] Peter Rossing.[4,7] *[1]Center for Cardiovascular Diagnostics and Prevention, Cleveland, OH; [2]None, Køge, Denmark; [3]Novo Nordisk Foundation Center for Basic Metabolic Research, København Ø, Denmark; [4]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [5]National Hospital, Copnehagen, Denmark; [6]Novo Nordisk A/S, Maaløv, Denmark; [7]University of Copenhagen, Copenhagen, Denmark.*

Background: Trimethylamine-N-Oxide (TMAO) is a metabolite of phosphatidylcholine, choline and carnitine produced by the gut microbiota from ingested animal foods. It has been suggested as an independent gut microbiota derived risk factor for renal and cardiovascular disease (CVD). Patients with type 1 diabetes are at increased risk of renal and cardiovascular disease and early mortality. We investigated associations between plasma TMAO and outcomes in a prospective study.

Methods: TMAO was measured at baseline in 384 patients with type 1 diabetes with diabetic nephropathy (u-AER > 300 mg/g), 61 % were male, mean age was 42 years and eGFR 66 ml/min/1.73m². Fasting plasma levels of TMAO were measured using stable isotope dilution tandem mass-spectrometry. Endpoints included mean yearly decline in ^{51}Cr EDTA GFR (follow-up (FU) up to 12 years), ESRD (n=65; mean FU: 7.2 years), fatal and non-fatal CVD (n=154; mean FU: 7.5 years) and all-cause mortality (n=134; mean FU: 9.0 years). Associations between TMAO and the endpoints were tested using linear regression or Cox proportional hazard regression in uni- and multivariate analyses adjusting for conventional risk factors at baseline.

Results: Plasma TMAO was inversely associated with baseline eGFR (R^2: 0.42; p<0.001). In univariate analysis higher TMAO was associated with all endpoints (p≤0.002). All endpoints remained significant associated with higher TMAO after adjustment for baseline age, diabetes duration, sex, smoking, systolic blood pressure, cholesterol, HbA_{1c} and u-AER (p ≤ 0.014). After further adjustment for baseline eGFR

significance was lost for all endpoints, except for CVD events (HR per doubling: 1.22, [1.05-1.41]; p=0.010).

Conclusions: In type 1 diabetes patients with diabetic nephropathy, higher fasting plasma TMAO level was predictive of poor renal outcomes, CVD events and mortality independent of conventional risk factors. Only the relation to CVD events remained after further adjustment for baseline eGFR. This elucidated the close relationship between TMAO and renal function.

Identification of Novel Urinary Biomarkers for Predicting the Renal Prognosis in Patients with Type 2 Diabetes by Glycan Profiling in a Multicenter Cohort Study: U-CARE Study 1 Koki Mise,[1] Hitoshi Sugiyama,[2] Haruhito A. Uchida,[3] Jun Wada.[1] *[1]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Department of Human Resource Development of Dialysis Therapy for Kidney Disease, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [3]Department of Chronic Kidney Disease and Cardiovascular Disease, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Recent studies have demonstrated that alterations of glycosylation are critically involved in the development of diabetes and in the progression of diabetic nephropathy (DN). However, the association between changes of glycosylation and the renal prognosis of DN patients remains unclear because of difficulty in quantifying glycans due to their complex structures.

Methods: A total of 680 patients with type 2 diabetes admitted to 8 affiliated hospitals in Okayama during 2012 were enrolled in this study. At baseline, we measured urinary levels of Cy3-labeled glycans that bound to 45 lectins with different specificities. The endpoint was a decrease of the estimated glomerular filtration rate (eGFR) by ≥ 30% from baseline or commencement of dialysis for end-stage renal disease (ESRD). Cox proportional hazards analysis was employed to calculate hazard ratios (HRs) and 95% confidence interval (CIs) for the death-censored endpoint.

Results: During a median follow-up period of 4.0 years (IQR: 3.9-4.0), the primary endpoint was reached in 60 patients. Baseline mean eGFR was 71.0 ± 17.7 ml/min/1.73 m^2, and 594 patients (87%) showed either normoalbuminuria (63%) or microalbuminuria (24%). After adjustment for known indicators of DN, including baseline eGFR and albuminuria, the urine levels of glycans binding to some lectins (including SNA, SSA, ABA, ACA, and MPA) were significantly associated with the primary endpoint (+1SD for log[glycan signal intensity/urinary creatinine concentration], HR for SNA: 1.43[95% CI: 1.07-1.89], HR for SSA: 1.43 [1.07-1.90], HR for ABA: 1.37 [1.05-1.80], HR for ACA: 1.37 [1.03-1.81], and HR for MPA: 1.33 [1.01-1.76], respectively). The glycan Siaα2-6Gal/GalNAc was reported to bind with SNA and SSA, while Galβ1-3GalNAc was reported to bind with ABA, ACA, and MPA.

Conclusions: Urinary Siaα2-6Gal/GalNAc and Galβ1-3GalNAc may be novel predictors of the renal prognosis in patients with type 2 diabetes.

ACE Inhibitor, ARB, or Combined Therapy in Patients with Diabetes and Microalbuminuria: The Long-term Impact of RAS Inhibition on Cardiorenal Outcomes (LIRICO) Randomized Clinical Trial Giovanni F. Strippoli,[1] Suetonia Palmer,[2] Valeria M. Saglimbene,[1] Marinella Ruospo,[1] Jorgen B. Hegbrant,[1] Jonathan C. Craig.[3] *[1]Diaverum, Bari, Italy; [2]University of Otago, Christchurch, New Zealand; [3]University of Sydney/Children's Hospital, Sydney, NSW, Australia. Group/Team: LIRICO trial Investigators*.

Background: Combination ACE inhibitor/ARB therapy may increase risks of end-stage kidney disease without evidence of improved cardiovascular outcomes. The Long-term Impact of RAS Inhibition on Cardiorenal Outcomes (LIRICO) randomized clinical trial evaluated the comparative efficacy of combined ACEi/ARB therapy versus monotherapy on cardiovascular and renal outcomes in patients with diabetes and microalbuminuria.

Methods: The LIRICO trial was a phase III, prospective, randomized, open-label, blinded-endpoint (PROBE) trial funded by the Italian Medicines Agency. Patients with microalbuminuria (ACR ≧30mg/g) or macroalbuminuria and diabetes were randomly assigned to an ACEi (n=427), ARB (n=428) or combination (n=432) titrated to full doses. Non-randomized antihypertensive therapy was administered to achieve blood pressure <130/80. The primary outcome was all-cause mortality. Secondary outcomes were cardiovascular death, non-fatal myocardial infarction, non-fatal stroke, hospitalization for cariovascular causes. end-stage kidney disease, and surrogate renal outcomes (doubling serum creatinine, chronic kidney disease [eGFR<60 ml/min/1.73 m2, development of macroalbuminuria, or normoalbuminuria).

Results: During a median follow-up of 2.8-3.0 years, the number of all-cause mortality events was similar between groups (15 deaths [3.6%] in the ACEi group (hazard ratio 0.84 versus combination group, 0.42-1.67), 20 [4.8%] in the ARB group (HR 1.11, 0.59-2.10), and 18 [4.3%] in the combination group). The secondary outcome end-stage kidney disease was similar between groups (6 events [1.5%, HR 1.53, 0.43-5.44], 7 events [1.7%, HR 0.50, 0.09-2.76] and 4 events [1.0%], respectively). There was no difference between groups for cardiovascular death, nonfatal myocardial infarction, nonfatal stroke, or renal outcomes.

Conclusions: In patients with diabetes and microalbuminuria, there was no evidence that combination ACEi and ARB therapy had different effects on all-cause mortality, and cardiovascular or renal outcomes compared with ACEi or ARB alone.

SA-OR116

Biomarkers Protective against ESRD in Advanced Diabetic Nephropathy Adam Smiles, Monika A. Niewczas, Jan Skupien, Bozena Krolewski, Andrzej S. Krolewski. *Joslin Diabetes Center, Boston, AL.*

Background: A population of patients with type 1 diabetes, persistent proteinuria and CKD stage 3 was followed for progression to End Stage Renal Disease (ESRD). From the group of 219 subjects, 119 were identified as cases, based on their progression to ESRD within 10 years. The control group was the remaining 100 subjects who did not progress to ESRD.

Methods: Baseline plasma from these subjects was assayed on the SOMAscan platform. Relative concentrations were measured for 568 proteins. A protein fold change was calculated as the ratio of mean protein concentration for cases dived by concentration in controls. 16 potentially protective proteins were identified by having a fold change < 1 and a p<0.001. This list was reduced to 12 proteins that also had nominal significance in a similar cohort of Type 2 patients.

Results: In Yamanouchi et al. (KI 2017) we have shown that plasma level of TNFR1 is the primary predictor of ESRD and accounts for most of the traditional risk factors. As such, we performed a Cox proportional hazards model for each protein, adjusting for TNFR1 concentration. Hazard Ratios and p values are reported in the table below. Cluster analysis grouped the proteins into 4 clusters.

Conclusions: Clusters of protective proteins might have similar physiological relevance, be part of common or related pathways or be under the same genetic regulation. Identification of proteins that protect patients from ESRD in the face of such advanced diabetic nephropathy may be useful targets for the development of therapeutics for preventing or delaying the onset of ESRD.

Funding: NIDDK Support, Private Foundation Support

Diabetic Kidney Disease (DKD) Alters the Transcriptome in Adipose Tissue-Derived Mesenchymal Stromal/Stem Cells (MSC) LaTonya J. Hickson, Alfonso Eirin, Ahmed Saad, Sandra Herrmann, Hui Tang, Stephen C. Textor, Lilach O. Lerman. *Mayo Clinic, Rochester, MN.*

Background: Cellular therapy applying autologous MSC may be a viable option for the treatment of DKD. However, patient-related factors, including hyperglycemia and uremia, may alter their reparative capacity. To explore the effect of these biological factors on MSC, we characterized the MSC transcriptome and compared to a set of healthy volunteers (HV).

Methods: MSCs were harvested from subcutaneous abdominal adipose tissue of DKD (n=21) and HV (n=8 kidney donors) subjects. Next-generation sequencing (RNA-seq) of MSC (3rd passage) and functional annotation analysis (DAVID 6.8 database) were then performed to identify differentially expressed mRNAs and rank the primary gene ontology categories.

Results: DKD subjects were older, had higher body mass indices, and lower glomerular filtration rates compared to HV (Table). RNA-seq generated reads for 13,182 mRNAs, of which180 were differentially expressed in DKD-MSC vs. HV-MSC (False Discovery Rate <5% and log2 fold change ≥2 or ≤-2) [Figure]. Functional analysis identified extracellular matrix remodeling and inflammation as the most prominent categories (enrichment score >10), followed by genes capable of modulating cellular pathways linked to tissue repair.

Conclusions: DKD and associated comorbidity modulate the expression of genes involved in inflammation, matrix remodeling, and tissue repair in adipose tissue-derived MSC. These alterations may impact the endogenous repair capacity of MSC and may have clinical implications for the capacity of exogenous autologous MSC delivery to repair DKD.

Symmetric and Asymmetric Dimethylarginine as Risk Markers of Cardiovascular Disease, All-Cause Mortality, and Deterioration in Kidney Function in Patients with Type 2 Diabetes and Microalbuminuria Frederik Persson,[4] Emilie Hein Zobel,[2] Bernt Johan Von Scholten,[3] Tine Hansen,[2] Hans-Henrik Parving,[1] Peter Rossing.[2] *[1]Rigshospitalet, Copenhagen, Denmark; [2]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]Novo Nordisk A/S, Soborg, Denmark; [4]Steno Diabetes Center Copenhagen, Gentofte, Denmark.*

Background: To evaluate symmetric dimethylarginine (SDMA) and asymmetric dimethylarginine (ADMA) as risk markers of cardiovascular disease, all-cause mortality and deterioration in renal function in a well characterised type 2 diabetic population with microalbuminuria and without symptoms of coronary artery disease.

Methods: 200 participants followed for 6.1 years. SDMA and ADMA were measured at baseline. Endpoints included 1) composite cardiovascular endpoint (n=40); 2) all-cause mortality (n=26); and 3) decline in eGFR of >30% (n=42). Cox models were unadjusted and adjusted for traditional risk factors (sex, age, systolic blood pressure, LDL-cholesterol, smoking, HbA_{1c}, creatinine and urinary albumin excretion rate). To assess if SDMA or ADMA improved risk prediction beyond traditional risk factors we calculated c-statistics and relative integrated discrimination improvement (rIDI).

Results: Higher SDMA was associated with increased risk of all three endpoints (unadjusted: p≤0.001; adjusted: p≤0.02). Higher ADMA was associated with all-cause mortality (unadjusted: p=0.002; adjusted: p=0.006), but not cardiovascular disease or decline in eGFR(p≥0.29). The c-statistics was not significant for any of the endpoint for either SDMA or ADMA (p≥0.11). The rIDI for SDMA was 15.0%(p=0.081) for the cardiovascular endpoint, 52.5%(p=0.025) for all-cause mortality and 48.8%(p=0.007) for decline in eGFR; for ADMA the rIDI was 49.1%(p=0.017) for all-cause mortality.

Conclusions: In patients with type 2 diabetes and microalbuminuria higher SDMA was associated with incident cardiovascular disease, all-cause mortality and deterioration in renal function. Higher ADMA was associated with all-cause mortality. SDMA and ADMA significantly improved risk prediction for all-cause mortality, and SDMA for deterioration in renal function beyond traditional risk factors.

SA-OR119

SGLT2 Inhibitors Induce Local Mitochondrial Unfolded Protein Responses in the Proximal Tubules by Suppressing Mitoribosome Proliferation and Influencing Mitonuclear Imbalance in Diabetic Nephropathy Hiroyuki Umino, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio University School of Medicine, Tokyo, Japan.*

Background: We have previously reported a molecular mechanism by which SGLT2 inhibitors maintain the anti-aging gene *SIRT1*. The findings that mitoribosome blockage causes mitonuclear imbalance and induces mitochondrial unfolded protein responses (UPRs) are reportedly linked to longevity. These changes also underlie the elongation occurring from modulation of NAD metabolism and SIRT1. In this study, we analyzed whether SGLT2 inhibition and SIRT1 retention would produce this effect in the proximal tubules.

Methods: Canagliflozin (Cana), a SGLT2 inhibitor, was administered to 8-week-old *db/m* and *db/db* mice, and the following parameters were evaluated at 16 weeks of age: (1) SGLT2 and SIRT1 expression; (2) mitoribosome and cytoplasmic ribosome (cytoribosome) numbers on electron microscopy; and (3) COX1, representing mitoribosome function, which is encoded by mitochondrial DNA and translated in mitoribosomes, and ATP5A, a marker protein reflecting cytoribosome function, which is encoded by nuclear DNA and translated in cytoribosomes.

Results: In *db/db* mice, SGLT2 expression was elevated and SIRT1 expression was decreased; these changes were suppressed in *db/db* mice treated with Cana. In *db/db* mice, an elevated mitoribosomal number was observed despite no marked change in the cytoribosomal number in the proximal tubules observed on electron microscopy. Consistent with mitoribosomal proliferation, a significant increase in COX1 was detected in *db/db*, whereas ATP5A was not changed. The elevation in mitoribosomal number and function was suppressed in *db/db* + Cana. Such specific inhibition of mitoribosome protein expression can lead to mitonuclear protein imbalance and associated UPR^{mt}. One of the marker proteins induced by UPR^{mt} is heat shock protein 60 (HSP60). Indeed, elevation of HSP60 was detected in *db/db* + Cana.

Conclusions: A mitoribosome synthesizes the enzyme complexes of the electron transport system in the inner membrane (Complexes I–IV). Its increase suggests excessive ATP and ROS production and is a sign of metabolic regulation failure. However, a SGLT2 inhibitor induces an apt stress response caused by UPR^{mt}. This newly identified organelle change occurs in early-stage diabetic nephropathy, and the mitoribosome may serve as a novel therapeutic target.

SA-OR120

Genetic Deletion of Myo-Inositol Oxygenase (MIOX) Rescues ob/ob Mice from the Progression of Tubulo-Interstitial Injury Isha Sharma,[1] Yashpal S. Kanwar.[2] *[1]NORTHWESTERN UNIVERSITY, CHICAGO, IL; [2]Northwestern University Medical School, Chicago, IL.*

Background: MIOX, a proximal tubular enzyme, is up-regulated in diabetic state and is involved in the pathogenesis of tubulo-interstitial injury. Previously, we reported that MIOX over-expressing mice with STZ-induced diabetes have remarkable tubulo-interstitial changes. These were largely attributed to excessive generation of ROS leading to increased activity of fibrogenic cytokines, especially in the tubulo-interstitial compartment. Such phenotypic changes were not observed in $MIOX^{-/-}$ mice.

Methods: Aim of this study was to assess if genetic ablation of MIOX ameliorates the progression of tubulo-interstitial injury in *ob/ob* mice by reducing the oxidant stress in proximal tubules. $MIOX^{-/-}$ mice were cross bred with *ob/ob* mice to generate mice with double mutation ($MIOX^{-/-}$/*ob/ob*). Animals were sacrificed at age of 20 weeks and kidneys were harvested for various studies. Prior to sacrifice blood and urine samples were obtained.

Results: The $MIOX^{-/-}$/*ob/ob* mice had improved levels of serum creatinine, urea and insulin compared to *ob/ob* mice. No change was observed in blood glucose levels. The double mutants had decreased urinary excretion of high molecular weight proteins. The MIOX expression was highly accentuated in kidneys of *ob/ob* mice compared to WT, and it was absent in $MIOX^{-/-}$ and mice with double mutation. The renal interstitial compartment had notable decreased staining of fibronectin, collagen I and III in mice with double mutation compared to *ob/ob* mice. The generation of ROS in the kidney tissues was notably less in $MIOX^{-/-}$/*ob/ob* mice compared *ob/ob* mice, as indicated by decreased DHE staining. Analyses of various metabolic sensors revealed revival of the expression of SIRT1, AMPK, YY-1, and of the master regulator of mitochondrial biogenesis, i.e., PGC-1alpha. In vitro, HK-2 cells treated palmitate-BSA had decreased expression of various metabolic sensors with increased ROS generation, and these aberrant parameters of metabolic sensors were normalized with the treatment of MIOX-siRNA.

Conclusions: In conclusion, these findings suggest that ablation of MIOX gene ameliorates the progression of tubulo-interstitial injury in the settings of diabetic nephropathy by reducing the oxidant stress and improving the status of various metabolic sensors.

DNA Methylation Changes of Aging-Related Genes in Renal Proximal Tubular Epithelial Cells Are Regulated by Complement: A Whole-Epigenome Analysis Giuseppe Castellano,[2] Rossana Franzin,[2] Fabio Sallustio,[2] Alessandra Stasi,[2] Claudia Curci,[2] Chiara Divella,[2] Giuseppe Grandaliano,[1] Loreto Gesualdo.[2] *[1]Nefrologia/Dialisi/Trapianto, Foggia, Italy; [2]University of Bari, BARI, Italy*.

Background: Complement, in particular C5a, is the major player of Ischemia Reperfusion injury. Renal Proximal Tubular Epithelial Cells (RPTEC) express the C5aR, however the underlying mechanisms of C5a-C5aR interaction remain poorly understood. We aimed to investigate the impact of C5a exposition on DNA methylation profile in RPTEC.

Methods: Genome-wide array-based DNA methylation levels were measured in several RPTEC lots stimulated with C5a for 24h by the Illumina 450 BeadChips. The analysis was performed on site and region level considering the difference in mean methylation levels both in gene centric regions (promoter, 5'UTR, first exon, gene body, and 3'UTR) and in CpG islands regions (CpG islands and CpG islands shore and shelves). Gene Ontology tools were used to determine genes interaction. qPCR, WB, SA-β Gal staining and MTT were performed for validation analysis.

Results: Compared to basal, 144 sites were hypomethylated and 24 sites were hypermethylated by C5a. Several sites differentially methylated were located in CpG island regions and promoters of genes involved in DNA damage checkpoints in response to genotoxic events, in cell cycle regulation, apoptosis, Hedgehog, Wnt and p53 pathways. The most representative protein classes were: nucleic acid binding proteins (DNA topoisomerase), enzyme modulators, transcription factors and cytoskeletal protein (classification analysis: 21,9%, 9,40%, 7,80% and 7,70% respectively). qPCR analysis confirmed that the hypermethylated genes were downregulated and hypomethylated genes were upregulated. Interestingly, among these genes we found several effectors involved in acquirement of a SAPS (Senescent-Associated Secretory Phenothype). In accordance, 3h of exposure of RPTEC to C5a induced cellular senescence as observed by up-regulating SA-β Gal and by cell proliferation reduction ($p<0.05$). Moreover, senescent RPTEC showed a significant increase in p53 and p21 protein level, as sign of cell cycle arrest ($p<0.05$).

Conclusions: These results suggest a role of complement in inducing tubular senescence affecting epigenetic programs, in particular the DNA methylation profile. Targeting epigenetic mechanisms may represent a strategy to protect tubular cells from aging.

Renal Crisis in Scleroderma: A Renal Complementopathy? Cybele Ghossein,[2] Yashpal S. Kanwar,[3] John Varga.[1] *[1]Rheumatology, Northwestern University Medical School, Chicago, IL; [2]Nephrology Division, Northwestern University FSM, Chicago, IL; [3]Pathology, Northwestern University FSM, Chicago, IL*.

Background: Scleroderma renal crisis (SRC) is an abrupt-onset and unpredictable complication of systemic sclerosis (SSc) generally presenting with acute kidney injury and severe hypertension. Despite the introduction of ACE inhibitors, the 5-yr survival of these patients remains<50%. The pathogenesis of SRC is still incompletely understood. Current paradigms implicate activation of renin- angiotensin system leading to accelerated hypertensive pathophysiology. Recently there has been an enhanced understanding of the role of acquired and/or genetic complement pathway dysregulation in the pathogenesis of thrombotic microangiopathies (TMA) such as in preeclampsia and aHUS. Pathologically SRC shares many similarities to TMA. We hypothesized that complement may play a role in SRC

Methods: We retrospectively reviewed all SRC patients who had a renal biopsy at our institution between the years of 1990 -2015. 19 renal biopsies of SSc patients with diagnosed SRC, defined as a clinical presentation and pathologic findings consistent with this diagnosis were evaluated. Light microscopy, immunofluorescence and electron microscopy were assessed with specific focus on vascular injury

Results: 14 out 19 renal biopsies had C3 deposition in arteriolar walls along with immunoglobulin reactivity. Biopsies with complement staining had active severe vascular lesions.5 out of the 19 renal biopsies showing no complement staining were more likely to have significant interstitial fibrosis with vessel undergoing impending hyalinosis.

Conclusions: C3 small vessel reactivity in renal biopsies of patients with SRC reflects the active role of complement in the pathogenesis of SRC. Once in the chronic phase of the disease, complement is no longer an important component of disease activity. These findings challenge the current dogma for SRC pathogenesis, and raise the possibility of alternative treatment approaches to SRC.

Funding: Clinical Revenue Support

Table 1

	C3+ (n= 14)	C3 - (n=5)	
Average Age at SRC onset (years)	48	55	
Male/Female	4/10	0/5	p=0.5
Hypertension on presentation (# of patients)	10	4	p=0.9
RNA Polymerase 3 + (# of patients)	5	2	p=0.9
>50% interstitial fibrosis (# of patients)	2	4	p=0.0173

Presentations, Outcomes, and Complement Gene Analysis in a Single-Center Cohort of Patients with Atypical Hemolytic Uremic Syndrome Sindhura Bobba, Jason M. Kidd, Daniel E. Carl, Dhiren Kumar, Anne L. King, Gaurav Gupta. *Virginia Commonwealth University, Richmond, VA*.

Background: Previous data suggests that up to 50% of patients with atypical hemolytic uremic syndrome (aHUS) might not have detectable complement gene mutations. In this single-center analysis of the aHUS registry we report our experience on 15 consecutive patients with aHUS.

Methods: Patients were enrolled between 2012-2017 at variable time points after initial presentation. The exonic regions of 12 genes including Complement Factor FH (CFH), MCP (CD46), CFI, C3, CFB, CFHR1, CFHR3, CFHR4, CFHR5, Thrombomodulin, Plasminogen and DGKE were analyzed using commercially available testing.

Results: The mean age at diagnosis was 42±18 years. A majority were females (10/15; 67%) and 40% (6/15) were African-Americans. Seven (47%) presented with thrombotic microangiopathy (TMA) and renal failure, of these 4 (out of 7; 57%) recovered kidney function with C5 blockade therapy (eculizumab). Only one patient did not respond to eculizumab therapy and progressed to end-stage renal disease (ESRD). Of the remaining eight, 6 (40%) were diagnosed in the setting of a pre-transplant evaluation or allograft failure. Of these six, 3 (50%) got transplanted. Two patients (13%) were diagnosed with aHUS post-transplant. All 5 patients with kidney transplants have been maintained on indefinite eculizumab and have intact graft function at a median follow-up of 2.5 years (range1-3 years). Genetic analysis of these 15 patients revealed 39 mutations. A majority of patients (13/15; 87%) were noted to harbor complement mutations with seven (47%) having mutations in more than one gene. CFH mutations and Complement Factor H-related protein (CFHR3- CHFR1) deletions were the most frequent (8 patients each; 61%). Three patients (20%) had MCP/CD46 mutations (IVS9-78 G>A). Patients with homozygous mutations had a trend towards presentation at a younger age (mean 35 vs 50 years; $p=0.1$) compared with those with heterozygous mutations.

Conclusions: In this single-center analysis of 15 consecutive aHUS patients, we report that a large majority (87%) had complement gene mutations. This might represent increasing knowledge of identifiable mutations in the contemporary era. A large majority of patients had an excellent response to C5 blockade. Patients being evaluated for kidney transplants with a history of unexplained TMA should be screened for aHUS.

TH-PO004

Abnormalities of Alternative Pathway of Complement in C3 Glomerulopathy Aishwarya Ravindran, Fernando C. Fervenza, Sanjeev Sethi. *Mayo Clinic, Rochester, MN*.

Background: C3G, comprising C3 glomerulonephritis (C3GN) and dense deposit disease (DDD), is characterized by glomerular accumulation of complement proteins due to abnormal regulation of the alternative pathway (AP) of complement. Large scale studies describing genetic and acquired abnormalities of AP associated with C3G are lacking. We describe our institutional experience of the abnormalities of AP associated with C3G.

Methods: Of the 114 C3G patients seen at the Mayo Clinic, 76 (66.7%) patients (65 C3GN/11 DDD) were evaluated for abnormalities of the AP of complement during the period 2007-2016.

Results: C3 levels were low in only 44.6% patients, while 11.8% patients also had low C4 levels. Overall, 29 (43.9%) were positive for mutations of complement factors/ complement regulating proteins, the most common (15.2%) was a heterozygous mutation in complement factor H (*CFH*). Other less common heterozygous mutations included mutations in *CFI, C3, C5, C8* and *C9*, and in the CFH-related genes, *CFHR2* and *CFHR5*. Forty-five (97.8%) patients were positive for genetic polymorphisms associated with C3G, the most common being *CFH* allele variants, which were present in 44 (95.7%) patients; CFH V62 (78.2%) and H402 (73.9%) were the most common. C3 nephritic factor was present in 29 (43.9%) patients; 1 patient also had a positive C5 nephritic factor. Seven (10.9%) patients were positive for other auto-antibodies, 3 (4.7%) to CFH and 4 (6.3%) to CFB. These findings are quite distinct from atypical HUS, where antibodies to CFH are frequently detected. There was no significant difference in prevalence of polymorphisms/ mutations or C3 nephritic factors/autoantibodies between C3GN and DDD.

Conclusions: Our studies show that the common drivers for C3G are: 1) C3 nephritic factor, and 2) mutations in complement regulating proteins, in particular CFH. Almost all patients carried allele polymorphisms of complement regulating proteins associated with C3G. Autoantibodies to other complement regulating proteins were less commonly present. Our study provides insight into the genetic and acquired abnormalities associated with C3G underscoring that appropriate treatment should be based on treating the abnormality driving the C3G.

TH-PO005

Clinicopathological Features, Triggers, Complement Abnormalities, Treatment, and Outcomes of C3 Glomerulopathy Aishwarya Ravindran, Fernando C. Fervenza, Sanjeev Sethi. *Mayo Clinic, Rochester, MN*.

Background: C3 glomerulopathy (C3G), comprising C3 glomerulonephritis (C3GN) and dense deposit disease (DDD), is characterized by glomerular accumulation of complement proteins due to over activation of the alternative pathway of complement.

Most of the reports on C3G are based on individual cases or small series of C3GN/DDD patients.

Methods: We provide a comprehensive evaluation of 114 patients seen at Mayo Clinic during a 10-year period (2007-2016), of which 102 (89.5%) had C3GN and 12 (10.5%) had DDD.

Results: The median age at diagnosis of C3G was 42 years; C3GN patients were older (median age 42 years) while DDD patients were younger (median age 23.5 years). The median serum creatinine and proteinuria at presentation was 1.6 mg/dL and 2605 mg/24 hours. Hematuria was present in 100 (87.7%) patients. C3 levels were low in only 44.6% patients. Monoclonal gammopathy was present in 37.9% patients; 65.1% of the patient's ≥ 50 years had a monoclonal Ig. 28.9% patients had a history of infection and 23.7% patients had an associated autoimmune abnormality. Mutations in complement regulating proteins including CFH, C3 nephritic factor, and other autoantibodies (anti-CFH and CFB) were detected in 43.9%, 43.9% and 10.9% patients, respectively. All patients tested carried C3G risk-associated polymorphisms, the most common being *CFH* allele variants. Membrano- and mesangial proliferative glomerulonephritis were most common patterns of injury on kidney biopsy. Most patients received steroids and other immunosuppressive drugs. After a median follow-up of 34.6 months, the median serum creatinine was 1.4 mg/dL and the median proteinuria was 809 mg/24 hours. Eighteen patients (15.8%) progressed to ESRD. The predictors of ESRD on univariate analysis were serum creatinine >1.5 mg/dL, proteinuria >3 g/24 hours at diagnosis, severity of global glomerulosclerosis and the extent of tubular atrophy and interstitial fibrosis.

Conclusions: C3G is a heterogeneous disease entity that affects both children and adults. In younger patients, both mutations and autoantibodies to complement regulating proteins are present, while in older patients, a monoclonal Ig, which presumably acts as an autoantibody to complement regulating proteins, is most frequently identified.

Dysregulation of the Alternative Complement Pathway in C3GN and IgAN Yifu Li,[2] Maddalena Marasa,[1] Nicholas J. Steers,[1] Vivette D. D'Agati,[3] Pietro A. Canetta,[4] Andrew S. Bomback,[1] Gerald B. Appel,[3] Krzysztof Kiryluk,[1] Ali G. Gharavi.[1] *[1]Columbia University, New York, NY; [2]Columbia University, New York, NY; [3]Columbia University College of Physicians and Surgeons, New York, NY; [4]None, New York, NY.*

Background: Dysregulation of the alternative pathway plays an important role in glomerular disease, including IgA nephropathy (IgAN) and *C3 Glomerulopathy (C3GN). These disorders share some clinical manifestations,* such as microscopic hematuria and episodes of synpharyngitic flares. Both are characterized by variable mesangial deposits of C3.

Methods: In this cross-sectional study, we collected plasma from 55 participants with IgAN, 105 diagnosed with C3GN, as well as from 62 unrelated healthy controls. All cases of IgAN and C3GN were diagnosed by biopsy. Major components of the alternative pathway, including C3, CFH and CFD levels, were measured by ELISA.

Results: Compared to controls, plasma CFD levels were higher in IgAN and C3GN groups. When compared to the IgAN group, the C3GN group has a significantly lower level of plasma C3 and CFH levels.

Conclusions: These data demonstrate dysregulation of the alternative complement pathway in both IgAN and C3GN. Lower C3 and CFH levels are characteristic of C3GN and differentiate it from IgAN. Analysis of larger cohorts during both active and inactive stages of the disease will better clarify shared and distinct complement profiles between these disorders.

The Complement System and Hemodialysis: Activity of the Lectin Pathway Philip De laval,[1] Katrine Pilely,[3] Peter Garred,[3] Bo Nilsson,[2] Bengt C. Fellstrom,[1] Inga Soveri.[1] *[1]Department of Medical Sciences, Uppsala university, Uppsala, Sweden; [2]Department of Immunology, Genetics and Pathology, Uppsala university, Uppsala, Sweden; [3]Department of Clinical Immunology, Rigshospitalet, Copenhagen, Denmark.*

Background: Complement activation occurring during hemodialysis (HD) has been put forward as a driving force for inflammation in HD patients, but the importance of the lectin complement pathway in HD is largely unknown. Aim: To quantify complement activity through the lectin pathway in contemporary HD.

Methods: Blood was sampled from 20 consecutive HD-patients before, at 30, 60, 120, 180 and 240 minutes and after the prescribed HD-session using either polysulphone or polyarylethersulfone/polyamide/polyvinylpyrrolidone dialyzers. Enzyme-linked immunosorbent assays were used to quantify plasma concentration of the lectin pathway initiator molecules, ficolin -1, -2, -3, mannose-binding lectin (MBL), lectin pathway regulator MAP-1 and enzyme MASP-3 as well as the soluble form of the terminal complement complex, sC5b-9.

Results: Plasma concentrations of ficolin-2, MAP-1 and MASP-3 decreased significantly after 30 minutes and remained low for the rest of the HD session. MBL decreased after 30 minutes and returned to baseline levels after 2 hours, while no change was seen for ficolin-1 and ficolin-3. Concentrations of sC5b-9 increased after 30 minutes and remained elevated for the rest of the HD session.

Conclusions: Complement activation occurs during HD as indicated by increase in sC5b-9. LP complement factors decrease, in particular ficolin-2 which is almost depleted, likely due to dialyzer adsorption and/or consumption. Further studies are needed to investigate the long-term kinetics and half-life of the changes and to examine their clinical impact.

Plasma Concentration of lectin pathway complement factors during hemodialysis

Factor	Pre-dialysis	1 h	p (Pre vs 1 h)	4 h	p (Pre vs 4 h)
Ficolin-1 (ng/ml)	271 (162 - 1200)	317 (142 - 1200)	0.952	267 (154 - 1200)	0.338
Ficolin-2 (µg/ml)	4.85 (1.44 - 12.5)	0.964 (0.246 - 5.1)	< 0.001	0.712 (0.156 - 2.94)	< 0.001
Ficolin-3 (µg/ml)	26 (13 - 45.9)	22.2 (14.5 - 35.2)	0.312	27.2 (12.5 - 55)	0.465
MBL (ng/ml)	314 (11.1 - 4348)	269 (11.4 - 3991)	0.007	284 (16.2 - 2629)	0.113

Modeling Glomerular Complement Activity In-Vitro Using a Novel Human Glomerular Endothelial Cell Assay Qin Ruan, Kishor B. Devalaraja-Narashimha, Shu Mao, Joshua R. Broden, Lori Morton, Scott Macdonnell. *Regeneron Pharmaceuticals, Tarrytown, NY.*

Background: Reproducible methods for evaluating inhibitory effects of drug candidates on complement activation are essential for preclinical development and potential clinical translation. Due to the complexity of complement activation pathways, an in-vitro assay should use relevant cells and endpoints to the given therapeutic indication. Here, using primary human glomerular endothelial cells (HGECs), we validated a complement C3 & C5 deposition model for use evaluating the blocking activity of C5 monoclonal antibodies (mAb).

Methods: Resting or adenosine 5′-diphosphate (ADP)-activated confluent HGECs were incubated for 4 hours with 50% normal human serum, C3 or C5 depleted human serum, or pretreated with anti-C5 mAbs. Thereafter, HGECs were fixed with BD Cytofix, stained with ThermoFisher anti-human C3/C3b or Abcam anti-human C5b-9 antibodies and complement deposits were analyzed (9 sites per well in duplicated wells) by ImageXpress.

Results: C3 and C5b-9 deposition was observed on ADP-activated HGECs exposed to normal human serum but not on non-activated HGECs (C3: $1.5x10^7±1.0x10^7$; C5: $7.9x10^6±6.6x10^6$, P<0.05 vs non-ADP-activated HGEC). The deposition of C3 and C5b-9 were significantly reduced on ADP-activated HGEC exposed to C3 or C5 depleted serum (C3: $3.3x10^5±4.8x10^4$; C5: $1.5x10^6±6.0x10^5$, P<0.05). Addition of a blocking anti-C5 mAb significantly reduced normal human serum derived C5b-9 deposition onto ADP-activated HGEC, deposition was comparable to C5 depleted sera (C5 mAb: $1.02x10^6±6.0x10^5$, Control mAb $3.7x10^6±1.6x10^6$, P<0.05 vs. control mAb).

Conclusions: These data demonstrate utility of an *in vitro* primary human glomerular endothelial cell assay to model complement C3 & C5 deposition. In addition to in-vitro screening, this assay offers potential as a translational model to evaluate anti-complement strategies in renal disease using patient derived serum samples.

Complement Factor D, a New Predictor of Renal Allograft Dysfunction and Rejection? Christoph Daniel,[3,2] Steffen Bobka,[1,2] Maike J. Buettner,[1,2] Kerstin U. Amann.[1,2] *[1]FAU Erlangen-Nürnberg, Erlangen, Germany; [2]Institute of Pathology, Dept. of Nephropathology, Erlangen, Germany; [3]University Erlangen-Nürnberg, Erlangen, Germany.*

Background: The complement system is part of innate immunity and thus important for graft function and survival. Here we focused on complement Factor D (CFD) that initiates alternative complement activation by cleavage of factor B. Triggers of CFD upregulation are unknown and it is unclear if CFD is already upregulated in zero-biopsies of transplanted kidneys. In addition, we assessed whether the alternative complement pathway is upregulated in the setting of delayed graft function.

Methods: CFD was investigated in renal zero- and corresponding transplant-biopsies of patients receiving a cadaveric kidney transplant using immunohistochemistry. Specimens were selected from patients with delayed graft function (DGF, n=12), T-cell mediated rejection (TCMR, n=10) and antibody mediated rejection (ABMR, n=8) and evaluated with regard to localization and degree of expression of CFD. Furthermore, renal complement factor D reactivity was correlated with renal function and transplantation conditions.

Results: CFD was located in different compartments of renal transplants. In 0-biopsies prominent CFD-staining was found in tubules in comparable amounts in all investigated groups. In contrast, glomerular CFD reactivity in 0-biopsies was at least 4-times lower compared to tubular staining but showed significant differences between groups. Highest glomerular CFD was detected in patients that later develop ABMR, being about 5-times higher compared to 0-biopsies from patients that developed DGF. Interestingly, CFD staining was prominent in glomerular, tubular and interstitial localization in post-transplant biopsies without clear differences between groups. The amount of glomerular CFD in 0-biopsies strongly correlated with renal changes including

glomerulitis (r=0.628; p<0.001), chronic transplant glomerulopathy (r=0.659; p<0.001) and mesangial matrix expansion (r=0.771; p<0.001) in transplant-biopsies taken after at a later timepoint. Furthermore, donor serum creatinine correlated with tubular CFD in post-transplant biopsies (r=0.463; p=0.006).

Conclusions: CFD is upregulated in DGF and in antibody as well as T-cell mediated rejection compared to zero-biopsies. Our findings implicate CFD reactivity in 0-biopsies as a potentially useful predictor of pathophysiologic changes in transplanted kidneys in the post-transplantation time course.

Increased Expression of Complement Receptor C5aR1 in Macrophages Contributes to Kidney Fibrosis Ranjit K. Sahu,[1,2] Sandhya Xavier,[1] Susan G. Landes,[1] Ronald P. Taylor,[1] Joerg Koehl,[3,4] Didier Portilla.[1,2] *[1]University of Virginia Health System, Charlottesville, VA; [2]Department of Veterans Affairs, Salem Veterans Affairs Medical Center, Salem, VA; [3]University of Luebeck, Luebeck, Germany; [4]Division of Immunobiology, Cincinatti Children's Hospital Medical centre, Cincinatti, OH.*

Background: We recently demonstrated increased expression and activation of the complement system with increased expression of C5 and C5aR1 in whole kidney tissue homogenates of mice subjected to folic acid and Unilateral ureteral obstruction (UUO) injury. Given the central role of complement activation product C5a in the development of the inflammatory response through interaction with C5aR1, in the present studies we examined the cellular localization of C5aR1 during injury, and the potential mechanism(s) by which its activation contributes to kidney fibrosis.

Methods: C5aR1 expression was studied by immunohistochemistry, flow cytometry, qPCR, and by western blot analysis of wild type, GFP-C5aR1-floxed, and C3$^{-/-}$ mice subjected to the UUO model. RAW264.7 cells were used as an in vitro model to study how increased C5aR1 expression on macrophages was linked to the process of fibrosis.

Results: Immunohistochemistry studies localized expression of C5aR1 to proximal tubules in sham mice but increased expression was seen mostly in interstitial cells after UUO. C5aR1 mRNA levels were increased in CD45+ cells isolated from UUO mice. Flow cytometry analysis using GFP/C5aR1-Floxed mice demonstrated a 75-fold increase of GFP+C5aR1+CD11b+, F4/80+, LyC6- macrophages after UUO. Reduced staining of GFP+-C5aR1+ Prominin-1+ cells by flow suggests loss of renal tubular epithelial cells during UUO. C5aR1 expression as well as kidney fibrosis were significantly reduced in C3 null mice when compared to wild type mice subjected to UUO. Our studies suggest that increased C5aR1 expression on macrophages during UUO is associated with increased kidney fibrosis. In vitro studies using RAW 264.7 cells treated with LPS showed increased C5aR1 protein expression associated with increased production of IL1β and IL6, as well as inflammasome activation, all indicative of an increased inflammatory response.

Conclusions: Our results are the first to report that increased expression of C5aR1 on CD11b+ F4/80+ LyC6- macrophages correlates with the advent of kidney fibrosis. Increased cytokine production and inflammasome activation represent cellular mechanisms by which increased C5aR1 expression contributes to kidney fibrosis.

TH-PO011

Role of Complement C1r and C1s Serine Proteases in Kidney Fibrosis Sandhya Xavier,[1] Ranjit K. Sahu,[1] Susan G. Landes,[1] Judit Megyesi,[2] Jing Yu,[3] Ronald P. Taylor,[3] Didier Portilla.[1,4] *[1]University of Virginia Health System, Charlottesville, VA; [2]University of Arkansas for Medical Science, Little Rock, AR; [3]University of Virginia, Charlottesville, VA; [4]Salem Veteran Affairs Medical Center, Salem, VA.*

Background: Complement C1 complex consists of C1q, and proteases C1r and C1s. Our previous studies of UUO (Unilateral Ureteral Obstruction) demonstrated complement activation with increased synthesis of C1q, C1r and C1s in whole kidney tissue homogenates. To better understand the cellular processes leading to increased classical complement activation we examined the cellular localization and potential mechanisms leading to increased expression of C1r and C1s in kidney cells.

Methods: We performed real time-PCR, immunohistochemistry, in situ hybridization in wild type and in C1ra-/- mice subjected to sham or UUO injury. Cultured Raw 264.7 macrophages were treated with interferon gamma to induce C1r/C1s expression.

Results: We show increased synthesis of C1q in pericytes and CD45 positive cells, but C1r/C1s was only increased in CD45 positive and PDGFRβ negative cells during UUO. In situ hybridization and immunohistochemistry showed that C1s is induced following UUO injury in cortical thick ascending loops (cTALs) and dilated collecting ducts (CDs). C1r immunostaining was increased in cTALs, distal tubules and dilated CDs. Cultured RAW 264.7 macrophages treated with Interferon gamma had increased expression of C1r and C1s mRNA due to activation of the IFN-regulatory factor-1 (IRF-1) binding site present in the C1r promoter. Expression of C1r mRNA was absent in kidney tissue from C1ra-/- mice as compared to wildtype littermates. The ablation of C1r also leads to reduced or no expression of C1s mRNA in kidney tissue from C1ra-/- mice. Preliminary studies in these mice suggest that protection against kidney fibrosis is dependent on the expression levels of C1s and C3, and this needs to be further investigated.

Conclusions: The results support the role of complement activation with de novo increased synthesis of C1r/C1s expression by tubular epithelial and immune cells as an important mechanism leading to tubulointerstitial fibrosis.

TH-PO012

The Relationship between Renal Arteriosclerotic Lesions in CKD and the Serum Levels of Complement C3 and Uric Acid Tsuyoshi Miyagi,[1] Chisato Fukuhara,[1] Ryo Zamami,[1] Kentaro Kohagura,[1] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]University of the Ryukyus, Okinawa, Japan; [2]Tomishiro Central Hospital, Okinawa, Japan.*

Background: We previously reported that hyperuricemia (HUA) was related to renal arteriosclerosis in patients with chronic kidney disease (CKD). Serum complement C3 (C3), which is also an adipocytokine, has also been suggested to be related to renal arteriosclerosis. Here we examined the significance of concurrent occurrence of HUA and elevated C3 levels in renal arteriosclerosis.

Methods: This study involved 172 CKD patients whose biopsies were taken at our department. Of these patients, we excluded those who were receiving corticosteroids or calcineurin inhibitors, those with hypocomplementemia, and patients affected by disease which could cause morphological change in the renal arterioles. Arteriosclerosis was analyzed in renal pathological specimens obtained from renal biopsy using arteriolar hyalinization grade, which represents the mean grade obtained following semiquantitative assessment of the degree of hyalinization. Scores equal to or higher than the C3 median were classified into a high (HC3) group. The definition of HUA was determined as those taking antihyperuricemic drugs or those with serum uric acid levels ≥7 mg/dL for men and ≥6 mg/dL for women. The subjects were divided into four subgroups of HC3–/HUA–, HC3+/HUA–, HC3–/HUA+ and C3+/HUA+ by the presence or absence of HC3 and HUA and we then compared their arteriolar hyalinization grades.

Results: The mean arteriolar hyalinization grade after HC3/HUA subgrouping, and after logarithmic transformation, was highest for the HC3+/HUA+ subgroup, and a significant difference was observed with that for HC3–/HUA–. However, the differences between the HC3–/HUA– and HC3+/HUA– or HC3–/HUA+ subgroups were relatively small. We performed multivariate analysis of the determination factors of high arteriolar hyalinization (median grade or higher) including age, sex, pulse pressure, HbA1c, LDL-cholesterol level, and HC3/HUA subgroups (Ref: HC3–/HUA–). We found that HC3+/HUA+ (OR, 4.3; 95%CI, 1.2–15.9) was a significant factor. Furthermore, in comparison to the HC3–/HUA– subgroup, the flow-mediated dilation (%FMD) in the HC3+/HUA+ subgroup was significantly decreased.

Conclusions: In CKD patients, the relationship between HUA and renal arteriosclerosis may become more notable in patients with high levels of serum complement C3.

TH-PO013

An Association of Renal Arteriolopathy with Combination of Hypertriglyceridemia and Increased Serum Complement Component 3 in CKD Chisato Fukuhara, Ryo Zamami, Tsuyoshi Miyagi, Masanobu Yamazato, Akio Ishida, Kentaro Kohagura, Yusuke Ohya. *University of the Ryukyus, Nishihara-cho, Japan.*

Background: Metabolic syndrome, which is characterized by adiposity, is a risk factor for progression of chronic kidney disease (CKD). Complement component 3 (C3), one of adipocytokines correlated with serum triglyceride (TG) levels. We previously reported that combination of hypertrigriceridemia (hTG) and increased serum C3 related to proteinuria via unknown mechanism. Arteriolar hyalinosis may relate to proteinuria via disrupted autoregulation of glomerular hemodynamics. In the present study, we examined the association between this combination and renal arteriolopathy, oxidative stress and inflammation in patients with CKD.

Methods: A total of 139 patients with non-nephrotic CKD who underwent renal biopsy were enrolled in this study. Renal arteriolar hyalinosis was semi-quantitatively assessed via arteriole grading. Oxidative stress and inflammation was assessed by d-ROMs (Diacron-Reactive Oxygen Metabolites) test that mainly evaluating the level of hydroperoxides and high-sensitivity C-reactive protein (hs-CRP), respectively. We examined a cross-sectional association between arteriolar hyalinosis and clinical factors such as serum TG and C3. To evaluate the effect of the combination of hTG and high C3, patients were divided into four groups based on the presence of hTG and high C3 levels (hC3), defined as equal or higher than their median values.

Results: The mean values for age, estimated glomerular filtration rate (eGFR), serum TG and C3 were as follows: 44 years, 74 ml/min/1.73m^2, 169 mg/dl and 106. Serum TG, but not C3 was significantly correlated with arteriolar hyalinosis index. Subgroup analysis showed that hTG+/ hC3+ group was characterized by higher levels of body mass index, urine protein, hs-CRP and dROMs. In multivariate regression analysis, hTG+/hC3+ as well as age, systolic blood pressure and HbA1c was positively associated with arteriolar hyalinosis.

Conclusions: These findings suggest that coexistence of hTG and hC3 may relate enhanced oxidative stress and inflammation, which may cause proteinuria in association with arteriolosclerosis.

TH-PO014

Association of Renal Artery Sclerosis with Serum Complement C3 and Triglyceride–Glucose Index in CKD Chisato Fukuhara, Tsuyoshi Miyagi, Ryo Zamami, Masanobu Yamazato, Akio Ishida, Kentaro Kohagura, Yusuke Ohya. *University of the Ryukyus, Nishihara-cho, Japan.*

Background: An association between serum complement C3 (C3) and renal artery sclerosis has been suggested to exist. We investigated the influence of triglyceride–glucose index (TyG), a marker of insulin resistance, in regard to this association.

Methods: Arteriolosclerosis was semiquantitatively evaluated from hyalinized arterioles of pathological specimens obtained from kidney biopsies, and average scores (grading of arteriole hyalinization) were calculated. Patients with median or higher C3 levels were classified as the high-C3 (HC3) group. TyG was calculated as fasting triglycerides (mg/dL) × fasting glucose (mg/dL) / 2, and patients with median or higher TyG value were classified as the high-TyG (HTyG) group. Patients were then divided into subgroups based on the presence or absence of HC3 and HTyG (HC3–/HTyG–, HC3+/HTyG–, HC3–/HTyG+, and HC3+/HTyG+).

Results: The average score for arteriole hyalinization grading after applying a subgroup-specific logarithmic transformation was significantly higher in the HC3+/HTyG+ group than in the other groups. A multivariate analysis was conducted wherein high degree of arteriole hyalinization (median grade or higher) was the determinant, and age, sex, systolic blood pressure, serum uric acid levels, presence or absence of diabetes, and HC3/HTyG subgroup (Ref: HC3–/HTyG–) were explanatory variables. Results indicated that HC3+/HTyG+ was significant but HC3+/HTyG– was non-significant. The HC3+/HTyG+ group also had the lowest percent flow-mediated dilatation.

Conclusions: An association between C3 and renal artery sclerosis in patients with chronic kidney disease may be prominent in terms of endothelial dysfunction under conditions of high insulin resistance.

TH-PO015

Complement C5a Moderates Renal Lipid Metabolism and Fibrosis in Diabetic Nephropathy Wai Han Yiu,[1] Ruixi Li,[1] Dickson W. Wong,[1] Haojia Wu,[1] Kam wa Chan,[1] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Kar Neng Lai,[1] Steven H. Sacks,[2] Wuding Zhou,[2] Sydney C. Tang.[1] *[1]Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [2]Medical Research Council Centre for Transplantation, King's College London, Guy's Hospital, London, United Kingdom*.

Background: Complement C5 activation has been implicated in tubulointerstitial injury with increased levels of tubular C5a in renal biopsies from patients with diabetic nephropathy. We investigated whether administration of a C5a inhibitor would confer protection against the progression of diabetic nephropathy in an animal model of type 2 diabetes.

Methods: Uninephrectomized diabetic *db/db* mice were administrated with novel C5a inhibitor, NOX-D21 (10 mg/kg, a kind gift from NOXXON) or an equal volume of saline for a total of 12 weeks. Non-diabetic *db/m* mice were used as control.

Results: In *db/db* mice, treatment with NOX-D21 for 12 weeks did not affect hyperglycemia, but significantly prevented the increase in serum creatinine and BUN levels. These NOX-D21 treated mice had reduced glomerulosclerosis and tubular damage compared to the vehicle-treated diabetic mice. In addition, blockade of C5 signaling reduced the overexpression of TGF-β1, activation of Akt signaling and interstitial expression of fibronectin and collagen type I in the diabetic kidney. NOX-D21 also ameliorated lipid abnormalities in *db/db* mice and resulted in significant decrease in serum triglycerides and expression of lipid metabolism-related genes (DAGT1 and SREBP-1) in the diabetic kidney.

Conclusions: Our findings suggest a pathogenic role of C5a in diabetic nephropathy, especially in regulating TGF-β-driven renal fibrosis. Inhibition of C5a signaling partially improves renal function and ameliorates dyslipidemia in diabetic animals. **Funding:** Hong Kong Society of Nephrology and Hong Kong Kidney Foundation Research Grant (2016).

TH-PO016

C-Terminal Oligomerization of Podocin Can Mediate Interallelic Complementation Eszter Balogh,[8,6] Pal Straner,[1] Gusztáv Schay,[4,6] Christelle Arrondel,[5] Ágnes Mikó,[8,6] Gerda L'aune,[8,6] Alexandre Benmerah,[2] Andras Perczel,[1] Dora K. Menyhard,[1] Corinne Antignac,[3] Geraldine Mollet,[7] Kalman Tory.[8,6] *[1]MTA-ELTE Protein Modeling Research Group, Eötvös Loránd University, Budapest, Hungary; [2]INSERM U1163, Imagine Institute, Paris, France; [3]Imagine Institute, Paris, France; [4]Department of Biophysics and Radiation Biology, Semmelweis University, Budapest, Hungary; [5]INSERM, Paris, France; [6]Semmelweis University, Budapest, Hungary; [7]Inserm U1163, Paris, France; [8]MTA-SE Lendulet Nephrogenetic Laboratory, Hungarian Academy of Sciences, Budapest, Hungary. Group/Team: MTA-SE Lendulet Nephrogenetic Laboratory*.

Background: Podocin, a membrane-anchored component of the slit diaphragm, is encoded by *NPHS2*, the major gene of steroid-resistant nephrotic syndrome. We formerly showed that its most frequent non-silent variant, R229Q, is pathogenic only when trans-associated to specific 3' missense mutations and suggested that an altered dimerization mediates their dominant negative effect. Here we aimed to determine the membrane targeting and the oligomerization capacity of podocin in function of its C-terminal integrity.

Methods: Podocin localization was studied in cultured podocytes co-transfected with GFP- and HA-tagged podocin variants. The role of endocytosis was studied by the coexpression of a dominant negative dynamin. Binding capacity of the dimers was measured as the FRET efficiency between podocin variants expressed either in HEK293 cells or in E.coli, extracted and stained with fluorescent maleimides. Oligomerization was studied by size exclusion chromatography.

Results: We found neither colocalization, nor FRET between the membranous R286Tfs*17 podocin lacking the C-terminal tail (CTT) and other podocin variants indicating that oligomerization occurs exclusively through the CTT. Podocin variants containing the first helix (H1) of the CTT (273-313) dimerized, and those also containing the 332-348 region, oligomerized. Truncated podocin variants with an intact H1 were significantly influenced in their localization by the coexpressed missense podocin variants. We found the F344Lfs*4 and F344* podocin mutants to be endocytosed. Interestingly, it was inhibited by the coexpression of some membranous podocin variants with an intact CTT. We found the F344Lfs*4 podocin, the first frameshift mutation that is pathogenic with R229Q to similarly retain R229Q podocin as other pathogenic associations. Its dominant negative effect was exerted through the FDL344_346LTY amino acid changes encoded by the frameshift sequence.

Conclusions: Oligomerization of podocin is mediated exclusively by the CTT. Though oligomerization is not prerequisite for membrane-targeting, it may mediate not only a dominant negative effect between podocin variants, but also normalization of the localization, i.e. interallelic complementation. Such a complementation can also modify the pathogenicity of *NPHS2* alleles.

Complement Activation Is Not Required for MPO-ANCA Induced Pulmonary Granulomatosis in Mice Hong Xiao, Peiqi Hu, Marco A. Alba, Ronald J. Falk, J. Charles Jennette. *University of North Carolina at Chapel Hill, Chapel hill, NC*.

Background: We previously developed an animal model of human pauci-immune crescentic glomerulonephritis (CGN) caused by myeloperoxidase (MPO) specific antineutrophil cytoplasmic autoantibodies (MPO-ANCA) by i.v. injection of mice with antibodies specific for mouse MPO. The induction of CGN by injection of anti-MPO IgG required activation of the alternative complement pathway, and was prevented in deficient in complement factor B (CFB) or C5. We now have developed a model of ANCA pulmonary granulomatosis that mimics granulomatosis with polyangiitis caused by i.v. injection of anti-MPO IgG after intratracheal spray of lipopolysacarride (LPS).

Methods: 9-11 wk-old B6 WT, CFB-/- and C5-/- mice were treated with an intratracheal spray of LPS (5ug) at day 0, plus two doses of anti-MPO IgG, i.v. (75ug/g BW) at day0 and day1. Mice were sacrificed at day7. Kidney and lung tissues were obtained for pathologic examination.

Results: With this regimen, all B6 WT mice (n=5) developed CGN (mean 20% glomeruli with crescents) and pulmonary necrotizing granulomatous lesions (mean scores = 2.6 out of 3). All CFB-/- (n=3) and C5-/- (n=4) mice developed pulmonary necrotizing granulomatous lesions (mean scores = 3) but none developed CGN. Negative control WT mice that received LPS alone (n=6), and MPO-/- mice that received LPS and anti-MPO (n=3) developed no CGN or pulmonary granulomatosis.

Conclusions: Absence of CFB or C5 protects from anti-MPO induced CGN but not anti-MPO induced pulmonary granulomatosis, indicating complement activation is not required for MPO-ANCA induced pulmonary granulomatosis in mice. These interesting and potentially impactful observations suggest that although both necrotizing CGN and necrotizing pulmonary granulomatosis are caused by MPO-ANCA, the mediators are different, and, thus optimum therapy for the kidney disease may differ from optimum therapy for the lung disease. For example, although blockade of alternative pathway activation may be effective adjunct therapy for ANCA CGN, it may have no effect on ANCA granulomatous disease.

The Role of Complement C9 as a Marker for Therapeutic C5 Blockade in Lupus Nephritis Hannah R. Wilson,[2] Alyssa C. Gilmore,[2] Nicholas R. Medjeral-Thomas,[2] Pritesh Trivedi,[2] Kathleen I. Seyb,[1] Ramin Farzaneh-Far,[1] Tom Cairns,[2] Liz Lightstone,[2] Matthew C. Pickering,[2] H. Terence Cook.[2] *[1]Ra Pharmaceuticals, Inc., Cambridge, MA; [2]Imperial College Lupus Centre, Imperial College Healthcare NHS Trust, London, United Kingdom*.

Background: Complement plays an important role in the pathogenesis of lupus nephritis (LN) and there are reports of therapeutic benefit with eculizumab, a C5 inhibitor. However, LN can also develop in complement-deficient individuals. With the emergence of therapeutic C5 inhibition, there is a need to identify patients in whom complement-driven inflammation, attributable to C5a, C5b-9, or both, is a major cause of kidney injury in LN.

Methods: Clinical and histopathological data from 54 patients with class III, IV and V LN were obtained retrospectively. Staining for C9, C5b-9, C3c and CD68 was performed and intensity assessed. Response was defined using urine protein-creatinine ratio and estimated glomerular filtration rate.

Results: C9 staining was equivalent to C5b-9 staining. C9 was detected in the mesangium of both active and chronic proliferative (class III and IV) LN in the majority of patients and in the capillary wall of class V LN in all patients. C9 staining intensity in the tubular basement membrane correlated with creatinine levels at the time of biopsy and with markers of tubulo-interstitial damage. C9 staining intensity did not correlate with C3c staining intensity or glomerular CD68 count. C9 staining also did not correlate with serological markers of activity, however C3c and CD68 staining did. Although not statistically significant, a low C9 staining intensity appears to indicate a greater chance of complete remission in active disease.

Conclusions: The widespread presence of glomerular C9 in LN supports a role for the C5b-9 membrane attack complex in renal injury. Importantly, the lack of correlation with C3c intensity suggests that the kinetics of glomerular C9 and C3c staining differ. Understanding the kinetics of complement deposition will be important in identifying patients most likely to benefit from C5 inhibition.

Decay Accelerating Factor (DAF), Local Complement Inhibitor, Protects from Adriamycin (ADR)-Induced FSGS Andrea Angeletti,[2,3] Chiara Donadei,[2,3] Vivette D. D'Agati,[1] Jenny Wong,[2] Kirk N. Campbell,[2] Gaetano La Manna,[3] Miguel L. Fribourg,[2] Peter S. Heeger,[2] Paolo Cravedi.[2] *[1]Columbia University College of Physicians and Surgeons, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Nephrology, DIMES, Bologna, Italy.*

Background: The impact of DAF, a cell surface expressed complement regulator, in the pathogenesis of proteinuric glomerular disease, including Adr-induced nephropathy is unknown.

Methods: We injected 20mg/kg Adr into B6 WT, and congenic DAF$^{-/-}$, DAF$^{-/-}$C3$^{-/-}$, DAF$^{-/-}$C3aR$^{-/-}$ mice and DAF$^{fl/fl}$ crossed to Cre-transgenics; the B6 strain is known to be resistant to Adr nephropathy. We serially measured urine albumin/creatinine (A/C) and at 35 weeks we quantified histological injury and stained sections for complement activation products.

Results: : Adr caused proteinuria in B6 DAF$^{-/-}$ but not in WT (Fig 1A), DAF$^{-/-}$C3$^{-/-}$, or DAF$^{-/-}$C3aR$^{-/-}$ mice, mechanistically implicating DAF-dependent restraint on complement activation and ensuing C3a/C3aR signaling in the disease process (Fig 1B). Using newly developed DAF conditional KOs, absent DAF from podocytes (DAF$^{fl/fl}$-podocin-Cre^{+}) conferred Adr-sensitivity, while DAF$^{fl/fl}$-CD11c-Cre^{+} did not develop disease (Fig 1A). DAF-deficiency-induced proteinuria correlated with higher histological scores (Fig 1C) and glomerular staining for C3b, without C1q, C4b, and MAC. Kidneys from Adr-treated DAF$^{-/-}$, DAF$^{fl/fl}$-CD11c-Cre^{+} but not control mice showed Claudin-1^{+} parietal epithelial cells (PECs) in the glomerulus.

Conclusions: Podocyte-expressed DAF mediates resistance to Adr-induced glomerular injury in B6 mice. In the absence of DAF, Adr-induced kidney injury is propagated by local C3a/C3aR signaling that likely contributes to PEC recruitment and glomerulosclerosis. Studies addressing a role for DAF/complement in human FSGS and related diseases are warranted.

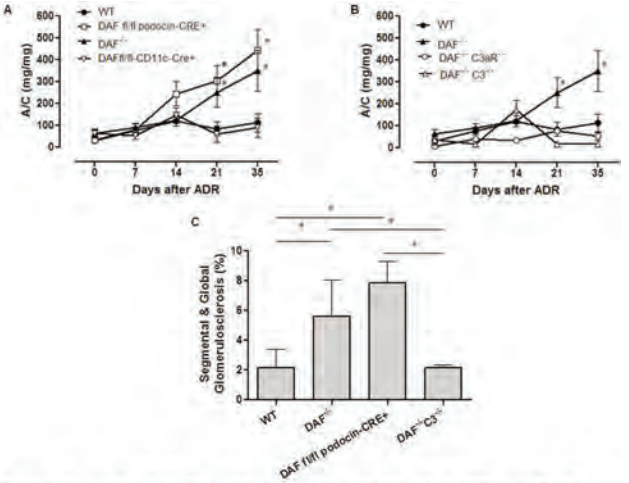

Figure 1. Urinary albumin/creatinine (A/C) WT, DAF$^{-/-}$, and DAF$^{fl/fl}$ podocin-CRE^{+} and in B) WT, DAF$^{-/-}$, DAF$^{-/-}$C3aR$^{-/-}$ and DAF$^{-/-}$C3$^{-/-}$ mice. C) Histological scores.

An In Vitro Model of Idiopathic Membranous Nephropathy Reveals PLA2R- and Complement-Dependent Pathways of Podocyte Injury George Haddad,[2] Andreas D. Kistler.[1] *[1]None, Winterthur, Switzerland; [2]University of Zurich, Zurich, Switzerland.*

Background: Idiopathic membranous nephropathy (iMN) is an autoimmune kidney disease that usually manifests as nephrotic syndrome through damage of podocytes and leads to progressive renal failure in a significant proportion of patients. Recently, the target antigen of autoantibodies in the majority of patients with iMN has been identified as the phospholipase A_2 receptor (PLA_2R). The definitive proof for pathogenicity of PLA_2R antibodies, however, is still lacking. Furthermore, mechanisms of podocyte injury remain elusive, although sublytic complement injury has been proposed. In this study, we aim to develop an *in vitro* model for iMN to determine downstream mechanisms of anti-PLA2R-antibody mediated injury to podocytes.

Methods: PLA_2R expression levels in conditionally immortalized human podocytes were modulated by infection with a lentivirus vector carrying FLAG-tagged full length human PLA2R or by siRNA-mediated knock down. These cells were then pretreated with sera from PLA_2R-positive iMN patients or control sera and subsequently, human complement was added. Cell lysates were collected and analyzed by qPCR, Western blot, and IF.

Results: Podocytes overexpressing PLA_2R treated with a high-titer (1:1000) PLA2R antibody positive sera and complement in sublytic concentration resulted in decrease synaptopodin and NEPH1 expression with a noticeable synaptopodin rearrangement. The complement sublytic effect on podocytes is likely to involve the activation of the lectin pathway and C3aR1 and C5aR1 signaling as knock down of these receptors rescued synaptopodin and NEPH1. Synaptopodin and NEPH1 degradation appeared to occur via two independent pathways that require cysteine and aspartate proteases, respectively.

Conclusions: Podocyte injury by iMN serum and sublytic complement includes synaptopodin and NEPH1 degradation. In addition, we have developed an in vitro assay to specifically assess the complement-dependent podocytopathic effect of iMN sera that will allow to screen for protective compounds.

TH-PO022

Calcineurin Inhibitor-Induced Endothelial Cell Injury – A Role for Complement Chia Wei Teoh,[2] Magdalena Riedl,[2] Valentina Bruno,[1] Lisa Robinson,[2] Christoph Licht.[2] *[1]None, Toronto, ON, Canada; [2]The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Calcineurin inhibitors (CNI) are associated with nephrotoxicity, endothelial cell (EC) dysfunction and thrombotic microangiopathy (TMA). Evolving evidence suggests a central role for complement dysregulation in the pathogenesis of CNI-induced TMA. However, the exact mechanism of CNI-induced complement-mediated injury remains unknown. We hypothesize that CNIs induce complement-mediated EC injury and impair complement regulation on EC surfaces.

Methods: Complement activation (C3c, C9) and regulation (CD46, CD55, CD59), and complement factor H (CFH) surface binding were assessed by flow cytometry. CFH surface cofactor activity was assessed by a surface cofactor assay. EC cytotoxicity was detected via LDH assay. Blood outgrowth EC (BOECs) from healthy donors and an aHUS patient with MCP mutation were incubated with cyclosporine (CsA) and subsequently exposed to 50% normal human serum (NHS) as source for complement. EC glycocalyx was assessed with wheat germ agglutinin staining on confocal microscopy.

Results: The sequence of CsA incubation and 50% NHS resulted in a dose and time dependent enhancement of EC complement deposition and EC death, exacerbated by serum starvation and sensitization with anti-CD59 antibody. An optimal balance of EC survival and CNI effect was obtained with CsA 10 mcg/ml for 24 hours. CsA led to upregulation of CD46, CD55 and CD59 on EC surface. CsA diminished the EC glycocalyx with subsequent decreased CFH surface binding and surface cofactor activity. In further support of our in-vitro findings, MCP-deficient BOECs exposed to CsA had significantly higher surface complement deposition compared to healthy controls.

Conclusions: Our findings suggest a role for complement-mediated EC injury induced by CsA, with CFH surface dysregulation playing a key role in CsA-induced complement activation on EC surfaces. MCP-deficient BOECs were genetically predisposed to be more susceptible to CsA-induced endothelial complement deposition. CsA-induced abolishment of EC glycocalyx may be the key mechanism leading to alternative pathway dysregulation, and warrants further studies.

The RS6677604 in Complement Factor H Is Associated with Long Term Graft Function in Transplant Recipients with IGA Nephropathy Francesco Pesce,[2] E. D. Stea,[2] Anna lucia Crispino,[1] Matteo Accetturo,[2] Francesca Cianciotta,[2] Chiara Divella,[2] M. Rossini,[2] Paola Laghetti,[2] Paola Pontrelli,[2] Donata Mininni,[1] Marcella Margiotta,[1] G. Lucarelli,[2] Michele Battaglia,[2] Loreto Gesualdo,[2] Giuseppe Castellano.[2] *[1]Policlinico di Bari, Bari, Italy; [2]University of Bari, Bari, Italy.*

Background: BACKGROUND The rs6677604 in Complement Factor H (CFH) and the deletion of complement factor H-related genes 1 and 3(CFHR3-1Δ), which is in linkage disequilibrium (LD) with rs6677604-A, have been associated with the development of IgA nephropathy (IgAN). IgAN has a negative outcome on renal transplantation. We tested the role of CFHR3-1Δ using rs6677604 as proxy, in IgAN patients who received a kidney transplant assessing the impact on long-term graft survival.

Methods: Our cohort consisted of 67 patients with a biopsy-proven diagnosis of IgAN on native kidneys that received a kidney transplant at the University of Bari (D.E.T.O.) between 1993 and 2017. Genomic DNA was extracted using standard techniques. The complement factor H (CFH) region containing the SNP rs6677604 was amplified through PCR and sequenced by Sanger technology. Relevant clinical parameters were retrieved from patients' files and periodically recorded during the follow-up. Univariate and multivariate survival analyses were performed with eGFR < 60mL/min/1.73m^2 as endpoint.

Results: Of 67 patients, 22 (32.8%) had the rs6677604-AG genotype and 45 (67.2%) the rs6677604-GG genotype. These two groups were comparable in terms of demographic characteristics, donor features and transplant-related factors such as the occurrence of delayed graft function, episodes of acute rejection and therapeutic regimen. No difference was found when we analyzed the progression of the disease before the

transplant. However, we observed a significantly worse outcome of the graft in patients with the rs6677604-GG genotype by univariate survival analysis (P=5.81E-05) during the follow-up (69 ± 62 months). A multivariate Cox survival analysis revealed that the rs6677604-GG genotype (HR 30.8; 95% IC 3.3-285.5; P=0.003) is the strongest independent predictor for the graft outcome in a model adjusted for age, gender, delayed graft function, episodes of acute rejection, HLA match and donor specific antibodies.

Conclusions: Our study suggests a major impact of CFHR3-1Δ on long term graft function in kidney transplant recipients with IgAN and that rs6677604 typing can be used to predict the outcome in these patients.

TH-PO024

IL-17C/IL-17 receptor E Signaling in CD4+ T Cells Is Required to Promote TH17 Cell-Driven Glomerular Inflammation Jasper Nies,[1] Sonja Krohn,[5] Hans-Joachim Paust,[2] Jan-Hendrik Riedel,[3] Christian F. Krebs,[1] Silke R. Brix,[4] Sonja Kapffer,[7] Tilman Schmidt,[1] Rolf A. Stahl,[6] Ulf Panzer.[5] *[1]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Hamburg University Hospital, Hamburg, Germany; [3]UKE, Hamburg, Germany; [4]University Hospital Hamburg-Eppendorf, Hamburg, Germany; [5]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [6]University of Hamburg, Hamburg, Germany; [7]Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany. Group/Team: Panzer Lab.*

Background: The IL-17 cytokine family (IL-17A-F) and their cognate receptors (IL-17RA-RE) play a unique role in organ-specific autoimmunity. So far, most studies focused on the IL-17 founding member, IL-17A, as the critical mediator of diseases. The specific function of the other IL-17 family members in immunity and inflammatory diseases is largely unclear. The aim of our study was to examine the potential role of these cytokines in human and experimental immune-mediated glomerular diseases.

Methods: Serum IL-17A/C/E/F levels of 70 patients with acute ANCA-associated crescentic GN (biopsy proven) and 20 healthy control subjects were analyzed by multiplex technology (Meso Scale Discovery). The function of IL-17 cytokines and their receptors was assessed in experimental models of glomerulonephritis.

Results: Serum IL-17C levels were significantly elevated in patients with acute ANCA-associated crescentic GN compared to healthy controls ($p < 0.001$). In contrast, no significant differences in serum IL-17A/F/E levels were detected between patient groups and controls. Using mouse models of crescentic GN (NTN) and pristane induced lupus nephritis, we showed that the lack of IL-17C and its unique receptor IL-17RE significantly ameliorated the course of the GN in terms of renal tissue injury and kidney function. Interventional studies using an anti-IL-17A neutralizing antibody demonstrated that this protective effect was due to a reduced Th17 response in IL-17C and IL-17RE gene-deficient mice. GN induction in bone marrow chimeric mice lacking IL-17C in either hematopoietic or tissue cells revealed that systemic and renal IL-17C is expressed by tissue resident cells and not by lymphocytes. Finally, we demonstrated that IL-17RE was predominantly expressed by $CD4^+$ Th17 cells and that this expression is instrumental for the induction / maintenance of the Th17 responses with subsequent tissue injury in crescentic GN.

Conclusions: Our findings indicate that IL-17C promotes Th17 cell responses and autoimmune kidney disease via IL-17RE signaling on $CD4^+$ Th17 cells. Targeting the IL-17C/IL-17RE pathway may present an intriguing therapeutic strategy for Th17 driven autoimmune disorders.

Amphiregulin Aggravates Glomerulonephritis via Recruitment and Activation of Myeloid Cells Simon Melderis,[1] Georg R. Herrnstadt,[1] Anna Nosko,[1] Gisa Tiegs,[2] Oliver M. Steinmetz.[1] *[1]III. Medical Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Institute of Experimental Immunology and Hepatology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Amphiregulin (AREG), a member of the epidermal growth factor family, plays a role in development and tumorigenesis. Recently AREG has also emerged as novel player in immune responses. Both, pro- and anti-inflammatory functions have been postulated, leaving the role of AREG in inflammatory diseases widely unclear. In particular, nothing is known about the role of AREG in glomerulonephritis (GN). Given that EGF-receptor directed therapies have recently become available, we aimed to clarify the function of AREG in an experimental model of crescentic GN.

Methods: Nephrotoxic nephritis (NTN) was induced in AREG-KO mice and wild type controls. Time course and tissue specific AREG expression was assessed. Renal histology, function and leukocyte influx were analyzed. Broad analyses of renal and systemic immune responses were performed.

Results: Renal AREG expression was undetectable under homeostatic conditions. After induction of NTN AREG mRNA levels increased within the first 5 days and peaked at day 7. Expression subsequently decreased to baseline levels at day 20. In contrast, splenic expression remained below detection level at all time points. Importantly, the course of NTN was significantly attenuated in AREG-KO mice in terms of kidney function, albuminuria and histological damage. In search of a potential mechanism, we found reduced renal expression of the pro-inflammatory cytokine IL-1β, the macrophage attracting chemokine monocyte chemotactic protein 1 (MCP-1), as well as granulocyte attracting C-X-C motif chemokine ligands 1 (CXCL1) and 5 (CXCL5). As a consequence, renal infiltration of macrophages and neutrophils was significantly impaired in AREG-KO mice. Furthermore, characterization of renal macrophage markers revealed a less inflammatory phenotype in the absence of AREG.

Conclusions: Our data strongly suggest that AREG has pro-inflammatory effects in acute GN. As one mechanism, we hypothesize, that AREG induces renal chemokine expression. This in turn results in enhanced recruitment and activation of inflammatory myeloid cells. AREG is thus a potential new therapeutic target for crescentic GN.

Erythroid ACKR1 Expression Has Profound Impact on the Development of Experimental Glomerulonephritis Katharina Artinger,[1] Igor Novitzky-Basso,[3] Alexander H. Kirsch,[1] Corina Schabhüttl,[1] Elin Hub,[2] Leah Etheridge,[2] Philipp Eller,[1] Alexander R. Rosenkranz,[1] Antal Rot,[2] Kathrin Eller.[1] *[1]Medical University of Graz, Graz, Austria; [2]University of York, York, United Kingdom; [3]Queen Elizabeth University Hospital, Glasgow, United Kingdom.*

Background: The majority of individuals of West African ancestry carry a polymorphic "erythroid silent" FyB(ES) variant of *ACKR*1. Individuals with FyB(ES) express ACKR1 on endothelial cells but not on erythroid cells. The FyB(ES) polymorphism is of special interest for understanding human kidney disease as the individuals of West African ancestry have higher incidence of chronic kidney diseases. Moreover, chemokine ligands of ACKR1 are involved in driving the inflammatory pathology in the experimental model of nephrotoxic serum nephritis (NTS).

Methods: We developed humanized transgenic mouse strains, which do not express mouse ACKR1 but instead either West African FyB(ES) or Caucasian FyB polymorphic *ACKR1* variants. These strains as well as ACKR1-deficient and WT mice were subjected to NTS, a murine model of immune complex glomerulonephritis. The parameters of immunepathogenesis and kidney phenotype were evaluated after 14 days.

Results: Albuminuria, PAS and tubular injury scores were significantly increased in FyB(ES)tg and ACKR1-deficient mice as compared to their respective control strains. While monocytes were unchanged in peripheral blood, we found significantly increased numbers of macrophages and neutrophils infiltrating the kidneys of FyB(ES)tg and ACKR1-deficient mice. Interestingly, T cell numbers in the draining lymph nodes were comparable between FyB(ES)tg and ACKR1-deficient mice and their respective controls.

Conclusions: We found that NTS was more severe in ACKR1-deficient and FyB(ES) mice as compared to their respective controls. Our results show that ACKR1 expression in the erythroid compartment has a significant impact on the development of kidney disease. These findings have important implications for the pathomechanisms of glomerulonephritis in individuals of West African ancestry who lack ACKR1 selectively in the erythroid lineage.

TH-PO027

Upregulation of Matrix Metalloproteinase-10 in Glomerular Cells and Macrophages by Inflammation Keisuke Osaki,[2] Yukiko Kato,[2] Naohiro Toda,[2] Akira Ishii,[2] Keita P. Mori,[2] Shoko Ohno,[2] Kiyoshi Mori,[3] Moin Saleem,[5] Taiji Matsusaka,[4] Masashi Mukoyama,[1] Motoko Yanagita,[2] Hideki Yokoi.[2] *[1]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]School of Pharmaceut Sci, University of Shizuoka, Shizuoka, Japan; [4]Tokai University School of Medicine, Isehara, Japan; [5]University of Bristol, Bristol, United Kingdom.*

Background: Recently, we and others have unveiled the novel renal function of natriuretic peptide receptor/guanylyl cyclase-A (GC-A) system on antagonizing aldosterone-induced podocyte injury as well as the conventional effects on natriuresis and reducing blood pressure. High salt-fed systemic or podocyte-specific GC-A knockout mice with aldosterone and uninephrectomy showed accelerated glomerular injury with massive albuminuria. However, genes involved in glomerular injury are elusive.

Methods: By using microarray analysis, we compared gene expression in the glomeruli of systemic GC-A knockout mice and wild-type mice with aldosterone and examined gene expression by glomerular cells and macrophages with TNF-α. We performed immunohistochemical study for an identified protein.

Results: We identified matrix metalloproteinase-10 (MMP-10) in glomeruli of aldosterone-induced systemic GC-A KO mice. We confirmed that the expression of MMP-10 from the glomeruli in systemic and podocyte-specific GC-A knockout mice was 50 and 3 times higher than that from control mice by real-time PCR, respectively. Immunostaining revealed that aldosterone–infused systemic or podocyte-specific GC-A knockout mice exhibited a mild increase in MMP-10-positive cells in glomeruli and distal tubular cells. MMP-10 staining of renal biopsy samples in human IgA nephropathy also demonstrated the increase of MMP-10 staining intensity in glomerular cells. *In vitro*, mRNA expression of MMP-10 was increased in human podocytes as well as murine mesangial cells with TNF-α stimulation. In murine macrophages (RAW264.7 cells), the expression of MMP-10 wasn't increased with TNF-α alone, but was upregulated when both TNF-α and connective tissue growth factor (CTGF) were given at the same time. Additionally, TGF-β stimulation induced MMP-10 overexpression in podocytes.

Conclusions: These results suggest that glomerular MMP-10 in podocytes, mesangial cells and macrophages is increased in aldosterone-infused GC-A KO mice, and could play a role on inflammation during glomerular injury.

TH-PO028

Podocyte-Specific Knockout of the Neonatal Fc Receptor (FcRn) Does Not Protect against Induction of Immune Complex Mediated Glomerular Disease James F. Dylewski,[2] Evgenia Dobrinskikh,[3] Linda Lewis,[4] Gabriela E. Garcia,[1] Judith Blaine.[1] *[1]University of Colorado Denver, Aurora, CO; [2]University of Colorado Hospital, Aurora, CO; [3]University of Colorado, Denver, Aurora, CO; [4]University of Colorado Denver, Aurora, CO.*

Background: Podocytes have been postulated to act as non-hematopoietic antigen presenting cells (APCs). In typical APCs the neonatal Fc receptor is required for antigen presentation and induction of an immune response. Global knockout of FcRn has been shown to protect against immune-mediated kidney disease. Podocytes express FcRn and the aim of this study was to determine whether knockout of FcRn in podocytes ameliorates immune complex mediated kidney disease.

Methods: MHC II and costimulatory marker expression in wild type (WT) and FcRn knockout (KO) podocytes was characterized at baseline and after stimulation with IFNg using flow cytometry. We compared antigen presentation in WT and FcRn KO podocytes using an in vitro antigen presentation assay. We created a podocyte-specific FcRn KO mouse and examined albuminuria, renal histology, intraglomerular neutrophil accumulation, and C3 deposition after induction of anti-glomerular basement membrane (anti-GBM) nephritis. Fluorescence lifetime imaging (FLIM) was used to examine metabolic changes in the glomeruli of KO and control mice after induction of nephritis.

Results: We found that treatment with IFNg upregulated MHC II expression in both WT and FcRn KO podocytes. At baseline, WT podocytes expressed significantly more CD80 than FcRn KO podocytes and there was no increase in CD80 expression in the KO after treatment with IFNg. Neither WT nor KO podocytes expressed CD86 at baseline or after treatment with IFNg. When treated with immune complexes in an in vitro antigen presentation assay, WT podocytes induced a very modest increase in T-cell IL-2 production whereas KO podocytes did not stimulate T cells at all. There was no difference in BUN, albuminuria, intraglomerular neutrophil infiltration, C3 deposition, glomerulosclerosis score, or percent crescents in control versus podocyte-specific FcRn KO mice after induction of anti-GBM disease. FLIM demonstrated a decreased shift in glycolysis in KO mice compared to control after disease induction.

Conclusions: This study demonstrates that podocytes are inefficient antigen presenting cells and podocyte specific KO of FcRn does not prevent induction of anti-GBM disease.

Absence of RORyt+ Foxp3+ biTregs Aggravates Glomerulonephritis Torben Ramcke, Anna Nosko, Rolf A. Stahl, Malte A. Kluger, Oliver M. Steinmetz. *Nephrology, University Hospital Hamburg Eppendorf, Hamburg, Germany.*

Background: Recently, cells expressing the unusual combination of the Treg transcription factor Foxp3, together with the Th17 charateristic RORyt were identified (biTregs). In models of glomerulonephritis, we found protection by transfer of exogenous biTregs. However, selective deletion of RORyt in biTregs revealed additional pro-inflammatory effects, including IL-17 secretion and suppression of Th2 immunity. The net effect of complete absence of RORyt+ biTregs, as opposed to sole knockout of RORyt in Tregs, remains unknown to date.

Methods: CD4+ T cells, containing or lacking biTregs, were sorted from RORyt Foxp3 double reporters and transferred into RAG1-/- recipients. Development of transfer colitis and nephrotoxic nephritis (NTN) were assessed at varying time points after cell transfer. Immune responses and renal outcome parameters were studied. Finally, immunosuppressive mechanisms of biTregs were analysed by adoptive transfer and in vitro assays.

Results: BiTregs were readily detectable at all time points after transfer. In contrast, they failed to develop de-novo in mice receiving biTreg depleted T cells. Furthermore, the Treg/Th17 balance was not disturbed, underlining their independent character. Selective absence of biTregs did not cause generalized lymphoproliferation or accelerated transfer colitis. Importantly, however, nephritis was aggravated in mice lacking biTregs with enhanced renal inflammatory mRNA expression, leukocyte infiltration and tissue damage. Interestingly, while selective ablation of RORyt in Tregs resulted in enhanced Th2 immunity, complete absence of biTregs did not. Transfer of exogenous biTregs into immunocompetent mice revealed broad immunosuppressive capacity with no preference for Th2 responses.

Conclusions: We developed a new model, which mimicks knockout of biTregs. Absence of biTregs did not accelerate transfer colitis but significantly aggravated glomerulonephritis. In contrast to isolated deletion of RORyt in Tregs, complete lack of biTregs did not result in selectively enhanced Th2 responses. In summary, we provide further evidence that biTregs are novel and independent regulators of inflammation with broad immunosuppressive capacity.

Group 1 Innate Lymphoid Cell Is Involved in the Progress of Experimental Glomerulonephritis Inhibited by PPAR-Alpha Yusuke Okabayashi,[1,2] Shinya Nagasaka,[1] Anri Sawada,[1] Sae Aratani,[1] Ai Katsuma,[1,2] Michiko Aoki,[1] Yusuke Kajimoto,[1] Dedong Kang,[1] Go Kanzaki,[2] Nobuo Tsuboi,[2] Takashi Yokoo,[2] Akira Shimizu.[1] *[1]Department of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Both $CD8^+$ lymphocytes ($CD8^+$Lym) and macrophages (Mϕ) associate with the progress of the anti-glomerular basement membrane glomerulonephritis (anti-GBM GN) in a rat model. However, the profile of $CD8^+$Lym has not been fully evaluated except that they do not express T-cell receptor. Previous studies have shown that peroxisome proliferator activated receptors (PPARs) have anti-inflammatory effects. This study evaluated the profile of $CD8^+$Lym and the effect of PPARs on $CD8^+$Lym.

Methods: Male Wister-Kyoto rats at 4 weeks of age were intravenously injected with 50μg anti-GBM antibodies on day 1 and divided into 7 groups and received fenofibrate (30, 100, 300mg/kg/day; PPARα agonist), pioglitazone (12.5, 50, 100mg/kg/day; PPARγ agonist) or vehicle once-daily from day 0. 24-hr urine samples were collected and the kidneys were harvested on day 8. Isolated glomeruli were analyzed by flow cytometry and quantitative RT-PCR (qRT-PCR) analysis.

Results: In immunofluorescence and flow cytometric analysis of isolated glomeruli, $CD8^+$Lym that infiltrated into glomerulus were lineage negative cells (negative for T-cell, B-cell, dendritic cell, NK cell, Mϕ and granulocyte markers). Both the treatments of PPAR agonists reduced the level of proteinuria, and the number of crescentic lesions and infiltrating Mϕ dose dependently. Notably, fenofibrate showed greater reduction in infiltration of $CD8^+$Lym than pioglitazone, which was associated with the decrease of *T-bet* and *IFN*-γ mRNA expression. Moreover, fenofibrate down-regulated inflammatory cytokines and chemokines mRNA expression. qRT-PCR analysis of $CD8^+$Lym harvested by cell sorting revealed that $CD8^+$Lym expressed *IFN*-γ mRNA more than Mϕ.

Conclusions: The phenotype of $CD8^+$Lym was consistent with characters of group 1 innate lymphoid cell (ILC) which were recently identified as the novel subset of innate immune cells that were lineage negative population and express T-bet and IFN-γ. In conclusion, we first identified that $CD8^+$Lym involved in the progression of a rat anti-GBM GN is group 1 ILC and PPARα attenuates the crescent formation in anti-GBM GN through the inhibition of group 1 ILC infiltration into glomerulus.

Inhibition of the TLR4/NF-κB Axis Attenuated Glomerular Inflammation and Injury in Long Term Experimental Diabetic Kidney Disease Orestes Foresto-Neto, Amanda H. Albino, Simone C. Arias, Viviane D. Faustino, Victor F. Avila, Claudia R. Sena, Camilla Fanelli, Vivian L. Viana, Marcos A. Cenedeze, Flavia G. Machado, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Roberto Zatz. *University of Sao Paulo, Sao Paulo, Brazil.*

Background: The TLR4/NF-κB signaling pathway promotes the transcription of inflammatory interleukin genes. There is evidence that activation of this innate immunity pathway is involved in the pathogenesis of diabetic kidney disease (DKD). We investigated whether NF-κB inhibition with pyrrolidinedithiocarbamate (PDTC) exerts long term renoprotection in experimental DKD.

Methods: Diabetes (DM) was induced in 27 Munich-Wistar rats by a single streptozotocin injection (65 mg/kg, iv). Blood glucose (BG) was kept between 300 and 400 mg/dL with daily NPH insulin. Rats were divided into Groups **DM** (untreated) and **DM+PDTC** (receiving PDTC, 60 mg/kg/day vo). Untreated nondiabetic rats (**C**, n=12) were also studied. After 12 months, we assessed: urinary albumin/creatinine (Ualb/Ucr); kidney/body weight (KW/BW); glomerular sclerosis (GS, %); glomerular zonula occludens-1 (gZO-1, %); glomerular macrophage infiltration (gMΦ, cells/mm^2); glomerular TLR4, IL-1β and NLRP3 positive staining (%), renal content of heme oxigenase-1 (HO-1) and nuclear p65 (NF-κB) (fold change).

Results: After 12 months, the untreated DM group exhibited high Ualb/Ucr, renal hypertrophy, high GS, loss of gZO-1, and more intense gMΦ than C. gTLR4 and NF-κB were activated in association with increased gIL-1β and HO-1 content, whereas gNLRP3 was similar to the C value. PDTC treatment inhibited NF-κB activation and prevented the augmentation of the gTLR4, gIL-1β and HO-1 contents. In addition, PDTC attenuated renal hypertrophy and prevented the increase in Ualb/Ucr, GS, gMΦ, as well as the loss of gZO-1, without interfering with BG.

Conclusions: TLR4/NF-κB inhibition with PDTC exerts glomerular protection in long-term DKD, without changing the abundance of the NLRP3 inflammasome. These findings suggest a specific involvement of the TLR4/NF-κB axis in the pathogenesis of DKD and the possibility that this signaling pathway becomes a therapeutic target. FAPESP/CNPq

Glomerular Mechanical Tension Promotes Activation of the NLRP3 Inflammasome Pathway in Experimental Diabetic Kidney Disease: Role of Podocytes

Simone C. Arias, Matheus T. Vellosa, Viviane D. Faustino, Victor F. Avila, Luciene dos Reis, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: We showed previously (ASN 2016) that in the 5/6 ablation the estimated glomerular capillary mechanical tension (GCMT) was increased along with activation of the TLR4/NLRP3/CASP1/IL1β innate immunity (InIm) axis, helping to explain the link between hemodynamic insult and glomerular inflammation. Here we investigated whether such effect of cell agression also manifests in streptozotocin diabetes mellitus (DM), and the possible role of podocytes in this response.

Methods: We analyzed retrospectively, by immunohistochemistry, renal tissue from male Munich-Wistar rats divided into Control (C), Uninephrectomy (UNx) and UNx+DM groups. Mean arterial pressure (MAP, mmHg) had been measured 60 days after DM induction, whereas GCMT (mmHg×μm) was estimated from glomerular pressures and mean glomerular radii. Glomerular infiltration by macrophages (MΦ, cells/mm^2) was also assessed. The protein content of TLR4, NLRP3, CASP1, and IL-1β was evaluated in DM glomeruli (% area), as well as in cultured murine podocytes in the presence or absence of 15% stretching.

Results: In UNX, MAP was elevated without change in GCMT or Inlm components. In UNx+DM, hypertension was associated with increased GCMT, MΦ and InIm components, whereas a positive correlation was observed between NLRP3 and IL-1β. Under stretching, the protein content of ERK 1/2 was increased in endothelial cells, mesangial cells and podocytes. However, only podocytes exhibited a significant effect of stretching regarding the TLR4/NLRP3/CASP1/IL1β axis.

Conclusions: Inlm activation may mediate the inflammatory effects of GCMT, thus participating in the initiation and perpetuation of progressive glomerular injury in both diabetic and nondiabetic kidney disease. FAPESP/CNPq.

RNA-Seq Profiling of Microdissected Glomeruli in Clinically Early IgA Nephropathy

Sehoon Park,[2] Jae Wook Lee,[1] Seung Hee Yang,[2] Dong Ki Kim,[2] Yon Su Kim,[2] Hajeong Lee.[2] *[1]National Cancer Center, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, SEOUL, Republic of Korea.*

Background: IgA nephropathy (IgAN) is the most common primary glomerular disease worldwide and also a leading cause of chronic kidney disease and renal failure. Although recent studies have shed light on genetic variants associated with IgAN, transcriptomic changes in the glomerulus and their relevance to the pathophysiology of IgAN have been poorly defined. To identify early gene-expression changes in IgAN, we profiled the transcriptome in microdissected human glomeruli using deep sequencing of RNA species (RNA-seq).

Methods: Glomeruli were microdissected from the biopsy specimen obtained from 6 IgAN patients with preserved renal function (eGFR > 60 mL/min/1.73m^2 and proteinuria < 1 g/d). As negative controls, normal glomeruli were obtained from patients undergoing nephrectomy (n=3). Glomerular mRNAs were captured using oligo-dT primers and made into cDNA libraries for Illumina sequencing. After mapping to the human reference genome (GRCh38 primary assembly), reads mapping to Ensembl genes were counted. Wald test for a negative binomial model was used to call differentially expressed genes.

Results: Each library produced 29-43 million pairs of reads, more than 70% of which were uniquely aligned to the human genome. Of 17,833 Ensembl genes with >10 reads, 285 were upregulated and 434 downregulated in the IgAN glomeruli. Downregulated genes included transcription factors (FOS, FOSB, ZFP36, EGR1, ATF3, JUNB, NR4A2, JUN, SKI, POU5F1, KLF9, KLF8, KLF4, KLF2, CTNNB1, DMTF1, and CREBBP), periostin (POSTN), cytoskeletal proteins (MYO15A and TPM2), and C-X-C motif chemokine ligand 2 (CXCL2). Among upregulated genes were integrin subunits (ITGAV, ITGA4, and ITGB3), histone deacetylase (HDAC5), adenylate cyclase 7 (ADCY7), cyclin D2 (CCND2), homeobox D1 (HOXD1), and interleukin-6 receptor (IL6R). None of the genes positively reported in the GWAS studies on IgAN have been found to be differentially expressed in our dataset.

Conclusions: In human glomeruli obtained from patients with clinically early IgAN, RNA-seq revealed altered expression of DNA-binding transcription factors, cytoskeletal proteins, and integrin subunits that are potentially important for maintaining the integrity of the glomerular filtration barrier.

Fecal Microbiome Profiles and Pathogenesis of IgA Nephropathy

Ji In Park,[1] Hyunjeong Cho,[5] Hajeong Lee,[4] Dong Ki Kim,[5] Seung Hee Yang,[2] Jung Pyo Lee,[3] Yon Su Kim.[4] *[1]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Mucosal immune system plays a role in pathogenesis of Immunoglobulin A nephropathy (IgAN); however, little has been known about the relationship between IgAN and the intestinal microbiome.

Methods: We prospectively enrolled 30 biopsy-proven IgAN patients at 3 centers and collected fecal specimens at the time of renal biopsy. Feces from thirty healthy volunteers were used as control. The composition of microbiota was analyzed using extracted metagenomic DNA from the feces by Illumina MiSeq system. Downstream analyses were performed using SPSS, Phylogenetic reconstruction of unobserved states (PICRUSt), and Linear discriminant analysis Effect Size (LEfSe).

Results: The age, sex, and BMI were comparable between the groups. The fecal microbiota of both IgAN and control group were dominated by two bacterial phyla, Firmicutes and Bacteroidetes. Compared to control group, fecal microbiota of IgAN patients showed significantly lower OTUs and Shannon diversity index. The relative abundances of Firmicutes and Acinetobacteria were higher, whereas those of Bacteroidetes and Proteobacteria were lower in IgAN patients than healthy subjects. At Genus level, the abundances of Blautia were higher and those of Bacteriodetes, Prevotella, and Escherichia were lower in the fecal specimens from IgA nephropathy patients compared to healthy subjects. PICRUSt analysis showed that genes involved in galactose metabolism were enriched in IgAN while those responsible for glycosyltransferases were significantly associated with the controls. By dividing patients on the basis of 3 g/day proteinuria, bacterial diversity was significantly lower in severe group compared to less severe group.

Conclusions: The fecal microbiota of IgAN patients differed from those of control group. We also showed that microbial difference was possibly related to galactose metabolism or glycosyltransferases. Such differences might be related with pathogenesis of IgAN.

TH-PO035

Dysregulation of Mucosal Immune Response in IgA Nephropathy

Toshiki Kano, Hitoshi Suzuki, Yuko Makita, Yoshihito Nihei, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is associated with dysregulation of mucosal immune system, which manifests as mesangial IgA deposition leading renal impairment. However, it is not unclear which gut-associated lymphatic tissue (GALT) or nasal-associated lymphoid tissue (NALT) is more involved in the pathogenesis of IgAN. Indeed, the origin of nephritogenic IgA has been obscure. Several studies demonstrated the efficacy of tonsillectomy and corticosteroid therapy, whereas recent NEFIGAN study suggested that the novel targeted-release formulation of budesonide targeting intestinal mucosal immunity reduced proteinuria in IgAN patients. In present study, we focused on the role of GALT in murine IgAN using IgAN-prone "ddY mice".

Methods: Mesenteric lymph node (MLN) is considered to be a key function of GALT in murine. Levels of aberrantly glycosylated IgA and IgA-IgG immune complexes (IC) in serum and supernatant from cultured MLN and splenocytes were measured using IgAN onset and quiescent ddY mice (each n=15). Level of aberrantly glycosylated IgA was measured by the binding of Sambucus nigra bark lectin and Ricinus communis agglutinin I.

Results: Serum levels of aberrantly glycosylated IgA and IgA-IgG IC in IgAN onset ddY mice were significantly higher than those in quiescent ddY mice (P<0.01). However, there were no significant differences in the levels of aberrantly glycosylated IgA and IgA-IgG IC produced by MLN between IgAN onset and quiescent mice. Serum levels of aberrantly glycosylated IgA and IgA-IgG IC correlated with those in culture supernatant of splenocytes (P<0.05). However, the sugar component of IgA produced by MLN was different from those in circulation in IgAN onset ddY mice. Furthermore, serum IgA-IgG IC levels did not associate with those levels produced by cultured MLN.

Conclusions: Serum levels of aberrantly glycosylated IgA and IgA-IgG IC elevated in IgAN onset ddY mice. Glycosylation pattern of circulatory IgA was different from those originated from GALT. Therefore, IgA originated from GALT did not form immune complexes with IgG. Present study suggested that the GALT may not be involved in the pathogenesis of murine IgAN.

Tonsillar Microbiome in IgA Nephropathy Ji In Park,[1] Hyunjeong Cho,[5] Hajeong Lee,[4] Dong Ki Kim,[5] Seung Hee Yang,[2] Jung Pyo Lee,[3] Yon Su Kim.[4] *[1]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]Seoul National University Hospital, Jongno- gu, SEOUL, Republic of Korea.*

Background: Mucosal immune system plays a role in pathogenesis of Immunoglobulin A nephropathy (IgAN); however, little has been known about the relationship between IgAN and the microbiome reside in tonsil.

Methods: We prospectively enrolled 29 biopsy-proven IgAN patients at 3 centers and collected tonsil swabs at the time of renal biopsy. Tonsil swabs from 29 healthy volunteers who visited hospital for a medical check-up were used as control. The composition of microbiota was analyzed using extracted metagenomic DNA from the tonsil swabs by Illumina MiSeq system. Downstream analyses were performed using SPSS, Phylogenetic reconstruction of unobserved states (PICRUSt), and Linear discriminant analysis Effect Size (LEfSe).

Results: The mean age was 32.4 and 42.9 in control group and IgAN patients group, respectively. Though the age was significantly different between the groups, there was no trend or clustering according to the age groups. Compared to control group, tonsil microbiota of IgAN patients showed significantly higher Shannon diversity index. The relative abundances of Firmicutes and Bacteroidetes were higher, whereas those of Proteobacteria were lower in IgAN patients than healthy subjects. At Genus level, relative abundances of Granulicatella were higher, whereas those of Acinetobacter and Veillonella were significantly lower in the tonsil specimens from IgAN patients compared to healthy subjects. PICRUSt analysis showed that genes involved in galactose metabolism were enriched in IgAN. By dividing patients on the basis of 3 g/day proteinuria, we tried to figure the microbial difference according to disease severity. However, the bacterial diversity or composition were not differed between severity groups.

Conclusions: The tonsillar microbiota of IgAN patients differed from those of control group although it was not associated with disease severity. In addition, these differences showed possible relation with galactose metabolism which was involved in pathogenesis of IgAN.

TH-PO037

Racial Comparison of IgA1 Hinge-Region O-Glycoforms by High-Resolution Mass Spectrometry Yukako Ohyama,[1] Kazuo Takahashi,[1] Shoko Matsushita,[1] Hisateru Yamaguchi,[2] Kazuki Nakajima,[3] Tomohiro Mizuno,[4] Hiroki Hayashi,[1] Shigehisa Koide,[1] Daijo Inaguma,[1] Midori Hasegawa,[1] Jan Novak,[5] Yoshiyuki Hiki,[1] Yukio Yuzawa.[1] *[1]Nephrology, Fujita Health University School of Medicine, Toyoake, Japan; [2]Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Japan; [3]Fujita Academy, Fujita health university, Toyoake, Japan; [4]Analytical Pharmacology, Faculty of Pharmacy, Meijo university, Nagoya, Japan; [5]University of Alabama at Birmingham, Birmingham, AL.*

Background: Prevalence of IgAN varies among racial groups, being more common in Asians, moderately prevalent in Europeans, and rare in Africans. IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans (Gd-IgA1) plays a key role in the pathogenesis of IgAN. Relationship of serum Gd-IgA1 levels and race-specific susceptibility to IgAN is not known. To understand race-specific IgA1 *O*-glycan heterogeneity, we determined serum Gd-IgA1 levels in healthy volunteers of different races and profiled the corresponding IgA1 *O*-glycoforms.

Methods: Serum Gd-IgA1 was determined by ELISA using novel monoclonal antibody specific for Gd-IgA1 (35A12, Tomiyama Laboratory Co. Ltd., Tokyo, Japan). Human serum IgA1 was purified by affinity chromatography. After neuraminidase treatment and trypsin digestion, IgA1 *O*-glycan HR heterogeneity was analyzed by liquid chromatography-high-resolution mass spectrometry (LC-MS). To increase the throughput of the analysis, we developed an in-house automated program, Glycan Analyzer. The attachment site(s) of the Gal-deficient *O*-glycan chain(s) were identified by electron-transfer dissociation (ETD) tandem MS after selective removal of galactosylated *O*-glycans.

Results: Serum Gd-IgA1 levels were determined in 50 healthy subjects recruited from White, Black, Hispanic, Asian, and Japanese. Gd-IgA1 levels were lower in Asians, including Japanese subjects. His^{208}-Arg^{245} HR was present in 12 different glycoforms with 3-6 *O*-glycans. Approximately 58% of HR *O*-glycoforms contained one to three Gal-deficient *O*-glycans in IgA1 samples from the subjects of all races. ETD tandem MS revealed that Gal-deficient *O*-glycans were consistently attached at specific sites.

Conclusions: Despite high susceptibility to IgAN in Asians, Gd-IgA1 levels in Asians were lower compared to other races. Furthermore, HR *O*-glycoforms with Gal-deficient *O*-glycans were found also in healthy subjects. Detailed analysis of IgA1 HR *O*-glycoforms, including sites of glycan attachment, will be important for investigation of pathogenic form(s) of IgA1 in IgAN.

TH-PO038

Expression of CD71 Mesangial IgA1 Receptor Predicts Progression of IgA Nephropathy Jong Hyun Jhee,[1] Seohyun Park,[1] Seong yeong An,[1] Ki Heon Nam,[1] Boyoung Nam,[2] Meiyan Wu,[2] Sukyung Kang,[2] Arum Choi,[2] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1,2] Seung Hyeok Han.[1] *[1]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea.*

Background: The transferrin receptor (CD71) is known as a receptor for IgA1 on mesangial cells and plays a key role in the pathogenesis of IgA nephropathy. However, little is known about the association between clinical outcomes and the level of CD71 expression.

Methods: We studied the clinical implication of mesangial CD71 in 282 patients with biopsy-proven IgAN between 2005 and 2014. Glomeruli were obtained from biopsy tissues by manual microdissection. The expression of glomerular CD71 was determined by real-time polymerase chain reaction. Disease progression was defined as a ≥ 30% decline in estimated glomerular filtration rate (eGFR).

Results: During a mean follow up of 51.6 months, 40 (14.2%) patients developed disease progression. The mRNA expression of CD71 was significantly higher in progressors than in non-progressors (P = 0.01). Immunnohistochemial study also confirmed the higher expression of CD71 in the former. In a multivariable Cox model adjusted for confounders, enhanced transcript level of CD71 was significantly associated with an increased risk of disease progression (P = 0.018). Furthermore, CD71 expression level independently predicted the development of persistent proteinuria of ≥ 1 g/g creatinine (P = 0.003). Among 4 components of the Oxford classification, only M1 score was significantly associated with a higher transcript level of CD71.

Conclusions: We showed that glomerular CD 71 expression is significantly associated with various clinically important parameters in IgA nephropathy. This finding suggests that incorporation of CD71 into risk stratification is helpful in determination of adverse outcomes.

TH-PO039

IgA Nephropathy Patients B Cells Producing IgA Exhibit High Epstein-Barr Virus Infection Rate in Comparison to Disease and Healthy Controls Katerina Zachova,[1] Milan Raska.[2] *[1]Palacky University Olomouc, Olomouc, Czech Republic; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: IgAN is the most common form of primary glomerulonephritis worldwide and is typical for deposition of immune complexes mostly of IgA-IgG in the glomerular mesangium. The mesangial IgA is exclusively of the IgA1 subclass and is aberrantly glycosylated in its hinge region (galactose deficient IgA1 – gd-IgA1). EBV infects preferentially B cells, mostly the precursors of IgA-producing cells in peripheral blood. That implies the possibility that EBV infection is somehow involved in Gd-IgA1 production. Relations between some autoimmune diseases (multiple sclerosis, diabetes mellitus) and Epstein Barr virus (EBV) infection were already described in several papers. Therefore it was obvious to focus on the impact of EBV infection on IgA nephropathy (IgAN).

Methods: By cell surface staining with monoclonal antibodies we analyzed B cell subpopulations to naive, regulatory, memory, plasmablast, and plasma cell and surface immunoglobulin subpopulations IgA, IgG from peripheral blood of IgAN patients, disease controls and healthy subjects. Using a specific approach combining cell surface staining with *in situ* hybridisation for EBV RNA (EBER) followed by flow cytometry analyses we made several observations.

Results: EBV infects preferentially IgA+ B cells followed by IgG+ B cells in either IgAN patients and in controls. **Nevertheless, the incidence of EBV^+ IgA and also EBV^+ IgG B cells in peripheral blood of the IgAN patients is more than 10x higher than in non IgAN patients.** Furthermore plasmablasts are the most EBV-infected cells (65%) following with memory cells (35%) in IgAN patients in contrasts to 100% of plasmablasts in non IgAN patients. No naive and regulatory B cells were observed to be EBV positive in any groups. These explorations were confirmed on IgA deficient patients, having low amounts of IgA in serum but still having IgA B cells (naive and memory) in peripheral blood. Analysis of those patients showed 10x lower co-incidence of IgA-EBV^+ cells. That clearly corresponds with our analysis showing that 2/3 of EBV^+ cells are plasmablasts.

Conclusions: Our data confirmed an important impact of EBV infection on IgA nephropathy. From these results it is clear that B cells producing IgA of IgAN patients exhibit high Epstein-Barr virus infection rate in comparison to disease and healthy controls.

The Immunoglobulin Repertoire in IgA Nephropathy Revealed by Deep Sequencing Nicholas J. Steers, Zizhang Sheng, Jason Mccutchan, Lawrence Shapiro, Ali G. Gharavi. *Columbia University, New York, NY.*

Background: Dysregulated IgA1 response is a central defect in the development of IgA nephropathy (IgAN), but it is not clear if the altered IgA1 response is attributable to a monoclonal or polyclonal expansion of the dysregulated of IgA plasma B-cells.

Methods: Our cohort consisted of 15 healthy controls (HC), 16 IgAN patients. IgA plasma cells were phenotyped by flow cytometry, IgA1, IgA, and IgG were measured by ELISA. The immunoglobulin repertoire was sequenced and analyzed using SONAR software.

Results: We studied peripheral B-cells in 16 IgAN patients, and 15 HC, in the steady state. Increased numbers of IgA plasma cells (88 per 1000 activated B-cells) were detected in the peripheral blood of IgAN patients compared to HC (20 per 1000 activated B-cells), correlating with increased levels of IgA and IgA1 detected in the plasma. Following *in vitro* stimulation, IgA cells from IgAN patients have a greater proliferative capacity compared to HC. We next asked if the increased number of peripheral IgA B-cells in IgAN patients arose by monoclonal or polyclonal expansion. We used NGS to sequence the immunoglobulin repertoire to determine if there were differences in usage of immunoglobulin heavy chain variable (V), heavy chain joining (J), kappa and lambda genes. We observed no differences in the heavy chain V, J and kappa usage, however we detected an enhanced usage of the IGLV2-8 lambda chain in IgAN patients compared to controls (12.9% Vs 7.9% respectively, p<0.01). Examination of the complementary determining region (CDR) 3 length or the somatic hypermutation (SHM) levels in the immunoglobulin sequences showed no differences between the IgAN patients and the HC.

Conclusions: We did not detect any consistent differences in usage of immunoglobulin heavy V and J chains, CDR3 length, or SHM levels between IgAN patients and HC at the repertoire level, with the exception of lambda IGLV2-8 usage. This indicates a global expansion of IgA plasma cells rather than a monoclonal expansion in IgA Nephropathy. Future studies will be directed towards identification of intrinsic and extrinsic regulatory factors leading to globally enhanced proliferative potential in IgA plasma cells.

TLR9 Activation Induces Overproduction of Aberrantly Glycosylated IgA through the APRIL Mediated Pathway in IgA Nephropathy

Yuko Makita,[1] Hitoshi Suzuki,[1] Yoshihito Nihei,[1] Bruce A. Julian,[2] Jan Novak,[2] Yusuke Suzuki.[1] [1]*Juntendo University Faculty of Medicine, Tokyo, Japan;* [2]*University of Alabama at Birmingham, Birmingham, AL.*

Background: Involvement of Toll-like receptor 9 (TLR9) that play a key role in the innate immune system has been discussed in the pathogenesis of IgA nephropathy (IgAN). There are increasing evidences that galactose-deficient IgA1 (Gd-IgA1) and Gd-IgA1 containing immune complexes (ICs) have critical roles in the pathogenesis of IgAN. We recently demonstrated that interleukin-6 (IL-6) can enhance the production of Gd-IgA1 by IgA1-producing cells. Moreover, A proliferation-inducing ligand (APRIL) may be involved in the overproduction of the nephritogenic IgA1. However, the mechanisms leading to overproduction of Gd-IgA1 and subsequent formation of Gd-IgA1 containing ICs are still unclear.

Methods: IgAN prone ddY mice were divided into two groups with CpG-ODN (TLR9 ligand) immunization (n=19) or without (n=19). CpG-ODN was injected intraperitoneally 3 times a week for 12 weeks. Renal pathology and serum levels of aberrantly glycosylated IgA (Gd-IgA), IgG-IgA ICs, IL-6 and APRIL were evaluated after 12 weeks. We also examined the mechanisms of production of Gd-IgA1 in human IgA1-secreting cells through TLR9 activation and stimulation with IL-6 and APRIL.

Results: Mice immunized with CpG-ODN, but not non-immunized mice, showed mesangioproliferative glomerulonephritis accompanied by mesangial deposition of IgA, and C3. Immunization with CpG-ODN elevated serum levels of Gd-IgA, IgG-IgA IC and APRIL (P<0.05). Serum levels of APRIL significantly correlated with serum level of Gd-IgA and IgG-IgA IC (P<0.05). The activation of TLR9 induced production of IL-6, and IL-6 stimulation induced overexpression of APRIL in splenocytes. Moreover, in human IgA1-secreting cells, TLR9 activation enhanced Gd-IgA1 production through overexpressions of IL-6 and APRIL. Production of Gd-IgA1 was reduced by anti-IL-6 and/or siRNA for APRIL. However, anti-IL-6 could not inhibit overproduction of APRIL completely.

Conclusions: TLR9 activation exacerbated murine IgAN by enhancing production of aberrantly glycosylated IgA and nephritogenic ICs. TLR9 activation induced overproduction of IL-6 and APRIL. Present study suggested that TLR9-induced overproduction of both IL-6 and APRIL resulted in enhancing production of Gd-IgA1 and subsequent formation of Gd-IgA1 containing ICs in IgAN.

O-Glycan Profiling of High Molecular Weight Forms of IgA1 in Archival Plasma Samples from IgAN Patients and Controls

Olivier Lardinois, Candace D. Henderson, Caroline J. Poulton, Patrick H. Nachman. *UNC Kidney Center, Chapel Hill, NC.*

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis worldwide. The hallmark of the disease is deposition of IgA1 in the glomerular mesangium. These deposited IgA1 are mainly polymeric in nature. Serum polymeric forms of IgA1 are diverse and may include homodimeric IgA, homodimeric secretory IgA, and heterodimeric complexes of IgA covalently bound to other plasma proteins. Abnormalities in *O*-glycosylation of circulating IgA1, resulting in increased Tn antigen, are hypothesized to be involved in IgAN pathogenesis, and *O*-glycan structures of monomeric and homodimeric form of IgA1 have been described before in great details. However, so far, very little information is available concerning the *O*-glycosylation patterns of heterodimeric and other polymeric forms of IgA1 present in the circulation of IgAN patients.

Methods: IgAs were affinity purified from serum samples from 16 patients with IgAN and 16 control subjects. Various molecular forms of IgA1 were size-separated by gel electrophoresis. Proteins were either visualized by Coomassie blue staining or transferred to nitrocellulose membranes for Western blotting. IgA1-containing bands were in-gel digested with trypsin, and the released glycopeptides were analyzed by electrospray ionization liquid mass spectrometry.

Results: Approximately 25 % of IgA1 in archival samples from IgAN patients and controls was found as high molecular mass complexes linked through disulfide bonds. Immunobloting demonstrated 1:1 complexes between IgA and albumin, alpha-1-antitrypsin, or alpha-1-microglobulin. Quantitative analysis of *O*-linked glycosylation showed no significant differences in glycan composition between different types of circulating IgA1 complexes and no significant difference between glycan composition of IgA1 complexes from IgAN patients and from healthy controls.

Conclusions: These data indicate that, in addition to homodimeric forms of IgA, a significant fraction of IgA1 molecules in the circulation of IgAN patients and healthy controls exist as heterodimeric complexes of IgA covalently bound to other plasma proteins. It is still unclear to what extend the galactose-deficient IgA present in these heterodimeric complexes play a role in the pathogenesis of IgA nephropathy.

Circulating Levels of Tumor Necrosis Factor Alpha Correlate with Clinicopathological Features and Progression of IgA Nephropathy

Guanhong Li,[1] Wei Wu,[2] Xinyao Zhang,[2] Yubing Wen,[1] Xuemei Li,[1] Ruitong Gao.[1] [1]*Department of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China;* [2]*Department of Clinical Laboratory, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China.*

Background: Tumor necrosis factor alpha (TNF-α) and interleukin-6 (IL-6) are considered to play an important role in IgA nephropathy (IgAN). However, it is still unknown whether circulating TNF-α or IL-6 is a prognostic marker of IgAN.

Methods: Circulating levels of TNF-α and IL-6 of 147 patients with IgAN and 20 healthy subjects were measured by chemiluminescence assay. Absolute renal risk (ARR) score was used to evaluate the dialysis/death risk. This study explored the relationship between the levels of serum TNF-α or IL-6 with clinicalopathological features and progression of IgAN.

Results: Circulating levels of TNF-α were higher in patients with IgAN than that in healthy controls (HC) (P=0.02). However, circulating levels of IL-6 in patients with IgAN did not differ from HC (P=0.54). Circulating levels of TNF-α, but not IL-6, were positively correlated with male (r=0.20, P=0.02), mean arterial pressure (r=0.26, P<0.01), 24 hour urine protein (r=0.22, P<0.01), urinary protein to serum creatinine ratio (r=0.26, P<0.01), serum creatinine (r=0.49, P<0.0001) and Cystatin C (r=0.51, P<0.0001) in IgAN. Circulating levels of TNF-α were negatively correlated with estimated glomerular filtration rate (r= -0.47, P<0.0001). According to Oxford classification, circulating levels of TNF-α were higher in patients with mesangial hypercellularity grade M1 than that in M0 (P=0.03). Circulating levels of TNF-α with tubular atrophy/interstitial fibrosis grade T2 were higher than that in T1 (P=0.02). Circulating levels of TNF-α in patients of Haas grade III~V were higher than Haas grade I~II (P<0.01). Circulating levels of TNF-α in patients of Lee grade III~V were higher than Lee grade I~II (P=0.02). Furthermore, circulating levels of TNF-α steadily increased with the ARR level (ARR=3 > ARR=2, P<0.001; ARR=2 > ARR=1, P=0.04).

Conclusions: Circulating levels of TNF-α, but not IL-6, detected by chemiluminescence immunoassay, were closely associated with main prognostic clinicopathological features and progression of IgAN.

Discovery and Engineering of VIS649, a First-in-Class Humanized IgG2 Targeting APRIL for the Treatment of IgA Nephropathy

James R. Myette, Hedy Adari, Ketan Deotale, Boopathy -. Ramakrishnan, Luke Robinson, Kristy J. Szretter, Andrew M. Wollacott, Zachary H. Shriver, Brian J. Pereira. *Visterra, Inc., Cambridge, MA.*

Background: IgA nephropathy (IgAN) is one of the most prevalent, chronic glomerular diseases worldwide. No disease-specific therapeutic modalities currently exist. APRIL (A PRoliferation Inducing Ligand; TNFSF13) has recently emerged as a potentially key immunobiological factor in disease pathogenesis and progression. We describe here the discovery and lead identification of VIS649, a highly potent, humanized IgG2κ antibody targeting human APRIL. A molecular description of the unique VIS649 epitope and correlation of its mode of target engagement to its potent neutralizing activity and pharmaceutical properties are described

Methods: VIS649 was derived from parental mouse antibody 2419 following immunization with recombinant APRIL. Parental mAb 2419 was humanized with conversion to an IgG2κ with full retention of *in vitro* activity. The VIS649 binding epitope on APRIL was mapped using an integrated platform approach that incorporated X-ray crystallography, deep mutational scanning with an APRIL yeast display library, and computationally driven structural modeling. Antibody effector function (ADCC, CDC) was assessed using recombinant human Fc receptor binding and cell-based assays.

Results: VIS649 binds to human APRIL with low picomolar affinity and possesses subnanomolar blocking potency of APRIL binding and signaling through both its receptors, BCMA and TACI. VIS649 also exhibits potent inhibition of relevant APRIL-mediated B-cell activities including B cell proliferation, IgA production, and terminal B-cell survival. VIS649 targets a critical quaternary epitope within APRIL that overlaps with the high affinity (CRD2) receptor binding site and spanning the interface between

two monomers to effectively neutralize oligomeric APRIL, the biologically relevant form of APRIL. VIS649 engages with Fc receptors reflecting the expected canonical binding characteristics of a human IgG2 isotype and binds only minimally to complement (C1q).

Conclusions: This work highlights the integrated platform used for the discovery, lead optimization, and structure-activity characterization of VIS649, a first-in class anti-APRIL antibody currently in development for the treatment of IgA nephropathy.

Funding: Commercial Support - Visterra, Inc.

TH-PO045

Pharmacokinetics/Pharmacodynamics of VIS649, a First-in-Class Humanized IgG2 Targeting APRIL for the Treatment of IgA Nephropathy, in Healthy Cynomolgus Monkeys Kristy J. Szretter, James R. Myette, Emily A. Helger, Bharathi L. Sundaresh, Ketan Deotale, Jose Trevejo, Susan E. Sloan, Brian J. Pereira. *Visterra, Inc., Cambridge, MA.*

Background: VIS649 is a humanized IgG2 monoclonal antibody that targets A PRoliferation-Inducing Ligand (APRIL), a cytokine that is part of the TNF superfamily that has been implicated in IgA nephropathy (IgAN) pathogenesis and progression. Because of its role in IgA class switching and plasma cell survival, targeting APRIL in IgAN patients may substantially reduce circulating levels of aberrantly glycosylated IgA and alter disease progression.

Methods: Cynomolgus monkeys (NHP; n = 4/group) were administered VIS649 (25 mg/kg) or vehicle alone once weekly for eight weeks by intravenous injection, and were then followed for an additional 3 weeks without treatment. Study endpoints included serum VIS649 and immunoglobulin (Ig) levels. In order to characterize the temporal relationship between circulating VIS649 and IgA, a population pharmacokinetic/pharmacodynamic (popPK/PD) model was developed. Temporal changes in IgA concentration following VIS649 administration was described with an indirect response model.

Results: Treatment of NHP with VIS649 resulted in significantly lower serum levels of IgA (up to 70%) and IgG (~40%), and minimal modulation of serum IgM levels. The changes in serum Ig levels were not reversed during the 3 week no-dose period, which was attributed to the saturating levels of VIS649 at the dose administered. Analysis of the VIS649 pharmacokinetic data revealed that serum levels of VIS649 accumulated following weekly dose administrations at 25 mg/kg, and estimated the VIS649 half-life in NHP as 15 days. The popPK/PD model fit available PK and PD data well. Simulations were performed over a range of doses to inform dose selection and frequency in a follow-on study that will test lower VIS649 doses. Model simulations predict that approximately 50% reduction in IgA levels may be achieved with lower dose levels.

Conclusions: VIS649, a humanized IgG2 monoclonal antibody that targets APRIL, reduced serum IgA levels significantly in healthy NHP following 8 weekly doses at 25 mg/kg. The specific targeting of APRIL confirmed its important role in the homeostasis of IgA, and confirmed our rationale for targeting it for the treatment of IgAN.

Funding: Commercial Support - Visterra, Inc.

TH-PO046

Preclinical Safety Profile of VIS649, a First-in-Class Humanized IgG2 Targeting APRIL for the Treatment of IgA Nephropathy Kristy J. Szretter, James R. Myette, Emily A. Helger, Jose Trevejo, Susan E. Sloan, Brian J. Pereira. *Visterra, Inc., Cambridge, MA.*

Background: IgA Nephropathy (IgAN) is the most common cause of glomerulonephritis worldwide, with no disease-specific therapies currently available. VIS649 is a humanized IgG2 monoclonal antibody targeting the cytokine named A PRoliferation Inducing Ligand (APRIL) that has been implicated in the pathophysiology of IgAN disease and progression. The preclinical effect of inhibiting APRIL activity by VIS649 was evaluated in nonhuman primates (NHP) to better understand the safety and tolerability profile of this development candidate.

Methods: Preclinical safety assessments of VIS649 included off-target binding analysis, cytokine release, and *in vivo* tolerability in a NHP study. Off-target binding analysis utilized the Retrogenix cell microarray platform, in which human plasma membrane proteins were transiently expressed on HEK293 cells and therapeutic antibody binding was measured by fluorescent staining. Cytokine release was assessed with whole blood from human donors and cytokines were measured by Luminex. *In vivo* safety and tolerability were evaluated in cynomolgus monkeys administered 25 mg/kg of VIS649 intravenously weekly for 8 weeks, followed by a 3 week recovery period. Clinical chemistry, clinical pathology, hematology, immune cell profiling by flow cytometry, and histopathology were assessed.

Results: VIS649 did not demonstrate off-target binding in the Retrogenix cell microarray platform including over 3,300 unique membrane-associated human proteins. Preliminary cytokine release assays demonstrated that compared to negative controls, VIS649 did not induce secretion of cytokines. Treatment of NHP with VIS649 as compared to the control group resulted in no significant abnormalities in clinical observations, clinical chemistry, clinical pathology, hematology, or pathology. Despite a ~70% reduction in serum IgA levels, no perturbations in immune cell populations in peripheral blood or lymphoid organs were observed.

Conclusions: VIS649 has a preclinical safety profile that supports its further development as a therapeutic monoclonal antibody candidate for the treatment of IgAN. Furthermore, targeting APRIL at a dose that reduced IgA levels by 70% did not result in any safety or tolerability findings in NHP.

Sympathetic Renal Denervation Locally Aggravates Kidney Inflammation in Crescentic Glomerulonephritis Alexander M. Böhner,[2] Christian Kurts.[1] *[1]Institute of Experimental Immunology, Bonn, Germany; [2]Institute of Experimental Immunology, University Clinic Bonn, Bonn, Germany. Group/Team: Research-Group Kurts.*

Background: Nephrotoxic nephritis (NTN) is a murine model of crescentic glomerulonephritis, a serious immune-mediated type of kidney disease. There is evidence that the autonomous nervous system can regulate immune responses in general, but its role in NTN is unknown. In the present study we performed unilateral sympathetic renal denervation (RDN), by depriving the left murine kidney of its sympathetic fibers using a mixture of ethanol and cyclic aromatic chemicals applied to the renal hilus. We compared the inflammatory response in the denervated and the contralateral kidney and studied consequences for renal function.

Methods: Renal denervation was performed by application of a mixture of ethanol and cyclic aromatic chemicals to the left renal hilus. We induced the nephrotoxic nephritis by intraperitoneal injection of nephrotoxic serum. Analytic methods included flow-cytometry, ELISA and histology. Furthermore we utilized light sheet microscopy in which we made use of fluorescent tracers, kidney tissue clearing and algorithm-based full kidney reconstruction and measurement.

Results: Unilateral renal denervation caused neither albuminuria nor tubular damage in healthy mice. But already at d3 after NTN initiation, proteinuria was exacerbated. We noted an an increased influx of neutrophils, which can directly mediate glomerular damage during the early phase of NTN, into the denervated inflamed tissue. Furthermore, we detected a more proinflammatory phenotype in dendritic cells of the denervated kidney, which might be causative for the increased PMN influx. Examination of histological sections showed stronger inflammation in the cortex of the denervated kidney. To distinguish effects on the glomerular function in denervated and contralateral kidney, we perfomed light sheet microscopy of cleared kidneys after injecting fluorescent tracers. This revealed that proteinuria commenced on d3 in the denervated kidneys, while the contralateral kidney fulfilled its function without noticeable alterations at this time point. Finally, we noted significant swelling of glomeruli in the denervated kidney.

Conclusions: Neuronal signals locally attenuate harmful inflammatory responses in experimental glomerulonephritis. Our findings suggest that renal denervation, for example in the treatment of arterial hypertension, might aggravate preexisting chronic inflammation in nephritis patients.

TH-PO048

Annexin A1 Promotes the Resolution of Inflammation in Murine Crescentic Glomerulonephritis Robert Labes,[1] Ralf Mrowka,[2] Christian Hugo,[4] Sebastian Bachmann,[1] Sibylle Von Vietinghoff,[3] Alexander Paliege.[4] *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Friedrich-Schiller-Universität, KIM III, Jena, Germany; [3]Hannover Medical School, Hannover, Germany; [4]University of Dresden, Dresden, Germany, Dresden, Germany.*

Background: Resolution of acute inflammation occurs in an active and tightly regulated process which involves the suppression of pro-inflammatory signals and a cessation of leukocyte influx. The glucocorticoid-inducible protein annexin A1 has been suggested to function as key-regulator of the resolution process but its role in acute crescentic glomerulonephritis has not been studied so far.

Methods: Acute crescentic nephritis was induced in annexin A1 deficient (n=8) and wildtype mice (n=8) using a sheep serum raised against rat glomerular basement membrane constituents. Animals were sacrificed 10 days after induction of the nephritis. Renal morphology was analyzed using routine histological techniques. Renal leukocyte abundance was studied by fluorescence activated cell sorting (FACS). Alterations in gene expression were determined by RNA-Seq and gene ontology analysis. Renal levels of eicosanoids and related lipid products were measured using lipid mass spectrometry.

Results: Histological analysis revealed an increased number of sclerotic glomeruli and aggravated tubulointerstitial damage in the kidneys of annexin A1 deficient mice as compared to the wildtype controls. FACS analysis confirmed an increased number of CD11b+/Gr1+ myeloid cells (+ 110 ± 32%; $p < .01$). Lipid mass spectrometry showed elevated levels of the proinflammatory prostaglandins PGE2 (+140 ± 62%, $p < .05$), and PGD2 (+78 ± 39%, $p < .05$) whereas the abundance of the anti-inflammatory and anti-fibrotic epoxy-derivates of docosapentaenoic acid (EDP) were reduced (10,11-EDP: -34 ± 2%; 13,14-EDP: -34 ± 5%; 16,17-EDP: -27 ± 4%; 19,20-EDP: -16 ± 5%; $p < .05$ each). RNA-Seq analysis demonstrated a higher abundance of several pro-inflammatory cytokines (IL-1b: +112 ± 62%; IL-5: +90 ± 29%; IL-6: +178 ± 58%; IL-12b: +70 ± 24%; IL-13: +260 ± 70%; TNF-:+82 ± 8%; $p < .05$ each) and Gene ontology analysis revealed induction of gene products related to neutrophil- (GO:0030593) and monocyte-(GO:0002548) chemotaxis ($p < .01$ each).

Conclusions: Deficiency of annexin A1 results in a defective resolution process of renal inflammation with a persistence of pro-inflammatory signals, infiltration of myeloid cells, and aggravated tissue damage. The annexin A1 signaling cascade may therefore provide novel targets for the treatment of inflammatory kidney disease.

Funding: Government Support - Non-U.S.

TH-PO049

CD4+ T Cells Control TH17 Responses in an IL-17 Receptor A-Dependent Manner Tilman Schmidt, Hans-Joachim Paust, Sonja Krohn, Sonja Kapffer, Christian F. Krebs, Ulf Panzer. *Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany*.

Background: The characterization of IL-17A producing $CD4^+$ T_H17 cells has substantially improved our understanding of organ-specific autoimmunity including crescentic glomerulonephritis. The biological effects of IL-17A are mediated via the IL-17 receptor A. Recent clinical trials targeting the IL-17 signaling pathway by IL-17RA antibodies, have been remarkable effective for the treatment of some autoimmune disorders (psoriasis) but even led to the exacerbation of colitis in patients with inflammatory bowel diseases. The reason for these controversial results are unknown.

Methods: We generated conventional and conditional IL-17RA deficient mice to analyze the effect of IL-17 signaling in models of inflammatory kidney and gut diseases. Cytokine production was analyzed using multi-color flow cytometry.

Results: Using the T_H17 dependent model of crescentic GN (nephrotoxic nephritis), we found that IL-17RA gene-deficiency, as well as IL-17RA antibody treatment, did not ameliorated the clinical course of the GN in terms of glomerular crescent formation, albuminuria, and renal function. Of note, Citrobacter rodentium induced colitis, that triggers a potent T_H17 cell response in the gut, was significantly aggravated in IL-$17RA^{-/-}$ mice. Mechanistically, we identified a unique pattern of dysregulated CD4 T cell immunity in these animals. Production of IL-17A, IL-17F and in particular the T_H17 associated cytokines IL-22 and GM-CSF were highly upregulated in the inflamed organs accompanied by tissue injury in the absence of IL-17 signaling. Competitive adoptive transfer experiments of wildtype and IL-$17RA^{-/-}$ CD4 T cells into nephritic $Rag1^{-/-}$ mice revealed that T_H17 genes were upregulated in cells lacking the IL-17RA. Using IL-17A reporter mice and cell-specific IL-$17RA^{-/-}$ mice we finally demonstrated, that IL-17RA is highly expressed by $CD4^+$ T_H17 cells and that this expression is critical for the control of the T_H17 response and subsequent tissue injury in crescentic GN and colitis.

Conclusions: Our findings indicate that IL-17RA expression on CD4 T cells control T_H17 immune response and production of IL-22 and GM-CSF via a self-inhibitory loop. This knowledge might help to understand organ specific outcome after anti-IL-17RA antibody treatment in immune-mediated disorders and indicate that IL-17RA blockade might be ineffective for treatment of RPGN or colitis.

TH-PO050

Staphylococcus aureus Sepsis Drives a Highly Flexible TH17 Immune Response in the Kidney Patricia Bartsch,[1] Michael Zinke,[1] Christoph Kilian,[1] Hans-Joachim Paust,[1] Thorsten Wiech,[2] Jan-Eric Turner,[1] Ulf Panzer,[1] Samuel Huber,[3] Holger Rohde,[4] Christian F. Krebs.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Nephropathologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]I. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [4]Medizinische Mikrobiologie, Virologie und Hygiene, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany*.

Background: $CD4^+$ T cells play an important role in autoimmunity and infections. IL-17A expressing T_H17 effector cells are involved in autoimmune diseases and in the immune response to bacterial infections. Plasticity within the $CD4^+$ T cell system seems to be a critical factor for their pathogenicity in autoimmune diseases. T_H17 cells have a high degree of plasticity in experimental autoimmune encephalomyelitis (EAE) a mouse model for multiple sclerosis (MS), while renal T_H17 cells in crescentic glomerulonephritis (cGN) show a high degree of stability (70% maintain IL-17 expression). However, the knowledge about the T_H17 cell immune response and their plasticity in bacterial infections in the kidney is very limited.

Methods: To investigate the $CD4^+$ T cells response in infections, we established a mouse model of *Staphylococcus aureus* (*S.aureus*) sepsis induced by intravenous injection of *S. aureus* SH1000 (10^8 cfu). Renal tissue was analyzed by histology and flow cytometry. To analyze T cell plasticity, we used fluorescent reporter mice (IL-17A fate reporter and $FoxP_3$-IL-10-IL-17 acute reporter).

Results: Viable *S. aureus* were detected in kidneys at day 3-6 after infection, while no live bacteria were found after 10 days. Infection resulted in abscess formation in the kidney with infiltration of neutrophils and T cells. Intracellular cytokine staining displayed a high abundance of IL-17 producing $CD4^+$ T cells specifically in the kidney (IL17-A^+:5.7%±0.64) as compared to liver (IL17-A^+:1.84%±0.05) and spleen (IL17-A^+:1.1%±0.06). Interestingly, renal T_H17 cells revealed a high degree of plasticity in septic animals (IL-17-A^+:43.7%±0.62;IFN-γ^+:8.8%±1.31; IL17-A^+ IFN-γ^+:35.7%±4.16). However, IL-10 expression of T_H17 cells was very low (<1%), indicating a proinflammatory phenotype of renal T_H17 cells in response to *S. aureus.*

Conclusions: Here, we demonstrate a high degree of plasticity of T_H17 cells in the kidney in a *S. aureus* sepsis model. In contrast, T_H17 cells in crescentic GN are rather stable, thus suggesting that T_H17 cell plasticity is not tissue specific but might rather depend on the trigger of inflammation. Further understanding of T_H17 cell plasticity will allow more specific targeting of beneficial and detrimental T cell populations in settings of autoimmunity and infection.

Azithromycin Modulates Giant Cell Formation in Granulomatosis with Polyangiitis (GPA) Scott R. Henderson, Nixon Phua, Alan D. Salama. *University College London, London, United Kingdom*.

Background: Macrolides have immunomodulatory properties influencing both innate and adaptive immune responses. Anti-inflammatory effects have been established on neutrophils, CD4 positive T cells and monocytes and macrophages. Monocytes are central to disease pathogenesis in GPA, with critical importance in the development of granulomatous inflammation which remains one of the hardest manifestations to treat. We have established a novel *in vitro* giant cell/granuloma model with GPA patients' cells and established the significance of persistent PR3 exposure on giant cell and granuloma formation in GPA patients. Upper and lower airway manifestations of GPA are often treated with macrolide adjuvant therapy and we described a case of apparent recovery from more severe vasculitic features with azithromycin alone. Therefore, we set out to evaluate whether modulating monocyte responses to PR3 with azithromycin would result in reduced giant cell formation in GPA patients.

Methods: Monocytes were isolated from healthy controls, GPA and microscopic polyangiitis (MPA) patients and stimulated with either proteinase-3 (PR3) (10ug/ml) or myeloperoxidase (MPO) (10ug/ml) and varying concentrations of azithromycin (0.5, 2, 5ug/ml) for 72 hours. Semi-automated fusion index was calculated, a measure of MGC formation, using imaging software. Cytometric bead assays were used to evaluate modulation of cytokine production.

Results: Spontaneous rates of giant cell formation were greatest in GPA patients (n=4). The addition of PR3 but not MPO significantly increased giant cell formation in GPA patients compared to healthy controls (n=4) and MPA patients (n=4) (p 0.02). Addition of Azithromycin decreased giant cell formation in GPA patients (p 0.001) with the greatest effect seen at a concentration of 5ug/ml (p 0.03), but was also observed at 2ug/ml (p 0.003). IL-6 was important in the formation of giant cells. Although levels remained unchanged despite a reduction in giant cell formation at 72 hours in the presence of azithromycin and PR3, a reduction in IL-1b and an increase in IL-10 levels were observed.

Conclusions: Anti-inflammatory and anti-bacterial treatment is important in the maintenance therapy of GPA. Azithromycin may therefore offer a new alternative adjunctive treatment to this strategy whilst being a cost-effective, safe therapeutic option.

TH-PO052

Alkylating Histone Deacetylase Inhibitor Treatment in Animal Models of MPO-ANCA Vasculitis Dearbhaile Dooley,[5] Eóin O'Brien,[5] Barbara Fazekas,[4] Charles D. Pusey,[3] Frederick W. Tam,[2] Fionnuala B. Hickey,[5] Thomas Mehrling,[1] Peter Heeringa,[6] Mark A. Little.[5] *[1]EDO GmbH, Basel, Switzerland; [2]Imperial College Kidney and Transplant Institute, London, United Kingdom; [3]Imperial College London, London, United Kingdom; [4]Trinity College Dublin, Dublin, Ireland; [5]Trinity Health Kidney Centre, Tallaght Hospital, Trinity College Dublin, Dublin, Ireland; [6]University Medical Center Groningen, Groningen, Netherlands*.

Background: Anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) is a systemic inflammatory, autoimmune condition that affects the microvasculature. The lungs and kidneys are most frequently affected, leading to lung haemorrhage and glomerulonephritis (GN). When left untreated, AAV has a mortality rate of around 80% in year one and a 25% five-year mortality rate with current conventional treatments consisting of cyclophosphamide and steroids. However, these therapies do not prevent disease relapse and patients often require long-term treatment which is associated with severe morbidity. Recently, histone deacetylase inhibitors (HDACi) were shown to have beneficial effects in inflammatory rodent models and have been found to act synergistically with a diverse range of pharmacological agents including cyclophosphamide.

Methods: EDO-S101, a small molecule compound developed by Mundipharma EDO GmbH, is an alkylating HDACi fusion molecule which combines the strong DNA damaging effect of bendamustine, with a fully functional pan-HDACi, vorinostat. In this study, we investigated the effects of EDO-S101 in 2 well established rodent models of AAV. These consisted of a passive mouse model of anti-myeloperoxidase (MPO) IgG-induced GN and an active rat model of MPO-ANCA microscopic polyangitis: experimental autoimmune vasculitis (EAV).

Results: Our data indicate that although pre-treatment with EDO-S101 reduced circulating leukocyte populations, it did not affect development of anti-MPO IgG-induced GN in mice. On the other hand, EDO-S101 in EAV significantly reduced the degree of lung haemorrhage, severe GN and almost completely abolished crescent formation. EDO-S101 treatment in EAV also significantly depleted B and T cells compared with vehicle-treated controls, suggesting a selective effect on the adaptive immune response.

Conclusions: Taken together, we have demonstrated that EDO-S101 is a promising novel therapy for treatment of AAV that operates primarily through its effects on the adaptive immune response to the autoantigen MPO.

Transcriptional Profile Distinguishes Two Groups of ANCA Vasculitis Patients Independent of Serotype Britta E. Jones,[1] Joshua Starmer,[4] Caroline J. Poulton,[2] J. Charles Jennette,[4,1] Ronald J. Falk,[1,3] Dominic J. Ciavatta.[4,1] *[1]UNC Kidney Center, UNC Chapel Hill, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]University of North Carolina Hospitals, Chapel Hill, NC; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Increased expression of ANCA autoantigen genes myeloperoxidase (*MPO*) and proteinase 3 (*PRTN3*) has been observed in several cell types, but global transcriptional changes are less well defined in ANCA vasculitis patients.

Methods: We isolated neutrophils, CD14+ monocytes and CD4-enriched cells, from 30 healthy controls and 75 patients during active disease or remission, including 25 longitudinal patient pairs. Expression of *MPO* and *PRTN3* in these purified cell populations was determined by quantitative real-time PCR. RNA-seq was performed on the CD4-enriched cell population from 12 active-remission pairs, 7 MPO-ANCA and 5 PR3-ANCA, to identify differentially expressed genes (DEGs) between active disease and remission.

Results: Expression of the autoantigen genes was elevated in patients with active disease compared to healthy controls in all three cell populations. A non-significant fold change in expression was seen in monocytes while the mean fold-change in expression for *MPO* and *PRTN3*, respectively, was 2.6; 3.6 in neutrophils and 7; 15.8 in the CD4-enriched cell population. Analysis of autoantigen gene expression in the CD4-enriched cell fraction and neutrophils in active-remission pairs revealed two groups of patients: patients with decreased expression from active disease to remission and those in which *MPO* and *PRTN3* mRNA did not change. RNA-seq of active-remission pairs detected three DEG in patients where *MPO* and *PRTN3* expression did not change. In patients who decreased autoantigen expression from active disease to remission, 468 significantly DEGs were detected including granulocyte genes [Figure 1].

Conclusions: The transcriptional profile that divides ANCA vasculitis patients into two categories suggests a molecular signature can distinguish disease status.

Monocytes Promote Crescent Formation in Anti-Myeloperoxidase Antibody-Induced Glomerulonephritis Anthony Rousselle,[2] Ralph Kettritz,[1,3] Adrian Schreiber.[1,3] *[1]Charite Berlin, Berlin, Germany; [2]ECRC, Berlin, Germany; [3]Charite, Experimental and Clinical Research Center, Berlin, Germany.*

Background: Neutrophils and monocytes express ANCA antigens, and activation of these cells by ANCA is central to ANCA-associated vasculitis (AAV) and necrotizing crescentic glomerulonephritis (NCGN). The importance of neutrophils is established; however, any role of monocytes is less clear. We tested the hypothesis that depletion of $CCR2^{+}$ inflammatory monocytes and their derivatives would abrogate anti-MPO antibody-induced NCGN in a mouse model.

Methods: We used anti-MPO IgG (50 µg/g body weight, BW) transfer to induce NCGN in LPS-challenged wild-type (WT) mice and in mice expressing the CCR2 promoter-controlled diphtheria toxin receptor (CCR2-DTR). Diphteria toxin (DT) then allows depletion of $CCR2^{+}Ly6C^{high}$ inflammatory monocytes in DTR mice. Urine was analyzed by dipstick, albuminuria by ELISA, glomerular necrosis and crescents by histology, and circulating and renal cell influx by flow cytometry.

Results: Both mouse strains showed similar circulating $Ly6C^{hi}$ and $-^{lo}$ monocytes and neutrophils at baseline. Diphtheria toxin robustly depleted circulating monocytes only in CCR2-DTR mice, whereas neutrophil numbers were similar. Anti-MPO antibody transfer resulted in nephritic urine by dipstick and albuminuria by ELISA, and monocyte depletion had no effect. However, monocyte depletion significantly reduced glomerular necrosis and crescent formation (21.4±10.5 vs. 4.3±2.2 for crescents and 12.0±7.1 vs. 3.0±1.1 for necrosis, $p<0.05$ for both) and abrogated monocyte, macrophage and dendritic cell increase in the affected kidneys, whereas renal neutrophil numbers were not affected. Soluble CD163 increased in serum, but not in urine with anti-MPO antibody treatment and was completely abolished with monocyte depletion.

Conclusions: Our findings provide novel experimental evidence that monocytes are important disease contributors in ANCA-mediated NCGN. Whereas neutrophils are sufficient to induce nephritic urine abnormalities, albuminuria, and some NCGN, inflammatory monocytes clearly enhanced necrosis and crescent formation.

Detecting Autoreactive Cells and Pathogenic Epitopes in MPO-ANCA Vasculitis Katherine G. Stember,[2] Jacob Hess,[1] Candace D. Henderson,[1] Simon Mallal,[3] J. Charles Jennette,[5] Ronald J. Falk,[4] Dominic J. Ciavatta,[5] Meghan E. Free.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina Chapel Hill, Chapel Hill, NC; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of North Carolina Hospitals, Chapel Hill, NC; [5]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Anti-neutrophil cytoplasmic autoantibody (ANCA) vasculitis is an autoimmune disease that damages blood vessels throughout the body, and treatment regimens include immunosuppression. Previous studies demonstrated dysregulation of the adaptive immune system and identified two autoantigens: myeloperoxidase (MPO) and proteinase 3 (PR3). GWAS studies found an association between ANCA vasculitis and human leukocyte antigen (HLA). Mouse and human studies identified pathogenic MPO epitopes. Our lab sought to investigate MPO epitopes recognized by autoreactive B and T cells in patients.

Methods: We used an in-house ELISA to test antibody reactivity to a previously identified linear MPO epitope. We HLA sequenced 203 patients to identify disease-associated alleles and used predictive and in vitro binding studies to assess MHC-peptide binding. MHC II tetramers were produced for DPB1*04:01 and DRB4*01:01 containing MPO epitopes and controls. Patient PBMCs were incubated with tetramers, stained with surface markers, and analyzed by flow cytometry day 1 ex vivo.

Results: Our ELISA revealed 53% percent of patients have autoantibodies that bind $MPO_{447\text{-}461}$, most often at disease onset. Patients carrying HLA of interest demonstrate specific CD4+ T cell recognition of tetramers containing MPO epitopes. The majority of tetramer positive cells are $CD25^{intermediate}$ cells, and are positive for CD45RO and CCR7 memory markers. Additionally they secrete IL-17 when stimulated.

Conclusions: Recently, it was shown that $MPO_{409\text{-}428}$ induced tolerance and attenuated disease in a mouse model of anti-MPO GN. Patient CD4+ T cells show significant reactivity to tetramers carrying the human homolog of this epitope. Ideally, we will use this region of MPO to inform the development of new therapies for patients with ANCA vasculitis.

Neutrophil-Gelatinase Associated Lipocalin (NGAL) Attenuates ANCA-Induced Glomerulonephritis by Inhibiting Th17 Immunity Adrian Schreiber,[1,5] Ulf Panzer,[3] Anthony Rousselle,[2] Ralph Kettritz.[4,5] *[1]Charite Berlin, Berlin, Germany; [2]ECRC, Berlin, Germany; [3]None, Hamburg, Germany; [4]Universitatsmedizin Berlin, Berlin, Germany; [5]Charite, ECRC, Berlin, Germany.*

Background: ANCA activate neutrophils and monocytes and thereby participate in vasculitis and necrotizing crescentic glomerulonephritis (NCGN). NGAL is a marker of intrinsic kidney injury and is expressed by neutrophils and renal tubular cells. Whether or not NGAL is merely a diagnostic marker or participates mechanistically in renal damage is not known. We hypothesized that neutrophil NGAL plays a pathogenic role in ANCA-induced NCGN.

Methods:

Results: Patients with active ANCA disease demonstrated strongly increased NGAL serum levels by western blot analysis (47.3±13.1 optical density, OD) compared to patients in remission (19.4±8.1OD) and healthy controls (2.1±0.4OD). By ELISA, both PR3-ANCA and MPO-ANCA stimulated NGAL release from human neutrophils (887±72 and 961±70 ng/ml, respectively), whereas control IgG induced much lower levels (105±21ng/ml). In addition, mice with anti-MPO-induced NCGN demonstrated upregulated NGAL serum levels. To assess the role of neutrophil NGAL in vivo, we used a murine model of anti-MPO induced NCGN, where mMPO-immunized MPO-deficient mice were transplanted with either WT- or NGAL-deficient BM. NCGN was significantly aggravated in mice that received NGAL-deficient BM (34.8±6.1% crescents in NGAL-KO versus 13.4±2.8% in WT mice). With respect to intrinsic neutrophil function, migration, ROS generation, degranulation and apoptosis were similar in NGAL-KO and WT neutrophils. In addition, humoral immunity to MPO did not differ between both groups. In contrast, flow cytometry demonstrated significantly increased renal T-cells in NGAL-deficient mice: TH17 cells were 21.7±7.6% of renal CD4 cells versus 5.7±1.0%. Splenocytes from NGAL-deficient mice demonstrated a higher proliferation rate than splenocytes from WT mice. Finally, to assess the specific role of TH17 immunity in anti-MPO-induced NCGN, immunized MPO-KO and MPO-/IL17A-double-KO mice were transplanted with either WT or IL17A-KO BM, respectively. NCGN was significantly attenuated in IL17A-KO mice compared to WT mice as assessed by urine pathology and

renal histology (2.5±1.3% crescents in MPO-/IL17A-double-KO versus 29.6±7.2% in MPO-KO mice).

Conclusions: Our findings indicate that neutrophil NGAL down-regulates inflammation in ANCA-induced NCGN by inhibiting TH17 immunity and TH17 cells are clearly necessary for induction of ANCA-mediated NCGN.

Microparticle Tissue Factor Activity Dominates Venous Thromboembolism Signature in ANCA Vasculitis Carmen E. Mendoza,[4] Elizabeth J. Brant,[1] Matthew L. Mcdermott,[4] Anne B. Froment,[2] Yichun Hu,[2] Susan L. Hogan,[8] J. Charles Jennette,[7] Ronald J. Falk,[5] Patrick H. Nachman,[6] Vimal K. Derebail,[3] Donna O. Bunch.[2] *[1]Dartmouth-Hitchcock Medical Center, Lebanon, NH; [2]UNC Kidney Center, Chapel Hill, NC; [3]University North Carolina at Chapel Hill, Chapel Hill, NC; [4]University of North Carolina, Chapel Hill, NC; [5]University of North Carolina Hospitals, Chapel Hill, NC; [6]University of North Carolina School of Medicine, Chapel Hill, NC; [7]University of North Carolina at Chapel Hill, Chapel Hill, NC; [8]University of North Carolina, Chapel Hill, Chapel Hill, NC.*

Background: Venous thromboembolism (VTE) is a complication of ANCA vasculitis whose mechanism remains incompletely elucidated. We tested biomarkers associated with disease activity in ANCA vasculitis and/or VTE in other diseases, including microparticle tissue factor activity (MPTFa) and anti-plasminogen (anti-Plg) to devise a thrombotic signature. We hypothesized that elevated MPTFa and anti-Plg may identify patients at risk for VTE.

Methods: Patients were enrolled during active disease. Twelve patients experienced a VTE (VTE^{pos}) and were compared to patients without VTE (VTE^{neg}, n=29) and 56 healthy controls (HC). Platelet free plasma and serum samples were assayed for MPTFa and anti-Plg. IL-6 was measured by a commercial ELISA; positivity was defined as 2 standard deviations above the HC mean. D-dimer, high sensitivity CRP (hs-CRP) and serum creatinine were measured by our clinical laboratory. Measures were assessed at active disease and remission. Univariate and bivariate analyses were performed by Cox regression.

Results: Demographics were similar in patients and HC. VTE^{pos} and VTE^{neg} patients did not differ in ANCA serotype, titer or BVAS. In univariate analysis, elevated MPTFa during active disease was associated with VTE (HR=1.06, 95%CI 1.01, 1.10; p=0.009). For every 10 units increase of MPTFa during active disease, the risk of VTE increased by 60%. This is a significant unit of measure as the threshold for positivity was set at 11% of the positive control. Assuming remission values before and after VTE are comparable, MPTFa at remission was also associated with VTE (HR=1.4, 95%CI 1.11, 1.77; p=0.005). Similarly, increased anti-Plg during remission was associated with VTE (HR=1.17, 95%CI 1.03, 1.33; p=0.02) but not at active disease. Per unit increases of both hs-CRP (HR=1.21, 95%CI 1.02, 1.45; p=0.04) and serum creatinine (HR=1.29, 95%CI 1.0, 1.66; p=0.05) were associated with VTE. IL-6 and D-dimer were not associated with VTE. In bivariate analysis, MPTFa adjusted for serum creatinine was still significantly associated with VTE (HR=1.05, 95%CI 1.01, 1.10; p=0.01).

Conclusions: Our data suggest that of the variables evaluated, elevated MPTFa provides the best marker of VTE and may identify patients at high risk for VTE in ANCA vasculitis.

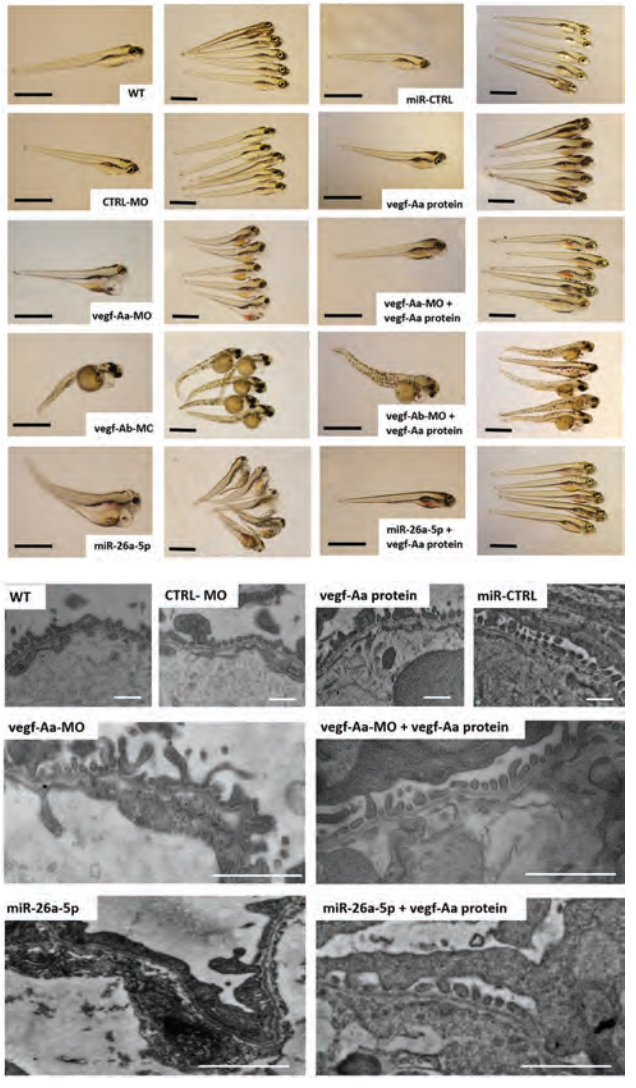
Overexpression of Preeclampsia Induced miR-26a-5p Leads to Proteinuria in Zebrafish Janina Müller-Deile,[1] Patricia A. Schroder,[3] Jenny C. Nystrom,[4] Hermann G. Haller,[2] Mario Schiffer.[2] *[1]Hypertention and nephrology, Hannover medical school, Hanover, Germany; [2]Hannover Medical School, Hannover, Germany; [3]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [4]University of Gothenburg, Goteborg, Sweden.*

Background: So far the pathomechanism of preeclampsia in pregnancy is focussed on increased circulating levels of sFLT1 that neutralizes glomerular VEGF-A expression and prevents its signalling at the glomerular endothelium. MiR-26a-5p is upregulated in the preeclamptic placenta.

Methods: We analyzed miR-26a-5p expression in podocytes and microinjected zebrafish eggs with a miR-26a-5p mimic. We analysed phenotype, proteinuria and ultrastructural changes of the glomerular filtration barrier.

Results: We found that miR-26a-5p targets VEGF-A expression in cultured podocytes and that its overexpression in zebrafish causes proteinuria, edema, glomerular endotheliosis and podocyte foot process effacement. Recombinant zebrafish vegf-Aa protein could rescue glomerular changes induced by miR-26a-5p. Preeclamptic patients with podocyte damage identified by podocyturia, expressed significantly more urinary miR-26a-5p compared to controls.

Conclusions: Thus, functional and ultrastructural glomerular changes after miR-26a-5p overexpression can resemble the findings seen in preeclampsia and indicate a potential pathophysiological role of miR-26a-5p in addition to sFLT-1 in this disease.



TH-PO059

Protective Effect of TRPC6 Knockout in Chronic PAN Nephrosis in Sprague-Dawley Rats Stuart E. Dryer, Eunyoung Kim. *University of Houston, Houston, TX.*

Background: Mutations in TRPC6 channels give rise to rare forms of focal and segmental glomerulosclerosis (FSGS). A possible role of wild-type TRPC6 channels in the progression of acquired forms of FSGS is not firmly established, and it is important to examine this in multiple species. Here we examined the role of TRPC6 channels in chronic puromycin aminonucleoside (PAN) nephrosis in Sprague-Dawley rats. Chronic PAN nephrosis is one of the most extensively studied models of secondary FSGS. A major advantage of this model is that experimental animals get a severe glomerular disease.

Methods: A global constitutive $TRPC6^{-/-}$ rat was generated on the Sprague-Dawley background using CRISPR/Cas9 technology. Experiments were carried out using $TRPC6^{+/+}$ and $TRPC6^{-/-}$ littermates. Rats were given two i.p. injections of PAN at 30 day intervals. Renal phenotypes were characterized by standard histological, ultastructural, and biochemical methods. All experiments were approved by the University of Houston IACUC.

Results: Nephrotic range albuminuria was present 9-10 days after the first PAN injection and there was no difference in 24-hour urine albumin excretion in $TRPC6^{+/+}$ and $TRPC6^{-/-}$ rats at that time. In marked contrast to the acute phase, at 30 and 60 days after the initial PAN injection, $TRPC6^{-/-}$ rats had biologically and statistically significantly reduced urine albumin excretion, reduced serum cholesterol and triglycerides, and improved BUN compared to $TRPC6^{+/+}$ littermates. Glomerulosclerosis was severe during chronic PAN nephrosis in $TRPC6^{+/+}$ rats, but was markedly reduced in $TRPC6^{-/-}$ littermates. TRPC6 knockout rats also had less severe tubulointerstitial fibrosis, and reduced foot process effacement and glomerular basement thickening compared to $TRPC6^{+/+}$ controls. $TRPC6^{-/-}$ rats also had reduced infiltration of monocytes or macrophages into glomeruli, and reduced expression of α-smooth muscle actin in renal cortex compared to $TRPC6^{+/+}$ littermates. Basal TRPC3 abundance in renal cortex was increased in $TRPC6^{-/-}$ rats compared to $TRPC6^{+/+}$ controls. However TRPC3 did not increase further in chronic PAN nephrosis. None of the manipulations in this study affected TRPC5 channels.

Conclusions: TRPC3/6 family channels may represent useful therapeutic targets for acquired forms of FSGS.

Funding: NIDDK Support

TH-PO060

Calpain Activation by TRPC6 in the Podocyte Louise K. Farmer, Gavin I. Welsh, Moin Saleem. *University of Bristol, Bristol, United Kingdom.*

Background: TRPC6 mutations have been shown to cause Focal Segmental Glomerulosclerosis (FSGS). Previously the pathology of these mutations was thought to be due to an increased calcium conductance of this membrane channel. However, several disease-causing mutations have been reported to have no change in, or decreased, calcium conductance. We have investigated whether these mutations affect protein interactions.

Methods: Conditionally immortalised podocyte cell lines were generated from TRPC6 KO C57Bl/6 mice. GFP tagged WT/mutant TRPC6 was stably reintroduced into the KO cell line using a lentiviral construct. Cell lines were then characterised to determine motility and adhesion using scratch and adhesion assays. GFP TRAP beads were used to immunoprecipitate TRPC6 and proteomics was performed to identify novel binding partners. Calpain assays were performed using a commercially available kit.

Results: TRPC6 KO (T6K) podocytes are less motile and more adhesive than those expressing WT TRPC6. Calpain 1 and 2, ERK 1/2 and caldesmon were identified as novel TRPC6 binding partners using GFP-TRAP pull down, proteomics and verified through co-immunoprecipitation experiments. Calpain is a protease with a variety of targets including focal adhesion kinase (FAK). T6K cells have decreased FAK cleavage and increased FAK phosphorylation compared to cells containing WT TRPC6. The cleavage of the calpain targets talin-1 and caldesmon was also decreased in T6K cells. Calpain assays demonstrated a loss of calpain activity in T6K cells. This suggests that in WT cells TRPC6 is responsible for calpain activation. The disease causing mutant form of TRPC6, K874*, has normal calcium conductance, however, as with T6K cells, cells expressing this mutant have decreased calpain activity and decreased cleavage of calpain targeted proteins. Co-IP experiments have shown that there is decreased binding of TRPC6 K874* to calpain compared to WT. We have also shown that treatment of WT cells with plasma from nephrotic syndrome patients during relapse, but not remission, causes an increase in calpain activity. This suggests that TRPC6 mediated activation of calpain could be playing an important role in disease.

Conclusions: TRPC6 mediated activation of calpain plays an important role in podocyte motility and detachment. Disease causing mutations in TRPC6 could be acting by preventing the binding of calpain 1/2 to TRPC6, decreasing calpain activation

TH-PO061

Targeting Podocyte Endoplasmic Reticulum Calcium Depletion to Treat Nephrotic Syndrome Sun-Ji Park,[1] Yeawon Kim,[1] Jeffrey H. Miner,[1] Fumihiko Urano,[2] Ying M. Chen.[1] *[1]Division of Nephrology, Washington University School of Medicine, St. Louis, MO; [2]Division of Endocrinology, Metabolism, and Lipid Research, Washington University School of Medicine, Saint Louis, MO.*

Background: Emerging evidence has demonstrated that podocyte endoplasmic reticulum (ER) stress caused by gene mutations contributes to the pathogenesis of nephrotic syndrome (NS). ER stress-mediated calcium efflux from the ER to the cytosol can activate calcium-dependent protease calpain 2, which underlies the development of proteinuria. Here for the first time, we have shown that a novel ER calcium stabilizer can inhibit podocyte calpain activation.

Methods: We have developed a NS mouse model in which C321R mutation of the glomerular basement membrane constituent laminin β2 (LAMB2), a mutation identified in human patients, leads to podocyte ER stress. We isolated mouse glomeruli and cultured primary podocytes at the early stage of the disease to investigate the functional impact of ER stress. Meanwhile, we generated human podocytes stably expressing WT or C321R β2. Moreover, a *Gaussia* luciferase (GLuc)-based assay utilizing secreted ER calcium-monitoring proteins (SERCaMPs), and fluorescent calcium indicator Fluo-4 detected by flow cytometry were employed to monitor ER calcium leak in live cells and to measure cytosolic calcium levels, respectively.

Results: Podocyte ER stress triggered by the C321R mutation induced calpain activation, as indicated by the cleavage of its substrate spectrin. In addition, calpain 2 hyperactivation in mutant podocytes activated the caspase 12 apoptotic pathway, cleaved the podocyte cytoskeletal protein talin, and downregulated the podocyte slit diaphragm proteins nephrin and podocin. Furthermore, cytosolic calcium levels were increased in human podocytes expressing C321R-LAMB2 compare to WT-LAMB2, directly demonstrating ER calcium depletion in the mutant podocytes. RNAseq further highlighted dysregulated ER calcium signaling pathways in C321R podocytes compared to controls. Most excitingly, by utilizing GLuc-SERCaMP as a high throughput drug screening tool, a novel ER calcium stabilizer was identified to suppress calpain 2 activation in C321R podocytes.

Conclusions: Currently there is no treatment for most genetic forms of NS. Our study may open up a new avenue for treatment of NS caused by podocyte ER calcium depletion.

TH-PO062

TRPM4 Is Expressed at the Apical Surface of Podocyte Just Above Slit Diaphragm, and Its Altered Expression Is Involved in Podocyte Injury Ying Zhang, Yoshiyasu Fukusumi, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University, Niigata, Japan.*

Background: TRPC6, a member of TRP channels is reported to play an important role in regulating the slit diaphragm (SD) function. To explore novel molecules involved in the development of proteinuria, we performed cDNA subtraction assay and RNA-seq analysis. 293 molecules were identified to be decreased to less than 20 % in PAN nephropathy. We found transient receptor potential melastatin 4 (TRPM4), another member of TRP channels was clearly downregulated. In this study we examined the expression and localization of TRPM4 in glomeruli and its possible roles in pathogenesis of proteinuria.

Methods: The expression and the localization of TRPM4 under the physiological and pathological conditions were analyzed by real-time PCR, dual-labeling immunofluorescence and Western blot. We prepared three rat models, PAN nephropathy, a mimic of MCNS, ADR nephropathy, a mimic of FSGS and anti-nephrin antibody (ANA) induced nephropathy, which is characterized as a slit diaphragm specific dysfunction.

Results: The mRNA expression of TRPM4 in glomeruli was more extensive than that in renal cortex and other tissues. The expression of TRPM4 was also detected in cultured mouse podocytes. Immunostaining of TRPM4 in renal cortex was restricted to glomeruli, and it was observed to be a discontinuous linear pattern along the glomerular capillary loops. TRPM4 staining was slightly aside from nephrin, an extracellular component of the SD, and some portions of TRPM4 were colocalized with podocyte apical membrane marker podocalyxin. TRPM4 first appeared in the presumptive podocytes in early S-shaped body stage, when nephrin was not detected yet. The mRNA expression of TRPM4 was evidently decreased immediately after disease induction (1h: 10 % in ANA, 31 % in PAN) and the decrease was still detected when proteinuria peaked (42 %, 57 %). The immunostaining of TRPM4 shifted to a discontinuous patchy pattern in PAN nephropathy. The staining intensity of TRPM4 was lowered in ANA nephropathy and ADR nephropathy.

Conclusions: TRPM4 is expressed at the apical surface of podocyte just above slit diaphragm. The mRNA expression of TRPM4 was clearly decreased before the onset of proteinuria. The immunostaining of TRPM4 was altered in proteinuric states. It is conceivable that the altered expression of TRPM4 is involved in initiating the slit diaphragm dysfunction.

TH-PO063

Brevin R-SNARES Provide a Cellular Address to Localize APOL1 to Podocyte Endosomal Compartments Sethu M. Madhavan,[2] John F. O'Toole,[1] Martha Konieczkowski,[1] Leslie A. Bruggeman,[1] John R. Sedor.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]MetroHealth Medical Center, Cleveland, OH.*

Background: Genetic variants in *APOL1* (G1 and G2) associate with non-diabetic kidney diseases in individuals with African ancestry. Kidney-expressed, but not circulating APOL1 variants, confer risk for CKD. Most subjects with high risk *APOL1* genotypes do not develop kidney disease, suggesting a second hit is necessary. Sites of APOL1 synthesis in kidney, its subcellular localization and the identity of its cognate binding partners as well as mechanisms by which variant APOL1s promote nephropathy remain unclear.

Methods: In situ hybridization (ISH) was performed in normal human kidney tissue to detect APOL1 transcripts. APOL1 subcellular localization was examined by immunoelectron (IEM) and confocal immunofluorescence microscopy. Co-immunoprecipitation (Co-IP) experiments to study APOL1-SNARE protein interaction was performed in 293T cells ectopically expressing tagged proteins. Bacterially expressed proteins purified by metal affinity and size-exclusion chromatography were used to study protein interaction by surface plasmon resonance (SPR).

Results: ISH demonstrated that APOL1 is synthesized in podocytes of human kidney and less so in tubules. In kidneys of mice transgenic for APOL1 and human nephrectomy samples, IEM localized the protein to double membrane vesicles and endocytic compartments in podocytes. APOL1 did not localize to plasma membrane in podocytes. By immunofluorescence, podocyte APOL1 did not localize with either a mitochondrial marker, beta-subunit of ATP synthase, or a lysosomal marker, LAMP1. APOL1 interacted with the R-SNAREs, VAMP8 and VAMP1 in Co-IPs. APOL1 colocalized with VAMP8 in podocytes of normal human kidney and Co-IP and SPR experiments confirmed that APOL1-G1 and -G2 interact with VAMP8 with lower affinity than -G0.

Conclusions: Reference APOL1 is expressed in the podocyte, localizes with vesicular structures and directly interacts with VAMP8, consistent with regulation of podocyte vesicular trafficking. APOL1 variants attenuate interaction with VAMP8. We propose that reference APOL1, by interacting with VAMP8 or other R-SNAREs, identifies vesicles containing cargo capable of mediating cellular damage, and activates a cellular response, which mitigates the pathogenic potential of these cargos. Variant APOL1 proteins fail to do so, disrupting vesicular trafficking and permitting kidney disease progression.

TH-PO064

The Effects of Mechanical Strain on Adhesion in MYH9- Ablated Podocytes Keith H. Keller,[3,4] Mostafa Belghasem,[3] Hui Chen,[1] Joel M. Henderson.[2,3] *[1]BMC, Boston, MA; [2]Boston University Medical Center, Boston, MA; [3]Boston University School of Medicine, Boston, MA; [4]Brigham and Woman's Hospital, Boston, MA.*

Background: Myh9 is a gene that encodes for non-muscle myosin IIA (NM-IIA), an actin cytoskeleton component and protein involved in cell movement and adhesion in most cells, including podocytes. Autosomal dominant mutations in NM-IIA have been associated with focal segmental glomerulosclerosis (FSGS). Podocyte specific Myh9 knockout in mice showed that this gene alone was not enough to cause proteinuria or glomerulosclerosis. However, in our own laboratory we have found that when these same mice are exposed to models of glomerular hypertension, glomerular damage is promoted. This damage was preceded by evidence of podocyte loss in urine and tissue. Podocyte loss is a hallmark of kidney disease, and while it is known to occur in vivo, the mechanisms behind this phenomenon are unknown. It is believed that increase in glomerular capillary blood pressure is likely to be a strong contributing factor. Here we investigated the effect of mechanical strain on adhesion and cell morphology in Myh9 ablated podocytes.

Methods: Myh9 was knocked down, using RNAi, in immortalized mouse podocytes cultured on flexible silicone 6-well plates at a density of 6000 cells per well. Cells were mechanically stretched in a step-change fashion for 24hrs then cells were fixed or lysed for protein. Each experiment included three groups with two conditions (stretch/no stretch): WT; lentiviral control; KD. Changes in adhesion were assessed using cell counts, and morphologic changes were evaluated using immunofluorescence and quantified using imageJ.

Results: Transfected cells showed marked decrease in cellular attachment (V.CTL: -53%; V.CTL-ST: -53%; KD: -50%; KD-ST: -60%), compared to control cells (CTL: +77%; CTL-ST: +120%). Mean focal adhesion area increased with stretch in each experimental treatment group except KD (CTL: 1.41+ 1.62 μm2; CTL-ST: 2.12+ 3.13μm2; V.CTL: 0.54+ 0.47μm2; V.CTL-ST: 2.77+ 3.59μm2; KD: 3.04+ 2.57μm2; KD-ST: 2.09+ 1.13μm2). KD-ST cells showed large decrease in focal adhesion number compared to all other groups. Mean cell size was drastically larger in the KD groups (CTL: 773.6+489.μm2; CTL-ST: 505.5+377.7μm2; V.CTL: 817.6+1008,5μm2; V.CTL-ST: 1306.9+787μm2; KD: 3576.5+2694.7μm2; KD-ST: 5461.7+13,456.3μm2)

Conclusions: Myh9/NM-IIA may necessary for cells to bolster cell adhesion structures during events of mechanical stress, and its loss may compromise this protective adaptation.

TH-PO065

MicroRNA671-5p Mediates Wnt/β-Catenin-Triggered Podocyte Injury by Targeting WT1 Chunhong Wang,[1] Wenjuan Zhu,[1] Lili Zhou,[1] Youhua Liu.[2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Podocyte injury is the major pathological feature of many proteinuric kidney diseases. It has been shown that dysregulated activation of Wnt/β-catenin signaling in podocytes can lead to podocyte dedifferentiation and mesenchymal transition, causing impaired glomerular filtration and proteinuria. MicroRNAs (miRNAs) are a class of short non-coding RNAs, which regulates specific genes by targeting and fine-tuning their expression. To study whether miRNA is involved in mediating Wnt/β-catenin-triggered podocyte injury, we performed a comprehensive miRNA expression profiling and sought to identify the miRNAs that may play a crucial role in this process.

Methods:

Results: Mouse podocytes were transiently transfected with expression vector encoding constitutively activated β-catenin (pDel-β-cat) or empty vector (pcDNA3). The differential expression of miRNAs was identified through a microarray analysis. Among several dozens of miRNAs which expression levels were altered after β-catenin activation, miR-671-5p was on the top of the list. Subsequent qRT-PCR confirmed that miR-671-5p was upregulated in cultured podocytes after β-catenin activation, as well as in the kidneys of proteinuric CKD. Bioinformatics analysis predicted that miRNA671-5p could target WT1 mRNA for degradation. Indeed, over-expression of miR671-5p induced down-regulation of WT1 protein and promoted podocyte injury, whereas it had no effect on the level of WT1 mRNA. Inhibition of miRNA671-5p mitigated podocyte injury caused by β-catenin activation. In mouse model of remnant kidney after 5/6 nephrectomy (5/6NX), miR671-5p was specifically up-regulated in glomerular podocytes, as shown by in situ hybridization. Furthermore, over-expression of miR671-5p in vivo promoted β-catenin activation, inhibited WT1, worsened podocyte injury and kidney fibrotic lesions in remnant kidney after 5/6NX.

Conclusions: These studies identify miR-671-5p as a novel mediator that plays a crucial role promoting podocyte injury through down-regulation of WT1. The study also provides new insights into the pathogenic mechanisms of Wnt/β-catenin in podocyte dysfunction. Therefore, miR-671-5p may be a potential therapeutic target for ameliorating podocyte injury in the proteinuric kidney diseases.

Isthmine-1, a New Podocyte Protein Involved in the Progression of Nephrotic Syndrome Jean-Jacques Boffa,[5,3] Lu Zhang,[2,1] Sahiri V. Marie aude,[6] Khalil A. Ghachem,[1] Placier Sandrine,[7] Chantal Jouanneau,[8] Christos Chatziantoniou.[4,3] *[1]INSERM U1155, Paris, France; [2]Jiangsu Province Hospital of Chinese Medcine, Nanjing, China; [3]INSERM UNIT 1155, Paris, France; [4]Tenon Hospital, Paris, France; [5]Tenon Hospital, AP-HP, Paris, France; [6]INSERM U1155 / UPMC, Paris, France; [7]INSERM 1155 - UPMC, Paris, France; [8]inserm, Paris 20, France.*

Background: Using differential transcriptomic analysis in renal cortical slices from hypertensive rats with nephrotic level of proteinuria, we identified and studied isthmine-1 (ISM-1), a new player of renal diseases.

Methods:

Results: Under control physiological conditions, ISM-1 is strongly expressed and colocalized with nephrin in rodents and humans as well. Immunogold electron microscopy revealed that ISM-1 localizes on podocyte foot processes. Because its two receptors, avb5integrin and grp78 (Bip) are involved in podocytopathy, we induced nephrotic syndrome in rats by PAN and doxorubicine injection. In both experimental models, we found increased expression of ISM-1 mRNA and protein on isolated glomeruli. Likewise, the expressions of its two receptors were increased and contrasted to the decrease of nephrin protein expression. In addition, ISM-1 expression increased after doxorubicine stimulation in primary cultured podocytes in vitro. To determine the role of ISM-1, ISM-1 antisens ODN were administered in experimental models of nephrotic syndrome in vivo. Although ISM-1 antisens administration blunted ISM-1 expression, no difference was observed in the progression and severity of the disease in PAN rats. Because, ISM-1 has been shown to act as a permeability factor during lung sepsis, we are pursuing our studies by examining its role on glomerular membrane permeability.

Conclusions: Our results show the discovery of a novel protein ISM-1 specifically expressed in podocyte in normal conditions. This expression is further increased in the progression of nephrotic syndrome. We are currently investigating the physiopathological role of this increase.

Loss of Robo2 Rescues Podocyte Number and Ultrastructure Defects in Adult Ilk Knockout Mice Richa Sharma, Hila Milo Rasouly, Xueping Fan, Sudhir Kumar, Arielle R. Strzelewicz, Mostafa Belghasem, Joel M. Henderson, David J. Salant, Weining Lu. *Boston University Medical Center, Boston, MA.*

Background: Previous studies showed that ROBO2 signaling functions as a negative regulator on podocyte actin polymerization and podocyte adhesion. Our data shows that ROBO2 forms a complex with integrin-linked kinase (ILK) and loss of *Robo2* improves the survival of *Ilk* podocyte-specific knockout (cKO) mice. However, the mechanism of this renoprotective role of *Robo2* loss in *Ilk* cKO is not clear.

Methods: *Robo2* and *Ilk* single cKO were crossed to generate *Robo2-Ilk* podocyte specific double knockout mice (dKO). Glomerular histology, podocyte number, and podocyte ultrastructure of single cKO and double dKO mice were analyzed at 4 weeks and 16 weeks of age. Glomerular histology was evaluated by PAS staining. Podocyte numbers were quantified using WT1 staining. Podocyte ultrastructure was analyzed and quantified by transmission electron microscopy (TEM). Quantitative data were analyzed using SPSS statistics software.

Results: Results: At 4 weeks old, the podocyte number and glomerular sclerotic index are almost the same in both *Ilk* single cKO and *Robo2-Ilk* dKO mice. However, analyses of podocyte number, glomerular histology, and TEM in 16 weeks old mice showed a significant improvement in podocyte number (p=0.02), sclerotic index (p=0.006), glomerular basement membrane width (p=0.03), podocyte foot process width (p=0.002), and slit diaphragm density (p=0.04) in *Robo2-Ilk* dKO as compared to *Ilk* single cKO mice.

Conclusions: Loss of *Robo2* improves the survival of *Ilk* podocyte-specific knockout mice by rescuing podocyte number and podocyte ultrastructure defects in adult mice. Our findings suggest that inhibition of ROBO2 signaling could be beneficial for glomerular disease associated with podocyte loss and be a potential therapeutic target.

In Vivo Characterization of Podocin Variants Based on a CRISPR/Cas9 Based Genome Editing Approach Linus Butt,[1,2] Lena K. Ebert,[1,2] Markus M. Rinschen,[1,2] Martin Höhne,[1,2] Branko Zevnik,[2] Paul T. Brinkkoetter,[1,2] Bernhard Schermer,[1,2] Thomas Benzing.[1,2] *[1]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, University of Cologne, Cologne, Germany.*

Background: *NPHS2* encodes for Podocin, a membrane protein at the inner leaflet of the plasma membrane of podocytes, and is the most frequently mutated gene in patients with Steroid-Resistant Nephrotic Syndrome (SRNS). Analyzing the role of posttranscriptional and -translational regulations of Podocin in the maintenance of the architecture and functional integrity of the slit diaphragm will contribute to the understanding of the underlying pathomechanisms. In previous studies, we confirmed the expression of a short isoform of Podocin in the human kidney, characterized its

biochemical properties *in vitro* and showed an altered localization of the protein. In addition, we identified phosphorylation sites within Podocin by analyzing the glomerular phosphoproteome and found evidence for their biological significance, e.g. for Podocin multimerization (p.T234).

Methods: We used different CRISPR/Cas9 based genome editing strategies that enabled us to alter the murine *Nphs2* gene in a targeted manner. The endonuclease Cas9 forms a complex with a guide RNA which selectively binds to DNA and induces double strand breaks. Subsequently, repair mechanisms can either lead to random indel mutations via Non-Homologous End-Joining (NHEJ) or precise mutations via Homology-Directed Repair (HDR). By pronuclear injection we generated a mouse line that, in analogy to the human short isoform, lacks the entire exon 5. In an additional approach we eliminated a phosphorylation site within the PHB domain (p.T234I) by integrating a point mutation.

Results: Strikingly, *in vivo* data of compound-heterozygous animals show a rapid development of proteinuria and elevated retention parameters indicating a loss of kidney function. Histological examinations reveal Fokal-Segmental Glomerulosclerosis (FSGS), a hallmark of glomerular disease. Mice homozygous for the T234I allele do not display an overt phenotype and up to now we did not observe living offspring homozygous for the short isoform allele.

Conclusions: CRISPR/Cas9 technology allows us to create a fast and efficient pipeline to generate mutant alleles mimicking human genetic diseases and our pioneer project already provided novel insights into the pathogenesis of SRNS.

TH-PO069

Par6β Interaction with Ephrin-B1 at the Slit Diaphragm Could Be a Differential Diagnostic Marker of Nephrotic Syndrome: Interaction of the Par-Complex Molecules with Ephrin-B1/Nephrin in Podocyte Sayuri Takamura,[1,2] Yoshiyasu Fukusumi,[1] Ying Zhang,[1] Ichiei Narita,[2] Hiroshi Kawachi.[1] *[1]Dept. Cell Biology, Kidney Research Center, Niigata University, Niigata, Japan; [2]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Japan.*

Background: Par-complex, Par3/Par6/Cdc-42/aPKC is reported to be a component of the slit diaphragm (SD) and to play a role in maintaining the podocyte function. However, the precise differential roles of the Par-complex molecules in podocyte are not fully understood. We have reported that ephrin-B1 is a novel component of the SD. Although ephrin-B1 is reported to control cell-cell junctions of vascular endothelial cells through Par-complex, no studies on the interaction of the Par-complex molecules with ephrin-B1 at the SD have not been analyzed.

Methods: The expressions of the Par-complex molecules in podocyte were analyzed in the normal adult and developing glomeruli and in the rat nephrotic models of MCNS and FSGS by immunofluorescence, Western blot and RT-PCR. The interactions of Par3 and Par6 with ephrin-B1 and nephrin were analyzed by the IP analyses with glomerular lysates and HEK-293 transfected cells. The expressions of the Par-complex molecules in the podocyte-specific ephrin-B1 conditional KO (CKO) mouse were analyzed.

Results: mRNA expressions of Par6β and Par3 decreased from the early phase in the MCNS model and the decreases were detected when proteinuria peaked in both models. mRNA of Par6α increased in both models. Western blot analyses showed Par6β decreased in both models and Par3 decreased in the MCNS model. Immunostainings of Par3 and Par6β clearly decreased in both models. The decrease of Par6β was more evident in the FSGS model than in the MCNS model (IF score: 2.1 in FSGS model vs control 5.0). By contrast Par3 staining decreased more evidently in the MCNS model. The Par6β staining in normal glomeruli was co-localized with ephrin-B1, whereas no co-localization of Par3 and ephrin-B1 was observed. Whereas, some portions of the Par6β staining were apart from nephrin, and the Par3 staining was almost co-stained with nephrin. The IP study showed Par6β was interacted with ephrin-B1. The expression of Par6β was altered in the ephrin-B1 CKO mice.

Conclusions: Altered expressions of Par3 and Par6β are involved in the pathogenesis of both nephrotic models, and these molecules could be differential diagnostic markers of nephrotic syndrome. Not Par3 but Par6β is highly associated with ephrin-B1 at the SD.

TH-PO070

Soluble Form of VCAM-1 Ameliorates Podocyte Phenotypic Change by Plasma Membrane PTEN Recruitment Shun Manabe,[5,6] Kazuo Sakamoto,[4] Naoko Ito,[3] Nobuyuki Saga,[7] Kosaku Nitta,[2] Michio Nagata.[1] *[1]Department of Renal Pathology, University of Tsukuba, Tsukuba, Japan; [2]Medicine, Kidney center, Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]Department of Renal Pathology, University of Tsukuba, Tsukuba, Japan; [4]Department of Renal Pathology, University of Tsukuba, Tsukuba, Japan; [5]Department of Renal Pathology, University of Tsukuba, Tsukuba, Japan; [6]Medicine, Kidney Center, Tokyo women's medical university, Shinjuku, Japan; [7]Department of Renal Pathology, University of Tsukuba, Tsukuba, Japan.*

Background: Podocyte stresses are the hallmark of glomerular diseases. The stresses cause podocyte phenotypic change and detachment. Podocyte has self-defense mechanism to resist and adapt against stresses by expressing several stress induced proteins. Vascular cell adhesion molecule-1 (VCAM-1) is a well-known stress induced protein that principally expressed in vascular endothelial cells. The VCAM-1 exerts physiological effects in membrane-bound form and soluble form. The membrane-bound form of VCAM-1 works as a pro-inflammatory molecule, whereas the soluble form of VCAM-1, that is generated by the cleavage of membrane-bound VCAM-1, antagonize the pro-inflammatory effect. However, the links between stress induced VCAM-1 and stress adaptation in podocyte remain largely unknown. Here, we aimed to investigate the role of VCAM-1 in podocyte stress adaptation.

Methods: We induced podocyte stress using NEP25 transgenic mice that develop podocyte specific injury by LMB2 toxin injection. We assessed glomerular VCAM-1 and protease expression eight days after the LMB2 injection. Immortalized podocyte with or without TGF-β1 stimulation was used to study the role of soluble VCAM-1.

Results: The glomerular staining of NEP25 mice indicated aberrant podocyte VCAM-1 expression. VCAM-1 and ADAM-13 (VCAM-1 cleavage enzyme) was simultaneously up regulated in isolated glomeruli that suggest the generation of soluble VCAM-1. Immortalized podocyte constitutively expressed integrin alpha 9 and beta 1, that works as receptor of soluble VCAM-1. The soluble VCAM-1 suppressed TGF-β1 induced podocyte migration and podocyte mRNA expression of EMT markers. The soluble VCAM-1 suppressed podocyte phenotypic change. Western blot analysis of Akt phosphorylation indicate soluble VCAM-1 to suppress the TGF-β1 induced Akt phosphorylation. Next, the treatment with soluble VCAM-1 recruited PTEN to plasma membrane by cell staining and western blot analysis of plasma membrane fraction. The soluble VCAM-1 suppressed PI3K/Akt pathway by plasma membrane PTEN recruitment.

Conclusions: We demonstrated stress induced podocyte VCAM-1 expression. The soluble form of VCAM-1 ameliorates podocyte phenotypic change by suppression PI3K-Akt pathway via plasma membrane PTEN recruitment. Podocyte VCAM-1 expression is one of the intrinsic stress adaptation mechanisms.

TH-PO071

Proteasomal or Lysosomal Degradation System Failures Have Different Consequences on Renal Cell Protein Homeostasis Wiebke Sachs,[2] Giorgia Di Lorenzo,[2] Marlies Sachs,[1] Sandra Pohl,[2] Catherine Meyer-Schwesinger.[3] *[1]UKE, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]University of Hamburg, Hamburg, Germany.*

Background: Protein degradation plays an important role in protein quality control and therefore in cell homeostasis. Two different degradation systems are responsible for clearance of disused or defective proteins, the ubiquitin-proteasome system (UPS) and the autophagy-lysosome system (ALS), which are interconnected and influence each other. The aim of the project is to understand the significance of the proteasomal and lysosomal degradation systems for proteostasis of renal cells such as podocytes.

Methods: In order to dissect the significance of the UPS and ALS for renal cells, Balb/C mice were treated with epoxomicin (proteasomal inhibitor) and leupeptin (lysosomal inhibitor) respectively over 4 days. Furthermore, mice with general lysosomal dysfunction due to defective targeting of all newly synthesized lysosomal enzymes (Mucolipidosis type II, MLII) were analyzed. The effects of altered proteasomal and lysosomal functions were investigated clinically, morphologically and biochemically.

Results: Epoxomicin treatment resulted in a successful proteasomal inhibition. Mice developed proteinuria with abnormal glomerular protein accumulations in the subepithelial space and in podocytes. The tubulointerstitium was morphologically inconspicuous. Leupeptin treatment successfully reduced lysosomal function. Mice did not develop proteinuria. Morphological analyses were significant for abnormal accumulations in tubular cells and the mesangium of glomeruli. MLII mice showed severe lysosomal dysfunction in combination with proteasomal dysfunction in glomeruli and tubulointerstitial cells. Clinically, MLII mice showed slight proteinuria. Morphologically, MLII mice exhibited accumulations of enlarged lysosomes in interstitial cells, in the mesangium of glomeruli and in podocytes, with abnormal protein accumulations in podocytes.

Conclusions: Based on our results we conclude that the UPS and ALS interplay in renal cells and are compensatory upregulated when the other is inhibited. Failure of the proteasomal degradation system has a greater impact on renal cell proteostasis and renal function that cannot be compensated by the lysosomal degradation system.

TH-PO072

Altered Hydrolysis Function of Ubiquitin C-Terminal Hydrolase L1 (UCH-L1) by Oxidative Modification Affects Protein Homeostasis in Podocytes Julia Reichelt,[6] Anna Reinicke,[2] Julia M. Fehlert,[4] Marlies Sachs,[1] Gunther Zahner,[5] Catherine Meyer-Schwesinger.[3] *[1]UKE, Hamburg, Germany; [2]University Clinic Eppendorf Hamburg, Hamburg, Germany; [3]University of Hamburg, Hamburg, Germany; [4]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [5]University hospital hamburg, Hamburg, Germany; [6]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: The ubiquitin proteasome system (UPS) represents the major system for protein degradation and is important for maintenance of protein homeostasis. Ubiquitin C-terminal hydrolase L1 (UCH-L1) regulates the pool of monoubiquitin required for tagging target proteins. The hydrolase-deficient mutant UCH-L1^{I93M} is highly associated with the development of neurodegenerative disease in humans and structurally resembles oxidative-modified UCH-L1. During podocyte injury UCH-L1 is *de novo* expressed resulting in proteasomal impairment and accumulation of polyubiquitinated proteins by unknown mechanisms. Aim of this project is to investigate the toxic gain of function of UCH-L1.

Methods: In order to dissect UCH-L1 hydrolysis versus UCH-L1 hydrolase-independent mechanisms transgenic mice with podocyte-specific overexpression of UCH-L1 wildtype or an enzymatic-deficient form UCH-L1^{I93M} were generated. The effects of altered degradation were investigated in cultured podocytes and in 5-7 week old naïve mice morphologically, clinically and biochemically. By use of PAS

and immunofluorescent stainings for podocyte-specific proteins and by measurement of proteinuria the glomerular integrity was characterized. To analyze the biochemical properties of UCH-L1 (such as expression levels or proteolytic capacity) quantitative real-time PCR, Western blot, activity assays and immunohistochemical stainings were executed.

Results: In cultured podocytes UCH-L1 expression was induced following oxidative stress. UCH-L1^{I93M} induced accumulations of polyubiquitinated as well as oxidative modified proteins in cultured podocytes and isolated glomeruli of transgenic mice. This conglomeration resulted from impaired proteasomal activity despite an enhanced proteasomal capacity. UCH-L1^{WT} mice on the other hand were characterized by increased proteasomal activity and a dedifferentiated phenotype. This was indicated by decreasing levels of podocyte-specific proteins nephrin and α-actinin-4 influenced by declining amount of WT-1 which seems to be regulated by the proteasome.

Conclusions: *De novo* expression of UCH-L1 in podocyte injury could mediate two effects: first, dedifferentiation of the podocyte and second, accumulation of polyubiquitinated proteins conditioned by defective enzymatic function.

TH-PO073

Lipoproteins Modulate Podocyte Damage and Proteinuria Yohei Tsuchida,[3] Jianyong Zhong,[3] Talat Alp Ikizler,[3] Agnes B. Fogo,[3] Taiji Matsusaka,[1] Haichun Yang,[2] Valentina Kon.[3] *[1]Tokai University School of Medicine, Isehara, Japan; [2]Vanderbilt University, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Although high density lipoprotein (HDL) and its main protein, apolipoprotein AI (apoAI) have established benefits in various cell types, their effects on renal cells remain unclear. We investigated the consequences of exposing normal and damaged podocytes to normal apoAI/HDL (HDL^{Cont}), apoAI mimetic (L-4F), and HDL from patients with established CKD known to have dysfunctional (HDL^{CKD}).

Methods: *In vitro*, primary mouse podocytes were injured by puromycin (PAN) and cellular viability, proliferation, migration and cellular production of reactive oxygen species (ROS) assessed. *In vivo*, transgenic mice expressing human CD25 in podocytes that can be selectively injured by injection of immunotoxin were used as the proteinuric model. At injury, half the mice recieved L-4F x 2 wks. Urinary albumin-creatinine ratio (ACR) was measured and expression of podocyte markers, synaptopodin and WT1 assessed.

Results: PAN reduced podocyte viability, proliferation, migration and increased ROS production *in vitro*. Each of these perturbations was significantly lessened by apoAI and HDL^{Cont} but not HDL^{CKD} (Table). Critically, while maximum proteinuria was similar in treated and untreated mice, L-4F significantly accelerated ACR reduction and preserved podocyte expression of synaptopodin and WT1-positive cell density.

Conclusions: The results indicate that normal apoAI and HDL, but not dysfunctional HDL^{CKD} protect against podocyte damage. ApoAI mimetic provides *in vivo* benefits to podocytes culminating in reduced albuminuria. We suggest supplemental apoAI may be a novel candidate to lessen podocyte damage and proteinuria.

Novel Role for Podocyte SIRPα and Pulmonary Surfactants in Minimal Change Disease Miguel A. Lanaspa, Ana Andres-hernando, Christina Cicerchi, Richard J. Johnson. *University of Colorado Denver, Aurora, CO.*

Background: Minimal change disease (MCD) is the most common cause of proteinuria and nephrotic syndrome in children whose primary cause is unknown. Recent studies identified podocyte CD80 as a key deleterious player in MCD. SIRPα is a receptor that regulates cell growth and differentiation by controlling phosphatases like PTPN11. SIRPα agonists include soluble surfactants SP-A and SP-D, produced by an anti-inflammatory response in the lungs. Here, we propose that MCD is associated with the elevation of serum SP-A and SP-D. that stimulate podocyte SIRPα to activate a signaling cascade mediated by PTPN11, nephrin dephosphorylation, CD80 expression and actin reorganization causing the activation of the podocye, loss of foot processes, proteinuria and nephrotic syndrome.

Methods: Serum, renal and urinary levels of surfactants are determined in MCD subjects in relapse and remission and correlated with albumin excretion and urinary CD80. To test the role of surfactants in podocyte activation, podocytes are exposed to serum from patients in relapse or in remission in which surfactants are added back and SIRPα, PTPN11 activity, nephrin phosphorylation, CD80 expression, actin re-organization and proteinuria is determined in these podocytes and in a mouse model of intranasal exposure to LPS.

Results: Human subjects with MCD in relapse but not remission and intranasal exposure to LPS in mice have elevated serum SP-A/D suggesting a crosstalk between lungs and kidneys. The stimulation of SIRPα in cultured podcytes with serum from MCD patients in relapse or by addition back of surfactants to serum of patients in remission releases PTPN11 from SIRPα to interact and dephosphorylate nephrin. This action results in NfkB activation and transcription of CD80 and pro-inflammatory cytokines, Similarly, nephrin loss results in loss of cell polarity that combined with the pro-inflammatory response re-organizes actin structure leading to the podocyte activation

Conclusions: Based on our data and the observation that 70% of the cases of MCD relapses are preceded by respiratory tract infections, we conclude that MCD is associated with the deregulation of podocyte SIRPα signaling leading to its activation characterized by PTPN11-mediated nephrin dephosphorylation, CD80 expression and actin reorganization ultimately causing loss of foot processes, proteinuria and nephrotic syndrome.

TH-PO075

Apoptosis Signal-Regulating Kinase 1 (ASK1) Inhibitor GS-444217 Mitigates Progression of HIV-Associated Nephropathy Kyung Lee,[1] Jin Xu,[1] Anqun Chen,[1] John T. Liles,[2] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Gilead Sciences, Inc., Foster City, CA.*

Background: Renal inflammation is the major pathology in chronic kidney diseases, including HIV-associated nephropathy (HIVAN) that ultimately progresses to end stage renal disease. Activation of apoptosis signal-regulating kinase 1(ASK1) has been shown to drive renal inflammation, apoptosis, and fibrosis by downstream activation of MAPK kinases p38 and c-Jun N terminal kinase (JNK). Recent studies have shown that a potent selective ASK1 inhibitor substantially reduced renal p38MAPK activation and halted the disease progression in mouse models of diabetic kidney disease. Thus we sought to determine whether the blockade of ASK1 would also attenuate renal injury and impede the progression of HIVAN.

Methods: A well-established transgenic model of HIVAN, Tg26 mice on FVB/N background, was used for the study. Tg26 mice typically start to develop proteinuria and mild glomerulosclerosis (GS) at 4 weeks of age, moderate GS and mild tubulointerstitial injury by 8 weeks of age, and advanced GS and tubulointerstitial fibrosis, tubular atrophy and dilatation by 12 weeks of age. 4-week old Tg26 mice received either standard control chow or chow supplemented with selective ASK1 inhibitor GS-444217 (0.1% or 0.2% in chow). There were 7 to 10 mice in each group. Urine and blood were collected weekly to assess their kidney functions, and kidneys were harvested for analysis after 6 weeks of treatment.

Results: Administration of ASK1 inhibitor GS-444217 at both 0.1% and 0.2% concentrations significantly reduced p38 activation and albuminuria, and improved renal function in Tg26 mice after 6 weeks of treatment. Histological analysis revealed a marked reduction in GS and tubular damage in mice treated with GS-444217 compared to control Tg26 mice. GS-444217 administration increased the expression of differentiated podocytes markers and significantly curtailed podocyte loss in Tg26 mice. GS-444217 also reduced marker expressions of inflammation and apoptosis. Furthermore, GS-444217 administration resulted in significant reduction in collagen deposition and renal fibrosis.

Conclusions: Selective ASK1 inhibition reduced both glomerular and tubular injury and mitigated the progression of HIVAN in Tg26 mice, suggesting that blockade of ASK1 pathway is a potential therapeutic approach against progression of CKD, including HIVAN.

Sox-9 Is a Marker for Activated Parietal Epithelial Cells and Potentially Involved in Podocyte Regeneration in a Rat Anti-GBM Nephritis Model Christoph Daniel,[2] Ania Prochnicki,[1] Jeffrey W. Pippin,[3] Stuart J. Shankland,[3] Kerstin U. Amann.[1] *[1]FAU Erlangen, Erlangen, Germany; [2]University Erlangen-Nürnberg, Erlangen, Germany; [3]University of Washington, Seattle, WA.*

Background: In healthy kidneys parietal epithelial cells (PECs) line out the Bowman's capsule. During renal disease PECs are thought to be involved in crescent formation as well as in podocyte regeneration. However, the activation of PECs during crescent formation and its potential role in scar formation or podocyte regeneration is not well understood. The aim of the study was to investigate a potential role of the transcription factor Sox9 as a marker of activated PECs in renal development, healthy adult kidneys and during anti-GBM nephritis.

Methods: Renal Sox9 expression was investigated in different species including mouse, rat, pig and humans using immunohistochemistry. Glomerular Sox9 expression was characterized in more detail in healthy (n=11) and anti-glomerular basement membrane (anti-GBM) nephritic (n=11) rats on days 7 and 14 after model induction as well as in newborn rats (n=3) using immunofluorescence double staining and confocal laser scanning microscopy.

Results: In glomeruli from healthy rat kidneys Sox9 expression is restricted to approx. 30% of PECs nuclei. During anti-GBM nephritis the number of glomerular Sox9-positive cells was increased 2-fold on day 7 and about 5-fold on day 14 after disease induction. In nephritic glomeruli Sox9 expression was not restricted to Bowman's capsule lining but was also found on cells of the glomerular tuft. Nearly all Sox9-positive cells also expressed the parietal epithelial marker Pax8 whereas Ox7-positive mesangial cells, CD31-positive endothelial cells and CD68-positive macrophages lacked Sox9 expression. While in healthy glomeruli only 4% of Sox9-positive cells showed proliferative activity, during anti-GBM nephritis more than 60% on day 7 and about 40% on day 14 of glomerular Sox9 positive cells also expressed PCNA, a proliferation marker. Of note, on day 7 0.8±0.9 and on day 14 1.6±1.3 cells per glomerular cross-section express both Sox9

and the podocyte marker podocalyxin. In addition, during glomerulogenesis Sox9 was expressed in parietal epithelial cells as well as podocytes.

Conclusions: Our data are in line with Sox9 being a marker of activated parietal epithelial cells and may further point to a potential role in podocyte regeneration.

TH-PO077

Morphometric Quantitation of Parietal Epithelial Cells in Human Kidneys Christopher L. O'Connor,[1] Mohamed A. Elshayeb,[1] Jeffrey B. Hodgin,[3] Roger C. Wiggins,[2] Markus Bitzer.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Michigan Health System, Ann Arbor, MI; [3]Pathology, University of Michigan, Ann Arbor, MI.*

Background: Parietal epithelial cells (PECs) play a key role in glomerulosclerosis. We therefore developed a method for quantitation of PECs usable in routine FFPE archival histologic sections. Initial data are reported.

Methods: PECs were identified by anatomic position, lining the inner aspect of Bowman's Capsule (BC), and positive immune-peroxidase nuclear staining for PAX8. The morphometric method used principles previously reported for podocyte quantitation in which observed PEC nuclear number per glomerular tuft profile is corrected according to nuclear size, shape and section thickness (Venkatareddy et al. JASN 2014). 600 glomerular profiles were assessed in 12 normal human kidneys obtained at nephrectomy (mean age: 64.9, range: 46-82y). Glomerular and tubule-interstitial parameters were assessed through quantitative computer-assisted image analysis on 50 glomeruli per case. Qualitative glomerular characteristics were assessed in all glomeruli (mean 198 glomeruli per sample, range 71-392). Quantitative morphometric parameters were evaluated in 50 randomly selected glomeruli per sample.

Results: PECs identified as cells lining the inner aspect of BC were >99% PAX8 positive. In contrast <5% of glomerular tufts contained PAX8-positive nuclei. In the normal human kidney sample tested the BC surface area was 159 (range 110-216) $x10^3 \mu m^2$). The number of PECs per glomerular tuft (total BC surface area) was 407 (range 70-722). The estimated average PECs per area of BC was 25.3 (range 5.2-43.6) PECS/$10^6 \mu m^2$. Average PEC cell area was 578μm^2 (range 247-2103 μm^2). PEC density correlated with podocyte nuclear density (p=0.02; r=0.64), mean podocyte volume (p=0.001; r=-0.82), podocytes per glomerulus (p=0.01; r=0.69), % of normal glomeruli (p=0.01, r=0.70), fractional interstitial area (p=0.002; r=-0.78), number of globally (p=0.03; r=-0.55) and segmentally sclerotic glomeruli (p=0.004; r=-0.76), and eGFR (p=0.05; r=0.75).

Conclusions: We report a method for quantitatively evaluating PECs. PEC number per glomerulus, density and estimated cell size varies substantially between individual samples. Furthermore, these PEC parameters significantly correlate with both podocyte parameters and clinical phenotype in the small sample evaluated. Additional samples from our human kidney biobank (n>150) will be used to confirm and extend these data.

TH-PO078

Microecological Imbalance of Intestinal Microflora Activates Renal Renin-Angiotensin System to Contribute to the Progression of Early Diabetic Nephropathy Chenchen Lu,[2,1] Kun ling Ma,[1] Yang Zhang,[1] Gui hua Wang,[1] Zebo Hu,[1] Peipei Chen,[1] Jian Lu.[1] *[1]Zhongda Hospital, Southeast University Medical School, Nanjing City, China; [2]Institute of Nephrology, Zhong Da Hospital, Nan Jing City, China.*

Background: It is well-known that activated renal rennin-angiotensin (RAS) plays a key role in the development of early diabetic nephropathy (DN). However, the initiating factors and potential mechanisms led to RAS activation have not been fully elucidated. This study aimed to investigate the underlying mechanisms of how abnormal intestinal microenvironment activates RAS to contribute to early renal injuries of DN.

Methods: Streptozotocin-induced diabetic rat model was randomly divided into three groups: Control group, diabetic group (DM), and diabetic+antibiotics (DM+AB) group. The rats of DM+AB group were fed for 8 weeks with regular chow and antibiotic mixed liquor (ampicillin 1g/L + vancomycin 0.5g/L + neomycin 1g/L + amphotericin B 0.1g/L). Gene sequencing of intestinal microflora was carried out using 16S-rDNA pyrosequencing technique. The morphological changes to the renal pathology and ultra-microstructures were checked by pathological staining and electron microscopy. The plasma RAS components were determined by radioimmunoassay. The protein expressions of RAS components in the kidneys were determined by immunohistochemical staining and Western blot.

Results: Compared with control group, DM group showed with abnormal intestinal microflora, which significantly increase the production of acetate in the plasma. There were increased ACR, thickened glomerular basement membrane, podocyte foot process effacement in kidneys of DM group compared with the controls. The plasma levels of angiotensin II and the protein levels of angiotensinogen, angiotensin II, renin, angiotensin-converting enzyme, and angiotensin II type 1 receptor in the kidneys of DM group were significantly increased compared to the controls, which were positively associated with kidney injuries of DM group. However, in DM+AB group, after intestinal microflora were completely killed by antibiotics, kidney damage and RAS activation were weakened accordingly compared with the DM group.

Conclusions: These findings suggest that microecological imbalance of intestinal microflora might be a potential mechanism for the progression of early DN, which leads to kidney injuries via the RAS activation.

TH-PO079

Glomerular Enhancer of Zeste Homolog-2 (EZH2) Histone Methyltransferase Reduces Glomerular Endothelial Glycocalyx during Diabetic Nephropathy by Regulating Hyaluronan Synthesis Marloes Sol,[2] Jiedong Qiu,[3] Johan Van der vlag,[1] Jacob van den Born,[4] Benito Yard,[3] Jan-luuk Hillebrands,[2] Jan A. Kamps,[2] Guido Krenning.[2] *[1]Dept. of Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Dept. of Pathology and Medical Biology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [3]Dept. of Nephrology, Endocrinology and Rheumatology, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [4]Dept. Internal Medicine, Div. Nephrology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal failure worldwide. The glomerular endothelial glycocalyx is the first barrier that prevents leakage of circulating proteins. Injury to the glycocalyx evokes proteinuria and kidney failure. The polycomb group methyltransferase Enhancer of Zeste Homolog 2 (EZH2) inhibits expression of its target genes through methylation of lysine 27 on histone 3 (H3K27Me3). We recently performed a target screen for genes involved in glycocalyx turnover, which indicated that EZH2 inhibits glycocalyx synthesis in glomerular endothelial cells. We hypothesized that EZH2 activity is increased in the glomerular endothelium during DN thereby reducing glycocalyx synthesis.

Methods: H3K27me3 was analyzed in glomerular endothelial cells by immunofluorescence in $BTBR^{ob/ob}$ mice, a mouse model for DN. Glycocalyx in these mice was measured by the binding of fluorescently-labeled wheat germ agglutinin. In glomerular endothelial cells, EZH2 was silenced by RNAi. Gene expression was assessed by Quantitative Real-time PCR.

Results: H3K27me3 in glomerular endothelial cells was increased 1.5-fold compared to non-diabetic mice (p=0.026). Albumin-creatinine ratios of $BTBR^{ob/ob}$ mice correlated with the increase in H3K27me3 (p=0.044; r^2=0.674). A 2-fold loss of glomerular glycocalyx was observed in $BTBR^{ob/ob}$ mice (p=0.002). Silencing of EZH2 in glomerular endothelial cells led to a decrease in H3K27me3 and an 8-fold increase in the hyaluronan synthesizing enzyme HAS1 (p<0.001). ENCODE database analysis revealed a binding site for EZH2 in the HAS1 gene, suggesting that HAS1 is a direct target of EZH2. Interestingly, the hyaluronan degrading enzymes, HYAL1 (p=0.002), HYAL2 (p=0.015), and HYAL3 (p=0.014) were all decreased upon knockdown of EZH2.

Conclusions: In conclusion, our data suggests that EZH2-mediated epigenetic changes reduce endothelial glycocalyx via reduction of hyaluronan in DN.

TH-PO080

Depletion of Gprc5a Promotes Development of Diabetic Nephropathy Jaakko Patrakka,[2] Mark Lal,[1] Sonia Zambrano Sevilla.[3] *[1]AstraZeneca, Gothenburg, Sweden; [2]Karolinska Institutet, Huddinge, Sweden; [3]None, Seville, Spain.*

Background: Renal glomeruli are the primary target of injury in diabetic nephropathy (DN). In the glomerulus, damage to podocyte cells plays a critical role in the disease progression. Transforming growth factor beta (TGF-β) signaling is involved in the pathogenesis but mechanisms regulating this pathway in podocytes are poorly understood. G-protein coupled receptors (GPCRs) have been the most successful protein class for drug discovery as 20-40% of currently clinically approved drugs are targeting them. In this study, we investigated glomerular GPCRs in DN with the aim of identifying novel molecular targets for pharmaceutical intervention.

Methods:

Results: We performed high throughput molecular profiling of GPCRs in human glomeruli and identified an orphan GPCR, Gprc5a, as a novel highly podocyte-specific molecule whose expression was significantly down-regulated in patients with DN. Inactivation of Gprc5a in mouse resulted in thickening of the glomerular basement membrane and activation of mesangial cells, which are two hallmark features of DN in humans. Gprc5a-deficient animals were susceptible to diabetic glomerular damage as demonstrated by higher albuminuria and more severe histological changes after induction of diabetes with streptozotocin. Mechanistically, we show that Gprc5a modulates TGF-β signaling pathway in podocytes through activation of epidermal growth factor receptor (EGFR).

Conclusions: We conclude that depletion of Gprc5a promotes the progression of DN. Gprc5a can provide us a possibility to develop pharmaceutical tools to manipulate pathogenic signaling pathways in a podocyte-specific manner.

Palovarotene, Selective Retinoic Receptor-γ Agonist, Inhibited Both BMP4 and TGF-β Signaling Pathways in Diabetic Nephropathy Yui Fujita, Tatsuya Tominaga, Masanori Tamaki, Taichi Murakami, Seiji Kishi, Kojiro Nagai, Hideharu Abe, Toshio Doi. *Tokushima University, Graduate School of Biomedical Sciences, Tokushima, Japan.*

Background: We have reported that the BMP4 / Smad1 signaling pathway play a key role for development of diabetic nephropathy (DN). In recent years, retinoic acid receptor

agonists have been focused as therapeutic targets for progressive fibrosis. In this study, we examined the effect of palovarotene, selective retinoic acid receptor-γ agonist, on DN.

Methods: 12-15 weeks old ICR mice were rendered diabetic by streptozotocin (STZ). Palovarotene was administered 2 times per week intraperitoneally at 60 μg / kg from 4 weeks after STZ injection. Histological analysis was performed at 12 weeks after administration of palovarotene. BMP4 and TGF-βsignaling pathways were analyzed with *in vitro* mouse mesangial cells to reveal the mechanism of palovarotene treatment.

Results: Diabetic mice showed significant extracellular matrix expansion associated with increased expressions of phosphorylated (p) Smad1 and type 4 collagen (Col4). The administration of palovarotene in DN reduced the expressions of pSmad1 and Col4 as well as mesangial matrix expansion. Phosphorylated Smad2/3 were increased in DN. Palovarotene administration decreased pSmad2/3. In cultured mesangial cells, the expressions of BMP4, pSmad1 and Col4 were increased by AGE stimulation. Palovarotene suppressed the increased expressions of BMP4 and Col4 under AGE stimulation. In addition, palovarotene decreased pSmad1 and pSmad2/3 signaling under BMP4 or TGF-β treatment.

Conclusions: Palovarotene has regulated the downstream molecules of the BMP type I receptors, and inhibited pSmad1 and reduced expression of Col4 in mesangial cells. The study has unveiled that palovarotene exerts the suppressive effect for both BMP4 and TGF-β signaling pathways. The findings suggest that the chemicals that targeted a retinoic acid receptor are useful as new therapy for DN.

TH-PO082

Plasminogen Activator Inhibitor-1 (PAI-1) Modulates Parietal Epithelial Cell (PEC) Activation and Migration after Podocyte Injury Xin Li,[1] Marcus J. Moeller,[3] Taiji Matsusaka,[2] Haichun Yang,[4] Agnes B. Fogo.[4] *[1]The Medicine College of Shanghai JiaoTong University, Shanghai, China; [2]Tokai University School of Medicine, Isehara, Japan; [3]University of Aachen, RWTH, Aachen, Germany; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Parietal epithelial cells (PECs) can migrate on to the glomerular tuft and serve as either progenitor cells to replace podocytes or profibrotic cells to secret matrix in response to injury. Claudin-1 is expressed on all PECs, while CD44 is expressed on activated PECs. PAI-1 affects matrix turnover, cell migration and mediates renal fibrosis. After glomerular injury, PAI-1 expression on PECs increases. We aimed to study effects of PAI-1 on PECs migration, activation and transdifferentiation after podocyte injury.

Methods: NEP25 mice express human CD25 only on podocyte, and podocyte injury is induced by exogenous immunotoxin (LMB2). By mating *NEP25/PAI-1*^{loxP} with *PEC-rtTA/ PAI-1*^{loxP} transgenic mice, we generated inducible PEC specific PAI-1 knockdown mice (PAI-1 KD, n=8) and control (WT, n=10). All mice underwent doxycycline induction at 9 weeks old followed by LMB2 injection at 10 weeks, and were sacrificed 10 days later.

Results: LMB2 induced similar albuminuria and segmental glomerular sclerosis in WT and PAI-1 KD mice. Podocyte density, measured by WT-1 staining, was similar in the two groups (WT 3.9±0.8 vs PAI-1 KD 3.7±0.5 /10^4 um^2), but synaptopodin expression was higher in PAI-1 KD (18.7 ±16.7%) than WT (5.3±2.4%, P<0.05). PAI-1 KD induced more CD44+ PECs on glomerular tuft (2.8±0.8 vs WT 1.3±1.2%, P<0.05), while WT showed more claudin-1+ cells on the tuft (4.14±1.57% vs. 2.51±0.87%, WT vs. PECs PAI-1 KD *P*<0.05). By double staining, we assessed the proportion of PECs expresses nephrin, a podocyte differentiation marker, finding 14.1±4.4% of claudin-1+ cells also expressing nephrin in WT, similar in PAI-1 KD (11.0±4.0%, pNS). CD44+ cells expressing nephrin were also similar in the two groups (WT 17.7±9.2 vs. PAI KD 13.0±5.9%, pNS).

Conclusions: We conclude that knockdown of PAI-1 increased the presence of activated PEC on the tuft and preserved podocyte differentiation, but does not affect PECs transdifferentiation to podocyte.

Epigenetics-Induced Down-Regulation of MicroRNA (miR)193a Determines APOL1 Expression in Parietal Epithelial Cells Vinod Kumar,[4] Xiqian Lan,[1] Seyedeh Shadafarin Marashi Shoshtari,[7] Sheetal Chowdhary,[3] Manali Bhooplapur,[2] Catherine Meyer-Schwesinger,[8] Ashwani Malhotra,[9] Karl Skorecki,[6] Pravin C. Singhal.[5] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Dix Hills, NY; [3]Feinstein Institute of Medical Research, New Hyde Park, NY; [4]Immunology, Fienstine Institute for Medical Research, New York, NY; [5]North Shore LIJ Health System, Great Neck, NY; [6]Rambam Health Care Campus, Haifa, Israel; [7]The Feinstein Institute for Medical Research, Manhasset, NY; [8]University of Hamburg, Hamburg, Germany; [9]Immunolgy and Inflammation, Feinstein Inst. Med research and NSLIJ, Manhasset, NY.*

Background: APOL1 is expressed in kidneys of some primate species, including humans. Its trypanolytic effect has been well studied. Podocytes express APOL1 and overexpression of APOL1G1 and G2 has been demonstrated to be cytotoxic to podocytes, both *in vitro* and *in vivo* studies. Parietal epithelial cells (PECs) do not express APOL1; however, HIV has the potential to induce APOL1 expression in PECs (submitted abstract ASN, 2017). We hypothesize an epigenetic mechanism for the induction of APOL1 in PECs.

Methods: Immortalized human PECs (at 33°C) were transduced with either vector (V) or HIV (NL4-3) (n=4); PECs were incubated in media containing variable concentration of IFN-γ (0, 5, 10, and 20 nM) for 48 hours (n=4); PECs were treated with either buffer, azacytidine (5 μM, a demethylating agent), or SAHA (10μM, an histone deacetylation inhibitor) for 48 Hours (n=4). Protein blots were probed for APOL1, DNMT 1-3, HDAC 1-4, H3K27me3, H3K4me3, H3K8/9ac, and reprobed for actin. cDNAs were amplified for DNMT1-4, HDAC1-4, and *APOL1.* RNAs were assayed for miR193a. To confirm histone acetylation at miR193a gene promoter, ChiP assay was carried out. To confirm binding of miR193a to *APOL1* gene promoter, RIP-ChIP assay was performed. To measure methylation of CpG islands at miR193a gene, Bisulphite sequencing was carried out in PECVs and PECHIVs.

Results: Both HIV and IFN-γ induced APOL1 expression in PECs. PECHIV and IFN-γ-treated PECs showed 2 to 2.5-fold decrease in miR193a expressions, respectively; on the other hand, miR193a knockout PECs displayed induction of APOL1expression in PECs. Both azacytidine and SAHA not only induced APOL1 expression but also decreased (3-fold) miR193a levels in PECs. Both HIV and IFN-γ-treated PECs displayed enhanced DNMT3b, HDAC4, HK4me3, and H3K27me3 but down-regulation of H3K8/9ac expressions. RIP-ChIP assay confirmed binding of miR193a to the APOL1 gene promoter. Bisulphite sequencing displayed enhanced methylation of CpG islands at miR193a gene in PECHIV. These findings suggest that HIV down regulates miR93a through methylation at CpG islands and at histone 3 lysine 27 residues.

Conclusions: HIV induces APOL1 expression in PECs through down-regulation of miR193a via epigenetic mechanisms.

VDR Agonist (VDA) Facilitates Transition of Parietal Epithelial Cells (PECs) to Podocytes (PDS) Molecular Phenotype through Induction of APOL1 Vinod Kumar,[3] Xiqian Lan,[1] Seyedeh Shadafarin Marashi Shoshtari,[6] Rukhsana Aslam,[2] Kamesh R. Ayasolla,[1] Catherine Meyer-Schwesinger,[7] Ashwani Malhotra,[8] Karl Skorecki,[5] Pravin C. Singhal.[4] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Glenoaks, NY; [3]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [4]North Shore LIJ Health System, Great Neck, NY; [5]Rambam Health Care Campus, Haifa, Israel; [6]The Feinstein Institute for Medical Research, Manhasset, NY; [7]University of Hamburg, Hamburg, Germany; [8]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: APOL1 is expressed intracellularly and also a minor component of circulating lipid-rich trypanolytic multiprotein complexes in certain primate species including humans. However, the role of kidney cell, both i*n vitro* and *in vivo* studies. We hypothesize that VDA is an inducer of APOL1 in PECs and plays an important role in the maintenance of PD homeostasis.

Methods: Immortalized human PECs proliferate at 33°C but enter into a transition mode (differentiated to PDs) after incubation in special media and collagen/fibronectin substrate at 37°C. PECs and differentiated PECs molecular phenotype (WT1 and podocalyxin vs. PAX2 and Claudin 1) was characterized. To determine the effect of VDA on the entry of PECs transition at 33°C, PECs were incubated in media containing either buffer or VDA (EB1089, 10 nM) for 48 hours at 33°C (n=4). TO evaluate the dose response effect, PECs were incubated in media containing different concentratios of VDA (0, 1, 10, 25, 50 and 100 nM) for 48 hours at 33°C (n=4). To determine the effect of other APOL1 stimulants, PECs were incubated in media containing variable concentrations of IFN-Y (0, 5, 10, and 20 nM) for 48 hours at 33°C. To examine a causal relationship, PECs were transfected with either control of miR193a plasmids/siRNA APOL1, followed by treatment with/without VDA (10 nM) or IFN-y (10 nm). Proteins and RNAs were extracted. Protein blots were probed for APOL1 and reprobed for WT1, podocalyxin, podocin, PAX2, Claudin 1, and GAPDH. cDNAs were probed for *APOL1, WT1, and podocalyxin*. RNAs were assayed for microRNA193a.

Results: VDA induced APOL1 protein expression in PECs in a dose dependent manner. IFN-y also induced APOL1 expression in PECs. Both VDA and IFN-γ also enhanced (2 to 3 fold) transcription of APOL1 in PECs. VDA-induced APOL1 expression was associated with down regulation of miR193a (2.3 fold), PAX2 (1.8 fold) and enhanced expression of WT1 (2.2 fold), podocalyxin (2.5 fold), and podocin (1.8 fold) (both mRNA and protein levels). However, the effects of VDA were partially reversed both by increasing miR193a or silencing APOL1 expressions.

Conclusions: VDA stimulates PECs transition through induction of APOL1 and down regulation of miR193a.

Funding: NIDDK Support

HIV Activates Epithelial Mesenchymal Transition (EMT) and Mammalian Target of Rapamycin (mTOR) Pathway in Parietal Epithelial Cells (PECs) via Down Regulation of MicroRNA193a Vinod Kumar,[4] Xiqian Lan,[1] Rukhsana Aslam,[2] Ali Hussain,[3] Seyedeh Shadafarin Marashi Shoshtari,[6] Manali Bhooplapur,[2] Sheetal Chowdhary,[3] Catherine Meyer-Schwesinger,[7] Ashwani Malhotra,[8] Pravin C. Singhal.[5] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Glenoaks, NY; [3]Feinstein Institute of Medical Research, New York, NY; [4]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [5]North Shore LIJ Health System, Great Neck, NY; [6]The Feinstein Institute for Medical Research, Manhasset, NY; [7]University of Hamburg, Hamburg, Germany; [8]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Micro-RNA (miR) 193a has been considered to be a tumor suppressor gene and its down regulation has been reported to stimulate EMT and mTOR pathways in cancer cells. HIV-associated nephropathy is characterized by collapsing variant of focal segmental glomerulosclerosis; in this glomerular phentype, proliferating cells in Bowman's space are considered to be of PEC lineage; however, the involved mechanism for PECs proliferation in HIV milieu is not clear. We asked whether HIV was inducing PECs proliferation through down regulation of miR193a.

Methods: Vector (PECV) - and HIV (NL4-3; PECHIV)-transduced human immortalized PECs were growth arrested and then incubated media (containing 1% serum) for 48 hours (n=4). In another set of experiments, PECs were incubated in media containing either buffer (control) or a microRNA193a inhibitor (25 nM) for 48 hours (n=4). To examine a causal relationship, PECV and PECHIV were transfected with either control or miR193a plasmids (n=4). *In vivo* studies, kidneys were harvested from 4- week old control (FVB/N) and HIV-transgenic (Tg26) mice. Proteins and RNAs were extracted. Protein blots were probed for EMT (α-SMA, SNAIL, and fibronectin), mTOR (p-mTOR, p-P70S6k, p-4EBP, and p-eEF)) markers and reprobed for actin. RNAs were assayed for miR193a. Renal cortical sections were immunolabeled for α-SMA, SNAIL, and p-mTOR.

Results: PECHIV and renal tissues of HIVAN mice displayed enhanced (P<0.05 vs. PECV/FVB/N) expression of EMT markers including alpha-SMA, fibronectin, and SNAIL. Similarly, PECHIV and renal tissues of HIVAN mice showed enhanced (P<0.05 vs. PECV/FVB/N) expression of p-mTOR, p-P70S6K, and p-4EBP and down regulation (P<0.05 vs.PECV/FVB/N) of p-eEF, indicating activation of mTOR pathway. PECHIV and renal tissues of HIVAN mice displayed 4 fold decreases in miR193a levels when compared to respective controls. Inhibition of miR193a in PECs, stimulated EMT and mTOR pathways. On the other hand, overexpression of miR193a in PECHIV attenuated activation of EMT and mTOR pathways.

Conclusions: HIV induces activation of growth pathways in PECs. This effect of HIV is mediated through down regulation of miR193a in PECs.

Ultrastructural Descriptors for Clinically Relevant Categorization of MCD/FSGS NEPTUNE Patients Jarcy Zee,[3] Q Liu,[3] A R. Smith,[3] Carmen Avila-Casado,[2] Jeffrey B. Hodgin,[6] Lawrence B. Holzman,[1] Brenda W. Gillespie,[6] L. Barisoni,[5] Virginie Royal.[4] *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Toronto, Toronto, ON, Canada; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Université de Montréal, Montréal, QC, Canada; [5]University of Miami, Miami, FL; [6]University of Michigan, Ann Arbor, MI.*

Background: Ultrastructural features of renal biopsies are rarely used in conventional classification systems, and their reporting is often limited to a few parameters. The aim of this study was to investigate the prognostic value of 12 electron microscopy (EM) descriptors from the NEPTUNE Digital Pathology Scoring System (NDPSS).

Methods: Study pathologists scored digital EM images from 172 MCD/FSGS patients using the NDPSS. We performed hierarchical clustering of patients based on EM descriptors. We compared demographics, clinical characteristics, time to proteinuria remission, and time to the composite of 40% reduction in eGFR or ESRD across the clusters. We used penalized multinomial regression with cross-validation to test descriptors driving cluster membership and Cox proportional hazards models to link EM descriptors to clinical outcomes.

Results: Of the 3 clusters found [figure], cluster 1 patients had the most EM damage, were older (p=0.018), had lower eGFR (p<0.001) and higher urine protein creatinine ratio (p=0.029) at baseline, had higher rates of the composite outcome (p=0.005) and lowest rates of remission (p=0.033). Clusters 2 and 3 did not have significantly different demographics, baseline clinical characteristics, or outcomes. Microvillous transformation was not predictive of clusters, but was independently predictive of remission (p=0.001).

Conclusions: The NDPSS descriptor-based assessment of EM uncovered the significance of ultrastructural parameters usually under-reported in clinical practice. EM descriptor-based patient clusters predicted remission and progression outcomes, reflecting quantifiable transitional vs. permanent damage.

Funding: NIDDK Support

Figure: Mean EM descriptor values in each of three clusters

Laser Capture Microdissection and Liquid Chromatography Tandem-Mass Spectrometry for Small Amounts of Formalin-Fixed Paraffin Embedded Kidney Tissue Sophie I. Nagelkerken,[1] George Janssen,[2] Kimberley Veraar,[1] Peter Van veelen,[2] H. J. Baelde,[1] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Department of Pathology, Leiden University Medical Center, Leiden, Netherlands; [2]Center for Proteomics and Metabolomics, Leiden University Medical Center, Leiden, Netherlands.*

Background: Liquid chromatography tandem-mass spectrometry (LC-MS/MS) is a sensitive and specific technique for in depth protein identification but diagnostic kidney material is scarce, limiting the number of protein identifications. Only a few studies have used this technique for protein identification in formalin fixed paraffin embedded (FFPE) glomerular material and only one used a practical amount that can be used for diagnostic biopsies. Therefore, we optimized a work-flow of laser capture microdissection (LCM) of glomeruli, followed by LC-MS/MS on FFPE tissue for a minimal amount of tissue with a maximum protein yield.

Methods: One FFPE tissue block of a normal human kidney was utilised. Cross-sections of randomly selected kidney and glomeruli were collected from 6 µm sections, mounted on a 1.0 PEN membrane, using LCM. Protein extraction and digestion was performed using filter aided sample preparation (FASP) with polyethylene glycol (PEG) as a carrier, adapted from previously described methods for microdissected colon tissue. Samples were purified using mixed anion exchange solid phase extraction (MAX-SPE) and analysed using LC-MS/MS.

Results: Using the PEG-FASP protocol, we established the optimum amount of tissue to be 3 nl, based on 605 protein identifications, compared to 216 and 693 identifications in 1 and 10 nl tissue respectively. In a reproduction analysis of 5 experiments, using both random kidney and glomerular tissue, an average of 457 and 228 proteins were identified respectively. The method was able to distinguish glomerular samples from random kidney samples, as demonstrated by differentially identified proteins and clustering of glomerular and random kidney samples.

Conclusions: The relative number of proteins detected was comparable to or higher than reported in previous studies using FFPE glomerular tissue. The presented work-flow expands the potential for novel protein identification in glomerular diseases, while keeping the amount of tissue small enough for diagnostic practicality. Therefore, the combination of LCM followed by LC-MS/MS, using PEG-FASP and MAX-SPE for sample preparation, is a suitable and promising technique for diagnostic applications, especially when specific proteins are overexpressed or abundant within glomeruli.

Identification of Glomeruli for Improved Enumeration in Renal Biopsies Using Convolutional Neural Networks and Deep Learning Jonathan Street,[2] Tiffany R. Bellomo,[2] Erik H. Koritzinsky,[2] Stephen M. Hewitt,[1] Peter S. Yuen,[2] Robert A. Star.[2] *[1]National Cancer Institute, Bethesda, AL; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Accurate detection and counting of glomeruli in renal biopsies is important to assess biopsy adequacy, and for diagnostic accuracy (for example, the percentage of sclerotic glomeruli). A recent evaluation indicates that traditional methods can under-count glomeruli by ~50% when compared to more labor-intensive annotation methods. In recent years, deep learning has significantly advanced in a variety of tasks including image recognition, classification, and segmentation. To improve the accuracy of glomerular enumeration in renal biopsy evaluation, we are developing a convolutional neural network/deep learning model to locate glomeruli.

Methods: Twenty-two biopsy sections stained with hematoxylin and eosin were imaged using whole slide scanners (Aperio and Hamamatsu) for use in training and validation of the model. A custom application was developed to record the position of glomeruli in each biopsy with masks processed as geometries (boundaries stored rather than each pixel). This approach minimized file sizes and supported complex operations. Training and validation was conducted at the NIH high-performance computing facility employing multiple NVidia K20 GPU equipped nodes. The keras software package was used to define and train the neural network. Data augmentation and a modestly sized network (3 convolutional layers, a single hidden fully connected layer and an output layer) were used to optimize performance without overfitting the dataset.

Results: The accuracy of the neural network model was 91%. The model performance was robust to changes in stain intensity and the scanner used for imaging. Importantly, manual review of disagreements revealed errors in annotation (the model correctly identified glomeruli that had been missed by the human annotator).

Conclusions: Deep learning techniques can be utilized to accurately identify glomeruli in renal biopsies and can be scaled to handle the large images generated by whole slide scans. A convolutional neural network may help to improve the accuracy of glomeruli localization and enumeration, without the need for human intervention. This model could be leveraged for classification of glomerular morphology.

Body Composition Parameters Do Not Contribute to Glomerular Hypertrophy Satoshi Aoki, Tasuku Nagasawa. *Nephrology, Japanese Red Cross Ishinomaki Hospital, Miyagi, Japan.*

Background: Glomerular hypertrophy is often observed in diabetic nephropathy and obesity-related glomerulopathy. A correlation between body-mass indices (BMI) and glomerulomegaly has been reported. However, specific contributing factors remain unknown. The aim of this study is to investigate relations between glomerular hypertrophy and clinical parameters.

Methods: We measured glomerular major axis length (GMAL) of 157 patients who underwent percutaneous renal biopsy from July 2013 to July 2015 in Japanese Red Cross Ishinomaki Hospital. Body composition parameters, subcutaneous fat area (cm^2), visceral fat area (cm^2), psoas major area (mm^2/m^2), and muscles of back proper area (mm^2/m^2) were calculated based on CT images. We performed a multiple regression analysis with GMAL as the dependent variable.

Results: 157 cases were separated into 4 groups depending on the primary diseases: diabetic nephropathy (DN, n = 25), focal segmental glomerular sclerosis (FSGS, n = 20), hypertensive nephrosclerosis (HNS, n = 36) and the others (n = 76). Hypertrophic glomeruli (GMAL ≥ 250 μm) were observed in 76% of DN, 75% of FSGS, 66.7% of HNS and 56.6% of the others. The average GMAL was significantly greater in DN and FSGS. BMI, body weight, subcutaneous fat area, visceral fat area, psoas major area, and muscles of back proper area were not correlated with GMAL. As for blood and urine parameters, only eGFR had an inverse correlation (β = -0.657, $p < 0.01$). Glomerular density, the number of glomeruli that did not present global sclerosis per renal cortical area ($/m^2$) was not interrelated to BMI.

Conclusions: eGFR was the significant contributor to enlargement of GMAL. Glomerular hypertrophy may arise as a result of compensatory mechanism to eGFR decline.

TH-PO090

Ultrastructural Examination of Glomerular Fibrillary Deposits in Diabetic Nephropathy Sophie I. Nagelkerken, P.h. Neeskens, Jan A. Bruijn, Ingeborg M. Bajema. *Department of Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: In diabetic nephropathy (DN), glomerular fibrillary deposits have been observed but there are no large-scale, ultrastuctural examinations in the literature about the nature of these deposits. We here report our investigation of fibrillary deposits found by transmission electron microscopy (TEM) in DN, and compare results to those in fibrillary glomerulonephritis (FGN).

Methods: Twenty-two patients with autologous biopsy confirmed DN were selected and routine light microscopic evaluation, classification and clinical data were reviewed. TEM was performed and fibril diameter was calculated from 60-90 measurements per glomerulus. For comparison, 7 non-diabetic FGN patients were selected.

Results: For detailed results we refer to Table 1. There were 7 cases with class II, 10 with class III and 5 with class IV DN. Irrespective of class, small, randomly organised fibrils with a diameter of 7-14 nm were present in glomeruli of all cases, while additionally, straight or curved, organised fibrils with a diameter of 17-37 nm were present in 11 cases. No renal comorbidity at time of biopsy or at clinical follow up that could explain fibrillary deposits was present. FGN patients had similar fibrillary deposits that were either small and randomly organised or had a more organised aspect and a diameter of 13-32 nm. None of the patients had diabetes. IF findings did not contribute to differentiate between DN and FGN, but patients with DN did have a significantly thicker GBM than those with FGN.

Conclusions: Fibrillary deposits found in glomeruli of all 22 DN patients are morphologically similar to those in FGN patients. The widespread presence of fibrils in DN was an unexpected finding; their similarity to fibrils in FGN may complicate the histological diagnosis, especially in patients with clinically overlapping symptoms. Therefore, we are currently investigating their composition using mass spectrometry.

Serum IgA/C3 Ratio May Be a Useful Serologic Marker to Predict Remission and Disease Progression in Patients with Adult Onset IgA Vasculitis Takeyuki Takamura,[1] Fumihiko Furuya,[1] Kenichiro Kitamura.[2] *[1]University of Yamanashi, Chuo, Japan; [2]University of Yamanashi School of Medicine, Chuo, Japan.*

Background: In adult cases**,** IgA vasculitis (IgAV) typically represents severe renal dysfunction. Various clinical and histological parameters have been associated with an increased risk of progressive renal disease in several studies. However, there are no serologic markers that can be employed to assess disease activities or to predict renal outcome in IgAV. On the other hand, recently the serum IgA/C3 ratio has been suggested to serve as a marker for the progression of IgA nephropathy.

Methods: The aim of this study was to examine whether the serum IgA/C3 ratio serves as a marker to predict remission and disease progression in adult onset IgAV. We studied 37 patients with adult onset IgAV (mean follow-up of 34.2±5.3 months) with a mean age of 50.8±3.7 years old. Based on the available medical records, we retrospectively evaluated clinical data, IgA/C3 ratio, and kidney biopsy findings according to the ISKDC classification.

Results: The serum IgA/C3 ratio at the renal biopsy was significantly lower in patients with remission (no hematuria and U-TP/Cr <0.15g/gCr) compared to those with non-remission group (2.52±0.16 vs 3.69±0.52, $p<0.05$); there were no differences in ISKDC classification. In addition, patients with small reduction in eGFR (<25%) showed significantly lower serum IgA/C3 ratio than those with large decline in eGFR (≧25%) (2.57±0.18 vs 4.42±0.77, $p<0.05$).

Conclusions: To our knowledge, this is the first report to demonstrate that the serum IgA/C3 ratio can be a good marker to predict remission and disease progression in patients with adult onset IgAV. However, long-term follow-up and further studies are required to clarify the validity of the serum IgA/C3 ratio.

TH-PO092

Clinical Impact of Modified MESC Classification for Renal Outcome among Japanese IgAN Patients Ahmad B. Kaihan,[1] Yoshinari Yasuda,[4] Takayuki Katsuno,[2] Sawako Kato,[2] Takahiro Imaizumi,[5] Takaya Ozeki,[3] Manabu Hishida,[1] Naotake Tsuboi,[2] Shoichi Maruyama.[2] *[1]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [4]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [5]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Our previous study revealed that MES and crescent (C) in the Oxford classifications could not predict real outcome among adult Japanese IgA nephropathy (IgAN) patients, probably because that Japanese IgAN patients were diagnosed in earlier and more active stage. The purpose of this study was to modify the cutoff point of MESC scores adequate for Japanese patients with IgAN.

Methods: A total of 86 adult IgAN patients diagnosed from 2001 to 2009 by renal biopsy retrospectively evaluated at Nagoya University Hospital by seven nephrologists. The ROC curve analyses were used to modify the traditional cutoff points for MESC. Then the modified and traditional MESC score was analyzed in association with renal outcome, defined as a 50% increase in serum creatinine.

Results: Baseline characteristics [median and IQR] of study subjects were: age 36 [24-46] years, 41 female, proteinuria 1.2 [0.7-1.8] g/day, and serum creatinine (sCr) 0.9 [0.7-1.1] mg/dL. The modified cutoff point for MESC was ≥ 40%, ≥ 10%, ≥ 20%, and ≥ 10% in glomeruli respectively. Number and proportion of traditional vs modified MESC were M1: 24 (27.9%) vs 30 (34.9%), E1: 35 (40.7%) vs 17 (19.8%), S1:57 (66.3%) vs, 20 (23.3%) and C1:45 (52.3%) vs 32 (37.2%). During a median follow-up period of 6.8 years, 13 (15%) patients achieved the renal outcome. In univariate analyses, the traditional MESC was not associated with renal outcome, while in modified cutoff point M (HR 2.99, p= 0.05), E (HR 4.94, p= 0.004), S (HR 3.51, p= 0.03), and C (HR 3.67, p= 0.03) were significantly associated with renal outcome. ROC curve analyses (Fig 1) revealed significant predictive value in modified MESC classification (AUC=0.851).

Conclusions: The modified cutoff points for MESC significantly improved predictive value for renal outcome in Japanese patients with IgAN.

The GRACE IgA Nephropathy in Indians (IgANI) Study

Suceena Alexander,[1] Vijayakumar Theophilus-Sunder,[1] Vinoi G. David,[1] Anjali Mohapatra,[1] Anna T. Valson,[1] Shailesh T. Kakde,[1] Charles D. Pusey,[3] Mohamed R. Daha,[5] Jonathan Barratt,[2] John Feehally,[2] George John,[4] Santosh Varughese.[1] *[1]Christian Medical College, Vellore, India; [2]University of Leicester, Leicester, United Kingdom; [3]Imperial College London, London, United Kingdom; [4]Royal Brisbane and Womens Hospital, Brisbane, NSW, Australia; [5]Leiden University Medical Center, Leiden, Netherlands.*

Background: In India, about 30-40% IgAN patients present with nephrotic syndrome and renal dysfunction and progress rapidly.

Methods: Prospective longitudinal single center cohort. **Inclusion Criteria:** Age ≥18 years. Renal biopsy proven primary IgA nephropathy. CKD EPI eGFR > 10ml/min/1.73m^2. Treatment naïve. **Definitions:** Rapid Progresser (RP): IgAN patients with ≥5ml/min/1.73m^2/year fall in glomerular filtration rate (GFR) as estimated by the CKD EPI equation. Slow/Non Progresser (S/NP): IgAN patients with <5ml/min/1.73m^2/year fall in CKD EPI eGFR. End of study outcome (EOS): Composite end-point of 50% decline in eGFR with eGFR <10ml/min/1.73m^2, RRT or death whichever occurs earlier.

Results: 165 patients were included. Refer table for baseline parameters. Average in-center follow-up duration of 135 patients was 5.0 ± 4.4 months. There were 82/135 (60.7%) S/NPs and 53/135 (39.3%) RPs at follow-up. EOS outcome was reached in 1.2% of S/NPs vs. 30.2% of RPs. The significant predictors of EOS outcome for the cohort by Cox Regression analysis are given in the figure.

Conclusions: 28% of patients were RPs at follow-up. Higher hsCRP levels were protective whereas female gender, Hb <10g/L and MEST T2 score were significant risk factors for EOS outcome.

Funding: Government Support - Non-U.S.

IgA Dominant Membranoproliferative Glomerulonephritis

Nicole K. Andeen,[4] J. Ashley Jefferson,[4] Shreeram Akilesh,[4] Charles E. Alpers,[6] Laura S. Finn,[5] John P. Higgins,[2] Neeraja Kambham,[1] Behzad Najafian,[4] Roberto F. Nicosia,[7] Megan L. Troxell,[3] Kelly D. Smith.[4] *[1]Stanford Medical Center, Stanford, CA; [2]Stanford University, Stanford, CA; [3]Stanford University School of Medicine, Stanford, CA; [4]University of Washington, Seattle, WA; [5]University of Washington / Seattle Children's Hospital, Seattle, WA; [6]University of Washington Medical Center, Seattle, WA; [7]VA Puget Sound HCS, Seattle, WA.*

Background: IgA dominant membranoproliferative glomerulonephritis (MPGN) has morphologic and clinical features distinct from IgA nephropathy, lupus, and IgA dominant infection related glomerulonephritis. We sought to better understand the clinical and pathologic characteristics of this disease.

Methods: Native kidney biopsies from 2000 through 2016 with IgA dominant deposition by IF and diffuse MPGN features were retrospectively identified. Cases with only focal or segmental MPGN features, exudative features, prominent subepithelial deposits, other significant nephropathies, or findings of Henoch Schonlein purpura were excluded.

Results: 25 biopsies from 21 patients were identified from 5 institutions. The cases were subclassified into two groups: 1) patients without known underlying medical conditions (idiopathic, n=12) and 2) patients with significant gastrointestinal disease or cirrhosis from various etiologies (GI, n=9). The idiopathic group consisted of 9 men and 3 women, with a median age of 38 (range 11-68) years, who typically presented with nephrotic range proteinuria, hematuria, mild renal insufficiency, normal lupus serologies and serum complement levels, and no history of bacterial infection. At a median time of 3 years, 7 had available follow-up. Two progressed to end stage kidney disease, one of whom had recurrent IgA dominant glomerulonephritis in the allograft less than one year post transplant; two had persistent disease with increasing chronic features on repeat biopsy, and three had persistent renal insufficiency and/or proteinuria. From the GI group, follow up was available for 7 patients. At a median time of 2 months after biopsy (range 9 days – 13 months), 6 died and the 7th became dialysis dependent.

Conclusions: IgA dominant MPGN represents a rare but distinct pathologic entity that occurs as an idiopathic form or in association with significant gastrointestinal disease or cirrhosis. The idiopathic form has a poor prognosis, with persistent or progressive disease despite immunosuppressive therapy and recurrence post-transplant. The GI-associated form is associated with death or renal failure within a year of biopsy due to underlying complex medical conditions. Recognition of IgA dominant MPGN may help better define prognostic factors and therapeutic interventions.

Thrombotic Microangiopathy Like Lesions in IgA Nephropathy: A Cohort Study

Qingqing Cai,[1] Sufang Shi,[1] Jicheng Lv,[2] Hong Zhang.[1] *[1]Peking University First Hospital, Beijing, China; [2]Peking University, Beijing, China.*

Background: Background: Thrombotic microangiopathy (TMA)-like lesion often occurs in IgA nephropathy (IgAN), but its role in disease progression is not well established, and recent Oxford MEST-C score system doesn't include this lesion. In this study, we aim to investigate TMA-like lesions in IgAN using a prospective IgAN database cohort in Peking University.

Methods: Methods: Patients with IgAN from 2003 to 2014 who were followed at least 1 year enrolled in this study. Kidney biopsies from all participants were re-reviewed by two investigators independently blinded to the clinical data. The TMA-like lesions

were graded according to criteria by El Karoui K et al (JASN 2012, 23(1):137) under light microscope(LM). The primary outcome was time to 50% decline in estimated glomerular filtration rate (eGFR), end-stage kidney disease(ESRD) or death. Multivariable Cox regression model was used to evaluate TMA-like lesions for prognosis of IgA nephropathy.

Results: Results: Among the 1052 patients, 985(93.6%) patients with pathological slides available entered the study. Overall 194 (19.7%) had TMA-like lesions. Patients with TMA-like lesions presented a higher proportion of malignant hypertension (9.8 vs 1.0%, p<0.001), a higher blood pressure (130±19 *vs* 122±15 mmHg, p<0.001), severer proteinuria [2.3(1.4-4.1) *vs* 1.4(0.7-2.8) g/d, p<0.001] and lower eGFR (58.8±26.8 *vs* 86.2±28.9 ml/min per 1.73 m^2, p<0.001) at baseline compared to those without TMA-like lesions. After a mean follow-up of 4.1 years, 75(38.7%) patients with TMA-like lesions and 89(11.3%) with non-TMA-like lesions reached end points (p<0.001). In a multivariable Cox regression model, after taking into account clinical and pathological indicators available at the time of biopsy, TMA-like lesion was an independent risk factor for kidney progression in IgAN (HR 1.88, 95%CI:1.30-2.72, P=0.001). Moreover, the risk for kidney failure rose as the severity of TMA-like lesions increased (mild: HR 1.66, 95%CI:1.11-2.48; moderate: 2.53, 1.49-4.30; severe: 2.99, 1.27-7.04). Other renovascular sclerosis (arterial intimal fibrosis and arteriolar hyalinosis) were not risk factors of the progression of IgAN (HR: 0.84, 95%CI:0.54-1.31, p=0.441).

Conclusions: Conclusion: TMA-like lesions were frequent in IgA nephropathy and were associated with high risk of renal failure. Future pathological score of IgA nephropathy should include TMA-like lesions.

TH-PO096

Immunoglobulin A-Dominant Glomerulopathy and Thrombotic Microangiopathy after Chemotherapy: A Report of Three Cases Zeljko Dvanajscak,[2] Bethany E. Karl,[4] Vighnesh Walavalkar.[1] *[1]Pathology, University of California San Diego, San Diego, CA; [2]University of California San Diego, San Diego, CA.*

Background: Chemotherapeutic agents are a well-known cause of renal dysfunction and are known to cause injury to all compartments of the kidney. Amongst the glomerular diseases, immune complex mediated glomerulonephritis (usually IgG-dominant) and thrombotic microangiopathy (TMA) are the most commonly reported patterns of injury. We have recently encountered three unusual cases of IgA-dominant glomerulonephritis with superimposed TMA occurring after chemotherapy.

Methods: All three had an unusual pattern of IgA dominant immune complex deposition, not entirely compatible with known IgA-dominant immune complex mediated glomerulopathies like IgA nephropathy or IgA-dominant infection associated glomerulonephritis. All three cases had superimposed TMA. The patients were closely followed prior to and after renal biopsy. In each case there was no suggestion of pre-existing renal disease prior to initiation of chemotherapy; and presenting symptomology leading to biopsy occurred after initiation of the drug, suggesting contemporaneous relationship/association to the drug. All patients were successfully treated by cessation of the drug and steroid therapy. Several months of follow-up shows stable renal function without proteinuria or active urinary sediment in both patients.

Results:

Conclusions: We present these cases to discuss the differential diagnosis, approach to biopsy, potential mechanisms of injury, treatment considerations and to spread awareness of this unique pattern of renal injury seen after chemotherapy.

TH-PO097

Glomerular FHR5 Associates with Severity in IgA Nephropathy Nicholas R. Medjeral-Thomas, Nicholas Constantinou, Hannah J. Lomax-Browne, H. Terence Cook, Matthew C. Pickering. *Imperial College London, London, United Kingdom.*

Background: Serum factor H-related protein 5 (FHR5) levels are higher in IgA nephropathy (IgN) patients than healthy controls and correlate with histological severity. We hypothesised that glomerular FHR5 deposition would associate with IgAN severity.

Methods: 37 IgAN patients had stored tissue available from diagnostic renal biopsy and were categorised as progressive (n=19) or stable (n=18) disease. Immunohistochemistry protocols to detect complement C3c/C3b/iC3b, C3d, C4d, C5b9, factor H (fH) and FHR5 were developed and glomerular staining intensity graded on a scale: 0 (absent), 0.5 (minimal), 1, 2 or 3.

Results: Glomerular FHR5 deposition was present in 31 and absent in 6 patients. All cases with FHR5 staining showed glomerular C3 staining. A greater proportion of progressive than stable patients had detectable glomerular FHR5 (18/19 progressive and 13/18 stable patients, p=0.09). Of the 6 patients with absent FHR5, 5 (83%) had stable IgAN. We next sub-divided our cohort into those with negative(0)/minimal(0.5) glomerular FHR5 staining (FHR5-) and those with staining intensity scores of 1-3 (FHR5+). Features of IgAN severity were more common in the FHR5+ cohort (Table). After median 51 months follow up (range 13-296 months), four of the FHR5+ but none of the FHR5- patients reached end stage renal failure (p<0.0001). A greater proportion of the FHR5+ cohort showed glomerular complement deposition (Table) with a positive correlation between FHR5 staining and C3c/C3b/iC3b (r=0.57, p<0.0001), C3d (r=0.74, p<0.0001), and C5b9 (r=0.68, p<0.0001).

Conclusions: We conclude that glomerular FHR5 associates with disease severity and glomerular complement activation and represents a novel IgAN biomarker.

Clinical feature	FHR5+(n=24), median	FHR5– (n=13), median	Difference of medians	95% CI	p value

TH-PO098

Utility of Subgroups of the Japanese Histological Grade Classification of IgA Nephropathy to Evaluate Effectiveness of Therapy Kensuke Joh,[1] Akinori Hashiguchi,[2] Satoshi Hisano,[3] Akira Shimizu,[4] Ritsuko Katafuchi,[5] Tetsuya Kawamura.[6] *[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Keio University School of Medicine, Tokyo, Japan; [3]Fukuoka University School of Medicine, Fukuoka, Japan; [4]Nippion Medical School, Tokyo, Japan; [5]National Fukuoka-Higashi Medical Center, Fukuoka, Japan; [6]The Jikei University School of Medicine, Tokyo, Japan.*

Background: Japanese Histological Grade Classification (JHGC; HG1-HG4) (J Nephrol, 2013) is a lumped system grading glomerular lesions constituting of active crescent, global sclerosis, segmental sclerosis (S) and fibrous crescent. Each group is divided into subgroups constituting of active lesion (A), chronic lesions (C), and mixed lesions (A/C) The purpose was to investigate a utility of these subgroups to evaluate an effectiveness of therapy in a cohort of a Japanese IgA nephropathy (IgAN) prospective cohort study.

Methods: Sequential clinical data as well as renal biopsies were obtained from 847 Japanese patients (pts) with IgAN (male 49%) collected from 32 centers in Japan. The pts, whose median age was 36 years old, were prospectively followed for a median of 42 months. The average amount of proteinuria at the time of the biopsy was 1.1 g/day. Mean eGFR was 76±29 ml/min/1.73m^2. Pts was divided into group A or A/C (320 pts), group C (410pts), and group without A, A/C, or C (117 pts). Percent of the cases receiving steroid therapy with/without tonsillectomy (ST) and those receiving tonsillectomy with/without ST (Tons) were 79% and 41%, respectively in group A or A/C, whereas ST and Tons were 58% and 31% in group C, respectively. An effectiveness of these choices of therapy was evaluated by multivariate Cox regression analysis to predict renal functional decline (RFD) for 1.5 time's increase of serum creatinine (sCr) and proteinuric remission (PUR) for an endpoint of proteinuria as 0.3 g/day.

Results: In group A or A/C**,** ST or Tons besides HG3 and HG4 were selected as independent parameters for RFD, whereas HG2, HG3 and HG4 but not ST or Tons were selected in group C, even after adjustment by RAS blockade, initial mean arterial pressure (MAP), initial proteinuria, and initial eGFR (p<0.05). For PUR, ST besides HG 3 were selected as independent predictors **i**n group A or A/C**,** whereas ST besides HG3, and HG4 were selected in in group C after adjustment by aforementioned clinical parameters (p<0.05).

Conclusions: A utility of the subgroups of JHGC was appraised for an evaluation of an effectiveness of therapy. The cases with A or A/C but not C is a target of ST and Tons for RFD, whereas for PUR, ST can be applied not only for the pts with A or A/C but also for the pts with C.

TH-PO099

Clinicopathological Findings of IgA Nephropathy with Subepithelial Deposits Mineaki Kitamura, Yoko Obata, Tomoya Nishino. *Nagasaki University Hospital, Nagasaki, Japan.*

Background: Approximately 10% of patients with adult IgA nephropathy (IgAN) show subepithelial deposits, although their clinical significance remains unknown. A few clinical analyses performed for IgAN with subepithelial deposits (IgAN-SD) were reported long ago, but were relatively small sized. We studied a large number of IgAN patients focusing on atypical findings of IgAN to elucidate clinicopathological features of IgAN-SD.

Methods: We examined 464 cases diagnosed as IgAN at Nagasaki University Hospitals and affiliated hospitals between 1996 and 2013. Clinicopathological findings were compared between patients with IgAN-SD and IgAN with no subepithelial deposits (IgAN-NSD). Complement levels, localization of immunoglobulins, light chain staining pattern, and intramembranous deposits were evaluated, besides typical IgAN features.

Results: Patient characteristics were: age 38 ± 18 years, 214 men and 250 women. Subepithelial deposits were noted in 51 cases (11%). Compared to IgAN-NSD, mean serum protein (6.4 g/dL vs. 6.7 g/dL; P=0.020), albumin (3.7 g/dL vs. 3.9 g/dL; P=0.018) and complement (C3) (94 mg/dL vs. 103 mg/dL; P=0.020) were significantly lower in IgAN-SD patients. Diffuse mesangial proliferation (M) (65% vs. 45%; P < 0.01), endothelial hypercellularity (E) (43% vs. 28%; P=0.029), IgA staining in glomerular capillary walls (22% vs. 8.2%; P < 0.01) were higher in IgAN-SD patients. The incidence of light chain lambda predominance was lower in IgAN-SD patients (47% vs. 63%; P=0.028). Seven cases of IgAN-SD showed intramembranous deposits.

Conclusions: We found IgAN-SD showed the tendency to display atypical findings for IgAN, viz., low C3, and light chain staining pattern. Subendothelial deposits, low C3

and not light chain lambda predominance are also observed in IgA dominant-infection related nephropathy (IgA-IRGN). Therefore, some cases of IgAN-SD might in reality be IgA-IRGN, but not get diagnosed as IgA-IRGN owing to lack of clinical history of infection. Secondary IgA nephropathy, resulting from other etiology of IgAN, could be refractory and therapeutic strategy differs from that for IgAN. Secondary IgA deposition should be considered and careful history and clinical course be monitored if we find atypical findings for IgAN.

Galactose-Deficient IgA1 Monoclonal Antibody Specifically Identifies Primary IgA Nephropathy and IgA Vasculitis with Nephritis Hitoshi Suzuki,[2] Junichi Yasutake,[1,2] Yuko Makita,[2] Kohei Yamasaki,[1,2] Toshiki Kano,[2] Yusuke Suzuki.[2] *[1]Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan; [2]Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) has been proposed as an important effecter molecule in patients with IgA nephropathy (IgAN) and IgA vasculitis with nephritis (IgAV-N). Our previous study revealed that Gd-IgA1-specific monoclonal antibody KM55 (KM55 mAb) could be a new tool for detecting circulatory Gd-IgA1 in patients with IgAN, which enabled us to study molecular roles of Gd-IgA1. In this study, we further examined pathophysiological significance of Gd-IgA1 in glomerular deposits of patients with IgAN and IgAV-N by immunohistochemical analysis with KM55 mAb.

Methods: Kidney biopsy specimens were obtained from 2013 to 2016 at Juntendo University Hospital with the informed consent from patients. Double Immunofluorescent staining of Gd-IgA1 with KM55 mAb and anti-human IgA antibody was performed in paraffin embedded sections of renal biopsy specimens from patients with IgAN (n=43), and other renal diseases (n=30); such as lupus nephritis, HCV-related nephropathy and IgAV-N.

Results: Glomerular Gd-IgA1 was specifically detected by KM 55 mAb in all patients with IgAN and IgAV-N. In patients with IgAN and IgAV-N, Gd-IgA1 was localized predominantly in the mesangial region as IgA deposition. Gd-IgA1 could not be detected even in patients with lupus nephritis accompanied by glomerular IgA deposition. Furthermore, HCV-related nephropathy with secondary IgA deposition after HCV infection did not show any glomerular Gd-IgA1.

Conclusions: This is the first observation to clearly indicate that Gd-IgA1 could be specifically deposited in glomeruli of IgAN and IgAV-N, strongly suggesting the pathophysiological function of Gd-IgA1 in those diseases. Further studies are necessary to clarify the underlying mechanisms of Gd-IgA1 deposition and induction of renal injuries in IgAN and IgAV-N. Monoclonal antibody against Gd-IgA1 could be a novel powerful tool to distinguish primary IgAN and IgAV-N from other renal diseases with glomerular IgA.

Glomerular Glucocorticoid Receptor Expression Associates with Treatment Response and Prognosis in Patients with IgA Nephropathy Boyoung Nam,[1] Youn kyung Kee,[2] Sukyung Kang,[1] Arum Choi,[1] Seung Hyeok Han.[2] *[1]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Corticosteroid is a potential therapeutic option in patients with IgA nephropathy (IgAN) who have persistent proteinuria of ≥ 1g/day after 3-6 months of maximal supportive care. Responsiveness to steroid is highly variable and unpredictable in patients receiving steroid treatment. Glucocorticoid receptor (GCR) is present in glomerular cells such as mesangial cells and podocytes. However, it is unknown on the association between GCR and steroid responsiveness in management of glomerular diseases. Therefore, this study aimed to evaluate whether steroid responsiveness may differ depending on GCR expression level in patients with IgAN.

Methods: Among 504 patients of biopsy-proven IgAN between 2010 and 2015, 78 patients had received steroid treatment. After excluding patients who did not give an informed consent and had estimated glomerular filtration rate (eGFR) of < 30 ml/min/1.73 m^2, nephrotic syndrome, and inadequate biopsy samples, a total of 35 patients were included in the analysis. Glomeruli were obtained from biopsy tissues by manual microdissection. Glomerular mRNA expression of GCR was assessed by real-time polymerase chain reaction. Complete (CR) was defined as random urine protein-to-creatinine ratio (UPCR) < 0.3 g/g creatinine and partial (PR) remission was defined as a ≥ 50% reduction of proteinuria from baseline and UPCR of ≥ 0.3 g/g creatinine. Disease progression was defined as a ≥ 30% decrease in eGFR during follow-up period.

Results: The mean age of study patients was 43.9 years and 74.3 % were men. All patients responded to steroid treatment; CR and PR occurred in 14 (40.0%) and 21 (60.0%) patients, respectively. There were no significant differences in baseline eGFR and proteinuria level between CR and PR groups. The mRNA expression of GCR was significantly higher in the patients with CR than those with PR (P = 0.008). Immunohistochemal study also confirmed the enhanced expression of GCR in the former. During a median follow-up of 21.2 months, disease progression occurred only in 1 patient (7.1%) in CR group, as compared to 10 patients (47.6%) in PR group (P = 0.013).

Conclusions: This study shows that higher expression level of glomerular GCR is associated with a higher probability of steroid-induced CR and better renal outcome in IgAN.

TH-PO102

Diffusional Kurtosis Imaging in Assessing Renal Function and Pathology of IgA Nephropathy: A Preliminary Clinical Study Yan Liu,[1] Gu-Mu-Yang Zhang,[2] Xiaoyan Peng,[1] Hao Sun,[2] Limeng Chen.[1] *[1]Nephrology, Chinese Academy of Medical Science, Peking Union Medical College Hospital, Beijing, China; [2]Radiology, Chinese Academy of Medical Science, Peking Union Medical College Hospital, Beijing, China.*

Background: Renal fibrosis is the strongest predictor of ESRD in IgA nephropathy, but noninvasive and repeatable imaging markers are missing. Magnetic resonance imaging (MRI) has higher range of applications in renal parenchyma diseases, and diffusion kurtosis imaging (DKI) is a new promising noninvasive method of MRI which can potentially provide more information about non-Gaussian diffusion using a polynomial model, but still not used to assess renal fibrosis. This study first applied this novel technique to evaluate renal fibrosis, compared with pathological findings of kidney in patients with IgAN.

Methods: Twenty patients with biopsy-proven IgAN were enrolled and divided into two groups (eGFR≥45ml/min and eGFR≥45ml/min). The clinical data were documented, and DKI was performed on a clinical 3T MR scanner. Region-of-interest (ROI) measurements were performed to determine apparent diffusion coefficient (ADC), mean kurtosis (MK) and mean diffusivity (MD) of the cortex of the kidneys. Renal biopsy specimens were scored based on the severity of renal fibrosis. The values of DKI metrics were compared between two groups and the association between DKI data and clinicopathologic data were investigated.

Results: Twenty patients consisted of 9 males and 11 females with mean age of 34.6±13.0 years. The pathologic indicators showed significant correlation with eGFR. In DKI model, both renal ADC and MK values not only correlated well with eGFR (ADC: r=0.713,p=0.000; MK: r=-0.622, p=0.003), but also significantly associated with glomerular sclerosis index (GSI) (ADC: r=-0.577, p=0.008; MK: r=0.634, p=0.003) and the percentage of tubular atrophy/interstitial fibrosis (TAIF) (ADC: r=-0.699, p=0.001; MK: r=0.611, p=0.004). The ADC and MK values between two groups were also significantly different (p=0.002 and p=0.007, respectively). But the MD values showed no correlation with all clinicopathologic features and no significant differences were found in MD values between two groups. Further multiple linear regression analysis showed that only eGFR and ADC values was related and only glomerular sclerosis index (GSI) and MK values was related.

Conclusions: Renal ADC and MK values obtained from DKI showed significant correlation with pathologic sclerosis scores of IgAN, could be a promising noninvasive technique in patients follow-up.

TH-PO103

Urine Biomarkers' Efficacy as a Disease-Activity Parameter for Children with IgA Nephropathy Taketsugu Hama,[1] Yu Tanaka,[1] Masashi Sato,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Yuko Shima,[1] Hiroyuki Suzuki,[1] Koichi Nakanishi,[2] Norishige Yoshikawa.[3] *[1]Wakayama Medical University, Wakayama, Japan; [2]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan; [3]Clinical Research Center, Wakayama Medical University, Wakayama, Japan.*

Background: Although there have been several reports of biomarkers in adults, few studies have reported their use in pediatric patients, especially non-invasive methods. Several biomarkers are thought to be useful for differential diagnosis in kidney diseases. However, it is still unknown which biomarkers are more reliable in childhood IgA nephropathy (IgAN). Moreover, there are few reports about the efficacy of biomarkers, especially non-invasive methods as a disease-activity parameter in IgAN.

Methods: We compare several biomarkers from cells in urine samples between patients with IgAN and other renal diseases. And we assess the correlation between biomarkers from urine of pediatric patients with IgAN and their clinical and pathological status. Fifty consecutive patients with kidney diseases (18 nephrotic syndrome, 13 IgAN, 3 Henoch-Schönlein Purpura Nephritis, 1 Lupus, 1 Membranoproliferative Glomerulonephritis, 5 isolated hematuria, 2 isolated proteinuria, 7 others) at our hospital were enrolled. We examined by quantitative real time PCR and compared the expression levels of urine liver fatty acid-binding protein (L-FABP), kidney injury molecule-1 (KIM-1), Cubilin, interleukin-18 (IL-18), neutrophil gelatinase-associated lipocalin (NGAL), Megalin, podocin and Thy1 between IgAN patients and others.

Results: IgAN patients showed significantly lower levels of L-FABP1 (p<0.01), Megalin (p=0.03), Thy1 (p=0.02) and Cubilin (p<0.01) than other patients. Only KIM-1 expression in IgAN patients correlated with proteinuria (p=0.01) and hematuria (p=0.03). IgAN patients with crescents expressed a significantly higher level of IL-18 (p=0.03) than IgAN patients with no crescent pathologic changes.

Conclusions: Some kinds of biomarkers from urine of IgAN patients have potential to diagnose IgAN, predict disease-activity and pathological findings of glomerular crescents. Urine biomarkers are effective invasive tools for long-term follow up for IgAN patients.

TH-PO104

The Oxford IgA MEST Score Is Associated with Worse Kidney Outcomes in Childhood Onset Henoch Schönlein Purpura Nephritis Sally A. Kellett,[1] Paul S. Thorner,[1] Rose Chami,[1] Natasha Jawa,[2] Rulan S. Parekh,[1] Damien G. Noone.[2] *[1]The Hospital For Sick Children, Toronto, ON, Canada; [2]The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Henoch-Schönlein Purpura (HSP) is one of the commonest forms of systemic small vessel vasculitis in children, with kidney involvement occurring in 40-50% of children. Current pathology classification systems have not proved useful in determining long-term kidney outcomes in children with HSP nephritis. Aim: Determine if Oxford IgA MEST score is associated with long-term outcomes in childhood onset HSP.

Methods: This was a single-center, retrospective cohort study of children aged 0 to 18 yrs who presented with HSP nephritis between 2002 and 2016. Initial renal biopsies were scored based on the MEST criteria (M=mesangial hypercellularity, E=endocapillary hypercellularity, S=segmental glomerulosclerosis, T=tubular atrophy/interstitial fibrosis) and also for presence of crescents (C=cellular or fibrocellular crescents) and level of C3 deposition. Analyzed by logistic regression, we determined if MEST score was associated with clinical outcomes at last clinical follow-up with a composite outcome of proteinuria (protein:creatinine ratio >20mmol/mmol and/or eGFR <90ml/min/1.73m^2) controlling for age at presentation and sex.

Results: We identified 44 children (F=63.6%) with biopsy data who were followed for at least 6 months. At presentation, median age was 8.3 yrs (IQR 5.8 – 11.5yrs) median protein:creatinine ratio was 239.6mg/mmol (IQR 151.5 – 608.9 mg/mmol). Median length of follow-up was 3 yrs (0.5 to 11yrs). Pathology review determined 34.1% had a combined MEST score ≥3, 63.6% had crescents (of those, 85.7% <50%) and 61.4% C3 staining >1+. A total of 79.5% were treated with steroids and 45.5% with an ACE inhibitor or angiotensin II receptor blocker. Median GFR at last follow up was 107.4ml/min/1.73m^2 (IQR 83.6 to 146.2). A MEST score ≥3 had an adjusted odds of 8.3 [95% CI 1.3-52.2] of having a poor kidney outcome when adjusted for age and sex. The presence of crescents gave an adjusted odds of 5.4 [95% CI 1.2-25.5] of reaching the composite outcome. C3 was not significantly associated with the composite outcome with adjusted odds of 1.9 [95% CI 0.5-7.3].

Conclusions: MEST pathological score of ≥3 and presence of crescents on first biopsy in children with HSP nephritis is associated with a worse outcome by 3 years. This study suggests that Oxford IgA MEST score may be useful for disease prognosis.

TH-PO105

Prognostic Evaluation of Pediatric IgA Nephropathy Using Histological Criteria Including Macrophage Accumulation Yohei Ikezumi,[1] Yuji Matsumoto,[1] Hiroya Hasegawa,[3] Takeshi Yamada,[3] David J. Nikolic-Paterson.[2] *[1]Fujita Health University School of Medicine, Toyoake, Japan; [2]Monash Medical Centre, Clayton, VIC, Australia; [3]Niigata University Medical and Dental Hospital, Niigata-City, Japan.*

Background: There is no histological classification to predict disease flare in children with IgA nephropathy (IgAN). As macrophage (MQ) accumulation correlates with histological injury, we investigated new histological criteria to predict disease flare in pediatric IgAN.

Methods: A total of 73 children with biopsy proven IgAN underwent 2 years of steroid treatment followed by a protocol biopsy and then steroid tapering. The non-flare group successfully discontinued steroid treatment (N=61, 20.1±9.2 years at biopsy); the flare group exhibited increased proteinuria during the taper or cessation of treatment (N=12, 11.6±2.3 years at biopsy, p<0.05). Histological findings were evaluated using Oxford classification. Macrophage number and phenotype was assessed by immunofluorescence.

Results: At first (diagnostic) biopsy, urine findings were comparable between the two groups, but the flare group had a higher serum IgA level (279±83 vs 214±87 mg/dL; P<0.05). Biopsies revealed no difference in mesangial proliferation (M), endocapillary proliferation (E), glomerulosclerosis (S), tubulointerstitial fibrosis (T), and crescent formation (C); however, the flare group had more total MQ (CD68+ cells) (p<0.05) and M1 MQ (CD68+CD86+ cells) (p<0.05). In addition, M1 MQ correlated with glomerular M, E, S, C lesions (all P<0.01). At second (protocol) biopsy, the flare group had more severe S (p<0.01) and T (p<0.05) lesions, and more glomerular and interstitial M2 MQ (CD68+CD163+ cells) (both p<0.01 vs non-flare group). In addition, M2 MQ correlated with S and T lesions (both p<0.001). ROC analyses revealed glomerular MQ number >2.2 cells at first biopsy could predict disease flare by sensitivity of 83%.

Conclusions: MQ accumulation is a potential marker to predict disease flare in pediatric IgAN. The number of glomerular M1 MQ in active lesions at the first biopsy was related to flare occurrence, while glomerular and interstitial accumulation of M2 MQ in chronic lesions may predict disease flare in pediatric IgAN.

Clinical and Pathological Differences in Patients with IgA Nephropathy with IgG Deposit and Position in Glomeruli Chang Ying Xing, Yanfang Zheng. *First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: It is not clear the clinical data, pathological changes in patients with IgA Nephropathy with or without IgG deposition in glomeruli. This paper is to explore the significance of IgG deposit in glomeruli in patients with IgA Nephropathy.

Methods: There were 327 patients with IgA nephropathy diagnosed by renal biopsy in our hospital in the past 2 years. All renal biopsy samples were examined by light microscopy and immunofluorescence. IgA nephropathy patients were divided into two groups: IgA+IgG group (n=82) with IgG deposit in glomerli, and IgA group (n=245) without IgG deposit. Patients in IgA+IgG group were divided 2 subgroups according to the position of IgG deposit, deposit in mesangial area(10) and along glomerular basement membrane(72).

Results: Patients with IgA Nephropathy in IgA+IgG group had more 24 hours urine protein, higher serum creatinine, uric acid, hypertension and lower complement C4, eGFR than those in IgA group(P<0.05). The score of renal tubular atrophy/interstitial fibrosis (T) was higher IgA+IgG group than that in IgA group (P<0.05). There was no significant difference in proliferation of mesangial cells, mesangial hypercellularity, segmental glomerulosclerosis or adhesion, hyperplasia of endocapillary cell (P>0.05). Patients with IgG deposits along glomerular basement membrane(GBM) subgroup had more numbers, younger age, higher blood pressure than those in patients with IgG deposit in mesangial area subgroup(P<0.05). The eGFR, urea nitrogen and uric acid in IgG along GBM deposit subgroup were lower than those in the IgG deposit in mesangial area subgroup (P<0.05). There was no significant difference in the pathological changes between the two subgroups (P>0.05).

Conclusions: The patients with IgA nephropathy with IgG deposition are younger, more 24 hours urine protein, higher serum creatinine, and hypertension. Even the different position of IgG deposit in glomeruli may also have different clinical significance. We should strengthen the understanding of IgA nephropathy with IgG deposition and delay the progress of IgA nephropathy.

TH-PO107

Crescentic Lesions and Renal Outcomes in IgA Nephropathy: Validation of the Updated Oxford Classification in Brazilian Patients Precil D. Neves,[2] Rafaela B. Pinheiro,[5] Cristiane B. Dias,[4] Luis Yu,[3] Leonardo A. Testagrossa,[5] Viktoria Woronik,[1] Lectícia Jorge.[5] *[1]None, Salvador, Brazil; [2]University of S?o Paulo, S?o Paulo, Brazil; [3]University of Sao Paolo School of Medicine, Sao Paulo, Brazil; [4]University of Sao Paulo, Brazil, São Paulo, Brazil; [5]University of São Paulo, São Paulo, Brazil.*

Background: Background: IgA Nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide. The Oxford Classification (OC) of IgAN has been recently updated and crescentic lesions were recognized as histological features related to worst renal outcomes. **Objectives:** Evaluation of crescentic lesions impact in renal outcomes in IgAN patients and validation of the new Oxford Classification of IgAN (MEST-C) in brazilian patients.

Methods: Methods: Analysis of medical reports database and kidney biopsy of patients with diagnosis of IgAN. Kidney biopsy were classified according new OC (MEST-C). Composite outcome was doubling of baseline serum creatinine concentration or end stage kidney disease. We performed comparative analyses between groups with and without crescentic lesions in kidney biopsy.

Results: Results: In the following image we describe baseline clinical data and kidney biopsy features of patients with IgAN as well comparative analysis of groups with (C1/C2) and without (C0) crescentic lesions in kidney biopsy.

Conclusions: Conclusion: Crescentic lesions were associated with both worst renal function at biopsy and outcomes in brazilian patients. These data ratify previous findings in the literature.

	Baseline (n=111)	C0 (n=80)	C1/C2 (n=31)	p

Urinary Excretion of C5a in Membranous Nephropathy Isabelle Ayoub,[5] Daniel J. Birmingham,[1] Jessica M. Nelson,[4] Lee A. Hebert,[2] Brad H. Rovin.[3] *[1]Ohio State University, Columbus, AL; [2]Ohio State University Medical Center, Columbus, OH; [3]Ohio State University Wexner Medical Center, Columbus, OH; [4]Ohio State Wexner Medical Center, Columbus, OH; [5]Medicine/ Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Using proteomic analysis we previously showed that glomeruli from patients with membranous nephropathy (MN) express increased levels of complement components C3 and C4 and decreased levels of the complement receptor CR1 compared to glomeruli from healthy kidneys. Here we measured complement component C5a in the urine of MN patients as a non-invasive surrogate of intra-renal complement activation.

Methods: Urine samples were collected at the time of first kidney biopsy of patients with active MN (n=13). These patients had primary MN as suggested by dominant (n=5) or co-dominant (n=6) IgG4 glomerular immunofluorescence. Two patients only had IgG1 glomerular immunofluorescence, usually seen in secondary MN, but no underlying etiology was found in either case, so they were treated as primary MN. Urine C5a levels were measured by a sandwich ELISA.

Results: Urine protein to creatinine ratios (uPCR) in this group of MN patients ranged from 2.2-11 g/g with a median of 4 g/g. Urine C5a levels were undetectable in 2 two patients. The median value for the group was 4 ng/mg urine creatinine with a range of 0-11 ng/mg. Patients with Ig4 dominant or co-dominant MN had a higher level of C5a (5.1±3.3 ng/mg) than patients who were IgG1 dominant (1.3±1.8). C5a levels correlated with spot uPCR (r=0.68, p= 0.01), however the correlation was mainly driven by those with heaviest proteinuria.

Conclusions: In immunologically active primary MN, C5a is present in the majority of urine samples. In secondary (IgG1-dominant) MN C5a levels were much lower than in primary MN, but this is difficult to interpret due to small sample size. The presence or absence of urinary C5a could be useful in differentiating immunologically active proteinuric patients with an historic diagnosis of MN from proteinuria driven by hemodynamic or other factors, facilitating decisions regarding immunosuppressive therapy without repeating kidney biopsy. The relationship between urinary C5a and anti-PLA2R levels remains to be determined.

TH-PO109

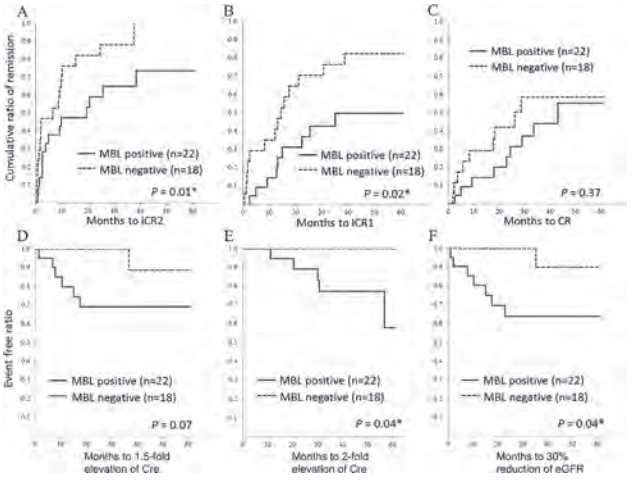
Clinical Impact of Glomerular Mannose-Binding Lectin Deposition in Intrinsic Antigen-Related Membranous Nephropathy Norifumi Hayashi,[1] Yuki Matsui,[1] Keiji Fujimoto,[1] Hiroki Adachi,[2] Hideki Yamaya,[1] Hitoshi Yokoyama.[1] *[1]Kanazawa Medical University, Kanazawa, Japan; [2]Kanazawa medical university, Kanazawa, Japan.*

Background: The M-type phospholipase A2 receptor (PLA2R) and thrombospondin type-1 domain-containing 7A (THSD7A) were identified as intrinsic antigens in primary membranous nephropathy (MN). Complement activation via the lectin pathway in intrinsic antigen-related MN is still unclear.

Methods: We retrospectively enrolled 60 primary MN patients and detected activated complement pathways by staining complement proteins in glomerular deposition. According to the findings of PLA2R and THSD7A staining in glomeruli, they were classified into intrinsic antigen-related or -unrelated MN. We evaluated clinicopathological characteristics and predictors of clinical outcomes in intrinsic antigen-related MN.

Results: Thirty-nine patients (65%) had PLA2R in glomerular deposits and 2 patients (3.3%) had THSD7A. One of them had both PLA2R and THSD7A (double positive). Forty patients were classified into the intrinsic antigen-related group. The other 20 patients were negative for both antigens (unrelated group). The prevalence and staining intensity of mannose-binding lectin (MBL) deposits was much higher in the intrinsic antigen-related group (55% vs. 20%, P<0.010, 1.0 [1.0-2.0] vs. 1.0 [0.0-1.0], p=0.01, respectively). The staining intensity of MBL in glomeruli also correlated with the IgG4 staining intensity. In intrinsic antigen-related MN, MBL staining intensity was an unfavorable predictor for remission of proteinuria (HR 0.40, p<0.01) and renal dysfunction (HR 3.81, p=0.01) in Cox proportional hazards analysis. Moreover, the glomerular MBL-positive group showed more severe interstitial fibrosis and worse clinical outcomes.

Conclusions: Intrinsic antigen-related MN was more strongly associated with complement activation by the lectin pathway, and was an unfavorable predictor for clinical outcomes.



TH-PO110

Clinicopathological Characteristics of Thrombospondin Type 1 Domain–Containing 7A-Positive Membranous Nephropathy Shigeo Hara,[2] Shinichi Nishi,[3] Akihiro Yoshimoto.[1] *[1]Kobe City Medical Center General Hospital, Kobe, Japan; [2]Diagnostic Pathology, Kobe University Graduate School of Medicine, Kobe, Japan; [3]Nephrology, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Recent studies suggested the possible association of Thrombospondin type 1 domain–containing 7A (THSD7A)-positive membranous nephropathy (MN) and malignancy; however, the clinicopathological characteristics of THSD7A-positive MN have been still poorly characterized.

Methods: Among 164 consecutive cases of pathologically-proven MN, 7 cases were immunohistologically positive for THSD7A (4.2%) and defined as THSD7A-positive MN. Clinical characteristics including renal function, proteinuria levels, and incidence of specific disease entities such as malignancy and other disorders were obtained from the data base record. IgG subclass profiles were examined in 6 cases using frozen sections. PLA2R1 immunostaining were evaluated in all cases.

Results: The patient age ranged from 42 to 73 (mean 63.7). Male-female ratio was 5:2. The median levels of serum creatinine and proteinuria were 0.84 mg/dl (range 0.53 – 1.4) and 7.41 g/gCr (0.37 – 16.1), respectively. Two patients had cancer concomitantly at the time of renal biopsy; one had small cell carcinoma in the lung and the other had prostatic adenocarcinoma. THSD7A immunostaining was available in the lung cancer case, which was negative for THSD7A. Two patients had concurrent incidence of inflammatory diseases; one had Kimura's disease, a chronic eosinophilic inflammatory disorder of unknown etiology, and the other had eosinophilic pneumonia in addition to asthma. Remaining three patients had no specific disease entity at the time of MN diagnosis, classified as primary MN. IgG subclass showed IgG4-dominant or co-dominant phenotype in 5 cases. One case with prostatic cancer had IgG2 and IgG3-dominant distribution. One case showed PLAR1 positivity (dual positive for PLA2R1 and THSD7A).

Conclusions: In contrast to the major distribution of IgG4-dominant/co-dominant phenotype, THSD7A-positive MN tends to be associated with various disease entities.

TH-PO111

Urine Anti-PLA2R Antibody Is a Biomarker for Diagnosis and Activity in Idiopathic Membranous Nephropathy Bing Li. *Department of Nephrology, 2nd Affiliated Hospital of Harbin Medical University, Harbin, China.*

Background: Detection of the serum anti-PLA_2R antibody ($sPLA_2R$-Ab) and the glomerular PLA_2R antigen ($gPLA_2R$) has been widely used as a diagnostic tool for idiopathic membranous nephropathy (IMN) and for the evaluation of IMN activity and severity. Since urine samples more directly reflect kidney damage and alterations than blood samples, we evaluated whether urine anti-PLA_2R antibody ($uPLA_2R$-Ab) could be utilized as a noninvasive biomarker for IMN.

Methods: In this study, we completed a qualitative analysis through indirect immunofluorescence test (IIFT) and measured $uPLA_2R$-Ab and $sPLA_2R$-Ab concentrations by enzyme-linked immunosorbent assay (ELISA) in 28 patients with biopsy-proven IMN and 12 patients with secondary membranous nephropathy (SMN).

Results: Overall, 64.3% (n=18) of patients with IMN had IIFT-positive $sPLA_2R$-Ab, 67.9% (n=19) of patients with IMN had IIFT-positive $uPLA_2R$-Ab IIFT, and none of the SMN patients had IIFT-positive $sPLA_2R$-Ab or $uPLA_2R$-Ab. The titers of the anti-PLA_2R antibody from the IMN patients in the urine (10.72±22.24 RU/mmol, presented as $uPLA_2R$-Ab/urine creatinine) or the serum (107.36±140.93 RU/ml) were higher than those from the SMN patients (0.51±0.46 RU/mmol, p<0.001; 0.008±0.029 RU/ml, p=0.02, respectively). Statistical analyses indicated that there were positive correlations between $uPLA_2R$-Ab and $gPLA_2R$, $sPLA_2R$-Ab or urinary protein and negative correlations between $uPLA_2R$-Ab and serum albumin in patients with IMN.

Conclusions: Our results indicate that uPLA$_2$R-Ab might serve as a biomarker, like sPLA$_2$R-Ab, for IMN diagnosis and that the antibody titer, as measured by ELISA, might reflect IMN activity and severity.

The Exact Time Difference between PLA2R Antibody and Proteinuria in Reflecting Disease Activity Change in Idiopathic Membranous Nephropathy Weifeng Lin,[2,4] Hang Li,[3,1] Xuemei Li,[1] Limeng Chen,[1] Xuewang Li.[1] *[1]Peking Union Medical College Hospital, Beijing, China; [2]Department of Nephropahty, Peking Universty Third Hospital, Beijing, China; [3]Peking Union Medical college hosiptal, Beijing, China; [4]Peking Union Medical College Hospital, Chinese Academy of Medicine Sciences & Peking Union Medical College, Beijing, China.*

Background: According to most studies, PLA2R antibody was faster than proteinuria in reflecting disease activity in idiopathic membranous nephropathy. However, the exact time difference is still unknown. This study was to reveal the precise time difference between them, which could guild clinical practice.

Methods: A total of 102 patients with IMN proven by kidney biopsy at Peking Union Medical College Hospital from January 1, 2014 to December 31, 2015 were enrolled. An observationally prospective follow-up was conducted monthly to monitor the changes in PLA2R antibody titer and disease activity changes based on proteinuria in IMN. The study end point was clinical remission based on proteinuria or the research deadline.

Results: The average follow-up time was (13.83±3.14) months, with a minimum time of 7 months and a maximum time of 21 months. The overall average time of PLA2R antibody turning negative in clinical remission group based on proteinuria was (3.11±2.97) months. In subgroups,the average time of antibody turning negative in the complete remission (CR) group and partial remission (PR) group were (3.17±3.23) months and (3.13±3.05) months, respectively. Importantly, our study showed that PLA2R antibody was (1.91±2.51) months earlier turning negative than proteinuria reaching clinical PR in IMN. Also, there was (6.91±3.33) months earlier for antibody to turn negative than proteinuria to achieve clinical CR. There was (3.09±4.66) months earlier for antibody turning positive again than proteinuria recurrence.

Conclusions: The PLA2R antibody changes was faster than proteinuria in reflecting disease activity changes in IMN,about 2 months ahead of proteinuria PR, about 7months ahead of proteinuria CR and about 3 months ahead of proteinuria recurrence.

Plasma C4d Differentiates PLA2R Positive Membranous Nephropathy from Other Primary Glomerular Diseases Congcong Jiao,[3] Junjun Luan,[3] Guangying Guo,[3] Wei Qu,[5] Ying Chen,[5] Weiwei Kong,[3] Yani Zhang,[3] Jingqi Fu,[1] Jingbo Pi,[1] Jeffrey B. Kopp,[4] Lining Wang,[2] Hua Zhou.[3] *[1]Chinese Medical University, Shenyang, China; [2]Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, P. R. China, Shenyang, China; [3]Nephrology department, The first hospital of China medical university, Shenyang, China; [4]NIDDK, NIH, Bethesda, MD; [5]China Medical University, Shenyang, China.*

Background: Renal C4d staining is a potential diagnostic biomarker for immune complex-mediated glomerular diseases. Positive M-type phospholipase A2 receptor (PLA2R) staining on kidney biopsy is specific for primary membranous nephropathy (pMN) diagnosis. We aimed to assess whether plasma C4d can differentiate PLA2R positive MN from other primary glomerular diseases and to correlate plasma C4d level with renal PLA2R staining.

Methods: Plasma C4d levels were measured by ELISA in 16 healthy volunteers and 187 untreated patients with biopsy-proven glomerular diseases, including 80 PLA2R positive and 55 PLAR negative MN cases, 20 IgA nephropathy, 18 minimal change disease, and 14 focal segmental glomerulosclerosis cases. There were 123 nephrotic and 26 nephritic cases among subjects with primary glomerular diseases. PLA2R negative MN cases included atypical pMN (n=17), hepatitis B virus (HBV)-associated MN (n=23) and autoimmune-associated MN (n=15).

Results: Plasma C4d levels significantly increased in pMN compared with each of the other groups. C4d differentiated pMN from these three primary glomerular diseases either in nephrotic (AUC=0.7, p<0.001, n=111) or nephritic diseases (AUC=1.0, p<0.001, n=21). C4d also distinguished PLA2R positive MN from PLA2R negative MN (AUC=0.98, p<0.001, n=135). Interestingly, C4d was significantly decreased in autoimmune-associated MN compared with HBV-associated MN and PLA2R negative MN without identified primary causes. Plasma C4d was positively correlated with the extent of renal PLA2R staining (r=0.64, p<0.001, n=135).

Conclusions: Plasma C4d differentiates PLA2R positive MN from other primary glomerular diseases and correlated with renal PLA2R staining. Plasma C4d may serve as a supplementary biomarker, together with circulating PLA2R antibody, as a measurement panel for diagnosing pMN in patients with a contraindication to renal biopsy.

Clinical Significance of Urinary Podocyte-Derived Microparticle Detection in Idiopathic Membranous Nephropathy Jian Lu, Kun ling Ma, Yang Zhang, Zebo Hu. *Zhongda Hospital, Southeast University Medical School, Nanjing City, China.*

Background: Microparticles (MPs) are a type of extracellular vesicles (EVs) shed from the outward budding of cytoplasma membranes during cell apoptosis and/or activation. These microsized particles release specific contents (lipids, proteins, microRNAs, etc.) and are active participants in a wide range of both physiological and pathological processes at molecular levels. This study aimed to observe the change of urinary podocyte-derived microparticle level and to explore its potential clinical significance in idiopathic membranous nephropathy(IMN).

Methods: We prospectively enrolled patients with IMN (n = 24) before initial Immunosuppressive therapy to study renal tissue pathology using Periodic acid–Schiff staining by light microscope and ultrastructural observation by transmission electron microscope. After isolation from urine samples, podocalyxin-positive podocyte-derived microparticles were characterized by flow cytometry. Twenty IMN patients were studied again 6 months after Glucocorticoids in combination with tacrolimus intervetion. Health Volunteers (n= 15) served as controls. The correlation of urinary podocyte microparticles and clinical and pathological factors in IMN patients was analyzed.

Results: Compared with the control group, there were increased serum PL2AR antibody tite and 24-hour urinary protein (all P<0.05). The fraction of podocyte microparticles among urinary microparticles was elevated in IMN compared with health volunteers (P<0.01) and decreased after 6 months therapy and after controlling for clinical parameters.

Conclusions: The excretion of urine podocyte-derived microparticles might reflect podocyte injury and might be closely associated with the progression of IMN.

TH-PO115

Practice Patterns in Management and Outcomes of Primary Membranous Nephropathy: A Single Centre Experience Martin E. Durcan, Mohamed Elsayed, Arvind Ponnusamy. *Royal Preston Hospital, Preston, United Kingdom.*

Background: Membranous nephropathy is a common glomerular disease. In the last number of years there has been many clinical trials addressing its management. These trials have altered the treatment patterns of this condition by giving the physician more treatment options. The aim of this study was to review the practice patterns in management and outcomes of primary membranous nephropathy at a single U.K centre.

Methods: Clinical demographics, relevant laboratory values and modalities of treatments were collected on all patients with biopsy proven membranous nephropathy between 2004 and 2011. Patients were followed up until November 2016. The following outcomes were of interest; complete remission (proteinuria less than 30mg/mmol and stable renal function), partial remission (at least 50% reduction in proteinuria from baseline and uPCR <300mg/mmol with stable renal function (<15% drop in eGFR), relapse (recurrence of proteinuria with ≥ 300mg/mmol) and a composite outcome of the following endpoints; doubling of baseline creatinine, start of renal replacement therapy or death.

Results: 129 incident patients were followed up for a median of 5.56 years. Mean age of patients was 56.5 ±16.7 years of age. 66.6% of patients were male and remainder were female. Prevalence rate of hypertension was 60.6% while 17.4% had diabetes. Mean baseline eGFR was 62.9 ± 34.6 ml/min/1.73m^2. Mean PCR and albumin at diagnosis was 769.83 mg/mmol and 27.9 ± 6.6 g/L, respectively. 56 (43.4%) received immunosuppressive therapy overall. 24 (19%) patients were treated with the Ponticelli regime.36 (28%) received a calcineurin inhibitor.12 (9.52%) received mycophenolate mofetial (MMF). Patient and renal survival at last follow up was 71.20%. 51% of study population obtained complete remission. 27% achieved partial remission. 40.17% achieved the composite outcome. Achieving remission (whether partial or complete)

decreases hazards of developing composite outcome by 64%. P=0.0007. Please see figure 1. for survival outcomes related to each treatment modality.

Conclusions: Outcomes are comparable and better than what is reported in the literature. Treatment of patients with a calcineurin inhibitor seems to be superior to treatment with other modalities. Further analysis of this finding is needed.

TH-PO116

Clinicopathological Manifestation in Patients of Idiopathic Membranous Nephropathy Assigned to a Heterogeneous Group with Nephrotic Syndrome Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[1] Yasunori Iwata,[1] Norihiko Sakai,[1] Miho Shimizu,[1] Kengo Furuichi,[1] Hitoshi Yokoyama,[2] Takashi Wada.[1] *[1]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Division of Nephrology, Kanazawa Medical University Hospital, Uchinada, Japan.*

Background: The 20-year renal survival of Idiopathic membranous nephropathy (IMN) in Japanese adults with nephrotic syndrome was reported around 60%. Based on the electron microscopic findings, we reported that there are two distinct types, homogeneous type and heterogeneous type; synchronous electron dense deposits or various phases of dense deposits in basement membrane, respectively. (Kidney International in 2004). Our previous analysis revealed that the rate of renal death was around 20 times higher in heterogeneous group (heterogeneous group; 25.6%, homogeneous group; 1.3%). In this study, we evaluated the predisposing clinicopathological factors for IMN patients assigned to heterogeneous group with nephrotic syndrome (NS).

Methods: Forty patients of NS (24 males and 16 females; mean age 45.7 years) with heterogeneous type IMN were evaluated in this study who were collected in Kanazawa University Hospital and affiliated hospitals from 1965 to 2013. The patients were followed for more than three years, or until renal or patient death. Clinicopathological factors, which might affect renal death were evaluated.

Results: Renal death was observed 12 out of 40 patients (30%). We divided two groups; renal death group and renal survival group. The renal death group showed lower remission rate (CR or ICRI;renal death group; 16.7%, renal survive group; 60.7%, p=0.01), and higher sustained NS rate (renal death group; 50.0%, renal survive group; 10.7%, p=0.006). There was no difference in clinical background at onset between two groups. In renal death group, two patients achieved remission, but relapsed after the remission and became renal death. The median duration to renal death after kidney biopsy was 107 months, and patients of sustained NS had a tendency to shorter duration (NS group; 76.5months, non-NS group; 139.1months, p=0.10).

Conclusions: These findings suggest that electron microscopic findings demonstrating heterogeneous type and no-remission of nephrotic syndrome was susceptible to renal death in patients with nephrotic IMN.

TH-PO117

Serological and Immunohistological Characteristics of Membranous Nephropathy in Children Anne K. Dettmar,[1] Thorsten Wiech,[4,3] Markus J. Kemper,[5] Jun Oh,[1] Rolf A. Stahl,[3] Elion Hoxha.[2,3] *[1]Pediatric Nephrology, University Medical Center Hamburg- Eppendorf, Hamburg, Germany; [2]III. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]SFB1192, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Department of Pathology, University Medical Center Hamburg Eppendorf, Hamburg, Germany; [5]Department of Pediatrics, Asklepios Nord-Heidberg, Hamburg, Germany. Group/Team: Pediatric MN Study Group.*

Background: In adult patients with membranous nephropathy (MN) phospholipase A_2 receptor 1 (PLA_2R1) and thrombospondin type 1 domain containing 7A (THSD7A) are the target antigens in 80% and 2-3% of patients, respectively. In children MN is less common and two more antigens are involved in disease development: neutral endopeptidase (NEP) and cationic bovine serum albumin (cBSA). In this study we performed a clinical, serological and immunhistological characterization of MN in children.

Methods: Twelve children with biopsy-proven MN were included. We analyzed the sera for PLA_2R1, THSD7A, NEP and cBSA-Antibodies (Ab). Clinical data and blood samples were evaluated every three months. Immunohistochemical analyses for all antigens and IgG subclasses were performed in five biopsies. The median follow-up time was 24 months.

Results: Six (50%) children had a PLA_2R1-associated MN. There were no antibodies against THSD7A, NEP or cBSA in any of the sera. To detect further potential antigens, all sera were analyzed by Western blot against human glomerular extracts, showing no further specific reactions. Immunohistochemical analyses of renal biopsies identified no THSD7A, NEP or cBSA-associated case in our cohort. Two biopsies from PLA_2R1-associated patients showed enhanced staining for PLA_2R1, but not for the other antigens. Both biopsies were positive for IgG2 and IgG4. In contrast, all three biopsies from patients with non-PLA_2R1-associated MN stained negative for IgG2 and IgG4. IgG1 and IgG3 staining was not different between PLA_2R1- and non-PLA_2R1-associated MN cases. Four PLA_2R1-Ab positive and five PLA_2R1-Ab negative patients had a remission of proteinuria. In PLA_2R1-associated cases remission was preceded by decline of PLA_2R1-Ab levels. In one patient a relapse of proteinuria occurred and was preceded by PLA_2R1-Ab reappearance in serum.

Conclusions: PLA_2R1-Ab levels are associated with disease activity and outcome in pediatric MN. PLA_2R1-associated MN is a common form of pediatric MN, however, in a considerable number of patients the pathogenesis of the disease remains unclear.

The Relationship between Interstitial Fibrosis and Tubular Atrophy Scores and Adverse Renal Outcomes among Patients with Primary Membranous Nephropathy: A Retrospective Study Martin E. Durcan, Mohamed Elsayed, Arvind Ponnusamy. *Royal Preston Hospital, Preston, United Kingdom.*

Background: Primary Membranous Nephropathy (MGN) is a major cause of adult onset nephrotic syndrome. The severity of interstitial fibrosis and tubular atrophy (IF/TA) has long been used in the prognostication of some glomerulopathies and renal allografts, little is known about their effect on MGN outcomes. The aim of this study was to investigate the association of IF/TA with adverse renal outcomes among a cohort of patients with biopsy-proven primary MGN.

Methods: A cohort of all patients diagnosed with biopsy-proven primary MGN between 2004 to 2011 was constructed. Follow up was until November 2016. Data was retrieved retrospectively. Renal biopsies were scored for (IF/TA) as 0 (absent/focal), 1(moderate) and 2(severe). Primary outcome was a composite of the following endpoints; doubling of baseline creatinine, start of renal replacement therapy or death. Achieving remission was a secondary outcome. Univariate and adjusted Cox regression models were used to calculate hazard ratios with 95% CI for each IF/TA group.

Results: 129 incident patients were followed for a median of 5.56 years. 33.3% were females with the remainder being male. Mean age was 56.4 ±16 years. Baseline mean eGRF was 62.9 ± 34.6 ml/min/1.73m^2 and PCR was 769.83 mg/mmol. Patients with IF/TA scores of 0,1 and 2 represented 72.5%, 17.5%and 6.8%, respectively. Unadjusted analysis revealed that patients with IF/TA scores of 1 and 2, in reference to IF/TA=0, were at elevated risk to develop the study primary outcome, HR 2.05 [95% CI, 1.04-4.17] and HR 2.73, [95% CI, 1.03-7.26], respectively. However, when adjusted for potential confounders, higher IF/TA scores were no longer associated with adverse outcomes, HR 1.78 [95% CI, 0.39-8.20] for IF/TA=1 and HR 1.62 [95% CI, 0.09-12.95] for IF/TA=2. Furthermore, those with lower scores didn't have greater likelihood to achieve remission, HR 0.69 [95%CI, 0.31-1.56] for IF/TA=1 and HR 0.34 [95%CI, 0.47-2.52] for IF/TA=2 (reference: IF/TA=0).

Conclusions: The degree of IF/TA on renal biopsy did not predict adverse outcomes among patients with primary membranous nephropathy. Moreover, it was not associated with a higher likelihood to attain remission. We propose that management not be dictated by IF/TA scores. Patients with severe IF/TA should still be considered for treatment.

TH-PO119

Kidney and Patient Survival in Glomerulonephritis: Results from a Mexican Cohort Petra Martínez,[1] Liliana Mondragon,[4] Benjamin Gomez-Navarro,[5] Arisbeth Villanueva-Perez,[6] Alfonso M. Cueto-Manzano,[3] Enrique Rojas-Campos.[2] *[1]Nephrology, Hospital of Specialties, CMNO, IMSS, Guadaljara, Mexico; [2]INSTITUTO MEXICANO DEL SEGURO SOCIAL, GUADALAJARA, Mexico; [3]None, Zapopan, Jalisco, Mexico; [4]IMSS, Guadalajara, Mexico; [5]IMSS, HECMNO, Zapopan, Jalisco, Mexico; [6]Patologia y nefropatologia, Guadalajara, Mexico.*

Background: Background: There is scarce information of glomerulonephritis (GN) survival in our setting. Objective: To evaluate kidney and patient survival in GN.

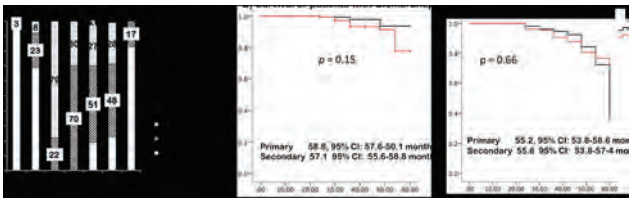
Methods: Methods: Retrospective cohort. From kidney biopsy records, all cases with GN diagnosis, ≥16 yrs, and any gender, were included; transplant biopsies excluded. Data were obtained from medical charts. At the end of follow-up, patient status was registered as alive, dead or lost, and kidney status as functioning or failure. Statistical Analysis: Kaplan Meier and Log-rank analysis used to evaluate mortality, and Cox Hazard Proportional Model to evaluate mortality risk factors.

Results: Results: 328 biopsies were analyzed; age 33±13 yrs, 67% female, follow-up 35±11 months. Comparison between primary vs secondary GN is shown in Table. Figure A, show the most common clinical presentation. Type of GN: Lupus nephritis 41%, Focal segmental glomerulosclerosis 23%, Membranous nephropathy 12%, other 24%. Figure B and C, shows patient and kidney survival; 32 (10%) developed ESRD, and 15 (5%) died at follow-up. In multivariate analysis, final systolic blood pressure (SBP, RR 1.29, 95%CI: 1.00-1.06, p=0.04), and age (RR 1.03, 95%CI: 0.99-1.07, p=0.06) predicted death, whereas baseline SBP (RR 1.45, 95%CI: 0.83-250, p=0.01) and baseline creatinine (RR 3.09, 95%IC: 1.03-9.26, p=0.02) predicted kidney survival.

Conclusions: Conclusions: Primary GN had lower SBP and higher cholesterol, CrCl and proteinuria at baseline than Secondary GN; however these differences disappeared at the end of follow-up. Patient and kidney survival were similar to other series, and were not different between Primary and Secondary GN.

Variable	GN primary		GN Secondary	
	Baseline	Final	Baseline	Final
SBP (mmHg)	122±15	120±16	125±16*	123±15
DBP (mmHg)	77±10	76±10	77±10	77±10
Cholesterol (mg/dL)	230 (180-270)	213 (154-254)£	220 (176-265)*	214 (152-247)£
CrCl (ml/min/1.73m2)	80 (60-107)	82 (55-97)	69 (42-92)	75 (48-94)*
Proteinuria (g/day)	3100 (1100-6500)	573(228-1400)£	1800 (595-3500)*	499 (210-1500)£

*p<0.05 vs same evaluation of primary GN; £p<0.05 vs baseline of the same-group.



TH-PO120

A Single Center Observation Study on Findings in Indication Biopsies and Autopsies after Stem Cell Transplantation Michael Y. Girsberger,[1] Helmut Hopfer,[3] Michael Dickenmann,[2] Thomas Menter.[3] *[1]None, Basel, Switzerland; [2]Universita Hospital, Basel, Switzerland; [3]University Hospital Basel, Basel, Switzerland.*

Background: Haematopoietic stem cell transplantation (HSCT) is a now widely used therapy both in the treatment of haematolymphoid malignancies as well as other malignant or autoimmune diseases. Renal impairment is an important problem after HSCT, yet its pathophysiology still needs more investigation, especially regarding the correlation of clinical findings and morphologic changes.

Methods: We retrospectively analysed indication renal biopsies and autopsies after HSCT of the HSCT patient cohort of the University Hospital of Basel, Switzerland. Data of patients' characteristics were retrospectively collected from the clinical records.

Results: The pathology reports of 17 indication biopsies and 137 autopsies were analysed. In the autopsy cohort, the most common changes were due to acute kidney injury (55/137) most likely as a consequence to the deteriorated state of the patients and thrombotic microangiopathy (14/137). In the indication biopsy cohort the most common changes were therapy related (12/17), with thrombotic microangiopathy (5/17) and Calcineurin-Inhibitor toxicity (4/17) representing the majority within this category.

Conclusions: This study gives a comprehensive overview on potential renal complications in HSCT patients and broadens the spectrum of diseases which have to be expected to occur in this special clinical setting.

Renal Findings

Diagnosis	Indication biopsy cohort (n=17)	Autopsy cohort (n=137)
Acute tubular damage/necrosis	2 (12%)	55 (40%)
Chronic vascular and interstitial changes	2 (12%)	20 (15%)
Thrombotic microangiopathy	5 (29%)	14 (10%)
Tumour infiltrates	1 (6%)	9 (7%)
Cholaemic nephrosis	0	8 (6%)
Presence of fungi or bacteriae in the glomeruli/kidney parenchyma	0	6 (4%)
Infarction	0	5 (4%)
Amyloidosis	0	2 (1%)
Fibrillary glomerulonephritis	0	1 (1%)
Membranous glomerulonephropathy	3 (18%)	1 (1%)
Renal vein thrombosis	0	1 (1%)
Calcineurin-Inhibitor toxicity	4 (24%)	0
IgG4 related interstitial nephritis	1 (6%)	0

TH-PO121

Clinicopathologic Features of Biopsy-Proven Kidney Diseases in Korean Elderly Patients over 65 Years Old Seong Sik Kang,[1,2] Woo Yeong Park,[1,2] Hayeon Park,[1] Sang Mok Yeo,[1] Kyubok Jin,[1,2] Sung Bae Park,[1,2] Seungyeup Han.[1,2] *[1]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: As the life expectancy increases and the aging society comes, the incidence of kidney disease (KD) is increasing in the elderly population. The purpose of this study was to evaluate the clinical and pathological spectrums of KD in the elderly population.

Methods: We retrospectively investigated 101 patients aged over 65 years with biopsy-proven KD. We analyzed the clinicopathologic manifestation, treatment strategy, and clinical course of KD.

Results: The mean age at the time of kidney biopsy was 71 ± 4 years, and 44.6% of patients had hypertension and 10.9% had diabetes. The median serum creatinine was 1.4 mg/dL (interquartile rage 0.9, 2.3). The most common clinical diagnosis was nephrotic syndrome (NS, 55%), followed by asymptomatic urinary abnormality (AUA, 12%). The most common primary glomerular disease was membranous nephropathy (MN, 33%) and, secondary glomerular disease was anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (AGN, 24%). The most common pathologic diagnosis classified based on clinical diagnosis was MN (33%) in NS, IgA nephropathy (IgAN, 33%) in AUA, AGN (67%) in rapidly progressive glomerulonephritis (RPGN), IgAN (88%) in acute nephritic syndrome, and hypertensive nephropathy (25%) in chronic GN. Treatment strategies for KD were angiotensin converting enzyme inhibitor or angiotensin receptor blocker (48%), and immunosuppressants (48%) such as steroid, cyclosporine, mycophenolate mofetil, or cyclophosphamide. The most common disease that was completely responded among NS was minimal change disease (39%). Of the 21 (21%) patients who received dialysis, 11 (52%) received dialysis due to the onset of acute kidney injury (AKI), and received maintenance dialysis without recovery. The most common cause of dialysis was AGN (38%). Death rate was 17%, and the most common cause was infection (53%).

Conclusions: KD in elderly patients showed various patterns in our study. The most common indication for kidney biopsy in elderly patients was NS. NS in elderly patients should be actively performed for kidney biopsy because of the high rate of complete remission when treated. All elderly patients with AKI were dialyzed and progressed to end-stage renal disease without recovery. RPGN in elderly patients should be diagnosed and treated early because the prognosis is poor.

TH-PO122

Primary Nephrologist Procedural Status Impact on Kidney Biopsy Findings Christopher B. McFadden,[2] Krystal Hunter,[2] Manjula J. Naik.[1] *[1]Clinical renal Associates, Phoenixville, PA; [2]Cooper Medical School of Rowan University, Camden, NJ.*

Background: A kidney biopsy is an important diagnostic procedure in the field of Nephrology. It generally yields information regarding multiple components of a patient's kidney problems including the diagnosis, therapeutic options, and prognosis. The decision to perform a kidney biopsy represents a balance of relevant risks and benefits by the provider (typically nephrologist) and patient. Frequently, the decision to perform a biopsy is guided most by the the likelihood the findings will alter patient care.

Methods: We performed a retropsective study of 99 native kidney biopsies perfromed within the last 10 years at our institution. Our primary hypothesis was the status of the primary nephrologist (performs biopsy or does not perform biopsy) had a signficant impact on the kidney biopsy findings as assessed by whether immune based therapy was used in the next 3 months after time of kidney biopsy (yes or no). A chi square test was used to compare the outcome (immune therapy or not) in the two referring nephrology groups. The study was reviewed and approved by the Cooper University Hospital IRB.

Results: A significantly higher rate of immune therapy (65.9 vs 29.3%, p <0.01) was noted in the group whose primary nephrologist performed biopsies (3 nephrologists) compared to the group whose primary nephrologist did not perform biopsies (6 nephrologists). The groups were similar in terms of their age, serum creatinine, and urine protein to creatinine ratio as presented in Table 1. The patient characteristics reported represent data from 30 and 46 subjects, respectively, in the biopsy/ non biopsy groups.

Conclusions: This retropepctive chart review suggests the status of the primary nephrologist (performing biopsy or not performing a biopsy) impacts which patients get a kidney biopsy. These potential biases should be considered as the decision to perform a biopsy is made. This study is limited by its single center design, retrospective nature, and lack of information about patient outcomes.

Nephologist Procedural Status Impacting Bx. Findings

	Nephologist performs Bx	Nephrologist does not perform Bx.
Biopsy Led to Immune Therapy	27/41 (65.9%)	17/58 (29.3%)
Patient Characteristics		
Age (years)	52.2	56.1

Histopathologic Findings and Mortality in Fibrillary Glomerulonephritis Ayman Hallab, Ranjani N. Moorthi, Jwalant R. Modi, Carrie L. Phillips, Pierre C. Dagher, Michael T. Eadon. *Indiana University, Indianapolis, IN.*

Background: Fibrillary glomerulonephritis (GN) is a rare glomerular disease with a paucity of literature. We present a retrospective collection of our single-center fibrillary GN experience.

Methods: We reviewed 7,579 kidney biopsies performed at our institution between 2001 and 2015 and identified 51 cases of fibrillary GN. Histopathologic features and clinical variables were recorded from the medical record by a nephrologist. Data is presented as mean (SD). Chi-squared test assessed correlation between histologic and categorical clinical variables.

Results: Fibrillary GN constituted 0.7% of kidney biopsies. Average age at diagnosis was 59.9 (8.8) years. Female to male ratio was 1.4:1 with 77% Caucasian patients. On light microscopy, mesangial proliferative/sclerosing GN was present in 62% of cases. Membranous (MGN), membranoproliferative GN (MPGN), and endocapillary proliferative GN accounted for 10%, 20%, and 8% of cases respectively. Mesangial changes were present in 92% of cases. Crescents were present in 7 cases (14%). Interstitial fibrosis and tubular atrophy IFTA was mild, moderate, and severe in 30%, 45%, and 21% respectively. The mean glomerular obsolescence was 30%. Immunofluorescence revealed universal staining for IgG and C3. IgM, IgA, C1q were positive in 56%, 12%, and 16% respectively. No Kappa or Lambda restriction was present. The average positivity (0-4) scale for IgG, IgM, IgA, C3, C1q was 2.6, 0.9, 0.1, 2.7, and 0.2 respectively. The pattern was granular in 38% and smudged in 62%. Electron dense deposits were seen in 7 of 51 cases (14%), mostly subepithelial. Podocyte effacement, seen in 100% of the cases, ranging from patchy to widespread. The average fibril diameter was 15.5 ± 3.4 nm [9 – 28]. Fibrils were deposited in both mesangium and GBM in 82% of the cases, and in either for the rest. Mortality was 15.7% (8 of 51). No histopathological features were associated with mortality.

Conclusions: Our fibrillary GN analysis confirms the results of prior cohorts. Histopathological features alone are insufficient to predict mortality. As this disease is infrequently reported, these cases will prove vital to pool with other cohorts in order to correlate pathologic features with outcomes.

TH-PO124

Predictive Factors of Renal Involvement in Cryoglobulinemia: A Retrospective Study of 153 Patients Vladimir Coliche, Jean-Christophe Lega, Maurice Laville, Clemence THERY-CASARI, Pierre Trolliet, Mathilde Nouvier, Basse Grégoire, Marie N. Sarda, Denis Fouque. *Hospices Civils de Lyon, Lyon 1 University, Lyon, France.*

Background: The course of cryoglobulinemia varies widely, from asymptomatic patients to severe vasculitis. Renal involvement (RI) is a major prognostic factor, and frequently occurs several years after diagnosis. Twenty to 56% of patients will develop RI. Predictive factors of RI have not been studied. The aim of our study was to identify factors associated with RI occurence in patients with cryoglobulinemia.

Methods: We retrospectively reviewed the clinical charts of a consecutive series of 153 patients positive for cryoglobulinemia (from January 2012 to December 2014) in the University Hospital of Lyon (France). Immunoglobulin (Ig) G, IgM and IgA concentrations as well as rheumatoid factor (RF) activity were assessed in cryoprecipitate. Complement fractions C3 and C4, CH50 activity and RF were simultaneously assayed in sera. RI was defined either histologically, or biologically if cryoglobulinemia was the only possible cause of nephropathy (proteinuria > 0.5 g/24h or hematuria > 10/mm3 or eGFR < 60 ml/min/1.73m^2 CKD-EPI).

Results: Among the 153 positive measures (mean age 55 years, male gender 37%), cryoglobulinemia was associated with RI in 45 pts (29.4%). The presence of IgA in cryoprecipitate was very significantly associated with RI (22% in RI group vs 1% in control group, p<0.0001) contrary to IgG or IgM. Type 3 cryoglobulinemia was more frequent in controls than in RI group (35% vs 11%, p=0.006). Regarding etiology, only B-cell lymphoma was statistically associated with RI (22% vs 9%, p=0.03), there was no difference for hepatitis C virus. RF activity was more frequent (42% vs 24%, p=0.03) and cryoglobulin total Ig concentration was higher (137 mg/l vs 39 mg/l, p=0.001) in case of RI, whereas C3 and C4 were similar. There were more men in RI group (60% vs 27%, p<0.0001), and slightly more patients had cutaneous purpura (38% vs 22%, p=0.048).

Conclusions: Several factors may be associated with the occurrence of RI in cryoglobulinemia (IgA, B-cell lymphoma, purpura), whereas type 3 cryoglobulinemia appears to be protective. In these at risk patients, kidney function monitoring and nephroprotection might be intensified. Further studies are needed to confirm these findings and understand mechanisms of theses associations with RI.

TH-PO125

Prevalence of Occult Hepatitis C Infection in Patients with Glomerulopathies and Chronic Renal Disease: A Pilot Study Luis H. Sette,[1] Savio Augusto vieira de oliveira,[3] Nathalia C. dos Anjos,[2] Norma Lucena-Silva,[3] Edmundo P. Lopes.[1] *[1]UNIVERSIDADE FEDERAL DE PERNAMBUCO, Recife, Brazil; [2]Nephrology, University Federal of Pernambuco, RECIFE, Brazil; [3]Instituto Aggeu Magalhães, Laboratório de Imunogenética, RECIFE, Brazil.*

Background: The Occult Hepatitis C Infection (OHCI) is characterized by the presence of the genetic viral material on polymorphonuclear cells (PMNC), plasma ultracentrifugation or hepatic tissue in the absence of antibodies in the serum. It has been demonstrated a high prevalence of OHCI in patients with glomerulopathies (GP), suggesting a pathophysiological association between the virus and GP. It is also known that there is a higher prevalence of chronic HCV infection in patients with dialytic chronic kidney disease (CKD) and that IOHC can be acquired before renal replacement therapy initiation. Therefore, this study aimed to evaluate the prevalence of OHCI in patients with GP and with CKD.

Methods: Patients were evaluated from April to August 2016. Patients younger than 18 years of age, pregnant, infected with HBV, HCV and HIV and less than 3 months of follow-up were excluded. PCR for hepatits C RNA were investigated in serum, plasma ultracentrifuged and PMNC.

Results: We evaluated 126 of which 56 were excluded. Of the 64 remaining patients, 32 were GP patients. Demographic and clinical data are shown in Table 1. When analyzing patients for OHCI, a prevalence of 18.2% was observed in patients with GP. Among the patients with CKD, the prevalence was 6.25%. Although there is almost 3-fold prevalence among cases of OHCI in patients with GP it was not statistically significant (p=0.35), probably due to the small number of patients enroled.

Conclusions: The existence of OHCI was observed in patients with GP and in pre-dialytic CKD. The prevalence in patients with GP was about three times higher than that observed in patients with CKD.

Baseline characteristics

	GP (n=32)	CKD (n=32)	p
Gender, female (%)	62.5	43.7	
AGE (SD)	38.7 ± 13.6	60.9 ± 15.2	
BMI (Kg/m2), ± SD	25.5 ± 5.8	27.2 ± 4.4	p<0.001
Acumputure (n,%)	2 (6.2)	0	
Tatoo (n,%)	5 (15.6)	1 (3.1)	p=0.19
Hemotransfusion, n (%)	12 (37.5)	9 (28.2)	p=0.18
Sexual transmited disease(n,%)	6 (18.7)	11 (34.4)	p=0.004
Piercing n,%	6 (18.7)	0	
Previous Dialysis (n, %)	3 (9.3)	2 (6.2)	p=0.28
eGFR (mL/min/1.73m2) ± SD (CKD-EPI)	78.1 ± 33.5	23.5 ± 11.8	p<0.001
OHCI n (%)	6 (18.2)	2 (6.2)	p=0.34

The Characteristics of Membranoproliferative Glomerulonephritis (MPGN) at a Single Center in Japan Marie Nakano, Kazunori Karasawa, Saeko Kumon, Takahiro Kamiyama, Takahito Moriyama, Kosaku Nitta. *Tokyo Women's Medical University Hospital, Tokyo, Japan.*

Background: MPGN has been recently proposed new classification, and alternative pathway (AP) mediated MPGN (C3 glomerulopathy), which was defined as isolated C3 deposition and absent of immunoglobulin deposition, has been recognized as a different glomerulonephritis from Immune complex (IC) mediated MPGN. However, there was no report analyzed about the difference of these two nephritis in Japan.

Methods: We reclassified 87 MPGN patients diagnosed between 1977 and 2014 in our institution according to the new classification. The clinical, pathological features and outcomes of patients between IC mediated MPGN and AP mediated MPGN were analyzed.

Results: Among 55 MPGN patients except 32 secondary MPGN, there were 42 IC mediated MPGN patients and 13 AP mediated. In the baseline clinical findings, the estimated glomerular filtration rate were similar between both groups (89.69 vs. 76.19, p=0.2581). The amount of proteinuria (2.34 vs. 5.20 d/day, p=0.0063), C3 (39.0 vs. 67.25, p=0.0317), and CH50 (22.4 vs. 36.4, p=0.0404) were significantly lower, and serum albumin was significantly higher (3.40 vs. 2.70, p=0.0186) in AP mediated MPGN than IC mediated MPGN. In the pathological findings, there were no significance in light microscopical findings, but all immunofluorescence staining except C3 were significantly higher in IC mediated MPGN. Immunosuppression therapy was used in 92.3% patients in AP mediated MPGN, and 90.5% in IC mediated. The 400 months renal survival rate were similar between both groups (70.0 vs. 74.0%, P=0.445).

Conclusions: We have shown that AP mediated MPGN had similar prognosis in comparison to IC mediated MPGN, though proteinuria at baseline was lower than IC mediated MPGN. Lower serum complements were resulted from higher alternative pathway activation, and this phenomenon might induce the poor prognosis in AP mediated MPGN, though their lower proteinuria.

Glomerulopathies Secondary to Schistosomiasis: Histological Forms and Follow-Up Cristiane B. Dias,[4] Lectícia Jorge,[5] Leonardo A. Testagrossa,[5] Denise M. Malheiros,[3] Viktoria Woronik,[1] Precil D. Neves,[2] Ramaiane A. Bridi.[5] *[1]None, Salvador, Brazil; [2]University of S?o Paulo, S?o Paulo, Brazil; [3]University of Sao Paulo, Sao Paulo, Brazil; [4]University of Sao Paulo, Brazil, São Paulo, Brazil; [5]University of São Paulo, São Paulo, Brazil.*

Background: Schistosomiasis mansoni (MS) is a parasitosis caused by Schistosoma mansoni that is endemic in several Brazilian states. Gastrointestinal involvement is the most frequent, but the kidney can also be injured, especially in the form of glomerulopathies. The aim of this study is to show the MS-related glomerulopathies and evaluation of the long-term follow-up

Methods: Evaluation of clinical data and renal biopsies of patients diagnosed with MS-related glomerulopathies in the period 1992-2017, in addition to clinical-evolutionary follow-up.

Results: Twenty eight patients, predominantly male (78.5%), white (64.2%), median age 38 (33; 44), all cases from the endemic area, most of them from Bahia (32,2%). The most common form of MS diagnosis was through fecal examination (94%), and 60.7% presented the hepatosplenic form of the disease. The most common clinical presentation was mixed syndrome (64.3%), with Cr: 1.51 ± 0.77mg / dL, MDRD: 69.3 ± 39ml / min / 1.73m2, 24h proteinuria: 6.56 ± 3.5g, serum albumin: 2.35 ± 0.91g / dL, low serum complement in 42.8% of patients. The distribution of the histological diagnoses to renal biopsy was: membranoproliferative glomerulonephritis (MPGN) 60.7%; focal segmental glomerulosclerosis (FSGS) 21.4%; membranous nephropathy 10.7% and proliferative mesangial 7.2%. The patients' follow-up time was 70 (14-124) months, after which 32.1% of the patients had started dialysis. Comparing the patients with MPGN vs non-MPGN, they differed in proteinuria of 24h (g) (5.19 vs 8.67, p = 0.04) and serum albumin (g / dL) (2.6 vs 1.0, P = 0.04), frequency of hypertension (%) (70.5 vs 9.0, p = 0.002) and hematuria (%) (94.1 vs 45.4, p = 0.007). Comparing patients that evolved and did not evolve to dialysis, they differed in the initial creatinine (1.99 vs 1.28, p = 0.05), MDRD (55/78, P = 0.03), renal response to anti-parasitic use (%) (0 vs 77, p = 0.0007) and follow-up time (months) (45.7 vs 9.7, p = 0, 03).

Conclusions: The glomerulopathies secondary to MS are still a reality in Brazilian daily life. Histological presentation as GNMP did not determine a worse prognosis for the patients in this series, but rather the severity of the initial clinical presentation and non-response to the use of antiparasitics.

An Automated Immunoassay for High-Throughput Measurement of Symmetric Dimethylarginine (SDMA) in Human Serum Joe M. El-Khoury,[2] Parker C. Wilson,[2] Shay Toohey,[2] Chirag R. Parikh,[3] Daniel Patch,[1] Maha Yerramilli,[1] Giosi Farace,[1] Murthy V. Yerramilli.[1] *[1]IDEXX Laboratories, Westbrook, ME; [2]Yale University, New Haven, CT; [3]Yale University and VAMC, New Haven, CT.*

Background: Symmetric dimethylarginine (SDMA) is a byproduct of protein methylation and degradation that is primarily eliminated by the kidneys. It is freely filtered at the glomerulus, with no active secretion or reabsorption by the renal tubules. As a result, SDMA plasma concentrations are affected by changes in GFR and it is emerging as a kidney function biomarker that has outperformed serum creatinine in several studies. SDMA has traditionally been measured using liquid chromatography tandem mass spectrometry (LC-MS/MS), which is a major limitation for its widespread application as a screening marker for kidney function. The objective of this study is to validate a high throughput automated immunoassay for measuring SDMA in human serum.

Methods: Left-over serum samples were used for this study. SDMA was measured using novel immunoassay reagents manufactured by IDEXX Laboratories (Westbrook, ME) loaded on a Roche c501 analyzer (Indianapolis, IN). The assay was evaluated to establish its analytical measurement range (AMR), imprecision, specificity and accuracy. Method comparison with a separate LC-MS/MS was performed using serum collected from 50 adults with varied kidney function.

Results: The analytical measurement range of the SDMA immunoassay was 4.2 to 100.5 µg/ml. Total coefficient of variation (CV) was less than 13.1% at the three different concentrations tested. Hemolysis did not affect assay performance up to a hemolysis index of 186 and common drugs tested did not interfere. Deming regression analysis of the method comparison with the LC–MS/MS revealed a slope of 1.001, intercept of 1.4, and correlation coefficient of 0.99

Conclusions: A novel immunoassay for measuring SDMA with comparable performance to LC-MS/MS is now validated for use in humans and better suited for high-throughput clinical laboratory testing. This assay will facilitate further research and widespread clinical adoption of this emerging biomarker.

Factors Influencing Initial Treatment Options for Idiopathic Membranous Nephropathy Huaiya Xie,[1] Xin Zhang,[3] Zhen Wu,[2] Yubing Wen,[1] Jianfang Cai,[1] Hang Li,[4] Xuemei Li,[5] Xuewang Li.[1] *[1]Peking Union Medical College Hospital, Beijing, China; [2]Beijing Frendship Hospital, Capital Medical University, Beijing, China; [3]Peking University First Hospital, Beijing, China; [4]Peking Union Medical college hosiptal, Beijing, China; [5]Peking Union Medical College Hospital, Chinese Academy of Medicine Sciences & Peking Union Medical College, Beijing, China.*

Background: This study aimed to analyze factors which may influence the initial therapy option for idiopathic membranous nephropathy (IMN) diagnosed in a tertiary center of China.

Methods: In this retrospective study, we consecutively enrolled 875 IMN patients diagnosed in a single tertiary center between 2004 to 2015. Data on age, sex, body mass index, presence of hypertension and diabetes mellitus, and laboratory tests at renal biopsy and treatment options after diagnosis of IMN were retrospectively retrieved from medical records. We retrospectively classified the initial therapy as glucocorticoids plus cyclophosphamide, calcineurin inhibitors alone or plus corticosteroids, corticosteroids alone or plus other immunosuppressives, and supportive treatment. Multinomial multiple logistic regression was employed to analyze the factors influencing the selection of a therapeutic regimen.

Results: The presence of diabetes(OR=5.06, 95% CI 2.90-8.84, P<0.001) and age <50 years was associated with selection of calcineurin inhibitors(OR=1.48, 95% CI 1.00-2.17, P=0.048), whereas a 24 hour urine total protein(24h-UP)<8g and a serum albumin> 25g/L were associated with selection of supportive treatment (OR=15.2, 95% CI 3.53-65.1, P<0.001 and OR=21.3, 95% CI 5.09-89.5, respectively) and corticosteroids alone or plus other immunosuppressives(OR=4.93, 95% CI 2.52-9.64, P<0.001 and OR=1.69, 95% CI 1.05-2.74, respectively) as opposed to selection of cyclophosphamide. When we restricted the analyses in non-diabetes patients, age <50 years was also associated with selection of calcineurin inhibitors as compared with selection of cyclophosphamide(OR=1.69, 95% CI 1.12-2.54, P=0.012).

Conclusions: Serum albumin level, amount of 24h-UP, presence of diabetes, and age may influence a physician's decision on initial treatment options for IMN.

TH-PO130

Clinical Advantage of Concomitant Use of Low Dose Mizoribine and Prednisolone on Primary Membranous Nephropathy in the Elderly Hajime Hasegawa,[1,2] Tetsuya Mitarai,[1,2] Yasuhiko Tomino,[1] Hitoshi Yokoyama,[1] Kunihiro Yamagata,[1] Masayuki Iwano,[1] Shin'ichi Akiyama,[1] Kaori Takayanagi.[1,2] *[1]Study group for nephrotic syndrome in the elderly, Kawagoe, Japan; [2]Nephrol and Hypertens, Blood Purification Center, Saitama Med Center, Saitama Med Univ, Kawagoe, Japan.*

Background: Initial therapeutic strategy of membranous nephropathy (MN) in Japan is sole administration of Prednisolone (PSL) of 1 mg/kg for 4 weeks, and then addition of immunosuppressant such as Cyclosporin. However, long-term administration of high dose PSL and immunosupressant in elder patients is controversial because of their multiple adverse effects. Here, we show the clinical efficacy of concomitant use of lower dose of Mizoribine (MZB) and PSL in terms of earlier induction to the remission by multicentered prospective cohort study.

Methods: Thirty-six patients diagnosed primary MN showing nephrotic syndrome were enrolled from 24 independent facilities. The patients, being older than 65 of age and preliminary obtained none of therapy, were randomly assigned to two groups, solely administered 30 mg of PSL (P group, n=18), or concomitantly administered 150 mg of MZB (MP group, n=18) and observed for 12 months. Remission rate was evaluated by remission score (RS) as follows: 1: Urine protein-to-Cr ratio (PCR)≥3.5, 2: 3.5>PCR≥1.0, 3: 1.0>PCR≥0.3 and 4: PCR<0.3 g/gCr. In some cases, anti-phospholipase A2 receptor antibody (PLA2R-Ab) titer was qualitatively measured.

Results: Mean ages of MP and P groups were 73.3 and 72.8. PCR at 12M was not different in the two groups. However, %PCR vs baseline and RS at earlier phase of MP were better than P (%PCR: 3M 50.0±47.0% vs 55.6±57.0%, 6M 31.4±27.2% vs 39.9±33.1%, RS: 3M 1.24±1.20 vs 1.00±0.93, 6M 1.69±1.03 vs 1.07±1.00). Those results were confirmed by the logistic analysis showed estimated odds ratio of the high responder in MP group was 1.50 (95%CI=0.33-6.83), suggesting that the concomitant use of MZB might accelerate the remission. Additionally, in cases showing qualitatively negative PLA2R antibody, the odds ratio of high responder cases was 2.67 (95% CI: 0.28-25.64) in MP vs 1.00 in P whereas the odds ratio was 0.33 (MP) and 0.40 (P) in cases showing positive PLA2R-Ab, suggesting that concomitant use of MZB might be more effective in PLA2R-Ab negative cases.

Conclusions: Concomitant use of low dose of MZB and PSL might contribute to save time until remission in elder patients with MN-based NS.

TH-PO131

Long Term Outcome of Apparent Treatment Resistant Patients with Idiopathic Membranous Nephropathy Coralien Vink- van Setten, Anne-Els van de Logt, Jack F. Wetzels. *Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Cyclophosphamide is effective in idiopathic membranous nephropathy (iMN). Still, some patients do not respond timely, and do not develop remission at the end of therapy. We evaluated the outcome of these "apparent treatment resistant" (ATR) patients.

Methods: We selected patients with iMN, treated with cyclophosphamide (6-12 months), persistent proteinuria (PCR > 3g/10 mmol) at 12 months after start of therapy, and a minimum follow-up of 24 months. Renal failure was defined as > 50% increase in serum creatinine concentration. Remission was defined as PCR of less than 3.0g/10mmol and stable renal function.

Results: Between 1995 and 2016, we evaluated 518 patients with iMN. 219 high risk MN patients were treated with cyclophosphamide. 110 with outcome data were followed for at least 24 months. At 12 months 84 (76.4%) patients achieved partial remission, one (0.9%) patient developed renal failure and 25 (22.7%) patients fulfilled ATR criteria. Of these 25 patients, 20 were males, mean age was 55 (± 12) years, median serum creatinine was 149 umol/L (108.5-195), median PCR 11g/10mmol (6.7-15.3). During follow-up (median 80 months (34.5-126), 16 patients developed partial or complete remission without additional therapy. A relapse has occurred in 4 patients, necessitating a second course of immunosuppressive therapy. Nine patients had persistent proteinuria. Five of these were treated with a second course of immunosuppressive therapy, which resulted in a remission of proteinuria in 4. Two patients with persistent proteinuria and no additional immunosuppressive therapy have developed renal failure after 60 and 237 months respectively.

Conclusions: Persistent proteinuria at 12 months after start of cyclophosphamide therapy is not evidence of treatment resistance. Most patients will develop remission of proteinuria. Patients with persistent proteinuria respond favourably to a second course of therapy. Risk of end stage renal is low.

TH-PO132

Role of Rituximab in Primary Membranous Nephropathy Refractory to Modified Ponticelli/Calcineurin Based Treatment Jasmine Sethi, Harbir S. Kohli, Raja Ramachandran. *Post Graduate Institute of Medical Education and Research (PGIMER), CHANDIGARH, India.*

Background: Rituximab is emerging as a promising therapeutic agent particularly in the management of refractory primary membranous nephropathy. What should be dosage schedule to avoid toxicity without compromising the efficacy is a matter of concern and data to this regard is limited. This is a single center prospective study to evaluate the role of B cell titrated protocol of rituximab in adults with PMN who failed treatment with conventional immunosuppressive agents and its possible association with $aPLA_2R$ antibodies.

Methods: 14 patients aged 14-65 years of refractory PMN were given intravenous rituximab at a dose of 375mg/m^2 in a tertiary center in northern India. Following rituximab injection, CD19 counts were monitored weekly for 4 weeks followed by monthly for 6 months. If CD19 count was >5/μL (or >1%), repeat doses of rituximab were given. The change in laboratory parameters (24 urinary protein, serum albumin and serum creatinine) were recorded at the baseline, and monthly till 6 months after rituximab administration. Serum sample drawn just before rituximab infusion and at the end of 6th month post-infusion were tested for $aPLA_2R$ by ELISA

Results: At the end of 6 months, 6 out of 14 patients (42.8%) responded, with 1/14 (7.1%) achieving CR and 5/14 (35.7%) achieving PR. Eight out of 14 (57.1%) patients showed no response to rituximab at the end of the 6 months. Mean proteinuria decreased from 4.6 ±1.7 g/day at baseline to 3.3 ±2.1 g/day at 3 months, and 3.2 ±2.3 g/day at 6 months (p=0.29). Mean serum albumin also increased from 2.4 ±0.6 g/dl at baseline to 2.8 ±0.6 g/dl at 3 months, and 3.2 ±0.6 g/dl at 6 months. (p=0.002). Average time to CD19 reconstitution was 3.1± 0.8 (2-4) months. Rituximab dose administered during 6 month period was 1289±720 (600-2800) mg. $aPLA_2R$ antibody testing was done in 13 patients. Among these, all 13 patients presented with high levels of antibodies before the treatment, eight of them experienced a reduction of aPLA2R antibody titer, while 5 patients experienced no change after treatment (all five patients continued to have resistant disease).

Conclusions: CD19 titrated rituximab therapy is effective in achieving remission in 42.85% of patients of PMN refractory to prior immunosuppression. Titrated therapy might enhance the safety without compromising the efficacy of the therapy.

Improvement of Clinical Outcomes in Kidney Diseases via the On-line Thai Glomerular Disease Registry: Membranous Nephropathy Pantipa Tonsawan,[5] Sakkarn Sangkhamanon,[4] Boonyarit Cheunsuchon,[3] Warangkana Pichaiwong,[2] Mongkon Charoenpitakchai,[6] Bancha Satirapoj.[1] *[1]Medicine, Phramongkutklao hospital, Bangkok, Thailand; [2]Medicine, RAJAVITHI HOSPITAL, Bangkok, Thailand; [3]Pathology, Siriraj hospital, Bangkok, Thailand; [4]Pathology, Khon Kaen University, Khon Kaen, Thailand; [5]Division of Nephrology, Department of Medicine, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand; [6]Pathology, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand. Group/Team: Thai Glomerular Disease Collaborative Network (TGCN).*

Background: The primary membranous nephropathy (MN) is the common cause of adult onset nephrotic syndrome. The Thai glomerular disease registry was established by Thai Glomerular Disease Collaborative Network (TGCN) to evaluate the prevalence, clinical features and outcomes in Thai glomerular disease patients. This study focused especially on MN.

Methods: We conducted a prospective cohort study in the adults with native kidney biopsy proven glomerular diseases between July 2014 and Mar 2017 from TGCN registry. The clinical features and laboratory parameters at the time of biopsy, pathologic findings, treatment regimens and clinical outcomes were monitored.

Results: MN was presented 111 (7.1%) of total 1,556 patients and 111 (15.5%) of total 742 patients with primary glomerular diseases. Mean age was 52.6±15 years. The clinical features of MN were identified; 86 % nephrotic syndrome, 46 % hypertension, 5.4 % acute kidney injury and 4.5% asymptomatic proteinuria. At the time of renal biopsy, median serum creatinine was 0.98 mg/dL (0.42-7.4), median urine protein creatinine ratio was 3.5 g/g. Cr (0.14-21.9), mean serum albumin was 2.5±0.7 g/dL, and median interstitial fibrosis was 5% (5-90). Median time to remission was 5.6 months. At 24 weeks of follow up, complete remission and partial remission were observed in 20.7% and 59%, respectively. The predicting factors for clinical remission were identified as young patients, low serum creatinine, high hemoglobin, and high serum albumin at time of kidney biopsy. After the multivariate analysis, high serum albumin and low serum creatinine were the independent factors for clinical remission. Doubling of serum creatinine was observed in only 1.6 % during this period.

Conclusions: This study suggested that the clinical course and outcomes of Thai MN were favorable with low incidence of end stage renal disease. Baseline serum albumin and renal function were significantly predict the renal remission. *Funding: Health Systems Research Institute, and Nephrology Society of Thailand support*

The Investigative Burden of Membranous Nephropathy in the UK Fiona Wilson,[2] Patrick Hamilton,[3] Rajkumar Chinnadurai,[4] Malinder Singh,[6] Smeeta Sinha,[5] Durga A. Kanigicherla,[1] Paul E. Brenchley.[2] *[1]Central Manchester University Hospitals, Manchester, United Kingdom; [2]Manchester Royal Infirmary, Manchester, United Kingdom; [3]NHS, Manchester, United Kingdom; [4]SALFORD ROYAL NHS FOUNDATION TRUST, Manchester, United Kingdom; [5]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [6]LTHTR, Preston, United Kingdom.*

Background: Membranous Nephropathy (MN) represents two distinct disease entities. Primary MN (PMN) is now recognized as an autoimmune condition associated with the anti-PLA_2R antibody and secondary MN occurs in tandem with malignancy, infection or drug therapy. Prior to the discovery of anti-PLA_2R antibody in 2009 and the development of accessible ELISAs, the diagnosis of MN was a diagnosis of exclusion. We investigated the investigative burden for patients with MN and the diagnostic yield of these tests

Methods: Patients from 2 UK centres with a diagnosis of MN between 2009 and 2014 were identified. Across the Northwest of England, anti-PLA_2R testing became readily available in 2012. Therefore patients were divided into those receiving a diagnosis 2009-2011 (pre-ELISA) and 2012-2014 (post-ELISA). Records were reviewed for the investigations which took place 6 months prior and 6 months following the biopsy date to see if these were normal or identified a secondary cause of MN. Investigations included viral and autoimmune screens, X-rays, CT, MRI, PET scan, ultrasound, upper and lower GI endoscopies and cystoscopies. Hypothesis The introduction of anti-PLA_2R testing leads to a modification of the investigative pathway for MN patients.

Results: 121 patients were identified, 104 with PMN and 17 with secondary MN. Patients went through an average of 7.38 tests with only 18 of 893 (2.0%) tests proving to be instrumental in helping with the diagnosis of secondary versus primary MN. For patients diagnosed with PMN they had an average of 7.48 tests, all of which were negative. With the introduction of anti-PLA_2R testing in 2012 there appears to be a trend towards a reduction in the investigative profile of patients with the average number of tests falling from 7.73 to 7.29. A significant reduction was noted in Hepatitis B and C (p=0.029 for both) and colonoscopies (p=0.012). There was also a reduction in the total cost of investigation per patient with PMN from an average of £553.41 in 2009-2011 to £366.02 in 2012-2014.

Conclusions: Patients with a diagnosis of MN undergo multiple investigations, many of which are negative, at a significant cost to both the healthcare system and patients quality of life. The anti-PLA_2R test has the potential to reduce this burden as its use becomes more widespread.

TH-PO135

Association of Presence of Diabetes with Failure to Complete Remission of Idiopathic Membranous Nephropathy Huaiya Xie,[1] Zhen Wu,[2] Xin Zhang,[3] Yubing Wen,[1] Jianfang Cai,[1] Hang Li,[1] Xuemei Li,[1] Xuewang Li.[1] *[1]Peking Union Medical College Hospital, Beijing, China; [2]Beijing Friendship Hospital, Capital Medical University, Beijing, China; [3]Peking University First Hospital, Beijing, China.*

Background: This study aimed to assess whether the presence of diabetes will influence renal outcomes in patients with idiopathic membranous nephropathy (IMN).

Methods: In this retrospective study, a total of 875 patients with pathology-proved IMN were consecutively enrolled. Among them, 101 were diagnosed as type 2 diabetes mellitus (T2DM) prior to their diagnosis of IMN. Data on age, sex, body mass index (BMI), presence of hypertension and diabetes mellitus, laboratory tests, and therapeutic regimens were retrospectively retrieved from medical record. Complete remission (CR) was defined as urinary protein excretion<0.3g/d with stable estimated glomerular filtration (eGFR). COX regression was used to analyze risks of failure to CR and renal function deterioration associated with the presence of T2DM.

Results: A total of 810 patients were followed at least once with a median follow-up of 23.6 (IQR 9.9-42) months, of whom 292 achieved CR and 95 developed a 30% decline in eGFR. Presence of T2DM was associated with failure to reach CR of IMN (*HR*=0.53, 95% *CI* 0.37-0.77, *P* =0.001), independently of age, sex, hypertension, therapeutic regimen, serum albumin, proteinuria, and baseline eGFR. The association remained statistically significant when we further excluded 103 patients with corticosteroid-induced diabetes(*HR*=0.49, 95% *CI* 0.34-0.71,*P* <0.001), or restricted the analyses in patients with nephrotic syndrome(*HR*=0.46,95% *CI* 0.28-0.67,*P* =0.002) or in those using calcineurin inhibitors(*HR*=0.58,95% *CI* 0.37-0.91, *P* =0.017). However, patients with and without T2DM did not differ in developing a 30% decline in eGFR, adjusting for age, sex, BMI, state of smoking, hypertension, therapeutic regimen, serum albumin, proteinuria, and baseline eGFR(*HR*=0.67,95% *CI* 0.39-1.16,*P* =0.156).

Conclusions: Presence of T2DM may be independently associated with failure to remission but not eGFR decline in IMN patients.

TH-PO136

Treatment of Membranous Glomerulopathy with Ponticelli's Modified Scheme and with Cyclosporine Are Comparable after 1 Year of Follow-Up: Retrospective Cohort

Nathalia C. dos Anjos,[6] Luis H. Sette,[5] Camila B. Oliveira,[2] Denise M. Costa,[1] Gisele Vajgel,[4] Maria Alina G. Cavalcante,[3] Lucila Maria Valente.[4] *[1]HOSPITAL DAS CLINICAS, RECIFE, Brazil; [2]HOSPITAL DAS CLINICAS-UFPE, RECIFE, Brazil; [3]Hospital das Clinicas - UFPE, Recife(PE) BRAZIL, Brazil; [4]None, Recife, Brazil; [5]UNIVERSIDADE FEDERAL DE PERNAMBUCO, Recife, Brazil; [6]NEPHROLOGY, University Federal of Pernambuco, RECIFE, Brazil.*

Background: The standard treatment recommended by KDIGO in patients with membranous glomerulopathy (MN) is performed with corticosteroids and cyclophosphamide (modified Ponticelli's scheme). However, there are few studies in the Latin American population about the comparative efficacy of an alternative regimen using oral cyclosporine (CSA). The hypothesis is CSA presents therapeutic equivalence and lower side effects when compared to Ponticelli's scheme. Therefore, this study sought to evaluate the response of these two therapeutic regimens in patients with MN.

Methods: a retrospective cohort was conducted from 1998 to 2016. Data from patients older than 18 years with idiopathic MN for at least 6 months without previous treatment, were analyzed. In addition to the clinical and epidemiological profile, the response to the treatment was evaluated (CyA and Ponticelli), in a period of 6 months and 1 year after initiation of therapy. Definitions of partial response, complete response, relapse, and therapeutic failure were based on KDIGO.

Results: Thirty patients were evaluated 16 were treated with CSA and 14 with Ponticelli's scheme. The baseline characteristics of the two groups treated with IMS are described in **Table 1**. After 6 and 12 months the partial and complete response rate was 50% and 69% in the cyclosporine group and 57% and 50% in the Ponticelli's group. There was no difference between response rates (complete response and parcial response) between groups after 6 months (p = 0.69); 12 months (p = 0.64).

Conclusions: the therapeutic regimens of immunosuppression evaluated showed similar response rates after the 6-month and 12-month follow-up.

	Cyclosporine (n=16)	Ponticelli (n=14)	p
Age (mean ± SD)	40 ± 14.8	39 ± 16.2	p=0.32

TH-PO137

HLA-DR3 Impact on Graft Survival in Membranous Nephropathy: A Tricontinental Registry Study

Patrick Hamilton,[4] Kay V. Poulton,[3] Lisa L. Mumford,[5] Laura H. Mariani,[6] Nathan P. Goodrich,[2] Robert Merion,[2] Stephen P. McDonald,[1] Paul E. Brenchley.[3] *[1]ANZDATA Registry, Adelaide, SA, Australia; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Manchester Royal Infirmary, Manchester, United Kingdom; [4]NHS, Manchester, United Kingdom; [5]NHS Blood and Transplant, Bristol, United Kingdom; [6]University of Michigan, Ann Arbor, MI.*

Background: Membranous nephropathy (MN) is a rare disease in which a third of patients will need a kidney transplant. The strong genetic predisposition to MN was initially associated with HLA-DR3, and more recently HLA-DQA. It is unknown whether a relation to graft survival is based on presence in the recipient, donor or both.

Methods: We investigated HLA-DR3 mismatching effects on graft survival using data on adult renal transplant recipients with MN from US, UK and Australasian renal transplant registries. Univariate and multivariable Cox proportional hazard regression (donor age, donor type, registry, recipient ethnicity and transplant year) analyses were fitted to compare overall and death-censored graft survival (GS & DCGS respectively) in the 9 combinations of HLA-DR3 mismatch. Analysis was repeated by grouping HLA-DR3 with other HLA-DR antigens to examine any combined effect that may implicate antigen presentation by HLA-DQ.

Results: There were 6660 MN patients. Using HLA-DR3 homozygous recipient/donor pairs as the reference group, multivariate analysis showed two combinations associated with significantly lower overall and death-censored graft survival: HLA-DR3 homozygous recipients with an HLA-DR3 negative donor (GS - HR 1.92, 95%CI 1.04-3.56, p=0.037 & DCGS - HR 2.18, 95%CI 1.13-4.21, p=0.020), and HLA-DR3 negative recipients with a donor homozygous for HLA-DR3 (GS - HR 2.83, 95%CI 1.01-7.95, p=0.049 & DCGS - HR 3.36, 95%CI 1.16-9.7, p=0.025). In combination with HLA-DR1, HLA-DR6, or HLA-DR7, the same two groups became more significant, with HLA-DR1 appearing to provide the greatest impact. HLA-DR3 +/- DR1 homozygous recipients with an HLA-DR3 +/- DR1 negative donor – HR 1.55, 95%CI 1.05-2.29, p=0.027 and for HLA-DR3 +/- DR1 negative recipients with an HLA-DR3 +/- DR1 homozygous donor – HR 2.36, 95%CI 1.4-3.98, p=0.001

Conclusions: HLA matching at HLA-DR3 does not appear to be associated with graft survival. However graft survival is reduced in HLA-DR3 negative recipients if the donor is HLA-DR3 homozygous, and in HLA-DR3 homozygous recipients receiving an HLA-DR3 negative donor kidney. These results become more significant if HLA-DR1, HLA-DR6 or HLA-DR7 is combined with HLA-DR3, suggesting an association with HLA-DQB polymorphisms

TH-PO138

Patients with Membranous Nephropathy (MN): A Real-World (RW) Clinical and Economic Analysis

Tara A. Nazareth,[2] Furaha Kariburyo,[4] Aaron Kirkemo,[2] Lin Xie,[4] Anna Pavlova-Wolf,[1] Laura Bartels-Peculis,[2] Neel Vaidya,[4] John J. Sim.[3] *[1]Mallinckrodt, Henderson, TX; [2]Mallinckrodt Pharmaceuticals, Hampton, NJ; [3]None, Los Angeles, CA; [4]STATinMED Research, Ann Arbor, MI.*

Background: MN is one of the most common causes of nephrotic syndrome (NS) in adults. Given varying clinical course and treatment response, where 1/3 of patients progress to end-stage renal disease, MN represents a high-risk population where management strategies can alter and improve outcomes (van den Brand et al., 2014). We describe RW outcomes in a prevalent MN cohort using US administrative healthcare claims data.

Methods: A retrospective analysis was conducted using Truven Marketscan®, among commercially-insured patients ≥ 18 years during 1/1/12-12/31/15. MN was identified using ≥2 MN diagnoses (Dx ICD-9-CM=581.1, 583.1; ICD-10-CM= N052, N062 and N072). The date of first Dx was designated the index date. Patients with Dx indicating secondary causes of NS were excluded. Patients were followed for 1 year post-index and evaluated with regards to demographics, clinical outcomes, all-cause healthcare resource utilization [HCRU: inpatient (IP), emergency room (ER), outpatient (OP), medications (Rx)], and all-cause costs using Dx, procedure and drug codes. Costs were assessed in patients enrolled in fee-for-service plans (FFS).

Results: 701 patients were identified [54.8% male, mean age=48.7 years, hematuria (7.6%), mean Charlson Comorbidity Index score=2.3, from South (37.5%) and North Central US (23.0%)]. 15.3% of patients had urinary tract infections, 3.9% pneumonia, and 1.1% septicemia. Treatment with dialysis and renal transplant occurred in 4.3%, and 1.1% of patients, respectively. 25.1% used the ER and 12.6% had IP stays; 20.0 mean Rx were dispensed. Among FFS patients (n=562), total and mean (SD) costs were $17.6 million and $31,412.3 ($97,654.3), respectively. 5% of patients (n=28) were responsible for 57.4% of costs or $10.1 million, for a mean (SD) cost per patient of $362,064.1 ($259,261.3); as a proportion of cost, OP and IP were responsible for 89.3%, while Rx and ER comprised 10.0% and <0.8%, respectively.

Conclusions: Our analysis characterizes 1-year RW outcomes among commercially-insured patients with MN, revealing a subset responsible for a large portion of costs incurred largely by IP and OP use. This group should be studied further to focus identification and treatment strategies. Burden of illness and costs over a longer–term horizon should be examined.

Can THSD7A Be a New Marker for Diagnosing Idiopathic Membranous Nephropathy? A Systematic Review and Meta-Analysis of the Diagnostic Value of THSD7A in IMN

Song Ren,[1] Changwei Wu,[1] Guisen Li,[2] Li Wang,[2] Daqing Hong.[3] *[1]Renal Department and Institute of Nephrology, Sichuan Provincial People?s Hospital, Chengdu, China; [2]Renal Division and Institute of Nephrology, Sichuan Academy of Medical Sciences and Sichuan Provincial People?s Hospital, Chengdu, China; [3]Sichuan Provincial People's Hospital, CHENGDU, China.*

Background: Thrombospondin type 1 domain–containing 7A (THSD7A) is a new target antigen in patients with idiopathic membranous nephropathy. Moreover, malignancies are also found in THSD7A-positive membranous nephropathy patients. We aimed to systematically evaluate prevalence of THSD7A in the IMN patients and malignancies in THSD7A-postive patients.

Methods: We searched English database including MEDLINE, Embase, Cochrane Library and Chinese database including CNKI, VIP and Wanfang database to Jan 4, 2017 with the term "THSD7A" or "thrombospondin type 1 domain-containing 7A". Meta analysis was used to explore the positive rate of THSD7A in the patients with idiopathic membranous nephropathy. Subgroup analysis was done according to the race, sample size, and detecting method of THSD7A. The incidence of malignancies in THSD7A positive patients was also summarized.

Results: Ten studies involving 3061 participants were eventually included in this review. The prevalence of THSD7A was 3% (95% CI, 3%–4%). In the anti-phospholipase A2 receptor (PLA2R)-negative patients, the prevalence of THSD7A was 10% (95% CI, 6%–15%). A total of 77 patients were detected for positive circulating antibodies, and the prevalence of THSD7A was lower at 3% (95% CI, 2%–4%). Overall 72 patients were THSD7Apositive detected by renal biopsy with immunohistochemistry, and the prevalence was 3% (95% CI 3%-4%). Subgroup analysis did not show significant differences in the prevalence of THSD7Abetween races and study sample sizes. Among THSD7A-postive patients, 2/10 studies reported malignancies with the incidence varied from 20% to 25%.

Conclusions: The prevalence of THSD7A is not uncommon in the patients with IMN, but more common in the PLA2R-negtive patients. Malignancies should be screened and closely monitored in THSD7A-positvie membranous nephropathy patients.

TH-PO140

Late Relapses of Membranous Nephropathy (MN) Yonatan A. Peleg,[4] Andrew S. Bomback,[1] Pietro A. Canetta,[3] Gerald B. Appel,[2] Wooin Ahn.[3] *[1]Columbia University, New York, NY; [2]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [3]None, New York, NY; [4]Nephrology, New York Presbyterian-Columbia University Medical Center, New York City, NY.*

Background: Most patients (pts) with MN who achieve remission carry a risk of relapse that diminishes over time. Relapse of disease after 5 years of sustained remission is considered a rare event.

Methods: We reviewed 15 idiopathic MN pts, who relapsed after a median time of 11 years of disease remission.

Results: 10/15 pts were male. All were white, and one was Hispanic. Median age at diagnosis was 34 y (range 3-71). Median baseline eGFR was 79.4 ml/min/1.73m^2 (range 26.8-110). 9 went into complete remission (CR) and 6 pts went into partial remission (PR). CR was achieved with immunosuppression (IS) in 6 pts. Median age at first relapse was 51 y (range 20-80), representing a gap of 11 y (range 6-36) from initial remission. Relapses presented as nephrotic syndrome in 8, while the other 7 were diagnosed by lab surveillance. 10/15 pts underwent repeat biopsy 12 y (range 8-33) after first biopsy: all showed pattern of primary MN. 12 pts received IS after relapse and 1 died prior to treatment. 8/14 surviving pts had PR after their initial relapse, 3 had CR, and 3 had no remission (NR). CR was not associated with IS use. 5 pts had additional relapse episodes after their first relapse, and all were treated with IS. Experiencing PR vs. CR did not predict risk of subsequent relapse. The results of the most recent relapse for these 5 patients are 1 in CR, 1 in PR, and 3 in NR. Median follow up duration was 19 y (range 9-56). The median most recent eGFR was 60.8 (range 16.8-105.6), and median yearly change in eGFR was -0.32 (range -2.73 to +2.82). None reached ESRD. Of 10 available biopsies during clinical relapse, 6 were stained for PLA2R with all staining positive. Serum PLA2R Ab was tested in 10 pts, with some surveilled with serial titers: 2 had positive titers during relapse, 5 had negative titers during relapse, and 3 had negative values during PR. In all, 8/10 pts were positive for either tissue PLA2R or serum PLA2R Ab while in clinical relapse.

Conclusions: We present 15 MN pts with proteinuric relapse a median time of 11 years after initial remission. Repeat biopsies, even as long as 33 years after complete remission, all showed MN, and 80% of pts were PLA2R positive by tissue or serum testing. Thus repeat biopsy to reestablish a diagnosis of MN may be unnecessary. There was no significant decline in renal function despite relapses and median follow up time of 19 years.

TH-PO141

Clinical and Pathological Analysis of Renal Tubulointerstitial Injury in Idiopathic Membranous Nephropathy Zilong Li,[1] Yibo Zhang,[4] Juan Wang,[1] Linlin Liu,[3] Jianfei Ma,[2] Li Yao.[2] *[1]Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, P. R. China, Shenyang, China; [2]The First Affiliated Hospital of China Medical University, Shenyang, China; [3]The First Hospital of China Medical University, ShenYang, China; [4]the first affiliated hospital of China Medical University, Shenyang, China.*

Background: It has been revealed that renal tubulointerstitial injury (TII) plays important roles in the progression of chronic kidney diseases, while how TII affects idiopathic membranous nephropathy (IMN) remains unclear. Herein, we retrospectively studied the clinical and pathological data of 134 IMN patients, to investigate the characteristics of TII in IMN.

Methods: 134 patients diagnosed as IMN via renal biopsy from January 2014 to December 2015 in our department were enrolled. All the patients didn't administrate with either corticosteroid or immunosuppressants before undergoing renal biopsy, and accepted appropriate therapy according to the clinical and pathological features after renal biopsy. The patients were divided into two groups: TII group and non-TII group. Clinical and pathological data were accumulated after 12-month follow-up.

Results: Among the 134 IMN patients, 79 were males (58.96%) and 55 were females(41.04%), age from 14 to 74 years. The pathological results suggested 65 cases (48.51%) existed TII in IMN. Compared to non-TII group, TII group appeared significantly higher levels of 24-hour urinary protein,urinary α1-microglobulin,urinary β2-microglobulin, urinary albumin, serum creatinine and cystatin C ($p<0.05$), and significantly declined eGFR ($p<0.05$). Renal tubulointerstitial injury score was positively associated with serum creatinine($r=0.304$,$p=0.00$), cystatin C($r=0.372$,$p=0.00$), 24-hour urinary protein($r=0.207$,$p=0.016$), α1-microglobulin($r=0.174$,$p=0.044$), β2-microglobulin($r=0.246$,$p=0.004$) and urinary albumin($r=0.206$,$p=0.017$), and negatively associated with eGFR($r=-0.304$,$p=0.00$). After 12-month follow-up, patients in TII group showed higher incidence of eGFR decrease.

Conclusions: TII occurs in IMN patients, which may be prompted by some clinical indicators. TII may affect the the progression and prognosis of IMN, and further researches are needed to elaborate the mechanisms and explore effective therapies.

TH-PO142

Initial States of Circulating Anti-Phospholipase A2 Receptor Antibody and Cigarette Smoking Predict a Clinical Outcome in Japanese Patients with Idiopathic Membranous Nephropathy Asaka Hachiya, Shin'ichi Akiyama, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Idiopathic membranous nephropathy (iMN) is the leading cause of nephrotic syndrome in adults, the clinical outcomes in iMN is difficult to predict. We reported that the prevalence of anti-PLA2R in Japanese patients with iMN is approximately 50%, which was lower than reports from any other countries (approx. 75%). In addition, we reported that cigarette smoking is a significant and dose-dependent risk factor for progression of Japanese patients with iMN. In this study, we had tried to reveal that the association of initial states of anti-PLA2R and cigarette smoking to clinical outcomes in Japanese patients with iMN.

Methods: We retrospectively enrolled consecutive 78 biopsy-proven iMN Japanese patients with nephrotic syndrome (# of male, 57; median age, 64 [IQR 60-70] years old; # of Current/Ex-smoker, 34) who admitted our hospitals between January 2003 and December 2012, and followed these patients for at least 3 months (median [IQR], 56 [35-81] months). All patients were not treated with any immunosuppressive therapies at renal biopsy, whose serum were collected at the same time of renal biopsy. Duration of complete remission (CR) and predictors of prolongation of CR were assessed and anti-PLA2R in serum was measured by ELISA.

Results: Anti-PLA2R was positive in 53% (41 of 78) of all patients with iMN. The prevalence of anti-PLA2R in current/ex-smokers (59%, 20 of 34) higher than that in never-smokers (47%, 21 of 44). In the follow-up period, CR was observed in 55 patients (anti-PLA2R positive, 27; negative, 28). In patients with anti-PLA2R positive and/or ex/current smoker, the period to CR tended to prolong. Duration of CR with anti-PLA2R positive and ex/current smoker was significantly longer than that of the other groups (log rank, $p = 0.009$). Multivariate Cox proportional hazards models revealed anti-PLA2R positive and current/ex-smokers (adjusted hazard ratio, 0.16 [95% confidence interval, 0.05–0.51]) associated with prolongation of CR.

Conclusions: The smoking experience and anti-PLA2R positive at diagnosis are risk factor for prolongation of complete remission. Our data suggested that check the initial states of circulating anti-PLA2R and cigarette smoking is useful and easy method to predict a clinical outcome of patient with iMN.

TH-PO143

Low Dose Rituximab Is Non-Inferior to Higher or Multiple Dose Schedules in the Treatment of Steroid Sensitive, Frequently Relapsing Nephrotic Syndrome in Children Ben C. Reynolds,[4] Rebecca A. Dalrymple,[2] Andrew P. Maxted,[6] Denise Chisholm,[6] John H. Mccoll,[5] Yincent Tse,[1] Martin Christian.[3] *[1]Great North Children's Hospital, Newcastle upon Tyne, United Kingdom; [2]Greater Glasgow and Clyde NHS, Glasgow, United Kingdom; [3]NHS, Nottingham, United Kingdom; [4]Royal Hospital for Children, Glasgow, Glasgow, United Kingdom; [5]University of Glasgow, Glasgow, United Kingdom; [6]Pediatric Nephrology, Nottingham Children's Renal and Urology Unit, Nottingham, United Kingdom.*

Background: Rituximab is an effective treatment for children with steroid dependent or frequently relapsing nephrotic syndrome. Dosing schedules vary between centres and are based on anecdotal evidence and non randomised controlled data. We hypothesised that a single low dose of 375mg/m^2 would be non-inferior to higher or multiple doses, in maintaining remission and time to B-cell reconstitution.

Methods: This was a retrospective, observational cohort study of children from three paediatric nephrology centres in the United Kingdom. Children with steroid sensitive, frequently relapsing nephrotic syndrome who received Rituximab since January 2007 were included. Data were extracted from clinical records on the dates of diagnosis, treatment and relapses; lymphocyte subset profiling pre-and post-rituximab administration; and the use of concomitant immunosuppression. The primary outcome was an absence of clinically confirmed relapse 12 months after Rituximab administration. Secondary outcomes were median time to relapse, probability of being relapse free at 6 and 24 months and time to reconstitution of $CD19^+$ B cells (CD 19^+ B cells $>0.2 \times 10^9$).

Results: 60 patients received 143 courses of Rituximab. Patients were grouped according to the dose of Rituximab received; those in group 1 (15 courses) received a higher total dose of 1.5g/m^2, group 2 (25 doses) received an intermediate dose between 750mg/m^2 – 1g/m^2, and group 3 (103 courses) received our current low dose regimen of a single dose of 375mg/m^2. There was no difference in event-free survival at 6, 12, or 24 months between groups. Of those who relapsed, the median time to relapse was not significantly different between the high and low dose groups, 317 days in group one and 299 days in group three. The median time to reconstitution of B-cells was not significantly different between groups at 175, 226 and 196 days for groups 1, 2 and 3 respectively.

Conclusions: We conclude that usage of a single low dosage of Rituximab in the management of frequently relapsing nephrotic syndrome does not affect the probability of relapse at 6 and 12 months, or the time to B-cell reconstitution in our cohort of patients.

TH-PO144

Initial Response to Corticosteroid Therapy and Native Kidney Biopsy Findings Predict Disease Recurrence Following Kidney Transplantation in Childhood Nephrotic Syndrome Adam R. Bensimhon, Jonathan H. Pelletier, Karan Kumar, Michelle N. Rheault, Tarak Srivastava, Caroline E. Straatmann, Thomas K. Davis, Cynthia J. D'Alessandri-Silva, Scott E. Wenderfer, Rachel M. Engen, Keisha L. Gibson, Christoph Licht, David T. Selewski, Larry A. Greenbaum, Rasheed A. Gbadegesin. *Pediatrics, Duke University Medical Center, Durham, NC.*

Background: Steroid resistant nephrotic syndrome (SRNS) is a leading cause of ESKD in children. Disease recurrence following kidney transplantation is the single most important cause of renal allograft loss in SRNS. Previous studies have not consistently identified risk factors associated with recurrence of disease. This study aims to determine predictors of disease recurrence in children with SRNS after renal transplantation.

Methods: A 10 year multicenter review of kidney transplants performed for SRNS in MWPNC participating centers. Data were collected on patients' demographics, clinical course, and biopsy findings. Patients with primary SRNS (PSRNS) were defined as those initially resistant to steroid therapy at diagnosis, and patients with late SRNS (LSRNS) were defined as those initially responsive who subsequently developed resistance. Groups were compared by chi-square tests or Fisher's exact test, and multivariate regression analysis was used to identify predictors of recurrence.

Results: We identified 116 patients (67 with PSRNS, 17 with LSRNS, and 32 with genetic SRNS/undetermined pattern of response). Disease recurrence occurred in 35.8% of patients with PSRNS compared to 70.6% of those with LSRNS ($p < 0.001$). Age at diagnosis and ESKD, sex, race, and ethnicity were similar in patients with and without recurrence. Patients with minimal change disease histology (MCD) on initial kidney biopsy had an 80% recurrence rate compared with a 31% recurrence rate in those with focal segmental glomerulosclerosis (FSGS) ($p = 0.005$). Unadjusted multivariate analysis identified MCD (OR 8.9; 95% CI 1.8-45.3, $p = 0.008$) and LSRNS (OR 4.3; 95% CI, 1.4 to 13.7, $p = 0.013$) as predictors of disease recurrence, but in adjusted analysis, only LSRNS predicted disease recurrence (OR 4.3; 95% CI 1.1-16.1, $p = 0.032$).

Conclusions: Pediatric patients with LSRNS and MCD histology are at significantly higher risk of disease recurrence following kidney transplantation. These findings may be useful for designing studies to test strategies for preventing recurrence.

TH-PO145

Management of Children With Congenital Nephrotic Syndrome: Challenging Treatment Paradigms Stephanie Dufek,[1] Elisa Ylinen,[2] Agnes Trautmann,[4] Enrico Vidal,[3] Tuula M. Holtta,[2] Rukshana Shroff.[1] *[1]Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom; [2]University Hospital Helsinki, Helsinki, Finland; [3]University-Hospital of Padova, Padova, Italy; [4]Center for Pediatrics and Adolescents Medcine, University Hospital Heidelberg, Heidelberg, Germany. Group/Team: On behalf of ESPN Dialysis Working Group.*

Background: Management of children with congenital nephrotic syndrome (CNS) is challenging and ranges from antiproteinuric treatment to uni- or bilateral nephrectomies followed by dialysis and transplantation. Early bilateral nephrectomies followed by dialysis and transplantation is currently practised in most centres, but conservative treatment may also be effective.

Methods: We conducted a 6-year survey across members of the European Society for Paediatric Nephrology Dialysis Working Group to compare management strategies and their outcomes in children with CNS.

Results: 81 children (51% male) across 17 tertiary nephrology units in Europe were included (NPHS1 n=57; NPHS n=2, WT1 n=10, others n=12; details of mutations were not examined). Antiproteinuric treatment was given in 48 (59%) with an increase in S-albumin in 68% by median 6 (interquartile range 3-8) g/L ($p<0.001$) and decrease of weekly albumin infusion dose by median 1 (0-3) g/kg/week ($p=0.021$). Unilateral nephrectomy (or first kidney removal) was performed in 16 children. In those, S-albumin increased by median 3 (1–7) g/L ($p=0.021$) and weekly albumin infusion dose decreased by median 4 (0-7) g/kg/week ($p=0.018$). The median age at bilateral nephrectomy was 9 (7-15) months. Dialysis was initiated in 53 (65%) at a median age of 9 (5.5-15) months, with PD in 91% of children. Children with NPHS1 mutations and >12 months follow-up were divided into two groups and their outcomes were compared: bilateral nephrectomy (n=26) versus conservative management (no nephrectomy; n = 17). Nephrectomised children presented earlier (3 vs 29 days; $p=0.01$), with comparable S-albumin ($p=0.21$) and S-creatinine ($p=0.19$). There was no difference in the number of septic or thrombotic episodes and growth was comparable. At final follow-up (median age 34 months) 9 (53%) children in the conservative group remained without renal replacement therapy, 4 (24%) received a renal transplant and 2 died. Amongst nephrectomised children 21 (81%; $p<0.01$) were transplanted and 1 died.

Conclusions: An individualised, stepwise approach, with prolonged conservative management, followed by unilateral nephrectomy may be a reasonable alternative to early bilateral nephrectomies in children with CNS and NPHS1 mutation.

Medication Adherence and Perceived Difficulties in Pediatric Nephrotic Syndrome Chia- Shi Wang,[1] Jonathan P. Troost,[2] Tarak Srivastava,[3] Darcy K. Weidemann,[3] Larry A. Greenbaum.[1] *[1]Emory University, Atlanta, GA; [2]University of Michigan, Ann Arbor, MI; [3]Children's Mercy Hospital, Kansas City, MO, Group/Team: cNEPTUNE Working Group.*

Background: In children with nephrotic syndrome (NS), there is limited information on the prevalence of medication nonadherence and the role of perceived barriers in determining nonadherence.

Methods: We surveyed a large cohort of prevalent pediatric NS patients enrolled in an international, prospective study, the Nephrotic Syndrome Study Network (NEPTUNE). Self-reports for patients ages 8-18 years and caregiver-reports for patients ages 0-10 years were administered to prevalent patients between 2015-2016. The surveys contained 2 questions on whether medications were taken/missed and 17 questions on difficulties with medication ingestion, regimen adaptation, and disease frustration. All responses were reported in a 5-item Likert-type scale. Non-adherence was defined as responses of "not sure" or affirmative responses to not taking all medications or having missed medications. Patients were noted to have perceived barriers to medication adherence if an affirmative answer was given to one of the seventeen questions on medication difficulties. Association between perceived barriers and adherence was assessed by Chi-square test.

Results: 129 patients/caregivers completed medication adherence surveys, and 113 responded to medication difficulties surveys. Median time of study enrollment at time of survey was 521 days (interquartile range = 10-1221 days). 51 (39.5%) of patients were non-adherent to medications by self-/caregiver-report. 56 (49.6%) reported difficulties with ingestion, 45 (39.8%) with regimen adaptation, and 69 (61.1%) with disease frustration. 86 (76.1%) patients reported difficulties within at least one domain. Report of perceived barriers was not significantly associated with medication nonadherence (odds ratio = 1.63, 95% confidence interval = 0.64-4.14).

Conclusions: Self-/caregiver-reported medication nonadherence was common among pediatric NS patients. The majority of patients and caregivers reported experiencing barriers to adherence, including difficulties with medication ingestion, adaptation to medication regimen, or frustration with the disease. Prospective studies are needed to assess the effects of reported difficulties on long-term medication adherence and disease outcome.

Cardiovascular Disease Risk Factors in Pediatric Glomerular Disease: An Early Analysis of the Cure Glomerulonephropathy (CureGN) Study Isa Ashoor,[1] Donald J. Weaver,[2] Amy Kogon,[3] Rulan S. Parekh,[4] Tetyana L. Vasylyeva,[5] Aftab S. Chishti,[6] Michelle N. Rheault,[7] Christine B. Sethna,[8] Michelle M. O'Shaughnessy,[9] Margaret Helmuth.[10] *[1]Children's Hospital of New Orleans, New Orleans, LA; [2]Levine Children's Hospital at Carolinas Medical Center, Charlotte, NC; [3]Nationwide Children's Hospital, Columbus, OH; [4]The Hospital For Sick Children, Toronto, ON, Canada; [5]Texas Tech University Health Sciences Center, Amarillo, TX; [6]University of Kentucky, Lexington, KY; [7]University of Minnesota, Minneapolis, MN; [8]Cohen Children's Medical Center of NY, New Hyde Park, NY; [9]Stanford University Medical Center, Palo Alto, CA; [10]Arbor Research Collaborative for Health, Ann Arbor, MI. Group/Team: CureGN Study Cardiovascular Working Group.*

Background: Chronic kidney disease (CKD) is major risk factor for subsequent development of cardiovascular disease (CVD). We sought to describe the burden of CVD risk factors in pediatric glomerular disease.

Methods: CureGN is a prospective multi-center cohort of biopsy-confirmed primary glomerular diseases (minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), and IgA Nephropathy/Vasculitis (IgAN/IgAV)). Descriptive statistics are used to assess CVD risk factors (hypertension, obesity, dyslipidemia, prematurity, and second hand tobacco exposure) and management practices among 578 participants under age 18. Data were obtained at enrollment.

Results: The *Table* summarizes baseline characteristics and prevalence of CVD risk factors overall and by primary glomerular disease. Prevalent cardiac disease was rarely reported. Overall, 20% had a history of hypertension. Enrollment BPs were hypertensive in 21% and pre-hypertensive in 14% of patients compared to 1.6% and 9.6% of general pediatric population. Among those with hypertensive readings, and those with UPCR>3.5, less than a third received RAAS blockers overall. Obesity was present in 31% and elevated total cholesterol (TC > 200 mg/dL) was present in 30% compared to 17% and 7.4% of general pediatric population. Use of lipid lowering medications in children with TC > 200 was infrequent (7%). Prematurity and second hand smoke exposure were similar to general population.

Conclusions: In this pediatric glomerular disease cohort, prevalence of traditional CVD risk factors is high, particularly hypertension and dyslipidemia. Further study is needed to optimize screening and management of CVD risk factors in this population.

Funding: NIDDK Support

Pregnancy in Women with Relapsing Minimal Change Disease – Experience of a Tertiary Centre Iolanda Godinho,[1,2] Philip Webster,[1,2] Liz Lightstone.[1,2] *[1]Imperial College London, London, United Kingdom; [2]Imperial College Healthcare NHS Trust London, London, United Kingdom.*

Background: Recent data suggest even patients with CKD stage 1 have an increased risk of pregnancy complications when compared to the general population. However, data on outcomes specifically in pregnant women with relapsing minimal change disease (MCD) are lacking. We now report the largest series to date.

Methods: Women with MCD were identified from our obstetric renal database from 1996-2016. We report maternal outcomes: relapse, AKI & worsening of renal function, HTN; & obstetric outcomes: number of successful pregnancies, preeclampsia, preterm delivery & low birth weight.

Results: Out of 797 pregnancies, we identified 14 in 10 women with MCD. Median maternal age: 35 years (19-40). Two patients had chronic HTN – one with relapsing MCD with IgM deposition for 11 years & 8 years of FK treatment; the other patient had dysmetabolic syndrome and MCD diagnosis made on post-partum biopsy. All women were in remission with no proteinuria at the time of conception & normal creatinine with CKD1 in 8, CKD2 in 6 using CKD-EPI eGFR. The majority (71%) of women were on immunosuppression (FK (n-7), CsA (n-2) or steroids (n-2) & one had an unplanned pregnancy diagnosed very soon after maintenance rituximab. None of the women developed worsening renal function. Relapses were seen in 2 pregnancies in women who stopped their maintenance immunosuppression. One hypertensive patient had worsening HTN during pregnancy. The majority of babies (69%, n=9) delivered at term (median gestation 38 weeks (range 28-40)). Preterm (35 & 36 weeks) & very preterm (28 weeks) were seen in 3 & 1 pregnancies respectively. Birth weight was 2923±622g. Just 1 baby had low birth weight (<2.5kg) & 1 very low (1.5kg). There was one miscarriage at 18 weeks. No women developed pre eclampsia & no congenital abnormalities were seen.

Conclusions: In this series, the largest reported to date, of women with CKD1/2 due to relapsing MCD, despite high rates of immunosuppression, pregnancies were largely uncomplicated (69%) & relapse rare unless maintenance immunosuppression stopped. Our data suggest pregnancies in MCD in remission are safe & that establishing secure remission especially with tacrolimus, is key to pregnancy planning. Our good results rely on pre-pregnancy counselling to optimise timing & medications & a highly experienced MDT obstetric renal antenatal clinic.

TH-PO149

Utility of Renal Biopsy for Proteinuria in Pregnancy Eri Kawashima, Yoshihiko Inoue, Kiyoko Inui, Fumihiko Koiwa, Ashio Yoshimura. *Showa University Fujigaoka Hospital, Yokohama, Japan.*

Background: We are often referred patients who have proteinuria in pregnancy. The patients present various clinical conditions; superimposed preeclampsia, normotensive nephrotic syndrome, complicating hematuria. These clinical conditions sometimes become the risk of pregnancy termination. The patients with proteinuria in pregnancy had renal biopsies, and were discussed utility of the biopsies based on histopathological findings and clinical courses.

Methods: 17 patients who had proteinuria in pregnancy had postpartum needle biopsies of their kidneys. Then we analyzed clinical findings to need aggressive treatments, based on histopathological diagnosis and onset of proteinuria.

Results: Before 20 weeks' gestation, the timing of onset of proteinuria, nine of 11 patients were diagnosed kidney diseases to need treatments. Histopathological diagnoses were IgA nephropathy (n = 6), focal segmental glomerular sclerosis (n = 2), mesangial proliferative nephritis (n = 1). Other 2 patients were thin basement membrane disease and minor abnormality. After 20 weeks' gestation, two of 6 patients were diagnosed kidney diseases to need treatments, there were IgA nephropathy (n = 1), membranous nephropathy (n = 1). Other 4 patients were histopathological findings of pregnancy induced hypertension (PIH). Compared histopathological PIH with non-PIH about clinical characters, gestational age (PIH; 28.7 ± 2.87, non-PIH; 30.7 ± 4.11 y.o., p = 0.32), maximum proteinuria (9.9 ± 3.03, 1.8 ± 2.71 g/day, p = 0.006), continuous hematuria (p = 0.00002), serum creatinine (0.75 ± 0.21, 0.68 ± 0.23 mg/dl, p = 0.59), eGFR (80.5 ± 26.8, 94.3 ± 43.0 ml/min/1.73m^2, p = 0.46), systolic blood pressure (156 ± 8.0, 141 ± 17.7 mmHg, p = 0.03). Significant clinical character of non-PIH was continuous hematuria.

Conclusions: The patients who have proteinuria in pregnancy with continuous hematuria were suspected kidney disease to need aggressive treatments, and renal biopsies were utility as early diagnoses and treatments.

TH-PO150

Factors Associated with the Initiation of renin-Angiotensin-Aldosterone System Blockade in Patients with Sustained Proteinuria Elaine S. Kamil,[9] Matthew Elliott,[5] Patrick E. Gipson,[4] Susan F. Massengill,[10] Sharon G. Adler,[1] Anne Pesenson,[8] Meg Modes,[7] Gia J. Oh,[3] David T. Selewski,[4] Lauren Lee,[6] Debbie S. Gipson,[4] Xuhui Zhong,[2] Anne Waldo,[4] Jonathan P. Troost,[4] Richard A. Lafayette.[3] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]Peking University First Hospital, Beijing, China; [3]Stanford University, Stanford, CA; [4]University of Michigan, Ann Arbor, MI; [5]Metrolina Nephrology Associates, Charlotte, NC; [6]NephCure Kidney International, King of Prussia, PA; [7]Patient Advocate, Livonia, MI; [8]The Polyclinic, Seattle, WA; [9]Cedars Sinai Medical Center, Los Angeles, CA; [10]Levine Children's Hospital, Charlotte, NC.*

Background: Renin-angiotensin-aldosterone system (RAAS) blockade plays an important role in the treatment of sustained proteinuria. The goal of this study was to investigate the time from the onset of sustained proteinuria to initiation of RAAS blockade therapy and associated characteristics.

Methods: Electronic health record derived NephCure Accelerating Cures Institute cohort data were used. Patients with primary proteinuric kidney disease and onset of sustained proteinuria, defined as two or more days within 6 months with measurements of UP:C>1 or dipstick proteinuria ≥2+, were eligible. Kaplan-Meier analysis was used to evaluate the time to initiation of RAAS blockade from the date of the second qualifying proteinuria measurement.

Results: Of 848 registry patients, 147 patients were excluded due to prior RAAS therapy and 496 due to intermittent proteinuria. 205 patients were eligible for this analysis. 89 (43%) patients were prescribed RAAS blockade, 64 of 110 adults and 25 of 95 children. The median time from onset of sustained proteinuria until initiation of RAAS blockade was 241 days (IQR 35 to 653). Patients with Focal Segmental Glomerulosclerosis (FSGS) or Membranous Nephropathy (MN) were more likely to receive RAAS blockade and receive it earlier than Minimal Change or NS-not biopsied patients (Figure). In a multivariable Cox-proportional hazards model, diagnosis but not age or sex, was a significant factor associated with time to initiation of therapy.

Conclusions: Following onset of sustained proteinuria, RAAS blockade was initiated within a median of 8 months. Patients with a diagnosis of FSGS or MN were more likely to be treated and to be treated earlier. This study highlights opportunities for improvements in health care delivery.

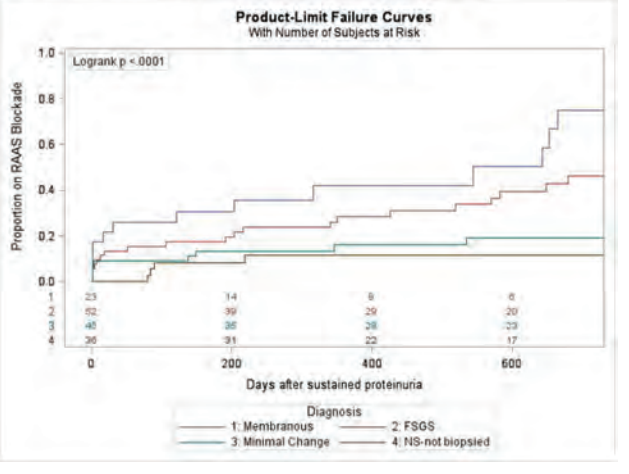
Figure. Time to initiation of RAAS blockade after sustained proteinuria by diagnosis



TH-PO151

Time to Initiation of Anti-Hypertensive Therapy after Onset of Elevated Blood Pressure in Patients with Primary Proteinuric Kidney Disease Susan F. Massengill,[1] Cheryl D. Courtlandt,[1] Matthew Elliott,[3] Patrick E. Gipson,[7] Elaine S. Kamil,[8] Anne Pesenson,[6] Meg Modes,[5] David T. Selewski,[7] Gia J. Oh,[9] Debbie S. Gipson,[7] Richard A. Lafayette,[9] Hailey Desmond,[7] Jonathan P. Troost,[7] Lauren Lee,[4] Sharon G. Adler.[2] *[1]Levine Children's Hospital, Charlotte, NC; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]Metrolina Nephrology Associates, Charlotte, NC; [4]NephCure Kidney International, King of Prussia, PA; [5]Patient Advocate, Livonia, MI; [6]The Polyclinic, Seattle, WA; [7]University of Michigan, Ann Arbor, MI; [8]Cedars Sinai Medical Center, Los Angeles, CA; [9]Stanford University, Stanford, CA.*

Background: Past research suggested a significant lag between onset of hypertension (HTN) and initiation of antihypertensive therapy (AHRx). The aim of this study was to evaluate the time to initiation of AHRx in patients with proteinuric kidney disease identified as hypertensive based on standard guidelines.

Methods: Longitudinal outpatient blood pressure (BP) measurements were available on 858 patients, 71% adults and 29% children, in the NephCure Accelerating Cures Institute cohort. Patients were defined as hypertensive either by ICD9/ICD10 diagnosis code or having 3 or more elevated BPs in a 6-month period. Patients already on AHRx at first observation were excluded. Kaplan-Meier and cox-proportional hazards analyses were used to evaluate the time to initiation of AHRx.

Results: Of the 858 patients available, 482 had evidence of HTN. 195 of these patients were excluded due to prior AHRx. Of the 287 remaining patients, 234 (82%) were subsequently started on AHRx. The median time from diagnosis or third qualifying BP until therapy initiation was 92 days (IQR=1 to 535). Adults were more likely to receive AHrx than children (87% vs 60%, p=0.04). Patients with Membranous Nephropathy had a shorter time to therapy initiation than those with other diagnoses (Figure). Patients with HTN by coded diagnosis were more likely to receive therapy compared to those with HTN by BP readings alone (83% vs 33%, p=0.03).

Conclusions: Patients with HTN in the setting of primary proteinuric kidney disease are prescribed AHRx a median of 3 months after HTN diagnosis. Having a coded diagnosis of HTN increased the likelihood of AHRx. Overall only 11% of the proteinuric patients in the NACI patient registry have HTN without the benefit of AHRx.

TH-PO152

Steroid Associated Side Effects in Patients with Glomerular Disease Gia J. Oh,[1] Patrick E. Gipson,[8] Anne Pesenson,[2] David T. Selewski,[8] Elaine S. Kamil,[4] Susan F. Massengill,[5] Richard A. Lafayette,[1] Meg Modes,[6] Sharon G. Adler,[3] Lauren Lee,[7] Debbie S. Gipson,[8] Richard Eikstadt,[8] Samara Attalla,[8] Zubin J. Modi,[8] Anne Waldo,[8] Jonathan P. Troost.[8] *[1]Stanford University, Stanford, CA; [2]The Polyclinic, Seattle, WA; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]Cedars Sinai Medical Center, Los Angelos, CA; [5]Levine Children's Hospital, Charlotte, NC; [6]Patient Advocate, Livonia, MI; [7]NephCure Kidney International, King of Prussia, PA; [8]University of Michigan, Ann Arbor, MI.*

Background: Steroid therapy is a common treatment for chronic glomerular disease with a goal of delaying or preventing end-stage kidney disease, but patients and families often express concerns about steroid-associated side effects (SA-SE). The goal of this study was to assess the occurrence of SA-SE in patients with primary proteinuric kidney disease.

Methods: 736 patients with preserved native kidney function enrolled in NephCure Accelerating Cures Institute registry within electronic health record sourced database were available for analysis. ICD-9 and ICD-10 code sets were generated for SA-SEs including HTN, obesity, diabetes, short stature, cataracts, glaucoma, and psychosis. Measures (elevated BP > 3 times and BMI) were also used to identify HTN and obesity. These side effects were identified through analysis of inpatient and outpatient encounter data. Events were considered steroid-associated if they occurred after the onset of steroid exposure.

Results: 413 of 736 (56%) registry patients were treated with steroids during study observation. Of these 413, 67% were adults, median age 41y, and 33% children, median age 11y, and the diagnoses were FSGS 26%, Membranous 11%, Minimal Change 19%, NS-not biopsied 16%, and other 29%. Median observation was 35 (IQR: 18-59) months. Table 1 presents SA-AE frequencies. 79% developed any SA-AE and 54% developed an event other than HTN. No episodes of glaucoma or psychosis were documented.

Conclusions: This study evaluated the incidence of medical encounter documented SA-AEs in patients with primary proteinuric kidney disease. The majority of patients treated with steroids developed at least one SA-AE. An accounting of the full patient experience of SA-AEs will likely require direct patient reported information to enrich the medical documentation.

Funding: Private Foundation Support

Table 1. Frequencies of SA-AEs among steroid treated proteinuric kidney disease patients by age group

	All Patients on steroids (n=413)	Patients < 18 y on steroids (n=159)	Patients >=18 y on steroids (n=254)	P value
Hypertension	289 (70)	131 (82)	158 (62)	<0.01
Obesity	173 (42)	76 (48)	97 (38)	0.05
Diabetes	44 (11)	8 (5)	36 (14)	<0.01
Short stature	16 (4)	10 (6)	6 (2)	0.04
Cataracts	11 (3)	2 (1)	9 (4)	0.16
>=1 SA-AE beyond HTN	221 (54)	128 (50)	93 (58)	0.11

TH-PO153

Tacrolimus as Monotherapy for Relapsing Minimal Change Disease in the Adult Population Anthony T. Chan, Tom Cairns, Jack W. Galliford, Charles D. Pusey, Megan Griffith. *Imperial College Renal and Transplant Centre, London, United Kingdom.*

Background: Minimal change disease (MCD) in adults is usually steroid responsive but the relapse rate is high, and some patients may develop steroid dependent disease. Tacrolimus has been used for relapsing/ steroid dependent MCD, however, the relapse rate during treatment has not been studied in adult population.

Methods: This is a retrospective cohort study of 27 patients with relapsing MCD treated with tacrolimus from 2011-2017. 21 males and 6 females with average age of 40.7 years old (Range 16- 80 years old). All patients had relapsing disease and 5 of 27 patients were steroid dependent. Prior to treatment with tacrolimus, 16 patients had 1 relapse, 3 patients had 2 relapses and 8 patients had 3 or more relapses. 23 patients had previously been treated with prednisolone alone, 2 patients had cyclophosphamide and prednisolone and 2 patients received cyclosporine and prednisolone.

Results: 15 of 27 patients remained in remission after receiving tacrolimus, with an average treatment time of 28 months (Range 3 to 69 months) and all these patients remain on maintenance therapy. 12 of 27 patients had a further relapse after commencing treatment with tacrolimus, average treatment time of 23.6 months (Range 3-65 months). 8 of 12 patients relapsed while still taking tacrolimus, with average treatment time of 21.3 months (Range 5-65 months), but 5 of these 8 patients had sub-therapeutic levels at time of relapse (<5 ng/ml). 4 of 12 patients relapsed after stopping tacrolimus with average time to relapse after stopping of 2.25 months (Range 2-3 months). The average estimated glomerular filtration rate before tacrolimus was 83.9 ml/min/1.73m^2 (Range 24-90 ml/min/1.73m^2) and during treatment was 85.73 ml/min/1.73m^2 (Range 48-90 ml/min/1.73m^2).

Conclusions: Tacrolimus is an effective treatment for relapsing MCD in adult. Patients often require long term maintenance treatment with careful drug level monitoring to avoid relapse. In this cohort all patients who had stopped tacrolimus went on to relapse. Retrospective extension of the study cohort is ongoing to investigate the optimal length of treatment with tacrolimus required to prevent future relapse, to facilitate design of a randomised controlled trial.

TH-PO154

Initial Therapy of Primary FSGS with Calcineurin Inhibitors Decreases Steroid Exposure without Compromising Renal Response Carlos A. Ch?vez-Mendoza, Jose A. Nino-Cruz, Ricardo Correa-Rotter, Juan M. Mejia-Vilet. *Nephrology and Mineral Metabolism, National Medical Sciences and Nutrition Institute Salvador Zubirán, Mexico City, Mexico.*

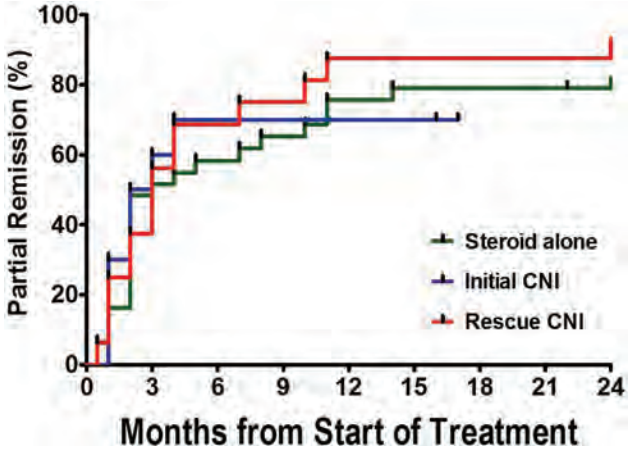
Background: Reduction of corticosteroid exposure has been a relevant focus in the management of glomerular diseases. High-dose glucocorticoid remains first-line therapy in primary FSGS, reserving calcineurin inhibitors (CNI) to patients with resistant disease or contraindication to corticosteroids.

Methods: Observational cohort. Sixty-two patients were segregated into 3 groups: high-dose steroid (n=35), initial CNI+low-dose steroids (n=11), rescue CNI+steroids (n=16). Groups were compared by survival analysis for complete (CR) and partial remission (PR), time to relapse (TTR), doubling of creatinine (DCr), end-stage renal disease (ESRD). Factors associated with each outcome were obtained by Cox-regression.

Results: Median follow-up was 44 months (IQR 24-69). There were no differences in time to CR/PR between steroid and initial CNI group (p=0.592 and p=0.962). Initial

CNI group had a shorter time to prednisone taper<10mg and lower cumulative steroids. There were no differences between the groups in TTR, DSCr, and renal survival. Although the rescue-CNI represented a steroid-resistant/dependent population, this group had no differences when compared to steroid and initial CNI groups. No differences in hospitalizations for infectious events between were observed in the three groups. The factors associated with lower renal survival were higher baseline creatinine, proteinuria, and chronicity score in the renal biopsy.

Conclusions: Treatment of FSGS with CNI as a first-line therapy may reduce exposure to steroids with similar response.



Multivariate Cox regression survival curves for partial remission according to the group of induction therapy for primary FSGS.

Five Year Outcome of Steroid Resistant Focal Segmental Glomerulosclerosis (FSGS) Treated with Tacrolimus Harbir S. Kohli,[2] Raja Ramachandran,[1] Krishan Lal L. Gupta.[3] *[1]Nehru Hospital, Chandigarh, India; [2]Post Graduate Institute of Medical Education and Research (PGIMER), CHANDIGARH, India; [3]Postgraduate Institute of Medical Education & Research, Chandigarh, India.*

Background: Calcineurin inhibitors (CNIs) are recommended for steroid-resistant (SR) nephrotic syndrome (NS) due to focal segmental glomerulosclerosis (FSGS) by KDIGO as the 1st line agents. We reported earlier a remission in 52% at 1year. CNI use is limited by relapse after stopping and nephrotoxicity on prolonged use. The objective of the study was to report the 5 year outcome of patients treated initially with tacrolimus (TAC) for SR-FSGS.

Methods: Patients were treated with TAC (trough level 5–10 ng/ml) and prednisolone (0.15 mg/kg/d). TAC was discontinued in nonresponders at 24 weeks(TAC resistant). TAC was continued for 48 weeks in responders. After completing the study period, patients were managed as per treating physicians discreetion. Patients were followed up furthur for 4 years or till end stage renal disease (ESRD)/death. Primary outcomes, doubling of serum creatinine, ESRD or death and secondary outcomes remission rate (CR and PR) and persistent NS were studied.

Results: Of 44 who received TAC, at 48 weeks, CR and PR were achieved in 17 (38.6%) and 6 (13.6%) respectively, 21 (47.7%) patients were TAC resistant. At end of 5 years of starting therapy, 2 patients were lost to follow up 1 in each group. Of 22 responders14 (61%) had relapse on stopping TAC, they were restarted on TAC for another year. Four had sustained remission, while 4 became TAC dependent and 6 TAC resiatant. Of 4 Tac dependent, 3 responded to rituximab, only 2 of 6 TAC resistant received rituximab of which 1 responded. while others took ACE inhibitors or indigenous drugs. Kidney biopsy done in 8 patients after 2 years of TAC showed chronicity. Of 20 TAC resistant 2 of 3 who received rituximab responded. At the end of 5 years of starting TAC, in responders CR, PR, persistent NS, CKD, ESRD and death were seen in 3 (13.6%), 13 (59.1%), 5 (22.7%), none, 1 (4.6%) and none respectively, and amongst resistant patients1 (5%), 2 (10%), 3(15%), 3 (15%), 7 (35%) and 4 (20%). Fourteen (70%) patients with resistant disease had attained primary outcome compared to 1 (4.5%) in the remission group (p=0.0001).

Conclusions: TAC resistance portends poor prognosis with 70% having doubling of serum creatinine, ESRD or death at the end of 5 years. TAC dependency was seen in 60% of the initial TAC responders. Rituximab appears to be promising agent in both TAC dependent and resistant patients.

TH-PO156

Repeat Rituximab Dosing Is Often Necessary but Effective in Relapsing Minimal Change Disease in Adults Nikki L. Wong,[3] Tom Cairns,[1] Jack W. Galliford,[2] Charles D. Pusey,[3] Megan Griffith.[3] *[1]IMPERIAL COLLEGE HEALTHCARE, LONDON, United Kingdom; [2]Imperial College Kidney and Transplant Institute, London, United Kingdom; [3]Imperial College London, London, United Kingdom.*

Background: Rituximab (RTX) is increasingly being used for relapsing minimal change disease (MCD) in adults, but data is lacking on the need for and efficacy of multiple dosing regimens.

Methods: We retrospectively reviewed 19 patients treated with RTX for relapsing, or steroid resistant MCD between 2006-2017. Median age at treatment was 35 years (20-66), mean time from diagnosis 15 years (1-39), and mean relapse rate was 4/last 3 years. Previous maintenance treatment included steroids (17/19), tacrolimus (19/19), ciclosporin (6/19), mycophenolate (1/19), cyclophosphamide/chlorambucil (8/19) and levamisole (3/19).

Results: 19 patients received RTX. 8 patients were nephrotic, and 11 were in complete or partial remission at time of treatment. B-cell depletion was achieved in all patients. 10 patients had more than one RTX course [mean 2 (1-4)], the mean follow-up was 34 months (1-127). Of 8 patients who were nephrotic at RTX initiation, 6 achieved complete or partial remission and 2 failed to respond. 1/2 was steroid resistant and on subsequent rebiopsy was found to have FSGS, the other was steroid intolerant. Of 17 patients in remission post RTX, 9 had no further relapse at mean follow-up of 17 months (1-60). 3/9 received a second course of RTX after a mean 13 months (9-16). At last follow-up 5/9 have reconstituted B-cells (>10) at a mean of 6 months post RTX (1-11), while 4/9 remain B-cell deplete. 8/17 patients relapsed post RTX, at a mean 13 months (5-35). All relapsed patients had B-cell reconstitution at time of relapse. 7/8 who relapsed had a second course of RTX. 6 of these 7 relapsed again at a mean of 22 months (7-53) post redosing, 5 of these 6 patients received a third course of RTX. All 5 are now in remission and relapse free at a mean 7 months (1-14). 1 patient received a prophylactic fourth RTX course at B-cell reconstitution. There were no serious infusion reactions; and one case of *Pneumocystis* infection requiring hospitalization.

Conclusions: RTX is effective for relapsing MCD in adults, but repeated treatment courses may be required. B-cell reconstitution is associated with relapse and may be helpful in guiding prophylactic redosing in some patients. Nonresponse to RTX may suggest underlying FSGS. Further trials are needed to determine which patients will relapse and appropriate dosing regimens for maintenance RTX therapy.

Rituximab Treatment of Minimal Change Disease (MCD) and Focal Segmental Glomerulosclerosis (FSGS) in Adults Renu Regunathan-Shenk, Andrew S. Bomback, Pietro A. Canetta, Wooin Ahn, Gerald B. Appel. *Columbia University College of Physicians and Surgeons, New York, NY.*

Background: Previous retrospective and prospective studies have suggested that rituximab may be an effective therapy for patients (Pts) with MCD and FSGS who have failed other therapies. Most studies have had small numbers of Pts and consisted largely of children.

Methods: We reviewed the charts of 58 adults (41 male) evaluated at Columbia University Medical Center between 2014 - 2017 who received rituximab for MCD or FSGS. We analyzed clinical, biopsy, and laboratory data pre-infusion and at follow up (F/U). We categorized Pts as frequently relapsing/steroid dependent (FRSD), infrequently relapsing (IR), steroid resistant (SR), and multi-drug resistant (MDR) based on their clinical course prior to rituximab.

Results: On renal biopsy, 31 Pts had MCD, 22 had FSGS, and 5 had podocytopathy associated with another diagnosis (e.g. IgA Nephropathy with MCD). There were 34 Whites, 13 Latinos, 6 Blacks, and 5 Asians. Disease category included 33 FRSD, 2 IR, 6 SR, and 17 MDR. Three patients (all FRSD) were excluded from further analysis; 2 Pts had <1 month (mo) of F/U and 1 was unable to complete treatment due to infusion reaction. The median number of immunosuppressant (IS) medications used prior to rituximab was 3 (range 1-6). The median number of concurrent IS was 1 (range 0-3) at time of infusion and 0 (range 0-2) at F/U. The median F/U was 15.8 mo (range 1.4-159). 62% (37/55) achieved a complete remission (CR, UPC <0.5 g/gCr) or partial remission (PR, UPC 0.5-3.5 g/gCr) during the F/U period; 32 remained in CR or PR and 5 relapsed by last F/U. Of patients in remission at last F/U, 13/22 Pts in CR and 5/10 Pts in PR were off all other IS. Of 23 Pts not in remission at last F/U, 12 never achieved CR or PR, 5 had relapsed, and 6 had progressed to ESRD. Of 17 MDR Pts, 3 achieved CR or PR after rituximab, 3 achieved CR or PR on other IS, and 11 never achieved CR or PR, with 3 progressing to ESRD. 18 Pts repeated rituximab treatment, 9 prophylactically, and 9 for treatment of relapse with all responding.

Conclusions: This is the largest study showing the benefit of rituximab in achieving remission of proteinuria and reduction of immunosuppression in adults with MCD or FSGS. Pts with MDR disease were less likely to respond to rituximab.

TH-PO158

Continuous B Cell Depletion for Resistant, Steroid Dependent, and Relapsing Nephrotic Syndrome in Adults Frank B. Cortazar, Colleen B. Dunbar, Karen A. Laliberte, John Niles. *Nephrology, MGH, Boston, MA.*

Background: The clinical course of minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) can be complicated by resistance to treatment, steroid dependence, and frequent relapses. Treatment options for such patients are limited. We present a retrospective series of patients with these phenotypes treated with rituximab (RTX)-induced continuous B cell depletion.

Methods: Patients were included if they had biopsy proven MCD or FSGS that was resistant, steroid dependent, or relapsing. All patients had a UPCR ≥ 3.5 g/g and were treated with RTX-induced continuous B cell depletion. Resistant disease was defined as failure to achieve a partial remission (PR) with prednisone at 1 mg/kg per day for 3 months or a calcineurin inhibitor or mycophenolate mofetil. Steroid dependence was defined as relapse during or within 2 weeks of steroid tapering. Relapsing disease was defined as at least two prior relapses. PR was defined as a urine protein:Cr ratio (UPCR) of ≤ 3.5 g/g and a 50% reduction from baseline, while CR was defined as a UPCR ≤ 0.3 g/g. Relapse after any remission was a UPCR ≥ 3.5 g/g.

Results: We identified 11 patients who met the inclusion criteria (Table). Over a median followup of 4.5 years (IQR, 2-5), patients received a median of 9 RTX doses (IQR, 8-15) and were in a state of B cell depletion for 3.7 years (IQR, 2-5). All patients entered PR at a median time of 89 (IQR, 34-144) days and 7 patients entered CR at a median of 362 (IQR, 34-1208) days. Prednisone dose was tapered from 60 mg/d (IQR, 15 to 60) at entry to 5 mg/d (IQR 0-7.5) at 1 year. Three patients sustained a relapse after PR, but all subsequently obtained a remission. No relapses occurred following CR.

Conclusions: Continuous B cell depletion is an effective treatment strategy for complicated cases of MCD and FSGS. Additional studies are needed.

High Doses of Rituximab Are Ineffective in Adult Patients with Focal Segmental Glomerulosclerosis Dario Roccatello,[1] Savino Sciascia,[2] Roberta Fenoglio.[1] *[1]Ospedale San GIovanni Bosco, Torino, Italy; [2]Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Torino, Italy.*

Background: a beneficial effect of rituximab on Focal Segmental Glomerulosclerosis (FSGS) in pediatric patients or in transplant recipients has been reported in isolated cases. However, the use of Rituximab in adult patients with idiopathic FSGS needs further investigation.

Methods: Eight patients who had biopsy-proven FSGS (63.9±14.0, range 40-81 yr, 4 women, 4 men) with major risk factors precluding corticosteroids or conventional immunosuppression were treated with high dose of rituximab (8 weekly doses of 375mg/m^2) and prospectively followed up for at least 2 years (29.1 ± 8.8 mo, range 24 to 42 mo).

Results: Rituximab failed to improve proteinuria in seven out of 8 patients, who had persistent nephrotic proteinuria. In one case, a rapidly deteriorating renal function was also observed. Only one patient showed an improvement of renal function and a remarkable proteinuria reduction. There were no differences in clinical or laboratory characteristics or in the CD20 B lymphocyte count after rituximab between the responder and the 7 non responders patients

Conclusions: Only a minority (one of eight) in our series of adult patients with FSGS showed positive effects of high doses of rituximab. Future studies are warranted to investigate more promising therapeutic options in the management of FSGS.

TH-PO160

Cetirizine and Montelukast Combination Therapy in Patients with Minimal Change Nephrotic Syndrome Concomitant with Allergic Disorders: A Single Center Study Yoichi Oshima,[1] Keiichi Sumida,[1] Masayuki Yamanouchi,[1] Junichi Hoshino,[1] Yoshifumi Ubara.[1,2] *[1]Nephrology Center, Toranomon Hospital, Kawasaki, Japan; [2]Okinaka Memorial Institute for Medical Research, Tokyo, Japan.*

Background: In minimal change nephrotic syndrome (MCNS) glucocorticoid treatment is a major therapeutic option; however glucocorticoid may cause many adverse effects since most patients with MCNS are dependent on glucocorticoid. It is known that MCNS often complicates with allergic diseases. We investigated if anti-allergy therapy with cetirizine and montelukast have therapeutic effect in disease control for MCNS.

Methods: We identified 125 patients who were diagnosed as MCNS by renal biopsy in our hospital between 1985 and 2015. As shown in figure 1, 15 patients were included in this study. Patients were evaluated by minimum glucocorticoid maintenance dose.

Results: Average age at the time of onset was 33.2 years. Nine out of 15 patients were men (60%). Average number of relapses was 4.3 times. Average duration of corticosteroid treatment before the study was 211.3 months. Complicated allergic disorders were allergic rhinitis in ten patients (66.7%), atopic dermatitis in eight (53.3%), sinusitis in five (33.3%), drug allergy in four (26.7%), food allergy in three (20%), and asthma in two (13.3%). Average predonisolone dose at the start of the study was 3.78 (range: 0.5-10) (mg/day). Eleven patients (73%) became glucocorticoid free without relapse for more than 28 months, while only three relapsed (20%). After the treatment, minimum predonisolone maintenance dose was 0.038 (mg/day) compared to 0.858 (range: 0-4) (mg/day) before the treatment (p=0.042, Wilcoxon nonparametric paired test).

Conclusions: Cetirizine and montelukast therapy may have steroid sparing effect in allergy concomitant relapsing MCNS.

Dyslipidemia and Outcomes in NEPTUNE Christine B. Sethna,[2] Kevin E. Meyers,[5] Tammy M. Brady,[3] Crystal A. Gadegbeku,[4] Tarak Srivastava,[1] Keisha L. Gibson,[8] Matthias Kretzler,[6] Laura H. Mariani.[7] *[1]Childrens's Mercy Hospital, Kansas City, MO; [2]Cohen Children's Medical Center of NY, New Hyde Park, NY; [3]Johns Hopkins University, Baltimore, MD; [4]Temple University, Philadelphia, PA; [5]The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [6]U.Michigan, Ann Arbor, MI; [7]University of Michigan, Ann Arbor, MI; [8]University of North Carolina Kidney Center, Chapel Hill, NC. Group/Team: NEPTUNE Cardiovascular Working Group.*

Background: Patients with nephrotic syndrome (NS) have a pronounced alteration in lipoprotein metabolism. Dyslipidemia is a major risk factor for cardiovascular disease and may be associated with progression of renal disease; however, this has not been well characterized in NS.

Methods: Baseline lipid studies from the Nephrotic Syndrome Study Network (NEPTUNE) were collected. Dyslipidemia was defined as total cholesterol ≥200 mg/dL, HDL <40 mg/dL, LDL ≥130 mg/dL or triglycerides ≥100 mg/dL (0-9 yr), ≥130 mg/dL (10-17 yr), ≥50 mg/dL (≥18 yr). Cox regression adjusted for age, sex, race, disease, disease duration, baseline eGFR and urine protein:creatinine [UPC] examined the association of lipids (per 10 unit increase) with the Composite Outcome (End Stage Renal Disease or eGFR decline by ≥40%) and first Complete Remission (UPC ≤0.3).

Results: 271 adults (45.4±16.1 yr, 62% M) and 123 children (10.2±4.8 yr, 59% M) were evaluated. At baseline, 85% of participants had dyslipidemia (table). In the overall group, lower HDL and greater triglycerides were associated with increased hazard of the composite outcome (HR 0.91, 95%CI 0.83-0.98, p=0.02 and HR 1.02, 95%CI 1.001-

1.03, p=0.001, respectively). Greater HDL (HR 1.05, 95%CI 1.001-1.1, p=0.045) was associated with increased hazard of Complete Remission. Similar relationships were found in adults for Composite Outcome (HDL: HR 0.88, 95%CI 0.79-0.98, p=0.03; triglycerides: HR 1.01, 95%CI 1.001-1.03, p=0.04) and Complete Remission (HDL: HR 1.1, 95%CI 1.03-1.18, p=0.006). In children, greater triglycerides (HR 1.05, 95%CI 1.02-1.08, p=0.001) were associated with increased hazard of the Composite Endpoint. Lipids were not associated with Complete Remission.

Conclusions: In NEPTUNE, dyslipidemia is common and is an independent predictor of renal outcomes.

Cross Sectional Study on the Clinical Manifestations of Focal Segmental Glomerular Sclerosis (FSGS) in Japan from the Data of the Japan-Renal Biopsy Registry (J-RBR) Takaya Ozeki,[2] Shoichi Maruyama,[2] Takehiko Kawaguchi,[4] Toshiyuki Imasawa,[4] Ritsuko Katafuchi,[3] Hiroshi Sato.[1] *[1]Clinical Pharamacology and Therapeutics, Graduate School of pharmaceutical Sciences, Tohoku University, Sendai, Japan; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]National Fukuoka-Higashi Medical Center, Koga, Fukuoka, Japan; [4]National Hospital Organization Chiba-East Hospital, Chiba, Japan.*

Background: Even though the clinical manifestations of FSGS varies amomg the underlying etiology, few reports had described the detail of its features comparing with MCD. J-RBR: Japanese nationwide registry started in 2007 and it has 32870 biopsy cases until December 2016. The aim of this study was to clarify the clinical characteristics of FSGS through analyzing the data of J-RBR.

Methods: A cross sectional study; patients were diagnosed with FSGS or MCD and were registered in J-RBR during 2007-2016. **<Analysis 1>** 1409 cases who were registered with histopathological diagnosis of FSGS were divided to 3 subgroups by age; Children (<18)/ Adult (18-64)/ Elderly (65≤), and clinical parameters were compared between subgroups. **<Analysis 2>**To compare the clincal features between nephrotic FSGS and MCD, patients who filfilled the criteria below were selected from the database. Criteria; histopathological diagnosis as FSGS or MCD, clinical diagnosis of nephrotic syndrome and over 18 years old.

Results: **<Analysis 1>**Among the 3 groups; Children (n=166), Adult (n=904), Elderly (n=339), the percentages of clinical diagnosis of nephrotic syndrome was 62.1, 32.9, 56.1 respectively. Adult group showed the lowest incidence of nephrotic syndrome. **<Analysis 2>**As compared with MCD (n=1522), FSGS (n=419) patients had higher age (FSGS: 59 vs MCD: 47.5) and higher rate of hypertension. And FSGS patients showed lower kidney finction (creatinine: 1.03 vs 0.83 mg/dL), higher serum albumin (2.2 vs 1.8 g/dL) and lower unine protein level (5.40 vs 6.28 g/day) at biopsy.

Conclusions: The incidence of nephrotic syndrome in FSGS patients was different among the age groups. Although FSGS patients showed lower kidney function and relatively milder proteinuria compared with MCD, it seemed to be difficult to distinguish these diseases only by initial clinical informations.

Improvement of Clinical Outcome in Kidney Diseases via the On-line Thai Glomerular Disease Registry: Focal Segmental Glomerulosclerosis Noppanit Pattanachaiwit,[2] Suchin Worawichawong,[1] Boonyarit Cheunsuchon,[5] Ngoentra Tantranont,[5] Warangkana Pichaiwong,[4] Pornpen Sangthawan.[3] *[1]Pathology, Ramathibodi Hospital, Bangkok, Thailand; [2]Medicine, Bhumibol Adulyadej hospital, Bangkok, Thailand; [3]Medicine, Prince of Songkla University Hospital, Songkhla, Thailand; [4]Medicine, RAJAVITHI HOSPITAL, Bangkok, Thailand; [5]Pathology, Siriraj hospital, Bangkok, Thailand.*

Background: Focal segmental glomerulosclerosis (FSGS) is one of the most common cause of end stage renal disease (ESRD) in adults. FSGS is more common in African-Americans than Asians. In Thailand, the data of FSGS have not been well determined. This study was conducted to investigate the prevalence and outcomes of FSGS via using the data from the on-line registry from Thai Glomerular Disease Collaborative Network (TGCN).

Methods: The data of biopsy-proven FSGS in adults were collected by the on-line registry from July 2014 to March 2017. Patients' clinical data including histopathological diagnosis at baseline, and clinical outcomes at 24, 48 and every 48 weeks after renal biopsy were analyzed.

Results: FSGS was diagnosed in 170 patients (10.9%) from 1,556 renal biopsy specimens. At the time of biopsy, 44.2% of FSGS was male, the mean age was 47.5±16.9 years, median serum creatinine level was 1.7 mg/dL (0.42-8.33), median urine protein creatinine ratio (UPCR) was 4.36 g/g. Cr (0.08-25.3), mean serum albumin (sAlb) was 2.8±0.9 g/dL. Nephrotic syndrome was 75%, whilst nephrito-nephrotic syndrome was only 2%. Most common histologic variant was not-otherwise-specified (NOS) (80.7%) followed by tip lesion (10.0%), perihilar variant (3.6%), cellular variant (3.6%), and collapsing FSGS (2.1%). At 24-week follow up, 22.9% of patients had complete remission and 62.7% had partial remission. The median time to all remission was 5.7 months. The only factor that was significantly associated with the remission rate was the percentage of tubular atrophy more than 50% with HR 0.24 (95%CI 0.07-0.81, *p = 0.021*) Three patients developed ESRD during the period of study.

Conclusions: The prevalence of FSGS in our study was 10.9%. NOS was the most common histologic variant. The severity of tubular atrophy was the only significant poor prognostic factor. *Funding: Health Systems Research Institute, and Nephrology Society of Thailand support*

Incidence of Focal Segmental Glomerulosclerosis in Olmsted County Musab S. Hommos,[2] An S. De Vriese,[1] Mariam P. Alexander,[2] Sanjeev Sethi,[2] Lisa E. Vaughan,[2] Kharmen A. Bharucha,[2] Ladan Zand,[2] Nicola Lepori,[3] Andrew D. Rule,[2] Fernando C. Fervenza.[2] *[1]AZ Sint-Jan, Bruges, Belgium; [2]Mayo Clinic, Rochester, MN; [3]Ospedale Brotzu, ----Cagliari, Italy.*

Background: Focal segmental glomerulosclerosis (FSGS) incidence is increasing. However, previous studies reported trends in relative disease frequencies and presented FSGS as a single disease entity. We now know that FSGS is a histological pattern of injury caused by a variety of conditions. Thus, we evaluated the incidence of primary vs. secondary FSGS in a population-based study.

Methods: Olmsted County residents with native kidney biopsy between 1994 and 2013 that showed FSGS as the only glomerulopathy were identified. Primary FSGS was defined as having nephrotic syndrome (serum albumin ≤3.5g/dl and proteinuria ≥3.5g/24h), foot process effacement ≥ 80% and no identifiable causes. Age and sex adjusted incidence rate per 100,000 person-years was calculated. Poisson regression models estimated the change in incidence rate over time.

Results: Among 370 adults biopsied during this period, 281 had glomerular disease of which 46 (16%) had FSGS as the only glomerulopathy.(Table 1) Estimated native

kidney biopsy incidence rates were significantly higher in 2004-2013 compared to 1994-2003 (22.9 vs. 14.7 per 100,000 person-years, 17% increase per 5 years, p<0.001). Total FSGS incidence rates also increased over the same time period from 1.4 in 1994-2003 to 3.2 per 100,000 person-years in 2004-2013 (41% increase per 5 years, p=0.02). Secondary FSGS accounted for 9/12 (75%) of cases during 1994-2003 and 25/34 (74%) of cases during 2004-2013.

Conclusions: The majority of cases are secondary FSGS. While the incidence of FSGS has increased over the past two decades, the proportion of primary and secondary FSGS has remained stable. Further studies are needed to understand the causes of this increasing Incidence though increasing biopsy rates may be a contributor. Importantly, primary FSGS rate remains low (0.85 per 100,000 person-years).

Table 1: Characteristics of FSGS patients by FSGS subtype and decade of biopsy

	1994-2003		2004-2013

Improvement of Clinical Outcome in Kidney Diseases via the On-line Thai Glomerular Disease Registry: Minimal Change Disease Pattharawin Pattharanitima,[6] Ratana Chawanasuntorapoj,[3] Warangkana Pichaiwong,[2] Pornpen Sangthawan,[1] Ngoentra Tantranont,[4] Boonyarit Cheunsuchon.[5] *[1]Prince of Songkla University Hospital, Songkhla, Thailand; [2]RAJAVITHI HOSPITAL, Bangkok, Thailand; [3]Siriraj Hospital, Bangkok, Thailand; [4]Siriraj Hospital, Mahidol University, Bangkok, Thailand; [5]Siriraj hospital, Bangkok, Thailand; [6]Thammasat University, Pathumthani, Thailand. Group/Team: Thai Glomerular Disease Collaborative Network (TGCN).*

Background: The data on prevalence, clinical characteristics and outcomes of minimal change disease (MCD) in Thailand is sparse. The available data came from few medical schools which might not represent the entire Thai population. The Thai Glomerular Disease Collaborative Network (TGCN) was established to determine the prevalence, clinical characteristics, outcomes and prognosis in Thai glomerular disease patients.

Methods: The data collected prospectively from TGCN included adult patients with biopsy-proven glomerular disease from institutes in Thailand participating in TGCN from July 2014 to March 2017. The clinical and renal pathology characteristics, treatment regimens at the time of renal biopsy, clinical outcomes, and complications at 24, 48 and every 48 weeks after renal biopsy were obtained via online data collection forms.

Results: Among 1,556 patients, 115 (7.4%) had MCD. At baseline, 53% of MCD patients were male, the mean age was 46.5 ± 17.2 years, median serum creatinine (sCr) was 1.02 mg/dL (0.5-10.7), mean urine protein creatinine ratio (UPCR) was 5.99±4.72 g/g. Cr, mean serum albumin (sAlb) was 2.4±0.9 g/dL, and mean serum cholesterol (sChol) was 422±194 mg/dL. At 24 weeks, 62% had complete remission, and 19% had partial remission. Median time to remission was 1.5 months. The odd ratio of remission was 3.13 in patients with UPCR >5 *(P=0.047)*. The age, sAlb, sChol, sCr at time of biopsy and pathological characteristics were not different between remission and non-remission groups. The 1.5% of them had doubling serum creatinine, none of them developed ESRD and 1.4% of patient died during the study.

Conclusions: Conclusions: The outcome of the adults with MCD was excellent. The patients with UPCR >5 at baseline had more favorable outcome. *Funding*: Health Systems Research Institute and Nephrology Society of Thailand support

Health Related Quality of Life (HRQOL) in Primary Glomerular Disease: The Initial CureGN Experience Pietro A. Canetta,[1] Sharon M. Bartosh,[2] Yi Cai,[3] Hilda E. Fernandez,[1] Alessia Fornoni,[4] Rasheed A. Gbadegesin,[5] Emily G. Herreshoff,[6] Amy Kogon,[7] John D. Mahan,[7] Shannon L. Mahoney,[8] Patrick H. Nachman,[8] David T. Selewski,[6] Tarak Srivastava,[9] Katherine R. Tuttle,[10] Chia- Shi Wang,[11] Jonathan P. Troost,[6] Debbie S. Gipson.[6] *[1]Columbia University, New York, NY; [2]University of Wisconsin Children's Hospital, Madison, WI; [3]Helen DeVos Children's Hospital, Grand Rapids, MI; [4]University of Miami, Miami, FL; [5]Duke University, Durham, NC; [6]University of Michigan, Ann Arbor, MI; [7]Nationwide Children's Hospital, Columbus, OH; [8]University of North Carolina, Chapel Hill, NC; [9]Childrens's Mercy Hospital, Kansas City, MO; [10]University of Washington, Spokane, WA; [11]Emory University, Atlanta, GA. Group/Team: CureGN Consortium.*

Background: There is little published data on HRQOL in patients with primary glomerular diseases.

Methods: We studied HRQOL in subjects enrolled in CureGN, an international cohort of participants with minimal change disease, FSGS, membranous nephropathy, and IgA nephropathy or IgA vasculitis. HRQOL was assessed at enrollment using the Patient Reported Outcomes Measurement Information System (PROMIS). Domains measured in adults were: Global Assessment of Physical Health, Mental Health, Fatigue, Sleep, and Anxiety; domains in children were: Global Health, Mobility, Fatigue, and Anxiety. Minimally important differences have been defined as score change of 3 for the pediatric domains and have not been defined for adult domains. Immunosuppression (IS) in the past 60 days was classified as None, Glucocorticoids alone, or Other IS. Differences in HRQOL scores are reported as mean [95% confidence interval]. Multivariable analysis was conducted by linear regression with backwards selection.

Results: Data were available from 349 children and 918 adults. In children, multivariable analyses revealed PROMIS Global Health scores were worse with edema (-3.2 [-5.5 to -0.9]) and obesity (-4.5 [-6.9 to -2.1]) but were not significantly different across levels of proteinuria or eGFR. In adults, PROMIS Global Physical Health scores were worse with edema (-6.3 [-7.7 to -5.0]), log UPC (-0.6 [-0.9 to -0.2]), eGFR per -30 ml/min (-1.1 [-1.6 to -0.5]), female sex (-1.8 [-3.1 to -0.5]), and obesity (-3.2 [-4.8 to -1.7]). Race, ethnicity, diagnosis, disease duration, hematuria, and IS were not associated with HRQOL. In multivariable analysis, edema was the strongest predictor of HRQOL across both age groups and PROMIS domains (Figure).

Conclusions: Children and adults with glomerular diseases report a range of HRQOL. Edema was a consistent predictor of poor HRQOL across all measured domains of Global Health, Anxiety, Fatigue, Sleep, and Mobility.

Funding: NIDDK Support

TH-PO167

Cost Analysis on the Use of Rituximab and Calcineurin Inhibitor in Children and Adolescents with Steroid Dependent Nephrotic Syndrome Oluwatoyin F. Bamgbola,[2] Diego H. Aviles,[3] Franca M. Iorember.[1] *[1]Phoenix Children's Hospital, Scottsdale, AZ; [2]SUNY Downstate Medical Center, Brooklyn, NY; [3]Dept. of Pediatrics, Louisiana state university health science center, New Orleans, LA.*

Background: To minimize adverse effects, steroid sparing agents are used in steroid dependent nephrotic syndrome (SDNS). Although effective, the main drawback of calcineurin inhibitors (CNI) is the need for therapeutic drug monitoring (TDM). Apart from proven efficacy, Rituximab produces a long lasting remission after 1 or 2 single intravenous doses. To reduce frequency of clinic visits and cost efficiency, we introduced rituximab particularly in patients living remotely from laboratory facilities.

Methods: A retrospective analysis of pediatric patients with SDNS treated with either CNI &/ or Rituximab from Jan 2008 to Dec 2012 at Children's Hospital of New Orleans, Louisiana. All patients were followed up for a minimum of 12 months. We compared the cost effectiveness, efficacy, and safety profiles of the 2 groups.

Results: Ten patients were treated with Rituximab while 8 received CNI. Baseline data were comparable. Annual cost of treatment was lower with Rituximab ($197,031 vs. $189,856; p > 0.05). Amount expended on Rituximab arm was mostly due to drug cost and mandatory hospitalization for infusion. Due to frequent clinic visits for TDM, cost of outpatient care was more for the CNI ($4383 vs. $7534). There was marginally better control of SDNS with use of Rituximab. Duration of freedom from steroid was twice longer for those treated with Rituximab (p > 0.05). This accounted for twice the annual gain in body mass index in the CNI arm (1.5 kg/m² vs. 0.8 kg/m²). There was no significant side effect in either group. Retrospective design & small sample size limited ability to demonstrate significant findings. In addition, study outcome may vary with

regional differences in health care financial system. Nevertheless, we believe this is the first study of this kind in the pediatric population.

Conclusions: Although Rituximab is marginally more efficacious than CNI, short-term safety profiles are comparable. The annual cost of health care for patients on Rituximab is essentially similar to that of CNI. By cutting the need for frequent outpatient visits, Rituximab may curtail number of school absences, parental loss of wages, and the burden of health care on family. By minimizing the need for steroids and CNI, Rituximab use may avoid hypertension, dyslipidemia, short stature and impairment in renal function.

Patients with Focal Segmental Glomerulosclerosis (FSGS): A Claims Analysis of Clinical and Economic Outcomes Tara A. Nazareth,[2] Furaha Kariburyo,[4] Aaron Kirkemo,[2] Lin Xie,[4] Anna Pavlova-Wolf,[1] Laura Bartels-Peculis,[2] Neel Vaidya,[4] John J. Sim.[3] *[1]Mallinckrodt, Henderson, TX; [2]Mallinckrodt Pharmaceuticals, Hampton, NJ; [3]None, Los Angeles, CA; [4]STATinMED Research, Ann Arbor, MI.*

Background: FSGS is the leading cause of idiopathic nephrotic syndrome (NS) in the US, accounting for 35% of cases (Haas et al., 1997; Kitiyakara et al., 2004). Given the complexity of diagnosis and treatment, many patients with FSGS have renal insufficiency at clinical presentation. Within 10 years, >50% develop kidney failure; post-transplant, FSGS can recur in 30-40% of patients (MedlinePlus FSGS; NephCure FSGS fact sheet). We studied a prevalent cohort to quantify the burden of illness with FSGS.

Methods: Commercially-insured patients ≥18 years with ≥2 diagnoses of FSGS [Diagnosis (Dx) code ICD-9=582.1 or ICD-10: N031, N033, N020, N040] were identified from Truven Marketscan® US healthcare claims data during 1/1/12-12/31/15; the first Dx date was denoted the index date. Patients with claims for secondary causes of NS (Dx) were excluded. During 1 year follow-up, demographics and clinical characteristics, clinical health outcomes, and all-cause healthcare resource utilization [HCRU: emergency room (ER), inpatient (IP), outpatient (OP), and medications (Rx)] were assessed using diagnosis, procedure and drug codes. Costs attributable to HCRU were evaluated in all patients enrolled in fee-for-service plans (FFS), as well as in the top 5% specifically.

Results: 1,187 patients were identified [59.0% male, mean age=45.1 years, with hematuria (17.7%), mean Charlson Comorbidity Index score=2.5, from South and North Central US (62.3%)]. 14.7% of patients had urinary tract infections, 4.6% pneumonia and 2.7% septicemia. 12.5% were placed on dialysis and 4.1% received a renal transplant. 29.0% of patients used the ER and 20.6% had IP stays. 21.9 mean Rx were dispensed. Among FFS patients (n=949), total and mean (SD) costs were $42.1 million and $44,397 ($102,481.8), respectively. 5% of patients (n=47) were responsible for 44.4% of total costs equaling $18.7 million, for a mean (SD) per patient cost of $397,973.8 ($219,457.3); OP, IP, Rx and ER represented 57.2%, 30.5%, 11.8%, and 0.5% of total costs, respectively.

Conclusions: Our study characterizes the 1-year burden of illness with FSGS and identifies a small group of patients incurring high cost, mostly via IP and OP use. Understanding this subset and their unmet needs, as well as their longer-term outcomes and costs, is a priority.

Clinical Features and Outcomes of Collapsing Glomerulopathy Giulia gabriela B. Figueiredo,[2] Lucas B. Mota,[3] Luanne F. Soares,[2] Precil D. Neves,[2] Hady S. Miguel,[4] Leonardo A. Testagrossa,[3] Cristiane B. Dias,[2] Luis Yu,[2] Viktoria Woronik,[1] Lectícia Jorge.[3] *[1]None, Salvador, Brazil; [2]University of Sao Paulo, Brazil, São Paulo, Brazil; [3]University of São Paulo, São Paulo, Brazil; [4]Univertty of sao Paulo, São Paulo, Brazil.*

Background: The collapsing variant of focal and segmental glomerulosclerosis (FSGS) has usually been associated with poor renal outcomes. The aim of our study was to evaluate clinical features and renal outcomes associated with collapsing FSGS.

Methods: A retrospective analysis was carried out on all collapsing FSGS diagnosed by kidney biopsy between 1996-2016. Clinical and laboratory data were collected at baseline and at the end of follow up. Primary outcome (PO) was defined as ESRD or doubling of baseline creatinine.

Results: Clinical features are summarized in table 1. The PO occurred in 54.8% of patients. Pathology data analysis showed a higher prevalence of acute tubular necrosis (ATN) in patients who did not achieved PO, 14,3% versus 0%, with a p value of 0.03. The percentage of interstitial fibrosis was similar in both groups.

Conclusions: Collapsing glomerulopathy is an aggressive disease, and patients who reached the PO had greater baseline proteinuria and less partial or complete remission. As baseline creatinine was not a predictor of PO, perhaps the therapy should not be withheld in patients with high creatinine at presentation.

Clinical aspects of Collapsing FSGS patients

	Baseline	With PO	Without PO
Patients	77	34 (54.8%)	28 (45.2%)
Age (Y)	28.5 (21-38)	24.5 (21-38)	23.5 (30-50.5)
Male	43 (55.1%)	21 (61.8%)	15 (53.6%)
Creatinine (mg/dL)	1.98 (1.2-3.16)	1.6 (1.2-2.2)*	2.2 (1.3-3.7)
Proteinuria (g/day)	5.4 (3.36-10.4)	8.8 (3.8-13.3)*	5.0 (3.6-7.9)
AKI (n.%)	47 (68%)	23 (67%)	20 (71%)
Hematuria	34 (50%)	15 (44%)	14 (50%)
Hypertension	24 (48%)	11 (52%)	12 (43%)
Albumin (g/dL)	2.26 ±0.9	2.0 ±0.8	2.4 ±0.9
Hb (g/dL)	12.5 ±2.2	13.1 ±2.2*	11.9 ±2.1
Final creatinine (mg/dL)	2.8 (1.1-8.5)	8.1 (2.7-12.8)‡	1.2 (0.9-2.3)
Final proteinuria (g/day)	2.8 (0.7-6.16)	4.4 (2.1-9.8)*	0.79 (0.36-3.08)
Follow up (mo)	18.5 (7.8-43.8)	15 (7.3-34.8)	21 (10-52.3)

Intermittent Dosing of Rituximab Induces Long-Term Remission in Children with Steroid Dependent Nephrotic Syndrome Cheryl P. Sanchez, Rita D. Sheth, Drew C. Cutler, Shobha Sahney. *Loma Linda University Children's Hospital, Loma Linda, CA.*

Background: Rituximab is frequently used as an alternative therapy in pediatric patients with nephrotic syndrome.

Methods: 17 children, 10.7 ± 3.4 years old, received rituximab infusion at 375 mg/m^2 per dose weekly x 4 weeks. Renal biopsy showed minimal change, n=10; IgM nephropathy, n=2; FSGS, n=3; C1Q, n=1; no biopsy n=1. All patients were taking prednisone and prograf at the time of rituximab infusion. Prior to rituximab, five out of 17 patients had ≥ 5 relapses per year, 4/17 ≥ 4 relapses per year, 3/17 ≥ 3 relapses per year, 5/17 without remission.

Results: After 4 weekly doses of rituximab, 12 patients (70%) had complete remission, 2/17 had partial remission and 3/17 did not respond to rituximab. Five of 12 relapsed within 6-12 months of receiving rituximab, 4/10 relapsed 12 months after rituximab, 3/13 remained in remission. CD20 levels decreased at 3 months after rituximab compared to baseline (10 ± 8% vs 0.03 ± 0.07%, p<0.05), and started to increase at 6 months, 2.3 ± 3.8%. There was no correlation noted between CD20 levels and proteinuria. Nine out of 12 patients who relapsed received 1.7 ± 0.8 additional doses of rituximab at 12 ± 3.2 months after last relapse, and remained in remission for an additional 6.4 ± 3.4 months. Five out of 9 children were off prednisone and prograf, and 4/9 remained on low dose prograf. One patient who had partial remission developed anaphylaxis to rituximab, but successfully treated with ofatumumab. There were no complications associated with repeated rituximab therapy.

Conclusions: Intermittent doses of rituximab can be used to maintain remission in steroid dependent nephrotic syndrome to avoid long term complications associated with prolonged prednisone and calcineurin therapy.

TH-PO171

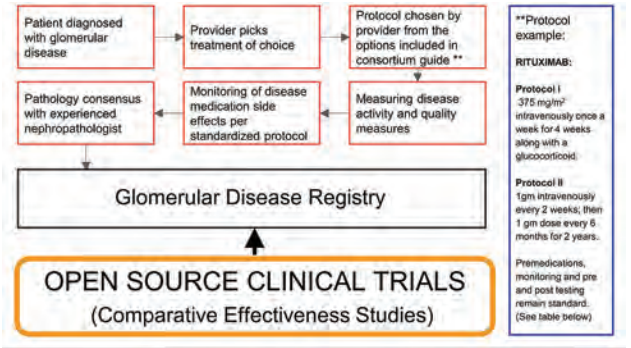
Enabling Large Observational Comparative Effectiveness Studies in Glomerular Disorders Rhea Bhargava,[6] Elizabeth J. Brant,[3] Jorge L. Castaneda,[4] David J. Friedman,[4] Neetika Garg,[6] Michael J. Germain,[5] Martin R. Pollak,[1] Johannes S. Schlondorff,[6] Tripti Singh,[4] Nikhil Agrawal,[6] Isaac E. Stillman,[6] Franco H. Cabeza Rivera,[2] Ali Poyan-Mehr.[4] *[1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [2]University of Mississippi Medical Center, Ridgeland, MS; [3]Dartmouth-Hitchcock Medical Center, Lebanon, NH; [4]None, Watertown, MA; [5]Renal and Transplant Assoc of New England, Hampden, MA; [6]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The heterogeneous presentation of glomerulopathies contributes to ambiguity in diagnosis and management making large comparative studies difficult

Methods: We created a network of nephrologists and nephropathologists in private practice and academic institutions, leveraging collective power to enroll patients to conduct comparative effectiveness studies(The Glomerular Disease Study and Trial Consortium)

Results: Major requirements identified for registry A Consensus on treatment standards & disease monitoring while preserving freedom of treatment selection B Standardized follow up laboratory studies and evaluations at predefined intervals C Review of tissue diagnosis by experienced nephropathologists, pathological work up and classification systems D Cloud-based clinical data repository A web-based, HIPAA secure system has been created for provider referral or patient self-referral for enrollment. Clinical data will be collected and updated quarterly. De-identified data will be available for research to collaborators. **Other opportunities**: Quality improvement measure development(e.g. TB surveillance, pregnancy counselling, diabetes, cancer screening) Active surveillance for therapy-related adverse outcomes (e.g. quality of life, osteoporosis, infection, malignancy)

Conclusions: Developing a synchronized approach for treatment of glomerular disorders will permit large scale comparative effectiveness studies on observational data. We refer to this as "Open Source Clinical Trial" initiative, where each nephrologist may treat patients per individual decision making while following similar protocols, enabling comparative studies of different treatment strategies. www.glomcon.org



Medication	Dosage protocol (questions to be answered by consensus)	Therapy-specific Surveillance, Prophylaxis, and Disease Monitoring (to be determined by consensus after review of current evidence and best practice recommendations)
Steroids	High-dose, low-dose regimen. Taper regimen	TB screening, baseline HbA1c, baseline bone density. Antibiotic prophylaxis, vitamin D, calcium, bisphosphonate, H2 blocker,
Azathioprine	Monitoring and titration protocol. Taper regiment	TMPT activity and genotype. Baseline and serial LFTs, interval CBC.
Rituximab	Dosage and interval of administration	CBC, HBV, B-Cell population. Vaccine status before and during maintenance phase.
Mycophenolate mofetil, Mycophenolate sodium	Up and down titration regimens. Dose equivalency and therapeutic interchange rules	Pre-treatment pregnancy test; contraceptive use; sun prophylaxis, interval blood and urine studies
Methotrexate	Dosage and maintenance therapy protocol	Interval blood and urine studies
CNI: Cyclosporine and tacrolimus	Default regimen and therapeutic interchange rules	Counsel and monitoring for drug-drug interaction, LFT, BMP, lipid panel and HbA1c monitoring
ACEI/ARB	Contraindications and additional interventions (e.g. potassium binder, diuretics)	Counsel about teratogenicity and ensure contraceptive use. Check BP and BMP 7-14 days post initiation
Cyclophosphamide	Harmonization of dosage, route and time course	Assessment of infertility and malignancy risk. Contraception use, and standardized preinitiation screening (pregnancy, Hep B, Hep C, TB (PPD or IGRA), HPV, cervical cancer screening, prophylaxis for PCP; Standardized follow up, including CBC, LFT, annual urine cytology, and long-term cancer surveillance.
Leflunamide		CBC, CMP, BP, contraception use, counselling against pregnancy, Urine pregnancy test. CBC, CMP, BP monitoring every 4 weeks, Neuropathy testing every 4-8 weeks
Bortezomib	New protocol determination	Contraception use , pregnancy test, Cardiac ECHO, pulmonary function test, peripheral neuropathy (monofilament test)
Hydroxychloroquine	Timing and dose titration	Muscle strength (especially proximal), Annual retinal exam

TH-PO172

Development of Nephrotic Syndrome and Tip-Variant Focal Segmental Glomerulosclerosis during Antiviral Therapy for Hepatitis C Virus Infection Arun Rajasekaran,[1] Edward T. Casey,[2] Mario A. Mendoza.[2] *[1]University of Central Florida College of Medicine, Kissimmee, FL; [2]Nephrology, Orlando VA Medical Center, Orlando, FL.*

Background: Focal segmental glomerulosclerosis (FSGS), associated with focal glomerular damage and podocytopathy, is classically accompanied by proteinuria and high rates of renal progression over time. We describe a patient with Hepatitis C virus (HCV) infection who developed nephrotic syndrome during treatment with direct acting antiviral (DAA) therapies, and a kidney biopsy that demonstrated FSGS-Tip variant.

Methods: A 51-year-old white male with treatment-naïve chronic HCV infection (Genotype-2b) was started on velpatasvir and sofosbuvir. After initiation of DAA therapy, he developed myalgias and lower extremity swelling on day 3, after one month his serum albumin was 1.5 mg/dl (previously 3.9 mg/dl) and at week fourteen a 24-hour-urine collection showed 3469 mg of protein. Evaluation revealed a serum creatinine of 0.8 mg/dl, normal ESR and complement levels. HIV, ANA, ANCA, and cryoglobulins were negative. He was started on lisinopril and atorvastatin. A renal biopsy 5 months after start of DAA treatment showed normal sized glomeruli that exhibited segmental increase in mesangial matrix and cellularity. Half of the glomeruli displayed segmental glomerulosclerosis, with cellular features that projected into the initial segment, and adherent to the origin of the proximal tubule segment, fulfilling criteria for glomerular tip lesions. Immunofluorescence revealed negative staining for IgG, IgM, IgA, C3, C1q, albumin, fibrinogen, and lambda and kappa light chains. Electron microscopy depicted visceral epithelial cells with severe diffuse foot process effacement, with no immune-type electron dense deposits. These findings were consistent with FSGS with glomerular tip lesions. High-dose steroids were initiated, and his proteinuria markedly improved in 3 weeks, with a urine protein-to-creatinine ratio of 0.431. He attained sustained virological response at 12 weeks post DAA therapy.

Results:

Conclusions: FSGS is a disease of podocyte injury that leads to proteinuria. We describe a patient with treatment-naïve HCV infection who developed nephrotic syndrome within days after starting DAA therapy and a kidney biopsy 5 months later revealed tip-variant FSGS. His proteinuria markedly improved after high-dose steroid therapy. Physicians should be aware of this newly emerging renal adverse effect associated with DAA therapy.

TH-PO173

Effects of Rituximab in Adult Patients with Minimal Change Disease Dario Roccatello, Savino Sciascia, Roberta Fenoglio. *Ospedale San GIovanni Bosco, Torino, Italy.*

Background: Minimal change disease (MCD) accounts for 15-20 % of adult nephrotic syndrome cases; adult-MCD patients (pts) may have more severe clinical features than pediatric pts. Therefore, active therapy and remission are very relevant for these patients. In children, rituximab (RTX) has been used since 2006 to treat frequently relapsing NS. In adults, data about the efficacy of RTX for MCD is limited. It is still not clear whether RTX is best used to induce remission or to maintain it, what the optimal dose should be and whether repeated doses improve response rates and prolong remission. We report a monocentric experience on the use of RTX in adult biopsy-proven MCD

Methods: Our series includes 5 adult pts (2 males and 3 females), aged 27-73 yrs treated with RTX (4 weekly doses of RTX 375 mg/m2 or 1 gr two weeks apart). RTX was administrated as a rescue therapy in 2 pts (1 pt with previous long term corticosteroid therapy; 1 pt received corticosteroids and immunosuppressive drugs in infancy). 3 pts with major risk factors precluding corticosteroids or conventional immunosuppression received RTX as a first-line treatment.

Results: Proteinuria decreased from 8.4 (19.5-4.8) g/24 h to 0.03 g/24 h after 6 months; creatinine decreased from 1.44 (0.7-3.2) mg/dl to 0.86 (0.7-1.1) mg/l. 3 pts achieved a complete renal remission, in 1 pt proteinuria decreased by 50%. 1 pt didn't achieved any response at 10 months; a ri-biopsy showed a focal-segmental-glomerulosclerosis. RTX successfully depleted CD19 lymphocytes in 100% of pts for at least 6 months. The follow-up ranged from 3 months to 24 months. No clinically relevant adverse events have been observed.

Conclusions: Our study shows a remarkable efficacy of RTX in treatment of MCD. RTX can be an attractive alternative as induction therapy or to manage recurrent forms of MCD. RTX may be preferentially used in pts at a high risk of development of the adverse effects of corticosteroids and should be considered as an important treatment alternative in patients with recurrent nephrotic syndrome. Randomized controleld trials are needed to confirmed our observations.

IgA Nephropathy in a Patient with Alcoholic Cirrhosis Itunu O. Owoyemi,[2] Negiin Pourafshar,[1] Julia Iezzoni,[3] Tushar Chopra.[2] *[1]None, Gainesville, FL; [2]University of Virginia, Charlottesville, VA; [3]University of Virginia Health System, Charlottesville, VA.*

Background: Impaired removal of IgA-containing complexes in the liver is thought to predispose to IgA deposition in the kidney. Portal hypertension has been implicated in IgA nephropathy in cirrhotic patients through various mechanisms leading to decreasing hepatic processing of IgA Immune complexes. Despite the frequency of glomerular IgA deposits in advanced liver disease, most adults have no clinical signs of glomerular disease. There is a dearth of literature regarding differentiation of primary and secondary IgA nephropathy (IgAN) in cirrhotic patients.

Methods: We report a 52-year-old male with alcoholic liver cirrhosis complicated by portal hypertension who presented with a recent history of fatigue and skin rash for three weeks. The serum creatinine (SCr) had increased from baseline 2.1mg/dl to 3.2 mg/dl with proteinuria of 6.5 g/g. Measured serum IgA level was elevated at 599.2 mg/dL (68-378 mg/dL). He had a MELD score of 17. Urinalysis was significant for microscopic hematuria. His kidney biopsy revealed a mild increase in mesangial cellularity, lambda mesangial predominance, endocapillary hypercellularity with moderate tubular atrophy and moderate interstitial fibrosis consistent with a diagnosis of IgA nephropathy. Skin rash was in line with psoriasis. The patient was eventually discharged home on conservative management with losartan, and fish oil. On follow-up, his SCr was 3.1mg/dl, and proteinuria decreased to 2 g/g.

Results:

Conclusions: Our case highlights the inherent difficulty in recognition of primary and secondary IgA nephropathy in the setting of liver cirrhosis which would result in difficulty in decision making regarding proper management. We present a case of primary IgAN with diffuse staining of IgA in the glomeruli, and lambda mesangial dominance. In IgAN, lambda is usually, but not invariably, stronger than kappa. Kappa dominance and focal IgA staining not involving all the glomeruli, slightly favors secondary IgAN. Primary IgAN is rarely associated with nephrotic syndrome. Given his multiple co-morbidities, conservative management of IgA nephropathy was implemented. Cirrhotic glomerulonephritis is usually a clinically silent disease; however, the diagnosis can be suspected by finding proteinuria or abnormalities of the urine sediment. The pathogenesis may relate to defective hepatic processing and portocaval shunting of circulating immune complexes.

TH-PO175

A Unique Case of IgA Cryoglobulinemia in the Setting of Staphylococcus aureus Infection Stephen L. Jenkins, Pace Romney, Catreena Marji, Laith Al-Rabadi. *University of Utah Hospital, Salt lake, UT.*

Background: IgA cryoglobulinemia is a rare entity with scarce literature regarding its pathogenesis and management. Herein, we describe a case of IgA cryoglobulinemia in the setting of Staphylococcus aureus infection.

Methods: A 75-year-old Caucasian man presented to the hospital with a two-week history of progressive weakness, lower extremity edema and decreased urine output. He was in acute renal failure with a serum creatinine of 8 mg/dL and serum potassium of 7

mmol/L. Urinalysis upon presentation was strongly positive for protein and blood. Urine microscopy revealed many red blood cells that were normal in shape with no cellular casts. Acute hemodialysis was initiated for hyperkalemia. His history was relevant for a chronic left foot ulcer infected with methicillin-sensitive Staphylococcus aureus (MSSA), for which he was receiving antibiotics. He was found to have a low serum C3 level of 41 mg/dL and a normal C4 at 28 mg/dL. Serum cyroglobulins were detected. Further workup was negative for ANA, ANCA, anti-GBM antibody and hepatitis serologies. Immunofixation serum testing revealed a polyclonal increase in IgA without monoclonal proteins. Biopsy of the kidney was performed and revealed glomeruli with diffuse endocapillary proliferation, frequent luminal neutrophils, few weakly PAS-positive hyaline thrombi, and more than 50% cellular crescents. Immunofluorescence showed capillary wall deposits in a mesangial and intraluminal distribution that were predominantly positive for C3 and, less intensely, for IgA and light chains. Electron microscopy revealed several mesangial, subendothelial and intraluminal deposits. The frequent intraluminal deposits suggested possible cryoglobulinemic glomerulonephritis, which can rarely be IgA-related. The patient did not receive steroids given his ongoing infection. He continued to require intermittent hemodialysis.

Results:

Conclusions: The presence of frequent glomerular neutrophils and C3 staining of higher intensity than IgA should raise concern for infection-related glomerulonephritis. Intraluminal deposits forming hyaline pseudo-thrombi and prominent hypercellularity should lead to consideration for cryoglobulinemic glomerulonephritis. There are no current recommendations for treating infection-related IgA cryoglobulinemia. Management should focus on supportive care while treating the primary infectious process.

TH-PO176

Atypical Hemolytic Uremic Syndrome Associated with Complement Factor H Mutation: First Case Report on a Patient with IgA Nephropathy Yukiya Iimura, Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: Several types of glomerulopathy, including focal segmental glomerulosclerosis, membranoproliferative glomerulonephritis, C3 glomerulonephritis, and Henoch–Schönlein purpura, can be complicated by atypical hemolytic uremic syndrome (aHUS). Although immunoglobulin (Ig) A nephropathy (IgAN) has been associated with HUS or thrombotic microangiopathy, no report on its association with aHUS has been published. A recent study has found that rare variants of complement factor H (*CFH*)-related protein 5 may contribute to the genetic susceptibility to IgAN.

Methods: Here we present the first case of a 76-year-old man with IgAN who developed aHUS and was confirmed of harboring a *CFH* gene mutation.

Results: This patient was admitted with thrombotic microangiopathy findings. On admission, he was afebrile without diarrhea. His blood pressure was 178/109 mmHg. Blood analysis data demonstrated platelets counts of $1.1 \times 10^4/\mu L$; hemoglobin level, 9.6 g/dL; lactate dehydrogenase level, 3270 IU/L; and creatinine level, 4.2 mg/dL. Schistocytes were detected on blood smears. The patient was suspected of having thrombotic thrombocytopenic purpura or aHUS and was treated with plasma exchange, hemodialysis, and methylprednisolone. The level of a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13, was not decreased. The patient was definitively diagnosed with aHUS, and subsequently, plasma exchange and hemodialysis were discontinued. Eculizumab (900 mg/week) was initiated on day 18. Light microscopy findings were consistent with those of HUS, and an immunofluorescence analysis revealed IgA and C3 in the mesangial area. A hemolytic assay using sheep red blood cells revealed increased hemolytic activity. A genetic analysis revealed a p.Arg1215Gln mutation in *CFH*. Eculizumab therapy was effective for 5 months. The serum creatinine level was approximately 2 mg/dL without hemodialysis, and the hemoglobin level was 9 g/dL without proteinuria or hematuria.

Conclusions: We report the first case of a patient with IgAN who developed aHUS and was confirmed of harboring a *CFH* gene mutation. Both IgAN and aHUS activate the alternate pathway. Accordingly, this chronic trigger, namely IgAN, might have facilitated aHUS development in our genetically predisposed patient.

TH-PO177

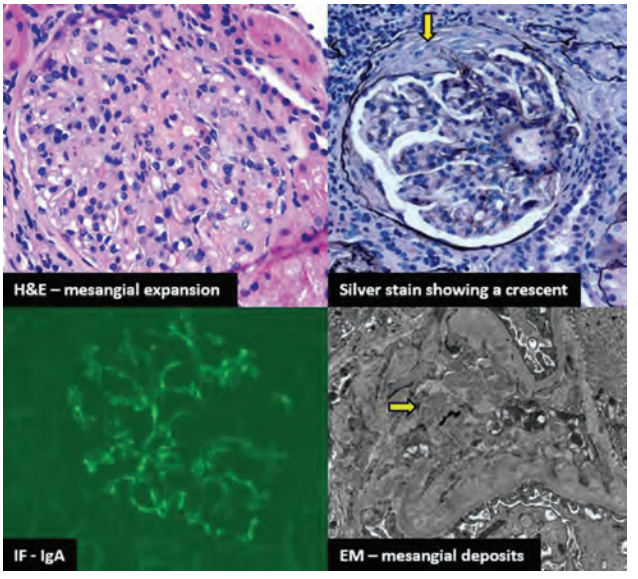
Does Your Differential for Glomerulonephritis in African Americans Include IgA Nephropathy? Abhilash Koratala,[2] Don H. Esprit,[1] William L. Clapp,[1] Jogiraju V. Tantravahi.[1,3] *[1]University of Florida, Gainesville, FL; [2]University of Florida, Gainesville, FL; [3]North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Background: Despite being the commonest primary glomerulonephritis in the world, IgA Nephropathy (IgAN) is rarely reported among African Americans (AAs), who otherwise have high renal disease burden. As nephrologists, we have been taught that IgAN should be considered as the last differential for GN in AA patients unless they have HIV. This assumption is based on the 'reported' rarity of this disease in AAs and the fact that AAs make up more than 50% of the new cases of HIV infection in the US. However, IgAN is being increasingly recognized in the non-HIV AA population. Factors such as level of disease awareness, access to appropriate diagnostic facilities and referral patterns may play a role in the underdiagnosis of IgAN in AAs. Moreover, there are reports suggesting that these patients may have more severe disease at presentation.

Methods: A 48-year-old woman was seen for IgAN. Her baseline serum creatinine (Scr) of 1.2 mg/dL. She was evaluated at an outside facility 3 months ago, when the Scr was 1.4 mg/dL with a UPCR of 1.7 g/g and 60/hpf RBCs in the urine. A month later, her Scr increased to 1.7mg/dL, which prompted a renal biopsy. It was suggestive of crescentic IgAN but the sample was inadequate. ANA, ANCA, HIV and hepatitis serologies were negative and complements normal. In our clinic, BP was 110/78mmHg, Scr 1.35 mg/dL and PCR ~1g/g. We elected to rebiopsy her to confirm the diagnosis of crescentic IgAN in an AA patient and possible treatment with an alkylating agent. It was surprisingly consistent with IgAN [Fig.1]. As there were fibrocellular crescents in only 2 of 11 glomeruli and the Scr remained stable, we chose to manage her conservatively.

Results:

Conclusions: Our case serves as a reminder that IgA nephropathy does occur in AAs and needs to be considered in the differentials when they present with nephritic picture.



TH-PO178

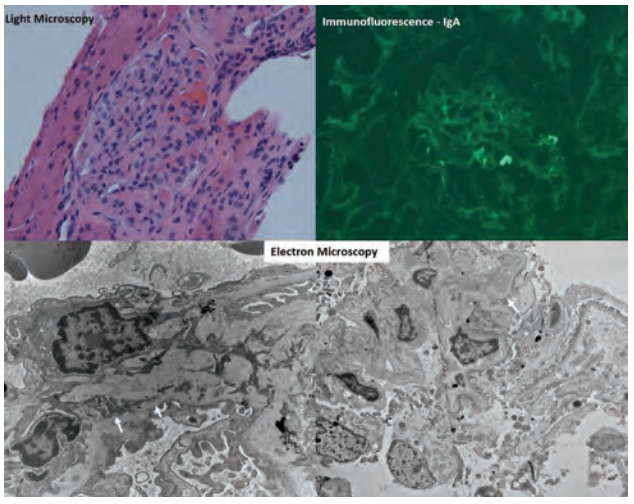
ANCA-Positive IgA Nephropathy: A Benign Coincidence or a Ticking Bomb? Abhilash Koratala, Xu Zeng, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: There have been a few reports of patients with IgA nephropathy (IgAN) who presented with circulating antineutrophil cytoplasmic autoantibodies (ANCAs). It remains unclear whether the presence of these antibodies reflects a mere incidental finding or a novel overlap entity with possibly untoward impact on the outcomes.

Methods: A 29-year-old woman referred for microscopic hematuria (MH) in the setting of positive ANCAs. She was first noted to have MH 2 years ago followed by mild hemoptysis and infiltrates on chest CT a few months later, which prompted a comprehensive autoimmune work up. Interestingly, both C-ANCA and P-ANCA were positive with anti-MPO and negative anti-PR3. Moreover, ANA and anti-dsDNA antibodies were found positive. Bronchoscopy ruled out diffuse alveolar hemorrhage. Serum creatinine was normal at 0.8 mg/dL, and urine studies revealed MH and mild proteinuria of 350 mg/g of creatinine. Renal biopsy was consistent with IgAN with mesangial expansion and electron dense mesangial deposits without cellular crescents or segmental necrosis [figure]. In the absence of histologic findings compatible with pauci-immune glomerulonephritis, the decision was made not to use immunosuppression and to follow expectantly.

Results:

Conclusions: There have been a few previous reports of ANCA positivity in the setting of IgAN; most cases presented with nephritic sediment, histologic picture of crescentic glomerulonephritis, and rapidly worsening renal function. ANCA-positive IgAN without these features is extremely rare. As the timeline of appearance of ANCAs need not correlate with that of crescentic IgAN, we opine that such patients should be closely monitored and a repeat biopsy be considered if there is any change in their renal manifestations.



TH-PO179

A Case of RPGN with Dual Positive Anti-GBM and PR3-ANCA Antibodies Nawsheen Chowdhury,[2] Shayan Shirazian,[1] Nobuyuki (Bill) Miyawaki,[1] James Drakakis.[1] *[1]Winthrop University Hospital, Mineola, NY; [2]Winthrop university hospital, Mineola, NY.*

Background: Anti-GBM disease and ANCA associated vasculitis are the major differentials for patients presenting with RPGN and pulmonary involvement. We report a case of unusual double positivity of both anti-GBM and PR3-ANCA antibodies, as most of the patients with both ANCA and anti-GBM antibodies are MPO-ANCA positive.

Methods: A 47-year-old female presented to the hospital with fatigue, malaise, and hemoptysis. Imaging of the chest revealed patchy consolidations and cavitary lesions. Initial creatinine was 1.1 mg/dL, but during the hospital course she developed rapidly progressive renal failure (peak creatinine of 2.6 mg/dL) in the setting of proteinuria and microscopic hematuria. An anti-GBM antibody titer was 135 units/mL and anti-proteinase 3 (PR3) antibody titers were > 100 units. Anti-myeloperoxidase (MPO) antibody titers were negative. Therapy was initiated with pulse steroids and plasmapharesis. Renal biopsy (done after having already received significant immunosuppression) revealed a focal crescentic glomerulonephritis with cellular crescents involving 29% of glomeruli. The patient received a dose of IV Cyclophosphamide and continued on tapering doses of prednisone. She was discharged with a creatinine of 1.5 mg/dL and negative PR3-ANCA and anti-GBM antibody titers. She completed 4 months of oral Cyclophosphamide and currently has a creatinine of 0.7 mg/dL on Azathioprine.

Results:

Conclusions: About 30% of patients with anti-GBM disease will have concurrent ANCA seropositivity, most of which are MPO-ANCA associated (74%). Our patient belonged to a smaller subset of patients with anti-GBM and PR3-ANCA antibodies. The reason for the emergence of dual antibody production is not known, however there have been some pathophysiological hypotheses for how MPO-ANCA may injure the glomerular basement membrane, expose antigens and lead to the development of an anti-GBM antibody. Most of the literature on patient and renal survival in dual positivity involves anti-GBM and MPO-ANCA antibodies. It is not clear that these descriptions of mechanism and outcome also apply to an overlap with PR-3-ANCA and more literature is required to help elucidate the potential clinical implications.

TH-PO180

Dual-Positive Anti-Myeloperoxidase and Anti-Glomerular Basement Membrane Antibody Vasculitis Muhammad Afzal, Krishna M. Baradhi. *OU Tulsa, Tulsa, OK.*

Background: Vasculitis secondary to the combination of anti-glomerular basement membrane (GBM) antibody and antineutrophil cytoplasmic antibodies (ANCA) is not common occuring up to 14% in patients with primary ANCA vasculitis and in up to 38% of patients with primary anti-GBM disease and moreover ANCA is usually directed against myeloperoxidase (MPO). Histologically, both are characterised by crescentic necrotizing glomerulonephritis. Immunofluorescence in anti-GBM disease reveals linear IgG staining, while ANCA vasculitis is pauci-immune.

Methods: 69 yr-old-male presented with abdominal pain & diarrhea and found to have acute oliguric renal failure. Labs showed BUN of 80 mg/dl and creatinine 8.34 mg/dl with associated hematuria and proteinuria. Serology revealed elevated MPO-ANCA (116.9 AU/ml) as well as anti-GBM antibodies (101 U). Renal biopsy showed diffuse necrotizing and crescentic glomerulonephritis with 1+ linear Ig G staining. Patient was started on plasmapheresis concurrently with hemodialysis and immunosuppressive therapy (cyclophosphamide and pulse steroids). Plasmapheresis was continued until Anti-GBM titers were < 20 U. Unfortunately his renal function did not recover and was discharged on tapering steroids, while continuing hemodialysis.

Results:

Conclusions: This is a unique case of rapidly progressive nephritis due to dual MPO-ANCA antibodies and anti-GBM antibodies (DAV). Clinical presentation of DAV may vary from isolated ANCA related vasculitis and mortality usually tends to be higher. Renal survival in dual-positive patients is not better than that in anti-GBM-positive patients and is inferior compared to patients with MPO-ANCA only. Relapse with Dual-antibody vasculitis is higher than in anti-GBM disease, hence clinical vigilance is necessary to detect relapse. Treatment of DAV is similar to anti-GBM disease with plasmapheresis, cyclophosphamide, and steroids. Patients with either ANCA-related disease or anti-GBM disease, whether diagnosed serologically or histologically, should be tested for the second antibody. This dual serological approach provides better prognostication and dictates appropriate management, as goal is to limit further immunosupression in dialysis dependent patients.

TH-PO181

ANCA Associated Vasculitis in Scleroderma: A Renal Perspective Sam Kant,[2] Duvuru Geetha.[1] *[1]John Hopkins Bayview Medical Center, Baltimore, MD; [2]University of Maryland, Baltimore, MD.*

Background: Overlap syndrome of ANCA associated vasculitis (AAV) and scleroderma (SS) is rare with conflicting data on renal outcomes. We describe the clinical characteristics and treatment outcome of ANCA glomerulonephriitis(GN) in SS patients followed at a single center

Methods: We conducted a retrospective study of 3840 patients in our SS database to identify SS patients who subsequently developed AAV with renal involvement. Patient demographics, serology, renal function with renal histology and treatment outcomes were assessed.

Results: Of the 3840 patients, we identified 5 patients who had ANCA GN. The median age at SS diagnosis was 52 years, all 5 patients were female and 4 had diffuse scleroderma. ANA was positive in all, with 3 of them having anti Scl 70 antibodies. Four patients had interstitial lung disease and gastrointestinal dysmotility as a part of the constellation of clinical characteristics of SS. Median time of onset of AAV from time of diagnosis of SS was 12 years and all of 5 patients were MPO positive. All patients had acute kidney injury, with biopsy proven crescentic glomerulonephritis and none requiring dialysis. One patient had sinus involvement while AAV was renal limited in the remaining 4 patients. Two patients were treated with cyclophosphamide(CYC) and steroids(GC) and three were treated with rituximab (RTX) and steroids. All patients achieved disease remission. The median follow up was 24 months, The mean GFR at diagnosis was 39 ml/min and at last follow up was 38 ml/min. Of the 5 patients, 2 did not receive maintenance immunosuppression and both experienced vasculitis relapse. None of the patients reached ESRD. Three patients died and of these 2 experienced relapse with fulminant alveolar hemorrhage

Conclusions: ANCA GN in SS is rare with disease manifestation and course similar to AAV. This case series demonstrates that disease remission can be achieved with standard induction therapy. However vasculitis relapse is common and associated with high mortality without remission maintenance therapy

Patient Characteristics

Patient	Induction Rx	Maintenance Rx	Vasculitis Relapse	ESRD	Death
1	GC + RTX	AZA	No	No	No
2	GC + CYC	MMF	No	No	Yes
3	GC + RTX	None	Yes (GN + DAH)	No	Yes
4	GC + CYC	None	Yes (DAH)	No	Yes
5	GC + RTX	AZA	No	No	No

AZA- Azathioprine; MMF- Mycophenolate mofetil; DAH- Diffuse alveolar hemorrhage

TH-PO182

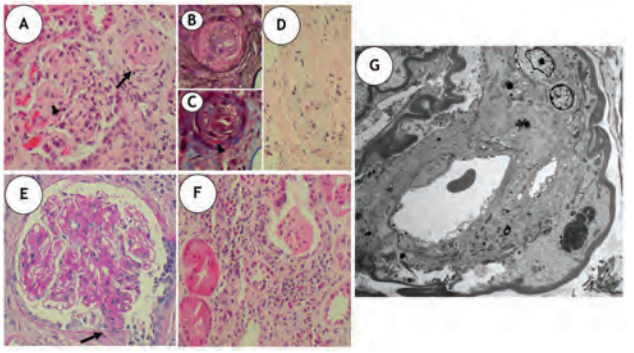
Renal Biopsy Teaching Case: A Patient with Scleroderma, Hypertension, AKI, and PR3 ANCA Positivity Sam Kant,[2] A Z. Rosenberg,[1] Duvuru Geetha.[1] *[1]Johns Hopkins University Hospital, Baltimore, MD; [2]University of Maryland Medical Center, Baltimore, MD.*

Background: A 65 year old African-American male, with a history of limited scleroderma for 16 years complicated by severe gastrointestinal dysmotility and interstitial lung disease, presented to the clinic with elevated blood pressure of 190/100 mm Hg, on a background of previously well controlled blood pressure. He was found to have an acute kidney injury with a serum creatinine of 2.5 mg/dL, compared to his baseline of 1.3 mg/dL. Urine studies demonstrated microscopic hematuria, with 3.4 grams of proteinuria. His hemoglobin was 7.4 and he had no evidence of hemolysis and platelet count was normal. Serologies revealed a positive c-ANCA serology with PR3 positivity at 97.4 IU/mL with negative ANA, ds-DNA, Scl-70, anti-smith, anti-Ro, Anti-La, and RNP. A renal biopsy was performed which demonstrated arteriolar microangiopathy with fibrinoid necrosis and concentric lamellation with no evidence of ANCA GN (Fig1). He was treated with ACE inhibitor with improvement of his BP and improved serum creatinine of 1.7 mg/dl.

Methods:

Results:

Conclusions: This case of late onset scleroderma renal crisis highlights that atypical presentations of scleroderma renal crisis can exist and ANCA positivity can be misleading in such situations. Therefore, clinical decisions for further management should be predicated on expedient renal biopsy.



A) Glomerulus (HE) and glomerular arteriole with entrapped RBCs (arrow) with vessel wall and surrounding interstitial edema and a consolidated ischemic glomerular appearance with potential entrapped RBCs (arrowhead).

B and C) Glomerular arteriole (b, silver stain) shows lamination of the vessel wall and fibrinoid material entrapped within the vessel wall (Masson's trichrome).

D) Small artery with subintimal mucoid change (HE)

E) Glomerulus (PAS) with synechial adhesion and associated glomerular solidification

F) Foci of interstitial inflammation including eosinophils (HE)

G) Ultrastructural evidence of microvascular injury including subendothelal widening with prominent cellular interposition.

TH-PO183

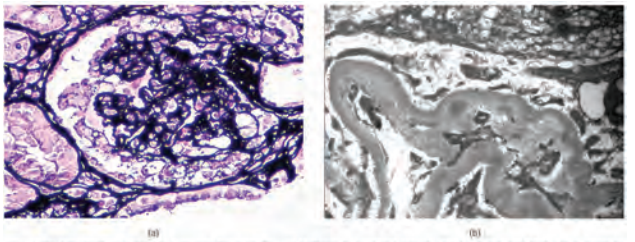
A Case of Collapsing FSGS Presenting with ANCA Positive Pulmonary Renal Syndrome George C. Bonifant, Steven D. Smith, Karim El Hachem, Mubasshar Rehman. *Icahn School of Medicine at Mount Sinai/St Luke's-Roosevelt Hospital Center, New York, NY.*

Background: Most cases of HIV-negative collapsing FSGS are idiopathic. However, a growing list of disorders, including mixed connective tissue diseases such as Sjogrens syndrome and SLE, are being reported to cause this lesion

Methods: A 22 y/o female with Sjogren's syndrome and pericarditis presented with dyspnea and cough. She complained of chronic nasal congestion, anosmia, pleurisy, dry mouth and Raynauds. There were basilar rales, facial acne, pale conjunctiva but no edema or arthritis on exam. Serum creatinine was 1.47 mg/dl (0.6 six months prior). Chest x-ray showed bibasilar airspace consolidations. She developed hemoptysis and respiratory failure requiring intubation. Bronchoscopy showed blood throughout the tracheobronchial tree thought due to diffuse alveolar hemorrhage. Urine protein creatinine ratio was 6.8g/g with an active urine sediment: dysmorphic RBCs and RBC casts. Negative serologies: HIV, parvo B virus, dsDNA, anti-GBM, anti-PR3, C3, C4. Positive serologies: anti SSA/SSB, anti-MPO. She received pulse steroids, cytoxan and plasmapheresis for presumed ANCA vasculitis. Creatinine peaked at 3.6 and improved to 2.0mg/dl with treatment. Renal biopsy showed focal and segmental glomerulosclerosis with collapsing features. Electron microscopy showed podocyte foot process effacement and no immune-type electron dense deposits or tubuloreticular inclusions. Outpatient treatment continues with oral prednisone

Results:

Conclusions: The patient presented as pulmonary renal syndrome and an active urine sediment with high titer anti-MPO Ab. Suspicion was high for ANCA vasculitis with expected pauci-immune crescentic GN on biopsy. Instead, collapsing glomerulopathy was diagnosed. Collapsing lesions can resemble crescents (pseudocrescents) and our case was reviewed by several renal pathologists to confirm the diagnosis. This challenges the notion that biopsy isn't necessary when pretest probability for pauci-immune glomerulonephritis is high. We propose that this patient's collapsing glomerulopathy is due to her collagen vascular disease (Sjogren's) and is analogous to lupus podocytopathy



Renal biopsy highlighting key features of Glomerular Podocytopathy. (a) Methenamine silver stain showing Focal Segmental and Diffuse Global sclerosing glomerulopathy with collapsing features. (magnification x200). (b) Electromicroscopy showing widespread attenuation and wrinkling of Basement Membranes with detachment of Podocyte foot processes. (magnification x1500).

TH-PO184

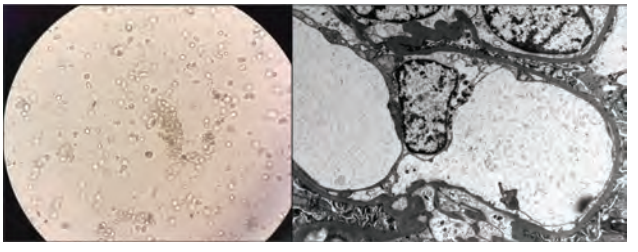
A Sheep in Wolf's Clothing: Hematuria in GPA Stefan C. Hemmings,[3] Duvuru Geetha,[1] Paul E. Segal,[2] Stephen M. Sozio.[3] *[1]John Hopkins Bayview Medical Center, Baltimore, MD; [2]Johns Hopkins Bayview Medical Center, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Performing a renal biopsy in a patient with RBC casts, rising serum creatinine (sCr) and positive ANCA serology is justifiable to evaluate for crescentic glomerulonephritis and determine best management strategies. Nonrenal involvement has a better prognosis in patients with ANCA-vasculitis. Finding underlying unrelated benign pathology in such instances can make future clinical decision-making challenging.

Methods: A 51 year-old man visited the rheumatology clinic in May 2017 for ongoing unexplained multisystem symptoms. He had been in good health until 10 months earlier when he started having recurrent bouts of sinusitis, cough, fatigue, otitis media leading to deafness and a 40lbs weight loss. Serology for cANCA was positive [1:40 titer; PR3: 87], this was negative earlier in his clinical course. He was noted to have microscopic hematuria and was seen in nephrology clinic within 24 hours for evaluation. His sCr notably had risen from 0.7 to 1.0 mg/dL over a 5 month-period, he had normal serum complements, and his random urine protein to creatinine ratio was 280 mg/g. Urine microscopy revealed RBC casts (Figure-left). An urgent renal biopsy was performed and pulse IV steroids initiated for presumed renal involvement of granulomatosis with polyangiitis (GPA). On biopsy, the 19 glomeruli sampled were histologically normal on light microscopy and immunofluorescence was unremarkable. Electron microscopy revealed thin basement membranes of width 218nm (Figure-right). Alport's immunostaining was negative.

Results:

Conclusions: Thin Basement Membrane Nephropathy (TBMN) likely explained his microscopic hematuria and RBC casts. This diagnosis portends a good clinical renal prognosis. However, finding benign pathology, including TBMN, does pose challenges in diagnosing a GPA relapse clinically as the hematuria and RBC casts can be intermittent and from the benign condition. Nevertheless, this case highlights the utility of performing renal biopsy even when there is a high index suspicion of renal involvement from ANCA-associated vasculitis.



RBC cast on microscopy (Right) and Electron Microscopy with TBMN (Left).

TH-PO185

Henoch-Schönlein Purpura Nephritis: Not Only a Childhood Disease Krystahl Z. Andujar,[1] Ileana E. Ocasio Melendez,[1] Nicolle M. Canales-Ramos,[2] Sharlene Medina aviles,[2] Fatima B. Cintron-Rosa,[1] Naomi Collazo Gutierrez,[2] Luis F. Alvarez,[4] Phillip Ruiz.[3] *[1]Nephrology, University of Puerto Rico, Medical Sciences Campus, San Juan, PR; [2]Internal Medicine, University of Puerto Rico, Medical Sciences Campus, San Juan, PR; [3]University Of Miami, Miami, FL; [4]Internal Medicine, VA Caribbean Healthcare System, San Juan, PR.*

Background: Henoch-Schönlein Purpura Nephritis (HSPN) is often regarded as a childhood disease. As adults are at more risk for developing chronic kidney disease (CKD) if treatment is delayed, it is vital for clinicians to be aware of this rare disease.

Methods: A 51-year-old Puerto Rican man without medical history presented with abdominal pain associated with bloody stools, a rash on lower extremities and arthralgias. Palpable purpura was visible on legs, back and buttocks. Vital signs were normal. Laboratories were remarkable for a creatinine of 2 mg/dl. Urine protein:creatinine ratio revealed proteinuria of 1,988 mg/g. Urine microscopy showed dysmorphic red blood cells. Abdomino-pelvic computer tomography scan was diagnostic of colitis. Skin lesions biopsied demonstrated leukocytoclastic vasculitis. A renal biopsy was performed revealing increased mesangial cellularity on light microscopy and mesangial staining with IgA on immunofluorescence. In the presence of palpable purpura, arthralgias, colitis, proteinuria and renal biopsy evidence of IgA deposition, he was diagnosed with HSPN. After a three-day course of intravenous methylprednisolone, he was started on oral prednisone and azathioprine. Two weeks later, creatinine returned to baseline of 1 mg/dL, proteinuria improved and skin lesions and abdominal complaints resolved. He was started on losartan and a decision for immunosuppression weaning was reached.

Results:

Conclusions: HSPN is most prevalent in the first decade of life, making our adult case unusual. Renal involvement in adults with HSPN is worse than in children and up to forty percent of patients can progress to CKD. A challenge the clinician must face is balancing the cost of immunosuppressive treatment versus the actual risk of developing CKD. Also, the difficult decision of choosing which immunosuppressive agent is most beneficial for the patient. A clinical trial by Bergstein *et al* suggest that corticosteroid and azathioprine therapy is beneficial in treating HSPN. In our case, treatment with this

immunosuppressive therapy proved to be effective in eliminating abdominal complaints, decreasing proteinuria and improving renal function. Nonetheless, more evidence-based recommendations are needed to pinpoint which immunosuppressive agent is the choice of therapy for HSPN.

TH-PO186

Unusual Cause of Visceral Infarcts Amar Pandit,[2] Aditya S. Pawaskar,[2] Randy A. Goldberg.[1] [1]*New York Medical College, Valhalla, NY;* [2]*Westchester Medical Center, White Plains, NY.*

Background: Thrombosis is an increasingly recognized feature of ANCA vasculitis

Methods: An 18 year old lady with history of celiac disease presented with high grade fevers, 10 lb. weight loss, nausea and epigastric tenderness. Physical exam was negative for lymphadenopathy, murmur, adventitious lung sounds, hepatosplenomegaly, joint swelling/tenderness or rash. Labs revealed anemia, elevated ESR and CRP and normal white count, renal and liver function tests. Infectious vs. inflammatory processes were considered and she was started on antibiotics. CT abdomen revealed renal and splenic infarcts. Infective endocarditis was ruled out by negative blood cultures and a normal echocardiogram, following which antibiotics were stopped. Urinalysis showed microscopic hematuria and 2+ proteinuria (Urine protein/creatinine ratio of 961), consistent with nephritic syndrome, likely due to collagen vascular disease vs. thrombotic disease. ANA and anti-PR3 were positive, and dsDNA, anti-Sm, anti-RNP, C3, C4, cryoglobulins, anti-GBM, anti-SS-A and anti-SS-B were negative. Hypercoagulable workup revealed decreased Protein S activity and negative anti-phospholipid antibodies. CT chest revealed a hemorrhagic infarct, but no nodules. Renal biopsy confirmed the presence of pauci-immune necrotizing crescentic glomerulonephritis, indicating GPA. She was started on IV methylprednisolone, rituximab and rivaroxaban with resolution of her symptoms.

Results:

Conclusions: Venous (DVT, PE) and arterial thrombosis are being increasingly recognized in GPA, although arterial involvement has predominantly been described in the coronaries. This predisposition to thrombosis is multifactorial: 1) Activation of neutrophils by antibodies and the interaction of activated neutrophils with the endothelium. There is also release of tissue factor which activates thrombosis. 2) Elevated thrombomodulin levels activate thrombosis and inhibition of conversion of plasminogen to plasmin inhibits fibrinolysis. There are no recommendations on use of anti-platelets or anti-coagulants at present.

TH-PO187

Be Brash: Name That Rash Amir Kazerouninia, Azka Afzal, Natasha N. Dave, Rajeev Raghavan. *Baylor College of Medicine, Houston, TX.*

Background: Granulomatosis with polyangiitis (GPA), is a relatively rare, potentially fatal anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis. It is characterized by necrotizing granulomatous inflammation and vasculitis, affecting predominantly small to medium vessels. Here, an uncommon manifestation of vasculitis—livedo racemosa—was not addressed and the patient suffered a stroke.

Methods: A 60-year-old woman with hypothyroidism presented to her PCP for rash, progressive weakness, stocking/glove numbness, and intermittent fevers. The rash was not described or addressed, but EMG was ordered. Within a week, she presented to the ED for the same complaints. She was febrile and studies were notable for leukocytosis, 1+ blood on urinalysis, anemia, and hypoalbuminemia. General medicine diagnosed polyneuropathy, began gabapentin, and discharged her from the ED. Shortly thereafter, she re-presented to the ED with a left fronto-temporal hemorrhagic stroke. Renal was consulted for AKI and noticed a purplish, lace-like, mottled, reticulated rash on both legs, suggestive of livedo reticularis, but with irregularities within the thickness of the reticulations, more consistent with livedo racemosa. Family noted the rash had been present for several months. Her urine had RBC casts, serum was positive for MPO-ANCA, and kidney biopsy showed interstitial granulomas and focal partial artery necrosis, all evidencing GPA. Given hemorrhagic stroke at an uncommon site, brain angiography was performed showing subtle luminal irregularities in the bilateral small cerebral vessels consistent with CNS vasculitis. Chest CT and EMG were consistent with pulmonary and PNS GPA, respectively. She was given pulse dose steroids and started weekly rituximab infusions. The patient's kidney function improved somewhat, but dysarthria continues, with only about 60% of her speech understandable by family members.

Results:

Conclusions: Livedo racemosa is always due to a secondary disorder and warrants further evaluation. Multiple clinicians missed the importance of her rash; any livedo-like rash in the setting of active urinary sediment, nondiabetic polyneuropathy, intermittent fevers, leukocytosis, anemia, and hypoalbuminemia should be biopsied allowing for early diagnosis of systemic illnesses such as vasculitis. If identified early, GPA remission is possible with immunosuppressive therapy, and may have prevented this patient's hemorrhagic stroke.

TH-PO188

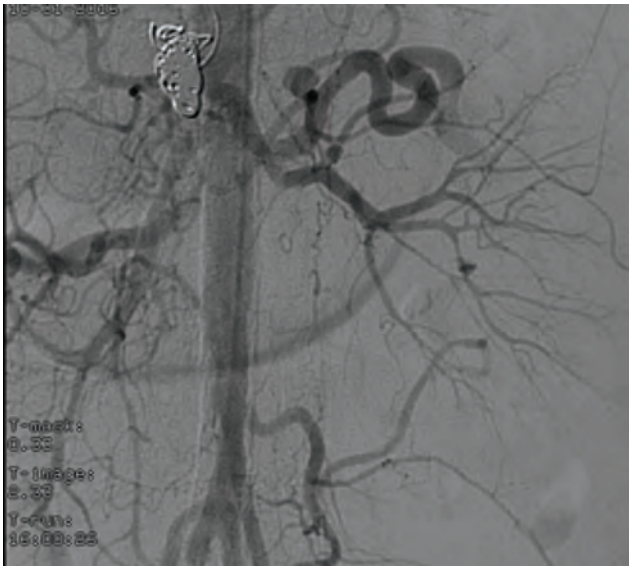
From a Complicated Biopsy to an Unexpected Diagnosis Haris F. Murad,[1] Randy L. Luciano.[2] [1]*Yale School of Medicine, New Haven, CT;* [2]*Yale University School of Medicine, New Haven, CT.*

Background: Polyarteritis Nodosa (PAN) is a rare systemic necrotizing vasculitis targeting medium sized arteries and can involve any organ in the body except for the lungs. Arterial inflammation causes tissue ischemia and hemorrhage and may present with a wide spectrum of clinical manifestations ranging from neuropathies and rashes to renal failure and bowel ischemia. Renal failure is thought to be secondary to ischemia from rupture of microaneurysms. Diagnosis requires an integration of clinical, radiographic and pathological findings, but the presence of medium vessel microaneurysms can suffice in the absence of tissue confirmation. We present a case in which the diagnosis was made in unusual circumstances.

Methods: A 46 year old lady with non-cirrhotic hepatoportal sclerosis presents with a gradually uptrending creatinine over two years reaching 4.1mg/dL, worsening proteinuria up to 5.6gm/day and a urine sediment showing granular casts. Renal ultrasound showed bilateral echogenic kidneys and elevated velocities in renal arteries and the aorta. She underwent a renal biopsy which was challenging and on the second pass she had severe abdominal pain. A color doppler demonstrated a pulsatile jet originating from the lower renal pole. She immediately passed a large amount of blood from her urethra. An emergent angiography showed several aneurysms in the liver, kidney and spleen (see figure) along with two pseudoaneurysms, consistent with a diagnosis of PAN. Unfortunately the biopsy sample was insufficient for interpretation. Subsequent labs showed elevated inflammatory markers, negative rheumatoid factor, cryoglobulins, hepatitis B and C titers.

Results:

Conclusions: This case demonstrates that a complication from a kidney biopsy was able to provide an important, and previously unthought of diagnosis in a patient. In addition it highlights the safety concerns of patients with vasculitis undergoing biopsy.



TH-PO189

Bartonella Endocarditis Mimicking ANCA-Associated Glomerulonephritis (GN) Joseph Vercellone, Lisa J. Cohen, Saima Mansuri, Ping L. Zhang, Paul S. Kellerman. *Oakland University/William Beaumont School of Medicine, Royal Oak, MI.*

Background: *Bartonella henselae* is a fastidious organism causing cat scratch disease, commonly associated with fever and lymphadenopathy. Rarely, *B. henselae* results in culture-negative endocarditis (IE). Herein, we describe a case of *B. henselae* IE mimicking ANCA-associated GN.

Methods: A 47-year-old male presented with 2 weeks of flank pain and four days of cola-colored urine. Exam revealed a soft murmur over the left-sternal border and severe CVA tenderness, with no fever. Labs showed a Hgb of 7.7 mg/dL, a creatinine of 2.36 mg/dL (up from 0.89 mg/dL), and UA showed 3+ blood, 1+ protein, 51-100 RBC/HPF,

0-5 WBC/HPF, and RBC casts. Kidneys were normal on ultrasound, but MRI noted wedge-shaped splenic infarcts. Pending serologic studies and biopsy, the patient was initially pulsed with steroids with no further immunosuppression. Serologies revealed normal C_3, C_4, ASO, ANA, anticardiolipins, IgA, and hepatitis panel. ANCA and anti-MPO were negative, but anti-PR3, CRP and ESR were markedly elevated. On biopsy, light microscopy showed focal proliferative injury with two non-necrotic crescents. Immunoflourescence was positive for IgM, IgA, C_3, and C1q. Electron microscopy showed subtle mesangial and subendothelial deposits without "humps". With possible immune complexes on kidney biopsy and a murmur, TEE was performed showing a bicuspid aortic valve with vegetation. A diagnosis of culture-negative endocarditis was made, doxycycline and rifampin were started, and valve replacement performed, with pathology identifying *B. henselae*. On antibiotics, the patient's symptoms resolved and creatinine decreased to 1.4 mg/dL with normalization of ESR and CRP over two months.

Results:

Conclusions: Culture-negativity comprises 3-48% of all endocarditis cases. This case highlights how *Bartonella* IE can present with crescentic GN and falsely elevated anti-PR3 antibodies mimicking ANCA-associated GN. Literature review revealed approximately 50 cases of *Bartonella*-induced IE with GN with ANCA and PR-3 positivity. Unique to our case was a negative ANCA with very high anti-PR3 antibody titer. Because of culture negative IE and false vasculitis titers, *Bartonella* can mimic ANCA-associated GN, thus kidney biopsy showing immune complex deposition is critical to diagnosis and appropriate therapy.

TH-PO190

An Unexpected Finding of Post Infectious Glomerulonephritis Superimposed on Cryoglobulin Mediated Membranoproliferative Glomerulonephritis in a Patient with Influenza

Sara Syeda, Jie Tang. *Div of Kidney Diseases and Hypertension, Brown University, Providence, RI.*

Background: Active glomerulonephritis with hypocomplementemia has a limited differential. Here we present an interesting case of acute kidney injury (AKI) with influenza, in which kidney biopsy showed cryoglobulinemic membranoproliferative glomerulonephritis (MPGN) and evidence of post-infectious glomerulonephritis (PIGN).

Methods: A 62-year-old man with history of clinically inactive low-grade B cell lymphoma (LGBL), presented with cough, myalgias, and tested positive for Influenza A. He was found to have AKI with a serum creatinine of 11.9mg/dL (baseline 1.1mg/dL), sub-nephrotic proteinuria and microscopic hematuria. Serologic studies showed low complements (C3, C4) and a weak monoclonal IgG lambda light chain on serum electrophoresis. All other infectious and rheumatologic work up were negative. Kidney biopsy revealed pattern of MPGN, with prominent sub-endothelial deposits and intra-capillary hyaline pseudo thrombi, staining predominantly for IgG and lambda light chain on immunofluorescence. By electron microscopy, he also had many sub-epithelial "humps" along with sub-endothelial and mesangial deposits. This was consistent with type 1 cryoglobulinemic glomerulonephritis with superimposed PIGN. In the interim, he was started on a course of steroids and over the next 2-3 weeks his kidney function returned to baseline with resolution of proteinuria and hematuria. He was eventually taken off steroids and his kidney function has remained normal.

Results:

Conclusions: This case is unique in several aspects. First of all, although his history of LGBL could explain weak paraproteinemia, our patient showed no clinical evidence of lymphoma on routine monitoring by Hematology. Moreover, we had no compelling reason to believe that he had an indolent lymphoproliferative disease causing his renal failure. Secondly, his quick and full recovery is consistent with a self-limiting acute process, possibly from Influenza. Thirdly, this case represents a rare finding of PIGN associated with influenza. We think concurrent findings of type 1 cryoglobulinemic MPGN associated with paraproteinemia and PIGN in this case, are likely a manifestation of the disease spectrum related to Influenza.

Incidental Finding of CFHR5 Mutation in a Case of Hemolytic Uremic Syndrome

Matthew H. Shapiro, Diego H. Aviles, Isa Ashoor. *LSUHSC Pediatrics, New Orleans, LA.*

Background: Hemolytic-uremic syndrome (HUS) is a triad of microangiopathic hemolytic anemia, thrombocytopenia, and renal insufficiency. It's divided into two categories, diarrhea-positive (D+HUS) or typical HUS and diarrhea-negative or atypical HUS (aHUS).

Methods: A previously healthy 7 year old boy presented with several days of abdominal pain, emesis and bloody diarrhea. Admission labs were notable for Hgb 13.7 gm/dL, Platelets 485k/mm3 and creatinine 0.5 mg/dL. Stool culture, C. diff and Shiga toxin assays were negative. He subsequently developed oliguria and acute kidney injury. Urine was positive for blood (+3), protein (+3) and granular casts. Hgb and platelets fell to 7.1 gm/dL and 22K/mm3, respectively. Creatinine peaked at 4 mg/dL at which point hemodialysis was started. aHUS was suspected and additional labs were drawn. Complement C3/C4 and ADAMST13 levels were normal. Genetic testing for 11 genes implicated in thrombotic microangiopathy identified a mutation of unknown significance in the intron of Complement Factor H Related Protein 5 (CFHR5) gene. Renal function returned to baseline within a week without complement inhibition therapy and remains normal 3 months later.

Results:

Conclusions: We present a case of likely D+HUS where we were unable to isolate shiga toxin. This is further complicated by the incidental finding of a mutation in a complement regulating gene of unknown significance in aHUS, that has other known associations with disease. CFHR5 is associated with protection of glomerular cells against complement activation, yet mutations in the CFHR5 gene do not necessarily cause HUS, as they are also present in control populations. CFHR5 exon mutations have been described in association with various nephropathies, particularly in Cypriot patients, but few mention HUS, and none have described an intron mutation or its relationship to HUS. Importantly, CFHR5 mutations described in aHUS patients are in coding regions, not the in intron. This CFHR5 intron mutation is not predicted to alter or affect splicing, therefore it is unlikely to play a role in this particular case. Hence, complement inhibition with eculizumab is perhaps not indicated. Long-term monitoring is warranted.

TH-PO192

Complement Factor C4d Staining in Gemcitabine-Induced Thrombotic Microangiopathy: A Case Series

Koji Muro, Hideki Yokoi, Kaoru Sakai, Shuichiro Endo, Takeshi Matsubara, Motoko Yanagita. *Department of Nephrology, Kyoto University Hospital, Kyoto, Japan.*

Background: Complement factor C4d staining is a common finding in thrombotic microangiopathy (TMA), regardless of the underlying clinical condition. However, there are few reports in the literature investigating C4d staining of drug-toxicity-induced TMA, especially of gemcitabine (GEM)-induced TMA (GCI-TMA). We aim to examine the pattern of C4d staining in renal biopsy specimens from three patients with GCI-TMA.

Methods: Case 1 A 52-year-old man was diagnosed with hilar cholangiocarcinoma at the age of 46. Following surgery, he had been treated with GEM therapy (cumulative dose of 64,400 mg). His serum creatinine (Cr) level started increasing to 3.5 mg/dL from a baseline of 0.8 mg/dL within 22 months. Proteinuria appeared and his urinary protein-to-Cr ratio reached 2.5 g/g Cr. **Case 2** A 64-year-old woman was diagnosed with pancreatic cancer. She was treated with concurrent chemoradiotherapy and GEM was administered. Four months later, cumulative dose of GEM was 23,800 mg and her serum Cr level started increasing to 1.69 mg/dL from a baseline of 0.7 mg/dL within 5 months. Her urine dipstick revealed 2+ proteinuria, and her urinary protein-to-Cr ratio was 1.5 g/g Cr. **Case 3** A 70-year-old woman with recurrent angioimmunoblastic T-cell lymphoma was referred to our hospital. She had started to receive GEM since the age of 69. After cumulative dose of 15,250 mg, her serum Cr level was elevated to 1.4 mg/dL from a baseline of 0.6 mg/dL within 17 months, and proteinuria appeared reaching to 3.4 g/day. **Result** Light microscopy showed mesangiolysis and double contours in glomeruli. Immunofluorescence study demonstrated segmental deposits of C4d along glomerular capillaries (GBM-C4d) in all cases. Electron microscopy showed glomerular basement membraine (GBM) duplication and no dense deposit. In all three cases, GEM was discontinued. Renal function of these patients partially improved but did not fully recover.

Results:

Conclusions: A recent study showed that isolated strong GBM-C4d can highlight architectural glomerular remodeling. In our cases, segmental GBM-C4d and GBM duplication were observed, and their renal function did not fully recover. GBM-C4d staining in GCI-TMA might imply relatively poor renal prognosis.

TH-PO193

Thrombotic Microangiopathy and AKI Associated with MT-3724

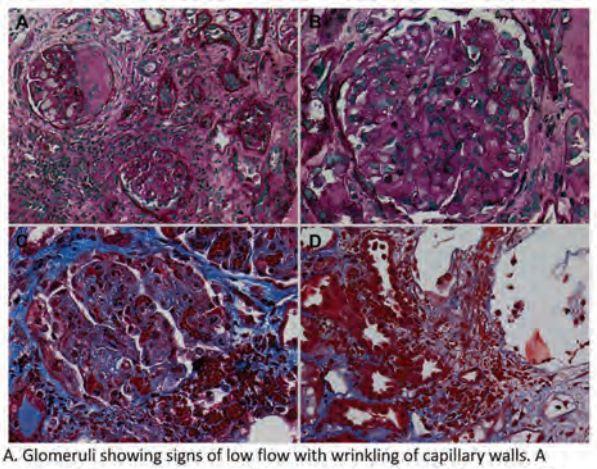
Mona Shaban,[3] Abhijit V. Kshirsagar,[2] Alexei V. Mikhailov.[1] *[1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Nephrology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Study drug MT-3724 is a CD20-targeting immunotoxin consisting of a recombinant fusion protein with a CD20 binding variable fragment fused to the enzymatically active Shiga-like toxin-I A1 subunit (SLT-I A1). Upon binding to the surface of CD20, SLT-I A1 leads to MT-3724 internalization, which inactivates cell ribosomes and causes cell death. MT-3724 is currently being studied in relapsed diffuse B cell lymphoma (DLBCL). Here, we report a case of acute kidney injury (AKI) secondary to thrombotic microangiopathy after administration of MT-3724 and leading to dialysis dependence.

Methods: A 70-year-old female with relapsed DLBCL presented with lower extremity swelling during the second cycle of study drug, MT-3724. Each cycle of MT-3724 is 75 mg/kg dosed on days 1,3,5,8,10, and 12. Exam was remarkable for significant peripheral edema. Serum creatinine (SCr) was 3.2 mg/dL from a baseline of 1.0-1.2 mg/dL. Urine protein to creatinine ratio (U P/C) was 20 g/g. Urine sediment revealed multiple oval fat bodies, hyalofatty casts, and dysmorphic red blood cells. Renal biopsy was performed and revealed thrombotic microangiopathy with evidence of fragmented red blood cells in the mesangium and interstitium. Glomeruli had signs of low flow and 1 fibrocellular crescent was observed. There was moderate to severe interstitial fibrosis and tubular atrophy (Figure 1, Panel A-D). 22 days after last dose of MT-3724, SCr continued to rise to 10 mg/dL associated with uremic symptoms and oliguria. Hemodialysis was initiated and patient continues to require outpatient dialysis.

Results:

Conclusions: The pathogenesis of this acute kidney injury is currently unclear, however we can speculate on the role of Shiga-like toxin given the clear association between Shiga toxin and hemolytic uremic syndrome (HUS). Novel targeted therapies in the treatment of DLBCL can potentially be nephrotoxic and early recognition and cessation of offending agent may prevent progression of kidney injury.



A. Glomeruli showing signs of low flow with wrinkling of capillary walls. A fibrocellular crescent observed in one glomerulus (upper left corner). The interstitial compartment demonstrates diffuse, moderate to severe fibrosis and tubular atrophy. Hematoxylin and Eosin, 20x.
B. Glomerular endothelial cells are diffusely and globally swollen; rare polymorphonuclear leukocytes are seen. Hematoxylin and Eosin, 40x.
C. A glomerulus with fragmented red blood cells in the mesangium. Trichrome, 40x.
D. Evidence of edematous interstitial regions with microscopic foci of hemorrhage with fragmented red blood cells are noted. Trichrome, 40x.

TH-PO194

Recurrent Venous Thromboembolism (VTE) in Membranous Nephropathy despite Direct Xa Inhibitor Therapy Monica L. Reynolds, Vimal K. Derebail. *University North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: In membranous nephropathy, the risk of VTE is high and increases significantly with a serum albumin of <2.8 g/dl. Apixaban, a direct factor Xa inhibitor, is non-inferior to warfarin for VTE treatment in the general population but has not been studied in the nephrotic syndrome. We report a patient with recurrent VTE while on therapeutic dosing of apixaban.

Methods: A 51-year-old Caucasian male presented with new hypertension and lower extremity edema. Imaging studies demonstrated bilateral pulmonary emboli and acute DVT of the left external iliac, femoral and popliteal vein with extension to the IVC. After mechanical thrombectomy and catheter-directed thrombolytics, he was placed on apixaban 2.5mg BID. Edema recurred two months later and CT demonstrated extension of clot. He was switched to fondaparinux and referred to Hematology. Serum albumin was 2.1 g/dl and urinalysis showed proteinuria. Urine protein to creatinine ratio was 13 g/g. Catheter-directed thrombolytics and mechanical thrombectomy were repeated. Thrombophilia work-up was negative for Antithrombin and Protein C/S deficiency. He was discharged on apixaban 5 mg BID as prior dosing was thought to be sub-therapeutic. Anti-Phospholipase A2 receptor (PLA2R) antibody titers were 424 RU/ml, and he was presumed to have membranous nephropathy. Given the need for anticoagulation and recent thrombolytics, renal biopsy was deferred. He was treated with alternating monthly corticosteroids and oral cyclophosphamide. Six months later, UPC was 5 g/g and serum albumin was 2.6 g/dl. Repeat PLA2R antibody was <2 RU/ml. However, D-dimer was elevated to 2345 ng/mL and doppler ultrasonography revealed left acute mid femoral DVT and acute on chronic proximal femoral DVT. Four-hour apixaban drug level was 50.4 ng/ml (mean peak value in healthy volunteers- 128.5 ng/ml). He was switched back to fondaparinux. At one year, he had no further VTE's and serum albumin was 3.3 g/dl.

Results:

Conclusions: Despite appropriate dosing of apixaban, our patient developed recurrent VTE. A four-hour drug level was below the range reported for healthy volunteers at the same dose. Due to its high protein binding, apixaban may have altered pharmacokinetics and pharmacodynamics in patients with nephrotic syndrome and hypoalbuminemia. More data is needed to determine appropriate use of novel oral anticoagulants in the nephrotic syndrome.

TH-PO195

Spontaneous Cerebral Venous Thrombosis as a Presenting Manifestation of Secondary Membranous Nephropathy Srijan Tandukar,[1] Helbert Rondon Berrios.[2] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Membranous nephropathy is one of the most common causes of nephrotic syndrome in adults and accounts for the glomerulopathy associated with the highest rate of thromboembolic complications. We present a case of an otherwise healthy man who presented with spontaneous cerebral venous thrombosis and ultimately was diagnosed with a form of secondary membranous nephropathy.

Methods: A 40 year-old previously healthy man presented with progressively worsening generalized headache and nausea. He had been taking occasional ibuprofen for headaches for 2 weeks. He was afebrile and hemodynamically stable at presentation. On examination, he was in moderate distress due to headaches without neck stiffness, temporal artery tenderness or other focal neurological deficit. Laboratory data revealed normal blood counts, chemistry profile and renal function but low serum albumin of 2.3 g/dL, high total cholesterol of 263 mg/dL and high LDL of 191 mg/dL. Urine protein-to-creatinine ratio was elevated at 10 g/g. CT angiography of the brain revealed bilateral transverse venous sinus thrombosis. Patient was initiated on warfarin with heparin bridging. Thrombophilia workup could not be performed since acute thrombosis and warfarin reduce levels of antithrombin, protein C, and protein S. However, antiphospholipid antibodies were negative. Serological workup demonstrated low normal serum complement (C3 95, C4 22) with positive ANA (1:320), anti-U1RNP, anti-SSA, anti-Smith and anti-dsDNA. Hepatitis screen was negative. Kidney biopsy was performed. Light microscopy revealed a diffuse thickening of the glomerular basement membrane with "spikes". Immunofluorescence studies showed a negative PLA2R staining and a classic "full house" staining pattern (IgG1-4, C3, C1q). Electron microscopy revealed subepithelial, subendothelial and mesangial deposits with tubuloreticular inclusions. Based on the above findings a diagnosis of mixed connective tissue disease with lupus overlap was made and patient was initiated on prednisone and mycophenolate mofetil.

Results:

Conclusions: Cerebral venous thrombosis is a rare but potentially fatal complication of nephrotic syndrome. Increased risk of thromboembolism has been classically demonstrated in primary, but is also commonly seen in secondary membranous nephropathy. The risk increases with the level of decline in serum albumin.

TH-PO196

Incidental Thin Basement Membrane Associated with Primary Membranous Nephropathy Felipe Naranjo Sanchez,[2] Helmut G. Rennke,[1] Kelly A. Burdge.[2,3] *[1]Brigham and Women's Hospital, Boston, MA; [2]North Shore Medical Center, Salem Hospital, Cambridge, MA; [3]Masschusetts General Hospital Danvers, Danvers, MA.*

Background: Thin basement membrane nephropathy (TBMN) is a benign recessive genetic condition caused by defects of α3 or α4 type IV collagen, presenting with hematuria. A thin BM can also be found in Alport syndrome, an x-linked disease affecting α5 type IV collagen, which presents with early renal failure and has poor prognosis.

Methods: 52 yo F, PMHx of HTN, CKD3, GERD and Takasubo cardiomyopathy, presented to the ER with severe headache and nausea, there she had one episode of seizure, lasting 45 secs, in the setting of PRES. In her workup, a UA demonstrated proteinuria, confirmed to be 8g/g creatinine in a random sample, but no hematuria. Medications included: amlodipine, lisinopril, metoprolol, atorvastatin and omeprazole. She denied NSAIDs, herbal or illicit drugs, smoking, travel. No family history of kidney or autoimmune diseases. She had negative cervical, breast and colon cancer screening. Physical exam demostrated stable vital signs and edema in lower extremities. Urine sediment findings: few muddy brown casts and several fat bodies. Laboratory showed: SCr 2 mg/dl (previous 1mg/dl); hypercholesterolemia, hypoalbuminemia, Alb/Cr 8,583 mg/g; negative serology for HBV, HVC, HIV and RPR; normal C3 and C4, negative ANCA, ANA, SPEP and positive PLA2r antibody; low IgG, normal IgA. Kidney biopsy reported membranous glomerulonephropathy (MGN) stage II. Immunofluorescence microscopy revealed co-dominant reactivity for IgG3 and IgG4, weakly reactive to PLA2r. Electronic microscopy showed diffuse attenuation and fraying of lamina densa and effacement of foot processes of the glomerular basement membrane (GBM); thickness of the GBM could not be measured due to marked distortion of the capillary wall; changes suggestive of TBMN, an inherited abnormality of the GBM, possibly involving collagen IV genes. Patient was started on rituximab, cyclophosphamide and steroids, with improvement Alb/Cr ratio to 89 mg/g. The underlying etiology for her proteinuria was primary MGN, but a concomitant TBMN was incidentally observed, probably heightened the primary glomerular disease.

Results:

Conclusions: Diagnosing female patients with TBMN should raise awareness to screen for GBM collagen-related inherited disorders in the patient's family members, especially in males. Careful clinical assessments and repeated urinalysis should be offered to discover the genetic basis of the disease.

TH-PO197

Primary Membranous Nephropathy and AKI Jessica D. Morris,[1] Tazeen H. Jafar.[2] *[1]Duke University, Durham, NC; [2]Duke-NUS Graduate Medical School, Singapore, Singapore.*

Background: Over 90% of patients with primary membranous nephropathy present with preserved renal function with only 10-20% of patients progressing to ESRD. Here we present a case of respiratory failure and acute anuric renal failure requiring renal replacement therapy found to have primary membranous nephropathy.

Methods: Our patient was a 60 year old man with hypertension, baseline serum Cr of 0.7-0.9 mg/dl who presented to an outside hospital with fevers, cough, and shortness of breath. Two months prior he had presented to his primary care physician with lower extremity edema and was found to have 10 g of proteinuria on a24 hour urine collection. During evaluation at the outside hospital he was hypoxic requiring supplemental oxygen and serum Cr was 1.4 mg/dl. Chest imaging demonstrated bilateral infiltrates and pleural effusions. Within three days hypoxic respiratory failure progressed and he required BIPAP with increasing serum Cr to 3.0 mg/dl, he was subsequently transferred. On arrival to our hospital he was intubated within first 24 hours of presentation. He was anuric despite

diuretics with increasing serum Cr to 4.0 mg/dl and was then started on dialysis. Given presentation of rapidly progressive pulmonary and renal failure, along with active urine sediment, methylprednisolone was started. Renal biopsy demonstrated findings consistent with membranous nephropathy and tubular injury. He was eventually extubated with negative influenza, bronchoscopy and blood cultures. Later, anti-PLA2R returned positive at 578 RU/mL and he was discharged on steroids. He continued to require dialysis at discharge. At follow up 2 months later renal function returned to baseline and dialysis was discontinued.

Results:

Conclusions: The AKI in this case was likely the combination of contrast, ARB therapy, NSAIDs, and hemodynamic insults in setting of hypoalbuminemia. This case highlights the importance of biopsy in determination of etiology of underlying diagnosis.

TH-PO198

Gastric Stimulator Infection Complicated by Post-Infectious Glomerulonephritis Tyler Woodell, Rupali S. Avasare. *Oregon Health & Science University, Portland, OR.*

Background: Acute poststreptococcal glomerulonephritis, though considered rare among adults in developed countries, remains a serious health concern. In contrast to the typical skin or throat infection preceding acute poststreptococcal glomerulonephritis, here we report to our knowledge the first case of infection-related glomerulonephritis associated with intraabdominal infection after gastric stimulator placement.

Methods: A 24 year-old woman with type 1 diabetes mellitus complicated by gastroparesis and proteinuric stage IIIa chronic kidney disease undergoes placement of a gastric stimulator after multiple emergency room visits for intractable vomiting. She develops severe abdominal pain on postoperative day 27 and presents to the emergency room. On physical exam she is febrile to 102.5 °F, tachycardic to 135 beats per minute and hypotensive to 80s/40s mmHg. Diagnostic studies are remarkable for a serum creatinine of 2 mg/dL (increased from 1.5 mg/dL one month prior), a white blood cell count of 29,000/mL (94% neutrophils) and a CT scan of the abdomen and pelvis that reveals a fluid collection adjacent to the gastric stimulator; blood cultures are negative. She is started on vancomycin and piperacillin-tazobactam and, on postoperative day 30, diagnostic laparoscopy reveals purulent fluid around the stimulator for which it is removed. Intraoperative cultures grow group A *Streptococcus pyogenes*. The patient's antibiotics are narrowed and her clinical status improves. Despite rapid initial improvement in renal function, the patient develops recurrent kidney injury four days after removal of the gastric stimulator characterized by a rise in creatinine from 1.4 mg/dL to 2.9 mg/dL over the subsequent two weeks and oliguria; C3 is reduced and C4 is normal. She is started on hemodialysis for volume overload. A kidney biopsy is performed and findings are significant for mesangial proliferation, exudative endocapillary hypercellularity and interstitial eosinophilia. Electron microscopy reveals mesangial and subepithelial deposits. A diagnosis of infection-related glomerulonephritis is established and, after two months of supportive care, she is able to discontinue hemodialysis.

Results: Clinicians should maintain suspicion for post-infectious glomerulonephritis in the absence of classic infection and, when appropriate, perform a kidney biopsy for its confirmation.

Conclusions:

TH-PO199

Possible Contribution of Vascular Endothelial Growth Factor A (VEGF-A) to the Pathogenesis of Membranous Nephropathy (MN) Ayumi Matsumoto, Isao Matsui, Tomoko Namba, Yusuke Sakaguchi, Masayuki Mizui, Takayuki Hamano, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Autoantibody against thrombospondin type-1 domain-containing 7A (THSD7A) is responsible for primary MN, but the mechanisms how is THSD7A-expression controlled and how is THSD7A recognized by the immune system remain uncertain.

Methods: Two cases of THSD7A-associated MN accompanying subcutaneous tumors were transferred to our hospital. Hypereosinophilia was evident in both cases. Histological analyses of forehead tumors of Case 1 revealed that the tumors were formed by swollen arteries. The arteries were nearly occluded due to small vessels lined by CD31-positive plump endothelial cells, which were surrounded by eosinophils. These findings indicated that the patient suffered from intra-arterial angiolymphoid hyperplasia with eosinophilia (ALHE). The right axillary tumor of Case 2 indicated that Case 2 also suffered from ALHE. Plasma VEGF-A before the initiation of prednisolone therapy was elevated to 109 pg/mL in Case 1 (normal level: 42 ± 20 pg/mL). Serum level of IL-5, a cytokine that upregulates VEGF-A production and secretion by eosinophils, was also elevated to 15.5 pg/mL in Case 1 (normal level: <3.9 pg/mL). These parameters were not measured in Case 2. Flow cytometric analysis of peripheral blood revealed that a substantial number of the circulating eosinophils was positive for VEGF-A in Case 1, and eosinophils infiltrated into the ALHE tumor were also positive for VEGF-A in both cases. Prednisolone therapy dramatically decreased the number of VEGF-positive eosinophils and plasma VEGF-A levels (57.3 pg/mL). We found that plump endothelial cells in ALHE strongly expressed THSD7A in both cases. VEGF-A upregulated THSD7A expression in a dose-dependent manner in cultured human umbilical-vein endothelial cells. Furthermore, double-positive cells for THSD7A and CD83, a molecule involved in antigen-presentation activity, surrounded the proliferated small vessels. These findings suggested that VEGF-A-induced THSD7A was presented to the immune system at ALHE foci.

Results:

Conclusions: Our study clearly demonstrated that VEGF-A induced THSD7A expression. The existence of THSD7A/CD83 double-positive cells in ALHE tumors suggested that THSD7A was immunized at ALHE foci. Therefore, VEGF-A-induced THSD7A-expression outside of the kidney plays important roles in MN pathogenesis.

TH-PO200

A Refractory Case of Membranous Nephropathy Concurrent with IgG4-Related Kidney Disease Hiroyuki Arai,[1] Ryo Kamimatsuse,[1] Naohiro Toda,[1] Keisuke Nishioka,[2] Shuichiro Endo,[1] Takeshi Matsubara,[1] Hideki Yokoi,[1] Motoko Yanagita.[1] [1]*Department of Nephrology, Kyoto University Hospital, Kyoto city, Japan;* [2]*Department of Nephrology, Osaka red cross hospital, Osaka city, Japan.*

Background: IgG4-related kidney disease (IgG4-RKD) is a recently recognized clinical entity characterized by IgG4-positive plasma cell infiltration and characteristic 'storiform' fibrosis. Tubulointerstitial nephritis is the most common finding, which responds well to corticosteroid therapy. However, it is uncertain whether the treatment for IgG4-RKD is equally effective for membranous nephropathy (MN), which occasionally coincides with IgG4-RKD. We present a refractory case of IgG4-RKD accompanied with MN, which warrants the combination therapy of prednisone (PSL) and cyclosporine (CyA).

Methods: A 58-year-old male was referred to our hospital for recently diagnosed nephrotic syndrome. He had a history of autoimmune pancreatitis (AIP), and was maintained on PSL 10 mg/day. Laboratory results revealed serum albumin 2.2 g/dL, creatinine 0.80 mg/dL, IgG4 473 mg/dL, and urinary protein 13.6 g/gCr. Anti-PLA2R antibody was undetectable. Renal biopsy revealed tubulointerstitial lymphoplasmacytic infiltration and storiform fibrosis with increased ratio of IgG4/IgG positive plasma cells (44.8%), predominant subepithelial granular deposits of IgG1 and IgG2 in glomeruli, and electron dense deposits in subepithelial and subendothelial regions along glomerular basement membrane. As other causes of secondary MN were excluded, we diagnosed secondary MN concurrent with IgG4-RKD. Although PSL was increased to 35 mg/day, proteinuria did not resolve. CyA was initiated, and urinary protein started decreasing. While serum IgG4 level increased by tapering PSL, urinary protein remained suppressed. After 1 year of follow-up, urinary protein decreased to 0.34 g/gCr and AIP did not recur under PSL 12.5 mg/day.

Results:

Conclusions: Renal biopsy findings and negative anti-PLA2R antibody argued for secondary MN concurrent with IgG4-RKD. While PSL was effective for the extrarenal lesion of IgG4-RKD, proteinuria was refractory to PSL and the addition of CyA was required. Generally IgG4-RKD responds well to PSL, in great contrast to our case. Moreover, our case is interesting in that serum IgG4 level did not correlate with proteinuria, indicating that serum IgG4 level does not reflect the activity of MN. These findings suggest that the underlying etiology of secondary MN concurrent with IgG4-RKD is different from other lesion of IgG4-RKD.

TH-PO201

Hepatitis C Virus-Associated Glomerulonephritis Following Sustained Virological Response with Direct-Acting Antiviral Therapy Bogdan Obrisca,[1] Roxana A. Jurubita,[1] Vlad T. Berbecar,[2] Bogdan M. Sorohan,[1] Andreea Andronesi,[1] Gener Ismail.[1] [1]*Fundeni Clinical Institute, Bucharest, Romania;* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, Bucharest, Romania.*

Background: Cryoglobulinemic membrano-proliferative glomerulonephritis (MPGN) is the most frequent type of renal involvement in HCV infection. The newer direct-acting antiviral (DAA) agents have been associated with sustained virological response (SVR) in over 95% of cases. However, the efficacy of this therapy on extrahepatic manifestations of HCV infection is still unknown. We report two cases of persistent and new-onset mixed cryoglobulinemia (MC) after successful eradication of HVC infection.

Methods: New onset MC. A 57 year-old male is admitted for purpuric rash and acute nephritic syndrome. His past medical history included psoriatic arthritis diagnosed 35 years ago and cirrhosis due to HCV infection (genotype 1b) for the past 11 years. Six months ago he received the ritonavir-boosted paritaprevir, ombitasvir and dasabuvir regimen and obtained SVR. Prior to this admission serum cryoglobulins were undetectable and urinalysis was unremarkable. The clinical exam revealed a purpuric rash on lower extremities, hepatomegaly and splenomegaly. Laboratory results are shown in table 1. The kidney biopsy was compatible with type I MPGN with extracapillary proliferation and the patient was started on cyclophosphamide and prednisone. After 6 months of immunosuppressive therapy the patient experienced a complete remission. **Persistent MC.** A 50 year-old male presented with nephrotic syndrome (NS). He was known with HCV infection and MC with renal involvement for the past 15 and 2 years, respectively. Initially he received Rituximab and corticosteroids without a clinical response. Three months ago he received the ritonavir-boosted paritaprevir, ombitasvir and dasabuvir regimen and obtained SVR, but with persistence of NS. He underwent a kidney biopsy that showed MPGN with extracapillary proliferation after which he was started on cyclophosphamide. Baseline laboratory results are shown in table 1.

Results:

Conclusions: Despite successful viral eradication with the newer DAA agents there is increasingly recognition that clonal B cell expansion associated with HCV infection can still persist, thus maintaining the autoimmune manifestations.

Table 1

	eGFR (ml/min)	Serum Albumin (g/dl)	Proteinuria (g/day)	Serum C3 (mg/dl)	Serum C4 (mg/dl)	Cryoglobulins
Case 1	68	3.7	1.9	55	1.6	Present
Case 2	63	3.1	9.6	98	3.6	Present

TH-PO202

Daclatasvir Plus Asunaprevir Treatment Ameliorated Proteinuria in Patients with HCV-Related Nephropathy in the Absence of Immunosuppressant Yoshihito Nihei, Hitoshi Suzuki, Maiko Nakayama, Masao Kihara, Tomohito Gohda, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: The standard therapy of a chronic HCV infection is IFN monotherapy or IFN combined with ribavirin; however, after the introduction of direct-acting antivirals (DAAs), the standard therapy for patients with HCV genotype 1 has dramatically changed. However, the effects of DAAs on extra-hepatic manifestations such as HCV-related nephropathy (HCV-RN), especially in cases with renal dysfunction, are not well elucidated. We report a case of HCV-RN successfully treated by Daclatasvir and Asunaprevir, which are IFN-free DAAs for HCV.

Methods: A 66-year-old man was diagnosed as having chronic hepatitis C. Blood examination revealed a high copy number of HCV-RNA (genotype 1b). He presented with microscopic hematuria and proteinuria at the age of 56. After 7 years from the onset of urinary abnormalities, levels of urinary protein increased up to 5 g/gCr, and kidney biopsy was performed. Pathological findings of kidney biopsy specimens revealed mesangioproliferative glomerulonephritis with IgA deposition, and he was diagnosed as HCV-RN. He developed severe nephrotic syndrome with pleural effusion due to the hypoalbuminemia, therefore, we initiated treatment with oral corticosteroid (PSL). However, liver dysfunction was exacerbated and a copy number of HCV-RNA increased after treatment with PSL. Then, we changed medication from PSL to antiviral treatment with Daclatasvir/Asunaprevir. Clearance of HCV-RNA was obtained by 4 weeks and sustained, and microhematuria turned negative, proteinuria decreased (1.5 g/gCr) by 24 weeks. After 2 years from treatment with Daclatasvir/Asunaprevir, level of proteinuria was 0.8 g/gCr.

Results:

Conclusions: Patients with HCV infection have a higher risk of end-stage renal disease. This case offers original evidence for the application of newer generation of IFN-free DAAs in the treatment of HCV-RN.

TH-PO203

Diagnostic Dilemma of a Vasculitic Rash in a Patient with Hepatitis C Infection Arjun Ghodasara,[2] Neha Jaswal,[1] Narottam Regmi,[3] Krishna M. Baradhi.[3] *[1]Family Medicine, University of Oklahoma, Tulsa, Tulsa, OK; [2]Internal Medicine, University of Oklahoma, Tulsa, Tulsa, OK; [3]Nephrology and Hypertension, University of Oklahoma, Tulsa, TULSA, OK.*

Background: Diagnosing ANCA vasculitis in patients with hepatitis C is challenging due to similarity of clinical presentation; moreover, treatment can worsen infection. We present a unique case of vasculitic rash in a patient with hepatitis C that, to our knowledge, has been reported only once previously in literature.

Methods: A 31-year-old man with history of intravenous drug use presented with fever, rash, malaise, and arthralgias. He was initially treated with antibiotics but when fever and rash did not subside was admitted to the hospital for further evaluation. Physical examination was pertinent for temperature of 102 F and a non-blanching purpuric rash on his extremities bilaterally including his palms and soles. Initial labs showed leukocytosis without bacteremia and hematuria and proteinuria on urine microscopy. Further evaluation revealed hepatitis C viral PCR load above 3 million IU/ml, negative cryoglobulins, normal complements, and elevated rheumatoid factor. Skin biopsy revealed leukocytoclastic vasculitis. Our presumptive diagnosis was hepatitis C-related mixed cryoglobulinemia. However, additional findings of C-ANCA 1:160 with positive proteinase-3 antibody and lung nodule on CT chest lead us to the kidney biopsy, revealing focal necrotizing and crescentic glomerulonephritis. Lung nodule biopsy showed necrotizing granulomatous inflammation. Patient was diagnosed with granulomatosis with polyangiitis (GPA). He was initiated on pulse steroids and rituximab along with concomitant treatment with ledipasvir and sofosbuvir for hepatitis C and was discharged with outpatient follow-up.

Results:

Conclusions: The diagnosis and treatment of GPA can be challenging in a patient with hepatitis C. Cryoglobulinemia and GPA may both present with renal dysfunction, hematuria, vasculitic rash, and arthralgia. Treatment of GPA with immunosuppresion can be complicated in a patient with an active infection. ANCA should be evaluated in patients with hepatitis C presenting with rash or other systemic symptoms. Determination of target ANCA antigens is invaluable as false positives are common in hepatitis C. Similarly, hepatitis C-associated infection should be considered in patients with positive ANCA in an appropriate clinical context.

TH-PO204

HCV-Associated Glomerulopathy and Cryoglobulinemia Despite Sustained Remission of Hepatitis C Viremia after Treatment with Oral Direct-Acting Antiviral Agents Rabia Akhtar,[1] Cory Handelsman,[2] John A. Walker.[2] *[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ.*

Background: Millions of people are infected with chronic hepatitis C worldwide. Aside from hepatic injury, hepatitis C virus infection may be associated with a multitude of extrahepatic complications. These include lymphoproliferative disorders (including essential mixed cryoglobulinemia, monoclonal gammopathies and lymphoma), dermatologic conditions such as lichen planus and porphyria cutanea tarda, and glomerular disease.

Methods: We present a case of a 47 year old woman who developed worsening azotemia, nephrotic-range proteinuria, hypocomplementemia, and mixed cryoglobulinemia nearly one year after demonstrating a sustained remission of hepatitis C viremia (genotype 1A) following treatment with the oral direct acting anti-viral agent Harvoni (ledipasvir/sofosbuvir). Kidney biopsy revealed extensive duplication of the glomerular basement membrane on light microscopy, predominant mesangial and capillary wall IgA deposits on immunofluorescence, and extensive dense subendothelial deposits on electron microscopy, consistent with a histologic diagnosis of a hepatitis C virus associated membranoproliferative glomerulonephritis with immune complex deposition. Hepatitis C RNA PCR was negative at the time of the biopsy

Results:

Conclusions: This case is noteworthy in that our patient developed a hepatitis C virus associated membranoproliferative glomerulonephritis with immune complex deposition in the setting of mixed cryoglobulinemia despite achieving a sustained remission of hepatitis C viremia 1 year earlier. Another intriguing and unusual feature of our case is that in membranoproliferative glomerulonephritis, immune complex depositions typically consist of IgG and C3, whereas in our patient the predominant immunoglobulin present was IgA. This case suggests that the immunostimulatory effects of hepatitis C infection may persist or recur despite a successful course of antiviral therapy, and these effects may be responsible for post-treatment glomerular injury.

TH-PO205

Response to Intravenous Immunoglobulin in Acute Parvovirus B19-Associated Nephrotic Syndrome from Collapsing Focal Segmental Glomerulosclerosis Nupur N. Uppal, Nishita Parikh, Hitesh H. Shah. *Hofstra Northwell School of Medicine, Great Neck, NY.*

Background: Human parvovirus B19 (HPV B19) has been associated with collapsing focal segmental glomerulosclerosis (c-FSGS). However, the optimal therapy for HPV B19-associated c-FSGS is currently unknown. While intravenous immunoglobulin (IVIG) therapy has been used for treatment of c-FSGS in immunocompromised patients, its role in immunocompetent patients remains unclear. We report the response to IVIG treatment in 2 immunocompetent patients with HPV B19-associated c-FSGS.

Methods: Case 1: 37-year-old African American (AA) female with sickle cell disease was hospitalized and treated for transient aplastic crisis secondary to acute HPV B19 infection. Five days later, patient presented with worsening lower extremity (LE) edema. She was found to have massive proteinuria (spot urine TP/CR: 56), hypoalbuminemia (serum albumin: 1.8 g/dL) and serum creatinine (Scr) of 1.8 mg/dL. HPV B19 DNA by PCR was markedly elevated (1.8 X 108 IU/ml). Other serological work up for nephrotic syndrome including HIV infection was negative. Kidney biopsy subsequently revealed c-FSGS. In addition to diuretics, patient received trial of 2 doses of IVIG therapy. Despite IVIG treatment, HPV B19 viral load remained elevated and our patient progressed to ESRD within 11 months of initial presentation. **Case 2**: 18-year-old AA male presented for evaluation of AKI (Scr: 2.74 mg/dL) and acute onset nephrotic syndrome. Patient was found to have significant proteinuria (spot urine TP/CR: 14.9) and hypoalbuminemia (serum albumin: 1.9g/dL). HPV B19 DNA by PCR was elevated (95,600 IU/ml). Other serological work up for nephrotic syndrome including HIV infection was negative. Kidney biopsy showed c-FSGS. Patient subsequently received trial of 2 doses of IVIG treatment. HPV B19 viral load remained elevated despite IVIG treatment. Patient did not respond to IVIG treatment and continues to have significant nephrotic syndrome and progressive renal failure.

Results:

Conclusions: Optimal therapy for HPV B19-associated c-FSGS is currently unknown. Role of IVIG treatment in immunocompetent patients with acute HPV B19-associated c-FSGS remains unclear. Our patients continued to have elevated HPV B19 viral load and progressive renal failure despite IVIG treatment. Well-designed studies are needed to understand the mechanisms and treatment of this devastating medical condition.

TH-PO206

Parvovirus Infection Mimicking Atypical Hemolytic Uremic Syndrome in an Immunocompetent Adult Gerald Shovlin,[2] Mark A. Kleman,[1] Joseph Vadakara,[2] Syam Prasad Mallampalli,[2] maria bermudez.[2] *[1]Geisinger Health System, Danville, PA; [2]Geisinger Medical Center, Danville, PA.*

Background: Human parvovirus B19 (PB19) has been associated with thrombotic microangiopathies (TMA) including hemolytic uremic syndrome (HUS) both in immunocompetent and immunosuppressed individuals. To our knowledge, specific pathophysiologic mechanisms for this association is unclear. We present a case of acute

PB19 infection presenting as atypical HUS and discuss potential pitfalls in the diagnosis and implications for therapy.

Methods: A 20-year-old female presents with anuric AKI, thrombocytopenia, and MAHA (low haptoglobin, presence of schistocytes and high LD 1500). Autoimmune diseases including lupus, antiphospholipid syndrome and cryoglobulinemia were ruled out. Her mono test, hepatitis panel, and HIV were negative. C3 complement level was low at 78. Bone marrow biopsy showed reactive neutrophilia and occasional RBC fragments. ADAMTS13 and alternate complement studies were sent and patient was started on dialysis and plasmapheresis (PLEX) for presumed diagnosis of HUS. Reticulocyte count was inappropriately normal for which PB19 PCR was checked and found to be > 600,000 copies. ADAMTS13 came back normal so the patient was started on Eculuzimab (900 mg weekly for 4 doses, then 1200 mg every two weeks) for possible atypical HUS. Alternate complement pathway (TMA functional panel) returned normal, without identifiable mutations predisposing the patient to aHUS. She completely recovered, came off dialysis, and Eculizumab was discontinued.

Results:

Conclusions: Our patient presented with features of atypical HUS in the setting of acute PB19 infection. Her ADAMTS13 and alternate complement pathway were normal making the exact pathophysiologic mechanism of this association unclear. Prompt search for PB19 as a potential trigger of her clinical picture and rapid initiation of PLEX appeared to favor her rapid improvement. Potential role of Eculizumab remains unclear but likely prudent until alternate pathway studies are available. Further studies to better understand this association and approach to therapy are mandated.

TH-PO207

Cytomegalovirus-Associated Collapsing Glomerulopathy and Tubulointerstitial Nephritis in an African American Patient with T-Cell Lymphoma Edgar Hernandez- Montalvo,[2] Sixto G. Giusti,[2] Agnes B. Fogo,[1] Paisit Paueksakon,[1] Juan Carlos Q. Velez.[2] *[1]Department of Pathology, Vanderbilt University Medical Center, Nashville, TN; [2]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Collapsing glomerulopathy (CG) may occur in association with human immunodeficiency virus (HIV) and parvovirus B19 (PVB19) infections. However, published reports of CG associated with cytomegalovirus (CMV) infection are sparse.

Methods: We describe a case of a 69 year-old African American woman with T-cell lymphoma who presented with 1-week history of fever, anorexia and delirium. She was on chemotherapy with alemtuzumab. On arrival, blood pressure was 110/64 mmHg, temperature 38.0 ºC. Physical examination was remarkable for 2+ pitting leg edema. She was pancytopenic with serum creatinine 2.6 mg/dL. Urinalysis revealed 3+ protein and 3+ blood without red blood cell (RBC) casts or dysmorphic RBCs. The urine protein-to-creatinine ratio was 24.8 g/g. Anti-nuclear, hepatitis C, HIV and PVB19 antibodies, polymerase chain reaction (PCR) for HIV RNA, complement levels, hepatitis B antigen and antibodies were all negative or normal. Acute CMV infection was subsequently diagnosed upon detection of serum CMV DNA PCR of 3,450,814 copies/mL. Renal ultrasound revealed normal sized kidneys with hyperechoic parenchymal echotexture. Her kidney function deteriorated and hemodialysis was initiated on hospital day 10. A kidney biopsy was performed. The biopsy showed 10-20% interstitial fibrosis, tubular dilatation, acute tubular injury and multifocal lymphocytic interstitial infiltrates with positive tubular CMV immunostaining. Glomeruli (2 out of 3) showed collapse of the glomerular tuft, overlying visceral epithelial cell hyperplasia and diffuse foot process effacement without immune complexes, characteristic of CG. Despite treatment with valgancyclovir, the patient progressed to require permanent hemodialysis.

Results:

Conclusions: Although CMV immunostaining was negative in glomeruli, we suspect that the glomerular lesion was induced by the viral infection. The patient described herein, as well as those described in the only 3 published cases of CMV-associated CG in the literature, are individuals of African descent. Therefore, we speculate that an interaction between CMV and apolipoprotein L1 risk alleles could trigger cases of CMV-associated CG.

TH-PO208

Recovery of Kidney Function Following Autologous Hematopoietic Stem Cell Transplant in a Patient with C3 Glomerulonephritis Associated with Monoclonal Gammopathy Nicola Lepori,[1] Wisit Cheungpasitporn,[1] Sanjeev Sethi,[2] Nelson Leung,[1] David L. Murray,[3] Fernando C. Fervenza.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN; [3]Laboratory Medicine, Mayo Clinic, Rochester, MN.*

Background: C3 glomerulopathy is associated with presence of monoclonal immunoglobulin (MIg) in almost 60% of cases after 50 years of age. Overall renal prognosis is poor with frequent progression to ESRD.

Methods: A 55 y/o man was referred to our clinic for renal insufficiency (serum creatinine [sCr] from 1.0 to 2.7 mg/dl in the previous 16 months) with a recent episode of gross hematuria. Urinalysis showed hematuria with dysmorphic RBCs and 24h proteinuria was 643 mg. Serology tests showed elevated soluble membrane attack complex (sMAC) and CBb levels, with normal C3, C4, CH50. SPEP with immunofixation showed an Ig kappa M spike of 2.0 g/dL with kappa free light chains of 10.2 mg/dL. Kidney biopsy showed mesangial proliferative glomerulonephritis with bright C3 staining on IF (negative for all immunoglobulins), supporting a diagnosis of C3 glomerulonephritis (C3GN). A bone marrow biopsy revealed 5% to 10% kappa restricted plasma cells; diagnostic work up for multiple myeloma was negative. Patient was treated with 12 cycles of CyBorD based regimen; renal function significantly improved (Table), but after discontinuation of cyclophosphamide and dexamethasone, C3GN relapsed. VRD based regimen was ineffective to induce remission. Thus the patient subsequently underwent high-dose melphalan (HDM) followed by autologous hematopoietic stem cell transplant (ASCT). Three months following ASCT, sCr had fallen to 1.3 mg/dL with M-spike of 0.8 g/dL and kappa free light chains of 2.31 mg/dL

Results:

Conclusions: Recent evidences indicate that treatment direct against underlying monoclonal disorder improves renal survive in MIg-associated C3 GN. As we described in our case, ASCT may potentially be an emerging treatment option for patients with MIg-associated C3GN, especially in those with poor response to classical chemotherapy.

Laboratory testing	Presentation	CyBorD regimen	Maintenance Bortezomib	VRD regimen	3 months following ASCT
sCr (mg/dL)	2.7	1.1	1.5	2.1	1.3
Hb (g/dL)	9.8	n/a	12.5	10.5	12.2
24 h Urine Proteine (mg)	643	347	n/a	280	224
Urinary RBC's (n/hpf)	>100	11-20	21-30	51-100	11-20
M spike (g/dL)	2.0	1.2	1.3	0.8	0.8
Kappa free light chain (0.33-2.63 mg/dL)	10.2	2.92	3.44	3.36	2.31

Crescentic C3 Glomerulonephritis in HIV Disease Muhammad Y. Jan, Jwalant R. Modi, Carrie L. Phillips, Tarek M. El-Achkar, Michael T. Eadon. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Crescentic C3 Glomerulonephritis (C3GN), a subtype of C3 glomerulopathy, presents a diagnostic and therapeutic challenge, especially in the setting of HIV infection.

Methods: A 24-year-old African-American male with no past medical history presented with leg swelling, upper respiratory tract symptoms and hematuria of 2 weeks duration. Physical exam showed signs of volume overload and uncontrolled hypertension. Lab showed serum creatinine of 3.01 mg/dl and urine with dysmorphic RBCs and spot proteinuria of 2.4 g/g. He was found to be HIV+ with viral load of 64,000 copies and CD4 count of 355 cells/µl. C3 and C4 levels were within normal limits. Clinical course showed worsening kidney injury and proteinuria. Anti-GBM IgG, ANA, ASO titer, hepatitis B and C, ANCA titers, cryoglobulins were all negative. A Kidney biopsy revealed crescentic glomerulonephritis with diffuse mesangial and capillary hypercellularity with patchy basement membrane duplication. Immunofluorescence staining revealed 4+ C3 and 1+ IgG. Work-up for other infections was negative. Alternate complement pathway analysis showed borderline low level of Factor H, normal C3 nephritic factor and low levels of Factor B and I confirming the diagnosis of C3GN. He was initiated on HIV treatment, pulse steroids, and Cellcept®. This lead to stabilization and subsequent improvement of renal function.

Results:

Conclusions: Diagnosis of glomerulonephritis with predominant C3 deposits in the setting of HIV disease is very challenging. The differential includes C3GN, infection related GN, and HIV immune complex disease (HIVICK). The overlap between these entities and the relevance to disease pathogenesis and management is still unclear. Correlation between isolated strong C3 staining on biopsy and normal C3 complement levels may be more suggestive of C3 glomerulopathy. Testing for abnormalities in the complement pathway is crucial to establish a firm diagnosis. The low levels of Factors B and I in this case suggest inhibited C3 activation, which could be related to HIV disease itself. We report a case of crescentic C3GN with altered factors B and I in a patient with HIV disease. Further investigation is required to determine whether HIV may dysregulate complement and precipitate C3 glomerulopathy.

TH-PO210

Congestive Glomerulopathy: An Uncommon Primary Finding in Nephrotic Syndrome Michael D. Donnan,[1] Yashpal S. Kanwar,[2] Daniel Batlle,[1] Shubhada N. Ahya.[1] *[1]Nephrology, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Pathology, Northwestern University Feinberg School of Medicine, Chicago, IL.*

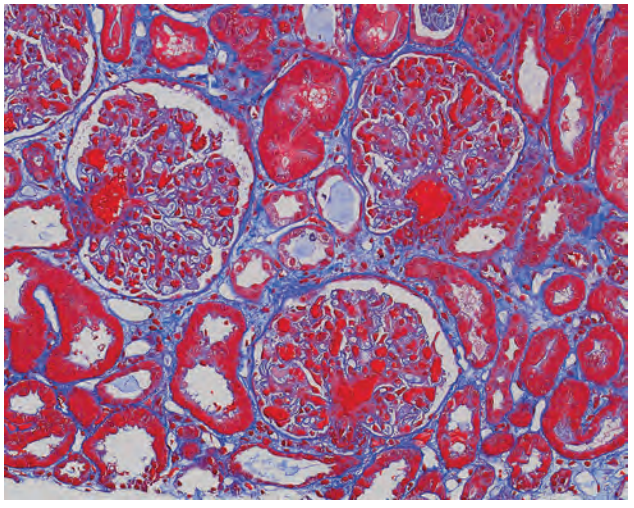
Background: Congestion of the intra-glomerular feeding arterioles is a pathologic feature uncommonly reported as a primary finding on renal biopsy. Here we present a case of significant congestion of the intra-glomerular arterioles in a man with nephrotic syndrome and oliguric renal failure.

Methods: A 42 yo man presented with 2 weeks of weight gain and dyspnea. His symptoms were preceded by arthralgias for which he was taking regular ibuprofen. Exam demonstrated anasarca. Labs showed a rising serum creatinine from 0.9 to 6.4mg/dl. Serum albumin was 1.9g/dl, urinalysis with blood and protein, and 24 hour urine protein collection was 8.4g. Serologies revealed a low C3 / C4 and positive ANA. A renal biopsy showed minimal mesangial proliferation, marked dilation of the intra-glomerular portion of the feeding arterioles with significant congestion in a majority of the glomeruli by light microscopy. No other vascular pathology or micro-thombi seen. Final pathology was consistent with class V lupus nephritis. Renal artery duplex did not show renal vein thrombosis. Patient developed an acute deep vein thrombosis of the right brachial vein; hypercoagulable studies were unremarkable. Initiated on steroids and mycophenolate

mofetil. One month after presentation, serum creatinine returned to baseline with <1g proteinuria.

Results:

Conclusions: Marked intra-glomerular congestion is an atypical pathologic finding whose mechanism and significance is not yet known. It has been reported concurrently with visible micro-occlusions, as in the setting of thrombotic microangiopathy or sickle cell crisis. It rarely has been reported with renal vascular flow limitations, such as states of shock and renal vein thrombosis. In the setting of nephrotic syndrome one may postulate smaller venous thrombembolisms may have been present. While not previously reported, we surmise the possibility that the use of NSAIDs may have contributed to these findings.



TH-PO211

Polycythemia Vera: An Unusual Cause of Proteinuria

Christin M. Giordano,[3] Marika Manolopoulou,[1] Ed Gould,[3] Mark Lusco.[2]
[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University School of Medicine, Nashville, TN; [3]Medicine, Vanderbilt University Medical Center, Nashville, TN.

Background: Introduction: Polycythemia vera (PV) is a myeloproliferative disease which is typpified by increased red cell mass; rarely it has been associated with renal manifestations, including nephrotic syndrome. Here, we present a case of PV associated with glomerular basement membrane thickening and consequent proteinuria.

Methods: Case Description: Patient is a 46 year-old male with a history of mild hypertension on lisinopril monotherapy who presented to nephrology clinic after urinalysis performed as part of a life insurance examination revealed proteinuria. He was otherwise asymptomatic. He was thin and muscular with mild rubot and blood pressure 148/81. Initial laboratory examination was notable for a hematocrit of 56%, creatinine of 1.0 mg/dL, and a urine protein-to-creatinine ratio (PCR) of 3.2 g/g. Renal ultrasound demonstrated normal appearing kidneys but raised concern for hepatatic pathologiy. Magnetic resonance imaging showed mild diffuse hepatic steatosis and splenic vein thrombosis. Laboratory examination was negative except for a mildly postive antinuclear antibody ratio of 1:80. Renal biopsy was pursued. This revealed diffusely thickened glomerular basement membranes concerning for dysmetabolic injury. Given his splenic vein thrombosis and increased hematocrit, he was referred to hematology for PV. He underwent JAK2 mutation testing which was positive. He was initiated on maximal renin-angiotensin-aldosterone blockade and his PCR decreased to 1.9 g/g. As his hematocrit decreased with phlebotomy, his PCR has continued to decrease, most recently to 1.5 g/g.

Results:

Conclusions: Discussion: Previous reports have shown an association between myeloproliferative disorders and various glomerulopathies. In the largest published series of these patients, though, only 1 of the 11 reported patients had PV as an explanation for nephrotic syndrome. While the natural history of this condition is uncertain, in a patient being evaluated for new proteinuria with the right clinical findings, PV should be included in the differential diagnosis. Further study of these patients will help us further understand the pathophysiology of the disease and whether treatment of the PV improves renal outcomes.

TH-PO212

Rituximab as Rescue Therapy for Difficult to Treat Lupus Nephritis: A Case Series

Jaime A. Baynes-Fields,[1] Al J. Lee,[3] Navneet Kaur,[2] Sandeep Aggarwal.[2] *[1]Drexel University, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA; [3]None, Philadelphia, PA.*

Background: Conventional treatment of lupus nephritis with antimetabolites, calcineurin inhibitors, and steroids may be associated with intolerable adverse events or treatment resistance. We present a case series of patient characteristics and treatment response to rituximab therapy in three patients with resistance or intolerance to conventional lupus nephritis therapy at our center.

Methods: Patient data for three lupus nephritis patients who were treated with rituximab was obtained from retrospective chart review. Student t-test was used for comparison of means. Demographic serological, clinical characteristics and indications for rituximab therapy are presented in (Table 1). There was a non-statistically significant improvement between pre-rituximab serum creatinine (sCr) (1.26 ± 0.18 mg/dl) and post-rituximab sCr (1.00 ± 0.3 mg/dl, p=0.153) and pre and post rituximab degree of proteinuria (1664 ± 1278 vs 739 ± 595 mg/g, p=0.18). There was a statistically significant improvement in pre and post rituximab serum complement C3 (66 ± 45 vs 94 ± 42 mg/dl, p=0.003) and serum complement C4 levels (10.7 ± 5.5 vs 22.3 ± 11.2 mg/dl, p=0.04). The average time to treatment response, defined as 50% reduction in proteinuria, and serological increase in complement levels, was 7 months. There were no adverse events reported. There was a clinically significant reduction in immunosuppression and medication side effects as well as tolerance (Table 1).

Results:

Conclusions: In conclusion, rituximab as a "rescue" therapy was efficacious and well tolerated in our patients. More research is required to ascertain the clinical and serological characteristics of patients with lupus nephritis who may benefit from rituximab therapy.

Table 1: Demographic, Serological and Clinical characteristics

Case Number	Demographics: age(years), ethnicity, gender	Lupus Nephritis Class	Pre-Rituximab Regimen, Total daily dose in mg (miligrams)	Post-Rituximab Regimen, Total daily dose in mg (miligrams)	Rituximab Indication*,**	Time to Peak Response (months)	Serology Profile
1	27, White, Female	4	Prednisone 10 mg Mycophenolate 3000 mg Tacrolimus 3 mg	Prednisone 1mg Mycophenolate 1000 mg	Treatment failure, osteoporosis, cushing syndrome	8	ANA (-), dsDNA (-)
2	54, Black, Male	4	Prednisone 5 mg Mycophenolate 2000mg - intolerant* Azathoprine 100mg - intolerant* Hydroxychloroquine 800mg	Prednisone 5mg Hydroxychloroquine 400mg	Multiple infections, Treatment failure	10	ANA (+), dsDNA (+), RNP (+), SSa/SSb (+)
3	25, Black, Male	4+5	Prednisone 10 mg Mycophenolate 2000 mg Tacrolimus 3 mg	Prednisone 5 mg Mycophenolate 2000mg Tacrolimus 1.5 mg	Multiple infections, Treatment failure	4	ANA (+), dsDNA (+)

*Intolerance secondary to multiple infections (empyema, pyelonephritis)

**All patients were given rituximab 1gram IV x 2 doses

TH-PO213

Unusual Case of Lupus Nephritis with Negative Serology

Eddy J. De jesus, Bindu Goel, Rabih Nasr. *Bronx Lebanon Hospital, Bronx, NY.*

Background: Lupus Nephritis (LN) is a common complication of Systemic Lupus Erythematous (SLE) and occurs in 43-55% of the cases, usually in first year of the disease. It is one of the highest predictors of morbidity and mortality, and thus requires prompt diagnosis and treatment

Methods: We report a case of a 25 year old hispanic female presenting to the nephrology clinic referred due to episodes of gross hematuria for 2 months followed by persistent asymptomatic microhematuria and proteinuria of 2g/day, In the initial workup she was found to have proteinuria up to 2 grams/day and further autoimmune workup revealed positive anti-myeloperoxidase of 115. She did not have any history of diabetes or hypertension, no edema, serum creatinine of 0.8 mg/dl, urinalysis 1-2+ protein microhematuria, no RBC cast, urine total protein/creatinine ratio 2.0 gm, serum albumin 3.6 g/dl, with positive anti-MPO ANCA, negative ANA, Hepatitis B Virus(HBV) and Hepatitis C. Initially she was suspected to have microscopic polyangiitis however kidney biopsy was done and revealed membranous and focal segmental endocapillary and extra capillary proliferative and sclerosis glomerulonephritis, immune complex type, suggestive of class V and III of moderate activity and moderate chronicity, and mild tubulointerstitial atrophy with P-ANCA/Anti MPO antibody associated/clinical. Since biopsy was suggestive of Lupus Nephritis, comprehensive serologies were sent once again and reported as negative for ANA, anti-ds DNA, Sm, RNP, SSA-SSB, cardiolipin and included normal complements. Patient was started on Mycophenolate Mophetil and prednisone (tapering) One year after diagnosis patient still denies any constitutional symptoms, rashes, photosensitivity, oral ulcers, joint pain/swelling or weight loss

Results:

Conclusions: Lupus Erythematous (SLE), is a heterogeneous autoimmune disease that affects multiple organs and particularly the kidneys. Fortunately anatomical and pathologic markers of Lupus nephritis are quite specific. Rare cases such as the one from Chi Young Park et al, where there is pathological confirmation of LN but negative serology have been reported. Nephrologists should still have high suspicion of Lupus nephritis in any patient that presents with proteinuria and hematuria and negative serology as limited data is available as it has shown poor prognosis.

TH-PO214

Podocytes Contact with the Mesangial Cells at the Mesangial Interposition in a Case of Human Lupus Nephritis: Three-Dimensional Observation by Serial Block-Face Scanning Electron Microscopy Takashi Takaki,[1] Nobuhiko Ohno,[2] Sei Saitoh,[3] Masaaki Nagai,[4] Kensuke Joh.[5] *[1]Showa University, Tokyo, Japan; [2]Jichi Medical University, Shimotsuke-shi, Japan; [3]National Institute for Physiological Sciences, Okazaki, Japan; [4]Narita Memorial Hospital, Toyohashi-shi, Japan; [5]Tohoku University Graduate School of Medicine, Sendai-city, Japan.*

Background: We employed serial block-face scanning electron microscopy (SBF-SEM) to examine the three-dimensional relationships among the cells and extracellular matrix in a case of human lupus nephritis.

Methods: A 25 year-old female, who presented nephrotic syndrome, microscopic hematuria 10-20/hpf, and hypocomplementemia with C3 47 mg/dl and C4 4 mg/dl. Anti-nuclear antigen titer and anti ds-DNA titer were x640 and 191 mg/dl, respectively. Renal biopsy revealed membranoproliferative glomerulonephritis like lesion of lupus nephritis, Class IV A/C in light microscopy. The detail of ultrastructural morphology was almost similar to that of TEM excepting a thicker staining on the nuclear membrane and thinner staining of immune deposits. Using SBF-SEM, we followed the localization of the cytoplasmic processes of the podocyte, which invaded into the lamina densa of the glomerular basement membrane (GBM) and penetrated finally into the mesangial matrix. On the other hand, mesangial interposition was seen of varying length beneath the lamina densa of the GBM along the glomerular capillary loop. The mesangial cells, which were recognized in the extended mesangial matrix as having dense patch on the cytoplasmic membrane, showed a proliferative change. We followed the cytoplasmic process of the podocyte penetrating into the mesangial matrix and have succeeded to find a manifestation of direct cytoplasmic contact of the podocytes with the cytoplasm of the mesangial cells (Figure).

Results:

Conclusions: Since a direct contact between podocytes and mesangial cells was found, it is easier to understand an effect of podocytes on the mesangial cells by assuming an intercellular signaling communication, which may result in a proliferation of the mesangial cells and an overproduction of the extracellular matrix. This finding provides a new insight on a mechanism of a progression of glomerular sclerosis via podocyte-mesangial interaction.

TH-PO215

Primary Tubulointerstitial Lupus Nephritis Complicated by Diffuse Alveolar Hemorrhage Farhan Qadeer,[1,2] George P. Bayliss,[1,2] Sairah Sharif.[1,2] *[1]Alpert Medical School, Brown University, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: Lupus nephritis (LN) most often affects the glomerulus. While tubulointerstitial nephritis (TIN) commonly accompanies glomerular lesions, predominant and isolated TIN is extremely rare. Here we describe the case of a woman with systemic lupus erythematosus (SLE) who presented with respiratory failure and acute kidney injury due to isolated TIN.

Methods: A 39 year old Caucasian woman with history of SLE for 7 years without renal involvement was admitted with complaints of abdominal pain, vomiting, diarrhea, fevers up to 103 F for 3 days. She took ibuprofen for symptoms. Physical examination revealed blood pressure 110/57, heart rate 116, temperature 98.6 F. She had right-sided basilar crackles and no edema. Lab data showed white blood cell 1.0/μl, platelet 200 x10^4/μl, hemoglobin 10.2gm/dl, blood urea nitrogen 58mg/dl, creatinine 3.7mg/dl, elevated titers of anti-ANA (1:10240) and anti-double stranded-DNA antibodies (25IU/ml); low C3 and C4. Urine sediment showed granular casts, no dysmorphic red blood cells. She was treated with penicillin for streptococcus bacteremia and received empiric high-dose corticosteroids after undergoing a renal biopsy. On hospital day 4 she developed respiratory distress and hypotension, requiring intubation and ICU transfer. Diffuse alveolar hemorrhage was suspected on the basis of hemoptysis, and she was started on cyclophosphamide. Creatinine rose to 5.8mg/dL; she required hemodialysis for worsening metabolic acidosis, oliguria. Renal biopsy showed normal glomeruli, patchy interstitial inflammation on light microscopy; tubular basement membranes stained positive for IgG, IgM, C3, kappa and lambda on immunofluorescence. After 4 dialysis sessions, renal function improved to baseline and dialysis was stopped. She was extubated and eventually discharged on prednisone with stable renal function.

Results:

Conclusions: TIN along with glomerular lesions has been reported in SLE in up to 66% of biopsy samples, but isolated TIN LN without glomerular lesions is a rare entity. The pathogenesis may be due to circulating immune complexes or cytotoxic T-cell mediated injury. Patients usually present with subnephrotic-range proteinuria, renal tubular acidosis and hypocomplementemia. Most patients have been treated with corticosteroids with reasonable response. To our knowledge this is the first reported case of SLE-TIN with diffuse alveolar hemorrhage.

Novel PLG Gene Mutation with Heterozygous CHFR1-R3 Deletion in a Patient with Atypical Hemolytic Uremic Syndrome and Lupus Nephritis Huzair Ali,[2] Taseen A. Syed,[3] Joe Ghata,[1] Mubasher Abbas.[4] *[1]OUHSC, Oklahoma City, OK; [2]University of Oklahoma, Oklahoma City, OK; [3]University of Oklahoma Health Sciences Center, Oklahoma cty, OK; [4]University of Oklahoma College of Medicine, Oklahoma City, OK.*

Background: Thrombotic Microangiopathy (TMA) is a disease characterized by intravascular thrombosis, hemolytic anemia, and endothelial cell damage, often contributing to renal failure. Atypical Hemolytic Uremic Syndrome (aHUS) is a complement mediated TMA. Most genetic abnormalities linked to aHUS relate to dysregulation of these complement and coagulation pathways. We describe a case of aHUS with lupus nephritis in a patient with a unique set of mutations, including the plasminogen (PLG) gene, recently linked to aHUS.

Methods: 19 yo male presented with facial swelling, rash and fever for three days. On evaluation, he was in hypertensive emergency (>200/100mmHg), hypopigmented facial lesions with vitiligo on right ear. Labs demonstrated acute renal failure (Creatinine (Cr) 7.80mg/dL) requiring intermittent hemodialysis Work up revealed pancytopenia, ANA titer 1:320, positive schistocytes, low C3/C4 levels, normal ADAMTS13 activity, and negative infectious work up. Kidney biopsy showed diffuse proliferative glomerulonephritis consistent with Lupus nephritis (Class IV-A). Moreover, TMA affected the afferent arterioles. Renal Failure was refractory to PLEX, Steroids, Cellcept, and Rituximab. Renal Failure and hemolytic anemia only improved after Eculizumab, with Cr nadir to 2mg/dL upon discharge. Genetics later showed: **(1)** Heterozygous missense mutation of exon 2 & 10 of PLG gene, **(2)** Two polymorphisms in CFH gene, **(3)** Heterozygous polymorphism within an intron in MCP/CD46 **(4)** Heterozygous for the large CFHR1-CFHR3 deletion.

Results:

Conclusions: Mutations in the complement pathway have been described with atypical HUS. Coagulation pathway mutations are being linked with the pathogenesis of aHUS. Our patient developed renal TMA through complement dysregulation (via both classical & alternative pathways) likely through a double hit from Lupus nephritis flare, as well as underlying heterozygous genetic mutations (CHFR, CFH, & MCP/CD46 genes). In addition, dysregulation of the coagulation pathway through his PLG gene mutation likely contributed to his persistent renal TMA. This case suggests heterozygotes for these mutations may benefit from Eclizumab, especially in refractory cases of aHUS.

TH-PO217

A Unique Case of Sjogren's Syndrome-Associated Cryoglobulinemic Glomerulonephritis Brad Long, Ryan Morton, Catreena Marji, Monique E. Cho, Laith Al-Rabadi. *University of Utah Hospital, Salt lake, UT.*

Background: Cryoglobulinemic Glomerulonephritis is rare and not well described in the absence of Hepatitis C virus. Sjogren's syndrome continues to be the second most common cause of mixed cryoglobulinemia after hepatitis C virus (HCV). We present a unique case of Sjogren's disease and cryoglobulinemic glomerulonephritis

Methods: Patient is a 65 year old male patient with medical history relevant for Sjogren's disease and hepatitis C, in remission after treatment with interferon 10 years ago, presented to the outside hospital with a 5-day history of fatigue, headache, facial swelling and lower extremity rash. His physical exam was relevant for petechial rash involving his low extremities. Initial investigation revealed well preserved renal function with creatinine of 1 mg/dL. Urine protein was 1346 mg per gram of creatinine. Urine microscopy showed many non-dysmorphic RBCs with no cellular casts. Further workup showed ANA 1:2560, with positive SSA/SSB. The antibodies for GBM, dsDNA, RNP, ASO, Smith Ab, and ANCA were all negative. Complement 3 and 4 levels were 44 mg/dL and undetectable, respectively. HCV PCR was undetectable. Cryoglobulin from outside hospital was negative. Rheumatoid factor was elevated at 411 IU/mL. Immunofixation showed a faint band in the IgM kappa region. Light microscopy showed 15 glomeruli, many with lobular membranoproliferative pattern, mesangial and endocapillary hypercellularity. There was also evidence of focal intra-capillary eosinophilic material and hyaline pseudothrombi. Immunofluorescence showed granular mesangial and capillary wall staining for the following: 3+ IgM, 1-2+ IgG (segmental), 2+ C3, trace C1q, 2+ Kappa, and trace lambda. Electron microscopy revealed segmental immune-type subendothelial and mesangial electron dense deposits with no definite substructural organization. Repeat Cryoglobulin done at our hospital was positive. Patient was started on prednisone 60 mg and Azathioprine 100 mg daily. He had complete resolution of proteinuria and hematuria in one month

Results:

Conclusions: Elevated rheumatoid factor, and very low complement 4 level were the key for suspecting cryoglobulinemic glomerulonephritis despite the absence of impaired GFR. Cryoglobulinemia in this case is likely related to Sjogren's syndrome, not hepatitis C, given the undetected Hepatitis C PCR. Early treatment is crucial in preserving renal function

TH-PO218

Cryoglobulinemic Glomerulonephritis in a Patient with Sjögren Syndrome Ramon Noriega,[2] Tina Kochar,[2] Hania Kassem,[2] Adam J. Ward,[1] Marjan Afrouzian.[2] *[1]UTMB, Galveston, TX; [2]University of Texas Medical Branch, Galveston, TX.*

Background: Background: Sjögren's Syndrome (SS) is a disease characterized by lympho-plasmacytic infiltration of exocrine glands. Interstitial nephritis is the most common form of renal involvement in SS. Glomerular involvement including Membranoproliferative glomerulonephritis (MPGN) is relatively rare.

Methods: Case Description: A 73 yr old Caucasian female with past medical history of uncontrolled hypertension and SS presented with fluid overload. Physical examination revealed pulmonary crackles and peripheral edema. Laboratory analysis was significant for a creatinine of 1.5 mg/dL and urine protein to creatinine ratio of 2.5g/g. Urine microscopy revealed dysmorphic red blood cells. Serologies for hepatitis B, C, HIV, cryoglobulins and ANA were negative. Serum complements were low. **Pathology:** Light microscopy revealed 14 glomeruli with the following findings: global sclerosis (1), segmental sclerosis (4), endocapillary proliferation (5), and intracapillary coagula of cryoglobulins (4). Mild tubular atrophy/ interstitial fibrosis/ inflammation, mild arteriosclerosis and arteriolar onionskin pattern were also present. By immunofluorescence microscopy 12 glomeruli showed granular mesangial and capillary loop staining with IgG/Kappa/Lambda (+++), IgA and IgM (++), and C1q (+). Electron microscopic findings in 2 glomeruli included thickened glomerular basement membrane, mesangial interposition, subendothelial, subepithelial, and mesangial deposits of cryoglobulins. Cryoglobulinemic GN (secondary MPGN) in the background of SS was diagnosed.

Results:

Conclusions: Discussion: In our patient, glomerular involvement by MPGN, an uncommon pathologic manifestation of SS, was complicated by mixed cryoglobulinemia which was not detected in serum but noted on renal biopsy. This reflects the high incidence of false-negativity of serum cryoglobulin testing due to suboptimal specimen collection and handling. Our case highlights the importance of SS as a non-HCV-related cause of mixed cryoglobulinemia, and the significant role of renal biopsy. Renal insufficiency in patients with SS may not always be secondary to acute/chronic tubulo-interstitial nephritis or primary MPGN, but rather a secondary glomerular disease such as Cryoglobulinemic GN. Patient was started on prednisone with significant improvement in her symptoms and renal function and resolution of proteinuria.

TH-PO219

Necrotizing Crescentic Glomerulonephritis after Allogenic Stem Cell Transplant Shehryar Anjum, Lin Liu, Luis Bent-shaw. *Nephrology, University at Buffalo, Buffalo, NY.*

Background: Renal disease in Allogenic stem cell recipients involves glomerular, tubular /vascular injury triggered by chemo/radiation/infection/ischemia/GVHD & Immunosuppression. Rare reports of collapsing FSGS, Fibrillary GN & Anti GBM noted.

Methods: 61 y/o female with Myelodysplastic Syndrome treated with Azacitidine & Decitabine, complicated by refractory thrombocytopenia & anemia. Allogenic stem cell transplant (Brother) June, 2016, complicated by GVHD (Skin, GI and likely Lung). Hospital admissions for seizures due to PRES likely to Tacroliumus use, Influenza A & RSVpneumonia with subsequent pulmonary GVHD. She developed non oliguric AKI. Creatinine 1.1 -> 1.5. ROS -ve, v/s stable. Physical exam revealed no JVD, Chest with bibasilar crackles. S1, S2 noted, no S3. Abdomen benign, non tender. Lower extremity +2 pitting edema. Urine under light micro. revealed many WBC/ RBCs but no dysmorphic RBC or cast noted. U/S Renal reveals RT. kid12.8 cm & LT. kid 14 cm, minimal increased echogenicity. No hydronephrosis. Subsequent large epistaxis relieved with nasal packing & transfusing platelets. Transferred to ICU for seizures/confusion. With current picture, concerns for TTP/HUS. Plasmapheresis started. Received 3 sessions + steroids with improved mental status. Cr 1.15 --> 4.5. ADAMST13 in limits. HIT +ve. Urine again revealed no casts however some dysmorphic RBC suspected. Initiated Hemodialysis due to her worsening renal parameters and oliguric state. She underwent Renal Biopsy which revealed 6/6 Glom. with Necrotizing Crescentic pattern, granulomatous interstit. inflammation & necrotizing vasculitis, moderate interstitial fibrosis and tubular atrophy, no glomeruli for IF. EM reveals disrupted, corrugated Basement membrane. Serologic studies negative except for anti-GBM(179). Started on oral Cyclophosphamide & prednisone, plasmapheresis resumed with no recovery. Treatment subsequently stopped & Steroids tapered off. Per Oncology team started weekly Rituximab 800 mg IV for chronic GVHD. Patient remains dialysis dependent for>8 weeks now deemed ESRD.

Results:

Conclusions: Rare case of RPGN with anti-GBM following allogenic stem transplant as a potential complication of GVHD. Interestingly our patient had clinical Pulmonary GVHD. Exposure of collagen type Iv alpha 3 epitope due to immune injury is speculated mechanism however unclear if true relation with Stem cell transplant/GVHD & Anti GBM disease.

TH-PO220

A Rare Case of Crescentic Glomerulonephritis Mimicking Multiple Myeloma Alinda M. Sarma,[1] Mohammad Alomari,[1] Anca C. Vlasie.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Comprehensive Kidney Care, Westlake, OH.*

Background: We describe a unique case of biopsy proven crescentic glomerulonephritis with an earlier presumptive diagnosis of multiple myeloma.

Methods: A 58 year old male with past medical history of hyperlipidemia and enlarged prostate was admitted to the hospital with worsening shortness of breath(SOB) and new onset generalized petechial non-pruritic rash. Vitals signs were temperature of 97.2 F, heart rate of 100 beats per minutes, and blood pressure of 112/64 mm Hg. Physical exam showed diffuse, raised, non-blanching, rash involving palms and soles, diffuse crackles on lung auscultation and bilateral foot drop. Initial laboratory studies showed hemoglobin of 8.3 g/dl, leukocytosis of 28,000(k/uL), severe acute kidney failure with creatinine of 12 mg/dl, and uric acid of 15 mg/dL. Urinalysis showed many RBCs and mild proteinuria without any cast. Based on sudden bilateral foot drop, anemia, axonal acute to sub-acute sensorimotor peripheral polyneuropathy on electromyography and elevated kappa to lambda ratio in blood workup, a presumptive diagnosis of multiple myeloma was made as an outpatient. On the day of bone marrow biopsy, patient developed severe SOB, confusion, and was brought to the hospital. On further inquiry, he endorsed a history of recurrent sinusitis for many years. Imaging studies including chest radiography, chest CT scan, brain CT scan and renal US were unremarkable. Bronchoscopy was done due to ongoing SOB, which showed diffuse alveolar hemorrhage. Further work-up showed a positive C-ANCA titer and elevated proteinase 3 antibodies. Subsequently kidney biopsy was done which was consistent with pauci-immune necrotizing crescentic glomerulonephritis(CrGN) with necrotizing arteritis. He responded very well to plasmapheresis, pulse dose steroid and cyclophosphamide.

Results:

Conclusions: Both ANCA –positive CrGN and mutiple myeloma can present with systemic manifestations of renal failure, peripheral neuropathy and skin lesions. An elevated kappa lambda ratio in this context can often perplex the clinical scenario. Careful history and serologic markers often aid in separating one from another. However, a kidney biopsy remains the gold standard in distinguishing amongst variants of RPGN to guide therapy and estimate prognosis. Prompt and aggressive plasmapharesis in addition to pulse therapy with cyclophosphamide can reverse kidney injury to a large extent.

TH-PO221

The "M" Factor: An Insight into IgM Nephropathy Divyanshu Malhotra, Randy L. Luciano. *Yale New Haven Hospital, New Haven, CT.*

Background: Nephrotic syndrome is an important clinical entity with multiple manifestations and a variety of causes. In addition to MCD, three other disorders causing a picture of nephrotic syndrome present initially with minimal changes on light microscopy. These include idiopathic mesangial proliferative glomerulonephritis, IgM nephropathy and C1q nephropathy. There is a controversy regarding these being a part of the spectrum of MCD/FSGS versus being separate clinical entities. We present a series of 2 patients with IgM nephropathy and their interesting clinical course.

Methods: Case 1 61 y/o male with DM who had initially presented with lower extremity edema, scrotal swelling and was found to have 3+ proteinuria. His further w/u revealed Hepatitis C Genotype 1b infection. He had a kidney biopsy which was consistent with IgM nephropathy and early diabetic nephropathy. Initially it was thought that this was secondary to the hepatitis C. He received Ledipasvir/Sofosbuvir for the Hepatitis C with SVR. This led to proteinuria resolution but recurrence in 3 months. Started on prednisone which controlled the proteinuria but with recurrence when he tapered off steroids. He had a another biopsy which showed evidence of IgM nephropathy again. He was then started on Cellcept and currently remains in remission on the same. Case 2 22 y/o male who came to our clinic with a diagnosis of FSGS and nephrotic syndrome. He had been steroid dependent with frequent relapses off prednisone. Repeat biopsy showed evidence of IgM nephropathy concomitant with FSGS. He was switched to Cellcept leading to remission but with relapse requiring steroids. His course waxes and wanes on cellcept and we have planned for an extended genetic testing panel for podocyte specific genes.

Results:

Conclusions: IgM nephropathy is a rare condition and has been a controversial entity since its first description. It is characterized by prominent diffuse mesangial deposits of IgM +/- complement, along with electron dense deposits in the mesangium. Limited case series suggest that it is typically more steroid resistant than idiopathic MCD. Progression to FSGS is possible in a number of cases. Exact pathophysiology and relationship to FSGS is not well defined. Clinical progression is intermediate between MCD and FSGS. Multiple steroid sparing immunosuppressants have been tried with variable responses thus it can be a challenging disease to manage as seen in our cases too.

TH-PO222

A Case of Low-Dose Rituximab for the Treatment of Steroid Resistant Nephrotic Syndrome Marie Murata,[5] Daisuke Ichikawa,[2] Tomo Suzuki,[6] Shiika Watanabe,[4] Mikako Hisamichi,[3] Yugo Shibagaki.[1] *[1]Division of Nephrology and Hypertension, St Marianna University Hospital, Kawasaki, Japan; [2]St Marianna University of Medical School, Yokohama City, Japan; [3]St.Marianna university school of medicine, Kawasaki, Japan; [4]the Kawasaki Municipal Tama Hospital, Kawasaki Citiy Tama Ward, Japan; [5]St.Marianna medical school of medicine, Kawasaki, Japan; [6]Kidney and Vascular Pathology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan.*

Background: The efficacy of rituximab for frequent relapsing nephrotic syndrome has been reported. Some reports have a use of low dose rituximab for treatment of the ABO incompatible kidney transplant patients. Rituximab dosage of 100 mg/body was administered, which led to immediate depletion of CD20-positive cells. Therefore, a low dose rituximab may have a possibility of same effect compared to the normal dose rituximab.

Methods: A 22-year-old Japanese man presented with severe peripheral edema within several days after onset. His past history is not in particular. Nephrotic syndrome was diagnosed and minimal change disease was diagnosed by renal biopsy.

Methyl-prednisolone was administered at 500mg/day for 3 days and prednisolone was administered at 1mg/kg/day. Nephrotic syndrome become a remission at 7 days, however nephrotic syndrome was replaced at 28 days. After that methyl-prednisolone was administered at 500mg/day for 3 days two times and cyclosporine was added however, nephrotic syndrome was not improved. An initial rituximab dosage of 100 mg/body was administered. Two weeks later, urinary protein was 1g or less. Rituximab dosage of 100 mg/body was administered. Two months later, it became possible to taper prednisolone by 5mg. Six months later, it became possible to taper off prednisolone. He maintains remission of nephrotic syndrome by administering of rituximab dosage of 100 mg/body every four months.

Results:

Conclusions: Low dose rituximab might be an option for the treatment of steroid-resistant nephrotic syndrome. It was expected a reduction of the cost-effectiveness and side effect of rituximab. This case could be steroid dependent nephrotic syndrome from this history, therefore low dose rituximab might be an option for maintenance of steroid dependent nephrotic syndrome.

TH-PO223

A Case of Rapid Remission Proteinuria with Ace Inhibitor Monotherapy in HIV Associated Minimal Change Disease Alfonso D. Moreno, Janice B. Desir, Juan P. Vera-Gomez, Libardo Rueda prada. *St Barnabas Hospital, Bronx, NY.*

Background: The use of antiretroviral drugs among HIV patients has been associated with a number of renal toxicities including proteinuria. Minimal-change disease (MCD) with nephrotic syndrome in this population has also been described, though uncommon. First line therapy includes corticosteroids with a need for prompt and efficient management since this is linked with increased mortality and poor outcomes. However, there is a higher chance for opportunistic infections with HIV. Here we report an atypical case of HIV associated MCD on Atripla (tenofovir/emtricitabine/efavirenz) with rapid remission of proteinuria on monotherapy with angiotensin converting enzyme (ACE) inhibition.

Methods: A 45-years old man with HIV-1/AIDS (diagnosed 2011) initially presented July 2016 to HIV clinic with three-week bilateral lower extremity edema. Screening labs showed creatinine 0.9 mg/dl, albumin 2.2 mg/dl, proteinuria >500 mg/dl and total cholesterol 274 mg/dl. His antiretroviral therapy with Atripla was switched to Triumeq (abacavir/dolutegravir/lamivudine). He returned September 2016 with temporal resolution of his peripheral edema and nephrotic range proteinuria at 13 g/L. He was hospitalized October 2016 with an unremarkable physical exam, and negative autoimmune workup. Pertinent findings included albumin 1.1 mg/dl and creatinine 0.9 mg/dl. Nephrology was consulted for ongoing nephrotic syndrome and renal biopsy showed podocytes with 90% foot process effacement consistent with MCD. The patient was discharged home with Lisinopril 2.5 mg and Lasix 40 mg daily. On November 2016 labs showed significant improvement of his proteinuria to 0.74 g/L. His Lisinopril was increased to 10 mg daily and he continued with Lasix. Recent follow up documented on April 2017 showed a urinalysis with 100 mg/dl.

Results:

Conclusions: In closing, it is important to consider optimization of ACE inhibitors or angiotensin II blockers as alternate therapy to corticosteroids among HIV infected patients with MCD. One isolated case of rapid decline of proteinuria exists in a diabetic patient with no literature seen in HIV. This case illustrates the need for additional research into the impact of therapy with sole ACE inhibition in lieu of corticosteroids for the treatment of MCD and other glomerular diseases associated with nephrotic proteinuria among this group.

TH-PO224

Role of DJ-1(PARK7) in Hepcidin-Mediated Protection of AKI in a Murine Model of Sepsis (LPS) Joseph T. Leeds,[3] Yogesh M. Scindia,[2] Saleh Mohammad,[3] Valentina Loi,[1] Ewa U. Mandziak,[3] Sundararaman Swaminathan.[3] *[1]AO Brotzu Cagliari, Cagliari, Italy; [2]Univerisity of Virginia, Charlottesville, VA; [3]University of Virginia, Charlottesville, VA.*

Background: Acute Kidney injury is a frequent complication of Sepsis and is associated with increased comorbidity and mortality. A new paradigm of sepsis-induced AKI suggest that responses to tubular injury with an uncontrolled pro-inflammatory response (TNFα, IL-6, IL-10) can further renal damage. Previously we have shown that Hepcidin (Hamp), an endogenous peptide which controls systemic and local iron homeostasis, ameliorates ischemia-reperfusion injury and LPS induced AKI, by reducing renal oxidative stress, inflammation and apoptosis. DJ-1 is an anti-oxidant protein that is expressed in the brain and kidney and known to reduce oxidative stress via multiple mechanisms. Importantly it is a positive regulator of glutathione peroxidase 4 (GPX-4) a protein implicated in Ferroptosis (Iron-mediated cell death).

Methods: C57BLK/6 (WT) and DJ-1 knockout mice on B6 background were injected with PBS or 50 ug of Hamp (i.p) and 24 hours later administered 6.5mg/kg LPS (i.p). Tissue were harvested 24 hours after LPS administration for measuring renal function, injury, and inflammation.

Results: Compared to PBS, Hamp pretreated WT mice were protected against LPS-induced AKI as indicated by significantly lower plasma creatinine (WT PBS+ LPS 1.11 ± 0.17 Vs Hamp + LPS 0.41 ± 0.03; p= <0.0001), NGAL and KIM-1 levels. Hamp + LPS treated animals also had less infiltrating neutrophils and CD11b positive cells compared to PBS + LPS treated ones. Hamp + LPS treated mice had significantly lower splenic IL-6, IL-10 and IL-22 mRNA levels compared to PBS + LPS. In contrast to WT mice, Hamp failed to protect DJ-1 KO mice against LPS induced AKI. DJ-1 KO mice treated with PBS or Hamp had comparable plasma creatinine (DJ-1 KO PBS + LPS; .95 ± 0.06 Vs Hamp + LPS 0.85 ± 0.15; p= 0.7776), NGAL, KIM-1 and infiltrating cells. The splenic inflammatory signature was also comparable between the two groups.

Conclusions: Hepcidin protects against LPS-induced AKI by reducing systemic inflammation. The protective effect of Hamp seems to be dependent DJ-1, as loss of DJ-1 in mice abrogated Hamp's protective effect.

Mitophagy Is Activated to Protect against Iodionated Contrast-Induced AKI Shaobin Duan,[1] Rong Lei,[1] Fei Zhao,[1] Min Luo,[1] Wei X. Li,[1] Wei Cheng,[1] Chengyuan Tang,[1] Zheng Dong,[2] Lin Sun,[1] Hong Liu.[1] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha410011, China, Changsha, China; [2]Georgia Regents University, Augusta, GA.*

Background: Contrast induced-acute kidney injury (CIAKI) is one of the most commmon causes of acute kidney injury in hospitalized patients, but the underlying pathogenesis is poorly understood. And there are little reports about the regulation and role of mitophagy in CIAKI.

Methods: The establishment of damaged cells model was performed. The cell viability, expression of LC3II/I and parkin, cleaved caspase 3, mitochondrial ROS, mitochondrial membrane potential, colocalization of LC3-FITC and parkin-FITC with mitotracker-red mitochondria, formation of autophagosome and mitophagy were measured. The Rapamycin (Rap) and 3-Methyladenine (3-Ma) were used to enhance and inhibit the formation of autophagososmes respectively. Male SD rats were deprived of water for 48 h and followed by furosemide (10 ml/kg) for 20 minutes before iohexol (15 ml/kg) administration to build CIAKI models. Pretreatmemt with Rap or 3-Ma was used at 1 h before iohexol injection. Serum creatinine were measured before and 24 h after the injection of iohexol. Kidney tissues were collected for HE staining, electron microscope examination and expression of LC3II/I, P62, Cleaved Caspase3, Parkin.

Results: Iohexol and iodixanol dose-dependently decreased cell ciability, also induced mitochondrial damage, cell apoptosis and mitophagy. Enhancing mitophagy with Rap markedly increased expression of LC3II, Parkin and formation of autophagosome and mitophagy, reversed iohexol induced apoptosis. Rap also significantly decreased expression of cleaved caspase 3 and serum creatinine. LC3-FITC and parkin-FITC puncta colocalization with mitotracker-red mitochondria were increased. In contrast, inhibiton of mitophagy with 3-Ma displayed increased serum creatinine, apoptosis and expression of cleaved caspase 3, decreased expression of LC3II and formation of autophagosome and mitophagy, compared with iohexol group.

Conclusions: Autophagy and mitophagy play an important role in mitochondrial quality control, tubular cell survival, and renal function during CIAKI. Enhancing mitophagy may offer a novel therapy for CIAKI.

Deletion of Sirtuin-5 (Sirt5) Protects Mice Against Ischemia-Reperfusion Kidney Injury Eric S. Goetzman,[1,2] Katherine V. Maringer,[1,2] Sivakama S. Bharathi,[1,2] Elina Mukherjee,[1,2] Sunder Sims-Lucas.[1,2] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Sirtuin-5 (Sirt5) is a deacylase enzyme that reverses the post-translational succinylation of lysine residues. Sirt5 is highly expressed in the kidney. In liver Sirt5 promotes function of the respiratory chain and of the mitochondrial fatty acid oxidation (FAO) pathway. While mitochondrial FAO is a critical source of energy for the proximal tubule, the role of Sirt5 in regulating kidney FAO during acute kidney injury (AKI) has not been investigated.

Methods: Sirt5 knockout mice (Sirt5KO) were subjected to ischemia-reperfusion kidney injury followed by contralateral nephrectomy on Day 6 and tissue harvest on Day 7. The oxidation of ^{14}C-palmitate was used to follow FAO. Immunofluorescence was used to visualize mitochondria and peroxisomes, the two intracellular sites of FAO, in proximal tubules. Kidney injury markers were assessed by immunofluorescence and real-time PCR.

Results: Sirt5KO kidneys had reduced mitochondrial staining and reduced mitochondrial FAO at baseline. Conversely, peroxisome staining and peroxisomal FAO were increased. Despite compromised mitochondrial function, Sirt5KO mice exhibited significant protection against AKI. Day 7 post-injury serum creatinine was significantly lower than in wild-type mice. Tissue staining indicated less tubular damage, less fibrosis, and less inflammation. There was markedly less expression of kidney injury molecule-1 (Kim1) and activated caspase-3. Day 7 wild-type tubules showed abundant mitochondrial staining but a near-complete loss of peroxisomes, while Sirt5KO tubules showed peroxisomes but a loss of mitochondria. Peroxisomal FAO in Sirt5KO kidney was several-fold higher than in wild-type kidney. Finally, we observed Sirt5 protein in purified wild-type kidney peroxisomes suggesting that Sirt5 may serve to coordinate FAO between intracellular compartments.

Conclusions: Deletion of Sirt5 limits kidney injury in response to ischemia-reperfusion, the opposite of what has been reported in in knockouts of other sirtuins such as Sirt1 and Sirt3. Absence of Sirt5 compromises mitochondria but stabilizes peroxisomes. Given previously published obserations that peroxisomal abundance is associated with better outcomes from AKI, we propose that metabolic switching from mitochondria to peroxisomes is the mechanism by which deletion of Sirt5 is beneficial during ischemia-reperfusion injury.

PINK1-Parkin Pathway of Mitophagy Is Activated to Protect against Renal Ischemia/Reperfusion Injury Chengyuan Tang,[1] Fuyou Liu,[1] Zheng Dong.[1,2] *[1]Department of Nephrology, The Second Xiangya Hospital of Central South University, Changsha, China; [2]Department of Cellular Biology & Anatomy, Medical college of Georgia at Augusta University and Charlie Norwood VA Medical Center, Augusta, GA.*

Background: Mitochondrial damage contributes to the pathogenesis of acute and chronic kidney diseases. Damaged or dysfunctional mitochondria are toxic to the cell by producing reactive oxygen species and releasing cell death factors. Therefore, timely removal of these organelles is critical to cellular homeostasis and viability. Mitophagy is the mechanism of selective degradation of mitochondria via autophagy. A major mitophagy pathway in mammalian cells is mediated by PINK1 and Parkin. The significance of mitophagy in kidney diseases, including ischemic acute kidney injury (AKI), has yet to be established, and the involved pathway of mitophagy remains poorly understood. In this study, we examined PINK1- and Parkin- mediated mitophagy in the acute kidney injury (AKI) model of renal ischemia-reperfusion.

Methods: PINK1 and Parkin single or double knockout mice were compared to their matched wild-type mice for the response to 30 minutes of bilateral renal ischemia followed by 48 hours of reperfusion. Renal function, histopathology, biochemical analysis and electron microscopy analysis were performed to evaluate the effect of PINK1 and Parkin deletion. In *vitro*, HK-2 cells were subjected to ATP depletion/repletion treatment with CCCP (mitochondrial uncoupler) to examine the effects of PINK1 and Parkin knockdown.

Results: Mitophagy was induced in renal proximal tubular cells in both *in vitro* and in *vivo* models of ischemic AKI, as evidenced by: (1) increased autophagy flux, (2) decreased expression of mitochondrial membrane proteins TOM20 and TIM23, and (3) increased formation of mitophagosomes. Mitophagy under these conditions was abrogated by *PINK1* and *Parkin* deficiency, supporting a critical role of the PINK1/Parkin pathway in tubular cell mitophagy. Moreover, ischemic AKI was deteriorated in *PINK1* and *Parkin* single as well as double knockout mice, as indicated by aggravated functional or structural renal damage, and enhanced tubular cell death. Mechanistically, *PINK1* and *Parkin* deficiency enhanced mitochondrial damage, ROS production, and inflammatory response.

Conclusions: These results indicate that PINK1/Parkin-mediated mitophagy plays an important role in mitochondrial quality control, tubular cell survival, and renal function during AKI.

TH-PO228

HDAC2 Deletion Mitigates Renal Ischemia-Reperfusion Injury by Stabilizing the CoREST Complex David D. Aufhauser,[3] Douglas R. Murken,[3] Zhonglin Wang,[5] Guanghui Ge,[6] Seth Concors,[4] Tricia Bhatti,[2] Wayne W. Hancock,[1,3] Matthew H. Levine.[3] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]University of Pennsylvania Health System, Philadelphia, PA; [5]University of Pennvania, Philadelphia, PA; [6]Surgery, University of Pennsylvania, Philadelphia, PA.*

Background: Class I histone/protein deacetylases (HDAC) 1 and 2 have reciprocal effects on renal ischemia-reperfusion injury (IRI) with HDAC1 deletion increasing vulnerability and HDAC2 protection providing profound protection. HDAC1 and 2 typically interact as heterodimers in multimeric corepressor complexes and are conventionally been viewed as functionally redundant.

Methods: Wild type C57BL/6 (WT) and whole animal-inducible HDAC1- or 2- gene deleted mice (HDAC1-/- or HDAC2-/-) were used in this study. Primary renal tubular epithelial cell (RTEC) cultures were derived from each genetic strain for protein analysis via Western blot. Standardized warm renal IRI was achieved through unilateral clamping of the renal pedicle and contralateral nephrectomy.

Results: In nuclear extracts, HDAC1 and 2 deficient RTEC have compensatory enhanced protein expression of the other (Fig 1a). HDAC1 pulldown in HDAC2 deficient RTEC demonstrated enhanced association with CoREST and LSD1 compared to wild type RTEC (Fig 1b). HDAC2 pulldowns in HDAC1 deficient RTECs showed no enhanced association with CoREST. *In vivo* CoREST inhibition increased vulnerability to renal IRI injury in both WT and HDAC2-/- mice and returned HDAC2-/- mice to a WT renal IRI phenotype (Fig 1c).

Conclusions: HDAC2 deletion leads to increased associated between HDAC1 and other members of the CoREST complex, indicating increased complex stability. Inhibition of the CoREST complex *in vivo* reverses the protection seen with HDAC2 deletion.

TH-PO229

Lysophosphatidic Acid Regulates FGF23 via LPAR1 in Response to AKI Petra Simic,[4] Wondong Kim,[4] Paola Divieti Pajevic,[1] Andrew M. Tager,[2] Harald Jüppner,[4] Marc N. Wein,[3] Eugene P. Rhee.[4] *[1]Boston University, School of Dental Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]MGH Endocrine Unit, Boston, MA; [4]Massachusetts General Hospital, Brookline, MA.*

Background: Lysophosphatidic acid (LPA) is one of the simplest phospholipids with a range of signaling actions throughout the body. It has been implicated as an important cofactor for calcitriol's effect on osteoblast differentiation *in vitro*, and LPA receptor 1 knock-out (*Lpar1*-/-) mice are known to have osteoporosis.

Methods: As FGF23 is a predominantly bone-derived hormone modulated by calcitriol, we have tested the effect of LPA on FGF23 production *in vivo* in C57Bl6 and *Lpar1*-/- mice and *in vitro* in a conditionally immortalized osteocyte cell line (Ocy454 cells).

Results: Exogenous LPA (50 mg/kg i.p. single dose) stimulated intact and C-terminal FGF23 production 2.4 fold in C57Bl6 mice as compared to vehicle treated mice (n=8 per group) at 24 hours (P=0.02). This effect was corroborated in Ocy454 cells, with a 10 fold increase in C-terminal and intact FGF23 protein levels 24 hrs following LPA treatment (P=0.05); this effect was specifically dependent on the LPAR1 receptor, as the effect of LPA on FGF23 was abolished in CRISPR generated *Lpar1*-/- Ocy454 cells but not in *Lpar4*-/- cells (the other major LPA receptor expressed in osteocytes). Next, we tested *in vivo* whether the effect of LPA on FGF23 is dependent on LPAR1, injecting *Lpar1*-/- mice or WT littermates with a single dose of LPA (50 mg/kg i.p.) or vehicle (n=8 per group). LPA increased serum FGF23 levels in WT, but not in *Lpar1*-/- mice (1215 ± 200 pg/ml vs. 664 ± 98 pg/ml, respectively, P=0.01) after 24 hrs. Finally, we subjected *Lpar1*-/- mice or WT littermates (n=4 per group) to AKI by performing 35 minutes of bilateral ischemia reperfusion injury (IRI). Circulating levels of FGF23 were 1.5 fold greater in WT mice as compared to Lpar1-/- mice following IRI (P=0.04).

Conclusions: In summary, LPA stimulates FGF23 production *in vitro* and *in vivo* via the LPAR1 receptor and the effects of AKI on FGF23 are attenuated in LPAR1 deficient mice.

Proximal Tubular Epithelial Expression of Kim-1 Causes Progressive Kidney Injury in Mice Wenqing Yin, M. Todd Valerius, Joseph V. Bonventre. *Brigham and Women's Hospital, Boston, MA.*

Background: Acute kidney injury (AKI) predisposes to the progression of chronic kidney disease (CKD) and the development of end stage renal failure. Previously, we had reported that early and persistent epithelial expression in nephrons of kidney injury molecule-1 (KIM1) causes murine kidney fibrosis, and zebrafish tubule damage through a mechanism involving mTOR. Since prenatal activation also decreases nephron number we tested the hypothesis that postnatal activation of KIM-1 expression specifically in renal proximal tubular epithelial cells would lead to fibrosis independent of any potential effect on kidney development.

Methods: We created proximal tubular cell specific KIM-1 transgenic mice by treating the Slc34a1 Cre-ERT2 mouse with tamoxifen to express KIM-1 in proximal tubules in a postnatal context. The resulting KIM-1^{PTCtg} transgenics (and non-KIM1

expressing controls) were subjected to bilateral renal ischemia-reperfusion injury for 26 minutes or sham surgery.

Results: KIM-1 was expressed on the proximal tubular cells after tamoxifen-induced Cre-ERT2 recombination starting at 4 weeks of age. Without any further intervention KIM-1^{PTCtg} mice developed fibrosis with progressive renal insufficiency at 6 months of age, while the kidney function and histology were close to normal at 3 months of age. Bilateral renal ischemia reperfusion injury in KIM-1^{PTCtg} kidneys at 3 months of age cause impaired repair with remained renal insufficiency, leading to progressive kidney fibrosis and renal failure.

Conclusions: Chronic activation of KIM-1 expression promotes kidney fibrosis and accelerates the progression of chronic kidney disease after acute kidney injury. Persistent expression of KIM-1 may play an important role on the link between acute kidney injury and progressive chronic kidney disease.

Dimethyl Fumarate Attenuates Renal Ischemia/Reperfusion Injury Yingchuan Li,[2,3] Junhui Li,[2,3] Hong Xue,[1] Feng Wang,[2] Julian H. Lombard,[1] Aron M. Geurts,[1] Kristie Usa,[1] Niansong Wang,[2] Mingyu Liang.[1,3] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China; [3]Physiology, Center of Systems Molecular Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: Fumarate is an intermediary in the tricarboxylic acid cycle and can activate NRF2 and HIF-1a. Emerging evidence suggests fumarate might be involved in ischemia-reperfusion injury (IRI). It remains unclear whether fumarate is protective against acute kidney injury (AKI) resulting from renal IRI and what mechanisms might be involved.

Methods: Male SD or *Nrf2*$^{-/-}$ rats (~250g) were anaesthetized with ketamine. Sham operation (controls) or bilateral renal artery occlusion for 30 min followed by reperfusion (IRI) were performed. For pre-IRI treatment, dimethyl fumarate (DMF, 30mg/Kg), a fumarate precursor, or Vehicle was administered via intraperitoneal injection twice daily for 5 days before surgery. For post-ischemia treatment, DMF (30mg/Kg) or Vehicle was administrated at the time of 0 and 3 hours after reperfusion. Serum was collected 6 h or 24 h post-reperfusion and kidney collected 24 h post-reperfusion for analysis of renal function and kidney injury.

Results: Pre-treatment with DMF for 5 days attenuated subsequent renal IRI in rats. Serum creatinine (Scr) was 1.05±0.26 mg/dl and 1.42±0.42 mg/dl in DMF- and vehicle-treated rats, respectively (n=11, $p<0.05$). Tubular injury score (TIS) was 2.76±0.64 and 4.00±0.88 in the two groups (n=5, $p<0.05$). The attenuation of renal injury was associated with up-regulation of mRNA expression of *HIF-1a, NRF2* and their target genes *Hmox1* and *Nqo1* in kidney tissue. However, the effect of DMF pre-treatment on renal IRI was preserved in *Nrf2*$^{-/-}$ rats. Post-ischemia Treatment with DMF also significantly attenuated renal IRI. Scr was 1.08±0.46 mg/dl and 1.76±0.74 mg/dl in DMF- and vehicle-treated rats, respectively (n=8, $p<0.05$). TIS was 2.82±0.71 and 4.06±0.92 in the two groups (n=5, $p<0.05$). The post-ischemia treatment with DMF resulted in up-regulation of *NRF2, Hmox1* and *Nqo1,* but not *HIF-1a*. The protective effect of post-ischemia treatment with DMF on renal IRI was significantly attenuated in *Nrf2*$^{-/-}$ rats.

Conclusions: These results suggest fumarate could have preventive as well as therapeutic effects on AKI induced by IRI. The therapeutic, but not preventive, effect of fumarate depends on the presence of NRF2.

Identification of the RNA Interactome of Ciliated Tubular Cells and Its Modulation by Hypoxia Roman-Ulrich Mueller,[2] Rainer Kaiser,[2] Constantin Rill,[2] Francesca Fabretti,[2] Michael Ignarski,[2] Markus M. Rinschen,[2] Ilian Atanassov,[1] Bernhard Schermer,[2] Thomas Benzing.[2] *[1]Max Planck Institute for Biology of Aging, Cologne, Germany; [2]Renal Unit, University Hospital Cologne, Koeln, Germany.*

Background: RNA-binding proteins (RBPs) control the fate of all RNA species and every step of messenger RNA generation and processing. Through specific binding of their targets, RBPs heavily influence the cellular transcriptome and proteome. The scale of their impact has been shown by recent studies that have linked RBPs to a number of human pathologies, ranging from neurological disorders to tumor growth. The global effect of RBPs in kidney physiology has never been assessed until now. Here, we identify RNA binding proteins in renal epithelial cells under both hypoxic and normoxic growth conditions as well as candidate RBPs that may play key roles in hypoxia signaling of of the kidney.

Methods: Using an oligo(dT) capture approach to precipitate mRNA-protein complexes in ciliated mIMCD-3 cells, we aimed to identify the kidney-specific mRNA interactome using mass spectrometry. UV-crosslinked samples were either exposed to hypoxia (1% O_2) or grown under normoxic conditions. In parallel, the proteome of whole cell lysates was identified to assess the total amount of protein in comparison to RBPs detected under different conditions. Using TALEN-mediated genome engineering for the creation of transgenic human cell lines, specific candidates were validated as RNA binding protein with the Polynukleotide (PNK) assay. Subsequent immunofluorescence studies on the same cell lines revealed the localization pattern of these RBPs.

Results: Our data revealed over 350 significant mRNA interactors and more than 300 additional candidate RBPs, 84 of which have not been described as RNA binding proteins in common data bases. We define these proteins as the renal epithelial cell mRNA interactome. Based on whole cell proteome analyses we hypothesize that the increased detection of RBP candidates in the hypoxia-treated Oligo(dT) captured samples is indeed due to differential binding to their target transcripts.

Conclusions: RNA binding proteins are important players in general cell biology and may also play a key role in the cellular response to hypoxia of kidney cells. Our data identify the first set of RBPs specific to renal epithelial cells and aid to understand their role in both kidney physiology and pathology, adding another regulatory layer to the diverse biology of the kidney.

Reduced Heat Shock Protein 90α/Endothelial Nitric Oxide Synthase Interaction in the Heart Contributes to Cardiovascular Injury in the AKI to CKD Transition Isabel Amador-Martinez, Rosalba Pérez-villalva, Norma Bobadilla, Jonatan Barrera-Chimal. *Molecular Physiology Unit, Instituto de Investigaciones Biomédicas, UNAM and INNSZ, Mexico City, Mexico.*

Background: Acute kidney injury (AKI) is a recognized risk factor for chronic kidney disease (CKD) development. CKD is associated with cardiovascular alterations and the associated mechanisms remain largely unexplored. CKD patients display reduced nitric oxide (NO) levels. The endothelial nitric oxide synthase (eNOS) is regulated by phosphorylation and by its interaction with proteins such as heat shock protein 90α (Hsp90α). We investigated some modifications in the eNOS activation pathway that occur in the heart during the AKI to CKD transition.

Methods: We included 50 male Wistar rats that were divided into sham surgery (n=25) or rats subjected to bilateral renal ischemia-reperfusion (IR) of 45 min (n=25). The rats were studied at 1, 2, 3, 4 or 5 months post-surgery (n=5). Urinary protein excretion was monitored every month. After each experimental period, plasma creatinine, renal blood flow, mean arterial pressure levels and heart and renal weights were determined. The apical part of the heart was snap frozen for western blot analyses.

Results: CKD progression in the IR group was characterized by proteinuria that went from 26.5±8 at month-1 to 127.6±24 mg/24h at month-5. The renal dysfunction was only manifested after five months of follow-up as shown by a 50% increase in the plasma creatinine levels and a 30% reduction in the renal blood flow. In contrast, heart hypertrophy was observed since the 4th month after IR, as evidenced by a 24% increase in the heart/body weight ratio. Heart dysfunction and fibrosis were determined by a significant increase in brain natriuretic peptide and collagen I levels, respectively ($p<0.05$). Moreover, an increase in the phosphorylation of eNOS at threonine 495 (inactivating eNOS) was observed. This effect was associated with reduced eNOS/Hsp90α interaction.

Conclusions: The AKI to CKD transition is characterized by cardiac hypertrophy, dysfunction and fibrosis, even before the renal dysfunction is manifested. These alterations were associated with fewer eNOS activation and reduced eNOS/Hsp90α interaction in the heart, which may result in reduced NO bioavailability and endothelial dysfunction. PAPIIT: IA200117

Klotho Reduces Necroptosis by Inhibiting Oxidative Stress Involved in Renal Ischemic-Reperfusion Injury Yingying Qian, Leyi Gu, Zhaohui Ni. *Renji Hospital, Shanghai, China.*

Background: Klotho is mainly expressed in kidney, but its functional relevance with AKI remains largely unclear. Although necroptosis has been suggested as a hallmark of the pathological progress of renal IRI, it is currently unknown what triggers this death mode during I/R induced AKI and whether the protective actions of Klotho have any relationship to necroptosis.

Methods: Male BALB/c mice were grouped as AKI and sham group. AKI model was generated by bilateral renal pedicles clamping. For the therapeutical investigation, recombined Klotho protein or nec-1 was intraperitoneal applied at 30 min or 0 min of reperfusion respectively. Besides, TCMK-1 cell was suffered to hypoxia/reoxygenation or H_2O_2 insult for pre-determined time. Recombinant Klotho protein or NAC was pre-applied for 1 h. Klotho levels in serum and urine were determined using ELISA. Expression of Klotho, RIP1, RIP3, Il-1 ß, 3-nitrotyrosine and SOD2 were assessed by Western Blot or/ and Real-Time PCR. TUNEL staining and immunohistochemistry for Kim-1 and Klotho were performed. The release of LDH was measured to assess the membrane integrity. Urinary 8-OHdG, renal MDA levels and SOD activity were determined to detect oxidative injury.

Results: Klotho levels were decreased in serum and kidney, but increased in urine post-IRI, accompanied by enhancement of oxidative stress and necroptosis. In contrast, Klotho administration ameliorated AKI. Klotho application reduced the expression of RIP1, RIP3, and Il-1 ß, and the number of TUNEL positive cells. In TCMK-1 cell, Klotho downregulated the expression of RIP1 and RIP3, and attenuated the release of LDH induced by H/R or H_2O_2 insult by dose dependent. These functional effects of Klotho on necroptosis can also be duplicated by NAC application. These indicate a critical role of ROS in triggering necroptosis in tubular epithelial cell, which can be partly abolished by Klotho. In support of this, Klotho exerted an anti-oxidant role evidenced by reducing the levels of u-8-OHdG, renal MDA and 3-Nitrotyrosine, and upregulating SOD2 expression and total SOD activity in AKI mice. Meanwhile, Klotho also abolished the generation of ROS and increased the expression of SOD2 in TCMK-1 cell when exposed to H/R injury.

Conclusions: Klotho protects tubular epithelial cell from I/R-induced necroptosis, which may be attributable to its inhibition of oxidative stress.

TH-PO235

Nucleophosmin (NPM) Phosphorylation Mediates Renal Cell Death: A New Therapeutic Target for Ischemic AKI Zhiyong Wang,[1] Chinaemere Igwebuike,[3] Erdjan Salih,[5] Andrea Havasi,[4] Ramon G. Bonegio,[5] John H. Schwartz,[2] Steven C. Borkan.[1] *[1]BOSTON MEDICAL CENTER, BOSTON, MA; [2]Boston Medical Center-Evans Biomedical Center, Boston, MA; [3]Boston Univerisity School of Medicine, Boston, MA; [4]Boston University Medical Center, Boston, MA; [5]Boston University School of Medicine, Boston, MA.*

Background: We hypothesize that renal ischemia alters site-specific NPM phosphorylation, converting NPM from an essential protein synthesis promoter to a killer Bax chaperone that causes renal cell death and AKI.

Methods: To detect site-specific phosphorylation and de-phosphorylation events, NPM was subjected to mass spectrometry before and after ischemic stress in both cell and cortical lysates harvested from: (1) normal vs. ATP deplete primary mouse and primary human proximal tubule epithelial cells (PTEC), (2) sham vs. ischemic mouse kidneys and (3) two pairs of human donor kidneys rejected for transplantation. One of the paired human kidneys was normally perfused, whereas the other was grossly ischemic due to perfusion pump malfunction. Site-specific NPM phosphorylation events were correlated with NPM alterations that mediate its cell death including: nuclear translocation, de-oligomerization, NPM-Bax complex formation, and mitochondrial complex accumulation. To confirm their biologic significance, NPM mutants with site-specific phospho-changes were generated in lentivirus and introduced into PTEC. Peptides that interfere with NPM phosphorylation were tested for their ability to prevent ischemic PTEC death.

Results: Mass spectrometry identified 92% of NPM residues that included all known serine, tyrosine and threonine residues capable of undergoing phosphorylation or de-phosphorylation. Five serine/threonine phosphorylation and de-phosphorylation events differed between NPM harvested from normal vs. ischemic conditions. NPM phosphorylation events were identical in both murine and human NPM harvested from either primary PTEC or intact renal cortex. Only the NPM phospho-mutant that mimicked phosphorylation events detected during renal ischemia caused cytosolic NPM translocation and de-oligomerization, NPM interaction with conformationally active Bax, mitochondrial complex accumulation, and increased PTEC death. In contrast, 2 distinct NPM peptides designed to interfere with NPM phosphorylation protected PTEC against ATP depletion-induced death.

Conclusions: Ischemia-induced NPM phosphorylation regulates Bax-induced cell death and contributes to human AKI. This study identifies a new, modifiable cell death pathway and reveals novel therapeutic approach for preventing and treating ischemic AKI.

TSA Can Induce Autophagy to Protect against Cisplatin-Induced Apoptosis Jing Liu,[1,2] Man J. Livingston,[2] Zheng Dong.[2,1] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; [2]Augusta University Medical College of Georgia, Augusta, GA.*

Background: HDAC inhibitors have protective effects against tubular cell injury and death in acute kidney injury (AKI). However, the underlying mechanism remains elusive. Autophagy is known to be an important protective mechanism in AKI. Whether HDAC inhibitors regulate autophagy and protect renal tubular cells from injury via autophagy is currently unknown.

Methods: In vitro, rat proximal tubular cells (RPTCs) were treated with cisplatin to induce apoptosis. In vivo, C57BL/6 mice were injected with cisplatin to induce nephrotoxic AKI. The effect of the HDAC inhibitor Trichostatin A (TSA) was examined both in vitro and in vivo models. Chloroquine and kidney proximal tubule-specific ATG7 knockout (PT-ATG7-KO) mice were used to determine the involvement of autophagy in the protective effect of TSA.

Results: In RPTC, cisplatin induced autophagy in 8 hours, which decreased at 20 hours of treatment as indicated by the analysis of LC3 II accumulation and autophagic vesicle formation. At 20 hours, cisplatin induced significant apoptosis in RPTC as indicated by cell morphology and caspase activation. TSA treatment increased autophagy at both 8 and 20 hours of cisplatin treatment. TSA also attenuated cell apoptosis. Importantly, the protective effect of TSA in RPTC was suppressed by the autophagy inhibitor chloroquine and also by ATG7 knockdown. In mice, cisplatin induced autophagy and AKI. TSA further increased autophagy in kidneys during cisplatin treatment and protected against AKI. The protective effect of TSA was suppressed by chloroquine. Moreover, the protective effect of TSA was diminished in PT-ATG7-KO mice.

Conclusions: TSA induces autophagy in renal tubular cells, which accounts for the protective effect of TSA during cisplatin-induced AKI.

TH-PO237

Extracellular Signal-Regulated Kinase 1/2 Regulates Kidney Injury Molecule-1 Following Renal Injury through STAT3 Phosphorylation Justin B. Collier,[1,2] Rick G. Schnellmann.[2] *[1]Medical University of South Carolina, Charleston, SC; [2]University of Arizona, Tucson, AZ.*

Background: Kidney injury molecule-1 (KIM-1) is a transmembrane glycoprotein that is highly upregulated during injury and is a renal injury biomarker. Because KIM-1 transcription is highly induced, we explored the role of extracellular signal-regulated kinase 1/2 (ERK1/2) in KIM-1 expression in cells and in different mouse models of acute kidney injury.

Methods: Mouse kidney proximal tubule cells (TK) were treated with varying concentrations of hydroxyurea, hydrogen peroxide, and tert-butyl-hydroperoxide with and without pretreatment with the MEK1/2 inhibitor trametinib (10nM). Trametinib (1mg/kg) was administered 1 h before renal I/R injury to mice. Trametinib was administered 1 h prior to I/R injury or LPS (10 mg/kg) exposure to TLR4 KO and WT mice and euthanized 18 h later, respectively. KIM-1 mRNA was measured by RT-qPCR.

Results: Trametinib blocked ERK1/2 phosphorylation in all experiments. Toxicant exposure to TK cells for 24 h upregulated KIM-1 mRNA and was blocked by trametinib. At 3 and 24 h post renal I/R cortical KIM-1 mRNA increased 4- and 600-fold, and pretreatment with trametinib resulted in a 50% and 66% decrease, respectively, in induced KIM-1 mRNA. Trametinib also decreased KIM-1 protein 24 h post I/R. ERK1/2 phosphorylated the transcription factor STAT3 at sites, Y705 and S727, following I/R and was prevented by trametinib. WT mice pretreated with trametinib before LPS had decreased KIM-1 mRNA and protein. In contrast to TLR4 KO mice subjected to I/R, TLR4 KO mice injected with LPS did not exhibit increased KIM-1 mRNA or protein, nor activated ERK1/2 after 18 h.

Conclusions: We have linked ERK1/2 to KIM-1 transcriptional upregulation in the kidney cortex through STAT3 Y705/S727 phosphorylation following renal injury. In I/R and LPS-induced kidney injury KIM-1 mRNA and protein increased and ERK1/2 inhibition attenuated this increase. However, ERK1/2 mediated KIM-1 upregulation was dependent on TLR4 in LPS treated mice but not mice subjected to I/R. These results demonstrate that ERK1/2 is a key initiator of renal KIM-1 expression and that KIM-1 expression is regulated by different ERK1/2 pathways following renal injury.

Hypoxia Induces Tubular Autophagy by Preventing Oxygen-Dependent Prolyl Hydroxylation and Degradation of Stress-Responsive Transcriptional Factor FoxO3 Ling Li, Catherine Ha, Qais Al-Awqati, Fangming Lin. *Collumbia University College of Physicians and Surgeons, New York, NY.*

Background: Renal hypoxia results in metabolic perturbations and cell stress which likely leads to CKD following AKI. Autophagy is an evolutionally conserved cellular response to stress. Recent finding in our lab has shown that the stress-responsive transcription factor, FoxO3, can activate renal epithelial autophagy.

Methods: We used the autophagy reporter line (*CREL* mouse), which expresses a tandem RFP and EGFP fused with LC3 protein, to study molecular regulation of autophagy during the AKI to CKD transition.

Results: At 2-4 weeks following left renal ischemic injury for 35 min and right nephrectomy, we found progressive increases in proximal tubular autophagy in areas of low capillary density and thus hypoxia. Concomitantly, FoxO3 was activated with a 4-fold increase in nuclear expression over controls in the hypoxic tubules. To test whether hypoxia is an upstream activator for FoxO3 leading to autophagy, we exposed primary cultures of proximal tubular cells to 1%O_2 and found an increase in FoxO3 protein levels (50% increase at 30 min and 115% increase at 60 min), as well as its prominent nuclear localization. In renal tubular cells isolated from *CREL* mice, hypoxia or nutrient deprivation (a potent stimulator for autophagy) led to a time-dependent appearance of autophagic dots and increased conversion of LC3I to LC3II proteins. How could hypoxia activate FoxO3? We found that FoxO3, like Hif proteins, is prolyl hydroxylated, which leads to its degradation. Immunoprecipitation with FoxO3 antibody followed by immunoblot analyses with pan-hydroxyl proline antibody showed that prolyl hydroxylated FoxO3 diminished in hypoxic or starved conditions. Treating tubular epithelial cells grown in normal conditions with a prolyl hydroxylase (Phd) inhibitor, dimethyloxalylglycine (DMOG), caused a 60% reduction in OH-FoxO3 and a 39% increase in FoxO3 protein abundance. Conversely, treating starved cells with DMKG, a cell permeable analogue of α-ketoglutarate, the Phd substrate, resulted in a 57% decrease in FoxO3 protein abundance.

Conclusions: Taken together, our results indicate that FoxO3 can be regulated by the O_2- and α-ketoglutarate-dependent Phd enzymes in the kidney. Hypoxia and metabolic perturbations inactivate Phd enzymes to inhibit FoxO3 degradation, thus allowing it to induce tubular autophagy.

Flow Cytometric Detection of Urinary Renal Tubular Epithelial Cells Directly Reflects Kidney Damage and Predicts Recovery from AKI Philipp Enghard,[1] Valerie S. Langhans.[2] *[1]Charité, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Acute kidney injury (AKI) is among the most frequent causes for renal damage and associated with significant increase of morbidity and mortality. Renal Tubular epithelial cells (TEC) are arguably the main target cell of AKI. The objective of our study was to establish flow cytometry based detection of different TECs in the urine and assess these cells as a biomarker for AKI.

Methods: Urine samples of 28 patients with AKI and 5 healthy controls were collected, immediately washed and the cells fixed using 2% formaldehyde. Proximal and distal TECs were identified using a staining for Cytokeratine (all TECs), CD10 (proximal TECs) and EPCAM (distal TECs). The amount of TECs per 100ml urine was correlated to AKIN stadium and subsequent recovery/non-recovery from AKI.

Results: Urinary numbers of TECs were increased upon kidney injury and only slowly decreased during recovery. TEC counts correlated with AKIN stadium of the patients (p=0.0006, r=0.57 proximal and p< 0.0001, r=0.67, for distal TECs, Spearman). TEC numbers were significantly higher in patients with AKI than in healthy donors and enabled to distinguish between different AKIN stadia. Importantly, the amount of distal TECs (Cytokeratine+EPCAM+) upon AKI was able to predict subsequent recovery/non-recovery from AKI. Applying a cut-off of 200.000 cells/100ml urine separated patients with and without recovery (Cytokeratine+EPCAM+, p= 0.0068).

Conclusions: Urinary cell counts of renal epithelial cells directly reflect the amount of tissue damage in human AKI. Our findings suggest proximal and distal TECs as biomarkers to diagnose and estimate the severity of kidney damage and to predict the outcome of patients with AKI.

Genetic Screening Reveals Potential Therapeutic Targets in Gentamicin-Induced AKI Chinaemere Igwebuike,[4] Zhiyong Wang,[1] Andrea Havasi,[5] Michael Y. Sherman,[6] Julia Yaglom,[6] Yongmei Wang,[6] John H. Schwartz,[2] Steven C. Borkan.[3] *[1]BOSTON MEDICAL CENTER, BOSTON, MA; [2]Boston Medical Center-Evans Biomedical Center, Boston, MA; [3]Boston Medical Center, Boston, MA; [4]Boston Univerisity School of Medicine, Boston, MA; [5]Boston University Medical Center, Boston, MA; [6]Boston University School of Medicine, Boston, MA.*

Background: Gentamicin is a highly effective, nephrotoxic antibiotic that accounts for >20% of AKI, a complication that increases morbidity and mortality but lacks effective therapy. We propose that high throughput genetic screening can characterize the signal pathways that mediate gentamicin-induced proximal tubule epithelial cell (PTEC) injury and that once identified, pharmaceuticals that favorably alter these signal pathways will ameliorate gentamicin-induced AKI.

Methods: Human proximal tubule cells (HK2) were exposed to gentamicin sulfate under conditions that replicate the human disease. An shRNA library directed against 5,000 signal genes was introduced into human PTEC exposed to gentamicin for 10 ("low stringency") or 11 days ("high stringency"). shRNA that were over-represented *vs*. luciferase control were considered "protective" and under-represented genes were considered "sensitizing" to gentamicin-induced death measured by image cytometry of Hoechst and propidium iodide stained cells. Signal pathways that mediate gentamicin toxicity were identified using Ingenuity Pathway Analysis based on genes with a similar change in expression under both low and high stringency conditions. PTECs were then exposed to drugs that either stimulate protective or inhibit sensitizing pathways during gentamicin exposure.

Results: Genetic screening detected 406 genes in gentamicin exposed *vs*. control PTEC with at least a 1.8-fold change in expression. Pathways analysis showed that these genes were involved in cell metabolism, survival and inflammatory pathways. Three distinct pathway modifying drugs, including metformin, an FDA approved agent, were found to be non-toxic to normal PTEC. Approximately 59% and 88% of PTEC died after 10 or 11 days exposure to 26 mM gentamicin, respectively. In contrast, pre-incubation with metformin, a CAMP and AMP kinase mediator, significantly prevented PTEC death ($P<0.05$).

Conclusions: Genetic screening successfully identifies modifiable pathways responsible for gentamicin-induced nephrotoxicity that can be selectively targeted using existing pharmaceuticals. Together, studies define an effective strategy for gaining mechanistic insight into the pathogenesis of nephrotoxic AKI, facilitating the selection of agents to prevent and treat its devastating consequences.

TH-PO241

Endogenous Fructose Production and Fructokinase Activation Mediate Rhabdomyolysis-Induced AKI Yuka Sato, Carlos A. Roncal-jimenez, Ana Andres-hernando, Thomas Jensen, Masanari Kuwabara, Richard J. Johnson, Miguel A. Lanaspa. *Renal Disease and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: Acute kidney injury (AKI) is associated with high mortality. Treatment of AKI is limited to supportive care, and no interventions to improve recovery from AKI have yet been developed. The cause of AKI is diverse including ischemia, nephrotoxic agents and rhabdomyolysis. Endogenous fructose production from glucose by the polyol pathway, and its metabolism by fructokinase (KHK) leads to ATP depletion, oxidative stress and inflammation. We have reported that the metabolism of endogenous fructose is a key deleterious step in the pathogenesis of ischemic AKI, and KHK blockade showed protective role. However, to further validate if the blockade of this pathway is clinically relevant for the treatment of other types of AKI, here, we tested the hypothesis that the endogenous fructose production and metabolism contributed to rhabdomyolysis related AKI.

Methods: To establish the rhabdomyolysis-induce AKI, male wild-type mice (WT) and KHK-deficient mice (KHK-KO) were injected with 50%v/v glycerol or saline (for control) of 6 ml/kg body weight to the two hind limbs intramuscularly. Mice were sacrificed at 24 hours after glycerol injection, and blood, urine, kidney and muscle collected for histological and biochemical analyses.

Results: Serum creatinine elevation was significantly suppressed in KHK-KO mice. (WT sham; 0.23mg/dL, KHK-KO sham; 0.10mg/dL, WT glycerol (Gly); 2.03 mg/dL, KHK-KO Gly; 1.47 mg/dL, $p<0.01$; WT sham vs WT Gly, $p<0.01$; WT Gly vs KHK-KO Gly). Serum creatine phosphokinase (CPK) levels were similar between WT and KHK-KO mice on glycerol (WT Gly; 207.5 IU/L vs KHK-KO Gly; 227.0 IU/L) suggesting equivalent muscle injury and the protective effect for rhabdomyolysis-induced AKI in KHK-KO was mediated locally at kidney. Consistently, renal endogenous fructose production and metabolism was activated in the kidney of WT Gly compared to WT sham as denoted by the up-regulation of aldose reductase and KHK.

Conclusions: Endogenous fructose production in kidney by activation of polyol pathway had a deteriorative role for rhabdomyolysis-induced AKI. The blockade of KHK could be the target for preventive and recovery for AKI.

Temporal Changes in Histone Deacetylases after Renal Ischemia/Reperfusion Injury Kelly A. Hyndman, Malgorzata Kasztan. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Histone deacetylases (HDACs) are epigenetic regulators of transcription through deacetylation of histone lysines. Increased HDAC activity causes uncontrolled proliferation, inflammation, and/or fibrosis. Moderate ischemia/reperfusion (IR) of the kidney results in an immediate decline of renal function and injury including fibrosis followed by a stage of repair and improvement of renal function. The aim of this study was to determine if renal HDACs are dysfunctional during injury and repair after IR.

Methods: Male and female 10 week old mice underwent sham or bilateral ischemia for 27 minutes, followed by reperfusion for 1, 24, 48 or 72 h.

Results: Abnormal tubular morphology and reduced nuclei number were evident after 1 h, followed by significant reduction by 24-48 h, and reappearance of larger nuclei by 72 h. Western blots of cortical samples showed the following effects of IR on class I HDACs compared to sham: HDAC1 was increased 2.5-fold by 48 h, HDAC2 was not affected, HDAC3 initially increased 50% but returned to sham levels by 48 h, and HDAC8 was significantly reduced 40% over the study period. The class II HDAC4 was significantly increased 4-fold over the study period. To determine if the increase in HDAC promoted renal damage and fibrosis, we delivered a class I inhibitor (MS275, 20 mg/kg/day) or a class I/II inhibitor (trichostatin A, TSA, 1 mg/kg/day) by i.p. osmotic minipump 3 days prior IR. In both sexes, plasma creatinine was 2-3-fold greater in MS275 and TSA mice compared to vehicle, suggesting that inhibition of HDACs during IR results in a worsening of renal function. Histological analyses revealed reduced fibrosis in the MS275 and TSA mice, however there was an increase in protein casts in these groups. In vitro studies in primary and immortalized proximal tubular (PT) cells determined that only class I/II inhibitors led to reduced proliferation. Overexpression of HDAC4, but not HDAC1, resulted in 55% greater PT proliferation.

Conclusions: From this study, we conclude that class I and II HDACs are significantly affected during IR and display isoform specific expression patterns. Our data suggest that class I HDACs may promote fibrosis, while class II HDACs, likely HDAC4, are critical for PT proliferation and repair.

Modulation of PPARδ with MTB-2 Post-Reperfusion Attenuates IR-Induced AKI Injury Biomarkers and Histopathology in Rats Christina Bracken, Katelyn Pulito, Effie Tozzo. *Mitobridge, Cambridge, MA.*

Background: Ischemic acute kidney injury (AKI) is characterized by persistent proximal tubule mitochondrial dysfunction. Due to their highly oxidative metabolism, proximal tubule cells utilize fatty acids to generate the energy required for their specialized function. We hypothesized that enhancing fatty acid oxidation with a PPARδ modulator will restore mitochondrial function, offering a potential therapeutic treatment for AKI.

Methods: Sprague-Dawley (SD) rats underwent a 45 minute bilateral ischemia-reperfusion (IR) AKI. Following reperfusion rats were treated with 2 IV doses of selective PPARδ modulator MTB-2 at doses varying from 0.3 to 10 mg/kg or vehicle. Plasma and urinary kidney injury biomarkers were measured at 10h, 24h and 48h post reperfusion. Histology assessment of kidney cortex was done 48h post AKI.

Results: MTB-2 treatment resulted in significantly lower plasma creatinine (up to 69% reduction), BUN (up to 60% reduction) and cystatin C (up to 69% reduction) levels at 24 and 48 hours post AKI compared to vehicle animals. Importantly, this translated to an improvement of renal function marked by increased creatinine clearance (up to 800%) and normalization of fractional excretion of Na^+ (FENa) (up to 90%) suggesting improved tubular function. Modulation of PPARδ after AKI also led to significantly reduced urinary levels of [TIMP-2]*[IGFBP-7], FABP-1 and NGAL. Assessment of kidney histopathology at 48 hours post reperfusion confirmed that MTB-2 reduced tubular injury and normalized renal tubular architecture, resulting in improvement of histopathology scores.

Conclusions: Our data demonstrates that selective PPARδ modulation after an ischemic AKI event in rats is sufficient to recover renal and tubular function, reduce clinically relevant urinary and plasma injury biomarkers and improve kidney histopathology.

TH-PO244

Identification of Urinary Activin A as a Novel Biomarker for AKI Shunsuke Takahashi,[2] Yoshinori Takei,[4] Masao Nakasatomi,[1] Toru Sakairi,[3] Hidekazu Ikeuchi,[5] Yoriaki Kaneko,[2] Keiju Hiromura,[2] Yoshihisa Nojima,[1] Akito Maeshima.[2] *[1]Gunma University, Maebashi, Japan; [2]Gunma University Graduate School of Medicine, Maebashi, Japan; [3]Gunma University Graduate School of Medicine, Japan, Maebashi, Japan; [4]Gunma University School of Medicine, Maebashi, Japan; [5]Gunma university graduate school of medicine, Maebashi, Japan.*

Background: Activin A, a member of TGF-beta superfamily, is known to regulate cell growth and differentiation in various tissues. We previously reported that activin A, which was absent in normal kidney, was increased in the ischemic rat kidney and negatively regulates the repair process of the kidney after injury (Maeshima et al. J Am Soc Nephrol 2001). To further investigate the role of activin A in acute kidney injury (AKI), we examined whether activin A can be detected in the urine of mice and humans with AKI.

Methods: Ischemia-reperfusion injury (I/R) was induced in C57BL/6 mice. At the indicated periods after operation, the kidneys and urine were collected for analysis. Expression and localization of activin A in ischemic kidneys (real-time PCR, immunostaining, and in situ hybridization) and urinary activin A (ELISA) were examined. Urine samples were also collected from fifteen patients with AKI as well as from eight healthy volunteers. Correlations of urinary activin A with other parameters were analyzed.

Results: Expression of activin A was markedly increased in the ischemic mouse kidney and peaked at 24 hours after I/R. Immunoreactive activin A was detected in proximal tubular cells of the outer medulla in ischemic kidneys, but not in normal kidneys. Activin A was absent in the urine of normal mice. In contrast, activin A was detectable in the urine of ischemic mice and bimodal peak (3 hours and 48 hours after I/R) was observed. In situ hybridization demonstrated that activin mRNA was expressed in tubular cells of the ischemic kidney, but was not in normal kidneys. Urinary activin A level became higher according to the ischemic periods. Urinary activin A was almost undetectable in healthy volunteers, but was significantly increased in patients with renal-AKI (7.2 ± 2.6 vs. 48.6 ± 15.3 pg/ml, $p<0.05$). Interestingly, urinary activin A was absent in the urine from patients with pre-renal AKI due to dehydration. There was a significant correlation of urinary activin A level with urinary follistatin (activin antagonist), but not with urinary KIM-1, urinary protein and serum creatinine.

Conclusions: Urinary activin A can be detected in mice and humans with AKI and might be a useful biomarker reflecting the severity of AKI.

Mapping the Spatiotemporal Transcriptional Landscape of the Collecting Duct During Ischemic Injury Using Non-Invasive Optical Guidance Neal A. Paragas, Tomoaki Miyazaki, Yun-Wei A. Hsu, Sina Gharib. *University of Washington, Seattle, WA.*

Background: Collecting duct (CD) cells are sensitive to acute kidney injury (AKI) before an appreciable rise in serum creatinine. CD cells are mitochondrial rich and sensitive to oxidative stress (OS), so we specifically targeted them to monitor H_2O_2 generation along with changes in gene expression.

Methods: To interrogate genetic changes at the peak of OS, we non-invasively monitored H_2O_2 generation to identify the most relevant time points tissue acquisition for CD specific RNA-seq. We created a CD, HoxB7-luciferase (CD-Luc) bioluminescent reporter animal, to monitor OS. CD-Luc cell-specific reporter mice were injured by 30 min bilateral ischemia reperfusion injury (IRI) and H_2O_2 activity monitored non-invasively. A H_2O_2 sensitive caged-luciferin substrate was used to quantify cell specific changes of H_2O_2 after IRI. In parallel, we created a CD, HoxB7-riboTRAP (CD-riboTRAP) RNA isolation animal, to selectively immuno-precipitate (ip) RNA transcripts from CD cells. CD population was RNA sequenced and analyzed.

Results: In vivo measures of CD-Luc H_2O_2 activity were in agreement with MDA levels (lipid peroxidation), and qPCR of biomarkers of hypoxic stress (Hspa1b and Hmox1) with all peaking at 6-9 h after IRI. In the parallel, CD-riboTRAP IRI animals 9 h after injury had ip RNA-seq. We identified over 14,000 transcripts with many up- and down-regulated genes between IRI vs. sham CD-riboTRAP populations. Previously validated biomarkers of renal injury to the medulla were upregulated (Lcn2, Clu, and Spp1). Pathways involved in mitochondrion-associated processes were down-regulated. We pretreated CD-Luc before IRI with a targeted mitochondrial antioxidant and were able to reverse the CD OS in vivo.

Conclusions: In sum, using our novel integrative approach we: (i) non-invasively and longitudinally imaged the peak time point of OS in the CD; (ii) used ip to isolate CD RNAs at that time point; (iii) successful carried out RNA sequencing; (iv) performed differential gene expression and pathway analysis to reveal mitochondrial OS as a potential target pathway; (v) reversed the acute OS state with a targeted mitochondrial antioxidant with reduced lipid peroxidation in the kidney; and (vi) validated the reversal of mtROS induction in ROS reporter animal model and as a result suppressed the strong inflammatory stimulus of IRI.

Iron Deficiency Sensitizes the Kidney to Acute Injuries Xueqiao Wang,[3] Wenjun Shang,[2] Xiaoqing Zheng,[4] Zhigang Wang,[2] Juanlian Zhang,[3] Jushan Zhang,[3] Jing Nie,[3] Jonathan M. Barasch,[1] Andong Qiu.[3,1] *[1]Columbia Presbyterian, New York, NY; [2]Zhengzhou University, Zhengzhou, China; [3]School of life science and technology, Tongji University, Shanghai, China; [4]School of life science and technology, Tongji University, Shanghai, China.*

Background: Iron deficiency is the most common micronutrient deficiency in both the developing and developed countries, and it causes defective development of organogenesis in embryos. However, it remains unknown whether iron deficiency impacts acute kidney injuries (AKI) during postnatal life. Here we studied the effects of iron deficiency on AKI in murine models.

Methods: Mice were fed either iron deficient (22ppm), moderate iron deficiency (60ppm) or iron-replete (260ppm) diets for 3 weeks, and then subject to cisplatin or rhabdomyolysis AKI. sCR and BUN were analyzed three days after i.p. injection of cisplatin and one day after muscular injection of glycerol. Pro-oxidant and antioxidant, cell death and iron proteins and inflammatory factors were analyzed by Q-PCR, western blot or immunofluorescence and CBA.

Results: We found that iron deficiency markedly exacerbate cisplatin- and rhabdomyolysis-induced AKI when compared with iron-replete condition, and even moderate iron deficiency had similar impacts. Nox4 and inflammatory factors were largely upregulated while catalase was markedly downregulated in the cisplatin-injured kidneys of iron-deficient mice when compared with iron-replete control. Further studies showed that the exacerbation of cisplatin-induced kidney injuries in iron deficient mice could be reversed by Fer-1, a ferroptosis inhibitor, demonstrating that the increased ferroptosis was a major mechanism for the aggravation of AKI. In contrast, Fer-1 failed to rescue the exacerbation of AKI induced by rhabdomyolysis, indicating the existence of a different mechanism for the impacts of iron deficiency on kidney injuries in this model.

Conclusions: Iron deficiency and even moderate iron deficiency markedly exacerbated AKI induced by either cisplatin or rhabdomyolysis, and increased ferroptosis represented a major mechanism of the exacerbation of kidney injuries in iron deficient cisplatin-induced AKI model.

Omega-3 Fatty Acids Attenuate Cisplatin Nephrotoxicity via Enhancement of Autophagy Flux Youngrok Ham,[1] Jin young Jeong,[2] Hong jin Bae,[1] Chang hun Song,[1] Kiryang Na,[3] Kang Wook Lee,[1] Jwajin Kim,[3] Jiwon M. Lee,[4] Dae Eun Choi.[1] *[1]Nephrology, School of Medicine, Chungnam National University, Daejeon, Republic of Korea; [2]Department of Medical Science, Chungnam National University, Daejeon, Republic of Korea; [3]Anatomy, School of Medicine, Chungnam national university, Deajeon, Republic of Korea; [4]Pediatrics, School of Medicine, Chungnam National University, Daejeon, Republic of Korea.*

Background: Various studies demonstrated that omega-3 polyunsaturated fatty acids (PUFAs) attenuate kidney injuries through anti-apoptotic and antioxidant properties. Recently, several studies showed that omega-3 PUFAs enhance induction of autophagy. We evaluated whether administration ω-3 PUFAs may induce autophagy in cisplatin nephrotoxicity, and investigated the role of autophagy in attenuating cisplatin nephrotoxicity by ω-3 PUFAs.

Methods: 10-week- old male C57BL/6 mice were divided into 4 groups; control, control plus omega 3, cisplatin, cisplatin plus omega 3; they were injected with a vehicle or single dose of cisplatin (16 mg/kg body weight) intraperitoneally. Omega 3 and vehicle were administered orally using an NG tube (Omega 32,000 μg/kg/day) from pre-injection day to 3 days after injection of cisplatin. Mice were sacrificed at 4 days after administration of cisplatin and kidney tissue were collected. Real time PCR, western blot and immunohistochemistry for molecular study and H&E stain and PAS stain for histologic examination were performed.

Results: Omega 3 treated cisplatin-mice showed improvement of renal cell survival, renal function, and pathologic damage compared to vehicle treated cisplatin-mice. Omega-3 treatment also reduced the renal expression of MCP-1 (Monocytye chemotactic protein-1) and OPN (Osteopontin) in cisplatin-treated kidney. Cisplatin-mice kidney showed that higher amounts of LC3, Beclin-1 and p62 compared to sham mice. Omega 3 treated cisplatin kidney showed higher amounts of LC3 and Beclin-1 and lower amounts of p62 compared to vehicle treated cisplatin kidney. Moreover, renal cathepsin D and ATP6E were also increased in omega 3 treated cisplatin-mice compared to vehicle treated cisplatin-mice.

Conclusions: Omega 3 fatty acids attenuate renal injury in cisplatin nephrotoxicity through stimulating autophagy flux

TH-PO248

Shroom3 Contributes to a More Severe AKI after Ischemia Reperfusion Darren Bridgewater, Thomas A. Drysdale. *McMaster University, Hamilton, ON, Canada.*

Background: Acute kidney injury (AKI) is a severe complication of ischemia reperfusion injury. Individuals who survive AKI have an increased risk of developing chronic kidney disease, end stage renal disease, and death. While several clinical risk factors are associated with AKI, the genetic contributions are limited. Genome-wide

association studies (GWAS) identified 53 novel single nucleotide polymorphisms (SNPs) robustly associated with variations in kidney function. *SHROOM3* is the second most significant gene identified in these studies. Shroom3 is an actin-associated protein that regulates tissue morphogenesis by regulating epithelial cell shape. In the kidney, Shroom3 is expressed in the parietal and visceral epithelial cells, in some tubular epithelial cells, and distal collecting ducts. While Shroom3 heterozygous mice develop chronic kidney disease at 1 year, the role of Shroom3 in AKI is not known.

Methods: Bilateral renal ischemia/reperfusion (I/R) procedure was performed in Shroom3 heterozygous mutant (*Shroom3*$^{Gt/+}$) and wild type (WT) mice at 12 weeks to mimic the I/R renal injury experienced during transplant and cardiac surgery. Serum creatinine and urine protein at baseline, days 1, 2, 3, 5, 7, and 10 were measured. Kidneys were collected 48 hours and 10 days after I/R the procedure to compare the histopathological changes of the initial AKI insult and the kidneys ability to recover.

Results: Twelve-week old *Shroom3*$^{Gt/+}$ and WT mice had similar serum creatinine and urinary protein levels at baseline. Twenty-four hours after I/R, *Shroom3*$^{Gt/+}$ mice had a 1.5 fold (P=0.038) increase of serum creatinine from baseline (Fold Mean±SD, 3.89±1.35, N=10) compared to WT mice (Fold Mean±SD, 2.58±1.01, N=8). The *Shroom3*$^{Gt/+}$ mice demonstrated worse histopathology as measured by tubular changes and cell death. Ten days after I/R, the serum creatinine in *Shroom3*$^{Gt/+}$ and WT mice returned to baseline levels. However, the histopathological changes in *Shroom3*$^{Gt/+}$ mice were markedly worse when compared to WT mice.

Conclusions: Our results demonstrate that genetic anomalies or aberrant expression of Shroom3 could lead to worse renal outcomes in patients after an I/R injury.

Paricalcitol Ameliorates Radiocontrast-Induced Nephropathy by Regulating Mitophagy Dong Jun Park,[3,4] Tae won Lee,[3] Eunjin Bae,[3] Hyun Seop Cho,[1] Ha nee Jang,[5] Hee jung Park,[2] Se-Ho Chang.[1,4] *[1]Gyeongsang National University Hospital and Gyeongsang National University, Jinju-si, Gyeongsangnam-do, Republic of Korea; [2]Gyeongsang national university hospital, Jinju, Jinju-si, Republic of Korea; [3]Internal Medicine, Changwon Gyeongsang National University Hospital and Gyeongsang National University, Changwon-si, Republic of Korea; [4]Institute of Health Science, Gyeongsang National University, Jinju-si, Republic of Korea; [5]Gyeongsang National Univ. Hospital, Jinju-si, Republic of Korea*.

Background: Radiocontrast-induced nephropathy (RCIN) is an important problem in clinical settings. However, strategies to prevent RCIN have been suboptimal. Paricalcitol was recently found to be effective in a variety of renal animal models, so it was hypothesized that paricalcitol would prevent RCIN

Methods: RCIN was induced in rats by injection of the radiocontrast medium Ioversol in addition to inhibition of prostaglandin and nitric oxide synthesis. Rats were randomly assigned to four groups: healthy controls (Con, n=10), received paricalcitol only (Parical, n=10), ioversol (CONT, n=10), and received paricalcitol before ioversol injection (Parical+CONT, n=10). Rats were treated with either paricalcitol (0.3 mg/kg, i.p) or saline (equal volume, i.p.) at 24 h and 30 minutes prior to ioversol injection.

Results: Administration of two doses of paricalcitol before the induction of nephropathy significantly reduced the renal dysfunction and histologic tubular injury. The apoptosis of renal tubular cells was inhibited by paricalcitol. Oxidative stress markers such as 8-OhdG and NOX-2, NADPH oxidase, were highly expressed in nephropathy rat model, but attenuated by paricalcitol administration. β-galactosidase, one of markers of cellular senescence, increased in tubules after contrast infusion. This was alleviated by paricalcitol. Furthermore, the expression of LC3, PINK1, and Parkin, representatives of mitochondrial autophagy, after radiocontrast injection was highly attenuated by administration of paricalcitol, suggesting that the effects of paricalcitol might be mediated by the autophagy pathway.

Conclusions: These findings suggest that paricalcitol may have potential as a new therapeutic approach to prevent RCIN.

TH-PO250

Histone Deacetylase 6 Inhibition Protects Against Cisplatin-Induced AKI Yingfeng Shi,[2] Na Liu,[1] Liuqing Xu,[4] Jinhua Tang,[1] Shougang Zhuang.[3] *[1]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China; [2]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China; [3]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [4]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China*.

Background: The function of histone deacetylase 6 **(**HDAC6**)** has been demonstrated in various pathophysiological events, including cancer, neurodegenerative disorders and inflammatory diseases. Its role in cisplatin-induced acute kidney injury (AKI) is still unclear.

Methods: We used a murine model to investigate the role and mechanism of HDAC6 in cisplatin-induced AKI.

Results: HDAC6 expression levels were markedly increased in the kidneys of cisplatin-treated mice. Blocking HDAC6 activity with tubastatin A (TA), a high selective inhibitor, protects against cisplatin-induced AKI as demonstrated by improved renal dysfunction, attenuated renal pathological changes, reduced expression of AKI biomarkers (NGAL and Kim-1), and decreased tubular cell apoptosis. Administration of TA also enhanced tubular cell dedifferentiation and regeneration as evidenced by increased expression of Pax2 and proliferating cell nuclear antigen protein in the injured kidney. In vitro studies demonstrated that TA increased acetylation of histone H3 and a-tubulin and decreased cell apoptosis in cultured human proximal tubular cells. Mechanistic studies demonstrated that TA treatment enhanced AKT phosphorylation and induced autophagy. Moreover, HDAC6 blockage restrained renal oxidative stress by raising superoxide dismutase activity and lessening malondialdehyde level. Finally, TA treatment inhibited NF-κB phosphorylation as well as expression of multiple cytokines/chemokines, thereby reducing macrophage infiltration in the injured kidney.

Conclusions: These data provide strong evidence that HDAC6 inhibition protects against cisplatin-induced AKI and suggest HDAC6 as a potential therapeutic target for AKI treatment.

Involvement of Sirtuins 1 and 3 during the Acute Phase of Aristolochic Acid Nephropathy Inès Jadot,[3] Pauline F. Mosseray,[3,4] Blanche Martin,[3] Olivia Botton,[3] Joelle L. Nortier,[1] Anne-Emilie Decleves,[2] Thierry Arnould,[4] Nathalie Caron.[3] *[1]Hospital Erasme, Brussels, Belgium; [2]Laboratory of Molecular Biology, University of Mons, Belgium, NIMY (MONS), Belgium; [3]Molecular Physiology Research Unit (URPHYM), University of Namur, Namur, Belgium; [4]Laboratory of Biochemistry and Cell Biology (URBC), University of Namur, Namur, Belgium*.

Background: Aristolochic acid (AA) nephropathy (AAN) is a rapidly progressive tubulointerstitial nephritis induced by intoxication with AA and is usually associated with end-stage renal disease and urothelial malignancy. While the carcinogenic mechanisms of AA have been well documented, the mechanisms by which AA exert cytotoxic effects on proximal tubular epithelial cells, AA's primary target, are poorly characterized. Since oxidative stress and mitochondrial damage are known to be drivers of acute kidney injury, the goal of this study is to characterize oxidative stress and mitochondrial dysregulation with a particular emphasis on sirtuins (SIRT) during the acute phase of experimental AAN. Indeed, SIRT1 and SIRT3 have been previously described to be protective in different models of kidney disease. Therefore, this study aims to investigate for the first time the involvement of SIRT1 and SIRT3 in the pathophysiology of AAN.

Methods: C57BL/6J male mice were randomly subjected to daily i.p. injection of AAI (3,5mg/kg) for 4 days. Mice were euthanized 24 hours, 5 days and 10 days after the beginning of AA intoxication.

Results: Polyuria and proteinuria were observed 5 days after AA intoxication as well as an increase in plasma creatinine and in blood urea nitrogen confirming renal failure. Histological analysis revealed early alterations of proximal tubules 24 hours after AA intoxication. At day 5, necrotic tubules with cellular debris in the tubular lumen were observed thereafter evolving at day 10 to atrophic tubules. Tubular injury was confirmed by upregulation of relative mRNA expression of *NGAL*. Along with renal failure, inflammation developed with upregulation of mRNA of inflammatory cytokines (*MCP1, MIP2, IL1*β, *IL6* and *TNF*α) and with macrophage infiltration. Antioxidant pathways were also downregulated as attested by decrease in mRNA expression of *NRF-2* and *SOD* at day 5 and day 10. Finally, relative mRNA expression of *SIRT1* and *SIRT3* was found to be downregulated from day 5 until day 10, the protein expression of SIRT3 being also reduced at the same time-points.

Conclusions: The downregulation of SIRT1 and SIRT3 observed in the acute phase of AAN could constitute a key event in AAN pathogenesis. Therefore, this observation could lead to a new potential strategy for improving outcomes of AAN.

Characterization of the Metabolome and Renal Tubular Cisplatin Disposition in Cisplatin Induced AKI Yong Jin (James) Lim,[1] Emily D. Hartjes,[1] Brad Urquhart.[1,2] *[1]Physiology and Pharmacology, Schulich School of Medicine & Dentistry, University of Western Ontario, London, ON, Canada; [2]Department of Medicine, Division of Nephrology, University of Western Ontario, London, ON, Canada*.

Background: Cisplatin induces acute kidney injury (AKI) in approximately 1/3 of patients. It is currently unknown why some patients develop AKI and others do not. Cisplatin AKI is diagnosed by increases in serum creatinine (SCr), but nephrotoxicity develops before rises in SCr can be detected. Novel diagnostic/predictive markers of AKI may help explain why some cisplatin patients get AKI while others are resistant. FVB mice have greater susceptibility to cisplatin AKI than C57BL/6 mice. These two mouse strains were used to model the variability of cisplatin response observed in humans. We aim to: 1) Determine the effects of AKI on expression of renal transporters and enzymes involved in cisplatin disposition; 2) Investigate metabolic differences between FVB and C57BL/6 mice using metabolomics, with the goal of biomarker discovery.

Methods: FVB and C57BL/6 strains were treated with 15 mg/kg cisplatin or saline by intraperitoneal injection. Mice were sacrificed 1 and 3 days following treatment, and blood, urine and kidneys were collected. Gene expression was assessed using RT-PCR. Liquid chromatography-mass spectrometry was used for untargeted metabolomics.

Results: In FVB mice, expression of renal uptake transporter Oct2 and metabolizing enzyme Ggt1 were 51% and 66% lower 3 days following cisplatin treatment compared to saline ($p<0.05$, $p<0.01$ respectively). Oct1 trended towards lower expression in day 3 cisplatin-treated FVB mice. Principle component analysis (PCA) of untreated FVB and C57BL/6 plasma samples showed clustering based on mouse strain. PCA of day 3 plasma samples clearly separated cisplatin and saline groups for both mouse strains. Multivariate

analysis revealed indoxyl sulfate and p-cresyl sulfate to be two metabolites associated with cisplatin AKI.

Conclusions: mRNA expression results suggest that cisplatin alters expression of drug disposition genes in FVB, but not C57BL/6 mice. PCA clustering of baseline mice indicates metabolic differences between the strains, while separation by treatment groups suggests that cisplatin administration alters the metabolic profile of the mice. Our preliminary data suggests possible mechanisms why FVB mice show increased susceptibility to cisplatin AKI compared to the C57BL/6 mice. Further work will to be done to identify additional metabolic changes associated with cisplatin AKI.

TH-PO253

Blockade of Sonic Hedgehog Signaling in Fibroblasts Protects against AKI Dong Zhou,[1] Haiyan Fu,[1,2] Yuan Tian,[1] Hongyan Mo,[1] Youhua Liu.[1] *[1]Department of Pathology, University of Pittsburgh, Pittsburgh, PA; [2]Division of Nephrology, Southern Medical University, Guangzhou, China.*

Background: Sonic Hedgehog (Shh), an evolutionarily conserved, secreted and extracellular signal protein, is an inducible, tubule-derived growth factor specifically promoting fibroblast proliferation and expansion through its receptor by the so-called canonical pathway in chronic kidney disease. However, whether activation of Shh signaling in fibroblast plays any role in acute kidney injury (AKI) remains to be defined.

Methods:

Results: Here we show that Shh, Smoothened (Smo) and fibroblasts were concomitantly activated after ischemic AKI. To investigate the potential role of activation of fibroblast-specific Shh signaling in AKI, we generated conditional knockout mice, designated as FC-Smo-/-, in which the Smo gene was specifically disrupted in renal fibroblasts by using the inducible Cre-LoxP system. The FC-Smo-/- mice are phenotypically normal and displayed no appreciable defects in kidney morphology and function. However, in AKI induced by ischemia reperfusion injury (IRI), loss of fibroblasts Smo substantially ameliorated renal dysfunction and lesions. Compared with controls, FC-Smo-/- mice displayed lower serum creatinine and reduced morphologic injury. Fibroblast-specific ablation of Smo significantly blocked the expression of pro-inflammatory cytokines including TNF-α and MCP-1, and retarded renal infiltration of inflammatory cells such as CD3+ T cells and F4/80+ macrophages after AKI. Less apoptosis was detected in FC-Smo-/- kidneys, accompanied by a decreased expression of Bax and Fas-associated protein with death domain (FADD). Interestingly, loss of Smo in fibroblast in turn caused an increased expression of Shh in tubules by feedback control, Shh then promoted activation of canonical Wnt signaling pathway including upregulation of the majority of 19 Wnt family members after AKI which is strongly associated with AKI recovery.

Conclusions: Collectively, these results suggest that loss of fibroblast-specific Shh receptor, Smo, is crucial in conferring renal protection after AKI, primarily via a reduced renal inflammation, as well as activation of Wnt signaling through cell-cell communication.

TH-PO254

Sex Differences in Renal Toxicity of the Neurotoxin Domoic Acid Robert G. Thompson,[1] Hernan E. Grenett,[1] Lan He,[3] P. Darwin Bell.[2] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: The algae-derived neurotoxin, domoic acid (DA), is an ionotropic receptor agonist and is currently considered an increasing threat to mammals and other species. Intraperitoneal administration (IP) of 4-5 mg/Kg/BW in mice has been found to cause neurological symptoms\damage. However, we recently reported (Funk, JASN 2014) that the kidney was 100 times more susceptible to injury with DA compared to brain. With IP injection, the kidney has a 4-fold higher concentration of DA compared to brain and prior probenecid treatment leads to even greater accumulations of DA, suggesting that DA is both filtered andis secreted by the kidney. Organic Anion Transporters such as OAT-1, OAT-2, and OAT-3 participate in helping mediate drug and toxin removal by the kidney through the process of secretion. In epithelial tissues, OAT-1 and OAT-3 are located at the basolateral membrane, and OAT-2 is located at the apical membrane (Nigam SK, Physiological Review 2015). The purpose of these studies was to determine if there is a gender sex difference in the renal injury response to DA.

Methods: Doses of 0.05 mg/Kg and 0.005 mg/Kg were IP injected into C57BL6 mice and 30 mins later the early injury-response genes *c-fos*, *Junb*, and *EGR-1* were quantified using RT-qPCR. RT-qPCR was also performed to assess the mRNA levels for organic anion transporters in both male and female mice at 0.05mg/Kg DA.

Results: After 30 minutes both male and female mice exhibited an increase in gene expression. Surprisingly, female mice expression of early response genes was significantly higher compared to male mice. OAT-1, OAT-2, and OAT-3 in males were slightly upregulated; however, female mice showed no change in mRNA expression for OAT-1, OAT-2, and OAT-3.

Conclusions: These results demonstrate that female mice are more susceptible to renal injury compared to male mice in response to very low doses of DA. This difference may be due to a reduced ability for the renal secretion of DA though organic anion transport pathways.

TH-PO255

Thrombospondin-1 (TSP-1) and Microparticles in AKI Begoña Campos,[2] Brittany N. Gleich,[2] Sonam S. Singh,[2] Karen M. Domenico,[1] Charuhas V. Thakar.[2,3] *[1]Shriners Hospitals for Children, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH; [3]Cincinnati VAMC, Cincinnati, OH.*

Background: We have previously shown (Thakar et al, JCI, 2005) that TSP-1 is up-regulated and mediates kidney damage (AKI) in murine ischemia reperfusion injury. TSP-1 exposure to renal epithelial cells is also known to induce apoptosis/necrosis. TSP-1 exerts its inflammatory modulating effects through signaling of CD36 (pro-inflammatory) and CD47 (anti-inflammatory) ligands. Microparticles (MP's) are released in response to stress or injury from various cells and can serve as markers of type and state of cell activation. Whether TSP-1 induced inflammatory ligands can be detected as MP's, and could play a role in organ cross-talk in models of AKI is unknown.

Methods: By studying *in vitro* models of AKI using immortalized human renal proximal tubular epithelial cell (RPTEC) line, we incubated cells with and without TSP-1 (1 μg/ml for 24 hours) (N = 3 sets). MP's were isolated and evaluated by flow cytometry techniques and with CD36 and CD47 flourescent antibodies. Analyses of microparticles was performed using flow-jo software and levels of MP's was expressed as mean and standard deviation times 10^{5}. Unpaired t-tests were used for comparison.

Results: Morphological assessment of TSP-1 treated cells confirmed characteristics assocaited with apoptosis. CD36 MP's were significnatly higher in TSP-1 treated cells vs controls (92.66 +/- 11.06 vs 229 +/-69.77; p = 0.007). CD47 MP's were statistically similar in TSP-1 and control cells (715.33 +/- 248 vs 759.6 +/- 220; p = 0.88). CD10 and CD13 MP's, as putative markers of RPTEC were also detected in response to TSP-1 exposure.

Conclusions: Our results show that MP's containing CD36 and CD47 are released from RPTEC upon exposure to TSP-1. CD36 MP's are significantly increased after TSP-1 exposure, whereas CD47 MP's are statistically similar. It is known that CD-36 serves as a pro-inflammatory ligand for various inflammatory proteins including TSP-1; thus raising the possibility that TSP-1 exposure could initiate a cross-talk between renal epithelium and other targets/tissues mediated thru CD-36 ligand interactions. This is the first report that demonstrates the release of CD36 and CD47 postive MP's in response to TSP-1 exposure. We propose that MP's originating from kidney under pathological conditions could release pro-inflammatory signals to other remote organs.

HIF-1-Mediated Production of Exosomes during Hypoxia Is Protective in Renal Tubular Cells Wei Zhang,[5,6] Xiangjun Zhou,[3] Hao Zhang,[4] Jin Wen,[2] Zheng Dong.[1] *[1]Georgia Regents University, Augusta, GA; [2]Sichuan University, Augusta, GA; [3]Taihe Hospital, Hubei University of Medicine, ----Shiyan, China; [4]The Third Xiangya Hospital of Central South University, Changsha, China; [5]Cellular Biology, Augusta University, Augusta, GA; [6]Nephrology Department, the Third Xiangya Hospital, Central South University, Changsha, China.*

Background: Exosomes are nano-sized vesicles produced and secreted by cells to mediate intercellular communication. The production and function of exosomes in kidney tissues and cells remain largely unclear. Hypoxia is a common patho-physiological condition in kidneys. This study was designed to characterize exosome production during hypoxia of rat renal proximal tubular cells (RPTC), investigate the regulation by hypoxia-inducible factor-1 (HIF-1), and determine the effect of the exosomes on ATP-depletion induced tubular cell injury.

Methods: RPTCs were treated with or without hypoxia. Exosomes were isolated by ultracentrifugation. Transmission electron microscopy and Nanoparticle Tracking Analyzer (NTA) Zeta View as well as Immunoblot analysis were used to qualify and quantify exosomes. HIF-1α inducer DMOG and its inhibitor YC-1 were used for HIF-1α induction or inhibition. A stable HIF-1α knockout MEF cell line and HIF-1α siRNA induced kknockdownRPTC cells were used to verify the role of HIF-1α in exosomes production. Conditioned exosomes were administrated as a pretreatment before Azide induced ATP-depletion injury in RPTC cells. Hoechst staining, morphology images and caspase-3 expression by immunoblot were conducted to evaluate the death and survival rate of the cells.

Results: The average size of exosome secreted in hypoxia condition was comparable to the normal condition by the NTA measurement. Hypoxia significantly increased exosome production in a time-dependent manner. HIF-1α induction by DMOG also slightly promoted exosomes secretion. Pharmacal or genomic inhibition of HIF-1α abrogated exosome increase under hypoxia condition; Pretreatment with hypoxic exosomes from tubular cells attenuated the apoptosis of RPTCs after Azide induced ATP-depletion. Exosomes form HIF-1α knock down cells failed to decrease cell apoptosis rate and caspase-3 expression.

Conclusions: Hypoxia stimulates exosome production and secretion in renal tubular cells. The exosomes from hypoxic cells are protective against renal tubular cell injury. HIF-1 mediates exosome production during hypoxia and contributes to the cytoprotective effect of the exosomes.

TH-PO257

Non-Classical MHC Class I Molecules Regulate Development and Maintenance of Kidney Double Negative αβ T Cells Mohanraj Sadasivam, Sanjeev Noel, Sul A Lee, Abdel Hamad, Hamid Rabb. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Despite strong evidence that immune cells mediate early injury and repair from ischemic acute kidney injury (AKI), the underlying mechanisms are poorly understood. A recently characterized subset of αβ T cells that is double negative (DN) for both CD4 and CD8 coreceptors is present in significant numbers in normal mouse and human kidney. Unlike $CD4^+$ and $CD8^+$ T cells, DN T cells divide actively in the steady state and rapidly increase in response to AKI. In addition, kidney DN T cells secrete anti-inflammatory cytokines IL-10 and IL-27, possess an in vitro and in vivo regulatory function and ameliorate AKI in mice. However, the exact MHC restriction element(s) required for homeostatic DN T cells development and maintenance is not known.

Methods: C57BL/6J (WT), B6.129P2-B2m^{tm1Unc}/J (β2m KO), B6.129S2-H2$^{dlAb1\text{-}Ea}$/J (MHC II KO) and B6.129P2-H2-K1^{tm1Bpe} H2-D1^{tm1Bpe}/DcrJ (KD KO) mice were used for analyses. The lymphocytes from the kidney, lymph node and thymus were isolated and analyzed for activation (CD69, CD44, CD62L & CD28), proliferation (Ki67) and apoptosis (annexin V). In vitro functional analysis of cytokines were performed by flow cytometry. Adoptive transfer of T and B cells were performed to assess the regulation of kidney DN T cells.

Results: Our data demonstrate that lack of β2m, but not classical MHC class Ia or class II molecule significantly reduces the frequency (WT, 28.8±3 vs. β2m KO, 9.5±2 vs. MHC II KO, 32.3±2; $P<0.05$) and the absolute number (WT, 3,355±1,077 vs. β2m KO, 1,016±471 vs. MHC II KO, 1,538±639; $P<0.05$) of kidney DN T cells. Subsequent studies show the reduction is due to impaired activation ($P<0.001$) and proliferation ($P<0.05$), and increased apoptosis ($P<0.05$) by kidney DN T cell. Further, most of the defects were restored by adoptive transfer of CD8 T cell from wild type mice, leading to activation and expansion ($P<0.001$) of endogenous DN T cells in β2m KO mice.

Conclusions: Our data indicate a critical role of β2m dependent MHC class Ib molecules in regulating homeostasis and activation of kidney DN T cells. Furthermore, CD8 T cells are appearing to be a source of MHC class Ib molecules and one strong candidate (Qa2) is being investigated using knockout mice, bone marrow chimera and adoptive transfer in the steady state and ischemic AKI.

TH-PO258

Loss of the Stress-Responsive Transcription Factor FoxO3 Accelerates AKI to CKD Transition Ling Li, Catherine Ha, Julia D. Liu, Qais Al-Awqati, Fangming Lin. *Columbia University College of Physicians & Surgeons, New York, NY.*

Background: AKI increases the risk for developing or worsening CKD. Capillary drop out and hypoxia occurs in kidneys transitioning from AKI to CKD. We recently found that hypoxia activated a stress-responsive transcription factor FoxO3 in mouse kidneys by the mechanism of preventing its oxygen-dependent degradation.

Methods: To test the function of FoxO3 activation during the AKI to CKD transition, we specifically deleted FoxO3 with high efficiency in tubular epithelial cells using *Pax8-rtTA;Tet-O-cre;FoxO3$^{f/f}$* mice.

Results: Ischemia-reperfusion injury (IRI) of a 35 min duration to the left kidney and right nephrectomy was performed. One week later, FoxO3 was deleted by giving mice doxycycline in the drinking water to study its role after the acute injury and recovery phase. Deletion of FoxO3 aggrevated renal damage 4 weeks post IRI indicated by significantly higher scores of brush border loss in proximal tubules, renal tubular atrophy and tubular cast formation (229 ± 5.3 vs. 22 ± 3.6 in wild type, n= 5). Furthermore, FoxO3 deleted mice had more prominent tubular cell apoptosis. However, neither interstitial fibrosis and inflammation nor microvascular density were significantly different compared with FoxO3 wild type mice. Mice with FoxO3 deletion also had higher urinary albumin:creatinine (53.2 ± 8.3 mg/g vs. 18.4 ± 4.6 mg/g in wild type, n=4) indicating that worse morphology was associated with functional decline. One potential mechanism for repair and survival of renal tubules is autophagy, a well-known cellular stress response. To examine the role of FoxO3 in renal autophagy, we examined the conversion of the core autophagy-related protein LC3I to LC3II, which is a key event in the formation of autophagic vesicles. Kidneys with FoxO3 deletion showed a 52% reduction in the ratio of LC3II to LC3I, suggesting lower level of autophagy.

Conclusions: In summary, our results indicate that FoxO3 activation induces renal autophagy as a stress response, which attenuates CKD development and progression.

TH-PO259

Optogenetic Stimulation of Specific Neural Circuits in the Neuroimmune Reflex Control of Inflammation in AKI Shinji Tanaka,[1] Tsuyoshi Inoue,[1] Diane L. Rosin,[2] Patrice G. Guyenet,[2] Mark D. Okusa.[1] *[1]Div of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, Dept of Medicine, University of Virginia, Charlottesville, VA; [2]Dept of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: We recently reported that electrical vagus nerve stimulation (VNS) protects mouse kidneys from ischemia-reperfusion injury (IRI) by activating the cholinergic anti-inflammatory pathway (CAP). A limitation of this study is the bidirectional stimulation of both the efferent and afferent vagus nerve fibers. We used optogenetics to begin to distinguish the specific functions of vagus efferent and afferent fibers within the vagus nerve bundle in controlling inflammation by the CAP. Optogenetic stimulation involves the expression of light-reactive ion channels, such as channelrhodopsin-2 (ChR2), in relevant neurons using the Cre/loxP system. When light of a specific wavelength is applied to the target nerve, the ion channels open, resulting in selective activation of the neurons.

Methods: We crossed *loxP-STOP-loxP ChR2-eYFP* mice with choline acetyltransferase (*Chat*)-*cre* and vesicular glutamate transporter 2 (*Vglut2*)-*cre* mice to generate *Chat-ChR2* and *Vglut2-ChR2* mice expressing ChR2 in vagal efferent and afferent fibers, respectively.

Results: ChR2 expression was confirmed by direct observation of the eYFP signal in the cervical vagus nerve. When blue laser (wavelength 473 nm, 50 Hz) was applied to the cervical vagus nerve of *Chat-ChR2* mice, heart rate decreased markedly (300→180 bpm) without a change in respiratory rate. Blue laser application to the intact vagus nerve or the central end of the cut vagus nerve of *Vglut2-ChR2* mice completely paused breathing by activation of Hering-Breuer inflation reflex, while application to the distal end of the cut vagus nerve did not affect the respiratory rate, which reflects the fact that Hering-Breuer inflation reflex needs afferent vagal input to the brain. In a preliminary experiment, optogenetic VNS (5 Hz to minimize the effect on respiration) in *Vglut2-ChR2* mice protected kidneys from IRI.

Conclusions: We have successfully created transgenic mice expressing ChR2 in vagus efferent (*Chat-ChR2*) and afferent fibers (*Vglut2-ChR2*) and validated their expression and functional effect following optogenetic stimulation. Our preliminary data showed that selective stimulation of the vagus afferent fibers was protective against kidney IRI. Optogenetics will be useful in identifying selective neural circuits of the CAP that control systemic inflammation and other neural circuits of the kidney.

TH-PO260

Dendritic Cell Expression of Rictor, but not Raptor, Protects Against AKI Natasha M. Rogers,[3] Helong Dai,[2] Daniel Fantus,[1] Alicia Watson,[2] Angus W. Thomson.[2] *[1]Comprehensive Transplant Center, Northwestern University, Chicago, IL; [2]University of Pittsburgh, Pittsburgh, PA; [3]Westmead Institute for Medical Research, Sydney, NSW, Australia.*

Background: Dendritic cells (DC) are critical to innate immunity in the kidney and orchestrate inflammation fundamental to the pathophysiology of acute kidney injury (AKI). The mechanistic target of rapamycin (mTOR) functions as 2 independent complexes: Raptor and Rictor. The role of mTOR in AKI pathophysiology has been poorly characterized, and the influence of DC-based alterations in mTOR signalling has not been investigated.

Methods: CD11c-specific Raptor$^{-/-}$ or Rictor$^{-/-}$ mice were generated by crossing respective floxed mice with mice expressing CD11c-Cre. Age- and gender-matched DC-mTOR-null mice or littermate controls underwent bilateral renal ischemia-reperfusion injury (IRI), followed by assessment of renal function, histopathology, and biomolecular analysis. Dendritic cells (DC) from WT control, Raptor$^{-/-}$ or Rictor$^{-/-}$ mice were isolated and assessed *ex vivo*.

Results: CD11c-specific Raptor$^{-/-}$ mice demonstrated no difference in renal function compared to control mice following IRI. However, CD11c-specific Rictor$^{-/-}$ displayed significantly worse renal function and histologic damage at 24 h reperfusion compared to littermate controls. Deterioration in renal function also reflected an aggravated pro-inflammatory cytokine profile (TNFα, IL-1β, IL-6), with kidney-specific increases in $CD11b^+Ly6G^+$neutrophil, $CD3^+$ T cell, $CD11b^+F4/80^+$macrophage and $MHCII^+CD11c^+$DC infiltrates. Increased splenic neutrophil and macrophage infiltrates were also demonstrated in Rictor$^{-/-}$ mice post-IRI. Renal Rictor$^{-/-}$ DC displayed enhanced expression of maturation markers CD40 and CD86, and decreased PD-L1 post-IRI. *Ex vivo* isolated Rictor$^{-/-}$ DC also demonstrated an enhanced maturation profile compared to WT DC, which was augmented by hypoxia-reoxygenation, and associated with depressed oxidative phosphorylation and increased glycolytic phenotype. Tracking of WT and Rictor$^{-/-}$ DC simultaneously adoptively transferred into B6 mice at the time of renal IRI showed increased numbers of Rictor$^{-/-}$ DC migrating to the injured kidney.

Conclusions: These novel data show that DC-targeted elimination of Rictor promotes IRI, highlighting the regulatory role of both DC and mTOR complex 2 in the pathophysiology of AKI.

Activation of the Cholinergic Anti-Inflammatory Pathway by GTS-21 Attenuates Cisplatin-Induced AKI Prodyot K. Chatterjee,[1] Michael M. Yeboah,[3] Malvika H. Solanki,[2] Gopal Kumar,[4] Xiangying Xue,[1] Valentin A. Pavlov,[1] Yousef Al-Abed,[5] Christine N. Metz.[1] *[1]The Center for Biomedical Sciences, Feinstein Institute for Medical Research, Manhasset, NY; [2]The Department of Pathology and Laboratory Medicine, Medical College of Wisconsin, Milwaukee, WI; [3]Dept. Division of Nephrology, Medical College of Wisconsin, Milwaukee, WI; [4]Elmezzi Graduate School of Molecular Medicine, Northwell Health, Manhasset, NY; [5]The Center for Molecular Innovation, Feinstein Institute for Medical Research, Manhasset, NY.*

Background: Acute kidney injury (AKI) is the most common side effect of cisplatin, a widely used chemotherapeutic agent. Although AKI occurs in up to 1/3 of patients treated with cisplatin, effective protective strategies are lacking. Cisplatin targets renal proximal tubular epithelial cells leading to the production of reactive oxygen species

(ROS), inflammation, tubular cell injury, and eventually cell death. The cholinergic anti-inflammatory pathway is a vagus nerve-mediated physiological mechanism that suppresses inflammation via α7nicotinic acetylcholine receptors (α7nAChRs). Our previous studies demonstrated the renoprotective effects of α7nAChR agonists (e.g. GTS-21) in murine renal ischemia reperfusion injury and sepsis-induced AKI. Therefore, we examined the effect of GTS-21 on cisplatin-AKI.

Methods: Male C57BL/6 mice were treated with either saline or GTS-21 (4mg/kg, i.p.) twice daily for 4 days before cisplatin (20mg/kg, i.p.); 72 hrs later mice were euthanized and their plasma and kidneys were analyzed for markers of renal injury, ROS, and inflammation, as well as renal ATP levels, renal cisplatin accumulation and the expression of cisplatin influx and efflux transporters.

Results: GTS-21 significantly reduced cisplatin-induced renal dysfunction and injury. GTS-21 significantly attenuated renal *Ptgs2*/COX-2, IL-6, IL-1β, and CXCL1 expression, as well as neutrophil infiltration and MPO activity after cisplatin. GTS-21 blunted cisplatin-induced ERK1/2 activation, oxidative stress, as well as renal ATP depletion and apoptosis ($p<0.05$). GTS-21 suppressed cisplatin influx transporter CTR1 expression and enhanced the expression of cisplatin efflux transporters MRP2, MRP4, and MRP6 ($p<0.05$). Using cancer cell lines we showed that GTS-21 did not inhibit cisplatin's tumor killing activity.

Conclusions: GTS-21 protects against cisplatin-AKI by attenuating renal cytokine/chemokine expression, ROS, and mitochondrial dysfunction, as well as by decreasing renal cisplatin influx and increasing efflux. GTS-21 does not impair cisplatin-mediated tumor cell killing. Our results support further exploring the cholinergic anti-inflammatory pathway for preventing cisplatin-induced AKI.

Implications of Short-Term Coxsackievirus Infection in Non-Obese Diabetic Mouse Kidneys Debra L. Walter, Rosemary J. Oaks, Ramiro Malgor, Frank L. Schwartz, Kelly D. Mccall, Karen T. Coschigano. *Ohio University, Athens, OH.*

Background: End stage renal disease (ESRD) can result from four primary diagnoses, diabetes, hypertension, glomerulonephritis and cystic kidney disease, all of which have viruses implicated as causative agents. Enteroviruses, like coxsackievirus (CV), are a common genus of viruses that have been implicated in both diabetes and cystic kidney disease, however, little is known about early CV infection in the kidney and how that infection may contribute to ESRD. This study, therefore, evaluates short-term CV infection in the kidneys of non-obese diabetic (NOD) mice; a strain of mice with a genetic predisposition to develop type 1 diabetes mellitus (the most common primary ESRD diagnosis), a condition which can be accelerated by CV infection in these mice. Characterizing the short-term effects of CV on the kidneys will define our understanding of how "innocent" viruses like CV may have a more significant impact on chronic kidney disease than previously described.

Methods: Eight-week-old NOD mice were infected with CV and euthanized 3, 7, 10 and 14 days post infection. Kidneys were collected and processed for histological and gene expression analyses.

Results: CV RNA in the kidney peaked 3 days post infection and was identified in both the glomerulus and tubulointerstitial regions. Virus was no longer detectible by real-time RT-PCR or *in situ* hybridization 14 days post infection. Percent kidney weight and urinary albumin creatinine ratio, hallmarks of kidney injury, did not demonstrate significant alterations in NOD mouse kidneys at these timepoints. Histological evaluation of PAS and H&E stained tissue did not reveal any significant pathological changes between infected and non-infected kidneys at any time point. However, gene expression of TLR3 and its signaling products TNFα, IL-6 and CXCL10 were found to be upregulated 3 days post CV infection, indicating a potential kidney cell response to virus infection. Further evaluation will be performed to determine in which cells of the kidney TLR3 is upregulated.

Conclusions: Together, these data will help identify initial kidney gene expression changes in response to virus infection that may play a role in later ESRD.

TH-PO263

Natural IgM and TLR Agonists Switch Murine Splenic Pan-B to "Regulatory" Cells That Suppress Ischemia Induced Innate Inflammation via Regulating NKT-1 Cells Peter I. Lobo, Kailo H. Schlegel, Amandeep Bajwa, Mark D. Okusa. *University of Virginia, Charlottesvillle, VA.*

Background: Innate inflammation after reperfusion of ischemic organ has a significant role in ischemic acute kidney injury (AKI). In prior studies, we showed that natural IgM anti-leucocyte autoantibodies (IgM-ALA) inhibit inflammation. Here we show that pan-B cells are switched to regulatory cells when pretreated *ex-vivo* with either IgM or CpG.

Methods: C57BL/6 mice were i.v. infused with 0.5X10^6 B cells that were cultured for 48h with either IgM or CpG and 24h later these mice underwent bilateral renal ischemia. Plasma creatinine and other studies were preformed 24h after ischemia.

Results: Pre-treatment with regulatory pan-B cells (IgM or CpG treated) protected kidneys from AKI via regulation of *in-vivo* NKT-1 cells which amplify the innate inflammatory response to DAMPS released after ischemia. Such *ex-vivo* induced regulatory pan-B cells express low CD1d and inhibit inflammation by regulating *in-vivo* NKT-1 in the context of low lipid antigen presentation and by a mechanism that involves either PDL1. CpG induced regulatory B cells, but not IgM induced regulatory B cells, also require IL10 for their regulatory activity. LPS, unlike CpG, fails to down-regulate CD1d and switch pan-B to regulatory cells that inhibit ischemia induced AKI despite increased IL10 production.

Conclusions: *Ex-vivo* induced regulatory pan-B cells could have therapeutic relevance as these easily available cells can be pre-emptively infused to prevent AKI that can occur during open heart surgery or in transplant recipients receiving deceased donor organs.

Genetic and Pharmacologic Blockade of Prostaglandin Transporter Attenuates Cisplatin Nephrotoxicity Molly Fisher, Victor J. Pai, Run Lu, Victor L. Schuster. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Cisplatin (CP) is used to treat a variety of malignancies but nephrotoxicity limits its use. CP nephrotoxicity is characterized by renal vasoconstriction and proximal tubular damage. Underlying molecular mechanisms include inflammation, reactive oxygen species, and apoptotic pathways. Prostaglandins have been shown to be cytoprotective in many tissues including the kidney. Prostaglandins are metabolized by the prostaglandin transporter, PGT. We have developed a PGT knockout mouse and a high-affinity PGT inhibitor, PV02076 ("PV"). Both have been shown to raise endogenous levels of PGE_2 and may be useful therapeutically. We hypothesized that genetic and pharmacologic blockade of PGT would prevent CP nephrotoxicity.

Methods: PGT wildtype and knockout mice were given a single dose of CP 20mg/kg intraperitoneally (IP). C57BL/6 wildtype mice were given vehicle or PV 20mg/kg IP 24 and 1 hour prior to, 24 and 48 hours after, one dose of CP 20mg/kg IP. All mice were sacrificed 72 hours after CP. Renal function was evaluated by serum creatinine, cystatin C, KIM-1 immunohistochemistry, and tissue histology by tubular injury score. Quantitative polymerase chain reaction (Q-PCR) and serum cytokine dot-blot assay were used to identify differences in the expression of inflammatory, oxidative stress, and apoptotic genes. TUNEL assay was performed to assess for cell apoptosis. Urine PGE_2 levels were measured by ELISA.

Results: Urine PGE_2 excretion was increased in KO and PV-treated mice, confirming blockade of PGE_2 metabolism. KO mice had reduced serum creatinine after CP. Pharmacologic blockade of PGT with PV significantly attenuated CP nephrotoxicity as assessed by serum biomarkers of renal injury (creatinine, cystatin C) and histologic measurements of tubular injury and cell apoptosis (KIM-1, tubular injury score, TUNEL assay). Serum biomarkers (TNF-alpha) and renal gene expression studies (IL-6, IL-1beta, bcl2, SOD-1, SOD-2) revealed decreased inflammation, apoptosis, and oxidative stress in CP mice given PV.

Conclusions: Genetic and pharmacologic blockade of PGT attenuates cisplatin nephrotoxicity. We hypothesize the mechanism involves PGE_2-mediated vasodilation and/or cytoprotection through reduction of inflammation, oxidative stress, and apoptosis. Pharmacologic blockade of PGT may be a novel renoprotective strategy for cisplatin nephrotoxicity.

A Distinct Kidney CD45intCD11bintF4/80+MHCII+Ly6C- Macrophage Population in Mice and Humans Sul A Lee, Sanjeev Noel, Mohanraj Sadasivam, Abdel Hamad, Hamid Rabb. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Kidney mononuclear phagocytic cells (MPCs) play important roles in the pathogenesis of acute kidney injury (AKI) and other inflammatory diseases. However, renal MPCs are incompletely understood. While focusing on murine kidney $TCR\alpha\beta^+CD4^-CD8^-$ [double negative (DN)] T cells, we identified a distinct kidney macrophage subset which differed from conventional renal macrophages in many key aspects.

Methods: MPCs were isolated from different lymphoid and non-lymphoid organs of C57BL6 male mice at baseline or following ischemic AKI and analyzed for the frequency and phenotypic markers. Macrophage ablation was performed by intraperitoneal injection of liposomal clodronate. MPCs in human kidney were analyzed in normal tissue from nephrectomies for renal cell carcinoma.

Results: While focusing on kidney DN T cells, we identified a cell population that binds only to TCRβ and CD8β antibodies but not to CD8α antibody. Further studies using Fc receptor blockers disclosed that this population was a renal macrophage subset which was different from conventional macrophages by its intermediate (int) expression

of CD45 and CD11b. These $CD45^{int}CD11b^{int}$ macrophages were further characterized as $F4/80^{+}MHCII^{+}Ly6C^{-}$ cells, comprising 16.8%±0.4% of total $CD45^{+}$ cells in normal kidney ($P = 0.002$), 4.5%±1.0% in heart but <1% of total $CD45^{+}$ cells in thymus, lymph node, spleen, lung, liver, lamina propria and intraepithelial layer. Systemic clodronate treatment had greater depletive effect on $CD45^{int}CD11b^{int}$ population than conventional $CD45^{high}CD11b^{+}$ population (77.1% vs. 19.3%) in mouse kidney, suggesting higher phagocytic function of $CD45^{int}CD11b^{int}$ population. $CD45^{int}CD11b^{int}$ cells increased rapidly after AKI and decreased after 48 hours compared to a persistent increase in $CD45^{high}CD11b^{+}$ population ($P < 0.05$). We also found $CD45^{int}CD11b^{int}$ macrophages (1.4% to 9.3%) in human kidney samples (n=3) compared to conventional $CD45^{high}CD11b^{+}$ population that comprised 12.5% to 42.4% of total $CD45^{+}$ cells.

Conclusions: Our data suggest that $CD45^{int}CD11b^{int}F4/80^{+}MHCII^{+}Ly6C^{-}$ macrophages are primarily found in kidney and have distinct pattern of phenotypic markers and response to ischemic AKI compared to traditional macrophages. We are currently studying functional characteristics of this population by analyzing their phagocytosis functions, cytokines, and role in kidney diseases.

Antisense Oligonucleotide Mediated Inhibition of NLRP3 Expression Attenuates Aristolochic Acid Induced AKI Aaron Donner,[2] Thomas Bell,[1] Mark Graham,[4] Rosanne M. Crooke.[3] *[1]Ionis Pharmaceuticals, Carlsbad, CA; [2]Antisense Drug Discovery, Ionis Pharmaceuticals, Carlsbad, CA; [3]Ionis Pharmaceuticals, Inc, Carlsbad, CA; [4]Isis Pharmaceuticals, Carlsbad, CA.*

Background: In addition to its role in innate immunity, there is increasing evidence that the inflammasome pathway is a crucial driver of pathology in immune, metabolic and renal diseases. Genetic and pharmacologic inhibition of components of the NLRP3-containing inflammasome (NLRP3, ASC and Caspase-1) or its downstream effectors (IL-1b, IL-18) has been shown to provide therapeutic benefit in animal models of disease. We have sought to target the upstream node, the inflammasome, using ASOs directed against NLRP3 in a mouse model of acute kidney disease. We demonstrated the ability to prevent aristolochic acid I induced acute kidney injury (AAI AKI) with prior administration of an ASO targeting NLRP3, a key component of the inflammasome. The NLRP3 ASO attenuated disease based on plasma and urinary biomarkers, renal expression of inflammatory and pro-fibrotic mRNA markers and histological changes. Disease-induced increases in plasma creatinine and BUN and urinary increases in protein:creatinine ratios were reduced by prior administration of NLRP3 ASO. AAI dependent induction of renal inflammatory (e.g. nlrp3, kim1, ngal) and pro-fibrotic (e.g. timp1, mmp2, col1a1) mRNAs was also reduced by the NLRP3 ASO. Histologically, the NLRP3 ASO protected from AAI induced morphological changes throughout the nephron. Based on our findings, ASO mediated inhibition of NLRP3 expression could provide therapeutic benefit for those suffering from kidney disease.

Microparticles in Oxidative Stress and Inflammatory Models of Kidney Injury Begoña Campos,[2] Brittany N. Gleich,[2] Keith L. Saum,[2] Karen M. Domenico,[1] Charuhas V. Thakar.[2,3] *[1]Shriners Hospitals for Children, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH; [3]Cincinnati VAMC, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is associated with significant morbidity, including remote organ dysfunction. In response to stress or injury cells release phenotypically and quantitatively distinct microparticles (MP's), representing both the cell type and metabolic stage (e.g. apoptosis, activation, proliferation). The *objective* of this study was to evaluate relelase of MP's from renal proximal tubular epithelial cells (RPTEC) in inflammatory and oxidative stress. We also examined MP's as putative biomarkers, and their role in remote organ cross-talk.

Methods: We used in vitro models of injury to human immortalized RPTEC line. Exposures of H_2O_2 (0.03 mM for 1 hour) and TNF-α (50 and 100 ng/ml for 72 hours were compared to controls (N = 3 sets). The presence of CD10, CD13 and CD146 proteins on the cells was evaluated by western blot and confocal microscopy. Flow cytometric analysis was used to detect the release of MP's containing CD10, CD13, and CD146. Analysis of MP's was performed using FlowJo software. MP levels were expressed as mean and standard deviations times 10^5 and compared by unpaired t-tests.

Results: Western blot and confocal microscopy, in controls and treated cells, confirmed the presence of CD10, CD13 and CD146 proteins on RPTEC. Under both oxidative stress (H_2O_2) and inflammatory stress (TNF-α) cells showed morphological changes associated with apoptosis. Compared to controls MP's were significantly increased in H_20_2 treated cells: CD10 (0.456 vs 9.842; p = 0.013), CD13 (3.190 vs 53.882; p = 0.0001) and CD146 (5.991 vs 142.474; p = 0.0018). TNF-α treated cells at both concentrations also released CD10, CD13 and CD146 MP's; however, only CD13 MP's were statistically higher than controls at 100 ng/ml of TNF-α (26.67 vs 56.911; p 0.02). CD146 MP's showed a trend at both concentrations of TNF-α.

Conclusions: This is the first report of detection of microparticles (CD10 and CD13) specific to and derived from human RPTEC. Furthermore, we demonstrate a significant increase in the level of MP's derived from renal cells that is specific to oxidative and inflammatory stress. Additionally, release of CD146 MP's by stressed RPTEC could serve as ligand for endothelial activation, suggesting renal origins of organ cross-talk. Thus, MP's expressed by RPTEC could serve as putative biomarkers for AKI, and once released, may mediate organ cross-talk.

Loss of Melanocortin 5 Receptor Exacerbates Endotoxic AKI via Impairing Regulatory T Cell Response Yahong Xu,[1,2] Rong Zhou,[1] Rujun Gong.[2] *[1]Yangpu Hospital, Tongji University, Shanghai, China; [2]Brown Medical School, Providence, RI.*

Background: Pituitary melanocortin neuropeptides, exemplified by α-melanocyte-stimulating hormone, have long been recognized to possess a remarkable renoprotective activity in diverse forms of acute kidney injury (AKI). However, the molecular mechanism responsible for this beneficial action has been illusive and exactly which type of melanocortin receptor conveys the renoprotective effect remains to be defined. Lately, there is growing evidence suggesting that melanocortin 5 receptor (MC5R) signaling confers a protective effect in multiple organ systems. The role of MC5R in kidney injury was examined in this study.

Methods: MC5R knockout mice (KO) and congenic wild-type (WT) littermates were injured with lipopolysaccharides (LPS) and AKI examined. Bone marrow derived cells were prepared from WT or KO mice and adoptively transferred to KO mice followed by LPS injury.

Results: Mice with global knockout of MC5R were phenotypically indistinguishable from their WT littermates, and exhibited normal development with undetectable difference in kidney physiology, function and histology. As compared with WT controls, KO mice developed much severer AKI upon LPS injury, as evidenced by higher serum creatinine levels, more urinary excretion and renal expression of lipocalin-2, exacerbated renal histologic damages and tubular cell death, and amplified renal inflammation. This worsened AKI in KO mice was unlikely attributable to a tubular cell-autonomous mechanism, because primary cultures of proximal tubular epithelial cells derived from KO and WT mice demonstrated similar cellular injury and death and comparable inflammatory response following LPS injury. Instead, the amount of CD4+Foxp3+ regulatory T cells in the injured kidney from KO mice was strikingly diminished, concommitant with a drastic amplification of renal inflammatory infiltrations, thus underscoring an impaired immune tolerance to LPS injury. Moreover, adoptive transfer of bone marrow derived cells derived from congenic WT littermates to KO mice substantially replenished CD4+Foxp3+ regulatory T cells in the kidney following LPS injury, resulting in a substantial improvement of the LPS-invoked AKI and renal inflammation.

Conclusions: Collectively, MC5R is likely essential for regulatory T cell response to LPS injury and thereby conveys a protective activity in endotoxic AKI.

The Yes Associated Protein (YAP) Facilitates Kidney Fibrosis in a Kidney Injury Molecule-1 (KIM-1) Dependent Manner Akinwande A. Akinfolarin, Venkata Sabbisetti, Amrendra K. Ajay, Emily Christie, Joseph V. Bonventre. *Brigham and Women's Hospital, Boston, MA.*

Background: The Salvador-Warts-Hippo (SWH) pathway controls organ size by modulating cell proliferation and apoptosis. The nuclear localization of the YAP drives cell proliferation through the transcriptional co-activation of the TEA domain family, a regulator of TGF-β signaling. Following cell confluence, the SWH pathway acts as a negative feedback system to cause nucleo-cytoplasmic shuttling, phosphorylation and inactivation of YAP. Chronic epithelial expression of the KIM-1 is associated with the development of murine kidney fibrosis. In this study we show that the presence of epithelial KIM-1 is associated with nuclear accumulation of YAP and development of kidney fibrosis in mice

Methods: C57B6 wild type (WT) mice or mice with a mutation of the mucin domain of KIM-1 ($KIM\text{-}1^{\Delta mucin}$) were examined either 14 days after 26 min of bilateral ischemia (I/R) or 10 days after unilateral ureteral obstruction (UUO). LLC-PK1 and HEK cells were transduced with human *KIM-1* full length cDNA (LLC-PK1-KIM1 and HEK-KIM1) or an empty pcDNA3 vector (PK1-pcDNA and HEK-pcDNA). Experiments with short hairpin RNA against *YAP* and inhibition of YAP signaling with a small molecule, verteporfin was also done in PK1 and HEK cells. These kidney cells were then examined for proliferation after TGF-β stimulation and Cisplatin treatment

Results: Proximal tubule (PT) expression of YAP was increased in WT mice that had more kidney fibrosis as compared to their $KIM\text{-}1^{\Delta mucin}$ littermates when examined by Masson's trichrome (MT) and Periodic Acid Schiff (PAS) staining after I/R and UUO. Western blot analysis of whole kidney cortex revealed greater levels of fibrogenic factors including CTGF, fibronectin and ACTA2 in the WT mice as compared with the $KIM\text{-}1^{\Delta mucin}$ mice. These animal data were supported by in vitro experiments which revealed less cell proliferation and production of pro fibrotic factors with either YAP knock down or inhibition when compared with WT, following TGF-β stimulation. KIM-1 expressing cells had increased nuclear YAP and CTGF levels as compared to cells expressing the control vector

Conclusions: YAP is up regulated in murine kidney fibrosis, more so in proximal tubule cells expressing KIM-1. Pharmacologic depletion of YAP or enhancement of SWH signaling may be of therapeutic importance in attenuating kidney fibrosis

Orai1 Mediated Ca+2 Signaling Influences IL-17 Expression in CD4+ T Cells Following I/R Purvi Mehrotra,[1] David P. Basile.[2] *[1]Indiana School of Medicine, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: T-helper 17 (Th17) cells have been implicated in the pathogenesis of acute kidney Injury (AKI). Renal Th17 cells transiently increase for up to 3-days post ischemia/reperfusion (I/R) and return to basal levels within a week. Exposure of post AKI rats to elevated dietary salt (4%) stimulates sustained induction of renal Th17 cells, which is associated with CKD progression. The store-operated calcium channel (SOCC), Orai-1 plays a role in models of inflammatory disease such as colitis or autoimmune encephalopathy, which may be influenced by dietary salt. We hypothesized that AKI primes CD4+ T cells to increase IL17 expression secondary to Orai1 dependent Ca^{2+} signaling.

Methods: FACs analysis demonstrated increased Orai1 protein in renal CD4+ T-cells 7 days following I/R (MFI:221644±3567) relative to sham operated controls (MFI:106924±467; p<0.05). To evaluate the role of Orai1 mediated Ca^{2+} influx in the progression of AKI, rats were subjected to bilateral I/R and the dependency of AKI primed T cells on Ca^{2+} entry was evaluated using an in vitro assay of renal CD4+ cells, which resulted in ~5 fold increase in IL17 expression in response to Ang II (10^{-7}M) and elevated extracellular Na^{+} (170 mM).

Results: The IL17 induction of AKI primed CD4+ cells in vitro was attenuated by > 95% (p<0.05) by 3 inhibitors that target Orai-1 (2-ABP (20mm), AnCoA4 (50mm) or YM58483 (120nm)). A significant percentage (40-50%) of AKI-primed CD4+ cells, but not sham-derived CD4 cells, manifested increased intracellular Ca^{2+} in response AngII+170 mM Na^{+}, a response that was completely abrogated by co-incubation with AnCoA4. Furthermore, treatment with YM58483 in vivo (1mg/Kg), reduced renal Th17 cells 2 days post I/R compared to vehicle treated rats (15,3076±1265 vs 7390±439 cells/gram of kidney; p<0.05). Interestingly, YM58483 had no effect on renal Th1 or Th2 cells. In addition, YM58483 significantly reduced the extent of renal injury by attenuating the increase in serum creatinine by ~66% (p<0.05) vs vehicle treated post AKI rats.

Conclusions: Taken together, these data suggest that I/R leads to increased Orai-1 mediated Ca^{2+} influx thereby enhancing IL-17 expression and may influence the severity of AKI.

TH-PO271

Mutation of the RORγC Gene in Rats Attenuates Th17 Cell Activity, Renal Injury, and Inflammation in Response to Ischemia Reperfusion Purvi Mehrotra,[1] Jason A. Collett,[2] David P. Basile.[2] *[1]Indiana School of Medicine, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: T cells have been implicated in initiation of renal damage following I/R injury, while recent studies have also suggested that a specific T helper subset, Th17 cells, is associated with both initiation of AKI and the AKI-to-CKD progression. To evaluate the direct role of Th17 cells in AKI, RoRgc (RAR orphan receptor gamma), a transcription factor considered the master regulator for Th17 cell differentiation and IL-17 gene expression was targeted for mutation in Lewis rats.

Methods: Using a CRISPR-CAS9 approach, an 8 bp deletion was introduced into the rat RoRgc gene. The verified sequence analysis predicted a mis-sense mutation at a.a.31 and premature truncation relative to the 508 a.a. protein in wild-type rats. Lewis$^{RORγT-/-}$ rats appear normal and healthy but show moderate growth retardation relative Lewis $^{RORγT+/+}$ control rats.

Results: Under basal conditions, reduced percentages of CD4+ (50±2.4 vs 24.45±1.7; p<0.05), B cells (21.4±7.2 vs 13.85±0.85; p<0.05) and Macrophages (13.07±3.5 vs 7.7±0.97; p<0.05) in the spleen of 6-8-week old Lewis$^{RORγT-/-}$ rats compared to wildtype controls. To evaluate the effect of RORgC mutation on the induction of Th17 cells during AKI, both mutant and wild type rats were subjected to bilateral renal I/R for 40 min. Renal Th17 cells were enhanced 2 days following I/R in wild type rats but were significantly reduced in Lewis$^{RORγT-/-}$ rats (63094±10498 vs 24434±4830; p<0.05) post I/R with no effect on Th1 and Th2 cells. In addition, Lewis$^{RORγT-/-}$ were resistant to AKI as measured by serum creatinine (4.5±0.4 vs 2.6±0.4; p<0.05) as well as reduced renal inflammation as indicated by total CD4+ (40%; p<0.05) and CD8+ (48%; p<0.05). After 7 days of recovery, AKI primed lymphocytes from wild type rats manifested an IL-17 mRNA induction in response to Ang II +170 mM Na+ in vitro, however AKI primed lymphocytes from Lewis$^{RORγT-/-}$ rats showed no increase in IL-17 mRNA expression.

Conclusions: Taken together these data that mutation of RORγC in rats impairs Th17 cell activity in response to renal I/R and modulates the sensitivity to the development of AKI.

CC-Chemokine Receptor 7 Deficient Mice Are Resistant to Renal Ischemia Reperfusion Injury Hiroshi Kojima,[1] Xuzhen Hu,[1] Erik H. Koritzinsky,[1] Myung-gyu Kim,[1] Jonathan Street,[1] Timothy J. Break,[2] Michail Lionakis,[2] Peter S. Yuen,[1] Robert A. Star.[1] *[1]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [2]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD.*

Background: One of the most prominent chemokine receptors in the adaptive immune system is CC-chemokine receptor 7 (CCR7), which has been established as an important component of lymphocyte-driven immune function. CCR7 promotes homing of T cells and Dendritic Cells (DCs) to T cells areas of lymphoid tissues where T cells priming occur. Apart from chemotaxis, CCR7 controls cytoarchitecture, rate of endocytosis, survival, migratory speed, and maturation of the DCs. Manipulation of CCR7 axis has either protective or deleterious role in mouse kidney injury models. We sought to clarify the role of CCR7 in the pathogenesis of renal injury after ischemia reperfusion injury (IRI).

Methods: CCR7 deficient mice (*CCR7*$^{-/-}$) or wild-type mice (*CCR7*$^{+/+}$) underwent IRI. Mice were euthanized at 1, 3 and 7 days after the surgery. Kidney & serum were collected for biochemical analysis & histological evaluation.

Results: Blood urea nitrogen, cystatin C, & creatinine levels in *CCR7*$^{-/-}$ were lower than *CCR7*$^{+/+}$ throughout experimental periods. Similarly, *CCR7*$^{-/-}$ developed milder tubulointerstitial injuries than *CCR7*$^{+/+}$. There was a significant correlation between serum markers & histology score.

Conclusions: *CCR7*$^{-/-}$ mice are resistant to IRI. We speculate that dendritic cells (DCs) are involved the reno-protective property in *CCR7*$^{-/-}$. In *CCR7*$^{+/+}$, IR induced danger signals induce normal maturation/activation of DCs, causing the development of effector T cell response. In *CCR7*$^{-/-}$, DC maturation is prevented; DCs would remain in the state of immune tolerance despite the presence of danger signals. **Implications:** Targeting DCs through CCR7 may have therapeutic potential for IRI.

TH-PO273

CD4 T Cells Activated by Ultrasound or Vagus Nerve Stimulation Protect Kidneys from Ischemia-Reperfusion Injury through β2 Adrenergic Receptor Tsuyoshi Inoue,[1] Chikara Abe,[2] Liping Huang,[1] Diane L. Rosin,[1] Patrice G. Guyenet,[1] Mark D. Okusa.[1] *[1]University of Virginia, Charlottesville, VA; [2]Gifu University, Gifu, Japan.*

Background: We recently showed that prior ultrasound (US) treatment and vagus nerve stimulation (VNS) protect kidneys from ischemia-reperfusion injury (IRI) through the cholinergic anti-inflammatory pathway (CAP). Although β2 adrenergic receptor-positive CD4+ T cells are thought to be components of the CAP, they have yet to be tested in mediating the protective effect of CAP activation following IRI.

Methods: Kidney IRI (bilateral, 26 mins) was used as an acute kidney injury (AKI) model and IRI was performed 24 hr after US (bilateral, 2 mins) or VNS (left side, 5 Hz, 50 μA for 10 min) treatment. Kidney injury was evaluated 24 hr later using plasma creatinine (PCr), kidney Kim-1 mRNA expression and histology (H&E). CD4+ splenocytes (MACS-enriched) were isolated from donor mice and transferred i.v. to recipient mice. Butoxamine was used as a β2 adrenergic receptor antagonist, and salbutamol was used as a β2 adrenergic receptor agonist.

Results: When butoxamine (15 mg/kg) was administered 30 mins prior to US and VNS, the renal protective effect of US and VNS was abolished (PCr: 0.20 and 1.76 mg/dl (P<0.001) for vehicle+US and butoxamine+US, respectively, n=7). Salbutamol (15 mg/kg) administration 24 hr prior to IRI protected the kidney. Adoptive transfer of CD4+

splenocytes (1x10^5 cells) from US-treated or VNS-treated mice to recipient mice subjected to IRI provided greater protection than CD4+ splenocytes from mice who received sham US or sham VNS (PCr: 0.44 and 1.31 mg/dl (P<0.001) for VNS- and sham VNS-treated CD4+ splenocytes from spleen, respectively, n=9). In addition, the kidney was protected when salbutamol-treated CD4+ splenocytes were transferred 24 hr prior to IRI.

Conclusions: These data demonstrate that activation of CD4+ splenocytes through β2 adrenergic receptors is important for the protective effect of US and VNS in AKI.

AKI Stimulates Inflammation Associated Lymphangiogenesis

Sarah A. Bowhay, Anupam Agarwal, Amie Traylor, Abolfazl Zarjou. *University of Alabama at Birmingham, Birmingham, AL.*

Background: The lymphatic system is crucial for maintaining fluid balance, transporting lipids, and aiding in immune function. The functions of the lymphatic system are further accentuated during pathological conditions such as inflammation, the latter a key component of acute kidney injury (AKI). Inflammation induces lymphangiogenesis through expression of vascular endothelial growth factors (VEGFs), particularly VEGF-C, VEGF-D, and their receptor VEGF-R3. While recent studies have shown lymphangiogenesis to be an active participant in a number of inflammatory diseases, very little is known about the role of the lymphatic system and more importantly, lymphangiogenesis, in the pathogenesis of AKI. Based on the prominent role of lymphangiogenesis in various inflammation induced disease models, this delicate and crucial pathway could serve as a novel target to be exploited for therapeutic interventions in AKI.

Methods: To study the role of lymphangiogenesis in the pathophysiology of AKI, we induced renal injury in mice via bilateral ischemia-reperfusion injury (I/R), a well characterized model of AKI and measured lymphatic vessel content as well as mRNA and protein levels of growth factors and inducers of lymphangiogenesis.

Results: We observed increased lymphatic vessel content in kidneys of mice that had undergone I/R compared to uninjured controls via LYVE1 (a cell surface receptor on lymphatic endothelial cells) immunohistochemistry. RT-PCR analysis revealed increased levels of lymphatic markers, LYVE1 and Podoplanin in kidneys 7 days after I/R. We also observed increased VEGF-R3 protein levels after injury peaking at day 3 post I/R in kidney lysates. ELISA analysis of VEGF-C levels showed a decrease in kidney VEGF-C with a simultaneous increase in serum levels of VEGF-C. VEGF-C protein was also detected in the urine at day 1 post I/R. VEGF-C immunofluorescence staining revealed expression in proximal tubule cells in uninjured kidneys. After I/R, VEGF-C is seen in the apical side of proximal tubule cells. This together suggests a mechanism in which VEGF-C is secreted from the tubules into the blood and urine following injury.

Conclusions: These results suggest that lymphangiogenesis is stimulated in kidneys after AKI and may represent a target for intervention in the pathogenesis of AKI.

TH-PO275

STAT5 Knockouts Are More Susceptible Than Wildtype Mice to Streptozotocin-Induced AKI

Karen T. Coschigano,[1] Avery M. Bogart,[2] Amber J. Mcdermott,[3] Jeffrey B. Hodgin,[4] Ramiro Malgor.[1] *[1]Interdisciplinary Program in Molecular and Cellular Biology, Diabetes Institute and Department of Biomedical Sciences, Heritage College of Osteopathic Medicine, Ohio University, Athens, OH; [2]The Diabetes Institute, Heritage College of Osteopathic Medicine and the Honors Tutorial College, Ohio University, Athens, OH; [3]Heritage College of Osteopathic Medicine, Ohio University, Athens, OH; [4]Department of Pathology, University of Michigan, Ann Arbor, MI.*

Background: We have previously shown that mice deleted for the first coding exon of the Signal Transducer and Activator of Transcription 5 genes (STAT5 A/B knockout or SKO) exhibit more kidney damage in comparison to wildtype (WT) littermates when examined 12 weeks after treatment with streptozotocin (STZ) to induce diabetes. However, it was not clear whether the kidney damage was a result of the STZ treatment or the resulting hyperglycemia. To try to address this question, this study sought to investigate the acute effects of STZ treatment on kidneys of SKO and WT mice.

Methods: SKO and WT mice received, on five consecutive days, an intraperitoneal injection of either vehicle (citrate buffer, V), STZ (50 mg/kg, M) or four daily injections of vehicle followed on the fifth day by a single dose of STZ (250 mg/kg, H). All mice (n=7/group) were euthanized three days after the last injection and serum and kidneys collected. A portion of each kidney was fixed in formalin and then embedded in paraffin for morphometric and *in situ* hybridization analyses. The remaining portions of kidneys were flash frozen in liquid nitrogen for gene expression analyses (real-time reverse transcription – polymerase chain reaction; RT-RT/PCR). Two-way (genotype vs. treatment) analysis of variance followed by Tukey post-hoc analysis was used to determine statistical significance at p<0.05.

Results: At the end of the study, blood glucose levels were significantly elevated in the four STZ treatment groups in comparison to the two vehicle groups (WT-V and SKO-V), with the high dose STZ SKO group (SKO-H) being significantly higher than the other three STZ treatment groups (WT-M, SKO-M, WT-H). Blood urea nitrogen and creatinine levels were significantly elevated in the SKO-H group in comparison to the other two SKO treatment groups and to the WT-H group. Histochemical analyses revealed the greatest degree of damage, mainly tubular necrosis with no glomerular damage, in the SKO-H group, with corresponding increased RNA expression of the genes for neutrophil gelatinase-associated lipocalin (NGAL) and cytokines interleukin-6 (IL6) and -1beta (IL1beta).

Conclusions: SKO mice are more susceptible than WT mice to the acute effects of STZ, especially when administered in a single high dose.

Transcriptional Response of the Intercalated Cells to UTI

Katherine Xu,[3] Tian Shen,[2] Jonathan M. Barasch.[1] *[1]Columbia Presbyterian, New York, NY; [2]Columbia University, New York, NY; [3]Medicine/Nephrology, Columbia University Medical Center, New York, NY.*

Background: Urinary tract infections (UTI) are among the most prevalent bacterial infections acquired in US hospitals, and complications can lead to urinary obstruction, bacteremia, urosepsis. We found that uropathogenic E. coli (UPEC) require iron for infection: loading with iron dextran resulted in significantly more urinary colony forming units (CFUs) than mice without prior iron loading; conversely iron-deficient mice (4 weeks of iron-deficient chow) demonstrated markedly reduced CFUs compared with iron-sufficient mice (regular chow). The form of iron was also important, heme iron was stoichometrically more powerful as a stimulant than ferric iron. These data raise the question as to how the nephron controls luminal and interstitial iron content and how bacteria disrupt these homeostatic mechanisms.

Methods: To study the process by which UPECs interact with the kidney to obtain iron, we generated a novel cell- and time-specific in-vivo RNA-labeling technique to purify specific RNA species from the intercalated cells (IC) in a UTI model.

Results: We analyzed newly synthesized RNA. RNA-sequencing demonstrated a robust transcriptional response of ICs 12 hours after UTI (95% of induced genes). Many of these upregulated genes were involved in iron and heme transport and storage, such as heme-responsive gene 1 (Hrg1), heme oxygenase (Ho1), and ferritin heavy chain (Fth1), suggesting that heme metabolism is a critical component of UTI and a mechanism of immune defense. After 24hrs these transcripts were no longer expressed.

Conclusions: A thorough investigation of iron transporters throughout the nephron revealed megalin in the proximal tubule, TfR1 in the thick limb of Henle, DMT1 in the distal convoluted tubule but remarkably none of these proteins were found in the collecting duct. In summary, we suggest that the nephron is able to recover iron using many different transport mechanisms, but the collecting duct is unique in its mechanisms of iron capture focused on heme transport. Consequently, the nutritional requirement of the collecting duct IC matches an essential component of innate defense, namely heme sequestration.

Myeloid Specific H-Ferritin Mediates Sepsis Induced Inflammation and Organ Injury

Abolfazl Zarjou,[3] Laurence M. Black,[2] Anupam Agarwal,[3] Subhashini Bolisetty.[1] *[1]UAB, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: Sepsis is a severe clinical syndrome that is characterized by profound and dysregulated inflammatory response to infection resulting in end-organ dysfunction distant from the primary site of infection. Despite fundamental findings that have expanded our understanding into the mechanisms that instigate and propagate sepsis and its deleterious effects on various organs including kidney, novel therapeutic agents and modalities have remained elusive. In fact, sepsis remains a leading cause of mortality and acute kidney injury in patients admitted to the intensive care unit. We previously demonstrated that macrophage polarization depends on expression of ferritin heavy chain (FtH) and such expression plays a key role to regulate the cross-talk between macrophages and renal epithelial cells during kidney injury and repair. This led to our hypothesis that macrophage specific FtH may be involved in development and consequences of sepsis.

Methods: Using transgenic mice with conditional deletion of FtH in myeloid cells (FtH LysM$^{-/-}$), we induced sepsis by a well characterized cecal ligation and puncture method.

Results: Our results demonstrate that myeloid FtH deficiency is associated with hyporesponsiveness to sepsis. We show that specific deletion of FtH in myeloid cells led to ~90% improved survival when compared to FtH LysM$^{+/+}$ littermates. Furthermore, renal function supported by serum creatinine was significantly more preserved in the FtH LysM$^{-/-}$ mice. In addition, we found decreased level of several pro-inflammatory cytokine expression in major organs, including the kidney. Our mechanistic studies show that myeloid FtH deletion causes derangements in pathways that are crucial in innate immunity and inflammation including NF-κβ, and hypoxia inducible factor.

Conclusions: Overall, our results for the first time signify the paramount importance of myeloid system iron metabolism in sepsis mediated organ injury and identify the central role of FtH in this context. As such, we propose a novel target to mitigate sepsis mediated inflammation and consequent organ injury that is urgently needed given the unacceptable rate of mortality and morbidity related to this devastating clinical condition.

Sensing of Bacterial Infection by Nerves and the Induction of Inter-Organ Communication during the First Hours of Pyelonephritis Svava E. Steiner,[1] Ferdinand X. Choong,[1] Anette Schulz,[1] Keira Melican,[1] Camilla Svensson,[2] Agneta Richter-Dahlfors.[1] *[1]Swedish Medical Nanoscience Center, Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden; [2]Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden.*

Background: Tissue microbiological studies have revealed that inter-organ communication occurs within the first hours of pyelonephritis. IFN-γ released from the spleen is known to modulate the host responses at the site of renal infection within 8 h. We hypothesize that this rapid inter-organ signaling is, at least in part, mediated by the nervous system. Here we investigate nervous sensing of the bacterial infection and implicate nervous signals as mediators of the inter-organ communication between infected kidney and the responding spleen.

Methods: GFP$^+$-expressing uropathogenic *Escherichia coli* (UPEC) were microinfused into single proximal tubules in exposed kidneys of anesthetized rats. After 4 h the infection site was examined by *ex vivo* immunofluorescence (IF) analysis. Nervous projections in the renal cortex were identified through IF analysis of fixed, uninfected rat renal tissue. Splenic *Ifng* mRNA expression was determined by qPCR on splenic tissue. Cytokine and ATP release of UPEC infected renal epithelial cells (A498) were investigated in cell culture *in vitro*. Primary sensory nerve cells from mice were used to determine immune and nervous responses to UPEC infection.

Results: Despite the very localized nature of the infection, splenic *Ifng* expression was found to be upregulated already within 4 h of kidney infection. We found that sensory nerves are present in the basement membrane of proximal tubules, where they can come into close contact with infection related products. *In vitro* we found that primary mouse sensory nerves can detect pathogen-associated molecular patterns and damage-associated molecular patterns during infection and have both immunological IL-6, and nervous CGRP, responses. In cell culture, nervous responses were found to only occur during infection with bacteria that produce the toxin α-haemolysin. Translating this finding *in vivo*, we found that inter-organ communication was abrogated in animals infected with a UPEC strain that does not produce α-haemolysin.

Conclusions: Our work shows the role of the sensory nervous system in sensing a local infection in the kidney and alerting distal organs to alter the systemic host response. Bacterial production of the α-haemolysin toxin plays an important role in initiating such an alerting signal.

C5aR1 Promotes the Pathogenesis of Acute Pyelonephritis Ke Li,[2] Steven H. Sacks,[1] Wuding Zhou.[1] *[1]King's College London, London, United Kingdom; [2]Xi'an Jiaotong University, Xi'an, China.*

Background: Our recent work in a murine mode of chronic pyelonephritis has shown that C5a/C5aR1 interaction play an important role in the pathogenesis of chronic renal inflammation and tubulointerstitial fibrosis. However, the role of C5aR1 in acute pyelonephritis is presently unknown.

Methods: To investigate this, we employed a murine mode of acute pyelonephritis, induced by human UPEC strain J96, in combination with either C5aR1 deficiency (*C5aR1*$^{-/-}$ mice), or chemical blockade of C5a/C5aR1 interactions, to determine the roles of C5aR1 in acute renal infection. In addition, we performed a serious of *ex vivo* (renal tissue) and *in vitro* (primary cultures of renal tubular epithelial cells [RTEC]) experiments to examine the relationship between C5a/C5aR1 and mannosyl residue expression and UPEC adhesion/colonisation in RTEC. We also explored the signal transduction mechanisms by which C5a regulates mannosyl residue expression in RTEC. Bone marrow chimera experiments were performed to specifically evaluate the relative contributions of C5aR1 expressed on renal and myeloid cells.

Results: *In vivo* analysis showed that C5aR1 deficient mice or C5aR1 antagonist treated mice displayed reduced bacterial load and tissue destruction in the kidney, which is associated with reduced expression of mannosyl residues (a ligand for type 1 fimbriae of E coli) at luminal surface of renal tubules and early bacterial colonization of the tubular epithelium. Chimera experiments suggest that C5aR1 on renal cells plays a more prominent role in this model. In vitro analysis of renal tubular epithelial cells showed that mannosyl-dependent adhesion and invasion were enhanced by C5a-mediated ERK1/2 and NF-kB phosphorylation and TNF-α production.

Conclusions: Our data demonstrate a pathogenic role for C5a/C5aR1 in acute pyelonephritis and define novel mechanism by which C5aR1 signalling enhances mannosyl residue-dependent colonisation of renal tubular epithelium that increases susceptibility to a common and harmful urinary pathogen, opening up a new avenue for therapeutic targeting.

TH-PO280

AKI Increases Gut Permeability and Provokes Dysregulation of Mucosal Immunity: Effect of Probiotics on AKI Severity Jihyun Yang,[1] Yoon kyung Choi,[1] Taeyeon Hwang,[1] Woori C. Cho,[3] Myung-gyu Kim,[2] Won-Yong Cho,[1] Sang-Kyung Jo.[1] *[1]Korea University Hospital, Seoul, Republic of Korea; [2]National Institutes of Health, North Bethesda, MD; [3]Korea University hospital, Seoul, Republic of Korea.*

Background: Emerging evidence indicate the presence of kidney-gut crosstalk in diverse pathological conditions. In normal condition, healthy microbiome help to maintain gut barrier and mucosal immune tolerance. In this study, we investigated kidney-gut crosstalk in AKI by assessing the effect of AKI on gut barrier integrity and mucosal immunity.

Methods: C57BL/6 mice underwent bilateral ischemia-reperfusion injury (IRI) or sham operation. In the probiotic treatment group, Bifidobacillus was administered via oral gavage once daily, started 3 weeks prior to the injury. The gut barrier integrity was assessed by measuring orally administered fluorescein isothiocyanate-dextran (FITC-dextran) activity in blood and western blot for various tight junction proteins was performed. Flow cytometric analysis of colonic macrophages as well as Foxp3 expression was performed.

Results: Following AKI, gut permeability increased significantly and it was accompanied by decreased claudin-1, occludin expression and increased number of apoptosis in colon. Ly6G$^+$ neutrophil infiltration and MPO activity increased after kidney IRI and the number of Ly6C^{high} CX3CR1.^{intermediate} macrophages also increased. Colonic Foxp3 mRNA expression showed a slight but statistically significant increase. Preconditioning with probiotics prior to IRI significantly attenuated functional, histological kidney injury and the renoprotective effect was accompanied by partial restoration of claudin-1, occludin expression and also by decreased number of colon epithelial cell apoptosis. Colon Foxp3 expression significantly increased in probiotic treated group

Conclusions: In conclusion, AKI induced gut barrier disruption and colonic inflammation might be one mechanism leading to systemic inflammation, kidney and other remote organ injury. Probiotic mediated renoprotective effect might be mediated by strengthening gut barrier and also mucosal immune tolerance mechanisms. Probiotics might be one promising strategy aiming for reducing AKI severity or remote organ injury.

TH-PO282

A Furosemide Excretion Stress Test (FEST) Predicts AKI Progression and Mortality after Sepsis Jonathan Street,[2] Tiffany R. Bellomo,[2] Erik H. Koritzinsky,[2] Hiroshi Kojima,[2] Lakhmir S. Chawla,[1] Peter S. Yuen,[2] Robert A. Star.[2] *[1]George Washington University, San Diego, CA; [2]NIDDK, Bethesda, MD.*

Background: The furosemide stress test (FST) measures urine production (diuresis) after a furosemide bolus. FST is a sensitive and specific predictor of a need for renal replacement therapy and mortality in the ICU. Furosemide causes a diuresis via 2 steps: 1) active secretion into the proximal tubule lumen, then 2) inhibition of thick ascending limb NKCC2. We hypothesize that tubule damage should reduce furosemide excretion (FEST) and prevent a subsequent increase in urine volume (FST). We developed FST and FEST protocols for a septic mouse model in which mortality is poorly predicted by filtration markers, and also tested the predictive performance of FEST in a human cohort.

Methods: We developed a sensitive reverse phase HPLC assay for urine furosemide. Male CD-1 mice underwent cecal ligation and puncture (CLP) to induce sepsis. 42 hrs post-CLP 1 mg/kg furosemide was given s.c. and urine was collected for the next 12 hrs to allow for intermittent urination. The mice were monitored every 8 hrs and euthanized if their clinical score exceeded the protocol threshold. Furosemide concentration was also measured in the post-furosemide challenge samples of 49 patients from the PASSKI cohort.

Results: A moderate severity of CLP injury was used; 32 mice survived to 42 hr and underwent FST/FEST, 19 mice survived 7 d. Urine production during 12 hr varied from 0.08 to 2.62 ml. Both urine production and the fraction of furosemide recovered in the urine predicted mortality [AUC ROC values of 0.92 ($p<0.0001$) for FST and 0.87 ($p<0.001$) for FEST]. In the human cohort, the fraction of furosemide recovered predicted progression to AKIN stage III and was comparable to FST [AUC ROC values of 0.864 for FST and 0.848 for FEST].

Conclusions: The furosemide excretion stress test and furosemide stress test strongly predict post-sepsis mortality in mice, allowing for early stratification by severity in future drug studies of late treatment or enhancing recovery. FEST performs comparably to FST in the human PASSKI cohort.

TH-PO283

LPS-Binding Protein (LBP)/TLR4 Signaling Mediates Pericyte (PC) to Myofibroblasts Trans-Differentiation (PMT) in Endotoxemic AKI Giuseppe Castellano,[1] Alessandra Stasi,[1] Rossana Franzin,[1] Fabio Sallustio,[1] Chiara Divella,[1] Alessandra Spinelli,[1] Giuseppe Grandaliano,[2] Giovanni B. Pertosa,[1] Loreto Gesualdo.[1] *[1]University of Bari, Bari, Italy; [2]University of Foggia, FOGGIA, Italy.*

Background: During sepsis, LBP/TLR4 signaling is central in the inflammatory cascade and its activation impairs renal function, leading to AKI. Renal fibrosis induced by PMT is a common pathological feature of chronic kidney disease but little is known in AKI.

Methods: AKI was induced by i.v. LPS infusion in 8 pigs (LPS). After 3h from LPS infusion, 8 pigs were treated with coupled plasma filtration adsorption (CPFA). Renal biopsies, performed at 9h from LPS infusion (T9), were analyzed by IHC and IF. Serum LBP and TGFβ were quantified by ELISA. In vitro, PC (PDGFRβ+) were analyzed by FACS, IF and WB. TGFβ-Receptor(R) neutralizing antibody was added to the cultures 30' before LPS or TGFβ stimulation.

Results: We found the occurrence of acute PMT in endotoxemic AKI by the reduction of PDGFRβ expression and αSMA increase in peritubular PC. CPFA treatment restored PDGFRβ expression ($p=0.03$) and significantly decreased $\alpha SMA^{+}PC$ ($p=0.001$), in accordance with reduced serum levels of LBP ($p<0.05$). In vitro, activation of PC with LPS or endotoxemic sera led to PMT with CollagenI synthesis and αSMA reorganization in contractile fibers ($p<0.05$). The removal of LBP from septic plasma maintained CollagenI and αSMA expression at basal level ($p<0.05$). On the contrary, exogenous LBP supplementation reversed CPFA effects. LPS increased phosphorylation of Smad2/3 and ERK1, respectively ($p<0.05$) suggesting that PMT was induced by both canonical TGFβ-Smad2/3 dependent and non-canonical TGFβ-Smad independent signaling (MAPK). Moreover, the serum levels of TGFβ increased in endotoxemic pigs and were reduced after CPFA treatment ($p<0.05$). It is well known that TGFβ induces PMT contributing to renal fibrosis. Interestingly, in vitro TGFβR-signaling blockade, did not affect LPS-induced PMT and phosphorylation of SMAD2/3 and ERK1, underlying a fibrotic role of LPS independently of TGFβ synthesis and release.

Conclusions: PC might be pivotal in the generation of myofibroblasts by PMT during AKI upon the activation of LBP/TLR4 signaling. Disrupting the persistent TLR4 signaling activation by the removal of LBP may represent a therapeutic option to prevent PC dysfunction and acute renal fibrosis.

TH-PO284

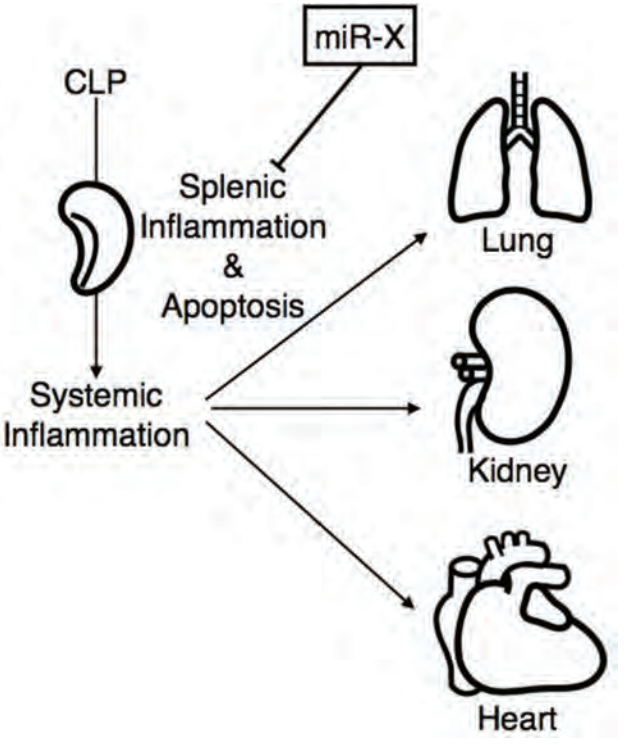
Indirect Therapeutic Role of Immunosuppressive Micro-RNA for Sepsis Induced AKI via Spleen Yoshio Funahashi. *Nagoya University, Nagoya,AICHI, Japan.*

Background: Sepsis is life-threatening organ dysfunction caused by dysregulated immune response to infection. It is known that sepsis with acute kidney injury (AKI) shows high mortality rate. However, therapies to treat sepsis and AKI are largely ineffective because of its pathophysiological complexity. Several studies have reported that some micro-RNAs (miRNAs) acted as a regulator of systemic inflammation. Here, we revealed the significance of spleen to regulate septic state by induction of immunosuppressive miRNA.

Methods: In vitro study, miR-X, which targeting toll like receptor/NF-kB pathway, was transfected into RAW264.7 cells. After transfection, cells were treated with lipopolysaccharide (LPS) for 6h, then RNA, protein, and supernatant were purified. In vivo study, 8-12 week-old C57BL/6 male mice, with or without splenectomy, were treated with miR-X expression plasmid combined with polyethyleneimine (PEI), 7 days before sepsis. Sepsis was induced by cecal ligation and puncture (CLP). Organs were harvested at 24h after CLP.

Results: In vitro study, miR-X transfected cells were tolerant toward LPS stimulation, and showed low NF-kB activity. In vivo study, miR-X expression plasmid/PEI complex was mainly detected in splenic macrophages. miR-X plasmid group showed the improvement of survival rate, inflammatory cytokine production, renal dysfunction, and renal tubular damage. In addition, less apoptotic cells were observed in spleen of miR-X expression plasmid group, than that of empty plasmid group. Interestingly, anti-inflammatory effect of miR-X was rarely observed in splenectomized mice.

Conclusions: Splenic induction of miR-X prevented dysregulated systemic inflammation in sepsis and attenuated AKI. In addition, we provided the new treatment strategy for sepsis induced AKI by targeting spleen with specific miRNA.



TH-PO285

Interleukin-10 Alleviates Ureteral Obstruction-Induced Renal Fibrosis by Reduction of Inflammation, Oxidative Stress, and Endoplasmic Reticulum Stress Kyong-Jin Jung. *Yeungnam University College of Medicine, Nam-gu, Daejeon, Republic of Korea.*

Background: Imbalance of oxidative stress, endoplasmic reticulum (ER) stressand accumulation of extracellular matrix results in renal fibrosis contributes to progressive renal failure. Recent studies suggested that interleukin (IL)-10 plays potent impacts on the fibrosis-related immunomodulation. However, the role of IL-10 against unilateral ureteral obstruction (UUO)-induced ER stress remains poorly understood.

Methods: Here, we investigated the mechanisms of IL-10 on ER stress-induced renal fibrosis by UUO model in IL-10 knockout (KO) mice and a normal kidney cell line (TMCK-1). Age-matched 10 weeks old male IL-10 KO mice and wild-type (WT) mice were divided into control (CON) and UUO groups. The mice were sacrificed at 3 days or 7 days after UUO. ER stress and profibrotic protein levels were evaluated by, western blotting. Periodic acid Schiff and Masson's trichrome stain were used for analyzed histologic changes and collagen deposition. To evaluate oxidative stress levels checked production of O_2^-, H_2O_2, malondihydrogenase and expression of 4-HNE. To investigate correlation among the IL-10, CHOP and α-SMA expression, immunofluorescence staining was used.*In vitro,* treatment of ER stress inducer (tunicamycin, thapsigargin and brefeldin A)with or without transfected siRNA (IL-10and CHOP) or CHOP overexpression in TMCK-1 cells.

Results: In this study, we found IL-10 KO UUO mice promoted renal fibrosis by more excessive tubular damage (tubular dilatation, cast formation andtubular cells infiltration), collagen deposition and oxidative stress production. We also confirmed IL-10 KO mice express higher level of profibrotic genes (α-SMA, COL1 and FN) and ER stress genes (GRP78/Bip and CHOP) after UUO. We observed IL-10, CHOP and α-SMA were highly expressed in tubulointerstitial lesion of UUO mice than CON mice. *In vitro,* transient depletion of CHOP attenuated expression of profibrotic genes.

Conclusions: Present study shows that IL-10 protecting was opposed to ER stress mediated-renal fibrosis. Combination of IL-10 and ER stress therapy could be a strong protective effect for patients with chronic kidney diseases.

TH-PO286

Keap1 Specific CRISPR/Cas9 Gene Editing in Primary Human T Cells Increases Nrf2 Activity and Anti-Inflammatory Phenotype Sanjeev Noel,[1] Sul A Lee,[1] Mohanraj Sadasivam,[2] Abdel Hamad,[2] Hamid Rabb.[1] *[1]Department of Medicine, Johns Hopkins University, Baltimore, MD; [2]Department of Pathology, Johns Hopkins University, Baltimore, MD.*

Background: T lymphocytes are established mediators of acute kidney injury (AKI) and other immune mediated kidney diseases. Previous work demonstrated significant protection from AKI in mice with enhanced T lymphocyte specific nuclear factor erythroid-derived 2-like 2 (Nrf2) activity, via deletion of kelch like-ECH-associated protein 1 (Keap1). In this study we applied CRISPR technology to edit *Keap1*, and

enhance Nrf2 activity, in human Jurkat and primary T cells to develop immune cell based therapy for humans.

Methods: We targeted *Keap1* exon 2 using site specific guide RNA. Briefly, $5X10^5$ cells were electroporated with cas9:guide RNA complex. Control cells were electroporated without cas9:guide RNA complex. Cells were harvested 72h after electroporation and assessed for *Keap1* editing and qPCR based analysis of Nrf2 target genes. Edited cells were further enriched using ATTO 550 positive sorting and analyzed for *Keap1* editing and immunological changes.

Results: Genomic cleavage analysis showed *Keap1* editing in up to 70% Jurkat cells and 40% primary T cells. qPCR analysis in Jurkat cells showed significant ($p \leq 0.05$) increase in Nrf2 regulated antioxidant genes, *Nqo1* (~11 fold), *Ho-1* (~11 fold) and *Gclm (*~2 fold) mRNA in *Keap1* edited cells compared to control cells. In primary T cells, CRISPR mediated *Keap1* editing resulted in significant ($p \leq 0.04$) increase in *Nqo1* (~16 fold), *Ho-1* (~9 fold) and *Gclm* (~2 fold) compared to control cells. Enrichment of ATTO 550 positive cells improved *Keap1* editing from 40% to 55% cells. qPCR analysis found significantly ($p \leq 0.01$) higher expression of *Nqo1* (~7 fold) in ATTO 550 positive cells compared to control cells. *Keap1* edited cells had increased ($p \leq 0.01$) frequency of CD4, CD25 and CD69 and reduced frequency of CD8 ($p \leq 0.01$) and IL-17 ($p \leq 0.05$) compared to control cells.

Conclusions: Gene editing using CRISPR/Cas9 successfully augments Nrf2 activity in primary human T lymphocytes resulting in increased expression of antioxidant genes and reduction in IL-17 expression. This sets the stage for immune cell therapy for AKI and other inflammation mediated diseases.

Antioxidant Regulation of Alarmin Redox and Function during Sepsis Wasan Abdulmahdi,[3] Devika Patel,[3] May M. Rabadi,[1] Tala F. Azar,[3] Edson Jules,[3] Anastasios Papanagnou,[2] Brian B. Ratliff.[3] *[1]Columbia University Medical Center, New York, NY; [2]Westchester Medical Center, Bayside, NY; [3]New York Medical College, Valhalla, NY.*

Background: During sepsis, oxidative stress is enhanced and the alarmin High Mobility Group Box 1 protein (HMGB1) is released into the circulation from immune, endothelial and kidney epithelial cells. Once in the circulation, HMGB1 can promote systemic inflammation, with the kidney particularly susceptible to damage. However, the severity of the pro-damage signal mediated by HMGB1 is dependent on the alarmin's redox state. Thus, we examined HMGB1 redox in kidney cells during sepsis and the ability of endogenous antioxidants to regulate HMGB1 oxidation.

Methods: Lipopolysaccharide (LPS) was administered at different doses to cells and animals to mimic different severities of sepsis. During LPS treatment, reactive oxygen species (ROS) generation was examined in cell cultures and in animals. After 24 hours of LPS treatment, HMGB1 redox state was examined in the nuclear and cytoplasmic compartments of kidney cells and in the plasma using a HMGB1 redox detection assay and also by mass spectrometry (LC-MS/MS) analysis. Glutathione and thioredoxin inhibitors were administered to endothelial and proximal tubule cell cultures to determine their impact on HMGB1 redox during LPS treatment. In addition, HMGB1 (of varying redox state) was isolated from mice that had received high or low LPS dose and was re-introduced to healthy mice for analysis of the alarmin's pro-inflammatory effects.

Results: CellROX and MitoSOX labeling of LPS-stressed endothelial and proximal tubule cells demonstrated increased ROS generation in cells as sepsis severity increased. Consequently, HMGB1 oxidation increased in the cytoplasm of kidney cells and was maintained after its release into the circulation, with the degree of oxidation dependent on the severity of sepsis. The greater the oxidation of HMGB1, the greater the ability of the alarmin to stimulate pro-inflammatory cyto-/chemokine release. Highly oxidized HMGB1 also increased mitochondrial ATP production. Administration of glutathione and thioredoxin inhibitors to cell cultures enhanced HMGB1 oxidation during sepsis in endothelial and proximal tubule cells.

Conclusions: In conclusion, as sepsis severity increases, ROS generation and HMGB1 oxidation increases in kidney cells, which enhances HMGB1's pro-inflammatory signaling. Conversely, the glutathione and thioredoxin systems work to maintain the protein in its reduced state

TH-PO288

Protective Effects of Brazilian Green Propolis in Sepsis-Induced AKI Marcelo D. Silveira,[1] Jose Manuel Condor Capcha,[1] Talita R. Sanches,[1] Roberto D. Moreira,[1,2] Margoth R. Garnica,[1] Maria H. Shimizu,[1] Flavio Teles de Farias Filho,[3] Lucia Andrade.[1] *[1]Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Federal University of Goias, Catalão, Brazil; [3]UNCISAL, Maceio, Brazil.*

Background: The pathophysiology of sepsis involves oxidative stress, as well as inflammatory mediator networks, to which NF-κB and TLR4 activation is central. The pharmacological benefits of propolis have been extensively explored, because it might be an important resource for the prevention and treatment of systemic diseases. Brazilian green propolis (BGP) has garnered attention for its promising anti-inflammatory, antioxidant and immunomodulatory properties. We used a cecal ligation and puncture (CLP) model to analyze the role of BGP in sepsis-related organ dysfunction.

Methods: We divided Wistar rats into groups: sham-operated; CLP; and CLP+BGP (500 mg/kg BW ip, 6 h after CLP). Studies were performed at 24 h post-CLP. Data are mean±SD.

Results: Blood GSH was higher in CLP+BGP rats than in CLP rats (0.87±0.4 vs. 0.33±0.1 mg/ml; $p<0.001$) as was protein expression of MnSOD and eNOS in kidney tissue (138.1±27.4 vs. 100.5±19.7%; $p<0.01$ and 109.3±14.1 vs. 81.2±26.4%; $p<0.05$, respectively). In kidney tissue, protein expression of TLR4 and NF-κB was lower in CLP+BGP rats than in CLP rats (111.9±11.9 vs. 164±26.6; $p<0.001$ and 93.50±7.1 vs. 132±11.3; $p<0.001$, respectively). Renal expression of CD68 (positive cells/mm^2) was lower in CLP+BGP rats than in CLP rats (5.1±1.0 vs. 7.1±2.0; $p<0.05$). Apoptosis (TUNEL) in kidneys and lungs was lower in CLP+BGP rats than in CLP rats (2.9±2.2 vs. 7.6±3.46 positive cells/0.087 mm^2; $p<0.05$ and 0.04±0.03 vs. 0.08±0.06 positive cells/Total Cells; $p<0.001$, respectively). BAX protein expression in kidney was lower in CLP+BGP rats than in CLP rats (97±10.9 vs. 135±24.7; $p<0.01$). BGP also improved kidney mitochondrial morphology (electron microscopy). Myeloperoxidase activity (AU/g) was lower in CLP+BGP rat lungs than in CLP rat lungs (2.32±3.4 vs. 3.62±4.7; $p<0.05$), as was the number of TLR4-positive cells (0.20±0.07 vs. 0.27±0.10; $p<0.001$).

Conclusions: In sepsis, BGP protects kidneys and lungs by attenuating oxidative stress and decreasing expression of NF-κB and TLR4. (FAPESP)

Antioxidant-Mediated Improvement of Kidney Function in the Adult LBW Neonate Wasan Abdulmahdi,[3] Edson Jules,[3] Noor Marji,[3] Lauren M. Nesi,[2] May M. Rabadi,[1] Magdi Abdelrahman,[3] Brian B. Ratliff.[3] *[1]Columbia University Medical Center, New York, NY; [2]NYMC, Scarsdale, NY; [3]New York Medical College, Valhalla, NY.*

Background: Low birth weight (LBW), as defined by the World Health Organization, is a birth weight of less than 5.5 pounds. Maternal malnourishment during pregnancy impairs nephrogenesis in the developing embryo and is a major cause of LBW. As a result, the LBW neonate has a decreased nephron compliment and is susceptible to kidney disease and hypertension. However, investigation is still required to fully understand disease progression in LBW neonates and the underlying causes. Hence, we established a pregnant mouse malnourishment model to further investigate the causes that promote kidney disease in LBW neonates and to examine potential therapeutic treatments.

Methods: Pregnant CD-1 mice were started on a food restricted diet on day 9 of gestation and were maintained on the diet throughout the rest of gestation. The malnourished diet consisted of a 50% daily caloric reduction combined with administration of a low protein chow (6%, vs control chow composed of 26% protein). We measured body weight, blood pressure, renal blood perfusion, glomerular filtration rate (GFR) and blood glucose levels in LBW mice 1, 3 and 6 months postpartum. We also included a direct analysis of gender differences in the aforementioned parameters. Since preliminary experiments indicated a dramatic increase of reactive oxygen specious (ROS) in the circulation of adult LBW neonates, we examined the therapeutic efficacy of tempol, a ROS quencher, which was administrated (via drinking water) to these animals.

Results: Our results showed that female and male LBW mice at 1, 3 and 6 months have higher blood pressure and blood glucose levels, while body weight, GFR and renal blood perfusion are reduced, as compared to controls. Conversely, tempol treatment improved GFR and renal blood flow, while it decreased blood glucose levels and blood pressure. Body weight was unaffected by tempol treatment. We did not observe any gender based differences in LBW mice.

Conclusions: In conclusion, our results confirmed the validity of our mouse model and indicated our model develops pathologies within 6 months postpartum that closely resemble pathologies observed in human LBW neonates. The potential efficacy of antioxidant based therapies was also highlighted when tempol treated mice showed improved kidney function, decreased blood pressure and blood glucose levels.

TH-PO290

Identification of the Oliguric Patient Using a Novel Electronic Device for Measuring Urine Output Mor Grinstein,[2] Aliza D. Goldman,[2] Hagar Azran,[2] Tal Stern,[2] Dafna Willner.[1] *[1]Hadassah-Hebrew University Hospital, Efrat, Israel; [2]RENALSENSE LTD, Brookline, MA.*

Background: The AKIN and KDIGO criteria for acute kidney injury (AKI) define oliguria as urine output (UO) over 6 hours of less than 0.5ml/kg/hr. While UO is an available biomarker of kidney function, only a small percentage of AKI studies incorporate UO criteria. In these retrospective studies, hourly UO is often inaccessible, and corresponds to the nursing shift. We developed a prospective observational study using real-time electronic monitoring of UO, and applied the AKIN criteria of UO to identify the oliguric patient in the intensive care unit (ICU).

Methods: 57 General ICU patients in Hadassah Hospital, Israel were electronically monitored for hourly UO using The RenalSense® *Clarity RMS™ sterile sensor kit.* The drainage bag was connected to the Foley catheter and placed on a scientific scale for measurement validation. Patient data was analyzed as follows: AKI defined by the AKIN criteria for oliguria only: NON-AKI UO (n=26), AKI UO Stage 1(n=10), AKI UO Stage 2 (n=21). AKI defined by AKIN criteria for SCr only (where available): NON-AKI SCr (n=44) and all stages AKI SCr (n=12). Additional analysis using both SCr and UO criteria was performed on all patients.

Results: 54% of patients had AKI according to UO criteria only. Patients with AKI UO Stage 2 received more fluid boluses than NON-AKI UO and AKI UO Stage 1 in the first two 12 hour periods of UO monitoring (p=0.0051 and 0.0091, respectively). 9 out of 21(43%) patients with AKI UO Stage 2 also had increased SCr. NON-AKI UO had an average ICU stay of 5.7 days, and AKI UO Stage 1 and 2 had 8.6 and 9.9 days respectively (p= 0.1048). Using only SCr criteria, NON-AKI SCr averaged 7.1 days in the ICU vs. all stages of AKI SCr of 10.8 days. When both UO and SCr were applied, 40% of patients were NON-AKI and averaged 5.9 days in the ICU. 15% of patients had AKI by both criteria and averaged 13.3 days (p=0.1002).

Conclusions: Studies have shown worse outcomes in patients that fulfill AKIN criteria for both SCr and UO versus SCr alone. Increased SCr alone may be an insufficient indicator of AKI, as ICU patients tend to be fluid overloaded. Our data shows a trend of increased ICU stay when AKI is analyzed according to UO. This unique study presents a tool for future research using reliable real time UO monitoring, where early intervention and appropriate treatment of oliguria may improve outcomes.

Dose Finding Safety Study for Bardoxolone Methyl and 6-Gingerol as Nephroprotectants against Cisplatin Induced Kidney Injury Stacey Tuey, Carolyn N. Brown, Charles L. Edelstein, Melanie S. Joy. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Nephrotoxicity is a major adverse effect that limits cisplatin (CIS) clinical use. CIS induced kidney injury is in part due to reactive oxygen species. Bardoxolone methyl (BARD) and 6-gingerol (6GNG), have shown nephroprotective potential through antioxidant properties. The purpose of this study was to conduct a dose finding safety study for use of BARD and 6-GNG as nephroprotectants against CIS induced kidney in a mouse model of cancer and cisplatin nephrotoxicity.

Methods: Study mice were injected with CMT167 lung cancer cells. In the first study, BARD (5, 10, or 20 mg/kg) or BARD vehicle (VEH) was given daily for 6 days and one dose of CIS (25mg/kg) was given on day 3 of BARD treatment. In the second study, mice were dosed with 6GNG (25, 50, or 100 mg/kg) or 6GNG VEH 3x weekly and CIS (12.5 mg/kg) or CIS VEH was given 1x weekly for 2 weeks. Treatments were compared to VEH using one-way analysis of variance with Dunnett's post-hoc test.

Results: See Table 1

Conclusions: The 10 mg/kg BARD and 50 mg/kg 6GNG demonstrated the best performance in terms of no potential adverse effects on ALT, BUN, and hematocrit and no discernable increases in tumor size. Additionally, these doses appear promising for protection of kidney function and cisplatin-induced anemia as demonstrated by the reduction in BUN and increase in hematocrit, respectively. Future studies will be conducted to confirm safety and efficacy in this mouse model relevant to human CIS induced nephrotoxicity.

Prothymosin Alpha-Derived Peptide Prevents Cisplatin-Induced AKI Kenta Torigoe,[1] Yoko Obata,[1] Miki Torigoe,[1] Takehiko Koji,[2] Hiroshi Ueda,[3] Tomoya Nishino.[1] *[1]Department of Nephrology, Nagasaki University Hospital, Nagasaki, Japan; [2]Department of Histology and Cell Biology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; [3]Department of Pharmacology and Therapeutic Innovation, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.*

Background: Cisplatin is one of the most used drugs for cancer treatment. However, cisplatin induces nephrotoxicity via apoptosis, necrosis or vasoconstriction, and this side effect limits clinical application of cisplatin. Prothymosin alpha (ProTα) is reported to exert protective effects against ischemia-induced necrosis and apoptosis in the brain and retina. Recently, the 6-amino acid peptide/P_6Q (NEVDQE), modified active core 6-amino acid peptide (a.a.51-56) in ProTa, also showed protective effect against retinal ischemia. Therefore, in this study, we investigated the renoprotective effect of P_6Q against cisplatin-induced acute kidney injury (AKI).

Methods: *In vitro* study, HK-2 cells were treated with cisplatin (12.5μM) for 24hrs to evaluate the cell viability by MTT assay. ProTα protein (0-40nM) or P_6Q (0-100μM) was added 30 minutes before cisplatin treatment. *In vivo* study, 8 week old male Wistar rats were divided into 3 groups: vehicle-treated group, cisplatin (8mg/kg)-treated group, cisplatin-treated group with P_6Q (30mg/kg) injection. P_6Q was injected 30 minutes before cisplatin treatment. Renal function was assessed by measuring serum creatinine. Renal histological change was assessed by PAS staining, and apoptosis of renal tubular cell was assessed by active caspase 3 and TUNEL staining. Renal hypoxia was assessed by HIF1α staining.

Results: Cisplatin treatment reduced the viability of HK-2 cells *in vitro*. Administration of ProTα improved cell viability dose-dependently. Furthermore, P_6Q administration was more effective to suppress the cytotoxicity by cisplatin compared with ProTa. Thus, we focused to investigate the protective effect of P_6Q against cisplatin-induced AKI *in vivo*. Serum creatinine level peaked at 5 days after cisplatin treatment. Histologic examination revealed extensive tubular damage in cisplatin-treated rats. Cisplatin treatment also increased the active caspase 3 positive area, number of TUNEL-positive apoptotic cells and HIF1α positive area at day 5. P_6Q injection significantly suppressed cisplatin-induced AKI and apoptosis of tubular cells, but not HIF1α expression.

Conclusions: We showed the renoprotective effect of ProTα-derived peptide against cisplatin-induced AKI via suppression of apoptosis. Our results suggest that ProTa-derived peptide may become a preventive drug for cisplatin-induced AKI.

Ischaemic Preconditioning of the Kidney: Total RNA Sequencing and Ingenuity Pathway Analysis David A. Foxwell,[1] Usman Khalid,[2] Robert Andrews,[1] Gilda Pino-Chavez,[1] Rafael E. Chavez,[2] Timothy Bowen,[1] Donald Fraser.[1] *[1]Cardiff University, Cardiff, United Kingdom; [2]University Hospital of Wales, Cardiff, United Kingdom.*

Background: Ischemia-Reperfusion Injury (IRI) is a common cause of Acute Kidney Injury (AKI). Clinical trials and animal models shows that Ischemic Preconditioning (IPC), delivered directly (to the tissue) or indirectly (to other tissues), may confer protection. However, reported efficacy is variable, and development of IPC as a therapy is hampered by the current lack of detailed mechanistic understanding. The purpose of the current study was to establish the main IPC response pathways in the protected kidney, and the extent of similarity between direct and indirect IPC.

Methods: Stepwise variation in warm ischemic time was used to develop moderate AKI in the rat (defined as Creatinine ≥1.5 x sham baseline creatinine; negative control) and pulsatile, continuous, direct and indirect IPC approaches were systematically compared.

Results: Optimum benefit was observed with direct pulsatile IPC and indirect aortic IPC. Subsequently, an unbiased transcriptomic profiling of whole kidney was performed using RNA-Sequencing in animals treated with these optimum direct and indirect approaches. Six animals were compared per experimental group (n=24), at a mean paired end sequencing depth of 23.2 million reads, mapping to 16.780 unique genes. Robust differences between groups were observed (IRI vs Sham; 2,193 genes differentially regulated to a Log2FC ≥1 or ≦-1 and a corrected p ≤1.0 E-04). Ingenuity Pathway Analysis revealed upregulation of pathways linked to inflammatory response, oxidative stress and cell cycle regulation in response to IRI, and reduction in oxidative stress, inflammation and cell cycle checkpoint regulation with IPC.

Conclusions: Together, the results displayed a molecular signature of IRI consistent with previous studies and, for the first time, uncovered a detailed signature of IPC protection that was shared between direct and indirect approaches. Our data provide novel insights into the pathogenicity of IRI injury and IPC signal, highlighting possible therapeutic targets for future investigation.

Elucidation of Mechanism for Indoxyl Sulfate (IS)-Promoted Renal Fibrotic Response in HK-2 Cells under Hypoxic Condition and Mice with Ischemia-Reperfusion (IR)-Induced AKI Mami Yamashita,[1] Moe Eto,[1] Go Yoneda,[1] Rika Fujino,[2] Hirofumi Jono,[2,1] Hideyuki Saito.[2,1] *[1]Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Kumamoto University Hospital, Kumamoto, Japan.*

Background: IR-induced acute kidney injury (AKI) is known to be a trigger for the development of renal fibrosis followed by the progression to chronic kidney disease. Under ischemia-caused hypoxia of the kidney, tubulointerstitial fibrosis is enhanced with the increased accumulation of matrix proteins such as collagen. A typical sulfate-conjugated uremic solute, IS, is known to be produced in the liver and accumulated in serum and renal tissue under IR-induced AKI, thereby promoting fibrotic responses. However, precise molecular mechanisms involved in IS-promoted renal fibrosis under hypoxia has not been elucidated. In this study, we examined the molecular biological effect of IS on fibrotic responses under hypoxic condition using HK-2 cells and IR-induced AKI model mice.

Methods: C57/BL6 mice (8-weeks old) were treated with IS or vehicle (control) intraperitoneally, after subjected to 20 min of renal IR. In IR-AKI mice, serum creatinine (SCr), BUN and serum IS levels were determined. HK-2 cells were cultivated in the medium with or without IS or vehicle. Hypoxic treatment of HK-2 cells was performed using AnaeroPack System™. mRNA expression of fibrosis-related gene including transforming growth factor (TGF)-β and plasminogen activator inhibitor (PAI)-1 were determined in the kidney of AKI mice and HK-2 cells cultivated under normal oxygen or hypoxic condition.

Results: IR treatment of murine kidney caused a marked elevation in SCr and BUN 24 hr after surgery. Administration of IS in IR-AKI mice synergistically enhanced these increases in SCr (2.2-fold vs control) and BUN (1.5-fold). Expression of PAI-1 mRNA was enhanced in IR-AKI mice (3.4-fold), and HK-2 cells (1.7-fold) under both hypoxic condition and IS treatments, compared with those under normal oxygen condition. GLUT1 mRNA expression, a downstream gene of hypoxia-inducible factor, was also elevated significantly under both hypoxia and IS treatments. By hypoxia and IS treatments, TGF-β expression was accelerated, whereas LY2157299, a TGF-β receptor inhibitor, suppressed dose-dependently PAI-1 expression induced by hypoxia with simultaneous addition of IS.

Conclusions: IS could play important roles in promoting renal fibrosis via TGF-β-mediated up-regulation of fibrotic gene expression under hypoxic condition.

Early Terlipressin Treatment for Hemorrhagic Shock-Induced AKI Leticia U. De Castro, Denise A. Otsuki, Talita R. Sanches, Débora R. Maia, Jose Manuel Condor Capcha, Denise M. Malheiros, Luiz M. Malbouisson, Lucia Andrade. *University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Although hemorrhagic shock (HS) remains the leading cause of mortality, early vasopressor use might restore hemodynamic parameters and vital organ perfusion, thereby reducing the need for aggressive fluid therapy and avoiding fluid overload. However, that strategy has yet to be included in the Advanced Trauma Life Support guidelines. This study aimed to compare the effects of three different levels of lactated Ringer's (LR) fluid therapy—aggressive (3× the blood volume removed, 3LR), conservative (2× the blood volume removed, 2LR) and low (1× the blood volume removed, 1LR)—with or without terlipressin (TLP), on acute kidney injury (AKI) in rats with HS.

Methods: We induced rats to HS, maintaining mean arterial pressure (MAP) at 30-40 mmHg for 60 min and thereafter submitting them to 30 min of LR fluid therapy, some rats also receiving TLP (10 μg/100 g BW, iv). Rats with HS were divided into 3 groups: 3LR, 1LR+TLP and 2LR+TLP. At 15 min after the end of the fluid therapy, the rats were resuscitated with the blood drawn previously. With the exception of MAP, which was measured at various time points, all studies were performed 24 h after HS induction. Data are mean±SEM.

Results: Mortality was 28%, 16% and 0% in 3LR, 1LR+TLP and 2LR+TLP rats, respectively. Creatinine clearance was higher in 2LR+TLP rats than in 1LR+TLP and 3LR rats (1.2±0.13 vs. 0.72 ± 0.1 and 0.53±0.2 ml/min/100 g BW, $p<0.05$). At 45 min after HS induction, MAP was higher in 2LR+TLP and 1LR+TLP rats than in 3LR rats. The acute tubular necrosis score was lower in 2LR+TLP rats than in 1LR+TLP and 3LR rats (5.8±0.8 vs. 14.2±3.5 and 18±4.3%, $p<0.05$). Protein expression of MnSOD was higher in 2LR+TLP rats than in 1LR+TLP and 3LR rats (130±7.1 vs. 110±4.5 and 103±4.3%, $p<0.05$). AQP2 expression was higher in 2LR+TLP and 1LR+TLP rats than in 3LR rats. TLR4 protein expression was lower in 2LR+TLP rats than in 1LR+TLP and 3LR rats (95±4.2 vs. 134±6.8 and 115±5.0%; $p<0.05$). There was less apoptosis (TUNEL-positive cells/0.087 mm2) in 2LR+TLP rats than in 1LR+TLP and 3LR rats (0.6±0.1 vs. 4.5±2.5 and 1.6±0.3; $p<0.05$).

Conclusions: Combining TLP with conservative fluid therapy appears to be a viable therapy for HS-induced AKI. We speculate that TLP attenuates AKI by modulating the inflammatory response via the TLR4 pathway. (FAPESP)

TH-PO296

ZO-1 Protein Is Required for H2O2-Induced, ERK 1/2-Dependent Increase in MDCK Cell Paracellular Permeability Sahar Bilal,[2] Shirin Jaggi,[2] Angelina Voronina,[2] Jessica Watari,[2] Josephine Axis,[1] Danielle Janosevic,[3] Kurt Amsler.[1] *[1]Biomedical Sciences, NYIT College of Osteopathic Medicine, Old Westbury, NY; [2]NYIT College of Osteopathic Medicine, Old Westbury, NY; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: Tight Junctions (TJ) are complexes of multiple proteins on the apicolateral membranes of adjacent epithelial cells that interact to form a selectively permeable paracellular barrier. Hydrogen peroxide (H_2O_2) treatment increases renal epithelial paracellular permeability but the mechanism(s) mediating this effect are unclear. Previous studies suggest kinase-mediated regulation may influence paracellular permeability. In this study, we examined the roles of ERK 1/2 activation and of specific TJ proteins (occludin, ZO-1, ZO-2) in H_2O_2-induced paracellular permeability in renal epithelial cell monolayers.

Methods: Paracellular permeability via the leak pathway (large solutes) was measured as transepithelial movement of calcein, a fluorescent dye, across monolayers of wild type and knockdown MDCK cells grown on permeable membrane filters. H_2O_2 and inhibitors were added prior to measurement of calcein flux. ERK 1/2 activation and TJ protein content were monitored by immunoblot.

Results: Treatment of MDCK cells with H_2O_2 at non-toxic concentrations increased both ERK 1/2 activation and paracellular calcein flux rate in a concentration-dependent manner. ERK 1/2 activation occurred within 30'. Inhibition of ERK 1/2 activation by U0126 blocked the ability of H_2O_2 to increase paracellular calcein movement. Knockdown of either occludin or ZO-2 protein did not block the ability of H_2O_2 to increase paracellular calcein movement nor its inhibition by U0126. In contrast, knockdown of ZO-1 protein, which links the TJ to the actin cytoskeleton, blocked the ability of H_2O_2 to increase paracellular calcein flux. H_2O_2 treatment also altered F-actin organization of confluent MDCK cells, including disruption of actin stress fibers.

Conclusions: We demonstrate that H_2O_2 treatment of renal epithelial cells activates ERK 1/2 which is required for H_2O_2 to increase MDCK cell paracellular permeability. ZO-1 protein, but not ZO-2 or occludin protein, is required for H_2O_2 to increase MDCK cell paracellular permeability. Since ZO-1 protein links the TJ to the actin cytoskeleton, these results may implicate ERK 1/2 modulation of the actin cytoskeleton in mediating the ability of H_2O_2 to increase MDCK cell paracellular permeability.

RNA-Seq Analysis of Mice Exposed Acutely to Low Levels of Domoic Acid Hernan E. Grenett,[1] Robert G. Thompson,[2] Lan He,[4] P. Darwin Bell.[3] *[1]Universiy of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL; [4]University of Alabama at Birmingham, Birmingham, AL.*

Background: Domoic acid (DA) is produced by diatoms of the genus Pseudo-nitzschia. Exposing mammals to this glutamate analog causes a neurologic condition known as amnesic shellfish poisoning. Recently we reported that very low levels of DA (Funk, JASN 2014) are highly toxic to the kidney. DA activates ionotropic receptors in the kidney which could have multiple cellular effects on renal epithelial cells. To begin a mechanistic understanding of the renal effects of DA on kidney, we undertook RNA sequencing (RNA-Seq) studies designed to investigate how acute exposure to low levels of DA affects kidney gene expression.

Methods: Mice were injected IP with 0.05 mg/kg DA and their kidneys were harvested after 0, 15, 30, and 60 min. Total kidney RNA was isolated for RNA-Seq analysis and a sequencing library was generated using the SureSelect Stranded mRNA kit (Agilent Technologies).

Results: RNA-Seq analyses showed DA treatment affected 41 differentially-expressed-genes (DEG) that were at least 2-fold up- or down-regulated ($p<0.05$). In particular systems analyses indicate that genes involved in (i) lipid metabolism [Angptl4, Star], (ii) terminal cellular oxidation [Cyp11a1, Cyp11b1, Cyp21a1, Cyp24a], and (iii) plasma membrane transport [Slc22a6, Scl22a22, Slc22a26, Slc25a25] respond to DA.

Conclusions: These data reveal a complex mechanistic response by the kidney to DA. Future studies will build on and expand this intriguing preliminary data to unravel the untoward biological effects of DA.

NAD+ Augmentation Ameliorates Cisplatin Toxicity via Enhanced Autophagy Matthew R. Lynch, Kenneth M. Ralto, Mei T. Tran, Samir M. Parikh. *Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: We recently reported that renal NAD+ (nicotinamide adenine dinucleotide) concentrations decline markedly in diverse etiologies of AKI and showed that nutritional NAD+ augmentation can treat experimental post-ischemic AKI. Downstream salutary mechanisms of NAD+ augmentation are incompletely understood. Based on evidence linking impaired autophagy to cisplatin-induced renal tubular injury, we hypothesized that NAD+ augmentation may enhance resistance to cisplatin by increasing autophagy.

Methods: Murine intermedullary collecting duct (IMCD3) cells were pre-treated with the NAD+ precursor NMN (nicotinamide mononucleotide) or vehicle for one hour before cisplatin. Cell survival was assessed by automated trypan blue. RNA and protein were isolated for quantitative PCR measurement of autophagy related genes and autophagocytic flux by western blot, respectively. Acidified lysosomes were imaged using Lysotracker DND-99.

Results: NMN supplementation increased NAD+ levels at baseline and preserved NAD+ levels despite cisplatin exposure. NMN-treated cells better tolerated cisplatin stress whereas the lysosomal inhibitor chloroquine exacerbated cisplatin toxicity. NMN enhanced expression of autophagy genes ($p < 0.05$). Finally, NMN-supplemented cells maintained lysosomes in a favorable low-pH-state (Figure 1).

Conclusions: Addition of NMN enhanced cell survival after cisplatin exposure. Autophagic gene and protein levels, along with lysosomal imaging, implicate NMN-related increase in autophagy. NAD+ augmentation may therefore counteract cisplatin-induced renal injury by promoting autophagy.

Funding: NIDDK Support

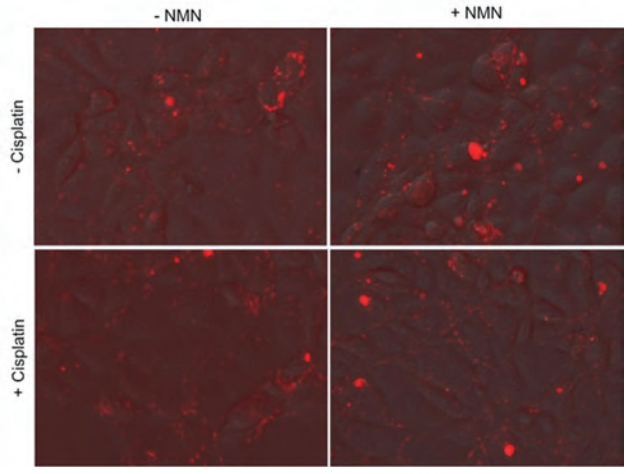

Figure 1. Lysotracker imaging reveals preservation of low pH state of lysosomes with NMN and cisplatin. Representative images (20X).

Chronic Tempol Treatment Preserves Afferent Arteriole Autoregulatory Behavior in Renal Ischemia-Reperfusion Rats Zhengrong Guan, Wenguang Feng, Ijeoma E. Obi, Jennifer S. Pollock, Paul W. Sanders, Edward W. Inscho. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Inflammation and increased reactive oxygen species (ROS) contribute to impaired renal autoregulatory capability under pathological conditions. We showed that renal ischemia-reperfusion (IR) impairs renal autoregulation in rats 24 hours after IR, but it was restored by acute exposure to the ROS scavenger, tempol. We postulated that chronic tempol treatment would reduce renal inflammation and preserve autoregulation in IR rats.

Methods: Renal IR was induced by bilateral renal artery occlusion (60 min). Renal cortical mRNA expression was measured for NADPH oxidase subunits, cytokines and adhesion molecules. Autoregulation was assessed with the *in vitro* blood-perfused juxtamedullary nephron preparation on day 7 post IR.

Results: Renal IR significantly increased mRNA expression for p47phox, p67phox, Gp91phox, MCP-1, TGF-β, TNF-α, P-selectin, VCAM and ICAM vs. sham kidneys (n=6/each group). Tempol pre-treatment (2 mM in drinking water) suppressed the IR-induced increase in mRNA expression for all parameters except TGF-β and TNF-α. IR also impaired afferent arteriole autoregulatory behavior. Baseline arteriole diameters were similar in sham, IR and tempol-treated IR kidneys at a renal perfusion pressure (RPP) of 100 mmHg and averaged 13.4±0.3, 11.7±0.8 and 13.4±1.2 μm (n=4-5/each), respectively. Decreasing RPP from 100 to 65 mmHg increased diameter in sham rats by 18±6%. Subsequent increases in RPP (15 mmHg) caused pressure-dependent vasoconstriction and reduced diameter by 30±5% at 170mmHg. In contrast, pressure-mediated diameter changes were blunted in IR rats. Diameter increased by 5±2% and decreased by just 8±9% at 65 and 170 mmHg, respectively (P<0.05 vs. sham), indicating impaired autoregulation. In different IR rats, chronic tempol treatment improved autoregulatory capability. Arteriole diameter increased by 12±1% and decreased by 33±6% at RPP of 65 and 170 mmHg, respectively (P>0.05 vs sham).

Conclusions: In conclusion, these results demonstrate that IR causes renal inflammation and impaired afferent arteriole autoregulatory capability. Scavenging ROS accumulation with tempol preserves normal autoregulatory reactivity, indicating that excessive ROS accumulation contributes importantly to impaired renal autoregulation in IR rats.

Inhibition of Bromodomain Protein BRD4 Suppresses Cisplatin Induced p53 Activation and Apoptosis in Renal Tubular Cells Xia Zhou, Xiaogang Li. *University of Kansas Medical Center, Kansas City, KS.*

Background: Bromodomain protein BRD4 recognizes and binds acetylated histones to regulate gene transcription. Inhibitor of bromodomain protein, JQ1, has been reported to be effective in treating a variety of cancers. Cisplatin has been used for the chemotherapy of cancers for decades with the side effect of nephrotoxicity and acute kidney injury. One of the mechanisms of nephrotoxicity is p53 mediated apoptosis. However, whether JQ1 has a cytoprotective effect during cisplatin treatment of renal tubular cells is unknown.

Methods: To understand the effect of JQ1 on cisplatin induced acute kidney injury, we treated rat renal proximal tubule cells (RPTC) and mice with cisplatin with or without the presence of JQ1, and analyzed the cells and kidneys by flow cytometry, western blot, TUNEL and immunohistochemistry staining.

Results: We found that BRD4 positively regulated the mRNA and protein expression of p53, and BRD4 bound with p53 promoter in renal epithelial cells as examined by ChIP-PCR analysis. Cisplatin treatment induced 16.5% of cell apoptosis in RPTC cells at the concentration of 20 μM. JQ1 at the concentration of 60 nM did not induced apoptosis. However, co-treatment with cisplatin (20 μM) and JQ1 (60 nM) decreased the percentage of apoptotic cells to 4.1% as analyzed by FACS. JQ1 treatment decreased cisplatin induced RPTC cell apoptosis was further confirmed by TUNEL assay. We further found that cisplatin treatment increased the expression of p53 and its downstream pro-apoptotic protein Bax, as well as the apoptotic cell markers, cleaved PARP and active caspase 3. Cisplatin induced upregulation of p53 and apoptotic associated proteins could be down-regulated by the co-treatment with JQ1. In consistent with the results *in vitro*, JQ1 treatment attenuated cisplatin induced nephrotoxicity *in vivo*. We found that JQ1 treatment preserved renal function as seen by decreased the serum BUN level in cisplatin treated mice, the cortical and medullary tubular necrosis, and the TUNEL positive tubular cells.

Conclusions: This is the first report that BRD4 regulated p53 transcription in renal tubule cells. Inhibition of BRD4 with JQ1 attenuates cisplatin induced acute kidney injury by suppressing cisplatin induced p53 activation and apoptosis in renal tubular cells.

Gender Differences in Renal Ischemia/Reperfusion Injury and the Protective Role of Sigma-1 Receptor Adam Hosszu,[1,2] Zsuzsanna Antal,[3] Lilla Lenart,[3,2] Edgar Szkibinszkij,[1,2] Dora B. Balogh,[3,2] Ádám Vannay,[4,3] Attila J. Szabo,[3,4] Laszlo J. Wagner,[1] Andrea Fekete.[2,3] *[1]Dept. of Transplantation and Surgery, Semmelweis University, Budapest, Hungary; [2]MTA-SE "Lendulet" Diabetes Research Group, Budapest, Hungary; [3]1st Dept. of Pediatrics, Semmelweis University, Budapest, Hungary; [4]MTA-SE Pediatrics and Nephrology Research Group, Budapest, Hungary.*

Background: Gender differences in the susceptibility to renal ischemia/reperfusion injury (IRI) is a known phenomenon. Tubular dysfunction following IRI can be prevented by heat shock proteins. We recently showed that Sigma-1 receptor (S1R) activation is protective in IRI through inducing the Akt-nitric oxide synthase molecular pathway. 17β-estradiol is known to have estrogen receptor-independent effects, possibly through modulating S1R which could explain superior outcomes in females. We aimed to describe gender differences in S1R expression and the heat shock response; to prove that S1R activation by 17β-estradiol or dehidroepiandrosterone (DHEA) induces the heat shock response and is thus involved in gender differences in renal IRI.

Methods: Adult female (F), male (M), ovariectomized female (Ovx), and S1R agonist DHEA-treated male (DHEA) Wistar rats (n=8/group) were subjected to 50 min renal ischemia. Kidneys were harvested 2 hours (T2) or 24 hours (T24) after reperfusion. Renal function and structural damage were assessed. Renal protein levels of S1R, phospho-Akt (Ser473), HSF-1, HSP72, HSP27 and Na^+/K^+-ATP-ase (NKA) were determined. Protein localization was determined by fluorescent immunohistochemistry.

Results: Renal function of F and DHEA rats was less impaired compared to M and Ovx. Structural lesions were less prominent in F, Ovx and DHEA rats than in M. S1R protein increased only in F and DHEA at T2, but returned to baseline by T24. Akt phosphorylation was induced in F and after DHEA treatment at T2. Heat shock response proteins (HSF-1, HSP72 and HSP27) were induced after IRI and were markedly more increased in F and DHEA rats than M and Ovx. Baseline NKA protein levels were higher in F rats. NKA disruption after IRI was suppressed in F and DHEA rats. In M and Ovx females NKA translocated from the basal membrane of tubular cells, thereby losing its function, while in F and DHEA rats it was mainly preserved in its physiological location colocalized with HSP72.

Conclusions: We confirmed previous data indicating that females are less prone to IRI than males. We showed that ovariectomy diminishes the protection that female rats enjoy. We identified S1R activation by 17β-estradiol or DHEA as a possible mediator of protective mechanisms in renal IRI by inducing the heat shock response.

Minimal Volume of Urine for Analysis of Urinary Extracellular Vesicles Recovered at Low Relative Centrifugation Force Luca Musante,[1] Sai Vineela Bontha,[1] Christine Rudy,[1] Sabrina La salvia,[1] Joanne Lannigan,[1] Valeria Mas,[1] Uta Erdbruegger.[2] *[1]University of Virginia, Charlottesville, VA; [2]University of Virginia Health System, Charlottesville, VA.*

Background: Urinary extracellular vesicles (uEVs) provide a relative novel source of valuable biomarkers for kidney and urogenital diseases. Although the bulk of the research has focused mainly on exosomes as the primary source of extracellular vesicles (EVs). Only recently have uEVs recovered at low relative centrifugation force (RCF) been regarded as an additional important fraction of EVs carrying biomarkers. The number of MVs released by podocytes has shown to be higher in the urine of patients with diabetes mellitus type 1 without any kidney complications. This study aims to investigate what is the minimal amount of urine which enables the detection and characterization uEVs in the low RCF pellet.

Methods: First morning urine was centrifuged at RCF of 3,200 g. The supernatant was split in 0.5, 1.0, 1.5, 3.0, 4.5, 9.0 and 13.5 ml fractions to enrich uEVs by centrifugation at RCF of 21,000g. Tunable Resistive Pulse Sensing (TRPS), imaging flow cytometry, Cryo-Transmission Electron Microscopy and quantitative real time PCR were employed to establish the minimal volume of urine to provide uEVs for analysis.

Results: uEVs could be detected by TRSP and imaging flow cytometry, and it was possible to quantify selected miRNA starting from 0.5 ml of urine. Cryo-Transmission Electron Microscopy provided adequate images starting from a minimal volume of 1.5 ml of urine, showing uEVs of different size (60-500 nm) and morphology. Finally, western blot detection of uEVs proteins listed in Vesiclepedia like TSG101, TMEM27,

IGFB-7 and TIMP-2 could be detected starting from 3.0-4.5 ml of urine. Interestingly, the detection of IGFB-7 and TIMP-2, approved early biomarkers of acute kidney injury (AKI), underlines the important role of uEVs in the detection and assessment of urinary biomarkers.

Conclusions: Depending on the sensitivity of the technique in use, a minimal volume of 0.5 ml urine is sufficient for a single analysis; however for multi analysis the volume of urine depends on the limit of detection of the techniques in use.

Outer Stripe of the Outer Medulla in Human and Pig Kidney Is Markedly Reduced or Absent Compared to Rat

Thomas L. Pannabecker,[2] Seymour Rosen.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]University of Arizona, Tucson, AZ.*

Background: In the rat inner and outer stripes of the outer medulla (ISOM, OSOM), there are clear, functionally defined architectural features that lead to physiologically significant nephron and vascular flows. The dynamics of these flows define, in part, our views of basic renal physiology, such as diabetic nephropathy, progression of kidney injury, oxygen delivery and the urine concentrating mechanism. The human and pig medullary architecture differ from the rat in distinct ways, consistent with published observations from the first decade of the 20th century that suggested that the human OSOM, along the corticomedullary axis, has minimal depth.

Methods: We investigated architecture of the human, pig and rat medulla near the corticomedullary junction using tissue embedded in paraffin or resin, followed by sectioning and staining with conventional histochemical (H&E) and immunohistochemical techniques (antibodies for aquaporin1, smooth muscle actin, CD34 and urea transporter UTB and wheat germ lectin). Sections were viewed and photographed using conventional microscopy.

Results: The rat OM has two distinct zones (ISOM, OSOM). The human equivalent of the OM is a single zone whose tubular/vascular structure is largely similar to the rat ISOM. The human basal cortex is almost completely composed of medullary rays, which merge confluently with this single zone (ISOM). The human glomerular efferent arterioles cluster to form the most superficial aspect of the outer medullary vasa recta, which descend, accruing a venous component to form an exclusively arteriolar-venous structure, in contrast to the rat, which also includes thin limbs. The ascending vasa recta bundles of the deeper ISOM become, in the superficial ISOM, composite groupings of venous vasa recta, collecting ducts and thick ascending limbs fusing with medullary rays.

Conclusions: Our studies suggest that in human and pig, the OSOM, as defined by rat medullary architecture, is minimal or absent. Importantly, vascular perfusion of nephron segments in the OM and the deep cortex follows patterns that differ from rat. Re-evaluation of vascular architecture and expected blood flows in human and pig models may provide insights into a number of renal disorders that have resisted advances in treatment and may challenge the use of rat and mouse experimental models that regard outer stripe injury as parallel to human AKI.

Cisplatin-Induced AKI: Proteomic and Transcriptomic Analysis Unravels Molecular Correlates of the Protective Effect of Caloric Restriction and Hypoxic Preconditioning

Martin Späth,[2,1] Malte P. Bartram,[2,1] Karla J. Hoyer,[2,1] Volker R. Burst,[2] Roman-Ulrich Mueller,[2,1] Markus M. Rinschen.[2,1] *[1]CECAD, Cologne, Germany; [2]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Cologne, Germany.*

Background: Acute kidney injury (AKI) is a strong risk factor for cardiovascular morbidity and chronic kidney disease, but causal treatment is still missing. In animal models it can be reduced by preconditioning protocols, but little is known about the underlying molecular mechanisms. We aimed for identifying these in two modes of preconditioning.

Methods: 20-week-old C57Bl6-wildtype mice were treated intraperitoneally with cisplatin comparing mice preconditioned by hypoxia (HP) or caloric restriction (CR) to controls. All mice were phenotyped (plasma creatinine, blood urea nitrogen, histology) and a proteomic and transcriptomic analysis of the renal cortex was done. Additionally we analyzed the whole-cell proteome in cultured proximal tubular cells after cisplatin-damage.

Results: CR completely prevented AKI and HP showed a significant damage reduction. Cisplatin-administration led to a significant increase of extracellular matrix-, complement- and MHC-proteins, in addition to several known markers for AKI. Kinases, receptors and ubiquitin ligases, potential therapeutic targets, were increased in cisplatin-treated kidneys. Brush-border and transport proteins were reduced. Treatment of tubular cells showed that the above mentioned findings can be partly recapitulated in-vitro. The integration of the proteomic with the transcriptomic data showed the largest posttranscriptional changes in mice only treated with cisplatin. The proteomic data was correlated with plasma kidney function values. A positive correlation of extracellular proteins and a negative correlation of brush-border proteins with the damage were shown. A bioinformatical integration of a text-mining-analysis with the correlation-analysis led to a prediction of new "damage-associated-molecular-patterns" partially strongly correlating (R>0.8) with the kidney function. Proteins related to fatty acid synthesis were increased in kidneys of calorie restricted animals, suggesting that increased renal fatty acid synthesis may be involved in renoprotection.

Conclusions: In conclusion these data shows mechanistic insights of the protective effect of preconditioning in cisplatin-induced AKI and the potential of proteome-phenotype-correlations in nephrological basic science.

TH-PO305

Activation of Endoplasmic Reticulum Stress Response by Enhanced Polyamine Catabolism Plays an Important Role in Cisplatin-Induced AKI

Kamyar A. Zahedi,[1,2] Sharon L. Barone,[1,2] Marybeth Brooks,[1] Manoocher Soleimani.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Administration, Cincinnati, OH.*

Background: Cisplatinis a commonly used and highly effective chemotherapeutic agent utilized for the treatment of a variety of solid tumors. Despite its effectiveness, cisplatin usage is limited due its nephrotoxic side effects. More than 25% of patients treated with cisplatin develop renal failure and have to discontinue treatment. The expression of enzymes involved in polyamine catabolism, spermidine/spermine N^1-acetyltransferase (SSAT) and spermine oxidase (SMOX) increase in the kidneys of mice treated with cisplatin. We hypothesized that enhanced polyamine catabolism contributes to tissue damage in cisplatin acute kidney injury (AKI).

Methods: Using knockout mice and chemical neutralization of toxic products of polyamine degradation, the role of polyamine catabolism in cisplatin AKI was examined.

Results: Deficiency of SSAT, SMOX or neutralization of the toxic products of polyamine degradation, H_2O_2 and aminopropanal, significantly diminished the severity of cisplatin AKI. *In vitro* studies demonstrated that the induction of SSAT and elevated polyamine catabolism in cells increases the phosphorylation of eukaryotic translation initiation factor 2a (eIF2a), and enhances the expression of binding immunoglobulin (BiP/GRP78) and CCAAT-enhancer-binding protein homologous protein (CHOP/GADD153). The increased expression of endoplasmic reticulum stress response (ERSR) markers was accompanied by the activation of caspase-3. These results suggest that enhanced polyamine degradation in cisplatin AKI may lead to tubular damage through the induction of ERSR and the consequent onset of apoptosis. In support of the above, we show that the ablation of the SSAT or SMOX gene, as well as the neutralization of polyamine catabolism products modulate the onset of ERSR (e.g. lower BiP and CHOP) and apoptosis (e.g. reduced activated caspase-3).

Conclusions: These studies indicate that enhanced polyamine catabolism and its toxic products are important mediators of ERSR and critical to the pathogenesis of cisplatin AKI.

NHERF1 Deficiency Increases Susceptibility to Cisplatin-Induced AKI

Adrienne M. Bushau,[2] Caryl Conklin,[2] Michelle T. Barati,[2] Susan C. Coventry,[2] Tess Dupre,[2] Leah J. Siskind,[2] Michael E. Brier,[2] Syed J. Khundmiri,[1] Kenneth Gagnon,[2] Eleanor D. Lederer.[3] *[1]Howard University College of Medicine, Washington, DC; [2]University of Louisville, Louisville, KY; [3]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

Background: Acute kidney injury (AKI) develops in 30% of patients who receive cisplatin (CIS), a widely used chemotherapeutic agent. We have demonstrated that NHERF1 deficiency results in differences in mitochondrial protein expression and function. We hypothesize that NHERF1-deficiency increases susceptibility to AKI through an underlying metabolic stress.

Methods: To test this hypothesis, we treated 2 month old male and female wild type (WT) C57BL/6 and NHERF1 knock out (KO) mice with vehicle or CIS (20 mg/kg dose IP) and euthanized after 72 hours. Blood was collected for blood urea nitrogen (BUN) levels. Kidneys were harvested for histology, TUNEL assay, RT-qPCR of Kidney Injury Molecule-1 (KIM-1), and Western Blot for eIF2α, GRP78, and AMPK.

Results: Significantly greater severity of injury was seen in CIS treated NHERF1 KO mice compared to WT mice as demonstrated by semi-quantitative injury score ($p<0.001$) and by BUN levels (WT 97.8 mg/dL +/- 10.01 vs KO 151.8 mg/dL +/- 17.2) ($p<0.05$). KIM-1 mRNA expression was significantly increased in both CIS treated WT (2063.7 fold control +/- 864.4) and NHERF1 KO mice (3802.1 +/- 2132.0) ($p<0.05$) in comparison to vehicle treated mice. TUNEL assay analysis showed significant increases in both NHERF1 KO (12.5 no. nuclei/ no. visual fields +/- 3.2) and WT (10.3 +/- 1.4) CIS treated mice ($p<0.001$) in comparison to vehicle treated mice. Neither KIM-1 expression nor apoptosis differed between CIS treated WT and NHERF1 KO mice. There was no difference in expression of GRP78 and p-eIF2α between WT and NHERF1 KO mice or in proximal tubule cell expression of pAMPK. There were no significant gender differences found between WT and NHERF1 KO mice for any of the measured parameters.

Conclusions: We conclude that NHERF1-deficient mice show an increase in susceptibility to CIS-induced AKI that is not due to an underlying increase in ER stress or a decrease in cell energy levels.

Experimental Confirmation of the Toxico-Pharmacological Role of Sulfate-Conjugated Uremic Solutes in Cisplatin Nephropathy Rika Fujino,[2] Shohei Unoki,[1] Hitomi Tanaka,[1] Keisuke Matsushita,[1] Go Yoneda,[1] Shunsuke Miyake,[1] Hirofumi Jono,[2,1] Hideyuki Saito.[2,1] *[1]Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Kumamoto University Hospital, Kumamoto, Japan.*

Background: The toxicological process leading to cisplatin-induced nephropathy is known to be caused by several mechanisms, including inflammatory responses, oxidative stress, DNA damage and apoptosis in renal tubules. We have reported that indoxyl sulfate (IS), a typical uremic toxin generated by hepatic sulfotransferase-mediated sulfation of indoxyl, accumulates markedly in serum and several tissues of animal models with cisplatin-induced acute kidney injury (AKI). AST-120, an orally administered spherical carbon adsorbent, suppressed the renal IS accumulation in association with a significant nephropreventive effect. The present study was aimed to confirm the toxico-pharmacological role of sulfate-conjugated uremic solutes, IS and p-cresylsulfate (PCS), in cisplatin-induced AKI models.

Methods: SD rats or C57BL/6 mice were treated with cisplatin (20 mg/kg body weight) by intraperitoneal injection. Serum and tissues were collected periodically after cisplatin administration. IS and PCS levels in serum and tissues were determined by LC-MS. Accumulation of IS and 4-Hydroxy-2-nonenal (4-HNE), an oxidative stress marker, in renal tissue was examined by immunohistochemical method.

Results: We developed an in vitro screening system for exploring inhibitors of hepatic production of IS. By using the screening system, we found that some compounds had a potent inhibitory effect on hepatic IS production. Administration of these compounds to rats with cisplatin-induced AKI ameliorated the disturbed renal function with the suppression of serum and tissue IS levels. In C57BL/6 wild type (WT) mice and sulfotransferase 1A1 gene-deficient mice (Sult1A1$^{-/-}$) treated with cisplatin, renal function was preserved (BUN, 193.5 mg/dl in WT vs 84.7 mg/dl in Sult1A1$^{-/-}$, $p<0.01$; sCr, 1.40 mg/dl in WT vs 0.42 mg/dl in Sult1A1$^{-/-}$, $p<0.01$) in association with the marked suppression of serum IS and PCS levels (IS, 88.3 μM in WT vs 20.0 μM in Sult1A1$^{-/-}$, $p<0.001$; PCS, 41.0 μM in WT vs 0.1 μM in Sult1A1$^{-/-}$, $p<0.01$). Renal accumulation of IS, PCS and 4-HNE were markedly reduced in Sult1A1$^{-/-}$ compared with those in WT.

Conclusions: IS and PCS appeared to be key progression factors in cisplatin-induced AKI *via* producing oxidative stress, suggesting that hepatic Sult1A1 could be a therapeutic target for cisplatin nephropathy.

Renal Selective Mesoscale Nanoparticles to Treat AKI Edgar A. Jaimes,[4,5] Ryan M. Williams,[3] Janki Shah,[2] Elizabeth Mercer,[1] Daniel A. Heller.[3,5] *[1]Indiana University School of Medicine, Evansville, IN; [2]MSKCC, NY, NY; [3]Memorial Sloan Kettering Cancer Center, New York, NY; [4]Memorial Sloan-Kettering Cancer Center, New York, NY; [5]Weill Cornell Medical College, New York, NY.*

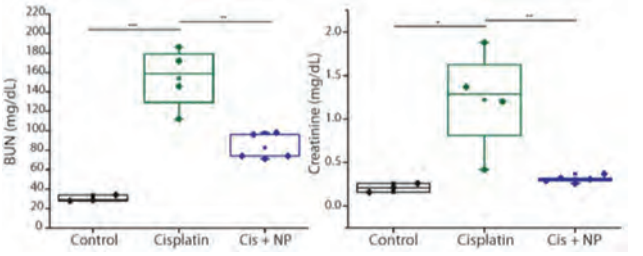
Background: Acute kidney injury (AKI) accounts for 1% of hospital admissions and up to 25% of patients in intensive care develop AKI. As many as 25% of these patients require renal replacement therapy and have high mortality rates. Despite the incidence and associated morbidities, there are no proven or effective therapies for AKI of different etiologies including cisplatin induced AKI, which occurs in 30% of patients receiving this chemotheraputic agent.

Methods: We synthesized nanoparticles from poly(lactic-*co*-glycolic acid) and polyethylene glycol (PLGA-PEG) encapsulating an antioxidant small molecule. The particles are 400 nm in diameter with a negative surface charge and when injected systemically they accumulate predominantly in the proximal tubules as we have shown (Williams, Nanoletters, 2015). Therapy experiments were performed in a mouse model (C57BL6, N = 4 to 6) of cisplatin induced AKI (25 mg/kg I.P.). MNPs (0.2 mg/kg nano-encapsulated drug) were injected IV 24 hours after AKI induction with cisplatin. Mice were sacrificed at 72 hours post-injury and blood urea nitrogen and creatinine measurements, and kidneys were fixed and saved for histology.

Results: MNPs exhibited significant therapeutic efficacy in cisplatin-induced AKI. In vivo, MNPs caused a significant decrease in serum biomarkers and histopathological hallmarks of AKI. AKI mice treated with therapeutic MNPs exhibited a 50% decrease in blood urea nitrogen and an 80% decrease in creatinine, with a marked decrease in tubular necrosis as assessed in PAS stained slides.

Conclusions: These studies demonstrate that targeted delivery of small molecules to the proximal tubule is an effective method of treatment for AKI. In future studies we will investigate the mechanisms of localization and optimization of therapy. This novel strategy may result in the development of novel strategies for the treatment and prevention of AKI of different etiologies.

Funding: Other NIH Support - P30 CA008748, DP2HD075698



In vivo AKI therapy with anti-oxidant-loaded nanoparticles. AKI mice treated with MNPs 24 hours after cisplatin administration. **(A)** BUN and **(B)** creatinine measurements show significant decrease in injury with MNP treatment.

TH-PO309

Systemic Effects of Long-Acting Albumin-Thioredoxin Fusion Protein against Distant Organ Injury Following AKI Kento Nishida,[1] Hiroshi Watanabe,[1] Masafumi Fukagawa,[2] Toru Maruyama.[1] *[1]Department of Biopharmaceutics, School of Pharmacy, Kumamoto University, Kumamoto-shi, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: The high mortality of acute kidney injury (AKI) is associated with distant organ injury such as lung and liver injury. Therefore, an effective strategy is highly desirable for preventing AKI-associated distant organ injury induced by increasing oxidative stress and inflammatory response. Thioredoxin-1 (Trx) is a redox-active protein that has anti-oxidative and anti-inflammatory properties. Although, Trx has great potential for use as a therapeutic agent against several types of oxidative stress-related diseases, its short half-life limits its clinical application. To overcome this problem, we produced a recombinant fusion protein that is comprised of human serum albumin and Trx (HSA-Trx), and examined its preventive effect against AKI-induced distant organ injury.

Methods: Recombinant HSA-Trx was expressed using *Pichia* expression system. AKI-induced distant organ injury mice were produced by renal ischemia reperfusion injury (IRI).

Results: A pharmacokinetic study of HSA-Trx or Trx in mice showed that the plasma retention of Trx was markedly increased by fusion with HSA. HSA-Trx treatment attenuated the renal IRI-induced decline in renal function and histological alterations. HSA-Trx also attenuated not only lung injury, including increased neutrophil infiltration, vascular hyper-permeability and alveolar expansion, but also liver injury, including elevated aspartate aminotransferase and alanine aminotransferase following renal IRI. In plasma, the elevation of inflammatory cytokine was suppressed by HSA-Trx treatment. In kidney, lung and liver, HSA-Trx suppressed the number of apoptosis-positive cells, cytokine and chemokine mRNA expression and oxidative stress. The administration of HSA-Trx resulted in a significant increase in survival rate, with 55% of the mice being alive at 7 days after the renal IRI.

Conclusions: HSA-Trx has potential for use in the treatment of AKI-induced distant organ injury via its extended effects of modulating oxidative stress and inflammation.

TH-PO310

Worsened Renal Fibrosis in Kras4bG12D Lung Adenocarcinoma-Bearing Mice Treated with Repeated Dosing of Cisplatin May Be EGFR-Mediated Cierra Sharp,[2] Mark A. Doll,[2] Tess Dupre,[2] Levi J. Beverly,[1,3] Leah J. Siskind.[2,3] *[1]University Of Louisville, Louisville, KY; [2]University of Louisville, Louisville, KY; [3]James Graham Brown Cancer Center, Louisville, KY.*

Background: Cisplatin (CDDP) is a first choice therapy for many solid cancers, but 30% of patients develop nephrotoxicity leading to acute kidney injury (AKI). AKI is defined as the rapid loss of renal function, marked by an increased mortality rate. Recent large-scale, longitudinal studies have indicated that AKI can progress to chronic kidney disease (CKD), which also has an increased mortality rate. Currently, there are no therapeutic interventions for AKI or CKD sustained from CDDP treatment. This may be due to the fact that the mouse model used to study CDDP AKI utilizes non cancer mice that are treated with one, high dose of CDDP leading to death 3-4 days after injection. Clinically, only cancer patients receive CDDP, and it is administered in low doses over an extended period of time to curtail CDDP nephrotoxicity.

Methods: We optimized a repeated dosing model of CDDP (7 mg/kg 1x/wk for 4wks), which induces fibrosis indicative of CKD. To incorporate cancer into our model, we utilized a Kras4bG12D transgenic mouse that develops lung adenocarcinoma within 6 months, and treated non cancer and cancer mice with repeated CDDP dosing.

Results: CDDP treated cancer mice had significantly decreased survival (25%) compared to CDDP treated non cancer mice. In urine, NGAL levels in CDDP treated cancer mice increased after Dose 1 (34.9 pg/ml) and Dose 2 (51.5 pg/ml), but not in CDDP treated non cancer mice. CDDP treated cancer mice had significantly worsened fibrosis as indicated by Sirius red (SR) staining (25.4% SR +), levels of myofibroblasts (α-SMA IHC; 4.6% +), and TGFβ protein levels as compared to CDDP treated non cancer mice (11.6% SR +, 2.2% α-SMA +). We hypothesized that CDDP treated cancer mice have worsened fibrosis due to the activation of different pathways involved in renal fibrosis. Indeed, CDDP treated cancer mice had increased EGFR and pEGFR Y1068 protein

levels. The role of EGFR was further supported by differential activation of downstream signaling pathways in these mice (JNK and NFκB).

Conclusions: These data suggest that worsened renal outcomes in CDDP treated cancer mice may be EGFR-mediated, and that targeting EGFR may prevent renal fibrosis.

TH-PO311

The Protective Effect of Transplanting Bone Marrow Mesenchymal Stem Cells with Over Expressed Klotho Gene for Kidney Injury Xin Wan,[1] Changchun Cao.[2] *[1]Nanjing Hospital Affiliated to Nanjing Medical University (Nanjing First Hospital), Nanjing, China; [2]Sir Run Run Hospital Affiliated to Nanjing Medical University, Nanjing, China.*

Background: The bone marrow mesenchymal stem cell (BMSC) is a kind of cell with multi-directional differentiation ability and has potent immuno-regulation ability which was confirmed in alleviating acute kidney injury(AKI). Klotho is a protein associated with aging and thought as an antagonist of Wnt/β-catenin pathways which can induce renal fibrosis. Thus a hypothesis was make that modify BMSCs with over expressed Klotho gene and then transplant the BMSCs to individuals with AKI can protect the kidney more efficiency.

Methods: BMSCs was isolated from mice and was cultured to the third generation, the BMSCs were transfected with adenovirus carrying Klotho gene in three days and harvested Klotho-BMSCs. A total of 18 healthy C57BL/6 male mice were used to establish renal IRI model by clamping unilateral renal pedicle for 60 minutes followed by reperfusion. The IRI mice were divided into three groups which was transplanted with PBS, BMSCs and Klotho-BMSCs separately. Kidney tissue and blood samples were collected at 3,14 days after AKI. Renal histological changes were estimated by HE staining and Masson staining. The expression of collagen III and IDO were determined by immunohistochemistry, the location of CD68 was observed by immunofluorescence.

Results: Compared with normal mice, classical tubular damage was found in IRI groups,accompanied by a lot of macrophage infiltrate. The mice transplant with Klotho-BMSCs have the lowest BUN and Cr serum level, while the PBS injected mice have the highest BUN and Cr serum level. The extent of kidney fibrosis at 14 days showed that the Klotho-BMSCs group was the mildest while the fibrosis of BMSCs group was better than PBS group. Compared with normal groups, the injury kidney expressed CD68 significantly which means macrophage infiltrated in kidney, and the infiltration was downregulated by transplanting BMSCs or Klotho-BMSCs. In vivo, Klotho-BMSCs showed more obviously proliferative capacity compared with BMSCs, while the Wnt pathway was significantly suppressed in Klotho-BMSCs.

Conclusions: Over expression of Klotho in BMSCs can improve the proliferative capacity of the BMSCs. That leads to potent down-regulated effect to macrophage cells. At the same time, secrete Klotho is an antagonism to kidney fibrosis. So Klotho-BMSCs exhibit synergistic effect and it can be a new medicine in therapy of kidney fibrosis after AKI.

TH-PO312

Limiting Reperfusion Pressure Protects against Renal Ischemia Reperfusion Injury Jin Wei,[2] Jie Zhang,[2] Lei Wang,[2] Shan Jiang,[2] Jacentha L. Buggs,[1] Ruisheng Liu.[3] *[1]Tampa General Hospital, Tampa, FL; [2]USF, Tampa, FL; [3]University of South Florida College of Medicine, Tampa, FL.*

Background: The role of hemodynamics in renal ischemia reperfusion injury (IRI) is not defined. We hypothesized that lowering renal perfusion pressure during the initial phase of reperfusion protects against renal IRI.

Methods:

Results: First, we evaluated renal autoregulation by measuring changes of renal blood flow (RBF) while elevating 20 mmHg in renal artery pressure (RAP). RBF increased by 94.4±8.1% (n=5, p<0.01) in mice with 15 min renal ischemia while kept constant without significant change in sham. Then, in isolated perfused afferent arteriole, we measured myogenic response by increasing perfusion pressure from 60 to 120 mmHg, which was 1.6±0.08 μm at basal but decreased to 0.9±0.06 μm following 20 min hypoxia (n=6, p<0.01). In isolated perfused juxtaglomerular apparatus, we measured tubuloglomerular feedback (TGF) *in vitro*, which was 3.7±0.6 μm at basal and blunted to 1.2±0.3 μm (p<0.01) following hypoxia. TGF *in vivo* measured using micropuncture was 4.7±0.5 mmHg in sham and inhibited to 0.8±0.6 mmHg right after 15 min renal ischemia (n=5, p<0.01). We next measured tubular free flow pressure (P_f) using micropuncture. P_f was 11.8±1.6 mmHg at basal and decreased to 2.4±0.5 mmHg during ischemia phase, then significantly elevated to 38.2±4.1 mmHg at the beginning of reperfusion and gradually decrease to 19.8±3.7 mmHg after 45 min of reperfusion (n=5, p<0.01). We adjusted the RAP at the initial 45 min of reperfusion to 66±3 mmHg by partially clamping aorta above renal arteries (LP group) and to 102±6 mmHg by clamping superior mesentery artery (HP group), compared with normal RAP 83±4 mmHg (NP group). Accordingly, P_t was significantly lower in LP group (9.4±1.1 mmHg) (n=4, p<0.05) and higher in HP group (30.8±2.5 mmHg) (n=4, p<0.05) at 45 min compared with NP group (22.6±3.5 mmHg) (n=6). Plasma creatinine was significantly decreased in LP group (0.21±0.04 mg/dl, n=5, p<0.05) and increased in HP group (1.95±0.2 mg/dl, n=5; p<0.01) compared with NP group (0.48±0.01 mg/dl, n=6) at 24h after IRI. The percentage of necrotic tubules in histology with PAS staining was decreased in LP (9.1±3.7%) and increased in HP (32.7±2.4%) compared with NP (20.3±2.9%) (n=5, p<0.05).

Conclusions: In conclusion, intratubular pressure is elevated during the initial phase of reperfusion. Attenuation of the increase in intra-tubular pressure by limiting RAP protects against renal IRI.

Lack of Vasohibin-1, a Negative Feedback Regulator of Angiogenesis, Exacerbates Renal Injury in a Murine Cisplatin Nephropathy Model Satoshi Tanimura, Katsuyuki Tanabe, Kana Masuda, Hiromasa Miyake, Hitoshi Sugiyama, Jun Wada. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Vasohibin-1 (VASH1) was originally identified as an endothelium-derived anti-angiogenic factor. In contrast to other anti-angiogenic factors, VASH-1 has been shown to enhance stress-tolerance and survival of endothelial cells via upregulation of Sirt1 and SOD2. We previously reported that VASH1 deficiency resulted in the exacerbation of renal inflammation and interstitial fibrosis in murine unilateral obstruction model (Watatani et al., Phys Rep 2012), and increased albuminuria and marked glomerular alterations in murine type 1 diabetes model (Hinamoto et al., PLoS ONE 2014). In the present study, we examined the effect of VASH-1 deficiency on cisplatin-induced AKI.

Methods: Nine-week-old male VASH1$^{+/-}$ (C57BL/6 background) and wild type (WT) mice received once intraperitoneal injection of 20mg/kg of cisplatin or saline (vehicle). Mice were divided into four groups; 1) WT-control (n=5), 2) VASH1$^{+/-}$-control (n=5), 3) WT-cisplatin (n=7), and 4) VASH1$^{+/-}$-cisplatin (n=7). 72 hours after the injection, these mice were sacrificed and blood and kidney samples were collected.

Results: There were no differences in renal function and histology between WT and VASH1$^{+/-}$-control mice. Renal dysfunction induced by cisplatin injection was more prominent in VASH1$^{+/-}$-cisplatin compared with WT-cisplatin mice (serum creatinine 1.18 ± 0.52 vs 0.39 ± 0.11 mg/dl; BUN 140.9 ± 16.1 vs 92.4 ± 14.0 mg/dl, respectively). Increased renal tubular injury scores and number of TUNEL positive nuclei were also greater in VASH1$^{+/-}$-cisplatin mice. Furthermore, loss of peritubular capillaries observed in WT-cisplatin mice was exacerbated in VASH1$^{+/-}$-cisplatin mice. Renal accumulation of oxidative stress markers, malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE) were markedly increased in VASH1$^{+/-}$-cisplatin mice compared with WT mice. Along with the results, decreased level of antioxidative enzyme SOD2 in WT-cicplatin mice was significantly accelerated in VASH1$^{+/-}$-cisplatin mice.

Conclusions: VASH1 deficiency exacerbated renal dysfunction and tubular injury as well as increased oxidative stress. SOD2 may influence the number of PTCs and renal function. These results suggest that VASH1 exerts renal protective effect in AKI through preserved peritubular capillaries and SOD2 expression.

Treatment with the SGLT2 Inhibitor Luseogliflozin after Ischemia/Reperfusion Attenuated Renal Fibrosis through Reversing the Endothelial Rarefaction in Mice Daisuke Nakano, Akira Nishiyama. *Kagawa University, Kagawa, Japan.*

Background: Sodium-glucose cotransporter (SGLT) 2 inhibitors increase glucose excretion in the urine by inhibiting glucose reabsorption in proximal tubules. However, the effects of SGLT2 inhibition on the severity of proximal tubular injury or on the efficiency of repair after injury have not been examined.

Methods: We investigated the effects of the SGLT2 inhibitor luseogliflozin on acute kidney injury and subsequent development of renal fibrosis in mice. Luseogliflozin (30 mg kg^{-1} day^{-1}, p.o.) was administered at 6 hours after renal ischemia/reperfusion (I/R), and the treatment was continued daily until day 7.

Results: Luseogliflozin did not affect blood urea nitrogen increases, histopathological damage, or autophagy induction at day 1 or 3 after I/R. In contrast, luseogliflozin significantly suppressed the development of renal fibrosis at day 7 and week 4 after I/R. Additionally, luseogliflozin prevented peritubular capillary congestion/hemorrhage, and attenuated renal CD31-positive cell loss after I/R injury. These changes were accompanied by an increase in renal VEGF-A mRNA levels. Furthermore, luseogliflozin failed to attenuate the renal I/R injury-induced fibrotic changes in the animals co-treated with sunitinib, a VEGF receptor inhibitor. Finally, low glucose concentration in the medium increased VEGF-A mRNA levels in cultured proximal tubular cells, and an in vivo glucose uptake analysis showed that luseogliflozin after I/R suppressed glucose uptake in the proximal tubules.

Conclusions: These results indicate that luseogliflozin prevented endothelial rarefaction and the development of renal fibrosis after renal I/R injury through a VEGF-dependent pathway.

Youthful Systemic Milieu Alleviates Renal Ischemia Reperfusion Injury in Elderly Mice Xiangmei Chen. *Department of Nephrology, Chinese PLA General Hospital, Beijing, China.*

Background: The incidence of acute kidney injury (AKI) is high in elderly people. Parabiosis is an experimental model that surgically joins the muscle and hypoderm of two organisms to develop a shared circulatory system. Within this common blood circulation, blood cells and soluble factors can exchange continuously at physiological levels. Parabiosis has been used to study the different internal environmental factors that affect organ function and recovery from damage. A young systemic environment may prevent the senescence of old organs.

Methods: The mice were divided into four groups at random.1). old sham group (O:sham), 2). old IRI group (O:IRI). 3). old-old parabiosis IRI group (O-O:IRI). 4).

young-old parabiosis IRI group (Y-O:IRI). The parabiosis model was established first. Then 3 weeks, the bilateral renal pedicles were clamped in the old recipient mouse.

Results: It was verificated that cross-circulation in the parabiosis model with the IVIS Spectrum Imaging System, fluorescence microscopy, flow cytometry analysis. At 24 hours after IRI, compared to old wild-type mice, the old IRI mice had significantly damaged renal histology, decreased renal function, and increased renal tissue apoptosis. Compared to old IRI mice, old-old parabiosis IRI mice did not show differences in renal histological damage, renal tissue apoptosis. Compared to the old-old parabiosis IRI mice, the old IRI mice in the young-old parabiosis showed less renal histological injury and better renal function. In addition, the renal tissue expression levels of proteins related to apoptosis were significantly decreased.

Conclusions: These results indicate that a young systemic milieu may ameliorate renal ischemia reperfusion injuries in old mice.

The Impact of Uninephrectomy on Subsequent AKI Outcomes Myung-gyu Kim, Hiroshi Kojima, Jonathan Street, Erik H. Koritzinsky, Xuzhen Hu, Peter S. Yuen, Robert A. Star. *NIH/NIDDK, Bethesda, MD.*

Background: The long-term risk of kidney donation (uninephrectomy) is controversial, but appears modest (hypertension; ESRD very rarely). However, the short-term risks including acute kidney injury (AKI) are not well studied. Although uninephrectomy (uni-Nx) alone causes a clinically silent hyperfiltration, the impact of hyperfiltration on AKI outcomes is still unknown. Here, we examine whether uni-Nx alone could be a risk factor for AKI development and recovery.

Methods: In C57BL/6 mice, uni-Nx or sham operation was performed and then renal and tubular function was assessed by transcutaneous measurement of glomerular filtration rate (GFR) using FITC-sinistrin and furosemide simulation test (FST), respectively. At 2 wks after uni-Nx or sham, animals were subjected to 28 min ischemia reperfusion injury (IRI) then followed for 4 wks.

Results: Uni-Nx induced renal hypertrophy and increased expression of tubular transporter in the remaining kidney. These structural changes were accompanied by functional compensation. GFR recovered to more than 70% of normal after 1 wk. Interestingly, urinary output in response to furosemide remained unchanged during 2 wks after uni-Nx, suggesting that hyperfiltration also increased tubular secretion and action of furosemide. Two weeks after uni-Nx, animals were subjected to IRI. The GFR one day post-IRI was lower and BUN was higher in uni-Nx than sham mice. Uni-Nx also significantly delayed recovery of renal function over the next 4 wks. Interestingly, a higher urine production in response to furosemide, but not GFR, just before IRI was strongly correlated with more ischemic renal damage in uni-Nx mice. This suggests that the changes in tubular function, rather than changes in GFR, after uni-Nx could be risk/protective factors for subsequent AKI development.

Conclusions: Mice with a single kidney 1) have the expected compensatory changes in GFR and tubular function; 2) an unexpectedly severe functional deterioration to IRI 2 wks after uni-Nx; and 3) an unexpectedly delayed recovery over the next 4 wks. In addition, the baseline tubular function (and not baseline GFR) can better predict the risk of subsequent AKI. These results may provide important clues in developing new risk stratification and management strategies in patients with a single kidney.

Role of MIF2 in Proximal Tubular Cell Proliferation and Survival after Ischemia-Reperfusion Injury Akinobu Ochi,[2] Dong Chen,[2] Luisa Averdunk,[1] Marta Piecychna,[2] Xin Du,[2] Lin Leng,[2] Richard Bucala,[2] Gilbert W. Moeckel.[2] *[1]RWTH Aachen University, Aachen, Germany; [2]Yale University School of Medicine, New Haven, CT.*

Background: Macrophage migration inhibitory factor (MIF) is a cytokine with pleiotropic actions including cell proliferation and survival. MIF is expressed in kidney tubular cells and released by various stimuli such as hypoxia. Renal tubular cells express MIF receptors: CD74/44, CXCR2/4. Recently D-dopachrome tautomerase, also known as MIF2 was characterized as a homologue of MIF. MIF2 is thought to exert more selective tissue protective action via CD74 activation than MIF. We examined the role of MIF2 in renal tubular cell proliferation and survival after ischemia-reperfusion (I/R) injury.

Methods: *Mif-/-*, *Mif2-/-*, *Cd74-/- and* wild type (*WT*) mice were subjected to 30 minutes bilateral I/R surgery. We then injected MIF2 intraperitoneally every 12 hours. We collected kidney and blood samples 48 hours after I/R surgery, and evaluated tubular damage and performed comprehensive RNAseq analysis. For *in vitro* modeling of I/R injury, we used mouse MPT proximal tubular cells incubated in a hypoxic chamber (0.1% O_2, 6 hrs, low nutrient medium). The cells then were cultured in normal condition with/without 100 ng/ml of MIF2 for different time points.

Results: *Mif-/-, Mif2-/-* and *CD74-/-* mice had more severe tubular injury compared to *WT* mice. MIF2 injection promoted proximal tubular cell proliferation and improved renal function. RNAseq analysis showed that MIF2 injection increased cell cycle associated genes (cyclinD1, D2, E1, E2), secretory leukocyte proteinase inhibitor (SLPI) and survivin expression. In MPT cells, MIF2 promoted cell proliferation via cyclin D1 upregulation following SLPI upregulation in 36 hours. The short time (30-120 min) impact of MIF2 on hypoxic MPT cells included activation of eIF2α and ATF4, which are involved in the integrated stress response. MIF2 also induced autophagy and inhibited apoptosis.

Conclusions: MIF2 promoted renal tubular cell proliferation and survival after I/R injury. MIF2 may be of therapeutic utility as a regenerative agent in the clinical setting of ischemic acute kidney injury.

TH-PO318

CNT/CD-Specific Injury Triggers Serial Proliferation of Aqp2+ Progenitor Cells in Adult Mouse Kidney Long Zhang,[1] Chao Gao,[1] Lihe Chen,[2] Ye Zhang,[1] Enuo Chen,[1] Qiaoling Zhou,[3] Wenzheng Zhang.[1] *[1]Albany Medical College, Albnay, NY; [2]NIH, Bethesda, MD; [3]Xiangya Hospital, Changsha, China.*

Background: The existence of stem/progenitor cells in adult kidneys and their function in kidney injury repair remain very controversial.

Methods: Hence, *iDTR$^{f/f}$ Aqp2Cre* mice were generated to selectively activate expression of the simian diphtheria toxin (DT) receptor in Aqp2$^+$ progenitor cells, which generate all known cell types of the connecting tubule/collecting duct (CNT/CD). Adult *iDTR$^{f/f}$ Aqp2Cre* and *iDTR$^{f/f}$* mice were injected with DT at 2-10 μg/kg to induce acute injury in CNT/CD.

Results: *iDTR$^{f/f}$ Aqp2Cre* mice died at a time- and dose-dependent manner, with 80% mice being dead by day 15 post DT injection. However, all *iDTR$^{f/f}$* mice survived the time course. To accurately label two sequential cell divisions, thymidine analogs, 5-chloro-2-deoxyuridine (CldU) and 5-iodo-2-deoxyuridine (IdU) were injected, either alone or sequentially. IdU$^+$ CldU$^+$ cells were exclusively detected in mice that received both IdU and CldU, verifying the labeling specificity. *iDTR$^{f/f}$ Aqp2Cre vs. iDTR$^{f/f}$* mice significantly increased the number of labeled cells (CIDU$^+$, IdU$^+$, or both) (88.3 vs. 0.4 cells/section, n=5-9 mice). Triple IF combining CIdU and IdU with various markers was performed with kidneys from 10 DT-induced, CIdU and IdU-chased *iDTR$^{f/f}$ Aqp2Cre* mice. For each marker, one section/mouse was completely examined for labeled cells that were positive for the marker. For Aqp2$^+$ cells, the double-labeled rate (CldU$^+$ IdU$^+$ / (CldU$^+$ + IdU$^+$ + CldU$^+$ IdU$^+$) was significantly higher (74.8%, 595/795) than the expected (19.4% CldU$^+$ × 5.8% IdU$^+$ = 1.1%) if cell division were stochastic. The high double-labeled rate was also seen in labeled V-ATPase B1B2$^+$ (84.3%, 118/140), Pendrin$^+$ (100%, 10/10), NCC$^+$ (87%, 174/200), THP$^+$ (75%, 18/24), Megalin$^+$ (61%, 183/300) and Aqp1$^+$ (73.5%, 189/257) cells. Only 87 of 31071 Aqp2$^+$ cells were labeled (0.28%). Among 595 double labeling cells, Aqp2$^+$ and Aqp2$^-$ cells were 25% and 75%, respectively.

Conclusions: The non-stochastic pattern argues against the notion that all surviving CNT/CD cells are capable of proliferating through self-duplication and suggests that adult Aqp2$^+$ progenitor cells selectively proliferate after injury resulting in a high double-labeled rate after sequential CldU and IdU pulses. CNT/CD-targeted injury induces a global effect within the kidney and invokes proliferation of other progenitor cells.

Role of CD133 Molecule in WNT Response and Renal Repair Benedetta Bussolati, Elli Papadimitriou, Alessia Brossa. *Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy.*

Background: The renal CD133$^+$ cells have been indicated as a resident scattered population able to survive and proliferate after injury. However, the biological function of CD133 molecule along with its possible modulation during damage are currently unknown. In the present study, we evaluated the role of stem cell marker CD133 in renal cellular repair at both molecular and functional level.

Methods: CD133 was silenced by two different shRNA against CD133. RNA sequencing was performed on CD133+ and CD133Kd cells after cisplatin damage. Functional Enrichment analysis tool and PANTHER software were used for pathways enrichment analysis. Wnt pathway activation was studied by Western Blot analysis of beta-catenin expression and Luciferase reporter assay for the TCF/LEF promoter. Proliferation, sphere formation, telomere length and senescence were evaluated in CD133+ and CD133Kd cells.

Results: We found that CD133+ cells dedifferentiated after damage, loosing the CD133 signature and acquiring metanephric mesenchymal genes such as SNAIL1 and KLF4 and regenerative genes such as SOX9 and WNT3. CD133 was reacquired in the recovery phase. Lack of CD133 limited cell proliferation after injury and was correlated with deregulation of Wnt signaling pathway. In parallel, CD133-Kd cells showed lower β-catenin levels and TCF/LEF promoter activation in respect to CD133+ cells. Finally, the lack of CD133 impaired clonal generation of spheres while favored senescence.

Conclusions: These data indicate that CD133 may act as a permissive factor for Wnt/beta-catenin signaling, regulating the cell proliferative response after damage, and may limit cell senescence. In addition, CD133 are not stable during damage, but rather undergo a mesenchymal dedifferentiation showing a plastic phenotype.

Tubule Interconnection after Zebrafish Kidney Injury Caramai N. Kamei,[1] Iain A. Drummond.[1,2] *[1]Massachusetts General Hospital, Charlestown, MA; [2]Genetics, Harvard Medical School, Boston, MA.*

Background: Cell-based therapies for kidney regeneration propose the use of renal epithelial or progenitor cells to generate new nephrons and replace damaged nephrons in injured kidneys. For cell-based approaches to fulfill their promise, newly made nephrons must establish tubule lumen interconnections with the collecting system.

Methods: The zebrafish adult kidney regenerates after gentamicin injury from an adult progenitor cell population, forming 20-100 new nephrons that subsequently invade and "plumb into" to the pre-existing collecting system and restore renal function. Using the zebrafish adult kidney as a model of synchronous nephron-collecting duct fusion, we investigated the role of growth factor signaling pathways in this process.

Results: *Tg(TCFLef-miniP:dGFP)* Wnt reporter expression revealed that new nephron aggregates are patterned by canonical Wnt signaling. High canonical Wnt signaling cells formed a single cell thick dome within cell aggregates and polarized to form rosettes with an apical constriction predicting the site of future tubule lumen formation. Cells under the dome exhibiting low levels of canonical Wnt signaling and low proliferation appear to invade the tubular epithelium, while cells corresponding to the dome flatten into a segment of the forming new nephron and continue to maintain high levels of canonical Wnt signaling activity and proliferation until lumen formation. *Tg(lhx1a:GFP)* reporter expression is maintained at high levels in the entire distal end of the new nephron, allowing visualization of the invasion process. Cells at the distal end of the new nephron extend invasive processes or invadopodia into the underlying tubular epithelium. Short term inhibition of Wnt signaling using the chemical inhibitors IWR1 and IWP2 inhibited invadopodia formation and blocked tubule interconnection events. Newly generated kidney cell-type specific transgenics will allow spatially and temporally controlled modulation of Wnt signaling to identify the cells responsible for generating and interpreting tubule interconnection signals.

Conclusions: Canonical Wnt signaling is required for tubule interconnection during adult zebrafish kidney regeneration.

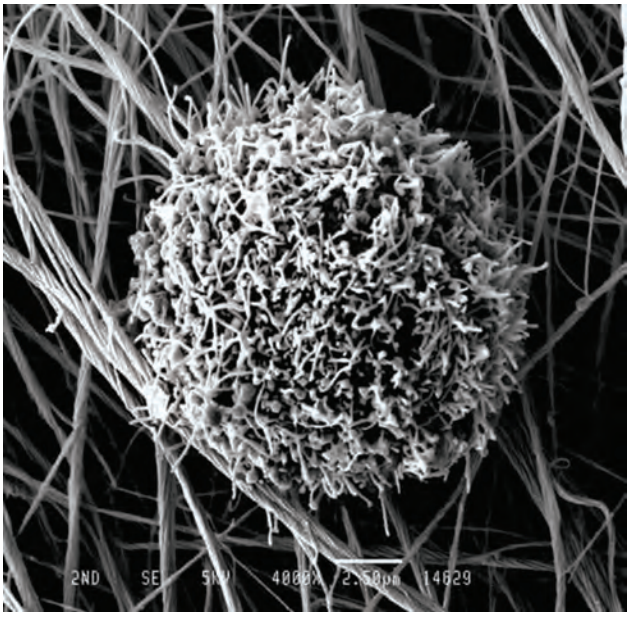
Synthesized Basement Membrane Substratum Provided Cultured Renal Tubular Cells with Scaffold upon Which They Aggressively Developed Filolpodia/Lamellipodia Needed for Cell Motility Kiyoko Inui,[1] Hiroyuki Morita,[2] Yoshihiko Inoue,[1] Eri Kawashima,[1] Fumihiko Koiwa,[1] Katsumi Mochitate,[3] Ashio Yoshimura.[1,4] *[1]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [2]Division of Endocrinology and Metabolism, Aichi Medical University School of Medicine, Nagakute, Japan; [3]BM Matrix Laboratory, National Institute for Environmental Studies, Tsukuba, Japan; [4]Shin-Yokohama Dai-ichi Clinic, Yokohama, Japan.*

Background: Little is known about the ultrastructure of renal tubular epithelium in culture. We previously reported imaging obtained by the use of scanning electron microscopy (SEM) for cultured cell allowed curious aspects of cellular morphology for discussion. In this study, we aimed to capture SEM images of synthesized basement membrane (sBM) we developed and see how it created conditions favorable for cellular proliferation.

Methods: The collagenous substrata, "fib", were prepared on 2 chamber culture dishes interconnected with pores. Type I collagen solution was cast on the second chamber, polymerized, air-dried and used as fib. SV40-T2 cells were seeded on fib, and cocultured with EHS tumor matrigel in the first chamber. During a week of culture, a lamina densa structure formed beneath the cells. The cells were removed and used as sBM substrata.

Results: In subculturing the cells, *rattus norvegicus* kidney tubular epithelialium, NRK-52E, attached fib substrata (Figure), formed lamellipodia, assembled, and proliferated until they became confluent. Application of sBM substrata increased the growth rate of NRK-52 3-fold. SEM images disclosed formation of filopodia / lamellipodia and cell flattening were much more aggresive with sBM substrata.

Conclusions: In vitro, sBM substratum provided NRK-52E cell with scaffold upon which it easily developed cellular structures needed for cell motility and proliferation.



TH-PO322

Analysis of Molecular Mechanisms of Human Kidney Tubulointerstitial Disease Driven by Interleukin 1β Dario R. Lemos,[5,2] Ryuji Morizane,[5,2] Navin R. Gupta,[5,2] Edgar Garcia,[1] Julia Wilflingseder,[5] Tomoya Miyoshi,[5] Koichiro Susa,[5,2] Guanghai Wang,[3,5] Jeremy S. Duffield,[4] Joseph V. Bonventre.[5,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Southern Medical University, Guangzhou, China; [4]Vertex Pharmaceuticals, Boston, MA; [5]Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Tubulointerstitial disease is characterized by tubular damage with interstitial fibrosis and persistent inflammation. While the deleterious effect of the whole inflammatory response is well documented, contribution of specific cytokines is virtually impossible to study *in vivo*.

Methods: Combined whole genome human data analysis with hPSC-derived organoid technology, experimental mouse models and CRISPR/CAS9 technology.

Results: Whole genome analysis of patients with severe kidney fibrosis indicated a correlation between inflammatory cytokines, mitochondria damage and elevated levels of glycolytic enzymes suggesting that inflammatory and metabolic pathways are mechanistically related. To overcome the limitations of studying inflammatory signals *in vivo*, we tested the effect of single inflammatory cytokines on human kidney organoids. Among other damage mechanisms, we found that IL1β stimulation resulted in cell cycle arrest in proximal tubule epithelial cells after 48hr, and KIM1-expressing damaged proximal tubules with near complete absence of brush borders 96hr post stimulation. Simultaneously, IL1β induced the proliferation and differentiation of stromal fibrogenic cells, resulting in hypertrophic expansion of the interstitium, and interstitial fibrosis. Further investigation into the mechanisms of fibrosis revealed the activation of MYC in organoid stromal PDGFRβ+ cells. Nuclear localization of MYC in interstitial fibrogenic cells was confirmed in Col1a1-GFP mice 72hs after acute damage in vivo. IL1β stimulation of human PDGFRβ+ fibrogenic precursor cells purified from human kidneys in vitro induced autophagy, loss of SQSTM1/P62 reduced mTOR signaling and triggered a MYC-dependent metabolic proliferative program encompassing upregulation of glycolysis enzymes and cyclin kinases. Mechanistically, in the absence of IL1β, SQSTM1/P62 interacts directly with MYC, driving its proteasomal degradation to keep MYC levels low. That interaction is interrupted by IL1β through induction of autophagy, resulting in SQSTM1/P62 degradation and MYC stabilization.

Conclusions: By studying components of the inflammatory response separately, we identified a novel molecular mechanism for tubulointerstitial disease triggered by one single inflammatory cytokine, namely IL1β.

TH-PO323

TLR3 Activation Enhances the Renoprotective Effect of Low Serum Cultured Adipose Derived Stromal Cell for Anti-GBM Nephritis Yutaka Kamimura, Naotake Tsuboi, Akimitsu Kitagawa, Takayuki Katsuno, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: We established human adipose tissue-derived stromal cells (hASC) cultured in low (2%) serum (LASC), which demonstrated great therapeutic potential for inflammatory diseases. We have already reported that LASC significantly attenuated rat anti-GBM glomerulonephritis than did hASCs cultured in high (20%) serum (HASC) by promoting the phenotypic conversion of macrophages to immunoregulatory cells. However, the mechanism for LASC to exert greater anti-inflammatory function than HASC was partly evaluated. Based on our DNA microarray data in hASCs, we identified TLR3 as a candidate gene that underlies LASC-mediated immuneregulation. In the current study, we investigated the effect of TLR3 activation of ASC in vitro and in vivo.

Methods: Human abdominal subcutaneous adipose tissue was obtained from patients underwent liposuction or gynecological surgery. Cells were cultured under the two conditions; a low serum culture medium containing 2% fetal bovine serum (FBS) and a high serum culture medium containing 20% FBS. ELISA for HGF, IL-6 and MCP-1 were performed on hASC supernatant cultured with or without poly(I:C) for TLR3 ligand or LPS for TLR4 ligand. Anti-GBM model rats were administered 1×10^6 hASC primed by poly(I:C) or not on days 0, 2 and 4 via the tail vain and we evaluated BUN, sCr, proteinuria and histologic assessment of glomerular crescent formation on day 7.

Results: LASC secreted more HGF, IL-6 and MCP-1 in response to poly(I:C) than HASC, but not to LPS, and these growth factor and cytokines were increased in a dose dependent manner of poly(I:C). In rat anti-GBM model, significant disease amelioration was verified in less elevation of BUN and sCr, and was further evidenced in significant reduction of glomerular crescent formation in animals treated with TLR3-activated LASCs compared to others.

Conclusions: Our data suggest that LASC can be characterized by immune response through TLR3 activation, and that poly(I:C) priming may enhance LASC-mediated renoprotective effects for anti-GBM nephritis.

TH-PO324

Tenascin-C Mediates the Protective Effect of HIF in AKI Xiaoyi Mao, Qionghong Xie, Min Zhang, Da Shang, Chuan-Ming Hao. *Division of Nephrology, Huashan Hospital, Shanghai, China.*

Background: Accumulating evidence suggests that the hypoxia-inducible factor (HIF) mediates cellular adaptions to hypoxia and has a protective effect in acute kidney injury, but the mechanism is not completely understood. The matricellular protein tenascin-C(TNC) which is transiently expressed during development can be re-induced after tissue injury and may be involved in creating a microenvironment that facilitates cell proliferation, adhesion and inflammation. The present study examined the role of TNC in mediating the protective effect of HIF in acute kidney injury using ischemia-reperfusion (IR) model.

Methods: A tenascin-C promoter driven inducible CreER2 knock-in mouse line with an eGFP reporter was generated. TNC-CreER$^{+/+}$ (TNC$^{-/-}$) mice were used to examine the role of TNC in of AKI. RNA sequencing was performed to analyze differentially expressed genes between TNC$^{-/-}$ mice and their wild type littermates.

Results: Following IR, TNC was markedly induced in the interstitium of corticomedullary junction of the kidney as early as 3 hours and peaked at 24-48 hours. Increased TNC expression was also observed in biopsy tissues from patients with AKI. Deletion of TNC in mice significantly aggravated IR induced AKI, showing lower survival rate, higher BUN and more severe tubular injury comparing to their wild type littermates. Then the mechanism underlying TNC induction following injury was investigated. Since 4 hypoxic response elements (HRE) were identified in the promoter region of TNC, we examined the effect of HIF on TNC induction. DMOG, a HIF stabilizer, significantly induced TNC expression both in mice and in primary cultured renal interstitial cells. Luciferase reporter assay showed that hif-2α promoted the transcription of TNC, while mutation of the HRE of the TNC luciferase reporter abolished this effect. To explore the mechanism by which TNC protects kidney from AKI, we did RNA sequencing using renal tissues of TNC$^{-/-}$ mice and their wild type littermates 2 days after IR. RNA-Seq data showed that TNC$^{-/-}$ mice had lower levels of pro-inflammatory cytokines, chemokines and their receptors than wild type mice. Our data suggested that TNC might play an important role in the recovery phase of IR by activating inflammatory response.

Conclusions: Hif-2α induced expression of TNC after ischemia-reperfusion and TNC facilitated recovery from IR injury by activating inflammatory response.

TH-PO325

Ala-Apelin, an Apelin Receptor Antagonist, Ameliorates Contrast-Induced Nephropathy in Rats Seda Kutlug Agackiran,[2] Abdullah Shbair,[2] Zarife Ozdemir,[3] Ozlem Tugce Cilingir Kaya,[1] Naziye Ozkan,[1] Sule Cetinel,[1] Berrak Yegen,[3] Mehmet Koc.[2,3] *[1]Marmara University Medical Faculty, Department of Histology, Istanbul, Turkey; [2]Marmara University Medical Faculty, Department of Internal Medicine, Istanbul, Turkey; [3]Marmara University Medical Faculty, Department of Physiology, Istanbul, Turkey.*

Background: With a dramatically increasing incidence in today's medicine, contrast-induced nephropathy (CIN) is the third common cause of acute kidney injury. Mechanisms of CIN include renal vasoconstriction, medullary hypoxia, endothelial injury, oxidative stress and direct tubular toxicity of contrast agents. Apelin (Ap) is a vasodilatatory molecule and has been shown to prevent cardiac ischemia-reperfusion injury. On the contrary, ala-apelin (Ala-Ap), an apelin receptor antagonist, has anti-fibrotic effects on CCl_4 induced liver fibrosis. In this study, we aimed to demonstrate the effects of Ap and Ala-Ap on CIN.

Methods: Male Sprague-Dawley rats were injected intraperitoneally with only saline (control group, n=8), while CIN groups were treated with either saline (SL, n=9) or Ap (100 mcg/kg/day, n=8) or Ala-Ap (100 mcg/kg/day, n=8) at 0, 24 and 48 hours of the experiment. CIN was established by intravenously injecting indomethacin (10 mg/kg), L-NAME (10 mg/kg) and a high-osmolar contrast agent (Urografin 76%, 6 ml/kg) at 24th h of the experiment. On the 72nd h, kidneys were removed for the assessment of histopathological changes and the determination of glutathione levels and myeloperoxidase activity. Data were analyzed using ANOVA and Student's t-test.

Results: Serum creatinine and BUN levels in SL, Ap and Ala-Ap-treated groups were elevated as compared to control group ($p<0.05$, 0.001 and 0.001), while the increases in serum creatinine in Ala-Ap-treated group was significantly lower as compared to Ap-treated group ($p<0.05$). In contrast to depressed 24-h creatinine clearance in SL and Ap-treated groups ($p<0.01$), creatinine clearance in Ala-Ap-treated group was similar to control group ($p=0.25$). CIN-induced increase in renal myeloperoxidase activity in SL-treated group ($p<0.01$) was abolished in Ala-Ap-treated group ($p<0.05$), while renal glutathione content was increased with Ala-Ap treatment ($p<0.01$). However, histopathological damage scores obtained by light microscopic examination were lower in both Ap and ala-Ap-treated groups as compared to SL-treated group ($p<0.01$).

Conclusions: The present data demonstrate that CIN is ameliorated by administration of Ala-Ap, which appears to act, in part, by diminishing oxidative stress via the inhibition of neutrophil infiltration.

TH-PO326

Onset and Resolution of Renal Inflammation Is Orchestrated by YB-1 Tammo Ostendorf,[3] Sonja Djudjaj,[7] Daniel M. Breitkopf,[7] Thomas Rauen,[6] Daniela Hermert,[5] Ina V. Martin,[4] Peter Boor,[2] Jürgen Floege,[4] Ute Raffetseder.[1] *[1]Div. of Nephrology, University Hospital Aachen, Aachen, Germany; [2]RWTH University Aachen, Aachen, Germany; [3]RWTH University Aachen, Nephrology, 52074 Aachen, Germany; [4]RWTH University of Aachen, Aachen, Germany; [5]Uniklinik Aachen, Aachen, Germany; [6]University Hospital Aachen, Aachen, Germany; [7]University Hospital RWTH Aachen, Aachen, Germany.*

Background: The Y-box-binding protein (YB)-1 plays a non-redundant role in both, systemic and local inflammatory responses. During the onset of inflammation, YB-1 upregulates the expression of pro-inflammatory factors such as interleukin (IL)-6 and CCL5. However, anti-inflammatory properties of YB-1 *via* a trans-repressive capacity on the *Ccl5* promoter upon macrophage differentiation have also been described. Thus, YB-1 influences the early phase of inflammation and also seems to contribute to its termination in the later phase.

Methods: We analyzed YB-1-mediated expression of the anti-inflammatory cytokine IL-10 in cell culture assays and *in vivo* in both, LPS induced inflammation and sterile inflammation induced by unilateral renal ischemia-reperfusion (I/R) in mice with half-maximal expression of YB-1 (*Yb1*$^{+/-}$ mice) and their wild type (WT) littermates. Parameters of renal inflammation/fibrosis were determined by immunohistochemistry and qRT-PCR. *Il10* gene regulation was investigated by *ex vivo* chromatin immunoprecipitation in kidney tissues.

Results: Within a decisive *cis*-regulatory region of the *IL10* gene locus, the 4th intron, we identified and characterized an operative YB-1 binding site *via* gel shift experiments and reporter assays in immune and different renal cells. *In vivo*, YB-1 phosphorylated at serine 102 localized to the 4th intron, which was paralleled by enhanced *Il10* mRNA expression in mice following LPS challenge and in I/R. *Yb1*$^{+/-}$ mice had diminished IL-10 expression upon LPS challenge. In I/R, *Yb1*$^{+/-}$ mice exhibited reduced kidney injury/inflammation in the early phase (days 1 and 5), however they exhibited aggravated long-term damage (day 21) with increased expression of *Il10* together with known mediators of renal injury and inflammation compared to their WT littermates.

Conclusions: In conclusion, these data support the notion that there are context-specific decisions concerning YB-1 function and that a fine-tuning of YB-1 e.g. *via* a post-translational modification regulates its activity and/or localization that is crucial for systemic processes such as inflammation.

TH-PO327

A Novel Hybrid Multifunctional Cytokine IL233 Promotes Regeneration Following Kidney Injury Vikram Sabapathy, Nardos T. Cheru, Rebecca L. Corey, Saleh Mohammad, Rahul Sharma. *University of Virginia, Charlottesville, VA.*

Background: Nephrotoxicity remains a principle concern among complications arising due to chemotherapy. For many chemotherapeutic agents and their metabolites, kidney remains the main pathway for elimination. Inflammation amplifies the renal injury and studies have demonstrated that regulatory T-cells (Treg) play a vital role in restricting inflammation thus facilitating recovery following injury. Based on our studies that interleukin IL-2 and IL-33 synergize to increase the number and function of Tregs, we generated a hybrid cytokine (IL233) bearing the activities of both cytokines in one molecule. Pretreatment with IL233 increased Tregs and protected mice from ischemia reperfusion injury (J Am. Soc. Neph., 2017). Here, we investigated, whether the IL233-mediated increase in Tregs can be used therapeutically in nephrotoxic injury model and whether it promotes renal repair.

Methods: The cytokine overexpressed in *E.coli* were purified using affinity and ion-exchange chromatography. A murine model of doxorubicin-induced renal injury was developed to investigate the therapeutic effect of the cytokine. BALB/cJ male mice were injected with doxorubicin (iv) and the protective effect of the cytokine treatment (ip) was examined both pre- and post- doxorubicin administration. The structure and function of the kidney were probed using flow cytometry, histology, immunohistochemistry, quantitative gene expression analysis and biochemical analysis.

Results: As expected, cytokine treatment rapidly increased Treg numbers in blood and spleen. Mice treated with IL233 hybrid cytokine either before or after doxorubicin treatment had lower kidney injury and inflammation scores. Plasma creatinine and blood urea nitrogen values also indicate that IL233 pretreatment significantly protected renal function. Importantly, IL233 administration post doxorubicin treatment restored the kidney function. The level of renal fibrosis was also significantly less in the treated group than saline group. Treatment with hybrid cytokine led in augmenting the levels of Th2 and anti-inflammatory cytokines but attenuating the pro-inflammatory cytokines.

Conclusions: The data from this study provides that IL233 hybrid cytokine bears strong therapeutic potential to rescue kidney injury associated with nephrotoxic drugs and promote repair.

Human Renal Tubular Cells and Their Exosomes in Rat Ischemic Renal Injury Jesus H. Dominguez,[2,3] Katherine J. Kelly,[1] James M. Dominguez.[1] *[1]Indiana University, Indianapolis, IN; [2]VAMC, Indianapolis, IN; [3]Medicine, IUMC, Indianapolis, IN.*

Background: We previously showed that intravenous infusion of 3E10 rat renal cells, previoulsy subjected to ischemia preconditioning, prevented rat acute kidney injury (AKI) one day after severe ischemia. The donor cells were found anchored to recipient kidney tubules in relatively small numbers.

Methods: We hypothesized that the relatively small number of donated cells amplified their action by releasing their exosomes in situ. Thus, a local spread of exosomes derived from ischemia preconditioned cells potentially amplified the effect. Therefore, normal human kidneys declined for transplantation were digested and their tubules stored frozen and then cultured, representing 70 % proximal tubular cells. These human cells or their exosomes were given intravenously to nude rats, and comparisons were made.

Results: We compared the protective effects of normal human kidney cells (HuCell) or their exosomes (HuExo) (from declined human kidneys) given intravenously, against untreated ischemia (Isch) 1 and 2 days after 50 minutes of bilateral renal ischemia in nude rats. A sham group was also included (Sh). We estimated each rat nephron received a maximum of 47 renal cells or 2E06 exosomes per injection. We found that 1 day after ischemia serum creatinine increased from 0.23 ± 0.02, n = 4-5, mean ± SE, to 1.23 ± 0.07 in all ischemic groups. After 2 days, Isch continue to rise 2.26 ± 0.36, but Huexo, 0.41 ± 0.05 was similar to Sh, 0.36 ± 0.02, and lower than HuCell ± 0.85 ± 0.17, p <0.02. After 6 days, % damaged tubules in Isch 89 ± 2 was higher than HuCell 49 ± 4 ; HuExo 23 ± 2 and Sh 1.5 ± 0.2 ; p < 0.001. Fibrosis (% area) was also higher in Isch 26 ± 1.5 than HuCell 12 ± 0.7, HuExo 8.5 ± 0.5 and Sh 5.5 ± 0.9, p < 0.001.

Conclusions: We conclude that HuExo are superior agents than HuCell, although the latter were also effective. However, the probability for larger numbers of HuExo to reach all affected nephrons is likely higher. Also, HuExo were effective 1 day after severe ischemia, which greatly enhances their therapeutic advantage over all other therapies in AKI. Finally HuExo therapy of AKI is a very feasible therapy in the clinical setting.

Regenerative Effects of Stem Cell Derived Nano-Extracellular Vesicles in AKI in Mice Ciro Tetta,[1] Daniel Gau,[2] John W. Larkin,[3] Franklin W. Maddux.[3] *[1]Fresenius Medical Care, Waltham, MA; [2]Unicyte AG, Oberdorf, Switzerland; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: The use of nano-extracellular vesicles (n-EVs) to treat several pathologies including cancers, inflammatory and heart disease has increased in the recent years (Ref). Various adult stem cells, including mesenchymal stromal cells (MSCs) and human liver stem cells (HLSCs), are known to promote regeneration involving n-EVs. We studied the regenerative potential of MSC- and HLSC-derived n-EVs in acute kidney injury (AKI) models.

Methods: We utilized two mouse models of AKI: glycerol-induced in severe-combined immune-deficient (SCID) mice and an ischemia reperfusion injury (IRI) model. One IV injection of n-EVs was administered 3 days after induction of AKI. The study was also performed *in vitro* using HLSC derived EV cell model of IRI induced by ATP depletion. miRNA-depleted n-EVs from MSCs were created by knocking down Drosha as a negative control.

Results: In glycerol-induced AKI, both MSC- and HLSC-derived n-EV injections accelerated injured kidney recovery. n-EVs localized only in injured kidney cells. In the IRI model, MSC n-EV treatment prevented damage and inhibited chronic functional and morphological sequelae. n-EVs treatment up-regulated anti-apoptotic genes (BCL-XL, BIRC8 & BCL2), down-regulated pro-apoptotic genes (LTA, CASP1 & CASP8), and inhibited transcription of pro-inflammatory genes, extracellular matrix-receptor interaction, cell adhesion molecules, and inhibition of cell cycle. In an HLSC EV model of IRI, n-EV administration reverted RNA changes in renal tubular epithelial cells and inhibited tubular cell apoptosis. In a miRNA-depleted n-EV model, the n-EV's protective effect in AKI was significantly decreased. MSC n-EVs treatment significantly improved survival in a lethal model of cisplatin-induced AKI in SCID mice.

Conclusions: The findings indicate that MSC- and HLSC- derived n-EVs have regenerative effects in AKI mouse models. n-EVs may be promising for the development of stem cell free therapies.

Adipose-Derived Mesenchymal Stem Cells Employed Exosomes to Attenuate AKI-CKD Transition through Tubular Epithelial Cell Dependent Sox9 Activation Rui Zeng,[1] Ying Yao,[2] Fengming Zhu.[2] *[1]Tongji Hospital, Wuhan, China; [2]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Acute kidney injury (AKI) predisposes patients to an increased risk into progressive chronic kidney disease (CKD). Mesenchymal stem cells (MSCs) have been shown to promote recovery of injured tubular epithelial cells (TECs) in many kidney diseases. The transcription factor Sox9 is critical for renal development and has been reported to be activated within TECs upon renal injury. However, all these studies focused solely on AKI, whether MSCs can prevent AKI-CKD transition and what is the relationship of Sox9 activation to this process are largely unknown. This study aimed to investigate the therapeutic efficacy of human adipose-derived MSCs (hAD-MSCs) in the prevention of AKI-CKD transition, and illuminate the role of Sox9 in this process.

Methods: 1. C57BL/6 mice were subjected to unilateral renal ischemia/reperfusion (I/R) with or without hAD-MSC treatment. 2. Exosomes derived from hAD-MSCs were extracted and injected into I/R mice through tail vein. 3. GW4869 was used to inhibit the release of exosomes. 4. The changes of kidney pathology, infiltration of inflammatory cells, hallmarks of kidney injury and repair were detected. 5. The activation of tubular Sox9 was assessed.

Results: We found that hAD-MSC treatment activated tubular Sox9, promoted tubular regeneration, attenuated AKI, and mitigated subsequent renal fibrosis. However, these beneficial effects were abolished by a drug inhibiting the release of exosomes from hAD-MSCs. Further, we verified that hAD-MSCs activated tubular Sox9 and prevented TGF-β1-induced transformation of TECs into pro-fibrotic phenotype through exosome shuttling in vitro, but the cells did not inhibit TGF-β1-induced transition of fibroblasts into myofibroblasts.

Conclusions: hAD-MSCs employed exosomes to mitigate AKI-CKD transition through tubular epithelial cell dependent activation of Sox9.

Intravenous Exosomes Decrease Apoptotic Cell Death Following Rat Ischemic Renal Injury Jesus H. Dominguez,[2] James M. Dominguez,[1] Katherine J. Kelly.[1] *[1]Indiana University, Indianapolis, IN; [2]VAMC, Indianapolis, IN.*

Background: In acute kidney injury with ischemia (AKI), multiple, redundant pathways promote inflammation, sustained ischemia tubular cell death. The most common interpretation of cell death in AKI is by necrosis. However, death by apoptosis is an important process that may evolve over longer time after the initial injury. There is no treatment that can prevent the implementation of the dying process in AKI.

Methods: We infused renal tubular cells to treat two rat models of AKI: SD rats (given rat kidney exosomes) and Nude rats (NR) (given normal human kidney exosomes) subjected to 50 min of bilateral renal ischemia. Cells were given 24 and 48 hrs post-ischemia, and prevented injury after 6 days. The broad benefit of a few donor renal cells led to the hypothesis that their exosomes (EX) are the therapeutic effector.

Results: Hence, we infused EX from renal cells, 24 and 48 hrs post-ischemia. In ischemic NR, renal apoptosis was 4.4 fold higher in untreated AKI, as compared to sham controls, and it was prevented by EX, n = 5-4, p <0.05, for all. Equally ischemic SD showed upregulation of renal pro-apoptosis transcripts, casp4, casp8, fas, apaf1, bak, bax, p53 and TRAIL, fold increase 2.7, 2.1, 2.86, 2.05, 1.84, 1.43, 1.53 and 1.91 fold, respectively, and these were blunted by EX treatment, n = 5, p <0.05 for all. Ischemia also activated the anti-apoptotic genes bag2, birc 3 and birc5, 1.8, 3.5 and 3.1 fold, respectively, and EX suppressed this activation as well, p <0.05. Renal function and structure was markedly compromised after 6 days in untreated AKI. In contrast, EX treatment protected renal function and structure to a level similar to that of sham control rats in both sets.

Conclusions: We conclude, the apoptotic transcriptome is stimulated in untreated AKI, promoting renal apoptosis after 24 hrs of the initial injury. The concurrent activation of anti-apoptosis genes is not sufficient to reverse the apoptotic process triggered by AKI. EX prevented ischemic renal apoptosis by interfering with pro and anti-apoptotic activation, and prevented long-term functional and structural renal compromise. The 24 hour lag time after injury is an opportunity for intervention with EX intravenous infusions in AKI.

TH-PO332

Superiority of Mesenchymal Stem Cell-Derived Exosomes versus Parent Cells for Rescue Therapy of Advanced Stage AKI Anna Gooch, Ping Zhang, Zhuma Hu, Christof Westenfelder. *University of Utah and VA Medical Centers, Salt Lake City, UT.*

Background: Bone marrow and Adipose-derived Mesenchymal Stem Cells (MSCs and ASCs) have proven both pre-clinically and clinically to be effective for prevention of Acute Kidney Injury (AKI). Yet studies in which MSCs are given 48 hrs. post-insult, a time at which most patients with severe AKI are diagnosed and when no rescue therapy is available, show them to be ineffective or potentially damaging due to compromised renal blood flow, where introduction of large cells (~50μm) causes further deterioration of renal function. ASCs' paracrine actions, including release of exosomes, are largely responsible for their protective effects, and others have shown that administration of ASC-derived exosomes can prevent AKI. Thus, we hypothesized that ASC-derived exosomes (40-150 nm), which can easily move through the microvasculature, may be effective rescue therapy for late stage AKI. Accordingly, we compared the therapeutic efficacy of ASC-derived exosomes vs. ASCs given late to rats with severe, non-spontaneously recovering AKI.

Methods: ASCs were isolated from Sprague Dawley (SD) rats and characterized by standard protocols. Exosomes were isolated from cultured ASCs using the ExoQuick TC kit (SBI), quantified (Nanosight and Bradford assay), and characterized by FACS for CD44 and CD29 surface protein expression. Adult, female SD rats were subjected to I/R AKI (52 min bilateral renal pedicle clamp). Serum Creatinine (SCr) was assessed at baseline, Days (D) 1, 2 and 3. If the SCr value on D2 was greater than that on D1, rats were treated via left carotid artery with either 1 ml of 1) 1x10e6 SD MSCs, 2) 200 ug protein-equivalent of SD MSC-derived exosomes (~4x10e10 exosomes), or 3) vehicle (1xPBS).

Results: SCr increased between D1 and D2 in all rats 1.6 ± 0.35 mg/dL (mean ± SD). As hypothesized, exosome administration on D2 caused a significant -1.7 ± 0.34 mg/dL drop in SCr by D3 vs. vehicle (+0.4 ± 1.1 mg/dL), while ASC administration did not, and in 25% of animals caused further functional deterioration.

Conclusions: Exosome therapy 2 days post-insult is superior to ASC therapy for rescue of AKI. Further optimization of the exosome therapy is expected to identify optimal treatment doses for advanced AKI.

Urinary Extracellular Vesicles in Tubular Cell Repair Benedetta Bussolati,[2] Veronica Dimuccio,[1] Cristina Grange,[4] Elli Papadimitriou.[3] *[1]Univerity of Turin, Turin, Italy; [2]University of Torino, Torino, Italy; [3]University of Turin Italy, Turin, Italy; [4]University of Turin, Turin, Italy.*

Background: Extracellular vesicles (EVs) are emerging as an integral component of the cell-to-cell communication network. EVs may actively transfer to target cells various molecules including proteins, mRNAs and microRNA, with stable epigenetic changes. Urinary EVs in particular, released by cells lining the nephron, are abundantly present in urine and may be involved in intra-nephron communication among cells. We here evaluate the possible role of urinary EVs in repair of renal tissue after AKI.

Methods: EVs were isolated by urine of normal subjects by ultracentrifugation and gradient sedimentation. CD133+ and CD133neg EVs were separated by magnetic sorting. EV populations were subjected to nanoparticle tracking analysis to define their dimension and profile and measure EV mean, distribution and concentration. EVs were characterized by marker expression using Western Blot and FACS analysis. MicroRNA content was assessed by qRT-PCR using a MicroRNA Assay Human Panel Early Access kit to profile 754 human mature miRNAs. EVs from mesenchymal stem cells were used as control. Urinary EVs were injected in mice undergoing AKI (day 1) by intramuscle injection of glycerol.

Results: CD133+ and CD133neg vesicles obtained from urine showed similar expression of exosomal markers. CD133+ and CD133neg EVs showed selective expression of a panel of microRNAs. Functional Enrichment analysis tool showed enrichment in pathways related to matrix-receptor interaction, adhesion as well as pathways regulating pluripotency in CD133+ EVs, where pathways involved in TGF-beta signalling, cell cycle and mTor signalling in CD133 negative EVs. EV administration to AKI mice showed a selective improvement of renal function and histology. In particular, CD133neg EVs promoted repair in a comparable level to MSC-EVs. CD133+ EVs did not show repairing effect. This was confirmed by administration of CD133+ EVs isolated by CD133+ cells in culture. Bioimaging of injected CD133neg EVs showed their rapid localization and internalization within tubules in AKI mice.

Conclusions: These data indicate that EVs within urine may support repair of tubular cells, indicating a possible paracrine action of EVs released within urine to damaged cells in lower tubular compartments. This was not obtained by CD133+ EVs suggesting selective effects of cells within tubules in its repair.

β-Hydroxybutyrate Attenuates Renal Ischemia-Reperfusion Injury Takaya Tajima, Ayumi Matsui, Tomoaki Ito, Kiyotaka Uchiyama, Shu Wakino, Hiroshi Itoh. *Keio University School of Medicine, Tokyo, Japan.*

Background: An endogenous ketone, β-hydroxybutyrate(βOHB) is used as an energy source in organs including kidney. It has been reported that βOHB has therapeutic benefits against stress conditions. In this study, we evaluated its protective effects and potential mechanisms in renal ischemia/reperfusion injury(IR).

Methods: Male C57BL/6J mice and human proximal cell line, HK-2 cells were used in this study. Two weeks before the study, the right kidney was removed and mice were separated into 4 groups: saline-treated sham-operated mice (n=6), βOHB-treated sham-operated mice (n=6), saline-treated mice with IR (n=8), βOHB-treated mice with IR (n=8). In IR injury mice were subject to clamping of both renal arteries and veins for 45 min and to reperfusion. βOHB was administered continuously by osmotic mini-pump at the dose of 8 mg/h. Kidneys were harvested 24 h after IR injury, and functional and molecular parameters were evaluated. In vitro studies, HK-2 cells were incubated for 1 h with mineral oil to induce hypoxic injury, and incubated for 24 h after medium replacement. These HK-2 cells were treated with various doses of βOHB and molecular parameters were evaluated.

Results: In mouse study, blood urea nitrogen, serum creatinine levels, and renal tissue injury scores in βOHB-treated IR mice were significantly lower than those of saline-treated IR mice. βOHB increased histone acetylation due to the inactivation of histone deacetylase, which increased the expression of anti-oxidative factors including FOXO3, MnSOD, Catalase, Nrf2 in IR-injured kidneys and hypoxic HK-2 cells. Consistently, βOHB decreased ROS production, decreased the MDA content in IR-injured kidneys as well as in hypoxic HK-2 cells. Moreover, βOHB decreased markers of inflammasome activation including NLRP3, ASC, caspase-1, and the proinflammatory cytokines IL-1β and IL-18 expression in IR-injured kidneys as well as in hypoxic HK-2 cells. Finally, βOHB decreased Bax expression and increased Bcl-2 expression in IR-injured kidneys as well as in hypoxic HK-2 cells. Consistently, βOHB improved cell survival in hypoxic HK-2 cells and reduced the numbers of TUNEL-positive cells in IR-injured kidneys.

Conclusions: βOHB attenuates renal IR injury. The anti-oxidation, anti-inflammation and anti-apoptosis effects by βOHB, may play a role in renoprotection against renal IR injury.

TH-PO335

Inhibition of the Transcriptional Activator Etv4 in Proximal Tubule Cells Protects Kidneys from Tubular Injury Susanne V. Fleig,[7] Flavia G. Machado,[5] Monica Chang Panesso,[6] Chia-Chun Wu,[1] Kohei Uchimura,[6] Rafael Kramann,[3] Motoko Yanagita,[2] Benjamin D. Humphreys.[4] *[1]Chi Mei Medical Center, Tainan, Taiwan; [2]Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]RWTH Aachen University, Lemiers, Netherlands; [4]Washington University School of Medicine, Clayton, MO; [5]Washington University in St Louis, School of Medicine, St Louis, MO; [6]Washington University in St. Louis, St Louis, MO; [7]Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: The transcription factor Etv4 regulates developmental programs in several organs including kidney, but roles for Etv4 in kidney injury are poorly defined. Here we have investigated the expression, function and regulation of Etv4 during dedifferentiation and repair after AKI.

Methods: We generated a novel mouse model with inducible expression of a dominant-negative Etv4 (DN-Etv4) in proximal tubule cells. NDRG1CreERT2; R26-DN-Etv4 bigenic mice were subject to moderate and severe bilateral IRI and tissue histology, gene expression and kidney function was monitored. Primary human proximal tubule cultures (RPTEC) and iPS-derived kidney organoids were used to assess regulation of Etv4 expression.

Results: At 24h after IR injury, mice with proximal specific DN-Etv4 expression had a significantly lower increase in creatinine and BUN than controls; a functional difference is not seen at 3 and 5 days past injury. DN-Etv4 expressing mice have a much lower tubular injury score at 24h than controls. Caspase 3 staining shows a significantly lower amount of apoptotic cells at 24h. The metabolic intermediate α-ketoglutarate (aKG) is upregulated in ischemia due to lack of decarboxylation via PHD2 (Olenchock BA et al, Cell 2016). aKG inversely controls etv4 expression in cancer, and high etv4 was linked to hypoxia-induced apoptosis (Keenan M. et al, PLoS Genetics 2015); we observed strong downregulation of Etv4 expression in human RPTECs after exposure to aKG. Finally, gentamicin treatment of human iPS-derived kidney organoids potently induced Etv4 mRNA.

Conclusions: The transcriptional activator etv4 is induced in dedifferentiatied proximal tubule after AKI. Our results suggest that it normally acts to induce apoptosis in the hypoxic postischemic tubule, as blocking its function improved cell survival, tubular injury scores and BUN after IRI. This pathway is conserved in humans, since gentamicin induced Etv4 mRNA in human iPS-derived kidney organoids. Finally, aKG downregulated Etv4 expression in vitro, suggesting a novel therapeutic strategy.

Role of Sirt2 in a Murine Cisplatin Induced AKI Model Woong Park,[2] Yujin Jung,[3] Won Kim,[1] Kyung Pyo Kang.[2] *[1]Chobuk National Univeristy Medical School, Jeonju, Republic of Korea; [2]Chonbuk National University Medical School, Jeonju, Republic of Korea; [3]chonbuk national university medical school, Jeonju, Republic of Korea.*

Background: Cisplatin based chemotherapy is commonly used in therapeutic strategies for solid tumor. However, limitation of this agent is adverse effect on normal tissue such as kidney, ear, and peripheral nerves. Mechanisms of cisplatin nephrotoxicity are proposed as oxidative stress, inflammation, cellular apoptosis and death, and cell cycle regulation. Sirt2 is one of sirtuins family, which is NAD^+ (nicotinamide adenine dinucleotide)-dependent deacetylase. However, there are a few reports about the role of Sirt2 on cisplatin-induced renal injury. In this study, we evaluated the effect of Sirt2 on renal injury induced by cisplatin.

Methods: We used *Sirt2* knockout mice (B6.129-*Sirt2*$^{tm1.1Fwa}$/J, *Sirt2*KO) and their wild type mice (C57BL/6, WT mice). Cisplatin nephrotoxicity was induced by intraperitoneal injection of cisplatin (20 mg/kg). After 3 days after cisplatin injection, blood and kidney tissues were harvested. Renal function and histology were evaluated. Tubular apoptosis and reactive oxygen species were evaluated by immunohistochemistry. Intercellular adhesion molecule (ICAM)-1 and acetyl-p65 were evaluated by Western blot analyses.

Results: After induction of cisplatin nephrotoxicity, renal function measured by serum BUN and creatinine was significantly improved in *Sirt2*KO mice group at 72 h after cisplatin treatment compared to WT mice. At 72 h after cisplatin treatment, tubular injury score was significantly decreased in *Sirt2*KO mice compared to WT mice. TUNEL positive tubular cells and renal caspase-3 expression were decreased in *Sirt2*KO mice compared to WT mice after cisplatin treatment. Cisplatin-induced increases of dihydrorhodamine-123 (DHR, a reactive oxygen species marker)-positive tubular cells were significantly suppressed in *Sirt2*KO mice compared to WT mice. Finally, cisplatin-induced increases of ICAM-1 and acetyl-p65 expression in Western blot or immunohistochemistry were decreased in *Sirt2*KO mice.

Conclusions: Sirt2 KO might have important pathophysiologic role in cisplatin-induced renal injury with regulation of apoptosis, a reactive oxygen species and inflammation.

Par1b Is Protective to Cisplatin Induced Renal Tubular Injury Abhijeet Pal,[2] Philip Chu,[1] James M. Pullman,[5] Frederick J. Kaskel,[3] Kimberly J. Reidy.[4] *[1]Albert Einstein College of Medicine, New York, NY; [2]Pediatric Nephrology, Children's Hospital at Montefiore, Bronx, NY; [3]Albert Einstein College of Medicine, Children's Hospital at Montefiore, Bronx, NY; [4]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [5]Montefiore Medical Center, Bronx, NY.*

Background: Nephrotoxic injury is an important contributor to childhood acute kidney injury (AKI). Partitioning defective(Par)1b is a serine threonine kinase member of Par polarity protein family. Dual loss of Par1b and its paralogue Par1a in mice leads to defects in Notch expression and glomerular and proximal tubule development. We identified increased expression of Par1b in proximal tubules in mouse models of AKI and in human kidney tissue with acute tubular necrosis(ATN). We hypothesized that Par1 proteins are protective and promote renal epithelial repair.

Methods: To test this, we used in vivo and in vitro approaches. We induced AKI in *Par1b*$^{-/-}$ (Par1b KO) mice with the proximal tubular nephrotoxin, cisplatin. In addition, loss of function was studied using primary proximal tubular cultures from Par1b KO and WT mice. For gain of function, adenoviral constructs were used to overexpress Par1b or control constructs in primary proximal tubular cultures.

Results: Par1b KO mice developed more severe ATN, with higher tubular injury scores and higher Kim-1 levels. Cytoskeletal architecture and cell-extracellular matrix structures were severely disrupted in cisplatin injected Par1b KO kidneys compared to WT as demonstrated by immunostaining of adhesion molecules (e-cadherin, β-catenin, and β1-integrin). To identify the mechanisms underlying the increased injury, we examined the effect of loss of Par1b on apoptosis and necrosis. Par1b deletion led to increased apoptosis following cisplatin treatment, as demonstrated by increased TUNEL staining in vivo and increased cleaved caspase 3 staining in vitro. Increased necroptosis was also demonstrated by increased RIP-1 levels in the Par1b KO kidneys. In WT kidneys, cisplatin exposure induced renal repair pathways, as evidenced by increased expression of Wnt4 and its effectors Axin2 and Lhx1 along with increased levels of activated cleaved Notch2 receptor and increased expression of its effectors Hes1 and Hes5. This effect was attenuated in Par1b KO kidneys. Par1b overexpression in proximal tubular cells showed increased cell viability following cisplatin treatment, demonstrating a protective role for Par1b.

Conclusions: Both in vivo and in vitro studies support the protective role for Par1b in cisplatin induced ATN. Further defining Par1b targets may lead to therapeutic options to prevent cisplatin induced AKI in the future.

TH-PO338

TWEAK and RIPK1 Mediate Secondary Cell Death During AKI Diego Martin-Sanchez,[1] Miguel Fontecha,[1] Susana Carrasco,[1] Maria Dolores Sanchez-Nino,[1] Marta Ruiz-Ortega,[2] Jesus Egido,[1,2] Andreas Linkermann,[3] Alberto Ortiz,[1,2] Ana B. Sanz.[1] *[1]IIS-Fundación Jiménez Díaz, Madrid, Spain; [2]Universidad Autonoma, Madrid, Spain; [3]University Hospital Carl Gustav Carus Dresden, Dresden, Germany.*

Background: TWEAK is a member of the TNF superfamily that, in a proinflammatory environment, induces renal tubular cell death. TWEAK, TNFα and IFNγ (TTI)-induced cell death has features of apoptosis and is associated to activation of caspases and mitochondrial stress. However, inhibition of caspases with zVAD in vitro and in vivo was not protective. Recently, it was reported that ferroptosis plays a key role in the initial wave of tubular cell death in AKI, and beyond cell death, it mediates upregulation of inflammatory molecules, as Fn14, and of necroptosis proteins. We hypothesized that TWEAK in collaboration with RIPK1 could contribute to a secondary wave of inflammation-related cell death during AKI.

Methods: Fn14 knockout (Fn14-KO), RIPK3 KO mice or wild type (WT) mice received a single i.p. injection of folic acid. Some WT mice were pretreated with Nec-1. In vitro studies were performed in murine proximal tubular MCT cells.

Results: Fn14-KO mice were protected from AKI, as assessed by serum BUN and creatinine levels, and reduced cell death, assessed by TUNEL, at 72h, while, at 24 hours there is not protection. This suggests that TWEAK contributes to secondary cell death in AKI. In cultured cells, TTI induces caspase activation, but zVAD changed the mode of cell death from apoptosis to necroptosis. The RIPK1 inhibitor Nec-1 prevented both cell death induced by TTI and by TTI+zVAD (TTI/Z), suggesting that RIPK1 is implicated in both apoptosis and necroptosis. Specifically, Nec-1 prevented features of apoptosis as caspase activation. By contrast, RIPK3 and MLKL siRNA only prevented TTI/Z-induced cell death suggesting that this process is mediated by necroptosis. Both Nec-1 and RIPK3 deficiency protected from AKI at 96h, showing the implication of necroptosis. This suggests that TWEAK/RIPK1 may mediate the secondary wave of cell death during AKI.

Conclusions: TWEAK in association with RIPK1, plays a key role in secondary, inflammation-related cell death in AKI. In vitro experiment showed that TTI-induced cell death has features of apoptosis but is dependent on the kinase activity of RIPK1. By contrast, caspase inhibition changed the mode of cell death to necroptosis. These results open a new therapeutic window to treatment of AKI once it has been established.

TH-PO339

PPARδ Modulator MTB-2 Enhances FAO In Vitro and Attenuates Ischemia-Reperfusion-Induced Gene Expression Changes In Vivo 48 Hours and 14 Days Post AKI Christina Bracken, Jeff H. Stanwix, Hien G. Hoang, Eric Bell, Effie Tozzo. *Mitobridge, Cambridge, MA.*

Background: Ischemic acute kidney injury (AKI) is characterized by persistent proximal tubule mitochondrial dysfunction. Due to their highly oxidative metabolism, proximal tubule cells (PTC) utilize fatty acids to generate the energy required for their specialized function. We hypothesized that enhancing fatty acid oxidation (FAO) with a PPARδ modulator will restore mitochondrial function, offering a potential therapeutic treatment for AKI.

Methods: Human hTERT RPTECs were treated with MTB-2 and analyzed for PPARδ target gene expression and their ability to utilize palmitate. Sprague-Dawley rats underwent a 45 minute bilateral ischemia-reperfusion (IR) AKI. Following reperfusion, rats were treated with 2 IV doses of selective PPARδ modulator MTB-2 at doses varying from 0.3 to 10 mg/kg or vehicle. At 48 hours and 14 days post reperfusion kidney cortex gene expression was assessed by qPCR.

Results: MTB-2 significantly increased expression of PPARδ-target genes associated with mitochondrial FAO (such as Cpt1a) and resulted in enhanced palmitate oxidation in hTERT RPTECs. In vivo, MTB-2 reduced plasma and urinary biomarkers of AKI at 24 and 48 hours. To elucidate the mechanism by which MTB-2 modulation of PPARδ improved AKI we measured expression of proximal tubulec abundance, mitochondrial homeostasis, kidney injury and fibrosis genes at 48 hours and 14 days post AKI. At 48 hours MTB-2 resulted in partial restoration of proximal tubules denoted by increased expression of PTC genes; this effect was maintained through 14 days post AKI. At the same time points, PPARδ modulation mitigated IR-induced reduction of genes regulating mitochondrial transcription such as PGC1α and many nuclear and mitochondrial-encoded transcripts of electron transport chain proteins. At both 48 hours and 14 days post AKI MTB-2 decreased the expression of kidney injury genes KIM-1and NGAL. Genes associated with fibrosis, such as, Col1a1, were induced at 14 days post AKI and MTB-2 treatment attenuated their upregulation.

Conclusions: Selective PPARδ modulation by MTB-2 after AKI in rats recovered renal function through preservation of proximal tubular and mitochondrial gene expression and reduction of kidney injury and profibrotic genes.

TH-PO340

Proximal Tubule DRP1 Deletion after AKI Promotes Recovery Heather M. Perry, Amandeep Bajwa, Liping Huang, Mark D. Okusa. *Medicine, University of Virginia, Charlottesville, VA.*

Background: Mitochondrial dysfunction plays a crucial role in the pathogenesis of kidney disease. A key mediator of mitochondrial function is the GTPase, dynamin related protein 1 (DRP1). The cell specific role of DRP1 during recovery from acute kidney injury (AKI) is unknown. Proximal tubule (PT) cells are highly dependent on

promoting mitochondrial function in proximal tubule cells during recovery from AKI may prevent kidney dysfunction and progressive fibrosis. Thus, we hypothesize that the spatio-temporal genetic deletion of DRP1 in proximal tubules after ischemia-reperfusion injury (IRI) promotes kidney recovery in mice.

Methods: *iSLC34a1CreER*^{T2} *Drp1*$^{fl/fl}$ (iDrp1 PTKO, n = 8) and littermate control *iSLC34a1CreER*^{T2} *Drp1*$^{wt/wt}$ (n = 5) mice were subjected to unilateral renal ischemia. Tamoxifen was initiated 3d later to induce deletion of DRP1 followed by a nephrectomy of the un-operated kidney at 13d and mice were euthanized on day 14. Plasma was collected for creatinine (PCr) measurement and kidneys were prepared for histology to assess renal injury by H&E, fibrosis by picro-sirius red and Masson's trichrome, and detection of myofibroblasts, macrophages and endothelial rarefaction by IF. Total kidney tissue mRNA levels of fibrosis markers, *SMA, Col1a1, Col3a1, Fn,* and *Vim* were measured by RT-qPCR. Mitochondrial function was assessed by Seahorse.

Results: iDrp1 PTKO mice had attenuated IRI-induced PCr levels compared to control mice (1.10 vs. 0.21 mg/dl respectively, $p < 0.05$). Consistent with preserved kidney function, iDrp1 PTKO mice had attenuated renal injury compared to controls. Histological measures of fibrosis and transcript levels of fibrosis markers were also reduced in IRI kidneys of iDrp1 PTKO mice compared to controls. Hallmarks of fibrosis including myofibroblast formation, macrophage infiltration and capillary rarefaction were attenuated in IRI kidneys of iDrp1 PTKO mice compared to control mice. Lastly, primary proximal tubule cells lacking DRP1 had enhanced mitochondrial function.

Conclusions: Loss of DRP1 after IRI allows for epithelial cells to recover and prevent kidney dysfunction and progressive fibrosis. Targeting DRP1 and mitochondrial function may be an effective therapeutic strategy to allow for epithelial recovery after AKI.

Tubular BMPR1A-SMAD1/5/8-ID Signaling Mediates Renal Recovery via Inhibition of Profibrotic Processes after Ischemia-Reperfusion Injury Emilia Vigolo,[2] Lajos Marko,[1,4] Christian Hinze,[2,3] Dominik N. Müller,[2,1] Ruth Schmidt-ullrich,[2] Kai M. Schmidt-Ott.[2,3] *[1]Experimental and Clinical Research Center, Berlin, Germany; [2]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [3]Charité University, Berlin, Germany; [4]Berlin Institute of Health (BIH), Berlin, Germany.*

Background: The signaling pathways that mediate renal recovery after acute kidney injury (AKI) constitute potential targets of pharmacologic intervention. Bone morphogenetic protein (BMP) signaling has been previously implicated in preventing profibrotic responses in the injured kidney, but its detailed role and molecular targets after AKI are incompletely understood. We therefore addressed the time course, molecular targets and cellular functions of BMP signaling after experimental AKI.

Methods: A unilateral ischemia reperfusion injury (IRI) mouse model was used to investigate renal regeneration. The modulation of BMP signaling after IRI was monitored in kidney tissue by examined the nuclear expression pattern of phosphorylated BMP-specific transcription factors SMAD1/5/8 (pSMAD1/5/8) using immunostaining and Western blotting. To study the role of BMP signaling in tubules, we generated a tubular-specific and injury-dependent BMP type 1A receptor (BMPR1A) knock-out (*Bmpr1a cKO*) mouse model. Tubular injury and inflammation were evaluated by renal histology, and immunostaining for infiltrating neutrophils and macrophages. Tubulointerstitial fibrosis was examined by Masson's trichrome staining and collagen IV Western blotting. pSMAD1/5/8 chromatin immunoprecipitation (ChIP-) and RNA-sequencing were performed to discover novel BMP targets during renal recovery.

Results: We observed that BMP signaling was transiently down-regulated during early injury phases and re-activated 7 days (d) after IRI, when the kidney is undergoing recovery. However, the *Bmpr1a cKO* kidneys failed to re-activate pSMAD1/5/8 and displayed an aggravated tubular injury and increased inflammation when compared to controls. 21 d after IRI the *Bmpr1a cKO* kidneys presented enhanced tubulointerstitial fibrosis. Comparative analyses between ChIP- and RNA-sequencing data revealed genes encoding inhibitor of DNA-binding (ID) proteins *Id1, Id2, and Id4* as direct targets of BMP signaling during regeneration. Down-regulation of *Id* genes in *Bmpr1a cKO* kidneys was associated with activation of profibrotic factors, including P38 mitogen-activated kinase (MAPK), P21 and P27.

Conclusions: Successful recovery after ischemia-induced AKI is mediated by BMPR1A-SMAD1/5/8-ID signaling that prevents activation of profibrotic pathways.

Sphingosine-1 Receptor Agonist SEW2871 Ameliorates Contrast-Induced Nephropathy in Rats Abdullah Shbair,[3] Seda Kutlug Agackiran,[3] Zarife Ozdemir,[2] Ozlem Tugce Cilingir Kaya,[1] Naziye Ozkan,[1] Sule Cetinel,[1] Berrak Yegen,[2] Mehmet Koc.[3,2] *[1]Marmara University Medical Faculty, Department of Histology, Istanbul, Turkey; [2]Marmara University Medical Faculty, Department of Physiology, Istanbul, Turkey; [3]Marmara University Medical Faculty, Department of Internal Medicine, Istanbul, Turkey.*

Background: With a dramatically increasing incidence in today's medicine, contrast-induced nephropathy (CIN) is the third common cause of acute kidney injury (AKI). Mechanisms of CIN include renal medullary hypoxia, endothelial injury, oxidative stress and direct tubular toxicity of contrast agents. A sphingosine-1 receptor agonist SEW2871 has been shown to prevent ischemia-induced AKI. In this study, we aimed to demonstrate the effects of SEW2871 on CIN.

Methods: Male Sprague-Dawley rats were injected intraperitoneally with only saline (control group, n=8), while CIN groups were treated with either saline (SL, n=9) or SEW2871 (10 mg/kg/day, n=7) at 0, 24 and 48 hours of the experiment. CIN was established by intravenously injecting indomethacin (10 mg/kg), L-NAME (10 mg/kg) and a high-osmolar contrast agent (Urografin 76%, 6 ml/kg) at 24th h of the experiment. On the 72nd h, kidneys were removed for the assessment of histopathological changes and the determination of glutathione levels and myeloperoxidase activity. Data were analyzed using ANOVA and Student's t-test.

Results: Serum creatinine and BUN levels in SL- and SEW2871-treated CIN groups were elevated as compared to control group ($p<0.05$-0.01), while the increases in SEW2871-treated group were relatively lower. In contrast to depressed 24-h creatinine clearance in SL-treated CIN group ($p<0.05$), clearance in SEW2871-treated group was not different than that of the control group. CIN-induced increase in renal myeloperoxidase activity ($p<0.01$) was abolished in SEW2871-treated group ($p<0.05$), while renal glutathione content was increased with SEW2871 ($p<0.001$). However, histopathological damage scores obtained by light microscopic examination were similar in SEW2871- or SL-treated CIN groups.

Conclusions: The present data demonstrate that CIN is ameliorated by administration of SEW2871, which appears to act, in part, by diminishing oxidative stress via the inhibition of neutrophil infiltration.

Renal Cholesterol Rafts Blockade Ameliorates Septic Multiorganic Failure Alberto Lazaro Fernandez,[3,4] Maria angeles GONZALEZ-NICOLAS GONZALEZ,[3,4] Blanca Humanes,[3,4] Raquel Herrero,[1,5] Mario Arenillas,[2] Antonio Ferruelo,[1,5] José Á. Lorente,[1,5] Alberto Tejedor jorge.[3,6] *[1]Critical Care Department, Hospital Universitario de Getafe, Madrid, Spain, Getafe, Madrid, Spain; [2]Hospital Universitario de Getafe, Madrid, Spain, Getafe, Spain; [3]Renal Physiopathology Lab, Instituto de Investigación Sanitaria Gregorio Marañón, Hospital G.U. Gregorio Marañón, Madrid, Spain, Madrid, Spain; [4]REDinREN, Madrid, Spain, Madrid, Spain; [5]CIBERES, Madrid, Spain, Madrid, Spain; [6]Department of Medicine, Universidad Complutense, Madrid, Spain, Madrid, Spain.*

Background: Sepsis is a potentially life-threatening condition that occurs due to systemic inflammatory response to infection that leads to organ failure and death. Acute kidney injury (AKI) has been reported as a particularly serious complication in patients with severe sepsis, where it is the leading cause of death among critically ill patients. In fact, the mortality of septic patients with AKI is about 75%, while those with severe sepsis without AKI ranges between 27 and 32%. Cilastatin, a renal dehydropeptidase-I inhibitor has shown its usefulness in the protection of AKI induced by nephrotoxic drugs due to disruption of lipid rafts cycling. Here, we evaluated the utility of cilastatin as a protector against renal damage induced by sepsis and its effect on survival.

Methods: Sepsis was developed on male Sprague-Dawley rats by cecal ligation puncture model (CLP). The animals were divided into 4 groups: SHAM, CLP, SHAM+cilastatin and CLP+cilastatin. Cilastatin (150 mg/kg bw, i.p.) was administered immediately and at 24h after induction of sepsis. Renal damage was evaluated 48h after surgery by measuring serum creatinine, BUN, glomerular filtration rate (GFR), proteinuria, renal injury biomarker KIM-1 and renal morphology. Survival was evaluated in another CLP model with greater perforation thickness, in the presence and absence of cilastatin.

Results: Sepsis increased serum creatinine, BUN and proteinuria levels and decreased the GFR in comparison with the sham groups. These renal effects of sepsis were confirmed by the increased of the acute kidney injury biomarker KIM-1 at protein level and the presence of severe morphological changes such as swelling of tubular cells, and hyaline cast in the tubular lumen. Treatment with cilastatin completely prevented renal dysfunction, restored KIM-1 into control levels, and reduced many of the histologic symptoms of renal damage. Importantly, these protective effects of cilastatin at the renal levels caused a decrease in mortality by 33%.

Conclusions: Our findings support the potential use of cilastatin as a useful drug in the treatment of sepsis, improving the AKI induced by it and preventing its lethality. Therefore, it could be a very beneficial therapeutic strategy for septic patients susceptible to renal damage in clinical practice.

Autophagy Activation in Circulating Proangiogenic Cells (PAC) Aggravates Interstitial Fibrosis Post-AKI in Type I Diabetes Mellitus Daniel Patschan,[2] Gerhard A. Mueller.[1] *[1]Georg-August University, Gottingen, Germany; [2]Department of Cardiology, Pulmology, Angiology and Nephrology, Brandenburg Medical School, Brandenburg an der Havel, Germany.*

Background: Diabetes mellitus increases the risk for AKI under experimental and clinical conditions. Circulating proangiogenic cells (PAC) have been proven as effective tool in ischemic AKI in recent years. Autophagy (AP) serves as endogenous mechanism of self-defense in situations of increased metabolic stress. Aim of the study was to analyze consequences of AP activation in syngeneic murine PAC, administered to diabetic animals suffering from ischemic AKI.

Methods: Insulin-dependent diabetes was induced in male, 8-12 weeks old C57/Bl6N mice by repeated i.p. injection of streptozotocin. Six weeks later, AKI was induced by bilateral renal ischemia of 45 minutes. Animals were injected with either untreated or pharmacologically preconditioned murine PAC (10^6) at the time of reperfusion.

Preconditioning was performed with zVAD or MD132, two established AP inducers. Animals were analyzed 48 hours and 6 weeks later.

Results: Excretory function (serum cystatin C) – ischemia induced significant kidney dysfunction in the short-term (48 h), IDDM aggravated this situation even further. Cell therapy did neither attenuate nor aggravate AKI. At week 6, excretory dysfunction remained affected in non-diabetic and diabetic mice without cell therapy. Administration of both, zVAD and MD132 pretreated PAC resulted in aggravated dysfunction in non-diabetic animals, serum cystatin C was lower in diabetic mice receiving zVAD treated PAC. Fibrosis – at 48 h, significant interstitial matrix accumulation was exclusively detected in diabetic mice receiving MD132 treated cells. At week 6 however, fibrosis occurred in almost every group with two exceptions (non-diabetic and diabetic AKI +native PAC). The morphological findings were most pronounced in diabetic mice undergoing treatment with preconditioned cells. EndoMT – mesenchymal transition of endothelium cells was detected in a significant manner in the following groups: 48 h – IDDM + zVAD and + MD132; 6 weeks – IDDM + MD132.

Conclusions: zVAD-/MD132-induced AP activation in PAC does not result in any functional improvement in diabetic AKI. Postischemic structural abnormalities however are being aggravated. Thus, pharmacological stimulation of autophagy in PAC has not been identified as effective strategy for improving the cells′ renoprotective capacity in diabetic AKI.

The Striking Finding of Multiciliated Proximal Tubular Cells in Patients with Tubular Injury Jennifer Eymael,[1] Brigith Willemsen,[1] Fieke Mooren,[1] Jack F. Wetzels,[2] Henry Dijkman,[1] Johan Van der vlag,[2] Bart Smeets.[1] *[1]Pathology, Radboudumc, Nijmegen, Netherlands; [2]Nephrology, Radboudumc, Nijmegen, Netherlands.*

Background: Cilia are evolutionary highly conserved antennae-like structures with important functions in cell signaling and homeostasis. In kidney epithelial cells, one primary cilium per cell can be detected, which serves as flow sensor and consists of 9 peripheral microtubular doublets. Motile cilia can be found on multiciliated cells and additionally express a central microtubule pair, dynein arms and radial spoke proteins (e.g. RSPH4A) required for ciliary motion. Motile cilia assembly involves activation of the transcription factors FOXJ1 and RFX3. In this study, the unexpected detection of multiciliated cells in patients with tubular injury was evaluated.

Methods: Immunofluorescent staining was performed on patient biopsies with markers for cilia, specific tubular segments and for motile cilia (RSPH4A). In addition the expression of FOXJ1 and RFX3 was studied. The ciliary ultrastructure was analyzed by transmission electron microscopy.

Results: Multiciliated cells were initially detected in five patients. All patients were affected by tubular injury with different underlying pathologies. Multiciliated cells were localized in the proximal tubule. Furthermore, cilia on multiciliated cells stained positive for RSPH4A and the motile cilia structure (9+2) was detected by transmission electron microscopy. Co-expression of FOXJ1 and RFX3 in multiciliated cells was observed, indicating activation of motile cilia assembly. Analysis of additional biopsies from 20 patients with severe tubular injury revealed the presence of multiciliated cells in 4 cases (20%).

Conclusions: Multiciliated proximal tubular cells with motile cilia were frequently observed in patients with tubular injury. The mechanism underlying this phenomenon and the possible function of multiciliated cells in the kidney, need further investigation.

Highly Specific RIPK1 Inhibition Significantly Improves Renal Ischemia Reperfusion Injury in Mice Kevin M. Gallagher,[5] Ewen M. Harrison,[4] Jeremy Hughes,[3] James A. Ross,[4] Lorna Marson,[2] Sheryl Beh,[4] Allison M. Beal,[1] John Bertin,[1] Stephen J. Wigmore.[4] *[1]GlaxoSmithKline, Collegeville, PA; [2]Queen's Medical Research Institute, Edinburgh, United Kingdom; [3]The Queens Medical Research Institute, Edinburgh, United Kingdom; [4]University of Edinburgh, Edinburgh, United Kingdom; [5]University of Edinburgh, Edinburgh, United Kingdom.*

Background: Non-specific RIPK1 inhibition with Nec-1, is beneficial in murine ischemia reperfusion injury (IRI). It is not known if tubular epithelial cells (TECs) undergo necroptosis nor how RIPK1 inhibition is beneficial. We aimed to determine if a novel, highly specific RIPK1 inhibitor (GSK963a) is beneficial in murine IRI and determine if TECs undergo necroptosis during IRI.

Methods: Mice were subjected to 23m (severe injury) bilateral renal vascular clamp then 24h reperfusion. Outputs included: Serum urea and creatinine; acute tubular necrosis(ATN) scoring and immunofluorescent(IF) staining of phosphorylated mixed lineage kinase like domain protein (pMLKL) (end effector of necroptosis) using MLKL phospho-S345 specific antibody. Dephosphorylation controls confirmed phospho-specific staining. The effect of GSK963a on TEC (HK2 cell line) viability, cytotoxicity and mitochondrial health (mito-tracker red) was also assessed in in-vitro models of TEC ischemic injury.

Results: GSK963a significantly reduced creatinine (131 umol/L (95%CI 134-175) vs 174 umol/L (154-194) p=0.01 N=7) and ATN score (Mean 3.29/4 (95% CI 2.83-3.74) vs 1.75/4 (1.16-2.34)p=0.008) compared to vehicle. Results with Nec-1s were similar. pMLKL was detected extensively with IF in injured moderately injured tubules (15m ischemia) but not glomeruli. With severe IRI (23 minutes), pMLKL was also detected within glomeruli. In-vitro, GSK963a significantly decreased TEC death in an ATP depletion and glucose deprivation model (12h injury % cell death (CellToxGreen) was: Vehicle: 67.2% (95%CI 62.8-71.5) vs GSK963a: 40.4% (34.3-46.5) N=6 p=<0.001). GSK963a also reduced mitochondrial perinuclear condensation and loss of membrane potential after 1.5 hours of physical hypoxia and glucose deprivation in HK2 cells (N=3).

Conclusions: Highly specific RIPK1 inhibition significantly improves biochemical and histological injury in severe murine IRI. We provide preliminary evidence that renal tubular cells undergo necroptosis in IRI.

Controlled Blood Pressure Increases the Appearance of Angiogenic Hemodialysis Patient-Derived Cells In Vitro Brooke M. Huuskes,[2] Ryan J. Debuque,[3] Kevan Polkinghorne,[1] Peter G. Kerr,[1] Chrishan S. Samuel,[4] Sharon D. Ricardo.[2] *[1]Department of Medicine, Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [2]Biomedical Discovery Institute, Department of Anatomy and Developmental Biology, Monash University, Clayton, VIC, Australia; [3]Australian Institute of Regenerative Medicine, Monash University, Clayton, NSW, Australia; [4]Biomedical Discovery Institute, Department of Pharmacology, Monash University, Clayton, VIC, Australia.*

Background: Endothelial progenitor cells (EPCs) are present in lower numbers in kidney disease patients who are dialysis-dependent and can be used to predict adverse cardiovascular events. The function of EPCs can be measured using colony forming unit (CFU) assays and the appearance of late outgrowth endothelial cells (OECs) *in vitro.* Specific clinical parameters can affect EPC function, yet less is known about the relationship between clinical observations and OEC function. Therefore the aim of this study was to determine if the appearance of OECs derived from dialysis-dependent patients was influenced by their clinical history.

Methods: Dialysis-dependent patients (n=20) were recruited to this study; and their age, time on dialysis, blood pressure (BP), erythropoietin (EPO), statin use and smoking status was collected as these parameters have previously demonstrated to affect circulating EPC levels. Blood (10mls) was obtained prior to a single dialysis session and peripheral blood mononuclear cells isolated and cultured. After 7 days CFU was

assessed, then cells were further cultured for 21 days or until OECs appeared (identified by cobblestone morphology).

Results: The patient cohort had a mean age of 64.2(±15.5) years and 80% were male. The mean time on hemodialysis was 46 months (±69.6) and blood pressures of 139.1(±27.1)/75.2 (±18.9). Half of the patients received EPO, 30% were administered statins and 65% had a history of or were current smokers. Circulating %EPC of patients receiving EPO was significantly lower then patients who were not (mean diff. 1.487±0.538, 95% CI 0.3-2.7. p=0.0184) and high systolic blood pressure was negatively correlated with %EPC (r=-0.59, p=0.033). We observed a 45% conversion of EPCs to OECs, which was not dependent on starting %EPC (p=0.19). Both systolic (mean diff. 24.95mmHg, 95% CI 1.7-48.1, p=0.0365) and diastolic (mean diff. 18.9, 95%CI 3.2-34.6, p=0.0208) blood pressures were significantly lower in patients when OECs appeared.

Conclusions: BP affects dialysis-dependent patient-derived OEC numbers in culture, suggesting that controlling BP may be key to maintaining vascular health in patients on dialysis.

Associations of Biomarkers of Angiogenesis with AKI and Mortality Post-Cardiac Surgery Sherry Mansour,[6] William R. Zhang,[4] Dennis G. Moledina,[6] Steven G. Coca,[1] Yaqi Jia,[7] Heather Thiessen Philbrook,[7] Jay L. Koyner,[5] Michael Shlipak,[3] Francis P. Wilson,[6] Amit X. Garg,[2] Chirag R. Parikh.[8] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]London Health Sciences Centre, London, ON, Canada; [3]San Francisco VA Medical Center, San Francisco, CA; [4]UCSF School of Medicine, San Francisco, CA; [5]University of Chicago, Chicago, IL; [6]Yale School of Medicine, New Haven, CT; [7]Yale University, New Haven, CT; [8]Yale University and VAMC, New Haven, CT.*

Background: Angiogenesis is a process of new blood vessel formation after renal injury. We hypothesize that unimpeded angiogenesis following acute kidney injury (AKI) leads to maladaptive repair resulting in poor long-term outcomes.

Methods: We tested the association of a panel of angiogenesis biomarkers with AKI and 1-year mortality in 1444 adult participants who underwent cardiac surgery from the TRIBE-AKI cohort. Using Mesoscale Discovery multiplex assay, we measured adaptive repair biomarkers, placental growth factor (PlGF) and vascular endothelial growth factor (VEGF), and maladaptive repair biomarker VEGF receptor 1 (VEGFR1) from plasma samples collected before (preoperative) and 0-6 hours after (postoperative) surgery. We defined AKI using AKIN stage 1 criteria, and evaluated 1-year all-cause mortality.

Results: A total of 492 developed AKI and at one year 81 died. Among the preoperative biomarkers, VEGF was independently associated with higher odds of AKI OR 1.19 (95% CI: 1.02, 1.39) but none of the preoperative biomarkers were associated with mortality. Each log increase of postoperative PlGF and VEGF was independently associated with lower odds of AKI, whereas each log increase of postoperative VEGFR1 had higher odds of AKI (**Table**). Each log increase of postoperative PlGF and VEGF was also independently associated with 44% and 20% lower odds of one-year mortality, respectively, whereas each log increase of postoperative VEGFR1 had a 2-fold increase in odds of mortality (**Table**). There was no interaction between angiogenesis biomarkers and mortality by AKI status. Preoperative and postoperative biomarkers were weakly correlated.

Conclusions: Although there was a slight increase in odds of AKI with higher preoperative VEGF, higher postoperative levels of adaptive repair biomarkers PlGF and VEGF were significantly associated with improved renal outcomes and reduced mortality whereas higher postoperative levels of maladaptive repair biomarkers VEGFR1 were associated with worse renal outcomes and higher mortality.

Postoperative Biomarkers	Adjusted odds ratio for each log increase in biomarker (95% Confidence Interval)	
	AKI*	1-year all-cause mortality^
Adaptive Repair	-	-
PlGF	0.69 (0.55, 0.87)	0.56 (0.38, 0.83)
VEGF	0.89 (0.82, 0.98)	0.80 (0.66, 0.96)
Maladaptive Repair	-	-
VEGFR1	1.56 (1.31, 1.87)	1.84 (1.28, 2.65)

*Adjusted for 13 clinical variables + pre-operative biomarker concentration.

A Rare Case of Secondary Amyloidosis with Kidney and Colon Involvement in Chordoma Ali Ziaolhagh,[4] Umut Selamet,[1] William F. Glass,[5] Amanda Tchakarov,[3] Ala Abudayyeh.[2] *[1]MD Anderson Cancer Center, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX; [3]University of Texas Medical School at Houston, Houston, TX; [4]University of Texas health Science Center at Houston, Housotn, TX; [5]University of Texas – Houston Medical School, Houston, TX.*

Background: Amyloidosis is characterized by extracellular deposition of abnormal proteins. Secondary Amyloidosis (AA) is associated with infectious, inflammatory and malignant diseases. Among neoplastic diseases, AA is mostly associated with renal cell carcinoma, Gastrointestinal (GI) stromal tumors, and intestinal carcinomas

Methods: We present a case of AA with GI and kidney involvement due to sacral chordoma. Patient presented with diarrhea and proteinuria. Colonoscopy showed severe colitis. Pathology findings suggested amyloidosis. He had nephrotic range proteinuria, renal biopsy showed amyloidosis with no monoclonal deposition and confirmed to be secondary with mass spectrometry. He had extensive diarrhea and history of recurrent ileus. He presented with normal renal function, but due to ongoing diarrhea, he had hypotension and developed acute renal failure.

Results:

Conclusions: Secondary amyloidosis in association with cancers are reported as case-reports in the literature. However, to the best of authors' knowledge, chordoma has never been reported as a cause of AA with severe systemic disease.

TH-PO350

A Case of Drug-Induced Acute Tubular Necrosis Associated with Focal Necrotizing Vasculitis in Veins and Periglomerular Arterioles Shintaro Masuko, Miho Karube, Hikaru Kukimoto, Hideki Shimizu, Shinya Kaname. *Kyorin University School of Medicine, Tokyo, Japan.*

Background: Although NSAIDs-induced acute tubular necrosis and tubulointerstitial nephritis are well known, drug-induced vasculitis including veins is rarely reported.

Methods: A 38 year-old female noticed headache and slight fever a week ago and received several medication including NSAIDs and antibiotics. Afterwards, she developed leg edema and oliguria and was admitted to a local hospital because of acute kidney injury with serum UN 87.4 mg/dL and Cr 9.06 mg/dL. The urinalysis showed urine protein 1+, RBC 0-1/HPF, WBC 20-29/HPF and some granule casts, with increased urinary NAG 13.6 U/L and β2-microglobulin 1,266 μg/L. The renal function deteriorated and hemodialysis was begun. She was transferred to our hospital and kidney biopsy was performed, showing acute tubular injury with diffuse tubular cell ballooning and atrophy, peritubular capillaritis and interstitial changes with a focal infiltration of lymphocytes and plasma cells. Interestingly, periglomerular vasculitis of efferent arteries and also granulomatous vasculitis in a part of the veins. The immunofluorescence study was negative. Renal function improved, and later DLST test for loxoprofen turned out to be positive.

Results:

Conclusions: We here reported a rare case of acute tubular necrosis and tubulointerstitial nephritis with vasculitis that is localized in periglomerular arterioles and veins with granulomatous lesion that may be induced by NSAIDs.

TH-PO351

Endothelial STAT3 Modulates Protective Mechanisms in a Mouse Model of AKI Shataakshi Dube,[3,1] Tejasvi Matam,[1] Jessica Yen,[2,1] Pierre C. Dagher,[1] Takashi Hato,[1] Timothy A. Sutton.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Jackson Memorial Health Systems, Miami, FL; [3]Duke University, Durham, NC.*

Background: Acute kidney injury (AKI) is a common clinical entity with devastating consequences. STAT3 is a transcriptional regulator that plays an important role in coordinating inflammation and there is a growing appreciation of the role STAT3 signaling plays in the response to organ injury following diverse insults. Since it is well recognized that endothelial alterations contribute to organ dysfunction in AKI, in this study we examine the role of endothelial STAT3 in a model of ischemic AKI.

Methods: A mouse with the genetic deletion of Stat3 restricted to the endothelium (eStat3-/-) was used to examine the role of endothelial STAT3 signaling in a bilateral renal artery clamp (BAC) model of ischemic AKI.

Results: Mean serum creatinine 24 hours after BAC was significantly higher in eStat3-/- mice (3.0+0.2 mg/dL) as compared to background C57BL/6 mice (1.2+0.9 mg/dL; $p<0.05$). Histologic damage was also significantly greater in the eStat3-/- mice with mean tubular damage scores of 3.7+5 in the eStat3-/- mice and 2.3+0.9 in the background C57BL/6 mice ($p<0.05$). Proximal tubular oxidant stress as determined by intravital imaging of carboxy-DCFDA fluorescence was 25% higher in eStat3$^{-/-}$ mice as compared to C57BL/6 mice ($p<0.05$). Heme oxygenase-1 (HO-1), a critical mediator of protective adaptations in the proximal tubule exposed to oxidant stress, and the expression of IL-22, a key promoter of tubular HO-1, were both significantly decreased in eStat3-/- mice as compared to C57BL/6 mice ($p<0.05$). Given the contribution of inflammation to oxidant stress and tubular injury during AKI and the coordinating role the microvascular endothelium plays in these responses, we examined the impact of endothelial Stat3 deletion on microvascular leukocyte trafficking and tissue leukocyte composition in this model of AKI. Leukocyte adherence to the microvascular endothelium as measured by intravital microscopy was 2-fold greater in eStat3-/- mice as compared to C57BL/6 mice ($p<0.05$); however, there was no significant difference in macrophage tissue infiltration between eStat3-/- and C57BL/6 mice.

Conclusions: These findings suggest the endothelial STAT3 signaling plays an important role in limiting kidney dysfunction in ischemic AKI and that selective pharmacologic activation of endothelial STAT3 signaling could serve as a potential therapeutic target.

Contrast-Enhanced Ultrasound for Assessing Renal Perfusion Impairment and Predicting AKI to CKD Progression Wei Cao. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Acute kidney injury (AKI) is increasing recognized as a major risk factor leading to progression to chronic kidney disease (CKD). However, the diagnostic tools for predicting AKI to CKD progression are particularly lacking. Here, we tested the utility of contrast enhanced ultrasound (CEUS) for predicting progression to CKD after AKI.

Methods: Mice treated with 20 or 45 min ischemia-reperfusion injury (IRI) was served as mild or severe AKI. Renal perfusion was evaluated by CEUS. Kidney morphological injury and function were assessed. We further measured renal perfusion by CEUS in patients who admitted for acute decompensated heart failure (ADHF) with or without AKI-CKD progression.

Results: Renal perfusion measured by CEUS reduced to 25%±7% and 14%±6% of the pre-ischemic levels in mild and severe AKI 1 hour after ischemia ($P<0.05$). Renal perfusion returned to pre-ischemic levels 1 day after mild AKI followed by restoration of kidney function. While severe AKI caused persisted renal perfusion impairment (60%±9% of baseline levels) accompanied by progressive renal fibrosis and sustained decrease in renal function. Renal perfusion at day 1-21 significantly correlated with tubulointerstitial fibrosis 42 days after AKI. For predicting renal fibrosis at day 42, the area under receiver operating characteristics curve of renal perfusion impairment at day 1 was 0.84. Similar changes in renal image of CEUS were observed in patients with AKI-CKD progression. By using microbubbles targeted to P-Selectin, CEUS was able to quantify the severity of renal microvascular injury after AKI.

Conclusions: These results indicate that CEUS enables the evaluation of renal perfusion impairment associated with CKD after ischemic AKI and may serve as a noninvasive technique for assessing AKI-CKD progression.

Tubule Specific Deletion of Cullin 3 Causes Cell Cycle Dysregulation and Kidney Fibrosis Turgay Saritas,[7,6] Catherina A. Cuevas,[8] Christoph Kuppe,[5] Rafael Kramann,[4] Marcus J. Moeller,[3] Jeffrey Singer,[2] Jürgen Floege,[1] James A. McCormick.[7] *[1]University Hospital RWTH Aachen, Aachen, Germany; [2]Portland State University, Portland, OR; [3]University Hospital RWTH Aachen, Aachen, Germany; [4]University Hospital RWTH Aachen, Aachen, Germany; [5]University Hospital RWTH Aachen, Aachen, Germany; [6]University Hospital RWTH Aachen, Aachen, Germany; [7]Oregon Health & Science University, Portland, OR; [8]Oregon Health & Science University, Portland, OR.*

Background: Cell cycle dysregulation is involved in the pathogenesis of acute kidney injury and kidney fibrosis, but the molecular details are still poorly understood. Cullin 3 (Cul3) is part of an E3 ubiquitin ligase which controls protein abundance by promoting proteasomal degradation. Cul3-dependent ubiquitination has emerged as a key mechanism to control various critical cellular processes including cell cycle progression.

Methods: We characterized the time-course of kidney fibrosis after tubule-specific deletion of Cul3 in adult mice (doxycyline-inducible Pax8-rtTA-LC1 system) using Western blot, immunofluorescence (IF) and immunohistochemistry (IHC). In addition, Cul3 expression was analysed in different mouse models of kidney fibrosis (unilateral ureteral obstruction (UUO), ischemia/reperfusion injury (IRI) and nephrotoxic nephritis (NTN)).

Results: Cul3 deletion caused progressive loss of kidney function within weeks and death at around 7-8 months. At 2 weeks after induction of Cul3 deletion, mice developed progressive tubular injury and were positive for NGAL and KIM-1 staining. At the same time-point, Cul3 substrates cyclin E (+62%, $p<0.05$) and p21 (+474%, $p<0.005$) were significantly increased, but p27 was reduced (-75%, $p<0.05$) by Western blot analysis. This was associated with increased tubular expression of cell cycle proliferation markers (cyclin D1 (5.2-fold), Ki67 (3.9-fold), PCNA (17.6-fold)), and also the G2/M pH3 (5.8-fold), using IF and IHC. 4 weeks after induction of Cul3 deletion, PAS/H&E-stained sections revealed loss of brush borders, tubule dilation, necrotic cell cast formation, caspase-3-positive apoptosis and interstitial inflammation (e.g. CD3-positive cells (14.7-fold)). Cul3-deficient tubules were adjacent to areas of increased extracellular matrix accumulation (30% and 18% of area positive for picrosirius red and alpha-smooth muscle actin (aSMA), respectively, $p<0.001$). In UUO, IRI and NTN, we observed reduced tubular Cul3 expression in areas where peritubular expression of aSMA was increased.

Conclusions: These data suggest a critical role for Cul3 in epithelial cell cycle dysregulation, dedifferentiation and the development of kidney fibrosis. Thus, Cul3 might be a promising novel therapeutic target in AKI to CKD transition and fibrosis development.

Extracellular YB-1, as Signal of Tissue Damage, Induces Mesangial Cell Migration and Proliferation Sabine Brandt, Florian G. Scurt, Jonathan A. Lindquist, Peter R. Mertens. *Otto-von-Guericke University, Magdeburg, Germany.*

Background: The Y-box protein-1 (YB-1) is the prototypic member of the cold shock protein family of RNA/DNA binding proteins. Recent findings indicate acetylation-dependent secretion of YB-1 via a non-classical pathway and profound extracellular effects mediated by Notch-3 receptors.

Methods: Here we determined changes in gene expression and proliferation in rat mesangial cells following stimulation with recombinant YB-1, truncated YB-1, and peptides corresponding to domains of YB-1.

Results: Stimulation of mesangial cells with recombinant YB-1 resulted in an up-regulation of defined target genes and surprisingly even YB-1 itself. Further analysis revealed that recombinant YB-1 is capable of enhancing proliferation and migration rates. We also confirmed the chemokine activity using human peripheral blood mononuclear cells in a Boyden chamber assay. YB-1 significantly increases the specific migration of cells compared to the basal rate. Additionally, subcutaneous injection of recombinant YB-1 induced immune cell infiltration. Furthermore activation of monocytes with pro-inflammatory stimuli induces the secretion of YB-1.

Conclusions: Taken together, our results indicate a feed-forward loop with activation of signaling cascades by extracellular YB-1 that results in the phosphorylation of Akt, MAPK/ERK, and STAT proteins, up-regulation of YB-1 expression and target gene regulation, as well as an increase in cell proliferation and migration. Thus, we identify extracellular YB-1 as potent extracellular mediator of cell activation in inflammatory diseases.

Proximity-Ligation Assay Identified the Rho Guanine Nucleotide Exchange Factor, β-PIX, as a Rac1-Interactor in Podocytes Mirela Maier,[1] Lamine Aoudjit,[1] Cindy Baldwin,[2] Tomoko Takano.[3] *[1]McGill University, Montreal, QC, Canada; [2]McGill university, Montreal, AB, Canada; [3]None, Montreal, QC, Canada.*

Background: Hyperactivity of Rac1 (a small GTPase) in podocytes has been implicated in the development of proteinuria and focal segmental glomerulosclerosis (FSGS). We sought to identify guanine nucleotide exchange factors (GEFs) that activate Rac1 in podocytes.

Methods: BioID, a proximity-based ligation assay, was used to identify Rac1-GEFs in human podocytes (HP). This assay consists of HP expressing a bait, Rac1G15A (a mutant of Rac1 reported to have high affinity to active GEFs), conjugated to a biotin ligase, BirA (BirA-Rac1G15A). BirA alone was used as control. HP were incubated with biotin for 18 hours in the culture medium, and biotinylated proteins (i.e. proteins that have come in close proximity of Rac1G15A) were isolated with streptavidin-beads and identified by mass spectroscopy. Active Rac1 was visualized with immunofluorescence staining (IF) and quantified using CRIB pulldown (PD). β-PIX binding to Rac1 was determined by PD with GST-Rac1, followed by immunoblotting (IB).

Results: BioID identified 5 GEFs in BirA-Rac1G15A expressing HP; β-PIX was by far the most abundant and the only one whose quantity was consistently enriched (20-fold or more) in three independent experiments, as compared with control cells expressing BirA alone. Thus, we proceeded to characterize β-PIX in podocytes. By IB, HP expressed only one isoform of β-PIX (75 kDa), whereas mouse podocytes (MP) expressed an additional isoform of 88kDa. These isoforms were verified by RT-PCR. By IF of kidney sections, β-PIX was expressed in human, mouse, and rat glomeruli, largely overlapping with nephrin and/or β1-integrin. By IF of un-stimulated MP, β-PIX was localized diffusely in the cytosol and at cell periphery, which, upon stimulation with epidermal growth factor (EGF), shifted to the tip of cellular projections, co-localizing with active Rac1. Biochemically, EGF increased Rac1 activity, and β-PIX binding to Rac1 by 5 and 10 minutes (5min: 1.56-fold ±0.24; 10min: 1.34-fold ±0.13, $n=5$, $p<0.05$).

Conclusions: BioID using RacG15A as bait identified β-PIX as a predominant Rac1-interactor in HP. β-PIX is expressed in podocytes, and its binding to Rac1 is modulated by EGF. Together, this data warrants further studies on the functional role of β-PIX in podocyte health and disease.

Toll-Like Receptor 8 and 10 Are Possibly Associated with Pathogenic Mechanisms of Idiopathic Nephrotic Syndrome Eriko Tanaka,[2] Miyuki Takagi.[1] *[1]Division of Nephrology, Tokyo, Japan; [2]Department of Pediatrics, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Idiopathic nephrotic syndrome (ISN) is still a disease of unknown cause, though many studies have been done to elucidate pathogenic mechanisms. Some studies suggest that disorder of immune system derived by toll-like receptor (TLR) is involved, however, expressions of TLRs in ISN patients are not fully examined.

Methods: We investigated RNA expressions of TLRs and its pathways in ISN patients. Total RNA was extracted from kidney biopsy specimens of each ISN patients. We performed RNA-sequencing and analyzed RNA expressions of TLRs and molecules related to TLR pathways.

Results: Three patients with ISN were enrolled in this study (P1, P2, and P3). At the time of kidney biopsy, proteinuria of P1 was decreasing and she achieved remission a few days after the biopsy. P2 and P3 had nephrotic range of proteinuria when they received kidney biopsy. Pathological diagnosis of both P1 and P2 was minor glomerular abnormality, while that of P3 was focal segmental glomerulosclerosis. We analyzed RNA expressions of patients and found that TLR 8 and TLR 10 were significantly low in P1 compared to those in P2 and P3. (Fold Change (FC) of P1 vs P2 and P1 vs P3 in TLR8 were -6.59 and -4.62, respectively, and FC in TLR10 were -25.38 and -40.03, respectively.) RNA expressions in TLR1, 2, 3, 4 and 9 showed no differences among the three patients. We explored the molecules in pathway of TLR8 and found that IRF7 and IRAK2, which

are the downstream molecules leading to type 1 interferon activation, are significantly low in P1 in comparison to those in P2 and P3. We next investigated expressions of molecules related to TLR10. On contrary to previous reports, RNA expressions of pro-inflammatory cytokines such as IL1β and IL-6 were significantly low in P1 who showed lower expression of TLR10, suggesting that TLR10 expression was secondary suppressed because of activation of pro-inflammatory cytokines.

Conclusions: The profile of RNA expressions in INS patients implies the possibility of TLR pathways' involvement in pathogenic mechanisms. Comparing the RNA expressions in INS patient in remission phase to INS patient in nephrotic phase revealed that pathways related to TLR8 and TLR10 may be associated with onset and remission of INS.

PolyIC Induces the Expression of Retinoic Acid-Inducible Gene I and Melanoma Differentiation-Associated Gene 5 in Podocytes and Modulates Inflammatory Responses and Podocyte Damage

Ikuyo Narita,[1] Michiko Shimada,[1] Takeshi Fujita,[1] Reiichi Murakami,[1] Norio Nakamura,[1] Moin Saleem,[2] Peter W. Mathieson,[2] Hirofumi Tomita.[1] *[1]Hirosaki University, Hirosaki, Japan; [2]University of Bristol, Bristol, United Kingdom.*

Background: Viral infection often exacerbates proteinuria and activation of innate immunity in renal cells is suggested as pathogenesis. As well as some of the toll-like receptors, retinoic acid-inducible gene-I (RIG-I)-like helicase receptors (RLRs) recognize double-stranded RNA (dsRNA) produced during viral replication. RLRs are located in the cytoplasm, and RIG-I and melanoma differentiation-associated gene 5 (MDA5) are the members of RLRs. It is reported that dsRNA induces the expression of RIG-I and MDA5 in mesangial cells, however, the effect on podocytes is not well elucidated. In this study, we tested the effect of polyinosinic polycytidylic acid (polyIC) on the expressions of RIG-I and MDA5 and on the down-stream inflammatory responses and podocyte damages.

Methods: Conditionally immortalized human podocytes were grown in 33 degrees centigrade and differentiated in 37 degrees centigrade, then treated with 2 to 500 μg/ml of polyIC, synthesized dsRNA for 3 to 36h. The expression levels of RIG-I and MDA5 were assessed by quantitative RT-PCR and western blotting. The expression of IFN-β, TNFα and IL-6 were assessed by quantitative RT-PCR. We further tested the role of RIG-I and MDA5 by the temporal knockdown utilizing siRNA. F-actin staining was performed to assess actin re-organization as a feature of podocyte damages.

Results: PolyIC induced the expression of RIG-I and MDA5 in podocytes in dose and time dependent manners, as demonstrated by quantitative RT-PCR and western blotting. PolyIC also increased mRNA expression of IFN-β, TNFα and IL-6. PolyIC induced actin re-organization by F-actin staining. Temporal knockdown of RIG-I by siRNA resulted in decreased expression of IFN-β and TNFα induced by polyIC, while temporal knockdown of MDA5 by siRNA inhibited IFN-β, TNFα and IL-6.

Conclusions: PolyIC dramatically induced the expression of RIG-I and MDA5 in podocytes in dose and time dependent manners. Temporal silencing of RIG-I and MDA5 by siRNA significantly suppressed the expression of inflammatory cytokines induced by polyIC leading to podocyte damages. These results suggest that not only TLRs but also RLRs play an important role in podocyte damage during viral infection.

The Impact of Sirtuin 3 in Renal Tubular Cell Apoptosis under Diabetic Conditions

Meiyan Wu,[1] Boyoung Nam,[1] Sukyung Kang,[1] Tae-Hyun Yoo.[2] *[1]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Reactive oxygen species (ROS) play roles in kidney diseases including diabetic nephropathy (DN). Central to tubular injury is mitochondrial dysregulation resulting in ROS overproduction. The role of mitochondrial sirtuins (SIRTs) has been reported to be implicated in numerous ROS-mediated diseases. Since SIRT3 is mainly localized in the mitochondria and regulates mitochondrial function via deacetylation of mitochondrial proteins, SIRT3 has been suggested to be involved in the pathogenesis of kidney diseases. However, the impact of SIRT3 on tubular cell apoptosis under diabetic conditions has never been elucidated.

Methods: *In vitro*, rat proximal tubular epithelial cells (NRK-52Es) were cultured in DMEM media containing 5.6 mM glucose (normal glucose, NG) or NG + TGF-β1 (10 ng/ml) with or without plasmid SIRT3 transfection. After 48 hours, cells were harvested and mitochondrial fraction was isolated. *In vivo*, 12 C57BL/6 mice were intraperitoneally injected with saline (Control, C) (N=6) or STZ (50 mg/kg/d) for 5 consecutive days (Diabetes, DM) (N=6), and were sacrificed after 6 weeks. The protein expression of SIRT3, MnSOD, and apoptosis-related proteins (Bax, Bcl-2, cleaved-caspase 3, cytochrome C, and p53) were determined by western blot analysis. Immunofluorescent staining for SIRT3 and Mitotracker staining were also performed with cultured cells, TUNEL assay was conducted with mice renal tissues.

Results: Compared to NG cells, the protein expression of mitochondrial SIRT3 was significantly decreased in TGF-β1-stimulated renal tubular cells, while SIRT3 protein expression in the cytoplasm was comparable between the two groups. Bax, cleaved-caspase 3, and p53 protein expression were significantly increased, whereas the protein expression of Bcl2, MnSOD, and cytochrome C were significantly decreased in tubular cells exposed to TGF-β1. In contrast, transfection with plasmid SIRT3 significantly abrogated the changes in apoptosis-related protein expression in TGF-β1-stimulated cells. A significant decrease in SIRT3 expression was also demonstrated in the kidney of DM mice compared to the C kidney along with a significant increase in TUNEL-positive tubular epithelial cells in the DM kidney.

Conclusions: These results suggest that SIRT3 plays a protective role in tubular injury under diabetic conditions and that SIRT3 can be a promising therapeutic target in patients with DN.

TH-PO359

Effects of High-Glucose Induced Epithelial to Mesenchymal Transition by Sulforaphan in Human Renal Tubule Cells

Young woong Song,[3] Jongho Shin,[1] Kyeong Min Kim.[2] *[1]Eulji Hospital, Daejeon, Republic of Korea; [2]Eulji medical center, Daejeon, Republic of Korea; [3]EUL-JI University hospital R Korea Daejeon, Dae-jeon, Republic of Korea.*

Background: Epithelial-to-mesenchymal transition (EMT) of tubular epithelial cells in the kidney is associated with the progression of renal tubulointerstitial fibrosis and contributes to the renal matrix protein accumulation that is associated with diabetic nephropathy.

Methods: In this study, we examined the role of Nrf2 and heme oxygenase-1 (HO-1) protein on EMT induced by high glucose (HG) in the human renal tubular epithelial cells (HK2 cells). We treated HK2 cells with HG and Nrf2 activator, Sulforaphan. EMT was assessed by the expression of mesenchymal markers such as α-smooth muscle actin (α-SMA) and vimentin, and epithelial marker, E-cadherin.
